

Civil, Architecture and Environmental Engineering

Editors: Jimmy C.M. Kao & Wen-Pei Sung

Two Volume set

About the pagination of this eBook

This eBook contains a multi-volume set.

To navigate the front matter of this eBook by page number, you will need to use the volume number and the page number, separated by a hyphen.

For example, to go to page v of volume 1, type "1-v" in the Go box at the bottom of the screen and click "Go."

To go to page v of volume 2, type "2-v"... and so forth.

VOLUME 1

Structural science and architecture engineering

Visual support vector machine-based method for reliability-based design optimization <i>Y. Xie & Y.Z. Wu</i>	3
Study on the tunnel group traffic accident risk using a fuzzy comprehensive evaluation model <i>B. Ma, R. Gao, Y. Gao, X.J. Wang & Z. Guo</i>	9
Applications of new reinforcement methods in city tunnels for shield launching and arriving <i>H. Jun, J.B. Shi, W. Hong & W. Xiaobin</i>	13
Research on the stress characteristics of concrete carrier pile based on finite element analysis <i>J.Y. Li, A.Q. Zhang & X.G. Han</i>	19
Theoretical analysis of the deformation of shield tunnel segment under fire <i>X.B. Han, Y.X. Xia & L.L. Chai</i>	25
Optimization of composition of the claddings of wooden structures <i>M. Halirova, H. Sevcikova, R. Fabian, E. Machovcakova & R. Janousek</i>	31
Evaluation of the ultimate strength of RC I-shaped members subjected to a combined action <i>P. Wang, Z. Huang & Q.S. Wang</i>	37
Three-dimensional centrifuge and numerical modeling of pile group due to twin tunnelling in different depth <i>S.K. Ma, Y. Shao, Y. Liu, J.Y. Chen & J. Jiang</i>	43
Index selection and weight analysis of the underground development of urban municipal public facilities <i>L. Ye & L.M. Zhu</i>	49
Risk assessment of pipelines in operation based on AHP and application of MATLAB <i>L. Chen, G.X. Wang & J. Zhao</i>	55
Effect of ground conditions on design parameters for bridge foundations <i>M.T.A. Chaudhary</i>	61
Research on multisource information fusion of tunnel geological prediction based on evidence theory <i>Z.H. Liu, Y.T. Wang, H. Ke, H. Wu & D. Zhou</i>	67
Pushover analysis of modularized prefabricated column-tree steel frame <i>Z.P. Guo, A.L. Zhang & X.C. Liu</i>	75

Study on reuse of heritages of an old industrial area in Harbin Gongyijie area against the backdrop of urban renewal <i>X.Z. Shan & W. Cheng</i>	83
Research on lateral resistant behavior and design of multicover plates connection for prefabricated steel plate shear wall with beam-only-connected infill plate <i>X. Zhang, A.L. Zhang & X.C. Liu</i>	89
Research on sensitivity and control criteria of cable length error in a double-strut cable dome <i>C. Sun & A.L. Zhang</i>	97
Structural design of a prefabricated steel frame structure with inclined braces <i>X.C. Liu, H.X. Wang & Z.P. Guo</i>	105
A study on the design of an ungated community <i>F. Jia, R.X. Wang & F.L. Ma</i>	115
Protection and utilization of Gaichun Garden ruins of the Summer Palace <i>D. Zhao & L. Zhang</i>	119
Development of a web-based hybrid BIM cost-estimating system for fire safety engineering <i>M.-H. Wen, W.-C. Huang & Y.-W. Wu</i>	125
Test and parametric analysis of postfire seismic performance of SRC column–RC beam joints <i>G.H. Li, L. Xie & D.F. Zhao</i>	135
Using agent-based simulation approach for estimating the efficiency of the building project design team <i>M.H. Tsai</i>	139
Field assessment of window daylighting with prismatic glazing <i>Z. Tian, D. Xue & Y.P. Lei</i>	145
Mechanical analysis of rockburst considering the “locked in” stress in the driving face of the roadway <i>X.-B. Yang, X.-X. Han, H. Wang & T.-B. Zhou</i>	149
Study on the identification of major safety defects in port engineering <i>J.H. Peng</i>	155
Investigating the impact of greenery on the driver’s psychology at a freeway tunnel portal <i>D.Q. Xiao, Z.W. Shen & X.C. Xu</i>	159
Modeling two-dimensional rubble mound breakwater using dolos at armor layer and geotube at the core layer <i>O.C. Pattipawaej & H.J. Dani</i>	167
Shear stress calculation of rubber asphalt overlay and stress-absorbing layer <i>J.Z. Tan, J.G. Wei, C. Pan & K.X. Huang</i>	171
Experimental study on beam-column joints of new prefabricate assembly frame structures <i>W.Z. Zhu & J.C. Zhang</i>	177
Seismic analysis of large span spatial steel frame with isolation system <i>W.Z. Zhu</i>	185
Effect of material ingredients on the cement-based self-leveling material <i>J. Liu, J.J. Hu, R.Q. Liu & Y.Q. Yang</i>	195
Rebuilding the city parks: How great is the effectiveness of environment-friendly constructions? <i>R. Y. Tallar, A.F. Setiawan & J.P. Suen</i>	201
Renaissance with recycled materials: Reconstruction of Guifeng Temple <i>Y.S. Gao & J. Xu</i>	205
Research on safety management of construction projects based on game theory <i>J.X. Zhao, M.M. Wang, J.H. Sun & K. Li</i>	209

Prestress distribution calculation method of a ridge tube cable dome with annular struts <i>A.L. Zhang, Y. Bai, X.C. Liu & C. Sun</i>	215
A new multiple-model analysis method considering structural uncertainty <i>F.Q. Zhu</i>	223
Promotion of transportation on urban spatial distribution and industrial development in Beijing <i>X. Peng</i>	227
Selection of interruptive protection methods in rapid transit underground construction <i>H.-C. Yang & C.-C. Liu</i>	233
Damage mechanism and dynamic analysis of tunnel lining structures under internal blast loading <i>C. Y. Chen, Y.B. Jiang, J. Yang, L.F. Zheng & Z.P. Li</i>	239
The seismic responses of near-fault frame structure cluster on basin induced by the rupture of reverse fault <i>W. Zhong</i>	247
Wave propagation FEA and experimental validation of aluminum plate using piezoelectric elements <i>S. Yan, S. Zhang, Z.Q. Wang, P.T. Zhao & Y. Dai</i>	253
Numerical simulation on seismic behavior of subway station structure under near-fault ground motions <i>B.Z. Tang, S. Chen, X.J. Li & H.Y. Zhuang</i>	259
Finite—infinite element analysis of soil dynamic response under moving load <i>C.Q. Tian & L.Q. Yuan</i>	265
Evaluation of the processing suitability of rural domestic sewage treatment, taking Fangshan in Beijing as a case study <i>Y. Wang</i>	269
Influence analysis of the incremental launching of steel box girder and local stability control <i>F.-J. Xie</i>	275
Study on active strategies for thermal environment regulation in the zero-energy houses of Solar Decathlon, China <i>F. Shi, W. Jin, W.W. Zheng & T. Zhuang</i>	285
Research and enlightening of ecological infrastructure-oriented “multiple planning integration” based on Germany’s spatial order and structure planning—illustrated by the example of Dujiangyan <i>Y.J. Li, F. Fu & Y. Yi</i>	289
Homogeneous generalized yield function and limit analysis of structures with rectangular sections <i>W. Ou, L.F. Yang & W. Zhang</i>	295
Numerical simulation analysis of the influence of shield tunneling on an adjacent tunnel <i>M.D. He & J. Liu</i>	301
Development and validation of the effective stress algorithm of the Davidenkov constitutive model using the Byrne pore pressure increment model <i>B. Ruan, G.X. Chen & D.F. Zhao</i>	309
Urban ITS framework and essential parts of the ITS frame structure <i>M.-Q. Li, Z.-H. Wang, W. Wan & Z.-T. Jing</i>	317
Development and implementation of a product module division system based on the function–principle–structure <i>J. Chen, L.M. Wang & L.L. Yang</i>	321

Parameter optimization of space truss and aerospace load viscoelastic damping composite structure	325
<i>Z. W. Zhang, P. Wang & H. T. Luo</i>	
A unified theory of thermodynamically consistent microplane elastoplastic damage, and elastoplastic damage models	331
<i>W. S. Li & J. Y. Wu</i>	
 <i>Building materials and materials science</i>	
Preparation of sebacic acid by a phenol-free method	341
<i>L. Xu, L. L. Mao, Y. M. Feng, J. C. Zhang, M. Wang, T. T. Zhao, X. J. Gao & R. Ren</i>	
Effects of electrospinning parameters on the pore structure of porous nanofibers	345
<i>Z. Y. Sun & L. Xu</i>	
Preparation of orderly nanofibers using bubble-electrospinning	349
<i>Z. B. Shao & L. Xu</i>	
Environmental radioactivity measure and dose estimation of ⁹⁰ Sr in some area	353
<i>L. Ma, X. Ren & K. Zhang</i>	
Effect of humic acid on the adsorption of levofloxacin to goethite	357
<i>X. P. Qin, H. Hou, L. Zhao, J. Ma, Z. J. Sun, W. J. Xue, F. Liu & G. C. Wang</i>	
Calcium and manganese affect ethanol fermentation by <i>Pichia stipitis</i> in cadmium-containing medium by inhibiting cadmium uptake	363
<i>M.-T. Gao, X. X. Chen, W. Zheng, Q. Y. Xu & J. J. Hu</i>	
Performance comparison of Biological Aerated Filters packed with polyurethane sponge and ceramic particles	367
<i>G. L. Yu, X. J. Yan, H. Chen, C. Y. Du, Y. J. Fu & J. X. Zhang</i>	
Preparation and evaluation of the Ni-Al catalyst derived from LDHs synthesized on γ -Al ₂ O ₃ support	373
<i>X. K. Zhao, Y. Q. Li, Y. Xu, X. H. Du & J. J. Xu</i>	
Synthesis and hydrodesulfurization performance of NiMo sulfide catalysts supported on an Al-Si mixed oxide	377
<i>Q. Yu, J. C. Zhang, J. Nan, H. B. Yu, X. F. Peng, H. Xiao, G. L. Song, S. Q. Zhang, S. Wang, Y. T. Zhang & G. H. Zhang</i>	
Study on solidification of Ningbo mucky soil	381
<i>J. Y. Lu, R. Q. Xu, Q. Yan & X. Wang</i>	
A study on the utilization of iron and steel industrial solid waste	387
<i>Y. B. Zhang, R. Zhu, Y. Wang, C. S. Yue & X. J. Piao</i>	
Experimental study of the drainage and consolidation characteristics of tailings discharge and accumulation by gradual height rising under the action of drainage material	393
<i>J. Su, X. D. Ou & K. W. Hou</i>	
LQR control of across-wind responses of tall buildings using composite tuned mass dampers	403
<i>Y. M. Kim, K. P. You, J. Y. You, S. Y. Paek & B. H. Nam</i>	
Time-dependent reliability analysis of steel fiber-reinforced concrete beams under sustained loads	411
<i>Y. Li, K. H. Tan & S.-M. Yu</i>	
Research on the heat transfer characteristics of rock and soil under the effects of vertical double U-type buried-pipe heat exchanger	417
<i>X.-D. Ou, X. Pan, H. Dai, Y.-C. Tang & Z.-Y. Liu</i>	
Nitrogen removal performance of ANAMMOX-PVA granules immobilized by different preparation methods	425
<i>Y. M. Han</i>	

Seismic response of a long-span cable-stayed bridge with slip-shear metal damper <i>C.K. Jiao & X. Dong</i>	429
Research on the interfacial bond behavior between CFRP sheet and steel plate under the static load <i>L. Zhang & S.-Y. Cao</i>	435
Influence of thick and loose sediments on the vacuum load transfer <i>J.X. Weng</i>	439
Enhancement on fireproof performance of construction coatings using calcium sulfate whiskers prepared from wastewater <i>T.-P. Tsai & H.-C. Yang</i>	447
Simulation of nonlinear ultrasonic waves in anisotropic materials using convolution quadrature time-domain boundary element method <i>T. Saitoh, T. Maruyama & A. Furukawa</i>	451
Study on the layout method of newly-added feeder bus lines coordinating with bus rapid transit <i>Z. Guo, P.H. Wei, X. Peng, C.Z. Chang, L. Tong & J.M. Velásquez</i>	457
Design of a campus view of a virtual roaming system based on VR <i>L. Yu</i>	465
Analysis on sustainable financial framework and fare adjustment strategy of China's urban public transit <i>S. Xu, C. Li, X.L. Liu & Y.K. Du</i>	471
Sanitation improvement and the bottleneck analysis of equity in China: From the perspective of specialists <i>X.L. Li & Y.Q. Miao</i>	479
Ultimate capacity of uniaxially compressed perforated steel plates strengthened by using CFRPs <i>X. Tao & S. Y. Cao</i>	483
Research on the measurement of the permeability coefficient of porous asphalt pavement <i>G.Q. Tang, L. Gao, T.J. Ji & J.G. Xie</i>	489
Mechanical performances of icing atop cement concrete surfaces coated with emulsion wax curing agents <i>J.-L. Yao & M.-J. Qu</i>	495
A study on residential area's adaptability design for the aged in China based on open building theory <i>X. Meng & B.C. Fu</i>	501
Safety management strategies for public infrastructure projects <i>C. W. Liao & T.L. Chiang</i>	507
The influence of the horizontal load on the stress-strain relationship of an asphalt layer <i>Y.H. Wang, X.M. Tan, X.J. He, Y. Wang, C. Wang & T. Liu</i>	511
A study on the protection type of flow-guided porthole dies with twin cavities for semi-hollow Al-profiles <i>R.R. Deng & P. Yun</i>	517
A study on covering and protection type porthole dies for semi-hollow Al-profiles <i>R.R. Deng & P. Yun</i>	521
A study on protection type porthole dies of semi-hollow Al-profiles with four cavities <i>R.R. Deng & P. Yun</i>	525
Numerical and experimental study on stability of aluminium alloy riveted and stiffened panels under in-plane shear <i>D.W. Wang, Z.K. Lei, R.X. Bai & Y. Ma</i>	531

Process optimization for the new nano-complex internal coating and its anti-corrosion and drag reduction properties in natural gas pipes <i>B.H. Hao, B. Sun, Z.H. Liu, Y.L. Han & L.F. Zhao</i>	535
An improved gray wolf optimization algorithm and its application in iron removal from zinc sulfate solution using goethite <i>T.B. Wu, J.H. Liu, Y.L. Liu, Q.M. Zhao & X.J. Li</i>	539
Determination of multi-element in abstergent by ICP-MS with microwave digestion <i>B.L. Wu, Z.X. Wang, J.M. Ye, Z.X. Lin, H. Wang & C. Luo</i>	545
Fabrication and application of superhydrophobic-superoleophilic porous Cu sponge <i>Y.J. Xing, Z.J. Han, J.L. Song, J. Sun, J. Luo, Z.A. Liu, J.Y. Liu, L. Huang & X. Liu</i>	549
Preparation of porous ceramics using CaCO ₃ as the foaming agent <i>J. Li & Y.L. Chen</i>	555
Spacing optimization modeling and simulation of thermo-optic VOA gold thin film interconnect <i>S.T. Ding, L. Xu, F. Huang & M.L. Gong</i>	559
Growth and characterization of thick Ge epilayers on Si and Silicon-on-Insulator (SOI) substrates with low temperature Ge buffers <i>Z. W. Zhou</i>	565
Effect of ZnSO ₄ and SnSO ₄ additions on the morphological of α -Al ₂ O ₃ flakes for pearlescent pigment <i>H. Qin, L. Wang & Y. Xiong</i>	569
A facile cost-effective method for preparing superhydrophobic carbon black coating on Al substrate <i>P. Wang, B. Sun, T. Yao, X. Fan, C. Wang, C. Niu, H. Han & Y. Shi</i>	573
Preparation of multifunctional flake alumina ceramics <i>Q.R. Wang, C. Liu, K.X. Du & Y. Xiong</i>	577
Study on the deformation of plastic films by virtual particle method <i>X.H. Yang, Z. Yang, Y.X. Wang, C.Y. Lv & X. Cheng</i>	581
An experimental study of installing-holes distances parameter optimization for metallic inserts bonded into CFRP laminates <i>J. Liu, H. Zhang & K. Hou</i>	585
Formation and test methods of the thermo-residual stresses for thermoplastic polymer matrix composites <i>C.C. Wang, G.Q. Yue, J.Z. Zhang, J.G. Liu & J. Li</i>	589
Effects of lithium slag from lepidolite on Portland cement concrete <i>Q. Luo, Y.F. Wen, S.W. Huang, W.L. Peng, J.Y. Li & Y.X. Zhou</i>	593
Sorption properties of TEMPO-oxidized natural cellulose to iron ions <i>C.Z. Geng, Y.H. Lou, D. Y. Yan, Z.H. Zhao, Z.X. Xue & Y.Z. Xia</i>	597
Research on the precision of grinding experiments in an iron ore <i>G.M. Shi, L.P. Jiang, J.M. Zhao, R.Q. Zhao, Y.C. Zhou & S.C. He</i>	603

Construction equipment and mechanical science

An experimental study on the dynamic characteristics of compact transmission lines bundles following ice shedding <i>K.P. Ji, B. Liu, X.P. Zhan, X.Z. Fei, C. Deng & L. Liu</i>	609
A single-lens optimal imaging system based on a liquid crystal spatial light modulator and micro-scanning optical wedge <i>N. Xu, Z.-Y. Liu & D. Pu</i>	613

A geometry-based path optimization approach for motion control of the NC grinding machine <i>F. Zhang, J. Gong, Y.J. Liu, W. Xia, M.F. Huang & Y.F. Fu</i>	621
A study on carbon electrode-based photoelectrochemical-type self-powered high-performance UV detectors <i>Q. Meng, X. Fan, E.Q. Wu & L. Chu</i>	625
A scheme study of CFB power generation by using pet coke <i>H.T. Liu, L. Xue & D.F. Xu</i>	629
Design of the pilot-scale double effect evaporator for high-concentration sodium hydroxide production <i>L. Gao</i>	633
Early fault diagnosis of wind turbine gearboxes based on the DS _m T <i>Z.Q. Liu & G.C. Chen</i>	641
A study of an improved method for horizontal alignment based on the line element <i>Y.H. Li, Y.J. Liu & Y.L. Li</i>	647
Theoretical analysis of mechanical properties and mechanical design for fabricated zero initial cable force friction dissipation <i>Q.X. Ye & A.L. Zhang</i>	651
An optimal allocation model of residual control rights in the hydraulic PPP project <i>Y.H. Zhang, J.C. Feng, S. Xue & K. Zhang</i>	659
A study on the optimized hydraulic circulation system of the artificial lake <i>Q.N. Jin, A.J. You & H.B. Xu</i>	665
Development of new elastic constant estimation method using laser ultrasonic visualization testing <i>T. Saitoh & A. Mori</i>	669
Selection for the frequency control point of the VAV air supply system in large underground spaces <i>K.D. Xue, Z.H. Zhou, Y.F. Zhang & Y.M. Sun</i>	675
The innovations of the ship lock design for the Tugutang Hydropower Station in the Xiangjiang river <i>H.Y. Liu & C.Y. Wang</i>	679
Knowledge management in construction—the framework of high value density knowledge discovery with graph database <i>Y. Jing, Y.-C. Wang & Z. Wang</i>	685
Research of cold region green hospital design specification and practice <i>Y.Z. Gao, H.Y. Mei & J.F. Dong</i>	689
Development of intelligent residual current devices based on the PIC micro-controller <i>H. Chen, J. Xiang, R. Huang, L.M. Shen, F.S. Chen, K. Li, W.N. Wang, L.M. Bu, X. He & X.Y. Xu</i>	693
Design of Control Moment Gyro equivalent sound source based on transfer function matrix inversion <i>W. Cheng, W.-Q. Sun, G.-Y. Wang, J.-P. Chen, X.-F. Li & J. Jia</i>	699
A study of the magnetic field distribution with saddle-shaped coil of the electromagnetic flow meter <i>H. Jia, Y.M. Wang, W.T. Li & Y.Y. Zhang</i>	707
A study on a localizable CMOS temperature sensor based on wireless transmission <i>L.Y. Chen, J.Q. Li & Y.X. Li</i>	713
Finite element analysis of the roller coaster wheel bridge based on virtual prototype technology <i>Y.M. Wang, J. Ye, X.T. Xu & S. Song</i>	719

Multi-axis coordination control based on siemens S7-CPU315T <i>C.H. Pan, Y.L. Li & M.W. Qin</i>	725
Short-term photovoltaic power forecasting based on the human body amenity and least squares support vector machine with fruit fly optimization algorithm <i>H.B. Chen, W. Han & L. Chen</i>	729
An RFID-enabled CEP model for cloud manufacturing shopfloor <i>K.Q. Chen, Y.Y. Qiu, M.L. Wang, Q.Y. Dai, R.Y. Zhong & C.M. Huang</i>	735
Optimization of extraction of polysaccharides from mulberries by using high-intensity Pulsed Electric Fields <i>S.L. Jin</i>	741
Stress analysis of the interference fit in helical gear transmission <i>T. Zhao</i>	747
A review of transformerless DC–DC boost converters for renewable energy sources <i>J. Luo</i>	753
The linear fatigue cumulative damage analysis of the welding seam <i>Y.Y. Wang</i>	759
Application of wavelet analysis and resonance demodulation in mechanical fault diagnosis <i>C.H. Shen & W. Wang</i>	765
A study on the modeling of the slider-crank mechanism based on parameter identification <i>X.J. Wang, X.H. Tang & J. Shen</i>	769
Angle measurement by comparing the amplitude technique of the sum-difference pattern radiometer <i>H. Wang, J. Xiao & B. Bi</i>	775
Tension control methodology of active continuous discharge and intermittent reciprocating work based on master-slave synchronous motion <i>L. Han, H. Hu, W.H. Ding & J.Y. Li</i>	781
Design and kinematics analysis of a novel liquid-brewing steamer feeding robot <i>J.S. Zhang, B. Li, T.C. Zhang & X.H. Zhao</i>	787
Design and simulation analysis of a new type of multi-gear pump <i>X.H. Zhang, P.Y. Liu, W.J. Wei, H.T. Li & G.P. Tian</i>	793
A study on the torsional fatigue fracture location of steel wires <i>W.J. Wei, D.C. Wang, P. Cheng & C.X. Shao</i>	799
The lightweight design of the support arm <i>Y.Q. Tian, D. Meng & X.Y. Lin</i>	805
An analysis of the thermal elasto-hydrodynamic lubrication performance of the slope of the thrust bearing <i>Y.L. Liu, Y.H. Li, T.Y. Niu, J.F. Huang & Y.X. Wang</i>	809
Simulation of submarine underwater motion with an external weapon module <i>Y.Q. Lian, C.L. Li & Y. Liu</i>	815
A multi-objective NC drilling parameter optimization model to achieve low energy consumption and costs <i>W. Yan, H. Zhang & Z.G. Jiang</i>	823
An experimental study of the dynamic equivalence leakage of rolling-piston compressors <i>K.H. Geng, W. Wei, X.B. Ma, X. Wang, X.G. Han, T.B. Zhao, C.L. Chen & H. Sun</i>	827

The structure and transmission efficiency analysis research of a new pattern F2C-T pin-cycloid planetary transmission <i>L. Xuan, H. Jiang & T.M. Guan</i>	833
A study on surface zinc plating and heat treatment of welding gears <i>R. Zeng, J.H. Luo, Z.R. Lin & L.L. Wang</i>	839
Development and application of a test platform for a battery management system <i>J. Xiong, Z.H. Jin & Z.C. Li</i>	843
Experimental study on yarn friction slip in the yarn pull-out test <i>W.K. Li, Z.K. Lei, F.Y. Qin, R.X. Ba & Q.C. Fang</i>	847
Analysis and research into the effect of dithering technology on ADC's SNR <i>K.K. Jin & X.L. Chen</i>	851
Design and implementation of a CANopen master stack for servomotor controllers in a 6-DoF manipulator <i>J.H. Ji, Z.H. Tao, T. Zhang & M.Z. Qi</i>	855
Design of a crane intelligent control system <i>C.C. Zhang, S.G. Liu & H.W. Xie</i>	861
Valve clearance fault diagnosis of an internal combustion engine based on wavelet packets and k-nearest neighbors <i>R. Tan, Y. Zhang, T.X. Zheng, B. Yang & Y.J. Wang</i>	865
RV reducer dynamic and static performance test system design <i>W.-B. Fu, C.-S. Ai, C.-L. Tang, Y.-S. Yang, G.-P. Li & H.-H. Zhao</i>	871
Analysis of automotive suspension compliance based on the main effects of rubber bushing <i>B. Chen, J.-H. Fu & Z.-M. Chen</i>	877
Experimental and simulation research on the friction and wear properties of surface textured friction pairs in CST <i>S.N. Sun, L. Y. Xie & R.S. Long</i>	883
Simulation and analysis of MPPT used in photovoltaic grid-connected systems based on the improved disturb-and-observe method <i>J.F. Wang & H.R. Zhao</i>	889
Automatic control loop optimization method of thermal power plant based on internal model control <i>S. Gao, X.K. Pang, J. Li, C.W. Li & H.D. Li</i>	895
Multidisciplinary optimization and parameter analysis of the in-wheel permanent magnet synchronous motor of a tram <i>X.C. Wang & Z.G. Lu</i>	899
Dynamic simulation and muzzle vibration analysis of vehicle-mounted automatic mortar <i>Y. Fang, J.-Q. Qin & C.-C. Di</i>	907
Numerical simulation of aspheric glass lens during the non-isothermal molding process <i>H.J. Duan, Z.L. Xiao & J.Y. Tao</i>	911
Temperature field analysis of a porous modified concrete composite pavement <i>Y.H. Wang, X.M. Tan, X.J. He, T. Liu, Y. Wang & C. Wang</i>	915
A retrieval method based on a CBR finite element template <i>Q.Y. Ma, D.P. Xie, L.H. Song & M.J. Zhou</i>	921
Improved reduction of graphene oxide through femtosecond laser pulse trains <i>R. Y. Yan, P. Zuo & X.J. Li</i>	927
A nanoparticle-decorated silicon substrate for SERS via circularly polarized laser one-step irradiation <i>G. Meng, P. Ran & Y.D. Xu</i>	931

An experimental study on rotation ultrasound-assisted drilling for high-strength engineering of mechanical connection components <i>S. Hong</i>	935
Synthesis of PbO nanosheet-based thin films for all-solid-state supercapacitors <i>J. Zhang, H. Y. Xie & Z.J. Chen</i>	939
A large-scale SERS substrate fabricated by using femtosecond laser with superhydrophobicity <i>Y.D. Xu, G. Meng & P. Ran</i>	945
A study on the ship model resistance test and numerical simulation <i>H.C. Pan, S.N. Yu & Y.J. Yang</i>	949
Magnetic memory testing signal analysis of Q345 steel welding parts under the static tension condition <i>M. Lou, X.-H. Lv, F. Lu & B. Li</i>	955
Research on reliability assessment of success or failure product based on small sample <i>H.-P. Li, Z.-L. Xuan & Y.-D. Wang</i>	959
Numerical simulation of hydroforming of a stainless steel sink <i>Q.H. Li, P. Zhu, X.Q. Guo, J.W. Hou & X.M. Li</i>	965
The fabrication and measurement of a bi-axial thermal convection acceleration sensor <i>H. Wang, Y.G. Li, P. Yan, Y. Huang & S. Sugiyama</i>	971
Innovative green design of the frog ramming machine based on TRIZ/FRT <i>Z.G. Xu, J.L. Li & Z. Y. Zhu</i>	975
Rotor fault diagnosis based on SVM and improved D-S theory <i>Z.-H. Yan & P. Liao</i>	979

Preface

The 2016 International Conference on Civil, Architecture and Environmental Engineering (ICCAE 2016) was held on November 4-6, 2016 in Taipei, Taiwan, organized by China University of Technology and Taiwan Society of Construction Engineers, aimed to gather professors, researchers, scholars and industrial pioneers from all over the world. ICCAE 2016 is the premier forum for the presentation and exchange of experiences, new advances and research results in the field of theoretical and industrial experience. The conference contained contributions promoting the exchange of ideas and rational discourse between educators and researchers from all over the world.

ICCAE 2016 is expected to be one of the most comprehensive Conferences focused on civil, architecture and environmental engineering. The conference promotes international academic cooperation and communication, and exchanging research ideas.

We would like to thank the conference chairs, organization staff, and authors for their hard work. By gathering together so many leading experts from the civil, architecture and environmental engineering fields, we believe this conference has been a very enriching experience for all participants. We hope all have had a productive conference and enjoyable time in Taipei!

Conference Chair
Dr. Tao-Yun Han
Chairman of Taiwan Society of Construction Engineers

Visual support vector machine-based method for reliability-based design optimization

You Xie & Yizhong Wu

School of Mechanical Science and Engineering, National CAD Supported Software Engineering Centre, Huazhong University of Science and Technology, Wuhan, China

ABSTRACT: In this paper, a method based on Virtual Support Vector Machine (VSVM) and Kriging response surface model is proposed to address Reliability-Based Design Optimization (RBDO) problems for black-box system. In many engineering optimization problems, the number of function evaluations is limited because of the expensive evaluation of the objection function and constraint functions. To get a more precise result, it is necessary to evaluate more samples in a small region, which includes the optimum point. Considering these characters, the RBDO method based on VSVM (RBDO-VSVM) is proposed in this article. RBDO-VSVM uses VSVM classification to approximate the limit state function, which can guide the constraint boundary sampling process. Besides, Trust Region (TR) method is used in the algorithm to downsize the search space to a local range around the constraint boundary, which probably contains the optimum point. Numerical optimization example is posed in the end of the article to validate the efficiency and accuracy of the proposed method.

1 INTRODUCTION

In recent years, RBDO has been studied to design safer and more reliable products, which take the uncertainty of loadings, material properties, environment, and other parameters into consideration. Reliability analysis aims to quantify the uncertainty of the output according to the uncertainty of the system inputs, environment, system itself, and so on. On the contrary, the relationship between inputs and outputs becomes increasingly complicated, and mostly they are black-box systems in the practical engineering application, which makes the aforementioned relationships highly nonlinear and not able to be characterized with explicit functions. Therefore, it is very important to do more research on the RBDO problems of black-box systems.

Several reliability analysis methods have been proposed. The First-Order Reliability analysis Method (FORM) is widely used because of its simplicity and efficiency (Du 2008; Yao et al. 2013). To improve the FORM, the Second-Order Reliability analysis Method (SORM) was developed, which can obtain a more precise result. Uncertainty optimization methods aim to find the optimum point by taking the effect of uncertainty into consideration. Traditional uncertainty optimization methods apply a double-loop algorithm, which inserts the reliability analysis into the process of optimization. Methods such as Reliability Index Approach (RIA) and Performance Measure Approach

(PMA) belong to the traditional optimization method. A serial Single-Level Approach (SLA) has been developed recently, which decompose the double-loop algorithm into a sequential single-level process. The key of SLA is how to convert the reliability constraints into certainty constraints. The widely used methods include Sequential Optimization and Reliability Assessment (SORA) and reliability index approximate approach. Other typical uncertainty optimization methods such as Single-Loop Single Vector (SLSV) and Single-Level Double Vector (SLDV) aim at uncertainty optimization problems, which insert uncertainty analysis based on the Most Probable Point (MPP) into optimization research.

Meta-Model-Based Design Optimization (MBDO) has been the mainstream method to achieve optimization of the Constrained Black-box system. Typical methods such as Efficient Global Optimization (EGO) emerged as one of the most promising methods for expensive simulators (Jones et al. 1998). EGO is based on the approximation of responses using a Gaussian process model so that the variance of the prediction is available over the whole design space. Expected Improvement (EI) of the object function can also be assessed; hence, the optimum value can be found by maximizing the EI with a global search. Recently, EGO has also developed Efficient Global Reliability Analysis (EGRA) [Bichon BJ et al. 2008]. The EGRA is based on expectation improvement. To improve

the efficiency and precision of RBDO, other theories are also developed to address RBDO, such as the Support Vector Machine (SVM). The SVM is a classification method, which constructs only the decision (i.e., limit state) function. Another advantage of this classification method is that SVM can deal with multiple constraints simultaneously. Besides, Virtual SVM (VSVM) (Song, 2013) is developed to improve the accuracy of SVM while maintaining its desirable features, by using the available response function values.

In this paper, the RBDO-VSVM method is proposed to improve the efficiency and accuracy of RBDO. This paper is organized as follows. In Section 1, the mainly situation of the RBDO is reviewed. Section 2 introduces the theoretical background, whereas Section 3 introduces the details of the proposed method. Numerical examples and welded beam design example are demonstrated in Section 4. Conclusion is proposed in the last section.

2 THEORETICAL BACKGROUND

2.1 EGO and EGRA

EGO was proposed by Jones [Jones, 2001]. In EGO, a new sampling point, which should be added to the Gaussian process model, is selected by maximizing the amount of improvement in the objective function that can be expected by adding that point. A point could be expected to produce an improvement in the objective function if its predicted value is better than the current best solution or if the uncertainty in its prediction is such that the probability of it producing a better solution is high. Because the uncertainty is higher in regions of the design space with fewer observations, this provides a balance between exploiting areas of the design space that predict good solutions and exploring areas, where more information is needed. EGO was developed in Bichon BJ et al. [2012] to address RBDO problems, which developed the EI into the Expected Feasibility Function (EFF) that can provide an indication of how well the true value of the response is expected to satisfy the equality constraint.

2.2 Virtual support vector machine

The basic idea of VSVM is to increase the probability of locating the decision function close to the true limit state function by inserting two opposite signed virtual samples between the given two samples. Virtual samples could be generated from the approximation method using any pair of real samples.

3 RBDO-VSVM

In this section, details of the proposed method will be presented.

The aim of optimization is to find the optimum point; therefore, orientating a small region, which contains the optimum point precisely, is important for optimization the algorithm. The method includes two phases. The aim of Phase 1 is to orientate the region, which contains the optimum point. With the base of Phase 1, the aim of Phase 2 is to refine the meta-model within the trust region, which is near the real optimum point. Detailed information of the two phases is proposed below. The abstract flowchart of the method is depicted in Fig. 1.

3.1 Phase 1—the coarse search process

Because the classification approach of VSVM to construct the explicit boundaries is good at dealing with discontinuous and binary responses, both the VSVM and Kriging models are used in Phase 1. In order to improve the efficiency of orientating the small region, which contains the optimum point in Phase 1, EFF and the nearest distance from the existing sample points are applied in the sampling criterion of Phase 1.

The flowchart of Phase 1 is depicted in Fig. 2.

Four steps will be carried out in this phase to find the coarse region, which contains the optimum.

Step 1: Initialize the sample set. In order to obtain the sample set, which meets the uniform distribution, the Latin Hypercube Sampling (LHS) method is used in this step. More than 2^{n+1} samples should be taken as the initial sample set for the problem with n dimensions.

Step 2: Evaluate objective function and constraint functions for each sample and construct/update Kriging models for the objective function and constraint functions based on samples. Besides, the VSVM model is also constructed/updated for constraint functions based on the samples.

Figure 1. Abstract flowchart of the proposed method.

Figure 2. Flowchart of Phase 1.

Figure 3. Trust region.

Step 3: Obtain the DOP according to the current object Kriging model and constraints Kriging model with Genetic Algorithm (GA). The optimization problem can be expressed as:

$$\begin{cases} \min \hat{f}(\mathbf{x}) \\ \text{s.t. } \hat{g}(\mathbf{x}) = 0 \end{cases}$$

where $\hat{f}(\mathbf{x})$ is the current Kriging model of objection function and $\hat{g}(\mathbf{x})$ is the current Kriging models of constraint functions. This optimization problem is addressed by GA. DOP will be added to the optimization set. The trust region is constructed/updated according to the current DOP \mathbf{x}_{k+1} and the former DOP \mathbf{x}_k , as shown in Fig. 3.

If $f(\mathbf{x}_{k+1}) < f(\mathbf{x}_k)$, which means that the solution can be trusted, then the trust region will be expanded, which means the value of r should be larger; if $f(\mathbf{x}_{k+1}) > f(\mathbf{x}_k)$, which means that the solution cannot be trusted, then the trust region will be downsized, which means the value of r should be smaller.

If the last two DOP points meet the criterion 1, which is expressed in Eq. (1), go to Step 5; if the

last two DOP points do not meet the criterion 1, go to Step 4:

$$\|\mathbf{x}_{k+1} - \mathbf{x}_k\| \leq 2 * r \quad (1)$$

Step 4: Select a new sample based on EFF, SVM, and trust region, which is expressed in Eq. (2), and add it to the sample set. Then, go to Step 2:

$$\begin{cases} \max \text{EFF} * D \\ \text{s.t. } s(\mathbf{x}) = 0 \\ \mathbf{x} \in \text{current trust region} \end{cases} \quad (2)$$

where D is the minimal distance from the current sample point to the existing sample points. EFF is the expected feasibility function. $s(\mathbf{x}) = 0$ is the VSVM decision function. In the criterion expression, EF is applied to improve the precision of the Kriging model. D is applied to make the sample distribution more uniform. The constraint function of the criterion ensure that the new sample point is located at the SVM decision function and belong to the trust region, which can ensure that the new sample is as close to the optimum as possible.

3.2 Phase 2—the accurate search process

The flowchart of Phase 2 is depicted in Fig. 4.

Two steps are included in this phase.

Step 5: Obtain the DOP according to current object Kriging model and constraints Kriging model with Genetic Algorithm (GA) and add it to the Optimization set. The trust region is updated with the method that is used in Step 3. Besides, the RBDO design point is obtained with SORA. If the last two DOP points meet Criterion 2, which is expressed in Eq. (3), the process is complete; if not, go to Step 6:

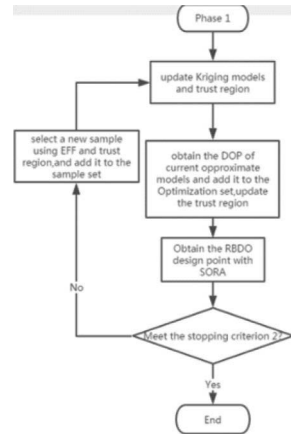

Figure 4. Flowchart of Phase 2.

$$\|x_{k+1} - x_k\| \leq \varphi \quad (3)$$

where φ is a small positive number (i.e., 10^{-3})

Step 6: Select a new sample on the basis of EFF and trust region, which is expressed in Eq. (4), and add it to the sample set. Then, go to Step 2:

$$\begin{cases} \max \text{EFF} * D \\ \text{s.t.} \\ x \in \text{trust region} \end{cases} \quad (4)$$

where EFF, D, and the trust region have the same meaning as that in Eq. (2). Kriging models of the constraints can be refined with the criterion within the trust region at each iteration. With the increase in the number of iterations, the accuracy of the Kriging model within the trust region will be increasingly higher.

In the RBDO-VSVM method, because of the uniform distribution of LHS sampling result, the stability of SVM, and taking the minimal distance, D, into consideration, the risk of finding the local optimum point can be reduced to some extent. Besides, the optimum point is obtained with Genetic Algorithm, which can also avoid falling into local optimum point.

4 NUMERICAL EXAMPLE

In this section, a numerical example is proposed to demonstrate the accuracy and efficiency of the proposed method. A comparison between the EGRA and RBDO-VSVM methods is made in this section. This example is the modified Haupt example (Lee and Jung, 2008), which has two design variables, whose objection function and constraint functions are nonlinear.

$$\begin{cases} \text{Find } \mathbf{X} = [x_1, x_2] \\ \text{Min } f(\mathbf{X}) = (x_1 - 3.7)^2 + (x_2 - 4)^2 \\ \text{s.t. } \text{prob}[g(\mathbf{X}) < 0] \leq \Phi(-\beta_r^i), i = 1, 2 \\ g_1(\mathbf{X}) = -x_1 \sin(4x_1) - 1.1x_2 \sin(2x_2) \\ g_2(\mathbf{X}) = x_1 + x_2 - 3 \\ 0.0 \leq x_1 \leq 3.7, 0.0 \leq x_2 \leq 4.0 \\ \beta_r^1 = \beta_r^2 = 2.0 \\ \mathbf{X}^{(0)} = [2.5, 2.5]^T \\ X_n \sim N(d_n, 0.1^2), n = 1, 2 \end{cases}$$

In Fig. 5, the feasible samples are denoted by red spots and the infeasible samples are denoted by blue spots. The VSVM decision function, $s(x) = 0$, is denoted by black lines. The Kriging models of the constraints boundary are denoted by the pink dotted line. The true constraints boundaries are denoted by the green line. The trust region is represented by a red rectangle.

Figure 5. Result of the RBDO-VSVM method.

The final RBDO design point is denoted by the red “+”. The RBDO design point obtained by the RBDO-VSVM method is [2.826, 3.268] with 14 samples; the RBDO design point obtained by EGRA is [2.834, 3.251] with 35 samples. To quantify the accuracy of these methods, we adopt the accuracy measure in Eq. (5):

$$\text{error} = \frac{X_d - \hat{X}_d}{X_d} \times 100\% \quad (5)$$

where X_d is the true optimum design point and \hat{X}_d is the optimum design point. The norm used in this equation is 2-norm.

The error percent of the RBDO-VSVM method is 0.0487%; whereas that of the EGRA method is 0.468%. Thus, it is evident that the accuracy and efficiency of the RBDO-VSVM method are significantly higher.

5 CONCLUSION AND FUTURE WORK

In this article, the RBDO-VSVM method is proposed to address the black-box system optimization problems. In the RBDO-VSVM method, Kriging models are used to approximate the constraints and objection function, and the VSVM method is used to approximate the limit state function. To improve the efficiency of the optimization process, trust region is used in this article. With the process of iteration, the trust region has an increasingly higher probability to contain the optimum design point so that the Kriging model near the optimum design point can be refined with a higher accuracy.

However, the RBDO-VSVM method still has some limitations in some extreme situation. For example, the method is not good at addressing the optimization problem, whose feasible region is very small, long, and narrow. Under these conditions, it is difficult to find the first sample point within the feasible region, which decreased the accuracy of the VSVM method. Therefore, how to improve the

sampling strategy to improve the accuracy of the VSVM still has much room for further research.

Study on the tunnel group traffic accident risk using a fuzzy comprehensive evaluation model

Bin Ma, Rong Gao & Ying Gao
Xijing University, Xi'an, Shaanxi, China

Xiaojie Wang & Zihan Guo
Xi'an University of Technology, Xi'an, Shaanxi, China

ABSTRACT: This paper aims to evaluate the tunnel traffic accident risk using an Analytic Hierarchy Process (AHP) and the fuzzy comprehensive evaluation methods. The concept of highway tunnel group was put forward for the first time. Three safety factors, including the human factors, vehicle factors, and road factors, were analyzed. The group tunnel traffic accident risk index system was established following the principles of integrity, scientific, credibility, and operable principle. The group tunnel traffic risk evaluation model was put forward using AHP and fuzzy comprehensive evaluation methods. Taking the Luan Chuan Highway Tunnel group traffic accident in Luoyang City as an example, the fuzzy comprehensive evaluation model was used in the application example. The results showed that the fuzzy comprehensive evaluation value of the Luan Chuan Highway Tunnel group traffic was 3.08, indicating that the traffic accident risk of the Luan Chuan Highway Tunnel group was medium.

1 INTRODUCTION

In view of the current serious situation of traffic accidents, this paper evaluates the risk of traffic accidents using the fuzzy comprehensive evaluation method. There are very few research works focusing on the tunnel group. Current references mainly focused on the definition of the tunnel group, the safety evaluation system of tunnel group, the influence factors of the safety of the tunnel group, and the practical safety technology of the tunnel group. However, the definition of the tunnel group and the operation environment of the identification are still not clear. Although the definition of the highway tunnel group is different, it can be mainly divided into two types: static definition and dynamic definition. The static definition of the highway tunnel group is used in the existing traffic environment, given the concept covers tunnel extension attributes, such as the limited value of the fixed distance between two tunnels. The value generally consists of various factors affecting the maximum distance. The dynamic definition of the highway tunnel group is set according to the tunnel design vehicle speed, traffic volume, and variable factors.

Shaofei Wang (2009) defined the tunnel group as the highway, where there are two or more intervals in the shorter tunnel, including the continuous tunnel and the adjacent tunnel. On the basis of the analysis of several factors affecting the role of distance, it is recommended that when the

distance between the two tunnels (L) is less than 250 m, it is defined as the adjacent tunnel. When $L > 250$ m and $L < 1000$ m, it is defined as the continuous tunnel. The adjacent tunnel and continuous tunnel are two types of the tunnel group. The maximum value of the range of the influence factors is selected as the dividing boundary between the tunnel group and the independent area, which belongs to the static definition. The advantage of the definition is its easy operation, whereas the disadvantage is its poor accuracy. Na Zhou (2010) proposed the concept of relative tunnel spacing and put forward the concept of the critical value of the interaction effect of the tunnel spacing. The tunnel section is a special cover structure of road. The tunnel traffic is still related to the human, vehicle, and road, which fully take into account natural attributes, characteristics of the environment, driver's visual requirements, and vehicle's space requirements (Wang, 2009).

In this paper, the dynamic definition of the tunnel group is used to determine the critical value according to the tunnel group and to determine whether the tunnel group is based on the distance S . Taking the Luan Chuan Highway in Luoyang City as an example, the driving safety characteristics of the highway tunnel group was systematically studied and analyzed. In order to improve the construction and operation of tunnel group, the tunnel group accident risk evaluation model is established and different sections of

the actual situation were carried out, which can provide references to deal with the traffic accidents.

2 MATERIALS AND METHODOLOGY

2.1 Study area and data

The design speed of Luan Chuan Highway in Luoyang City is 80 km/h, and the running mode is one-way travel. The total distance is 66.58 km, containing 24 tunnels, with a total length of about 10.3 km, accounting for 15% of the total length of the road. The longest tunnel is 2 km, and the rest are short tunnels. The average tunnel spacing is 270 m (Zhang, 2009). The West ditch tunnel group of the Luan Chuan Highway consists of seven tunnels, as shown in Table 1.

2.2 Establishment of risk evaluation index system

People (the driver visual characteristics, psychological characteristics), car (vehicle speed, vehicle's own factors), and road (the road itself and environmental factors, including tunnel) are three aspects of the highway tunnel safety factors described in this paper. The evaluation criteria are determined through the concrete analysis of the influence factors of the tunnel group. Then, the risk index system of the highway tunnel group traffic accidents is established (Chao, 2012).

The tunnel group and safety factors are combined with the actual situation to discuss the classification and itemized fixed factors of the tunnel group according to the above principles. The comprehensive safety evaluation system of the highway tunnel group is mainly established from the tunnels of the main structure, traffic engineering facilities, import and mouth and the surrounding environment, electromechanical facilities, emergency rescue system, ventilation and lighting, security management, and maintenance services. According to the reality of the situation of highway tunnel traffic accidents and morphology, Luan Chuan Highway Tunnel group of individual tunnel is divided into three sections. According to the purposes and

principles of the highway tunnel traffic accident risk assessment system, the highway tunnel traffic accident risk assessment index system framework is divided into the target layer, the criterion layer, and the index layer. To analyze the key indicators of the evaluation system, the evaluation index value uses five conventional grades according to the various risk indicators assignment.

2.3 Safety influence factors of tunnel group

The analytic Hierarchy Process (AHP) method and the fuzzy comprehensive evaluation method are applied to the established risk evaluation index system and then the evaluation method of the risk assessment model is built.

1. AHP

AHP was first proposed by American operational experts in the mid-20th century proposing the use of the decision-making method. The complex problem is to decompose it into a hierarchical structure. The next level of various factors is relative to the level of each factor for pairwise comparison judgment. The judgment matrix is constructed by the calculation to determine the holding level, with the sorting and the consistency test. Finally, a general arrangement of administrative levels, the combination weights of the factors and sorting, are conducted through the analysis of results to solve the problem (Satty, 1978). This method has the characteristics of a small amount of information and the short-time decision process. Using the analytic hierarchy process, the weight can be determined by the following three steps (Kayastha, 2013):

1. Establish hierarchical structure

First, a hierarchical structure model is constructed. The same element has a dominant effect on some elements of the next layer, and it is subject to the domination of the upper layer. In each level, there should not be more than nine elements dominated by the next level of the general; otherwise, it will cause more difficulty to judge.

2. Structure judgment matrix

Judgment matrix $A = (a_{ij})_{n \times n}$ has the following properties:

$$a_{ij} > 0, a_{ij} = 1 / a_{ji}, a_{ij} = 1 (i, j = 1, 2, \dots, n)$$

In the formula $a_{ij} (i, j = 1, 2, \dots, n)$, U_i and U_j represent the scale of the importance of a layer of elements relative to its upper layer. The value of the judgment matrix directly reflects people's understanding of the relative importance of each factor, and it is generally used to assign values to the degree of importance and scale. The meanings are shown in Table 2.

Table 1. Luan Chuan highway tunnel in Luoyang city.

Tunnel name	Length	Slope (%)	Distance
Taishang tunnel	302	2.9/2.5	1237
Wangyuan tunnel	161	-1.92	1845
Dayangti ditch tunnel	480	+2.45/2.35	73
West ditch tunnel No. 1	95	+2.95	44
West ditch tunnel No. 2	124	+2.95	33
Yangjuan tunnel	753	+2.2/-1.2	691
Yachi ditch tunnel	640	-	-

Table 2. Judgment matrix scale and its implication.

Scaling	Meaning
1	Compared with the two elements, which is of the same importance.
3	Compared with the two elements, the former is a little more important than the latter.
5	Compared with the two elements, the former is more important than the latter.
7	Compared with the two elements, the former is more important than the latter.
9	Compared with the two elements, the former is more important than the latter.
2, 4, 6, 8	The intermediate values of the two adjacent judgments are indicated.
Reciprocal	The importance ratio of element j is $a_{ij} = 1/a_{ji}$.

3. Calculation of the relative weights of elements under a single criterion and the consistency check
 The maximum characteristic root of A is λ_{\max} , and the corresponding characteristic vector is W , which is the weight of the corresponding elements for the relative importance of a certain element at the same level. It is necessary to carry out the consistency test and calculate the consistency test index CI :

$$CI = \frac{\lambda_{\max} - n}{n - 1}$$

where n is the order of the judgment matrix.

If random consistency ratio $CR = \frac{CI}{RI} < 0.1$, the judgment matrix is satisfied with the consistency; otherwise, it is required to adjust the element value of the judgment matrix. RI value is showed in Table 2.

2. Fuzzy comprehensive evaluation model
 In the fuzzy comprehensive evaluation model, the evaluation object is judged according to the specified criteria. The comprehensive evaluation aims at making a comprehensive evaluation of the evaluation object affected by multiple factors. The basic principle of Fuzzy comprehensive evaluation method for risk assessment is as follows: the influence degree of all risk factors is considered, and the weight difference of each factor is set to distinguish the importance difference. By constructing a mathematical model, all possibility degrees of risk and the degree of possibility value are higher for the level of risk to determine the final value. As a kind of concrete application method of fuzzy mathematics, it has been widely used.

First, a set of factors U is set up, $U = \{u1, u2, u3, u4\}$, to determine the value of comprehensive evaluation. Then, we should divide the judgment matrix by using the theory of fuzzy mathematics. The weight of evaluation index is calculated and

the results of the fuzzy comprehensive evaluation are finally obtained.

3 RESULTS AND DISCUSSION

According to the established fuzzy comprehensive evaluation model, the evaluation standard, the measured value, the fuzzy switching principle, and the maximum membership principle are used to make a general evaluation of the things or objects, which are restricted by many factors.

1. Set up a set of factors
 The factors that affect the traffic accident of tunnel section 1 are set as follows:

$U_1 = \{u1, u2, u3, u4\} = \{\text{Highway alignment, The alignment of tunnel entrance section, Traffic characteristics of tunnel, Tunnel traffic environment}\}$.

Inside: $U1 = \{c1, c2, c3\} = \{\text{Highway curve radius, Slope of Expressway, Highway pavement adhesion coefficient}\}$.

$U2 = \{c4, c5, c6\} = \{\text{Curve radius of tunnel entrance, Longitudinal slope of tunnel portal section, Sight distance}\}$.

$U3 = \{c7, c8, c9\} = \{\text{Traffic saturation, Cart proportion, Average speed}\}$.

$U4 = \{c10, c11, c12\} = \{\text{Road adhesion coefficient of tunnel entrance section, Tunnel ventilation, Tunnel lighting}\}$.

The risk index system of traffic accidents of highway tunnel sections 2 and 3 is set up. The set of factors of accidents of sections 2 and 3 was set up as follows:

$V = \{v1, v2, v3, v4, v5\} = \{\text{Very good, Good, General, Poor, Very poor}\} = \{5, 4, 3, 2, 1\}$.

2. Comprehensive evaluation of traffic accidents risk of tunnel group

As the different sections of the tunnel are interrelated and influence each other, the comprehensive evaluation value of the tunnel, which is determined by the ‘‘compromise generalized criterion’’, is adopted. The tunnel group is supposed to be consistent with t_i tunnels. The tunnel is set into three sections of the entrance, intermediate, and export. The evaluation values of the tunnel sections are ($I = 1, 2 \dots J = 1, 2, 3$). For a group composed of a plurality of tunnel, ‘‘bucket theory’’ is used to determine the value of comprehensive evaluation of the tunnel group, as well as the tunnel traffic accident risk comprehensive evaluation values for all segments of the tunnel evaluation value minimum value:

$$V = \min(v_{ij})(i = 1, 2, \dots; j = 1, 2, 3)$$

3. The highway tunnel traffic accident risk assessment
 First, the traffic accident risk of the Dayangti ditch tunnel section 1 is assessed. According to the membership function of the fuzzy mathematics, the evaluation matrix of the four subfactors of the criterion layer is obtained from R_1, R_2, R_3 , and R_4 :

$$R_1 = \begin{pmatrix} 0 & 0 & 0.7 & 0 & 0 \\ 0 & 0.9 & 0 & 0 & 0 \\ 0 & 0 & 0.45 & 0 & 0 \\ 0.49 & 0 & 0 & 0 & 0 \\ 0.55 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \end{pmatrix} R_2 = \begin{pmatrix} 0 & 0 & 0 & 1 & 0 \\ 0 & 0.9 & 0 & 0 & 0 \\ 0 & 0.55 & 0 & 0 & 0 \\ 0 & 0.53 & 0 & 0 & 0 \\ 0 & 0 & 0.47 & 0 & 0 \\ 0.76 & 0 & 0 & 0 & 0 \end{pmatrix}$$

Weights of the four factors are:

$$W_1 = (0.0910, 0.4545, 0.4545), \\ W_2 = (0.6370, 0.1047, 0.2583), \\ W_3 = (0.1047, 0.2583, 0.6370), \\ W_4 = (0.6491, 0.0719, 0.2790).$$

A comprehensive evaluation of the four subfactors set is $B_i = W_i \bullet R_i$

$$R = \begin{pmatrix} B_1 \\ B_2 \\ B_3 \\ B_4 \end{pmatrix} = \begin{pmatrix} 0 & 0.4091 & 0.2862 & 0 & 0 \\ 0 & 0.2363 & 0 & 0.637 & 0 \\ 0.1934 & 0 & 0.637 & 0 & 0 \\ 0.21 & 0.344 & 0.034 & 0 & 0 \end{pmatrix}$$

As the weight of factor set U1 is $W = (0.1091, 0.1891, 0.3509, 0.3509)$, the two-level fuzzy comprehensive evaluation vector of Dayangti ditch tunnel section 1 traffic accident is given as follows:

$$B = WgR = (0.1416 \quad 0.2100 \quad 0.2623 \quad 0.2235 \quad 0)$$

As the two-level comprehensive evaluation vectors have been normalized, the weighted-average method is used as $v = \sum_{j=1}^m b_j v_j$.

The fuzzy comprehensive evaluation results of three-section traffic accidents of Dayangti ditch tunnel are shown in Table 3.

Similarly, the fuzzy comprehensive evaluation results of West ditch tunnel No. 1, West ditch tunnel No. 2, and Yangjuan Tunnel are shown in Table 4.

On the basis of the above calculation, the final fuzzy comprehensive evaluation result of Luan Chuan Highway Dayangti ditch tunnel group is $v = 3.0819$, which means that the accident risk

Table 3. Fuzzy comprehensive evaluation result of Dayangti ditch tunnel.

Section i	1	2	3
v_i	2.7819	3.1027	2.8536

Table 4. Fuzzy comprehensive evaluation result.

	Dayangti ditch tunnel	West ditch tunnel 1#	West ditch tunnel 2#	Yangjuan tunnel
v	3.0819	3.0859	3.1028	3.1153

for Luan Chuan Highway Dayangti ditch tunnel group in Luoyang city is "medium".

4 SUMMARY AND CONCLUSION

In this paper, the definition of the highway tunnel group is proposed for the first time. The AHP and fuzzy comprehensive evaluation methods are used to establish the highway tunnel group traffic accident risk evaluation model. The tunnel group safety factors are analyzed from three aspects, including human factors, car factors, and road factors. Taking the tunnel group of the Luan Chuan Highway Tunnel group in Luoyang City as an example, the results showed that the fuzzy comprehensive evaluation result of the Luan Chuan Highway Tunnel group is 3.0819, and traffic accident risk is "medium". The evaluation results have great practical significance for strengthening the safety operation of the tunnel group, which should improve the safety of highway engineering. It thus has good application value in the same projects.

Applications of new reinforcement methods in city tunnels for shield launching and arriving

Hu Jun, Jiang Baoshi & Wei Hong

College of Civil Engineering and Architecture, Hainan University, Haikou, Hainan, China

Wang Xiaobin

Management Department of Changshu Institute of Technology, Changshu, Jiangsu, China

ABSTRACT: The reinforcement methods at shield shaft will be directly related to the security of shield's departure and reception. Choosing the correct reinforcement method in that phase is crucial. The common reinforcement method at shield shaft is summarized in this paper. The conclusion is as follows: the frequently used reinforcement method for the soft soil area is cement-soil deep mixing pile + high-pressure rotary jet grouting pile. The artificial freezing method is also used when the environment restrains reinforcement and water is the primary method in the soft soil area. When encountering a full-face rock formation, it is not necessary to reinforce and a slice grouting method can be used. A special method may be taken to the special stratum. Meanwhile, three new reinforcement methods are given. Results and conclusions in this research may play a useful role to aid designs of similar projects in the future.

1 INTRODUCTION

The 21st century is the underground engineering age, which is a peak time for the underground space development and utilization of China (Hu, 2013 & 2013). The shield method has been widely applied and rapidly developed, along with sea crossing, hydraulic, hydroelectric, and municipal engineering accompanied with the tunnel construction in the subway. However, the shield method has some construction difficulties and risks, with the entry and exit construction of shield tunnelling being one of the most difficult problems.

Reinforcement methods at shield shaft are important parts of the entry and exit construction technology. Accidents often take place at the end of shield tunnel, so the reinforcement effect of shield shaft is directly related to the safety of the entry and exit construction. Because it plays an important role in the shield tunnel, it is important to select a suitable reinforcement method to ensure that the project is going well (Hu, 2012; Hu, 2011). Based on the common reinforcement methods at the shield shaft and considering the safety, economy, and environment feasibility of the entry and exit construction, in this paper, a special reinforcement method will be used. This may play a useful role to the foundation treatment and soil reinforcement of similar projects in the future.

2 THE COMMON REINFORCEMENT METHOD AT SHIELD SHAFT

There are several reinforcement methods used in the shield shaft, such as the cement-soil deep mixing, high-pressure rotary jet grouting, SMW, artificial freezing, grouting, concrete filling pile, and water lowering methods. A single or a variety of methods can be used for the soil reinforcement (Zeng, 2011; Hu, 2012).

The reinforcement methods at the shield shaft can be divided into the following two categories:

- I. Chemical reinforcement,
- II. Physical reinforcement.

The cement-soil deep mixing pile + the high-pressure rotary jet grouting pile, SMW pile + high-pressure rotary jet grouting pile, and high-pressure rotary jet grouting pile are often used in the soft soil area. The cement-soil deep mixing pile + high-pressure rotary jet grouting pile has been widely used. The artificial freezing method is used when the environment is restricted on the ground.

SMW pile + high-pressure rotary jet grouting pile and high-pressure rotary jet grouting pile + deep well dewatering could be used in the sand soil area. The reinforcement + artificial freezing method can be used if serious water and sand leakage occurs while drilling or the water can't be pumped by dewatering the well.

A full-face rock formation has a strength far greater than mixing pile or rotary spray pile, which is usually between 0.8 MPa and 1.2 MPa. Therefore, it is not necessary to reinforce when encountering it. However, when fractures develop, a slice grouting method can be used in order to block fissure water. By controlling the grouting pressure to guarantee the effect of grouting seal, a slice-grouting hole is created in a 0.5 m line along the enclosure structure.

When constructing the entry and exit, a particular reinforcement method should be used on the special stratum, including highly weathered soft rock, medium-weathered soft rock, hard clay, and high-density sand layer. For example, the stratum in tunnel portal part is hard plastic silty clay layer between chalukou station and hedingqiao station for the Nanjing subway No. 1 line. Neither mixing pile nor jet grouting pile reinforcement is ideal. Finally, concrete filling pile + rotary spray water stopping are used to solve the problem. According to the actual construction site effects, because there was no leakage or deformation, the reinforcement method was proven to have its own suitability to the special stratum.

3 SEVERAL NEW REINFORCEMENT METHODS FOR SHIELD TUNNEL END

3.1 Large-diameter cup-shaped horizontal freezing

Mostly, the cup-shaped horizontal freezing is conducted based on 6.34 m shield diameter. However, the ends of a very large-diameter shield tunnel generally adopt several reinforcement methods. There are few cup-shaped horizontal freezing methods for the ends of the shield tunnel with a large or very large diameter.

This reinforcement method is mainly used for the ends of the shield tunnel with a large or very large diameter. For a shield tunnel with a large excavation diameter of 11.64 m, 122 horizontal freezing holes are designed in this layout. Freezing circle holes with $\Phi 12.3$ m are designed along the mouth of the cup body, with a hole pitch with the arc length of 0.76 m. A freezing pipe is often referred to an outer pipe whose length shall be shield host length + 2–3 times the segment width. The freezing circle holes with $\Phi 9.9$ m, $\Phi 7.5$ m, $\Phi 5.1$ m, and $\Phi 2.7$ m are designed at the cup bottom along the mouth with hole pitches of 1.11 m, 1.12 m, 1.14 m, and 1.21 m (arc length) respectively. The freezing pipe with circles of $\Phi 9.9$ m, $\Phi 7.5$ m, and $\Phi 5.1$ m along the mouth is called the middle pipe, with a total of 63 pipes. The freezing pipe with a $\Phi 2.7$ m circle along the mouth is called the internal pipe,

with a total of 7 pipes. A central pipe has one freezing hole at the mouth. The freezing pipe at the cup bottom consists of the middle pipe, inner pipe and central pipe, and the length of freezing hole should ensure a thickness of 2 m of the cup bottom. Fig. 1 refers to the layout of the freezing hole.

One outer pipe, three middle pipes, one inner pipes and one central pipe are used in this reinforcement method. The freezing pipe on the cup body is made from the outer pipe. The length of the freezing hole is the shield host length + 2–3 times the segment width. The cup bottom of the freezing pipe consists of the inner pipe, middle pipe and central pipe, with a freezing hole length to ensure a thickness of 2 m of the cup bottom. The 20# low-carbon seamless steel pipe with $\Phi 127 \times 5$ mm can be used as a freezing pipe. It is connected by welding the outer pipe hoop and using the $\Phi 48$ mm \times 3.5 mm steel pipe as a feed pipe. This method is used to ensure the formation of the sup-shaped freezing wall with an excavation diameter of 11.64 m at the ends of the shield tunnel with a large diameter, which allows the large-diameter shield tunnelling machine to smoothly get in and out, and to meet the strength and anti-seepage requirements.

3.2 Combined method of cup-shaped horizontal grout and pipe shed reinforcement

A combined construction method of the cup-shaped horizontal grout and pipe shed reinforcement is used for the shield tunnel end strata. This

Figure 1. Layout of freezing holes.

method is based on a shield diameter of 6.34 m, with an advanced grouting long pipe shed by a row of 26 $\Phi 108$ mm \times 5 mm seamless steel pipes 400 mm above the mouth of the working well. The four specifications of the segment length are 1.0 m, 1.5 m, 2.0 m and 3.0 m. Two fabricated interfaces of the pipe shed cannot be assembled at the same section. A hole should never be drilled within 1.0 m of the steel pipe at the retaining structure near the working well. Quincuncial grouting hole is drilled at the other parts of the pipe, with a diameter of 8 mm, 300 mm longitudinal pitch, and 4 rows of even drilling on the pipe body. A box and pin with a drilling casing is used to connect the steel pipe sections. 65 horizontal grouting holes are set in the mouth of working well, and then a $\Phi 45$ mm PVC sleeve valve pipe is used in order to form a cup-shaped horizontal grouting reinforcement. The diameters of the circle-grouting hole is 1.5 m (5, 5 m L), 2.7 m (7, 5 m L), 3.9 m (14, 5.2 m L), 5.1 m (14, 12 m L), and 6.1 m (25, 8.6 m L). The circle grouting hole is horizontal at the section of the shield tunnel with diameters 5.1 m and 6.1 m. The lower section is vertical and 13° down from the mouth. A circle grouting hole with a diameter of 3.9 m is vertical and 5° from the mouth. Fig. 2 refers to the layout of the cup-shaped horizontal grouting pipe and pipe shed.

This reinforcement method includes an advanced grouting long pipe shed reinforcement within 160° section at the shield section, as well as

65 horizontal sleeve valve pipes in the mouth for grouting reinforcement. When mixing piles, this reinforcement method can be adopted. While the ground, environment or serious water sand leakage occurs after the chemical reinforcement is used to improve the soil strength, stop water at the shield tunnel end, and to ensure the safety of the shield tunneling machine. This reinforcement method has advantages of a short construction period, low cost, and simple entry and exist operation, compared with reinforcement scheme of “drilling in working well and horizontal freezing” (like cup-shaped horizontal freezing method). Moreover, it can save time, labor, and material cost.

3.3 Reinforcement method of glass fiber reinforced polymer diaphragm wall and reinforced concrete box

Firstly, this reinforcement method completes the major structure of the shield well. It adopts the underground diaphragm wall as the retaining structure. The Glass Fiber Reinforced Polymer (GFRP) is used at the mouth of the slurry wall of the underground diaphragm wall. The shield tunneling machine breaks through to substitute the bar of the underground diaphragm wall. After that, a reinforced concrete box is constructed before the mouth and sealed with the backfill. At the beginning, the shield tunneling machine is closed with backfill in the reinforced concrete box. Then the reinforced concrete box is full of backfill. Lastly, starting or reaching the direct cutting mouth by shield tunnel machine is completed. The shield tunnel machine directly cuts the mouth in the closed reinforced concrete box to finish starting, as well as to finish reaching.

GFRP can meet safety demands for the foundation ditch during the excavation stage of the shield well due to the glass fiber features. There is no need to set an outer reinforcement lateral to retain the structure at the excavation stage of the shield tunneling machine. Instead, the shield tunnel machine can directly cut the mouth slurry wall to cross the mouth. Not only can this reduce the incidence rate of the collapse accident resulted from the exposed mouth while excavating the mouth, but it can also save time of construction. Using backfill to seal the reinforced concrete box can balance the water and earth pressure in and out of the shield well foundation ditch, as well as avoid the flowing risk of the entry and exit of the shield tunneling machine.

Other similar materials which can substitute the Glass Fiber Reinforced Plastic bars (GFRP) will meet functional requirements of retaining the structure of the shield well, as well as direct cutting mouth demands by the shield tunneling machine after the substitution.

Figure 2. Layout of cup-shaped horizontal grouting pipe and pipe shed.

Figure 3. Layout of GFRP diaphragm wall and reinforced concrete box.

The reinforced concrete box in this reinforcement method can be substituted by other similar structures, which shall meet demands for balancing the water and earth pressure in and out of the shield well foundation ditch.

This method is applicable for the entry and exit construction of the shield tunneling machine at rock stratum or complex strata, for the hob of the earth pressure balance shield machine can cut the GFRP diaphragm wall. The shield tunnel machine with scraper cannot break the GFRP concrete. In order to avoid serious concrete blocking in the pipe, the slurry balance shield machine has to be controlled.

The layout of GFRP diaphragm wall and reinforced concrete box in this reinforcement method refer to Fig. 3.

4 CONCLUSIONS

1. The cement-soil deep mixing pile + high-pressure rotary jet grouting pile, SMW pile + high-pressure rotary jet grouting pile, and high-pressure rotary jet grouting pile are often used in the soft soil area. When the environment is restricted on the ground, the artificial freezing method is adopted.
2. SMW pile + high-pressure rotary jet grouting pile and high-pressure rotary jet grouting pile +

deep well dewatering could be used in the sand soil area. It is essential that pumping tests are taken prior to reinforcement. Generally, the reinforcement should be completed before the dewatering well building in order to avoid high-pressure cement slurry to damage it.

3. It is not necessary to reinforce when encountering a full-face rock formation. However, if a rock fracture develops, a slice grouting method should be used. Some special method may be taken to the special stratum when the common reinforcement methods cannot meet the ideal effect. When the common reinforcement methods can't meet the ideal effects, a special method for the special stratum may be used.
4. The Large-Diameter Cup-Shaped Horizontal Freezing method is used to ensure the formation of the sup-shaped freezing wall at large-diameter shield tunnel end with 11.64 m excavation diameter, to meet requirements for strength and anti-seepage, and to smoothly allow the large diameter shield tunnelling machine to get in and out.
5. This reinforcement method is of short construction period, low cost and simple entry and exit operation when compared with reinforcement scheme of "drilling in working well and horizontal freezing" (like cup-shaped horizontal freezing method). Additionally, it has the ability to save time, labor, and material cost.
6. The advantages of Reinforcement Method of Glass Fiber Reinforced Polymer Diaphragm Wall and Reinforced Concrete Box are obvious.
 - ① The construction period is shortened because no labor is needed to excavate the mouth.
 - ② Engineering costs are reduced because no reinforcement is needed in the lateral retaining structure.
 - ③ Retaining structure can directly stop soil and water at the entry and exist stage of the shield tunneling machine, and reinforced concrete box sealed with backfill can balance the water and earth pressure in and out of shield well mouth, therefore improving the safety of entering and exiting the construction of the shield tunnelling machine.

Research on the stress characteristics of concrete carrier pile based on finite element analysis

Jinyun Li

Tianjin College, University of Science and Technology Beijing, Tianjin, China

Aiqing Zhang & Xiangang Han

School of Civil and Environment Engineering, University of Science and Technology Beijing, Beijing, China

ABSTRACT: It is of great significance to describe the stress characteristics of concrete carrier pile in foundation reasonably and accurately for ensuring the safety of superstructures. On the basis of the finite-element numerical simulation method, cast-in-place pile is used as contrast to analyze the change rules of Q - s curve of carrier pile by applying axial pressure and lateral pressure repeatedly and verify the correctness of the rules through field test. The result indicates that the stress and displacement of the carrier pile are smaller than those of cast-in-place pile, stress concentration does not exist at the end of carrier pile, displacement change of the soil around the pile end is distributed symmetrically, the displacement at pile end is only 0.07 cm, and there is parabola change between the load increase and subsidence values. Static load test of a single carrier pile was designed in site, the stress reflection wave value of the test pile was measured, Q - s curve of the carrier pile is drawn, and the result of the numerical calculation verified the accuracy of numerical calculation.

1 INTRODUCTION

Carrier pile is capable of compacting foundation soil and enlarging the action area of pile end. When soft soil layer exists at the shallow soil layer of the construction site and there is a good soil layer with a certain thickness underneath, it has high application value. In recent years, it has substituted traditional foundation and ground treatment forms in medium and small architectural works as it has high bearing capacity and can adjust the uneven settlement to some extent to show good mechanical properties. According to the principle of the role of vector piles from analysis and research, a concise exposition of the principle of the piles with the force, design, and calculation of bearing capacity was given by Wang (2009). Li (2011) studied the bearing capacity and settlement of the ram-compaction piles with composite bearing. Hou (2015) studied the carrier pile bearing performance and engineering application using the method of field test and theoretical analysis. To explain the stress characteristics of carrier pile, in this paper, we carry out research on the stress of carrier pile and cast-in-place pile, conduct modeling, perform analysis on the bearing process of axial and lateral stresses by the two piles in foundation using large numerical simulation software, and draw the Q - s curve.

2 DESIGN OF THE SIMULATION SCHEME

2.1 Constitutive model of pile and soil materials

In this paper, concrete refers to a nonlinear material model with the nonlinear constitutive relation; generally, concrete plastic damage model can well describe the constitutive relation. However, in this paper, especially in pile–soil interaction, elasticity modulus of concrete is much greater than that of soil, and damage rarely occurs in vertical action.

Figure 1. Elastic–plastic Coulomb friction model.

Thus, a linear elastic model is adopted for the constitutive relation of concrete in this paper. The model of soil often refers to Mohr–Coulomb plastic model and Drucker–Prager model. Both of the strength criteria exist in the constitutive relation in an implicit form.

ABAQUS contact simulation refers to point–surface contact analysis based on the surface, and the pile surface is taken as the main surface because of its great rigidity, while soil surface is taken as the auxiliary surface. The point–surface contact unit is composed of coordinate and contact surface. Before using such contact unit, there is no need to know the exact contact position in advance or keep consistent network among the contact surfaces, and large deformation and relative sliding are allowed. Coulomb friction model prevails as the contact constitutive relation, and the relationship between shearing stress and normal stress of the model contact surface is shown in Figure 1.

2.2 Calculation model

During modeling, the radius of the soil is 10 times that of the pile cross section and the soil of double pile length is extended below the pile end to minimize the influence of model boundary on the analysis area. The soil body influenced by the carrier of carrier pile is 2–3 m deep in the horizontal direction and 3–5 m deep in the vertical direction. Conduct pile modeling inside Part model, assemble the soil layer model in Assembly, set materials in Property, set analysis step in Step, set pile soil contact surface in Interaction, set birth–death element, set load in Load module, and divide mesh in Mesh module; after completing modeling, submit in Job module for post-treatment process. The

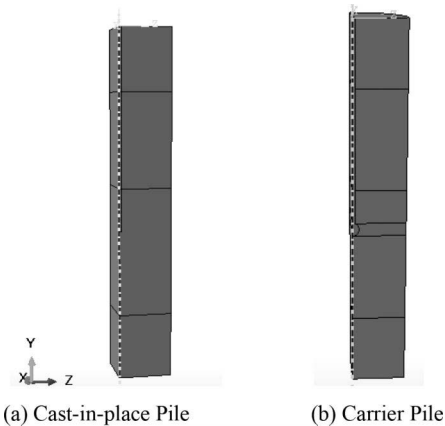

Figure 2. Models of cast-in-place pile soil and carrier pile soil.

Table 1. Summary of soil modeling parameters (1).

Name of the soil layer	Elasticity modulus (MPa)	Density (kg/m ³)	Cohesion (kPa)
Plain fill	30.6	1700	25.3
Muddy clay	4.8	1800	19.6
Silty clay	26.6	1900	24.3
Wholly weathered rock	2600	2400	82.0

Table 1. Summary of soil modeling parameters (2).

Name of the soil layer	Internal friction angle (o)	Expansion angle (o)	Poisson's ratio
Plain fill	6.4	3	0.3
Muddy clay	16.5	8	0.3
Silty clay	17.2	8.5	0.3
Wholly weathered rock	28.8	0	0.2

model established is shown in Figure 2. Figure 2 (a) refers to cast-in-place pile soil model and Figure 2 (b) refers to carrier pile soil model.

To ensure that the model conforms to actual engineering, we conduct the survey and sampling of actual engineering geology of the place and obtain the summary of soil parameters required for modeling through indoor test, as shown in Table 1.

The order of soil layer is plain fill, muddy clay, silty clay, and wholly weathered work from the surface, with thicknesses of 6, 9, 12, and 6 m, respectively.

The two models established above are of the same soil-layer structures, and all soil body parameters are obtained from Table 1. The friction coefficient is the same as that of pile body, and the elasticity modulus of the concrete is 2.36×10^4 MPa.

2.3 Load application

Apply load to both of them, respectively, by 12 steps, and the applied load is N (measured in kN). To apply the load to the pile evenly, adopt local loading, that is, apply load with the converted P , wherein:

$$P = F / S \quad (1)$$

The loading mode is shown in Table 2.

As for cast-in-place pile, the loading mode is the same as that of concrete carrier pile; to distinguish both of them, apply load by 12 steps, and the loading model is shown in Table 3.

Table 2. Successive load application to concrete carrier pile (kN).

P (kPa)	1783	2038	2293	2547	2802	3057

2.4 Calculation result

Apply load to the carrier pile and cast-in-place pile separately as per the loading mode above, and read the data after each load application. Considering the limit to the paper length, this study only conducts analysis on the stress diagram and displacement diagram of a certain point.

2.4.1 Stress diagram

It is evident from Figure 3 (a) and (b) that, under the same vertical load effect, the maximum stress borne by the cast-in-place pile is 904.4 kPa and that borne by the carrier pile is 484.2 kPa. Stress concentration occurs to the end of cast-in-place pile, which indicates that the soil has punching shear destruction, thus being against bearing upper load. While the stress at the end of the concrete carrier pile is distributed evenly and a stress vacuum area appears on the soil layer of the carrier, that is, the stress borne by the carrier pile is much less than that borne by the cast-in-place pile because of the interaction between carrier bottom and soil.

2.4.2 Displacement diagram

It is evident from Figure 4 (a) and (b) that, under the same vertical load effect, a certain displacement occurs to the soil around the cast-in-place pile body

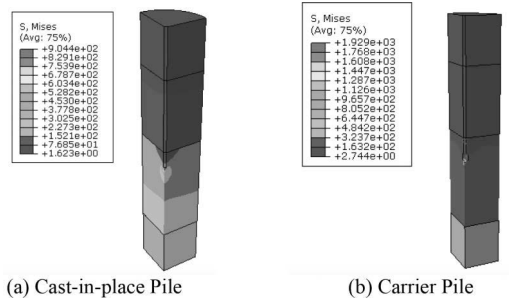

Figure 3. Stress diagram of cast-in-place pile and carrier pile under the 300-kN load effect.

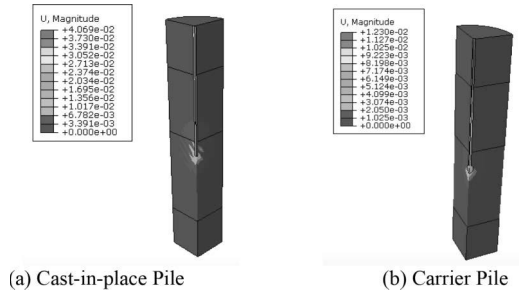

Figure 4. Displacement diagrams of cast-in-place pile and carrier pile under the 300-kN load effect.

and the pile end, the displacement distribution of soil around the pile end is uneven, and the pile end displacement is 0.27 cm. Displacement also occurs to the soil around the carrier pile body and the pile end; however, the displacement change of soil around the pile end is symmetrically distributed, and the pile end displacement is only 0.07 cm. It is shown through comparison that the displacement of carrier pile is less than that of the cast-in-place pile.

2.4.3 Q-s curve

Because it is difficult to calculate the pile lateral friction at present, in this paper, we take the settlement curve of pile body as reference during the numerical simulation process, judge the ultimate bearing capacity of pile according to specification, and draw the numerical calculation results to Q-s curve of the carrier pile and the cast-in-place pile, as shown in Figures 5 and 6. During the numerical calculation process, when the cast-in-place pile is loaded to 600 kN, the corresponding Q-s curve has no obvious turning change. Thus, the load is increased to 700 and 800 kN, and the corresponding P values are 3,567 and 4,076 kPa.

It is evident from Figure 5 that the Q-s curve is approximately parabolic and the curve change

is relatively gentle. Subsidence value of the carrier pile increases with the increase of load; when the load exceeds 2,500 kN, the soil at the carrier pile bottom is damaged; then, settlement increases rapidly. Such phenomenon occurs because when bearing load, the carrier pile relies on the friction force between the pile and soil, and the carrier at the bottom of carrier pile restricts the sinking of pile body.

Through observation of Figure 6, Q-s curve is in a steep fall shape. Subsidence value of the cast-in-place pile also increases with the increase of load; before the load reaches 500 kN, the sinkage and load value vary linearly; after the load exceeds 700 kN, the curve decreases sharply. Such phenomenon occurs because that at the beginning of load application, the friction force between the pile and soil is the main source of bearing capacity; after the friction force reaches the limit, the pile end bears the load, but the bearing capacity of pile end is limited, which is less than the bearing load of friction force.

Figure 5. Q-s curve of the carrier pile.

Figure 6. Q-s curve of the cast-in-place pile.

A comparison of Figures 5 and 6 shows that although the subsidence value of both of the piles increases with the increase of load, the variation type of the Q-s curve is different. If the corresponding load values of the same subsidence value are selected for comparison, the load borne by the carrier pile is larger, which indicates that the carrier pile bears a higher load than the cast-in-place pile, and there is parabolic variation rule between the load increase and subsidence value.

3 FIELD LOADING TEST

3.1 Static load test design of carrier pile

Select an engineering carrier pile to conduct vertical static load test of single pile and adopt 2h load-keeping method at each step in reference with domestic and international engineering cases. During the testing of 1# test pile, there are 12 steps of load application in total, the first step a 240 kN load is applied, then in each of the subsequent steps, a 160 kN load is applied. The maximum load value is 2,000 kN; after each step of loading, read every 5, 10, 15, 15, 15, 15, 15, and 15 min, and the accumulated time of load keeping is 24h. During the test of 2#, 3#, and 4# test piles, there are 12 steps of load application in total. In the first step, a load of 250 kN is applied; then, in each of the subsequent steps a 250 kN load is applied; after each step of loading, read every 5, 10, 15, 15, 15, 15, 15, and 15 min, and the accumulated time of load keeping is 24h. The load test of the field carrier pile is shown in Figure 7.

3.2 Static load test results of carrier pile

The stress wave reflection method is used in site for measuring the pile, which assumes the medium as a one-dimensional section homogeneous bar with continuous elasticity, without taking into account

Figure 7. Load test of the field carrier pile.

Table 4. Analysis results of measured curve of reflection wave for test pile (1).

Test pile no.	Construction no.	Pile length (m)	Pile diameter (mm)

2	3300	II
3	3300	I
4	3300	I

Table 5. Load-subsidence corresponding analysis of 2#, 3#, and 4# test piles at each step.

Step	Load (kN)	Accumulated subsidence (mm)		
		2# test pile	3# test pile	4# test pile
1	250	0.68	0.64	0.79
2	500	1.78	1.05	1.47
3	750	3.04	1.82	2.07
4	1000	4.63	2.84	2.71
5	1250	7.35	3.48	3.54
6	1500	11.26	4.62	4.56
7	1750	14.78	6.92	5.92
8	2000	20.38	9.83	8.06
9	2250	27.63	12.45	11.33
10	2500	32.54	15.86	17.32
11	2750	37.63	18.46	25.42
12	3000	46.55	21.37	34.92

Figure 8. Q-s curve of 2#, 3#, and 4# test piles.

the influence of substances around the medium on the stress wave, which is propagated along the medium. The property of pile body defect and pile end can be exactly judged according to the phase, amplitude, and frequency characteristic of the reflection wave as well as the stratum data, construction record, and practical analysis experience. The measured curve of the reflection wave for test pile and the analysis results of the measured curve of reflection wave for the test pile are shown in Table 4.

It can be known from Table 4 that an obvious defect exists in 1# pile body, which does not meet the specification requirements; thus, the static load test data results of 2#, 3#, and 4# test piles are selected as the test data of the carrier pile. Specific results are shown in Table 5.

The data of Table 5 is drawn as a Q-s curve chart, as shown in Figure 8.

It is evident from Figure 8 that Q-s curve variation trends of the three test piles are the same, all referring to a parabolic change. The variation of 2# test pile is more obvious than that of the 3# and 4# test piles, which is mainly resulted from poor integrity of the pile. However, overall variation rules of the three test piles are the same.

4 CONTRASTIVE ANALYSIS ON FIELD LOAD TEST RESULTS AND NUMERICAL SIMULATION RESULTS

The results of a comparison of the field load test results presented above with the ABAQUS numerical simulation results are shown in Figure 9. It is evident from the figure that the numerical simulation results are similar to the field test results, which indicates that the modeling of numerical simulation and the selection of parameters and loading process are accurate, thus reflecting the actual situation of the field. Therefore, the Q-s curve variation rules of the carrier pile obtained through numerical simulation are correct and authentic.

Figure 9. Q-s curve of field test piles and simulation results.

5 CONCLUSION

By comparing the stress, displacement, and Q-s curve of the carrier pile with those of the cast-in-place pile under the same vertical load effect via numerical simulation, it can be concluded that the stress and displacement of the carrier pile are smaller than those of the cast-in-place pile, the displacement change of the soil around the carrier pile end is distributed symmetrically, and the displacement at the pile end is only 0.07 cm, being approximately steady. The carrier pile bears a higher load at the same subsidence value, and there is parabolic variation rule between the load increase and subsidence value. The static load test of a single carrier pile is designed in site, the value of stress reflection wave of the test pile is measured, the Q-s curve of the carrier pile is drawn, and the result agrees with the numerical calculation result. These observations verify that the Q-s curve variation rule of the carrier pile obtained through numerical simulation is accurate.

Theoretical analysis of the deformation of shield tunnel segment under fire

Xingbo Han, Yongxu Xia & Lunlei Chai
School of Highway, Chang'an University, Xi'an, China

ABSTRACT: Shield tunnel segment would be exposed to elevated temperature when fire occurs. The elevated temperature will decline the mechanical properties of the segments as well as complicate their deformation and force analysis. The impact of elevated temperature is not fully considered in most studies on the deformation of shield segments. This paper presents a theoretical analysis on the deformation of the segments subjected to elevated temperature. Considering the nonlinear segment section thermal degradation and mechanical property declination, a somewhat generic theoretical calculation model for the segment deformation is established. On the basis of the Free-Form Deformation theory, an analytical solution via the model is then proposed. Moreover, the application of the formulation is illustrated by presenting a case study of Nanjing Metro tunnel segments. The result shows that, when fire lasted 2 h, the maximum deflection reached to 79 mm at the segment crown. The upper half of the segment shows a significant downtrend, whereas its lower half rises. The maximum horizontal deflection occurs at 60 mm down from the crown and reaches to 45 mm at 2 h. Compared with the Chinese code for the design of road tunnel, it would not be safe enough for the escape or rescue of people after the fire lasted 40 min.

1 INTRODUCTION

Tunnel fire is an irresistible rare event, which would bring great damage to both human life and the tunnel structure. The influence of fire on the tunnel lining has been studied wisely. Recently, shield tunnel construction has dramatically increased in China because of its advantage of high mechanization and very little influence on the environment. Thus, the influence of fire on shield tunnel has become a central issue in tunnel disaster release and proof.

Mechanical behavior of a beam subjected to elevated temperature has been widely studied in bridge and construction engineering (Huang et al. 1999, Huang et al. 2000, Bailey 2004). Compared with the normal beam (Heidarpour & Bradford 2009, Bradford 2001, Bradford et al. 2006, Kruppa & Zhao 1995), only few studies have been conducted on the tunnel lining—a curve beam (Pi et al. 2002, Pi & Bradford 2004, Heidarpour et al. 2010). As to the tunnel lining, the thermal degradation along the tunnel section, and lining thickness, the external loads and the boundary condition are more complex than those of a bridge or building beam.

There still have been some studies on the influence of fire on a lining. Several laboratory experiments were carried out by many researchers (Yan et al. 2013, Yan et al. 2015, Lai et al. 2014, Guo 2013,

Yan 2007, Choi et al. 2013). Their experiments are mostly concentrated on spalling of the lining concrete or the force of a single segment. Very few studies have been done on the deformation of the whole ring of the segment. Numerical simulation is also well used in studying the influence of fire on lining (Guo 2013, Kodur 2008).

Compared with experiment or numerical simulation, theoretical analysis is relatively weak. A theoretical result of pinned arches under thermal loading was given by Heidarpour (2010). Zhongyou Li (2012) also established a theoretical analysis model of the lining under fire loading. The influence of fire on lining is significantly made clear by this model, but its boundary condition is inconsistent with the real project.

In this paper, we present a mechanical analytical formulation for the deformation of segment ring at elevated temperatures in which the segment ring was treated as a circle. With the symmetry of geometric model and external loads, only half of the ring was analyzed. The calculating model is restrained at its bottom. The cross-section axial force and bending moment are obtained via the free deformation theory by considering external loads such as vertical pressure of soil, lateral pressure of soil, segment self-weight, water pressure, and subground resisting force. Following the segment deformation, regulation under fire situation is obtained from the case study.

2 ANALYTICAL MODEL

The nomenclatures used in this paper are listed as follows:

\overline{M}	Bending moment at segment section
N	Axial force in the segment section
M	Bending moment considering the eccentricity caused by temperature
N	Axial force considering the eccentricity caused by temperature
k	Coefficient of thermal expansion of concrete
E_T	Moduli of elasticity of segment
$T(y)$	Function of segment cross-section temperature distribution
$\alpha_1, \dots, \alpha_4$	Parameters of the calculating process
y_0	Location of neutral axis of the segment
y	Eccentricity caused by temperature
h	Segment thickness
T_t	Segment temperature of the left-hand side
T_b	Segment temperature of the right-hand side
R	Segment radius
φ	Angle from segment crown to any section
$\theta(\varphi)$	Rotation
$u(\varphi)$	Radial deflection
$u_x(\varphi)$	Horizontal deflection
$u_y(\varphi)$	Vertical deflection
P_i	Horizontal pressure
q_i	Soil pressure
P_R	Soil resistance
X_i	Unknown redundant force
δ_{ij}	Flexibility coefficient
Δ_{ij}	Unit load deflection
g	Segment self-weight
h	Underground water depth

According to Zhi-guo Yan et al. (2013, 2015), the thermal degradation of a segment section under fire is not a line but a curve, as shown in Fig. 1.

Figure 1. Temperature distribution of lining cross section.

Current experiment shows that concrete elastic modulus decreases and maximum strain increases when subjected to elevated temperature. However, it could still meet the elastic deformation condition before its yield. The concrete could meet the elastic deformation rule before its yield. Hence, the assumptions of this model are:

1. The metric is still in the range of elastic deformation;
2. The section deformation meets the plane cross-section assumption.

As shown in Fig. 1, T_b is the fire close face of the segment, T_t is the fire away face, and h is the segment thickness. According to assumption (1), the strain of segment section can be expressed as:

$$\varepsilon = (y - y_0)\kappa \quad (1)$$

The elevated temperature would lead to a thermal expansion of concrete. The strain caused by thermal expansion is:

$$\varepsilon_T = kT(y) \quad (2)$$

Using Eqs. (1) and (2), the elastic strain of the segment section can be written as:

$$\varepsilon_e = \varepsilon - \varepsilon_T = (y - y_0)\kappa - kT(y) \quad (3)$$

According to assumption (2), ignoring the temperature distribution along tunnel drive direction, the stress of the segment section is:

$$\sigma = E_T \varepsilon_e = E_T [(y - y_0)\kappa - kT(y)] \quad (4)$$

The axial force (N) in the concrete typical cross section can be obtained by integrating the stresses as:

$$N = \int_0^h E_T [(y - y_0)\kappa - kT(y)] dy \quad (5)$$

Eq. (5) leads to a relationship between the total internal axial force and the location of the neutral axis in each part of the cross section as:

$$y_0 = \frac{\kappa \int_0^h E_T y dy - k \int_0^h E_T y dy - N}{\kappa \int_0^h E_T dy} \quad (6)$$

Using Eq. (4), the typical cross-section bending moment can be expressed as:

$$M = \int_0^h E_T [(y - y_0)\kappa - kT(y)] y dy \quad (7)$$

The curvature (κ) at the cross section can be formulated as a function of the total internal moment and axial force using Eq. (7) as:

$$\alpha_1 M - \alpha_2 N - (\alpha_3 - \alpha_4) k = \kappa \quad (8)$$

where $\alpha_1, \alpha_2, \alpha_3$ and α_4 are defined as:

$$\left. \begin{aligned} \alpha_1 &= \frac{\int_0^h E_T dy}{\int_0^h E_T dy \int_0^h E_T y^2 dy - \left(\int_0^h E_T y dy \right)^2} \\ \alpha_2 &= \frac{\int_0^h E_T y dy}{\int_0^h E_T dy \int_0^h E_T y^2 dy - \left(\int_0^h E_T y dy \right)^2} \\ \alpha_3 &= \frac{\int_0^h E_T y dy \int_0^h E_T T(y) dy}{\int_0^h E_T dy \int_0^h E_T y^2 dy - \left(\int_0^h E_T y dy \right)^2} \\ \alpha_4 &= \frac{\int_0^h E_T dy \int_0^h E_T T(y) y dy}{\int_0^h E_T dy \int_0^h E_T y^2 dy - \left(\int_0^h E_T y dy \right)^2} \end{aligned} \right\} \quad (9)$$

The cross-section bend angle can be represented by the sectional curvature (Bradford MA, 2006), which can be computed as:

$$\theta(s) = \int [\alpha_1 M - \alpha_2 N - (\alpha_3 - \alpha_4) k] ds \quad (10)$$

As to the circular tunnel segments, Eq. (1) can be further expressed as:

$$\theta(\varphi) = \int [\alpha_1 M - \alpha_2 N - (\alpha_3 - \alpha_4) k] R d\varphi \quad (11)$$

The radial deformation can be determined from:

$$v(\varphi) = \int \theta(\varphi) R d\varphi \quad (12)$$

Further, the horizontal and vertical deformations can be calculated as:

$$\left. \begin{aligned} u_x(\varphi) &= v(\varphi) \cos(\varphi) \\ u_y(\varphi) &= -v(\varphi) \sin(\varphi) \end{aligned} \right\} \quad (13)$$

Considering the decrease of elasticity modulus with temperature, the axial force would cause an additional bending moment. Therefore, the axial force and bending moment can be expressed as:

$$N = \bar{N}; M = \bar{M} + \bar{N} \bar{y} \quad (14)$$

where \bar{y} is the location of the neutral axis which is given by:

$$\bar{y} = \frac{\int_0^h E_T y dy}{\int_0^h E_T dy} - \frac{h}{2} \quad (15)$$

3 SEGMENT DEFORMATION ANALYSIS

The theoretical segment deformation calculating result is established on the basis of free deformation method and time-dependent material property.

3.1 Free-form deformation method

The hypothesis of this calculating result is that the tunnel segment is built in a soft sandy soil or cohesive soil; thus, the soil would not produce a pronounced resistance to the segment. Under this hypothesis, the tunnel segment can be treated as a deformation-free homogeneous circle. The main loads applied on the segments are soil pressure above the segment (q_1), soil horizontal pressures (p_1 and p_2), and soil resistance (p_R).

The segment is a three-time redundant-degree structure, whose internal forces can be solved by force method. The segment structure and its loads are symmetrical with the segment vertical axis; thus, the shearing force along the symmetrical face is 0. Without the shearing force, only two forces are redundant. The basic structure calculating diagrams are shown in Fig. 2. The bottom of the circle is fixed, and the unknown forces, X_1 and X_2 , are moved to the elastic central. The flexibility coefficient δ_{12} equals 0 and then the equation of displacement coordination is expressed as:

$$\left. \begin{aligned} X_1 \delta_{11} + \Delta_{1p} &= 0 \\ X_2 \delta_{22} + \Delta_{2p} &= 0 \end{aligned} \right\} \quad (16)$$

The angle between the lining section and the vertical axial force are supposed to equal φ . According to the free-form deformation method, the axial

Figure 2. Structure load distribution of the segment.

force and bending moment of any of this section can be solved by:

$$\left. \begin{aligned} \bar{M} &= M_p + X_1 - X_2 R_n \cos \varphi \\ \bar{N} &= N_p + X_2 \cos \varphi \end{aligned} \right\} \quad (17)$$

in which M_p and N_p are expressed by:

$$M_p = \left\{ \begin{aligned} & -q_1 R^2 \frac{\sin^2 \varphi}{2} - p_1 R^2 \frac{(1 - \cos \varphi)^2}{2} \\ & -p_2 R^2 \frac{(1 - \cos \varphi)^3}{12} - R^3 \quad \left(0 \leq \varphi < \frac{\pi}{2}\right) \\ & -g R^2 (\varphi \sin \varphi + \cos \varphi - 1) \\ & + (\cos \varphi + 0.5 \varphi \sin \varphi - 1) \end{aligned} \right. \quad (18)$$

$$\left. \begin{aligned} & q_1 R^2 \left(\frac{1}{2} - \sin \varphi\right) - p_1 R^2 \frac{(1 - \cos \varphi)^2}{2} \\ & -p_2 R^2 \frac{(1 - \cos \varphi)^3}{12} - p_R R^2 \frac{(1 - \sin \varphi)^2}{2} \quad \left(\frac{\pi}{2} \leq \varphi < \pi\right) \\ & -g R^2 (\varphi \sin \varphi + \cos \varphi - 1) \\ & + (\cos \varphi + 0.5 \varphi \sin \varphi - 1) R^3 \end{aligned} \right\}$$

$$N_p = \left\{ \begin{aligned} & q_1 R \sin^2 \varphi - p_1 R (1 - \cos \varphi) \cos \varphi \\ & -p_2 R \frac{(1 - \cos \varphi)^2}{4} \cos \varphi + g R \varphi \sin \varphi \\ & + R^2 - 0.5 R^2 \varphi \sin \varphi - R^2 \cos \varphi + h R \end{aligned} \right. \quad \left(0 \leq \varphi < \frac{\pi}{2}\right) \quad (19)$$

$$\left. \begin{aligned} & q_1 R \sin \varphi - p_1 R (1 - \cos \varphi) \cos \varphi \\ & -p_2 R (1 - \cos \varphi)^2 \frac{\cos \varphi}{4} \quad \left(\frac{\pi}{2} \leq \varphi < \pi\right) \\ & -p_R R (1 - \sin \varphi) \sin \varphi + g R \varphi \sin \varphi \\ & + R^2 - 0.5 R^2 \varphi \sin \varphi - R^2 \cos \varphi + h R \end{aligned} \right\}$$

Eq. (20) resulted from structural mechanics and expressed as:

$$\left. \begin{aligned} X_1 &= -\frac{\Delta_{1P}}{\delta_{11}} = -\frac{1}{\pi} \int_0^\pi M_p d\varphi \\ X_2 &= -\frac{\Delta_{2P}}{\delta_{22}} = \frac{2}{\pi R} \int_0^\pi M_p \cos \varphi d\varphi \end{aligned} \right\} \quad (20)$$

Eq. (20) can be expanded by Eqs. (18) and (19) so that the unknown forces (X_1 and X_2) can be written as a function of applied loads like

$$\left. \begin{aligned} X_1 &= -q_1 R^2 \left(\frac{1}{8} - \frac{1}{\pi}\right) + p_1 R^2 \frac{3}{4} + p_2 R^2 \frac{5}{24} \\ & + p_R R^2 \left(\frac{3}{8} - \frac{1}{\pi}\right) + g R^2 + \frac{R^3}{2} \\ X_2 &= -q_1 R \frac{1}{3\pi} + p_1 R + p_2 R \frac{5}{16} \\ & + p_R R \frac{1}{3\pi} - \frac{gR}{2} + \frac{3R^2}{4} \end{aligned} \right\} \quad (21)$$

Eq. (17) can be re-expressed using Eqs. (18), (19), and (21) as follows:

$$\bar{M} = \left\{ \begin{aligned} & -q_1 R^2 \frac{\sin^2 \varphi}{2} - p_1 R^2 \frac{(1 - \cos \varphi)^2}{2} \\ & -p_2 R^2 \frac{(1 - \cos \varphi)^3}{12} - q_1 R^2 \left(\frac{1}{8} - \frac{1}{\pi}\right) + \frac{3}{4} p_1 R^2 \\ & + \frac{5}{24} p_2 R^2 + p_R R^2 \left(\frac{3}{8} - \frac{1}{\pi}\right) \quad \left(0 \leq \varphi < \frac{\pi}{2}\right) \\ & + \left(\frac{q_1}{3\pi} - p_1 - \frac{5}{16} p_2 - \frac{p_R}{3\pi}\right) R^2 \cos \varphi \\ & + g R^2 \left(2 - \frac{1}{2} \cos \varphi - \varphi \sin \varphi\right) \\ & - R^3 \left(\frac{1}{2} - \frac{1}{4} \cos \varphi - \frac{1}{2} \varphi \sin \varphi\right) \\ & -q_1 R^2 \left(\sin \varphi - \frac{1}{2}\right) - p_1 R^2 \frac{(1 - \cos \varphi)^2}{2} \\ & -p_2 R^2 \frac{(1 - \cos \varphi)^3}{12} - p_R R^2 \frac{(1 - \sin \varphi)^2}{2} \end{aligned} \right. \quad (22)$$

$$\left. \begin{aligned} & -q_1 R^2 \left(\frac{1}{8} - \frac{1}{\pi}\right) + \frac{3}{4} p_1 R^2 + \frac{5}{24} p_2 R^2 \quad \left(\frac{\pi}{2} \leq \varphi < \pi\right) \\ & + \left(\frac{q_1}{3\pi} - p_1 - \frac{5}{16} p_2 - \frac{p_R}{3\pi}\right) R^2 \cos \varphi \\ & + p_R R^2 \left(\frac{3}{8} - \frac{1}{\pi}\right) + g R^2 \left(2 - \frac{1}{2} \cos \varphi - \varphi \sin \varphi\right) \\ & - R^3 \left(\frac{1}{2} - \frac{1}{4} \cos \varphi - \frac{1}{2} \varphi \sin \varphi\right) \end{aligned} \right\}$$

$$\bar{N} = \left\{ \begin{aligned} & q_1 R \sin^2 \varphi - p_1 R (1 - \cos \varphi) \cos \varphi \\ & -p_2 R \frac{(1 - \cos \varphi)^2}{4} \cos \varphi \\ & - \left(\frac{q_1}{3\pi} - p_1 - \frac{5}{16} p_2 - \frac{p_R}{3\pi}\right) R \cos \varphi \quad \left(0 \leq \varphi < \frac{\pi}{2}\right) \\ & + g R \left(\varphi \sin \varphi - \frac{1}{2} \cos \varphi\right) + R^2 \\ & - \frac{1}{2} R^2 \varphi \sin \varphi - R^2 \cos \varphi + h R \end{aligned} \right. \quad (23)$$

$$\left. \begin{aligned} & q_1 R \sin \varphi - p_1 R (1 - \cos \varphi) \cos \varphi \\ & -p_2 R \frac{(1 - \cos \varphi)^2}{4} \cos \varphi \\ & -p_R R (1 - \sin \varphi) \sin \varphi \quad \left(\frac{\pi}{2} \leq \varphi < \pi\right) \\ & - \left(\frac{q_1}{3\pi} - p_1 - \frac{5}{16} p_2 - \frac{p_R}{3\pi}\right) R \cos \varphi \\ & + g R \left(\varphi \sin \varphi - \frac{1}{2} \cos \varphi\right) + R^2 \\ & - \frac{1}{2} R^2 \varphi \sin \varphi - R^2 \cos \varphi + h R \end{aligned} \right\}$$

The rotated angle is solved by substituting Eqs. (22) and (23) into Eq. (14) and Eq. (8):

$$\theta(\varphi) = \alpha_1 R \left(\int \bar{M} d\varphi + \bar{y} \int \bar{N} d\varphi \right) - \alpha_2 R \int N d\varphi - (\alpha_3 - \alpha_4) k R \varphi + C_1 \quad (24)$$

Rewrite Eq. (12) using Eq. (24), the displacement can be determined by:

$$u(\varphi) = \int \left\{ \alpha_1 R \left(\int \bar{M} d\varphi + \bar{y} \int \bar{N} d\varphi \right) - \alpha_2 R \int N d\varphi - (\alpha_3 - \alpha_4) k R \varphi + C_1 \right\} R d\varphi + C_2 \quad (25)$$

Unknown constants C_1 and C_2 can be worked out by the boundary conditions. The complex functions can be solved by MATLAB or other math-calculating tools.

3.2 Time-dependent material property

When a fire occurs, it is reasonable to treat the temperature distribution along the tunnel face homogeneously because of the narrow space of a city metro sector tunnel. A temperature distribution function of the lining section under fire situation was proposed by Qiang Jian (2007) as:

$$T(y) = \alpha(T_{f \max}, t) e^{\frac{h-y}{\beta(T_{f \max}, t)}} + \gamma(T_{f \max}, t) \quad (26)$$

where $\alpha(T_{f \max}, t)$, $\beta(T_{f \max}, t)$, and $\gamma(T_{f \max}, t)$ are the parameters correlated with the fire highest temperature and fire lasting time. These parameters can be found in Qiang Jian (2007).

The time-dependent elastic modulus established by Guo Zhenghai & Shi Xudong (2003) can be presented as:

$$E_T = [0.83 - 0.0011T_{(y)}] E_0 \quad (27)$$

Parameters $\theta(s)$ and $\nu(s)$ can be calculated by manipulating Eqs. (24) and (25) using Eqs. (22) and (23). The integration constants of $\theta(\varphi)$ and $\nu(\varphi)$ can be worked out by the boundary condition.

4 CASE STUDY

Taking Nanjing Metro as an example, from the in suit test, we knew that the soil pressure is 237 kPa, horizontal pressures p_1 and p_2 are 131 and 58 kPa, respectively, soil resistance is 228 kPa, segment self-weight is 8.75 kPa, and underground water depth is 9 m.

The thickness of the segment is 0.35 m, racial of segment is 3 m, and the elastic modulus is 29.5 GPa. The recommend highest temperature is approximately 1000–1200°C; hence, 1100°C is taken as the highest temperature in this section. A fire lasting time of 3h is assumed. According to the previously proposed method, the results are shown in Figs. 3–6.

As can be seen from Fig. 3, the whole segment shows a shrinkage trend with the increase in time. The shrinkage of the upper half of the segment is greater than that of the lower half. As shown in Figs. 4 and 5, horizontal shrinkage is smaller than vertical shrinkage. The vertical deflection of the upper half of the segment is greater than that of the lower half. The maximum vertical deflection

Figure 3. Radial deflection of the segment.

Figure 4. Vertical deflection curve of the segment.

Figure 5. Horizontal deflection curve of the segment.

occurs at the segment crown. It reaches to 41, 61, and 80 mm at times 30 min, 1 h, and 3 h, respectively. As to the lower half of the segment, the maximum vertical deflection occurs when $\varphi = 130^\circ$.

The maximum horizontal deflection occurs at the position where $\varphi = \pi/3$. It reaches to 17, 24, and 45 mm at times 30 min, 1 h, and 3 h, respectively.

5 CONCLUSION

In this paper, we presented a technique for investigating the shield tunnel lining segment deflection regulation under fire situation. The lining segment was treated as a ring. The nonlinear temperature distribution along the segment thickness and temperature-dependent concrete mechanical properties were considered in this model, which paved a way to solve the deflection of segment at elevated temperature. An analytic formula is established to calculate the segment cross-section bending moment and axial force based on the Free-Form Deformation. The model of this paper is a thermo-plastic model. The elastoplasticity of the concrete under fire should be considered further.

According to the case study results, the elevated temperature has a greater influence on the upper half of the segment; hence, more attention should be paid on the upper half when designing as well as repairing after a fire accident.

ABSTRACT: In this paper, we show a possible method for responsible choice of the optimal composition of the claddings of wooden structures with plasterboard or gypsum board in terms of selected criteria. The proposal unaffected by subjective opinions of solvers will be ensured by comparing the compositions of the claddings of wooden structures.

1 INTRODUCTION

Selection of building materials and technologies can be done in the initial design phase, taking into account the quality of the claddings of wooden structures (Halirova, M., 2015). Multicriterion optimization of selection of individual materials is the selected objective method, which eliminates or minimizes subjective view of solvers and is suitable for the design of claddings and other structures (Takano A., 2014). Six variations of the claddings of wooden structures were assessed using the multicriterion optimization method (Table 1). Seven evaluative criteria were selected (Table 2): thermally technical criteria (heat thermal transmittance

value, the lowest indoor surface temperature of the structure, moisture transfer in the structure) (Sevcikova H, 2015), ecological criteria (energy consumption and CO₂ production of building materials), and the economic criterion (cost of materials and assembly).

2 METHODS OF PROCESSING

We determine a set of real material structure variants of cladding and a set of evaluation criteria. Then, we choose the optimal variant using multicriterion optimization (Halirova M, 2013). Requirements for the cladding as well as the requirements

Table 1. Type of claddings with used materials.

Type of cladding	Structure of cladding—building material
A	Fiber gypsum board (12.5 mm) + moisture stop (foil) + squared timber 60 × 140 + mineral insulation (140 mm) + fiber gypsum board (12.5 mm) + polystyrene foam (80 mm) + plaster (7 mm)
B	Fiber gypsum board (12.5 mm) + squared timber 60 × 60 + mineral insulation (60 mm) + moisture stop (foil) + squared timber 60 × 140 + mineral insulation (140 mm) + fiber gypsum board (12.5 mm) + polystyrene foam (150 mm) + plaster (7 mm)
C	Fiber gypsum board (12.5 mm) + squared timber 60 × 60 + wooden fiber insulation (60 mm) + fiber gypsum board (12.5 mm) + squared timber 60 × 140 + wooden fiber insulation (140 mm) + fiber gypsum board (12.5 mm) + wooden fiber board (2 × 80 mm) + plaster (7 mm)
D	Fiber gypsum board (12.5 mm) + moisture stop (foil) + squared timber 60 × 140 + mineral insulation (140 mm) + fiber gypsum board (12.5 mm) + polystyrene foam (80 mm) + plaster (7 mm)
E	Fiber gypsum board (12.5 mm) + squared timber 60 × 60 + mineral insulation (60 mm) + moisture stop (foil) + squared timber 60 × 140 + mineral insulation (140 mm) + fiber gypsum board (12.5 mm) + polystyrene foam (150 mm) + plaster (7 mm)
F	Gypsum board (12.5 mm) + squared timber 60 × 60 + wooden fiber insulation (60 mm) + moisture stop (foil) + squared timber 60 × 140 + wooden fiber insulation (140 mm) + gypsum board (12.5 mm) + wooden fiber board (2 × 80 mm) + plaster (7 mm)

Table 2. Selected evaluation criteria for multicriterion optimization.

Number of criterion	Criterion	Unit of measure
1	Thermal transmittance value U	W m ⁻² K ⁻¹
2	Temperature factor at the internal surface f _{Rsi}	–
3	Annual amount of condensed water vapor M _{ca}	kg/m ² · year
4	Energy consumption for the production of building material E	MJ/m ²
5	Production of CO ₂ during production of building material	g/m ²
6	The price of material in a cladding	CZK/m ²
7	The price of assembly of a cladding	CZK/m ²

for each building material vary. It also depends on the characteristics of the environment in which the building project will be implemented. The method of multicriterion optimization is one of the ways to successfully solve the selection of optimal variant of the cladding according to the specified requirements (Perina Z, 2016).

2.1 The method of multicriterion optimization

The optimal variant of the situation is selected using the multicriterion optimization method.

Step 1 – Formulation of goal—usually selection of the optimal variant for specific cladding.

Definition of the structure and design of the possible material variants (Perina Z, 2014).

Step 2 – Determination of specific criteria for comparison of various variants. The selection of criteria can be different because of different user or contractor (Halířova M, 2015 & 2016).

Step 3 – Numerical values of individual criteria are obtained here. Each variant and criterion is assessed by the value a_{ij}, and decision matrix (1) is formed. Variants are in columns and criteria are in rows (Lipušček I, 2010). The criterion can be assessed by points from 0 to 10 or from 0% to 100% if the calculation of the criterion is too complicated (Halířova M, 2014).

The decision matrix:

$$\begin{pmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \cdot & \cdot & \dots & \cdot \\ \cdot & \cdot & \dots & \cdot \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{pmatrix} \left\| \begin{matrix} f_1 \\ f_2 \\ \cdot \\ \cdot \\ f_n \end{matrix} \right. \quad (1)$$

a_{ij} the value of criterion i, variant j (i-criterion 1 to m, j-variant 1 to n)

f₁–f_m weights, the valid rule $\sum_{i=1}^m f_i = 1$

2.2 Formation of a decision matrix

Decision matrix is formed of six claddings, which are denoted by alphabets A to F and seven evaluation criteria, which are identified by numbers 1 to 7 (Tables 1 and 2). The values of maximum and minimum (it depends on which value is more useful) can be seen in Table 3.

Step 4 – Determination of criterion weight is the most important step in multicriterion optimization. Each property that is expressed by a criterion has a different significance. It is very important to determine the importance of a certain criterion, and the optimization for different weights of the criterion must be effectively performed (Adekunle, T.O. 2016).

2.3 Determination of criterion weight

Determination of weight requires an assessment of the significance of each criterion against other criteria. The weight of a certain property must be preferred. Criteria include an objective element that emphasizes the qualities of claddings and a subjective element, which is the decision-making element. The weight is assigned to individual properties, thereby the seriousness and importance of each criterion is determined (Friedrich D, 2016).

Several different methods can be used for the determination of weights. Each method is more or less suitable for certain criterion. Optimal variant of the solution of all used methods must be evaluated.

The method of quantitative paired comparison belongs among the best methods. This method uses Saaty's matrix highlights priorities of the evaluation criteria. This method is best suited to the elimination of the subjective view of the evaluator. Therefore, this method was selected for further calculations.

2.4 Method of quantitative paired comparison of criteria

Scale 1, 2, 3 ... 9 and reciprocal values are used for the production of paired comparisons S = (s_{ij}). Matrix elements are estimations of proportion of weights of i-th and j-th criteria:

$$S_{ij} \approx \frac{f_i}{f_j}, \quad S_{ii} = 1, \quad S_{ji} = \frac{1}{S_{ij}} \quad (2)$$

i, j = 1, 2, 3, ... n

Table 3. Decision matrix.

Type of cladding	Max. Min.	Criterion number						
		1	2	3	4	5	6	7
		Min	Max	Min	Min	Min	Min	Min

F		0.14	0.953	0	1066.92	4.83	2277.2	843.5

Table 4. The method of quantitative pair comparison of criteria.

Criterion number	1	2	3	4	5	6	7	S _{ij}	R _{ij}	Weight f _i
1	1	5	4	6	7	2	3	5040	3.38	0.32
2	1/5	1	1/3	3	5	1/5	1/5	0.040000	0.63	0.06
3	1/4	3	1	5	7	1/3	1/3	2.916667	1.17	0.11
4	1/6	1/3	1/5	1	3	1/7	1/7	0.000680	0.35	0.04
5	1/7	1/5	1/7	1/3	1	1/9	1/9	0.000017	0.21	0.02
6	1/2	5	3	7	9	1	2	945	2.66	0.25
7	1/3	5	3	7	9	1/2	1	157.5	2.06	0.20
n = 7									Σ = 10.46	Σ = 1

$$f_1 = \frac{\left(\prod_{j=1}^n S_{1j} \right)^{\frac{1}{n}}}{\prod_{i=1}^n \left(\prod_{j=1}^n S_{ij} \right)^{\frac{1}{n}}} \quad (3)$$

2.5 The method of quantitative pair comparison of criteria

Saaty's matrix expresses criteria preferences that contain the equal criteria and slightly and strongly preferred criteria.

Step 5 – The values of the weights of individual criteria are set into the sequence. The sequence of the criteria is made in accordance with the requirements. These values are converted to dimensionless numbers.

a. Cost type is used when the requirement is based on the minimum value (e.g., the cost of energy intensity). Transformation into a dimensionless quantity is as follows: the highest value of max a_{ij} is the lowest value of the evaluation (usually b_{ij} = 0); the lowest value of min a_{ij} is the highest value of the evaluation (b_{ij} = 1):

$$b_{ij} = \frac{(\max a_{ij}) - a_{ij}}{(\max a_{ij}) - (\min a_{ij})} \quad (4)$$

b. Profit type – is used when the requirement is based on the maximum value (the higher the better).

Transformation is as follows:

$$b_{ij} = \frac{(a_{ij}) - (\max a_{ij})}{(\max a_{ij}) - (\min a_{ij})} \quad (5)$$

Step 6 – unsuitable variant is eliminated. The used criteria are evaluated. The matrix contains variants in columns and criteria in accordance with Step 5 in rows, including weights of each criterion.

Calculation matrix:

$$\begin{bmatrix} b_{11} & b_{12} & \dots & b_{1n} \\ b_{21} & b_{22} & \dots & b_{2n} \\ \vdots & \vdots & \dots & \vdots \\ b_{m1} & b_{m2} & \dots & b_{mn} \end{bmatrix} \begin{bmatrix} f_1 \\ f_2 \\ \vdots \\ f_m \end{bmatrix} \quad (6)$$

Table 5. Calculation matrix.

Type of the cladding $c_{ij} = b_{ij} \cdot f_i \cdot 100$	Weight f_i	Criterion number							Σ
		1	2	3	4	5	6	7	
		0.32	0.06	0.11	0.04	0.02	0.25	0.20	1
A		0	0	3.6	4	0.2	24.5	18.8	51.1
B		32	5.9	0	3.6	0.2	21.9	15.5	79.1
C		32	6	11	0.5	1.7	0	0	51.2
D		0	0	5	3.9	0	25	20	53.9
E		32	5.9	0.3	3.5	0.1	22.5	17.6	81.9
F		32	5.6	11	0	2	3	10.5	64.1

$$b_{ij} \cdot f_{ij} = c_{ij}; \max \sum_{j=1}^n c_{ij} = H_i \Rightarrow optimum \quad (7)$$

where:

b_{ij} ... transformed value by Eqs.(4) and (5).

f_i ... criterion weight.

2.6 Transformation of the decision matrix into the calculation matrix

The decision matrix is transformed into the calculation matrix. The matrix contains criteria including weights of each criterion in columns and variants of the cladding in rows. The calculation is performed using the calculation matrix. Optimal variant has the highest sum of the products of transformed values and weights.

Step 7 – The result of the calculation is analyzed.

The decision-making process can be monocriterial optimization (searching for variant with maximum gain) or multicriterion optimization using different criteria. The result depends on the experience of the researcher and the preferences of the individual criteria. Each researcher (builder, user) prefers other criteria.

3 CONCLUSION—EVALUATION OF MULTICRITERION OPTIMIZATION

The best variant based on the multicriterion optimization is variant E in this case. Variant B is on the second place in this case. This variant has a higher rating for energy consumption for the production of building material and the production of CO₂ during production of building material. The assessment of economic criteria is lower compared to that in variant E. Variant F is on the third place in this case. This variant has lower rating for economic criteria. Variant C has the lowest rating for economic criteria. Variants A and D have the lowest

ratings. These variants have the lowest ratings for heat thermal transmittance value and temperature factor at the internal surface. The above mentioned walls have shown that gypsum board has similar, comparable properties and is suitable as a board material for cladding like fiber gypsum board.

Evaluation of the ultimate strength of RC I-shaped members subjected to a combined action

Pu Wang, Zhen Huang & Quanshen Wang

School of Naval Architecture, Ocean and Civil Engineering, Shanghai Jiaotong University, Shanghai, P.R. China

ABSTRACT: Under complex loads, especially for earthquakes and wind loads, RC I-shaped members are usually subjected to load combinations of axial forces, bending moments, shear forces, and torsion. In this paper, we deduce the relationships between the external forces and the cracking degrees. Then, a model for the evaluation of the ultimate strength of RC I-shaped members is established based on the ultimate equilibrium of twist failure surface. Finally, the model results are compared with the experimental results of former researchers. The model coincides well with the experiment.

1 INTRODUCTION

Nowadays, Reinforced Concrete (RC) I-shaped members have been widely used in construction. RC I-shaped members are mainly designed to undertake the loads of bending moments and shear forces. However, RC I-shaped members in hazards usually fail under different load combinations of axial loads, bending moments, shear force, and torsion. The failure mechanisms of these members are very complex.

Although the theory for the ultimate strength of RC members under axial forces and bending moments is well recognized, there are many different theories for the mechanisms of RC members under shear forces. In the engineering application, equations based on the regression analyses of experimental results are widely used, such as “Code for design of concrete structures” (GB50010-2010).

Empirical equations lack theoretical foundations. Researchers have developed many different theories for the ultimate strength of RC members subjected to combined actions for decades. Collins (1973) established Compressive-Field Theory (CFT) by introducing the compatibility conditions of RC members under shear force. Then, Vecchio & Collins (1986 & 2000) developed CFT into Modified Compressive-Field Theory (MCFT) and Disturbed Stress Field Mode (DSFM). Hsu (1988) established Softened Truss Model Theory by overall consideration of the equilibrium, compatibility conditions, and softened stress-strain relationship of concrete. Pang & Hsu (1996) further developed Fixed Angle Softened Truss

Model. These two series of theories could analyze the behavior of RC members under combined actions fairly well by the help of finite-element method.

Huang & Liu (2007) proposed a theoretical model for RC box-section members under combined actions. Wang et al. (2014) proposed a theoretical model for RC rectangular members under combined actions. These two models try to have a clear theoretical basis and be convenient for application. In this paper, we attempt to determine the relationship between the external force and the twist failure surface. Then, a model is established on the basis of the ultimate equilibrium of twist failure surface.

2 MODEL DEDUCING

2.1 Basic assumption

The factors affecting the ultimate strength of RC member are very complex. To simply the expression, only main factors are considered and the following basic assumptions are adopted.

1. After cracking, the core concrete is assumed to not undertake any torsion load. All the torsion is assumed to be undertaken by the out-box walls of the concrete.
2. All the reinforcements are assumed to achieve their yield strengths when crossing the warped failure surface.
3. The dowel actions of longitudinal reinforcements are ignored.

2.2 Shear stress

Figure 1 shows the section of RC members. A is the area of section, A_{cor} is the area enclosed by the shear flow ($A_{cor} = 2h_1b_{cor} + b_2h_2 = \alpha A$), t is the equivalent wall thickness of the section, and $b_{cor} = b - 2t$, $h_{cor} = h - 2t$. According to the Bredt thin-walled theory, the shear flow on the out-box wall can be expressed as a constant (q). The shear flow (q) is expressed as:

$$q = \frac{T}{4qh_1b_{cor} + 2qb_2h_2} = \frac{T}{2A_{cor}} \quad (1)$$

where T is the torsion on the member and α is the ratio of A_{cor} to A .

Figure 2 shows the warped failure surface. The left, right, and bottom sides are denoted by 1, 2, and 3, respectively.

The shear force on each side wall due to the torsion (T) can be expressed as:

$$\begin{aligned} V_{T1} &= qh_2 = \frac{Th_2}{2\alpha A}; V_{T2} = qh_2 = \frac{Th_2}{2\alpha A}; \\ V_{T3} &= qb_{cor} = \frac{Tb_{cor}}{2\alpha A}; V_{T4} = qb_{cor} = \frac{Tb_{cor}}{2\alpha A} \end{aligned} \quad (2)$$

Figure 1. Section of RC members.

Figure 2. Warped failure surface.

The shear stress due to the external shear force (V) can be approximately regarded as a constant value ($\tau_v = V/A$). Then, the shear forces on the left and right side walls can be expressed as:

$$V_{V1} = V_{V2} = \tau_v h_2 t = \frac{Vh_2 t}{A} \quad (3)$$

By adding the shear forces from Eqs. 1 and 2, the total shear force on each side wall under the torsion and shear force is equal to:

$$\begin{aligned} V_1 &= V_{T1} + V_{V1} = \frac{Th_2}{2\alpha A} + \frac{Vh_2 t}{A} \\ V_2 &= V_{T2} - V_{V2} = \frac{Th_2}{2\alpha A} - \frac{Vh_2 t}{A} \\ V_3 &= V_{T3} = qb_{cor} = \frac{Tb_{cor}}{2\alpha A} \\ V_4 &= V_{T4} = qb_{cor} = \frac{Tb_{cor}}{2\alpha A} \end{aligned} \quad (4)$$

The shear force on each side wall is undertaken by the concrete and transverse reinforcements. On the basis of this assumption, transverse reinforcements achieve the yield strength when approaching the failure. Therefore, the shear force on each side wall can be expressed as:

$$\begin{aligned} \tau_1 &= \frac{V_1 - n_1 A_{sv1} f_{yv}}{th_2} = \frac{T}{2\alpha At} + \frac{V}{A} - \frac{n_1 A_{sv1} f_{yv}}{th_2} \\ \tau_2 &= \frac{V_2 - n_2 A_{sv1} f_{yv}}{th_2} = \frac{T}{2\alpha At} - \frac{V}{A} - \frac{n_2 A_{sv1} f_{yv}}{th_2} \\ \tau_3 &= \frac{V_3 - n_3 A_{sv1} f_{yv}}{tb_{cor}} = \frac{T}{2\alpha At} - \frac{n_3 A_{sv1} f_{yv}}{tb_{cor}} \end{aligned} \quad (5)$$

where A_{sv1} is the area of a single stirrup, f_{yv} is the yield strength of transverse reinforcements, and n_1 , n_2 , and n_3 are the numbers crossing the failure surface.

The relationships between n_1 , n_2 , n_3 , and crack degrees are:

$$n_1 = \frac{h_{cor} \cot \theta_1}{s}; n_2 = \frac{h_{cor} \cot \theta_2}{s}; n_3 = \frac{b_{cor} \cot \theta_3}{s} \quad (6)$$

where θ_1 , θ_2 , and θ_3 are the inclined degrees of warped failure surface and s is the space of stirrups.

2.3 Normal stress

The mean normal stress on the section is $\sigma = N/A$. On the left side wall of the member, the principal stresses can be calculated as:

$$\sigma_1 = \frac{\sigma + \sqrt{\sigma^2 + 4\tau_1^2}}{2}; \sigma_2 = \frac{\sigma - \sqrt{\sigma^2 + 4\tau_1^2}}{2} \quad (7)$$

where σ_1 and σ_2 are the principle stresses on the section and τ_1 is the shear stress on the section.

Figure. 3 shows the failure criterion of Tasuji–Slate–Nilson. On the basis of the failure criterion, it can be deduced that:

$$\tau_1 = \frac{\sqrt{f_c^2 + (1-\beta)f_c\sigma - \beta\sigma^2}}{1+\beta} \quad (8)$$

where f_c is the compress strength of the concrete, f_t is the tensile strength of the concrete, and β is defined as f_c/f_t .

The shear strength of the concrete will decrease with the development of cracks. Considering the decreasing, a factor γ is added to the right-hand side of Eqs. 7 and 9 as:

$$\tau_1 = \frac{\gamma\sqrt{f_c^2 + (1-\beta)f_c\sigma - \beta\sigma^2}}{1+\beta} = \Phi(N) \quad (9)$$

where the equation is defined as $\Phi(N)$ and γ is a factor considering the strength lowering after cracking.

Substituting Eq. 9 into Eq. 5, we obtain Eq. 10:

$$n_1 = \left(\frac{T}{2\alpha At} + \frac{V}{A} - \Phi(N)\right) \frac{th_2}{A_{sv1}f_{yv}} \quad (10)$$

Similarly,

$$\begin{aligned} n_2 &= \left(\frac{T}{2\alpha At} - \frac{V}{A} - \Phi(N)\right) \frac{th_2}{A_{sv1}f_{yv}} \\ n_3 &= \left(\frac{T}{2\alpha At} - \Phi(N)\right) \frac{tb_{cor}}{A_{sv1}f_{yv}} \end{aligned} \quad (11)$$

Figure 3. Failure criterion of Tasuji–Slate–Nilson.

Substituting Eq. 6 into Eqs. 10 and 11, we obtain Eq.12:

$$\begin{aligned} \cot \theta_1 &= \left(\frac{T}{2\alpha At} + \frac{V}{A} - \Phi(N)\right) \frac{th_2s}{h_{cor}A_{sv1}f_{yv}} \\ \cot \theta_2 &= \left(\frac{T}{2\alpha At} - \frac{V}{A} - \Phi(N)\right) \frac{th_2s}{h_{cor}A_{sv1}f_{yv}} \\ \cot \theta_3 &= \left(\frac{T}{2\alpha At} - \Phi(N)\right) \frac{ts}{A_{sv1}f_{yv}} \end{aligned} \quad (12)$$

2.4 Model formula

On the basis of the equilibrium of moment to the center of compressive reinforcement, Eq. 13, $\Sigma M_z = 0$, can be established:

$$\begin{aligned} M + N \frac{h_{cor}}{2} &= f_y A_s h_{cor} \\ &- n_1 A_{sv1} f_{yv} \left(\frac{h_{cor} \cot \theta_1}{2} + \frac{b_{cor} \cot \theta_3}{2} \right) \\ &- n_2 A_{sv1} f_{yv} \left(\frac{h_{cor} \cot \theta_2}{2} + \frac{b_{cor} \cot \theta_3}{2} \right) \end{aligned} \quad (13)$$

where A_s is the area of longitudinal reinforcements in the tensile area and f_y is the tensile strength of longitudinal reinforcements.

Substituting Eqs. 10, 11, and 12 into Eq. 13, we obtain Eq. 14:

$$\begin{aligned} \frac{N}{2f_y A_s} + \frac{M}{f_y A_s h_{cor}} + \frac{h_2 s t^2 V^2}{h_{cor} f_y A_s A^2 f_{yv} A_{sv1}} \\ + \frac{h_2 s (b_2 + h_2) (T - T')^2}{4\alpha^2 h_{cor} f_y A_s A^2 f_{yv} A_{sv1}} = 1 \end{aligned} \quad (14)$$

Define

$$\begin{aligned} N_0 &= 2f_y A_s; M_0 = f_y A_s h_{cor}; \\ V_0^2 &= \frac{h_{cor} f_y A_s A^2 f_{yv} A_{sv1}}{h_2 s t^2}; \\ T_0^2 &= \frac{4\alpha^2 h_{cor} f_y A_s A^2 f_{yv} A_{sv1}}{h_2 s (b_2 + h_2)}; \\ T'' &= T - T'; T' = 2\alpha At \Phi(N) \end{aligned} \quad (15)$$

Equation 14 becomes Eq. 16:

$$\frac{N}{N_0} + \frac{M}{M_0} + \frac{V^2}{V_0^2} + \frac{T''^2}{T_0^2} = 1 \quad (16)$$

3 VALIDATION OF THE PROPOSED MODEL

Because of the scarcity of studies on the ultimate strength for RC I-shaped members subjected to the

Table 1. Reinforcements and concrete strength.

Variation coefficients					14.96%

combined actions of axial force, bending moment, shear force, and torsion, it is very difficult to find the experimental data. In order to verify the validation of the proposed model, experimental results of RC I-shaped members subjected to bending moment and shear force by Sudhira et al. 2008 are referred and compared with the proposed model. Table 1 and Figure.4 are obtained from Sudhira et al. (2008). The stirrup space is 225 mm for IPC-2 and 125 mm for others. The yield strength is 353 MPa for IPC-3 and 438 MPa for others.

Table 2 shows the comparison of model and experimental results. The model results are safer and more conservative than the experimental results. From Sudhira et al. (2008), the first five members failed when the tensile reinforcements were ruptured. Therefore, the ultimate strength of reinforcement should be used in the calculation of ultimate strength of members. However, the model adopts the yield strength of reinforcements in calculation. As a result, the values from the model are less than the experimental results. If we use the ultimate strength of longitudinal reinforcements in the calculation of model, the ratios of model calculation to experimental results are 1.06, 1.07, 1.01, 1.06, and 1.09, respectively, for the first five members. Considering this, the model results can be regarded to coincide well with the experimental results.

Figure 4. Cross section of experimental beams.

4 CONCLUSION

The study leads to the following main conclusions:

1. Compared with the experiment data, the validation of the proposed model is verified. The physical concept of the model is clear, and the expression of the model is concise. Therefore, the proposed model is convenient to be used in the application.

2. In the consideration of the requirement of torsion, the width of web plate should be confined with a minimum value, which should be further studied. In order to use the flange plates of I-shaped members to bear torsions, it is recommended that the overhang length of flange plates should be less than three times of its thickness.
3. In the text, the transverse reinforcements are assumed to achieve the yield strength. However, in fact, the transverse reinforcements may not yield in many situations. It needs to be further studied.
4. The experiments are very difficult for RC I-shaped members under combined actions of axial force, bending moment, shear force, and torsion. As a result, the experimental data are very rare in the aspect. The experimental studies are much needed in order to study the ultimate strength of RC I-shaped members under combined actions.

Three-dimensional centrifuge and numerical modeling of pile group due to twin tunnelling in different depth

Shaokun Ma, Yu Shao, Ying Liu, Junyu Chen & Jie Jiang

College of Civil Engineering and Architecture, Guangxi University, Nanning, China

ABSTRACT: Tunnelling activity inevitably induces change of soil stress and hence may cause adverse effects on nearby pile foundations. In this study, a three-dimensional centrifuge model test and a series of numerical analyses were carried out to investigate the effects of pile group in clay due to twin tunnelling in different depth. The springline of twin tunnels in the test were located at half a tunnel diameter above the pile toe (Test FF). Numerical back-analysis of centrifuge model test and parametric study were also carried out to get more insight of twin tunnels-pile interaction. Two more configurations, i.e., twin tunnels located at mid-depth of the pile (Simulation MM) and below the pile toe (Simulation BB), were investigated in the numerical analyses. The relative elevation between the twin tunnels and pile group has a significant effect on the pile settlement and the pile bearing capacity. Apparent loss of the pile bearing capacity (i.e., 90.2%) and the largest pile settlement (i.e., 5.5% of pile diameter) due to twin tunnelling are identified in Simulation BB. The maximum value of the loss of the pile bearing capacity was 2.7 times of the minimum value (Simulation MM). Additionally, the maximum transverse tilting of pile group induced by twin tunnelling is also observed when $C/D = 3.7$ (i.e., Simulation BB).

1 INTRODUCTION

In congested urban areas, tunnel construction inevitably induces ground deformation and stress redistribution in the soil. This may cause adverse effects on adjacent pile foundations. The effects of pile foundations due to tunnel excavation have been investigated by many researches.

Numerical and analytical studies have been carried out to investigate the effects of tunnelling on pile foundations. Marshall (2012) investigated on the effects of tunnelling on end-bearing piles located above the tunnel by using a new analytical method based on cavity expansion theory. It was found that pile failure occurred when the load-carrying capacity reduced below 80% of its initial value due to stress redistribution by tunnelling. Three-dimensional coupled-consolidation analyses were adopted by Soomro et al. (2015) to investigate the responses of pile group subjected to single tunnelling located at different depths. The results show that the largest bending moment in the piles occurs when a tunnel is excavated at a cover-to-diameter ratio (C/D) of 1.5.

Centrifuge model tests have also been carried out to investigate the tunnel-pile interaction mechanism (Jacobsz et al. 2004, Loganathan et al. 2000, Marshall 2009, Marshall & Mair 2011). Loganathan et al. (2000) investigated the responses of a 2×2 pile group with working load in stiff clay subjected to a single tunnel excavation. The induced bending moments and settlement of pile

group were significantly influenced by the relative positions between the tunnel and the pile toe.

Recently, more and more twin tunnels are being constructed near piles with the development of metro system in cities. However, only limited research was carried out to study the effects of twin tunnelling on piles. In the centrifuge tests reported by Ng & Lu (2014), they investigated the responses of a loaded pile subjected to twin tunnelling at different depths located on both sides of the pile. It was revealed that the effects of the tunnelling sequence on the pile settlement and the loss of pile capacity were significant.

In order to comprehend the responses of pile group induced by twin tunnelling, a centrifuge model test and the displacement controlled finite element model (DCM) based on ground loss were applied to investigate the responses of pile group under working load in clay to twin tunnelling with different depth. The effects of the three-dimensional tunnel excavation process were simulated in-flight and investigated by the numerical analysis. In addition, pile group settlement, apparent loss of pile capacity and transverse tilting of pile cap obtained from the two approaches were compared with each other.

2 CENTRIFUGE MODELLING

2.1 *Experimental program and setup*

The centrifuge model test was carried out at the Geotechnical Centrifuge Facility of Hong Kong

University of Science and Technology. According to the size of the model tunnel and model pile group, the centrifugal acceleration of 40 g (where g is the acceleration due to earth gravity) was adopted in the test. Fig. 1 shows the cross section of Test FF, where the springline of the tunnels was located half tunnel diameter above the pile toe. The diameter of each model tunnel (D) was 152 mm (6.08 m in prototype scale) and the cover-to-diameter ratio (C/D) was 2.5. The pile group was centered between the tunnels, so that the horizontal distance between the tunnel axis and the closest pile was 0.75D.

2.2 Simulation of tunnel excavation

In this study, the tunnel excavation was simulated using the equivalent volume loss method. This was achieved by draining out 2% of water in the rubber bag. Fig. 2(a) shows the model tunnels and the pile group. Each model tunnel consists of five cylindrical rubber bags with de-aired water corresponding to five advances of tunnel construction. The three-dimensional tunnel excavation process was simulated in-flight by draining away a controlled amount of water from each rubber bag.

2.3 Model pile group and instrumentation

All the model piles were fabricated from aluminum tubes, 20 mm in diameter and 600 mm in length. The spacing between two piles was $3.5d_p$ (pile diameter), 70 mm in the model. The size of the pile group is often applied in building engineering and bridge engineering. As shown in Fig. 2(b), each pile was equipped with semiconductor Strain Gauges (SGs) bonded at 10 levels, with a spacing of 60 mm,

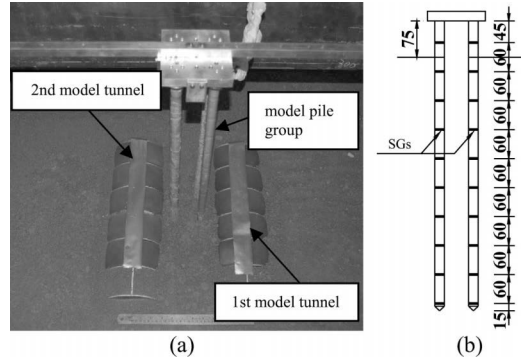

Figure 2. (a) Model tunnels and model pile group; (b) The distribution of SGs (dimensions in millimetres).

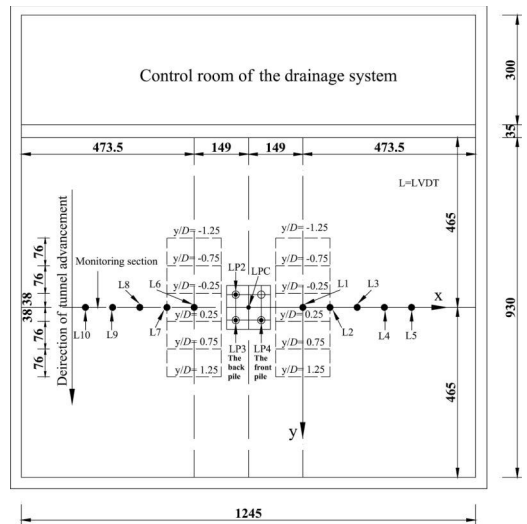

Figure 3. Plan view of the centrifuge model test (dimensions in millimetres).

Figure 1. Elevation view of the centrifuge model test and the other two more configurations (dimensions in millimetres).

along the external surface to record the axial force and bending moments. The SGs were protected by a thin layer of epoxy coating uniformly pasted to the shaft of each pile. The Young's modulus (E_p) of the aluminum model pile was 70 GPa. Thus, the model piles are equivalent to a 0.8 m diameter (in prototype scale) concrete pile with flexural stiffness and bending moment capacity of 721 MNm² and 800 kNm, respectively. In the paper, the effects of pile installation were not considered, and the pile group was "wished-in-place".

Fig. 3 illustrates the plan view of the model pile group, model tunnels and instruments. 10 Linear Variable Differential Transformers (LVDTs) were installed to measure ground surface settlement. Four LVDTs (LP2 to LP4 and LPC) were installed on the pile cap to measure the settlement of the pile group.

Table 1. Physical and mechanical parameters of soil.

Free expansion ratio	Maximum dry density	Plastic limit	Liquid limit	Plasticity index	Optimum water content
59%	1880 kg/m ³	25%	53%	28	12.9%

Table 2. Testing procedure.

Events	Testing time (min)
Centrifuge acceleration spun up from 1 g to 40 g	10
Apply working load to the pile until 1500 N was reached	240
Excavate the first and second tunnel	20
Pore water pressure dissipated gradually	1200
Centrifuge acceleration reduced from 40 g to 1 g	30

2.4 Model preparation and Testing procedure

The clay used in the tests was obtained from Nanning, Guangxi Province, China. The mechanical properties of the clay are summarized in Table 1. The clay was dried in the laboratory and then crushed and sieved at 2 mm, and mixed uniformly with a certain amount of water to reach a water content of 18%, then cured for 24 h.

The testing procedure of the test is shown in Table 2.

3 3D FINITE ELEMENT NUMERICAL SIMULATION

In order to provide more insights into the effects of twin tunnelling with different C/D ratios on a pile group, the finite element software ABAQUS was used in this study. A displacement controlled method (DMC) based on ground loss was used to back-analyze the centrifuge Test FF. After verifying the numerical model, a numerical parametrical study was performed. As shown in Fig. 1, two C/D (C/D = 1.5 and 3.7) ratios were adopted in the numerical parametric study.

3.1 Constitutive model and model parameters

In this study, the Modified Cam Clay model was adopted for the soil. The model parameters obtained by oedometric test and triaxial test were summarized in Table 3. The model pile group was modelled as a linear elastic material with Young's modulus, Poisson ratio and unit weight of 33 GPa, 0.2 and 25 kN/m³, respectively. The soil-pile interface was simulated according to the Coulomb friction law included in ABAQUS. According to the

Table 3. Model parameters of soil.

Parameter	Value
Soil density ρ_d (kg/m ³)	1800
Initial void ratio e_0	0.9
Coefficient of earth pressure at rest K_0	0.68
Poisson ratio ν	0.35
Gradient of normal compression line of soil λ	0.09
Gradient of swelling line κ	0.015
Gradient of critical state line M	0.9

test results obtained from Peng (2012), the two parameters i.e. interface friction coefficient (μ) and limiting displacement (γ_{lim}) were assumed as 0.5 and 5 mm, respectively.

3.2 Finite element mesh and boundary conditions

The mesh had dimensions of 50.6 m × 26 m × 34 m in prototype scale. Eight-node brick elements were adopted for both the soil and the pile group. The boundary conditions assumed for the bottom and vertical sides were pin and roller supports, respectively. In numerical analysis, the piles were modelled using “wished-in-place” method. This was the same as that in the centrifuge model test.

3.3 Numerical modeling procedures

Each numerical analysis followed the same procedures as those in the centrifuge test. Firstly, set up the 3D finite element mesh and the initial boundary conditions. Then applying working load to the pile group, 160 kN at a time until 2.4 MN is reached. The displacement boundary of the tunnel sections to be excavated should be restrained before killing the soil elements inside the tunnel. According to the construction sequence of the centrifuge test, apply the target displacement boundary conditions to reach the target volume loss (i.e. 2%). The displacement pattern of the tunnel cross sections adopted in this study was suggested by Park (2004). It is important to note that the restrained displacement boundary should be released during applying the target displacement boundary conditions. Finally, impose the same displacement boundary conditions to the other tunnel sections by repeating the step stated above to simulate the three-dimensional tunnelling process.

4 INTERPRETATION OF MEASURED AND COMPUTED RESULTS

All the results presented in this paper are in prototype scale unless stated otherwise.

4.1 Determination of the axial load-carrying capacity of the pile

In order to evaluate the security of the pile group and the quantitative effects on the pile group due to twin tunnelling excavation, first of all, a simulation was carried out to determine the bearing capacity of the pile group. In the simulation, the pile group was loaded incrementally, with each loading increment of 800 kN (500 N in model scale), up to the final load of 24 MN (15000 N in model scale).

Fig. 4 shows the load settlement relationship of the pile group obtained from the numerical simulation. In the figure, settlement of the pile group (S_p) was normalized by the pile diameter (d_p).

In this study, the failure criterion (i.e., 10% of pile diameter) proposed by IMMMFE (1985) and the failure criterion proposed by Ng et al. (2001) for large diameter piles (i.e., $d_p > 0.8$ m) were used to determinate ultimate bearing capacity of the pile group, the equation of the displacement failure criterion proposed by Ng et al. (2001) as follows:

$$\delta_{ph,max} \cong 0.045d_p + \frac{1}{2} \frac{P_h L_p}{A_p E_p} \quad (1)$$

where $\delta_{ph,max}$ is the pile settlement used to define the ultimate load, L_p is the length of the portion of pile inserted in soil, P_h is the pile head load, d_p is the pile diameter, E_p is the elastic modulus, A_p is the cross-sectional area of the pile. As was showed in Fig. 4, based on the failure criterion proposed by Ng et al. (2001) and IMMMFE (1985), the ultimate bearing capacity of the pile group were deduced as 9.3 MN and 15.7 MN, respectively. It is known that the working load of 1500 kN (2.4 MN in prototype) was much smaller than the ultimate bearing capacity of the pile group deduced by Ng et al. (2001) and IMMMFE (1985). Thus, the pile group with the load of 2.4 MN was secure.

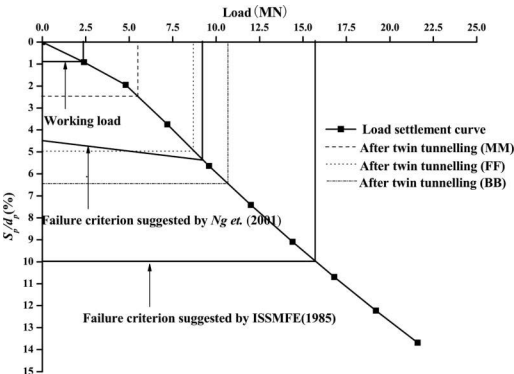

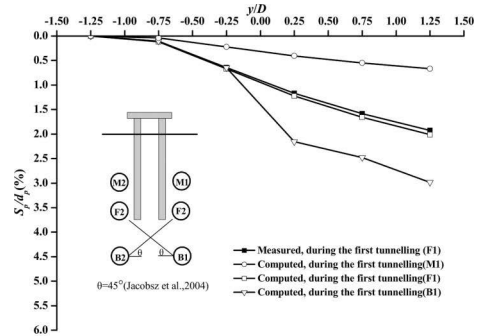

Figure 4. Load-settlement curve obtained from the result of simulation.

4.2 Settlement of pile group

Fig. 5(a) and (b) show the development of measured (Tests FF) and calculated (Simulations MM, FF and BB) pile settlement. The pile settlement was normalized by the pile diameter (d_p). As was shown in Fig. 3, the y value which was normalized by the tunnel diameter (D) is the distance between the tunnelling face and the monitoring section. In addition, settlement data was obtained from the LPC in Fig. 3.

It can be seen that the pile group settled linearly during the first tunnelling in Simulation MM in Fig. 5(a). In contrast, non-linear settlement characteristics of the pile group were observed in Simulations FF and BB and Tests FF. The settlement of pile group in the cases of Simulation FF calculated by the DCM was fitted well with the results measured from the centrifuge test. In the Simulation FF, BB and Test FF, the settlement of pile increased rapidly as the tunnel face approached the monitoring section, i.e., when the first tunnel advanced from $y/D = -0.25$ to 0.25. However, the pile settlements increased at a lower rate as the tunnel face continued to advance beyond the monitoring section. Similar settlement characteristics of the pile group subjected to twin tunnelling in sand were observed in the centrifuge tests reported by

(a)

(b)

Figure 5. Settlement of pile group due to twin tunnelling: (a) during the first tunnelling; (b) during the second tunnelling.

Ng et al. (2014). After the first tunnelling, in the cases of Simulation MM, Test FF, Simulation FF and Simulation BB, the settlement of the pile group were $0.67\% d_p$, $1.93\% d_p$, $2.02\% d_p$ and $2.98\% d_p$, respectively. It can be seen that the maximum settlement of the pile group induced by the first tunnelling occurred in Simulation BB. This was because the pile group was completely located within the major influence zone (as was shown in the inset of Fig. 5(a)), as proposed by Jacobsz et al. (2004).

It can be seen from Fig. 5(b) that the settlement characteristics of the pile group subjected to the second tunnelling were similar to that induced by the first tunnelling. In addition, the settlements of the pile group induced by the second tunnelling were only 112%, 111%, 110%, 84% and 85% of that induced by the first tunnelling, respectively. In addition, the final maximum settlement of pile group induced by twin tunnelling were $1.42\% d_p$, $4.07\% d_p$, $4.26\% d_p$ and $5.51\% d_p$ in Simulation MM, Test FF, Simulation FF and Simulation BB, respectively. Based on the centrifuge and computed results, the maximum settlement of pile group induced by twin tunnelling increased with the increase of C/D . However, from the parametric study, it can be concluded that the effect of excavation of twin tunnels on pile group settlements can be ignored when C/D is higher than 5.5.

4.3 Apparent loss of pile group capacity due to twin tunnelling

The pile bearing capacity is often quantified using the pile settlements. In this study, the relative loss of the pile bearing capacity (P_{Loss}) was used to quantify the apparent loss of pile group capacity due to twin tunnelling. P_{Loss} , and was defined as:

$$P_{Loss} = \frac{N - N_w}{N_0} \cdot 100\% \quad (2)$$

where N is the load deduced from the load-settlement curve (see Fig. 4), N_w is the working load, and N_0 is the ultimate bearing capacity of pile group.

As shown in Fig. 4, in Simulation MM, the settlement of the pile group due to working load was $0.91\% d_p$ (i.e. 7.3 mm), and the induced pile group settlement due to twin tunnelling was $1.6\% d_p$ (i.e. 12.8 mm), which was equivalent to apply an additional load of 3.1 MN on the pile cap (based on the load-settlement curve shown in Fig. 4). In the Simulation MM, the ultimate bearing capacity of the pile group (N_0) was 9.3 MN deduced by the failure criterion proposed by Ng et al. (2001). Hence, the loss rate of pile group capacity due to twin tunnelling (P_{Loss}) was 33.7%. In the Simulation FF and BB, the values of P_{Loss} were 68.7% and 90.2%, respectively. In addition, the value N_0 is 15.7 MN if

the failure criterion proposed by IMMFE (1985) be used. Hence, in Simulation MM, FF and BB, the values of P_{Loss} were 19.7%, 40.1% and 52.7%, respectively. It can be seen that, no matter which criterion was adopted, the maximum value of P_{Loss} was induced in Simulation BB, while the minimum value of P_{Loss} was induced in Simulation MM. This was consistent with the centrifuge tests reported by Ng et al. (2014). The maximum value of P_{Loss} was 2.7 times of the minimum value.

4.4 Transverse tilting of pile cap

Fig. 6 (a) and (b) shows the transverse tilting of the pile cap during the first and second tunnelling (i.e. Simulation MM, Test FF, Simulation FF and Simulation BB). The tilting was determined as the ratio of differential settlements measured from the central points of the front pile (LP4) and the rear pile (LP3) to the distance between them. A positive value means the pile cap tilts towards the first tunnel and vice versa.

It can be seen from Fig. 6(a) that the maximum calculated tilting of the pile cap (0.116%) occurred in Simulation BB. This was due to the stress reduction induced by tunneling in Simulation BB, which was the largest among the three configurations.

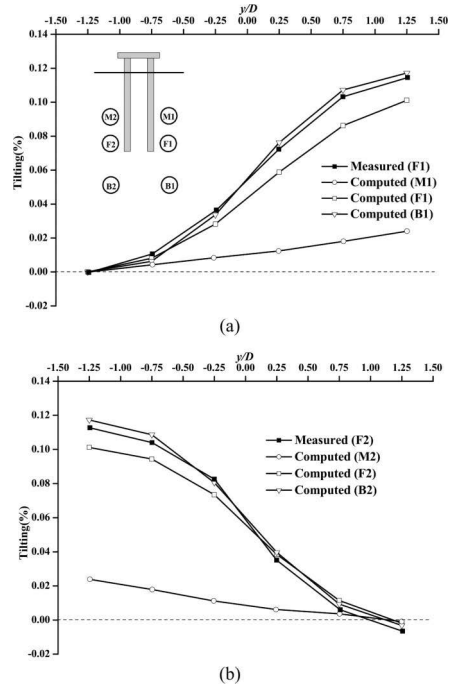

Figure 6. Transverse tilting due to twin tunnelling: (a) during the first tunnelling; (b) during the second tunnelling.

Similar to the settlement of the pile group, the increment of tilting of the pile cap also increased as the tunnel face approached the monitoring section and decreased as tunnel face continued to advance beyond the monitoring section. Different from the test or the simulations in this study, the relation between tilting of the pile cap induced by the first tunnelling and second tunnelling in Simulation MM and the process of tunnelling was linear. Comparing Fig. 6(a) with Fig. 6(b), the value of tilting was reduced gradually and close to zero during the second tunnelling. It implies that the plastic strains generated adjacent to the two tunnels did not overlap with each other.

The maximum tilting of pile cap induced by the first tunnelling in Simulation MM, Test FF, Simulation FF and Simulation BB were 0.024%, 0.114%, 0.100% and 0.116%. It can be seen that the maximum value of tilting was lower than the tilting limit suggested by Eurocode 7 (2001) for buildings and Technical code for building pile foundations (China industry standards for buildings, JGJ 94-2008) (i.e. 0.2%).

5 CONCLUSIONS

In this study, a three-dimensional centrifuge test and a series of numerical analyses were carried out to investigate the effects of pile group under working load in clay due to twin tunnelling in different depth. A centrifuge model test, i.e., Test FF (i.e., $C/D = 2.5$) was carried out. In addition, Simulation MM (i.e., $C/D = 1.5$), FF (i.e., $C/D = 2.5$) and BB (i.e., $C/D = 3.7$) were investigated using numerical analysis. Based on the results obtained from centrifuge model test and numerical analysis, the following conclusions can be drawn.

1. In all the cases, the pile settlement increased as the tunnel face approached the monitoring section and then decreased as the tunnel face continued to advance beyond the monitoring section. The maximum settlement of the pile group induced by twin tunnelling occurred in the case of $C/D = 3.7$ (i.e., Simulation BB).
2. The maximum loss of pile bearing capacity induced by twin tunnelling occurs when the whole pile group is located within the major influence zone due to tunnelling proposed by Jacobsz (2001). In the cases of $C/D = 1.5$, $C/D = 2.5$ and $C/D = 3.7$, the loss rate of the pile bearing capacity (P_{Loss}) are 33.7%, 68.7% and 90.2%, when the displacement failure criterion proposed by Ng et al. (2001) was used.
3. The maximum transverse tilting of pile group induced by twin tunnelling is also observed in the case of $C/D = 3.7$ (i.e., Simulation BB). The maximum tilting of the pile cap is lower than

the tilting limit suggested by Eurocode 7 (2001) for buildings and Technical code for building pile foundations (China industry standards for buildings, JGJ 94-2008) (i.e. 0.2%).

Index selection and weight analysis of the underground development of urban municipal public facilities

Lu Ye

College of Architecture, Soochow University, Suzhou, Jiangsu, China

Liming Zhu

Suzhou Institute of Architectural Design Co. Ltd., Jiangsu, China

ABSTRACT: Municipal public facilities underground development is one of the most important contents of urban underground space planning. In this paper, we study the major factors affecting the underground development of public facilities in the urban planning, including locational factor, geological environment, economy, engineering technology conditions, policies and management mechanisms, and disaster prevention safety. The subjective and objective weighting methods are adopted to analyze the weights of these factors. Weight analysis lays the foundation for the establishment of evaluation model and provides scientific and reasonable evidences for establishing the “feasibility and appropriateness of underground development of municipal public facilities” evaluation system and the resolutions of the underground development of municipal public facilities.

1 INTRODUCTION

Underground development of municipal public facilities is one of the major functions of urban underground space development and utilization. Underground municipal public facilities have great advantages in upgrading the safety, stability, and post-stage maintenance of infrastructure. In large cities like Shanghai, Beijing, Shenzhen, and Guangzhou in China, the underground development of municipal public facilities has achieved certain development, for example, large-scale underground transformer substation, underground sewage treatment site, and underground comprehensive pipe rack.

The development of urban underground space facilities shall be closely combined with urban planning. With the development of the city and social economy, it shall consider multiple factors when making resolutions on whether the facility shall be developed underground. Even if the development conditions and construction technologies are feasible, only when the expected “benefits” of underground development of municipal public facilities are more obvious than the ground development, it would present the specific enforceability. However, “benefits” do not only include the direct economic ones resulted from land savings generated from underground development, but also bring more social and environmental benefits, such as the contribution to urban transportation and the

environmental improvement. Meanwhile, municipal projects are the life projects mainly invested by the government. It shall be planned in advance for intensive utilization of land source, low-carbon sustainable development planning, and improving the comprehensive benefits of the engineering.

In this paper, we study the influential factors of urban underground space development level and specific indicator factors of underground development from macro and micro perspectives, respectively.

2 LOCATIONAL FACTOR

Locational factor can be analyzed from macro, medium and micro levels. For the construction location, it judges from the municipal public facility’s requirement level on the underground development according to the requirements of urban planning.

Macro and medium locational factors represent the development level of urban underground space indirectly. According to the current practices of Chinese cities, the management development of urban underground space is mainly taken charge by the civil air defense departments. The civil air defense level of these cities affects the development force for underground space to a large extent. Therefore, in the macro locations, the air defense level and population of cities directly decide the

importance of the underground space in their urban development.

Medium location mainly represents the position of cities in the surrounding city clusters. For instance, cities in the core positions of the city clusters are superior to those not in the core positions in terms of the urgency of underground space development.

Micro location factor mainly evaluates the influences of the micro environment of different locations in the city on the development conditions and approaches of municipal public facilities. For example, the feasibility for carrying out underground development in the city center is completely different from that in the suburb. The soundness of micro location conditions affects the benefits resulted from the underground development directly. As urban area in China is expanding continuously, many municipal public facilities in the suburb previously gradually move to the city center and the value of the land is becoming increasingly higher. Therefore, underground development enjoys an increasingly higher feasibility. To sum up, the level-2 factors under locational factor are divided into three items: macro location of macro factor, medium location, and the micro location of micro factor.

3 ECONOMIC FACTOR

3.1 *Influential mechanism*

In accordance with the actual status, China is still in the stage of prioritizing the economic development. Therefore, when it comes to the underground development of municipal public facilities, economic strength and input–output ratio are the biggest concerns of decision makers.

The main factors hindering underground development of municipal public facilities under the current status are as follows: the financial income of the city is too low to have capacity to make the underground development of municipal public facilities; underground development calls for huge investment. For example, for a 110 kV transformer substation, the capital consumed by its underground development and ground development is 1.5–5.1. The capital for development is available, but the benefits brought by underground development are not obvious.

Economic factor comes first, which is applicable for not only municipal public facilities but also other urban facilities. However, it is common that there are multiple plans for municipal public facilities. Among the evaluation standards, the weight of economic factor varies.

3.2 *Evaluation indicator selection*

Economic factor is mainly divided into three level-2 indicators: Per capita GDP, per capita financial income, and per capita disposable income.

3.2.1 *Per capita GDP*

Per capita GDP mainly represents the economic development level of the city and affects the strength and model of underground space development. It facilitates us to master the stage of urban underground space development from the overall perspective. Widely recognized “threshold theory” holds: When the per capita GDP reaches US \$3000, it indicates that the city has entered the large-scale underground development stage (Shu 2002a, b, Tong 1994).

3.2.2 *Per capita financial income*

In the current stage, a major model for Chinese municipal public facility development is the allocation from government finance. Therefore, the financial income of the city affects the ability of municipal public facility development to a large extent, especially when the underground development increases the financial investment.

3.2.3 *Per capita disposable income*

Per capita disposable income is one of the important factors evaluating the living standards of urban residents. Cities featuring high per capita disposable income have strong economic dynamics, and their residents have high recognition and acceptance on the new facilities. If the residents of a city are still striving to meet daily necessities and its government is developing new municipal public facilities, it would receive great resistance from residents and leads to unsound social effects.

4 POLICY MECHANISM FACTOR

4.1 *Influential mechanism*

The current municipal public facility planning face the following problems: lack of large-scope regional municipal public facility planning; municipal public facilities are separate and lack connection with each other; traditional land supply model leads to the shortages of intensive land use of municipal public facilities; municipal public facility regulations are old and there are contradictories among them; and the integration with other public service facilities is insufficient. One of the advantages of underground development of municipal public facilities is intensive land use and land saving. However, because of the factors of governmental system or policy mechanism, the underground intensive development for some municipal public

facilities faces great difficulties. The most collective representation is in the construction and operation of integrated trenches. Integrated trenches have been developed for several years abroad. It has been proved to be a sound measure in solving the underground pipe problem. Since the development and operation of Zhangyang Road of Pudong District in Shanghai nearly 20 years ago, there has been no significant progress. The development of some integrated trenches could hardly make ends meet when it enters the operation stage with suffering losses. The major reason is that the integrated trench joining-responsible units failed to clarify the responsibility ratios of their departments. The integrated trench, which had been proved to have sound benefits in foreign countries, came across many problems in the domestic development. The fundamental reason derives from the problem of Chinese municipal public facility management system and management mechanism. In 2015, 69 cities throughout China initiated the underground integrated pap rack development, and the construction scale was about 1000 km. In March 2016, it was pointed out that the urban planning construction management shall be strengthened in the government working report and proposed the clear target of over 2000 km underground integrated pap rack. It is foreseeable that urban underground integrated pap rack would become the important content for urban infrastructure development in the future.^[8] This indicates that the changes of policy mechanism have huge influences on the development of urban municipal public facility.

4.2 Evaluation indicator selection

It shall follow the line of comprehensive planning, integrative planning, and establishing indicators to study the underground development of municipal public facilities. Standardized municipal public facilities and planning system are beneficial for the underground development of municipal public facilities. On the basis of the above mentioned analysis, level-2 indicators under government factor are mainly divided into the optimal level of related policies and regulations and the implementation force of government in driving the underground development of municipal public facilities.

5 URBAN CONSTRUCTION FACTOR

The urbanization process of cities has significant influences on their public facility development. The higher the urbanization level, the larger the burden for the urban life engineering system and the higher the requirements and scale for construction. Therefore, urbanization ratio is a macro

factor in evaluating the underground development level of the city in this model.

Urban annual completion ratio is the objective indicator in evaluating urban construction strength. The completion level presents the construction capacity and construction efficiency of the city. Therefore, two level-2 indicators would be set under the first indicator of urban construction: urbanization rate and urban annual completion ratio.

Meanwhile, from a micro perspective, plot ratio, population density, land using property, construction land level, and seismic grade of the region also serve as factors in analyzing whether the underground development is worthy.

6 CONSTRUCTION BASIS OF UNDERGROUND SPACE DEVELOPMENT

If the construction basis is weak, it would encounter the following resistances in considering the underground development of facilities: shortage of the engineering geological documents of the city, shortage of the underground development capacity, shortage of government decision-making experience, and shortage of residents' acceptance. The main level-2 indicators for underground space development foundation are per capita underground space area and underground space construction ratio.

7 GEOLOGICAL AND ENGINEERING TECHNOLOGY FACTOR

Analyzing engineering technology condition and geological condition together, they represent the difficulty in implementing the municipal public facilities in the project implementation stage from subjective and objective aspects. If the economic condition policy mechanism is permitted, the underground development could not be realized without the guarantee of mature engineering technology. The mutuality of the geological conditions decides whether the underground development could be carried out smoothly for this facility. They have close relation with the economic factor. The investment of the underground development of a project is in inverse proportion to the engineering technology and local geological situations. If engineering technology conditions in Beijing and Shanghai are the same, the costs for developing underground transformer substation are different because of the geological condition. In some regions of Beijing, they do not need foundation pit dewatering and enclosure. In comparison, the

expense of enclosure of a large foundation pit in Shanghai is approximately 40–50% of that of the whole project.

In the same way, Shanghai now has the capacity to make underground development of 500 kV transformer substation, which is developed on the strong engineering technology condition and economic foundation. As the engineering technology condition is becoming more mature, the geological conditions of a region are by no means the decisive factor anymore. For example, the underground space of Shanghai stands at the cutting edge and serves as the model for domestic cities under the support of construction capacity and capital of the government.

8 ENVIRONMENTAL FACTOR

Environmental factor mainly analyzes the influences of underground municipal public facilities in pre-setting areas on the surrounding environment.

First, underground development of municipal public facilities could significantly reduce pollutions of the surrounding area, such as the underground development of transformer substation and sewage treatment plant. Meanwhile, the underground development of these facilities could alleviate the psychological depression of surrounding residents. Greening implementation on the land of underground development could increase the greening ratio of this area and improve air quality in the surrounding areas.

Furthermore, Chinese society is confronting with increasingly large pressure from the international community in terms of carbon reduction and environmental protection. How to maximize the environment-friendly and low-carbon development strategies in the underground space planning and whether the above mentioned targets could be fulfilled through underground development of ground facilities have become the research hot spots for people in the industry.

Urban municipal public facility is the foundation for urban development, serving as a crucial point in guaranteeing the sustainable development of cities. “The connotation of low carbon development of municipal public facility is the same with that of low-carbon economy, that is, improve energy efficiency and minimize the carbon emission. The final target is to reduce environmental pressure and realize sustainable development; the core is low-carbon technology innovation, system innovation and the transformation of the development concept” (Zhang, B. et al. 2010).

It is apparent that carbon emission mainly exists in the last three stages among planning, designing, construction, operation, and dismantles stages of

municipal public facilities. However, the soundness of planning and designing is extremely important for the emission volume in the last three stages. These two stages are the key for carbon emission reduction. Therefore, the underground development of municipal facilities is apparently beneficial for the whole lifecycle of the municipal public facilities.

9 WEIGHT ANALYSIS OF FACTORS

To sum up, Tables 1 and 2 show the evaluation indicators and influential factors. After analyzing and selecting major factors, defining the weight of these factors is an important procedure in defining whether the underground development is applicable for this facility by using mathematic model as “indicator + weight + analysis model → analysis result”.

9.1 Methods for the weight of micro factors

In this paper, micro factors are mainly presented as major planning control indicators. Therefore, it could adopt the objective weighting method to redistribute the weight of these factors.

9.2 Methods for the weight of macro factors

Analytic Hierarchy Process is the decision-making method that breaks down decision-related factors to hierarchies of target, standard, and plan and

Table 1. Macro influencing factors.

Indicator (level 1)	Indicator (level 2)	Unit
Location	Urban location (macro)	—
	Urban location (medium)	—
Economy	Urban per capita GDP	10,000 RMB
	Per capita financial income	10,000 RMB
	Per capita disposable income	10,000 RMB
Urban construction	Urbanization ratio	—
	Urban annual completed area	10,000 m ²
Underground space	Underground space status	10,000 m ² 10,000 m ²
	Facility construction volume of underground space	
Policy mechanism	Government implementation force, soundness of government-related policies	— —

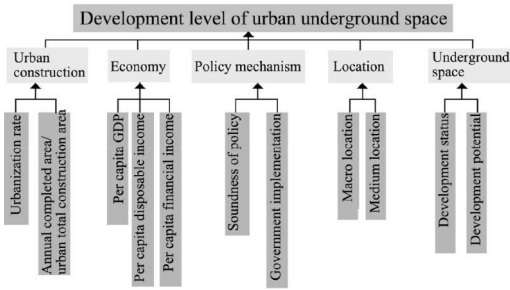

Figure 1. Analysis hierarchy process model.

Table 2. Micro influencing factors.

Evaluation indicators	Unit
Land use property	—
Locational value (micro)	—
Greening ratio	%
Population density	10,000 men/km ²
Land development intensity	—
Construction density	—

Population density	10,000	0.125
Land development intensity	men/km ²	0.125
Construction density	—	0.125
Construction land grade	—	0.125
Building antiseismic grade	—	0.125

Table 4. Macro factor weights.

Macro factor	Unit (RMB)	Weight (ranking)
Per capita GDP	10,000	0.1705 (1)
Government implementation force	—	0.1584 (2)
Macro location	—	0.1197 (3)
Per capita disposable income	10,000	0.1000 (4)
Underground space construction rate	—	0.0942 (5)
Urbanization ratio	—	0.0905 (6)
Policy optimization level	—	0.0712 (7)
Per capita financial income	10,000	0.0587 (8)
Medium location	—	0.0538 (9)
Per capita underground space area	—	0.0423 (10)
Annual completion rate	—	0.0407 (11)

then makes qualitative analysis and quantitative analysis on this basis. In this paper, we adopt yaahp, the Analytic Hierarchy Process software, to analyze the macro factors and establish target hierarchy, standard hierarchy, and plan hierarchy (Figure 1).

Four major procedures in establishing a model in the Analytic Hierarchy Process are as follows: establish the hierarchical structure model on the basis of the mentioned analysis: highest hierarchy (target hierarchy), middle hierarchy (standard hierarchy), and bottom hierarchy (plan hierarchy); construct all judgment matrixes in different hierarchies, that is, defining weights of all factors by comparing the importance of different indicators of the same hierarchy. In this paper, we constructed a judgment matrix through yaahp software; separated hierarchy sequencing, made computing sequencing on factors of relatively high hierarchy. The overall hierarchy sequencing and re-sequencing weights of targets for all factors in this model, especially in the plan of the bottom level, were used to obtain the final weight of the analysis.

In evaluating the weight of factors subordinated to “urban underground space development level”, it shall first compare the important level of factors in the standard level and then compare all factors, especially in the plan level, and finally find the weight of macro factors in the plan level through software in Table 4.

10 CONCLUSIONS

In this paper, we analyzed and selected indicators affecting the underground development of urban municipal public facilities and adopted corresponding weighting approach to make weight analysis on various indicators. It lays a foundation for establishing “feasibility and applicability of the underground development of municipal public facilities” evaluation indicator system.

After defining weights for corresponding indicators, it could select appropriate constitutive model to establish “feasibility and applicability of the underground development of municipal public facilities” evaluation indicator system. The applicability of underground development of municipal public facilities deduced through this method makes the primary exploration for introducing quantitative calculation to the decision of underground development of urban facilities.

Risk assessment of pipelines in operation based on AHP and application of MATLAB

Lei Chen, Guixuan Wang & Jie Zhao

Civil Engineering Technology R&D Center, Dalian University, DaLian, LiaoNing, China

ABSTRACT: The pipeline risk evaluation model is established on the basis of the analysis of risk factors encountered in the operating period of pipeline. Moreover, subfunction program of the model is written using MATLAB. Applying the model to the risk evaluation of a real oil pipeline in Dalian, which can identify the risk safety grades and the risk response measures in the operating period, the calculated result is consistent with the actual one. Examples show that using the risk evaluation model established by the combination of Analytic Hierarchy Process (AHP) and MATLAB can not only draw the specific quantitative indicators to carry out the objective assessment of pipeline risks, but also simply and efficiently provide a reliable basis to the risk assessment and management of the operating pipeline.

1 INTRODUCTION

With the increase of urbanization, the demand for oil, natural gas, and tap water is increasing, which promotes the rapid development of pipeline transportation. It is expected that, in the period of “Thirteen Five”, the total length of China’s oil, gas, and water supply pipelines will reach 200,000 km, and the government will build the inter-regional oil and natural gas supply network system and urban water supply pipe network system (ZHANG Zhihong, 2012). With the passage of time, a number of pipelines are in “sick” operating state; with the increasing use of pipelines, it is necessary to perform health diagnosis and risk management for those pipelines.

In recent years, scholars specialized in pipeline fields in China have made a preliminary exploration and research on the risk of pipeline and obtained some fruitful results. Liu Jiaming (2014) determined that the weight of pipeline corrosion, equipment, third-party damage, and natural environment are, respectively, 0.49, 0.31, 0.12, and 0.08. By introducing several improvements in AHP, it obtained the pipeline health index, which is 0.707, by fuzzy comprehensive evaluation, which is in potentially unsafe levels. Wang Junfang, Yu Qianxiu (2009) evaluated 10 pipe sections of an oil pipeline using the unascertained measure model. The evaluation results were consistent with the actual ones, which indicates that unascertained measure model can effectively evaluate the oil and gas pipelines. Wang Kai (2009) carried out qualitative and quantitative analyses for long-distance pressure pipeline by using fault tree analysis method to identify the

weak sections of pipeline and the risk factors and the degree of risk, which provides specific data to operation of pipeline and improves the safety. All these evaluation methods lack a procedural calculation model. The calculation and analysis process still needs to be simplified and the computational efficiency also needs to be improved.

In this paper, we conducted a research on risk factors encountered in the operation of pipeline on the basis of AHP, wrote the subfunction program of AHP using MATLAB, and built the pipeline risk evaluation model. This model can not only carry out quantitative assessment of pipeline risk, but also make the corresponding risk management program according to assessment results, which can provide a reliable judgment basis for the follow-up risk management of pipeline. Besides, the calculation and analysis process are simple and it can work efficiently.

2 AHP STRUCTURE EVALUATION MODEL

2.1 *The basic principles and steps of AHP*

Analytic Hierarchy Process is a hierarchical weight decision analysis method put forward by Professor Saaty from the United States in the early 1970s (SU Yi, 2011). This method lists all elements related to the target issues and then establishes goal, rule, and index layer so as to establish a multilevel structural analysis model. It is a modeling, quantitative, and systematic process referred to the thought process of decision makers on complex systems. Furthermore, it reflects the subjective

importance of each factor and thus expands the quantitative analysis and research, which can be divided into the following steps: establishing a hierarchical structure analysis model; constructing judgment matrix; calculating the weight vector of judgment matrix; testing the consistency; and making judgment.

First, the analytic hierarchy process is to construct a hierarchical analysis model with issue principled. Second, the analytic hierarchy process stresses the upper and lower subordinate relationships strictly and uses the 1–9 scaling method to carry out a quantitative comparison of the importance of this level of factors with the previous layer and establish the judgment matrix:

$$A = (a_{ij})_{m \times n} \quad (1)$$

where a_{ij} is the important degree of the i factor relative to the j factor and the matrix A is a reciprocal matrix, which satisfies $a_{ij}, a_{ij} = 1/a_{ji}, a_{ii} = 1$. For hierarchical structure, the number of judgment matrix is the same as the number of affiliations from the top layer to the bottom layer. After the establishment of the judgment matrix, the most important thing is to obtain the maximum eigenvalue and the corresponding eigenvector, that is, the weight vector. Usually, the characteristic polynomial is used to obtain the eigenvalue of matrix, which can be expressed as:

$$\det(A - \lambda I) = 0 \quad (2)$$

where I is the unit vector, λ is the eigenvalue, from which the characteristic vector can be obtained.

Practice shows that with the increase in the complexity and the structures of the problem, the calculation and analysis process of AHP will be very complex, especially for the solution of the matrix eigenvalue and eigenvector. In fact, the eigenvalues and eigenvectors can be easily obtained and the consistency test of judgment matrix by writing a function program in MATLAB, which greatly simplifies the calculation.

2.2 Pipeline risk index evaluation system

The number of risk factors that affect the operation of pipeline is high; therefore, the selection of evaluation index will have an important effect on the accuracy and reliability of the final evaluation results. Referring to the research of pipeline damage in China and abroad (JIANG Delin, 2011; Thomas jones, 1992 & Benkherouf A, 1988) and pipeline integrity specifications, we selected 12 representative risk indicators affecting the safety operation of pipeline to build a hierarchical evaluation model, which can more fully reflect the risk characteristics of the pipeline operation period, as shown in Figure 1.

2.3 Classification of pipeline risk safety grade

Currently, most of the pipeline condition assessment using fuzzy evaluation method, such as pipeline operation safety, exists some security risks and other fuzzy qualitative evaluation, and there is no clear pipeline operation risk safety grade classification method and corresponding risk response measures. With reference to the four-level method used in pipeline security status evaluation in industrial pipeline, we determine to use the four

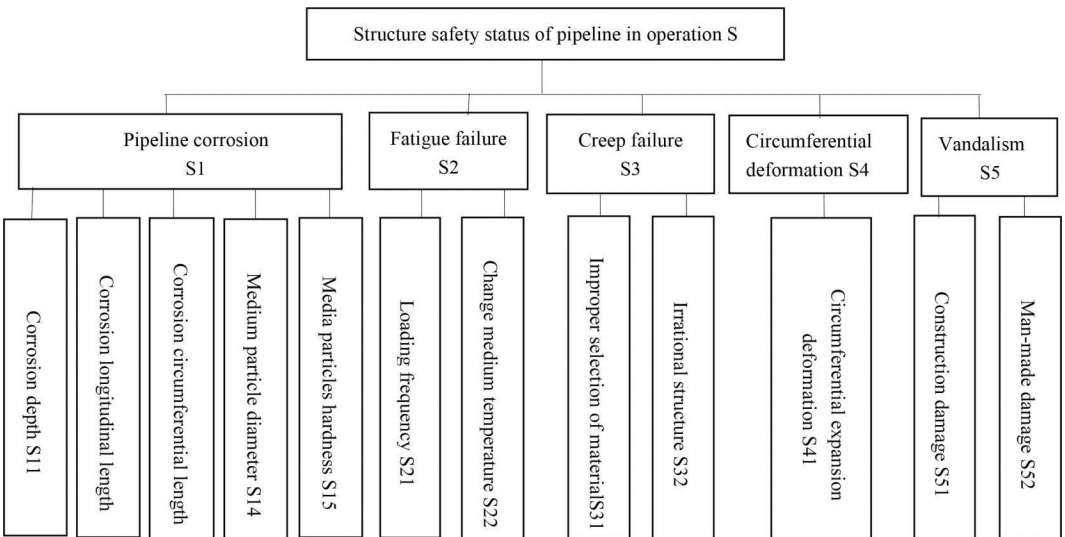

Figure 1. Safety assessment system of operating pipelines.

Table 1. Risk level and response mechanisms of operating pipelines.

Risk level	Response mechanisms
First level of risk	(Weight greater than or equal to 0.2; extremely dangerous): take immediate measures
Second level of risk	(Weight ranged from 0.15 to 0.2; severely damaged): master the risk dynamic and make preparations to cope
Third level of risk	(Weight ranged from 0.1 to 0.15; moderate damage): exclude potential risks within 7 days
Fourth level of risk	(Weight less than 0.1; slight damage): strengthen risk management to eliminate risk as soon as possible

division methods as the operational pipeline risk safety level classification method, and according to the weights of risk factors and the experience of experts and site management personnel, it established the pipeline risk security level and response mechanisms, as shown in Table 1.

3 PROGRAMMING MODEL DESIGN OF AHP

We use MATLAB programming language to write the subfunction of Analytic Hierarchy Process (AHP) to achieve the calculation and analysis procedure. The procedure is that when inputting the judgment matrix, seeking single-level sorting, total sorting, consistency checking, and eventually getting the total ranking weight of all risk factors will be carried out automatically in the procedure (SONG Fei, 2008).

3.1 Solving normalized eigenvectors

Calling function *eig* in MATLAB is to solve the maximum eigenvalue and the corresponding eigenvector of matrix. The call format is $[V, D] = eig(A)$, where V is the eigenvector matrix and D is eigenvalue matrix. Defining function *maxeigvalvec.m* to implement.

```
function [maxeigval, w] = maxeigvalvec (A); %
Seeking maximum eigenvalue and the corresponding
normalized eigenvectors of judgment matrix A
[v, d] = eig (A); % v is eigenvector matrix and d
is eigenvalue matrix
eigenvalue = diag (d);
maxeigval = max (eigenvalue); % Seeking maximum
eigenvalue maxeigval
maxeigvec = v (:, 1); % Seeking eigenvector
corresponded to the maximum eigenvalue
w = maxeigvec ./sum(maxeigvec); % Eigenvector
maxeigvec normalization
end
```

3.2 Calculation of single-level sorting and consistency test

When constructing judgment matrix, because of the diversity of risk the pipe encountered and the

understanding limitations of inspectors for each risk factor, the consistency of the judgment matrix will inevitably be damaged and result in the biased judgment result. In order to avoid the error, emergence of A is more important than B, B is more important than C, while C is more important than A; in the same layer, the consistency of judgment matrix is checked by the obtained maximum eigenvalue λ_{max} . Therefore, it is necessary to test the consistency of the judgment matrix. Defining function *examine.m* to test the consistency of matrix:

```
function [CI, RI] = examine (maxeigval, A); %
Consistency test of single-level sorting weight vector,
maxeigval is maximum eigenvalue, A is judgment
matrix
```

```
N = size(A,1);
RI = [0.0 0.0 0.58 0.90 1.12 1.24 1.32 1.41 1.45
1.49 1.51 1.54 1.56 1.58 1.59]; % RI is consistency
index of average random (He Furong, 2014)
```

```
RI = RI(n);
CI = (maxeigval-n)/(n-1); % CI is consistency
index
CR = CI/RI; % CR is consistency ratio
if CR < 0.1
disp ('Judgment matrix A passes the consistency
test')
else
disp ('Judgment matrix A does not pass the
consistency test, please readjust the judgment matrix')
end
```

3.3 Calculation of total-level sorting and consistency test

Defining function *tsw = tolsortvec* (utw, dw, CIC, RIC); % Seeking total-level sorting weight vector and testing its consistency, *tsw* is the total ranking weight of risk factors in the second layer, *utw* is the total ranking weight row vector of factors in the upper layer, *dw* is the single-sorting weight vector matrix of the lower-layer factors for the upper-layer factors, *CIC* is the consistency index column vector, and *RIC* is the index column vector of random consistency.

```
tsw = dw * utw;
CR = utw .* CIC / (utw .* RIC);
if CR >= 0.1
```

disp ('total-level sorting does not pass the consistency test, please readjust the judgment matrix')
 else
 disp ('total-level sorting passes the consistency test')
 end

4 ENGINEERING APPLICATIONS

4.1 Project overview

A tank farm is located in the Ganjingzi district of Dalian, the pipeline of which operated for more than 10 years. The length of the oil pipeline is about 600 m, the diameter of pipe is 200 mm, and the thickness of wall is 6 mm. The pipeline adopted an overhead layout scheme; the bottom of the pipe is about 30 cm above the ground. According to the

site investigation and inspection records of staff, we know that both the inner surface and the outer surface of the pipe have a different degree of corrosion; it is accompanied by a certain degree of micro deformation and damage caused by human factors.

