Preface

We are fortunate to have Southwest Jiaotong University (SWJTU, Chengdu, China) to host the Fifth International Conference on Transportation Engineering (ICTE 2015). Transportation and Development Institute (T&DI) of the American Society of Civil Engineers (ASCE) is a key sponsor of the conference and ASCE is the publisher of the conference proceedings. SWJTU, formerly known as Tangshan Jiaotong University, is renowned for its prestigious engineering programs in various transportation related disciplines, dating back to 1896. The editors are grateful for the kind support of SWJTU, and the organizations and individuals who played important roles for the success of the conference, which are acknowledged at the beginning of the proceedings. This conference is held in the city of Dalian with outstanding support of Dalian Jiaotong University. This is the first time that ICTE is held outside of Chengdu, China. We all appreciate the diligent work by Dalian Jiaotong University for ICTE.

The motif of ICTE 2015 is "Comprehensive, Wisdom, Green, Safety, High-Speed and Innovation". ICTE 2015 is a platform of communication and discussions among worldwide experts and scholars in the field of transportation engineering. During the conference, they will present their latest achievements and innovations to promote mutual study and collaboration.

All papers in the proceedings were peer-reviewed resulting in over 400 papers selected for publication. The School of Transportation and Logistics of SWJTU provided various support for the conference, including soliciting abstracts and papers, organizing sessions and presentations, and managing the peer-review process.

There were a number of volunteers who reviewed the submitted papers. The conference and the editors appreciate their valuable work. The editors thank their important contributions to the conference. The diligent work by members of the Secretariat in organizing the vast number of papers is critical for the publisher to meet the deadlines.

Lastly, we would like particularly thank ASCE T&DI Director, Mr. Muhammad Amer, and staff of ASCE publications for their support of this conference.

Editors of ICTE 2015 Proceedings

Abstract: The present paper hypothesizes that when the safety motive of sustainable development pursued by financial organizations and the service motive aimed by government financial control contradict, effectiveness of policy conduction would be undermined. Fuzzy comprehensive evaluation method is employed by different target groups to evaluate policy satisfaction. The study has shown that target groups are satisfied with credit system in post-disaster reconstruction.

Keywords: Post-disaster reconstruction; Credit policy; Fuzzy comprehensive evaluation method; Policy evaluation.

1 Introduction

In accordance with monetary policy, credit policy, an integral part of national Macro-economic Control system, led by industrial policies, exercised by commercial banks, whose principles of safety, fluidity and profitability are respected by central bank, cooperates national social and regional development policies, guides and standardizes bank credit funds channeled by a series of policies and regulations and regulatory system (Tang Yingwei, Hong Bo, 2012). Some scholars claim that in post-disaster reconstruction, powerful monetary policy can provide efficient and reliable, long-term and standardized capital supply for relief and rehabilitation work. (Song Xuguang, Pang Mingchuan, Wang Xiaoling etal, 2008). Meanwhile, some scholars maintain that principles of safety, profitability and fluidity pursued by commercial banks when allocating credit will undermine the role of control played in emergency rescue and post-disaster reconstruction (Feng Xiaobin, Wang Yong,2010). Especially at present, China's financial system inadequate to catastrophe relief and precautions is insufficient to carry out post-disaster reconstruction. (Qin Chijiang, 2009). The present paper hypothesizes that when the safety motive of sustainable development pursued by financial organizations and the service motive aimed by government financial control contradict, the effectiveness of policy conduction would be affected.

At the same time, different policy-targeted groups' or stakeholders' subjective evaluation of policy implementation and relevant effects results from such facts as the relatively long time-lag between credit policy implementation and anticipation of target groups in post-disaster reconstruction, the manifestation of loan benefits (such as income change, project progression, production restoration .etc) brought by preferential credit policy, which target groups participate, and emergency of conflicts between target groups' policy anticipation and the goal of government macro-economic control.

2 Proposal of Evaluation Scheme and Establishment of Index System

2.1 Design of evaluation scheme

The target groups of credit policy on post-quake reconstruction are mainly afflicted inhabitants and small and medium-sized enterprise. This study is conducted with questionnaires, and afflicted inhabitants and small and medium-sized enterprises are survey target. Counties (prefecture or district) with an economic edge in pre-disaster days that are severely affected by earthquake and recovered significantly in post-disaster days, are within our sample scope. Sample size is devised according to the principle of average sample size conforming to normal distribution. Questionnaire informs the present authors of the afflicted inhabitants' and small and medium-sized enterprises' evaluation results of credit policy implementation and relevant effects. In the process of data organization and analysis, a fuzzy mathematical method is used to analyze the final membership grade level of policy implementation effects so as to investigate the implementation results of customer-led credit policy in post-disaster reconstruction, namely afflicted inhabitants' and enterprises' satisfaction level of policy.

2.2 Selection of samples and description of data

Of the 40 heavily and severely afflicted counties (prefectures, districts), Aba prefecture, Chengdu and Mianyang are chosen to be the key areas to be investigated, and 11 counties (prefectures, districts), which account for 25% of heavily and severely afflicted counties, are included to be our survey target. Questionnaires are distributed to afflicted inhabitants and enterprises who enjoyed preferential credit. Valid questionnaires obtained from afflicted rural inhabitants, urban inhabitants and small and medium-sized enterprises are with efficacy rate of questionnaires being 85.46%, 76.36% and 87.27% respectively.

2.3 Establishment of index system and rating scale

(1)Determination of index system

On the basis of evaluation index system related to credit policy, integrating practical credit situation of post-Wenchuan Earthquake reconstruction, index system of satisfaction evaluation, which can reflect different target groups' anticipation of credit policy, is screened through credit policy of key support work aimed at different target groups.

The evaluation of implementation effects of credit policy on post-Wenchuan earthquake reconstruction is shown in table 1.

Table 1. Evaluation of implementation effects of credit policy on post-Wenchuan earthquake reconstruction

Fist class index	Second class index	Third class index
Target groups'satisfaction evaluation of credit policy on post-Wenchuan Earthquake reconstruction R	Afflicted rural inhabitants' Satisfaction evaluation R1	Evaluation of credit cost in housing reconstruction x1
		Evaluation of infrastructure after credit investment x2
		Evaluation of agricultural restoration after credit investment x3
		Evaluation of post-quake income change x4
	Afflicted urban inhabitants' satisfaction evaluation R2	evaluation of loan interest after adjustment y1
		Evaluation of maximum loan limit after adjustment y2
		Evaluation of credit period after adjustment y3
		Evaluation of approval efficiency y4
	Afflicted enterprises' satisfaction evaluation R3	Evaluation of approval efficiency z1
		Satisfaction evaluation of fund supply z2
		Evaluation of "Four Nos" policy z3
		Evaluation of support magnitude of credit policy z4

(2)Determination of rating scale

This paper grades influence factors of credit policy on post-Wenchuan Earthquake reconstruction on the scale of "very satisfied", "adequately satisfied", "not very satisfied", and "extremely not satisfied".

$$B = \{b_1 \quad b_2 \quad b_3 \quad b_4\} = \{\text{VS} \quad \text{AS} \quad \text{NVS} \quad \text{ENS}\}_*$$

(*VS=Very satisfied, AS=adequately satisfied, NVS=not very satisfied, ENS=extremely not satisfied)

3 Systematic Analysis of Fuzzy Comprehensive Evaluation of Credit Policy on Post-Wenchuan-Earthquake Reconstruction

3.1 Satisfaction evaluation of different target groups

Probability and statistics are employed to evaluate different target groups' policy implementation satisfaction, on the basis of which evaluation matrix Ri can be obtained.

Every respondent made their sole satisfaction evaluation of credit policy on post-quake reconstruction. After normalizing frequency of statistics results, with satisfaction value of each factor in the range of 0 to 1, with the sum of satisfaction value of every factor totaling 1.

3.2 Determination of index weight

The result of first-level index weight and second-level index weight obtained after standard treatment of original matrix and entropy calculation are as follows:

Fist-level index weight: $W = \{0.273 \quad 0.281 \quad 0.446\}$

Rural index weight of the second-level index: $W_1 = \{0.221 \ \ 0.221 \ \ 0.273 \ \ 0.285\}$

Urban index weight of the second-level index: $W_2 = \{0.245 \ \ 0.269 \ \ 0.255 \ \ 0.23\}$

Enterprise index weight of the second-level index: $W_3 = \{0.223 \ 0.326 \ 0.246 \ 0.205\}$

Every index weight stands for the influence the index has on the target level. And weight value is proportional to its influence.

3.3 Different target groups' satisfaction evaluation of credit policy on post-quake reconstruction

Weighted average method ($\cdot$, $\oplus$)with the advantage of comprehensiveness, intensification of the role played by weights and full exploitation of result matrix R, is chosen to be the fuzzy operator in this paper. Relatively objective and precise fuzzy evaluation results can be conducted and the weakness of little difference between rating scale and evaluation results can be effectively overcome. Such a result as table2 can be got at last.

Table 2. Different target groups' satisfaction evaluation of credit policy on post-quake reconstruction

Index Level	Membership grade			
	VS	AS	VNS	ENS
B1	0.1907	0.6034	0.1765	0.0293
B2	0.1025	0.6032	0.2565	0.0378
B3	0.3608	0.2730	0.2884	0.0777
B'	0.2768	0.3089	0.2826	0.1317

(1)Analysis of afflicted rural inhabitants' satisfaction evaluation

Afflicted rural inhabitants are adequately satisfied with the overall evaluation factors of implementation effects of credit policy（B1=0.6034）, with its weight influence factors sequencing x4>x3>x1>x2; According to the frequency statistics of evaluation matrix, the sequence of factors that afflicted rural inhabitants that are very satisfied with is x3>x1>x2>x4; the sequence of factors that they are extremely not satisfied with is x4>x1>x2=x4. It can be seen that afflicted rural inhabitants are adequately satisfied with the overall implementation effects of credit policy, and that the result of income raise, which they concern most, failed to meet their expectation of credit policy on post-disaster reconstruction.

(2)Analysis of afflicted urban inhabitants' satisfaction evaluation

Afflicted urban inhabitants are adequately satisfied with the overall evaluation factors of implementation effects of credit policy（B2=0.6032）, with its weight influence factors sequencing y2>y3>y1>y4;According to the frequency statistics of evaluation matrix, the sequence of factors that afflicted urban inhabitants that are very satisfied with is y4>y1>y2>y3; the sequence of factors that they are extremely not satisfied with is y3>y1=y2>y4. Judging from frequency statistics of the survey results, the proportion of evaluation factors that afflicted urban inhabitants rated "very satisfied" is low, and the score of every evaluation factor on the "very satisfied" scale is less than 0.2. Less than 10% of afflicted urban inhabitants are very satisfied with maximum credit limit and credit period, while around 30% are not very satisfied.

(3)Analysis of afflicted enterprises' satisfaction evaluation

Afflicted enterprises are very satisfied with the overall evaluation factors of implementation effects of credit policy（B3=0.3608）, with its weight influence factors sequencing z2>z3>z1>z4; according to the frequency statistics of evaluation matrix, the sequence of factors that afflicted enterprises that are very satisfied with is z3>z4>z2>z1; The sequence of factors that they are extremely not satisfied with is z4>z2>z1=z3; The main reason behind it is that though the policy did not last long, it greatly alleviated repayment pressure of afflicted enterprises, transferring their risks to financial organizations. But in the meantime, it means that the policy poses a challenge to sustainable development of financial organizations and increases the pressure of exposing the financial organizations to bad loans.

(4)Target groups' satisfaction evaluation of credit policy on post-Wenchuan Earthquake reconstruction

Target groups are adequately satisfied with credit policy on post-Wenchuan Earthquake reconstruction (after normalization B'=0.3089).The overall satisfaction evaluation integrates afflicted rural and urban inhabitants' and enterprises' satisfaction evaluation. Enterprises are most satisfied with overall policy framework, afflicted rural inhabitants are not satisfied with it, and afflicted urban inhabitants are least satisfied with it.

4 Conclusions

Here we may draw the following conclusions:

(1)In general, Target groups are adequately satisfied with credit policy on post-Wenchuan Earthquake reconstruction (B'=0.3089), the implementation of the credit policy effect is positive.

(2)In terms of the target groups' importance, enterprises accounted for the largest in the three groups (W = 0.446), and largely affected the final result. Hence, there is a necessity to strengthen the credit policy support to enterprises.

(3)In terms of the target groups' satisfaction, rural inhabitants and urban inhabitants are most satisfied with credit policy, the AS>0.5. By contrast, enterprises satisfaction with credit policy is low, and its VS and AS are both less than 0.5. In line with(2), the credit policy still need to focus on enterprises.

5 Suggestions on the Perfection of Credit Policy on Post-disaster Reconstruction

According to the target groups' satisfaction survey, the credit policy on post-Wenchuan Earthquake reconstruction has been recognized by target groups. Judging from the recovery and development level of regional economy and social enthusiasm, the policy has basically achieved its goals. Meanwhile, to form effective governmental coping experience of economic policy under emergencies, there is room for improvement. Firstly, in the process of policy formulation, adhere to the commercial banks' principle of safety, fluidity and profitability, government should play an dominant role, give priority to actual demand and interest of financial organizations and individuals and shorten the time-lag of fund demand in afflicted areas. Secondly, financial support system of post-disaster reconstruction should be further improved, the role that policy finance plays should be reinforced, domestic demand should be reasonably regulated and controlled, economic growth should be steadied and development of regional economy should be stimulated and the skills of afflicted inhabitants to recover production should be elevated. Thirdly, the building of catastrophe insurance system should be strengthened, and ability of financial organizations to cope with catastrophes should be improved to alleviate the burden of shouldering catastrophic risks.

Acknowledgment

This research was supported by the yearly project of 2011 "Study on Policy Assessment of Finance and Taxation and Financial Policy in Post-Wenchuan Earthquake reconstruction" (Project No.SC11C036), one of the Twelfth Five-year Programs of philosophy and social science in Sichuan Province.

Connection-Consider Decision-Making Model of Emergency Rescue Scheduling under an Earthquake

Benmin Liu; Du Chigan; and Lingzong Kong

Key Laboratory of Road and Traffic Engineering, Ministry of Education, Tongji University, 4800 Cao'an Rd., Shanghai 201804. E-mail: chigandu@163.com

Abstract: After the earthquake, road transport lifelines were seriously damaged, for this situation, this paper presents the concept of emergency rescue scheduling decision under earthquake, which is, when the road traffic is interrupted, other modes of transport connections will replace to ensure the fluency of traffic lifelines. Based on the theory of traffic ergonomics, timeliness, security and economy, the three properties of emergency rescue connection, were nondimensionalized and polymerized by weight. Using the multi-attribute decision-make theory, established the utility function model, Finally, verified the model through concrete examples.
Keywords: Traffic engineering; Earthquake disaster; Emergency rescue; Connections.

1 Introduction

Natural disasters occurred frequently in China, especially earthquakes, brought huge losses to economy and society. To reduce the loss caused by disasters, the state departments developed appropriate emergency response plans for different disasters. Transportation program of emergency relief supplies plays an important role in the rescue work, in which the scheduling of transport vehicle is the key. During earthquake, the road transport lifelines, including roads, bridges and tunnels, are easily damaged, for the security and quick transportation of people and supplies, the lifeline need to be connected by air, water or rail.

2 Description of the Model

Emergency transportation decision-making model refers to a decision-making model for decision-makers alternative which within the scope of an integrated transport network, depending on the level of emergency needs, give the appropriate connections program based on different security, economy and timeliness. The model includes not only the choice of transport routes, more important is to choose the modes of connection, the existing connections to a road-main emergency lifeline are: highway - aviation - highway; highway -waterway - highway; highway - railway - highway. The process of integrated transport connections can be expressed by Figure 1.

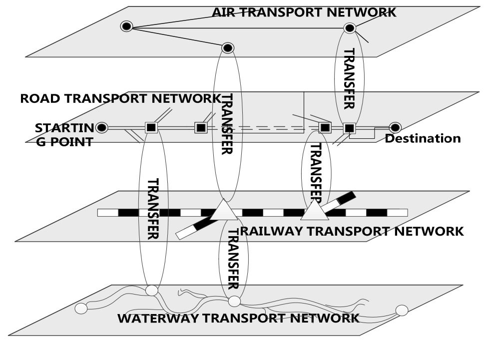

Figure 1. Process of integrated transport connection

2.1 Process analysis

From the factors and nature of the transport scheduling decision in emergency situations, it can be seen that the choice of emergency connection modes, can be seen as a multicriteria decision problem. Its decision-making goal is to select the transport route which make three attribute vectors (timeliness, security and economy) achieve the ideal value (maximum or minimum). The key to solve this problem is to construct the utility functions of attribute components (FU Jialiang, 2006). According to the multi-attribute decision theory, the properties of each attribute component of the alternative routes should be nondimensionalized firstly, and then determine the weight of each attribute, and then each component is polymerized by the decision utility function. Finally select the maximum expected utility value as a recommended decision program.

2.2 Parameter analysis

Based on the points of chapter 2.1 , transportation scheduling decision of emergency rescue needs considering timeliness, security and economy. We can construct the following network diagram (Xu Peiwen, 2011):

$$B = \begin{cases} E = \{0,1,2,\dots,k\} \\ F = \{(a,b)|a,b = 0,1,2,\cdots,k, a \neq b\} \\ G = \{(m,n)|m = 1,2,3; n = 1,2,\cdots,s\} \\ H = \{h_{ab}(a,b)|a,b = 0,1,2,\cdots,k, a \neq b\} \end{cases}$$

E and F are the sets of nodes and lines that vehicles may go through during the process of transportation, a and b are any two nodes of set E, showing the two ends of a line; G is a set of modes and frequency of connections, $m = 1,2,3$ respectively represents air, waterway and railway connection. n represents the frequency of each connection modes from starting points to the destination; H is the set of road rights, represents the weights of (a, b), indicating its importance of particular attributes (or a comprehensive attribute) in decision-making; Q is the set of connection rights, indicating the weights of connection mode in a connection. Such multicriteria decision problem can be solved with the linear assignment.

The objective function is constructed as follows:

$$\min\left[\sum_{a=1}^{k}\sum_{b=1}^{k}x_{ab}+\sum_{m=1}^{3}\sum_{n=1}^{s}y_{mn}q_{mn}\right],$$

$$\text{when:}\begin{cases} x_{ab}=\begin{cases}1, & When\ the\ vehicle\ through\ line(a,b);\\ 0, & when\ the\ vehicle\ does\ not\ through\ line(a,b).\end{cases}\\ y_{ab}=\begin{cases}1, & When\ \ mode\ m\ is\ used;\\ 0, & When\ \ mode\ m\ is\ not\ used.\end{cases}\end{cases}$$

$h_{ab} = M$, $q_{mn} = N$, M and N are sufficiently large integers; k is the total number of nodes in the road network, s is the number of connections in the process of comprehensive transportation.

The objective function satisfies the following constraints:

$$\begin{cases}\sum_{a=0}^{k}x_{ab}=1, b=0,1,2,\cdots,k;\\ \sum_{b=0}^{k}x_{ab}=1, a=0,1,2,\cdots,k;\\ \sum_{m=1}^{3}y_{mn}=1, n=0,1,2,\cdots,s;\\ \sum_{m=1}^{3}\sum_{n=0}^{s}y_{mn}=s,\\ X=(x_{ab})\in S.\end{cases}$$

According to the above mathematical model, we can obtain three components of the objective function:

（1）Timeliness

Time calculation obey the addition rule, we can set T as the total time from the starting point to demanding point of any transport route. T_{ab} is the travel time for vehicles in the line (a, b), t_{mn} is the travel time of connection NO. n using mode m, the objective function of time component is:

$$\min T=\min\left[\sum_{a=1}^{k}\sum_{b=1}^{k}T_{ab}x_{ab}+\sum_{m=1}^{3}\sum_{n=1}^{s}y_{mn}t_{mn}\right]$$

（2）Security

The security attributes of transport scheduling scheme is generally represented by the probability of security pass, its operations obey the multiplication rule, in order to ensure its consistency with the transport distance algorithm (timeliness property has the consistency), Need to do Mathematical transformation for the probability of security pass, so that the resulting index can obey the addition rule, logarithmic way just meet this requirement (Li Mao, 2008).

Suppose P is the total security pass probability of transportation routes from the start point to the demand point, P_{ab} is the security pass probability of line (a, b), P_{mn} is the security pass probability of connection (m, n). In the alternative route u_{st}, P_i is the security pass probability of the line No. i, P_j is the security pass probability of the No. j connection point. Entire transportation route consists of m lines and n connection points. The security pass probability of route u_{st} is:

$$P(u_{st}) = \prod_{i=1}^{k} P_i \cdot \prod_{j=1}^{s} P_j$$

To ensure its additivity and non-negative . Both sides multiplied by "-1" after taking logarithm:

$$-\log P(u_{st}) = -\sum_{i=1}^{k} \log P_i - \sum_{j=1}^{s} \log P_j \qquad 0 < P_i, P_j \le 1$$

So the objective function based on security attribute is:

$$\max P = \min\left[\sum_{a=1}^{k}\sum_{b=1}^{k} x_{ab}(-\log P_{ab}) + \sum_{m=1}^{3}\sum_{n=1}^{s} y_{mn}(-\log P_{mn})\right]$$

（3）Economy

Suppose E is the total economic consumption of route from the starting point to demand point, E_{ab} is the economic consumption of line (a, b), e_{mn} is the economic consumption of connection (m, n), Economic attribute similar to the time attribute, they obey the addition rule.

Similarly, the objective function based on economic attribute is:

$$\min E = \min\left[\sum_{a=1}^{k}\sum_{b=1}^{k} E_{ab}x_{ab} + \sum_{m=1}^{3}\sum_{n=1}^{s} y_{mn}e_{mn}\right]$$

2 Establishment of the Model

According to the multi-attribute decision theory, Because of the relative independence among timeliness, security and economy of the relief supplies transportation after the earthquake disaster, the utility function of multi-attribute model can be expressed as the sum of each single-attribute utility in a unified dimension. According to the previous results of the parametric analysis, Each property has maintained consistency in the form of transport distance algorithm, so, Dimensionless Processing for The resulting utility function of each attribute is just need, the sum of Dimensionless index can be easily attained (Wang Qiang, 2013).

Assume that T_{min} and T_{max} are the minimum and maximum transit time, P_{min} and P_{max} are the minimum and maximum security pass probability, E_{min} and E_{max} are the minimum and maximum transit economic cost.

Assume that the set of the transportation scheduling schemes from starting point to demand point is:

$$M = \{i | i = (a, b, m, n), a, b = 0,1,2, \cdots, k, m = 1,2,3, n = 0,1,2, \cdots, s\}$$

g_i is the dimensionless index of total transport time of option NO. i, T_i is the total transport time of option NO. i, T_{max} and T_{min} are the maximum and minimum transit time of all the options. According to the dimensionless principle (Yu Wuyang, 2013), it can be Obtained:

$$g_i = \frac{T_{max} - T_i}{T_{max} - T_{min}}, \quad T_{min} \leq T_i \leq T_{max}, \ i \in M$$

Assume that h_i is the dimensionless index of transportation security of option NO. i, P_i is the safe pass probability of option NO. i, P_{max} and P_{min} are the maximum and minimum safe pass probability of all the options. To ensure the consistency of each property component indicator, we hope that h_i will increase with the increasing of safe pass probability, According to the dimensionless principle, it can be obtained:

$$h_i = 1 - \frac{P_{max} - P_i}{P_{max} - P_{min}}, \qquad i \in M$$

Assume that k_i is the dimensionless index of transportation economy of option NO. i, E_i is the economic cost of option NO. i, E_{max} and E_{min} are the maximum and minimum economic cost of all the options. According to the dimensionless principle, it can be obtained:

$$k_i = \frac{E_{max} - E_i}{E_{max} - E_{min}}, \qquad i \in M$$

Assume that the weight of timeliness, economic and security the dispatchers give is (Vaidya, 2006):

$$\lambda = (\lambda_1, \lambda_2, \lambda_3)^T, \qquad \begin{cases} 0 \le \lambda_1 \le 1 \\ 0 \le \lambda_2 \le 1 \\ 0 \le \lambda_3 \le 1 \\ \lambda_1 + \lambda_2 + \lambda_3 = 1 \end{cases}$$

Based on the above analysis, the utility function model of transportation scheduling scheme under emergency conditions is:

$$G_i = \frac{\lambda_1(T_{max} - T_i)}{T_{max} - T_{min}} + \lambda_2\left(1 - \frac{P_{max} - P_i}{P_{max} - P_{min}}\right) + \frac{\lambda_3(E_{max} - E_i)}{E_{max} - E_{min}}, G_i \in [0,1]$$

In the formula, G_i is the decision utility index of NO. i alternative transportation scheduling scheme. Larger G_i indicates better comprehensive evaluation result of transportation scheduling scheme, so, we choose the transportation scheduling scheme which have the maximum G_i as the final decision result.

3 Analysis of Example

3.1 Introduction

March 10, 2011, a 5.8 level earthquake occurred in Yingjiang in Yunnan. The earthquake caused damage to roads and bridges in varying degrees, But the earthquake did not cause traffic disruption，the major trunk roads leading to Yingjiang can meet the basic requirements for access. Rescue vehicles arriving Yingjiang are mainly from Baoshan, so the purpose of this example is to find the optimal path from Baoshan to Yingjiang. The surrounding road network of Yingjiang is schematically shown in Figure 2, the path Information is shown in Table 1.

Table 1. The basic information of section

Routes	Safe pass probability	Lines	Connection points	Length （km）	Speed （km/h）
A—B—C	0.9 0.7	G56—S317	— —	23 57	60 40
A—D—C	0.9 0.8	G320—S317	— —	50 52	60 40
A—E	0.9	G320	waterway	181	60
C—F	0.6	S233	aviation	83	40
E—F	0.7	S233	—	100	40

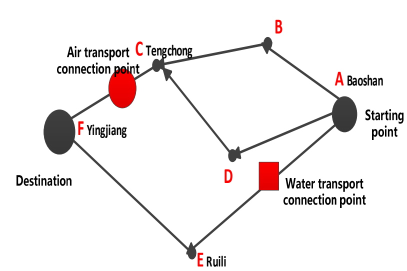

Figure 2. Network diagram

3.2 Discussion of optimal connections program

(1) Decision parameters

Follow the route segment of Table 1, determine the Decision Parameters as Table 2 (Zhang Yi, 2008).

(2) Weights

Calculate the weight of the three indicators by the analytic hierarchy process, Assume in the three factors of security, timeliness and economy, timeliness is slightly more important than security, security is Significantly more important than economy, timeliness is strongly important than economy, we can list the judgment matrix as Table 3 (Zhou Ping, 2010).

Table 2. Decision parameters

Routes	Timeliness	Security	Economy
A—B	12.7	35.6	9.2
B—C	40.1	53.5	22.8
A—D	27.6	35.6	20.0
D—C	36.6	41.0	20.8
A—E	100.0	35.6	72.4
C—F	58.4	100.0	33.2
E—F	70.3	67.9	40.0
Waterway connection	13.9	100.0	200.0
Aviation connection	111.2	35.6	9.0

Table 3. Judgment matrix

Index	Security	Timeliness	Economy
Security	1	2/3	6
Timeliness	3/2	1	9
Economy	1/6	1/9	1

Through consistency test, its matrix consistency ratio $CR=8.28\times10^{-3}<0.1$, the inconsistency of the matrix within the allowable range. The weight vector of Each attribute can be obtained under the above conditions prevailing emergency as follow:

$$(\lambda_1, \lambda_2, \lambda_3) = (0.375, 0.562, 0.063)$$

According to Figure 2, there are three possible transportation scheduling schemes: $A-B-C-F, A-D-C-F, A-E-F$ the attribute index and utility function value of each scheme can be listed as Table 4 (Shen Zhiyun, 2011):

Table 4. Calculation of decision effect

Scheduling scheme	Standardized time	Standardized security index	Standardized economic index	Decision effect index
A-B-C-F	1.000	1.000	0.058	0.941

A-D-C-F	0.927	0.917	0.000	0.863
A-E-F	0.000	0.000	1.000	0.063

It can be concluded that under the assumption of emergency traffic conditions, scheme $A-B-C-F$ can get a larger effect index, should be recommended as an emergency transport scheduling scheme under this kind of situation.

4 Conclusions

Analyzed the differences of transportation scheduling decisions goals between emergency and general situations through the three properties of timeliness, security and economy, pointed out that the issue of transport scheduling decisions under emergency conditions essentially is multicriteria decision problem， firstly nondimensionalized each attribute components, then obtained the decision utility function by polymerizing the attribute components with the weighting method, the multicriteria decision problem changed into a single one, Successfully established a mathematical model, chose the scheme has the highest expected utility as the decision-making program. Finally, verified the model with an example, the results are close to the actual, proved its applicability. This model can also be used in the general transport scheduling decisions. The further study will be expanding the scope of the model.

Abstract: In consideration of the insecurity and high energy consumption of motorcycle, over 200 Chinese cities have implemented motorcycle forbidden policy since 1985. Taking Changzhou as an example, this paper firstly summarizes the policy implemented in Changzhou, and then analyzes the impaction upon motorcycles, including the deceleration of motorcycle ownership, change of usage and improvement of safety. Changzhou's experience shows that the ban has obvious effect on reducing the ownership and usage of motorcycle. But there is still strong demand for motorcycle in the suburb area. The ban policy should be strengthened progressively and varied in different zones rather than one-style-fits-all or one-step-fits-all.
Keywords: Motorcycle; Forbidden policy.

1 Introduction

Motorcycle, as a convenient and efficient individual traffic, used to play an important role in urban traffic system. (Zhao, 2007) At the end of twentieth century, the development of motorcycle reached the peak point and it was common that over 20% of all trips were motorcycles'. But the rapid growth stood out the weakness of motorcycle like insecurity, high energy consumption and air pollution. (Wang, 2003, Xu, 2005 and Zhao, 2005) In view of this, over 200 Chinese cities have implemented motorcycle forbidden policy since the first motorcycle ban in Beijing in 1985. (Deng, 2009, Huang, 2005 and Lin, 2007)

Changzhou implemented motorcycle forbidden policy in 2005. Taking it as an example, this paper summarizes the motorcycles' characteristics before and after the ban, including the deceleration of motorcycle ownership, the change of usage characteristic and the improvement of safety. Finally, the applicable countermeasures are put to solve the problems existed in the period of the traffic mode transferring.

2 Motorcycle Forbidden Policy in Changzhou

2.1 Background

Changzhou is a city in Jangsu Province in China with an area of 4385 km^2. There are totally 4.65 million people in 2012. The whole city can be divided into the central part and the suburb area. The central part of the city is 616.12 km^2 with a population of 1.75 million.

Before the implement of the motorcycle forbidden policy in 2004, there were over 140,000 motorcycles in Changzhou, accounting for 68.6% of the total motor vehicles. Every 6.5 person owned a motorcycle calculated on the urban resident population of 920,000. There were more than 250,000 vehicle-times per day at that time. The excess motorcycles brought a series of problems like chaotic traffic order, air pollution, traffic accidents and motorcycle robbery.

Chaotic Traffic Order. In 2005, there were averagely 2800 motorcycles entering intersection in peak hour. If converted into equivalent car, the motorcycle flow will account for more than 30% of the whole traffic volume. What's worse, the motorcycle illegal rate up to 40% on average in central part of the city.

Air Pollution. In 2003, motorcycles totally discharged 78.5% carbon monoxide, 60.2% nitrogen oxide and 74.7% Non-methane hydrocarbon of all urban vehicle emissions. The concentration of Carbon monoxide was seven times as the national standard.

Traffic Accidents. From 2002 to 2004, the traffic accidents caused by motorcycles were 1183, 5089 and 12495 respectively, which were 9.9%, 24.6% and 46.8% of all vehicle accidents. What's worse, over 300 people died in the motorcycles' accidents.

Motorcycle Robbery. There were totally 879 motorcycle robberies in 2004 which were a threat for residents' properties as well as psychological insecurity.

2.2 Evolution of the motorcycle forbidden policy

Faced with the problems, Changzhou issued a document called "Suggestion on Motorcycle Limited Development in Changzhou" to restrict motorcycle development on October 15, 2005. Since then, the authority stopped motorcycle registration in the central part of city.

The ban policy has experienced three times adjustment on enlarging the limited scope and extending the limited time. Before 2005, there was no limitation on motorcycle travel. Since October 15, 2005, all kinds of motorcycle traffic were banned in a heart area (3.32 km^2) of the downtown from 8:30 to 17:00. Since January 15, 2007, the limited scope expanded from the original 3.32 km^2 to 34.58 km^2. On March 20, 2008, the local authority extended the limit time from 8:30-17:00 to 8:00-18:30, meanwhile some of the street in the core area banned on motorcycle traffic throughout the day.

In aspect of supporting facilities, Changzhou worked mainly for three aspects: one was the installation of 284 road signs on the 127 entrance around the limited area; Secondly, construct 57 motorcycle parking lot around the limited area; thirdly, set up a motorcycle trading market and three motorcycle scrap points to ensure the scrap of transfer of the motorcycle. In 2008, the local authority set 114 more traffic signs and adjusted 152 original signs to ensure the completeness of the indicators.

3 Impaction upon Motorcycles

3.1 Motorcycle ownership

(1) Ownership of motorcycles

The ownership of motorcycle in central part fell steeply since the forbidden policy adopted in 2005. The ownership of motorcycle in 2006 decreased by 53.5 thousands (34.5%) compared with 2005. In 2013, the motorcycle ownership is only 28.2 thousands, which is about 1/6 of that in 2005. 64.7% of all vehicles are motorcycles in 2005, while it is only 11.6% in 2013. (Figure 1) According to the forecasting of the authority, motorcycles will completely disappear in 2018 in central part of the city.

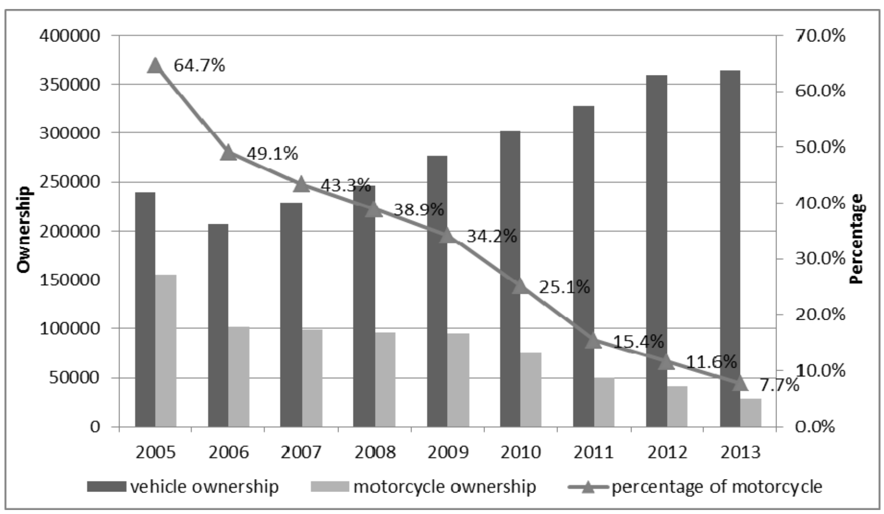

Figure 1. Development of Motorcycle and Vehicle

(2) Regional difference

Although the motorcycle ownership has declined, but in suburb area motorcycle is still a very important means of transportation.

In 2005, 78.3% of all vehicles are motorcycle in suburb area. From 2005 to 2013, the motorcycle ownership of suburb area dropped from 350 thousands to 241 thousands. But the percentage of motorcycle is still 39.2%. In some district like Jintan County, motorcycles still occupied more than half of the whole motor vehicles in 2013. It can be seen that motorcycle is still an important traffic tool in suburb area.

3.2 Usage of motorcycles

(1) Mode share

Motorcycles were once the most important transportation mode in Changzhou. According to the residents' trip survey in 2004, the motorcycle trip proportion accounted for 26.2% of all modes, ranking secondary to the bike. The data showed that motorcycle used to be the initial motorized mode. The proportion of private cars and public transportation was only 4.72% and 8.39% respectively at that time.

Since the ban, motorcycle share rate has dropped rapidly. From 2001 to 2009, it dropped from 27.9% to 14.5%. (Figure 2) What' more, motorcycle trips occurred mainly in suburbs where motorcycles were not limited. According to an investigation in 9 intersections in the central part of Changzhou, motorcycle traffic accounted for only 0.4% of the total flow in 2013.

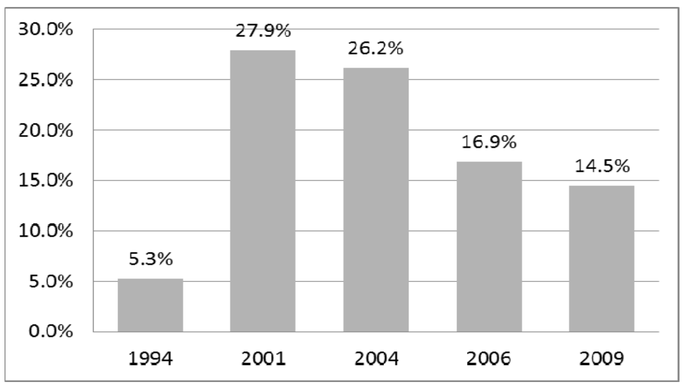

Figure 2. Mode Share Rate of Motorcycle

(2) Travel purpose

Motorcycle used to be the main commuter traffic tool. In 2004, 45% of total motorcycle travel purposes were "go home" and 36% were "go to work". While the travel purpose like sports, shopping, visiting friends or other recreational elastic trips were rarely. However, after the extension of the ban time for 8:00-18:30 in 2008, rigid demands like "go to work" cannot be satisfied by motorcycle. Thus the demand of motorcycle was switching to other traffic tools.

3.3 Improvement of motorcycle safety situation

A large number of traffic accidents were caused by motorcycle before the ban. In 2004, most of motorcycles in Changzhou were straddle motorcycles or mid-range motorcycles. The poor stability and bad braking performance make the rider unsafe. What's worse, the safety awareness of motorcycle drivers was poor, illegal drive behaviors like driving without a helmet or without a license are common.

These reasons led to a growing number of motorcycle accidents. From 2002 to 2004 motorcycle accidents rose from 1183 to 12495 and the proportion of motorcycle accidents grew from 10% to 47%. What's worse, the numbers of deaths grew from 45 to 170. The annually growth rate was 108%. (Figure 3) 6138 persons were injured in motorcycle accidents in 2004 as well.

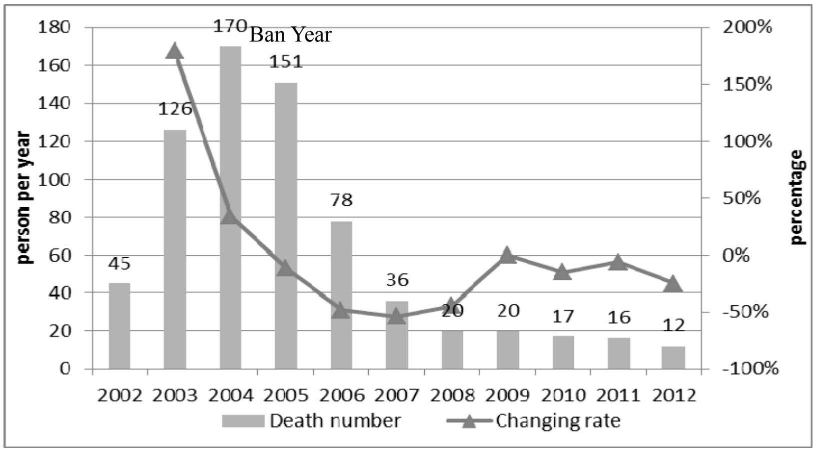

Figure 3. Death Number Change of Motorcycle Accidents (2002-2012)

After the ban, the number of deaths caused by motorcycle accidents reduced year by year. It dropped from 78 in 2006 to 12 in 2012. (Figure 3) From 2004 to 2013, the proportion of deaths caused by motorcycle accidents has fallen from 40.96% to 20% according to the local traffic department. Most of the motorcycle accidents happened in the suburbs like Wujin district.

3.4 Transformation to electric bicycle

Electric bicycle is quite similar with motorcycle in convenient and efficient. But electric bicycle don't need driving license and much cheaper than motorcycle. After the motorcycle ban, electric bicycle developed rapidly. In 2013, the electric bicycle ownership was as high as 1.39 million. (Table 1) What's more, the electric bicycle mainly developed in the central part. It has become the main traffic mode for the dwellers.

Table 1. Development of Electric Bicycle in Changzhou(2011-2013)

Zone	Ownership （2011）	Ownership （2012）	Growth rate compared with 2011	Ownership （2013）	Growth rate compared with 2012
All zone	1143377	1313433	14.9%	1395562	6.3%
central part	631110	753171	19.3%	819711	8.8%
Wujin district	351976	391455	11.2%	402838	2.9%
Liyang county	97666	106182	8.7%	110388	4.0%

Electric bicycles has replaced motorcycle and become the main body of traffic accident. In the first quarter of 2013, accidents involved with electric bicycle accounted for 48.7% of all. What's worse, 30% of the death accidents are involved with it. Abundant overweight and overspeed electric bicycle is one reason. Electric bicycle riders don't need professional training or driving licenses. The lack of driving skill and safety consciousness are more significant.

4 Conclusions

The motorcycle forbidden policy in Changzhou achieved the predicted result. The ownership, mode share rate and motorcycle accidents are all dropping rapidly since the ban. In 2013, there are only 28,151 motorcycles left in the central part. Meanwhile the death number caused by motorcycle accidents is less than one-tenth of before.

But it should be noticed that there is still strong demand for motorcycle in suburb area. The motorcycle percentage of all kind motor vehicles is still nearly 40% in 2013. Meanwhile the suppressed demand will transfer to the other modes like electric bicycles. If not handled properly, the motorcycle forbidden policy will just transfer problems from one to another.

Changzhou's experience shows that the ban policy should be different in different zone and limited level should be strengthened step by step rather than one-style-fits-all or one-step-fits-all. Meanwhile the assorted measures should be implemented ahead to lead the motorcycle demand to a sustainable way.

Abstract: As for some Chinese cities as Chengdu which is mostly flat, electric bicycles take the place of manual bicycles to become the first choice of middle and short distance transport for lower-and-middle income groups due to their low cost, higher speed and carrying capacity. But more and more traffic problems resulted from a large magnitude of electric bicycles appeal to universal attention. Aimed at the absence of practical survey and research on electric bicycle traffic, this paper carried out practical traffic survey on electric bicycles in Chengdu, presents statistical analysis on the structure scale, traffic volume, violations and proportions, especially on the speed distribution. According to traffic practices of electric bicycles in Chengdu, this paper affirms their main body position, proposes type selection diversification, coordination with urban transit, standardization and strict management, and humanization in traffic organization. And eight strategies and five kinds of facility designs are pointed out.
Keywords: Non-motorized vehicle transport; Electric bicycles; Traffic characteristics; Application management.

1 Introduction

Urban development requires a multilayer transport network with reasonable structure. Biking trips are favored by lower and middle income groups as a cheap, green and fast alternative for trips up to a distance of some 3.5 km. Applied as the transfer mode for mainline trips of urban transit, bicycles are also considered as an essential mode of urban traffic system.

Just as electric vehicles in comparison with the traditional fuel motors, electric bicycles not only inherit such advantages as green, cheap and healthy of manual bicycles, but also add the new functions of fast, high bearing and transporting capacity similar to automobiles. That makes electric bicycles develop rapidly, especially in the plain districts suitable to their driving properties. And electric biking trips have become a primary travel type for the citizens in Chengdu, Sichuan Province. The total amount of electric bicycles in this area reached 5 million (Li Xin, 2013), accounting for more than 90% of the total amount of non-motorized vehicles. The traditional manual bicycle proportion is decreasing year by year, urban trip structure has changed greatly.

New traffic structure has led to the urban transport in Chengdu city highlights a series of sharp contradictions. There are frequent electric bicycle traffic violations, speeding, ignoring red lights, illegal carrying things and taking more riders, and so on. Many motor vehicle accidents are caused by electric bicycle violations. At intersections, their competing to go through, occupying the space of motor traffic and riding on the motor carriageway have become the causation of the decreasing capacity and growing congestion of urban road network. These problems result from both the lack of awareness of civilized traffic behavior, and the vehicular and traffic characters that different from manual bicycles' characters. Are electric bicycles the "trouble-maker" or the key factor of urban traffic system? Should the total amount of electric bicycles be controlled? Or should electric biking traffic be lead in cooperation with other urban transport types? It is necessary to study the traffic characteristics of electric bicycles deeply in order to orient electric bicycles correctly and optimize their application and management.

2 Review of current applications and researches

The studies on the traffic characteristics of electric bicycle are relatively less, especially little attention has been paid to such a topic abroad where there is a lower non-motorized proportion. The existing literature and data emphasize mostly on the design and improvement of the vehicle structures and overall management tactics. Some strong correlation results include: Ma Guozhong et al. pointed out that the design speed and weight of electric bicycles are the main factors to influence the traffic safety (Ma Guozhong et al., 2006). Zhu Wenting et al. discussed the relationship among traffic accident, speed and load, deduced different safe braking distances under the road, speed and load conditions respectively (Zhu Wenting et al., 2011). Zhou Wenhua et al. analyzed the influence of electric bicycles to urban traffic structure in China (Zhou Wenhua et al., 2005). Chen Yanyan et al. researched the development of electric bicycles in Beijing from safety, environment, urban transport strategy and so on (Chen Yanyan et al., 2002). Ye Xiaofe et al. obtained that the conversion coefficient of electric bicycle relative to manual bicycle is 1.2295 based on the data of traffic survey in Nanjing City (Ye Xiaofei et al., 2012).

Altogether, the present researches fall short in the group behaviors, macro and micro characters descriptions under practical traffic environment. And domestic management regulations of electric bicycles are formulated mostly from the perspective of administrators or by means of artificial experiences, there is a urgent need of research on practical traffic operation of electric bicycles.

3 Traffic survey on electric bicycles

3.1 Operation overview

This survey focused on where are No.3 ring road and the sections of radial main road. In consideration of the road network structure in Chengdu City, with the land layout and development, population distribution and economic development and so on, 16 intersections, 32 sections of urban roads and 4 roads out of the city were selected as the survey spots. The investigations included traffic volume, speed, violation behavior and infrastructure, and the works started at the end of October and finished at the beginning of November in 2012. The investigating time ranged over morning and evening rush hours.

3.2 Data analysis

By statistical analysis on the practical investigating data (Chengdu Transportation Committee and Southwest Jiaotong University, 2013), some results can be found. For example, the electric bicycle traffic accounted for above 70% of non-motorized traffic. The proportion of electric bicycles to non-motorized vehicles on over 88.2% survey spots is over 75% and on over 50% spots is over 80%. So it indicates that electric bicycles have been replacing manual bicycles as the main transporting types of personal traffic in short distances in Chengdu.

Electric bicycles in Chengdu tend to light motorization corresponding with their taking dominant position increasingly. Due to higher speed, greater mass, large number and good mobility of electric bicycles, the traffic accidents related to them appear the characteristics of higher accident prone and severity. The common violation behaviors take many forms as speeding, carrying people and cargo together, competing to occupy motorway, riding on the wrong side of the road, running the red light or across the stop line at intersections. Through sampling observation of sections, it could be found that some riding on the wrong side of the road are resulted from the absence of convenient crossing facilities. For example, the crossing road is too far, overpass or underpass are planned and designed irrationally that is unable to meet the demand of the electric bicycle crossing the street. From the data on the 16 intersections and their 32 approaches, it also can be seen that running the red light or across the stop line at intersections accounted for 40.8% of the total traffic violations and 10% of total traffic volume, resulting in more serious safety problems. Electric bicycles often compete with motor vehicles for traffic time and space. There exist serious conflicts and interferences of the electric bicycles and motor vehicles at large intersections. At some bus stations, the non-motorized vehicle lanes are occupied by the platforms. Not only the lane width is cut down but the normal electric bicycle riding also disturbed seriously by the passengers waiting at the stations. That results in the poor continuity of non-motorized traffic.

The average speed of motor vehicles on the main roads downtown in Chengdu is 18 km/h. But the running speeds of electric bicycles are generally above 15 km/h, around 17-20 km/h far more than the average speed of about 10 km/h of manual bicycles. The practical running speed of electric bicycles has been in close to that of motor vehicles. In other words, the motor vehicles have not any advantages compared to the electric bicycles from the perspective of speed during rush hours. For example, the electric bicycle speeds and corresponding frequencies on Xihua Avenue are shown as Figure 1.

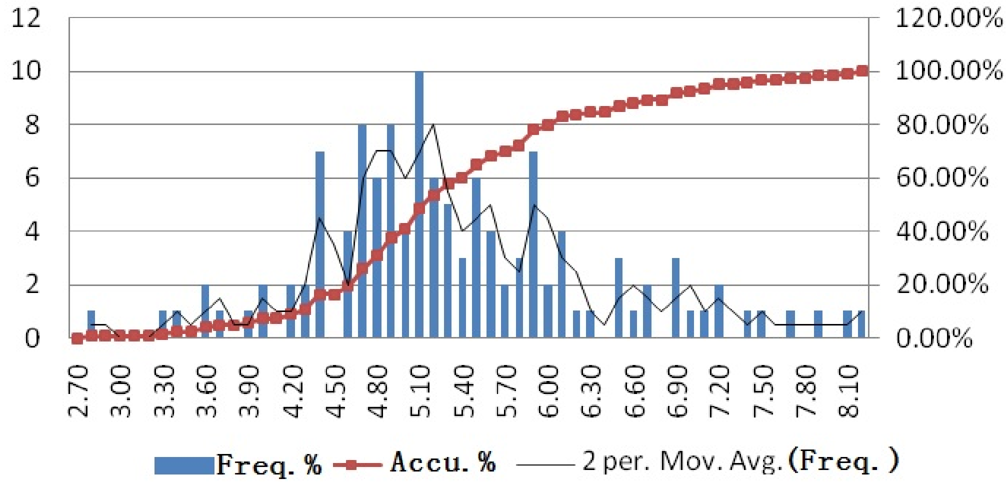

Figure 1. The speed –frequency distribution of electric bicycles

Figure 1 indicates that even in the traffic peak period the electric bicycles still maintained a high speed, about 70% of electric bicycles ran at the speed from 15 km/h to 23 km/h, over 70% of electric bicycles ran at more than 20 km/h, far exceeding the upper bound of 15 km/h regulated by the *Chengdu Non-motorized Vehicle Management Rules* (CNVMR).

4 Development orientation and mode

According to the traffic characteristics of electric bicycles, as well as their advantages and disadvantages in the practical operation of Chengdu, the development orientation in Chengdu should be positioned as main body of non-motorized vehicles ownership, type diversity, coordination with urban transit, standardization and strict management, and humanization in traffic organization. By extension some instructions could be obtained as below.

(1) Electric bicycle is the direction of development of non-motorized travel.

(2) Electric bicycle should be promoted to develop orderly as the structural element of the comprehensive transportation system by scientific guide.

(3) More strict regulations and implementations.

(4) To enhance the level of traffic service facilities for electric bicycles.

For electric bicycle travel, the transfer mode of “electric bicycle + public transport” should be implemented, and B+R (Biking & Riding) transfer system should also be established.

This is a green development mode consistent with the actual traffic in Chengdu. On the one hand, the normal "manual bicycle mode" in transferring has been converted into the "parallel mode of electric and manual bicycles" from such aspects as policies, going and parking facilities, improving electric bicycle travel conditions. On the other hand, the speeding and other violations of electric bicycles have been controlling strictly and the electric bicycles exceeding national standard have been reduced and will be eliminated, promoting electric bicycle transport into effective and sustainable development.

5 Application management

Electric bicycle transport problems couldn't be simply attributed to the product or industry itself. The causes include riders, vehicles and facilities. But the main problem is management. With further popularization of electric bicycles, higher and higher traffic pressure will be induced, forming a series of challenges on road traffic management. It is necessary to present systematic countermeasures to solve new traffic problems due to electric bicycles.

5.1 Basic strategies

In general, there are eight aspects of contents:

(1)To implement the registration mechanism of electric bicycle;

(2) To implement the qualified products list management for electric bicycles;

(3) To strengthen the enforcement of relative laws and regulations on the traffic violations of electric bicycles;

(4) To establish the waste battery recycling system for electric bicycles;

(5) To strengthen the supervision and management of the electric bicycle production and sales from source;

(6) To make a clear distinction among the relevant management department responsibility, improve the efficiency of management;

(7) To improve relevant laws and regulations

(8) To improve the supporting facilities in order to ensure the effect of measures.

5.2 Traffic facility design

Firstly the coordination planning should be prepared comprehensively among the traffic facilities of electric bicycles and other vehicles, as well as urban architecture. Then the detailed engineering works include traffic designs on the non-motor vehicle lane, non-motor vehicle crossing facilities, non-motor vehicle parking facilities, non-motor vehicle traffic signs and markings, and non-motor vehicle lighting system.

How to implement the above strategies and take or select the designing parameters could refer to the *Study on the Orientation and Guidance Strategies of Non-motorized Vehicle Development* (Chengdu Transportation Committee and Southwest Jiaotong University, 2013), which is developed by Prof. Liu Lan and his team.

6 Conclusion

Chengdu's practices indicate that electric bicycle is a kind of energy saving, environmental protection, economic, fast and safe transport means. And it is an effective way to solve the travel problem for low-income groups in urban districts. And it is also an important element of urban integrated transport system. Electric bicycles should be selected as one of the main transport means in urban districts. But they may also become the important causes of traffic violation and congestion due to their special characters of speed, weight and size, which is different from manual non-motorized vehicles.

It is necessary to represent a compromise to balance the interests of all parties, neither harming electric bicycle production enterprises and riders, nor ignoring the dangers of electric bicycles. Therefore strict production supervision and traffic management should be implemented for electric bicycle traffic. And the service facilities must be improved to match traffic characteristics of electric bicycles. It is worth noting that the transfer trip with mass transit would be the function orientation and application direction for electric bicycles. Such application requires perfect biking and riding facilities and effective information service system.

Network Development of Modern Trams

Xu Yan

School of Transportation and Logistics, Southwest Jiaotong University, Chengdu, China; and National United Engineering Laboratory of Integrated and Transportation, Chengdu, China. E-mail: 859756536@qq.com

Abstract: In the trends of rail transit network development, this paper gives a brief analysis of the superiority and impact factors of the modern tram network development. On this basis we present three kinds of adaptation modes of the modern tram network development. These three modes respectively focus on the small and medium-sized cities groups, the new town in big cities and the ecological tourism zone. At the same time we conduct the case studies.
Keywords: Modern tram; Network development; Adaptation mode.

1 Introduction

Since the 1990s, a large number of major European countries restore or create some new modern tram lines, which are planned into networks in small and medium cities to replace the buses. The modern tram's revival gradually attracts our country's attention, and lead to a construction boom by virtue of its own advantages. By the end of 2013, a total of 24 cities planned or constructed the modern tram, some had already completed the construction and put into operation (LAN Lan,2014). With the growing scale of the modern tram construction, the pace of its network develops faster and faster. Combining the modern tram's system characteristics, we research on its own advantages, factors and applicable models in network development, to provide the impetus and further promote to China's modern tram scientific network development and operations.

2 Rail Network Features

Rail network operators system emphasizes the result itself overall functionality and scale effects with respect to a single line when the size of urban rail transport network develops by a number of rail lines staggered convergence to form an overall "net" system. Rail network evolution process can be viewed as a development process from a single independent rail line to rail network operators having functional classifications, shown in Figure 1.

Figure 1. Rail Network Diagram

Rail network development will significantly improve the network traffic attractive features and enhance the function in the transportation system. According to the domestic rail network mileage scale threshold defined in accordance with the rail singlet average length estimates, the rail network usually develops into a rapid stage by the construction of 2 to 3 rail singlet and develop into a stable stage by the construction of 8 to 9 rail singlet (GUO Xiucheng, et al,2013).

3 Modern Tram Network Development Advantages

Modern trams system is in the volume of rail transport. Its main functions are regarded as a link connecting the metropolitan main city and outlying areas, and as the backbone transportation bearing peripheral groups in big cities and main areas in small cities (ZI Haibo, et al,2009). The former is the extend and complement for large capacity rail network. Its lines are relatively fragmented and low degree of networking. The advantages of modern tram network development are highlighted in the latter one, mainly shown in the following points:

(1) Highlight the advantages of green transport

Domestic cities in the process of economic development are always bound to face such problems as traffic congestion, excessive energy consumption and pollution. Urban transport system is one of the main sources of energy consumption and environmental pollution. So the development of non-polluting, energy-efficient modes of transportation undoubtedly is the promotion to solve urban social problems. Modern tram is a clean and energy-saving mode of transportation by electric driving without consuming non-renewable resources such as oil. Its introductions improve urban transport system structure. After a net operating the entire modern tram system efficiency will be enhanced, and so do the traffic environment capacity. At the same time it will reduce environmental objective constraints sustainable of urban transport development.

(2) Flexible running cross path

Modern trams can take unique or mixed road rights, also can take a variety of different running cross paths after network. Trains can run line collinear, or choose a variety of lines. It can give better service comparing to other rail transportation cross-line operations which mature technology is not yet convenient and flexible.

(3) Network effects reflect the value-added benefits

There are two points to rationally plan the modern tram network to reach a certain scale, coverage and liquidity. On one hand through the plan of network layout, construction sequence, transfer node program and entrances and exits, can attract tourists to achieve the network passenger benefits. On the other hand at the site perimeter do the implementation of property development, business development, media and information development and other aspects of the whole network co-ordination, to enlarge the value of the network operators and increase non-fare revenue sources. Network efficiency and value-added benefits of passenger will be bumper.

(4) Humanistic philosophy more in-depth

Modern trams own beautiful appearance and sit comfortable. It can run with undulating terrain and landscapes to make urban transport and natural landscape complement. With its network development, modern tram have become ubiquitous network traffic landscape. It carries the characteristics of different cities and cultures, deepening the humanities transportation philosophy, playing an important advocacy role values heritage and humanities. It has considerable recognition.

4 The Modern Tram Network Development Affecting Factors

Modern tram has developed over 120 years so far. The technical conditions of separate construction are more mature. The construction of modern tram in our country is changing from simple "Line type" to "Network type". Only when the transition fully completed, the modern tram's advantages are in order to truly reflect such as large capacity, convenient, safe and quasi-point. It is worth noticing that the network development process will bring opportunities. But the development is affected by many factors, mainly on national policy, urban environment, planning and operational control and the operational organization.

(1)National policy

There are many rail alternative ways, so we should consider many factors in the choice of city rail transportation, including national policies on rail transport like development strategy and overall development plan. China has not yet issued any relevant policies of the modern tram construction. The existing city modern tram networks are mostly in infancy. We need national policy to support providing more evidence and guarantee for the development of the modern tram network.

(2)Urban environment

Modern tram network development needs both in-depth studying of its own network characteristics and paying attention to study the relationship between the modern tram and other external networks like urban master planning and urban bus network. It helps further optimize the network structure, play network efficiency, and improve operational efficiency of the whole urban transport system. In addition, more considerations need to focus on urban geography and climatic conditions, especially those areas in special or bad weather. We should ensure the modern tram having safe and efficient operations.

(3)Planning and operational control

It's easy to implement the project at formation stage of the early modern tram network because the factors subjecting to construction are few in each line. The network construction will be related to the multi-line hubs operating line constructions, and more affected by the constraints. The implementation of the project is extremely difficult. Its main feature is the high construction of large-scale, complexity, quality, engineering, and technology risks content. Network constructions are reflected in the planning stage. Whether the transfer station synchronized planning, implementation, or network parking depot, the network level of planning control center, are extremely important to the main substation.

(4)Operational organization

The modern tram network development requires operators to organize urban spatial, land use and traffic adapted distribution. Operations management should change from a single sub-population management to co-ordinate transformation management. Regulatory should approach to the fine transition. Data management should focus on sharing information. By this way the lines or a combination of cooperation can form a unified overall operational efficiency. For example, wire mesh size, the lines and transfer passengers are increasing. There are more needs to select a matching cross-road tram running form and train plan. At the same time, the setting of lines in the transfer station, back line, lines cord, tie lines and other infrastructures, can also restricts the application of network operations organization methods and techniques.

5 The Modern Tram Network Development Adaptation Model

Modern tram network has significant advantages. The modern tram "into a network " is different from the "line type" modern tram because the former come up a higher requirement. By studying the modern tram network adaptation mode can provide theoretical guidance to the development of modern urban tram network. Most of our cities are pushing bus priority development strategy. Small and medium cities are suitable for building the modern tram. Building a modern tram network as the backbone of transportation to guide the development of public transport, supplementing by regular buses, taxis and other modes of transport, can be order to create efficient multi-level comprehensive urban transportation system. But for large cities inside, traffic resource constraints. The development of high strength, concentration of high traffic and mixed traffic issues are outstanding. More and more objective environmental constraints require large volume of rail lines as the backbone network and the modern tram extend and complement the backbone network. Therefore the scope of the modern tram network development should be explored combining the characteristics of urban development needs and considering the special circumstances.

5.1 Between small and medium cities groups

With the development of small and medium cities, urban space functional structure is gradually clear. It forms some different city groups, focusing on the development of competitive industries or economic characteristics, or achieving specific social function. Among different functional small and medium city groups there are greater demand for transport corridors. Taking into account the moderate population and land size, it is particularly suited to modern tram network development by different group centers. By this way meet passengers demand and use rail network radiation to adjust and optimize the function of each tour location. Similarly, no matter what kind of functional group, they all need fast and convenient transportation to increase green area attractivity. The modern tram network uses its advantages to create a harmonious and comfortable traffic environment. So it can largely replace private cars and long-haul buses for those powerful life groups. The modern tram spread internal group to external access site for the center of the ring-type network. Thus it focuses the internal life of the area around the site and creates a "door to door" traffic community development models, build a beautiful environment, quiet life living area (WANG Mingwen, et al,2007). With the development of modern tram network, residents can also customize the modern tram's time of departure frequency according to their needs. For example, at the peak of shorter headway, schedule most vehicles to meet peak passenger flow direction, and at night to reduce the train to mitigate the impact on the lives area. In special events we increase train to meet the special needs of passenger flow, make the modern tram operating organization more efficient, humanistic, a resident of their own "private train".

Yibin is planning the modern tram which belongs to this model. Yibin is in the full implementation of bus priority development strategy, planning to build 7 tram lines into the net total of 168.1km. It strives to form integrated public transport system that the modern tram as the backbone system, regular bus as the main body, small buses and ferry system as the complement. Yibin is a typical urban development group city. The modern tram lines network plan cover all 15 groups, and make each of the core groups together. Thus it separates groups in old city area's population, eases traffic pressure, promotes the development of new groups, and enhances the overall quality of the city center. At the same time it forms the special features of the landscape along the belt line, rail travel fast lane, airport express high-speed rail lines. T4 line in network goes into a ring at the South Stream independent groups which is a national industry model. So the internal groups travel more convenient and comfortable. The South Stream live groups can concentrate on creating "door to door" transportation community development model, making the development of the modern tram network into a deeper level.

5.2 Inside metro cites

When urban development reaches a certain size, it will make the original spatial organization development model change to begin gradually expanding the space outside the city that is the construction of the metro. As the expansion of the metro area shares the downtown urban functions, it generally drive the development and utilization of regional economic development along transportation through the construction of rail transit or urban freeway. At the same time it support and guide the metro superior resources. Peripheral metro is in the development stage, which generally have a clear function of unified planning. It has more moderate passenger demand and road construction is also in the initial stage. But planning perspective passenger demand is growing faster, having higher capacity loading rate environment. These are suitable for modern tram network development system. From the development of long-term strategic significance, the area plan overall in advance, and the modern tram take advantage of green transportation and create a livable town.

The development of modern tram network makes the new town transport no longer route through a single connection into the center of the city. It greatly facilitates the travel of passengers, also share the single connection point at traffic congestion, make the traffic channel between town and the downtown unimpeded. Due to the lower bound metro road environment, the modern tram lines network can use a central green belt laying unified way. It should be considered to construct contact line between different lines, to make up trams better.

The modern tram construction in Hunnan new town in Shenyang belongs to this model. Shenyang City let the "Golden Corridor, silver belt" as the skeleton, plan the “two cities, two districts, multi-center” to form a spatial structure. Hunnan area focuse on the development of large business exhibition, researching, recreational sports and other modern services. It will become the city's future administrative and cultural center. So till 2013 there is an opportunity to build a modern tram network, a one-time planning and construction of nine lines, length of 139.3km (WANG Yingjie, et al, 2014). Hunnan modern tram network as trunk transportation full account of the extended reservation network operators to meet the needs of rail transport separation, to meet future demand for passenger transport development corridor. It not only provides a safe, comfortable, fast, user-friendly service , but also makes full use of the existing road resources to provide a solution for metro transportation development model. It’s guided by the construction of public transport infrastructure in advance of travel modes and residents car regulatory development. Thus promote the metro ecological sustainable development of Hunnan new area.

5.3 Eco-tourism zone

Eco-tourism industry due to its characteristics, urban transportation needs seasonal change, and visitors have a motorize, individual tendencies. Urban transport systems assume the dual pressures of local and foreign traffic. Urban residents and visitors focus on the different transport services. This requires the construction of transportation systems with eco-tourist attractions. Modern streetcar system’s fast, comfortable, green, and other features in such a city will be fully reflected. But considering the limitations factors, we particularly definite the eco-tourism zone as the fitness area the modern tram network development.

Eco-tourism zone, which is special ecological environment and tourist attractions in eco-tourism city, gather related services industries driven by scenic or ecological tourism development. Modern tram network cover the entire eco-tourism zone and band together to support their strengths and meet the different seasonal variation, high mobility, strong individual tourist flows, acting as a wide range of "public tourist traffic". Thus not only meet passengers traveling quality, comfort and high travel requirements, but also service as a unique transport landscape itself into eco-tourism area, to develop related industries.

Here we need also talking about crossover model of eco-tourism zone network development. If the zone is located in the center of major cities, where has been built a higher level of rail transportation such as subways, then the modern tram network development's main direction is the existing rail line network encryption, characterized by emphasis on the existing rail. Each line is wire short length and complex. If the zone is located in the center of the small and medium city, then modern tram network development's direction will also consider both factors among small city groups and ecological tourism function. Similarly, if the zone is located in the metro or district, also take into account two models of new city and ecological tourism.

SND(Suzhou New District) modern trams is this development model that make eco-tourism zone and the metro district balanced. SND is located in the core area of the Yangtze River Delta, west downtown of Suzhou. It will create an overall spatial structure called "one core, one center, two biaxial, three areas". SND plan to construct six modern tram lines, total length 80km, including three basic lines, two complementary lines and a characteristic line. Thus will form four integrated transport hub including Suzhou park, intercity rail, eco-city and wetland (MIAO Caixia, 2013). The role of T1, T2, T4 line are connections between high-tech zone and the main city rail to play extended transitional and complementary. These six lines as the backbone of transportation systems adapt to high-tech zones to guide urban development. At the same time gather the scenic Taihu, Wetland Park, Suzhou park and related industries eco-city linking up, belong to the eco-tourism zone network development model. It shows the ecological characteristics of the bus system style of high-tech zones.

6 Conclusions

The development of modern tram network, takes advantages in the economic, safe, convenient, environmentally friendly, humane, and enhance to be further "green transport" and "human traffic" reflect. It is great significance for the improvement of urban transport environment, reducing urban traffic pressure and improving the image of the city. Therefore, to those small and medium cities which have built the modern tram lines, should actively promote their construction development. To those big cities which overall plan and integrate metropolitan transportation planning, should recognize the role of the modern tram fit. It should be recognized in demand, function, sustainable development and other aspects, choose rational planning and compatible network construction mode of urban development.

Abstract: The lightweight design of vehicle has become an important research topic of green transportation because of many advantages with high security, energy-saving, emission reduction and so forth in the environment of the green traffic. In a premise of clear understanding of lightweight vehicles, the article discussed the factors influencing lightweight vehicle design from the two aspects of design cost and vehicle energy consumption. The research results show that: through the use of green welding forming technology, it can effectively reduce the vehicle quality and the energy consumption. By using aluminum alloy, weathering steel and composite material composite structure design, not only it can satisfy the requirements of the integration of the vehicle structure, but also can reduce the vehicle weight to realize the balancing of benefits and costs so as to provide a good direction for the green traffic to build a resource conserving and environment friendly society.
Keywords: Green transportation; Structure design; Lightweight design of vehicle; Green manufacturing.

1 Introduction

1.1 The Green Transportation and the lightweight design of vehicle

The Green Transportation is important for the inevitable choice to acquire sustainable economic development. It also plays an important role for providing a humanity living environment. The core of Green Transportation includes trip accessibility, passenger safety and convenience, minimization of the expense of the resource and land, compromise between transportation and environment, and the system self extensibility.

For conventional fuel vehicles, the current research and development are heading for efficient, low energy consumption and emission development, these indicators are closely related with the quality of automobile. Also, automobile lightweight is the most effective way to reduce vehicle fuel consumption and emissions.

For the sustainable development of the automotive industry, energy saving, environmental protection and safety problems have been in urgent need to solve, where the lightweight design of vehicle ought to be put forward.

1.2 Research status

Cristello put natural frequency, torsional and bending stiffness, maximum Mises stress as constraint, considering the quality, manufacturing speed reduction and the collision process, the use of multidisciplinary optimization design method of zero emission vehicle frame is optimized.

Abhijit Londhe uses the method of test design of lightweight design of natural frequency, stiffness and strength of a SUV model based on the research.

Alimardani considers the car dashboard support NVH and crashworthiness, and use the size optimization method to carry on the structure lightweight design.

Based on the Cui Xintao body quality, structure performance and cost, using the method of lightweight multi material body, in all parts of the body material type and thickness as design variables to build the body material and structure optimization design mathematical model, finally has carried on the optimization using genetic algorithm.

Zhang Weigang for automobile front rail structure, optimize the use of the structure of the multi objective optimization design method of stepwise regression model based on the research.

2 The forming of lightweight technology

As is discussed above, lightweight automobile body is the purpose of the car performance unchanged as the premise, reduces the quality of body in order to reduce the vehicle quality, thus reducing the fuel consumption, reduce pollution, but also the manufacturing cost of automobile try not to be improved. At present, the main ways to reduce mass of body including the use of lightweight materials, advanced forming technology and manufacturing process and body structure optimization design.

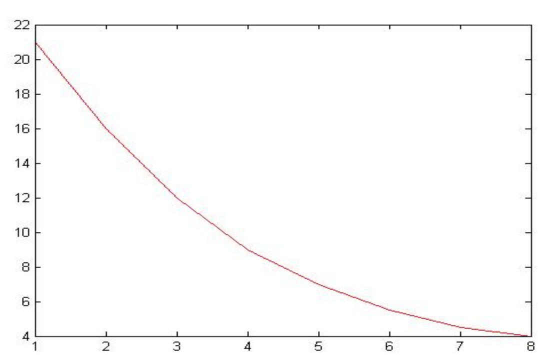

Fig. 1 Lightweight and body weight diagram

As is shown from the diagram drawn in matlab. Light weight does not necessarily reduce the performance of the vehicle, the automobile lightweight in reducing vehicle quality and can also reduce the vehicle 's center of gravity, thus effectively improving the performance of motor vehicles; smaller car quality can improve drivetrain load; in passive safety, lightweight can shorten the braking distance and reduce the collision process of inertia and kinetic energy in the collision of the automobile lightweight; at the same time can also reduce the automobile in the running process of a lot of resistance.

The forming of lightweight technology refers to meet the application of high strength material, and realizes the part integrated design need to adopt technology. At present, these are the widely used: TWBs Technology (TWB), hot pressing forming technology (HPF) and hydraulic forming technology (HF) etc..

2.1 TWBs Technology

Over the past 10 years, the rapid development of technology in aerospace and automobile industry in laser welding. Tailor welded blanks can according to the requirements of the different properties of each part of body parts, the use of welding method to weld two block or plate of different thickness, performance or materials together, the formation of laser tailor welded blanks (TWB) for stamping, so as to reduce the number and weight of parts and reduce the cost for such purposes, at the same time also ensure the integrity of structure and precision of variable cross section plate; continuous extrusion (TRB) is the use of flexible rolling technology a sheet rolling forming. Due to the continuous change of the cross section shape, compared to the performance of TWBs with material has better. In recent years, variable cross section plate technology has been widely used in the automotive industry.

2.2 hot pressing forming technology

Plate body structure and body used determines the body strength, the body of some key parts often need steel high strength steel plate. Hot forming is one of the many solutions. Hot forming, the yield strength of the steel plate can reach more than 1000Mpa, if the use of heat molding plate in the body, it can be in constant mass based on the strength is improved 30%. And the tensile strength of steel plate, hot forming is about 3 times that of ordinary steel, but also have very high hardness of both the steel toughness. Application of hot forming of steel can greatly improve their safety performance, the collision process can give good protection of occupant.

2.3 hydraulic forming technology

Hydroforming is a plastic processing technology for force transmission medium using liquid alternative to traditional die or punch to make parts processing. Technology is not only used in the precondition of ensuring the parts stiffness, strength and uniformity of the lower hydraulic forming, but also can improve the quality of products and forming limit.

3 Lightweight technical indicators

Lightweight technical indicators can give body to develop a directional guidance, it is difficult to form a highly recognized in the industry index. The following is the application of several kinds of lightweight car body index:

(1) Light Weight Index

Type (1) is defined as a light Weight Index:

$$L = \frac{M}{C_T \cdot A} \times 10^3 \tag{1}$$

In the formula, L is a light Weight Index; M for body in frame quality, kg; C_T for static torsional stiffness, Nm/ (DEG), including the windshield and side frame; A is the projection area, m^2; A= wheelbase * (track front + rear wheel) /2.

(2) The minimum yield strength

The minimum yield strength reflects the high intensity ratio of timber in the body, the body is minimum yield strength per unit mass of the yield strength values, the calculation method of formula (2):

$$R = \frac{\sum_1^n R \times m_i}{\sum_1^n m_i} \tag{2}$$

In the formula, n is the number of body parts; m is the quality of the parts; R is the yield strength of the material.

In the process of lightweight design, using different types of stainless steel with different yield strength and tensile strength, the relevant mechanical properties of common stainless steel material in the vehicle design comparison diagram, including the yield strength, tensile strength and elongation of the comparison in the concrete implementation step, should be based on the design of the construction unit requirements to determine the specific.

Table 1. The mechanical properties of different types of stainless steel sketch

Grade	Yield strength (N/mm^2)	Tensile strength (N/mm^2)	Elongation rate %
SUS301L-LT	≥215	≥550	≥45
SUS301L-DLT	≥345	≥690	≥40
SUS301L-ST	≥410	≥760	≥35
SUS301L-MT	≥480	≥820	≥25
SUS301L-HT	≥685	≥930	≥20
SUS304	≥205	≥520	≥40

(3) The quality of body volume unit

Body mass per unit volume refers to quality in the whole body in space in the unit volume of material contains, the calculation method of formula:

$$Q=\frac{M}{V}=\frac{M}{L\cdot H\cdot W} \tag{3}$$

In the formula, M is the quality of body; L, W and H respectively for white body length, width and height.

(4) Lightweight cost coefficient

In modern lightweight trolley in design process, the design cost lightweighting is for lightweight design can fully applied to an important constraint condition of the course of events. Therefore, how to coordinate the application significance of lightweight design and cost of the technology is very practical.

In the green traffic environment, the design of the lightweight body needs not only many physical properties of the vehicle's consideration, also need to ensure energy conservation and environmental protection concept of green transportation, so in the light of quantitative assessment index, need to research and development, materials, repair and so on. The calculation method of the following specific formula is shown:

$$LC=\frac{\sum h_i\times k_i\times t_i}{K\times T} \tag{4}$$

In the formula, h refers to the number of design units, k refers to the unit cost of the design units, t refers to the unit time design. K refers to the total cost of the design units, t refers to the total time design.

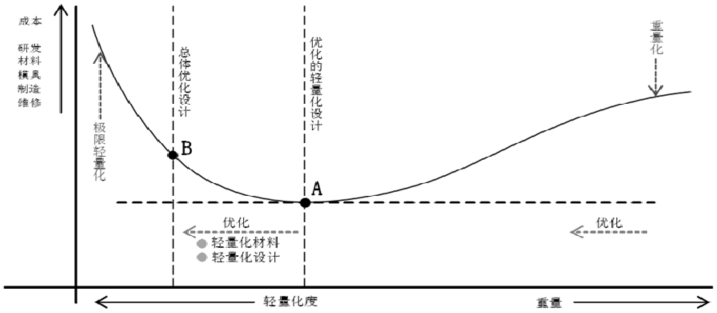

Fig. 2 Relationship between the lightweight design and technology costs diagram

From Figure 2, the existence of optimization of the lightweight design of A and the total light weight design of B between the vehicle's lightweight degree and cost of the technology, according to the actual need proper selection of the weight of the meet, in the appropriate technologies cost range, get the optimal design of vehicle lighter .

4 Sensitivity analysis

Sensitivity analysis of the objective in lightweight optimization of body structure design, is not only to determine the body in structure on its performance but also to design sensitive variables to lose weight.

The response of a system is determined by the properties of composition of the various parts of this system, and each attribute parts and the influence degree of the system response of each are not identical. Sensitivity analysis can be obtained which attributes influence on the response of the system to larger or smaller, so as to provide suggestions for designers.

In the sensitivity analysis method, the parameters of the system by using the variable V_i parameter, for the design goal of G, the function relation is formed between V_i and the design variables, namely g=G (V_i), if the design of the variable V_i has small changes, the design goal was to produce corresponding change:

$$\Delta g = \frac{\partial G}{\partial V_i} \Delta V_i \tag{5}$$

When the design variables change the same value, namely the I Delta V = Delta, Delta and variation of the design goals of g each are not identical, iGv can sensitivity is defined as the design goal of G to the design variables V_i. Using the body stiffness sensitivity of each plate thickness analysis as an example, the finite element equilibrium equation for elastic statics:

$$[G]_{n\times n}[J]_{n\times 1}=[F]_{n\times 1} \tag{6}$$

In the formula, N is the degree of freedom; $[G]_{n\times n}$ is the the total stiffness matrix; $[J]_{n\times 1}$ is the structure of displacement vector; $[F]_{n\times 1}$ is the load vector.

On the design variables V derivative can be obtained:

$$[G]_{n\times n}\left\{\frac{\partial J}{\partial v}\right\}_{n\times 1}+\left\{\frac{\partial G}{\partial v}\right\}_{n\times n}[J]_{n\times 1}=\left\{\frac{\partial F}{\partial v}\right\}_{n\times 1} \tag{7}$$

Among them, the design variables can be focused on the lightweight design according to different determined, and then complete the sensitivity analysis of lightweight car body design.

5 Model of lightweight design

The design variables, constraints and the objective function are the three elements of the optimization design. In the lightweight body structure design, with each plate thickness as design variables and body first-order torsion and bending natural frequency as the constraint conditions, using the body quality minimum, torsional and flexural rigidity and maximum the optimization goal, the definition of the natural frequency changes the amount not less than the original frequency of 95%, and the lightweight cost coefficient of cost and weight coefficient of the standard deviation of not more than 30% to get the body of multi-objective lightweight optimization design mathematical model:

$$\min f(x)=\{f_G(x),-f_{\Delta L}(x),-f_b(x)\} \tag{8}$$

$$f_{\Delta L}(x)=\sqrt{|f_L(x)-f_{LC}(x)|} \tag{9}$$

Among them, $f_L(x)$, $f_{LC}(x)$ need through the following algorithm for data standardization processing, then into operation of $f_{\Delta L}(x)$:

```
X=X/;
Stdr=std(x);
[n,m]=size(x);
Sddata=x/stdr(ones(n,1):);
```

Then:

$$f_{\Delta L}(x) \leq 0.3 \tag{10}$$

$$\frac{g_b(x) - g_{ob}(x)}{g_{ob}(x)} \leq 0.05 \tag{11}$$

$$\frac{g_b(x) - g_{\mathrm{ot}}(x)}{g_{ot}(x)} \leq 0.05 \tag{12}$$

$$x = [x_1, x_2, x_3 \cdots, x_i]^T, i = 1,2,\cdots \tag{13}$$

$$-0.1 \leq \frac{x_{oi} - x_i}{x_{oi}} \leq 0.3, i = 1,2,\cdots \tag{14}$$

In the formula, $f(x)$ is the objective function; $f_G(x)$ respectively for yield stiffness objective function ; $f_{\Delta L}(x)$ is the quality objective function; $f_b(x)$ is the torsional rigidity of objective function; $g_b(x), g_t(x)$ is first order bending natural frequency model and first-order torsional inherent frequency during the process of optimization, $g_{ob}(x), g_{ot}(x)$ is first order bending natural frequency model and first-order torsional inherent frequency in the initial model.

6 Conclusions

The lightweight body structure multi-objective collaborative optimization design method to the body is established seeing the minimum mass and stiffness maximum as optimization objective. The whole body a twist modal frequency taken as constraints, design variables on the sensitivity analysis is about to determine the thickness of the multi object body the collaborative optimization design.

Abstract: Developing battery electric bus (BEB) has become a good means to help cut down the increasing greenhouse gas emissions and global crude oil demand. Due to the limited driving range and long charging time of BEB, battery swap station (BSS) seems the best option for BEBs to replenish energy at present. This paper presents a novel method to design the BSS for BEBs. Based on several assumptions and running rules for BEBs, the swapping and charging demand of BEB fleets are analysed to calculate the design scale of the BSS, which include the scales of battery packs, battery swapping system and battery charging system. As a case study, the BSS serving for 120 BEBs in World Expo 2010 Shanghai China, are simulated through a Matlab program. The results show that the simulation can provide an equivalent level of operation. And the scales calculated by the method are close to the actual values, which indicates that the design method we proposed is effective.
Keywords: Battery electric bus; Battery swap station; Swapping and charging demand.

1 Introduction

Developing battery electric bus (BEB) is a good choice to limit the emissions and demand for fossil fuel due to increasing number of vehicles. To overcome the disadvantage of driving range, it's necessary to construct charging/battery swap infrastructure for these BEBs.

There have been a number of studies related to this subject. But these studies mostly focused on the charging infrastructure for electric cars not including BEBs (Aultman-Hall et al. 2012; Dong et al. 2014; Kuhne 2010; Lee et al. 2014; Nie and Ghamami 2013; Sellmair and Hamacher 2014; Tuttle and Fellow 2012). The charging demands of BEB fleets are quite different from those of electric cars. So it's necessary to propose some new and special infrastructure planning methods for the BEBs.

On the other hand, most researches only study the charging station rather than the battery swap station. Only a few literatures involved the battery swapping. Yu et al. (2014) proposed a model and efficient method for the optimal planning of charging station and BSS, whoes results show that BSS is more suiTable for public transportation. Kaschub et al. (2012) proved the economic feasibility of BSS for

BEBs. But they did not discuss how to calculate the scales of the BSS based on swaping and charging demand of the BEB fleets. None of the existing literatures have ever studied the design of the BSS for BEBs.

The objective of this paper is to propose a method to calculate the economically ideal scales of swapping/charging facilities and battery packs that BSS should deploy to meet the swapping and charging demand. As a consequence, the BEBs can be widely adopted in the marketplace.

2 Method

2.1 Running Rules of BEBs

Several assumptions and rules are made for BEBs to follow.

Assumption 1: The BSS is built near by the bus terminal station of several routes.

Assumption 2: Each battery pack in BEB is full initially and will be replaced with another full one in BSS;

Assumption 3: The energy consumption of battery pack is linearly associated with mileages ignoring the impact of weather and passenger flow;

Assumption 4: The charging time of battery pack is in direct proportion to charging depth, in inverse proportion to charging rate.

Rule 1: BEB only departs from bus terminal station, running back and forth along the route counts as a round. All BEBs of the same route go to the same BSS for battery swapping, then back to bus terminal station waiting for next round;

Rule 2: BEB won't go to the BSS during a round until it has finished this round. Namely, if the energy is not enough to support next round, it's time for the BEB to swap battery;

Rule 3: When BEB finishes the daily running hours, it heads for the BSS to replace the battery pak with a full one, no matter how much energy is left. Then, back to the bus terminal station for parking, ending the operations of a day.

The running track of BEB is showed in Figure 1.

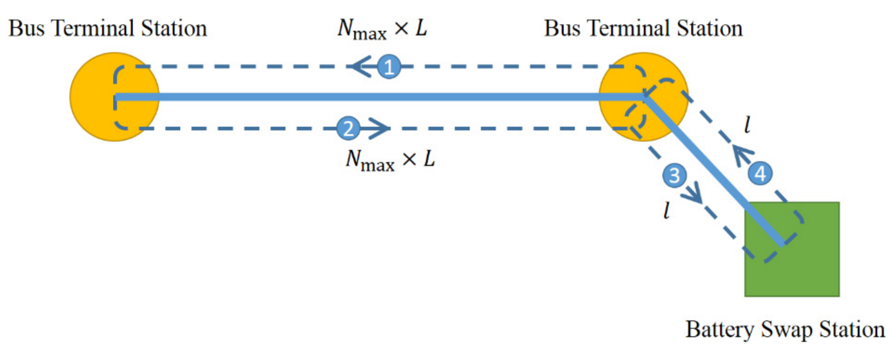

Figure 1. The running track of BEB.

Given the operating schedule of the route, departure and arrival time of each BEB can be obtained, then:

$$Arrive(m,n) = Depart(m,n) + T_c \quad (1)$$

$$T_c = \frac{L}{V} \times 2 \times 60 + n_{stop} \times t_{stop} \times 2 \quad (2)$$

$$N_{bus} = \frac{T_c}{I_P} \quad (3)$$

where n the serial number of each bus, *m* the serial number of each departure, *Depart(m,n)* represents m-th departure time of the bus n, *Arrive(m,n)* represents m-th arrival time of the bus n, T_c the cycling time of the route (min), *L* the route length, *V* the average speed of buses (km/h), n_{stop} the number of stops in the route, t_{stop} the average time of each stop (min), N_{bus} the bus configuration of the route, and I_P the departure interval in peak hours(min).

2.2 Swapping and Charging Demand Analysis

2.2.1Time Distribution of Battery Swapping

Plenty of researches show that depth of discharge between 70% and 80% is beneficial to the life of battery and provides a favorable working environment for BEB. So we make SOC_{min}>0.3, then actual max range of BEB can be calculated as follows:

$$range = Range \times (1 - SOC_{\min}) \quad (4)$$

where *Range* is the theoretical max range of BEB (*km*), and *range* the actual max range of BEB (*km*). Then max number of rounds per charge is calculated.

$$N_{\max} = fix(\frac{range - 2 \times l}{2 \times L}) \quad (5)$$

where *l* is the distance from bus terminal station to the BSS (km), fix(x) rounds the x to the nearest integer towards zero.

Whenever the BEB finished N_{max} rounds, it should run to BSS from terminal station for battery swapping. The swapping start and end time of BEB can be calculated based on arrive time of the last round.

$$SwapS(h,n) = Arrive(h \times N_{\max}, n) + \mathrm{T}_l \quad (6)$$

$$SwapE(h,n) = SwapS(h,n) + T_s \quad (7)$$

where *SwapS (h, n)* represents the start time of *h*-th swapping of the bus *n*, *SwapE (h, n)* represents the end time of *h*-t swapping of the bus *n*, both of them are $h \times n$ matrixes, T_l the time of BEB running from terminal station to BSS, and T_s the time each battery swapping should take. The number of battery swapping in every minute can be counted based on *SwapS (h, n)* and *SwapE (h, n),* which is denoted as *SwapDis(t)*, the time distribution of battery swapping.