According to the hierarchy structural diagram in Figure 1, the safety state *S* of the pipeline is the target layer, the pipeline corrosion (*S1*), fatigue damage (*S2*), creep rupture (*S3*), circumferential deformation (*S4*), and vandalism (*S5*) are the criterion layer, and the index layer is specifically divided into 12 influencing factors. We use 1–9 scale methods to carry out the pairwise comparison of risk factors so as to establish the judgment matrix of criterion layer and index layer, as shown in Tables 2–6.

For the circumferential deformation, the influence factor is only expansive deformation, so the judgment matrix is $S4 = [1]$.

Table 2. Judgment matrix (*S*).

<i>S</i>	Pipeline corrosion <i>S1</i>	Fatigue failure <i>S2</i>	Creep failure <i>S3</i>	Circumferential deformation <i>S4</i>	Vandalism <i>S5</i>

4.2 Write calculation program

4.2.1 Input judgment matrix

Clear; % Clear all variables

S = [1 7 6 4 2; 1/7 1 1/2 1/5 1/6; 1/6 2 1 1/3 1/5; 1/4 5 3 1 1/2; 1/2 6 5 2 1];

S1 = [1 3 2 7 5; 1/3 1 1/2 4 3; 1/2 2 1 5 4; 1/7 1/4 1/5 1 1/3; 1/5 1/3 1/4 3 1];

S2 = [1 3; 1/3 1];

S3 = [1 1/2; 2 1];

S4 = [1];

S5 = [1 3; 1/3 1];

4.2.2 Calculation of single-level sorting and consistency test

[maxS, wS] = maxeigvalvec (S);

[maxS1, wS1] = maxeigvalvec (S1);

[maxS2, wS2] = maxeigvalvec (S2);

[maxS3, wS3] = maxeigvalvec (S3);

[maxS4, wS4] = maxeigvalvec (S4);

[maxS5, wS5] = maxeigvalvec (S5);

[RIS, CIS] = examine (maxS, S);

4.2.3 Calculation of total-level sorting and consistency test

dw = zeros (12, 5);

dw (1:5,1) = wS1; dw (6:7,2) = wS2; dw

(8:9,3) = wS3; dw(10,4) = wS4; dw(11:12,5) = wS5;

CIC = [CIS1; 0;0;0;0];

RIC = [RIS1; 0;0;0;0];

tsw = tolsortvec (wS, dw, CIC, RIC)

By default, the order of judgment matrix S2, S3, S4, S5 is less than 3, which completes consistency and does not need to carry out the consistency test, so RIS2 = 0, CIS2 = 0; RIS3 = 0, CIS3 = 0; RIS4 = 0, CIS4 = 0; RIS5 = 0, CIS5 = 0.

4.3 The operation result of program

Running the above procedures, the interface will pop up two times “judgment matrix passes the consistency test” and a time “total-level sorting passes the consistency test”, which explains that judgment matrix S, S1, and the total-level sorting all pass the consistency test and will obtain the total-level sorting weight of each risk factor in the second layer at the same time: tsw = [0.1968 0.0782 0.1231 0.0205 0.0381 0.0320 0.0107 0.0218 0.0436 0.1604 0.2061 0.0687].

According to the 1.3 section of safety level of pipeline risk, by comparing the calculated results,

we can know that the weight of construction damage or vandalism is 0.2061, which belongs to the first level of risk; the weights of corrosion depth and circumferential expansion deformation are 0.1968 and 0.1604, respectively, which belong to the second level of risk; the weight of circumferential corrosion length is 0.1231, which belongs to the third level of risk; and the weight of transmission medium, loading frequency, pipeline structure, and material are all less than 0.1, which belong to the fourth level of risk. By combining with the operating conditions and daily management records of site management staff, it is clear that the construction of surroundings and man-made structures accidentally damage and cause a lot of adverse effects on the operation of the pipeline. Besides, because of the external natural environment and internal medium, the pipe also faces the risk of corrosion. As a result, the calculation results are in agreement with the actual condition of pipeline. Finally, we determine the corresponding risk response measures according to the calculated risk level so as to ensure the safe operation of the pipeline.

5 CONCLUSION

Here, we realized the calculation and analysis steps of AHP by MATLAB programming language and established the pipeline risk evaluation model. The model was applied to the risk evaluation of an actual pipeline risk assessment; by comparing the calculated results with the actual condition of pipeline, we can draw the following conclusions:

1. According to the fundamental principles of AHP, pipeline risk factors, and industrial pipeline security status level, the risk hierarchy assessment model of pipeline structure in operation period was established. The use of MATLAB programming language to write the AHP calculation procedure realizes the procedure of calculation and analysis and reduces the quantitative calculation to derive more accurate results.
2. Application of the programmed calculation model of AHP to the risk assessment of an actual oil pipeline can quickly obtain the weight value of each risk factor the pipe has faced in the operation period and can determine the risk level and take the corresponding risk

response measures. After the above procedure, the problem which primary seemed vague and difficult to judge became clear. Therefore, it is a good method to deal with the fuzzy problem and has strong generalization and practicability in the future.

Effect of ground conditions on design parameters for bridge foundations

M.T.A. Chaudhary

Department of Civil Engineering, Kuwait University, Kuwait

ABSTRACT: Ground conditions (geotechnical properties and geological setting) influences the near surface response of a strata subjected to seismic excitation. Geotechnical parameters required for computation of dynamic impedance of bridge foundations include damping ratio (β), shear wave velocity (V_s) and soil shear modulus (G). Values of these parameters are sensitive to the level of non-linear strain induced in the strata due to seismic ground motion. This paper attempted to investigate the effect of variation in soil properties like Plasticity Index (PI), Over Consolidation Ratio (OCR), effective stress (σ'), depth of soil strata over bedrock (H) and Impedance Contrast Ratio (ICR) on seismic design parameters (β , V_s and G) for two soil types (C and D in AASHTO code). It was found that variation in soil properties influenced seismic design parameters in soil type D more profoundly than soil type C.

1 INTRODUCTION

Influence of site conditions on seismic design spectra is well recognized in current codes. AASHTO code (2010) caters for these effects by characterizing the site conditions into six classes based on shear wave velocity in the top 30 m depth (V_{s30}) or alternative procedures based on average SPT N values or undrained shear strength of top 30 m strata. Design spectrum for a bridge is constructed based on the mapped PGA of the site, short period spectral acceleration, S_s and long period spectral acceleration, S_1 along with site modification factors F_{PGA} , F_a and F_v . Effect of variation in soil properties like Plasticity Index (PI), Over Consolidation Ratio (OCR), effective stress (σ'), depth of soil strata over bedrock and variation in stiffness of the bedrock are currently not included in the code based site characterizing and design spectrum construction processes. This study examined the influence of these geotechnical and site parameters on spectral acceleration, S_A , used for seismic design of bridges.

2 METHODOLOGY

2.1 Background

Site conditions are classified into six categories (A to F) in the AASHTO code based on V_{s30} . Site Classes A and B are rock sites with V_{s30} more than 760 m/s. Shallow spread footings are commonly used for bridges in these site classes. Site class C represents very hard soil or soil-rock with V_{s30} between 360 and 760 m/s. Shallow spread foundations are suitable in this site class for upper range of V_{s30} while deep pile foundations can be used for the lower values of

V_{s30} . Site class D has V_{s30} from 175 m/s to 360 m/s. Pile foundations are commonly used for bridges in this site class. This study focused on the most commonly occurring soil classes C and D which are suitable for both shallow as well as deep foundations and are characterized by a wide variation in V_{s30} (175–760 m/s), PI (0–60), OCR (1–10) and σ' (20–1500 kPa). It is to be noted that AASHTO site classes C and D roughly corresponds to EC-8 soil classes B and C respectively (CEN, 2003).

2.2 Procedure

Sensitivity of seismic design parameters (β , V_s and G) to variation in V_{s30} , PI, OCR, σ' , depth of soil strata and variation in bedrock stiffness; characterized by variation in V_{sR} based on CSIR classification for rocks (Bieniawski 1974) was undertaken in this study. The seismic bedrock characteristics considered in this study are classified as rock classes I to V in which class I is a very good rock ($V_s > 3353$ m/s) and class V a poor rock ($V_s = 600$ m/s). Five generic soil profiles falling within the V_{s30} range for soil classes C and D were selected from Douglas et al (2009) as depicted in Fig. 1. Variations in PI, OCR, σ' , strata depth and Impedance Contrast Ratio (ICR) between soil strata and bedrock considered in the study are summarized in Table 1. Twenty actual far-field ground motions varying in PGA from 0.036 to 0.47 g were selected from ATC-63 (2008) and Chaudhary (2016a) to perform one-dimensional non-linear seismic site response analysis. Acceleration response spectra of these strong motions is depicted in Fig. 2. Table 2 lists the salient features of the selected ground motions as well as group these

Strata depth (m)	40, 110
$V_{s \text{ bedrock}}$ (m/s)	600, 760, 1350, 2251, 3353

into Design Basis Earthquakes (DBE), Functional Evaluation Earthquakes (FEE) and Maximum Credible Earthquake (MCE) based on a design PGA of 0.2 g. Ground motions 18 to 20 were scaled down to match MCE for the design PGA.

More than 2400 analysis were carried out using 1-D site response analysis software STRATA (Kottke and Rathje, 2008) for various combinations of soil profiles, soil properties, strata depth and ICR. STRATA performs a 1-D linear/non-linear seismic response analysis of the soil column in the time domain and incorporates strain dependent non-linear shear modulus reduction and damping curves from a number of sources. In this study, modulus reduction and damping curves developed by Darendeli (2001) were used for the soil classes included in the study.

The choice of PI values as listed in Table 1 were based on the generally accepted limit for sand, medium plastic and highly plastic soils. OCR was kept constant ($= 1$) for all soil profiles based on the observations of Guerreiro et al. (2012). Two values of confining pressure were considered: 2 atm for sandy soils ($PI = 0$) and 4 atm for soils with $PI = 15$ and 60. The choices of confining pressure were made based on the observations of Guerreiro et al. (2012) and to limit the number of simulation cases to a realistic number. Salient results of 110 m deep strata analysis are presented herein. Refer to Chaudhary (2016b) for other cases.

3 RESULTS & DISCUSSIONS

3.1 1-D site analysis results

Variation in damping ratio, shear wave velocity and shear modulus along strata depth for various analysis cases as outlined in Table 1 were determined by conducting 1-D site response analysis for the chosen ground motions. Figure 3 presents typical variation in these parameters along depth for Soil type D-avg for 110 m deep strata. Median and 16 & 84 percentile values of these parameters are marked in the figure with solid bold and dashed bold lines respectively.

In the design of deep bridge foundations, soil parameters in the top 30 m depth are mostly used. Therefore, weighted damping ratio in the top 30 m depth is computed by the following relationship for a particular earthquake in an analysis case:

$$\beta_{30m} = \frac{\sum d_i \beta_i}{30} \quad (1)$$

Time averaged V_{s30} is the shear wave velocity based on the time for the shear wave to travel from a depth of 30 m to the ground surface and was computed as:

$$V_{s30} = \frac{30}{\sum \left(\frac{d_i}{V_{si}} \right)} \quad (2)$$

Variation in the average values of damping ratio, shear wave velocity and shear modulus in top 30 m depth with respect to PGA, PI and ICR are presented in Figure 4 for soil type C_avg as an

example. Tables 2 and 3 list the median values of β and V_{s30} for 110 m strata. The following observations were made:

1. Damping ratio increases while V_{s30} and G decrease with an increase in PGA.
2. Damping ratio decreases with an increase in PI. This means that non-plastic (sandy) soils exhibit more damping than plastic (clayey) soils. Whereas V_{s30} and G increase with increasing PI. This means that non-plastic (sandy) soils have smaller shear wave velocity compared to clayey soils.
3. Damping ratio increases with a decrease in V_{s30} . That is, weaker soils exhibit more damping. The reverse is true for V_{s30} and G , which decrease as the soil becomes weaker.
4. An increase in ICR within a soil type and for the same PI value, increases the damping ratio. Whereas, increase in ICR within a soil type and for the same PI value, decreases the shear wave velocity and soil shear modulus.
5. The impact of ICR on variation in damping ratio, shear wave velocity and shear modulus is more in soil type D compared to soil type C.

3.2 Effect of ICR on β & V_{s30}

Effect of ICR at the bedrock-soil interface on seismic wave propagation and design parameters like β & V_{s30} was investigated in the study. ICR varied between 1 to 6.75 for type C soils and between 1 to 18 for type D soils. Difference in β & V_{s30} for various ICR values within the same soil type and PI with respect to the median values in the group (as reported in Tables 2 and 3) were used to delineate the impact of ICR on these parameters.

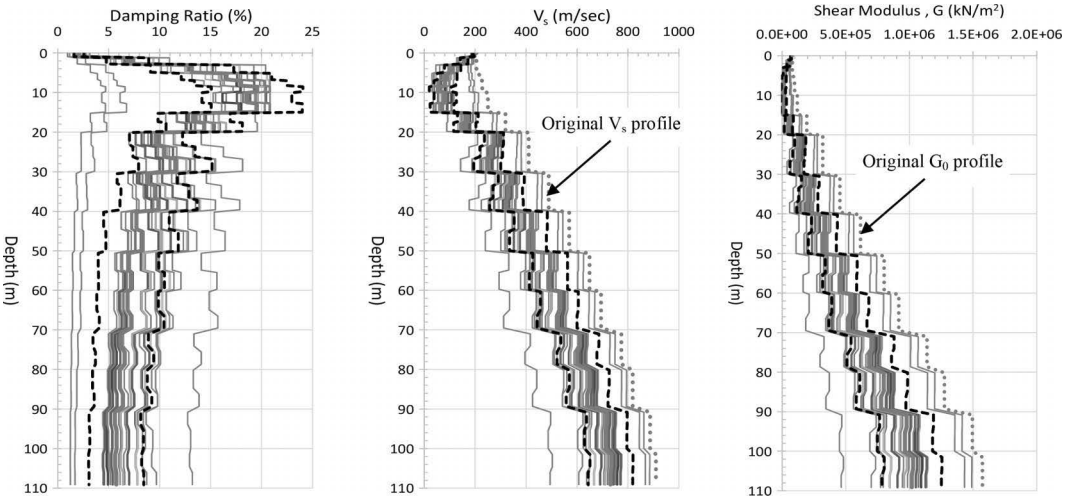

Figure 3. Variation in β , V_{s30} and G with depth for Soil Class D_avg., PI = 0 & $V_{s \text{ bedrock}} = 3353 \text{ m/s}$ – 110 m profile.

Figure 4. Variation in β , V_{s30} and G with PGA in top 30 m depth for Soil Class C_{avg} – 110 m profile depth.

Table 3. Median values of V_{s30} (m/s) – 110 m strata.

Soil	DBE (PGA < 0.27g)			FEE (0.27g < PGA < 0.36g)			MCE (0.38g < PGA < 0.46g)		
	PI 0	15	60	0	15	60	0	15	60
C_{high}	558.73	578.01	589.54	516.68	554.11	576.74	491.42	543.02	571.84
C_{avg}	408.65	436.72	453.75	377.94	415.96	442.21	340.20	394.01	430.54
D_{high}	247.52	302.06	329.45	211.27	253.37	297.23	164.52	225.79	278.09
D_{avg}	160.91	210.95	242.06	144.59	185.94	225.91	101.75	140.32	201.93
D_{low}	103.46	116.60	136.79	100.36	115.77	133.89	84.10	98.31	118.58

Figure 5. Effect of ICR on damping ratio.

Figure 7. Reduction in V_{s30} with earthquake intensity.

Figure 6. Effect of ICR on shear wave velocity.

A difference in β of more than 1.75% was taken as the threshold for considering the influence of ICR. Whereas a spread of more than 10% between V_{s30} for extreme ICR cases with respect to the median V_{s30} for the group was taken as the threshold for shear wave velocity. Figures 5 and 6 depicts the results for critical cases for damping ratio and shear wave velocity respectively for 110 m deep strata. It can be observed that variation in ICR has most effect of soil type D for both β and V_{s30} .

3.3 Reduction in V_{s30} as compared to V_{s0}

Figure 7 depicts the reduction in final median value of V_{s30} as compared to V_{s0} for a soil type. Reduc-

tion in V_{s30} can be noted with increasing PGA as well as reducing PI values. Type D soils displayed more reduction than type C.

4 CONCLUSIONS

The following conclusions are drawn from this study:

- i. β , V_{s30} and G are strongly influenced by PGA, soil type and PI.
- ii. ICR influences β , V_{s30} and G more profoundly in soil type D.
- iii. V_{s30} reduces with PGA and the reduction is very significant (up to 60%) in soil type D with $PI = 0$.

Research on multisource information fusion of tunnel geological prediction based on evidence theory

Zonghui Liu, Yetian Wang, Hui Ke, Heng Wu & Dong Zhou

College of Civil Engineering and Architecture, Guangxi University, Nanning, China

Key Laboratory of Disaster Prevention and Structural Safety of the Ministry of Education, Guangxi University, Nanning, China

ABSTRACT: On the basis of a great amount of multivariate obtained information (geological information, geophysical prospecting data, etc.), tunnel geological comprehensive prediction is the procedure to predict the unexcavated geological situations. According to the characteristics of the current tunnel geology comprehensive prediction method, D-S evidence theory is introduced to construct the multisource information fusion model of tunnel geological comprehensive prediction in this paper. The evidence obtained in each step is superposed layer by layer following the comprehensive prediction process from macroscopic prediction to the geological analysis in tunnel and then comprehensive geophysical prospecting (long distance and short distance). With more sufficient evidence, the unfavorable geological information is much more clear for predicting the unfavorable geology of tunnel barrel, which can be narrowed down to a specific location. Citing the instance of comprehensive geological prediction of the left line in the LingJiao Tunnel, the proposed application processes and results of multisource information fusion model of tunnel geological comprehensive prediction based on the evidence theory are introduced in detail. The prediction of four anomalies are in good agreement with the prediction of the expert groups and the actual excavation results, which shows that the proposed comprehensive prediction model can fuse various information and is capable of simulating multiexpert decision-making process without reducing the accuracy.

1 INTRODUCTION

Geological comprehensive prediction of tunnel is a very complicated process and the geological predicting workers have to face large amounts of geological materials and field data, which should be organized and analyzed effectively to obtain correct predicting results. Recent years have seen some comprehensive predicting models put forward (Ge et al. 2010, Xu et al. 2013, Xu et al. 2011, Yuan et al. 2011), which can integrate multiaspect information and have achieved good results in some engineering cases. There are still some shortcomings and limitations in these studies; for instance, the fuzzy evaluation method in the existing comprehensive predicting model mainly reflects the consistency but no clear description of conflict between each evaluation index. Meanwhile, as a complicated engineering system, the geological prediction of tunnel produces several uncertainties, but the current fuzzy evaluation methods are difficult to fully reflect the uncertain characteristics of the information.

The evidence theory is a generalization of the probability theory, which has a weaker axiom

system and a more rigorous reasoning process than the probability theory, and can reflect the uncertainty of objects more objectively (Fan & Zuo, 2006; Tan & Xiang, 2008). As a method of uncertainty reasoning, it can express the uncertainty caused by randomness and fuzziness. Dempster evidence combination rule can integrate evidences without complete information simply and effectively and reflects the conflict of different evidences to some degree. The evidence theory is widely used in the fields of information fusion and expert system, and it is a relatively frontier research topic worldwide (Du et al. 2014, Jia et al. 2014). The multisource information fusion method of tunnel geological comprehensive prediction proposed in this paper aims at maximum elimination of the multisource results of the single predicting method and improvement of the accuracy of prediction.

2 OVERVIEW OF D-S EVIDENCE THEORY

2.1 *Frame of discernment*

The set Θ , in which any result that people care about can be found, is a set of mutually

exclusive proposition of problems that need to be determined, and the determination often depends on the level of knowledge of the decision maker. Shafer calls Θ as the frame of discernment, and the formula is expressed as follows:

$$\Theta = \{F_1, F_2, \dots, F_n\} \quad (1)$$

where F_n is an element of frame of discernment.

2.2 Basic function

To describe and deal with the uncertainty after establishing the frame of discernment, the concepts of basic probability assignment function, belief function, and likelihood function are introduced.

The set 2^Θ composed of all subsets of Θ is the power set of Θ . If the function set $m: 2^\Theta \rightarrow [0, 1]$ satisfies

$$m(\emptyset) = 0 \quad (2)$$

$$\sum_{A \in \Theta} m(A) = 1 \quad (3)$$

then m could be named as the Basic Probability Assignment (BPA) of Θ , which expresses the trust of evidence in subset A of the frame of discernment. Formula (2) demonstrates that a null proposition does not generate any probability, and formula (3) shows that the sum of the probability assignment of all subsets is equal to 1. A which satisfies $m(A) > 0$ is called the focal element. If subset A obtained only one element, it could be called a single-element focal element.

The belief function of D-S evidence theory is also named as the lower function, which indicates the trusting level in an assumed set and its value is defined as the sum of the current basic probability assignment of all subsets, and is expressed as follows:

$$Bel(A) = \sum_{B \subseteq A} m(B) \quad (4)$$

The plausibility function can be described as the upper function, reflecting the extent of doubt about A , that is, how we do not doubt A or A is reliable, and the formula is given in the following expression:

$$Pl(A) = \sum_{B \cap A \neq \emptyset} m(B) \quad (5)$$

The trust interval, $[Bel(A), Pl(A)]$, is made up of the belief function and the plausibility function, to measure the degree of certainty of some hypotheses.

2.3 The Dempster evidence combination rule

The Dempster combination rule is the essence of the D-S evidence theory, which reflects the combined action among evidences. Using the rule, a new belief function could be figured out from several belief functions based on different evidences, which does not conflict completely, in the same frame of discernment. Therefore, the new belief function can express the combined actions of those evidences.

Assuming that there are two independent evidences in the same frame of discernment whose focal elements are B_i and C_j ($i = 1, 2, \dots, m; j = 1, 2, \dots, n$), where m and n , respectively, represent the number of the two evidence focal elements, then m_1 and m_2 are the corresponding two BPAs, and the formula of the synthetic BPA $m_\oplus: 2^\Theta \rightarrow [0, 1]$ is as follows:

$$m_\oplus(A) = \frac{\sum_{B_i \cap C_j = A} m_1(B_i) m_2(C_j)}{1 - K}, A \neq \emptyset \quad (6)$$

$$m_\oplus(A) = 0, A = \emptyset \quad (7)$$

where \oplus is the combination mark and $K = \sum_{B_i \cap C_j = \emptyset} m_1(B_i) m_2(C_j)$ is the conflict coefficient. When the number of evidence is more than two, they can be combined one by one according to the formula as Dempster rule meets commutative law and associative law. Dempster rule can integrate multi-information and reflect the conflict condition between different information or evidences. Generally, a larger value of K means a greater conflict between two evidences. However, some studies show that K is not enough to describe the conflict, which should combine other factors such as the distance of evidence and evidence similarity measure (Bi et al. 2016). They are not discussed in detail.

3 D-S EVIDENCE INTEGRATION MODEL OF TUNNEL GEOLOGICAL COMPREHENSIVE PREDICTION

3.1 D-S evidence integrate model of tunnel geological comprehensive prediction

According to the characteristics of the current comprehensive prediction method of tunnel geology, D-S evidence theory is introduced to construct the multi-source information fusion model of tunnel geological comprehensive prediction in this paper.

The evidence obtained in each step is superposed layer by layer following the comprehensive prediction process from macroscopic

prediction to the geological analysis in tunnel and then comprehensive geophysical prospecting (long distance and short distance).

With the more sufficient evidence, the unfavorable geological information is much more clear for predicting the unfavorable geology of tunnel barrel, which can be narrowed down to a specific location.

The four most common geophysical prospecting methods included in this model are the Tunnel Seismic Prediction (TSP), the Landsonar (LDS), the Transient Electromagnetic (TEM), and the Ground Penetrating Radar (GPR). Other geophysical methods can be also incorporated into this system in a similar way.

According to the characteristics of various predicting methods system, the tunnel geological prediction information fusion process consists of three stages, and the model structure is shown in Figure 1.

The first stage is information sorting and preprocessing, which then extracts corresponding characteristic parameters to construct some evidence subspaces in which all evidence reflects the tunnel geological condition from an independent aspect.

For example, the main sources of the basic geological information of the tunnel macro-geological prediction come from the existing survey and design results, regional geological data, and complementary surface geological survey results.

What comes in first is the extraction of the stratigraphic lithology, geological structure, topography and geomorphology, climate conditions and surface water features, and other indicators to construct the subspace of the macro-geological predicting evidence.

The second stage is the local information fusion, namely evidences obtained from each prediction method are input onto the constructed local

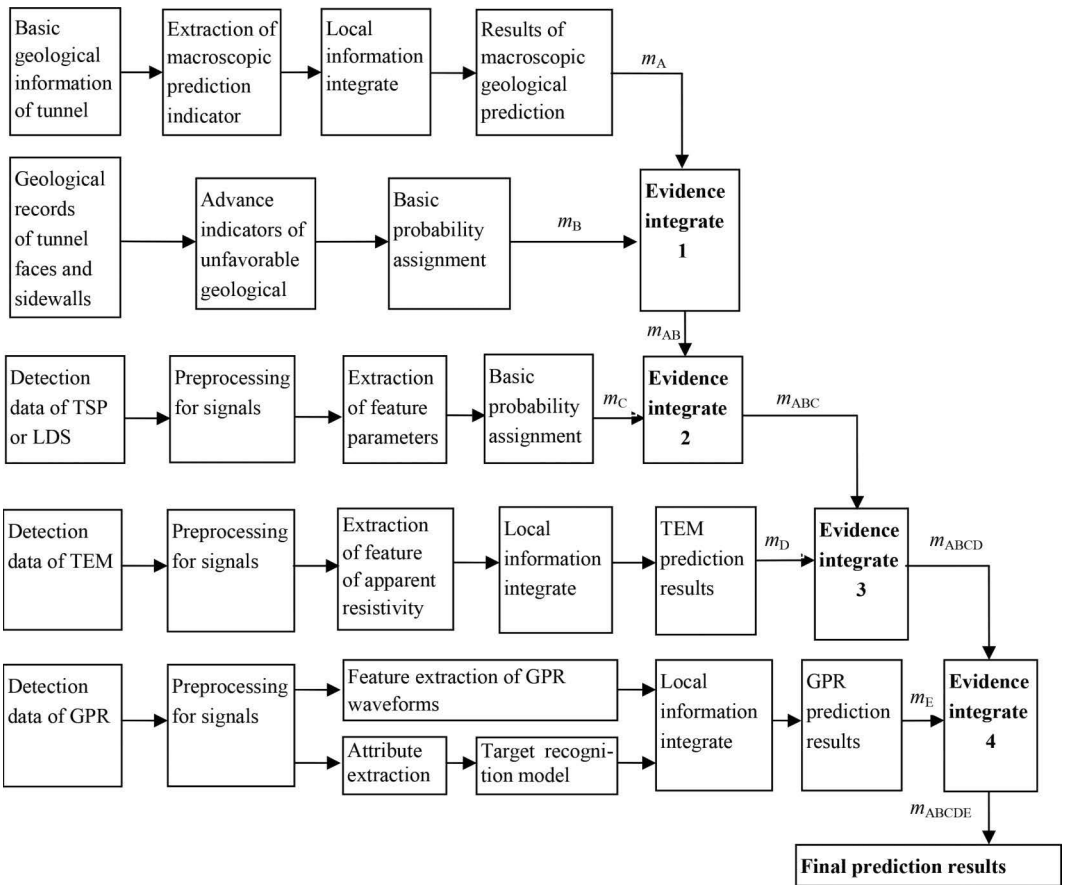

Figure 1. Structure frame of the information fusion model for tunnel geological prediction.

information fusion submodel. This paper consists of three submodels of local information fusion: macro geological prediction, TEM data interpretation, and GPR target recognition.

With step-by-step integration of framework shown in Figure 1, the third stage is transferring the predictions of each submodel to new evidences. Then, the final prediction, F_c , can be drawn as according to the following rules:

$$\text{Rule No.1: } Bel(F_c) = \max\{Bel(F_j), F_j \subseteq \Theta\}$$

$$\text{Rule No.2: } Wm(\Theta) < \varepsilon_1$$

$$\text{Rule No.3: } Bel(F_c) - Bel(F_j) > \varepsilon_2$$

$$\text{Rule No.4: } Bel(F_c) > Wm(\Theta)$$

where $[Bel, pl]$ is the belief interval of evidence to all propositions in the frame of discernment Θ and $Wm(\Theta)$ is the uncertainty of evidence. Rules 1 and 2 are the basic conditions to ensure that the predicting results can be sufficiently distinguished. Rules 3 and 4 guarantee the advantage of reliability of the determined predictions, in which $\varepsilon_1, \varepsilon_2$ should be chosen based on the actual situations. If the above four rules can not be satisfied at the same time, the prediction would not be determined. Two reasons may explain this situation: (1) the prediction does not include in the frame of discernment; therefore, it is necessary to re-identify the frame; (2) the evidence selection is not reasonable; therefore, it is necessary to select again or further selecting more evidences for fusion calculation.

4 THE GENERATION METHOD OF THE BPA

Because of the complexity and diversity in application of D-S evidence theory, it is always difficult to construct the BPA of all evidence in practice, which should be constructed according to the characteristics of the research issue, as there is no unified mode (Lin et al. 2007, Xiang et al. 2015).

Some scholars have already proposed several methods to different problems, such as the BPA generation method based on fuzzy membership, the BPA converted from the measure value based on pattern recognition (Jiang et al. 2008); the determination of BPA according to the types of target and the weighting coefficient of environment (Han et al. 2014); and the establishment of the BPA based on the Euclidean distance of the interval.

Geological analysis and various geophysical methods are involved in the geological

comprehensive prediction of tunnel. Different BPAs are adopted in different methods for which they have different principles according to their own characteristics. In this paper, the three adopted methods are as follows.

- The formation of the BPA of all evidence based on the Euclidean distance of interval number (Cao et al. 2015). The quantitative value of the j th evidence is $Q_j = [x^l, x^u]$, and the evaluating interval of the j th evidence corresponding to the i th prediction is $F_i = [y^l, y^u]$. According to the definition of Euclidean distance, the Euclidean distance between interval $Q_j = [x^l, x^u]$ and interval $F_i = [y^l, y^u]$ is:

$$D_2(\tilde{Q}_j, \tilde{F}_i) = [(x^l - y^l)^2 + (x^u - y^u)^2]^{0.5} \quad (8)$$

Using formula (8), all Euclidean distance between the j th evidence and each possible prediction F_i can be calculated. A smaller Euclidean distance means a higher supporting degree of the j th evidence to F_i . As the Euclidean distance can reflect the support degree of evidences to the prediction, there is further determination of the BPA of the prediction corresponding to the j th evidence:

$$m[A_j(F_i)] = \frac{1/D_2(\tilde{Q}_j, \tilde{F}_i)}{\sum_{i=1}^n \frac{1}{D_2(\tilde{Q}_j, \tilde{F}_i)}} \quad (9)$$

- The conversion of pattern recognition results to the BPA. Using Ground Penetrating Radar (GPR), for example, to identify the unfavorable geological body, the corresponding attribute parameters (such as spectral attributes and instantaneous attributes) based on the measured GPR data are extracted first (Forte et al. 2012). Obtained by pattern recognition method, the recognition measure of the unfavorable geological body in the frame of discernment can be finally converted to the BPA after normalization. This method embraces the objectification of the BPA and the avoidance of the complexity when constructing the BPD.
- The acquisition of the BPA on the basis of the measured data by the assistance of experts experience. The interpretation of TEM, LDS, and other geophysical methods being difficult to be quantified and the artificial intelligence methods, like pattern recognition, being difficult to be applied, experts in relevant fields are often needed to interpret the measured data and give the corresponding BPA.

5 FIELD APPLICATION

5.1 Field description and geological condition

Lingjiao Tunnel located in Cenxi, Guangxi Province, China, is a separated highway tunnel (length = 790 m, maximum burial depth = 130 m). The distance between the center lines of the two openings is 30 m, whereas the net distance is 17 m.

The tunnel is located in the northeastern foot of Yunkai Mountain, an erosional-denudation landform of high hills. The main litho-stratigraphic stratum of the tunnel is weathered migmatite with regional metamorphism. Overall, the rock mass has a broken and inlaid cataclastic structure with weak interlayer bonding.

There are two regional faults, F1 and F2, in the tunnel location, whose intersection causes many complicated conditions in geology.

To guarantee safety during construction, comprehensive geological prediction conducted by Censhui highway headquarters for the preceding geology is undertook by several research institutes using multiple predicting means as well as comprehensive analyses about the prediction by experts.

On the basis of the comprehensive geological prediction of the left line in the LingJiao Tunnel, the application process and effect are introduced in detail for the method proposed in this paper as multisource information fusion based on evidence theory for tunnel geological comprehensive prediction.

Geological analysis process, field geophysical process, and the corresponding geophysical result involved in this paper can be found in Zhou et al. (2015). Because of the limited length of this paper, no further details are included.

5.2 Comprehensive geological prediction processes and results based on evidence theory

The following is the prediction of geology circumstance in front of the tunnel face FK18+230 by using the proposed information fusion model based on the evidence theory, geological analysis, and geophysical prospecting results.

5.2.1 Constructing the frame of discernment

According to the macroscopic geological predicting conclusion, unfavorable geology in fault fracture zones mainly includes: fractured rock mass (fractured rock mass with mud zone), soft layer (filled cavity) mainly filled with soft plastic and flow plastic clay, and fracture cleft (cavity) without filling material. Therefore, the frame of discernment can be expressed as: $\Theta = \{A, B, C, D\}$.

Where A is the relatively intact surrounding rock; B is the fractured rock mass (fractured rock

mass with mud zone), C is the soft layer (filled cavity) mainly filled with soft plastic and flow plastic clay, and D is fracture cleft (cavity) without filling material.

5.2.2 The basic probability assignment

1. Section FK18+228–FK18+202

Evidences of tunnel geological prediction in this section include the result of four prediction methods: geological analysis, LDS detection, TEM detection, and GPR detection. Therefore, the evidence set can be expressed as: $P = \{P_1(\text{geological analysis}), P_2(\text{LDS}), P_3(\text{TEM}), P_4(\text{GPR})\}$.

Geological experts believe that the geological analysis can only determine that the above three types of unfavorable geologies are all likely to exist when entering section FK18+220 in the fault fracture zone; however, the uncertainty of specific location and the reason for their anomalies make it almost impossible to be a intact rock. Consequently, the basic probability of the evidence m_1 can be assigned as $m_1(A) = 0.25$, $m_1(B, C, D) = 0.75$.

Detecting results of the LDS method show that the range of abnormal area is obviously reduced and there are several faults and cavities, in which, however, the material can not be determined and there may be false anomalies because of far detecting distance. The BPA of LDS detection, which has higher accuracy than geological analyses, and the location of the anomalies of LDS are unified as $m_2(A) = 0.2$ and $m_2(B, C, D) = 0.8$.

The Transient Electromagnetic Method (TEM) can only determine the region where low resistance exists of the tunnel space. The detection results show that the section FK18+213–FK18+207 is obvious in the area of low-resistance anomalies, where there is a high possibility of low-resistivity, water-bearing formations, compared to other areas whose relatively high apparent resistivity means little possibility of low-resistivity, water-bearing formations. Therefore, the BPA of the TEM detection are $m_3(A, B, D) = 0.2$, $m_3(C) = 0.8$ in obvious low-resistivity abnormal zone and $m_3(A, B, D) = 0.8$, $m_3(C) = 0.2$ in other regions. The targets A, B, and D are all regarded as high-resistance areas.

Using the attribute extraction and target recognition technology of GPR described in Forte et al. (2012), we can divide abnormal zones and distinguish the types of the unfavorable geology. Consequently, attributes, instantaneous amplitude, instantaneous phase, amplitude spectrum, and phase spectrum are extracted. Table 1 shows the result of BPA converted from pattern recognition of three abnormal regions in Fig. 7 of Zhou et al. (2015). According to the pattern recognition result, the abnormal regions and the types of unfavorable geology can almost be determined; however, the

superiority in reliability of the abnormal types is not obvious.

2. Section FK18+202~FK18+150

Evidences of tunnel geological prediction in this section include the result of geological analysis, TEM detection, and LDS detection. Therefore, the evidence set can be expressed as $P = \{P_1 \text{ (geological analysis)}, P_2 \text{ (LDS)}, P_3 \text{ (TEM)}\}$.

The detection result of TEM and LDS shows the existence of a large cavity in the upper right of section FK18+188~FK18+183. Synthesis of evidences is mainly used to determine the type of filling materials.

The BPA of geological analysis results can be also assigned as $m_1(A) = 0.25, m_1(B, C, D) = 0.75$.

Although the detection results of LDS detected inside and outside both show that there is a cavity, and the filling material still remains unknown. Therefore, the BPA is $m_2(A) = 0.1, m_2(B) = 0.1, m_2(C, D) = 0.8$.

Meanwhile, TEM can show obvious existence of low-resistivity anomalies and the BPA is $m_3(A, B, D) = 0.2, m_3(C) = 0.8$.

5.2.3 Combination of multiple evidence

Using D-S evidence fusion, the above four anomalies are fused separately, and their results are shown in Table 2.

5.2.4 Conclusions of prediction

According to the reliability-dominance judging rule in Section 3, the above four types of abnormal geological condition can be determined. Section

FK18+220~FK18+219 is the fracture rock mass (fracture rock mass with mud zone); there is a cavity without filler in the right wall of section FK18+220; section FK18+213~FK18+207 is the soft layer (filled cavity) mainly filled with soft plastic and flow plastic clay, and the right side of section FK18+188~FK18+183 is a filled cavity whose filling material is loose and mixed rock soils with the saturated water.

It can be seen from the above processes of evidence fusion that a single prediction method can not determine the specific type of the unfavorable geology. With the fusion of multiple evidences, the state of uncertainty declines continuously while the superiority of reliability of the detection target was observed simultaneously; finally, the type of anomalies can be judged clearly. For instance, the GPR can only show the existence of a cavity in the right wall of section FK18+220, with no information of whether filled or not for its strong interference. Fortunately, this problem is addressed after the fusion of TEM result.

5.3 Expert predictions and actual excavating situations

To guarantee the accuracy, the prediction of geological conditions ahead of the FK18+230 is made after discussion, organized by the command, of experts in geological and geophysical fields. The agreement of prediction between experts and the evidence fusion theory demonstrates that the evidence fusion theory proposed in this paper can fuse multiaspect information to simulate the decision-making process of experts.

Excavation was completed by using advanced support, and it was performed in the fault fracture zone. The excavation shows that the main anomalies lie in section FK18+212~FK18+206, which has cavities, and is a fault fracture with mud zone mainly filled with yellow soft plastic and flow plastic clay. A small scale of mud burst occurred when the excavation came to section FK18+18 but without large-scale disaster because of early prevention. Precisely, the excavation is in good agreement with the prediction.

Table 1. BPA of abnormal areas of the GPR.

Abnormal regions	Mass function			
	$m_1(A)$	$m_1(B)$	$m_1(C)$	$m_1(D)$
FK18+220~FK18+219	0.151	0.452	0.296	0.101
FK18+213~FK18+207	0.054	0.285	0.439	0.222
The right wall of FK18+220	0.070	0.126	0.402	0.402

Table 2. Synthesis results of the mass function.

Abnormal regions	Mass function			
	$m_{1234}(A)$	$m_{1234}(B)$	$m_{1234}(C)$	$m_{1234}(D)$
FK18+220~FK18+219	0.021	0.706	0.116	0.158
FK18+213~FK18+207	0.002	0.126	0.775	0.098
The right wall of FK18+220	0.011	0.198	0.158	0.633
The upper right of FK18+188~18+183	0.010	0.024	0.774	0.194

6 CONCLUSIONS

Information fusion is a process of combination or comprehensive processing of multisource data and information, and the information fusion technology is actually a function simulation of complex problems handled in the human brain, in order to obtain more accurate and reliable conclusion than single information. The geological comprehensive prediction of tunnel is a typical information fusion process, which aims at predicting the unexcavated tunnel geological situations according to massive obtained information (geological information, geophysical prospecting data, etc.). Its ultimate goal is to eliminate the multiplicity of the single predicting method and improve the predicting accuracy.

According to the characteristics of the current comprehensive prediction of tunnel geology, D-S evidence theory is introduced to construct the multisource information fusion model of tunnel geological comprehensive prediction in this paper. The evidence obtained in each step is superposed layer by layer following the comprehensive prediction process from macroscopic forecast to the geological analysis in tunnel and then comprehensive geophysical prospecting (long distance and short distance). With the more sufficient evidence, the unfavorable geological information is much more clear for predicting the unfavorable geology of tunnel barrel, which can be narrowed down to a specific location.

Suffered from the wide fractured zone originated by the intersection of two regional faults and thick water dykes formed by magmatic intrusion into the fault zone, the geological conditions of the Lingjiao Tunnel are very complicated, which may contain many types of unfavorable geologies. On the basis of this project, the application process and result of multisource information fusion model of tunnel geological comprehensive prediction based on the evidence theory are introduced in detail. Predictions of four anomalies in this project are in good agreement with the prediction of the expert groups and actual excavating results, which shows that the proposed comprehensive predicting model can fuse various information and is capable of simulating multiexpert decision-making processes without reducing the accuracy.

Pushover analysis of modularized prefabricated column-tree steel frame

Z.P. Guo, A.L. Zhang & X.C. Liu

College of Architecture and Civil Engineering, Beijing University of Technology, Beijing, China

ABSTRACT: A prefabricated steel frame with Z-shaped cantilever beam splicing is proposed, which can realize a good seismic performance through the slip of the splice. The moment-rotation relationship model of the splice is constructed through force analysis about various states of loading process of splice. A simulation method utilizing connecting element of ABAQUS to realize the constitutive relation of the splice in the overall structure is proposed. Then modal analysis and pushover analysis are conducted on the modularized prefabricated column-tree steel frame and rigid frame under the same condition, and the result shows that there is a very small difference of the natural periods of vibration of the two frames and the performance points under seismic action. The column-tree frame can dissipate seismic energy by utilizing slip of the splice, and compared with the rigid frame, the column-tree frame achieves the purpose of multiaspect seismic fortification.

1 INTRODUCTION

Quality of welding joint can be guaranteed as welding of beam and column is completed in the factory for column-tree frame. What's more, high-strength bolt connection has been conducted on the site to quicken installation. Therefore, column-tree frame structure system has been widely applied (Astaneh-Asl 1997). The seismic behavior of column-tree frame is analyzed and the improvement measures are put forward. McMullin et al. (2003) have conducted theoretical and experimental researches about seismic performance of semi-rigid column-tree steel frame and put forward that column-tree construction can utilize splice assemblies to provide stable energy dissipation during lateral movement. Chen & Lin (2006 & 2013) have researched seismic performance of reinforced column-tree connection, put forward that the specimens can successfully develop ductile behavior with no brittle fracture by forming the plastic hinging of the beam away from the beam-column interface. Oh et al. (2014) have conducted quasi-static test for column-tree connections with weakened beam splices, and put forward the moment resisting capacity of the specimens doesn't obviously decrease. Also, their energy dissipation capacity is better than that of the specimen following the full-strength design principle.

Above all, most of traditional column-tree connections follow the full-strength design principle. The seismic damage of the weld between beam and column can't be effectively reduced and the number of bolts is too much. One effective way to resolve brittle failure of beam column connection is to shift

away plastic hinge of beam to prevent beam column connection from brittle fracture in the earthwork via energy dissipation of shift-away plastic hinge (Kim et al. 2002, Lee & Kim 2007, Popov et al. 1998, Uang et al. 2000). In this paper, the splice is designed as semi-rigid and shift-away of plastic hinge is achieved by using slip energy dissipation of the splice. What's more, modular plate installation has not been formed and assembly degree is not high because placing and maintenance are conducted for concrete floor on the construction site. Therefore, a kind of column-tree frame that is applicable to modularized prefabricated steel structures is proposed on the basis of traditional column-tree structure system. The frame is assembled through the splicing of connection on the construction site after the beam and slab are assembled in the factory. Assembly experiment has been conducted for sample engineering of two-floor modularized prefabricated steel structure frame as shown in Figure 1. The experiment proves that the structure has advantages of simple on-site installation and quick assembly.

As stated above, it is necessary to research the seismic performance of modularized prefabricated column-tree steel frame (Liu et al. 2015a, b, Zhang & Liu 2013). In this article, aimed at the modularized prefabricated steel frame with Z-shaped cantilever beam splicing, a method of utilizing connecting element of ABAQUS finite element software to simulate the beam and column connection with Z-shaped cantilever beam splicing of the overall structure is proposed, and the reliability of using the connecting element method in the overall structure is verified. On this basis, modal analysis and pushover analysis are conducted on

Figure 1. Assembly experiment of two-floor structure.

the overall structure of prefabricated column-tree steel frame, and the result is compared with the rigid frame under the same condition.

2 CONNECTING ELEMENT METHOD

The moment-rotation relationship model of the splice is constructed through force analysis about various states of loading process of splice. ABAQUS finite element software connecting element is employed to simulate the constructive relation of splice in the overall structure, and the moment-rotation curve of beam and column connection simulated with this method is compared with the completed static loading curve and skeleton curve.

2.1 Moment-rotation relationship model of the splice

Taking the splice as the research object, the moment-rotation relationship model of the splice is constructed according to the mechanical theory and finite element calculation result.

According to the analysis on the overall loading process, the states of loading process of the splice can be divided into four stages: elastic stage, slip stage, bearing capacity strengthening stage and elastic-plastic stage. Each stage is analyzed to determine the moment, rotation and rotation stiffness of the splice in each stage, and the moment-rotation relationship model finally determined of the splice is shown in Figure 2.

2.2 Verification of connecting element method

Figure 3 shows the test picture of column-tree connection with Z-shaped cantilever beam splicing, and static loading and quasi-static loading tests

Figure 2. Moment-rotation relationship of the splice.

Figure 3. Failure modes of specimen.

are conducted to this connection, with the column being rolled square steel tube $RHS200 \times 10$ and beam $H300 \times 200 \times 8 \times 12$, both of which are made of Q235B steel, and during the test 10.9 grade high-strength bolt of M 20 is employed, which is made of 40 Cr steel, and anti-slip coefficient of specimen is 0.51 through test.

In the overall structure model, the constructive relation of the splice under the static load is simulated by defining the nonlinear connecting element, the connection property is defined as HINGE, which is composed of translation connection property JOIN (restriction u_1, u_2, u_3) and rotational connection property REVOLUTE (restriction ur_2, ur_3), and rotation is only allowed in the direction of ur_1 , the moment-rotation relationship of the splice is entered as the connection property in this direction. Based on the completed static loading and quasi-static loading tests and by reference to the actual boundary condition in the test, both the bottom and top of the square steel tube in the finite element simulation are simulated as hinge, and the lateral support in the test is simulated by setting a lateral restriction in the

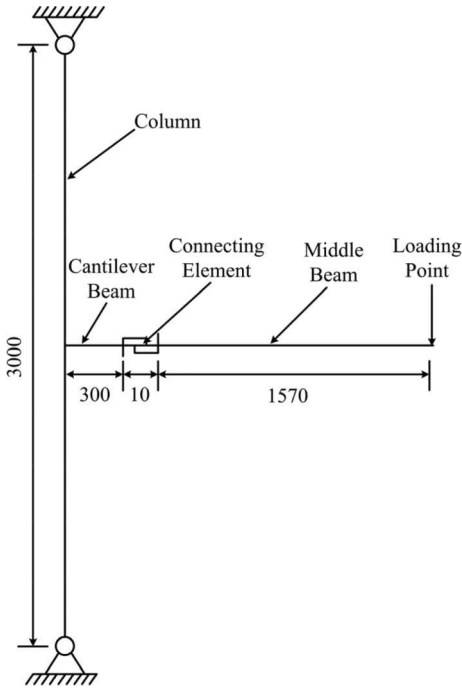

Figure 4. Finite element analysis model.

I-shape steel beam. A finite element analysis model is constructed with the same size as the test piece, beam and column are simulated with beam element, and the splice is simulated with nonlinear connecting element, as shown in Figure 4.

Static loads are applied to the loading point in both the positive and negative directions, and the moment-rotation curve at beam end obtained from the finite element analysis is compared with the moment-rotation curve at beam end obtained from the static test and skeleton curve obtained from the quasi-static test, as shown in Figure 5. Due to only one-way loading in the static loading test, the moment-rotation curve at beam end obtained from the static test only has the positive part. Figure 5 shows that the finite element analysis result coincides with the test result well, so it can be considered that the connecting element method is feasible to the application in the overall structure.

3 FINITE ELEMENT MODEL OF OVERALL STRUCTURE

3.1 Overview of overall model

A calculation example of 3×8 -span steel frame residence building of nine-story is designed in this section, which is proposed to be built in a

(a)

(b)

Figure 5. Comparison of moment-rotation curves between experiments and FEM analysis. (a) Static test. (b) Quasi-static test.

region of 8 degree of fortification intensity, with a plane size of $28.8 \text{ m} \times 12 \text{ m}$ and it has 8 spans transversely, with a span of 3.6 m and 3 spans longitudinally, with a span of 4 m. The overall structure is 27 m high, with 3 m of each floor. The structure is designed to a rigid structure with the structural design software, with column being rolled square steel tube $\text{RHS } 200 \times 10$ and beam $\text{H } 300 \times 200 \times 8 \times 12$. This structure is named as frame RF, and then the rigid joint of the frame RF is changed as column-tree joint, and the sectional size of the beam and column remains unchanged, the column-tree frame named as frame CTF is constructed, as shown in Figure 6. The beam and column are simulated with beam element B32 for which the shear deformation can be considered, and the floorslab is simulated with shell element S4R. The detailed size of splice connection in the frame CTF is shown in Figure 7, modal analysis and pushover analysis are conducted of the rigid structure and column-tree steel frame respectively, and the difference of frame RF and frame CTF

Figure 6. Schematic of three-dimensional frame model.

Figure 7. Details of splice connection.

is compared in terms of seismic performance in details.

3.2 Definition of material parameters

Both the beam and column are made of Q235B steel, and the multilinear isotropic hardening model is employed. The floorslab concrete has a strength grade of C 30, and based on the consideration of elastic material, the elastic modulus is 3.0×10^4 MPa. The representative value of gravity load is calculated by “ $1.0 \times$ dead load $+0.5 \times$ live load”, which is considered by increasing the density of floorslab during modeling.

3.3 Boundary condition and load application

In the structural model, the bottom of the column is fixedly connected, and all 6 degrees of freedom are restricted, the seismic force is applied according to the inverted triangle model.

$$F_i = \frac{G_i H_i}{\sum_{j=1}^n G_j H_j} V_b \quad (1)$$

Where, F_i represents the horizontal load on floor i , G_i and H_i represent the representative value of gravity load and calculated height of floor i , and V_b represents the total seismic shear at the bottom of the structure.

4 COMPARISON OF STRUCTURAL CHARACTERISTICS

A linear perturbation analysis step is set in ABAQUS for modal analysis and to obtain the structural frequency. Lanczos method is selected for the solver of eigenvalue, and the first 12-order frequency and natural period of vibration are calculated respectively for frames RF and CTF, and by observing the vibration mode in each order of the two frames, it is found that frame CTF has its mode of vibration consistent with that of RF in each order, i.e. the change of rigid joint into column-tree joint does not change the original mode of vibration of the structure. The first 6-order natural period of vibration of the structure is shown in Table 1. According to Table 1, compared with the traditional frame, frame CTF has its rigidity reduced slightly with a very small amplitude, and the difference of natural period of vibration is very small, only 1.71% maximally, so it can be considered that the change of the rigid joint into column-tree joint has a very small influence on the natural period of vibration, and it can be neglected basically.

5 PUSHOVER ANALYSIS RESULT OF THE STRUCTURE

In this article, a pushover analysis is made on two steel frames RF and CTF, and capacity spectrum

Table 1. Natural vibration period comparison of RF and CTF.

Vibration mode	T_{RF}^*	T_{CTF}^*	Difference
	s	s	
1	1.71%	1.58	1.60
2	1.50%	1.53	1.56
3	1.61%	1.37	1.39
4	1.13%	0.53	0.54
5	1.53%	0.52	0.53
6	1.54%	0.45	0.46

* T_{RF} refers to natural vibration period of frame RF, T_{CTF} refers to natural vibration period of frame CTF.

method is adopted. The response of the two frames under frequent earthquake and rare earthquake has been analyzed, so as to illustrate the characteristics of seismic performance of the overall structure of column-tree steel frame.

5.1 Capacity spectrum method

Pushover analysis method is to apply a monotonic increasing horizontal load to the structure according to a certain horizontal loading model, push the structure to a given target displacement or a ultimate status gradually, analyze the mechanical behavior of the structure after entering the plastic status and judge whether the bearing capacity and deformation of the structure and members can meet the requirements of seismic design.

The analysis steps of capacity spectrum method are as follows:

1. Solve the internal force of the structure under the action of vertical load, and then apply the horizontal pushover force. The inverted triangle loading model is employed in this article.
2. Carry out pushover analysis to obtain the pushover curve. Then convert the pushover curve into acceleration spectrum-displacement spectrum relation curve. The conversion formula is:

$$S_a = \frac{V_b}{M_1^*}, S_d = \frac{U_n}{\Gamma_1 \phi_{n1}} \quad (2)$$

Where, Γ_1 and M_1^* are respectively the participation coefficient of the first mode of vibration of the structure and effective mass; V_b and U_n are respectively the base shear and top displacement.

3. Establish the elastic-plastic demand spectrum curve: first, convert the elastic response spectrum curve with damping ratio of 5% into an elastic demand spectrum curve, and the conversion formula is:

$$S_d = \left(\frac{T}{2\pi} \right)^2 S_a \quad (3)$$

Then, preset the acceleration values as a_p and displacement value as d_p on the capacity spectrum, and according to the principle of equal energy, the capacity spectrum is double linearized to obtain the acceleration value a_y and displacement value d_y at the yield point, as shown in Figure 8.

Then calculate the hysteretic damping ratio β_0 based on formula (4), and reduce the elastic demand spectrum to obtain the elastic-plastic demand spectrum.

$$\beta_0 = \frac{1}{4\pi} \frac{E_D}{E_{SO}} \quad (4)$$

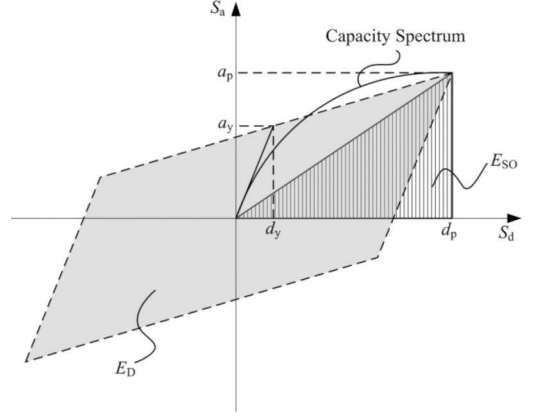

Figure 8. Response spectrum reduction with damping ratio.

Figure 9. Demand spectrum and capacity spectrum.

Where, E_D is the energy consumption of hysteretic damping, E_{SO} is the maximum strain energy, d_p and a_p are respectively the maximum displacement and the corresponding acceleration of the equivalent single degree of freedom system; d_y and a_y are respectively the corresponding displacement and acceleration at yield of equivalent single degree of freedom system. The sum of hysteretic damping ratio β_0 and inherent damping ratio β can be expressed with equivalent damping ratio β_{eff} , as follows:

$$\beta_{eff} = \kappa\beta_0 + \beta \quad (5)$$

Where κ is the adjustment coefficient of equivalent damping, used to consider that the structure with different energy consumption capacities has different hysteretic damping ratios.

The equivalent damping ratio β_{eff} can be used to calculate the reduction factors SR_A and SR_v of the response spectrum. In Figure 9, SR_A and SR_v respectively represent the reduction coefficient of

the constant acceleration zone and constant speed zone. C_A and C_V are the seismic factors, C_A represents the effective peak acceleration, C_V represents the speed response spectrum of the structure system with damping ratio of 5%.

4. Determination of performance point. If the error between the intersection of capacity spectrum and elastic-plastic demand spectrum and the trial point is within 5%, it is considered that the intersection is the performance point, otherwise, this intersection should be used as a new trial point for calculation in the same way, until the point solved is within the permissible error range.

5.2 Calculation of structural performance point

After determination, the performance point is converted into the top displacement of the structure, i.e. the target displacement. The seismic performance of the structure can be evaluated by analyzing the plastic zone and story drift angle at the moment when the structure reaches the target displacement. If there is no intersection between the capacity spectrum and demand spectrum, the structure does not have anti-collapse capacity. According to the calculation steps above, the frames RF and CTF are respectively calculated, and the results is as shown in Figure 10.

According to the figure above, the performance point of the frame is as shown in Table 2, it can be seen that the two frames have a very small difference in performance point, and under the frequent earthquake and rare earthquake, the two frames have a very small difference of top displacement, indicating that under the condition of achieving prefabrication, the frame CTF does not have a great difference from the frame RF in terms of seismic performance of overall frame.

5.3 Evaluation on structural seismic performance

Under the frequent earthquake, there is no plasticity occurring in each component of the frames RF and CTF when the structure reaches the state of performance point, and both frames are in an elastic state. Under the rare earthquake, some beams of frame RF are in plastic state, and there is no plastic deformation of the column. Some connecting elements of the frame CTF are in nonlinear state, and without plastic deformation of column and beam. This shows that under the rare earthquake, the frame RF can utilize the plastic deformation of beams to dissipate energy, and the frame CTF can utilize the slip of splices to dissipate energy. With the development of plasticity in frame RF, plastic deformation occurs to the column gradually, and

the yield mechanism of the structure is: frame beam-frame column. With the development of plasticity in frame CTF, plastic deformation occurs to the beam and column respectively, and the yield mechanism of the structure is: splice—frame beam-frame column. The yield mechanisms of the two frames show that both frames conform to the seismic requirements of strong column and weak beam, and frame CTF realizes the energy dissipation of the splice, and compared with frame RF, it achieves the purpose of multispect seismic fortification.

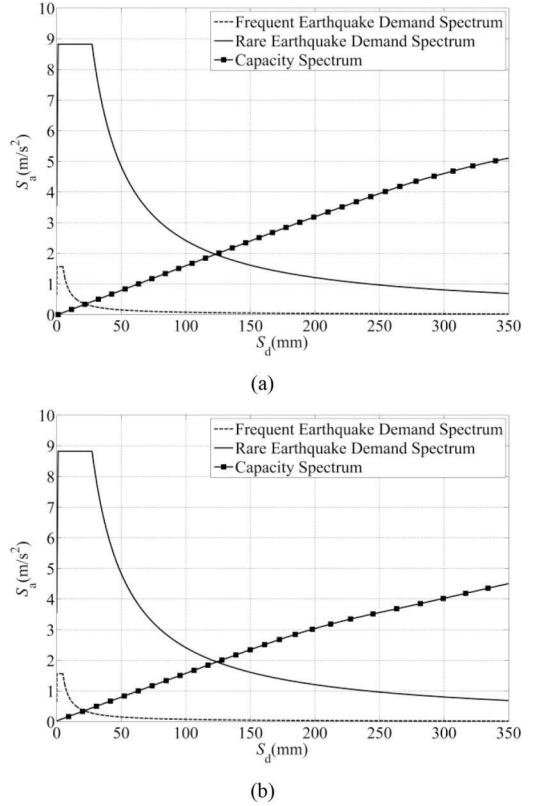

Figure 10. Analysis result of pushover. (a) Frame RF. (b) Frame CTF.

Table 2. Performance points of RF and CTF.

Frame	Earthquake	S_d mm	S_a mm	Top displacement m/s ²
RF	Frequent	22.3	0.34	28.6
	Rare	123.0	1.97	157.7
CTF	Frequent	21.4	0.36	27.4
	Rare	124.0	1.94	159.0

(a)

(b)

Figure 11. Story drift ratio of the frames. (a) Frame RF. (b) Frame CTF.

The curve of change of story drift angle of the two frames with the number of floors and multiple of load is extracted, as shown in Figure 11. It shows that with the increase of load, the story drift angle of each floor increases, and on the first 8 floors, with the increase of floor, the story drift angle increases, and on the 9th floor, it decreases. The maximum story drift angle of both frames RF and CTF occurs on the 8th floor under the frequent earthquake and rare earthquake, the maximum story drift angles of frames RF and CTF under the frequent earthquake are respectively 1/689 and 1/764, both less than 1/250, meeting the requirements of seismic code. The maximum story drift angle of frames RF and CTF under the rare earthquake are respectively 1/121 and 1/109, both less than 1/50, meeting the requirements of seismic code.

Figure 12 shows the distribution of story drift angle of the structure along the height under frequent earthquake and rare earthquake, and it can be seen that under the frequent earthquake, the structure has a relatively even deformation,

Figure 12. Story drift ratio of the frames in frequent earthquake and rare earthquake.

and under the rare earthquake, there is a sharp increase deformation on the 8th floor, which is the weak layer in the structure, and during design, it is required to mainly check whether its story drift angle meets the seismic requirements.

6 CONCLUSIONS

In this article, ABAQUS is employed to build two steel frame models, and the modal analysis and pushover analysis are respectively conducted on the overall structures. The calculation results of rigid frame and column-frame steel frame are compared and analyzed in details, and it is concluded that:

1. The moment-rotation curve of the beam column joint obtained by the connection element method and the experimental results have been compared and analyzed. The results show that the connection element method can simulate the response of the tree column frame under the static load accurately.
2. The column-tree frame has its mode of vibration consistent with that of rigid frame, and the difference of natural period of vibration is very small, only 1.71% maximally. The change of the rigid joint into column-tree joint has a very small influence on the natural period of vibration.
3. The two frames have a very small difference in performance point under the frequent earthquake and rare earthquake, indicating that under the condition of achieving prefabrication, the column-tree frame does not have a great difference from the rigid frame in terms of seismic performance of overall frame.
4. The yield mechanisms of the two frames show that both frames conform to the seismic

requirements of strong column and weak beam, and the column-tree frame realizes the energy dissipation of the splice, and compared with the rigid frame, it achieves the purpose of multi-aspect seismic fortification.

5. The maximum story drift angle of both column-tree frame and rigid frame occurs on the 8th floor under the frequent earthquake and rare earthquake and the 8th floor is the weak layer in the structure.

Study on reuse of heritages of an old industrial area in Harbin Gongyijie area against the backdrop of urban renewal

Xuezhu Shan & Wen Cheng

School of Architecture, Harbin Institute of Technology, Harbin, Heilongjiang, P.R. China

ABSTRACT: The urban old industrial area, because of its geographical location and close spatial relationship with the urban land, has become an important aspect of urban renewal. Against the backdrop of decreasing new land development in China, there is a huge demand of transforming the old industrial area. To study the transformation style of the urban old industrial area and to promote implementation of the transformation project is a major approach to enliven the urban old industrial area and increase the environmental quality of the urban material space. In this paper, we adopt the transformation planning of the old industrial area in Harbin Gongyijie Area as an example and summarize characteristics and problems facing the old industrial area. Combining the characteristics and specific transformation requirements of urban renewal in the Area, the author hopes that this study can provide technical support and references for planning and implementation of heritage reuse in the urban old industrial area through the functional integration of the urban space, the ecological environmental construction, the historical heritage protection, and the space culture re-shaping.

1 INTRODUCTION

Currently, China's urbanization and industrialization has entered a new development period. With constant adjustment of the urban space structure and the industrial layout, a large number of industries have been migrated because of their singular functions and serious pollution. The remaining industrial land is closely related to the urban space. Being convenient in transportation, the old industrial area has been a major target for urban construction against the backdrop of urban renewal. However, as the urban construction level uplifts and the new urban land development decreases, the large-scale extended construction and the old urban area-levelled reconstruction have gradually shown their defects, and the urban development mode is seeking for adjustment (Li, R. et al. 2014).

Through urban renewal, the regional economic development and construction can be enhanced, the public service facility and infrastructure construction level can be lifted to a new level, and more attention will be paid to protecting ecological environment, reshaping space culture, and protecting and reusing industrial heritages. Transformation of the urban old industrial area on the basis of the backdrop of urban renewal can improve urban functions, alleviate pollution, protect the ecological environment, sustain the history and culture of the old industrial area, and improve

both economic efficacy and social and ecological efficacy (Li, D. 2009).

2 CHARACTERISTICS AND TRANSFORMATION DEMANDS OF URBAN OLD INDUSTRIAL AREAS

2.1 *Major characteristics of urban old industrial areas*

Because of historical transformation and urban industrial structural adjustment, old industrial areas of Harbin are mainly located on the edge of downtowns and feature the traditional manufacturing industry enterprises. Its disadvantages include a small industrial development space and serious environmental pollution, and its advantages are favorable geographical conditions, profound industrial cultural deposit, and strong space plasticity.

To sum up, the old industrial area in Harbin Gongyijie Area has the following characteristics: 1) Favorable geographical conditions: Because of historical reasons, urban industrial areas are often located in expensive areas such as the main urban area. With the acceleration of urbanization, improvement of the urban space layout, and the constant adjustment of the industrial structure, old industries are moved out, leaving a space with a high added-value area. Such areas have favorable

basic conditions for redevelopment. 2) Carrier of history and culture: The material space and environment peculiar to the urban old industrial area, including the industrial texture, the large-scale production, construction and space and the structures, and its industrial production atmosphere, including production slogans and sounds of machine operation—all these form a part of a city's history and its characteristics. They are basic elements of the indispensable industrial slogans during the urban renewal and transformation. 3) Strong plasticity of the space environment: The texture of the urban old industrial area is highly orderly. The industrial buildings are huge in size, high in floors, and large in space. Their spatial integrity is strong. Therefore, the urban old industrial area shows a high degree of flexibility and plasticity in terms of space structure, layout mode, industrial building transformation, and facade shaping.

2.2 Transformation demands of urban old industrial areas

On the one hand, urban old industrial areas boast advantages in terms of geographical location and transportation; on the other hand, they are faced with challenges, including industrial decline, waste of resources, and environmental pollution. Against the backdrop, renewal and transformation of urban old industrial areas have put forward more specific requirements in terms of reasonability of the regional industrial structure, supplement of the city functions, protection and utilization of regional industrial heritages, and improvement of regional space environment.

Specific requirements are as follows:

1. Adjustment of the industrial structure: In the current stage, the urban industrial structural adjustment mainly aims to develop the tertiary industry, stimulate new demands of land use, and put forward more reasonable requirements of the current urban space and the land use structure. Generally speaking, because of the fact that the industrial land use takes up a huge percentage in the urban old industrial area and lack of land for the tertiary industry, it is imperative to supplement relevant land use types and adjust the land structure for the convenience of upgrade and transformation of the overall industrial structure and stimulation of the regional economic development.
2. Improvement of the city functions: Transformation of urban old industrial areas calls for supplementation and improvement of the urban functional space in these areas. Realization of a city's economic and ecological functions relies on renewal and transformation of the urban

land utilization structure, optimization of the urban industrial space layout, and enhancement of the urban greening construction. At the same time, the relationship among residence, public services, and infrastructure construction should be coordinated, the residents' living environment should be improved, the public service level should be upgraded, and the infrastructure construction should be strengthened so as to address problems such as the outdated infrastructure and lack of public services in urban old industrial areas. Besides, reusing of heritages of urban old industrial areas has a significant effect on the function of urban culture, for example, doing tourism exploitation is a principal means to enhance the regional cultural functions.

3. Improvement of the comprehensive urban environment quality: Urban old industrial areas mainly feature traditional industrial enterprises. Current industries, such as the ordinary machine manufacturing industry and the boiler industry, are mostly traditional industries with an extensive development mode, backward equipment conditions, and a huge influence on ecological environment. They pose a great obstacle to improvement of the urban ecological environment.
4. Protection of history and culture: Industrial heritages are a record of historical traces with precious cultural value. Therefore, to dig the historical and cultural deposit of industrial heritages and to protect them have become key development tasks of a city. (Li, H. & Xiao, Y. 2014) In the current era, as a large number of industries move out, buildings, industrial process, and other cultural information left behind to date need carriers to further preserve them. While endowing land with new functions and value, urban renewal can maximally meet a city's requirements of making use of industrial areas and protecting industrial heritages.

3 PROBLEMS EXISTING IN HARBIN GONGYIJIE OLD INDUSTRIAL AREA

3.1 Overview

Harbin Gongyijie Industrial Area is located in the Harbin Urban-Rural Continuum. The Gongyijie Area is close to Majiagou River on the east. The major research area is the area enclosed by Gongyijie Street, Huaneng Railway, and Majiagouhe River, which covers an area of 0.3 km² (Fig. 1).

There are dozens of plants in Gongyijie Area (Table 1). The boiler industry, the manufacturing industry, and other relevant industries are dominating in the area. The remaining are processing links at the bottom of the industrial chain.

Figure 1. Local map.

Table 1. List of industrial types in Gongyijie Area.

Industrial type	Industrial institutions
Plantation	Material companies
Fishery	Fish farms
Manufacturing	Furniture plants, asbestos tile plants, boiler plants, building material companies, steel manufacturers, electricity plants, special equipment plants, machinery plants of light industry, oxygen plants, boiler plants, fuel companies, and material plants
Building	Cement plants
Catering	Fishing villages
Wholesales and retails	Steel markets and goods yards
Logistics warehousing	Ceramic warehouses

3.2 Main problems

3.2.1 The single industrial structure

In Harbin, the tendency of industries' outsourcing and core industries' hollowing gradually appears in Gongyijie Area. The overall industrial structure is imbalanced: In the secondary industry, the priority is given to the general machinery manufacturing industry and boiler industry, which account for a large proportion but are at the low level. Besides, the developmental model of industrial chain is extensive and the technical foundation is weak, which has a little effect on the overall economic development. Moreover, the proportion of tertiary industry is small, with its development lying behind (Fig. 2).

3.2.2 Waste of land resources

With the increasing expansion of Harbin urban land, the geographical position of Gongyijie Area has gradually been the downtown area, which was originally the industrial area at the edge of

Figure 2. Distribution map of plants.

city. Now, its geographical condition has obvious advantages, and the land value is significantly promoted. As for the present internal situation of this area, the priority is given to the industrial land with scattered usage and mixed organization in which the lands of industries, residents, and corporate facilities are mixed. In addition, because of various reasons such as history and economic development, the majority of its internal factories have been abandoned without production or in the half-production state, but they still occupy most of land in this area, which leads to a waste of land resources in land use (Fig. 3). Here, the industrial land use accounts for 50.97% of the total land area.

3.2.3 Disappearance of distinctive features

The Gongyijie is near Majiagou, and its good ecological landscape resources have not been effectively utilized. At the same time, the constructional situation and quality in jurisdictional area of Gongyijie is comparatively poor: The industrial landscape, such as the original large workshops and the private sidings of railway transportation, has been lacking maintenance for many years. The phenomena of private and arbitrary construction could be seen everywhere, which forms a large number of negative space and landscape, and seriously affects the style of urban landscape. In addition, the evaluation system in Table 2 is used to evaluate the status of the construction quality, and quality evaluation of the existing industrial heritage is shown in Fig. 4.

3.2.4 Serious environmental pollution

The industries and enterprises that contribute to serious environmental pollution in Gongyijie district include asbestos tile factories, sewage treatment plants, boiler factories, and special equipment

Figure 3. Land use ratio map.

Table 2. List of industrial heritage evaluation index.

First-level index	Factor	Second-level index	Factor
Representative	62.95%	Historical value	28.87%
		Artistic value	6.27%
		Technology value	4.05%
		Social value	9.16%
		Economic value	14.61%
Authenticity	12.64%	Plane function	7.02%
		Facade appearance	3.18%
		Structure equipment	1.22%
		External environment	1.22%
Integrity	6.84%	Material form	5.13%
Regional	17.57%	Nonphysical form	1.71%
		Regional traditional technology	2.85%
		Regional characteristics	2.52%
		Regional rarity	5.54%
		Mark local industry beginning	6.66%

Figure 4. Construction quality evaluation map.

factories. In the production process, soot, sewage, toxic or harmful gases, solid wastes, etc. have been emitted for a long period of time. Meanwhile, this type of industries and enterprises has always been the traditional industries with outdated equipment

and lack of technological innovation, leading to problems such as high energy consumption and serious environmental pollution. They seriously interfere with the surrounding residents' daily production and living and threaten the urban ecological environment that needs to be governed.

3.2.5 Incomplete coverage of public service and backward infrastructure construction

The public service facilities in Gongyijie Area are in the lack of system with the incomplete type of internal corresponding public service facilities, low constructional standard, and poor constructional quality. The service radius of the only schools is too large with small radiation scope. The current urban construction is seriously backward. For example, the roads have no specific scales, and the system is in the chaos. The hardening of road surface has not been finished, and there is no bus passing through the area. Besides, the corresponding infrastructure set of water and energy supply is insufficient, which does not match with the further development of city, the improvement of living standard, and the modernization of lifestyle.

4 THE RECONSTRUCTION STRATEGY OF THE RENEWAL OF INDUSTRIAL HERITAGES IN GONGYIJIE AREA

According to the goal of regional development, the present situation and problems, and the updating demand, the reconstruction of industrial heritages preservation in Gongyijie Area adjusts the regional positioning and industrial structure, reshapes the spatial environment, and revitalizes the regional energy. The specific strategies and working paths of the renewal of industrial relic preservation in Gongyijie Area are analyzed from the perspectives of industrial development, urban context, urban function, urban material environment, and urban spatial environment.

4.1 Functional positioning of Gongyijie area in Harbin

As for the update and reconstruction of Gongyijie Area, the actual demands of its industrial heritages in Harbin's future urban development should be comprehensively considered in order to achieve the overall development of city. Analyze the relative developmental strategies of Harbin at the current stage with gradually achieving "the secondary industry's exist and the tertiary industry's entrance" and outsourcing the second industries under the backdrop of heavily developing the tertiary industries; combine Gongyijie Area with the present situation of its surroundings and relative planning;

comply with the actual situation of regional economic development; balance the land use structure and ratio in Gongyijie Area; adjust industrial structure; put the Gongyijie Area on the position of vice center of external Harbin that is guided by modern service; and possess a comprehensive area of being open, dynamic, ecological, and livable.

4.2 *Specific strategies of the renewal planning in Gongyijie area*

4.2.1 *Adjust the original industrial structure and encourage the development of the tertiary industry*

The original industrial structure in Gongyijie Area is imbalanced with the secondary industry occupying a large proportion. First, the industrial layout should be adjusted. The companies with limited special equipment, and the factories with occupying large land, consuming much energy, and heavily polluting environment such as steel plants, asbestos plants, and cement plants should be relocated or shut down. At the same time, capital investment should be increased, the relevant supporting policies should be perfected, and the great efforts should be made in developing tourism, finance, information, and community service. Besides, the ecological tourism along the river, industrial tourism, and other modern service industries with low energy consumption, no pollution, and high added value in the tertiary industry should be introduced in order to achieve the upgrade and transformation of industrial structure in Gongyijie Area.

4.2.2 *Extend the urban context and reasonably protect and utilize the industrial heritages*

Industrial old area records the history of urban development. Thus, the principle of historical preservation should be adhered to in the reconstruction planning. The industrial remaining buildings and structures with certain memorable significance, such as blast furnace, chimney, tower crane, and railway and transport equipment, inside the base should be protected and utilized (Li, L. 2012). Taking the workshop of cement factory that possesses the industrial atmosphere in Gongyijie Area as an example, its function should be replaced by introducing multiple functions of business, resident, culture, and so on, and making a reconstruction design of its space corresponding to the functional demand in order to protect the industrial relics and inject the new vigor into Gongyijie Area.

4.2.3 *Perfect the urban functions, and complement public service and basic infrastructure construction*

The original land use model in Gongyijie Area lacks planning of the public service facilities and attention

to the infrastructure construction, and the overall function lacks a systematic planning. The updating process should be based on the public service facilities of Gongyijie Area and its surroundings as well as the functional layout of business and finance, culture and entertainment, sports and health, education and scientific research, and so on to supplement the categories of facilities and improve the service level. On the one hand, the original scale of education facilities and medical facilities within the jurisdictional area should be improved, and the social welfare facilities and sports facilities should be supplemented so as to complete the public service system. On the other hand, the water supply facilities ought to be repaired, and the level of infrastructure services should be improved to perfect the urban functions from all aspects.

4.2.4 *Strengthen the construction of green system and improve the urban environment by using the ecological restoration measures*

In the need of thoroughly improving the ecological environment in Gongyijie Area, the ecological and livable environment should be built within the internal Gongyijie Area in which a green system has not been planned at the current stage. Now, there still exists more public space to be developed in Gongyijie Area such as the green space with ecological protection (such as isolating noise) and ecological restoration function (such as easing land pollution) (Nan, X. 2013). For example, Majiagou River with good ecological landscape and osmosis should be first developed as the public green space. The priority should also be given to restore the industrial land that is seriously polluted by the original cement factory as the public green space so as to partly construct the green system and curb the pollution and negative effect, construct an urban landscape with high quality, and improve the urban environmental quality (Zhou, Q. et al. 2009).

5 CONCLUSION

Through the way of urban renewal and on the basis of regional functions, the planning should optimize the allocation of land resources and adjust the land using type and proportion. Besides, the planning should guide the adjustment of industrial structure, strengthen the public service facilities and infrastructure construction, perfect the urban functions, protect and utilize industrial heritages, and improve the quality of urban environment so as to enable the urban old industrial areas to adjust to the demands of regional social and economic development, protect historical context, and restore ecological environment. Because the renewal of urban old industrial area has an

extensive involvement and is a complex system, this study on the strategic renewal of urban old industrial areas by taking the Gongyijie Area in Harbin as an example, basing on its current conditions and existing problems, is certainly one-sided. With the gradual deepening of relative studies in the future, the renewal and reconstruction strategies of urban old industrial areas would be continually and systematically improved so that it can provide a more complete and specific guideline for the reuse of different types of old industrial areas.

Research on lateral resistant behavior and design of multicover plates connection for prefabricated steel plate shear wall with beam-only-connected infill plate

X. Zhang, A.L. Zhang & X.C. Liu

College of Architecture and Civil Engineering, Beijing University of Technology, Beijing, China

ABSTRACT: In this paper, the design principle for the connection of prefabricated steel plate shear wall with beam-only-connected infill plate is investigated. Expressions for determining single-bolt demands for the purposes of design are developed, and a multicover plates connection for prefabricated steel plate shear wall with beam-only-connected infill plate is designed. The lateral resistant behavior for both welded connections and multicover plates connections for steel plate shear wall with beam-only-connected infill plate are analyzed and compared by using ABAQUS finite-element software. The effects of changes in the bolt pre-tightening force for multicover plates connection are investigated as well. Then, the FEM simulation results are verified by monotonic loading test of a multicover plates connection with 6 mm infill plate, the lateral resistant behavior and the deformation of cover plates for both FEM simulation results and test results are compared. The results show that the lateral resistant capability of beam-only-connected steel plate shear wall with prefabricated multicover plates connection is less than that with welded connection; in tension field, severe tearing happens on the bolt holes, and the loss of bolt pre-tightening force is large; the tearing of bolt holes and the loss of bolt pre-tightening force get smaller when they are away from the tension field; the buckling of infill plate can cause deformation in cover plates. There was no significant difference on force transmission performances between welded connections and prefabricated multicover plates connections.

1 INTRODUCTION

After entering the 21st century, China's construction is facing an urgent need for industrial technology improvement. Combining with the highest crude steel output ranks of the world and the current situation of oversupply of steel, there are opportunities for the development of prefabricated steel structure. Prefabricated steel structure has many advantages such as high quality, short construction period, energy conservation, and clean production and construction (Zhang 2013). Comparing with concrete structure, prefabricated steel structure system is more suitable for industrialization. This is because steel has better machinability and it is more suitable for industrial production and processing; steel structure is lighter and more suitable for transportation and assembly; steel structure is suitable for the high-strength bolt connection and much easier for assembly, maintenance, and replacement (Zhang 2014). The A.L. Zhang research group of Beijing University of Technology earlier proposed and studied the industrial prefabricated steel structure. However, the different lateral resistant systems for

prefabricated high-rise steel structure still need to be further researched.

Steel plate shear wall system is a type of efficient lateral resistant system, which was developed in the 1970s. It consists of infill steel plate and boundary frame members. The infill steel plate can be connected with the boundary frame members by bolts or welding (Guo 2009). Infill steel plate is a lateral resistant member in steel plate shear wall system, which provides the primary lateral strength and energy dissipation (Clayton, Berman & Lowes 2015). It protects the main frame structure and damages before the main frame structure as the first line of defense and improves the collapse-resistant capacity of the structure.

In most steel plate shear walls, infill plates are connected to both the beams and columns. However, connecting the infill plates to the beams only has been proposed as a means of reducing boundary frame demands and mitigating infill steel plate damage (Xue 1994). Steel plate shear wall with beam-only-connected infill plate can also provide convenience for structural openings and lateral stiffness adjustment (Choi & Park 2009). Because bolted connection is more suitable for assembly,

steel plate shear wall with bolted connection is more suitable for prefabricated high-rise steel structure than the welded one.

At present, most of the researches mainly focus on different infill steel plates and boundary frame members, and only few researchers investigate different welding connections between infill steel plates and boundary frame members. Studies on bolted connections are almost none. In this paper, expressions for determining single-bolt demands for the purposes of design are developed first. Then, a multicover plates connection for prefabricated steel plate shear wall with beam-only-connected infill plate is designed and analyzed.

2 DESIGN FOR PREFABRICATED STEEL PLATE SHEAR WALL WITH BEAM-ONLY-CONNECTED INFILL PLATE

2.1 Design principle

The earliest design principle of steel plate shear wall is to ensure that the shear buckling of the plate is not earlier than the shear yield. This means that the buckling of the infill plate is not allowed. Therefore, the shear buckling stress of the infill steel plate is designed as the ultimate bearing capacity. The later studies show that the infill steel plates can form a tension field after buckling (Thorburn 1983). When tension field develops, the structure still has efficient lateral stiffness and shear capacity. Ever since then, many studies are focused on the tension field, the results of which show that rational utilization of tension field can provide not only the good seismic performance and energy dissipation capacity but also low steel quantity, light weight, and small seismic response (Hosseinzadeh & Tehranizadeh 2014).

The strain of tension field is large and the stress is greater than the yield strength of infill steel plate. Therefore, steel plate shear wall needs to be designed by using the ultimate tensile strength of the tension field. For frictional high-strength bolted connection, the slippage between infill plate and fishplate should be avoided in the design. The shear capacity of single bolt should not be less than the ultimate tensile strength of the tension field it takes.

2.2 Expressions for determining single-bolt demands

As Figure 1 shows, take the diameter of bolt hole as d . Assuming that the spacing between two bolt holes is the minimum:

$$b = 2d \quad (1)$$

Figure 1. Model for design calculation. (a) Model for prediction of inclination angle of tension field. (b) Buckling of infill plate.

$$a = 3d \quad (2)$$

$$e = 2d \quad (3)$$

$$c = b + \frac{a}{2} = 2d + \frac{3d}{2} = 3.5d \quad (4)$$

where a , b , e , and c are shown in Figure 1. If the angle of tension field is α , then:

$$\tan \alpha = \frac{L_{BC}}{L_{AB}} = \frac{h - 2e}{l - c} = \frac{h - 4d}{l - 3.5d} \quad (5)$$

$$\sin \alpha = \frac{L_{ED}}{L_{FD}} = \frac{b_v}{c} = \frac{b_v}{3.5d} \quad (6)$$

The width of the tension field for single bolt (b_v) is given in equation (7):

$$b_v = 3.5d \cdot \sin \left(\tan^{-1} \left(\frac{h - 4d}{l - 3.5d} \right) \right) \quad (7)$$

The cross-sectional area of tension field for single bolt (A_v) is given in equation (8):

$$A_v = 3.5d \cdot \sin \left(\tan^{-1} \left(\frac{h - 4d}{l - 3.5d} \right) \right) \cdot t \quad (8)$$

The ultimate tensile strength of tension field for single bolt (N_v) is given in equation (9):

$$N_v = 3.5d \cdot \sin \left(\tan^{-1} \left(\frac{h - 4d}{l - 3.5d} \right) \right) \cdot t \cdot f_u \quad (9)$$

As Figure 1(b) shows, buckling of infill steel plate will cause out-of-plate load on bolts, the magnitude of which can reach 10% of the yield strength of tension field. If the out-of-plate load is ignored, the bolt hole will slip easily. Therefore, the out-of-plate load should be considered while designing. The out-of-plate load for single bolt (N_t) can be design using equation (10):

$$\begin{aligned} N_t &= (A_t \cdot f) \times 10\% \\ &= (b_y \cdot t \cdot f) \times 10\% \\ &= 0.35d \cdot t \cdot f \end{aligned} \quad (10)$$

For frictional high-strength bolted connection, the shear capacity of single bolt (N_v^b) can be calculated by equation (11):

$$N_v^b = k_1 \cdot k_2 \cdot n_f \cdot \mu \cdot P \quad (11)$$

where μ is the friction coefficient. For ordinary steel structure, take k_1 as 0.9; for large bolt hole, take k_2 as 0.85; the number of friction surface (n_f) should be 2 in multicover plates connection, then the expression for shear capacity of single bolt can be simplified as equation (12):

$$N_v^b = 0.9 \times 0.85 \times 2 \times \mu \cdot P = 1.53\mu \cdot P \quad (12)$$

Table 1. Assembled connection design sheet.

l	H	t	d	η	α	N_v	N_t	i
mm	mm	mm	mm			kN	kN

900	900	4	30	0.5	0.78	110	9	0.69

Figure 2. Design layout for multicover plates connection. (a) Cross section of connection, (b) front view of connection, and (c) back view of connection.

The design value of tensile capacity for a single bolt can be calculated by equation (13):

$$N_t^b = 0.8P \quad (13)$$

When frictional high-strength bolt undertakes shear and tension simultaneously, the bearing capacity should satisfy equation (14):

$$i = \frac{N_v}{N_v^b} + \frac{N_t}{N_t^b} \leq 1 \quad (14)$$

The multicover plates connection for prefabricated steel plate shear wall with beam-only-connected infill plate can be designed by using the design sheet shows in Table 1, when Q235B steel and level 10.9 M24 high-strength bolts are used.

2.3 Design of multicover plates connection for prefabricated steel plate shear wall with beam-only-connected infill plate

From the calculated results in Table 1, the difference between ultimate tensile strength of tension field for single bolt in full-size model and the one in reduced scale model is less than 1%. For the convenience of finite-element analysis and test, the reduced scale model has been designed.

The characteristics of prefabricated multicover plates connection of prefabricated steel plate shear wall with beam-only-connected infill plate are: 1) large bolt holes are arranged at the top and bottom of the infill steel plate in order to increase the allowable value of machining error and make the installation more convenient; 2) multiple welded angle steel are used for connecting the infill plate and boundary beam. There are normal bolt holes on both sides of the cover plates. In this paper, there are three normal bolt holes on each side of the cover plate and a 10 mm space between each cover plate; 3) the bolt holes on beam flange are large; 4) there are stiffeners at both ends of the bottom plate to avoid deformation caused by buckling

of infill steel plate. The design layout of multicover plates connection of prefabricated steel plate shear wall with beam-only-connected infill plate is shown in Figure 2.

3 FINITE-ELEMENT ANALYSIS

3.1 Introduction of the FE model

In this paper, six models are analyzed by using ABAQUS software. The details of the six models are shown in Table 2. All models are made by Q235B steel. H-section beams of $H200 \times 200 \times 8 \times 12$ are used as the boundary beam.

There is no connection between infill plate and columns. To avoid the lateral stiffness of columns, the simplified analysis model is shown in Figure 3.

In order to simplify the finite-element model further and make the calculation more convenient, columns are modeled as rigid wire element of RB3D2, and the other parts are modeled as 3D solid element of C3D8R. The models are under displacement-controlling loading, and the loading point is at one end of the top beam. The models are fixed at both ends of bottom beam, and they make sure that there is no out-of-plane displacement of the top beam. The finite-element models are shown in Figure 4.

3.2 Lateral capacity analysis

Figure 5 shows the loading-displacement curve of six finite-element models. By comparison, the lateral capacities of multicover plates connections are lower than those of the welding connections; however, the trends of the curves are similar. As can be seen from the deformation of the models, the effective height of infill plate with welding connection is smaller because the welded part between infill plate and bottom plate has nearly no deformation. This means the effective height of infill plate with welding connection should be the distance between upper and lower bottom plates, which is smaller than the one with multicover plates connection.

Figure 3. Model for simplified calculation.

Figure 4. Model for finite-element analysis. (a) Assembled connection. (b) Welded connection.

As can be seen from the curves, when the lateral loading reaches a certain value, every curve has its own descent part. The thinner the infill steel plate, the larger the reduction. The reduction of lateral loading is caused by the buckling of infill steel plate. When the infill steel plate starts to buckle, the tension field has not developed, the lateral loading will decrease until the tension field is formed. For models A5, A4, W5, and W4, the tension fields are obvious by the end of the simulation, but the tension fields of models A6 and W6

Table 2. Details of finite-element model (mm).

Model	Assembly connection			Welding connection		
	A6	A5	A4	W6	W5	W4
Bolt diameter	24	24	24	24	24	24
Height of infill plate	900	900	900	900	900	900
Width of infill plate	900	900	900	900	900	900
Infill plate thickness	6	5	4	6	5	4
Cover plate thickness	10	10	10	10	10	10
Bottom plate thickness	10	10	10	10	10	10

Figure 7. Loading device.

Figure 6. Bolt pre-tightening force-story drift angle curves. (a) Model A4. (b) Model A5. (c) Model A6.

are still developing. This means models A6 and W6 do not belong to thin steel plate shear wall.

3.3 Bolt pre-tightening force analysis

Figure 6 shows how the bolt pre-tightening force changes in models A4, A5 and A6 when they are under lateral load. The bolts are the bottom connection bolts on the infill plate, and the bolt numbers are 1–9 from the left to right. This means bolts 1 and 9 are the first and last bolts in the tensile zone.

By comparison, from bolt 1 to bolt 9, the losses of bolt pre-tightening force are decreasing. The largest loss happens on bolt 1, which is about 70% of the total bolt pre-tightening force. The farther the bolt from the tensile zone, the less loss of the bolt pre-tightening force. Only about 10% of total bolt pre-tightening force was lost until the end of simulation. This loss is caused by the buckling of infill plate.

From the deformation of the FE models, the bolt hole of bolt 1 slips and tears first, then the bolt 2, and so on. The farther the bolt from the tensile

zone, the smaller the slippage of the bolt hole. There is nearly no slippage at bolts 7, 8, and 9.

4 MONOTONIC LOADING TEST

4.1 Introduction of the test

In order to verify the results of FE analysis, a test specimen is designed on the basis of the FE model. A prefabricated steel plate shear wall with 6-mm-thick infill plate has been tested under monotonic loading. The loading device is depicted in Figure 7. Because of the stroke limit of the loading device, the test specimen was pulling at the end of the top beam instead of pushing.

4.2 Comparative analysis of lateral capacity

Figure 8 shows the comparison of the loading-story drift angle curve for both test results and FE results. The lateral capacity of the test member is about 8% less than the FE results, but the trends of both curves are similar. The test results prove the validity of the finite-element modeling.

Figure 8. Loading-story drift angle curve for FEM and test specimen.

4.3 Comparative analysis of deformation

When the story drift angle is 0.005, the first bolt holes in the tensile zone of both the test specimen and the FE model start to slip until the story drift angle reaches 0.02. Then, the bolt hole touches the bolt shank and starts to deform.

Buckling of the infill plate happens at nearly the same time when the infill plate slips. Figure 9(b) shows the deformation of test specimen at the end of pulling. Comparing with the deformation of FE model under pushing, they are close to completely symmetrical. Therefore, the FE modeling is verified.

The beams have obvious shear deformation at the tensile end of the connection. The cover plates are slightly deformed because of the buckling of the infill plate. Therefore, the suggestion is that the

Figure 9. Final deformations. (a) Finite-element model. (b) Test specimen.

Figure 10. Comparison of residual deformation. (a) Infill plate connection zone. (b) Side view of cover plates. (c) Top view of cover plates.

stiffening rib is arranged on the beam at the end of the connection.

4.4 Comparative analysis of residual deformation

Figure 10(a) shows the comparison of residual deformations on infill plate after loading. The bolt hole in tension is teared, and the hole at the other

end is unwounded. Figure 10(b) and (c) shows the cover plates, which are removed after test; both sides of the cover plates have slightly deformed. The deformation of cover plates is slightly smaller than that of the FE model, because after the pulling, the test specimen has been pushed to the original position before dismantling.

5 CONCLUSION

In this paper, first, the design principle for the connection of prefabricated steel plate shear wall with beam-only-connected infill plate is investigated, expressions for determining single-bolt demands for purposes of design are developed, and a multicover plates connection for prefabricated steel plate shear wall with beam-only-connected infill plate is designed. Assuming that the spacing between two bolt holes is the minimum, the angle of tension field is related to not only the dimension of infill plate but also the diameter of bolt holes. Together with the development of the tension field, the angle of it will increase.

In order to study the influence of lateral capacity on welded connection and bolted connection of steel plate shear wall, six FE models have been analyzed by using ABAQUS finite-element software. By comparison, the lateral capacities of multicover plates connections are lower than the welding connections, but their trends are similar. The effective height of the infill plate with welding connection is smaller than that of the multicover plates connection. The bolt pre-tightening force will decrease during loading; the closer the tension field, the larger the loss of bolt pre-tightening force. The deformation and slippage of tension field are serious.

Then, the FEM simulation results are verified by monotonic loading test. The results show that the multicover plates connection has a good force transmission performance. The beams have obvious shear deformation at the tensile end of the

connection. To ensure that the steel plate shear wall gets damaged first, the stiffening rib at the end of the connection on the beam is suggested.

Research on sensitivity and control criteria of cable length error in a double-strut cable dome

C. Sun & A.L. Zhang

College of Architecture and Civil Engineering, Beijing University of Technology, Beijing, China

ABSTRACT: Cable dome is a kind of lightweight and efficient large-span tensegrity structure. The manufacturing error of cable length will seriously affect the pre-stress distribution of cable dome and deviate structural performance from the design goal. With a new type of double-strut cable dome as calculation example, the sensitivity of cable length error to structural behavior is analyzed, under the construction method of “fixed length cable”. Then, using reliability theory and nonlinear programming method, the control criteria of cable length error are obtained for this structure. The accuracy of control criteria is verified by the Monte Carlo method. The results show that for the double-strut cable dome, the length errors of ridge cables, inner diagonal cables, and outer hoop cables have an obvious effect on the internal forces of other cables. The method used in this paper can get reliable control criteria of cable length error. However, the excessive allowable error in specification will lead the structure unable to meet the design requirements.

1 INTRODUCTION

In recent years, tensegrity systems have attracted much attention of engineers and become popular as roofs for arenas and stadiums because of their lightweight and architectural impact. Cable dome is the first civil structure inspired by the tensegrity principle (Richard 1962), and its engineering applications include two forms: Geiger type (Geiger et al. 1986, Zhang et al. 2012) and Levy type (Levy, 1994), as shown in Figure 1.

As a tensegrity structure, the pre-stress of cable dome depends on the change of cable length during the tensioning process. To control the pre-stress distribution conveniently, the construction method of “fixed length cable” is always adopted as shown in Figure 2, which makes the anchor end of cable unadjustable so that we can stretch the cable from its original length to the connection directly through jack equipment (Guo et al. 2011). The construction method of “fixed length cable” is economical and efficient, avoiding time

and labor consumption to adjust cable force repeatedly. However, if there is a big error in the original cable length, the pre-stress distribution will seriously deviate from the design value after completing construction, which will impact subsequent mechanical properties under the external load. Therefore, it is necessary to study the influence of cable length error and the control criteria.

At present, the research of tensegrity structure mainly concentrates on form finding (Juan & Tur 2008, Tibert & Pellegrino 2011) and structural behavior (Fu 2005, Ge et al. 2011); however, the research on the sensitivity of cable length error and control criteria is rare. Quirant et al. (2003) studied the effect of cable length error on tensegrity gird by the Monte Carlo method. Gao (2004)

Figure 1. Cable domes: (a) Geiger type and (b) Levy type.

Figure 2. Unadjustable anchor end of cable.

and Zhang (2011) adopted the orthogonal test to study the sensitivity of manufacturing error for suspen-dome and cable dome. Tian (2011) studied construction tolerance of spoke structure through reliability theory and experiment test. Both the American standard ASCE/SEI 19-96 (1997) and Chinese specification JGJ 257-2012 (2012) provided allowable error according to the manufacturing level, without considering the requirement of structural behavior.

In this paper, we study the sensitivity and control criteria of cable length error for a new type of double-strut cable dome. First, under the construction method of “fixed length cable”, the sensitivity of cable length error to structural behavior is analyzed. Then, reliability theory and nonlinear programming method are used to obtain the control criteria of cable length error. Finally, the accuracy of error limit is verified by the Monte Carlo method.

2 DOUBLE-STRUT CABLE DOME STRUCTURE

2.1 Structural features

Double-strut cable dome is composed of ridge cables (RC1, RC2, and RC3), diagonal cables (DC1, DC2 and DC3), hoop cables (HC1 and HC2), central strut (ST1), and diagonal struts (ST2 and ST3), as shown in Figures 3–4. In Geiger and Levy cable domes, only one strut is connected between the top and bottom nodes. However, in double-strut cable dome, except for central strut, each node is connected to two diagonal struts, so diagonal struts are continuously arranged in circular direction.

Figure 3. Perspective view of double-strut cable dome.

Figure 4. Member arrangement and profile view of double-strut cable dome.

Double-strut cable domes (Zhang et al. 2016) have better structural stiffness than the Geiger type because of the presence of triangular nets. Furthermore, the number of diagonal cables is only half that of the Levy type; thus, it needs fewer scaffolds and jack equipment to apply pre-stress through tensioning diagonal cables.

2.2 Calculation model

The calculation model is a double-strut cable dome with 60 m span and 12 divisions in circular direction. To ensure a reasonable structural design and safety reserves, optimization was carried out to guarantee that no cable relaxes and no strut buckles under the design load (1.05 kN/m²), and the cable force does not exceed 50% of breaking force. The optimal design results of all components under the initial pre-stress state and design load are shown in Table 1.

Numerical analyses were carried out using ANSYS, a nonlinear finite-element software package. In the finite-element model, element Link180 is applied to simulate both cables and struts, and the elasticity modulus of cables and struts are 1.6×10^5 and 2.06×10^5 MPa, respectively. The paper only discusses the impact of cable length error under the initial pre-stress state, without considering gravity and the external load.

3 SENSITIVITY ANALYSIS OF CABLE LENGTH ERROR

Sensitivity analysis of cable length error was carried out under the pre-stress state, as shown in Table 1. Taking the cable force on axis 1 as the

Table 1. Design of components.

* F_0 is the internal force under initial pre-stress state, F_p is the internal force under design load, and F_u is the ultimate capacity of components.

reference value, a micro error of the initial length was assigned for each cable from axis 1 to 12 successively to obtain the changes of reference value. If the inner ridge cable (RC1) on axis i has an initial cable length error as δ_{RC1} , and it leads to the cable force changes of RC1 on axis 1 as $\Delta F_{RC1,RC1(i)}$, then we define:

$$s_{RC1,RC1(i)} = \Delta F_{RC1,RC1(i)} / \delta_{RC1} \quad (1)$$

where s = sensitivity to cable length error, which reflects the impact of unit length error of a cable on axis i on the internal force of a cable on axis 1. By repeating the above process, all values of sensitivity s in the double-strut cable dome can be calculated as shown in Figures 5–8.

Figure 5 shows that the cable force of ridge cables on axis 1 is affected by the length error of ridge cables and diagonal cables on all axes. Because of structural symmetry, the impact of ridge cables' (RC1, RC2, and RC3) length error is shown on the right-hand side, and the impact of diagonal cables' (DC1, DC2, and DC3) length error is shown on the left-hand side.

It can be seen from Figure 5 that the length error of RC1 and RC2 has a significant impact on RC1 and RC2 of the same axis and RC3 of adjacent axes, but has few impact on the ridge cables far away from axis 1. If the initial length error of RC1 on axis 1 is 5 mm, the cable force variation of RC1 on the same axis is 5.08% and that of RC2 is 2.85%, while the cable force variation of RC1 on axis 2 is only 1.84% and that of RC2 is 1.01%. Therefore, the impact weakens rapidly from axis 1.

The length error of DC1 has a significant impact on RC1 and RC2 of the same axis. If the length error of DC1 on axis 1 is 5 mm, the cable force variation of RC1 on the same axis is 1.49% and that of RC2 is 0.96%. The other diagonal cables have little impact on the ridge cables force.

Figure 6 shows that the cable force of diagonal cables on axis 1 is affected by the length error of ridge cables and diagonal cables on all axes. It can be seen from Figure 6 that only DC1 is sensitive to the length error of DC1 and ridge cables of the same and adjacent axes. If the length error of DC1 on axis 1 is 5 mm, the cable force variation of DC1 on the same axis is 9.99%, and that on the adjacent

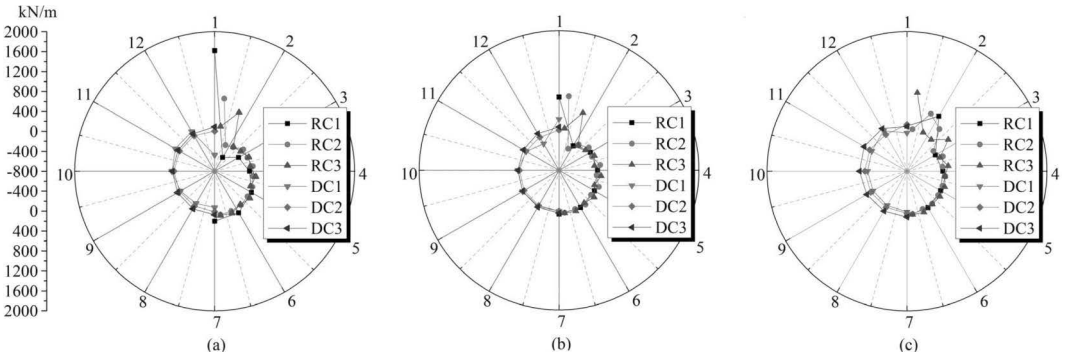

Figure 5. Sensitivity of ridge cables force: (a) RC1, (b) RC2, and (c) RC3 to cable length error.

Figure 6. Sensitivity of diagonal cables force: (a) RC1, (b) RC2, and (c) RC3 to cable length error.

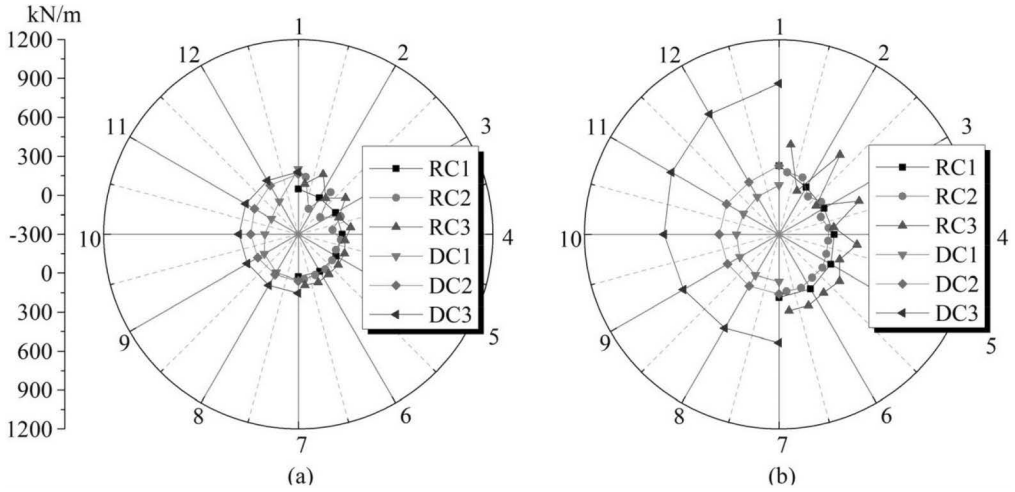

Figure 7. Sensitivity of hoop cables force: (a) HC1 and (b) HC2 to cable length error.

Figure 8. Sensitivity of all cables force to the length error of hoop cables.

axis 2 is 3.01%. However, both DC2 and DC3 are not sensitive to the length error of ridge cables and diagonal cables. If the length error of DC3 on axis 1 is 5 mm, the cable force variation of DC3 on the same axis is only 0.48%.

Figure 7 shows that the cable force of hoop cables on axis 1 is affected by the length error of ridge cables and diagonal cables on all axes. The figure also shows that hoop cables are not sensitive to the length error of ridge cables and diagonal cables. When the length error of HC1 on axis 1 is 5 mm, the cable force change of HC2 on the same axis is only 0.18% and that of HC2 is only 0.29%.

Figure 8 shows that all cables force is affected by the length error of hoop cables. The impact of HC2's length error is shown on the left-hand side,

and the impact of HC1's length error is shown on the right-hand side. It can be seen that HC2 has a significant impact on all cables, much greater than that of HC1. If HC2's length error on axis 1 is 5 mm, then the average cable force variation of each group of similar cables would exceed 0.50%.

In conclusion, the length error of ridge cables and internal diagonal cables has a significant impact on the internal force of adjacent local cables. And that of the outer hoop cables has a significant impact on the overall cable force.

4 CONTROL CRITERIA OF CABLE LENGTH ERROR

4.1 Constraint inequations of error variance based on reliability theory

Let the structural resistance be R and load effect be S . Then, the structural state equation is $G=R-S$. In the case of $G>0$, the structure is safe. If the structural state equation is expressed as a linear form, as shown in (2), then the structural reliability index, β , can be expressed as (Nowak 2012):

$$G = g(X_1, X_2, \dots, X_n) = a_0 + \sum_{i=1}^n a_i X_i \quad (2)$$

$$\beta = \frac{a_0 + \sum_{i=1}^n a_i \mu_{X_i}}{\sqrt{\sum_{i=1}^n (a_i \sigma_{X_i})^2}} \quad (3)$$

Let ΔF_{RC1} be the total force change of RC1. According to the sensitivity analysis in Section 3,

we can obtain ΔF_{RC1} by adding the impact of all cables as (4). Repeating the similar process, the force change of all cables write as (5).

Let $[\Delta F_{RC1}]$ be the force deviation limit of RC1 under initial pre-stress state. On the basis of the reliability theory, the state equation of RC1 is expressed as (6). Set δ_{RC1} to satisfy a normal distribution with mean 0 and variance σ_{RC1}^2 , namely $\delta_{RC1} \sim N(0, \sigma_{RC1}^2)$. According to (2) and (3), we can obtain the reliability of the RC1 as (7).

inside the surface is a valid combination of the variance of different cables' length error. The points closer to the original point present a higher reliability, while those farther from the original point present a lower reliability. A proper variance combination shall meet the following two conditions: First, its distance to the original point shall be as far as possible to relax the request of manufacturing accuracy. Second, the value of each σ_i shall be as close as possible to take similar control criteria for different cables.

$$\Delta F_{RC1} = \sum_{i=1}^n s_{RC1,RC1(i)} \delta_{RC1} + \dots + \sum_{i=1}^n s_{RC1,DC1(i)} \delta_{DC1} + \dots + \sum_{i=1}^n s_{RC1,HC2(i)} \delta_{HC2} \quad (4)$$

$$\begin{pmatrix} \Delta F_{RC1} \\ \vdots \\ \Delta F_{DC1} \\ \vdots \\ \Delta F_{HC2} \end{pmatrix} = \begin{pmatrix} s_{RC1,RC1(1)} & \cdots & s_{RC1,RC1(n)} & \cdots & s_{RC1,HC2(1)} & \cdots & s_{RC1,HC2(n)} \\ \vdots & & \vdots & & \vdots & & \vdots \\ s_{DC1,RC1(1)} & \cdots & s_{DC1,RC1(n)} & \cdots & s_{DC1,HC2(1)} & \cdots & s_{DC1,HC2(n)} \\ \vdots & & \vdots & & \vdots & & \vdots \\ s_{HC2,RC1(1)} & \cdots & s_{HC2,RC1(n)} & \cdots & s_{HC2,HC2(1)} & \cdots & s_{HC2,HC2(n)} \end{pmatrix} \begin{pmatrix} \delta_{RC1} \\ \vdots \\ \delta_{DC1} \\ \vdots \\ \delta_{HC2} \end{pmatrix} \quad (5)$$

$$g_{RC1}(\delta) = [\Delta F_{RC1}] - \sum_{i=1}^n s_{RC1,RC1(i)} \delta_{RC1} - \dots - \sum_{i=1}^n s_{RC1,DC1(i)} \delta_{DC1} - \dots - \sum_{i=1}^n s_{RC1,HC2(i)} \delta_{HC2} \quad (6)$$

$$\beta_{RC1} = \frac{[\Delta F_{RC1}]}{\sqrt{\sum_{i=1}^n (s_{RC1,RC1(i)} \sigma_{RC1})^2 + \dots + \sum_{i=1}^n (s_{RC1,DC1(i)} \sigma_{DC1})^2 + \dots + \sum_{i=1}^n (s_{RC1,HC2(i)} \sigma_{HC2})^2}} \quad (7)$$

$$\sum_{i=1}^n (s_{RC1,RC1(i)})^2 \sigma_{RC1}^2 + \dots + \sum_{i=1}^n (s_{RC1,DC1(i)})^2 \sigma_{DC1}^2 + \dots + \sum_{i=1}^n (s_{RC1,HC2(i)})^2 \sigma_{HC2}^2 \leq \left(\frac{[\Delta F_{RC1}]}{[\beta]} \right)^2 \quad (8)$$

where n = the total number of similar cables. For RC2 and RC3, $n = 24$; and for other cables, $n = 12$.

The structural reliability must satisfy certain tolerance value $[\beta]$, namely $\beta \geq [\beta]$. By substituting (7) to $\beta \geq [\beta]$, we get (8). Following the same process, eight critical state equations and reliability expressions of all ridge cables, diagonal cables, and hoop cables can be obtained successively. Finally, a set of inequalities can be obtained and simplified as (9), where $m = 8$.

$$\begin{aligned} a_{11} \sigma_1^2 + a_{12} \sigma_2^2 + \dots + a_{1m} \sigma_m^2 &\leq 1 \\ a_{21} \sigma_1^2 + a_{22} \sigma_2^2 + \dots + a_{2m} \sigma_m^2 &\leq 1 \\ \dots & \\ a_{m1} \sigma_1^2 + a_{m2} \sigma_2^2 + \dots + a_{mm} \sigma_m^2 &\leq 1 \end{aligned} \quad (9)$$

4.2 Calculation of error limit based on nonlinear programming

The set of inequalities in (9) can enclose a high-dimensional curved surface. Each point $(\sigma_1, \sigma_2 \dots \sigma_n)$

Therefore, the maximum value of σ_i arithmetic product is chosen as the selection principle of variance combination. Set $x_i = \sigma_i^2$ and this issue can be transformed to a nonlinear programming problem. The objective function is: $\max \{\prod x_i\}$. The constraint conditions are:

$$\begin{aligned} a_{11} x_1 + a_{12} x_2 + \dots + a_{1m} x_m &\leq 1 \\ a_{21} x_1 + a_{22} x_2 + \dots + a_{2m} x_m &\leq 1 \\ \dots & \\ a_{m1} x_1 + a_{m2} x_2 + \dots + a_{mm} x_m &\leq 1 \\ x_1 \geq 0, x_2 \geq 0, \dots, x_m &\geq 0 \end{aligned} \quad (10)$$

Use the double-strut cable dome structure mentioned above as an example. Select the allowable deviation of cable force as 10% of the designed value; thus, $[\Delta F]$ can be calculated. Set the allowable structural failure probability to 10^{-5} and the corresponding reliability index $[\beta]$ to 4.27. Combining with the sensitivity analysis results in Section 3, all the coefficients a_{ij} (mm^{-2}) in (10) can be calculated through (4)–(8), and the

Table 2. Control criteria of cable length error.

Component	Original length l_0		Error limits δ_c
	m	mm	δ_c/l_0
RC1	9.971	2.471	0.025
RC2	10.791	3.105	0.029
RC3	12.283	5.799	0.047
DC1	10.237	1.339	0.013
DC2	9.937	18.654	0.188
DC3	9.622	19.828	0.206
HC1	5.337	6.803	0.127
HC2	10.683	9.592	0.090

Table 3. Error limits of cable length in JGJ 257-2012.

Cable length m	Allowable error mm
≤ 50	± 15
$50 < L \leq 100$	± 20
> 100	$\pm L/5000$

final results are shown in (11). Then, MATLAB is adopted to solve the nonlinear programming issues to obtain the optimal variance combination of length error.

If the cable processing satisfies 3σ quality management standards, then all cables' length error control criteria (δ_c) is shown in Table 2. Table 3 also presents the control criteria in Chinese specification JGJ 257-2012. It can be seen through comparison that, for most cables in double-strut cable dome, the error limits of cable length calculated by the method proposed in this paper are much less than 15 mm. Therefore, the allowable error of JGJ 257-2012 may lead to an unacceptable deviation of cable force and fail to guarantee the structural behavior.

5 VERIFICATION OF CONTROL CRITERIA BASED ON THE MONTE CARLO METHOD

To verify the validity of the error limits of cable length δ_c in Table 2, 1200 samples of random length error satisfying $\delta \sim N(0, (\delta_c/3)^2)$ were extracted using the Monte Carlo method (Olsson et al. 2003) and introduced into the finite-element model. All the statistics data of cable force for double-strut cable dome structure under the initial pre-stress state are shown in Figure 9.

Curves a, b, and c in Figure 9 present the maximum, minimum, and average values of different cable forces. It can be seen that while considering the impact of random cable length error, the average value of cable force coincided with the design value, which demonstrates that the quantity of samples is sufficient. When the error limits satisfy δ_c in Table 2, cable force of DC1 deviates from the design value most obviously. The maximum force deviation is 6.54%, followed by RC1

Figure 9. Statistics data of cable force.

$$a = \begin{Bmatrix} 162.196 & 55.769 & 32.374 & 14.230 & 0.106 & 2.303 & 0.380 & 9.521 \\ 51.256 & 71.394 & 33.877 & 8.294 & 0.731 & 2.417 & 4.047 & 10.086 \\ 5.796 & 6.599 & 14.823 & 0.456 & 0.618 & 2.988 & 1.642 & 11.911 \\ 184.983 & 117.196 & 33.108 & 634.038 & 3.233 & 2.819 & 24.430 & 12.010 \\ 0.095 & 0.712 & 3.107 & 0.223 & 2.121 & 2.371 & 4.532 & 9.610 \\ 0.201 & 0.230 & 1.462 & 0.019 & 0.231 & 4.385 & 0.870 & 16.222 \\ 0.090 & 1.040 & 2.183 & 0.447 & 1.199 & 2.364 & 4.728 & 9.500 \\ 0.212 & 0.245 & 1.485 & 0.021 & 0.239 & 4.134 & 0.891 & 16.081 \end{Bmatrix} \quad (11)$$

and RC2, with the maximum force deviations of 4.27% and 4.50%, respectively. The force deviation of all cables has not exceed 10% of the design value, which demonstrates that control criteria in the paper are accurate and reliable.

Figure 9 also presents the statistical data of cable force when we adopt the control criteria of JGJ 257-2012. The error limit of cable length is 15 mm, and the random sample satisfies $\delta \sim N(0, 5^2)$, as shown by curves e and f. The maximum force variations of DC1, RC1, and RC2 are 30.5%, 16.7%, and 12.8%, respectively, higher than the 10% of the design value. Therefore, the excessive allowable error of cable length in JGJ 257-2012 would cause the structural performance failure to satisfy the design requirements.

6 CONCLUSIONS

On the basis of the research on the sensitivity and control criteria of cable length error for a double-strut cable dome, the following conclusions were drawn:

1. For the double-strut cable dome, the length error of ridge cables (RC1, RC2, and RC3) and internal diagonal cables (DC1) has a significant impact on the internal force of adjacent local cables, and that of outer hoop cables (HC2) has a significant impact on the overall cable force.
2. The constraint inequations of the variances of cable length error have been derived on the basis of the reliability theory. Then, on the basis of the results of sensitivity analysis and nonlinear programming method, the control criteria of cable length error were obtained from the optimal combination of variances. This approach can be adopted to study the manufacture control of cables for other tensegrity structures.
3. The accuracy and reliability of the control criteria in this paper were verified by the Monte Carlo method. To guarantee the structural behavior, the error limits of most cables in double-strut cable dome shall be much less than the Chinese specification's value. The excessive allowable error of JGJ 257-2012 would lead to an unacceptable deviation of cable force and fail to meet the design requirements.

Structural design of a prefabricated steel frame structure with inclined braces

Xuechun Liu, Hexiang Wang & Zhipeng Guo

Beijing Engineering Research Center of High-rise and Large-span Prestressed Steel Structures, Beijing University of Technology, Beijing, China

ABSTRACT: A new modular prefabricated steel structure that is characterized by high construction efficiency, low labor intensity, convenient quality control, and consumption of excess capacity of the steel industry is used in this paper. The structural design and in-depth research are performed in this paper using a finite-element method. The strength, rigidity, and stability of the structure and relevant components are calculated. The results show that all indices are compliant with the standards and regulations. Through pushover analysis and finite-element analysis of the joints, the mechanical characteristics of the system under the design load and the failure mode under the ultimate load are obtained, together with the elastoplastic development pattern; yield failure mode and potential mechanisms were further explored. The results also show that the structural system is consistent with the design philosophy of “strong joint, weak component”. The system is basically in the elastic stage with reasonable yield mechanisms in case of major earthquakes. Therefore, both the elastic and elastoplastic performances comply with structural design requirements. This paper presents an innovative design method that suits the system and provides a technical reference for the design of similar structures.

1 PROJECT OVERVIEW

Let us assume a building containing 28 floors above ground with a total building height of 99.35 m. The 1st through 3rd floors are the annex with a height of 5.5 m, length of 144 m, width of 56.1 m, and total area of 21,503 m². The main functions of the annex include offering dining, leisure, conference, and cultural exchange facilities. Meanwhile, the floors above the 4th floor are divided into two towers, with a length of 42.9 m, width of 46.8 m, and total area of the main building of 88,345 m². The height of the tower’s 4th floor is 3.6 m, the height of the tower’s 5th floor through 28th floor is 3.3 m, and both are mainly used as office space. The building also contains three basements, with a height of 3.9 m, length of 188.7 m, width of 64.9 m, and total area of 36,126 m². They are mainly used for parking and equipment rooms. The total floor area of the project is 147,025 m². The building design is depicted in Figure 1.

Two seismic joints are set between the two towers and the middle annex building, which actually divide the superstructure into three independent structural units, as shown by the architectural elevation in Figure 2. The figure shows that the basement and middle annex building are constructed using reinforced concrete, whereas the towers adopt the prefabricated steel frame structures with

Figure 1. The building design sketch.

Figure 2. The architectural elevation.

inclined braces. Because the two towers are left-right symmetric, only the left tower is chosen for structural calculation and analysis in this paper.

2 STRUCTURAL SYSTEM

A new type of steel structural system, namely prefabricated high-rise steel frame structural system with inclined braces, is applied to the project. The prefabricated structural system is characterized by high construction speed, industrialized production, and low labor intensity, with its industrialization level exceeding 90%. The structure is composed of a mainboard and lean-brace column. As shown in Figure 3, the mainboard consists of the column base, profiled steel concrete floor, and truss. The beam is a welded steel truss with channel steel, angle steel, and a steel plate, and is commonly used to facilitate the laying of pipelines. In a factory, the beams and floor are prefabricated into mainboards that are used as modules for the assembly of water, heat, and electrical facilities. Before the mainboards are shipped from the factory, the decorative layer of the floor slabs and the placement of pipelines for water, heat, and electrical facilities are completed; the interfaces of the connections between the modules are deliberately reserved for a later step.

As shown in Figures 4–6, the lean-brace column consists of a column and lean brace that are welded at approximately one-third of the length of the column and bolted to the truss at approximately 45° to the other end. Therefore, the lean brace works together with the beam and column. During the construction process, the prefabricated mainboards and lean-brace columns are connected by high-strength bolts via flanges at both ends of the column and the mainboard column base. The connection between mainboards is a semi-rigid connection that connects the end of the truss to the column base by a high-strength bolt. The lean brace allows the connection of the beam and column to become more compact and strengthen the joint area. Meanwhile, the lean brace and beam-column frame jointly carry the load, which helps solve the common problem that the joints of a traditional frame are easily damaged during

Figure 3. Mainboard.

Figure 4. Diagonal braces column.

Figure 5. Diagonal braces joint.

earthquakes. In addition, the installation process is convenient. Figure 6 shows the assembly process of the whole structure.

The modular prefabricated steel structure is a new type of steel structural system. Compared with conventional structures such as reinforced concrete structures, the modular prefabricated steel structure is characterized by a short construction period, low self-weight, low labor intensity, and high industrialization level. Therefore, it is a green building (Zhang A. L, 2013 & Liu W. L, 2012). The design standards of this type of structure are fixed, and the components are fabricated by automatic

Figure 6. Assembly of the whole structure.

production lines. At the construction site, only connecting components such as bolts, self-tapping screws, and sealing materials are used for dry assembly, and the practice of wet operation is not required. As a result, the construction process is convenient and fast (Xiaoyun G, 2001), and it has been widely applied in developed countries and regions including Europe, the United States, Japan, and Canada (Jaillon L, 2009). However, the steel structures are only applied to multistory buildings, especially to low-rise frame structures currently (Wang W, Dao T. N, Teh L. H, 2012 & Zha X. X, 2010). By contrast, studies on the applications of prefabricated steel structures for high-rise frame structures are rare (Ye Z. H, 2012; Case F, 2014 & Festjens H, 2013). In this paper, we propose solutions to the key problems of the design process of prefabricated high-rise steel frame structures with lean-brace joints on the basis of computational analysis and empirical research on a modular prefabricated high-rise steel frame structure with lean-brace joints used by Zhuhai International Business Service Base, which provides technical support for the design of similar frame structures.

3 COMPUTATIONAL MODEL

ETABS, the software for the finite-element design and analysis, is applied in the present study for the

elastic analysis. It includes static analysis, response spectrum analysis, and structural design. Because ETABS is based on the method of finite-element analysis, it could provide linear analysis, nonlinear analysis, dynamic seismic analysis, and static pushover analysis on the basis of the Chinese code for steel frame structures. Through repeated trial calculations and adjustments, the final analytical model of the project is determined, as shown in Figure 7.

To be consistent with the true load-bearing conditions of the structure, beam element modeling is applied to all components. Meanwhile, webs and

Figure 7. The whole finite-element model: a) isometric view, b) elevation, c) plan of floors 1–3, and d) plan of a standard floor.

chords of the trusses are modeled independently, and their joints are rigid connections. The floor slabs are modeled by profiled steel plate models, which are integral within a slab sector. Gaps are reserved between the slab sectors to conform to the actual situations. The test results show that the connection of the truss and column is a semi-rigid connection, which is simulated by the spring element built at the joints of the beam and the column; the rigidity of the joints is obtained from the test results. The material of the jack truss and keel is Q235B, and the remaining component is Q345B. Table 1 provides the component section sizes.

4 LOAD AND BOUNDARY CONDITIONS

The design reference period of the project is 50 years, and the safety class of the building structure is Class II. The design category of the foundation is Category I; the seismic fortification intensity is Degree 7, Class III site; the design earthquake grouping is Group I; the characteristic period is 0.45 s; and the classification of the seismic fortification is Class C (Class B for the skirt building). The basic wind pressure for 50 and 10 years are 0.85 and 0.50 kN/m², respectively. The floor load is chosen based on the GB50009-2012 Load Code

Table 1. Component section size and specifications.

No. of Sections	Position	Section size (mm)
3-section (1st–3rd floor)	Main beam chord	C160 × 80 × 12

for Design of Building Structures and JGJ3-2010 Technical Specification for Concrete Structures of Tall Buildings. Two methods, namely the response spectrum method and nonlinear pushover analysis are applied to consider the impacts of earthquakes on the prefabricated steel structure. The seismic spectrum analysis considers bidirectional horizontal earthquakes. More details of the load case and combinations are shown in Table 2. Overall, 19 load combinations that consider seismic and wind direction cases simultaneously were evaluated.

5 ANALYSIS RESULTS

5.1 Modal analysis

The 30-order modal is computed, and the modal mass participation ratio reached more than 90%, which meets the requirements of the code. The developed modal is shown in Figure 8, and the 1st- and 2nd-order modal of the structure is horizontal vibration, with a period $T_1 = 2.594$ s and $T_2 = 2.424$ s, respectively. The 3rd-order modal is the torsional vibration modal, with a period $T_3 = 1.684$ s. The period ratio of torsional to translation modal is $0.65 < 0.90$, which conforms to the code requirements.

5.2 Analysis of story drift

For the case of common earthquakes, the maximum story drift angle along the X-direction under the influence of X-directional earthquakes is 1/995 and that along the Y-direction under the influence of Y-directional earthquakes is 1/1471, which is far less than the limit value of 1/250 stipulated by the reference. Under the influence of wind loads, the displacements of various floors change uniformly, indicating that the change of structural rigidity is uniform. The maximum story drift angle along the X-direction is 1/862 and 1/680 along the

Figure 8. Modal shape: a) 1st order ($T_1 = 2.594$ s), b) 2nd order ($T_2 = 2.424$ s), c) 3rd order ($T_3 = 1.684$ s), and d) 4th order ($T_4 = 0.847$ s).

Y-direction, which are lower than the limit value of 1/400 stipulated by the reference.

5.3 Shear-weight ratio

Under the influence of X-directional earthquakes, the minimum shear-weight ratio is 0.019, which is larger than 0.015. Under the influence of Y-directional earthquakes, the minimum shear-weight ratio is 0.019, which is larger than 0.015. Therefore, both cases are in compliance with the relevant standards.

5.4 Strength and stability of components

The aspects of computing the component strength and stability, the strength and stability of columns, chord, web of the truss, and lean brace are all calculated using press and bend components model. The computational results show that the equivalent stress ratios under various load combinations are all less than 1.0, which are in accordance with the requirements of the corresponding strength and stability.

6 PUSHOVER ANALYSIS

As shown in Figure 9, when developing an overall ANSYS finite-element model, a beam is modeled

Table 2. Combinations of the design load.

Combination type	Combination formula
Gravity load	1.35 Dead + 1.4(0.7) Live
Gravity load + wind load	1.2 Dead + 1.4 Live ± 1.4(0.6) Wind
	1.2 Dead + 1.4(0.7) Live ± 1.4 Wind
	1.0 Dead + 1.4(0.7) Live ± 1.4 Wind
Gravity load + wind load + horizontal earthquake	1.2 (D + 0.5 L) ± 1.3 R ± 1.4(0.2) W

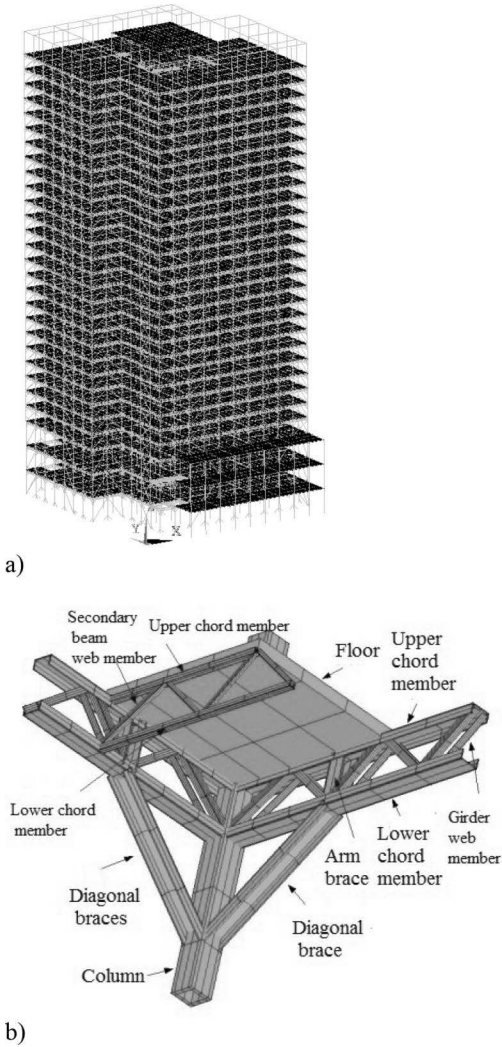

Figure 9. Finite-element model: a) complete model and b) structural detail.

using a beam 189 element and a floor slab is modeled using a shell 181 element. The model has 1,190,391 joints and 872,827 elements.

A pushover analysis is performed for the finite-element model. First, the gravity equivalent load is applied, and 0.2 times the total base reaction force under common earthquakes is applied to each step until the results are divergent with damage occurring to the whole or a portion of the structure. Because the shape is almost the same along the vertical direction and the stiffness varies smoothly along the vertical direction, only the influence of the first vibration mode is considered. The total seismic reaction force distributed

in an inverted triangle is applied to the structural model. The structure is damaged when the total X-horizontal reaction is 5.81 times the reaction of common earthquakes. Additionally, the structure is damaged when the total Y-horizontal seismic reaction is 5.6 times the reaction of common earthquakes. As shown in Figure 10, the maximum ultimate story drift angle occurs on the 10th floor, and the story drift angle between the 7th and 14th floor is larger, with the maximum value of 1/200, which is less than the limit value of 1/50 stipulated by the code. Therefore, the lateral rigidity of the structural system is larger, and the story drift angle meets the requirements of the standards. However, it also shows that this structure has poor ductility.

The load displacement curve of the top point of the structure is shown in Figure 11. It is evident from the figure that during the whole loading process, the load displacement curves along the X- and Y-directions are straight lines, which indicates that the structure is in the elastic state. Additionally, under the ultimate load, large-scale yield of the structural components has not been observed, and the yield positions are mainly concentrated on the webs and some chords at the outer edges of the structural plane. Therefore, the yield mechanism of the structural system is first the beam web is damaged, and then, the beam chord is damaged, while, all of the column stress is lower than the yield

Figure 10. Ultimate story drift angle.

Figure 11. Curve of the base reaction-vertex displacement.

strength. The yield mechanism of the structure is reasonable; the structure is basically in the elastic state for major earthquakes, so no collapse events would occur at this time.

The capacity spectrum proposed by American ATC-40 is applied in the capacity spectrum analysis of the load displacement curve of the base reaction-vertex displacement. The capacity curve is converted into the capacity spectrum by using formulas (1) and (2):

$$\text{Ordinate of the capacity spectrum: } S_{ai} = \frac{V_i / G}{\alpha_1} \quad (1)$$

$$\text{Abscissa of the capacity spectrum: } S_{di} = \frac{\Delta_{i,\text{roof}}}{\gamma_1 \phi_{1,\text{roof}}} \quad (2)$$

The mass participation factor of the first vibration mode is:

$$\alpha_1 = \frac{\left[\sum_{i=1}^N (m_i \phi_{i1}) \right]^2}{\sum_{i=1}^N m_i \left[\sum_{i=1}^N (m_i \phi_{i1}^2) \right]} \quad (3)$$

a)

b)

Figure 12. Capacity spectrum and demand spectrum: a) X-direction and b) Y-direction.

The participation factor of the first vibration mode is:

$$\gamma_1 = \frac{\sum_{i=1}^N (m_i \phi_{i1})}{\sum_{i=1}^N (m_i \phi_{i1}^2)} \quad (4)$$

$\Delta_{i,\text{roof}}$ — Vertex displacement of the structure
 $\phi_{1,\text{roof}}$ — Vertex amplitude of the first vibration mode

Formula (5) is used to convert the standard response spectrum in the Building Seismic Code into an ADRS spectrum. The abscissa of the demand spectrum is the same as the standard response spectrum. The ordinate is:

$$S_{di} = \frac{T_i^2}{4\pi^2} S_{ai} g \quad (5)$$

The structure is basically in the elastic state before damage occurs. Therefore, an elastoplastic reduction of the demand spectrum is not necessary. The curves of the capacity spectrum and demand spectrum are shown in Figure 12.

In Figure 12(a), in the curve of the capacity spectrum and demand spectrum in the X-direction, the vertex displacement corresponding to the performance points for degree 7 major earthquakes is 301 mm, and the total base reaction force is 25,851 kN. Under these loads, the damage rates of the Q235 steel components, Q345 steel

a)

b)

Figure 13. Stress of members under ultimate load: a) stress in the frame and b) stress in the truss.

a)

b)

Figure 14. Maximum component stress diagram under the limit load a) Q235 steel and b) Q345 steel.

components, and concrete floor slab are 0.02%, 0.23%, and 0.37%, respectively. Therefore, all structures in the elastic state display low damage rates. By contrast, the main damaged positions are webs and some chords at the building outer edges. In Figure 12(b), in the curve of the capacity spectrum and demand spectrum in the Y-direction, the vertex displacement corresponding to the performance points for degree 7 major earthquakes is 294 mm, and the total base reaction force is 24,280 kN.

The structure loses bearing capacity under loads that are 5.81 times the common earthquake forces in the X-direction. Under this ultimate load, the maximum stress is 633 MPa, and the yielding components are mainly distributed along trusses at the outer surfaces of the floor plane positions. As shown in Figure 13, under the ultimate load, the stress of columns is smaller; the maximum stress occurs at the truss web and the first chord close to the inclined brace. Because the ductility of the shear failure is lower than the bending failure, the web section should be increased during the design process to assure that the bending failure first occurs within the chord of the truss, followed by failures of the web, and finally column failures.

This process assures a reasonable yield mechanism of the structure, and the performance of structure in the Y-direction is the same as that in the X-direction.

To study the failure state and safety after failure, a statistical analysis is performed on the stress of each member under the ultimate load, as shown in Figure 14. The result shows that the stress of only 418 members of the Q235B steel exceed the yield strength in the X-direction load because the Q235B steel is mainly used for secondary trusses that bear gravity loads but no horizontal loads. The stress of only 2544 members of the Q345B

a)

b)

c)

d)

Figure 15. Equivalent stress under the design load: a) L-type connection, b) T-type connection, c) cross-type connection I, and d) Cross-type connection II.

steel exceeded the yield strength. The damage rate is only 0.23% because most of other members are in the elastic state, which indicates that the failure of the structure is due to the failure of a few members including a truss, but not including a column and brace, so the structure would not collapse. The structure could continue to be used after the broken members are repaired or replaced. The performance of the structure in the Y-direction load is similar to that in the X-direction. Therefore, the failure mechanism could be summarized as follows: the web and chord members fail first by an axial force and end bending moment, the column may or may not fail next, and the brace may or may not fail last; the whole structure will not collapse, but local failure will occur.

7 FINITE-ELEMENT ANALYSIS OF THE JOINTS

To study the performance of the joints, finite-element models of four typical joints are established in this paper. The loads for the most unfavorable load cases are extracted from the ETABS overall model and applied to the joint. The mechanical characteristics of the joints under either the design load or ultimate load are analyzed, and the mechanical characteristics of joints under the design load are shown in Figure 15. Through an ultimate bearing capacity analysis, the ultimate load and ultimate failure mode are determined. The safe reserves of the joints are obtained, and the design safety of the structure is guaranteed.

As shown in Figure 14, all four typical joints are in the elastic state without component yielding or buckling under the design load. Meanwhile, no gaps and relative slippage appear between the bolted gusset plates and columns, which suggest that the internal forces between the beam and column joints are very small because of the existence of the inclined braces. Under the design load, the

Figure 16. Load-displacement curve of the end of truss.

size and arrangement of the bolts are reasonable, and all joints and beam-column components are well connected in a safe load-bearing state.

As shown in Figure 16, the load-displacement curve of the end of truss, four typical joints would not reach the ultimate state until the actual load force is 3.08–3.59 times the design load (i.e., the most unfavorable load case), so the safety reserve is large enough. The failure positions are all on the trusses outside the inclined braces that are designed to protect these joints. In general, the structural system complies with the design principle of *strong joint, weak component*.

8 CONCLUSIONS

In this paper, we introduced the design method of a modular prefabricated high-rise steel frame structure with inclined braces used by Zhuhai International Business Service Base Project. Using joint analysis in an ANSYS finite element and elastoplastic pushover analysis of major earthquakes, the following conclusions are drawn:

1. The modal, story drift, shear-weight ratio, stability, and strength of the components of the structure are in accordance with the design control indices of the relevant standards and requirements, and the structural system is both safe and reliable.
2. Four typical joints under the design load are in the elastic state without the occurrence of component yielding. The ultimate load of the typical joints is 3.08–3.59 times the design load; therefore, there is a large safety reserve.
3. The ductility of the structural system is worse. The maximum elastoplastic story drift angle is only 1/200, and the maximum elastic floor displacement is 1/416. Therefore, compared with conventional structures, the design of the structure needs to limit the story drift angle more strictly.
4. The load bearing and displacement of the structure meet the requirements of major earthquakes. For major earthquakes, only a few structural components are damaged, and the whole structure generally displays linear elastic properties. Therefore, the safety reserve of the entire system is relatively high. Meanwhile, after rare earthquakes, the structure could continue to be used upon replacement of partially damaged components.
5. According to the requirement of a performance-based design, the bearing capacity of the structural system meets the requirement of performance standard I, and the story drift could meet the requirement of performance standard II.

6. All failure positions are on the truss outside the lean brace, indicating that the lean brace has served to protect the joints. Additionally, the entire structural system conforms to the design principle of *strong joint, weak component*.

A study on the design of an ungated community

Fan Jia

Internal Trade Engineering Design and Research Institute, Beijing, P.R. China

Renxiang Wang

Institute of Information Engineering, CAS, China

Fuli Ma

College of Architecture and Civil Engineering, TYUT, China

ABSTRACT: Gated community is a very common residential area in Chinese mainland. Now, it is time to think about the gated lifestyle and the current situation of a city. The ungated community can help a city to reduce the number of traffic jam events and let citizens enjoy more open landscapes and more convenient public facilities. Establishing an ungated community needs open-road network system, density architectural forms, friendly urban interface, and open landscape.

1 INTRODUCTION

From ancient to modern times, the traditional mode of dwelling in mainland China is the quadrangle courtyard, which is the basic unit of the court–alley–street pattern. While time has developed, our family patterns and lifestyles have changed a lot. Quadrangle courtyard changed to multistorey residential, even high-rise buildings, and the courtyard walls changed to residential walls and railings. These changes are all based on the closed form of the residential quarters and happen inside the community, despite the various aspects of the Chinese communities have got huge progress in the last several decades.

On October 1, 2014, *Green Residential Area Standards* was formally implemented, which was hosted and compiled by the China Real Estate and Housing Research Association. The standards clearly put forward the concept of open residential district and block in the general principles. The standards also advocated opening the residential area to the city, sharing green spaces and service facilities with citizens, constructing a harmonious and unified development system of urban communities. Today, the design of open community has exceeded the simple concept of breaking the wall of the residential area. It stresses that the community is an integral and organic part of the whole city instead of a small independent city in the urban space.

2 LITERATURE REVIEW

Since the release of the *CPC Central Committee and State Council on further strengthening urban planning and construction management*, it quickly sparked a heated debate. Two views of management raises high concerns, which are *China will no longer build closed residential area in principle and Residential quarters and units that have been built will compound to gradually open*. The management has made architectural experts to study it carefully. The most famous expert for the research of ungated community is Christiande Portzamparc. He not only put forward the concept of an ungated community, but also put this idea into practice in his design, which creates a method of reinterpreting city streets and shaping the urban space. According to him, the urban district is full of urban vitality, pluralistic, and open. In China, the research of ungated community is affected by Chinese policy. There are two tendencies to study the ungated community. The first one is research about foreign ungated community theory, for instance, *The Planing Concept of Open Block and Its Enlightenment on the Urban Residential Construction in China!* Yong YU, Zhitao Li. The other one is the analysis about the practice of ungated community, for example, *Discussing open community based on the Aga Khan Award winners-Aranya Community/Shanshan Wu, Gangyi Tan*. As there has been no research about exploring how

to design the ungated community to date, it will be discussed and studied in this paper, and the conclusion may provide the guide and reference to build the ungated community.

3 CONCEPT AND CONNOTATION ANALYSIS

3.1 Residential district

A residential area (50–100 ha) or residential quarter (10–35 ha) and even smaller scales of place for living. The connotation of the core is the space for living, recreation, and daily activities within a certain geographical area.

3.2 Community

Generally defined as a social community, people of which have common value view and close relationship. The basic elements of community are certain number of population, certain extent of the region, certain scale of facilities, certain characteristics of the culture, and certain type of organization.

3.3 Gated community

Generally defined as a residential area with a strict access control. Its internal parks, trails, sports fields, and even the public spaces like river and the sea are owned by residents. The most obvious feature is closed and forbidden or restricted to enter.

3.4 Ungated community

In contrast to the gated communities, there is no entrance guard, wall, or fence. Public spaces (roads, service facilities, green spaces, etc.) are all open to citizens. Its core is connectivity, sharing, and mixing.

Connectivity: Integration of community and the surrounding urban areas. Integration of the road network of community and the city road system. Integration of the community neighborhood green and the city green system.

Sharing: Landscape architecture, recreation facilities, roads, gardens, and other public venues in the open community are shared by urban residents.

Mixing: Building types in the open community not only meet the needs of urban functional diversification, but also accommodate the needs of residents of different classes, races, and ages.

4 ANALYSIS OF ADVANTAGES AND DISADVANTAGES OF A GATED COMMUNITY

4.1 Advantages

1. Gated community has good privacy and security of living space for the residents. First, effective

community boundary creates a small scope of territory, which conforms to the human psychological demand of security. Then, because of the limit of the external citizens and vehicles, children can play safely and elderly persons can move around freely. The management of gated community is safe and easy and also suitable for traditional living habits.

2. Gated community has good community attachment. The creation of community attachment needs appropriate population and the similar value orientation. It is easy to produce a sense of attachment in gated community in certain boundary.

3. Gated community has rich and varied interior space and landscape environment. Despite the walls to the urban space that gated community gives, the interior residential space is very rich. It is another garden world within the cold enclosure, where there is beautiful and gorgeous views, many activity spaces, and different and useful facilities.

4.2 Disadvantages

1. Gated community causes traffic jams. Gated community, especially large ones, generally use walls to make several public roads of a few blocks privatization and to prevent external vehicles to travel. The road network within the walls can not continue the city road system, forming a circular or flexural road network. It forms a large scale of city road network outside the walls of community so that there is not so many roads for vehicles to choose, and then, they gather in those several major roads, which naturally leads to congestion.

2. Gated community occupies public resources. The public spaces in gated community are not shared by the citizens. Public resources in different communities have been probably duplicated. The phenomenon of gated community is the symbol of urban pathology. The reduction of social public space is the plunder of the poor class.

3. Gated community disappears the street life, which is a virtuous circulatory community's necessary space state. However, the walls of gated community weaken the fun of strolling along the street and reduce business activity of the street. The function of the street is only traffic.

Gated community is an isolated place, just like heavily guarded fortress. It makes the urban space depressed. It takes security as an excuse to digest the information like that of the traditional city. When public service, public facilities, and public

roads are private, community responsibility ends in front of the wall, where shall we to talk about the so-called equal democracy? It reduces the motivation of residents to communicate and the chances of social intercourse. Where there is no social intercourse, the nation will be lazy to fulfill its social responsibilities.

The mode of gated community destroys the overall planning of the whole city and runs in the opposite direction with economic benefit, social benefit, and environmental benefit.

5 THE SIGNIFICANCE OF BUILDING AN UNGATED COMMUNITY

5.1 *Urban perspective: The sustainable development of residential area and urban area*

On the road system, it is different with the gated community road system that un gated community gives road space back to the city so that much more space changes into city road system. The way people can choose is more by the net road system, which helps to solve the problem of traffic jam.

On the landscape system, greens and facilities of un gated community have more accessibility and are easier to share. It helps to have more and larger open space of the city, to reduce the same facilities and improve the utilization of the existing ones, to avoid unnecessary waste, and to achieve a sustainable development.

5.2 *Residents perspective: Diversity of living environment and experience*

Un gated community mixes functions of dwelling, commerce, working, and so on. It offers a more convenient physical environment. Interface of continuous blocks integrated with service facilities is easier to create a vibrant street life, which provides a safe environment for working and increases the communication between citizens.

5.3 *Developer perspective: Flexible methods of developing*

The way that divides land into small scales and large numbers is beneficial to flowing of fund and phased development of large-scale projects. Smaller block is a flexible layout mode, which can be combined or divided according to the city plan. In addition, un gated community provides a large number of street interface, which has a huge commercial value. Through the reasonable arrangement of the space of streets, developers can gather popularity, and the new development projects can be quickly transformed into a mature area.

6 EXPLORATION OF THE DESIGN OF AN UNGATED COMMUNITY

6.1 *Establishing un gated residential district space*

1. Establishing un gated residential district space requires building density with certain features. It needs an appropriate scale to control block, as a space carrier to bear the interactive mode of life. The building density with certain features ensures the level of opening and closing, and it also creates living atmosphere that belongs to the block. In addition, it will make certain that people will obtain plenty of experience level of vision, and hence it is easier to make people approve residential environment.
2. Establishing un gated residential district space requires open-road network system. It will be fully considered that keeping the good connection between the road organization in dwelling districts, which belongs to cities, so un gated residential district will promote traffic smoother both in dwelling districts and cities. It will make appropriate road network density, and the most important is that un gated residential district will solve the increasingly serious traffic problems in modern urban design.
3. Establishing un gated residential district space requires friendly urban interface. Urban interface of open community needs to be coordinated with the urban street landscape. We should not only focus on elevation and skyline, but also take into consideration that space element and details should penetrate into residential district. Public area of community must always be located in the urban interface, and there is an outgoing space characteristic. This area is the part that people in community and city can share and exist. The space of un gated residential district is mainly reflected in the opening of public area.
4. Establishing un gated residential district space requires designing open landscape.

6.2 *Creating un gated community life*

Un gated community life is mainly reflected in psychological experience of neighborhood association and community activity. Planners and designers find that creating community life will be affected positively by focusing on the following points.

1. *Mixed plentiful living experience*

What we most importantly focused on is the plentiful and mixed living experience, and it is helpful to diversify the formation of residents. Diverse residents come from several residential products. Apart from residential products, there will be a substantial proportion of public buildings and facilities, and it will not only attract other community

residents to communicate here, but also will save land and energy. In addition, residential district with good green landscape environment design will make community attract people stay longer and go sightseeing more interestingly, so it will form a mixed living experience.

2. *Interactive communication lifestyle*

Ungated community provides a wealth of space of communication and includes a composite function of the public buildings and open public space. Diverse demographic composition is main part of Interactive communication. It can arouse people's curiosity more and also facilitate communication that took place. The style of multiple residents living is not only an important way to reach living in harmony in the long run, but also to put an end to the situation of "elite" exclusive advantages of resources and satisfy the psychological needs of all residents. Therefore, it is important to make it obtain a positive and inclusive attitude of mind, promoting social harmony.

3. *Planning model of shared resource*

Supporting open public service facilities not only conform to the law in the operation, but it is also beneficial to the sharing of resources. Public services can be determined according to a reasonable size and positioning of the entire region, to avoid duplication and homogeneous competition. Meanwhile, the facility can be gathered by leveraging economies of scale to attract a large number of community people, to ensure that all kinds of traffic facilities, is conducive to survive and avoid unnecessary waste.

Community green space can be united with urban parks and green resources as system. Residents can enjoy the different resources in their

own communities and share resources belonging to other communities through the convergence of urban space.

7 CONCLUSION

It is rational to exist that closed community is the current resident situation in the stage when urbanization rate grows rather fast in Chinese mainland. However, in the long run, single closed communities restrict the sustainable development of cities. Open community is a kind of practice mode, which has more positive impact on urban space because of its open-space structure. For the current situation of China, we should neither negate closed community completely nor give up the exploration of new styles of residence. When the open communities and closed communities coexist, China's residential environment and the urban quality can progress continuously.

Protection and utilization of Gaichun Garden ruins of the Summer Palace

Di Zhao & Long Zhang

Tianjin University School of Architecture, Tianjin, China

ABSTRACT: The Summer Palace enjoys the last and most complete large-scale royal garden in Chinese feudal society. Gaichun Garden, located in the Longevity Hill, was built in Qianlong Period. As a garden located in mountainous region, with gullies in front and cliff on the back wall, Gaichun Garden contains profound artistic conception, where multiple cultures such as Confucianism, Taoism, and Buddhism converge, reflecting the ideology of unification of Emperor Qianlong and the saint, and is of profound cultural connotation and historical research value. The surviving gardens and buildings have suffered destruction too many times to reflect the historical appearance. In this paper, research will be carried out on the remaining buildings, rockery and stone settings, ancient trees, and visitor utilization to understand cultural relics content, analyze existing problems and safety hazards, and propose relevant protection strategies, playing a positive role on the overall protection of the Summer Palace, display, and value cognition.

1 INTRODUCTION

The construction of Qingyi Garden was started in the 15th year reign of Emperor Qianlong (1750) and completed in his 30th year reign (1765), with the basic framework constituted by the Longevity Hill and Kunming Lake, known as one of “Three Hills and Five Gardens” of the Royal Gardens in the northwestern suburbs of Beijing. In the 10th year reign of Emperor Xianfeng (1860), the Anglo-French Allied Force incinerated and plundered many gardens in the suburb of Beijing, due to which Qing-Yi Garden also suffered serious damage. In the 12th year reign of Emperor Guangxu (1886), Empress Dowager CiXi decided to repair Qingyi Garden and renamed it as the Summer Palace. However, the repair was only concentrated on the main sceneries in the first part of the Longevity Hill and Kunming Lake as well as partial sceneries in the second part of the Longevity Hill and Kunming Lake due to the economic and political situation, and no repair was done to gardens within the Garden, containing the most compact designs and the richest architectural forms. Remains are still present in Gaichun Garden, Gouxuxuan, Qiwangxuan, Kanyunqshi, and Huacheng Pavilion, which serve as a rich wealth of historical information and cultural connotations.

The river area of the second part of the Longevity Hill and Kunming Lake is located in the north part of the Summer Palace, accounting for 12% of the total area, where the mountain terrain

and water system remain almost the same as that in Qingyi Garden, but are artificially created, able to shape a profound quiet canyon view, and a perfect place to build scattered, profound small garden.

Garden architectures are shaded in the mountains and plants by these scattered gardens within the Garden, not in pursuit of the architectural scale but focusing on details and artistic conception. Besides, Gaichun Garden, located at the gentle slope, with three tablelands piled by human, combines the royal garden feature of elegance and wealthy and mountainous feature of natural wilderness. The overall architectural layout of Gaichun Garden has skillfully made use of mountainous region and palisades to successfully shape varied spaces, in line with the artistic conception in the book of *Yuan Ye*, Jicheng (1988) Mountainous region, which is the best place to build garden as the terrain will be high and low, twist and turn, and precipitous and flat, naturally.

2 OVERVIEW OF GAICHUN GARDEN

Gaichun Garden was initially built in the 23th year reign of Emperor Qianlong (1758) as an early garden architecture complex, located on the slope beside Taohua Gully in the west of the second part of the Longevity Mountain, composed of Gaichun Garden and Weixianzhai. Architectures inside the garden buildings like Yunzhenchangqie Palace, Zhuyu, Qingkexuan, Xiangyanshi, and Liuyun Tower have

taken advantage of natural rock gully to form a mountainous garden through adjustment based on local conditions (Fig. 1). Gaichun Garden and Weixianzhai were places for Emperor Qianlong to study, rest, play the zither, brew tea, worship Buddha, and where multiple cultures such as Confucianism, Taoism, and Buddhism converge, reflecting the ideology of unification of Emperor Qianlong and the saint. Cong Yipeng & Zhao di (2015) Fresh and elegant decoration and local plants and trees embody leisure life in mountain. According to the record in the poems written by Emperor Qianlong, he had been to Gaichun Garden for 60 times and composed 98 poems to show his affection towards it. Unfortunately, Gaichun Garden did not escape from the damage when the Anglo-French Allied Force incinerated and plundered many gardens in the suburb of Beijing. During the reign of Guangxu, Gaichun Garden did not receive any repair and thus the residual architectures gradually dilapidated. In the 1950s, Clock Pavilion and the Gate of Qingkexuan were repaired. Summer Palace Management Office(ed) (2006) in the 1990s, the Management Office of the Summer Palace, cleaned, protected, and displayed the ruins.

3 GARDEN CREATION AND FEATURES

Emperor Qianlong named this garden as “Gaichun Garden”, literally meaning “the garden is full of the beauty of spring”, indicating that there were plenty of flowers and plants in this garden where spring was in the air. The second part of the Longevity Hill is mostly quiet natural scene, and Emperor Qianlong did not mention any kind of plants or flowers in the poetry, so he might be inspired by the beauty of spring. Gaichun Garden and Weixianzhai are, respectively, located on both sides of the west part of Taohuagou, connected by corridors on which Clock Pavilion was located, 84 m from east to west and 60 m from north to south. Gaichun Garden was built on hills with multilayer tablelands and 15 m elevation difference, with each layer linked by

Figure 1. Restored scene of Gaichun Garden and Xianwei study.

corridors or stairs (Figs. 2, 3). Climb the corridors to the top terraces and overlook the mountains; Qingkexuan, Liuyun Tower, and Xiangyanshi are located along the cliffs. Weixianzhai at the first layer in the lowest terrain is a closed courtyard. The tableland at the second layer is higher than courtyard walls where you can enjoy scenery outside of the garden. Yunzhenshangqie Palace is also built on the tableland, bamboo open hall, called Zhuyu, on the east side, and corridor on the west side to Weixianzhai. Climb the corridors to the third tableland and overlook the mountains, where Qingkexuan, Liuyun Pavilion, and Xiangyanshi are built along the cliffs, and the back walls of Qingkexuan and Liuyun Tower as well as large rocks beneath are natural (Fig. 4). Liuyun Tower is built on the rocks and some of the buildings are outstanding, mentioned as the pavilion of Yongji Temple of Jinling in the poems written by Emperor Qianlong. Xiangyanshi is a stone cave artificially created using natural caves to worship Guanyin and a place for Qianlong’s study and self-cultivation.

4 GAICHUN GARDEN STATUS OVERVIEW AND ANALYSIS

Repair record in the reign of Guangxu showed that the surviving buildings in Gaichun Garden

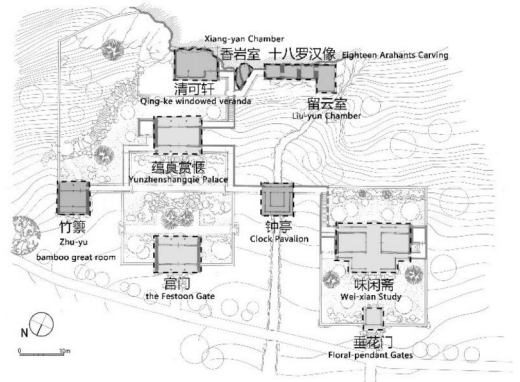

Figure 2. Gaichun Garden plan.

Figure 3. Map of tableland slope in Gaichun Garden.

were the Gate, the Festoon Gate of Weixianzhai, Weixianzhai, Qingkexuan, Yunzhenchangqie Palace, Zhuyu, and Clock Pavilion. In the 12th year reign of Guangxu (1886), Empress Dowager CiXi decided to rebuild the Summer Palace, but Gaichun Garden was not repaired and gradually reduced to ruins. Hence, only a restored gate of Gaichun Garden is available now, whereas others became ruins, such as architectural platform, plinth, damaged walls, and partially-damaged components, among which architectural platform and plinth are relatively well-preserved; therefore, we can get architectural plane measurement, column distribution and architectural frontal width and depth based on the platform measurement and plinth distribution (Fig. 5).

4.1 Building and construct remains

In the 1990s, the Clock Pavilion and the Gate were renovated. Now, the building bases are still distinguish-

Figure 4. Cut national rock of the back wall of the Qingkexuan ruins.

Figure 5. Surveying and mapping of Gaichun Garden ruins.

able in Gaichun Garden ruins, artificial hills and stones are well-preserved, and there are still some palisades left at the back walls of Qingkexuan. Emperor Qianlong's inscription and the josses of the 18 Arhats are still distinguishable, but the remaining building bases and damaged constructs are incomplete and suffer weathering and shifting (Figs. 6, 7). For example, architectural platforms become flexible and landslide, trees grow on some platforms, and architectural components are missing, damaged, and repaired by other material. Plenty of pavements, both indoor and outdoor, are missing, and remaining pavements suffer serious weathering; trees are grown here and there on the ground.

4.2 Stone inscription

The remaining artificial hills and stones can be classified as chiseled cliffs and piled artificial hills or as yellow stone and green stone by material. Chiseled cliffs imitate natural extraordinary power and highlight the history, whereas yellow and green stones are heavy and dense, in line with the fun of mountain garden. In general, the forms of groups of artificial hills and cliffs in Gaichun Garden are well preserved, but the stones suffer weathering and some artificial hills crumble down, having negative impact on sight view. Emperor Qianlong's poems and inscriptions on the cliff of the back wall of

Figure 6. Weixianzhai ruins.

Figure 7. Difference between the repair material and original architectural material for Clock Pavilion.

Qingkexuan are partly distinguishable. As for the josses of the 18 Arhats at Liuyun Pavilion, their heads are damaged during wars and by human, but their dress lines are distinguishable, although there are some weathering impact (Figs. 8, 9).

4.3 Ancient trees and vegetation

Wang Qiheng et al. (2009): According to the description in the poems written by Emperor Qianlong, the vegetation in Longevity Hill are transplanted, mainly evergreen pines and cypresses, also with many deciduous trees. As for the second part of the mountain, Xuan and Tang are scattered, landscapes have twists and turns but quiet, so there are many pine trees but also some other plants, like peach tree, apricot tree, *Acer truncatum*, locust tree, and *Koelreuteria paniculata*, to highlight seasonal changes. There remain seven second-level ancient trees in Gaichun Garden, that is, Chinese junipers and *Platycladus orientalis*, planted at the period of Qingyi Garden. Besides, there are several Chinese pines and cypresses outside of the garden, reflecting the air of emperor. In the poems written by Emperor Qianlong, there are 36 poems related

to plants, describing the plant species, configuration mode, and the artistic conception, to express the aesthetic taste of Emperor Qianlong for plants. In the poems, more than 10 plants are clearly mentioned, like the pine, plum, willow, bamboo, rattan, lotus and lotus moss as well as quiet grove, flower rain, and field scenes.

There are remains of three ancient cypress trees and four *Platycladus orientalis* in the garden and remains of *Pinus tabulaeformis*, *Platycladus orientalis*, and Chinese junipers outside of the garden. Others are mainly wild species grown in recent years, basically common trees of North mountain, broadly in line with the species and the garden environment, plant varieties totally up to 11 (91 trees), three species of evergreen, and eight species of deciduous plants, including *Acer truncatum*, *Koelreuteria paniculata*, Chinese scholar trees, *Platycladus orientalis*, Chinese junipers, *Amygdalus davidiana*, *Broussonetia papyrifera* and elm, but the plant species and configuration method cannot reflect the original appearance of Qingyi Garden. Plant landscape restoration should reflect the artistic conception of gardens, increase space level, highlight seasonal changes, protect ecology and water environment, and strengthen the role of display.

Figure 8. Stone sculpture of 18 Arhats.

Figure 9. Stone sculpture's mapping of 18 Arhats.

4.4 Water and soil erosion

Because of changes in water resource in the west mountain area of Beijing City, in the second part of the Longevity Hill, there are some surface water only in the rainy season, but short of water apparently in the remaining seasons. The barren area in Gaichun Garden accounts for 30% of the whole garden, especially in the upstream of Taohuagou and the east area of Qingkexuan (Fig. 10), where there are no vegetation cover but only few trees. As the mountain topography belongs to slope with

Figure 10. Serious water and soil erosion area.

loose soil surface and the soil erosion is obvious after rainfall; therefore, it is speculated that the soil decline is more than 20 cm. In this area, there are two ways: (1) to cover shrubs and to plant taller trees and (2) to restore the artistic concept of the garden and conserve water and soil. The areas with tableland and stones to keep water and soil have better surface condition, as the soil is blocked to a certain degree, it is speculated that the soil decline is within 10 cm, and the recovery focuses on protecting buildings and stacked stone from erosion.

4.5 Management and display

In the 1990s, the Management Office of the Summer Palace has cleaned, preserved, and presented the ruins of Gaichun Garden. It has set up stone signs in the ruins to briefly introduce each building and display area inside the gate of Gaichun Garden to introduce historical changes and cultural connotations and to show remains and the full-recovery model (Fig. 11). However, there are some safety concerns in the remain; it is not fully open to visitors, about 200 visitors each day to Gaichun Garden and Weixianzhai, mostly for short stay to rest and enjoy the scenery, relics, or wall inscription. The visitor questionnaire statistics showed that about 86% of visitors to Gaichun Garden were mostly those accidentally passing by, majority of whom had no idea about the history and culture of Gaichun Garden and surrounding garden sites, but showed great interest in the history evolution, site ontology show, and garden culture and aesthetic; however, this kind of publicity and display facilities obviously cannot meet the demand.

5 GAICHUN GARDEN RELICS PROTECTION AND UTILIZATION

The ruins at the second part of the Longevity Hill, as part of the Summer Palace, have an important

Figure 11. Renovated palace gate display and commercial services.

historical and cultural significance. The research on such ruins should adhere to the approach of “overall protection, scientific renovations, and rational use”, and the core of explicit protection is refurbishment and use. On the basis of their own characters, we should explore history feature and the overall aesthetic effect from the viewpoint of sustainable development and consider the layout and visual integrity combined with the surrounding environment. The sites, including Yamagata, drainage, vegetation, and architectural sites, must be protected to reflect the original style and features when Qingyi Garden, which was in a period of great prosperity, and must be restored and renovated on the basis of full and accurate historical information to protect and use the sites in a sustainable way. Now, we should give priority to site preservation and protection, and the subsequent restoration and presentation must be conducive to reflect the historical authenticity of the Summer Palace.

In order to ensure the minimum interference to the relics and maintain the landscape to the greatest degree, those existing but in good condition or those able to use after conservation treatment will maintain the status quo; most natural stone, rockery, and stacked stone will continue to be used after weathering treatment. The dislocated building components should return to the seat and components, which can be clearly identified, and added according to the site situation. Inscriptions and poems of Qianlong Emperor of Qing dynasty remain on the back wall of Qingkexuan and carvings of 18 Arhats, which are of great historical value, and protection components can be added to prevent further weathering and destruction.

Meanwhile, ruins information publicity should be enhanced to show the public Chinese traditional culture and garden activities, giving full play to its historical, artistic, and scientific value and educational role. The publicity and display should reflect the original state of Gaichun Garden as real as possible and deliver accurate historical information. The original artistic conception, design techniques, garden artistic concept, history, and other information about Gaichun Garden should be displayed through panels, poems, paintings, and models. Inside building remains is evident the technology of Chinese architectural traditional carpentry and masonry, as well as ruin protection method. Gardening activities like Qianlong reading, playing the zither, brewing tea, and worshiping Buddha in Gaichun Garden should be reproduced; illustrated by poems, calligraphy, and paintings; and displayed. For protecting buildings and building sites, ancient trees should be paid more attention for conservation, and garden plant landscape should be repaired and garden artistic concept at Qingyi Garden should be reproduced.

6 CONCLUSION

Relevant historical documents collection and collation, site collection of spatial information, and the systematic analysis of gardening ideas, art, and cultural connotation can not only fulfill the gaps of the study of the Gaichun Garden, but also enrich the overall research achievements about the Summer Palace and deepen the value. The conservation of Gaichun Garden sites should focus on the sustainable development of the garden and surrounding ecological environment, improve overall quality and landscape values, realize “authenticity protection, rational utilization and sustainable development” of the world cultural heritage, and emphasize the importance of continuity, maintenance, and preservation in the protection planning. The case study of Gaichun Garden can provide basic information for the Summer Palace site protection, promote the present relics protection, and display the progress.

ACKNOWLEDGMENT

Development of a web-based hybrid BIM cost-estimating system for fire safety engineering

Ming-Hui Wen

Department of Commercial Design and Management, National Taipei University of Business, Taiwan

Wei-Chin Huang & Yun-Wu Wu

Department of Architectural Design, China University of Technology, Taiwan

ABSTRACT: In this study, a building project cost estimation system is developed using the Web-based technology. Also known as the Web-based hybrid BIM cost-estimating system, it incorporates the Building Information Management (BIM) with external cost estimation data to facilitate cost estimation in the early design stage and increase the efficiency of project implementation. The system is mainly composed of the following modules: “Basic Project Information”, “BIM System”, “Fire Safety Equipment Property Database”, and “Web-based System Management Interface”. Through its BIM components, it can provide efficient estimation and references for decision making. To verify the feasibility and benefits of the system, a case study is conducted by using the Web-based hybrid BIM cost-estimating system and the traditional 2D CAD method to evaluate the same case and then compare the cost evaluation accuracy and efficiency of these two methods. According to the comparison results, the system developed in this study is better than the 2D CAD method in terms of both cost estimation accuracy and efficiency.

1 INTRODUCTION

1.1 *Research background*

In project planning, cost estimation about the budget, materials, and all the other required resources is a fundamental task for policy making (Lee, Kim & Yu 2014). However, in the early design stage, cost estimation can be made more challenging because of the restrictions of insufficient time and information (Sonmez 2004). For project managers, both accuracy and efficiency of cost estimation are very important in order to ensure the overall efficiency of the following work.

Cost estimation is one of the critical activities for construction projects (Zhiliang et al. 2011). In the past, project managers often depended on subjective judgments based on prior experiences in their cost estimation (Yu 2014). However, this method is mainly based on personal experiences and cannot produce accurate cost estimation due to the differences between the estimated prices and actual market prices of certain items.

In recent years, with the emergence of Informational Communication Technology (ICT), project managers can use CAD 2D computer software for assistance in their cost estimation. However, the components in the CAD 2D design drawing may not be fully comply with the on-site operation. In addition, most of the CAD 2D software lacks

information consistency and data connections of the operation and, therefore, cannot help project managers to achieve efficient cost estimation.

BIM is a type of digital information model that can integrate all the architecture design graphics and documents (Chen & Hou 2014; Chien, Wu & Huang 2014; Porter et al., 2014; Meža, Turk & Dolenc 2014). It can help project managers to quickly access detailed design information and find out the required quantities of materials by automatically calculating related figures. However, without sufficient information or data from cost estimation, BIM will not be able to provide comprehensive references for project managers.

To help project managers to achieve rapid and accurate cost estimation in the early design stage, the Web-based hybrid BIM cost-estimating system is developed in this study. In addition to the characteristic features of a traditional BIM system, the system developed in this study can provide geometric and nongeometric information from its 3D modeling for project managers. Moreover, in this system, there is a cost database and cost-estimating model established for each construction project component. This mechanism can enable the BIM system developed in this study to have more accurate cost estimation of the construction (Jarde & Alkass 2001). Moreover, together with the rapid development of the construction industry,

construction projects nowadays are growing in size and complexity and require participation of more professionals (Choi, Choi & Kim 2014).

1.2 *Research purpose*

This study is intended to develop a Web-based system. Through the systematic and synchronized management of project information on the Web, specialists and professionals from different fields can work together to estimate the costs of a project whenever and wherever they are needed. To verify the feasibility and benefits of the BIM system, a case of fire safety system inside a factory building is used in this study to explore the cost estimation accuracy and efficiency of the system.

The following discussion in this paper is divided into four chapters (with the Introduction above as the first chapter). The second chapter is the literature review, covering issues about difficulty in cost estimation, BIM system, Web-based technology, database, and fire safety equipment. The third chapter introduces the BIM system developed in this study, including its framework structure and operation procedure. The fourth chapter is the comparison of the cost estimation accuracy and efficiency of the BIM system developed in this study and the traditional 2D CAD method by using these two methods to evaluate the case of fire safety system deployment in a factory building. The last chapter discusses the research restriction of this study, benefits of the BMI system developed in this study, and directions of related future research to promote its application.

2 LITERATURE REVIEW

2.1 *Difficulty in cost estimation*

In the stage of early planning and design, it is important to consider the required amount of capital investment in the construction project first. Therefore, the accuracy of cost estimation is the key to successful operation and future profitability of the project. However, if the cost estimation itself is time-consuming and difficult to implement, it will cause extra costs instead. Therefore, this study is mainly intended to explore how to establish an efficient cost estimation system in order to solve the above-mentioned problems.

The cost estimation for construction projects is subject to difficulties caused by uncertainties in architecture information and requirements. To achieve fast, economic, and accurate cost estimation within limited time, computer software can be used to help obtain the cost information of facili-

ties and equipment for the architecture (Kim, Seo & Hyun 2012).

In the existing method of construction design and planning, CAD 2D graphics are used. However, manual estimation and calculation is still required to determine the costs and quantities of building elements and required equipment. The failure to automatically generate quantity information of the required equipment and materials results in extra cost estimates in the early design and lack of accurate quantity information of required materials for cost estimation.

2.2 *Building Information Model (BIM)*

The greatest change brought by the rapid development of ICT for the construction industry is the application of BIM (Bryde, Broquetas & Volm, 2013). The concept of visualization, communication, and integration of BIM (Ding, Zhou & Akinci 2014; Grilo & Jardim-Goncalves 2011; Park et al. 2011) enables architects and professional technicians to work together on the same platform, sharing and exchanging information (Isikdat 2012). This can help reduce conflicts of wire, pipe, and duct configuration as well as omissions in quantity calculation of building elements. In addition, it can allow the users to preview the design results before the project is implemented, promote effective team communication and cooperation (Chen & Luo 2014; Qiu 2011; Cheng & Wang 2010; Popov et al. 2006; Han, Yue & Lu 2012), integrate drawings and documents, reduce conflicts (Chen & Luo 2014), and shorten lead time (Kim, Kim & Seo 2012). It can also solve the problems of wire, pipe, and duct collision/interference and calculation errors in CAD 2D configuration and material estimation caused by its lack of 3D specification presentation. In addition, the integral database of BIM can be customized to directly display the WBS component information and quantity information. Without manual calculation, it can help reduce man-made errors and improve design quality (Miettinen & Paavola 2014). However, BIM itself does not contain sufficient cost information or data for cost evaluation while it cannot integrate or analyze data from similar cases. Such problems can be solved by integrating the BIM system with external cost estimation data.

2.3 *BIM database*

The database can help BIM to realize the storage, exchange, and sharing of data (Vanlande, Nicolle & Cruz 2008). Through the Database Management System (DBMS) software, users can create projects, operate the system as well as maintain, manage, and inquire data. In addition, it can help

ensure data safety and integrity as well as enable data transmission among multiple users. With the DBMS software, manual management of project data is no longer needed and all the project data can be centrally stored and accumulated. The information/data of cost estimation items and unit price analysis are integrated in the Relational DataBase Management System (RDBMS), which can provide detailed cost estimation information/data in the early design stage and then improve the accuracy of cost estimation. By incorporating the database, the BIM system developed in this study can effectively facilitate information sharing/exchange among engineers and solve the problem of data integration and interoperability among different construction projects (Isikdag 2012).

2.4 *Web-based technology*

The major purpose of incorporating the Web technology into the BIM system in this study is to provide a communication and cooperation platform (environment) for users, promote organizational efficiency, and enhance the values of BIM (Vanlande, Nicolle & Cruz 2008). Through the information connection, contribution, and exchange on the WWW or central server (Chou & O'Connor 2007; Turban et al. 2007), engineers can quickly access and exchange different types of required information and knowledge and then work on the same project even if they are located in different places. This can solve the problems of inconvenient access to historical data and lack of communication among engineers in the traditional manual and CAD 2D cost estimation. Therefore, in this study, interactive and dynamic Web pages are developed, and the open-source and free software of LAMP (LINUX + Apache + MySQL + PHP) is used to establish the server database and processing program. Users can access and use this Web-based system through any interface device that can open Web browsers. For cost evaluators, the web-based system can enable more flexibility of time and space, save time and costs, and promote cooperation and communication among users and peers to work more seamlessly. With ICT, all the data in the evaluation process can be fully recorded to provide valuable information for the evaluators for their future analysis and improvement of the cost evaluation method.

2.5 *Fire safety equipment*

Fire safety equipment is intended to prevent buildings from the potential threat of fire hazards and, more importantly, give people more time of evacuation in a fire so as to reduce casualties (Kobes et al. 2010). Poor design, maintenance, and use of

fire safety equipment due to consideration of cost reduction pose a huge threat to people's safety and property. Therefore, to ensure reasonable investments in fire safety equipment, it is necessary to develop an effective method of cost estimation to prevent both excessive and insufficient budgets for fire safety equipment installation and maintenance. By introducing BIM into the fire safety equipment deployment design in a building's spatial structure (Isikdag, Underwood & Aouad 2008), it is possible to manage the design through 3D model visualization and integrate with other digital monitoring systems. For future use and management of the design, it can also help prevent spatial conflicts and modification costs during the installation process, reduce personnel costs, and improve the efficiency of fire safety equipment management and maintenance (Godager 2011).

3 DEVELOPMENT OF THE WEB-BASED HYBRID BIM COST-ESTIMATING SYSTEM

3.1 *System introduction*

The Web-based hybrid BIM cost-estimating system developed in this paper is composed of the following modules: "Basic Project Information", "BIM System", "Fire Safety Equipment Property Database", and "Web-based System Management Interface". Through the system, project managers can have efficient access to data and information required to make decisions and judgments in cost evaluation. The following is a brief introduction to each module and the process of using this system. The conceptual flowchart of the proposed system is shown in Figure 1.

Basic project information: initial collection and analysis of basic information of the evaluation factors in the project, including basic information investigation of the fire safety equipment legally required for buildings, definition of each item in cost evaluation as well as investigation scope and restrictions.

BIM system: providing the project model, property information of fire safety equipment in building elements as well as quantity and drawing information of each component.

Fire Safety Equipment Property Database: transferring information from previous projects and providing information about fire safety equipment classification budget list, detail price list, and unit cost required for the connections between the BIM model and the Web-based interface.

Web-based system management interface: binding the information inquiry module with the other modules and providing an easy-to-use interface for

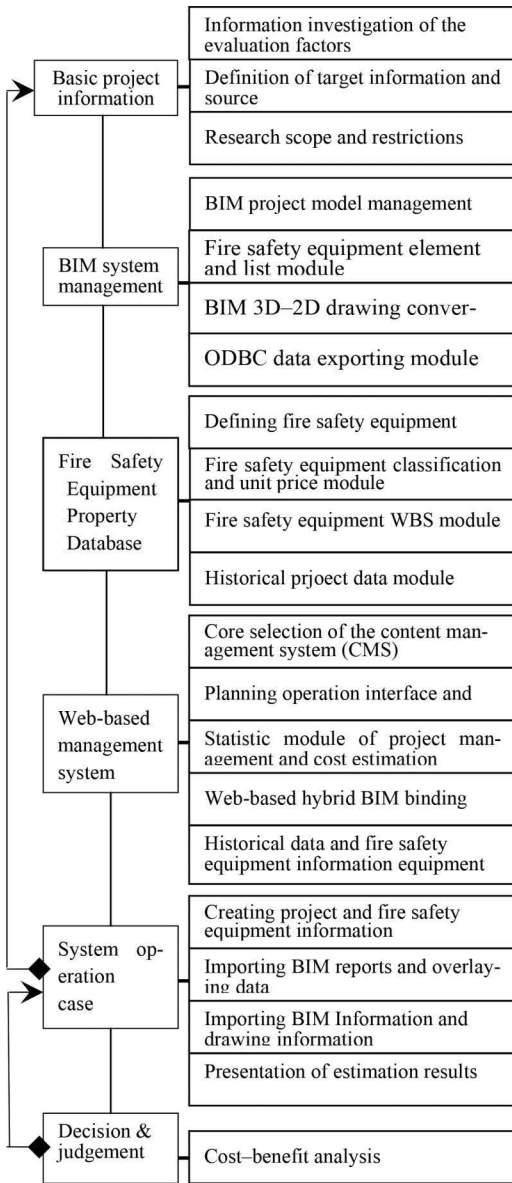

Figure 1. Conceptual flowchart of the Web-based hybrid BIM cost-estimating system.

users, allowing them to create projects, budget lists, detailed price lists for the project cost estimation.

System operation and case analysis: First, a project is created on the Web-based system management interface together with its budget list and detailed price list. Then, the fire safety equipment elements of the BIM model and the detailed quantity reports are imported into the Web-based interface. By overlaying the binding module and

the Fire Safety Equipment Property Database, the Web-based hybrid BIM cost-estimating system can generate accurate estimation results and produce the budget list and detailed price list after receiving the quantity reports of the BIM project. Finally, the BIM 3D models are imported and converted into 2D drawings to fully present the documents required for cost estimation.

Decision and judgment: producing the cost estimation results for the evaluators to conduct cost-benefit analysis and find references for decision makers.

3.2 Work Breakdown Structure (WBS) and unit cost estimation of components

For the code classification of the fire safety equipment, budget lists, and detailed price lists in the case of this study, references are drawn from the cost estimation of similar cases by some engineering consultancies as well as the listing prices of material/equipment of the suppliers to quantify the estimation basis for each item. In addition, references are also drawn from the Public Construction Computer Estimate System (PCCES) and the code classification of the Public Construction Work Guideline Codes developed by the Public Construction Commission under the Executive Yuan in Taiwan based on the CSI Master Format.

The codes for the BIM system in this study can be divided into two types: work codes (10-digit codes) and resource codes (11-digit codes for materials and miscellaneous items with the prefix code and 10-digit code; and 13-digit codes for labor and equipment with the prefix code and 12-digit code):

- XXXXX: Public Construction Work Guideline Codes (totally five digits)
- □□□□□: Code for function or specification (four digits for materials and miscellaneous items and six digits for labor and equipment)
- Δ: Code for pricing unit (one digit)
- L: Code for labor (prefix code)
- E: Code for equipment (prefix code)
- M: Code for materials (prefix code)
- W: Code for miscellaneous items (prefix code)

The code classification structure developed for the BIM system in this study can help project managers to understand the type of each work related to the fire safety equipment, work structure, connections among components, and unit price of each component in the project (Choi, Choi & Kim 2014; Chou & O'Connor 2007). The WBS of the fire safety equipment work in the project is mainly divided into eight categories (Table 1). Each category represents a type of the most fundamental work in the project, and each category is com-

posed of several subcategories. By comparing with the historical data of fire safety equipment in 10 other projects, the components and their unit costs in the case of this study show no significant differences from those data in more than 70% of the compared cases, indicating that the WBS categorization developed in this study can be used as a standard.

3.3 Work categorization and relational matrix of the work components

The fire safety equipment work in this study is categorized into “fire extinguishing equipment”, “fire alarm equipment”, “refuge and escape equipment”, and “necessary equipment for fire escape” in accordance with the categorization in the “Standard for Installation of Fire Safety Equipment Based on Use and Occupancy” promulgated

Table 1. Work breakdown structure of fire safety equipment project.

Code	Classification
EA	Equipment and apparatus
TL	Transportation & lifting
TW	Tubing and wiring
TC	Testing costs
IC	Installation costs
DF	Documentation fees
MD	Maintenance and diagnostics
FV	Fire technician visa fees

by the National Fire Safety Agency of the Ministry of the Interior in Taiwan.

According to related research and the basic requirements in governing legal regulations, fire safety equipment generally include fire extinguishers, indoor hydrants, outdoor hydrants, automatic sprinklers, manual fire alarm equipment, emergency broadcasting equipment, direction indicating equipment, evacuation equipment, emergency lighting equipment, water supplying pipes, fire water reservoirs, and exhaust equipment. Therefore, the content of the Web-based hybrid BIM cost-estimating system can satisfy the demand for cost estimation of at least 60% of the fire safety equipment used in buildings in Taiwan.

The amount of required manpower and working hours is evaluated on the basis of the working progress to estimate the unit price and labor ratio of each category of fire safety equipment and then calculate the installation cost of each category of equipment on the basis of the algorithm rules in the database. The relational matrix of the work components is illustrated in Table 2.

3.4 User interface flow of the Web-based hybrid BIM cost-estimating system

After the input of the required information, such as quantity and unit cost, of the fire safety equipment is completed, the Web-based hybrid BIM cost-estimating system exports all the data in the form of a .txt file to the ODBC database.

Table 2. Relational matrix of the work components in the project.

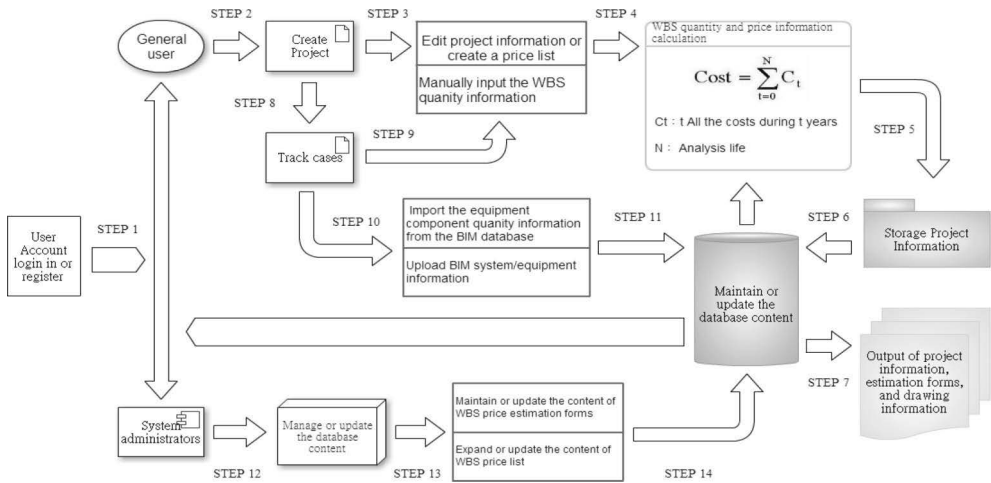

Figure 2. User interface flow of the web-based hybrid BIM cost estimating system.

When the system is connected to the Internet, users can view and modify their projects via the Web browser anytime and anywhere on devices or platforms connected to the Internet. The framework of the BIM Web-based cost estimation system is illustrated in Figure 2, and the following is an introduction to its function flows respectively for nonadministrators and administrators:

Function flow A: Nonadministrators

- Step 1: Log into the system as general users by entering their passwords;
- Step 2: Create a new project (continue with Step 3) or modify an existing project (jump to Step 8);
- Step 3: Input the information and data required for project such as basic information of the building, building site information, basic information of fire safety equipment of different categories, budget list, and detailed price list. Then, the system will provide cost estimation examples and updated unit price information about each category of fire safety equipment for the references of the users;
- Step 4: The input data will be imported into the cost estimation module to calculate the required quantities;
- Step 5: Complete the newly created project and obtain the initial cost estimation;
- Step 6: The data of the newly created project are stored in the Fire Safety Equipment Property Database for future modification or addition of any subproject;
- Step 7: After the creation of the project is complete, the system can generate the budget list and detailed price list as well as provide related BIM 2D drawings and documents;

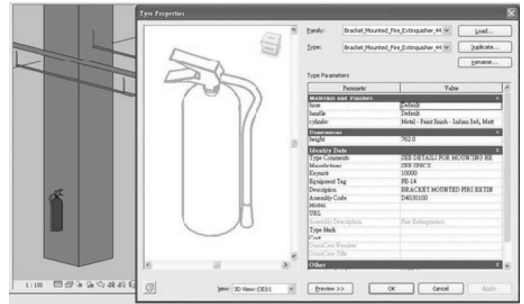

Figure 3. Models of fire safety system component and building element.

Figure 4. Quantity information of the fire safety system components.

- Step 8: After the completion of the new project, the users can track and modify the project (Step 9) or import the .txt file of the BIM model quantity report into the binding module of the Web-based hybrid BIM system to update the quantity information stored in the BIM system

toward the quantity of fire safety equipment actually used in the project (Step 10) or upload the BIM 2D drawings (Step 11);

Function flow B: Administrators

- Step 12: Log into the system as administrators to maintain and update information in the system on a regular and irregular basis;
- Step 13: Use of the administrator privileges, including: (a) maintain the Web-based hybrid BIM cost-estimating system and manage the general user access; (b) expand, maintain, and update the unit cost, detailed price list and total budget list of the fire safety equipment as well as the content of historical projects; (c) change, maintain, and update the content and format of the detailed price list, total budget list, and BIM 2D drawings;
- Step 14: Updated data are stored in the Fire Safety Equipment Property Database for future maintenance and updating of the content in the system.

4 EMPIRICAL STUDY

4.1 Case description

The case in this study is a factory building (six floors above ground and one floor below) with a total floor area of 7,780 m². The total project cost of this building is NT\$ 67,690,000 (~US \$2,256,000). Then, in accordance with governing legal regulations, 3D BIM models of the following fire safety equipment in a building must have fire extinguishing equipment, fire alarm equipment, refuge and escape equipment, and necessary equipment for fire rescue.

4.2 Web-based hybrid BIM cost-estimating system

The Web-based hybrid BIM cost-estimating system is used as a communication platform for drawing and cost estimation. First, the Web-based hybrid BIM system is used for the fire safety equipment design and cost estimation of the above-mentioned case. Second, the 2D CAD model is used for the fire safety equipment and cost estimation of the same case. Then, the time and costs used in the two cost estimation methods are compared. The process of using the Web-based hybrid BIM cost-estimating system for cost estimation is shown below:

- Step 1: Build the 3D model of the building;
- Step 1.1: Build the models of parametric building elements;
- Step 2: Generate the drawings of fire safety system components and set up their properties;

- Step 3: Generate the model of the fire safety system (Figure 3);
- Step 4: The content of the inbuilt list-making tool of the BIM system is used to automatically generate the quantity information of the required fire safety system components;
- Step 5: Import the BIM quantity information of the fire safety system components to the BIM cost-estimating system (Figure 4);
- Step 6: Conduct unit price analysis and create the detailed price list;
- Step 7: Create the budget list.

In general, the 3D BIM models created by the Web-based hybrid BIM cost-estimating system in this study can fully represent the actual conditions of the fire safety equipment in all aspects and then generate the detailed price list and budget list for cost estimation. By quantifying the evaluation criteria for each fire safety system component and evaluating the amount of required manpower and working hours on the basis of the working progress, the BIM system can estimate the unit price and labor rate of each component to calculate the costs of establishing different categories of the fire safety equipment in this case.

4.3 2D CAD cost evaluation method

The 2D CAD cost evaluation method is also used in this study to evaluate the same case as a comparison against the Web-based hybrid BIM system to find out the differences in the costs and benefits of these two cost evaluation methods. The process of using the 2D CAD cost evaluation method is shown below:

- Step 1: Create the 2D CAD drawings;
- Step 2: Create the “BLOCK” symbol drawings that represent the fire safety system components;
 - Step 2.1: Create the shop detail drawing of the fire safety equipment;
- Step 3: Design the fire safety system and create the disposition plan of the fire safety system;
 - Step 3.1: Create the riser diagram of the fire safety system;
- Step 4: Manually estimate the quantity of each component in the fire safety system and building element;
- Step 5: Conduct unit price analysis of the fire safety equipment and component;
- Step 6: Create the detailed price list for the cost estimation;
- Step 7: Create the budget list.

4.4 Comparison and discussion

By comparing the working hours required to evaluate the same case using the traditional 2D CAD method and the Web-based hybrid BIM

system in this study (see Table 3 for comparison results), it is found that the 3D BIM system takes 19.6% and 22.2% less working hours than the 2D CAD method, respectively, to create the building (drawings) models and component (blocks) models. In the estimation of the quantity of the system and component, the BIM system takes 75% less working hours than the 2D CAD method because of its automatic output of the component quantity information. However, the 3D BIM system requires 25% more working hours for the system and equipment layout than the 2D CAD method for the former to adjust the height of each water pipe, electrical wire, and/or water duct to ensure its connection with the corresponding fire safety system component while the 2D CAD method just uses the schematic drawing with the shop detail drawing and the rise diagram as supplements to indicate 3D specifications. Nevertheless, in terms of the overall working hours, the 3D BIM method still requires 22.2% less time than the 2D CAD method. It is because the 2D CAD method requires manual estimation of the quantity, length, and height of the system, equipment, and component while the automation function of the 3D BIM model can significantly reduce time required for these estimation activities.

The above-mentioned case analysis and comparison results reflect the fact that the construction industry is a highly fragmented industry with a very detailed and complex division of work (Ahmad, Russel & Abou-Zeid 1995; Cheah & Chew 2005). With the integration of work information through the BIM system, the problems with complex division of work can be solved. With the BIM system,

design modifications and conflict detection can be done in the design stage, saving both time and money (Miettinen & Paavola, 2014). The BIM system is also helpful for the construction industry to improve its design development efficiency, reduce working hours, prevent construction material waste, and effectively improve productivity and design quality (Park et al. 2011). In the early design stage, the cost estimation using the BIM system can help architects and building owners to analyze the feasibility of building projects and effectively control the costs of the projects (Cheng, Tsai & Hsieh 2009).

By comparing the cost estimation of the 2D CAD method and the Web-based hybrid BIM system for the same case (see Table 4 for comparison results), it is found that, with the same fire safety equipment categories and quantities, the cost of water pipes, electrical wires, and air ducts as well as the miscellaneous cost estimated by the Web-based hybrid BIM system are 5.7% less than those estimated by the 2D CAD method, whereas the labor cost estimated by the BIM system is 2% less than that estimated by the 2D CAD method. In terms of the overall cost, the estimate of the Web-based hybrid BIM system is 2.2% less than that of the 2D CAD method.

As indicated by the comparison results, the Web-based hybrid BIM system has more accurate estimates of the pipe/wire/duct cost, miscellaneous cost, and labor cost, whereas its estimate of the total cost is 2.2% less than that of the 2D CAD method. With more accurate cost estimation, the BIM system is helpful for effective cost control.

By comparing the working hours of the Web-based hybrid BIM system and the traditional 2D

Table 3. Working hour comparison between the 2D CAD method and the Web-based hybrid BIM system.

Item	2D CAD method (working hour)	Web-based hybrid BIM system (working hour)	Cost–benefit analysis (%)
Creating building (drawings) models	56	45	19.6
Creating component (blocks) models	36	28	22.2
Layout of the system and equipment	8	10	–25.0
Quantity estimation of the system and component	8	2	75
Total	108	84	22.2

Table 4. Comparison of cost estimations of the 2D CAD method and the Web-based hybrid BIM system.

Item	2D CAD method (US \$1,000)	Web-based hybrid BIM system (US \$1,000)	Cost–benefit analysis (%)
Equipment cost	54.5	54.5	0
Pipe, wire, and duct cost	29.3	27.6	5.7
Miscellaneous cost	10.3	9.7	5.7
Labor cost component	66.9	65.7	2.0
Estimate of total cost	161.0	157.5	2.2

CAD method for the same case, we obtained some main results. First, the BIM system requires 75.0% less working hours than the 2D CAD method in the quantity estimation of the system and component, 41.8% less working hours in the Creating building (drawings) models & creating component (blocks) models, and 22.2% less time in the total working hours.

The result is contributed by the following reasons: (1) The system can allow different experts to work together whenever and wherever they need and, therefore, promote more efficient work cooperation. In addition, because of the component quantity data stored in the database, manual evaluation is not needed, which also helps to reduce time for design modification in the design planning stage. (2) In the Web-based hybrid BIM cost-estimating system, the basic information/data about the evaluation items, component cost, component unit price, and so on, are stored in the database, which saves time to collect public information about the price of each component or to visit suppliers to inquire the price. (3) The system also saves time for the production of the shop detail drawing and riser diagram for each component of the system.

Second, by comparing the cost estimation of the Web-based hybrid BIM cost-estimating system and the 2D CAD method, it is found that the total cost estimate of the former is 2.2% less than that of the latter. It is probably because of the following reasons: (1) The 2D CAD method only uses the schematic drawing with the shop detail drawing and the rise diagram as supplements to indicate 3D specifications. Therefore, it is difficult for the 2D CAD method to have accurate estimates of the lengths of the pipes, wires, or ducts because of the lack of accurate 3D specifications. In addition, the measure standard may vary from people to people, which may also result in inconsistent estimation results. (2) The estimated lengths of the pipes, wires, and ducts are positively correlated with the labor cost. With longer pipes, wires, and ducts to install, more labor is needed, which will also increase the total cost.

5 CONCLUSION

In this study, the Web-based hybrid BIM cost-estimating system is developed with the intention of providing assistance to the cost estimation work in the early design stage of a building project and promoting the efficiency of the project implementation. To verify the feasibility and performance of the system, a case study is conducted by using the BIM system and the traditional 2D CAD method to evaluate the same case, and then the working

hours and cost estimates of the BIM system and the 2D CAD method are compared. The comparison results indicate that the Web-based hybrid BIM cost-estimating system is better than the 2D CAD system in terms of estimation efficiency and accuracy.

It is probably because the Web-based hybrid BIM cost-estimating system is built on the basis of work cooperation while its inbuilt database can directly display relevant information and quantity of each component. Therefore, the statistic information/data of the BIM system about the layout, relative position to building structure, and 3D specifications of the components are more accurate and helpful for effective cost control than those of the 2D CAD method. In addition, the BIM model system can incorporate the dimension, position, 3D specifications, and other information of the equipment as 3D models inside the building structure; therefore, it can obtain accurate quantification data of the equipment. Finally yet importantly, on the basis of the requirements of difference projects, the equipment quantity information can be modified and then directly exported via the database of the BIM system or exported as a .txt report and then printed out. To conclude, the Web-based hybrid BIM cost-estimating system uses its database to integrate all the information/data and, as a result, makes it more convenient and fast for cost estimation.

Moreover, by incorporating the fire safety equipment into the 3D building structure model, the BIM system can accurately represent the spatial configuration of the power line and cable tray (power supply), water pipes (water supply), and air ducts (exhaust system). Such a visualized design is helpful in eliminating problems caused by uncertain factors (3D spatial configuration and quantity of required materials) in the initial cost estimation of a building project.

The restriction of this study lies in its exclusion of economic factors, such as net values, internal rate of return, price index, inflation rate, and interest rate, in the cost estimation analysis. Therefore, a further analysis of sensitivity toward these factors is required. In addition, the influence of the life-cycle cost of a building project for different types of relevant entities (such as owner, investor, developer, building administrator, and building operator) is also a topic that requires further exploration in future research on the economic benefits of fire safety equipment for buildings.

To promote future application of the Web-based hybrid BIM cost-estimating system, the technology acceptance model can be applied to determine the requirements and preferences of fire safety professionals in their cost estimation operation and explore their possible interest in the

BIM system, providing references for the future online application and digital learning of this system.

Test and parametric analysis of postfire seismic performance of SRC column–RC beam joints

Guohua Li, Long Xie & Dongfu Zhao

School of Civil and Transportation Engineering, Beijing University of Civil Engineering and Architecture, Beijing, China

ABSTRACT: In order to study the hysteretic behavior of SRC column–RC beam joints after fire, fire and pseudo-static tests were carried out. On the basis of the experimental results, the numerical simulation was developed to study the influence of parameters such as heating time, axial compression ratio, concrete strength, and profiled steel ratio on the hysteretic behavior of the joint after fire. The results show that the bearing capacity and stiffness of joints will degrade after fire. With the increase of axial compression ratio, concrete strength, and profiled steel ratio of column, the bearing capacity and stiffness of the SRC column–RC beam joints were improved.

1 INTRODUCTION

Building fire is not only a serious threat to people's lives and property, but also it causes damage to the building itself. Sometimes, although building collapses are not caused by fire, the structure performance of building must be estimated to decide whether it can be used continuously. Because of the superiority of high bearing capacity, good earthquake resistance, and high stiffness, the Steel Reinforced Concrete (SRC) structure is widely used in high-rise buildings. At present, most of the studies on the column–beam joints are mainly focused on the seismic behavior at ambient temperature, and only few studies have been concerned with the seismic behavior after fire.

In this study, three pseudo-static tests were conducted, and the influence of heating time on the seismic behavior of the SRC column–RC beam joints after fire was determined. Then, the influence of bearing capacity and stiffness under cyclic loading was studied by numerical simulation.

2 EXPERIMENTAL PROGRAMS

2.1 Test specimens

Three specimens were used in the test: A, B, and C. The main purpose of the test is to investigate the influence of heating time on the seismic behavior of the SRC column–RC beam joints, and three specimens are of the same. The joints $1960 \times 300 \times 300$ mm for columns and $2870 \times 300 \times 300$ mm for beams were designed on the basis of the relate Chinese codes (JGJ. 1996,

JGJ. 2001, YB. 2007). The H-shaped steel section encased in column is $HW175 \times 175 \times 7 \times 10$, which is fabricated from Grade Q345. The longitudinal reinforcement, 18mm diameter bar, and transverse reinforcement, 10mm diameter bar, were used for both the columns and beams. The yield strength of bars is 345 MPa, and the concrete with grade C40 for the specimens was constructed in specimens.

2.2 Test method

In this study, two types of test were conducted: fire test and pseudo-static test. Figure 1 shows a fire furnace and setup of the pseudo-static test. Specimen A was the control one, and pseudo-static test was developed directly without fire condition. Specimens B and C were exposed to fire before the pseudo-static test. Specimens B and C were fire-tested under ISO834 standard fire (GB/T. 2008), whose heating times are 60 and 90 min, respectively. The fire conditions were simulated in a burning furnace with dimensions $3000 \times 3000 \times 1000$ mm in the China Academy of Building Research.

Figure 1. The furnace and test setup.

After fire test, pseudo-static test was conducted, and three column–beam joint specimens were tested on a special steel girder frame for the pseudo-static test. Equal and opposite displacements were imposed at the beam ends by hydraulic jacks, and the top and bottom of the column were pinned against translation. An axial load of 0.35 column axial load capacity was applied on the top of columns. The test was displacement-controlled and the specimens were subjected to an increasing cyclic displacement up to its failure.

2.3 Hysteretic loops and envelopes

Table 1 shows the test results. The yield load (P_y), maximum load (P_{max}), and ultimate load (P_u) decreased with the prolongation of heating time. The bearing capacities of J2 and J3 are 85.2%, 72.9% of those of J1. Ductilities of the joints are 2.59, 2.53, and 2.0, respectively, which shows that the bearing capacities of the specimens reduced significantly when the heating time exceeds 60 min. Hysteretic loops and envelopes of the specimens are shown in Figure 2. An obvious pinch effect was observed in the hysteretic loops, primarily due to the slip between the reinforced bars, profiled steel,

and concrete. The area surrounded by the hysteresis loops of Specimen A is larger than that of Specimens B and C, showing that when undergoing fire, the energy dissipation capacity would decrease. From the envelopes, the stiffness of the joint also decreased with the prolongation of heating time.

3 FINITE-ELEMENT ANALYSES

On the basis of the pseudo-static test after fire, parameter analysis was carried out to study the influence of parameters such as heating time, axial compression ratio, concrete strength, and steel ratio on the hysteretic behavior of joint after fire. A total of 10 finite-element models of SRC column–RC beam joint were established by using the general finite-element package, ABAQUS/Standard v6.10, as shown in Figure 3. The values of the parameters are shown in Table 2. For validation, Specimens J1, J2, and J3 are test pieces simulated by the finite-element method.

Thermo-structural analysis was conducted to simulate the behavior of the SRC column–RC beam joints after fire. For thermal analysis, concrete and profiled steel were modeled with the element DC3D8, which was replaced by the element C3D8R in structural analysis. Element DC1D2 was used to model the reinforcement bar and replaced by the element T3D2 during structural analysis. ISO834 standard heating curve is used as the heating curve

Table 1. Test results.

	P_y	Δ_y	P_{max}	Δ_{max}	P_u	Δ_u
Specimen	kN	mm	kN	mm	kN	mm
A	67.7	14.8	100.1	33.4	84.6	38.3
B	55.9	16.3	85.2	36	72.3	41.2
C	53.9	18.5	72.9	32	64.5	37.1

Figure 3. Model of the finite analysis.

Table 2. The parameters.

No.	Heating time min	Axial compression ratio	Concrete strength MPa	Steel ratio %
J1	–	0.35	40	4.96
J2	60	0.35	40	4.96
J3	90	0.35	40	4.96
J4	120	0.35	40	4.96
J5	60	0.45	40	4.96
J6	60	0.55	40	4.96
J7	60	0.35	30	4.96
J8	60	0.35	50	4.96
J9	60	0.35	40	4.23
J10	60	0.35	40	6.72

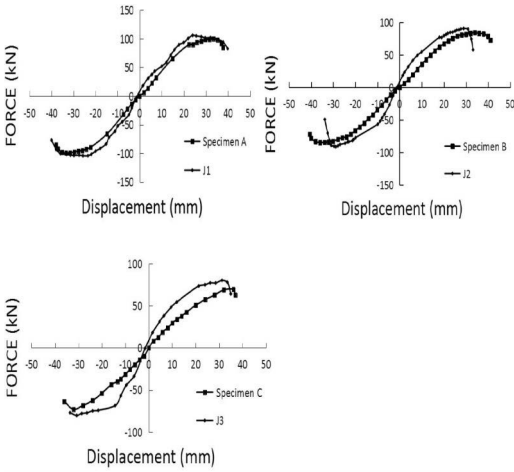

Figure 4. Envelopes of the test and numerical simulation.

and the cooling process is considered to be a straight line. The heat radiation and heat convection are considered in heat analysis. Because of the analysis focusing on the postfire behavior of the joints, as the temperature field of the joints was known, a special program was used to extract the maximum temperature of each element in the whole process of heating and cooling. On the basis of the maximum temperature of the element, the correct constitutive model of concrete was chosen in structural analysis.

For structural analysis, the concrete and steel are considered as isotropic materials, and the bond slip between concrete and profiled steel and the slip between concrete and reinforcement bars are not considered. The relationship between stress and strain of concrete at high temperature was adopted in accordance with Zhoudao Lu (Zhoudao Lu et al. 1993), and the constitutive relation model of steel after high temperature recommended by Linhai Han (Linhai Han. 2007) is used as the material constitutive relation. In order to better simulate the damage process of concrete, the concrete damage plasticity model is used, which could simulate the concrete cracking and crushing conveniently.

Figure 4 compares envelopes of the test with numerical simulation. It is evident from the figure that the bearing capacity gives a close prediction of the test results. The stiffness value obtained from numerical simulation is larger than that of the test, which is mainly because of some simplification in the numerical model, such as homogeneous material of concrete, no slip between concrete and profiled steel, no slip between concrete and reinforced bars, and the support restraint ideally. The difference between test results and numerical simulation results is in the control scope and acceptability.

4 PARAMETRIC STUDY ON BEARING CAPACITY AND STIFFNESS OF JOINT AFTER FIRE

4.1 Heating time

Figure 5 illustrates envelopes of the joints at different heating times. It can be seen that the bearing capacity of the specimen decreases gradually with the prolongation of heating time. The bearing capacities of J2, J3, and J4 are 85.2%, 75.6%, and 54.2% of those of J1, respectively. The stiffness values obtained from the simulation of J1–J4 are 3.71, 3.15, 2.59, and 1.69 kN/mm, respectively, for three specimens, which show that the prolongation of the heating time would lead to the stiffness degradation. The material properties deteriorate at high temperature, which causes degradation of the bearing capacity and stiffness. When heating time exceeds 120min, the bearing capacity and stiffness decreased sharply, about half of those of specimen J1.

4.2 Axial compression ratio

According to specification regulated data in the *Technical Specification for Steel Reinforced Concrete Composite Structures*, the axial compression ratios were assigned as 0.35, 0.45, and 0.55, respectively. Figure 6 shows envelopes of J2, J5, and J6. It is found that the influence of axial compression ratio on the bearing capacity of the joints is very small. The bearing capacities of the three specimens are 90.3, 93.6, and 101.39 kN. And the simulation gives stiffness values of 3.15, 3.25, and 3.43 kN/mm, respectively. Therefore, the axial compression ratio increase can lead to the stiffness increase, but the amplitude is very small.

4.3 Concrete strength

For this investigation, concrete strengths C30, C40, and C50, are selected, which are commonly used

Figure 5. Effect of heating time on strength and stiffness.

Figure 6. Effect of axial compression ratio on strength and stiffness.

Figure 8. Effect of profiled steel ratio on strength and stiffness.

Figure 7. Effect of concrete strength on bearing capacity and stiffness.

in engineering practice. The envelopes, as shown in figure 7, of Specimens J7, J2, and J8 illustrate that the bearing capacity and stiffness of the joint increased effectively when the strength of concrete is improved, as well as the stiffness, which are 3.07, 3.15, and 3.36 kN/mm, respectively. The bearing capacities of the three specimens are 82.1, 90.3, and 107.6 kN, respectively.

4.4 Profiled steel ratio

The influence of profiled steel ratio was examined by changing the cross section of steel. The type of profiled steel is based on the regulations of the *Technical Specification for Steel Reinforced Concrete Composite Structures*, and the profiled steel ratios of J9, J2, and J10 are 4.23%, 4.96%, and 6.72%, respectively. The results in Figure 8 indicate that the bearing capacity and stiffness are greater when the profiled steel ratio is improved. The values of stiffness are 2.25, 3.15, and 3.71 kN/mm, respectively.

5 CONCLUSIONS

The fire test and pseudo-static test were conducted to study the seismic performance of SRC column-RC beam joints. Then, on the basis of the test, the finite-element analysis was developed to conduct parameter study. The test and numerical simulation results indicate that the bearing capacity and stiffness will degrade after fire, and the longer the heating time, the more is the deterioration effect. The increase of axial compression ratio, concrete strength, and profiled steel ratio of column can lead to the significant improvement of bearing capacity and stiffness of the SRC column-RC beam joints, except for the axial compression ratio, which has a small influence on the bearing capacity.

Using agent-based simulation approach for estimating the efficiency of the building project design team

M.H. Tsai

Department of Civil Engineering, Tamkang University, Taipei City, Taiwan

ABSTRACT: The Project Team Collaborative Efficiency Simulator (PTCES) proposed by Tsai and Huang (2015) was an agent-based simulation tool helping project managers to estimate the workflow efficiency resulted from the collaborative behaviour of the team members. Applying the PTCES, this study continuously extended the practice of efficiency estimation to the architectural design project team and facilitated the architectural design project efficiency evaluation. A case of four-floor nursery school building design was studied in this paper including verification, validation and sensitivity analysis experiment steps. According to simulation results of the case study, the efficiency bottleneck activities of the design process were revealed, and the collaboration willing threshold, communication unit time and the exception probability were found to be the most significant factors influencing the design process efficiency (EC) and the project design duration.

1 INTRODUCTION

In many project tasks, teamwork plays a vital role in getting things done and the efficiency of the results. Effective teamwork is one of the predictors of organisational success since it can cause rapid information exchange and increase responsiveness (Farhangian et al. 2013). The design is a complex process which always involves many participants from different disciplines to work together during the design process (Girard & Robin 2006). Therefore, design collaboration becomes a crucial element in the design process and has a significant effect on the final design performance (Yin et al. 2011). Moreover, large scale and multidisciplinary architectural and engineering projects (e.g., the design of a commercial building) are often complex. They usually involve many interdependent activities and require intensive collaboration among actors (i.e., designers) to deal with activity interdependencies (Jin & Levitt 1996). To make such projects more effective and efficient, managers need to understand where collaboration requirements are and whether the collaborations could be finished efficiently and effectively by the current project team. Consequently, a large amount of research has paid attention to improving collaborative design performance (Girard & Robin 2006; Bstieler 2006; Busi & Bititci 2006; Lahti et al. 2004; Easley et al. 2003; Jin & Levitt 1996).

Jin and Levitt (1996) successfully developed the Virtual Design Team (VDT), a computational model of project organisations, to analyse how activity interdependencies raise coordination needs

and how organisation design and communication tools change team coordination capacity and project performance. Based on the VDT foundation, Levitt (2012) illustrated the method applying agent-based simulation, such as VDT model, to help managers design the work processes and organisation of project teams engaged in a great, semi-routine but complex and fast-paced projects. Although the large numbers of organisational and individual level behavioural parameters available in the VDT model can potentially represent cultural phenomena, the social factor is one of the essential perspectives for developing the next generation simulation model (2012). To enhance the social collaborative capability of the project team in the simulation model, Tsai and Huang (2015) adopted the social network philosophy and the Agent-Based Modelling and Simulation (ABMS) approach to develop the Project Team Collaborative Efficiency Simulator (PTCES), which breaks the project team into individual agents and modeling the behaviors and the social network to simulate the collaborative interactions and performance.

The simulation approach provides a useful way to evaluate the dynamic status of a project team efficiency. With repeatable scenario experiments, we can access not only the collaboration performance but also the efficiency improvement strategies by using the simulation approach. Following this idea, this study focused on the architectural design project team and continuously used the PTCES to facilitate the collaborative efficiency analysis of social-network-based and agent-based simulation.

2 METHOD

2.1 Problem description

The social-network-based Project Team Collaboration Efficiency Simulation (PTCES) model has been developed for the performance analysis of project teams by Tsai and Huang (2015) using the ABMS approach and has also appropriately used to simulate the construction project duration and cooperation efficiency of the project team. Since the PTCES is an ongoing research project aiming at estimating the project team performance with different organisational structures and collaboration mechanisms, this study adopts the PTCES to evaluate the collaborative efficiency of the project design team for validating the soundness of the PTCES and even discovering the essential impact factors of design performance.

The design process itself is the result of collaboration developed by the designers during the design phrase (Girard & Robin 2006). A building design process composed of the designing activities can be revealed by extracting the functional requirements of the owner, and executed by the corresponding actors of the design team. The PTCES crumbled the activities of design processes into single-actor-performed ones to bring the simulation model into a micro-level perspective so that users can model the detail behaviors of designers with their interdependencies and relevant information/skills.

Following the ABMS philosophy, team members are modeled as agents possessing individual characteristics and social network properties, kept performing assigned activities not only dealing with information but by also communication with one another through his/her existing connections in both the formal and informal networks. That is, team members need to communicate with the neighbors via their collaboration networks for their insufficient information or skills.

2.2 Project team collaborative efficiency simulation

The PTCES (Tsai & Huang 2015) refers to the information-processing view of organisations in the VDT model (Jin & Levitt 1996; Anon 1999; Fridsma 2003) to calculate the design process collaboration efficiency. Accordingly, the following mathematical relations referred to Jin and Levitt (1996) are applied to be the foundation of efficiency calculations of the PTCES.

For a given activity of a building design project, TW presents the total work volume of it, which is the sum of the Primary Work volume (PW) and the Collaboration Work volume (CW) as shown in Equation (1).

$$TW_i = PW_i + CW_i \quad (1)$$

where the TW_i , PW_i and CW_i are the corresponding TW , PW , CW of the activity i .

Besides, the PW consists of originally-planned Production Work (PW_o) and the production for rework (PW_r) resulted from the failure of the original production work as shown in Equation (2).

$$PW_i = PW_{o_i} + PW_{r_i} \quad (2)$$

where the PW_i , PW_{o_i} and PW_{r_i} are the corresponding PW , PW_o , PW_r of the activity i .

From Equation (1) and (2), TW is the sum of the PW_o, PW_r and CW (Equation 3); the spent time of PW is the sum of the processing time of PW_o, PW_r and CW (Equation 4).

$$TW_i = PW_{o_i} + PW_{r_i} + CW_i \quad (3)$$

$$t_{TW_i} = t_{PW_{o_i}} + t_{PW_{r_i}} + t_{CW_i} \quad (4)$$

According to Equation (4), for management viewpoint, we could say the project team is perfectly well performed if the time of TW (t_{TW}) equals to the time of PW_o (t_{PW_o}). Therefore, the ratio (EC, Efficiency coefficient) of t_{PW_o} and t_{TW} is the presentation of activity efficiency. As Equation (5) shows, lower EC implies that more PW_r time (t_{PW_r}) or CW time (t_{CW}) has occurred during the project performed and vice versa.

$$EC_i = \frac{t_{PW_{o_i}}}{t_{TW_i}} \quad (5)$$

$$EC_p = \frac{\sum_{i=1}^n t_{PW_{o_i}}}{\sum_{i=1}^n t_{TW_i}} \quad (6)$$

where EC_i ($0 \leq EC_i \leq 1$) presents the efficiency coefficient of activity i , and EC_p ($0 \leq EC_p \leq 1$) is the efficiency index of the whole project performed by the team members.

Besides, since PTCES assumes one communication task takes one-unit time in the simulation model, the CW time spent by an actor for one activity depends on the total communication frequencies between him and his coworker.

Unlike CW time, as shown in Equation (7) and (8), PW_o time and PW_r time will be calculated according to actor's information processing speed and the work volumes (PW_o and PW_r).

$$RPS_{ji} = [x \sim \text{poisson}(APS_{ji})] \quad (7)$$

$$t_{PW_{o(ij)}} = \frac{PW_{o_i}}{RPS_{ji}} \quad (8)$$

$$t_{PWr(ij)} = \sum_{i=1} \frac{PW_{o_i}(t) + PW_{c_i}(t)}{RPS_{ji}} \quad (9)$$

where RPS_{ji} is actor j 's Random Processing Speed for action i ; APS_{ji} is actor j 's Average Processing Speed for action i ; $t_{PWo(ij)}$ is the PWO time of activity i performed by actor j ; $t_{PWr(ij)}$ is the PWr time of activity i performed by j ; the $PWo_i(t)$ is primary production work volume of activity i at time t , and $PWc_i(t)$ are the correction production work volume of activity i as exception occurred to activity i at time t .

Based on Equation (7), (8) and (9), the PWO time and PWr time can be calculated according to Actor j 's RPS which is randomly generated by the Poisson distribution function of Actor j 's APS. In this study, the values of actors' APS need to be surveyed with the project team members. According to the aforementioned mathematical model, Figure 1 illustrates the primary function of PTCES.

Figure 1. Inputs and outputs PTCES (Tsai & Huang 2015).

2.3 Data collection of case study

This study applied a real building design project case for testing the soundness of the PTCES and discovering the potential strategy of design efficiency enhancement. The historical data of the study case are collected by deep interviews with the project managers and observation surveys for the design actors of the architectural and planning firm. Table 1 shows the 43 activities of the four-floor nursery school building design case, which are the process data inputted to the PTCES. The actual design time in Table 1 are compared with the simulation results to calibrate the simulation model. Figure 2 reveal communicative social network of the team members that will be transferred to the collaborative design network matrix and actors' skills and information list as shown in Figure 1.

Figure 2. (a) Project team structure (formal relationships); (b) Collaborative design network of project team.

2.4 Simulation plan

To facilitate the collaborative performance analysis of the building design teams by using ABMS and social network philosophy, this study continues applying the PTCES above as the tool for simulation experiments. Four steps, namely, (1) calibration, (2) verification, (3) validation and (4) sensitivity analysis, are included in the simulation plan.

3 RESULTS

3.1 Calibration

While running simulations in PTCES, the tunable parameters of the PTCES includes (1) exception (failure) probability (P_e), (2) failure for rework probability (P_r), (3) unit time of communication (C_u), (5) correction volume ratio (C_r), and (6) collaborative willing threshold (\bar{W}) (Tsai & Huang 2015). The values of all parameters vary from project to project. Accordingly, we can only estimate the value range of each parameter by interviewing the staff of the studied project team and surveying the historical data. Since users need to set up the default values of all parameters in the PTCES, this study tunes the case model based on the surveyed value ranges to approach the actual state of the project. Table 2 shows the calibration result

Table 2. Calibration Results with 100 experiments (300 simulations per experiment).

Parameter settings after calibration:
 $P_e = 30\%$, $P_r = 40\%$, $P_c = 40\%$, $C_r = 40\%$,
 $W_{thr} = 0.1$, $C_u = 1.2$

Output factors	Process duration (Days)	PWo Time (Days)	PWr Time (Days)	CW Time (Days)	EC
Values after calibration	119.39 (118*)	66.73	15.26	46.5	0.54

*actual project design duration.

Table 3. The stability of the PTCES outputs.

Factors	Project				Average EC ($0 \leq EC \leq 1$)
	Duration	PWo Time	PWr Time	CW Time	
Average	118.67 day	66.81 day	15.11 day	46.24 day	0.54
SD	1.628	0.759	0.722	1.151	0.024
MAD	1.364	0.617	0.607	0.971	0.020

SD: Standard Deviation, MAD: Mean Absolute Deviation.

and the corresponding parameter settings which fit the actual performance mostly. The validation and the following experiments could be performed with the same parameter settings in Table 2.

3.2 Verification

The statistical verification, including the discrete degree and the t-test approaches, is applied to ensure the soundness of the simulation model of the case study and the PTCES (Xiaorong Xiang et al. 2005; Sargent 2012). Table 3 shows the discrete degrees of the case study simulations (100 experiments and 150 simulations per experiment). According to the standard deviation and mean absolute deviation of each estimated value, since they are relatively small, we could say that the stability of the PTCES is acceptable.

3.3 Validation

After calibration and verification, the outputs of the conceptual model of the PTCES and the case study are verified to be correct, consistent, and stable. In this step, we further compared the simulation outputs with the actual performance in the real project to validate the reasonability of the addressed conceptual model (Xiaorong Xiang et al. 2005).

Figure 3 shows the result of each design activity simulated by the PTCES of the case study. The average value of EC of the whole project is 0.54 and the project design total time is 120 days. The histogram diagram in Figure 3 shows the time spent in each activity, including PWo time, PWr time and CW time; the line chart illustrates the EC

Figure 3. Design time and EC value of each design activities (estimated by PTCES).

value of each activity. Ideally, we need to validate the results with the real values of the project; however, it is almost impossible to collect the exact time spent for each activity. Accordingly, this study can only verify the results in Figure 3 with the roughly-estimated values by interviewing all project staff.

The distribution of the output values in Figure 3 match the estimation of the interviewed staff. Taking activity AEC21 (Building sections and elevations design) as an example, since the architect needs to collaborate with the actors “C1”, “E1”, “F1” and “G1” to integrate the design results, the efficiency of the activity AEC21 is below 30% in average. Accordingly, the simulated efficiency of the activity AEC21 is 26.3% which is reasonably within the range estimated by the architect.

Meanwhile, based on the time distributions and the efficiency values of all activities, we can also discover the bottlenecks of the efficiency and the project duration (total design time). Figure 4 shows the distribution of each activity with its TW and EC values. Taking $EC = 0.5$ and $TW = 6.2$ day (average time) as the thresholds, the coordinate can be divided into four zones (Zone “A”, “B”, “C” and “D”). For the company, the 11 activities in the zone “D” would be the critical performance bottlenecks of the workflow because of very low EC values and long durations.

Summarily, the model after the verification and the validation provides the quantitative and meaningful information inside the design workflow. Managers could discover the potential efficiency bottlenecks and causes related to the social networks of the project team.

3.4 Sensitivity analysis

According to the results of the sensitivity analysis, the highly-influencing parameters of the project efficiency can be determined. Meanwhile, since the all the parameters in the PTCES, i.e., Pr, Pe, Cr, \hat{W} , and Cu, are holistic factors of a project, the project

Figure 4. Activity EC—TW distribution diagram.

Figure 5. Sensitivity analysis for (a) EC and (b) total project design time (total duration of the architectural design project).

managers could find the way improving the total project efficiency from the global perspective.

Figure 5a shows the liner adverse effect on the EC of each parameter, in which the collaborative willing threshold (\hat{W}) provides the highest influence on the project efficiency as the incremental percentage is positive, and the unit time of communication (C_u) is the factor with the most significant impact in the negative incremental percentage area. In Figure 5b, \hat{W} is still the most significant factor for the project design time, while the P_e is the secondary one. Therefore, how to reduce \hat{W} and C_u values could be the vital issue for enhancing the efficiency, and \hat{W} and P_e are primary factors controlling the total project design time.

4 CONCLUSIONS AND FUTURE WORKS

By using the PTCES proposed by Tsai and Huang (2015), this study facilitated the architectural design project efficiency evaluation. A small but complete building project design case was addressed to be the test model in this study. Following the framework of the PTCES, the communicative design network of the project team, the design process with all activities and their corresponding information were collected to build a simulation input data model. Through the calibration, verification, and validation experiment steps, we can grasp the estimated quantitative efficiency information of the global project and the one in the manner of micro perspective.

Based on the simulation, the potential efficiency bottleneck activities can be revealed, and the cause could be analysed by tracing back to the social network features and the interdependency relationship between activities. Moreover, with the sensitivity analysis results, the collaborative willing threshold (\hat{W}) and the communication unit time (C_u) are the highest influence factors on the project efficiency.

Summarily, in this study, the architectural design project with a small design team was modelled and simulated successfully with the PTCES. However, due to the limitations and model assumptions of

the PTCES, some specific and unusual features of the studied case were ignored or simplified. How to modify the model of the PTCES to match the behaviours of the project team in AEC industry is the critical issue in the future.

Field assessment of window daylighting with prismatic glazing

Z. Tian & D. Xue

School of Architecture, Soochow University, Suzhou, China

Suzhou Institute of Building Science Group, Suzhou, China

ABSTRACT: Prismatic glazing has the potential to improve indoor luminance levels and luminous comfort. Through field measurements and the comparison with Desktop Radiance simulation results, this study shows that using prismatic glazing at side windows can improve indoor luminance levels and luminance uniformity, especially for inner spaces. The technology can work effectively in both sunny and cloudy days with better performance in the former. Prismatic glazing systems refract light into inner spaces and thus can provide better luminous comfort environment for building occupants.

1 DAYLIGHTING MEASURES

Daylight is an effective resource to improve the health and energy savings of indoor occupants (HesChong Mahone Group Inc. 2003). In general, there are two methods for daylight: skylight daylight and side window daylight, with the latter having much wider applications. Limited by the aperture parameter factors such as size, shape, and position, providing good daylight for large depth spaces through side-windows presents a challenge.

To improve daylight area, two approaches are often utilized: light shelf on the window or a solar tube on the roof or above the basement. Light shelf can reflect daylight to the ceiling and then reflect to the inner spaces. The solar tube has a similar function to skylight but through more modular structure and intensive light accumulation.

Because of dust accumulation on the panels, it is necessary to maintain routine housekeeping to clean the light shelf so that the light reflective system can work effectively. Meanwhile, adding the light shelf may bring hurdles to elevation maintenance.

Basically, solar tubes are utilized in the top floor or the first floor of basement, and the utilization of solar tubes in other cases is very rare.

2 DAYLIGHT WITH PRISMATIC GLAZING

The mechanism of prismatic glazing is adding a sawtooth prismatic film between double-glazing (Jiangsu HURD, 2013) so that the light passing through prismatic film will be majorly refracted upward to the ceiling (Figure 2) and then reflected

Figure 1. Light shelf on the windows.

Figure 2. Light transmittance through prismatic film.

downward to the inner spaces. The prismatic film works similarly to the light shelf, but no light will be blocked by the light shelf panels.

Prismatic glazing has wide applications. It can be utilized in elevation side windows to increase daylit areas and spaces as well as to improve luminous comfort by luminance uniformity (Figure 3). Prismatic glazing can also be utilized in skylight in atrium of courtyard to increase the daylit hours (Figure 4).

As a new light directive guidance system, prismatic glazing systems can reduce the excessive daylight close to the window areas by reflect light to the inner spaces and thus can improve the daylit area and luminance uniformity. As light is refracted in the prismatic film, the appearance of prismatic glazing is translucent. In many cases, it is utilized in the clearstory and combined with conventional glazing in the low windows so as to accommodate both the visual and daylighting functions in office buildings (Figure 5).

3 FIELD ASSESSMENT CASE STUDY

The ground floor of Sumin Decoration Company Office Building was chosen as the field assessment study case. The exterior and interior of the building are shown in Figures 6 and 7. The floor plan and field measurement spots grid set according to Liu (2010) and Standard GB/T5699 (GAQSIQ, 2008) are illustrated in Figure 8.

Field measurements are conducted throughout for a year. For simplification, the Spring Equinox, Summer Solstice, Autumn Equinox, and Winter Solstice are the typical times for field measurement (Yun, 2007).

Figure 3. Prismatic glazing on the side windows (Suzhou linshine optronics building).

Figure 4. Prismatic glazing on the atrium (Kushan Hushi electronics office building).

Although the field measurement results were collected through each hour from 9 AM to 5PM, according to the LEED requirement (USGBC, 2009), field measurement results were presented as 9 AM, 12PM, and 15PM for both sunny days and cloudy days in this paper.

4 FIELD MEASUREMENT RESULTS VS. SIMULATION DATA

The field measurement results of luminance levels within the ground floor were compared with Desktop Radiance (LBNL, 2016) simulation data for analysis. The sunny summer season results and cloudy autumn season were presented.

4.1 Summer sunny day's data

From Table 1, in sunny days at 9 AM, the exterior direct sunlight is majorly on the east side. The luminance levels on the west side are higher than the simulated ones with conventional glazing, especially at the areas close to west side windows.

At 12PM, the luminance levels on the west side are overwhelmingly higher than simulated data

Figure 5. Combined prismatic and conventional glazing (Shanghai green building technology incubator building).

Figure 6. Exterior of Sumin Decoration Office.

with conventional glazing, especially at the inner spaces where the luminance levels increased from 72% to 81%.

At 3PM, the luminance levels with prismatic glazing have a much better luminance uniformity distribution.

Figure 7. Interior of ground floor of Sumin Decoration Office.

Figure 8. Field measurement spots grid.

Simulated data showed that the luminance may reach 33137 Lux with direct sunlight and strong solar radiation at the space 4 m from west side windows, while only around 278 Lux at the space 20 m from windows. This may cause luminous discomfort and glare issues. In the field measurement, the corresponding luminance levels are 3089 and 490 Lux and thus the luminance contrast is reduced from 119 to 6.3 by using prismatic glazing (the cells in Table 1 marked as “X” mean there is a column so that no measurement was conducted at this point).

4.2 Autumn cloudy day's data

The data of autumn season cloudy days are presented in Table 2. The data are field measurement of the luminance levels on the east side of the building with prismatic glazing and simulated data with conventional glazing.

At 9 AM, the luminance levels with prismatic glazing are higher than the data with corresponding conventional glazing, except the data at spots 4 m from window, where the prismatic reflect light to the inner spaces and increase the luminance levels.

At 12PM, at spots 20 m from window with prismatic glazing, the luminance levels are 100% higher than the data with conventional glazing.

At 3PM, the luminance difference with prismatic glazing and conventional glazing is not significant. Although the luminance with prismatic glazing at spaces within 10 m to window

Table 2. Luminance levels with conventional and prismatic glazing (autumn cloudy days, east side).

are lower than the data with conventional glazing, at the inner space 20 m from windows, the luminance levels are still around 30% higher than the luminance with conventional glazing at the east side of the building. Tables 1 and 2 indicate that even prismatic glazing systems have better luminous performance on luminance level and luminance uniformity improvement than conventional glazing in sunny days; the system still work effectively in cloudy days, especially at the inner spaces.

5 CONCLUSIONS

This paper introduced the properties and advantages of prismatic glazing system. By comparing the indoor luminance levels measurement with prismatic glazing to Desktop Radiance simulation results with conventional glazing, we summarized the following features with prismatic glazing:

1. Prismatic glazing can provide better luminance levels and luminance uniformity for interior spaces, especially for inner spaces.
2. Prismatic glazing can avoid direct sunlight with conventional glazing by refracting light into inner spaces and thus can provide better luminous comfort environment for building occupants.
3. Both the incident light angle and intensity will affect the performance of prismatic glazing system for side window daylight.

4. Side window prismatic glazing systems can significantly improve the luminance levels for spaces over 10 m from windows.
5. Prismatic glazing can improve indoor luminance levels for both sunny days and cloudy days while the improvement of luminance levels is more obvious and effective in sunny days.

Mechanical analysis of rockburst considering the “locked in” stress in the driving face of the roadway

Xiao-Bin Yang, Xin-Xing Han, Hao Wang & Tian-Bai Zhou

School of Resource and Safety Engineering, China University of Mining and Technology (Beijing), Beijing, China

ABSTRACT: In the driving face of rock roadway in underground engineering, local dynamic phenomena or dynamic disasters often occur, such as rockburst, pressure bump, shock bump, etc, in which the occurrence of rockburst in the driving face is more frequent. In order to study its formation mechanism, a stress inclusion was assumed to exist in front of the driving face of rock roadway based on the “locked in” stress hypothesis and the mechanical model of driving roadway was simplified under consideration of “locked in” stress. Then based on the basic theory of elastic mechanics, the stress distribution laws of the rock around a stress inclusion under the combined stress of the overlying rock and the inclusion was deduced. By analyzing the stress distribution of the surrounding rock of the inclusion, a conclusion is obtained that when there is a certain distance from the driving head to the inclusion, the surrounding rock would be destroyed along the direction of the maximum principal stress. When the excavation work is close to the inclusion, the rock between destroy weak surfaces will be thrown to the excavation space causing dynamic disasters under the combined stress of the overlying rock and the inclusion and left the crater section of “V” type. The mechanical analysis results of this paper can provide theoretical support for the prevention of rockbursts in the excavation process of underground geotechnical engineering.

1 INTRODUCTION

Local dynamic phenomena or dynamic disasters such as rockburst, pressure bump and shock bump often take place in the driving face of rock roadway of underground engineering, in which, especially, rockburst occurs frequently. Rockburst is one of geological hazards about dynamic instability in the mining process of underground cavity under high geostress, the cave wall will arise stress differentiation due to unloading function caused by the excavation of surrounding rocks, the elastic strain energy stored in rock mass is released suddenly and at the same time the rock mass will generate burst loose, peeling off, ejection and even throwing phenomenon (Xu & Wang 2000). After the occurrence of rockburst, the crater section of “V” type often appears (Tan 1989, Feng et al. 2012, Chen et al. 2012, Zhou et al. 2015). Rockburst seriously affects the construction schedule of underground excavation works, damages the support and construction equipment and endangers the safety of the workers (Wang et al. 2003). However, due to the complexity of the rockburst phenomenon, it is still one of the worldwide difficult problems of rock mechanics (Zhang & Fu 2008). So far, many experts and scholars have studied the occurrence mechanism of rockburst, and made important

contributions. Xie (1993) used the method of fractal geometry to study the occurrence mechanism of rockburst. Ge and Lu (1999) simulated rockburst behavior and preliminarily discussed the rockburst phenomenon in the tunnel based on the concept of DDA (Discontinuous Deformation Analysis) and artificial jointing. Chen et al. (2009) simulated the failure process of rock under different conditions by laboratory experiments and put forward the index of judging the occurrence of rockburst from the point of view of energy. Qin et al. (2009) expounded the source, destination and the release reason of the energy of the deformation rockburst from the point of view of energy and put forward the principle of the energy storage of the rock mass. However, these research results can not explain the localization of dynamic disasters about rock and the formation of the pit of “V” type.

Considering the non homogeneity of rock mass and its complicated physical and mechanical environment, the “locked in” stress hypothesis proposed by Academician Tan in 1979 is an important theory about the occurrence of localization, the hypothesis thinks that the “locked in” stress is the cause of rock engineering disasters (Tan 1979, Tan & Kang 1980, Tan & Kang 1991). Academician Qian et al. discussed the existence of “locked in” stress from the point of view of

microstructure and deformation of rock (Qian et al. 2004, Qian & Zhou 2013). Academician Wang (2009) also considered that rock contained unreleased sealing stress. Yue (2014, 2015) put forward and tried to demonstrate the fluid inclusion was a specific, real, measurable and computable stress inclusion. He thought the inclusion was a specific form of existence and function of “locked in” stress and strain energy and further analyzed and discussed the fluid inclusions in the rock were the tensile or expanding volumetric force sources of the dynamic disasters of rock in underground engineering.

This paper thought that the inclusion in rock mass led to the occurrence of the localization disaster of rock, the combined function of the stress closed in inclusions and tectonic stress resulted in the local energy concentration in the rock mass. When excavating to a certain distance, the balance of the energy of the inclusions and the bearing capacity of the surrounding rock will be broken, the release of energy will form a dynamic phenomenon or dynamic disaster. Based on these, the paper simplified mechanical model of rock containing an inclusion in the driving face, theoretically deduced the stress distribution of rock mass under the combined action of “locked in” stress and overburden stress and verified the reason for the existence of the pit of “V” type after rockburst.

2 MECHANICAL MODEL OF THE ROCK MASS CONTAINING AN INCLUSION IN THE DRIVING FACE OF THE ROADWAY

In order to explain the localization characteristics of rockburst survival and the occurrence of the pit of “V” type after rockburst, a stress inclusion containing “locked in” stress was assumed to exist in the rock in front of the driving face in the process of advancing the roadway. The mechanical model was simplified under considering the interaction effect of the inclusion and the surrounding rock on the heading face. The stress distribution of rock containing an inclusion in the driving face of roadway was obtained by applying the basic theory of elastic mechanics.

Without consideration of the influence of the driving force and the horizontal stress, the mechanical model of rock mass containing an inclusion in the driving face of rock roadway was simplified as shown in Fig.1. In the model, we symmetrically chose a REV (Representative Elementary Volume) with a certain size containing a inclusion, the size of the REV was much larger than that of the inclusion. In consideration of the infinite length dimension (compared to the width of the roadway) perpendicular to the excavation direction of

the roadway, the model was simplified as a plane strain model, the vertical direction of the model was influenced by the vertical stress of the overlying strata and the size of the stress was assumed to be P ; The front of the roadway was considered to be infinitely extended along the driving direction and the driving head was a free surface, so it was approximately considered that the rock in front of working face was not affected by horizontal stress. The inclusion in rock mass was regarded as a sphere, which was a circle in the plane problem. The “locked in” stress in the conclusion is uniformly distributed internal pressure, which interacted with the surrounding rock and formed a mechanical model of relative equilibrium. Without taking into account the deformation and failure process of the inclusion, the effect of the “locked in” stress contained in the conclusion on the surrounding rock mass and the effect of the overlying strata on the REV were only considered. For this model, a stress conclusion with a radius of a and uniformly distributed internal pressure of q was assumed to exist in the middle of it; we took the center of the stress inclusion as the coordinate origin of the model, the direction horizontal to the right (the driving side of roadway) as the positive direction of x axis, the vertical downward direction as the positive direction of y axis.

Under consideration of the function of the “locked in” stress in the circular inclusion, the problem of the rectangular coordinate was converted into that of the polar coordinate by using the basic theory of elastic mechanics. The line boundary outside was transformed into the circle one. With the origin O as the center, a big circle with a radius of b much larger than a was made. The stress boundary of the model is: $\sigma_x = 0$, $\sigma_y = -P$, $\tau_{xy} = 0$ (σ_x , σ_y and τ_{xy} are the horizontal stress, vertical stress and shear stress respectively).

Figure 1. Simplified mechanical model of rock around the inclusion in the driving face of rock roadway.

By using the coordinate transformation formulas, the stress components of A in polar coordinates can be expressed as

$$\begin{cases} (\sigma_r)_{r=b} = \frac{\sigma_x + \sigma_y}{2} + \frac{\sigma_x - \sigma_y}{2} \cos 2\theta + \tau_{xy} \sin 2\theta = \\ -\frac{P}{2} + \frac{P}{2} \cos 2\theta \\ (\tau_{r\theta})_{r=b} = -\frac{\sigma_x - \sigma_y}{2} \sin 2\theta + \tau_{xy} \cos 2\theta = -\frac{P}{2} \sin 2\theta \end{cases} \quad (1)$$

where σ_r is the radial stress; $\tau_{r\theta}$ is the shear stress; θ is the polar angle; r is the pole diameter.

The mechanical model in the polar coordinate was changed into a model of thick wall cylinder with a inner diameter of a and a outer diameter of b , the stress boundary condition can be expressed as

$$\begin{cases} \text{inner boundary: } \begin{cases} (\sigma_r)_{r=a} = -q \\ (\tau_{r\theta})_{r=a} = 0 \end{cases} \\ \text{outer boundary: } \begin{cases} (\sigma_r)_{r=b} = -\frac{P}{2} + \frac{P}{2} \cos 2\theta \\ (\tau_{r\theta})_{r=b} = -\frac{P}{2} \sin 2\theta \end{cases} \end{cases} \quad (2)$$

According to the stress situation of the model and based on the superposition principle of elastic mechanics, the mechanical model of thick wall cylinder in polar coordinates was split into model I and model II, which were shown in Fig. 2 and Fig. 3 respectively.

The stress boundary condition of the mechanical model I can be expressed as

$$\begin{cases} \text{inner boundary: } \begin{cases} (\sigma_r)_{r=a} = -q \\ (\tau_{r\theta})_{r=a} = 0 \end{cases} \\ \text{outer boundary: } \begin{cases} (\sigma_r)_{r=b} = -\frac{P}{2} \\ (\tau_{r\theta})_{r=b} = 0 \end{cases} \end{cases} \quad (3)$$

Figure 2. Schematic diagram of mechanical model I.

Figure 3. Schematic diagram of mechanical model II.

The stress boundary condition of the mechanical model II can be expressed as

$$\begin{cases} \text{inner boundary: } \begin{cases} (\sigma_r)_{r=a} = 0 \\ (\tau_{r\theta})_{r=a} = 0 \end{cases} \\ \text{outer boundary: } \begin{cases} (\sigma_r)_{r=b} = \frac{P}{2} \cos 2\theta \\ (\tau_{r\theta})_{r=b} = -\frac{P}{2} \sin 2\theta \end{cases} \end{cases} \quad (4)$$

3 SOLUTION OF THE MECHANICAL MODEL OF THE DRIVING FACE CONTAINING AN INCLUSION

The model I and II in the polar coordinate above-mentioned were solved respectively, and the results were superimposed to obtain the stress situation of the original model.

1. Solution of the mechanical model I

The solution of model I is a axisymmetric plane problem, so set stress function as

$$\varphi = A \ln r + Br^2 \ln r + Cr^2 + D \quad (5)$$

where φ is a stress function; A, B, C, D are undetermined constants.

The stress components can be expressed as

$$\begin{cases} \sigma_r = \frac{1}{r} \frac{d\varphi}{dr} = \frac{A}{r^2} + B(1 + 2 \ln r) + 2C \\ \sigma_\theta = \frac{d^2\varphi}{dr^2} = -\frac{A}{r^2} + B(3 + 2 \ln r) + 2C \\ \tau_{r\theta} = \tau_{\theta r} = 0 \end{cases} \quad (6)$$

where σ_r is the radial stress; σ_θ is the circumferential stress; $\tau_{r\theta}$ and $\tau_{\theta r}$ are shear stress.

The mechanical model I is a axisymmetric model, in which $B = 0$. Substituting $B = 0$ into Eq.(6) yields

$$\begin{cases} \sigma_r = \frac{A}{r^2} + 2C \\ \sigma_\theta = -\frac{A}{r^2} + 2C \\ \tau_{r\theta} = \tau_{\theta r} = 0 \end{cases} \quad (7)$$

Combining Eq.(3) and Eq.(7), the solution can be expressed as

$$\begin{cases} A = \frac{(P-2q)a^2b^2}{2(b^2-a^2)} \\ 2C = \frac{2qa^2 - Pb^2}{2(b^2-a^2)} \end{cases} \quad (8)$$

Substitution of Eq.(8) into Eq.(7) yields

$$\begin{cases} \sigma_r = \frac{(P-2q)a^2}{2\left(1-\frac{a^2}{b^2}\right)} \frac{1}{r^2} + \frac{2q\frac{a^2}{b^2} - P}{2\left(1-\frac{a^2}{b^2}\right)} \\ \sigma_\theta = -\frac{(P-2q)a^2}{2\left(1-\frac{a^2}{b^2}\right)} \frac{1}{r^2} + \frac{2q\frac{a^2}{b^2} - P}{2\left(1-\frac{a^2}{b^2}\right)} \\ \tau_{r\theta} = \tau_{\theta r} = 0 \end{cases} \quad (9)$$

Because of $b \gg a$, Eq.(9) can be simplified as

$$\begin{cases} \sigma_r = \left(\frac{P}{2} - q\right) \frac{a^2}{r^2} - \frac{P}{2} \\ \sigma_\theta = \left(q - \frac{P}{2}\right) \frac{a^2}{r^2} - \frac{P}{2} \\ \tau_{r\theta} = \tau_{\theta r} = 0 \end{cases} \quad (10)$$

2. Solution of the mechanical model II

Stress function can be assumed as

$$\psi = f(r) \cos 2\theta \quad (11)$$

where ψ is a stress function; r is polar radius; $f(r)$ is only a function of r .

Compatible equation can be written in the following form

$$\nabla^4 \psi = \left(\frac{\partial^2}{\partial r^2} + \frac{1}{r} \frac{\partial}{\partial r} + \frac{1}{r^2} \frac{\partial^2}{\partial \theta^2} \right)^2 \psi = 0 \quad (12)$$

Substituting Eq.(11) into Eq.(12) produces

$$f(r) = Ar^4 + Br^2 + C + D \frac{1}{r^2} \quad (13)$$

where A, B, C, D are undetermined constants. Substituting Eq.(13) into Eq.(11) yields

$$\psi = \left(Ar^4 + Br^2 + C + D \frac{1}{r^2} \right) \cos 2\theta \quad (14)$$

The stress components can be expressed as

$$\begin{cases} \sigma_r = \frac{1}{r} \frac{\partial \psi}{\partial r} + \frac{1}{r^2} \frac{\partial^2 \psi}{\partial \theta^2} = -\left(2B + \frac{4C}{r^2} + \frac{6D}{r^4} \right) \cos 2\theta \\ \sigma_\theta = \frac{\partial^2 \psi}{\partial r^2} = \left(12Ar^2 + 2B + \frac{6D}{r^4} \right) \cos 2\theta \\ \tau_{r\theta} = -\frac{\partial}{\partial r} \left(\frac{1}{r} \frac{\partial \psi}{\partial \theta} \right) \\ = \left(6Ar^2 + 2B - \frac{2C}{r^2} - \frac{6D}{r^4} \right) \sin 2\theta \end{cases} \quad (15)$$

Combining Eq.(4) and Eq.(15), and make $a/b = 0$, the solution can be expressed as

$$\begin{cases} A = 0 \\ B = -\frac{P}{4} \\ C = \frac{Pa^2}{2} \\ D = -\frac{Pa^4}{4} \end{cases} \quad (16)$$

Substitution of Eq.(16) into Eq.(15) generates

$$\begin{cases} \sigma_r = \frac{P}{2} \left(1 - \frac{a^2}{r^2} \right) \left(1 - \frac{3a^2}{r^2} \right) \cos 2\theta \\ \sigma_\theta = -\frac{P}{2} \left(1 + \frac{3a^4}{r^4} \right) \cos 2\theta \\ \tau_{r\theta} = -\frac{P}{2} \left(1 - \frac{a^2}{r^2} \right) \left(1 + \frac{3a^2}{r^2} \right) \sin 2\theta \end{cases} \quad (17)$$

By adding Eq.(10) and Eq.(17), the stress solution of the original model can be expressed as

$$\begin{cases} \sigma_r = \left(\frac{P}{2} - q \right) \frac{a^2}{r^2} \\ -\frac{P}{2} + \frac{P}{2} \left(1 - \frac{a^2}{r^2} \right) \left(1 - \frac{3a^2}{r^2} \right) \cos 2\theta \\ \sigma_\theta = \left(q - \frac{P}{2} \right) \frac{a^2}{r^2} - \frac{P}{2} - \frac{P}{2} \left(1 + \frac{3a^4}{r^4} \right) \cos 2\theta \\ \tau_{r\theta} = -\frac{P}{2} \left(1 - \frac{a^2}{r^2} \right) \left(1 + \frac{3a^2}{r^2} \right) \sin 2\theta \end{cases} \quad (18)$$

4 RESULT ANALYSIS OF THE STRESS SOLUTION

In the absence of excavation or the working face is still far from the stress inclusion, the stress inclusion and the surrounding rock are in a stable equilibrium state. From the point of view of long-term stability and statistical significance, it is approximately considered that the stress q of the stress inclusion is equal to the vertical stress P of the original rock (Yue 2014, Yue 2015), so Eq.(18) can be simplified as

$$\begin{cases} \sigma_r = -\frac{P a^2}{2 r^2} - \frac{P}{2} + \frac{P}{2} \left(1 - \frac{a^2}{r^2}\right) \left(1 - \frac{3a^2}{r^2}\right) \cos 2\theta \\ \sigma_\theta = \frac{P a^2}{2 r^2} - \frac{P}{2} - \frac{P}{2} \left(1 + \frac{3a^4}{r^4}\right) \cos 2\theta \\ \tau_{r\theta} = -\frac{P}{2} \left(1 - \frac{a^2}{r^2}\right) \left(1 + \frac{3a^2}{r^2}\right) \sin 2\theta \end{cases} \quad (19)$$

Considering the stress situation of the rock in the driving face, combining the dynamic phenomenon of rockburst with the spatial failure structures of rock after disasters, based on the stress distribution of rock mass containing an inclusion, the occurring mechanism of the dynamic phenomenon of rock mass was analyzed. This paper used the maximum principal stress criterion to determine whether the rock mass containing an inclusion was broken and the rupture direction.

The calculation formula of maximum principal stress about the surrounding rock containing an inclusion in the polar coordinate can be expressed as

$$\sigma_{\max} = \frac{\sigma_r + \sigma_\theta}{2} + \sqrt{\left(\frac{\sigma_r - \sigma_\theta}{2}\right)^2 + \tau_{r\theta}^2} \quad (20)$$

Substituting Eq.(19) into Eq.(20) yields

$$\sigma_{\max} = \left\{ \left[\frac{P \cos 2\theta \left(\frac{3a^4}{r^4} + 1\right)}{4} - \frac{Pa^2}{2r^2} + \frac{P \cos 2\theta \left(\frac{a^2}{r^2} - 1\right) \left(\frac{3a^2}{r^2} - 1\right)}{4} \right]^2 + \frac{P^2 \sin^2 2\theta \left(\frac{a^2}{r^2} - 1\right)^2 \left(\frac{3a^2}{r^2} + 1\right)^2}{4} \right\}^{\frac{1}{2}} \quad (21)$$

$$\begin{aligned} & - \frac{P}{2} + \frac{P \cos 2\theta \left(\frac{a^2}{r^2} - 1\right) \left(\frac{3a^2}{r^2} - 1\right)}{4} - \frac{P \cos 2\theta \left(\frac{3a^4}{r^4} + 1\right)}{4} \\ & \left\{ \left[\sin 2\theta \left(\frac{6}{k^4} - \frac{4}{k^2} + 2\right) \right] \left[\frac{1}{2k^2} - \frac{\cos 2\theta}{4} \left(\frac{6}{k^4} - \frac{4}{k^2} + 2\right) \right] + \cos 2\theta \sin 2\theta \left(\frac{1}{k^2} - 1\right)^2 \left(\frac{3}{k^2} + 1\right)^2 \right\} \Big/ \\ & 2 \left\{ \left[\frac{\cos 2\theta}{4} \left(\frac{6}{k^4} - \frac{4}{k^2} + 2\right) - \frac{1}{2k^2} \right]^2 + \frac{\sin^2 2\theta}{4} \left(\frac{1}{k^2} - 1\right)^2 \left(\frac{3}{k^2} + 1\right)^2 \right\}^{\frac{1}{2}} + \frac{2 \sin 2\theta}{k^2} = 0 \end{aligned} \quad (22)$$

In Eq.(21), σ_{\max} is a function of r and θ . The angle of the extreme value of the principal stress of radius r can be solved when $\partial \sigma_{\max} / \partial \theta = 0$. Making $r=ka$, $\partial \sigma_{\max} / \partial \theta = 0$ can be simplified as Eq.(22).

Because Eq.(22) is a complex implicit function of k and θ , the curve of the implicit function when $k \in [1, 20]$ and $\theta \in [-90^\circ, 90^\circ]$ can be obtained by applying MATLAB software. Combining with Eq.(21), the data points of the curve of the maximum principal stress can be found and the relation between the angle of the maximum principal stress and the radius of surrounding rock was shown in Fig.4 through using Origin software. With the center of the stress inclusion as the origin O , The failure trace of surrounding rock close to the side of the mining space ($\theta \in [-90^\circ, 90^\circ]$) was shown in Fig.5.

From Fig.4, we can see that the angle of the maximum principal stress of the surrounding rock close to the inclusion ($r \leq 1.54a$) is located in the direction of $\pm 90^\circ$, with the increase of the radius, the angle θ of the maximum principal stress gradually decreases and the reduced amplitude of the angle gradually decreases until the angle is approximate constant. When there is a certain distance from the driving head to the inclusion body, according to the maximum principal stress criterion, the surrounding rock containing an inclusion will be destroyed along the direction of the maximum principal stress under the combined stress of the overlying rock and the inclusion, the extended and perforative cracks will form a structural section of "V" type in the upper and lower part of the inclusion which was shown in Fig.5.

When the excavation work is close to the inclusion, due to the loss of the binding effect of the rock close to the side of the mining space, the rock between destroy weak surfaces would be thrown to the excavation space causing dynamic disasters under the combined stress of the overlying rock and the inclusion and left the blasting crater of "V" type, which is consistent with the appearance of "V"-shaped section after rockburst in the process of spot excavation.

Figure 4. Relation between the angle of the maximum principal stress and the radius of surrounding rock.

Figure 5. Failure trace line of surrounding rock.

5 CONCLUSIONS

Considering the localization problem of dynamic disasters and the formation of the pit of “V” type after disasters in the excavation process of rock roadway, based on the “locked in” stress hypothesis and the basic theory of elastic mechanics, Through theoretical analysis, the following conclusions were obtained:

1. Assuming that an inclusion is existed in the rock mass in the driving face, combining with the stress situation of the surrounding rock containing a inclusion, the mechanical model of the surrounding rock containing a inclusion is established through theoretical analysis.
2. Based on the basic theory of elastic mechanics, the stress distribution law of the surrounding rock containing an inclusion is obtained by theoretical derivation.
3. By applying the maximum principal stress criterion, the distribution law of the maximum principal stress and the destruction direction and trajectory about the surrounding rock containing an inclusion are gained, which explain the formation of the blasting crater of “V” type after the occurrence of the dynamic disaster.

Study on the identification of major safety defects in port engineering

Jianhua Peng

China Academy of Transportation Sciences, Beijing, China

ABSTRACT: At present, no regulation or standard has been developed for the identification of major safety defects in port engineering in China, as well as there is no common cognition for the identification of major safety defects in port engineering, which varies widely. In this paper, three research methods (accident deduction, risk assessment of safety defects, and expert consultation) are proposed for the identification of major safety defects in port engineering, which provide technical support to the development of standard for the identification of major safety defects in port engineering. By using the above three methods, the list of major safety defects in port engineering is put forward.

1 INTRODUCTION

The impacts of different safety defects on the safe production are not the same. In order to distinguish them and to find the focus of prevention and control of safety defects, it is usually needed to classify the safety defect and identify the major safety defect. However, there is no regulation or standard developed for the identification of major safety defect in port engineering in China, and there is no common cognition on the identification of major safety defect in port engineering, which varies widely. To a certain extent, it has affected the investigation and management of safety defect of port engineering in China. Therefore, it is necessary to study the identification method of major safety defect and propose the list of major safety defects.

2 DEFINITION OF MAJOR SAFETY DEFECT IN PORT ENGINEERING

From the viewpoint of accident statistic data of China port engineering in recent years (see Table 1), the number of deaths per year is generally no more than 10. Major safety defect is often defined as the safety defect, which may cause more than 10 deaths. Therefore, the definition of major safety defect in port engineering needs to be different from the former.

With reference to classification of safety defect in the “Interim provisions on the management of safety defect”, major safety defect in port engineering can be defined as the safety defect for which hazard is great, rectification is difficult, all or part of the construction should stop, and rectification needs a period of time. Great hazard refers to the death or significant property damage. Difficult

Table 1. Accident statistic data of China port engineering (2005–2013).

Year	Number of accidents	Number of deaths
2005	2	2
2006	6	8
2007	3	3
2008	2	2
2009	4	4
2010	2	2
2011	3	3
2012	1	8
2013	1	2

rectification refers to the rectification requiring high costs or a long time.

3 METHOD FOR THE IDENTIFICATION OF MAJOR SAFETY DEFECT IN PORT ENGINEERING

3.1 Accident deduction

An accident is caused by safety defect. By means of accident deduction, analyzing the cause of accidents (major accidents) is an effective method to identify the major safety defect. Select 24 port engineering accidents (2005–2013) to analyze their causes and perform statistical analysis of deductive results. Distribution of safety defect in port engineering is shown in Table 2.

In addition, both highway engineering and port engineering are traffic construction projects, which are more common in safety management. Therefore, select some typical highway engineering major accidents to analyze their causes, such

Table 2. Distribution of safety defect in port engineering (24 port engineering accidents).

Type of safety defect in port engineering	Occurrence frequency
Workers do not use protective equipment	7
Violation of operating procedures	6
Violation in commanding	4
Risk-taking operation	3
Absent responsibility of the guardianship	3
Employees do not receive safety education and training	2
Special operation personnel do not obtain the certificate of operation qualification	2
Absent responsibility of safety technical disclosure	2
No regular safety check	2
Wire rope defect	2
Operate or stay under lifting object	2

as Dongjiashan tunnel project “12.22” major gas explosion accident, Tuojiang bridge “8.13” special major collapse accident, Jianshan bridge collapse accident, and Meliet interchange ramp bridge falsework collapse accident. According to the accident deduction data, the main safety management defects are shown below:

- Disordered safety management;
- Illegal subcontracting;
- Absent responsibility of supervision personnel;
- Without a license;
- Without training;
- Unauthorized alteration of construction scheme;
- Unreasonable schedule;
- Absent responsibility of supervisor.

3.2 Risk assessment of safety defect

Risk assessment of safety defect is a direct research method for the identification of major safety defect. Risk assessment of safety defect from two aspects of the possibility of the accident and the possible consequence is expressed as:

$$R = f(p, s) \tag{1}$$

where R is the risk of safety defect; p is the possibility of the accident; and s is the possible consequence.

The specific risk assessment methods include risk matrix, LEC, and so on. The risk matrix model of safety defect is shown in Figure 1.

Safety defect in the first quadrant, which can easily lead to an accident and huge loss, can be identified as the major safety defect. Of course, this applies only to a rough analysis. It is more scientific to draw the risk contour lines on the

Figure 1. Risk matrix model of safety defect.

“risk matrix”. The upper right area of contour in Figure 1 is the distribution of major safety defect.

On the basis of the risk of safety defect, considering the difficulty of the rectification, the major safety defect is determined as:

$$M = f(p, s, d) \tag{2}$$

where M is the decision value of safety defect; p is the possibility of the accident; s is the possible consequence; and d is the difficulty of the rectification.

At this point, the risk matrix is extended to 3D risk map, where p , s , and d are located in x , y , and z axes, respectively, and risk contour lines are extended to contour plane.

However, considering the three indicators make it is difficult to determine the major safety defect, a simplified method is used to determine the risk of safety defect (R) through coupling of p and s first and then the decision value of safety defect (M) through coupling of R and d (see Equation 3):

$$M = f(p, s, d) = f(p \times s, d) = f(R, d) \tag{3}$$

where M is the decision value of safety defect; p is the possibility of the accident; s is the possible consequence; d is the difficulty of the rectification; and R is the risk of safety defect.

Rating criteria of p , s , and d are shown in Table 3.

The numerical distribution of R (p, s) is shown in Table 4.

Classification criteria of R (p, s) is shown in Table 5.

Taking into account the correlation between the accident and safety defect, the risk of safety defect should be priority to the rectification difficulty of safety defect. Therefore, when the risk of safety defect is very high, regardless of the difficulty of rectification, it should be regarded as a major safety defect. The risk matrix of R and d is shown in Table 6.

The lower right corner of Table 6 shows the distribution of major safety defect, including 10 types

Table 3. Rating criteria of p , s , and d .

Numerical value ^①	p ^②	s ^③	d ^④
1	Very low possibility	Slight consequence	Very easy

4	High possibility	Severe consequence	Difficult
5	Very high possibility	Extraordinarily severe consequence	Very difficult

Notes: ^①Values 1, 2, 3, 4, and 5 refer to different degrees of state. ^②Very low possibility = less than 10%; Low possibility = 10–30%; Medium possibility = 30–70%; High possibility = 70–90%; Very high possibility = more than 90%. ^③Slight consequence = minor injury but not be in hospital, or property damage below 20,000 RMB; Common consequence = minor injury and be in hospital, or property damage 20,000–100,000 RMB; Great consequence = seriously injured but not disabled, or property damage 100,000–200,000 RMB; Severe consequence = seriously injured and disabled, or property damage 200,000–500,000 RMB; Extraordinarily severe consequence = death or property damage more than 500,000 RMB. ^④Very easy = rectification time less than 3 days, or rectification fund less than 20,000 RMB; Easy = rectification time 3–7 days, or rectification fund 20,000–50,000 RMB; Medium = rectification time 7–15 days or rectification fund 50,000–100,000 RMB; Difficult = rectification time 15–30 days or rectification fund 100,000–200,000 RMB; Very difficult = rectification time more than 30 days or rectification fund more than 200,000 RMB.

Table 4. Numerical distribution of $R(p,s)$.

p	s				
	1	2	3	4	5
1	1	2	3	4	5
2	2	4	6	8	10
3	3	6	9	12	15
4	4	8	12	16	20
5	5	10	15	20	25

Table 5. Classification criteria of $R(p,s)$.

Numerical value	R (Folding point)	Description of risk
(1,2,3,4)	(1')	Very low risk
(5,6,8,9,10,12)	(2')	Low risk
(15,16)	(3')	Medium risk
(20)	(4')	High risk
(25)	(5')	Very high risk

Table 6. Risk matrix of R and d .

R	d				
	1	2	3	4	5
1'	—	—	—	—	—
2'	—	—	—	—	—
3'	—	—	—	3' × 4	3' × 5
4'	—	—	4' × 3	4' × 4	4' × 5
5'	5' × 1	5' × 2	5' × 3	5' × 4	5' × 5

Table 7. Determination of major safety defect (an example).

Safety defect	Without use of personal protective equipment (safety belt) in the process of aerial work
$p = 5$ (very high possibility)	$s = 5$ (extraordinarily severe consequence)
$R(p \times s) = (25)/(5')$	$d = 1$ (very easy)
$M = (R, d) = 5' \times 1$	

of state: (3' × 4), (3' × 5), (4' × 3), (4' × 4), (4' × 5), (5' × 1), (5' × 2), (5' × 3), (5' × 4), and (5' × 5). Take the safety defect “Without use of personal protective equipment (safety belt) in the process of aerial work” as an example. It can lead to an accident easily, so the possibility of the accident is very high and the value of p is 5. It can lead to casualties, the possible consequence is extraordinarily severe, and the value of s is 5. It is easy to rectify, the value of d is 1. Its decision value in the major safety defect determination is shown in Table 7.

M is located in the area of major safety defect. Therefore, the safety defect “Without use of personal protective equipment (safety belt) in the process of aerial work” is determined as a major safety defect.

3.3 Expert consultation

Through consulting with experts in the field of port engineering construction and safety production extensively and understanding their views on the major safety defect in port engineering, the list of major safety defect is revised constantly. In the application of this method, designing some questionnaires or conducting in-depth communication on specific issues can ensure that expert consultation is more efficient.

4 LIST OF MAJOR SAFETY DEFECT IN PORT ENGINEERING

By using the above three methods, the list of major safety defect in port engineering (Table 8) is put forward.

Table 8. List of major safety defect in port engineering.

Type	Major safety defect
Human unsafe behavior	<ol style="list-style-type: none"> 1. Without use of personal protective equipment in aerial work, water operation, etc. 2. Violation of operating procedures or violation in commanding in water and underwater operation, blasting operation, etc. 3. Risk-taking operation, such as working at height when the wind degree is greater than 6
Unsafe physical condition	<ol style="list-style-type: none"> 1. No or improper protective measures 2. Defect of equipment, facilities, accessories, and material 3. No obvious safety warning signs are set up.
Adverse environmental conditions	<ol style="list-style-type: none"> 1. Inadequate lighting in excavation and support of foundation pit, lifting operation, etc. 2. The construction resident set in debris flow area, landslide, etc.
Defects in management	<ol style="list-style-type: none"> 1. Disordered safety management 2. The safety management personnel of the construction unit has not passed the examination 3. Special operations personnel do not obtain the certificate of operation qualification 4. Illegal subcontracting 5. Unauthorized alteration of construction scheme 6. Unreasonable schedule 7. The safety production cost is less than 1.5% of the engineering cost 8. Absent responsibility of safety technical disclosure

5 CONCLUSIONS

1. From the viewpoint of accident statistic data of China port engineering in recent years and with reference to classification of safety defect in the “Interim provisions on the management of safety defect”, major safety defect in port engineering is defined.
2. Three research methods (accident deduction, risk assessment of safety defect, and expert consultation) for the identification of major safety defect in port engineering are proposed.
3. By using the above three methods, the list of major safety defect in port engineering is put forward, including four types of human unsafe behavior, unsafe physical condition, adverse environmental conditions, and defects in management.

Investigating the impact of greenery on the driver's psychology at a freeway tunnel portal

D.Q. Xiao, Z.W. Shen & X.C. Xu

School of Civil Engineering and Mechanics, Huazhong University of Science and Technology, Wuhan, Hubei, China

ABSTRACT: The great environment difference inside and outside freeway tunnels is the major cause for a higher accident rate than that in other tunnel sections. To assess the psychology of drivers because of load and distract factors form the traffic environment, investigation and analysis of heart rate of drivers was carried out in this paper. By using the illumination meter and dynamic electrocardiograph, based on a mass of experimental data, we found the quantitative relationship between the greenery form and the drivers' heart rate changes. The results showed that: following the deepening process of greenery level, illuminance gap narrowed and greenery on the tunnel portals can effectively reduce the illumination difference inside and outside the tunnel. Drivers are mentally released because of the greening settings when traveling in a tunnel section.

1 INTRODUCTION

With the rapid development of freeway construction in China, traffic accidents occur everywhere especially at the tunnel portal. According to statistics in China, the frequency of accidents near the entrance and exit of tunnels is much higher than that in the interior parts, as the amount of accidents that happened within 200–400 m from the entrance accounts for 70% of the total (Ma Z.L. et al. 2009). This type of crash tends to be more severe, increasing the probability of fatalities or incapacitating injuries.

The cause of freeway tunnel accidents is extremely complex and can be generally summarized to be caused by three factors: the driver, the vehicle, and the environment. From a subjective aspect, the driver, as an operator of the vehicle, a road user, and an experimenter of the environment, is the primary factor affecting the traffic safety. The vehicle condition and outer environment stimulation are also important for a secure trip.

From the viewpoint of objective conditions, freeway tunnel is narrow and relatively closed. Compared with the general freeway sections, the main variation of tunnel sections is the sudden change in illumination. Significant contrast between darkness and brightness increases the visual and psychological burden on drivers. In the daytime, drivers need to adapt to sudden darkness when entering tunnels and sudden brightness when leaving tunnels. At night, drivers need to suffer from bright adaptation when entering and dark adaptation when leaving tunnels. To overcome this visual adaptation issue, in

addition to narrowing the illumination gap inside and outside the tunnel by tunnel lighting, reasonable greenery configuration can also play an important buffering role in sudden change of light; however, this method was rarely applied in tunnel landscape.

Therefore, the aim of this study is to investigate the impact of greenery on driver's psychology located at freeway entrance/exits. With the implementation of illumination meter and dynamic electrocardiograph into abundant tests, the driver's physiological and psychological indicators and environmental indicators were achieved; the impact of greenery on drivers' psychology was investigated via quantitative analysis methods; and the application of greenery to reduce tunnel accidents was discussed.

2 LITERATURE REVIEW

The variations of physiological and psychological characteristics of drivers describe the impact of environment changes on drivers when approaching and leaving the tunnels. Many studies have investigated this problem all over the world.

Initially, Groeger and Rothengatter (1998) studied the cognitive process and social psychology of drivers. Byung Chan Min et al. (2002) found that subjects feel tension under the high-speed driving condition, and as the speed of a car increased, the sympathetic nervous system of passengers became more highly activated. Hoogendoorn (2010) evaluated the mental load of drivers in the perception process of traffic accidents with the application of

the driver's physiological indices such as breathing and heart rate. Bucchi et al. (2012) investigated the construction process of driver personality with psychological methods. In this way, the authors provided useful indications for the design of safe roads.

Other research efforts have been made to tunnel lighting and road greening. The lighting specification of China (2000) stipulated detailed parameters of luminosity of tunnels in daytime but ignored the fact that drivers would suffer from different visual disturbances between day and night. International Commission on Illumination (2004) published "Guide for the Lighting of Road Tunnels and Underpasses" in 2004. Kircher and Ahlstrom (2012) investigated how driving performance was influenced by tunnel design factors and proposed that tunnel design and illumination have some influence on the drivers' behavior, but visual attention given to the driving task is the most crucial factor. Wei et al. (2012) explored the relationship between night lighting and driving safety in long express tunnels. On the basis of real road experiments and fuzzy assessments, this study showed that night luminosity was too high and should be controlled below 9 Lx.

In China, tunnel entrance and exit are regarded as black points of traffic accident. Wang et al. (2010) analyzed the illumination design in tunnels, especially at entrance and exit. Du et al. (2007, 2013) investigated the pupillary change of the driver at the entrance and exit of highway tunnel. The purpose of these studies was to analyze the phenomena of visual turbulence during light and dark adaption and the conversion duration for visual turbulence. From the viewpoint of content and methods, this study attributed pupil area variation completely to drivers' nervousness and ignored the impact of illumination and dark adaptation time. Most of the developed countries have their own technical standards on highway greening design in highway engineering. In 1965, the United States enacted the Highway Beautification Act, and Japanese government issued the Greening Technology Benchmark in 1976. As mentioned in Flexibility in Highway Design (2000) published by the federal highway administration, an important aspect of highway landscape design is the handling of the trees. The AASHTO (1996) put forward three suggestions about landscape design and plant configuration, the first and most important one was that drivers should benefit from the beauty and safety vegetation.

To sum up, previous studies have showed that the driver's visual adaptation difficulty caused by sharp variation of luminance is the prime reason of accident black spot at tunnel entrance. Although some of them mentioned the improvement of light environment by greening, the support of driving experiments is lacked (Pan X.D. et al. 2001, Xiao D.Q. 2011, Zhang Q & Chen Y.R. 2005).

3 METHODOLOGY

3.1 Experiment design

Because of the particularity of tunnel sections and the differences in tunnel illumination, length, and design, drivers will suffer visual adaption generated by physical and psychological reactions.

3.1.1 Vehicle selection

We select Volvo XC-60 as the experimental vehicle, which can fully meet the experimental demand for its performance. Besides, drivers are familiar with the vehicle's condition, which could lower the possible heart rate fluctuation caused by the experimental car.

3.1.2 Tunnel selection

The experimental tunnel sections belong to the Huring Freeway in Hubei Province of China (also known as Huyu Freeway, Hubei). About 30 typical tunnels were selected, whose lengths are between 186 and 9,000 m. The speed limits of these tunnels range from 60 to 80 km.h⁻¹. All the tunnels are one-way traffic without interference from vehicles in the other way, and all the measurement was done in a normal traffic flow.

3.1.3 Participants

Two male drivers, aged 34 and 22, with different driving experience and a corrected visual acuity above 5.0 were selected. Both of them are not familiar with the experiment sections.

3.1.4 Apparatus

In this experiment, Qingxin L8 Dynamic Electrocardiograph (Shenzhen Qingxin Electronics co., LTD.) is selected to record drivers' physiological data (mainly heart rate data) when traveling through tunnel sections, UNIT UT382 Series Illumination Meter produced by UNI-TREND Technology (China) Limited for illumination data, and Driving Recorder for the driving environment.

3.2 Experimental measurement factors

3.2.1 Tunnel illuminance

The illumination device is capable of storing and analyzing data in real time; moreover, it can transfer data to a PC for analysis by specialized software UT382 Interface Program. The experiment was carried out in daytime on a cloudy day.

Illuminance Coefficient here is defined to assess the illuminance variation, and the specific equation is as follows:

$$\Delta I = \frac{I_{out} - I_{in}}{T} \quad (1)$$

where ΔI is the illuminance Coefficient; I_{out} is the mean illumination value over time interval (5 s)

before the vehicle entered the tunnels; I_{in} is the mean illumination value over time interval (5 s) after the vehicle entered the tunnels; and T is a time interval (10 s) before and after the vehicle entered the tunnels.

3.2.2 Driver's electro cardio data

During the driving cognitive process, the driver would generate psychological and physiological changes due to external environmental stimuli. When the environment is relatively simple and the information density is low, the driver will be in a relatively relaxed state with a regular heart rate. Contrarily, the driver will be more intense and the heart rate is relatively high under a complex environment. Therefore, continuous heart rate detection can be used to assess the workload of drivers.

Compared with Heart Rate (HR), Heart Rate Growth (HRG) is a more practical index to evaluate drivers' psychological changes. The specific calculation is shown in the following formula:

$$HRG = \frac{HR1 - HR2}{HR2} \times 100\% \quad (2)$$

where HRG is the heart rate growth; HR1 is the heart rate when driving; and HR2 is the heart rate under normal condition. This paper focused on the impact on drivers when driving in a particular tunnel road, so the formula (1) can be improved as follows:

$$N_j = \frac{n_j - \bar{n}}{\bar{n}} \times 100\% \quad (3)$$

where N_j is the heart rate growth when driving in moment j (%); n_j is the heart rate when driving in moment j (bpm); and \bar{n} is the average heart rate when driving in the freeway (bpm).

4 DATA COLLECTION AND PROCESSING

The experimental tunnels were classified into three types to perform a better analysis: nongreenery tunnels, unilateral greenery (or high cut) tunnels, and bilateral greenery (or high cut) tunnels. Thus, we selected 12 eligible tunnels in three different greenery forms from 30 experiment tunnels.

Average Heart Rate Growth (AHRG), used to describe the impact of the greenery, is defined as the average heart rate growth during this specified 20 s: 10 s before and after the moment when the HRG reaches a peak. The definition of AHRG made the heart rate changes of drivers more obvious and easier to describe during the adaption period.

4.1 Illumination variation

In general, the illuminance outside the tunnel can reach tens of thousands of lux, but only dozens of lux inside on a sunny day. Three representative tunnels in different forms were selected. The luminosity variation pattern could be seen in Figure 1. Graph (a) is the illumination variation curve of nongreenery tunnel, graph (b) belongs to unilateral

(c)

(d)

Figure 4. Drivers' psychology variation in bilateral greenery tunnels.

greenery tunnel, and graph (c) corresponds to bilateral greenery tunnel.

Seen from the three graphs above, all of the three tunnels have the similar illumination variation. The luminosity inside the tunnel was much lower than that at both ends. The illumination was enhanced in entrance and exit, which could reach to several thousands.

4.2 Drivers' psychological variation

We selected 12 eligible tunnels in three different greenery forms and drew the diagram on how drivers' heart rate changes over time. As shown in Figures 2, 3, and 4, the solid line represents the location of the tunnel entrance, and the dotted line represents the tunnel exit. Average heart rate of driver A is 77 bpm, whereas that of driver B is 93 bpm. Graphs (a) and (b) show the heart rate variation curves of driver A, and graphs (c) and (d) show the corresponding figures of driver B.

Driver's heart rate increase rapidly when approaching the tunnel entrance and then reaching a HRG peak (Figs. 2, 3, and 4). After leaving the tunnel, the HRG also reached a peak, which is lower than the first peak when entering. The peak HRG of three types of tunnels varies from each other. For nongreenery tunnels, all of the peak HRG values are over 12% (Fig. 2). For unilateral greenery tunnels, the peak HRG is more than 8% but less than 12% (Fig. 3) and for bilateral greenery tunnels the peak HRG is more than 6% but less than 8% (Fig. 4).

5 RESULTS

Illuminance coefficient of different types of tunnels can be figured out and exhibited in Table 1. By comparison, we found that the illuminance coefficient decreases with the development of greenery at entrance, particularly in unilateral greenery tunnels where the illuminance factor drops by 56.6% compared with nongreenery tunnel; in the bilateral greenery tunnel, the illuminance factor declines by 68.3%.

The AHRG indicators are figured out in Table 2. As the greenery develops, both drivers' AHRG show a downward trend, drivers are mentally released when traveling in a tunnel section with better greening. Besides, while approaching the entrance of a tunnel, the drivers' heart rate rises rapidly and levels out after a peak; interestingly, the heart rate increases less near the exit. There is a tendency in each curve that the HRG descends over time. It indicates that drivers are more intense at entrance than at exit, as dark adaption is more difficult than light adaption.

Table 1. Illuminance coefficient of different tunnel forms.

Tunnel form	Luminance outside I_{out} (lx)	Luminance inside I_{in} (lx)	Luminance coefficient ΔI
Nongreenery	7361	2247	511.4
Unilateral greenery	3846	1625	222.1
Bilateral greenery	4023	2400	162.3

Table 2. Drivers' AHRG indicator when travelling in tunnels.

Tunnel form	Driver	Tunnel length (m)	AHRG (%)
Nongreenery	A	707	9.03
		2722	6.34
	B	1141	4.36
		672	8.05
Unilateral greenery	A	286	7.21
		1182	4.09
	B	1570	3.96
		890	6.61
Bilateral greenery	A	1080	3.18
		751	2.99
	B	724	3.38
		900	3.55

6 CONCLUSION AND FUTURE WORK

This study investigated the impact of greenery free-way tunnel on driver's psychology, and statistics of heart rate and environmental illumination at tunnel portals has been recorded and quantitatively analyzed. With the implementation of illumination meter and dynamic electrocardiograph into abundant tests, we collected the driver's physiological and psychological indicators and environmental indicators, achieved the effect of studying the impact of greenery on drivers' psychology via quantitative analysis methods, and discussed the possibility of the application of greenery to reduce the number of tunnel accidents. The following conclusions are drawn:

1. Greenery in tunnel portals can decrease the illuminance variances, moderate the illuminance difference, and help drivers be easier to adapt to dark and light variation; with the deepening of greenery, the tunnel illuminance coefficients of three greenery forms decreased gradually; the illuminance factor of nongreenery tunnel has reduced 68.3% compared with the data of bilateral greenery tunnel.

2. Greenery in portal dramatically alleviate drivers' nervousness and ensure traffic safety; with the greenery promoting, the heart rate of two drivers rise less, especially in bilateral greenery tunnel, where the AHRG has fallen by 52.1% averagely. On the basis of the drivers' psychological analysis in three different greenery tunnel, we could learn that greenery at portal can effectively ease the anxiety of drivers through the tunnel, thereby improving traffic safety.

In this paper, the information of illumination and psychology in expressway tunnels was obtained according to Chinese traffic condition and characteristics of drivers. The conclusion was verified by sufficient driving tests in Hurong Freeway. In fact, on the one hand, the greenery in expressway tunnel entrance and exit is not only a type of road landscape design or ecological restoration design, but it can also play a role like sunshade or light-abatement grille, which could remove dark and light adaptation. For example, under the premise of not shielding the sightline of driving, tall and leafy arbors with a large crown diameter should be planted in a higher density in the tunnel entrance and exit sections. The planting space and height change in a transitional way, that is, along the direction of the vehicle travelling toward the tunnel, gradually narrowing planting space and improving planting height. On the other hand, green plants can relieve tension while driving, thus making the driver feel safer. Therefore, for the sections that could make drivers tense and nervous such as the tunnel sections, greenery should be used to eliminate or reduce the fear and anxiety of drivers to a certain extent, thus improving traffic safety.

However, it would be better to include other traffic information such as speed, flow, and lane-changing behaviors because illumination and greening may not be the only reason for increasing the heart rate. And as a result, we should have compared crashes with greening to find out how greening affects crash occurrences. Therefore, in future studies, we will conduct more tests to take other factors, such as speed, flow, and position of the sun with respect to the tunnel entrance, into account.

Modeling two-dimensional rubble mound breakwater using dolos at armor layer and geotube at the core layer

O.C. Pattipawaej & H.J. Dani

Civil Engineering Department, Universitas Kristen Maranatha, Bandung, Jawa Barat, Indonesia

ABSTRACT: Coastal protection structure is used to protect the coast against erosion that is usually determined by the availability of materials at or near the job site, the sea conditions, water depth, and the availability of equipment for the implementation of the work. The purpose of this study is to conduct experimental research in the laboratory to obtain the rubble-mound breakwater design optimum and tools before it is applied directly in the field to reduce the risk of failure of construction. This study is conducted for laboratory testing of a two-dimensional rubble-mound breakwaters model with dolos at armor layer and geotube at core layer using regular wave and three variations of slope in front of the structure facing seaward, that is, 1:1.5, 1:2, and 1:2.5. The water level varies for the conditions of non-over-topping, over-topping, and submerged. The two-dimensional rubble-mound breakwaters model with the slope in front of the structure facing seaward 1:2.5 shows the most stable rubble-mound breakwater model.

1 INTRODUCTION

Indonesia as an archipelago country does not escape the impact of global warming due to the sea level rise. The impact of sea level rise results in the coastline change due to erosion and/or abrasion. In addition to global warming, forces of nature such as waves, currents, tides, and construction errors caused major damage to the existing breakwater. In general, construction fault lies in the tilt angle of the building, a thick layer, and heavy rock, in addition to other factors. This can lead to the collapse of the breakwater.

Breakwater is a structure on the coast to protect the coast against erosion. The type of breakwater structure used is generally determined by the availability of materials in or near the work site, the sea conditions, water depth, and the availability of equipment for the implementation of the work. Rubble-mound breakwaters use structural voids to dissipate the wave energy. Rock or concrete armor units on the outside of the structure absorb most of the energy, while gravels or sands prevent the wave energy's continuing through the breakwater core.

Construction of a breakwater on the field will take considerable time and cost. A laboratory test using a physical model is proved to be effective in avoiding such costs before constructing breakwater in the field. In this study, we will discuss the optimization of two-dimensional model of the rubble-mound breakwater using dolos at the armor layer

and geotube at the core layer, because it has a high permeability that balances the water pressure. Wave run-up will be included in determining the peak elevation breakwater.

2 COASTAL PROTECTION STRUCTURE

Coastal structures are intended to protect shoreline or navigation channels from the effects of waves and other hydrodynamic force (Fith, et al., 2014). Design of coastal structures must consider a range of wave heights and periods combined with water level variations. The most common types of coastal structures are breakwaters. Breakwater is a structure constructed on coasts as part of coastal protection from the effects of both weather and longshore drift. Breakwater reduces the intensity of wave action in inshore waters and thereby reduces coastal erosion. Breakwaters may also be small structures designed to protect a gently sloping beach and placed at a distance of 1–300 feet offshore in relatively shallow water. Breakwaters can be constructed with one end linked to the shore, in which case they are usually classified as sea walls; otherwise, they are positioned offshore from as little as 100 m up to 300–600 m from the original shoreline. The types of breakwaters are rubble-mound structures, impermeable sloping structures, vertical wall structures, composite

Figure 1. Cross section of a typical rubble-mound breakwater.

structures, floating structures, and pneumatic and hydraulic breakwaters (Hughes, 1993).

Rubble-mound structure is used extensively for breakwaters, jetties, revetments, seawalls, and wave absorber. Rubble-mound structures have a core of quarry-run stones, sand, slag, or other suitable materials protected from waves action by one or more stone under layers and a core layers of relatively large, selected quarry stones or specially shaped concrete armor units (Hudson, 1959). Rubble-mound breakwaters use structural voids to dissipate the wave energy. Rock or concrete armor units on the outside of the structure absorb most of the energy, while gravels or sands prevent the wave energy's continuing through the breakwater core. The integrity of a rubble-mound structure is primarily a function of the stability of the individual armor units that form the seaward face of the structure. In shallow water, revetment breakwaters are usually relatively inexpensive. As water depth increases, the material requirements and, hence, costs increase significantly. Figure 1 shows a typical cross section of a rubble-mound breakwater.

3 STABILITY OF RUBBLE-MOUND BREAKWATER

An important aspect in the design of a rubble mound is its stability to wave attack. Three aspects of the effect of waves on rubble-mound breakwater are wave run-up, overtopping, and transmission (Figure 2). Run-up is defined as the vertical height above still water level to which waves incident upon a structure can be expected to travel up the face of the structure. Wave run-up is important in defining both the amount of wave energy transmitted over and through permeable rubble-mounds and also the quantity of water that may be expected to overtop the structure (Hur, Lee, and Cho, 2012).

Figure 2. Waves on rubble-mound breakwater.

4 EXPERIMENT SETUP AND PROCEDURE

The experimental test was conducted on the wave flume at Laboratory Balai Pantai, Ministry of Public Works in Buleleng, Bali, Indonesia. The wave flume is 40 m long, 0.6 m wide and 1.2 m high. It is equipped with a piston-type wave generator that produces regular wave. Figure 3 shows three wave probes that are installed in the wave flume.

Simulation of the wave generated by the wave maker uses regular wave model. The model of rubble-mound breakwater is constructed with the seaward face at slopes 1:1.5, 1:2, and 1:2.5 using an armor layer composed of individual units of weight W and density ρ . The armor units use dolos with the average weight of 265 g, relative density of 2.209 g/cm³, and K_d of 8. The dolos is randomly placed at the armor layer (CIRIA, 2007). The core layer is set to be stable by using geotube. Three variations of slopes facing the seaward side of the breakwater model are applied: 1:1.5, 1:2, and 1:2.5. The wave period is 2 s. The wave height for different slopes of breakwater models can be seen in Table 1.

The water level tests are conducted at four different water levels: 38 cm (mean low water level), 54 cm (mean high water level), 63 cm (crest elevation), and 70 cm (submerged). The structure is assumed to be founded on an impermeable bed, and the duration of exposure to waves is not considered.

Figure 3. Side view of the flume.

Table 1. Wave heights at different slope of breakwater model.

Slope	Wave height (cm)
1:1.5	12.42
1:2	13.66
1:2.5	14.72

Figure 4. Side view of rubble-mound breakwater model with slope of 1:1.5.

The rubble-mound breakwater model is designed on the basis of the stability of rubble-mound structure using the Hudson formula (Hudson, 1959). The similarity of the rubble-mound breakwater model is 1:10. Figure 4 presents the side view of the rubble-mound breakwater model with the slope of 1:1.5.

5 RESULT AND DISCUSSION

Wave direction, either normally incident or oblique, refers to the direction of wave travel with respect to the breakwater axis. Tables 2–4 present the results of wave height measured using zero upcrossing statistic in front of rubble-mound structure model with slopes 1:1.5, 1:2, and 1:2.5 facing the seaward side, respectively. The highest wave height occurred at crest elevation.

The significant wave height, runup, and rundown at 38 cm of water elevation can be seen in Table 5. It can be concluded that $H_{1/3}$ and $R_u - R_d$ at the mean low water level show the lowest values at the

Table 2. Wave heights based on zero upcrossing statistics in front of rubble-mound structure with slope 1:1.5 facing the seaward side.

Water level (cm)	H_{max} (cm)	$H_{1/3}$ (cm)	$H_{1/10}$ (cm)	$H_{average}$ (cm)
70	18.0	15.5	16.7	14.4

54	17.6	16.7	17.1	15.4
38	13.8	12.6	13.1	11.3

Table 5. Significant wave height, runup, and rundown at 38 cm of water elevation.

Format of slope	$H_{1/3}$ (cm)	Runup, R_u (cm)	Rundown, R_d (cm)	$R_u - R_d$ (cm)
1:1.5	13.7	32.0	8.5	23.5
1:2	14.5	28.0	8.0	20.0
1:2.5	12.6	20.0	6.0	14.0

slope 1:2.5 of the rubble-mound breakwater model. It means that the highest energy of wave absorption occurred at the slope of 1:2.5 facing the seaward side of the rubble-mound breakwater model.

When the water level is 54 cm or at the mean high water level, only rundown occurred. The rundown for each different slope of the rubble-mound breakwater model is shown in Table 6. The wave absorber gives the highest value for the slope of 1:2.5 for the rubble-mound breakwater model.

The elevation of the crest should be minimum at which overtopping occurs. This should be based on maximum wave runup (Palmer and Christian,

Table 6. Rundown at the mean high water level.

Format of slope	Rundown, R_d (cm)
1:1.5	14.5
1:2	17.0
1:2.5	22.0

Table 7. Wave transmission coefficient at the water level 70 cm.

Slope	H_t (cm)	H_i (cm)	K_t
1:1.5	13.1	15.5	0.85
1:2.0	9.0	16.2	0.56
1:2.5	8.3	15.7	0.53

1998). Unfortunately, the overtopping at 63 cm of water elevation cannot be recorded due to the instrument's problem during the experiment.

The wave transmission coefficient (K_t) is defined as the ratio of the transmitted wave height (H_t) at the leeside to the incident wave height (H_i) at the breakwater seaward, as follows:

$$K_t = \frac{H_t}{H_i} \quad (1)$$

The value of K_t indicates the effectiveness of a rubble-mound breakwater at submerged condition to attenuate waves (Yuliasuti and Hashim, 2011, Zhang and Li, 2014). The value of K_t varies between 0 and 1. A value of zero implies that there is no transmission, whereas 1 means no reduction in wave height (there is no barrier in front of the wave). The result of wave transmission coefficient is presented in Table 7 at the water level of 70 cm (submerged).

On the basis of the result of wave transmission coefficient, slope 1:2.5 of the rubble-mound breakwater model can reduce the wave height more significantly than the slopes 1:1.5 and 1:2 of the breakwater model.

6 CONCLUSIONS

The function of rubble-mound breakwater is to protect the coastal area. Because the rubble-mound breakwater needs to be stable, the two-dimensional physical model of rubble-mound breakwater is conducted using three different slopes, 1:1.5, 1:2, and 1:2.5, facing the seaward side. The water levels are applied at the mean low water level, the mean high water level, the crest elevation, and submerged using the flume with regular wave. The rubble-mound breakwater model is designed on the basis of stability of this breakwater using the Hudson formula. The armor units of the rubble-mound breakwater model are dolos placed randomly facing the

seaward side. The core is set stable using geotube. The wave absorber, transmission wave, and displacement of armor units give the best result for the slope of 1:2.5 of the rubble-mound structure model.

The results of two-dimensional physical testing for this rubble-mound breakwater model will certainly be helpful in making the optimum slope of rubble-mound breakwater facing the seaward side in coastal areas of Indonesia with erosion and/or abrasion condition. The results of the two-dimensional rubble-mound breakwater model will be very useful if it can proceed to the next stage of the three-dimensional physical test by using regular and irregular waves. In addition, test results of physical model of this structure can also improve the existing rubble-mound breakwater, especially damaged rubble-mound breakwater.

ABSTRACT: By using BISAR mechanical calculation software to calculate and analyze the rubber asphalt compound pavement shear stress of different interlayer adhesive states and under the condition of stress-absorbing layer thickness, we know that the adhesive states of stress-absorbing layer, rubber asphalt surface layer, and underlying cement pavement have a direct impact on the distribution of shear stress of asphalt overlay and stress-absorbing layer, and the maximum shear stress of asphalt layer bottom will first decrease and then increase with the increase of friction parameters. Therefore, the bottom layer should have good adhesion to prevent the premature entry of shear stress growth period.

1 PREFACE

The stress-absorbing layer is arranged on the general cement concrete deck and asphalt surface layer, which can effectively disperse the stress concentration of cement concrete joints or cracks under load effect in order to delay or prevent the appearance of reflective crack of asphalt pavement. The commonly used stress-absorbing layer types mainly include the layer distribution method stress absorbing layer (such as SAMI), modified asphalt mixture stress absorbing layer, the compound stress absorbing interlayer, geosynthetics, and synchronous macadam transition layer, among which the first three have better impermeable, crack resisting, and bonding properties, whereas the effect of the latter two in the practical application is not significant. The cost of modified asphalt stress absorbing layer and compound stress absorption interlayer engineering is high, and the difficulty of construction is relatively high. By contrast, the layer distribution method stress absorbing layer is relatively more economical, reasonable, and convenient for construction. Rubber powder-modified asphalt with high elasticity, toughness, and high deformation is

more applicable to the layer distribution method stress absorbing layer. In addition, the rubber powder-modified asphalt stress absorbing layer is also an effective measure of waste tires.

The layer distribution method for rubber powder-modified asphalt stress absorption layer is widely used in compound pavement engineering; however, some technical problems still remain to be solved, including setting rubber powder-modified asphalt binder stress-absorbing layer asphalt overlay design theory and method of structure, the rubber asphalt binding material to improve the technical performance, and the construction technology and other aspects. In light of this, the above rubber asphalt stress-absorbing layer shear characteristics are studied in this paper, in order to further improve the technology of rubber powder-modified stress absorbing layers.

2 ANALYSIS OF THE INTERLAMELLAR SHEAR STRESS

The combination form of general rubber asphalt compound pavement structure is shown in Fig. 1.

Figure 1. Pavement structure combination.

Table 1. Pavement structure parameters.

Structure layer	Thickness (cm)	Modulus (MPa)	Poisson's ratio
Asphalt overlay	4.0	1200	0.35
Absorbing layer	0.6-1.0	400	0.35
Cement concrete	24.0	30000	0.15
Cement-stabilized stone base	20.0	1500	0.20
Graded stone	25.0	350	0.35
Soil matrix	-	100	0.40

In addition to the rubber powder-modified asphalt stress-absorbing layer structure of each layer of compressive resilient modulus and Poisson's ratio, we refer to "asphalt pavement design specification" -JTG D50-2006 value. However, the rubber powder-modified asphalt stress-absorbing layer refers to the modified asphalt stress-absorbing layer parameters. The values of the pavement material parameters for each layer are shown in Table 1.

Using BISAR pavement structure in Table 1 in the interlayer under BZZ-100 standard axle load conditions, shear stress is calculated to analyze the thickness of the shear stress distribution, contact conditions, the interlayer shear stress, and the effects of stress-absorbing layer thickness on shear stress.

2.1 Distribution of shear stress in the lower layers of different adhesive states

In this analysis, the stress-absorbing layer and the upper and lower positions under different conditions of friction parameters ∂ each point along the driving direction (0,1a,2a,3a) at the XX and YY normal stress component analysis asphalt surface and the bottom of the maximum stress absorbing layer shear stress distribution. The results are shown in Figures 2-6.

As can be seen from Figures 2-6, the maximum shear stress distribution of the stress-absorbing compound pavement overlay and the stress absorbing underlying layer can be changed with different adhesive statuses, and the main changes are as follows:

Figure 2. Shear stress at the underlying layer under the condition of complete continuity between two layers.

Figure 3. Shear stress at the underlying layer when the upper layer is 0.5.

Figure 4. Shear stress at the underlying layer when the upper layer is completely sliding.

Figure 5. Stress absorbing layer friction parameter is 0.5.

(a) Asphalt layer (b) Stress-absorbing layer

Figure 6. Shear stress at the underlying layer when the absorbing layer is completely sliding.

Table 2. Shear compliance under different friction parameters.

Adhesive layers	Friction parameters	Modulus (MPa)	Poisson's ratio	AK (N/m ²)
Asphalt overlay and stress-absorbing layer	0	1200	0.35	0
	0.25			3.99E-11
	0.5			1.20E-10
	0.75			3.59E-10
Stress-absorbing layer with the original concrete pavement	0	400	0.35	1.19E-08
	0.25			1.20E-10
	0.5			3.59E-10
	0.75			1.08E-09
	0.99			3.56E-08

1. When every level of compound pavement is completely in continuous state, asphalt layer and stress-absorbing layer stress was basically consistent along the direction of travel distribution, and auto axial and driving direction stress are all parabolas, and the axial stress is always greater than the direction of traffic stress.
2. When an adhesive status between the asphalt surface layer and the stress-absorbing layer changes, the distribution of stress in asphalt overlay takes a significant change along the directions of traffic. When the friction parameter is in the case of 0.5, the axial stress and stress variation of the direction of travel are exactly opposite, and the maximum shear stress is travel direction stress in load center, which proves that the interlayer adhesive status affects the stress distribution of the asphalt surface layer and the maximum shear stress direction. At the same time, under three friction parameter conditions, absorbing layer stress changing rules along the direction of traffic are not obvious, but there still exists possibility of the presence of the influence of different friction parameters on stress variation.

3. When the stress-absorbing layer and the original cement coagulation pavement adhesive status change, the variation of asphalt overlay and stress-absorbing layer of stress were significantly changed. When the friction parameter is 0.5, that is to say, when the stress-absorbing layer and the cement concrete road surface are not fully bonded, the stress distribution is basically equal to the effect generated the asphalt layer—the changing adhesive status of the stress-absorbing layer. Changes in stress distribution stress-absorbing layer occurs when incomplete bonding is not large; however, when the layers completely coincide, the driving direction and the distribution of the axial stress are exactly opposite with fully bonded case, namely the maximum shear stress is seen as a parabola, which decreases first and then increases.
4. From the distribution of stress in different layers and the variation of bonded conditions, it can be seen that the interlayer shear stress distribution varies, and this effect will change with the variation of friction parameters.

2.2 Variation of maximum shear stress between the layers with different bond states

BISAR is used to make mechanical analysis for stress-absorbing layer and the upper and lower positions, respectively, under different conditions of friction parameters. The friction parameters were 0, 0.25, 0.5, 0.75, and 0.99, in which the friction parameter 0 is for complete adhesion and 0.99 is for nearly complete slide. The variation of the maximum shear stress under different conditions of friction parameters is shown in Figs. 7 and 8.

As shown in Figures 7 and 8, the change of the bonding condition between stress absorption layer and the upper and lower layers affects the maximum shear stress between itself and the bottom layers of asphalt directly. With the increase in friction parameters between asphalt layer and stress-absorbing layer, the maximum shear stress

Figure 7. Maximum shear stress at the bottom of the layer under the condition of friction parameter of different asphalt overlay stress-absorbing layer.

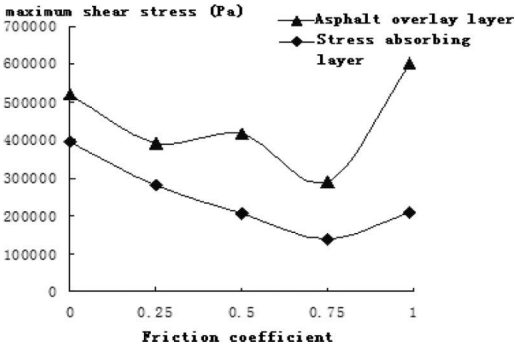

Figure 8. Maximum underlying shear stress between cement pavement and stress-absorbing layer under the condition of different friction parameter.

of rubber asphalt overlay will first decrease and then increase with the increase of friction parameters, while the maximum shear stress of the bottom stress absorption layer increases with it. The good bonding state of asphalt overlay layer can reduce the maximum shear stress of the stress absorption layer and prevent the premature failure of the stress absorbing layer. Although the change trend of asphalt overlay was first reduced and then increased, reducing the maximum shear stress of asphalt overlay by reducing the bonding degree between layers is not suitable, because at the beginning of building, the initial bonding state between the layers is not ideal. At the same time, over time, the bonding condition of interlayer will be gradually reduced, so it should not be the measures to prevent premature to enter the maximum shear stress growth. The bonding condition between the stress-absorbing layer and the cement pavement has a significant impact on the maximum shear. The maximum shear stress of rubber asphalt overlay and stress absorption layer bottom will first decrease and then increase with the increase of friction parameters. And for the asphalt layer bottom, completely sliding and in relatively complete bonding condition, the maximum shear stress increases by 15.23%, which also proves that we cannot reduce the maximum shear stress by reducing the adhesion of the layers.

2.3 Effect of different stress-absorbing layer thicknesses on the maximum shear stress of the bottom layer

BISAR is used for the mechanical analysis of rubber asphalt overlay (stress-absorbing layer) under different conditions of stress-absorbing layer thickness.

The thicknesses were 0, 0.6, 0.7, 0.8, 0.9, 1.0 and 1.5 cm. It can be found from calculation that when

we do not set stress-absorbing layer, the maximum shear stress of the asphalt overlay bottom layers is 5.959×10^5 , and the calculation results of bottom shear stress when settings with other different thickness of stress absorption layer are as shown in Figure 9.

As it can be seen from Figure 9, with the increase in the thickness of stress-absorption layer, the maximum shear stress between asphalt overlay and the bottom stress-absorbing layers decreases continuously, the maximum shear stress decreases by 12.59% when stress absorbing layer thickness is set at 0.6 cm. When the thickness is 1.0 cm, it decreases by 23.55%, and when the thickness is 1.5 cm, under the maximum shear stress, it decreases by 32.01%, which proves that the thickness effect is the effective measure to reduce the maximum shear stress of asphalt pavement; however, this effect increases with the thickness gradually. At the same time, for rubber powder-modified asphalt stress-absorbing layer, its thickness is 0.6–1.0 cm, and in the actual use of the process, because of the influence of Webster effect, the lower layer of asphalt will form a certain thickness of the oil-rich layer, the actual reduction effect of the maximum shear stress is greater than the one of calculation results. Therefore, the rubber powder-modified asphalt stress-absorbing layer is an economical and reasonable anticracking measure. In addition, from the variation of the maximum shear stress of absorption bottom layer in different thickness, it can be seen that increasing thickness cannot effectively reduce the maximum shear stress of stress-absorption layer. When the thickness of the stress-absorbing layer increases from 0.6 to 1.0 cm, the maximum shear stress decreases by only 3.44%. When the thickness of the stress-absorbing layer increases to 1.5 cm, the maximum shear stress decreases by only 7.5%. Therefore, the increasing of thickness of the stress-absorbing layer cannot effectively reduce the maximum shear stress by itself, which requires the stress-absorbing layer material's good elastic recovery, and the rubber powder asphalt has

Figure 9. Bottom layer maximum shear stress under different thicknesses of stress-absorbing layer.

a high modulus and a high viscoelasticity trait, which is in line with this request.

3 CONCLUSION

1. By using BISAR mechanical calculation software, we calculated and analyzed the rubber asphalt compound pavement shear stress of different interlayer adhesive states, and under the condition of stress-absorbing layer thickness, we knew that the adhesive states of stress-absorbing layer, rubber asphalt surface layer, and underlying cement pavement have a direct impact on the distribution of shear stress of asphalt overlay and stress-absorbing layer, and the maximum shear stress of asphalt layer bottom will first decrease and then increase with the increase in friction parameters. Therefore, the bottom layer should have good adhesion to prevent the premature entry of shear stress growth period.
2. With the increase in the thickness of the stress-absorbing layer, the maximum shear stress of asphalt overlay is significantly reduced, but the effect of the maximum shear stress of the stress-absorbing layer is not obvious.

Experimental study on beam-column joints of new prefabricate assembly frame structures

W.Z. Zhu & J.C. Zhang

School of Civil Engineering, Guangzhou University, Guangzhou, China

ABSTRACT: The seismic performance of four new-type beam-column joints and two ordinary cast-in-site beam-column connections was compared with low-cycle loading tests. The study is mainly on the failure modes and mechanisms, hysteresis loops, ductility, and stiffness degradation of the joints. It is demonstrated that the specimens, belonging to classical bending failure, meet the seismic requirement of strong-shear and weak-bending for beam-column joints. There are no cracks on the surface of the joint region, and no relative slips along the interfaces between the cast-in-site column and composite beams for the bonds raised with concrete keys and reinforced bars. The seismic resistance performance of the new-type beam-column joints is almost equal to that of the ordinary connections. The construction measures of the prefabricate assembly frame structure can guarantee the safety and reliability of the novel joints.

1 INTRODUCTION

Construction measures, including composite beam and concrete shear key, used in New Prefabricate Assembly Frame Structure (NPAFS), could ameliorate troubles in traditional assembly structure system, such as low precision and poor structural integrity, and effectively improve construction quality and structural performance, shorten the construction period, reduce environmental pollution, and save resources and energy (Zhang, 2013). The NPAFS, good in integrity and seismic performance, and high production efficiency, is applicable for multi-layer and small high-rise structure, and is significant to the development of urbanization construction and housing industrialization of China.

Most related experiment researches at home and abroad assume that the NPAFS can achieve the same or similar seismic performance of the cast-in-site structures (Li, 2006). By the full-scale model tests, Zhao Bin et al. (2005) had studied the seismic behaviors of cast-in—site high strength concrete beam-column sub—assembly, precast concrete beam-column sub—assembly with cast-in-site high strength concrete joint and precast concrete beam-column sub—assemblies with fully assembled joints, such as the failure pattern, hysteresis characteristic, skeleton curve, strength and stiffness deterioration, shear deformation of the joint core zone, rotation of the beam end and column end. Through testing the seismic behavior of precast layered slab and beam to column exterior joints under high axial loading and low—cycle reversed loading, Yan Weiming et al (2010) indicated that the earthquake resistance performance of this type of

connection is almost equal to that of monolithic connections. At present, connections assembled with cast-in-site column and composite beams and monolithic connections are frequently used in Assembly integral frame joints in Chinese (2004). Luo Qinger et al. (2009) conducted contrast tests of one precast monolithic R.C. frame interior column joint and one cast-in-site R.C. frame interior column joint. Additionally, connecting techniques of precast columns used presently are not ideal to structural integrity, only suitable to multi—layer structures (CECS43:92).

In the paper, a novel beam column joint, composed of composite beams and cast-in-site column, was proposed. As shown in Fig. 1, the main construction measures of the joint include composite beams, protruding bars of the beams welded in the joint region, and concrete shear keys at the beam—ends. Concrete shear keys are used to improve the shear-resistance capacity of the joint.

In the actual construction process, protruding bars are unable to be accurately aligned for deviation of component fabrication, positioning

Figure 1. New-type joint for reinforced frames.

inaccuracy, and space restriction in the node, so it is difficult to be welded together. While welding the bars in edge region of the node can reduce the difficulty in adjusting them.

In order to ensure the safety and reliability of the construction measures, low-cycle reverse loading tests were conducted on the novel frame beam-column joints for comparing the lading process, failure mode, hysteretic ductility, energy dissipation, and stiffness degradation of the joints with cast-in-site beam-column joints.

2 SPECIMEN DESIGN

A total of six full-scale specimens of interior RC beam-column joints from an assembled integral residence was made and tested. Four of the specimens are the novel beam-column joints presented in the paper, only different in welding positions of the bottom steel bars, in specimens 1 and 2 (PC-1-1 and PC-1-2) the bottom bars welded at the column center-line, and in specimens 3 and 4 (PC-2-1 and PC-2-2) at the edge region of the joints. Specimens 5 and 6 (RC-1-1 and RC-1-2) are ordinary cast-in-site concrete connections. The numbers and sizes of the components are shown in Tables 1 and 2, and material performance of the steel and concrete used is demonstrated in Tables 3 and 4.

For these specimens, the beam and column ends were the points of inflection under the applied lateral load. The beam length was measured as

3 TEST LOADING AND DESCRIPTION

3.1 Loading system

Considering the effect of earthquake, vertical load is subjected on the beam ends of the joints by two vertical actuators. To simulating the actual mechanical behavior of the beams, the loading positions are 1.1 m away from the edge of the column.

Axial compression ratio, u , is an important parameter to ensure the failure modes of the concrete column in earthquakes being large eccentric compression and ductility damage (GB50011). Previous studies believe that when $u \geq 0.3$, the angles of seismic waves have little effect on the section ductility of column; and when $u \leq 0.3$, the influence of concrete strength grade on the section ductility may be neglected (Xu, 2012). So a constant axial load of $0.3f_cA_g$, in which f_c and A_g are design value of compression strength of concrete and sectional area of the column, respectively, was subjected on the top of the column, and maintained in the testing.

The loading system selected is a load—displacement hybrid control (STMERB, 1997), as shown in Fig. 3. The estimated cracking load f_{cr} of the composite beam is 80 kN, and the yield load f_y is 160 kN. Before yield of steel bars in the beam, the tests were executed with force control, and one cycle for each load level. The first 3 load increments are 50%, 30%, and 20% of the cracking load, respectively. When the beam cracking, the load increment applied is switched to 20% of the yield load, and changed to 10% of the yield load when the loading approaching the yield load.

When the beam reaches its yield strength, the loading system was switched to the displacement

Figure 3. Loading system of the test.

control. Each load level was subjected on the specimens for three cycles gradually to achieve the displacement ductility factor $\Delta/\Delta_y = \pm 1.5, \pm 2.0, \pm 2.5, \dots$, where the yield displacement Δ_y was measured during the test. The ultimate deformation of the specimens is determined corresponding to the beam-end displacement when the bearing capacity reduced to 80% of the maximum load. The setup of the loading test are shown in Fig. 4.

The stress values in the specimens were measured with DH3815N static strain instrument, with measuring range of $\pm 20000 \mu\epsilon$, system error of $0.5\% \pm 3 \mu\epsilon$, resolution of $1 \mu\epsilon$, and drift of $4 \mu\epsilon/4 \text{ h}$. Deflection was collected with an automatic displacement acquisition system. Load was read with pressure sensors. All instruments were calibrated in accordance with specified criteria before tests, and a cyclic vertical load of 5 kN was applied on the beam-ends for 2 times to check whether the instruments performing normally or not. The arrangement of steel and concrete strain gauges for the test components is shown in Figs. 5 and 6.

Figure 4. Setup of the loading test.

Figure 5. Arrangement of the steel-stress gauges.

Figure 6. Arrangement of the concrete-stress gauges.

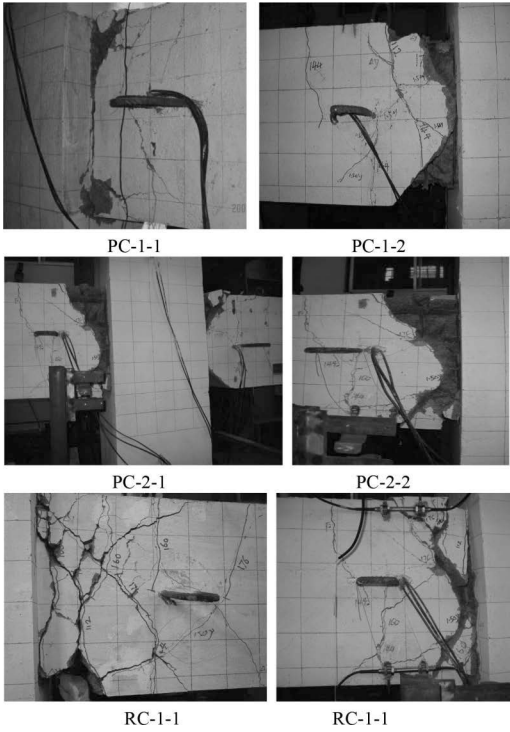

Figure 7. Patterns for the failure modes of the joints.

3.2 Test process

The failure modes of the components tested are shown in Fig. 8. All specimens exhibit bending failure modes under cyclic loading, plastic hinges fully developed in beam body near the joint. For the specimens having present basically similar failure features, the loading process was divided into three phases.

In the first phase, concrete cracks in these specimens are firstly observed in the beams, and the width, depth and distribution range develop with load increasing. In the second phase, new cracks

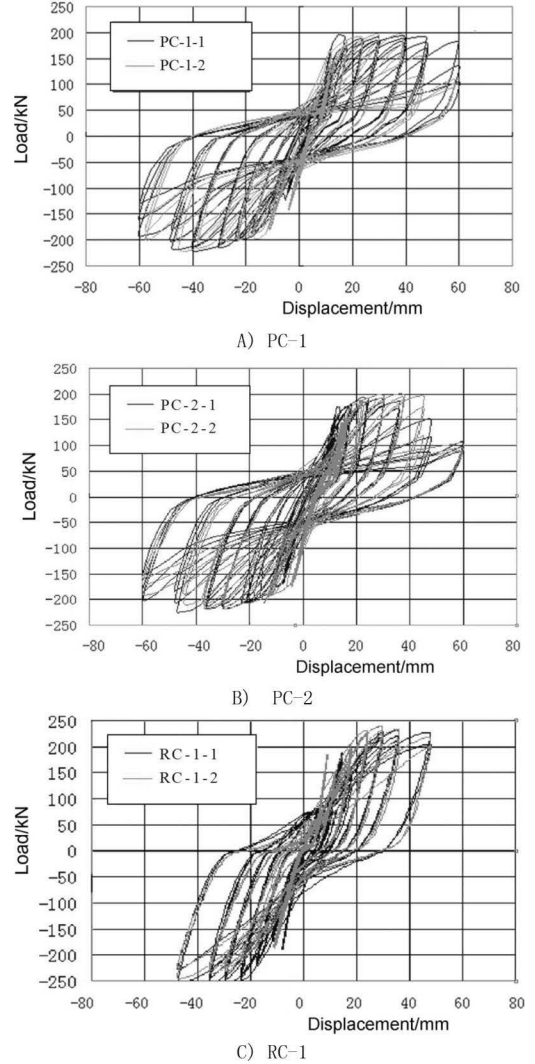

Figure 8. Load-displacement hysteretic loops.

appear constantly and the original cracks are gradually developing into crossing cracks. In the last phase, cracks develop rapidly, with concrete crushed in compression zone, plastic hinge formed in the beam, and loading capacity of the column decreased. In the process, no cracks were observed on the surface of the joint core while reinforced bars show no brittle failure. The observed crack patterns of the specimens are shown in Figure 7.

At the third loading stage, there are no obvious changes on the surface of the PC-1 specimens, while measured strains show that the beam concrete has reached cracking degree. At the fourth loading stage, hair cracks are observed at the bottom of the left beam in the region near the joint. At the fifth

stage, about 144 kN, vertical cracks with different width appear on beams, with the largest length of 170 mm and width of 0.06 mm. To the sixth stage, the vertical cracks have developed in varying degree, and form diagonal cracks gradually. At the seventh stage, crossing cracks are formed at different extent, and the beams yield. The corresponding beam-end displacements are 12.0 and 13.0 mm, respectively, for PC-1-1 and PC-1-2. In the displacement control phase, the width, length and the distribution range of the cracks expand continuously with the displacement increasing gradually, and plastic hinge formed at the beam-end. Finally, when the deformations reach $5\Delta_y$, the hysteresis curves become unstable, and the specimens are failure.

At the third loading stage, hair cracks were observed at the top of the right beam of PC-2 specimens in the region near the column. At the fourth loading stage, cracks are observed at the top of both beams. At the fifth stage, vertical cracks with different width appear on the bottom of beams, and origin cracks develop continuously. At the sixth stage, origin cracks extend further, and form diagonal cracks gradually. At the seventh stage, the original cracks have various degree of development with a main diagonal crack formed obviously. The corresponding beam-end displacements are 12.3 and 13.7 mm, respectively, for PC-2-1 and PC-2-2. The appearance in the displacement control phase is similar to PC-1 specimens.

The demonstration of RC-1 specimens during 3 to 6 load stages is similar to that of PC-1 basically. While reinforced bars of PC-1 are not yield at the 7th load stage, 10% of the estimated yield load of the beam is still used as the load increment in the 8th stage. The corresponding beam-end displacements are 12.6 and 13.4 mm, respectively, for RC-1-1 and RC-1-2. In the displacement control phase, the hysteresis curves become unstable when the deformations reach $4\Delta_y$, and the specimens are failure.

4 RESULTS AND DISCUSSION

4.1 Hysteresis behavior

The hysteretic responses of specimens, shown in Figure 8, are presented in the form of displacement versus corresponding vertical applied load on beam-ends. Pinching is obviously observed in the hysteresis curves (Mansour, 2001). Skeleton curves, shown in Fig. 9, were obtained from the curves. Some results inferred from the experimental phenomena and Figs. 9 and 10 are given below.

1. The hysteretic behavior of the specimens is depended on the rotation capacity of the

Figure 9. Comparison of load-displacement skeleton curves.

Figure 10. Comparison of energy dissipation.

beam-end plastic hinge. The reduction in strength of the specimens is mainly corresponding to the yield of the reinforced bars and concrete crushing in the beams.

2. The ultimate bearing capacity of the ordinary beam-column connections is greater around 10% than that of the novel beam-column joints.
3. The novel beam-column joints with different welding position of the reinforced bars at beam bottom are similar in hysteresis curves and skeleton curves. Welding position of the reinforced bars has little effect on hysteretic behavior of the specimens.

4.2 Ductility coefficient of beam

Ductility Coefficient is ratio of extreme deformation to yield deformation, and reflects plastic deformation capacity of structural components (Cai, 2005). In structural seismic analysis, ductility coefficient is usually used to represent the ductility of structural elements, and can be calculated by equation (1).

$$\beta_D = \frac{\Delta_u}{\Delta_y} \quad (1)$$

Table 5. Displacement ductility coefficient of the joints.

Specimen	P_j/kN	Δ_j/mm	P_{\max}/kN	Δ_{\max}/mm	P_u/kN	Δ_u/mm	β_D
PC-1-1	176.2	12	219.9	40.3	186.9	59.9	4.99
PC-1-2	178.5	13	223.6	47.4	190.1	48.1	3.70
PC-2-1	179.1	12.3	229.0	29.3	203.2	47.6	3.87
PC-2-2	179.6	13.7	216.6	37.3	184.1	52.9	3.86
RC-1-1	193.2	12.6	258	47.9	221	46.4	3.68
RC-1-2	195.4	13.4	242	45.2	219	45.2	3.37

where, β_D is ductility coefficient, Δ_u is extreme deformation, and Δ_y is yield deformation.

Ductility coefficient calculated of each specimen, shown in Table 5, is between 3.37 and 4.99, and meets the requirements of seismic ductility^[12]. Ductile deformation capacity of the novel beam-column joints is greater than that of the ordinary beam-column connections with equivalent reinforcement and concrete strength. Additionally, no obvious effect of welding position of the reinforced bars is observed on ductility performance of the novel beam-column joints.

4.3 Energy dissipation capacity

Area of hysteresis loop can be used to evaluate the energy dissipation capacity of the component in earthquake. Average energy dissipation of each specimen under each levels of deformation for each specimen is shown in Fig. 10.

The figure indicates that plastic hinges of the novel beam-column joints appear earlier than those of the ordinary beam-column connections, and the energy dissipation capacity of the joints inclines when ductility coefficient greater than 4.0, demonstrating that plastic hinge start to destroy. Additionally, the energy dissipation capacity of the novel beam-column joints is greater than that of the ordinary beam-column connections, and two types of the novel joints are more or less similar in energy dissipation.

4.4 Stiffness degradation

Stiffness degradation is that stiffness of structural members decreases with their deformation increasing under cyclic loading. Rate of the degradation, used for evaluating seismic capacity of the joints, can be demonstrated with average stiffness of each circulation at all levels:

$$K_j = \sum_{i=1}^n \frac{(|P_j^{i+}| + |P_j^{i-}|)}{(|\Delta_j^{i+}| + |\Delta_j^{i-}|)} / n \quad (2)$$

Figure 11. Comparison of stiffness degradation.

In which, P_j^{i+} , P_j^{i-} are the positive and negative peak load of the i th cycle in j th loading stage, respectively, Δ_j^{i+} , Δ_j^{i-} are deformation values corresponding to P_j^{i+} and P_j^{i-} , respectively, n is the number of cycles.

Deductions on the stiffness degradation of each specimen, shown in Fig. 11, are given below.

1. The stiffness degrades with deflection increasing after beam yield. However, the deterioration trends tend to mitigation.
2. Stiffness degradation of the novel beam-column joints is similar.
3. In the process of stiffness degradation, the stiffness of the ordinary beam-column connections is greater than that of the novel beam-column joints.

5 CONCLUSION

Based on the low-cycle loading tests of four novel beam-column joints and two ordinary cast-in-site beam-column connections, we can draw the following conclusions.

1. All the joints exhibit typical bending failure modes, and plastic deformation capacity of the beams is fully developed. The construction measures, such as concrete keys in the joint and steel bars welded, meet the ductility requirement of strong-shear and weak-bending for concrete frame joints.

2. The ultimate strength and stiffness of the novel concrete frame joints are slightly lower than those of the ordinary beam-column connections, but their ductility and energy dissipation capability are higher, so two types of joints are similar in seismic performance.
3. Welding positions of the bottom steel bars of the beams have little effect on the mechanical properties of the tested specimens, for two kinds of the novel joints having similar stiffness degradation, ductility and energy dissipation.

In conclusion, the novel frame joints of assembling integral reinforced concrete frame structure presented in this paper can reach the mechanical level of ordinary beam-column concrete connections, and the construction measures for the novel frame joints can ensure the safety and reliability of buildings.

Seismic analysis of large span spatial steel frame with isolation system

W.Z. Zhu

School of Civil Engineering, Guangzhou University, Guangzhou, China

ABSTRACT: Base isolation technique was employed in the E Block of the Guangdong Science Center (GSC) to protect the huge span frame from damage under external loads, especially typhoon and earthquakes. In this application, isolating bearings are directly placed at the base of the main columns of the building. Non-linear dynamic analysis and shaking table tests were conducted to study the effect of the base isolation on vibration modification, evaluate the improvement of the seismic-resistance capability, and estimate the deflection compatibility of the isolation. A 1/35th scale model was constructed and tested on shaking table under a series of base excitation with gradually increasing acceleration amplitudes. The results show that the experimental test setup can simulate the vibration characteristics of the prototype structure perfectly, and the stiffness simulation for isolating bearings is successful. With the comparison of the natural vibration characteristics and the dynamic responses, such as accelerations and displacements, of the structure for the cases with or without base isolation, it was demonstrated that base isolation can remarkably improve the seismic-resistance capability of the building and improve the torsion performance of structure with irregular plan. The investigation indicates that the isolation design for GSC is rational and is a useful effort for isolation design in huge civil engineering.

1 INTRODUCTION

Base isolation is an effective measure to alleviate earthquake disasters to structures. Since the 60's of last century, extensive researches on isolation technique have been conducted in practical engineering. It has been indicated that base isolation is very effective in keeping the utilization functions of buildings under severe earthquakes (Skinner, 1993; Su, 2001; Masahiko, 2006). Topkaya (2004) conducted a parametric study using three-dimensional finite elements with geometric and material non-linearities, and identified the important geometric specimen properties that influence the measured shear modulus. Providakis (2009) discussed the aseismic performances of two actual Reinforced Concrete (RC) buildings with various Lead-Rubber Bearing (LRB) isolation systems. Kilar et al. (2009) analyzed the positive and negative effects of different bearing distributions on displacements and rotations of the superstructure as well as the base isolation system and tried to determine the most favorable distribution of isolators that is able to balance the effects of introduced eccentricities. Goda et al. (2010) assessed the cost-effectiveness of seismic isolation technology from the lifecycle cost-benefit perspective. All of the above studies indicated that seismic isolation can reduce vibration in superstructures significantly, especially the unfavourable torsion effect and can be cost-effective in mitigating seismic risk. The study reported by Jangid (2007)

found that the optimum yield strength of the LRB is in the range of 10%–15% of the total weight of the building under near-fault motions. Dicleli et al. (2007) indicated that the accuracy of the equivalent linear analysis results is affected by the ratio of peak ground acceleration to peak ground velocity of the ground motion as well as the intensity of the ground motion relative to the characteristic strength of the isolator, and the effective damping equation currently used in the design of seismic-isolated structures must incorporate the effective period of the structure and frequency characteristics of the ground motion for a more accurate estimation of seismic response quantities.

Although the isolation technique has been used in civil engineering for more than 40 years, such as U.S. Court of Appeals, San Francisco Airport International Terminal, with isolation systems mainly consisting of sliding bearings (Charleson, 2008), Lead-Rubber Bearings (LRB) used in large span structures are seldom reported.

Guangdong Science Center (GSC), a large span steel frame consisting of special shaped components, is new landmark architecture of Guangdong Province, China. The potential fatality to the Block is of great seriousness for its extremely complex internal force state. To ensure the safety of the building and people, devices and exhibitions in it under external loads, especially typhoons and strong earthquakes, the base isolation system of LRB was employed in the E Block of GSC.

Since isolation system was used in such a large span steel framework for the first time, whether the huge columns directly mounted on the isolating bearings could work compatibly or not, liking the case with a uniform isolating layer, is curious. To achieve optimum design and favorable seismic effect, a shaking table test and nonlinear dynamic analysis were conducted to compare the seismic performance of the base isolated structure with that of the base-fixed one. In this study, a 1/35th-scale shaking table specimen was constructed and tested to evaluate the seismic characteristics.

2 PROJECT OVERVIEW

GSC is located at Wanzuitou, west of Xiaogwei Island in Panyu district of Guangzhou. The construction area is at the northern of the Cenozoic era sedimentation basin of Pearl River Delta of China, 1.1 km from a nearest fault line. The area has a geological condition of high hazard level, and many potential geological disasters, such as liquefaction, earthquake-induced landslides. The fortification intensity for the construction site is categorized as 7. The type of site-class is specified as type II corresponding to the equivalent shear-wave velocity and the overlaying thickness of the soil profile, and the predominant period of the ground motion is taken as 0.45 s.

The main structure consists of seven Blocks, A, B, C, D, E, F, and G, as shown in Fig. 1. Among them, E Block is the biggest exhibition hall, liking a ship sailing on the sea, used for exhibiting valuable space instrumentations, and its structural style is the newest large span steel frame with many special shaped components ever used in China.

The E Block has three stories with span length of 40 m, and the supporting system consists of six huge truss columns with cross sectional area of 4 m × 9 m. Huge trusses of 15 m high, linking the huge columns along the longitudinal direc-

Figure 1. Building model of GSC.

Figure 2. Structural plan of Block E.

Figure 3. Sketch map of main structure.

tion, are installed at the 2nd storey and reached out to support the ship's bow. Lattice beams are connected to the huge columns along the transverse direction on each floor. Then huge trusses, lattice beams and huge columns are made up of the huge irregular frame structure, and the lateral and vertical force resisting system. Junior trusses, 3 m in height and 6 m in space distance, are installed on the 2nd and 3rd floor. The structural plan and the elevation of E Block are shown in Figs. 2 and 3.

3 ISOLATION DESIGN

It is very difficult to design base isolation in the E Block, for the span length of about 40 m. If a uniform isolation layer was chosen, the layer would be about 1.5 m high, and the isolating bearings should be embedded about 2 m into soil with the level of the structure unchanged. While the ground-water level is only 0.4 m below existing surface grade, the bearings would be immersed into water. If the mounting height of the bearings was higher than the existing ground, the level of the building should be lifted up about 2 m. Therefore isolating bearings are placed directly at the base of the structure unchanged. LRBs (Lead Rubber Bearings) were chosen as isolating bearings for the well-rounded research and the received computational model.

Table 1. Parameter of the bearings /mm.

Item	GZY-1100	GZY-1000	GZY-800	GZP-500	GZY-500*
Diameter	1100	1000	800	500	500
Height	347	339	325	194	347
Thickness of rubber layers	6 × 27	6 × 27	5 × 32	4.68 × 19	6 × 27
Thickness of steel plates	3.1 × 26	2.8 × 26	2.8 × 31	2.5 × 18	3.1 × 26
Diameter of the lead plug	220	200	160	—	220
First shape coefficient	45.8	41.7	40	24.5	12.1
Second shape coefficient	6.8	6.2	5	5.5	3.15

Figure 4. Arrangement of bearings under huge columns.

Figure 5. Arrangement of bearings under EKJZ1 column.

To secure the deformation harmony of the isolating bearings with different sizes and satisfy the requirement of the practical engineering, isolating bearings, with the diameters of 1100, 1000, 800 and 500 mm, are selected for bearing stability under extreme earthquakes. The 1100 mm bearings were the biggest bearings ever used in China. The parameters of the bearings are shown in Table 1, in which, GZY500* is a damping bearing for wind resistance formed by the commonly used GZP500 bearing through increasing the cross sectional area of lead bars. The arrangement of bearings under the huge columns is shown in Figs. 4 and 5.

In addition, there are three other standalone steel columns shown in Fig. 2. Considering the smaller cross sectional area of the columns, a partial isolation layer was used to connect all the smaller columns to two huge columns nearby. Then the seismic deformation compatibility of the smaller columns with the whole building is achieved.

4 FEM SIMULATION

4.1 Analytical model

In the analytical model, isolating bearings were modeled with two-directional coupled viscous damping element models. The non-linear relationship of the two-directional coupled force and displacement can be written as

$$\begin{cases} f_{u2} = m_2 k_2 d_{u2} + (1 - m_2) F_{y2} z_2 \\ f_{u3} = m_3 k_3 d_{u3} + (1 - m_3) F_{y3} z_3 \end{cases} \quad (1)$$

where, k_2 and k_3 are the lateral stiffness of the isolating bearing in two directions respectively [kN/m]; m_2 and m_3 are the ratios of the post yield stiffness to the elastic stiffness in two directions; F_{y2} and F_{y3} are the yield force in two directions; z_2 and z_3 are hysteresis variables of the isolating bearing, under the condition of $\sqrt{z_2^2 + z_3^2} \leq 1$ and the yield surface is $\sqrt{z_2^2 + z_3^2} = 1$. The initial values of z_2 and z_3 are zero, and meet the differential equations:

$$\begin{cases} \dot{z}_2 \\ \dot{z}_3 \end{cases} = \begin{bmatrix} 1 - a_2 z_2^2 & -a_3 z_2 z_3 \\ -a_3 z_2 z_3 & 1 - a_3 z_3^2 \end{bmatrix} \begin{bmatrix} k_2 F_{y2} / d_{u2} \\ k_3 F_{y3} / d_{u3} \end{bmatrix} \quad (2)$$

In which,

$$a_2 = \begin{cases} 1 & d_{u2} z_2 > 0 \\ 0 & d_{u2} z_2 \leq 0 \end{cases}, a_3 = \begin{cases} 1 & d_{u3} z_3 > 0 \\ 0 & d_{u3} z_3 \leq 0 \end{cases}.$$

The steel trusses, girders and columns were modeled with linear elastic beam-column elements, and the floors and curtain walls as shell elements. The analytical model of the prototype structure is

shown in Fig. 6, in which there are shell element of 2578, beam-column element of 12907 and viscous damping element of 78.

According to the Chinese Code for seismic design of buildings (CCSDB, GB 50011-2010), at least 2 sets of strong earthquake records and one set of artificial acceleration time-history curve should be selected based on the intensity, the design seismic group and site-class, and the maximum value of the calculated results should be chosen as the final result of the time-history analysis method. Considering the spectral density properties of Type-II site soil, El Centro (1940) and Taft (1952) ground motion records were selected as the ground motions for the model tests, for the frequency spectrum feathers of the two waves being similar to those of the site soil. The time history of artificial acceleration is developed considering the motion design spectrum for Type-II site soil. The spectrum characteristics of the wave are shown in Figs. 7 and 8. The peak ground accelerations of the selected records were scaled to 0.055, 0.1 and 0.31 g, corresponding to seismic intensity of frequent, basic and rare earthquakes, respectively.

The artificial time history of acceleration is 1-D wave, while El Centro and Taft ground motion records are all 2-D waves. If the main direction is X , the peak acceleration in the direction Y can be calculated by:

$$a_y = 0.85 \cdot a_x \quad (3)$$

Figure 6. FEM model of the structure.

where, a_x , a_y represent the peak acceleration in direction X and Y , respectively. The factor of 0.85 was regulated by CCSDB.

4.2 Analysis of FEM results

4.2.1 Natural periods and vibration modes

The vibration periods and modes calculated for the base-isolated and base-fixed buildings are presented in Table 2, Table 3, Fig. 9, and Fig. 10, respectively. The results illustrate that the isolation system prolongs the building's periods of vibration, and the vibration energy concentrates to

Figure 7. Time history curve of artificial acceleration.

Figure 8. Spectrum of the artificial acceleration.

Table 2. Comparison of periods and modes from FEM.

Type	Mode	Period (s)	Direction
Base-fixed structure	1	0.854	Y
	2	0.717	Torsion
	3	0.590	X
Isolated structure	1	1.819	Y
	2	1.710	X
	3	1.495	Y

Table 3. Participating mass ratios of vibration modes and accumulated values for the isolated structure.

Mode	UX translation of X-Dir	UY translation of Y-Dir	UZ translation of Z-Dir	$\sum UX_i$	$\sum UY_i$	$\sum UZ_i$	RX Rotation of X-Dir	RY Rotation of Y-Dir	RZ Rotation of Z-Dir
1	0.03307	0.86	0.0000038	0.03307	0.86	0.0000038	0.25	0.002043	0.89
2	0.96	0.03816	0.0000051	0.99	0.9	0.0000089	0.01077	0.06025	0.01648
3	0.004791	0.09566	0.0000055	1	0.99	0.0000149	0.0482	0.0005402	0.08844

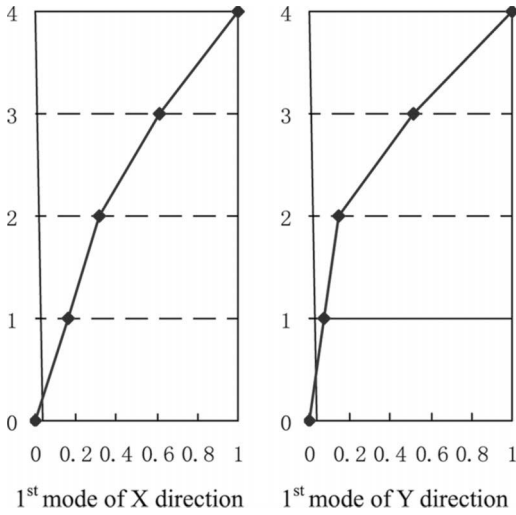

Figure 9. Vibration modes of base-fixed building from FEM.

Figure 10. Vibration modes of isolated building from FEM.

the first three modes. (In Fig. 9 and Fig. 10, the number “0” denotes the surface of the shaking table, and “1” denotes the first floor). In the base-isolated building, the isolation system has large deformation but the superstructure behaves essentially rigid, while the base-fixed one behaves like a flexural beam. With isolation system, the main modes change from bent or/and torsion vibrations to translations. Isolation system can upgrade the vibration modes of the irregular superstructure, and make the seismic response smooth and regular.

4.2.2 Acceleration response

The maximum acceleration responses for each floor of the buildings subjected to the 1940 El Centro ground motion record, scaled to 0.31 g PAG, in two directions are shown in Table 4. It is shown that the maximum accelerations on the roof of base-fixed building are 0.496 and 0.412 g in x and y directions, with corresponding amplification factors of 2.65 and 1.87, respectively. The maximum accelerations on the roof of base-isolated building are 0.061 and 0.076 g in x and y directions, with amplification factors of approximately 0.30. The amplification factors for the roof of isolated building are far below those of the base-fixed one, with a reduction of about 85%.

4.2.3 Displacement response

Analytical results indicate that with isolation system, the structural deformation converges to the isolating bearings, and the maximum deformation of the bearings is about 107 mm for the base-isolated building subjected to the 1940 El Centro record with rarely intensity. The ratios of the maximum storey drift to the ground motions, scaled to frequent, basic and rare intensity, along X and Y direction are shown in Table 5. According to CCSDB, the analytical results in Table 5 are all less than the limit value of elastic story drift rotation for multi-story and tall steel structures (1/250), which means that both buildings are in elastic range.

Table 4. Maximum accelerations of all floors from FEM/g.

Floor	Response of X-Dir			Response of Y-Dir		
	Isolated	Base-fixed	Isolated/Base-fixed	Isolated	Base-fixed	Isolated/Base-fixed
4	0.061	0.496	0.123	0.076	0.412	0.184
3	0.060	0.291	0.206	0.067	0.287	0.234
2	0.055	0.213	0.258	0.066	0.229	0.288
1	0.055	0.187	–	0.066	0.220	–
0	0.187	0.187	–	0.220	0.220	–
Maximum amplification factors	0.30	2.65		0.33	1.87	

Table 5. Analytical ratios of the maximum inter-storey drifts from FEM.

Seismic intensity	Base-fixed structure (1/θ)		Isolated structure (1/θ)		Reduction ratio	
	X-Dir	Y-Dir	X-Dir	Y-Dir	X-Dir	Y-Dir
	Frequently	5213	2726	13581	7976	0.62
Basic	1719	1205	5643	3876	0.70	0.69
Rarely	1077	726	3418	2183	0.68	0.67

Comparisons between the base-fixed and the based-isolated buildings in Table 5 show that the isolation system reduces the storey torsion drift and the internal forces of the base-isolated building, while maximum elastic storey drift for the isolated building are probably only one third of that for the base-fixed one.

5 MODEL TEST

5.1 Description of the shaking table

The shaking table test was conducted on MTS shaking table system at Guangzhou University. The table can input three-dimensional and six degree-of-freedom motions. The dimension of the table is 3 m × 3 m, and the maximum payload is 150 kN. The shaking table can vibrate with two maximum horizontal direction accelerations of 1.0g and a maximum acceleration of 2.0g vertically, with the frequency ranging from 0.1 Hz to 50 Hz.

5.2 Model manufacture

The model was designed by scaling down the geometric and material properties from prototype structure (Lu, 2007; Deyin, 1996). The basic model similitude rules were established from the scaling theory (Sabnis, 1983), which is generally known and therefore there is no need for further explanation of the theory. Since the dynamic behavior of a structure is fully described by means of three basic quantities, only three independent parameters can be selected when designing a model. Subsequently, other parameters are expressed in terms of the basic scale factors chosen. Considering the capacity and the size of the shaking table to be used, the dimension scaling parameter (S_L) was chosen as 1/35, so the weight of the model was kept less than 200 kN, the maximum load of the shaking table.

Steel structural elements were modeled with grade Q235 steel pipe, which is used as main materials in the prototype structure. Its Young's modulus scaling parameter (S_E) is 1.0.

Table 6. Similitude scale factors for the test model.

Controls parameters	Symbols	Calculation Equations	Values
Length	S_L	L_m/L_p	1/35
Young's modulus	S_E	E_m/E_p	1.00
Acceleration	S_a	$S_a = S_E S_L^2/S_m$	2.439
Time	S_t	$s_t = \sqrt{S_L/S_a}$	0.11
Frequency	S_f	$S_f = 1/S_t$	9.26
Mass	S_m	Q_m/Q_p	1/3000
Displacement	S_d	$S_d = S_L$	1/35
Strain	S_e	$S_e = 1$	1.00
Stress	S_σ	$S_\sigma = S_E$	1.00
Stiffness of isolating bearings	S_k	$S_k = S_m S_a/S_L$	1/35

Subsequently, the third parameter (S_a) concerning the horizontal acceleration can be determined. Since the peak value of the noise is close to or larger than the amplitude of seismic waves under frequent occurrences intensity (the maximum acceleration is 35 cm/s²), errors would occur in the test data acquisition. Amplified accelerations are demanded to prevent measurement from being distorted by the noise. According to the instrument capacities, S_a was selected to be 2.439. The test program was designed on the basis of the final similitude scaling relationship. The main scaling parameters are presented in Table 6. It is noted worthy that the following equation should be established according to the similitude rule:

$$\alpha_m/\alpha_p = g_m/g_p \quad (4)$$

where a_m is the horizontal acceleration of the model structure, α_p is the horizontal acceleration of the prototype structure, g_m is the gravitational acceleration of the model structure, and g_p is the gravitational acceleration of the prototype structure. However, Eq. 4 is no longer feasible unless the model is excited in a centrifuge. In this case, adoption of the artificial mass becomes the only choice to fulfill the similitude requirements. In practical test, this is achieved by the addition of suitably distributed weights, which are attached to the model in a manner that does not change the strength and stiffness of the floor beams and slabs.

To ensure an effective transmission for the earthquake motions to the base of the test model, the base plate of the model was mounted on the shaking table through two methods, bolt connections and isolation connections. The arrangement of the isolation bearings on the shaking table for the experimental model is shown in Fig. 11, while the performance param-

Type	GZP200G6		GZY200G6	
	50%	100%	50%	100%
Lateral deformation				
Yield stiffness (kN/mm)	0.39	0.37	1.97	1.32
Yield load (kN)	0.437		0.758	
Effective lateral stiffness (kN/mm)	0.38	0.33	1.86	1.20
Effective damping ratio (%)	5	5	8	10

Figure 12. Test model on the shaking table.

eters are presented in Table 7. Fig. 12 shows the constructed test setup. The displacements of the bearings were measured with laser displacement transducers. It should be pointed out that the designed input acceleration amplitudes differ from the measured amplitude on shaking table, to some extent due to the effects of the control system and mechanical system of the shaking table. So the acceleration amplitude on shaking table should be measured.

The ground motions applied to the test setup with increasing amplitudes are the same as the records selected for previous dynamic analysis. According to the similitude factors shown in Table 6, the frequency ratio 9.26 means that the time ratio is 1/9.26. The incrementally scaled excitations are input successively in a manner of time-scaled earthquake waves. After different series of ground acceleration are inputted, white noise is scanned to determine the natural frequencies of the model structure.

5.3 Results analysis for model test

5.3.1 Natural periods and vibration modes

According to similarity law (Zhou, 2005; Huang, 1997), the vibration characteristics of the prototype building are shown in Table 8, Fig. 13 and Fig. 14.

Table 8. Comparison of natural periods from the analytical and experimental studies (s).

	Direction of mode	Base-fixed structure	Isolated structure
Analytical value	x	0.590	1.710
	y	0.854	1.819
Experimental value	x	0.67	1.54
	y	1.02	1.77
Error	x	11.54%	-9.94%
	y	16.27%	-2.59%

Figure 13. Vibration modes of base-fixed building from model test.

Figure 14. Vibration modes of isolated building from model test.

The fundamental period of the base-isolated building from the experimental data is 1.54 s, which is within 9.94% of the analytical results, while the fundamental period of the base-fixed building from the experimental studies is 0.67 s, with a difference of 11.54%. It is indicated that the fundamental periods of the building from experimental studies meet well with the analytical results. The shapes of the vibration modes for the test specimen with base-fixed and base-isolated are similar to the analytical modes for both building, respectively. It reveals that the test specimen can capture the vibration characteristic of the prototype structure perfectly, and the stiffness simulation for isolation bearing is successful.

5.3.2 Acceleration response

According to the Eq. 5, the peak acceleration of the prototype structure can be calculated from the experimental results:

$$a_{pi} = K_i a'_m / S_a \quad (5)$$

where a_{pi} is the peak acceleration for the i th floor of the prototype structure (g); K_i is the magnification factor of the acceleration at the i th floor; a'_m is the peak acceleration of the applied ground motion (g); S_a is the similitude scale factor for acceleration, 2.439, as shown in Table 6.

Subjected to ground motions scaled to 0.31 PGA, the peak accelerations of each floor of the prototype structure are shown in Table 9. It indicates that the acceleration response of the base-fixed structure is increasing as the height increased, and the magnification factors of the acceleration

on the roof are approximately 2.10 and 1.57 in x and y directions, respectively. The acceleration response on the roof of the isolated building is only 0.056 and 0.064 g in x and y directions, with the magnification factor of approximately 0.30. The acceleration magnification factors for the roof of the base-isolated building are about 6 times smaller than those for the base-fixed one, meet well with the analytical results.

5.3.3 Displacement response

The peak displacement for the prototype structure can be calculated from the experimental results using Eq. 6:

$$D_{pi} = \frac{a'_m}{a_i} \frac{D_{mi}}{S_d} \quad (6)$$

where D_{pi} is the peak displacement for the i th floor of the prototype structure (mm); D_{mi} is the peak displacement for the i th floor of the test model (mm); a_i is the peak acceleration measured on the shaking table corresponding to a'_m (g); S_d is the similitude scale factor for displacement, 1/35, as shown in Table 6.

The ratios of the peak drifts on each storey to the ground motions are presented in Table 10. It is indicated that the ratio of the maximum inter-story drift rotation for the base-fixed building to rare intensity earthquakes is 1/785, and the ratio for the isolated building is 1/2339, less than the limit value of elastic story drift rotation for multi-story and tall steel structures (1/250). The average storey drifts of the isolated building are less than

Table 9. Maximum accelerations of all floors from experimental studies /g.

Floor	Response of X-Dir			Response of Y-Dir		
	Isolated	Base-fixed	Isolated/Base-fixed	Isolated	Base-fixed	Isolated/Base-fixed
4	0.056	0.393	0.14	0.064	0.345	0.19
3	0.041	0.268	0.15	0.062	0.193	0.17
2	0.038	0.192	0.20	0.053	0.191	0.28
1	0.053	0.187	–	0.056	0.220	–
0	0.187	0.187	–	0.220	0.220	–
maximum magnification factor	0.30	2.10		0.29	1.57	

Table 10. Ratios of the maximum inter-story drifts of the prototype building from experimental studies.

Earthquake intensity	Base-fixed building (1/θ)		Isolated building (1/θ)		Reduction ratio	
	Y-Dir	X-Dir	X-Dir	Y-Dir	X-Dir	Y-Dir
Frequently	5593	2880	14269	8318	0.61	0.65
Basic	1852	1395	6035	4322	0.69	0.68

	Taft	63.7	57.05

those of the base-fixed one by reducing the peak story drifts by a reduction of 61–69%, which is within 10% of the analytical drifts.

The peak displacement of the isolation layer for the prototype structure estimated from the experimental results of the test specimen subjected to the rare intensity ground motions is shown in Table 11. The peak displacement in the case of the 1940 El Centro record reaches to 111.65 mm, consisting well with the previous analytical results, 107 mm.

6 CONCLUSION

The E-Block of Guangdong Science Center is a complex large span steel frame. Isolation system was introduced in the mega structure for the first time in the China. Through the non-linear dynamic analysis and shaking table test, the following conclusions are the main finding of the study:

1. Base isolation system lengthens the fundamental period of the building, and the basic vibration modes change from bent or/and torsion to translation, upgrade the vibration modes of the superstructure, and make the seismic response smooth and regular.
2. The natural characteristic of the prototype structure calculated from the experimental results matches the FEM analytical results well, so the experimental test setup can simulate the dynamic properties of the prototype structure preferably.
3. During the ground motions scaled to 0.31 g PGA, the acceleration magnification factors for the base-isolated building are about 6 times smaller than those of the base-fixed one. The modification effect of the isolation system is remarkable.
4. The storey drifts of the base-isolated building are less than those of the base-fixed one greatly, and the reduction ratios are about 0.61–0.69. The deviation to the analytical values is less than 10 percent.
5. Subjected to the ground motions scaled to 0.31 g PGA, both the base-fixed and the base-

isolated buildings are in elastic stage, while the internal forces in the base-isolated building is probably one third of those in the base-fixed one. The peak deformations of the isolating layer in the case of the 1940 El Centro record are in the range of 39.9–111.65 mm, which consists with the analytical value.

On the whole, the isolation system can improve the seismic performance of the structure, especially for the structure with an irregular plan. Besides, because of the stiffness of the huge columns, the response of each huge column of the base-isolated building is harmony basically. The study indicates that the isolation design of GSC is rational, and is a helpful explore to the seismic design measure for huge civil engineering.

Effect of material ingredients on the cement-based self-leveling material

Jun Liu, Jiajian Hu, Runqing Liu & Yuanquan Yang

School of Materials Science and Engineering, Shenyang Jianzhu University, Shenyang, China

ABSTRACT: The effect of water-reducing agents, fly ash, and re-dispersible latex powders on the flexural strength, compressive strength, and fluidity of the cement-based self-leveling material was investigated. The results show that the addition of fly ash can improve the fluidity of self-leveling mortar; however, excessive fly ash leads to a higher water requirement. Fluidity of the system decreases when additional fly ash is added at a constant water–cement ratio, which decreases the compressive strength and flexural strength. Water-reducing agents can improve the fluidity of self-leveling mortar; however, their compressive strength decreases after 1–7 days. Addition of re-dispersible latex powders leads to more water absorption and unfavorable fluidity.

1 INTRODUCTION

Compared with developed countries, the research on the ground leveling materials started late in China, which was proposed about at the end of the 1980s and began about the 1990s. Originally, the development speed, popularization, and promotion are relatively slow (Dong Sufen, 2009). Because of the rapid development of China's reform and opening-up policy and rapid development of economy, high quality of foreign re-dispersible latex powder, water-reducing agent, and other materials were introduced (Ren Zengzhou, 2010). Therefore, the quality of these materials has been greatly improved in China, and their price is relatively low too. Thus, it is important to provide a good environment for further research so that self-leveling materials undergo fast development.

Cement-based self-leveling mortars have advantages of good fluidity, fast strength development, simple construction, and good leveling, and they are often used in concrete ground of office buildings, apartments, shopping malls, schools, hospitals, factories, parking lots, and ship (Gao Shujuan, 2013 & Huang Tianyong, 2015). They have unique advantages compared with conventional mortar in floor construction. However, there are many problems in their popularization and application. Their high price is a particularly serious problem; therefore, it is very important to control the cost of self-leveling mortar. Because the total amount of the emission of fly ash from China's coal-fired power plant annually increased, the pressure on the environment became severe. Use of fly ash can not only reduce the price, but also reduce the enormous pressure on the ecological environment and improve the self-leveling mortar's fluidity at a certain extent.

Recently, researchers have studied the preparation and properties of self-leveling mortar in China. Gu Jun (2008) studied polycarboxylate superplasticizer-modified self-leveling cement and pointed out that the polycarboxylate was suited for self-leveling cement mortar and is highly cost-effective. However, polycarboxylate superplasticizer may change air entraining performance slightly, so bubble problem should be attended. Wu Jie and Guo Qiang found that the complex retarder can make up for the deficiency of a single retarder, which has the advantages of each retarder and improves the comprehensive performance of the retarder. Hassan et al. used POFA and PBC in self-leveling cement mortar; POFA and PBC can prevent the separation of the mortar with a high-efficiency water-reducing agent. The paper by Canbaz M described that the setting time of cement increased with the increase of the additive. In Self-Compacting Mortar (SCM), Gneyisi et al. used fly ash instead of natural fine aggregate, in which the work of self-leveling mortar was improved effectively.

It is very important to study the effect of material composition on the physical properties of cement-based self-leveling material, considering that the composition of the cement-based self-leveling material was decided by the mixture ratio. According to the different mixture ratios, different properties of self-leveling materials resulted. Fly ash, water-reducing agent, and re-dispersible latex powder were critical factors and hence their effects on the mechanical properties of leveling material were investigated. It is significant to guide the production and preparation of self-leveling materials. The experimental research program in this paper is designated to change fly ash, water-reducing agent,

and re-dispersible latex powder content, aiming to study the influence of mixture ratio on compressive strength and flexural strength of cement-based self-leveling mortar.

2 EXPERIMENT

2.1 Materials

Portland cement used in this study is provided by Dalian Xiao Ye Tian cement plant. Fly ash, water-reducing agent, re-dispersible latex powder, calcium hydroxide, and sand are also used in this experiment.

2.2 Mix ratio design

The proportions of mortar mixture were 20:40:40:0.6:0.35:1:1 by mass of ordinary Portland cement, fly ash, water-reducing agent, re-dispersible latex powder: retarder: calcium hydroxide, respectively. Fly ash, water-reducing agent, and re-dispersible powder were selected as the three main variables. Fly ash was used at 20%, 25%, 30%, 35%, and 40% replacement by weight for cement while others were kept constant. Re-dispersible latex powder was used at 0.3%, 0.35%, 0.4%, 0.45%, 0.5%, and 0.55%, and water-reducing agent was used at 0.5%, 0.55%, 0.60%, 0.65%, 0.70%, and 0.75%, respectively.

2.3 Methods

In accordance with the proportion of raw materials, the materials were weighted and then poured into a mixing container. Then, low-speed stirring was performed for 1 min, stopped for 30 s, continued at high speed for 1 min, stopped for 5 min, and then continued at high speed for 15 s. If there are bubbles, stirring was stopped for 1 min. The specimens were demolded and cured in lime-saturated water at $23 \pm 2^\circ\text{C}$ until testing.

The specimens were kept in molds for 24 h at the room temperature of $23 \pm 2^\circ\text{C}$, and the relative humidity was 50. Wind speed of the test area was less than 0.2 m/s. All experimental methods were in accordance with the JC/T985-2005, “ground with cement-based self-leveling mortar”.

3 RESULT AND DISCUSSION

3.1 Effect of addition of fly ash on the performance of self-leveling mortar

According to the experiment, the mixture ratio of fly ash was changed. The fly ash was used at 20%, 25%, 30%, 35%, and 40%, while others were kept

constant. The compressive strength and flexural strength of the mortar were determined at 1 and 7 days; the test results are presented in Figure 1(a) and Figure 1(b). Fluidity of the self-leveling material was determined, and the test results are presented in Figure 1(c).

Fly ash has a certain effect on fluidity in the cement-based self-leveling material, and the fluidity

(a)

(b)

(c)

Figure 1. Effect of addition of fly ash on the strength and fluidity of the self-leveling mortar.

of fly ash can be improved by appropriate addition of fly ash. Figure 1(a) shows the effect of fly ash on the fluidity of the self-leveling mortar, the initial fluidity and 20-min fluidity of self-leveling mortar are more than 130 mm in accordance with the national standard. The fluidity at 20 min is higher than the initial fluidity, which is due to the effect of retarder. The cement flocculation structure is destroyed by the retarder, and more free water is released so that the fluidity increases. When the fly ash is 30%, the fluidity of fly ash reaches its maximum. The initial fluidity and 20-min fluidity are 150 and 153 mm, respectively. With the increase of fly ash content, the fluidity of self-leveling mortar first increases and then decreases. The result may be attributed to the existence of a large amount of glass beads from fly ash. Because of the particle size effect and water-reducing performance from these glass beads, the fluidity of self-leveling mortar increases. When fly ash content is more than 30% and the water cement ratio is kept constant, a large amount of water is needed, so fluidity of self-leveling mortar decreases. It is important to choose an appropriate amount of fly ash to improve the fluidity of self-leveling mortar.

Figure 1(b) shows the effect of fly ash content on the flexural strength of self-leveling mortar, and the amount of fly ash has a great influence on the flexural strength at 7 days. When the amount of fly ash is less, its flexural strength is higher, the flexural strength at 1 day reaches 2.6 MPa, and that at 7 days reaches 5.4 MPa. With the increase in fly ash content, the flexural strength of the self-leveling mortar at 1 day decreased slowly and remains almost unchanged. This result may be attributed to the pozzolanic effect of fly ash. There is almost no hydration reaction for fly ash at 1 day, during which period fly ash just plays the role of a micro aggregate and a filler. When the amount of the fly ash is 20–25%, mortar flexural strength at 7 days decreased slowly. However, when the amount of the fly ash is 25–30%, the flexural strength at 7 days decreased rapidly, by about 26.4%. When the amount of the fly ash mortar is 30–45%, the flexural strength at 7 days tends to be low. With the increase of fly ash content, the flexural strength of self-leveling mortar showed an overall downward trend. On the one hand, the rate of cement hydration decreases by low activity of fly ash. On the other hand, calcium silicate hydrate is reduced, which results in a gradual decrease in the strength of the self-leveling mortar.

Figure 1(c) shows the effect of fly ash content on the compressive strength of self-leveling mortar. When fly ash content is 20%, the compressive strength reaches its maximum value, that is, 18 MPa. With the increase of fly ash, strength at 1 and 7 days were gradually decreased. Compared

45% with 20%, self-leveling mortar's compressive strength at 1 and 7 days were decreased by 40.9% and 29.4%, respectively. When the amount of fly ash is more, the pozzolanic effect of fly ash is very low and reaction cannot fully take place, so the strength decreases by a large margin. Considering the influence of fly ash content on the fluidity and compressive strength, fly ash content of 35% is the best.

3.2 *Effect of addition of water-reducing agent on the performance of self-leveling mortar*

According to the experiment, the mixture ratio of water-reducing agent was changed. The water-reducing agent was used at 0.5%, 0.55%, 0.60%, 0.65%, 0.70%, and 0.75%, respectively, while others were kept constant. The compressive strength and flexural strength of mortar were determined at 1 and 7 days, and the test results are presented in Figure 2(a) and Figure 2(b). Fluidity of self-leveling material was determined, and the test results are presented in Figure 2(c). High-performance water-reducing agent is the primary material of self-leveling mortar, and it is the most important influential factor on the fluidity and strength.

Figure 2(a) presents the effect of addition of fly ash water-reducing agent on the fluidity of self-leveling mortar. The effect of water-reducing agent on the fluidity is obvious. When water-reducing agent is 0.5%, fluidity of self-leveling mortar is the minimum. Initial fluidity and 20-min fluidity are 120 and 135 mm, respectively, but the initial fluidity does not meet the national standard. The national standard requested the initial fluidity to be more than 130 mm. With the increase of water-reducing agent, the fluidity increases obviously. When the content of water-reducing agent is low, liquidity is not large. This is because water-reducing agent is not enough to disperse cement particles, and the thickness of adsorbed water film on the surface of cement was reduced. When the amount of water-reducing agent is large, the fluidity of self-leveling mortar is gradually increased. This is because the water-reducing agent is mixed into fresh cement paste and cement particles dispersed by water-reducing agent become more and more obvious. The flocculation structure of cement particles was damaged more significantly, thus more free water from flocculation structure was released. Therefore, the fluidity of cement paste increased. Fluidity at 20 min did not decrease; however, it was higher than the initial fluidity, which is mainly caused by the combined effect of retarder and water-reducing agent during the hydration.

Figure 2(b) presents the effect of water-reducing agent on the flexural strength of self-leveling

(c)

Figure 2. Effect of addition of water-reducing agent on strength and fluidity of the self-leveling mortar.

mortar. The influence of water-reducing agent on the flexural strength at 1 and 7 days is different. With the increase of water-reducing agent, the flexural strength at 1 day first increases and then decreases. When the amount of water-reducing agent is 0.60%, the flexural strength at 1 day is the best. At the low content of water-reducing agent, cement particles were dispersed by water-reducing agent more homogeneously. Mortar specimens become more compacted, so strength at 1 day increases. When the content of water-reducing agent increases, $\text{Ca}(\text{OH})_2$ of the hydration products become plate from the block, hardening structure of the mortar become loose, so the appropriate water-reducing agent has strong effect on the early strength of the self-leveling mortar. However, with the increase in the content of water-reducing agent, the mortar flexural strength at 7 days decreases. The result may be attributed to the hydration. With water-reducing agent, more plate calcium silicate hydrates were produced, and the mortar structure was more loose, thereby reducing the strength.

Figure 2(c) presents the effect of water-reducing agent on the compressive strength of self-leveling mortar. The effect of water-reducing agent at 1 and 7 days is the same. With the increase in the content of water-reducing agent, the compressive strengths at 1 and 7 days are gradually reduced, 0.5% was compared to 0.75%, compressive strengths at 1 and 7 days were decreased by 29.3% and 32.3%, respectively.

3.3 Effect of addition of re-dispersible latex powder on the performance of self-leveling mortar

According to the experiment, the mixture ratio of re-dispersible latex powder was changed. The re-dispersible latex powder was used at 0.3%, 0.35%, 0.4%, 0.45%, 0.5%, 0.55%. The fluidity, compressive strength, and flexural strength are measured.

Figure 3(a) presents the effect of re-dispersible latex powder on the compressive strength of self-leveling mortar. The influence of re-dispersible latex powder with water-reducing agent and fly ash is different. When re-dispersible latex powder is 0.3%, the initial fluidity reached 143 mm, 20-min fluidity reached 145 mm; in other words, 20-min fluidity is not lost. When re-dispersible latex powder is 0.5%, the initial fluidity is 128 mm, 20-min fluidity is 135 mm, 0.5% compared with 0.3%, the initial fluidity and 20-min fluidity decreased by 11.7% and 6.9%, respectively. With the increase of re-dispersible latex powder, the fluidity of mortar is gradually reduced, which is due to the function of water retention. When re-dispersible latex pow-

(a)

(b)

(c)

Figure 3. Effect of addition of re-dispersible latex powder on strength and fluidity of the self-leveling mortar.

der was excessive, cohesion of the new self-leveling mortar became so large that fluidity was reduced. Therefore, the amount of emulsion powder should not be too high.

Figure 3(b) presents the effect of re-dispersible latex powder on the flexural strength of self-leveling mortar. When re-dispersible latex powder is 0.4%,

the flexural strength at 1 and 7 days are the lowest, 1.9 and 3.1 MPa respectively, and the flexural strength at 1 day does not meet the national standard. When the powder is 0.35%, the maximum flexural strength at 1 day is 2.4 MPa. When the powder is 0.45%, the maximum flexural strength at 1 day is 4.0 MPa.

Figure 3(c) presents the effect of re-dispersible latex powder on the compressive strength of self-leveling mortar; with the increase of powder, compressive strength at 1 day increased gradually. When the powder content is 0.3%, the compressive strength at 1 day reached 6 MPa. When the powder content is 0.5%, compressive strength at 1 day reached 8.3 MPa and the strength was increased by about 27.7%. Because of the initial hydration, the water content is further reduced by the hydration of cement or dry powder. The polymer particles gradually condensed, and a thin film was formed. The film has a higher ability of deformation, and the hydration products and cement aggregate coming together, resulting in an increase of compressive strength. However, the compressive strength at 7 days is different from that at 1 day. With the increase in the amount of powder, the compressive strength decreased from 11.9 to 10.4 MPa gradually, which is due to the destruction of the original structure by hydration product, so the mortar strength at 7 days did not increase but decrease. Therefore, the amount of the re-dispersible latex powder should be controlled in a certain range.

4 CONCLUSIONS

1. In a certain extent, fly ash can increase the fluidity of self-leveling mortar, early strength of the mortar almost is not influenced; however, fly ash is not unfavorable to mortar compressive strength and compressive strength at 7 days.
2. Water-reducing agent can improve the fluidity of self-leveling mortar; however, it is unfavorable to the compressive strength of self-leveling mortar at 1 and 7 days.
3. Re-dispersible latex powder can increase the water absorption and raise the corresponding consistency. With the increase of re-dispersible latex powder, the fluidity of mortar is gradually reduced, the strength at 1 day was increased, and the compressive strength at 7 days was decreased.

J.P. Suen

National Cheng Kung University, Tainan, Taiwan, R.O.C

ABSTRACT: Recently, the number of ecological restoration projects at waterbodies have increased significantly and applied in many areas. Many researchers have been working on large-scale restoration projects with some complex variables and considerations involved, but only few are focused on small-scale projects. The purposes of this study are: (1) to evaluate and monitor the ecological restoration projects at Barclay City Park, Tainan City, Taiwan R.O.C, by using Post Project Appraisals (PPAs) and compare with several city parks in Bandung, Indonesia; (2) to promote an ecological approach that incorporates public perceptions into city parks restoration projects in Bandung City, Indonesia, to determine the environment-friendly constructions that provide long-term benefits to the ecosystem. The data were collected by kick samplings and used following the Before-After-Control-Impact (BACI) method. We sampled and analyzed seven water quality parameters, including temperature, electrical conductivity, salinity, pH, dissolved oxygen, and so on, at several sections, and then identified the aquatic habitat within. The results showed that water quality condition was still unclear with limited ecological value. The study also identified that the degraded water quality condition has increased the public awareness. Therefore, the application of sustainable ecological projects in urban drainage systems could also improve the aesthetic value in the context of urban landscape and gain growing public interest due to its positive effects on water quality and quantity issues. Furthermore, the study recommended water quality monitoring and public hearings programs. Further recommendation is the principles of ecological effectiveness, methodological and economic efficiency, and sociocultural engagement, which should be interwoven in the application of the guidelines and the framework for planning and implementing ecological restoration.

1 INTRODUCTION

1.1 *Background*

Recently, the number of ecological restoration projects at waterbodies has increased significantly and applied in many areas. Many researchers are working on large-scale restoration projects with some complex variables and considerations involved, but only few are focused on small-scale projects. Restoring degraded ecosystems or creating new ones has become a huge global concern. In Indonesia, for instance, many cities are rebuilding their city parks to achieve a sustainable ecological development through environment-friendly construction. This patchwork movement to rebuild the city parks is well supported by the government. Such projects are, moreover, likely to become far more common as the cities rapidly urbanize, turn to green infrastructure, or environment-friendly construction to address problems like climate change, flood control, and pollution within cities. However, hardly anyone does a proper job of

measuring the results, and when people do, it generally turns out that ecological restorations seldom function as intended.

Therefore, an appropriate approach was introduced, that is, Post Project Appraisals (PPAs). PPAs involves the evaluation of the effectiveness of restoration projects on the basis of systematic data collection (Tompkins and Kondolf, 2007). PPAs are not just the records of project assessment, but rather are the references to improve future projects.

The purposes of this study were: (1) to evaluate and monitor the ecological restoration projects at Barclay City Park, Tainan City, Taiwan R.O.C, using Post Project Appraisals (PPAs) and compare with several city parks in Bandung, Indonesia; (2) to promote an ecological approach that incorporates public perceptions into city parks restoration projects in Bandung City, Indonesia, to determine the infrastructure components or environment-friendly constructions that provide long-term benefits to the ecosystem.

2 METHODS

Several methods were used in this study. In order to analyze by using PPAs, the first methods were facies mapping and water quality sampling for the first study areas. In the second set, we used statistical analysis by SPSS 17.0 and a set of questionnaire prepared for the respondents in the second study. A simple and short presentation was also prepared to introduce the purpose of this questionnaire. In the questionnaire, the respondents were asked to rank their satisfactions about the features at city parks related to environment-friendly construction. The respondents were asked to rate each statement by marking one of five boxes that most exactly/closely matched their perspectives. The responses were later coded on a five-point numerical scale for analysis: 1 = Dissatisfied, 2 = Somehow dissatisfied, 3 = Neither satisfied nor dissatisfied, 4 = Somehow satisfied, and 5 = Satisfied. Then, they were asked to respond to written items on the basis of their suggestions, if they have any.

3 STUDY AREA

In this study, two areas with several sites were selected. The first locations were Barclay Memorial Park and Tainan Athletic Park in Tainan City, Taiwan R.O.C. The second locations were Lansia Park and Maluku Park in Bandung City, Indonesia. The Barclay Memorial Park was located in the southern Tainan City with Zhu Creek flowing across and its site is about 3.3 ha. The site was abandoned in 1994 due to the land dispute between the Tainan City and Tainan County Governments causing garbage and safety problems until the reconstruction in 2001 (Tainan Business Culture and Art Foundation, 2008). The second site was Tainan Athletic Park, which was enclosed by Jiangkang road to the north, Datong road to the east, Dalin road to the south, and Nanmen road to the west. The park is about 130 acres and contains facilities for all types of sporting activities. Meanwhile, the second locations were conducted in two city parks at Bandung City, Indonesia. Bandung City is counted as the capital of West Java province in Indonesia (Fig. 1). It is Indonesia's third largest city by population, with over 2.4 million persons from 30 districts. Geographically, Bandung City has an area of about 16.729,65 ha. In 2014, the average temperature ranged between 22.5 and 23.7°C. The average annual rainfall precipitation in 2014 is 198.8 mm. Meanwhile, Bandung City is reported to have around 600 parks, with the city government targeting the adoption of thematic concept in 30 parks. The major purpose of the city parks in Bandung City is recreation intended for

Figure 1. Location of Bandung City, Indonesia.

improving ecological environment with harmoniously formed landscapes and waterscapes of natural features.

4 RESULTS AND DISCUSSIONS

On the basis of the water quality sampling result, DO varies inversely with the temperature; increasing temperature (warm water) can hold less dissolved oxygen because a portion of oxygen converts from liquid state to a gas, and decreasing temperature (cold water) can hold more dissolved oxygen. It was indicated in the last survey in Barclay Memorial Park on December 2013 that the value of DO was higher than that in the previous survey because in the data collected during the beginning of the winter season, DO was higher than the DO measured in March 2010, which was in the spring season. It was also known that DO in the upstream is higher than in the downstream and it was very poor, which was attributed to the nonflowing water. Nonflowing water occurs because there was no elevation on the surface and no aeration naturally of creek's water. Low DO due to large amounts of floating plants consumes oxygen and algae. When organic matter, such as animal waste or improperly treated wastewater, enters a body of creek, vegetation and algae growth increases and DO decreases and is decomposed through the action of aerobic bacteria.