2.2.2 Charging Time of Battery

The charging time of battery is determined by the depth of charge (*DOC*) which is equal to the depth of discharge (*DOD*). According to the Assumption 4, the charging time of battery is expressed as follow:

$$DOC = DOD = (N_{\max} \times 2L + 2 \times l) / Range \quad (8)$$

$$T_{ch} = \frac{1}{CR} \times DOC \times 60 \quad (9)$$

where T_{ch} is the charging time of the battery pack (min), *CR* the charge rate of the chargers.

2.2.3 Time Distribution of Battery Charging

In case the replaced battery pack will be transported to charging rack immediately, the start time of battery charging is equal to end time of battery swapping ignoring the transport time. Given the charging time, the end time of charging can be obtained.

$$ChargeS(b) = SwapE(h,n) \quad (10)$$

$$ChargeE(b) = ChargeS(b) + T_{ch}(b) \quad (11)$$

where *ChargeS(b)* represents the start time of *b*-th battery charging, *ChargeE(b)* represents the end time of *b*-th battery charging, both of them are $b\times1$ matrixes. The number of battery charging in every minute is counted based on *ChargeS(b)* and *ChargeE(b),* which is denoted as *ChargeDis(t)*, the time distribution of battery charging.

2.3 Design of the Battery Swap Station

The battery swap station maily consists of battery charging system, battery swapping system and monitoring system (Figure 1). Design of the BSS aims to decide the scales of BSS, which include the number of charging devices and swapping robots, the amount of battery packs, the power capacity of BSS, etc.

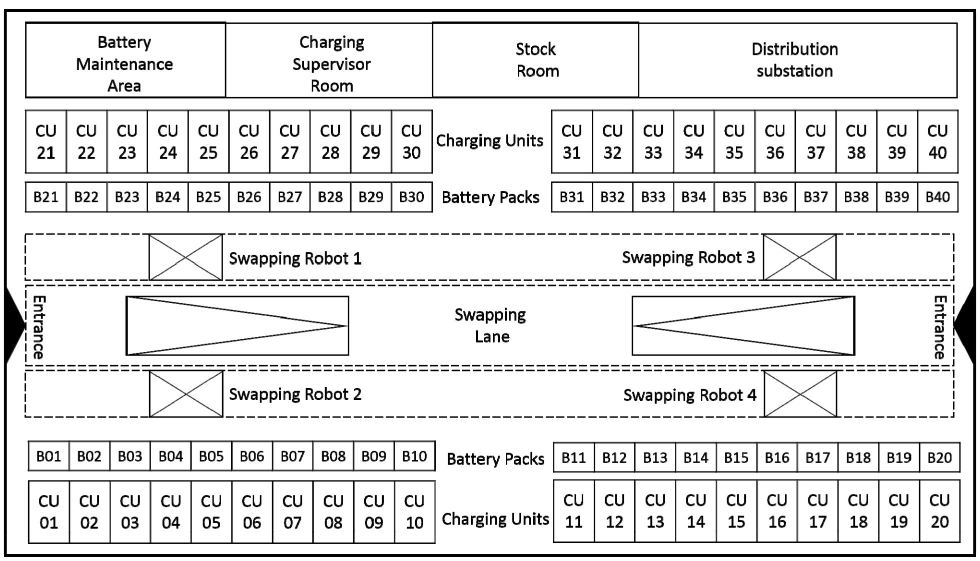

Figure 1. The example layout of battery swap station.

2.3.1 Scale of Battery Packs

With battery swap mode, BEBs should be equipped with a certain amount of backup battery packs to relive the disadvantages of short range and long charging time. So the number of the battery packs the BSS should hold is calculated as:

$$N_{Battery} = N_{Bus} + N_b \quad (12)$$

where N_{Bus} is the number of buses of all routes, N_b the number of the backup batteries. Due to the expensive cost of battery, the number of backup battery packs should be minimized when the normal operation is ensured. Therefore we propose an algorithm (Figure 2) to get the optimal number of backup battery packs.

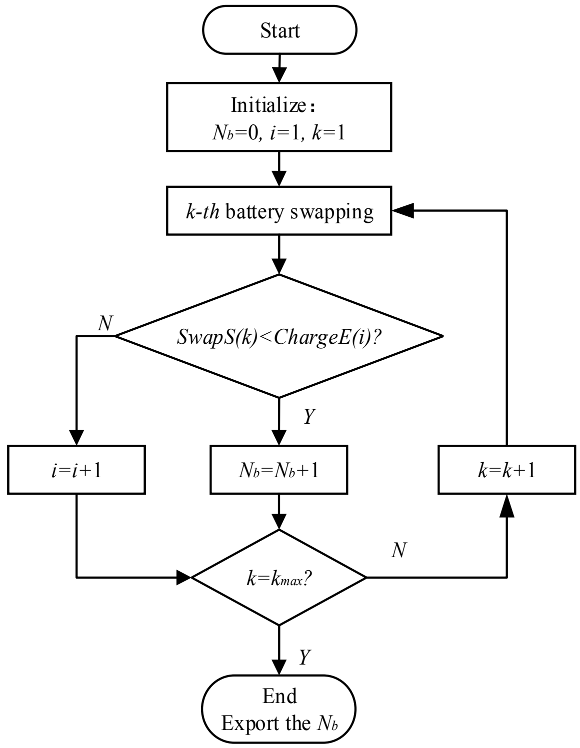

Figure 2. Algorithm of calculating number of backup battery packs.

2.3.2 Scale of Battery Swapping System

The battery swapping system is made up of several swapping units, each of which consists of a swapping lane and two swapping robots.When the BEB drives into the swapping lane and stops at specific location, the two robots can automatically complete the battery swapping. The number of battery battery swapping units (N_{SU}) is equal to the maximum number of BEBs whose batteries are being swapped at the same time in the BSS, which can be obtained from the time distribution of battery swapping.

$$N_{SU} = \underset{t=t_S}{\overset{t_E}{MAX}} \left(SwapDis(t) \right) \tag{13}$$

2.3.3 Scale of Battery Charging System

The battery charging system consists of a series of charging units responding to battery packs. Therefore the output power of charging unit should be matched with the energy of battery pack.

$$P_{CU} = \frac{U \times I}{\eta_{\max} \times \varphi} = \frac{U \times C \times RC}{\eta_{\max} \times \varphi} \tag{14}$$

where P_{CU} is the output power of the charging unit, U the charging voltage, I the charging current which is equal to the product of battery pack capacity(C) and charging rate(RC), η_{max} the max efficiency of charger, and φ the reactive loss of lines.

The number of charging unit (N_{cu}) should not be less than the maximum number of batteries that are charged at the same time, which can be obtained from the time distribution of battery charging.

$$N_{CU} = \underset{t=t_S}{\overset{t_E}{MAX}} \left(ChargeDis(t) \right) \times (1+\gamma\%) \qquad (15)$$

where t_S is the start of service time of BSS, t_E the end of service time, and $\gamma\%$ the design margin (10%~20%).

The power capacity of battery charging system depends on the output power and number of charging units in BSS, which can be expressed as:

$$P_S = N_{CU} \times P_{CU} \times (1+\gamma\%) \qquad (16)$$

3 Case Study

3.1 Data Preparation

The BSS of World Expo 2010 Shanghai China was the first large scale application in public transit system. There were 120 BEBs runnnig on 3 routes in the expo park (Figure 3).

Figure 3. Layout of BEB routes and BSS.

The operation and scheduling of the 3 BEB routes are shown in the Table 1.

Table 1. Operation and Scheduling of the BEB Lines (Cai 2012)

Details	Expo Avenue Cross-river Line	Expo Guozhan Line	Longhua East Road Line
Number of Buses	80	30	10
Service Time	9:00-24:00	9:00-24:00	9:00-24:00
Number of Stops	11	7	12
Length of Route	6.7 km	1.8 km	2.65 km
Average Speed	28 km/h	28 km/h	28 km/h
Distance between Terminal Station and BSS	3.3 km	1 km	3 km
Cycling Time of the Route[a]	40 min	15 min	18 min
Departure Interval (peak)	1 min	1-2 min	3-4 min
Departure Interval (off-peak)	30-45 s	30-45 s	2 min

[*a*]: average time of each stop is 0.5 min.

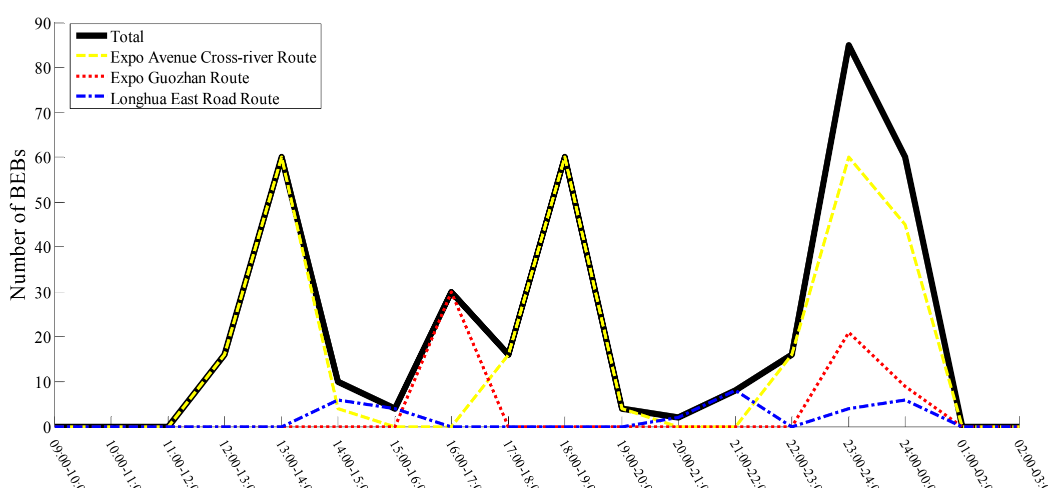
Other parameters for simulation are presented in Table 2.

Table 2 Simulation Parameter Setting

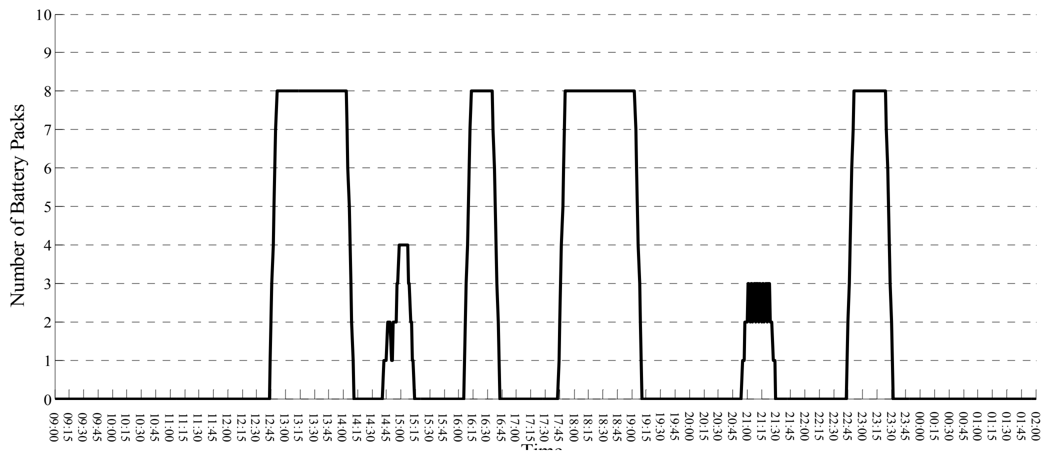
Parameter	C	U	I	RC	$Range$	SOC_m	η_{max}	φ	$\gamma\%$	T_s
Value	360Ah	440V	100A	0.3C	100km	30%	85%	90%	10%	8 min

3.2 Simulation of Operation

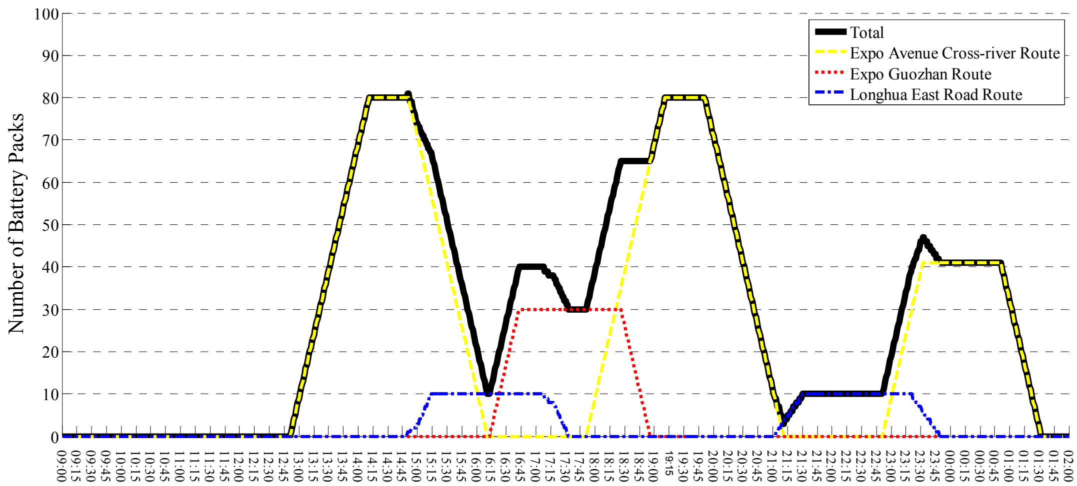
Based on the method proposed above, we designed a MATLAB program to simulate operation of the BSS and BEBs. Input the prepared data and run the program, the operation of the BSS in one day will be simulated minute by minute. As a consequence, the minutely state of the BEBs, swapping systems and charging systems can be recorded in matrixes: *Depart(m,n)* & *Arrive(m,n)*, *SwapS(h,n)* & *SwapE(h,n)*, *and ChargeS(b)* & *ChargeE(b)* respectively. By these matrixes, we can analyse the swapping and charging demand (Figure 4).



(a) Time distribution of BEBs arriving at BSS



(b) Time distribution of battery swapping



(c) Time distribution of battery charging

Figure 4. Swapping and charging demand analysis.

As shown in Figure 4(a), different routes have different time distributions of BEBs arriving at BSS. According to Rule 3, every BEB need go to swap battery pack after finished its last round of one day. Since there is no more tasks for the BEB, it is not necessary to complete the swapping and charging immediately. In consequence, we exclude the last swapping and charging of all BEBs when plot the Figure 4(b) and Figure 4(c). It can be concluded that there are at most 8 BEBs being swapped and 80 battery packs being charged at the same time, which decide the sacles of battery swapping systems and battery charging systems.

3.3 Results and Discussion

There are several parameters evaluating the operation of the BSS in Table 3. Comparing with actual values, the simulation provides an equivalent state of operation.

Table 3. The Simulated and Actual Values of the Operation Parameters

Operation Parameters	Number of BEBs	Average Daily Mileage	Max Range per Charge	Average Daily Swapping Times	Average Charging Time
Simulated Value	120	178.4 km	62.6 km	3.0	111.9 min
Actual Value	120	181.4 km	67.8 km	2.7	118.5 min
Deviation	0.00%	-1.65%	-7.67%	11.11%	-5.57%

Through the Matlab simulation of operation, we can calculate the design scales of the BSS. Compare the simulated values with actual values in Table 4. It indicates that the scales calculated by our method are close to the actual scales with small deviations, which verifies the validity of the simulation and method above.

Table 4. Comparison of the Simulated and Actual Scale of BSS

Scales	$N_{Battery}$	N_{SU}	N_{CU}	P_{CU}	P_S
Simulated Value	240	8	89	62 kW	7.2 MW
Actual Value	232	8	112	63 kW	8 MW
Deviation	3.45%	0.00%	-20.54%	-1.59%	-10.00%

4 Conclusions

This paper presents a novel method to design the battery swap station for battery electric buses. Base on the swapping and charging demand analysis of the BEB fleets, the design scale of BSS can be calculated, which include the scales of battery packs, battery swapping system and battery charging system. We verified the method via a case study of BSS in World Expo 2010 Shanghai China. With a Matlab program, we simulated one day operation of the 120 BEBs and analysed the swapping and charging demand for the BSS. The operation parameters and scales of the BSS in simulation are close to the actual values, which concludes that the design method is effective.

This paper contributes to the construction of the electric public transit system. It provides a planning and design guide for government, bus companies, infrastructure operators and other decision makers, avoiding blind constructions.

Abstract: For the bulk and stable cargo, railway commonly uses the protocol transport. The railway transport enterprise can avoid the market risk at the same time when providing security to transportation capacity. This paper introduces the option theory to the process of protocol transport in pricing, establishes the optimal decision model based on the largest returns of enterprise and customer and solves the problems of setting option exercise price and buying option quantity. This paper considers the changes in market prices and the competition of other modes of transport when building the model and finally applies the model to a simple example.
Keywords: Protocol transport; Option; The optimal decision; Exercise price.

1 Introduction

Option is a kind of derivative financial tools generated from the base of futures, refers to the buyers and sellers have a transaction of a certain number of the subject matter with a specific target price at a certain period of time or a certain time point in the future. During this process, the buyers can exercise option or not at expiry. In September 2012, the railway freight implements "real goods" reform and one thought of the reform is to ensure the transportation capacity of the bulk and stable cargo by protocol transport. In June 2013, the railway implements the reform of railway freight transportation which includes the protocol transport.

In the railway freight market, the transport demand of coal, ore and other large enterprises is relatively stable, so the railway transport enterprises usually sign transport protocols with these large enterprises, which stipulates the price, the amount of transportation capacity and the expiration and so on. In this way, these large enterprises provide stable, adequate supply of goods to the railway transport enterprises and the railway transport enterprises provide adequate, reliable transportation capacity. The railway transport enterprises can sell the remained capacity in the railway freight market. However, there is a certain risk of selling out the remained capacity because of the changeable demand and price in the railway freight market. According to the above analysis, we can find some similarities between option and transport protocol, so we try to introduce the option theory to the railway freight transportation.

2 Railway Freight Option

Railway freight option is a kind of option contract in which the railway transport enterprise is a seller, the large enterprise is a buyer (called protocol client) and the subject matter is the railway freight transportation service. At the same time, we need to make clear the following contents.

(1) The option premium: It means the fees that used to buy the option are given to the railway transport enterprise by protocol client.

(2) Strike price: It means the price of transport services that paid by protocol client when it received the rail transport services from the railway transport enterprise.

(3) Protocol expiration: It means the option is expired at the period of time or the time point agreed by railway transport enterprise and protocol client. After the period of time or the time point, the option is no longer in force.

(4) Quantity of the purchased option: It means the quantity of transport services that given to protocol client from railway transport enterprise by strike price.

After signing transport protocol, protocol client pays option premium which agreed by both sides to railway transport enterprise. During the protocol expiration, if protocol client exercises the option, it will buy the option quantity of transportation capacity from railway transport enterprise by strike price. If not, railway transport enterprise will sell out the option quantity of transportation capacity and not return the option premium.

3 Analysis of Railway Freight Transport Protocol Price Based on Option

Under a series of assumptions and base on the principle of maximize the revenue of railway transport enterprise and protocol client, this paper establishes the optimal decision model and determines a reasonable option strike price and quantity.

3.1 Symbol definitions and assumptions

p_0 means the unit price of transport capacity in spot market, p_u and p_d means the up or down unit price of transport capacity in spot market on option expiration day, $p_1^{'}$、$p_2^{'}$ means the average up or down unit price of transport capacity of other transport mode and u^*、d^* means the percent of up and down, r means risk-free rate, c_0 means the option premium of unit transport capacity, c means the strike price of unit transport capacity, n means quantity of the purchased option agreed by both sides, c_L、c_S means long or short preparation cost by providing unit transport capacity, KC means fixed cost by providing transport capacity. Equation

$D = a - bp + \varepsilon$ indicates functional relation between the market demand D and the price p in spot market. There are only two changes (up and down) with the price of transport capacity in spot market on option expiration day. Equation $c_0 = h(c)$ means option premium is influenced by strike price. Railway transport enterprise and protocol client can accept the price of transport capacity in spot market.

3.2 The establishment of model

According to the assumptions, $c_0 = (1-P)(p_u - c) + P(p_d - c)$, $r = (1-P)u^* + P(-d^*)$, $p_u = p_0(1+u^*)$, $p_d = p_0(1-d^*)$, then $P = \dfrac{u^* - r}{u^* + d^*}$. Assume $u^* = e^{\sigma\sqrt{t}/3} - 1$, $d^* = 1 - e^{-u^*}$ based on the data of different years, σ means standard deviation of railway freight market returns and t means the length of time (year).

Situation 1: During the protocol expiration, assume the unit price of transport capacity in spot market decline (probability is P) and less than the strike price of unit transport capacity, then protocol client dose not exercise the option.

(1)Protocol client still choose railway freight transportation (probability is P_1). The equation $C_G = \alpha T + \beta E$ means generalized cost include time cost and expenditure cost. α and β are conversion factors. Assume there are m kinds of transport modes, the probability of choosing railway is $P_1 = \dfrac{e^{-C_G^1}}{\sum_{i=1}^{m} e^{-C_G^i}}$, so the profit functions of protocol client and railway transport enterprises are:

$$G_1 = pD - c_0 n - p_d D = (p - p_d)D - c_0 n \tag{1}$$

$$Q_1 = c_0 n + p_d D - c_s D - KC = c_0 n + (p_d - c_s)D - KC \tag{2}$$

Bring in $D = a - bp + \varepsilon$ and the profit expected values of protocol client and railway transport enterprise are:

$$E(G_1) = \int_{-\infty}^{+\infty} [(p - p_d)(a - bp + x) - c_0 n] f(x) dx \tag{3}$$

$$E(Q_1)=\int_{-\infty}^{+\infty}[c_0n+(p_d-c_s)(a-bp+x)-KC]f(x)dx \tag{4}$$

(2)Protocol client choose other transport modes (probability is $1—P_1$) and the profit functions of protocol client and railway transport enterprise are:

$$G_1^{'}=pD-c_0n-s_1^{'}D=(p-p_1^{'})D-c_0n \tag{5}$$

$$Q_1^{'}=c_0n-KC \tag{6}$$

The profit expected values of protocol client and railway transport enterprise are:

$$E(G_1^{'})=\int_{-\infty}^{+\infty}[(p-p_1^{'})(a-bp+x)-c_0n]f(x)dx \tag{7}$$

$$E(Q_1^{'})=\int_{-\infty}^{+\infty}(c_0n-KC)f(x)dx \tag{8}$$

Situation 2: During the protocol expiration, assume the unit price of transport capacity in spot market rise (probability is $1-P$).

(1)Protocol client still choose railway freight transportation (probability is P_1). If the quantity of purchased option in protocol is greater than the actual demand when exercising option, it will need to buy $D-n$ transport capacity in spot market and consider choosing the railway or not. The profit functions of protocol client and railway transport enterprise are:

$$G_2=\begin{cases}pD-c_0n-cD, D\le n\\ [pD-c_0n-cn-p_u(D-n)]P_1+[pD-c_0n-cn-p_2^{'}(D-n)](1-P_1), D\succ n\end{cases} \tag{9}$$

$$Q_2=\begin{cases}c_0n+(c-c_L)D-KC, D\le n\\ [c_0n+(c-c_L)n+(p_u-c_S)(D-n)-KC]P_1+[c_0n+(c-c_L)n-KC](1-P_1), D\succ n\end{cases} \tag{10}$$

The profit expected values of protocol client and railway transport enterprise are:

$$E(G_2)=\int_{-\infty}^{n-a+bp}[(p-c)(a-bp+x)-c_0n]f(x)d(x)+\int_{n-a+bp}^{+\infty}Af(x)d(x) \tag{11}$$

$$E(Q_2)=\int_{-\infty}^{n-a+bp}[c_0n+(c-b_0)(a-bp+x)-KC]f(x)d(x)+\int_{n-a+bp}^{+\infty}Bf(x)d(x) \tag{12}$$

With

$$\text{A}=[(p-p_u)(a-bp+x)-c_0n-cn+p_un]P_1+[(p-p_2^{'})(a-bp+x)-c_0n-cn+p_2^{'}n](1-P_1)$$

$$\text{B}=[c_0n+(c-c_L)n+(p_u-c_S)(a-bp+x-n)-KC]P_1+[c_0n+(c-c_L)n-KC](1-P_1)$$

(2)Protocol client choose other transport modes (probability is $1—P_1$) and the profit functions of protocol client and railway transport enterprise are:

$$G_2^{'} = pD - c_0 n - p_2^{'} D = (p - p_2^{'})D - c_0 n \quad (13)$$

$$Q_2^{'} = c_0 n - KC \quad (14)$$

The profit expected values of protocol client and railway transport enterprise are:

$$E(G_2^{'}) = \int_{-\infty}^{+\infty} [(p - p_2^{'})(a - bp + x) - c_0 n] f(x) dx \quad (15)$$

$$E(Q_2^{'}) = \int_{-\infty}^{+\infty} (c_0 n - KC) f(x) dx \quad (16)$$

Comprehensive situation 1 and 2, the profit expected values of protocol client and railway transport enterprise are:

$$E(G) = P[P_1 E(G_1) + (1 - P_1) E(G_1^{'})] + (1 - P)[P_1 E(G_2) + (1 - P_1) E(G_2^{'})] \quad (17)$$

$$E(Q) = P[P_1 E(Q_1) + (1 - P_1) E(Q_1^{'})] + (1 - P)[P_1 E(Q_2) + (1 - P_1) E(Q_2^{'})] \quad (18)$$

Differentiate the equation (17) and (18) by n and equate to zero, we found

$$F(n - a + bp) = 1 - \frac{c_0 (2 - P_1 + PP_1)}{P_1 p_u - P_1 p_2^{'} + p_2^{'} - c} \quad (19)$$

$$F(n - a + bp) = 1 - \frac{c_0 (2 - P_1 + PP_1)}{-P_1 p_u + P_1 c_S - c_L + c} \quad (20)$$

Comprehensive equation (19) and (20), the optimal option strike price c is:

$$c = P_1 p_u - \frac{P_1 p_2^{'} - p_2^{'} + P_1 c_S - c_L}{2} \quad (21)$$

4 Example Analyses

Assume the protocol expiration in transport protocol signed by railway transport enterprise and protocol client is a half of a year and ε is the uniform distribution by [-100， +100], we found its density function and distribution function are $f(x) = \begin{cases} \frac{1}{200}, -100 \le x \le 100 \\ 0, \text{other} \end{cases}$ and $F(x) = \begin{cases} 0, x \le -100 \\ \frac{x+100}{200}, -100 \le x \le 100 \\ 1, x \ge 100 \end{cases}$. Assume risk-free rate r is 4%, standard deviation of railway freight market returns σ is 0.4068, the unit price of transport capacity in spot market p_0 is 100, long preparation cost by providing unit transport capacity c_L is 80, short preparation cost by providing unit transport capacity c_S is 120, the average up unit price of transport capacity of other transport mode in spot market on option expiration day $p_1^{'}$ is 95, the average down unit price of transport capacity of other transport mode in spot market on option expiration day $p_2^{'}$ is 105 and in order to simplify, assume P_1 is 0.9.

According to the above contents, we found u^*=0.10, d^*=0.095, P=0.308, $1-P$=0.692, p_u=110, p_d=90.5. Bring to the equation (21), the optimal option strike price c=90.25 and the option premium c_0=13.744. Bring to the equation (20), the optimal quantity of the purchased option n=279.

In this part, the paper just uses a simple example to apply the above model by simplifying the process and is aimed at proving the availability of the model.

5 Conclusions and Future Research

This paper introduces the option theory to the railway freight transportation and establishes the optimal decision model based on the largest returns of railway transport enterprise and protocol client. We explore the problems of how to reasonably set option exercise price and buy option quantity. During the research, this paper considers simple changes of supply, demand and price in spot market and competition among transport modes. However, the changes of supply, demand and price in real market are more and more complex than in this paper. This is the insufficient part of this paper, we hope for further study and analysis.

Abstract: Nowadays railway transportation developed towards High-speed in passenger transport, heavy load in freight transport and High density in urban railway system. As a result, the rail/wheel wear become more and more serious, thus decreased the rail rigidity and changed the rail-wheel contact and impact the safety and comfort of railway transportation. In this paper, we are committed to make a precise prediction of rail wear in order to guide wheel/rail profile optimization and rail grinding cycle making by introduced a numerical model in predict of rail wear along with the passing gross weight grow. Firstly, a wheel-rail wear model based on non-Hertzian rolling contact theory and the energy dissipation principle are carried out with the help of vehicle-rail coupling dynamics software and MATLAB fixed-point iteration. Then, the wheel-rail contact geometry was calculated and the development of wear area, wear depth distribution along with the passing gross weight grow was calculated. At last, for the purpose of verifying the accuracy of the model, a comparison between the calculated results and the measured value was made. As a result of analysis the relationship between wear and passing gross weight, the impact of wear on the rail/wheel geometry is summarized.
Keywords: Heavy haul rail; Rail wear; Passing gross weight; Non-Hertzian rolling contact theory; Energy dissipation principle; Wheel-rail contact geometry.

1 MODEL ESTABLISHMENT

1.1 ROLLING CONTACT MODEL

At present, There are two theories in wheel-rail rolling contact investigation: Hertzian rolling contact theory and non-Hertzian rolling contact theory. Both of the calculation method have great accuracy and high calculate speed. The Hertz theory assume the contact patch is oval and the size of spot size is decide by the radius of the curve. The distribution of the normal force is ellipsoid and the curve radius is constant. But the curvature radius of wheel-rail contact surface apparently changes when wear appeared. The Non-Hertzian Contact Theory use the wheel/rail normal spacing to calculate the wheel/rail contact issues, and is applicable to most rail type condition except two-point contact with different normal direction and conforming contact with curved surface. It is obvious that the non-Herztian is more suitable to our calculation.

Trace line method is used to solve the relationship of wheel-rail contact geometry. The CONTACT is written with non-Hertzian theory by Kalker. Though it is precise enough but not suitable for repeated interactive process in wear calculation. We developed a fixed point interaction program instead of CONTACT. As the wear grinds on, the wheel/rail tends to conforming contact. In the computation model, increase the number of computing units with the growth of contact patch area to ensure the calculation accuracy and improve the computing speed. The results of compared CONTACT outcome with our program value is shown in Tab 1.

Table 1. Comparison result with CONTACT

Project	Optimized program	CONTACT	Differ
Normal force peak(MPa)	1896	1920	1.3%
Longitude shear force peak(MPa)	384	362	6.1%
Lateral shear force peak (MPa)	52	55	5.5%
Longitude creep force(N)	10749	10530	2.1%
Lateral creep force(N)	1770	1757	0.7%
Torque of spin creepages(N·mm)	4607	4926	6.5%
Number of stick zone cells	105	104	1.0%
Number of Sliding area cells	27	28	3.6%
Number of noncontact area cells	36	36	0.0%

As is shown in Tab.1, the results are nearly the same, and the largest differ is about seven percent. It means our method for non-Hertzian contact is accurate enough and feasible.

1.2 RAIL WEAR MODEL

Rail wear is mainly composed of adhesives wear, abrasive wear, fatigue wear, corrosion wear and fretting wear. And abrasive wear and adhesive make up the bulk of rail wear. Only the abrasive wear and adhesive wear are considered in the model. The Archard wear model and energy dissipation model has been developed, both of them have high accuracy in solving rail wear issues, while the energy dissipation model take the effect of friction coefficient into consideration witch is seen as a large impact on rail wear. It is obvious that the energy dissipation model is more practical to calculate rail wear.

1.3 GENERY MODEL

Based on the analysis above, we use energy consumption model to estimate the total amount of wear with the help of fixed point iteration algorithm in MATLAB. Assume the contact region flat and ignore plastic deformation. Use the trace line method to analysis wheel-rail contact geometry and non-Hertzian rolling contact theory to get the relationship between rail wear and wheel-rail contact geometry with the change of wear. Thus the model was built and the relationship between wear and passing gross weigh was get. The simulation procedures are as follows:

1) Use multi-dynamic software package in modeling vehicle/rail interaction to analysis the interaction force and the creep forces/creepages of wheel/rail rolling contact.
2) Calculate the normal gap between wheel and rail with the track line method.
3) Perform wheel-rail rolling contact calculation to get friction power density with energy consumption model, then calculate the wear depth and position.
4) Work out the rail cross-section after wheel-rail wear.

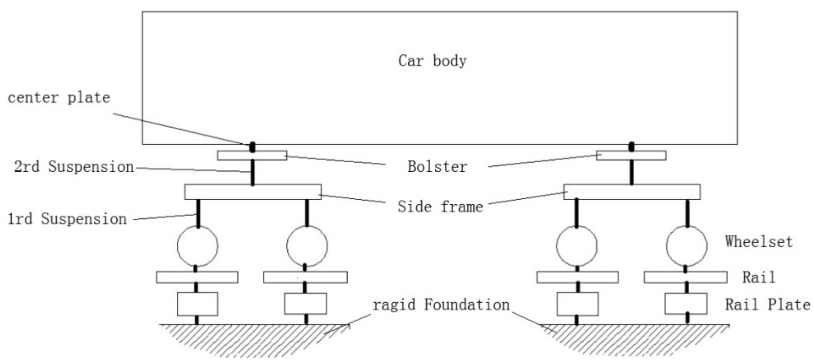

Figure 1. The topological structure of vehicle track model

2 CALCULATION RESULT

2.1 THE MODEL INPUT

The analysis example is C80 which is widely used in China. The curve is composed with straight line, transition curve, circular curve, transition curve and straight line. All of them are 200 meters long. The schematic diagram is as follows:

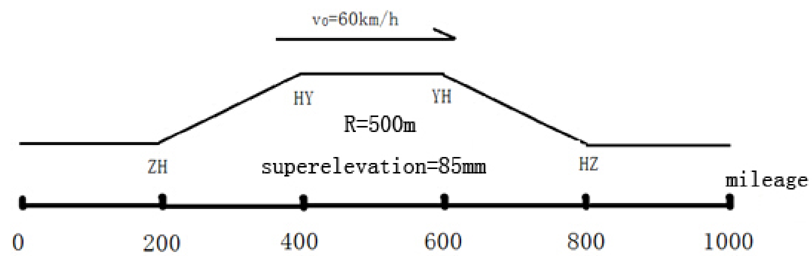

Figure 2. Rail curve schematic diagram of model

2.2 MODEL RESULT VERIFICATION

Comparison between results of numerical simulation and filed test to verify the correctness of the wear prediction. As we can see in Fig.3, the result of model is closed to the field test data except the inconsistent in the early stages. For the predicted results, the vertical wear of outer rail grows at a constant speed of 0.018mm/MGT. While the measured vertical wear grows rapidly at first, then gets steady at about 0.018mm/MGT until the passing gross weight reaches 30MGT. the decarburized layer on the surface of the new rail which is easily to wear and rail hardening phenomenon cause this to happen.

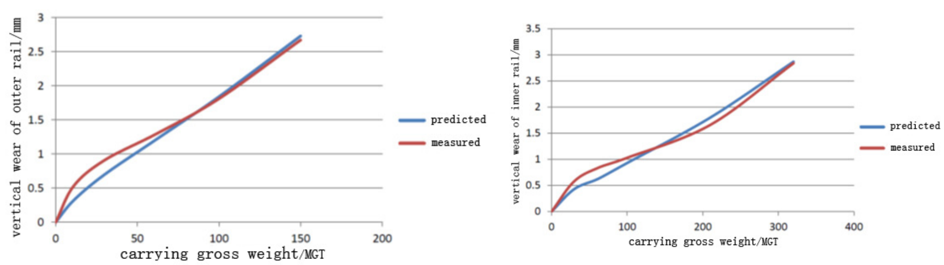

Figure 3. Model result verification outer/inner rail

2.3 WEAR AREA PREDICTION

Calculation was made to predict the rail profile change, and the chosen curve includes 30 observation points, the interval of adjacent point is 20 meter. The length of the chosen curve is 600 meters and consist of two transition curve and one circular curve. It is thought that the inner rail wear faster than the outer rail, so we reveal the wear area of the inner rail at 0-300MGT passing gross weight, and 0-150MGT of the outer one.

In Fig.4, we connect the thirty observation points with smooth curve to show the relationship between gross weight and wear area of both side of rail.

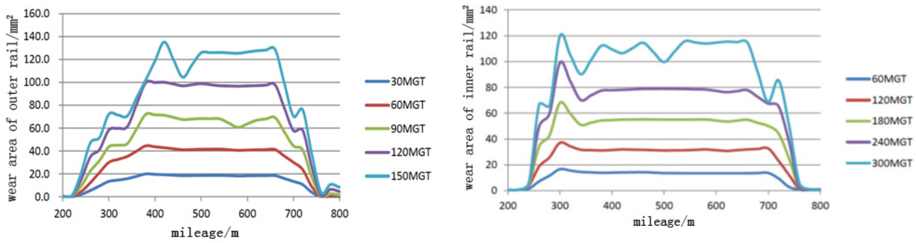

Figure 4. Predicted wear area along outer/inner rail

In the midpoint of the outer rail, the average wear area of the circular curves is about 40 percent larger than those on transition curves, while 20 percent of the inner rail. The results show positive correlation between wear area and curvature.

2.4 WEAR DEVELOPMENT ON MIDDLE POINT OF CURVE

According to the simulation results, in Fig.5, we illustrate the wear development on midpoint of rail profile The abscissa represents the arc length from wear prediction point to the center point of rail top and the working side as the negative direction

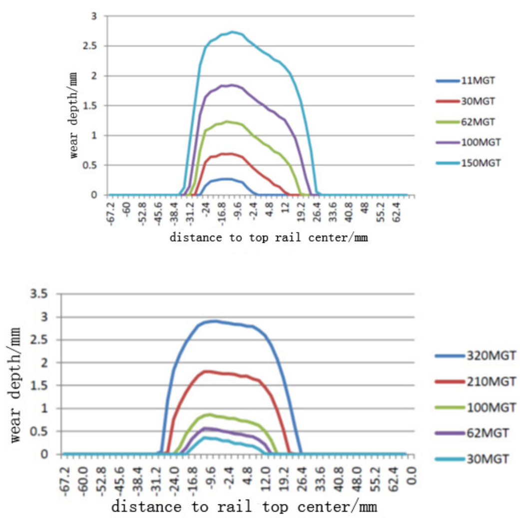

Figure 5. Abrasion loss on the midpoint of outer/inner rail

As shown in Fig.5, at the beginning, the wear area position ranges from -2mm to -23mm to rail top center, and then extends to both side of the rail top. The speed of wear zone growth on the working side is slower than the other side.

3 CONCLUSIONS

From the analysis above, our model successfully predict the relationship between rail wear and passing gross weight, which is precision enough when compared with field test data. In this model, we take profile change and the coefficient of friction into consideration and complete the calculation with high accuracy and speed. Side wear of rail and wheel wear can also be predicted. Comprehensively consider wheel-rail friction control, rail wear and grinding, a better wheel/rail maintenance and repair strategy can be established.

Influence of Axle Loads on Rail Wear in Heavy Haul Railways under Different Gross Tonnage

Xiaohui Sun; Yude Xu; Ruiying Chen; Ye Lu; and Kai Wei

The Key Laboratory of Road and Traffic Engineering, Tongji University, No. 4800, Caoan Highway, Jiading District, Shanghai 201804, China. E-mail: sxh1991@outlook.com

Abstract: In railway transportation, the rail wear decreases the sectional area, not only reduces the rail's strength, but also changes the wheel-rail contact geometric. Furthermore, rail wear affects the stability of the trains. This paper presents a rail wear prediction model. First, to know if the prediction model was credible, a circle curve center point rail wear was predicted and the results compared with the field measured value. Then, we predicted wear value under different axle loads and gross tonnages through the model. As the results shown: (1) Before the passed gross tonnage exceeds 30MGT, the wear depth increased significantly with the increase of axle load; (2) While the passed gross tonnage reached 60MGT or 90MGT, the wear depth under different axle load hasn't too much discrepancy; (3) As the gross tonnage continued to increase, reached 120MGT or 150MGT, the wear depth under 23t was the shallowest, while the wear under 21t and 25t were the same.

Keywords: Heavy haul railway; Rail wear prediction; Axle load; Gross tonnage.

1 Introduction

In China, high-speed and heavy load are the symbols of modern railway transportation. With the increase of velocity, axle load and traffic density, rail wear's increasing is inevitable. In railway transportation, the rail wear decreases the sectional area, not only reduces the rail's strength, but also changes the wheel-rail contact geometric. Furthermore, rail wear affects the stability of the trains. Analysis on the influence of axle load on rail wear contributes to perfecting the measure to reduce rail wear.

In this paper, a numerical wear prediction model was established. Then, the heavy haul rail wear was predicted through the model. Moreover, the prediction results were compared with the field measured value. At last, the rail wear under different conditions (axle load, gross tonnage) was predicted and the results were analyzed.

2 Wear Prediction Methodology

A wear prediction model consists of three main parts, (a) dynamics simulation of vehicle/track, (b) wheel/rail rolling contact analysis, (c) rail wear calculation. The wear prediction model general architecture is showed in Figure.1

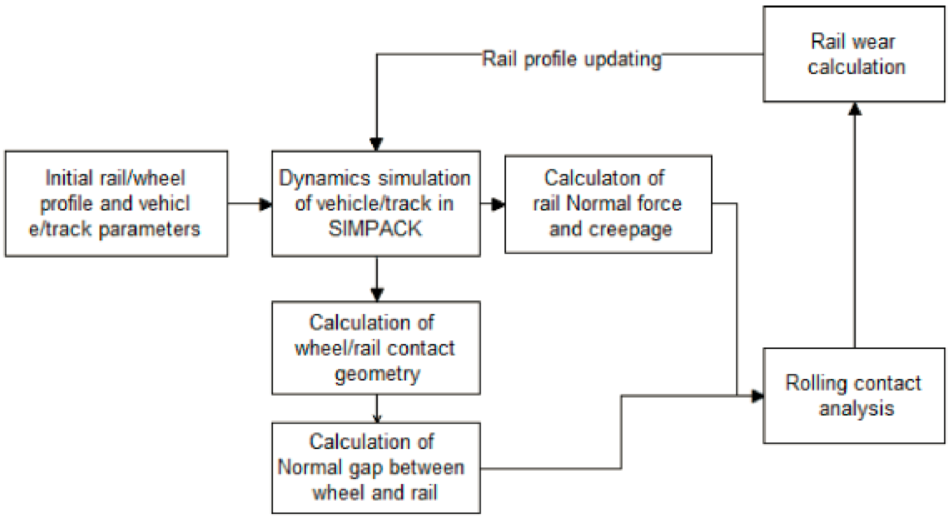

Figure 1. Process flow chart of wear prediction model

2.1 Dynamics Simulation of Vehicle/track

SIMPACK software was used to reproduce the dynamics of vehicle/ track. The vehicle model was simplified and consisted of three parts: car body, bogie and wheelset, and every part was rigid. The wheelset and the bogie were connected by primary suspension, while the car body and the bogie connected through the secondary suspension. The vehicle model in the SIMPACK is showed in Figure.2. The track model was simplified as slab track.

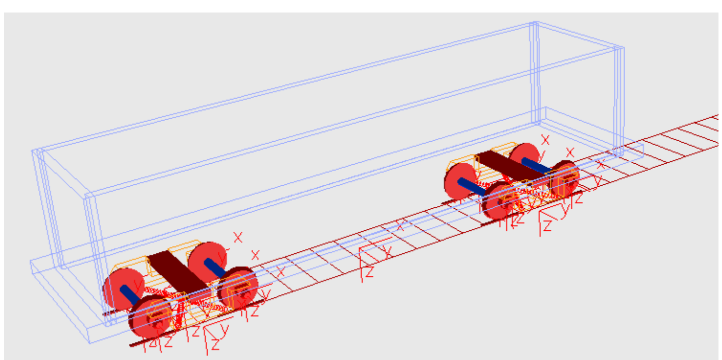

Figure 2. UIC gateway software architecture

2.2 Wheel/rail Rolling Contact Analysis

The rolling contact analysis was based on Kalker's three-dimensional elastic bodies rolling contact theory, which was very fit for wheel/rail contact analysis.

2.3 Rail Wear Calculation

Rail wear calculation was based on energy consume theory. The theory believes that wear value is proportional to the wheel/rail frictional work and inversely proportional to hardness.

2.4 Calculation Parameters of the Model

Considering that some other factors also have influence on wear value, some calculation parameters of the model are showed in Table.2.

Table 1. Calculation parameters of the model

	Calculation parameters	Value
Vehicle parameters	primary suspension longitudinal stiffness K_{px}	11MN/m
	primary suspension lateral stiffness K_{py}	13MN/m
	primary suspension vertical stiffness K_{pz}	160MN/m
	secondary suspension longitudinal stiffness K_{sx}	3MN/m
	secondary suspension lateral stiffness K_{sy}	3MN/m
	secondary suspension vertical stiffness K_{sz}	4MN/m
Track parameters	cushion layer vertical stiffness K_{bv}	187.5MN/m
	cushion layer vertical damping C_{bv}	0.03MN•s/m
	cushion layer lateral stiffness K_{bl}	39.2MN/m
	cushion layer lateral damping C_{bl}	0.04MN•s/m
	curve radius	500m
	curve superelevation	85mm
Other parameters	running speed	60Km/h
	coefficient of friction between wheel and rail	0.3

3 Wear Prediction Results and Analysis

3.1 Wear Model Valuation

To valuation the model, the wear circle curve center point which is severest was predicted. Our engineers measured the wear value in filed. The railhead midpoint wear value is showed in Table.1.

Table 2. Railhead midpoint wear value in circle curve center point

	High rail		Low rail	
gross tonnage /MGT	prediction value (mm)	measured value (mm)	prediction value (mm)	measured value (mm)
11	0.32	0.53	0.43	0.58
30	0.7	0.91	0.63	0.84
62	1.22	1.3	0.93	1.03
100	1.84	1.81	1.8	1.66
150	2.73	2.67	2.87	2.84

The prediction results and measured results were compared, shown in Figure.3 and Figure.4. The comparison showed that the prediction value was nearly consistent with the measured value, and the wear prediction model was credible.

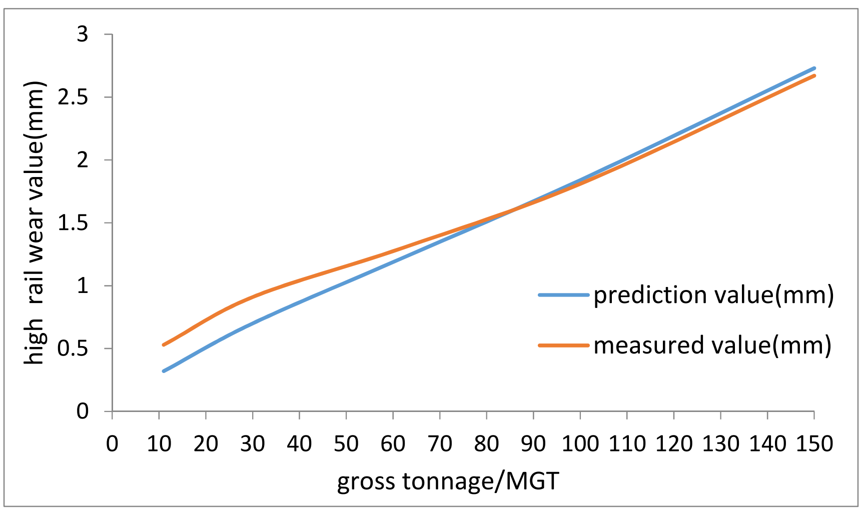

Figure 3. Railhead midpoint wear value comparison for high rail

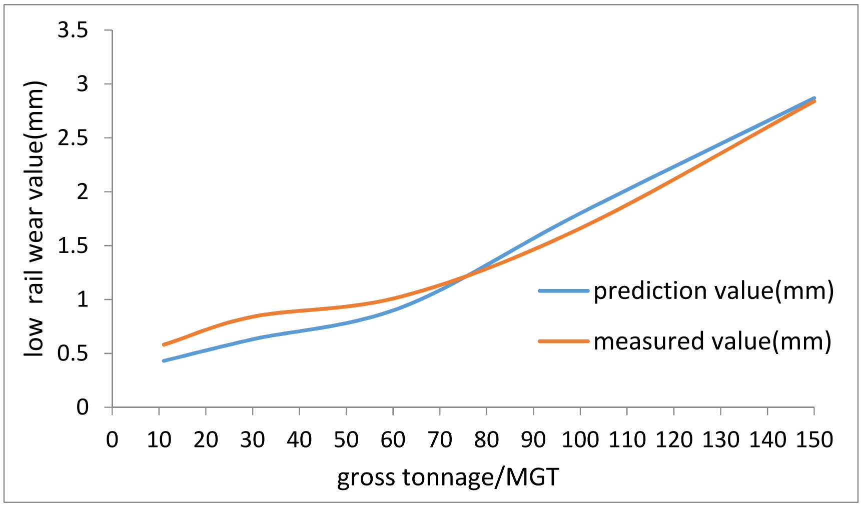

Figure 4. Railhead midpoint wear value comparison for low rail

3.2 Wear Prediction Results and Analysis

To know the influence of axle load under different gross tonnage, 21t, 23t, 25t axle loads were considered in the model. While the passed gross tonnage reaches 30MGT, 60MGT, 90MGT, 120MGT, 150MGT, wear of circle curve center point were calculated and the results were showed in Figure.5, Figure.6, Fiureg.7, Figure.8 and Figure.9 respectively.

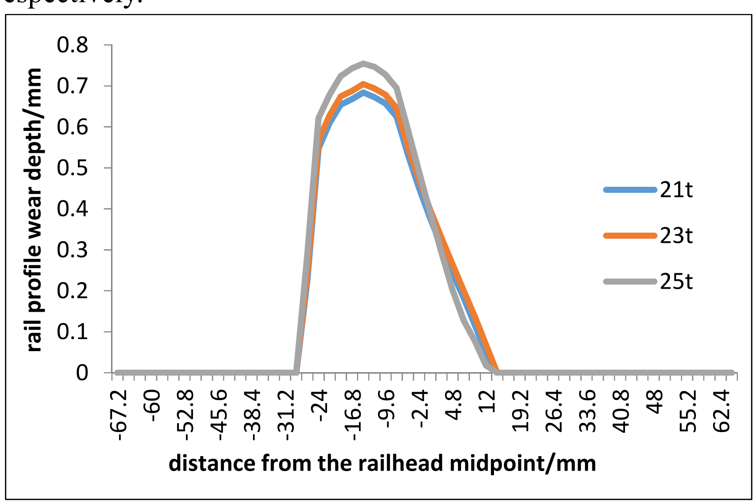

Figure 5. the rail profile wear while the gross tonnage reaches 30MGT

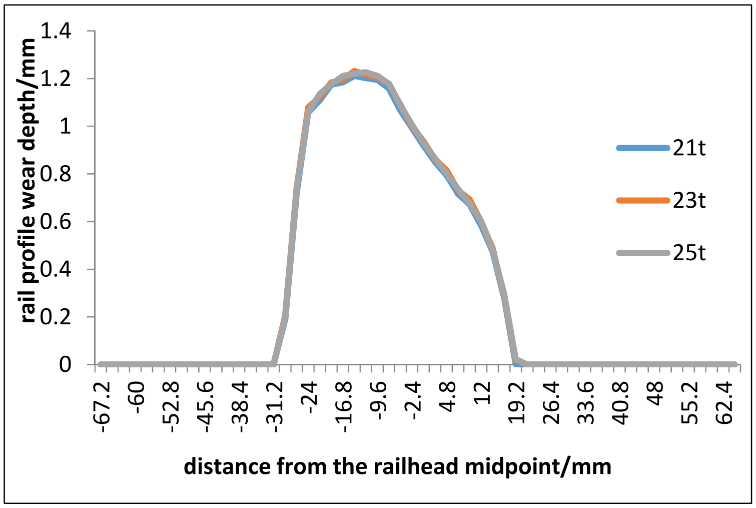

Figure 6. the rail profile wear while the gross tonnage reaches 60MGT

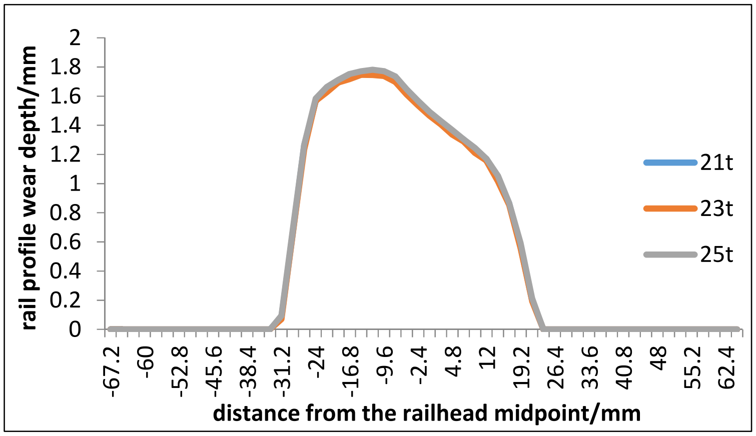

Figure 7. the rail profile wear while the gross tonnage reaches 90MGT

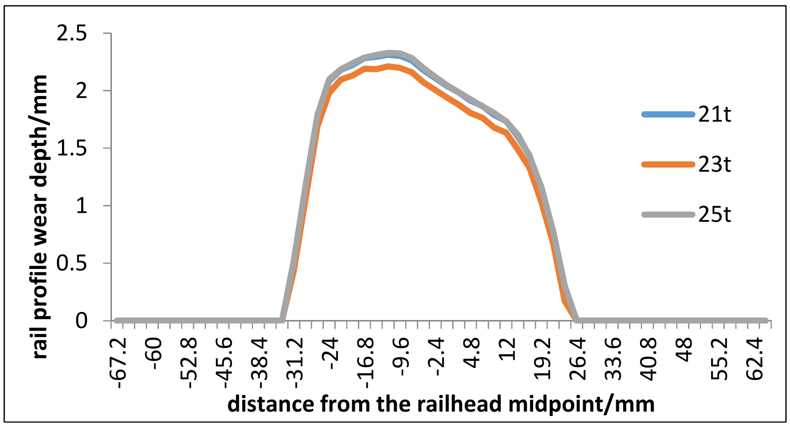

Figure 8. the rail profile wear while the gross tonnage reaches 120MGT

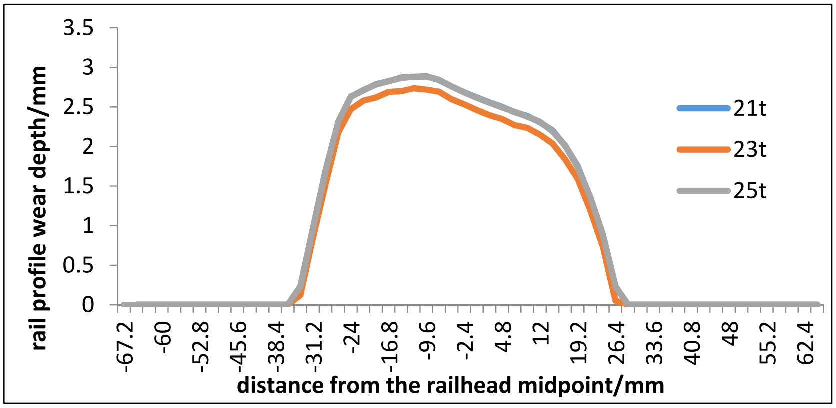

Figure 9. the rail profile wear while the gross tonnage reaches 150MGT

As the calculation results shown, before the passed gross tonnage exceeds 30MGT, as showed in Figure.5, in the left half of the rail head, the wear depth increased significantly with the increase of axle load. However, while the passed gross tonnage reached 60MGT or 90MGT, the wear depth under different axle load hasn't too much discrepancy as showed in Figure.6 and Figure.7. As the gross tonnage continued to increase, reached 120MGT or 150MGT as shown in Figure.8 and Figure.9, the wear depth under 23t was the shallowest, while the wear under 21t and 25t were the same.

4 Conclusions

In this paper, wear of a heavy haul railway circle curve center point were calculated under different conditions based on a wear prediction model. The results showed:

(1) Before the passed gross tonnage exceeds 30MGT, the wear depth increased significantly with the increase of axle load;

(2) While the passed gross tonnage reached 60MGT or 90MGT, the wear depth under different axle load hasn't too much discrepancy;

(3) As the gross tonnage continued to increase, reached 120MGT or 150MGT, the wear depth under 23t was the shallowest, while the wear under 21t and 25t were the same.

5 Recommendations for Future Research

In this paper, only three kinds of axle loads and five gross tonnages were considered. If there were more time, many conditions could be considered and calculated, and the results would be more enrich.

Abstract: Railway freight volume is an important index in railway transportation. This paper combined ARMA model with multivariate regression model to analyze the variables that affected the rail freight volume. Ten variables are selected as explanatory variables to study their relationship with rail freight volume. The results show that the rail freight volume is affected by many factors together and we also get the rail freight regression equation. Our results can provide the support for the traffic department to develop the transport plan.
Keywords: Rail freight volume; ARMA model; Regression analysis.

1.Introduction

Railway freight reflect the transport demand of various sectors of the government. It plays an important role in formulating the national and regional economic development plan. Prediction of railway freight has attracted a lot of interest by many researchers. Previous research on this area has been diverse. From an methodological standpoint, watched fractal theory(Lin,2005), rough set theory(Zhang,2007), neural network theory(Xie,2009 and Li,2003), the complex network theory(Li,2004) et.al have been used to forecast the volume of railway freight. As rail transport system is a complex system of uncertainty, rail freight affected by many factors, previous study mainly include the following three aspects: national economic factors(Zhao et.al,2004); transport system factors(Li,2004); policies and other factors(Li,2004; Zhao et.al,2004).

This paper takes advantage of the ARMA and regression analysis at the same time, which is bebeficial to overcome the lack of single method. We make use of rail freight data from China Statistical Yearbook to verify the validity of the model. And the results and conclusions can provide references for the development of railway transport development plan and to determine the operational decisions.

2.Rail freight factors analysis and data preprocessing

Factors affecting rail freight transport is very extensive and complex. This paper will divide the related factors that affected rail freight into two categories: external factors and internal factors. External factors refer to external factors that could affect the railway freight. such as gross domestic product, total fixed asset investment, the total freight of other means, express volume and total production of primary energy. Internal factors refer to rail freight competitiveness and attractiveness of their own. Such as national railway wagon ownership, national railway mileag, transit van residence time, freight train travel speed and truck turnaround time.

The factors affected railway freight transport can be expressed as Fig.1.

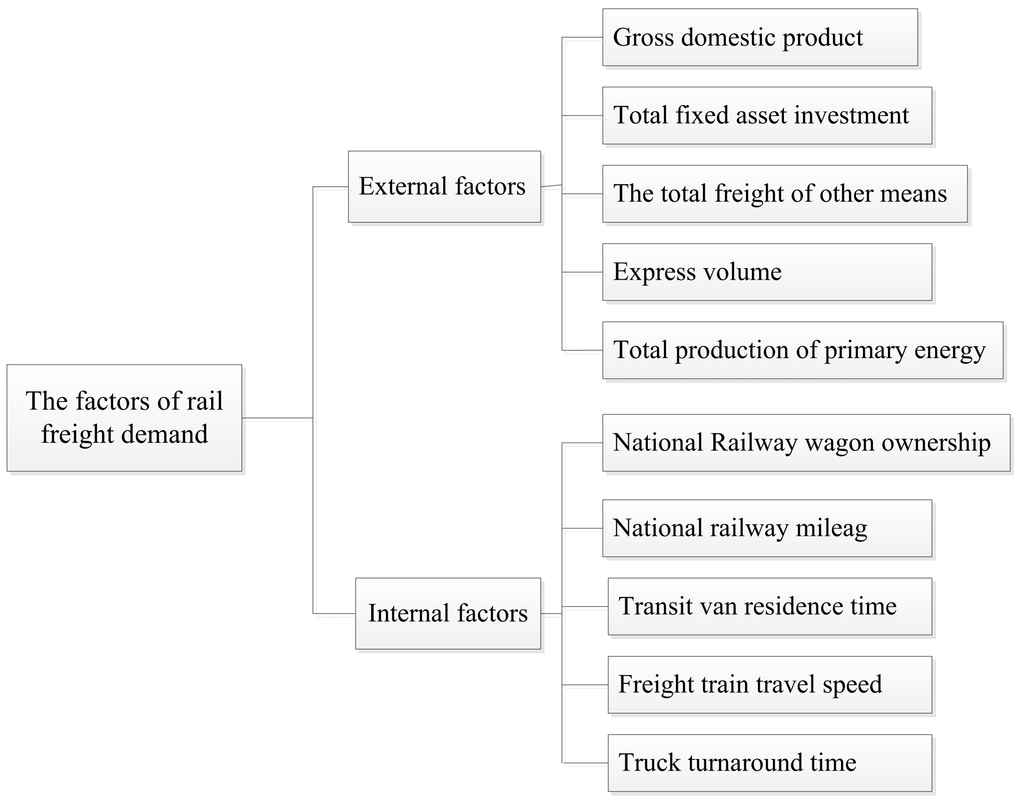

Figure1. The factors that affected rail freight volume

To facilitate the description, we give the following abbreviations of the related variables in Table 1.

Table 1. Abbreviations for variables

Symbol	Meaning	Units
X1	Gross domestic product	One hundred million yuan
X2	Total fixed asset investment	One hundred million yuan
X3	The total freight of other means	Ten thousand tons

X4	Express volume	Ten thousand tons
X5	Total production of primary energy	Ten thousand tons
X6	National Railway wagon ownership	Vehicles
X7	National railway mileag	Ten thousand km
X8	Transit van residence time	Hours
X9	Freight train travel speed	Km/h
X10	Truck turnaround time	Days
Y	Freight Volume of Railways	Ten thousand tons

In order to test the validity and usefulness of the method, we sort out rail freight data and its related factors data in China from 1998 to 2012 .fitting and testing the data use SPSS17.0 and R3.2.1, Explanatory variables includes 10 Variables and railway freight volume are selected as response variable. The raw data of factors and national rail freight data in Table 2. It is noted that all data in Table 2 come from "China Statistical Yearbook."

3. Method

In the statistical analysis of time series,autogressive-moving-average(ARMA) models provide a stationary stochastic process in terms of two polynomials, one for auto-regression(AR) and the other is moving average(MA).

The AR (p) model of order p is written:

$$X_t = c + \sum_{i=1}^{p} \varphi_i X_{t-i} + \varepsilon_t \quad (1)$$

Where $\varphi_1, \cdots, \varphi_p$ are parameters, c is a constant, ε_t is the random variable.

The MA(q)model of order q is written as

$$X_t = \mu + \varepsilon_t + \sum_{i=1}^{q} \theta_i \varepsilon_{t-i} \quad (2)$$

Where θ_i are parameters, μ is the expectation of X_t ,and ε_{t-i} are error terms.

The ARMA(p,q) model can be written as:

$$X_t = c + \varepsilon_t + \sum_{i=1}^{p} \varphi_i X_{t-i} + \sum_{i=1}^{q} \theta_i \varepsilon_{t-i} \quad (3)$$

Regression analysis is a statistical method to determine between two or more quantitative variables interdependent relationships. Specifically, the regression analysis is Variables determined by the provisions of the causal relationship between variables, regression model, and based on the measured data to solve the various parameters of the model, and then evaluate whether the regression model can fit the measured data; can be a good fit if you can predict based on the argument further. The specific steps of regression analysis are as follows:

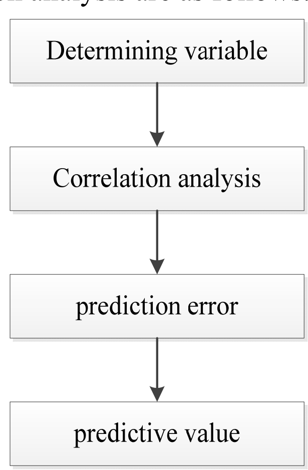

Figure 2. Steps of regression analysis

4. Results and analysis

Correlation analysis is first conducted, the results are listed in table 3, most variables have strong relationship with railway freight volume Y, and their Zero-order correlations more than o.8 basically, X_8 and X_9 have weak relationship with Y. The relationship of $X_1, \cdots, X_{10}$ with Y are presented in Table.3.

Table 3 The correlation coefficient of X with Y

	Zero-order correlations	Partial correlation		Zero-order correlations	Partial correlation
X1	.965	.904	X6	.992	.251
X2	.942	-.212	X7	.989	.524
X3	.946	-.709	X8	-.411	-.696
X4	.833	.116	X9	.069	-.368
X5	.994	.399	X10	-.908	-.469

Despite the influence of each variable on the rail freight are different, all these variables have an impact on cargo sizes. In order to learn the trend of the railway freight volume and factors, we use ARMA model to analyze the data. As the raw data have a different dimension, we first conduct logarithmic transformation for the raw data, the trend figure of the transformed data can be see in Fig.3.

It can be seen from Fig.3 that X_4 have the maximum fluctuation in all variables, as X_4 refer to express volume, in 2007, the internet experienced rapid development, which leads to a larger growth of express volume.

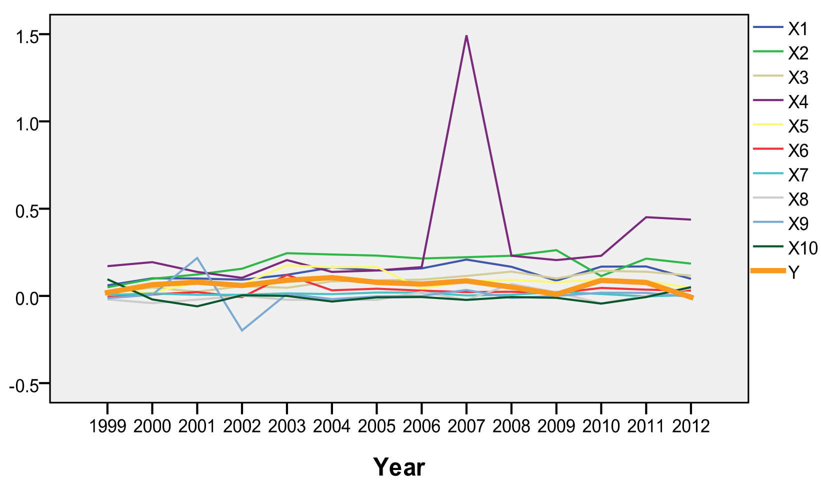

Figure 3. The trend of variables

Furthermore, we make use of R to achieve the order of the regression equation, the Fig.4 are the trend and stationary of the railway freight volume from 1998 to 2012, it shows that the rail freight volume experienced a relatively high growth in 2001, and its value back to its previous level in 2002. Overall, the growth of railway freight volume is very slow.

Figure.4 The trend of rail freight and the first order differential of rail freight

Then we can make multiple regression analysis for the explanatory variables and the response variable, the anova of the model is presented in Table 4, it shows that regression analysis for these variables are statistically significant.

Table 4 ANOVA of variables

Model	SS	df	MS	F	Sig.
Regression	9.115E10	10	9.115E9	703.686	.000
residual	5.181E7	4	1.295E7		
sum	9.120E10	14			

Table 5 Multiple regression model

	Coefficients	Std. Error	t Stat	Sig.
Intercept	95549.834	266494.642	.359	.738
X1	.895	.212	4.219	.013
X2	-.148	.342	-.434	.686
X3	-.100	.050	-2.009	.115
X4	.016	.070	.234	.826
X5	.184	.212	.869	.434
X6	.076	.146	.519	.631
X7	42935.468	34935.680	1.229	.286
X8	-26315.700	13568.263	-1.940	.124

X9	-524.832	663.183	-.791	.473
X10	-9804.594	9231.805	-1.062	.348

The results of regression analysis are presented in Table 5, we can write out the multiple regression equation as follows. And we can use this equation to analysis the relationship between Y with X_i ($i = 1, \cdots, 10$).

$$\begin{aligned} Y = 95549.834 + 0.895X_1 - 0.148X_2 - X_3 + 0.16X_4 + 0.184X_5 + 0.076X_6 \\ + 42935.468X_7 - 26315.700X_8 - 524.832X_9 - 9804.594\ X_{10} \end{aligned} \quad (4)$$

From regression equation (4), we could know that Y have positive correlation with X_1, X_4, X_5, X_6, X_7, Y have negative correlation with X_2, X_3, X_8, X_9, X_{10}. And regression equation (4) can be used to predict the short term rail freight volume if we know $X_1, \cdots, X_{10}$

5.Conclusions

Railway freight volume analysis play a fundamental role in making freight traffic plan. This paper analyzed the influence factors on rail freight volume based on ARMA model with multivariate regression model, we get the regression equation that characterized the relationship between rail freight volume and ten selected indicators. we found that rail freight volume is affected by many factors together, and gross domestic product produce a vital role on rail freight volume. For one hand, our results can be used to analysis how the ten selected variables influence the rail freight volume. For another, the regression equation can be used to predict the short term rail freight volume. In the future, we can combine the time series method with the machine learning method to analyze this question.

Abstract: Adaptability of high-speed passenger transport products is assessed from the service level and market competitiveness. Index system of service level is established and grey comprehensive evaluation method is used to calculate the service level of Wuhan-Guangzhou high-speed line. Sharing rate of high-speed railway is calculated by non-disaggregate model, and analyzed the influence of fares and travel time on the sharing rate. It is concluded transport enterprises should design products based on demand of market and itself, and then discount fares and adjust travel time to improve adaptability of high-speed passenger transport products.

Keywords: High-speed railway; Adaptability; Service level; Sharing rate.

Introduction

With the development of high-speed railway, railway transport capacity is released, and it creates conditions for improving high-speed railway services. Passenger channel gradually formed in some economically developed cities, in which high speed railway, ordinary railway, highway and other transportation ways compete with each other (BaoJingjing, 2012). Transportation market competition is becoming increasingly fierce, high-speed railway transport enterprise must evaluate on existing products, then design and optimize the transportation service to provide high quality products, which can help maximize attract traffic and strengthen the competitiveness in the transport market. Based on this, this paper firstly analyzes the internal service characteristics of high-speed railway transportation product, and calculates the share rate of high speed railway; then based on demand, paper evaluates the product from the high-speed rail competition in the transport market to analyze the suitability of high-speed railway product (Liu Dongfei, 2013).

1 Measurement index system of service level

Service level of high-speed railway transportation product reflects the extent to meet the transportation needs. The evaluation index system of service level of transportation product is shown in the figure below:

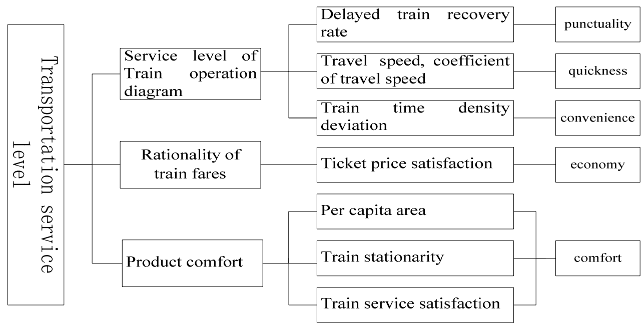

Figure 1.Evaluation index of transportation service level

1.1 Service level of train operation diagram

Service level of train diagram includes recovery rate of late trains, travel speed, coefficient of travel speed and deviation of train time-density.

Recovery rate of delayed trainrefers to the ratio of late trainsthat can be restored punctuality of total delayed trains by setting buffer time in train diagram, under the conditions of certain capacity utilization and probability distribution of delayed time.

Travel speed is referred to the average speed of train running in the segment, including stop time in intermediate stationsand additional time of start-stop. Coefficient of travel speed is the ratio of the average travel speed of running speed, which reflects the reduction degree resulted bytrain stopping on the way.

Train time density deviation R is to contrast passenger travel time preference and statistics of departuretrains from train schedules in different periods, and measures the matching degree between train departure time and passenger travel time preference.

1.2 Rationality of train fares

Economy mainly depends on the level of high-speed railway freight rate, and freight rate levels associate with income, transportation costs and competitive factors. This paper selects fares satisfaction to measure the rationality of train, it reflects satisfaction of passengerson fares from the passengers'point of view.

1.3 Product comfort

Product comfort refers to the comfort level of passengers perceived on the train, and decided by the per capita area, operation stability and to train service satisfaction.

Per capita area is calculated depending on the type of emu, and refers to the ratio of the area passengers can useof the train capacity.Running stability N is subjective feelings of passengers on the magnitude and frequency of train vibration.

Train service satisfaction refers to all the passengers' satisfaction on the train service, that will begetaccording to the questionnaire statistical analysis.

1.4 Classification standard of evaluation index

The indexes will be divided into five grades in order to get a unified evaluation results, A grade (5 points) is the best, class B (4 points) is second, and so on, each level corresponds to a certain range of parameter values. Specifically, the classification standard of each index is shown in table 1.

Table 1.The evaluation index system and grading standard

Rule layer	Index layer	A/5	B/4	C/3	D/2	E/1
punctuality	Recovery rate	≥0.95	[0.9,0.95)	[0.85,0.9)	[0.8,0.85)	<0.8
quickness	Travel speed	[240,300)	[200,240)	[160,200)	[120,160)	<120
	Coefficient of travel speed	[0.85,0.9]	[0.8,0.85) (0.9,0.95]	[0.7,0.8) >0.95	[0.6,0.7)	<0.6
economy	Fare satisfaction	≥0.9	[0.8,0.9)	[0.7,0.8)	[0.6,0.7)	<0.6
comfort	Per capita area	≥1	[0.8,1)	[0.6,0.8)	(0.3,0.6)	≤0.3
	Train stationarity	≤1	(1,2]	(2,4]	(4,5]	>5
	Service satisfaction	≥0.9	[0.8,0.9)	[0.7,0.8)	[0.6,0.7)	<0.6
convenience	Train time density deviation	≤0.2	(0.2,0.4]	(0.4,0.6]	(0.6,0.8]	>0.8

1.5 Evaluation results and conclusions

On the basis of operation data of Wuhan-Guangzhou high-speed line and passenger questionnaire survey, the calculated results and service levels of each index is determined. We issued 2000 questionnaires by face-to-face form, and effective rate is 88.2% According to passenger preference for the transport product quality, we judge the relative importance ofevaluation indexes and construct judgment matrix by Analytic Hierarchy Process, then the weights for each indicator is shown in table 2.

Table 2.Evaluation index calculation results and the weight

Rule layer	Weight	Index layer	Results	Level	Level 2 weight	Level 1 weight	Rating
punctuality	0.081	Delayed train recovery rate	0.96	A/5	0.5	0.041	5/A
quickness	0.220	Travel speed	246.3	A/5	0.67	0.147	5/A
		Coefficient of travel speed	0.852	A/5	0.33	0.073	
economy	0.116	Ticketpricesatisfaction	0.29	E/1	0.34	0.040	1/E
comfort	0.158	Per capita area	1.03	A/5	0.33	0.052	4.33/ A-B
		Train stationarity	1.19	B/4	0.33	0.052	
		Train service satisfaction	0.86	B/4	0.34	0.054	
Convenience	0.200	Train time density deviation	0.44	C/3	1	0.200	3/C

The service level evaluation result is 3.67 through grey comprehensive evaluation method based on the above results.Therefore, the service level of high-speed transportation supply in the Wu-Guang channel is between B and C grade. Among them, quickness, punctuality belongs to grade A, comfort is between class A and class B, convenience belongs to class C, and economy belongs to E grade.

Following conclusions are get: 1) Increasing the speed of train travel can make high-speed railwaymore attractive; 2) The level of high-speed railway train service process needs to be improved; 3) Train time density deviation degree is higher and should be adjusted to improve the convenience; 4) Passenger considerfares high because of fare mechanism not flexible enough. So this paper will analyze the suitability of high-speed railway passenger transport products on the basis of fares.

2 Calculation on sharing rate of high-speed railway

Based on analysis and evaluation on internal service properties of high speed railway transportation product, the market share in the channel still need to be calculated to analyze high-speed rail products adaptability from the perspective of the competition with other modes. Logit model is one of the most commonly used model of non-disaggregate model, paper will use it (Wu Wenxian, 2011).

2.1Selection and calibration of characteristic variables

According to the results of existing research and software, this paper finally choose income, travel time and cost as characteristic variables of linear utility function, specific calibration method is as follows.

The income level determines on the travel consumption desireto a certain extent, there are significant differences in main factors considered by different passengers when choosing the mode of transportation, the feature variables can be directly obtained from the questionnaire. This questionnaire takes monthly income of 4,000 or less as low-income groups; monthly income between 4000 and 8000 for income levels; monthly income of more than 8000 as high-income people.

Travel time is generally defined as passengers' travel timein transit, and is calculated as follows:

$$T_n^i = \frac{L_{od}^i}{V_i} + 2t_{nd}^i + t_{ns}^i + t_{nx}^i + t_{nw}^i \quad (1)$$

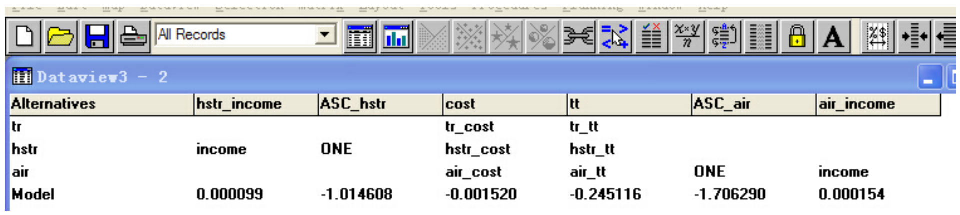
In the formula, t_{nd}^i —time needed of traveler n choose the mode i to arrive/depart the station ; t_{ns}^i 、 t_{nx}^i 、 t_{nw}^i —time required to get on、get off and wait; L_{od}^i —distance of i way; V_i —average speed of i mode of transportation.

Travel cost is determined through fare rate multiplied by the distance between each OD.Quantitative values of characteristic variables are listed in the table below.

Table 3.Service parameters of transportationmodewithinWuhan-Guangzhou channel

The mode of transportation	Operating range（km）	Freight rate （Yuan/km）	average time of city traffic（h）	average waiting time（h）
High speed train	1069	0.45	0.96（Guangzhou） 0.96（Wuhan）	0.83
Train	1069	0.16	0.46（Guangzhou） 0.60（Wuhan）	1
Air	873	0.762	1.56（Guangzhou） 1.56（Wuhan）	1.5

To model parameters are calibrated by Transcad:



Alternatives	hstr_income	ASC_hstr	cost	tt	ASC_air	air_income
tr			tr_cost	tr_tt		
hstr	income	ONE	hstr_cost	hstr_tt		
air			air_cost	air_tt	ONE	income
Model	0.000099	-1.014608	-0.001520	-0.245116	-1.706290	0.000154

Figure 2 Results of parameters calibration

Combined with average time-consuming of urban passenger traffic in cities along Wuhan-Guangzhou railway, the utility function formis shown.

$$V_{tr} = -0.001520C - 0.245116T \quad V_{hstr} = -0.001520C - 0.245116T + 0.000099inc - 1.014608 \quad V_{air} = -0.001520C - 0.245116T + 0.000154inc - 1.706290$$

In the formula, C—travel cost; T—travel time; inc—the income.

The sharing rate of existing railway, high-speed passenger railway and air three ways is shown in the table below:

Table 4.Passenger transport sharing rate of differentways in the channel

interval / mode	Wuhan-Guangzhou	Wuhan-Changsha
Train	26.92%	48.57%
Hs train	49.91%	35.86%
Air	23.17%	15.57%

For Wuhan-Guangzhou channel, railway has higher market share, which reached more than 70%.Sharing rate of high-speed railway and air passenger transport is relatively low because the distance is short and time advantage is not obvious.

2.2 Influence of high-speed railway fares on passenger sharing rate

Research about influences of high-speed railway fares on passenger sharing rate provides the basis forestablishing reasonable fares and improving the market competitiveness of high-speed railway products.

Here take Wuhan - Guangzhou section as an example,study the effects of fare for the sharing rate, the specific results as shown in the figure in figure 3.

For Wuhan-Guangzhou segment, price elasticity of share rate among income groups is a constant, with a mean of 3.36×10^{-4}.The fare is lower, the greater the share rate is.Therefore,transport companies want to increase the sharing rate of high speed railway, they can make a certain degree of reduction of ticket pricesaccording to different income groups.

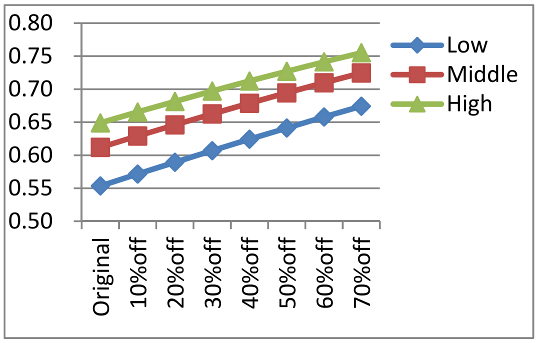


Figure 3.The influence of high-speed rail fares

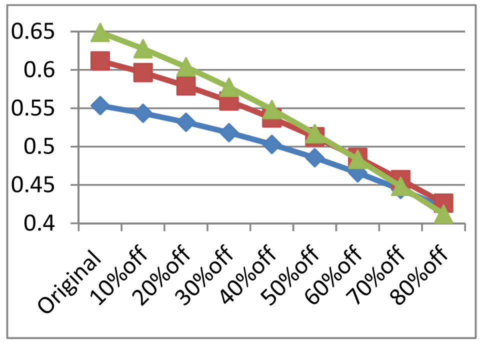

Figure 4. The influence of air fares

Air fare is lower,the sharing rate of high-speed rail is lower. Sensitivity change of income groups to air fares is not big;high-income people have greater susceptibility to airline fares; and when the air ticket discount gets to a certain degree, the sharing rate of different groups is basically the same. When air fareis down, high-speed railway transport enterprises can also make a certain degree of reductionaccording to the specific situation; when high-speed fares and air fares changes at the same time, sharing rate of high-speed railway change as shown in figure5.

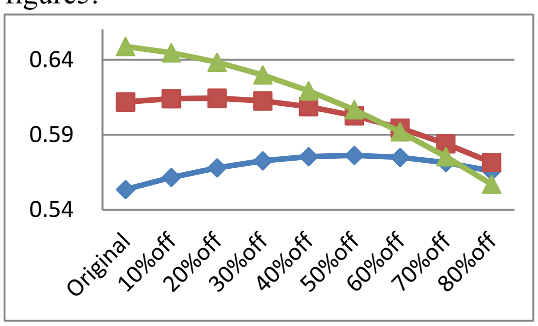

Figure 5.Influence of high-speed rail and air fares

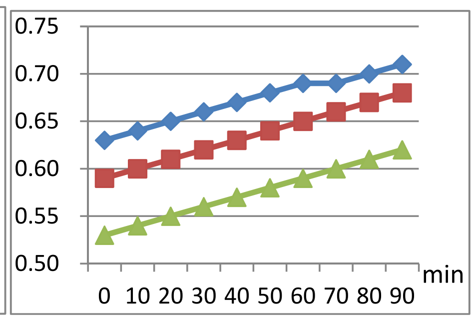

Figure 6. The influence of travel time

From the foregoing: 1) High-speed railway and air ticket prices fall at the same time, the sharing rate of high income and middle income groupsis on the decline. The sharing rate of low-income groupsrise first with ticket prices down, then itrises no longer when fare discount is 5 fold, if discount continues high-speed railway sharing rate willedcrease; 2) High income passengers have higher sensitivity to the high-speed rail and air fares.

Currently, fares developing of various modes of transport should be well adapted to the market mechanism and make different price strategy according to different consumer groups. Enterprises should raise the ticket prices of high and intermediate grade groups andreduce fares of ordinary seats at the same time; take fare difference between high and intermediateseats to compensate fares of ordinary seats.

2.3 Influence of travel time on sharing rate

Studying the influence of travel time on sharing rate can provide technical basis for designing high-speed railway transportation products and increasing the amount of visitors attracted. It can be seen from figure 6.

(1) The sensitivity of travel time to the sharing rate basically remains unchanged. Compared withthe average of price elasticity above, travel time has greater impact on the sharing ratethan the fares;

(2) High-speed sharing rate shows a trend of gradually increasing with the shortened travel time;

(3) According to the needs of enterprise itself and passengers to design high-speed passenger rail products and make a certain compression on running time, such as raising speed, which can help to improve the market competitiveness.

3 Conclusion

This paper set up index system of service level from the supply service level of railway transportation and market share; and then conducts a preliminary assessment on service level of high-speed products. Finally, it calculates the sharing rate of high-speed through non-disaggregate model, andadaptability of high-speed passenger rail products is evaluatedfrom the angle of market competitiveness. Conclusion is transport enterprisecan make a certain degree of price discounts and compress travel time according to specific market demand and the needs of itself.Based on characteristics of passengers' choice behavior, enterprise can design different products to meet the demand of passengers, improve the adaptability of the high-speed railway transportation products, and make the high speed railway transport enterprise has a stronger market competitiveness.

Abstract: Based on the multi-body dynamics software SIMPACK, a vehicle-track dynamics model on heavy haul railway is established. And effects of curve radius and superelevation on wheel-rail dynamics performance are analyzed by the model. The results show that wheel-rail dynamics performance is improved with the increase of curve radius of heavy haul railway, but it is improved to a lesser extent when curve radius is over 800 m. And wheel-rail dynamics performance will be decreased when the superelevation on curve is excessive or inadequate. So deficient superelevation is advantageous for improving the wheel-rail dynamics performance and the reasonable superelevation is recommended to decrease 5% to 10% of balanced superelevation.

Keywords: Curve radius; Superelevation; Wheel-rail dynamics performance; Heavy haul railway.

1 Introduction

With the development of heavy haul railway and the increase of axle load and density of heavy haul train, dynamic interaction will further enlarge between wheel and rail. More factors affect wheel-rail dynamic characteristics and there are many domestic and foreign scholars have done a lot of research on this. The effect of track stiffness on vehicle vibration is investigated by means of the theoretical method of vehicle-track coupling dynamics (ZHAI Wanming, 2000). And the impact of suspension parameters of heavy haul train on wheel-rail dynamic performance is analyzed and the lower suspension wheel-rail dynamic interaction purposes can be achieved by optimizing parameters (HAO Jianhua, 2005; WANG Kongming, 2005; YANG Chunlei, 2011). The impact of mutations on the high-speed vehicles fastener stiffness and dynamic characteristics of the track is calculated and analyzed considering different fastener stiffness mutation conditions (LIU Xueyi, 2014). Although scholars analyze the influence of different factors on wheel-rail dynamic characteristics from multiple angles, the depth analysis of relationship between railway line parameters and wheel-rail dynamic characteristics is not much from the point of railway line design. So the paper will study effects of curve parameters such as curve radius and superelevation on wheel-rail dynamic characteristics of heavy haul railway and the theoretical basis is provided for improving wheel-rail dynamics performance in railway line design.

2 Calculation model and evaluation index

A dynamics simulation model of vehicle/track system in heavy haul railway curves is made by SIMPACK. The 30t axle vehicle model is used, including rigid bodies of one body, two bolsters, four side frames, four wheelsets and so on. And many principal nonlinear factors on vehicle system are considered. The DOFs of vehicle dynamics model were 60, as shown in Table 1. The vertical and lateral DOFs of rails and the integral vertical stiffness, damping of track as well as the integral lateral stiffness, damping of track are considered in the dynamics model. In the simulation model, LM tread and 75kg/m rail of China are used. In order to study the influence of single factor of railway curves on the wheel-rail dynamic characteristics of heavy haul railway, the track irregularity is out of consideration.