This study also identified that Fragrant Water Lilies (*Nymphaea odorata*) dominate as the floating plant in Barclay Memorial Park. Basically, this plant is desirable because they enhance the aesthetics of waterbody, create nice flowers, and are essen-

tial to a healthy ecosystem. Besides, they can serve as a food source for organisms in the waterbody, hiding places for fish and insects, and nutrient sinks. However, they can overrun the waterbody and become undesirable if not controlled, as happened in the Barclay Memorial Park. These floating aquatic weeds can cause severely low DO levels because they physically block the transfer of oxygen from the atmosphere to the water's surface. They can also block light and prevent photosynthesis (oxygen production) by submerged plants. Moreover, death and decay of floating plants provides the conditions for a further depletion of DO levels.

At Barclay Memorial Park, the DO level was poor with a value of 3.54 mg/l on upstream, 8.39 on middle stream, and 1.57 mg/l on downstream. At Tainan Athletic Park, the dissolved was also poor with a value of 4.44 mg/l on upstream, 5.89 on middle, 4.66 on downstream, indicating neighborhood sewage and no elevation on the surface of water. At levels below 5 mg/l, some fish become stressed. Large fish usually have a greater need for oxygen than smaller fish of the same species. On the basis of visual investigation, small fish have adapted to waters that were chronically low in DO level. At downstream of Barclay Memorial Park, fish cannot survive because of the DO level lower than 1.57 mg/l.

At Barclay Memorial Park and Tainan Athletic Park, pH condition in water was neutral (7.44–7.71). Stream water usually ranges from a pH of 6.5 to a pH of 8.5; this range is considered to be an optimal range for most aquatic life. The natural pH varies from river to river, but the pH range of a river will generally remain stable. The conductivity in Barclay Memorial Park was higher than that in Tainan Athletic Park because of the higher temperature in the former. However, the conductivities in Barclay Memorial Park and Tainan Athletic Park were below the SPC minimum standard for freshwater lakes/streams, which is 2 $\mu\text{S}/\text{cm}$ (range: 2–100 $\mu\text{S}/\text{cm}$). By knowing that the conductivity of Zhu Creek was below the minimum standard, it does not mean that the Zhu Creek was not polluted because again on the basis of visual investigation, there were some fish like *Java tilapia* that can survive in polluted waterbody. Conductivity in waterbody was affected primarily by the geology of the area through which the water flows. The stream that passed through Tainan Athletic Park consisted of concrete bedrock; that is why the streams tend to have a lower conductivity because concrete was composed of more inert materials that did not ionize (dissolve into ionic components) when washed with water. On the contrary, streams that run through Barclay Memorial Park areas with clay soils tend to have a higher conduc-

tivity because of the presence of materials that ionize when washed with water. A failing sewage system would increase the conductivity because of the presence of chloride, phosphate, and nitrate; an oil spill would also lower the conductivity (<http://water.epa.gov>). Besides, the conductivity depends on temperature. During higher winter flows, the lower saline surface waters dominate, resulting in a decrease in in-stream conductivity.

Salinity of Barclay Memorial Park and Tainan Athletic Park were in the low range (around the Minimum Amount of Salinity of Brackish Water = 0.5 ppt). The low amount of salinity depends on the low amount of conductivity. The higher conductivity indicates higher salinity. Some solutions were offered, which can partly remove floating plants (Fragrant Water Lilies—*Nymphaea Odorata*) to increase dissolved oxygen content, water flow, and aeration.

On the contrary, the study also used public perceptions through satisfaction survey for the second study area in Bandung City, Indonesia. The data obtained from the questionnaires were processed using the SPSS 17.0 program for statistical analysis. Specifically, Multivariate Analysis of Variance (MANOVA) was used, and this was a way to test hypotheses in which one or more independent variables or factors were proposed to have an effect on a set of two or more dependent variables (Mathew 1989). MANOVA was used in this work to test whether different types of respondents and locations of city parks affect the perceptions of the respondents with regard to a measure of aesthetic value based on various perceived environment-friendly construction attributes (bioretention, buffer strips, permeable pavements, canopy trees, and others). In SPSS, there are four multivariate measures: Wilks' lambda, Pillai's trace, Hotelling's trace, and Roy's largest root. The difference between the four measures is the way in which they combine with the dependent variables in order to examine the amount of variance in the data. The results of the multivariate analysis cannot be shown in this paper due to the space limitation. However, in Wilks' lambda criteria, the intercept showed Wilks' $\lambda = 0.003$, $F(5, 155) = 9008.768$, $p < 0.001$, and the parks showed Wilks' $\lambda = 0.444$, $F(21, 1316) = 57$, $p < 0.001$.

The results indicated that most visitors satisfied with the available environment-friendly construction features in targeted city parks. Canopy is the most preferable environment-friendly construction feature according to public perceptions, whereas bioretention is the least preferable one. Some comments from respondents mentioned that they agreed and supported environment-friendly construction to be applied in public city parks. Most of them also stated that it is necessary to improve

the aesthetic value by applying those features in study area.

5 CONCLUSIONS

The study also identified that the degraded water quality has increased public awareness. Therefore, the application of sustainable ecological projects in urban drainage systems could also improve the aesthetic value in context of urban landscape and gained growing public interest, as a result of its positive effects on water quality and quantity issues. Furthermore, the study recommended the necessary of continuing water quality monitoring and public hearings programs. Further recommendation is that the principles of ecological effectiveness, methodological and economic efficiency, and sociocultural engagement should be interwoven in the application of the guidelines and the framework for planning and implementing ecological restoration.

The outcomes showed that the public city parks are one of the most effective application areas for green infrastructure concept design. Green infrastructure investments in the study area boost the economy, enhance community health and safety, and provide recreation, wildlife, and other benefits that can increase the level of public satisfaction. This study can guide local planners and decision makers from the other cities to create and develop their public city parks on the basis of green infrastructures concept design. As with other forms of infrastructure, green infrastructure requires sustainable management and maintenance arrangements to be in place if it is to provide benefits and services in the long term. Arrangements for

managing green infrastructure and funding its management over the long-term should be identified as early as possible when planning green infrastructure and factored into the way that it is designed and implemented.

Xi'an, Shaanxi, China

ABSTRACT: Green building materials represent not only the material itself, but also it is a representation of a use policy, covering the whole life cycle of a construction. In view of this, when it achieves some success in energy saving, nonpollution, and recycling of building materials, it provides new ideas for the green building materials research. In the reconstruction of Guifeng Temple in Mount Zhongnan, the designers considered the future development trend of the region, especially taking three factors of the reuse of building materials in account, selected of the structure and installment construction, and finally made the plan and design systematically with local building materials. More than protecting the traditional architectural style, meanwhile, it diversifies the development of the temple, leading to a preliminary mode of reconstruction, which adapts to the local economy and culture.

1 INTRODUCTION

This design is a part of historical area planning design of Guifeng Temple, located in Mount Zhongnan, over 30 km away from Xi'an at 667 m above sea level. The climate here is warm and semi-humid with clear four seasons, known as continental monsoon climate with warm spring, hot and rainy summer, moderate moist autumn, and cold and dry winter.

There is a tradition of seclusion for literati and Buddhist, with natural environment in good condition. "Guifeng Moonlight" is the most famous sight in temple so far. Besides, it is rich in natural resources, and several natural villages connect with each other into a town at the foot of the mountain, where strawberry plants have been extensively cultivated as the main economic crop. Buildings in the town and structures in the field are all built up with the local materials in various and flexible ways.

After communicating with presiders many times, we arrived at two main contradictions, the first is building materials can only rely on local human transportation, so we chose the construction process as simple as possible and the other is building insulation design. Resolution strategies are grouped into two measures, one is building materials are all set in a standard size within two men's luck (the longest edge no more than 3.3 m), and the construction technologies limiting to stitching or

masonry local mature technologies; the other is to choose the unified and closed architectural layout in north China, thus the whole building forms several organic, closed yard as well as half-covered space for outdoor activities to adjust the micro climate.

2 RECONSTRUCTION OF GUIFENG TEMPLE

2.1 *Local green building materials*

An investigation was put forward before design, simply about the local building materials.

Agriculture is the pillar industry of this region, thousands of cement columns stand in fields as supports of strawberry cultivation, which are now being replaced by metal industries. Such cement columns share a common size about 1.2 m high and a section size of 150*150 (mm), for they are produced by pouring cement into the template until solidification. Without internal reinforcement, their bending strength is very low.

In addition, there are serious problems among houses in the villages around and most of the original buildings in the temple, especially structure security and thermal properties. After evaluating their cultural value, we planned to rebuild all those prefabricated and adobe houses, gaining a large amount of bricks from demolition.

The selection of building materials goes through an assessment by “resource recycling”, for the reference factors include local source of construction waste, the strength of stock, transportation cost, safety, and sustainable aspects of comparison. Finally, we used the cement column in strawberry fields, clay brick from demolition, coal cinder from production or living, and steel from prefabricated houses.

2.2 Various structure

As building materials are diverse, different structures are used. Houses in villages are masonry structures in forms of multistories, holding a strength high enough until the villagers start to build additional structures on roof, which greatly reduced the structure security. Moreover, some villagers misuse prefabricated houses as permanent buildings, which causes a great damage to both thermal insulation and safety performance.

Besides, since the prefabricated houses are steel-framed structures while the common house are masonry structures, connections between the two parts are extremely weak.

In the existing constructions of Guifeng Temple, masonry structure and brick-concrete structure take the main part. Although they are made from bricks, the connection materials or masonry constructions are simply mud or mixed with cement mortar. Thus, these constructions are easily damaged and easy to dismantle.

2.3 Installment construction

The first reconstruction in Guifeng Temple was a hovel divided into three bedrooms for monks, followed by an expansion of one prefabricated house serving as a monastery and apartments since the monks increased. Along with the temple’s further development, several brick houses were built for the monastery, which have a library and a meditation room attached to them. Soon afterward, one more brick house was built for reception. After the recovery of “law” in the temple, a bathroom and laundry room in masonry structure was added.

The “law” requires more strict patterns to the layout of the temple, so an entrepreneur among the believers decided to donate a new reconstruction, thus the design team is invited.

As a heritage ontology of the Qing dynasty, reparation of the main hall varies from the using requirements; not only the construction needs to be repaired, but also lights or other technical equipment need to be added. In the latest design, because the wood rot of the hall cracked, it needs a replacing wood, whose raw material is donated by

devotees fundraising and other temples’ old material. Benefitting from the gradual accumulation of those old material, construction realized a condition of “repair the old as old”.

It is obvious that compared with one-time construction, an installment construction is more suitable for the continuous development as well as a stable reparation.

3 OPTIMIZATION THEORY SUPPORT

3.1 Green building materials

On the basis of Lynn Froeschle’s book, Environmental Assessment and Specification of Green Building Materials, green building materials perform well especially in resource efficiency, affordability, and so on. In this process, green building materials represent a use policy throughout the whole life cycle of a construction.

Resource efficiency can be accomplished by utilizing recycled or renewable, natural, durable, local available, and plentiful materials.

Affordability means building costs are comparable to those of conventional materials or within a project-defined percentage of the overall budget throughout its life cycle. From another perspective, it also means lower operating costs associated with changing space configurations and greater design flexibility.

3.2 Composite structure

Composite structure has high flexibility to cope with differences in building materials and the demand of the architectural space. The last few decades have witnessed that composite materials not only revolutionized traditional design concepts but also made possible an unparalleled range of possibilities, for composite structures have expanded its range of application to nearly all types of combination. Therefore, a cantilever structure can composite with a masonry structures.

Composite structures offer benefits of using materials in various sizes and reducing cost by combining large components and small components. While structures composed of large components are usually better than a structure composed of a large number of smaller components more easily without damage and dismantling, it is recommended to use large components in a composite structure.

Connection mode within a composite structure also has an important effect on reducing cost for easy dismantling, so materials adopt the mechanical connection method involving wood or steel structures.

3.3 Installment construction

Installment construction has been popular among several construction units because of the gradual collection mode of recycled material from demolitions in pace with updates of villages nearby.

According to a project management, the main factors in the installment construction are size, capital, planning, risk, costs, using requirements project promotion, and reasonable tax avoidance. Temples' demand changes constantly; learning the lessons of the temple overextended in early "Reform and Opening up", requirements of the reconstruction of temple need to be tested by time, and can only be realized gradually rather than overnight. In terms of saving money, the most effective way of controlling cost is reasonable tax avoidance.

The administration of taxation on real estate development enterprises on the management of land value-added tax liquidation of circular (Guoshuifa [2006] NO.187) regulation states: "the land value-added tax should be calculated according to departments of the state in real estate projects approved, while in the installment construction, the land value-added tax should be carried out cooperating with each stage."

Conventionally, an estate feasibility study report should be submitted when applying for a land approval, including the development schedule. Companies tend to pick up the land overall, but construct in installment. Because of the different land range, a discount in tax is obvious.

4 MORE SYSTEMATIC RECONSTRUCTION MODE

4.1 Recycling resources from surrounding villages

Local materials in most stock that can be conveniently transported are recycled clay brick from demolition. Bricks are used to build up walls whose

thickness is 240 mm, the most common mode of local wall (see Figure 1(a)).

The second most common stock and the most convenient one to be transported is cement column in strawberry fields. According to section size and length, cement columns will be piled up in the orthogonal direction alternately, without any adhesive material (see Figure 1(b)), beneath which waterproofing materials are set at the interface with steel beams, forming the roof construction.

To make it easier to be disassembled and built, steel beams are applied as structure, which come from prefabricated houses or old buildings. All the qualified beams are set at a length of 3.6 m, considering the size of clay brick and cement column.

Coal cinder from production or living is used to build square and road (see Figure 1(c)). After the compaction process, the surface can gain enough leveling and compaction.

As mentioned above, "resource recycling" in this design is locally available, plentiful, and renewable, forming a building strategy as an implementation of green building materials.

4.2 Designed for disassembly

Spaces with different functions in the temple require different forms or sizes of a space, leading to differences among structures.

Small-span spaces like monk's apartment, guest room, and bathroom use the masonry structure, for the local traditional building method is to pile up the bricks, with special mud masonry.

Long-span spaces like the main hall, meditation room, and monastery use large cantilever structures. In this case, only one column is needed to support a whole square (see Figure 1(d)), less than a frame structure, in which four columns are needed in every square.

Besides, to realize a recycle of resources both in constructing this temple and making it recyclable for other construction in the future, it is designed

Figure 1. Structures used in the reconstruction.

for disassembly at the beginning. The steel components are connected by mechanical joint, and the cohesion between curtain wall and brick wall is applied to a construct site.

Finally, for the convenience of construction and disassembly, decorative components are avoided as much as possible, and all detail structures use dry hanging method rather than the wet homework.

4.3 *Installment construction in pace with local development*

Throughout the reconstruction of the Guifeng Temple, it is realized systematically in pace with the temple demands to build more constructions, not scaled up sharply. Neither the capital volume of Buddhist support nor the probability of one-time funds from a big benefactor is the focus, but the economical construction in every few years itself was supported by clear function and demands. In this way, it avoids a massive rapid construction, causing a waste of resources, and ensures adequate following funds for reconstruction, which helps realize an update in the life cycle.

It has always been a tradition, whenever it is, temples accept believers' donation, which flows to construct the temple. This type of capital circulation pattern results in a persistent update and becomes a reference for the latest reconstruction. Although the latest capital volume can push the temple achieve a rapid expansion, both the public who donated and monks prefer to regard the mass recovery as long-term planning, which should be realized in a staggered way, attaching a fund's plan divided into construction funds and operating funds. In this plan, gradual capital represents a capital using patterns, advocating to guarantee a continuous supply of operating funds.

Except from gradual collection of materials and the actual requirement of temple, what is more important in the necessities of installment construction is to keep pace with the local development, that is, the town at the foot of the mountain.

Temple in essence belongs to the cultural construction, taking on a function of presenting the social culture, whose service object is the public. In terms of the Guifeng Temple, a sharp expansion may limit the temple's normal operation because of the inability of the local foundation facilities to meet the demand; or it causes an uncontrolled impact on local development because of a sudden change on land use mutation, which closely related to the local public, the main force of the temple protection.

In view of this, the designers considered the relationship between the reconstruction of Guifeng Temple and the development of the towns in a systematic and careful way. Finally, we put forward a plan covering issues about waste management, scenic area development, support facilities, and

people's livelihood improvement, which adapts to the development of the local economy and culture.

5 SUBTOTAL

The reconstruction of Guifeng Temple is a renaissance with recycled materials, exploring a systematic using policy complying with the principles of green building materials. All the building materials applied in the design are not only local available but also expanding the source from local development and the agricultural facilities. On the one hand, the material is not limited to present conditions, but in combination with regional development trend, so the abandoned clay bricks from demolition of houses are used. On the other hand, it is not limited to materials served as buildings neither, but using agricultural facilities engineering materials as well, such as strawberries in the field of concrete column and coal production and living. Considering material sources are collected in installment, construction is designed to be realized in stages. Meanwhile, the use of materials for building maintenance operation stages is well planned.

In short, in pursuit of the green building material using policy, material selection, structure, construction, and operation management methods are all considered in an integrated way. Such a material using policy leads to a preliminary mode of reconstruction adapting to local economy and culture, whose background is thus a more universal solution, which remains to be explored by concluding more experience in projects.

Research on safety management of construction projects based on game theory

J.X. Zhao, M.M. Wang, J.H. Sun & K. Li

School of Management, Qingdao University of Technology, Qingdao, China

ABSTRACT: Shortage of construction project safety management has been one of the problems that hinder the development of construction industry. Strengthening the construction safety management can not only promote the development of the construction industry, but also promote the social stability. This paper uses game theory to study the relationship between the main parties of construction project from the macro perspective. In this paper, we first use the static game theory of mixed strategy to establish the game model between supervision units and contractors, then use principal-agent system to establish the game model between owners and supervision units, and finally use the first model into the second model to construct an extensive form between owners and supervision units and contractors. Furthermore, in this paper, we obtain the construction project safety equilibrium point and put forward the safety management strategy for the supervision unit and contractor. Finally, the application of the model is introduced by a case study.

1 INTRODUCTION

At present, in China, increasing attention has been paid to the security problem of construction, and if we cannot effectively carry out safety management in construction project, it will result in a wide range of security incidents, such as casualties, machinery and equipment damage, and project entity damage, which resulted in huge economic losses to project participants and caused serious negative impact on society. Therefore, increasing attention has been paid to the safety of construction projects, and various theories and methods for the safety management of construction projects have emerged in an endless stream.

As early as 1996, Blair put forward that all project stakeholders (owners, design units, contractors (subcontractors), government, and insurance companies, and so on) are responsible for the safety of the project (Blair 1996). Ngowi and Rwelamila (1997) pointed out that in the construction industry, safety and health are the only responsibilities of the contractor, which has been regarded as one of the main causes of frequent accidents (Ngowi et al. 1997).

In the process of safety management of construction project, the problem of responsibility and benefit distribution has a direct impact on the effect of safety management. Therefore, scholars such as F.L. Zhang introduced the game theory into the construction safety management and set up a game model of safety management

between project safety supervision authorities and contractors to determine the proportion of the supervisory organ carrying out sampling of the contractors and the punishing the contractors for unsafe construction (Zhang et al. 2002). On the basis of that, P.H. Tu also concluded the relationship between security costs, punishment, and the probability of inspection (Tu 2004). J.M. Wang and other scholars further concluded the relationship between safety construction costs, regulatory costs, penalties, and regulatory efficiency (Wang 2007). The above studies were largely limited to the game relationship between the safety supervision authorities and contractors and less consideration of the impact of owners and supervision units on the construction safety management. In view of this, in this paper, we established the noncooperative game model between supervision units and contractors, and owners and supervision units.

2 THEORETICAL ANALYSIS

Game theory mainly studies decision-making parties, which present a conflict of interest to make a set of strategies and behaviors that are interdependent in the process of mutual antagonism and competition (Wang et al. 2015). All participants in the premise of following a certain rule analyze the strategies other people may take, to choose decisions that meet their own interests, thereby obtaining a certain interest. Game theory involves the

most basic elements such as participants, strategies, and benefits.

In the process of project construction, the involved subjects include design units, owners, supervision units, supply units, and contractors, and they are mutually independent and self-financing economic entities. The actions and interests of each participating subject have a certain effect on the formation of construction safety. Although the overall goal of all participation units is consistent, as various units consider their own benefits, there will be a certain exclusion between them, so we cannot exclude the behaviors that participants do not follow the contract to construction and not seriously examine, which led to the construction project safety problems (Wang, 2013). Game theory happens to be a kind of method to study the behavior of decision-making parties, so the introduction of the game theory into the construction project safety management restricts the occurrence of adverse behavior. This paper mainly uses the mixed strategy of static game theory to establish the game model between supervision units and contractors, and then uses principal-agent system to establish the game model between owners and supervision units.

3 GAME MODEL BETWEEN SUPERVISION UNITS AND CONTRACTORS

3.1 Introduction of mixed-strategy game

1. A set of participants in a game $i, i \in (1, 2, \dots, n)$;
2. Strategic space for each participating party $S_i, S_i = \{s_{i1}, \dots, s_{ik}\}$;
3. Benefit function of each participating party $u_i(S_1, S_2, \dots, S_n)$;
4. Random selection of each participating party in k optional strategies with probability distribution $p_i = (p_{i1}, \dots, p_{ik})$, where $0 \leq p_{ij} \leq 1, j = 1, \dots, k$ and $p_{i1} + \dots + p_{ik} = 1$.

The participating parties involved in the mixed-strategy game model are the supervision units and contractors. The supervision unit's strategic space is:

$S_1 = [s_{11}, s_{12}, s_{13}] = [\text{Supervision and inspection and the conclusion is correct, Supervision and inspection but the unsafe construction is wrong to see as a safe construction, No supervision and inspection}]$

and the contractor's strategic space is:

$S_2 = [s_{21}, s_{22}] = [\text{Carry out construction according to the contract, Does not carry out construction according to the contract}]$

3.2 Model hypothesis

1. The total cost at which contractors carry out safe construction in accordance with the provisions of the safety is defined as C_1 ; the total cost at which contractors do not carry out safe construction in accordance with the provisions of the safety is defined as C_2 , and $C_1 > C_2$. The probability that the supervision units find and punish contractors who do not carry out safe construction in accordance with the provisions of the safety is defined as $\gamma (0 \leq \gamma \leq 1)$, and it reflects the efficiency of supervision and inspection of the supervision units, and the contractors should pay a fine, which is defined as a . If the supervision units do not find the illegal acts of contractors, then the supervision unit should bear certain economic responsibility, which is defined as f . The cost of supervision and inspection by the supervision units is defined as k , and if the supervision units do not carry out supervision and inspection, then they do not need to pay any cost.
2. The probability that the supervision unit conducts supervision and inspection is p_{11} , and the probability of not conducting supervision and inspection is p_{12} , where $p_{11} = 1 - p_{12}$. The probability that the contractor conducts safety construction according to the contract is p_{21} , and the probability that the contractor does not carry out safety construction according to the contract is p_{22} , where $p_{22} = 1 - p_{21}$.

3.3 Model construction and solution

According to the model hypothesis, the payoff matrix between the supervision unit and contractor was obtained, as shown in Table 1.

In the case of the mixed strategy, the expected payoff of the supervision unit is:

$$\begin{aligned} u_1 &= p_{11}\gamma[-kp_{21} + (a-k)(1-p_{21})] + p_{11}(1-r)[-kp_{21} \\ &\quad + (-k-f)(1-p_{21})] - (1-p_{11})f(1-p_{21}) \\ &= ap_{11}r - ap_{11}rp_{21} - p_{11}k + fp_{11}r - fp_{11}rp_{21} - f + fp_{21} \end{aligned}$$

According to the mixed-strategy Nash equilibrium, it is necessary to select an appropriate value

Table 1. Payoff matrix between the supervision unit and contractor.

Strategic space of the supervision unit	Strategic space of contractor	
	$s_{21}(p_{21})$	$s_{22}(1-p_{21})$
$s_{11}(p_{11}*\gamma)$	$-k, -C_1$	$a-k, -C_2-a$
$s_{12}(p_{11}*(1-\gamma))$	$-k, -C_1$	$-k, -f, -C_2$
$S_{13}(1-p_{11})$	$0, -C_1$	$-f, -C_2$

for p_{11} , which makes the u_1 maximum; therefore, the optimal first-order condition is:

$$\frac{\partial u_1}{\partial p_{11}} = a\gamma - a\gamma p_{21} - k + f\gamma - f\gamma p_{21}$$

To make the above expression equal to 0, that is:

$$p_{21}^* = 1 - \frac{k}{a\gamma + f\gamma} \quad (1)$$

the expected payoff of contractor is:

$$\begin{aligned} u_2 = & p_{21}[-C_1 p_{11} \gamma - C_1 p_{11} (1 - \gamma) - C_1 (1 - p_{11})] \\ & + (1 - p_{21})[(-C_2 - a) p_{11} \gamma - C_2 p_{11} (1 - \gamma) \\ & - C_2 (1 - p_{11})] = -p_{21} C_1 - C_2 - a p_{11} \gamma \\ & + p_{21} C_2 + p_{21} a p_{11} \gamma \end{aligned}$$

The partial derivative of u_2 to p_{21} : $\frac{\partial u_2}{\partial p_{21}} = -C_1 + C_2 + a p_{11} \gamma$

To make the first-order derivative equal to 0, we draw the simplification as:

$$p_{11}^* = \frac{C_1 - C_2}{a\gamma} \quad (2)$$

It can be concluded that the mixed-strategy Nash equilibrium for the game is $(p_{11}^* = \frac{C_1 - C_2}{a\gamma}, p_{21}^* = 1 - \frac{k}{a\gamma + f\gamma})$. From the model, it can be seen that the value of Nash equilibrium (p_{11}^*, p_{21}^*) is related to C_1, C_2, a, γ, k , and f .

The probability that the supervision unit conducts supervision and inspection is proportional to the cost difference between the cost at which the constructor conducts safety construction according to the contract and the cost at which the contractor does not conduct safety construction according to the contract; the greater the difference in cost, the greater the probability of supervision and inspection. At the same time, p_{11} is inversely proportional to a and γ ; the more fine and the higher the regulatory efficiency, the lower the probability of supervision and inspection.

Probability p_{21} is inversely proportional to k ; the less the cost of supervision and inspection, the greater the probability that the contractor will carry out safety construction. Probability p_{21} is proportional to a, γ , and f ; the more fine and the higher the regulatory efficiency and the greater the economic responsibility of supervision units when the supervision fails, the greater the probability that the contractor will carry out safety construction. Therefore, in order to urge the construction

unit to carry out safety construction, not only do the supervision units increase the penalties to the contractor who does not carry out safety construction, but also improve their regulatory efficiency continuously and reduce the cost of supervision and inspection.

4 ESTABLISHMENT OF GAME MODEL BETWEEN OWNER AND SUPERVISION UNIT

4.1 Principal-agent theory

The relationship between principal and agent is an important part of modern economic research, which is often referred to as the "principal agent theory". Its core content is a two-side dynamic game. The principal's interests is closely related to the agent's behavior, but the principal cannot directly control the agent's behavior and even difficult to supervise the agent's work, and can only influence indirectly agent's behavior by remuneration.

Principal-agent model is divided into four categories. The first category is the principal-agent model without uncertainty. It refers to the agent's work without uncertainty, indicating that the agent's output is a deterministic function of the degree of effort. The second category is the uncertain but can be supervised, that is, the agent's efforts results are uncertain, but the principal can supervise the agent completely. The third category is the uncertain and non-supervised principal-agent model, that is, the agent's efforts results are uncertain, and the principal cannot supervise the work of agent. The fourth category is the principal-agent model of selecting continuous reward and continuous effort level, whose efforts results are uncertain and not be supervised, but the principal can choose reward function, and the agent's effort level is continuously changing.

4.2 Model hypothesis

1. When the safety performance of construction project is up to the standard, the owner's income is $R(g)$, and the supervision unit's remuneration is w , where $w > k, w > f$.
2. When the safety performance of construction project is not up to the standard, the owner's income is $R(b)$, and the supervision unit's remuneration is $w - f$.
3. If the owner does not carry out the commission, then the payoffs of the owner and the supervision unit are 0.
4. If the supervision unit refused to commission, the payoffs of the owner and the supervision unit are 0.

4.3 Establishment and solution of the uncertain and non-supervised principal-agent model

The relationship between owners and supervision units is the same as that between the principal and the agent. The supervision unit's work not only has uncertainty, but also there are certain difficulties in owner's supervision to supervision unit; therefore, in this paper, we use the third category of principal-agent model, that is, the uncertain and non-supervised principal-agent model.

The extensive form between the owner and the supervision unit is shown in Figure 1.

In Figure 1, digital 1 represents the owner and digital 2 represents the supervision unit. Because of the uncertainty, the "natural" game player '0' is introduced. In the square brackets, the former symbol is on behalf of the owner's benefit, and the latter symbol is on behalf of the supervision unit's benefit.

When the supervision unit works hard and the safety performance of the construction project is up to the standard, the benefit of owner is $R(g) - w$ and that of the supervision unit is $w - k$ or $w - k + a$. When the supervision unit works hard and the safety performance of the construction project is not up to the standard, the benefit of the owner is $R(b) - w + f$, and the benefit of the supervision unit is $w - k - f$. When the supervision unit does not work hard but the safety performance of the construction project is up to the standard, the benefit of the owner is $R(g) - w$, and the benefit of the

supervision unit is w . When the supervision unit does not work hard and the safety performance of the construction project is not up to the standard, the benefit of the owner is $R(b) - w + f$, and the benefit of the supervision unit is $w - f$.

Complete and perfect information dynamic game needs to use the backward induction method for analysis. In the third stage, because the safety performance of the construction project is related to contractor and combined with the mixed-strategy game model among the supervision unit and the contractor, we further improve the principal-agent model between the owner and the supervision unit by adding contractor into the third stage, as shown in Figure 2.

In Figure, digital 3 represents contractor. In the third stage, we used the backward induction method to analyze the incentive compatibility constraint that the supervision unit works hard, which is the expected benefit of efforts is more than lazy, as shown below:

$$p_{21}(w - k) + (1 - p_{21})[\gamma(w - k + a) + (1 - \gamma) \times (w - k - f)] > (1 - p_{21})(w - f) + p_{21}war \times (1 - p_{21}) + fr(1 - p_{21}) - k > 0$$

$$p_{21} < 1 - \frac{k}{ar + fr} \tag{3}$$

When the probability that the contractor carries out safety construction is less than $1 - \frac{k}{ar + fr}$, the supervision unit will choose to work hard. This is consistent with the result of static game theory of mixed strategy. On the contrary, when the

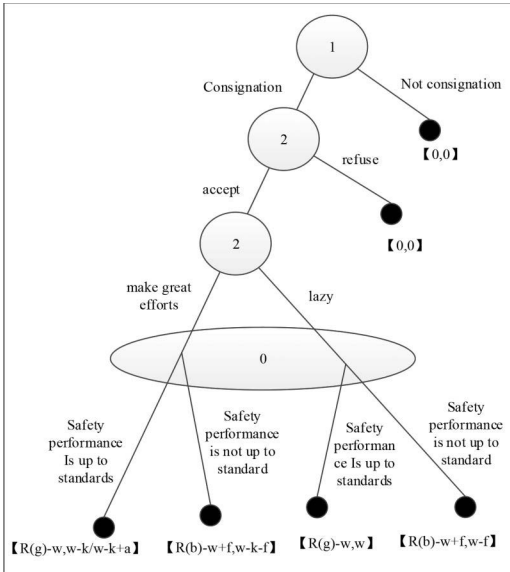

Figure 1. Game extensive form between owner and supervision unit.

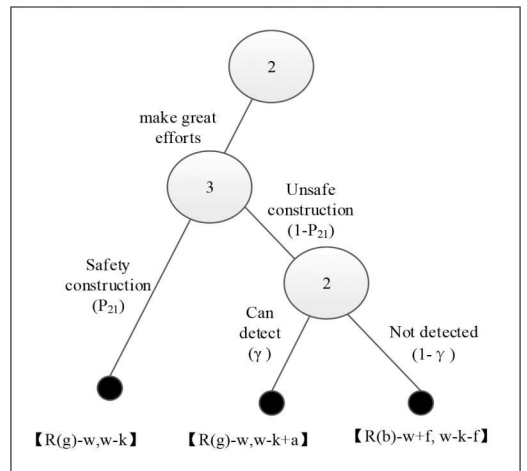

Figure 2. The extensive form that the supervision unit works hard.

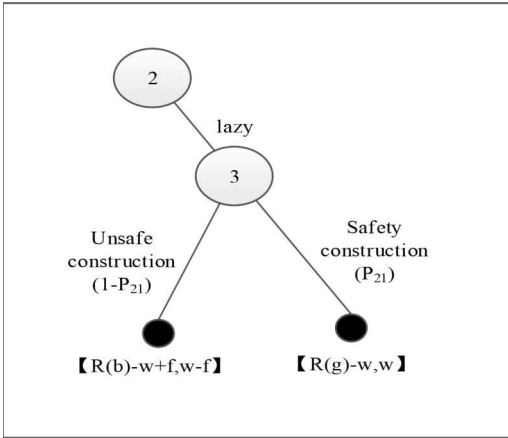

Figure 3. The extensive form that supervision unit does not work hard.

probability that the contractor carries out safety construction is more than $1 - \frac{k}{ar+fr}$, the supervision unit may choose to be lazy.

Back to the second stage, the participation constraint of supervision units is the expected benefit of accepting a commission more than lazy. Regardless of the state of supervision unit selection efforts, and its benefits are greater than 0, the supervision unit must choose to accept the commission.

Similarly, push back to the first stage, the expected benefit that the owner selects to commission is greater than that without commission, so the owner unit will also choose to commission.

5 CASE ANALYSIS

Construction unit “A” develop and construct a residential area of two residential buildings, the construction area is 40,000 m². Now the construction project will be entrusted to the supervision company “B”, and contractor “C” obtains the construction project by bidding. The cost at which contractor “C” carries out safe construction in accordance with the provisions of the safety is 20,000 yuan more than the cost at which contractor “C” does not carry out safe construction in accordance with the provisions of the safety, and the probability that the supervision company “B” conducts supervision and inspection is 1, the efficiency of supervision and inspection of the supervision company “B” is 0.9. Then, according to the mixed-strategy Nash equilibrium: $p_{11}^* = \frac{c_1 - c_2}{a\gamma}$. Therefore, the contract should be specified that the fine of contractor C’s unsafe acts is more than 220,000 yuan. Keeping the efficiency of supervision and inspection unchanged, if the probability

of supervision and inspection is reduced to 0.5, then in the contract, contractor “C” shall be fined more than 440,000 yuan for unsafe acts. If the provisions of the contract for contractor “C” of a fine of 500,000 yuan, and the efficiency of supervision and inspection is raised to 0.95, then the probability that the supervision company “B” conducts supervision and inspection can be reduced to 0.42. Thus, if supervision units want to reduce the probability of inspection and the probability of occurrence of safety accident, they should improve their efficiency of supervision and inspection and increase the fine for contractors not carrying out safe construction in accordance with the provisions of the safety. The model can be used to make a reasonable amount of fines, thus restricting the contractor’s unsafe construction behavior.

Similarly, if the contract stipulates k for 50,000 yuan, γ for 0.9, f for 200,000 yuan, and a for 200,000 yuan, then according to the mixed-strategy Nash equilibrium: $p_{21}^* = 1 - \frac{k}{a\gamma + f\gamma}$. It can be concluded that the probability of contractor “C” for the safe construction is 0.86. If the cost of supervision and inspection is reduced to 40,000 yuan and the other conditions are unchanged, then the probability of contractor “C” for the safe construction is 0.889. It can be seen that by reducing the cost of supervision and inspection, the probability that contractors carry out construction in accordance with the provisions of the safety can be improved.

6 CONCLUSIONS

1. The study shows that safety problems of construction project is closely related to supervision units’ efficiency of supervision and inspection and construction quality of contractors. Therefore, the owners shall take comprehensive consideration to select the supervision units with high efficiency and contractors with good construction quality.
2. Supervision units shall improve the quality of employees, strengthen their sense of responsibility, and reduce or avoid the mistakes in work or dereliction of duty to improve the efficiency of supervision and inspection and to make full use of modern information management technology, such as visual management of the project to reduce the cost of supervision and inspection.
3. Through the above game model, we can make a reasonable amount of punishment to restrict the behavior that contractors do not carry out construction in accordance with the provisions of the safety. If contractors do not carry out safe construction, then the supervision units shall consider the comprehensive use of a variety

of ways to punish them, for example, warning, fines, and downtime rectification.

ABSTRACT: Cable dome structure is a large-span spatial structure with high structural efficiency, which is suitable for large-span roof structure. In order to compensate the weaknesses of traditional cable dome and enrich cable dome structure schemes, a new type of cable dome, ridge tube cable dome with annular struts, was proposed by the authors of this paper. Compared with the traditional cable domes, the structure avoids the disadvantage of ridge cable easy relaxation, has greater whole rigidity and good static performance, and relatively less construction difficulty. The cable dome structure and the whole rigidity are mainly determined by the prestress distribution, so force-finding analysis is the key to the new cable dome research. In this paper, the redundant constraint was replaced by constraint force, and according to the node equilibrium relationship and considering self-weight, the prestress distribution calculation formulas of the ridge tube cable dome with annular struts were deduced. The calculation method reduced the operation cost, made the horizontal force and vertical force transfer in the internal structure clear, and made the calculation convenient for engineers both by hand and by computer. Simulation results using ANSYS finite-element iteration method verified the accuracy of the calculation formulas. Using derived calculation formulas, the prestress calculation table of the ridge tube cable dome with annular struts, with self-weight, and under different constraint force level was obtained to provide reference for engineering design and study the mechanical properties.

1 INTRODUCTION

The cable dome is a full-tension space structure with light form and high efficiency (Lu et al. 2005), where components are prestressed to provide the whole rigidity. The traditional Geiger and Levy cable domes have been successfully applied in many domestic and foreign large-span structures, such as the 1985 Seoul Olympic Games gymnastics and fencing arenas (Geiger et al. 1986) and the 1996

Atlanta Olympic Games stadium (Levy 1994). In 2010, the first cable dome building in mainland China—National Fitness Center in Ejin Horo Banner, Ordos City, Inner Mongolia, was established (Zhang, Liu, Ge, Zhang et al. 2012). However, several limitations existed in the traditional Geiger and Levy cable domes: (1) under high roof vertical load, ridge cables are prone to slackening, causing stiffness, sudden decline, and large displacement; (2) a large number of components are

flexible cables, and the whole rigidity of the structure is not adequate and sensitive to the eccentric load; and (3) in the flexible hinge cable system, it is difficult to control component size precision and construction deviation and results in tension forming scheme increasingly difficult. Therefore, scholars worldwide have put forward the new cable dome structure scheme, which mainly includes the layout change of ridge cables (Yuan & Dong 2005, Bao 2007), key member replacement of the structure (Li 2007), or combination forms of the structure (Dong et al. 2010, Zhang & Liu 2010, Lu et al. 2015), thus improving the weakness of the traditional cable force characteristics or relatively lowering the difficulty of construction, which promoted the construction of cable dome structure.

Because of the facts that the cable dome structure has almost no natural rigidity and the whole rigidity is provided by prestress tension, the initial prestress distribution determination according to the topology of cable dome structure, namely the force-finding analysis, is the key in tension forming of the cable dome structure. Methods of force-finding analysis mainly include the singular value decomposition method of the main balance matrix (Pellegrino 1993), integrity-feasible prestressing method (Yuan & Dong 2001), the nonlinear finite-element method (Dong Z.L. et al. 1995), and the node equilibrium method (Wang et al. 2010, Dong et al. 2009). However, methods above are mostly based on the theory of complex matrix, which require professional software analysis and fail to clear the internal structure force mechanism; some do not usually consider member and node weight, only to calculate the initial prestress, while in fact cable dome is the equilibrium state of the prestress under gravity, so ignoring self-weight does not conform to the reality.

In order to further improve the limitations of the traditional cable domes and enrich the cable dome structure schemes, the author presented a new full-tension structure system—ridge tube cable dome with annular struts. The new system avoids the shortcomings of ridge cable easy slackening, the whole rigidity of the structure is greater than the traditional cable dome, and the construction difficulty is lowered. In this paper, the structural characteristics of ridge tube cable dome with annular struts were introduced. Aiming at the form finding, the redundant constraint was replaced by constraint force; according to the node equilibrium relationship and considering self-weight, the prestress distribution calculation formulas of ridge tube cable dome with annular struts was deduced. The formulas reduced the operation cost, made the horizontal force and vertical force transfer in the internal structure clear, and made the calculation convenient for engineers both by hand and by computer. Simulation results using ANSYS finite-

element iteration method verified the accuracy of the calculation formula. Using derived calculation formulas, the prestress calculation table of ridge tube cable dome with annular struts, which considering self-weight and under different constraint force level, was obtained, to provide reference for the study of engineering design and mechanical properties.

2 RIDGE TUBE CABLE DOME WITH ANNULAR STRUTS

Ridge tube cable dome with annular struts replaced ridge cables of the traditional cable dome with rigid tube, that is, a seamless pipe. The rigid tube topology was triangular, and struts were connected serially and annularly, namely horizontal projection and hoop cable found in coincidence. The three-dimensional structure schematic diagram of the ridge tube cable dome with annular struts is shown in Figure 1.

Compared with the traditional cable dome, struts were arranged annularly, the number of components connected to the upper and bottom nodes were seven and five, respectively, and a triangular mesh formed by the struts and hoop cable enhanced the stability of the structure significantly, which resulted in a greater whole rigidity and high convenience for installation and positioning. The number of diagonal cables was half of that of the traditional Levy type cable dome, so material consumption and tension construction workload were significantly reduced. The ridge tubes prevented ridge cables' slackening, which avoided causing sudden decline of stiffness and large displacement, with higher structure bearing capacity. In addition, round steel tubes were cheaper than high-strength cables, with more price advantage and reduced construction cost.

Figure 1. Three-dimensional structure schematic diagram of ridge tube cable dome with annular struts. Specification: 1—ridge tubes; 2—inclined cables; 3—hoop cables; 4—struts.

3 PRESTRESS DISTRIBUTION CALCULATION FORMULAS WITH SELF-WEIGHT

The $1/n$ unit with single strut as the center of ridge tube cable dome with annular struts was chosen, as shown in Figure 2. The upper node number of struts from the inside to the outside were $1, 2, \dots, m$, and the corresponding bottom node numbers were $1', 2', \dots, m$, where m and n represented radial and circular section numbers, respectively. In morphological analysis of the ridge tube cable dome with annular struts, states of self-equilibrium stress mode were 19, mode of mechanism displacement was 0, so the cable dome was geometric stability system with no mechanism displacement. Considering the symmetric conditions and the uniaxial deformation of cables and struts, the cable dome had only one integral feasible prestress mode.

The radial horizontal constraint of the central strut upper node was set as the redundant constraint, which was then replaced by the constraint force. According to the moment equilibrium of isolated bodies in each circle, vertical force and radial force transferred by ridge tubes, inclined cables were calculated from inside and out.

3.1 Vertical force transfer process

The vertical load of cable dome was transferred through ridge and inclined cables, from the inside out by ring to the outer ring. Horizontally arranged hoop cables did not transfer the vertical load. The weight of elements and nodes were supposed as the equivalent vertical node load (G_j) at upper nodes, as shown in Figure 2. Vertical transfer force from the center node to the second node was calculated as:

$$G_{1 \rightarrow 2} = G_1 = \frac{G_0}{n} \quad (1)$$

$$\text{when } i \geq 2, \quad G_{i \rightarrow (i+1)} = \frac{1}{2} \sum_{j=1}^i G_j$$

where G_j was the vertical load at the j node from the center. When single strut as the center, one-piece vertical load was $G_{1n} = G_0/n$, where G_0 is the

Figure 2. $1/n$ unit with single-center strut.

equivalent vertical load at the center node; $G_{i \rightarrow (i+1)}$ was the vertical transfer force from node i to node $(i+1)$.

3.2 Horizontal force transfer process

Upper and bottom nodes were subjected to the radial horizontal forces H_i and $H_{i'}$, respectively, gradually transferred to the outside. Select typical isolated body with struts inside, as shown in Figure 3, according to moment equilibrium, and the bottom radial horizontal force was calculated as:

$$H_{i'} = \frac{G_{1 \rightarrow 2} L_1 + H_i h_1'}{h_1^x} \quad (2)$$

$$\text{when } i \geq 2, \quad H_{i'} = \frac{2G_{i \rightarrow i+1} L_i + H_i h_i'}{h_i^x \cos \frac{\pi}{n}}$$

where h_i' and h_i^x represent vertical heights from the upper and bottom nodes of the i strut to the horizontal level of the $(i+1)$ node, respectively, and L_i represents the horizontal projection distance between the upper node i to the line $(i+1) - (i+1)'$:

$$L_i = r_i \cos \frac{\pi}{n}, \text{ when } i \geq 2, \quad L_i = r_{i+1} \sin \frac{\pi}{n} \cot \varphi_{i,(i+1)}$$

The upper node radial horizontal force (H_i) was obtained using formula (2), so the bottom node radial horizontal force ($H_{i'}$) could be calculated.

Analyzing the relationship of the node radial horizontal force by rings, as shown in Figures 3 and 4, the recurrence formula of the node radial horizontal force was obtained using formula (3). To illustrate this, the third-ring nodes were taken for example. The third node radial horizontal force was transferred through two ridge tubes in the third ring to the fourth node, the bottom $3'$ node

Figure 3. Typical isolated body.

Figure 4. Upper node radial horizontal force.

radial horizontal force was transferred through one inclined cables in third ring to the fourth node; the fourth node radial horizontal force was transferred through two ridge tubes and one inclined cable in third ring to the third node. Provided directions of different node radial horizontal force, H_i , was calculated as:

$$H_2 = H_{1'} + H_1 \quad (3)$$

$$\text{when } i \geq 3, \quad H_i = H_{i-1'} + H_{i-1} \frac{\cos \varphi_{i,(i-1)}}{\cos \varphi_{(i-1),i}}$$

where $\varphi_{(i+1),i}$ is the angle between the horizontal projection of ridge and inclined cables at node $(i+1)$, $\varphi_{i,(i+1)}$ is the angle between the horizontal projection of ridge tubes and radial lines at node i .

$$\varphi_{(i+1),i} = \arctan \left(\frac{r_i \sin \frac{\pi}{n}}{r_{i+1} - r_i \cos \frac{\pi}{n}} \right)$$

$$\varphi_{i,(i+1)} = \arctan \left(\frac{r_{i+1} \sin \frac{\pi}{n}}{r_{i+1} \cos \frac{\pi}{n} - r_i} \right)$$

3.3 Prestress distribution with self-weight considered

The initial prestress of the cable dome was composed of two parts: one part was the ideal initial prestress when the constraint force was P and weight was neglected; the other part took self-weight into consideration and the constraint force was zero.

First part: When the constraint force was P , and the weight was neglected, radial horizontal constraint of the center strut upper node was replaced by the constraint force P , namely, $H_1 = P$, $G_i = 0$. According to the derived formulas (1)–(3), each node radial horizontal force formula could be obtained from the inside to the outside when weight is neglected:

$$H_{1'} = \frac{h_1'}{h_1^X} P \quad (4)$$

$$H_2 = H_{1'} + H_1 = \frac{h_1'}{h_1^X} P \quad (5)$$

$$H_{2'} = \frac{H_2 h_2'}{h_2^X \cos \frac{\pi}{n}} = \frac{h_1 h_2'}{h_1^X h_2^X \cos \frac{\pi}{n}} P \quad (6)$$

$$H_3 = H_{2'} + H_2 \frac{\cos \varphi_{3,2}}{\cos \varphi_{2,3}}$$

$$= \left(\frac{h_1 h_2'}{h_1^X h_2^X \cos \frac{\pi}{n}} + \frac{h_1 \cos \varphi_{3,2}}{h_1^X \cos \varphi_{2,3}} \right) P \quad (7)$$

$$H_{3'} = \frac{H_3 h_3'}{h_3^X \cos \frac{\pi}{n}}$$

$$= \left(\frac{h_1 h_2'}{h_1^X h_2^X \cos \frac{\pi}{n}} + \frac{h_1 \cos \varphi_{3,2}}{h_1^X \cos \varphi_{2,3}} \right) \frac{h_3'}{h_3^X \cos \frac{\pi}{n}} P \quad (8)$$

From the formulas above, the ideal initial prestress varied linearly with P , so an increase in constraint force enhanced cable domes' overall prestress level.

Second part: When the constraint force was zero and the weight was considered, the radial horizontal constraint of the center strut upper node was $H_1 = P$, $G_i \neq 0$. According to the derived formulas (1)–(3), each node radial horizontal force formula could be obtained from the inside to the outside under gravity:

$$H_{1'} = \frac{G_{1 \rightarrow 2} L_1}{h_1^X} \quad (9)$$

$$H_2 = H_{1'} \quad (10)$$

$$H_{2'} = \frac{2G_{2 \rightarrow 3} L_2 + H_2 h_2'}{h_2^X \cos \frac{\pi}{n}} \quad (11)$$

$$H_3 = H_{2'} + H_2 \frac{\cos \varphi_{3,2}}{\cos \varphi_{2,3}} \quad (12)$$

$$H_{3'} = \frac{2G_{3 \rightarrow 4} L_3 + H_3 h_3'}{h_3^X \cos \frac{\pi}{n}} \quad (13)$$

Adding the two-part prestress together, on the basis of the geometric relationship of components, supposing the internal force of the cable tension as positive and the struts compression as negative, internal force formulas of each component types could be deduced.

Force of ridge cables was calculated as:

$$J_1 = \frac{H_1}{\cos \alpha_1} \quad (14)$$

$$\text{when } i \geq 2, \quad J_i = \frac{H_i}{2 \cos \alpha_i \cos \varphi_{i,(i+1)}}$$

Force of inclined cables was calculated as:

$$X_i = \frac{H_i}{\cos \beta_i} \quad (15)$$

Force of struts was calculated as:

$$S_i = n \tan \beta_i H_i - G_i^X \quad (16)$$

$$\text{when } i \geq 2, \quad S_i = \frac{\tan \beta_i H_i - G_i^X}{2 \sin \theta_i}$$

Force of hoop cables was calculated as:

$$R_i = \frac{1}{2} H_{i+1} \left(\sin^{-1} \frac{\pi}{n} + \frac{\tan \beta_{i+1} - G_{i+1}^X}{\tan \theta_{i+1}} \right) \quad (17)$$

where α_i represents the angle between ridge cables and the horizontal plane, β_i represents the angle between inclined cables and the horizontal plane, and θ_i represents the angle between struts and the horizontal plane:

$$\alpha_i = \arctan \left(\frac{h_i^J \sin \varphi_{(i+1),i}}{r_i \sin \frac{\pi}{n}} \right)$$

$$\beta_i = \arctan \left(\frac{h_i^X}{r_{i+1} - r_i \cos^{-1} \frac{\pi}{n}} \right)$$

$$\theta_i = \arctan \left(\frac{h_i}{r_i \sin \frac{\pi}{n}} \right)$$

4 CASE VERIFICATION

In order to verify the correctness of the derived formulas, the results of internal force distribution using ANSYS finite-element modeling and the prestress distribution calculation method were compared. Case: a ridge tube cable dome with annular struts; span, 60 m; height, 4 m; circumferential segment number, 12; with two hoop cables; and the angle between inclined cables and the horizontal level was 15° . The calculation diagram is shown in Figure 5, where JG, XS, HS, and CG represent the ridge tubes, inclined cables, hoop cables, and struts, respectively, and 1–3 are ring numbers from the inside to the outside. Q345B seamless steel tubes were adopted as ridge tubes and struts, whose yield strength was 345 MPa and the elastic modulus was 2.06×10^5 MPa. High-strength steel wires were adopted as cables, with the tensile strength of 1670 MPa and the elastic modulus of 1.85×10^5 MPa. Component specification from the inside to the outside: the ridge tubes of $\Phi 245 \times 8$, $\Phi 203 \times 8$, $\Phi 168 \times 7$, inclined cables of $\Phi 14$, $\Phi 28$, $\Phi 40$, struts of $\Phi 159 \times 8$, $\Phi 102 \times 4$, $\Phi 168 \times 10$, hoop cables of $\Phi 42$, $\Phi 75$.

The finite-element model of ridge tube cable dome with annular struts was established, applied with the ideal initial prestress and under gravity, structure internal force distribution, and the maximum vertical displacement under the effect of gravity were obtained. While the initial prestress level remained unchanged, the last obtained prestress distribution was taken as the new initial prestress into the next analysis. After several iterations, when the internal force distribution under the gravity was stable and the maximum vertical displacement was minimum, the iteration of prestress distribution was terminated. In this way, after seven iterations, the final prestress distribution of ridge tube cable dome with annular struts was obtained, and the iterative process is shown in Table 1.

By using the simple calculation formulas proposed, considering the gravity of the structure, the weight was transformed into the equivalent vertical node load (G_i) acting on the upper nodes, constraint force P as 500 kN . By substituting the

results of formulas (4)–(13) into formulas (14)–(17), the internal force value of all types of components were calculated, and the formula calculation results are shown in Table 1.

As Table 1 indicates, the results of the simple calculation formulas proposed and the finite-element

modeling results after several iterations were basically the same, while the force maximum error was less than 0.3%, which indicated that the theoretical formulas proposed in this paper did not require the finite-element software calculation, reduced the computational cost of iterative process, and deter-

mined the cable dome's prestress distribution with self-weight accurately.

For convenience of structure design for technicians, by adopting prestress distribution calculation formulas proposed in this paper, the prestress reference table of ridge tube cable dome with annular struts in different constraint force level and under gravity is shown in Table 2. According to the engineering requirement, selecting the corresponding constraint force level and the prestress distribution under gravity, the initial prestress distribution with self-weight of ridge tube cable dome with annular struts was calculated rapidly.

5 CONCLUSIONS

In order to determine the initial prestress distribution of ridge tube cable dome with annular struts, this paper set the radial horizontal constraint of the central strut upper node as the redundant constraint, which was then replaced by the constraint force. According to the moment equilibrium of isolated bodies in each circle, vertical force and radial force transferred by ridge tubes and inclined cables were calculated from inside and out. Thus, the calculation formulas of prestress distribution with self-weight were derived. The initial prestress of the cable dome was composed of two parts: one part was the ideal initial prestress when the constraint force was P and weight was neglected; the other part took self-weight into consideration and the constraint force was zero. Compared with the finite-element iteration method, the calculation formula results were accurate, which cleared the horizontal and vertical force transmission relationship in the internal structure and was convenient for technicians. In this paper, the prestress reference table of ridge tube cable dome with annular struts in different constraint force level and under gravity was given. According to the engineering requirement, selecting the corresponding constraint force level and the prestress distribution under gravity, the initial prestress distribution with self-weight of ridge tube cable dome with annular struts was calculated rapidly.

A new multiple-model analysis method considering structural uncertainty

Fengqi Zhu

Southeast University, Nanjing, China

ABSTRACT: Because of the corrosion of the main body structure and connection, difference between construction and design, and so on, structure parameters cannot be known according to the original design or existing data. Thus, the structural uncertainty is generated, which widely exists in the actual structure. It is very necessary that uncertainty analysis is carried out on the structure. However, classical Finite-Element (FE) method could only establish a certain FE model and could not react and transmit uncertainty of key parameters. From a practical engineering perspective, this paper provides the intuitivism apprehension of uncertainty of probability and statics by multiple-model probability FE method. The specific method of improved multiple model was that multiple FE models were established on the basis of the model of the key parameters of Markov Chain Monte Carlo (MCMC) sampling first. Thus, it was considered, transmitted the influence of uncertainty, and reflected the actual structure character. Then, the second-order response surface method was brought to fit the structural dynamic and static response results to improve the efficiency of multiple-model modeling. Through the above methods, multiple models could be applied to the engineering practice. In a numerical example, the parameters of girder elasticity modulus, section height, and support spring stiffness were analyzed, multiple models were built, and reliability was assessed.

1 INTRODUCTION

In general, structures would deteriorate over time; especially, the degeneration of structural critical areas might lead to monolithic catastrophic failure. In the inspection of a structure, the phenomena of crack and corrosion of the main structure and the padding and failure of connection parts were discovered (Shinae 2013). They are the main sources of structural uncertainty for structural performance evaluation; therefore, it is of great importance to figure out the way of quantitatively evaluating their influences on structure performance.

Many scholars have done a lot of work in this research field. Subrata Chakraborty et al. updated the finite-element model through response surface method; Ching and Beck gave the initial key parameter a certainty probability and proceeded finite-element model update through Bayesian theory combining structural monitoring data. Both of them treated model updating as an optimization problem. Through different kinds of optimistic algorithm, they searched for an optimal model that keeps with the field test data. Koh et al. utilized multiple models to partially solve this problem. First, they relegated the key parameter by PCA method and then by using K-means method to cluster the models. Jianzhang et al. proposed utilizing Markov chain

Monte Carlo sampling method to calibrate the uncertainties. The process utilizes high-quality sampling algorithm to generate multi-finite-element model library and then utilizes multi-finite-element model library to assess structural response. However, because of the high cost, it is hardly executed at practical engineering structure. Zong et al. used RSM to optimize finite-element model to find the best single model. In this paper, response surface technology and multimodel idea are used to analyze structure uncertainty. Because of the influence of uncertainty, the key parameters of the model is difficult to decide in the process of establishing the finite-element model of engineering structure; at the same time, utilizing the usual model correction technique is not reliable. Therefore, in this paper, a multimodel idea was used to sample the key parameters of structure, which can provide the structural probabilistic information to engineers. Furthermore, the structural probability response can be predicted by sampling. In order to improve the computational efficiency, this paper will inlet response surface model in the computational model. By using the response surface model to replace multiple models, we can greatly improve the computational efficiency, which could make the idea of multimodel possible in structural engineering.

This paper is organized as follows. First, a multiple-model method is proposed using the

MCMC sampling and RSM technologies. Then, ANSYS batch tool is used to operate ANSYS in background under MATLAB control to achieve multiple-model method. Finally, a multimodel was built and reliability assessment was studied with a numerical example.

2 MULTIPLE-MODEL METHOD

Multiple-model method is used to sample the key parameters of a structure, which can provide the structural probabilistic information for engineers. At the same time, in order to improve the computational efficiency, response surface model is brought in the computational model.

Introduction of the Markov Chain Monte Carlo (MCMC) sampling method can rapidly converge to the objective function, $\pi(x)$, under the framework of Bayesian theory. The MCMC sample can realize the chain sample and overcome the impact of high-dimensional parameters. The process is a recursive procedure, involving the following steps:

1. Randomly generated initial parameters θ_0 .
2. Assuming that θ_{i-1} is the k^{th} parameter of the Markov chain, candidate parameter θ_c is generated by proposal distribution $q(x)$:

$$\theta_c = q(\theta_c / \theta_{k-1}) \quad (1)$$

3. Acceptance probability of candidate parameter θ_c is:

$$\alpha(\theta_{k-1}, \theta_c) = \min \left\{ 1, \frac{\pi(\theta_c)q(\theta_c / \theta_{k-1})}{\pi(\theta_{k-1})q(\theta_{k-1} / \theta_c)} \right\} \quad (2)$$

4. If θ_c is accepted, then $\theta_k = \theta_c$; otherwise, repeat steps 2 and 3 until θ_c is received.
5. Make $k = k + 1$, repeat steps 2–4 until the process converges.

In a multiple-model framework, objective function π is elected as the model probability conditioned by known structural information G ; proposed distribution q is elected as the prior distribution of the key unknown parameters; the key unknown parameter θ in the studied structure is a combination of elasticity modulus, stiffness of expansion joint, bearing longitudinal stiffness, and bearing vertical stiffness:

$$\pi(\theta) = P(M(\theta)|G); \quad q = P(M(\theta)) = \prod_1^4 P(\theta_j) \quad (3)$$

where $P(\theta_j)$ is the prior distribution of the j^{th} parameter.

According to Bayesian theory, $P(M/G) = \frac{P(G|M)P(M)}{\int P(G|M)P(M)}$. Assuming $\int P(G/M)P(M)$ is constant and combining (2) and (3), we have:

$$\alpha(\theta_{i-1}, \theta_c) = \min \left(1, \frac{P(G/M_c(\theta_c))P(M_c)}{P(G/M_{i-1}(\theta_{i-1}))P(M_{i-1})} \right) \quad (4)$$

Assuming that the error of the model belongs to normal distribution and independent from each other:

$$P(G|M_i(\theta_i)) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp \left(-\frac{obj^2}{2\sigma^2} \right) \quad (5)$$

To further improve the sampling efficiency, an extended M-H algorithm is adopted because of its high efficiency. Two novel ideas, Adaptive Metropolis (AM) and Delayed Rejection (DR), are successfully combined to improve the computational efficiency of the M-H algorithm. The reader is advised to refer to ref. [Haario *et al.* (2006)].

Response Surface Method (RSM) is used to approximate implicit functions between response value and design parameter by explicit response surface model. RSM is very good at coping with the issue with implicit multiresponse object function for its satisfied accuracy and good efficiency. Because the amount of sample set used to reconstruct the response surface is small (Zhao and Qiu 2013), the second-order RSM is reconstructed by Central Composite Design (CCD) method, F test of variance analysis is used to identify the parameter of significance, and the second-order polynomial is the following fit response surface:

$$y = \beta_0 + \sum_{i=1}^n \beta_i x_i + \sum_{i=1}^n \sum_{j=1}^n \beta_{ij} x_i x_j + \sum_{i=1}^n \beta_i x_i^2 \quad (6)$$

3 NUMERICAL EXAMPLE OF MULTIPLE-MODEL METHOD

Through a numerical example of nonuniform beam of the MM method proposed in this paper, the high precision and the whole performance of this method is verified for the natural frequencies

Figure 1. The numerical example.

Table 1. Parameters of real value and initial value.

	Elasticity modulus	Height of Section 1-1	Height of Section 2-2	Spring stiffness
Real value	3.5×10^{10} Pa	0.6 m	0.3 m	1×10^5 Pa
Initial value	3.1×10^{10} Pa	0.4 m	0.2 m	0.5×10^5 Pa
Distribution	Normal	Uniform	Uniform	Uniform

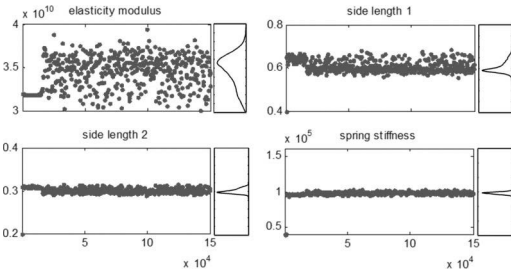

Figure 2. Four-parameter MCMC results.

and formation of the structure and the displacement and strain under the action of static loads. The numerical example is shown in Fig. 1 and the real values of the parameters are as below: the elasticity modulus of the non-uniform beam is 3.5×10^{10} ; section of the beam is square; the heights of Sections 1-1 and 2-2 are 0.6 and 0.3 m, respectively; and the spring stiffness of the bearing is 1×10^5 Pa (Table 1).

The parameters of elasticity modulus, height of Section 1-1, height of Section 2-2, and spring stiffness are elected to consider uncertainty. Extraction of the first five-order natural frequency and formation are displacement and strain under two load cases: loading of 100 kN at mid-span and 1/4 span of the beam, respectively. On the basis of the modal and static response result constructing the objective function (Eq. 7), 15,000 samplings were carried out using MCMC sampling method and response surface technology (Fig. 2):

$$\pi(\theta) = \sum_{i=1}^m \frac{|\omega_{ai} - \omega_{ei}|}{\omega_{ei}} + \sum_{i=1}^m (1 - MAC_i) + \sum_{i=1}^n \frac{|\delta_{ai} - \delta_{ei}|}{\delta_{ei}} + \sum_{i=1}^n \frac{|\epsilon_{ai} - \epsilon_{ei}|}{\epsilon_{ei}} \quad (7)$$

where ω_{ai} and ω_{ei} are analytical and experimental natural frequencies of the i th mode, respectively, and Φ_{ai} and Φ_{ei} are the analytical and experimental modal shapes of the i th mode. MAC value can be calculated from Φ_{ai} and Φ_{ei} .

Figure 3. Displacement of spring support.

As shown in Fig. 3, on the basis of the above established multiple-model library of the variable cross-sectional beam displacement of spring support forecasting 0.3 m, the probability follows normal distribution. It equals the real displacement value of 0.3 m.

4 CONCLUSION

1. A multiple-model method through MCMC sampling and response surface technology is proposed in this paper, which is used in structure performance evaluation.
2. Using the response surface technology, the uncertainty problem of large finite element in real structure can be solved by combining the large FE technology with the multiple-model idea.

Promotion of transportation on urban spatial distribution and industrial development in Beijing

Xiao Peng

China Urban Sustainable Transportation Research Center (CUSTReC), China Academy of Transportation Sciences, Beijing, China

ABSTRACT: The relationship between urban transportation and urban spatial layout and industry is the eternal topic of urban development. On the basis of the mechanism analysis of urban transportation infrastructure construction and urban industry and spatial layout, the solution and relative suggestions of the coordinated development of urban transportation, urban industry, and spatial layout are put forward. The research results are helpful to change the transportation infrastructure, which restricts the city industrial development and urban space layout and realizes the benign interaction of the transportation and urban industry and spatial layout in Beijing. The research result will also provide technical support for the traffic infrastructure construction in Beijing and promote the adjustment and upgrading of industrial structure to guide the harmonious coexistence of industry between center city and new town.

1 INTRODUCTION

The relationship between urban transportation infrastructure and urban industrial and spatial layout is interaction and reaction. It is not only a simple single direction but also a complex cycle. The adjustment of industrial development and urban spatial layout is an important characterization of urban economic and social development. Realizing the interaction mechanism of traffic infrastructure construction and the development of industry and urban spatial layout are the important basis to formulate transportation policy and solve complex urban traffic problems. It helps to solve the efficiency problems in limited land resources.

1.1 *Urban industrial development and urban spatial layout affect the trip mode choice and travel demand distribution*

In urban areas, besides the living district, the main travel demand and trip distribution come from the workplace. All kinds of urban industrial layout are the main components of workplace and also an important part of urban spatial layout. Eventually, a different urban spatial layout affects the urban industrial distribution and position, which results in different trip generation in different areas. By the way, different urban industrial and spatial layouts may lead to different trip directions and

routes, which directly determines the distribution of whole urban traffic.

1.2 *Traffic infrastructure distribution makes different accessibilities in different spaces and affects the urban industry layout*

Accessibility is one of the important elements for selecting the location of industrial areas. The location quality is the main reason directly affecting the industry development. As accessibility is caused by the different traffic infrastructure distribution, the ultimate factor affecting the urban industry layout is the urban traffic infrastructure construction and distribution.

It is necessary to spread the industry in space if it is wanted to be developed. Transport can play a role in the spatial diffusion of the urban industry. The construction of traffic infrastructure will stimulate the industrial development along the line. The population and main industrial activities gradually increase the urban transportation line, thereby forming industrial centers. At the same time, a good urban traffic infrastructure will reduce the cost of trip and product transportation and provide the possibility to expand the industrial agglomeration and diffusion.

The practical experience worldwide shows that the actual shape and structure of the city are the result of the interaction between the transportation

Figure 1. Traffic infrastructure promotes and guides the urban spatial layout.

development strategy and the spatial development strategy. Among all types of transport mode, rail transit will bring great changes in the passenger flow, improve the accessibility, and change the location condition along the rail lines. Hence, the urban land use and the industrial spatial layout will be affected profoundly, followed by the urban spatial structure and morphology. As the most important component, rail transit will promote city renewal and urban spatial layout restructure.

2 CURRENT SITUATION ASSESSMENT

2.1 Beijing urban transportation supply

In recent years, the increasing transportation construction investment has resulted in the rapid growth of urban roads in Beijing. Taking 2005 as the base year, the total mileage of urban streets reached 6223 km at the end of 2015, with an average annual increase of 11%. The total mileage of highway reached 21885 km at the end of 2015, with an average annual increase of 9%. However, compared with the developed cities, the current urban road density and land use rate of Beijing are still significantly lower. The total mileage of urban buses and tram vehicles reached 21716 km by the end of 2015.

At the end of 2015, the motor vehicle and private car ownership reached 5.62 and 4.4 million in Beijing, respectively, which are more than 0.81 million and 0.66 million from the corresponding figures in 2010. In line with international practices of 10 cars per 100 households, on average, per 100 households in Beijing have 25.8 motor vehicles and 14.6 private cars. It means that Beijing has begun to enter the automobile society. In the future, Beijing will face more and more serious transport pressure. In addition, mobile population is also increasing rapidly. A number of private cars are used for commuting, which results in the surging of motor travel demand.

At the end of 2015, the city's highway mileage was 21876 km, with an increase of 27.2 km over 2014 and 762 km over 2010. Among them, the expressway mileage was 982 km, in agreement with that of the previous year and an increase of 79 km over 2010. In 2015, the urban road mileage is 6435 km, an increase of 9 km over 2014 and 80 km over 2010.

Table 1. Various indicators of bus and tram in 2011–2015.

Year	2011	2012	2013	2014	2015
Routes (number)	740	779	813	877	876
Length (km)	19338	19547	20575	20347	20315
Vehicles (units)	21575	22146	22486	24083	24347

Table 2. Vehicle ownership in 2011–2015.

Year	Motor vehicle ownership (10,000)	Private vehicle ownership (10,000)	Private car ownership (10,000)
2011	498.3	389.7	286.2
2012	520	407.5	298.2
2013	543.7	426.5	311
2014	559.1	437.2	316.5
2015	561.9	440.3	316.5

Figure 2. Urban road network of Beijing.

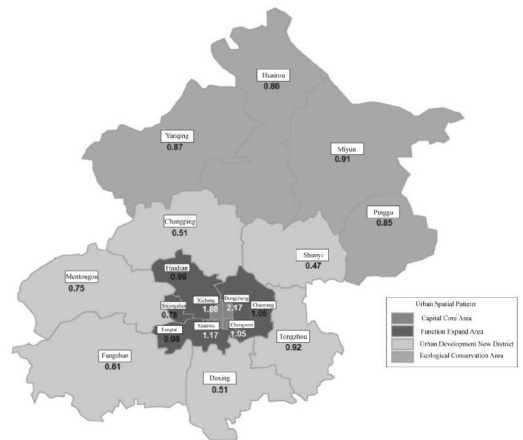

Figure 3. Layout of urban functions.

2.2 *Beijing urban industrial space layout*

In accordance with the latest urban planning, Beijing, under the jurisdiction of 16 areas, can be divided into four parts: the Capital Core Area, the Function Expand Area, the Urban Development Area, and the Ecological Conservation Area.

The main features of the urban industry in Beijing are: (a) The spatial structure is evolved from the single center to the suburbanization, which means Beijing is in the direction of the development phase to the multicenter layout. (b) The six areas (the original eight districts) in the city are still the main bearing area of the urban population and industry. (c) The economic growth of the core area of the capital function and urban function development zone is the fastest, and the population growth in the urban function development zone and the urban development zone are important. (d) Industrial agglomeration effect is gradually emerging, and development zones and industrial parks have become the important carrier of economic development in the capital. (f) A number of different functions and industrial positioning of different professional parks or bases have begun to emerge.

2.3 *Main problems*

a. The single-center urban spatial structure led to the central area of traffic travel and tidal traffic congestion.

The construction of Beijing city is still a layout pattern of the old city as the center, surrounded by the edge. The old city, set in a 62 km² in the second ring, as the center of the political, economic, and cultural centers, sums up three commercial centers of Xidan, Wangfujing, and the front door and the Financial Street business district. In addition, it also has more than 20 central ministries, 100 bureau level authorities, and 250 units of the Beijing Municipal Committee and government owned units, while the other is the residential area. With the fourth and fifth ring roads constructed, the Beijing pie continues spreading, which is called “where is the ring road, where is the pie spreading”. This city development mode moves residents out of the old city, while all types of social activities are still in the old downtown. At the same time, strengthening the construction of functional areas in the fifth ring and the construction of three new key city is sluggish, and the functions of population living, industrial development, public service in the core area, and development area are still concentrated, and the new cities are weak to ease the downtown population; instead, they possess a large proportion of foreign population, which failed to effectively undertake the center area population ease.

b. The unbalance of economy and industry increases traffic congestion.

There is a big gap per capita GDP between the south and north of Beijing. The state administrative organs, universities, and other cultural and educational institutions and large and medium-sized hospitals most concentrated in the north of Beijing. The important resource in north Beijing is more than that in south Beijing, which results in more traffic density in north Beijing than south Beijing. The high-density resource allocation in north Beijing crowds out the traffic infrastructure space, increasing the difficulty to alleviate the traffic flow by using the transportation methods. The back end of south Beijing exacerbates the traffic flow between south Beijing and north Beijing.

c. The “closed courtyard” or “large-scale design” planning reduces the traffic capacity and public transportation attraction.

Traditional courtyard culture and large-scale design planning in Beijing is not suitable for the current city development. On the one hand, due to walk out of the courtyard to take public transport, bigger courtyard means that the walk distance and time are larger, which reduces the attraction of public transportation. On the other hand, although the self-structure of the courtyard is relatively complete, it cuts the urban spatial structure result in the lack of branch road and impedes microcirculation, which weakens the traffic organization ability of main urban road.

d. “Demand following” traffic development mode lags behind urban development

Traffic construction is always lagging behind the development of urban land use, which results in passivation following the urban construction.

At present, the traffic construction standards of all types of building and facilities are relatively low.

It cannot meet the travel demand when the building is completed. The main features lack enough parking spaces and do not have building for public transportation facilities. In addition, the traffic impact evaluation mechanism is not perfect, and public transportation construction always lacks behind the urban land development.

3 TREND AND DEMAND

3.1 *Population of Capital Core Area is further reduced*

Because of the differential rent and other economic factors, the population of Capital Core Area will continue to transfer to the Function

Expand Area. The industrial spatial structure of Capital Core Area will change little. Economic activity in this area is still along the traditional “two axis” distribution. The main industry includes administrative office, commercial, tourism, and culture. In the meantime, education and medical service functions will expand outside Capital Core Area by stimulating Function Expand Area, and the attraction of Capital Core Area will decrease.

3.2 *Function Expand Area will become the agglomeration area of industry and population*

The population of Function Expand Area will increase. However, because of the limited land capacity, the growth rate will decrease. Because various high-quality resources are still mainly distributed in the central area and the traditional concept, Function Expand Area will remain the most active area of economy in Beijing, which is also affected by the traditional concept. Various function parks will develop rapidly. The traditional center, such as CBD and Zhongguancun Science and Technology Park will become more and more mature, and the Olympic Center, Lize financial center, Dahongmen business district will get into the fast lane.

3.3 *The urban fringe community is gradually improved*

The population of 10 marginal groups will further expand. However, the area of 10 marginal groups will not continue to expand through the control of land development and transportation infrastructure. Affected by the development of new towns, the industry in marginal groups will limit development. The main industry includes the living facilities of education, health care, entertainment, and business. The population is mainly composed of two parts: one is the relocation residents in Capital Core Area and the other is new Beijing people who work at Function Expand Area.

3.4 *The city develops along the rail track of beads*

Because of the driving effect from rail traffic, the land development density surrounding the rail station will further increase. The population will also gather surrounding the rail station. As the land use in downtown is limited, the leading role of rail traffic in this area is limited, which is less than that outside downtown. Urban development will be along the rail track of beads between downtown and new towns.

Figure 4. Traffic connection strength between new towns.

3.5 *Population and industry in new town grow rapidly*

As the land resources in new town is abundant and there are some encouragement policies and measures, such as the investment policies about urban infrastructure and other various industrial development, the new town will enter a period of rapid growth. Especially the four new towns, namely Shunyi, Tongzhou, Yizhuang, and Daxing, will form a certain scale first.

3.6 *Travel demand in downtown and new town tends to be stable and that in new town and between new towns enhances*

In the future, new town will reach a certain scale. Travel demand internal new town and between new towns will enhance. Therefore, the traffic infrastructure in those areas will be strengthened. Along with the formation of antimagnetic system in new town, the travel demand between downtown and new town will become stable gradually.

4 SCHEME AND MEASURES

In the future, the overall development ideas of Beijing are designed. The first is for the downtown. The main task is to improve the transportation system and enhance the quality of public transport services. The second is for the new town. The main task is to adhere to the Transit Oriented Development mode to build the new town. According to the urban comprehensive planning of Beijing, the buildings of Daxing, Tongzhou, Yizhuang, and Shunyi will be focused. The third is for the

inter-city traffic. The main task is to build Beijing–Shenyang high-speed rail, huge logistics base, and other traffic infrastructure to promote the metropolitan development. The important tasks are as follows.

4.1 *To continuously increase public transport to guide the construction in new towns*

According to the development needs of traffic demand in new towns, three main tasks need to be carried out: (a) building the BRT system timely to connect different function areas in new town, which alleviates the pressure of rail traffic; (b) according to the urban space development in new town, the public transportation should be built in the same time; and (c) promoting the construction of rail transit and guiding urban industry and spatial layout from downtown to new towns. It is the key period of building rail transit in Beijing currently. Therefore, the development ideas of connecting new towns and easing downtown should be adhered. The rail transit corridor construction will continue to be enhanced to guide the urban industry and urban spatial layout.

4.2 *To increase the capacity of the road network and the service level of public transport*

As the Function Expand Area is the largest urban development area and the most active area, two main tasks need to be carried out: (a) to expand the capacity of road network through opening the broken road, dredging transport congestion points, increasing branch network construction, and other measures; (b) to improve the accessibility and comfort of public transportation through additional rail and BRT construction in the Function Expand Area.

4.3 *To build a diversified and high-quality public transportation in Capital Core Area*

The transportation system should be built unswervingly with public transportation-oriented walking and bicycle traffic. During promoting the rail system, a small electric bus service should be built according to the alley system; free bicycle system should be promoted through the integration of the existing bicycle rental network. At the same time, the congestion charging system should be studied and designed in order to ease the road congestion within the fourth ring road.

4.4 *To improve transportation infrastructure in the urban fringe area*

In the future, the urban fringe area will become more and more mature. Therefore, it is necessary to improve the connecting transportation facilities level with downtown and other neighbor functional

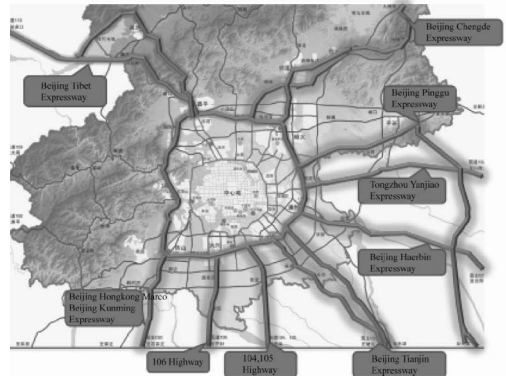

Figure 5. Freight corridor scheme in Beijing.

area. A BRT system connecting urban fringe area and neighbor functional area should be built. In the same time, the BRT system connecting urban fringe area and downtown should be built timely according to the subway operation. The aim is to alleviate the pressure of subway.

4.5 *To develop the traffic corridor between the new towns*

With the development of the new town, the traffic demand is bound to increase.

It is necessary to establish complex rail transport and road transport corridors between the new towns. The six ring road toll is proposed to make the road as a urban passenger corridor. Rail S6, which is proposed to connect the new town, is proposed to be extended as a passenger corridor.

4.6 *To improve the traffic corridor of big Beijing metropolitan area*

With the development of the new town, the six ring road will bear more and more passenger traffic. Therefore, it is very necessary to build a new freight corridor to reduce the pressure. The big city freight corridor surrounding Beijing is proposed to be built. The corridor, which will connect Zhuozhou, Guan, Langfang, Xianghe, Sanhe, Pinggu, and Dachang, will intersect Jinggangao, Jingkun, Jingkai, Jingtai, Jingjin, Jingjintang, Jingha, Tongyan, and Jingping expressways. It will improve the freight flow capacity in the Jingjinji city groups and reduce the traffic pressure of Beijing transit transportation.

5 CONCLUSION

The method of guiding the development of urban industry and urban spatial layout by the traffic

infrastructure is studied in this paper. The proposals and measures for the superlarge cities are put forward to realize the integrated development of transportation and city. The relative research result can provide experience and reference for growing upto superlarge cities. Then, it is possible to promote the cities in China to experience a more sustainable development path.

Selection of interruptive protection methods in rapid transit underground construction

Hsi-Chi Yang

Department of Construction Management, Chung Hua University, Hsinchu, Taiwan

Chen-Chung Liu

Department of Civil Engineering, Chung Hua University, Hsinchu, Taiwan

ABSTRACT: Since the MRT construction is mainly shield tunneling and deep excavation, it is important to select proper interruptive protection method to prevent the impact of MRT construction on the existing structures and vice versa. The purpose of this research is to select the proper interruptive protection method to be used along the MRT lines to ensure the safety of existing structures and tunneling excavation. This research first determines the criteria and sub-criteria to be used in the initial assessment framework for the protection of the existing structures and tunneling excavation, and then it establishes the final assessing framework by using Delphi method. Furthermore, the Analytic Hierarchical Process is used to determine the relative weights of elements of each level in the hierarchical structure of assessment framework. Finally, the selection process is presented by using a study case in the Nan-Gang line of the Taipei Metropolitan Rapid Transit system.

1 INTRODUCTION

Taiwan is heavily populated in most of metropolitan areas. Since the MRT demand has been increased drastically, there is a sharp increase of rapid transit routes. However, a lot of structures, either nature or man-made, have been existed along the planned routes. It is generally required to protect the safety of the nearby existing structures when the routes are constructed. The MRT construction is mainly shield tunneling and deep excavation. When its adopted preventive strategies cannot reduce the external impact on the existing structures, some supplemental protective methods have to apply to the existing structures. The generally used supplemental protective methods can be classified into two categories, the interruptive protection methods and the existing structure reinforcement methods. Generally speaking, it is highly unlikely to reinforce the existing structures, especially when they are privately owned. Thus, it is important to select proper interruptive protection method to cut off the impact of existing structures on the MRT construction and vice versa. When neglecting the impact from either tunneling excavation or existing structures along the MRT line, disasters can occur. The Taipei MRT tunneling projects had encountered a lot of exist-

ing structures including airport facilities, historical monuments, viaducts and rivers. This research tries to investigate how to select the proper interruptive protection method to be used when the protection of existing structures becomes necessary. The selection of a proper interruptive protection is a decision making process influenced by a lot of criteria. The criteria to be used are different based on the nature of a project. Pan (2006) had determined the criteria to be used in deep excavation. Yang and Deng (2012) had determined the criteria to be used in supplementary grouting.

The purposes of this research are: (1) Establish the assessment framework for the selection of interruptive protection methods and determine the criteria and sub-criteria to be used in the framework, and (2) Use the decision mechanism in the framework to select the proper protection method for an underground MRT project.

2 METHODOLOGY

In this study, foreign and domestic literatures were reviewed and experts were interviewed to formulate the criteria and sub-criteria to be used in the initial assessment framework. The final assessment framework was determined by using the

Delphi method. The relative weights of criteria and sub-criteria were identified by using the Analytic Hierarchical Process (AHP). The Delphi and AHP questionnaires were conducted with a panel of 15 senior engineers and professionals in foundation engineering. They had 14 to 30 years of working experience with an average of 20 years.

The Delphi method is designed to explore opinions of a group of knowledgeable persons in order to gain a consensus on a particular topic without bringing the group together (Uhl 1983). The Delphi method pools expert judgment in an iterative process that involves anonymity and opportunity to reflect on and respond to other experts' opinions. Questionnaires are mailed to a group of expert panelists, soliciting their opinion on a topic of interest. Researchers then synthesize the results and distribute them to the panelists in additional waves for reflection and comment.

The AHP developed in the early 1970's by T. Saaty. There are six procedures to run AHP: (1) analyzing problem and displaying evaluative factors, (2) constructing the hierarchy, (3) establishing pair-wise comparison matrices, (4) computing eigenvectors and eigenvalues, (5) testing inconsistency of pair-wise comparison matrices, and (6) computing the relative weight of each factor (Lee 1999). Chen et al. (2012) had used the above two methods to study the application of green architecture to residential buildings. Yang and Lo (2016) had used them to study green energy management.

3 INTERRUPTIVE PROTECTION METHODS

Five commonly used interruptive protection methods in Taipei Metropolitan Rapid Transit construction are considered in this research. They are (1) Pile wall method, (2) Slurry wall method, (3) Pipe roofing method, (4) Freezing method and (5) Grouting method (Sun 2010).

4 ASSESSMENT FRAMEWORK

4.1 Establishment of assessment framework

The assessment framework was established first using the Delphi Method. Through literature reviews and expert interviews, an initial assessment framework was formulated with four major criteria, including Safety, Environment, Time and Cost along with a total of 18 sub-criteria for the four major criteria (see Table 1). In order to validate its integrity and completeness, three rounds of expert questionnaires had been conducted when the opinions of the respondents were converged. The four-level (A, B, C, D) hierarchical diagram of the final assessment framework is

shown in Fig. 1. The 18 sub-criteria in the initial framework have been cut to 13. The alternatives (Level 4) are the above five interruptive protection methods.

4.2 Identification of relative weights of elements

After having establishing the elements of each level in the hierarchical diagram of the assessment framework, the AHP method was used to identify the relative weights of elements of each level. Three types of pair-wise comparisons matrices had been established: (1) the evaluation matrix of level 2 criteria with respect to the goal (A); (2) the evaluation matrix of sub-criteria with respect to the related criterion; and (3) the evaluation matrix of alternatives with respect to each sub-criterion. At level 2, the evaluation matrix of criteria to the goal (A) is shown in Table 2. At level 3, four evaluation matrices were required to perform. The evaluation matrices of sub-criteria with respect to the four criteria are shown respectively in Table 3, Table 4, Table 5 and Table 6. At level 4, a total of 13 evaluation matrices were required to perform so that the relative weights of the alternatives (shown in the following study cases) with respect to each of the 13 sub-criteria could be obtained.

4.3 Interruptive protection methods scoring table

Based on the relative weights for the four major criteria at Level 2 and the 13 sub-criteria at Level 3, an interruptive protection method scoring table can be established (see Table 3). Among the four major criteria, "Safety" is the most important criterion with a weight of 54.2%; followed by Cost, Time and Environment. Among the sub-criteria, geological conditions, underground water, planned structure conditions and protected structures conditions in "Safety" criterion are the top four sub-criteria to be considered first. Then, the contractor can consider the cost effect. The relative weights in the table reflect what really happens in the construction site. If the top four sub-criteria have more or less been ignored, it may require more than the original estimated cost later on. The purpose of establishing a scoring table is that it can be used as a basis for planning personnel to select a proper interruptive protection method.

4.4 Priority weights for alternatives

From the relative weights at Level 4 and using the relative weights in the scoring table, the priority weights for the alternatives could be obtained (shown in the following study cases) and the proper interruptive protection method determined.

Table 1. Criteria and sub-criteria of the initial assessment framework.

	Sub-criteria	Descriptions
Safety	Geologic conditions	Soil stratum properties and N values
	Underground water	Water head & soil permeability
	Construction technique	Construction technique used in the interruptive protection method
	Project structure conditions	Location and position of the structure to be build and its construction technique (Ex. Pipe Jacking, Shield Tunneling, NTAM, etc.)
	Protected structures conditions	The type (building, airport, historical monument or itself, etc.), area, height of structures to be protected; Relative distance between the planned and protected structures
	Drift woods	The presence of drift wood in soil
Environment	Interrupted objects	Objects to be interrupted include force, displacement, water and vibration, etc. and their locations
	Environmental impact	Environmental pollution (Ex. Noise, vibration, grout water pollution, etc.) caused by the interrupter construction
	Traffic impact	Traffic impact on users and surrounding facilities when the interrupter is going to build.
	Constructibility	Construction position and available operational space for the interrupter to be built
Time	Machine & manpower	Machine availability and maneuver; Available laborers and Coordination of different laborers
	Construction duration	The time required to complete a project when the interruptive protection method chosen is used.
	Construction progress	Daily work load; Off-day construction
	Weather conditions	Rainfall, typhoon & earthquake
	Construction method characteristics	The construction characteristics of the chosen protection method will affect the time to complete the interrupter.
Cost	Construction cost	Direct cost and indirect cost
	Benefit cost	Cost difference among using different interruptive protection methods
	Loss cost	Tangible and intangible cost due to construction accidents

tunnels passing through the aircraft stands, taxiways and runways of Sung-Sun airport first, and then No. 1 National Highway and Keelung River. Since this section of shield tunneling construction has to pass through operational Sung-Sun airport, the key points of design and construction are to maintain its regular operation and flight safety. During the design stage, two very stringent control values for the runway and taxiway were set, ± 2.0 cm for warning and ± 2.5 cm for taking action. These values are far above the requirement

Rank		3	2	4	5	1

for general shield tunnel construction. Also, in order to minimize the amount of settlement, the distance between the inbound and outbound tunnels had been increased to reduce the magnifying settlement effect of two tunnels being too close together. The analytic shield tunneling section is shown in Fig. 2(b). In addition to design, to satisfy the stringent control values, the interruptive protection method has to be used to control the settlement caused by shield tunneling excavation. It was decided to use the grouting method.

After having conducted questionnaire on Level 4 for CB420, the relative weights of alternatives with respect to the 16 sub-criteria were obtained. Table 8 shows how to use the relative weights in Level 3 and Level 4 to determine the priority weights for the alternatives. The grouting method (D1) with a weight of 0.27 was perceived to be the best alternative for interruptive protection.

6 CONCLUSIONS

Since the environment of each underground project is not quite the same, it is not easy to select a proper interruptive protection method. If a wrong method is used, the risk of having a failure project will increase. However, a lot of uncertainty in the selection process has made the selection even more difficult. Therefore, it is not easy to properly select a safe, fast and economical method. This research established the criteria and sub-criteria to be used in the assessment framework for selecting a proper interruptive protection method by Delphi method. Then, AHP was used to help the planning personnel effectively evaluate and select the proper interruptive method. The selection process and scoring table established had been verified by a study case. It has proved that the selection process presented is suitable to help decision makers select the proper interruptive protection method.

ACKNOWLEDGMENT

This work was partially supported by National Science Council, Taiwan, under grant NSC101-2622-E-216-004-CC3, which is greatly acknowledged. The authors also gratefully acknowledge the helpful comments and suggestions of the reviewers, which have improved the presentation.

Damage mechanism and dynamic analysis of tunnel lining structures under internal blast loading

Changyu Chen, Yibo Jiang & Jun Yang

PowerChina RoadBridge Group Co. Ltd., Beijing, China

Lifu Zheng & Zhipeng Li

University of Science and Technology Beijing, Beijing, China

ABSTRACT: Considering the intense threats of explosion caused by gas leaks or terrorist activities in highway tunnels, a Three-Dimensional (3D) Finite-Element (FE) method was used to study the dynamic response and damage mechanism of tunnel lining structures subjected to internal blast loading. Motivated by the reality that explosion in tunnels damages not only the lining structures but also lives and properties of people, a study based on the gas explosion in Luodai Tunnel is carried out. The coupled fluid–solid interaction was considered in this study, and the explosive–gas–lining system was modeled by using AUTODYN. The result of the numerical study shows that the part of inverted arch close to the hypocenter damages first under the impact load of gas explosion, followed by the sidewall nearby two arch springing exhibiting various degrees of damage. Eventually, the entire tunnel lining was divided into pieces of concrete blocks by the longitudinal and circumferential cracks, and the carrying capacity of the lining structure was degenerated. In addition, the deformation caused by a direct blast impact can also increase steadily because of the continuous fluctuation of the explosion shock wave due to inertia.

1 INTRODUCTION

With the sustainable and rapid development of highway, railway, and urban transportation system, tunnels are widely used, and are becoming an inextricable part of the modern civil infrastructure. In recent decades, tunnel explosion accidents have resulted from gas leaks or terrorist attacks, which are proved to be a great threat to human society. Explosion inside a tunnel may not only damage the tunnel lining structures, but also lead to further loss of lives and properties of people. The blast behaviors of tunnel structures will be distinct from those of other structures caused by their features, especially (1) high longitudinal to cross-sectional dimension ratio, (2) pressures reflected from the tunnel boundary, (3) completely confined by the surrounding ground, and (4) coupled behavior of air blast inside the tunnel and wave propagation through the surrounding ground. On the basis of the above reasons, unique requirements, which differ from the design strategies for other structures, are essential to designing a tunnel to endure a potential blast; therefore, it is imperative to understand its dynamic response under the blast loading. Because of sociopolitical issues, it is normally difficult to carry out the experimental determination of tunnels' dynamic response. Hence, applying

the advanced numerical analysis to practical tunnel problems is very important.

Analyses of the behaviors of tunnels subjected to the blast loading have been conducted by researchers worldwide. On the basis of 3D numerical analysis methods, Chille et al. (1998) studied the dynamic response of underground electric plant under internal explosive loading. They took coupled fluid–solid interaction into account, but not considered the nonlinearity and failure of rock and concrete as well as the interaction between different solid media. For traffic tunnels, Choi et al. (2006) carried out 3D FE analyses to investigate the blast loading and deformation in lining structures. They found that blast loading on lining structures was different from the normal one obtained by using CONWEP. The above two studies focused on underground structures in rock mass, as we all know, which are more resistant to internal blast loading than in soils. Dynamic analysis of circular lined tunnels under external blast loading was studied by Lu et al. (2005) and Gui and Chien (2006) using the FE program. Then, a difference method to analyze underground tunnels and cavities under blast loadings was adopted by Feldgun et al. (2008). Liu (2009) analyzed subway tunnels subjected to blast loading using FE method and modeled blast loading using CONWEP, while

the high strain rate behavior of soils under blast loading was not considered. A similar study considering this soil characteristic was carried out by Higgins et al. (2012). However, their research only considered elastic stress–strain response of lining structures. And the explosive was simulated using the JWL equation of state. The performances of different shock absorbing foam materials, steel, and concrete tunnel linings subjected to explosion were compared by Chakraborty et al. (2013). They calculated blast loading by using a coupled fluid dynamics simulation. Nevertheless, using the JWL equation of state to carry out rigorous 3D simulations of lining tunnels in rock mass with properly simulated explosive load is rather unused in the literature because of the complex practical problems.

The specific objective of the present study is to use a 3D nonlinear FE analysis to understand the dynamic response and damage of lining structures under blast loading; meanwhile, researchers and practicing engineers will have more interests to study the behavior of tunnels under non-nuclear explosions so that this field can be understood further. With these purposes, numerical simulation was used to study such problems by using the 3D Finite Element program, AUTODYN. The numerical study was based on the Luodai Tunnel in Chengdu, which encountered an explosion caused by gas leaks in February 2016, according to the scale of explosion in Luodai, the equivalent explosive is 800 kg TNT. Considering its importance as well as its representativeness, the coupled fluid–solid interaction was adopted and the pressure was applied as impulse loading at appropriate positions in the tunnel lining structures. In addition, the possible effects of the reflection and superposition of pressure were discussed.

2 PROJECT BACKGROUND

Town Luodai is located in Chengdu, Sichuan Province, China. As the passenger volume increases, extension of the Luodai to Wufeng Line has been planned. The extension involves two tunnel drives, with a total length of 4924 m, route length of 11.056 km, and total investment of 1.5478 billion yuan. Luodai Tunnel is the one pass through the Town Luodai, with a total length of 2915 m, which is judged to be a high gas tunnel.

Explosion caused by a gas leak occurred at the entrance of the Luodai Tunnel on February 24, 2015. Two detonation points were determined on the right track and one on the left, causing different degrees of damage to the structures of the primary lining, secondary lining, and invert arch. Longitudinal cracks and widespread damage appear in the

secondary structure, with the most serious fracture mainly concentrating at the section near the explosion and the maximum fracturing area up to 28 m². In the primary lining section, concrete damage and localized rock collapses occurred and part of the steel was twisted. Also, longitudinal cracks appeared in the invert arch section at the entrance of the tunnel.

3 EXPLOSION DAMAGE CONDITIONS AT LUODAI TUNNEL

Above all, the specific damage situation of lining structures in Luodai was investigated and summarized below, mainly including four aspects: primary lining structure damage, secondary lining structural damage, inverted arch damage, and the situation of seepage.

3.1 Primary lining

Section ZK2+812–ZK2+925 of the left tunnel is a primary lining structure. Because of the impact of the explosion, the shotcrete has been cracked and flaked off; the uneven and rough phenomenon on the surface is much more evident, as shown in Figure 1(a). Steel at the arch section has also been cracked, causing large deformations, part of the concrete fell on the ground, and there are also some depression areas, as can be seen at the top of the lining structures in Figure 1(b). Seven large cavities came into sight in section ZK2+815–ZK2+895, and many concrete blocks and broken steel fell off and piled up on the pavement.

Section K2+818–K2+925 of the right tunnel is also a primary lining structure. Similar damage occurred on the surface of the shotcrete. Steel arch in section K2+820–K2+870 cracked, part of the concrete fell off, thereby causing large deformations. Five large cavities can be seen in the section K2+820–K2+858. In addition, section K2+818–K2+925 was excavated by phases, the sidewall on both sides and arch lining were also badly damaged. Many concrete blocks and broken steel fell off and piled up on the pavement.

Figure 1. Primary lining damage in Luodai Tunnel.

3.2 Secondary lining

Secondary lining damage mainly occurs due to concrete cracks, water seepage, and partial breakage. Longitudinal cracks mainly distributed in the vault and the lining near the waist, slit width mostly ranges from 0.2 to 3 mm, individuals near the detonation point with a width greater than 3 mm, most of the depth of cracks penetrate the secondary lining thickness, as shown in Figure 2(a). Water seepage phenomenon appeared in the partial fracture position. Partially broken area localized mainly in the vault near detonation point, and the maximum crushing area is up to 28 m², as shown in Figure 2(b).

Statistics indicate that there are 10 cavities in the left tunnel, with six in the vault and four on the sidewall. The right tunnel involves two cavities, both seriously damaged and located in the vault, whose specific conditions are shown in Table 1.

3.3 Inverted arch

Tunnel inverted damage was mainly in the form of radial cracks and concentrated in the section of the entrance of the tunnel. As shown in Figure 3, the cracking position coincides with the longitudinal concrete construction joints, and the specific distribution is shown in Table 2.

Figure 2. Secondary lining damage in Luodai Tunnel.

Figure 4. Actual situation of water leakage in Luodai Tunnel.

3.4 Water seepage

Section ZK2+040~ZK2+170 pavements in the left tunnel has local waterlogging problems. There are even some water flows from both sides of the pattern outside the tunnel. A similar case can be seen in section ZK2+230~ZK2+290. Figure 4(a) and 4(b) show the occurrence of dome seepage and haunch water seepage in section ZK2+240 and ZK2+370, respectively. The left sidewall in section ZK2+760~ZK2+790 and the right pattern in section ZK2+773~ZK2+787 were filled with puddles. Section K2+040~K2+190 in the right tunnel has partial waterlogging problem on the pavement as well as some water flows from both sides of the pattern outside the tunnel. The left side of the haunch of the section K2+147 emerges slight seepage. Sections K2+320 and K2+350 have serious water seepage along the circumferential of

the lining, which has obvious waterlogging on the road, with other sections having no significant ponding. On the right side of the pavement, section K2+625~K2+635 has a slight water log.

4 THREE-DIMENSIONAL FINITE-ELEMENT MODELING

Sophisticated analytical simulations must be required to assess the effect of explosions on the underground facilities properly. In addition, several factors, such as explosion, structure, and ground, need to be considered for the application of numerical analyses (Du et al. 2009). Current traditional approaches for determining the effect of underground internal explosion often seem too simple to get reliable results. The coupled Euler–Lagrange nonlinear dynamic analysis is a better analysis method, which has been widely applied in dynamic or earthquake analyses. Euler–Lagrange coupling is especially fit for simulating procedure of the explosion and the interaction with the underground structure (Ngo et al. 2008). It is a powerful feature to deal with fluid–structure and gas–structure interaction problems.

AUTODYN is an entirely integrated analysis program, which is particularly designed for nonlinear dynamics problems. This computer program is used to study underground internal explosion by conducting 3D coupled Euler–Lagrange nonlinear dynamic analysis. AUTODYN-3D is a finite-difference, finite-volume, and finite-element-based calculation program, which has been well developed and validated for a wide range of impact penetration and blast problems (Autodyn, 2003). It is designed to simulate contact problems, such as nonlinear dynamics, large strain and deformation, fluid–structure interaction, explosion, shock and blast wave, impact, and penetration, and it has been widely utilized in gas and oil industry, aerospace, national defense, nuclear power, automotive, chemical, and other dynamic related fields.

The FE models in this paper were established on the basis of double single-line tunnels in Luodai, Chengdu, by using AUTODYN-3D. The inner diameter of this circular tunnel was 5.5 m, with a 50-cm-thick concrete liner. As presented in Figure 5(a), the model is a half model layout, with a symmetrical boundary set along the longitudinal direction and 800 kg of TNT equivalent detonating at 1.5 m above the tunnel pavement. With a strong foundation paved by the Euler–Lagrange coupling method, serial analysis of 3D nonlinear dynamic explosion–lining–ground interaction was carried out to study the response to internal explosion of tunnel lining structure.

(a) The model layout

(b) The FE mesh of lining

Figure 5. 3D finite element model.

4.1 Lagrangian finite-element modeling of concrete lining

The 3D FE model of the tunnel in rock mass was developed by using AUTODYN with the Lagrangian analysis option. Figure 5(b) shows the FE mesh of the tunnel lining structures, while both mesh convergence and boundary convergence studies were not considered at this stage. A tunnel with a length of 30 m was modeled in rock, and the thickness of concrete lining is 50 cm.

Involving the dynamic response of concrete materials, a strain-rate-dependent concrete model, namely RHT concrete model, is introduced to the analysis in this paper, which is a modular strength model for brittle materials that contain several features in common with many similar constitutive models (Li et al. 2006). It can represent the material characteristics of concrete better and reasonably describe the entire process, from elastic to plastic, until crushed by introducing three different failure surfaces, as shown in Figure 6. It is proved to be a suitable model to simulate the dynamic behavior of concrete material under blast loading.

4.2 Material properties for concrete

The grade of concrete in the tunnel lining model has been set as M35, and the properties of concrete are listed in Table 3, utilizing the concrete damage plasticity model, whose yield function was given by Lubliner et al. (1989). The peak tensile strain of concrete under quasi-static load is 0.0002. Taking the softening stage into consideration, the strain when the concrete completely fails is reasonably valued 0.0006. Under blast loading, concrete strain

Figure 6. Curve of elastic limit surface, yield surface, and residual strength surface.

Table 3. Concrete material properties.

Properties	Material Concrete (M30)
Density (kg/m ³)	2750
Yield strength (MPa)	35
Tensile strength (MPa)	3.5
Shear strength (MPa)	6.3
Shear modulus (GPa)	16.7
Poisson's ratio	0.22

rate ranges from 10 to 10³ s⁻¹, correspondingly, and the dynamic increase factors can reach the point 5.0 or more (Carreira et al. 1986). While the failure strain enhanced slower than the amplification of strength, the concrete failure tensile strain should take 0.001 when RC structural damage analysis was carried out under blast loading.

4.3 Eulerian finite-element modeling of explosive

The explosive material has been modeled in AUTODYN using the Eulerian modeling technique. A typical FE mesh of explosive is shown in Figure 5(b). Eulerian continuum three-dimensional eight-node reduced integration elements have been used to simulate Eulerian explosive material and the surrounding air domain inside the tunnel (TM5-1300). Through the general contact defined between explosive, air, and tunnel lining surface, the Eulerian and Lagrangian elements can interact with each other. Free outflow boundary condition has been defined at the boundary of air domain. Thus, blast pressure propagates freely out of the air domain without any reflection when it reaches boundaries of the air domain. The rationality of Eulerian elements mesh determines the efficiency of capturing the propagation of blast wave through air and the surrounding concrete lining.

Table 4. JWL material properties for TNT explosive.

Properties	Material TNT
Density (kg/m ³)	1630
Detonation wave speed (m/s)	6930
C ₁ (GPa)	373.7
C ₂ (GPa)	3.747
r ₁	4.15
r ₂	0.9
ω	0.35

Jones Wilkens Lee (JWL) equation of state is used to simulate the pressure–volume relation of explosives (Zukas et al. 2003). In this model, the pressure (Ps)–volume (v) relationship can be represented as the sum of functions given by:

$$p = C_1 \left(1 - \frac{\omega}{r_1 v} \right) e^{-r_1 v} + C_2 \left(1 - \frac{\omega}{r_2 v} \right) e^{-r_2 v} + \frac{\omega \theta}{v} \quad (1)$$

C₁, r₁, C₂, r₂, and ω are material constants in which C₁ and C₂ have dimensions of pressure and the remaining constants are dimensionless.

During the numerical calculation, air is assumed to be an ideal gas, with its properties generally described by using the linear polynomial equation of state (Welch et al. 1997), according to the Gama equation, which can be expressed as:

$$p_\alpha = (\gamma - 1) \frac{\rho}{\rho_\alpha} E_\alpha \quad (2)$$

where p_α, γ, ρ, ρ_α, and E_α are gas pressure, ratio of specific heats, the current air density, initial air density, and the internal energy of gas per volume, respectively.

4.4 Material properties for TNT

In the JWL equation of state (equation (1)), the former two exponential terms are high-pressure terms, whereas the latter is a low-pressure term, which deals with the high volume of cloud due to explosion (Veyera et al. 1995). Table 4 lists the material properties used for TNT explosive.

5 RESULTS AND DISCUSSION OF NUMERICAL SIMULATION

5.1 Dynamic response

The explosive–gas–lining structure system exhibiting a similar dynamic response under the internal

blast loading though the magnitudes distinctly varied from different tunnel, ground, or explosive parameters (Goel et al. 2011). Both the velocity and displacement of structures under explosion are regarded as important factors to measure the extent of damage (Goel et al. 2012). According to the specific damage situation in the Luodai Tunnel, the responses of the system when subjected to a blast loading of 800 kg TNT explosion are studied in this section. Defining upward and toward the left is positive, downward and toward the right is negative.

The lining structures velocity, which was accompanied with extreme lining, vibration increased dramatically under the blast loading. Figure 7 shows the change of velocity at the measuring points in the lining with time. The velocity in the inverted arch increased immediately after explosion and reached the peak value (34.8 m/s) at about 2 ms, followed by a fluctuation with overall decreasing magnitude. The velocity in vault and haunch exhibited a similar trend, originally, although their peak value is less than that in the inverted arch and was followed by a fluctuation with increasing magnitude.

Figure 8 shows the displacement at measuring points in the lining structures with internal explosion increased continuously, and they were found

Figure 7. Velocity at measuring points subjected to 800 kg TNT.

Figure 8. Displacement at measuring points subjected to 800 kg TNT.

to be different at different locations. The large displacements concentrated at the section close to inverted arch right under the explosion point, with measuring points in vault and haunch both move upward. To sum up, under the blast loading of 800 kg TNT, the tunnel lining structures exhibited an expansion deformation in the vertical direction. The measuring points located on the left haunch moves to the left, similarly, the right moves to the right, which means tunnel lining also exhibited an expansion deformation in the horizontal direction. Lining structures undergo deformation subjected to the direct blast impact, and the deformation will continue to increase, due to the continuous fluctuation of the explosion shock wave after attenuation due to inertia. By simulating and observing the displacements of the measuring points in the lining, the result shows that failure occurred only at limited location of the lining in this case under blast loading, which is consistent with the reality of the damage situation in Luodai Tunnel.

5.2 Damage mechanism

The damage distribution in the tunnel lining at 2, 4, 6, 8, 10, and 13 ms are shown in Figure 9. Several pictures are taken in the Luodai Tunnel, as shown in Figure 10, which reflect the actual damage at the accident site. The analysis for damage mechanism and the comparative analysis between numerical simulation and actual situation are discussed in this subsection.

Under the gas explosion impact load, the damage first appears in the inverted arch and vault, which are in the vertical direction of the explosion point, then expands outward, eventually causing a burst

Figure 9. Process of damage in concrete tunnel lining subjected to 800 kg TNT.

Figure 10. Actual damage of concrete lining structure.

pit of radius 4 m right under the explosion point, leading to the inverted arch pavement damage. As Figure 10(a) shows, many cracks travel through inverted arch have arisen. The part of arch springing damage earlier due to the tensile stress is caused by vertical deformation of inverted arch. Then, the sidewall nearby two arch springing, especially at the two sides close to the hypocenter, exhibits different degrees of damage subjected to the blast loading. Meanwhile, under the blast loading, the lining structure damaged range keeps evolving, as shown in Figure 10(b), and the tunnel vault lining is locally broken and a cavity formed. As the shock wave spreads to the entire inner wall of the tunnel lining, the initial compression waves first act on the wall and then turn to tension wave after reflection leading to tension along the surface of the inner ring. There are many longitudinal cracks exhibited in the hypocenter, arch springing, haunch 45° and 60°, and vault parts. Meanwhile, a certain distance from the blast center has cracks along the inner ring, and the specific actual damage situation is shown in Figure 10(c),(d). These cracks divided the entire tunnel lining structures into pieces of concrete blocks, and with the blast undergoing multiple reflections inside the tunnel, the damage and cracks keep aggravating (Bischoff et al. 1991). Although the shock wave gradually decays, the internal structure, because of the inertia, will continue to fluctuate and further deepen the damage on tunnel lining, eventually leading to the loss of the carrying capacity of the lining structure, which is also consistent with the actual damage situation in Luodai Tunnel.

6 CONCLUSIONS

According to the gas explosion and the specific damage situation in Luodai Tunnel, the explosive-

gas-lining system was modeled by using AUTODYN. In this paper, 3D nonlinear finite element analyses of highway tunnels in rock mass under internal blast loading have been simulated. The Coupled Eulerian-Lagrangian (CEL) analysis tool in finite element software AUTODYN has been utilized for research purpose. The explosive TNT has been modeled using the Eulerian elements. The pressure-volume relationship of TNT explosive has been performed by using the JWL equation of state. Considering fluid-structure and gas-structure interactions, dynamic response and damage mechanism of the lining structures are discussed in this paper. On the basis of the extensive numerical simulations, the following conclusions are drawn:

1. Subjected to the internal explosion, the velocity of lining structures increased heavily, accompanying with extreme lining vibration. The velocity in the inverted arch increased dramatically and reached the peak velocity after explosion immediately, which was followed by a fluctuation with overall decreasing magnitude. The velocity in vault and haunch exhibited a similar trend, originally, however, their peak values were less than the 1 in the inverted arch, and were followed by a fluctuation with increasing magnitude.
2. Subjected to the blast loading, the displacement in the lining structures with internal explosion increased continuously. To sum up, the tunnel lining structures exhibited an expansion deformation in both the vertical and horizontal directions. It is found that lining structures undergo deformation subjected to the direct blast impact, and the deformation will continue to increase, resulting from the continuous fluctuation of the explosion shock wave after attenuation due to inertia.
3. Under the gas explosion impact load, part of inverted arch and arch springing were damaged earlier. Then, the sidewall nearby two arch springing, especially at the two sides close to the hypocenter, exhibits different degrees of damage subjected to the blast loading. The tunnel vault lining is locally broken and a cavity is formed. The longitudinal and circumferential cracks divided the entire tunnel lining into pieces of concrete blocks, and the damages and cracks keep aggravating, with the blast undergoing multiple reflections inside the tunnel. Although the shock wave gradually decays, the internal structure, because of the inertia, will continue to fluctuate, to further deepen the damage on tunnel lining, eventually leading to the loss of the carrying capacity of lining structure. On the basis of this conclusion, it can be seen that more attention should be paid to those critical sections while evaluating blast-resistance of tunnel structures.

4. By simulating and analyzing, it is found that the results of numerical simulation are in good agreement with the actual damage situation in Luodai Tunnel, which means that the simulation can reasonably and effectively reflect the dynamic response process and reveal the damage mechanism of the lining structure of highway tunnel subjected to the blast loading. This paper offers a reference for the antiknock performance evaluation and postdisaster rehabilitation, ultimately accomplishing the purpose of guiding and helping the repair work in Luodai Tunnel. Similar principles could also be applied for designing new highway structures and other structures, which are recommended to take blast resistance into account.

The seismic responses of near-fault frame structure cluster on basin induced by the rupture of reverse fault

W. Zhong

Chongqing College of Electronic Engineering, Chongqing, P.R. China

ABSTRACT: The objective of this article is to study the effects of basin on seismic responses of near-fault frame structure cluster during an earthquake. An integrated simulation method, which can simultaneously implement wave propagation in structures and earth medium, is used to obtain seismic responses of superstructures due to the rupture of reverse fault. The seismic responses of near-fault frame structures for two cases without basin and with basin are simulated during a hypothetical M_w 6.0 earthquake. The existence of basin can increase greatly the shear forces of structural members and change earthquake risk positions of frame structures. It is observed that there exists the trend of beating for the case with basin. The geological structure of basin should be considered in simulating seismic responses of near-fault structure cluster.

1 INTRODUCTION

It is known that the basin has great effects on seismic ground motions, which is also named as basin effects such as ground-motion amplification, ground-motion duration extension and so on. Many researchers studied the basin effects and suggested that the subsurface geology of basin needs to be known in detail to simulate ground motions (Pitarka & Irikura 1996, Morales et al. 1996, Graves et al. 1998, Graves & Wald 2004, Graves 2008, Day et al. 2008). The basin regions that they concerned are San Fernando basin, the Los Angeles basin, Granada basin and San Bernardino basin, which include many building clusters in actual cities. Their research works have neglected the existence of structures on the surface of the basins.

In fact, the earthquake response of the structures in urban region is one of the main reasons for resulting in the severe seismic hazard. So the reasonable computational model should not only include earth media and seismic sources but also include structure clusters in city.

Since 1996, some researchers have combined building clusters in urban area at the surface of basin with half-space earth media and incident plane waves, which include plane P wave, plane SV wave and plane SH wave, to study far-field site-city interaction or earthquake responses of buildings. There are three different types of building models they used: (1) the buildings simplified as blocks (Wirgin & Bard 1996, Tsogka & Wirgin 2003a, b, Groby et al. 2005, Groby & Wirgin 2008, Semblat et al. 2002, Semblat et al. 2004, Kham et al. 2006,

Semblat et al. 2008), (2) the single oscillator models of buildings (Guéguen 2002, Boutin & Roussillon 2004, Boutin & Roussillon 2006, Uenishi 2010, Uenishi 2013), (3) FEM models of frame structures (Lombaert & Clouteau 2006, Lombaert & Clouteau 2009).

Apart from the far-field cities as mentioned above, there are also many other near-fault cities during an earthquake. For the near-fault cities, the rupture process of causative fault produces the characteristics of near-fault ground motions such as hanging-wall effect, directivity effect, near-fault velocity pulses, and static offsets, which can often result in complicated seismic responses and severe earthquake disaster of near-fault superstructures in city. Therefore, the rupture process of causative fault should be considered in studying site-city interaction or earthquake responses of building clusters in near-fault cities.

In recent years, a few researchers used finite-fault seismic sources and building clusters in city situated on the basin to study the site-city interaction during a near-fault earthquake. Guidotti et al. (2012) studied the site-city interaction during the 22 February 2011 M_w 6.2 Christchurch earthquake. The concerned region is Christchurch Central Business District, which is situated on the surface of the alluvial basin and is composed of around 150 buildings. The research results showed that the presence of the city changes considerably ground motions inside the city of Christchurch. Isbiliroglu et al. (2015) studied coupled soil-structure interaction effects of building clusters during earthquakes. They simulated the coupled responses of

multiple simplified building models located within the San Fernando Valley during the 1994 Northridge earthquake.

In the research works mentioned above, a building or a set of buildings on urban area is simplified as a low-velocity block and then is connected to substratum. All blocks and half-space medium underneath the free surface constitute heterogeneous continuum. This type of block model of building is first proposed by Wirgin & Bard (1996). However, this kind of simplified building model can not be used to obtain the actual earthquake responses of structures, e.g. the internal forces (bending moments, shear forces and axial forces of structural members) and the deformations of structure as well as the structural members.

In our previous work, Liu & Zhong (2014) introduced an integrated system consisting of frame structure clusters, half-space viscoelastic earth medium and causative fault. Based on this integrated system, an integrated numerical simulation method was developed for achieving flexural wave propagation in frame structure clusters and wave propagation in viscoelastic earth medium as well as bidirectional wave propagation between structure cluster and earth medium due to a near-fault earthquake.

In this article, I shall use the integrated numerical simulation method in the literature (Liu & Zhong 2014) and construct the computational model including one building cluster, earth media (with basin and without basin) and finite-fault seismic source to simulate seismic responses of frames in structure clusters during a hypothetical M_w 6.0 earthquake induced by the rupture of reverse fault. I shall study the shear forces of structures in cluster, earthquake risk positions of frame structures and snapshots of displacement of all structures.

2 THE NUMERICAL METHOD FOR SEISMIC WAVE PROPAGATION IN THE INTEGRATED SYSTEM

Figure 1(a) describes the integrated system including plane frame structure cluster, half-space viscoelastic earth medium with basin and causative fault. In order to achieve integrated simulation for seismic wave propagation in near-fault frame structure clusters and viscoelastic earth medium due to rupture of the causative fault, we have constructed three types of the investigated lumps (Liu et al. 2012, Liu & Zhong 2014, Zhong & Liu 2016): (1) the investigated lump in plane frame structure, (2) the investigated lump in viscoelastic earth medium and (3) the investigated lump for structure-soil connection. The schematic illustrations about these three types of investigated lumps

Figure 1. Schematic illustration of the investigated lumps in the integrated system. (a) Simplified diagram of the integrated system including structure cluster, half-space earth medium with basin and fault. (b) The investigated lump (shaded part A1) in the plane frame structure in structure cluster shown in figure 1(a). (c) The investigated lump (shaded part A2) in earth medium and the investigated lump (shaded part A3) for structure-soil connection.

Figure 2. Computational model of the integrated system. The three circles denote three subfaults. The “model 1” of earth media considers the basin. The “model 2” neglects basin and the material property of basin region in “model 1” is the same as sedimentary layer. The epicentral distance of center of the structure cluster is 4.18 km. The $b1$ – $b5$ are identical 3-bay 3-story plane frames. The $b6$ – $b10$ are identical 3-bay 6-story frames.

in integrated simulation for wave propagation are respectively shaded parts A1, A2 and A3 shown in Figures. 2(b), (c).

In our previous work, Liu & Zhong (2014) have established governing equations of the above three types of the investigated lumps and given an integrated numerical simulation method, which can implement simultaneously flexural wave propagation in plane frame structures and viscoelastic wave propagation in earth medium as well as bidirectional wave propagation between the plane frame structure and earth medium during an near-fault earthquake. The key of implementation of

the integrated method is the connection between structures and earth medium.

It is simple for program implementation of this integrated numerical simulation method. On the one hand, the structures model and half-space earth media are built independently. On the other, the method will be implemented by only telling the computer which investigated lumps in ground floor columns of frame structures and at the surface of half-space earth medium belong to the same investigated lump for structure-soil connection.

In this article, I shall use the integrated simulation method to obtain seismic responses of structure cluster due to the rupture of causative fault and study the influences of basin on earthquake responses of plane frame structures in structure cluster.

3 NUMERICAL SIMULATION

In this section, in order to study the influence of basin on the earthquake responses of structure cluster during a M_w 6.0 hypothetical near-fault earthquake, two different models of earth media will be constructed. I will obtain the seismic responses of near-fault structure cluster on hanging wall during a M_w 6.0 hypothetical earthquake by using the integrated simulation algorithm. The shear forces of structure cluster and earthquake risk positions of all frame structures for the cases without basin and with basin as well as snapshots of simulated displacement of all structures in cluster with basin are given during a reverse fault earthquake.

3.1 Computational model

For the seismic source, finite-fault earthquake model used here is the same as the literature (Liu & Zhong 2014). For a hypothetical earthquake of M_w 6.0, the optimal size of each subfault is about 2.5 km, and then the number of subfaults along the dip-slip direction is 3. The final slip displacement for each subfault and the average rise time are respectively 0.35 m and 2.0 s. The focal depth and dip angle are set about 15.6 km and 48°, respectively.

For the earth media, two different geological configuration models are constructed to obtain earthquake responses of structure cluster on the surface of earth media. The models are referred to hereafter as “model 1” and “model 2”. In “model 1”, as is shown in Figure 2, the geological structure includes basin, sedimentary layer and half-space bedrock. The length and the maximum depth under free surface of basin is 3.1 km and 450 m, respectively. The epicentral distance of the center of basin is about 5.18 km. Depth of the

uniform interface between sedimentary layer and the half-space bedrock is 1.0 km. In “model 2”, comparing to “model 1”, the interface between basin and sedimentary layer is neglected and “model 2” is only composed of sedimentary layer with flat free surface and the half-space bedrock. The interface of them is also 1.0 km in depth. For the “model 1”, the material properties are shown in Table 1. For the “model 2”, the material properties of only II (sedimentary layer) and III (half-space bedrock) in Table 1 are used.

For the frame structure cluster, as is shown in Figure 2, one structure cluster is considered, the center of the cluster is 4.18 km far from the epicenter. The cluster consists of 5 RC plane frame structures of 3-bay 3-storey (see $b1$ – $b5$ in Figure 2) and 5 RC plane frame structures of 3-bay 6-storey (see $b6$ – $b10$ in Figure 2) distributed with equal interval of 27.6 m. The spans of all plane frame structures are 6.9 m. C25 concrete is used in all structural members. Elastic modulus and density of concrete are respectively 2.8×10^{10} N/m² and 2500 kg/m³.

3.2 Simulation results

Figure 3 shows time history curves of the shear forces of structure clusters without basin and with basin during a hypothetical M_w 6.0 near-fault earthquake. The outputs are the middle sections of the first column (from left to right) in the first story of the structures $b1$ – $b10$. Compared with the case without basin, the increase rate of peak values of the shear forces is about 11.8% ($b6$)–146.3% ($b1$) for the case with basin. It is shown that the presence of basin can increase greatly the shear forces of plane frame structures in structure cluster at the surface of the basin.

Figure 4 shows the positions where peak column shear force and peak beam-end bending moment of each structure in structure cluster is maximum value due to rupture of causative fault for the cases without basin and with basin. These positions are named as earthquake risk positions of frame structures.

Table 1. Material properties of “model 1”.

No.	thk. (km)	Velocity (km/s)	Density (kg/m ³)	Quality factor	
I	0.45	V_s	1.04	2000	Q_s 20
		V_p	1.80		Q_p 30
II	1.0	V_s	1.73	2500	Q_s 173
		V_p	3.00		Q_p 260
III	∞	V_s	3.46	2700	Q_s 346
		V_p	6.00		Q_p 519

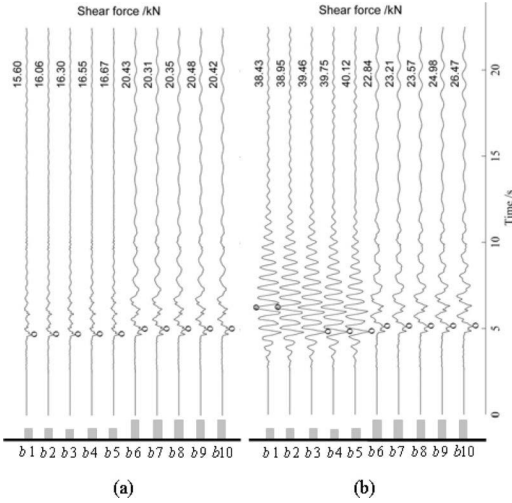

Figure 3. The shear forces of structure cluster (a) without basin and (b) with basin during a hypothetical M_w 6.0 earthquake. The outputs are the middle sections of the first column (from left to right) in the first story of the structures $b1$ - $b10$. The symbol circle denotes the position of peak shear force of the output for each structure.

Figure 4. Earthquake risk positions of the structures in structure cluster during a M_w 6.0 hypothetical earthquake for the cases without basin (a) and with basin (b).

For the case without basin, earthquake risk positions of beam ends and columns in 3-story structures are all located on the third story, earthquake risk positions of beam ends and columns in 6-story structures are respectively located on the first story and the sixth story.

From the Figure 4(b), for the case of 3-story structures with basin, earthquake risk positions of beam ends and columns are respectively located on the second story and the first story. For the case of 6-story structures with basin, earthquake risk positions of beam ends are located on the first story, earthquake risk positions of columns are located on the sixth story ($b6$ - $b9$) and the third story ($b10$).

The simulating results show that the existence of basin changes the earthquake risk positions of frame structures.

Figure 5. Snapshots of displacements of all structures in structure cluster at time 4.8 s (a) and 5.4 s (b) after initial rupture of the causative fault for the case with basin. The deformations of the structures are magnified here by a factor 50.

Figure 5 shows snapshots of simulated displacement of all structures in cluster at time 4.8 s and 5.4 s after initial rupture of the causative fault for the cases with basin. The simulated displacements includes displacements of ground motion and displacements resulting from structure deformation. Following the figure, the vertical displacement of each structure are apparently larger than the horizontal displacement. It is observed that the structures $b5$ and $b6$ at time 5.4 s have the trend of beating with basin.

4 CONCLUSIONS

An integrated numerical simulation method is used to study the influence of basin on earthquake responses of near-fault structure cluster induced by the rupture of reverse fault. By constructing two different models of earth media without basin and with basin, the seismic responses of near-fault structure cluster on the hanging wall are obtained during a hypothetical M_w 6.0 earthquake due to the rupture of reverse fault. And then the shear forces of structure cluster and earthquake risk positions of all structures are given for the cases without basin and with basin. The snapshots of displacement of structure cluster at different times are illustrated for the case with basin. Some numerical simulation results and conclusions are obtained as follows:

1. The presence of basin can increase greatly the shear forces of structure cluster at the surface of the basin.
2. The existence of basin have a great influence on the earthquake risk positions of frame structures.
3. The trend of beating for the case with basin is observed from snapshots of simulated displacement of structure cluster.

In view of the results and conclusions mentioned above, the geological structure of basin need to be

known in detail and should not be neglected when simulating seismic responses of near-fault structure cluster induced by the rupture of causative fault.

Wave propagation FEA and experimental validation of aluminum plate using piezoelectric elements

S. Yan, S. Zhang, Z.Q. Wang, P.T. Zhao & Y. Dai

School of Civil Engineering, Shenyang Jianzhu University, Shenyang Liaoning, China

ABSTRACT: In this paper, we aim to develop a new Finite-Element Method (FEM) to analyze a coupled aluminum plate structure pasted with a pair of Piezoelectric ceramic (PZT) patches as transducers for Structure Health Monitoring (SHM) and validate the efficiency of the proposed method. The finite-element software ABAQUS is applied directly to the coupled SHM system by using piezoelectric elements. Piezoelectric ceramic patches are used as either generating or receiving signal device. The piezoelectric elements are directly used for the PZT material. It is considerably focused on the influence law of PZT polarization direction and detection wave spectral characteristics for detection effectiveness. The whole process of generating, propagating, and receiving of the detection signal is numerically simulated and the results are analyzed. In order to verify the efficiency of the proposed method, a model test of an aluminum plate structure under the same condition is carried out, and the results are compared to that of the finite-element analysis. The results show that the proposed finite-element model and the finite-element detection method match well with the experimental results.

1 INTRODUCTION

As a kind of common structure, aluminum plate is widely used in engineering, especially in the manufacture of aircraft, vessels, and many other structures in various fields. It has a very important significance to monitor the working state of aluminum plate structures over time. At present, ultrasonic Lamb wave Nondestructive Testing (NDT) technology is widely applied in the health monitoring of aluminum plate structures (Wang 2007, Liu 1999). Recently, more and more people use finite-element software for the simulation of Lamb wave detection of aluminum plate (Xu 2015); however, in the present simulation analysis, most of the analysis methods are directly exciting and extracting the Lamb wave displacement signal on the structure surface, which still have a certain difference with the actual experiment using the sensor to detect the aluminum plate, especially the influences of adhering layers on the transformation between electric voltage and structural movement, resulting in a great difference between numerical simulation using equivalent displacement input and output and experimental results. Accordingly, in this paper, on the basis of the research of the existing active Lamb wave detection (Yan & Zhang & Meng 2010, Cao 2008, Yan et al 2013), using finite-element software ABAQUS and considering the influence of PZT polarization direction and the detection wave spectrum characteristics

of the detection result, a finite-element method is proposed for the detection of aluminum plate by directly using the piezoelectric element, and the results are verified by experiments. This method can utilize the piezoelectric effect of the piezoelectric element to directly excite and receive the voltage signal, which is closer to the actual experiment than the previous simulation method.

2 NUMERICAL SIMULATION MODEL

2.1 Excitation signal selection

Lamb wave propagation is a dispersive and multi-mode method. The modes of Lamb waves excited by different frequency bands are also different. Through the frequency dispersion curve of Lamb wave propagation in aluminum plate, it can be found that when the frequency and the plate thickness of the product are less than 1 MHz and 1 mm, there are only two modes of guided waves of S_0 and A_0 , which is convenient for the analysis of the signal. Therefore, the excitation signal is selected as the five peak wave narrowband signal modulated by Hanning window function, whose center frequencies are 150, 200, and 300 kHz, respectively, and the amplitudes are all 1V, as shown in Figures 1–3, respectively.

From the figures, we can find that when the frequencies are increasing in time domain, the amplitudes of the spectra are decreasing and the frequency band is expanding in frequency domain.

Figure 1. 150 kHz excitation signal.

Figure 2. 200 kHz excitation signal.

Figure 3. 300 kHz excitation signal.

2.2 Model establishment

The aluminum plate and PZT patch models provided by ABAQUS and used in this paper are the shell elements. They use the solid element and the piezoelectric element, respectively. The size of the aluminum plate model is 80 mm × 80 mm × 1 mm, and the size of the piezoelectric patch element is 12 mm × 6 mm × 1 mm. The distance between driver (PZT1) and receiver (PZT2) is 480 mm, and the distance between the exciter and the left boundary is 160 mm along the horizontal direction, and the distance between the exciter and the right boundary is also 160 mm, as shown in Figure 4. The parameters of the materials are shown in Tables 1–2.

2.3 Boundary conditions

The polarization directions of PZT1 and PZT2 are set to be perpendicular to the thickness direction of the plate from the upper surface to the lower surface. The periodic potential of 100V is applied on the upper surface of the PZT1 along thickness direction, and the lower surface is set as the zero-potential-energy surface. At this point, the electric

potential direction is parallel to the polarization direction, and PZT1 will generate a periodic vibration along the thickness direction of the plate. Meanwhile, the lower surface is set as the zero-potential-energy surface along the thickness direction of the receiving piezoelectric element PZT2, which can extract the voltage change caused by the deformation in the thickness direction. Similarly, when the polarization direction and the electric potential direction of the piezoelectric element are set along the length direction, the displacement and voltage signals along the length direction of the piezoelectric element will be excited and received.

2.4 Time incremental step selection and size of element

The element size and time increment of FEM have a great influence on the convergence and accuracy of numerical solution. In general, the smaller the incremental step, the finer the grid division and higher the accuracy of the model. In order to ensure the accuracy of the calculation and to consider the influence of the computational efficiency, the cell grid size is set to 2 mm, and in order to improve the efficiency of the operation, the difference grid is adopted and the grid of plate boundary section is rough. And on the basis of ensuring that the incremental step size is less than 1/20 of the corresponding period of the maximum frequency wave, the time increment step is set to 0.1 μ s. Figure 5 shows the mesh division of the model.

2.5 Simulation result analysis

During simulation results analysis, the potential along the length direction of the sensor, caused by the S_0 mode, and the electric potential along the thickness direction of the sensor, caused by the A_0 mode of the reference point, are extracted. According to the frequency dispersion curve and the corresponding frequency, the S_0 and A_0 modes are identified by checking and comparing with the group velocity, and the time between the peak values in the signal wave packet is taken as the arrival time of the signal center frequency group. The detection signals in time domain are shown in Figures 6–11.

The Figures show that both the S_0 and A_0 mode Lamb waves have energy attenuation phenomenon in the propagation process, and the energy attenuation of mode A_0 is more serious than that of mode S_0 . When reaching the boundary, both the mode signals have reflections and phase transition. With the increase of the excitation frequency, the energy attenuation effects of the two mode signals are more serious in the propagation process. In the above-mentioned figures, the first wave packet

from the left is the initial received signal, and the second wave packet is the boundary reflection signal.

3 EXPERIMENTAL VERIFICATION

3.1 Experimental setup

To validate the efficiency of the numerical simulation, a model test of an aluminum plate pasted with a pair of PZT transducers are performed. The size of the aluminum plates used for test specimens is 800 mm × 800 mm × 1 mm (length × width × thickness). The piezoelectric ceramic patches with a square single-side electrode as sensor and actuator are pasted on aluminum plate surface. The system equipment is mainly composed of a DG1022 arbitrary waveform transmitter (signal generator), an aluminum plate, and a DS1102E digital oscilloscope. The excitation signal used in the experiment is a five-peak wave signal, and the central frequencies of the excitation signal are 200 and 300 kHz.

3.2 Experimental analysis

The central frequencies of 200 and 300 kHz modulation five-peak wave signals are selected as the excitation voltage, and the voltage amplitude is 100V. The experimental data are shown in Figures 12 and 13, respectively.

Figure 12. 200 kHz received signal.

Figure 13. 300 kHz received signal.

Because the piezoelectric plate used in the experiment is in the direction of vibration along the length, the electric potential signal is mainly based on the S_0 mode. In the experiment, the boundary of the aluminum plate is adhered to the rubber mud, which is used to absorb the reflection wave of the boundary, and the interference of the boundary reflection signal is too small to be measured. In the above figures, the first wave packet is the initial received signal, and the second small wave packet is the boundary reflection signal. By comparison, the waveform and the amplitude of the two central frequency detection signals in both FEM simulation and experiment match well, indicating the validation of the efficiency for the proposed method.

4 CONCLUSION

Using ultrasonic Lamb wave to detect the structure of an aluminum sheet has very important significance, according to the basic principle of the piezoelectric effect and the frequency dispersion curve of Lamb wave in aluminum plate, and a new method for the detection of aluminum sheet based on the piezoelectric element is proposed by using finite-element software. The results were compared with the experiment results. This new method takes

voltage as the excitation and the extraction signal, and it is more applicable to the actual situation than the commonly used simulation method, which takes displacement as excitation and extraction signal. In this paper, the element properties, time increment, and mesh division of the model used in finite-element software are introduced, which may provide some references for the future research on the piezoelectric simulation of ABAQUS.

Numerical simulation on seismic behavior of subway station structure under near-fault ground motions

Baizan Tang, Su Chen & Xiaojun Li

Institute of Geophysics, China Earthquake Administration, Beijing, China

Haiyang Zhuang

Civil Engineering and Earthquake Disaster Prevention Center of Jiangsu Province, Nanjing, China

ABSTRACT: Based on the finite method of ABAQUS software, the numerical simulation on seismic response of the soil-subway station structure interaction were performed to reveal the obvious nonlinear properties of soil and the effect of soil-structure interaction under near-fault ground motions. In the numerical simulation, an advanced numerical model was crafted to consider the nonlinear static and dynamic coupling interactions between the soil and the underground structure. Dynamic behavior of the underground structure, including the lateral displacement and acceleration response of the structure, acceleration response of soil-subway station structure, were analyzed, respectively. The research results could provide references for the seismic design and construction of underground structure.

1 INTRODUCTION

With rapid development and urbanization in China, exploitation and utilization of underground space has become a major concern. By the end of 2015, subways have been built or approved for construction in 37 Chinese cities with a total operating mileage 2933 km and 1947 operating subway station approximately. As a result, the structural styles of the subway underground structure become more and more complicated. In recent years, the strong earthquake disaster investigations indicate that underground structures suffered severe damage in near-fault area, such as the 1994 Northridge earthquake, 1995 Kobe earthquake, 1999 Kocaeli earthquake and 1999 Chi-Chi Earthquake (Samata et al. 1997, Kalkan et al. 2006, Corigliano 2007, Cunha et al. 2014). But the studies on the effect of near-fault ground motion on the seismic behavior of underground structures are limited (Chen et al. 2010, Tao et al. 2011, Corigliano et al. 2011, Davoodi et al. 2013, Zhao et al. 2015). Selected a set of near-fault ground motions of Loma Prieta and Coalinga records as seismic inputs, Chen et al. (2010) carried out the simulation analysis for the Double-layer vertical overlapping metro tunnels based on finite element software ABAQUS to investigate the seismic response of subway underground station. It was shown that the relative horizontal displacement induced by near-fault ground motion was greater than that induced by far-field ground motion in metro tunnels. At present, the subway station model with double-layer three-span

is widely used in China, accordingly, this paper focused on analyzing the seismic behavior of double-layer three-span subway station structure under near-fault ground motions with a commercial Finite Element Model (FEM) software. To simulate the dynamic properties of soil, a modified Martin-Seed-Davikendov viscoelastic constitutive model was applied.

2 DEFINITION AND CHARACTERISTICS OF NEAR-FAULT GROUND MOTION

Near-fault ground motion is the motion that is typically assumed to be restricted to within 20 km of a fault (Mavroeidis & Papageorgiou 2003). However, this definition is not universal because near-fault effects attenuate as distance increases, which, in turn, leads to a greater effect of factors such as magnitudes and local site conditions on ground motion. The special characteristics of near-field ground motions are directly related to the earthquake source mechanism, rupture direction relative to the site, and slip direction of the rupture fault. The distinguishing characteristic of near-fault ground motion is the pulses generated by the directivity effect and fling-step effect. These pulse-type ground motions often contain one or more distinct pulses in the acceleration, velocity and displacement time histories, most frequently in velocity. Meanwhile, many new typical characteristics including hanging wall effect and vertical effect are also gradually recognized (Li &

Xie 2007). The ground motions are characterized by pulse-type wave shape, long pulse period, abundant long-period components, and sometimes large permanent ground displacement.

3 NUMERICAL MODEL

3.1 Soil foundation and underground station structure

A 2-dimensional subway station numerical model with regular cross-section performed by ABAQUS was shown in Figure 1. The nonlinear static and dynamic coupling model was developed for the soil-underground structure dynamic interaction. In this numerical model, CPE4R (a 4-node plan strain, reduced integration) elements were used to mesh the soil foundation and the subway station structure; B21 (a 2-dimensional linear beam) elements were embedded into the concrete to simulate the rebar. The CPE4R element size is $0.2\text{ m} \times 0.2\text{ m}$ for the subway station structure. Based on Liao's study (2013), the maximal height of element h_{\max} in the case of shear wave propagation in the soil should be determined by:

$$h_{\max} = \left(\frac{1}{75} - \frac{1}{160} \right) \cdot V_s / f_{\max} \quad (1)$$

where V_s means the shear wave velocity. f_{\max} denotes the maximal vibration frequency of the input motion. Hence, the maximum element height of the soil foundation from the top to the bottom of the ground ranges from 0.8 to 2.3 m.

3.2 Material properties

The stress-strain relationship of soil shows characteristics of nonlinearity, hysteresis, and accumulative deformation under cyclic loading. The constitutive model for soil used in the paper is a

modified Martin-Seed-Davikendov viscoelastic model (Chen et al. 2005), which is based on the Davikendov skeleton curve of a one dimensional dynamic stress-strain relation. The dynamic shear stress-strain curves were constituted by Masing rules (Martin & Seed 1982). This soil constitutive model was recently implemented into the commercial software ABAQUS (Chen et al. 2011). The Davikendov skeleton curve was corrected by sectional functions, and the upper limit of failure shear strain amplitude (γ_{ult}) was applied as the sectional point. The modified skeleton curve could approach the upper limit of failure shear stress (τ_{ult}) when the shear strain amplitude approached infinite.

The Davikendov skeleton curve is given as follows:

$$\tau(\gamma) = G \times \gamma = G_{\max} \times \gamma [1 - H(\gamma)] \quad (2)$$

where

$$H(\gamma) = \left\{ \frac{(\gamma/\gamma_0)^{2B}}{1 + (\gamma/\gamma_0)^{2B}} \right\}^4 \quad (3)$$

The actual shear stress and strain relationship of soil is $\gamma \rightarrow \infty, \tau(\gamma) \rightarrow \tau_{ult}$. Therefore, the piecewise function method was used to describe the skeleton curve, and the Davikendov model was modified as follows:

$$\tau(\gamma) = \begin{cases} G_{\max} \times \gamma [1 - H(\gamma)] & \gamma \leq \gamma_{ult} \\ G_{\max} \times \gamma_{ult} [1 - H(\gamma_{ult})] & \gamma > \gamma_{ult} \end{cases} \quad (4)$$

$$\tau_{ult} = G_{\max} \times \gamma_{ult} [1 - H(\gamma_{ult})] \quad (5)$$

The equations used to calculate the damping ratio can be derived. The hysteretic curve of the modified shear stress-strain relationship and

Figure 1. The cross-sectional dimensions and distributed rebar of the subway station.

calculation flow diagram were shown in Figure 2. Table 1 presents the physical and mechanical parameters of the soil foundation.

The concrete damaged plasticity constitutive model presented by Lee & Fenves (1998), which was adopted to simulate the material plasticity and continuum damage mechanics behavior of concrete. The strength level of concrete adopted in the subway station is No. C30, and its material properties are summarized in Table 2.

3.3 Boundary condition and input motion

The static and dynamic coupling boundary condition of the soil foundation adopted the artificial constrained boundary. According to the method, the lateral boundary is constrained in the

horizontal direction, and the horizontal reaction forces (RF) at the nodes on the lateral boundary output at the end of static analysis. Prior to the dynamic analysis, the lateral boundary condition is released in the horizontal direction with a horizontal RF that is reserved by the artificial loading method and constrained in the vertical direction. The conversion process of boundary condition is shown in Figure 3. To weaken the reflected wave effect on the lateral boundary of soil foundation, the horizontal distance from the lateral boundary to the subway station was set as 89.4 m, and the damping factor of the elements near the boundary was amplified fivefold (Zhuang et al. 2015).

Prior to the dynamic simulation, the interaction system is subjected to gravity loading and hydrostatic pressure. In the ABAQUS/Standard analysis, these loads are specified in two consecutive static steps. To examine the effects of near-fault ground motions on the dynamic response of the subway station, three representative near-fault ground motion recordings with forward directivity effect were selected as seismic input from the Next Generation Attenuation Project database (PEER NGA Database 2005), which were recorded at NO.07-SN El Centro strong motion station during the Ms 6.5 Imperial Valley earthquake on Oct 15, 1979 in California, United States, and NO. TCU075-EW, TCU129-EW during the Ms 7.6 Chi-Chi earthquake on Sep 21, 1999 in Taiwan. The near-fault

ground motions were oriented in the fault-normal direction with rupture distance of 0.56, 0.91 and 1.84 km, respectively. The acceleration and velocity time histories of three near-fault ground motions are shown in Figure 4.

4 RESULTS AND ANALYSIS

4.1 Acceleration responses of the soil foundation

The peak acceleration amplification factors along the soil depth under the three ground motions are shown in Figure 5. Note that the peak acceleration amplification factor increases from the bottom to the top of the soil foundation, especially visible from the bottom slab of subway station to the ground surface. The result means that the soil had different effect on the propagation of waves with different frequency components and the presence of the subway structure had a strong effect on the response of the soil foundation. It's clear that the

Figure 5. Peak acceleration amplification factors of the model soil.

peak acceleration amplification factor is almost larger than 1, and the curve shapes were basically similar for the forward directivity effect of near-fault ground motions. The values for the PGA amplification factors at the ground surface are much larger than 1.50 (Chen et al. 2015), ranging from 2.28 to 2.65. It indicates that the softening behavior of the topsoil was more sensitive to the near-fault ground motion with characterize of long pulse period and abundant low frequency components.

4.2 Acceleration responses of the subway station structure

Figure 6 presents the peak acceleration amplification factor at the subway station slabs subjected to near-fault ground motions. Note that the peak acceleration amplification factor at the middle slab of the subway station is smaller than that of the bottom slab, and then it increases obviously at the top slab. This finding is obviously inconsistent with the acceleration response rule for the general ground structure, and the effect of the soil-underground structure interaction should be the main factor. In addition, the peak amplification factor at the middle slab induced by the input motion of TCU129 record is the smallest with the same inputting $PGA = 0.23 \text{ g}$ and it reaches the largest for the input motion of E07 record due to the different frequency spectrum characteristics of input near-fault ground motion.

4.3 Lateral displacement responses of the subway station

Figure 7 plots the relative displacement distribution of measuring points along the structural height subjected to near-fault ground motions. It's quite clear that the lateral displacements of the subway station have positive correlation with the height of the subway station, and the peak relative lateral displacements on the top slab range from 32.99 to 34.89 mm. The maximum story drift was 20.40 mm on the middle slab under input motion

Figure 6. Peak Acceleration amplification factor for the slabs of the subway station.

Figure 7. Relative displacement of the subway station.

of TCU075 record, and 15.44 mm on the top slab under input motion of TCU129 record with $PGA = 0.23 \text{ g}$. Meanwhile, the inter-story drift reached 1/356 at the middle slab and 1/339 at the top slab, respectively. The result shows that frame-type subway station was regular on the vertical direction, and also had excellent integrity. According to the code for seismic design of buildings (GB 50011–2010) and recent research (Zhuang et al. 2015), the ultimate value of elastic inter-story drift for Reinforced Concrete (RC) frame structure should range from 1/550 to 1/430. It indicates that the structural members of subway station may be damaged under the near-fault ground motions. In addition, the curve shapes show that the deformation form of subway station structure is basically shearing type.

5 CONCLUSIONS

The FEM simulation model was crafted to model the soil foundation and the underground structure. Acceleration responses of the soil-underground structure system and the lateral displacement response of the subway station were analyzed. The following concluding remarks and recommendations could be drawn:

1. The softening behavior of the topsoil was more sensitive to the near-fault ground motion with character of long pulse period and abundant low frequency component.
2. The frequency spectrum characteristics of the input near-fault ground motion had significant effect on the dynamic response of the subway station structure.
3. The structural members of subway station may be damaged under the near-fault ground motions, and the deformation form of subway station structure is basically shearing type.

Finite—infinite element analysis of soil dynamic response under moving load

Chenqi Tian & Liqun Yuan

School of Civil Engineering, Shandong Jianzhu University, Jinan, Shandong, China

School of Architecture and Civil Engineering, Liaocheng University, Liaocheng, Shandong, China

ABSTRACT: In recent years, the rail transit in China has been developed rapidly. But the noise and vibration caused by rail transit have serious impact on people’s working and living. The propagation of vibration wave in the foundation soil is the key problem for the reasearch of environmental vibration. In this paper, different element stiffness matrices and group sets are obtained by using three dimensional, one direction bidirectional, and three direction mapping infinite element methods. Dynamic responses of semi-infinite soil are calculated under different loads. The characteristics of vibration for the semi-infinite soil space under surface load are also analyzed and summarized.

1 INTRODUCTION

After the emergence of the concept of infinite element, the domestic and foreign scholars have put forward various kinds of static, dynamic, wave frequency domain or infinite element in the time domain, which can simulate the infinite domain. Infinite element method is developed to solve the effectively. Researchers have proposed different types of infinite element and shape function. But most of the methods are based on the unite shape function, which is multiplied by an attenuation factor, to represent the amplitude of wave decay gradually when the wave extends to infinite element in the relevant direction. Although at present theoretical researchers for the coupling method between finite element and infinite element have made some progress, infinite element method is a new kind of special method compared with the finite element method. Theory and application of infinite element method are limited. Many questions in practical engineering applications still exist. In this paper, the coupling finite element and infinite element method is used to explore the dynamic problem of the three-dimensional elastic semi infinite soil under moving load.

2 ESTABLISHMENT OF THE MODEL

In this paper, we mainly consider the dynamic response of the arch at the end of the tunnel. So the formation parameters are calculated by

Table 1. Material parameters of the finite element model.

Gravity density $\gamma/\text{kN/m}^3$	Elastic modulus E/MPa	Poisson ratio v	cohesion C/kPa	internal friction angle $\phi/^\circ$
19.2	4.0	0.30	30	21°

stratum soils selection. Detailed parameters of the materials used in the numerical calculation model are shown in Table 1.

3 FINITE ELEMENT BOUNDARY CONDITION

Dynamic calculation, the first to calculate the characteristic value of the model. The key to the eigenvalue calculation is to define the elastic boundary condition. Model boundary is adopted in the form of curved spring, and the spring coefficient is calculated according to the following formula.

Vertical ground reaction coefficient: $k_v = k_{v0} \times \left(\frac{B_v}{30}\right)^{-0.75}$

Horizontal ground reaction coefficient: $k_h = k_{h0} \times \left(\frac{B_h}{30}\right)^{-0.75}$

The calculation formula of the damping ratio is as follows:

P-wave: $C_p = \rho \times A \times \sqrt{\frac{A+2G}{9.81 \times \gamma}} = c_p \times A$

S-wave: $C_s = \rho \times A \times \sqrt{\frac{G}{9.81 \times \gamma}} = c_s \times A$

Through the calculation of the model: $k_x = 139.4 \text{ kN/m}^2$, $k_y = 116.8 \text{ kN/m}^2$, $k_z = 139.4 \text{ kN/m}^2$, $c_p = 101.9 \text{ kN} \cdot \text{sec/m}$, $c_p = 54.5 \text{ kN} \cdot \text{sec/m}$

4 FINITE ELEMENT ANALYSIS

Finite element model of moving load calculation y, x, z directions of the dimensions are 10 m, 15 m, 5 m, the outer and the bottom of the infinite element. The loading is divided into two kinds, respectively for moving load and moving harmonic load.

4.1 Moving force load

Moving force load size as $P = 1 \text{ N}$, moving along y axis, speed is V .

In Figure 1 and the thick solid line is the load moving trajectory.

Figure 1. Schematic diagram of subsoil model.

Figure 2. Time curves of vertical acceleration ($V = 2 \text{ m/s}$).

Figure 2 to Figure 5 shows the dynamic response of the node E at different speeds. The position of the node E distance from the moving load 4 m.

Through the calculation, it is known that the acceleration of the node E is larger when the

Figure 3. Time curves of vertical acceleration ($V = 5 \text{ m/s}$).

Figure 4. Time curves of vertical acceleration ($V = 10 \text{ m/s}$).

Figure 5. Time curves of vertical acceleration ($V = 20 \text{ m/s}$).

moving load speed is 10 m/s. When the velocity is 0~10 m/s, the root mean square value of the acceleration increases with the speed. When the velocity is greater than 10 m/s, the root mean square value of the acceleration decreases.

4.2 Moving harmonic load

Different frequency moving harmonic loads are applied on the ground and loads velocity is 5 m/s. Table 2 gives effective value of acceleration for the different frequency loads of the node A and E.

In order to study the dynamic response characteristics of the foundation soil, the acceleration response of the node E under different load frequencies is analyzed by Fourier transform, which are shown in Figures 6~11.

By comparing the acceleration time history curves of the joints under different loading frequencies, it is known that the dynamic response

Table 2. Effective value of acceleration (10^{-8} m/s²).

Frequency (Hz)	0.16	0.8	1.6	5	10	16	20	30
A	196.3	287.1	598.9	233.8	406.4	2017	7028	5070
E	0.200	0.201	0.2134	1.462	69.239	44.42	36.13	39.85

Figure 6. Time curves of vertical acceleration (5 Hz).

of the foundation increases with the increase of the load frequency, but the attenuation of the dynamic response of the foundation is accelerated. At the same time, by means of the Fourier transform of the acceleration of the joint, the frequency value of the Fourier transform is the frequency of the load.

5 CONCLUSIONS

In this paper, the three-dimensional finite element and infinite element method are employed to simulate the soil dynamic response. Some valuable results are found. The results obtained are of great reference value for the analysis of formation dynamic response under traffic load. The research results not only have a certain academic value for the infinite element method and soil mechanics, but also provide technical support for the important transportation infrastructure construction in the future. The results can be also a good reference for the study of underground space security.

Evaluation of the processing suitability of rural domestic sewage treatment, taking Fangshan in Beijing as a case study

Yong Wang

College of Resources and Environmental Science, China Agricultural University, Beijing, China
Fangshan District Beijing Water Authority, Beijing, China

ABSTRACT: In order to understand the adaptability and the effect of multiple rural domestic sewage treatment techniques in rural areas, their technical suitability could be evaluated by using the entropy fuzzy matter-element model and the AHP analysis method by taking the rural sewage treatment station in Fangshan District, Beijing, China, as an example. The result showed the high repeatability of the two evaluation methods. The sequence of processing suitability was: Constructed Wetland (CW) > MBR > Solar Anaerobic Biological Filter (SABF).

1 INTRODUCTION

The features of rural domestic sewage are of small scale and dispersed, which have large difference for the water quantity and water quality of different regions. In fact, it was difficult to collect and had high organic pollution concentration and low processing ratio (LI Juan, 2012; WANG Shou-zhong, 2008). For the quality, the COD and BOD₅ were higher than the city domestic sewage but with good biochemical reactivity (WANG Shou-zhong, 2008; HOU Jing-wei, 2012). According to the specialties, the common treatment technologies were frequently used as constructed wetlands, underground soil permeability system, aerobic biological treatment system, and anaerobic biological treatment systems (WANG Baoxue, 2015).

China is an agricultural country with a large population, consisting of 634,000 villages and 22,000 towns. According to statistics, 50% of the total displacement came from the counties, towns, and villages. The county wastewater treatment rate was 11%, whereas the corresponding figures of villages and towns were less than 1%. The promulgation of “water pollution prevention action plan” will drive RMB 2 trillion yuan of investment in water pollution governance. However, the fault management shows that a number of sewage treatment stations have low efficiency of operation. The inadequate analysis and evaluation of planning, designing, construction, operation, maintenance, management, and so on have resulted in insufficient understand of the applicability and reliability of different treatments in different areas (Liang Han-wen, 2011). Therefore, suitability analysis is really important for rural domestic sewage treatment.

Recently, Fangshan District has invested more than 300 million RMB for the rural domestic

sewage control and constructed 115 wastewater treatment stations in 20 towns and more than 80 villages, were including Changyang Town, Qinglonghu Town, and Zhoukoudian Town.

This paper aims to provide a reference for the rural sewage treatment processing construction and management by discussing different treatment technologies and carry out adaptability investigation and evaluation of actual running rural sewage treatment station in Fangshan District.

2 METHODS

2.1 Investigation

The specific information of Fangshan District wastewater treatment station’s processing type, investment, designed quality of inflow and outflow, operation management, and pollutant treatment effect was gathered by questionnaires, investigation, and data collection.

2.2 Monitoring

The evaluated stations were sampled and monitored for water quality five times from January to April, 2016. The monitored indicators were water temperature, COD, BOD₅, NH₄⁺-N, and TP.

2.3 Evaluation method

At present, the widely adopted evaluation methods are contrast method, Analytic Hierarchy Process (AHP), and causal analysis and comprehensive evaluation method (Li Jicheng, 2007). For this study, the entropy weight fuzzy matter-element model (HAO Rui-xia, 2013) (EWFEM) and AHP method (GUO Jin-yu, 2011 & Bottero M, 2011) were applied.

3 RESULTS AND DISCUSSION

3.1 Selection of evaluation stations

During the analysis and research, 115 treatment stations were classified into 11 processing types (whose position and process distribution are shown in Figure 1).

The representative potential stations were selected according to the topographies, technology penetration, and operation situation. After discussing with the local management department, five processing types were chosen: Membrane Bioreactor (MBR), Constructed Wetland (CW), Pretreatment + Constructed Wetland (PCW), Solar Anaerobic Biological Filter (SABF), and Multistage Vertical-flow Constructed Wetlands (MVCW). In addition, the representativeness of plain, hills, and mountainous areas should be considered, so finally six stations were evaluated on the research. The names and process types of the selected stations are shown in Table 1.

3.2 Evaluation by entropy weight fuzzy matter-element model

First, the investment and operating cost was uniformed to price of per ton. The station serviced population was in accordance with the equivalent population: a calculation of the resident population and the tourist population who had same pollution discharge with resident population per

day. The Fangshan tourism resource abundance value was 26% (Li Jun, 2007). For qualitative and semi-qualitative indicators, the standard of evaluation was established for quantitative evaluation. The quantitative evaluation used 10 division systems, whose scoring standards are shown in Table 2.

According to the investigation and water quality monitoring results, the researchers established recombination fuzzy matter-element and uniformed data, whose results are shown in Table 3. Judgment matrix was uniformed for the value of optimal subordinate degree. It was a nondimensional process for the various elements, which achieved element comparability.

The calculated definition entropy (S_j) of each evaluation indicators and built vector S .

$$S^T = \begin{pmatrix} A & B & C & D & E \\ 0.987 & 0.979 & 0.987 & 0.968 & 0.981 \\ F & G & H & I & J \\ 0.980 & 0.989 & 0.989 & 0.984 & 0.982 \\ K & L & M \\ 0.981 & 0.980 & 0.974 \end{pmatrix}$$

The calculated weight of each evaluation indicator (ρ_j) as vector ρ .

$$\rho^T = \begin{pmatrix} A & B & C & D & E \\ 0.056 & 0.087 & 0.055 & 0.132 & 0.080 \\ F & G & H & I & J \\ 0.085 & 0.048 & 0.047 & 0.066 & 0.074 \\ K & L & M \\ 0.080 & 0.083 & 0.107 \end{pmatrix}$$

From the results of entropy weight, its average was 0.070, the value of the annual operating rate was the highest, followed by ammonia nitrogen removal rate, actual running scale/design scale, and the investment cost per ton. The weight of emergency response capability was the lowest and significantly lower than other indicators. Calculated Euclid Approach Degree (EAD) of evaluation stations (φ_i) and built vector (R_{φ}). The results are as follows:

NH ₃ -N removal rate (M)	0.39	0.03	0.99	0.97	0.10	1.00

Table 4. EAD value.

Station	Process	EAD	Difference from the EAD
HSY	MVCW	0.70	-
NH	MBR	0.63	-0.07
HTP	PCW	0.58	-0.05
SMT	CW	0.56	-0.02
MRG	MBR	0.51	-0.05
LMT	SABF	0.46	-0.05

$$R_{\varphi}^T = \begin{pmatrix} M_1 & M_2 & M_3 & M_4 & M_5 & M_6 \\ 0.63 & 0.51 & 0.56 & 0.58 & 0.46 & 0.70 \end{pmatrix}$$

According to the calculated results, sorted by the EAD of evaluation station treatment process, the results are shown in Table 4.

The order of stations according to the advantages of the station treatment process suitability was HSY (MVCW) > NH (MBR) > HTP (PCW) > SMT (CW) > MRG (MBR) > LMT (SABF).

Combined with the distribution map, the EAD was lower in the mountainous area. There was a general lack of management issues in the stations

in mountains area, increasing the equipment maintenance cost and reducing the actual scale/design scale. These lead to the low adaptability to the environment, which caused the low EAD value. Although MRG is in the plain area, the equipment has high operating cost, and it could not immediately put into service.

3.3 Evaluation by analytic hierarchy process

The data in AHP kept same with entropy weight fuzzy matter-element model; partially quantitative data were marked on a scale of 0-10, scoring followed rules:

The bigger optimal indicators:

$$\nabla_{ji} = \frac{v_{ji}}{\text{Max } v_j} \times 10$$

$$1 \leq j \leq n$$

The smaller optimal indicators:

$$\nabla_{ji} = \frac{\text{Min } v_j}{v_{ji}} \times 10$$

$$1 \leq j \leq n$$

The scoring matrix C of qualitative and quantitative indicators is obtained as follows:

$$C = \begin{pmatrix} A & B & C & D & E & F & G & H & I & J & K & L & M \\ 7 & 5 & 3 & 10 & 3 & 7 & 5 & 7 & 6 & 6 & 9 & 7 & 4 \\ 6 & 1 & 3 & 10 & 9 & 8 & 5 & 8 & 10 & 6 & 6 & 4 & 0 \\ 5 & 5 & 5 & 3 & 2 & 2 & 7 & 10 & 8 & 10 & 10 & 10 & 10 \\ 6 & 3 & 3 & 3 & 1 & 10 & 4 & 8 & 10 & 9 & 9 & 9 & 10 \\ 6 & 3 & 3 & 10 & 10 & 3 & 10 & 8 & 7 & 3 & 3 & 2 & 1 \\ 6 & 5 & 3 & 10 & 1 & 10 & 6 & 6 & 8 & 9 & 10 & 9 & 10 \end{pmatrix}$$

The building judgment matrix is shown in Table 5.

Matrix biggest characteristic root was $\lambda_{\max} = 14$, CI = CR = 0, the corresponding characteristic vector unit was the unit vector ω_1 :

$$\omega_1^T = \begin{pmatrix} A & B & C & D & E \\ 0.047 & 0.057 & 0.066 & 0.066 & 0.066 \\ F & G & H & I & J \\ 0.057 & 0.075 & 0.066 & 0.066 & 0.075 \\ K & L & M \\ 0.075 & 0.075 & 0.057 \end{pmatrix}$$

The comprehensive scores of the evaluation stations could come from element matrix, multi-

Station (process)	Score of AHP	EAD × 10
HSY (MVCW)	7.4	7.0
NH (MBR)	6.5	6.3
HTP (PCW)	6.9	5.8
SMT (CW)	7.0	5.6
MEG (MBR)	6.2	5.1
LMT (SABF)	5.7	4.6

ply characteristic vector, and the corresponding matrix's biggest characteristic root, and the results are shown in Table 6.

3.4 Comparison of the two evaluation models

Compared the results of the EWF and AHP methods, the Euclid approach degree was 10 times as that of the EWF model score (Table 7), and two evaluation methods showed a highly repeatability.

The entropy weight matter-element model reduced the fuzziness of evaluation indicators and avoided the subjective judgment influence. The AHP represented the experts' experienced judgments. The result showed that the two evaluation methods showed a good repeatability, and their advantages were slightly different.

4 CONCLUSION

- Using the EWF model and AHP method to evaluate the technological suitability of rural sewage treatment station, the evaluation results had good repeatability.
- In the EWF model, the entropy weight of the annual operating rate, NH₃-N removal rate, and actual scale/design scale were high, which were the main basis for the selection of wastewater treatment processes.
- CW processing type had obvious advantages in mountainous areas. Also, the MVCW and MBR processing types had advantage in plain areas.

Influence analysis of the incremental launching of steel box girder and local stability control

Fu-Jun Xie

Central South University, Changsha, Hunan, P.R. China

Transport Bureau of Hengyang City, Hengyang, Hunan, P.R. China

ABSTRACT: Incremental launching method is generally used for steel box girders of long-span self-anchored suspension bridge during construction. First, the mechanical characteristics of the pushing process and the three bending moment equations were introduced. Second, in Guihua Bridge, design parameters influence analysis of the incremental launching process of steel box girder was carried out. The results of the analysis showed that the maximal displacement at the front of guide beam, the bending moment at steel guide beam root, and the maximum tensile stress of steel box girder as well as the compressive stress of steel box girder periodically change along with the construction process. Meanwhile, elastic modulus and Poisson's ratio have a little influence on the stress and deformation of the steel box girder during incremental launching process. The length of the steel guide beam and its average line weight density have an important influence on the stress and deformation of the steel box girder during incremental launching process. Finally, on the basis of the elastic thin plate theory of small deflection, local stability analysis of steel box girders during the process of incremental launching was carried out. Theoretical calculation showed that the local stability of the steel box girder does not meet the requirements before stiffening, but after stiffening, the local stability fulfills the requirements. By considering the constraint factors of plate groups, material nonlinearity, initial geometric imperfection as well as residual stress, finite-element analysis showed that the stress by self-weight has a little influence on critical buckling stress, which can be neglected. Installing a diaphragm plate to improve the effect of local buckling of the steel box girder is obvious. The analysis results show that the stress of local buckling for the steel box girder is less than the structural maximum working stress during the process, and the risk of instability would be presented.

1 INTRODUCTION

At present, construction of long-span suspension bridge is a trend. In order to reduce the number of anchor constructions and balance the tension of main cable, the main cable is directly anchored on a stiffening girder, which is a self-anchored suspension bridge (Dong & Li 2015). Regardless of the type of self-anchored suspension bridge, the main girder is built inevitably by the methods of support construction method and incremental launching method. In most cases, with regard to the limited space and cost control, incremental launching method is more used for building bridges.

Existing analysis of the incremental launching method is more focused on concrete girders (Ding & Liu 2002) and less focused on steel girders (Beaney & Martin 1993), especially for the local stability analysis of the construction process of the incremental launching method (Li & Shao 2011). It is much less reported (Guo & Wei 2009). By taking Guihua Bridge as an example, the influence parameters of steel box girders were analyzed by

incremental launching method and the local stability was evaluated.

2 INTRODUCTION TO INCREMENTAL LAUNCHING METHOD

The incremental launching method is a bridge construction method (Li & Zuo 2006). The specific construction process is as follows. First, beam bodies are built using cast-in-place technique or assembled on the bridge end. Second, the beam bodies get through temporary sliding supports on the top of piers by pushing jack action. Finally, the beam bodies are in place. The main characteristics of a continuous beam bridge under dead load determined by the incremental launching method are the same as those of the main girder segment presented above, and internal force of every section in the whole bridge is a cycle with repetitive change (Qin & Chen 2013).

Finite-element method is generally used for internal force calculation during construction

under dead load by incremental launching method (Rosignoli 1995). Solving steps and methods are briefly introduced in Figure 1.

1. The basic structure is shown in Figure 1(b). M_1 , M_2 , and M_i represent superfluous moments at intermediate support.
2. According to the following general formula, three bending moment equation (i) for each bearing is taken as:

$$M_{i-1} \frac{l_i}{I_i} + 2M_i \left(\frac{l_i}{I_i} + \frac{l_{i+1}}{I_{i+1}} \right) + M_{i+1} \frac{l_{i+1}}{I_{i+1}} = -6 \left(\frac{B_i^\phi}{I_i} + \frac{A_{i+1}^\phi}{I_{i+1}} \right) \quad (1)$$

where l = span length, I = Cross section of the bending moment, and A^ϕ and B^ϕ are the reaction forces of the virtual beam.

3. By solving simultaneous equations, M_1 , M_2 ... are obtained; then, every span's internal force and deformation are calculated according to a single span beam.
4. Fixed end and cantilevered end dispose.

After the structure in Figure 1(a) changes to that shown in Figure 1(b), repeat steps (1)–(3) to obtain the problem solutions.

In order to avoid solving simultaneous equations, for designing of a constant section, such as two spans to five spans continuous beam, a rele-

vant engineering handbook can be consulted and bending moment can be obtained directly from that (Shi & Lin 2012).

3 INTRODUCTION OF STEEL BOX STIFFENING GIRDER WITH INCREMENTAL LAUNCHING METHOD

Guihua bridge is a three-span self-anchored suspension bridge with twin towers in Shaoyang City. The main span arrangement is 60 m+120 m+60 m. Its steel box stiffening girder is built by incremental launching method; after main girders pushing, the main cable can be erected by PPWS method; next, a suspender can be installed, eventually into a whole bridge.

A temporary pier is set across 1#–2# span in Guihua Bridge. During steel box stiffening girders launching construction, a variable stiffness guide beam is used. Its height decreased gradually from root to end. The connection between guide beam and steel box girders uses big box structures, whereas double-H structure is used in other places. Between the two-beam and the double-H structure, $\Phi 140 \times 4$ steel tube trusses can be used as supports. The steel guide beam in the connection parts, such as bottom slab and web and top slab, were thickened and strengthened.

4 PARAMETER INFLUENCE ANALYSIS

According to the characteristics of the incremental launching method, the Elastic modulus (E), Poisson's ratio (μ), and Length (l) as well as the average line weight density of the guide beam are chosen as parameters for launching construction influence analysis. Standard parameters of the influence analysis are shown in Table 1. The results are shown in Figures 2–5.

Table 1. Standard parameters of incremental launching influence analysis.

Location	Parameters	Value
Steel box girder	E	2.06×10^{11} Pa
	α	$1.2 \times 10^{-5}/^\circ\text{C}$
	γ	76.98 kN/m ³
	μ	0.3
Guide beam	E	2.06×10^{11} Pa
	α	$1.2 \times 10^{-5}/^\circ\text{C}$
	γ	76.98 kN/m ³
	μ	0.3
	Average line weight density	44.44 kN/m

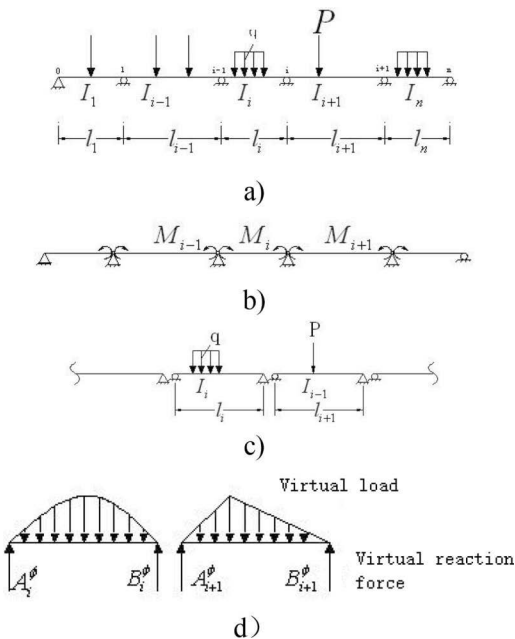

Figure 1. Three bending moment equations solving steps.

Figure 2. Deflection at the front of guide beam with construction steps.

Figure 3. Bending moment at guide beam root with construction steps.

Figure 4. Maximum tensile stress during incremental launching process at the top of the main girder.

Figure 5. Maximum compressive stress during incremental launching process at the bottom of the main girder.

As the steel box girder is pushed forward, the maximum deflection at the front of guide beam presents a periodic change (Figure 2) and appears

in the first span at the maximum cantilever state, whose maximum value is 1.20113 m.

As the steel box girder is push forward, the bending moment at guide beam root presents a periodic change, and there is a numerical value stable stage in every push cycle (Figure 3). The analysis shows that the theoretical maximum bending moment is $0.5ql^2 = 44995.5 \text{ kN.m}$ at the maximum cantilever state, considering the actual pushing length of the steel box girder; the simulation result of the maximum bending moment is 45.01728 MN. m.

From Figures 4–5, the maximum tensile stress of the top plate and compressive stress of the bottom plate in the steel box girder appear in the CS28 state, and the maximum stress is 351.951 MPa, which is less than 380 MPa (allowable stress) and meets the requirements.

4.1 Elastic modulus influence analysis

Several steel structural commonly used elastic moduli of guide beam are taken as examples for steel box girder launching construction elastic modulus influence analysis. The maximum tensile stress and compressive stress and the maximum bending moment at guide beam root as well as displacement at the front of guide beam are chosen for computing objects, and the results are shown in Table 2 and Figures 6–7.

Table 2. Analysis results for guide beam changes with the elastic modulus.

E: $\times 10^{11}$ Pa	(1) MPa	(2) MPa	(3) MN.m	(4) m
1.95	351.951	351.951	44.9959	1.20521
2.0	351.951	351.951	45.0076	1.20327
2.05	351.951	351.951	44.9954	1.20142
2.06	351.951	351.951	45.0172	1.20113
2.1	351.951	351.951	44.9964	1.19966

* (1) = maximum tensile stress of steel box girder, (2) = maximum compressive stress steel box girder, (3) = bending moment at guide beam root, (4) = deflection at the front of guide beam. The same below.

Figure 6. Variation of the maximum bending moment at guide beam root with elastic modulus.

Figure 7. Variation of the maximum deflection at the front of guide beam with elastic modulus.

With the increase of elastic modulus, the maximum bending moment at guide beam root presents periodic changes (Figure 6). From Table 2, its extreme difference is 12.2 kN. m, less than 1% of the average value, which meets the engineering precision requirement. Carefully analysis is required, as computer rounding-off errors may be caused during the rigidity integration.

With the increase of elastic modulus, the maximum deflection at the front of guide beam decreases. Both show an approximate linear relationship (Figure 7 and Table 2). The ratio of elastic modulus variation to displacement variation is $26.96 \times 10^{11} \text{ Pa/m}$. With the change of elasticity modulus, the maximum tensile stress and compressive stress of the steel box girder are constants.

4.2 Poisson's ratio influence analysis

Poisson's ratio of 0.2, 0.25, and 0.3 are adopted for the guide beam are taken as examples for steel box girder launching construction Poisson's ratio influence analysis. The maximum tensile stress, the maximum compressive stress, and the maximum bending moment at guide beam root as well as displacement at the front of guide beam are chosen for computing objects, and the results are shown in Table 3.

From Table 3 and Figures 8–9, with the increase of Poisson's ratio, the maximum bending moment at guide beam root increases. Both show a non-linear relationship. With the increase of Poisson's ratio, the maximum deflection at the front of guide beam increases; both show a linear relationship, and the ratio of Poisson's ratio variation to displacement variation is 714.2857/m.

Through the analysis, it was found that the maximum tensile stress and compressive stress of steel box girders that are constants appear in a double cantilever state of continuous beam.

4.3 Length of guide beam influence analysis

The length of the guide beam is 45 m, the longest span is 60 m during launching construction, and their ratio is 0.75. According to "Code for

construction and quality acceptance of bridge works in city" (CJJ2-2008), the length of the guide beam should be 0.6–0.8 times of the launching construction span (Chen & Tan 2015). On this basis, guide beam's length and analysis results are shown in Table 4.

From Table 4 and Figures 10–11, with the increase in the length of the guide beam, the maximum bending moment at the guide beam root increases. Both show a linear relationship, and the ratio of length variation to bending moment variation is 0.54775 m/MN.m.

Figure 10. Variation of maximum bending moment at guide beam root with length.

Figure 11. Variation of maximum deflection at the front of guide beam with length.

With the change of length of the guide beam, the maximum deflection at the front of the guide beam presents periodic changes. The reason for this phenomenon is that when the length of guide beam is less than the span length, the maximum deflection appears in the maximum cantilever state. With the increase in the length of the guide beam, the deflection increases gradually. When the length of beam is larger than the span length, the maximum deflection appears in the double cantilever state of continuous beam with two spans; with the increase in the length of the guide beam, the displacement increases gradually.

Analysis results show that the maximum tensile stress and compressive stress of the steel box girder that are constants appear in double cantilever state of continuous beam.

4.4 Influence analysis of average line weight density of guide beam

The designed average line weight density of guide beam for the bridge is 44.44 kN/m. Now, at the same length, change the average line weight density of guide beam between 0.6 times and 1.1 times, Analysis results are shown in Table 5.

From Table 5 and Figures 12–13, we know that the maximum bending moment at guide beam root and maximum deflection at the front of guide beam increase gradually with the increase of average line weight density of guide beam. Both present a linear relationship. The ratios of average line weight density variation to bending moment variation and

Table 5. Analysis results of guide beam changes with average line weight density.

deflection variation are 0.9779 kN.m/MN.m and 53.49284 kN.m/m, respectively.

Analysis shows that with the change of equivalent average line weight density, the maximum tensile and compressive stress of steel box girder, which are constants appear in a double cantilever state of continuous beam.

5 LOCAL STABILITY CONTROL OF STEEL BOX GIRDER PUSHING

According to the small deflection theory of elastic thin plate, the plate only bears lateral loads and the deflection is small (Yang & Chen 2001). In this case, all point displacements in neutral surface parallel to the surface are not considered. An elastic curved surface of the thin plate is a neutral surface, whose stretching and shear strains are zero.

The elastic thin-plate element is analyzed as shown in Figure 14.

Figure 14. Balanced infinitesimal body of elastic thin plate.

From the analysis, the stability equation of thin plate (formula 2) is found.

$$D\nabla^4\omega - \left(F_{1x} \frac{\partial^2\omega}{\partial x^2} + 2F_{1xy} \frac{\partial^2\omega}{\partial x\partial y} + F_{1y} \frac{\partial^2\omega}{\partial y^2} \right) = q \quad (2)$$

During incremental launching construction, plates at different positions are chosen for analysis, its lateral load $q=0$, which is comparable to the internal force of structure is small and can be neglected. In this case, according to constraint conditions and load conditions, the corresponding longitudinal load F_x can be solved by the (heavy) trigonometric series.

Simply supported at four edges, a pair of opposite edges bearing uniform distributed pressure F_x (acting on the edge of b length) is given by:

$$F_x = \frac{\pi^2 a^2 D}{m^2} \left(\frac{m^2}{a^2} + \frac{n^2}{b^2} \right)^2 = k \frac{\pi^2 D}{b^2} \quad (3)$$

where k is the stability coefficient of plate, given by $k = \left(\frac{mb}{a} + \frac{n^2 a}{mb} \right)^2$, $n=1, m$ for any natural number, $k_{\min}=4$.

Simply supported at four edges, one pair of opposite edges bearing uniform distributed pressure F_x (acting on the edge of b length) and another pair of opposite edges bearing uniform distributed pressure $F_y = \alpha F_x$ (acting on the edge of a length) are given by:

$$F_x = \frac{\pi^2 D}{a^2} \frac{\left(m^2 + \frac{n^2 a^2}{b^2} \right)^2}{m^2 + \alpha \frac{n^2 a^2}{b^2}} = k \frac{\pi^2 D}{a^2} \quad (4)$$

where k is the stability coefficient of the plate, given by $k = \frac{\left(m^2 + \frac{n^2 a^2}{b^2} \right)^2}{m^2 + \alpha \frac{n^2 a^2}{b^2}}$, $n=1, m=1$, $k = \min \left(\frac{2\alpha-2}{\alpha}, \frac{4\alpha-4}{\alpha^2} \right)$.

When F_y denotes tension, α is negative.

Simply supported at three edges, and one edge paralleled to pressure is free, a pair of simply supported edges bearing uniform pressure F_x (acting on the edge of b length) is given by:

$$F_x = k \frac{\pi^2 D}{b^2} \quad (5)$$

where k is the stability coefficient of the plate, the solution expression as a four-order coefficient determinant is zero. Because of space constraints, the concrete expressions are not listed. Analysis shows that when $a \gg b$, $k_{\min}=0.425$. In other cases, k is associated with Poisson's ratio and a/b .

A pair of opposite edge is fixed, and the other pair of edges is simply supported by bearing uniform distributed pressure F_x (acting on the edge of b length). The expression of critical load F_x (formula 5) is found. Analysis shows that when a/b is approximately equal to 0.7, $k_{\min}=6.97$; in other cases, k is associated with a/b .

A pair of opposite edge is fixed, and the other pair of edges is fixed and simply supported by bearing uniform distributed pressure F_x (acting on the edge of b length). The expression of critical load F_x (formula 5) is found. Analysis shows that $k_{\min}=5.42$; in other cases, k is associated with a/b (Zhang 2003).

A pair of opposite edge is fixed, and the other pair of edges is fixed and free from the bearing uniform distributed pressure F_x (acting on the edge of b length). The expression of critical load F_x (formula 5) is found. Analysis shows that $k_{\min}=1.28$; in other cases, k is associated with Poisson's ratio and a/b (Zhang & Yuan 2014).

Thus, the following expression is given for critical buckling stress:

$$\sigma = \frac{F_x}{t} = k \frac{\pi^2 D}{b^2 t} = \frac{k \pi^2 E}{12(1-\mu^2)} \left(\frac{t}{b} \right)^2 \quad (6)$$

The steel box girder that is axial-bending component during pushing construction bears compressive and bending stresses. The standard section is 5 m long, with two pieces of diaphragm plate at 1.67 m interval in it. Analysis shows that the maximum compressive stress is 351.951 MPa during pushing construction.

A top plate (5 m × 2.8 m × 22 mm) is chosen for analysis, without considering the local stress change of plate near the pushing jack action. According to Saint Venant principle, using formula (5), $F_x = 14.70 \text{ MPa} \ll 351.951 \text{ MPa}$. It shows that local buckling under pressure will occur and stiffening measures need to be taken. The reinforcement design shown in Figure 15 is adopted, and a

Figure 15. Local stability calculation model for steel box girder.

top plate between two longitudinal stiffeners ($5\text{ m} \times 0.35\text{ m} \times 22\text{ mm}$) is taken as an example. Using formula (5), $F_x = 940.64\text{ MPa} \gg 351.951\text{ MPa}$. It shows that the structure meets the local instability requirements.

In a similar way, a bottom plate ($5\text{ m} \times 2.8\text{ m} \times 24\text{ mm}$) is chosen for analysis. Using formula (5), $F_x = 17.49\text{ MPa} \ll 351.951\text{ MPa}$. It shows that local buckling under pressure will occur and stiffening measures need to be taken. The reinforcement design shown in Figure 15 is adopted, and a bottom plate between two longitudinal stiffeners ($5\text{ m} \times 0.35\text{ m} \times 24\text{ mm}$) is taken as an example. Using formula (5), $F_x = 1119.4\text{ MPa} \gg 351.951\text{ MPa}$. It shows that the structure meets the local instability requirements.

A web plate ($5\text{ m} \times 2.5\text{ m} \times 16\text{ mm}$) is chosen for analysis. Using formula (5), $F_x = 9.75\text{ MPa} \ll 351.951\text{ MPa}$. It shows that local buckling under pressure will occur, and stiffening measures need to be taken. The reinforcement design shown in Figure 15 is adopted, and a web plate between two longitudinal stiffeners ($5\text{ m} \times 0.415\text{ m} \times 16\text{ mm}$) is taken as an example. Using formula (5), $F_x = 353.88\text{ MPa} > 351.951\text{ MPa}$. It shows that the structure meets the local instability requirements. However, its safety reserve is too small, so the construction process should be controlled strictly to ensure the safety.

The constraint factors and material nonlinearity and initial geometric imperfections as well as residual stresses are also considered in the local stability analysis of the plate. With consideration of the above factors, the buckling stress is smaller than that of formula (5). Meanwhile, the finite-element analysis software is used for the analysis. The local buckling analysis model of steel box girder in Guihua Bridge and its results are shown in Figure 16 and Table 6.

The analysis shows that, without considering the influence of diaphragm plate, the buckling

(a)

(b)

	Critical axial load	Buckling stress of top plate	Buckling stress of web plate	Buckling stress of bottom plate
(1)	13232.13	69.04	82.70	63.29
(2)	13306.65	69.43	83.17	63.65
(3)	42421.60	221.34	265.15	202.92

*(1) Do not consider the influence of diaphragm plate and structural weight; (2) Consider structural weight but do not consider the influence of diaphragm plate; (3) Consider the influence of diaphragm plate and structural weight.

of plate around the box section occurs under axial pressure, and its buckling mode is shown in Figure 16(a). Considering the influence of the diaphragm, the first part of local buckling is the web, whose buckling mode is shown in Figure 16(b).