Table 1. The DOFs of vehicle dynamics model

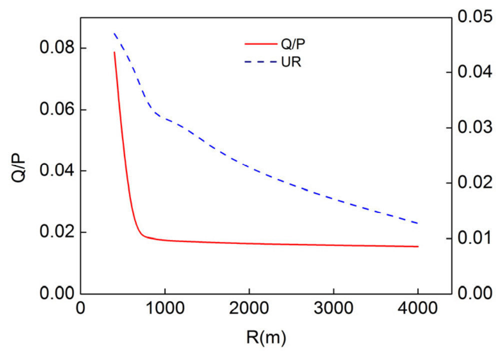
Rigid bodies	Longitudinal movement	Lateral movement	Vertical movement	Anti-roll	Pitch	Yaw	remark
Car-body	x_c	y_c	z_c	α_c	β_c	γ_c	—
Bolster	—	—	z_{bj}	α_{bj}	—	γ_{bj}	j=2
Side frame	x_{tj}	y_{tj}	z_{tj}	α_{tj}	β_{tj}	γ_{tj}	j=4
Wheelset	x_{wj}	y_{wj}	z_{wj}	α_{wj}	β_{wj}	γ_{wj}	j=4

The traditional evaluation methods (ZHAI Wanming, 2007) are used in the evaluation of the wheel-rail dynamic characteristics of heavy haul railway system. The main evaluation indexes include derailment coefficient, wheel unloading rate, lateral wheel-rail force, vertical wheel-rail force and wheel-rail wear index.

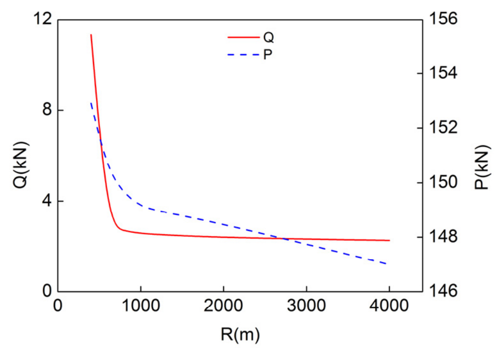
3 Results and Discussion

3.1 Influence of curve radius on wheel-rail dynamic characteristics

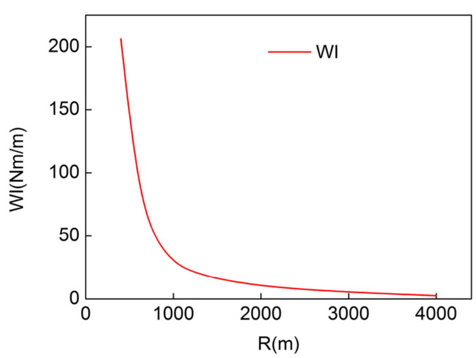
When calculating the speed of heavy vehicle on curve is 60km/h and seven kinds of operating conditions are considered according to 400 m and 600 m, 800 m, 1000 m, 1200 m and 2000 m and 4000 m on curve radius (R). And all curves of superelevation adopt balanced superelevation. Figure 1 shows influence law of wheel-rail dynamic responses in the condition of different curve radius, including derailment coefficient (Q/P), wheel unloading rate (UR), lateral wheel-rail force (Q), vertical wheel-rail force (P) and wheel-rail wear index (WI).



(a) Q/P and UR



(b) Q and P



(c) WI

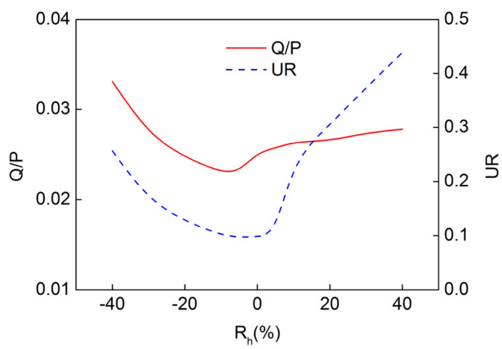
Figure 1. Influence of curve radius on wheel-rail dynamic performance

Figure 1 shows that wheel-rail dynamics performance is improved with the increase of curve radius of heavy haul railway and the values of Q/P, UR, Q, P and WI are decreased by 80.3%, 73%, 80.1%, 3.9%, 98.7% when the curve radius is increased from 400m to 4000m. The influence on wheel-rail wear index is maximum while influence on vertical wheel-rail force is minimum with change of curve radius.

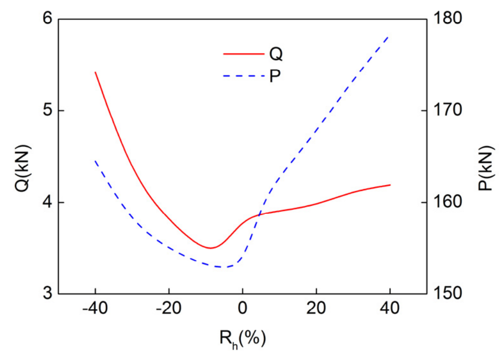
And the curve radius is less than 800m, the wheel rail dynamics performance decreases obviously with decreasing curve radius. But the curve radius is more than 800 m, they increase slower with the growth of curve radius. Therefore, curve radius should be adopted more than 800 m as far as possible in the design of heavy haul railway in order to reduce dynamic interaction between wheel and rail.

3.2 Influence of superelevation on wheel-rail dynamic characteristics

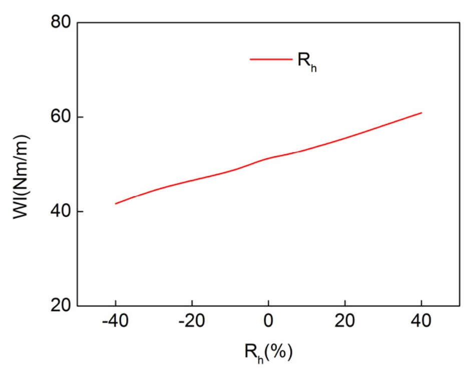
When calculating the speed of heavy vehicle on curve is 80km/h and curve radius is 800m. Superelevation value is used by superelevation change rate (R_h) that is the ratio of difference value between actual superelevation and balanced superelevation and balanced superelevation. And the range of R_h is -40%~40%. Figure 2 shows influence law of wheel-rail dynamic responses in the condition of different R_h.



(a) Q/P and UR



(b) Q and P



(c) WI

Figure 2. Influence of superelevation on wheel-rail dynamic performance

Figure 2 shows that WI grows but Q/P, UR, Q and P decrease after increasing with the increase of curve superelevation. Compared to the maximum value of dynamic response on balanced superelevation (i.e., superelevation change rate is 0), the values of Q/P, UR, Q and P increase respectively by 31.3%, 161.9%, 42.5%, 7.4% when superelevation change rate is -40%, but WI decreased 18.9%.When the superelevation change rate is 40%, the values of Q/P, UR, Q, P and WI rise respectively 10.3%, 348.7%, 10.2%, 16.5%, 18.5%. Also we can see from Figure 2 that the values of evaluation indexes except WI on wheel-rail dynamics performance will be decreased when the superelevation on curve is excessive or inadequate. And when R_h is in the -5%~-10% range, the values of Q/P, UR, Q and P reached the minimum and the largest decreasing range respectively is 30.5%, 62.6%, 36.4%, 7.1%. Therefore, the reasonable superelevation is recommended to decrease 5%~10% of balanced superelevation and deficient superelevation helps to reduce the dynamic wheel-rail interaction.

4 Conclusions

The following conclusions can be drawn from the study.

(1)When the curve radius of heavy haul railway is less than 800 m, the wheel-rail dynamics performance decrease greatly with decrease of radius curve, but the wheel-rail dynamics performance increase with a small range when the radius is more than 800 m. And the curve radius of more than 800m should be used to effectively reduce the wheel rail interaction in the design of heavy haul railway.

(2)The wheel-rail dynamics performance will be decreased when the superelevation on curve is excessive or inadequate. And it is small deficient superelevation, the better wheel-rail dynamic performance can obtain. And the reasonable superelevation of heavy haul railway is recommended for 90%~95% of balanced superelevation.

(3) It is shown through the analysis that the wheel-rail dynamics performance of heavy haul railway is enhanced accordingly with the improvement of heavy haul train speed. But the influence law of curve parameters of heavy haul railway on wheel-rail dynamic characteristics is similar under the condition of different train speed. So only calculation results for the train speed of 60 km/h are given in this paper.

(4)The curve parameters of heavy haul railway have a large influence on the wheel-rail dynamic characteristics. Only the relationship between single parameter of railway curve and wheel-rail dynamic characteristics is analyzed in the paper. Main parameters of railway curve can be matched reasonably to further improve the wheel-rail dynamic performance in the design.

Analysis of Effect Parameters of Track Settlement in Heavy Haul Railways

Jianfeng Shen[1]; Yude Xu; Haifeng Li; Qing He; and Ye Lu

Key Laboratory of Road and Traffic Engineering, Ministry of Education, Tongji University, Shanghai 201804, China. [1]E-mail: 463694958@qq.com

Abstract: Ballast bed in heavy haul railway will accumulate residual deformation and lead to track accumulative settlement under the repeatedly influence of the dynamic load of train. Studying on rule LU Ye s of track settlement of heavy haul railway is the premise of variant design and maintenance management, the effects of transportation conditions and track structure parameters on ballast settlement were analyzed by improving the existing track settlement calculation model and building track structural finite element analysis model. The results show that vehicle running speed, axle load and railway traffic are main factors of controlling track deformation; it benefits to decrease track settlement by adopting heavy rail, increasing bottom area of sleeper, reducing space of sleeper; track settlement reduces by 12.3% when thickness of ballast increases from 30cm to 40cm, and track settlement increases by 25% when elastic modulus of ballast increases from 90MPa to 150MPa, however, increasing thickness of ballast leads to more maintenance work and small elastic modulus reduces the capacity of structure, therefore, it is important to select track structural parameters reasonably.
Keywords: Heavy haul railway; Ballast bed settlement; Effect parameters; Vertical deformation.

1 Introduction

Two reasons caused settlement and deformation of line: ballast bed settlement and track bed disease. Ballast bed settlement account for 90% of total subsidence of ballasted track. Indoor and field tests (Augustin, 2003; Baessler, 2003) were conducted to study on characteristics of ballast bed accumulated settlement and the calculation formula, theoretical simulation (Indraratna, 2003; Saussine, 2006; Martin, 2012; Eric, 2012) were conducted to analyse settlement rule and influence parameters of ballast bed settlement. So existing track accumulative settlement calculation models are insufficient for heavy haul railway

This paper derive and transform the settlement model of China Academy of Railway Sciences as the calculation model, build finite element model for heavy haul railway by finite element analysis program, analyse ballast bed settlement of different ballasted track structure under different transportation conditions.

2 Building Track Settlement Calculation Model

This paper use the settlement model of China Academy of Railway Sciences(Eq. 1) for reference, transform some parameters of it and build a more reasonable model.

The model include compressive strain and vibration acceleration of ballast bed, but compressive strain of ballast bed(ε) is not convenient to simulate in the model, accumulated settlement is related to transportation conditions and track structure, especially vibration acceleration of ballast bed and stress on the surface of ballast bed is the direct factors of ballast deformation. Therefore, vibration acceleration, stress and height of ballast bed and parameter of sleeper are in the model of this paper.

$$\beta = 1.27 \times 10^{-6} (\varepsilon a_b)^{2.4} \quad (1)$$

with β: amount of ballast bed settlement under load for one time(mm/10^6 times); a_b: vibration acceleration of ballast bed (g); ε: stress of ballast bed($\mu\varepsilon$)

The relationship between pressure of sleeper and amount of compression of ballast bed can be obtained by fitting the experimental data, as shown in Eq. 2

$$\Delta y = 14.591 Q^{0.553} \quad (2)$$

Stress of ballast bed is amount of compression of ballast bed(Δy) divided by thickness of ballast bed(H), as shown in Eq. 3

$$\varepsilon = \frac{\Delta y}{H} \quad (3)$$

Fed Eq. 2 into Eq. 3,

$$\varepsilon = \frac{\Delta y}{H} = \frac{14.591 Q^{0.553}}{H} \quad (4)$$

pressure of sleeper and stress on the surface of ballast bed are in Eq. 5

$$\sigma_b = \frac{2Q}{bl} \quad (5)$$

with σ_b: stress on surface of ballast bed (kPa); Q: pressure of sleeper (kN); b: effective support width of sleeper (m); l: effective support length of sleeper (m)

Fed Eq. 4 and Eq. 5 into Eq. 1, settlement calculation model of ballast sleeper with parameters:pressure and vibration acceleration of ballast sleeper is in Eq. 6.

$$\beta = 5.854 \times 10^{-2}.\left(\frac{a_b}{H}\right)^{2.4}.(\sigma_b bl)^{1.3272} \quad (6)$$

In the following, we refer settlement to ballast bed settlemen for simplification.

3 Transportation Conditions Effect on Ballast Bed Settlement

3.1 Speed

Take speeds are 60km/h, 80km/h, 100km/h and 120km/h, axle load is 27t, type Ⅲ concrete sleeper, analyse regulation between settlement and speed.

Table1. Ballast bed settlement under different speeds

speed /km/h	60	80	100	120
maximum ballast bed settlement /×10^{-6}mm	4.904	6.104	7.708	19.743
average ballast bed settlement /×10^{-6}mm	2.551	3.753	4.912	7.907

As shown in Table 1, amount of settlement increase as speed increase. When speed increase from 60km/h to 120km/h, amount of maximum settlement increase from 4.904×10^{-6}mm to 19.743×10^{-6}mm under one time load, with the increase of speed, change rate is large. When speed is more than 100km/h, amount of settlement increase rapidly, so speed should not be too high.

3.2 Axle Load

Take axle load is 25t, 27t and 30t,speed is 80km/h. As shown in Table 2, axle load has great impact on settlement, When axle load increase from 25t to 30t, amount of maximum ballast bed settlement increased by 38.6%. Therefore, axle load become one of major parameter to control track deformation.

Table2. Ballast bed settlement under different axle loads

axle load（t）	25	27	30
maximum ballast bed settlement /×10^{-6}mm	5.339	6.104	7.398
average ballast bed settlement /×10^{-6}mm	3.246	3.753	4.620

3.3 Traffic

Amount of settlement would increase with traffic increase, due to unable to reflect influence of traffic, using times of load to reflect cumulative settlement. The relationship between carrying gross weight and number of load replication as follow.

$$N_L = \frac{10^6}{A_t \cdot N_a} \quad (7)$$

with N_L: number of load replication corresponding to 1 million tons of carrying gross weight; A_t: axle load; N_a: axle replication under one time load

Firstly, calculated the amount of settlement under one time load, used Eq. 7 to calculate the number of times, then it can calculate a amount of ballast bed settlement under certain traffic. As shown in Figure 1.

From Figure 1, amount of settlement increase along with number of loads, i.e. amount of subsidence of track structur become large when the traffic increase.

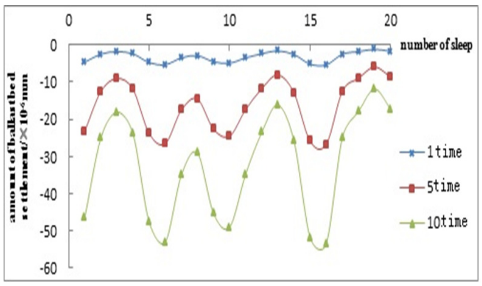

Figure1. Amount of maximum ballast bed settlement under different loads

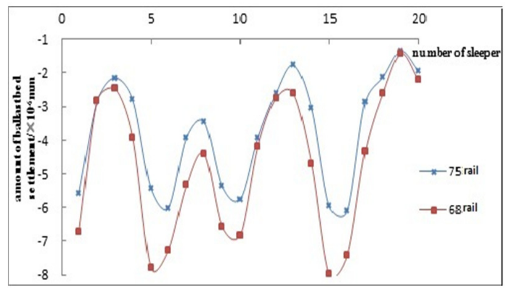

Figure2. Maximum ballast bed settlement under different type of rails

4 Track Structure Effect on Ballast Bed Settlement

4.1 Rail

This paper calculated amount of settlement when the type of rails are 68 rail and 75 rail, axle load is 27t, speed is 80km/h and type Ⅲ concrete sleeper.

Table3. Ballast bed settlement under different type of rails

type of rails	68 rail	75 rail
maximum ballast bed settlement /$\times10^{-6}$mm	7.977	6.104
average ballast bed settlement /$\times10^{-6}$mm	4.721	3.753

From Figure 2, maximum settlement decrease when quality of rail is enlarged, amount of settlement decrease by 23.5% if use 75 rail rather than 68 rail, therefore, type of rails have strong effect on settlement.

4.2 Sleeper

Calculated amount of settlement when sleepers are type III concrete sleeper and type Ⅱ concrete sleeper, axle load is 27t, 80km/h speed and 75 rail.

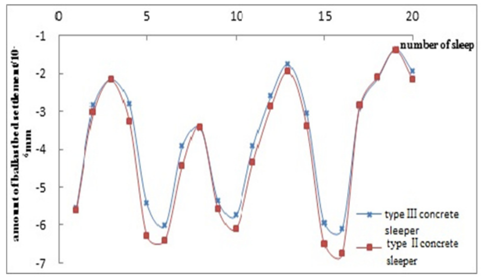

Figure3. Maximum ballast bed settlement under different type of sleeps

Table4. Ballast bed settlement under different type of sleeps

sleeper	type Ⅱ concrete sleeper	type Ⅲ concrete sleeper
maximum ballast bed settlement /$\times 10^{-6}$mm	6.766	6.104
average ballast bed settlement /$\times 10^{-6}$mm	4.031	3.753

From the above, amount of settlement under type Ⅲ is 10% lower than type Ⅱ, increase area size of sleeper bottom can reduce amount of settlement, for increasing contact area of sleeper will reduce stress of the surface of ballast bed.

4.2 Sleeper Span

There are 1667 sleepers in per kilometer in heavy haul railway, calculate amount of settlement under 1760 sleepers and1840 sleepers in per kilometer, corresponding to sleeper span of 0.600m, 0.568m and 0.545m. Axle load is 27t, speed is 80km/h,75 rail and type Ⅲ concrete sleeper, results are shown in Table 5.

Table5. Ballast bed settlement under different spaces of sleeps

sleeper span（m）	0.600	0.568	0.545
maximum ballast bed settlement /$\times 10^{-6}$mm	6.104	5.367	4.846
average ballast bed settlement /$\times 10^{-6}$mm	3.753	3.532	3.315

Amount of settlement increase with the increase of sleeper space, amount of settlement increase by 25.9% when sleeper space increase from 0.545m to 0.600m. Therefore, rational sleepers should be configured to control settlement.

4.4 Elastic Modulus of Ballast Bed

Calculated amount of settlement when elastic modulus are 90, 110, 130 and 150MPa.Results are shown in Table 6.

Table6. Ballast bed settlement under different elastic modulus

elastic modulus（MPa）	90	110	130	150
maximum ballast bed settlement /$\times10^{-6}$mm	4.867	5.345	5.806	6.104
average ballast bed settlement /$\times10^{-6}$mm	3.149	3.305	3.559	3.753

From table 6, the greater of elastic modulus,the stronger of track structure vibration, this increase amount of settlement, amount of settlement increased by 25% when elastic modulus increased from 90MPa to 150MPa, thus, different elastic modulus have different effect on settlement. Too small elastic modulus can decrease settlement but also decrease the bearing capacity of track structure.

4.5 Thickness of Ballast Bed

Calculating amount of settlement when thickness of ballast bed are 30cm, 35cm and 40cm. Results are shown in Table 7.

Table7. Maximum ballast bed settlement under different thickness of ballast

thickness of ballast bed（cm）	30	35	40
amount of ballast bed settlement /$\times10^{-6}$mm	3.753	3.485	3.292

Amount of settlement decrease with the increase of thickness, and the influence to settlement of thickness is larger. Amount of settlement decreased by 12.3% when thickness increased from 30cm to 40cm. The greater thickness of ballast bed can be advantageous to the dispersion of train load, but increase maintenance workload.

5 Conclusions

(1)Transportation conditions have a large effect on ballast bed settlement. Amount of settlement will increase with the increase of speed, amount of settlement increases about 3 times when speed increases from 60km/h to 120km/h, and amount of settlement increases rapidly when speed is more than 100km/h; amount of settlement increases by 38.6% as axle load increases from 25t to 30t, with increasing traffic, there is a linear relationship between amount of settlement and traffic.

(2)Track structure also have effect on ballast bed settlement. Amount of settlement decreases by 23.5% by using 75 rail; type III concrete sleeper and type Ⅱ concrete sleeper are almost the same; amount of settlement increases by 26.9% when sleeper space increases from 0.545m to 0.6m; amount of settlement increases by 25% when elastic modulus increases from 90MPa to 150MPa; the thicker of ballast bed, the smaller vibration acceleration of ballast bed, amount of settlement decreases by 12.3% when thickness increases from 30cm to 40cm; Therefore, comprehensive consideration should be taken during selecting the track structure in view of each track structure parameter have different effect on settlement.

Reconstruction and Modeling Method for Rail Head Checks in Heavy-Haul Railways Based on X-Ray Computed Tomography and the Extended Finite Element Method

Yu Zhou; Junnan Jiang; Xinwen Yang; Jie Zhang; and Miao Yu

Key Laboratory of Road and Traffic Engineering, Ministry of Education, Tongji University, No. 4800, Cao'an Rd., Jiading District, Shanghai 201804, China. E-mail: yzhou2785@tongji.edu.cn

Abstract: To understand the characteristics of head check (HC) propagation, the methods for reconstruction and modelling HCs in the rail were presented by realizing the geometry morphology and spatial position of HCs with the help of some creative technologies: X-ray computed tomography (CT) was applied to detect the rail specimens taken from a curve in a heavy-haul railway and the three dimensional (3D) internal information of HC was extracted and digitalized to the point cloud data with 3D coordinate by thresholding of the grey level. For splicing HCs in different rail specimens, removing the abnormal points, extracting and fitting the edges of HCs, the algorithms for investigating the geometry characteristics, including geometry morphology and spatial angle were designed and programmed. Therefore, the reconstruction of 3D HCs in rail was realized by reconfiguration of geometry morphology and spatial position. By defining the contact property, the fitted 3D HCs were assembled and coupled with a 3D rail model for further crack propagation analysis with the eXtended finite element method (XFEM). The reconstruction results can provide an accurate method for reconstruct HC and a reliable model for study the HCs propagation in the rails of the heavy-haul railway.
Keywords: Heavy-haul railway; HCs; X-ray CT; 3D reconstruction; XFEM.

1 Introduction

With the application of the alloy rail and heat-treated rail with high hardness and good wear-resistance in China heavy-haul railway, rolling contact fatigue (RCF) cracks came to be one of the main defects to rail lifetime. Head Check (HC), one kind of RCF cracks, initiated at rail gauge corner and shoulder at the early stage after new rail installation and propagated rapidly while it could not be worn away easily. To investigate the characteristics of HCs propagation, a model with information about the geometry morphology and spatial position of HCs should be built and analyzed for simulating further. The traditional destructive examinations only allowed to observe the crack from the cross-section along the longitudinal or transverse direction of the rail by cutting, of which only the projection of the crack in the longitudinal or transverse planes were observed and the true morphologies of HCs were damaged (Zhou, 2014) since the HCs often took an orientation of a certain angle with respect to the longitudinal or transverse direction of the rail, and it was hard to reconstruct HCs. Thus, the shape of the HCs were often assumed as standard semi-circular or semi-elliptical in traditional models (Bogdanski, 2002). As HC was micro-scale and distributed densely, 3D image software had the limitation on the precision of reconstruction the geometry and spatial position automatically, while error was larger if dealt with by manual operation, e.g., defining the value of HC in size and spatial position.

In this paper, X-ray computed tomography (CT) was applied for examining the three dimensional (3D) shape of the HCs inside the rails. 3D rendering of the HCs shape were obtained by thresholding of the grey level, and the 3D internal information of the HCs were extracted from the surrounding rail microstructure and digitalized to the point clouds data with 3D coordinate, by which the geometry and spatial position of HC was defined. Considering wheel-rail interaction and with the help of eXtended finite element method (XFEM) (Ding, 2007), 3D rail finite element (FE) model coupling with reconstruction 3D HC was built, which provided a reliable model for study the HCs propagation.

2 Extraction of point cloud data of 3D HCs

A 500m radius curve in a dedicated coal heavy-haul railway was chosen as field test line. The samples were 75 kg/m U75V heat-treated rails. As shown in Figure 1, samples were cut to specimens by the size of 5mm high, 10mm wide, and 50mm long along the longitudinal direction of rail. HCs in specimen 1 and 2 were chosen to CT scan because it located 12 mm away from the gauge face where HCs were first observed at this location in field tests.

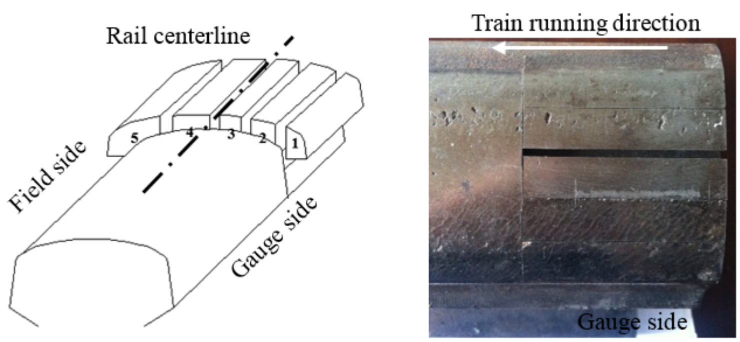

Figure 1. Schematic diagram and actual specimens

CT scan devices scanned the rail specimens by X-ray. The reflected energy was converted into 3D grey value, forming the original RAW format data; the images of scanned specimen with HCs could be shown in 3D image software, shown as figure 2. Because of different grey values of rail and HCs, the STereo Lithography (STL) file of HCs which contained point cloud data, could be exported by thresholding of the appropriate grey value.

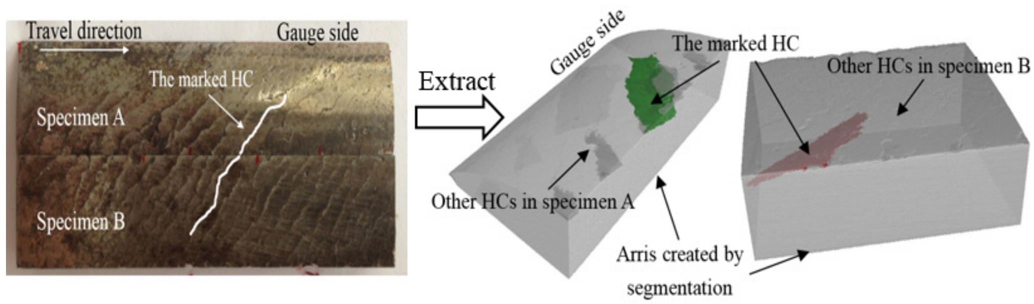

Figure 2. Process of extraction of HCs data

By numerical calculation, the complicated STL file was simplified to points represented by 3D coordinate. As a result, the spatial position and geometry shape of HCs could be obtained.

3 3D reconstruction of HCs

The specimen A and B were examined respectively and the marked HC in Figure 2 were segmented. As HC was micro-scale and distributed densely, 3D image software could not guarantee the precision of the reconstructed geometry and spatial position by automating, while it had larger error by manual aligning. Thus, a several algorithms were used to ensure the accuracy of reconstruction of HCs.

3.1 Splicing HCs in different rail specimens

Because the same HC were segmented in specimen A and B, they should be spliced to ensure the integrity of geometry. The procedure was shown as figure 3. Point M, N, O' and P were the boundary points in the bottom.

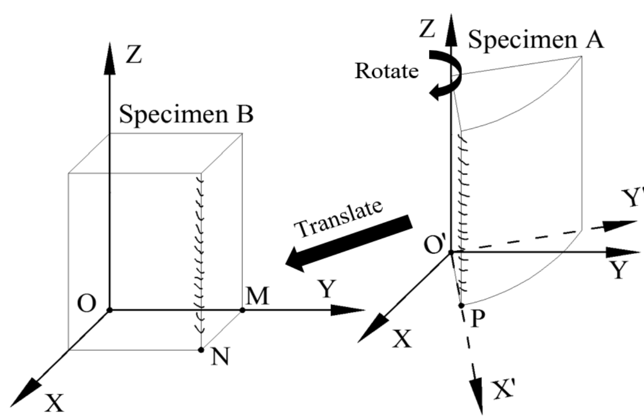

Figure 3. The translation and rotation of HCs in two specimens

Considering the two specimens were an integral part, point M and point O' should coincide, point N and point P as well. There were one rotational degree of freedom (about z axes) and three translational degrees of freedom (about x axes, y axes and z axes) as the two specimens were parallel when scanned. The algorithms of translation and rotation are shown as follow:

$$\begin{bmatrix} x'_{Ai} \\ y'_{Ai} \\ z'_{Ai} \end{bmatrix} = \begin{bmatrix} x_{Ai} \\ y_{Ai} \\ z_{Ai} \end{bmatrix} + \begin{bmatrix} \Delta x_{MO'} \\ \Delta y_{MO'} \\ 0 \end{bmatrix} \quad (1)$$

$$\begin{bmatrix} x_2 & y_2 & z_2 \end{bmatrix} = \begin{bmatrix} \cos\theta & \sin\theta & 0 \\ -\sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} x_1 & y_1 & z_1 \end{bmatrix} \quad (2)$$

In formula (1), x'_{Ai}, y'_{Ai} and z'_{Ai} are the coordinate of HC after translation; x_{Ai}, y_{Ai} and z_{Ai} are the original coordinate; $\Delta x_{MO'}$ and $\Delta y_{MO'}$ are the difference between point M and O'. In formula (2), (x_2, y_2, z_2) are the coordinate of HCs after rotation; (x_1, y_1, z_1) are the original coordinate; θ is the angel between vector $\overrightarrow{MN}$ and vector $\overrightarrow{O'P}$, with $cos\theta = (\overrightarrow{MN} \cdot \overrightarrow{O'P}) / (|\overrightarrow{MN}| \times |\overrightarrow{O'P}|)$.

3.2 The shape definition of HCs

(1) Rotating projection in 3D spherical coordinate system

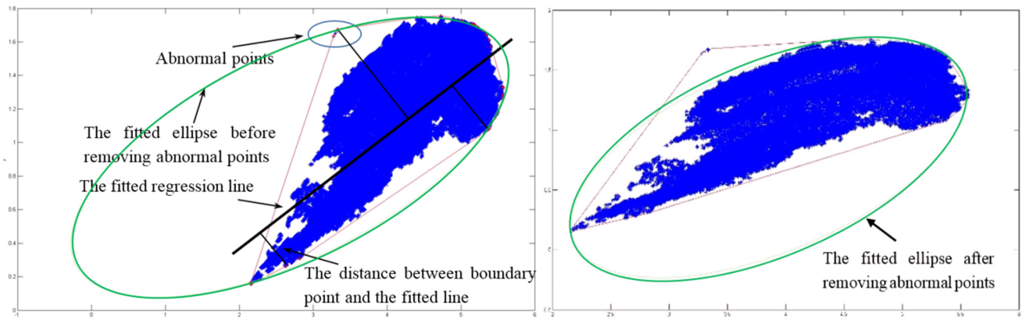
As the HCs point cloud data were curved surface instead of plane, it would be smaller than actual size by vertical projective operation. Therefore, 3D spherical coordinate was adopted for rotating projection. In order to calculate effectively, all the data were projected to XOY-plane by rotating projection, ensuring original size of HC. Transformation matrix of projection to XOY-plane was as follows:

$$\begin{cases} x'_i = x_i + (\sqrt{x_i^2 + y_i^2 + z_i^2} - \sqrt{x_i^2 + y_i^2}) \cdot \cos\theta \\ y'_i = y_i + (\sqrt{x_i^2 + y_i^2 + z_i^2} - \sqrt{x_i^2 + y_i^2}) \cdot \sin\theta \\ z'_i = 0 \end{cases} \quad (3)$$

Where $\cos\theta = x_i / \sqrt{x_i^2 + y_i^2}$, $\sin\theta = y_i / \sqrt{x_i^2 + y_i^2}$.

(2) Removing the abnormal points and fitting the shape of HC

The outline shape of HC was decided by its boundary points, and the boundary information could be obtained by computing the point set of the convex hull (Liu, 2007). However, abnormal boundary points seriously affected the accuracy of the fitted shape of HC, shown as figure 5(a). Thus, PauTa criterion was applied to remove the abnormal points (Zeng, 1988).



(a) The original fitted ellipse (b) The amended fitted ellipse

Figure 4. The comparison of fitted ellipse after removing abnormal points

By the least square method, the fitted regression line of HC points was obtained. The distance of all the boundary points to the fitted regression line could be calculated and PauTa criterion was applied if they obeyed the normal distribution:

$$P\left(\left|x-\bar{x}\right|\leq 3\sigma\right)=0.9974 \tag{4}$$

After removing the abnormal points, the direct least square fitting of ellipse method (Andrew, 1999) was taken to fit the shape of HC. The length of semi-major axis and semi-minor axis could be shown as

$$\begin{cases} a^2 = 2(AXc^2+CYc^2+BXcYc-1)/(A+C+\sqrt{(A-C)^2+B^2}) \\ b^2 = 2(AXc^2+CYc^2+BXcYc-1)/(A+C-\sqrt{(A-C)^2+B^2}) \end{cases} \tag{5}$$

Where, Xc and Yc are the coordinate of ellipse center; A, B, C are coefficients of normalized ellipse $AX^2+BXY+CY^2+DX+EY+1=0$ in XOY-plane.

After that, the crack tip (i.e., HC edge inside the rail) was fitted with the calculated ellipse shape, while the crack mouth (i.e., HC edge bordering on the rail top or gauge corner) was fitted with rail profile of the corresponding position to make the fitted HC shape be consistent with the actual case as much as possible.

3.3 Definition of HC's spatial position by plane fitting

The spatial plane where point cloud data of HC located could be defined through the least square plane fitting method, by which the spatial position could be obtained. Assuming that $Ax+By+Cz+1=0$ represented a spatial plane which did not pass through the origin, the transfer matrix can be seen in formula (6) and the matrix of coefficient was calculation in formula (7), according to the least square method.

$$\begin{bmatrix} x_1 & y_1 & z_1 \\ x_2 & y_2 & z_2 \\ \vdots & \vdots & \vdots \\ x_i & y_i & z_i \end{bmatrix} \begin{bmatrix} A \\ B \\ C \end{bmatrix} = \begin{bmatrix} -1 \\ -1 \\ -1 \end{bmatrix} \tag{6}$$

$$\begin{bmatrix} A \\ B \\ C \end{bmatrix} = \begin{bmatrix} \sum x_i^2 & \sum x_i y_i & \sum x_i z_i \\ \sum x_i y_i & \sum y_i^2 & \sum y_i z_i \\ \sum x_i z_i & \sum y_i z_i & \sum z_i^2 \end{bmatrix}^{-1} \begin{bmatrix} -\sum x_i \\ -\sum y_i \\ -\sum z_i \end{bmatrix} \tag{7}$$

By rotating the fitting shape of HC (in XOY-plane) to the position where were perpendicular to the normal vector ($\vec{n}$=(A,B,C)) of the plane, the spatial position of HC could be defined.

4 XFEM model of rail assembling with HC

4.1 Discrete equation

Considering the actual propagation of the HCs, the more effective method XFEM was applied, which had the advantages of allowing modeling of complex shaped cracks in 3D media by the level set method, easy intersecting them in the elements by the enriched finite element and considering the stress singularity, which could provide reasonable meshes and calculation time. Like FEM, the discrete equation of each element could be shown:

$$K^e d^e = F^e \tag{8}$$

Where K^e is the element stiffness matrix, F^e is the equivalent nodal force and d^e is the element node displacement. Each direction component of d^e could be expressed by (Xiao, 2012)

$$u(x) = \sum_{i \in N} N_i(x) u_i + \sum_{j \in N^{disc}} N_j(x) H(f(x)) a_j + \sum_{k \in N^{asy}} N_k(x) \sum_{a=1}^{4} \phi_t(x) b_k^t \tag{9}$$

To explain the stress singularity of crack tip, $\phi_t(x)$ is used with

$$\phi_t(x) = [\sqrt{r}\sin\frac{\theta}{2}, \sqrt{r}\cos\frac{\theta}{2}, \sqrt{r}\sin\frac{\theta}{2}\cos\theta, \sqrt{r}\cos\frac{\theta}{2}\cos\theta] \tag{10}$$

4.2 FE rail model with the constructed HC

The fitted ellipse was imported into CAD software, in which the ellipse was modified by combining with the rail profile around gauge corner to correspond to the actual geometry. Then, the fitted HC was transferred into finite element (FE) sketch data (Yang, 2011) and 3D HC shell was created. 3D rail solid model was built by assembling and coupling with the fitted 3D HC shell, it was shown in figure 5. As under the wheel-rail force, hard contact property with a penalty function was defined in case of penetration (Jim, 2014).

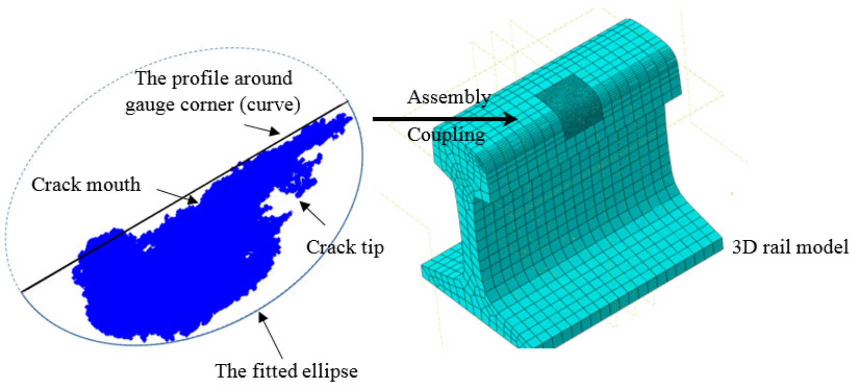


Figure 5. Finite element model of HC coupling with 3D rail model

For simulating the effect of wheel-rail interaction, moving Hertz contact normal pressure and creep force was applied on the rail, which made the stress and strain result close to the actual case.

5 Conclusions

Reconstruction and modeling method for HC in heavy-haul railway based on CT scan technology could implements the following features:

(1) With CT scan technology, 3D point cloud data of HCs could be precisely distinguished and extracted by thresholding of the grey level; the integrity of geometry was insured by splicing, which could restore the actual geometry of HCs more accuracy.

(2) By rotating in 3D spherical coordinate system, removing the abnormal boundary points by the least square method and PauTa criterion, the outline shape and size of HC could be obtained; the spatial position of HC in rails was defined by the least square plane fitting method, which guaranteed the reliability of the fitted HC.

(3) 3D HCs reconstruction could be realized by the definition of HC geometry and spatial position, which provided a more realistic basic for FE model; XFEM provided a more effective and accurate way to FE calculation.

It was shown that the 3D reconstruction and modeling method for HCs based on CT had a good applicability for crack propagation simulation, which could provide reliable model for study the HCs propagation in heavy-haul railway. By this method, further work, such as the propagation of HC in rails at different traffic and the relationship between HC propagation and wear growth can be investigated.

Abstract: heavy-haul loading transportation can improve efficiency, greatly reduce the transportation cost in shipping bulk cargo. This article discussed the organization mode of heavy-haul loading transportation, comprehensively consider the operation condition of heavy-haul loading train and its economic benefits, use the running time consumption minimum and operation benefit maximization as objective function, use the uniqueness of operation scheme and Loading and unloading capacity as the constraint condition, built the 0-1 nonlinear optimization model of heavy-haul loading operation plan. For the convenience of the model solution, use the Linear weighted method to change the model objective function into single objective function. Design the genetic algorithm to acquire the prioritization scheme of heavy-haul loading train plan.
Keywords: Heavy-haul train; Loading area; Train operation scheme; Genetic algorithm.

Heavy haul transportation has put forward higher requirements to the traffic organization and technology station reorganization work in order to play the advantages of heavy haul transportation, we need improve train marshalling and traffic organization scheme, rationally adjust the labor division of marshalling station, solve the successive problem of supply, freight and transport capacity. Finally improve the formation of the network in the whole region.

1 The construction of model

Organizing the wagon flow into heavy haul train can speed up the delivery of the goods, improve the section carrying capacity, but the grouping of heavy haul train needs more centralized supply and adequate supply of empty car, put forward higher requirements for marshalling capacity of loading area technology station. Therefore we cannot simply organize the wagon flow into heavy haul train form. we need consider the station line operation capacity and transport organization form. use the train plan benefit maximization as the goal to determine the optimal train operation plan. Freight train need loading, adaptation and truck operations in the way, use M as the total time cost, then the formula of the objective function is:

$$\min M = M_H + M_{NH}$$

Use M_H indicate the consumption of heavy haul train technical operation time, use M_{NH} indicate non heavy haul train time consumption.

Defined the decision variables:

$$X_{st}^{H} = \begin{cases} 1 \text{ if there is heavy haul train in the } N_{st} \\ 0 \; others \end{cases} \qquad X_{st}^{H(k)} = \begin{cases} 1 \; marshalling \text{ heavy haul train in the first marshalling station} \\ 0 \text{ others} \end{cases}$$

$$X_{st}^{k} = \begin{cases} 1 \text{ if the first marshalling station of non heavy haul train is k} \\ 0 \text{ others} \end{cases} \qquad X_{st}^{H(k)} = \begin{cases} 1 \text{ marshalling heavy haul train in the last marshalling station} \\ 0 \; others \end{cases}$$

$$X_{st} = \begin{cases} 1 \text{ if there is non heavy haul train in the } N_{st} \\ 0 \; others \end{cases}$$

use c_{st}^{H} as heavy haul train assembling parameter from s to t, use c_{sk}^{NH} as heavy haul train assembling parameter from s to k. use m_{st}^{H} as numbers of heavy haul train from s to t, use m_{sk}^{H} for numbers of heavy haul train from s to k. use t_{k}^{H} for technical operation time consumption of heavy haul train at technical station, use o_{st}^{H} for time consumption of heavy haul train in indirect way, use v_{st}^{H} for time consumption of heavy haul train in direct way, use c_{st}/c_{sk} for non-heavy haul train assembling parameter, use m_{sk}/m_{st} for numbers of non-heavy haul train, use t_k for technical operation time consumption of non-heavy haul train at technical station, use

o_{st} for time consumption of heavy haul train in indirect way, use v_{st} for time consumption of non-heavy haul train in direct way.

If there is no coding work in the way at marshalling station, the consumption of Nst in the loading area and unloading area can be divided into the following three kinds of circumstances.

(1) if marshalling heavy haul train in the first mashalling station, the consumption in the loading area, first marshalling station and unloading area is:

$$E_1^H = N_{st}(w_{st} + t_k^H + o_{st}^H)\ x_{st}^{H(k)},\ k \in v(s)$$

(2) Send the heavy haul train to the final collapse from loading area, the consumption in the loading area, technology station and unloading station is:

$$E_2^H = \left[c_{sk}^H m_{sk}^H + N_{st}(t_k^H + o_{st}^H)\right] x_{st}^{H(k)},\ k \notin V(s), k \in V(t)$$

(3) Directly send Nst to the unloading area from loading area, the consumption in the loading area and unloading area is:

$$E_3^H = (c_{sk}^H m_{st}^H + N_{st} v_{st}^H)\ x_{st}^H$$

If there is non heavy haul train in the Nst, the consumption in the loading area, way and unloading area can be divided in to following three circumstances:

(1) the traffic were sent to the front technology station as technical traffic, the consumption in the loading area and unloading area is:

$$E_1^{NH} = N_{st}(w_{st} + o_{st}) x_{st}^k, k \in V(s)$$

(2) the traffic was centred in loading area and sent to technology station k, the consumption in the loading area and unloading area is:

$$E_2^{NH} = (c_{sk} m_{st} + N_{st} o_{st}) x_{st}^k, k \notin V(s)$$

(3) Directly send Nst to unloading area from loading area, the consumption in the loading area and unloading area is:

$$E_3^{NH} = (c_{sk} m_{st} + N_{st} v_{st}) x_{st}$$

(4) as long as there is no through train from loading area to unloading area ,then there will be marshalling consumption in the technology station. if wagon flow's last marshalling station is j, wagon flow Nst were marshalled in the k station, then V (k, t) represents a collection that wagon flow need to be marshalled in the way. and V (k, t) includes k station. then the consumption of wagon flow Nstin the way is:

$$E_4^{NH} = N_{st} \sum_{k \in \rho(s,t)} \sum_{i \in V(k,t)} t_i x_{st}^k$$

The total consumption of wagon flow is:

$$E_{\mathrm{st}}^{C} = E_{H} + E_{NH}$$

Heavy haul train can improve the transportation efficiency, it has higher economic profit. when calculating the income, we only need to compare the two different parts of the organization form's save and loss. because the gain of heavy-duty train is currency as the unit.so it needs to be converted to consume hours of car in the optimization model. Set operation 1 column heavy-duty train to unload area, the increase transportation income in relative to the heavy-duty train is W_c, in order to conversion the yield to hours car consumption, introduce the conversion factor, the revenue calculation formula of heavy-duty train is:

$$E_{H}^{C} = \beta N_{\mathrm{st}}^{H} / \mathrm{m}_{\mathrm{st}}^{H} W_{C}^{\mathrm{s\text{-}t}} (x_{\mathrm{st}}^{H} + x_{st}^{H(\mathrm{k})})$$

The goals of the mode require to minimum car hour consumption and maximum returns of heavy-duty train, the objective function of the model is:

$$E = \min E_{st}^{C} + \max E_{H}^{S}$$

Traffic into heavy-duty train or heavy-duty train, there are three ways can be used, we can organize through train to unload area, or we can send it to the technical station, then incorporate it into the corresponding technical traffic. either assemble with shaft in the loading area, then organize through train to unload area. There is only one kind of the operation mode, namely operation scheme has uniqueness.

$$x_{st} + \sum_{k \in \rho(s,t)} x_{st}^{k} + x_{st}^{H} + \sum_{k \in V(s) \cup V(t)} x_{st}^{H(k)} = 1$$

if organize heavy-duty train or non heavy-duty train, we must satisfy the conditions of loading and unloading area, calculating formula of allowed intensive number of loading and unloading car from loading area to unloading area is:

$$m_{st} = \min(m_{st}^{l}, m_{st}^{u})$$

If we organize through train to k station, we must meet the following requirements:

$$\sum_{t \in D(k)} m_{st} \geq m_{sk}$$

Use m_{sk} for number of car directly from s to k, D (k) for the collection of station that attract traffic.

When marshalling heavy-duty train from loading area to a fulcrum station k, allowable dense number of car attracted by the direct traffic needs to satisfy the following requirements:

$$m_{st}^{H} I \left(\sum_{t \in Q(s)} x_{st}^{H(k)} \right) - \sum_{t \in Q(s)} m_{st} x_{st}^{H(k)} \leq 0$$

I (x) is a step function, defined as

$$I(x)=\begin{cases}1 & x\rangle 0\\ 0 & x\le 0\end{cases}$$

When marshalling non heavy-duty train from loading area to a fulcrum station k, allowed intensive number of train that attracted by the through traffic need to satisfy the following requirements.

$$m_{st}I(\sum_{t\in Q(s)} x_{st}^{k})-\sum_{t\in Q(s)} m_{st}x_{st}^{k}\le 0$$

Organize heavy-duty train or non heavy-duty train, if it is through traffic from loading area to unloading area, whether single or more, its operation must meet that the car hours saving on the way without adaptation through technical station ≥ car time consumption in loading area, otherwise, it should not be commonly is divided into separate marshalling. For a single traffic, it meet the necessary conditions for:

$$\sum_{j\in\rho(s,t)} t_j^H N_{st} x_{st}^H \ge c_s^H m_{st}^H$$

$$\sum_{j\in\rho(s,t)} t_j N_{st} x_{st} \ge c_s m_{st}$$

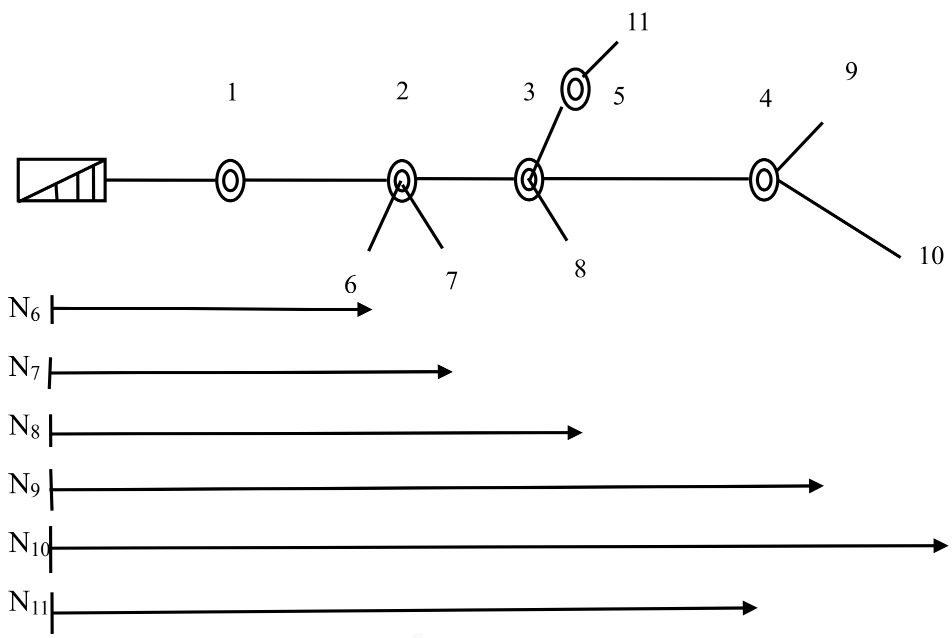

Figure 1. Loading area train diagram

L for loading area, label 1-5 for technical station that can marshall heavy-duty train,6-11 for unloading station, a simplified road network structure and the flow diagram is shown in figure 1. a simplified road network structure and the flow diagram is shown in figure 1. There are 6 direct traffic,, if loading flow respectively N6=75, N7=35, N8=20, N9=70. N10=40 and N11=45, cost parameters respectively wt = 10, ot= 10, vt = 7, ot= 8 and vt= 5, average plait bought for heavy-duty train mt= 70, average plait bought for direct train to reach the unloading point mt = 40,, and parameter ck/ct= 12, ck/ct= 10, $\lambda 1=\lambda 2= 0.5$。The average conversion consumption of heavy-duty train at technical station is 8,the average conversion consumption of non heavy-duty train at the technical station is 4,assume organize 1 column heavy haul train that has 60 cars, its earnings 350, 450, 550, 500, use MATAlab software to design genetic algorithm, get the following loading heavy-duty train operation plan:

The traffic N6 and N11 organize the direct train from loading area to unloading area.

The traffic N7and N8 does not meet the condition of overloading and direct train, use rolling off the train to send to the front technology stand into the site traffic.

The traffic N9,N10 organize the direct heavy-duty train to unloading area when gather full shaft.

2 Conclusion

Built the nonlinear 0-1 programming model of loading area heavy-duty train, the objective function is the sum of time consumption at loading area, unloading area and on the way and heavy-duty train economic benefit. The model can comprehensive describe various combination of loading area heavy-duty train and guarantee the maximum benefits of operation scheme. Numerical example verifies the various traffic combination scheme in loading area, use maximum benefits of operation plan to confirm the rationality and validity of the operation plan .At the same time, building loading area heavy-duty train operation plan should also be coordinated with technical train stations on the way very well, so as to ensure normal execution. of operation plan .

Network Assignment Model of Passenger Train Scheme on a High-Speed Railway

Kefei Zhu

Faculty of Graduate, China Academy of Railway Sciences, Beijing 100081.

Abstract: Passenger flow assignment has a direct influence on optimization of the high-speed railway train operation plan, thus the rational assignment passengers is a basic link and an important role. Considering the level of passengers demand and the impact of passenger product attribution on the passenger assignment, this paper classifies passengers and trains into different category, and shows the cost conversion coefficients of between each passenger set and train set. During the construction of distribution network, this paper divides network into 4 types of nodes and 6 directed arcs: running arc, accumulation arc, transfer arc, stop arc, getting on arc and getting off arc, according to the train arrival and departure time and passenger getting on and off procedure. Every arc has its calibration parameters. Research shows that the essence of assignment under this network is the problem of maximum flow with minimal fare, the assignment process has characteristics of self-driven, the getting on and getting off arc is only used to limit capacity and with no assignment cost produced. The assignment process can be achieved by looking for OD node circuits of corresponding passenger flow from the assignment network. Corresponding algorithm is designed by the use of the properties and the algorithm steps are present-ed.
Keywords: High-speed railway; Train operation plan; Assignment network; Maximum flow with minimal fare.

1 Introduction

Although the high-speed railway transportation is taking the social responsibility of passenger transport, the economic benefit should be considered. Meanwhile, high-speed railway should also try to improve service, expand market share, cut costs, and improve profitability, while meeting the transport needs of the community.

The key problem of passenger transportation organization is high-speed railway train operation plan [1]. It’s the foundation of computerized train graph and train-set scheduling, which directly reflects the management strategy and service quality of railway passenger transportation. A rational high-speed railway train operation plan not only contributes to improve the operational efficiency of railway passenger transportation, which represents competitive ability compared with other transport, but relates to the ability to provide a consistently high level of service and to get the expected economic returns [2]. Therefore, the key demanding prompt solution problem is that how to compute a rational high-speed railway train operation plan or how to optimize train operation plan [3].

Optimization of high-speed trains is a large and complex system optimization problem, with the numerous influence factors and optimizing the links. Determining the train plan of passenger service information is a key to solve the optimization of high-speed train problem, as passenger flow information is the basic principle of operation scheme[1]. Although many studies, no matter in China or international, have already carried out a more in-depth study and achieved a certain theoretical results, most studies were directed at a single speed and does not take into account differences in passenger levels in practical situation. Chinese high-speed passenger transport organization mode is trains in different speed rating sharing the same line, and the delivery of passenger flow structure is not uniform. Therefore, the key problem is to optimize passenger flow at different levels, such as in the high and medium speed train, operation scheme reasonable distribution.

This paper focuses on how to turn a reasonable distribution of passenger flow in the train involving on operation plan, so that provide the basis principles and specified direction for the further optimization train operation plan, rather studying on computing train operation plan.

2 Assumptions

(1) Fixed passenger flow

Assume all the relevant passenger flow data, which is divided into middle and upper levels in accordance with a specific principle, have been fixed. In other word, passenger flow of different levels in any OD is fixed.

(2) Fixed train path

Assume there is a completed train operation plan. In this plan, two speed rating trains (i.e. high-speed and mid-speed) correspond to two level passenger flows (i.e. high level and middle level); and the transport capacity is over the transport demand. Moreover, the object of this study focuses on one single direction trains. This is because, in reality, the train is usually symmetrical opening lines in pairs, and thus, the results of the plan in one direction can be applied to the reverse trains.

(3) Classified train in different speed

In order to corresponding the level of trains with the level of passengers, this study classifies the train not only according to the initial, final and intermediate stops, but also according to the level of passenger flow on trains, due to the high speed railway served different level passengers. To take train's speed level into account, the initial train operation plan contains the high-speed and medium-speed train, and any type of train contains only one speed-level train. In other words, two trains are classified into different levels as long as they have different speeds, though these two trains have same the initial, final and intermediate stops.

(4) Fixed sensitivity of traveler time and money

The sensitivity of passengers for components of the generalized travel cost (includes payments for time and money) is different, because the impact of factors for passengers, such as the travel purposes, the economic capacity, is different. For instance, the high level passengers have relatively low sensitivity for money, because of their high time value; the low level passengers have high sensitivity for the money (i.e. they prefer to spend more time to save money), because of their relatively poor economic conditions. Although, the sensitivity of the time and money is an important criterion to classify the travelers' level, it's hard to quantify, due to it involves traveling behavior, economic capacity, consumption habits and values. Therefore, this study assumes passengers' sensitivity of time and money is fixed.

(5) Fixed train seating capacity

China's CRH series are mainly used on high-speed railway motor train, there are several different models and the seating capacity of every model is different. Sometimes, the seating capacity is changed even in the same model motor train, as the marshalling mode is different. Therefore, in order to facilitate the study and description of the nature of the problem, while reducing model size, this study assumes the train seating capacity is fixed in the train operation plan.

(6) Fixed the additional time for starting and stopping

Additional time for starting and stopping, whose proportion of value is very small in the train running time, depends on motor train performance, railroad track condition, speed, etc. To facilitate this research, this study treats the additional time for starting and stopping as a part of the stopping time, which won't bring an obvious error. This means this study assumes the stopping time has included the additional time for the starting and stopping, which produces by train stopping. What's more, this study assumes the stopping time is related to the station nature, which means if the station nature is the same, the stopping time is the same.

3 The Model

3.1 The objective of the passenger flow distribution

Rational distribution of passenger flow is the basis for optimization of high-speed trains and an important part. To improve the social benefit and marketing efficiency of high-speed railway by optimizing the train operation plan, the passenger travel demand and travel costs should be considered during the distributing the passenger flow. On the premise of meeting the whole passengers need, the passengers total travel cost, which includes the travel fare, travel time and travel expenditure [4], is the objective of the passenger flow distribution. That is：

$$\min z = \sum_{i=1}^{m} T_i N_i + \varepsilon \qquad (1)$$

Where

T_i is passengers' average travel cost of the i^{th} passenger flow;

N_i is the total number of passengers of the i^{th} passenger flow;

m is the total number of passengers flow in initial train plan of high-speed railway;

ε is penalty values variables, if there are some passengers outside the service train at the end of passenger flow distribution process, ε is infinity, which means this distribution plan cannot meet the need of passenger flow; if there is no passenger outside the service train at the end of passenger flow distribution process, ε =0, which means this distribution plan can be applied.

3.2 Passengers' travel cost analysis

T_i is mainly composed of passengers' travel fare and time consumption. Travel fare makes up of the urban traffic fare for arriving railway station, the urban traffic fare for leaving railway station and the fare for railway ticket. Time consumption consists of the time for arriving railway station, waiting railway time, train running time, stopping time, the time for leaving railway station and transfer time.

（1）This study only focuses on the travel cost caused by the high-speed railway, rather those travel cost outside the railway, which have no effect on the passenger flow distribution in the train operation plan, such as the time and fare for the arriving and leaving railway station.

（2）The accumulation time can be calculated by the method in reference [1]. But the accumulation time will change with the train's number and frequency of some level passengers, due to the level of trains and passengers. However, the passengers' stopping time is irrelated to the passengers' level, then, the passengers' stopping time consumption can be fixed in the train operation plan, if some level passenger's is distributed to the l^{th} level train.

（3）The travel cost T_g (i.e. travel ticket fee and the running time) of the g^{th} train can calculate:

$$T_g = \frac{L}{v_g} + \frac{L\rho_g}{\omega_g} \qquad (2)$$

Where

L is the train's running time;

v_g is the velocity of the g^{th} train;

ρ_g is the fare rate of the g^{th} train;

ω_g is the time cost of the g^{th} passenger.

If a high level passenger is sent to a medium-speed train, he may be unsatisfied, because he cares more about the time compared with money. Similarly, it is unsatisfied to send a middle level passenger to a high-speed train, because middle level passengers have high sensitive to the money. Therefore, it is necessary to conversion travel cost T_g from the two aspects: time and price, for the above situation. That is, the scaling factor η :

$$\eta = \left(\gamma_{ti}\frac{v_{pa}}{v_{tr}} + \gamma_f \frac{\rho_{tr}}{\rho_{pa}}\right) \quad (\gamma_{ti} + \gamma_f = 1) \qquad (3)$$

Where

γ_{ti} is the sensitivity to the time of every specific level passengers;

γ_f is the sensitivity to the fare of every specific level passengers;

v_{pa} is the train's running speed which every specific level passengers should have;

ρ_{pa} is the train's fare rate which every specific level passengers should have;

v_{tr} is the train's running speed which passenger stake in reality;

ρ_{tr} is the train's fare rate which passengers take in reality;

$\eta=1$ when the passengers' level equals to the trains' level which they take.

3.3 Network setting up

To research a high speed railway corridor, the stations in the research direction are defined as set $St = \{1,2,...,N\}$, and then set $\overline{St} = St - \{1\}$ and set $\underline{St} = St - \{N\}$

are defined. Set $St = \{1,2,\ldots,N\}$ is defined as the train operation plan of the n kinds of trains in origin stop order, and the corresponding train network is defined as Net=(V,E), where, V is the network point set which includes subset V_i(i=1,2,3,4) , E is the network arc set which includes subset E_i(i=1,2,3,4,5,6). The subsets are defined as in table 1.

Table 1. The definition of subsets

Name	Subset	Constraint Condition	Explanation	Nature	Operation
Point Set	$V_1=\{v_{1j}\}$	$j\in St$	The station for dispatching passengers	Getting on node	Dispatching passengers
	$V_2=\{v_{2j}\}$	$j\in St$	The station for arriving passengers	Getting off node	Arriving passengers
	$V_3=\{v^l_{3j}\}$	$j\in St\bigcap l\in Sh$	The station for the l^{th} train dispatching	Dispatched train node	Dispatching trains
	$V_4=\{v^l_{4j}\}$	$j\in St\bigcap l\in Sh$	The station for the l^{th} train arriving	Arrived train node	Arriving trains
Arc Set	$E_1=\{e^l_{FD}\}$	$l\in Sh$; $F,D\in St\,\&\,F\prec D$	The l^{th} train from F station to D station	Running are	Train running process
	$E_2=\{e^g_{ZS}\}$	$g=midium,$ high ; $Z,S\in St\,\&\,S\prec Z$	S-Zorigin station passengers take g level train	Accumulation arc	Train accumulating process
	$E_3=\{e^l_j\}$	$l\in Sh; j\in\overline{St}\cap\underline{St}$	The $l$level train stopping by j station	Stopping arc	Train stopping process
	$E_4=\{e^j_{QH}\}$	$j\in\overline{St}\cap\underline{St}$; $Q,H\in Sh\,\&\,Q\neq H$	Passengers transfer from Qlevel train to H level train at $j$station	Transfer arc	Passenger's transfer process
	$E_5=\{e^C_{jl}\}$	$j\in\underline{St}; l\in Sh$	Passenger taking l level train at j station	Getting on arc	Passenger's getting on process
	$E_6=\{e^X_{jl}\}$	$j\in\overline{St}; l\in Sh$	Passenger taking l level train getting off at j station	Getting off arc	Passenger's getting off process

The steps of setting up network are as follows:

(1) Setting up the getting on and getting off node at each station according to the

corridor station order;

(2) Setting up the getting on node and getting off node at each origin station, intermediate station and terminal station of each level train in the train running direction;

(3) Setting up the running arc for the each level train from the dispatched node to the arrived node;

(4) Setting up the stopping arc for the each level train between the dispatched node and the arrived node;

(5) Setting up the transferred arc between the dispatched node and the arrived node, according to the possible transfer plan.

(6) Setting up the accumulation arc between the getting off node and getting on node of each *g* level passenger flow in the OD;

(7) Setting up the getting on arc and getting off arc between the getting on node and getting off node and *l* level train's dispatched node and arrived node, according to the OD passenger flow and intermediate station in the train operation plan;

(8) Deleting the isolated node.

Following the above steps, the train running network of given OD passenger flow and initial operation plan is finished. This network is a simple connective directed network without parameter.

3.4 Network Parameters

In order to solve the passenger flow distribution problem, the parameters will be set up in the network, which should involve in all the information about the factors of passenger flow distribution. The parameters are named in the table 2 to table 6.

Table 2. Arc Parameters

e^l_{FD} parameter	The meaning of parameter	Parameter's value	The set of parameter
g	The grade of the l^{th} level train	The grade of the train	{g, T_g, H, f_h^l, f_m^l, C^l}
T_g	The ticket and train running time of the g^{th} grade train from F station to D station	T_g	
H	The scaling factor caused by the level of passengers no match with grade of the l^{th} level train	$\eta \cdot T_g$	
f_h^l	The passenger flow of the high level passengers in the l^{th} level train	Variable, initial value equals 0	
f_m^l	The passenger flow of the medium level passengers in the l^{th} level train		
C^l	The capacity of the l^{th} level train	$l_n \cdot S_l$	

*l_n is the number of the train in reality

S_l is the seating capacity of the l^{th} level train

Table 3. The Accumulation Arc Parameters

e^{g}_{ZS} parameter	The meaning of parameter	The value of parameter	The set of parameter
J^{h}_{j}	The accumulation time, if the grades of passengers and trains are high	Accumulation time	{ J^{h}_{j} , J^{m}_{j} , J_{j} , f^{h}_{SZ} , f^{m}_{SZ} , A^{h}_{SZ} , A^{m}_{SZ} }
J^{m}_{j}	The accumulation time, if the grades of passengers and trains are medium		
J_{j}	The accumulation time, if the level of passengers no match with grade of the train		
f^{h}_{SZ}	The number of the distributed high level passengers between S and Z station	Variable, initial value equals 0	
f^{m}_{SZ}	The number of the distributed medium level passengers between S and Z station		
A^{h}_{SZ}	The high level passenger flow between S station and Z station	The passenger flow data between S station and Z station	
A^{m}_{SZ}	The medium level passenger flow between S station and Z station		

Table 4. Getting on and Getting off Arc Parameter

e^{C}_{jl} (e^{X}_{jl}) parameter	The meaning of parameter	Parameter value	The set of parameter
g	The grade of the l^{th} level train	The grade of the train	{ g , U^{l}_{j} , D^{l}_{j} , C^{l} }
U^{l}_{j}	The number of passengers in the l^{th} level train who is getting on at j station	Variable, initial value equals 0	
D^{l}_{j}	The number of passengers in the l^{th} level train who is getting off at j station	Variable, initial value equals 0	
C^{l}	The capacity of the l^{th} level train	$l_{n} \cdot S_{l}$	

Table 5. The Stop Arc Parameter

e^{l}_{j} parameter	The meaning of parameter	Parameter value	The set of parameter
g	The grade of the l^{th} level train	The grade of the train	{g , T^{t}_{jl} , P^{t}_{jl} , C^{l} }
T^{t}_{jl}	The stopping time at j station of the l^{th} level train	The standard of stopping time	

P^{t}_{jl}	The total number of passenger l^{th} level train who pass by j station	Variable, initial value equals 0	
C^{l}	The capacity of the l^{th} level train	$l_n \cdot S_l$	

Table 6. The Transfer Arc Parameter

e^{j}_{QH} parameter	The meaning of parameter	Parameter value	The set of parameter
Th^{QH}_{j}	The transfer time from the Q^{th} level train to the H^{th} level train at j station	The reference [1]	$\{Th^{QH}_{j}, Ph^{QH}_{j}, Ch^{QH}_{j}\}$
Ph^{QH}_{j}	The number of passenger transfer from the Q^{th} level train to the H^{th} level train at j station	Variable, initial value equals 0	
Ch^{QH}_{j}	The capacity of transfer from the Q^{th} level train to the H^{th} level train at j station	$\min\{C^{j}_{Q}, C^{j}_{H}\}$	

* C^{j}_{Q} （C^{j}_{H}） means the rest capacity of the Q^{th} level train after it arriving j station and then departure from j station

3.5 The application of network

The nature of this built distribution network above is as follows:

(1) In this network, the distribution problem is a min-cost max-flownetwork optimization problem, actually.

(2) The sets of getting on arc and getting off arc parameters $\{g, U^{l}_{j}, D^{l}_{j}, C^{l}\}$, only including the grade of the train, passenger flow and the train capacity, are direction arcs and the constraint conditions of the passenger flow without any fare.

(3) This distribution network is a self-driven network because it can be finished by calculating the named parameter, without any other data involved.

(4) This distribution network is a loop network because for some level passengers it connected the getting off node with getting on node by accumulation arc.

(5) As a loop network, when distributing the passenger flow from S to D, the trains' level of passenger flow $A_{SZ}(S \in \underline{St}; Z \in \overline{St};$ 且 $S \prec Z)$ can be inferred by finding the minimum distance between the S station node（$S \in V_1$）and Z station node（$Z \in V_2$） in the network.

Therefore, this network distribution problem is changed to a minimum distance problem of any pair of getting on node and getting off node with given passenger flow. The constriction conditions are network structure and passenger travel demand, as the distribution loop network has to include the pair of passenger's getting on node and getting off node. The objective function is the minimum total cost at the entire direction arc.

$$\min z = \sum_{i=1}^{4} F_i + \varepsilon \qquad (4)$$

$$\begin{cases} F_1 = \sum_{e_{FD}^l \in E_1} (F_{e_{FD}^l}(f_g^l) \cdot F_{e_{FD}^l}(T_g) + F_{e_{FD}^l}(f_{!g}^l) \cdot F_{e_{FD}^l}(H)) \\ F_2 = \sum_{e_{ZS}^g \in E_2} (F_{e_{ZS}^g}(J_j^g) \cdot F_{e_{ZS}^g}(f_{SZ}^g) + F_{e_{ZS}^g}(J_j) \cdot F_{e_{ZS}^g}(f_{SZ}^{!g})) \\ F_3 = \sum_{e_j^l \in E_3} F_{e_j^l}(P_{jl}^t) \cdot F_{e_j^l}(T_{jl}^t) \\ F_4 = \sum_{e_{QH}^j \in E_4} F_{e_{QH}^j}(Ph_j^{QH}) \cdot F_{e_{QH}^j}(Th_j^{QH}) \end{cases} \tag{5}$$

In the equation (5), $F_e(K)$ is self-defining function. Its return value is element k values belonging to arc-e parameter. $!g$ means the grade of train no match with the level of passengers.

The penalty values variables ε depends on the residual passenger number at the end of passenger flow distribution process. The function of ε is

$$\varepsilon = M \cdot \left[\sum_{e_{ZS}^g \in E_2} (F_{e_{ZS}^g}(A_{SZ}^h) + F_{e_{ZS}^g}(A_{SZ}^m) - F_{e_{ZS}^g}(f_{SZ}^h) - F_{e_{ZS}^g}(f_{SZ}^m)) \right] \tag{6}$$

In the equation (6), M is a sufficiently large positive number.

4 The Algorithm

4.1 The principle of distribution flow

The principle of distribution is based on the traveler transport demand and the railway transportation company's benefit, so the principle is:

(1) To meet the transportation market diversity demand and to improve passenger satisfaction, the level of passenger should match with the grade of train, so that the market capitation can be increased.

(2) The high level passenger as the main service object of high-speed railway should have the priority.

(3) In order to expending the attendance rate and increasing the enterprise profit, the long distance passenger should be distributed in advance.

4.2 The step of algorithm

According to the principle mentioned above, the steps of the distribution algorithm are:

Step1: Set up the distribution network according to the initial train operation plan and set down all parameters depending on the related data.

Step2: Sort passenger flow by the distance of OD.

Step3: Find the same level loop path which includes the getting on node and getting off node corresponding to the passenger's OD in the passenger flow priority order. Then distribute the maximum passenger flow for the each loop path from the minimum cost loop. At the same time write down the trains' information of passenger service and the parameters of network update.

Step4: If the network gets the maximum passenger flow, then go to step 6; if not, then go to step 5.

Step5: Find the entire loop path which includes the getting on node and getting off node corresponding to the rest passenger's OD in the passenger's distance and passenger's level order. Then distribute the maximum passenger flow for the each loop path from the minimum cost loop. At the same time write down the trains' information of passenger service and the parameters of network update. Go to step 4.

Step6: Calculate the distribution plan's minimum total cost according to the function (4) to function (6).

5 Conclusions

The network passenger flow distribution model and algorithm in this paper are the solution only for the passenger flow distribution problem of the initial train's operation plan or the train given the operation plan. In order to optimize the passenger flow, the distribution result in this solution need a further adjustment according to the matching information of passenger flow and the train's information. Finally, adjust the operation plan depending on the situation, and repeating iteration to get an optimal operation plan. In these whole process, there are three core problem, network passenger flow distribution optimization, passenger flow transport plan optimization, and train operation plan optimization. The optimization process shows in Figure 1.

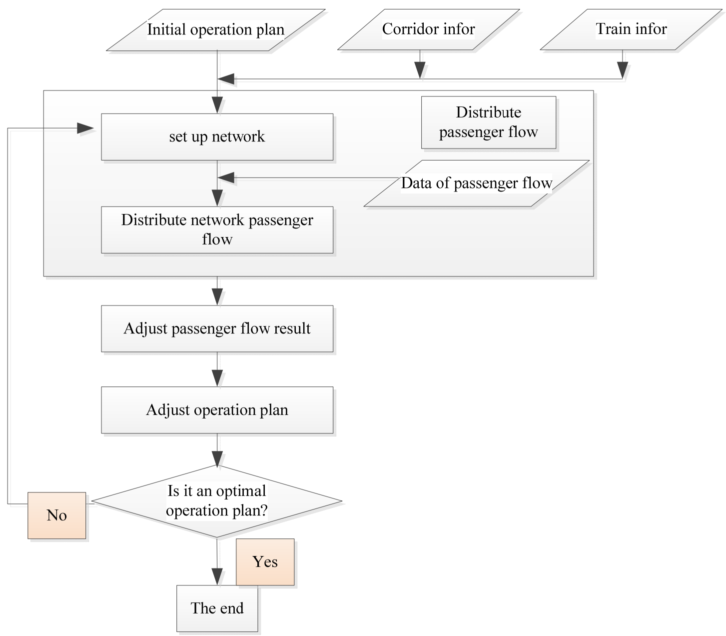

Figure 1. The Process of Optimizing Operation Plan

As a basic link in the high-speed railway transportation operation plan, a reasonable passenger flow distribution has a directly influence on the optimization result. The method in this paper applies to the Beijing- Shanghai high-speed railway corridor in 2005 operation plan and passenger flow data. The network passenger flow distribution is optimized with computer programming technique. And the optimization result has arrived at the aim expected by comparing the initial plan to the optimized plan.

Abstract: In the study of high-speed railway viaduct, structural noise is becoming a hot issue, the root cause is the local vibration which is generated when the trains pass the bridge, the vibration frequency is between 20-200 Hz. Based on the vehicle - track coupling dynamics, the local vibration of the box girder is analyzed by the Finite Element Method (FEM) in detailed. Six representative sensitive points were selected to analyze the vibration response under various conditions. Different section forms are analyzed, including different thickness, dip angle of the web plate, and so were the double room beam. The results show the local vibration can be controlled effectively by the improvement of the cross-sectional form in the practical engineering, in particular changing the thickness of the top plate, and the thickness inclination web plate, at the same time the form must meet other precondition. At last the effects of local vibration on double room box girder beam are discussed. The vibration response of double room box girder is lower than single room box girder.
Keywords: Local vibrations; Box girder; Section forms; Double room.

1 Introduction

The structural noise is caused by the local vibration which is generated when the trains pass the bridge, the vibration frequency is between 20-200Hz. The vibration is affected by many factors, so it will be discussed in this paper to find the mainly factors influencing the local vibration.

Several factors on local vibration characteristics of the box girder form is analyzed in this article, including the thickness of the each plate, dip angle of the web plate and the chamber of beam. First, the different finite element models of box girder are established, and then its time domain characteristics and frequency domain characteristics are analyzed. The previously methods (Luo wenjun, 2013, 2014) to analysis local vibration are used in this paper. The details of each analysis are as follows.

2 The effects of different forms of cross-sectional dimensions on the local vibration

The box girder is divided into the top, web, bottom and flange plate, then changing the thickness of the each part to solve, analyze the impact of each plate thickness on the bridge of local vibration. The variation in thickness of flange plate is not considered. Because flange plate is located in the edge of the beam and the effect of the variation on other parts are very little.

2.1 Thickness of top plate

Four kinds of conditions of the thickness were used to analysis—290mm, 340mm, 390mm, 440mm. The RMS curve of vibration acceleration of each sensitive points of different top thickness is shown in the figure:

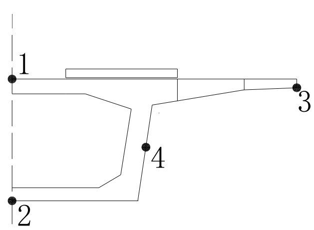

Figure 1. The sensitive point layout two kinds of box beam

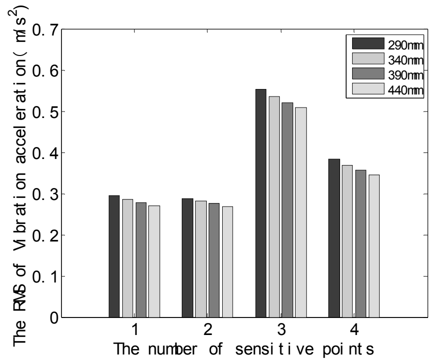

Figure 2. Vibration acceleration RMS of different thickness of top plate

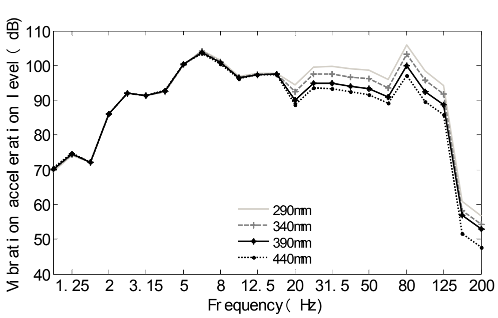
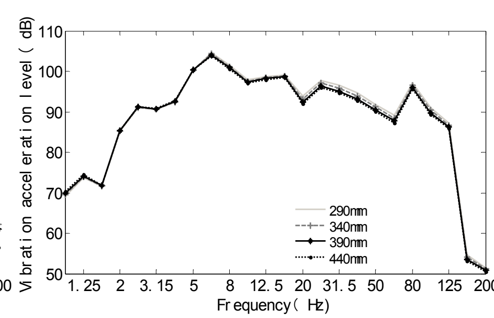
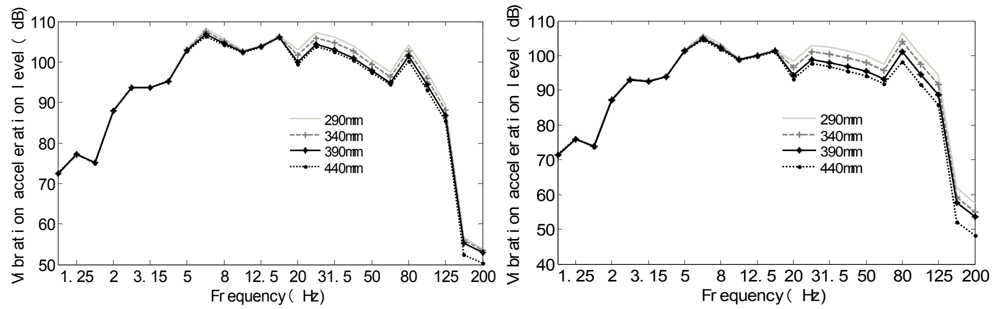
As can be seen from the figure, the acceleration RMS of all sensitive points has been reduced as the thickness from 290mm to 440mm. The reduce magnitude of each point are similar, but this cannot reflect impact of the local vibration on the points are the same, the impact on the high frequency local vibrations need to be determined through the spectrum analysis.



Point one



Point two



Point three Point four

Figure 3. The 1/3 octave of vibration acceleration

Based on the spectrum, the impact of changing the thickness on low frequency vibration 0-20Hz is relatively small, vibration level curve of the points are coincided. Between 20-200Hz, it has a more significant impact on local vibration response of point one and four, the impact on point one is the greatest. As the top become thicker, vibration level is smaller and these points are mainly located in the top and around the adjacent position. And for point three, the influence is relatively small. There is no effect on the point two. It may because these points are far away the top plate.

2.2 Bottom thickness

Four kinds of conditions of the bottom thickness were used to analyzed—250mm,250mm,300mm,350mm. The RMS bar charts of each sensitive point about different bottom thicknesses are shown in the figure:

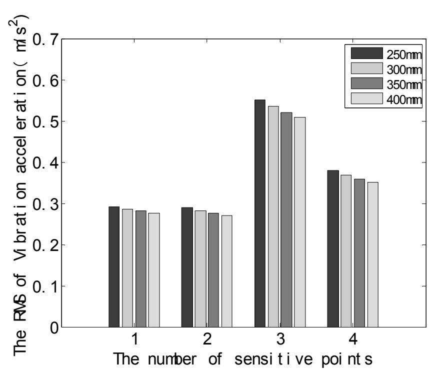


Figure 4. Vibration acceleration RMS variation

The figure shows the RMS of acceleration of all sensitive points has been reduced by the top thickness increasing and the point one decreases relatively small.

Spectrum analysis of vibration acceleration of each point is shown below. Here the expression is same with the top plate.

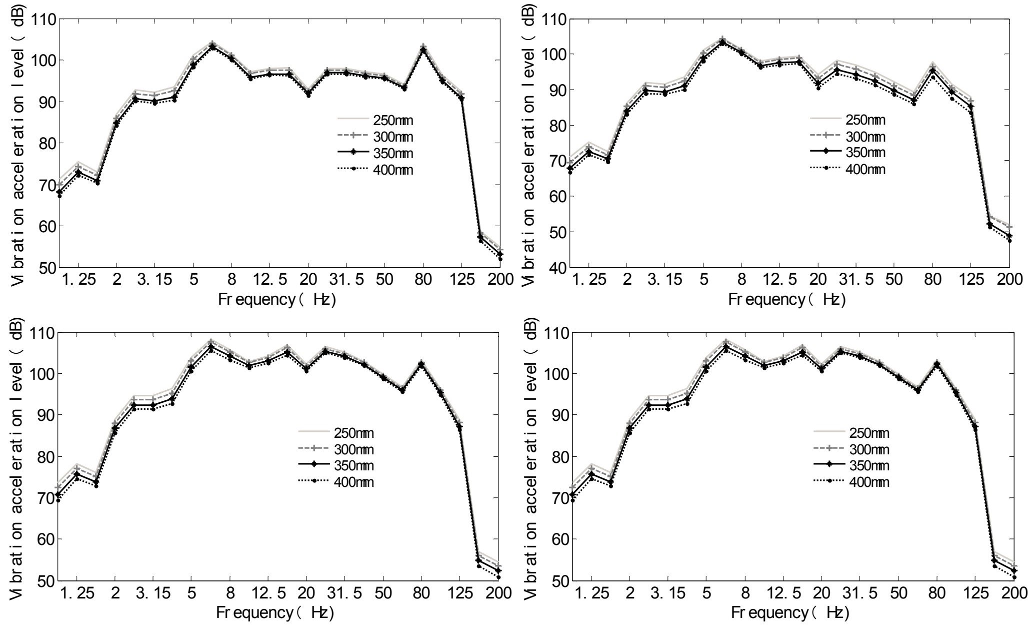

Figure 5. The 1/3 octave of vibration acceleration

According the one-third octave curve, bottom thickness of the points have little influence on each point at low frequency 0-20Hz. The situation is different from the change of the top plate; vibration level curve of four points has no too obvious differences between 20-200Hz except point two. Taken together, by changing the thickness of the bottom to control the local vibration has general effect.

2.3 Web thickness

Four different web thickness were used to be analysis—370mm, 420mm, 470mm, 520mm. The RMS curve of variation acceleration of each sensitive points of different web thickness is shown in the figure:

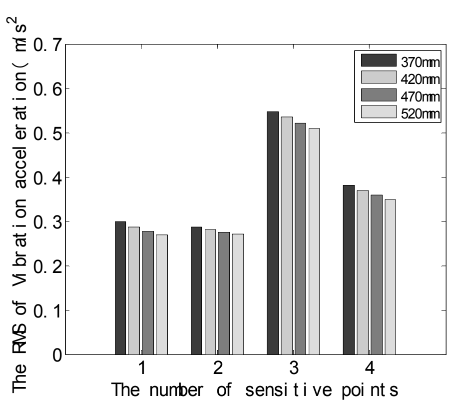

Figure 6. Vibration acceleration RMS variation

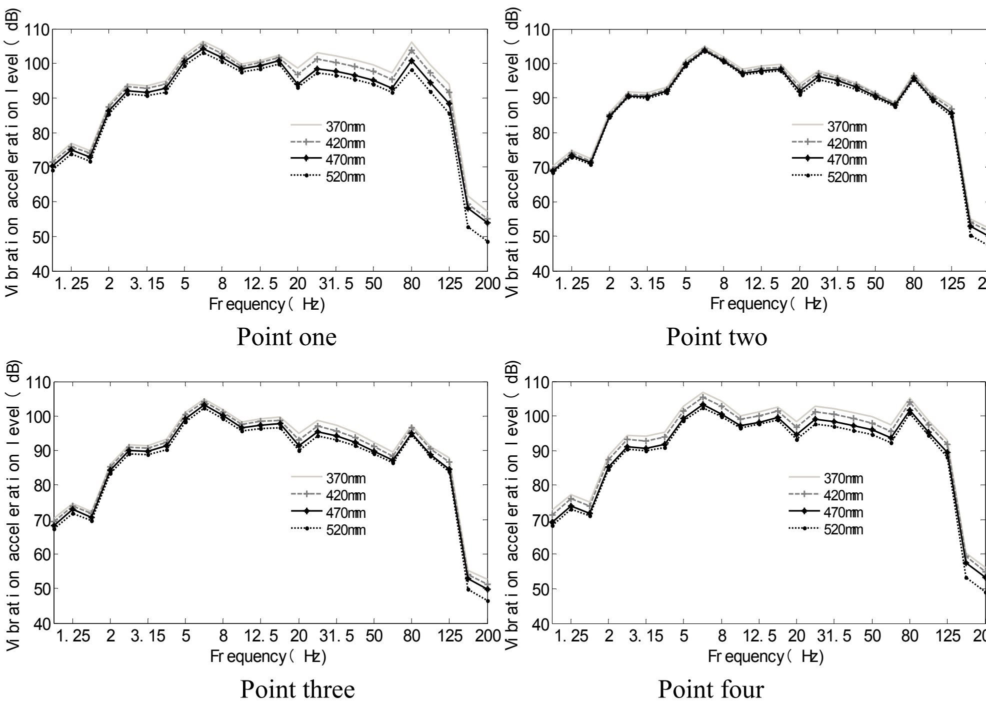
This case is similar with the above content. The difference of vibration acceleration RMS of the points is little. Now analyze the points of local vibration by discussing one-third octave curve.



Point one Point two

Point three Point four

Figure 7. The 1/3 octave of vibration acceleration

As the changing of the web thickness, the most obvious influence is on point one which located at the top plate and the point four followed. And point five which located in the middle of the web is very sensitive to the changes of web thickness at the entire band (0-200Hz). Point three which located in flange plate is not sensitive particularly. And it has no effect on the sensitive point two basically.

In summary, the changes of the top and the web thickness control the local vibration effectively.

3 Analysis of different webs inclination

The original design angle of the web plate is about 9 °. Now we analyze the influence on local vibration of the web inclination. The model diagram of 18 and 0 degrees are listed below.

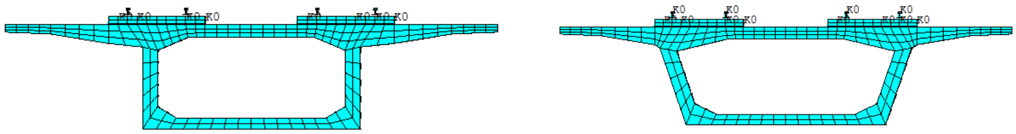


Figure 8. The model of different web inclination

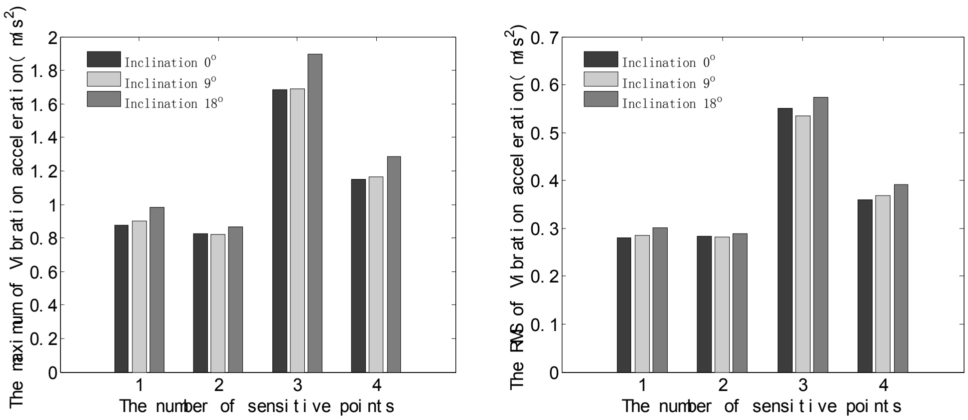

Figure 9. The maximum value and RMS of sensitive points

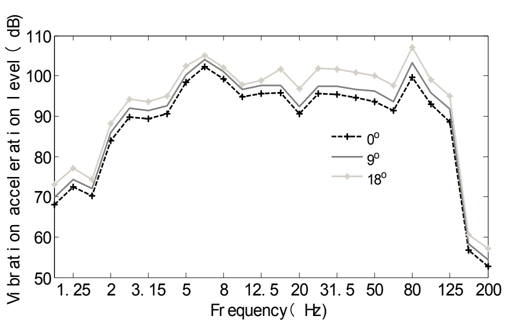
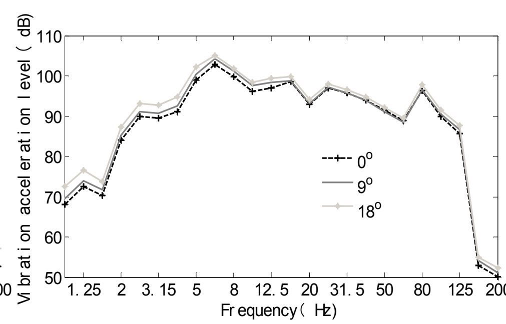
Through transient dynamic analysis of the three beams, maximum and RMS acceleration of three different inclinations are shown in the figure.9. As can be seen from the figures, vibration acceleration of each point is the largest as the inclination is 18 °, it is followed at 9 ° and it is least at 0°. However the difference between the three cases is not a simple linear. The numerical difference between 9 ° and 0 °is much smaller than the difference between 9 ° and 18 °.

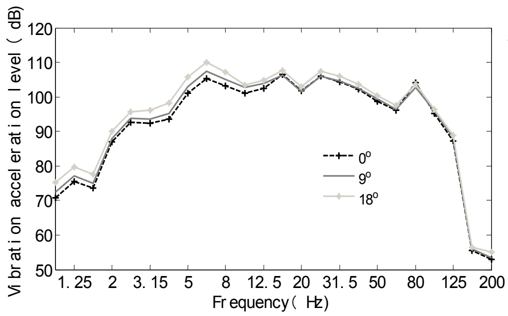
Now analyze the points of local vibration by discussing one-third octave curve:



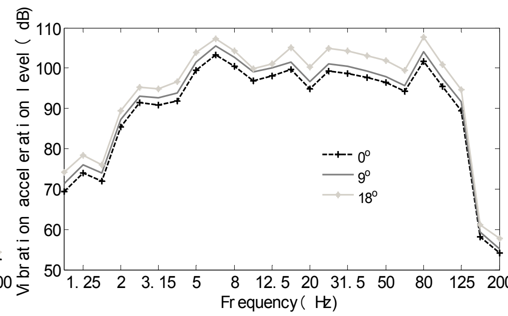
Point one



Point two



Point three



Point four

Figure 10. The 1/3 octave of vibration acceleration

The vibration level of each point in the conditions of inclination 18° were significantly larger than the other conditions, the maximum difference is about 2dB. And the difference of the inclination of 0 ° and 9 ° (design inclination) in the entire frequency band is very small. In most frequency interval, the vibration level of inclination 0 ° is smaller than it is 9°.Theoretically, it is appropriate if we can use a smaller inclination, but it does not necessarily mean it is best to set the dip to be 0 ° (Zhang xun,2012).

4 Analysis of the changing of girder chamber

This section focus on comparative study of local vibration characteristic between double-chamber girder and single room girder.

4.1 Natural vibration analysis of girder chamber

The method to establish model of double-chamber girder is similar to the single chamber beam; The model is shown in Figure 11. First the natural vibration of the girders are contrasted and it is shown in table 1.

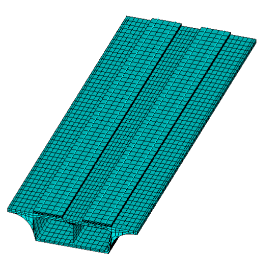


Figure 11. Double chamber beam model

Table 1. Contrast of natural vibration

Mode order	*Natural vibration frequency（Hz）*	
	Single room girder	*Double room girder*
1	*5.6113*	*5.8203*
2	*5.8784*	*5.9431*
3	*10.584*	*15.535*
4	*12.67*	*15.956*
5	*14.707*	*16.853*
6	*17.544*	*19.258*

Natural vibration characteristics of single chamber are slightly different with double room beams. The first two natural frequencies of them are similar, but the modes are contrary.

4.2 Analysis of local vibration

The dynamic analysis method of dual-chamber box is used the same with the single-chamber girder. Layout of sensitive point on double chamber beam is as follows:

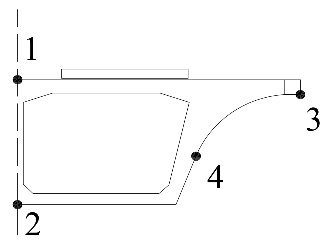

Figure 12. The contrast point layout two kinds of box beam

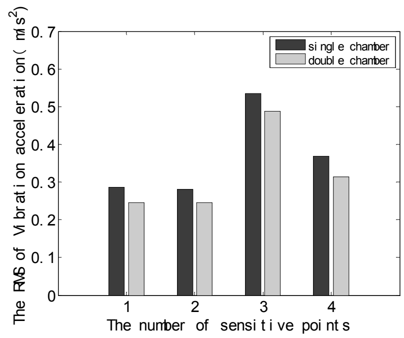

Figure13. Vibration acceleration RMS of the two types of beam

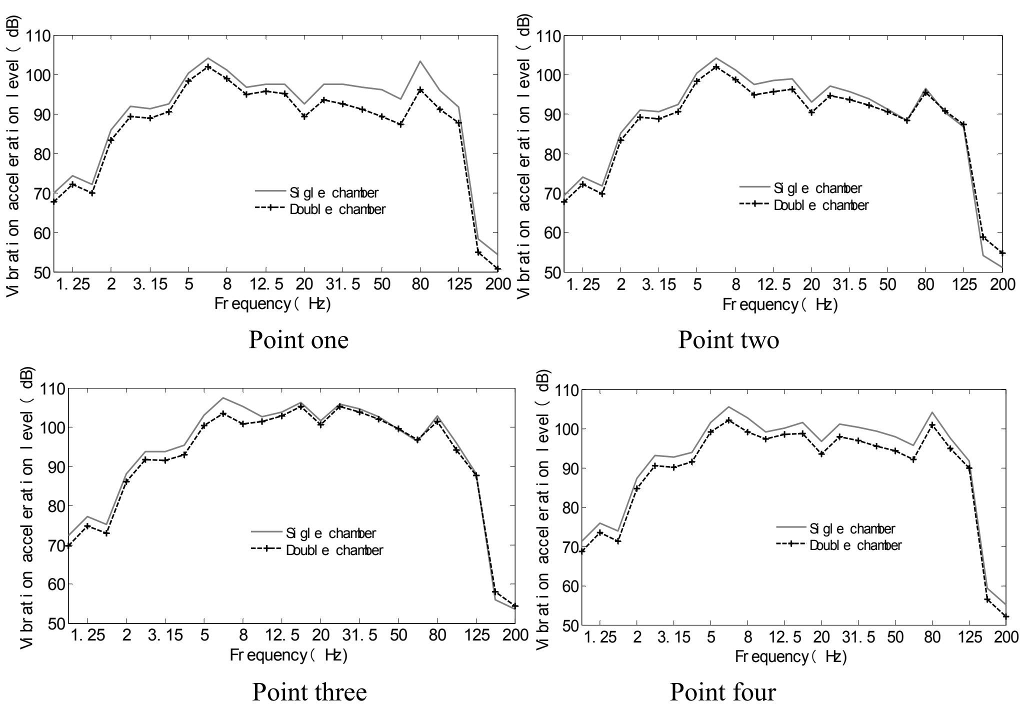
From the figure we can know that the double room in exchange for a substantial reducing of the vibration at a very low weight; The one-third octave curve are below:



Point one Point two

Point three Point four

Figure 14. Each sensitive vibration acceleration

As can be seen in the figure changes of the local vibration from 20 to 200Hz, the sensitive point one, two and four of double-chamber are significantly higher than the single-chamber, the difference of point three is not very obvious. That is, selecting the dual-chamber beam to control top and bottom plates of local vibration has obvious effect between 20 to 200Hz.

5 Conclusions

(1) Establish the models of different plate thicknesses to analysis. In a word, good effect on controlling the local vibration by changing the thickness of top web plate .

(2) Small angle has certain effect on local vibration control of structure. However, the best angle is not set to 0, other factors also need to be considered, take the most appropriate web inclination.

(3) Compared the single chamber with double chamber beam, the local vibration response of the latter is significantly weaker. In engineering selecting the double chamber beam at the corresponding position can reduce the structure noise radiation.

Abstract: Chinese high-speed railway got a fast development in recent years, several new lines have been put into operation. After analyzing the mixed passenger and cargo marshalling modes in foreign countries, the high-speed train operation cost quantitative analysis and the calculation formula was given, which was suitable for Chinese actual practice. Using the operation cost method to calculate basic work and operational work between the existing railway line and the high-speed railway passenger-dedicated line. By apportioning the single carriage single cost to calculate the equivalent under the condition of high-speed train mixed passenger and cargo marshalling into operation costs.
Keywords: Mixed passenger and cargo marshalling; High-speed train operation costs; Quantitative analysis.

1 Introduction

High-speed railway in our country in terms of passenger transportation, and domestic high-speed railway cargo has just started; the research is not deep enough. Nowadays, Wuhan-Guangzhou high-speed railway confirming train has been used to develop mass transport of ordinary express, but mixed marshalling high-speed railway has not came true.

(Gerhard Troche, 2010) for high-speed rail transport of goods to the definition, in Sweden, Denmark, France and other countries of the high-speed rail freight handling, transit and train vehicle technology, such as the train operation are summarized. (Seung-Ju, 2007) considers the transportation cost, the influence of the transit time to cost, operation plan compiling model is established.

(Lin zhonghong, 2012) analyze the feasibility of high-speed railway to carry out the fast freight, suggest should be as soon as possible to carry out the research. (Wu yunyun, 2010) studies on the pros and cons of the overseas high-speed railway freight transportation mode, analyzes the feasibility of using this mode. (Zhao chen,2009) using the activity cost method to passenger and cargo transportation costs for research. However, the domestic most of activity cost method for cost calculation is macro qualitative analysis, lack of quantitative analysis. Mixed transportation potential market of high-speed railway, the feasibility of the train operation, and the researching mode of operation is less. This paper is mainly considering different marshalling modes and under the influence of running speed, combined with the cost of high-speed railway passenger dedicated line and existing lines freight cost by the activity cost method ,using the influence coefficient of high-speed railway passenger and cargo mixed into the running cost of the train.

2 Transportation cost allocation

2.1 The high-speed railway passenger dedicated line transportation cost allocation

According to the characteristics of the high-speed railway transportation production organization, combined with the requirements of the activity cost method calculate principle of railway transportation, the high-speed railway passenger transport production process is divided into operation and basis two parts. The passenger dedicated line operation cost allocation is divided into sending activity, operating activity and maintenance activity. In order to analyze the structure of high-speed railway passenger dedicated line operation cost, divided the high-speed railway operation cost into wages, power, material, depreciation, capital costs and other expenses six parts by economic nature.

High-speed railway passenger dedicated line operation assignments, operating index and corresponding allocation of spending grouped collection, the collection summary as shown in figure1.

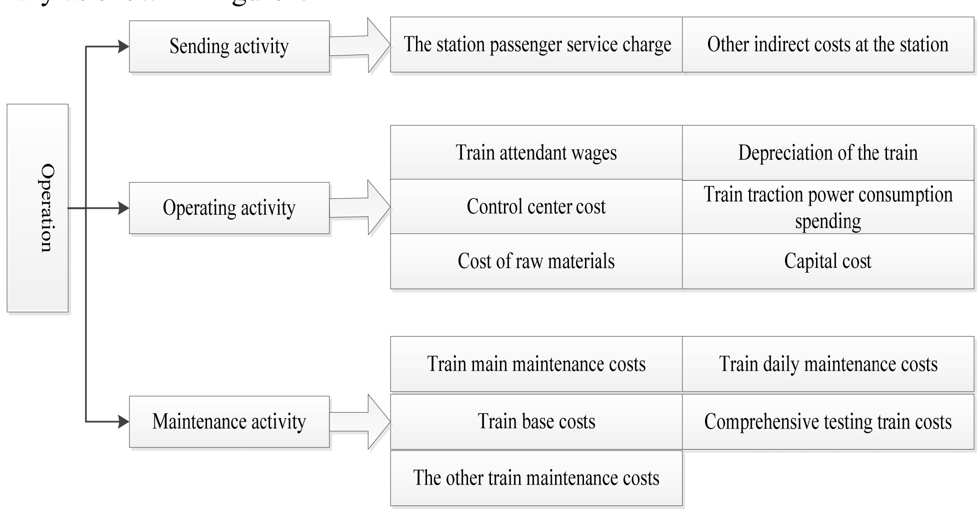

Figure1. Summary of passenger dedicated line operation assignments

The above mentioned can determine the dedicated line which has the certain starting station and a high-speed railway passengers , then every carriage daily produced in the process of train running average operating costs C_{Y_1} computation formula is as follows.

$$C_{Y_1} = (\sum \text{ Operating expenditure project} \times \text{The single running operating indexes})/T_1 \quad , \quad T_1 = 16\mu + 8(1-\mu) \qquad (1)$$

In the (1) formula, T_1 is passenger railway marshalling carriage number, General Chinese high-speed railway marshalling for 8 or 16 carriages. μ is a 0-1 variables, $\mu = 0$, shows the marshalling train running, but $\mu = 1$, shows the marshalling train is not running.

High speed railway passenger dedicated line's basic assignments, operating index and corresponding allocation of spending grouped collection and the collection summary as shown in figure2.

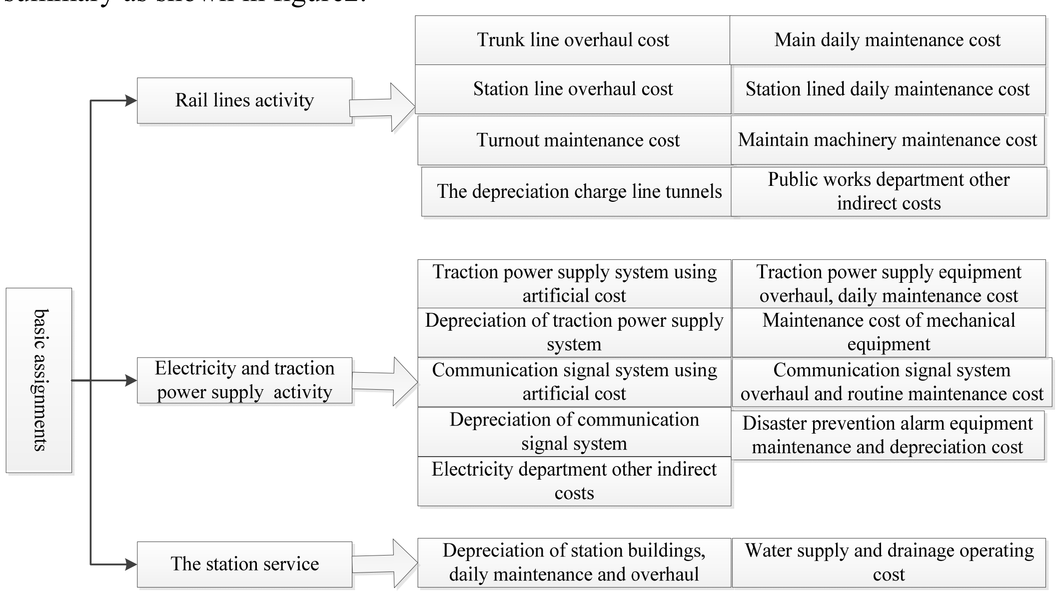

Figure2. Summary of passenger dedicated line basic assignments

By the above-mentioned can be in determining the starting station and a high-speed railway passenger dedicated line determined, every carriage daily produced in the process of train running average basic assignments C_{Z_1} computation formula is as follows.

$$C_{Z_1} = (\sum \text{ Basic assignment expenditure project} \times \text{Basic assignment index})/T_2 \quad ,$$

$$T_2 = W_1 \times 365 \times (16n_1 + 8n_2) \quad (2)$$

In the (2) formula, W_1 is the maximum operating life of high-speed railway lines, n_1 is the number of daily operation class of high-speed railway passenger dedicated line to 16 carriages marshalling. n_2 is the number of daily operation class of high-speed railway passenger dedicated line to 8 carriages marshalling.

2.2 Existing railway cargo transportation costs

Also existing railway cargo transport operations can be divided into the cost of cargo operations assignments and foundational assignments.

2.2.1 Cargo transport operations assignments cost allocation

Cargo transport operations are divided into sending assignment, transit assignment, operating assignment. The rail cargo operations indexes and cost range as shown in figure3.

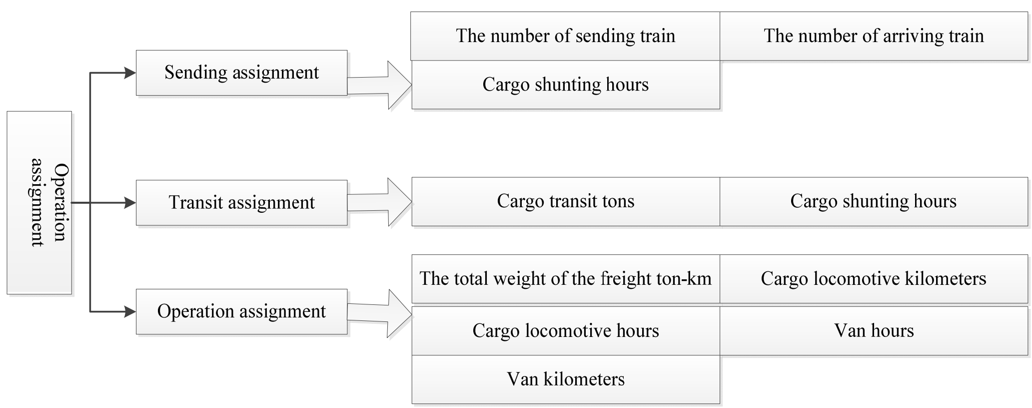

Figure3. Summary of cargo operation assignments

By the above can be in determining the starting station and arriving station into an existing railway to transport goods, every carriage daily produced in the process of train running average operating assignment costs C_{Y_2} computation formula is as follows.

$$C_{Y_2} = (\sum \text{The operational indexes} \times \text{The single running operating costs}) / T_3 \quad (3)$$

In the (3) formula, T_3 is the marshalling freight carriage number of existing railway cargo trains.

2.2.2 Existing railways mixed running cost allocation proportion

Li Daian by applying the method of railway line engineering model system research and calculation analysis concluded that the cargo on the basic assignments cost ratio of the railway line is 68.72%, passenger is 28.32%.To determine the existing lines and passenger, cargo cost allocation proportion is 28.32% and 68.72% respectively, roughly 3:7. So the proportion of existing railway passenger and cargo basic assignment costs allocation is 3:7.

2.2.3 Carriage of goods by basic assignment costs

Existing railway basic assignments cost calculation, the operating indexes and cost range summary as shown in table1.

Table1.Summary of basic assignments cost

Assignment		The index of transportation activities	Corresponding to the cost
Basic assignment	Line based assignments	The past total weight of ton kilometer	Public works department cost
	Train operation signal	Freight train kilometer	The communication signal cost
	Station operation	The number of sending goods	The cost of the maintenance, depreciation, etc.

By the above can be in determining the starting station and arriving station into an existing railway to transport goods, every carriage daily produced in the process of train running average basic assignment costs C_{Z_2} computation formula is as follows.

$$C_{Z_2} = 0.7\times(\sum \text{The operational indexes} \times \text{Corresponding to the cost}) / T_4$$

$$T_4 = W_2 \times 365 \times n_3 \times T_3 \qquad (4)$$

In the (4) formula, W_2 is the largest operating life of existing railway lines, n_3 is the number of daily operation class of existing cargo railway line marshalling with T_3.

2.3 Mixed marshalling modes

On the marshalling modes, from abroad to carry out high-speed railway passenger and cargo mixed into the model, there has been passenger and cargo coexist in a high-speed train. In theory, it is suitable for the high-speed railway in passenger and cargo mixed marshalling can be divided into the following two modes, as shown in figure 4.

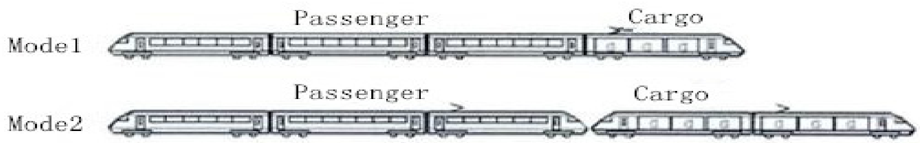

Figure4. Mixed marshalling mode of the high-speed railway

The first is passenger carriages and cargo carriages coexist in the same model of high-speed train, which is the highest degree in mixed mode.

The second is the goods and passengers in different train transportation respectively. In this mode, the cargo train and passenger train on the same line can united together to run from the different starting and end point. From the above figure 4 we can know that mode 1 and mode 2 on the number of passenger and cargo carriages ratio is 3:1, 3:2 respectively. General Chinese high-speed railway marshalling is 8 or 16 carriages marshalling. To choose different marshalling mode with the number of passenger and cargo carriages（$N_1 : N_2$） that show in table2.

Table2. Mixed carriages number of different marshalling modes

Carriages number（N_1:N_2）	8 marshalling	16 marshalling
Mode 1	6:2	12:4
Mode 2	5:3	10:6

2.4 The influence coefficient of running speed under mixed marshalling

In terms of speed, the high-speed railway passenger dedicated line and cargo train of existing lines in the process of transport of the two speeds is different, and there is a certain gap. For mixed marshalling operation, passenger and freight coordinated transport makes for reasonable running under the same speed. For passenger transport, due to the change of speed, consider the influence of mixed marshalling for the passenger transportation costs into an influence coefficient λ_1.

$$\lambda_1 = \frac{\overline{V}_2}{\overline{V}_1 + \overline{V}_2} \times \frac{2V_3}{\overline{V}_1 + \overline{V}_2} \quad , \quad \overline{V}_2 \le V_3 \le \overline{V}_1 \tag{5}$$

In the (5) formula, $\overline{V}_1$ is the high-speed railway passenger dedicated line average running speed, $\overline{V}_2$ is existing railway cargo train average running speed, V_3 is mixed marshalling high-speed train running speed under the condition of mixed marshalling, $\frac{2V_3}{\overline{V}_1 + \overline{V}_2}$ is mixed marshalling under the condition of high-speed railway running speed of passenger and cargo operation speed impact factors as a whole. Because of the influence of the speed of the operation of the passenger is mixed into relative decline, it should also multiply $\frac{\overline{V}_2}{\overline{V}_1+\overline{V}_2}$ as the cost ratio.

Due to the change in the speed of the effect of the cargo costs it should into an influence coefficient λ_2.

$$\lambda_2 = \frac{\overline{V}_1}{\overline{V}_1+\overline{V}_2} \times \frac{2V_3}{\overline{V}_1+\overline{V}_2} \quad , \quad \overline{V}_2 \le V_3 \le \overline{V}_1 \tag{6}$$

$\frac{\overline{V}_1}{\overline{V}_1+\overline{V}_2}$ is as mixed into the running speed of cargo relatively increase, the operation cost of the cargo ratio should be increased.

3 The running cost calculation model of high-speed railway mixed marshalling

After determining the departure point and the end, considering the same starting and arriving station to the same line of existing railway with high-speed railway passenger dedicated line running average allocation cost in each compartment, calculating mixed cycling times daily high-speed railway marshalling produced in the process of car running cost as flows.

$$C_W = \lambda_1 \times N_1 \times C_P + \lambda_2 \times N_2 \times C_g \quad , \quad C_P = C_{Z_1} + C_{Y_1} \quad , \quad C_g = C_{Z_2} + C_{Y_2} ,$$

$$\lambda_1 + \lambda_2 = \frac{2V_3}{\overline{V}_1+\overline{V}_2} \quad , \quad \overline{V}_2 \le V_3 \le \overline{V}_1 \tag{7}$$

In the (7) formula, C_W is a certain passenger and mixed marshalling under the condition of high-speed railway running costs, C_P is high-speed railway passenger dedicated line single carriage single running costs, C_g is existing railway single cargo carriage single running costs, N_1、N_2 is the number of passenger and cargo carriage of different mode mixed marshalling respectively. It is shown from table 2.

4 Conclusions

For the current situation of high-speed railway in our country, this paper is based on one of the same station, same line, application of operate cost method, respectively, calculated existing lines and high-speed railway passenger dedicated line in the basic assignment and operation assignment, by using single carriage single cost to calculate the equivalent under the condition of high-speed railway passenger and mixed marshalling of running costs. Utilization of equivalent existing line freight and high-speed railway passenger dedicated line operation cost, considering both the difference between average running speeds, under the condition of passenger and cargo mixed into the unity of the running speed of the impact of different types carriages cost allocation, introduced changes in the rate of correction effect coefficient will affect in operating costs, it is more convenient to use quantitative method of cost calculation.

5 Recommendations for Future Research

High-speed railway passenger and cargo mixed marshalling mode mentioned in this paper was suitable for bulk transport, this paper is based on the alignment of the proposed model will send stations between mixed into all the way, also need to consider in the process of the actual intermediate stop stations to exchange passengers, unloading streamline cross interference on running cost impact on each other and there is some differences between the high- speed railway operation cost of the existing railways. This is the ongoing work of the next.

Abstract: Night train is a form of adapting to development of high-speed railway and passenger transport demand in China. High-speed rail train operation at night exist such as waiting for line, transferring line and “a line of maintenance, a line of traffic” three modes, corresponding respectively the way of two line totally closed maintenance and one line closed maintenance. Through comparative analysis, it can be found that high-speed rail window setting should adopt fully closed mode. Based on summary analysis of traditional rectangular window feature, this paper proposes the set form of two-day segmenting rectangle window, and it can effectively avoid the disadvantages of traditional segmenting rectangle window. Finally, taking the Beijing-Shanghai high-speed railway as an example, the paper analyzes the set of two-day segmenting rectangle window.
Keywords: High-speed railway; Trains operating in night (night trains); Comprehensive maintenance window; Sectional rectangular window.

1 Introduction

So far, China has opened the Beijing-Guangzhou, Beijing-Shanghai, Beijing-Harbin high-speed railway having the length of more than 500 km, which basically have communicated with each other, with the conditions for running across the line. High-speed long distance trains run across the line, the operation time of which is significantly longer, having a great impact on the setting of window. At the same time, with the development of social economy and improvement of people's living standard, the public per capita trip time becomes more and more, and travel ways also become more and more diverse; the main service object of the high-speed railway is the business flow, high level commuter passenger flow and tourist flow, who have higher sensitivity to the travel comfort and time. To attract more passenger groups, China’s railway sector needs provide more diverse high-speed railway transport products to socialization. Therefore, it is necessary to consider opening the high-speed train at night, which will also generate conflict between operation and maintenance.

2 Night train operation mode analysis of high-speed railway

2.1 Types of driving mode at window time

At present, the vast majority of worldwide high speed railway adopts the mode of transportation driving during the day and comprehensively maintaining at night. While the mode of driving at night is associated with the maintenance mode of window, generally divided into the following two categories:

(1)Line full closed mode at window time

As lines are full closed in window time, high-speed trains entering the window time have only two choices:

① Waiting for line mode : Stop waiting in the front station before the window opens, then the trains continue to run on high-speed lines after the closure of the window.

②Transferring line mode: In front of the station within the range of window, the high-speed trains run down to the existing line, running again up to the high-speed line after the closure of the window.

Compared to the transferring line mode, the waiting for line mode has higher requirements to the ability of window station equipment, and not conductive to the repair work at night. There night trains should use the transferring line mode.

(2)The mode of "a line of maintenance, a line of traffic" in the window time

When working on comprehensive repair at night, only a line is repaired, however another line organizes bidirectional train operation.

2.2 Driving mode comparison of window time

(1) The full closed mode uses complete closure of service sector, and external factors influencing the repair work are less, requiring shorter window time; because the mode of "a line of maintenance, a line of traffic" is affected by the train operation of adjacent lines, part of repairing work can be performed under certain conditions, requiring longer window time.

(2) The full closed mode does not provide capacity in the window time; while the mode of "a line of maintenance, a line of traffic" has certain driving conditions in the window time.

(3) Under the full closed mode, because of less factors of influencing repair work, repair efficiency is high; the mode of " a line of maintenance, a line of traffic" both influence each other in train's running and maintenance, so repair efficiency is low. According to the above comparative analysis, the window of high-speed railway should be set to the full closed mode.

3 Analysis of high-speed railway window setting

3.1 Traditional segmenting rectangle window

Rectangle window can realize fully closed repair of lines, is the comprehensive repair window way commonly adopted by the national high-speed railway. It is divided into vertical rectangle and segmenting rectangle, and the vertical rectangle is a special form of segmenting rectangle window. Traditional segmenting rectangle window, refers to take the daily (24h) as the cycle, between 0:00 and 6:00, respectively open rectangle window according to the window sublevel, none of which has the same opening time, as shown in figure1. It has the following characteristics:

(1) Has great flexibility, namely can choose the right time, tilt direction, inclination angles across the line according to the need of actual traffic, opening in a variety of ways such as segmentation, combination and continuation.

(2) By adjusting the opening time of each segmentation window, it can provide certain night operation conditions for trains of the slope direction in a smaller range.

(3) Full consecutive set will produce great influence area, even can affect daytime departure; it has greater influence on the train in the opposite direction to the window sloping direction. Therefore, the window should not be continuously opened across the line.

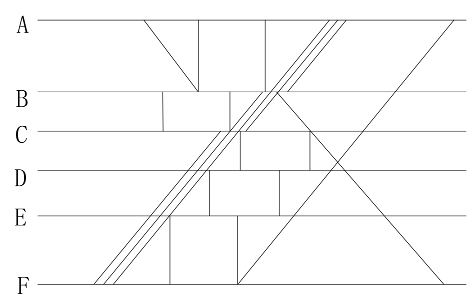

Fig.1 Schematic diagram of sectional rectangular window

3.2 Two-day segmenting rectangle window

Two-day segmenting rectangle window, refers to take the two days (48h) as the cycle, between 0:00 and 6:00, respectively open rectangle window according to the window sublevel. Thus, segmentation rectangular window will be opened in two different ways in a cycle, to ensure the capacity balance between the uplink and downlink, as shown in figure 2.

Fig.2 Schematic diagram of two-day segmenting rectangle window

Based on the adjustment of opening period of segmenting rectangle window, and in harmony with train running chart drawing, two-day segmenting rectangle window has not only the characteristics of traditional segmenting rectangle window, but also can effectively avoid the disadvantages:

(1) The line can be integrated maintenance by taking the full closed mode;

(2) Having the same capacity with traditional segmenting rectangle window, it can achieve balance of the train operation between the uplink and downlink;

(3) It can reduce the efficiency of traditional segmentation rectangular window due to limited capacity of motor train-set and be uneven;

(4) The deficiency is that part of night train need to organize the next day trip.

4 Case study

Taking the Beijing-Shanghai high-speed railway as an example, 4 hours two-day segmenting rectangle window is opened between 0:00 and 6:00, the train running speed is 200km/h in the period of time, and the night train adopts referring line mode in Ji'nan-Xuzhou section. According to the above description, the Beijing-Shanghai high-speed railway window is set, as shown in figure 3(the shaded areas in figure 3 indicate the running time of the night train).

Through the figure 3 as you can see, opening two-day segmenting rectangle window can increase night capacity of the line section; within two days, the capacity of the uplink and downlink balances, also ensuring the efficiency of the bottom of the train.

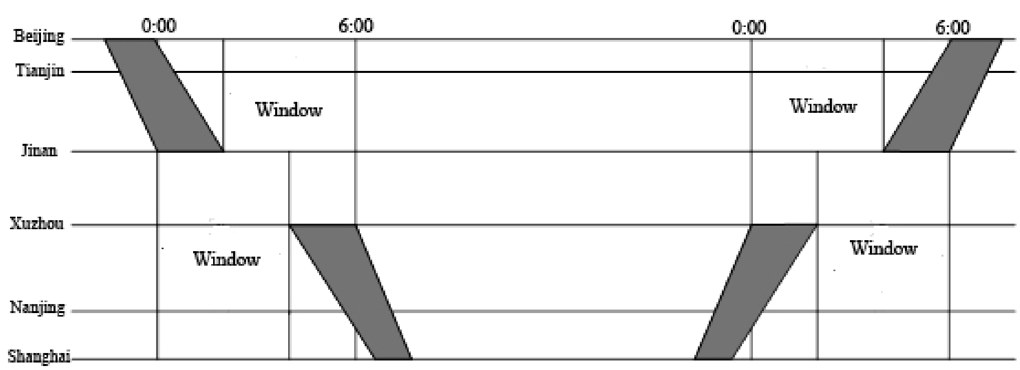

Fig.3 The window set of night operation plan of Beijing-Shanghai high-speed railway

5 Conclusions

The operation of high-speed railway night train, not only conforms the characteristics of long line and train operation time of China's high-speed railway, also accords with the requirement of mining the potential of high-speed railway in the greatest efficiency.By analyzing of night train plans for high-speed railway, on the basis of the traditional segmentation rectangular window, this paper puts forward two-day segmenting rectangle window suitable for long-distance high-speed railway train operation at night, providing certain reference for opening night train of our country high-speed in the future. However, this pattern is only a kind of discussion, these related contents coordinate with train plans and running chart drawing for the process of implementation still need further research.

Abstract: From 4 aspects of technical condition of fixed equipment, running speed of middle-speed trains, passing capacity of high-speed railway and technical condition of mobile equipment, this paper studies the reasonable matching program of high-speed railway by using mixed operation of two speed types of trains, then the allowable speed matching programs under each condition were achieved. Combining with each factor, the paper suggests that during mixed operation of two speed types of trains on high-speed railways, 3 speed matching programs shall applied, which including 300/200 km/h and above, 250/200 km/h and above as well as 200/140 km/h and above.
Keywords: High-speed railway; Train speed; Reasonable matching.

1 Introduction

The differences of passenger transportation products in High-speed railway mainly reflected on the train speed. Because the train speed is different, its operating costs and the time value of passenger are different. Because of different high-speed railway operation speed of trains, it will cause economic war of freight rate and time saving between railway enterprises and passengers. And reasonable matching speed of high-speed trains needs to consider fixed equipment condition, mobile devices, and transport organization.

2 The status about reasonable matching speed of high-speed trains in China

The speed matching situation is shown as table 1.

Table 1. The speed matching situation about line and cross-line trains

Railway line	Line train speed/(km/h)		Cross-line train speed/(km/h)	
	High-speed train	Motor train	High-speed train	Motor train
Beijing-Shanghai	300	250	300	250
Wuhan-Guangzhou	300	250	300	—
Guangzhou-Shenzhen-Hong Kong	200	—	200	—
Zhengzhou-Xian	300	250	—	250

Shanghai-Nanjing	300	—	300	250
Shanghai-Hangzhou	300	—	—	250
Hefei-Nanjing	—	—	—	250、200
Hefei-Wuhan	—	200	—	200
Qingdao-Jinan	—	200	200	200
Ningbo-Taizhou-Wenzhou	—	—	—	200
Wenzhou-Fuzhou	—	200	—	200
Fuzhou-Xiamen	—	200	—	200
Hefei-Bengbu	300	—	300	—
Zhengzhou-Wuhan	300	250	300	250
Beijing-Zhengzhou	300	250	300	250
Harbin-Dalian	200	200	—	200

As shown in the table 1, there are following three kinds of situations about high-speed railway operation of train speed matching in China.

(1) Use 300 km/h high-speed trains match more than 250 km/h emu trains.

(2) Use 250 km/h high-speed trains match more than 200 km/h emu train.

(3) Use only one kind speed of above 200 km/h emu trains.

3 Technical condition of fixed equipment

3.1 Basic technical condition

Reasonable matching speed between line train and cross-line train need to consider technical condition of this line and the adjacent lines.

(1) When different speed trains collinear run, maximum speed and minimum speed are limited by technical condition of high outer rail and minimum radius of curve(The Ministry of Railways,2008). The lowest speed matching of different speed trains operation in high-speed railway is: 200/120 km/h, 250/140 km/h and 300/160 km/h.

(2) Existing railway and high-speed railway in China widely used CTCS train control system, and there are five levels now: CTCS-0, CTCS-1, CTCS-2, CTCS-3 and CTCS-4.

3.2 The condition of train control system

(1) The existing lines whose speed is no more than 160km/h generally use CTCS-0 or CTCS-1 train control system.

(2) The existing lines of transformation whose speed is 200km/h and the passenger special line whose speed is 200~250km/h generally use CTCS-2 train control system.

(3) The high-speed railway whose speed is no less than 300km/h generally use CTCS-3 train control system.

(4) CTCS-0 and CTCS-1 can switch with CTCS-2; CTCS-3 can switch with CTCS-2, but CTCS-3 can't switch with CTCS-0 and CTCS-1.

If collinear trains don't slow down to run, it should promise that the train control system match each other. Therefore, the minimum matching speed of different trains in high-speed railway is 200/120km/h, 250/120km/h and 300/200km/h.

4 Travelling speed of middle-speed trains

When the high-speed trains and middle-speed trains run collinear, the influence for middle-speed trains is the basis of reasonable matching speed. The coefficient of travelling speed for middle-speed trains is estimated by formula 1(PENG Qiyuan,2008).

$$\beta_B = \frac{v_{Bl}}{v_{By}} = \frac{T_B}{T_B + T_{Be} + [T_B(1-\Delta B)]/1\,440 \times n_A[0.5(1-\Delta \mathrm{B})t_y + 2I + t_q]} \quad (1)$$

From formula 1: v_{Bl} (v_{By}) is travelling speed for middle-speed trains; T_B (T_{Be}) is running time (station time for passengers taking down); ΔB is the speed ratio of middle-speed trains and high-speed trains; n_A is the number of railway traffic of high-speed trains; t_y (t_q) is the running time in section of middle-speed train (Additional parking time is 4 min); I is the average tracking interval time of middle-speed train (5 min).

According to the reference of Wuhan-Guangzhou, Zhengzhou-Xian, Shanghai-Nanjing, Shanghai-Hangzhou, Beijing-Shanghai and Hefei-Nanjing passenger special lines, determine the relevant parameter value (As shown in table 2). Base on formula 1, compute speed factor of middle-speed train in different speed matching programs, as shown in the figure 1.

Table 2. Travelling speed calculation parameters of middle-speed trains

Train speed/(km/h)	Line length /km	Average station distance /km	T_{Be} /min	n_A /double
300	600	60	15	50
250	300	35	15	50
200	300	35	15	50

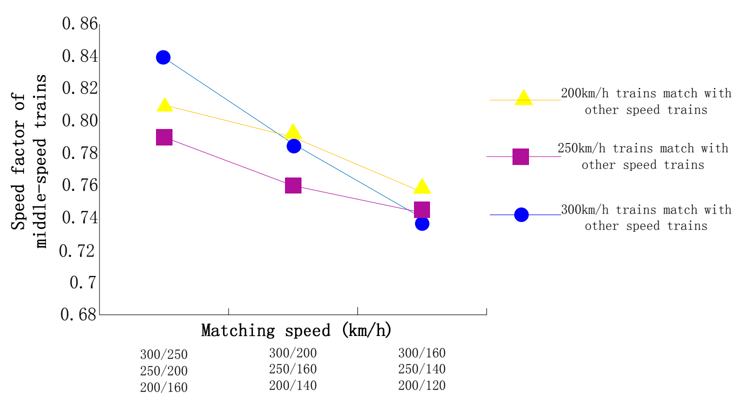

Figure 1. Speed factor curve of middle-speed trains in matching programs

The figure 1 shows that the bigger of speed difference, the smaller the speed factor of low level train. When high-speed and middle-speed trains matching speed are above 200/120km/h, 250/160km/h and 300/200km/h, the speed factor of middle-speed trains are all more than 0.75. This shows that the speed difference of high-speed and middle-speed trains is no more than 100km/h.

5 Passing capacity of high-speed railway

Most high-speed railway in China are passenger special lines, so it will must take place that high-speed trains overtake middle-speed trains when the train runs collinear. Therefore, determining the speed of the train operation plan must consider the impact of speed difference for passing capacity. When use coefficient of train removal to calculate passing capacity of high-speed railway, determine the average coefficient of train removal is the key.

5.1 The determination of coefficient of train removal

(1) Coefficient of high-speed train removal. High-speed train stopping will have to deduct for passing capacity of railway line. When high-speed trains stop at a rate of 20%, and stopping time is between 1 min and 5 min, coefficient of high-speed train removal ε can be valued between 1.4 and 1.6(LIU Xiaoqing,2008).

(2) Coefficient of middle-speed train removal. When the number of railway traffic of high-speed trains is a, and the number of railway traffic of middle-speed trains is b, the probability of train running by automatic block signals between overtaking stations is b/(a＋b), and the probability of single train running is a/(a＋b). Base on whether the train is parking, middle-speed train formation of the train operation can be set is divided into 8, and calculate coefficient of train removal, as the table 3. When the distance between two overtaking stations is 100 km, calculate the probability of 6 kinds (As shown in the table 3). The average coefficient of middle -speed train removal is the weighted average of 6 kinds.

Table 3. Coefficient of middle -speed train removal and occurrence probability

<table>
<tr><th>NO.</th><th colspan="2">Trains in front</th><th colspan="2">Trains in after</th><th>Coefficient of train removal</th><th>probability</th></tr>
<tr><td>1</td><td>High-speed</td><td>Don't stop</td><td>Middle -speed</td><td>Don't stop</td><td>$\varepsilon_1 = 1 + \Delta t / I$</td><td>$\omega_1 = 2a/5(a+b)$</td></tr>
<tr><td>2</td><td>High-speed</td><td>Don't stop</td><td>Middle -speed</td><td>Stop at station</td><td>$\varepsilon_2 = 1 + (\Delta t + t_q) / I$</td><td>$\omega_2 = 2a/5(a+b)$</td></tr>
<tr><td>3</td><td>High-speed</td><td>Stop at station</td><td>Middle -speed</td><td>Don't stop</td><td>$\varepsilon_3 = 1 + \Delta t / 2I$</td><td>$\omega_3 = a/10(a+b)$</td></tr>
<tr><td>4</td><td>High-speed</td><td>Stop at station</td><td>Middle -speed</td><td>Stop at station</td><td>$\varepsilon_4 = 1 + (\Delta t + t_m - t_h + t_q) / I$</td><td>$\omega_4 = a/10(a+b)$</td></tr>
<tr><td rowspan="3">5</td><td rowspan="3">Middle-speed</td><td>Don't stop</td><td rowspan="3">Middle -speed</td><td>Don't stop</td><td rowspan="3">$\varepsilon_5 = 1$</td><td rowspan="3">$\omega_5 = 3b/4(a+b)$</td></tr>
<tr><td rowspan="2">Stop at station</td><td>Stop at station</td></tr>
<tr><td>Don't stop</td></tr>
<tr><td>6</td><td>Middle-speed</td><td>Don't stop</td><td>Middle -speed</td><td>Stop at station</td><td>$\varepsilon_6 = 1 + (t_m + t_q) / I$</td><td>$\omega_6 = b/4(a+b)$</td></tr>
</table>

Note: The stopping proportion of high-speed trains is 20%, the stopping proportion of middle-speed trains is 50%, and average distance between stations is 50 km; t_h (t_m) is stopping time in the station of high-speed (middle-speed) trains; Δt is the running difference time of high-speed train and middle-speed train at the overtaking point.

5.2 The calculation of passing capacity

From the above, the passing capacity of high-speed railway in different overtaking distance and different matching speed. When L=100 km, coefficient of train removal for 300km/h high-speed trains is 1.5, coefficient of train removal for 200～250km/h high-speed trains is 1.4(The Ministry of Railways,2008). Passing capacity of high-speed railway in different matching speed is as shown in table 4.

Tab. 4. Passing capacity of high-speed railway in different matching speed

Matching situation		b=5	b=10	b=15	b=20	b=25	b=30	b=35	b=40
300/250 km/h	$\varepsilon_{parallel}$	3.11	3.05	2.99	2.92	2.85	2.78	2.70	2.62
	a	166	156	146	136	126	117	108	99
300/200 km/h	$\varepsilon_{parallel}$	4.95	4.82	4.67	4.50	4.31	4.11	3.89	3.67
	a	160	144	129	115	101	89	79	69
300/160 km/h	$\varepsilon_{parallel}$	7.24	7.00	6.69	6.32	5.88	5.42	4.95	4.50
	a	152	130	109	90	74	62	52	44
250/200 km/h	$\varepsilon_{parallel}$	3.73	3.65	3.57	3.48	3.38	3.27	3.16	3.03
	a	175	162	149	137	125	114	103	93
250/160 km/h	$\varepsilon_{parallel}$	6.03	5.86	5.65	5.41	5.13	4.82	4.50	4.16
	a	167	146	127	109	93	79	68	58
250/140 km/h	$\varepsilon_{parallel}$	7.67	7.42	7.09	6.67	6.19	5.67	5.14	4.64
	a	161	135	111	91	73	60	50	42
200/160 km/h	$\varepsilon_{parallel}$	4.19	4.09	3.99	3.87	3.74	3.61	3.46	3.30
	a	172	158	144	130	118	106	94	84
200/140 km/h	$\varepsilon_{parallel}$	5.83	5.67	5.48	5.25	4.99	4.70	4.39	4.08
	a	167	147	128	110	95	81	69	60
200/120 km/h	$\varepsilon_{parallel}$	8.02	7.74	7.38	6.92	6.37	5.79	5.22	4.69
	a	159	132	107	86	69	56	46	39

Note: $t_h = t_m = 3\min$, I=3min, $t_q = 3\min$

The table 4 shows that the larger the speed difference is, the smaller the passing capacity is. The passing capacity difference of train speeding matching plan (300/160 km/h, 250/140 km/h and 200/120 km/h) is increasing with increased number of middle-speed trains. When the number of middle-speed trains is more than 20, decrease in the number of passing capacity is more than 50%. So those three train speed matching plan is not recommended. Base on passing capacity, the minimum of train speed matching are 200/140 km/h, 250/160 km/h and 300/200 km/h.

6 Technical condition of mobile equipment

6.1 The matching condition of different speed emu trains

When the doors and windows of train are closed, the time of indoor pressure changes from 3600 Pa to 1350 Pa should be more than 18 s. When the train speed is more than 200 km/h, the train must meet the requirements of air tightness, but some of CRH_1 emu trains don't meet the requirements. As a result, the emu trains can achieve more than 300/250km/h, 300/200km/h and 250/200km/h speed matching.

6.2 Matching conditions of ordinary speed trains and emu trains

According to the relevant provisions, track design live load concentration of passenger special line whose speed are 300~350 km/h and 350~250 km/h is not more than 20 t; Track design live load concentration of passenger special line whose speed is 200 km/h is not more than 22 t; Ordinary speed train driving by locomotive should keep less than 200km/h speed when they run in high-speed railway. At present, ordinary speed trains don't reach conditions of running in passenger special line, and only reach conditions of running in 200km/h passenger and goods collinear.

7 Conclusions

At present, matching speed of Chinese high-speed trains in operation are 300/250 km/h, 250/200 km/h or 200 km/h.This paper studies the reasonable matching program of high-speed railway by using mixed operation of two speed types of trains, and gets the following conclusions.

(1) In the condition that maximum speed and minimum speed are limited by technical condition of high outer rail and minimum radius of curve, the lowest speed matching is: 200/120 km/h, 250/140 km/h and 300/160 km/h.

(2) In the condition of train control system the lowest speed matching of train is: 200/120 km/h, 250/120 km/h and 300/200 km/h.

(3) In the condition of train mobile equipment the lowest speed matching of train is: 200/120 km/h, 250/200 km/h and 300/200 km/h.

(4) From the point of travelling speed of middle-speed trains, reasonable matching train speed is not less than 200/120km/h, 250/160km/h and 300/200km/h.

(5) From the point of passing capacity of high-speed railway, reasonable matching train speed is not less than 200/140km/h, 250/160km/h and 300/200km/h.

Integrate the above five aspects, it is recommended that during mixed operation of two speed types of trains on high-speed railways, 3 speed matching programs shall applied, which including 300/200 km/h and above, 250/200 km/h and above as well as 200/140 km/h and above. At present the actual speed matching program of high-speed railway in China is reasonable.

Abstract: With great-leap-forward development in the last decade, the operation of high speed railway in China has entered into network era from single line. With expanded service area and long traveling time, the high speed railway in China is qualified for overnight operation in net structure and time space, which is significantly different from that of high speed railway in other countries and areas. The overnight operation of high speed railway is of significance for capacity utilization improvement, besides diverse travelling demand in time horizon. Waiting, transferring, running and maintenance in adjacent lines meanwhile, and periodic operation are the alternative modes for overnight operation. The technical condition, operation feature and applicability are presented, respectively. With rational range of departure time from original station and arrival time at destination, spatial span of network in vertical and horizontal direction, maintenance demand taken into consideration, the rational travelling distance of overnight high speed train are calculated with different operation mode and travelling speed. The work in this paper on operation mode and rational travelling distance is salutary and leading, which provides particular supports for night operation in Chinese high speed railway, in theory and technique.
Keywords: High speed railway in China; Overnight operation mode; Technical conditions; Maintenance; Rational travelling distance.

1 Introduction

By the end of 2014, the revenue kilometers of high speed railway in China have reached to 16,000, over 50% of total kilometers worldwide. With large-scale network, advanced technology and busy operation, the high speed railway system in China has good performances in safety, speed and economy. As an important part of comprehensive system of transport, the high speed railway system markedly shortens the journey time and promotes economic and social developments. In the past 5 decades, the transport service of high speed railway is available only in daytime, and the nighttime (generally from 0:00~6:00) is arranged as railway curfew for infrastructure maintenance. With small national territorial area, besides short travelling distance and time, the high speed railway system in countries and areas except China, is not qualified in practice for overnight operation in network condition and travelling demand. The operation and infrastructure maintenance are staggered in time, leads to interactive influence avoidance and efficiency improvement.

With vast territory, the travelling time by taking high speed train between major cities in China, is much more than that in other developed countries and cities in high speed railway worldwide. More than 1000 passenger flow ODs are formed by the major node cities in China, in which the amount of passenger flow ODs with travelling distance over 2,000 km reaches to 328 , and travelling time more than 7h, about 500. With large scale in network and spatial span, besides long distance of single backbone line in vertical and horizontal direction, the network operation of high speed railway in China is characterized by extensive high speed train and their long travelling time and wide service range. The overnight operation of high speed railway can provide much more diverse transport service, and expand the time horizon of travelling, leading to improvement in temporal accessibility, especially with long travelling distance. Besides, the overnight operation can upgrade capacity utilization in network, and expand efficient service areas, with prominent effects on attractions promotion compared to airline and long road transport. Based on national and railway conditions in practice, it is imperative for overnight operation in Chinese high speed railway, with qualified conditions in network, space and time. The overnight operation is the joint demand from passenger and enterprise. However, as an emerging operation in high speed railway, it is pressing and valuable to work on overnight operation mode and rational travelling distance, based on prior operation experience.

There are very few academic papers published on overnight operation in developed countries and areas in high speed railway except China, due to the little or no demand for overnight operation. However, the dusk-to-dawn train (departing from original station between 18:00 and 23:00, besides arriving at destination station between 6:00 and 9:00) in traditional rail lines, is a popular transport product promoted from 1997. Many efforts are taken on the dusk-to-dawn train in Chinese high speed railway, and they generally took the high speed railway from Beijing to Shanghai as instance. The joint optimization with both overnight train and track maintenance, the operation mode and technical conditions were studied (Peng et al. 2006). The different situations were presented, besides the travelling distances with different curfew time for maintenance were calculated, respectively. The feasibility of dusk-to-dawn train in high speed railway with rectangle curfew was discussed (WANG et al. 2007). The effects of vertical rectangle curfew and inclined rectangle curfew on operation were analyzed, and the specific organization method was proposed by taking the high speed railway from Beijing to Shanghai as instance.

The rational departing time horizon of dusk-to-dawn train was calculated by congruence strategy (LUO et al. 2007). The joint optimization model between train plan and maintenance curfew was established, and the optimal time for maintenance curfew was obtained. Based on the interaction effects between vertical rectangle curfew and overnight train, the mathematical model was established and the corresponding algorithm was designed, for the optimal time of maintenance curfew

(NIE et al. 2010). To minimize the number of affected train by curfew was set as the objective in the optimization model, besides the rational time horizon, as constraints. Three organization modes (waiting, transferring to adjacent parallel traditional rail line, transferring and back to high speed line) were proposed for dusk-to-dawn train in high speed railway (ZHANG et al. 2014). The indexes and rules were presented by establishing candidate scheme generation model and analyzing the solution process. The conclusion was made that the transferring mode is prior for medium and long travelling distance and the waiting mode, for long travelling distance. Based on the previous achievements, running in one direction, transferring twice, transferring once and waiting were the four alternative modes for overnight operation, and the adaptability and security were analyzed respectively(SUN et al. 2014). The train plan was obtained by optimization model, which took operation safety, running time and stop demand as constraints, besides the optimal travelling time as objective.

Based on the achievement on dusk-to-dawn train in high speed railway, five different overnight operation modes are defined and described. The overnight operation modes are avoidance, waiting, transferring to adjacent parallel traditional line, running and maintenance in adjacent lines meanwhile and passenger transferring, and their technical conditions, organization features and adaptability are presented. Finally, the rational travelling distances with different operation mode and travelling speed, are calculated based on the complete operation process of overnight train in Chinese high speed railway.

2 Overnight Operation Modes in High Speed Rail Line

The technical equipment are dispersive, used frequently and continuously, thus the routine maintenance and recondition are necessary for safety and comfort. The maintenance curfew is scheduled at night in advance and large-scale maintenance machinery is adopted, which is the tradition in practice worldwide. However, as essential technical measurement keep equipment in sharp, the maintenance curfew occupies the section exclusively, which leads to negative effects on operation process of overnight train in high speed railway. Under the influence from maintenance curfew, avoidance, waiting, transferring to adjacent parallel traditional line, running and maintenance in adjacent lines meanwhile, passenger transferring are the feasible alternatives for overnight operation mode. The technical conditions, organization features and adaptability are different.

2.1 Avoidance Mode

Avoidance is defined as a particular operation mode for overnight train in high speed railway, in which high speed train plan and maintenance curfew are disperse in time-space. With avoidance mode adopted, the running process of high speed train and maintenance are not interactive, which leads to improvement in safety and efficiency. Avoidance mode is the best overnight operation mode, without particular demands for technical conditions. With avoidance mode, the operation environment, method and process are uninfluenced, the same as that in daytime. The avoid mode is illustrated in figure 1. Maintenance curfews with short duration in different sections are set respectively, and certain idle time interval is reserved for overnight train in 1（a）. Besides, the overnight operation is not affected without maintenance curfew, as shown in 1（b）.

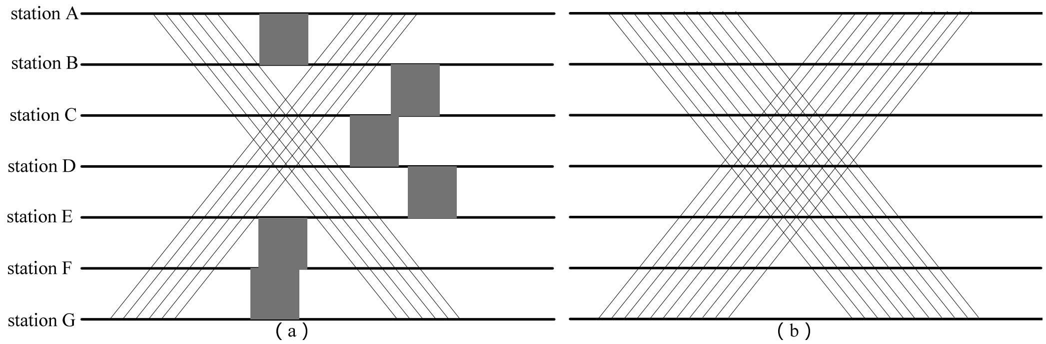

Figure 1. Avoidance mode illustration for overnight operation in high speed railway

As for single section in high speed railway, the avoidance mode is particularly adaptable for maintenance curfew with short duration or no maintenance curfew. However, the implementation of avoidance mode in network is a complex mathematical programming problem, with constraints in time and space. In practice, it is very difficult for overnight train in high speed railway to avoid negative influence from maintenance curfew in its every section. Thus the number of overnight train in high speed railway without influence from maintenance, is extremely limited.

2.2 Waiting Mode

Waiting mode is defined as an overnight operation mode of high speed train, in which the overnight train moves forward as far as possible, suspends at right station prior to maintenance curfew, and restores running to destination station after curfew in high speed line. The waiting mode is illustrated in figure 2(a) and 2(b), in the form of graph and network respectively.

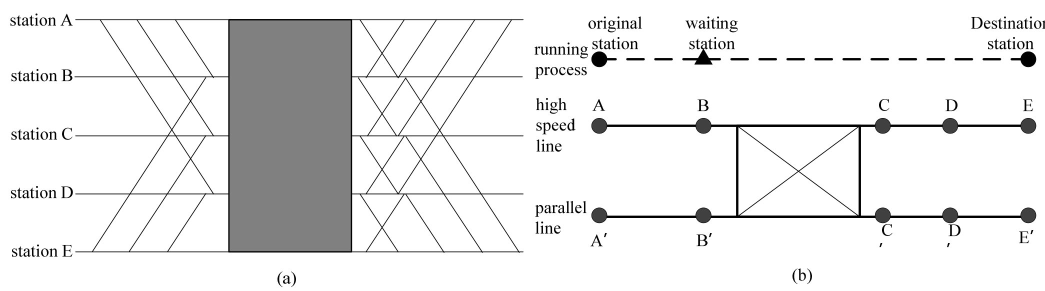

Figure 2. Waiting mode illustration for overnight operation in high speed railway

With waiting operation mode, the running environment (track, signal and control system, power supply et al.) keeps constant in its whole process. The operations in high speed railway and its adjacent parallel traditional rail line, are staggered and not interactive. However, overnight train suspends at station, and occupies arrival-departure track in waiting duration. Idle track resource and routine life power supply are necessary assurance conditions for waiting mode. Thus the technical conditions are listed as:(1)enough arrival-departure available tracks in every station involved with overnight operation; (2)effective power supply equipment for routine life need in waiting process.

The organization method is relatively not complex in all alternatives. However, the continuity and equilibrium of operation in time horizon are affected seriously, and increment of travelling time is the most salient. Constrained by boundary of power supply section, the waiting duration is definitely more than that of maintenance curfew, and is the biggest in all modes under equal conditions. The waiting mode is adaptable for high speed railway with capacity defect or without parallel line. Certain advantages emerge when duration of maintenance is small and the travelling distance of overnight train is long.

2.3 Transferring to Adjacent Parallel Line

Transferring mode is defined as an overnight operation mode of high speed train, in which the overnight train transfers to adjacent parallel line prior to maintenance curfew, moves forward in parallel line in curfew duration, and continues moving ahead or return back to high speed railway after curfew, to destination station. The transferring mode to adjacent parallel line is illustrated in figure 3(a) and 3(b), in the form of graph and network respectively.

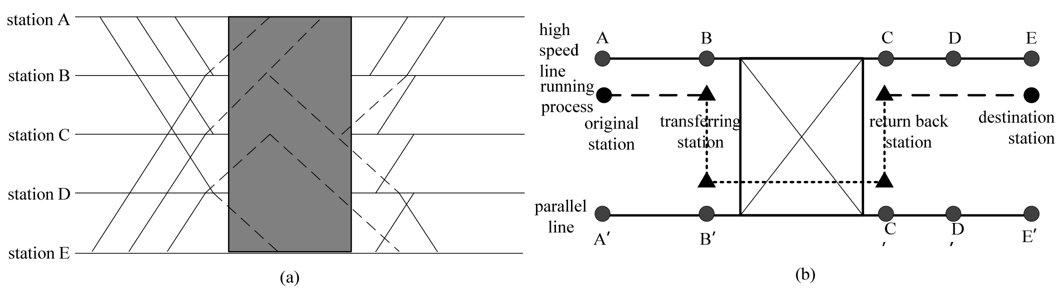

Figure 3. Transferring to adjacent parallel line mode illustration for overnight operation in high speed railway

When transferring mode to adjacent parallel line is adopted, the high speed train transfers to adjacent parallel line by link rail line, prior to maintenance curfew. The train moves forward in parallel line in curfew duration, and continues moving ahead or return back to high speed railway after curfew, to destination station. Its basic technical conditions are presented as: (1) rail line linking high speed rail line and its adjacent parallel line; (2) satisfied track conditions of paradise line for safety and comfort; (3) compatible communication and control system in parallel line with high speed train; (4) affluent capacity in parallel line.

Constrained by rational time horizon for original departure and destination arrival, the transferring section and time may be various for different trains. The number of transferring train and travelling time in transferring process may be also various in different transferring sections. The capacity is occupied by transferring train in parallel line, and the imbalance of remaining available capacity will leads to utilization efficiency of whole capacity. According to the detailed transferring process, the increment of travelling time is small, which results in particular advantage with long maintenance curfew. However, the operation of transferring train is interactive with that of trains in parallel line. The higher requirement for on-schedule rate is needed, otherwise it is difficult to transfer to parallel line prior to maintenance curfew or return back to high speed line after maintenance curfew.

2.4 Running and Maintenance in Adjacent Lines Meanwhile

Running and maintenance in adjacent lines meanwhile is defined as an overnight operation mode, in which one line is occupied by maintenance and the adjacent line is available for overnight train. The overnight operation in maintenance curfew can be organized in the way of multi-train tracking or running in pairs. The running and maintenance in adjacent lines mode is illustrated in figure 4(a) and 4(b), in the form of graph and network respectively.

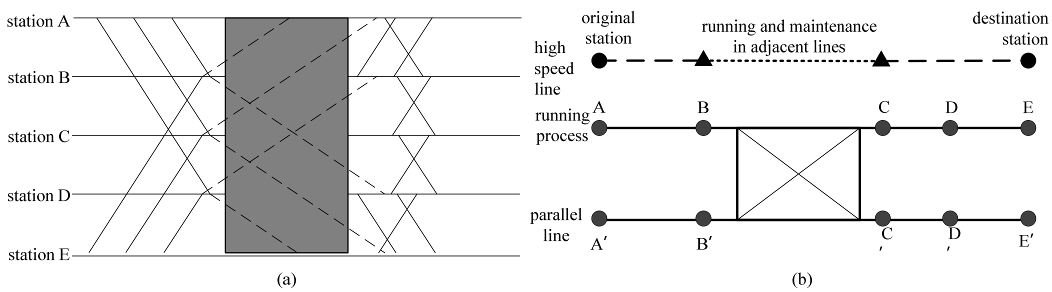

Figure 4. Running and maintenance in adjacent lines mode illustration for overnight operation in high speed railway

Operation in one-direction line will reduce the available capacity greatly, and the temporary capacity bottleneck may lead to part of trains waiting at stations, at both end of maintenance section. The technical conditions for running and maintenance in adjacent lines are listed as: (1) matching maintenance curfew plan; (2) operation conditions in converse direction; (3) running speed lower than 160km/h; (4)necessary safeguard measures for maintenance operator; (5)the same conditions as that of waiting mode.

An available line in single direction is left for overnight train in this operation mode. However, the it is complex in transport organization, and necessary to transfer between two organization methods in short time. Meanwhile, particular maintenance works cant be carried out in this mode, such as the maintenance on junction line or overhead line system. The overnight train on adjacent line may rise risk of maintenance safety and increase time of auxiliary operation, which leads to great potential negative influence on efficiency and safety.

2.5 Passenger Transferring Mode

Passenger transferring mode is defined as an overnight operation mode, in which high speed train moves forward as far as possible prior to maintenance curfew, and passengers are transferred to another train running on adjacent line to destination station when suffering curfew. Passenger transferring mode is illustrated in figure 5(a) and 5(b), in the form of graph and network respectively.

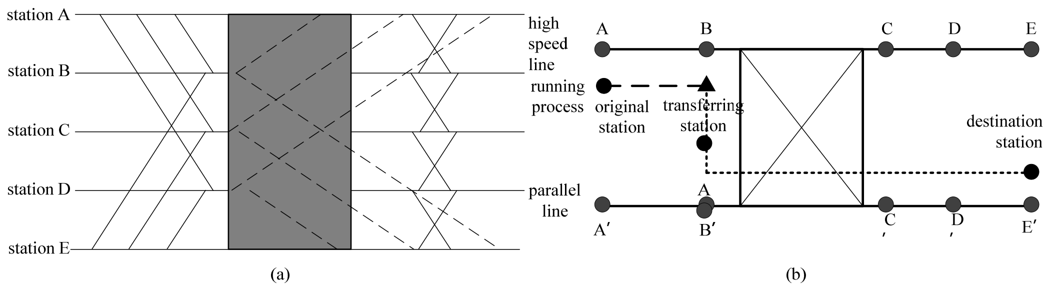

Figure 5. Passenger transferring mode illustration for overnight operation in high speed railway

With passenger transferring mode, the transport service is provided jointly by trains in high speed railway and its adjacent parallel line in nature. The transferring station is the destination station for overnight train in high speed railway, and the original station for following train in its adjacent parallel line. The basic technical conditions are presented as: (1) adjacent line and the linking line with high speed railway; (2) capable of technical operation for original and destination train; (3) sufficient arrival-departure track; (4) good conditions for transferring in same platform or station hall; (5) good coordination in passenger flow and time.

The passenger transport organization is complex and brings inconvenience to transferring passengers. When the high speed line is introduced into traditional rail station directly, passengers can transfer to the following train in platform. Otherwise, the transferring operation can be carried out by linking line between high speed rail station and traditional station. Besides, the fixed number of passenger may be not matched between high speed rail train and traditional train. Only a part of passengers in the high speed train transfer to the following traditional train, and the latter undertakes the routine task in traditional line. It is adaptable for overnight passenger transport in long high speed rail line, and is obviously preferable when the transferring time is earlier than midnight.

As for single overnight train, the negative influence is limited almost in one section, and the operation mode is just one of the previous alternatives. Based on the dynamic interaction between maintenance curfew and train, the avoidance mode owns the highest priority. When the avoidance is not feasible, transferring to adjacent line is the following choice, with long duration of maintenance, and waiting mode, with short duration. As for passenger transport in long high speed rail line, passenger transferring is an alternative to be considered. Finally, the Running and maintenance in adjacent lines meanwhile is the last choice. As for the network of high speed rail line, the overnight operation mode is a combination for the previous 5 alternatives. The operation modes may be various for different trains or in different sections. The operation mode and corresponding train plan are determined by taking operation and maintenance curfew into consideration, to minimize the total negative influence of maintenance curfew on overnight trains in high speed rail line.

3. Rational Travelling Distance

From the perspective of overnight passenger, the overnight train is expected to depart from original station before midnight, and to arrive at destination station after 6:00 in next day. The total travelling time is more than six hours, which is the basic basis for the down bound of travelling distance. With high travelling speed, the upper bound of travelling time is constrained by the space span in vertical and horizontal direction. Taking the high speed rail network in China as instance, the travelling time is less than 16h definitely, and the down bound of travelling time is the only issue need to consider for rational travelling distance. The comparison with traditional transport product in travelling speed is necessary to determine the rational travelling distance. The overnight high speed train is preferable when its travelling speed is higher than that of train in traditional train.

3.1 Parameter Definition

v_1 and v_2 are defined as the top speed in high speed railway and parallel traditional rail line, respectively. β_1 and β_2 are the coefficients of travelling speed in high speed railway and parallel traditional rail line. According to operation practice, β_1 is valued as 0.9 when top speed is higher than 250km/h, and 0.85, otherwise. S_1 and S_2 are the travelling distances in high speed rail line and parallel traditional rail line respectively. S_0 and t_0 mean the down bounds of total travelling distance and time, and $t_0 = 360\,\text{min}$. t_1, t_2 and t_3 are the travelling time in various operation stage, prior to maintenance curfew, in duration of maintenance curfew and after maintenance curfew. t_1' and t_2' are defined as the transferring time from high speed rail line to parallel traditional rail line and reversely, respectively. T is the duration of maintenance curfew. I_b means the minimum interval between high speed train and the beginning of maintenance curfew, and I_e, between the end of maintenance curfew and high speed train. $I_{\min}$ is the minimum tracking interval between adjacent train in the same direction and section.

3.2 Rational Travelling Distance with Various Overnight Operation Modes

（1）Rational travelling distance with avoidance mode

With avoidance mode adopted for overnight operation in high speed railway, the overnight train is not influenced from maintenance curfew in its travelling process. The down bound of travelling distance S_0 can be calculated by formula (1).

$$S_0 = \frac{\beta_1 v_1 t_0}{60} = \begin{cases} 1620km & (v_1 = 300km/h) \\ 1275km & (v_1 = 250km/h) \end{cases} \tag{1}$$

（2）Rational travelling distance with waiting mode

With waiting as overnight operation mode, the waiting time of single train includes three different parts at least, the duration of maintenance curfew, the time interval between high speed train and the beginning of maintenance curfew, and that between the end of maintenance curfew and the high speed train. With more than one train in the same direction scheduled to wait at the same station, the waiting time increases with the increase of the number of waiting trains. The waiting time increases by $(n-1)I_{\min}$ due to the minimum tracking interval, in which n is the number of train in the same direction scheduled to wait at the same station. The rational down bound of travelling can be calculated as formula (2).

$$S_0 = \beta_1 v_1 (t_0 - T - I_b - I_e - (n-1) I_{\min}) / 60) \qquad (2)$$

In formula (2), the values of I_b, I_e, n and $I_{\min}$ are determined by rail network and train plan, and S' is determined by v_1 and T. I_b is valued as 10 min and I_e is valued as 20 min according to operation practice. n is determined by detailed train plan and valued as one in the following calculation. The down bounds of rational travelling distance are changed as shown in figure 6, with top travelling speed as 250 km/h and 300 km/h, respectively. With top travelling speed in traditional rail line as 160 km/h, the farthest reachable distance is about 820 km in six hours, which is necessary to be considered as the down bound of travelling distance for overnight high speed train.

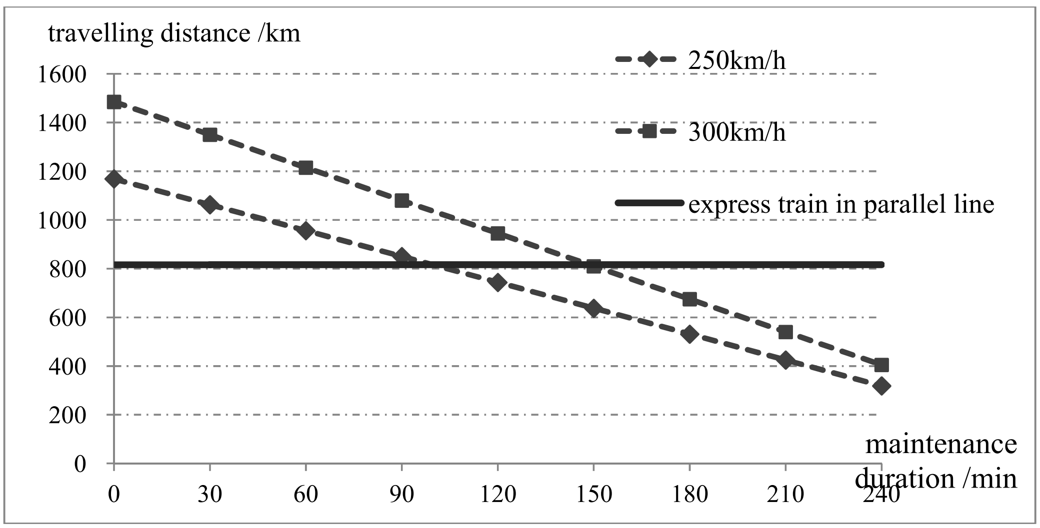

Figure 6. the variation tendency of down bound of overnight travelling distance with the duration of maintenance curfew, in waiting mode

The down bound of rational overnight travelling distance inclines with the increase of maintenance duration. With [120,240] as the maintenance curfew duration range, the down bound of travelling distance is 816 km when 250 km/h is considered as the top travelling speed, and the down bound of distance is in the range [816,945].

（3）Rational travelling distance with transferring to adjacent parallel line mode

The complete operation process includes three stages: (1) the first stage in high speed rail line prior to maintenance curfew; (2) the second stage in adjacent parallel rail line in the duration of maintenance curfew; (3) the last stage to return back to high speed rail line. According to the previous introduction, the transferring time is more than the sum of duration of maintenance and the minimum interval time. The first kind of transferring mode is defined when the previous three stages are involved, and the second is defined when the first stage and the second stage are involved.

In the first transferring mode, the transferring time condition can be presented as $t_2 + t_1' + t_2' \geq T + I_b + I_e$. In the second transferring mode, the transferring time condition can be presented as $t_2 + t_1' \geq T + I_b$. The down bounds of rational travelling distance in the first transferring mode can be calculated by formula (3), and that in the second transferring mode, by formula (4).

$$S_0 = (\beta_2 v_2 t_2 + \beta_1 v_1 (t_0 - t_1' - t_2' - t_2)) / 60 \\ = (\beta_2 v_2 (T + I_b + I_e - t_1' - t_2') + \beta_1 v_1 (t_0 - T - I_b - I_e)) / 60 \quad (3)$$

$$S_0 = (\beta_2 v_2 t_2 + \beta_1 v_1 (t_0 - t_2 - t_1')) / 60 \\ = (\beta_2 v_2 (T + I_b - t_1') + \beta_1 v_1 (t_0 - T - I_b)) / 60 \quad (4)$$

Set $I_b = 10\,\text{min}$, $I_e = 20\,\text{min}$ and $t_1' = t_2' = 15\,\text{min}$, the down bounds of rational travelling distance are changed with the duration of maintenance curfew, as shown in figure 7.

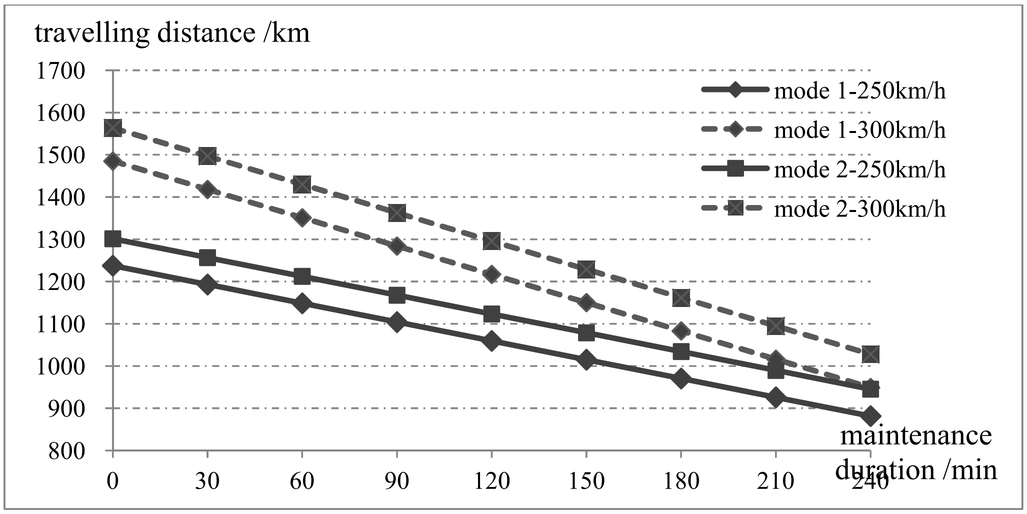

Figure 7. the variation tendency of down bound of overnight travelling distance with the duration of maintenance curfew, in transferring to adjacent parallel line mode

With transferring to adjacent parallel line mode, the down bound of rational overnight travelling distance inclines with the increase of maintenance duration. With [120,240] as the maintenance curfew duration range, the down bounds of travelling distance in first transferring mode are distributed in [882, 1238] and [949, 1485], with 250km/h and 300km/h as top travelling speed respectively. And the corresponding ranges are [945, 1301] and [1028, 1564] in second transferring mode.

（4）Rational travelling distance when running and maintenance are carried out in adjacent lines meanwhile

When running and maintenance are carried out in adjacent lines meanwhile, the duration for operation in single line mode is definitely not less than $T + I_b + I_e$, and the top travelling speed is limited to be less than 160km/h. Without regard to the increase of waiting time due to temporary capacity deficiency, the down bound of overnight travelling distance is calculated by formula (5). The down bounds of rational travelling distance are changed with the duration of maintenance curfew, as shown in figure 8.

$$S_0 = (\beta_2 v_3 t_3 + \beta_1 v_1 (t_0 - t_3)) / 60 \quad (5)$$

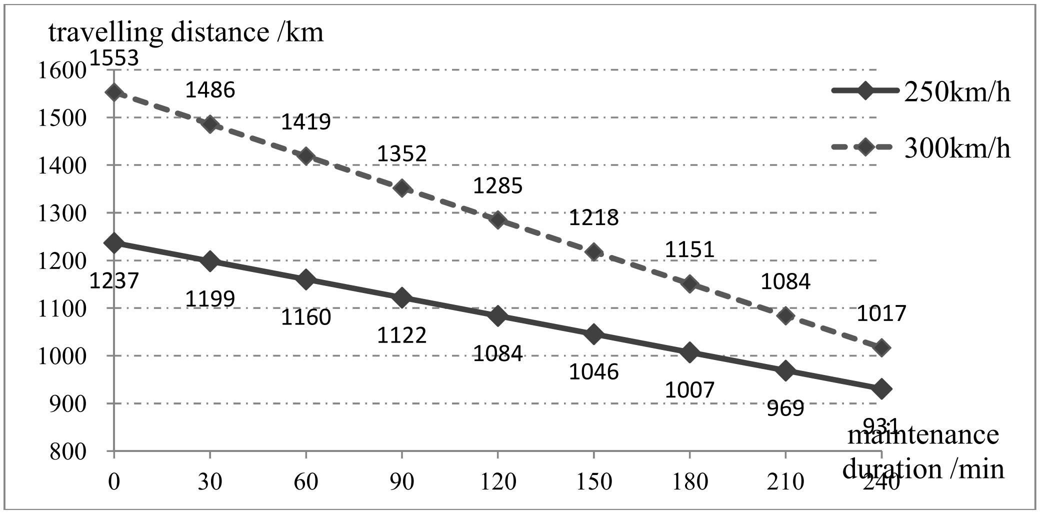

Figure 8. the variation tendency of down bound of overnight travelling distance with the duration of maintenance curfew, when running and maintenance are carried out in adjacent lines meanwhile.

When running and maintenance are carried out in adjacent lines meanwhile, the down bound of rational overnight travelling distance inclines with the increase of maintenance duration. With [120,240] as the maintenance curfew duration range, the down bounds of travelling distance in first transferring mode are distributed in [931, 1238] and [1017, 1553], with 250km/h and 300km/h as top travelling speed respectively.

（5）Rational travelling distance with passenger transferring mode

With passenger transferring mode, the transport service is provided jointly by trains in high speed railway and its adjacent parallel line in nature. For passengers' convenience, transferring before midnight is preferable, and the running time in traditional rail line is at least 6h. Due to the necessary time consumption in transferring process, the passenger transferring mode may be attractive when its whole travelling time is not more than the average travelling time between the same original and destination stations. The critical condition is presented as formula (6).

$$\beta_1 v_1 t_1 = \beta_1 v_2 (t_1 + t_h) \quad (6)$$

According to previous practical experience, set $t_h = 60$ min, and the value of parameter t_1 are approximately 120min and 90min, with 250km/h and 300km/h as top travelling speed respectively. With the travelling distance in parallel traditional rail line, the down bound of travelling distance in passenger transferring mode can be calculated as following:

$$S_0 = (\beta_2 v_2 t_2 + \beta_1 v_1 t_1)/60 = \begin{cases} 1119km & (v_1 = 250km/h) \\ 1221km & (v_1 = 300km/h) \end{cases} \quad (7)$$

The rational travelling distances of overnight train in different operation modes, are calculated by the previous formulas, which is helpful decision-making for overnight train plan. In practice, the mismatching between running section and the shortest increase of travelling time will increase the whole travelling time, which leads to further reduction of rational travelling distance. These factors are uncertain and their effect is limited, so they are not taken into consideration in calculations.

4 Conclusions

Under the influence from maintenance curfew, avoidance, waiting, transferring to adjacent parallel traditional line, running and maintenance in adjacent lines meanwhile, passenger transferring are the feasible alternatives for overnight operation mode. The technical conditions, organization features and adaptability are different. Based on the dynamic interaction between maintenance curfew and train, the avoidance mode owns the highest priority. When the avoidance is not feasible, transferring to adjacent line is the following choice, with long duration of maintenance, and waiting mode, with short duration. As for passenger transport in long high speed rail line, passenger transferring is an alternative to be considered. Finally, the Running and maintenance in adjacent lines meanwhile is the last choice. As for the network of high speed rail line, the overnight operation mode is a combination for the previous 5 alternatives. The operation modes may be various for different trains or in different sections. The operation mode and corresponding train plan are determined by taking operation and maintenance curfew into consideration, to minimize the total negative influence of maintenance curfew on overnight trains in high speed rail line.

With high travelling speed, the upper bound of travelling time is constrained by the space span in vertical and horizontal direction. In Chinese high speed rail network, the travelling time is less than 16h definitely, and the down bound of travelling time is the only issue need to consider for rational travelling distance. The down bound of rational travelling distance are calculated at various speeds and in different operation modes. It is the same that the down bound of rational overnight travelling distance reduces with the increase of maintenance duration. In practical scheduling process to determine the overnight train plan, the travelling demand and its temporal and spatial characteristics, the technical conditions and section capacity are the factors of significance.

Abstract: The prediction of high speed railway passenger demand volume is important for not only development of railway but also meeting the passenger transport demand. Because of the volatility and uncertainty of the passenger transport demand, this paper puts forward a regression forecasting model based on Grey Relational Analysis (GRA). The correlation between passenger demand and its influencing factors is worked out by using GRA. A multivariate nonlinear regression equation is established to predict high speed railway passenger demand volume. Base on the method, a more reasonable transportation plan and marketing strategy can be developed to meet passenger transport demand better.
Keywords: High speed railway; Passenger demand; Grey relational analysis; Regression forecasting.

1 Introduction

Transportation demand volume means the amount of transportation products purchased by transportation consumers who are willing and able to purchase them at different prices during a certain period of time (Liu, 2010).

The uncertainty of the transport demand determines the complexity of forecasting methods. The methods of Grey Relational Analysis (Liu, 1999), Grey prediction model and exponential smoothing (Huang, 2011) are used in the past research. However, Grey Rational Analysis method cannot provide a reliable prediction. Both Grey prediction model and exponential smoothing method all need the information of historical data. As we known, there is no historical data can be used in demand prediction.

2 Method Analysis

There are many factors that can affect passenger transportation demand. The macro factors include social economic development level, resident income and consumption level, population size and structure, tourism development, substitutability of transportation, national policy, and so on. The direct influencing factors include velocity (travel time), density (departure frequency), fares, comfort, and so on. Since passenger transportation demand is influenced by various factors comprehensively, it is reasonable to determine the importance of influencing factors using the method of GRA.

2.1 Passenger demand and its influencing factors

Through the investigation of factors influencing the passenger demand, we can set up a data sequence of passenger demand. On the conditions of analyzing the transport demand, the data of passenger demand volume can be replaced with passenger volume.

2.2 Data transformation

After transforming the original survey data, it can be compared easily. Data transformation also needs certain principles and methods.

A sequence is $x=(x_1,x_2,\cdots,x_n)$, then, the data transformation from sequence x to sequence y is

$$f:\ x\rightarrow y\ f_{(x_k)}=y_k \quad k=1,2,3,\cdots,n \tag{1}$$

Transformation principle:

① $x_k>0$, $y_k\geq 0$, $k=1,2,3,\cdots,n$;

② $x_i<x_j$, $y_i<y_j$; $x_i>x_j$, $y_i>y_j$;

③For any i, t, k, j: $\frac{x_i-x_t}{x_k-x_j}=\frac{y_i-y_t}{y_k-y_j}$.

Transformation method:

① Initial-value transformation

$$f_{(x_k)}=\frac{x_1}{x_k}=y_k,\quad x_1\neq 0 \tag{2}$$

where, x_1 is the first original data of a sequence; x_k is the original data of the same sequence.

② Mean transformation

$$\bar{x}=\frac{1}{n}\sum_{k=1}^{n}x_k \tag{3}$$

where, x_k is the original data of the same sequence; $\bar{x}$ is the average of each sequence.

③ Normalized transformation

$$f_{(x_k)} = \frac{x_k}{x_0} = y_k, \quad x_0 > 0 \tag{4}$$

2.3 Determining the connection coefficients

Setting the reference sequence as $x_{0(k)} = (x_{0(1)}, x_{0(2)}, x_{0(3)}, \cdots, x_{0(n)})$.

The comparison sequence is $x_{i(k)} = (x_{i(1)}, x_{i(2)}, x_{i(3)}, \cdots, x_{i(n)})$.

When $t = k$, the correlation coefficients of $\{x_{0(t)}\}$ and $\{x_{i(k)}\}$ is $\xi_{0i(k)}$,

$$\xi_{0i(k)} = \frac{\Delta \min + \rho \Delta \max}{\Delta_{0i(k)} + \rho \Delta \max} \tag{5}$$

where, $\Delta_{0i(k)} = \left| x_{0(k)} - x_{i(k)} \right|$ is the absolute difference between the two sequences;

$\Delta \min = \min_i \min_k \Delta_{0i(k)}$ are two level minimum differences;

$\Delta \max = \max_i \max_k \Delta_{0i(k)}$ are two level maximum differences;

ρ is distinguishing coefficient, which is used to improve the significant difference between the correlation coefficient, $\rho \in (0,1)$, usually values 0.1-0.5.