From Table 6, without considering the influence of the diaphragm plate and considering

structural weight, the critical axial load is 13306.65 kN. Without considering the influence of diaphragm plate and structural weight, the critical axial load is 13232.13 kN, which is slightly less than the critical load of considering the structural weight value (0.9944 times). It shows that the influence of bending moment caused by structural weight on critical buckling stress is very small and can be neglected. Considering the influence of diaphragm plate and structural weight, the critical axial load is 42421.60 kN, which is 3.188 times that without considering the influence of diaphragm plate and considering structural weight. It shows that the application of the diaphragm plate to improve the effect of local buckling of steel box girder is obvious. At the same time, it is not difficult to see that the maximum stress of local buckling of steel box girder is smaller than the structural working stress. Again, the instability risk of launching construction may happen.

6 CONCLUSIONS

The maximum deflection at the front of guide beam and maximum bending moment at guide beam root and maximum tensile stress of steel box girder as well as its maximum compressive stress have changed periodically during launching construction.

The change of guide beam elastic modulus of guide beam has little influence on stress and deformation of launching construction. With the increase of elastic modulus, the maximum bending moment at guide beam root presents periodic changes. With the increase of elastic modulus, the maximum deflection at the front of guide beam decreases, and both show an approximate linear relationship. The ratio of elastic modulus variation to displacement variation is 26.96×10^{11} Pa/m. With the change of elasticity modulus, the maximum tensile stress and compressive stress of steel box girder are constants.

The change of Poisson's ratio of guide beam also has little influence on stress and deformation of launching construction. With the increase of Poisson's ratio, the maximum bending moment at guide beam root increases. Both show a nonlinear relationship. With the increase of Poisson's ratio, the maximum deflection at the front of guide beam increases. Both show a linear relationship, and the ratio of Poisson's ratio variation to displacement variation is 714.2857/m. The maximum tensile stress and compressive stress of steel box girders that are constants appear in double cantilever state of continuous beam.

The change of the length of guide beam and its average line weight density have a great influence

on stress and deformation of launching construction. With the increase in the length of the guide beam, the maximum bending moment at guide beam root increases. Both show a linear relationship, and the ratio of length variation to bending moment variation is 0.54775 m/MN.m. With the change in the length of guide beam, the maximum deflection at the front of the guide beam presents periodic changes. The maximum tensile stress and compressive stress of the steel box girder, which are constants, appear in the double cantilever state of continuous beam.

With the increase in average line weight density of guide beam, the maximum bending moment at guide beam root and maximum deflection at the front of guide beam increase gradually. Both present a linear relationship. The ratios of average line weight density variation to bending moment variation and deflection variation are 0.9779 kN.m/MN.m and 53.49284 kN.m/m, respectively. The maximum tensile and compressive stresses of steel box girder, which are constants, appear in a double cantilever state of continuous beam.

Theoretical calculation shows that the local stability does not meet the requirements before stiffened in steel box girder. After stiffening, local stability meets the basic requirements, but its safety reserve is too small, so the construction process should be controlled strictly to ensure the safety.

Analysis by using the finite-element model shows that the influence of bending moment caused by structural weight on critical buckling stress is very small, and can be neglected. The application of the diaphragm plate to improve the effect of local buckling of steel box girder is obvious. Analysis shows that the maximum stress of local buckling of the steel box girder is smaller than the structural working stress, thereby increasing the possibility of occurrence of instability risk of launching construction.

Study on active strategies for thermal environment regulation in the zero-energy houses of Solar Decathlon, China

Feng Shi, Wei Jin, Weiwei Zheng & Tao Zhuang

School of Architecture and Civil Engineering, Xiamen University, Xiamen, China

ABSTRACT: Active strategies for thermal environment regulation are the key point to create a comfortable building environment and important in building energy efficiency. In this paper, we take the zero-energy buildings in Solar Decathlon competition as examples to analyze the active strategies in solar houses and sort them out according to their technical characteristics. Energy-consuming active strategies such as the HVAC systems, which are used to control the building thermal environment and air quality, are analyzed in the paper. And their application in SDC2013 has been discussed to provide references for contemporary green building design.

1 INTRODUCTION TO SOLAR DECATHLON, CHINA

The international solar decathlon competition (Solar Decathlon) is a solar building technology competition for global universities, which is called “The Olympic Games in the field of solar building”, and is launched and hosted by the U.S. Department of Energy. It challenges collegiate teams to design, build, and operate solar-powered houses that are comfortable, livable, and sustainable living spaces. Solar energy is the only energy source of each house with an area of about 80 m². These solar houses must meet the requirements of the various functions of residence and be operated actually for test contests. Five sessions of the competition are hosted in the United States (SDA2002, SDA2005, SDA2007, SDA2009, and SDA2011), two sessions in Spain (SDE2010, SDE2012), and one session in China for the first time (SDC2013). SDC2013’s participants include 20 teams from 35 universities with students from over 35 nationalities in 13 countries on six continents, which reflect that China attaches a great importance to the application and promotion of new energy and performs the action of building energy conservation and emissions reduction, and also greatly expands the influence of the competition.

Zero-energy solar houses exhibited in SD reflect different universities’ progress in the field of building energy conservation and solar energy application (Peng et al. 2015). In the contests, indoor air temperature and air humidity were measured during the schedule time in the competition, and HVAC system design, ventilation design, and air quality were also evaluated by experts. Therefore, active strategy for thermal environment regulation was one of the key points for each team in their solar house design.

2 ACTIVE DESIGN STRATEGY

Every competition has strict requirements for the building indoor temperature and humidity, according to the scoring criteria of the competition. For example, indoor temperature should be controlled between 22 and 25°C and humidity within 60% in SDC2013. If outdoor climate is comparatively awful, the use of active environmental control equipment to control the indoor environment is extremely important. How to combine HVAC system with building design to achieve the purpose of energy saving and take full advantage of the solar energy attract significant attention of each competition team.

3 AIR-CONDITIONING SYSTEM

The competition site for all sessions of Solar Decathlon are chosen in places that have an abundance of solar energy, and the competition time is always in summer or early autumn; therefore, during the competition, an air-conditioning system is generally needed. There are various types of air-conditioning systems in different teams’ house, such as common split-type air-conditioning system, central air-conditioning system, and other special types of air-conditioning systems (Real et al. 2014).

3.1 All air-conditioning system

All air-conditioning systems use outdoor air as the cold and heat source. The outdoor air will be cooled and dehumidified by a centralized processing unit in the system. Because of the small building size, the pipelines of all air-conditioning system will not be complicated, which could deal with sensible heat and latent heat load in the meantime,

and the effect of temperature and humidity control is so good that there is no need to set a fresh air system. For these reasons, all air-conditioning systems have been widely used. This system's processing unit has a large volume, which needs a large equipment room in the house. Its air duct dimensions are larger than those of the cryogen-type air-conditioning system, which means it needs higher ceiling.

For example, Wellington Victoria University took part in SDA2011. Their house "First Light" adopted the all air-conditioning system. The schematic diagram of their processing unit and supply and return pipes are shown in Fig. 1. In order to handle the fresh air, Mitsubishi's heat recovery new fan is used in this system, which can recycle the heat of exhaust air to save energy.

3.2 VRF air-conditioning system

VRF air-conditioning system is a frequency conversion air-conditioning system with high energy-saving efficiency by using one outdoor unit to connect several indoor units. Air cooling heat transfer method is used in outdoor units, which use refrigerant as transmission medium adapting to the changes of air-conditioning load by changing the refrigerant flow rate. Heat recovery VRF air-conditioning system can do better; it controls not only the refrigerating capacity of different indoor units but also two parts of indoor units for cooling and heating, fitting the different needs of different space thermal environment regulation.

Xiamen University's house "Sunny Inside" in SDC2013 uses VRF air-conditioning system, connecting one outdoor unit to three indoor units to

Figure 1. Schematic diagram of air-conditioning system in "First Light".

satisfy the cooling and heating demand of the living room, dining room, and bedroom. Because of the different service conditions of these three rooms, VRF system can meet the different needs of each room. Meanwhile, system efficiency can be higher when part of indoor unit is working after the system works at full capacity, which saves energy.

3.3 Solar energy air-conditioning system

Solar energy air-conditioning system is a new type of air conditioning system that uses solar thermal collector to get hot water to drive absorption or absorbing-type refrigeration unit to get the required refrigerant water. This system is mostly used in large and medium-sized central air-conditioning systems, in which the higher the water temperature in the collector, the higher the cooling efficiency.

However, Tel Aviv University's house "Living Patio" in SDC2013 uses a special small solar energy air-conditioning system with a TIGI honeycomb solar thermal collector made of transparent insulation material, which can collect high-temperature hot water (110°C) to heat the refrigerant to be gas and drive the compressor to refrigerate (Fig. 2). This system greatly reduces the electricity consumption of the compressor by saving a lot of energy.

A night radiation cooling system is also used in "Living Patio". Water radiant coils are set on the north side of the building using the sky long wave radiation cooling effect, which can open the circulating water to make and collect cold water in a cold water tank at night. When there is little cloud in Datong, cold water with temperature 2–3°C lower than air temperature will be guided into phase change materials storage tank to exchange heat with phase change materials, whose phase transition temperature is around 18°C as auxiliary cold source of the air-conditioning system (Fig. 3).

3.4 Temperature- and humidity-independent control air-conditioning system

Temperature- and humidity-independent control air-conditioning system with a sensible heat disposal unit and a latent heat disposal unit can control indoor temperature and humidity, respectively, to achieve the goal of energy saving. Because of

Figure 2. TIGI honeycomb solar thermal collector in "Living Patio".

Figure 3. Night radiation cooling system in “Living Patio”.

- a: water radiant coils on the north side of the building

- c: system diagram.

the sensible heat disposal unit control-independent indoor temperature, there is no need to use refrigerant at low temperature for condensation dehumidification. On the contrary, refrigerant at higher temperature is preferred. It can improve the performance coefficient of refrigerant and save energy at the same time. Higher-temperature refrigerant also solves the problem of moisture condensation preventing the growth of bacteria on wet surfaces, which can improve indoor air quality effectively. Latent heat disposal unit, in other words dehumidification system, is mostly set with fresh air system that supplies dry fresh air, which undertakes the task of dehumidification and ensuring air quality. Dehumidification system can adopt these methods, such as cooling dehumidification, solution type dehumidification, and wheel-type dehumidification.

Xi’an University of Architecture and Technology’s house “Qi Ju” use capillary net radiation at the end of system to control indoor temperature. The temperature of circulating water in the capillary, which is at the end of air conditioning system, is 16°C, and when the system is on, the temperature of architecture radiation surface can reach 17–19°C, with refrigerating efficiency of 85 W/m². Meanwhile, this system is quiet and has a strong ability of heat storing as well as self-adjusting to balance (Fig. 4).

4 HEATING SYSTEMS

The climate characteristics at the competition site during the competition and one year’s climate characteristics at the permanent place for the house must be considered when designing houses

Figure 4. Capillary net radiation air-conditioning system in “Qi Ju”.

for Solar Decathlon. The heating system that regulates thermal environment should also be taken into consideration. Cold and warm air-conditioning system that can provide refrigeration and heating at the same time could be used in places that do not need heating in winter. On the contrary, in places that need the heating, the independent heating system is necessary for the need of heating.

On account of the fact that hot water item occupies one of the 10 scoring items, which highlights the importance of hot water, teams often combine hot water system with the need of heating in design to ensure the supply of hot water. Southeast University’s house “Solark” in SDC2013 uses floor radiation heating system with a water tank to store hot water, which is connected to the hot water supply system. This way of heating is good for the indoor temperature uniform distribution and has a strong heat storage capacity to improve the comfort of heating.

5 PHASE CHANGE MATERIALS VENTILATION SYSTEM

Phase change materials ventilation system is a special ventilation system that makes use of the large temperature difference between day and night during the competition time, storing cooling capacity of cold air in the night by phase change materials and releasing it for refrigeration in the daytime (Lin et al. 2014). The phase transformation point of phase change materials in the system is very important, which should be chosen according to the local average temperature in day and night.

For example, there are four phase change materials energy storage ducts under the courtyard of “Sunny Inside” of Xiamen University. Phase change materials whose phase transformation point is 23°C and phase change latent heat value is

187 kJ/kg packaged with aluminum foil bag are put into the ducts with a fan in each duct. There is also a duct on the ceiling of living room with phase change materials packaged by stainless steel tube using the material whose phase transformation point is 19°C for one half and 23°C for the other half. Air inlet, outlet, and electric air valve are set on each duct to control ventilation module of the duct. The temperature in Datong at night during the competition is around 16°C and 30°C at noon, which means the temperature difference between day and night is large. At night, open the outdoor air vents using cold air outside to cool the phase change materials, shut down the outdoor air vents, open indoor air vents when needed in the daytime to cool indoor air, which can partly replace the air conditioning.

6 INTELLIGENT CONTROL SYSTEM

Intelligent control system is widely used in Solar Decathlon, in which sensors are set to monitor the climate parameters in and out of the house and target controlling all types of devices in the building according to the feedback parameters. Through the intelligent control method, all types of devices in the building are connected together for automatic control. And the system can regulate the operation mode of various devices according to the needs of energy conservation. Different technical strategies can be reasonably integrated in this way, promoting each other to achieve the effect of $1 + 1 > 2$.

Intelligent control system is also used in Tsinghua University and Florida International University's house "O-House" (Zhang et al. 2014), which can control air-conditioning system, the angle of the photovoltaic panel bracket, and so on. It is strict for the control requirement of temperature and humidity in the competition that relying on the automatic control of air conditioning is a risk that the indoor temperature may easily go out of control between 22 and 25°C. In consequence, an air-conditioning control system that can automatically adjust the operation of air conditioner according to the indoor temperature and humidity is set in

Figure 5. Result of temperature and humidity test of "O-House" on August 5, 2013.

"O-House" in order to keep the indoor temperature within the prescribed scope (Rodriguez-Ubinas et al. 2014). Finally, their team won the first place in the test item of temperature and humidity with this system in SDC2013 (Fig. 5).

7 CONCLUSION

For green building, passive strategies could be used initially in the regulation of building thermal environment and make the most use of natural conditions to improve the local thermal environment. However, when the passive measures cannot be used to meet the requirements of indoor thermal environment, the active strategies can be combined with passive measures to reduce energy consumption and improve the performance of some equipment. Among this, the progress of technology intelligent control system can be used to monitor climate parameters and optimize the working performance of all the equipment, which integrate all types of technical strategies reasonably according to the different applicability to achieve the goal of energy-saving firmly.

Research and enlightening of ecological infrastructure-oriented “multiple planning integration” based on Germany’s spatial order and structure planning—illustrated by the example of Dujiangyan

Yanjin Li & Fei Fu

Southwest Jiaotong University, Chengdu, Sichuan, China

Yang Yi

Sichuan Branch of Chongqing Planning and Designing Institute, Chengdu, Sichuan, China

ABSTRACT: Spatial order and structure planning based on overall planning of “multiple planning integration” plays a guidance role for other spatial plans. In this paper, we analyze Germany’s spatial planning system and explore highest-level spatial order planning and spatial structure planning on the basis of spatial order planning. Dujiangyan is one of the second-batch pilot cities of “multiple planning integration” in Sichuan Province. On the basis of absorbing the experience of Germany’s spatial order and structure planning, Dujiangyan innovatively constructs spatial base map of ecological infrastructure-oriented “multiple planning integration” and specifies ecological infrastructure-oriented spatial order and structure planning. The above innovation practice aims to strengthen the overall planning and coordination of the citywide space and to provide reference experience to other practice of other cities’ “multiple planning integration”.

1 INTRODUCTION

Integrated Reform Plan for Promoting Ecological Progress published by the Communist Party of China (CPC) Central Committee and the State Council in September, 2015, asks for solving the outstanding problems of ecological environment, safeguarding national ecological security, improving environmental quality, improving the efficiency of resource utilization, and promoting the formation of the new pattern of modernization of harmonious development between human and nature. Therefore, this paper proposes the consideration of ecology-oriented “multiple planning integration”. In the field of spatial planning, Germany’s spatial planning system restricts and guides the inferior spatial planning through superior spatial order and spatial structure planning, which has overall consideration. Dujiangyan is one of the second-batch pilot cities of “multiple planning integration” in Sichuan Province. Its pilot work analyzes spatial order and spatial structure planning of Germany’s spatial planning and absorbs successful experience, combining with its own rich ecologi-

cal infrastructure to be used for reform practice of ecological infrastructure-oriented “multiple planning integration”.

2 GERMANY’S SPATIAL PLANNING SYSTEM

Germany’s spatial planning system (Turowski, Gerd, 2012) has the explicit level relationship and appropriate legal basis. Each level of Germany’s spatial planning system coordinates with each other to achieve spatial sustainable development. Germany’s spatial planning system is based on Spatial Planning Act. Germany’s spatial planning system emphasizes coordination among all levels. On the basis of spatial order and structure planning, Germany’s spatial planning system coordinates different spatial influences and probable conflicts among different levels of spatial planning system and proposes solutions and preventive measures for protecting independent spatial function and land use to coordinate social sustainable development, contradictions in economic

construction, and the relationship between land use and ecological protection of land to achieve sustainable development.

Comprehensive spatial planning at Federal Level does not focus on coordination but makes spatial planning principles to implement the vision and to provide actions of saving space for possible foreseeable trends. Comprehensive Spatial Planning at State level includes comprehensive spatial planning at land level and regional planning. Comprehensive spatial planning at land level launches spatial structure planning to provide sustainable development goals for respective planned territory. Regional planning establishes relationships for spatial structure, plans functional relationships between regional and urban land use, and constructs legal framework for planning bureaus and projects such as residence, industry, and infrastructure. Comprehensive spatial planning at municipality level is dominated by urban land use planning. Urban land use planning, the core tool of urban development, specifies the purpose of land in the process of urban development (like commercial purposes and public purposes), determines floors of highest buildings, maximum proportion of limits of construction land and relevant additional conditions and measures during the construction to realize urban sustainable development, to ensure suitable living environment for human beings, to provide natural foundation, and to maintain a fair land use. Sectoral planning is different from other plannings. It aims at special planning like natural conservation, forest, land conservation, water resource management, agriculture, transportation, and communication to establish the system procedures of development measures. Collaborative planning at public institutions level does not participate in the actual spatial planning, but it requires corresponding public institutions to provide suggestion and information for the positive development of urban space in the coordination with comprehensive spatial planning at Federal State, municipalities level, and sectoral planning.

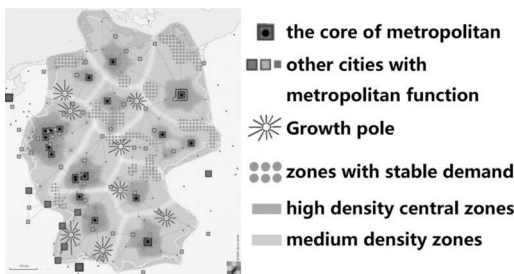

Figure 1. Germany's spatial order planning.

3 SPATIAL ORDER AND STRUCTURE PLANNING OF GERMANY'S SPATIAL PLANNING

3.1 *The-highest-level spatial order planning*

Spatial order planning is launched by comprehensive spatial planning at Federal Level. First, space is divided into three parts: metropolitan zones, radiation zones of countrysides, and transition zones among metropolitan areas (flexible development space zones). Second, spatial order includes two parts: high-density central zones and medium-density zones. Third, zones with stable demand are determined in different density zones. Thus, comprehensive spatial planning at Federal Level determines the principle of national spatial development (Min Xie, 2011).

3.2 *Spatial structure planning based on superior spatial order planning*

Comprehensive spatial planning at land level (Turowski, Gerd, 2012) follows policy requirements and requirements of spatial order planning. Comprehensive spatial planning at land level launches spatial structure planning on the basis of spatial order planning and land use status, economic development, population size, and so on. Spatial structure planning determined central-place systems and axes of spatial development axis.

Table 1. Central-place systems of Germany's spatial structure planning (Turowski, Gerd, 2012).

Characteristic	Classification	Role
To ensure that all parts of the national territory are supplied with both public and private sector services they require, and that employment is available in all parts of the country	Lower-order center (open zones)	To supply the basic everyday needs solely of the local population
	Intermediate-order center (relative high-density zones)	To supply the less everyday needs of the population of a larger area
	Higher-order center (high-density space)	To supply the "higher" or more specialized needs of the population of a wider ("higher-order") region

4 SPATIAL ORDER AND STRUCTURE PLANNING OF ECOLOGICAL INFRASTRUCTURE-ORIENTED “MULTIPLE PLANNING INTEGRATION” — ILLUSTRATED BY THE EXAMPLE OF DUJIANGYAN

4.1 *Spatial base map of ecological infrastructure-oriented “multiple planning integration”*

4.1.1 *Background*

Germany’s spatial planning based on inter-regional planning achieves coordination of each region to safeguard sharing and using of spatial function and resource with location advantage and special geographical environment. Dujiangyan is one of the second-batch pilot cities of “multiple planning integration”. Its work based on overall city planning innovatively pays attention to space division of ecological infrastructure, which is changed from resource factors. Paying attention to evaluation of the present situation transforms into evaluation of intensive optimization potential of ecological infrastructure evaluation. And spatial development pattern of advantage resources transforms into intensive optimization development pattern of ecological infrastructure of regional space.

4.1.2 *Concept*

Dujiangyan’s spatial base map based on the direction of the main body function, environmental carrying capacity of resources, urban development potential, cognition of the base map of ecological infrastructure resources, and spatial development vision pattern has two characteristics: static presentation of ecological infrastructure and adapting to the spatial development pattern. Spatial base map is the objective reflection of the spatial elements and generally forms three types of space: urban space, village ecological infrastructure space, and ecological protection space, which can

Figure 2. Space division of Dujiangyan’s “multiple planning integration”.

be expressed by various types of “polygon-chain”. Village ecological infrastructure (Liang Mao, 2012) is the material basis for residents’ existence and development and for the normal operation of urban residents. It provides natural service for village residents and sustainable development of urban; village ecological infrastructure space includes ecological productive land in village, such as natural or artificial forest land, farmland, grassland, river wetland, coastal beach, green space, and water body in the village built area and living space for residents. Spatial development pattern changes with the appreciation of space resource to form a different spatial pattern.

4.2 *Improving spatial order and structure planning based on spatial base map of ecological infrastructure-oriented “multiple planning integration”*

Dujiangyan’s “multiple planning integration” by analogy with Germany’s spatial order planning determined the spatial structure on the basis of three types of space: high-density central city zone, medium-density village ecological infrastructure space zones, and low-density ecological protection zone. Satellite towns, key towns, general towns, and regions with a stable demand are further determined in different density zones.

Germany’s spatial structure planning based on spatial order planning determines the principles and objectives of state spatial coordinated development and structural relationship between dense space and open space. On the basis of overall planning, Dujiangyan preliminarily forms space pattern of “one city and four town” to achieve coordination of whole-region space and to strengthen the relationship between urban space and ecological infrastructure. On the basis of space pattern of

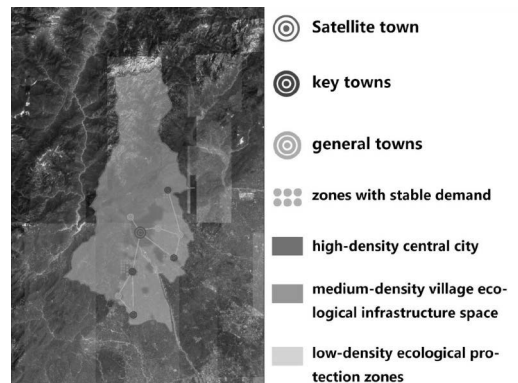

Figure 3. Spatial order planning of Dujiangyan’s “multiple planning integration”.

Table 2. Central-place systems of spatial structure planning of Dujiangyan's "multiple planning integration".

Classification	Corresponding region
Lower-order center (open zones)	General towns of village ecological infrastructure space
Intennediate-order center (relative high-density zones)	Key towns of village ecological infrastructure space
Higher-order center (high-density space)	Central city

Figure 4. Central-place systems and "one city, four towns and four points" structures of Dujiangyan's "multiple planning integration".

overall planning and by analogy with central-place systems of Germany's comprehensive spatial planning at land level, central city (high-density space) is treated as higher-order center. Key towns (relative high-density space) are treated as higher-order centers. General towns (open space) are treated as intennediate-order centers. Finally, spatial structure of "multiple planning integration" of "one city, four towns and four points" is formed.

On the basis of spatial structure planning, Germany's spatial planning links up the densely populated zones and the more peripheral zones through existing transport and public infrastructure to form the communication axes to vest with the location advantage and for structure development. Besides, Germany's spatial planning linearly connects proper living center to form the settlement spatial development axes to safeguard ordered settlement development and to protect open space (Turowski, Gerd, 2012). Dujiangyan's "multiple planning integration" based on spatial structure of "multiple planning integration" of "one city, four towns and four points", relying on the existing transportation and ecological infrastructure, determines the spatial development axes to strengthen the coordination of whole-region space: riverside development axes (settlement spatial development)

Figure 5. Riverside development axes of Dujiangyan's "multiple planning integration".

Figure 6. Three comprehensive development axes of Dujiangyan's "multiple planning integration".

and three comprehensive development axes (communication axes). Three comprehensive development axes, relying on Chengguan Expressway, Duwen Expressway, the third Chengdu Expressway, link central city, "four towns and four points", and the more peripheral zones of the urban space, village infrastructure space, ecological protection space to highlight the advantages of the central city and to strengthen the relationship between the spatial structures. Three comprehensive development axes divide ecological protection space into two zones (north and south). Riverside development axes maintain the orderly development of living space. Riverside development axes link urban space and village infrastructure space and divide urban space and village infrastructure space into

four regions. Relying on spatial development axes and rich tourism and culture resource along the mountains, tourism service industry and leisure creative agriculture can be developed to inspire development for mountainous areas and to open ecological protection space. On the basis of spatial structure of “multiple planning integration” of “one city, four towns and four points”, the spatial structure development model of “one core, two axes, four regions and two zones” is formed.

5 CONCLUSION

Germany’s spatial planning uses spatial order and structure planning as principles, which has confinement effect and shows their scientific rationality. The practice of Dujiyan’s “multiple planning integration” put forward a spatial base map of ecological infrastructure-oriented “multiple planning integration” and ecological infrastructure-oriented spatial order and structure planning. The above innovation practice aims to strengthen the overall planning and coordination of the citywide space and provides reference experience to other practice of other cities’ “multiple planning integration”.

Homogeneous generalized yield function and limit analysis of structures with rectangular sections

Wei Ou, LuFeng Yang & Wei Zhang

Key Laboratory of Engineering Disaster Prevention and Structural Safety of China Ministry of Education, School of Civil Engineering and Architecture, Guangxi University, Nanning, China

ABSTRACT: A problem for the Elastic Modulus Adjustment Procedure (EMAP) is that the limit load solution varies with the initial load when the Generalized Yield Function (GYF) is employed. To overcome this problem, we use a Homogeneous Generalized Yield Function (HGYF)-based Elastic Modulus Reduction Method (EMRM) for structures with rectangular section. The procedure for selecting fitting points from the yield surface was determined by the original generalized yield function and is presented here for the formulation of the relevant HGYF. The HGYF for rectangular section is presented based on regression analysis. The Element Bearing Ratio (EBR), the reference EBR and the uniformity of EBR for rectangular section are defined on the basis of the HGYF, the strategy of elastic modulus adjustment is proposed for the evaluation of the lower bound limit load based on deformation energy conservation principle. Numerical examples show that the proposed method can provide a promising result for limit analysis of the structures with rectangular section.

1 INTRODUCTION

The limit load is an important index for measuring the overall safety of an engineering structure. The limit analysis method for complex structures can be classified into two categories: experimental and numerical methods. Although experimental methods are intuitive, they are time-consuming and expensive. The numerical analysis method has been widely employed because it overcomes the experimental method's aforementioned deficiencies.

The EMAP is a promising numerical method for determining limit loads using a series of linear elastic finite element analysis iterations. In the past 20 years, a number of EMAPs have been proposed, including generalized local stress-strain method (Seshadri & Babu 2000), elastic compensation method (Mackenzie *et al.* 2000), linear matching method (Chen & Ponter 2001), modified elastic compensation method (Yang *et al.* 2005) and m_σ -Tangent (Seshadri & Hossain 2009). Most EMAPs are based on the state of stresses and strains; therefore, a refined finite element analysis model that is discretized with solid elements is usually adopted. The limit analysis using this model is inconvenient for calculations involving large and complex structures. To overcome this problem in the limit analysis of constructions, Generalized Yield Functions (GYFs) have been introduced into the EMAPs (Shi *et al.* 1996; Hamilton *et al.* 1996; Hamilton 2002; Marin-Artieda & Dargush 2007; Pisano & Fuschi 2011). Yang *et al.* (2012, 2014) developed the GYF-based

Elastic Modulus Reduction Method (EMRM) for determining the limit load. The EMRM improves the efficiency and accuracy of EMAPs by developing the Element Bearing Ratio (EBR), the reference EBR—a dynamic criterion for identifying highly stressed components—and the strategy for adjusting the elastic modulus.

Research has shown that limit load solutions vary with the initial load when the structure is under a combination of internal forces. This variation occurs because most of the GYFs are non-homogeneous functions that cannot maintain the proportional relationship between GYFs and the external load claimed by the EMAPs. A solution to this problem for structures with angle steel proposed preliminarily by Yang *et al.* (2014). However, there is still a need for HGYF-based EMRM for structures with rectangular section.

In this paper, the principle of point selection for establishing HGYF is presented considering the curvature and shape characteristics of GYF. The HGYF is then established for rectangular section. The key parameters for limit analysis are defined; these parameters include EBR, reference EBR and uniformity of EBR. The strategy for the elastic modulus adjustment procedure is given in terms of the conservation of energy. Based on the above analysis, a HGYF-based EMRM is provided for the limit analysis of structures with rectangular section. Numerical examples demonstrate that the provided HGYF-based EMRM can perform promising limit analyses of structures with rectangular section.

2 ELASTIC MODULUS REDUCTION METHOD FOR LIMIT ANALYSIS

2.1 Generalized Yield Criterion and EBR

A Generalized Yield Criterion (GYC) that is expressed by internal forces is used to determine the limit state of a cross-section from the elastic stage to the plastic stage. The general formula of GYC under a combined axial force and biaxial bending moments is as follows:

$$f(n_x, m_y, m_z) \leq 1, \quad (1)$$

where $f(\cdot)$ denotes the GYF, which is determined with respect to different section; $f(\cdot)$ equals 1 and represents the plastic yield of a cross-section. $n_x = N_x / N_{px}$, $m_x = M_x / M_{px}$, $m_y = M_y / M_{py}$, where lowercase n_x , m_y , and m_z are dimensionless parameters. N_x , M_y , and M_z are internal forces, and the variables with subscript p denote the corresponding fully plastic section forces that depend on the geometric shape of the cross-section and the strength of the material.

The EBR is developed as a governing parameter of the EMRM. Based on the GYF, EBR can be expressed as follows:

$$r_k^e = N_1 \sqrt{f(n_x, m_y, m_z)}. \quad (2)$$

where N_1 is the highest power of the GYF.

2.2 Strategy for elastic modulus adjustment

The deformation energy conservation principle and the linear elastic finite element method were adopted to develop the strategy of elastic modulus adjustment:

$$E_{k+1}^e = \begin{cases} E_k^e \frac{2(r_k^0)^2}{(r_k^e)^2 + (r_k^0)^2}, & r_k^e > r_k^0 \\ E_k^e, & r_k^e \leq r_k^0 \end{cases} \quad (3)$$

where E_k^e and E_{k+1}^e are the elastic moduli for element e in the k th and $(k+1)$ th iterations, and r_k^0 is the Reference EBR (REBR) that provides the threshold for determining whether the elastic moduli are reduced. To improve the accuracy and efficiency of the calculations, the REBR r_k^0 was defined by employing the uniformity of the EBR as follows:

$$r_k^0 = r_k^{\max} - d_k \times (r_k^{\max} - r_k^{\min}), \quad (4)$$

where r_k^{\max} and r_k^{\min} are the maximum and minimum of the EBRs in the k th iteration, respectively, and d_k is the uniformity of the EBR, which can be defined as follows:

$$d_k = \frac{\bar{r}_k + r_k^{\min}}{\bar{r}_k + r_k^{\max}}, \quad (5)$$

where \bar{r}_k is the mean value of the EBRs in the structure, and d_k with a dynamic value range of $(0, 1]$ reflects the uniformity of the EBR.

The parameters, r_k^{\max} , r_k^{\min} , \bar{r}_k and d_k , reflect the distribution condition of the EBR for each iteration step and are the characteristic distribution parameters of the EBR. The REBR is defined in expression (4) and provides dynamic adaptive criteria for identifying the highly stressed element with an EBR greater than the REBR. The failure evolution and plastic limit state of engineering structures are simulated by reducing the elastic moduli of highly bearing elements in the iterative process.

2.3 Limit load solution

According to the linear elastic finite element, the limit load P_L^k in the k th iteration can be determined by

$$P_L^k = P_0 / r_k^{\max}, \quad (6)$$

where P_0 is the initial load.

The above iterative process is repeated until the limit load of two adjacent iteration steps meets the following criterion of convergence:

$$\left| (P_L^k - P_L^{k-1}) / P_L^{k-1} \right| \leq \varepsilon, \quad (7)$$

where ε is the prescribed admissible error; 0.001 is adopted in this paper.

If the convergence criterion is met in the m th iteration, the lower bound of the structural limit load P_L is obtained as follows:

$$P_L = \max(P_L^1, P_L^2, \dots, P_L^m). \quad (8)$$

3 HOMOGENEOUS GENERALIZED YIELD FUNCTION BASED ELASTIC MODULUS REDUCTION METHOD FOR STRUCTURES WITH RECTANGULAR SECTIONS

3.1 GYF for rectangular section

The GYF for rectangular section derived by Duan & Chen (1990) is introduced here and then employed in a HGYF formulation in the EMRM.

The GYF for rectangular section using combined n_x , m_y , and m_z can be expressed as follows (Duan & Chen 1990):

$$f = m_y^\alpha + m_z^\alpha - (1 - n_x^\alpha)^\alpha + 1, \quad (9)$$

where $\alpha = 1.7 + 1.3n_x$.

According to equation (9), the GYF for plane structure with a rectangular section can be deduced as follows:

$$f = n_x^2 + m_y. \quad (10)$$

The N_{px} , M_{py} and M_{pz} values of rectangular section can be expressed as follows:

$$N_{px} = \sigma_s b h, \quad M_{py} = \frac{1}{4} \sigma_s b h^2, \quad M_{pz} = \frac{1}{4} \sigma_s b^2 h, \quad (11)$$

where b and h are the width and height of the cross-section, respectively.

3.2 Limitation of the GYF and its improvement

The GYFs mentioned above have been introduced into the EMAPs using sparse mesh for improving calculation efficiency. equation (6) shows that the limit load P_L^k can be obtained from the maximum EBR of r_k^{\max} in the k th iteration, where GYF is employed in r_k^{\max} by the basic EMRM. However, results may vary with different initial loads because there is a non-proportional relationship between the external load P_0 and the GYF of f .

To overcome the nonproportional problem, the homogeneous formula for GYF, i.e. HGYF, can be expressed as follows:

$$\bar{f}(n_x, m_y, m_z) = \sum_{i=1}^H a_i n_x^q m_y^g m_z^{N_2 - q - g} \quad (12)$$

$(q = 0, \dots, N_2; g = 0, \dots, N_2 - q),$

where H , N_2 and a_i are the number of polynomial terms, power and undetermined coefficients of the HGYF, respectively.

Figure 1. Internal forces in rectangular section.

3.3 Selection principle of points from GYF

To give the HGYF shown in equation (12), the representative points from the GYF must first be selected. For better illustrating the features of the GYF, the selection principle of points for HGYF regression analysis is given as follows:

1. Determination of the range of all the dimensionless parameters n_x , m_y and m_z .
2. Calculation of the extremum points of $f = 1$ using the method of the extremum of function.
3. Selection of representative points in a principle of reflecting the shape of yield surface, considering its global and local features.
4. Provision all the sample points for fitting the HGYF.

For the rectangular section defined in equation (9), the detailed process of points selection is as follows:

1. First, the range of n_x , m_y and m_z can be determined as $[0, 1]$ according to equations (1) and (9). The range of m_y is then determined as $[0, 1 - n_x^2]$ by considering equation (10).
2. Second, when $n_x = 0$ and $n_x = 1$, the GYF of $f = 1$ is found at its extremum points.
3. Third, m_y can be obtained from the formula of $a(1 - n_x^2)$, in which the values of a and n_x are incrementally selected in a step of 0.01 at the range of $[0, 0.05]$ and $[0.95, 1.00]$ to reflect local features of the GYF, while the values are evenly selected in a step of 0.05 at the range of $[0.05, 0.95]$ to reflect global features of the GYF.
4. At last, m_z can be calculated according to equation (9), and all 841 sets of sample points $(n_{x,j}, m_{y,j}, m_{z,j})$, $j = 1, 2 \dots 841$, are determined for fitting the HGYF.

3.4 HGYF for rectangular section

According to the aforementioned principles and steps for regression analysis, the 4th power HGYF for rectangular section is obtained as follows:

$$\begin{aligned} \bar{f}_4 = & 1.02n_x^4 + 0.89n_x^3m_y + 1.41n_x^3m_z + 4.30n_x^2m_y^2 \\ & - 2.05n_x^2m_y m_z + 3.55n_x^2m_z^2 - 0.12n_x m_y^3 \\ & - 1.21n_x m_y^2 m_z - 0.69n_x m_y m_z^2 + 0.03n_x m_z^3 \\ & + 0.99m_y^4 + 0.38m_y^3 m_z + 2.29m_y^2 m_z^2 \\ & + 0.33m_y m_z^3 + 0.99m_z^4. \end{aligned} \quad (13)$$

3.5 HGYF based EMRM for limit analysis

The r_k^e can be rewritten according to the HGYF formulated in equation (13):

$$r_k^e = N_2 \sqrt{f_{N_2}(n_x, m_y, m_z)}. \quad (14)$$

Equation (14) overcomes the problem of variation of limit load P_0 result with different initial loads because r_k^e is proportional to P_0 . The HGYF-based EMRM for limit analysis is then established by replacing equation (2) with equation (14).

4 NUMERICAL EXAMPLES

A user routine in a commercial FE package of ANSYS 8.0 purchased by the Guangxi University was employed for constructing FE models and computation in the following examples.

4.1 Multi-story multi-span frame

In this example, we considered a four-span, four-story frame structure under a concentrated load and a uniformly distributed load, as shown in Figure 2. The span length L is 4.0 m and the story height of column H is 2.0 m. The rectangular section aforementioned are used here, and their geometry parameters are given in Table 1. The initial elastic modulus is 210 GPa, and the initial yield strength is 310 MPa. Every member is discretized as four elements of beam189 in the FEM model. The HGYF-based EMRM with aforementioned \bar{f}_4 is employed to determine the limit load of the frame. The results calculated by the HGYF-based EMRM with rectangular section are compared to the results from the EMRM with the original

Figure 2. Multi-story multi-span frame.

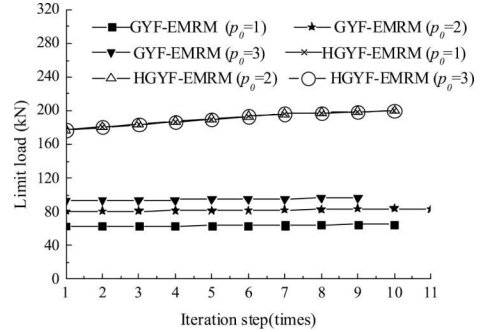

Figure 3. Iterative process of limit load.

GYF f and the Elasto-Plastic Incremental Analysis (EPIA), as listed in Table 2. The iteration process of the limit load calculated is shown in Figure 3.

The results yielded by the HGYF-based EMRM agree with the results from the EPIA, while the results yielded by the GYF-based EMRM vary with different initial loads due to nonhomogeneity.

4.2 Spatial frame

This example considers a three-story spatial frame under some concentrated loads, as shown in Figure 4. The geometry parameters of rectangular section are the same as the previous example. The initial elastic modulus is 210 GPa, and the initial yield strength is 310 MPa. Every member is discretized as four elements of beam189. The HGYF-based EMRM with aforementioned \bar{f}_4 is employed to perform the limit analysis of this three-story spatial frame structure. The results calculated by the HGYF-based EMRM with the rectangular section were compared to the results from the EMRM with the original GYF f and EPIA, as listed in Table 3.

The results of the EMRM with f vary with different initial loads and are inaccurate because of the nonhomogeneity of f , whereas the limit loads calculated by the HGYF-based EMRM was not affected by the initial load P_0 and agreed well with the results calculated by the EPIA.

The iteration process of the limit load calculated is shown in Figure 5. It can be seen that a calculation result without varying with initial load, yielded by the HGYF-based EMRM, can

be obtained after a few times of iterative analysis, whereas the results of the GYF-based EMRM show that application of the original GYF will result in variability of results with different initial load and iteration steps.

The results of this example verified that the HGYF-based EMRM is a promising limit analysis method for overcoming the nonhomogeneity problem that existed in EMAPs.

5 CONCLUSIONS

In this paper, the HGYF-based EMRM for structures with rectangular section is presented. The HGYF for rectangular section was determined precisely using the selection principle of points from the GYF; the 4th power HGYF \bar{f}_4 was elaborately provided. Numerical examples show that the HGYF-based EMRM is an accurate and efficient calculation method for the limit load analysis of structures with rectangular section that overcome the nonhomogeneity problem that existed in EMAPs.

Numerical simulation analysis of the influence of shield tunneling on an adjacent tunnel

Meide He

Beijing Municipal Engineering Research Institute, Beijing, China
Beijing Construction Engineering Quality Third Test Co. Ltd., Beijing, China

Jun Liu

Beijing University of Civil Engineering and Architecture, Beijing, China

ABSTRACT: In the case of a shield tunnel construction in Beijing, on the basis of the interaction mechanism of neighborhood tunnels during tunnel excavating, a 3D nonlinear numerical simulation model was set up. The developing laws of the segment lining stress, ground deformation around tunnels, segment lining deformation, and changing bending moment of segment lining in different tunnel spaces are analyzed in detail. The results show that the stress growth rate of segment lining and tunnel space are linearly descending related to the situation of the immediately adjacent shielding. The ground settlement form is similar to the case of the single-tunnel construction due to space constraint. Furthermore, it is found that the form is single mode. Under horizontal compression and vertical tension, the segment lining deformation is in ellipse deformation trend. The response of the left existing tunnel to adjacent shielding has hysteresis effect. The result shows that 3D numerical model is a useful method, which can directly display the interaction law of neighborhood tunnels during construction. The study results can be used to guide the construction of immediately adjacent shield tunnels.

1 INTRODUCTION

With the continued construction of the urban subway engineering, shield is increasingly used in the underground engineering; increasingly acute problems are met in the construction of neighboring tunnels. He Meide (2014) studied a certain large-section pedestrian upper passageway crossing the running shield tunnel of Beijing subway. The vertical displacements of shield tunnel structure, the horizontal convergence displacements of shield tunnel structure, and the vertical displacements of track bed structure were monitored and analyzed. The analysis result of this project shows that grouting from floor of passageway can significantly control upfloating, which can be applied in similar projects. On the basis of a constructing running shield tunnel subway side-through close to a high building (He Meide, 2010) using the finite-element method calculation model and site-monitoring method, the foundation characteristics of the high building affected by the constructing shield tunnel are studied. The settlements of the monitoring points reach the maximum value when the shield is 10.0 m away from the monitoring surface. The simulation and the site monitoring results agreed well. Through the analysis of the ground movement law

resulted by three typical location relations during the excavation process of the adjacent tunnel with the boundary element method, (Liao Shaoming et al. (2006) drew the conclusion that the tunnel depth and the relationship between the adjacent tunnels has a great impact on the ground displacement. Bi Jihong et al. (2005) carried out numerical simulation on the two-lane tunnel engineering with the shield spacing transiting from 7.2 to 3.0 m constructed by shield tunneling with the finite-element method and analyzed the impact of excavation of right line works on the left tunnel. Hu Wei and Zeng Dongyang (2007) studied the distribution and variation law of surface lateral settlement tank and vertical settlement–uplift curve caused by the construction of parallel shield tunnel with the double-lane tunnel spacing of 6.0 m, 12.0 m with three-dimensional finite-element method, and used three-dimensional curves to draw the spatial distribution variation law of surface settlement–uplift variance curves during the parallel shield tunneling process. In the case of the proximity-overlapped shield tunnel construction in the second phase of Shanghai Mingzhu Transit. Zhang Haibo (2005) simulated the stress and deformation of the old tunnel caused by the post-built tunnels in the case of short-distance overlap with three-dimensional

nonlinear finite element. Yamaguchi et al. (1998) summarized and analyzed the interaction of the four parallel tunnels near Tokyo from the angle of design and construction, respectively.

Because of the importance of the interaction during the construction process of the immediately adjacent tunnel, the domestic research of the interaction on the adjacent tunnel is focused on the variation law of the surface settlement and the surrounding layer movement caused in the process of tunnel excavating, and little analysis is done on the influence of the succeeding tunnel on the existing tunnel. Consequently, the development law of segment lining stress, ground deformation around tunnels, segment lining deformation, and changing bending moment of segment lining in different tunnel spaces were analyzed with the 3D numerical simulation method based on the interaction mechanism of neighborhood tunnels during tunnel excavating in this paper, and the research result was used to guide the engineering practice.

2 ENGINEERING SITUATION

Earth pressure balance shields were used in the construction of the two-lane tunnel project. The two shields were advancing in the left and right tunnels with a certain distance apart with the left shield in the front. The tunnel segment lining had an external diameter of 6.0 m and internal diameter of 5.4 m; the precast reinforced concrete segment lining with a ring width of 1.2 m and thickness of 0.3 m was used. The whole ring was divided into six parts, including three standard A-type segment linings, two adjacent capped block B-type segment linings, and a capped block C-type segment lining. Precast reinforced concrete segment lining was C50 grade concrete with the impermeability grade of S10; M24 high-strength

bolts were also adopted in the vertical and circumferential connecting bolts for the lining. The minimum tunnel clearance was 1.68 m; the section with the clearance between two lines of less than 2.0 m was about 300 m long, which was the immediately adjacent construction.

The formation conditions of the shield construction section from top to bottom were as follows: miscellaneous fill layer ①, mixed fill layer ①₁; silt layer ③, silty clay layer ③₁; silty clay layer ④, silt layer ④₂; medium-coarse sand layer ⑦₁, fine sand layer ⑦₂; silty clay layer ⑧; pebble gravel layer ⑨, medium-coarse sand layer ⑨₁; silty clay layer ⑩, clay layer ⑩₁. The layers crossed by the tunnel are mainly silt clay layer ④ and silt layer ④₂; the formation was mixed up with a small amount of fine sand layer ⑦₂. The physical and mechanical parameters of the main formation are shown in Table 1.

3 THREE-DIMENSIONAL NUMERICAL MODEL

Analysis was conducted with three-dimensional continuum fast Lagrange finite difference software FLAC3D, and Mohr–Coulomb model was adopted for the soil mass in the calculation; shield segment lining was considered as a linear elastic material. The main parameters of the segment lining were: elastic modulus, 34.5 GPa; weight, 25.0 kN · m⁻³ and; Poisson's ratio, 0.2. In view of the constantly changing distance between the left and right tunnels, the cross-sectional size of the established model was 90 m × 52 m (in the x- and y-axis direction), the vertical dimension was 204 m (in the z-axis direction), namely the spacing between the left and right tunnels was 4.77 m at the 1131st ring from one end of the model, from which the spacing between the left and right tunnels was gradually decreased until the minimum spacing at the 1280th

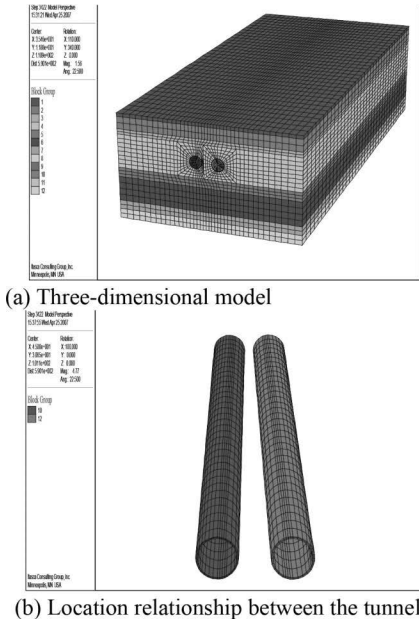

Figure 1. 3D numerical calculation model.

ring section in the left line reached 1.62 m. Then, the tunnel spacing gradually increased again until the spacing between the left and right tunnels was increased to 1.88 m at the 1300th ring section of the left line at the other end of the model. The tunneling construction process of the shield was considered to be advanced gradually; the advance step of the shield in this model was set as the width of five segments of 6.0 m. The optimized model was divided into 47,872 units and 67,027 nodes.

In order to eliminate the displacement produced during the generation of the initial stress field, the left tunnel was further advanced after the displacement was set to zero after the formation of the initial stress field. The view of three-dimensional model and the location relationship between the left and right tunnels is shown in Figure 1.

4 ANALYSIS OF RESULTS

4.1 Stress of segments

During the advance process of the shield, the stress of segment lining in the left tunnel was closely related to the damage of segment lining, and the maximum principal stress (σ_1) of the segment lining was an important indicator of its stress state. Therefore, the maximum principal stress was extracted in the result to analyze the change and development status of the stress of the segment. During the advance process of the shield in the right tunnel, the

maximum principal stress of the segment was also constantly changing, as shown in Figure 2.

During the construction process in the right tunnel, because of the compression of the shield tunneling on the left tunnel, the segment of the left existing tunnel showed the horizontal compression state in the x-axis direction and stretched state in the y-axis direction so that the left tunnel assumed an oval development trend. As seen from the calculation result of the overall model in Figure 2, the maximum principal stress of the segment of the left tunnel was -7.44 MPa after the two-lane tunnel was completed, which was 32.15% greater

Figure 2. Contour of the maximum principal stress of segment lining during shield tunneling.

Figure 3. Curve of the maximum stress of segment lining in left tunnel monitoring sections.

Table 2. Stress of segment lining in left line monitoring sections.

	No. 1140	No. 1186	No. 1219	No. 1255	No. 1287
Tunnel spacing (m)	4.53	3.35	2.63	1.73	1.65
Maximum stress of segment after left through (MPa)	-4.28	-4.32	-4.29	-4.24	-4.32
Maximum stress of segment after right through (MPa)	-4.58	-4.71	-4.83	-4.87	-4.98
Maximum stress corresponding to excavation steps (step)	1	11	18	25	32
Monitoring sections where excavation steps (step)	2	12	18	25	32

than the maximum principal stress of the segment of -5.63 MP when the left tunnel was completed.

As could be seen from the curve of the maximum stress of segment lining in monitoring sections of the left tunnel in Figure 3, before the shield in the right line reached the monitoring segments, the stress of the monitoring sections had changed. Because both the 1140th and 1287th rings were located adjacent to the two ends of the model, the segment stress curve was not complete. However, according to the curve variation law of the remaining three sections, it could be seen that the changing trend of the curve was consistent, that is, before the arrival of the shield, the stress of the segment began to increase; the stress of the segment was the largest when the shield reached the monitoring section or the shield advanced into the monitoring section. It could be seen that the segment region with significant changes of stress was in the range of -D to 0. The stress result of the monitoring sections of the segment is shown in Table 2.

In the stress results of the monitoring sections in Table 2, the segment showed the compression state in the 1140 ring with the largest clearance between the left and right tunnels. The maximum stress was increased by 7.00% from 4.28 to 4.58 MPa; in the 1287th ring, with a clearance between the left and right tunnels of only 1.65 m, the maximum stress was increased by 15.28% from 4.32 to 4.98 MPa, and the compression trend of the segment was further strengthened.

As was seen from the step at which the monitoring sections of the segments achieved the maximum stress, both the 1140th and 1186th rings in the immediately adjacent section of the left and right tunnels reached their respective maximum stress one advance step before the shield's arrival, with stress growth rates of, respectively, 7.00% and 9.03%. As was seen from the 1219th ring of the proximity section to the 1255th ring, the 1287th ring in the basically parallel section of the left and right tunnels and the segment lining stress in the three monitoring sections reached their respective maximum stress with the segment stress growth of the three sections of, respectively,

Figure 4. Relationship between clearance and stress growth rate of segment lining.

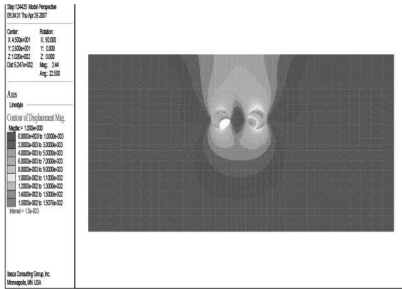

12.59%, 14.89%, and 15.28%. According to the relationship between the segment stress growth rate of five monitoring sections and the tunnel spacing, the linear fitting curves of the stress growth rate $\Delta\sigma = -2.984\Delta s + 20.0477$ (where $\Delta\sigma$ is the segment stress growth rate and Δs is the clearance of the two-lane tunnel) reflected that the segment stress growth rate was basically linearly descending with a clearance between the left and right tunnels, as shown in Figure 4.

4.2 Ground deformation around the tunnel

During the construction process of the immediately adjacent tunnels, besides the great impact on the left existing tunnel, the surrounding stratum would certainly be disturbed in a certain degree. As there was a very small spacing between the left and right tunnels, the surface subsidence distribution caused by the construction of two tunnels was very similar to that caused by a single tunnel, as shown in Figure 5. In the vertical axis location of center line of the left and right tunnels, the surface sedimentation was the greatest, the surface sedimentation tank was very similar to that of single lane, and the sedimentation tank was also a "single peak" rather than the "twin-peak" sedimentation tank caused by the general construction of left and right tunnels.

4.3 Deformation of segments

Because of the compression on the left existing tunnel during the shield tunneling process in the right tunnel, the segment showed the deformation trend

(a) Right half of the tunnel boring after the left through

(b) After two tunnels through

Figure 5. Contour of deformation in surrounding rocks.

Figure 6. Duration curve of maximum deformation of segment lining in monitoring section.

of horizontal compression and vertical tension. The left shield tunnel was also shifted as a whole compared with the new right tunnel; during the construction process of the right tunnel, the deformation of the segment was also affected by “space effect”. The duration curve of maximum deformation of segment lining in Figure 6 showed that when the shield approached the five monitoring sections and passed through the right tunnel segment, the overall deformation of the segments had the slowing trend with varying degrees; after the shield passed some excavation steps, the maximum deformation of the segments began to stabilize after some moderate growth, and the final deformation was slightly larger than the initial deformation. Through comparison of the deformation of the segment in the monitoring sections before and after the passing of the shield, the deformation was increased to 2.46 mm in the 1140th ring with the largest increment of 8.85%; the deformation was increased to 3.79 mm in the 1219th ring with the smallest increment of only 1.30%.

4.4 Bending moment of segments

During the different construction stages of the tunnel, there were some differences among the maximum plus-minus bending moments of the segment, as shown in Table 3. Through the comparison of the plus-minus segment bending moment (M_x), it could be seen that during the excavation process of the left tunnel, there was a small difference between the maximum plus-minus bending moments, the largest difference between their absolute values was not more than 0.2%; during the excavation process of the right tunnel, the absolute difference between the maximum plus-minus bending moments of the left and right tunnel was 5.03%. As was seen from the bending moment of the segment, during the excavation process of the left tunnel, the largest difference between their absolute values was 55.53%; during the excavation process of the right tunnel, the difference between the absolute value of the maximum bending moment of the left and right lines of the tunnel was up to 276.32%. It could be seen that the segment bending moment (M_x) was apparently greater than M_y at the same construction phase, and the absolute

Table 3. Statistical comparison of bending moment in segment lining during different construction stages.

		Excavation of the left half tunnel	Left tunnel through	Excavation of the right half tunnel	Right tunnel through
M_x (kN · m)	Sagging moment	33.91	33.63	38.17	40.02
	Hogging moment	-33.97	-33.70	-40.09	-39.82
M_y (kN · m)	Sagging moment	4.43	5.24	7.18	8.40
	Hogging moment	-6.89	-6.83	-27.02	-28.39

value of the maximum plus–minus bending moment of M_y was significantly greater than that of M_x . It could be seen in the shield tunneling process of the right tunnel, through comparison of the bending moment M_x and M_y on the same section, M_y is more affected by the existing tunnel than M_x .

During the shield tunneling in the right line, the bending moment of five monitoring sections in the left line followed the same change rules, as shown in Figure 7. Before the shield arrived at the monitoring section, the plus–minus bending moment of M_x and M_y of the ring segments began to increase at different levels; after the shield passed the corresponding sections in the right line, the plus–minus bending moments of M_x and M_y of the ring segments began

Figure 7. (Continued).

Table 4. Statistical comparison of maximum bending moment of segment lining in different monitoring sections.

		No. 1140	No. 1186	No. 1219	No. 1255	No. 1287
M_x ($kN \cdot m$)	Sagging moment	32.12	36.23	37.57	39.92	39.90
	Hogging moment	-29.91	-31.15	-33.35	-36.27	-37.31
M_y ($kN \cdot m$)	Sagging moment	6.70	7.40	8.73	9.76	10.15
	Hogging moment	-8.96	-8.87	-8.81	-9.09	-10.88

to reduce at different levels until it becomes stable. The monitoring sections of the moment, both the maximum positive moment and maximum negative moment, withstood by the same ring showed the trend of symmetrical change, which was consistent with the “ellipse” deformation trend of the segment. After the shield passed the sections in the right line, the bending moments of the monitoring sections were increased at varying degrees. As could be seen from the comparison between the maximum bending moments of the segments in Table 4, the change of bending moment of the segment was also related with the distance between the left and right tunnels, namely the smaller the clearance between the left and right lines, the greater change of the bending moment withstood by the segment.

5 CONCLUSIONS

In the case of construction of an immediately adjacent shield in Beijing, in this paper, the influence of shield construction on the immediately adjacent tunnel is analyzed through establishing a 3D nonlinear elastic-plasticity numerical model of the construction of immediately adjacent shield tunnels. The calculation result shows that:

1. In the light of the analyses of four indexes, namely the stress variation of the segment lining, the deformation law of the ground around the tunnel, deformation of the segment itself, and the variation law of the bending moment of segment lining reflect the sensitive degree of the clearance between the left and right tunnels at different levels. Because the segment itself has a higher rigidity, the deformation development of the segment itself is less influenced by the existing tunnels. The process of tunnel excavating has certain hysteresis effect on the influence of immediately adjacent left existing tunnel.
2. The stress growth rate of the adjacent segments caused by the tunnel excavating is basically linearly descending related to the situation of tunnel space.
3. The ground settlement form caused by the construction of double-line tunnel is similar to that caused by the single-tunnel construction due to

the little space between the left and right tunnels, which is single-mode.

4. Development of the maximum plus-minus bending moments (M_x and M_y) of the segment is in a trend of symmetrical variation, which is consistent with the ellipse deformation trend of the whole segment of the left existing tunnel under horizontal compression and vertical tension.

Development and validation of the effective stress algorithm of the Davidenkov constitutive model using the Byrne pore pressure increment model

Bin Ruan, Guoxing Chen & Dingfeng Zhao

Institute of Geotechnical Engineering, Nanjing Tech University, Nanjing, China

Civil Engineering and Earthquake Disaster Prevention Center of Jiangsu Province, Nanjing, China

ABSTRACT: In this paper, the initial stress–strain skeleton curve was simulated using the Davidenkov model, and simplified loading and unloading rules were proposed instead of the “upper boundary” rule of the extended Masing criteria. Through a large number of resonant column tests of undisturbed Nanjing fine sandy soil samples, the fitting parameters of the small shear modulus (G_{\max}) and reference shear strain (γ_0) formulations, including the effect of confining pressure, are given. A new effective stress method using the integration algorithm of the modified Davidenkov constitutive model and the Byrne pore water pressure increment model was implemented in ABAQUS. Using the drained cyclic triaxial test data of the saturation Nanjing fine sand, the parameters of the Byrne pore model are given. Undrained cyclic triaxial tests and its three-dimensional numerical simulation for the saturation Nanjing fine sand have been performed, and the results of the measurement in tests and the calculation almost agreed. The results indicated that the effective stress algorithm proposed in this paper can well simulate the pore pressure increasing process of the liquefiable sand, and the scientific rationality and validity of the integration algorithm were also verified.

Keywords: effective stress algorithm; modified Davidenkov constitutive model; Byrne incremental model; numerical simulation; cyclic triaxial tests

1 INTRODUCTION

Earthquake-induced liquefaction is a common phenomenon. The root cause of liquefaction is that the pore water pressure increase and then soil layers liquefy under the ground motion. In recent years, with the development of computer technology, many scholars are using numerical simulation method to simulate the development of pore pressure and liquefaction characteristics during the vibration of the engineering site. Its primary problem is to use the reasonable soil dynamic constitutive model and the vibration pore pressure model for describing the phenomenon of sand liquefaction and its programming.

A large number of experimental studies have shown that the use of ideal Davidenkov constitutive model with three parameters can describe the nonlinear dynamic characteristics of various types of soil, and a large amount of experimental data has been accumulated (Chen Guo-xingm 2005 & Rong Mian-shui, 2013). Because the amplitude of actual ground motions are often unequal, additional provisions need to be added to correct the irregular loading and unloading stress–strain

hysteresis curve of the Davidenkov model. “Extended Masing Rule” builds the theoretical framework of soil stress–strain curves under irregular loading and unloading. On the basis of previous research, this paper proposes the modified irregular loading and unloading criteria, which follows the Davidenkov “Backbone Curve Rule”, the “N Times Method” proposed by Pyke (Pyke R M, 1979), and the “Upper Skeleton Curve Criteria”. On the basis of the explicit module of ABAQUS, this paper developed explicit subroutine modules.

Seed and Martin et al. (Seed H B, 1975 & 1976) proposed a stress model to calculate the average pore water pressure according to the dynamic triaxial experiment data of isotropic consolidation sand under undrained conditions. Finn and Lee et al. (1977) amended the Seed and Martin model considering the effect of initial shear stress on dynamic pore pressure. Martin and Finn et al. (1975) established a seismic vibration strain model of pore water pressure on the basis of the consistency condition of saturated soil volume change. Byrne (1991) utilized the experimental data to establish the experience function between accumulated volume strain and the incremental volume

strain on the basis of Martin and Finn's model, which made the model more simple and practical.

On the basis of the work above, in this paper, we will describe the Davidenkov constitutive model, which was modified with irregular loading–unloading criterion and the Byrne pore pressure increment model. It describes the nonlinear characteristics of soil liquefaction by the subroutine in ABAQUS. Undrained cyclic triaxial tests of Nanjing fine sand and the corresponding three-dimensional numerical simulation were carried out, and the target of simulating pore water pressure growth process of liquefied foundation was achieved. The initial verification of the three-dimensional effective stress subroutine and the feasibility analysis of the results were also analyzed in ABAQUS.

2 MODIFIED DAVIDENKOV CONSTITUTIVE MODEL

2.1 The loading–unloading criterion of the Davidenkov skeleton curve under irregular loading and unloading situation

Martin and Seed (Martin P P, 1982) proposed the skeleton curve formula of the Davidenkov constitutive model:

$$\tau = G \cdot \gamma = G_{\max} \cdot \gamma \cdot [1 - H(\gamma)] \quad (1)$$

where

$$H(\gamma) = \left\{ \frac{(\gamma / \gamma_0)^{2B}}{1 + (\gamma / \gamma_0)^{2B}} \right\}^A \quad (2)$$

where τ is the shear stress, γ is the shear strain, G_{\max} is the initial shear modulus, and A , B , and γ_0 are the experimental parameters of soil.

To construct the hysteresis curve of the Davidenkov constitutive model under irregular cyclic stress, the Masing rules suitable for constant amplitude loading need to be modified, as shown in Figure 1. The loading–unloading criterion can be amended as follows:

1. The initial loading curve goes along the skeleton curves, such as 0→1 curve.
2. If the loading and unloading curve encounters skeleton curves before the steering, it should follow the extended Masing rules and the “upper backbone curve” rule, that is, the subsequent stress–strain curve goes along skeleton curve, 2→1→3 curve before correction should be corrected to 2 → 1 → 3 curve.
3. After stress is up to the steering point, the subsequent stress–strain curve goes along the direction

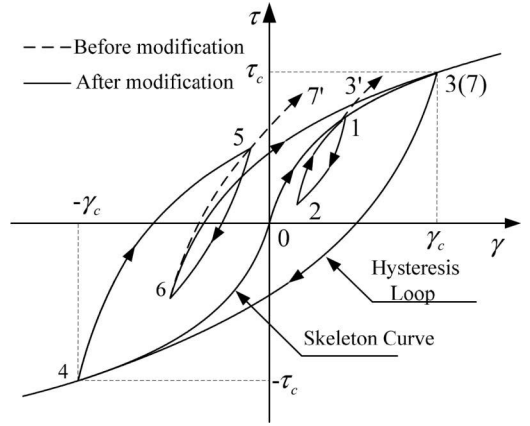

Figure 1. Stress–strain curves of the Davidenkov model with irregular loading and unloading rules.

from the current inflection point to the maximum (minimum) point in history 6→7 curve before correction should be corrected to 6→7 curve. On the basis of the “N-Times Law” proposed by Pyke, at this time, the stress–strain hysteresis curve obeys the following relationship:

$$\tau - \tau_c = G_{\max} \cdot (\gamma - \gamma_c) \cdot \left[1 - H \left(\frac{|\gamma - \gamma_c|}{2n} \right) \right] \quad (3)$$

where γ_c is the strain at loading and unloading inflection point.

According to criterion (3), in addition to recording the point of most value in history, when stress is up to the steering point, this criterion just needs to remember the current strain and parameter N at the inflection point, that is, determine the direction of stress–strain curve. This is an effective solution to the problem of large amount memory of to expand the “Masing rule” at inflection points.

2.2 Modification of G_{\max} and γ_0 considering the initial effective confining pressure

When using the average modulus of the soil layers in seismic response analysis, most of the high-frequency component of ground motion cannot propagate to the surface through the site. By modifying shear modulus and the reference strain with the initial effective confining pressure, we can fix this problem, so that the seismic response analysis results are more in line with the actual situation. Guoxing Chen (Zhuang H, 2015) summarized a number of experimental studies, which showed that: For noncohesive

soils, in the same shear strain amplitude, the greater the initial effective confining pressure, the slower the movement of the shear modulus attenuation curve. Parameter γ_0 of the curve of dynamic shear modulus ratio plays a major role in the performance of the attenuation. The higher the value of γ_0 , the slower the attenuation of the curve, that is, the greater the initial effective confining pressure, the greater the value of γ_0 . Therefore, we need to add the correction formula of G_{\max} and γ_0 considering the initial effective confining pressure in the subroutine to meet the needs of different users.

Through abundant resonant column tests of undisturbed soil samples of Nanjing fine sand, 43 groups of test data with initial effective confining pressure, soil shear modulus, and parameter γ_0 were selected. Using Origin to fit data, variation curves in which G_{\max} and γ_0 increase with the increase of σ'_c , as shown in Figure 2. At the same time, according to empirical formulas in the literature (Zhang J & Zhang J, 2005), G_{\max} and γ_0 were calculated as:

$$G_{\max} = G_{\max}^{\text{ref}} \cdot \left(\frac{\sigma'_c}{\sigma'_{\text{ref}}} \right)^a \quad (4)$$

$$\gamma_0 = \gamma_0^{\text{ref}} \cdot \left(\frac{\sigma'_c}{\sigma'_{\text{ref}}} \right)^a \quad (5)$$

where G_{\max}^{ref} and γ_0^{ref} are experimental values under confining pressure σ'_{ref} and a is the fitting parameter associated with soil characteristics.

3 BYRNE PORE WATER PRESSURE INCREMENT MODEL

On the basis of the consistency condition of volumetric change of saturated soil during earthquakes, Martin and Finn established the basic formula to obtain the increment of pore water pressure of saturated soil. As the decrease of effective stress will cause the rebound of soil volume, the volume permanent compression is induced by cyclic shearing and the pore water discharge and soil volume rebound are induced by the decrease of effective normal stress to meet the compatibility criterion. Assuming positive volume change of soil compression and pore water discharge:

$$\Delta\varepsilon_{v,d} + \Delta\varepsilon_{v,r} = \Delta\varepsilon_{v,f} \quad (6)$$

where $\Delta\varepsilon_{v,d}$ is the soil compression volume induced by shearing at each cycle, $\Delta\varepsilon_{v,r}$ is the soil volume increment induced by the decrease of effective normal stress, and $\Delta\varepsilon_{v,f}$ is the discharge volume of pore water at each cycle induced by shearing. Assuming that at the moment the earthquake occurs, there is no drainage in saturated sand, that is, $\Delta\varepsilon_{v,f} = 0$. Then, equation (6) can be written as:

$$\Delta\varepsilon_{v,d} = -\Delta\varepsilon_{v,r} \quad (7)$$

Assuming E_r as resilient modulus of saturated sand, Δu as the increment of pore water pressure, and $\Delta\sigma$ as the increment of effective normal stress, we get:

$$\Delta\varepsilon_{v,r} = \frac{\Delta\sigma}{E_r} = -\frac{\Delta u}{E_r} \quad (8)$$

Substituting equation (8) to (7), we get:

$$\Delta u = E_r \Delta\varepsilon_{v,d} \quad (9)$$

Byrne (1991) obtained the relation between cumulative volume strain ($\varepsilon_{v,d}$) and volumetric strain increment ($\Delta\varepsilon_{v,d}$) using experimental data of Martin and Finn (1975):

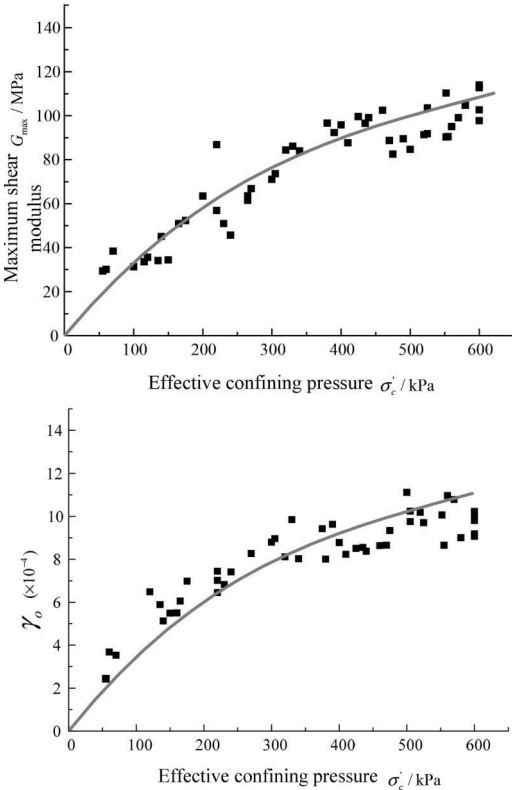

Figure 2. Fitted curve of tests.

$$\frac{\Delta \varepsilon_{v,d}}{\gamma_a} = C_1 \exp(-C_2 \frac{\varepsilon_{v,d}}{\gamma_a}) \quad (10)$$

$$E_r = \frac{(\sigma'_c - u)^{1-m}}{mk(\sigma'_c)^{n-m}} \quad (11)$$

In equation (10) and equation (11), γ_a is the shear strain amplitude of the Nth stress cycle, and σ'_c is the initial effective normal stress, which are represented by octahedral shear strain amplitude (γ_{oct}) and initial octahedral effective normal stress (σ'_{oct}), respectively, in two-dimensional and three-dimensional conditions, u is the excess pore water pressure, and C_1 , C_2 , m , n , and k are parameters related to soil characteristics.

Byrne used the experimental data of Martin and Finn (1975) and Tokimatsu and Seed (1987) (Tokimatsu K, 1987) to obtain the empirical formula of coefficients C_1 and C_2 represented by the sand relative density (D_r) or the modified blow counts of standard penetration test N_1 :

$$C_1 = 0.076 D_r^{-2.5} \text{ or } C_1 = 8.7 N_1^{-1.25} \quad (12)$$

$$C_2 = \frac{0.4}{C_1} \quad (13)$$

The generation of excess pore water pressure will lead to the decrease of soil shear modulus, in order to consider the influence induced by the rise of pore water pressure on the mechanical properties of the soil, the formula of dynamic pore water pressure, soil shear modulus, and reference shear strain was established according to the experiment (Liyanathirana D S, 2002):

$$G_{\max} = G_{\max}^{ref} \cdot \left(\frac{\sigma'_c}{\sigma'_{ref}} \right)^a \cdot \left(\frac{\sigma'_c - u}{\sigma'_c} \right)^b \quad (14)$$

$$\gamma_0 = \gamma_0^{ref} \cdot \left(\frac{\sigma'_c}{\sigma'_{ref}} \right)^a \cdot \left(\frac{\sigma'_c - u}{\sigma'_c} \right)^b \quad (15)$$

where u is the pore water pressure and b is the fitting parameter related to soil characteristics.

4 IMPLEMENTATION OF EFFECTIVE STRESS ALGORITHM IN ABAQUS

4.1 Secondary development platform in ABAQUS

ABAQUS modules support constitutive model programs written by FORTRAN language, users can realize the subroutine development through the interface provided by ABAQUS UMAT/VUMAT (implicit/explicit), and the main program will automatically call the constitutive model specified by the user in the calculation process.

The development involved the interface program, which is the material custom programs of VUMAT, is briefly introduced as follows:

The main task of the VUMAT subroutine is: (1) the stress increment ($\Delta\sigma$) should be achieved on the basis of the incoming strain increment ($\Delta\varepsilon$) from ABAQUS; and (2) the state variables need to be transferred in the process of updating and solving.

The simulation of soil pore pressure needs coupling calculation with both static and dynamic steps, which can be achieved by multitasking. However, the multitasking calculation method is complicated to be adopted. In order to facilitate the employment of the subroutine, the constitutive model program was divided into two computing stages, including the static stage and the dynamic stage. The static calculation stage used the original in situ stress balance calculation method in ABAQUS. The soil dynamic stress–strain relationship during dynamic calculation phase relied on the modified Davidenkov constitutive model based on irregular loading and unloading criterion, and the Byrne pore water pressure increment model presented above is embedded in the constitutive model.

4.2 Calculation procedure of the constitutive model

For large-scale numerical simulation problems, explicit algorithm can ensure the calculation accuracy, while providing higher computational efficiency (Chen Guo-xing, 2011). Therefore, explicit algorithm subroutine was compiled through ABAQUS VUMAT interface. Figure 3 shows the

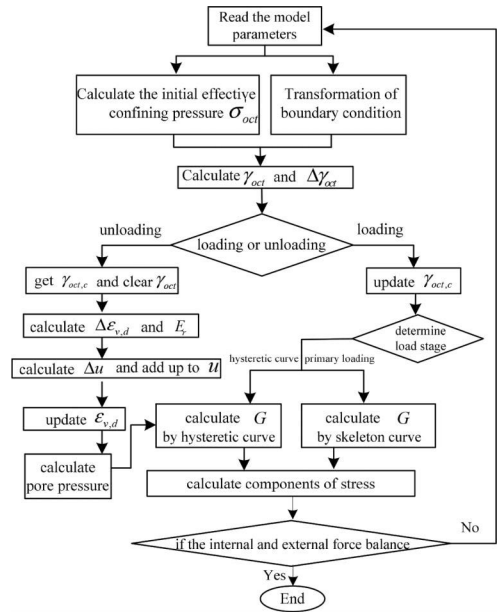

Figure 3. Flowchart of subroutine.

subroutine calculation process. First, the subroutine obtains the initial octahedral effective confining pressure (σ'_{oct}) in static analysis phase and the transition of the boundary conditions. Second, in the stage of dynamic analysis, the initial loading section should be judged and the shear modulus (G) is obtained using the initial load curve. Then, the turning point of loading and unloading must be judged. If there is a turning point, then update the octahedral shear strain amplitude and calculate pore water pressure increment (Δu) and the volumetric strain increment ($\Delta \varepsilon_{v,d}$), update pore water pressure (u) and the accumulated volume strain ($\varepsilon_{v,d}$) after accumulation, and update the stress.

5 VERIFICATION OF THE SUBROUTINE MODULE

5.1 Determination of parameters in Byrne pore pressure increment model

Saturated drained cyclic triaxial tests of remolded Nanjing fine sand were carried out. The sample diameter was 39.1 mm, the height H was 80 mm, and the relative density was 50%. The basic physical parameters are shown in Table 1. The layered wet ramming method and saturated vacuum extraction method were applied to remold the soil. The saturation time was more than 24 h. The sinusoidal shear strain load was applied on the specimen with amplitudes of 0.1%, 0.2%, and 0.3% at 1Hz.

The relation curve between volumetric strain and cyclic number (N) was achieved by tests mentioned above, as shown in Fig. 4. The experimental results of crystal silica sand were represented by dotted lines from Byrne P M (1991). Data points of different shear strain amplitudes were selected in Fig. 4. According to formula (10), the modified relation curve between volumetric strain increment ($\Delta \varepsilon_{v,d} / \gamma_a$) and volumetric strain ($\varepsilon_{v,d} / \gamma_a$) was fitted out, as shown in Fig. 5. The Byrne pore pressure increment model parameters of Nanjing fine sand are $C_1 = 0.730$ and $C_2 = 0.475$. Besides, the dotted lines are the fitting curves of crystal silica sand obtained from Byrne P M (1991).

As shown in Figs. 4 and 5, the development trends of relation curve between volumetric strain ($\varepsilon_{v,d}$) and cyclic number (N) of Nanjing fine sand and crystal

silica sand were basically consistent. Under the cyclic loading of same shear strain amplitude, volumetric strain increased as the cyclic number increases. At the same certain cycle, with the increase of shear strain amplitude, the volumetric strain increased too; the development trends of relation curve between the modified volumetric strain increment ($\Delta \varepsilon_{v,d} / \gamma_a$) and volumetric strain ($\varepsilon_{v,d} / \gamma_a$) were basically coincident, the values of parameters are relatively close.

Figure 4. Volumetric strains from constant amplitude cyclic simple tests.

Figure 5. Normalized incremental volumetric strains.

Table 1. Basic physical properties of the Nanjing fine sand.

Mean diameter d_{30} (mm)	Uniformity coefficient $c_u = d_{60} / d_{10}$	Curvature coefficient $c_c = d_{30}^2 / (d_{10} d_{60})$	Specific gravity G_s	Maximum void ratio e_{max}	Minimum void ratio e_{min}	Relative density D_r (%)
0.12	2.31	1.07	2.72	1.15	0.62	50

Notes: Effective diameters d_{10} , d_{30} , and d_{60} mean that 10%, 30%, and 60% (by weight) of particles are smaller than the number, respectively.

These conclusions illustrated the validity of the test results with each other.

5.2 Undrained cyclic triaxial tests of saturated Nanjing fine sand

Saturated undrained triaxial tests of remolded samples of Nanjing fine sand were carried out. The sample diameter $D = 39.1$ mm, height $H = 80$ mm, relative density $D_r = 50\%$, and the basic physical parameters are shown in Table 1. When pore pressure ratio $\mu_N / \sigma'_c = 1$, the test was stopped. The dynamic sinusoidal stress of 1Hz was exerted on the sample, and N_c represents the experienced cyclic number.

Time history curves of pore water pressure and hysteretic curves of soil samples are shown in Figs. 6 and 7 from triaxial tests, where initial effective stress $\sigma'_c = 100$ kPa and dynamic cyclic shear stress ratio $\tau_d / \sigma'_c = 1.05$.

Figure 6. Time-history curve of pore pressure.

Figure 7. Strain-stress curve in the test.

5.3 Numerical simulation of undrained cyclic triaxial tests of saturated Nanjing fine sand

Undrained cyclic triaxial tests of Nanjing fine sand were compared with the corresponding three-dimensional numerical simulation, which was utilized to verify the correctness of the calculation results with effective stress algorithm in subroutine modules under simple stress condition. The sample model was made of an eight-node hexahedron reduced integration unit (C3D8R), whose unit number was 96. Two rigid blocks with same cross section without weight were set on the top and bottom of the model, which made the load uniformly distributed under cyclic load. The rigid block on the bottom was fixed. Cyclic load was applied on the upper rigid block. Stress artificial boundary was applied around the model, as shown in Fig. 8. Parameters for numerical calculation are shown in Table 2.

The relation curves between pore pressure ratio (μ_N / σ'_c) and cyclic number ratio (N/N_c) of undrained cyclic triaxial tests of Nanjing fine sand under different isotropic consolidation conditions are described in Fig. 9, with the corresponding numerical simulation results. The figure shows that with the gradual increase of cyclic number, the pore pressure finally developed to the initial effective confining pressure. From the overall shape of the curve, we can see that, under the same initial effective confining pressure, with the increase of axial dynamic shear stress ratio, the curve shape developed from S-type to hyperbola. The conclusion was in agreement with Binghui Wang's (Wang Bing-hui, 2011) summary of the transition about

Figure 8. Numerical mode of cyclic triaxial test.

Table 2. Parameters of numerical calculation.

Model type	Parameter	Parameter values	Model type	Parameter	Parameter values
Modified Davidenkov model parameters	Unit weight	21.2 kN/m ³	Pore pressure model parameters	u	0.444
	shear wave velocity	205.8 m/s		C_1	0.730
	A	1.02		C_2	0.475
	B	0.36		m	0.43
	u	0.49		n	0.62
	r_0	0.00038		k	0.0025

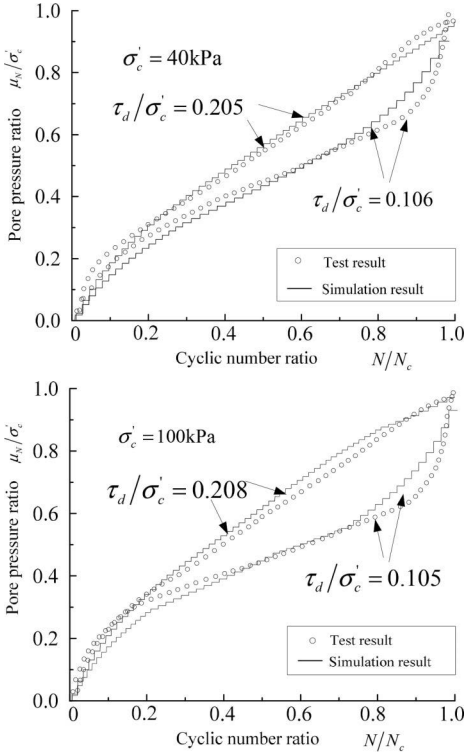

Figure 9. Development of pore pressure of cyclic triaxial test and numerical simulation.

pore pressure ratio development from type B to type A. With the increase of the initial effective confining pressure, pore pressure development regulation under the same (τ_d/σ'_c) of development basically remained unchanged.

Fig. 10 shows the axial strain curves of cyclic triaxial tests and numerical simulation under cyclic loading at constant amplitude with different initial effective confining pressures. Furthermore, with the increase of the initial effective confining pressure, the samples took longer time to reach the liquefaction state. Sample failures of cyclic triaxial

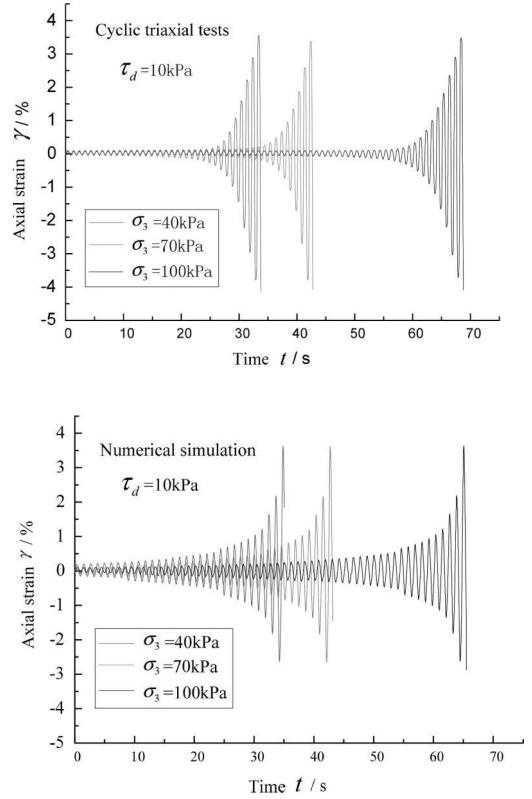

Figure 10. Time-history curves of strain in different initial confining pressure.

tests and numerical simulation were, at the same time, 35, 45, and 70 s, respectively. Both results were in accordance with the trumpet-shaped development regulation. The numerical simulation results in the initial stage of cyclic load are not almost unchanged as the triaxial test results, but slowly grew. In strain mutation stage, the simulation results were not as obvious as the results of triaxial tests. The simulation liquefaction timing and the strain amplitude of the sample model basically agreed with the results of triaxial tests.

6 CONCLUSION

- On the basis of the Davidenkov constitutive model modified by irregular loading and unloading criterion and the introduction of Byrne-modified Martin and Finn pore pressure model, as well as a large number of resonant column test data fitting, this paper proposed the modified formula of G_{\max} and γ_0 considering the different initial effective confining pressure. On account of the explicit module of ABAQUS platform, it realizes the subroutine development of the modified Davidenkov constitutive model with irregular loading and unloading criterion and the Byrne incremental model of pore water pressure. In order to get the parameters of Byrne pore pressure model of Nanjing fine sand, the saturated Nanjing fine sand drained cyclic triaxial tests were carried out. Undrained cyclic triaxial tests were also conducted for the same sand, and three-dimensional numerical simulation was conducted for the tests. The following conclusions are drawn:

1. The trends of relation curves between volumetric strain and cyclic number (N) of Nanjing fine sand and crystal silica sand are consistent basically. Under the cyclic loading of same shear strain amplitude, volumetric strain increases with the number of cycles. At the same cycle, the volumetric strain increased, while the shear strain amplitude increased.
2. As the cyclic number ratio increased, the pore pressure ratio (μ_N/σ'_c) increased gradually, and the pore pressure (μ_N) finally developed to the initial effective confining pressure (σ'_c). Under the same initial effective confining pressure, the shape of μ_N/σ'_c curve changed from S-type to hyperbola with the increase of axial dynamic shear stress ratio (τ_d/σ'_c). At the same cyclic shear stress ratio τ_d/σ'_c , as the initial confining pressure (σ'_c) increased, the pore pressure development was essentially constant, and the pore pressure development trend of simulation results and triaxial test results were basically the same.
3. Under the condition of invariable amplitude of cyclic loading, as σ'_c increased, the soil sample took more time to liquefy. The simulation liquefaction time basically agreed with the result of triaxial tests, and both results accorded with the trumpet-shaped development regulation. The axial strain in the initial stage of cyclic load in numerical simulation is not the same as the corresponding results in triaxial tests, which remain almost unchanged, but slowly grows; the strain mutation is not as obvious as the result of triaxial tests.

Urban ITS framework and essential parts of the ITS frame structure

Meng-qi Li, Zhen-hua Wang, Wei Wan & Ze-tao Jing
China Aerospace System Engineering Company, Beijing, China

ABSTRACT: Urban ITS systems have been constructed by different departments batch by batch and stage by stage at present; hence, there are many problems among them, such as mutual independence, difficulty of information sharing, and lack of top-level design. To resolve these problems, the method of urban ITS framework and important content of its construction is presented in this paper, which is based on the advanced information technologies such as big data. The framework includes six parts, including the data center, the efficient dispatching system, the convenient services, publishing system, and so on. The framework provides a reference and guideline for the urban ITS system design from the overall view of the city.

1 INTRODUCTION

Since the 1990s, China has made several achievements in the urban ITS construction in many cities, but not without problems. On the one hand, because of the lack of overall planning and top-level design, most ITS systems have so many problems, such as mutual independence, self-containment, lack of information sharing, and business collaboration. On the other hand, the new generation technologies, such as IOT, cloud computing, and big data, have developed rapidly. Meanwhile, new demands and requirements of the urban ITS construction are put forward. Therefore, not only how to build a more seamless-connected ITS systems, but also how to integrate the existing intelligent transportation systems and information resources to mining and applying have become new challenges. A new framework of the urban ITS system and its important construction contents are presented on the basis of the aerospace system engineering and the advanced information system architecture design method in developed countries. The objective of this paper is to provide a reference and guidance for the urban ITS construction of cities in China.

In the 1980s and 1990s, the United States, Japan, and the European Union have proposed the ITS framework (Wang, 2004). Meanwhile, the ITS framework of China is also proposed in the “Eleventh Five” period (Liu, 2004; Zhang, 2005), and the system framework effectively promoted the development of the ITS in various countries. However, because of the rapid development of the information technology, the urban intelligent transportation system framework has been difficult to adapt to the requirements based on new technologies and businesses. The urban ITS systems primarily constructed by government are the fastest growing and more mature e-government systems. With the large-scale construc-

tion of e-government and the development of new technologies, the United States, Britain, Australia, and other European countries have proposed different methods of e-government architecture design, such as Federal Enterprise Architecture (FEA) in the United States, the UK E-Government Interoperability Framework (E-GIF), the Australian Government architecture (AGA), the U.S. Global Information Grid (GIG) and other methods (Jin, 2008; Fang, 2007). In these methods, the United States has first begun to study the architecture design method of e-government, and is also the most advanced and mature one. Frameworks of other countries are referenced from ideas and methods of the FEA more or less. The above advanced information system design methods are referenced also by the paper.

2 URBAN INTELLIGENT TRAFFIC INFORMATION SYSTEM STATUS AND PROBLEMS

With the development of the information technology, integration of the urban intelligent transportation construction has become a major challenge and a strategic issue.

Information integration includes four aspects: information collection, information processing, information mining, and information publishing operations. Its aim is to achieve traffic information to optimize the allocation of resources to broaden the application field of information resources and maximize the value of information mining.

2.1 *Traffic information collection*

Traffic information is composed of static and dynamic traffic information. Specifically, dynamic traffic information currently collects operational

data including highways, public transportation information, long-distance passenger statistics, and rail and air data. Static traffic information focuses on the basic geographic information. Traffic information collection has some problems such as limited scope of the acquisition, lack of integration of information processing, and noncomprehensive information collection.

2.2 Processing and handling traffic information

Traffic information processing in accordance with the processing methods can be divided into two sites: collected traffic information within their decentralized processing application system and collected traffic information is aggregated to the data processing center for centralized processing. Traffic information system processes have the following problems: data sharing limitations, insufficient processing depth, lack of standards and process specifications, inadequate public service and interdepartmental applications, and lack of appropriate mechanisms and funding.

2.3 Use of traffic information

The traffic control department achieves several management functions by using processed traffic information such as transport command and control, traffic monitoring, traffic enforcement, and traffic information services. The current e-transport information mining degree is not deep enough, has information use limitations, and is a single source of information.

2.4 Traffic information release and operations

Traffic management departments can provide traffic information through a variety of ways of public traffic information, such as website, radio, mobile client, and roadside traffic guidance. This type of the problem, including traffic information services market, is not mature, lacks legal protection, and the operating system is not perfect.

3 THE URBAN IT FRAMEWORK

Urban Intelligent Transportation System mainly consists of many aspects: road traffic management, emergency roads, rails, transportation companies, traffic governments, e-charges, and so on. The definition of the level and relationship in urban ITS will play an important role for the future building. On this basis, this paper proposes a more scalable and advanced urban intelligent transportation system framework, namely “one data center, and five application systems” (the red by category data centers need to exchange information, shown in Figure 1), from the perspective of the overall city.

3.1 Construction of the urban traffic data center

A comprehensive data center can effectively coordinate the relationship between data centers and data exchange platform to achieve acquisition integration, intensive treatment, and the depth of excavation. Other modules can use sharing data in time from five system modules storage in a traf-

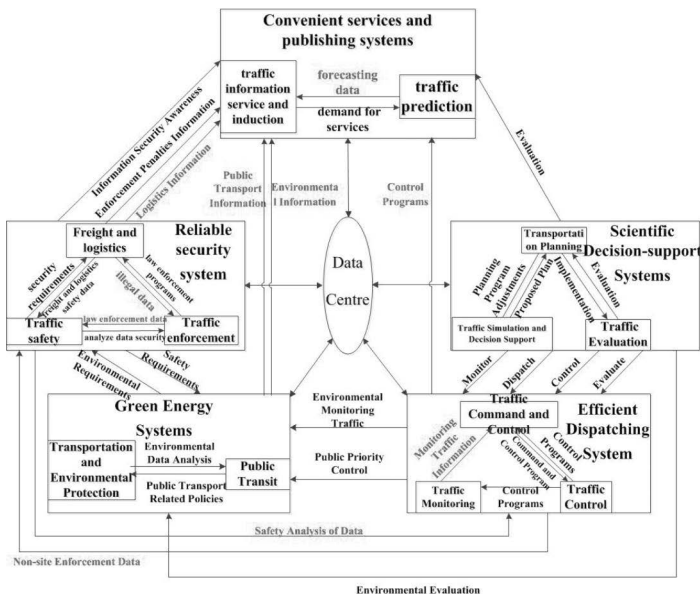

Figure 1. Top-level framework of urban IT.

fic data center. Meanwhile, the other data do not have to put in a data center, so modules can take full advantage of the resources within the system to process traffic information as well as reduce the pressure on the comprehensive traffic data center.

We constructed an urban transportation data center that meets the demands of national transport planning, construction, operation, management, and public transport information service. This data center integrates urban transportation data resources to achieve the purposes of storage, management, search, share, analysis, and publicizing of national traffic data resources. Furthermore, advanced ITS construction method will enhance the service quality of the city traffic management.

3.2 Efficient dispatching system

Urban road network has its own characteristics. Although increasing the construction of transport infrastructure can solve part of the traffic problem, it does not solve the problem fundamentally. Under the limited growth conditions of the road network infrastructure and minimal traffic operating costs, building an efficient dispatching system can improve the capacity of the largest possible pass through and rapidly respond to emergencies. A blameless and efficient dispatching system should include daily dispatch and emergency dispatching for major urgent events.

The relationship between dispatching system and external system is shown in Figure 2. Traffic departments draft control plan for the transportation program has to use comprehensive information. After the implementation of traffic control plans, the management needs to get evaluation data in time. On the basis of the above evaluations, the traffic control department can understand the method effectiveness. Traffic control plans also need to agree with the traffic information forecast and traffic information service and issue specific traffic control measures to the public by ways of forecasting and services.

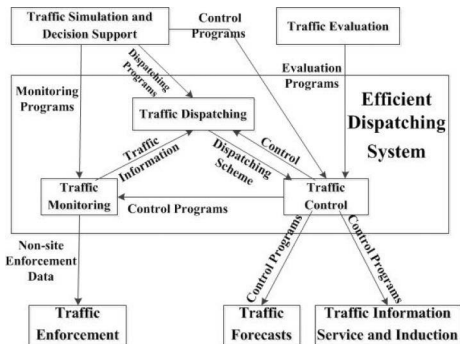

Figure 2. Efficient dispatching system.

3.3 Convenient services and publishing system

Convenient services and publishing system can provide convenient travel information services for the public by road-side traffic guiding panels or application programs. Meanwhile, this system can guide public to avoid traffic congestion.

3.4 Scientific decision support system

Scientific decision support system includes traffic simulation and decision support, transportation planning, and traffic evaluation. This system can not only propose quantitative assessment analysis of traffic scheduling management program, but also give analysis and mining report on historical traffic data, providing decision-making support for the basis of transportation infrastructure planning and construction or other studies.

3.5 Reliable security system

The number of traffic accidents increasing with the increasing number of vehicles in cities. Improving road safety and establishing a reliable security system is a long and complex process.

To ensure the operation coordination between all systems, the interlayer and intralayer data transmission require a unified specification in the Intelligent Transportation System. These specifications and system operation management together constitute the essential standards system. In addition, the unauthorized use of the Intelligent Transportation System, which is an information system that has a direct effect on the transport system, may seriously affect the normal operation of transportation systems or even cause inestimable confusions. Therefore, the entire Intelligent Transportation System should be subjected to comprehensive and strict control under the security system to prevent data theft, illegal system intrusion, and other issues.

3.6 Green energy system

Green environmental protection system can improve the quality of the environment and the satisfaction of urban transportation. This system is the inherent requirement of the whole society to achieve sus-

Figure 3. Green energy system.

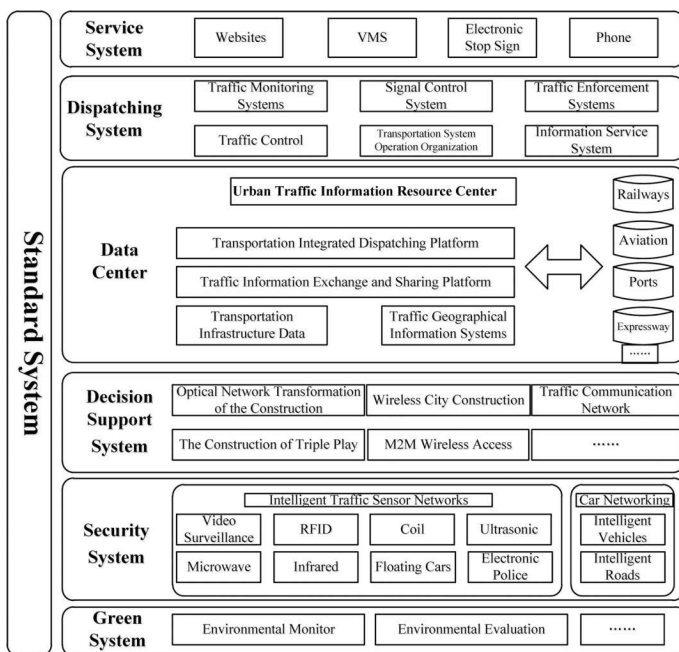

Figure 4. Application of urban ITS framework.

tainable development. Creating energy-saving and environmental protection systems should build an appropriate detection system that will use big data technologies to summarize the causes of pollution, put forward recommendations of environmental protection, and promote the construction of environmentally friendly transportation by means of information.

Transportation and environmental protection is responsible for the traffic pollution monitoring and supervision, mainly for monitoring emissions compliance, noise pollution, and dust pollution. Public transportation administration uses the surveillance to introduce the policy of traffic and environmental protection, set reasonable bus routes, and reduce rail traffic noise pollution. This system can effectively improve the quality of urban environment and create favorable conditions for the city's construction.

3.7 The application of urban ITS framework

Combining with the city's characteristics, the urban intelligent framework described in this paper has been utilized in its traffic system. It includes one data center and five systems (shown in Figure 4). The framework has been applied to intelligent traffic plan, design, and construction works in the city. It can effectively solve the problem presented in the second chapter.

4 CONCLUSIONS

To resolve the urban ITS construction problems, the new urban intelligent transportation system framework is proposed in this paper. The framework provides a reference and guidance to further research, plan, design, and construction of urban intelligent transportation system. However, due to space constraint, only the urban intelligent transportation system framework has been described in brief, and details of ITS system architectural design method and construction method based on this framework need further research.

ABSTRACT: According to the theory of modular design and module partition key technology, we design and develop a product module partition system, which is based on the included system management, product management, expert evaluation, and module partition. Taking the gearbox for example, here, we use the module division principle and the method proposed in this paper to divide its main parts into several modules. The experimental results have verified the feasibility and validity of this method, and we have preliminarily realized the engineering application of the product module partition method on the basis of function–principle–structure.

1 INTRODUCTION

Modular design takes the module as object and mainly includes module division, module planning, and module combination. Modular design technology first appeared in the early 20th Century. Since the concept of modular design was put forward in the 1950s, it has been applied in many fields, such as furniture and machine tools. After the 1970s, the modular design method in Chinese machine tool industry has gradually emerged and has been widely used in other industries (Gong, 2007). Pahl and Beitz (Pahl, 1996) thought that the modular design is used to complete the mapping from the demand domain to the functional domain and then complete the mapping from the functional domain to the domain based on the consideration of the performance of the modules. Li Yupeng (Li, 2011) aimed at modeling the difficulties of traditional module identification method, computed complexity, could not effectively deal with the evaluation data problem of fuzzy and uncertainty, and put forward the product module clustering method based on rough set. The evaluation data are transformed into the form of rough numbers to fuzzy cluster analysis. In the cluster graph, the module is divided according into upper and lower threshold values, which makes the data processing more objective. On the basis of the simulated annealing algorithm, Shan quan (Quan, 2007) integrated the population of the genetic algorithm

and proposed the module division method on the basis of improved simulated annealing algorithm, which combines the advantages of both, thus avoided the following shortcomings: the simulated annealing algorithm is difficult to operate, the efficiency is not high, and the genetic algorithm is easy to fall into the local optimal solution.

This paper takes the composition of the product components for the module object and considers the number of assembly and the relationship among the parts. With a gearbox as an example, we analyzed the Function–Principle–Structure (F-P-S) on the basis of the product module partition method and introduced the system of product module partition on the basis of F-P-S implementation.

2 PRODUCT MODULE PARTITION

2.1 *Product module partition principle and overall planning*

The most basic principle of module division is independent of function and structure. On the basis of functional requirements, it takes structure as the carrier to meet customers' needs and ultimately ensures that the strong correlation among the internal modules and the weak coupling among the modules. Another basic principle is the changing needs of customers, including the higher needs for quantity and quality. These higher needs will create products with more functions. The existing module partition

method (Quan, 2012) mainly includes two types: one is the function analysis method, which emphasizes the function of the module, and it is mainly used in the phase of requirement analysis and conceptual design; the other is to emphasize the independence of the module structure of the parts analysis method; this method is carried out mainly through the analysis of product components and structural correlation between parts and combined with other factors to complete the division of modules. Product module division process is summarized as: the establishment of the existing product structure parts information management database. According to the total function of product design code, the model is decomposed into subfunctions by F-P-S mapping model and the establishment of the functional structure of the product. The principle of each subfunction and its realization structure are analyzed, and the principle of division based on F-P-S is obtained. The function–principle–structure of the characteristics of indicators or related characteristics is quantified as a module division of the comprehensive evaluation of the data. Finally, through the fuzzy clustering method to achieve the cluster analysis of product components, we get the final module partition scheme. The process of product module partition is shown in Figure 1.

2.2 Product module partition method based on cluster analysis

The integrated correlation matrix is transformed into fuzzy equivalent matrix by using the transitive closure method (Wang, 2003). On the basis of the

fuzzy equivalent matrix, the parts of the product are clustered by the method of calculating the maximum correlation degree among the components.

First, the threshold of cluster analysis is determined. In the cluster analysis, the threshold value can be artificially set; however, there is some uncertainty in the selection of threshold. In this paper, by calculating the average value of the correlation distance among parts, as the threshold of cluster analysis, the formula for calculating the average correlation degree is:

$$K = \frac{\sum_{i=1}^n \sum_{\substack{j=1 \\ i \neq j}}^n d_{ij}^*}{n(n-1)} \quad (1)$$

Second, a pair of components with the largest correlation degree is calculated, and they are gathered together as a module. Each line represents a correlation between one part and other parts of the $n-1$, and $d_{ii}^* = 1 (i = 1, \dots, n)$. Therefore, by calculating the largest element in the fuzzy equivalent matrix D^* , the formula to calculate the parts x_p, x_q with the largest correlation degree is:

$$T_{(p,q)} = \max \{d_{ij}^* (i = 1, 2, \dots, n; j = 1, 2, \dots, n; i \neq j)\} \quad (2)$$

Because the parts x_p, x_q correlation is the largest, the module is denoted as $M(p,q)$.

The processing method for the original matrix is: First, paddle the p,q line and the p,q column in the matrix D^* . Second, calculate the relationship

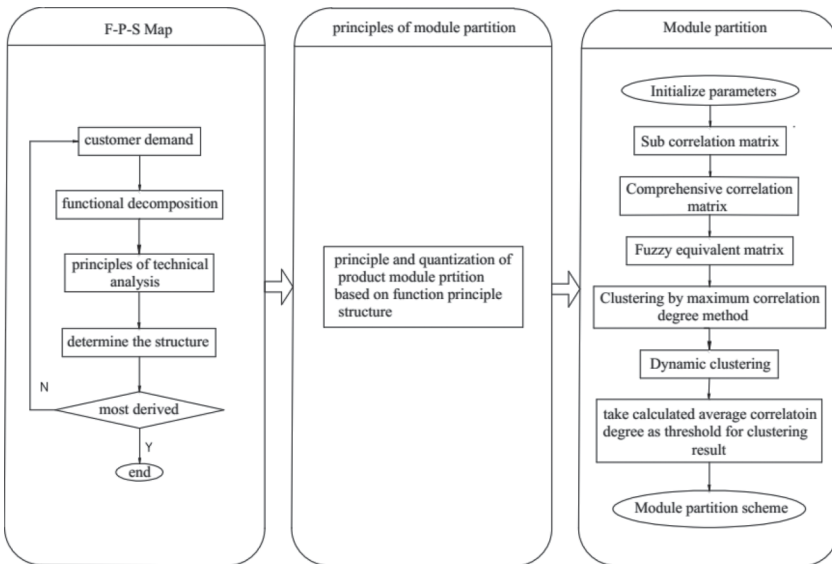

Figure 1. Product module partition process.

distance between the module $M(p,q)$ and the rest of the parts as:

$$d_{iM}^* = \max\{d_{ip}^*, d_{iq}^* (i = 1, 2, \dots, n; i \neq p \neq q)\} \quad (3)$$

Third, add the module $M(p,q)$ to the matrix and take the relationship distance d_{iM}^* between the module $M(p,q)$ and the remaining parts as an element that the module $M(p,q)$ is in the matrix. Therefore, the order of the new matrix after processing the original matrix is $n-1$.

Then, use the second step of the algorithm to calculate the largest correlation degree of a pair of components or modules and put them into a module. In the second step, the processing for $n-2$ order matrix is determined by using the original matrix.

Finally, with the average correlation degree K as threshold, according to the second step and the third step cycle operation, until the largest correlation degree is less than the average correlation matrix K , terminate the process of clustering algorithm. The resulting matrix is the result of cluster analysis as well as module partition.

3 THE SYSTEM DEVELOPMENT BACKGROUND AND THE OVERALL FRAMEWORK OF THE SYSTEM

For system implementation, the choice of development platform is very important. The development platform can realize the algorithm and play a powerful role in computer-aided product design. The design in this paper, based on the F-P-S of the product module partition of the system algorithm, mainly uses Microsoft's mainstream development tool Microsoft Visual studio 2005. This tool has superior application range and execution efficiency. System development platform and environment selection are as follows:

The hardware configuration: core T5870; 1024 MB of memory; 256 MB of memory

Software configuration: Windows 7 Operating System; Microsoft Visual studio 2005

Management module includes system management submodule and product submanagement module. System management module mainly carries out the management tasks of the personnel, the system involves the process of expert score, the system management module achieves the expert's account number, password, and permissions management, and product management module is mainly composed of parts of the product information management, including the entry, query, delete, and update function. The management module is to provide the necessary information and data support for the main module.

Figure 2. System integrated framework.

Main modules include expert evaluation submodule and module partition submodule. Expert evaluation module scores mainly through the experts on the correlation between parts, and factor score includes three aspects: the function-principle-structure score results in real-time display, and data can be queried, modified, deleted. The submodule mainly provides expert evaluation results and clustering analysis of parts using fuzzy clustering algorithm, and displays the final module partition results.

4 SYSTEM FUNCTION REALIZATION

In order to facilitate the evaluation of information between parts statistics and calculation, in this paper, with the aid of computer-aided methods and combining with the proposed product module of the F-P-S based on the developed theoretical knowledge and the F-P-S product module partition system, the system mainly consists of management module and the main module. The main module is mainly used for the cluster of the product module. The management module mainly manages the data in the process of product division. Both seamless integration and information sharing in the whole system, to a large extent, improve the efficiency of product modular design.

4.1 Management module

The management module includes system management submodule and product management submodule. The system management module includes two parts: user login and personnel management. User login part includes user authority identification and determines user's permissions; personnel management part allows system users to add, delete, and modify permissions and passwords. Product management submodule mainly manages the relevant information of the components of products. The add part is mainly to add parts' name which is composed of the structure of the parts, parts drawing number, component properties, parts material, procurement company information, and so on.

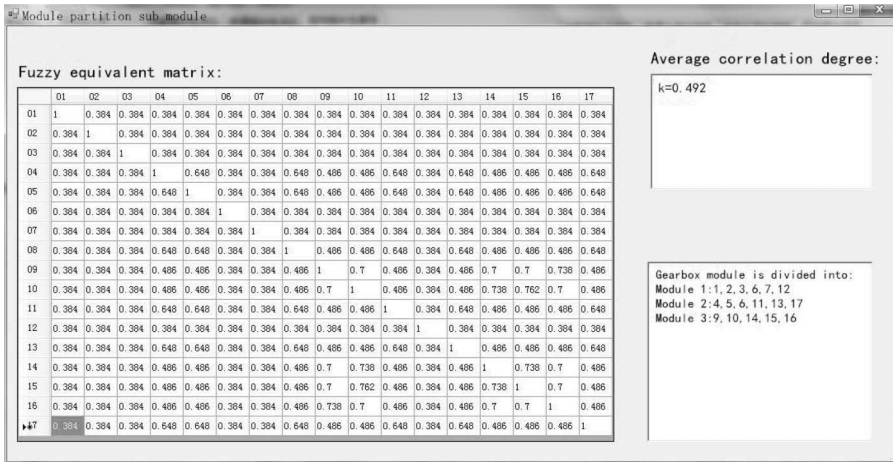

Figure 3. Module cluster analysis interface.

4.2 Main module

The main module of product module division system based on F-P-S consists of two parts: expert evaluation submodule and module partition submodule.

4.2.1 Expert evaluation submodule

After the expert raters choose two parts, there comes the need to score, the score of each of the two parts between the function correlation, structure correlation, and principle correlation. Evaluation data would be displayed in real time by reading documents based on F-P-S module division principle and quantitative methods. Experts determine the product function, the principle, and the structure in to evaluate weight. In the construction of the integrated correlation region enter function, principle, and structure of weight value, the system will automatically calculate the two parts between the integrated correlation results of real-time display. Then, the cycle is completed by evaluating each two component and the final comprehensive correlation matrix is obtained.

4.2.2 Module partition submodule

The system applies the method of transitive closure, transforms the comprehensive correlation matrix into fuzzy equivalence matrix, and finally displays the transformation, thereby completing the matrix transformation process. To calculate the fuzzy equivalence matrix element, the average correlation degree is obtained. The matrix interface is shown in Figure 3.

5 CONCLUSION

In this paper, we introduced the product module division system, design platform, development

tools, management module, and main module on the basis of function-principle-structure. Furthermore, the relationship between parts and components based on function, principle and structure was evaluated. On the basis of the cluster analysis of the comprehensive correlation matrix, the division of product modules based on function-principle-structure is realized. The effectiveness of this method is verified by the example of the division of the gearbox. The product module partition method can provide support to product design on the basis of modular, and the further research works will focus on the evaluation of the product module partition results.

Parameter optimization of space truss and aerospace load viscoelastic damping composite structure

Zhenwei Zhang & Peng Wang

School of Mechanics, Northeastern University, Shenyang, China

Haitao Luo

Shenyang Institute of Automation, Chinese Academy of Sciences, Shenyang, China

ABSTRACT: The acceleration response value of space truss and aerospace load structure is exceeded in the acceptance level vibration test. The method of applying the viscoelastic damping layer is used to reduce the vibration of the space truss and the aerospace load structure. The test results show that the damping effect is obvious, and it is needed to determine the structure parameters and material parameters of the viscoelastic damping layer. The structural parameters include the location of the viscoelastic damping layer, the thickness of the damping layer, and the thickness of the constrained layer. The material parameters include the shear modulus of the damping layer, damping factor of the damping layer, and the selection of the constrained layer. With index of damping factor and the resonance frequency of vibration, the influence of structural parameters and material parameters on the damping effect of viscoelastic damping materials is obtained by the optimization and comparison of damping factors.

1 INTRODUCTION

According to the practical need, the method of applying the viscoelastic damping layer (Shen, 2006) to the aerospace load box structure is used to reduce the vibration. In this paper, the constrained damping layer is adopted, which is composed of damping layer and constrained layer. Viscoelastic damping layer is in the form of simple, light weight, easy to paste, excellent damping performance, does not need to change the existing structure, the use of less material will be able to achieve a larger damping effect (Wang, 1990).

For a viscoelastic damping scheme, it needed to determine the structural parameters and material parameters of viscoelastic damping layer. The structural parameters include the location of the viscoelastic damping layer, the thickness of the damping layer, and the thickness of the constrained layer. The material parameters include the shear modulus of the damping layer, the damping factor of the damping layer, and the selection of the constrained layer. In general, the material of the general constrained layer is the same as that of the structure layer. For the space truss and aerospace load structure, the 2A12 plate is selected as the constrained layer. The existence of the viscoelastic damping layer, on the one hand, has a great influence on the quality and stiffness of the

structure, thus affecting the natural frequency of the structure. On the other hand, due to the viscoelastic damping layer is damping material, so the damping characteristic of the whole structure will be affected, and the resonance response peak and damping factor of the whole structure will be greatly affected.

2 EVALUATION INDEX OF VIBRATION REDUCTION EFFECT

The fundamental frequency of the vibration reflects the vibration characteristics of the structure. High vibration frequency shows that the structure stiffness is large, then the vibration is easy to decay. Therefore, the fundamental frequency of vibration from one side reflects the damping effect of the structure is good or bad. The damping factor (Yang, 2011) as an index to evaluate the damping effect because viscoelastic damping vibration reduction method is based on the form of no significant change in structure to increase the damping of the structure, so the damping level can accurately reflect how the damping effect of the scheme. The resonance response peak value of the structure is another index of evaluating the effect of vibration reduction because the resonant response of the structure is greatly influenced

by the damping. The greater the damping is, the smaller the resonance response is, the smaller the damping is, the greater the resonance response is. In this paper, the vibration frequency and damping factor is the evaluation index of vibration reduction effect.

3 CALCULATION OF DAMPING FACTOR

Damping factor is obtained firstly for simple beam and plate structure through theoretical analysis (Ross, 1959; Mead, 1969). Johnson (Johnson, 1982) proposed using modal strain energy method to calculate damping factor, which makes it possible to use the finite element software to calculate the damping factor. The method of finite element software to calculate the damping factor has a direct frequency response method, modal strain energy method (Ren, 2004; Zhao, 2013) and complex eigenvalue method. In this paper, the complex eigenvalue method (Rikards, 1993) is used to calculate the damping factor. By using the complex eigenvalue calculation function provided by MSC/NASTRAN, it can be more convenient to determine the damping factor of the structure. By using the complex modulus model, the constitutive relation of viscoelastic materials is:

$$\begin{aligned}\sigma_0 &= E^*(\omega)\varepsilon_0 = [E'(\omega) + iE''(\omega)]\varepsilon_0 \\ &= E'(\omega)[1 + i\eta(\omega)]\varepsilon_0 \\ \eta(\omega) &= \frac{E''(\omega)}{E'(\omega)}\end{aligned}$$

In the formula, σ_0 and ε_0 represent the time-varying harmonic stress respectively. $E''(\omega)$ is complex modulus of materials. $\eta(\omega)$ is material damping factor. The free vibration equation of the composite structure is:

$$\begin{aligned}M\ddot{u}^* + K^*u^* &= 0 \\ K^* &= K + iK'\end{aligned}\quad (1)$$

In the formula, M is mass matrix. K^* is complex stiffness matrix. K and K' represent the real part and imaginary part of the complex stiffness matrix respectively. u^* is displacement. To make $u^* = \phi^* e^{i\omega^* t}$, formula (1) can be transformed into:

$$K^*\phi^* = \lambda^* M\phi^* \quad (2)$$

In the formula, ω^* is complex frequency. ϕ^* is complex feature vector. λ^* is complex eigenvalue. After solving formula (2) can be obtained:

$$\lambda^* = \lambda + i\lambda'$$

Thus, the n-th order modal damping factor η_n^* :

$$\eta_n = \frac{\lambda_n'}{\lambda_n}$$

This method is more intuitive and clear, and can describe the dynamic mechanical properties of viscoelastic materials very well (Bagley, 1979).

4 THE COMPOSITION OF SPACE TRUSS AND AEROSPACE LOAD STRUCTURE

The simulation model of space truss and aerospace load is mainly composed of the following parts, as shown in Figure 1. They are: box structure, long tube, short tube, connector, connection box, constrained damping layer and tooling.

Here, the exterior of the box structure is plate structure, and the interior is a hollow structure. The box structure is composed of the upper and lower cover plate, left and right cover plate, the front and back cover plate. Each two faces are connected by screws. The viscoelastic damping layer on the outer wall of the box structure is a constrained damping layer, as shown in Figure 2. The box structure is connected with the four connection boxes at the top of space truss through screws. In addition to the four surfaces in contact with the box structure, it has a diameter of 18 mm and a depth of 2 mm circular recess at central position of each remaining surface, for positioning the connector, as shown in Figure 3.

5 PARAMETER OPTIMIZATION OF VISCOELASTIC DAMPING COMPOSITE STRUCTURE

In order to study the influence of damping layer thickness on the damping effect, take six groups of thickness values in the range of 0.25 mm–2.5 mm. The resonance frequency and damping factor increment obtained by the Nastran complex eigenvalue method are shown in Table 1. List the first six orders damping factor values. In order to express the influence of the damping layer thickness on the resonant frequency and damping factor, draw data from the table into a graph. Wherein the horizontal axis is the resonance frequency, and the vertical axis is the damping factor increment.

It can be seen from the figure that the resonance frequency decreases with the increase of the thickness of the damping layer. It can be seen from the data in table, when the damping layer thickness is 0.25 mm, the fundamental frequency is 23.7 Hz, the thickness is 2.5 mm, the fundamental frequency is 23.1 Hz. By referring to the second order to sixth order data, we can see that with the increase of the thickness of the damping layer, the decrease of the resonance frequency is not large. When the thickness of the constrained layer is constant, with the increase of the thickness of the damping layer, the damping factor increases. The reason is that the thickness of the damping layer increases and the energy consumption in the process of vibration increases. Then study the influence of the thickness of the constrained layer on the vibration damping effect, take six groups of thickness values in the range of 0.5 mm–3 mm, and the thickness of the damping layer is constant.

It can be seen from the figure that the resonance frequency decreases with the increase of the thickness of the constrained layer. It can be seen from the data in table, when the damping layer thickness is 0.5 mm, the fundamental frequency is 24.8 Hz, the thickness is 3 mm, the fundamental frequency

is 22.8 Hz. By referring to the second order to sixth order data, we can see that with the increase of the thickness of the constrained layer, the decrease of the resonance frequency is not large. When the thickness of the damping layer is constant, with the increase of the thickness of the constrained layer, damping factor firstly increases and then decreases, and the damping factor reaches the maximum when the thickness of the constrained layer is 2 mm. The reason is that the constrained layer thickness increases, and the restraining ability of the constrained layer is increased, damping layer deformation is bigger, the energy consumed in the vibration process is more, and the damping factor increases. With the increase of the thickness of the constrained layer, the mass increases and plays a leading role, and the damping factor decreases.

Next, the influence of damping layer material on the damping effect is studied, and the shear modulus of the damping layer are chosen as the material property parameters. Viscoelastic damping materials

are generally a kind of high molecular polymer, mainly rubber and plastic, shear modulus is less than 20 MPa. Take six groups of data in the range of 0.25 Mpa–15 Mpa for research and analysis.

It can be seen from the figure that the resonance frequency increases with the increase of the shear modulus of damping layer. It can be seen from the

data in table, when the shear modulus of damping layer is 0.25 Mpa, the fundamental frequency is 23.5 Hz, the shear modulus is 15 Mpa, the fundamental frequency is 23.6 Hz. By referring to the second order to sixth order data, we can see that with the increase of the shear modulus of damping layer, the increase of the resonance frequency is not large.

With the increase of the shear modulus of damping layer, damping factor firstly increases and then decreases, and the damping factor reaches the maximum when the shear modulus of damping layer is 1.5 Mpa. The reason is that the shear modulus of damping layer increases, on the one hand, the stiffness of space truss and aerospace load structure is gradually increased, the relationship between the frequency and the stiffness of the structure shows that the fundamental frequency of the structure increases gradually. On the other hand, the stiffness of the damping material is gradually increasing, and the deformation of the damping layer decreases gradually. The damping factor of the structure is related to the strain energy of the damping layer, and the strain energy is proportional to the stiffness and strain. Therefore, under the common influence of the increasing stiffness and the decreasing of the strain, the damping factor appears to increase first and then decrease.

The placement of constrained damping layer is an important aspect of constrained damping layer optimization design. Because the constrained damping layer is to rely on the energy dissipation of the damping layer to achieve the vibration of the structure. The constrained damping layer is applied to the different locations to generate different modal strain energy distribution, its energy dissipation is also different, which will affect the vibration reduction effect. In this paper, the constrained damping layer is pasted on five different locations as shown in Figure 7.

Figure 9. Modal strain energy distribution of eight order to ten order.

mum in position 3. In order to analyse the reasons, the modal strain energy distribution is investigated. at first. According to the results of modal analysis, in the first ten orders modes, the vibration mode of the space load box is in the order of eighth to tenth. The modal strain energy distribution of the three order is listed.

It can be concluded from the variation law of damping factor at different position of constrained damping layer and position diagram of modal strain energy: The greater the modal strain energy is, the greater the damping factor is. The reason is that the constrained damping layer is applied to the position where the modal strain energy is larger, and the shear deformation of the damping layer is large in the course of the vibration of the structure, the energy consumption is large, the damping factor of the structure is big, the resonance response peak is small, and the effect of vibration reduction is good. Therefore, the position where the modal strain energy is larger should be chosen to paste constrained damping layer in the optimization process.

6 CONCLUSION

1. When the thickness of the constrained layer is constant, the thickness of the damping layer is in the range of 0.25 mm–2.5 mm, with the increase of the thickness of the damping layer, the damping factor increases.
2. When the thickness of the damping layer is constant, the thickness of the constrained layer is in the range of 0.5 mm–3 mm, and damping factor increases first and then decreases with the increase of the thickness of the constrained layer.
3. The shear modulus of the damping layer gradually increased from 0.25 MPa to 15 MPa. The damping factor of the structure is related to the strain energy of the damping layer, and the strain energy is proportional to the stiffness and strain. Therefore, under the common influence of the increasing stiffness and the decreasing of the strain, the damping factor appears to increase first and then decrease.
4. The constrained damping layer is applied to the position where the modal strain energy is larger, the more energy is consumed by the damping layer, the greater the damping factor is, the more obvious the effect is.

J.Y. Wu

State Key Laboratory of Subtropical Building Science, South China University of Technology, Guangzhou, China

ABSTRACT: Microplane theory is a class of general approach to establish the three-dimensional constitutive relation of materials from the simpler one- or two-dimensional behavior on the generic planes with predefined spatial orientations. Although successfully implemented, verified, and applied to almost all types of materials, the theoretical aspects of microplane theory is still an open issue and further investigations are necessary. Within the framework of irreversible thermodynamics, we proposed a unified microplane theory in this paper. A detailed description of the general formulation, including evolution laws of the involved internal variables derived from the principle of maximum dissipation, was presented. As illustrative examples, the microplane elastoplastic, damage, and combined elastoplastic damage models were derived as the special cases of the proposed unified theory. The predicted results under cyclic uniaxial compression and biaxial compression show that the proposed theory is capable of describing the nonlinear behavior of concrete under dominant compression. This paper is the first step of the research work aiming to develop a thermodynamically consistent microplane model for concrete.

1 INTRODUCTION

Microplane theory is a class of general approach to construct a three-dimensional constitutive relation of materials from the simpler one- or two-dimensional behavior on the generic planes with predefined spatial orientations. Although the word “microplane” was coined by Bažant and Oh (1983) to refer in particular to the kinematically constrained models, the microplane theory can be traced back to the classical elastoplastic concept of Mohr–Coulomb-type failure envelope for a generic plane (Mohr 1900). The slip theory of plasticity for crystalline metals (Taylor 1938, Batdorf & Budiansky 1949) and the multilaminate model for fractured rocks (Zienkiewicz & Pande 1977) can be viewed as the special cases of the generalized microplane theory, although the static constraint was adopted in these models.

Although the (generalized) microplane theory has been successfully implemented, verified and applied to almost all types of ductile, brittle, or quasi-brittle materials, the theoretical aspects of the microplane theory is still an open issue and further investigation is required. The interrelations between microplane models and the classical disciplines of solid mechanics, such as plasticity and damage mechanics, have been discussed in detail

by Carol et al. (1991, 1997). It was only recently that the earlier versions of microplane models have been found to be thermodynamically inconsistent, and during some loading cases, negative dissipations would be produced (Carol et al. 2001). To eliminate this deficiency, a new thermodynamically consistent microplane damage model was proposed by Kuhl et al. (2001) and further elaborated in Wu (2009); however, the capability of fitting the test data of concrete cannot be guaranteed.

Noticing the above facts, we aim to develop a new microplane model, which is not only capable of good data fitting but thermodynamically consistent. This paper is the first step of this work, in which a unified microplane theory was proposed within the framework of irreversible thermodynamics. The general formulation, including the consistent evolution laws of the involved internal variables, was presented in detail. As illustrative examples, by adopting different microplane unloading/reloading stiffness, the microplane elastoplastic, damage, and combined elastoplastic damage models were derived as the special cases of the proposed theory. Finally, the proposed model was applied to concrete under cyclic uniaxial compression and biaxial compression, respectively, and the numerical predictions were also presented to preliminarily verify its validity.

2 GENERAL FORMULATION

2.1 Kinematic and kinetic settings

Let the configuration occupied by a solid with reference position vector x in $\mathbb{R}^{n_{\text{dim}}}$ be denoted by $\mathcal{B} \subset \mathbb{R}^{n_{\text{dim}}}$. The boundary $\partial\mathcal{B}$ is subdivided into two disjoint parts: $\partial\mathcal{B} = \partial\mathcal{B}_u \cup \partial\mathcal{B}_t$ with $\partial\mathcal{B}_u \cap \partial\mathcal{B}_t = \emptyset$. In solid \mathcal{B} , the displacement fields are denoted by $\mathbf{u} : \mathcal{B} \subset \mathbb{R}^{n_{\text{dim}}}$. The macroscopic stress and symmetric strain tensors are introduced as $\boldsymbol{\sigma} : \mathcal{B} \rightarrow \mathbb{R}^{n_{\text{dim}} \times n_{\text{dim}}}$ and $\boldsymbol{\varepsilon} : \mathcal{B} \rightarrow \mathbb{R}^{n_{\text{dim}} \times n_{\text{dim}}}$, respectively. Upon the assumption of infinitesimal strains, the macroscopic strain tensor $\boldsymbol{\varepsilon}$ is defined as the symmetric part of the displacement gradient $\nabla\mathbf{u}$:

$$\boldsymbol{\varepsilon} = \nabla^{\text{sym}}\mathbf{u} \quad (1)$$

The macroscopic strain tensor $\boldsymbol{\varepsilon}$ is usually decomposed into the following additive form:

$$\boldsymbol{\varepsilon} = \boldsymbol{\varepsilon}_{\text{vol}} + \boldsymbol{\varepsilon}_{\text{dev}} \quad (2)$$

with the macroscopic volumetric and deviatoric strain tensors, $\boldsymbol{\varepsilon}_{\text{vol}}$ and $\boldsymbol{\varepsilon}_{\text{dev}}$, respectively, given by

$$\boldsymbol{\varepsilon}_{\text{vol}} = \mathbb{I}_{\text{vol}} : \boldsymbol{\varepsilon}, \quad \boldsymbol{\varepsilon}_{\text{dev}} = \boldsymbol{\varepsilon} - \boldsymbol{\varepsilon}_{\text{vol}} = \mathbb{I}_{\text{dev}} : \boldsymbol{\varepsilon} \quad (3)$$

where \mathbb{I}_{vol} and \mathbb{I}_{dev} denote the corresponding symmetric fourth-order volumetric and deviatoric projection operators:

$$\mathbb{I}_{\text{vol}} = \frac{1}{3}\mathbf{I} \otimes \mathbf{I}, \quad \mathbb{I}_{\text{dev}} = \mathbb{I} - \mathbb{I}_{\text{vol}} = \mathbb{I} - \frac{1}{3}\mathbf{I} \otimes \mathbf{I} \quad (4)$$

According to the kinematic constraint, the volumetric and deviatoric strain vectors on a specific microplane (represented by its unit normal vector \mathbf{n}), e_{vol} and e_{dev} , are determined by:

$$e_{\text{vol}} = \mathbf{n} \cdot \boldsymbol{\varepsilon}_{\text{vol}} = e_{\text{v}}\mathbf{n}, \quad e_{\text{dev}} = \mathbf{n} \cdot \boldsymbol{\varepsilon}_{\text{dev}} = e_{\text{D}}\mathbf{n} + e_{\text{T}} \quad (5)$$

with the microplane volumetric strain e_{v} , deviatoric strain e_{D} , and tangential strain e_{T} resolved as the projections of the macroscopic strain tensor:

$$e_{\text{v}} = \mathbf{V} : \boldsymbol{\varepsilon}, \quad e_{\text{D}} = \mathbf{D} : \boldsymbol{\varepsilon}, \quad e_{\text{T}} = \mathbf{T} : \boldsymbol{\varepsilon} \quad (6)$$

where the projection tensors \mathbf{V} , \mathbf{D} , and \mathbf{T} are expressed as:

$$\mathbf{V} = \frac{1}{3}\mathbf{I}, \quad \mathbf{D} = \mathbf{n} \otimes \mathbf{n} - \frac{1}{3}\mathbf{I}, \quad \mathbf{T} = \mathbf{n} \cdot \mathbb{I} - \mathbf{n} \otimes \mathbf{n} \otimes \mathbf{n} \quad (7)$$

It is more convenient to express the microplane tangential strain vector e_{T} as the product of its magnitude e_{T} and its unit vector \mathbf{I}_{T} :

$$e_{\text{T}} = e_{\text{T}}\mathbf{I}_{\text{T}}, \quad e_{\text{T}} = |e_{\text{T}}| = \sqrt{e_{\text{T}} \cdot e_{\text{T}}}, \quad \mathbf{I}_{\text{T}} = \frac{e_{\text{T}}}{e_{\text{T}}} \quad (8)$$

The macroscopic stress tensor ($\boldsymbol{\sigma}$) is specified by the constitutive equation $\boldsymbol{\sigma}(\boldsymbol{\varepsilon}, \boldsymbol{\alpha})$ and satisfies the balance of linear momentum at equilibrium:

$$\text{div } \boldsymbol{\sigma} + \mathbf{f} = \mathbf{0} \quad (9)$$

for the body force \mathbf{f} in the domain \mathcal{B} , with $\boldsymbol{\alpha}$ denoting the set of internal variables (including the damage and plastic internal variables in this paper). In contrast to microplane strain components, the conjugate microplane stress components on the microplane cannot in general be equal to the projections of the macroscopic stress tensor $\boldsymbol{\sigma}$ if the microscopic strain components represent the projection of macroscopic strain tensor $\boldsymbol{\varepsilon}$. Thus, static equivalence or equilibrium between the micro and macro levels, here called the micro-macro homogenization formulation, has to be enforced in the weak form.

2.2 Elastoplastic damage model in strain space

In the formulation of strain space plasticity, the stress tensor $\boldsymbol{\sigma}$ is expressed as the difference between the reversible elastic part $\boldsymbol{\sigma}^e$ and the permanent plastic part $\boldsymbol{\sigma}^p$:

$$\boldsymbol{\sigma} = \boldsymbol{\sigma}^e - \boldsymbol{\sigma}^p \quad (10)$$

where the elastic stress $\boldsymbol{\sigma}^e$ is related to the strain tensor $\boldsymbol{\varepsilon}$ by the generalized Hookean law:

$$\boldsymbol{\sigma}^e = \mathbb{E} : \boldsymbol{\varepsilon}, \quad \boldsymbol{\varepsilon} = \mathbb{C} : \boldsymbol{\sigma}^e \quad (11)$$

with \mathbb{E} and $\mathbb{C} = \mathbb{E}^{-1}$ being the unloading stiffness and compliance tensors, respectively. For a pure elastic degradation (fracturing, damage, etc.) material, we have, $\mathbb{E} = \mathbb{E}^{\text{sec}}$ with \mathbb{E}^{sec} representing the secant stiffness. However, for a pure elastoplastic material, the unloading stiffness \mathbb{E} is the same as the elasticity tensor \mathbb{E}^0 :

$$\mathbb{E}^0 = \frac{E^0}{1-2\nu^0}\mathbb{I}_{\text{vol}} + \frac{E^0}{1+\nu^0}\mathbb{I}_{\text{dev}} \quad (12)$$

where E^0 is Young's modulus and ν^0 is Poisson's ratio.

The differentiation of stress (11)₁ to time yields the following rate form constitutive relation:

$$\dot{\boldsymbol{\sigma}} = \mathbb{E} : \dot{\boldsymbol{\varepsilon}} + \dot{\mathbb{E}} : \boldsymbol{\varepsilon} - \dot{\boldsymbol{\sigma}}^p = \dot{\boldsymbol{\sigma}}^{\text{co}} - \dot{\boldsymbol{\sigma}}^{\text{cr}} \quad (13)$$

where $\dot{\boldsymbol{\sigma}}^{\text{co}}$ is the continuum stress rate, $\dot{\boldsymbol{\sigma}}^{\text{d}}$ is the degradation stress rate, and $\dot{\boldsymbol{\sigma}}^{\text{cr}}$ is the cracking stress rate, which are defined by:

$$\dot{\sigma}^{\text{co}} = \mathbb{E} : \dot{\boldsymbol{\varepsilon}}, \quad \dot{\sigma}^{\text{d}} = -\mathbb{E} : \dot{\boldsymbol{\varepsilon}}, \quad \dot{\sigma}^{\text{cr}} = \dot{\sigma}^{\text{d}} + \dot{\sigma}^{\text{p}} \quad (14)$$

Herein, the continuum stress rate ($\dot{\sigma}^{\text{co}}$) is the stress rate that would be obtained by preventing the microcracks from evolution further, whereas $\dot{\sigma}^{\text{cr}}$ is the decrease or relaxation of the incremental elastic behavior due to the microcracks evolution, consisting of two parts: (i) the degradation stress rate ($\dot{\sigma}^{\text{d}}$) that is recoverable and (ii) the irreversible plastic strain rate ($\dot{\sigma}^{\text{p}}$). In the 1-D case, the above definitions of the continuum, damage, and cracking stress rates are illustrated in Fig. (1). It is worth noting that Eq. (13) is rather similar to the counterpart in the strain space elastoplasticity. However, the constant elastic isotropic stiffness (\mathbb{E}^0) in the later formulation is replaced by the variable stiffness tensor (\mathbb{E}) herein, which means $\sigma^{\text{e}} \neq \sigma^{\text{co}}$.

Because of the evolution of microcracks, the concrete-like quasi-brittle material exhibits both the stiffness degradation and the permanent irreversible deformations or the elastoplastic coupling referred in the literature (Dafalias 1977; Han & Chen 1986). Therefore, to complete the entire model, we have to also give the evolution laws for the stiffness. This would be a rather difficult job if a tensor invariant-based macroscopic constitutive model (e.g., plasticity, damage mechanics, or their combinations) is used. Comparatively, within the framework of microplane theory, because the macroscopic properties of material can be determined as the integral or weighted summation of

the contributions from all the predefined microplanes over, we can easily solve this problem.

2.3 Thermodynamics description

For any isothermal and pure mechanical process, the second law of thermodynamics reads the following Clausius–Duhem inequality:

$$D = \boldsymbol{\sigma} : \dot{\boldsymbol{\varepsilon}} - \dot{\bar{\psi}} = \dot{\psi} - \boldsymbol{\varepsilon} : \dot{\boldsymbol{\sigma}} \geq 0 \quad (15)$$

where D is the energy dissipation during the process to be considered; the Gibbs Free Energy (GFE) (ψ) is related to the Helmholtz Free Energy (HFE) ($\bar{\psi}$) by the classical Legendre transformation:

$$\bar{\psi} + \psi = \boldsymbol{\sigma} : \boldsymbol{\varepsilon} \quad (16)$$

A standard assumption is the existence of a macroscopic GFE potential of material in isothermal conditions:

$$\psi = \psi(\boldsymbol{\sigma}^{\text{e}}, \boldsymbol{\phi}, \boldsymbol{q}) = \psi^{\text{co}}(\boldsymbol{\sigma}^{\text{e}}, \boldsymbol{\phi}) - \psi^{\text{cr}}(\boldsymbol{q}) \quad (17)$$

where the continuum GFE potentials (ψ^{co} and ψ^{cr}) are assumed to be decoupled, where $\boldsymbol{\phi}$ is the set of damage variables that characterize the stiffness degradation and \boldsymbol{q} is a given set of stress-like internal variables that fully describe the irreversible plastic deformations. For the hyperelastic material, the continuum GFE potential of the material (ψ^{co}) is equal to the continuum HFE potential ($\bar{\psi}^{\text{co}}$):

$$\psi^{\text{co}} = \frac{1}{2} \boldsymbol{\sigma}^{\text{e}} : \mathbb{C}(\boldsymbol{\phi}) : \boldsymbol{\sigma}^{\text{e}} = \frac{1}{2} \boldsymbol{\varepsilon} : \mathbb{E}(\boldsymbol{\phi}) : \boldsymbol{\varepsilon} = \bar{\psi}^{\text{co}} \quad (18)$$

In the microplane theory, the continuum HFE potential ($\bar{\psi}^{\text{co}}$) (or the equivalent GFE potential ψ^{co}) can be expressed as the integral of its microplane counterpart $\bar{\varphi}^{\text{co}}$:

$$\begin{aligned} \psi^{\text{co}} = \bar{\psi}^{\text{co}} &= \frac{3}{2\pi} \int_{\Omega} \bar{\varphi}^{\text{co}} \, \text{d}\Omega \\ \bar{\varphi}^{\text{co}} &= \frac{1}{2} (\phi_{\text{V}} E_{\text{V}}^0 e_{\text{V}} \cdot e_{\text{V}} + \phi_{\text{D}} E_{\text{D}}^0 e_{\text{D}} \cdot e_{\text{D}} + \phi_{\text{T}} E_{\text{T}}^0 e_{\text{T}} \cdot e_{\text{T}}) \end{aligned} \quad (19)$$

where Ω is the surface of a unit hemisphere representing the set of all possible microplane orientations; E_{V}^0 , E_{D}^0 , and E_{T}^0 are the microplane elastic moduli to be determined; and $\boldsymbol{\phi} = \{\phi_{\text{V}}, \phi_{\text{D}}, \phi_{\text{T}}\}$ represents the set of microplane volume, deviatoric, and tangential damages, respectively. Similarly, we further assume that the cracking GFE potential (ψ^{cr}) can be expressed in the integral of its microplane counterpart (φ^{cr}) over all possible spatial orientations:

Figure 1. Definitions of the continuum, degradation, and cracking stress rates under 1-D case.

$$\psi^{cr}(\mathbf{q}) = \frac{3}{2\pi} \int_{\Omega} \varphi^{cr}(\mathbf{q}) \, d\Omega \quad (20)$$

where $\mathbf{q} = \{q_V, q_D, q_T\}$ denotes the set of stress like internal variables on each microplane that fully characterizes the microplane volumetric, normal deviatoric, and tangential deviatoric plastic flows. Therefore, the rate of the macroscopic GFE potential is given by:

$$\dot{\psi} = \frac{\partial \psi^{co}}{\partial \boldsymbol{\sigma}^e} : \dot{\boldsymbol{\sigma}}^e + \frac{1}{2} \boldsymbol{\sigma}^e : \dot{\mathbb{C}} : \boldsymbol{\sigma}^e - \frac{3}{2\pi} \int_{\Omega} \boldsymbol{\kappa} \cdot \dot{\mathbf{q}} \, d\Omega \quad (21)$$

where $\boldsymbol{\kappa} = \partial \varphi^{cr} / \partial \mathbf{q}$ denotes the set of strain-like internal variables conjugated to \mathbf{q} .

Substituting Eq. (21) into the Clausius–Duhem inequality (15) and making use of the standard arguments along with the additional assumption that the unloading is recoverable, we obtain the same constitutive relation as in Eq. (11):

$$\boldsymbol{\varepsilon} = \frac{\partial \psi^{co}}{\partial \boldsymbol{\sigma}^e} = \mathbb{C} : \boldsymbol{\sigma}^e, \quad \boldsymbol{\sigma}^e = \frac{\partial \bar{\psi}^{co}}{\partial \boldsymbol{\varepsilon}} = \mathbb{E} : \boldsymbol{\varepsilon} \quad (22)$$

In accordance with Eq. (22), the continuum HFE potential defined in Eq. (19) leads to:

$$\boldsymbol{\sigma}^e = \frac{3}{2\pi} \int_{\Omega} (\mathbf{V} \cdot \mathbf{s}_V^e + \mathbf{D} \cdot \mathbf{s}_D^e + \mathbf{T}^T \cdot \mathbf{s}_T^e) \, d\Omega \quad (23)$$

where the microplane elastic stress components are given by:

$$\mathbf{s}_V^e = \phi_V E_V^0 \mathbf{e}_V, \quad \mathbf{s}_D^e = \phi_D E_D^0 \mathbf{e}_D, \quad \mathbf{s}_T^e = \phi_T E_T^0 \mathbf{e}_T \quad (24)$$

and the stiffness tensor \mathbb{E} is expressed as:

$$\mathbb{E} = \frac{3}{2\pi} \int_{\Omega} (\phi_V E_V^0 \mathbf{V} \otimes \mathbf{V} + \phi_D E_D^0 \mathbf{D} \otimes \mathbf{D}) \, d\Omega + \frac{3}{2\pi} \int_{\Omega} (\phi_T E_T^0 \mathbf{T}^T \cdot \mathbf{T}) \, d\Omega \quad (25)$$

Upon initial virgin state, substituting the relation $\phi_V = \phi_D = \phi_T = 1$ into Eq. (25) and comparing the obtained result to Eq. (12), we obtain the definitions for the microplane elastic moduli:

$$E_V^0 = \frac{E^0}{1 - 2\nu^0}, \quad E_D^0 = E_T^0 = \frac{E^0}{1 + \nu^0} \quad (26)$$

where, as discussed in Carol et al. (1991), the deviatoric and tangential elastic moduli, $E_D^0 = E_T^0$, are assumed to take the same value herein.

Therefore, the continuum stress rate ($\dot{\boldsymbol{\sigma}}^{co}$) in Eq. (13) can be expressed in the form similar to Eq. (23):

$$\dot{\boldsymbol{\sigma}}^{co} = \frac{3}{2\pi} \int_{\Omega} (\mathbf{V} \cdot \dot{\mathbf{s}}_V^{co} + \mathbf{D} \cdot \dot{\mathbf{s}}_D^{co} + \mathbf{T}^T \cdot \dot{\mathbf{s}}_T^{co}) \, d\Omega \quad (27)$$

where the microplane volumetric, deviatoric, and tangential continuum stress rates are defined in an incremental elastic form:

$$\dot{\mathbf{s}}_V^{co} = \phi_V E_V^0 \dot{\mathbf{e}}_V, \quad \dot{\mathbf{s}}_D^{co} = \phi_D E_D^0 \dot{\mathbf{e}}_D, \quad \dot{\mathbf{s}}_T^{co} = \phi_T E_T^0 \dot{\mathbf{e}}_T \quad (28)$$

In accordance with the second law of thermodynamics, the constitutive relation derived above has to satisfy the following energy dissipation inequality:

$$D(\boldsymbol{\Gamma}) = \boldsymbol{\varepsilon} : \dot{\boldsymbol{\sigma}}^e - \frac{1}{2} \boldsymbol{\varepsilon} : \dot{\mathbb{E}} : \boldsymbol{\varepsilon} - \frac{3}{2\pi} \int_{\Omega} \sum_i \boldsymbol{\kappa}_i \cdot \dot{\mathbf{q}}_i \, d\Omega \geq 0 \quad (29)$$

with $\boldsymbol{\kappa}_i = \frac{\partial \psi^{cr}}{\partial \mathbf{q}_i}$

where and thereafter, to make the algebraic manipulations more convenient, the compact notation $\boldsymbol{\Gamma} := \{\boldsymbol{\varepsilon}, \boldsymbol{\kappa}\}$ is introduced for the strain-like variables constrained within a closed convex (not necessarily smooth) admissible domain in the strain space (\mathcal{E}):

$$\boldsymbol{\Gamma} \in \mathcal{E} := \{\boldsymbol{\Gamma} \in \mathfrak{R}^{n \dim \times n \dim} \times \mathfrak{R}^q \mid F_i(\boldsymbol{\Gamma}) \leq 0\} \quad (30)$$

where $F_i(\boldsymbol{\Gamma}) \leq 0$ are the microplane volumetric, deviatoric, and tangential loading surfaces.

2.4 Evolution laws for internal variables

The evolution laws for the stiffness tensor (\mathbb{E}) and the stress-like variables ($\boldsymbol{\Sigma} := \{\boldsymbol{\sigma}^{cr}, \mathbf{q}\}$) can be obtained from the postulate of maximum energy dissipation: for given admissible strain state variables $\boldsymbol{\Gamma}$, the rates $\dot{\mathbb{E}}$ and $\dot{\boldsymbol{\Sigma}} = \{\dot{\boldsymbol{\sigma}}^{cr}, \dot{\mathbf{q}}\}$ are those values that lead to a stationary point of the energy dissipation D :

$$\boldsymbol{\Gamma} = \arg \max[D] \in \mathcal{E} \quad (31)$$

To find the solution of the above constrained optimization problem (31), the following Lagrangian function is generally introduced:

$$\mathcal{L}(\boldsymbol{\Gamma}) = -D(\boldsymbol{\Gamma}) + \frac{3}{2\pi} \int_{\Omega} \sum_i \dot{\lambda}_i F_i(\boldsymbol{\Gamma}) \, d\Omega \quad (32)$$

where $\dot{\lambda}_i$ denotes the Lagrangian multipliers constrained by the Karush–Kuhn–Tucker conditions:

$$F_i \leq 0, \quad \dot{\lambda}_i \geq 0, \quad \dot{\lambda}_i F_i = 0 \quad (33)$$

Although other forms of functions can be postulated, herein, we assume that the individual cracking surfaces are simply expressed in the following same form:

$$F_i = f_i(e_i) - \kappa_i(q_i) \leq 0, \quad f_i = |e_i| \quad (34)$$

where f_i are the non-negative microplane loading functions. The cracking stresses increase for virgin loadings, whereas they remain constant for unloading and reloading. The case of virgin loading corresponds to the actual value of the cracking strain-like internal variables, as it is larger than the maximum values reached so far, that is, the cracking thresholds κ_v , κ_D , and κ_T . Once further cracking process occurs, the cracking thresholds are updated as:

$$\kappa_i = \max_{t_0 \leq t \leq t_n} [0, |e_i|] \quad (35)$$

From the necessary optimality conditions we obtain the associated evolution laws (normality rule) for the strain-like internal variables $\mathbf{\Gamma}$:

$$\begin{aligned} \dot{\boldsymbol{\sigma}}^{\text{cr}} &= \frac{3}{2\pi} \int_{\Omega} (\mathbf{V} \cdot \dot{s}_V^{\text{cr}} + \mathbf{D} \cdot \dot{s}_D^{\text{cr}} + \mathbf{T}^T \cdot \dot{s}_T^{\text{cr}}) \, \text{d}\Omega \\ \dot{q}_i &= -\dot{\lambda}_i \frac{\partial f_i}{\partial \kappa_i} = \dot{\lambda}_i \end{aligned} \quad (36)$$

for the microplane cracking stress rates:

$$\begin{aligned} \dot{s}_V^{\text{cr}} &= \dot{\lambda}_v \frac{\partial f_v}{\partial e_v} = \dot{\lambda}_v \text{sign}(e_v) \\ \dot{s}_D^{\text{cr}} &= \dot{\lambda}_D \frac{\partial f_D}{\partial e_D} = \dot{\lambda}_D \text{sign}(e_D) \\ \dot{s}_T^{\text{cr}} &= \dot{\lambda}_T \frac{\partial f_T}{\partial e_T} = \dot{\lambda}_T \frac{\partial f_T}{\partial e_T} \mathbf{I}_T = \dot{\lambda}_D \mathbf{I}_T \end{aligned} \quad (37)$$

When the material lies in the elastic domain, that is, $F_i(\mathbf{\Gamma}) < 0$, from Eq. (33)₃, we have $\dot{\lambda}_i = 0$; upon virgin loading state, the Lagrangian multipliers $\dot{\lambda}_i > 0$ are determined by the following consistency conditions:

$$\dot{\lambda}_i \dot{F}_i(\mathbf{\Gamma}) = 0 \quad \Rightarrow \quad \dot{F}_i(\mathbf{\Gamma}) = 0 \quad (38)$$

from which we can solve the Lagrangian multipliers as follows:

$$\begin{aligned} \dot{\lambda}_v &= H_v \text{sign}(e_v) \dot{e}_v \quad \Rightarrow \quad \dot{s}_V^{\text{cr}} = H_v \dot{e}_v \\ \dot{\lambda}_D &= H_D \text{sign}(e_D) \dot{e}_D \quad \Rightarrow \quad \dot{s}_D^{\text{cr}} = H_D \dot{e}_D \\ \dot{\lambda}_T &= H_T \dot{e}_T \quad \Rightarrow \quad \dot{s}_T^{\text{cr}} = \mathbf{H}_T \cdot \dot{\mathbf{e}}_T \end{aligned} \quad (39)$$

where the second-order tensor (\mathbf{H}_T) is defined as $\mathbf{H}_T = H_T (\mathbf{I}_T \otimes \mathbf{I}_T)$, and $H_i = \partial q_i / \partial \kappa_i$ denotes the hardening/softening functions.

For the continuum stress rate expressed in Eq. (27) and the cracking stress rate given in Eq. (36a), we can rewrite the stress rate (13) as:

$$\begin{aligned} \dot{\boldsymbol{\sigma}} &= \frac{3}{2\pi} \int_{\Omega} (\mathbf{V} \cdot \dot{s}_V + \mathbf{D} \cdot \dot{s}_D + \mathbf{T}^T \cdot \dot{s}_T) \, \text{d}\Omega = \mathbb{E}^{\text{tan}} : \dot{\boldsymbol{\epsilon}} \\ \dot{s}_V &= \dot{s}_V^{\text{co}} - \dot{s}_V^{\text{cr}}, \quad \dot{s}_D = \dot{s}_D^{\text{co}} - \dot{s}_D^{\text{cr}}, \quad \dot{s}_T = \dot{s}_T^{\text{co}} - \dot{s}_T^{\text{cr}} \end{aligned} \quad (40)$$

where the tangent stiffness tensor (\mathbb{E}^{tan}) is expressed as:

$$\begin{aligned} \mathbb{E}^{\text{tan}} &= \mathbb{E} - \frac{3}{2\pi} \int_{\Omega} (H_v \mathbf{V} \otimes \mathbf{V} + H_D \mathbf{D} \otimes \mathbf{D}) \, \text{d}\Omega \\ &\quad - \frac{3}{2\pi} \int_{\Omega} (\mathbf{T}^T \cdot \mathbf{H}_T \cdot \mathbf{T}) \, \text{d}\Omega \end{aligned} \quad (41)$$

2.5 Hardening/softening functions

In accordance with Eq. (39) we have $H_i = 0$ during the unloading/reloading regimes. Therefore, we only need to determine the hardening/softening functions H_i of virgin loading regions, which can be derived if the microplane stress–strain curves are known. On the basis of the previous experiences of microplane models, in the presented paper, we use the following secant stress–strain curves for the virgin loading:

$$s_v = \omega_v E_v^0 e_v, \quad s_D = \omega_D E_D^0 e_D, \quad s_T = \omega_T E_T^0 e_T \quad (42)$$

where ω_i are the appropriate functions in terms of the corresponding internal variables κ_i :

$$\omega_i = \hat{\omega}_i(\kappa_i) = \hat{\omega}_i(|e_i|) \quad (43)$$

3 EXEMPLIFIED MODELS

In accordance with the selection of damage variables ϕ_i , which characterize the stiffness degradation upon unloading/reloading/reloading states, different microplane models, elastoplastic model, damage model, and combined elastoplastic damage model can be postulated.

3.1 Microplane elastoplastic model

We first consider the case that under both tensile and compression states, all the microplane volumetric, deviatoric, and tangential behaviors follow the classical elastoplasticity. That is, the microplane unloading branches always have the initial slopes E_i^0 :

$$\phi_i = 1 \quad (44)$$

Therefore, the stiffness tensor (\mathbb{E}) in Eq. (25) becomes the elasticity tensor (\mathbb{E}^0), and the stress

relaxation ($\dot{\sigma}^{cr}$) is entirely contributed from the plastic flows on each microplane.

The microplane elastoplastic model obtained above is very similar to the strain space elastoplasticity, which can deal with strain softening. The theoretical and numerical comparisons between this strain-based microplane elastoplastic model with kinematic constraint, the stress-based one with kinematic constraint (Brocca and Bažant 2000; Kuhl et al. 2001), and the one with static constraint (Batdorf and Budiansky 1949; Carol and Bažant 1997) will be presented elsewhere.

3.2 Microplane damage model

Comparatively, we assume that under both tensile and compression states, all the microplane volumetric, deviatoric, and tangential tensile behaviors follow the pure elastic degradation (damage) model, namely the unloading–reloading branches point to the origin point:

$$\phi_i = \omega_i \quad (45)$$

Under such cases, the obtained microplane damage model is entirely the same as the one proposed in Kuhl et al. (2001).

3.3 Microplane elastoplastic damage model

To realistically describe both stiffness degradation and plastic flows, we adopt the following simple rule: the volumetric and deviatoric tensile behavior is assumed to be pure elastic degradation (damage), whereas the volumetric, deviatoric compressive behavior and the tangential performance are assumed to follow the classical plasticity.

More specifically, the volumetric and deviatoric unloading–reloading branches are assumed to be straight lines with a certain slope. The compressive behavior is assumed to be elastoplastic, that is, the unloading branches are assumed to always have the initial slopes E_v^0 and E_D^0 , that is, $\phi_v = \phi_D = 1$, and the origins of the tensile parts of the diagrams always shift to the points in which the unloading compressive branches intersect the horizontal (strain components) axis. On the contrary, the unloading–reloading behavior in tension is assumed to be a straight line pointing to the origin of that curve, that is, $\phi_v = \omega_v$ and $\phi_D = \omega_D$.

For the tangential unloading–reloading behavior, we assume a differential rule. For the unloading branch with initial stiffness E_T^0 , zero stress is assumed when the horizontal axis is reached during unloading. For the reloading branch, a straight line pointing to the maximum point reached so far is followed. Thus, a reloading branch with a slope smaller than the initial stiffness (E_T^0) is postulated herein.

3.4 Illustrative numerical results

Let us adopt the expressions for the nonincreasing function ω_i (Carol et al. 1992):

$$\hat{\omega}_v(e_v) = \begin{cases} \exp[-(|e_v|/a_1)^{p_1}] & \text{Iff } e_v \geq 0 \\ (1 + |e_v|/a)^{-p} + (|e_v|/b)^q & \text{Iff } e_v < 0 \end{cases}$$

$$\hat{\omega}_D(e_D) = \begin{cases} \exp[-(|e_D|/a_1)^{p_1}] & \text{Iff } e_D \geq 0 \\ \exp[-(|e_D|/a_2)^{p_2}] & \text{Iff } e_D < 0 \end{cases}$$

$$\hat{\omega}_T(|e_T|) = \exp[-(|e_T|/a_3)^{p_3}]$$

where a , b , p , and q are parameters to control the volumetric compressive behavior; parameters p_1 , p_2 , and p_3 are exponential parameters determining the curve shape; and a_1 and a_2 are positive parameters that affect the peak strength of the individual stress component. To model the macroscopic confinement on the behavior of the tangential stress, the value of parameter a_3 is assumed to depend on the macroscopic confinement represented by the volumetric strain e_v , that is, $a_3 = a_3^0 + \xi \langle -e_v \rangle$, where ξ is an additional parameter. Seven parameters can be generally assumed to have the same values for most concrete: $a = 0.005$, $b = 0.225$, $p = 0.25$, $q = 2.25$, $p_1 = 1.0$, $p_2 = p_3 = 1.5$. Moreover, Poisson's ratio is fixed as $\nu_0 = 0.18$.

The first example corresponds to the cyclic behavior of a concrete specimen subjected to a uniaxial compression. In this example, the uniaxial strain (ϵ_{xx}) unloads at 0.0015, 0.0024, 0.0035, 0.0045, and finally increases to the final value of 0.006. The predicted stress–strain curves are shown in Fig. 2, with the parameter values being $E^0 = 26.8$ GPa, $a_1 = 7.0 \times 10^{-5}$, $a_2 = 2.0 \times 10^{-3}$, $a_3^0 = 1.7 \times 10^{-3}$, and $\xi = 0.0$. It is remarked that because of the many possible combinations of loading/unloading/reloading on each microplane, both the macroscopic envelop curve and the hysteretic loops can

Figure 2. Cyclic uniaxial compression.

Figure 3. Comparison of strength envelop with biaxial compressive test by Kupfer et al. (1969).

be obtained realistically, although the latter is not a specific purpose of this work.

In the second example, we consider the behavior of concrete under biaxial compression, with the parameters being $E^0 = 30$ GPa, $a_1 = 5.0 \times 10^{-3}$, $a_2 = 1.7 \times 10^{-3}$, $a_3^0 = 1.5 \times 10^{-3}$, and $\xi = 0.88$. The parameters yield the uniaxial compressive strength of 32.4 MPa. We fixed the first principal stress σ_1 as zero during all the simulations and changed the ratio between the second and third principal stresses (σ_2/σ_3). The predicted strength envelope under biaxial compression is illustrated in Fig. 3, which agrees with the test data (Kupfer et al. 1969) well.

4 CONCLUSIONS

In this paper, a unified microplane theory was proposed within the framework of irreversible thermodynamics. A detailed description of the general formulation, including the consistent evolution laws of the involved internal variables, was presented. As illustrative examples, the microplane elastoplastic, damage, and combined elastoplastic damage models were derived as the special cases of the proposed microplane theory. The numerical predictions show that the proposed theory is capable of realistically describing the nonlinear behavior of concrete.

It is important to note that the proposed model does not eliminate the inherent deficiencies exhibited by the kinematically constrained microplane theory, that is, the pathological tensile behavior. Moreover, because the associated evolution laws of internal variables were used, the deviatoric-induced dilatancy, typical for quasi-brittle materials, cannot be realistically described by the proposed model. It is the next step of this research work to solve these two problems.

ABSTRACT: At present, wastewater containing phenol has been produced due to the addition of phenol or cresol as diluent in the preparation of sebacic acid via the traditional high-temperature cracking castor oil method, which resulted in severe pollution. Recently, an environment-friendly method has been introduced to prepare sebacic acid by cracking castor oil. In this process, liquid paraffin is used as diluent and iron oxide is the catalyst. The optimal reaction temperature for preparing sebacic acid is 553 K, and the alkali concentration is 14 mol/L in the alkaline hydrolysis process.

1 INTRODUCTION

Sebacic acid is named from Latin sebaceous, which means the production of fat. It is freely soluble in alcohols, ethers, and ketones and slightly soluble in water (Diamond, 1965; Liang, 1996). Sebacic acid is an important chemical raw material, mainly used in the preparation of sebacic acid ester. In addition, sebacic acid is one of the main reagents for manufacturing nylon engineering plastics, resins, and fibers, which can also be used for the preparation of polyamides, polyurethanes, lubricating oil, and lubricating oil additives (Zhao, 2006; Ma, 2007). Therefore, the manufacturing technique of sebacic acid has attracted increasing attention in the past several decades. Many methods have been proposed to prepare sebacic acid, such as high-temperature alkali fusion cracking of castor oil, and nitrate epoxidation of decane ring decanol.

It is reported that sebacic acid is one of China's important traditional export products, whose production has reached more than 10000 ton/year, meeting about one-third of the global demand (Chen, 1990). The main raw material for the production of sebacic acid is castor oil. However, China is one of the three largest castor-planting countries, and Tongliao City accounts for a quarter of the national castor-cultivated area. Therefore, using castor oil hydrolytic cleavage to produce sebacic acid at Tongliao City has the advantage of raw materials. Especially in recent years, castor industries have been listed as essential development

project. The pace of modernization and industrialization of castor was constantly accelerated due to the opportunity of the Western big development in the Inner Mongolia Autonomous Region. In addition, it is significant to use castor oil as raw material to produce chemical products in Tongliao, which highlights the local characteristics and also promotes the development of regional economy.

In the traditional process, sebacic acid was prepared by cracking castor oil using phenol or cresol as diluent, and the yield of sebacic acid was comparatively low, that is, 35.7–44.0% (Stephen, 1973). At present, a large amount of wastewater containing phenol was produced in the process of preparing sebacic acid from castor oil by the traditional high-temperature alkali fusion cracking method. Using this method, phenol content was 2000–3000 mg/L by water quality analysis and 120 million tons of wastewater containing phenol was produced each year. It is generally known that phenol or cresol is poisonous to all living individuals. Especially, it can mouse into organisms through skin, and contacts with protoplasmic protein to form insoluble protein, which makes cells lose their activity. Especially, it has a greater affinity to the nervous system and causes lesions to the nervous system. Therefore, developing a phenol-free method for the production of sebacic acid is highly recommended.

In addition, Wang et al. (Wang, 2012) reported that the yield of sebacic acid can reach 67.3% by cracking castor oil under the condition of alkali

by using liquid paraffin as diluents and Pb_3O_4 as catalyst. However, lead oxide is harmful to the environment. To solve this problem, research on phenol-free method has been carried out to the preparation of sebacic acid. The poisonous phenol diluents and lead oxide catalyst were replaced by green paraffin oil and iron oxide, respectively. It can reduce the cost and avoid the pollution of phenol.

2 EXPERIMENT

2.1 Materials and instruments

NaOH, Fe_2O_3 , castor oil, hydrochloric acid, and liquid paraffin used in this experiment were analytically pure.

PD-10 precision pH meter (Beijing sartorius Instrument System Co. Ltd.), DHT-type stirring electric heating sleeve (Shandong Juancheng Hualu Electric Instrument Co. Ltd), and FT-IR Spectrometer (Thermo Nicolet Corporation) were used.

2.2 Preparation of sebacic acid

2.2.1 Saponification castor oil

Castor oil (30 mL) and NaOH (120 mL, 3 mol/L) were mixed in a three-neck flask, and then the mixture was heated to boil under stirring for 30 min. After cooling, the solution was adjusted to pH 6 by adding 6 mol/L HCl, and was allowed to standing for 20 h.

2.2.2 Alkali cracking of castor oil

Liquid paraffin was added to a 500 mL three-neck flask, and then a certain concentration of NaOH was added to the flask. When the temperature reached the reaction temperature, a certain amount of Fe_2O_3 was added into the solution. At the same time, the saponification castor oil and 40% NaOH solution dropped slowly into the mixed solution. After that, the reaction was controlled at a certain temperature and kept for 1 h.

2.2.3 Product separation

At the end of the reaction, three times volume of distilled water was added into the mixture when the temperature dropped below 333 K. Then, the mixture was heated to 363 K and adjusted to pH 6 by adding 6 mol/L HCl. The mixture separated was separated into three layers, with the upper layer consisting of liquid paraffin, middle water, and the bottom layer white precipitate. The middle water layer was adjusted to pH 2, and the white precipitate was collected in aqueous phase. Finally, the crude product of sebacic acid was obtained by the filtering and drying process.

2.2.4 Product purification

About 15 times of water was mixed to the crude sebacic acid and the crude sebacic acid products and then heated to boiling for 3 h to increase the soluble content of sebacic acid in the water. After natural cooling, the crystal obtained was purified of sebacic acid (Li, 2009).

3 RESULTS AND DISCUSSION

3.1 Temperature of the alkali cracking

Figure 1 shows the FT-IR spectra of the crude product of sebacic acid, which was prepared at different temperatures.

When the temperature was below 533 K, the purity of sebacic acid was relatively low. With increasing alkali cracking temperature, the purity of sebacic acid was improved. When the cracking temperature reached 553 K, the main peaks of FT-IR spectrum were consistent with the standard spectrum of sebacic acid (Zhou, 2014). The bands at 2927 and 2855 cm^{-1} were assigned to saturated C-H stretching vibration. The bands at 1697, 1421, and 1353 cm^{-1} were for the C=O stretching vibration, the O-H bending vibration in the dimer as well as the C-O stretching vibration, and the C-H bending vibration in CH_2 , respectively. The bands at 1239–1186 cm^{-1} correspond to the characteristic absorption of C-O bond in the monomer. The peak at 930 cm^{-1} was O-H bending vibration of sebacic acid dimer. When the temperature was higher than 553 K, carbonation phenomenon of the reagent and product occurred.

Figure 2 shows the FT-IR spectrum of purified sebacic acid at a cracking temperature of 553 K.

Figure 1. FT-IR spectra of the crude product of sebacic acid under different reaction temperatures. a: 473 K, b: 493 K, c: 513 K, d: 533 K, and f: 553 K.

Figure 2. FT-IR spectrum of purification of sebamic acid at 553 K.

Figure 3. FT-IR spectra of crude sebamic acid with different alkali concentration. a: 7 mol/L, b: 14 mol/L.

The relative intensities of infrared diffraction peaks at 1697, 1421, 1353 cm^{-1} were significantly enhanced. The result shows that crystallization and purification of sebamic acid was beneficial.

3.2 Alkali concentration in alkali cracking process

The effect of different concentrations of NaOH on the alkali cracking castor oil to prepare sebamic acid has been investigated. The FT-IR result is shown in Figure 3. When the reaction temperature was controlled at 553 K, the amount of castor oil and liquid paraffin was 30 mL and 90 mL, respectively, the dosage of catalyst was 1% of the quality of castor oil, the alkali concentration was 14 mol/L, and the purification and crystallization of sebamic acid was optimal (as shown in Figure 3).

3.3 Effect of different catalysts on the yield of sebamic acid

Without catalyst, the yield of sebamic acid was less than 20%. After the addition of various metal oxide catalysts, the yield of sebamic acid increases. Compared with Al_2O_3 and ZnO, Fe_2O_3 exhibits a higher catalytic activity. Hence, Fe_2O_3 was selected as the catalyst for the preparation of sebamic acid.

4 CONCLUSION

Sebamic acid was prepared by cracking castor oil by a phenol-free method. The parameters for the optimal manufacturing technique are as follows: temperature, 553 K; alkali, 14 mol/L NaOH; catalyst, Fe_2O_3 ; and diluent, paraffin oil. This method can reduce environmental pollution because of the paraffin oil substitution of poisonous phenol, and is a potentially industrialized method for the preparation of sebamic acid.

Effects of electrospinning parameters on the pore structure of porous nanofibers

Zhaoyang Sun & Lan Xu

National Engineering Laboratory for Modern Silk, College of Textile and Engineering,
Soochow University, Suzhou, China

ABSTRACT: Electrospinning provides a simple and convenient method for generating polymer fibers which have been widely applied to produce porous nanofibers. The fibers produced by electrospinning have several excellent properties such as high surface-area-to-volume ratio, surface functionality and outstanding mechanical performance. The effects of collect distance and spinning voltage on the pore length distribution as well as the variation trend were explored and researched.

1 INTRODUCTION

The Electrospinning is regarded as one of the most simple and powerful technique for fabricating continuous and thin fibers. It has been widely utilized for preparation of polymer, ceramic, metal and composite fibers with high specific surface area (Dai, 2011), porosity and diameters ranging from tens of nanometers to a few micrometers (Panthi, 2015). In the past years, electrospinning technique has become an effective method for fabricating multifunctional nanometer materials from various polymers and composites (Zhang, 2015). One of the advantages of using electrospinning to fabricate porous nanofibers is its potential for control of pore structure. Xu et al. added sodium alginate in the hole of the nanofibers to make the wound dressing (Xu, 2016). Zhang et al. found as absorbent, the porous CeO_2 nanofibers adsorbed the MO were not only determined by the specific surface area, but closely related to the pore size (Zhang, 2016).

Due to its low cost, mechanical strength, and minimal inflammatory response, Polylactic Acid (PLA) has been widely studied for use in the biomedical industry (Sun, 2016). Although widely used in tissue engineering applications, biocompatible PLA electrospun meshes have displayed a high degree of shrinkage (Rowe, 2015).

In this paper, we fabricated porous PLA nanofibers with high specific surface area via the electrospinning method and investigated systematically the effects of electrospinning parameters, such as collect distance and spinning voltage, on the pore structure of PLA nanofibers.

2 EXPERIMENTAL SECTION

2.1 Materials

The base material for electrospun fibers was Polylactic Acid (PLA) with a molecular weight of 100,000 g/mol. Chloroform (CF) was obtained from Shanghai Chemical Reagent Co. Ltd, and N, N-dimethylformamide (DMF) was purchased from Guoyao Chemical Reagent Co. Ltd. All materials were used without any further purification.

All concentration measurements were done in weight by weight (w/w). PLA solutions were prepared at a concentration of 7 wt% by using mixture of CF and DMF with the weight ratio 9/1. The obtained solutions were magnetically stirred at 25°C for 3 h.

2.2 Instrumentation

The electrospinning setup consisted of a syringe, a needle, a grounded collecting plate, a flow meter and a variable DC high-voltage power generator (0–30 KV, DW-P303-1ACF0, Tianjin DongWen high-voltage power generator Co, LTD). The needle tip was connected to a DC high-voltage generator via an alligator clip.

2.3 Electrospinning process

The PLA solution was dropped into a 10 ml syringe connected with a metal needle that was controlled by a syringe pump at a constant flow rate 0.6 mL/h. The collect distance ranged from 8 cm to 14 cm. The spinning voltage ranged from 10 kv to 30 kv. All the experiments were carried out at $25 \pm 3^\circ\text{C}$ with the relative humidity of $50 \pm 5\%$.

3 RESULTS AND DISCUSSION

Fig. 1 and Table 1 showed SEM images and pore length distribution under the influence of different spinning voltages. The collect distance was 15 cm. It could be seen that the distribution of pore length of the electrospun porous fibers was more nonuniform with the increase of the applied spinning voltage. In this process, when the values of the flow rate and the collect distance were constants, higher voltage meant higher value of the jet speed. With increasing

Table 1. The relationship between the spinning voltage and the pore length.

Spinning voltage	Average length (nm)	Minimum length (nm)
10 kv	77.97	65.19
15 kv	86.38	84.95
20 kv	99.78	96.28
25 kv	96.09	76.80
30 kv	90.81	83.05

Figure 1. SEM images and pore length distribution under the influence of different spinning voltage.

the jet speed, the bending instability of jets could be exacerbated, as a result, both the distribution of pore length became nonuniform. That meant the most optimized spinning voltage was 10 kv.

Fig. 2 and Table 2 showed SEM images and pore length distribution under the influence of different collect distance. The applied spinning voltage was 15 Kv. It showed that the uniformity of pore distribution was improved firstly and then deteriorated with the increase of the collect distance. When the values of the flow rate and the applied

Table 2. The relationship between the collect distance and the pore length.

Collect distance (cm)	Average length (nm)	Minimum length (nm)
8 cm	79.53	68.59
11 cm	86.45	84.70
14 cm	78.19	78.58
18 cm	80.04	75.12
20 cm	92.96	80.85

Figure 2. SEM images and pore length distribution under the influence of different collect distances.

voltage were constants, with the increase of the collect distance the charged jet could be more easily accelerated to the higher speed before it was collected. Higher value of the jet speed resulted in the exacerbated bending instability of jets and the nonuniformity of pore distribution. In addition, when the collect distance was too small the formation of pores on the jets would be hindered due to inadequate volatilization in the electrospinning process. Therefore, the most optimized collect distance was 11 cm.

4 CONCLUSION

In this paper, electrospun porous fibers were prepared by adjusting electrospinning parameters, such as collect distance and spinning voltage. And the pore distribution of obtained porous fibers was investigated. The results showed that electrospinning parameters played an indispensable and crucial role

in electrospinning process, which directly affected the porous structure having uniform but tunable lengths could be controlled by adjusting electrospinning parameters in the process.

Preparation of orderly nanofibers using bubble-electrospinning

Zhong-Biao Shao & Lan Xu

National Engineering Laboratory for Modern Silk, College of Textile and Engineering, Soochow University, Suzhou, China

ABSTRACT: Aligned nanofibers fabricated by electrospinning have extensive applications. Bubble-electrospinning as a mass production technology has some advantages compared with other electrospinning techniques to prepare nanofibers. The highly aligned PAN nanofibers were successfully fabricated by the simple rapid method which was a bubble-electrospinning with the parallel micropipette electrodes. The effects of spinning voltage on the degree of nanofiber alignment and diameter distribution were investigated.

1 INTRODUCTION

Electrospinning provides a simple and convenient method for generating nanofibers (Dai, 2011), which has been applied to prepare nanofibers made of organic polymers, ceramics, and polymer/ceramic composites (Zhao, 2016). Due to the wide application of orderly nanofibers in tissue engineering (Mehrasa, 2015), drug deliver (Goh, 2013), reinforcements (Terao, 2010), filtration membranes (Kaur, 2012), and so on, a number of methods have been proposed to fabricate aligned nanofibers (Zhang, 2012; Heidari, 2013). But all these methods have respective defectiveness, accompanied with the problems of easily jammed and inefficiency. Preparation of highly aligned nanofibers has received much attention in recent years. In this regard, bubble-electrospinning technique as an interesting and effective alternative to the classical electrospinning technique are explored to prepare aligned nanofibers (He, 2014).

In this paper, we modified a bubble-electrospinning with the parallel micropipette electrodes was successfully developed for mass production of highly aligned nanofibers for a long spinning time (Shao, 2010). And also, the morphology and the degree of alignment of nanofibers with the effect of voltages of polymer solution were researched.

2 EXPERIMENTAL SECTIONS

2.1 Materials

Polyacrylonitrile (PAN) with a molecular weight of 150,000 g/mol was supplied Beijing lark branch co., LTD. N,N-Dimethylformamide (DMF) was obtained from commercial source and used as solvent. All materials were used without any further purification.

2.2 Instrumentation

The bubble-electrospinning setup included a bubble generator, a spinneret, an air pump, a pair of parallel electrodes, and a variable DC high-voltage power generator (0–100 KV, DW-P303-1ACF0, Tianjin DongWen high-voltage power generator Co, LTD).

2.3 Bubble-electrospinning process

All concentration measurements were done in weight by weight (w/w). A control amount of PAN powder was dissolved in the DMF with the weight ratio 1:9 (PAN: DMF). The mixture was magnetically stirred at 80°C for 4 hours in an electromagnetism stirrer (Angel Electronic Equipment (Shanghai) Co., LTD), stirring speed from 950 to 1200 rounds/min. The mixture was dropped into in a 10-ml syringe which was mounted in a syringe

pump. A pair of parallel electrodes was placed vertically upper to the spinneret, and the distance was 15 cm. The applied voltage connected to the generator varied from 25 KV to 45 KV. All processes were carried out at room temperature (25°C) in a vertical spinning configuration at a relative humidity of 45%.

3 RESULTS AND DISCUSSION

Fig. 1 and Table 1 showed SEM images and diameter distribution of aligned nanofibers under the influence of different spinning voltages. As could be seen, when the applied voltage was 25 KV, the diameter distribution of nanofibers was sparse and

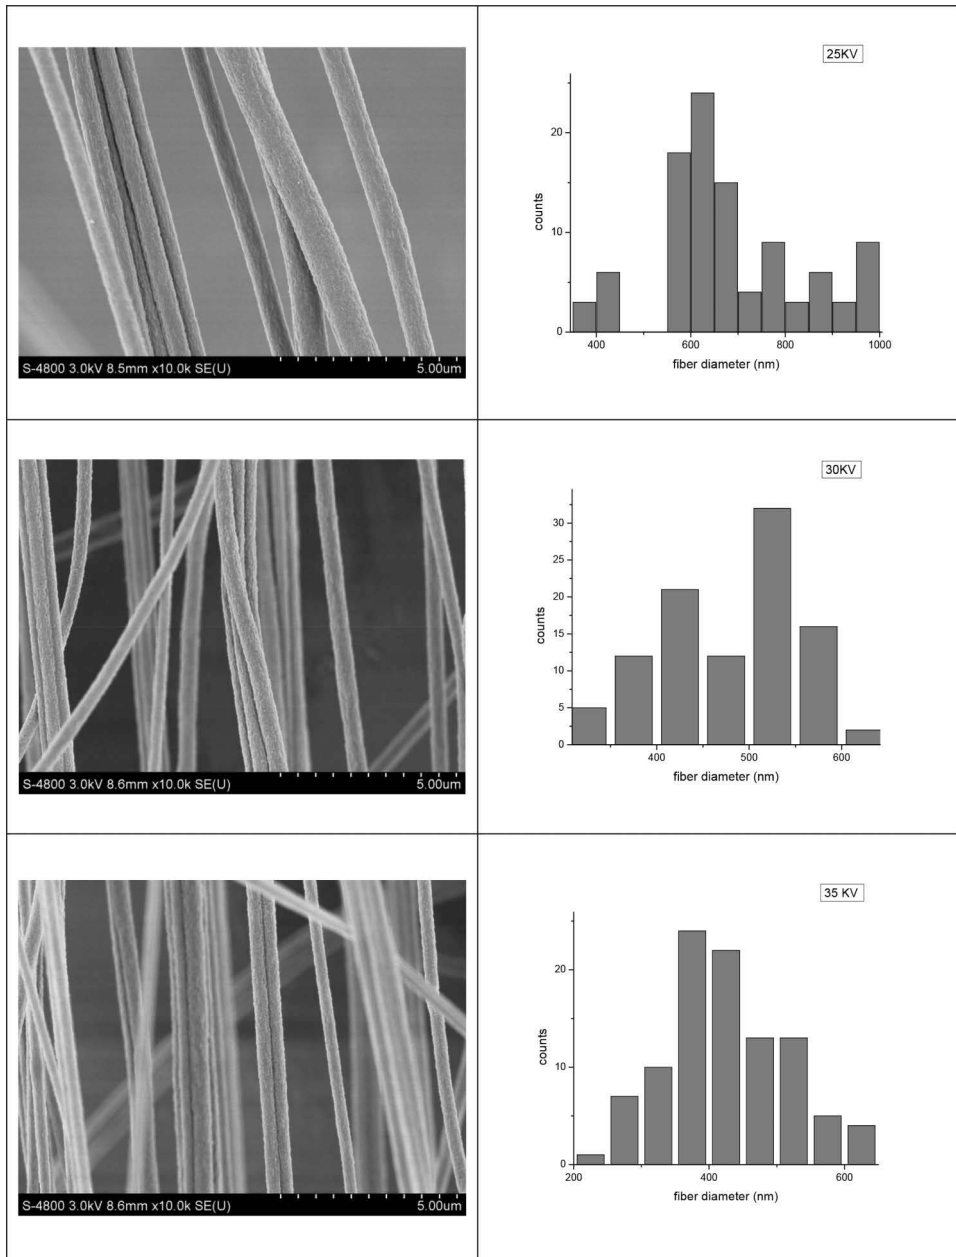

Figure 1. (Continued).

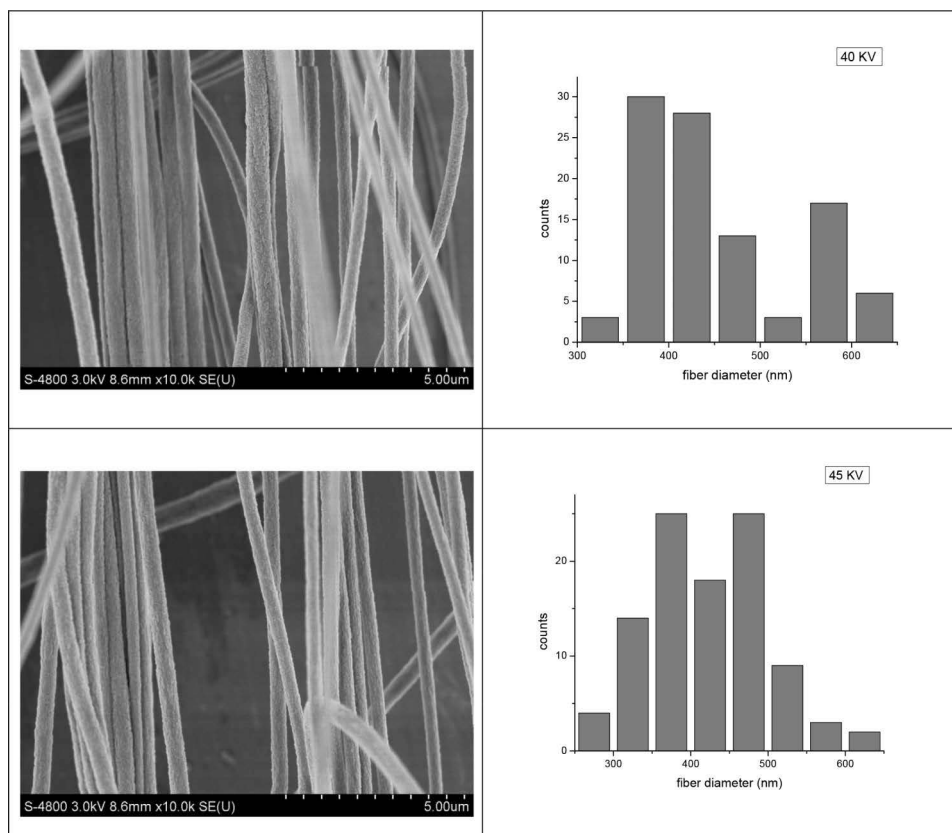

Figure 1. SEM images and diameter distribution of aligned nanofibers under the influence of different spinning voltage.

Table 1. The relationship between spinning voltage and nanofiber diameter.

Voltage	Average diameter (nm)	Minimum (nm)
25 KV	680	379
30 KV	480	318
35 KV	754	550
40 KV	464	335
45 KV	445	275

nonuniform. Moreover, with the increase of the applied spinning voltage, the diameter distribution of nanofibers became dense and more uniform. However, when the applied voltage was 45 KV, the bending instability of jets was exacerbated, the diameter distribution of nanofibers became sparse again. That meant the most optimized spinning voltage was 30–40 KV.

4 CONCLUSION

In this work, the aligned PAN nanofibers have been successfully fabricated by the bubble-electrospinning with the parallel micropipette electrodes. And the effects of spinning voltage on the nanofiber alignment and diameter distribution were researched. The results showed the optimized spinning voltage ranged from 25 KV to 45 KV. A large number of highly aligned nanofibers produced by the modified bubble—electrospinning would have promising applications of fiber-reinforcement, fiber-oriented liquid crystal, and tissue engineering.

Environmental radioactivity measure and dose estimation of ^{90}Sr in some area

Li Ma

Medical Protection Laboratory, Naval Medical Research Institute, Shanghai, China

Xin Ren

Graduate School, National Defense University, Beijing, China

Kai Zhang

Medical Protection Laboratory, Naval Medical Research Institute, Shanghai, China

ABSTRACT: Objective To measure the current environmental radioactivity levels of ^{90}Sr in the area, and to estimate the doses to local residents. Methods The water samples, surface soil and biologic samples were collected and analyzed by radiochemistry techniques. Results Based on the data, the annual effective dose rate of ^{90}Sr to the local people was $1\ \mu\text{Sv}$ per year, only 1% of per year limited by national standards. Conclusion the annual effective dose rate of ^{90}Sr to the local people is far less than the dose of national standards.

1 INTRODUCTION

In the 1960s, the Ministry of health has established environmental radioactivity monitoring network in the national scope, which has played an important role in the effect evaluation of the impact of previous nuclear tests and foreign major nuclear accidents on the regions of our country, and the valuable information on environmental radioactivity level in our country has been accumulated. With the development of the national nuclear power industry and the establishment of military nuclear base and facilities, the radiation environment investigation in the surrounding areas has also been included in the routine monitoring. According to the requirements of environmental protection work, a large number of studies on the investigation and evaluation of radionuclides background in environmental medium have been carried out since 2003 in this unit.

As the artificial radionuclides in the environment, radioactive strontium has a total of 17 isotopes (the atomic number is from ^{81}Sr to ^{97}Sr), and they are β radiation source and ^{89}Sr and ^{90}Sr have the most significant meaning of Toxicology. ^{90}Sr has a long half-life, with severe damage to agriculture and animal husbandry, and it can enter the human body through the food chain. Consequently, ^{90}Sr pollution has attracted people's attention. The present situation investigation and evaluation of nuclear radiation environment in a certain area has been carried out by the unit in 2012, the radioactive levels of ^{90}Sr in water, soil and biological samples within the scope of evaluation have been investigated and monitored, and the accumulated

effective dose is calculated using the corresponding dose conversion factor recommended by the ICRP (International Commission on Radiological Protection) and it is compared with the relevant dose limit in order to evaluate the adult personal annual effective dose caused by ^{90}Sr in this area.

2 INSTRUMENTS AND METHODS

Equipments are as follows: F6000-60 ashing furnace, Thermo Fisher Company, America. BH1216 III type two channel low background alpha and beta measuring instrument, Beijing nuclear instrument factory. XDB030301 type undisturbed soil sampler, Kardinal Technology and Trade Co., Ltd.

2.1 *The principle of layout and area*

The evaluation scope is 20 km area of taking nuclear facilities as the center (10 km area is the key investigation scope). The concentric circle is used to dispose the dot in different directions within the scope of the evaluation range, and the development of layout scheme and selection of measuring point are assigned combined with the terrain features of the surrounding and the situation of population distribution.

2.2 *Samples acquisition and measurement*

In this investigation, the 4 the water samples, 12 biological samples and 7 soil samples were collected.

2.2.1. Water samples

The drinking water of residents including reservoir water and tap water was collected, the sampling methods are used according to the radiation environmental monitoring technical specifications of HJ/T61-2001, and the radiochemical analysis method of strontium-90 in the water 2-(2-ethylhexyl) phosphate extraction chromatography of GB 6766-86 is used as the methods for measuring.

2.2.2 Soil samples

The soil sampling points are selected in a relatively open, domesticated and less activities of livestock zones, the soil below 10 cm of surface is taken, and the sampling methods are used according to the HJ/T 61-2001 radiation environmental monitoring technical specifications and the general rules and regulations of EJ 428-1989 environment nuclear radiation monitoring in the collection and preparation of soil samples, and the methods of measurement use the strontium 90 analysis method of EJ/T 1035-1996 in the soil.

2.2.3 Biological samples

The local representative samples of wheat, sweet potatoes, pork, spinach, scallops, noodle fish and seaweed etc. are collected. The sampling methods are used according to the HJ/T 61-2001 radiation environmental monitoring technical specifications and the the basic rules of biological sampling in environmental radiation monitoring of EJ 527-1990, and the methods of measurement use strontium-90 radiochemical analysis method in biological samples of GB11222.1-89-(2-ethylhexyl) phosphate extraction chromatography method.

2.3 Effective dose evaluation method of ⁹⁰Sr for residents in a year

2.3.1 Transfer coefficient

The transfer coefficient P_{ij} is used to describe the environmental behavior of the nuclide and calculate the dose as the basic parameters in the calculation model. Transfer coefficients are used to describe the relationship between the cumulative concentration or dose in a series of environmental compartments, such as the transfer relationship from I compartment to J compartment. The migration pathway and transfer coefficient of radionuclides commonly used in the environment dose evaluation by UNSCEAR can be shown in Figure 1. For example, P_{34} is the value that the activity concentration of the nucleus is divided by the time integral concentration of the nucleus in the food.

2.3.2 Evaluation of radiation dose through the food

Because the residents personal annual effective dose of ⁹⁰Sr is mainly caused by the diet (water), the residents annual intake of various types of food and drinking water in this area must be considered in the calculation. The average personal annual drinking water intake of adult is 730 L/year, the average annual individual consumption of food can be shown in Table 1.

To evaluate the exposure dose based on the biological sample (including water) radionuclide monitoring data:

$$D_a = \sum_{i,j} D_{ai,j} = \sum_{i,j} C_{ai,j} v_{ai} P_{aj45} \quad (1)$$

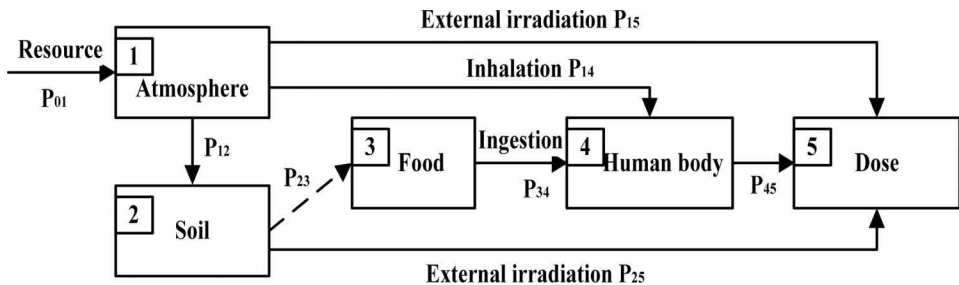

Figure 1. Land transfer pathway of radionuclide and the dose effect on human body.

Table 1. Food consumption of adults in a region (kg/year).

Food	Vegetable	Fruit	Grain	Livestock	Poultry meat	Egg	Milk	Fresh water produc	Sea food	Tea
Adult	133.7	7.8	210.6	8.2	3.2	7.6	4	1	3	0.3
Self sufficiency in the evaluation area	100	80	100	100	100	100	100	100	100	100

Among them, D_a is the radiation dose of personal annual ingestion, Sv. D_{ai} is the individuals annual ingestion of the i th food, Sv. C_{aij} is the quality activity of radionuclides j in the i th food, Bq/kg. v_{ai} is the annual intake of the i th food, kg. p_{aij45} is the dose caused by the intake of unit radionuclide radioactivity j , Sv/Bq, and the value of ^{90}Sr is taken for 28 nSv/Bq. The irradiation dose of intaked food is evaluated based on the outdoor radionuclide monitoring data of soil:

$$D_a = \sum_i D_{ai} = \sum_i 150 * A_i * p_{i2345} * (1 - \delta) \quad (2)$$

Among them, D_a is the radiation dose of personal annual ingestion, nSv. D_{ai} is the individuals annual ingestion of the i th food, nSv. A_i is the quality activity of the i th radionuclide in soil, Bq/kg. p_{ai2345} is the dose caused by intaking the j th unit radioactivity radionuclide, nSv/Bq·m², and the value of ^{90}Sr is taken for 53nSv/Bq. δ is the containing water in soil, %.

3 RESULTS

3.1 Measurement of water samples

The analysis results of artificial radionuclides ^{90}Sr in drinking water samples around the area are shown in Table 2. As can be seen from Table 2, the activity range of artificial radionuclide ^{90}Sr in the water samples around the investigate area is from 2.7 mBq/L to 5.1 mBq/L, the average value was 4.1 ± 0.2 mBq/L, and the maximum value was about 1.5 times of the control point.

Table 2. Radiochemical analysis results of the water samples.

Name of samples	reservoir water of number one	Tap water of number one	Tap water of number two	Well water of number one	Control point
^{90}Sr (mBq/L)	2.7 ± 0.1	4.5 ± 0.2	5.1 ± 0.3	4.2 ± 0.2	3.0 ± 0.1

Table 3. Radiochemical analysis results of the biological samples.

Name of samples	Wheat	Apple	Sweet potato	Spinach	Scallop in Shell	Noodle fish
^{90}Sr (mBq/kg·fresh)	108.3 ± 2.8	13.8 ± 3.0	68.1 ± 2.4	81.5 ± 4.7	129.0 ± 3.0	21.2 ± 5.0
Name of samples	Pork	Chicken	Kelp	Milk	Tea	Crucian carp
^{90}Sr (mBq/kg·fresh)	155.3 ± 5.8	107.8 ± 2.6	92.5 ± 6.6	94 ± 4.6	128.1 ± 6.1	35 ± 5.2

Table 4. Radiochemical analysis results of the soil samples.

Name of samples	Point 1	Point 2	Point 3	Point 4	Point 5	Point 6	Point 7
^{90}Sr (mBq/kg·fresh)	1.31 ± 0.05	1.77 ± 0.06	2.43 ± 0.06	2.04 ± 0.05	1.02 ± 0.05	0.70 ± 0.05	1.72 ± 0.05

3.2 Measurement of biological samples

The results of artificial radionuclide ^{90}Sr in the sample of biological samples around the area are shown in Table 3. It can be seen as follows from Table 3: the activity of ^{90}Sr in the scallops, pork, tea, wheat and chicken is relatively higher, the activity of ^{90}Sr in milk, kelp, spinach, sweet and potato is relatively lower, and the activity of ^{90}Sr in noodle fish, crucian carp, and apple is the lowest. In the above mentioned biological samples, the content of artificial radionuclide ^{90}Sr is lower than the limit of national standard.

3.3 Measurement of soil sample

The analysis results of artificial radionuclides ^{90}Sr in the soil samples around the area are shown in Table 4. As can be seen from Table 3, the activity range of artificial radionuclide ^{90}Sr in the soil samples around the investigate area is from 0.7 mBq/kg·fresh to 2.43 mBq/kg·fresh, the average value was 1.57 ± 0.05 mBq/kg·fresh, and the maximum value was about 4 times of the control point.

3.4 Evaluation of personal annual effective dose

Considering that the uncertainty of dose evaluation can be effectively reduced by reducing the migration process of radionuclides in the environment and the human body, the ingestion exposure dose assessment value of food is used based on the full access of radionuclide concentration monitoring data in the biological samples. According to the nuclide dose calculation model shown in Figure 1 and provides the food consumption of

adults in average and personal drinking water in a year shown Table 2, the resident personal annual dose of ^{90}Sr is about 38.7 Bq and it is far below the national standards dose limit of 3.8×10^4 Bq. The calculation value of personal annual effective dose of ^{90}Sr is 1 μSv according to the formula (1), and it is only 1 per thousand of national standard annual dose limit value.

4 DISCUSSION

The radioactive contents of ^{90}Sr in the water, soil and biological samples around are measured through the investigation of environmental radioactivity level in a certain area, the content of ^{90}Sr in the biological samples is lower than the national standard limit values, and the content of ^{90}Sr in the water and soil samples is slightly higher than the control trace, but the calculations results show that the personal annual effective dose is rarely little, and it is only 1 per thousand of national standard annual dose limit value, which indicate that the public exposure caused by ^{90}Sr is minimal in human activities around the area. In this investigation, the exposure of ^{90}Sr on the human body is produced by beta ray, the annual effective dose estimation measurement data of ^{90}Sr is mainly from the measurement results of drinking water and food, and the external radiation caused by soil will not be considered. The results of this investigation and evaluation can provide an effective basis for the radioactive level scientific evaluation

of ^{90}Sr in the surrounding environment of nuclear facilities and the individual annual effective dose and collective effective dose of the public in the region caused by ^{90}Sr .

ABSTRACT: Adsorption of a widely used antibiotic Levofloxacin (LEV) to goethite was studied using batch experiments. The adsorption of LEV to goethite increased proportionally with the increase of Humic Acid (HA) concentration, therefore the additional LEV adsorbed can be attributed to its adsorption to LEV. The amounts of LEV adsorbed to NOM are consistent with the literature values for adsorption of antibiotics with similar structures on free (*i.e.* in the absence of goethite) HA and Fulvic Acid (FA). The Excitation-Emission Matrix (EEM) spectra results indicated the interactions (*i.e.* adsorption) between HA and LEV, which become strong at neutral conditions, and much weaker at pH 3.0 and 9.0. The presence of goethite and HA will affect the environmental fate of antibiotics.

1 INTRODUCTION

Antibiotics have been widely used in human and veterinary treatments, and they are frequently detected in the environment (Hu et al., 2010). The presence of antibiotics may change the microbial community and the antibiotic resistance genes (Zhang et al., 2013). The environmental fate of antibiotics is influenced by their adsorption to soil minerals and Natural Organic Matter (NOM) (Tolls, 2001).

Adsorption of antibiotics to minerals and to NOM has been studied previously. In this respect, a range of minerals (*i.e.* goethite, hematite, and kaolinite) and NOM have been investigated. Cation exchange and surface complexation were considered as the major mechanisms in their adsorption on respectively clay minerals (Figueroa et al., 2004) and metal (hydr)oxides (Gu and Karthikeyan, 2005). Contradictory results have been reported regarding the effects of NOM on antibiotics adsorption to minerals. Some studies have shown that presence of NOM promoted antibiotic adsorption to goethite (Zhao et al., 2011). However, different results were reported as well. Peng et al. (2012) observed that the addition of HA (5–50 mg/L) suppressed the adsorption of norfloxacin on Titanium Oxide (TiO₂). Similarly, inhibition of norfloxacin adsorption to soils by small organic acids was also reported (Zhang and Dong, 2008). In addition, several authors found that NOM had no significant influence on the adsorption of antibiotics to soil minerals (Yan et al., 2012). Clearly, a

consistent picture regarding the effect of NOM on antibiotics adsorption to minerals is still lacking.

In this work, a common iron mineral goethite (α -FeOOH) was used as the adsorbent, and a widely used antibiotic Levofloxacin (LEV) was used as an example. The aim is to investigate its adsorption to goethite in the presence of HA, and the complexation between HA and LEV.

2 MATERIALS AND METHODS

2.1 Materials

LEV (> 98.0%, Tokyo Chemical Industry Co.) was used without further purification. The commercial HA was purchased from Sinopharm Chemical Reagent Co. Acetonitrile (HPLC grade, Honeywell Burdick & Jackson) was obtained. Goethite was prepared using the common method (Hiemstra et al., 1989; Antelo et al., 2005). Other chemicals were analytical reagent grade or higher. MilliQ water was used in the experiments. The properties of LEV, HA, and goethite were reported in our previous studies (Qin et al., 2012; Qin et al., 2014b).

2.2 Adsorption experiments

Adsorption isotherms of LEV to goethite at pH 5.0 in the absence or presence of PHA at two concentrations (3.63 and 7.25 mg C/L PHA) were obtained from results of batch experiments.

During the experiments, the 50 mL polyethylene centrifuge tubes that contained the suspensions were flushed with N_2 gas to minimize the influence of CO_2 . Both the LEV-NOM and goethite stock solutions were prepared in the background of 0.01 M NaCl. The final goethite concentration was 0.8 g/L. The total LEV concentration was 1–10 μM , and the final NOM concentration was 0, 3.63, or 7.25 mg C/L. The pH of all suspensions was adjusted to 5.0 using either 0.01 M HCl or 0.01 M NaOH solutions. All suspensions were shaken for 24 h at 175 rpm in the dark under room temperature. After equilibration, the end pH of each suspension was measured with a pH meter (Sartorius PB-10, Germany). Then the suspensions were centrifuged at 12000 rpm for 20 min, and the supernatants were analyzed immediately. All treatments were carried out in triplicates.

2.3 Chemical analyses

The concentration of LEV in solutions was determined using the High Performance Liquid Chromatography (HPLC) method as reported (Qin et al., 2014a). The concentration of LEV adsorbed to goethite was calculated from the differences in the concentrations of LEV in solutions before and after adsorption.

The Excitation-Emission Matrix (EEM) spectra of PHA or (and) LEV was measured with a fluorescence spectrophotometer (Hitachi F-7000, Japan). The emission wavelength and excitation wavelength were in the range of 250–600 nm and 200–500 nm, respectively. The concentrations of PHA and LEV were 5 mg C/L and 10 μM , which were diluted 25 times during the EEM spectra measurements.

3 RESULTS AND DISCUSSION

3.1 Effect of HA on LEV adsorption

The adsorption of LEV to goethite was measured at pH 5.0 at a range of LEV concentrations in the absence and presence of 3.63 and 7.25 mg C/L HA (Figure 1). It seems that an adsorption plateau for LEV has been reached at 0.021 $\mu mol/m^2$ in the absence of NOM, which indicates a relative weak adsorption. The presence of PHA promoted LEV adsorption significantly even when only 3.63 mg C/L PHA was added. Increasing HA concentration to 7.25 mg C/L increased LEV adsorption further. More than 16%, 42%, and 62% of the total LEV were removed from the solution in the absence and presence of 3.63 and 7.25 mg C/L PHA, respectively. According to the preliminary experiments, nearly all (100% and 96%) of the added HA was

Figure 1. Adsorption of LEV to goethite in the absence and presence of HA at pH 5. The concentration of goethite is 0.8 g/L. Error bars (± 1 Standard deviation, $n = 3$) are shown in the figures.

adsorbed to goethite in our study, which is equivalent to a PHA loading on goethite of 0.047 mg C/ m^2 and 0.089 mg C/ m^2 .

The adsorption isotherms of LEV were well fitted to the Langmuir model ($R^2 > 0.84$) as shown in Table S1. The fitted maximum adsorption (q_m) of LEV increased from 0.029 (without PHA) to 0.099 $\mu mol/m^2$ (7.25 mg C/L PHA). The fitted affinity constants (K) in the presence of PHA were about 2 times larger than that without PHA. The results show that both the adsorption affinity and the maximum binding capacity have increased due to the presence of PHA.

Under different pH, the ratios between the various LEV species in solution change due to the protonation or deprotonation of their functional groups (*i.e.* carboxyl group, amine group). At pH 5.0, most of LEV molecules will be cationic, because under this pH most of the piperazinyl groups and carboxyl groups will be protonated. Goethite surface will also be positively charged at pH 5.0 (PPZC = 9.0–9.3). The electrostatic repulsion between LEV molecules and the surface of goethite is part of the reasons for the small amount of LEV adsorbed to goethite ($< 0.025 \mu mol/m^2$).

The adsorption of LEV to goethite increased significantly in the presence of HA added at two concentrations (Fig. 1), which can be attributed to two reasons, (1) synergistic electrostatic effects from PHA adsorbed, and (2) co-adsorption of LEV to mineral-bound HA. NOM is usually negatively charged under common pH in natural systems. With sufficient amount of NOM adsorbed on the mineral surface, the NOM-mineral assemblages may become negatively charged, and even when the mineral surface is initially positively charged, a charge reversal can take place (Weng et al., 2005;

Kumpulainen et al., 2008). The positively charged antibiotics molecules (at pH 5.0 in solutions) can be adsorbed more easily to the negative charged NOM-mineral assemblages due to electrostatic attraction. On the other hand, it has been shown that antibiotics are also strongly adsorbed on NOM (Carmosini and Lee, 2009; Ding et al., 2013). Consequently, when PHA is adsorbed, some LEV will be co-adsorbed with PHA to goethite.

From the fitted adsorption maximum (q_m), we can derive that the q_m increased by $0.036 \mu\text{mol}/\text{m}^2$ at 3.63 mg C/L HA, and by $0.070 \mu\text{mol}/\text{m}^2$ when PHA was doubled. These results indicate an increase in adsorption capacity proportional to the amount of PHA added, which suggests that the electrostatic interaction plays probably a smaller role than the co-adsorption mechanism in determining the effect of NOM on LEV adsorption to goethite. However, because the NOM loading at both HA concentrations (0.047 and $0.089 \text{ mgC}/\text{m}^2$) is relatively low, the electrostatic effect may still be in the range that is almost proportional to the amount of NOM present. Therefore based on the data we cannot make definitive conclusion regarding the mechanisms of NOM effect on LEV adsorption.

If we assume that the additional amount of LEV adsorbed when PHA was added is solely due to LEV adsorption to adsorbed PHA, we can calculate the amount of LEV adsorbed to HA (excluding LEV adsorbed to goethite in the absence of HA). The calculated amounts of LEV adsorbed to HA are in the range of $90\text{--}820 \text{ mmol}/\text{kg C}$, which are in the same order of magnitude as the reported values for ciprofloxacin adsorption on LHA, PPHA, and PPHA ($200\text{--}650 \text{ mmol}/\text{kg C}$) (Carmosini and Lee, 2009), norfloxacin adsorption on a coal HA ($260\text{--}380 \text{ mmol}/\text{kg C}$) (Zhang et al., 2012), ofloxacin adsorption on a sediment HA ($150\text{--}720 \text{ mmol}/\text{kg C}$) (Pan et al., 2012), and tetracycline adsorption on LHA and AHA ($30\text{--}45 \text{ mmol}/\text{kg C}$) (Ding et al., 2013). In these literatures, the equilibrium dialysis technique, fluorescence quenching method, and Solid Phase Extraction (SPE) method were used to measure antibiotics adsorption at different concentrations ($2.5\text{--}79 \text{ mg C/L}$) of NOM in the absence of minerals. The advantages of using the mixtures of NOM and minerals in our current work are first of all that the NOM-mineral assemblages are more representative for the adsorbents in the natural systems; and secondly, in the NOM-mineral-antibiotic ternary experiment, the soluble and adsorbed antibiotics can be separated much more easily compared to when only NOM is present.

3.2 EEM spectra measurements of HA and LEV

In order to investigate the interactions between NOM and LEV, the EEM spectra contour maps

of HA, LEV, and their mixtures were determined (Fig. 2). In all the contour maps, there are two red lines. The left one is the Rayleigh scattering peak ($\lambda_{\text{em}} = \lambda_{\text{ex}}$), and the right one is the second-order Rayleigh scattering peak ($\lambda_{\text{em}} = 2\lambda_{\text{ex}}$). There are three peaks in the contour maps of HA and LEV, and four peaks in their mixtures. The positions and fluorescence intensities of the peaks change with the solution pH (Table 1).

As shown in the EEM spectra of HA under different pH (Figure 2a, b, and c), three peaks at around E_x/E_m of $225/335 \text{ nm}$, $325/465 \text{ nm}$, and $285/485 \text{ nm}$ are observed (Table 1), which are respectively related to aromatic protein, model HA

Figure 2. The EEM spectra contour maps of HA (a, b, and c, 0.2 mg C/L), LEV (d, e, and f, $0.4 \mu\text{M}$), and the mixtures of HA and LEV (g, h, and i) at pH 3.0, 6.0, and 9.0. The positions and intensities of the peaks are shown in Table 1.

Table 1. Three-dimensional fluorescence characteristics of HA, LEV, and their mixtures.

System	Peak 1 ($\lambda_{em}/\lambda_{ex}$)	Intensity	Peak 2 ($\lambda_{em}/\lambda_{ex}$)	Intensity	Peak 3 ($\lambda_{em}/\lambda_{ex}$)	Intensity	Peak 4 ($\lambda_{em}/\lambda_{ex}$)	Intensity
HA (pH 3.0)	220/330	1016	325/490	469.4	290/495	1272	ND ^a	ND
HA (pH 6.0)	225/335	828.4	325/465	203.4	285/485	533.7	ND	ND
HA (pH 9.0)	220/325	977.5	330/450	272.4	280/445	604.0	ND	ND
LEV (pH 3.0)	ND	ND	325/490	4297	290/495	9999.9 ^b	230/500	4980
LEV (pH 6.0)	ND	ND	330/470	4226	290/480	9999.9	230/495	4224
LEV (pH 9.0)	ND	ND	330/455	5065	290/465	9999.9	255/450	6154
LEV-HA (pH 3.0)	225/325	1221	325/495	3805	290/495	9999.9	225/485	4378
LEV-HA (pH 6.0)	225/325	1120	330/480	3372	290/490	9427	225/490	3615
LEV-HA (pH 9.0)	225/330	1124	330/465	4230	285/470	9999.9	225/480	4108

^aND means not detected, or no peaks are found.

^bThe value exceeds the detection limit of the fluorescence spectrophotometer.

polymers, and HA-like regions (Chen et al., 2003). The fluorescence intensities of the peaks are the highest at acidic conditions (pH 3.0). The λ_{em} values of peak 2 and 3 decrease with the increasing pH. These results support that pH affects the morphology of NOM.

There are a main peak (290/480 nm) and two nearby small peaks in the EEM spectra of LEV (Figure 2d, e, and f). At high pH, the λ_{em} values of the three peaks also decrease, and the intensity is the highest. This is because under different pH conditions, LEV molecule is mainly cationic, zwitterionic (or neutral), or anionic.

Four peaks are observed in the mixtures, which seems to be the simple sum of the EEM spectra of PHA and LEV (especially for peak 1), and the intensities of the peaks should be larger than that of the single one. However, as shown in Table 1, the intensities of the other three peaks are much smaller than the sum values, even smaller than that of LEV alone, especially at pH 6.0. As a result, the interactions (*i.e.* adsorption) between HA and LEV occur, which become strong at neutral conditions, and much weaker at pH 3.0 and 9.0.

4 CONCLUSIONS

Adsorption isotherms at different concentrations of PHA were well fitted to the Langmuir model, and additional amount of LEV adsorbed is proportional to the amount of PHA added, which indicates that the main mechanism of increased LEV adsorption is probably co-adsorption with NOM adsorbed. The Excitation-Emission Matrix (EEM) spectra results indicated the interactions (*i.e.* adsorption) between HA and LEV, which become strong at neutral conditions, and much weaker at other conditions.

Calcium and manganese affect ethanol fermentation by *Pichia stipitis* in cadmium-containing medium by inhibiting cadmium uptake

ABSTRACT: In this study, the effect of Cadmium (Cd) on ethanol fermentation by *Pichia stipitis* was investigated. *P. stipitis* was sensitive to Cd, which reduced cell growth and diminished ethanol production. The inhibitory effect of Cd on ethanol fermentation decreased upon the addition of Calcium (Ca) and Manganese (Mn); the role of Mn was less significant compared to that of Ca. These results correlated with the inhibitory effect of the metals on the uptake of Cd by *P. stipitis*, with Ca having a greater effect on the uptake of Cd than Mn. However, Mn could also increase the inhibitory effect of Ca on the uptake of Cd. Simultaneous addition of both Ca and Mn lowered cellular Cd level and resulted in a greater degree of fermentation, demonstrating that this treatment can be used to improve ethanol production from Cd-contaminated biomass.

1 INTRODUCTION

Bioethanol is considered an alternative to petroleum. It can be easily produced from agricultural products (Nikolić et al., 2010), such as corn meal and sugar-cane. However, bioethanol production from such biomass competes with food suppliers and thereby causes food shortages and price increases. Lignocellulosic materials, such as forest and agricultural residues, are a potential alternative feedstock for the production of bioethanol because their use would not affect the food supply. However, lignocellulosic biomass contains a greater amount of lignin and complex polysaccharides than starch and monosaccharides. These features make lignocellulosic biomass difficult to be hydrolyzed to fermentable sugars that can then be bioconverted into ethanol, resulting in high costs for ethanol production.

To reduce the high cost of ethanol production from lignocellulosic biomass, research has focused on biorefinery improvements such as efficient production of cellulase, improvement of pretreatment, and process development for ethanol production. Although improvements in the efficiency of biorefinery processes could lead to a decrease in the cost of ethanol production, such efforts would be insufficient for substituting ethanol for petroleum since the price of ethanol would still be much higher than petroleum. Therefore, alternate research strategies should be considered.

Environmental pollution by toxic metals has been increasing worldwide because of industrial progress (Xue et al., 2014). Cd is toxic at low levels;

it can enter the food chain, accumulate in the body through repeated exposure, and can exert irreversible effects (Abadin et al., 2007). Crops grown on heavy metal-contaminated soils can absorb heavy metals. Cd absorbed by plant roots and transported to ground tissues of plants poses a potential threat to human health through the food chain (Kuboi and Yazaki, 1986). Chronic exposure to Cd causes a variety of health problems, such as Itai-Itai disease. Xu et al. (2013) studied the uptake and distribution of Cd in sweet maize grown on contaminated soils and demonstrated that the Cd concentration in sweet maize decreases from its highest levels in the sheath to its lowest levels in the fruit. Therefore, soil remediation with crops (phytoremediation) could be a promising technology. In the future, the demand for soil remediation would increase markedly, resulting in the generation of a potentially huge market. However, fruits contaminated with Cd cannot be used as food and the contaminated straws of crops cannot be used as fodder. The disposal of metal-containing biomass has been a significant limitation of this technology. However, since metal-contaminated biomass contains starch, cellulose, and hemicelluloses, it could be repurposed as raw materials for biorefinery. The combination of biorefinery and soil remediation can not only ease environmental problems, but can also reduce both costs for biorefinery and soil remediation. Furthermore, problems concerning the disposal of metal-containing biomass could potentially be solved and the released heavy metals could be removed from the food chain.

In the past decade, a few teams have studied the response of *S. cerevisiae* to Cd. Oliveira et al. (2011) found that the use of vinasse minimized the negative effects of Cd on cell mass concentration, cell viability, and budding rate. Gharieb and Gadd (2004) showed that a *S. cerevisiae* strain deficient in Glutathione Synthase Hydroxylase (GSH) displayed a higher sensitivity to Cd than its wild-type strain. Mielnicki-Pereira et al. (2011) reported that the detoxification of Cd is mainly dependent on ion binding with GSH in *S. cerevisiae*. GSH detoxification of Cd also occurs in other organisms (Rehman and Anjum, 2010). Moreover, metal ions can affect uptake of Cd and subsequently reduce its toxicity (Zhao et al., 2004). This detoxification could be linked to competitive transport between metal ions due to the similar radii of Ca and Cd (Long et al., 2012); in support of this, Ca^{2+} -ATPases contribute to Cd tolerance in *S. cerevisiae* (Mielnicki-Pereira et al., 2011).

Despite numerous studies on toxicity of Cd towards *S. cerevisiae*, no study has investigated its effects on ethanol production by the yeast strain *P. stipitis*. In particular, there has been no study on the effect of Cd on the metabolism of xylose for ethanol production. The objective of this work was to study the effects of Cd on the metabolism of glucose and xylose in order to enhance detoxification and increase fermentation efficiency in *P. stipitis*, a highly efficient xylose-fermenting strain. Accordingly, the effects of Ca and Mn on Cd uptake by *P. stipitis* were investigated.

2 MATERIALS AND METHODS

2.1 Fermentation

The yeast strain *Pichia stipitis* (CICC 1960) used for ethanol fermentation was obtained from Shanghai Industrial Microbiology Institute Tech. Co., Ltd. Fermentations were carried out in shaking test tubes with 5 mL medium containing 40 g/L glucose, 20 g/L xylose, 8 g/L peptone, 2 g/L yeast extract, 2 g/L $(\text{NH}_4)_2\text{SO}_4$, 1 g/L $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$, and 1.5 g/L KH_2PO_4 . Fermentations were started at an initial OD_{600} of 1.0 and incubated at 30°C and 200 rpm. For the investigation of the effect of metal ions on ethanol production, the concentration of CdCl_2 ranged from 25 to 100 $\mu\text{mol/L}$. In preliminary experiments, the optimum molar ratios of Ca and Mn to Cd were found to be 100:1 and 1:1, respectively, and were therefore used in this study.

2.2 Cell dry weight and enzyme activity

After 24-h fermentation, cells were collected for measurements of cell dry weight and enzyme activity. For cell dry weight measurement, cells were washed with water followed by drying at 105°C overnight. For enzyme activity measurement, cells were rup-

tured with glass beads (425–600 μm) by vortexing at 30-s intervals and were then kept on ice for 30 s. The resulting suspensions were centrifuged at 12,000 rpm, 4°C for 10 min and the supernatants were used for enzyme activity measurement. Xylitol Dehydrogenase (XDH) activity was measured by monitoring the reduction in NAD(P)^+ at 340 nm and 30°C in a reaction mixture containing: 71 mM Tris-HCl buffer (pH 8.2), 0.5 M xylitol, and 1.2 mM $\text{NAD}^+/\text{NADP}^+$. Xylose Reductase (XR) activity was measured by monitoring the oxidation of NADPH at 340 nm and 30°C in a reaction mixture containing: 71 mM Tris-HCl buffer (pH 7.2), 2 M xylose, and 1.2 mM NADPH. One unit of enzyme activity was defined as the amount of enzyme that reduced or oxidized 1 μmol NAD(P)^+ or NAD(P)H per min.

2.3 Measurement

Samples were taken periodically and centrifuged at 15,000 rpm for 5 min. Glucose, xylose and ethanol concentration in the fermentation broth were analyzed on an Exformma EX1600 HPLC system (Shanghai Wufeng Scientific Instruments Co., Ltd., Shanghai, China) using an Aminex HPX-87H column (300 \times 7.8 mm, Bio-Rad, USA). The separation of sugars and ethanol was performed at 0.6 mL/min and at 65°C with 5 mM H_2SO_4 as the mobile phase.

The concentration of NAD(P)^+ or NAD(P)H was measured with a spectrophotometer (UV-2102C, Unico Instrument Co., Ltd, Shanghai, China) at 340 nm. The concentration of Cd was measured with an atomic absorption spectrophotometry (AH-670, Shimadzu Co., Ltd, Japan).

3 RESULTS AND DISCUSSION

Since *P. stipitis* can ferment both glucose and xylose, fermentation was carried out in media containing both glucose and xylose, and Cd concentration was varied from 25 to 100 $\mu\text{mol/L}$; fermentation without Cd was used as a reference. As shown in Fig. 1, at 25 $\mu\text{mol/L}$ Cd, both glucose and xylose were completely consumed within 48 h, resulting in 17.6 g/L ethanol. Compared to fermentation without Cd, fermentation with 25 $\mu\text{mol/L}$ Cd had much lower consumption rates of glucose and xylose, and consequently lower titer of ethanol, indicating the inhibitory effect of Cd on ethanol fermentation by *P. stipitis*. The inhibitory effect became more severe with increasing Cd concentration. At Cd concentrations above 50 $\mu\text{mol/L}$, xylose consumption at 48 h markedly decreased, resulting in a sharp decrease in ethanol titer (Fig. 1C, D). The lesser consumption of xylose could result from much low consumption rate of glucose (Fig. 1B). It should be noted that OD_{600} also decreased proportionally with increasing Cd concentration (Fig. 1A). However, the decrease in OD_{600}

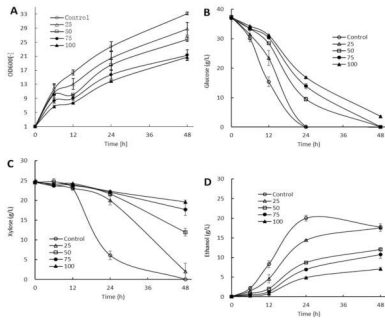

Figure 1. Effect of Cd on ethanol fermentation. The concentrations of cell mass (A), glucose (B), xylose (C) and ethanol (D) change over time during fermentation in the presence of Cd at increasing concentrations (25, 50, 75, 100 µmol/L) compared to that in the absence of Cd. All values are expressed as the mean \pm standard deviation (SD) for two experiments (n = 2).

was lower than that in ethanol production; e.g., the maximum OD 600 at 100 µmol/L was 1.6-fold lower than that without Cd, while the maximum concentration of ethanol at 100 µmol/L was 2.9-fold lower than that in the absence of Cd. These results demonstrated that Cd had higher influence on ethanol production than on cell growth.

Cd toxicity towards plants and microorganisms has been widely reported (Perfus-Barbeoch et al., 2002). Its toxicity is mainly related to induction of oxidative stress and interference with intracellular signaling and DNA repair. Other metals (e.g., zinc (Zn), magnesium (Mg), Mn and Ca) can affect plant uptake of Cd and subsequently reduce toxicity of Cd to the plants (Zhao et al., 2004, Long et al., 2012). The effects of Mn, and Ca on ethanol fermentation are shown in Figure 2. In these experiments, Cd concentration was set at 50 µmol/L. Among the metals, Zn and Mg had little effect on the tolerance of *P. stipitis* towards Cd (data not shown). In contrast, Ca and Mn had apparent effects on the tolerance of *P. stipitis* towards Cd (Fig. 2). When Ca or Mn was added, the increase in OD 600 was much higher than that with Cd alone at 12 h (Fig. 2 A). In the earlier period (0–12h) of the fermentations, the effect of Ca on the growth rate was similar to that of Mn, and after 24 h, the effect of Ca was higher than that of Mn (Fig. 2 A). The addition of Ca or Mn also had positive effects on sugar consumption, as both the consumption rates of glucose and xylose increased sharply relative to those where only Cd was present (Fig. 2B, C). However, there were little differences in the effects of Ca and Mn on glucose consumption, while Ca had more significant effect on the consumption of xylose than that of Mn (Fig. 2B). The effects of Ca and Mn on sugar consumption can be explained by the uptake of Cd. As shown in Fig. 3, when Ca or Mn was not present, the Cd concentration in cells increased markedly at 24 h. The maximum

Cd concentration was 297.8 µg/g of dried cell. This uptake of Cd was limited by the addition of Ca or Mn. When Ca or Mn was present, the Cd concentration in cells increased very little by 12 h. Afterwards, Cd concentration in cells maintained a low level relative to Cd alone even though there were increases in Cd concentration along with time, indicating the inhibitory effects of Ca and Mn on the uptake of Cd. The lower uptake of Cd would be responsible for the higher rates of sugar consumption. The inhibitory effects of Ca and Mn on the uptake of Cd could be linked to competitive transport between metal ions, owing to their similar atomic radii. Because cellular Cd concentrations were maintained at a relative low level in the presence of Ca or Mn in the earlier periods of fermentation, minimal inhibitory effect of Cd on glucose consumption was observed. In contrast, when xylose began to be consumed, large amounts of Cd accumulated in cells, e.g., at 24 h the cellular Cd concentrations were 157.9 µg/g of dried cell and 237.9 µg/g of dried cell, for Ca and Mn additions, respectively. The accumulation of Cd in cells would

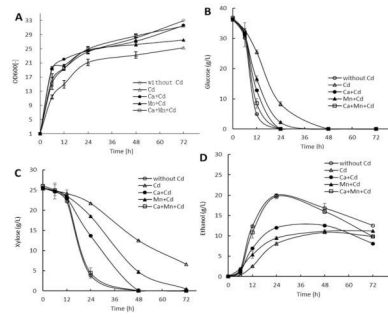

Figure 2. Effects of Ca and Mn on ethanol fermentation with Cd. The concentrations of cell mass (A), glucose (B), xylose (C) and ethanol (D) change over time during fermentation with addition of metals (Ca, Mn, both Ca and Mn) in the presence of Cd compared to that in the absence of Cd. The results represent the mean of two independent experiments.

Figure 3. Effects of Ca and Mn on Cd uptake by *P. stipitis*. The intracellular Cd content changes over time during fermentation with addition of metals (Ca, Mn, both Ca and Mn) in the presence of Cd. Bars indicate means (n = 2).

Table 1. Effects of Cd on XR and XDH activities.

	Relative enzyme activities (%)	
	XR	XDH
Without Cd	100	100
With Cd	76.22 ± 3.78	32.81 ± 2.21

result in lower consumption rates of xylose. Enzyme activity assays reveal that Cd significantly inhibited xylose metabolism (Table 1). Inhibited metabolism of xylose could be attributable to the low conversion rate of xylose into ethanol in the presence of Cd. Since Ca had a marked effect on Cd uptake compared to Mn, the consumption rate of xylose during fermentation was higher in the presence of Ca than that in the presence of Mn.

We found that the addition of ions had a positive effect on the production of ethanol at 12 h (Fig. 2D), while ethanol was hardly produced after 24 h even though the consumption of xylose was improved by the addition (Fig. 2C). This result demonstrates that the production of ethanol was linked to the accumulation of Cd in cells, and under Cd-induced stress, the conversion of xylose into ethanol decreased, which could explain why Cd had marked influence on ethanol production compared to its effects on cell growth. After 24 h, Cd release was apparent (Fig. 3), which may be owing to destruction of cell membrane by Cd accumulation.

Taken together, it was clear that the addition of Ca or Mn was not sufficient to cope with Cd toxicity towards *P. stipitis*, even though the addition could limit the uptake of Cd. Surprisingly, the use of both Ca and Mn significantly inhibited the uptake of Cd (Fig. 3). The Cd concentration in cells was maintained at a very low level and did not drastically change during fermentation. The reason for these effects is not clear; however, ethanol fermentation was not inhibited by Cd in the presence of both Ca and Mn (Fig. 2D). Under these conditions, the production rate of ethanol, the consumption rates of sugars were no different from those in media with only Cd (Fig. 2B,C), while the maximum titer of ethanol was 4-fold higher (Fig. 2D).

4 CONCLUSIONS

In this study, we found inhibitory effects by Ca and Mn on the uptake of Cd by *P. stipitis*. The tolerance of *P. stipitis* towards Cd increases upon joint application of Ca and Mn, an effect that would be beneficial to the development of *P. stipitis* as a key player in cellulosic ethanol production. However, the exact mechanism through which Ca and Mn together limit the uptake of Cd by *P. stipitis* remains unknown; further, how *P. stipitis* utilizes xylose for cell growth under Cd stress is unclear. A more

detailed study is therefore required to investigate the mechanism of the effect of the joint application of Ca and Mn on the uptake of Cd by *P. stipitis*.

ABSTRACT: Biological Aerated Filters (BAFs) are a promising biological oxidation technology for wastewater treatment and reuse. The characteristics of packing media in BAFs considerably affect the removal of pollutants. This study aims to compare and investigate the pollutant removal performance of two identical bench-scale BAFs, BTF 1 and BTF 2, to evaluate the feasibility of employing polyurethane sponge as BAF media. BTF 1 and BTF 2 were packed with polyurethane sponges and ceramic particles, respectively, and evaluated for COD and $\text{NH}_4^+\text{-N}$ removal at various hydraulic loadings. When the hydraulic loading was varied from 5 L/h to 20 L/h, the overall COD removal efficiencies of BAF 1 and BAF 2 reached 82.8% and 78.5%, respectively. BAF 1 performed better in COD removal than did BAF 2 under low hydraulic loadings of 5 and 10 L/h. The removal efficiency for COD and $\text{NH}_4^+\text{-N}$ rose with increasing media height in both BAF systems. The majority of COD and $\text{NH}_4^+\text{-N}$ removal occurred within a media height of 0.4 m. The BAF 1 system exhibited a higher and steadier treatment performance for COD and $\text{NH}_4^+\text{-N}$ removal because of the large specific surface area and high porosity rate of the polyurethane sponges. These results indicate that polyurethane sponges have potential as media in BAFs.

1 INTRODUCTION

Biological Aerated Filters (BAFs) are a promising biological oxidation technology for wastewater treatment and reuse (Bao et al., 2011; Qiu et al., 2010). A BAF is a fixed film biological process used for the simultaneous removal of carbonaceous matter, ammonia, and suspended solids in a single unit primarily by interception, biological metabolism, and adsorption (Ryu et al., 2008). The advantages of this system include high efficiency, small footprints, ease of operation and management, and modular construction; the system also does not require a secondary clarifier (Osorio and Hontoria, 2001). Given these merits, BAFs serve as an effective alternative to the traditional activated sludge process commonly used in wastewater treatment. BAF systems are currently widely used for secondary and tertiary treatment of wastewater or reclaimed water reuse. Improving the treatment efficiency and operation stability of BAFs necessitates further study of impact factors such as packing media and operation optimization (Shen et al., 2009; Qiu et al., 2010).

The packing materials in BAFs act as solid interceptors, solid/liquid separators, and biofilm carriers. The characteristics of the packing media used

in BAFs considerably affect wastewater treatment performance. Moreover, packing media determine capital construction investment and operating cost (Han et al., 2009; Qiu et al., 2010). The media used in BAFs fall under two categories. The first comprises conventional packing media, such as ceramic particles, granular zeolites, sands, shales, and carbonate media (Qiu et al., 2010). Extensive research has been done on this category. Although these mineral materials show excellent biological performance, they are prone to attrition and easily form clogging in media by biomass or attached high-density solids, thereby leading to frequent backwashing (Kent et al., 1996). The other category is synthesis media, which include plastic materials and carbon foams (Bao et al., 2011). They have very low attrition levels but exhibit inferior performance (Mendoza-Espinosa and Stephenson, 1998). Therefore, the development of novel and effective packing materials for BAF is a crucial requirement.

As a synthesis media, polyurethane sponge has a high porosity and external surface area, rough surface, and uniform open-pore reticulated construction. However, no report has been published on the performance of BAF systems that use polyurethane sponge as packing media. The present study aims to

compare the performance of two BAFs packed with the polyurethane sponge and ceramic particles under the same operational conditions to evaluate the suitability of polyurethane sponge as BAF media.

2 MATERIALS AND METHODS

2.1 Experimental set-up

Two identical bench-scale biofilters, designated as BAF 1 and BAF 2, were packed with polyurethane sponge and ceramic particles, respectively. Fig. 1 shows a schematic of the BAFs. The reactors are made of transparent Plexiglas. Each reactor is cylindrical with an overall height of 1.2 m and a diameter of 0.1 m. The media within a reactor measures 0.8 m with a total effective volume of 6.3 L. Aside from a sample port placed at the base of each reactor, four liquid sampling ports are located at 0.2 m intervals along the height of each reactor. A sieve plate divides each of the reactors into two sections. The bottom section (height, 0.15 m) of the column serves as a reservoir for influent water and provides uniform water distribution. The upper section (height, 0.1 m) of the column houses a gravel support layer, which is located beneath a media layer. The support gravel protects the water nozzle from clogging by smaller media and improves the distribution of gas bubbles over the cross-sectional area of the media. To provide backwash water, a storage tank collects effluent. A water pump injects the liquid influent at the base of each column and oxygen is supplied by an air blower that injects air through porous stones located at the bottom of each reactor. An air flow meter controls the airflow according to operational requirements.

Figure 1. Schematic diagram of the BAFs.

Table 1. Characteristics of polyurethane sponge and ceramic particles.

Media	Shape	Size (mm)	Surface area (m ² /m ³)	Porosity rate
Polyurethane	Cylindrical	φ100 × 100	≥ 950	95%
Ceramic particles	Granular	4–6	≤ 400	30%

Table 2. Main ingredients of the simulated domestic wastewater.

C ₆ O ₆ H ₁₂ (mg/L)	NH ₄ Cl (mg/L)	KH ₂ PO ₄ (mg/L)	CaCl ₂ (mg/L)	FeCl ₃ (mg/L)	MgSO ₄ (mg/L)
300 ± 1.0	80 ± 0.5	20 ± 0.5	25 ± 0.5	3.7 ± 0.05	2.5 ± 0.05

For the experiment, both BAFs were operated in co-current modes with gas and wastewater flowing upward. The BAFs were backwashed every 48 h. Combined air–water backwashing was employed, with the procedures implemented in sequence as follows: air scouring for 4 min, air and water washing for 6 min, and water rinsing for 10 min. The water and air flushing strength were set at 8 and 10 (L/m²·s).

Two BAF reactors were packed with polyurethane sponge and ceramic particles. Open-pore reticulated polyurethane sponges with a pore size of 10 pores per cm (Shenzhen Jiechun Filter Material Co., Ltd., Guangdong, China) were used as the filter bed media. Table 1 shows the characteristics of the two media.

2.2 Synthetic wastewater

The two BAFs were fed with synthetic wastewater throughout the experimental period. Table 2 shows the composition and concentration of synthetic domestic wastewater.

2.3 Analytical methods

Samples from the influent, effluent, and sampling ports were obtained regularly at different filter heights. The concentrations of Chemical Oxygen Demand (COD), ammonia-N (NH₄⁺-N), and Suspended Solids (SS) were analyzed according to the Standard Methods for the Examination of Water and Wastewater (APHA, AWWA, WEF, 2005). Air and water temperatures, pH, and Dissolved Oxygen (DO) were routinely monitored daily during the evaluation period. Flow rates to the BAFs were measured with a glass rotameter. Head loss was measured using a piezometric tube. All the samples were measured in triplicate.

3 RESULTS AND DISCUSSION

3.1 Startup stage

To accelerate biomass growth, the polyurethane sponge was marinated and inoculated with activated sludge from a secondary sedimentation tank at Changsha Guozhen Wastewater Treatment Co., Ltd (Hunan, China). The concentration of mixed liquor suspended solids in the original activated sludge was 3500 mg/L. The two BAFs were inoculated simultaneously.

The startup of the BAFs was carried out with the bioreactor operated in batch mode and seeded with sludge and synthetic wastewater for three days. After this, the operation mode was shifted to continuous flow mode. The synthetic wastewater flow rate adopted for 4 days was 3 L/h. During this startup period, the operational parameters were kept at a hydraulic retention time of 2.5 h and a Dissolved Oxygen (DO) concentration higher than

2 mg/L at room temperature. The accumulation process lasted for one week, after which a yellowish-brown biomass was observed to have accumulated on the packing materials. Figs. 2 and 3 present the removal performance of polyurethane sponge and ceramic particles during the start-up. As shown in the figures, COD and $\text{NH}_4^+\text{-N}$ removal during the start-up did not differ significantly between the two BAFs. Over the first 7 days of the start-up, the volumes of effluent COD and $\text{NH}_4^+\text{-N}$ in the two BAFs declined with running time. On day 8, the first backwashing was carried out. COD and $\text{NH}_4^+\text{-N}$ removal was relatively steady as indicated by the effluent quality. This result shows that a successful startup was conducted for the two BAFs. The BAFs were then switched to normal operations to evaluate treatment performance.

3.2 COD removal performance of the BAFs under various media heights

Fig. 4 shows the COD removal performance of the two reactors under different hydraulic loadings with media height. The results illustrate promising COD treatment performance for the two materials. At hydraulic loadings of 5, 10, 15, and 20 L/h, the COD concentration and removal efficiency of both reactors showed a similar tendency. The total average removal efficiencies of BAF 1 and BAF 2 were 82.8% and 78.5%, respectively. Even under a hydraulic loading of 20 L/h, the COD removal efficiencies of the two BAFs were 78.0% and 80.6%, respectively. The corresponding residual COD concentrations were 56.9 and 50.2 mg/L for BAF 1 and BAF 2, respectively [Fig. 4(d)]. Therefore, the effluent quality satisfies the requirement for reuse.

Figure 2. COD removal performance in BAFs with polyurethane sponge and ceramic particle during start-up.

Figure 3. $\text{NH}_4^+\text{-N}$ removal performance in BAFs with polyurethane sponge and ceramic particle during start-up.

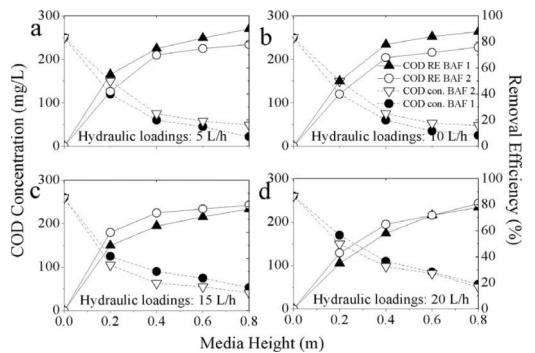

Figure 4. Profile of COD removal in BAFs with different media under hydraulic loadings of 5, 10, 15 and 20 L/h (●) COD concentration in polyurethane sponge BAF; (▽) COD concentration in biological ceramic BAF; (▲) COD removal efficiency in polyurethane sponge BAF; (○) COD removal efficiency in biological ceramic BAF.

Moreover, Fig. 4 shows that the majority of the COD content in the BAFs can be removed within a 0.4 m media in the upflow direction under various hydraulic loadings. At a media height of 0.4 m, the COD removal efficiency of the BAFs reached more than 63% and 56%. The removal efficiency depended primarily on the accumulation of activated biological film in the filter media and mass transfer efficiency. Organic matter degradation occurred primarily in the inlet area because of the competitive advantage of heterotrophic bacteria. The biofilm attached from the lowermost to the uppermost section media contributed to the degradation of organic matter, whereas only the biofilm in some sections close to the inlet played an important role in the aforementioned process. The lowermost surface of the sponge media contributed significantly to COD removal for the upflow BAFs because of the accumulation of a more active biomass in this region. The concentrations of organic compounds and DO were sufficient at the bottom of the filters, which favored the growth of heterotrophic bacteria.

BAF 1 performed better for COD removal than did BAF 2 under low hydraulic loadings (5 and 10 L/h; Fig. 4). The difference in removal efficiency between the two BAFs is more than 10%. By contrast, BAF 2 exhibited higher removal efficiency under high hydraulic loadings, but its performance did not differ sharply from that of BAF 1. The differences in the surface characteristics, specific surface areas, and morphological characteristics of the media were the principal factors that influenced COD removal. The polyurethane sponges used in BAF 1 presented a considerably more regular shape, which allows for even biofilm distribution on the BAF. This uniform distribution resulted in a high mass transfer coefficient under low shear by water. However, an increase in hydraulic loadings resulted in the low removal efficiency for biofilm runoff from the media.

3.3 NH_4^+ -N removal performance of the BAFs under various media heights

Fig. 5 shows the average removal efficiency for and variations in concentration of NH_4^+ -N in the BAFs under hydraulic loadings of 5, 10, 15, 20 L/h. Overall, BAF 1 performed slightly better than did BAF 2 for ammonia removal under the same hydraulic loadings. The BAF functioned as a push-flow reactor, in which competition between carbonation heterotrophic and autotrophic nitrifying bacteria exists. In addition, organic matter inhibited the growth of autotrophic nitrifying bacteria. Therefore, organic matter should generally be degradable first along the flow direction for NH_4^+ -N removal to gradually increase. In this

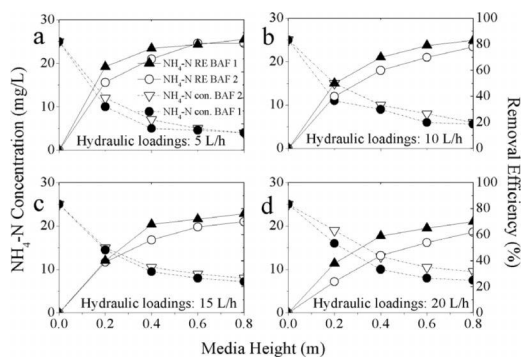

Figure 5. Profile of NH_4^+ -N removal in BAFs with different media under hydraulic loadings of 5, 10, 15 and 20 L/h. (●) NH_4^+ -N concentration in polyurethane sponge BAF; (▽) NH_4^+ -N concentration in biological ceramic BAF; (▲) NH_4^+ -N removal efficiency in polyurethane sponge BAF; (○) NH_4^+ -N removal efficiency in biological ceramic BAF.

study, however, the tendency of concentration and removal efficiency for NH_4^+ -N with media height in the two BAFs was the same as that for COD. The removal efficiency for NH_4^+ -N increased with increasing media height. Most of the NH_4^+ -N reductions also occurred at a media height of 0.4 m (Figs. 4 and 5).

Three possible factors explain the phenomenon of most of the NH_4^+ -N reductions within 0.4 m media. The first is influent wastewater quality. Glucose and ammonium chloride, which are easily decomposed and absorbed by microbes, were used as carbon and nitrogen source, respectively. There was adequate DO within a media height of 0.4 m in the two BAFs, thereby promoting the possibility of coexistence between carbonation heterotrophic and nitrifying autotrophic bacteria. In addition, as carbonation heterotrophic bacteria degrade organic matter, they consume some of the nutritional substances including NH_4^+ -N.

The second factor is the manner by which the media was configured. The microbes in the BAF can be divided into the biofilm attached on the media and the activated sludge suspended in the media gaps. The morphological characteristics of the ceramic particles thickened and stabilized the biofilm in the inner surface and concavity of the ceramic particles. The biofilm was also minimally affected by hydraulic conditions. Therefore, the ceramic particles are suitable for the growth of bacteria with long generation times. The convexity or angularity of ceramic particles, which were subjected to collision and attrition, as well as the shear stress on water flow and air bubbles, which had a high concentration of organic matter and DO, promoted the growth and rapid reproduction of heterotrophic bacteria. Therefore, the configura-

tion of the ceramic particles induced carbonation, which caused heterotrophic and nitrifying autotrophic bacteria to occupy different locations, and reduced the competition for space between them. Polyurethane sponge has a large specific surface area and high porosity rate, which allowed for sufficient space for the carbonated heterotrophic and nitrifying autotrophic bacteria.

The third factor is once the autotrophic nitrifying bacteria that were cultivated in the biofilm matured, they were able to grow steadily (Ohashi et al., 1995). During the stable operation of the BAFs, the maturation of the nitrifying bacteria in the biofilm weakened and eventually eliminated the competitive inhibition between carbonated heterotrophic and nitrifying bacteria.

Fig. 5 shows that the concentration of effluent $\text{NH}_4^+\text{-N}$ increased when the hydraulic loading was increased from 5 L/h to 20 L/h. The hydraulic loading imposed a more obvious effect on $\text{NH}_4^+\text{-N}$ than on COD removal. In particular, the effect on $\text{NH}_4^+\text{-N}$ removal efficiency was sharper under high hydraulic loadings (10 and 20 L/h). These results differ from those of a previous study conducted with a single-stage Biofor system: nitrification efficiency was suggested to improve with increased hydraulic loading (Pujol et al., 1998). The effect of hydraulic loading on BAF performance is dual: high hydraulic loading improved the substrate, DO, and mass transfer rates between the environment and biofilm, but it also meant a short retention time for the substrate. The other factor that may have led to this dual effect is the competition between the heterotrophic and nitrifying bacteria for oxygen and space.

4 CONCLUSION

BAFs packed with polyurethane sponge or ceramic particles were employed for the treatment of synthetic wastewater under the same conditions. The overall COD removal efficiencies of the BAFs were an average of 82.8% and 78.5%. BAF 1, packed with polyurethane sponge, exhibited better performance for COD removal than did BAF 2, packed with the ceramic particles, under low hydraulic loadings of 5 and 10 L/h. The removal efficiency for COD and $\text{NH}_4^+\text{-N}$ increased with increasing media height in both BAFs, while most of the reductions in COD and $\text{NH}_4^+\text{-N}$ occurred within a media height of 0.4 m. The polyurethane sponges with large specific surface areas and high porosity rates provided sufficient space for the carbonated heterotrophic and nitrifying autotrophic bacteria, which resulted in the higher removal efficiency for $\text{NH}_4^+\text{-N}$.

Compared with the BAF 2 system, the BAF 1 system exhibited a higher and steadier treatment

performance for COD and $\text{NH}_4^+\text{-N}$ removal. Therefore, a BAF system for wastewater treatment can extensively use polyurethane sponge as its packing media.

ABSTRACT: In this paper, Ni-Al catalyst derived from LDHs was prepared. CH₄-CO₂ reforming was chosen as the probe reaction to evaluate the catalytic activity. The traditional catalyst with alike composition (Ni-Al-IMP) was also prepared as the reference. At the temperature range of 650–850, the Ni-Al-LDH catalyst exhibited a higher activity, and the side reaction of reverse water-gas reaction was inhibited. The related samples, including catalyst support, catalyst precursor, and catalyst, were characterized by XRD, SEM, and FT-IR. The results showed that the Ni-Al-LDH with CO₃²⁻ serving as the interlayer anion was successfully synthesized on the γ -Al₂O₃ support and presented in the layer structure. Ni existed as the divalent cation in this LDH and was present in the atomic-level dispersion, resulting in a smaller crystal size, better dispersion, and more active sites. It can be concluded that the highly dispersed Ni crystal played a key role in the enhanced catalytic activity of Ni-Al-LDH catalyst.

1 INTRODUCTION

With the rapid development of society and economy, fossil energy has been widely used. And the resulting experimental issues have aroused widespread attention in recent years (Feely et al. 2011, Wang et al. 2015, Saidi et al. 2015). Moreover, the finite-energy resource is difficult to meet the increasing energy demands of the society in the long run. Thus, the sustainable global development of energy and environment is a critical and strategic challenge.

Although CO₂ has been considered to be the main human-related greenhouse gas (Liu et al. 2016), it is also a kind of carbon resource. By means of chemistry and chemical engineering, converting CO₂ and CH₄ to syngas (a mixture of H₂ and CO), which can be converted to liquid fuel, is an effective way to realize the carbon cycling, relieving the experimental and energy crisis.

Ni-based catalyst has been recognized as the strongest candidate for the industrial application of CH₄-CO₂ reforming because of its lower price and higher catalytic activity. As CH₄-CO₂ reforming (CH₄ + CO₂ = 2H₂ + 2CO) is strongly endothermic, a higher temperature is required to achieve better conversion. However, the Ni catalyst can be easily deactivated by the sintering and agglomeration of Ni atoms. Furthermore, the carbon content of this system is relatively high (compared with the

commercial CH₄-H₂O reforming system), and the deposited carbon generated by side reactions may cover and wrap the Ni atoms, thereby deactivating it. It is reported that the size of Ni crystal has a close relationship with the generation of deposited carbon, more Ni atoms are needed to promote the side reaction (CH₄ = C + 2H₂) at high temperature. Thus, a catalyst with better Ni dispersion, smaller Ni crystal size, and stronger interaction between Ni and support can be produced by CH₄-CO₂ reforming (Han et al. 2014).

Layered Double Hydroxides (LDHs) are lamellar mixed hydroxides containing positively charged main layers and undergoing anion exchange chemistry. Researches revealed that LDHs have high specific surface area, inherent metal atom dispersion, and alkalinity, which make them possible to become a good candidate catalyst material (Romero et al. 2014, Rezende et al. 2015, Zhang et al. 2014, Montañez et al. 2014). Ni-Mg-Al catalyst derived from LDHs has been prepared and used in the autothermal reforming of CH₄ by Katsuomi Takehira (2004), and a higher catalytic activity was obtained by comparing with the conventional catalyst prepared by the impregnation method. Alak Bhattacharyya et al. (1998) synthesized a hydrotalcite clay catalyst via CH₄-CO₂ reforming and gained prospective excellent performances. In our previous work, we prepared Ni-Co-Al catalyst with LDH precursor for CH₄-CO₂

reforming and found that the catalyst with Ni/Co ratio of 8/2 achieved the highest conversions and best stability in 100 h testing (Long et al. 2013).

Several studies focused on catalysts derived from pure LDH materials. However, the mechanical strength of this type of catalyst is poor, which makes it not well suited for the $\text{CH}_4\text{-CO}_2$ reforming. In this paper, LDHs were in-situ synthesized on a porous $\gamma\text{-Al}_2\text{O}_3$ support. And its catalytic activity was evaluated and compared with the reference catalyst prepared by impregnation method. XRD, SEM, and FT-IR were used to analyze its microstructure.

2 EXPERIMENTAL

2.1 Preparing Ni-Al catalyst derived from LDHs

Details of the preparation process of Ni-Al catalyst derived from LDHs were described as follows: first, 1.783 g of $\text{Ni}(\text{NO}_3)_2\cdot 6\text{H}_2\text{O}$ and 0.737 g of $\text{CH}_2\text{N}_4\text{O}$ (the molar ratio of $\text{CH}_2\text{N}_4\text{O}/\text{NO}_3^-$ was 1) were mixed and dissolved in 5 ml of deionized water to make a solution. Second, 2.64 g of $\gamma\text{-Al}_2\text{O}_3$ particles (the diameter was about 0.38–0.83 mm) serving as support and Al^{3+} source were added to the prepared solution and impregnated for 2 h. Then, the excess liquid was removed, and the obtained particles were aged for 6 h at 130°C to form the LDH structure followed by filtering, washing to neutral pH, and drying for 12 h at 70°C in sequence. The obtained product was the precursor of the Ni-Al catalyst, that is, Ni-Al-LDHs/ $\gamma\text{-Al}_2\text{O}_3$. The precursor was then calcined (air atmosphere, 550°C , 5 h) and reduced (H_2 atmosphere, 700°C , 2 h) to obtain the target catalyst, Ni-Al-LDH.

The reference catalyst was prepared by the common impregnation method described as follows: first, 1.783 g of $\text{Ni}(\text{NO}_3)_2\cdot 6\text{H}_2\text{O}$ was dissolved in 5 ml of deionized water. Then, 2.64 g of $\gamma\text{-Al}_2\text{O}_3$ particles was put into the solution and impregnated for 4 h followed by drying, calcination, and reduction under the same conditions mentioned above to obtain the reference catalyst noted as Ni-Al-IMP.

2.2 Evaluation of catalyst

The catalytic activity was evaluated in a fixed-bed continuous-flow reactor. The reactor, made of quartz with 6 mm internal diameter, was mounted horizontally inside a tubular furnace. The catalyst (200 mg) was charged in the quartz tube reactor. The reaction temperature varied within the temperature range of $650\text{--}850^\circ\text{C}$, and the reactant feed was $\text{CH}_4/\text{CO}_2 = 2/3$ with the GHSV of 30 L/(g·h). The effluent was passed through a trap to condensate residual water and then analyzed by an in-line gas chromatography (GC-102) equipped with a TCD detector. The conversions of CH_4 and CO_2 and the selectivities of H_2 and CO were calculated.

2.3 Characterization of catalyst

X-Ray Diffraction (XRD) analysis used to speculate the average Ni crystal size and Ni dispersion of catalyst was operated on the DX-1000 equipment with Cu $K\alpha$ radiation source at 40 kV and 25 mA in the diffraction range of $2\theta = 5\text{--}80^\circ$. The sweep rate was $0.08^\circ/\text{min}$. The microstructure of the sample was observed using JSM-6340F Scanning Electron Microscopy (SEM) developed by JEOL company at 0.5–30 keV with an amplification of 50–200000 X. Fourier transform IR (FT-IR) spectra of samples were obtained by Thermo Scientific™ Nicolet™ iS™50 FT-IR spectrometer to confirm the interlayer exchangeable anions. The scan region was $400\text{--}4000\text{ cm}^{-1}$.

3 RESULTS AND DISCUSSION

3.1 Evaluation results

The catalytic performance of Ni-Al-LDH and Ni-Al-IMP catalyst is shown in Figure 1. It can be seen clearly that the Ni-Al-LDH catalyst has obviously better catalytic performance. It is worth noting that the Ni-Al-IMP showed higher H_2 selectivity but lower CO selectivity, which may be caused by the side reaction of reverse water-gas-shift reaction ($\text{CO} + \text{H}_2\text{O} = \text{H}_2 + \text{CO}_2$). The better performance of Ni-Al-LDH catalyst should be ascribed to the more active sites produced by the atom level dispersion of Ni atoms in the LDH precursor.

3.2 Characterization of catalyst

Figure 2 shows the XRD patterns of different samples, where there are visible peaks at $2\theta = 10.4^\circ$, 20.63° , 33.77° , and 61.44° on the Ni-Al-LDH precursor, which are the typical characters corresponding to the diffraction of LDHs at crystal faces of 003, 006, 009, and 110, respectively (Manukyan et al. 2015, Khan et al. 2016, Mikulová et al. 2007). It can be deduced that the LDHs have been successfully synthesized on the $\gamma\text{-Al}_2\text{O}_3$ support.

These peaks disappeared once the precursor was calcined and reduced. Comparing the XRD pattern of Ni-Al-LDH to that of Ni-Al-IMP, it can be discovered that there is a relatively sharp Ni crystal peak at $2\theta = 76.1^\circ$ on the pattern of Ni-Al-IMP catalyst, indicating that the Ni crystal agglomerated to some extent. There is no obvious peak on the pattern of Ni-Al-LDH catalyst, which means a better dispersion and a smaller crystal size were obtained.

The images of the microstructure of $\gamma\text{-Al}_2\text{O}_3$ support and Ni-Al-LDH precursor obtained by SEM are shown in Figure 3. Apparently, the surface of $\gamma\text{-Al}_2\text{O}_3$ support is tough and irregular, and there are a number of small pores, creating favorable

Figure 3. Images of different samples: (a) γ-Al₂O₃ support; (b) Ni-Al-LDH precursor.

Figure 4. FT-IR spectra of catalyst precursor.

properties for serving as the catalyst support. The Ni-Al-LDH precursor exhibited the expected layer structure shown in Figure 3(b), which also proved the formation of LDHs on the γ -Al₂O₃ support.

As there are two types of anions (NO₃⁻ and CO₃²⁻) in the LDH preparation system, the FT-IR spectrums of Ni-Al-LDH and Ni-Al-IMP precursors were obtained to certain the interlayer anion. As shown in Figure 4, the peaks at 1430 and 1640 cm⁻¹ belong to the vibration of the carbonate species and the bending vibration of interlayer water (Qi et al. 2008, Zhang et al. 2011), respectively. Therefore, it can be concluded that the LDHs synthesized on the γ -Al₂O₃ support with CO₃²⁻ serving as the interlayer anion, the crystal water exists in the synthetic LDHs.

4 CONCLUSIONS

LDHs with the interlayer anion of CO₃²⁻ were synthesized on the γ -Al₂O₃ support, and the resulting Ni-Al-LDH catalyst was evaluated by CH₄-CO₂ reforming. Compared with the Ni-Al-IMP catalyst, the Ni-Al-LDH showed an enhanced catalytic activity, which is ascribed to the unique layer structure of LDHs. Ni existed as a divalent cation in LDHs and was of the atomic level dispersion, resulting in smaller Ni crystal size, better Ni dispersion, and more active sites, leading to a better catalytic activity.

ABSTRACT: This work presents a comparative study of the textural, superficial and catalytic properties of NiMo/Al₂O₃-SiO₂ sulfide catalysts during the Hydrodesulfurization (HDS) of complex organic sulfur compounds, such as DBT and Cn-DBT. The Al-Si mixed oxide support was synthesized by the sol-gel method, the catalysts were synthesized by the co-impregnation method using an atomic ratio of Ni/[Ni/(Ni+Mo)] = 0.42. The materials were characterized by N₂ physisorption, XRD, SEM and HRTEM. The hydrogenation activity was investigated on a 100 ml high-pressure hydrogenation unit, using high-nitrogen catalytic cracking diesel oil as feedstock. This catalyst exhibited the best pore size and high specific surface area, coupled with the presence of Ni and Mo species in octahedral coordination, as well as good morphological properties.

1 INTRODUCTION

As a consequence of the increasing concern about environmental pollution, more stringent legislation to limit the sulfur content in transportation fuels has been introduced throughout the world (C. Song, 2003 & P. Raybaud, 2007). One of the most cost-effective ways is to improve the HDS activity of catalysts. Conventional NiMo catalysts are usually prepared by depositing molybdenum and nickel oxides on the surface of alumina. The activity of conventional supported catalyst is limited by the support, so it is difficult to have a more substantial increase. It is now known that one of the main factors that affect catalyst activity is the interaction between the active components and the support, since metal-support interactions influence not only the dispersion of the active species, but also their reducibility and sulfidability. The strong interaction between Mo oxide and the support leads to the difficult and incomplete reduction-sulfidation of Mo⁶⁺ to Mo⁴⁺. Extensive research studies have been dedicated to develop improved catalysts for the process in order to meet with legislations. In this sense, different materials have been studied as catalyst supports, specially the mixed oxide supports, such as the Al₂O₃-SiO₂(-TiO₂), since the presence of SiO₂ in alumina could facilitate redox processes for the active phases of Mo (J.R. Grzechowiak, 2001 & S.K. Maity, 2006) and W and therefore facilitate the

formation of active octahedral type sites of the Mo and W oxide species. Due to the fact that this type of sites exhibits higher HDS activity, it is expected to obtain better catalysts.

The objective of this work is to contribute to elucidate their catalytic activity differences through a comparative study of the textural and superficial properties of NiMo sulfide catalysts supported on an Al-Si mixed oxide during the Hydrodesulfurization (HDS) of complex organic sulfur compounds, such as DBT and Cn-DBT.

2 EXPERIMENTAL

2.1 Support preparation

The Al-Si mixed oxide was synthesized by the sol-gel method, using 5 wt% of SiO₂. The required amounts of alkoxide precursors Al(OC₄H₉)₃ and Si(OC₂H₅)₄ were added to 150 ml of isopropanol at 60°C and kept stirred constantly for an hour, later, the system was cooled down to low temperature (3°C). Separately, a hydrolysis solution was prepared (water, ethanol, isopropanol and nitric acid using 13:8:5:0.5 ml, respectively). This solution was added drop-wise to alkoxides in solution to form a gel. The obtained gel was aged and then dried at room temperature. Finally, the materials was extruded, dried at 120°C for 12 h and calcined

at 550°C (10°C/min) for 3 h under air flow. The γ -Al₂O₃ ($S_{\text{BET}} = 292 \text{ m}^2 \cdot \text{g}^{-1}$) support was prepared, used as the reference support.

2.2 Catalysts preparation

NiMo sulfide catalysts were synthesized using the co-impregnation method with atomic ratio Ni/[Ni/(Ni+Mo)] = 0.42. As precursors we used: Ammonium Thiomolybdate (TMA), which were synthesized in the laboratory by previously reported methods and Ni(NO₃)₂·6H₂O. These thiosalts and nickel nitrate were separately dissolved in MEA/water and then mixed to obtain a solution. After that the support was impregnated, dried at 120 °C for 2 h, then calcined at 400 °C for 3 h under N₂ flow. Finally, the catalysts were cooled down to room temperature under nitrogen gas flow. The catalysts were labeled as NiMoS/Al₂O₃-SiO₂. The NiMoS/ γ -Al₂O₃ catalyst was prepared, used as the reference catalyst.

2.3 Materials characterization

2.3.1 N₂ physisorption

The textural properties for the oxide support and sulfide catalysts were determined from the adsorption-desorption isotherms of nitrogen at -196°C, recorded with a Quantachrome Autosorb 1. The specific surface areas were calculated by means of the Brunauer, Emmett and Teller (BET) model. Previous to their measurements, the samples were treated at 250°C for 3 h under vacuum.

2.3.2 Scanning Electron Microscopy (SEM)

The sulfide catalysts were studied by Scanning Electron Microscopy using a Phillips XL30 (ESEM) microscope with an energy dispersive X-ray spectroscopy (EDX) attachment. Samples were suspended in isopropanol by sonication and then deposited on carbon coated copper grids.

2.3.3 XRD and HRTEM

The X-Ray powder Diffraction (XRD) determinations were carried out in a Panalytical X'Pert Pro MPD diffractometer, equipped with a curved graphite monochromator, using Cu-K α radiation ($\lambda = 1.5406 \text{ \AA}$) operating at 45 kV and 40 mA at a scanning rate of 5 min⁻¹. HRTEM was performed with a JEM-2100 analytical microscope operated at 200 kV.

2.3.4 Catalytic activity measurement

The activity evaluation was carried out in a fixed bed system, using FCC diesel as feedstock. The operating conditions were set as follows: reaction temperature = 320, 340, 360°C, reaction pressure = 6.5 MPa, LHSV = 1.5 h⁻¹ and H₂/Oil rate = 500:1. Prior to the activity test, the catalysts

were presulfided in situ. The sulfur concentration was measured in a Multi EA3100 trace S/N analyzer of German Jena Company.

3 RESULTS AND DISCUSSION

3.1 N₂ physisorption

Figure 1 and Figure 2 show the N₂ adsorption-desorption isotherms for the supports and the catalysts. The supports and catalysts exhibit a type IV isotherms (IUPAC classification), which indicates that they are mesoporous materials (R. R. Xu, 2004). However, it possible to observe different type of hysteresis, since the Al₂O₃-SiO₂ oxide support and the corresponding catalyst show a H1 type of hysteresis, indicating that these materials have regular mesoporous channels. On the other hand, the γ -Al₂O₃ and the NiMo catalyst exhibit a clear H2 type of hysteresis loop, characteristic of materials with irregular mesoporous chan-

Figure 1. N₂ adsorption-desorption isotherms for the Al₂O₃-SiO₂ oxide support and γ -Al₂O₃.

Figure 2. N₂ adsorption-desorption isotherms for the NiMoS/Al₂O₃-SiO₂ and NiMoS/ γ -Al₂O₃ catalysts.

Table 1. BET surface area and pore volume of Al_2O_3 - SiO_2 and $\gamma\text{-Al}_2\text{O}_3$ support.

Sample	BET surface area ($\text{m}^2\cdot\text{g}^{-1}$)	Pore volume ($\text{cm}^3\cdot\text{g}^{-1}$)
Al_2O_3 - SiO_2	335	0.71
$\gamma\text{-Al}_2\text{O}_3$	292	0.65
$\text{NiMoS}/\text{Al}_2\text{O}_3\text{-SiO}_2$	192	0.40
$\text{NiMoS}/\gamma\text{-Al}_2\text{O}_3$	165	0.36

Figure 3. XRD patterns of the $\text{NiMoS}/\text{Al}_2\text{O}_3\text{-SiO}_2$ and $\text{NiMoS}/\gamma\text{-Al}_2\text{O}_3$ catalysts.

nels, which suggest that pores occlusion probably takes place. By comparison (Table 1), the $\text{NiMoS}/\text{Al}_2\text{O}_3\text{-SiO}_2$ catalyst presents higher surface area ($192 \text{ m}^2/\text{g}$) and pore volume (0.40 mL/g), which is obviously larger than that of $\text{NiMoS}/\gamma\text{-Al}_2\text{O}_3$ ($165 \text{ m}^2/\text{g}$ and 0.36 mL/g , respectively). The higher specific surface area and pore volume mean more active sites, so that high catalytic activity is to be expected.

3.2 XRD Analysis

In Fig. 3, the XRD patterns of the $\text{NiMoS}/\text{Al}_2\text{O}_3\text{-SiO}_2$ and $\text{NiMoS}/\gamma\text{-Al}_2\text{O}_3$ catalysts are displayed. Four weak reflections at 14.4 , 33 , 40 , and 58° are observed which are the characteristic reflections (002), (101), (103) and (110) of a poorly crystalline 2H-MoS_2 structure. No reflection of nickel sulfide phases is detected for all the catalysts, suggesting that Ni atoms replace the Mo atoms on the edge or corner sites and form so-called Ni-Mo-S phase.

3.3 SEM Analysis

The surface morphology of the support materials prepared via different methods are shown in Fig. 4 A and 4B. The main particles of $\text{Al}_2\text{O}_3\text{-SiO}_2$ oxide materials are comprised of sphere-like nano-

Figure 4. SEM images of $\text{Al}_2\text{O}_3\text{-SiO}_2$ and $\gamma\text{-Al}_2\text{O}_3$ support, S1(A) and S2(B).

particles, and the distribution of the particles seems to be practically uniform, with the average size of about 500 nm . The three-dimensional porous structure can supply with more channels for participating molecules to contact the active sites. The images of $\gamma\text{-Al}_2\text{O}_3$ materials presents that the materials are composed of massive particles with irregular shape and severely agglomerated. It is obvious that the utilization of active components is lower. During the co-precipitation process, the introduce of Si influenced the form of the primary grains and the particle growth is controlled, which result in higher surface area and pore volume. It is possible to improve the textural properties for the catalyst.

3.4 HRTEM Analysis

The HRTEM images of the $\text{NiMoS}/\text{Al}_2\text{O}_3\text{-SiO}_2$ and $\text{NiMoS}/\gamma\text{-Al}_2\text{O}_3$ catalysts are shown in Fig. 5a and 5b. HRTEM is a powerful technique for studying the changes in the morphology of active phases

Figure 5. SEM images of NiMoS/Al₂O₃-SiO₂ and NiMoS/ γ -Al₂O₃ catalysts, C1(a) and C2(b).

and has been applied in many studies of sulfide catalysts. The black thread-like fringes correspond to the MoS₂ or Ni-Mo-S crystallites. It is clear that the MoS₂ slabs are homogeneously dispersed on the support and no exceptionally large aggregates of MoS₂ are observed. In all catalysts, only few are single slabs and most of the MoS₂ slabs contain two or three layers.

3.5 Catalytic activity

The hydrotreatment of FCC diesel was studied under conditions of 6.0 MPa and 1.5 h⁻¹, which are close to those used in industrial applications. Table 2 summarizes the activity results of FCC diesel on the NiMoS/Al₂O₃-SiO₂ and NiMoS/ γ -Al₂O₃ under steady-state conditions after 5 h of reac-

Table 2. The activity evaluation results of FCC diesel on NiMoS/Al₂O₃-SiO₂ and NiMoS/ γ -Al₂O₃ catalysts.

Catalyst	Sample	S content, $\mu\text{g/g}$	N content, $\mu\text{g/g}$	Density, g/ml
C1	FCC diesel	2483	1040	0.9263
	330°C	122.5	50.3	0.8960
	350°C	42.8	13.1	0.9111
	360°C	15.2	9.3	0.8902
C2	330°C	138.4	69.1	0.8966
	350°C	51.3	23.2	0.9114
	360°C	22.5	13.6	0.8906

tion. As can be seen from the table, the NiMoS/Al₂O₃-SiO₂ shows an improvement of activity. This enhancement of higher activity observed in the NiMoS/Al₂O₃-SiO₂ catalyst is more closely related to the textural and superficial properties, since this catalyst exhibited the largest pore size, as well as the best HDS precursor species, such as Mo and Ni species in octahedral symmetry (S. Eijssbouts, 2007).

4 CONCLUSIONS

We shown that the Ni-Mo catalyst, using the Al-Si mixed oxide as support increases the HDS activity compared to NiMoS/ γ -Al₂O₃, confirming the beneficial effect of using the mixed oxide as support for the preparation of highly active catalysts. This change in metal dispersion and the decreased interaction of the molybdate with the support probably leads to a slight improvement in the sulfidation of the Ni and particularly of the Mo phase.

ABSTRACT: Response Surface Methodology (RSM) was utilized to optimize the admixtures and ascertain the quantitative equation. For Ningbo soil with the natural water content of 89.5% and organic matter content of 17.1%, the optimum ratio of four additives was obtained as 12: 8.87: 3.96: 1.28, which is named ZJU-15. Through another set of response surface tests, a quantitative equation was gained, which relates the 28-day unconfined compressive strength of soil about three parameters of organic matter content, water content and ZJU-15 content. The influence of the three factors on the strength of solidified soil was determined by the single factor and mutual-influence analysis.

1 INTRODUCTION

Ningbo soil is the typical case of soil of coastal areas and inland cities in China, which has the characteristic of high contents of water and organic matter. Before constructions were launched, the soil stabilization must be carried out first on those grounds (Wang, 2012; Huang, 2012; Feng, 2007).

This study employs Response Surface Methodology (RSM) to study on the solidification of Ningbo soil (Ragonese, 2002). RSM is a combination of statistical and mathematical techniques, and we have some experience on its application on soil stabilization. Furthermore, we choose the 28-day unconfined compressive strength as the response values, taking into account the 28-day strength as an important indicator of the actual project.

So far, some scholars have done a lot of study related to either the water content or the organic matter content (Tang, 2000; Chen, 2005). However, there is hardly any research considering both of them. On the other hand, many scholars have devoted themselves to the optimization of admixtures to enhance the solidification effect of cement (Chang, 2014; Paulo, 2013; Jacob, 2012).

This study is divided into two stages. Firstly, the undisturbed mucky soil was taken as object, and its physical parameters can be tested by geotechnical test. RSM was utilized to optimize the admixtures and ascertain the quantitative equation. Secondly, based on the quantitative equation which was ascertained at the first stage, we varied the contents

of organic matter, water and ZJU15 in order to verify their influence on the strength of solidified soil.

2 MATERIALS AND METHODOLOGY

2.1 Soil samples

The soil samples used in this investigation were obtained from Ningbo, China. Basic index properties (see Table. 1) were determined according to the American Society for Testing and Materials (ASTM) standards.

2.2 Stabilized materials

The cement used in this study was ordinary Portland cement produced by Qianjiang Cement Company, China. Gypsum was produced by Hangzhou Gypsum Company, China.

The slag, fly ash and triethanolamine were produced by Shanghai Jiangfu Company, China.

Table 1. Physical and mechanical properties of soil.

soil	w %	r $kN \cdot m^{-3}$	d_s	e	W_p %	W_L %	W_o %
clay	89.5%	16	2.73	1.67	54.2	26.1	7.1

Note: w is content of water, r is the unit weight, d_s is specific gravity of soil, e is porosity ratio of soil, W_p is plastic limit of soil, and W_L is liquid limit of soil. W_o is content of organic matter.

2.3 Unconfined Compressive Strength tests (UCS)

In this study, the UCS values of 28-day was selected to establish response values. UCS tests were conducted after the following process according to the ASTM standards. At first stage, the undisturbed mucky soil, cement, slag, fly ash and triethanolamine were added into a container with certain mix proportions, and then the mixture was stirred until it acquired a uniform consistency. The mixture was poured into cube samples of 70.7 mm × 70.7 mm × 70.7 mm, which were to be cured in a temperature-controlled room at 20 ± 2°C. After a fixed period (28D), the cube samples were taken out and UCS test was carried out.

2.4 Single doped experiment

Based on the research (LI, 2012), when the cement content is 15%, there is a turning point on the curve of cement soil strength for the soil with 6% humic acid content. When the humic acid content is increased, its adverse impact on the strength of cement-stabilized soil will tend to be stable. In addition, the strength of cement-soil will increase with the initial water content increasing. At the point of peak strength, the corresponding water content approaches the soil liquid limit.

We chose slag, fly ash and triethanolamine as additives for the following reasons: slag and fly ash have preferable chemical activity, which can promote the hydration reaction; triethanolamine can regulate the overall curing effect.

According to the test results, the range of additives for the next phase could be decided as: 15% cement, 5 ~ 7% slag, 5 ~ 7% fly ash, and 1.4 ~ 1.6% triethanolamine (additive percentages are that of the soil).

2.5 Response surface method

Based on the result from the single doped experiment, we adopted the Central Composite Rotatable Design (CCRD) response surface method.

RSM was applied to the experimental data by using a statistical software. Regression coefficients were obtained by fitting the experimental data into a second order polynomial model. The generalized second-order polynomial model proposed for the response surface analysis is as follows:

$$Y = \beta_0 + \sum \beta_i X_i + \sum \beta_{ii} X_{i2} + \sum \sum \beta_{ij} X_i X_j \quad (1)$$

where β_0 , β_i , β_{ii} , β_{ij} , are regression coefficients for constant, linear, quadratic and interaction terms, respectively. X_i and X_j are the coded values of the independent variables.

3 RESEARCH ON THE COMPOSITE ADDITIVE EQUATION

This stage of the study comprised of cement content of W_c (%), slag content of W_s (%), flyash content of W_f (%), and triethanolamine content of W_t (%), corresponding to the three code levels and the actual content as presented in Table 2. The results

Table 2. Independent variables and their levels for CCRD.

Variables	Coded	Coded levels				
		-2	-1	0	1	2
W_c (%)	X_1	0	12	15	18	21

X ₄ ²	420.65	420.65	0.054	0.8190
Model	R ² = 0.9856			

obtained from the four-factor (X₁, X₂, X₃, X₄) and five-level (-2, -1, 0, 1, 2) Central Composite Rotatable Design (CCRD) are summarized in Table 3. Depending on the Design Expert software, it is convenient to obtain the response surface regression analysis of the results in Table 3. The regression model coefficient and variance analysis results are shown in Table 4.

This research adopts the F distribution to study the regression analysis results for a more rigorous analysis. In the analysis process, firstly, we need to determine the significance level α . In Table 4, if the P value is lower than 0.05, it indicates that the variable is statistically significant. Otherwise, it must be removed in the optimization analysis just for its not being significant. In this study, the significance level (α) is 0.05.

Accordingly, excluding the non-significant items X₃, X₄, X₁X₃, X₁X₄, X₂X₃, X₂X₄ in the 28d regression model, we obtained the regression equation after adjusting as:

$$Y_{28} = 1049.21 + 503.75X_1 + 240.42X_2 + 85.13X_1X_2 + 62.13X_3X_4 - 69.36X_1^2 - 102.73X_2^2 \quad (2)$$

This calculation showed that the coefficient of determination R² of the adjusted regression equation is 0.9856, which indicates that Equation (2) fits well with the actual situation. The further optimization analysis by Design Expert software revealed that the 28d strength of the stabilized soil reaches its maximum value when the contents of cement, slag, fly ash and triethanolamine are 12%, 8.87%, 3.96% and 1.28%, respectively. Thus, the composite additive ratio is W_c: W_s: W_f: W_t = 12: 8.87: 3.96: 1.28. And the predicted value of Y₂₈ is 2.403MPa against the actual value of 2.388MPa. This optimum ratio is named ZJU-15 in this paper.

Form the variance analysis, we get the linear effect of X₁ and X₂ on the strength of solidified soil. The linear effect and surface effect are both significant. At the same time, the interaction effect of X₁X₂, X₃X₄ are significant.

4 SOLIDIFICATION SCHEME

4.1 Soil samples

The soil samples used in this investigation were obtained from Ningbo, China. Basic index properties (see Table 1) were determined according to the American Society for Testing and Materials (ASTM) standards. The natural water content of these soils is higher than their liquid limit. The soil samples were conserved in the oven with the temperature ranging 105~110°C for more than 8 hours. After the soils have been smashed completely, they were put through a 2 mm sieve, and sealed to be spare.

The research (Aslan, 2008) has shown that, humus is the main component of the organic matter in soil, and humic acid is the main ingredient that affects the solidification effect of cement.

Humic acid was produced by Changsheng Industry Co., Ltd., China. Its purity is 90%. Considering the test requirements of soil samples with different contents of humic acid, we made trial mixes with different contents of humic acid beforehand.

4.2 Experimental design and results

As introduced above, this stage of the study comprised of organic matter content of W_o (%), water content of W_w (%), ZJU-15 content of W_z (%),

corresponding to the three code levels and the actual content as presented in Table 5. The results obtained from the three-factor (X_5 , X_6 , X_7) and five-level (-1.682 , -1 , 0 , 1 , 1.682) Central Composite Rotatable Design (CCRD) are summarized in Table 6. Depending on the Design Expert software, it is convenient to obtain the response surface regression analysis of the results in Table 6. The regression model coefficient and variance analysis results are shown in Table 7.

As the research on the composite additive equation, we determine the significance level α as 0.05. After excluding the non-significant items X_5X_6 , X_6X_7 in the 28d regression model, we obtained the regression equation after adjusting, as:

$$Y'_{28} = 1186.77 - 88.52X_5 - 86.89X_6 + 73.71X_7 - 41.14X_5X_7 - 20.65X_5^2 - 72.67X_6^2 + 9.95X_7^2 \quad (3)$$

Table 5. Independent variables and their levels for CCRD.

Variables	Coded	Coded levels				
		-2	-1	0	1	2
$W_o(\%)$	X_5	0.795	2.5	5	7.5	9.205
$W_w(\%)$	X_6	26.36	40	60	80	93.64
$W_z(\%)$	X_7	1.272	4	8	10	14.728

Note: $X_5 = (W_o - 5)/2.5$, $X_6 = (W_w - 60)/20$, $X_7 = (W_z - 8)/2$.

X_5X_7	13538.35	13538.35	67.65	<0.0001
X_6X_7	677.12	677.12	3.38	0.0957
X_5^2	6147.11	6147.11	30.72	0.0002
X_6^2	76096.72	76096.72	380.25	<0.0001
X_7^2	1427.92	1427.92	7.14	0.0234
Model	$R^2 = 0.9766$			

The calculation shows that the coefficient of determination R^2 of the adjusted regression equation is 0.9766, which indicates that Equation (3) fits well with the actual situation.

The quantitative equation (3) shows the relationship between strength (Y'_{28}) and organic matter content (X_5), water content (X_6), ZJU-15 content (X_7). X_5 and X_6 could be determined by geotechnical test. As long as the strength need is designed, the volume of ZJU-15 can be calculated accurately, instead of empirical estimation or lurching a new research. Therefore, the quantitative equation is very practical and has great application prospect.

4.2 Single factor and mutual-influence analysis

From Equation (3) it is easy to find out that X_5 , X_6 and X_7 have significant linear effect on the strength of solidified soil. The mutual-influence of X_5 and X_7 is also significant.

The first derivative of Y'_{28} with respect to X_5 :

$$d(Y'_{28})/d(X_5) = (-88.52 - 41.14X_7) - 41.3X_5 \quad (4)$$

The value $X_5 = -(88.52 + 41.14X_7)/41.3$ is an Extreme Point (EP). It means when W_o is greater than extreme point, the negative effect increases with the increase of content on the strength. However, the value of ZJU-15 content (X_7) determines EP(X_5). The increase of X_7 will reduce EP(X_5). It means that the increase of ZJU-15 content will effectively eliminate the negative effect of organic matter on strength of solidified soil.

The first derivative of Y'_{28} with respect to X_6 :

$$d(Y'_{28})/d(X_6) = -86.89 - 145.34X_6 \quad (5)$$

EP(X_6) = -0.598 , the corresponding true water content is 48.04%. It means when $X_6 < -0.598$, the increase of water will promote the strength of solidified soil. All the substances involved in the curing reaction depend on the water environment. When $X_6 > -0.598$, if there is too much water, it will

lead to too low ion concentration. Furthermore, the curing reaction is weakened, and the formation of crystals and the coupling effect with the soil particles will be greatly reduced.

The first derivative of Y'_{28} with respect to X_7 :

$$d(Y'_{28})/d(X_7) = (73.71 - 41.14X_5) + 19.9X_7 \quad (6)$$

$EP(X_7) = (41.14X_5 - 73.71)/19.9$, the organic matter content (X_5) determines $EP(X_7)$. When $X_7 < EP(X_7)$, ZJU-15 can not have a positive effect on the strength of solidified soil. When $X_7 > EP(X_7)$, the increase of ZJU-15 will promote the strength evidently.

5 CONCLUSION

For Ningbo soil with the natural water content of 89.5% and organic matter content of 17.1%, the optimum ratio of cement, slag, fly ash and triethanolamine is 12: 8.87: 3.96: 1.28.

The quantitative equation (3) shows the relationship between strength and organic matter content, water content and ZJU-15 content. It is very practical and has great application prospect.

According to the synthesis of single factor and mutual-influence analysis, ZJU-15 can effectively

eliminate the negative effect of organic matter on strength of solidified soil, and more than 48.04% of water content will reduce the effect of ZJU-15.

ABSTRACT: As by-products of iron and steel industry, blast furnace slag has been widely used as supplementary cementitious material in concrete. However, the utilization rate of steel slag is still relatively low and its open-air stacking occupies more space. Corrosion of reinforcement is regarded as one of the most important indexes of concrete durability. In this paper, we report the effect of slag admixture on the corrosion of reinforcement on the basis of the investigation of pore liquid pH, electric flux, and corrosion behavior of the reinforcement under dry-wet circulation conditions. Experimental results show that concrete with ground granulated blast furnace slag has better resistance of chloride-ion penetration but lower level of liquid-phase alkalinity. The pore liquid alkalinity of concrete with ground steel slag keeps at a high level, but the density of concrete is lower because of the slower growth of concrete strength in the early period. Compared with single-doped slag, ground iron and steel slag helps the concrete maintain a high pore liquid alkalinity as well as good resistance of chloride-ion penetration, which would provide a better protection to fixture within concrete.

1 INTRODUCTION

Production of crude steel has been increasing since 2000 worldwide. From 2013, China's crude steel output has occupied nearly half of the global production (see Figure 1), yielding large amounts of by-products as iron slag, steel slag, fly ash, and so on. In recent decades, several studies have been conducted all over the world, especially in the field

of utilization as construction materials because of its feasibility and market space.

Steel slag is generated from the process of steel production, which has cementitious activity due to its composition of a certain amount of C_3S , C_2S , etc. Steel slag is often called as "Over-burnt Portland Cement Clinker", different from the cement clinker, with calcination temperature of about 1450°C and formation temperature of about 1650°C . Relatively, minerals crystallized from steel slag are more complete and compact, leading to its slow hydration.

Blast furnace slag comes from iron-making sections. As a result of water quenching treatment, the mineral structure remains vitreous in a thermodynamically unstable state, remaining potential hydraulic cementitious activity. Reactive SiO_2 and Al_2O_3 are the main factors influencing slag activity under an alkaline stimulating agent, $\text{Ca}(\text{OH})_2$. In the progress of the reaction of minerals and water, strength is derived from hydrated calcium silicate, hydrated calcium aluminate, and so on.

In addition to saving energy and resources and reducing environmental impact, slag powders are

Figure 1. Global crude steel production statistics.

adopted in concrete to improve its working performance (Zheng 2005). With the active mineral admixture, concrete would improve particle size distribution and pore structure, which leads to good performance in liquidity, secretion of water, setting time, resistance to chloride ion permeability (Kyong 2005, Erhan 2008, Hüseyin 2007), and so on.

Durability is an essential factor in the life and safety of concrete structures (Ann 2009). Corrosion of reinforcement that is usually caused by carbonation or chloride is considered the most important and direct reason of concrete durability failing. During concrete hydration process, calcium hydroxide $[Ca(OH)_2]$, calcium silicate hydrate $[3CaO \cdot SiO_2 \cdot 3H_2O]$, unhydrated tricalcium silicate, and dicalcium silicate are the main carbonized materials reacted with carbon dioxide, which diffuses into the concrete from atmosphere. $CaCO_3$, $Al(OH)_3$, and other products cause the formation of loose and non-cementitious state in concrete structures, which finally results in the destruction of concrete structures (Feng 2009). Another issue is that chloride ions would penetrate into the concrete reaching the steel surface to cause electrochemical action. Steel surface passivation film is destroyed in the first place. Therefore, the formation of pitting gradually spread throughout the steel surface (Ann 2007). Corrosion products bring about an increase in volume leading to concrete cracking, delamination, and flaking. The destruction facilitates the

passage of water and chloride intrusion, accelerating corrosion development even more.

2 MATERIALS AND METHODS

2.1 Raw materials

Ground granulated Blast Furnace slag (BF) and ground steel slag (SS) used in the experiment were both sourced from a large iron and steel corporation in Jiangxi province, China. As seen from Table 1, composition difference between the two kinds of slag mainly concentrates in siliceous and aluminum constituents. Slag were ground by a ball mill to the specific surface area of $400 \pm 5 \text{ m}^2/\text{kg}$, when density of blast furnace slag was 2900 kg/m^3 and density of steel slag was 3350 kg/m^3 . Basic physical property of slag is shown in Tables 2~3 (according to Chinese standard GB/T 18046-2008 and GB/T 20491-2006). Standard cement was ordinary Portland cement supplied by Jidong Cement Co., Ltd, China.

2.2 Experimental apparatus

As strong alkaline substances, concrete's range of pH remains 12.5-13.0. Carbonation mainly affects the pH value of pore liquid within the concrete. The alkalinity of the concrete gradually lowered from surface to interior. The passivation film on the steel surface would become unstable and lose

Table 1. Chemical composition of slag (%).

	CaO	SiO ₂	Al ₂ O ₃	Fe ₂ O ₃	FeO	MgO	P ₂ O ₅	MnO

100	/	308	254	8.5	11.2	45.0	58.1
70	30	400	262	6.6	9.0	30.9	46.9

Table 3. Flexural and compressive strengths of cement mortar with BF.

Ratio(%)		Specific surface area (m ² /kg)	Fluidity (mm)	Flexural strength (MPa)		Compressive strength (MPa)	
Standard cement	BF			7d	28d	7d	28d
100	/	327	223	5.7	8.0	29.4	47.0
50	50	400	247	5.0	7.7	24.2	50.9

the protective effect on reinforcement when the pore liquid pH around reinforcement is up to about 11.5. Besides, chloride ions reaching the surface of steel may also cause electrochemical effect; thus, corrosion of reinforcement occurs.

Therefore, through the pore liquid pH tests, carbonation performance, and electric flux of the concrete with slag admixtures and corrosion behavior of the reinforcement within the concrete under dry-wet circulation conditions, the effect of slag admixture on the corrosion of reinforcement would be determined.

2.2.1 Pore liquid alkalinity test

Cement paste with 30% or 40% (mass ratio, same mentioned below) SS or BF and ordinary Portland cement under standard curing conditions (temperature $20^{\circ}\text{C}\pm 2^{\circ}\text{C}$; relative humidity, 95%). Tests were carried out at specified curing periods (1, 3, 7, 28, 60, 100, 140, 170, and 200 days).

2.2.2 Electric flux test

Chloride ion permeability of concrete would be reflected by the electric flux values. The greater the electric flux values, the better the chloride ion permeability in the concrete. As test objects, ground iron and steel slag (IS) are composed of SS and BF at certain ratio of 2:8, 3:7 or 4:6. According to Chinese standard GB/T 50082-2009, concrete was prepared with a mineral admixture (SS-30%, BF-30%, IS-30%, IS-40%, and IS-50%). Tests were conducted at a specified curing period (28 days).

2.2.3 Corrosion behavior test

In the corrosion of reinforced concrete, alternative wet and dry condition is the most adverse environmental effect. The situation of steel corrosion can be reflected directly by measuring the mass loss of steel corrosion. According to Chinese standard GB/T 50082-2009, the samples were prepared with mineral admixture (SS-10%, SS-30%, SS-40%, BF-30%, BF-50%, BF-70%, IS-10%, IS-30%, and IS-40%). Tests were carried out at specified periods (15 and 20 cycles). Mass loss rate of steel corrosion was calculated by the following formula:

$$L_w = \frac{w_0 - w - \frac{(w_{01} - w_1) + (w_{02} - w_2)}{2}}{w_0} \times 100$$

- L_w – mass loss rate of steel corrosion (%);
 - W_0 – initial weight of steel (g);
 - W – mass of pickled corroded steel (g);
 - W_{01}, W_{02} – initial mass of standard steel (g);
 - W_1, W_2 – mass of pickled standard steel (g).
- Accuracy of mass loss results should be 0.01%.

3 RESULTS AND DISCUSSION

3.1 Pore liquid pH value

During the 200-day test period, pore liquid pH values of samples mixed with steel slag (SS-30% and SS-40%) and pure cement sample (CE) develop with the same trend, where pH of early age (3 days) is low and then returns to normal along with gradual decrease over time. pH values reach the lowest point at 140 days. However, pH values of samples mixed with blast furnace slag (BF-30% and BF-40%) fluctuate, decreasing over the test period, as shown in Figure 2.

From the overall perspective, the pore liquid alkalinity of pure cement sample remains in the highest state, followed by SS and BF samples. Also, the impact shows a positive correlation with dosage of admixture content due to the alkalinity order from high to low in the cement, steel slag, and blast furnace slag.

As for CE and SS samples, the same trend shows that ground steel slag has no significant impact on the alkalinity characteristics of the cement paste. In another word, as alkaline substances, the cementitious property of steel slag depends on its minerals such as C_2S and C_3S , which is similar to that of Portland cement, and the hydration process was almost similar.

However, for BF samples, as low-alkalinity slag powder, the blast furnace slag has potential hydraulic cementitious activity due to its reactive SiO_2 and Al_2O_3 activated by the alkaline agent, $\text{Ca}(\text{OH})_2$. As a result, alkaline substances are produced and consumed at the same time, forming a fluctuating trend. Because of the lower level of alkalinity caused by blast furnace slag, dosage of the blast furnace slag in concrete engineering should be emphasized and controlled strictly (Song 2006).

3.2 Electric flux

As is shown in Figure 3, electric flux test results reflect the resistance to chloride-ion penetration

Figure 2. pH values of cement paste pore liquid.

Figure 3. Electric flux of concrete samples.

of concrete primarily related to compactness. Test results of pure cement sample (CE) and 30% steel slag sample (SS-30%) are beyond the scope of the instrument test, both of which were recorded as 4000 C. As a result of the slow pace of hydration of steel slag, SS-30% displays no significance. Studies have shown that the relative diffusion coefficients of chloride ion of concrete mixed with 30% ground steel slag in curing ages of 28 and 90 days are 5.22×10^{-12} and 1.45×10^{-12} m²/s, respectively (Li 2003), indicating that as the curing period extends, the slag powder can sufficiently hydrate and improve the density of concrete.

Compared with sample CE, sample BF-30% shows an obvious advantage, as the ground blast furnace slag has a short term of activating and reacting. Furthermore, pore structures of concrete are filled with hydration products, making the structure denser and improving the impermeability of concrete.

When it comes to the IS-series samples, it is found that incorporated slag powders demonstrate good performances. Influences show positive relation with slag content. Especially in the samples IS-50% (2:8 and 3:7), electric fluxes fall more than 50% margin compared with sample CE's, which evidence that the admixture composed of both ground steel slag and ground blast furnace slag can show improvement in concrete compactness, surpassing single-doped slag powder. As for the results of different ratio of IS, 2:8 and 3:7 are almost at the same level, but addition of ground blast furnace slag leads to weaken the effect, especially when the percentage of IS reaches 50%.

3.3 Steel corrosion behavior within concrete

Mass loss rate of steel corrosion within concrete gives a direct visual comparison between different samples, as shown in Figure 4, where light-colored bars refer to the test of 15 cycles and dark ones represent that of 20 cycles. It is found that all the

Figure 4. Mass loss rate of steel corrosion.

concrete samples result in significant differences between 15 and 20 cycles.

For results of 15-cycle samples, the component of concrete has a little effect; however, data of 20-cycle samples show difference to some degree. For the samples mixed with ground steel slag (SS series), because of the longer test period, the cementitious property of SS plays a role in ensuring the alkalinity of the liquid within concrete, meanwhile improving its compactness, which effectively reduce steel corrosion. For the samples added by blast furnace slag (BF series), steel corrosion reduced significantly, which mainly depend on the hydration products of BF, playing the role of concrete and improving the pore structure of the concrete. However, it is noted that the dosage of BF reached 70% and the steel corrosion rate recovered, which is consistent with the above findings. It should be taken to control of the content when BF is used as admixture in concrete. For the incorporation of the slag powder sample (IS series), with the increase of the slag powder content, the effect tends to improve significantly, while the composition of the slag powder has little effect on the results.

4 CONCLUSION

As inevitable by-products of iron and steel industry, metallurgical slag needs to be utilized as a reasonable resource through technical means to avoid dumping, occupation of land, and environmental pollution. Mineral composition causes cementitious activity or potential activity in steel slag and blast furnace slag, which is an important issue in the application in the field of construction materials. Steel slag can help the concrete alkalinity keep a higher level, but concrete strength can hardly increase fully at early age because of the slow pace of steel slag hydration. Blast furnace slag can improve the density of concrete by quick reaction of products; however,

because of the possible low alkalinity, the slag cannot adequately protect steel, so its dose should be controlled strictly. When the two types of slag mentioned above were mixed at a certain ratio, it can ensure the strength and compactness of concrete as well as keep the pore liquid alkalinity at a higher level. In these regards, this research would shed light on improving the concrete durability, reducing steel corrosion rate, and effectively extending the service life of reinforced concrete.

Experimental study of the drainage and consolidation characteristics of tailings discharge and accumulation by gradual height rising under the action of drainage material

Jian Su, Xiaoduo Ou & Kaiwen Hou

Key Laboratory of Disaster Prevention and Structural Safety of Ministry of Education, Guangxi University, Nanning, China

Key Laboratory of Disaster Prevention Mitigation and Engineering Safety, Guangxi University, Nanning, China

ABSTRACT: A tailing drainage-consolidated physical model with discharge and accumulation process by gradual height rising, in which geotechnical composite drainage material is used as vertical drainage channel, was established. At the same time, the drainage-consolidated process was simulated by a self-developed test device, which was designed on the basis of the physical model described. The results showed that: (1) the rate of drainage is in accordance with the autoregressive integrated moving average model: $ARIMA(2,1,8) \times (0,0,0)$ on the condition of drainage-consolidated process of tailings with gradual height rising. The results predicted by the model show that: the growth trend of maximal drainage rate becomes gradually higher, which is much less than the actual peak rate, and the drainage performance fitness has a large scope for its development; (2) excreting dry upper water accumulation in time provides the essential conditions for consolidation of tailings under the effect of geotechnical composite drainage material, the average stress degree of consolidation can reach 62.32–70.81%, and the average strain degree of consolidation can reach 61.27–68.91% after the experiment of 104 days, which clearly reveals the promotion of consolidation effect.

1 INTRODUCTION

The resource of bauxite is abundant in Guangxi, China, with reserves reaching about 5.15 hundred million tons. Tailings reservoir for washing tailings storage is an indispensable part of mineral mining and processing. The hydraulic transmission and wet storage are used for the bauxite tailing of Guangxi. The tailing slurry, with low permeability, high void ratio, and high water content, has the maximum moisture content rate up to more than 300% (OU Xiao-duo 2014). Because of the lack of effective drainage channel in the tailings accumulation body, the accumulation of water in the reservoir is severe. With plenty of rainfall and extremely developed karst landform, overtopping and underground karst leakage accident of Guangxi bauxite tailings dam occur frequently (LI jie-quan 2012).

Therefore, there are a lot of research about the characteristics of sedimentation-consolidation (Ofori 2011, Shamsai 2007, YIN Guang-zhi 2011), the drainage consolidation mechanical model (Hann 2013, ZHANG Nan 2013), and the drainage consolidation technology (Suits 2010, Wickland 2010) of tailings slurry that are carried out by many scholars. However, because the Guangxi bauxite tailing has unique characteristics (DU Chang-xue 2006), the achievements of these studies have not been effective for practical application yet. On the

basis of the typical bauxite tailings heap environment, we put forward to produce a geotechnical drainage material with good drainage performance and effective filtration of fine-grained tailing as vertical drainage channels. By equal proportion model test, the drainage mechanism and soil consolidation effects of tailings under the influence factors, such as side pressure, soil particle clogging effect, and the consolidation of the soil and water, have been stimulated. Combined with the model test results, the drainage performance and the consolidation effect of tailings slurry in the step piling environment were analyzed. On the basis of summarizing and analyzing the change of water displacement and the characteristics of the drainage rate, the mathematical model of drainage rate has been established by using SPSS and combined with the pore water pressure and sedimentation data to calculate the mud consolidation and makes the contrastively analysis.

2 TEST OF DRAINAGE-CONSOLIDATED MODEL OF TAILINGS BY GRADUAL WET STACK

2.1 *Drainage-consolidated physical model for tailings*

Tailings slurry is discharged to the tailings reservoir by hydraulic transportation after a special

grinding, choosing, and washing process. The resulting product is a type of completely disturbed suspended slurry with extremely high content of clay particles. The suspended state of mud eventually formed structural clays with certain intensity after settlement and self-weight consolidation under the action of vertical drainage water. The sedimentation consolidation process of grading a heap of discharge slurry is not only the sedimentation consolidation process of this pile row mud, but it is also affected by the completed pile row mud, which is also a process of interaction. By comprehensive consideration of consolidation characteristics of tailings and operation characteristics of tailings, the drainage-consolidated physical model of model test was established:

1. The tailing slurry pile row, step-by-step continuous drainage;
2. Sedimentation consolidation process was carried out with the help of gravity, that is, it adopts the gravity sedimentation consolidation of the lower drainage method;
3. The top is the draining profile, the bottom in addition to the drain is the draining profile, and the rest is not the draining profile. The surrounding of the cylinder is not the draining profile.

The drainage-consolidated model of tailings by gradual wet stack is shown in Figure 1.

2.2 Model test design

2.2.1 Model design

In order to give full play to the drainage performance of geotechnical composite drainage material and fully understand the changing situation of tailings consolidated with geotechnical composite drainage material as the vertical drainage channels.

Figure 1. Experimental model of drainage consolidation.

The design and manufacture of test equipment is based on the equal-ratio physical model of drainage consolidation. The test device is mainly composed of a base, a test chamber, and a sensor mounting bracket (as shown in Figure 2). The test chamber is a thickening cylindrical stainless steel water tank with the bottom diameter, height, and thickness of 2.0 m, 1.8 m, and 7 mm, respectively. There are mounting brackets on both ends of the test chamber, which were independent of the test chamber instrument, in case they do not deformation due to the test load. The test chamber adopted a concrete pouring special drain at the bottom according to the requirement of drainage. The test used geotechnical composite drainage material as vertical drainage material, which consists of two parts: thin fabric and plastic core material. The high-strength support of core material ensures adequate drainage section, at the same time, outsourcing membrane, as the filter prevents the particles from moving into the blocking drainage channels and ensures that the drainage material can be unobstructed along the horizontal direction. The drainage material bottom was fixed in a special drain of the test chamber. And because of the pre-pull of the fixed device at the top, the drainage material can be in a state of uniform elongation. After the geotechnical composite drainage material installation was complete, sand was chosen to be laid in the port as a filter layer based on the situation of fine clay grain size distribution, by which the chamber used to discharge filter membrane water.

2.2.2 Tailings slurry preparation and heap row

The selected tailings mud came from the branch of China aluminum industry in Guangxi 2[#] tailings. Through indoor test, its basic properties are shown in Table 1.

Figure 2. Test device.

Table 1. Formatting sections and subsections.

Proportion (g/cm ³)	Plastic index (%)	Liquidity index (%)	Permeability coefficient (m/s)	Slurry concentration (%)
2.83	23.5	5.97	2.44×10^{-6}	11–25

Figure 3. The status in the middle/last stage of experiment.

Figure 4. Layout plan of sensors test.

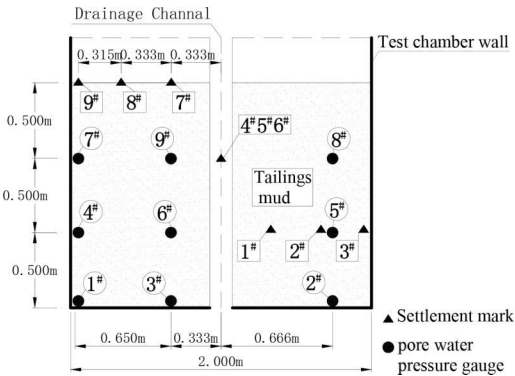

Figure 5. Layout profile of sensors test.

Tailings soil samples became dispersed mud evenly after the process of “dry—preliminary crushing—fully soaked—stirring”, and then the mixed mud began to heap row after being diluted and stirred until the concentration reached 20% (row rate and per level pile row height is based on the branch of China aluminum industry in Gangxi 2# tailings in nearly 2 years to simulate the actual situation). The test lasted 21 days, with a total pile of 21 times and row height of 0.070 m. Eventually, mud surface height is 1.475 m and the water surface height is 1.747 m (as shown in Figure 3).

2.2.3 Test index test

The test design consists of monitor displacement, velocity, pore water pressure, layered settlement, and other indicators (sensor layout as shown in Figures 4–5).

Collect displacement by 4–8 h one time, and after that record the displacement in 2 min. Because the test chamber volume is large enough, displacement of drainage material in 2 min basic remains the same. Therefore, it can be thought that short-term water collecting data reflect the instantaneous velocity.

Because of the frequent fluctuation of the water surface height in the heap row period of the text and the gradual change of the last stage of test drainage tailing parameter, the frequency to monitor the pore water pressure monitoring data is divided into two periods: before trial begins to upper water draining, test one time in every 8 h; and the upper water drained until the end of test, one time in every 2 days.

Taking into account the impact of the heap row mud on the sedimentation scale test is large, the test of subsidence starts when heap row is complete; test frequency is once a week.

3 DRAINING PERFORMANCE ANALYSIS OF GEOTECHNICAL DRAINING MATERIAL

3.1 Analysis of the influence factors on displacement

To figure out the influence of the thickness of the mud and the overlying water on the displacement of geotechnical composite draining material, the 17 valid piling up data were analyzed, whose displacement is shown in Figure 6.

It can be seen from Figure 6 that the growth trend of daily average displacement is obvious, but changes in growth between the early piling up and the late piling up is large, which can be divided into two phases: linear growth and nonlinear growth phases. In the linear growth phase (which is one to

Figure 6. Total water discharge of discharge and accumulation process per day.

Figure 7. Flow velocity of discharge and accumulation process of tailings.

four times piling up), the growth of displacement is large and the increment is average, the average increment is around 50 kg every time; in the phase of linear growth (which is 5–17 times piling up), growth of displacement significantly slows, the average increment is only around 12 kg every time.

3.2 Analysis of the characteristics of the drainage rate

In the experiment, test of flow was conducted in different times of a day (e.g., before piling up, after piling up, and any two time between them), and instantaneous flow values were obtained in four different time points each day, as shown in Figure 7.

Figure 7 illustrates that drainage rate has the following characteristics:

1. Time correlation: because the test was conducted by the manner of piling up gradually, there is a lot of relevance between the velocity distribution of later period and the early piling up, and the velocity shows the great characteristics of the time series.
2. Long-term trend: along with the tailings, slurry pile up continuously, maximum velocity shows an obvious increasing trend, and its growth and changing law of flow is consistent. When it is one to four times piling up, the velocity shows almost a linear increase; and when it is 5–17

times piling up, the growth slows significantly. The minimum flow rate has also increased, but the growth is small. The reason is that when the water level goes down to a certain degree, membrane filter and mud seriously hindered the drainage rate.

3. Cycle variability: because of the intermittent of piling up, the flow rate shows obvious cycle changes; in a pile and idle period for one cycle, the velocity level changes cycle.

3.3 Drainage rate model establishment and prediction

The velocity values above reflect the velocity variation characteristics under the environment of particular pile up, but it is difficult to obtain quantitative values of the drainage rate in the late piling up stage. For this purpose, this paper uses autoregressive integrated moving-average model by SPSS software to simulate the drainage rate of mathematical modeling. It does not consider the causal relationship between the variables, but considers the laws of changes and developments of the variable in time. It can be used in the quantitative forecast and analysis in the late velocity. The model mathematical expression from the software is as follows:

$$\Psi(B)\Phi(B^s)w_t = \theta(B)\Theta(B^s)u_t, \quad (1)$$

formula:

$$\Phi(B^s) = 1 - \Phi_1 B^s - \Phi_2 B^{2s} - \dots - \Phi_p B^{ps},$$

$$\Theta(B^s) = 1 - \Theta_1 B^s - \Theta_2 B^{2s} - \dots - \Theta_p B^{ps},$$

where $w_t = \nabla_s^d \nabla_{z_t}^d$, ∇ is the difference operator, B the is backward-shift operator, $\Psi(B)$ and $\theta(B)$ are established functions, and u_t is the random residual term.

$AR(p)$ is the order- p autoregressive process and $MA(q)$ is the moving-average process. Fixing both of them, the autoregressive moving-average model $ARMA(p, q)$ was established. By using d times differential transform to stabilize it, the model can also be referred to: $ARIMA(p, d, q) \times (P, D, Q)$; parameters $p, d, q, P, D,$ and Q need to set up when simulating.

3.4 Establishment of the autoregressive moving-average model

For model building, the continuous date of time unit 1 is essential, but the in-practice the data could not be collected continuously, so it is necessary to fill the missing values to form a complete

Figure 8. Sequence chart of flow velocity, thickness of tailings, and thickness of overlying water.

Figure 9. Sequence chart of velocity of stabling.

time series of the observed data. The missing value is completed with a linear interpolation; then the thickness of the mud and water surface elevation, both corresponding to the velocity as the independent variable condition in model, are introduced; time variables are defined by using “day/24 hour”; finally, the time sequence is drawn in Figure 8. Because the time series models are based on smooth sequence, the mean condition has no change over time, variance does not change with time, and the relevant number only relates to the time interval and has nothing to do with time point. Therefore, the second-order difference and the seasonal difference were used to smooth the data, which is shown in Figure 9.

After the parameters are put into the model, the model parameters could be analyzed as $ARIMA(2,1,8) \times (0,0,0)$. Smooth coefficients (R^2 and R^2) of the model were 0.964 and 0.990, respectively, which shows that the model fits very well, and the trend and seasonal volatility had a good performance.

3.5 Model prediction

By using the above model, the drainage rate of 17–23 times piling up has been forecast. Because the model is built on two independent variable conditions of clay surface height and water height, using piling up rate to calculate relevant and putting the data into the model, the projections can be obtained as shown in Figure 10.

The prediction shows that the maximum velocity prediction is relatively reasonable, but the predictive value of the minimum velocity is significantly large. The reason is that the model is just introduced in the mud surface height and height of the water as a condition of the independent variables, but the velocity is also affected by

Figure 10. Predicting outcomes of discharge and accumulation process for 17–23 times.

cortical thickness, mud consolidation degree, and the overlying water turbidity factors. From its change trend, as tailings pile up, the thicknesses of both the mud and the overburden layer increase, the maximum displacement increases gradually, far from peak flow in capacity of composite drainage material, and drainage performance has much space.

4 ANALYSIS OF THE CONSOLIDATION EFFECT OF TAILINGS SLURRY

4.1 Analysis of stress degree of consolidation

The trial has installed nine pore water pressure meters (1#–9#), and the pore water pressure monitoring last 125 days. Among them, the pile row period was 21 days and the stopping discharge period was 104 days. According to Terzaghi's one-dimensional consolidation theory, stress degree of consolidation in the arbitrary point of tailings is defined as effective stress and total super hydrostatic pressure value in that point. The degree of dissipation of the pore water pressure can be used to define the degree of consolidation when the consolidation degree was calculated according to the measured pore water pressure data:

$$U_{\sigma} = \left(1 - \frac{\Delta u_t}{\sum \Delta u} \right) \times 100\%, \quad (2)$$

where Δu_t is the t time pore water pressure increment value and $\sum \Delta u$ is the cumulative pore water pressure increment.

According to the measured curve of pore water pressure, the stress degree of consolidation of 1#–9# pore water pressure gauge measuring point in 21 days, calculated by formula (2), is shown in Figures 11–13.

By contrast, Figures 11–13 show that the change of stress degree of consolidation of the tailings has the following characteristics:

1. In terms of stress degree of consolidation at a different depth, the average degree of consolidation of the underlying (67.51%) is slightly higher than that of the middle layer (62.32). Because the upper layers are greatly influenced by factors such as surface evaporation and sunshine, the average degree of consolidation (70.81%) is significantly larger.
2. In terms of the stress degree of consolidation at the same height and at different distances from the center of the drainage, the stress degree of consolidation value increase gradually with the distance, but the growth rate decreases in the same period of time.

Figure 11. Stress degree of consolidation curve for measured No. 1#–3# points of pore water pressure.

Figure 12. Stress degree of consolidation curve for measured No. 4#–6# measured points of pore water pressure.

Figure 13. Stress degree of consolidation curve for measured No. 7#–9# measured points of pore water pressure.

4.2 Analysis of strain consolidation degree

The trial has installed nine settlement marks (1#–9#), and the settlement deformation monitoring last 117 days. Among them, the pile row period was 14 days, and the stopping discharge period was 104 days. The degree of consolidation of tailings is quantitatively analyzed by the degree of strain consolidation through the change in the volume of tailings. As tailings continue in heap row, post-stack tailings discharge mud can be regarded as the load of the upper part of the lower tailings, so the expression of its strain consolidation is:

$$\bar{U} = \frac{s_t - s_d}{s_{\infty} - s_d}, \quad (3)$$

where \bar{U} is the strain consolidation degree, s_t from the T - S curve takes any t time settlement, s_d is the instantaneous settlement, and s_∞ is the final settlement.

The settlement s_t can obtain settlement–time curves of each moment when the degree of consolidation is calculated. Through formula (3), it is known that only the instantaneous settlement s_d and the final settlement s_∞ need to be calculated to calculate the strain consolidation degree of tailings. In this paper, the method of exponential function was used to calculate the consolidation degree of tailings, and the expression of average consolidation degree of the soil layer is:

$$\bar{U} = 1 - \alpha e^{-\beta t}, \quad (4)$$

where \bar{U} is the average degree of consolidation, α , β are the parameters of the theoretical solution under different drainage conditions, α is the theoretical value, and β is the undetermined parameters.

Choosing any three times, t_1 , t_2 , and t_3 , after the load stopped from the measured settlement–time (i.e., s - t) curve when calculating, and $t_3 - t_2 = t_2 - t_1$. According to formula (4), three equations can be written as follows:

$$s_\infty = \frac{s_3(s_2 - s_1) - s_2(s_3 - s_2)}{(s_2 - s_1) - (s_3 - s_2)}, \quad (5)$$

$$s_d = \frac{s_t - s_\infty(1 - \alpha e^{-\beta t})}{\alpha e^{-\beta t}}, \quad (6)$$

$$\beta = \frac{\ln\left(\frac{s_2 - s_1}{s_3 - s_2}\right)}{t_3 - t_2}, \quad (7)$$

On the basis of the measured data of settlement, settlement of 1[#]–9[#] standard strain curve of degree of consolidation of measuring points can be calculated from formulas (5)–(7), as shown in Figures 14–16.

By contrast, Figures 14–16 show that each settlement test point has the following characteristics:

1. In terms of different depths of strain degree of consolidation, the lower degree of consolidation, is higher than the upper value. At the test ending, the average strain consolidation degree of 1[#]–3[#] settlement measuring point (0.5 m stack depth) is 68.91%, the average strain consolidation degree of 4[#]–6[#] settlement measuring point (1.0 m stack depth) is 63.87%, and the average strain consolidation degree of 7[#]–9[#] settlement measuring point (tailings surface) is 61.27%.
2. In terms of the strain degree of consolidation in the same height, strain consolidation degree

Figure 14. Strain degree of consolidation curve for measured No. 1[#]–3[#] measured points of settlement.

Figure 15. Strain degree of consolidation curve for measured No. 4[#]–6[#] measured points of settlement.

Figure 16. Strain degree of consolidation curve for measured No. 7[#]–9[#] measured points of settlement.

decreases with the increase of the distance from drainage channels; however, damping decreases in the same period of time.

4.3 Comparative analysis between stress degree of consolidation and strain consolidation degree

The classical consolidation theory adopts small strain and linear hypothesis and regards stress and strain consolidation degree as equivalent. However, engineering practice and laboratory tests showed that the soil constitutive relationship is definitely not a simple linear relationship, especially due to the high compressibility of soft U_σ and U_ε , there are obvious differences. On the basis of the characteristics of pore water pressure and settlement mark arrangement, the average stress consolidation degree and average strain consolidation

degree of the 0.5 m height (corresponding to the pore water pressure meter number: 4[#]-6[#] and corresponding settlement standard serial number: 1[#]-3[#]) and 1.0 m height of the cabinet (corresponding to the pore water pressure meter number: 7[#]-9[#] and corresponding settlement standard serial number: 4[#]-6[#]) were compared. The results are shown in Figures 15 and 16. Considering that the sedimentation will depress with tailings, the pore water pressure gauge was respectively fixed at 0.5 and 1.0 m, so the actual test position of the average strain consolidation degree is less than the average stress consolidation degree.

As Figures 17 and 18 show, the calculation results of two types of consolidation degree have minor variations, and these variations have the following characteristics:

1. Both the strain and stress average consolidation degrees at the depth of 1.0 m of tailings were better than those at the depth of 0.5 m. To average strain consolidation degree, the growth of the largest interval is before 21 days (the pile row), which means the upper load has a great influence on the calculation of strain consolidation degree; however, to average stress consolidation degree, the growth of the largest interval is 20-40 days, which illustrates that the drainage has more influence on the calculation of stress consolidation degree.

Figure 17. Average value of strain degree of consolidation and stress degree of consolidation for tailings depth of 0.5 m.

Figure 18. Average value of strain degree of consolidation and stress degree of consolidation for tailings depth of 1.0 m.

2. By comparing the average strain consolidation degree and the stress consolidation degree of the tailings at 0.5 m depth, the former is larger than the latter. The study (WEI Ru-long 1993) shows that the time lines of strain consolidation degree and stress consolidation degree were connected from beginning to end. Although there is difference in the middle of the process, the strain consolidation degree was always larger than the consolidation stress degree. The results of the experiment are consistent with those in Figures 22 and 23.

The average strain consolidation degree and stress consolidation degree of tailings at 1.0 m depth are still larger than the stress consolidation degree in 35 days. Then, it is just the opposite. After 35 days, the overlying water drained. As the distance between the tailings surface to the pore water pressure gauge at 1.0 m depth is only 0.3 m, the stress consolidation degree calculation results are larger than those of the strain consolidation degree, due to external factors such as evaporation, sunshine, and others.

5 CONCLUSION

This paper begins with the study of the drainage consolidation of tailings reservoir as the target area, bauxite tailings reservoir in the west of Guangxi, China. It adopts geotechnical composite drainage material as vertical drainage channels and simulated the mud consolidation effect by indoor pile model test and then reaches following conclusions:

1. In the condition of tailings slurry step piling, the drainage rate of geotechnical composite drainage material has the characteristics of time correlation, long-term trend, and periodic cycle, which is consistent with the characteristics of the autoregressive moving-average model. The model was established by SPSS and the computational fitted are $ARIMA(2,1,8) \times (0,0,0)$. Smooth coefficient of the model of R^2 and R^2 were 0.964 and 0.990. It shows that model fits very well. Model prediction analysis shows that the maximum water displacement has a tendency of gradually increase, so the performance of the geotechnical composite drainage material still has a large space.
2. The varying curve of pore water pressure has the following characteristics: lower-layer pore water pressure was significantly higher than that of the upper layer; for each additional 0.5 m on the tailings thickness, the pore water pressure value average increases about 5 kPa. The pore water pressure value of same height layout increases

gradually with the increase in the distance from the drainage channel; however, the growth rate decreases gradually. During the heap period, pore water pressure and height of water layer show good synchronization with the gradual increase of water level fluctuation wave. During the stop-discharge period, the pore water pressure value generally showed a decreasing trend, but at about 35 days, an obvious inflection point appeared, and the speed of decline also decreased significantly.

3. For the same height layout sedimentation test points, sedimentation value decreases gradually with the increase of the distance from drainage channels, but the decrease slows down gradually. The sedimentation curve can be divided into two stages: during the heap period, the lower part of the tailings soil is under staging load of upper part and the sedimentation value increased considerably; and in the stop-discharge period, the sedimentation value increased significantly and decreased.
4. After tailings mud stop heap 104 days, variation range of the average stress consolidation degree of each depth becomes 62.32–70.81%, and the average strain consolidation range of the variation is 61.27–68.91%. The time curves of strain consolidation degree and stress consolidation degree were connected at the beginning and end, but they were different in the middle of the process. The strain consolidation degree was always larger than the stress consolidation degree in the process.

ABSTRACT: Composite Tuned Mass Damper (CTMD) is a vibration control device, which consists of an active-passive tuned mass damper supported on the main vibrating structure. The performance of CTMD in suppressing wind-induced vibration of tall building is investigated. Optimum tuning frequency and damping ratio of a single Passive Tuned Mass Damper (PTMD) for minimizing the variance response of the damped main structure under random loads derived by Krenk are used for the optimum parameters for CTMD. Optimum parameters of CTMD with different mass ratios of an Active Tuned Mass Damper (ATMD) to PTMD are 0.01, 0.03, 0.05, 0.1, 0.3, and 0.5, which are chosen as the parameters of CTMD. The control force generated by the actuator of ATMD is estimated by a Linear Quadratic Regulator (LQR) controller. Fluctuating across-wind load, considered as a stationary random process, was simulated numerically using the across-wind load spectrum by Kareem. Comparing the controlled across-wind responses of a tall building with CTMD with those of an original tall building, the reduction rate of rms responses is 15–30%. Therefore, CTMD system is effective in mitigating excessive wind-induced vibrations of a tall building.

1 INTRODUCTION

Modern tall building are more lighter and slender with a lower natural frequency and damping ratio, so these tall buildings are more sensitive to wind-induced vibration. One way of mitigating such an excessive wind-induced vibration of tall buildings is by using vibration control devices. Passive Tuned Mass Damper (PTMD) is a classical vibration control device, which consists of a mass, a spring, and a damper supported on the main vibrating structure (Den Hartog 1956). The original idea of PTMD was proposed by Frahm in 1909, who invented a vibration control device called a vibration absorber using a spring-supported mass without damper (Frahm 1909). It was effective when the absorber's natural frequency was close to the excitation frequency. However, it was difficult tuning the absorber's natural frequency to the excitation frequency. This control device was improved by introducing a damper in the spring-supported mass (Ormondroyd et al. 1928). Later, Den Hartog derived optimum tuning frequency and damping ratio for the undamped main structure under harmonic load (Den Hartog

1956). While Den Hartog considered harmonic loading only, Warburton and Ayroinde derived optimum parameters of PTMD for the undamped main system under harmonic and white noise random excitations (Ayoringde 1980, Warburton 1981, 1982). Krenk derived the optimum parameters of PTMD for the damped main structure under random excitations with the condition that the mass ratio is small and the main structure's damping ratio is less than that of PTMD (Krenk et al. 2008). And a number of PTMDs have been installed in tall buildings to suppress wind-induced vibrations of tall buildings (McNamara 1977, Housner et al. 1997). The Center Point Tower in Sydney is one of the first PTMDs in a building, and a 400-ton PTMD has been installed for the Citicorp Center in New York. Another PTMD has been designed in the John Hancock Tower in Boston (Housner et al. 1997). All of the PTMDs have been installed to mitigate wind-induced vibrations. At that time, it was accepted as a fact that the performance of PTMD could be improved by incorporating a feedback controller through the use of an actuator as an active control force in the design of PTMD, which

was called Active Tuned Mass Damper (ATMD) (Housner et al.1997). In 1972, Yao introduced the modern control theory into vibration control of a civil engineering structure, and many auxiliary control devices combining with modern optimal control theory have been developed for mitigating the excessive wind-induced vibrations of tall buildings (Yao 1972). One way of ATMD design for reducing wind-induced vibration of tall building using assumed deterministic harmonic wind loading was presented by Chang and Soong in 1980 (Chang et al. 1980). That was the first active control study for mitigating wind-induced vibration of tall buildings with ATMD using a Linear Quadratic Regulator (LQR) controller. Since then, many studies have been advanced for obtaining optimal control force for reducing wind-induced vibration of tall buildings on the basis of the modern optimal control technique (Ankireddi et al. 1996, 1997). However, the fact that ATMD is superior to PTMD reducing wind-induced vibration of tall buildings is still question (Ricciardelli et al. 2003). From the viewpoint of the modern optimal control theory, fluctuating across-wind load acting on a tall building can be treated as a stationary random process, and a constant power spectrum could be considered as a system noise. Then, many advanced studies for mitigating wind-induced vibration of tall buildings on the basis of the modern optimal control theory, including Linear Quadratic Gaussian (LQG), H_2 and H_∞ have been developed, and a number of tall buildings are currently implemented with active control device systems (Yang et al 2002, 2003). Nishimura and Wang et al. pointed out that the disadvantage of a single PTMD is its error in tuning the natural frequency of PTMD to that of the main structure and fitting the optimum damping ratio of PTMD. The size restriction of PTMD limits the vibration control effect (Nishimura et al.1994, 1998, Wang et al. 1999).

In overcoming such problem of PTMD, an active-passive composite tuned mass damper, that is, a Composite Tuned Mass Damper (CTMD), was proposed by Nishimura and Wang et al. (Nishimura et al. 1994, 1998, Wang et al. 1999). CTMD system consists of ATMD, which is attached to the PTMD supported on the main vibrating structure, as shown in Figure 1.

In this study, the performance of CTMD for suppressing across-wind induced vibrations of tall building is investigated. The control force generated by the actuator of ATMD is estimated by a Linear Quadratic Regulator (LQR) controller. Fluctuating across-wind load was simulated numerically using the across-wind load spectrum proposed by Kareem (Kareem 1982). Dynamic across-wind responses of tall buildings with CTMD are estimated and compared with the responses of a

Figure 1. Tall building CTMD model.

single PTMD and the original tall building without CTMD. The controlled rms responses with CTMD is reduced about 15–30% rms response of the original tall building without CTMD, which is close to the controlled response with PTMD. Therefore, CTMD systems are effective in mitigating excessive wind-induced vibrations of tall building.

2 EQUATIONS OF MOTION

Dynamic response analysis procedure can be simplified if the contribution of higher modes of the tall building is ignored, so the response is represented by the motion of the first mode (Kareem et al. 1995, Ankireddi et al. 1996). Therefore, tall building-CTMD system can be modeled as the first-mode generalized SDOF/CTMD system, as shown in Figure 1.

The linear dynamic equations of motion of the CTMD system can be written as:

$$M_S \ddot{X}_S + C_S \dot{X}_S + K_S X_S - C_P \dot{X}_P - K_P X_P = f(t) \quad (1)$$

$$M_P \ddot{X}_P + C_P \dot{X}_P + K_P X_P - C_A \dot{X}_A - K_A X_A + M_P \ddot{X}_S = u(t) \quad (2)$$

$$M_A \ddot{X}_A + C_A \dot{X}_A + K_A X_A + M_A \ddot{X}_S + M_A \ddot{X}_P = -u(t) \quad (3)$$

These equations of motion can be rewritten in the state space variable representation as:

$$\dot{X} = AX + Bu(t) + Ff(t) \quad (4)$$

where

$$X = [X_S \quad X_P \quad X_A \quad \dot{X}_S \quad \dot{X}_P \quad \dot{X}_A]^T \quad (5)$$

$$A = \begin{bmatrix} 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ -\frac{K_S}{M_S} & \frac{K_P}{M_S} & 0 & -\frac{C_S}{M_S} & \frac{C_P}{M_S} & 0 \\ \frac{K_S}{M_S} & -\left(\frac{K_P}{M_P} + \frac{K_P}{M_S}\right) & \frac{K_A}{M_P} & \frac{C_S}{M_S} & -\left(\frac{C_P}{M_P} + \frac{C_P}{M_S}\right) & \frac{C_A}{M_P} \\ 0 & \frac{K_P}{M_P} & -\left(\frac{K_A}{M_A} + \frac{K_A}{M_P}\right) & 0 & \frac{C_P}{M_P} & -\left(\frac{C_A}{M_A} + \frac{C_A}{M_P}\right) \end{bmatrix} \quad (6)$$

$$B = \begin{bmatrix} 0 & 0 & 0 & 0 & \frac{1}{M_P} & -\left(\frac{1}{M_A} + \frac{1}{M_P}\right) \end{bmatrix}^T \quad (7)$$

$$F = \begin{bmatrix} 0 & 0 & 0 & \frac{1}{M_S} & -\frac{1}{M_S} & 0 \end{bmatrix}^T \quad (8)$$

where M_S , C_S , and K_S are generalized mass, damping, and stiffness coefficients corresponding to the first mode of the tall building;

M_P , C_P , and K_P are the mass, sdamping, and stiffness coefficients of the PTMD;

M_A , C_A , and K_A are the mass, damping, and stiffness coefficients of the ATMD;

X_S and \dot{X}_S are the main structural displacement and velocity;

X_P and \dot{X}_P are the relative displacement and velocity of the PTMD with respect to the main structure;

X_A and \dot{X}_A are the relative displacement and velocity of the ATMD with respect to the PTMD;

$u(t)$ is active control force;

$f(t)$ is the generalized fluctuating across-wind load associated with the first mode.

3 OPTIMUM PARAMETERS OF PTMD

While the basic concept of PTMD for reducing vibrations of the main structure has been well established, the optimum parameters of PTMD could be different for different structures and external loading conditions (Ayoringde (1980), Warburton (1981, 1982)). Warburton derived the optimum parameters for tuning the natural frequency and damping ratio of PTMD for the undamped main structure under stationary random load (Warburton 1982). Krenk derived the optimum parameters of PTMD for the damped main structure under the condition of mass ratio is small and the primary structure's damping ratio is less than that of PTMD as (Krenk et al. 2008):

$$f_{opt} = \frac{1}{1+\mu} \quad (9)$$

$$\xi_{opt} = \frac{\sqrt{\mu}}{2} \quad (10)$$

where f_{opt} is the optimum tuning frequency ratio, ξ_{opt} is the optimum damping ratio, and μ is the mass ratio.

4 OPTIMUM PARAMETERS OF CTMD

The optimum parameters of ATMD for minimizing rms responses of the main structure are similar to those of PTMD. It was known that tuning the frequencies of PTMD to the fundamental natural frequency in the main structure is more effective than tuning it to different natural frequencies (Kareem et al. 1995). Accordingly, the natural frequency and applied damping ratio of ATMD are tuned to the natural frequency and damping ratio of PTMD as in Eq. (9) and Eq. (10) with small mass ratios.

5 LINEAR QUADRATIC REGULATOR CONTROLLER

The LQR control method is a widely used modern optimal control technique in structural vibration control problems (Chang et al. 1980). In LQR control law, all continuous time state-space variables are available, and linear dynamic equations of motion of the system can be written in terms of the state-space formulation as in Eq. (4). The external force term in Eq. (4) can be treated as a system noise input and hence Eq. (4) can be written as (Dorato et al. 1995):

$$\dot{X}(t) = AX(t) + Bu(t) \quad (11)$$

The objective of LQR control law is to find out a state-feedback optimal control force, $u(t)$,

that minimizes the deterministic cost functional J , maintaining the state close to the zero state. The cost functional (J) is given by:

$$J = \int_0^{\infty} (X(t)^T Q X(t) + u(t)^T R u(t)) dt \quad (12)$$

where Q is a positive semi-definite state weighting matrix and R is a positive definite control weighting matrix. The term $X(t)^T Q X(t)$ in Eq. (12) is a measure of control accuracy and the term $u(t)^T R u(t)$ is a measure of control effort (Dorato et al. 1995, Lewis et al. 2012). Minimizing J with keeping the system response and the control effort close to zero needs appropriate choice of the weighting matrices Q and R (Suhardjo et al. 1992). If it is desirable that the system response be small, then large values for the elements of Q should be chosen by selecting the matrix Q to be diagonal and to make the large value of the diagonal element for any respective state variable to be small (Suhardjo et al. 1992). If the control energy needs to be small, then large values of the elements of R should be chosen. The state-feedback optimal control force, $u(t)$, is derived as (Dorato et al. 1995, Lewis et al. 2012):

$$u(t) = -KX(t) \quad (13)$$

where $K = R^{-1}B^T P$

In Eq. (13), K is called an optimal controller gain and P is the unique, symmetric, positive semi-definite solution to the Algebraic Riccati Equation (ARE) given by Dorato et al. (1995) and Lewis et al. (2012):

$$A^T P + PA - PBR^{-1}B^T P + Q = 0 \quad (14)$$

Then, the closed-loop system using the optimal control force, $u(t)$, becomes:

$$\dot{X} = (A - BK)X(t) = A_c X(t) \quad (15)$$

where A_c is the closed-loop system matrix

In LQR control law, the cost functional J keep minimizing, indicating that a larger value of state weighting matrix Q makes the state $X(t)$ smaller, that is, the poles of the closed-loop system matrix A_c is further left in the s -plane so that the state $X(t)$ decays faster to zero (Lewis et al. 2012).

6 NUMERICAL SIMULATION OF A FLUCTUATING ACROSS-WIND LOAD

The dynamic along-wind response of tall buildings can be estimated reasonably by a gust factor approach (Solari 1993). However dynamic across-wind response cannot be estimated by a gust factor

approach. The complex nature of the across-wind loading, resulting from an interaction of incident turbulence, flow separation, vortex-shedding, and unsteady wake development, has prevented theoretical prediction from estimation (Kareem 1982). The fluctuating across-wind load can be treated as a stationary random process, which can be simulated numerically in the time domain using the across-wind load power spectral density data. That is particularly useful for some response estimations that are more or less narrow-banded random processes, such as the across-wind response of tall buildings (Shinozuka 1987). The numerical simulation procedure presented in this work is taken from Shinozuka (Shinozuka 1987):

$$f(t) = \sum_{k=1}^N \sqrt{S_F(\omega_k) \Delta \omega} \cos(\omega_k t + \phi_k) \quad (16)$$

where $S_F(\omega_1)$ is the value of the spectral density of across-wind load corresponding to the first modal resonant frequency.

$$\Delta \omega = (\omega_u - \omega_l) / N;$$

$$\omega_k = \omega_l + (k - 1/2) \Delta \omega;$$

$$\omega_u = \text{upper frequency of } S(\omega);$$

$$\omega_l = \text{lower frequency of } S(\omega);$$

$$\Phi_k = \text{uniformly distributed random numbers between } 0 \text{ and } 2\pi;$$

$$N = \text{number of random numbers.}$$

The across-wind load power spectral density used in Eq. (16) is that proposed by A. Kareem

Figure 2. Normalized reduced spectra of across-wind load in a suburban (BL1) and urban (BL3).

(Kareem 1982). Kareem used a 5 sq in. (127 mm²) square, 20-in. (508 mm²) tall prism model and eight pressure transducers, integrating eight simultaneously-monitored channels of pressure data on a building model's surface and obtained the normalized across-wind load spectra of the across-wind forcing function on a square cross section tall building that is exposed to urban and suburban atmospheric flow conditions as shown below:

7 NUMERICL EXAMPLE

This numerical example is taken from “Numerical Example” by A. Kareem (Kareem 1982). A tall building was chosen, whose height (H) is 180 m, width (B) is 30 m, depth (D) is 30 m, natural frequency (f_n) is 0.2 Hz, critical damping ratio is 0.01, air density is 0.973 kg/m³, hourly mean wind speed at the building height (V_h) is 24.4 m/s, the reduced velocity ($V_h/f_n B$), corresponding to the mean hourly wind speed, is 4.0, generalzation mass of a first mode shape is 10,942,500 kg, and $S_y(f_n)$ is 3.149×10^8 kg²/Hz. The optimum parameters of CTMD are considered to have the same values as for the PTMD. The optimum parameters of PTMD are: mass ratio (μ) = 0.01, tuning frequency (f_{opt}) = 1.0, and damping ratio (ξ_{opt}) = 0.05. The numerically simulated across-wind load and response without CTMD are shown in Figures 3 and 4. The rms displacement response without CTMD shown in Figure 4 is 0.0047 m, which is a good approximation to that of Kareem’s closed-form response of 0.0040 m.

7.1 Across-wind responses with PTMD

The rms response with a single PTMD with optimum parameters is shown in Figure 5, which shows that the controlled rms response is reduced

Figure 3. Simulated across-wind load in time domain.

Figure 4. Across-wind response without CTMD (rms = 0.0047 m).

with reduction ratio of 28% comparing with that of the original tall building without PTMD.

7.2 Across-wind responses with CTMD

For estimating LQR controller, the weighting matrices Q and R are selected as:

$$Q = 1.0 * 10^8 * \begin{bmatrix} 100 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 100 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad R = [1.0 * 10^{-12}]$$

The dynamic across-wind responses of tall building with CTMD, which have a different mass ratio (μ_{AP}) of ATMD to PTMD are 0.01, 0.03, 0.05, 0.1, 0.3, and 0.5, which are presented in Figures 6–11.

As shown above, comparing the controlled rms responses with those of the original tall building, about 15–30% reduction effect was presented, which shows close to the reduction effect of using PTMD. And the effectiveness of CTMD is increased as the mass ratio of ATMD to PTMD is increased within an allowable limit. That is, as

Figure 5. Across-wind response with PTMD (rms = 0.0034 m).

Figure 6. Across-wind responses with CTMD ($\mu_{AP} = 0.01$, rms = 0.0037 m).

Figure 7. Across-wind responses with CTMD ($\mu_{AP} = 0.03$, rms = 0.0034 m).

Figure 8. Across-wind responses with CTMD ($\mu_{AP} = 0.05$, rms = 0.0035 m).

Figure 9. Across-wind responses with CTMD ($\mu_{AP} = 0.1$, rms = 0.0033 m).

Figure 10. Across-wind responses with CTMD ($\mu_{AP} = 0.3$, rms = 0.0037 m).

Figure 11. Across-wind responses with CTMD ($\mu_{AP} = 0.5$, rms = 0.0040 m).

the mass ratio of ATMD to PTMD is increased 10 times with the optimum tuning frequency ratio and damping ratio, a reduction effect of 10% is presented. However, an adverse effect of 8–15% increased response is obtained when the mass ratio is increased to 0.3 and 0.5. Therefore, CTMD system is effective for suppressing wind-induced vibrations of tall buildings.

8 CONCLUSIONS

The performance of Composite Tuned Mass Dampers (CTMDs) with LQR controller for mitigating across-wind responses of tall buildings is

investigated. Optimum values of tuning frequency ratio, damping ratio, and mass ratio for PTMD were used for the optimum parameters for ATMD of CTMD. The fluctuating across-wind load was simulated numerically using the across-wind load spectrum by Kareem. Comparing the rms response with CTMD with that of the original tall building without CTMD, the rms responses of a CTMD is reduced about 15–30% than that of the original tall building, which is close to that of PTMD. Therefore, CTMD system with an LQR controller, which has optimum parameters, is effective in mitigating excessive wind-induced vibration of tall buildings.

ABSTRACT: This study was aimed at examining the time-variable flexural capacity of Steel Fiber Reinforced Concrete (SFRC) sections subjected to long-term loading. Based on tests results of two series of steel fiber reinforced concrete beams subjected to sustained loading over a period of ten years, the time-variable reliability indices for flexural strength were obtained considering the time-dependent resistance of SFRC beams under applied loads. Results show that under a specified sustained load, the reliability index is significantly higher in SFRC beams than in beams without steel fibers. With the same steel fiber content, the larger the applied load, the smaller is the reliability index. For a service life of 100 years, the reliability index of SFRC beams was found to first increase and then decrease; with the reliability index reaches the maximum value when $t = 2a$ and steel bars begin to rust, and the reliability index significantly decreased when $t = 37.8a$

1 INTRODUCTION

Steel Fiber-Reinforced Concrete (SFRC) has wide applications in the field of civil engineering as it can effectively improve the cracking and toughening characteristics, thus eliminating the inherent defects of concrete. On the long-term behavior of structural elements under service loads, Goistseone et al. (2009) had studied the time-dependent characteristics of the flexural capacity, curvature and neutral axis depth of reinforced concrete beams placed in sodium chloride solution with a concentration of 5%, and subjected to sustained loads for 70 days. Lee et al. (2013) studied the middle span displacement, section stiffness, and stresses and strains in reinforced concrete beams subjected to repeated loads at frequencies of 0.2 and 1 Hz for 80 days. Creep was found to influence the mechanical properties and structural response of long-span concrete-filled steel tube arch bridges (Ma et al. 2015). The effect of creep and shrinkage on the deflection and structural response of steel-concrete composite bridges after 300 days of service under different ambient temperature and humidity has also been studied (Hui et al. 2015).

Based on flexural tests, the deformation and cracking characteristics of the steel-polyester fiber

beams under sustained load over 17 months was determined by Emilia et al. (2013). The reliability index of in-service pre-stressed concrete bridge was calculated by Jin (2013) by using neural network with sampling methods. The time-dependent reliability of prestressed sleeper has been analyzed by Monte Carlo Method (Saeed et al. 2011).

Previous studies dealt with concrete elements subjected to sustained loads sustained over a relatively short period. Adding steel fibers makes the material more complex, it is difficult to ensure the stability in sustaining loads for a long period. Thus, for SFRC beams, the change in reliability index as a result of long sustained load period being influenced by many factors has not been reported.

This paper is based on flexural test results from the SFRC beams subjected to sustained loads over a period of ten years. The time-variable load effect and resistance level of SFRC beams under long-term load is considered for two groups of beams; Group I beams with the same sustained load level but with different steel fiber content, and Group II with the same fiber content but with different sustained load levels. The time-dependent flexural resistance of SFRC sections is established for the evaluation of time-dependent reliability.

2 STATISTICAL PARAMETERS

2.1 Tensile strength of concrete

The average and standard deviation of time—dependent tensile strength for concrete grade C10~C110 are respectively (Faxing et al. 2004):

$$\mu_{f_t(t)} = 0.24 \mu_{f_{cu}^{2/3}}(t) \quad (1)$$

$$\sigma_{f_t(t)} = 0.24 \sigma_{f_{cu}^{2/3}}(t) \quad (2)$$

where $f_{cu}(t)$ = time-dependent axial compressive strength of concrete cube.

2.2 Effective cross-section area of reinforcement

Due to corrosion caused by carbonation, the reduced steel reinforcement area at time t is taken as (Zhenping et al. 2009):

$$A_s(t) = \begin{cases} A_{s0}, & (t \leq t_1) \\ A_{s0} \left[1 - \frac{\lambda}{r_0} (t - t_1) \right]^2, & (t > t_1) \end{cases} \quad (3)$$

where A_{s0} = initial area of rebar; λ = rebar corrosion rate; r_0 = initial radius of rebar; t_1 = initial corrosion time, calculated according to Yi et al. (2009).

2.3 Bond strength between rebar and concrete

With the extended service time, $\varphi(t)$ is used to account for the loss in bond strength between steel and concrete; $\varphi(t) = 0$ when the steel bars are not corroded, and 0.95 while the steel began to rust.

2.4 Uncertainty coefficient of calculation model

The uncertainty coefficient of calculation model P can be expressed in general as:

$$P = \frac{K_s}{K_j} \quad (4)$$

where K_s = actual resistance of the structure and K_j = resistance calculated by code using real geometric parameters and mechanical properties of materials.

3 TIME-DEPENDENT RELIABILITY ANALYSIS OF FLEXURAL CAPACITY

The flexural capacity of SFRC can be calculated as:

$$M_{fu} = f_{fc} b x \left(h_0 - \frac{x}{2} \right) + f'_y A'_s (h_0 - a'_s) - f_{fu} b x_t \left(\frac{x_t}{2} - a \right) \quad (5)$$

where x is the depth of concrete compression zone, given by:

$$f_{fc} b x = f_y A_s - f'_y A'_s + f_{fu} b x_t \quad (6)$$

in which M_{fu} = design value of the flexural capacity; f_{fc} = design value of axial compressive strength; f_y, f'_y = design value of tensile and compressive strength of longitudinal reinforcement, respectively; A_s, A'_s = total area of tensile and compressive bars, respectively; b = section width; h_0 = section effective height; a = distance from the centroid of longitudinal tension reinforcement to the tension edge of the section; a'_s = distance from the centroid of longitudinal reinforcement in compression zone to the edge of the section; x_t = height of equivalent stress in tensile zone; f_{fu} = tensile strength of equivalent stress block of steel fiber reinforced concrete in tensile zone.

3.1 Height of tensile zone of concrete

The tensile stress distribution is simplified as an equivalent rectangle stress block, with height as (CECS38-2004):

$$x_t = h - \frac{x}{\beta_1} \quad (7)$$

where x = height of equivalent rectangular stress pattern in compression zone

3.2 Tensile strength of tensile zone

Tensile strength of the equivalent rectangular tensile stress block can be calculated as:

$$f_{fu} = f_t \beta_{tu} \lambda_f \quad (8)$$

where β_{tu} = effect of steel fiber on tensile strength; λ_f = characteristic value of steel fiber content. Over time, considering the reduced strength of material and the reduced effective cross section of the concrete and reinforcing steel bars, along with Eqs. (1) - (8), the time-dependent flexural capacity is:

$$R(t) = p \cdot \varphi(t) \cdot \left[\begin{array}{l} f_y(t) b x(t) \left(h - \frac{x(t)}{2} \right) + f'_y A'_s(t) (h - a'_s) \\ - f_t(t) \beta_{tu} \lambda_f b \left(h - \frac{x(t)}{\beta_1} \right) \left(\frac{h - \frac{x(t)}{\beta_1}}{2} - a \right) \end{array} \right] \quad (9)$$

where x can be calculated as:

$$x(t) = \frac{f_y A_s(t) - f'_y A'_s(t) + f_t(t) \beta_m \lambda_f b h}{f_{fc}(t) b + \frac{1}{\beta_1} f_t(t) \beta_m \lambda_f b} \quad (10)$$

in which $f_{fc}(t)$ = axial compressive strength of SFRC; $A_s(t)$, $A'_s(t)$ = area of longitudinal tensile reinforcement and compression bars, respectively; $f_{tm}(t)$ = tensile strength of equivalent rectangular stress block of SFRC in tensile zone; $f_t(t)$ = tensile strength of steel fiber reinforced concrete; at time t .

The time-dependent load effect is expressed by $S(t)$, and the time-dependent limit state function of SFRC beams is

$$Z(t) = p \cdot \varphi(t) \left[\begin{array}{l} f_{fc}(t) b x(t) \left(h_0 - \frac{x(t)}{2} \right) + f'_y A'_s(t) (h_0 - a'_s) \\ - f_t(t) \beta_m \lambda_f b \left(h - \frac{x(t)}{\beta_1} \right) \left(\frac{h - \frac{x(t)}{\beta_1}}{2} - a \right) \end{array} \right] - S(t) \quad (11)$$

4 EXAMPLE CALCULATION

4.1 Test specimen design

Ten RC beams were subjected to sustained flexural loading over a period of 10 years (Tan et al. 2005), using hanging weights to ensure the stability of long term load. The sustained load level was 0.5 times the ultimate load capacity, and the content of steel fiber was varied in Group I specimens (Table 1). Whereas, the content of steel fiber was 0.1% and the load level was varied in Group II specimens.

The beams measured 100 mm × 125 mm × 2000 mm with an effective span of 1800 mm. Concrete

consisted of ordinary portland cement, natural sand and granular granite stone with maximum size of 10 mm. The steel fiber has a length of 0.5 mm, width of 30 mm and hook ends. Longitudinal tensile reinforcement consisted of two 10-mm diameter bars; transverse reinforcement comprised 6-mm links at 75 mm spacing. Concrete grade was C40.

4.2 Test instrumentation

The beams were loaded at quarter points. Deflections at mid-span were measured at 10 mm from the front and back faces and averaged. Crack width was measured by hand-held microscope, with an accuracy of ±0.02 mm. The deflection and crack widths were measured at 1d, 50d, 138d, 230d, 370d, 2284d (6.25 years) and 3678d (10 years).

4.3 Time-dependent reliability

The statistical parameters were determined using the deterioration model for each mechanical property. Using the first-order second-moment method, the time-dependent reliability of flexural capacity of SFRC beams was obtained. The time-dependent reliability indices for beams under 10-year sustained load are shown in Figure 1(a) and Figure 2(a). The time-dependent reliability indices of beams under 100-year sustained load were predicted as shown in Figure 1(b) and Figure 2(b).

1. As shown in Figure 1(a), when the external load was kept constant (0.50P_u) and the steel fiber content varied (0, 0.5%, 1.0%, 1.5%, 2.0%), the reliability index of SFRC beams is always higher than Beam A-50 without steel fiber at any time. The reliability index of Group I specimens in descending order is:

$$\beta(B-50) > \beta(C-50) > \beta(D-50) > \beta(E-50) > \beta(A-50)$$

Therefore, the incorporation of steel fiber can significantly improve the flexural capacity of the beam. The optimal steel fiber content was 0.5% (Beam B-50).

2. As shown in Figure 2(a), for Group II beams with the same steel fiber content but with different sustained loads (0.35P_u, 0.50P_u, 0.59P_u, 0.65P_u, 0.80P_u), the reliability index in descending order is:

$$\beta(C-35) > \beta(C-50) > \beta(C-59) > \beta(C-65) > \beta(C-80)$$

Indicating that the larger the sustained load, the smaller the reliability index. Also, $\beta(C-59)$ and $\beta(C-65)$ are close to each other, indicating that the closer the applied loads, the closer are the reliability indexes, and that the results are consistent with the experimental results.

Table 1. Beam designation.

Group	Test specimen	Steel fiber content ρ_f / %	Sustained load level
I	A-50	0	0.50
	B-50	0.5	0.50
	C-50	1.0	0.50
	D-50	1.5	0.50
	E-50	2.0	0.50
	C-35	1.0	0.35
II	C-50	1.0	0.50
	C-59	1.0	0.59
	C-65	1.0	0.65
	C-80	1.0	0.80

*Sustained load level = applied load Ps divided by design ultimate load Pu; Pu = 23.3 kN (based on Beam A-50).

(a) 10 years sustained load

(b) 100 years sustained load

Figure 1. Time-dependent reliability of Group I beams.

(a) 10 years sustained load

(b) 100 years sustained load

Figure 2. Time-dependent reliability of Group II beams.

- As shown in Figures 1 and 2, the reliability index of SFRC beams first increased and then decreased during the service period. The reliability index of the test specimens reaches the maximum value when $t=2a$; this phenomenon may be due to the increase in early strength of the beam. With increasing time of service, the performance of concrete and reinforcing steel bar is deteriorated, the bond strength is weakened, and the reliability index is gradually reduced. According to the reliability evaluation criteria, when $t = 50a$, Group I: E-50 and Group II: C-59, C-65, C-80 do not meet the requirement of flexural capacity. When $t = 100a$, Group I: C-50, D-50, E-50 and Group II: C-50, C-59, C-65, C-80 do not meet the requirement of flexural capacity.
- According to the Zheng et al. (2009), the steel bars begin to rust when $t_r = 37.8a$. As shown in Figures 1(b) and 2(b), the reliability index curves of all the specimens show a sharp drop at this point. This is because the carbonation depth has reached the surface of the steel bars. As a result, the steel bars begin to rust which

leads to a significant decrease in the yield tensile strength, and consequently a significant reduction in the flexural capacity of the beams.

5 CONCLUSION

The reliability index of SFRC beams is significantly higher than a beam without steel fibers. For Group I beams, with the same applied load but different steel fiber content, the reliability index in descending order is:

$$\beta(B-50) > \beta(C-50) > \beta(D-50) > \beta(E-50) > \beta(A-50)$$

For the same steel fiber content, the larger the sustained load, the smaller is the reliability index. The reliability index of Group II beams in descending order is:

$$\beta(C-35) > \beta(C-50) > \beta(C-59) > \beta(C-65) > \beta(C-80)$$

For 100 years of service, the reliability index of SFRC beams first increases and then decreases,

with the reliability index reaching a maximum value while $t = 2a$. The steel bars begin to rust, resulting in a significant reduction in the reliability index when $t = 37.8a$.

Research on the heat transfer characteristics of rock and soil under the effects of vertical double U-type buried-pipe heat exchanger

Xiao-duo Ou, Xin Pan, Heng Dai, Ying-chun Tang & Zi-yan Liu

Key Laboratory of Disaster Prevention and Structural Safety of Ministry of Education, Guangxi University, Nanning, China

Key Laboratory of Disaster Prevention Mitigation and Engineering Safety, Guangxi University, Nanning, China

ABSTRACT: This study based on a vertical double U-type buried-pipe heat exchanger of ground source heat pump engineering project in Nanning through an in situ test monitored the temperature changes in horizontal and vertical directions of the buried-pipe surrounding rock layer and explored the geotechnical heat transfer characteristics. Our results showed that in the deepest measuring point of the monitored hole, the temperature progressively drops in the unit run-time, which accumulated a drop of 5.2°C in 3 years. However, the temperature did not change during the running of the unit stop. This research also revealed that the change of temperature at other measuring points has a correlation with the operation of the unit. The measuring point temperature decreased during the unit run time, whereas the measuring point temperature increased but is still lower than the initial ground temperature when the unit was not operating. It is also found that the increasing degree of the temperature at each measuring point diminished with the increasing depth of each point. For example, the accumulation of temperature at 5 m deep, 1# hole, amounted to 2.4°C in 2009, whereas at a depth of 15 m, it amounted to 0°C. The research further showed that the temperature of each measuring point dropped every year and that the variation degree of temperature decreased with the increase of the depth of the measuring point, which suggests that the ground source heat pump has a cumulative effect on the ground temperature.

1 INTRODUCTION

The sustainable development of society requires the development and utilization of energy to coordinate with the development of environment protection and ecological balance, minimize the damage to our environment in the process of utilizing energy, exploit renewable and clean energy, and to increase the efficiency of energy utilization (Yu Zhongyi 2008). Geothermal energy, one kind of renewable resources, has drawn researchers' attention because of its sustainability and wide applicability across regions. In order to make better use of geothermal energy, many scholars have studied the characteristics of geotechnical heat transfer and obtained some achievements. Wang Wei (2010) performed a large number of tests for determining the properties of permafrost heat transfer. Wang Tie-hang (2010) summarized previous studies on water heat coupling in the field of loess, frozen soil, expansive soil, soil science, and so on. He further pointed out the limitations of research on the water heat coupling function. Sutton et al. (2005) worked out the drilling soil thermal resistance analytic expression when groundwater flows around. As a widely used ground source, the ground source heat pump also

produces many research results. Relevant literature (Michel A B 2001 & 2002, Yavuzturk C et al 2001 & 2002, Michel P. A 2001) established the mathematical model of the buried-pipe heat exchanger and the numerical simulation, and North America choose IGSHA model (Ball D A et al. 1983) method as the standard method to determine the size of the underground buried-pipe heat exchanger. Studies (ZHANG Guozhu et al. 2012, Yingchun Tang et al. 2011, Yan Ren 2010, Chen Ying et al. 2009, Hu Yingning et al. 2009) have shown the characteristics of soil heat transfer under the influence of ground source heat pump. However, in terms of different hydrogeology and engineering geology, soil heat transfer has different characteristics. As the ground source heat pump is finding wider and wider application in Guangxi, in view of the Guangxi Nanning basin characteristics in geotechnical layer, buried pipe heat exchanger under the action of soil heat transfer experiment research is necessary.

2 SUMMARY OF OBSERVATION STATION

The surface of the field is flat and belongs to the north shore of Yong Jiang River of the Nanning

basin II level terrace. The field has two layers of groundwater within the drilling depth. The first layer is surface water and perched water, assigned product in fish ponds, depression, and tillage soil, mainly from atmospheric precipitation and surface water, and the volume of water in this layer is relatively minor. The second layer is pore water, whose static level was buried deeply, 5.80–8.50 m, in the exploration period. Figure 1 shows the geological histogram of the field based on the geological survey report. The result of the thermal physical property test and the physical and mechanical properties test of the geotechnical layer sampling of the field are shown in Table 1.

Figure 1. Profile of sensor layout.

3 TEST DESIGN OF OBSERVATION STATION

This research was based on the ground source heat pump engineering of student apartments of Guangxi University Xingjian College of Science and Liberal Arts. The heat pump is a ground-source heat pump, using 60 double U vertical buried-pipe heat exchangers at an embedment depth of 25 m and spacing of 5 m. We selected an engineering well at the edge for monitoring. The temperature sensors were arranged around the monitoring well. In the horizontal direction, the distance between the monitoring holes and the heat exchange tube were 0.5, 1, and 2 m. In the vertical direction, temperature sensors were embedded at different depths in each monitoring hole. The temperature sensors were buried underground at depths of 5, 7.5, 10, 15, 18, and 24 m in the 1# monitoring hole. The temperature sensors were also buried at the same depth (except 15 m deep outside) in the 2# monitoring hole. The temperature sensors were buried at depths of 5, 10, and 15 m in the 3# monitoring hole. In sum, there were 3 holes and 14 temperature sensors to monitor the temperature of the surrounding rock layer of the engineering well. The specific arrangement of sensors is shown in Figures 1 and 2 (temperature sensor number: X–Y means the temperature sensor is embedded in X# monitoring hole and depth Y)

Figure 2. Arrangement plan of sensor.

4 IN SITU TEST PROCESS

After all the heat pump engineering wells have been completed, we selected a well at the edge as the research object. The monitoring holes were drilled surrounding the well according to the test design, and temperature sensors were buried in each monitoring hole in order to monitor geotechnical temperature changes of the well. First, we tied the temperature sensor to the PPR pipe on the corresponding position according to the experimental design depth and then put the pipe and temperature sensor into the monitoring hole and refilled the hole with sand. After all the sensors were embedded, we monitored the change of rock layer temperature surrounding the buried pipe.

1. Before the running of heat pump units, we detected the temperature of various rock layers

using the temperature checking instrument twice a day for a week, taking its mean value as the initial temperature of a rock layer.

- In the early operation of heat pump units, our monitoring frequency is twice a day. After the temperature change of rock layer became relatively stable, our monitoring frequency reduced to once a day. Finally, according to the monitoring results of temperature change of geotechnical layer during early stages, our monitoring frequency gradually became once every 2 weeks.

5 TEST RESULTS AND ANALYSIS

5.1 Soil Initial Temperature test

Before the running of heat pump units, we detected the temperature of various rock layers twice a day for a week, taking its mean value of 14 times as the rock layer's initial temperature. The test results are shown in Table 2 and Figure 3.

As Figure 3 shows, the lowest geotechnical layer temperature is at the depth of 10 m, and the average temperature is 23.1°C. The soil temperature within the depth range of 0–10 m reduced as the depth increases; however, the soil temperature below the depth of 10 m increased as the depth increases.

Cause analysis: during the whole test period, the outside temperature is higher than the soil temperature. The soil temperature nearing the ground surface was affected by the external temperature to a great extent. The ground surface and 5.80–8.50 m deep soil layer contain groundwater, which can transfer heat as it flows and thus result in a decrease of soil temperature within that depth. Therefore, soil temperature decreased as depth increased from 0 to 10 m. On the contrary, there is no groundwater in soil layers of 10–24 m depth range. Its temperature is less affected by the external temperature, and the heat diffusion to the ground is less possible, which resulted in an increase of rock layer temperature with an increase of its depth.

Table 2. Initial soil temperature of observatory.

Depth/m	Temperature/°C					
Number	5.0	7.5	10	15.0	18.0	24.0
1# hole average	24	23.3	23.1	23.2	23.5	23.6
2# hole average	24	23.4	23.1	—	23.5	23.7
3# hole average	23.9	—	23.1	23.2	—	—
Each hole average temperature	24.0	23.4	23.1	23.2	23.5	23.6

	2011–10–18		

Figure 4. Nanning produced historical average temperature profile.

5.2 Soil temperature change in the monitoring hole at different depths

Our analyses of soil temperature change were based on the monitoring data during the 3-year time span from 18 October 2008 (beginning of the research) to 18 October 2011. The unit's running condition during this period is shown in Table 3. The unit's stop running period represents the convalescence of surrounding rock-layer temperature.

Figure 4 lists the average temperatures of Nanning. As can be seen from the graph, the

average air temperature is higher during the period of the unit's nonrunning period from May to October, which was above 20°C. The average temperature is lower during the period of the unit's running period from November to April, which was between 10 and -20°C.

In order to understand the geotechnical vertical heat transfer condition, we compared temperature changes of different soil layers of each monitoring hole as time changes and listed the temperature decrease degree of every year, as shown in Figures 4 and 5. Points 1-24, 2-5, 2-24, 3-5, 3-10, and 3-15 were destroyed in 2011 so part of the data is missing.

As shown in Figure 5 (a), the temperature of point 1-24 (1# hole buried depth 24 m, the same below) continued to decline during the unit's running period, which accumulated at 5.2°C in 3 years. However, the temperature remained unchanged when the unit stopped running. Except for point 1-24, the temperature changes of all the other monitoring points has linked with the unit running condition. The temperature kept declining when the unit was running, whereas the temperature started to increase when the unit

stopped running. The temperature of each point reached the maximum in October (before unit running). In 2009, the highest degree of temperature increase was monitored in point 1-5, increasing gradually from 18.9 to 21.3°C with a total increase of 2.4°C. The lowest degree of temperature increase was in point 1-15, increasing gradually from 20.6 to 20.4°C and then up to 20.6°C, with an accumulated increase of 0°C. In 2010, the highest degree of temperature increase was monitored in point 1-5, increasing from 17 to 18.7°C with a total increase of 1.7°C. The lowest degree of temperature increase was in point 1-10, increasing from 17.6 to 17.5°C and then up to 17.6°C with a total increase of 0°C. In 2011, the highest degree of temperature increase was monitored in point 1-5, increasing from 15.1 to 18°C with a total increase of 2.9°C. The lowest degree of temperature increase was in point 1-10, increasing from 15.5 down to 14.9°C and then up to 15.2°C with a total increase of -0.3°C. The temperature of all monitoring points decreased every year, and failed to return to the initial temperature. The temperature of some points dropped first and then rose while the unit stopped running, but both the decrease and increase of temperature was relatively small within no more than 1°C. The temperature change of each point has a similar tendency that the degree of temperature change decreased as the depth of monitoring point increased. As Figure 4 (b) and (c) show, the temperature change of each monitoring points of 2# hole and 3# hole was similar to that of the corresponding points of 1# hole. However, as there were fewer points in 3# hole and because of the data loss in 2011, this tendency of temperature change is not that obvious.

As Figure 6 (a) shows, the difference between the highest and initial temperature of each monitoring points in 1# hole during the unit's stop running period is as follows: In 2009, the maximum detectable temperature change was 3.1°C with points 1-7.5 and 1-10; In 2010, the maximum detectable temperature change was 5.6°C with point 1-7.5. In 2011, the maximum detectable temperature change was 8.2°C with point 1-15. The figure also shows that the difference between the highest and initial temperatures of each monitoring point in 1# hole during the unit's stop running period was increasing every year. The difference between the highest and initial temperatures of each monitoring points in 2# hole and 3# is shown in Table 4. As Figure 5 (b) and (c) show, the highest difference between the highest and initial temperatures of each monitoring points in 2# hole and 3# hole during the unit's stop running period was also increasing every year. Figure 6 (c) shows that the temperature change of both points 3-5 and 3-15 in 3# hole was higher

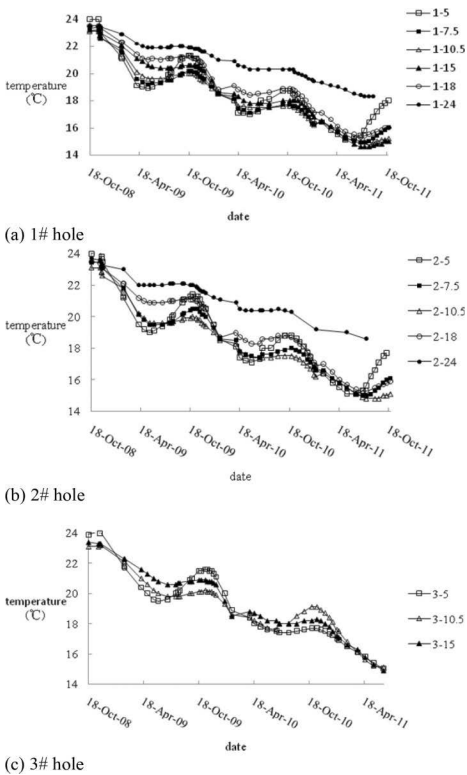

Figure 5. Temperature variation with time in different strata at each hole.

(a) 1# hole

(b) 2# hole

(c) 3# hole

Figure 6. Variation of maximum temperature and initial.

Table 4. Shows that 2# and 3# holes have the highest difference between the temperature in the unit's stop running period and the initial temperature.

	2009	2010	2011
2# hole the most difference point and change value	1-10, 3.1°C	1-10, 5.6°C	1-10, 8°C
3# hole the most difference point and change value	1-15, 2.5°C	1-5, 6.2°C	

than that in point 3-10 in 2010. Nevertheless, because of inadequate monitoring points in 3# hole, the finding is not conclusive and requires a further investigation.

5.3 Soil temperature change at monitoring points of same depth in different holes

In order to understand the geotechnical lateral heat transfer, we compared the soil temperature

(a) 5m at each hole

(b) 7.5m at each hole

(c) 10m at each hole

(d) 15m at each hole

Figure 7. (Continued)

change of monitoring points at the same depth as time changes. The results are shown in Figure 7.

(e) 18m at each hole

(f) 24m at each hole

Figure 7. Temperature variation with time in the same depth of different hole.

As Figure 7 (a) shows, the temperature of monitoring point at a depth of 24 m in each hole dropped when the unit was running, but the temperature did not recover when the unit stopped running. As Figure 6 (a)–(f) show, the temperature change of monitoring points at the same depth in each hole showed a similar tendency and change values. The temperature change of monitoring points has correlation with the unit's operation condition. The temperature of each monitoring point was dropping when the unit was running in winter, whereas the temperature was rising when the unit stopped running in summer. Additionally, the temperature change of each monitoring point was decreasing in degree with the increase of depth. During the unit's running period for each year, the closer it is to the heat pump, the earlier the minimum temperature will emerge. The minimum temperature first appeared in 1# hole, and then in 2# hole and finally in 3# hole. The deeper the monitoring point, the later the minimum temperature will emerge. For example, the minimum temperature at 5 m deep point generally appeared in May, but the temperature at 10 m deep point and 15 m deep point

continued to drop until the minimum temperature appeared in July. The time span for temperature dropping to the minimum was longer.

Cause analysis: Figure 1 shows that the soil is clay at 5 m deep, silty clay at 7.5 m deep, silt at 10 m deep, sand at 15 m deep, round stone at 18 m deep, and mudstone at 24 m deep. As Table 1 shows, the specific heat capacity of the soil increases with depth, for example, the specific heat capacity of clay is $2.716 \text{ kJ}/(\text{m}^3 \cdot \text{K})$ at 5 m deep and $3.625 \text{ kJ}/(\text{m}^3 \cdot \text{K})$ of mudstone at 24 m deep. This shows that the temperature change needs to absorb or release more heat with the increase of soil depth, thus the temperature change of soil fluctuated less with the increase of soil depth. On the contrary, with the continuous effect of the higher temperature of outside air, the shallow soil will exchange energy with the outside air and lead to an increase of soil temperature, which may explain the larger temperature fluctuation of shallow soil when the unit stopped running.

6 CONCLUSION

Through the establishment of in situ observation station, we have obtained long-term observation data. By analyzing the soil temperature variation surrounding the engineering well, we concluded that:

1. Soil layer initial temperature distribution: the temperature of soil layer at the depth range of 5–10 m decreased with the increase of depth; however, at the range of 10–24 m the temperature increased with the increase of depth. The average temperature of the minimum temperature point (10 m deep) was 23.1°C .
2. The temperature of the deepest monitoring point decreased to some extent when the unit was running, but it did not recover when the unit stopped running. The temperature changes of other monitoring points have correlation with the operation of the unit. The temperature of monitoring points was dropping when the unit is in operation, whereas it began to increase when the unit is off operation but did not recover to the initial temperature. The 3# hole, 2 m horizontal distance from the engineering well, was the furthest one from the well, but showed temperature variation when the unit was on and off operation. This result suggested that the engineering well's thermal radius of influence is more than 2 m.
3. The variation in temperature of each monitoring point in the same monitoring hole was similar, so was the variation of temperature of each monitoring hole at the same depth. The degree of temperature change decreased with the

increase of the depth of monitoring points. The main reason for this tendency is that the shallow soil layer was influenced by the temperature of the outside world and that the heat capacity of the soil increased with the increase of depth. The difference between the highest and initial soil temperatures when the unit stopped running increased every year, which suggests the cumulative effect of soil temperature.

Nitrogen removal performance of ANAMMOX-PVA granules immobilized by different preparation methods

Y.M. Han

College of Mechanical Engineering, Dalian University, Dalian, China

R&D Institute of Fluid and Powder Engineering, Dalian University of Technology, Dalian, China

ABSTRACT: PVA (Polyvinyl Alcohol) was used to encapsulate ANAMMOX (ammonia oxidation bacteria) in order to decrease microbial loss in ANAMMOX and its related process for wastewater treatment. Different types of granules with ANAMMOX sludge immobilized in PVA gel of different mass concentrations 6%, 10%, 15%, and 20%, were prepared by cross-linking in calcium chloride solution and deep-freezing method with 10% PVA solution. The results of nitrogen removal experiments showed that 10% was the best concentration for ANAMMOX sludge to be immobilized in PVA gel when better nitrogen removal performance and longer life could be achieved; the granules prepared by chemical cross-linking method had better performance than those prepared by freezing cross-linking method. The granules prepared using the former method removed nitrite in a shorter time period (after 24 h), whereas those prepared using the latter method reacted in 7 days.

1 INTRODUCTION

PVA is a type of macromolecule organic used widely in pharmaceuticals industry and biological field for its nontoxic and excellent biocompatibility organic compounds. S. Okabe (2011) indicated that ANAMMOX processes were promising for nitrogen removal and recognized them as cost-effective with low energy and no extra organic carbon. Although there are several running wastewater treatment plants via ANAMMOX and its related process in Europe, the practical engineering applications of the ANAMMOX process are limited and still in laboratory process because of the low growth rate of ANAMMOX bacteria in many other countries. Because of this limitation, one of the main challenges in implementing the ANAMMOX process is to ensure bacterial cells' retention inside the reactors. In practical engineering applications of ANAMMOX process, microbial loss is always a problem due to aeration and stirring. For this reason, immobilization of microbial cells has received increasing interest in wastewater treatment to minimize the risk of biomass washout from the reactors and provide stabilized treatment reports. Most immobilization methods were carried out by attachment on the surface of carriers forming biofilm or forming granular biomass directly. Entrapment of the microbial biomass into gel pellets has been reported in recent years.

The use of synthetic polymers such as urethane, Polyethylene Glycol (PEG), and Polyvinyl Alcohol

(PVA) for the entrapment of microorganisms was reported as advantageous in the field of wastewater treatment. There were two techniques reported to immobilize microorganisms using PVA; the first step in both cases was to combine ANAMMOX sludge with a PVA solution, and then the mixture was polymerized. In order to solidify the mixed-solution PVA and ANAMMOX sludge, some chemical solution was used in one technique and freezing method was used in the other. In the chemical cross-linking method, the mixed gel solution was shaped into spherical gel beads first and then dropped into a saline solution by G.L. Zhu (2009). Physical cross-linking through the freezing method was the other preparation technique reported by T.H. Hsia (2008), who immobilized ANAMMOX in polymer gel by the physical cross-linking method. The lowest temperature reported in freezing cross-linking was -20°C from A. Magri (2012), who successfully immobilized swine wastewater nitrifying sludge in PVA by freezing at -8°C .