2.4 Determining the correlation

When $t = k$, the correlation between the two sequences $\{x_{0(t)}\}$ and $\{x_{i(k)}\}$ is $\gamma(x_0, x_i)$ as:

$$\gamma(x_0, x_i) = \sum_{k=1}^{n} \omega_k \cdot \xi_{0i(k)} \tag{6}$$

where, ω_k is the weight of index k, $\omega_k \in [0,1]$, and $\sum_{k=1}^{n} \omega_k = 1$; $\xi_{0i(k)}$ is the correlation coefficient.

By using the method of GRA, all the impacts on passenger transport demand caused by influencing factors can be determined.

3. Model Establish

The correlation between passenger demand and influencing factors can be worked out by using GRA, and the primary and secondary factors influencing high speed railway passenger demand are also worked out. Based on the main factors as independent variables, and the passenger volume as dependent variable, a multivariate nonlinear regression equation is established to forecast the passenger demand, which is a multiple regression equation based on grey rational grade analysis.

Regression analysis prediction method utilizes causal relationship between the factors, by establishing regression equation to forecast. This method is known for high forecast precision, easy to use, and suitable for long-term forecast. Because the factors influencing the passenger demand are a lot, and the influencing relationship is complex, a multivariate nonlinear regression equation is needed.

3.1 Determining the main factors influencing the passenger demand

Calculating the correlation - $\gamma(x_0, x_i)$ between the factors influencing high speed railway passenger demand and the passenger demand by GRA, and then, identifying the main influencing factors.

3.2 Establishing the regression equation

Suppose that predictor variable y is in linear dependence relation with a group of variables $x_1, x_2, x_3, \cdots x_m$:

$$y = a + b_1 x_1 + b_2 x_2 + \cdots + b_m x_m + e \tag{7}$$

where, e is random error term;

a, b_i are unknown parameters, $i = 1,2,3,\cdots,m$;

m is the number of variables.

3.3 Test of the regression effect

Solving the regression model and calculating the test statistics to test the regression effect.

Test statistic F is as:

$$F = \frac{RSS / m}{ESS / (n - m - 1)} \tag{8}$$

where, RSS is the regression sum of squares, that is the sum of squares of the differences between estimate value $\hat{y}_i$ and the average value; ESS is the residual sum of square, that is the sum of squares of the differences between observed value y_i and estimate value $\hat{y}_i$.

Comparing the value of F with $F_\alpha(m, n-m-1)$. If $F > F_\alpha$, the regression equation is significant, otherwise, the regression equation is not significant.

3.4 Accuracy test

Comparing the predicted data in regression model with real data, the relative error can be worked out to determine the accuracy of regression model.

4. Data Analysis and Discussion

Dalian North Railway Station at the end of Harbin-Dalian high speed railway is selected as an example.

4.1 Data selection

It is invested that the transport capacity of Dalian North Railway Station can satisfy the demand of passengers since its opening. So the passenger volume, fares, velocity, departure density, marked capacity of passenger train seating, days of the holiday in the station are investigated to analyze the relationship between the passenger demand and influencing factors. The data in the first half of 2014 is selected as Table 1.

Table 1. Outcomes in Dalian North Railway Station in the first half of 2014

Month	Passenger volume (Ten thousand)	Velocity (km/h)	Departure density (train)	Fares (yuan/ km)	Marked capacity of passenger train seating (Ten thousand)	Days of the holiday (day)
Jan	24.08	166.17	1085	0.45	61.59	3
Feb	25.06	166.17	980	0.45	58.16	7
Mar	21.08	166.17	1085	0.45	64.89	0
Apr	24.56	191.25	1050	0.50	60.70	5
May	23.68	216.33	1085	0.60	59.95	1
Jun	24.13	216.33	1050	0.65	58.12	3

4.2 Calculation and analysis of correlation

Using GRA and according to formula (6), the correlation between all the factors and passenger volume can be calculated as following:

$$\gamma_{(x_0,x_1)}=\frac{1}{6}\times 4.96=0.83 \tag{9}$$

$$\gamma_{(x_0,x_2)}=\frac{1}{6}\times 5.51=0.92 \tag{10}$$

$$\gamma_{(x_0,x_3)}=\frac{1}{6}\times 4.90=0.82 \tag{11}$$

$$\gamma_{(x_0,x_4)}=\frac{1}{6}\times 5.51=0.92 \tag{12}$$

$$\gamma_{(x_0,x_5)}=\frac{1}{6}\times 3.75=0.63 \tag{13}$$

The results show that the rank of correlation of influencing factors is $\gamma_2=\gamma_4>\gamma_1>\gamma_3>\gamma_5$.

The largest correlation is departure density and marked capacity of passenger train seating, and secondly is velocity, and then is fares, the final is the days of the holiday. This illustrates that departure density and marked capacity of passenger train seating affected the most during the first half of 2014 in many influencing factors.

4.3 Passenger demand forecasting

According to the results of the grey correlation analysis, multivariate nonlinear regression prediction model is established to forecast the passenger demand.

According to the results of the grey rational grade analysis, setting the passenger demand as the predicted target y, and setting departure density and marked capacity of passenger train seating as influencing factors x_1, x_2, and then regression equation is established based on formula (7) and Table 1.

$$y = 0.023017x_1 + 0.506515x_2 + 17.85523 \tag{14}$$

When significance level is $\alpha = 0.10$, then $F_\alpha(2,3) = 5.46$, $F > F_\alpha$, it shows that regression effect is significant under the lever of $\alpha = 0.10$.

Comparing the predicted data in regression model with real data in Table 2. It is shown that the error is about $\pm 4\%$, and the accuracy of the regression model remains high.

Table 2. Analysis of the error between the actual and the predicted data

Month	The actual data (Ten thousand)	The predicted data (Ten thousand)	Error %
Jan	24.08	23.21	3.66
Feb	25.06	25.23	-0.66
Mar	21.08	21.68	-2.77
Apr	24.56	24.79	-0.93
May	23.68	23.34	1.43
Jun	24.13	24.35	-0.92

When the departure density and marked capacity of passenger train seating are known, passenger demand of Dalian north station can be predict with the help of the formula (14).

5. Conclusions

This paper uses the regression forecast method based on GRA, without considering the numbers of the sample and the typical distribution or not. The main factors influencing the passenger demand can be dig out, especially when the information is poor, relevant materials and data are shortage, statistics gray is high. The method is so effective, and can greatly reduce the analysis time of selecting variables, that the convenient prediction and high precision overcome the insufficient short-term prediction and too much dependence of the data in the quantitative prediction method. The method is also suitable for medium and long-term prediction.

If regression effect established by regression prediction model is not very ideal, reselecting factors and analyzing correlation can establish prediction model with high regression effect and prediction accuracy.

Abstract: With great development in the last decade, the operation of high speed railway in China has entered into network era from single line era. With expanded service area and long traveling time, the high speed railway in China is qualified for overnight operation in net structure and time space, which is significantly different from that of high speed railway in other countries and areas. The overnight operation of high speed railway is of significance for capacity utilization improvement, besides diverse travelling demand. The service area and operation demand of high speed railway from Beijing to Guangzhou were analyzed. The alternatives of overnight operation mode are waiting, transferring to adjacent parallel traditional line, running and maintenance in adjacent lines meanwhile and passenger transferring, and their technical conditions, organization features and adaptability are presented respectively. With the basic information of high speed railway from Beijing to Guangzhou, the waiting mode was selected as the preferable overnight operation mode, and the optimized maintenance curfew scheme was proposed to increase the travelling speed. The work in this paper on operation mode and rational travelling distance is salutary and leading, which provides particular supports for overnight operation in Chinese high speed railway.
Keywords: Beijing-Guangzhou high speed railway; Overnight operation; Waiting mode; Maintenance curfew.

1 Introduction

By the end of 2014, the revenue kilometers of high speed railway in China have reached 16,000km, over 50% of total kilometers worldwide. With large-scale network, advanced technology and busy operation, the high speed railway system in China has good performances in safety, speed and economy. As an important part of comprehensive system of transport, the high speed railway system markedly shortens the journey time and promotes economic and social developments. In the past 5 decades, the transport service of high speed railway has been available only in daytime, and the nighttime(generally from 0:00~6:00) is arranged as railway curfew for infrastructure maintenance. Due to small national territorial area, short travelling distance and time, the high speed railway system in countries and areas excluding China, is basically not qualified in practice for overnight operation in network condition and travelling demand. The daily operation and infrastructure maintenance are staggered in time or space, leading to interactive influence avoidance and efficiency improvement.

With vast territory, the travelling time by high speed train between major cities in China, is much longer than that in other developed countries and cities in high speed railway worldwide. With large scale in network and spatial span, as well as long distance of single backbone rail line in vertical and horizontal direction, the network operation of high speed railway in China is characterized by extensive high speed trains, besides their long travelling time and wide service range. The high speed railway from Beijing to Guangzhou is the most typical high speed railway in the world, with long travelling distance and busy daily operation.

The overnight operation in Chinese high speed railway is the joint demand from passenger and enterprise. It provides much more diverse transport service, and expands the travelling time horizon, leading to in temporal accessibility improvement, especially with long travelling distance such as the line from Beijing to Guangzhou. Besides, it upgrades capacity utilization in network, and expands efficient service areas, with prominent effects on attractions promotion compared to airline and long road transport. Based on national and railway conditions in practice, it is imperative for overnight operation in Chinese high speed railway, especially from Beijing to Guangzhou, with qualification in network, space and time. However, as an emerging operation mode in high speed railway, it is pressing and valuable to research on overnight operation mode in Beijing-Guangzhou high speed, based on the prior literature and operation experience.

There are very few academic papers published on overnight operation in developed countries and areas in high speed railway except China, due to the little even definitely no demand for overnight operation. However, the dusk-to-dawn train (departing from original station between 18:00 and 23:00, and arriving at destination station between 6:00 and 9:00) in traditional rail lines, is a popular transport product promoted from 1997. Many efforts are taken on the dusk-to-dawn train in Chinese high speed railway, and they generally took the high speed railway from Beijing to Shanghai as instance. The joint optimization with both overnight train and track maintenance, the operation mode and technical conditions were studied (Peng et al. 2006). The different situations were presented, besides the travelling distances with different curfew time for maintenance were calculated, respectively. The feasibility of dusk-to-dawn train in high speed railway with rectangle curfew was discussed (WANG et al. 2007). The effects of vertical rectangle curfew and inclined rectangle curfew on operation were analyzed, and the specific organization method was proposed by taking the high speed railway from Beijing to Shanghai as an instance.

The rational departing time horizon of dusk-to-dawn train was calculated by congruence strategy (LUO et al. 2007). The joint optimization model between train plan and maintenance curfew was established, and the optimal time for maintenance curfew was obtained. Based on the interaction effects between vertical rectangle curfew and overnight train, the mathematical model was established and the corresponding algorithm was designed to obtain the optimal time of maintenance curfew (NIE et al. 2010). To minimize the number of affected train by curfew was set as the objective in the optimization model, besides the rational time horizon, as constraints. Three organization modes (waiting, transferring to adjacent parallel traditional rail line, transferring and back to high speed line) were proposed for dusk-to-dawn train in high speed railway (ZHANG et al. 2014). The indexes and rules were presented by establishing candidate scheme generation model and analyzing the solution process. The conclusion was drawn that the transferring mode is prior for medium and long travelling distance and the waiting mode, prior for long travelling distance. Based on the previous achievements, running in one direction, transferring twice, transferring once and waiting were the four alternative modes for overnight operation, and the adaptability and security were analyzed respectively(SUN et al. 2014). The train plan was obtained by optimization model, which took operation safety, running time and stop demand as constraints, the optimal travelling time as objective.

Based on the achievement on dusk-to-dawn train in high speed railway, the service area and operation demand of high speed railway from Beijing to Guangzhou were analyzed. The alternatives of overnight operation mode are waiting, transferring to adjacent parallel traditional line, running and maintenance in adjacent lines meanwhile and passenger transferring, and their technical conditions, organization features and adaptability are presented respectively. With the basic information of high speed railway from Beijing to Guangzhou, the waiting mode was selected as the satisfied overnight operation mode, and the optimized maintenance curfew scheme was proposed to increase the travelling speed.

2 The Service Area and Overnight Operation Demand of Beijing-Guangzhou High Speed Railway

2.1 The Service Area of Beijing-Guangzhou High Speed Railway

Beijing-Guangzhou high speed railway, with the longest running mileages

(2118km) in the world and 36 stations, starts from Beijing West Railway Station, and ends at Guangzhou South Station, through Beijing, Hebei, Henan, Hubei, Hunan and Guangdong province. Operated from December 26, 2012, as a parallel rail line to the traditional Beijing-Guangzhou railway, the particular high speed railway is developing into a "economic broadband” to connect the Bohai Economic Rim, Central Plains Economic Zone, Wuhan city circle, Changsha-Zhuzhou-Xiangtan metropolis, Pearl River Delta and other developed and densely-populated regions.

Its designed operation speed is up to 350km/h and the maximum speed in daily operation is up to 310km/h. In current net operation mode, the daily timetable, weekend timetable and peak timetable are designed respectively, based on the passengers flow characteristics. In the initial operation stage, 155 pairs trains are scheduled in Beijing-Guangzhou high speed railway, among which 58 pairs are transferring trains with Shijiazhuang-Taiyuan Passenger Dedicated Line, Zhengzhou-Xi an high speed railway and the Guangzhou-Shenzhen-HongKong high speed railway. Beijing-Guangzhou high speed railway has connected Hefei-Wuhan high speed railway at Wuhan Station since July 2013, connected Beijing-Shanghai high speed railway in Shandong province. The service range, line mileage and operating speed of Beijing-Guangzhou high speed railway are shown in figure 1.

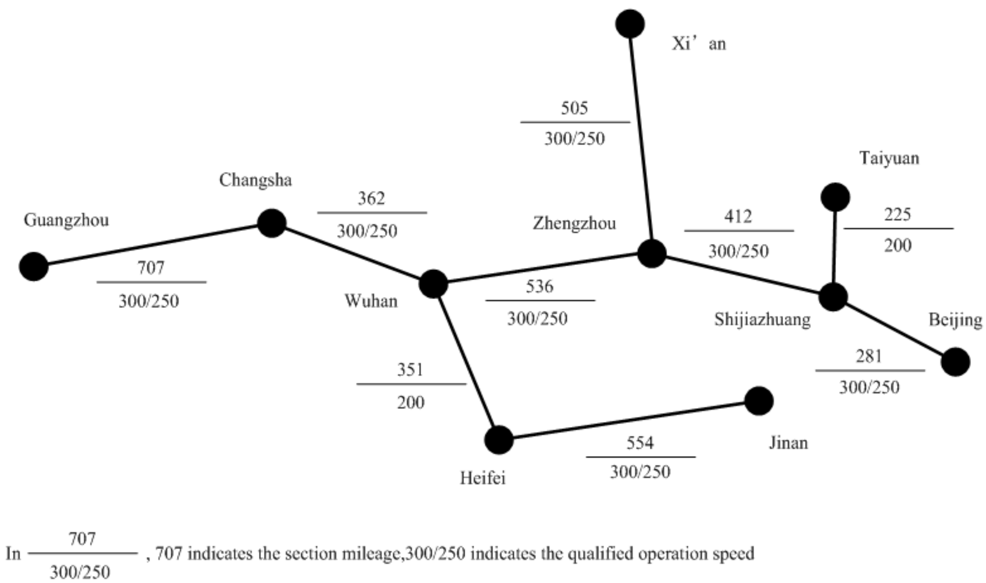

Figure1. Train service area, line mileage and operation speed in Beijing-Guangzhou high speed railway

Based on the previous field experience, the coefficients of high speed train are 0.9 and 0.85, responding to the operation speed 300km/h and 250km/h, respectively. The access time between two important cities in service area of Beijing-Guangzhou high speed railway is listed in table 1.

Table 1. The access time between important cities in Beijing-Guangzhou high speed railway service area (unit:min)

1.2 Overnight Operation Demand in Beijing-Guangzhou High Speed Railway

Under the daytime-only mode, the daily operation is limited definitely in daytime, generally from 7:00am to 11:00pm. The longer the travelling time is, the narrower the time horizon of train departure is. If the overnight operation is unavailable, The departure and arrival time ranges from Beijing to Guangzhou is about [8:00,13:00] and [17:40,22:30], which is definitely inconvenient for rail passengers. The overnight operation in Beijing-guangzhou high speed railway is the joint demand from passenger and enterprise. It provides much more diverse transport service, and expands the travelling time horizon, leading to in temporal accessibility improvement, especially with long travelling distance such as the line from Beijing to Guangzhou.

The overnight passenger flow is mainly soured from the dusk-dawn travelling demand between important cities. It is generally bidirectional between original and terminal stations, with great quantity. The departure and arrival time ranges are [17:00, 24:00] and [6:00, 9:00], respectively. The whole travelling time is from 6h to 16h. Based on the above OD cities and their access time, 11 OD cities illustrated in figure 2, are qualified for overnight operation in the service area of Beijing-Guangzhou high speed railway.

3 Alternative Operation Modes in High Speed Railway

The technical infrastructures in high speed railway are dispersive, used frequently and continuously, thus the routine maintenance and recondition are necessary for safety and comfort. The maintenance curfew is scheduled at night in advance and large-scale maintenance machinery is adopted, which is the tradition in practice worldwide. However, as essential technical measurement keeping equipment in sharp, the maintenance curfew occupies rail section exclusively, which leads to negative effects on operation process of overnight train in high speed railway.

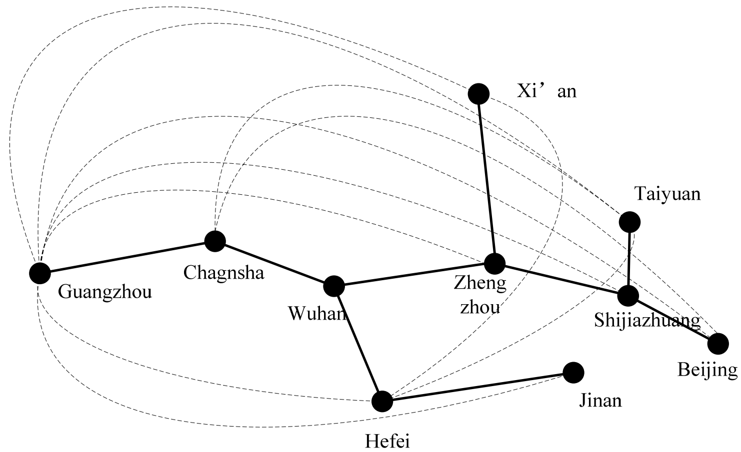

Figure 2.The overnight operation qualified OD cities in the service area of Beijing-Guangzhou high speed rail line

3.1 Alternative Operation Modes

In spite of the type of maintenance curfew, a dynamic interactional relationship exists between the maintenance curfew schedule and overnight high speed train plan, due to the resource assignment in the same duration. Good coordination means better operation conditions for overnight train, while satisfying the necessary maintenance need. Under the effects from maintenance curfew, waiting at station, transferring to adjacent parallel traditional line, running & maintenance in adjacent lines meanwhile, passenger transferring are the feasible alternative modes for overnight operation in high speed railway. The operation alternatives are different in technical conditions, organization features and adaptabilities.

Waiting mode is an operation mode of high speed train, in which the overnight train moves forward as far as possible, suspends at right station prior to maintenance curfew, and restores running to destination station after curfew in high speed line. Transferring mode is defined as an overnight operation mode of high speed train, in which the overnight train transfers to adjacent parallel line prior to maintenance curfew, moves forward in parallel line in curfew duration, and continues to move ahead or return back to high speed railway after curfew, to destination station. Running and maintenance in adjacent lines meanwhile is an overnight operation mode, in which one line is occupied by maintenance and the adjacent line is available for overnight train. The overnight operation in maintenance curfew can be organized in the way of multi-train tracking or running in pairs. Passenger transferring mode is defined as an overnight operation mode, in which high speed train moves forward as far as possible prior to maintenance curfew, and passengers are transferred to another train running on adjacent line to destination station when suffering curfew.

The operation modes are illustrated in figure 3, in which the imaginary lines in (b), (c) and (d) mean the operation in single direction, through transferring train and segmented transferring train in adjacent parallel line, respectively.

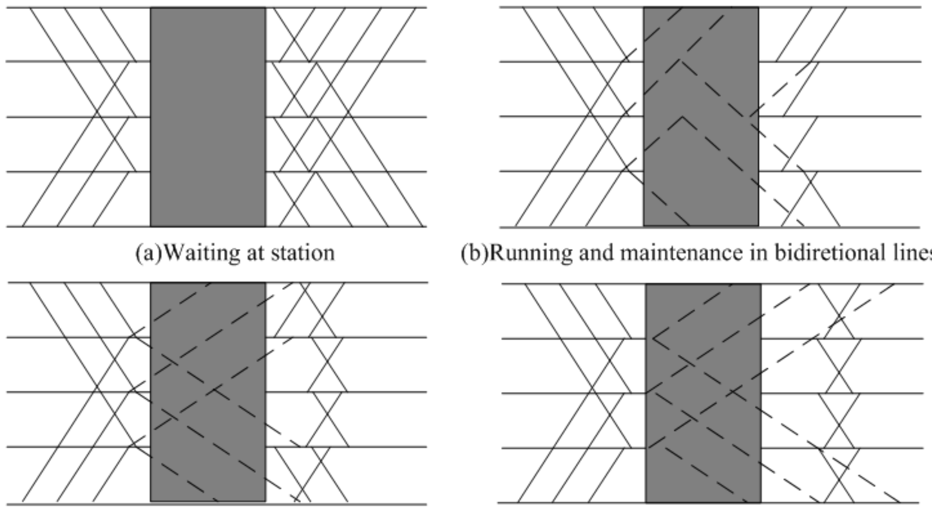

Figure 3. The overnight operation modes illustration in high speed railway

3.2 Technical conditions, features and adaptability

The operation mode for overnight high speed train is featured by its particular operation process, and the corresponding technical conditions are the basic premises. Besides, the organization features and adaptability are diverse for different operation modes. The technical conditions and organization features are listed by operation mode in table 2.

Table 2. The technical conditions and features for overnight operation

	Technical conditions	Organization features
Waiting at station	**(a)** sufficient arrival-departure track at waiting station; **(b)**household power assurance for waiting train	**(a)**uncomplicated organizations, but great negative effects on continuity and balance of operation; **(b)g**reat increment in travelling time and prominent reduction in travelling speed
Operation and maintenance in bidirectional lines	**(a)**matching maintenance curfew plan;**(b)** operation qualification in reverse direction;**(c)**necessary reinforce in safety protection;**(d)**operation speed not more than 160km/h	**(a)**complicated organizations and twice mode transformations; **(b)**available passage way in single direction, with limited reduced capacity; **(c)** increased maintenance risk and declined efficiency; **(d)**incapable of maintenance for

		certain equipments, such as switch
Transferring to parallel adjacent line	**(a)**adjacent parallel line and corresponding linking rail line; **(b)**safety and comfort qualification in technical conditions of parallel line; **(c)**compatible communication and control system in parallel line; **(d)**affluent capacity at night in parallel line.	**(a)**complicated organizations and interaction between transferring train and existing train in parallel line, **(b)**less increment in travelling time and less reduction in travelling speed. **(c)**unbalance in capacity utilization leads to declined available capability in parallel line, **(d)**high demand for punctuality of transferring train
Passenger transferring mode	**(a)**adjacent parallel line and corresponding linking rail line, **(b)**sufficient arrival-departure track in transferring station, **(c)**sufficient multiple unit train or motor coach train	**(a)c**omplicated passenger organization **(b)** short travelling distance and time for each segmented train, **(c)**less utilization ratio of multiple unit train or motor coach train

The waiting mode is adaptable for high speed railway with capacity deficiency or without parallel rail line. Particular advantages emerge when duration of maintenance is short and the travelling distance of overnight train is long, in which the travelling speed can be achieved at a certain high level. Operation and maintenance in bidirectional lines is adaptive to high speed line qualified for operation in reverse direction, with limited reduced capacity. However, the mode is incapable of maintenance for certain equipments, such as switch. Transferring to parallel adjacent line is adaptive for the high speed with parallel adjacent line with capacity deficiency. The linking line between high speed and its parallel line is necessary, besides the sufficient capacity in its parallel line. Passenger transferring mode is adaptable for overnight passenger transport in long high speed rail line, and is preferable especially when the transferring time is earlier than midnight.

As for single overnight train, the negative influence is limited almost in one section, and the operation mode is just one of the previous alternatives. As for passenger transport in long high speed rail line, passenger transferring is an alternative to be considered. Finally, the Running and maintenance in adjacent lines meanwhile is the last choice. As for the network of high speed rail line, the overnight operation mode is a combination for the previous alternatives. The operation modes may be various for different trains or in different sections. The operation mode and corresponding train plan are determined by taking operation and maintenance curfew into consideration, to minimize the total negative influence of maintenance curfew on overnight trains in high speed rail line.

4 Overnight Operation Method in Beijing-Guangzhou High Speed Railway

4.1 The optimal overnight operation mode

In order to keep operation safety and travelling comfort in high speed railway, the necessary maintenance scheme is reserved in advance, and generally scheduled at night, in the duration with least travelling demand. Due to difference in equipment and operation, the maintenance curfew plan (type, duration and beginning time, etc.) is made based on the practical demand in maintenance and operation.

Without overnight operation in high speed railway, the vertical rectangle type of maintenance curfew is preferred worldwide, with long duration for maintenance. It involves good maintenance performance in efficiency and quality, without negative effects on daily operation in daytime. The maintenance curfew scheme for Beijing-Guangzhou high speed railway, without overnight operation is illustrated in figure 4. Under the daytime-only mode, the operation is limited definitely in daytime, generally from 7:00am to 11:00pm. The longer the travelling time is, the narrower the time horizon of train departure is. If the overnight operation is not available, the latest departure time of high speed train from Beijing to Guangzhou is about 13:00, and the later high speed rail service between the two cities is not available

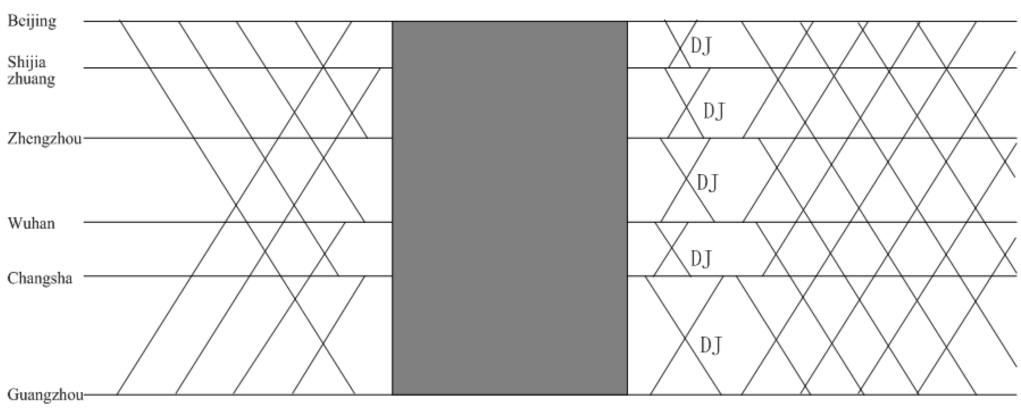

Figure 4. Illustration for passenger train plan and maintenance curfew without overnight operation in Beijing-Guanghzou high speed railway

With long travelling distance and huge passenger flow, the overnight operation in Beijing-Guangzhou high speed railway is valuable, people-beneficial and urgent. However, the negative effects on travelling speed and organization from maintenance curfew is unavailable, in spite of its type, duration and beginning time of maintenance curfew. With organization complexity, maintenance demand, travelling speed decline and mode adaptation taken into consideration, the waiting mode and transferring to parallel rail line are the better mode alternatives for overnight operation in high speed railway, compared with the other two modes.

The linking lines between the high speed railway with the traditional rail line are designed and constructed in significant stations respectively, such as Wuhan, Changsha, etc. The linking lines make it to be qualified for transferring mode. However, the Beijing-Guangzhou high speed railway was designed and operated especially in order to relieve the great capacity deficiency in the traditional Beijing-Guangzhou rail line. After the operation of Beijing-Guanghzou high speed line, most passenger trains are scheduled in the high speed railway, and the rest capacity of traditional rail line is reserved particularly for freight train. Due to the capacity deficiency in traditional Beijing-Guangzhou rail line, the waiting mode takes certain advantages for the overnight operation in Beijing-Guangzhou high speed railway, compared with the transferring to parallel rail line.

4.2 Particular Organization method in Waiting Mode

The waiting mode is featured with long waiting time at station, uncomplicated organization, the obvious reduction in continuity and balance. Under waiting mode, the waiting train is qualified to departure after the end of maintenance both at waiting station and the following section. The waiting at station leads to travelling time increase, and travelling speed decline. The waiting time at station is determined by maintenance duration, the number of waiting train in the same direction, and minimum tracking interval and the necessary interval between maintenance curfew and train operation. Define T , I_b and I_e as the duration of maintenance curfew, the necessary interval between maintenance curfew and train operation before the beginning of maintenance and after the end of maintenance. n and $I_{\min}$ indicate the number of waiting train in same direction, and the minimum tracking interval, respectively. T_l and T_l' mean the travelling time in ordinary case and in overnight waiting mode, respectively. With first-arrival first-departure rule, the waiting time T_d can be calculated by formula (1) and (2).

$$T_d = T + I_b + I_e + (n-1)I_{\min} \qquad (1)$$

$$T_l' = T_l + T_d \qquad (2)$$

Determined by the operation mileage, the highest operation speed and maintenance duration, the travelling speed can be calculated by formula (3). In formula (3), β_1 indicates the travelling speed coefficient of high speed train, and is valued as 0.9 based on previous practice. With 300km/h as the highest operation speed, the travelling speeds with different operation mileage and maintenance duration are listed in table 3.

$$v' = \frac{L}{T_l'} = \frac{L}{L/(\beta_1 v_1) + T_d} \tag{3}$$

Table 3. The travelling speed with different operation conditions（km/h）

L /km \ T /min	500	1000	1500	2000	2500	3000	3500	4000
120	119	166	190	205	216	223	229	233
180	96	142	169	186	199	208	215	220
240	81	124	152	170	184	194	202	209

With the above calculation, the travelling speed changes based on the rule that, at certain operation speed, shorter maintenance duration and longer travelling distance is corresponding to higher travelling speed and thus weaker negative effects. And long travelling distance assures travelling speed at a higher level, and reduces the negative effects.

In practice, certain technical measures can be adopted to improve the travelling speed, with maintenance demand satisfaction and basic operation conditions as premise. The available measures can be concluded as:(1)Make different maintenance curfew schemes for adjacent sections to improve the operation conditions; (2)Increase the number of maintenance worker and strengthen the maintenance operation, to shorten the auxiliary operation time and improve maintenance efficiency;(3)Optimize the waiting scheme to assign the trains to wait at different station and to reduce the waiting time.

Based on the technical features of power supply and the maintenance and operation demand, the high speed railway from Beijing to Guangzhou can be divided into several maintenance sections. The divided maintenance section is the fundamental unit of maintenance curfew, and their curfew plans constitute the whole maintenance curfew plan of the high speed rail line. With the same duration, the only difference between the different maintenance curfews is in their beginning times. With overnight operation demands and their features into consideration, the beginning time of maintenance curfew in different sections are scheduled differently to decrease the waiting time at station, besides the negative effects from maintenance curfew. A segmented maintenance curfew plan in Beijing-Guangzhou high speed railway is illustrated in figure 4.

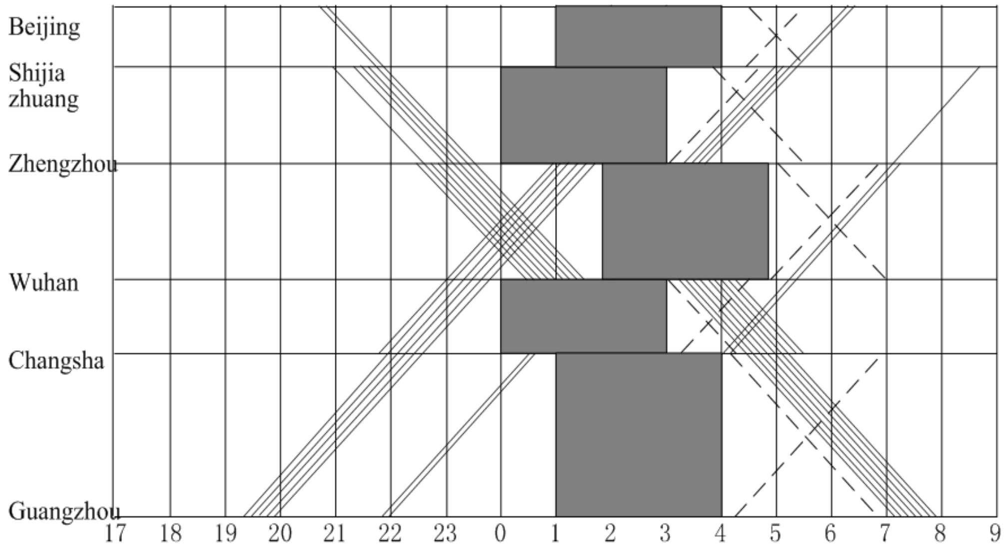

Figure 5. illustration for segmented maintenance curfew to increase the travelling speed in Beijing-Guanghzou high speed railway

The overnight operation in Beijing-Guanghzou high speed railway provide more travelling choices for medium-long distance, with sleeping time as travelling time. Due to the decline of travelling speed, the operation mileage is preferred more than the certain threshold to keep the travelling speed at certain higher level. With targeted travelling speed v_0 as objective, the mileage threshold can be calculated by formula (4). The mileage thresholds under different situations are listed in table 4 . It is concluded that the longer the maintenance duration is, the lower the operation speed is, and the higher targeted travelling speed, the longer the mileage threshold is. The average travelling speed of through express passenger train in traditional rail line is about 130km/h, and the minimum distance of overnight train reaches as high as 1400km, to obtain higher travelling speed.

$$L_0 = \frac{T_d}{(1/v_0 - 1/(\beta_1 v_1))} \quad (4)$$

Table 4. The mileage threshold with targeted travelling speed

Threshold /km; T /min	Highest operation speed /average travelling speed（km/h）				
	300/200	300/160	300/130	250/160	250/130
120	1800	920	585	1510	780
180	2570	1310	836	2160	1120
240	3340	1700	1086	2810	1450

5 Conclusions

With expanded service area and long traveling time, the high speed railway in China is qualified for overnight operation in net structure and time space, which is significantly different from that of high speed railway in other countries and areas. The overnight operation of high speed railway is of significance for capacity utilization improvement, besides diverse travelling demand in time horizon. The service area and operation demand of high speed railway from Beijing to Guangzhou were analyzed. The alternatives of overnight operation mode are waiting, transferring to adjacent parallel traditional line, running and maintenance in adjacent lines meanwhile and passenger transferring, and their technical conditions, organization features and adaptability are presented respectively. With the basic information of high speed railway from Beijing to Guangzhou, the waiting mode was selected as the satisfied overnight operation mode, and the optimized maintenance curfew scheme was proposed to increase the travelling speed. The work in this paper on operation mode and rational travelling distance is salutary and leading, which provides particular supports for overnight operation in Chinese high speed railway.

Abstract: High-speed railway Transport Organization Mode is very important for transport operation plan formulation, the improvement of transport efficiency, economic and social benefits. The determination of Transport Organization Mode under high-speed railway network has become a urgent problem need to be addressed with the high-speed railway network gradually constituting in China. This paper gives the definition of Transport Organization Mode based on analyzing the connotation of high-speed railway network Transport Organization Mode. And this paper introduces the influence factors and basic principles of Transport Organization Mode under high-speed railway network. Analyzing the types and characteristics of domestic and foreign high-speed railway Transport Organization Mode, putting forward four types of Transport Organization Mode under high-speed railway network, which are "various speed trains share the same line, one-line and over-line trains share the same line, trains with different stop schedule plans share the same line, trains with various characters share the same line".

Keywords: Network; Transport organization mode; Cooperation on the same line.

1 The connotation of Transport Organization Mode under high-speed railway network and the train combinations

Mode is the standard style of stuff, which is abstracted from concrete complex phenomenon. It describes the evolution law of object through the summary of the system, obtains logical structure and the method to solve problem via the deductive method which carries the strict reasoning (LIU Hua, 2005). Transport Organization Mode under high-speed railway network is referred to the train organization form and method of high-speed railway under certain operating management system, a certain level of social economy and science and technology development, under the condition of a certain network function structure. In particular, it is a comprehensive description of the train properties, types, running speed and the cross line train running (cross line passenger transportation) under the condition of joining each other between the high speed railway lines or between high-speed railway lines and existing lines.

According to the analysis of Transport Organization Mode under high-speed railway network, we can get the following different train combinations, as shown in *table 1*:

Table1. Train combinations of high-speed railway in different Transport Organization Modes

Classification standard	type	characteristic	Train combination
Train property	Mixed passenger and freight train	Mixed passenger trains and freight trains run in high-speed railway	Mixed passenger and freight trains;passenger trains and freight trains run in different period of time but in the same line
	Passenger dedicated line	Only Passenger trains run in high-speed railway	Only dedicated train;mixed dedicated trains and over-line trains;trains run at the same speed;trains run in the same line at different speed
Train speed	Same speed train in the same line	Train run at the Same speed	Dedicated trains run；mixed dedicated trains and over-trains run; trains run at the same speed
	Different speed train in the same line	Trains run at the different speed	Dedicated trains run at different speed;passenger trains and freight trains run at different speed;dedicated trains and over-line trains run at different speed;dedicated line trains、over-train and freight trains run
Over-line train operation	Dedicated train transfer	No over-line train	Dedicated trains run at same speed；dedicated trains run at different speed
	Over-line train go on line	Over-line train and dedicated train in the same line	Over-line trains and dedicated trains run at same speed；Over-line trains and dedicated trains run at different speed；Passenger trains and freight trains run
	Over-line train off line	Over-line train and dedicated train in the same line	Over-line trains and dedicated trains run at same speed；Over-line trains and dedicated trains run at different speed；Passenger trains and freight trains run
	Over-line train go on and off line	Over-line train and dedicated train in the same line	Over-line trains and dedicated trains run at same speed；Over-line trains and dedicated trains run at different speed；Passenger trains and freight trains run

2 The influence factors of Transport Organization Mode under high-speed railway network

The influence factors of Transport Organization Mode under high-speed railway network are complex. The main influence factors are as following:

(1)The properties and characteristics of passenger flow

The nature and characteristics of the passenger flow are the core influence factor of the high-speed railway Transport Organization Mode. High-speed railway Transport Organization Mode should be consist with the properties and characteristics of passenger flow. Passenger flow is divided into the line passenger flow and cross line passenger flow. The line flow is divided into big station passenger flowand passenger flow along the merge (XU Xingfang,2010). Across line can be divided into two parts, passenger flow from other line to the line or set off from this line to other line of passenger flow through the line of the passenger flow. Analyzing the characteristics of passenger flow is to analyse the line passenger flow, cross the line passenger flow, passenger flow of the shape and size. In addition, the demand characteristics of passenger flow should be researched from ticket costs, travel time, convenience and so on.

(2)Railway network structure and scale

Network structures mainly contain the situation of railway network joining and each line of joining compatible. Therefore, network under the condition of high speed railway is mainly divided into two kinds: one is the railway network system, separating the existing lines to form a single high-speed rail network structure. Another is connecting with existing lines to form a high-speed rail network and complex network structure of existing railway network combination. With the advancement of the high-speed railway construction in china, the railway network structure is clear, a high-speed line between the big nodes to join each other, and join the existing lines, thus form between highway system, the high railway system between the existing network and complex network structure.

(3) Macroscopic environment

Macroscopic environment mainly includes railway situation, human geography, economic environment, cultural tradition, passenger travel habits, policies and regulations and so on. When the macroscopic environment changes, high-speed railway Transport Organization Mode should also be changed accordingly. On a world scale, high-speed railway Transport Organization Mode is different from country to country. Macroscopic environment have influence on the determination of Transport Organization Mode.

(4)The train types and their mutual relations

The research of high speed railway Transport Organization Mode is bound to involve in the process of the type of the train, a single or multiple. If there are many types of trains, it inevitably involves the interaction relationship between different types of trains. From the world of high speed railway operation management, they involves different types of trains and the influence of relationship, just different from concrete manifestation.

(5)Safety and reliability of system and equipment (HU Siji,1996)

Safe system and reliable equipment are prerequisite condition to research and determine the Transport Organization Mode. No matter what kind of Transport Organization Mode, it must be based on system and equipment to ensure its security. System mainly includes the hardware and software system, equipment mainly includes fixed devices and mobile devices. System and equipment mainly includes train command system, control system, adjusting system, train control system, lines, locomotive, vehicle and so on.

（6）Carrying Capacity

Different Transport Organization Modes have different influence on carrying capacity. The loss of carrying capacity in high-speed railway is mainly caused by the different train stops and different train speeds. In addition, it is also affected by interval length, train combinations, the influence of different levels of speed train number, and many other factors, grasping these factors in a correct way will help planners formulate reasonable solution (ZHENG Jinzi,2012). Therefore, determine the Transport Organization Mode must consider its effect on the capacity.

(7)Transportation service quality

Important advantage of high speed railway is the high quality of service and mainly reflected in the rapid, on time and comfort. Determining high-speed railway Transport Organization Mode should try to improve transport service quality. In the condition of meeting the demand of passenger flow, achieve rapid, on time and comfortable goal.

3 Basic principles of Transport Organization Mode under the high-speed railway network

The way to choose the Transport Organization Mode of high-speed railway is based on starting point and foothold.

(1)Making the best use of high-speed railway's capacity

The starting points to ensure the Transport Organization Mode of high-speed railway are based on three aspects: understanding the connotation of high-speed railway deeply, seizing the essence exactly and making the best use of the capacity. As the high-speed railway forming into network, there are both existing line and high-speed railway coexisting between the same corridor. Based on the connotation and essence of the high-speed railway of our country, we should organize and encourage passengers to choose the high-speed railway, improve passenger trains operation speed, decrease the quantity of trains on the existing line to increase the quantity of freight trains and make the best use of high-speed railway's capacity. These methods would make a best use of the synthetical capacity of the transportation corridor.

(2) Acquiring the maximization of both passenger satisfaction degree and performance of enterprises

The foothold to ensure the Transport Organization Modes of high-speed railway is to acquire the maximization of both passenger satisfaction degree and performance of enterprises. To improve the passenger satisfaction degree, we should satisfy the demand of different kinds of passengers, try the best to make the passengers feel convenient and decrease the travel time. As for the performance of enterprises, we could try the best to reduce transportation costs, enhance the attractiveness, improve enterprises' competitiveness and increase scale of passenger flows. The two aspects have complex relationship for being in conflict and being accelerate. The scale of passenger flows is the link of the two aspects. The choice of Transport Organization Modes has to coordinate the two parts and achieve a win-win relationship of them.

4 The Transport Organization Modes of high-speed railway at home and abroad

4.1 The Transport Organization Modes of high-speed railway abroad

The realized time of Transport Organization Modes of high-speed railway abroad is earlier, their modes have many characteristics as following *table 2*.

Table 2. The Transport Organization Mode of high-speed railway abroad

Country	*Mode*	*Remark*
Japan	High-speed railway of whole journey	Japanese Railway Company achieves the over-line transportation between the existing line and high-speed railway through technical transformation. The East Japan Railway implements the over-line transportation between different Shinkansen.
France	Trains use both the high-speed railway and exiting line	Using the over-line transportation between different.
Germany	Passenger trains and freight trains share the same line	Passenger trains and freight trains share the same line in different time bucket.
Italy	Passenger trains and freight trains share the same line	High-speed and medium-speed passenger trains and the high-speed freight trains share the same line.
Spanish	High-speed and medium-speed passenger trains use the same line.	The dedicated train AVE (300km/h) and the over-line train Talgo (200km/h) share the same line.
Sweden	Passenger trains and freight trains share the same line	Using the tilting trains to achieve a speed of 200km/h through the transformation of a part of the existing line.

4.2 The Transport Organization Modes of high-speed railway in china

According to the Long-term Planning of Chinese Railway in 2004, the "four vertical and four horizontal" high-speed railway network begin to take shape and has basic formation after ten years of construction, the mileage has reached 16,000 kilometers which is the longest mileage in the world.

Overall considering the practical operation condition of high-speed railway, passenger transport line and interurban railway and the intension of Transport Organization Mode, the Transport Organization Modes of our country are summed up as the following *table 3*.

Table 3 The different Transport Organization Modes in china

Type of line		*Transport Organization Mode*
300km/h and over		Over-line trains could use the high-speed railway line and different speed trains share the same line
200km/h-250km/h	New line	Passenger dedicated train only
	Reconstructive line	Passenger trains and freight trains share the same line
Interurban passenger transport line		Operating the one-line high speed train only

5 The types and characteristics of Transport Organization Modes

5.1 The types of Transport Organization Modes

Overall referencing the related studying achievements, this paper summarizes the modes into four types which are as follows:

(1)High-speed line with over-line train mode: The high-speed railways are only offered for the high speed trains, while the high speed train could operate on both high-speed line and the existing lines. This mode satisfy the need of both one-line and over-line passenger flows. Specifically, there are three modes: trains operate on a high-speed line and transferring to an existing line; trains operate on an existing line and then transferring to high-speed line; train operate on an existing line and transferring to a high-speed line then down to an existing line again.

(2)High-speed line with transference: The high-speed railways are only offered for the high speed trains. The high speed trains operate only on the high-speed lines. This mode asks the over-line passenger flow to transfer to the existing line on the transfer station.

(3) High-speed passenger trains with medium-speed passenger trains mode: There are different speed levels on the high-speed line, including high speed trains and ordinary speed trains. This mode achieves the transportation task of the one-line and over-line passenger flows. In this mode, there are two methods to transport the over-line passengers. One is to use the ordinary speed trains, the other is to use both the high speed trains and ordinary speed trains.

(4) Passenger trains and freight trains sharing the same lines mode: The high-speed railways are offered for the passenger trains and freight trains to accomplish the whole transportation task.

5.2 Characteristics of different Transport Organization Modes

Different Transport Organization Modes are referred to meeting the demand of passenger flow, the level of train on high speed railway, the operating range of high-speed railway train and the type of train, the different specific forms include. The characteristics of four different kinds of modes are listed as *table 4*.

Table 4 The characteristic of different Transport Organization Modes

Type	*Advantage*	*Disadvantage*
High-speed line with over-line train mode	High travelling speed, short travelling time for one-line passenger flows, high service level for one-line passenger flows, large transportation capability, simple transportation organization, easy to manage	Over-line passenger flows have to transfer to another line; the service level for over-line passenger flows is low; the attraction for over-line passenger flows is lacked.
High-speed line with transference	Decreasing the transference of Over-line passenger flows, higher service level, more attractive, high capacity use	The demands of motor train units are large, adjoining line have to use high standard and are mutually compatible, Maintenance amount of the motor train units is large, complex operation
Mixed high-speed passenger trains and medium-speed passenger trains	Satisfying different levels of passenger flows' demands	Lower transportation capability
Mixed passenger trains and freight trains share the same line	Less over-line passenger flow transference, high service level, high capacity, high line's capacity factor, attracting more freight transportation	Operation of freight trains would influence the whole line operation, adjoining line have to use high standard and are mutually compatible, Maintenance amount of the motor train units is large, lower capacity factor for passenger trains, complex operation

5.3 Limitations of different Transport Organization Modes

The various development histories of countries and multiple social economic statuses lead to a lot of operation forms and various Transport Organization Modes. According to the characteristics of our country, complete adoption of any mode would have certain limitations (such as *table 5*).

Table 5 The limitation of different Transport Organization Modes

Mode	*Limitation in our country*
High-speed line with over-line train mode	The design of station in our country is lack of transference which increases the cost of transference and causes loss of passenger flow.
High-speed line with transference	The huge demand of motor train units would take a large cost. The existing line are not completely electrified which doesn't match the high speed trains. The speed standard of the existing line is low. The operation of over-line freight trains is complex.
Mixed high-speed passenger trains and medium-speed passenger trains	This mode would decrease the capacity of high-speed railway, and reduce the influence of it.
Mixed passenger trains and freight trains share the same line	The construction standard is different. The axle load standard of high-speed line and ordinary line are diffetrent. This mode does not fit the goal of our country, which is separating the passenger trains and freight trains into different lines.

According to the analysis of table 4 and table 5, it's not hard to know that whichever mode our country chooses, it would have some limitation. But we could summarize some enlightenments.

(1) When the benefits reach a certain extent, we could reform the line network, let the high-speed train operate on the existing line and improve the high quality of high-speed railway.

(2) We could use the high-speed line to transport the freights and attract some fixed high-value freight sources.

(3)Separating the passenger trains and freight trains into different lines would crease the transference cost of passengers while save the transforming cost.

(4) We could adopt the passenger trains and freight trains sharing the same lines mode on the high-speed lines which have lower design standard and less transportation tasks. These methods could delay constructing second-line.

(5)Using the high-speed passenger trains with medium-speed passenger trains mode could attract different consumption levels passengers and extend volume growth of high-speed railways.

6 Determination of Transport Organization Modes under the high-speed railway network

The high-speed trains in our country have their own characteristics and they are much more complex than other countries. We have to find out the basic principles of Transport Organization Modes under the high-speed railway network, analyze the relevant factors about the Transport Organization Modes comprehensively and take the construction original intentions into considered. The original intentions are as follows: High-speed lines in our country have to undertake the most medium-term and long-term one-line and over-line passenger flows while the existing lines undertake the freight transportation and some passenger flows with lower speed. According to the railway situation in our country, the most amounts of high-speed railways have to be used as passenger transport lines. Meanwhile, the construction and operation of them are divided into several stages. Thus, determine the Transport Organization Modes under the high-speed railway network needs systematic planning and have to be divided into several parts. The stage of today is called “four operation trains sharing same line”.

(1) Various speed trains share the same line: There are two and more speeds of trains operating on the high-speed railway lines.

(2) One-line and over-line trains share the same line: There are one-line and over-line trains operating on the high-speed railway lines.

(3)Trains with different stop schedule plans share the same line: There are trains with different stop schedule plans operating on the high-speed railway lines.

(4)Trains with various characters share the same line: There are high-speed trains, ordinary-speed passenger trains and freight trains operating on the high-speed railway lines.

The “four operation trains sharing same line” is the most suitable high-speed Transport Organization Mode of our country. The reasons are as follows:

(1) This mode has the advantages of “Trains use both the high-speed line and exiting line” and solving the problem of the lack of capacity on existing lines.

(2) In these years, the manufacture of locomotives and vehicles grows quickly. Homebred motor train units account for a very great proportion. These backgrounds offer a strong technology support for using motor train units for over-line trains.

(3) After the raising of speed in Chinese railway, the technology and equipment conditions of existing lines improve a lot. Ordinary passenger and freight trains have less speed differences of the high-speed trains. This condition makes an advantage for trains using both the high-speed lines and exiting lines.

(4) Trains with different stop schedule plans guarantee the nonstop of high-speed trains and satisfy the service frequency of high-ranking stations. It’s the embody of high-speed railway satisfying various kinds of transportation demands and the important guarantees of transportation quality.

(5) This mode matches the functional orientation and passenger flows of high-speed line in the railway network which could improve the railway service quality and market competitiveness.

(6) Although the high-speed railway network initially formed at this stage, it is not perfect about the operation areas. The over-line trains could increase the operation areas of high-speed trains and improve the availability of high-speed lines.

(7) The high-speed lines which are transformed from existing line could operate the freight trains. And most of these lines do not have double lines between the same origin and destination. Using “passenger trains and freight trains sharing the same lines mode” could play a bigger role.

7 Conclusions

Based on the analysis of intensions and influence factors about Transport Organization Mode, this paper discusses the types and characteristics of Transport Organization Modes at home and abroad and proposes the Transport Organization Mode of our country under the high-speed railway network, namely "four operation trains sharing same line". With the developments of the high-speed railway network, it is important to increase the quantity and operation areas of high-speed trains and to decrease the quantity of over-line trains to achieve a goal of high-speed lines running high-speed and high-level trains.

Calculation Methods of Minimal Headway for High-Speed Railways

Yongxiang Zhang

School of Transportation and Logistics, Southwest Jiaotong University, Chengdu 610031, China. E-mail: bk20100249@my.swjtu.edu.cn

Abstract: This paper analyzes the interaction process of the running trains associated with the minimal headway for high-speed railway in a more reasonable and sophisticated way after systemically investigating previous researches. A set of new formulas are proposed to improve the calculation accuracy of minimal headway. In the case study section, the proposed methods are tested to calculate the minimal headway of the running trains of different speeds range from 250 km/h to 350 km/h with the calculation step of 10 km/h. The case study results show that with the increase of the maximal allowed speed, the headway between two trains running in one section, the headway between two arrival trains and the minimal headway of the high-speed railway increase, while the headway between two departing trains is a constant. The main conclusions can be drew from the case study results: (1) Headway between two arrival trains is always the bottle neck to narrow down minimal headway of high-speed railway no matter how the maximal allowed speed of the train changes from 250 km/h to 350 km/h. (2) The minimal headway of high-speed railway is always greater than 180s with the maximal allowed speed of the train ranges from 250 km/h to 350 km/h, which means that some improvement measures should be taken to accomplish the goal of reducing minimal headway to 3min. (3) The improvement of braking performance of the train can reduce the minimal headway of high-speed railway.

Keywords: High-speed railway; Minimal headway; Maximal allowed speed.

1 Introduction

The minimal headway is the minimal time interval that is needed for the station to accomplish necessary train receiving and departure operations, which is also the key to ensure the safety of trains running in the section (Li et al., 2008). Many studies have been implemented on calculation of the minimal headway for high-speed railway. Shi (2005) calculated the minimal headway of high-speed railway at the speed of 350km/h and analyzed the relationship between minimal headway and train acceleration, train deceleration, length of the station throat and switch number etc. Liu et al. (2006) proposed new methods to calculate the minimal headway of high-speed railway and come up with some measures to narrow down the minimal headway. Wu et al. (2007) built section and station train headway model under the condition of high-speed railway signal system to calculate the minimal headway. Li et al. (2008) applied computer simulation technology to simulate running process of the train while the train runs in the section, arrives at the station and departs the station to calculate the minimal headway of high-speed railway. Huang (2009) designed an optimization process to optimize minimal headway of high-speed railway after analyzing formation mechanism of the headway between two arrival trains. Li et al. (2013) analyzed the train headway of high-speed railway with speed restriction and used opentrack simulation software to verify the calculation results. However, after systematically investigating previous studies, it is found that previous studies do not have consistent analysis method for interaction process of the running train when calculating the headway between two trains running in one section, arriving at the station and departing the station which are three kinds of headway and this difference has made the calculation results of minimal headway for high-speed railway vary greatly. Most important, analysis of most studies on the interaction process of the running train are very rough, which has made it harder to calculate the throughput capacity of passenger dedicated line accurately.

This paper mainly have the following three contributions to the calculation of minimal headway for high-speed railway compared with previous studies. First, calculation method of every parameter in the calculation formulas of this paper is introduced in detail which makes it easier for the proposed calculation methods of this paper to be applied in practical situations by practitioners, and calculation methods of those parameters are determined by considering both the actual situation of high-speed railway and other relevant studies which makes values of those parameters more reasonable. Second, this paper assumes that final position of arrival trains and starting position of departing trains within the station are at the centerline of station arrival and departing track which is not considered by other studies and this assumption has great influence on calculation result of minimal headway. Third, running processes of trains approaching the station and trains departing the station are very complicated and many studies merely assumes those running processes as uniformly accelerated motion or uniformly retarded motion which is not reasonable, and this paper assumes those processes as a combination of uniform motion and uniform variable motion instead. The structure of this paper are arranged as below. Firstly, this paper analyzes basic principle of one-brake control mode curve. Then this paper introduces the deduction process of calculation formulas for minimal headway in detail. Finally, the proposed methods are tested to calculate minimal headway of high-speed railway.

2 One-brake control mode curve

One-brake control mode curve is the most commonly used train control method in Chinese high-speed railways. As shown in figure 1, the safe distance L_x between two trains in the section equals to the sum of L_{g1}, L_{g2}, L_{g3}, L_{g4} and L_{g5} (Liu et al., 2006). L_{g1} is the additional train running distance during the response time of equipment and train driver; L_{g2} is the total braking distance of the train; L_{g3} is the safety protection distance considering operation tolerance of equipment and operator of the train; L_{g4} is the distance considered under the worst tracing situation; L_{g5} is the length of the train.

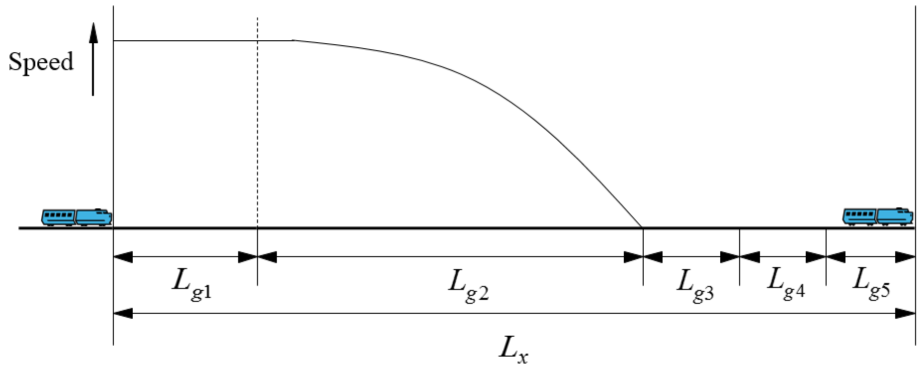

Figure 1. Principle of one-time braking mode curve train control method

3 Minimal headway of high-speed railway

The minimal headway of high-speed railway I equals to the maximal value among the headway between two trains running in one section I_z, the headway between two arrival trains I_d and the headway between two departing trains I_f as shown in formula (1) (Shi, 2005; Su et al., 2008; Li et al., 2008), that is because only the maximal headway can ensure that two adjacent trains run safely on the same railway line at the same time.

$$I = \max\{I_z, I_d, I_f\} \quad (1)$$

3.1 Headway between two trains running in one section

The distance between two trains running in one section L_x is shown in Figure 1, the formula to calculate L_x is shown below:

$$L_x = L_{g1} + L_{g2} + L_{g3} + L_{g4} + L_{g5} \quad (2)$$

L_{g1} can be calculated according to the formula bellow:

$$L_{g1} = t_g v_{\max} / 3.6 \quad (3)$$

Where t_g is the response time of equipment and train driver, t_g consists of section clear inspection time, response time of train control center, response time of on-board equipment and the time a driver needs to acknowledge the signal, t_g usually equals to 15s (Liu et al., 2006); $v_{\max}$ is the maximal speed of the train, km/h.

L_{g2} is the total braking distance of the train and L'_{g2} is the emergency braking distance. L'_{g2} can be calculated according to the formula bellow (Yang, 2008):

$$L'_{g2} = v_1 t_k / 3.6 + 4.17 \times (v_1^2 - v_2^2) / (1000 \vartheta_h \varphi_h + \omega_0 + i_j) \qquad (4)$$

Where t_k is the idling braking time, t_k usually equals to 1.5s for emergency braking (Yang, 2008); v_1 is the initial braking speed of the train, km/h; v_2 is the final braking speed of the train, km/h; ϑ_h is the train conversion braking rate, ϑ_h usually equals to 0.277 (Ma et al., 1998).

φ_h is the disc braking fraction coefficient, it can be calculated according to the formula bellow (Ma, 2011):

$$\varphi_h = 0.358 \times (2v + 150) / (3v + 150) \qquad (5)$$

Where v is the speed of the train, km/h.

ω_0 is the train unit basic resistance, it can be calculated according to the formula bellow (Ma et al., 1998):

$$\omega_0 = 0.608 + 0.008v + 0.000136v^2 (\text{N} \bullet \text{KN}^{-1}) \qquad (6)$$

i_j is the track gradient resistance, this paper doesn't consider track gradient resistance, then i_j equals to 0 N•KN^{-1}.

To ensure safety of the train and consider that the tolerance of disc braking fraction coefficient is controlled within 10%, then:

$$L_{g2} = L'_{g2} \times (1 + 10\%) \qquad (7)$$

The value of L_{g3} is related to the precision of the speed and distance measurement system, train speed and accuracy of the train braking rate. L_{g3} can be calculated according to the formula bellow (Ning, 1995):

$$L_{g3} = \beta(c + a \cdot v_{\max} + \sum_{j=1}^{n} \Delta s_j) \qquad (8)$$

Where β is the reservation coefficient and its value range is 1.1~1.4, this paper lets β equal to 1.4; c is the experience base number and its value range is 40~100m, this paper lets c equal to 100m; a is the experience constant and its value range is 0.4~0.6m, this paper lets a equal to 0.6m; $\sum_{j=1}^{n}\Delta s_j$ is the distance tolerance caused by the tolerance of braking rate as well as the tolerance of speed and distance measurement system, it usually equals to 50m.

L_{g4} usually equals to the length of the block section of high-speed railway, this paper lets L_{g4} equal to 1300m.

L_{g5} is the length of the train, the paper assumes that the train is made up of 16 coaches, then L_{g5} equals to 410m (Shi, 2005).

After L_{g1}, L_{g2}, L_{g3}, L_{g4} and L_{g5} are determined, the headway between two trains running in one section I_z can be calculated according to the formula below:

$$I_z = 2\times 3.6\frac{(L_{g2} - 1.1\times t_k v_{\max}/3.6 + L_{g3} + L_{g4} + L_{g5})}{v_{\max}} + 1.1\times t_k + t_g (s) \tag{9}$$

3.2 Headway between two arrival trains

The principle of determining the headway between two arrival trains is to ensure that the latter train will not slow down or even stop at the outside the station because the station has not prepared the receiving route. The distance between two arrival trains L_z is shown in Figure 2 and L_z can be calculated according to formula (10) (Wu et al., 2007; Yang, 2008; Huang, 2009; Li et al., 2013).

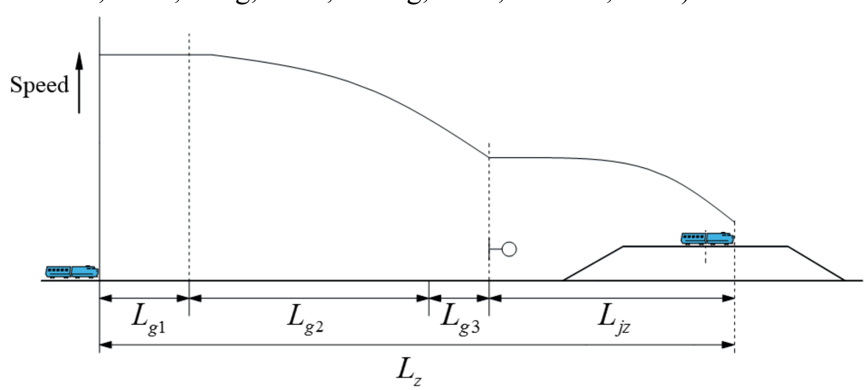

Figure 2. Distance between two arrival trains

$$L_z = L_{g1} + L_{g2} + L_{g3} + L_{jz} \tag{10}$$

L_{g1} is the additional distance produced during the period of train arrival operation and driver operation, L_{g1} can be calculated according to the formula bellow:

$$L_{g1} = \frac{(t_{dz} + t_s) \times v_{\max}}{3.6} \tag{11}$$

Where t_{dz} is the station receiving operation time, t_{dz} usually equals to 27s (Liu et al., 2006); t_s is the time that a train driver needs to acknowledge the signal, t_s usually equals to 6s (Liu et al., 2006).

L_{g2} is the total braking distance of the train, it can be calculated according to the formula bellow (Yang, 2008):

$$L_{g2} = (v_{\max} t_k / 3.6 + 4.17(v_{\max}^2 - v_y^2) / (1000\vartheta_h \varphi_h + \omega_0 + i_j)) \times (1 + 10\%) \tag{12}$$

Where v_y is the maximal allowed speed of the train while passing through switch side direction of the station, this paper lets v_y equal to 75km/h (Li et al., 2008); the meaning of other parameters are same as those in section 3.1.

L_{g3} is same as the L_{g3} in section 3.1.

L_{jz} is the running distance of the train while coming into the station, it can be calculated according to the formula bellow:

$$L_{jz} = L_n + 0.5 \times L_c + 0.5 \times L_u \tag{13}$$

Where L_n is the length of the station throat, L_n usually equals to 850m (Huang, 2009); L_c is the length of the train, this paper lets L_c equal to 410m (Shi, 2005); L_u is the length of the station effective track length, L_u usually equals to 700m (Li et al., 2008).

After L_{g1}, L_{g2}, L_{g3} and L_{jz} are determined, headway between two arrival trains I_d can be calculated according to the formula below:

$$I_d = 2\times 3.6\frac{(L_{g2} - 1.1\times t_k v_{\max} / 3.6 + L_{g3})}{v_{\max} + v_y} + 3.6\frac{\max\{(L_{jz} - L_{z0}), 0\}}{v_y} + \frac{2\times 3.6\times L_{z0}}{v_y} + t_{dz} + t_s + 1.1\times t_k \quad (14)$$

Where L_{z0} is the running distance of the train within the station while its speed reduces from v_y to 0 km/h. L_{z0} can be calculated according to the formula bellow:

$$L_{z0} = v_y t_k / 3.6 + 4.17(v_y^2 - 0^2) / (1000\vartheta_h \varphi_h + \omega_0 + i_j) \quad (15)$$

3.3 Headway between two departing trains

The principle of determining the headway between two departing trains is to ensure that the latter train will not slow down, which means that starting signal can only be opened until the former train has left the second departure section. The distance between two departing trains is shown in Figure 3 (Li et al., 2008; Yang, 2008; Li et al., 2013).

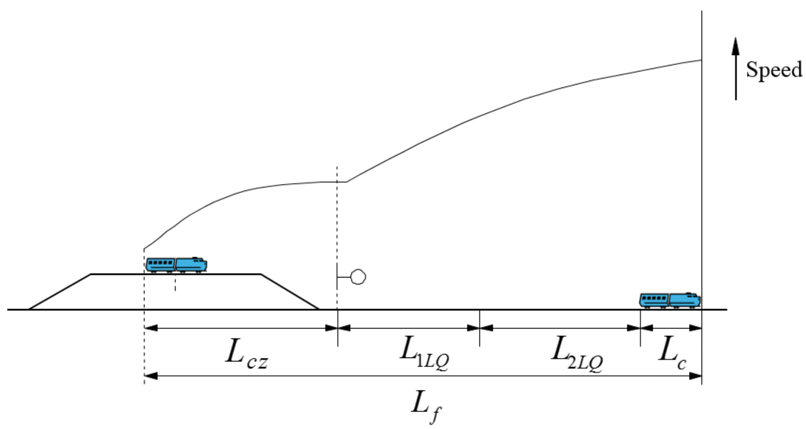

Figure 3. Distance between two arrival trains

The distance between two arrival trains L_f can be calculated according to the formula bellow:

$$L_f = \max\{L_{cz}, L_j\} + \max\{(L_{1LQ} + L_{2LQ}), L_{yb}\} + L_c \quad (16)$$

L_{cz} is the running distance of the train while departing the station, it also can be calculated according to formula (13).

L_j is the running distance of the train while it's speed reaches to v_y from 0 km/h, L_j can be calculated according to the formula bellow:

$$L_j = ((v_y / 3.6)^2 - 0^2) / 2a \tag{17}$$

Where v_y is the maximal allowed speed of the train while passing through switch side direction of the station, this paper lets v_y equal to 75km/h (Li et al., 2008); a is the acceleration of the train, this paper lets a equal to 0.35 m•s^{-2} (Shi, 2005).

L_{1LQ} and L_{2LQ} is the length of the first departure section and second departure section respectively, L_{1LQ} usually equals to 800m, L_{2LQ} usually equals to 1300m.

L_{yb} is the running distance of the former train during the period while the station is preparing the departure route for the latter train, it can be calculated according to the formula bellow:

$$L_{yb} = (v_y / 3.6) \times (t_{yb} - t_x) + 0.5a \times (t_{yb} - t_x)^2 + (v_y / 3.6) \times t_x \tag{18}$$

Where t_{yb} is the time that a station needs to handle departure route, this paper lets t_{yb} equal to 13s (Liu et al., 2006); t_x is the time interval from the moment when train comes into the first departure section to the moment when train starts to accelerate, this paper lets t_x equal to 9.5s (Liu et al., 2006).

After checking in advance, it is found that $L_{cz} > L_j$ and $L_{1LQ} + L_{2LQ} > L_{yb}$, then the headway between two departing trains I_f can be calculated according to the formula bellow:

$$\begin{aligned} I_f = t_{fz} + t_s + \frac{v_y}{3.6a} + 3.6\frac{L_{cz} - L_j}{v_y} + t_x + \frac{-2v_y / 3.6 + \sqrt{(2v_y / 3.6)^2 + 8a\min\{s, s_1\}}}{2a} \\ + 3.6\frac{\max\{(s - s_1), 0\}}{v_{\max}} \end{aligned} \tag{19}$$

Where t_{fz} is the station departure operation time, this paper lets t_{fz} equal to 11s (Liu et al., 2006); t_s is the time a driver needs to acknowledge the signal, this paper lets t_s equal to 6s (Liu et al., 2006); s_1 is the running distance of the train while its speed increase from v_y to $v_{\max}$, it can be calculated according to the formula bellow:

$$s_1 = \frac{(v_{\max}/3.6)^2 - (v_y/3.6)^2}{2a} \tag{20}$$

s can be calculated according to the formula bellow:

$$s = L_{1LQ} + L_{2LQ} + L_c - v_y t_x / 3.6 \tag{21}$$

4 Case study

The speed of the busy railway passenger dedicated line usually ranges from 250km/h to 350km/h, then this paper uses the proposed calculation methods to calculate the minimal headway of high-speed railway of different speeds range from 250km/h to 350km/h with calculation step of 10km/h. The calculation results are shown in Table 1.

Table 1. Calculation of the minimal tracing time interval

Speed(km/h) / Time Interval(s)	250	260	270	280	290	300	310	320	330	340	350
I_z	178	179	180	181	183	184	185	186	188	189	190
I_d	197	200	203	207	210	213	216	219	221	224	227
I_f	194	194	194	194	194	194	194	194	194	194	194
I	197	200	203	207	210	213	216	219	221	224	227

It is shown in Table 1 that with the increase of the maximal allowed speed, the headway between two trains running in one section I_z, the headway between two arrival trains I_d and the minimal headway I increase, while the headway between two departing trains I_f is a constant. The main conclusions can be drew from Table 1 as shown below:

(1) Because I_d is always greater than I_z and I_f, then minimal headway I is determined by I_d, which means that I_d is the bottle neck to narrow down minimal headway I no matter how the speed of the train changes from 250km/h to 350km/h. This finding is consistent with other researches' results (Liu et al., 2006; Wu et al., 2007; Li et al., 2008).

(2) Minimal headway of high-speed railway I is always greater than 180s with the maximal allowed speed of the train ranges from 250km/h to 350km/h, which means that some improvement measures should be taken to accomplish the goal of reducing minimal headway to 3min.

(3) After analyzing calculation formulas of headway between two arrival trains I_d, it is found that improvement of braking performance of the train will reduce the minimal headway of high-speed railway.

5 Recommendations for Future Research

Our future research will focus on designing parameters of the station yard, railway track and the train to narrow down the minimal headway of high-speed railway by analyzing calculation formulas of the proposed methods. We will be testing how I_z, I_d and I_f changes if some of the parameters in these formulas increase or decrease. Different combination of those parameters will lead to different construction costs and corresponding minimal headway, we will try to find out the best combination of those parameters to make a balance between construction cost and minimal headway to maximize the economy and social benefit of the railway.

Abstract: Public transportation companies generally establish a scheduling command center, and gradually develop the mode of cluster scheduling in large-sized and medium-sized cities in China. Realizing the mode of "multiple lines and a scheduling center" is one of the advantages of cluster scheduling so that it can improve the utilization of transport capacity resources. Based on the background, the paper studies a method of cross-line timetable coordinated optimization under cross-line buses with single depot, the synchronization timetable model of which not only considers the decrease of the total passengers' time cost, including the time cost of cross-line transfer passengers and non-cross-line waiting passengers, but also optimizes the buses' arriving time and buses' departure time in order to facilitate to link up the different trips. In addition, the paper established a model of seamless transfer timetable, which effectively reduces the waiting time and the cross-line transfer walking distance of cross-line transfer passengers.
Keywords: Cluster scheduling; Single depot; Cross-line operation; Synchronization timetable optimization; Seamless transfer timetable optimization.

1 Introduction

Vehicle-scheduling plan is an important production plan for transit agency as it is the key part of vehicle operation scheduling and has a great effect on operation cost and service level. The book of "Public Transit Planning and Operation-Theory, Modelling and Practice" introduces that vehicle operation scheduling has four parts: Network route design, timetable development, vehicle scheduling and crew scheduling (Ceder, 2007). Among, timetable development is an important factor of the vehicle scheduling problem (VSP) in the bus operation plan, which measures of bus punctuality and reliability. Thus, reasonable optimization of the bus departure interval and frequency is crucial to improve the punctuality of bus stations. In order to better use the bus traffic capacity and human resources, and be able to better serve the passengers, it is often to fix the timetable through adjusting the vehicle departure intervals based on passenger waiting time and vehicle operating time.

There are some researches about bus schedule coordination under the regional cross-line. Ceder (1987) proposed a method of forming variety kinds of bus schedule timetable based on passenger volume. It contained six goals: timetable change under the new integration; adjusting the departure interval of each line in the transfer nodes to make each line bus arriving most vehicles at the same time based on passengers service demand; offering a variety of schedules for the use of operators under different situations; adjusting the arrangement of different bus operation patterns to respond to the emergency; schedules ensuring the departure interval smoothness as far as possible; compiling schedule under collaborative departure. Ceder (2001) made a schedule optimization model under collaborative departure for each line based on the maximum bus approaching times online in the network. The purpose is to achieve synchronization of the schedules for each bus line. Then, Ceder (2007) put forward an optimization model to adjust the departure intervals on transit network level by minimizing passengers' transfer time through the synchronization of bus arrival. He also discussed that the synergy mainly depends on the real time bus control. Therefore, the reliability and punctuality of the timetable are very important. Liu (2007) reduced the passengers' waiting time through establishing a timetable synchronization of bus departure of multiple lines. The problem was classified as a 0-1 knapsack problem without capacity constraint of and defined the collaborative coefficient. A corresponding nested tabu search algorithm was set up to solve the model. Song (2013) proposed a timetable optimization model based on single line passengers demand and the benefit of the bus agency. This model achieved the optimized schedules which could reduce the waiting time of the cross-line transfer passengers. A particle swarm optimization (PSO) algorithm was used to solve the model. The result showed that this model could reduce the waiting time sharply.

To better meet the demand of bus service, this paper establishes a model of synchronization timetable to decrease the time cost of all passengers, including the waiting time cost of cross-line transfer passengers and the waiting time cost of non-cross-line passengers. In addition, in view of the bus lines with large cross-line transfer passenger flow in the peak hours, the model need consider the convenience of the cross-line passengers and to reduce their waiting time and walking distance. Then this paper establishes a seamless transfer timetable optimization model based on the vehicle under cross-line operation.

2 Problem Description

Figure 1 shows the cross-line operation mode based on a terminal in this paper.

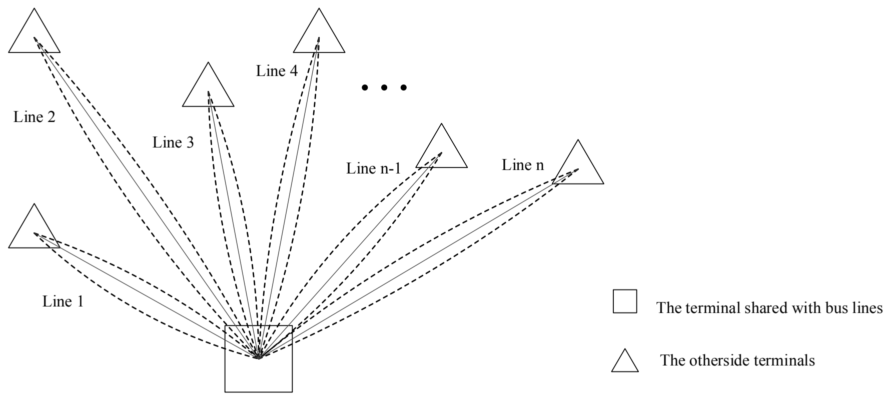

Figure 1.The cross-line operation mode based a terminal

The background of this operation mode are as follows:

(1) There are many bus terminals or intermodal transit terminals established or being planned in big cities, especially Transit-oriented Development based on terminals has become one tendency of urban planning in developing countries, such as China;

(2) Laying out bus transit network based on terminals is beneficial for fleet management and maintenance, and is also convenient for transferring organization of passenger flow;

(3) Many terminals are located among functional areas to exchange passengers. Some of lines could connect residential zones, and some could connect commercial zones or industrial zones. The peak time of the passenger volume of these lines are staggered. The transport capabilities required for these lines are complementary;

(4) It is much easier for crew-scheduling based on the SDVS vehicle-scheduling than based on MDVS.

With the widespread technology adoption of AVL, APC, RFID, wireless communication technology and other kinds of equipment in the public transportation industry, the transit agencies have the ability of information collection, processing and application. Many bus enterprises have set up scheduling command center, which provides implementation condition of bus multi-lines centralized scheduling. The condition to conduct the cross-line dispatching is mature. Therefore, it is a pressing problem to build regional dispatching timetable based on passenger service demand.

Comprehensive above, it is necessary to think over how to develop the detailed, practical and feasible regional cross-line dispatching timetables in order to guide public transport intelligent dispatching. Timetable is a connecting link between transit agency companies and passengers. And building favorable timetable is an important measure to improve the operational efficiency, increase bus service level and reduce operational costs.

3 The model building of synchronization timetable

3.1 Optimizing goal

Timetables for single line mainly meet the basic traveling demand of passengers, which do not consider transfer cost of the cross-line transfer passengers. On the basis of meeting each line passengers flow volume, this paper decreases the transfer waiting time and transfer cost of the cross-line transfer passengers. Therefore, there are three main optimization goals in timetable model with synchronization, such as the minimal difference value of departure intervals compared with timetables for single line, the minimal cross-line transfer waiting time and the minimal waiting time of the non-cross-line passengers of original line. As multi-objective optimization model, it is suitable for the heuristic algorithm to solve the optimal model.

3.2 Premise assumption

There are some premises to be stated before proposing the model:

(1) Passenger flow rule is same in optimized time range in minutes;
(2) The number of the cross-line transfer passengers is known and its arrival pattern is complied with uniform distribution because of the unknown timetable distribution;
(3) Vehicle type of each line is same, which has the same rated capacity;
(4) The cross-line transfer passengers and the non-cross-line waiting passengers of original line would get on the first coming bus, and they would not wait the later bus no matter what happened;
(5) The number of the non-cross-line waiting passengers of original line is known and its arrival pattern is complied with poisson distribution because of the known timetable distribution.

3.3 The mathematical symbol

Let $\overline{L} = \{L_j \mid j = 1,2\ldots\ldots n\}$ be the set of cross-lines departed from the identical terminal, in which j is the serial number and n is the number of lines satisfied regional scheduling.

Let $\overline{D} = \{D_{jt} \mid j = 1,2\ldots\ldots n,\ \ t = 1,2\ldots\ldots y_j\}$ be the set of the whole trips departed from the identical terminal. Let D_{jt} mean the trip t of the bus line j. Let y_j be the trips of bus line j.

Let $\overline{K}=\{K_{jt}\mid j=1,2\ldots\ldots n,\ \ t=1,2\ldots\ldots y_j\}$ be the set of the vehicles departed from the identical terminal. Let K_{jt} mean the vehicle to conduct the trip t of the line j. Let y_j be the trips of bus line j.

Let t_{djt} be the departure time from the identical terminal and t_{ajt} be the arrival time (the time back the identical terminal).

Let h_{jt} be the departure interval of the trip t of the line j.

Let $t_{jt}^{'}$, $t_{jt}^{''}$ be the running time for up and down.

Let $tt_{jt}^{'}$, $tt_{jt}^{''}$ be the stop time of the other terminal relative to the same terminal.

Let P_{jt} be the number of the non-cross-line passengers of the trip D_{is}.

Let $P_{jt,is}$ be the number of the cross-line transfer passengers from D_{jt} to D_{is}.

Let λ be the arrival rate of non-cross-line passengers per unit time.

Let β be the rate of passengers to get on the bus.

3.4 The model building

With the above mathematical symbol, the model of synchronization timetable would be built in this section.

(1) The difference value of departure intervals compared with timetables for single line:

$$\Delta t_l=\sum_{i=1}^{l}\sum_{s=1}^{y_i}(\left|h_{is}-h_{is}^{'}\right|) \quad (1)$$

(2) The transfer waiting time:

Supposing that line L_j and line L_i are from the identical terminal, the arrival times of the trips D_{jt} and D_{is} are as follows:

$$\begin{cases} t_{ajt} = t_{djt} + t_{jt}^{'} + tt_{jt}^{'} + t_{jt}^{"} = t_{dj1} + (t-1)h_j + t_{jt}^{'} + tt_{jt}^{'} + t_{jt}^{"} \\ t_{ais} = t_{dis} + t_{is}^{'} + tt_{is}^{'} + t_{is}^{"} = t_{di1} + (s-1)h_i + t_{is}^{'} + tt_{is}^{'} + t_{is}^{"} \end{cases} \quad (2)$$

And the departure times of the trips D_{jt+1} and D_{is+1} are as follows:

$$\begin{cases} t_{d,jt+1} = t_{djt} + h_j = t_{dj1} + th_j \\ t_{d,is+1} = t_{dis} + h_i = t_{di1} + sh_i \end{cases} \quad (3)$$

Assume that the arrival time of the trip D_{jt} is earlier than the departure time of the trip D_{is}, $P_{jt,is}$ means the number of the cross-line transfer passengers from D_{jt} to D_{is}; On the contrary, the number of the cross-line transfer passengers from D_{is} to D_{jt} is represented by $P_{is,jt}$.

Therefore, the transfer time of the cross-line transfer passengers is as follows:

$$\Delta T_{j,i} = \left[\sum_{t=1}^{y_j} \sum_{s=1}^{y_i} P_{jt,is}(t_{dis} - t_{ajt}) \right] + \beta_{i,j} \left[\sum_{t=1}^{y_j} \sum_{s=1}^{y_i} P_{is,jt+1}(t_{d,jt+1} - t_{ais}) \right] \quad (4)$$

Among, $\beta_{i,j}$ is logic variable.

$$\beta_{i,j} = \begin{cases} 1, 0 \le (t_{dis} - t_{ajt}) \le \min(h_{jt}, h_{is}); \\ 0, otherwise \end{cases} \quad (5)$$

If there are more than two lines from the identical terminal, the total transfer time of the cross-line transfer passengers is as follows:

$$\Delta T_l = \sum_{i=1}^{l} \sum_{j=1}^{l} \Delta T_{j,i} \quad (6)$$

(3) The waiting time of the non-cross-line passengers of original line:

Supposing that the arrival number of the non-cross-line waiting passengers of original line is complied with poisson distribution per unit time, probability density function is as follows:

$$p(x) = \frac{\lambda^x e^{-\lambda}}{x!} \tag{7}$$

Among, $p(x)$ is the arrival probability per unit time when there are x passengers arriving. Therefore, the number of the arrival passengers is $p_{is} = \lambda_i h_{is}$ in the departure interval h_{is}. And the waiting time of the non-cross-line passengers of original line is as follows:

$$\Delta T_i = \sum_{s=1}^{b_i} \frac{(\lambda_i h_{is})^2}{2} \tag{8}$$

Among, $h_{is} = t_{dis} - t_{d,is-1}$.

The total waiting time of all kinds of lines is as follows:

$$\Delta T_{ll} = \sum_{i=1}^{l} \sum_{j=1}^{l} \Delta T_i = \sum_{i=1}^{l} \sum_{j=1}^{l} \sum_{s=1}^{y_i} \frac{(\lambda_i h_{is})^2}{2} \tag{9}$$

(4) The model of synchronization timetable

Based on above three aspects, this paper builds the model of synchronization timetable. Because of multi objective optimization problem, this paper makes use of the linear weighted method to convert the model. As considering two lines synchronized to depart from the identical terminal, the model is as follows:

$$\min(\alpha_1 z_1 + \alpha_2 z_2 + \alpha_3 z_3) = \min\left\{ \begin{array}{l} \alpha_1 \sum_{i=1}^{l} \sum_{s=1}^{y_i} (|h_{is} - h_{is}^{'}|) \\ +\alpha_2 \left\{ \left[\sum_{t=1}^{y_j} \sum_{s=1}^{y_i} P_{jt,is} (t_{dis} - t_{ajt}) \right] + \beta_{i,j} \left[\sum_{t=1}^{y_j} \sum_{s=1}^{y_i} P_{is,jt+1} (t_{d,jt+1} - t_{ais}) \right] \right\} \\ +\alpha_3 \left[\sum_{s=1}^{y_i} \frac{(\lambda_i h_{is})^2}{2} + \sum_{t=1}^{y_j} \frac{(\lambda_j h_{jt})^2}{2} \right] \end{array} \right\} \quad (10)$$

Among, z_1, z_2, z_3 respectively represent the deviation cost compared with timetables for single line, the cross-line waiting cost and the waiting cost of the non-cross-line passengers of original line. $\alpha_1, \alpha_2, \alpha_3$ respectively represent the weights of the three optimization goals. What's more, $\alpha_1 + \alpha_2 + \alpha_3 = 1$ and $0 < \alpha_1, \alpha_2, \alpha_3 < 1$. According to the importance of the three optimization goals, we could give values of $\alpha_1, \alpha_2, \alpha_3$.

Generated from the above mathematical model, if there are more than two lines from the identical terminal, the model of synchronization timetable is as follows:

$$\min(\alpha_1 z_1 + \alpha_2 z_2 + \alpha_3 z_3) = \min\left\{ \begin{array}{l} \alpha_1 \sum_{i=1}^{l} \sum_{s=1}^{y_i} (|h_{is} - h_{is}^{'}|) \\ +\alpha_2 \left\{ \sum_{i=1}^{l} \sum_{j=1}^{l} \left\{ \left[\sum_{t=1}^{y_j} \sum_{s=1}^{y_i} P_{jt,is} (t_{dis} - t_{ajt}) \right] + \beta_{i,j} \left[\sum_{t=1}^{y_j} \sum_{s=1}^{y_i} P_{is,jt+1} (t_{d,jt+1} - t_{ais}) \right] \right\} \right\} \\ +\alpha_3 \sum_{i=1}^{l} \sum_{j=1}^{l} \sum_{s=1}^{y_i} \frac{(\lambda_i h_{is})^2}{2} \end{array} \right\} \quad (11)$$

4 The model building of seamless transfer timetable

4.1 The model building

The model with synchronization timetable has three optimization goals, which are the minimal difference value of departure intervals compared with timetables for single line, the minimal transfer waiting time and the minimal waiting time of the non-cross-line passengers of original line. However, for some cross-line transfer passengers, not only would they like to reduce transfer waiting time, but also want to reduce cross-line walking distance. Therefore, this section would build the model of seamless transfer timetable to improve passenger perception service requirements, which is suitable for some lines having lots of cross-line transfer passengers or some lines having intensive passengers flow during the peak. Seamless transfer timetable is a cross-line timetable suited for vehicles cross-line operation, which means a vehicle can continue conducting another line's trip after conducting one line's trip in order to improve passenger transfer convenience, reduce the cross-line transfer passenger walking distance and reduce the transfer waiting time.

Assume that the arrival time of the vehicle K_{jt} is earlier than the departure time of the trip K_{is}, and let the vehicle K_{jt} continue conducting the trip D_{is} after conducting the trip D_{jt}. Then for the cross-line transfer passengers from D_{jt} to D_{is}, the identical terminal is a middle station, in which the dwell time of the vehicle K_{jt} should be diminished as soon as possible. When all the passengers get on the bus, the vehicle could be departed. Therefore, a constraint of dwell time should be added up in the model of seamless transfer timetable. Because the cross-line transfer passengers do not get off the bus, the dwell time is proportional to the non-cross-line waiting passengers.

Let β be the rate of passengers getting on the bus. Then the time to getting on the bus is the departure interval, which is as follows:

$$\begin{cases} h_{is} = \beta P_{\text{other},is} + \beta P_{is} \\ \quad = \beta \sum_{j=1}^{l} \sum_{t=1}^{y_i} P_{jt,is} - \beta P_{jt,is} + \beta P_{is} \\ \quad = \beta \sum_{j=1}^{l} \sum_{t=1}^{y_i} P_{jt,is} - 0 + \beta P_{is} \\ \quad = \beta \sum_{j=1}^{l} \sum_{t=1}^{y_i} P_{jt,is} + \beta P_{is} \\ \quad = \beta \sum_{j=1}^{l} \sum_{t=1}^{y_i} P_{jt,is} + \beta \lambda_i h_{is} \end{cases} \Rightarrow h_{is} = \frac{\sum_{j=1}^{l} \sum_{t=1}^{y_i} P_{jt,is}}{\frac{1}{\beta} - \lambda_i} \tag{12}$$

According to the departure intervals of connecting trips, seamless transfer timetable can be developed.

4.2 The solution domain

Through solving out the model with seamless transfer timetable, we could get the departure intervals of all kinds of lines. Based on the premise that the departure time of first trip is known, the timetable for each line could be set out as follows:

$$\begin{bmatrix} t_{11} & t_{11}+h_{12} & \dots & t_{1,s-1}+h_{1s} & \dots & t_{1,y_i-1}+h_{1y_i} \\ \vdots & \vdots & \dots & \vdots & \dots & \vdots \\ t_{i1} & t_{i1}+h_{i2} & \dots & t_{i,s-1}+h_{is} & \dots & t_{i,y_i-1}+h_{iy_i} \\ \vdots & \vdots & \dots & \vdots & \dots & \vdots \\ t_{n1} & t_{n1}+h_{n2} & \dots & t_{n,s-1}+h_{ns} & \dots & t_{n,y_i-1}+h_{ny_i} \end{bmatrix} \quad (13)$$

5 Conclusions

This paper studied the model of synchronization timetable and the model of seamless transfer timetable for single-depot based on vehicle capacity sharing. The optimization goals of the two models are to decrease the waiting time cost of the whole passengers, reduce the transfer waiting time and cross-line walking distance of the cross-line transfer passengers.

Future research will focus on two aspects:

- To find out the suitable algorithms to solve the two models;
- To find out applicability of the two models and to calculate through cases.

Abstract: With the comprehensive construction of high-speed railway and deepening reform of the railway freight transportation, high-speed railway is labeled with safe, fast, punctual and other features, which will bring infinite possibility for the railway freight transportation, therefore the research of fast freight trains on high-speed railway is a meaningful exploration. Combining with the current situation of the development of high-speed railway freight transportation in China and abroad, six modes of high-speed railway freight transportation in theory is put forward in this paper. By analyzing the operation conditions of all aspects of the six modes, the suitable mode of China in the short term is the mode of the high-speed train with the mixed marshalling of passenger and cargo. Then this paper prove the feasibility of the mixed marshalling of passenger and cargo transportation on the high-speed railway through selecting and transforming the appropriate freight train, constructing the freight line and platform in the stations on the high-speed railway, analyzing the transport organization technology and the economic operation conditions. In the end, the further research work and the operation mode of the high-speed railway freight transportation in the future are put forward.

Keywords: High-speed railway; Freight transportation; Operation mode; Mixed marshalling of passenger and cargo; Feasibility.

1 Introduction

Since the 1990s, high-speed railway developed rapidly in China, passenger dedicated line network has been initially formed, and the construction large-scale high-speed railway construction has begun. At the same time, the reform of railway freight also begun along with the founded of the railway corporation. Railway freight transportation participated in market competition actively in order to adapt to market requirements. And the development of high-speed railway provides a good condition for the freight reform, because the characteristics of high transport speed, high punctuality rate, security and environmental protection can effectively meet the various demands of today's freight transportation. However, at the beginning of the design of high-speed railway, the possibility of the transport of cargos didn’t be taken into consideration. This paper seeks the suitable high-speed railway freight operation mode for China in the short term from six possible high-speed railway freight operation modes, and discusses its feasibility.

2 The development of high-speed railway freight

France is the earliest country that developed high-speed railway freight transportation, with the opening southeast of Paris TGV line in Paris – Lyon, two TGV passenger train were transformed to transport letters , packages and other small freight transportation at the speed of 270 km/h on the line. It is generally known that Germany and Italy are the countries that use the operation mode of high-speed freight train. In 2000, the German railway company transformed a kind of special container train to the high-speed freight train which shipped intercity packages. And Italy transport fresh, perishable cargos on the high-speed railway. The speed of high-speed freight train is controlled within 160 km/h in Germany and Italy (Wu Yunyun, 2010).

With the establishment of China Railway Corporation and improvement of the freight organization reform, high-speed express products are planned to develop. At present there are two main types of high-speed railway express train in China, one is the first train which is used to check the situation of line in the morning every day, without picking up passengers; another is the passenger train which loads part expresses and parcels. However, the possibility of the transport of cargos wasn't considered in the original design of high-speed railway, therefore, freight lines and the corresponding platforms weren't built in the plans. Furthermore, the limited stop time of high-speed trains in the along high-speed railway station and the lack of special high-speed railway freight train in China, will lead to the limitation on the size and number of freight. So the research on finding the right high-speed railway freight transportation operation mode is urgent and important.

3 The selection of high-speed railway freight operation mode

Combining with present situation in China and abroad, freight traffic transport capacity and technical conditions, there are six modes of high-speed railway freight operation mode in theory: transport freight on the high-speed passenger train, the high-speed railway confirm train, the high-speed freight train, the high-speed train with the mixed marshalling of passenger and cargo, the coupling train of passenger and cargo and high-speed freight railway (Wu Yunyun, 2010).

The comparison results of six modes is showed in Table 1.Among them, the mode of transport freight on the high-speed passenger train and the high-speed railway confirm train are used in China, but high-speed freight transportation can't be developed on the basis of the two modes because of the small transport capacity. Although the mode of high-speed freight railway has the largest transportation capacity without the crossover operation of passenger and cargo, it needs a set of high-speed freight railway equipment which includes lines, vehicles and stations, requiring a huge construction cost and a long construction cycle. The mode of the coupling train of passenger and cargo can solve the shortage of high-speed railway freight station equipment and freight line. But at the same time the link of shunting operation is increased, and the speed of the passenger train operation will be reduced. The operation of loading and unloading is handled in the station on existing lines, hence the signal equipments on the existing line should be connected with the ones on high-speed railway, so the implementation of the mode is also difficult to achieve in the short term.

Table 1. The contrast table of operation modes

Operation mode	Transport capacity	The impact on the passenger capacity	Vehicle equipment requirements	The station requirement	The technical requirements	The instance
Transport freight on the high-speed passenger train	Small	No	Rack with slightly modified	No special requirements	No special requirements	CRE
The high-speed railway confirm train	The relatively small	No	No special requirements	No special requirements	No special requirements	Wuhan-Guangzhou high-speed railway
The high-speed freight train	Big	Yes	Design special freight trains	Special freight base	The modified signal equipment on existing lines; Increased freight organization	TGV
The high-speed train with the mixed marshalling of passenger and cargo	The relatively big	Yes	Existing freight trains with modified	Special station platform; The corresponding handling equipment	Increased freight organization	Talgo XXl type tilting train in the United States
The coupling train of passenger and cargo	Big	Yes	Design special freight trains	No special requirements	The modified signal equipment on existing lines; Increase the shunting operation	No
The high-speed freight railway	Big	No	Design special freight trains	Special high-speed freight railway station	Special high-speed freight railway	No

The mode of the high-speed freight train is used in France, Germany and Italy. But in China, firstly, vehicle equipment of dedicated freight train is the problem which is still unsolved. In addition, because of the shortage of the freight line and freight platform, special freight base is required to be built in China. Moreover, the connected signal equipment is needed on the existing lines and high-speed railway. Therefore, although the operation of high-speed freight train in short term is unlikely in China, the high-speed freight train is the trend of high-speed railway freight transportation in the long run.

The transport capacity of the mode of the high-speed train with the mixed marshalling of passenger and cargo is relatively big, the existing freight trains can be reformed in order to reach the standard of high-speed railway, and the problem of signal equipment can be solved through increasing the freight line and platform in high-speed railway station. It's a suitable mode in short term in China, we can open the market of high-speed railway freight transportation through this mode and prepare for the later development of the high-speed freight train.

4 The feasibility of the high-speed train with the mixed marshalling of passenger and cargo

4.1 The feasibility of trains

At present, there are two kinds of fast freight train which are operated in China. One is the dedicated mail train whose speed reaches 160km/h and the other is the dedicated package train whose speed reaches 120km/h for the reason of the different weights of the cargos. The representative of dedicated mail train is the 25T package train developed by China CNR Corporation, using the passenger train bogie. The dedicated package train is mainly remolded from the P65 and PB freight train, using the freight train bogie. The mode of the high-speed train with the mixed marshalling of passenger and cargo is the pattern which mix passenger motor train unit with freight train into an integrated train, therefore the speed, transportation organization and structure of the freight train should be close to the passenger motor train unit.

Table 2. The contrast table of trains

Train model	Axle load（t）	Speed（km/h）	Bogie
CRH5	≤17	200	Passenger
25T package train	≤16.5	160	Passenger
P65 freight train	18	120	Freight

The table above is the comparison between CRH5, 25T package train and P65 freight train on the axle load, speed and bogie type. It shows that 25T package train, which uses the passenger train bogie and has the closely speed and axle load, is more close to the passenger motor train unit. Therefore, 25T package train is selected to be remolded as follow. Firstly, the boundary dimension of the freight train should be consistent with passenger motor train unit due to the mixed grouping of them. In addition, the handling operation of the passenger and cargo is proceeded in the high-speed railway station, thus the operation should be safe, efficient and convenient. The delivered cargos mainly consist of expresses and postal parcels hence the inner structure should be designed in the form of cargos warehouse in order to use interior space adequately, and the cargos should satisfy the standardization of the size and weight at the same time to achieve the requirements of rapid, balanced and reasonable loading. Moreover, the door should be designed to be wide enough for easy access and have the function of automatic switch as passenger motor train unit to accelerate the degree of automation.

4.2The feasibility of station

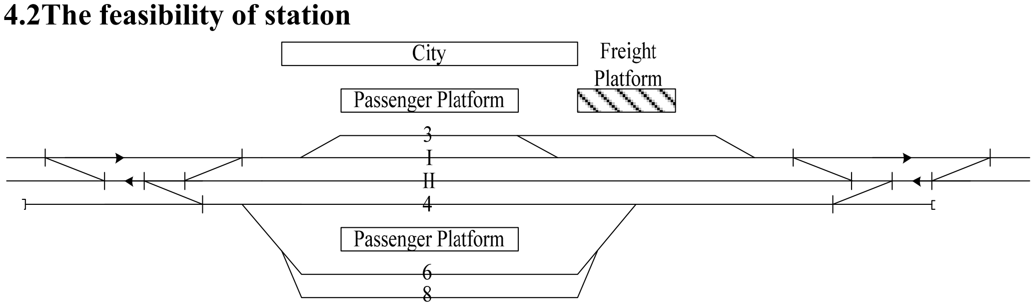

Figure 1. Modified figure of intermediate station

The station stoppage time in the intermediate station of high-speed railway is short, and the corresponding city is small, thus the cargo quantity handled in the station is relatively confined. Therefore, the situation can be solved by setting through-type freight yard in the intermediate station of high-speed railway, and lengthening the existing arrival-departure lines and constructing another freight line and corresponding freight platform. Considering the convenience for picking up and delivering the cargos, the through-type freight yard should be set by the side near the city.

In the operation process of high-speed railway freight train, the junction center station is responsible for loading and unloading of cargos, maintenance and marshaling of the vehicle. Therefore, the requirement of massive handled cargos cannot be satisfied by the through-type freight yard, thus end-type freight yard should be set on the side of the maintenance base line and maintenance of the mixed train will be convenient, and handling operation time of the cargos can be satisfied as well.

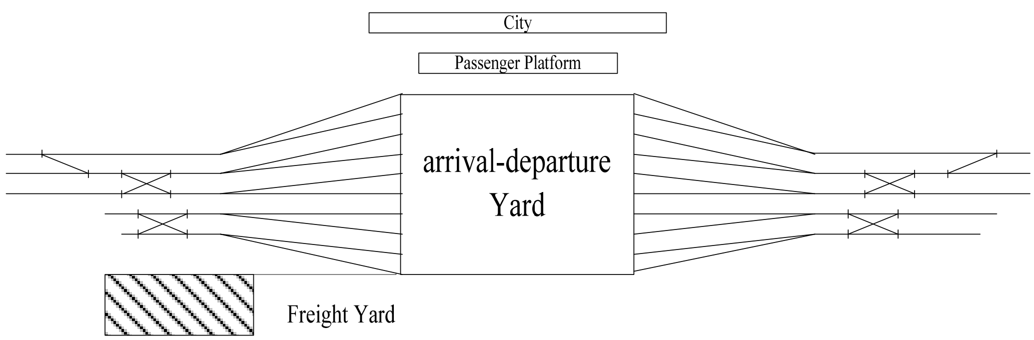

Figure 2. Modified figure of junction center station

4.3 The feasibility of transportation organization

For the mode of the high-speed train with the mixed marshalling of passenger and cargo, loading and unloading operations can be done in high-speed railway stations which are remolded in the short term. Therefore, trains can use the existing signal equipments of high-speed railway instead of switching to the existing lines. High-speed railway station should be equipped with corresponding handling equipment. According to the standard specification and weight, the cargos should be handled with corresponding handling equipment as the plans in the station stoppage time.

Furthermore, operation situations of passenger trains which have been opened at present are shown in table 3 (Gu Xuejing, 2014). From the table, operation situation of the Beijing-Shanghai passenger dedicated line is the best, and the daily operation numbers are approximate to the largest traffic capacity. The remains of traffic capacity and the low attendance opportunely provide the technical conditions for the operation of the high-speed railway freight transportation. It should be pointed out that the operation of the high-speed railway freight transportation will increase the stop time and influence the passenger service, the loading and unloading of passengers and cargos will be operated on the same platform in intermediate station, the above problems will be the focus in further research.

Table 3 Operation table of high-speed railway

High-speed railway line	Daily operation log	Attendance
The Beijing-Tianjin inter-city	90	70%
Shijiazhuang-Taiyuan	17	90%
Wenzhou-Fuzhou	31.5	-
Ningbo-Wenzhou	35	160%
Wuhan-Guangzhou	70	105%
Zhengzhou-Xi'an	15	-
Fuzhou-Xiamen	37	-
Chengdu-Dujiangyan	20	-
Shanghai-Nanjing	80	121.7%
The Nanchang-Jiujiang inter-city	9	85%
Shanghai-Hangzhou	93	80%
Nanjing-Hangzhou	86	70%
Beijing-Shanghai	112.5	107%
Beijing-Guangzhou	3	-

4.4 The feasibility of economy

At present, high-speed railway network with the longest operation mileage and fastest speed has been built in China. According to the long-term schemes of railway network, until 2020, operation mileage at the speed of 200km/h will reach 3000 kilometers. In recent years, the prosperity of electronic commerce and online shopping market prompted the rapid development of express industry in China.

The advantages of large capacity, high speed, high on-schedule rate and less influence of the climate make the high-speed railway freight occupy the advantageous position in competition of the express industries. Such a massive network of high-speed railway and the express industry with great increments provide excellent economic conditions for the rapid development of the high-speed railway freight and the cooperation between express companies and Railways Corporation.

5 Conclusions

According to analysis on the merits and demerits of six kinds of high-speed railway freight operation modes, the mode of the high-speed train with the mixed marshalling of passenger and cargo which is suitable for China's high-speed railway freight operation mode in the short term is summed up in this paper. The mode is feasible by proof in vehicle equipment, transformation of high-speed railway station, organizational technology and economy of transportation in the short term. Especially, the viable solutions are put forward to the selection and renovation of vehicle equipment and maintenance of the station freight line.

The present research works are in the primary phase, in order to realize the freight transport of high-speed railway further, specific operation lines and schemes of the mode of the high-speed train with the mixed marshalling of passenger and cargo should be researched in the further work. In addition, through the future research and renovation of the infrastructure, China's freight operation mode of high-speed railway should be the mode of high-speed freight train.

Abstract: As the civil seaplane is an emerging industry in China, its navigation safety needs to be studied. The research on the three-dimensional model of seaplane domain provides the site supervision with technical support during taking-off and landing, and also helps to improve the safety and efficiency of navigation in the operation area. Fujii and Goodwin ship domain model are analyzed by comparison in between. Combined with the navigational characteristics and the safety requirements of seaplane during taking-off and landing, the basic theory of seaplane domain is proposed. On the basis of ship following model, the safety distance between seaplane and ship in encounter is calculated, and a two-dimensional seaplane domain model is established. Additionally, the third vertical dimension model of seaplane domain is determined by its requirements on headroom clearance to prevent collision with the superstructure of ships around. Finally, the developed three-dimensional model is applied in the case in Sanya, China.

Keywords: Seaplane; Taking-off and landing; Ship domain; Three-dimensional model.

1 Introduction

The civil seaplane is one of the important members of general aviation. Currently, the civil seaplane industry is in the initial stage in China. According to the risk factors of seaplane-vessel collision by *Weng et al. (2013)*, it stated the first civil seaplane project had settled in Sanya City, Hainan Province in 2012.

Seaplane, as a new means of marine transport in China, its navigation safety is urgent to be studied. Despite the impact of environmental factors, the navigation safety of seaplane is also strongly affected by the disturbance from small vessels around. Guaranteeing a basic seaplane domain provides the seaplanes with a safe operation during taking-off and landing, and gives the vessels around a reference of collision avoidance with the moving seaplane.

2 Seaplane characteristics

2.1 Property of seaplane as a ship

According to COLREGs by *IMO (2012)*, the third article 'General Definitions' defines 'seaplane' including any aircraft designed to be able to maneuver on the water. When the seaplane is contacting with the surface of the water, it is seen as a vessel and COLREGs apply. While it leaves the water surface, seaplane is taken as aircraft and suitable for *Aviation Rules*. According to *People's Republic of China Maritime Traffic Safety Law*, seaplanes are regarded as ships.

2.2 Features of seaplane comparing to general ships

(1) Faster speed

Compared to general ships, the speed of seaplane is significantly higher during taking-off and landing. For instance, the highest flight speed of 'SH-5' is 556km/h, and 'US2' 560km/h. Similar to the civil aircrafts on land, the first phase for taking-off is taxiing to the operation area. Upon arrival, the seaplane accelerates and takes off after the speed reaching 200 km/h or so. Generally speaking, the speed during landing is slightly lower than for taking-off.

(2) Larger taking-off and landing waters

Before taking off and after landing, the seaplanes need a long time to taxi between the berth and the operation area. Since the speed for taking-off and before landing is rather high, the seaplanes need a larger area to accelerate or decelerate. For instance, the water length for taking-off of 'SH-5' is 482m, and the landing area is 653m long. As for 'US2' from Japan, the taking-off distance is 280m, and the landing distance is 330m.

(3) More flexible maneuverability

Seaplanes have flexible maneuverability. Despite operating on the open water area, they also can take off or land on the rivers, lakes and reservoirs with the depth of 2.5m, length is 1500m and width is 200m. Some seaplanes can also use the land for taking-off and landing. *Lu et al. (2011)* have simulated the process of aircraft landing. Due to the unique structure of seaplanes, they are designed with good turning ability, anti-wave performance and flexible maneuverability.

2.3 Movements for taking-off and landing of seaplane

As shown in (Figure1) the seaplanes take off and land in a defined operation area, e.g. a circle with diameter 1000m in port of Sanya in China. After leaving the berth, seaplanes taxi to the operation area and accelerate to take off.

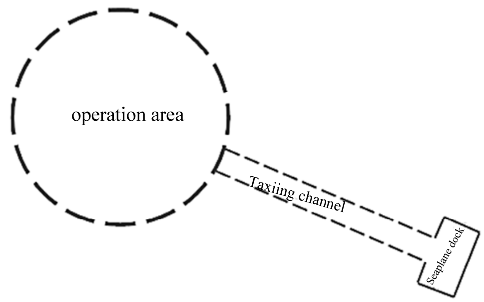

Figure 1. The operation waters of seaplane

The process of seaplane leaving the berth to taking off, the changes in speed and movement of seaplane can be divided into three phases.

(1) Taxiing

After leaving the berth, seaplanes taxi to the operation area at an average speed of 5 to 6 knots, which is similar to the sailing ships in port. In this phase, the seaplane can be regarded as a general ship and COLREGs apply.

(2) Accelerating

Upon arrival at the operation area, the pilot determines the taking-off direction according to the current meteorological and hydrological information. Normally, a direction against the wind is preferred. After receiving the order from the Aviation Control Center, the seaplane begins to accelerate and takes off when the required speed is reached. It is easy to collide with vessels around in this phase.

(3) Aerial adjusting

After taking off, the seaplane will adjust its flight direction. At this moment, the seaplane is seen as an aircraft totally.

3 Safety distance calculation based on the following theory

3.1 Safety distance between sailing seaplane and ships around

For any vehicle in movement, it will keep a certain distance with the others around to guarantee its safety. To a seaplane, it also needs to keep such a safety distance with the ships around during taking-off and landing. The distance is required to guarantee enough time for a seaplane to stop or pass with each other at a safe distance when encountering with a ship. In this way, there is a safety distance around the seaplane, which is called the seaplane domain. It is a quantitative scope of the seaplane rather than a particle, which describes the minimum distance for the safe navigation of seaplane.

3.2 Following model of seaplanes

The following theory was firstly proposed in the road traffic research. *Chen (2011)* has stated the main point of the following theory is to simulate the macroscopic traffic flow in a single lane. In such a circumstance, the cars ahead cannot be overtaken, and the behavior of the cars behind is restricted by the former one.

The ship following theory is developed on the basis of the following theory of vehicles, which simulates the vessels sailing in a one-direction channel. Since the seaplanes move in a determined direction during taking-off or landing, and the ships will be in the front or at the rear, the following theory can apply. By the analysis on the original ship following model, if a seaplane encounters with a vessel, the biggest safety distance can be obtained when the speed of vessel is lowest, and it is namely for the stationary state of the vessel. In order to ensure the largest navigation safety of ships, the revised following model of encounter between a seaplane and a vessel is shown in (Figure.2).

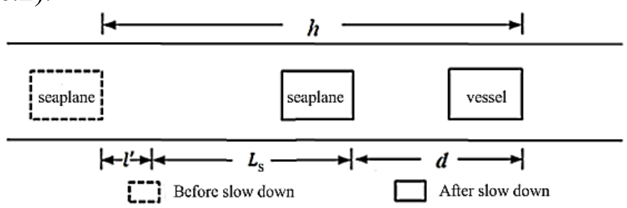

Figure 2.The following model of seaplane and veseel

According to Fig. 2, the minimum safety distance between seaplane and ship is calculated as Equation (1).

$$h = l' + L_S + d = d + Vt_r + \frac{V^2}{2a} \tag{1}$$

In which

h is the minimum safety distance between ship and seaplane; d is the safety distance between the ship's bow and the seaplane's head, l' is the sailing distance within the response time of the pilot; t_r is the response time of seaplane pilot; L_S is the stopping distance of seaplane; V is the speed of the seaplane, a is the maximum braking acceleration of the seaplane.

4 2D seaplane domain development

4.1 Applicability analysis of ship domain theory

Ship domain refers to the scope existing around the sailing vessel, which describes the distance for safe navigation. The studies on the statistical analysis of the relative positions between the ships are to obtain the shape and size of the ship domain. The most representative ship domain models are the Fujii model and Goodwin model.

According to comparative study on ship domain models by *Liu et al. (2009)*, Fujii defined the ship domain as the field around the navigating ship, in which the following ships should avoid entering into. In this way, the ship domain model is an oval.

Inspired by Fujii, Goodwin developed an asymmetrical ship domain model by the means of radar simulator, considering the impacts of COLREGs on ships' behavior for collision avoidance. According to the display range of ship's lights, the model consists of three sectors, as shown in Figure 3.

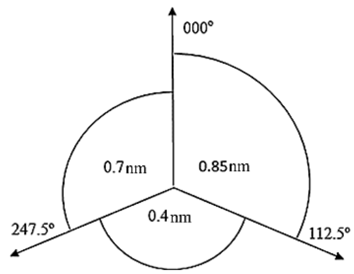

Figure 3. Ship domain model of Goodwin

Fujii determined the size and boundary of ship domain by considering the traffic capacity and the risk of collision in a channel, while the model of Goodwin considers the risk level of marine traffic, the latter is more accurate in open waters.

The core of the above two models are similar, but each of them also has its own characteristics. The research on the encountering situation in the operation area of seaplane is similar to the basic conditions of Goodwin model. Therefore, the seaplane domain model is developed according to the theory of Goodwin.

4.2 Development of 2D model for seaplane domain in operation area

Referring to the analysis of the seaplane characteristics by *Zhong et al. (1989)*, due to the flexible maneuverability of seaplanes in the operation area, the capability of collision avoidance for turning port or starboard are almost the same. Therefore, the left and right part of the seaplane domain can be seen as symmetrical.

When the seaplane is taking off and landing, the speed of the seaplane is much larger than the following ships. There is almost no following ship can overtake a seaplane. Hence, the rear part of the seaplane domain can refer to the theoretical values of the Fujii model.

Combined with the movement characteristics of the seaplane, the preliminary seaplane domain model is developed based on the theory of Goodwin as Figure 4.

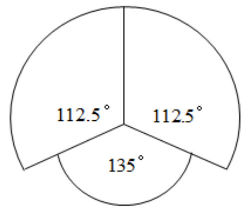

Figure 4. Preliminary seaplane domain model

The size of the two-dimensional (2D) seaplane domain is determined by the speed of seaplane. According to the analysis of the safety distance, within the range of 225 ° in front of the seaplane, the safety distance is *h*, while within the range of 135° in the rear, the safety distance is valued by half of the long axis of Fujii model, which is three times the length of seaplane.

The seaplane domain is a revision of the Goodwin model. Due to three different encounter situations between ships, the safety distance varies in different directions. In order to avoid a sharp change in the safety distance, the preliminary model is further modified. The connecting points of the lines locate at 22.5 degrees both at the left and right sides, and the radian of each arc is 45 degrees. Then a coordinate system is built up with the seaplane at the center point, as shown in Figure 5.

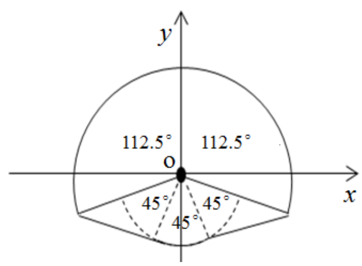

Figure 5.Coordinate system of 2D seaplane domain

In the coordinate system, the scope of the seaplane's ship domain is respectively introduced in a sectional function.

In the range of 0° to 202.5° and 337.5° to 0°, the function formula is as Equation (2).

$$x^2 + y^2 = h^2 \tag{2}$$

In the range of 202.5° to 247.5°, the function formula is as Equation (3).

$$y = -\frac{(\sqrt{2}-1)h - 3(\sqrt{2}+1)L}{(\sqrt{2}+1)h - 3(\sqrt{2}-1)L}x + \frac{\sqrt{2}h^2 - 3(\sqrt{2}+1)hL}{(\sqrt{2}+1)h - 3(\sqrt{2}-1)L} - \frac{2-\sqrt{2}}{4}h \tag{3}$$

In the range of 247.5° to 292.5°, the function formula is as Equation (4).

$$x^2 + y^2 = 9L^2 \quad (4)$$

In the range of 202.5° to 247.5°, which is symmetrical with the second situation, the function formula is as Equation (5).

$$y = \frac{(\sqrt{2}-1)h - 3(\sqrt{2}+1)L}{(\sqrt{2}+1)h - 3(\sqrt{2}-1)L}x + \frac{\sqrt{2}h^2 - 3(\sqrt{2}+1)hL}{(\sqrt{2}+1)h - 3(\sqrt{2}-1)L} - \frac{2-\sqrt{2}}{4}h \quad (5)$$

Based on the above calculation, the size and shape of the seaplane domain is determined as in Figure 6. Since the shape of the model is similar to 'scallops', the seaplane domain model is named as 'scallops model' in this paper.

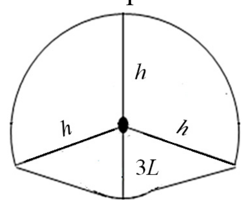

Figure 6. 2D scallops seaplane domain model

5 3D seaplane domain development

The development of s three-dimensional (3D) seaplane domain model is to avoid collision with the superstructures of ships during the climbing phase of the seaplane. The 3D seaplane domain model is developed from the 2D seaplane domain model by considering its requirement of headroom clearance after the seaplane leaving the water surface.

According to characteristics of seaplane during taking-off, set the climbing angle of seaplane as α (usually about 10°), the height above the water of the ship as *H*, and the distance which will cause collision between seaplane and ship as *d* , which is the minimum safety distance analyzed above. The parameters can be shown in Figure 7.

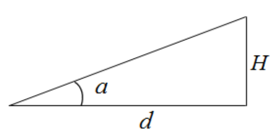

Figure 7. Trigonometry relationship between seaplane ane ship in headroom

The relation between the horizontal and the vertical distance is as Equation (6).

$$d = \frac{H}{\tan a} \quad (6)$$

The 3D coordinate system for seaplane is established as shown in Figure 8.

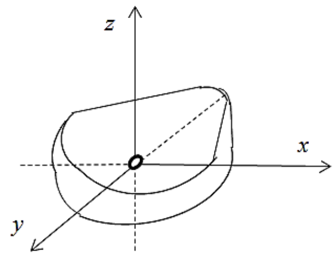

Figure 8.3D coordinate system of seaplane domain

In the 3D coordinate system, headroom requirement z varies with change in x and y as in Equation (7).

$$z=\begin{cases}\frac{H}{h}\sqrt{x^2+y^2}, & z>G\\ G, & z\le G\end{cases} \qquad (7)$$

In which, G is the height of seaplane.

According to the relations between variables in the coordinate system, a 3D seaplane domain model can be developed. The maximum length of the model is the length of 'scallops', which is the safety distance h plus three times of L the length of seaplane. The maximum width of is $2h$, which is double of the safety distance. The height of the model is the headroom for safety navigation of seaplanes. The 3D seaplane domain model is finally developed as shown in Figure9. And the orthographic views of the model are shown in Figure10.

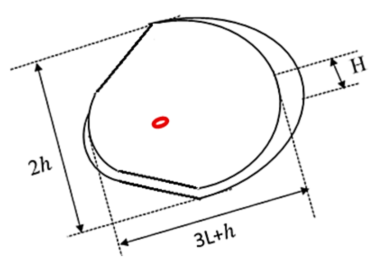

Figure 9. 3D seaplane domain model

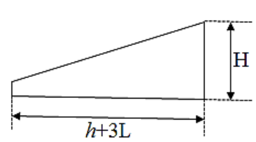
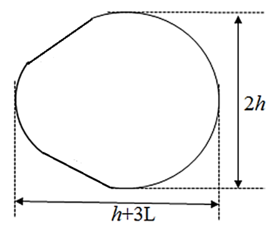
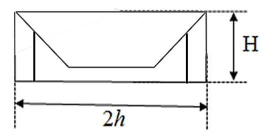


(a) Front view of the model



(b) Top view of the model



(c) Left view of the model

Figure 10. Orthographic views of the model

The shape and size of the 3D seaplane domain is related to the parameters of both the seaplane and the ship. In this way, the length, width, and height of the model are different to different participants. According to the acquired statistics of ships and seaplanes, the size of the model can be determined. In the different phases of taking-off and landing, the 3D seaplane domain model also varies dynamically.

6 Case study

A case study is performed choosing a particular seaplane model in port of Sanya, China by *Pan et al. (2014)*. The seaplane is named VIKING DHC-6/400 (Twin Otter) with its performance parameters listed in Table 1：

Table 1.Performance parameters of VIKING DHC-6/400

Taking-off distance	Landing distance	Length	Height	Taking-off speed
374m	337m	15.77m	2.95m	180km/h

According to the study on the response time of pilots by *Xu et al. (2007)*, 0.6s is the statistical results. And the value of the seaplane pilot's response time t_r is set as 0.6s. The safety distance between the bow of the ship and the seaplane d can be obtained when the height above the water of the ship H is confirmed. In this paper H is set as 10m. The calculation results are shown in the follow Table 2:

Table 2.Parameters calculation of 3D seaplane domain model

Parameter	Value	Paramete r	Value
V	50m/s	a	43.3m/s^2
t_r	0.6s	Ls	374m

H	10m	**α**	10°
d	57m	***L***	15.77m
Parameter	***h***	**Value**	461m

On the basis of the above calculation results, when the seaplane encounters with a ship whose superstructure is 10m, the minimum safety distance is 461m. Within this distance the seaplane can avoid the collision with the ship and take off safely. Comparing the size of the 3D ship domain model designed for seaplane to the diameter of operation area 1000m (vessels are forbidden to sail in or through) set in Sanya currently, the size of the model is considerably smaller. If the exclusive area for seaplane is set according to the 3D seaplane domain, the navigation efficiency in this area is expected to increase.

Acknowledgement

The navigation safety of seaplane is affected by many factors, by the study on the process of seaplane during taking-off and landing, the three-dimensional seaplane domain model is established. The developed 3D seaplane domain model can be used as reference to set the exclusive water area for taking-off and landing of seaplane. After implementing efficient methods and means for site supervision, the safety of both seaplanes and ships can be guaranteed at a least decrease of the navigation efficiency in the area.

Benefits of the Tram System in Zhuhai, Guangdong Province, China

Lin Hong; Ying Jiang; Yaqian Li; Zekai Xu; Fan Li;
Zijie Liang; and Weixiong Huang

School of Management, Beijing Normal University, Zhuhai. E-mail:
honglin@bnuz.edu.cn

Abstract: The research focused on the new built tram system, Tram Line 1, in Zhuhai, which the tram is one kind of urban track traffic systems. Three kinds of benefits are analyzed as following. Firstly, the economic benefits have been studied including the passenger time-saving benefit and the land value-added benefit. Secondly, the social benefits, which means according to the results of the reducing traffic accidents benefit prediction model and the reducing journey fatigue model, have been analyzed. Thirdly, the environmental benefits have been analyzed, which means by using the prediction of the energy saving benefits, the reducing air pollution benefits forecasting model and the CRTN model to predict the noise effects on the surrounding environment. The paper tried to let the public fully understand the indirect and external social interests which the tram system would bring up. It also gave some suggestions for the sustainable development of the tram system.
Keywords: Economic benefits; Social benefits; Environmental benefits.

1 Introduction

The tram network system is one kind of urban track systems in China. After reviewed some literatures, this paper found that many domestic researches only focused on the financial evaluation and the national economic evaluation of a project feasible. But in the actual operation, the data of passenger flow, investment and others often appeared deviation. The model and method of economic evaluation of rail tram in the period after the whole, not a single line of cases. From the view of economic attribute, it belongs to the public product which is based on the needs of the social economy and development. For a country, the macro social benefits generated from the customers on the society or the users of the traffic are much more than the micro economic benefits generated from the constructers or the operators.

On the other hand, since 1980s', the overseas researches and academic circles paid more attention to the economic growth, the relationship between the economic development and the level of infrastructure. Alfonso (2007) proposed the infrastructure as an impact of investment on the regional economic growth and used the vector auto regression (VAR) to analyze the infrastructure system.

The project of modern tram Line 1 (ZIUPD, 2013) is the first line of tram system in Zhuhai, which the total length is about 19km. The first phase of the Line 1 is about 8.9 km including 14 stop stations and a vehicle base. The line start point is Haitian Park Station and the line end point is Shangchong Station. Line 1 is all ground line which is along the east-west route through the main areas of the city, such as Xiangzhou, New Xiangzhou and Shangchong. The carriage is 100% low-floor and steel wheels. The steel rail is 32 meters long and 2.65 meters wide. The maximum operating speed is 70 km/h. The maximum capacity of a carriage is 300 persons according to the standing standard of 6 people per one square. Along the whole line, the track structures are constructed with the whole track bed, buried rail structure and steel rail groove. The green lawn is mainly paved with some local areas using brick pavement. There are 9 island stations and 5 side stations, which are all on the ground with the open platform. The average station space is 0.7 km. The stations are designed simply and concisely with the automatic ticket vending machines and passenger information systems. The passengers can enter the station by underground walkway or intersection crosswalk line to solve the pedestrian crossing and access platform problems. The power supply adopts Ansaldo's ground power supply system which is a patent technology from Italy. Except to in the vehicle base, all the line does not have the overhead catenary line (commonly known as "braid"), which means the landscape effect is obvious. The operating control systems, including the switch control system, automatic carriage position system, signal priority system, monitoring system and wireless communication system, can control and manage the carriages to run as far as possible in accordance with the schedule to ensure the punctuality requirements. The signal for tram along the line is prior based on the green wave and active request. The total investment is 2.62 billion Yuan. For the modern tram Line 1, the average cost of the first phase of the project is about 160 million Yuan/ km.

2 Economic Benefits

The economic benefits (Jiang Yuzhen, 2002) include the passenger time-saving benefit and the land value-added benefit. The passenger time-saving benefit can be measure based on the off-job travel time-saving value. The land value-added benefit had been studied based on the real estate value-added model. In addition, the establishment of the effective and scientific return model of tram system benefits has an important theoretic and applied value.

2.1 Passenger Time-saving Benefit

Passenger time-saving benefit is a benefit of economic value that is created by passengers who save their traffic time base on the choice of tram traffic but not the traditional public buses. From theoretic aspect, the time-saving benefits of the tram passengers include the job travel time-saving value, which the tram saved the working time and improved the work efficiency, and the off-job travel time-saving value according to the welfare benefits of leisure time. The passenger time-saving benefit can be calculated according to a formula in what follows text by (1).

$$B1 = Q \times T \times G \times 50\% \tag{1}$$

B1 is the passenger time-saving benefit.

Q is the passenger traffic data per year.

T is the average saving time per person.

G is the gross domestic product per hour and per person.

50% means that the value created by people during off-job time is half of the value created during the job time.

2.2 Land Value-added Benefit

Hedonic price model (HPM) originated from the new customer theory (NCT) (Lancaster, 1966) and the market supply and demand equilibrium model (Rosen, 1974) indicates that the customers' demand for the heterogenetic goods is not based on the goods itself but based on the features or attributes of the goods. The features or attributes of heterogenetic goods are combined all together to become a feature package that can affect the benefit. The goods are sold as an aggregate of the intrinsic characteristics or features which can affect the choice of customer. In this paper, the feature variables are divided into three kinds that are the location, the neighborhood and the structure.

(1) Location Feature Variable

In the research of Adair and McMillan, they stated that the traffic reachability and the distance to CBD were the important features for the real estate price. This paper uses the distance to a tram station and the distance to the city backbone road to scale the traffic reachability. The previous literature review found that the researchers had different views on the radius of influence of a tram station, including 1 to 3 miles, 0.5 miles, 1 km, etc. Considering the habit of Chinese, the researchers chose 1 km to be the radius of influence

(2) Neighborhood Feature Variable

Clark and Herrin found that a school is the important neighborhood variable for real estate price, especially for the residential real estate price. The famous school can affect the education problem of children. The distance to a famous school is chosen to be the scale, which means that the distance is more close to a famous school the prices of real estate is more high. In addition, the public park is very important for the real estate around the park that is a place for residents to make exercises and recreations. So the famous school and the public park are the two neighborhood feature variables.

(3) Structure Feature Variable

Project scale, project type and project pre-sale year are selected as the structure feature variables. A large scale real estate project usually means a better living environment, better facilities and more standardized property management than other projects. Project types include residential, commercial and office real estate. In this paper, the focus variable of project type is residential real estate. The project pre-sale year reflects the time effect of tram system affected on a real estate project.

3 Social Benefits

The social benefits include the reducing traffic accidents benefit and the reducing journey fatigue benefit.

3.1 Reducing Traffic Accidents Benefit

The rapid growth of motor vehicles in the city resulted in the urban traffic congestion and the chaotic traffic. The number of accidents increased year by year, resulting in a huge loss. But the tram system is an isolated system because the isolated route right. So, basically, the other motorized or non-motorized vehicles and the weather can not disturb the tram system. The probability of traffic accidents on the tram is very low. The reduction of traffic accidents brings the relative social benefit.

$$B2 = M \times N \tag{2}$$

B2 is the reducing traffic accident benefit of a year.

M is the average annual cost of a bus.

N is the number of buses that need to be increased when no tram system.

3.2 Reducing Journey Fatigue Benefit

A long time journey or jam can lead to poor comfort, which the passengers may be tired and feel fatigued. But the modern tram is fast and comfortable, which reduces the journey fatigue. People can quickly enter the working state. So the production efficiency can be enhanced. According to the research result of Shi-xun Chen, the reducing journey fatigue benefit can be calculated by the following equation in the text by (3).

$$B3 = U \times H \times W \times G \times \frac{Q}{P} \tag{3}$$

B3 is the reducing journey fatigue benefit.

U is the work flow coefficient.

H is the work time of a day.

W is the increased margin of the labor productivity by tram but not by bus.

G is the gross domestic product per hour and per person.

Q is the passenger traffic data per year.

P is the round-trip work passenger coefficient.

4 Environmental Benefits

The environmental benefits (Chen, 2001) include the energy saving benefits, the reducing air pollution benefits and the reducing noise benefit.

4.1 Energy Saving Benefits

The traditional bus uses fuel but the tram' driving force is the electricity. The average energy consumption of a traditional bus is 670 kJ per person and per kilometer, which the energy consumption per unit of a traditional bus is 2.8 times than that of a tram vehicle. So the saving energy of a tram sending one person for a kilometer is about 430.7 kJ (Wang, 2011).

4.2 Reducing Air Pollution Benefits

The pollution caused by fuel combustion is the main impact of transport tools on the environment. With the increasing number of motor vehicles, the concentration of pollutants in the air is increasingly high. Compared with the motor vehicles, the modern tram vehicles can greatly reduce the release of harmful gases and respirable particulate matter. The modern tram vehicle has no direct release of gases, but its pollution comes from the energy consumption process of electricity, which is an indirect emission of the pollutions.

4.3 Reducing Noise Benefit

The noise caused by road traffic accounts for about 70% to 80% of the total urban noise. The noise does not only disturb the people's normal life, but also reduce people's work efficiency. The modern tram vehicle using steel wheel, steel rail and streamlined design can minimize the noise pollution. Based on the Calculation of Road Traffic Noise (CRTN, 1988) prediction model, the reducing noise benefit can be calculated by the following equation in text by (4).

$$B4 = 0.1 \times \sum_{i=1}^{n} H_i \times C_i \tag{4}$$

B4 is the reducing noise benefit.

H_i is the i-th residential district needed to reduce the noise along the line.

C_i is the installation cost of soundproofing for i-th residential district.

5 Conclusions

The public traffic problem is a very important factor that constricts the rapid development of the city. In the future, the backbone traffic system in the big cities will be modern tram system because it is safety based on the well-organized operation and is comfortable for the passengers. It can combine the economic benefits, the social benefits and the environmental benefits organically together to generate some enormous and external long-term benefits.

Abstract: Optimization of transport capacity combinatorial procurement facing the actual carrier is an important decision that affects the operation efficiency and competitiveness of the non-vessel operating common carrier (NOVCC) type of sea-rail intermodal transport operator. Based on the hub-and-spoke network structure of container sea-rail intermodal transport, this paper conducts comprehensive consideration of sea-rail intermodal transport demand in various OD markets, capacity limitations of shipping liners and regular railway trains, connections between space and time and so on from the perspective of multimodal transport operators (MTO). In order to minimize the total cost, the slots volume of procurement based on combinatorial selection in shipping liner and regular railway train is as the decision, an optimization model of transport capacity combinatorial procurement in container sea-rail intermodal transport is established, and an algorithm is designed for solving. The experimental results show that the model and algorithm are feasible, and achieve good application effect.
Keywords: Container transport; Sea-rail intermodal transport; Transport capacity procurement; Optimization model.

1 Introduction

The container sea-rail intermodal transport is the multimodal transport mode of container cargoes which is organized by multimodal transport operator (MTO) and completed jointly with the actual carriers within the shipping and railway transport sections. The MTO shall not only provide container transport services for the shipper as the carrier, but also purchase the transport capacity resources of the above transport services from the actual shipping and railway carriers as the shipper. Therefore, it has become a difficulty for the MTO to take a systematic and scientific method to optimize the procurement in transport capacity combination under different modes of transport and transport routes, in order to effectively carry out the container sea-rail intermodal transport.

At present, the problem of transportation services procurement in container multimodal transport has attracted the attention from many scholars. Chang, et al. (2010) established the optimization model of multimodal transport for the international container in Korea highway, railway and near-sea shipping line with the objective of achieving minimum total transportation cost and the external cost caused by air pollution. Fan, et al. (2010) optimized the container sea-rail intermodal transport network of the United States imports by adopting the theory of linear programming and with the minimum total cost of rail-sea intermodal transport as the objective function. Wang and Wang (2012) studied the selection of container type and combinatorial optimization of modes of transportation in container multimodal transport system; established the mathematical model to minimize the transportation cost under condition of fuzzy demand, and optimized the algorithm solution by using the improved particle-ant colony. Riessen, et al. (2013) studied the multimodal transport network planning of the Rotterdam Port and between the inland points of northwestern Europe, and established the network programming model combining route combination with minimum network flow. Wang, et al. (2011) studied the mode of transportation and route selection model of multimodal transport based on the random characteristics of node operations in the process of modes of transportation conversion. Fan and Le (2011) established the mathematical programming model on route optimization of multimodal transport with soft time window constraint based on the random factors in intermodal transport. Jiang, et al. (2012) studied the solution selection of multimodal transport plan minimizing the transportation cost and transshipment cost, and put forward the cross entropy algorithm.

To sum up, most of the existing studies focus on the procurement in transportation services from the perspective of the shipper for the demand of once transport between single pair of OD market, and with minimum cost or time as the goal and route selection as the decision under the general multimodal transport network structure. However, existing studies have not yet considered the unique hub-and-spoke network structure of container sea-rail intermodal transport and slot volume purchased by the MTO under the scale operation. Therefore, this paper will study long-term transport capacity procurement facing the actual shipping and railway carriers from the perspective of MTO. Considering the time and space connectivity between shipping and railway transport, slot volume of procurement based on route selection is set as the decision and minimum total cost is as the objective, this paper will study the optimization model of transport capacity combinatorial procurement in container sea-rail intermodal transport and its solution methods, so as to provide scientific decision-making tool for the operation and management of MTO.

2 Problem Description

The NOVCC type of sea-rail intermodal transport operators do not own any transportation resources directly, and the allocation process of their transportation resources include purchase stage and allocation stage. In the first stage, first of all, the MTO should plan the sea-rail transport lines or network to be operated based on the investigation and prediction of long-term market demand, and then sign the purchase agreement with the actual carriers for certain amount of transport capacity within a certain period of time, so as to obtain a certain number of slots operation right on the shipping liners and regular railway trains within a lower contract price. This method not only can ensure relative stability of transportation capacity, but also reduce the operating costs, which is conducive to the realization of scale economies. In the second stage, the MTO, acting as the contractual carriers, should sign the sea-rail transport contracts with each shipper within the delivery time of each shift, and allocate the transportation capacity to each shipper rationally, in order to meet the differentiated demand of shippers. In fact, this paper studies the problem in the first stage, which is the optimization of transport capacity combinatorial procurement in container sea-rail intermodal transport facing the actual carriers.

Assume that the sea-rail intermodal transport network to be operated by the MTO is a "hub-and-spoke network" structure with two ports as the hub and radiating to their own hinterlands, of which A and B are the two hub ports; $A_1, A_2, \cdots, A_m$ are the interior hinterland railway container freight stations of port A, and $B_1, B_2, \cdots, B_n$ are the interior hinterland railway container freight stations of port B, as shown in Figure 1.

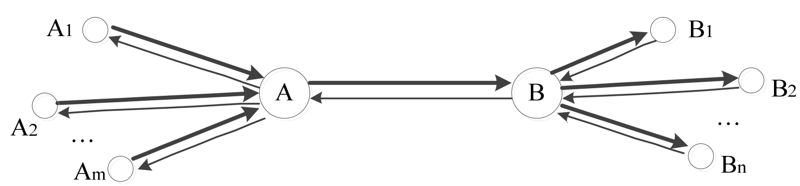

Figure 1. Hub and spoke network structure diagram of container sea-rail intermodal transport

Generally, the two-way sea-rail intermodal transport market demand at both ends of A and B is independent each other, so the MTO can adopt the strategy of one-way purchase of transport capacity respectively. This paper discusses the transport capacity combinatorial procurement decision-making in container sea-rail intermodal transport from end A to end B, as shown in Figure 1 in bold lines. Suppose that there is only one marine container liner between the hub port A and B, and a number of regular railway container trains for branch collecting and dispatching between the hub port A and B and their own inland railway freight stations. The shipping liner and each regular railway train have their own fixed transport routes, transport time, transport schedule, transport capacity (slot capacity) and transport rates. Therefore, it is necessary for the MTO to conduct comprehensive consideration of the space and time convergence of each liners and regular train, and limitations of slot capacity when conducting transport capacity combinatorial procurement decision-making. In addition, the MTO needs to determine the routes and shift of trains to be purchased in given network and the slot volume to be purchased on corresponding trains with the objective of minimizing the total cost, in order to meet the demand in each OD market formed between various inland railway freight stations of port A and various inland railway freight stations of port B.

3 Optimization Model and Algorithm

3.1 Symbolic description

(1) Relevant parameters:

i is the number of railway line from A_i to A, $i \in \{1,2,\cdots,m\}$; j is the number of railway line from B to B_j, $j \in \{1,2,\cdots,n\}$; h is the shift number of regular train on line i, $h \in \{1,2,\cdots,M_i\}$; f is the shift number of regular train on line j, $f \in \{1,2,\cdots,N_j\}$; k is the shift number of shipping liner from A to B, $k=1$; Q_{ih} is the slot capacity of regular train h on line i; Q_{jf} is slot capacity of regular train f on line j; Q_k is slot capacity of liner k; C_{ih} is slot procurement price of regular train h on line i; C_{jf} is slot procurement price of regular train f on line j; C_k is slot procurement price of liner k; T_{ih}^1 and T_{ih}^2 are departure and arrival time of regular train h on line i respectively; T_{jf}^1 and T_{jf}^2 are departure and arrival time of regular train f on line j respectively; T_k^1 and T_k^2 are departure and arrival time of liner k respectively; T_A and T_B are fixed loading and unloading time of port A and port B respectively; $\bar{D}_{AiBj}$ and $\underline{D}_{AiBj}$ are upper and lower limit of predicted container sea-rail intermodal transport demand value from A_i to B_j respectively.

(2) Decision variables:

ρ_{ih} is a 0-1 decision variable, referring to whether the MTO purchases the transport capacity of regular train h on line i; ρ_{jf} is a 0-1 decision variable, referring to whether the MTO purchases the transport capacity of regular train f on line j; x_{ih} is slot volume purchased by the MTO from regular train h on line i; x_{jf} is slot volume purchased by the MTO from regular train f on line j; x_k is slot volume purchased by the MTO from liner k.

3.2 Model building

The optimization model of transport capacity combinatorial procurement in container sea-rail intermodal transport can be described as:

Objective: $$\min z = \sum_{i=1}^{m}\sum_{h=1}^{M_i} C_{ih}\rho_{ih}x_{ih} + \sum_{k=1}^{K} C_k x_k + \sum_{j=1}^{n}\sum_{f=1}^{N_j} C_{jf}\rho_{jf}x_{jf} \quad (1)$$

Constraints: $\rho_{ih}x_{ih} \le Q_{ih}$, $\forall i, \forall h$ (2)

$$\rho_{jf}x_{jf} \le Q_{jf}, \quad \forall j, \forall f \tag{3}$$

$$x_k \le Q_k, \quad k=1 \tag{4}$$

$$\sum_{j=1}^{n} \underline{D}_{AiBj} \le \sum_{h=1}^{M_i} \rho_{ih}x_{ih} \le \sum_{j=1}^{n} \overline{D}_{AiBj}, \quad \forall i \tag{5}$$

$$\sum_{i=1}^{m} \underline{D}_{AiBj} \le \sum_{f=1}^{N_j} \rho_{jf}x_{fj} \le \sum_{i=1}^{m} \overline{D}_{AiBj}, \quad \forall j \tag{6}$$

$$\rho_{ih} = \begin{cases} 1, & T_{ih}^2 + T_A \le T_k^1 \\ 0, & T_{ih}^2 + T_A > T_k^1 \end{cases}, \quad \forall i \forall h \tag{7}$$

$$\rho_{jf} = \begin{cases} 1, & T_k^2 + T_B \le T_{jf}^1 \\ 0, & T_k^2 + T_B > T_{jf}^1 \end{cases}, \quad \forall j \forall f \tag{8}$$

Among them, formula (1) is the objective function, indicating that the total cost that the MTO purchases the transport capacity from the actual carriers is minimum.

Formula (2), (3) and (4) are the capacity constraints, indicating that the slot volume purchased by the MTO from one regular train or liner shall not exceed the maximum slot capacity of that regular train or liner;

Formula (5) and (6) are demand constraints, indicating that the sum of slot volume purchased by the MTO from various trains on a certain line shall meet the demand of all OD markets through that line;

Formula (7) and (8) are the 0-1 variable constraints, indicating that if the arrival time of the fore shift plus the handling time in a certain port earlier than the departure time of the rear shift, select to purchase the transport capacity on that shift; otherwise, do not purchase it.

3.3 Algorithm design

In the above mathematical model, the 0-1 constraints in formula (7) and (8) exist, which are used for screening whether the transport capacity of the train is purchased by using time convergence conditions, so the model is a nonlinear programming problem. Therefore, the following algorithms are designed in this paper:

Step 1: Determine ρ_{ih} and ρ_{jf} of 0-1 decision variables first, that is determine whether the MTO can choose the transport capacity of a train on a line to purchase slots according to the time convergence conditions constraints of formula (7) and (8);

Step 2: Substitute ρ_{ih} and ρ_{jf} of 0-1 decision variables determined in step 1 into the model, and transform the above model into the standard model of general linear programming problem.

Step 3: For standard linear programming model, design the program algorithm of the objective function constraints by using the solving syntax of software LINGO, and then solve the function and optimize the model.

4 Example verification

It is supposed that a MTO operates container sea-rail intermodal transport in the hub-and-spoke network with two hub ports. Take the transport capacity combinatorial procurement in this network as an example, to verify the above model and algorithms.

Suppose that there are 3 railway container freight stations in interior hinterland of port A and B respectively, namely A_1, A_2, A_3 and B_1, B_2, B_3. There is only one sea route and one liner from port A to port B, and its departure time and arrival time are known and fixed. Furthermore, there are many trains with different departure time and arrival time on each line from the inland handling stations A_1, A_2, A_3 to port A and from the inland handling stations B_1, B_2, B_3 to port B. According to step 1 of the above algorithm, with time cohesion constraint, we can determine the shift selected to be purchased by the MTO on the inland routes, as shown in Table 1.

Table 1. Situation of routes and shift selected to be purchased by the MTO

Line	Number of line	Number of shift	Price (yuan/TEU)	Slot capacity (TEU)
A_1-A	1	1	3 185	130
A_2-A	2	1	2 539	120
		2	2 235	100
A_3-A	3	1	1 560	150
B-B_1	1	1	4 562	90
		2	4 136	100
B-B_2	2	1	1 685	160
B-B_3	3	1	2 780	100
		2	2 489	80
A-B	1	1	4 576	3000

The MTO has obtained the demand of sea-rail intermodal transport in various OD markets according to the long-term investigation and forecast of sea-rail intermodal transport between the interior hinterlands of port A and B, as shown in Table 2.

Table 2. Predicted sea-rail intermodal transport demand in various OD markets

Line	Lower limit of demand (TEU)	Upper limit of demand (TEU)
A_1-B_1	30	50
A_1-B_2	40	90
A_1-B_3	50	70
A_2-B_1	70	90

A_2-B_2	60	70
A_2-B_3	80	80
A_3-B_1	50	70
A_3-B_2	50	60
A_3-B_3	40	50

Running the solving programs designed by software LINGO, we can obtain the optimization results of transport capacity combinatorial procurement in sea-rail intermodal transport conducted by the MTO, as shown in Table 3.

Table 3 Optimization results of transport capacity combinatorial procurement in sea-rail intermodal transport

Line	Number of line	Number of shift	Slot volume (TEU)	Objective value (yuan)
A_1-A	1	1	120	4 597 880
A_2-A	2	1	110	
		2	100	
A_3-A	3	1	140	
B-B_1	1	1	50	
		2	100	
B-B_2	2	1	150	
B-B_3	3	1	90	
		2	80	
A-B	1	1	470	

As seen from Table 3, the MTO conducts an effective transport capacity combinatorial procurement on the railway section and shipping section, which can not only meet the sea-rail intermodal transport demand in various OD markets, but also realize the goal to minimize the total cost under the optimization of time convergence, which lays foundation for the next allocation of transport capacity.

5 Conclusions

This paper focuses on the study of long-term transport capacity combinatorial procurement decision-making facing the actual carriers from the perspective of MTO. First of all, this paper conducts comprehensive consideration of sea-rail intermodal transport demand in various OD markets, capacity limitations of shipping liners and regular railway trains, connections between space and time. Furthermore, , this paper set the slots volume of procurement based on combinatorial selection in shipping liner and regular railway train as the decision, and established an optimization model of transport capacity combinatorial procurement in container sea-rail intermodal transport with the objective of minimum total cost. Finally, an algorithm is designed for solving.

This paper breaks through the boundary that the existing studies only focus on the transportation services for the demand of once transport under general ultimodal transport network, and studies the method of long-term transport capacity combinatorial procurement by the MTO under the scale operation based on the unique hub-and-spoke network structure of sea-rail intermodal transport. This study provides a new perspective of management and scientific technical support for the operation and organization of container sea-rail intermodal transport. The future research can focus on further improvement and in-depth study on the model and algorithm based on the hub-spoke network structure of multiple hub ports, demand uncertainty and other factors.

Abstract: E-business is a great challenge and opportunity to the railway passenger transportation. Through detailed analysis of the current situation of railway passenger transportation system, the logic structure and function framework of dynamic E-business system based on Web services and RFID technology in railway passenger transport are designed, which is excellent interoperability, reliability and maintainability, and will be the trend of railway passenger E-business development. Considering the current situation of railway ticket system and the operation features of the future passenger-dedicated line, the general framework of RFID-based China railway ticket system is put forward, and the key technologies of the system include: safety control system which consists of information coding, key management, access authentication, data integrity audit; the design of ticket reader compatible with multi-tickets; and the application whose characteristics reflected in the flexible check-rule control strategies, efficient gate access and fast payment self-service ticketing.

Keywords: Railway dynamic E-business; Web services; RFID; E-ticket; SSL protocol; Double signature.

1 Introduction

With the growth economy and the continuous improvement of quality of life people demand, as well as rapid popularization and wide application of information technology and network technology in China, the developing trend from the conventional business activities to E-business between enterprises as well as between enterprises and customers is inevitable.

The railway, as the main artery of China's economic construction, aims to provide a safe, efficient and convenient transportation service. Therefore, the dynamic E-business systems of railway passenger transportation which is on the basis of RFID and Web services technology will undoubtedly accelerate the information and intelligence processing, which meet the operation demand of high passenger flow and high density of high-speed passenger-dedicated line. As a result, the efficiency and automation level of fare collection are further improved and the passenger fatigue of ticketing and travel is reduced and logistics and supply chain management (SCM) are also improved, which enhances the market competition ability of passenger railway transportation in China.

2 Logic structure of railway passenger dynamic e-business system

The characteristics of dynamic E-business are to design the reusable and flexible components in respect with modeling software which is in accordance with business process.

By technical modularized and standardized means, the inter-enterprise distributed isomerous and loose-coupled application resources are modularly packaging. Moreover, the inter-module dynamic connection and messaging are realized on the basis of standard interfaces and protocols. With dynamic E-business, enterprises can instantly search for business partner, which realizes the timely search and fast dynamic integration of enterprise resources as well as provides the business processes and the dynamic extension and connection function of customers and manufacturers with enterprises (Li, 2002).

From the perspectives of technology, the railway dynamic E-business system based on Web services and RFID technology is made up of railway external network, railway dynamic E-business platform and railway internal information network Intranet. The main difference between the railway dynamic E-business system and the conventional railway E-business system is that it can provide a consistent interface for the various E-business software applications and public services (such as customer relationship management, supply chain management, etc.) support, which can integrate railway partners including suppliers, distributors, service providers and banking via Internet to form a complete end-customer-oriented E-business supply chain. Based on the consideration of the technical support from hardware and software of E-business system together with the reality of railway passenger transport, the logical structure of railway passenger transport dynamic E-business system to be built is shown in Figure 1.

The data center is the operation foundation of railway passenger dynamic E-business system. On the one hand, E-business platform provides data support and accept the information feedback from the platform in the meantime. On the other hand, the data center needs the support from the information acquisition based on TDCS, TMIS and RFID-based ticket system. The data center accepts the information from two aspects at all times and implements data updating in time. With the support of the railway passenger dynamic E-business platform, E-business system provides dynamic service for users through the specific E-business software and hardware.

The railway dynamic E-business system transforms from mainly dealing with business itself which means consumer request from the front-end to mainly dealing with back-end commercial trade and business contact which means dealing with back-end interaction of supply chain rather than the early human-computer interaction mode which B2C leads.

(l) Through open standard protocols, the dynamic E-business simplifies the integration and transaction processing of the railway enterprise and E-business related business systems.

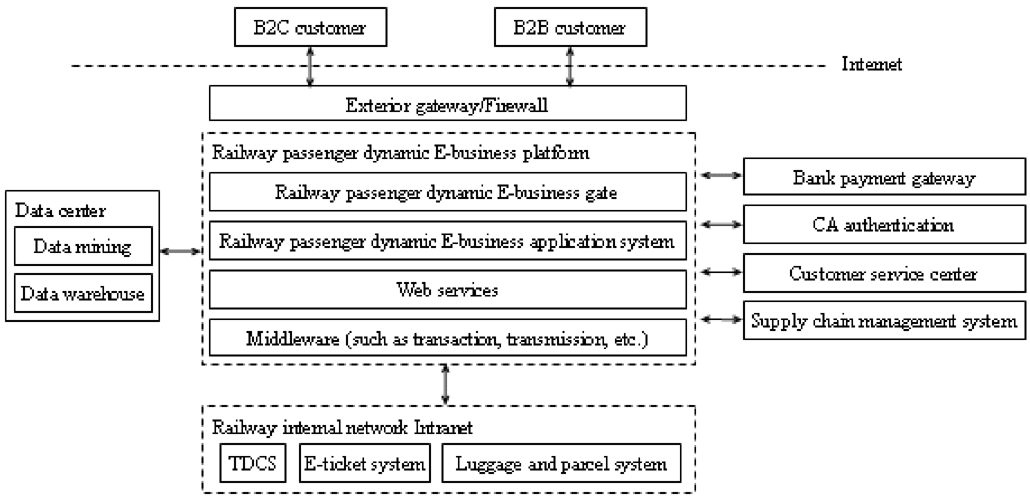

Figure 1. Logic structure of railway passenger dynamic E-business system

(2) The dynamic web pages can provide the personalized service for the customers such as passengers, business-partners and etc. In the environment of internet, the customer basic data is collected in all in the background database. Moreover, the business analysis carried out by means of data mining technology to understand the characteristics and category of customer group. According to the demand type and the consumption tendency, the related services are dynamically offered to the customer.

(3) After the packaging applications by Web services, it facilitates service integration and service customization, which realizes the information query of the ticket and the baggage and parcel as well as the omni-bearing service such as internet booking, online payment, acceptance of complaint and other value-added service.

(4) Improve the logistics and supply chain management. Through Web services, the integration of information platform between railway enterprises and the partners is realized. In addition, the information of the upstream and downstream enterprises in the supply chain is connected, which realizes the transformation of the railway from the logistics undertaker into the organizer of logistics supply chain and also improves business operation level.

3 Function structure of railway passenger dynamic e-business system

The railway passenger dynamic E-business system can simultaneously provide the decision support for the traveler and the railway transportation organization department, and the function structure is shown in figure 2.

(l) Data accessing layer. The information in the existing business system is extracted to realize resource sharing. The data source in railway system includes the file-type data and the real-time data of railway transportation production besides the traditional relational data.

(2) Data processing layer. It includes middleware, transaction processing, system data classification, mining and so on, which realizes the functions such as uniform data access, data conversion and data exchange. Data isolated island is eliminated to realize the unified management of distributed data source through data integration. However complex the bottom data source is, data access can be implemented in uniform method in all the upper application by means of changing data access into Web services.

(3) Business processing layer. It is the processing core of the railway passenger dynamic E-business system. On the one hand, data is accepted from application layer, which is sent to corresponding payment interface after filtering and integrating to realize online payment, authentication interface and other application program interface. On the other hand, business data, office data and etc. are transferred to general data stream in the bottom database. This layer takes advantage of Web services technology to package the enterprise application program into Web services, which becomes the application module. Through the established Web services interface, other systems can be connected with these Web services at any moment to complete the application integration of B2B and achieve the railway passenger dynamic E-business.

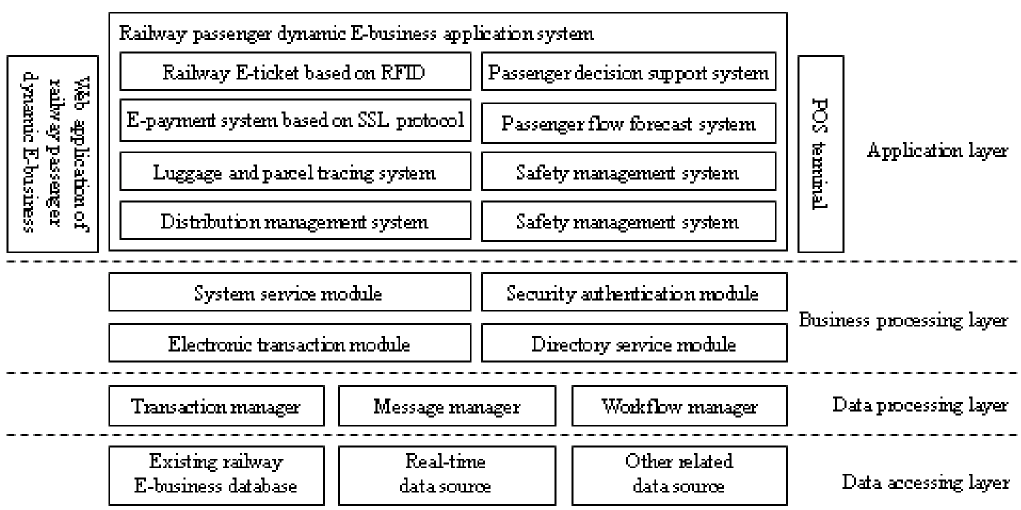

Figure2. function structure of railway passenger dynamic E-business system

(4) Application layer. It is a specific business interface which orients the railway passenger dynamic E-business system, which is the communicating bridge between the user and the system and includes the B2C application and the B2B application.

4 Railway E-ticket based on RFID

The Radio Frequency Identification (RFID) is a technology of non-contact automatic identification, which identifies target objects automatically by radio frequency signal, and obtains related data. The identification course is self-service, which has many advantages, such as long service life, good anti-collision quality, long working distance, high working speed, encrypted label data, large memory capacity, modification freely stored information and so on. Railway E-ticket based on RFID has become an important part of railway passenger dynamic E-business system.

4.1 General structure of RFID-based railway ticket system

The RFID-based railway ticket system can divide into five layers by function: the first layer is the Ministry data center; the second layer is the regional ticket data center operating on railway bureau or railway passenger-dedicated line dispatching center; the third layer is the passenger ticket system operating on owned station; the forth layer is the station AFC terminal devices, which include window ticketing machine, ticket vending machine (TVM), automatic gate machine (AGM) and so on; the fifth layer is various ticket, that is RFID single journey ticket, RFID season ticket, RFID stored-value card and so on (Zhu,2006).

The functions realized by railway ticket system based on RFID include existing operation management, transaction processing, business management, seat management, route computation, fare computation, revenue management, statistics, system management and monitoring and so on. The business functions of season ticket management, stored-value card management, passenger information management, liquidation and settlement are added. The key devices of system include ticket reader RFID-based compatible with multi-tickets and automatic fare collection (AFC) device, the application software include single journey ticketing, season ticket and stored-value card issuing, and the subsystems of stored-value card automatic ticketing, single journey ticket and season ticket checking and so on.

4.2 Key technologies of railway ticket system based on RFID

(1) Security control

According to the railway ticket rules, the read-only unique identification code (ID) of RFID chip is coded and the authentication units such as encryption bits, parity bits and so on are set. Then the non-meaning sequence code is changed into the meaning pseudorandom code to enhance the anti-counterfeiting capability which can prevent most of the active attack (GARFINKEL,2006).

Key management system is the security core of RFID-based ticket system which runs through the life cycle of the RFID-based ticket usage. By means of the key management system of multistage and dispersion, it realizes the functions such as generating, inputting, outputting, backing up, recovering, updating, destructing and etc. of the various sub-keys which the RFID-based ticket needs in the application system. The whole key system use the DES/3DES encryption algorithm and the key is stored in the key card in the form of key card which transmits in the system in security message mode, that is to say using 3DES cipher-text + MAC which means the key plaintext inside the system can not appear outside the card to guarantee the confidentiality and integrity in the transmitting processes.

The non-contact read-write equipment and IC card are mutually authenticated through the external authentication key and the internal authentication key. While the external authentication means that IC card's legitimacy identification for the equipment, the internal authentication means that the equipment's legitimacy identification for IC card. In order to guarantee the transaction legitimacy, 2 times of authenticated transactions are carried out through 2 MAC. Before the deduction, the IC card authenticates MAC1 which the equipment generates. After the deduction, the equipment authenticates MAC2 which the IC card generates.

(2)RFID-based reader and writer

With the implement of RFID-based railway ticket system, AGM can read and write the single journey ticket, the season ticket and the stored-value card which take advantage of different technology. The choice of read- write device is the key to guarantee high passenger passing efficiency. Moreover, the read- write device is directly related to the ticket system and also different ticket demands different handling of the read-write device (Wang,2008).

In order to adapt the RFID-based ticket based on the different technology standard, the read- write device supports multiple card standard including A-class, B-class and Felica-class based on ISO14443 standard, NFC standard, ISO15693 standard and etc. which is in accordance with PBOC2.0 standard to facilitate the connection with the commercial bank or the union pay system. The read- write device sets several SAM card holders to be compatible with different E-payment mode.

(3)Application system

The automatic gate system is not only compatible with multi-tickets read-write, but also its control software take advantage of the multithread structure design to realize the real-time detection and data processing for the multi-tickets. In order to improve the flexibility of the system, the checking plan and the accounting rules are stored as a unique file. The control software interprets the checking plan and the accounting rules through the internal rule engine so as to decrease the system coupling degree (Wang,2008).

Based on the combination of the application of the technology such as the process and thread pool, the workflow management and so on, the automatic gate software system with clear business state and flexible architecture is designed to increase the passenger ticketing speed. Compared with the cash payment, the stored-value card payment reduces the service links such as cash recognition, change and etc. Compared with the bank card payment, the stored-value card payment reduces the conversion and data resolution of the complex interface protocol in bank system. While the typical time of the transaction process in cash payment is 2 min, the bank card payment and the stored-value card payment is just 3s.

5 Conclusions

The development of dynamic E-business from information sharing and simple transaction to the application sharing and cooperative transaction is the new trend of railway E-business development. By using web services technology, the railway dynamic E-business system has many advantages, such as good interoperability, reliability and maintainability. It can realize the interoperation between the trade partners by integrating the existing application system, and is an effective method to process B2C and B2B E-business application integration. As an important part of railway passenger dynamic E-business system, ticket system adopts RFID technology to modify the current ticket system in both software and hardware, and it realizes the automatic fare collection, improves the passenger traveling efficiency, and makes it possible to collect passenger transport information. Secure E-payment system is the key of E-business, and the railway passenger E-payment system is based on the improved SSL protocol. By using the double signature technology in SSL protocol, the safety in trade is increased, and the transaction cost is reduced.

Abstract: With the acceleration of urbanization process, the problem of urban traffic is increasingly prominent. In particular, there is a dispute about whether to cancel the existing conventional rail transit buses after the rail transit goes into operation. This paper comes up with BP neural network model basing on the principle of complementarities, by analyzing the relationship between running rail and conventional public transport, and solves the problem of the adjustment of regular bus lines under the operations of both collinear.
Keywords: BP neural network; MATLAB; Complementary.

1 Introduction

Residents travel mode choice behavior research as an important part of traffic demand planning（Moshe, 1998）has always been an important content in research of transportation planning. When the rail transportation is in operation, whether to delete the original collinear bus lacks of theoretical basis. Therefore, this paper proposes the complementary relationship to determine whether the both could coexist.

Through learning the neural network we can establish BP neural network model which could automatically obtain the object of study of the relationship between input and output and strong learning training abilities. By using the model to predict the results of the transportation options and calculate the share rate of rail and bus. Finally, the levels of service are compared of coexist and non-coexist.

2 The Rail Transit and Conventional Public Relations Research

2.1 Function and location

Urban public transportation is a large system composed of a variety of public transportation. Each has its particular transportation service object and function. All kinds of transportation orderly form the system of urban public transportation through the cooperation of labor division and mutual coordination. Rail transit and conventional bus are the two most common modes of transportation in the system of public transportation. Here is the relationship among three kinds of different types of bus and rail transit shown in Figure 1.

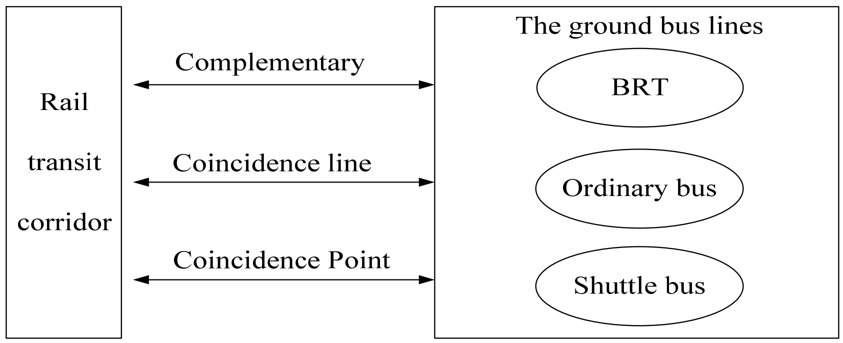

Figure 1. The relationship between rail transit and ground bus lines

2.2 The cooperation and competition of the rail transit and bus

The different modes of transportation are interdependent in the system of urban transportation, according to the different travel demand of urban residents. Therefore, any kind of transportation services are indispensable. The transportation passengers select to complete a trip will be diversified, and therefore, which requires the orderly combination of different modes of transportation, mutual coordination, and better service for residents to travel. At the same time, there are competition relations, both of the urban rail transit and conventional public traffic service object is usually urban residents, the service area is generally limited to the scope of the city and surrounding, service content, goals, and achieve results are consistent. So, faced with the same service object and range, there is inevitably a competitive relationship between providing urban rail transit and conventional public.

2.3 Complementary study theory of rail transit and conventional bus

2.3.1 Complementary theoretical implications

Complementary applies in many professional fields. In economic, the definition of complementary is reducing of costs or increasing of earnings caused by this kind of behavior of individuals, with the number of people taking some sort of behavior or the behavior itself is increasing. (Huapu,1998). As you can see both sides of the complementary is complement and promotable to each other, while directing the common to the right way. At first, the concept of complementary originated in the field of physics, the so-called "complementary", Bohr explained: "complementary is the meaning of the word: any determinable application of the concept of some classic will eliminate some other concept of classic application at the same time, the other concept is also indispensable to clarify phenomenon in another condition." It emphasizes that the both sides of the complementary cannot be separated.

2.3.2 The characteristics of relationship between rail transit and bus based on the theory of complementary

As known in economics, there is complementary relationship between commodity A and B, which refers that the two goods are complementary in utility. In traffic areas, there is also the relationship for the demand and combination of transportation. But complementary relationship in science of transportation is different from the areas of economics. The purpose of the complementary relationship applied in economics is profit to both parties maximization, while the complementary in transportation is to strengthen mutual cooperation, pursuit traveler's largest aspects of convenience, and minimize the problem of road traffic congestion.

3 The Choice Model of Residents Travel Traffic Mode

3.1 Transportation mode selection factors

There are many factors that can affect choice of urban residents travel mode, related to resources of domestic and foreign urban residents travel mode choice behavior research, it mainly including the macroscopic properties and microscopic properties of traveler (Haifeng, 2007). Personal factors also influence the choice of the ways of traffic: age, gender, family income, etc.

To test the relationship between the above property variable and the traffic mode selection, two important factors in selecting indicators of travel time and travel expenses to measure mode selection for rail transit and conventional public traffic complementary to draw reasonable basis in this paper.

3.2 The dimensionless factor

Due to various factors between different dimensions, so we need to transform the value of 0~1 according to membership functions, the normalized factors dimensionless. Membership function is divided into two kinds: ①down half a trapezoidal distribution, ②liter and a half trapezoidal distribution. Specific formula is as follows:

① lower half trapezoidal distribution

$$f(x_i) = \begin{cases} 1 & x_i \le m_i \\ \dfrac{M_i - x_i}{M_i - m_i} & m_i \le x_i \le M_i \\ 0 & x_i \ge M_i \end{cases} \tag{1}$$

② liter and a half trapezoidal distribution

$$f(x_i) = \begin{cases} 0 & x_i \le m_i \\ \dfrac{x_i - m_i}{M_i - m_i} & m_i \le x_i \le M_i \\ 1 & x_i \ge M_i \end{cases} \tag{2}$$

4 The Algorithm of BP neural Network

Regarding travel mode choice results as output, the influenced attribute variables of travel mode choice as input. By setting on the parameters of neural network such as the number of input or output layer nodes and hidden layer nodes, learning speed .etc. to carry on network training, and establish the relatively much more fitting and simulation performance of residents travel mode choice neural network model, which could map out the way to travel choices and the relationship between various influencing factors.

4.1 The BP neural network training

$net = newff(\min\max(p),[3,1],\{'\tan sig', ' purelin'\},'trainlm');$

$net.trainparam.goal = 0.001;$

………

$[net,tr] = train(net,p,t);$

When the input p (Xilin,2001), output t, after the above-mentioned non-linear function of training, the p t establish correspondence between the number of training set, the required accuracy, the learning rate parameters such as training, network training, the network of learning values and expectations to reach the precision requirements, save weights and thresholds.

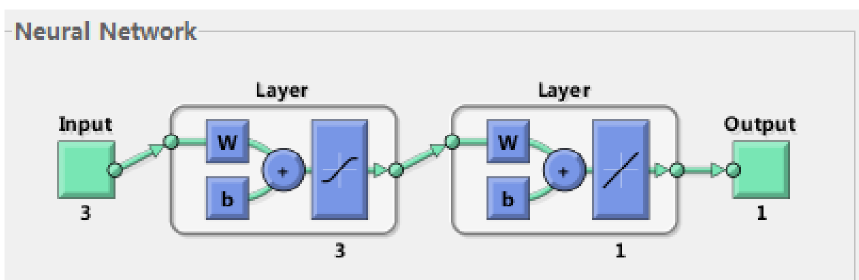

Figure 2. BP network structure

4.2 The BP neural network simulation

After the model training (Huanhuan, 2011), the network could be simulated by using the Sim function. The plot function is called to linear regression analysis the network simulation output and target output after training, to verify the training effect of the network.

$t_{12} = sim(net,[]');$

$t_2 = sim(net,p);$

$plot(4:11,t_2,'+',4:11,t)$

5 The Determination of Service Level

Road saturation is an important indicator of the level of road service, the calculation expression is: V/C, where V represents the maximum amount of traffic, C represents the maximum capacity. In this paper, in view of concept and grading of roads saturation，the concept of public transport saturation is came up , combined with levels of service to define urban road public transport passenger services. Taking the ratio of section traffic and rated capacity in peak-hours between the two sites is defined as the load factor of public transport, namely saturation.

Saturation is calculated with the formula as shown in （3）:

$$S = \frac{V}{C} \quad (3)$$

In the formula：S—Public transport saturation；V—A section of the public transport patronage；C—Public transportation rated capacity

Public transport utilized as road saturation, and is inversely proportional to the service level. The higher the saturation value is, the lower the level of public transport services.

Depending on difference of road saturation and other indicators, our country divides the level of service into the following four levels:

Table 1. The service level

Level	Saturation（V/C）	Vehicle Inside Condition	Service Level
1	0～0.6	More Spacious Interior	A
2	0.6～0.8	A Little Crowded	B
3	0.8～1.0	More Crowded	C
4	>1.0	Serious Crowded	D

6 The instance

According to a survey data of urban rail transit and conventional public traffic, the concrete numerical value shown in Table 2:

Table 2. Sample data

30	38.17	40.01	2.81	1.43		a

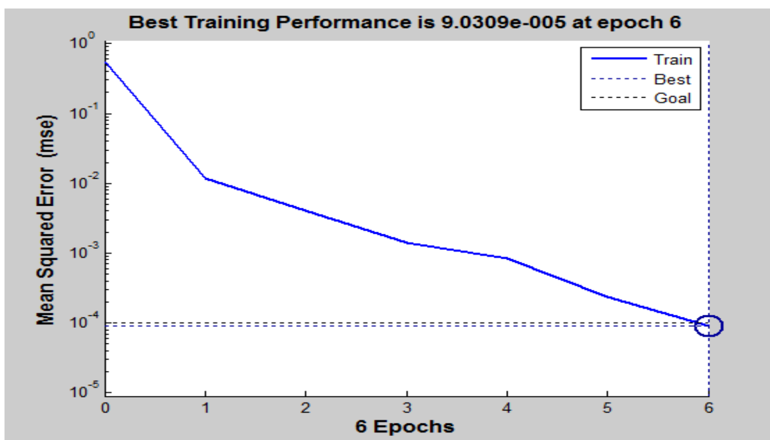

Figure 3. Training error convergence curve

According to the above calculated 30 sets of data, we can calculate the share rate of the rail transportation and conventional public traffic: about 19 travelers choose rail travel as a tool, and the rest of the travelers choose public transport, so rail transit is 63.3%, regular bus is 36.7%. It shows two kinds of traffic tools play a different role in the public traffic, which can cooperate and complement with each other, it also reflects the necessity of this research for complementary.

Based on previous forecasting section traffic data of rail transportation planning, service level of rail transportation is compared around coexist with the regular bus. The former before improvement is a single rail transportation, after improvements is rail transit and bus complementary coexistence. Comparative results are as follows:

Table 5. Comparation of improve service levels of rail decisions before and after the program

Location	Service Level					
	Initial Stage		Recent Stage		Future Stage	
	Before Improved	After Improved	Before Improved	After Improved	Before Improved	After Improved
Road1-R2	B	A	C	C	D	C
R2-R3	A	A	B	B	C	B
R3-R4	A	A	C	B	D	C
R4-R5	A	A	B	B	C	B

As can be seen from Table 5 to retain the bus, rail transportation for long-term planning is essential. For the initial construction of rail transit, traffic is not great, the supporting role of bus is not very significant. But over time, inducing and transferring passenger is becoming more and more, while service levels of rail transit will be reduced, then the role of the bus will be very important. If remove the bus lines in the early, it will cause a waste of facility resources.

6 Conclusions

Residents travel mode choice is the process of selecting the most suitable one mode of transportation to travel based on their personal property, family property and trip purpose, trip distance, traffic characteristics. The factors of residents travel mode choice are manifold. The rail transportation and bus achieve a complementary in function, although fares of rail are more than regular buses, but the running time is better than the latter, which fully reflects the two aspects. The travelers will not select single rail transportation and give up regular bus traffic, or choose to give up rail transportation. There is also fully a show about the relationship between complementary and conventional rail public transportation.

In this paper, there exists complementarities between modes of transportation which are proved by both BP neural network and the assessment about level of service, because of that relationship mode of transportation is not free to cancel. A rational suggestion has been put forward to solve these problems。

Abstract: Multimodal transportation becomes an effective way to improve logistics efficiency and boost the regional economy eventually. The government introduced a number of multimodal transport subsidies to enterprises from different capital subsidies and tax subsidies. In addition, the government increased multimodal transportation infrastructure investment and achieve international clearance facilitation is also implicit subsidies to enterprises. This study established a "multimodal subsidies productivity" model and used DEA method to calculate the subsidies productivity value under different multimodal transportation systems. The study analyzed government and enterprises relationship under Stackelberg game theory with symmetric information. The result showed that logistics companies prefer the transportation infrastructure subsidies, producers prefer the tax incentives and freight forwarding companies prefer international cooperation policies.
Keywords: Government subsidies; Game theory; Productivity.

1 Introduction

This paper analyzed an effective way to improve logistics efficiency and boost the regional economy. The government introduced a number of multimodal transport subsidies to enterprises from different capital subsidies and tax subsidies. In addition, the government increased multimodal transportation infrastructure investment and achieve international clearance facilitation is also implicit subsidies to enterprises. First, this study established a "multimodal subsidies productivity" model and used DEA method to calculate the subsidies productivity value under different multimodal transportation systems. Second, the study analyzed government and enterprises relationship under Stackelberg game theory with symmetric information.

The nature and scale of their demand for shipping services can also affect the level of maritime emissions. Shippers also take a broader, supply chain perspective on the low-carbon process, looking beyond the sea voyage to the other finks and nodes in the supply chain which emit CO_2 and are technically part of their corporate carbon footprint. In the case of deep-sea container chains, these additional activities can account for around a third of total emissions (Woolford and McKinnon, 2011).

So we can say low-carbon logistics is not only related to a link of the whole supply chain, but also many links combined with multimodal transport. The low-carbon logistics strategy of the multimodal transport enterprise is about the future development.

Over the past decade there has been increasing company participation in government and industry led initiatives to improve the environmental performance of freight transport. The US, UK government and organization (US Environ-mental Protection Agency, 2013; UK Freight Transport Association, 2013) have attracted high levels of company participation. One of the first and most influential of the industry-sponsored initiatives has been the Clean Cargo Working Group, set up in 2004 to bring together leading cargo carriers and their customers, dedicated to environmental performance improvement in marine container transport through measurement, evaluation, and reporting (BSR, 2013).

Although the available evidence confirms that the management of multimodal transport is dominated by financial considerations, these do not necessarily conflict with environmental goals. There are several studies are quite a close correlation between the economic efficiency of a logistics operation and its environmental impact (Rao and Holt, 2005). Peter Lorange (2001) and Photis M.Panayides (2003) tried to research the relationship between the competitive strategies and organizational performance on shipping companies. The result displayed they had the positive relationship. From the perspective of quantitative analysis, decision-making through the use of fuzzy comprehensive evaluation model for in-depth analysis of the status of the shipping companies operating performance (Tsung-Yu and Gin-Shuh Liang, 2001). Compared to decentralized decision making scenario,the low-carbon level and total profit will reach its highest under the fully cooperation scenario (YANG Jian-hua et al, 2014). Some researches improve low carbon performance through estimating the value on a computer simulation system or a numerical model (WANG Lu-ping et al, 2014; Tatjana V. Sibalija et al, 2014). Our research combined the qualitative and quantitative method and gave comprehensive suggestions for the multimodal transport enterprises development.

2 Model

Suppose a product differentiation in the market, each consumer to purchase up to one unit of product, there are two different types of products in the market. Two products have different utility green, green utility is to describe the content of toxic and hazardous substances, recyclable products, product components, the use of energy consumption and the use of materials such as the level of volume, is a measure of green products from the perspective of the entire life cycle degree. Practice from simple energy efficiency rating index logo, carbon labels to indicate the effectiveness of green products. Products based on differences utility green products and green products are divided into general categories. Assuming general utility of green product v_0, product of green utility green v_1, where v_0、v_1 is a fixed constant and $v_1 > v_0 > 0$. Selling price of the product types for p_0、p_1, due to the high cost of green products, so the consumer preference for green products, θ evenly distributed between $[0,1]$. Provided consumer surplus U，$U \geq 0$ and U between the remaining consumer relations function θ. Let θ_0 represent the purchase of ordinary consumers do not buy the product and no difference in preference parameters. Consumer surplus is the relationship between green preference shown.(Figure 1.)

$$U = \theta v_i - p_i, (\mathrm{i} = 0,1) \tag{1}$$

$$\theta_0 = \frac{p_0}{v_0} \tag{2}$$

$$\theta_1 = \frac{p_1 - p_0}{v_1 - v_0} \tag{3}$$

$$q_0 = (\theta_1 - \theta_0)\,\mathrm{M} = (\frac{p_1 - p_0}{v_1 - v_0} - \frac{p_0}{v_0})\,\mathrm{M} \tag{4}$$

$$q_1 = (1 - \theta_1)\,\mathrm{M} = (1 - \frac{p_1 - p_0}{v_1 - v_0})\,\mathrm{M} \tag{5}$$

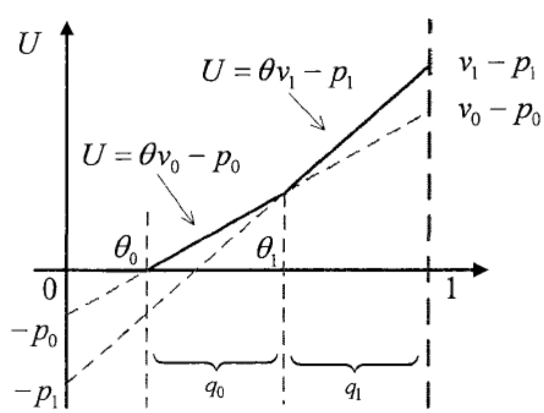

Figure 1.Consumer surplus function schematic

3 Data Analysis

The data results showed that operational factors of low carbon path highest score in 2007, the lowest in 2004. From the year 2004 to 2007, that factor is not continuously improved, indicating that the steady improvement in the level of company C operating low-carbon path. However, in the year 2008 and 2009, the factor scores dropped significantly in 2007, indicating that company C implemented a low-carbon path level operational impact of the financial crisis is showing signs of decline. In the subsequent 2010, the factor score again slightly improved description of company C implemented a low-carbon path level operations to eliminate the impact of the financial crisis began and a rebound.

Table 1. i subsidy object game show different forms of subsidies

`	Transportation Infrastructure	Tax incentives	International cooperation policies.
Producer enterprises	0.709	0.969	0.627
Freight forwarding enterprises	0.866	0.819	0.901
Logistics enterprises	0.915	0.833	0.746

4 Discussion of Results

In Germany, the first principle of government planning freight center location is to achieve seamless integration of two or more modes of transport, with transport functions. Germany has formed a standards-based vehicle system, the introduction of a series of effective support policies, such as: federal and local government to give the intermodal logistics park facilities, financial subsidies, engaged in intermodal truck to give incentives, including relaxation of the total weight limit, exempt from highway use tax, vehicle without restrictions forbidding the weekend, giving a modest operating loss for intermodal subsidies. In addition, the government also involving multimodal technology research and development, equipment improvements, public infrastructure platform for building projects and special action projects direct investment, to promote the development of multimodal transport, improve integrated transport system plays an important role.

Currently local governments in order to encourage intermodal many subsidies, these subsidies for intermodal market had an impact. This paper intends to compare with and without government subsidies environmental impact of subsidy policy on the "rail, water, iron, iron empty" and intermodal markets, analyze the key factors that influence the efficiency of intermodal operations and market development, for now There are policies to provide improved solutions to quantify the effect of improving the front and rear, to clarify the different types of cargo in intermodal pricing strategies, as well as the characteristics of different multimodal transport modes, provides a theoretical basis for government subsidies.

Promulgated the "long-term planning of the logistics industry (2014-2020)", the intermodal logistics as an effective way to improve efficiency and reduce logistics costs, was again mentioned the strategic development of the logistics industry.

Over the years, our understanding of multimodal have stayed in the choice of a single mode of transport on, but the practice has proved that all modes of transport through the rational division of labor and the establishment of an effective interface integrated intermodal transport system is to achieve foundation. We all know, China's total freight accounted for 79 percent of highway, railway 9%, water 11%, aviation 0.3%, 1% of the pipeline, transportation structure is irrational. At present, China Intermodal current prominent contradictions are various modes of transport division unreasonable, poor convergence.

Ability does not match the rules are not uniform, the information is not shared, the network is not perfect, the subject is not clear, the policy is not in place and so are the main problems existing intermodal. Li Mu original thought these questions focus on performance in nine areas: First, an early start, but slow development; the second is the mode of transport containerized rate is very low; the third is the low proportion of iron transport, and the lack of ability to dress up facilities; Fourth Intermodal rail is still the bottleneck of development; Fifth intermodal business entities is unclear; six intermodal logistics park did not become a node; Seven is multimodal resource use is low; eight is multimodal information platform construction is lagging behind; nine is no unified multimodal operating rules.

In addition, our main mode of transport containerized low, resulting in lack of multimodal core carrier; new logistics park their own way, there is no ability to form a multimodal network; rail freight structure and operating rules, customs clearance mode restricts intermodal development; emerging international logistics channel construction disorderly competition are all outstanding issues facing our country in the current intermodal.

"Ministry of Transport guidance on transport to promote the healthy development of the logistics industry," clearly the advance of the general idea of modern logistics development, key tasks and work, focusing on the economy combined with the construction of the Silk Road, the Yangtze golden waterway, Beijing, Tianjin and one major strategic implementation of construction, push forward the construction of logistics major thoroughfare. Ministry of Transport and preparation of the implementation of the "" five "road freight hub construction planning" to encourage the establishment of modern logistics park relying on the port, airport, railway hub, and create conditions for the development of intermodal transport; continue to push and pull transport pilot Container transport channel iron demonstration projects.

The study analyzed government and enterprises relationship under Stackelberg game theory with symmetric information. The result showed that logistics companies prefer the transportation infrastructure subsidies, producers prefer the tax incentives and freight forwarding companies prefer international cooperation policies.

Abstract: Non-motorized modes are those whose speeds are slower than motorized modes, represented as walking, bicycles and electric bicycles. With the expansion of urban size, non-motorized modes could not meet the residents' need of trips, so more people would like to choose motorized modes.

The research took trip chain as a unit based on data from a within-day travel survey in Zhongshan, Guangdong province in China. According to the cooperation of non-motorized modes and motorized modes, there are four types for the cooperation, including "non-motorized+non-motorized", "motorized+motorized", "non-motorized + motorized (mainly non-motorized modes with longer distance)", "non-motorized + motorized (mainly motorized modes with longer distance)". In order to clear the influencing factors of combined modes choice, after preliminarily analyzing the characteristic of trip chain attributes including trip purpose, departure time, consumed time, distance and stops, the research used disaggregate model Multinomial Logistic regression model to build a combined mode choice model for combined modes.

The results show age, gender, occupation, personal income, the ownership of transport tools, trip purpose, trip chain consumed time have different significant influence on mode choice. Those with low personal income prefer to choose combined mode with non-motorized, and those with high income like choose motorized mode or combined mode with motorized, so the service level of non-motorized mode should be improved to attract more people with high income to use. And especially those who have private car prefer to choose "motorized + motorized" combined mode, so the service level of "non-motorized + motorized" combined mode should be improved to attract more private car owner.

Keywords: Non-motorized modes; Motorized modes; Combined modes; Trip mode choice characteristics; Disaggregate model.

1 Introduction

Combined mode refers to contain at least 2 kinds of traffic ways. Non-motorized modes are those whose speed are slower than 15km/h, represented as walking, bicycles and electric bicycles, and motorized modes includes motor, bus and car. Foreign study on choice influence factors of combined modes mainly select individual household characteristics, travel (chain) feature, providing travel information and other aspects, which are similar to the factors of travel behavior in general(Golob, Hensher,2007). Nobis (2007) pointed out that the age of the traveler has a significant impact on young people who are more likely to choose combined modes in the study. And car use is a major cause of many traffic problems. Another part of the study show that (Bhat CR, 1997; Tringides CA, 2004; Krygsman S, Arentze T, Timmermans H, 2007) compared to combined modes mainly consists of public transport, travelers using cars and other private vehicles to travel tend to arrange a number of activities in the trip chain taking travel time and travel cost into account, namely the existence of a complex chain of its travel trend.

Affected factors by domestic scholars considered in the study of combination mode choice are similar with international mainstream research, which can be divided into family property, personal property, information and so on(Yang M, Wang W, Chen X, et al ,2007; Xianyu Jian-chuan, Juan Zhi-cai, 2010). Mei-Ping Yun and Zhen-Huan Chen (2014) compared mode choice behavior for work tours and non-work tours considering trip chain complexity. The paper suggests that if intermediate stops increase, compared to choosing car, respondents are more likely to choose non-driving modes (walk, bicycle, motorcycle, and bus) for non-work tours, whereas they are less likely to choose bicycle or bus for work tours.

Non-motorized modes and motorized modes are seen as main combined modes in this study, which are divided into four types.

2 Survey data

2.1 Survey Overview

The travel survey data came from Zhongshan city in Guangdong province, which is a typical Southern small and medium-sized city.

Survey time: Dec 1, 2009, Thursday (work day);

Survey method: SP, home interview survey;

Sample size: The objects are residents over 6 years old for each family, a total of about 30000 households, covering 53339 respondents, the overall sampling rate is 3.6%, obtaining 144496 effective travel records.

Table 1.Survey content

Basic information	Survey content
personal	age, gender, occupation, income, driving license and so on
family	population size, income, vehicles and so on
travel	times, purpose, mode, time, the departure and arrival time and so on

2.2 The use of data

Trip train links all travel starting from home until back home which has been widely used in the study of travel choice behavior, its characteristic has effects on the mode choice behavior, such as the transfer times, travel time, travel distance of chain etc.. According to the definition of trip chain, the survey data were integrated into the trip chain. The research selects trip train with one or two transfer stops and makes statistical analysis for each type (Table 2 and Table 3).

Table 2. Proportion of combined modes

proportion（%）	walk	bicycle	electric vehicle	bus	motor	car

"motorized +motorized"	253	10.1
other	278	11.1
total	2501	100.0

3 Study on combined mode choice model

The study analyzes the choice behavior of combined modes which consist of non-motorized modes and motorized modes, clearing the cooperation of non-motorized modes and motorized modes. The combined mode choice model uses disaggregate model, by determining the choice limbs, analyzing the influence factors, the calibration model and the model test, and ultimately obtain the combined modes choice characteristics.

3.1 Determination of model choice limb

Combined mode refers to contain at least 2 kinds of traffic ways, in order to understand the cooperation of non-motorized modes and motorized modes. According to the cooperation of non-motorized modes and motorized modes, there are four types for the cooperation, including "non-motorized +

non-motorized" , "motorized + motorized", "non-motorized + motorized (mainly non-motorized modes)", "non-motorized + motorized (mainly motorized modes)", generally the "motorized + motorized" as a reference item.

3.2 Analysis of influence factors

Combined modes choice model makes analysis according to personal property, family property and trip train property (Table 4). Because of at least 2 kinds of modes included in the combined modes, so the trip trains with the transfer over mode are taken as sample for statistical analysis to determine influence factors, providing a basis for follow-up model.

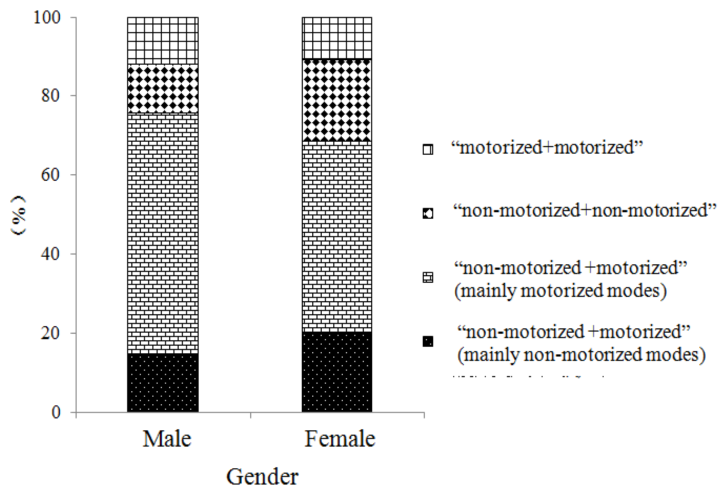
Table 4. Influence factors

Factors category	Influence factors	
Personal property	gender	
	age	
	occupation	
	personal monthly income	
	traffic cost/month	
	driving license	
Family property	population size	
	Income/year	
	vehicles ownership	bicycle
		electric vehicle
		motorcycle
		car
Trip train property	purpose	
	departure time	
	trip train time	
	trip train distance	
	number of stops	
	time of walking to bus station	

3.2.1 Personal property

1) Gender

According to the figure 1, gender has effect on the combined modes: male are more likely to choose "non-motorized + motorized" than female and the "non-motorized + motorized (mainly motorized modes)" most.

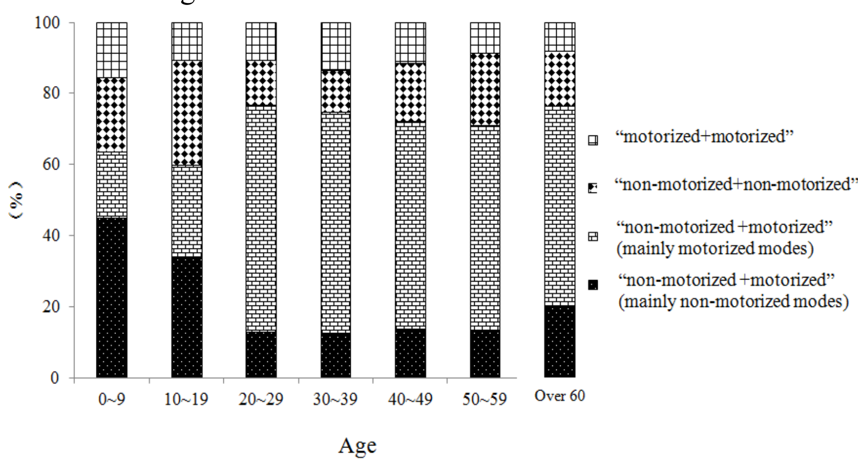


note：number of samples=2223

Figure 1. Gender effect on the combined modes

2) Age

According to figure 2, effect of age on combined modes choice is travelers under 20 years old mainly choose the "non-motorized + motorized(mainly motorized modes)" and "non-motorized + non-motorized", and there are no significant differences in the combined modes choice among travelers over 20 years old. Therefore the effect of age on combined modes is smaller.

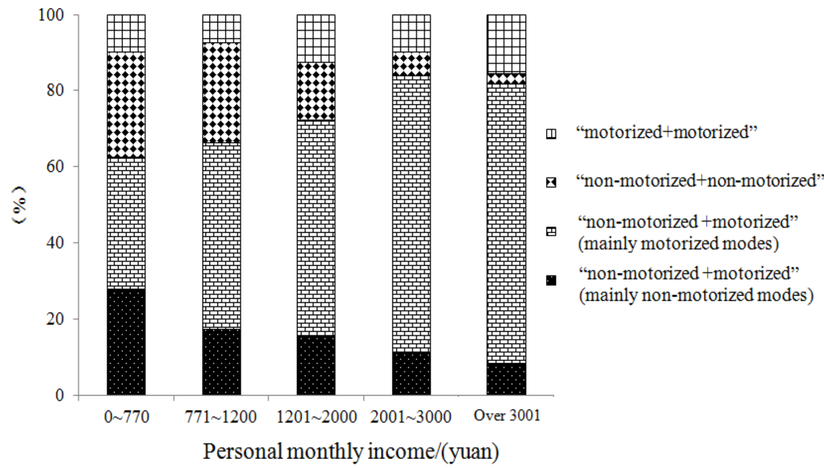


note：number of samples=2223

Figure 2. Age effect on the combined modes

3) Personal monthly income

Personal monthly income has obvious influence on combined modes choice, and presented pretty negative correlation: the higher the income, the more inclined to choose the "non-motorized + motorized (mainly motorized modes)", the other 3 kinds of combined mode ratio reduced at the same time.



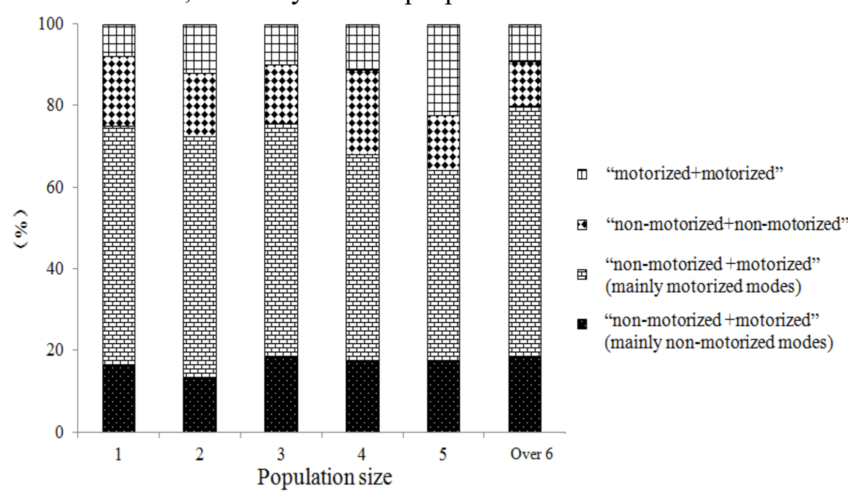
note：number of samples=2223

Figure 3. Personal monthly income effect on the combined modes

i. Family property

1) Population size

As can be seen from figure 4, population number has smaller effect on combined modes choice, basically similar proportions of all kinds of modes.

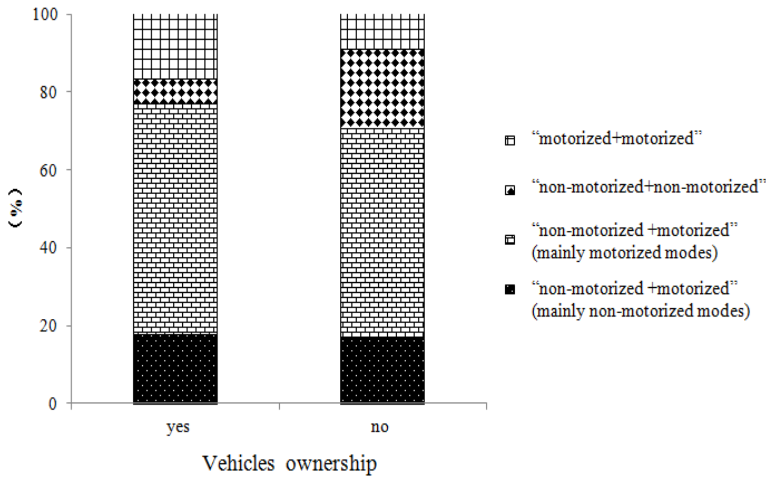


note：number of samples=2223

Figure 4. Population size effect on the combined modes

2) Vehicles ownership（car as a case）

Vehicles ownership can be seen as a necessary condition for the use of this means of transportation and is considered to have a greater influence on travel mode choice. According to figure 5 that made of cars as a case, whether owned cars will tend to choose the "non-motorized + motorized (mainly motorized modes)", and travelers owned a car prefer to choose this mode than those who do not own a car. And the “motorized + motorized” has a greater proportion which can be understood as the use of the car try to make travel after buying.



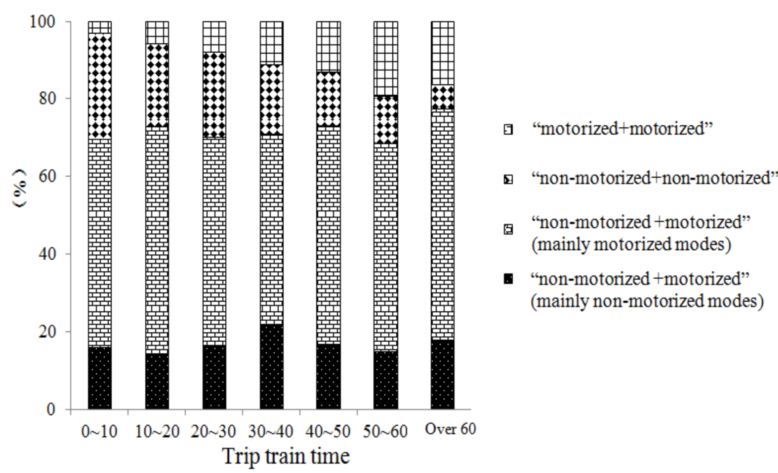
note：number of samples=2223

Figure 5. Vehicles ownership effect on the combined modes

ii.Trip train property

1) Trip train time

Trip chain time is pointed out the cost to complete whole trip chain, which has smaller effect on the “non-motorized + motorized” for travelers based on figure 6. And with the increase in time consumption, the proportion of “motorized + motorized” modes increase and “non-motorized + non-motorized” modes reduce, which explains the motorized modes are more popular among travelers with long travel time.

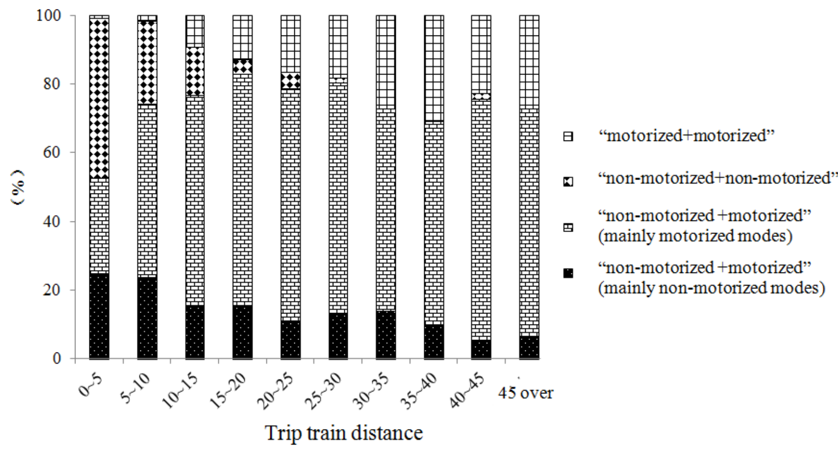


note：number of samples=2223

Figure 6. Trip chain time effect on the combined modes

2) Trip train distance

Trip train distance is all the travel distance of a completed trip train. Therefore, trip train distance not only has a significant effect on mode choice, but also has the correlation with the positioning of modes. According to figure 7, the proportion of combined modes with non-motorized reduces significantly with the increase of train distance, motorized modes increases on the contrary.



note：number of samples=2223

Figure 7. Trip chain distance effect on the combined modes

Choice characteristic variable

This study devides choice characteristic variables into two categories: general variable for all mode choice and inherent variable for particular mode choice, inherent variables (Xianwei Liu, 2013) include vehicle ownership because of the significant impact on mode choice, the significance level of 0.01 or 0.05.

Table 5.General variable chi-square correlation test

general variable	Combined modes choice model N=1000	
	Pearson correlation	**Sig.（2-tailed）**
gender	-0.082**	0.010
age	0.082**	0.009
occupation	0.088	0.065
personal monthly income	0.249**	0.000
Traffic cost/month	0.286**	0.000
driving license	0.270**	0.000
family population number	-0.054	0.088
family income/year	0.124**	0.000
travel purpose	-0.009	0.783
departure time	0.017	0.595
trip train time	0.017**	0.000

trip train distance	0.185**	0.000
number of stops	0.183**	0.000

note：**- 1% Significance level，*- 5% Significance level

From the chi-square correlation test, substantially all of the general variables are concerned with the travel mode choice. The impact of occupation, population number, trip purpose, departure time for combined modes choice are not significant, therefore they are excluded from the model of the independent variables.

Taking into account that each variable of the disaggregate model should be independent of each other, it is necessary to make the correlation analysis (Qiuli Rao, 2011) between general variable and inherent variable, getting the final model variables as shown in the following table.

Table 6. Independent variable of the model

Independent variable classification	Independent variable
Traveler characteristic variable	gender age personal monthly income
Options inherent variables	bicycle electric vehicle motorcycle car
Trip train characteristic variable	trip train time

3.4 Model calibration

In this study, by Multinomial Logistic regression model with 1000 samples of SPSS software, the optimal model is found according to the results of fitting test model and pseudo R square statistic after repeated attempts, as the following table.

Table 7. Combined modes choice model calibration results

Variable Description		"non-motorized + motorized(mainly non-motorized modes)"		"non-motorized + motorized(mainly motorized modes)"		"non-motorized + non-motorized"

3.5 Model test

The significance level of model fitting information here is less than 0.01, the significant level of Pearson statistics for goodness of fit and error statistics are all greater than 0.1, McFadden value reached 0.411 that far greater than 0.1, and therefore the goodness of fit of the model is better.

Table 8. Combined modes choice model fitting information

model	Model fitting standard	Likelihood Ratio Test		
	-2 log-likelihood values	Chi-square	DF	Significant level

Nagelkerke	.372
McFadden	.178

4 Discussion of Results

The model calibration results show that significant effect of age on the combined modes choice reflects that the older travelers are more likely to choose the "non-motorized + motorized(mainly motorized modes)", followed by "non-motorized+ non-motorized"; the proportion of male choosing "non-motorized + motorized(mainly motorized modes)" is greater; personal monthly income parameters show that lower income people tend to choose the "non-motorized+ non-motorized" or "non-motorized + motorized(mainly non-motorized modes)", and as incomes rise, the proportion of "non-motorized + motorized(mainly motorized modes)" grows up; traveler with a car tend to use the car as only way to travel, which can be speculated that the reason travelers reluctant to adopt "non-motorized + motorized" is the lower service level; trip train time is closely related to the mode speed, so travelers tend to choose "non-motorized + motorized(mainly motorized modes)" as time rises.

5 Conclusions

This paper uses the disaggregate model to analyze the combined modes choice of non-motorized modes and motorized modes, in order to understand the effect and impact of various variables on the combined modes under the cooperation between non-motorized modes and motorized modes. Through the establishment of the combined modes choice model, the study quantifies the influence factors for mode choice. The paper reveals influencing factors of trip chain mode choice and the relationship between non-motorized mode and motorized mode. The results of research could be applied to similar cities as reference, as well as guide and reference value to the development of urban transport system.

Quality Evaluation Indicator System for Rail Freight Service

Weijie Qin

School of Transportation and Logistics, Southwest Jiaotong University, Chengdu 610031, China. E-mail: 574799052@qq.com

Abstract: On the basis of extensive research and interviews with experts, we propose a quality evaluation indicator system for rail freight service, which consider both factors of rail transport enterprise and customer satisfaction. We recommend the application of these indicators to assess the quality of rail freight services in order to improve the market competitiveness of railway enterprise.
Keywords: Rail freight; Indicator system; Evaluation.

1 Introduction

After the establishing of China Railway Corporation, a wide range of rail freight reforms was carried out, aimed to increase market share. Therefore, evaluating the quality of rail freight service, improving customer satisfaction and enhancing market competitiveness has become one of the priorities. Existing quality evaluation indicators of rail freight service emphasis on internal production management, and lack of systematic evaluation for customer satisfactory. At present, many domestic and foreign scholars studied the quality of rail freight service. Feng Fenling (2007) proposed that the current railway freight services lack of comprehensive evaluation method, she used SERVQUAL method to evaluate the rail freight service quality, proved that SERVQUAL method can be used in the field of rail freight service quality. Agrawal, R. (2008) put forward that staff's behavior is an important factor related to customer satisfaction in rail freight transportation. Yang Kai (2010) analyzed the influence factors of railway freight service quality, formed an evaluation system, and used the approximate ideal solution sorting method to evaluate.

Based on the theoretical analysis, extensive research on various types of rail customers and soliciting the views from staff of Railway Bureau, this paper propose a quality evaluation indicator system for rail freight services under the background of freight reform.

2 Principles of the Indicator System

Railway freight has a complex process, involves many units and departments (including collaboration of multisectoral, such as locomotives, electricity, finance and so on), and also includes the participation of logistics companies. Any quality defects are likely to affect the final services quality. Taking into account the quality of rail freight service has the following characteristics:

(1) Subjective judgment and dynamic differences;

(2) Fluctuation and volatility;

(3) Comprehensive and systematic;

(4) Representative;

At the same time, a general assessment of the quality for rail freight service relying on indexes is basis for National Railways to announce rewards and punishments for rail freight departments. Therefore, the establishment of the quality evaluation indicator system for rail freight service must meet the following principles:

(1) Principle of comprehensiveness: The selection of indicators should be able to reflect the quality of rail freight service comprehensively and systematically, mainly selected from the functional quality indicators and technical quality indicators, and overcome shortcomings like one-sidedness and so on.

(2) Principle of concise and science: The selection of indicators should be able to reflect the quality of rail freight service accurately and timely , have a simple method, and meet requirements of simple and scientific .

(3) Principle of stability and comparability: The results of the general assessment is a quantitative value, need to be applied to the practice, promoted to the public, meet the demands of enterprises of all types at different levels, and suit for horizontal comparison and analysis, so the evaluation index must be quantified, in order to reduce the influence of subjective factors by statistics and calculations.

(4) Principle of operability and flexibility: General assessment of the quality for rail freight service will generate new customer expectations, and promote freight companies to take corrective action, but if the rail freight enterprises cannot improve in a particular area, we should cancel the terms of evaluation index, ie the selection of indicators should be realistic and operable, and can be convenient collected.

(5) Principle of independence: Low degree of correlation between the indicators can effectively avoid intersectional, overlapping content covered by different indicators.

(6) The principle of customer satisfaction: That evaluation indicator system determined by the customer is the most basic requirement of the establishment of index system, we need to grasp the needs of customers accurately, and choose the most important evaluation indicators customers think.

3 The Establishment of the Indicator System

The quality evaluation indicator system for rail freight services is a method for National Railway Administration to supervise and evaluate the quality of rail freight services from the perspective of a third party. At present, rail freight has developed to become managers, organizers and operators of rail freight' acceptance, transport (including multimodal transport and door to door service), delivery, inquiries, complaints, and compensations. A very wide range of its business makes it difficult to proposed evaluation indicators for all parts related to their business. Therefore, the quality evaluation indicator system for rail freight services will examine seven aspects from perspectives of customers and rail transport enterprise ,including the arrival time, cargo damage、complaint handling、transportation cost、information services、Freight station service and freight operation service according to the production process.

3.1 Indicators from internal production

Existing evaluation indicators of rail transport enterprise emphasis on internal production management，through collecting statistical indicators from rail freight department and the communication with experts from rail freight department, we select effective indicators to evaluate the quality of freight services as Table 1

Table 1 The meaning of indicators from internal production

First level index	Second level index	The meaning of indicators
The arrival time	The ratio of punctuality	Batches of cargo arrived timely/ The total number of batches of cargo
Cargo damage	The ratio of cargo damage	Batches of cargo damage/ The total number of batches of cargo
	The ratio of compensation	The compensation of cargo damaged/ The total number of freight revenue
Complaint handling	The ratio of complaint	The number of customers' complaint / The number of customers
	The ratio of handling complaint satisfactorily	The number of handled complaints with customer' satisfaction/ The number of customers' complaint
Information services	The ratio of replying telephone satisfactorily	The number of telephone connected and get an evaluation "satisfaction" / The number of telephone connected

3.2 Indicators from customer satisfactory

Customer is a main part of quality evaluation for rail freight service, through the conversation with large customers of rail freight as well as questionnaires to rail customers, we conclude the factors that customer mainly concern, shown in table 2.

Table 2 The meaning of indicators from customer satisfactory

First level index	Second level index	Questions
The arrival time	The satisfaction of arrival time	Are you satisfied with the arrival time of cargo?
Cargo damage	The satisfaction of cargo damage	Are you satisfied with the safety of cargo
		Are you satisfied with the compensation service?

Transportation cost	The satisfaction of transportation cost	Are you satisfied with the transportation cost?
Complaint handling	The satisfaction of complaint handling	Are you satisfied with the way for complaint?
		Are you satisfied with the results of complaint?
Information services	The satisfaction of information services	Are you satisfied with the service of information inquiry（including the Internet and the telephone）?
Freight station service	The satisfaction of freight station service	Are you satisfied with the attitude of service in freight station?
		Are you satisfied with the environment of freight station ?
		Are you satisfied with the ease of handling process(including on Internet and in freight station)?
		Are you satisfied with the service facilities in freight station?
Freight operation service	The satisfaction of freight operation service	Are you satisfied with the service of acceptance in the originating station?
		Are you satisfied with the quality of loading and unloading of freight?
		Are you satisfied with the assigning work of railway container?

3.3 Sources of indicators

The quality evaluation indicators of rail freight services can be divided into two categories, namely quantitative indicators and qualitative indicators, both complement each other, and improve accuracy and objectivity of the evaluation ,but different indicators have different sources:

(1) For indicators from internal production，we may collect from the rail freight information system, such as railway production information system, railway e-commerce platform, railway operation management system of customer service center and so on.

(2) For indicators from customer satisfactory, We may collect from doing research on customers. The research can be carried out by a third-party professional organization, which is independent of the government and rail freight enterprise. The research on customers needs a combination of periodic surveys and occasional surveys, and must form an investigation report at last.

4 Conclusions

The quality evaluation indicator system for rail freight services proposed above is based on an extensive field research and interviews with experts, and is more close to the actual work and the demand of customers. After the indicator system, we use fuzzy comprehensive evaluation method for evaluating, taking into account the enterprise technical indicators and customer satisfaction, and propose an exercisable implementation process for the quality evaluation of rail freight services, which will cause a more accurate assessment results than ever.

Abstract: The single variety of goods transportation route optimization is the basic link of organization and implementation of multimodal transport. Transport costs, transport time, multimodal transport network carriage capacity and change trains ability are the main factors affecting the multimodal transport path selection. The multimodal transport network is described as a simple undirected graph. Contrast and analyze the network characteristics. Based on the parameters definition and borders assumption, using point-arc model, structure the multimodal transport path selection model of a single variety of goods. Further analysis found that: through transforming the network and reconstructing the objective function, it can simplify a linear constraint model about shortest path.
Keywords: Multi-modal transport; Transportation path; Optimization model.

1 Introduction

In recent years, the demand for structure of transportation has been changed. The demand for mass freight has relatively substantially declined, but bulk freight and other types of goods demand have a rapid increase. Therefore, enterprises have to provide more efficient and personalized transportation services.

Cargo transport in human economic activities plays a very significant role, also provides basic material guarantee for the sustainable development and human survival economy. Because of this, cargo transport on the economic, social and human development of the country plays a vital role. Multimodal transport, an advanced form of transport organization, is a transport activity through which transport enterprises can integrate the technical and economic advantages of transport. Multimodal transport is the innovation of the method of transportation organization; also it can reduce transportation costs effectively, improve the efficiency of transportation, enrich the types of cargo, as well as expand the service scope of transportation enterprises.

The main job of transportation path selection is to select a transportation route between the start and end point, and allocate the freight volume rationally to each city node, thereby forming a viable transportation scheme. Path selection is a significant part of organization and implementation of multimodal transport.

In the past, most of the studies explored that constructing a multi target model of path selection about minimum transport times and costs, reasonable path set as the basis for the choice of path. However, the network description and model structure had some problems. But for a single variety of goods, there would be no network transport volume distribution problem, the effect of capacity constraints limit is so minimal. We can use the point-arc model, and the form will be simpler.

2 Influence Factors of Path Selection

Considering the whole process of intermodal transportation companies completing the tasks, the route selection is affected by multiple factors, including transport costs, transportation time, multimodal transport network carriage capacity, change trains ability in the city node and other factors.

(1)Transport cost

Transport cost is the major basis of how the multimodal transport enterprises select routes and transportation solutions. As for multimodal transport enterprises, faced with increasingly fierce competition on the transportation market, effectively reducing the costs is of vital importance to their survival and development. By utilizing reasonable transportation solutions, multimodal transport enterprises can effectively reduce the costs and thus acquire greater pricing space, which effectively improves their competitiveness and viability in the market.

(2) Transport time

Shorter transport time means rapid speed of goods turnover and transportation of goods with high efficiency. In the actual transport process, multimodal transport enterprises need to balance transport time and cost, and find the most favorable transportation scheme.

(3) Network transport capacity

The maximum volume of freight transport line can load, which constitutes the basis of the transportation network. The transport capacity will be greatly restricted multimodal transport enterprises to develop transport organization flexibility.

(4) Nature of goods

This is one of the important factors of transportation path choice. Generally speaking, coal, iron and steel, oil and other mass freight would certainly not use air transport and high effectiveness of goods will not be transported by water.

3 Multimodal Transport Network

3.1 Network description

Transport network can be described as a simple undirected graph $G (V, E, C, T, H, F)$, V, a set of nodes, means city; E, a set of undirected arc, means some modes of transport between two cities; C is a set of arc capacity; T is a set of arc time; H is a set of arc cost; F is a set of goods flow.

3.2 Multimodal transport network characteristics

Compared with the single mode of transport, Multimodal transport has some obvious differences.

(1)More nodes. Due to a variety of modes of transport, farther transport distance, larger transport cover areas.

(2) More alternative modes of transport.

(3) Problem is on a larger scale.

4 Model Constructions

4.1 Boundary assumption

(1) Assuming that a single variety of goods and its corresponding transport OD determined completely

(2) The structure of transportation network has been completely determined.

(3) The cargo can't exceed the time limit in the transport process.

(4) The cargo in transform modes of transport allows only one mode of transport to carry.

(5) The cargo isn't allowed to contain a loop in the transport path.

4.2 Define variables and parameters

T_{ij}^{k}——the transport time cost in code i to j by using the k mode of transport.

T_{i}^{kl}——the time cost about a mode of transport by the k converted to l.

C_{ij}^{k}——the transport capacity of the k mode of transport in code i to j.

C_{i}^{kl}——the change trains ability of transport by the k converted to l in code i.

H_{ij}^{k}——the transportation cost in code i to j by using the k mode of transport.

H_{i}^{kl}——the transfer cost in code i of transport by the k converted to l.

$$Y_{ij}^{k}=\begin{cases}1 & using\ the\ k\ mode\ of\ transport\ in\ code\ i\ to\ j\\0 & otherwise\end{cases}$$

$$X_{i}^{kl}=\begin{cases}1 & transport\ by\ the\ converted\ to\ l\ in\ code\ i\\0 & otherwise\end{cases}$$

4.3 Objective function

The objective function is determined as the minimum total transportation cost, including transportation costs inside city and transfer cost.

$$\min Z = Z_{y} + Z_{z} = Q\cdot\left(\sum_{k=1}^{M}\sum_{i=1,i\neq j}^{N}\sum_{j=1}^{N}H_{ij}^{k}\cdot Y_{ij}^{k}+\sum_{i=1}^{N}\sum_{k=1}^{M}\sum_{l=1}^{M}H_{i}^{kl}\cdot X_{i}^{kl}\right)$$

4.4 Constraint condition

(1) Path constraint

$$\begin{cases} \sum_k \sum_a Y_{ab}^k - \sum_l \sum_c Y_{bc}^l = 0 & \left(b \notin \{\mathrm{O,D}\}\right) \\ \sum_k \sum_a Y_{\mathrm{O}a}^k = \sum_l \sum_c Y_{c\mathrm{D}}^l = 1 & \end{cases} \tag{1}$$

$$\sum_{k=1}^{M} \sum_{i=1}^{N} \sum_{j=1}^{N} Y_{ij}^k \le 1 \tag{2}$$

Through (1) to ensure that the goods form a complete path in OD, through (2) to ensure that the path does not contain the "ring" structure.

(2)Transit constraint

$$\begin{cases} \sum_k \sum_j Y_{ij}^k \ge \sum_k \sum_l X_i^{kl} & (i \ne \mathrm{O}) \\ \sum_k \sum_i Y_{ij}^k \ge \sum_k \sum_l X_j^{kl} & (j \ne \mathrm{D}) \\ \sum_k \sum_l X_{\mathrm{O}}^{kl} = \sum_k \sum_l X_{\mathrm{D}}^{kl} = 0 & \end{cases} \tag{3}$$

$$\left(\sum_a Y_{ab}^k - \sum_c Y_{bc}^l \right) X_b^{kl} = 0 \tag{4}$$

$$\sum_{i=1}^{N} \sum_{k=1}^{M} \sum_{l=1}^{M} X_i^{kl} \le R \tag{5}$$

The (3) ensure that goods are only in the transport path to transfer, (4) means using the same method of transportation through the node is also considered a transfer, (5) ensures the required number of transit.

(3)Transport capacity constraints

$$\left(Q \cdot X_i^{kl} \le C_i^{kl} \right) \cap \left(Q \cdot Y_{ij}^k \le C_{ij}^k \right) \tag{6}$$

(4) Transport time constraint

$$\sum_{k=1}^{M} \sum_{i=1}^{N} \sum_{j=1}^{N} T_{ij}^k \cdot Y_{ij}^k + \sum_{a=1}^{N} \sum_{l=1}^{M} \sum_{m=1}^{M} T_a^{lm} \cdot X_a^{lm} \le T \tag{7}$$

This constraint ensures that the total transportation time does not exceed the time limit of requirements.

(5) Ordinary variables constraint

$$Y_{ij}^{k}, X_{i}^{kl} \in \{0,1\} \tag{8}$$

4.5 Model Analysis

(1) This model is a nonlinear programming, due to (4), in order to ensure the corresponding transit and transportation mode so produced quadratic term.

(2) For (6) its essence is consistent with res.8, it can use the method of simplified network to slack off those constraints.

(3) The objective function form are same with (7), it can directly be constructed as a part of objective function.

5 Conclusions

Transport network path optimization for a single variety of goods is the basis for optimization problem. Its essence is a simple network shortest path problem. For many varieties of goods transport task problem in a certain limit number of locomotive arriving at depot conditions, is same with optimal locomotive routing problem. For node splitting, network reconstruction, algorithm design, all of those are the focus of the next step research.

Preponderant Haul Distance of the Harbin-Dalian High-Speed Railway under Competition

Xu Zhang; Jitao Li; Zhiyuan Wang; and Yu Wang

School of Traffic and Transportation Engineering, Dalian Jiaotong University, Dalian 116028, China. E-mail: 86578692@163.com

Abstract: After the operation of Harbin-Dalian high-speed railway, the market share of air transport in northeast area declined obviously because high-speed railway took over a part of aviation customers in various haul distances. On the basis of analyzing the influencing factors on travelers' choices in high-speed passenger transport, this paper provided a questionnaire based on SP survey. Through the field investigation in Dalian and Harbin, Logit model to analyze the preponderant haul distance of high-speed railway was demarcated. After solving the model and analyzing the competitive edges of Harbin-Dalian high-speed railway in different haul distances.
Keywords: Integrated transportation; Dominate transport distance; Logit; Passenger-sharing rate; Competition.

1. Introduction

Harbin-Dalian High-speed Railway is the important constituent part of Beijing-Harbin Passenger Dedicated Line in the "four vertical and four horizontal" system of China's high-speed railway, it is the "aorta" of high -speed transport in northeast China, at the same time, it is also the current high speed railway with highest designing construction standard in the most northern cold region of China, it was officially opened on December 1st, 2012. Seeing from the statistical data of relevant departments in Dalian city, the loss of business customers of Dalian civil aviation is about 40 percents, the shock of high-speed railway is obvious. Civil aviation passenger transport will adjust flights and fares to redeem the loss customers, and the competition between high-speed railway and civil aviation in northeast China region will become more intense.

This paper chooses Harbin-Dalian line as the study area, and has made indeed SP questionnaire survey to the passengers, analyzed the results, and identified the factors which influence passengers' travelling choices, demarcated Logit, and constructed high-speed railway's preponderant transport distance analytical model with the competition of civil aviation, discusses the preponderant transport distance of high-speed railway.

2. Modeling

A The construction of competition model and the utility function testing passengers' choice of high speed passenger transports is comprised of observable utility and random utility. Then the utility function of passenger choosing the k high speed passenger transport can be expressed as

$$U_{ik} = V_{ik} + \varepsilon_{ik} \tag{1}$$

Wherein V is the fixture of the utility function, ε is the probability of the utility function. Currently, there are two ways of high speed passenger transport net of high-speed rail way and air transport, therefore, the probability of high speed rail way to be chosen is.(K1 represents high speed rail way, K2 represents air transport)

$$p(k_1) = \frac{e^{V(k_1)}}{e^{V(k_1)} + e^{V(k_2)}} \tag{2}$$

There are a variety of relationships between V_{ik} in term (1) and the influence variables contained in it, in the specific form, the utility determination function can be expressed by one or more functional forms, taking convenience in results analysis and coefficients marking into accounts, currently linear function is commonly used as an expression for the utility function, namely

$$V_{ik} = \sum_{j=1}^{n} \theta_j X_{ikj} \tag{3}$$

Wherein X_{ikj} is the j influence factor of i passenger choosing the k high speed passenger transport, θ j is the parameter X_{ikj} corresponds to. Term (5) can be expressed as

$$p(k_1) = \frac{e^{\sum_{j=1}^{n} \theta_j X_{ik_1 j}}}{e^{\sum_{j=1}^{n} \theta_j X_{ik_1 j}} + e^{\sum_{j=1}^{n} \theta_j X_{ik_2 j}}} \tag{4}$$

$$p(k_2) = 1 - p(k_1) \tag{5}$$

3 .The calibration of Influence factors

Before travel, travelers usually in the subconscious, based on subjective ideological factors choice which way to travel. Through the analysis of disaggregate model of the individual requirements of the traveler's property, The main factors affecting the selections of high-speed passenger transportation way can be divided into personal attributes, transport properties and trip properties, each attribute contains factors and define variables as shown in table 1.

Table 1.BL model parameters table

	Factors	Variable	Explanation
Personal Attributes	Sex	X1	Men 1,Women 2
	Old	X2	Divided into 5 age groups: under 18, 18 to 30, 31 to 50, 51 to 60, 61 years and older, X2 values of 1 to 5
	Profession	X3	Professional for five: Students, civil, servants, enterprise staff, teachers and others,X3 values of 1 to 5
Transport Properties	Fare	X4	Ticket prices according to the discount division: the full price, 7 fold,5 fold, 4 fold, 3 fold and the following, X4 values of 1 to 5
	Punctuality Rate	X5	Punctuality rate divided according to time delays: On time,$0 < L\leq 0.5h$,$0.5h < L\leq 1h$,$1h < L\leq 1.5h$,$1.5h < L\leq 2h$,$L > 2h$, X5 values of 1 to 5
	Occupied Space	X6	Occupied space is divided into: $0 < S\leq 0.5m3$,$0.5 m3 < S\leq 1 m3$,$1 m3 < S\leq 1.5 m3$,$1.5 m3 < S\leq 2 m3$,$S > 2 m3$, X6 values of 1 to 5
	Security	X7	In accordance with the number of incidents classified as 1,2,3,4,5 and above, X7 values of 1 to 5
	Interval	X8	Interval is divided into: 1h,2h,3h,4h,5h and above, X8 values of 1 to 5
Trip Properties	Trip Purpose	X9	Travel purpose is divided into: school, travel, friends and relatives, business and others, X9 values of 1 to 5
	Trip Distance	X10	Trip distance is divided into:0 to 500km,501 to 1000km,1001 to 1500km,1501 to 2000km,2001km and above, X10 values of 1 to 5
	Before Time and After Time	X11	Before time and after time is divided into: 0.5h,1h,1.5h,2h,2h or more, X11 values of 1 to 5
	Before Cost and After Cost	X12	Before cost and after cost is divided into:30yuan,50yuan,100yuan,150yuan, 200yuan or more, X12 values of 1 to 5

4. Model calibration and result analysis

Since there are many influence factors involved in the questionnaire, so parts of the influence factors are selected, which are the five influence factors of age, costs for reaching the junction station, journey fare, time for reaching the junction station and waiting time, the survey data is integrated again, and Guibiogeme software is used to solve the model and calibrate model parameters, the calibration results of each parameter are seen in Table 2.

Table 2. The parameters of the model calibration results

Influence factor	Variable		Parameter values	T_ test	P_ test
ASC_ civil aviation		α_7	2.54	2.86	0.00
ASC_ high-speed railway		α_6	0.00		
Age	X_1	α_1	1.10195	2.23	0.01
Costs for reaching the junction station	X_2	α_2	-0.259	-0.04	0.06
Journey fare	X_3	α_3	-0.00786	-1.02	0.03
Time for reaching the junction station	X_4	α_4	-3.57	-3.36	0.05
Waiting time	X_5	α_5	-3.07	-0.98	0.04

According to the values of t_ test and p_ test in Table 3, test indexes of each factor meet with the accuracy requirement after query. It can be seen from the parameter values of each influence factor that the parameters of other influence factors are negative values except age, and it shows that the utility of this kind of trip mode increases with the decrease of costs before journey, whole time before journey and journey fare. So influence factors calibrated in Table 3 can be used to establish the utility model in Formula 6, and the data of questionnaire can be used for analysis.

$$U_i = \alpha_1 X_1 + \alpha_2 X_{2i} + \alpha_3 S_i c_i + \alpha_4 X_{4i} + \alpha_5 X_{5i} + \alpha_6 R_{HSR} + \alpha_7 R_{air} + \varepsilon_i \qquad (6)$$

$\alpha_1 - \alpha_7$ in Formula are the corresponding calibration coefficients of influence factors in Table 4, X1、X2i、X4i、X5i corresponds to the influence factors in Table

2; Si represents the transport distance of the i kind of transportation mode; c_i represents the freight rate of per unit distance of the i kind of transportation mode; $S_i c_i$ is the fare, according to the current pricing situation of high-speed railway fare and air ticket, the freight rate of per unit distance of high-speed railway is 0.43 Yuan per kilometer, and civil aviation passenger transport is 1.16 Yuan per kilometer, the freight rate of per unit distance of civil aviation passenger transport is 0.812 Yuan per kilometer when air ticket fare is 30% off, and it is 0.464 Yuan per kilometer when air ticket fare is 60% off. The related attribute value of high-speed railway and civil aviation passenger transport can be seen in Table 3 according to the investigation.

Table 3.The related attribute value of Harbin Dalian line of high speed railway and civil aviation passenger transport

	Fare（yuan）	Trip distance（km）	Time before journey（min）	Costs before journey（yuan）
High-speed railway	400	921	48	33
Civil aviation passenger transport	1 200	857	54	36

It is assumed that the transport distance of two kinds of high-speed transportation mode of high speed railway in Harbin Dalian line and civil aviation was the same, and then Formula 6 can be used to calculate the market shares of high-speed railway and civil aviation in different transport distances according to the above conditions of utility model and parameter setting, the calculation results are shown in Figure 1.

It can be seen in Figure 1 that the variation tendencies of high-speed railway share rate curve under different air ticket discounts are basically the same, the most intense competition (the both sides share the market equally, which means that the market share rate of high-speed railway and civil aviation is equal to 0.5) transport distance changes from 1000km to 850km between high-speed railway and civil aviation with the decrease of air ticket price. It shows that the preponderant transport distance of high-speed railway reduces, and the competitive advantage of civil aviation increases with the decrease of civil aviation ticket price.

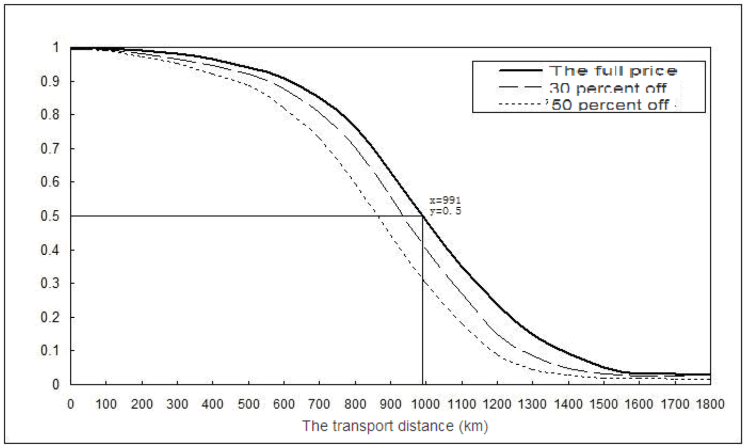

Fig1. Civil aviation under the competition of Harbin Dalian high speed railway passenger transport sharing rate and distance diagram

We analyze the share rate change of high-speed railway when civil aviation is full price at the same time, it can be seen from the figure obviously that there are two mutational sites in the curve, the first mutational site is in the distance of 700km, the passenger transport share rate of high-speed railway is 0.85 at the moment, the second mutational site is in the distance of 1400km, the passenger transport share rate of high-speed railway is 0.092 at the moment. The passenger transport share rate of high-speed railway has been at a higher level in the transport distance range of 0 to 700km; in the range of 700 to 1400km, the passenger transport share rate of high-speed railway decreases sharply with the increase of transport distance; the passenger transport share rate of high-speed railway decreases below 0.1 when the transport distance is above 1400km, and the decline range of share rate starts to decrease with the increase of transport distance.

5. Analysis on the preponderant transport distance of Harbin Dalian high speed railway

Considering that the current shortest voyage of civil aviation in our country is 150km, so Analysis on the preponderant transport distance starts with the transport distance above 150km.

(1)The transport distance of 300km to 600km

It can be seen from Figure 1 that high-speed railway still can bear more than 90% passenger flow volume with its advantages and characteristics in competition with civil aviation transportation. In this transport distance, the decline change of passenger transport share rate of high-speed railway is not obvious with the increase of transport distance in competition with civil aviation transportation, it is because that in this range of transport distance, high-speed railway has inborn advantages in aspects of travel time, travel cost, convenience and so on. The total travel time of high-speed railway is less than civil aviation transportation, and junction stations of high-speed railway are easier to connect with urban transport, the travel cost is lower than civil aviation transportation obviously. Along the line of Harbin Dalian high speed railway, the distance between Shenyang and Dalian is 400km. Hainan Airlines used to open the airline in the interval of Shenyang and Dalian, the lowest fare is 360 Yuan, a group per day, and the run time is 50 minutes, the overall travel time is more than 210 minutes if time before journey and check-in time is calculated. And the fare of second-class seats of high-speed railway that opened on December, 2012 is 180 Yuan, there are 35 high-speed trains every day, the run time is 115 minutes, the overall travel time of passengers is about 180 minutes when time before journey and waiting time is calculated. It can be seen that no matter on cost or travel time, high-speed railway both has advantages over civil aviation transportation in this transport distance.

(2)The transport distance of 600km to 800km

It can be seen from Figure 4-1 that the absolute advantage of high-speed railway starts to weaken with the increase of transport distance in competition with civil aviation transportation. It is because that the rapidity advantage of high-speed railway weakens with the increase of transport distance in the range of 600 to 800km, and it is the initiative transport distance that civil aviation transportation starts to give full play to its rapidity advantage in this range of transport distance, the rapidity of civil aviation transportation brings corresponding passenger flow volume for it. But on the whole, the transport distance is also in the range with advantage of high-speed railway, the mode share forecast of high-speed railway can still accounted for more than 70%.

(3) The transport distance of 800km to 1200km

The transport distance range is the region with intense competition between high-speed railway and civil aviation, at the same time, the market domain is paid close attention by high-speed railway and civil aviation. The competitive advantage of high-speed railway within this transport distance scope is decreasing rapidly, and the corresponding side is competitive advantage of civil aviation grows rapidly, both of the two want to take advantage in the competition, and therefore, the competition is quite fierce. The economy-class high-speed railway ticket between Changchun and Dalian is 304 Yuan, and the run time is 154 minutes.

Abstract: In order to provide different result to the decision makers with different risk preference of hazardous materials transportation adaptively, we bring conditional value-at-risk (CVaR) modal into the risk assessment question of multimodal transportation of hazardous materials. First we analyzed the entire process of multimodal transportation of hazardous materials systematically, and then we built the CVaR model, and tried to change the traditional model into a new optimization model. According to the characteristics of the model, we designed an algorithm based on node-arc. A numerical example shown that CVaR model of different confidence level could be solved by the algorithm quickly and efficiently. The results show that the CVaR model could cover risk preference from risk-neutral to risk-averse, and it is a more proper and flexible risk measure for multimodal transport of hazardous materials decision making.
Keywords: Hazardous materials; Risk assessment; CVaR model; Multi-modal transportation; Link-based algorithm.

1 Introduction

Hazardous materials (hazmat) are usually transported by highway, rail and water, etc. Since China is currently in the process of industrialization phase, the transportation volume of hazmat is increasing year by year. With the increase in volume, the number of hazmat transportation accidents are increasing too. Taking into account that the low accident probability and low cost characteristics of railway and waterway, and the flexibility and convenience of highway, multimodal transportation that combine the advantages of various modes has become a major choice of long-distance transport of hazmat.

In hazmat transportation research field, risk assessment problem has been extensively studied, and the detailed review is in Shuai (2014). But in the field of multimodal theory, risk assessment problem is mainly involved with other problems. Verma (2010, 2012a, 2012b) published three papers which defined hazmat rail-road intermodal transportation total risk as the summation of in-bound and out-bound highway transportation risk and rail-haul transportation risk while studying hazmat network design problem, and among them, the first two papers chose population exposure as risk measurement index, and the last one chose expected consequence. Xie (2012) also chose expected consequence as the index while studying hazmat location routing problem, and define the total risk as the summation of transportation risk of each arc and the transshipment risk of each node along the path. Wei Hang described total risk as the summation of transshipment and transportation risk, but gave no specific risk measurement model. Kai Yanxia (2009) define total risk as the expected loss of intermodal transportation accidents of link and transshipment accident of nodes.

CVaR model is proposed based on VaR model. Kang (2014) pointed out that traditional risk assessment models (such as tradition risk, population exposure et al.) only reflect limited risk preference, therefore, she proposed VaR risk assessment model of hazmat transportation, and utilize it in the study of hazmat routing problem and network design problem. After that, Kwon pointed out that VaR model may ignore the extremely high risk which is distributed in the long tail, and the author introduced CVaR risk model into hazmat transportation, since CVaR model obviously concerns more about the distribution in the long tail in order to avoid the extreme accident, and CVaR is more appropriate to be used in hazmat transportation.

From the above analysis, we can see that there is lack of systematically study about risk assessment model of the whole process of multimodal hazmat transportation, and the existed study doesn’t provide preference-adaptive risk assessment model for different kind of decision makers according to their risk preference. We verified that CVaR model is flexible (Shuai,2014), scalable and preference-adaptive in assessment of hazmat highway transportation. Thus, in this paper we are about to introduce CVaR model into hazmat multimodal transportation risk assessment problem, build a CVaR model after systematical analysis of the whole process, and design an effective algorithm for the model. Finally, we will test the validity of the model and algorithm through a numerical example.

2.CVaR risk assessment model of hazmat multimodal transportation

2.1 Process analysis of hazmat multimodal transportation

Generally, hazmat multimodal transportation contains three processes. First one is highway drayage, includes inbound drayage and outbound drayage. Second one is long-distance transport, which is to move the goods from the starting to the ending transshipment station, and the carriers often choose railway and waterway. The last process is transshipment operation, which is to transfer goods from one vehicle to another. Therefore, while building the risk assessment model, we have to systematically consider every part of the risk, includes inbound and outbound risk, rail/water haul risk and transshipment risk.

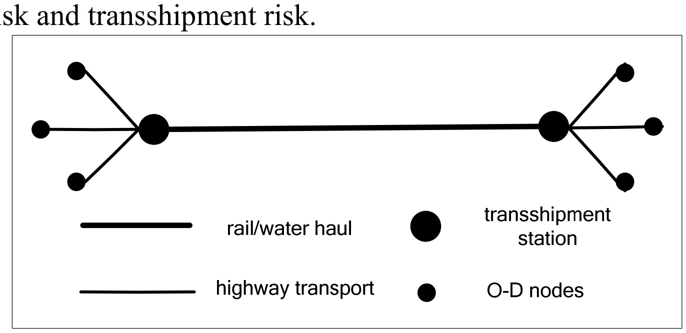

Figure1. Process of hazmat multimodal transportation

2.2 Mathematical models

We consider a graph of hazmat multimodal transportation network $G=\{V,A,A'\}$, where V means the set of nodes, both A and A' are set of arcs, respectively represent all the links and all the transportation modes of the links. Suppose a path l consists of an ordered set of arcs, transportation modes and transshipment nodes $\Re^l=\{(i,j)_\theta^{k'}\in A, i^{k''}\in V: k=1,2,...,m_l;\theta\in A'\}$, where $(i,j)_\theta^{k'}$ is transportation mode θ in the path's k' process, and $i^{k''}$ means the transshipment node i in the path's process k''. For each $(i,j)\in A,\theta\in A'$, accident probability is p_{ij}^θ, and accident consequence is c_{ij}^θ. For each transshipment node $i\in V$, transshipment accident probability is p_i, and accident consequence is c_i. To simplify the calculation, we suppose that the accident probability is of the k step is p_k, and the accident consequence is c_k.

Suppose hazmat is transported along path ,conditional probability of the accident happens in k step is:

$$p_k^l=\left[\prod_{(i,j)^h\in\Re^l, i^h\in\Re^l, h<k}(1-p_k)\right]p_k \tag{1}$$

According to hazmat transportation accident statistics(Abkowitz,1988), accident probability of hazmat transported by rail and highway is extremely small, usually in the range of $10^{-8}\sim10^{-6}$ per mile traveled, and therefore, $\prod_{(i,j)^h\in A^l, i^h\in A^l, h<k}(1-p_k)\approx1$. Thus $p_k^l\approx p_k$. So in the following words, arcs' and nodes' accident probability can be used to replace the conditional probability of that the accident happens in that arc or node in the path.

Set the value of accident consequences of $\Re^l$ in ascending order, and we can get $(C_{(1)}^l,C_{(2)}^l,...,C_{(h)}^l,...,C_{(n_l-1)}^l,C_{(n_l)}^l)$, and the corresponding order ff risk probability is $(p_{(1)}^l,p_{(2)}^l,...,p_{(h)}^l,...,p_{(n_l-1)}^l,p_{(n_l)}^l)$. Among them, $C_{(h)}^l$ means the h th accident consequence of path $l\in\wp$. Then the risk measure R_l of path l takes the following values:

$$R_l=\begin{cases}0, & w.p.\ 1-\sum_{\eta=1}^{n_l}p_{(\eta)}^l\\ C_1^l, & w.p.\ p_{(1)}^l\\ \vdots & \\ C_{(n_l)}^l, & w.p.\ p_{(n_l)}^l\end{cases} \tag{2}$$

Where n_l represents the number of arcs and transshipment nodes of $\Re^l$, and $w.p.$ represents with probability. And for a given R_l, its cumulative distribution function is as follows:

$$F_{R_l}(r)=\Pr(R_l\le r)=\begin{cases}0, & if \quad r<0\\ 1-\sum_{\eta=1}^{n_l}p_{(\eta)}^l, & if \quad 0\le r<C_{(1)}^l\\ 1-\sum_{\eta=2}^{n_l}p_{(\eta)}^l, & if \quad C_{(1)}^l\le r<C_{(2)}^l\\ \vdots & \vdots\\ 1-\sum_{\eta=h}^{n_l}p_{(\eta)}^l, & if \quad C_{(h-1)}^l\le r<C_{(h)}^l\\ \vdots & \vdots\\ 1, & if \quad C_{(n_l)}^l\le r\end{cases} \tag{3}$$

Set $\wp$ to be the paths set of the road network, when the confidence level is α, the VaR value of path $l\in\wp$ is:

$$VaR_\alpha^l=\min\{r:\Pr(R_l\le r)\ge\alpha\} \tag{4}$$

And when the confidence level is α, the CVaR value of path $l\in\wp$ is as follows.

$$CVaR_\alpha^l=\frac{1}{\alpha}\int_0^\alpha VaR_\beta^l d\beta \tag{5}$$

From (5) we can see CVaR means the conditional expectation when the losses exceed VaR.

Formula (5) is difficult to be solved, since VaR_β^l is unknown during the analysis. Based on that, Rockafellar define CVaR as the solution(Rockafellar,2000) of a optimization problem as formula (6).

$$CVaR_\alpha(X)=\min_C\left\{C+\frac{1}{1-\alpha}E[X-C]^+\right\} \tag{6}$$

Where $[t]^+=\max\{0,t\}$.

Inspired by equation (6), since the variable we study in this article is a discrete random one, we can obtain that for a given confidence level α, the CVaR value of path l of hazmat multimodal transportation is:

$$\Phi_\alpha^l(C)=C+\frac{1}{1-\alpha}E[X-C]^+\approx C+\frac{1}{1-\alpha}\left\{\sum_{(i,j)_\theta\in A^l}(p_{ij}^\theta[c_{ij}^\theta-C]^+)+\sum_{i\in V^l}(p_i[c_i-C]^+)\right\} \tag{7}$$

As can be seen from equation (7) , if we want to get the smallest value of CVaR, we have to choose path $l\in\wp$ which has the smallest Φ_α^l when the confidence level is α. That is $\min_{l\in\wp}CVaR_\alpha^l=\min_{l\in\wp,C\in R^+}\Phi_\alpha^l(C)$, where $C\in R^+$ represents C is a positive number. Therefore, we can get formula (8).

$$\min_{l\in\wp} CVaR_{\alpha}^{l} = \min_{l\in\wp, C\in R^{+}} \Phi_{\alpha}^{l}(C)$$
$$= \min_{C\in R^{+}} \min_{l\in\wp} \left\{ C + \frac{1}{1-\alpha} \left\{ \sum_{(i,j)_{\theta}\in A^{l}} (p_{ij}^{\theta}[c_{ij}^{\theta} - C]^{+}) + \sum_{i\in V^{l}} (p_i[c_i - C]^{+}) \right\} \right\} \tag{8}$$

3 Algorithm

Taking into account that the direct calculation method needs all the paths of the OD pair, and it is complicated and difficult to calculate. So we can change the path-based model into traditional link-based model, and then solve the optimization model . The specific process is as formula (9).

$$\min_{l\in\wp, C\in R^{+}} \Phi_{\alpha}^{l}(C) = \min_{C\in R^{+}} \min_{l\in\wp} \left\{ C + \frac{1}{1-\alpha} \left\{ \sum_{(i,j)_{\theta}\in A^{l}} (p_{ij}^{\theta}[c_{ij}^{\theta} - C]^{+}) + \sum_{i\in V^{l}} (p_i[c_i - C]^{+}) \right\} \right\}$$
$$= \min_{x\in\Omega, y\in\Omega', C\in R^{+}} \left\{ C + \frac{1}{1-\alpha} \left\{ \sum_{(i,j)_{\theta}\in A} p_{ij}^{\theta}[c_{ij}^{\theta} - C]^{+} x_{ij}^{\theta} + \sum_{i\in V^{l}} (p_i[c_i - C]^{+} y_i) \right\} \right\} \tag{9}$$
$$= \min_{C\in R^{+}} \left\{ C + \frac{1}{1-\alpha} \left\{ \min_{x\in\Omega} \sum_{(i,j)_{\theta}\in A} p_{ij}^{\theta}[c_{ij}^{\theta} - C]^{+} x_{ij}^{\theta} + \min_{y\in\Omega'} \sum_{i\in V^{l}} (p_i[c_i - C]^{+} y_i) \right\} \right\}$$

Where x_{ij}^{θ} means if link (i,j) use transport mode θ, and y_i means if transshipment happens in node i.

$$\Omega \equiv \left\{ x : \sum_{(i,j)\in A} \sum_{\theta\in A'} x_{ij}^{\theta} - \sum_{(j,i)\in A} \sum_{\theta\in A'} x_{ji}^{\theta} = \begin{cases} 1, & i = o \\ -1, & i = d \\ 0, & otherwise \end{cases} \quad \forall i \in V, x_{ij}^{\theta} \in \{0,1\} \quad \forall (i,j) \in A \right\} \tag{10}$$

$$\Omega' \equiv \left\{ y : \begin{matrix} \sum_{(j,i)\in A} x_{ji}^{p} + \sum_{(i,j)\in A} x_{ij}^{q} - 1 \le y_i & \forall i \in V, y_i \in \{0,1\}, p \in A', q \in A', \text{且} p \ne q \\ y_i = 0 & \forall i \in V, p \in A', q \in A', \text{且} p = q \end{matrix} \right\} \tag{11}$$

Set the value of accident consequences of all the links and nodes in the network in ascending order, and we can get $(C_{(1)}, C_{(2)}, ..., C_{(h')}, ..., C_{(n'-1)}, C_{(n')})$, and the corresponding order of risk probability is $(p_{(1)}, p_{(2)}, ..., p_{(h')}, ..., p_{(n'-1)}, p_{(n')})$. Among them, $C_{(h')}$ means the h' th accident consequence of the links and nodes $\{c_{ij}^{\theta} \,\&\, c_i : (i,j)^{\theta} \in A, i \in V, \theta \in A'\}$. Because $C \in R^{+}$, the value of C could be consisted of the following segments:

$[0, C_{(1)}], [C_{(1)}, C_{(2)}], ..., [C_{(n'-1)}, C_{(n')}], [C_{(n')}, +\infty]$, then defining $C_{(0)} = 0$, we obtain:

$$\min_{x\in\Omega}\sum_{(i,j)_\theta\in A} p_{ij}^{\theta}[c_{ij}^{\theta}-C]^{+}x_{ij}^{\theta}+\min_{y\in\Omega'}\sum_{i\in V^{l}}(p_i[c_i-C]^{+}y_i)$$
$$=\begin{cases}\sum\limits_{(i,j)\in A,\theta\in A',c_{ij}^{\theta}>C_{(h)}} p_{ij}^{\theta}(c_{ij}^{\theta}-C)x_{ij}^{\theta}+\sum\limits_{i\in V,c_i>C_{(h)}} p_i(c_i-C)y_i, if \quad C\in\left[C_{(h')},C_{(h'+1)}\right], h'=0,2,...,n'-1 \\ 0 \qquad if \quad C\in\left[C_{(n')},+\infty\right]\end{cases} \quad (12)$$

Therefore, $CVaR_{\alpha}^{*}=\min_{h'=0,1,...,n'} CVaR_{\alpha}^{h'}$, where problem:

$$CVaR_{\alpha}^{h'}=\min_{C\in R^{+}}\left\{C+\frac{1}{1-\alpha}\left[\min_{x\in\Omega}\sum_{(i,j)\in A,\theta\in A',c_{ij}^{\theta}>C_{(h')}} p_{ij}^{\theta}(c_{ij}^{\theta}-C)x_{ij}^{\theta}+\min_{y\in\Omega'}\sum_{i\in V,c_i>C_{(k)}} p_i(c_i-C)y_i\right]\right\}, C\in\left[C_{(h'-1)},C_{(h')}\right] \quad (13)$$

From formula (13) we know, for each h', we just need to minimize a linear function of C in (13), over the interval $\left[C_{(h')},C_{(h'+1)}\right]$. Since (13) is a linear function, we can get that the optimal value will be obtained either at $C=C_{(h')}$ or at $C=C_{(h'+1)}$. So we can obtain an optimal solution C^* by examining only the values in the set $(C_{(1)},C_{(2)},...,C_{(h')},...,C_{(n'-1)},C_{(n')})$. The function is as follows:

$$CVaR_{\alpha}^{*}=\min_{C=0,C_{(1)},...,C_{(n')}}\left\{C+\frac{1}{1-\alpha}\left\{\min_{x\in\Omega}\sum_{(i,j)\in A,\theta\in A'} p_{ij}^{\theta}\left[c_{ij}^{\theta}-C\right]^{+}x_{ij}^{\theta}+\min_{y\in\Omega'}\sum_{i\in V} p_i\left[c_i-C\right]^{+}y_i\right\}\right\} \quad (14)$$

We can use the following algorithm to solve (14:)

Step 1: For $h'=0,1,...,n'$, solve the following formula (15):

$$CVaR_{\alpha}^{h'}=\min_{C\in R^{+}}\left\{C_{(h')}+\frac{1}{1-\alpha}\left[\min_{x\in\Omega}\sum_{(i,j)\in A,\theta\in A',c_{ij}^{\theta}>C_{(h')}} p_{ij}^{\theta}(c_{ij}^{\theta}-C_{(k)})x_{ij}^{\theta}+\min_{y\in\Omega'}\sum_{i\in V,c_i>C_{(h')}} p_i(c_i-C_{(k)})y_i\right]\right\}, C\in\left[C_{(h'-1)},C_{(h')}\right] \quad (15)$$

Step 2: Let $h'^{*}=\arg\min_{h'=0,1,...,n'} CVaR_{\alpha}^{h'}$。

Step 3: Then we get: $CVaR_{\alpha}^{*}=CVaR_{\alpha}^{h'^{*}}$, and $x^{*}=x^{h'^{*}}$, $y^{*}=y^{h'^{*}}$。

4 Numerical Example

In order to verify the effectiveness of the CVaR risk assessment model and algorithm of hazmat multimodal transportation, we specially set up a simple multimodal transportation network shown in Figure 3. The example network consists of 7 nodes and 11 links. There are three kinds of transportation modes, highway, railway and waterway, and the OD pair of the hazmat is from node 1 to node 7. Each arc has a binary weights, respectively means accident probability and accident consequence. Probability and consequences of transshipment accidents are shown in Table1.

For the above example, we can easily get the results of the optimal CVaR values under different confidence level by using the algorithm described before, in an ordinary PC (OS Windows system , CPU is AMD Turion X2 RM-75 2.20GHz, RAM is 3GB). And the results are shown in table 2. Farther more, in order to compare the CVaR model with other models, we also find the optimal path using other models, and the results are shown in table 3.

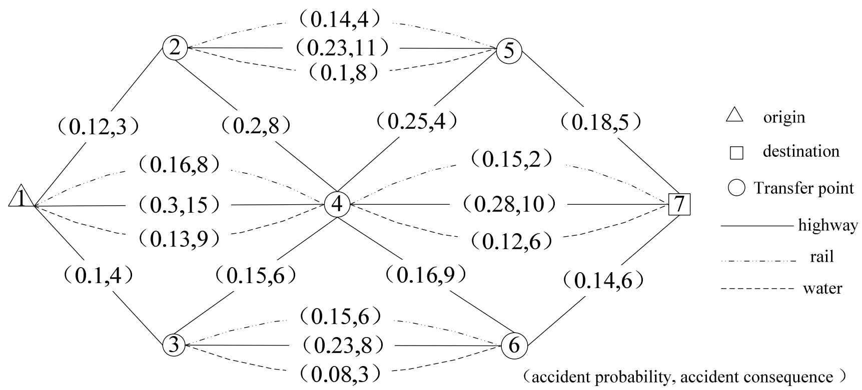

Figure 2. Network of the example

Table 1. Transshipment parameters

Transportation modes	rail		highway		water	
	Accident probability	Accident consequence	Accident probability	Accident consequence	Accident probability	Accident consequence
rail	0	0	0.1	3	0.1	3
highway	0.1	3	0	0	0.1	3
water	0.1	3	0.1	3	0	0

Table 2. CVaR results (R means rail, and W means water)

α	≤ 0	≤ 0.1	≤ 0.2	≤ 0.3	≤ 0.4
CVaR	1.58	1.76	1.98	2.26	2.63
Path*	1-R-4-R-7	1-R-4-R-7	1-R-4-R-7	1-R-4-R-7	1-R-4-R-7
α	≤ 0.5	≤ 0.6	≤ 0.7	≤ 0.8	≤ 0.9
CVaR	3.16	3.95	4.6	4.9	5
path*	1-R-4-R-7	1-R-4-R-7	1-R-4-R-7	1-2-5-R-7	1-2-5-R-7

Table 3. Alternative risk model comparison (TR & IP & PE & VaR & CVaR)

α	≤ 0		≤ 0.1		≤ 0.2		≤ 0.3		≤ 0.4	
model	*VaR*	*CVaR*	*VaR*	*CVaR*	*VaR*	*CVaR*	*VaR*	*CVaR*	*VaR*	*CVaR*
value	0	1.58	0	1.76	0	1.98	0	2.26	0	2.63
number	31	1	31	1	31	1	29	1	24	1
α	≤ 0.5		≤ 0.6		≤ 0.7		≤ 0.8		≤ 0.9	
model	*VaR*	*CVaR*	*VaR*	*CVaR*	*VaR*	*CVaR*	*VaR*	*CVaR*	*VaR*	*CVaR*
value	0	3.16	0	3.95	0	4.6	2	4.9	5	5
number	7	1	4	1	1	1	1	1	2	1
model	TR			IP				PE		
value	1.58			0.25				10		
path*	1-R-4-R-7			1-W-4-W-7				1-R-4-R-7		

From the results in Table 2, we can see that multimodal transportation of hazmat is a more competitive transportation mode. In addition, as can be seen from Table 3, compared with the conventional models, giving a different confidence level α, CVaR model could obtain different optimal solutions, while the conventional model can only obtain an optimal solution. Therefore, CVaR model could provide different path choices according to the different risk preferences of different decision makers. And with low confidence level α, the VaR value of each path might be the same, so the decision makes could choose every path they want, but compared with the VaR model, CVaR model could avoid the big accident in some links , which is more suitable for the hazmat transportation risk assessment problem.

5 Results

In this article we established a CVaR model for hazmat multimodal transportation risk assessment, and taking into the subadditivity of the CVaR model which is different with other conventional models, we customized a link-based algorithm for the model. By a computational experiment, we verified the validity of the model and algorithm. And we obtained that CVaR model has an advantage of the adaptive risk preference compared with the traditional model, and it could avoid the extreme accident to reduce the transportation risk which is different from the VaR model, and it is suitable for risk assessment of hazmat multimodal transportation.

Abstract: This paper analyzes travel mode choice of equilibrium problems in three kinds of travel ways that constituted the way of car, bus, subway. The research subjects are urban residents in the peak period, in the process of travel mode choice selection basis for their own travel costs. Urban road don't have bus lanes, that is to say cars and buses in the mixture on the same roads. In order to make the residents travel mode choice more accord with people's actual travel characteristics, the travel cost function are considered main factors in the residents travel mode choice process. The urban resident's travel mode choice model was established in travel peak period and under the condition of cars and buses mixed driving and based on the user equilibrium theory and the traffic bottleneck theory. Obtain the maximum delay time, the number of trips and travel costs in travel costs equilibrium station. The rationality of the model was verified by a numerical example, the next was further discussed that the high value time of travel and low time value of travel traveler's impact on travel division and time delay are analyzed in comparison. The examples show that: Firstly, subway travel was to be choice of the majority of residents, whether they are high time value of travel or low time value of travel. Secondly, there are more high time value of travel residents choose car travel, compared with the low time value of travel residents.
Keywords: Multi ways of travel; Balance of travel cost; Mode share; Delay time.

1 Introduction

In 1956, Beckmann put forward mathematical programming model to meet the user equilibrium principle based on Wardrop user equilibrium (Wang Wei, 2004) which can be defined as: travelers select the shortest path according to the traffic station, travel costs are the same in the path actually used and less than any unused path (Zhou Jing, 2001). User equilibrium principle is mainly used in route choice, research of travel mode choice barely refer to user equilibrium. We can define travel mode choice equilibrium problem as travel path choice equilibrium problems under the travel network. This will introduce user equilibrium principle to the travel mode choice.

According to the definition of route choice of user equilibrium, travel mode choice equilibrium can be defined as: in the travel peak, all residents travel from the starting points to the ending points will choose minimum cost of travel mode independently, when reaching the station of travel mode choice equilibrium, residents cannot unilaterally change their way of travel and reduce the cost of travel, all travel costs are the same. This paper will research residents travel mode choice under mixed traffic conditions according to the travel mode choice equilibrium and the relevant research results of traffic bottleneck theory (Vickrey, 1969; Arnott et al, 1988, 1990, 1993, 1998; Tabuchi, 1993; Lin Zhen, Yang Hao, 2003, 2004), establishing travel mode choice model to analyze mode share and time delay between high value travel time residents and low value travel time residents under the equilibrium station of travel mode choice.

2 Basic assumptions and associated symbol definition

2.1 Basic assumptions

The travel network consists of cars, buses and subways, residents in the morning peak travel from home to workplaces. The starting point and ending point are connected by a subway line and a road. Assuming cars and buses share a road, there is a bottleneck at the end of the road. The capacity of the bottleneck is s, when the road vehicles exceeds s, people have to queue up and wait to pass the neck.

For cars, travel have no walking time, bus and subway have walking time; comparing the convenience of bus and subway, assuming subway have longer walking time than bus. For buses, departure time interval (q) is fixed, capacities are the same, so the conveying capacity of bus line (S_2) is fixed. Similarly to the metro, conveying capacity (S_3) is fixed too.

Suppose there are N residents travel from living areas (starting points) to workspaces (ending points) every morning, in relatively stable travel process, N can be regarded as constant. Every morning peak, N_1 residents choose cars, N_2 residents choose buses, N_3 residents choose subways, the number of each travel mode is unknown.

2.2 Symbol definition

Symbols are defined as follows:

t ——Departure time of car mode and the time that arrive at the pick-up point of bus and subway;

t^* ——The time of arriving destination on time;

$C_j(t)$ ——The cost of mode j;

T_j^c ——General time of travel mode j in off-peak;

$T_j^e(t)$、$T_j^p(t)$、$T_j^l(t)$ ——When being early, on time or late, queue waiting time at the bottleneck of mode j;

T_2^o、T_3^o ——The time of walking to the bus and subway, assuming constant;

$T_2^d(t)$、$T_3^d(t)$ ——The time of residents waiting at bus station and subway station;

t_j^e、t_j^p、t_j^l ——For cars, they refer to earliest departure time, departure time when arrive on time and latest departure time; For buses and subways, they refer to earliest arriving time, arriving time when arrive on time and latest arriving time at bus station or subway station;

θ_1、θ_2、θ_3——Residents travel cost per unit time, the unit cost of penalty for early and late;

P_j——The fare of mode j;

q——Bus departure interval time;

π_j——uncomfortable cost function produced by crowded inside of mode j;

α、β——uncomfortable cost coefficient produced by crowded outside in the rush hour of bus and subway;

Among them : $j=1,2,3$; represent cars mode, buses mode and subways mode.

3 Model of travel mode choice

In the rush hour, the number of cars equals to N_1; the number of buses has to meet the demand of N_2 passengers, because the transmission capacity of buses is known, departure interval time is known too. So the number of buses in the rush hour is $K = N_2/(qS_2)$.

In order to reduce unnecessary errors in the process of modeling, convert buses into standard vehicles, conversion factor is λ. Therefore, in the rush hour standard vehicle number can be expressed as:

$$N_{12} = N_1 + \lambda K = N_1 + (\lambda N_2)/(qS_2) \qquad (1)$$

3.1 Equilibrium of cars travel cost

Cost for car mode: travel time cost (walking time, bus travel time, queue waiting time and delay time at bottleneck), penalty cost for early or late, fixed monetary cost. Residents can be divided into three categories respectively: early, on time and late. Residents bear the penalty cost for early or late.

Therefore, the cost of all residents that choose car mode can be expressed as:

$$C_1(t)=\begin{cases}\theta_1[T_1^c + T_1^e(t)] + \theta_2[t^* - t - T_1^c - T_1^e(t)] + P_1 & t\in[t_1^e, t_1^p) \\ \theta_1[T_1^c + T_1^p(t)] + P_1 & t = t_1^p \\ \theta_1[T_1^c + T_1^l(t)] + \theta_3[T_1^c + T_1^l(t) + t - t^*] + P_1 & t\in(t_1^p, t_1^l]\end{cases} \qquad (2)$$

When car mode is at equilibrium, residents' travel costs are the same. Suppose in the earliest and latest departure time, there is no delay time at bottleneck. It means residents set out at $t\in(t^e, t^l)$ have to queue up and wait. So in the station of equilibrium, the expected travel costs of residents that set out at $t = t_1^e$, $t = t_1^p$, $t = t_1^l$ are the same. Therefore, following is the equation:

$$E[C_1(t)]=\begin{cases}\theta_1 E[T_1^c] + \theta_2 E[t^* - t_1^e - T_1^c] + P_1 & t = t_1^e \\ \theta_1 E[T_1^c + T_1^p(t_1^p)] + P_1 & t = t_1^p \\ \theta_1 E[T_1^c] + \theta_3 E[T_1^c + t_1^l - t^*] + P_1 & t = t_1^l\end{cases} \qquad (3)$$

Rush hours at the bottleneck starts at t_1^e and ends at t_1^l, so queue waiting duration in the rush hour is $T = t_1^l - t_1^e$. The capacity of a path is determined by the bottleneck, it means $T = N_{12}/S$, therefore:

$$t_1^l - t_1^e = N_{12}/S = (N_1 + \frac{\lambda N_2}{qS_2})/S \quad (4)$$

When cars travel cost is at equilibrium, N_1 residents that choose car mode have same travel cost. Simultaneous equation (3) and (4), to solve t_1^e , t_1^l , t_1^p and $C_1(t)$ in the equilibrium condition of the residents that choose car travel.

$$\begin{cases} t_1^e = t^* - T_1^c - \frac{\theta_3}{\theta_2 + \theta_3} \cdot (N_1 + \frac{\lambda N_2}{qS_2}) \frac{1}{S} \\ t_1^l = t^* - T_1^c + \frac{\theta_2}{\theta_2 + \theta_3} \cdot (N_1 + \frac{\lambda N_2}{qS_2}) \frac{1}{S} \\ t_1^p = t^* - T_1^c - \frac{\theta_2 \theta_3}{\theta_1(\theta_2 + \theta_3)} \cdot (N_1 + \frac{\lambda N_2}{qS_2}) \frac{1}{S} \end{cases} \quad (5)$$

$$T_1^p = \frac{\theta_2 \theta_3}{\theta_1(\theta_2 + \theta_3)} \cdot (N_1 + \frac{\lambda N_2}{qS_2}) \frac{1}{S} \quad (6)$$

$$C_1(t) = \theta_1 T_1^c + \frac{\theta_2 \theta_3}{\theta_2 + \theta_3} \cdot (N_1 + \frac{\lambda N_2}{qS_2}) \frac{1}{S} + P_1, \qquad t \in [t_1^e, t_1^l] \quad (7)$$

3.2 Equilibrium of buses travel cost

The cost for bus mode include: travel time cost, penalty cost for early or late, uncomfortable cost produced by crowded inside and bus fare. Uncomfortable cost produced by crowded inside is associated with travel time and number of passengers, assuming the coefficient is α, so uncomfortable cost produced by crowded is $\pi_2[\alpha T_2^c(t)]$.

The cost of bus mode can be expressed as:

$$C_2(t) = \begin{cases} \theta_1[T_2^o + T_2^c + T_2^d(t) + T_2^e(t)] + \theta_2[t^* - t - T_2^c + T_2^d(t)] + \pi_2(\alpha T_2^c) + P_2 & t \in [t_2^e, t_2^p) \\ \theta_1[T_2^o + T_2^c + T_2^d(t) + T_2^p(t)] + \pi_2(\alpha T_2^c) + P_2 & t = t_2^p \\ \theta_1[T_2^o + T_2^c + T_2^d(t) + T_2^l(t)] + \theta_3[T_2^c + T_2^d(t) + t - t^*] + \pi_2(\alpha T_2^c) + P_2 & t \in (t_2^p, t_2^l] \end{cases} \quad (8)$$

Similar to cars, we can get t_2^e , t_2^l , t_2^p, T_2^w and $C_1(t)$ as follows:

$$\begin{cases} t_2^e = t^* - T_2^c - \frac{\theta_3}{\theta_2 + \theta_3} \cdot \frac{N_2}{S_2} \\ t_2^l = t^* - T_2^c + \frac{\theta_2}{\theta_2 + \theta_3} \cdot \frac{N_2}{S_2} \\ t_2^p = t^* - T_2^c - \frac{\theta_2 \theta_3}{\theta_1(\theta_2 + \theta_3)} [\frac{N_2}{S_2} - (N_1 + \frac{\lambda N_2}{qS_2}) \frac{\alpha}{\theta_1 S}] \end{cases} \quad (9)$$

$$T_2^w = T_2^d + T_2^p = \frac{\theta_2 \theta_3}{\theta_1(\theta_2 + \theta_3)} [\frac{N_2}{S_2} - (N_1 + \frac{\lambda N_2}{qS_2}) \frac{\alpha}{\theta_1 S}] \quad (10)$$

$$C_2(t) = \theta_1(T_2^o + T_2^c) + \frac{\theta_2\theta_3}{\theta_2+\theta_3}\cdot\frac{N_2}{S_2} + \pi_2(\alpha T_2^c) + P_2, \quad t\in[t_2^e, t_2^l] \tag{11}$$

3.3 Equilibrium of subways travel cost

Similar with buses, we can get t_3^e, t_3^l, t_3^p, T_3^d and $C_3(t)$ as follows:

$$\begin{cases} t_3^e = t^* - T_3^c - \dfrac{\theta_3}{\theta_2+\theta_3}\cdot\dfrac{N_3}{S_3} \\ t_3^l = t^* - T_3^c + \dfrac{\theta_2}{\theta_2+\theta_3}\cdot\dfrac{N_3}{S_3} \\ t_3^p = t^* - T_3^c - \dfrac{\theta_2\theta_3}{\theta_1(\theta_2+\theta_3)}\cdot\dfrac{N_3}{S_3} \end{cases} \tag{12}$$

$$T_3^d = \frac{\theta_2\theta_3}{\theta_1(\theta_2+\theta_3)}\cdot\frac{N_3}{S_3} \tag{13}$$

$$C_3(t) = \theta_1(T_3^o + T_3^c) + \frac{\theta_2\theta_3}{\theta_2+\theta_3}\cdot\frac{N_3}{S_3} + \pi_3(\beta T_3^c) + P_3, \quad t\in[t_3^e, t_3^l] \tag{14}$$

3.4 Equilibrium model of travel mode

When travel mode reaching equilibrium station, residents set out at rush hours have same travel cost no matter which mode they choose. A resident cannot reduce his cost by unilaterally changing his travel time or mode. That is to say, in the equilibrium condition of travel modes, meet the formula (15):

$$\begin{cases} C(t) = C_j(t) & N_i > 0 \\ C(t) \le C_j(t) & N_i = 0 \quad i = 1、2、3 \\ N = \sum N_i \end{cases} \tag{15}$$

$C(t)$ is the travel cost in the equilibrium condition of travel modes.

In practical situation, it is impossible that any travel mode isn't selected at rush hours. So, formula (15) can be converted into formula (16).

$$\begin{cases} C(t) = C_1(t) = C_2(t) = C_3(t) \\ N = N_1 + N_2 + N_3 \end{cases} \tag{16}$$

Total number of residents N is known already, $C_1(t)$、$C_2(t)$ and $C_3(t)$ have been calculated respectively；Bringing formula(7),(11) and (14) into (16):

$$\begin{cases} C = C_1(t) = \theta_1 T_1^c + \dfrac{\theta_2\theta_3}{\theta_2+\theta_3}\cdot(N_1 + \dfrac{\lambda N_2}{qS_2})\dfrac{1}{S} + P_1 \\ C = C_2(t) = \theta_1(T_2^o + T_2^c) + \dfrac{\theta_2\theta_3}{\theta_2+\theta_3}\cdot\dfrac{N_2}{S_2} + \pi_2(\alpha T_2^c) + P_2 \\ C = C_3(t) = \theta_1(T_3^o + T_3^c) + \dfrac{\theta_2\theta_3}{\theta_2+\theta_3}\cdot\dfrac{N_3}{S_3} + \pi_3(\beta T_3^c) + P_3 \\ \quad N = N_1 + N_2 \end{cases} \tag{17}$$

We can get C and [N_1, N_2, N_3] by solving formula(17):

$$\begin{cases} N_1 = \dfrac{(S-\frac{\lambda}{q})(B+S_2N)-(S_3+S_2)A}{S_2(S_3+S_2+S-\frac{\lambda}{q})} \\ N_2 = \dfrac{B+S_2N+A}{(S_3+S_2+S-\frac{\lambda}{q})} \\ N_3 = N-N_1^2-N_2^2 \end{cases} \quad (18)$$

$$C=\theta_1(T_2^o+T_2^c)+\frac{\theta_2\theta_3}{\theta_2+\theta_3}\cdot\frac{B+S_2N+A}{S_2(S_3+S_2+S-\frac{\lambda}{q})}+\pi_2(\alpha T_2^c)+P_2 \quad (19)$$

In formula(18)and(19):

$$\begin{cases} A=\dfrac{SS_2(\theta_2+\theta_3)}{\theta_2\theta_3}[\theta_1(T_1^c-T_2^o-T_2^c)+(P_1-P_2-\pi_2(\alpha T_2^c))] \\ B=\dfrac{S_2S_3(\theta_2+\theta_3)}{\theta_2\theta_3}[\theta_1(T_3^o+T_3^c-T_2^o-T_2^c)+(\pi_3(\beta T_3^c)-\pi_2(\alpha T_2^c)+P_3-P_2)] \end{cases} \quad (20)$$

4 Example analysis

According to the equilibrium model of travel mode, set up relevant numerical parameters, show the result by a numerical example, analyze the travel conditions of residents of low and high value of time. A numerical example set parameters are shown in table 1 and table 2.

Table 1. parameters 1

Parameters	N	T_1^c	T_2^c	T_3^c	T_2^o	T_3^o	P_1	P_2	P_3
Value	2000	1.0	1.5	1.2	0.1	0.15	12	2	5

Table 2. parameters 2

Parameters	α	β	S	S_2	S_3	q	λ
Value	0.8	1.2	6000	4000	10000	0.025	2

Parameters of per unit time cost of residents that have low or high value of time are shown in table 3.

Table 3. Parameters of per unit time cost

Parameters	θ_1	θ_1	θ_1
High value of time	20	15	25
Low value of time	15	10	20

According to (18),(19) and(20).and make $\pi_2(\alpha T_2^c)=\alpha T_2^c,\pi_3(\beta T_2^c)=\beta T_3^c$. We can figure the related parameters out in table 4.

Table 4. Numerical value in equilibrium station

Value	C	N_1	N_2	N_3	T_1^p	T_2^w	T_3^d
High Value of time	33.577	5843	3826	10331	0.438	0.402	0.459
Low Value of time	42.766	6825	3228	9947	0.538	0.400	0.466

Figure 1 shows the share rate of three travel modes in equilibrium station.

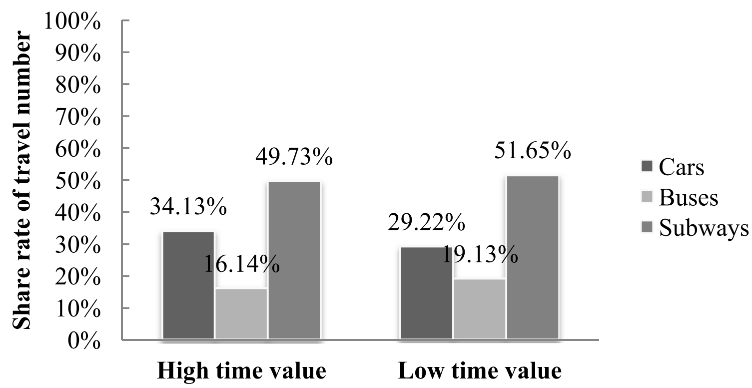

Figure 1. Share rate of three travel modes in equilibrium station

Figure 2 shows the total delay time of residents arrive on time in equilibrium station.

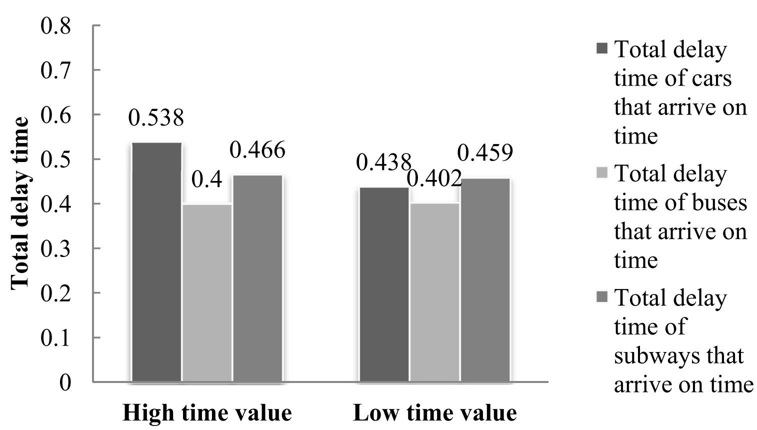

Figure 2. Comparison of total delay time of high and low time values

5 Conclusion

This paper defines travel mode equilibrium choice model based on user equilibrium theory. In the equilibrium model, analyze relevant parameters by numerical example, the result showed that: (1) Residents of high time value prefer car travel than bus travel, which is consistent with actual situation;(2) Summarize from the proportion of all travel modes, whether residents have high or low time value, subway is most residents' choice with the characteristics of time stability, large volume and cheap fares, it also explains why now in many big cities develop orbit traffic to ease urban congestion;(3) The analysis of numerical example also shows the rationality and applicability of travel mode choice equilibrium model.

Service Demand Forecast for an Inland Waterway Service Area: A Case Study on the Grand Canal, China

Peng Liao

Department of Waterway, Port and Coastal Engineering, School of Transportation, Southeast University, P.O. Box 210096, Nanjing, China. E-mail: pliao@seu.edu.cn

Abstract: As a public auxiliary navigation facility for improving the service quality of inland water transport (IWT), inland waterway service area (IWSA), similar to the expressway service area, has been put forward at the Yangtze Delta in China recently. In order to satisfy the service demand, an appropriate water area for the vessel's mooring is a key point for the planning of IWSA. In this paper, with the questionnaire and field survey on main waterways in Jiangsu and Zhejiang provinces, the characteristics of service demand of IWSA were analyzed, such as the type of demand, driving-in rate, turnover rate. A model was established to forecast the service demand, the number of vessels driving-in, based on the traffic stream characteristics. Then the required water area can be calculated with the relationship between the area and tonnages of inland freight vessels. Finally, the method was applied to the Beijing-Hangzhou Grand Canal in the southern Jiangsu province, where the result is in accordance with the practical case.
Keywords: Inland waterway transport; Service area; Demand forecast; Grand canal.

1 Introduction

Inland waterway transport (IWT) is often claimed to be reliable, economic and environmentally friendly for its huge transport capacity (Lowe, 2005). IWT is an important part of the domestic transportation network in many countries and districts, such as China, the U.S., and Europe. They all insist on developing, operating and maintaining the infrastructure of their navigable inland waterway to satisfy the waterway freight demand. In the past decade, an inland waterway service area (IWSA), an excavated water zone along a navigation channel, was put forward to improve the efficiency and service quality of IWT at the Yangtze Delta in China (Wen et al, 2005; Liao et al., 2008).

As a public auxiliary navigation facility, IWSA, similar to the expressway service area (ESA), offers rest, convenience, and safety to vessels and crews. For most vessel's voyage, some fundamental service demands, such as refueling, clean water, fresh vegetables, are very necessary due to the poor living condition of vessels at present. This is also the original intention of the IWSA to provide these services. With the questionnaire and field survey on main waterways at the Yangtze Delta in China, the types of service demand of the IWSA were analyzed (Wen et al, 2005; Liao et al., 2008; Peng et al, 2011; Fan et al., 2014). Peng et al (2011) classified an IWSA into the mooring service area and the comprehensive service area according to the scale and service range, and discussed the site selection and distance for an IWSA. Fan et al (2014) proposed a feasible approach for the site selection of the IWSA whose function was divided into several categories: provision service, regulating service, cultural service, physical health, information exchange and sharing, financial and technical assistance, and repair service.

Based on the characteristics of service demand and the length of service time in the Yangtze Delta, Liao et al (2008) classified the service into three types and analyzed their corresponding service demand probability and averaged service time. The first type (Type I) is a locking service provided by a navigation lock. Due to the congestion on most main waterways in China, those locks almost provides upstream and downstream anchorages and other auxiliary facilities to wait for lockage. So, the existing facilities can be expanded and added functions to accommodate the service demand of the IWSA if necessary. The second type (Type II) is a mooring service independent of locks. The mooring service area can provides mooring at the origin and destination of a trip or having a rest at night during a voyage. The mooring services are characterized a longer time in the IWSA, usually in a few hours and even a few days. Furthermore, the other service demand also can be satisfied during the mooring including refueling, visa, daily necessities, garbage collection, and so on. The third type (Type III) is a brief service independent of locks. The brief service area usually accommodates those vessel paused temporarily for demand within one hour, such as refueling, shopping, logistics information. Obviously, as far as the water area is concerned, Type II and Type III services can be offered simultaneously or individually in a service area while they are separated from Type I.

The demand forecast is an important index for the planning of IWSAs and is also necessary to determine the scale reasonably, striking a balance between the service and investment. The earlier works mostly focused on the number of IWSAs as an index of demand forecasting for site selection (Peng et al, 2011; Fan et al., 2014). However, there is little information for the detailed design of a certain IWSA, such as the maximum vessels accommodated simultaneously, water area required, proper land area, and so on. Therefore, this paper pays more attention to the demand analysis for a certain IWSA based on the investigation by Liao et al (2008). The model is established to forecast the service demand which is denoted by the water area required for an IWSA. Then a case study, an application to the Beijing-Hangzhou Grand Canal in the southern Jiangsu province, is discussed.

2 Methodology

2.1 Method

Generally, it is a queuing process when a vessel drives into an IWSA. The service demand of the IWSA is the average length of the queue, or the mean volume of vessels in the queuing system. If the vessel arrival distribution, service time distribution and queuing discipline are known in advance, the mean length can be determined based on the queue theory. However, there are few researches on the information of the IWSA and considerable error could be made. Since the IWSA is similar to the ESA, it may be a proper method to refer the design of the ESA. For an ESA, the parking space is related with types of facilities, location, traffic volume, pause rate, turnover rate, peak rate, and so on (Japan Highway Public Corporation, 1991). Koo et al. (2014) shows the conventional process for determining the size of a new ESA in South Korea.

Therefore, based on the vessel flow characteristics, the process for determining the water area of the IWSA is shown in Figure 1. According to the observed or estimated vessel volume at a navigable section, the average vessel density can be calculated by the traffic stream characteristics (Gartner et al, 1996). Due to the stochastic vessel flow (Liao, 2013), the averaged vessel density indicates the mean level, and considerable error in density estimation could be made at the peak hour. Liao (2009) introduced a daily-flow disequilibrium coefficient with a guarantee percentage to analyze the temporal stochastic characteristics. So, the vessel density with a certain guarantee percentage can be determined on a navigable segment. Considering the demand probability or driving-in rate and average service time, the service demand, the number of vessels driving in an IWSA, can be forecasted when these factors are quantitatively analyzed by the questionnaire and flied survey. Finally, the water area required to moor those vessels can be determined with the transfer coefficient which comes from the relationship between the area and tonnage (RAT) of inland freight vessels (Liao and Zhang, 2009).

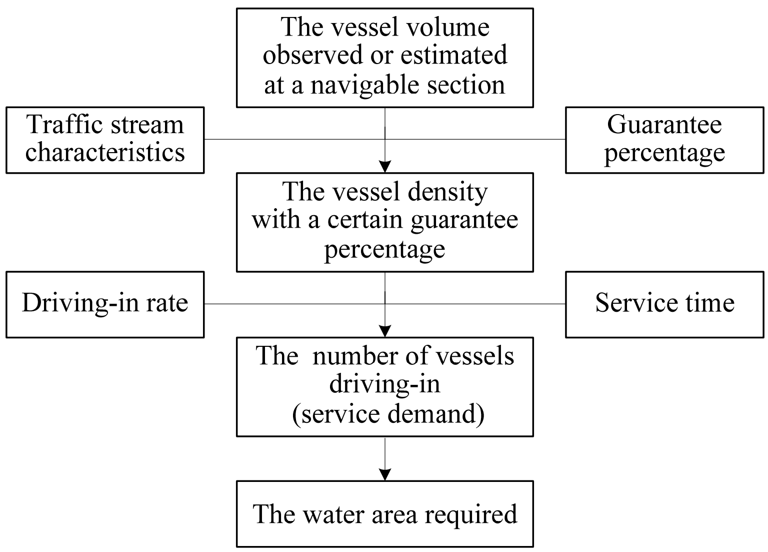

Figure 1. Process for determining the water area of the IWSA

2.2 Model

With the observed or estimated vessel flow on a navigable section at different planning years, the average vessel density can be expressed as:

$$k = \frac{Q}{Tg_a u} \tag{1}$$

where k is the average vessel density on a navigable segment interested (vessels/km); Q is the annual tonnage of vessels through a certain section (tons/a); T is the time of a year, 365 days/a or 8760 hrs/a; g_a is the averaged tonnage of a set of vessels (tons/vessel); and u is the average speed of a set of vessels (km/hr). The vessel density with a certain guarantee percentage is

$$k_p = k\alpha \tag{2}$$

where k_p is the vessel density with a p% guarantee (vessels/km), and the mean has a 50% guarantee, namely, $k = k_{50}$; α is the unit flow disequilibrium coefficient with a p% guarantee. Then, the number of vessels driving into the service area is

$$Q_{sp} = \beta k_p L_s \tag{3}$$

where Q_{sp} is the number of vessels driving into the service area with a p% guarantee (vessels); β is the demand probability or driving-in rate; L_s is the queuing length of vessels driving-in or waiting for service (km), and its value can calculated by

$$L_s = ut_s \tag{4}$$

where t_s is the averaged service time (days or hours). If the queuing length is longer than the length L covered by the IWSA, L_s is equal to L.

So, the water area required to moor those vessels for an IWSA is

$$A_{sp} = \eta Q_{sp} g_a \gamma \tag{5}$$

where A_{sp} is the value of water area with a p% guarantee (m^2); η is a safety factor related with the berthing and entrance/departure styles of vessels, more than one; γ is the transfer coefficient of the area and tonnage of inland freight vessels (m^2/ton).

Finally, combined Equations (1) ~ (5), the water area required for an IWSA is

$$A_{sp} = \eta \frac{Q}{T} t_s \alpha\beta\gamma, \quad ut_s < L \tag{6.a}$$

$$A_{sp} = \eta \frac{Q}{Tu} L \alpha\beta\gamma, \quad ut_s \geq L \tag{6.b}$$

If a service area may cover more than two navigable segments with different vessel flows, the water area can also be expressed as:

$$A_{sp} = \frac{t_s \eta\alpha\beta\gamma}{T} Q_1, \quad ut_s < L_1 \tag{7.a}$$

$$A_{sp} = \frac{\eta\alpha\beta\gamma}{Tu} \sum_{i=1}^{j} Q_i L_i + \frac{\eta\alpha\beta\gamma}{Tu} Q_{j+1} \left(ut_s - \sum_{i=1}^{j} L_i \right), \quad \sum_{i=1}^{j} L_i \leq ut_s < \sum_{i=j+1}^{r} L_i \tag{7.b}$$

$$A_{sp} = \frac{\eta\alpha\beta\gamma}{Tu} \sum_{i=1}^{r} Q_i L_i, \quad ut_s \geq \sum_{i=1}^{r} L_i \tag{7.c}$$

where r is the number of navigable segments covered by the IWSA, a positive integer; Q_i, L_i is the annual vessel flow and length covered by ith (i = 1, 2, …, j, …, r, $r \geq 2$) navigable segment, respectively. It is suggested that the serial number of the sequence begins from the segment where the service area is located or nearest.

For the equation (6) or (7), the several parameters need be discussed carefully before application. Firstly, Q can be observed at present or be estimated for the future, which is not the focus of this paper but can be referred Beuthe et al. (2001). The average speed u can also be observed or estimated easily. The values of α and γ can be analyzed with observed traffic data according to the works conducted by Liao (2009) and Liao and Zhang (2009). The value of η can be referred the design experience of other navigation facilities. Finally, the values of β and t_s can be determined based on the method developed for this work by Liao et al (2008). For example, Table 1 summaries the recommended values of the parameters for each type of service area to determine the water areas of the IWSAs on the Grand Canal in the Yangtze Delta based on the above mentioned investigation and researches.

3 Case Study

The Beijing-Hangzhou Grand Canal, the longest artificial canal in the world since 1400 years ago, becomes an indispensable part of the inland waterway network in China. Nowadays, the Grand Canal plays a huge role for the logistics and economic development at the Yangtze River Delta. Recently, the Grand Canal in the southern Jiangsu province, from the Jianbi Lock (JBL) located in Zhenjiang to Yaziba (YZB) located in Wujiang as shown in Figure 2, has being promoted the infrastructure to accommodate 1000-ton-vessels entirely.

According to the prior work conducted by Zou et al (2007), five different IWSAs, Zhenjiang, Changzhou, Wuxi, Suzhou, and Wujiang, are planned as shown in Figure 2. So, based on the Equation (7) and parameters in Table 1, the service demand and water areas can be calculated and are listed in Table 2.

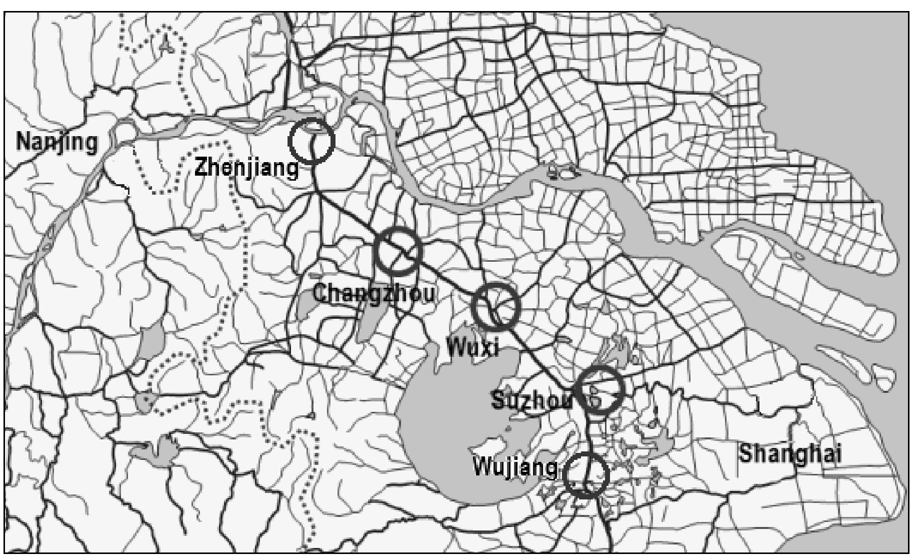

Figure 2. IWSAs on the Grand Canal in the southern Jiangsu

Table 1. List of parameters for the determination of the IWSA

Par.	u	T	t_s	α	β	γ	η
Type I	220 $km \cdot d^{-1}$	365 d	0.2 ~ 1.0 d	1.5*	0.5	$\frac{4.8g_a^{2/3}+56}{g_a}$	1.1 ~ 1.3

* the density with a 98% or 85% guarantee for daily-flow or hourly-flow, respectively.

Table 2 shows that there are maximum 189 vessels to drive into the Zhenjiang Service Area dependent of Jianbi Lock simultaneously, which is in accordance with the practice. The area of the water area required is about 57545 square meters, about eight football fields. The mooring service (Type II) should be considered at Changzhou, Wuxi, and Suzhou to provide anchorage ground for those vessels at their origins and destinations since these segments are important component of the inland ports, which are top ten inland ports in China. Wujiang service area mainly provides the mooring and visa service due to the boundary between Jiangsu and Zhejiang provinces. It should be mentioned that the model and Table 2 only give the size of each service area without the consideration of its site selection.

4 Conclusions

In this study, the service demand and water area required analyzed for the IWSA, a public auxiliary navigation facility similar to the expressway service area. According to the characteristics analysis of service demand in the Yangtze Delta, the demands are classified into a locking service, a mooring service, and a brief service. Based on traffic stream characteristics, the model has been successfully established to forecast the number of vessels driving-in and water area required. The case study shows that the result is in accordance with the practice. This work only pays attention to the demand analysis for a single certain IWSA. More interaction between service demand and site selection of IWSAs can be considered in future studies.

Abstract: For the situation that taxi passenger volume is diverse and uncertain, this paper constructs combined model of gray GM(1,1) and linear regression for a taxi passenger volume forecasting. The model which depends on the sample data itself, use linear regression equation and exponential equation to fit the curve of passenger volume. It requires less sample data and operates simply. The Lhasa city taxi passenger volume prediction indicates that the combined model obtained higher prediction accuracy than a single gray system or linear regression model. Finally, we predict the demand of taxi for the next two years in Lhasa city, and this will play a reference role in the formulation of policies for taxi industry.
Keywords: Taxi passenger volume; GM(1,1) model; Linear regression model; Gray linear regression combination model.

1 Introduction

In the abroad and domestic relevant study of taxi passenger volume, linear regression models are widely used. For example, the existing research of (Xin et al.,2005) tries to give the residents travel intensity regression forecasting method by using the city size, population and disposable income of residents and other explanatory variables. By analyzing the urban population, economic level, travel characteristic factors, taxi operating status and its law of development, the total amount of taxi travel prediction model is established. Instead of studying the internal influence factors and their mutual relations influencing taxi passenger volume, the gray model deem taxi passenger volume gray in a certain range of time-related changes and mine useful information to establish the model, reveal the law and make a prediction from its own data. This paper will combine the two methods, constitute a grey linear regression model, and predict the taxi passenger in Lhasa city as an example to illustrate. Example proves that the combined model obtained higher prediction accuracy than a single model, so it has higher practical application value.

2 Model

2.1 GM(1,1) model

Given $X^{(0)}$ is a non-negative original sequence, $X^{(0)}=(x^{(0)}(1),x^{(0)}(2),x^{(0)}(3),\ldots,x^{(0)}(n))$. After $X^{(0)}$ is accumulated, a new data column $X^{(1)}=(x^{(1)}(1),x^{(1)}(2),\ldots,(x^{(1)}(n))$ is generated, where $x^{(1)}(t)=\sum_{i=1}^{t}x^{(0)}(i),(t=1,2,\ldots,n)$ .z

For the generated sequence $X^{(1)}(t)$, there is a linear first-order albinism differential equation $dx^{(1)}/dt+ax^{(1)}=b$. When t is unit time, the difference form of the first-order differential equation is equal to the differential form, $dx^{(1)}/dt=x^{(1)}(t+1)\text{-}x^{(1)}(t)=x^{(0)}(t)$, so the differential equation of GM(1,1) model can be expressed as $x^{(0)}(t)+ax^{(1)}(t)=b$, which is called the original form of GM(1,1) model(Wang ,2011;Zhou,2005).

In order to obtain a smoother sequence of accumulated generating operation, $X^{(1)}$ is averaged with consecutive neighbors to generate the sequence $Z^{(1)}=(z^{(1)}(2),$ $z^{(1)}(3),z^{(1)}(4),\ldots z^{(1)}(n))$, where $z^{(1)}(t)=0.5(x^{(1)}(t)+x^{(1)}(t-1))$, $x^{(0)}(t)+a\mathrm{Z}^{(1)}=b$ is the basic form of GM(1,1) model, *a* is development coefficient, *b* is grey action, and $Z^{(1)}$ is the averaged sequence of $X^{(1)}$ with consecutive neighbors.

The parameters *a* and *b* of the basic form of GM(1,1) model are estimated with the least square method

$$\begin{bmatrix} a \\ b \end{bmatrix}=(\mathrm{B}^T\mathrm{B})^{-1}B^TY \tag{1}$$

Where $\mathrm{B}=\begin{bmatrix} -Z^{(1)}(2) & 1 \\ -Z^{(1)}(3) & 1 \\ \vdots & \vdots \\ -Z^{(1)}(n) & 1 \end{bmatrix}$ and $Y=(x^{(0)}(2),x^{(0)}(3),\ldots,x^{(0)}(n))^T$. The values of *a* and *b* are substituted into the albinism equation $dx^{(1)}/dt+ax^{(1)}=b$ of GM(1,1) model, and the time response function of GM(1,1) model is as follows:

$$\hat{x}^{(1)}(t+1)=(x^{(0)}(1)-\frac{b}{a})e^{-at}+\frac{b}{a}\ (t=1,2,\ldots,n-1) \tag{2}$$

Its form can be expressed as $\hat{x}^{(1)}(t+1)=c_1e^{at}+c_2$ and regressed to

$$\hat{x}^{(0)}(t+1)=\hat{x}^{(1)}(t+1)-\hat{x}^{(1)}(t)\ (t=1,2,\ldots,n) \tag{3}$$

2.2 Linear regression model

Regression analysis is a statistical analysis method to study the dependence of a random variable Y on another random variable X or a set of variables $(X_1, X_2, \ldots,.$ $X_k)$.The principle of inertia and the correlation theory were used to build the correlation model between the independent variable and the dependent variable affecting changes in taxi passenger volume. Then based on this model and the future value of the independent variable, the future value of the taxi passenger volume was predicted. The taxi passenger volume was taken as the dependent variable to build a regression model as follows:

$$X(t) = aY(t) + b \tag{4}$$

Where t is the actual year, $X(t)$ is the taxi passenger volume, and $Y(t)$ is the most significant factor affecting the taxi passenger volume.

2.3 Grey linear regression model

Use the sum of equation of linear regression and exponent equation for fitting and accumulation to generate the sequence $x^{(1)}(t)$, and generated sequence can be written as:

$$\hat{x}^{(1)}(t+1) = c_1 e^{ut} + c_2 t + c_3 \tag{5}$$

Where: u, C1, C2, and C3 are undetermined parameters.

Given $$Z(t) = \hat{x}^{(1)}(t+1) - \hat{x}^{(1)}(t) \ (t = 1, 2, \ldots, n-1) \tag{6}$$

Given

$$Y_m(t) = Z(t+m) - Z(t), (m = 1,2, \ldots, n-3; t = 1,2, \ldots, n-m-2) \tag{7}$$

Get $u = \ln[Y_{(m+1)}(t+1) / Y_{(m)}(t)]$, change $\hat{x}^{(1)}$ in (5)as $x^{(1)}$, and get approximate solution of the u $\tilde{V}_{(m)}(t) : \tilde{V}_{(m)}(t) = \ln[Y_{(m)}(t+1) / Y_{(m)}(t)]$, calculate the amount of $\tilde{V}$ as $(n-2)(n-3)/2$, that is

$$\hat{V} = \frac{\sum_{m=1}^{n-3} \sum_{t=1}^{n-m-2} \tilde{V}_m(t)}{(n-2)(n-3)/2} \tag{8}$$

Make $L(\mathrm{t}) = e^{\hat{V}t}$, and $\hat{x}^{(1)}(t) = c_1 L(t) + c_2 t + c_3$. Use least square method to get

$$C = \begin{bmatrix} c_1 \\ c_2 \\ c_3 \end{bmatrix} = (\mathrm{A}^T \mathrm{A})^{-1} \mathrm{A}^T X^{(1)} \tag{9}$$

Where $A = \begin{bmatrix} L(1) & 1 & 1 \\ L(1) & 2 & 1 \\ \vdots & \vdots & \vdots \\ L(n) & n & 1 \end{bmatrix}$; $X^{(1)} = (x^{(1)}(1), x^{(1)}(2), \ldots, x^{(1)}(n))^T$. Expectation value of generated sequence is $\hat{x}^{(1)}(t) = c_1 e^{\hat{V}t} + c_2 t + c_3$, it is arrived at: if $c_1 = 0$, linear accumulation generation sequence is linear regression model; if $c_2 = 0$, accumulation generation sequence is GM(1,1), new model improves the cases in which linear regression model does not include exponent increase trend and the GM(1,1) model does not include linear element. Down and restore are conducted as:

$$\hat{x}^{(0)}(t+1) = \hat{x}^{(1)}(t+1) - \hat{x}^{(1)}(t) \ (t = 1, 2, \ldots, n) \tag{10}$$

3 The Example Analysis

Historical statistical datas of annual taxi passenger number from 2008 to 2013 are shown in Table 1 according to the Statistical Yearbook of Lhasa. Table 1 is used for modeling and forecasting results for comparison.This paper intends to compare the predict results of the linear regression model, GM(1,1)model and gray combination of linear regression model and then predict the 2015 and 2017 passenger number in Lhasa.

Table. 1 Taxi passenger volume of Lhasa from 2008 to 2013 (ten thousands)

Years	2008	2009	2010	2011	2012	2013
Taxi passenger volume	1090.2	1249.5	1580.2	1812.9	2228.4	2606.1

3.1 Linear regression forecasting model

Using data in Table 1, respectively draw scatter plot of taxi passenger volume and various factors. A close linear relationship between taxi passenger volume and the year is found while observing the scatter plot shape and the coefficient of determination $r^2 = 0.9827$ is close to the constant 1 indicating that the fitting degree of regression straight line on the sample data points is very high. After solving linear regression equation with method of least squares, values are found to be $a = 307.11$, $b = \text{-}615690$. Get the linear regression equation $X(t) = 307.11t - 615690$ by substituting parameters into formula (3)and predictive value $X^{(0)} = (x^{(0)}(2), x^{(0)}(3), x^{(0)}(4), x^{(0)}(5), x^{(0)}(6)) = (1300.5, 1607.7, 1914.8, 2221.9, 2529)$ can be worked out.

3.2 Grey forecasting model

From previous section, it is known that: select Table 1 data for simulation and set up GM(1,1) model, original sequence is $X^{(0)} = (1090.2, 1249.5, 1580.2, 1812.9, 2228.4, 2606.1)$,conduct linear accumulation generation and close neighbor average value generation on original data, and get the values of B and Y as: $B = [-1714.95, -3129.8, -4826.35, -6847, -9264.25; 1, 1, 1, 1, 1]^T$, $Y = (1249.5, 1580.2, 1812.9, 2228.4, 2$

$606.1)^T$ .Use Matlab software, and substitute B and Y and get a and b as $a=-0.17801$ and $b=977.53$. Substitute a and b into time response function (2), and get $\hat{x}^{(1)}(t+1)=6581.6e^{0.17801t}-5491.4$. Use the equation (3) to conduct down regression and get simulation value of GM(1,1) model for original sequence as $\hat{X}^{(0)}(\mathrm{t})=(1282.3,1532.2,1830.7,2187.4,2613.6)$.

3.3 Gray linear regression combination forecasting model

Set up grey linear regression combination model based on linear regression function and exponent function,then use equations(6)~(8) and Matlab software to calculate $\hat{V}$ value as $\hat{V}=0.087$, linear regression combination model is get according to equation(5) : $\hat{x}^{(1)}(t)=c_1e^{\hat{V}t}+c_2t+c_3=c_1e^{0.087t}+c_2t+c_3$

According to equation (9), use Matlab matrix manipulation tool to get C value as $C_1=32511,\ C_2=-1972.2, C_3=-32400$, and get grey linear regression combination model as : $\hat{x}^{(1)}(t)=32511e^{0.087t}-1972.2t-32400$,then get the forecasting value of gray linear regression combination model as: $\hat{X}^{(0)}(\mathrm{t})=(1251.6,1544.6,1864.2,2213,2593.4)$

4. Error Detection

Forecast passenger traffic from 2009 to 2013 using linear regression model, GM(1,1) model and gray combination model and get the results in Table 2.

Table 2. Model error check list

Years	Actual value	Linear regression model		GM(1,1) mode		Combined model	
		Predicted value	Relative error/%	Predicted value	Relative error /%	Predicted value	Relative error /%
2009	1249.5	1300.5	4.08	1282.3	2.63	1251.6	0.17
2010	1580.2	1607.7	1.74	1532.2	3.04	1544.6	2.25
2011	1812.9	1914.8	5.62	1830.7	0.98	1864.2	2.83
2012	2228.4	2221.9	0.29	2187.4	1.84	2213.0	0.69
2013	2606.1	2529.0	2.96	2613.6	0.29	2593.4	0.49
Average relative error /%		2.94		1.76		1.29	

By comparing the results of the above example average relative error we found that although three kinds of models can be a taxi passenger volume forecasts, but the combination model has increased prediction accuracy compared with gray model and linear regression model. Use a combination model to predict the next three years taxi passenger volume of Lhasa based on the comparison and analysis of three kinds of prediction models, predicting the results in Table 3.

Table 3. Prediction value of Lhasa taxi passenger volume from 2008 to 2013 (ten thoustands)

Years	2015	2016	2017
Taxi passenger volume	3461.1	3955.0	4493.7

As can be seen from Table 3, the next three years taxi passenger volume will increase year by year and increase significantly. Lhasa as an important international tourist city, with Qingzang railway and Lari railway opened one after another, a large number of domestic and foreign tourists flocked to the city of Lhasa. As the floating population of the passengers has great impact on the taxi demand, the effects of population grow with each passing day, and frequent occurrence of various socio-economic activities resulting in travel increase dependence on motorized, which directly stimulate the taxi passenger volume growth.

5. Conclusions

Based on the gray GM(1,1) model and linear regression model, this paper constructes combination of gray linear regression model to improve deficiencies of which the original linear regression model is not include exponent increase trend and the GM(1,1) model lack of linear factor. Through analysis, this combination forecasting model is not only a true reflection of the evolving situation in Lhasa taxi passenger volume, and the prediction accuracy is higher than a single gray forecasting model or linear regression model. Finally, by forecasting the next three years taxi passenger volume in Lhasa shows that the amount of taxis need to increase.

Abstract: This research explores the relationship between urbanization and regional transportation by using the coupling model. Evaluation indexes which reflect the coupling relationship have been selected out. The research evaluates the coupling relationship between urbanization and regional transportation on the basis of data stem from the city of Chengdu in Sichuan province from 2003 to 2013. The statistical results show the level and developing trend of coupling relationship in Chengdu. In the future research, the effective measures will be proposed for the mutual development of urbanization and regional transportation according to the results of this study.
Keywords: Urbanization; Regional transportation; Coupling relationship.

1 Introduction

Urbanization is not only the developing trend of society, but also the symbol of social progress. According to Ma and Zhang (2005), it refers to the gradual increase in the population of people living in urban areas. However, different attention has been paid to the term of urbanization in different research field. For instance, economists think of urbanization as the economic transition from rural to urban areas; anthropologists pay attention to the process whereby a society changes from a rural to an urban way of life; ecologists stress the environmental change in the process of urbanization. No matter how different the viewpoint on urbanization is, it has the common characteristics, including the migration of population to cities, the shift of economic structure, the change of the way of production and life, and the change of urban form.

As for the term of transportation, it is defined as the spatial displacement of people, goods and services (Chen and Shao, 1999). Modes of transportation include air, rail, road, water, cable, pipeline and space. Each way of transportation can be divided into line infrastructure, transport infrastructure, transport mobile devices, transport human resources and transport management system (Han, 2000). In detail, line infrastructure consists of roads, railways, pipelines and canals. Transport infrastructure consists of the fixed installations including terminals such as airports, railway stations, bus stations, warehouses, trucking terminals, refueling depots (including fueling docks and fuel stations) and seaports. Transport mobile devices are systems for vehicle operation. Transport human resources are people and organizations related to transport services. Transport management system is the platform for transport scheduling, cooperation and administration.

Transportation is very important because it leads to the shift of industrial structure and the change of urban spatial form, which is essential for the development of urban civilizations. Hence, most researchers focused on the interaction effect between urbanization and transportation. According to Wang and Rong (2014), urbanization asks for more demands of transportation, which causes the development of transportation; vice versa, transportation improves the urban economy and enhances effectiveness of space and time, because of its locational performance and network features. In recent years, transport oriented development (TOD) has become the mainstream of social development.

Based on the discussion, the research will evaluate the coupling relationship between urbanization and regional transportation (transportation of Chengdu which is the capital of Sichuan province) statistically. The results will help with clear understanding of the level and trends of coupling relationship between urbanization and transportation in Chengdu for a period of time.

2 Variables and Data Resources

The index system is the valid instrument for evaluating the coupling relationship between urbanization and regional transportation. Based on document reviewing (He, 2014; Wang and Rong, 2014), urbanization is measured by 6 indexes, while regional transportation is measured by 6 indexes as well. Proportion of non-agricultural population, proportion of employee in the service sector, proportion of the output value in the service sector, value of gross output per capita, the number of employee in health agency and population density are used to measure urbanization. Total distance of highway, the number of taxi, road area per capita, passenger capacity, the number of employee in transportation and volume of freight traffic are used to measure regional transportation. All the data are collected from the statistical yearbook of Sichuan province and the statistical yearbook of Chengdu city, from the year of 2003 to 2013.

3 Methodology

3.1 Data Standardization

In order to decrease the dimensional effect of variables on the results, this research takes standardization to original data by using the method of maximum difference standardization. After the data's standardization, all the data will be located in the range from 0 to 1. Because all the variables in the research are positive, the formula of maximum difference standardization will be introduced as:

$$x'_{ij} = \frac{x_{ij} - minx_{ij}}{maxx_{ij} - minx_{ij}} \quad i = 1,2,3 \dots m \ (, \ j = 1,2,3 \dots n) \tag{1}$$

m means the number of variables, while n means the number of indexes. $maxx_{ij}$ and $minx_{ij}$ are the maximum and minimum data of each index.

3.2 Weight Calculation

This research will take the way of principal component analysis (PCA) to calculate the weight of the indexes. The first step is to compute the communality of all indexes. The formula is shown as:

$$H_i^2 = \partial_{i1}^2 + \partial_{i2}^2 + \cdots + \partial_{ip}^2 \tag{2}$$

In this formula, *i* stands for the number of indexes, while *p* means the number of common factors.

The second step is to calculate the weight of each index according the results of communality of all indexes. The formula is shown as:

$$\lambda_i = \frac{H_i^2}{\sum_{i=1}^{n} H_i^2} \tag{3}$$

In this formula, *i=1,2,3…n,* $\lambda_i \in (0,1)$, and $\sum_{i=1}^{n} \lambda_i = 1$.

3.3 Evaluation of Urbanization and Regional Transportation

The evaluation results of urbanization and regional transportation can be calculated according to the formula shown as:

$$u_i = \sum_{j=1}^{n} \lambda_{ij} \times x'_{ij} \tag{4}$$

In this formula, u_i is the evaluation result of each variable. x'_{ij} are the standardized data, while λ_{ij} stands for the weight of each index.

In order to clearly understand the developing level of urbanization and regional transportation, this research divided the evaluation results into four levels which are shown in Table 1.

Table 1. Evaluation results and developing levels

Evaluation results	Developing levels
$u_i \in (0,0.25]$	Low
$u_i \in (0.25,0.5]$	Primary
$u_i \in (0.5,0.75]$	Medium
$u_i \in (0.75,1]$	Senior

3.4 Construction of the Correlation Model of Coupling Relationship

This research defines the correlation model of coupling relationship between urbanization and regional transportation as:

$$C_t = f(u_{1t}, u_{2t}) = 2\{(u_{1t} * u_{2t})/[(u_{1t} + u_{2t})(u_{1t} + u_{2t})]\}^{1/2} \quad (5)$$

The value of C_t reflects the strength of correlation between urbanization and regional transportation in the year of *t (t=1, 2, 3…T)*. In this formula, $u_i \in [0,1]$, u_{1t} and u_{2t} stand for the devotion of each index to the two variables -- urbanization and regional transportation. This research defines the relationship between the value of C_t and the levels of correlation which is shown in Table 2.

Table 2. Correlation values and levels

Correlation values	Correlation levels
$C_t \in (0,0.25]$	Low
$C_t \in (0.25,0.5]$	Primary
$C_t \in (0.5,0.75]$	Medium
$C_t \in (0.75,1]$	Senior

3.5 Construction of the Coordination Model of Coupling Relationship

This research also establishes the coordination model of coupling relationship between urbanization and regional transportation. The calculating functions are shown as followings.

$$U_t = \alpha * u_{1t} + \beta * u_{2t} \quad (6)$$

In formula (6), α and β are the weight of urbanization and regional transportation. Because of the same significance of both variables, this research deems α=β=0.5. U_t is the comprehensive evaluation index which reflects the comprehensive benefits of both urbanization and regional transportation.

$$D_t = \sqrt{C_t * U_t} \quad (7)$$

In formula (7), D_t is the coordination index of coupling relationship between urbanization and regional transportation. For C_t and U_t are located in the range from 0 to 1, D_t also belongs to the range from 0 to 1.

This research also divided the coordination values of coupling relationship into four levels. See Table 3.

Table 3. Coordination values and levels

Coordination values	Coordination levels
$D_t \in (0,0.25]$	Low
$D_t \in (0.25,0.5]$	Primary
$D_t \in (0.5,0.75]$	Medium
$D_t \in (0.75,1]$	Senior

4 Results Analysis

The standardized data were plugged into the formula (2) and (3) to calculate the communality and the weight of each index which belongs to the dimensions of urbanization and regional transportation. The results can be seen from Table 4.

Table 4. Communality and weight of urbanization and regional transportation

Indexes of urbanization	Communality	Weight	Indexes of regional transportation	Communality	Weight
Proportion of non-agricultural population	0.966345	0.164299	Total distance of highway	0.904041	0.159225
Proportion of employee in the service sector	0.980395	0.166688	The number of taxi	0.953457	0.167928
Proportion of the output value in the service sector	0.995429	0.169244	Road area per capita	0.957154	0.168579
Value of gross output per capita	0.979445	0.166527	Passenger capacity	0.932345	0.16421
The number of employee in health agency	0.984179	0.167332	The number of employee in transportation	0.986386	0.173728
Population density	0.975818	0.16591	Volume of freight traffic	0.944381	0.16633

According to the results of communality and the weight of each index, the research calculated the evaluation, correlation and coordination results of coupling relationship between urbanization and regional transportation by substituting the values of the weight and the standardized data into formula (4), (5), (6) and (7).

Based on the results shown in Table 5 and the categories of level of coupling relationship shown in Table 1, 2 and 3, we can find that the coordination level of coupling relationship between urbanization and regional transportation was quite low in the year of 2003 and 2004. The coordination level in the year of 2005 and 2006 was primary, while in the year of 2007 and 2008 the coordination level was medium. From 2009 to 2013, the coordination level of coupling relationship between urbanization and regional transportation was senior.

As for the correlation level of coupling relationship between urbanization and regional transportation, the level was medium from the year of 2003 to 2005. Since the year of 2006, the correlation level rose up to senior.

As to the developing level of urbanization and regional transportation in Chengdu, the level of urbanization and regional transportation was very low in the year of 2003 and 2004. The level of urbanization was at the stage of primary in the year of 2005, 2006, 2007 and 2013, while in the year of 2008 and 2009 it was medium. Since the year of 2010, the level of urbanization rose up to senior. In the year of 2005 and 2006, the level of regional transportation was very low, but in 2007 and 2008 it was primary. Except the year of 2013, in which the level of regional transportation was senior, it was at the level of medium from 2009 to 2012.

Table 5. Evaluation results of coupling relationship between urbanization and regional transportation

Years	Evaluation results of urbanization	Evaluation results of regional transportation	Correlation of coupling relationship	Coordination of coupling relationship
2003	0.014404	0.13244	0.59487	0.208989
2004	0.104304	0.017455	0.700879	0.206566
2005	0.342038	0.043656	0.633648	0.349567
2006	0.421205	0.139073	0.863962	0.491965
2007	0.435599	0.328878	0.990208	0.61522
2008	0.604378	0.46859	0.99196	0.7295
2009	0.686206	0.616934	0.998586	0.806628
2010	0.83705	0.596684	0.985847	0.840667
2011	0.900331	0.593234	0.978633	0.854884
2012	0.907766	0.725103	0.993723	0.900727
2013	0.493933	0.978651	0.944274	0.833823

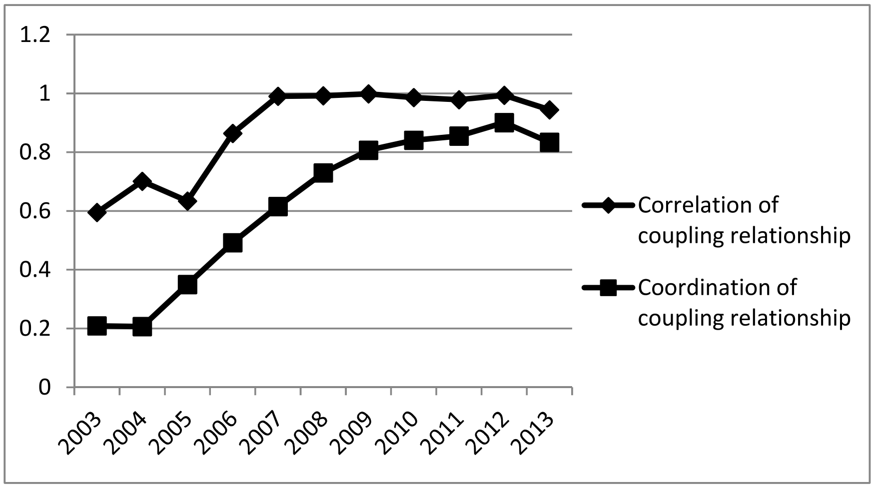

Figure 1. The trend of coupling relationship

Figure 1 shows us the trend of coupling relationship between urbanization and regional transportation in Chengdu from 2003 to 2013. From this figure, we can find that both of the correlation and coordination of coupling relationship are above the value of 0.8 since 2009. After the year of 2012, the correlation and coordination of coupling relationship show a slight drop.

5 Conclusions

Based on document reviewing, this research selected 12 indexes to describe urbanization and regional transportation. By using the model of coupling relationship, the data which stem from the city of Chengdu from the year of 2003 to 2013 were used to calculate the correlation and coordination of coupling relationship between urbanization and regional transportation. The results clearly show the strength and the developing trend of coupling relationship between the two variables during a sample period. According to the results, we can propose proper measures for the harmonious development of both urbanization and regional transportation in the future research.

Abstract: Due to merging movements of on-ramp vehicles, the characteristics of traffic flow at upstream and downstream of merging area have significant differences. Based on the traffic data collected by loop detector in urban expressway of Shanghai, this paper firstly analyzed variation condition of traffic volume at entire merging area during the whole daytime, and then compared traffic flow characteristics at three different sites (i.e. upstream of merging area, downstream of merging area and on-ramp) based on fundamental diagram. The study found, at merging area of the Inner Ring Expressway in Shanghai, traffic volume keeps in saturating status in the daytime without obvious peak features. The upstream traffic volume can't reach maximum capacity of normal roadway segment due to early-onset breakdown of traffic flow; on the contrary, downstream traffic volume can achieve maximum capacity without early-onset breakdown phenomenon. Downstream speed-occupancy model mathematically fits well with linear model, while, upstream and on-ramp speed-occupancy models conform to exponential model.
Keywords: Urban expressway; Merging area; Traffic flow characteristics.

1 Introduction

The urban expressway, as urban road network and mass rapid transport corridor, can release the traffic pressure and improve traffic efficiency. Due to the consideration of accessibility, the distance of exit and entrance on urban expressway is short, which brings about itself unique features: overmuch weaving vehicles and a low possibility of free flow (Hao, 2007). Therefore, it is necessary to conduct a research on traffic flow characteristics of urban expressway.

In general, study on traffic flow features can start with relations among basic parameters of traffic flow: traffic volume, speed and density. The linear speed-density model was constructed at the earliest (Greenshields, 1935). Later, a more comprehensive study on the relations among the three parameters was conducted in order to explain the inherent law of traffic flow (Greenberg, 1959), (Underwood, 1961), (Persaud, 1988).

With research continuing, it was found that there is a discrepancy on traffic flow features across different lanes even at the same site (Wagner, 1997). Besides, due to the impact of ramp, the traffic flow characteristics at different sites have significant discrepancy (Hao, 2008). Therefore, using data from inductive loop detectors equipped in three different sites: upstream of merging area, downstream of merging area and on-ramp, this paper compared the discrepancy of the traffic flow characteristics and constructed basic parameters models of traffic flow at different sites. The research in this article will provide a more comprehensive understanding on traffic flow characteristic of urban expressway, which have important real-world implications to improve service capability and traffic efficiency.

2 Field Data

By the end of 2013, about 200km urban expressway network has been established in Shanghai, including Inner Ring Expressway, South-North Expressway, Mid Ring Expressway and so on. The Inner Ring Expressway is selected to be study site in this paper. The specific site is the merging area, where the ramp connects the main traffic corridor-Wuning Road(see Fig.1).

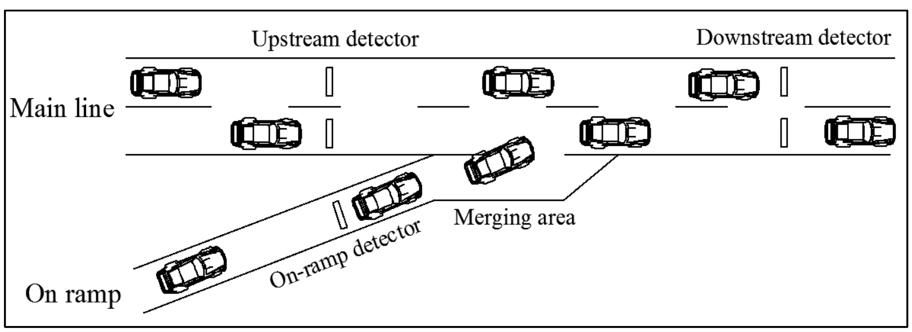

Fig.1 The sketch map of detector disposal

The data was achieved from Shanghai Municipal Roadway Administration Bureau, and it was collected from Monday to Sunday, July 2 to July 8,2012. As shown in Fig.1, the data is get through inductive loop detectors equipped in upstream of merging area, downstream of merging area and on-ramp. The detectors record vehicle count, time occupancy and time mean speed in each lane in 5minutes, a total of 21168 records. Due to equipment failure, communication failure and ramp closed control, the abnormal data often generates. The valid data set applied in this study includes 18792 records (used for training sample and validation sample).

3 Analysis of Traffic Flow Characteristics on Urban Expressway

3.1 Variation condition of traffic volume at merging area

Fig.2 shows the time series of traffic volume on workdays and weekends at downstream of merging area, from July 2,2012 to July 8,2012 (Monday to Sunday). According to the variation trend of volume, it contains two phases and three states:

The first phase is from 22:00pm to next day 07:00am (10:00am at weekends). It contains two states: traffic volume declining and traffic volume increasing. As shown in Fig.2, traffic volume declines at 22:00pm, and hits bottom at next day 04:00am. Subsequently, traffic volume becomes increasing at 04:00am, and reaches the maximum value (about 1800veh/h/lane) at 07:00am through 3 hours. However, at weekends, traffic volume reaches the maximum value at 10:00 due to the slow grow.

The second phase is from 07:00am(10:00am at weekends) to 22:00pm. This phase has the only one state: traffic volume saturation. During this phase, traffic volume of workdays keeps in 1800~2000veh/h/lane, and that of weekends is slightly less. No matter workdays or weekends, traffic volume keeps in saturation, without obvious rush hours, in the daytime.

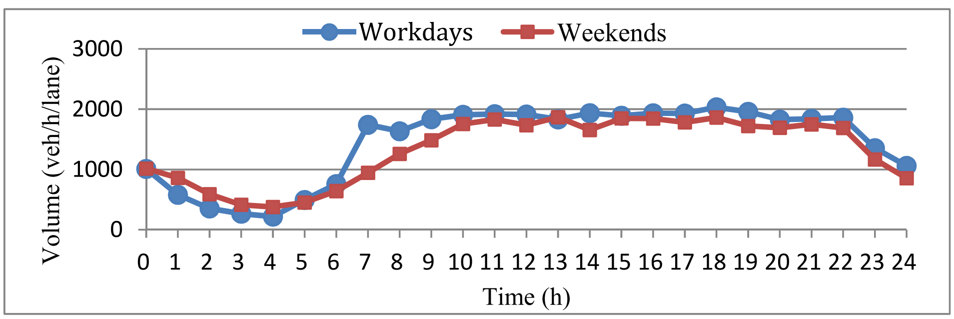

Fig.2 Variation of traffic volume on workdays and weekends

As shown in Fig.2, although traffic volume differs between workdays and weekends, variation trend of traffic volume is generally similar. So, this paper only focus on traffic flow characteristics at different sites on workdays.

3.2 Relations among traffic flow parameters at different sites

(Gartner, 1997) there is a linear relation between time occupancy and density, and time occupancy can be detected directly by detection equipment. So this paper substitutes time occupancy for density in research.

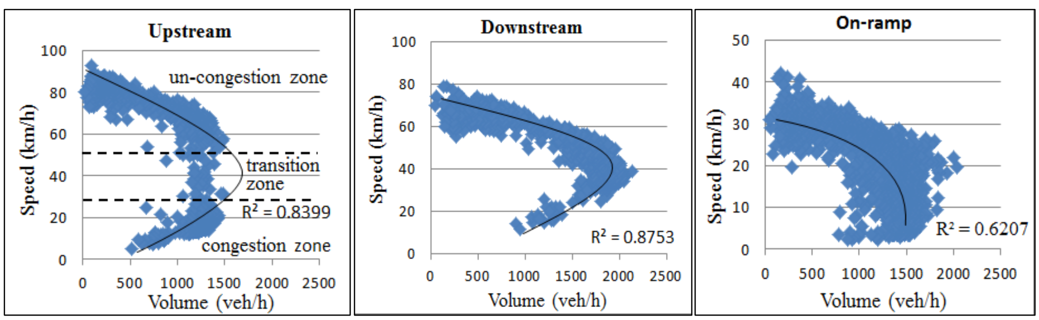
3.2.1 Traffic volume vs. Speed

Fig.3 is scatter plots of traffic volume vs. speed. It is obvious that the relations between traffic volume and speed conform to parabolic model, but the distribution law of data exists some differences at different sites.

Fig.3a is volume-speed scatter plot at upstream. It is found that data points mainly cluster into two regions: un-congestion zone(50~90km/h) , congestion zone(5~30km/h). Besides, there is a space with sparse data points, which is defined as transition zone(31~49km/h). Vehicles at un-congestion zone has faster speed and less disturbance. While at congestion zone, due to the large demand from ramp and main line, vehicles travel slowly with serious conflict. Finally, vehicles are travelling in an unstable state at transition zone, and data points are almost distributed vertically without volume falling in 1500~2010veh/h/lane. That is to say, an early-onset breakdown phenomenon (traffic flow breaks down far sooner before reaching capacity) occurs. Because of the merging movements of on-ramp vehicles, un-congestion zone contains 40.1% records; 54.8% records fall in congestion zone; the other 5.1% records belong to transition zone.

Fig.3b is volume-speed scatter plot at downstream. It is obvious that flow-speed relation at this site fits best with parabolic model ($R^2 = 0.8753$). As shown in Fig3b, the data points has no obvious zonal phenomenon. That is to say, the vehicle is traveling in a stable state, and there is no early-onset breakdown phenomenon. Furthermore, traffic capacity could be reached at downstream, and the largest volume reaches about 2100veh/h/lane.

Fig.3c is volume-speed scatter plot of on-ramp. Data distribution shows slightly parabolic form, but data points are quite scattered. Merging area has a strong impact on on-ramp traffic flow, and flow-speed relation doesn't conform to parabolic model.



(a) (b) (c)

Fig.3 Relations between traffic volume and speed

3.2.2 Traffic volume vs. Occupancy

Fig.4 is the flow-occupancy scatter plots. The volume-occupancy relations at upstream and downstream of merging area conform to parabolic model. Because there is an early-onset breakdown phenomenon at upstream, Fig.4a has obvious zonal phenomenon. When occupancy is between 0 to 20%, it is un-congestion zone; occupancy between 21% to 40% belongs to transition zone; the others from 41% to 70% fall in congestion zone. Fig.4b is the flow-occupancy scatter plot at downstream. Just like the flow-speed scatter plot, the flow-speed relation fits best with parabolic model at this site ($R^2 = 0.9843$). Beside, most data points cluster into the left side of the figure, which also verifies vehicles traveling in a stable state. Finally, Fig.4c shows the flow-occupancy relation at on-ramp. The first half of the diagram increase linearly, while the latter part is horizontal and traffic volume undulates fiercely (range: 800-2000veh/h/lane) as occupancy rising. So, flow-occupancy relation at on-ramp don't conform to parabolic model.

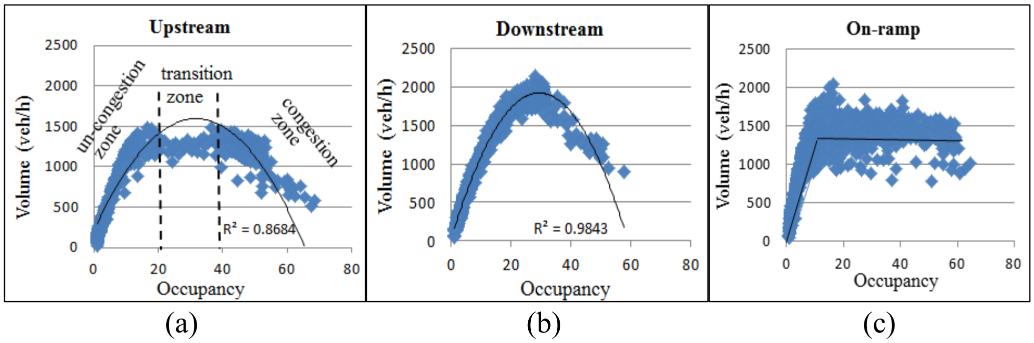


Fig.4 Relations between traffic volume and time occupancy

3.2.2 Speed vs. Occupancy

(Li,2013) Speed-density relation is the research foundation of the relations among volume, speed and density. Fig.5 is the speed-occupancy scatter plots at different sites. It is found that speed and occupancy has the obvious correlation. At downstream of merging area, variation trend of speed vs. occupancy is identical to that of Greenshields' speed-density linear model. However, at upstream and on-ramp of merging area, speed-occupancy scatter plots show obvious exponential distribution. According to the change rules of speed vs. occupancy at different sites, the optimal equations at different sites are summarized in Table.1 based on curve fitting method (y: speed, x: occupancy)

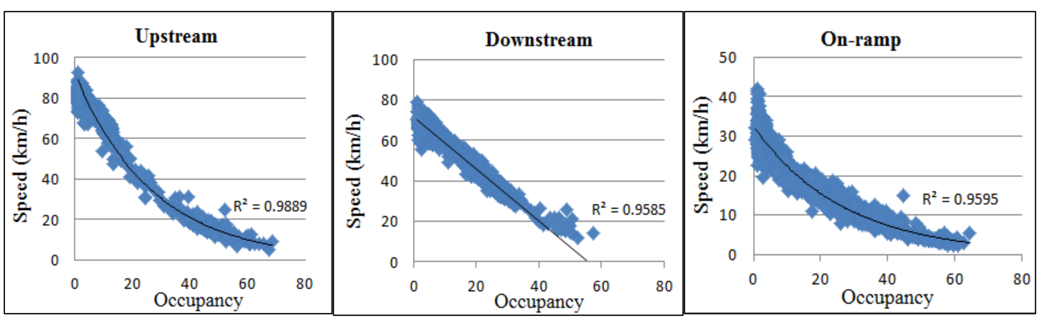

Fig.5 Relations between speed and time occupancy

Table1. Relations of Speed-Occupation at Different Sites about Merging Area

Sites	Formula	R^2(training sample)	R^2(validation sample)
Upstream	$y = 92.429e^{-0.037x}$	0.9889	0.9832
Downstream	$y = -1.2706x + 71.177$	0.9585	0.9624
On-Ramp	$y = 32.51e^{-0.037x}$	0.9595	0.9558

In summary, there is obvious discrepancy about the relations among volume, speed and occupancy at different sites. The discrepancy mainly attributes to merging area, where vehicles from main line and on-ramp scramble for the right of way, which causes disorder and conflict, especially at rush hours. Besides, the excessive traffic demand from main line and on-ramp often can't be satisfied due to the limited capacity of downstream, and at this moment, an early-onset breakdown phenomenon happens. However, traffic flow at downstream is only limited to traffic capacity itself, so no early-onset breakdown phenomenon happens. Therefore, the comprehensive research in this paper about traffic flow feature at different sites is meaningful to improve service capability and traffic efficiency of urban expressway.

4 Conclusions

In this paper, we collected inductive loop data from three locations around merging area at the Inner Ring Expressway in Shanghai. The locations are categorized into three types: upstream, downstream and on-ramp. Traffic flow characteristics at the three different sites were studied. By the comparison and statistical analysis of relations among the traffic flow parameters(volume, speed, occupancy), this paper compared discrepancy about traffic flow features at the three sites. Besides, traffic flow parameters models were constructed according to the three sites. The findings are as follows:

(1)The traffic volume, at merging area of the Inner Ring Expressway in Shanghai, keeps in saturation, without obvious rush hours and off-peak hours, in the daytime. Furthermore, no significant variation on traffic volume between workdays and weekends.

(2)Volume-speed model and the volume-occupancy model conform to parabolic model at upstream and downstream of merging area. The upstream traffic volume can't reach maximum capacity of normal roadway segment due to early-onset breakdown of traffic flow; on the contrary, downstream traffic volume can reach maximum capacity without the early-onset breakdown phenomenon

(3)Speed-occupancy model at downstream of merging area fits well with the traditional linear model; while, that at upstream and on-ramp of merging area conforms to exponential model.

Abstract: In order to further reduce the cost of road freight transport, the influence of the railway freight transport reformation on Ningbo road general freight transport industry are analyzed based on the review of background and core contents of the reformation. As a result, the railway freight reform will bring more cooperation opportunities than competition, which created new opportunities for Ningbo to build a comprehensive land transport system and the development of logistics services. From the standpoint of cooperation-competition development, multimodal transport and the transformation of modern logistics, countermeasures are proposed for the transport of less-than-truckload freight on road.
Keywords: Railway freight transport reformation; General freight; Road transport; Multimodal transport.

1 Introduction

The increase of railway mileage and double-track rate as well as the separate transport of cargoes and passengers, improve the railway freight capacity, while rail volume declining, China Railway Corporation put forword a railway freight reform measures in June 2013 (Huang, 2013): reforming the way of freight accepting formalities, transport organization and standardizing freight charges, developing the railway "door to door" services comprehensively. Subsequently, raising the railway freight price, opening e-commerce express train and launching business in national railway freight operating station which basically covers at or above the county level cities etc. These will fully participate in modern logistics competition by expanding services type and enhancing service level.

As two ways of land transport, railway has long been undertaking the “cfs to cfs” transport of bulk cargoes, while road responsible for “cy to cy” and “door to door” transport of breakbulk (Lee, 2013). Besides natural division of collecting & distributing relations, there are also direct competition in lines, types of cargo and special transport demand between them. The reform aims to newly participate in the less-than-one carload transport, globally, which will directly influence the relationship between competition and cooperation of general cargo transport.

Many scholars have studied the freight industry in China, some of them (Wei, 2013; Wei, 2013; Gao, 2014) concluded that the industry concentration, transportation organization and informationization level of road freight enterprises are relatively low, and put up strategies to cultivate intermediary organizations, adjust the structure of transport capacity and set up information platform; Others (Ma, 2012; Wang, 2013; Jiang, 2014) aim at the low modernization level of railway freight logistics, they put forward to carry out freight organization reform and develop traditional transportation value-added services, build a unified modern logistics information system platform, and cultivate modern rail logistics talents etc. But most of these studies are aimed at domestic road freight industry or domestic rail freight respectively, which lack conjoint analysis on both sides from the perspective of competition and cooperation.

As a national logistics node and regional logistics center of Yangtze river delta, road transport is the main way for Ningbo Port to have the goods picked up from the marine terminal and then delivered to other areas and cities, which occupies more than 80% of the total traffic volume; and its transport business covers major cities of almost all mainland provinces, municipalities directly under the central government and autonomous regions, which played an important role in improving the scope of material circulation as well as the quality of social life.

From the aspects of business space and types, this paper will analysis the impact that the railway freight reform may have on Ningbo road cargo transport industry, and from three perspective, namely competition, cooperation and the development of comprehensive transportation, put forward the countermeasures and suggestions for road freight Industry and competent authorities.

2 The Impact of Railway Freight Reform on General Cargo Transport Industry in Ningbo

Although the reform of railway freight aimed at restarting less-than truckload transport, due to the carrying capacity of train is much larger than truck, besides, it includes truckload and less-than truckload transport at the same time. As the timeliness demanding of less-than truckload transport is growing, which gradually separated from the conventional cargo transport business, and formed small goods transport business. Small goods transport is the fastest growing business in road transport industry, which is also one of the important content of the reform.

From the aspects of less-than truckload, truckload and small express, this paper will analysis the influence of the reform on Ningbo general cargo road transport.

2.1 The impact of railway freight reform on general cargo transport space

Through the survey on Ningbo road freight enterprises, it is obvious that the general freight business in Ningbo covering almost all inland provinces and cities, some even covered above the county level in developed areas; Vehicle transport is given priority to Zhejiang province, a few lines in northern Jiangxi province, Shanghai, southern Jiangsu and other surrounding areas. Because of cross-provincial lines must base on an extension of the lines in Zhejiang, as a result, the following part will discuss the impacts of railway freight reform on Ningbo road freight space.

Currently, the road cargo transport lines start from Ningbo involving all at or above the county level cities in Zhejiang. According to the transport distance and nonstop feature to, these lines are divided into three categories, as shown in table 1.

Table 1. The categories of general cargo transport lines in Ningbo

Categories	Transport Destination
Similar distance and nonstop lines of railway and road	Hangzhou、Shaoxing、Shangyu、Huzhou、Changxing、Taizhou、Wenling、Sanmen、Linhai、Wenzhou、Rui'An、Yongjia
transport distance: railway>road, and direct railway	Jinhua、Dongyang、Lanxi、Wuhan、Yiwu、Yongkang、Jiande、Quzhou、Jiangshan、Longyou、Lishui、Jinyun、Qingtian、Jiaxing、Haining、Jiashan、Zhuji
Indirect railway	Pan'an、Pujiang、Changshan、Kaihua、Jingning、Longquan、Qingyuan、Songyang、Suichang、Yunhe、Haiyan、Pinghu、Tongxiang、Chun'An、Fuyang、Lin'An、Tonglu、Shangxing、Shengzhou、Xinchang、Huangyan、Jiaojiang、Luqiao、Tiantai、Xianju、Yuhuan、Cangnan、Leqing、Pingyang、Taishun、Wencheng、Anji

On the condition that railway can provide "door to door" service, considering the same distance for both road and railway, the owner of cargo has two transport choice, therefore, the competition between the two is relatively fierce; For long route lines, the owner's choice mainly depends on the efficiency and timeliness of railways; for those indirect railway area, road transport has absolute advantages.

2.2 The impact of railway freight reform on road cargo transport business

According to the statistics of Ningbo Road Transport Administration, by the end of 2013, there are 48755 general freight enterprises, accounting for 98.76% of the total; 64717 ordinary truck, which occupies 79.20% of the total. Similar to the nationwide situation, few are large and medium-sized enterprises. According to the statistics, in the general freight enterprises, those who own more than 50 vehicles accounted for about 0.35%, and vehicles owned range from 20 to 49 accounted for about 0.68%, while the rest 99% only own less than 20 trucks.

From the aspects of less-than truckload, truckload and small express, the following will analysis the influence of the reform on Ningbo general cargo road transport.

(1) the impact of railway freight reform on less-than truckload transport in Ningbo

As to less-than truckload transport started from Ningbo, transport via networks of expressways and urban trunk roads to send goods to the receipt places, generally passing two pivotal hubs and two neighboring regional distribution centers, so as to sort and handle. Due to road transport vehicles tonnage is relatively small, the time of sorting, loading and unloading is short, while to long distance transport, laboring, energy consumption, transport time and economic costs may be the disadvantage. As to breakbulk cargo from Ningbo to destinations by railway network, which have to regroup in more than two railway administration districts, and to be sorted in two or more railway stations. To guarantee its economic benefit, the train must have its load ratio achieved before operation. High speed, short transport time, low cost, energy conservation and environmental protection are all the benefits of railway transport, but it consumed more time than road transport in both ends of loading and unloading, sorting and marshalling, therefore, its overall timeliness is not necessarily better than road transport.

To confirm the above analysis, this paper set 300 kilograms of clothing groceries as an example, from north Ningbo station to Shanghai Anting station, both ends of the door distance are 20 km and 50 km respectively. There are two truckload freight price, one is 10.2 yuan, the other is 14.28 yuan, and not responsible for door-to-door service. So the pickup time is unpredictable. If CRE undertakes the transport, the total freight is 570 yuan, including the pickup charge in Ningbo (50 yuan), and delivery in Shanghai is free of charge, which needs 3 to 4 days in total. If Yangtze River Delta Express Railway undertakes the transport, the freight is 20 yuan, both ends shuttle fees amounted to 208 yuan, the railway running 2 days and 9 hours, but sorting and delivery time on both ends is not included. A certain less-than truckload transport company in Ningbo charges 60 yuan, both ends shuttle fees amounted to 250 yuan, which delivering on the third day.

The survey results show that among all the schemes for middle and short distance transport, total freight by regional express train is the cheapest, but its timeliness is bad, for railway cannot cover all middle and short lines in Ningbo. Therefore, the current shunt effect on Ningbo is not obvious. CRE has good spatial coverage, but its freight and timeliness is not in advantage, which will not greatly influence road cargo transport in Ningbo. For long transport distance, the price and spatial coverage of railway transport is obvious, but the gap between convenience and timeliness, would no impact Ningbo road network.

In the long run, the strength of railway freight reform will further increase, then the frequency of freight train will increase, and the possibility of raising transport price also increase. The former is beneficial for decreasing waiting time at the station yard; the latter will weaken the price advantage of rail freight. Due to the longer the transport distance, the more obvious the advantages price and currency of railway, therefore, for those transport of longer than 800 km, railway transport has more attractions. General less-than truckload transport business can provide "door to door" service, and its customers are usually "small, scattered and frequently". Considering the costs and resources, railway freight enterprises are hard to achieve "door to door" service. After long-term accumulation, road transport enterprises have established good scattered goods distribution network, which created initiative for them to collaborate with the railway in long-distance transport.

(2) The impact of railway freight reform on general cargo vehicle transport in Ningbo

From the survey, we found that general cargo vehicle transport mainly focused on Zhejiang province, a small amount are distributed in the south of Shanghai, Jiangsu and surrounding areas in the north of Jiangxi. Zhejiang region is small, about 378 km from jinxing to Wenzhou, the farthest distance in the province; as for the transport from Ningbo to Shanghai, southern Jiangsu and northern Jiangxi, transport mileage is less than 800 kilometers, which takes six to eight hours to reach the destination.

For rail and road are at the same distance, or at a longer but direct route, vehicle road transport can serves "door to door" and start at any time. As for vehicle transport with the same direction railway freight lines, entrusting the vehicle cargo to railways will increase the sorting, loading and unloading and marshalling time, besides, departure interval limitations also further increased the waiting time. As for the non-express cargo, railway hasn't provided "door-to-door" service, thus time and costs have to be borne by the road transport enterprises. If the "door to station" and "station to door" transferring process causes large goods loss, then further reducing the feasibility of entrusting road vehicle goods to rail.

(3) The impact of railway freight reform on small goods

According to the National Bureau of Statistics, from 1995 to 2005, the national express parcel average growth rate is 115.5%, especially from 2006 to 2013, when e-commerce developed rapidly, the national express parcel average growth rate reached 192.2%. In 2013, there were 9.2 billion express parcels in China, which is expected to exceed 12 billion pieces in 2014 (Xie, 2014). From B2C, B2B to O2O, then to cross-border e-commerce, parcel express will be improved significantly.

CRE provided small ordinary express and time-limited express. Ordinary express provide from more than 700 cities, deliver "door to door" to nearly 2000 cities and counties nationwide, and arrive destinations within 4 days once delivery; for transport mileage above 3500 km or unable to direct delivery between cities, it provide within 4 to 6 days' "door to door" service. Time -limited express including "Next Day Delivery" and "Third Day Delivery", there are 101 major cities in China can deal the service, and 163 cities can be delivered. Compared with small road express business, railway ordinary express has the absolute advantage in price, but the gap in its service area, the scope of free "door-to-door" service, the receipt charges in non-free areas and timeliness are large; Time-limit express significantly improved the timeliness of ordinary express, and lowered its freight; but its service coverage, the free service area and its charges etc. has not changed.

Although small railway express's price advantage is obvious, its limitation on the density of distribution network, business spot, timeliness and economy of its service are still the bottleneck.

(4) The overall impact of railway freight reform on general cargo transport

From the above, it can be found that the railway freight reform bring both opportunities and challenges for road transport enterprises in Ningbo, overall, opportunities are more than challenges.

Firstly, less-than truckload transport by road in Ningbo has comprehensive advantages in terms of timeliness, convenience and economy, thus it will not significantly affected by the reform in the short term, while in the long run, road and railway has a potential for cooperation. Secondly, road vehicle transport has more advantages in timeliness and convenience than railway transport in Ningbo, it will not significantly affected by the reform in the short term. Thirdly, the price of small road express is a little in Ningbo, but its service coverage, convenience and delivery timeliness has significant advantages, thus it will not significantly affected by the railway freight reform in the short term, but small express and railway has a potential for cooperation in the long run.

To sum up, as for general cargo road freight industry in Ningbo, the railway freight reform will bring more cooperation opportunities than competition, which created new opportunities for Ningbo to build a comprehensive land transport system and the development of logistics services.

3 Development Countermeasures for Road Cargo Industry Under The Condition of Railway Freight Reform

"Two Belts and One Road" strategy and its continuous promotion, the emerge of national new urbanization and long-term planning of logistics industry development, as well as the continuing growth of the e-commerce, all of these have created a prosperous perspective for the development of land transport industry; the current railway freight market reform, bring more cooperation opportunities than competitive challenges for road freight industry in Ningbo. Combined road transport with railway, which will cause the excess of freight capacity in part of road freight enterprises, the transforming from traditional goods transport to specialized transport and logistics service is forced by the situation, is also a leapfrog development opportunity. Under the background of railway freight reform, development strategies for the road less-than truckload transport freight industry in Ningbo are put forward as follow.

(1) Hierarchical cooperation with railway

Considering the features that railway freight enterprises are absolutely monopoly and the regional-management oriented, therefore, Ningbo's road transport enterprises should cooperate with railway hierarchically. Firstly, strategic cooperation. merging and consolidating, restructuring and shareholding to form large groups, or based on the experience of the shipping industry, to form a more powerful new enterprises as a truck free carrier, and strategic cooperating with Ningbo's railway freight department, establishing a long-term cooperation mechanism and participating in planning and construction of intermodal transit depot, coordinating transport price formation mechanism and the mechanisms of freight trains resource allocation. Secondly, the higher level cooperation. Large and medium-sized freight enterprises, relying on multimodal transport operations and large, medium-sized enterprise alliance and cross-regional enterprise alliance, multimodal transport transshipment terminal yard warehouse in contracting, train, freight train, railway freight departments with higher level of cooperation. Thirdly, indirect collaboration. setting up small transport enterprises oriented information service system, small road freight enterprises can join in 'door station', 'stand to door' services by competing large and medium-sized enterprises, or join in large and medium-sized enterprises' service outlets, so as to participate in intermodal service with railway freight enterprises indirectly.

Only under the macro management, such as laws, regulations, policy support, can market mechanism in the development play a proper role. Firstly, establishing regular communication mechanism on road and rail freight enterprises. As the multi-body and small scale of road freight enterprises, cooperate with railway is relatively weak, the dialogue platform is helpful to enhance mutual trust, expand and deepen cooperation models; also conducive to timely solve the cooperation problem, and then develop more targeted supportive policy. Secondly, supporting Hierarchical cooperation, so as to improve the distribution efficiency of road and rail multimodal transport. Thirdly, providing more priorities to the intermodal terminal planning and land using, learning from the patterns of ports construction, road freight enterprises are encouraged to participate in multimodal transport facilities construction, and improve the stability of the multimodal transport resources and bargaining power. Fourth, to multimodal transport as the breakthrough point, promoting the less-than truckload transport containerization, miniaturization and encouraging containers and vehicles miniaturization; intensifying the development of drop and pull transport, improving the transfer efficiency and reducing the energy consumption and pollutant emissions of distribution centers.

(2) Expanding new field of goods transport coverage

In cooperating with railway under the condition of combined goods transport, making the excess capacity of long road cargo transport enterprises more serious, therefore, road freight enterprises still have to improve services and open up new markets.

With the implementation of urbanization, the huge demand potential of small and medium-sized cities and small towns will be satisfied by road transport, so rural transport network should be layout as soon as possible. Due to the vast area and low cargo demand, building and maintenance of the rural freight network is much more difficult than in cities, therefore, it is necessary to build large and medium-sized enterprise alliance, unified planning and hierarchical divided countryside transport network, so as to develop rural transport of goods. Duo to railway network is not as dense as road network, and its capacity may not completely satisfied with all needs of the goods on the trunk line transport. According to the market demand, road freight enterprises should choose the favorable freight competition area, provide high-quality services for cargo transport. Make full use of its timeliness advantages, develop professional high value goods transport service, and compete with rail freight.

Formulate small towns oriented logistics parks, distribution centers and end distribution network planning layout, improve the storage, transshipment, unloading and other infrastructure, further promote the experience of Ninghai mailed urban and rural distribution project, and build public service platform, promote the transport network system. Providing appropriate policies to the enterprises engaged in rural transport in a certain period, and promotes the integration of urban and rural construction.

(3) Developing new logistics business

Except carrier, Expanding road freight business chain, new business development of logistics has stronger comparative advantages, which is the inevitable choice to realize transformation and upgrading. By cartels, cross-combination alliance and merger and reorganization, large and medium-sized enterprises should extend to warehousing, distribution processing, distribution etc., developing and participating in the logistics business. There are three main directions for road goods transport logistics to develop new business; one is to form a coalition with manufacturing enterprises, so as to develop manufacturing logistics. The second one is to form a coalition with business enterprise, so as to develop business logistics and city distribution logistics. The third one is to form a coalition with circulation enterprise, so as to develop agricultural products logistics.

Participants in the survey said they were planning to develop logistics business, but the transformation need more logistics parks and public warehouses, which is difficult to achieve individually. Therefore, it is necessary to further improve logistics hub layout planning, and increase the strength of freight hub port, produce service, business service and port service etc. Supporting utilizing old factories, warehouses and inventory land resources to construct logistics facilities or provide logistics services, creating conditions for road freight enterprises to develop integrate and specialized logistics services, manufacturing logistics, city distribution logistics and the logistics of agricultural products.

(4) Improving the degree of informationization

To carry out joint with the railway transport and cooperate with other similar enterprises, road freight enterprises should further improve the management of goods transport and informatization degree, and reduce the possibility of inefficient operation due to lack of information sharing. Small and medium-sized enterprises also have to strengthen their own information construction, actively mining business resources with the help of the public information platform and raise their credit rating; expand the opportunity to building enterprise alliance.

Speeding up the construction of data center, and comprehensively optimize the operation management system, increase the public service function of the government affairs information system. Strengthening data sharing with commerce, taxation, public security, roads, ports and other departments, improving the credit rating mechanisms and credit system of road transport enterprises, so that providing information support for strengthening their integrity service. Based on the transport logistics public information platform, actively guiding and encouraging large and medium-sized road transport enterprises to further perfect the function of information system, with information as the link, strengthening cooperation with small freight enterprises.

4 Conclusions

As two ways of land transport, there are obvious cooperation and competition between road and rail. The reform of railway freight set less-than truckload transport as the breakthrough point, in the long run, it will have an impact on the road freight industry which have direct relationship on competition and cooperation.

From the aspects of space scope and business types, this paper analyzed the possible impact of railway freight reform on general cargo transport in Ningbo. The result shows that the current railway freight market reform, bring greater opportunities than challenges to the road freight enterprises in Ningbo. Among them, less-than truckload transport, vehicle transportation and small express will not significantly affected by the railway freight reform in the short term, while in the long run, there is potential for less-than truckload and long-distance small express to make joint transport with railway.

Abstract: Containership slot exchange is a new cooperation strategy allowing participating carriers to seek to benefit from sharing capacities. On the basis of analyzing the characteristics of containership slot exchange and allocation problem in short sea cycle routes operated by liner alliances, this paper considers the uncertainties in revenue and demand then proposes a fuzzy chance-constrained slot exchange and allocation optimization programming model. The model takes marginal revenues and demands of different markets in fuzzy environments as fuzzy variables and aims at maximizing the total revenue of the liner alliance which operates multi-routes. A numerical example is applied to attest the method's practicability and feasibility. The conclusion suggests that in fuzzy environments, a proper containership slot exchange and allocation strategy can increase the total revenue of liner alliances significantly.

Keywords: Fuzzy environments; Liner alliances; Slot exchange; Fuzzy chance-constrained programming.

1 Introduction

In the contemporary international sea transportation industry, containership liner service has become the dominant mode. With the rapid development of economic globalization, more and more carriers began operating in alliances. Recently, slot exchange has become a common cooperation strategy adopted by many alliances. Slot exchange allows carriers to benefit from exchanging some of their capacities among certain routes. By adopting slot exchange, carriers can reduce cost, simplify management and decrease the risk brought by fluctuations in transportation demand markets. Due to these unparalleled advantages, slot exchange is gaining more and more popularity among liner alliances.

In the last decades, many scholars studied the slot allocation problem of liner services. Ha (Ha, 1994) and Maragos (Maragos, 1994) first studied slot allocation, slot control strategy, dynamic slot allocation in multi-legs and joint slot allocation of loaded and empty containers. Recently, scholars began to study slot allocation in a Joint fleet or alliance. Lu et al. (