This study was carried out in order to find out the best PVA concentration for better nitrogen removal and mechanical strength through the chemical cross-linking method and then contact the effectiveness of entrapping and activity recovering period for ANAMMOX cross-linking through chemical method and freezing method in this concentration. Our experiments included preparation of PVA gel granules by cross-linking in calcium chloride solution and nitrogen removal process; preparation of

PVA gel granules through the aforementioned two methods and nitrogen removal process.

2 MATERIAL AND METHOD

2.1 Immobilization procedure

2.1.1 Seed sludge and pretreatment

ANAMMOX seed sludge was derived from a running ANAMMOX biofilm reactor, which was stably operated for more than 400 days with Nitrogen Loading Rate (NLR) of $2.0 \text{ kg-N}\cdot\text{m}^{-3}\cdot\text{d}^{-1}$ and Nitrogen Removal Rate (NRR) of more than $1.7 \text{ kg-N}\cdot\text{m}^{-3}\cdot\text{d}^{-1}$. The ANAMMOX seed sludge solution kept static for 30 min to cause the sludge deposit in the first; then, the liquid supernatant was removed and the remaining sludge was washed thrice with PBS (pH 7.2); the sludge was put into the centrifugal machine and centrifuged for 10 min at 1000 rpm, and the supernatant liquid was removed.

2.1.2 Preparation of PVA solution

The PVA polymer used in this study was in powder form (average molecular weight was about 10000 and purity 94%). The PVA powder was sprinkled on warm water and mixed by hands to form a polymer suspension. The suspension was then heat preserved to 55°C and stirred on a magnetic stirrer for 2 h to obtain a complete PVA dissolution. After cooling to room temperature, the PVA solution is ready. The mass concentration of PVA solution was set to 6%, 10%, 15%, and 20% to investigate the concentration effect on the nitrogen removal capability of the gel granules.

2.1.3 Preparation of gel granules

① Cross-linking in calcium chloride solution

PVA solutions (30 mL) prepared in Section 2.1.2 at different concentrations were mixed with the same volume of sludge. The solution was pumped by a peristaltic pump with a soft pipe of inner diameter 4.8 mm installed and dropped into the calcium chloride solution with a mass concentration of 4% and was kept at 4°C before immobilization. The ANAMMOX-PVA solution drops solidified to form granules with diameter between 4 and 6 mm. Then, the floating granules and calcium chloride solution were kept at 4°C together. After 24 h, the granules in calcium chloride solution were put out.

② Cross-linking in freezing

The same volume and scale solution with ① were mixed and packed into a sheet; then, the ANAMMOX-PVA solution was kept under low-temperature condition (-10°C). After 2 h, the whole gel pieces were put out and cut to squares with sides 4 cm.

Table 1. Components of the influent.

Composition	$(\text{NH}_4)_2\text{SO}_4$	NaNO_2	KHCO_3	KH_2PO_4
Concentration/ $\text{mg}\cdot\text{L}^{-1}$	100-300	187.5	162	

2.2 Composition of synthetic wastewater and analytical procedure

The concentrations of $\text{NH}_4^+\text{-N}$ and $\text{NO}_2^-\text{-N}$ in the influent and effluent were analyzed to determine the NRR of the total inorganic nitrogen. The nitrogen removal rate was calculated by the difference of the total nitrogen concentrations between the influent and effluent. The concentrations of $\text{NH}_4^+\text{-N}$ and $\text{NO}_2^-\text{-N}$ were measured by ordinary method. The dissolved oxygen in the reactor was measured using a DO meter (JB-2, linesa, China), and the pH of the effluent was measured using a pH meter (METTLER TOLEDO FE20, USA).

2.3 Nitrite removal performance

The gel granules were put into conical flasks with an effective volume of 250 mL after washing thrice with PBS. Synthetic wastewater (250 mL) with components in Table 1 was then fed and the neck was sealed. The flasks were placed into the orbital shaker incubator and cultivated under the conditions of 10 rpm and 28°C . The cultivation period was 25 days, and the concentrations of $\text{NH}_4^+\text{-N}$ and $\text{NO}_2^-\text{-N}$ were detected once every 2 days.

3 RESULTS AND DISCUSSION

3.1 PVA concentration effect

The biological sludge immobilization would affect the growth of bacteria, so the nitrogen removal performance must be tested. In addition, the mechanical property of the gel granules was another important influence factor for the wastewater treatment because the purpose of biological sludge immobilization was to decrease the loss of biomass in the reaction process. The period of wastewater treatment was always several months or years, so the life span of the gel granules would play an important role on the test performance. The concentration of PVA solution was the key influence factor to the degradation period and mechanical property of the gel granules.

The nitrogen removal experiments were carried out for almost 20 days, and $\text{NH}_4^+\text{-N}$ and $\text{NO}_2^-\text{-N}$ were detected once every 2 days. The results are shown in Figs. 1 and 2.

Obvious nitrogen removal could be achieved in all the samples, and the nitrogen removal efficiency was

Figure 1. Ammonia and nitrite concentration changing profile.

Figure 2. ARR and NIRR changing profile.

almost in inverse proportion with the PVA concentration. The highest Ammonia Removal Rate (ARR) and Nitrite Removal Rate (NIRR) about 97% was achieved in the PVA-ANAMMOX sample at 6% concentration on the 12th and 20th days, whereas the ARR and NIRR of all the other samples were lower. It was also indicated that the lowest ARR and NIRR about 50% appeared in the sample of 15% PVA concentration but not in the sample with 20% concentration. That was because the PVA-ANAMMOX solution with 20% PVA was so sticky that it was difficult to prepare the granules, and many sheets, sticks, and other out-of-shape granules were formed. The abnormal granules had worse mechanical property and shorter degradation period, so there were no obvious granules existing after 7 days and the flocculent remainder increased ARR and NIRR up to 80%.

Sample with 15% PVA had the lowest nitrogen removal efficiency (only 50% after 48 h) for the gel with a higher PVA concentration, which blocked the mass transfer although the granules had the better shape even on the 20th day.

3.2 Contrast nitrogen removal experiments by two different preparation methods

The PVA-ANAMMOX gel granules were prepared by the two methods described in Section 2.1.3 with a PVA concentration of 10%. The gel granules were put into conical flasks after cross-linking and then the flasks were placed into the orbital shaker

Figure 3. Nitrite removal performance in 72 h. ① Chemical cross-linking ② Freezing cross-linking.

incubator and cultivated under the conditions of 10 rpm and 28°C. The concentration of ammonia and nitrite in the influent was 100 mg/L. The cultivation period was 72 h, and the concentrations of NH_4^+-N and NO_2^--N were detected once every 12 h. The experimental results are shown in Fig. 3. The profiles indicated that there was obvious nitrogen removal performance in the flask containing sample prepared through method ① after 24 h, and most of the gel granules in sample ① came up to the water surface and there are also plenty of white lucid bubbles on the water surface instead of sinking at the bottom at the time of the reaction beginning. The concentrations of ammonia and nitrite were below 40 mg/L after 48 h, and almost all of the gel granules came up to the water surface. The gel granules came up because there was some

Figure 4. SEM images of the granule's section. a) $\times 200$; b) $\times 5000$; c) $\times 10000$.

nitrogen inside the gel granules, and the average density of the granules was reduced. The nitrogen removal rate increased continually after then on.

The sample prepared using method ② had distinct performance from sample ①. No obvious nitrogen removal could be achieved in 72 h, and the gel pieces still sank at the bottom of the flask. ARR and NIRr increased slowly from the 4th day and reached to 70% after 7 days.

It was indicated from the contrastive analysis that the gel granules by method ① were kept at 4°C for only 24 h, so the activity of ANAMMOX was restrained in a short time and they could be recovered in 24 h. The gel pieces by method ② were kept under a low-temperature condition at -10°C for 2 h so the ANAMMOX bacteria came into a short dormancy and the recovery period would be much longer than that of method ①. The preparation method: cross-linking in calcium chloride solution was superior, and cross-linking in freezing of most wastewater treatment process for quick setup operation was necessary.

3.3 SEM images

SEM imaging was used to observe the structure and characterize the morphology of the gel granules after pretreatment of the samples on the 10% PVA concentration by method ①. The gel samples were frozen for 1 h initially after washing thrice with distilled water and then vacuum-dried (the pressure less than 30 Pa) for 3 h in a freeze-dryer. Then, they were put under SEM to observe after being sliced up and metal-sprayed. Figure 4 shows the SEM images. The cellular structure is shown in Fig. 4 a), acquired at $\times 5000$ magnification, and all the holes inside of the granule formed a channel through which nutrition could be shipped. ANAMMOX cenobium was immobilized on the thick wall of gel from Fig. 4 b) acquired at $\times 5000$ magnification, and the structure was proved to be useful for ANAMMOX growth. Images of Fig. 4 c) were acquired at $\times 10000$ magnification, which clearly showed that there were plenty of spherical bacteria.

4 CONCLUSION

There was obvious nitrogen removal in all the immobilized gel samples prepared by PVA and hence the immobilization method was successful and could be used to decrease the biomass loss in wastewater treatment. The preparation method of gel granules had a great impact on nitrogen removal: the ANAMMOX-PVA gel granules prepared by chemical cross-linking recovered in 24 h and NRR reached 60% in 48 h, whereas those produced by physical cross-linking could not remove any nitrogen in 72 h, so the method of cross-linking in calcium chloride solution was suitable for reactor setup phase. The nitrogen removal capability of ANAMMOX-PVA gel granules was under influence and inversely proportional to PVA concentration (10%), which was higher than the other three.

Seismic response of a long-span cable-stayed bridge with slip-shear metal damper

ABSTRACT: The relative displacement between floors is utilized by a Shear Metallic Damper (*abbr. SMD*) to dissipate energy during earthquake and has been used widely in buildings to protect the main structure from damage under strong seismic motions. *SMD* can be driven by the relative displacements between girder and towers or piers to dissipate energy for long-span cable-stayed bridge with floating or half-floating structural style. Hazardous internal force may be induced by implementing an *SMD* between girder and tower or piers directly, as the normal displacement requirements for temperature or vehicles are needed for long-span cable-stayed bridge with floating or half-floating structural style, and it may damage the superstructure of the substructure of bridges. In this paper, a strategy is presented to eliminate the above hazardous internal force by implementing a limit groove above *SMD* with initial gaps in moving direction, named as Slip-shear Metal Damper (*abbr. SSMD*). The initial gaps can satisfy the daily displacement requirement, and the *SMD* can dissipate energy once the displacement between girder and tower or pier exceeds the initial gaps. In this study, the implementation of a hysteric model for *SSMD* is presented and the seismic reduction of *SSMD* for long-span cable-stayed bridge is investigated.

1 INTRODUCTION

Shear Metallic Damper (*abbr. SMD*) has been widely used in building structures to reduce the seismic response due to the excellent performance of dissipating energy during earthquake. The yield displacement of *SMD* is very small as the allowed displacements between adjacent floors of buildings are small, and the stiffness of *SMD* is relative large in the deformed plane. The initial stiffness can be strengthened by extending the steel plate of the damper in its own plane, the energy dissipating ability can be increased by changing the geometry of the steel plate of the damper, which was proposed by Li (2006), and quasi-static tests of five types of *SMD* were carried out. A novel steel shear panel damper called a buckling restrained shear panel damper (*abbr. BRSPD*) was proposed by Deng (2014, 2015), in which two restraining plates were used to limit the out-plane displacement of energy dissipation plate, quasi-static tests of five specimens were carried out to investigate the performance of the *BRSPDs*, and the dampers were used to reduce the seismic response of the bridge. However, the expansion caused by temperature was not considered. The hysteric model for *SMD* and Buckling-Restrained Brace (*abbr. BRB*) can be sim-

plified by bilinear model (Lanning, 2016). Hazard internal force may be caused by installing *SMDs* or *BRBs* between girder and piers or tower directly for bridge, in which expansion movements are required by bridges usually. The dynamic characteristic of the bridge may change dramatically by installing *SMDs* or *BRBs* directly, which may influence the seismic response of bridge. *BRB* were used in long-span bridges for seismic mitigation by Lanning (2016), and Vincent Thomas Bridge was taken as a case study. Several *BRBs* were installed between girder and towers directly, which causes the first three mode frequency to increase about 22%, 30%, and 4%, respectively. The effects of bilinear spring on the seismic response of multispan cable-stayed bridges were determined by Okamoto (2011), and bilinear springs were very effective in reducing the dynamic displacements and bending moments of the towers. However, the effects of the bi-linear springs on the expansion caused by temperature were not considered. The effect of E-shape metal damper on seismic reduction of longitudinal displacement of Bosphorus bridge was carried out by Apaydin (2010), and it was pointed out that the application of damper affects the distribution of internal loads because the E-shape damper connected deck and tower directly.

Figure 1. Schematic of the simplified girder model.

SMD can be driven by relative displacements between girder and towers or piers for long-span cable-stayed bridge with floating or half-floating supporting systems. There is a significant difference between the building structures and bridges, and expansion movements are required by bridges between girder and towers or piers, which may be caused by temperature or moving vehicles. For example, temperatures may cause a significant internal force in the girder. A simply supported steel bridge is taken as an example to demonstrate the effect of temperature on the expansion, and the diagram is shown in Fig. 1. The length of the bridge (L) is 500 m, the section area (A) is 0.9 m^2 , and the temperature change (ΔT) is 20°C ; the gravity of the bridge is ignored. The elastic module (E) and temperature coefficient (α) of steel are $2.06 \times 10^8 \text{ kPa}$ and 1.2×10^{-5} respectively. *SMD* was installed directly between girder and supports, with the lateral stiffness of *SMD* $k_{\text{horizontal}}$ of $2e5 \text{ kN/m}$ and the free expansion of each end of 0.06 m (calculated by $\alpha\Delta TL/2$), and the axial force is 7795.4 kN (calculated by $F = 0.5\alpha\Delta T/[1/EA+1/(Lk_{\text{horizontal}})]$). It is obvious that the internal force caused by temperature is very high.

Improvements are proposed to ordinary *SMD* by adding a U-shaped groove on the top of *SMD*, with an initial gap y_{slip} , named as *SSMD*, and the hazard internal force (such as temperature internal force) can be avoided by the initial gaps. *SSMD* dissipates energy when the displacements between tower and girder or pier and girder exceed y_{slip} . In this paper, slip model for *SSMD* is present in the finite-element model, and the influence of *SSMD* on the seismic response of long-span cable-stayed double-deck bridge is investigated.

2 HYSTERIC MODEL OF SSMD

The main parameters of the bilinear model (Fig. 2(a)) of *SMD* are initial stiffness (k_1), yield displacement (y_d), and enhanced stiffness (k_2). The U-shaped groove above *SMD* can be modeled as a nonlinear elastic spring (Fig. 2(b)) with slip gap y_{slip} and big stiffness k_∞ . The hysteric model of *SSMD* can be simulated by a combination of bilinear spring and the nonlinear elastic spring (Fig. 2 (c)), and it will be demonstrated by a single degree of freedom with *SSMD*. The configuration of *Sdof* is shown in Fig. 3(a), and the ground motion (u_g)

$k_\infty/\text{kN/m}$	3×10^8
m/t	100

Figure 4. Hysteric curves for *SSMD* (a) and the sliding-stop slot (b).

is depicted in Fig. 3(b). The parameters of *SSMD* are listed in Table 1. Automatic dynamic increment time step is adopted because the stiffness suddenly changes at the maximum slip displacement (y_{slip}), and the minimum step allowed in the analysis is set to 1×10^{-5} s.

Hysteretic curves for *SSMD* and the groove are depicted in Fig. 4, and the developments of *SSMD* are the same as the one shown in Fig. 1(c). From the sudden changes happened to the nonlinear elastic spring at the maximum displacement of y_{slip} , it is clear that the combination of bilinear and nonlinear elastic spring can be used to simulate the behavior of *SSMD* properly.

3 FE MODEL

The FE model for Shanghai Minpu Bridge was established with beam and shell elements (Fig. 5 Jiao 2013). The bridge has a span of 1212 m and the arrangement is $4 \times 63 \text{ m} + 708 \text{ m} + 4 \times 63 \text{ m}$. There are eight lanes on the top deck and six on the bottom deck. The girder of mid-span is a combination of orthotropic steel truss and bridge decks. The side-span is a combination of concrete decks and steel truss web members. The web members include oblique, side-oblique, and vertical ones. The H-shaped reinforced concrete tower has two transverse beams, and the height of the tower is 210 m. Cables are simulated with a single truss element with no compression. Initial stresses were set in cables before analysis. The frequencies of the first lateral, vertical, and torsional vibration modes are 0.08275, 0.2575, and 0.28547 Hz, respectively.

Four *SSMDs* are arranged between towers and girder, and the parameters for *SSMDs* are shown

in Table 2. Two groups of slip gap are considered during the nonlinear dynamic time history analysis. The ground motion or *Tianjin* is applied at the bottom of the tower and piers, and the magnitude of ground motion is adjusted to 0.3 g.

Temperature effects on the static displacements between girder and pier (PW4 and PE4) at the end of the girder are shown in Table 3, in which negative (-30°C) and positive ($+30^\circ\text{C}$) values indicate that the temperature of structure rises and falls 30°C from zero. Fig. 6 illustrates the effect on the axial force of girder (identified as SF1), when *SMDs* are installed directly between towers and girder. It can be found that the variety of axial force of girder are dramatically up to 25%, which may induce a harmful influence on the bridge and can be avoided by *SSMD* with initial gaps.

4 SEISMIC RESPONSES ANALYSIS

Seismic responses of the bridge with *SSMDs* are shown in Figs. 7 and 8. The hysteretic curves of *SSMDs* are divided into two parts by the distance of $2y_{slip}$ (Fig. 7(a)). It is indicated that the *SSMD* may dissipate less energy than *SMD* during the ground motion because *SMDs* dissipate energy all the time while slip motions happen to *SSMDs* without dissipating energy. The time history of longitudinal displacements between girder and

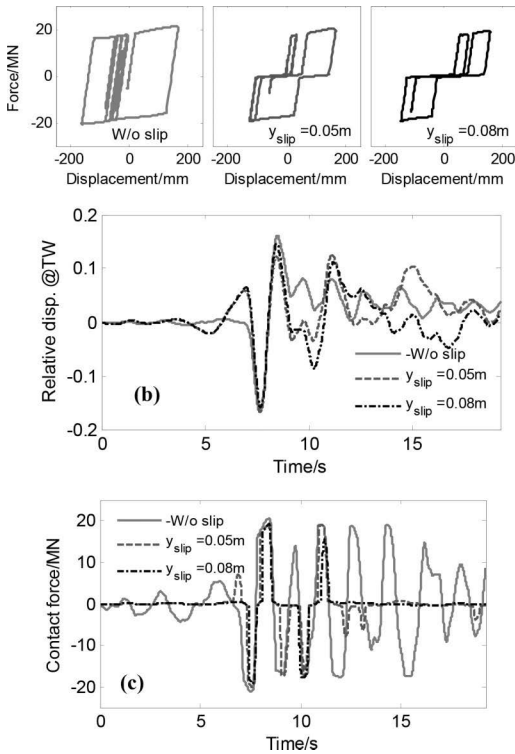

Figure 7. Hysteric curves of *SSMD* (a), history of relative displacement between girder and tower (b), and contact force between groove and *SMD* (c).

tower is totally different from that without slip gaps (Fig. 7(b)), and the connection strength between towers and girder by *SSMDs* is weaker than that by *SMDs*. The time history of contact forces between groove and *SMDs* is demonstrated in Fig. 7(c). The contact forces exist all the time when *SMDs* are installed directly between girder and towers during the ground motion and change with the relative displacement between girder and towers. However, zero contact force appears for *SSMD*, when *SMDs* are separated from the above grooves.

Envelop of shear forces (identified as SF2) and bending moments (identified as SM1) of tower column are shown in Fig. 8(a). Shear and moment below the transverse beam of tower are reduced about 20% by *SSMDs* compared to that of *SMDs*. It is due to the fact that as some of inertia force of girder is not translated to the transverse beam of tower by *SSMDs*, it has little influence on the shear and moment for column above transverse beam. Envelopes for axial forces of oblique (identified as *XYXFG*) and vertical (identified as *XYSG*) web members are depicted in Fig. 8(b), and *SSMDs* can also reduce the maximum axial forces for some

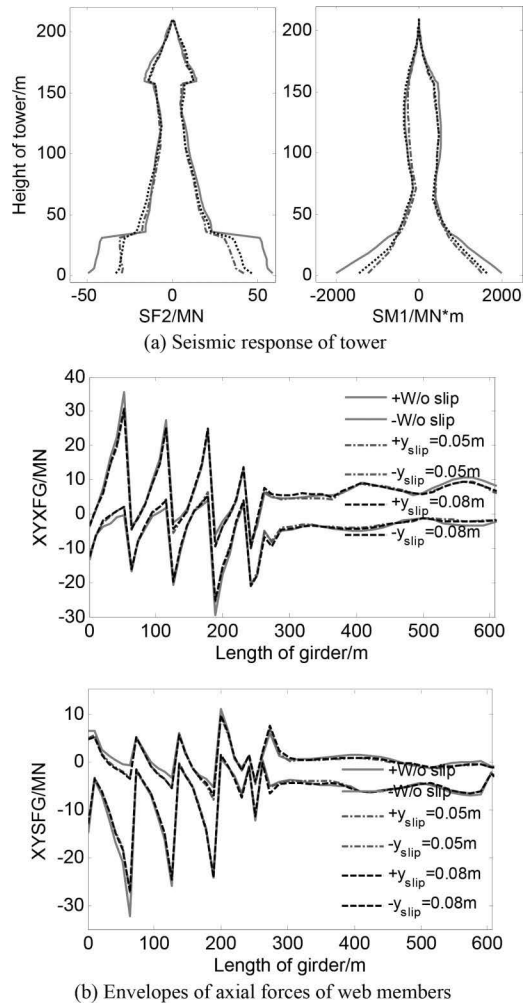

Figure 8. Seismic response of tower (a) and the envelopes of axial forces of web members (b).

web members especially near piers, which may be up to 20%.

5 CONCLUSIONS

The disadvantage of installing *SMDs* between girder and piers or towers directly may arise due to internal restraint, and a strategy is presented in this paper to eliminate the above hazardous internal force by implementing a limit groove with initial gaps between *SMD* and the groove, namely *SSMD*. The initial gaps can satisfy the daily displacement requirement, and the *SMD* can dissipate energy once the displacements between girder and tower

or pier exceed the initial gaps. The implementation of hysteric model for *SSMD* is present, and a case study is performed in detail. The results show that:

1. The strategy is feasible and the implementation of the hysteric model is reasonable.
2. *SSMD* can overcome hazardous internal forces caused by increase in the decrease of temperature or motions of vehicles.
3. Compared with ordinary *SMDs*, *SSMDs* can reduce the connection stiffness between girder and piers or towers, and the displacement response may increase slightly and internal forces reduce significantly when proper parameters of *SSMDs* are chosen.
4. It is recommended that the ordinary *SMD* should not be installed directly on bridge to dissipate energy, and an *SSMD* with proper parameters may be a good alternative option.

ity chamber for curing for 7 days when CFRP sheets were pasted onto the surface of steel plates. The test control parameters are shown in Table 1.

2.3 Arrangement of measuring points and testing process

For each specimen, some strain gauges were installed on the surface of testing part in order to measure the strain distribution on the surface of CFRP sheets. One strain gauge was installed at a distance of 5 mm from the middle span while the rest of them were installed with a gap of 15 mm from each other along the longitudinal axis. Particularly, strain gauges were installed in a double row on S120-55-1 for discussing the regularities of transverse strain distribution as shown in Fig. 2. The static strain recorder (DH3816) was used to collect the static strain values.

All specimens were tested by a universal testing machine (CMT5105) with a maximum capacity of 100 kN, as shown in Fig. 3. The displacement control mode was adopted with a loading rate of 0.2 mm/min in this test. The test was stopped

Table 1. Specimen number and control parameters.

S200-30-1	200	30	1
S200-55-1	200	55	1
S120-55-1	120	55	1

Figure 2. Demonstration of mounted strain gauges on S120-55-1.

Figure 3. Test setup.

when the CFRP sheets stripped from the steel plate completely.

3 TEST RESULTS AND DISCUSSIONS

3.1 Fatigue test phenomenon

In the initial stage, there was no obvious change in the appearance of the specimens, which were in elastic phase. After a certain period of loading, a slight fabric tearing sound could be heard, indicating CFRP strips started peeling from the middle span. Peeling of CFRP sheets propagated steadily with the increment of load, while the peeling developed rapidly with scratching noise after load reached 80% of the ultimate load. CFRP sheets stripped from the steel plate completely with a loud noise while the specimen reached the ultimate load, and then the test stopped.

3.2 Failure mode

Recent studies (Zhao & Zhang 2007) have shown that the common failure modes in a CFRP bonded steel system subjected to a tensile force include: (a) steel and adhesive interface failure; (b) cohesive failure; and (c) mixed failure including the first two modes. In this paper, only mode (a) and mode (c) appeared in the tests, which are shown in Fig. 4.

a. Mixed failure (S200-40-1)

b. Steel and adhesive interface failure (S200-40-3)

Figure 4. Two failure modes.

Table 2. Test results.

Specimen no.	Bond strength/kN	Major failure mode
S200-40-1	14.72	Mode c
S200-40-2	22.81	Mode a
S200-40-3	23.08	Mode a
S200-30-1	11.01	Mode a
S200-55-1	28.22	Mode c
S120-55-1	28.01	Mode c

As shown in Table 2, the bond width and layer number have a directly influence on the failure mode of specimens. Mixed failure occurred in S200-40-1, whereas S200-40-2 and S200-40-3 are subjected to steel and adhesive interface failure. Meanwhile, the former shows a better ductility than the latter through analysis, as failure of the latter are controlled by the performance of steel-adhesive interface, which is a weaker region. Also, the failure modes of the specimens turn from mode (a) to mode (c) with the increase of bond width. This is because the bond area is enlarged with the increase of bond width, which can reduce bond stress and improve stress performance of the interface.

3.3 Bond strength

In Table 2, the bond strength of S200-40-2 increased as much as 55% compared with S200-40-1, whereas the bond strength of S200-40-3 has no significant improvement as S200-40-2. The results indicate that the bond strength is largely influenced by the layers of CFRP sheets within certain limits. And also, the bond strength of specimens rapidly increased with the increment of bond width, but the relationship was not linear. A conclusion that the bond length that exceeds the effective bond length (about 45 mm) has hardly caused any inflection to the bond strength can be reached through the result of S120-55-1 compared with others.

3.4 Strain distribution of CFRP

The strains of S120-55-1 that have almost identical value along the transverse section are shown in Table 3, which indicates that the CFRP sheets are stressed uniformly along transverse section when the specimens are subject to axial tension.

Typical strain distribution of CFRP along the bond length under the static loading is shown in Fig. 5. It can be seen that the changing processes of strains include two phases: the strain distribution locate mainly in the small area of 25 mm nearby the middle span before the peeling and gradually decrease to zero with an increment of distance from the middle span. The strains increase with

the increment of load, and the shear stress transfer of the interface is only completed by the friction after peeling. At the moment, from Fig. 5, there is a long straight segment, which coincidentally equals the peeling length for almost all curves. The area of delamination enlarges with the increment of load, and develops gradually to the load-end until final failure occurs.

3.5 Bond-slip relationship

The bond-slip curve reflects the constitutive relation of the local interfacial bond performance. The average shear stress between the two strain gauges mounted on the longitudinal axis of the CFRP sheet were calculated using the following relationship:

$$\tau_i = \frac{(\varepsilon_{i+1} - \varepsilon_i) \times t_i \times E_i}{\Delta l_i} \quad (1)$$

where Δl_i is the distance between strain gauges i and $i+1$; ε_i is the strain in the CFRP sheet at strain gauges i ; and E_i and t_i are the elastic modulus and thickness of the CFRP sheet, respectively. The local slip can be derived from equation (2):

$$s_i = \int \varepsilon(x) dx \quad (2)$$

The relationship between local slip of CFRP-steel and shear stress of CFRP at each measuring

Figure 5. Strain distribution of S200-40-2.

Load	Strain along longitudinal axis			Strain of the row sideways			Ratio		
	A1	A3	A6	A9	A11	A13	A9/A1	A11/A3	A13/A6
5.05 kN	292	70	71	309	73	72	1.06	1.04	1.01
6.99 kN	439	104	104	470	105	104	1.07	1.01	1.00
11.29 kN	887	182	180	963	181	175	1.09	0.99	0.97
14.83 kN	1462	267	256	1573	262	247	1.07	0.98	0.96
17.18 kN	1877	322	299	1988	314	290	1.06	0.98	0.97
20.79 kN	2753	434	392	2910	419	373	1.06	0.97	0.95

Figure 6. Bond-slip relationship of S200-40-3.

Figure 7. Approximate mode of bond-slip relation.

point can be calculated by Eqns. (1) and (2). Fig. 6 shows the typical bond-slip relationship curve, in which the horizontal and vertical axes represent the calculated slip and local bond stress, respectively, and the curve generally shows a bilinear shape. Also, previous study by Xia & Teng (2005) indicated that a bilinear model, which is similar to that for concrete, could be adopted for the CFRP-bonded steel system. Combining with the results of experiment and existing studies, the curve in Fig. 7 can approximately represent the interfacial bond-slip relationship of CFRP-steel.

It can be seen that the curve consists of an ascending elastic stage and a descending softening stage. In the elastic stage, the shear stress increases linearly with the increment of slip, while the specimen will enter the softening stage after the shear stress reaches maximum shear stress (τ_0). Then, the shear stress decreases with the increment of slip until τ_r , which is caused by the interfacial friction and test error. It should be noted that τ_r equals zero in an ideal conditions.

4 CONCLUSIONS

In this paper, experimental studies considering different bond width and layer number were

conducted under static load based on six double-shear specimens. The following conclusions can be drawn:

1. Although the bond strength can be significantly improved by increasing the layers of CFRP sheets, the failure mode changes from mixed failure to steel and adhesive interface failure, which is a relatively brittle failure mode. However, the bond strength of the specimen rapidly increase with the increment of bond width, and the stress performance of the interface can be well improved. The bond length, which exceeds the effective bond length, can hardly cause any infection to the bond strength.
2. The CFRP sheets are stressed uniformly along the transverse section when the specimens are subject to axial tension. The strains and the area of delamination, which develops gradually to the load-end, increase with the increment of load until final failure occurs.
3. The bond-slip relationship of CFRP-steel generally emerges as a bilinear shape, which is similar to that for concrete and consists of an ascending elastic stage and a descending softening stage.

Influence of thick and loose sediments on the vacuum load transfer

Jiaxing Weng

Geotechnical Engineering Institute of Southeast University, Nanjing, Jiangsu Province, P.R. China

ABSTRACT: Field experiments were carried out to determine the influence of thick and loose sediments on the vacuum load transfer in vacuum preloading. The results indicate that it is greatly affected by the loose sediment when vacuum load is transferred to Prefabricated Vertical Drain (PVD) through sand layer and not influenced when the transfer is through a pipe system because of its good airtightness. Thus, pipe system is more suitable as the horizontal transfer medium of vacuum load than sand layer in the case of overlying loose and thick soil layer. Besides, vacuum pressure in the PVD (VP_{PVD}) decays rapidly in the loose sediment layer, especially in the unsaturated zone, and the decay rate increases with the increase of VP_{PVD} in this layer. The settlement analysis validates the transfer rule of vacuum load indirectly. Soil compression occurs mainly in the loose sediment layer because most of vacuum energy is consumed in this layer.

1 INTRODUCTION

Vacuum consolidation was proposed in the early 1950 by Kjellmann (1952). The studies and promotions of vacuum-induced consolidation have been continuing to date (Holtz, 1975; Choa, 1989; Cognon et al., 1994; Bergado et al., 1998; Tang & Shang, 2000; Chai & Miura, 2000; Mohamedel-hassan & Shang, 2002; Indraratna et al., 2004, 2005; Chai et al., 2005, 2006, 2007, 2008; Yan & Chu, 2005; Walker & Indraratna, 2006, 2009; Rujikiatkamjorn & Indraratna, 2007; Rujikiatkamjorn et al., 2007, 2008; Saowapakpiboon et al., 2008a, b, 2009, 2010). Vacuum preloading technique is a soft ground improvement method that has been successfully applied to accelerate the rate of consolidation and to eliminate the instability problem. The engineering practice has proved that the vacuum preloading developed based on the soil consolidation theory is a relatively economic, convenient, and reliable method for soil improvement.

Generally speaking, vacuum preloading technique is most suitable to reinforce the reclaimed soft foundation and not applicable to the foundation with an overlying thick (not less than 3 m) and loose soil layer. It greatly limits the application of the vacuum preloading in engineering because thick and loose sediments in quaternary are widespread around the world (Guorui, 1991).

The transfer of vacuum load has a significant influence on the reinforcement effect of vacuum preloading technique. Thus it is necessary to determine the influence of thick and loose sediments on the vacuum load transfer in the vacuum preloading for the further improvement of the method.

2 FIELD EXPERIMENT

2.1 Experimental site

The field experiments were adopted here because it was difficult to simulate the thick and loose sediments in the laboratory. The experimental site was selected in the Chongwan zone of the west dyke of Grand Canal (pile No. 49+580-50+335) (Fig. 1) after extensive investigation. According to the engineering investigation data, the soil profile here mainly includes three layers. The upper layer is a loose sediment in quaternary with thickness of about 5 m. The second layer below is clayey sludge with the almost same thickness. And the lower layer is silty sandy loam. The geological conditions of the site meet the requirements of the experiment well.

Figure 1. Position of the experimental site.

The plasticity chart of soil samples is shown in Figure 2. In accordance with the Unified Soil Classification System (USCS), loose sediment is low plasticity clay (CL), clayey sludge is high plasticity clay (CH), and silty sandy loam is low plasticity silt (ML).

2.2 Experimental scheme

A sand layer is generally used as the horizontal transfer medium of vacuum load in the vacuum preloading method (Fig. 3). Vacuum load generated by vacuum pump is transferred into Prefabricated Vertical Drains (PVDs) through the sand layer. Then, vacuum load is transferred into surrounding soil layers through PVDs. Both of the transfer chains above may be affected by the overlying loose sediment, which has direct interfaces with the sand layer and PVDs.

Figure 2. Plasticity chart of soil samples.

Figure 3. Schematic diagram of vacuum load transfer of SVP.

In order to determine the influence of the overlying thick and loose sediments on each transfer chain of vacuum load in vacuum preloading, a newly developed type of horizontal transfer medium of vacuum load was introduced here (Saowapakpiboon et al., 2008; Saowapakpiboon et al., 2011; Liang et al., 2013; Long et al., 2015). In this method, airtight pipe system is adopted to replace the sand layer (Fig. 4). PVDs are connected to the vacuum pump through an airtight pipe system to form a whole by a prefabricated fitting cap for each individual PVD. Thus, vacuum load generated by vacuum pump can be transferred into the surrounding soil layers through PVDs directly, and the overlying thick and loose sediments can only affect the vacuum load transfer in the PVDs. For convenience, the vacuum preloading methods with sand layer and pipe system are, respectively, referred to simply as SVP and PVP below. Schematic diagrams of SVP and PVP are shown in Figures 3–4, respectively.

2.3 Implementation process

A plain layout of the trial site is presented in Figure 5. PVP was applied in zone I, and SVP was applied in zone II. Major implementation processes (Fig. 7) are summarized as follows.

- Leveling the trial site and removing the sharp objects.
- Installing PVDs on a square grid with a spacing 1.0 m into an average depth of 15.0 m (Fig. 8)
- SVP: Layering the sand layer with medium-coarse sand, with mud content not more than 5%. A sand layer of 20 cm thickness was laid firstly. Then, perforated pipes were placed on the top of the sand layer to collect the water, and

Figure 4. Schematic diagram of vacuum load transfer of PVP.

Figure 5. Plain layout of the trial site and monitoring instruments.

Figure 6. Profile diagram of monitoring instruments.

exposed parts of PVDs were put on the surface of the perforated pipes. Finally, laying of the sand layer was continued to 50 cm (Fig. 9).

- PVP: Assembling PVDs with fitting caps and reinforced pipes of 25 mm diameter. Then, connecting the branch pipes with the PVC main tubes to form a whole by fitting joints (Fig. 10).
- Installing monitoring instruments including vacuum gauges, surface settlement plates, and layered settlement apparatuses according to the plain layout and profile diagram of monitoring instruments (Figs. 5–6).

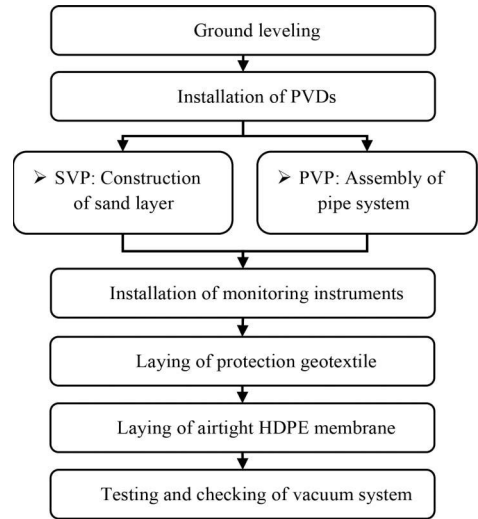

Figure 7. Implementation processes.

Figure 8. Installation of PVDs.

Figure 9. Construction of the sand layer.

- Laying down a layer of nonwoven geotextile with 350 g/m² to protect the High-Density Polyethylene (HDPE) membranes against punching from sharp materials (Fig. 11).
- Laying down three layers of the airtight HDPE membranes with 1.5 mm thickness on the top of protection geotextile (Fig. 12). Then, the edges

of membranes were embedded in the excavated trench with about 1.5 m depth and backfilling with in situ clay and bentonite slurry (Fig. 13).

- Starting vacuum pumping for testing and checking of airtightness (Fig. 14). Then, covering the membrane with water to prevent aging of the membrane.

3 RESULTS AND DISCUSSION

3.1 Vacuum pressure at vacuum pump

Each zone was controlled independently by one vacuum pump with a vacuum gauge. Vacuum pressure at Vacuum Pump (VP_{VP}), which is shown in the vacuum gauge, can reflect the working performance of the vacuum pump and airtightness of the trial zones. The magnitude and change rate of VP_{VP} are plotted against time in Figures 15 and 16, respectively.

It can be seen that change law for VP_{VP} of the two vacuum pumps is almost the same. VP_{VP} rises to 80 kPa rapidly in the first 10 days, then increases slowly between 10 and 25 days, and finally stabilizes at about 85 kPa. This is because air under the airtight membrane is pumped out rapidly at an early stage of vacuum pumping and then the change rate of VP_{VP} decreases with the decreasing of air density (Fig. 16). It indicates that the trial zones are well sealed and the initial conditions of the two trial zones are basically the same.

3.2 Vacuum pressure in the horizontal transfer medium

Vacuum gauges were installed at different locations of the horizontal transfer medium to monitor the distribution of the vacuum pressure in the horizontal transfer medium (VP_{HTM}). VP_{HTM} of different locations are shown in Figure 17. VP_{HTM} of different locations is almost the same whether in

Figure 15. Vacuum pressure at vacuum pump.

Figure 16. Change rate of vacuum pressure at vacuum pump.

Figure 17. Distribution of the vacuum pressure in the horizontal transfer medium.

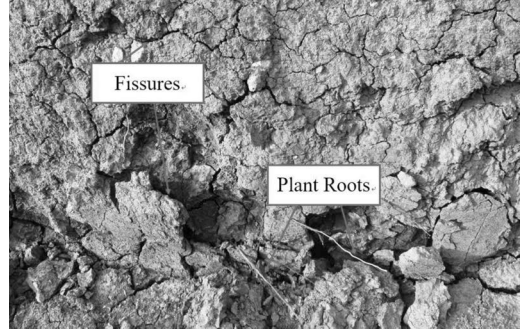

Figure 18. Status of the overlying loose sediment.

the sand layer or pipe system. VP_{HTM} in the pipe system is about 85 kPa, which is almost the same as VP_{VP} . VP_{HTM} in the sand layer is only about 50 kPa, which is 35 kPa lower than that in the pipe system.

However, the engineering practice proved that VP_{HTM} in the sand layer could also achieve 80–90 kPa (Shang, 1998) under good sealing condition. Therefore, it is most likely due to the influence of the loose sediment. It belongs to the point-to-point contact that pipe system directly connects with the PVDs. It is not influenced by the loose sediment when vacuum load is transferred to the PVDs through the pipe system because of its good airtightness (Fig. 4). To the sand layer, it belongs to the surface-to-surface contact that the sand layer directly overlays on the loose sediment. It may be greatly affected by the loose sediment when vacuum load is transferred to the PVDs through the sand layer because both of them are loose and porous. According to the engineering geologic investigation, buried depth of underground water level is about 1.0 m. Thus, the loose sediment layer can be divided into unsaturated loose sediment (about 0.0–1.0 m) and saturated loose sediment (about 1.0–5.0 m) further. Large numbers of plant roots and fissures in the unsaturated loose sediment (Fig. 18) can also be the vacuum transfer channels besides PVDs. Therefore, large amounts of vacuum energy can be consumed on the interface between the sand layer and the unsaturated loose sediment or in the soil cracks (Fig. 3).

Therefore, it can be inferred that the pipe system is more suitable as the horizontal transfer medium of vacuum load than the sand layer in the case of overlying loose and thick soil layer.

3.3 Vacuum pressure in the PVD

Vacuum pressure along the PVD is a key parameter of vacuum preloading technique. Thus, vac-

uum pressure was measured at the different depths of PVD to identify the effect of loose sediment on the vacuum load transfer in the PVD. Vacuum pressure at the top of the PVD (VP_{TOP}) is approximately equal to the average of VP_{HTM} . Vacuum pressure in the PVD (VP_{PVD}) after the stabilization of VP_{VP} is plotted against depth in Figure 19. It can be seen that VP_{PVD} has a clear loss along the depth direction of the PVD. And VP_{PVD} values of PVP at different depths are significantly greater than those of SVP at the corresponding depths. VP_{PVD} of PVP can be transferred up to 13.0 m in PVP, whereas that of SVP cannot be detected at the depth of 13.0 m all the time. This indicates that the transfer depth of vacuum load is less than 13.0 m in the SVP zone.

Besides, it can also be observed that the decay of VP_{PVD} is obviously influenced by the properties of the surrounding soil layers. VP_{PVD} decays rapidly in the loose sediment layer, especially in the unsaturated zone. It decays almost linearly and more slowly in the soil layers beneath the loose sediment. The VP_{PVD} curve of "Translational SVP" in Figure 19 is obtained by translating the curve of "SVP" until the two VP_{PVD} points at the depth of 5.0 m coincide. Comparing with two curves, the decay rate of VP_{PVD} increases with the increase of VP_{PVD} in the loose sediment layer. However, in the soil layers beneath the loose sediment, the decay rate of VP_{PVD} of SVP and PVP is almost the same with a constant being about 3–4 kPa/m. It indicates that the decay rate of VP_{PVD} is irrelevant to the magnitude of VP_{PVD} in the soil layers beneath the loose sediment.

3.4 Surface and layered settlement

Surface settlement plates and layered settlement apparatuses were installed to monitor the settle-

Figure 19. Vacuum pressure in the PVD.

ment of ground surface settlement and different soil layer interfaces, respectively. The settlement data can be used to validate the transfer rule of vacuum load indirectly because the compression of soil layers is caused by the vacuum load. The surface and layered settlement of SVP and PVP is plotted against time in Figures 20 and 21, respectively. In the SVP zone, the compression of the loose sediment layer is about 27.9 cm, which is almost equal to the surface settlement. The settlement of the 5 and 10 m interface is not detected. In the PVP zone, the compression of the loose sediment layer is about 26.5 cm, which accounts for about 78% of the surface settlement (34.0 cm). The compression of the clayey sludge layer is about 7.5 cm and that of the silty sandy loam is almost zero. Accordingly, soil compression caused by vacuum load occurs mainly in the loose sediment layer. It is in accordance with the analysis results

Figure 20. Surface and layered settlement of the SVP zone.

Figure 21. Surface and layered settlement of the PVP zone.

above that most of vacuum energy is consumed in the loose sediment layer.

Besides, it can also be seen that the compression of the loose sediment layer of the SVP zone is greater than that of the PVP zone although the surface settlement of the SVP zone is less. This also confirms the front analysis results that more vacuum energy is consumed on the interface between the sand layer and the unsaturated loose sediment or in the soil cracks because of more vacuum transfer channels including plant roots, fissures, and PVDs (Figs. 3, 18).

4 CONCLUSION

Field experiments have been carried out to determine the influence of thick and loose sediments on the vacuum load transfer. On the basis of the analysis results, the following conclusions can be made:

1. It is greatly affected by the loose sediment when vacuum load is transferred to the PVDs through the sand layer because both of them are loose and porous. And it is not influenced by the loose sediment when vacuum load is transferred to the PVDs through the pipe system because of its good airtightness.
2. Pipe system is more suitable as the horizontal transfer medium of vacuum load than sand layer in the case of overlying loose and thick soil layers.
3. Vacuum pressure in the PVD decays rapidly in the loose sediment layer, especially in the unsaturated zone, and the decay rate increases with the increase of vacuum pressure in the PVD in this layer. While it decays almost linearly and more slowly in the soil layers beneath the loose sediment, the decay rate is irrelevant to the magnitude of vacuum pressure in the PVD.
4. The settlement analysis validates the transfer rule of vacuum load indirectly in the case of overlying loose and thick soil layers. Soil compression caused by vacuum load occurs mainly in the loose sediment layer because most of vacuum energy is consumed in this layer.
5. The compression of the loose sediment layer of the SVP zone is greater than that of the PVP zone although the surface settlement of the SVP zone is less. It is mainly due to more vacuum transfer channels, including plant roots, fissures, and PVDs.

Enhancement on fireproof performance of construction coatings using calcium sulfate whiskers prepared from wastewater

Tsung-Pin Tsai

Department of Civil Engineering, Chung Hua University, Hsinchu, Taiwan

Hsi-Chi Yang

Department of Construction Management, Chung Hua University, Hsinchu, Taiwan

ABSTRACT: This work is dealing with the fireproof performance of CaSO_4 composite painting for fire passive protection in building construction. An efficient microwave-assisted method is adopted to fabricate high-crystalline CaSO_4 whiskers from wastewater. The as-prepared CaSO_4 whiskers display one-dimensional structure with a high aspect ratio of 40. The thermal resistive behavior of CaSO_4 -containing paints are investigated by using thermo-gravimetric analyzer, differential scanning calorimetry, and direct flaming test. The addition of CaSO_4 whiskers not only improves the anti-flammability but also reduces the ignition temperature of construction painting. Accordingly, the CaSO_4 whiskers can be considered as an effective fire retardant additive for improving the fireproof ability of construction coatings.

1 INTRODUCTION

With the crisis of resources and environmental issues becoming serious, the development of eco-materials is still taken into account as a global challenge. One strategy to counter this is to use the materials from sustainable sources, which would be renewable and economically competitive, capable of providing sustainable percentage of the resources for human utilization (Jiang J.X, 2015). Recently, there is an increasing demand to rationalize industrial wastewater treatment methodologies, including chemical precipitation, ion exchange, liquid-phase adsorption, reverse osmosis, and electrochemical methods (Deng L.C, 2013). The goal of the methods is to accommodate any reductions in discharge limits or step towards zero-discharge industries (Baltpurvins K.A, 1996). It is generally known that many industrial wastewaters contain high concentrations of sulfate, mainly originated from mining and mineral process. The sulfate concentration usually ranges from 250 to 2000 mg/L, which surpasses the secondary drinking water standard of 250 mg/L. To reduce the amount of wastewater, herein this present work proposes an efficient microwave method to recycle the sulfate species from acidic wastewater, opening a “green” gate for making calcium sulfate (CaSO_4) whiskers as fireproofing construction materials.

Recently, CaSO_4 whiskers have gradually earned much attention in scientific and technological applications owing to their superior properties.

The CaSO_4 whiskers, single crystals of calcium sulfate with a high aspect ratio, display excellent performance in mechanical strength, thermal stability, chemical resistance, and compatibility (Mao X.L, 2014). Thus, the CaSO_4 whiskers exhibit great potential as reinforcing agents in plastics, ceramics, paper, and so on. Within the above scope, the target of the present study is to examine an optimal ratio of CaSO_4 whiskers on the improved fireproof performance of construction painting. Both thermal stability and flammability of CaSO_4 -containing paintings are systematically investigated. This study proves that the usage of CaSO_4 whiskers is very beneficial for fire retardant in terms of enhanced fire-barrier performance, low cost and waste utilization.

2 EXPERIMENTAL SECTION

Both Thermo-Gravimetric Analyzer (TGA, Perkin Elmer TA7) and differential scanning calorimetry (DSC, TA Instrument Q20) were adopted to inspect the thermal stability and calorimetric change of CaSO_4 whiskers. The TGA analysis was conducted under an oxygen atmosphere with a heating rate of 30°C/min, ramping between 50°C and 900°C.

To examine the fireproof performance, one water-soluble painting mixed with different amounts of CaSO_4 whiskers were prepared to coat over calcium silicate plate. Herein the calcium silicate (CaSiO_3)

plates were carefully cut into an area of $5 \times 5 \text{ cm}^2$, and its thickness was around 0.8 cm. Four recipes were set at 0, 5, 10, and 15 wt% in the weight ratios of CaSO_4 whiskers to water-soluble painting. For good uniformity, the CaSO_4 -containing paintings were blended with a three-dimensional mixer using zirconia balls for 10 min. The as-prepared paintings were then pasted on the substrates with a doctor blade and then dried at 80°C in an oven overnight. The flame retardancy of as-prepared paintings on calcium silicate plates was tested by using a high-performance flamethrower. The distances between the paintings and the top of flame were set at 1, 5, and 10 cm, where the surface temperatures on the calcium silicate plates were 1100, 570, and 150°C , respectively. In the fireproof test system, three thermocouples (K type) were adopted to detect surface temperatures of the plates.

3 RESULTS AND DISCUSSION

TGA has been considered as a common technique that offers quantitative decomposition information on a composite material and can be used to investigate degradation kinetics and char formation. Herein the paintings mixed with different ratios of CaSO_4 whiskers were subjected to a controlled temperature regime of $50\text{--}900^\circ\text{C}$ at a heating rate of $30^\circ\text{C}/\text{min}$. The weight loss for each sample was monitored throughout the chemical decomposition in air, as shown in Fig. 1.

Without the addition of CaSO_4 whiskers, the TGA curve of original painting consists of three weight-loss stages: (i) $100\text{--}200^\circ\text{C}$ (dehydration), (ii) $200\text{--}350^\circ\text{C}$ (ignition and decomposition), and (iii) $650\text{--}800^\circ\text{C}$ (pyrolysis and degradation). The main weight loss takes place during the stage (ii) for all samples, liberating gases and volatiles from the

Figure 1. Typical TGA curves of the painting with different amounts of CaSO_4 whiskers.

paintings. The effectiveness of flame retardant can be evaluated on the basis of volatiles with increasing temperature, depended on the amount of residue produced. It can be found that the weight loss is a decreasing function of the amount of CaSO_4 whiskers.

In comparison, the residual weight of original painting is approximately 68.6 wt.% after thermal oxidation at 900°C , whereas the maximal residue can reach as high as 77.6 wt.% for the painting mixed with 15 wt.% CaSO_4 whiskers. Accordingly, the introduction of CaSO_4 whiskers displays a positive effect on the anti-flammability of construction painting. This improved retardancy is attributed to the fact the CaSO_4 crystals offer a high melting temperature (i.e., 1460°C), allowing its use for high-temperature operation.

To support this argument, DSC was adopted to examine the heat flux as a function of temperature under air flow starting from 25°C to 300°C , as depicted in Fig. 2.

For comparison, the DSC curve of pure CaSO_4 whiskers is also provided. As observed from Fig. 2(a), two endothermic peaks at 90°C and 180°C can be found. The former can be attributed to the departure of 1.5 mol H_2O from dihydrated calcium sulfate, whereas the later originates from the departure of 0.5 mol H_2O from hemihydrated calcium sulfate obtained after the incomplete dehydration of dihydrated calcium sulfate and from the

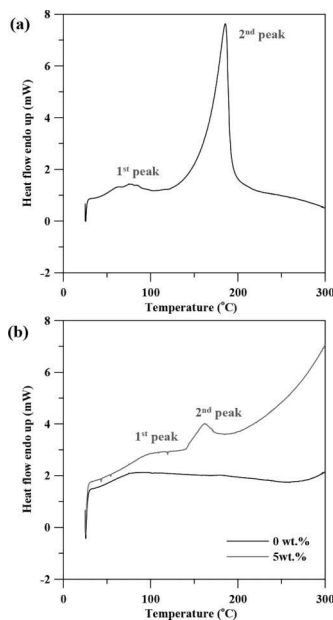

Figure 2. Typical DSC curves of (a) as-prepared CaSO_4 whiskers and (b) the painting without and with 5 wt.% CaSO_4 whiskers.

β -hemihydrate of plaster (i.e., a phase transformation) (Abidi S, 2015). This result reveals that the heat transfer through the CaSO_4 -containing painting can be impeded until the endothermic steps are totally completed (Kolaitis D.I, 2014). Therefore, the thermal decomposition of CaSO_4 -containing paint delivers a trailing effect, resulting in the delay of ignition temperature. On the basis of experimental results, the CaSO_4 whiskers can serve as an effective fire retardant additive for tailing away the decomposition reactions.

4 CONCLUSIONS

This work presented an efficient microwave-assisted method to fabricate high-crystalline CaSO_4 whiskers from wastewater. The introduction of CaSO_4 whiskers displayed a positive effect on the anti-flammability and the reduced ignition temperature of construction painting, demonstrated by TGA and DSC analyses. This result could be attributed to the fact that the heat transfer through the CaSO_4 -containing painting is seriously impeded until the endothermic reaction steps (i.e., dehydration of gypsum ($\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$) and crystalline phase change of β -hemihydrated plaster) were totally completed. On the basis of experimental results, the CaSO_4 whiskers could serve as an effective fire retardant additive for improving the fire protection and thermal resistive coatings. The present study shed some lights on an eco-environmental pathway to prepare “green” materials (i.e.,

CaSO_4 whiskers) for high-performance retardant additive in construction applications.

A. Furukawa

Department of Civil and Environmental Engineering, Tokyo Institute of Technology, Tokyo, Japan

ABSTRACT: In recent years, a new ultrasonic nondestructive testing method that utilizes nonlinear ultrasonic behavior generated in cracks or at a bi-material interface has emerged. However, the mechanism of generating subharmonics and higher harmonics is theoretically still not well understood. In this research, to simulate higher harmonics, dynamic contact problems of a crack face with contact boundary conditions in anisotropic materials are investigated by the Convolution Quadrature Time-Domain Boundary Element Method (CQBEM). Numerical results show that the cracks with contact boundary conditions in anisotropic materials excite higher harmonics as well as those in isotropic ones.

1 INTRODUCTION

Nonlinear ultrasonic testing has shown promise as a nondestructive method for testing materials used in nuclear power plants and in other important industries. In general, nonlinear ultrasonic testing uses subharmonics or higher harmonics, which include the frequency components corresponding to half harmonics or the harmonic series of an incident wave. Nonlinear ultrasonic testing has, however, not been applied in practical applications because the mechanism of generating these harmonics is theoretically still not well understood. Several researches on nonlinear ultrasonic testing have been done (Solodov, 2011) to investigate the mechanism of generating subharmonics and higher harmonics. Numerical analyses of nonlinear ultrasonic waves have been implemented by Saitoh et al. (2010), Hirose et al. (2014) and Maruyama et al. (2014), using the Convolution Quadrature time-domain Boundary Element Method (CQBEM). The CQBEM has been researched by Schanz (2001), Saitoh et al. (2009) and Maruyama et al. (2016) for transient wave analysis. In the CQBEM formulation, the convolution integrals of the time-domain boundary integral equation are numerically approximated by the Convolution Quadrature Method (CQM). Application of the CQM to time-domain BEM improves the numerical stability of the classical time-domain BEM, even

for small time step sizes, which are not allowed in the classical time-domain BEM. Therefore, the CQBEM is particularly helpful for the simulation of nonlinear ultrasonics, which requires a time step as small as possible for high precision solutions. In this paper, simulation of nonlinear ultrasonic waves in anisotropic materials is carried out using the CQBEM. In the following sections, the CQBEM for 2-D anisotropic elastodynamics is presented. Next, contact boundary conditions on the crack face are discussed. Finally, nonlinear ultrasonic waves generated by a crack with the contact boundary Conditions are demonstrated.

2 ANISOTROPIC ELASTODYNAMIC PROBLEMS

2.1 BEM formulation

We consider the scattering of an incident wave $u_i^{\text{in}}(\mathbf{x}, t)$ by a crack with surface S in an anisotropic solid D , as shown in Figure 1. The small indices used throughout this paper, such as $(\)_i$, range from 1 to 2 unless otherwise stated. Additionally, summation over repeated subscripts is implied throughout this paper. The equation of motion at point \mathbf{x} and time t is given as follows:

$$C_{ijkl}u_{k,lj}(\mathbf{x}, t) + f_i(\mathbf{x}, t) = \rho\ddot{u}_i(\mathbf{x}, t) \quad (1)$$

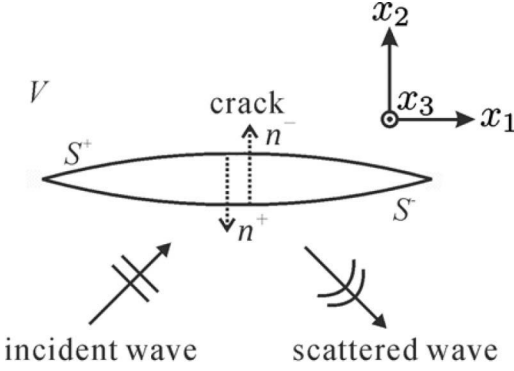

Figure 1. Scattering of an incident wave by a crack.

where $u_i(\mathbf{x}, t)$, $\sigma_{ij}(\mathbf{x}, t)$, and $f_i(\mathbf{x}, t)$ represent the displacement, stress, and body force component, respectively. The dot notation (\cdot) and the symbol $(\cdot)_{,i}$ denote the partial derivative with respect to time t and space x_i , respectively. ρ is the density of the anisotropic elastic material V . In addition, the constitutive equation is given by

$$\sigma_{ij}(\mathbf{x}, t) = C_{ijkl} u_{k,l}(\mathbf{x}, t) \quad (2)$$

where C_{ijkl} is the elastic constant. The boundary conditions on traction free cracks are given by

$$t_i^\pm(\mathbf{x}, t) = 0 \text{ on } S^\pm, \quad \phi(\mathbf{x}, t) = 0 \text{ on } \partial S \quad (3)$$

where $t_i(\mathbf{x}, t)$ is the traction corresponding to the displacement $u_i(\mathbf{x}, t)$, and $\phi(\mathbf{x}, t)$ is the crack opening displacement defined by $\phi(\mathbf{x}, t) = u_i^+(\mathbf{x}, t) - u_i^-(\mathbf{x}, t)$. Moreover, ∂S denotes the edge of the crack, and S^+ and S^- show the positive and negative sides of the crack face, respectively. The regularized hypersingular integral equation is written as follows:

$$\begin{aligned} t_p^{\text{in}}(\mathbf{x}, t) &= C_{pckl} n_c(\mathbf{x}) \left[-\rho \int_S U_{ik}(\mathbf{x}, \mathbf{y}, t) * \ddot{\phi}_i(\mathbf{y}, t) n_l(\mathbf{y}) dS_y \right. \\ &\quad \left. + e_{db} e_{lj} \int_S C_{ijna} U_{nk,a}(\mathbf{x}, \mathbf{y}, t) * \phi_{i,b}(\mathbf{y}, t) n_d(\mathbf{y}) dS_y \right] \end{aligned} \quad (4)$$

where $*$ is the convolution integral with respect to time t and $U_{mj}(\mathbf{x}, \mathbf{y}, t)$ is the fundamental solution for 2-D anisotropic elastodynamics, and $n_k (= n_k^+)$ represents the outward unit normal vector component. The zero initial condition is assumed in the boundary integral equation. In addition, $t_p^{\text{in}}(\mathbf{x}, t)$ is the traction component of an incident wave $u_p^{\text{in}}(\mathbf{x}, t)$ and e_{st} is the permutation symbol. Nor-

mally, the time-domain boundary integral equation (4) is discretized by the timestepping scheme. However, the well known timestepping scheme sometimes produces numerical errors if we use small time step size Δt . To overcome the difficulty, the CQM is utilized for the time discretization of the boundary integral equation (4).

2.2 Time discretization by the CQM

Discretizing the regularized hypersingular integral equation (4) using a piecewise constant approximation of the unknown crack opening displacement $\phi_i(\mathbf{y}, t)$ and using the CQM for the convolutions of equation (4) yield the discretized boundary integral equation as follows:

$$t_p^{\text{in}}(\mathbf{x}, n\Delta t) = \sum_{\alpha=1}^M \sum_{k=1}^n \left[A_{pi}^{n-k, \alpha}(\mathbf{x}) + B_{pi}^{n-k, \alpha}(\mathbf{x}) \right] \phi_i(\mathbf{y}^\alpha, n\Delta t) \quad (5)$$

where M is the number of discretized boundary elements. In addition, $A_{pi}^{m, \alpha}(\mathbf{x})$ and $B_{pi}^{m, \alpha}(\mathbf{x})$ are the influence functions, which are defined by

$$\begin{aligned} A_{pi}^{m, \alpha}(\mathbf{x}) &= \rho C_{pckl} n_c(\mathbf{x}) \\ &\times \frac{R^{-m}}{L} \sum_{l=0}^{L-1} \left[-\int_{S_\alpha} n_l(\mathbf{y}) s_l^2 \hat{U}_{ik}(\mathbf{x}, \mathbf{y}, s_l) dS_y \right] e^{-\frac{2\pi i m l}{L}}, \end{aligned} \quad (6)$$

$$\begin{aligned} B_{pi}^{m, \alpha}(\mathbf{x}) &= C_{pckl} C_{ijna} n_c(\mathbf{x}) e_{lj} \\ &\times \frac{R^{-m}}{L} \sum_{l=0}^{L-1} \left[\int_{\partial S_\alpha} \frac{\partial}{\partial y_a} \hat{U}_{nk}(\mathbf{x}, \mathbf{y}, s_l) d(\partial S_y) \right] e^{-\frac{2\pi i m l}{L}} \end{aligned} \quad (7)$$

where $\hat{U}_{ik}(\mathbf{x}, \mathbf{y}, s)$ and $d(\partial S_y)$ are the Laplace-domain fundamental solution for 2-D anisotropic elastodynamics and sides of each boundary element S_α respectively. S_l denotes the Laplace parameter. Moreover, \mathcal{R} and L are the CQM parameters (Lubich, 1998). Equation (5) can be solved with initial and boundary conditions from the first time step to the last time step.

3 CONTACT BOUNDARY CONDITIONS

In a usual analysis of elastic wave scattering by a crack, it is assumed that the boundary condition on the crack face is traction free in all time steps. In this paper, however, we consider the contact boundary conditions on the crack face proposed by Hirose (Hirose, 1994). The summary of the contact boundary conditions are described in this section.

3.1 Separation state

The separation state shows the usual boundary condition imposed on the crack faces for dynamic

Figure 2. Contact boundary conditions.

crack problems. The crack faces S^+ and S^- are separated from each other as shown in Figure 1. Therefore, the traction free boundary condition $t_i = 0$ is considered at this state.

3.2 Stick contact state

In the stick contact state, the relative velocity of the horizontal crack opening displacement $\dot{\phi}_1(x, t)$ and the vertical crack opening displacement $\dot{\phi}_2(x, t)$ must be zero as shown in the lower left of Figure 2.

3.3 Slip contact state

In the slip contact state, we can assume the boundary condition given by

$$\phi_2 = 0, \quad t_1 = \text{sgn}(\dot{\phi}_1) \mu_d |t_2| \quad (8)$$

where μ_d and $\text{sgn}(\cdot)$ are the crack face frictional coefficient and signum function, respectively. The difference between stick and slip contact states is whether the crack opening velocity $\dot{\phi}_1(x, t)$ can be allowed or not. In each time step, the stick, slip, or separation contact boundary condition is determined by the crack opening displacement and stress states. The transition from one state to the others is summarized in Figure 2.

4 NUMERICAL RESULTS

Some numerical results are shown in this section. We assume the material V with a crack as CFRP with the following material constants:

$$C_{pq} = \begin{bmatrix} 45.91 & 1.84 & 41.87 & 0 & 0 & 0 \\ & 3.98 & 1.84 & 0 & 0 & 0 \\ & & 45.91 & 0 & 0 & 0 \\ & & & 1.0 & 0 & 0 \\ & \text{sym.} & & & 2.02 & 0 \\ & & & & & 1.0 \end{bmatrix} \quad (9)$$

Note that the material constants are normalized by the C_{66} .

4.1 Elastic wave scattering by non-contacting crack in anisotropic solid

First, in order to check the validity of the CQBEM, we consider the scattering of elastic waves by a noncontacting crack as shown in Figure 3(a). The incident plane qP wave is given by

$$u_i^{\text{in}}(x, t) = u_0 d_i \frac{1}{2} \left[1 - \cos(2\pi f h) \right] \left\{ H(h) - H\left(h - \frac{1}{f}\right) \right\} \quad (10)$$

where u_0 is the amplitude, d_i is the polarization vector component, H is the Heaviside step function,

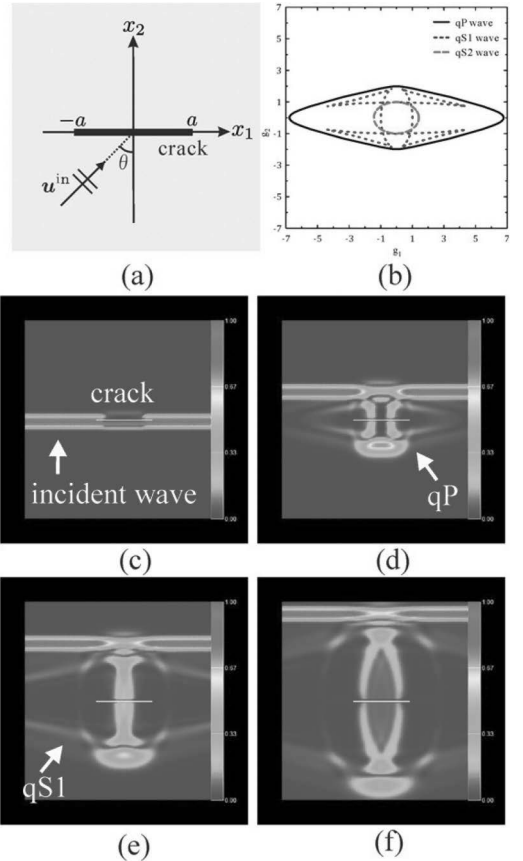

Figure 3. Numerical results for the analysis of elastic wave scattering by non-contacting crack. (a) analysis model (b) group velocities of the CFRP, (c)-(d) absolute value of the total wave fields around the crack.

and f is the frequency of the incident wave, respectively. In addition, c^{in} is the wave velocity for the incident wave propagation direction. The function h is defined by

$$h = t - \frac{x_1 + a}{c^{\text{in}}} \sin \theta - \frac{x_2}{c^{\text{in}}} \cos \theta \quad (11)$$

In this analysis, we set the parameters as $\mathbf{d} = (0, 1)$, $\theta = 0$, $c^{\text{in}} \Delta t / a \approx 0.1$, and $N = L = 128$. The incident wave length λ^{in} is given by $\lambda^{\text{in}} / a = 1.0$. The group velocity curves of the CFRP with the material constants given in equation (9) are shown in Figure 3(b). The group velocity of qP wave propagating in the x_1 direction is faster than that in the x_2 direction. Figures 3(c)-(f) show the absolute value of the total wave field around the crack at $c^{\text{in}} t / a = 0.4, 1.89, 3.39$, and 4.89 . The scattered qP and qS1 waves are generated by the interaction between the incident wave and the crack. The wave fronts of these scattered waves concord with the group velocity curves. Therefore, it is confirmed that the obtained numerical results are valid from the physical point of view.

4.2 Simulation of nonlinear ultrasonic waves

Next, the scattering of an incident plane qP wave by a crack with the contact boundary conditions analyzed by the CQBEM. In this analysis, the following incident qP wave is considered:

$$u_i^{\text{in}}(x, t) = u_0 d_i \sin(2\pi f h) H(h) H\left(\frac{10}{f} - h\right) \quad (12)$$

where

$$h = t - \frac{x_1 + a}{c^{\text{in}}} \sin \theta - \frac{x_2}{c^{\text{in}}} \cos \theta. \quad (13)$$

In this analysis, we set the parameters as $\mathbf{d} = (0, 1)$, $c^{\text{in}} \Delta t / a \approx 0.1$, $N = L = 128$. The incident wave length λ^{in} is given by $\lambda^{\text{in}} / a = \pi$. Figure 4(a) shows the time histories of the total displacements u_2 / u_0 at the point $(x_1, x_2) = (0.0, -4.0a)$. The total displacement obtained by considering the contact boundary conditions is distorted compared with the non-contacting result shown by dashed line in Figure 4(a). Figure 4(b) depicts the Fourier spectrum of the total displacements u_2 / u_0 of Fig. 4(a). As shown in Figure 4(b), the scattered wave by the non-contacting crack has only one spectral component at $k^{\text{in}} a = 2.0$, which is corresponding to the fundamental frequency of the incident wave. However, the scattered wave by the crack with contact boundary conditions has not only the fundamen-

Figure 4. (a) Total displacements u_2/u_0 and (b) their Fourier spectra.

tal frequency but also the higher frequency component at $k^{\text{in}} a = 4.0$ and $k^{\text{in}} a = 6.0$, which are the two and three times of the fundamental frequencies and called the second and third order harmonics, respectively. The use of Fourier spectrums of the scattered waves may have a potential to detect a closed crack in anisotropic materials which cannot be detected by the linear ultrasonic testing based on the acoustic impedance mismatch.

5 CONCLUSIONS

In this paper, the simulation of nonlinear ultrasonic waves is implemented by the CQM. In the future, we will extend this 2-D simulation to 3-D one.

ACKNOWLEDGEMENT

ABSTRACT: With a rapid development of Bus Rapid Transit (BRT) system in China, many studies on planning and design of BRT have been conducted; however, there is only little research on the feeder system of the BRT system, especially for the layout of the newly added feeder lines. In this paper, we first put forward that the reasonable influence area of BRT and the layout of feeder lines should be determined on the basis of questionnaire surveys of passengers close to the BRT stations. Second, the selection principle of newly added feeder lines and the feeder stops were proposed. Then, a mathematical model with the connection benefits (including travel time cost and operation cost) as a minimum objective function has been conducted for the first time, an improved genetic algorithm was designed to calculate the model, and the layout scheme of newly added feeder lines was solved. Finally, the methodology was applied to the case of Beijing BRT line 1. With the goal of 80% passengers' interest, the reasonable influence radius of Beijing BRT line 1 is 3.89 km. After the calculating the model, eight newly added feeder bus lines were designed linking to the Beijing BRT line 1. The results reveal that the layout method of newly added feeder bus lines coordinating with BRT can be well used to support the feeder system design of Beijing BRT.

1 INTRODUCTION

Bus Rapid Transit (BRT) can be defined as that with a large capacity and high speed, similar to those of rail transit. It is also as flexible and cheap as regular bus transit, so it is widely used throughout the world (2013). Between 2004 and 2014, 23 major cities in China established and implemented 40 BRT corridors, reaching a total length of 2761 km (2014).

However, the development of BRT is still in an early stage. It has not formed network operation and is still insufficient in service scope, so it is necessary for regular bus lines to collect and distribute passengers and provide feeder service, thus improving the operational efficiency of bus rapid transit and cultivating passenger flow for newly added bus rapid transit lines. Therefore, it is particularly important to carry out the research on the method of laying newly added feeder buses to BRT lines.

A utility model is developed and a quantitative study on reasonable influence area of BRT and feeder lines is conducted in this paper. The study also designed a genetic algorithm to calculate the model and give the layout scheme on new-added feeder lines.

2 LITERATURE REVIEW

In recent years, with the rapid development of rail and BRT, many studies have begun to focus more on feeder bus lines. The methodologies on feeder lines layout are of two types: benefit analysis and network optimization. The objective function of benefit analysis is to find the optimal interest and analyze the interests of feeder bus system on the basis of public transit demand spatial and temporal distribution function.

Among the international studies on the layout of feeder bus lines, Vuchic (2005) provided internationally recognized methodologies to determine the structure of feeder bus network according to the maximum passenger transport demand. Martins and Pato (1998) established the optimal number of feeder bus lines for urban rail transit systems and the methods or algorithms for laying them. Kuan et al. (2006) introduced the heuristic genetic algorithm to solve the complex N-P problem concerning feeder bus network optimization. Verma and Dhingra (2005) formulated an optimization model of line layout to account for the integration of rail transit and feeder line operations. Wiasinghe

(1977, 1980), Kuah et al. (1988), Schonfeld et al. (1998), and MD. Shoaid Chowdhury (2001) established the profit analysis model from different perspectives and carried out studies on the possible maximum benefit of feeder bus system. Shrivastava (2006, 2001) and S.N. Kuan (2005) studied the application of different heuristic algorithms in bus network optimization model.

However, because the construction and operation of BRT systems is relatively later in China, there is little research regarding the layout of BRT feeder lines. Among the existing research, it is important to highlight the work of Dong (2011) to research methodologies to add new feeder bus lines on the basis of land use characteristics, for example, of universities, hospitals, and other densely populated areas. Fang (2013) also explored feeder line layout on the basis of the shortest path method and the optimal searching algorithm to lay feeder bus lines one by one. In 2009, Zhu (2009) put forward a method on the time-value model and network coordination of regular bus network adjustment on the basis of coordination theory of BRT and regular network. In 2011, Bi (2011) did malicious attack experiment on BRT network coordinated with regular bus network, testing the robustness of BRT network and verifying the importance of BRT linked to regular bus.

Because most of the above-mentioned studies investigated the layout of feeder bus lines for rapid rail transit, this paper aims to propose a methodology specific to BRT, using genetic algorithms, which will consider improving access to public transport while minimizing passenger and operation costs. Section 2 will depict the methodology to determine the influence area of BRT lines, section 3 will discuss the methodology proposed to determine the layout of feeder lines, including a genetic algorithm. Section 4 presents an application for the case of Line 1 in Beijing, China, and Section 5 includes the paper conclusions.

3 METHODOLOGY

3.1 *Definition of reasonable influence area of BRT*

The first step in the methodology is to determine the reasonable influence area of BRT lines. We define influence area as the area around BRT lines where passengers will have access to the BRT system. This influence area should take into account passengers who might walk as well as those transferring from other modes such as cycling or feeder buses.

The influence area of a station can be divided into reasonable influence area and potential influence area (2013). The definition of the reasonable influence area is based on the reasonable distance

that most passengers are willing to travel to access the BRT line, including passengers who walk, cycle, or drive and use park and ride facilities (2011). The concept that corresponds to a reasonable influence area is the potential attraction, which refers to the distribution of some areas that still attract passenger flow in addition to the stations that reasonably attract passenger flow.

The reasonable influence area of a BRT station includes the influence area of bicycles and the influence area of regular bus transit; the emphasis of this paper is the reasonable influence area of bus rapid transit lines to conventional public transport passenger flow, which is used to determine the layout scope of feeder bus lines. According to the concept of reasonable influence area, it is a quantity value aiming for meeting most passengers' benefits and not wasting transport resources; therefore, on the basis of GIS network information and station questionnaires and with the goal of considering the benefits of a certain proportion of passengers, a buffer analysis can be carried out, to determine the reasonable influence area of bus rapid transit lines to the passenger flow of regular bus transit.

3.2 *Selection of feeder stations*

3.2.1 *Selection of BRT stations*

Not all BRT stations need a feeder bus, and their need should be judged according to the size of the feeder or the existing station passenger volume. If the feeder passenger volume is too small, the feeder bus line will probably be not cost-effective to increase new feeder bus lines; if a rapid transit station already has a heavy passenger flow volume, and newly added feeder passenger flow will lead to exceeding the platform's capacity, then it is not suitable to add new feeder bus lines to this station.

3.2.2 *Selection of regular bus stops*

If it is determined that adding feeder lines is suitable, the station selection of regular bus should be conducted within the identified reasonable influence area of the BRT line. Stations should be divided into two categories: one category is the stations for passengers to get on regular buses. These can be obtained by looking at passenger transfers from regular bus stops to BRT stations in the Origin-Destination (OD) survey. The other category is the regular bus transit stops that do not allow passengers to transfer to BRT. When selecting the above two types of regular bus stops, the size of the feeder passenger flow volume should also be considered, and if the resulting feeder passenger flow volume is too small, it is not economical to add new feeder bus lines. Moreover, feeder stations can be added according to specific needs; for example, new feeder stations can be considered at special locations, such

as scenic spots, stations, residential areas, and public central areas with potential passenger demand.

4 MODEL ESTABLISHMENT

4.1 Analysis of influencing factors

There are many factors that affect the layout of feeder bus lines; therefore, it is necessary to make simplifications and assumptions. The basic assumptions of this model are as follows:

1. The feeder passenger flow volume at each regular bus stop that needs the layout of feeder bus lines is known, and the distance between these stops and the BRT station are known.
2. The bus capacity (passenger/bus) and operating speed of each vehicle running on feeder bus lines are known.

3. The feeder buses stop at every feeder lines' stops, the dwell time at stops is constant.
4. There is only one feeder bus line passing through every feeder regular bus stop.
5. All feeder lines must start or end at a BRT station, and they can only be connected to one BRT station.
6. Depending on passenger volume, two or more feeder bus lines can be laid for a bus rapid transit station.

4.2 Analysis of influencing factors

On the basis of the above requirements, a layout model for newly added feeder bus lines can be established. In this model, the basic parameters are defined as shown in Table 1:

The layout model can be established as follows, and the objective function is:

Table 1. Parameter description.

Name	Meaning	Name	Meaning
N	Total Quantity of regular bus transit stations that need the layout of feeder bus lines	v_0	Operating speed of the vehicles on feeder bus lines
T_i	Total in-vehicle travel time of all the passengers	t_0	Stopping time of vehicles at each station on feeder bus lines
k_n	Ridership at the nth feeder regular bus transit station	c_1	Unit in-vehicle travel time cost of passengers
d_n	Length of feeder bus line from the nth feeder regular bus transit station to the bus rapid transit station	S_n	Quantity of stations through which the line between the nth feeder regular bus transit station and the bus rapid transit station has passed
T_w	Total waiting time of all the passengers	c_2	Unit waiting time cost of passengers
h_l	Departure interval of the nth feeder regular bus transit station on the lth feeder bus line	F_l	Fleet scale of the lth feeder bus line
N_l	The quantity of regular bus transit stations through which the lth feeder bus line has passed	d_l	Length of the lth feeder bus line
L	Total quantity of feeder bus lines required to be laid	c	Operating cost per vehicle per unit time on a feeder bus line
d_{max}	Upper limit value of the length of a feeder bus line	d_{min}	Lower limit value of the length of a feeder bus line
h_{max}	Upper limit value of the departure interval of a feeder bus line	h_{min}	Lower limit value of the departure interval of a feeder bus line
P	Rated passenger capacity of a feeder bus	Col_{max}	Maximum operating cost of the lth feeder bus line that can be provided by enterprises
q_{max}	Maximum section passenger volume of a feeder bus line	R	Maximum feeder passenger flow volume that can be accepted by the bus rapid transit stations
D_l	Spatial straight-line distance between the origin and end stops of the lth feeder bus line	ρ	Constant, nonlinear coefficient

$$\min C_T = C_1 \sum_{n=1}^N k_n \left(\frac{d_n}{v_0} + s_n t_0 \right) + C_2 \sum_{n=1}^N \frac{1}{2} k_n h_l + \sum_{l=1}^L \frac{2 d_l / v_0 + t_0 \cdot N_l}{h_l} \cdot c \quad (1)$$

where the first part refers to the total in-vehicle travel time cost of all the passengers transported by feeder buses, the second part refers to the total waiting time cost of all the passengers who are waiting for feeder buses at regular bus stops, and the third part refers to the feeder operation cost based on Xiong et al. (2013).

The following constraints should be considered:

1. Line length constraint: Long feeder bus lines can lead to complicated line functions, and short lines can lead to insufficient passenger flow; thus, the line cannot be operated normally.

$$d_{min} \leq d_l \leq d_{max} \quad (2)$$

2. Departure headway constraint: The departure headway of feeder bus lines is determined by comprehensively considering feeder lines' passenger demand per unit of time and operation costs:

$$h_{min} \leq h_l \leq h_{max} \quad (3)$$

$$h_{min} = \frac{c \cdot (2 d_l / v_0 + t_0 \cdot N_l)}{C_{obmax}} \quad (4)$$

$$h_{max} = \frac{P}{q_{max}} \quad (5)$$

3. BRT station capacity constraint: If a BRT station has a large passenger volume, and newly added feeder passengers will cause the platform to exceed its capacity, then it is not suitable to set up a feeder bus line at the station:

$$\sum_{l=1}^L \sum_{n=1}^{N_l} k_n \leq R \quad (6)$$

4. Nonlinear coefficient constraint:

$$\frac{d_l}{D_l} \leq \rho \quad (7)$$

In conclusion, the above layout model can be written as:

$$\min C_T = C_1 \sum_{n=1}^N k_n \left(\frac{d_n}{v_0} + s_n t_0 \right) + C_2 \sum_{n=1}^N \frac{1}{2} k_n h_l + \sum_{l=1}^L \frac{2 d_l / v_0 + t_0 \cdot N_l}{h_l} \cdot c \quad (8)$$

$$s.t. \begin{cases} d_{min} \leq d_l \leq d_{max} \\ h_{min} \leq h_l \leq h_{max} \\ \sum_{l=1}^L \sum_{n=1}^{N_l} k_n \leq R \\ \frac{d_l}{D_l} \leq \rho \end{cases}$$

5 DESIGN OF GENETIC ALGORITHM

In this paper, we propose the following process to create feeder lines: First, calculate the distance between each regular bus stop within the influence area and the BRT station, then choose two BRT stations with the shortest distance as the potential stations to connect with the feeder line. Boolean variables 0–1 can be defined as control variables for the final selection of the two stations: “0” indicates the nearest BRT station to the regular bus stop regular bus, and “1” indicates the next-nearest BRT station regular bus. Then, select value 0 or 1 in the control variables for all the regular bus stops according to a probability of 50%.

Finally, on the basis of the selection results of the control variables for all the feeder regular bus station and aiming at each BRT station, connect the potential feeder regular bus stations to the BRT station with feeder lines, starting with the closest in distance regular bus, thus generating a scheme of feeder bus lines as an individual. It is important to note that a BRT station may not be connected to any feeder line.

To improve the process of creating feeder lines, an improved genetic algorithm to solve the model can be designed as follows.

5.1 Chromosome coding

The chromosome coding should be conducted by using binary encoding, that is, using 0–1 to indicate the connection between each feeder regular bus station and a BRT station.

For example, there are n regular bus stops numbered from 1 to n and four BRT stations (A, B, C, and D). If we assume that the nearest and next-nearest BRT stations of regular bus stop 1 are A and B, respectively, the two-numbered feeder regular bus station's nearest and next-nearest bus rapid transit stations are B and C, respectively, and the three-numbered feeder regular bus station's nearest

and next-nearest bus rapid transit stations are C and D, respectively, then the individuals (1 0 1...) indicate that among the eventually-generated set of feeder bus lines, the one—and two-numbered feeder regular bus stations are connected to the bus rapid transit station B and the three-numbered feeder regular bus station is connected to the bus rapid transit station D.

5.2 Population initialization

The population should be initialized through the chromosome coding of all feeder regular bus stations by selecting control variable 0 or 1 at the probability of 50%.

5.3 Fitness function

In order to avoid superindividual (having a fitness value that is considerably greater than the average fitness value of the population and leads to the problem of early convergence in genetic algorithm) in the population, this paper transforms the fitness function as follows:

$$F(x) = \left[\frac{f(b) - f(x)}{f(b) - f(a)} \right]^2 \quad (9)$$

where $f(a)$ and $f(b)$ indicate the minimum and maximum values among the objective function values, respectively; $f(x)$ indicates the objective function value; and $F(x)$ indicates the fitness value.

5.4 Selection strategy

Selection strategy adopts a method that combines the optimal individual conservation, the fitness proportionate selection, and the roulette wheel selection. Specific steps are as follows: first, sort the individuals in the population according to the fitness values, retain 2% of total individuals in the population number that have higher fitness values, and directly copy them to the next generation. Then, calculate the fitness proportion, that is, the probability of each individual to be selected. Finally, calculate the cumulative probability of each individual in accordance with their selection probability and generate a random number, then the corresponding individual should be selected for the crossover if the random number fell into a region of the cumulative probability, and in order to select the individual for the crossover, it is necessary to carry out several rounds of selection.

5.5 Crossover strategy

As for the crossover operation, two-point crossover should be adopted, that is, after randomly

setting up two crossover points in two matching individual coding strings, exchange part of the chromosome between two crossover points set up by two individuals, and the crossover probability is $p_{\text{cross}} = 0.4$.

5.6 Mutation strategy

As for the mutation operation, the site mutation should be adopted, and the mutation probability is $p_{\text{muta}} = 0.2$. In terms of a binary-encoded individual, if the original site is 0, then it will become 1 through the mutation operation and vice versa.

6 CASE STUDY

6.1 Survey design and data collection

The layout of newly added feeder buses to the Beijing BRT line 1 is analyzed as an example. A questionnaire survey was carried out at 17 stations along the lines at morning peak 7:00–9:00 during two working days, thus obtaining the departure points of the passengers that are transferring from regular buses to BRT. A total of 3,076 valid samples are obtained and 83 regular bus lines and 225 stops are involved; according to a statistics based on regular bus stations, the quantity of the passengers that need feeder buses to bus rapid transit lines at each regular bus station can be obtained. In order to meet the research needs, it is necessary to map BRT lines and their station information as well as the information about 225 regular bus stops in ArcGIS, which stores regular bus stop names, the quantity of passengers with feeder needs, and latitude and longitude coordinates among other attributes.

6.2 Influence area definition

When selecting the layout scope, it is necessary to fully consider the needs of passengers to transfer from regular bus transit to bus rapid transit and the efficient use of newly added feeder bus lines, thus considering most passengers' travel demands and making no waste of transport resources. On the basis of the above analysis, this paper selects the reasonable influence area of bus rapid transit lines to the passenger flow of regular bus transit as the layout scope of feeder bus lines. By using the method in Section 2 and by considering 75%, 80%, and 85% of the passengers' interests respectively as the goals, the reasonable influence area of the Beijing BRT line 1 can be determined, as shown in Figure 1. This paper uses the value of 80% to layout feeder lines.

With the goal of 75%, 80%, and 85% passengers' interest, respectively, reasonable influence area of Beijing BRT line 1 (as shown in Figure 1) and the influence radius under different goals (as shown in Table 2) are identified.

6.3 Selection of feeder stops

The selection of feeder stops includes the selection of BRT stations and the selection of regular bus stops. The regular bus stations should be selected according to the quantity of the passengers at each station, estimated from the survey, who need feeder buses to connect to BRT lines. This paper chose 29 stations with relatively large demand for feeder (passenger volume is more than 20 people), and new feeder bus lines are added to these stations to meet the constraint of large passenger demand for feeder. The selection of BRT stations is based on the size of feeder passenger volume at stations. The 29 regular bus stops are numbered 1–29, five bus rapid transit stations are numbered A–E, and the station information is initialized, as shown in Table 3. The distances between stations are calculated through latitude and longitude coordinates in the ArcGIS.

6.4 Feeder lines layout

1. Parameter value

The model's parameter values are shown in Table 4:

2. Calculation

By using the Matlab2013b (as shown in Figure 2), the layout scheme consisting of a total of eight feeder bus lines were generated, including: Route1:1–3–4–7-A; Route2:2–6–5-A; Route3:10–11–8–9-B; Route4:12–14–13–15–16-D; Route5:17–18-A; Route6:20–22–23–21–19-A; Route7:25–24-B; and Route8:29–28–27–26-D. The layout of each line is shown in Figure 3.

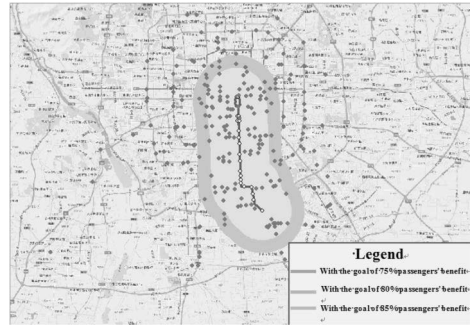

Figure 1. Reasonable influence area of bus rapid transit lines under different goals.

Table 2. Influence radius of BRT with different goals.

Indicators	75% passengers' interest	80% passengers' interest	85% passengers' interest
Reasonable influence area			
Influence radius (m)	3430	3890	4940

Table 3. Passenger quantity at each feeder regular bus station (Unit: person).

No.	Passenger quantity	No.	Passenger quantity	No.	Passenger quantity
1	32	11	27	21	34
2	23	12	26	22	25
3	53	13	47	23	23
4	31	14	42	24	47
5	27	15	36	25	32
6	34	16	33	26	41
7	30	17	41	27	30
8	35	18	34	28	28
9	52	19	39	29	35
10	38	20	36	–	–

Table 4. Model's parameter values.

Parameter name	Unit	Value	Parameter name	Unit	Value
Stopping time of feeder buses at each station	sec	20	Operating speed of feeder buses	km/h	15
The operating cost per feeder bus per unit time	Yuan	1,500	Unit in-vehicle travel time cost of passengers	Yuan/min	0.2
The maximum operating cost of each feeder bus line that can be provided by operators	Yuan	4,500	Unit waiting time cost of passengers	Yuan/min	0.4
Rated passenger capacity of a feeder bus	Person	80	The upper limit value of the length of a feeder bus line	km	8
The upper limit value of the departure headway of a feeder bus line	min	8	The lower limit value of the length of a feeder bus line	km	2
The lower limit value of the departure headway of a feeder bus line	min	5	–	–	–

7 CONCLUSIONS

The layout of newly added feeder buses to BRT lines is an important issue that relates to increase the efficiency of the whole city's public transportation system. In this paper, we discussed the method to determine the reasonable influence area of BRT and the method to lay feeder bus lines within the influence area, proposed a mathematical model for feeder bus line layout, put forward an improved genetic algorithm to solve it, and conducted a case study for adding feeder buses to the Beijing BRT line 1. The following conclusions can be summarized from this study.

First, through the survey and GIS analysis on Beijing BRT line 1, in reasonable passenger attract area aspects, because of sparse stops at the suburban district, the trip distance of passengers is much longer with a high average speed for regular bus, so it is more attractive for regular bus passengers. Conversely, the influence area is smaller in the central district. With the goal of 80% passengers' interest, the reasonable influence radius should be 3.89 km.

Second, this paper proposed the selection principle of newly added feeder lines and the feeder stops. A mathematical model with the connection benefits (including travel time cost and operation cost) as a minimum objective function has been conducted for the first time. Using genetic algorithm to calculate the model, the layout scheme of newly added feeder lines was planned. Applying to the Beijing case, eight feeder bus lines were designed linking to the Beijing BRT line 1, and the results prove the validity of the model.

It is important to note that although in this study the model involved the BRT capacity constraint issues, the coordination of departure frequency of BRT and feeder lines was not taken into account. The newly added feeder lines should be designed considering the operating coordination as well as the reasonable influence area, which will improve the efficiency of the feeder system and will be the directions for our future work.

Design of a campus view of a virtual roaming system based on VR

Ling Yu

Art and Design School, Dalian Polytechnic University, Dalian, China

ABSTRACT: Virtual reality is a new and advanced technology that produces a three-dimensional space by computer simulation to provide users with visual, auditory, tactile, and other sensory simulations. In this paper, by comprehensively using Vega Prime and Visual Studio software, we construct a virtual campus roaming system. The main research work of this paper is as follows: 1. On the basis of early use of three-dimensional modeling of MultiGen Creator on the campus of Nanchang University, we use Vega Prime and Visual Studio software to build a virtual campus roaming system. 2. We design the virtual campus roaming system database, which covers the data of various functional departments of the school, in order to facilitate the user's inquiry and understanding of the school. 3. We study the key technologies of virtual simulation technology: roaming technology and collision detection technology. The design improves the flexibility, immersion, and interaction of the system.

1 INTRODUCTION

Before the 21st Century, because of the less development of computer hardware and computer technology, people's understanding and description of the real world were still in the form of binary. The binary description of the real world is quite different from the actual real world, which cannot reflect various types of images of the three-dimensional world. Therefore, under many circumstances, it will affect people's understanding of the real world. With the rapid development of computer technology, virtual reality technology (referred to as VR, also translated as the spirit and reality) is increasingly widely used. This is an integrated technology, relating to the field of computer graphics, simulation technology, multimedia technology, human-computer interaction technology, sensor technology, artificial intelligence, and so on. Its core idea is to simulate a real world as realistic as possible in a computer model. People are roaming, driving, and training in this virtual model so as to achieve the equal effect as it is in the real world. As a result, it is widely used in commercial, military training, and fields with emergency and uncertainties (such as reproduction of the scene of the traffic accident, fire rescue simulation, aerospace, and micro simulation). VR has three main features: immersion, interaction, and imagination.

2 THE OVERALL DESIGN OF THE VIRTUAL CAMPUS ROAMING SYSTEM

The design of the virtual campus roaming system is divided into three parts: the establishment of a

virtual campus model, using Prime Vega to quickly customize the virtual campus roaming system ACF files and using Studio2005 Visual to write a virtual campus roaming system on the basis of MFC (Biocca F, 2013).

2.1 System environment configuration

Real-time rendering three-dimensional virtual scene and large-scale spatial data have high requirements on the system hardware. In the following, it describes the hardware configuration and software used in the system.

The hardware configuration of the system is as follows:

CPU: Intel (R) Core2 Q9500 2.83 GHz
Memory: 2GB
Hard disk: 500GB
Graphics: 1GB independent memory
Operating system: Windows XP
Three-dimensional modeling software: Multi-Gen Creator 3.2
Virtual campus roaming configuration software: Vega Prime 2.2.1
Virtual campus roaming system development platform: Visual Studio 2005
Database: Microsoft Access 2003

In the early implementation of the project, the computer configuration is low, resulting in when using Gen Creator Multi 3.2 software modeling, it cannot normally display the texture image and thus unable to continue to carry on this project. We suggest using 1GB or more independent video card so that the system can smoothly carry out interactive roaming, query, and so on.

2.2 Overall design of virtual campus roaming system based on MFC

2.2.1 ACF file of virtual campus roaming system

The development of visual simulation application program is usually divided into the establishment of virtual 3D model and the design of virtual roaming engine. In the design of virtual roaming engine, if we do not use ACF file, then it can only use the program code to replace the ACF file, create an instance of all objects, and proceed relationship configuration of these objects of a class. If the virtual scene is more complex, not using the ACF file will cause lots of problems and inconvenience for configuration and modification of the scene. As a consequence, in this paper, we use the ACF file in the design of virtual roaming engine. If there are changes in the virtual scene, it can be modified in the ACF file. In the framework of virtual campus roaming system, the function of Vega Prime is written in C++ language, and the developing environment of roaming engine is Vega Prime 2.2.1, so we use Visual Studio 2005 as the development platform of the system; choose application program based on MFC (Microsoft Foundation Classes), so it can be liberated from the implementation details of the cumbersome framework program in the study, and put the main focus on the study of simulation function and interactive function of the system. To sum up, the construction of virtual campus roaming system is divided into three steps, shown as follows.

1. On the basis of collecting the campus data in the previous period, we make use of Gen Creator Multi to build the virtual campus three-dimensional model.

The campus map file *.dwg is stored in the South CASS7.0 mapping software as CAD R12/LT2 DXF *.dxf Auto format. File *.dxf is input into the Gen Creator Multi, namely the upcoming map is input into the Gen Creator Multi modeling software. On the basis of the two-dimensional map in Gen Creator Multi, respectively, we model buildings, roads, trees, streetlights, lakes, grasslands, gates, and so on.

We use Photoshop software to process the photos taken in the early stage and produce texture image. Virtual campus 3D model will be used for Prime Vega visual simulation, and the size of the texture must be $2n \times 2n$, so the size of the texture is set to 1024×1024 pixels. Make the texture on the surface of the three-dimensional model, and then the establishment of three-dimensional virtual campus modeling is completed.

2. Load the modeling file *.flt in step (1) into Prime Vega, the virtual campus, and proceed the preliminary design of engine of virtual campus roaming system, such as pipeline

configuration, window configuration, rendering of virtual environment, motion mode, and navigation path configuration, so as to get the *.acf file.

3. Load *.acf file obtained in step (2) into the MFC framework built to complete various functions of the system, such as walking and driving mode, fixed-path roaming mode, environment control, improvement of query, and modification of attribute.

2.2.2 Development of virtual campus roaming system based on MFC framework

MFC is a fairly mature library. Developing application program having a good graphical user interface under Windows platform based on MFC library is the most convenient way. Therefore, a good graphical user interface based on MFC is the most convenient way to develop visual simulation program.

The development of virtual campus roaming system based on the MFC framework needs to solve two problems. One is how to render the three-dimensional scene of virtual campus to MFC view window. The other is how to proceed frame cycle of the virtual scene. First, vp Window provided by Vega Prime comes from vs Window, which is generated from vr Window that provides a set Parent (Window win) function. It is seen that it only needs to transfer the kind of MFC view window to the vp Window, namely vp Window *vp Win = *vp Window: begin (); vp Win->setParent (m_h Wnd); only by doing like this can the virtual campus 3D scene be rendered to view window (Earnshaw R. A, 2014). Second, the system frame cycle can be achieved in two types of methods. The first one is to set a timer, namely after application program completing, run the initialization, definition, and configuration, setting a timer, and then proceed frame cycle in the message processing function. The second method is to create an additional Windows thread and complete Vega Prime application in the thread.

3 DETAILED DESIGN OF SYSTEM FUNCTION

3.1 Specific design of system function

Consistency of style is very important. Note the spacing, punctuation, and caps in all the examples below.

3.1.1 Walking mode

In Vega Prime, use vp Motion to define abstract motion model, while the specific motion patterns are as follows: Motion Drive, Motion Fly, Motion Walk, Motion UFO, and so on, all of which inherit

the class of vp Motion. vp Motion can specify input device as the method of controlling motion mode, such as keyboard and mouse. If no input device is specified, the motion model will enable default of their devices as the input of the system. The control of default in the motion mode is packaged in the various classes of motion mode. For example, in the driving mode, Source Boolean controls the acceleration and deceleration of the vehicle model, and Source Float controls the left turn and right turn of the vehicle model.

In the navigation interface of the system in Visual Studio, add a Radio type button and a Slider type controlling button, respectively, to set up whether choose walking mode or not and the speed of walking mode, and the control node of walking control code mode is as follows:

```
Vp Transform *Transform_walk = vp Transform: find ("Transform_walk").
```

3.1.2 Automatic roaming mode

In the realization of the automatic roaming mode function, the tool to be used is Path in the LynX Prime. Path Tool is a tool used to create path control points and navigation files in the automatic roaming of a system. Fixed path in Vega Prime has two meanings: the first is a series of control points of the navigation path set by the users, which are stored in the .way file. The file stores the 3D coordinates of each control point and the attitude of each point; which is followed by a navigation device. Navigation file provides a data structure for each control point. Information stored in the data structure contains the connection method from current control point to the next control point, moving speed from the current control point to the next control point and so on. These messages are stored in the .nav file, and the navigator, through the interpretation of the data in the .nav file, controls the motion of object or the observer's state.

In the automatic roaming mode, five automatic roaming paths are set up, which basically cover the whole campus scene. Five school bus models are added in the virtual scene of the campus, each of which uses an automatic roaming route. In the navigation system interface, add a Radio button to control the automatic roaming mode selection, and a dropdown list box to determine which path the user should choose. The realization code of the two controllers is shown as follows.

Realization process of Radio button is:

If Radio button is pressed, the automatic path is set up as the first path.

```
Int nCount = m_Combo Auto.Get Count();
if (n Count > 0)
{
m_Combo Auto.Set Cur Sel(0);
On Selchange Combo Auto ();
```

```
}
vp Transform *tran = vp Transform:
find("Transform_car0");
Drop-down list box control implementation
process is:
int n Sel = m_Combo Auto.Get Cur Sel ();
if (n Sel != -1)
{
// obtain the selected path and set up it
vp Transform *Trans = (vp Transform*) m_
Combo Auto.Get Item Data (n Sel);
if (Trans)
(*vp Observer::begin()->set Look from(Trans);
}
```

In order to prevent the emergence of the car model in the mountain drill, it is necessary to add tripod Isector detector whose target is the terrain. Tripod Isector detector is composed of line segment that is, respectively, perpendicular to the Isector (X-Width/2, Y-Length/2), (X+Width/2, Y-Length/2), and (X, Y, +Length/2); these three coordinates, coordinate, and X and Y represent the current position of Isector. The method is that three line segments and the points intersect with the terrain form a triangle, output the triangle center value of Z and pitch value and roll value corresponding to the center Z and the current direction of the intersect vector, so the car and terrain model can be tightly attached together, but not to drill into the mountain, and the effect is shown in Figure 1.

3.2 Application of system database

3.2.1 Establishment of tree structure and modification of nodes

In order to enhance the interactivity and immersion of the whole system, users can browse the virtual campus scene better and have a better understanding of the whole virtual 3D scene, add a

Figure 1. Tripod detection effect diagram.

set of tree structure and attribute display bar at the interface of the system, and all objects in the three-dimensional scene has a corresponding node in the tree structure. As shown in Figure 2, the three-dimensional scene is the Information Engineering Institute of the campus. In the tree structure, there is a corresponding node called “Information Engineering Institute”.

The structure of the tree building method is as follows: first, to create a global database object and connect to the database each time the system boots; second, when the database connection is successful, to create the tree structure by using a recursive function according to the relationship of nodes in the Observer Position table.

When we use the right mouse button to click the node in the tree structure, the management menu will pop up. When the root node is clicked, the deleting item node and the modified position item will become gray, which is unable to be used. When the other node is right-clicked, all options are available. When the user clicks the adding node option, it will pop up a dialog box, and then the user can choose the type of node and add a subnode. For example, when the school builds a few teaching buildings, the school has introduced a number of new teachers, and in the new term school has recruited some freshman, able to add subnodes through the user’s choice. Therefore, the realization of this function has a significant impact on the school management, planning, and user’s perception of the school. The method to add a subnode is first adding a subnode for the current node in the tree structure, then setting up the value of new nodes in Observer Position table, and finally inserting the attribute data in the attribute table for the new nodes. The method to delete a node is as follows: first, to find the brother node or parent node of this node, to ensure that after deleted, it still exists the selected node, and then delete the node and all subnodes. Finally, delete the information in response to the database.

Figure 2. Tree structure.

3.2.2 Realization of modifying location and querying function

When the user opens the tree and right-clicks on a node, it will pop up a menu, in which there exists an option called “modify the location”, whose function is to record the current position of the view and store it in a database. The implementation of this function is convenient for users to modify the scene position in the database and the major node to achieve the function as shown below (Gan, Q, 2015):

```
observer->get Position (&x, &y,&z);
observer->get Rotate (&heading, &patch, &roll);
// obtain the current selected point
HTREEITEM itm = this->Get Selected Item ();
Observer Position * obp = (Observer Position*)
    this->Get Item Data(itm);
// store the data in the database
sz SQL.Format(“UPDATE observerposition
    SET x = %lf, y = %lf, z = %lf, heading
    = %lf, patch = %lf, roll = %lf WHERE
    id = %d”,
    x, y, z, heading, patch, roll, obp->id);
p SYSDB->Execute SQL (so SQL);
Update the data in the system
obp->x = x;
obp->y = y;
obp->z = z;
obp->heading = heading;
obp->patch = patch;
obp->roll = roll;
```

The function of query is that when the user does not know the position of a node in the virtual scene, it can double-click the node in the tree structure and render the 3D virtual scene on the left-hand side of the screen, and the view will be cut from the view of the current node to the view of the node that the user double-clicks. That is to say, “fly” to the destination from the current position, and complete the inquiry work. As a result, this function improves the user understanding of 3D virtual scene and greatly enhances the interactivity and immersion of virtual campus roaming system. The design idea of the function: when the user double-clicks a node, it will first calculate the six parameters, X, Y, Z, H, P, and R, of the current view and the difference value of the view of the destination node, and then the difference value is averagely divided into several parts, to get the increment of each flight, and finally open a timer (Jiao, N, 2014). In each period of time, complete a viewpoint change of flight increment. Destruct the timer and complete query function until six freedom parameters of the current viewpoint is equal to the six freedom parameters of the viewpoint that the user double-clicks The main code of this function is as follows:

```
// Calculate the difference value between the two
view points
```

```

double x Len = m_pos End.x - m_pos Begin.x;
double y Len = m_pos End.y - m_pos Begin.y;
double z Len = m_pos End.z - m_pos Begin.z;
double h Len = m_pos End.heading - m_pos
Begin.heading;
double p Len = m_pos End.patch - m_pos
Begin.patch;
double r Len = m_pos End.roll - m_pos Begin.
roll;
Calculate the increasing amount in each flying
m_pos Delt.x = x Len/n Times;
m_pos Delt.y = y Len/n Times;
m_pos Delt.z = z Len/n Times;

3.2.3 Voice information broadcasting function

Music added in the virtual scene usually has three modes: the first one is to simulate a real sound in life, which usually considers the factors that the sound reduces due to the propagation in the medium and Doppler effect, so it is true. For example, the roar of aircraft in flight and driving sound will be weakened as the car and the airplane objects get away from the observer; the second kind is background music, whose sound does not change with the location of the observer; the third is speech information, namely voice introduction. The sound will not change with the change of the location of the observer.

Essential node objects in the tree structure of the object system are added with the voice information. The voice information, through special recording, has been added to the sound value of each node objects in the database, and users can also use the menu item to manually add voice information for the node object. When the node object in the tree structure is double-clicked, the speech information will automatically play so that the user can increase understanding of 3D virtual campus.

4 CONCLUSION

People's understanding and accepting ability of visual, acoustic, tactile, and other sensory information is far greater than that of numbers in such kind of abstract information. Along with the rapid development of computer technology, visual simulation is more and more widely used in military training, emergency, simulation of driving, city planning, and many other areas.

This paper completes the development of the virtual campus roaming system based on MFC framework, in which the research is on environment rendering technology, so users can browse through the mouse to control to roam in virtual campus. The research work is summarized as follows. First, use GPS and total station to measure the whole area of the campus, then get a two-dimensional map of the campus, and finally use Multigen Creator to make a three-dimensional model of the scene of the campus (Jun, T, 2015). In addition, by in-depth study using Vega Prime software technology, import the virtual campus 3D model into Prime Vega software and configure the relevant parameters to get the ACF file, namely the initial and simple visual simulation of the virtual campus.

The Access is chosen as the virtual campus roaming system of external database to realize data query, modify, and carry out other functions. The model in the scene is corresponding to the attribute information model, to complete the query function of the virtual campus scene model, and be convenient for users' understanding and cognition of the 3D virtual campus; add data model and node of the tree structure for the system to modify the attributes of the nodes to enhance the system scalability and performance management; add voice information broadcasting function for each data node in the system to improve the immersion and interactivity of the system, so as to increase users' awareness of the system. Three-dimensional virtual campus technology plays a very important role in the external propaganda, enrollment, and the appearance of the campus, and it is an important part of campus information construction. Therefore, the development of the virtual campus roaming system is of great significance to the development of visual simulation system in the future.

Analysis on sustainable financial framework and fare adjustment strategy of China's urban public transit

Sa Xu, Cheng Li, Xianglong Liu & Yunke Du

China Academy of Transportation Sciences, Ministry of Transport, Beijing, China

ABSTRACT: This paper aims to design a feasible financial framework and fare adjustment strategy to intensify the financial sustainability of China's urban public transit service, therefore to support the policy of transit priority and the development of transit metropolises in China. The fiscal problems in China's public transit, the skyrocketing operating costs of public transit companies, unsustainable urban public financial subsidies, decreasing attraction of low fares to the passenger flow, are analyzed by the data on the operating costs, fares, subsidies and other information collected from Beijing, Shenzhen, Zhengzhou and other China's typical urban public transit companies. The relationship among transit service quality, costs, fares and government subsidies is analyzed systematically based on the demands of three major interest subjects in city public transit, namely passengers, businesses and governments. Based on the principle of "acceptable for the public, sustainable for businesses, and affordable for government finance", the paper proposes a feasible service quality-oriented and sustainable financial framework of urban public transit operation for China which clarifies the responsibilities of all the stakeholders in the framework. Finally, the paper offers specific fare adjustment strategy, in which the public transit fare adjustment coefficient is playing the role in the trigger mechanism.

1 INTRODUCTION

With China's urbanization and mechanization pressing ahead, cities continue to expand, and urban population and traffic volume increase rapidly. As a result, traffic congestion, security issues, environmental pollution and energy depletion are increasingly prominent, becoming the bottleneck of urban sustainable development and imposing great pressure to the construction of a resource-conserving and environment-friendly society. Urban public transit possesses advantages such as high holding volume and efficiency, and low energy consumption and pollution. Learning from Europe, Japan, Singapore and South America, China is striving to prioritize public transit to reduce environmental pollution and energy consumption, and to achieve low carbon and sustainable development.

Chinese government has attached great importance to the development of urban public transit, and issued many important documents, including Guiding Opinions of the State Council on Giving Priority to Public Transportation in Urban Development, to further specify national prioritization of public transit development. Pushed by the accelerating urbanization and guided by the national transit priority policies, China's urban public transit has come a long way. As shown in the annual report of China urban passenger trans-

portation development, (MoT, 2011–2013), by the end of 2013, the annual passenger capacity and daily capacity of China's urban public transit have amounted to 128.335 billion person times and 351 million person times respectively. There are 41,783 operating routes for buses and trolleybuses nationwide, totaling 749,000 km. Metro construction is moving forward steadily. 15 cities in China have 81 rail transit lines with a total length of 24,079 km. An urban rail transit network covering major cities like Beijing, Shanghai, Guangzhou and Shenzhen have taken shape. 22 cities have operated the BRT (Bus Rapid Transit) system with the operating routes amounting to about 2,752 km. Cities like Jinan, Changzhou and Zhengzhou have built a preliminary online operating system for BRT which is gradually playing a major role in urban transport systems.

To implement the transit priority policies, governments in many cities have issued a series of relevant policies and measures. One important measure is to combine low fares with large financial subsidies. In other words, governments purchase public services from businesses through financial subsidies. The measure has promoted the utilization and share of public transit by reducing the traveling costs of the public. Due to deficient support in relevant policies, however, urban public transit faces problems on the sustainability

of finance, such as the ever-increasing operating costs, the difficulties of public transit businesses in operation, the overwhelmed financial subsidies and so on. Those problems have affected, to some extent, the healthy and sustainable development of China's urban public transit.

2 REVIEW OF LITERATURES AND INTERNATIONAL EXPERIENCES

Methods of fare and subsidy adjustment is a common issue in many cities worldwide and there are many valuable experience in their practices.

In 1998, Singapore adopted the price-cap model for the regulation of public transit fares. The fare adjustment cap formula of this model was "CPI+X", among which CPI represented change in the Consumer Price Index over the preceding year, and "X" was set to compensate the operators for net cost (after considering wages and productivity) increases beyond inflation. When economy growth slowed down or passengers' capacity to pay fares declined markedly, the Public Transport Council would launch this model to adjust fares. This formula was optimized in 2005, further balancing the interest of public transport operators and passengers. Some macroeconomic indexes such as CPI and WI were involved. The optimized formula was: fare adjustment cap = price index = $0.5CPI + 0.5 WI - X$. Between 2005 and 2012, X was set at 1.5%.

In South Korea, the Seoul Metropolitan Government (SMG) is authorized by the Seoul Metropolitan Council (SMC) to adjust the basic fare of public transit every two years. The requirement for adjustment is usually proposed by public transport businesses and associations to relevant authorities who will, after examination and approval, report to the President. The decision is approved for execution by the mayor of Seoul. Besides, SMG will also solicit opinions from SMC.

In Hong Kong, bus companies have been allowed to promote fares with the increase of inflation. The government has a Fare Adjustment Arrangement for Franchised Buses (FAA): operators can decide by themselves when to submit a fare adjustment application, and the government also has the right to lower fares. In every season, the Hong Kong Transport Department (HKTD) will calculate the supportable fare adjustment rate based on a formula: supportable fare adjustment rate = $0.5 \times \text{Change in Wage Index for the Transportation Section} + 0.5 \times \text{Change in CCPI} - 0.5 \times \text{Productivity Gain}$.

Chinese scholars have conducted broad studies on the financial sustainability of public transport in recent years.

He and Ye (2012) pointed out the problems in existing subsidies, including ambiguous targets (cannot guarantee that the limited subsidies are

used by the most needy ones), a lack of diverse forms (mainly direct financial subsidies for state-owned public transit companies) and limited capital resources (all come from local finance). They proposed that a clear line should be drawn between policy-related losses and operational losses, routes making profits and ones suffering losses; subsidies for producers and those for consumers, infrastructure construction and public transit operation, and between two purposes, namely providing universal services and guiding the way to travel.

Mao and Sun (2011) pointed out that to address problems facing the operation of public transit companies, the government should, first, innovate its subsidy mechanism for public transit and build a long-term mechanism, and second, create a reasonable linkage pricing mechanism and properly introduce market regulation.

Li, Song and Ren (2009) provided many suggestions. First, completing subsidy procedures to ensure that subsidies are provided and utilized in a scientific and efficient way. Second, building an information disclosure mechanism to provide institutional guarantee for the efficient use of subsidies. Third, strengthening social evaluation and supervision of public transit subsidies to ensure timely feedback, and making service quality an important evaluation indicator of financial subsidies. Forth, supporting IT application in public transit and introducing a competition mechanism.

Yang (2011) pointed out three problems existing in China's low fare policy. First, as people with their own cars are not sensitive to public transport fares, it is difficult to promote the utilization of public transport. Second, as low fares have attracted many cyclists and pedestrians, public transport means have become increasingly crowded, forcing some passengers to travel by their own cars. Third, targeted measures are lacked in subsidizing the traveling of vulnerable groups. Yang suggested that more subsidies should be used to aspects that can promote public service quality, such as shortening traveling distance and passengers' waiting time, reducing transfer times, and shortening passengers' distance to bus stations.

3 ANALYSIS ON FINANCIAL SUSTAINABILITY OF CHINA'S PUBLIC TRANSIT

The policy of combining low fares with large financial subsidies in urban public transit service has promoted the utilization and share of public transit markedly in China. Simultaneously, the urban public transit is facing problems on the sustainability of finance, which has affected, to some extent, the healthy and sustainable development of China's urban public transit.

The first problem is the ever-increasing operating costs. The operating costs of public transit companies can be divided into the following categories: labor cost, fuel cost, depreciation cost of fixed assets, maintenance cost, management cost, financial expense, sales tax and additional expenses. According to a survey on the operating costs of urban public transit businesses in 18 municipalities directly under Henan Provincial Government (Figure 1), labor cost and fuel cost together, totaling almost 65% of the overall costs, form the largest part in the cost structure of public transit businesses.

As global economy has a fast growing demand for energy, global oil prices have increased steadily in the past decade, so have the gasoline and diesel prices in China. In 2014, global oil prices declined markedly, but decline in China's domestic gasoline prices has been much shallower than that in the international market. Figure 2 shows the growth of China's gasoline prices between 2003 and 2013.

With rapid economic growth, national income and per capita wage have increased at a rather high speed, driving up the labor costs in almost every industry. As shown in Figure 3, according to the Statistics data (National Bureau of Statistics of China, 1990–2012), the annual salaries of urban employees in China between 1990 and 2013.

According to above analysis, the major reason for the rising operating costs for urban public transit companies lies in the fast growth of price index, energy cost, labor cost and other costs (see Figure 4).

The second problem China's urban public transit facing is the low fares and no fare adjustment

mechanism. Guided by transit priority policies, many provinces and cities have regarded public transit as a commonweal cause and kept the low fare policy for a long time. A survey conducted in six cities, namely Beijing, Shanghai, Shenzhen, Guangzhou, Zhengzhou and Jinan (see Table 1) shows that these cities haven't changed public transit fares for years and do not have a stable and complete fare adjustment mechanism.

In these cities, the implementing fares (fares that passengers actually pay) are lower than cost prices, and the part of price higher than cost prices is compensated by the fuel subsidies of the Central Government and public financial subsidies from local governments. A survey shows that the ratio of implementing fares to cost prices are less than 50% in Beijing, Shanghai and Shenzhen, and that in Beijing is even lower than 20%. This means Beijing Municipal Government provides a financial subsidy that is four times of the implementing fares for public transit companies to support the daily operation of the public service system.

The third problem is the difficulties of public transit businesses in operation in China. According to the above data and analysis, the fast increasing price index, labor cost and fuel prices have driven up the operating costs of China's public transit businesses. Fares have dropped away from costs for a long time, leading to severe losses of public transit companies. Most of them are counting on public financial subsidies for operation. Meanwhile, under the strategy of prioritizing public transit development, governments have asked these companies to

Figure 4. Operating costs of Zhengzhou Municipal Public Transport Corporation between 2008 and 2010.

Table 1. Public transit fares in 6 Chinese typical cities (2013).

City	Base fare (RMB)	Years without adjust	Price discount	Fare comparing to cost
Beijing	Base fare: 1	6 years	Have	Lower than cost
Shanghai	Aver. 1.8 /ride	14 years	Have	Lower than cost
Shenzhen	Aver. 2.02 /rid	7 years	Have	Lower than cost
Guangzhou	Base fare: 1 or 2	14 years	Have	Lower than cost
Zhengzhou	Flat price: 1	10 years	Have	Lower than cost
Jinan	Base fare: 1 or 2	14 years----	Have	Lower than cost

Table 2. The ratio of implementing fares to cost prices in 3 Chinese typical cities (2011).

City cost price (RMB)	Amount and ratio of cost for each ride		
	Implementing fare	Subsidy from central government	Subsidy from municipal government
Shenzhen	49%	16%	35%
Beijing	0.40	0.29	2.46
Shanghai	13%	9%	78%
	1.80	0.42	1.38
	50%	12%	38%

add new routes and increase frequencies. Some of the newly added routes have little passenger flow and thus little fare revenue, imposing more pressure on the policy-related losses of these companies. Besides, these companies indicate that financial subsidies have fallen short of their policy-related losses. Governments have had no auditing methods to check the authenticity of the financial information submitted by companies, and while authorizing subsidies, they would simply lower the subsidies applied by companies, leading to greater losses of the companies. Long-term losses have led to high working intensity of drivers, low salaries, and bad vehicle conditions, lowering the service quality and attraction of urban public transit and affecting the healthy operation of public transit companies. Citizens are quite dissatisfactory towards the vicious cycle in public services.

Overwhelmed financial subsidies is the fourth problem in current China's urban public transit. Under the background of China's transit priority policies, many cities such as Beijing and Shenzhen have started to subsidize low fares of public transit to make up for the policy-related losses of public transit businesses.

Beijing started to adopt low fares and financial subsidies in 2007. Bus routes adopted a single fare of 1 RMB. Passengers with an ordinary card could get a discount of 60% off, and those with student cards, 40% off. Only a small amount of routes adopted distance-graduated fares. A flat fare of 2 RMB was needed for all metros except the airport line. Since the implementation of low fare policies, the subsidies provided by Beijing Municipal Government skyrocketed from 1.81 billion RMB in 2005 to 20 billion RMB in 2013, an average growth rate of 38% in 8 years. The proportion of public

transit subsidies in urban budget revenue increased from 2.24% to 5.89% (Figure 5).

Shenzhen also started to adopt low fares and financial subsidies in 2007. Since the implementation of low fare policies, the subsidies provided by Shenzhen Municipal Government skyrocketed from 1.033 billion RMB in 2008 to 6.3 billion RMB in 2013, an average growth rate of 44% in 6 years (Figure 6).

According to the above data, all cities carrying out low fare policies and public transit subsidies see a remarkable increase in their subsidies and the proportion of subsidies in local budget revenue and expenditure, and suffer from extreme pressure on public finance.

The fifth problem is the decreasing attraction of low fares. Low fares have greatly saved people's traveling costs, and promoted the utilization and share of public transit at the initial stage. In recent years, however, companies suffering from skyrocketing operating costs and low fares have made it harder to guarantee or improve service quality. As the public has become less interested in low fares and asked for higher service quality, and families have been buying more cars, the single preferential policy of low fares can no longer attract more people to use public transit, thus leading to the declining utilization rate of public transit. Figure 7 shows changes in the proportions of various transportation modes in Beijing's urban traffic from 1986 to 2011. Although the overall proportion of public transit including rail transit had been increasing due to the fast growth of passenger flow in urban rail transit, the contribution rate of public buses and trolleybuses declined from 28.9% in 2009, two years after ticket price reform, to 28.2% in 2011.

Figure 5. Proportion of Beijing transit subsidies in budget revenue between 2005 and 2013 (%).

Figure 6. Shenzhen public transit subsidies between 2008 and 2013.

Figure 7. Proportions of transportation modes in Beijing from 1986 to 2011.

4 SPECIFIC STRATEGY OF FARE ADJUSTMENT MECHANISM

Only when costs change will the proposed framework launch a fare adjustment, and the adjustment range should take into consideration changes in costs and profits (involving subsidies) and citizens' acceptance and affordability. Improving service quality is the precondition for promoting fares.

4.1 *An analysis of key factors influencing operating costs of urban public transit companies with cost composition of a few public transportation companies as examples*

The operating costs of urban public transportation, which include labor cost, fuel cost, maintenance, depreciation cost of fixed assets, financial expense and other cost items directly related with operation, are core factors influencing fares of urban public transportation. Different cost items have a varying degree of influence over the total operating cost, among which labor cost and fuel cost take about 70% or even higher of the total operating cost and thus have biggest impact on the total operating cost.

Within a certain period of time, there are many factors influencing cost levels. Among them, labor cost is affected by the overall economic level in a city

and the supply and demand dynamics of human resources in the industry, fuel cost and maintenance cost are affected by price indexes and depreciation and financial expense are mainly affected by the scale and speed of asset expansion of public transportation companies. On the basis of the analysis of key operating cost items of public transportation companies and the factors influencing each cost item, a fare adjustment model of urban public transportation is put forward. Meanwhile, along with social and economic progress, while experiencing rising operating costs, public transit companies also benefit from an increase in productivity. Therefore, in the fare adjustment model, we shall take into account some modifying factors by learning the experiences of Singapore and Hong Kong so that the public can share the benefits of economic and social progress while the public transit companies interests can be protected too.

Singaporean government developed the first fare adjustment formula for urban public transportation in 1998 and has since optimized and adjusted its formula along with social and economic development. The formula developed in 1998 was as follows: The ceiling of fare adjustment = $CPI + X$. CPI here refers to the change of CPI of the previous year and X refers to sharing of productivity rise. In 2004, Singaporean government optimized this formula to better balance the interests of public transport providers and commuters. The new formula was as follows: the ceiling of fare adjustment = $Price\ index - X = 0.5 \times CPI + 0.5 \times WI - X$. In this formula, X was 1.5% during 2005 to 2012. This formula incorporated macro-economic indicators such as CPI and Wage Index (WI) which is an index for national monthly average wage change. In 2014, the formula was fine-tuned as: the ceiling of fare adjustment = $price\ index - X = 0.4 \times CPI + 0.4 \times WI + 0.2 \times EI - 0.5\%$. The key change here is the incorporation of energy index into the formula. Obviously, along with the change in economic level, industrial scale and energy mix, the key factors influencing the operating costs of public transit companies have evolved. Besides CPI which is a key economic indicator, wage level and energy price index have a growing impact on the operating costs.

Hong Kong has also established a fare adjustment mechanism for public transit. The adjustment can be upward or downward. Bus companies have the discretion to decide when to submit a fare increase application while the government has the authority to launch the downward adjustment mechanism. Transport Department derives a range of fare change every quarter on the basis of the following formula: the range of fare change = $0.5 \times wage\ index\ change\ in\ the\ transport\ sector + 0.5 \times CPI\ change - 0.5 \times productivity\ increase$.

Wage level, CPI, energy price index are still the key factors influencing the operating costs of urban public transit companies. However, with the

implementation of low fare policy and a growing demand for public transport, under the condition that the fiscal and taxation support system for public transit is still underdeveloped by all levels of government, urban public transit companies are faced with capital shortfall in general and borrowing to make ends meet is quite common, therefore, financial cost becomes a key factor. With capital shortfall, overheads can not be neglected in the cost structure.

In a nutshell, a fare adjustment formula is put forward that is well suited to the features of the urban public transit industry in China. We did a trial run on the formula using Qingdao Bus Group as an example. Through analyzing the operating cost data of Qingdao Bus Group in 2012–2014, we estimated the weighting coefficient and key indicators of each factor in the formula.

4.2 *Trigger mechanism of fare adjustment*

4.2.1 *Considerations*

- Computing results of the fare adjustment formula.
- Changes in operating costs and profits since last adjustment.
- Prediction of future costs, earnings and returns.
- Reasonable rates of return of public transit companies.
- Acceptance and affordability of citizens,
- Service level of public transit.

4.2.2 *Conditions*

Public transit fare adjustment coefficient K:

$$K = C_1 \times \left(\frac{L_n}{L_0} \right) + C_2 \times \left(\frac{E_n}{E_0} \right) + C_3 \times CPI_n + C_4 \times \left(\frac{F_n}{F_0} \right) + C_5 - 0.5 \times X$$

If K exceeds the threshold (such as 5%), operators and government departments can launch an application for adjustment.

4.2.3 *Notes for K*

- n: the year of fare adjustment;
- 0: base/reference year (the time of the last adjustment);
- C1: weight coefficient of salaries in the overall costs;
- C2: weight coefficient of fuel cost in the overall costs;
- C3: weight coefficient of other operating costs that are closely related to the overall price index (such as cost in tires and repair cost) in the overall costs;
- C4: weight coefficient of other major changes in operating costs (such as tax change) in the overall costs;

- C5: weight coefficient of other operating costs that are slightly related to the overall price index (such as depreciation cost in fixed assets) in the overall costs;
- X: Absorptivity of businesses through their own efforts, the proportion of cost increase when companies promote productivity through technological innovation and management optimization.

$$4.2.4 \quad C_1 + C_2 + C_3 + C_4 + C_5 = 1$$

4.2.5 *Basis for factors in the formula of K*

- L represents the average salary in the city;
- E represents the average fuel price in the city;
- CPI is the Consumer Price Index of the city released authoritative institutions;
- F represents the weighted average of three-five years lending rate published by the people's bank of China (the people's bank of China's Announcement);
- Absorptivity is settled by the government in advance.

4.2.6 *Design idea of the formula*

As mentioned in section 2, labor cost and fuel cost account for a major part (about 70%) in the operating costs of China's urban public transit, and thus C1 and C2 should be calculated separately. To simplify the calculation, expenses closely related to CPI can be calculated together as C3, and changes that are less related to CPI but will greatly affect operating costs (such as tax change) should be calculated as C5. Any normal companies should reduce costs through technological innovation and management optimization, and thus absorptivity is involved to encourage the self-improvement of the companies.

4.3 *The decision mechanism of fare adjustment*

The computing result of K should serve as the basis for fare adjustment, but it shall not determine the adjustment range. The final range shall be recalculated based on the computing result of the fare adjustment formula, changes in operating costs and profits since last adjustment, prediction of future costs, earnings and returns, reasonable rates of return of public transit companies, and acceptance and affordability of citizens. It is suggested that the recalculation be conducted by an independent third-party, such as a professional consulting agency, entrusted by the city financial departments.

Acceptance and affordability of citizens is a crucial consideration. Price policies in public transit directly affect the interests of the public especially the low income group. While investigating the affordability of the public, China can refer

to the achievements of cities like Singapore, and set an affordability indicator, such as an upper limit in the proportion of public transit spending in monthly family income for typical families. As an important standard measuring whether ticket price is reasonable, the affordability indicator should follow closely the following indexes: 1) the proportion of monthly average public transit spending in total family income; 2) the proportion of monthly average public transit spending in total family spending. Under the precondition of a stable ratio between fares and citizens disposable income and stable passenger flow, the fare can be adjusted based on the increase of family income, and a diverse fare system can be built based on the principle of high quality and competitive price to provide differentiated public transit services and meet the various demands of different groups.

Fare adjustment does not only mean the increase or decline in fares, but also refers to the adjustment in the fare system which serves as an expression and adjustment method of fare level and price relations. At present, fare systems can be divided, based on factors such as travel time, distance and areas, into flat fare, metered fare, time sharing fare and partition fare. One form of fare adjustment is that cities can design its fare system by comprehensively taking into consideration its passenger transport structure, features of passenger flow and systemic conditions, and build a multi-level, differentiated price system to strengthen the attraction of public transit.

In the proposed framework, improving service quality is the precondition for promoting fares. While applying for promoting fares, public transit companies should promise to enhance their services. Assessment on service level should follow standard procedures to ensure its fairness and accuracy.

As shown in Figure 8, detailed procedures for fare adjustment are:

1. Public transit companies submit a fare adjustment application and an introduction report to city departments of transport and finance.
2. City departments of transport and finance work together to decide, based on the launching formula of fare adjustment, whether to accept the application or not.
3. After the application is accepted, the reasonable adjustment range would be recalculated. This is suggested to be done by an entrusted independent third party such as professional consulting institutions.
4. The city public transit consulting agency consisting of relevant government departments, companies, experts and citizen representatives would study the adjustment plan after the recalculation.
5. The city public transit consulting agency consisting of relevant government departments,

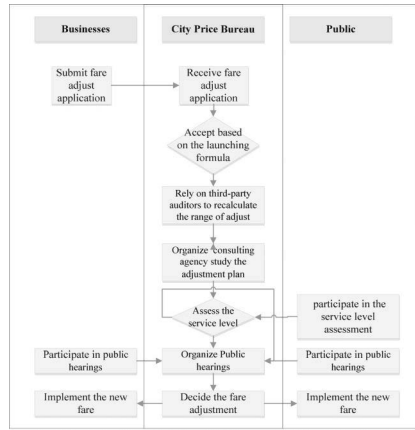

Figure 8. Flow chart of fare adjustment.

companies, experts and citizen representatives would assess the exiting service level of public transit, and make the assessment result the precondition for promoting fares. Public transit companies shall promise to provide better services after the adjustment.

6. Relevant departments disclose the reasons and range of fare adjustment to the public based on relevant laws and regulations, and organize hearings.
7. Relevant departments make the decision of fare adjustment.

When companies do not apply for adjustment, relevant government departments shall recalculate fares on a regular basis, for example, every three years. Based on the recalculation, and considering the economic and social development, the government shall decide whether to conduct fare adjustment or not.

5 THE FARE ADJUSTMENT CAST STUDY-QINGDAO

Average adult base cash fare level of Qingdao Bus transportation is CNY1.00 with no adjustment from 2000 to now. By analyzing the operating cost data of Qingdao Public Transportation Group in 2012–2014 and statistics of Qingdao government, the factors of fare adjustment formula are as followings:

According to the fare adjustment formula, $K_{qingdao2014} = 1.113$, the Qingdao government should trigger the fare adjustment mechanism and the upper limit of new adjusted average adult base cash fare level should be $1.113(K_{qingdao2014} * P_{2012} = 1.113 * 1)$. Even Qingdao government adjust the fare level up to CNY1.113, the new fare level would be much lower than the real cost fare.

Table 3. The factors of fare adjustment formula-Qingdao case study.

Factors	Value
L_{2014}/L_{2012} (a)	1.296
E_{2014}/E_{2012}	0.942
$CPI_{(2014.12)}$ (b)	1.026

Operating cost fare	2.845
Implementing fare	1.000
Adjusted fare	1.113

6 CONCLUSIONS

Sustainable finance is essential for the stable development of public transit companies, efficient utilization of government subsidies, and better service quality in public transit. Focusing on the three major stakeholders of public transit, namely the government, businesses and the public, this paper deeply analyzed issues related to the financial sustainability of China's urban public transit. Based on the principle of "acceptable for the public, sustainable for businesses, and affordable for government finance", the paper proposed a service quality-oriented framework featuring the interaction among operating costs, financial subsidies and fare adjustment and offered specific strategy in fare adjustment, providing a reference for cities in China and other countries to build a scientific fare and subsidy adjustment system and to foster the healthy development of public transit.

ABSTRACT: Accessible improved sanitation is critical to child health, and inequities in improved sanitation can be interpreted as health inequities across socio-economic groups. This study assesses the equity of sanitation improvement in China and finds out the bottleneck problems on equity across provinces. Based on United Nations Children's bottleneck analysis framework and practical situation, we established a scale questionnaire, which included four dimensions—policy environment, supply, demand and quality. A new equity-score model was generated to review sanitation improvement. We regarded questions with the three lowest scores as the bottleneck of sanitation improvement within province. The bottleneck problem of policy environment, demand, quality across provinces were Question 11, Question 23, Question 29 and 30. Questions on supply dimension were much better. As for the equity score, Question 6,9,25,27,28 were the lowest scores and indicated the inequity on sanitation improvement. The bottleneck problems of equity derive from relevant propaganda campaign, training and following interventions. Economic condition was the primary factor influencing sanitation improvement. The key work should be more effectively promoting the sanitation improvement on demand dimension. Health Departments should highlight the announcement of health-related knowledge.

1 INTRODUCTION

Globally, approximately 2.4 million deaths (4.2% of all deaths) could be prevented each year if everyone practiced appropriate hygiene and had good, reliable sanitation and safe drinking water (Prüss-Üstün et al. 2008). Most of these deaths are children in developing countries and result primarily from diarrhea and subsequent malnutrition, as well as other diseases that are attributable to malnutrition. It has been acknowledged worldwide that good sanitation plays an important role in reducing domestic 0-5-year-old child mortality (Hutton 2013). The World Health Organization estimates that there are 74,000 children under 5 years old die each year in China due to diarrhea (Boschi-Pinto et al. 2008). The keys to diarrhea disease control are access to safe water, improved sanitation and regular hygienic practices.

Sanitation improvement in rural China is worthy of close attention because China is one of the largest developing countries, and has a rural population of 971 million people. The rural population accounts for approximately 72% of the total population (National Bureau of Statistics of China 2012). The Chinese government has attached importance

to sanitation improvement for over the last decade and has incorporated the improvement of sanitation in rural areas into its national 5-year plan since the 1990 s. In 2009, to promote public health service levels and equity, the Chinese government launched a 3-year health reform program and set sanitation improvement as one of the major public health services. Opinions of the Communist Party of China (CPC) Central Committee and the State Council on expanding medical and health system reforms indicated that government input on health services would be gradually increased (Zhang et al. 2013). In recent 3 years, the Chinese government invested a total of 4.448 billion yuan (0.74 billion US dollar) for rural sanitation improvement (Ministry of Finance 2012). In addition, the coverage rate of improved sanitation in rural China rose from 50.9% in 2003 to 71.7% in 2012 (Ministry of Health P.R. China 2013).

In terms of the disparity in sanitation coverage rates among different regions, by the end of 2011, the highest was 98% in Shanghai and the lowest was 40.9% in Guizhou Province (Laiyun 2012). Clearly the sanitation coverage rate varies greatly among different regions due to substantial gaps in economic development levels, efficiency of government execution, and

other factors. However, macro-data on the national level often concentrates on economy, education and temperature etc. which are essential but not easy to change in a short term. Therefore, some influential factors encountered in the process of public health service program may be more visible and practical. It will be considerably beneficial to improve sanitation and health equity. Based on the current situation and equity, the objective of this study was to better understand the sanitation conditions in rural China and identify the factors that influence sanitation improvement and its equity. In addition, the implications of the findings can be provided as references for policy-makers.

2 DATA AND METHODOLOGY

2.1 Questionnaire design and data collection

In accordance with United Nations Children's bottleneck analysis framework and practical situation, we established a scale questionnaire, which included four dimensions-policy environment, supply, demand and quality. The questionnaire had 31 questions. Specifically, Question 1-3 were basic information. Question 3-14, 15-18, 19-26, 27-31 were questions on environment, supply, demand and quality respectively. Each question's score range was from 1 to 5. We chose Patriotic Health Campaign Committee Offices with more than 3 staff to fill out the questionnaire in each province and used average values to represent the score.

109 questionnaires were handed out in Anhui, Beijing, Chongqing, Fujian etc. 29 provinces and all were taken back. The number of questionnaires every province were not less than 3, and 14 questionnaires was taken back in Gansu province.

2.2 Methodology

We summarized the methods of previous scholars to quantify influential factors and generated a new equity-score model to review sanitation improvement:

$$SC_i = \sum_{j=1}^N (1 - \mu_j) \cdot (ASP_{ij} - \overline{ASP}_i)$$

$$ASP_{ij} = SP_{ij} \cdot \mu_j$$

$$\overline{ASP}_i = \frac{\sum_{j=1}^N ASP_{ij}}{N}$$

where SC_i is the equity score of Question i for national sanitation improvement. μ_j is the sanitation coverage rate in province j , using the data in 2012. ASP_{ij} is the absolute score of Question i in

province j . SP_{ij} is the original score of Question i in province j in the questionnaire. ASP_i is the average absolute score of question i .

This model was constructed as follows:

The score in the questionnaire just reflected the situation within province. If we want to standardize the results, we should adjust for the score consistent with overall situation in each province. Here we used the SP_{ij} to multiply μ_j , then we could get the standardized score across province;

Not the overall level of questions but differences among provinces should be focused on if we aimed to find out the equity and relevant bottleneck. For example, every province had a low score of Question A and provinces with higher sanitation coverage owned higher scores of Question B while those with lower sanitation coverage had lower score of Question B, then we should regard Question B not A as the bottleneck question of equity;

We used $ASP_{ij} - \overline{ASP}_i$ to eliminate national common information and just keep difference information. However, as for the information $ASP_{ij} - \overline{ASP}_i$, we should add weight value for further adjustment. For example, two provinces with different sanitation coverage had the same value of $ASP_{ij} - \overline{ASP}_i$. But the province with lower sanitation coverage would bring about worse health results, so we used $(1 - \mu_j) \cdot (ASP_{ij} - \overline{ASP}_i)$ to obtain the adjusted score.

Total score of Question i was calculated by summarizing all scores of every province. The score of SC explained the equity of sanitation improvement and low scores indicated which were bottleneck problems.

3 RESULTS

3.1 Score distribution and bottleneck problems

We regarded questions with the three lowest scores as the bottleneck of sanitation improvement within province. The bottleneck problem of policy environment across provinces was mainly Question 11- "Sanitation Management department is independent on Health department". Questions on supply dimension were much better. As for the dimension of demand, Question 23- "Local living standard has reached the level of being fairly well off" was the bottleneck problem. The bottleneck problems of quality dimension were Question 29 (most local government equips sanitation-improvement workers with excrement-processed vehicles) and Question 30 (excrement exposure is monitored and recorded regularly and sustainably).

Finding out the dimensions where bottleneck problems existed was essential to policy-making and direction improvement. So we calculated the

average score of each dimensions, as was shown in Table 1. We can see that the dimension of demand had the lowest score in most provinces (21 out of 29). 6 provinces out of 29 had the lowest score in the quality dimension. It was very evident that the bottleneck problems in dimension of demand were worst. Therefore, demand dimension should be

specially concentrated on in future work to further improve the sanitation coverage.

The equity score in each question are shown in Table 2. Questions with the lowest scores were Question 6 (The sanitation institute's level is high within province, -307.29), Question 19 (Areas without sanitation improvement yet can be fully aware

Table 1. Score of each dimension in each province.

	-335.16	-249.67	-269.56	-240.73	-239.05	-294.04	-311.19	-270.36
	27	28	29	30	31			
Quality	-300.82	-298.41	-218.41	-224.27	-270.82			

of the expense, -335.16), Question 25 (Residents' knowledge, attitudes and behaviour were improved in recent year and understand the harmful consequence of no sanitation, -311.19), Question 27 (All family who have had sanitation improvement can use toilet consistently, without going back to the situation of excrement exposure, -300.82) and Question 28 (Training on sanitation knowledge and improvement is fully and consistent, -298.41). Question 11 (Sanitation Management department is independent on Health department, -127.45) had the highest equity score among all questions.

4 DISCUSSION

The analysis is divided into two steps: the first step is to establish the questionnaire and get the absolute score, which in fact quantify the potential problems in public health service work and directly reflect weak aspects within province and on the national level; the second step is to find the disparities between provinces through equity score model and therefore bottleneck problems of equity can be found.

According to the research results, Economic condition was the primary factor influencing sanitation improvement. The key work in the foreseeable future should be more effectively promoting the sanitation improvement on demand dimension. Specifically, government should advance levels of people's daily life. Besides, Health Departments should highlight the announcement of health-related knowledge.

The bottleneck problems of equity derive from relevant propaganda campaign, training and following interventions, which also prove the right measures of human resources, financial and material investment on sanitation improvement in previous healthcare reform. However, the quality of service and training should not be ignored and it will generate enormous improvement effect on the sanitation equity in China.

Equity in sanitation improvement is difficult to measure, so we put forward a method to calculate the equity score. It is also the first time a study has systematically evaluated sanitation improvement during these years in China. Sanitation improvement is in fact influenced by many other factors, including climate and nationality (Whittington et al. 1993; Chen J et al. 2013, Hossain 1996). How these factors influence the equity of sanitation improvement and any bottlenecks in further equity improvement must be included in further study. It is also important to consider variables such as

Knowledge, Attitude and Practice (KAP) which cannot be arrived at directly. We believe there is a marked effect of disparity in KAP on sanitation improvement in China and can strongly influence the ratio of improved sanitation. In addition, our study is based on provincial panel data for China, which means that the imparities we discussed are among provinces, not within each province. To determine provincial imparities, more detailed data are needed, such as data at the municipal level or county level.

The ultimate goal of evaluating equity in sanitation improvement is to eliminate inequity, which requires determining what caused the inequity so the bottleneck and any constraints on sanitation improvement can be removed. This is the common perspective of many researchers and related departments and an important research goal.

Ultimate capacity of uniaxially compressed perforated steel plates strengthened by using CFRPs

Xin Tao & Shuangyin Cao

Key Laboratory of Concrete and Prestressed Concrete Structures of Ministry of Education, Southeast University, Nanjing, China

ABSTRACT: The aim of the present study is to investigate the ultimate capacity of perforated plates strengthened by using CFRPs under uniaxial compression along its longitudinal direction. A new test rig combined with an existing universal hydraulic testing machine has been designed to achieve simply supported along all edges. Some 36 plates were tested. Test results showed that if a CFRP is pasted on the convex surface of initial deflection, it will improve the capacity of uniaxially compressed perforated steel plates very well; otherwise, it will almost be of no effect. It also shows that the use of CFRP-strengthened perforated plates exhibit better results in a big slenderness plate with a small hole and a medium slenderness plate with a big hole. And with the use of CFRP-strengthened perforated plates with a certain plate slenderness ratio (b/t), such as $b/t = 66$, no matter how the size of the hole' diameter changes, the CFRP-strengthening effect remains stable. Also, it can be seen that the pasting of a CFRP cannot increase the stiffness before buckling, but it can improve the mechanical property afterwards.

1 INTRODUCTION

Fiber-Reinforced Polymers (FRPs) have a high strength to weight ratios and excellent resistance to corrosion and environmental degradation. It is also very flexible and forms all kinds of shapes, and it is easy to handle during construction (Alsayed et al., 2000, Moy, 2001, Teng et al., 2002); and so, it has been widely used in the strengthening of steel structures recently (Zhao and Zhang, 2007, Teng et al., 2012).

Steel plate elements are the main structural components of the deck and platforms on ships and ship-shaped offshore structures, box girder bridges and architecture structures. Openings are usually introduced in such plates for various reasons (Cheng and Zhao, 2010). The openings can significantly reduce the ultimate load of the plates. The ultimate strength of plates with openings has then been studied in the literature, e.g. Narayanan and Rockey, 1981, Narayanan and Chow, 1984, Paik, 2007. Cheng and Zhao, 2010 study the opening and strengthening of perforated steel plates that are subjected to uniaxial compressive loads and four types of stiffeners are mainly discussed; FEM has been employed to analyze the elastic and elasto-plastic buckling behaviors of strengthened and un-strengthened perforated plates.

It is clear from the above description that FRP is good at strengthening steel structures, many perforated plates need to be strengthened, and several ways to strengthen the perforated plates have been provided, but no one had tried to strengthen the perforated steel plates by pasting CFRP, and no research has been carried out on the ultimate capacity of

uniaxially compressed perforated steel plates strengthened by CFRP.

In this study, the ultimate capacity of uniaxially compressed perforated steel plates strengthened by CFRP has been studied.

2 PROBLEM DEFINITION

Ultimate capacity of perforated steel plates strengthened by CFRP subjected to uniaxial compression along its longitudinal direction is considered in the study. About 36 plates were designed, and all of them possessed the following properties: (i) square shape; (ii) four edges simply supported; (iii) circular hole as if it has an opening; (iv) one layer of transverse CFRP inside and one layer of longitudinal CFRP outside in signal or both sides of the plate if it was strengthened. A perforated steel plate strengthened by CFRP is shown in Figure 1. The length and width of the plates

Figure 1. Geometrical conditions of specimens.

are represented by a and b . The thickness of the steel plate and CFRP are given as t and t_f , respectively.

In this paper, some variations have been considered as follows:

1. The situation of the CFRP pasting: one-third was plates without CFRP pasting, the other one-third was single-side CFRP pasting and the rest was plate with double-side CFRP pasting.
2. Plate slenderness ratio b/t , which is an important parameter that governs the plate strength: in this study, the plate slenderness ratio b/t was 92, 66 and 43, respectively, corresponding to the steel plate's width t of 2.61 mm, 3.64 mm and 5.58 mm.
3. The hole diameter ratio d/b is unlikely to be larger than half the width of the plate in practice, and so it is confined to half the width of the plate in this paper. In this study, the hole diameter ratio d/b was 0, 0.1, 0.3 and 0.5, respectively.

3 METHOD OF ANALYSIS

The ultimate capacity of uniaxially compressed perforated steel plates strengthened by using a CFRP was studied with experimental methods,

and a test rig was fabricated in the laboratory (see Figure 2); the test rig was used in combination with an existing universal hydraulic testing machine. The applied loads were measured by using the dial of the universal hydraulic testing machine and static strain testing systems, which were composed by using a force sensor, DH3816, and computer. The displacement and deformation of the plates are achieved by using a displacement meter. The

	0.167	260	300	3492.5
Epoxy resin	-	Tensile shear strength (MPa)	Compressive strength (MPa)	Tensile strength (MPa)
	-	19.6	87.9	48.4

details of the plate specimen are shown in Table 1, d_0 is the initial deflection of the steel plate, and if δ_0/b is positive, it means that the CFRP was pasted on the convex surface of initial deflection, if δ_0/b is negative, it means that the CFRP was pasted on the concave surface of the initial deflection. The material properties are listed in Table 2.

4 RESULTS AND DISCUSSION

4.1 Failure patterns

Figure 3 shows the typical failure pattern of these plates. The reason why it is not so obvious to see the final out-of-plane deflection is that the experiments were ended soon after the bearing capacity declines. From Figure 3, we can see that the failure mechanism consists of four yield lines which start from the four corners and end near the hole edges, and also the steel plates and CFRP have a good coordinated working performance throughout the experiment.

4.2 Ultimate load

In Table 3, the ultimate load of each specimen is presented. It can be easily seen that the ultimate load of specimens with two sides CFRP pasting (FSCP) is bigger than specimens with no CFRP pasting (CP); however, the ultimate load of specimens with one-

side CFRP pasting (SFSCP) was not stable. Considering the initial deflection in Table 1, it seems that if the CFRP is pasted on the convex surface of initial deflection, it will improve the capacity of uniaxially compressed perforated steel plates very well; otherwise, it will almost be of no effect. This result can be explained as the CFRP has a good tensile behavior, but its compressive behavior is very poor.

Figure 4 shows the influences of the plate slenderness ratio (b/t) on the ultimate load. P_y is the yield load of the steel plate. A comparison of Figure 4a and b shows that the trends of perforated plates strengthened by using the CFRP are very similar to those curves of perforated plates without CFRP strengthening, that is, P_u/P_y degrades as b/t is gradually enlarged. Figure 4c shows that when the holes are small, such as $d/b = 0$ and $d/b = 0.1$, the CFRP strengthening effect increases as the plate slenderness ratio (b/t) is gradually enlarged. When the holes are large, such as $d/b = 0.3$ and $b/t = 0.5$, the CFRP strengthening effect first increases and then degrades as the plate slenderness ratio (b/t) is gradually enlarged. It means that the use of CFRP-strengthened perforated plates yield better results in a big slenderness plate with a small hole and a medium slenderness plate with a big hole.

Figure 5 shows the influences of the hole diameter ratio d/b on the ultimate load.

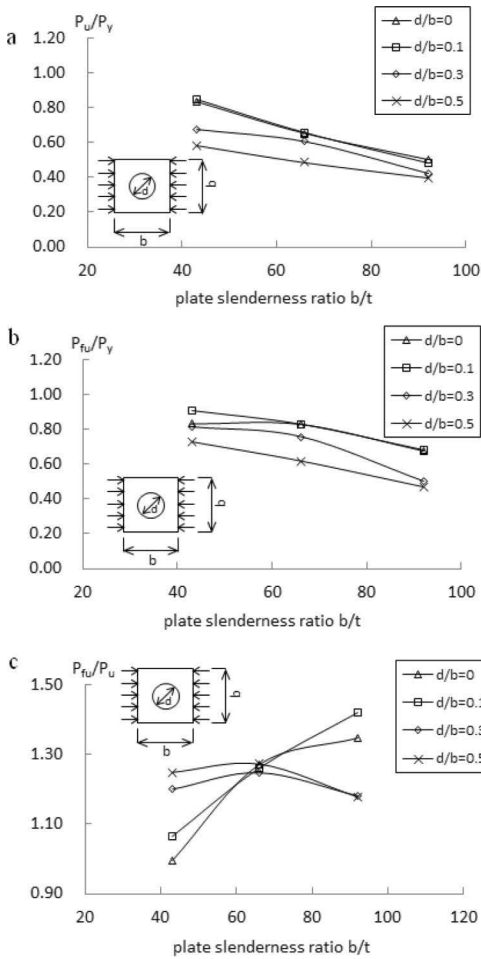

Figure 4. Graphs showing the influences of plate slenderness ratio.

The results of perforated plates strengthened by CFRP are also very similar to those curves of perforated plates without CFRP strengthening, that is, P_u/P_y first remains unchanged and then degrades as d/b is gradually enlarged. Figure 5c shows that when plate slenderness ratio (b/t) is small, such as $b/t = 43$, the CFRP strengthening effect increases as d/b is gradually enlarged. When the plate slenderness ratio (b/t) is medium, such as $b/t = 66$, the CFRP strengthening effect remains unchanged as d/b changes. When the plate slenderness ratio (b/t) is high, such as $b/t = 92$, the CFRP strengthening effect first increases and then degrades as d/b is gradually enlarged. It means that, with the use of CFRP-strengthened perforated plates with a certain plate slenderness ratio (b/t), such as $b/t = 66$, no matter how the size of the hole diameter

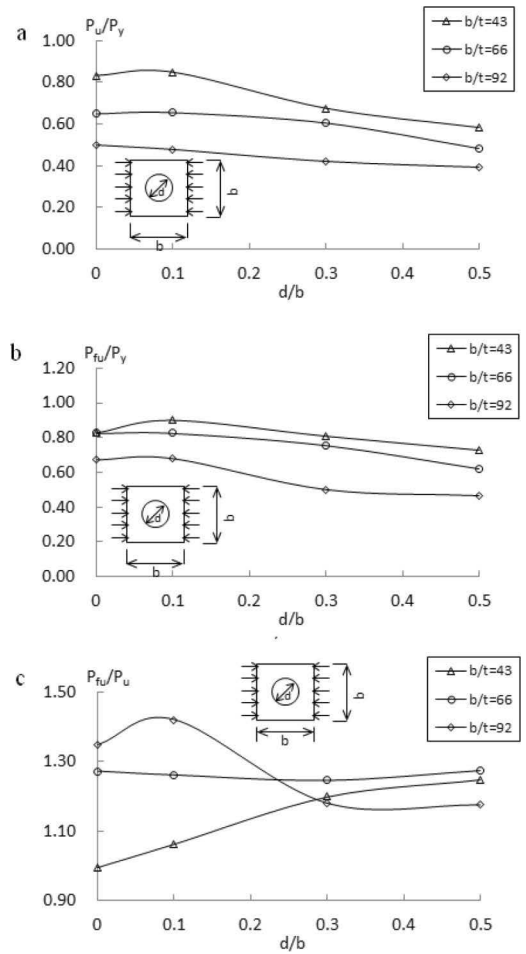

Figure 5. Graphs showing the influences of the hole diameter ratio.

changes, the CFRP strengthening effect remains stable.

4.3 Load-deflection curves

Some typical relationships between compressive load and in-plane displacement of the plates have been plotted in Figure 6. Some conclusions can be obtained as follows:

1. By comparing Figure 6a and b, we can see that the pasting of CFRP cannot increase the stiffness before buckling, but it can improve the mechanical property afterwards.
2. From Figure 6c, d and e, it can easily be seen that the stiffness of the specimens decreases along with an increase in the hole's diameter.
3. From Figure 6c, d and e, we also know that the greater the slenderness ratio b/t , the more

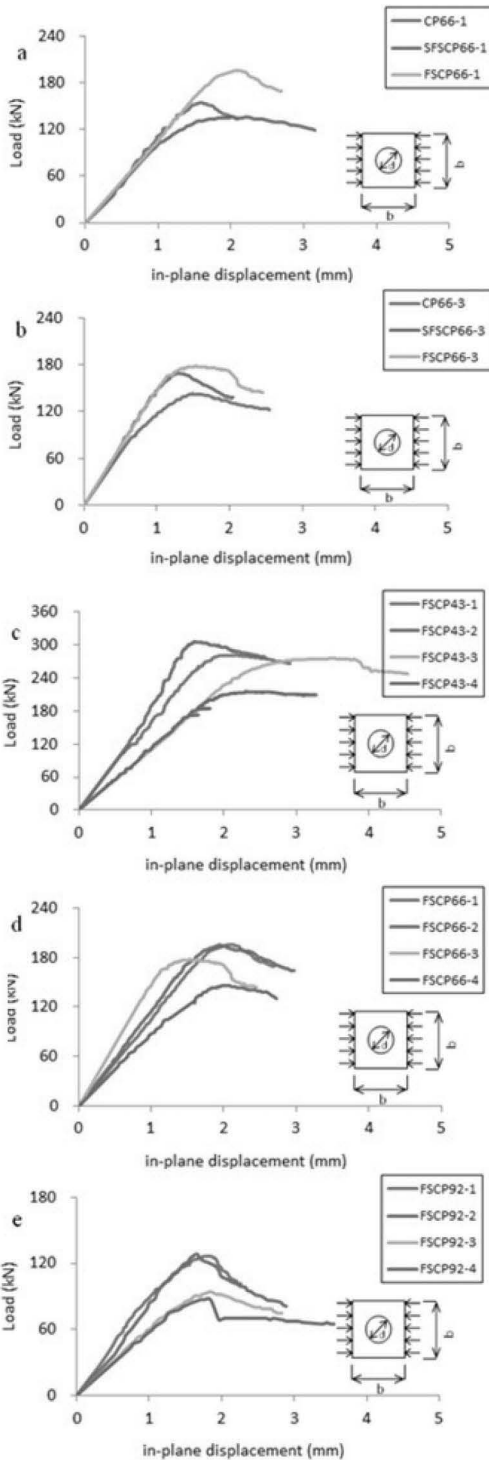

Figure 6. Load—deflection curves of specimens.

instable the compressive load and in-plane displacement curve.

5 CONCLUSIONS

In this study, the perforated steel plates strengthened by using the CFRP that are subjected to uniaxial compression are studied. Some general conclusions can be summarized as follows:

1. The failure mechanism of perforated plates strengthened by using the CFRP consists of four yield lines which start from the four corners and end near the hole's edges.
2. If the CFRP is pasted on the convex surface of initial deflection, it will improve the capacity of uniaxially compressed perforated steel plates very well; otherwise, it will be almost of no effect.
3. The use of CFRP-strengthened perforated plates yields better results in a big slenderness plate with a small hole and a medium slenderness plate with a big hole.
4. With the use of CFRP-strengthened perforated plates with a certain plate slenderness ratio (b/t), such as $b/t = 66$, no matter how the size of the hole's diameter changes, the CFRP strengthening effect remains stable.
5. The pasting of the CFRP cannot increase the stiffness before buckling, but it can improve the mechanical property afterwards.

Research on the measurement of the permeability coefficient of porous asphalt pavement

Guoqi Tang

Southeast University, Nanjing, China

Lei Gao, Tianjian Ji & Jianguang Xie

Nanjing University of Aeronautics and Astronautics, Nanjing, China

ABSTRACT: The drainage capacity of the porous asphalt pavement is related with the permeability of the porous asphalt concrete. On the basis of drainage mechanism of the asphalt pavement, the horizontal permeability coefficient and vertical permeability coefficient of the drainage pavement can be measured by the experimental test. The relationship between the water permeability coefficient and permeability coefficient tested by the pavement seepage meter was established in this research. Finally, the measurement method of the permeability coefficient of the drainage asphalt pavement was proposed. It is proved that the permeability coefficient of the porous asphalt pavement can be measured in a rapid way by the pavement seepage meter.

1 INTRODUCTION

The permeable asphalt mixture is used for the porous asphalt pavement as the surface layer. The porous asphalt pavement can take the rainfall into the drainage function layer, and laterally discharge the rainwater through the inside layer. It significantly improves the driving safety and comfort of the rainy days. Discharging the rainwater fallen on the road surface is the primary function of the porous asphalt pavement, and its drainage capacity is related with the permeability of porous asphalt concrete (Pisciotta M. 2010). The permeability coefficient is the parameter of the penetrating quality of the representation material. The permeability coefficient is mainly influenced by the composed particle size, gradation, and void content. Carman, Kozeny and Carman, established the aggregate permeability coefficient equation through the theory of capillary and the hydraulic radius (Kozeny J. 1927 & Carman P C. 1956). Walsh, J B and Brace, W F introduced the void shape distribution parameters, and revised Kozeny-Carman equation (Walsh J B. et al. 1984). Masad et al. proposed the simple equation to approximately calculate the asphalt concrete permeability coefficient through the theory of capillary and the hydraulic radius (Masad E. et al. 2004). Cooley, L et al. designed the asphalt concrete mixture ratio in accordance with the method of Superpave, and made the asphalt concrete penetration test (Cooley L A. et al. 2002). It was considered that the permeability of drainage asphalt road was closely related to the concrete density of the coarse

graded asphalt. Kanitpong Kunnawee et al. considered that the permeability of asphalt concrete is not only significantly influenced by the void content, but also by the thickness of the specimen, aggregate shape and grading and other factors (Kanitpong K. et al. 2001). Therefore, in order to assess the drainage of pavement permeability, it is necessary to measure the permeability coefficient of road surface drainage. The permeability coefficient of the drainage asphalt pavement can be rapidly determined by the pavement seepage meter.

2 ANALYSIS ON THE DRAINAGE MECHANISM OF THE POROUS ASPHALT PAVEMENT

The rainwater falls on the surface of the road and then it is permeated to the inside of the pavement through the air voids. Firstly, the initial moisture void is filled with water. Then, the water is accumulated in the structure layer. Finally, the seepage is happened. After absorption and accumulation of the pavement to the moisture, it begins producing seepage. But due to the rainfall intensity and rainfall duration and other condition, the rainfall could completely laterally infiltrate to discharge to the pavement through the drainage surface. Part of the water may infiltrate into the drainage layer and the surface runoff could form, which leads to the adverse effect on the performance of the pavement.

The difference between the runoff producing situations of the drainable pavement is that the

drainage surface void content of the drainable pavement is large while the thickness is thinner. The bottom of the draining-layer is a water-proof (sealing) layer, but the moisture is only accumulated and infiltrated in the drainage layer. Moreover, with the different moisture content, the capacity of the transmitting water of the draining-layer material has been changed. Therefore, there are large differences in runoff producing between the drainable pavement and the soil.

The rainwater is vertically downward infiltrated into the drainage asphalt surface which is the two-phase process. The first stage is the external control stage. If the external water supply rate does not exceed infiltration capacity, then the infiltration rate is equal to the Inflow rate. The second phase is the drainage layer control phase. With the drainage surface saturation degree increasing, the capacity of the surface water conduction is reduced. When it is less than external water supply rate, the rainwater begins forming the runoff to discharge it to the surface of the pavement through the comprehensive slope of the pavement surface. At this time, the infiltration rate is equal to the infiltration capacity of the surface layer. At last, the infiltration capacity reduces to the saturated hydraulic conductivity of the draining-layer.

The air void content of the drainage asphalt pavement is 20% or above, which is much larger than the soil. It is not easy to form a super runoff. Due to the limited thickness of the porous structure and its impermeable bottom, the rain that falls to the road surface mostly discharges through lateral seepage.

The reasons for road surface runoff formation saturation is not only related to the rainfall intensity or the rainfall duration, but also related to the drainage condition, drainage in the surface layer, the ditch drainage condition and the side ditch drainage conditions. Especially, the road surface runoff is affected by the drainage of permeation performance of the pavement material (Zhu Y. et al. 2004). Therefore, the foremost precondition of research on the drainage performance of the drainage pavement is to study the permeation performance of the drainage pavement surface.

3 THE TEST OF THE PERMEABILITY COEFFICIENT OF THE DRAINAGE SURFACE LAYER

3.1 Test device of the permeability coefficient

The permeability coefficient is significantly affected by the gradation of the material and the air void content. For a specific material, the air void content is more important. The void content

of the asphalt concrete material is relatively easier to determine and in the drainage asphalt pavement construction, the drainage performance of the pavement is also ensured by the void content. And the relationship between the void content and the permeation performance of the porous asphalt concrete can be determined by the penetration test of drainage asphalt mixture (Ma X. et al. 2004).

According to the principle of penetration test of soil mechanics, two sets of tester for vertical permeability and horizontal permeability of the asphalt concrete were designed as shown in Figure 1 and Figure 2. In the vertical penetration test, the big Marshall specimen without remolding was directly installed in the penetrant test device. The rutting plate specimen without the two side baffles was used for the horizontal permeability test. In order to ensure the precision of test results, the constant water head was used for the permeability test, which makes the penetrant test conforming to the range of application of Darcy law.

3.2 Test method of the PAC permeability coefficient

At present, the commonly used drainage asphalt mixture structure layer in China is PAC-10, PAC-13 and PAC-16 mixture. The penetrant test is mainly used to test the permeability performance of these several materials. First of all, according to the gradation composition of the asphalt mixture and the former engineering experience, the pass rate of the different void content situation of these several kinds of asphalt concrete can be determined. The dosage of each grade material and the theoretical density should be calculated. For the vertical penetration test, the specimen height of the big Marshal specimen under different void content should be calculated according to the theoretical density. The big Marshal Marshall specimen with the different void contents should be the same static pressure molding. For the horizontal seepage, the quality of specimen in the different void content shall be calculated, to form the rutting plate of the different void contents.

According to the material composition characteristics of the drainage asphalt concrete and the related construction experience, the material compositions of the several kinds of asphalt concrete were determined. The mix proportions of the three kinds of drainage asphalt mixture are shown in Table 1. The test results of the vertical permeability coefficient and the lateral permeability coefficient of rolling rutting plate by using static pressure molding specimens were described in Table 2.

Table 2 shows that with the increase of void content, the vertical permeability coefficients and lateral permeability coefficients of the three kinds of drainage asphalt mixture are increased, and the lateral permeability coefficient and vertical permeability coefficient of the same void content are almost the same. This is consistent to the research conclusions of Zhang Fan and other scholars on the relationship between the vertical permeability

coefficient and lateral permeability coefficient of the drainage asphalt mixture (Zhang F. et al. 2009).

4 THE SIMPLIFIED DETERMINATION TECHNOLOGY OF THE PERMEABILITY COEFFICIENT OF DRAINAGE ASPHALT MIXTURE

4.1 The method of indoor testing permeability coefficient of the pavement seepage meter

The pavement seepage meter can be used for the lateral water penetration ability of the drainage asphalt mixture specimen and the test shall be made according to the site water permeability test method in the Japan drainage pavement guideline (scheme), and to calculate and determine the seepage coefficient. But due to the varying-head is used

for the test method of pavement seepage meter, which the height of the water head is from 100 ml to 100 ml. So, the flowing of water flow within the specimen is non-laminar, and the permeability coefficient is not able to be calculated by the Darcy law. Therefore, the pavement seepage meter is used to make the Permeable coefficient of determination of taking off side mode. The rutting plate is shown as Figure 3. In the test process, through the method of external water pipe, the height of water head is kept at 100 ml scale line.

The surface height of control pavement seepage meter constantly determines the water discharge. Then, according to the related theory and through the seepage meter, and based on the formula (1), to calculate the lateral permeability coefficient K :

$$K = \frac{Q}{\rho_w t A i} = \frac{Q L}{\rho_w t A (h_1 - h_2)} \quad (1)$$

In the formula, Q is the quality of water which the Infiltration is passing test specimen in the t time period, g ; ρ_w is the density of water; g/cm^3 ; L is the effective flow length in the test specimen cm . A is the effluent cross sectional area of the specimen, cm^2 ; h_1 , h_2 are respectively water head height and the seepage water head height under the constant water head, cm .

The PAC-13 rutting plates with different void contents of 18%, 20%, 22% and 24% are used to test the constant water head of pavement seepage meter. The test results are as shown in Figure 4.

Figure 4 shows that with the increase of void content, the permeability coefficient of rutting plate also gradually increasing. And, permeability coefficient numerical value and lateral permeability coefficient of the rutting plate which is using dismantling the two side baffles along the rolling direction are basically the same. By using the pavement seepage meter with a suitable hydraulic gradient, the permeability coefficients of porous asphalt mixtures of the same gap are basically the same, which lays the foundation for rapidly testing the water seepage coefficient.

Figure 3. The lateral permeability coefficient of the rutting plate measured by the pavement seepage meter of constant water head.

Figure 4. The relationship between the void content of the rutting plate and permeability coefficient tested by the pavement seepage meter.

4.2 The rapid test of the pavement seepage meter in the construction site

The water surface in the seepage meter was declined from 500 ml to 400 ml scale. With the water yield of 15 s, the permeable coefficient of road surface can be calculated. The method is simple in operation and distinguish the conditions of water seepage of road surface well, but is unable to accurately determine the void content and permeability coefficient of road surface. If through a lot of test to determine the relationship between the void content and the seepage time first, and according to the relationship between the void content and permeability coefficient, then we can through the time tested by the seepage meter to determine the relationship between void ratio and permeability coefficient of the road surface more accurately. The pavement seepage meter was used to test the water seepage time of the rutting plate with the above different void contents. The relationship between void content and the water seepage time is as shown in Figure 5. Based on the void content as the medium, to determine the relationship between rutting plate seepage time tested by the pavement seepage meter and the lateral permeability coefficient is shown in Figure 6.

Figure 5 shows that there is good curvilinear relationship between the void content and the water seepage time of the drainage pavement. R^2 is 0.991. Therefore, in the drainage asphalt pavement construction acceptance, according to the Figure 5, we can quickly determine whether the void content of this section pavement can meet the requirements or not, so we can speed up the construction progress. The relation curves of the seepage time of the rutting plate and the horizontal permeability coefficient has been established in Figure 6. In the construction, the permeability coefficient of this pavement can be calculated according to the seepage time, so we can evaluate the water seepage performance of the drainage asphalt road surface.

Figure 5. The relationship between void content of the rutting plate and the seepage time tested by the pavement seepage meter.

Figure 6. The relationship between the seepage time of the rutting plate tested by the pavement seepage meter and the lateral permeability coefficient.

5 CONCLUSION

In order to evaluate the permeability performance of drainage asphalt mixture, a large number of indoor experiments were conducted to test the permeability coefficient of drainage asphalt mixture. It comes to the following conclusions:

1. Based on the simple operation of the device of the vertical permeability and horizontal permeability of the seepage drainage asphalt mixture, which has the seepage principle. The test result showed good representative and stability, which can be used to accurately test the permeability coefficient of drainage asphalt mixture.
2. The vertical permeability coefficient measured by the big Marshall specimen of not mold releasing and the lateral permeability coefficient measured by the lateral permeability apparatus are almost the same, which shows that drainage asphalt mixture has good isotropic properties, and it can be considered that in engineering applications. The big Marshall compaction specimen is relatively convenient, and can be used to determine the vertical permeability.
3. The seepage meter can be used to make simple experiment to test the permeability coefficient

of drainage asphalt mixture, through the rutting plate specimen of the remolding overhead frame. The lateral seepage meter shows there are good linear correlations between the seepage time of the different void content and the permeability coefficient measured. Through this relationship, the seepage time tested in the field can be used to calculate the permeability coefficient of drainage asphalt mixture. It is helpful to establish drainage asphalt pavement construction quality control and maintenance countermeasures.

ABSTRACT: In road engineering, Emulsion Wax Curing Agents (EWCAs) are mainly used for cement concrete construction curing or as the bond breaker between the cement concrete pavement surface layer and the lean concrete base layer. Inspired by the lotus leaf effect, in this research work, a series of the laboratory tests were performed to evaluate the mechanical performances of the icing atop the cement concrete surface coated with an EWCA. The test results indicate that friction and bonding between the icing and the concrete surface coated with an EWCA have been reduced, and the icing is easier to be broken and removed. Thus, spraying EWCA atop the cement concrete surfaces might improve the efficiency of the mechanical deicing process on the cement concrete surface.

1 INTRODUCTION

Icing atop pavements tends to disrupt the entire transport network, thereby leading to traffic paralysis and huge economic losses. Therefore, deicing and skid resistance of pavement surfaces have been a crucial part of pavement curing and maintenance work in winter, as well as a menace for the road management departments in winter.

At present, various approaches including chemical, mechanical, thermal and coating are used to deice pavements in winter. The mechanical deicing approach is performed by using the mechanical devices to remove snow and ice atop pavements. In spite of the low efficiency of deicing, the mechanical approach is environment-friendly, thereby doing less harm to the vegetation and the environment around. Consequently, the mechanical approach is widely used. However, under low temperature conditions, with an increase in the bonding between the ice and the pavements, the efficiency of the mechanical deicing approach alone usually reduces to an unacceptable level. What is worse is that the pavements may be damaged by the violent deicing.

The coating approach has been used in some asphalt pavement projects. Ma et al. (2014) reported that the silicone hydrophobic material which is used as the surface coating of the asphalt pave-

ment could effectively reduce the bonding between the asphalt pavement and the icing atop. However, the coating approach is rarely reported to be used for deicing in cement concrete pavement projects. Therefore, the authors of this paper wanted to explore the mechanical performances of the icing atop the surface of cement concrete coated with an Emulsion Wax Curing Agent (EWCA) through a series of laboratory tests. The test results were expected to be used as a reference for improving the efficiency of the mechanical deicing process with the help of EWCAs.

2 METHODOLOGIES

2.1 *Emulsion Wax Curing Agents (EWCAs)*

In cement concrete pavement projects, the cement concrete pavement is likely to be bonded to stabilized or lean concrete subbases. Thus, it is a common practice to place a bond-breaking medium atop the subbase surface. The common practice in the United States is to place two coats of a wax-based curing compound on the subbase surface as the bond breaker layer (Okamoto 1994).

The major components of the EWCA used in this research work are paraffin emulsion and compound emulsifiers that are mixed in a given

proportion which is determined by the projects' conditions, including weather, structure types, and the depth of the EWCA layer to be formed. EWCA's have been applied extensively in various areas, including textile, paper, leather, fiberboard, polishing, fruit preservation, architecture, gardening, ceramics and otherwise. In road engineering, EWCA's have been used with success worldwide to cure several thousand kilometers of cement concrete pavements, and cement-treated or lean concrete subbases. The corresponding technical specifications for EWCA's have been established by the American Society of Testing Materials C309 (ASTM 2007) and American Association of State Highway Officials M148 (AASHTO 2005). Note that the material requirements for EWCA's in both AASHTO M 148 and ASTM C309 are identical.

The choice of the EWCA used in this research was primarily determined by its curing function and bond-breaking function, with inspiration from the lotus leaf effect. In this research, the solid content of the EWCA was no less than 25%, with the mass ratio of polymer materials to paraffin being 1:2 and a qualified film-forming or solidifying performance. A special device was used to spray the EWCA so as to ensure uniformity of spraying and to control the spraying volume.

2.2 Tests for shear failure stress and integrated coefficient of friction

In order to better evaluate the mechanical performances of the icing atop the pavements, the shear failure stress and friction between the icing and the concrete pavement with or without EWCA coating were tested. In this research work, a shear test apparatus was self-developed. And the specimens for the direct shear test were casted in PVC pipe molds, as shown in Figure 1.

Figure 1. Picture showing specimens for shear tests.

The molded specimens were cylinders that measured 110 mm in diameter, 100 mm in height, and 2.3 kg in weight. After the specimens were cured under the standard curing conditions and reached 30–35 MPa compressive strength, the specimens were divided into two groups. EWCA's were sprayed on the top-ends of one group with the spraying volume set at 0.2 L/m² while the control group of specimens was not sprayed with the EWCA. After the sprayed EWCA solidified, cold water was poured into the molds of the two groups of specimens to form a 5-cm-thick icing atop the specimens by placing the molds with specimens in a freezer at -18°C for 12 hours. After the molds were removed, the specimens with icing atop were prepared, as shown in Figure 2.

When the specimens were fully prepared for tests, the centers of the jack, the measuring force ring, and the specimen were arranged in a horizontal line. The load pushed the jack slowly until the bond between the icing and the cement specimens was completely broken, and the value of the measuring force ring at that time was recorded. This value was regarded as the maximum horizontal thrust.

After the maximum horizontal thrusts were measured, the maximum shear failure stresses and the integrated coefficients of friction could be calculated.

2.3 Pull-out tests

The pull-out tests were carried out to measure the pull-out forces to pull out the icing from the cement concrete surface, so as to determine the pull-out normal failure stress of the icing.

To perform the pull-out test, first, the cement concrete specimens were casted in cylindrical steel molds that measured 110 mm in diameter (the bottom molds). After the specimens were cured under the standard curing conditions and reached 30–35 MPa compressive strength, the specimens were divided into two groups. An EWCA were

Figure 2. Picture showing cement concrete specimens with icing atop.

sprayed on the top-ends of one group with the spraying volume set at 0.2 L/m² and was solidified while the control group of specimens were not sprayed with an EWCA. Next, another set of steel molds of the same diameter (the top molds) were attached to the bottom molds, and the joints were sealed. The connected top molds and bottom molds with specimens were placed in a freezer at -18°C for 1 hour, and then cold water was poured into the top molds and the whole set was placed back into the freezer to form the 50-mm-thick icing atop all specimens.

When the specimens were fully prepared for tests, pull-out devices were used to draw the top molds and the bottom molds to the opposite directions. At the time when the icing and the concrete were broken apart, the pull-out force P was the maximum and was recorded.

2.4 Tests for impact on icing

The tests for impact on the icing were performed by following the drop-weight method with a set of self-made test apparatuses.

Cement concrete specimens were prepared by means of machine vibrations, with dimensions of 300 mm by 300 mm and thickness of 50 mm, cured under the standard curing conditions and reached 30–35 MPa compressive strength. The ready specimens were divided into two groups with one sprayed with EWCA of 0.2 L/M² on the top-ends and the other without EWCA as the control group. Next, the top surfaces of two groups of specimens were covered with ice and the icing was 10 mm thick. Afterwards, a ball weighing 200 grams was allowed to fall down through the hole in the fixed bracket from a height of 100 cm. The center of the hole in the fixed bracket and that of the specimens were in a vertical line. The impacts were repeated to observe the cracking of the icing atop the specimens and the related data were recorded, including two sets: the cycles of impact (N1) for the initial cracking (when the first crack on the icing appeared, the cycles of impact taken by the icing); the cycles of impact (N2) for the final fracture of the icing.

3 RESULTS

3.1 Results of shear failure stress and integrated coefficient of friction

In order to obtain the shear failure stresses and the integrated coefficients of friction between the icing and the cement concrete surface of two groups of specimens, the maximum horizontal thrusts to break the icing from the concrete surface were measured. The measured maximum horizontal

thrusts of two groups of specimens are listed in Table 1.

The maximum shear failure stress can be determined by the ratio of the maximum horizontal thrust T_{max} to the shear area A ($1/4\pi \times 110^2 \text{ mm}^2$):

$$\tau = T_{max} / A \quad (1)$$

According to equation (1), when the specimens are coated with an EWCA, the shear failure stress is 0.14 MPa in average, while the ice shear stress for the control group of specimens is 0.37 MPa in average. It can be seen that the shear failure stress of the specimens with an EWCA coating is decreased by 62%, which indicates that the EWCA tends to reduce the bonding of the icing to the concrete surface, which makes it easier for the icing to be broken apart from the concrete surface under the horizontal thrusts.

With respect to the integrated coefficient of friction f_h , it is the ratio of the maximum horizontal thrust of specimen T_{max} to the dead weight of the specimen m :

$$f_h = T_{max} / m \quad (2)$$

According to equation (2), when the specimens are coated with EWCA, the integrated coefficient of friction is 57 in average, while the integrated coefficient of friction for the control group of specimens is 155 in average. It can be seen that the integrated coefficient of friction of the specimens with EWCA coating is reduced by 63%. Such a reduction indicates that the EWCA coating has great effects on the interface condition between the icing and the cement concrete surface, with the interface shifting from bonding to semi-bonding. This shift makes it easier for the icing to be removed away from the concrete surface under the horizontal thrusts.

3.2 Results of pull-out tests

The results of the pull-out forces to pull out the icing from the concrete surface are shown in Table 2.

Table 1. Results of maximum horizontal thrusts to break the icing from a concrete surface.

	Specimens with EWCA coating	Specimens without EWCA coating
Maximum horizontal thrust P/KN	1.6	3.2
Average value P/KN	1.0	3.4
	1.3	3.6
	1.3	3.5

Table 2. Results of pull-out forces.

	Specimens with EWCA coating	Specimens without EWCA coating
Pull-out forces	1.5	2.2
P/KN	1.4	2
Average value	1.4	2.3
P/KN		

The pull-out normal failure stress σ can be defined as the ratio of the maximum pull-out force P_{max} to the cross-sectional area A ($1/4\pi \times 110^2 \text{ mm}^2$) of the specimen for the pull-out tests:

$$\sigma = P_{max} / A \tag{3}$$

According to equation (3), when the specimens are coated with EWCA, the pull-out normal failure stress is 0.15 MPa in average, while the pull-out normal failure stress for the control group of specimens is 0.24 MPa in average. It can be seen that the pull-out normal failure stress of the specimens with EWCA coating is reduced by 38%, which indicates that the EWCA tends to lessen the bonding of the icing to the concrete surface, which makes it easier for the icing to be pulled out from the concrete surface under the pull-out forces.

3.3 Results of tests for impact on icing

Through the tests for impact on icing, the cycles of impact for the initial cracking of the icing (N1) and the cycles of impact for the final fracture of the icing (N2) were recorded, as shown in Table 3.

Table 3 shows that the value of N1 for the specimens coated with EWCA is 60% less than N1 for the control specimens without EWCA coating; while the value of N2 for the concrete surface coated with EWCA is 52% less than N2 for the control specimens without EWCA coating. And the difference between N1 and N2 for the specimens with EWCA coating is 6, while the difference between N1 and N2 for the control specimens without EWCA coating is 12, which indicates that the icing atop EWCA coating is more prone to breaking after the initial cracking. The underlying reason might be that the EWCA coating has great effects on the interface condition between the icing and the cement concrete surface, with the interface shifting from the bonding to the semi-bonding state. This shift makes it easier for the icing to be broken under the impacts.

Table 3. Results of cycles of impact on icing.

	Specimens with EWCA coating	Specimens without EWCA coating
Cycles of impact for the initial cracking (N1)	2	5
Average value of N1	2	6
Cycles of impact for the final fracture (N2)	2	5
Average value of N2	7	5
	8	15
	7	18
	8	17
	8	17

4 CONCLUSIONS

This research explored the feasibility to improve the efficiency of the mechanical deicing process on the cement pavement surfaces by spraying the EWCA atop the cement concrete surfaces, through a series of laboratory tests (including the tests for shear failure stresses and integrated coefficients of friction, the pull-out tests, and the tests for impact on the icing) to test the mechanical performances of the icing atop the cement concrete surface with or without the EWCA coating. By comparing the test results of the specimens coated with EWCA with those of the control specimens without EWCA coating, the following conclusions can be drawn:

1. By spraying the EWCA coating atop the cement concrete surface, the latter is changed from a hydrophilic surface into a hydrophobic one, which is conducive for the good drainage of rainwater, and thus helps to prevent the concrete surface from icing.
2. If rainwater or snow on the cement concrete surfaces turns to be the icing layer, by spraying the EWCA coating atop the concrete surface, the bonding between the icing and the concrete surface can be reduced greatly, and the same is true for the cycles of impact to break the icing. The underlying reasons might be that the EWCA coating has great effects on the interface condition between the icing and the cement concrete surface, with the interface shifting from the bonding to the semi-bonding state. This shift makes it easier for the icing to be de-bonded from the concrete surface, and to be cracked and broken.

Thus, the results of the laboratory tests mentioned in this research indicate that spraying the EWCA atop the cement concrete surface might improve the efficiency of deicing through the mechanical approach greatly. Further studies will be performed to confirm the above conclusions through a series of field tests.

ACKNOWLEDGMENTS

This research was supported by the National Natural Science Foundation of China under grant no. 51578080, grant no. 51178064, and grant no. 51302020. And it was also (Project No. 2013-01) funded by the Transportation Department of Hunan Province, China.

A study on residential area's adaptability design for the aged in China based on open building theory

Xue Meng

Harbin Institute of Technology, Harbin, China

Benchen Fu

The Architectural Design and Research Institute of HIT, Harbin, China

ABSTRACT: Through the analysis of serious aging problems in China, this paper aimed to explore the value of Open Building Theory for guiding residential area's adaptability design for the aged in China. The main concepts involved in open building theory, including overall concept, hierarchy control, showing respect to individual interests and dynamic adjustment to need, were highly associated with residential area's adaptability design for the aged by the combination of theoretical research and case study. Based on that, this paper proposed two aspects of adaptability design techniques, including the design of residential planning and dwelling units, providing references for future rational design of residential areas for the aged in China.

1 INTRODUCTION

1.1 Open building theory

1.1.1 The development of open building theory

In 1961, N. John Habraken published *Support: An Alternative to Mass Housing*, in which he proposed to separate housing design and construction into two parts- "Supports" and "Detachable Units". This reflects his thinking between housing's stability and change in deal with the built environment (Kendall 2009). The research aims to advocate residents to participate in the design and construction process and then realize the diversity and individuality in mass housing construction (Jiang & Jia 2014). As the Director of SAR (Stichting Architect Research), he led the research institute to search in this field and formed the prototype of open building theory (Miao et al. 2016).

In 1980s, open building was proposed by Stephen Kendall (Fig. 1), who studied with John Habraken in MIT. After that, this theory went through a long-term complement investigation and gained the great influence via OHI (Open House International) and Open Building Foundation's promotion. In the last tens of years, housing construction in many countries got boost based on open building theory.

1.1.2 The main concepts involved in open building theory

Open building theory emphasizes several main concepts, including overall concept, hierarchy

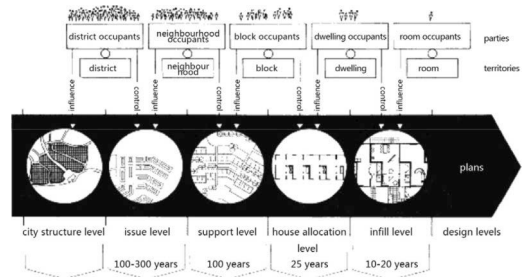

Figure 1. Environmental levels in Open Building (Kendall 2009).

control, showing respect to individual interests and dynamic adjustment to needs (Habraken & Teicher 2000). The proposal's original intention was to deal with contradictions between urgent needs for mass housing and diversity of social housing after World War II's rapid urban development (Jiang & Jia 2014). However, with the continuous evolution of open building theory in the following few decades, it has been more than a design theory. In a broad way, "Open Building" in this theory stands for "open-type building", implying a way to achieve dynamic, adjustable and adaptive design methods for architecture, which would help realize the sustainable and better urban living environment. It has already got rid of the initial limitations of housing design and construction technology. From urban environment

and collectivity to living unit and individual, open building theory covers the extensive ranges, becoming a significant component of sustainable urban built environment.

1.2 Problems of residential area's adaptability for the aged in China

1.2.1 Aging population in China

Since 1999, China has entered an aging society with increasingly aging degree. By the end of 2015, the elderly (>60 years old) population would have increased to 221 million, reaching 16% of the total population according to the statistics of China State Council (2011). By 2030, the amount of older adults would double to 400 million and China would be faced with the world's highest degree of aging population (2011). Challenges brought out by aging population are everywhere.

1.2.2 Problems of aging at home

With the development of undertakings for the aged in China, pension mode gradually improves. The national implementation of "9073" Policy provides various pension choices for the elderly. Nearly 90% residents would adopt the manner of "aging at home". Compared with the other two types, aging at home is "tangible and relevant" (Senior Homes 2016). It is in accordance with residents' conventional ideas and long-term living habits, which is accepted by more families (Liu et al. 2015). However, this brings about enormous pressure of aging at home. In addition, more problems still remain, including demographic changes, relatively backward residential service facilities, etc.

1.2.3 Problems of residential areas

As the space carriers of aging at home, residential areas become the key to implementation of the national pension policy. Figure 2 shows the continuous and vigorous development of newly started housing area in China (NBSC 2015). While the quality of the living environment could hardly meet the dynamic needs of residents.

Figure 2. Development of housing area newly started by real estate enterprises.

In the face of aging crisis, the so-called "settlements for the aged" is far from enough. What we need is the residential area where we could generally live for long until old age according to *Elderly Housing Construction in Japan* (2011). This reflects the residential adaptability for the aged.

In conclusion, the design and construction of residential areas equipped with adaptability is imperative. Thus, open building theory was introduced into this study to explore the rational design concept. Then two aspects of design techniques (planning and dwelling units) were proposed, providing approaches to better achieve dynamic, long-term and sustainable living environments.

2 OPEN BUILDING THEORY'S REFERENTIAL VALUE

2.1 The practical application of open building theory in housing

Based on open building theory and its expansion, many countries have set up their own construction system and standards according to their national conditions. Japan experienced the development of KEP (Kodan Experimental Housing Project), NPS (New Planning System), CHS (Century Housing System), etc. Since 21th century, KSI (Kikou Skeleton Infill) system obtained a comprehensive implementation. KSI emphasizes the separation of skeleton and infill, indicating the structure's durability and living pattern's flexibility for long (Qin et al. 2014). In 1980s, universal design concept was proposed in the US in order to create safe, convenient, healthy and comfortable environment for all. According to this concept, the particular needs of various people were taken into consideration, including the elderly, the disabled, etc. Then based on that, *Universal Design in House* presented the housing's separation into structural section and non-structural section, achieving a high degree of residential adaptability. The Building and Construction Authority in Singapore enacted *Universal Design Guide*, giving consideration to different group's pension and housing needs. Through the references of Japan's KSI and western countries housing experience, China achieved the establishment of CSI (China Skeleton Infill) in 2010, giving response to better residential adaptability, quality improvement and extension of life-cycle (Li 2010).

2.2 Open building theory's introduction into residential area's adaptability design

Faced with serious aging problems and stress on aging at home, residential area's adaptability for the aged, which aims to provide inclusive,

flexible and sustainable living environment, is imperative.

As a complex living system, residential areas contain a series of components including residential buildings, residential exterior space, public service facilities, etc. And the main concepts involved in open building theory provide rational approaches to realize the long-term sustainability. At this time, from the perspective of open building theory, a residential area is regarded as a whole system. Overall concept emphasizes the system's long-term integrity. Hierarchy helps to achieve relatively independent and stable subsystems. Showing respect to individual interests and division of decision-making are conducive to instant feedbacks. Dynamic adjustment provides guarantee of flexibility and adaptability in the long term. All these four aspects guide and constraint to ensure the sustainable development of residential areas. In this case, residential adaptability design for the aged may be suitable for everyone.

3 DESIGN TECHNIQUES

Based on open building theory, buildings and its surroundings are never static. They should always make adjustment according to the development of society and technology. Thus interaction between people, time, building and environment should be established to realize the high-quality and sustainable living environment (Lan & Wei 2015). In general, there are mainly two aspects (Table 1). First, in residential planning level, the function and scale of subsystems (e.g. exterior space, service facilities) should be adjusted and optimized according to the population, behaviors and needs of elderly people. Second, in unit level, the interior space ought to be alterable and flexible to meet the living habits of the elderly.

3.1 Residential planning

Specifically, the guiding value of open building theory mainly reflects in the following aspects.

Table 1. Adaptability design for the aged.

Concepts of open building theory	Design techniques
□ Overall concept	Planning: adjustment in function and scale
□ Hierarchy	Unit: flexibility of space separation and utilization
□ Showing respect to individual interests	
□ Dynamic adjustment	

3.1.1 Flexible configuration of public service facilities

Based on the planning and construction standards, the configuration (e.g. type, scale, inner function) of facilities should be adjusted according to residential population structure, regions and urban location (Wu et al. 2012). In addition, either residential objective conditions (e.g. construction time, resource allocation) or residents' subjective preferences would make a difference on the demands of service facilities. Thus relatively elastic and flexible configuration are appropriate for the implementation of sustainable living environment (Fig. 3).

3.1.2 Reservation land for future extension and replacement

Reserving part of land for future extension and replacement is encouraged in response to residential dynamic requirements. The reservation area could first be utilized as residential external public space. Along with the growing aging population, the shortage of required facilities gradually worsens. Then the reservation land could be converted into supplementary service facilities to fulfill the greater demands of the elderly.

3.1.3 Utilization and renovation of the remaining

More attention ought to be paid to focus on the present living status and residents' behavior habits. With aggravating trend of aging problems and demographic change, the existing standards of planning is no more applicable. Some buildings may stand empty as the present needs for some facilities such as kindergartens and primary schools are not that much. In addition, other idle facilities (e.g. factory buildings) could also be renovated to serve for the elderly (Zhan & Wu 2014). We should make full use of idle and inefficient status of facilities and balance the function utilization. Either function replacement or ratio adjustment would be beneficial to ease the supply imbalances of residential service for the aged.

3.2 Dwelling units

The main problem involved in residential adaptability design for the aged is that changes in family

Figure 3. Flexibility of configuration in residential planning.

structure and members' physical conditions would lead to variation of functional layout and space details (Pan & Ding 2014). Conventional housing's integrated construction methods lead to the lack of flexibility and adaptability. While the separation design and construction of "Supports" and "Infills", which is one of the most significant design principles of open building theory, provides a guarantee for unit's orderly optimization and dynamic adaptability (Wang & Mei 2014). First, "Supports" (e.g. structural system) are regarded as the basic skeletons for residential interior space segregation. The durability of "Supports" also extends the utilization life of residential dwellings. Then, the flexible segregation of "Infills" (e.g. light partition walls) enables the instant adaptability, satisfying the diverse needs of occupants at different ages. It realizes the richness and practicability of space utilization. This is the expression of "maintaining the status quo" under hierarchy control, reflecting the typical characteristics of residential adaptability for the aged, namely spatial versatility and variability. The combination of "Supports" and "Infills" ensures the long-term utilization during life cycle as well as improving living comfort (Qin et al. 2014). For instance, Figure 4 shows Tila housing block whose apartments have no space segregation except for 2 baths.

Figure 4. The apartment with no space segregation except for 2 baths (CIB W104 2015).

Figure 5. Occupants' various preferences for space division (CIB W104 2015).

The occupants could divide the inner space regarding their daily behaviors, preferences and willingness (Fig. 5). And adjustments would also be made to adapt to changing ages.

4 CONCLUSIONS

With the intensification of aging situation in China, residential area's adaptability design for the aged is required. The introduction of open building theory would help guide and promote the residential area's construction and renovation. In this way, the disadvantages of conventional design methods could be avoided. The theory emphasizes building is not one-time but long-term (Jia 2009). The hierarchy control enables the overall system as well as independent subsystems to be stable and durable. And the more open decision-making provides positive ideas for diversity, stability and sustainability of residential area's construction in China. Meanwhile, we could see that the some attempts have been made to pursue residential area's adaptability design for the aged, such as Summit's Guanghe Yuanzhu project in Beijing based on SI system (Qin et al. 2015). These projects help confirm the referential value of open building theory and provide practical experience for future construction of livable, healthy and sustainable residential areas in China.

Safety management strategies for public infrastructure projects

C.W. Liao

China University of Technology, Taipei, Taiwan

T.L. Chiang

Occupational Safety and Health Administration under the Ministry of Labor of Taiwan, New Taipei City, Taiwan

ABSTRACT: Labor inspection services in many countries are not capable of carrying out their roles and functions. In Taiwan, the Lowest Bid Tendering method (LBT) has been adopted by most public entities. As a result, occupational safety management for public construction projects faces challenges such as diminishing budgets, a reduction in staff, and the continued growth of the workforce, and thus it is getting increasingly difficult. This article examines management strategies for occupational safety in the construction industry. Several strategies were conducted to improve the safety performance of a public construction project in Taiwan—the widening project of the Wugu-Yangmei section of National Freeway No.1. A questionnaire method is used to analyze different strategies in order to explore the understandability and effectiveness of each strategy. The findings identified in this article provide a direction for more effective safety management strategies and injury prevention programs.

1 INTRODUCTION

The Government Procurement Law in Taiwan has two categories of contract award methods: the Lowest Bid Tendering method (LBT) and the most favorable Tendering method (MFT), a type of multicriteria bid evaluation method (Wang et al., 2006). LBT features simple tendering procedures and non-controversial issues, making it one of the most popular contract-awarding methods (Tzeng et al., 2006). In Taiwan, LBT has been adopted by most public entities (project owners) for a long time. As contractors compete solely on the bidding price, the LBT method may result in awarding contracts to unreasonably low bidders (Tzeng et al., 2006). Such cases imply that the winner may cut corners during construction to maintain profits, especially in occupational safety and health issues (Wang et al., 2006). Multi-level contracting and illegal sub-contracting in the construction industry may worsen this situation. As a result, occupational safety management for public construction projects faces challenges such as diminishing budgets, a reduction in staff, and the continued growth of the workforce, and thus it is getting increasingly difficult to manage.

In addition, the owner of a public project (government agencies) typically takes an overseeing rather than a proactive role in safety management for public construction projects. This situation implies that safety for public construction projects is entirely determined by the supervisory practices

carried out by the supervisors and the spontaneous activity of the contractors. If the supervisor does not carry out supervision and constrain the contractor actively, or if the contractor lacks a sound approach to construction management and safety, accidents are highly likely to occur.

In Taiwan, occupational safety is the responsibility of the employer, while the occupational safety and health laws are enforced by the Occupational Safety and Health Administration under the Ministry of Labor. The inspectors are mandated to carry out site visits without prearranged appointments to inspect work situations, working hours, construction safety, or any aspect of accident risk (Yrjänheikki and Savolainen, 2000). Generally, inspectors seek to modify worker behavior by raising the penalties for non-compliance with the regulations but they may also take a more flexible approach. For example, they may aid in helping workers adapt work systems to conform to production demands while at the same time correct compliance problems. Nevertheless, labor inspection services in many countries are not capable of carrying out their roles and functions (Eisenbraun, 2013; International labour office, 2006; Weil, 2008). They are often understaffed, under-equipped, undertrained, and underpaid. A labor inspectorate must develop its strategies and deploy its resources in the most effective way. Ranking management strategies from worst to best is perhaps the most straightforward way for safety management on construction sites.

In this article, a public infrastructure project was selected for a single case study. The Occupational Safety and Health Administration were taken as a leading role, and the owner, the supervisors, and the contractors were united to explore effective safety management strategies. This article examines management strategies for occupational safety in the construction industry. Several strategies were conducted to improve the safety performance of a public infrastructure project in Taiwan—the widening project of the Wugu-Yangmei section of National Freeway No. 1.

2 SAFETY MANAGEMENT STRATEGY

Several safety studies have investigated occupational accidents within the construction domain. Much has been discussed about the factors that drive safety performance. Organizational safety policy is essential to safety performance on construction projects. It can ensure that proper safety management should not be seen as a burden or something rigid to be isolated from other aspects of management (Sawacha et al., 1999; Hinze and Wilson, 2000; Jaselskis et al., 1996). Since effective training of workers can greatly reduce unsafe acts, worker training is the most influential factor that improves safety performance (Hinze and Wilson, 2000; Huang and Hinze, 2003). At a construction project, more formal and informal safety meetings with supervisors or specialty contractors are important for achieving better safety performance (Jaselskis et al., 1996). Construction accidents occasionally result because the safety equipment necessary to perform the job safely is not present on construction sites, or workers cannot effectively use the safety equipment that is provided for their use (Chi et al., 2005; Toole, 2002). Safety inspections can be used to monitor safety compliance on sites. Increasing the number of site safety inspections has a positive impact on safety performance (Hinze and Wilson, 2000; Jaselskis et al., 1996). The use of safety incentives and penalty schemes can effectively increase safety awareness to mitigate

site casualties. Safety incentives and penalties should be applied to promoting safety practices (Jaselskis et al., 1996; Tam and Fung, 1998). Workers' safety attitude is an important factor contributing to occupational accidents. If positive attitudes of workers towards safety can be reinforced and embedded within a group, successful safety management can then be achieved (Abdelhamid and Everett, 2000; Aksorn and Hadikusumo, 2008; Toole, 2002). As the high turnover rate makes it more difficult for workers to adjust to varying work conditions with different demands set by different employers, it is associated with higher injury rates (Harper and Koehn, 1998; Hinze and Gambatese, 2003; El-Mashaleh, et al., 2010).

Based on the above, there are eight important influence factors: organizational safety policy, worker training, safety meetings, safety equipment, safety inspections, safety incentives and penalties, workers' safety attitude, and labor turnover rates. For the factors, workers' attitude towards safety and labor turnover rates, occupational safety and health administration has no direct influence. Checks on safety equipment and implementation of safety incentives and penalties are typically merged into safety inspections. Therefore, factors to reduce construction accidents that are available to the competent authorities can be divided into four main types: organizational safety policy, safety training, safety meetings, and safety inspections. Further, On the basis of the four main factors for occupational safety management, some applicable strategies and activities have to be identified.

Through in-depth interviews with the responsible employees from the labor inspectorate, project owner and supervisors, and regard for current labor safety management practices in Taiwan, we develop related strategies to prevent construction accidents. Then the corresponding safety activities were progressively presented for the entire project during 2009–2011, as shown in Table 1.

With regard to the seminars, as soon as construction accidents or near misses occur, using an internet platform to immediately disseminate this information as well as gathering relevant cases and developing

countermeasures, a seminar is also organized. This aims to ensure that related construction personnel are immediately aware of the risk of similar incidents and can jointly develop countermeasures.

3 PROJECT PROFILE

The widening Project of the Wugu-Yangmei section of National Freeway No.1, approximately 40 km in length, starts from the Xizhi-Wugu viaduct and ends north of the Yangmei toll station. A separate viaduct is adopted as the main construction type of the Widening Project. The section between Taishan and Zhongli intermediate transfer connections is designed as a 3-lane viaduct while the other section is a 2-lane bridge according to the traffic demand. Taishan intermediate transfer connection and Zhongli intermediate transfer connection serve as traffic exchanges between the ground section of National Freeway No.1 and the elevated bridge of the Widening Project. One interchange is also established to connect National Freeway No.2 to access Taoyuan International Airport. The total budget of the project is about USD 2.72 billion, making it Taiwan's highest per-unit cost road to date (Taiwan Area National Expressway Engineering Bureau, 2014).

The project was taken over by the Taiwan Area National Expressway Engineering Bureau on February 4, 2009, and opened to traffic in April 2013 (Taiwan Area National Expressway Engineering Bureau, 2014). The entire route is divided into 12 bids, and it is elevated, making construction work very dangerous. The elevated road was very high, with many of the columns more than 30 meters in height. In addition, construction took place very close to the existing Freeway No. 1 and neighboring houses. During the pre-construction phase, it was needed to demolish houses and acquire land, lay out a large number of construction roads, and build gantries and other construction facilities. It was necessary to make multiple crossings of freeways, expressways, and local roads during construction. This article examines the influence of several management strategies for occupational safety on public construction projects in Taiwan using this project for a single case study.

4 CONCLUSIONS

In this article, we examine management strategies for occupational safety in the construction industry. Several strategies were conducted to improve the safety performance of the widening project of the Wugu-Yangmei section of National Freeway No.1. Subsequently a questionnaire method will be used to analyze the advantages and disadvantages of different strategies in order to understand the effectiveness of each strategy. The final part of the

study will use the results of questionnaire survey to provide a direction for more effective safety management strategies.

ABSTRACT: With the popularization and development of the highway network, many heavy duty vehicles run on every grade highways. The continuous braking, starting and steering of the vehicle in the position of the intersection of the highway bring about common problems such as the passage of the asphalt pavement and the cracking of the vehicle (Wang Jun, 2010 & Roque R, 2000). In addition, the thawing environment such as high temperature in summer or winter freezing will reduce the shear resistance of the asphalt mixture, resulting in track, elapse, crowd etc. These early problems have seriously affected vehicle comfort and have hindered the normal operation of the road, and have caused huge losses to the national economy. Therefore, it is significant to master the influence law of the asphalt pavement structure under horizontal load conditions.

1 INTRODUCTION

Because of the popularization and development of the highway network, more and more heavy duty vehicles are on every grade highways. High temperatures in summer or winter freezing temperatures will reduce the shear resistance of the asphalt mixture. It also will result in track, elapse, crowd etc. So, it is important to master the influence law of the asphalt pavement structure under horizontal load conditions.

2 THE ESTABLISHMENT OF THE FINITE ELEMENT MODEL

2.1 *The force characteristic analysis of the asphalt layer when the horizontal force is acting on the asphalt surface layer*

The main design method of the asphalt pavement is to place the wheel load as equivalent with double

circular vertical loads for the structure design on the pavement thickness. This method only considers the vertical force of the wheel load without considering the horizontal force and vertical force on the road. But the asphalt pavement is not only influenced by the vehicle, but also will be influenced by a horizontal force, such as friction etc. Therefore, when the vehicle is on the road surface, the vertical force and the horizontal force of the vehicle should be considered together.

2.2 *Establishing the finite element model structure*

When the asphalt pavement is loaded by using a car, the rear wheel of the vehicle will generate force that includes the vertical force and the horizontal tangential force. The horizontal tangential force of the asphalt pavement is mainly caused by the friction between the tire and the road surface. The pavement structure and parameters' values are listed in Table 1.

Table 1. Pavement structure and parameters.

Structure layer	Thickness (cm)	Modulus (MPa)	Poisson's ratio
Asphalt layer	4	1200	0.25
PMC layer	28	21000	0.18
Subgrade	500	40	0.35

Figure 1. Schematic diagram of the surface effect element SURF154 geometry.

Figure 2. Schematic diagram of horizontal force loading along the driving direction.

Figure 3. The loading pattern of the horizontal force in finite element calculation.

The main method is to use the ANSYS finite element software to analyze the loading level of the pavement structure and the selection of the asphalt surface effect unit is SURF154 (Jiang Yi, 2009). Asphalt surface effect element SURF154 can simulate the vertical force and horizontal force together on the 3D cell surface. The SURF154 geometry of the surface effect unit is shown in Figure 1. At the same time, the vertical load and horizontal load are added to the SURF154 unit to simulate the vertical force and horizontal force generated by the vehicle load on the pavement structure.

The schematic diagram of horizontal force loading along the driving direction is shown in Figure 2. In the finite element calculation, the loading diagram of the horizontal force along the driving direction is shown in Figure 3.

3 CONSIDERING THE EFFECT OF THE HORIZONTAL LOAD ON STRESS AND STRAIN OF THE ASPHALT LAYER

3.1 The effect of the bonding state between the asphalt layer and PMC layer on the stress and strain of the asphalt layer

The effects about the incorporation conditions on the maximum shear stress, shear strain, and tensile stress of the asphalt layer are listed in Tables 2–4.

As can be seen from the Tables 2–4, it indicates that the absolute smooth state of the stress and strain is greater than the completely continuous state. It can be explained that the asphalt layer and PMC layer between the continuous ratio of the pavement structure under the load is more favorable. Taking into account the actual situation for the large gap between the PMC and asphalt layers, the surface is very rough, and so the two layer interface is nearly continuous and the calculation of the layer between the combined states are set to completely continuous states.

Table 2. The effects about the incorporation conditions on the maximum shear stress.

Incorporation conditions	Thickness (cm)	Maximum shear stress (MPa)
Absolutely smooth	0	0.437
	2	0.461
	4	0.452
Completely continuous	0	0.385
	2	0.392
	4	0.304

Table 3. The effects about the incorporation conditions on the shear strain.

Incorporation conditions	Thickness (cm)	Maximum shear strain
Absolutely smooth	0	0.450
	2	0.480
	4	0.471
Completely continuous	0	0.450
	2	0.480
	4	0.471

Table 4. The effects about the incorporation conditions on the tensile stress.

Incorporation conditions	Thickness (cm)	Tensile stress (MPa)
Absolutely smooth	0	0.215
	2	0.237
	4	0.284
Completely continuous	0	0.080
	2	0.091
	4	0.104

3.2 Effect of transverse force on the stress and strain of the asphalt layer

When the vehicle is in an emergency braking, climbing or turning state on the asphalt pavement, the horizontal force coefficient is about 0.5, and its maximum value is approximately equal to the friction coefficient of the road surface. Therefore, it is important to analyze the impact of the transverse force on the stress and strain of the asphalt layer. The analysis of the transverse force coefficient is 0.1, 0.3, 0.5, and 0.7 and the asphalt thickness is 8 cm.

With an increase in the horizontal force coefficient, the maximum shear stress increases to 41.5% and 32.8% when the horizontal force coefficient increases from 0.1 to 0.7 on the road surface and the depth is 2 cm. It will be normal running of the vehicle when the horizontal force coefficient is about 0.2, and so the level of load generated by the normal running of the vehicle on the road affects the road surface to a little extent. When the car is in the uphill, emergency braking or turning will have a greater impact on the road.

When the horizontal force coefficient is less, the horizontal shear stress becomes smaller, but the value and the maximum shear stress become larger. When the horizontal force coefficient is large, the horizontal shear stress is large. Its value is very close to the maximum shear stress value. The larger the lateral force coefficient, the more prone it is to horizontal shear damage. Figure 4 shows the tensile stress of the asphalt surface.

As can be seen from Figure 4, the maximum tensile stress of the asphalt surface appears in front of the wheel, which is due to the action of the backward horizontal force. With an increase in the transverse force coefficient, the tensile stress also exhibits an obvious increase. When the transverse force coefficient increased from 0.1 to 0.7, the maximum tensile stress increased by more than two times. The horizontal displacement of the asphalt layer also increases with an increase in the lateral force coefficient, and it will have a significant impact on the horizontal displacement when the

Figure 4. Tensile stress of the asphalt surface.

lateral force coefficient is larger. The production of horizontal displacement can induce the disease of the asphalt layer, and so it is more likely to occur in an area in which the lateral force coefficient of the vehicle load is large in the intersection.

3.3 Influence of the asphalt layer thickness on the stress and strain of the asphalt layer in summer and winter

An asphalt mixture is regarded as a special temperature sensitive material, in which the mechanical index and pavement performance of the asphalt mixture will also undergo a significant change with the change of temperature of the external environment (Chen Fengfeng, 2007 & Ma Xin, 2008). In a high temperature environment such as summer, the asphalt modulus becomes small and the mixture shows a softening flow in the high temperature. And so, it will reduce its own shear performance. If the traffic in the asphalt pavement shear performance is less, the asphalt pavement will form the possibility of permanent deformation failure which is quite big. In winter, the stress relaxation performance of asphalt is decreased, the modulus and brittleness increase, and low temperature cracking is the main failure mode. Therefore, it is necessary to study the temperature distribution of the asphalt pavement in the pavement structure when the asphalt pavement is driving at high temperature. The modulus of asphalt in summer is 450 MPa and the modulus of asphalt in winter is 3400 MPa. The force coefficient can be assumed as 0.3 when calculating the transverse.

The vertical shear stress of the asphalt layer will increase with an increase in the depth; but when the depth is more than 6 cm, the vertical shear stress (shear strain) will no longer increase, and slowly decrease. The increase of the asphalt layer thickness will increase the vertical shear stress (shear strain)

in the asphalt layer. With an increase in the depth of the road surface, the maximum tensile stress gradually decreases and the amplitude increases with an increase in the asphalt layer thickness, and the maximum tensile stress of the pavement increases with an increase in the thickness.

According to the chart, the maximum shear stress and the maximum tensile stress in summer and winter are not quite different. When the asphalt layer is less than 6 cm, the maximum shear stress is larger in summer than in winter, but when the asphalt layer thickness is greater than 6 cm, the stress value of summer and winter is basically the same. At the same time, the maximum tensile stress values of summer and winter are also different and the value of tensile stress in summer is slightly larger than that in winter.

It can be obtained through the contrast analysis in the winter and summer, in which low temperature and high temperature asphalt layers are under the action of the vertical force and the horizontal force is nearly the same. The shear capacity of the asphalt mixture is greatly lower under the high temperature than the low temperature conditions. It is very important to improve the high temperature performance of the asphalt concrete mixture on resistance of the asphalt pavement shear failure.

4 REASONABLE TYPE AND THICKNESS RANGE OF ASPHALT LAYERS

The effect of the horizontal force has a certain effect on the stress of the asphalt layer. By the analysis of the different layers of the state, it can be seen that the maximum shear stress of the PMC layer changes little when the asphalt layer is under the absolute smooth and completely continuous conditions, but the maximum tensile stress of the absolutely smooth state is two times larger than the completely continuous state.

The different asphalt layer thickness stress analysis results show that the maximum shear stress (shear strain) location is the asphalt surface layer. When the depth is more than 2 cm, the shear stress (shear strain) will decrease with an increase in the depth. It is important to improve the shear performance above the asphalt layer to prevent the shear failure. At the same time, the change of the asphalt layer thickness has little effect on the internal shear stress (shear strain). When the thickness of the asphalt layer is more than 6 cm, the maximum shear stress can be increased by an increase in thickness. All of these indicate that the location of the asphalt near the pavement is the most unfavorable position of the asphalt layer in PMCCP. It is important to improve the high temperature performance of the asphalt concrete mixture on the resistance of the asphalt pavement shear failure.

Under different vehicle driving conditions, the lateral force of the road surface is different, and the lateral force size is characterized by the lateral force coefficient (Ahmed Abdelazim Eltahan, 1996 & Yang Xueliang, 2007). The asphalt layer stress changes in the different lateral force coefficients show that the horizontal force coefficient remained at a low level, the shear stress (strain), tensile index, and horizontal displacement will not produce significant changes with horizontal force coefficient changes. When the value of the transverse force coefficient is larger, the magnitude of the reduction is more obvious, while the normal travel of the car or the prediction of the lateral force coefficient of the brake is generally no more than 0.3. But on the ramp or city road intersection, the horizontal force of the vehicle caused is large. And so, necessary measures should be taken to improve the performance of the asphalt layer to resist the lateral force caused by shear stress and tensile stress. From the above analysis, it can be observed that the reasonable thickness of the asphalt layer that is based on the shear resistance can be recommended as 4 to 8 cm.

5 CONCLUSIONS

1. Establish the finite element model of the pavement structure and determine the parameters of the pavement structure layer, element type, and calculation parameters. The direction of the horizontal force is parallel to the driving direction, which is used to simulate the horizontal force generated by the vehicle acceleration, braking, or uphill.
2. The influence of the horizontal stress on the stress and strain of the asphalt layer when the PMC and the asphalt surface are in different contact states (i.e., completely continuous and absolutely smooth). Different depths of the absolute smooth state shear stress tensile stress is greater than that of the completely continuous state, which can be used to explain that between the asphalt layer and the PMC layer such that the continuous state is more favorable than the smooth state. The pavement structure will generate a stress response when the asphalt mixture is considered by using the horizontal force in the summer and winter.
3. The different thicknesses of the asphalt layer on the asphalt layer shear stress (shear strain) and tensile stress have little effect on the asphalt layer. It set up a thick layer of asphalt that may lead to internal shear stress (shear strain) that is increased by a certain extent. It can be obtained from the analysis of the influence of vehicle load on the asphalt pavement stress that the asphalt concrete pavement should not set the asphalt layer thickness.

A study on the protection type of flow-guided porthole dies with twin cavities for semi-hollow Al-profiles

Rurong Deng & Peng Yun

Guangzhou Vocational College of Science and Technology, Guangzhou, China

ABSTRACT: Through an actual example, a new structure with twin cavities in a die for semi-hollow Al-profiles was introduced. A structure named protection type of flow-guided porthole die to solve the cantilever strength is presented. And the selection and the optimization of structure parameters are described in detail. The design of the portholes, the determination of the bridge, and the selection of bearing belt are included. It is shown that the structure with twin cavities for semi-hollow profiles is effective, and the structure can greatly improve the production efficiency and reduce the cost. It is worth promoting. The purpose of this work is to provide reliable data and reference for further research and development of this technology on the extrusion die with multi-cavities in a die.

1 INTRODUCTION

Semi-hollow Al-profiles are quite common in the production of aluminum profiles extrusion dies. The key to the production of a semi-hollow section is the die. The die design of semi-hollow profiles is more difficult and complicated, and the main problem to be solved is the strength of the die. In order to solve the problem, domestic and foreign scholars, experts and engineering and technical personnel have carried out a wide range of exploration and research. In addition to the study of mold materials and heat treatment, more studies are required to explore the die structure, by changing the die structure and changing the stress condition of the cantilever to improve the die strength. This way is particularly effective. In recent years, with the rise of land, labor and energy costs, the overall cost of enterprises rose significantly. In such an economic environment, it is not realistic for enterprises to depend on increasing the number of equipment, the expansion of the plant or to human-intensive and other traditional investments to expand the production scale. The best way to improve productivity and reduce costs is to rely on technological innovation and the use of innovative ways to drive. The extrusion technology of multi-cavities in a die is one of the best ways and methods. The key factor in this extrusion technology is the die, especially for a wide variety of semi-hollow sections, because this type of material usually forms a relatively small section. Therefore, it is more practical to use a model of multi-cavities extrusion. Through an actual example, a new structure named protection type of flow-guided porthole with twin cavities in

a die for the semi-hollow Al-profiles will be introduced for peer reference. And to provide reference data for the development of more and more effective die structures for similar profiles.

2 DETERMINATION OF DIE STRUCTURE PARAMETERS

2.1 *The formation of structures*

The semi-hollow sections of the flow guide protection type die structures are formed, that is, for some of the profile sections with a length to width ratio of more than three of the narrow and long sections, according to the structural characteristics of the profile. The porthole bridges are used to cover and protect the cantilever, and there is a certain stress space between the bridge and cantilever. In the extrusion process, even if the porthole bridge bends downward flexibly under force, it would not touch the cantilever instead of bearing the force, and the cantilever will not bear the extruded metal's positive pressure. In the die, the cantilever can be considered as a cantilever beam, and the bridge is a simple supported beam under a uniform load and the strength of the simple supported beam is greatly improved under the same loading conditions. Obviously, the change or shift of the force conditions can improve the strength of the mold. And so, as long as the bridge has sufficient strength, the strength of the cantilever will be ensured. At the same time, as the cantilever beam, this bending moment that the end of the beam exerts on the root is the biggest, and so in order to improve the stress state and metal supply of the

cantilever end, the guide grooves must be set in the place of the corresponding bridge, and the end of the cantilever is completely under the protection of the bridge; through the bridge, the metal will perform welding and diversion actions into the sites, thereby reducing the extrusion force of the end, so as to improve the strength of the cantilever.

2.2 The arrangement of die holes

A typical section of the semi-hollow profile is shown in Figure 1.

The maximum tongue ratio of the section was 6.3, and the ratio of the width to the length was 3.1. In the layout of the die with twin cavities, the die strength and smooth extrusion must be considered, but more important is taking into account the full use of the potential of the extrusion machine, thereby making it conducive to the adjustment of the metal flow and saving costs. The layout of the die is shown in Figure 2.

The layout shown in Figure 2(a) is a symmetrical layout of the left and right, but its requirement of the size of the die is more larger, and the parts of the die hole that are close to the edge of the container and away from the extrusion center are not conducive to shape, so that the layout cannot fully play the capacity of the container. The scheme shown in Figure 2(b) is just the opposite; the lack is that the die holes are arranged up and down, and the

Figure 1. Schematic showing the signal of the semi-hollow section.

surface of the two profiles will come in contact in the extrusion. But according to the surface quality requirements and the final selection of the profile surface treatment and comprehensive consideration, the scheme shown in Figure 2(b) will be more appropriate. By this way shown in Figure 2(b), if changing the site of the positioning pin in the die, the way of a symmetrical layout of the left and right can be realized similarly; the way shown in Figure 2(b) is similar to the symmetry of the left and right, and it is more conducive to solve the balanced distribution of the metal in the design.

2.3 The design of feeder holes and the bridge

2.3.1 The design of feeder holes

On the basis of the layout shown in Figure 2(b), the arrangement of portholes is carried out, which mainly includes the determination of the area and size of the portholes, the feeder ratio, and the area relationship between the portholes. According to the experience, the preliminary programs should be completed. With the help of CAD software, a mature arrangement of portholes by experience will be selected to establish a three-dimensional model under the environment of UG, and the models must be saved as a fixed pattern into the extrusion simulation software. Simulation, calculation, and observation were carried out, and the results were compared and analyzed, and combined with the experience to make correction, in particular, the effect of the communal porthole S1 on the metal flow and deformation, simulation and correction were repeated, until the final determination of the best program was completed. The latter program is shown in Figure 3.

Its main parameters are as follows:

1. The feeder ratio is 16.
2. The bridge size is of width 22 mm and thickness 85 mm.
3. The area relationship between the porthole S1 and S2 is shown in Equation 1.

Figure 2. Schematic of the signal of die holes arrangement.

Figure 3. Schematic of the signal of portholes arrangement.

$$S1 = 0.8S2 \quad (1)$$

4. The result of the simulation shows that when the area relationship meets certain conditions as shown in Equation 2, it is easy to maintain consistency of the flow rate of the metal. The deformation degree of the cantilever can be almost neglected.

$$S1 = (0.70 \sim 0.85)S2 \quad (2)$$

In addition, the common porthole is the form that one divides into two; its advantage is that it is easy to adjust the distribution of the metal; more important is that the metal flow of two portholes does not affect each other ahead of the allocation. If the separation that one porthole divides into two is not carried out, on one hand, it will form a rigid zone and dead zone of the metal flow in the central part of the common porthole, which will make the corresponding profile surface appear as coarse grains or a bright band, which will affect the surface quality and performance of the profile. On the other hand, the sensitivity to the manufacturing error will increase, which will affect the synchronization of the extrusion. But the length of the original flow of the metal into the first porthole named as first stage depth can be obtained by simulation, when the metal reaches the depth. It is divided into two strands of the metal into two portholes respectively, and from the simulation, it is found that when the depth of the first stage is greater than 25 mm, the depth will have almost no effect on the metal flow.

2.3.2 The structure of the bridge

It is mainly used to determine the appropriate distance from the bottom edge of the bridge to the

die hole and the size of flow guiding groove of the corresponding end of the cantilever. The structure of the bridge is shown in Figure 4.

From the simulation, it is found that the distance of 3 mm–5 mm from the bottom edge of the bridge to the die hole is more suitable. If the distance is too small, the metal flow becomes complicated, the extrusion force will increase, and if the distance is too big, the deformation of the cantilever will increase.

2.3.3 The stress gap

In order to ensure that the bridge does not touch the cantilever in the extrusion process, the stress gap should be set up to prevent the bridge from touching the cantilever, the gap value of the experience can be taken from 0.15 mm to 0.25 mm.

2.3.4 The selection of bearing

In the die with twin cavities, the choice of the bearing can be selected according to the ordinary single cavity. When one is selected, the other one is the same as it.

For the flow guide protection type die structure, because the central part of the cantilever end is completely under the protection of the bridge, through the bridge, the metal will make a welding and diversion into the site, and therefore it is difficult for the metal to reach the site. Corresponding to the site, the length of the bearing is the shortest, and the choice of the bearing must be based on the point. The selection of the bearing based on experience can be modified through the simulation operation. The latter bearing is shown in Figure 5.

2.4 The die structure composition

The die is composed of the male die and the female die, as shown in Figure 6.

A study on covering and protection type porthole dies for semi-hollow Al-profiles

Rurong Deng & Peng Yun

Guangzhou Vocational College of Science and Technology, Guangzhou, China

ABSTRACT: A new structure named covering type for the semi-hollow Al-profiles is presented. Through a common actual case, the determination of structure parameters is introduced in detail. The arrangement of portholes, the structure design of the chamber, and the selection of the bearing are included. The method of checking the die strength is introduced. According to the extrusion results, the structure of the traditional solid die and the covering type structure are compared. The characteristics of the latter structure are simple and easy to process. The practical application shows that the new die structure can enhance the die life, improve the production efficiency, and reduce the cost. High precision and the surface brightness of the profiles were obtained. The structure is worth promoting. The aim is to provide reliable data and reference for further research and development on the structure of semi-hollow Al-profiles.

1 INTRODUCTION

With the development of modern manufacturing technology as well as the understanding and research of aluminum alloys, aluminum alloy profiles have been widely used, and the market demand is huge. In the huge market demand, the proportion of the half hollow section is quite common. And in the semi-hollow section of the production, the mold is the key element. This is because the mold design of the semi-hollow profile is of a higher grade, and the strength of the mold is the key. Therefore, vigorously developing a suitable semi-hollow profile extrusion die structure has a very important significance. In this paper, through the common actual examples, a covering type porthole die structure is introduced specially for semi-hollow aluminum profiles to offer reference.

2 THE COVERING AND PROTECTION TYPE PORTHOLE DIE STRUCTURE

The covering and protection structure is a kind of structure which is used with a porthole structure with covering and protection instead of the traditional solid structure for semi-hollow profiles. At present, the porthole structure commonly used in the semi-hollow section is the cutting type porthole die, but the structure can easily produce raised wire and convex flanges on the surface of profiles. The covering and protection type porthole die structure is constructed in such a manner that the center part of the male die is used as a cover or shelter to protect the cantilever, so that the cantilever does not

bear the positive pressure of the metal during the extrusion process, and the cantilever is completely protected. And in the female die, the cantilever must protrude or raise upward, but it has no contact with the male die, and there is a gap named stress gap between the top of the bulge and male die; as a result of the gap, even if the male die is bent downward by force in the extrusion process, the male die cannot touch the cantilever, and the cantilever will be protected effectively, which improves the stress state of the cantilever and reduces the force area of the cantilever, so as to greatly improve the strength of the cantilever and the die. And the porthole die structure is used to make full use of the bridge as the protective shield of the cantilever, avoid the cantilever and its end in particular, thereby bearing directly the positive pressure of the metal extrusion, so as to improve the strength of the die.

3 DETERMINATION OF DIE STRUCTURE PARAMETERS

3.1 *The design of portholes and the bridge*

The design of the portholes includes the determination of the feeder ratio, the size of the portholes, and the structure of the bridge. This is the key. The section shown in Figure 1 is a common section of civil building doors and windows, which is a typical semi-hollow section.

The purpose of using the new structure is to protect the cantilever from the direct impact of the metal. Therefore, it is important to avoid the impact of the end part of the cantilever directly to withstand the impact of the metal, as far as possible by

the use of the bridge for shelter. According to the characteristics of the profile shown in Figure 1, it is more suitable to use two portholes and a bridge, as shown in Figure 2. And so, one can do what the cantilever is arranged for under the protection of the porthole bridge, and the use of the structure and the area of portholes can be taken larger to increase the feeder ratio, which can reduce extrusion pressure, lighten the cantilever force, and improve the cantilever strength.

Because the cantilever must protrude or raise upward, the structure of the bridge should be designed according to the protruding boundary dimension of the corresponding cantilever. The structure of the bridge is shown in Figure 3.

Figure 1. Schematic of the signal of a typical semi-hollow section.

Figure 2. Schematic of the signal of the portholes arrangement.

Figure 3. Schematic of the signal of the structure of the bridge.

3.2 The welding chamber and the bearing

The shape of the welding chamber is determined in terms of the outer contour of the portholes. The key is to determine the size of the raised boundary of the cantilever, which is the key to the structure of the covering and protection type. The size relation between the raised part and the die hole of the cantilever is shown in Figure 4.

The principle is that the distance from the edge of the protruding part to the edge of the die hole of the cantilever can be determined to be in the range from 2 mm to 3 mm. At the same time, with a stress gap between the top of the raised part of the cantilever and the bottom of the bridge, for ease of processing, the gap is built by cutting the top of the cantilever, the experience value shows that the gap is a range from 0.5 mm to 1.2 mm, the bridge does not produce a force to a cantilever, and so the value of the gap is taken as 1.0 mm. The welding chamber structure and bearing are shown in Figure 5.

3.3 The die structure composition

The die is composed of the male die and the female die, as shown in Figure 6.

Taking the cost of the die, extrusion coefficient, and die strength into account, we chose a 10MN extrusion machine, with a container with an inner diameter of 135 mm. After a calculation, the extrusion coefficient is determined to be 61.2, the feeder ratio is 20.1, and the die size of the selection is that the diameter is 200 mm and its thickness is 130 mm.

Figure 4. Schematic of the signal of the raised part of the cantilever.

Figure 5. Schematic of the signal of the welding chamber and the bearing.

Figure 6. Schematic of the signal of the die structure composition.

4 CHECK THE STRENGTH OF THE DIE

Although the cantilever of the semi-hollow profile extrusion die is equivalent to a cantilever beam, because of the protection of the bridge, the bridge bears positive pressure directly instead of the cantilever during the extrusion process, and so checking the bridge strength instead of the cantilever is allowed. In the process of extrusion, the bridge is subjected to a cyclic stress, and so it is more effective to use an empirical formula to check the strength of the bridge in the actual process, as shown in Equation 1.

$$n = \frac{h \times b \times 2 \times [\sigma]}{s \times p} \quad (1)$$

where

1. n is the safety factor (the porthole die is greater than three and the solid die is greater than two).
2. b is the thickness of the bridge, mm.
3. s is the total area of the pressure on the bridge, mm^2 .

4. p is the extrusion press, MPa.

5. $[\sigma]$ is the bending stress of the die material in the working area, and the value is 1150 Mpa.

The strength was calculated according to Equation 1.

$$n = \frac{60 \times 24 \times 2 \times 1150}{14 \times 80 \times 690} = 4.3$$

The results show that the mold has sufficient strength.

But in practice, the covering and protection type porthole die structure for the semi-hollow section material must be supported by using a special die support; otherwise, the die life will be greatly reduced. The thickness of the special die support should not be less than 70 mm.

5 EXTRUSION RESULTS' COMPARISON

According to the extrusion tracking for the profile shown in Figure 1, the traditional solid and the

Table 1. A comparison of the die structure and extrusion results.

Die structure	Die life (tons)	Wall thickness deviation	Extrusion marks and brightness	Dimension precision level	Change of opening size	Processing difficulty	Die material
Traditional solid	Less than 1.2	Obvious	Deep and rough	General	Big	Big	62 kg
Covering and protection type	26.7	Not obvious	Low and shining	High	Medium	Simple	35 kg

covering and protection type of the porthole die structures were used, and the results of the comparison are given in Table 1. The results show that the new structure has the obvious advantage.

6 CONCLUSIONS

When the test of extrusion and use tracking were completed, the results show that the die is successful in one time. And by the repeated use after being nitrided, the die extrusion production life reached 26.2 tons. Thus, it can be shown that the new structure named covering and protection type is effective and the new structure can improve production efficiency and reduce cost. The new structure is worth promoting. At the same time, we can see that the design of portholes, the bridge structure, the die welding chamber structure, and the selection of the bearing are key and important to the new structure.

A study on protection type porthole dies of semi-hollow Al-profiles with four cavities

Rurong Deng & Peng Yun

Guangzhou Vocational College of Science and Technology, Guangzhou, China

ABSTRACT: A new porthole die structure named protection type with four cavities in a die for semi-hollow Al-profiles is presented in this article. Through a practical case, the determination of parameters for the new structure were described, mainly including the structure composition that it is made up of three parts in replacement of the traditional two piece structure; the design of portholes and the structure of chamber in the female die and the selection of the bearing were also included. The method of checking the die strength was introduced. And according to the extrusion results, the structure of the traditional porthole die in a common code, the cutting type of porthole die with single cavity and twin cavities and the protection type of four cavities were compared. It indicated that the characteristics of the latter structure with four cavities are simple and easy to process. The practical application shows that the new structure can greatly improve the efficiency of the extrusion machine and significantly prolong the die life. Furthermore, the high precision and the surface brightness of profiles are obtained. The structure is worth promoting. The purpose is to promote the technology, provide reliable reference data for further development of the porthole die with multi-cavities in a die for semi-hollow profiles.

1 INTRODUCTION

The porthole extrusion die with four cavities, in particular for the semi-hollow section, is a multi-cavity die extrusion technology. It is designed particularly for semi-hollow profiles, with four cavities in a die, where four identical profiles will be extruded synchronously at a time. It is a good method to rely on technological innovation to cope with the continued rise of cost of human resources and energy costs and the lack of land supply. Especially in an extrusion machine equipped with a trend of large scale, it can solve the problem since a small machine has too many orders to complete, and a large machine has not enough orders to work on. In the extrusion of multi-cavities, the die is the key. Research on this technology exhibits an ascending trend in our country; especially in recent years, the majority of experts, scholars, and engineering and technical personnel carry out lot of research and exploration. Through an actual case, a new kind of four cavities protection type structure will be introduced, which is specially designed for the semi-hollow section, as a reference to designers.

2 THE SECTION ANALYSIS AND DIE STRUCTURE

Figure 1 shows a typical civil profile used in building doors and windows.

The section of the profile is provided with a hollow part and a typical semi-hollow part, the area of the section is 291 mm², and the maximum tongue ratio of the semi-hollow part is 6.5.

Compared with the determination principle of the semi-hollow section, the ratio of the tongue is more than the maximum value allowed in the opening, and so the part can be determined as a semi-hollow section. In practice, if the die structure is still an ordinary structure, then the strength of the cantilever in the extrusion process is very dangerous and prone to fracture, thereby resulting in premature failure of the die. Therefore, this section should be ruled as a semi-hollow section with a hollow part. For single-cavity dies, in order to solve the strength of the cantilever in semi-hollow profile extrusions, more structures are usually used in a cutting type porthole die, and its cantilever is cut into two parts, and one part is separated as the core of the male die. In the die with single

Figure 1. Schematic of the signal of the section of the profile.

cavity, the cores can be placed in the center region of the container, the core force is in a state of equilibrium, and it will not be affected by an additional force with the pressure difference formed around the core. But in a die with multi-cavities, with an increase in cores, it cannot achieve this arrangement. Because of a pressure gradient that is formed across the section of the container, the pressure gradient makes the core take an elastic offset in the extrusion process, the phenomenon of raised wire and convex flange is produced in the porthole die with single cavity by the cutting type porthole die, but the problem will be more serious in the porthole die with multi-cavities. At the same time, with an increase in the number of cores cut from the cantilevers, the manufacturing difficulty and error will increase and the difficulty to realize the synchronization of the extrusion will increase. In order to eliminate the phenomenon, in the die with multi-cavities, especially for the dangerous site of the cantilever, we can set a fake core in the male die to protect the cantilever with the help of the feeder bridge. In the extrusion, the fake core cannot touch the cantilever, and the cantilever will be protected effectively by the fake core and the bridge, which will improve the stress state of the cantilever and reduce the force area of the cantilever, so as to greatly improve the strength of the cantilever and the die. The die structure is shown in Figure 2.

An extrusion machine of capability 35MN is selected and the die dimensions are as follows: the diameter is 400 mm and thickness is 230 mm. In order to facilitate the processing of the die and the adjustment of metal flow velocity, the traditional structure type of the porthole die is changed, and a front feeder plate is added. For the determination of the number of cavities in portholes, on one hand, the equipment condition to realize the extrusion should be considered to improve the efficiency of the equipment, the larger in capability the machine is, the higher the efficiency of the equipment is, and the lower the cost will be. But it is more important to consider the difficulty of the die design and manufacture to ensure the synchronization and operability of the extrusion. On the other hand, it is necessary to select a reasonable extrusion coefficient, which is advantageous to the extrusion forming and production processes. If the extrusion coefficient is not reasonable, the waste will increase, and the rate of finished products will reduce. Under a comprehensive consideration, experience shows that the extrusion coefficient is more appropriate in the range from 60 to 80. A comparison of the extrusion program and the die structure for the section is shown in Figure 1 and given in Table 1.

Figure 2. Schematic of the signal of the die structure.

Table 1. A comparison of the die structure and extrusion program.

Die structure	Capability of machine	Inner diameter of container	Number of cavities	Extrusion coefficient	Die dimension (diameter and thickness)	Operator number
Cutting type single cavity	10MN	130 mm	1	45.6	200 × 130	5
Cutting type twin cavities	18MN	185 mm	2	46.2	250 × 160	5
Protection type four cavities	35MN	300 mm	4	63	400 × 230	5

3 PARAMETERS' DETERMINATION OF THE DIE STRUCTURE

3.1 The die hole arrangement

It must be considered to make full use of the capacity of the machine and give play to the potential of the container in the arrangement of the die hole. It is important to avoid as far as possible to make the die lie close to the inner wall of the container, because this is not conducive to metal forming and will increase the size of the die. At the same time, the arrangement should make the holes in a symmetrical arrangement as far as possible; it is conducive to realize consistency of the flow of the metal in the extrusion process and ease of adjustment and balance of the flow of the metal. The die holes layout is shown in Figure 3.

3.2 The front feeder plate

The traditional porthole die consists of a male die and a female die. However, for a die with multicavities used in a large machine, if the male die

thickness is too large, when the strength is sufficient, it will increase the difficulty of the die-making process and reduce quenching of the die in the heat treatment. And an addition of the front plate can ensure predistribution of the metal before entering the male die with a larger feeder ratio, which will help to achieve synchronization and reduce the pressure of extrusion. During the determination of the die holes layout, the front feeder plate can be designed. The metal supply of the two die holes can be separated from the left and the right or up and down. Its structure is shown in Figure 4.

3.3 The design of port holes

The design of port holes include hole layout, the area of the port holes, and determining the feeder ratio of port hole area and the size of false core is more important. The arrangement of the port holes can be in many forms. Based on the layout in Figure 3, the design of the portholes is carried out, according to the experience, the preliminary programs should be finished With the help of CAD software, two or

Figure 3. Schematic of the signal of die hole arrangement.

Figure 4. Schematic of the signal of the front plate.

three kinds of mature arrangement of portholes by experience will be selected to establish a three-dimensional model under the environment of UG, and the models must be saved as a fixed pattern into the extrusion simulation software, the simulation and calculation and observation are carried out, and the results were compared and analyzed, and combined with the experience to make correction, repeating simulation and correction, until the final determination of the best program. The arrangement of the port holes is shown in Figure 5.

The advantage of this layout is that, in the simulation, it is found that consistency of the metal flow velocity can be easily achieved. Each die hole is supplied separately with metal from two portholes. As long as the area of the porthole S1 is determined, the area of the porthole S2 is relatively easy to adjust, and the adjustable range is large, and the layout of the bridge and the die hole need not be modified or changed. On the other hand, the arrangement can enable the cantilever to be placed under the protection of the bridge, and the metal will not directly impact the cantilever, especially the end of the cantilever, so that the force of the cantilever is minimal. And so, the strength of the cantilever is the best. More important is that, from the simulation it can be observed that the change of the area of the portholes has an effect on the cantilever.

Its main parameters are as follows:

1. The feeder ratio is 17.4.
2. The dimensions of the bridge are as follows: width is 24 mm and thickness is 85 mm.
3. The area relationship between the portholes S1 and S2 are shown in Equation 1.

$$S1 = 0.81S2 \quad (1)$$

Figure 5. Schematic of the signal of port hole arrangement.

4. The result of the simulation shows that when the area relationship meets certain conditions, as shown in Equation 2, consistency of the flow rate of the metal can be easily achieved.

$$S1 = (0.75 \sim 0.85) S2 \quad (2)$$

5. The largest circumcircle of the porthole is 270 mm.
6. The structure of the bridge is similar to dripping of water and its feeder position is a trapezoid, which is conical in shape in the outlet part.
7. The stress space is taken in false core, the stress gap is measured according to the experience of 1.0 mm, and so the height of the false core is 24 mm.

In the above-mentioned die structure parameters, determination of the size of the false core is very important. Experience and simulation show that the minimum distance from the fake core to the cantilever's opening is 3 mm and to other die hole edge is 2 mm, and the shape of the rules must be designed as far as possible in order to facilitate processing. The size of the protection type false core is shown in Figure 6

Figure 6. Schematic of the signal of the fake core.

Figure 7. Schematic of the signal of the chamber and the bearing.

Table 2. A comparison of the die structure and extrusion results.

Die structure	Capability of machine	Wall thickness deviation	Extrusion marks and brightness	Dimension precision level	Die life (tons)	Die material
Ordinary single cavity	10MN	Obvious	Deep and rough	General	Less than 1	52
Cutting type single cavity	10MN	Not obvious	Low and shining, raised wire	General	8.5	65
Cutting type twin cavities	18MN	Not obvious	Low and shining, raised wire	General	21.7	105
Protection type four cavities	35MN	NO	Low and shining	High	More than 73.2	290

3.4 The chamber of the female die and the bearing

In order to eliminate the effect of manufacturing errors on the extrusion synchronization and to avoid the rigid region of metal flow in the central part of the cavities to cause the coarse grain in the profile, the welding chamber must be designed to be independent respectively. A wall must be set between the welding chamber, with a desirable width of 6–8 mm and the height is 8–10 mm. For the choice of the bearing is selected according to the single cavity. When one is selected, the other one is the same as it is. The welding chamber and the bearing are shown in Figure 7.

4 A COMPARISON OF EXTRUSION RESULTS

According to the section shown in Figure 1, the traditional ordinary porthole die with single cavity,

the cutting type porthole die with single hole, the cutting type porthole die with twin cavities, and the protection type porthole die with four cavities were separately used. We have carried out the test of extrusion and extrusion production tracking, and the results and comparison are shown in Table 2.

It can be seen from the results that the protection type die of the porthole die with four cavities in a die for the semi-hollow section can significantly improve the efficiency of extrusion and greatly improve the life of the die, as well as reduce costs.

5 CONCLUSIONS

The structure of the protection type porthole with four cavities is used in the section, as shown in Figure 1. The results show that the die life of this kind of structure can reach 73.2 tons. It can be seen that this structure is effective and it can significantly improve the efficiency and reduce the

cost of the production. If we use more number of dies with multi-cavities in a die for extrusion production, we can completely solve the problems in that small machines have too many orders to complete, and large machines have not enough orders to work on and significantly improve the efficiency. In the die structure with four cavities, especially for the semi-hollow profiles, the determination of the capability of the machine, the design of portholes, and the welding chamber structure and bearing is very important. But it is more critical to select a reasonable and effective die structure to reduce the extrusion force and to ensure the strength of the cantilever and to make it easy to process. This structure is worth promoting. For further research and development of the new die structure with multi-cavities for the semi-hollow section, we have accumulated experience and reliable practice data.

Numerical and experimental study on stability of aluminium alloy riveted and stiffened panels under in-plane shear

Dawei Wang, Zhenkun Lei, Ruixiang Bai & Yu Ma

State Key Laboratory of Structural Analysis for Industrial Equipment, Dalian University of Technology, Dalian, China

ABSTRACT: Shear experiment on aluminium alloy riveted and stiffened panel was conducted to obtain the shear buckling mode, buckling load, load capacity, and failure mode of the structure. Using a combination of fringe projection method and strain gauge sensor, the shear buckling morphology and instability evolution process were detected in real-time. Finite Element Method (FEM) was used to analyze the buckling performance and load capacity. Experimental and simulation results show that the shear instability of the structure forms the skin local buckling between stiffeners.

1 INTRODUCTION

Stiffened aluminium alloy panel structure with a low weight can significantly improve the buckling critical load, which had been widely used in aircraft wing and fuselage structure. The riveting technology avoids the residual stress problem caused by high temperature in laser welding technology. The stiffened panel as a typical aircraft structure has a common failure mode of buckling under compression, shear, torsion and bending. The stiffened panel still has a considerable post-buckling load capacity, which can be used to increase structure loading capacity.

There are many theoretical and experimental works on the buckling of stiffened panels in recent years. Rossini et al. (2016) has studied the pre-buckling and post-buckling behavior of adhesively-bonded and riveted and panels subjected to in-plane compression by numerical simulation and experiments. It showed that the bonded panels have a superior performance than the riveted panels in buckling load and buckling mode. Villani et al. (2015) measured the buckling load, collapse load and failure mode of bonded panels, which agreed to FEM simulations.

However, the selection of element, mesh, and material modeling have a important role for the nonlinear FEM analysis of riveted panels under uniform shear loading (Murphy, 2005). Cricri et al. (2014) designed a novel multi-hinged test fixture to provide a pure shear load for stiffened panels, and the experimental results showed that there are different buckling modes in comparison with that of a traditional picture frame test fixture. Therefore, the nonlinear FEM analysis of riveted panels has influenced by the selection of boundary conditions and must be validated by experiments.

The manufacturing defects, contact and damage problems are inevitable, which need to be considered in the nonlinear FEM analysis. Anyfantis et al. (2012) studied the progressive post-buckling and the final failure response of stiffened composite panels based on the structural nonlinear FEM. Orifici et al. (2008) combined the post-buckling deformations and several composite damage mechanisms to successfully predict the damage growth and collapse behaviour of composite stiffened structures under compression. The buckling behavior influenced by the type of stiffeners, panel orthotropic ratio, tensile stiffness and shear stiffness ratios of stiffener and skin (Jain, 2010).

In this paper, a shear experiment on the aluminium alloy riveted and stiffened panel was conducted to investigate the buckling mode and failure, which were compared with the FEM stability analysis. The experimental and simulation results provide a reference for engineering application of the structure.

2 EXPERIMENTS

2.1 Specimen description

As shown in Fig. 1(a), the specimen was made of high strength aluminium alloy, which consists of skin and 4 Z-shaped stiffeners, and the skin and stiffeners were riveted. The shear load was applied to the specimen by a diagonal tension, as shown in Fig. 1(b). The strain gauges were pasted to the symmetrical and back-to-back positions (shown as the “+” symbol in Fig. 1) on the skin to monitor the initial buckling and post-buckling failure.

2.2 Test procedure

The shear experiment was carried out in a four-column tester (CSS-100T, Changchun tester Co.), as shown in Fig. 2(a). The diagonal tensile load was applied to the specimen until a large deformation failure. A loading rate was 6 kN/min and the final failure load was 471.5 kN, as shown in Fig. 2(b).

Figure 1. (a) Specimen geometry and (b) diagonal tensile shear.

Figure 2. (a) Tensile shear test and (b) loading history.

3 RESULTS AND DISCUSSIONS

3.1 Strain measurement

The strain history for typical positions is shown in Fig. 3. An obvious strain bifurcation phenomenon appeared at the moment of 10 min., which implies that the initial skin buckling appeared at the time. Then, the stiffeners bear the main load and the post-buckling deformation occurs with the increase of strains until to the maximum load of stiffener instability. At this time, the panel structure cannot afford a more load, namely the failure load.

3.2 Optical measurement

A multi-frequency fringe projection method was adopted to measure the buckling mode of skin at different time (Lei, 2015). Four sets of sinusoidal and phase-shifted fringes with the fringe frequencies of 1, 4, 16 and 64 were projected by a projector (TLP-X2000) onto the skin in turns, and the distorted fringe patterns were simultaneously grabbed by a CCD camera (F-080B). An image acquisition frame rate was 4 fps and the image size was 1024×768 pixels.

Then a four-step phase-shifting method and a multi-frequency phase unwrapping technique were combined to obtain the phase of surface topography. The phase difference before and after deformation was converted to the skin deflection (Lei, 2016).

The full-field deflections of buckling wave were given by optical measurement, as shown in Fig. 4, which is more vivid than the electrical strain measurement (Fig. 3). Some peaks and troughs of local buckling appeared in the skin between the stiffeners and there are 4 buckling half waves on the skin. The direction of the wires is along the direction of the stiffeners. The horizontal direction of the buckling waveforms is consistent with the direction of diagonal loading.

3.3 FEM simulation

Numerical simulation on the shear behaviour of the stiffened panel was implemented by ABAQUS/

Figure 3. Bifurcation phenomenon of strains.

Figure 4. Buckling modes at back of the specimen under different loads, (a) 300 kN and (b) 400 kN.

Standard module. The finite element mesh, loading and boundary conditions of the stiffened panel are shown in Figs. 5(a) and 5(b). A 4-node doubly curved thin or thick shell element of S4R was chosen from the ABAQUS element library according to the basic assumption of Kirchhoff thin plate theory.

In order to improve the computational efficiency and accuracy, a 2-node linear beam element “B31” has been chosen to discrete clamps and the MPC constraint was used to simulate the pin connection between the clamps. A hard contact without friction was adopted. A fixed support constraint was applied to a diagonal point of the finite element model. A tensile displacement load was applied to the other corner of the diagonal and the out-of-plane displacement of the four-side loading regions were constrained.

Before analyzing the load capacity of the stiffened panel, a linear buckling analysis should be performed firstly to obtain the buckling modes. The initial geometric imperfections of the panel were assumed to be a linear buckling of a certain order of deformation. The post-buckling load capacity analysis was performed by editing the INP file for introduction of the initial defect. The result is shown in Fig. 5.

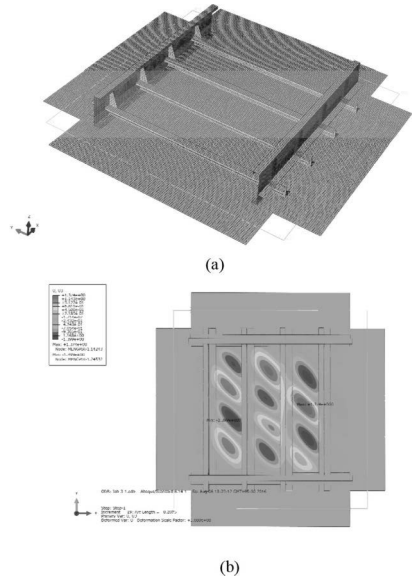

Figure 5. (a) FEM model and (b) out-of-plane displacement under the critical buckling load.

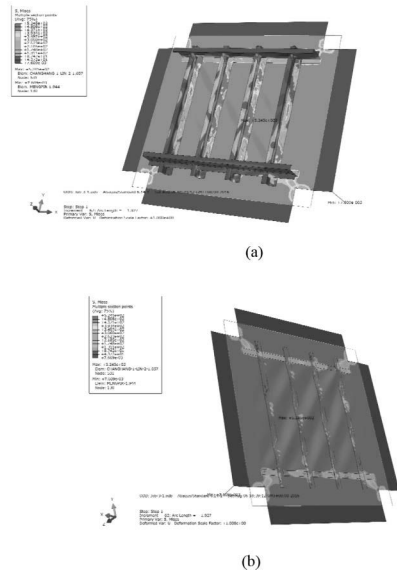

Figure 6. Misses stress distribution on the (a) front and (b) back of stiffened plate under failure load.

Fig. 6 is the Misses stress distribution of the structure under the ultimate load. It shows that the failure mode of the structure is the skin deformation between the stiffeners, and the plastic deformation is very large near the diagonals, which are in agreement with the experiment.

The connection strength of the riveting area in the actual structure is determined by the rivet strength. Through the experiment, it is found that the failure mode of the stiffened panel is the rivet failure. In this paper, the connection mode of the riveting is simplified, and the effect of the rivet failure is ignored. It is believed that the structural loss of load capacity is mainly caused by the plastic deformation of the skin and stiffeners, which is the main reason for the calculation error.

4 CONCLUSIONS

The riveted and stiffened aluminium alloy panel under in-plane shear test was conducted. The experimental result shows that the failure mode of the stiffened panel under in-plane shear includes the skin local buckling between the stiffeners, the skin plastic deformation, the stiffener bending and torsion deformation, and the partial rivet connection failure. Then, the FEM model was established and successfully predicted the buckling load and the failure load, which are close to the experimental ones.

Process optimization for the new nano-complex internal coating and its anti-corrosion and drag reduction properties in natural gas pipes

Baohong Hao, Bin Sun, Zhihong Liu, Yulong Han & Longfei Zhao

School of Mechanical Engineering, Beijing Institute of Petrochemical Technology, Beijing, China

ABSTRACT: A new nano-composite coating is developed by using the blending method for use inside the pipe of natural gas. The “systematic effect” and the “cascading effect” produced by the hybrid composition of nanoparticles and the matrix are used to achieve optimization for the complex coating on functions such as anti-corrosion and drag reduction. The difficult-to-coordinate bottleneck problem which is an “internal and external trouble” existing inside the pipe will be solved at the same time. The optimized composite coating, on one hand, can exert a “super bonding force” with the wall of the pipe which is not easy to peel; on the other hand, the coating can show a “super alienation” behavior to the medium which is not easy to scale. An acceleration simulation method has been used to evaluate the performance indicators of anti-corrosion and drag reduction through experiments. The results of experiments show that the composite coating added with nano-additives shows a decline of surface roughness and visible latent function of drag reduction. The results of the experiments also show that the corrosion rate has declined by an average of more than one time.

1 INTRODUCTION

By referring the literature, we know that (Luo, 2010; Ma, 2012; He, 2013; Fan, 2008) the most prominent problems in our country’s existing coating are high surface roughness and poor durability of coatings. Firstly, the roughness of the pipe directly affects the transport efficiency. Secondly, poor durability is a potential security risk which will affect the secure transportation of natural gas. And the roughness is a precipitating factor for the decline of durability. Especially for the occasion where too much H_2S and CO_2 are present in the natural gas, the corrosive environment of the internal wall of the pipe will become more severe, and a little increase in the surface roughness of the pipe will directly cause a significant decline in the durability. Therefore, it is imperative that a composite coating needed to be developed to deal with the durability of coating and the roughness of the surface of coating synchronously. Developing a new, long-lasting and efficient nano-composite coating can alleviate fundamentally the coating’s peeling inside the pipe. When the temperature and pressure of the medium change and wear is caused by the impurity of the medium etc., an efficient and long-lasting protection is realized for the internal wall of the natural gas pipe, thereby resulting in control of corrosion, reduction of wear, prolonging of service life and improvement of durability so as to ensure the safe operation of natural gas pipelines in the West–East Gas Transportation Project (Zhu, 2006).

2 EXPERIMENTAL MATERIALS AND EXPERIMENTAL METHODS

X65 (micro-alloyed high-strength low-alloy steel) is a model of the test specimen of the pipe; the additive is nano-aluminum dioxide and nano-titanium dioxide; the matrix coatings are epoxy resin paint, alkyd anti-rust paint and synthetic thinner. The testing device applied is the CS electrochemical workstation; the instruments involved are ORION420A type pH meter, X-ray diffractometer, and scanning electron microscope.

3 ANALYSIS FOR EXPERIMENTAL RESULTS

3.1 Mechanism of drag reduction and contrastive analysis of experimental figures

Fig. 1 shows the schematic diagram of the vortex produced when the natural gas flows through the pipe.

From Fig. 1, we can see that when the internal wall of the pipe is not coated, the height (roughness) of embossments on the internal wall is high and the vortex zones formed behind these are large in size; therefore, the drag loss produced is also big; When the internal wall is coated, as the fineness of the internal wall surface is increased, the vortex zones produced behind the embossments are smaller in size, and the drag loss therefore becomes small. From Fig. 1(c), we can see that the fineness of the internal wall of the pipe (boundary) has a big impact on the drag coefficient; that is to say that, we

Figure 1. Schematic diagram of the vortex zone and effect chart of fineness and drag reduction rate.

Figure 2. Visual and microscopic analysis figures for the surface roughnesses of nano-composite coating and common coating.

can reduce the drag in the later transportation of natural gas by improving the fineness of the composite coating. Fig. 2 shows the visual and microscopic analysis comparison figures of the surface

appearances, which are enhanced with additives and without additives.

From Fig. 2, we can see directly that the composite coating added with nano-additives can exhibit a higher level of fineness; the fine, smooth, and flat surface predicts a potential of drag reduction when the fluid flows through, while for the composite coating added without nano-additives, whose surface is rough and has grooves on it, it is easy for the liquid to attach to produce channeling or vortex and form the fluid drag force. Through scratch test, it was confirmed that the nano-composite coating possesses a higher scratch resistance.

3.2 Anti-corrosion self-cleaning effect and analysis for the simulated accelerated corrosion test

Fig. 3 is the principle diagram of the lotus leaf effect.

From Fig. 3, we can see that the natural nano-structure of the lotus leaf determines its self-cleaning

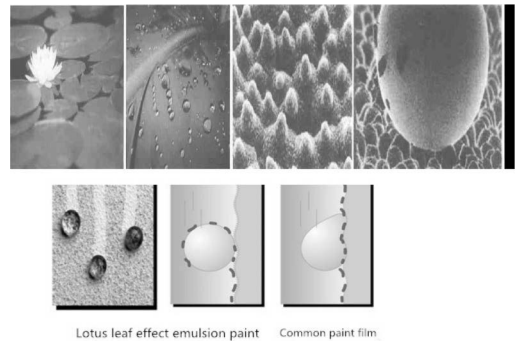

Figure 3. Schematic diagram of the self-cleaning function of the nano-composite coating.

Figure 4. Simulated accelerated corrosion test and chart of the corrosion rate of electrochemical detection.

function, which means that we can adjust the structure of the composite coating to make it nano-crystallized through method of composite modification and realize the super alienation effect between the material and the outside world. Fig. 4 shows intuitionistic figures of the corrosion test and a comparative analysis chart of the corrosion rate of the electrochemical detection result for the coatings with nano-additives and without nano-additives.

From Fig. 4, we can see that after accelerated corrosion for 22 days, the test specimen of the nano-composite coating in the corrosive bath in a strong acid environment (pH = 3) can be observed with only little signs of corrosion, with no bubbling phenomenon and no peeling phenomenon. However, for the common coating, we can see that the visible corrosion products are formed and a certain degree of deposits occurred on the surface. Through electrochemical detection, it shows that the corrosion rate of the nano-composite coating is obviously lower than the common coating and it will be stable basically along with the time of corrosion and exhibits a rising trend just at the later stage of the corrosion; however, the corrosion rate of the common coating exhibits a rapid growth trend. From the contrastive analysis, we can see that the corrosion rate of the composite coating added with nano-additives is only half of the corrosion rate of the common coating, which indicates that the nano-additive can reduce the corrosion rate of the test speci-

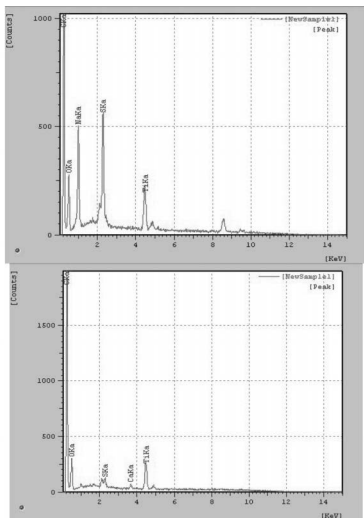

men of the composite coating exponentially and improve the corrosion resistance exponentially. Fig. 5 shows EDAX spectra to prove the existence of nano-additives.

From Fig. 5, we can see that when the composite coating is enhanced with nano-additives, the X-ray diffraction peaks show a visible epoxy characteristic peak of the matrix coating, after adding with nano-additives, as the nanoparticles have initiated a chemical reaction with the matrix, and so it weakens the strength of the characteristic peak. This proves the existence and true effectiveness of the nano-additive in the composite coating.

4 CONCLUSION

In conclusion, after a visual inspection for macro-appearance and micro-observation for local appearance, the nano-composite internal coating owns a higher surface fineness which can reduce the drag force exerted during the transportation effectively. Through the simulated accelerated corrosion and the electrochemical detection, it indicates that the nano-composite coating exhibits a better “self-cleaning” function and “anti-corrosion function”. The existence of the nano-additives in the composite coating and the effectiveness that it can improve the corrosion resistance to the test specimen has been verified by energy spectrum detection and analysis. The conclusion is summarized as follows:

1. From the visually observed corrosion situation of the test specimen, we can see that the nano-composite coating in the process of stimulated accelerated corrosion shows a strong acid resistance and corrosion resistance. The maximum pH that can be resisted is 3, and the tolerance time can reach to 20 days such that there is nearly no corrosion occurred on it. It is evident that the nano-composite coating has better strong acid resistance when compared to the common coating.
2. Nano-composite coating has a higher level of surface fineness and a potential of drag reduction. The addition of nanoparticles can, on one hand, act as a “nail” going deep into the coating to form a relatively strong bonding force with the wall of the pipe and prevent blisters and folds; on the other hand, it can suspend on the surface of coating and play a role in shimming, compacting, and repairing the surface.
3. The anti-corrosive function of the coating enhanced with nanoparticles also shows a certain degree of self-repair function; the related mechanism is to be studied and discussed later.

ABSTRACT: The Gray Wolf Optimization (GWO) algorithm has disadvantages including low solution accuracy and being easily trapped in the local optimum. In order to overcome these disadvantages, an Improved Gray Wolf Optimization (IGWO) algorithm is proposed. The research applies chaos theory to generate the initial population to ensure that more individuals are distributed in the searching space. A non-linear convergence factor described based on the logarithmic function is proposed to replace the linear decreasing convergence factor so as to coordinate the exploration and development capacities of the algorithm. In order to avoid occurrence of the premature convergence of the algorithm, a mutation operator with adaptable mutation probability is introduced. The numerical experimental results of four benchmark test functions and the data simulation results in the removal of irons from zinc sulfate solution using goethite show that the IGWO algorithm has a favorable optimization performance.

1 INTRODUCTION

The swarm intelligent optimization algorithm, as a global optimization method derived from the simulation of the behavior mechanism of biotic communities in nature, has developed rapidly in recent years. Gray Wolf Optimization Algorithm (GWO) is a new swarm intelligent optimization algorithm proposed by Mirjalili et al. (Mirjalili, 2014) in 2014. Originating from simulating the class mechanism and predation of gray wolf groups, the algorithm can be realized easily through programming, needs little parameters, and shows a strong global searching ability (Mirjalili, 2014). Since its proposal in 2014, the GWO algorithm has been widely used in various fields, including power flow optimization (El-Fergany, 2015) and optimum control of direct current motors (Madadi, 2014). However, similar to other swarm intelligent optimization algorithms, the GWO algorithm also has disadvantages such as low solution accuracy and premature convergence.

In order to solve these disadvantages of the standard GWO algorithm, some improvement methods are proposed. By using four benchmark

test functions and parameter optimization of iron removal from zinc sulfate solution through goethite, the optimization performance of the algorithm proposed in this study is verified.

2 STANDARD GWO ALGORITHM

Gray wolves in a gray wolf population are divided into head wolf α , deputy leader β , common wolves δ , and underclass wolves ω according to the class mechanism. In addition, the lower the class is, the larger is the number of individuals. To capture a prey, other individuals besiege the prey in an organized manner under the leadership of head wolf α . In the GWO algorithm, the individual with the highest fitness in the group is defined as α and those whose fitness is ranked second and third are defined as β and δ . In addition, others are described as ω . Moreover, the position of the prey is defined as the global optimal solution of an optimizing problem. In a D-dimensional searching space, if the position of the i th wolf is $X_i = (X_i^1, X_i^2, \dots, X_i^D)$, X_i^d represents the position of the i th wolf in the d -dimensional space.

For the position of the i th wolf in the d -dimensional space, the behavior of the gray wolf gradually approaching and besieging a prey is described by Equation (1).

$$X_i^d(t+1) = X_p^d(t) - A_i^d |C_i^d X_p^d(t) - X_i^d(t)| \quad (1)$$

where t represents the current iteration times and $X_p = (X_p^1, X_p^2, \dots, X_p^D)$ describes the position of the prey. $A_i^d |C_i^d X_p^d(t) - X_i^d(t)|$ stands for the besieging step and A_i^d and C_i^d are defined as follows:

$$A_i^d = a \cdot (2 \cdot \text{rand}_1 - 1) \quad (2)$$

$$C_i^d = 2 \cdot \text{rand}_2 \quad (3)$$

where rand_1 and rand_2 represent random variables in the range of $[0, 1]$. Variable a is the convergence factor, which plays an important role in coordinating exploration and development capacities of the algorithm. a decreases linearly from 2 to 0 with an increase in the iterations during the evolution, as shown in Equation (4).

$$a = 2 - t / t_{\max} \quad (4)$$

where t_{\max} refers to the maximum iteration times.

While solving optimization problems, there is no priori knowledge concerning the global optimal solution beforehand. In addition, the gray population updates their positions according to their distances to the positions of α , β and δ , namely, X_α , X_β and X_δ .

$$\begin{cases} X_{i,\alpha}^d(t+1) = X_\alpha^d(t) - A_{i,1}^d |C_{i,1}^d X_\alpha^d(t) - X_i^d(t)| \\ X_{i,\beta}^d(t+1) = X_\beta^d(t) - A_{i,2}^d |C_{i,2}^d X_\beta^d(t) - X_i^d(t)| \\ X_{i,\delta}^d(t+1) = X_\delta^d(t) - A_{i,3}^d |C_{i,3}^d X_\delta^d(t) - X_i^d(t)| \end{cases} \quad (5)$$

$$X_i^d(t+1) = \sum_{j=\alpha,\beta,\delta} w_j \cdot X_{i,j}^d(t+1) \quad (6)$$

where w_j ($j = \alpha, \beta, \delta$) represents the weight coefficients of α , β , and δ , and $d = 1, 2, \dots, D$.

$$w_j = \frac{f(X_j(t))}{f(X_\alpha(t)) + f(X_\beta(t)) + f(X_\delta(t))} \quad (7)$$

where $f(X_j(t))$ refers to the fitness of the j th wolf in the t th generation. $f(X_\alpha(t))$, $f(X_\beta(t))$, and $f(X_\delta(t))$ represent the fitness values of head wolf α , deputy leader β , and common wolves δ in the t th generation, respectively. The detailed pseudo codes of the GWO algorithm can be found in the literature (El-Fergany, 2015).

3 IMPROVED GRAY WOLF OPTIMIZATION ALGORITHM

3.1 Population initialization based on the chaotic method

It can be obtained from the mechanism of evolutionary algorithms that the quality of the initial population has a great influence on the convergence, searching efficiency, and stability of evolutionary algorithms. The individuals of the initial population need to be uniformly distributed within the whole searching space as much as possible.

Chaos, as a non-linear phenomenon characterized by ergodicity and randomness, can traverse all states without repetition within a certain range according to its own law. For this characteristic, it can be applied in optimization algorithms to initialize populations so as to ensure diversity of individuals. A transcendental function is selected in the study, as shown in Equation (8).

$$x_{k+1} = \beta \cdot \sin(\pi x_k) \quad (8)$$

where β is a non-negative real number. Given an initial value x_0 , a random sequence within the range of $[-\beta, \beta]$ is produced. Given that the optimal individual in a certain generation of a population is x_p , and selected individuals who are about to enter into the next generation are described as x_j . And then, the Euclidean distance d_{ip} of each individual from the optimal individual is calculated by using Equation (9).

$$d_{ip} = \sqrt{\sum_{j=1}^n (x_{pj} - x_{ij})^2}, \quad j = 1, 2, \dots, n \quad (9)$$

where $i = 1, 2, \dots, N$, and N represents the population size. A threshold value σ is set. If $d_{ip} < \sigma$, then the population x_i ($i = 1, 2, \dots, N$) is initialized by using a chaos sequence, which is produced by employing Equation (8).

3.2 Non-linear convergence factor

For swarm intelligent optimization algorithms, only when the exploration and development capacities are coordinated, a strong robustness and quick convergence rate can be obtained.

By improving Equation (4), the equation for the non-linear convergence factor is updated based on a logarithmic formula, as shown in Equation (10).

$$a(t) = a_{\text{initial}} - \log\left(1 + \lambda \cdot \frac{t}{t_{\max}}\right) \quad (10)$$

where t represents current iteration times and t_{\max} refers to the maximum iteration times. In addition, a_{initial} stands for the initial value of the convergence factor a whose value is two in this study. $\lambda \in [0, 1]$ is called the regulatory factor and $\lambda = 0.7$.

It is obtained from Equation (10) that the convergence factor a non-linearly decreases with an increase in the number of iteration times and therefore effectively coordinates the exploration and development capacities of the GWO algorithm.

3.3 Mutation mechanism with adaptable mutation probability

The standard GWO algorithm is short of the mechanism of getting rid of the local optimum, and so premature convergence is likely to occur in the later period of the optimization.

Therefore, a mutation mechanism with adaptable mutation probability is introduced. That is to say that, mutation occurs in the process of evolution and the mutation probability is shown in Equation (11).

$$p_m = \phi(f) \times p_{m0} + (1 - \phi(f)) \times p_{m1}$$

where p_{m0} and p_{m1} represent small and large mutation probabilities ($p_{m0} \in [0.01, 0.10]$ and $p_{m1} \in [0.2, 0.6]$), respectively. In addition, $\phi(f)$ stands for the function relating the objective function value of the GWO algorithm, as shown in the following equation.

$$\phi(f) = \begin{cases} 0 & \text{if } \frac{f_{\text{avg}}}{f_{\text{max}}} > h_f \\ 1 & \text{if } \frac{f_{\text{avg}}}{f_{\text{max}}} \leq h_f \end{cases}$$

where f_{avg} represents the average value of objective functions of all gray wolves (suppose that all objective function values are more than or equal to zero). In addition, f_{max} refers to the objective

function value corresponding to head wolf and h_f stands for the coefficient ($h_f \in [0.85, 1.0)$). Obviously, if f_{max} and f_{avg} are close, it shows that the diversity of the population decreases. That is to say that, the population activities decrease, so it calls for mutation with great probabilities to improve the population activities.

4 NUMERICAL EXPERIMENTS AND ANALYSIS

4.1 Test functions

In order to prove the validity of the Improved Gray Wolf Optimization (IGWO) algorithm based on the logarithmic function proposed in this study, four benchmark test functions are widely used across the world from the literature (Mirjalili, 2014) and are utilized to conduct numerical experiments. The dimensions of the four test functions are all set as 30.

4.2 Comparing IGWO with GWO and HGWO algorithms

By using the IGWO algorithm proposed in the study, the four benchmark test functions are solved. In addition, the IGWO algorithm is compared with the standard GWO algorithm and Hybrid GWO algorithm with differential evolution (HGWO) (Zhu, 2015). In order to ensure fairness, the parameters of the three algorithms are set as follows: the population size and maximum iteration times are set as $N = 30$ and 500 separately. Each function independently operates for 30 times with above parameters and their optimal values, average values, worst values, and standard deviations are recorded. Additionally, the comparison results are shown in Table 2. In which, the results of the HGWO algorithm are directly excerpted from the literature (Zhu, 2015). The bold figures in Table 2 represent the best results in the comparison.

Table 1. List of four benchmark test functions.

Function name	Dimension	Function expressions	Searching regions	f_{\min}	Convergence precision
Sphere	30	$f_1(x) = \sum_{i=1}^n x_i^2$	[-100,100]	0	1×10^{-10}
Schwefel 2.22	30	$f_2(x) = \sum_{i=1}^n x_i + \prod_{i=1}^n x_i $	[-10,10]	0	1×10^{-10}
Schwefel 1.2	30	$f_3(x) = \sum_{i=1}^n \left(\sum_{j=1}^i x_j \right)^2$	[-100,100]	0	1×10^{-10}
Schwefel 2.21	30	$f_4(x) = \max_i \{ x_i , 1 \leq x_i \leq n \}$	[-100,100]	0	1×10^{-10}

Table 2. Optimization results of the four functions using the three algorithms.

Function	Algorithm	Optimal value	Average value	Worst value	Standard deviation
f_1	GWO	8.42E-29	8.08E-28	1.71E-27	6.09E-28
	HGWO	2.92E-34	1.12E-32	8.95E-32	2.32E-32
	IGWO	1.57E-56	8.76E-54	4.23E-53	1.47E-53
f_2	GWO	1.77E-17	1.97E-16	6.66E-16	1.82E-16
	HGWO	1.65E-20	9.33E-20	3.60E-19	6.92E-20
	IGWO	2.96E-33	2.66E-32	6.75E-32	2.53E-32

	HGWO	6.07E-11	3.18E-08	3.08E-07	6.55E-08
	IGWO	1.09E-17	1.52E-12	6.41E-12	2.22E-12
f_4	GWO	1.34E-07	7.96E-07	2.03E-06	6.76E-07
	HGWO	5.81E-09	4.17E-08	2.39E-07	4.56E-08
	IGWO	1.98E-16	7.99E-15	2.08E-14	6.73E-15

Table 3. A comparison of oxygen consumption.

Working conditions	Oxygen additive amount optimized using the IGWO algorithm	Oxygen additive amount optimized in the literature (Xiong, 2013)	Oxygen additive amount in the actual working operation
1	517.97	529.80	646
2	539.23	550.19	674
3	551.33	552.91	708
4	577.31	591.31	732

As shown in Table 2, the IGWO algorithm proposed in the study is obviously superior to the other two algorithms.

5 APPLICATION IN INDUSTRIAL OPTIMIZATION

Zinc sulfate solution leached in the process of zinc hydrometallurgy contains many iron ions. In order to ensure the safe and stable operation of subsequent procedures, the iron ions in the solution need to be removed to a proper content. Removing irons by using goethite is to oxidize ferrous irons in the solution gradually into ferric irons by adding oxygen into five successive reactors. The optimization model of the iron removal process by using goethite is established in the literature (Xiong, 2013). In addition, four typical working conditions proposed in the literature (Xiong, 2013) are optimized by applying the IGWO algorithm proposed in the study. The overall optimal values of the oxygen additive amount in the five reactors are given in Table 3.

From Table 3, it can be seen that under the four typical working conditions of precipitating iron using goethite, the oxygen additive amounts optimized using the IGWO algorithm were separately

saved by 19.82%, 19.99%, 22.12%, and 21.13% when compared with those in the practical commercial process. The optimized oxygen additive amounts were 1.82%, 1.59%, 0.22%, and 1.93% less than those optimized using the double population coevolution algorithm, respectively.

6 CONCLUSIONS

The simulation experiment results of four benchmark test functions show that, when compared with other swarm intelligent optimization algorithms, the IGWO algorithm is more competitive. The simulation results of the industrial process of iron removal using goethite show that the IGWO algorithm is applicable to the parameter optimization of the complex industrial process.

ABSTRACT: An efficient method was developed for the determination of the multi-element in abstergent by ICP-MS with microwave digestion. Using the pressure control device to monitor the process of digestion and to explore the conditions of digestion, the parameter of ICP-MS and appropriate inner internal standard element were optimized and chosen in terms of the amount of digestion, digestion system and the procedure of microwave digestion. The detection limit was between 0.002–0.362 ng/ml. The relative standard deviations were less than 10%. The spiked recoveries were 90.8%–109.6%.

1 INTRODUCTION

The detergent is one kind of inseparable chemical in daily life. Benefiting from the new technology, detergent producers may add some harmful ingredients during the production process in order to obtain better performance for their products, which will lead to the environment deterioration. For example, the phosphorus detergent will make rivers and lakes become eutrophic, which can lead to serious fish deaths, red tide, etc. and heavy metals accumulating in the environment. The heavy metals will be transferred into the animal and human body through the food chain, finally causing teratogenic and carcinogenic diseases.

Since the 1960s, Europe and the United States have successively promulgated a number of directives and standards for detergent specifications. The EU released 2011/382/EU and 2011/263/EU. The USA released GS-8 and GS-11. China has promulgated and implemented several national and industrial standards, such as GB/T 9985-2000 and HJ 458-2009 standards, which standardized the composition and dosage of the detergent. According to those directives and standards, there are 14 kinds of heavy metals having been severely restricted, but the existing detection technology is still stuck in traditional chemical detection method. It is necessary to have a quick, effective and accurate detection method. Therefore, it is necessary to study the efficient detection method for the 14 kinds of heavy metals.

Currently, pre-treatment methods are dry ashing, reflux wet digestion, catalytic wet digestion and extraction. Those methods have disadvantages, such as waste of reagents, long-time consuming, easy sample contamination, low efficiency, poor accuracy, etc. Microwave Digestion is a new sample digestion technology in recent years, with small reagent consumption, shorter operation time, uneasy to pollution, great precision and other advantages (Chen, 2009; Liu, 2005; Chen, 2006; Luo, 2013; Luo, 2015). The microwave digestion-inductively coupled plasma mass spectrometry is used to determinate multi-element in abstergent.

2 EXPERIMENTAL

2.1 Instruments

Agilent 7700x ICP-MS (Agilent Technologies Co. Ltd, USA), replace the injection set and torch set to resistant to hydrofluoric acid special set. Milli-Q water purification system (EMD Millipore Co., Ltd USA); MARS microwave digestion system (CEM Technologies Co. Ltd, USA), with pressure control device.

2.2 Reagents

All reagents were of analytical-reagent grade or higher. Nitrate acid (71%) and Hydrogen peroxide (30%) (Suzhou Crystal Clear Chemical Co., Ltd, China); Hydrofluoric Acid (Sinopharm Chemical

Table 1. ICP-MS optimization parameter for determination multi-element.

Parameter	Value	Parameter	Value
RF Power	1550 w	Spray chamber temperature	2°C
Sample depth	8.0 mm	Assistant gas flow	0.13 L/min
Carrier gas flow	1.0 L/min	Reaction gas flow (He)	0.43 L/min

Reagent Co., Ltd, China); Multi-element Calibration standard 2 A (Agilent Technologies Co. Ltd, USA) contains 27 elements, including the 9 kinds of elements measured in this article. Concentrations were 10 mg/kg; Single standard of Tin (1.0 mg/mL) and Mercury (1.0 mg/mL) (Central Iron and Steel Research Institute, China). Single standard and Multi-element Calibration standard 2A was diluted by 5% nitric acid solution, with the configuration of 100 ng/mL, 50 ng/mL, 20 ng/mL, 10 ng/mL and 1 ng/mL standard working solution standbys.

2.3 Analytical procedures

0.2 g (accurate to 0.1 mg) abstergent sample was weighed and placed at PTFE microwave digestion barrels. Then 6 mL nitric acid was added. After 3 hours, 2 mL hydrogen peroxide was added, the lid was closed, and the barrels were put into the microwave digestion system. After the program of digestion completed, there was a natural cooling process, followed by transferring the solution to a 50 mL calibrated flask. Then the solution was diluted to a vessel with ultrapure water. Reagent blanks were included in each series of digestions. Sample solution was analysed by ICP-MS.

The parameter of the ICP-MS was shown in the Table 1.

3 RESULTS AND DISCUSSION

3.1 Amount of sample

There are variety kinds of detergents. Most of the detergents contain volatile organic compounds. Therefore, the digestion process will release a lot of gas when the sample weight is too heavy, resulting in insecurity. However, it will reduce accuracy of the determination of certain elements when the sample weight is too light. By choosing different sample weight in the experiments, the digestion tank pressure would be controlled in the safe range when the sample weight is 0.93 g, as shown in Figure 1. It is recommended to control the sample

Figure 1. Effect of the sample weight on pressure of the microwave digestion system.

weight of microwave digestion in the range of 0.5~1.0 g to avoid experiment accidents.

3.2 The digestion solution

Nitric acid was used as digestion reagents in experiments. In order to determine a proper amount of nitric acid, 4 mL, 6 mL and 8 mL HNO₃ were used during washing supplies microwave digestion sample test. When the amount of nitric acid reached 6 mL, the sample could be digested well with transparent digestion solution. Peroxide hydrogen was added to help reduce stress and promoting digestion. Tests showed that for the detergent sample with weight of 0.5 g, 2 ml peroxide hydrogen was needed. Microwave digestion with medium pressure led to gentle reaction which conduced to shorten experiment time and safe operation.

3.3 The program of microwave digestion

Microwave digestion process was studied. Detergents can have several states, such as shower gel is in good mobility as a liquid, cleanser presents paste and detergent is in powder state. Therefore, to study digestion procedures for different samples must use different experimental temperature. The affection of temperature, time and temperature program were studied by a segmented temperature program, heating up to 120°C in the first 5 minutes, holding 2 minutes, then raising temperature to 170°C in next 5 min, holding 2 minutes, finally raising temperature to 180°C in 2 min, holding 20 minutes. The heating power of the whole digestion process is set up to 1200 W as constant power.

3.4 Linear equation and detection limit

Linear equation was created by the five different concentrations of solution; the detection limit of each element was calculated by the linear equation. Linear equation and detection limit of each element were shown in the Table 2.

Table 2. Linear equation and detection limit of each elements.

4 CONCLUSIONS

A rapid method was established for the determination of 14 kinds of harmful elements in detergent by using nitric acid and peroxide hydrogen for sample digestion and using ICP-MS for simultaneous determination of the harmful

elements with a wide linear range and better accuracy. Microwave digestion process is monitored by a pressure control device, meanwhile the amount of solvent for digestion, acid digestion system and procedures have been optimized so that the digestion effect of various sample is good. Optimizing the parameters of ICP-MS, the accuracy of this method was judged by standard addition recovery methods. Reproducibility of this method was validated by the repeated measurement samples.

ABSTRACT: Superhydrophobic-superoleophilic materials arises more and more attention because of their possible application on oil/water separation. Here, chemical oxidation and palmitic acid modification were used to fabricate superhydrophobic-superoleophilic surface on porous Cu sponge. Scanning Electron Microscope (SEM), Energy Dispersive Spectrometer (EDS) and Intelligent Roman Spectroscopy (DXR) were used to detect the surface micromorphology, chemical composition and wettability of the Cu sponge. The results show that the nanometer-scale structures with the composition of CuO and Cu₂O were covered on the whole 3D skeleton of Cu sponge after chemical oxidation and the resulted surfaces show superhydrophilicity and superoleophilicity. After palmitic acid modification, the surface wettability was transferred into superhydrophobicity with contact angle of 156° and tilting angle of smaller than 10°, but still showing superoleophilicity. Based on the fabricated superhydrophobic-superoleophilic porous Cu sponge, pouring-type, gravity driven oil/water separation and surface-tension-driven, gravity assisted oil/water separation was realized with a high separation efficiency.

1 INTRODUCTION

1.1 Type area

Water and oil are the important resource of our daily life. The qualities of water and oil affect numerous aspects of the human productivity. The waste water in oil seriously affects the quality and service efficiency of the oil. Research on oil/water separation technology has great significance in terms of improving the quality of oil and water. Researchers have showed keen interest in the special performance of the extreme wettability in some materials in the nature (Barthlott W & Neinhuis C 1997). Thanks to the different applications in the special wettability of water and oil, achieving oil/water separation has been in the center of public concern (Sanhu Liu et al. 2015). Porous materials like fibrous membranes (Viswanadam G 2013), filter paper (Zhang M et al. 2012), metal net (Lec C H et al. 2011, Wang C X et al. 2009) and polymeric

sponge (Yang Y et al. 2014) are all applied to the research of superhydrophobic surface preparation and oil/water separation. Although the aforementioned materials have favorable extreme wettability, there are limitations in the separation efficiency, separation velocity, pressure resistance, and stability of resisting water attack.

With the characteristics of high porous rates, large specific surface area and high specific strength, porous Cu sponge has been a new object of study in the oil/water separation area. Porous Cu sponge is a three-dimensional and multi-functional material with a large amount of connected or non-connected holes in the Cu substrate. It presents good machinability and processing properties and has excellent electromagnetic shielding and noise elimination ability. Simultaneously, porous Cu sponge still retains the properties of Cu-like good electrical conductivity, excellent thermal conductivity, ductility and strong base solution in reserve,

thus having a wide range of application prospects such as electronics, medical, mechanics and national defense (Wen Zhang et al. 2015). In this paper, a simple method that combines chemical oxidation and low surface energy modification was used to construct nano-roughness and achieve the superhydrophobicity. The influence of oxidation time on the surface structure was studied in this paper, and the extreme wettability, water pressure resistance, oil/water separation efficiency of the porous Cu sponge were studied at the same time.

2 EXPERIMENTS

2.1 Materials

Porous Cu sponge (99.9%, pore size 160 μm) was purchased from Kunshan descco Industrial Co., Ltd. acetone, HCl (37%), H_2O_2 (30%), ethanol, palmitic acid, hexane, hexadecane, mineral oil was purchased from Tianjin Kemiou Chemical Reagent Co., Ltd. Corn oil was purchased from Luhua Co.

2.2 The preparation of superhydrophobic–superoleophilic porous Cu sponge

Firstly, porous Cu sponge was cut into 20 mm \times 20 mm squares and ultrasonically cleaned by acetone, 1 mol/L dilute hydrochloric acid and deionized water in sequence for two minutes. To prevent rusting of porous Cu sponge after cleaning, its moisture was mostly absorbed by absorbent paper immediately and porous Cu sponge was then put into the oven with 60°C to dry and for later experiments. After that, the samples were heated in the boiling water, and three-or-four drops of 30% H_2O_2 water solution were dropped into water every ten minutes for four times. After 40 minutes, the samples were taken out and cleaned before put in the oven with 60°C. Then, the dried porous Cu sponge was put in 0.1 mol/L ethanol solution of palmitic acid at room temperature for 30 minutes. Finally, the superhydrophobic-superoleophilic porous Cu sponge could be obtained after cleaning by absolute ethanol.

2.3 Characterization

Scanning Electron Microscope (SEM) was employed to observe the surface micro topography of the samples. Energy Dispersive Spectrometer (EDS) was used to characterize surface elements of the samples. Raman spectrometer was employed to qualitatively analyze ingredients of the samples.

The contact angle and rolling angle measuring instruments were used to characterize wettability of porous Cu sponge at room temperature. When measuring the static water contact angle, 5 μL water droplets were dropped on one sample

surface for 5 different places, and the average value was regarded as the measured data. During measurement of the rolling angle, the samples were rotated, and the average of 5 measurements values with different rolling direction were taken as the rolling angle of the sample surface.

Home-made gravity-driven oil/water separator and surface tension-gravity dual driven oil/water separator (Song J L et al. 2015) were used to conduct the oil/water separation experiments of four types of oil with less dense than water. The oils used are hexane, hexadecane, mineral oil, corn oil. The corresponding surface tensions are 17.9 mN/m, 27.5 mN/m, 33.4 mN/m and 32.15 mN/m. The surface tension of water is 72.1 mN/m.

3 RESULTS AND DISCUSSION

3.1 The construction of nanostructure in the surface of porous Cu sponge

Figure 1(a-f) shows the SEM images of porous Cu sponge oxidized in the boiling water for different time. It can be observed that the surface morphology of the porous Cu sponge changes obviously with the oxidation time. When the oxidation time was relatively shorter (10 min), the nanoparticles on the surface of porous Cu sponge formed gradually, their sizes were quite different, and the distribution of them was uneven (Figure 1(b)). When the oxidation time was 20 min, porous Cu sponge surfaces were evenly covered by a layer of nanoparticles

Figure 1. SEM images of porous Cu sponge at different oxidation times: (a) 0 min; (b) 10 min; (c) 20 min; (d) 30 min; (e) 40 min; (f) palmitic acid modification.

with the uniform size, and the diameter of the nanoparticles was about 10 nm (Figure 1(c)). When the oxidation process lasted for 30 min, the nanoparticles became larger, and a dense and even oxide layer was formed on the porous Cu sponge surface with the diameter of nanoparticles being 20 nm (Figure 1(d)). When the oxidation time was 40 minutes, the nanoparticles developed upward and became column-like with the height of 30 nm (Figure 1(e)). As shown in Figure 1(f), after the porous Cu sponge was oxidized for 40 minutes followed by immersing in 0.1 mol/L palmitic acid ethanol solution for 30 minutes, a lot of even floes with the length of 100 nm appeared on the surface. This demonstrates that the porous Cu sponge formed nanoscale oxide layers when being boiled, and that rough nanostructures were fabricated by the self-assembly reaction during the modification process of palmitic acid ethanol solution.

3.2 Analysis of the composition of porous Cu sponge surface

EDS was employed to detect the surface elements of samples, as shown in Figure 2. Before the oxidation process, porous Cu sponge just has Cu element (Figure 2(a)). After oxidation for 40 min, there was O element on the surface of porous Cu sponge (Figure 2(b)), thus further confirming the oxidation reaction between Cu and the oxygen from the H_2O_2 in the boiling water. Figure 2(c) shows the EDS result of the porous Cu sponge surface after 40 minutes oxidation and 30 minutes modification of palmitic acid ethanol solution, it can be observed that C element appeared on the

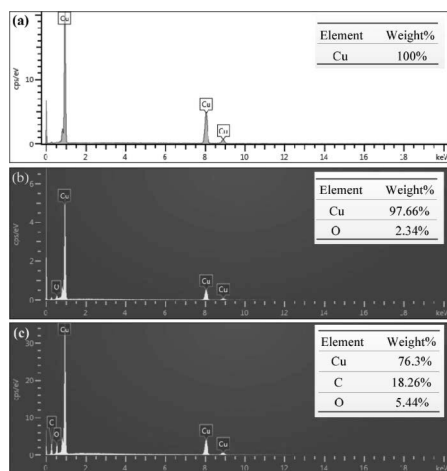

Figure 2. EDS spectrum of porous Cu sponge: (a) ordinary porous Cu sponge; (b) oxidation treatment 40 minutes; (c) palmitic acid modification.

Figure 3. DXR spectrum of porous Cu sponge after oxidation.

surface of porous Cu sponge and the content was 18.26wt%. In addition, the content of oxygen element also increased, which demonstrates the self-assembly process of palmitic acid ethanol solution.

The ingredients of the samples surface were qualitatively analyzed by Raman spectroscopy. Figure 3 shows the spectrum of the porous Cu sponge surface after 40 minutes oxidation. The peaks around 274, 300 and 632 cm^{-1} are attributed to CuO (Masudy-Panah S et al. 2015), while the one at 220 cm^{-1} was contributed by Cu_2O (Abdel-fatah M et al. 2016). During the modification process of palmitic acid ethanol solution, CuO and palmitic acid reacted and generated Cu palmitate, a low surface energy substance, which has a low enough surface energy to be superhydrophobic (Sheng Lei. 2014).

3.3 Wettability of the porous Cu sponge surface

Figure 4 is the digital photo of static water droplets on porous Cu sponge which have been processed differently. Oxidation and modification process have great influence on the wettability of porous Cu sponge surface. For a clean ordinary porous Cu sponge surface, water droplet can be semi spherical on it and the static contact angle of water is 118° (Figure 4(a)). Even if overturning the porous Cu sponge, water droplet will not fall off from the surface. Palmitic acid is used to reduce the surface energy of porous Cu sponge. As a result of the slowly self-assembly reaction between palmitic acid and porous Cu sponge, Cu palmitate which has low surface energy generated on the surface. After modification by palmitic acid, the wettability of porous Cu sponge surface was reduced significantly and the static contact angle of water

Figure 4. The static contact angles of water droplets on porous Cu sponge: (a) ordinary porous Cu sponge; (b) after modification; (c) after oxidation; (d) after oxidation and modification.

could be 134° (Figure 4(b)), showing hydrophobicity. However, the reaction between palmitic acid and Cu is very slow and the porous Cu sponge surface cannot obtain superhydrophobicity in a short time. Figure 4(c) shows the porous Cu sponge that has been oxidized in the boiling water for 40 minutes. Uniform nanostructures are formed on the surface which shows superhydrophilicity and water droplet can spread rapidly on it with a static contact angle of 0° . The superhydrophilic porous Cu sponge can obtain superhydrophobicity after modification by palmitic acid which has a static contact angle of 156° with a tilting angle smaller than 10° . The water pressure resistance of the porous Cu sponge was measured by using a homemade pressure-resistant measuring device and the porous Cu sponge can withstand 1.1 kPa pressure. The results clearly indicate that the superhydrophobicity of the porous Cu sponge surface is owing to the joint action of oxidation and low-surface energy material modification.

3.4 Oil/water separation characteristics of the porous Cu sponge

Oil/water separation methods include biodegradable methods (Qiqi Shi et al. 2009, Huan Liu & Yongming Sun. 2014), chemical treatments (New Japan Chemical Co Ltd. 1982, Zhonghua Yao. 1993) and traditional physical treatments (Eiichi Kobayashi et al. 2011, Yongge Wang. 2011). However, these methods have a great number of drawbacks: biodegradation methods have a high demand to the environment; chemical treatments are easy to cause secondary pollution; traditional physical treatments are cumbersome and the final recovery of oil usually needs to take further separation. The extreme wettability of the surfaces can make oil and water show two different kinds of wettability. Using these materials can avoid the disadvantages of the conventional oil/water separation methods.

3.4.1 Pouring type gravity driven oil/water separation

In the pouring type gravity-driven oil water separation process, due to the fact that the light oil

firstly contacted and wetted the filter, the after reaching water could not pass through the superhydrophobic filter and formed a barrier below the light oil which hinders the contact of the light oil. Superhydrophobic filter could not use this method to separate light oil water mixture. Similarly, dry-superhydrophilic filter could not use this method to separate light oil water mixture either. When using the superhydrophilic filter which was pre-wetted by water, due to the microstructure of the filter screen was filled with water, light oil could not pass through the filter. In contrast, water would contact the filter due to its greater density to light oil (Song, J.L. 2015). Therefore, the superhydrophilic porous Cu sponge pre-wetted by water in pouring gravity-driven water separation was used, as shown in Figure 5. Figure 6 is the oil/water separation efficiency of n-hexane, hexadecane, mineral oil and corn oil. The maximum of separation efficiency can be up to 99.4%. Separation efficiency could maintain 90% after repeating the separation

Figure 5. Oil/water separation using pouring type gravity driven method.

Figure 7. The oil/water separation process driven by both surface tension and gravity.

Figure 8. Oil/water separation efficiency of surface tension-gravity dual driven method.

experiment by 10 times, showing a good oil/water separation recycling capacity.

3.4.2 Oil/water separation driven by both surface tension and gravity

According to the reference paper, we installed the prepared superhydrophobic porous Cu sponge in the glass tub which has an opening at the top to constitute an oil skimmer. During the oil/water separation and the collection of the oil slick, the skimmer was placed in the mixture of oil and water. The oil skimmer can float on the water due to buoyancy and part of the superhydrophobic porous Cu sponge could contact with the oil slick and water below. Owing to the superhydrophobic porous Cu sponge has different wettability to water and oil, oil slicks could penetrate the Cu when the oil slick contacted with porous Cu sponge. Then oil flowed into the bottom of skimmer, and water was prevented from the skimmer. The process of using an oil skimmer to collect the oil slick was shown in Figure 7. Figure 8 shows the oil water separation efficiency of collecting n-hexane, hexadecane, mineral oil and corn oil mixture using this method, which shows a high oil/water separation efficiency more than 90%.

4 CONCLUSION

A simple chemical oxidation process to construct nano-roughness on the surface of porous Cu sponge was suggested. The surface morphology

of porous Cu sponge was gradually changed from a smooth surface to a rough surface covered with Cu_2O and CuO nanoparticles with the increasing of the oxidation time. At last, the surface becomes a homogeneous nano-columnar structure, forming nanometer-scale rough structures. With the help of nano-roughness, the Cu sponge shows superhydrophilicity and superoleophilicity. After palmitic acid modification, the surface wettability was transferred into superhydrophobicity with contact angle of 156° and tilting angle of smaller than 10° , but still showing superoleophilicity. The fabricated porous Cu sponge can be used in the oil/water separation with separation efficiency more than 90%.

Preparation of porous ceramics using CaCO_3 as the foaming agent

Jin Li & Yanlin Chen

School of Material and Chemical Engineering, Hubei University of Technology, Wuhan, China
Hubei Provincial Key Laboratory of Green Materials for Light Industry, Hubei University of Technology, Wuhan, China
Collaborative Innovation Center of Green Light-weight Materials and Processing, Hubei University of Technology, Wuhan, China

ABSTRACT: Porous ceramics were synthesized by using oily soil and waste glass as the main materials, calcium carbonate as the foaming agent, and sodium silicate as the fluxing agent by controlling the sintering process. The samples were characterized by using XRD and SEM. The influence of the quantity of oily soil used on the porosity and flexural strength of samples were further evaluated. The results show that when the quantity of the oily soil increased, the porosity increased first and then decreased regularly, and the flexural strength decreased first and then increased. When the quantity of the oily soil was 40 wt%, the corresponding highest porosity was 69.44% and the lowest flexural strength was 2.16 MPa.

1 INTRODUCTION

The oil wells are used to drill for oil. In recent years, with the rising demand for oil, a large number of oil wells was established. This leads large quantities of oily soil becoming solid waste. People are not paying attention to this, and oil wells caused large quantities of pile and soil in the atmosphere and water and soil pollution (Cao & Yu 2005, Jia et al. 2009). C. M. Kao et al. (2001) published that oil pollution is one of the world pollution causes. At present, soil pollution in the oil wells is mostly treated by using biological technology processing (Deng et al. 2012, Lösekann et al. 2007, Jones et al. 2008). And for the use of problem is almost a blind spot. There is less reported literature in this arena. Therefore, these have become important problems to be solved, such as how to deal with the waste oil soil and how to recycle waste.

The development of the porous inorganic material materials began in the 1930s. Saint-Gobain company was first developed with calcium carbonate as the foaming agent of porous glass in 1935 (Zhang et al. 2010). At present, China and the United States are the main production agent countries of porous ceramics (Tian et al. 2014). With the improvement of people environmental protection consciousness, people began to attach importance to the sustainable development cycle use of solid wastes. Porous ceramics is prepared by using ceramics as the main raw material, by adding foaming agent and a porous material of various kinds of modified additives (Gao et al. 2014). Its interior is

filled with uniform connected or closed pores; it is a light-weight material, and has high strength, flame retardancy and good sound absorption and water retention properties (Qiao et al. 2009). Therefore, the porous ceramics have extremely broad prospects for development in building energy efficiency, noise reduction, and green engineering areas (Zhang & Zeng 2006).

This study describes a method for manufacturing porous ceramics. With oily soil and waste glass as the main raw materials, calcium carbonate as the foaming agent, and sodium silicate as the fluxing agent, preparation of porous ceramics is carried out. In this article, oily soil and waste glass and the relationship between the porosity and flexural strength of samples are studied.

2 EXPERIMENTAL

2.1 *The raw materials of experiments*

The oily soil used in experiment was derived from Dongying Shengli Oil Field. Waste glass was obtained from Wuhan Changli Glass Co., Ltd. The foaming agent calcium carbonate and flux of sodium silicate were purchased from Sinopharm Chemical Reagent Co., Ltd. The main chemical compositions of oily soil and waste glass are given in Table 1.

2.2 *Preparation of porous ceramics*

Oily soil was placed in a ventilated area to dry to achieve half dryness. The oily soil and waste glass

Table 1. Chemical compositions of oily soil and waste glass (wt%).

Raw materials	SiO ₂	Al ₂ O ₃	Fe ₂ O ₃	MgO	CaO	K ₂ O	Na ₂ O	LOI
Oily soil	62.50	21.00	7.39	2.59	2.47	1.88	1.51	8.42
Waste glass	69.59	5.18	0.53	4.42	5.59	1.00	13.69	0.44

Table 2. Quantity of raw materials provided by oily soil and waste glass in different experimental plans.

Sample	Main raw material ratio (wt%)			
	Oily soil	Waste glass	CaCO ₃	Sodium silicate
A1	30	45	20	5
A2	35	40	20	5
A3	40	35	20	5
A4	45	30	20	5
A5	50	25	20	5

were placed in two ball milling tanks; water was added to the mixture and grinding balls were prepared such that the ratio of the weight of materials to the ball to the water is 1:2:1. After that, the mixture was milled in a ball mill for 2 hours and the mixture was placed in an oven to dry and ground to powder. Oily soil and waste glass raw materials were made to pass through a 100 mesh screen. According to Table 2, oily soil, waste glass, and calcium carbonate were mixed in different proportions and the mixture was pressed into a substrate at a pressure of 10 MPa. It was placed in a muffle furnace for sintering in an air atmosphere. The sintering system is given as follows: first the speed was increased at the rate of 7°C/min up to reaching 400°C, and then was held for 30 min. The furnace temperature was then increased at the rate of 15°C/min up to reaching the foaming temperature of 850°C, and then was held for 20 min. Finally, the speed was reduced at the rate of 15°C/min down to 600°C, and then was held for 30 min. Samples were removed from the furnace and allowed to cool.

2.3 The test method of the sample

The elementary composition and content of the sample were examined by using a scanning X-ray fluorescence spectrometer XRF-1800. The crystalline phases were analyzed by using a D/MAX-RB1 X-ray diffraction instrument. The surface morphology could be observed by using JSM 6390 filament lamps for a scanning electron microscope. The porosity of the sample was measured according to National Standard GB/T 1966-1996

Standards. The flexural strength of the sample was detecting by using an INSTRON-1195 electronic Universal Material Testing Machine (0.5 mm/min loading speed) according to National Standard GB/T 1964-1996.

3 RESULTS AND DISCUSSION

3.1 SEM analysis

It illustrates the microstructural changes with an increase of oily soil in Fig. 1. The pore sizes increases with an increasing in oily soil reaching maximum values (251 μm) at the 40 wt%. Further, increasing the content of oily soil at 45 wt% (132 μm) and 50 wt% (47 μm) caused a decrease in the pore size. The formation of crystalline phases and the extent of crystallinity, as well as their dependence on the starting composition and sintering temperature, are other important factors that determine the structural evolution of porous ceramics were studied (Fernandes et al. 2009). The preparation of desirable porous ceramics requires ceramics with low crystallizing tendency (Spiridonov & Orlova 2003). Crystals influence the viscosity of the glass and its foaming behavior. Furthermore, crystals affect the structural integrity of the foam because of the mismatch of thermal expansion coefficients. This can cause opening or cracking of the lamellae between adjacent pores, which enhances further coalescence of the pores during the foaming process (Hashemina & Yekta 2012). Thus, the different contents of oily soil changed the phase composition of the resulting porous ceramics by an increased rate of the crystallization process. For the samples with lower contents of oily soil, as the crystallization of glasses increases with addition of the oily soil, pore sizes increase and become less homogeneous due to the increasing number of pores (Fig. 1b and c). However, the excess amounts of oily soil tend to limit the foaming ability of the system. This effect is also attributed to the formation of more crystallites on the surface of the glass particles, which would increase the viscosity of the system, thereby resulting in increasing densification. Therefore, the contents of samples (45 wt% and 50 wt%) decrease again. Due to the higher content of crystallites, the pores of 50 wt% are not homogeneous in nature (Fig. 1e).

Figure 1. SEM images of samples: (a) A1 (30 wt% oily soil); (b) A2 (35 wt% oily soil); (c) A3 (40 wt% oily soil); (d) A4 (45 wt% oily soil); and (e) A5 (50 wt% oily soil).

3.2 XRD analysis

The crystalline phases formed in the samples with different contents of oily soil after heat treatment at 850°C are presented in Fig. 2. The XRD pattern of the content of 30 wt% consists of quartz and calcium silicate characteristic peaks. More extensive crystallization of CaAl_2O_4 and augite ($\text{Ca}(\text{Mg}, \text{Fe})\text{Si}_2\text{O}_6$) phases occurred for the higher added quantities of oily soil and the quartz phase gradually disappears. When the oily soil reached up to 50 wt%, the content is the most crystalline according to the XRD pattern. It is suggested that the contents of oily soil has a great influence on the crystalline phase types of samples since the relative intensity of the peaks change dramatically with an increase in the quantity of oily soil.

3.3 Porosity and flexural strength analysis

As shown in Fig. 3, when the content of oily soil was about 30 wt%, 35 wt%, 40 wt%, 45 wt%, and 50 wt%. The porosities of samples were 39.48%, 50.36%, 69.44%, 41.31%, 27.71%, respectively. The flexural strengths were 3.93 MPa, 2.57 MPa, 5.49 MPa, respectively. The porosity was in the range of 27.71%–69.44%. Results show that, at first, an increase in the quantity of oily soil only slightly increased the porosity (69.44%), thus reaching maximum values at the 40wt% oily soil. Further increasing the quantity of oily soil to 50 wt% caused a sharp decrease in the porosity. The Table 3 shows open porosity and closed porosity evolutions of different quantities of oily soil. The content of oily soil has no big influence to open porosity, but it is obvious that the closed porosity first increased and then decreased. When the content of oily soil is less than 40 wt%, as the contents increased, increasing the viscosity of the system has a good effect on the reservation of bubbles, thus the closed porosity increased. However, when the content of oily soil is more than 40 wt%, because of the formation

Figure 2. XRD patterns of samples: (a) A1 (30 wt% oily soil); (b) A2 (35 wt% oily soil); (c) A3 (40 wt% oily soil); (d) A4 (45 wt% oily soil); and (e) A5 (50 wt% oily soil).

Figure 3. Graph showing porosity and flexural strength evolution for different quantities of oily soil.

Table 3. Open porosity and closed porosity evolutions of different quantities of oily soil.

Oily soil (wt%)	30	35	40	45	50
Open porosity (%)	21.53	22.83	24.15	21.24	22.57
Closed porosity (%)	17.95	27.53	45.29	20.07	5.14

of crystals, the viscosity is too big to be bubbles, and thus the closed porosity decreased. This is in correspondance with the microstructure shown in Fig. 1.

Generally, the porous materials' size and thickness of walls play an important role in the flexural strength (Bernardo & Albertini 2006). As shown in Fig. 2, the smaller pore size and their homogeneous distribution in 30 wt% of oily soil (72 μm) resulted in a flexural strength (3.93 MPa) that is significantly higher than that obtained for 35 wt% of oily soil (2.57 MPa). The higher oily soil quantity of 45 wt% and 50 wt% showed higher values of

flexural strength (3.53–5.49 MPa) due to a denser microstructure and smaller porous structure. More extensive crystallization phases occurred for higher added quantities of oily soil. This also increased the flexural strength of porous ceramics. The results of the present study demonstrated that the porosity and flexural strength of porous ceramics presented a negative correlation.

4 CONCLUSION

In this study, with oily soil and waste glass as the main materials, calcium carbonate and sodium silicate were used to synthesize porous ceramics of different properties by controlling the sintering process and changing the ratio of raw materials. We provide a feasible solution to make full use of the oily soil. The porosity increased first and then decreased regularly, and the flexural strength decreased first and then increased with an increase in the quantity of oily soil used. These present a negative correlation. When the amount of the oily soil was 40 wt%, the corresponding highest porosity was 69.44% and the lowest flexural strength was 2.16 MPa.

Spacing optimization modeling and simulation of thermo-optic VOA gold thin film interconnect

Shanting Ding, Lei Xu, Fei Huang & Menglan Gong

School of Mechanical Engineering, Hubei University of Technology, Wuhan, China

ABSTRACT: Along with increase of interconnects in thermo-optic devices, its overall size is becoming larger and larger. Aiming at the challenges of miniaturization and integration, a method to optimize the spacing of thin film interconnects in thermo-optic devices was proposed. Based on the working principle, the relationship between the distance and interaction as well as the temperature distribution and the refractive index were analyzed by finite element simulation and optical simulation software respectively. The simulation results were compared with those of reliability experiments. It is obvious that the method of reducing the interconnect spacing is feasible for the 100 μm interconnect spacing, and it is meaningful for device design and manufacture.

1 INTRODUCTION

With the rapid development of optical communication industry, thermo-optical devices with the characteristics of small size, low driving power, low cost and easy manufacture, represented by Variable Optical Attenuator (VOA) and optical switch, have been widely applied (Xingjian Lv et al. 2004, Junxing Yu 2014). However, the device size has been growing obviously along with the fast increasing of channels. For example, a typical commercial available thermo-optical VOA has 16 channels for the early products. When the channel number is improved to 20, the overall size of the device has increased 1.5 times. According to the working principle of thermo-optic devices, each channel requires a film interconnect as the role of heater to establish a temperature gradient and achieve light attenuation. The requirements for high integration and miniaturization of the device are needed in the size and spacing of the thin film interconnects. At present, there are a lot of researches on the problems of size optimization and reliability of the thin film interconnects, but there is little research on the spacing optimization.

To investigate the influence of interconnect spacing on the interaction of the optical waveguides, the temperature distribution of polymer optical waveguides under the heating of gold thin film interconnects has been analyzed. On this basis, the interaction of multiple heating interconnects are studied, and the influence of interconnects spacing on the device operation is clarified.

2 WORKING PRINCIPLE OF THERMO-OPTIC VOA

Thermo-optic VOA is based on the Thermo-optic effect to achieve the attenuation. In general, the production of thermo-optic VOA requires the use of micro-processing technology in the formation of thin film interconnect as a heating electrode on the optical waveguide. After the electrode is energized, heat will be transferred to the optical waveguide and the temperature field distribution will be generated. Finally changes the refractive index of the waveguide and attenuates the optical signal. Figure 1 gives the structure of a thermo-optic VOA. The input and output single-mode waveguides are connected to the optical fiber and they have the same matching coefficients. The heating electrode is at an angle β to the plane of the multi-mode waveguide so that the attenuation ratio of the optical signal is conformed to the design claim. After the electrode is energized, the refractive index of the waveguide decreases as the temperature

Figure 1. Structure of the thermo-optic VOA.

Figure 2. Optical signal attenuation of the thermo-optic VOA.

increases, the direction of the refractive index gradient forms an angle β with the beam, and then the beam in the multimode region is reflected at 2β . When the reflection angle is greater than the transmission angle, the reflected light beam enters the high-order mode and is attenuated. Figure 2 shows the attenuation of optical signal. ΔT is the rising temperature of the waveguide core relative to the substrate. When ΔT equals 0°C , the refractive index of the waveguide does not change and the input optical signal is not attenuated. When ΔT equals 42°C , the refractive index of the waveguide core layer is smaller than that of the surroundings and the optical signal is totally refracted.

3 THERMO-OPTIC EFFECT AND THERMAL FIELD ANALYSIS

3.1 Thermo-optic effect

Thermo-optic effect is the optical properties of the optical medium. When the temperature gradient of the material exists, it will cause the changes of the refractive index of the material corresponding to the temperature gradient distribution changes (Yuliang Liu et al. 1996). Therefore, the change of refractive index n with temperature T can be attributed to the change of n with density ρ and the change of polarization rate with temperature. The expression of thermo-optic coefficient dn/dT can be written as (Edmond J. Murphy 1999):

$$\frac{dn}{dT} = -\left(\rho \frac{\partial n}{\partial \rho}\right)_T \gamma + \left(\frac{\partial n}{\partial T}\right)_\rho \quad (1)$$

γ refers to the expansion coefficient of the material. According to the Lorentz-Lorenz (Lorentz) equation, $(\rho \partial n / \partial \rho)_T$ can be derived from:

$$\left(\rho \frac{\partial n}{\partial \rho}\right)_T = (1 - \Lambda_0) \frac{(n^2 + 2)(n^2 - 1)}{6n} \quad (2)$$

Λ_0 is the strain polarization constant, which indicates the density change effect in the material

caused by atomic polarization. For polymer materials, the intermolecular effect is very weak and much smaller than 1, such as Polymethyl-Methacrylate, $\Lambda_0 = 0.15$. Since the refractive index of most polymer materials is close to 1.5 and the expansion coefficient is $2 \times 10^{-4}/^\circ\text{C}$ in glassy state (Sihua Zeng 2004), the following equations can be obtained according to equations (1) and (2).

$$-\left(\rho \frac{\partial n}{\partial \rho}\right)_T \gamma \sim -10^{-4}/^\circ\text{C} \quad (3)$$

For polymers of constant density, the refractive index varies with temperature is about 10^{-6} per degrees Celsius. Therefore, the value of equation (1) is mainly determined by the first term.

$$\frac{dn}{dT} \sim -\left(\rho \frac{\partial n}{\partial \rho}\right)_T \gamma \sim -10^{-4}/^\circ\text{C} \quad (4)$$

That is, the refractive index decreases by 10^{-4} per degree of temperature rise.

3.2 Thermal field analysis

The steady-state heat conduction equation can be solved by a two-dimensional temperature field model established through a buried channel waveguide (Ying Li 2004). The heating model of the thermo-optic VOA is given in Figure 3. The upper layer is the Au thin film interconnect; the lower layer is the polymer optical waveguide; the middle green is the waveguide core layer which has the highest refractive index to realize the transmission of optical signal in it. When electric current is applied to the electrode, heat is generated and transferred to the lower polymer optical waveguides. Thereby a temperature field distribution is formed. The thermal conductivity of polymeric materials is in the range of 0.17 to 0.22, which is very close and isotropic. So the core and cladding of the waveguide can be considered to have the same thermal conductivity. Since the thermal conductivity is much greater than the thermal radiation and thermal convection in this model, the steady-state analysis only takes into account the

Figure 3. Heating model of the thermo-optic VOA.

heat transfer problem. In addition, gold interconnects are so thin (only a few hundred nanometers) that it can be regarded as a thin wall and all the heat is passed to the lower layer. Compared to the polymer, the silicon material under the polymer has good thermal conductivity. So the temperature of the silicon substrate is considered to be room temperature.

Thus, the basic thermal physical model has been established. For the two-dimensional steady-state heat conduction problem with constant heat source (Jianmin Liu 2006), the heat conduction equation is presented by:

$$\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\dot{q}}{\lambda} = 0 \quad (5)$$

The domain of the equation is partitioned into rectangular finite difference meshes with step sizes Δx , Δy , and $x = i\Delta x$, $y = j\Delta y$. According to the known second-order central difference formula, the finite difference of the second partial derivative of the temperature in equation (5) can be shown as:

$$\left. \frac{\partial^2 T}{\partial x^2} \right|_{i,j} = \frac{T_{i-1,j} - 2T_{i,j} + T_{i+1,j}}{(\Delta x)^2} \quad (6)$$

The above two equations are substituted into equation (5) to obtain the finite difference scheme of two-dimensional steady-state heat conduction equation with internal heat source.

$$\frac{T_{i-1} - 2T_{i,j} + T_{i+1,j}}{(\Delta x)^2} + \frac{T_{i,j-1} - 2T_{i,j} + T_{i,j+1}}{(\Delta y)^2} + \frac{\dot{q}_{i,j}}{\lambda} = 0 \quad (7)$$

where $T_{i,j}$ and $\dot{q}_{i,j}$ are the values of the temperature and the internal heat source at node (x,y) , respectively.

4 SIMULATION ANALYSIS

4.1 Thermo-optic VOA interconnect simulation model

According to the relevant parameters of the thermo-optic VOA, the geometric model is established in Figure 4. The upper layer is gold thin film interconnects and the lower layer is polymer optical waveguide. In order to make the simulation results more accurate, the arc structure of the interconnect is neglected during modeling. The interconnect structure is designed as follows: length equals 1000 μm , width equals 10 μm , height equals 0.3 μm and the spacing between intercon-

Figure 4. Thermo-optic VOA multiple interconnects model.

Table 1. Material parameters.

Material	Thermal conductivity W/m.K	Resistivity $\Omega\cdot\text{m}$
Gold	315.5	2.20E-08
Polymer	0.18	1.00E+15

nects is constant. The thickness of the polymer material is 15 μm .

4.2 Model parameter setting

By means of the finite element analysis software of ANSYS, the thermo-optic VOA model with different interconnect spacings is simulated to study the influence of interaction of multiple interconnects. The material parameters involved in the simulation are shown in Table 1.

4.3 Simulation results

In the simulation, the ambient temperature is set to 25°C, the current of gold film interconnects is 0.07 A and the interconnect spacing is 100 μm . Contours are drawn from eight fixed and equant points through Y direction as shown in Figure 5. It can be seen from the figure that there is a minimum temperature SMN = 25°C at the bottom of the polymer and a maximum temperature SMX = 149.742°C on the most intermediate interconnect. The temperature decreased along the interconnects toward the polymer. When $\Delta T = 42^\circ\text{C}$, the refractive index of the waveguide core is less than the refractive index of the cladding so that all the light can be attenuated. From the contour map it can be determined that the position of the waveguide core is between D and E.

From equation (4), we know that the change of refractive index can be known by temperature distribution. In order to clearly show the correspondence, the ANSYS simulation results were imported into Rsoft optical simulation software. The change of temperature distribution and refractive index are presented in Figure 6, where ΔT is the temperature

Figure 5. Thermo-optic VOA cross-section temperature counters.

Figure 6. Temperature distribution and refractive index.

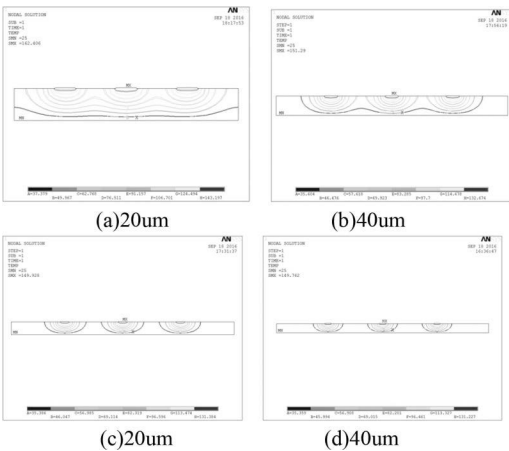

Figure 7. The cross-sectional temperature distribution of VOA with different interconnect spacing.

rise of the position relative to the substrate, Δn is the change of the corresponding refractive index.

To explore the relationship between the interconnection distance and interaction, the four models of 20 μm , 40 μm , 60 μm and 80 μm are simulated respectively, and the temperature distribution is shown in Figure 7.

5 DATE ANALYSIS AND RESULTS DISCUSSION

As the temperature distribution data are close, difference method is used to study the relationship between the size of the interconnect spacing and the interaction. The temperature distribution at each spacing is compared with the temperature distribution at 100 μm , which can be seen in Figure 8. It can be seen that the temperature of the waveguide increases gradually from point 1 to point 8, and the increasing rate gradually decreases. When the interconnect spacing is 80 μm or 60 μm , the value of $\Delta^\circ\text{C}$ is very small and close. When the distance is 20 μm , $\Delta^\circ\text{C}$ sharply increases and the value of the eighth equalization point even reaches 10°C that would have a great impact on the life and reliability of the device. Taking into account the interconnect and the electrode is connected through the arc, 20 μm size is too small and is not conducive to the design of the device layout. Contrasting the four curves, it was found that the interaction was enhanced with the reduction of the interconnect spacing.

According to the spacing optimization simulation results, the trial sample of 80 μm interconnect

Figure 8. The curve of temperature difference under different spacing.

Figure 9. 80 μm interconnect spacing test sample.

spacing is made and the experimental result is shown in Figure 9. The reliability experiment results show that the layout of interconnect spacing is feasible.

6 CONCLUSION

In order to reduce the overall size of the device, the finite element simulation software is used to analyze the interaction of interconnects at different spacings, and the results show that the interaction increases gradually with the decrease of the interconnect spacing. The test samples with 80 μm interconnect spacing are fabricated by the spacing optimization design. The reliability test results show that the simulation results are correct and the distance can be optimized, which can be used as a reference for the miniaturization and integration of devices in optoelectronic industry.

Growth and characterization of thick Ge epilayers on Si and Silicon-on-Insulator (SOI) substrates with low temperature Ge buffers

Zhiwen Zhou

School of Electronic Communication Technology, Shenzhen Institute of Information Technology, Shenzhen, Guangdong Province, P.R. China

ABSTRACT: High-quality thick Ge epilayers on Si and Silicon-on-Insulator (SOI) substrates with smooth surface and low threading dislocation densities are critical for device performance. In this work, Ge epilayers on Low Temperature Ge (LT Ge) buffer layers were grown utilizing two-step approach by ultrahigh vacuum chemical vapor deposition and characterized by atomic force microscope, x-ray diffraction, transmission electron microscopy, counting etch pit density and photoluminescence measurements. The results showed that the surfaces of LT Ge buffers were rough, but the misfit strains were nearly fully relaxed (strain relaxation reached 95%). However, the rough LT Ge surface was smoothed by subsequent growth at elevated temperature. It suggested that LT Ge buffer was not essential to be atomically flat as known for the high quality Ge growth. On proper LT Ge buffer, 1- μm thick Ge epilayers with narrow symmetric diffraction peak (full width at half maximum of about 90 arcsec), smooth surface (root mean square roughness is about 3 nm), low Threading Dislocation Density (TDD, $6 \times 10^7/\text{cm}^2$), and strong photoluminescence spectra at 1.55 μm wavelength were obtained both on Si and SOI substrates.

1 INTRODUCTION

The heteroepitaxy of thick Ge epilayers on Si and Silicon-on-Insulator (SOI) substrates with ideal characteristics, i.e., flat surface morphologies, few misfit dislocations and thin intermediate buffer layers, has attracted great attention due to the high compatibility of Ge with mature Si complementary metal oxide semiconductor processes and the extensive applications in optoelectronics for high-volume and large-scale electronic–photonic integration, such as efficient photodiodes operating in the infrared wavelength range of 1.3–1.55 μm (Wang 2015), high mobility field effect transistors (Wu 2015), ultralow energy electro-absorption modulators (Liu 2008), innovative direct bandgap light emitting diodes (Sun 2009), and even monolithic lasers (Liu 2010). Moreover, Ge is the preferred template for the integration of Sn (Wirhns 2015) and III-V compound semiconductors (Liu 2011) on Si. However, the greatest challenge to grow high quality thick Ge layers on Si is the 4.2% lattice mismatch between the two elements, which could cause high surface roughness resulting from Stranski–Krastranov growth mode and high density threading dislocations due to plastic strain relaxation. Various growth techniques and treatments have been put forward to solve the problems. These include compositionally graded SiGe buffer layers (Thomas 2003), two thin SiGe intermediate

buffer layers (Luo 2003), and two-step approach (Liu 2008, Sun 2009, Liu 2010). In two-step approach, a Ge film is initially deposited at low temperature (LT: 300–400°C) in first step, which constitutes a buffer whose thickness lies between 30 and 100 nm and enables plastic strain relaxation without the nucleation of any 3D islands. In second step, the growth temperature is increased to high temperature (HT: 500–850°C) for the formation of additional thicker Ge layer with higher crystalline quality and growth rate.

In this paper, we reported the growth of thick Ge epilayers on Si and SOI substrates by Ultrahigh Vacuum Chemical Vapor Deposition (UHVCVD) and characterizations by Atomic Force Microscope (AFM), X-Ray Diffraction (XRD), High-Resolution Transmission Electron Microscopy (HRTEM), counting Etch Pit Density (EPD) and Photoluminescence (PL) measurements.

2 EXPERIMENTAL DETAILS

All samples were grown by a single-wafer cold wall UHVCVD system. The base pressure is 5×10^{-8} Pa. Pure Si_2H_6 and GeH_4 were used as precursors. The substrates were 4 inch N-type Si (100) and SOI (100) wafers with resistivity in the range of 0.1–1 $\Omega\cdot\text{cm}$. After baking the wafer at 850°C and the growth of 300 nm Si buffer at

Figure 1. Ge deposition diagram.

750°C, it's ready for Ge growth. The growth of Ge epilayers proceeded in two steps. First, thin LT Ge buffer layers were grown at the temperature of 310°C with the thickness of 90 nm. Second, thick HT Ge epilayers were grown at fixed 600°C with various thicknesses. Figure 1 shows the Ge deposition diagram. The chamber pressure is about 2×10^{-2} Pa during deposition. The growth rate is 0.5 nm/min and 1.2 nm/min for LT Ge and HT Ge, respectively. In the present study, we focus on four samples (A to D). Sample A to C were grown on Si wafers, but sample D was grown on SOI wafer. Sample A is the thin LT Ge buffer with thickness of 90 nm. Sample B and C are the thick HT Ge epilayers on the LT Ge buffer. The thickness of LT Ge buffer is 90 nm, but the thickness of HT Ge is 210 nm and 910 nm for sample B and C, respectively. Sample D is a replica of sample C except that the wafer is SOI.

The surface morphologies and roughnesses of all samples were analyzed by atomic force microscopy (Seiku Instruments, SPI4000/SPA-400) in a tapping mode, and Nomarski optical microscope. The strain status and crystal quality of Ge layers were evaluated by double crystal x-ray diffraction measurements (Bede, D1 system), using a $\text{Cu } \kappa_{\alpha 1}$ ($\lambda = 0.15406$ nm) as the x-ray source. The threading dislocation densities of Ge films were characterized by counting pits formed by selectively chemical etching and high-resolution transmission electron microscopy. The photoluminescence spectra were measured at room temperature using an Ar^+ laser emitting at 488 nm.

3 RESULTS AND DISCUSSION

Figure 2 shows the large-scale surface morphologies of four samples viewed by Nomarski optical microscope. For sample A of LT Ge buffer, the sur-

Figure 2. Optical images of samples (a) A, (b) B, (c) C, and (d) D.

Figure 3. AFM images of samples (a) A, (b) B, (c) C, and (d) D.

face is rather rough, but samples B to D with HT Ge epilayers on LT Ge buffers have flat surfaces. The detailed surface morphologies were measured by AFM and shown in Figure 3. The surface root mean square (rms) roughness for sample A is 16.9 nm. After the growth of HT Ge epilayers, the rough surfaces were smoothed; the rms roughness is 2.3, 3.4 and 2.9 nm for sample B to D, respectively. The rms value was largely reduced. It is interesting to note that a typical cross-hatch surface pattern, due to strain fields arising from

inhomogeneous distribution of misfit dislocations, associated with thick SiGe layers grown on Si substrates is not visible in these samples.

Figure 4 shows the XRD results of these four samples along with the theoretical positions of bulk Si and Ge. Sharp peaks from Si substrates and relatively broad peaks from Ge epilayers are clearly observed. For sample A of LT Ge buffer, Ge diffraction peak is much broader and asymmetric, which are signs of some imperfection of a crystal quality, like mosaicity, due to the presence of defects, and the non-uniformly distributed strain. Based on the peak positions, the calculated degree of strain relaxation reached 95% for sample A. For sample B to D with HT Ge epilayers, Ge peaks become symmetric and narrower. The Full Width at Half Maximum (FWHM) for sample A to D is 1200, 490, 90 and 95 arcsec, respectively. The modified Ge diffraction peaks suggest the improvement of crystal quality. Based on the peak positions of the HT Ge epilayers (samples C and D), which are much closer to that of the Si substrate in comparison with the bulk Ge one (-5640 arc sec), the Ge epilayers are tensile strained. The tensile strain in Ge epilayers is calculated to be 0.16%. The tensile strain is induced by the thermal expansion coefficient mismatch between Ge and Si.

Figure 5 shows cross-sectional HRTEM images of sample C. Although we cannot evaluate the exact TDD by HRTEM for its localized view, the TDD distribution can still be outlined by analyzing HRTEM images. It can be seen that most of misfit dislocations are confined at the LT-Ge and Si interface as shown in the inset. Some of them thread upward and generate threading dislocations and then some of the threads meet and annihilate in a region at the beginning of the HT-Ge layer.

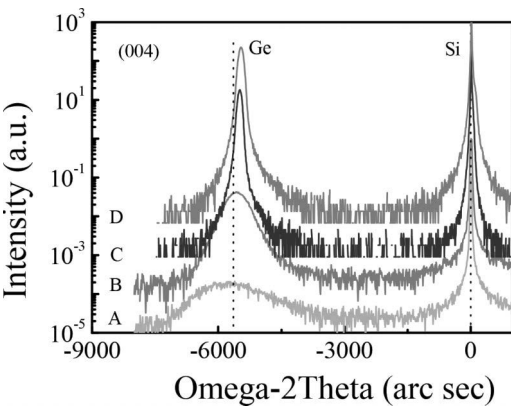

Figure 4. Omega-2Theta XRD scans around (004) order for samples A, B, C, and D. Straight dashed line indicates the theoretical peak position of bulk Si and Ge (-5640 arc sec).

Figure 5. Cross-sectional images of HRTEM of sample C.

Figure 6. Optical image of sample C after chemical etching.

The typical optical image of the etched Ge surface for threading dislocation measurement is shown in Figure 6, and the etch pit densities are averaged to be $6 \times 10^7 \text{ cm}^{-2}$. TEM result is in fair agreement with the EPD measurements.

The PL spectra of the Ge epilayers on Si and SOI wafers (samples C and D) are shown in Figure 7. The PL peak of the sample C with the Ge layer on Si wafer is at about $1.56 \mu\text{m}$, which shifts to longer wavelength compared to $1.52 \mu\text{m}$ for bulk Ge. This red shift should be due to the tensile strain-induced Γ point conduction band down forward shift. The tensile strain induced Ge band gap shrinkage is shown in Figure 8. For sample D with the Ge epilayer on SOI wafer, the PL spectrum is

Figure 7. PL spectra of samples C and D.

Figure 8. Direct bandgap of Ge vs. tensile strain.

modulated by Fabry-Perot cavity formed between the surface of Ge and the interface of buried SiO_2 . The enhancement of the luminescence peak intensity of the Ge layer on SOI wafer in comparison with the Si wafer is about 2.5 fold and the FWHM of the maximum peak is reduced from 200 to 76 nm. What more interesting is that the integration over all spectra of the Ge layer on SOI wafer has a factor of 1.5 fold increases compared to that on Si wafer. This result implies that the absolute amount of light emitted in the Ge on SOI substrate is significantly increased.

4 CONCLUSION

We have grown high quality thick Ge epilayers on Si and SOI substrates utilizing low temperature Ge buffers by ultrahigh vacuum chemical vapor

deposition. It has been demonstrated that LT Ge buffers were rough, but the misfit strains were fully relaxed. On 90 nm thick LT Ge buffer, high quality 1 μm thick of Ge epilayers were obtained both on Si and SOI substrates. XRD peaks were narrow and symmetric with the FWHM of about 90 arc-sec. AFM showed the smooth surfaces with rms roughness of about 3 nm. TEM and counting etch pit methods indicated the Ge epilayers had a low TDD of $6 \times 10^7/\text{cm}^2$. Strong photoluminescence spectra at 1.55 μm wavelength were shown.

Effect of ZnSO_4 and SnSO_4 additions on the morphological of $\alpha\text{-Al}_2\text{O}_3$ flakes for pearlescent pigment

Huan Qin, Ling Wang & Yan Xiong

School of Materials Science and Engineering, Hubei Province Key Laboratory of Green Materials for Light Industry, Hubei University of Technology, Wuhan, P.R. China

ABSTRACT: The flaky $\alpha\text{-Al}_2\text{O}_3$ is one of desirable substrate materials for pearlescent pigments. In the present work, the flaky $\alpha\text{-Al}_2\text{O}_3$ with aspect ratio larger than 100 were prepared via a novel routine combining the sol-gel process with molten-salt growth method. Furthermore, ZnSO_4 or/and SnSO_4 were selected as the morphology modifiers and the effects of the ratio and amount of the modifiers on the morphologies of $\alpha\text{-Al}_2\text{O}_3$ platelets were investigated by Scanning Electron Microscopy (SEM). The results showed that the flaky $\alpha\text{-Al}_2\text{O}_3$ with an average size of $\sim 30\ \mu\text{m}$ and $\sim 0.2\ \mu\text{m}$ in thickness were prepared using 2 wt% ZnSO_4 and 0.2 wt% SnSO_4 as the modifiers by fired at 1100°C for 5 h.

1 INTRODUCTION

The flaky $\alpha\text{-Al}_2\text{O}_3$ with the special two-dimensional structure not only has good performance like mechanical strength, hardness and high heat conductivity as general $\alpha\text{-Al}_2\text{O}_3$, it is also equipped with double peculiarities of micro powder and nano-powder properties, appropriate surface activity, preferable adhesion and ability of reflecting rays, remarkable shielding effect and etc. Therefore, the flaky $\alpha\text{-Al}_2\text{O}_3$ has extensive application in areas of cosmetics industry, fire-proofing (Cemal (2002), Karlsson (2006)), pearlescent pigment (Egashira (2006), Teaney (1999) & Sharrock (2000)), toughening ceramics (Matthew (1997), Zhang (2010)). For example, ceramic matrix composite enhanced with the flaky $\alpha\text{-Al}_2\text{O}_3$ has higher breaking tenacity, compared to that enhanced with alumina granules (Shukla (2007), (2011), Bonderer (2009)). In addition, the alumina platelets with high-quality is the ideal high-grade pearlescent pigment substrate. As a pearlescent pigment base material, it has a high surface reflectivity and a high reflectance capability over other powdery materials. And it improved the color brightness, hue and saturation greatly, and produced special effects of color vector angle. The flaky $\alpha\text{-Al}_2\text{O}_3$ is the ideal high-grade pearlescent pigment substrate (Wu (2014), Zhang (2014)).

At present, many studies are focusing on adjusting the thickness and size of the flaky $\alpha\text{-Al}_2\text{O}_3$ (Tan (2012), Zhu (2011) & Su (2011), among others), but some of them are faced with the problem of poor stability and repeatability (Jin (2004), Su (2011) & Zhu (2011)). In this work, a method of molten salt

growth which combined the sol-gel method was adopted, and that can prepare the flaky $\alpha\text{-Al}_2\text{O}_3$ with characteristic of large radius-thickness ratio, stability of physical and chemical performance and good repeatability.

2 EXPERIMENT PROCEDURE

2.1 Raw materials

The $\text{Al}_2(\text{SO}_4)_3 \cdot 18\text{H}_2\text{O}$ and Na_2CO_3 were used as raw materials. K_2SO_4 and Na_2SO_4 were used as molten salts. ZnSO_4 or/and SnSO_4 were added as morphology modifiers. All of the materials above were produced in Sinopharm Group Chemical Reagent Co., Ltd. and were 99.7% in purity.

2.2 Sample preparation

$\text{Al}_2(\text{SO}_4)_3 \cdot 18\text{H}_2\text{O}$ was dissolved in de-ionized water to form an Al^{3+} solution with 1 mol/L in concentration, K_2SO_4 and Na_2SO_4 were added separately into the $\text{Al}_2(\text{SO}_4)_3$ solution with the molar ratio of 1.6:2.4:1. The Na_2CO_3 solution which was prepared with the concentration of 3 mol/L was dropped in the speed of 15 ml/min into the $\text{Al}_2(\text{SO}_4)_3$ solution at 65°C until the pH reached about 6.8. And the intermediate product was aged at 95°C for one day to obtain a translucent colloid after stirred rapidly for 15 min. Then dried at 110°C and sintered at 1100°C for 5h to obtain a precursor. Finally the sintered product was dispersed in a sulfuric acid solution, repeatedly washed with distilled water and alcohol, and dried to obtain a flaky $\alpha\text{-Al}_2\text{O}_3$ sample.

2.3 Characterization

The crystal structure of the samples were characterized by X-ray diffraction pattern (XRD, Bruker D8 Advance diffractometer) with monochromatized Cu K α radiation ($\lambda = 1.5418 \text{ \AA}$) in the 2θ range of 10–90 deg. The morphologies of the prepared samples were observed by field-emission Scanning Electron Microscopy (SEM, S4800 Hitachi, Japan) with a voltage of 80 kV.

3 RESULTS AND DISCUSSION

The effect of ZnSO₄ content on the morphology of flaky α -Al₂O₃ was investigated by SEM (Fig. 1). With the addition of ZnSO₄, the average size of the sample was also increasing, but its thickness was gradually thickening. When the amount of ZnSO₄ was 2.0 wt%, the average size of the alumina can be up to 25 μm or more and the thickness was about 0.2 μm .

The SEM micrographs of alumina platelets in Fig. 2 (a–f) shows the effect of SnSO₄ content on the morphology of platelets. The addition of small amounts of SnSO₄ had a large effect on the sample morphology. The increased addition amount of SnSO₄ led to the decrease of the size of the flaky

Figure 1. SEM micrographs of α -Al₂O₃ platelets prepared through a 5 h calcination at 1100°C. (a), (b) 1 wt%, (c), (d) 2 wt%, (e), (f) 3 wt% of ZnSO₄.

Figure 2. SEM micrographs of α -Al₂O₃ platelets prepared through a 5 h calcination at 1100°C. (a), (b) 0.2 wt%, (c), (d) 0.4 wt%, (e), (f) 0.8 wt% of SnSO₄.

α -Al₂O₃, and the corresponding reduction of thickness. When the amount of SnSO₄ was 0.4 wt%, the average size of the alumina can be 30 μm and the thickness was about 0.4 μm .

Fig. 3 (a–f) presents the SEM micrographs of alumina platelets with various amounts of both ZnSO₄ and SnSO₄. The addition of the two materials exerts a competitive effect on the morphology of the flaky α -Al₂O₃ particles. When the addition amount of ZnSO₄ and SnSO₄ was 2 wt% and 0.2 wt%, the average size of the alumina can be 30 μm or more and the thickness was about 0.2 μm , which to achieve the best.

In present study, the samples added additives would get flake-like structure, may be the additives could inhibit the growth of the longitudinal crystal, so that it presents a special two-dimensional plane structure. And the larger size and thinner thickness of the sample, the more beautiful streamer color it has. That may as a result of its translucent sheet structure that occurred in the interference effect of light.

The samples obtained after calcination at 1100°C for 5h at a heating rate of 5°C/min were analyzed by XRD in Fig. 4. The sharp diffraction peaks appeared at 2θ of 35.2°, 57.56°, 43.4°, 25.66° and 37.9°, which were consistent with the diffraction peak positions of standard spectra. Thus it

Figure 3. SEM micrographs of α - Al_2O_3 platelets prepared through a 5 h calcination at 1100°C . (a), (b) 2 wt% /0.8 wt%, (c), (d) 2 wt%/0.2 wt%, (e), (f) 3 wt%/0.8 wt% of $\text{ZnSO}_4/\text{SnSO}_4$.

Figure 4. XRD pattern of Al_2O_3 particles.

can be concluded that the flaky α - Al_2O_3 prepared by this method was α - Al_2O_3 , which belongs to the trigonal system, and has good crystallinity.

4 CONCLUSIONS

The flaky α - Al_2O_3 prepared by the novel routine which combined the sol-gel process with molten-

salt growth method could be used as substrate materials for pearlescent pigments successfully. During the reaction, individual additions of ZnSO_4 and SnSO_4 had adverse effects on the morphology of the platelets. The particles of α - Al_2O_3 would be large and thick as the amount of ZnSO_4 increased. SnSO_4 had the opposite effect on the morphology which resulted in the formation of small and thin α - Al_2O_3 flakes. But when the mixtures of the ZnSO_4 and SnSO_4 were used as morphology modifiers, the average size and the thickness were both improved. And the flaky α - Al_2O_3 with the average size $\sim 30 \mu\text{m}$ and $\sim 0.2 \mu\text{m}$ in thickness under the condition of adding 2 wt% ZnSO_4 and 0.2 wt% SnSO_4 .

A facile cost-effective method for preparing superhydrophobic carbon black coating on Al substrate

P. Wang, B. Sun, T. Yao, X. Fan, C. Wang, C. Niu, H. Han & Y. Shi

School of Energy, Power and Mechanical Engineering, North China Electric Power University, Baoding, China

ABSTRACT: In this research, a simple technique for fabrication of superhydrophobic coating was prepared via spraying hydrophobic carbon nanoparticles suspension on aluminum alloy surface. The static water contact angle and sliding angle on the silica nanoparticle deposited aluminum alloy surface were $160 \pm 1^\circ$ and 5° , respectively. In addition, the as-prepared superhydrophobic surface exhibited excellent self-cleaning property. This approach may open a new way in the fabrication of superhydrophobic surfaces with self-cleaning property.

1 INTRODUCTION

As is well known, aluminum and its alloys have achieved extensive industrial applications owing to its abundance in nature, good ductility, low specific weight, excellent electrical conductivity and excellent machinability (Zheng et al. 2016). However, aluminum and its alloys are prone to contamination in damp environment. Therefore, it is a need to form a surface layer on Al and its alloys which protect them from a wide range of contamination. One promising approach is to transform the hydrophilic nature of Al and its alloy surfaces to be superhydrophobic.

Superhydrophobic surfaces with static water contact angles higher than 150° and sliding angles lower than 10° have attracted more and more attention because of their numerous applications in self-cleaning (Wang et al. 2015), anti-icing (Ganne et al. 2016), anti-corrosion (Zhang et al. 2016, Zhang et al. 2014), oil-water separation (Liu et al. 2015), and so forth. It is well known that the superhydrophobic property is the result of a combination of suitable surface roughness and low surface energy (Du et al. 2007). A great number of artificial superhydrophobic surfaces have been developed by various methods such as layer-by-layer deposition (Zhai et al. 2004), template-based methods (Chang et al. 2013), sol-gel process (Latthe et al. 2014), lithography (Park et al. 2012), etc. However, these artificial surfaces are prone to lose their self-cleaning properties when they are subjected to impact of water (Deng et al. 2012). Moreover, fluoropolymers such as perfluorooctanoic acid and perfluorooctyltrichlorosilane are conveniently utilized to prepare superhydrophobic surface. Recent researches revealed that long-chain

polyfluorinated compounds have a documented ability to bioaccumulation and potential adverse effects on human offspring (Li et al. 2016). Therefore, there is an increasing demand to prepare non-fluorinated superhydrophobic materials for their nontoxic and low-cost benign.

In this paper, we presented a simple, cost-effective and environmental-friendly way to prepare an aluminum alloy sheet with superhydrophobicity and self-cleaning properties. Painting is intrinsically cheap, low-expertise route to mass production and applicable to almost any substrate types (Wang et al. 2016). Here, the suspension was simply prepared by one-pot process at room temperature. Through painting the as-prepared suspension, the aluminum alloy sheet shows a contact angle of $160 \pm 1^\circ$ and a sliding angle of 2° . It also shows perfect self-cleaning property. When the water droplet is dropped on the nano silica deposited aluminum alloy sheet covered with graphite powder, it roll off the surface and carried the graphite powder away.

2 EXPERIMENTAL PROCEDURE

Carbon black (VXC 72R) was supplied by Cabot. Trimethoxypropylsilane (PTMS, assay: 97%) and ethanol were supplied by Sinopharm Chemical Reagent Co., Ltd. Acetic acid (assay: 36%) was purchased from Tianjin Fuchen Chemical Reagents Factory.

Carbon black was first dispersed in ethanol, and PTMS was added dropwise under stirring at room temperature. The concentration of carbon black and PTMS was 20 and 50 mg/mL, respectively. The solution was further adjusted at PH = 3.5 with acetic acid. In the following experiments, the solution

was painted onto the Al 6061 substrate using a disposable Pasteur pipette (1 ml), and cured at room temperature for 24 h.

FE-SEM (Field-emission scanning electron microscope) images were obtained on a Zeiss Supra 55 instrument at 5–10 kV. Prior to FE-SEM measurements, a thin Au layer (ca. 5 nm) was deposited on the specimens by sputtering. The water contact angle and sliding angle were measured with a SL100B apparatus at ambient temperature. The volume of the individual water droplet in all measurements was 5 μ L. The average contact angle and sliding angle values were obtained by measuring the same sample at least in five different positions.

3 RESULTS AND DISCUSSION

The synthesis of hydrophobic carbon nanoparticles was a key part of our strategy for the fabrication superhydrophobic coating. During the preparation of coating solution, the hydrolysis reaction of PTMS could be described as Figure 1, where R is $\text{CH}_2\text{CH}_2\text{CH}_3$. Furthermore, the hydrophilic carbon nanoparticles were functionalized through the attraction of hydrogen bond formation by pairs of Si-OH groups.

Figure 2a and b showed the SEM top-images of carbon nanoparticle deposited Al 6061 substrate with low and high magnifications, respectively. From the low magnification SEM images (Figure 2a), it could be founded that carbon nanoparticles uniformly cover the paper substrate. The high magnification SEM (Figure 2b) showed nanoscale porous structure. During the evaporation of ethanol, the distance between nearby nanoparticles is much greater than several nanometers (Li et al. 2015). Thus, the interparticle forces display attractive force rather than repulsive force which lead to the nanoparticle aggregation. Furthermore, as the nanoparticles come closer, one nanoparticle tended to combine with another nanoparticle through van der Waals force and hydrogen bonds. Therefore, after the evaporation of ethanol solvent, the porous structure with large scale homogeneity but local irregularity was spontaneously formed.

Figure 1. Scheme of creating a carbon nanoparticle superhydrophobic coating.

Figure 2. Top-view SEM images of carbon black deposited aluminum alloy surface with low magnification (a) and high magnification (b), respectively.

As shown in Figure 2b, the pore size ranged from nanoscale to sub-microscale.

To study the surface wettability of carbon nanoparticle superhydrophobic coating, the water contact angle and sliding angle of the as-prepared sample were measured, as shown in Figure 3. The carbon nanoparticle deposited superhydrophobic surface showed a high water contact angle of $160 \pm 1^\circ$ (Figure 3a). Meanwhile the water droplets don't come to rest on the surface when the sliding angle is 5° , suggesting low adhesion between water droplet and carbon nanoparticle deposited surface (Li et al. 2012). As is known to all, the surface wettability can be described by the Wenzel (Wolansky et al. 1999) and Cassie-Baxter models (Johnson et al. 1964). Both two wettability states can lead to a high contact angles. However, only the Cassie-Baxter model can result in a very low sliding angle (Liu et al. 2013). Herein, Cassie-Baxter theory was employed to explain the mechanism of superhydrophobic behavior on the carbon nanoparticle superhydrophobic coating. On the as-prepared surface, the apparent solid-liquid contact

Figure 3. Water droplets on the nano silica deposited aluminum alloy substrate with (a) a contact angle of $160 \pm 1^\circ$ and (b) a sliding angle of 5° .

is a real composite contact of solid-liquid-gas due to the hierarchical structures. In this composite state, air layer can be trapped in the micro cavities and nanopores between silica nanoparticles, and then water droplets will be suspended due to the “air cushion” underneath water droplets. Thus, the surface adhesion between droplets and superhydrophobic silica nanoparticle deposited surfaces is extremely low and the water drops can slide off with a slight sliding angle.

The silica nanoparticle deposited aluminum alloy surface also shows excellent self-cleaning property. The self-cleaning performance of the carbon nanoparticle superhydrophobic coating was investigated using sand as contaminant dust particles (Figure 4). First, a thin layer of sand was sprinkled onto the as-prepared superhydrophobic coating (Figure 4a). Then, water droplets were gently placed on this contaminated surface. The dust particles were immediately adsorbed on the surface of the water droplet as soon as they came into contact with the water droplet (Figure 4b and 4c). After several sliding and rolling processes,

Figure 4. (Continued).

Figure 4. Self-cleaning process on the carbon nanoparticle deposited aluminum alloy surface: (a) the surface with sand as a model of contaminant; (b-c) the contaminated surface with one water drop on it; (d) the contaminated surface after the sliding of water droplets.

water droplets brought away the contaminants completely and left a clean surface (Figure 4d), which confirmed the excellent self-cleaning ability of the prepared graphene coating.

4 CONCLUSION

In conclusion, we have developed a facile and cost-effective spray-coating method to prepare carbon nanoparticle superhydrophobic coating. The carbon nanoparticle deposited aluminum alloy surface exhibited high water contact angle ($160 \pm 1^\circ$) and low sliding angle (5°). Furthermore, the as-prepared superhydrophobic aluminum surface exhibited excellent self-cleaning property. Thus, the aforementioned great properties make this method a promising candidate to fabricate a superhydrophobic surface on an aluminum sheet for wide application.

Preparation of multifunctional flake alumina ceramics

Qianrui Wang, Chong Liu, Kaixuan Du & Yan Xiong

School of Materials Science and Engineering, Hubei Province Key Laboratory of Green Materials for Light Industry, Hubei University of Technology, Wuhan, P.R. China

ABSTRACT: In the field of inorganic non-metallic materials, flake Al_2O_3 is one of the hot spots of research due to its unique two-dimensional structure and the larger aspect ratio. $\text{Al}_2(\text{SO}_4)_3$, Na_2SO_4 , K_2SO_4 , Na_2CO_3 and Na_3PO_4 are used as raw materials. And a novel routine method obtained by combining the sol-gel process with molten-salt growth is used to prepare flake Al_2O_3 . Meanwhile, the effects of additive content and sintering temperature on its aesthetic properties and micro-structure are also investigated. The results show that the best aspect ratio and the excellent aesthetics property of flake Al_2O_3 are obtained by using 0.0136% SnSO_4 , 0.1000% TiOSO_4 , and 0.0900% ZnSO_4 as the additives and by sintering at 1200°C for 7 h.

1 INTRODUCTION

In recent years, flake Al_2O_3 has emerged into a kind of composite materials with excellent performance. It has extensive applications in different fields, including cosmetics industry, refractory (Cemail (2002), Karlsson (2006)), pearlescent pigments, toughening ceramics (Matthew (1997), Zhang (2010)), and other fields. Generally, flake Al_2O_3 grain size is 5–50 μm , and the thickness is 100–500 nm. The well-developed crystal particles of flake Al_2O_3 also show a regular hexagonal morphology (Yang (2004), Pei (2010)). Flake Al_2O_3 ceramics with excellent performance are widely used in expensive automobile basic paint materials, high-grade pearlescent pigments and cosmetics (Egashira (2006), Teaney (1999), Sharrock & Schuel (2000)), and advanced abrasives (for the electronics industry, mono-crystalline silicon substrate polishing) (SU (2004)). But these raw materials are mainly dependent on import, such as Germany's Merck and BASF companies. Although, there are some reports in the Chinese literature, flake Al_2O_3 mentioned in the report is not big in size, the aspect ratio is small and the stability and repeatability of preparation are poor. However, in China, automotive-related industries have a huge demand of flake Al_2O_3 , providing broad prospects for flake Al_2O_3 . When compared with the traditional molten salt method (Jin & Gao (2004), Hsiang (2007), Su & Li (2011)) to prepare ceramic powder, we have adopted a novel routine method by combining the sol-gel process with molten-salt growth (Hill & Supancic (2002), Zhou (2003), Akkaya (2014)), the flake Al_2O_3 prepared by this method has a large aspect ratio, stable physical and chemical properties, and good repeatability.

2 EXPERIMENTAL PROCEDURE

2.1 Raw materials and reagents

All of the following materials were produced in Sinopharm Group Chemical Reagent Co. Ltd. and were 99.7% pure:

$\text{Al}_2(\text{SO}_4)_3 \cdot 18\text{H}_2\text{O}$, Na_2SO_4 , K_2SO_4 , SnSO_4 , Na_2CO_3 , $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$, TiOSO_4 , and Na_3PO_4 .

2.2 Preparation process

The molar ratio of the molten salt and Al^{3+} is 4:1. The concentration of 0.5295 mol/L $\text{Al}_2(\text{SO}_4)_3 \cdot 18\text{H}_2\text{O}$, 0.8469 mol/L K_2SO_4 , and 1.2787 mol/L Na_2SO_4 are prepared respectively, thereby composing solution 1. And then, a certain percentage of SnSO_4 , TiOSO_4 , and $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ are added to solution 1. Next, 0.3396 mol/L Na_2CO_3 and 0.0018 mol/L Na_3PO_4 are prepared as the second solution, namely 2. The solution 2 is dropped at a speed of 5 ml/min into solution 1 at 65°C and is kept under continuous stirred at a rate of 400 r/min for 15 min by using a peristaltic pump until the reaction is completed to obtain a gel mixture of the two solutions. The temperature of the reaction container is raised to 90°C and aged for 24 h. The gel is evaporated to dryness. And then, the dried precursor powder is placed in a corundum crucible and compacted and placed in a muffle furnace. The dried precursor powder is heated respectively to 1000°C, 1100°C, 1200°C and 1300°C at the rate of 9°C/min. The solid agglomerate obtained after calcination is dispersed with concentrated sulfuric acid and then repeatedly washed with a large amount of distilled water and alcohol to remove impurities and finally dried to obtain a test sample.

2.3 Properties and characterization of the sample

The morphology analysis instrument of flake alumina employs a JSM-5610 LV scanning electron microscope, made by Japanese Electronics Co., LTD, by using high-energy electron beam, on the surface of flaky alumina powder through scanning frame by frame, inspiring different physical signals, which are saved as printing results. The microstructure phase analysis of samples uses an X-ray Microanalysis System (EDS) made by the American General Company, as the attachment configuration of scanning electron microscopy in a JSM-5610 LV Scanning Electron Microscope (SEM). A Phoenix spectrometer is a spectrum analysis system with high resolution images and component diagram.

3 RESULTS AND DISCUSSION

3.1 Surface morphology characterization and mechanism analysis

Figure 1 shows the XRD pattern for flake aluminium oxide.

According to the XRD pattern of the sample, the crystal shape of flaky aluminium oxide is α - Al_2O_3 . Through the contrast with the standard peak, the location of the characteristic peak is conformed to the standard. And so, the crystal type of the final samples is the alpha type of the crystal. α - Al_2O_3 is a kind of nanometer alumina. The size and specific surface area of α - Al_2O_3 , which appears in a white fluffy powder state, are respectively 20 nm and 50 m^2/g or higher. In view of the existence of defects, semiconductor and metal composite materials, etc. present a rare superiority instead. Addition of inhibitors inhibits the grain's longitudinal growth, thereby bringing out the special two-dimensional plane structure on flake alumina.

Figure 1. XRD pattern of flake Al_2O_3 .

Figure 2 shows the SEM image of the analysis of the crystal microstructure of flake alumina, which is prepared under the condition of aging at 95°C for 36 h and sintering at 1000–1300°C, at the rate of 9°C/7 min for 7 h. Results indicate that, at 1200°C, the grain size and thickness of the flake alumina are the best and the aspect ratio is the largest. Meanwhile, the samples possess a translucent shape and the macroscopical morphology has a beautiful streamer color. Because of its translucent sheet-like structure, the light interference effect was observed through the light path through reflection. Due to the anisotropy of the crystal, the addition of appropriate additives can inhibit the growth of the crystal in the longitudinal direction, so that it presents a special two-dimensional planar structure.

From the SEM images shown in Figure 2, we can observe that most of the α - Al_2O_3 exhibit a flaky structure and stay in a translucent crystalline state when not dispersed. On this basis, we measured the size and thickness of grain and compared the aspect ratio through the chart, in order to explore a suitable formula to produce a low-cost and high quality semi-transparent flaky alumina matrix.

Tables 1–3 provide the analysis of the sample of the flake alumina shown in Fig. 2. ZnSO_4 , SnSO_4 , and TiOSO_4 were added at 65°C, and then aged

Table 1. The morphology of the sample obtained at 1100–1300°C by adding ZnSO₄ during sintering of alumina.

Sintering temperature (°C)	Biggest size (μm)	Average thickness (μm)	Particle size (μm)	Aspect ratio
1000	31.04	0.43	20.30	47.21
1100	20.13	0.40	13.60	34.00
1200	28.40	0.18	27.70	153.89
1300	31.00	0.20	24.40	122.00

Table 2. The morphology of the sample prepared at 1100–1300°C by adding SnSO₄ during sintering of alumina.

Sintering temperature (°C)	Biggest size (μm)	Average thickness (μm)	Particle size (μm)	Aspect ratio
1000	25.71	0.58	21.50	37.09
1100	44.96	0.20	33.80	169.00
1200	49.02	0.86	40.80	47.44
1300	26.75	0.29	24.20	83.45

Table 3. The morphology of the sample prepared at 1100–1300°C by adding TiOSO₄ during sintering of alumina.

Sintering temperature (°C)	Biggest size (μm)	Average thickness (μm)	Particle size (μm)	Aspect ratio
1000	36.89	0.30	26.12	87.07
1100	34.46	0.25	25.50	102.00
1200	26.55	0.21	15.60	74.29
1300	25.68	0.22	20.23	91.95

at 95°C for 36 h, and sintered for 7 h at the rate of 9°C/min at 1000–1300°C; the aspect ratios of different additives at different temperature points vary greatly; Table 1 aims to explore the impact of temperature on its molding, which additive is added and the quantity of additives.

It can be seen from Table 1 that under the same conditions of additive ZnSO₄, sintering temperature, holding time, and so on, the samples sintered at 1200°C are very thin. SEM images show that the samples are translucent and thin and their grain sizes have reached the best level, and also the diameter to thickness ratio is relatively large, but the maximum size is not perfect when compared to other temperatures.

It can be seen from Table 2 that under the same conditions of additive SnSO₄, sintering tempera-

Figure 3. Chart of the average thicknesses obtained by adding ZnSO₄, SnSO₄, and TiOSO₄ at different temperatures.

Figure 4. Chart showing the particle size distribution of samples prepared by adding ZnSO₄, SnSO₄, and TiOSO₄ at different temperatures.

ture, holding time, and so on, the maximum size and grain size of samples sintered at 1200°C are very large, but the average thickness is the largest when compared to the other samples. Therefore, it can be concluded that addition of SnSO₄ can increase the grain size of flaky alumina, but it will also greatly increase the thickness of the sample.

It can be seen from Table 3 that under the same conditions of additive TiOSO₄, sintering temperature, holding time, and so on, the average thickness of samples sintered at 1200°C is smaller than that of other samples. But the maximum size and grain size of the sample are the largest among the several temperature points. Therefore, it can be concluded that the addition of TiOSO₄ can reduce the thickness of the flaky alumina, but it will also increase the grain size of the sample.

It can be seen from Table 4 that under the conditions of adding additive ZnSO₄, SnSO₄, and

Table 4. The morphology analysis of sintering powder obtained at 1200°C and 7 h by adding ZnSO₄, SnSO₄ and TiOSO₄ at different temperatures.

0.20	
33.60	

TiOSO₄ together, the average thickness and particle size of the samples sintered at 1200°C are much better than those obtained by using the individual additives.

4 CONCLUSION

The composite molten salt method is adopted to prepare flake alumina with the raw materials of Al₂(SO₄)₃, Na₂SO₄, K₂SO₄, Na₂CO₃, Na₃PO₄, and additives such as ZnSO₄, SnSO₄, TiOSO₄ to ensure that samples have a more perfect microscopic appearance. The results show that when the sintering temperature is 1200°C, sintering time is 7 h, the amount of SnSO₄, ZnSO₄, TiOSO₄ is 0.0136%, 0.1000% and 0.0900%, respectively, the flaky alumina obtained has the largest diameter to thickness ratio and a beautiful streamer color. It can also meet the needs of applications market for being employed in expensive automobile basic paint materials and high-grade pearlescent pigments.

Study on the deformation of plastic films by virtual particle method

X.H. Yang, Z. Yang, Y.X. Wang, C.Y. Lv & X. Cheng

School of Mechanical Engineering, Shandong University of Technology, Zibo, China

ABSTRACT: Sorting of waste plastics by wind is a kind of high-efficient and energy-saving processing method. However, the deformation of plastic films in the wind sorting process seriously affects the theoretical analysis accuracy. A novel virtual mass method has been introduced in this paper. The mathematical model for film deformation has been created and the line unit equation has been deduced. Based on the method, the deformation values at the wind speeds of 0.2 m/s and 0.35 m/s have been obtained. It coincides well with the analytical results from dynamic meshes and fluid solid coupling by the Ansys Fluent software. The wind sorting accuracy can be improved by achieving the deformation rules of plastic films. It can be used to guide the optimization of wind sorting machines for plastic films.

1 INTRODUCTION

With the urbanization goes forward, domestic waste increases year by year. According to the statistics, waste plastics occupy 10% of total waste in large and medium-sized cities (Zhu 2010, Li 2013). The wind sorting of waste plastics has been attracted increasingly attentions because it is a kind of non-pollution and high-efficient sorting method. The optimal dimensions of wind nozzles have been identified for accurate sorting of waste plastics by wind sorting devices (Hu 2015). The wind blowing machine's optimal wind entrance angle has been identified for horizontal wind sorting of domestic wastes (Li 2012). The efficiency of separation and sorting has been enhanced by developing a separation and sorting system for plastic waste (Gao 2009). These studies provide references for further studies of plastic sorting.

The plastics in domestic wastes are composed of plastic films. Therefore, the sorting accuracy and efficiency will be affected seriously due to the deformation of films in the sorting process. The novel virtual particle method is introduced in the paper to study the deformation of plastic films in the separating and sorting process. The mathematical model for film deformation has been created and the deformation rules have been analyzed. The method has been evaluated by the fluid solid coupling analyses using the Ansys Fluent software. It lays solid calculating and analysis foundations for enhancing the accuracy and efficiency of sorting.

2 VIRTUAL PARTICLE METHOD

There are limited plastic deformation studies in sorting processes since it is very difficult to model

and calculate the plastic films. The consequences are that the errors between theoretical and experimental results are very large. Aiming at this problem, a novel virtual particle method is proposed to study the deformation of plastic films in the sorting process.

By the virtual particle method, limited uniformly distributed particles are applied to describe the film. The mass of the film is lumped at the particle. The particle is connected by line cell without masses. Positions of line cells are calculated by position functions. The schematic view of the simplified model is shown in Figure 1 with mesh structures. The internal and external forces bearing by the films are described the equivalent concentrated forces of the particles. The overall deformation and spatial positions of the films are defined by position vectors of particles.

The mass of the particle can be described as,

$$M_a = \frac{M}{n} \quad (1)$$

where, M_a is the mass of the point, M is the mass of the film, and n is the particle number in the model.

Figure 1. Film models described by particles.

In order to solve the internal forces of the unit, the pass unit concept is introduced by neglecting the effects of unit geometrical changes in variations of films positions. By the virtual particle method, film behaviors are described by the motion trajectories of all particles under loads. The motion and deformation of films are time functions of particle position vectors. Then, the time trajectory of the particle can be solved, where the time trajectory is also called the path.

As shown in Figure 2, given the starting and ending time as t_0 and t_f for particle A, y_0 and y_f is the corresponding position vector, respectively. The time function $y(t)$ is the position vector at time t . The path of the particle between time t_0 and t_f is divided into three segments. The segments between time t_a and t_b is defined as path cell. The time function is continuous inside one path cell. The path cell abides by motion laws and Hooke law while the rigid body motions are excluded.

The virtual reverse motion concept is proposed in order to obtain the deformation value from overall displacement by excluding the rigid body displacement after the deformation of films. Inside the path cell between time t_a and t_b , the geometrical structure of the film at the starting time t_a is selected as the reference. The rigid body movement of line cell at the time between t_a and t will be estimated. The translation is defined as the displacement value of arbitrary point at the line cell. The rotational motion is defined as the spinning value of the line cell between time t to t_a . According to the estimated values, the line cell makes a virtually inverse rigid body movement at time t , which is called the virtual inverse movement. Inside one path cell, the difference between the formation after virtually reverse movement and the actual one is the tiny deformation and rigid body movement, which can be calculated by micro strain and engineering stress. Therefore, the node force can be solved. The force direction will be changed after the positive rigid body movement since the node force is a group of balance forces. Therefore, the internal force inside the cell can be obtained by vector rotation of the node force direction.

Figure 2. The path cell ($t_a \leq t \leq t_b$).

3 MATHEMATIC MODELLING AND ANALYSIS

3.1 Deformation of line cells

A standard bar cell ($1_a 2_a$) is selected from the standard path cell between time t_a and t_b . Its cross section area is A_a and the Young's modulus is E . The bar axis coordinate (x') is set up with the superimposition of node 1_a and original point, where the x' axis is parallel to the bar axis. Then, the position vector X_a on the bar at time t_a and t can be calculated by,

$$\begin{cases} x_a = (1-s)x_{1a} + sx_{2a}, s = \frac{x'_a}{l_a} \\ x = (1-s')x_1 + sx_2, s = \frac{x'_a}{l_a} \end{cases} \quad (2)$$

The cross section of the bar remains unchanged and s is equal to s' . Therefore, the node deformation is,

$$(x - x_a) = (1-s)(x_1 - x_{1a}) + s(x_2 - x_{2a}) \quad (3)$$

namely,

$$u = (1-s)u_1 + su_2 \quad (4)$$

where, u is the displacement of arbitrary point on the bar, u_1 and u_2 are the node displacements of the rod cell.

The relative displacement between the two points is,

$$u - u_1 = \Delta s(u_2 - u_1), \Delta s = \frac{\Delta x'_a}{l_a} \quad (5)$$

where, $\Delta x'_a$ is the distance between arbitrary two points on the bar at time t_a .

3.2 Internal forces of line cell

The bar cell takes node 1 as the fixed reference point. The rotational angle is $-\theta$. The position variation between two arbitrary points on the bar is $\Delta \eta^r$. If the relative position variation is $\Delta \eta_2^r$ between node 2 and node 1 on the bar, then,

$$\Delta \eta^r = \Delta s \eta_2^r \quad (6)$$

Given the deformations of two nodes on the bar as η_1^d and η_2^d , the following equation can be got since $\eta_1^d = 0$.

$$\eta^{2d} = (u_2 - u_1) + \eta^{2r} \quad (7)$$

After rotation, the cell and the bar cell are collinear. The geometrical relationship satisfies the hypothesis of mechanics of materials for calculating axial deformations. Under the coordinate,

$$\eta^{2d} = (l - l_a)e'_{ax} \quad (8)$$

The relative displacement in virtual formation is,

$$\Delta\eta^d = (\Delta x' - \Delta x'_a)e'_{ax} \quad (9)$$

It is tiny deformation and rotation of the bar cell. The geometrical variation can be neglected. The tiny strain ε and its value ε' are,

$$\varepsilon = \varepsilon'e'_{ax} = \frac{\Delta\eta^d}{\Delta x'_a} = \frac{l - l_a}{l_a}e'_{ax} \quad (10)$$

Under the defined coordinate, the internal force vector f and axial stress σ between two points on the bar are,

$$\sigma = \frac{f}{A_a} = \frac{f}{A_a}e'_{ax} = \sigma'e'_{ax} \quad (11)$$

The bar cell is elastic. Based on Hooke law, there are linear relationships between stress and strain at the time t_a and t . Namely,

$$\sigma' - \sigma'_a = E_a\varepsilon' \quad (12)$$

Therefore,

$$f = f'e'_{ax} = (f_a + A_a E_a \varepsilon)e'_{ax} \quad (13)$$

Given relative virtual displacement $\delta(\Delta\eta^d)$, virtual deformation power is,

$$\Delta(\delta U) = f\delta(\Delta\eta^d) \quad (14)$$

The deformation virtual power of the bar cell can be calculated after the integration of the overall bar cell.

$$\delta U = \left[f_a + \frac{A_a E_a}{l_a}(l - l_a) \right] \delta(l - l_a) \quad (15)$$

Since the axial force of the bar cell is in balance and $\sum F = 0$, then $f_1 = f_2$ and the virtual power is,

$$\delta W = f'_2 \delta \eta^d_2 \quad (16)$$

Based on virtual power theory, $\delta U = \delta W$ and the internal force of the node is,

$$f'_1 = f'(-e'_{ax}), f'_2 = -f'_1 \quad (17)$$

After obtaining the internal force of nodes, positive motions are processed. Since the force is in balance for two node point, the value remains unchanged after translation. Only the rotation makes the force direction change. Then, the internal force between two nodes under the coordinate is,

$$f'_1 = f'(-e'_x), f'_2 = -f'_1 \quad (18)$$
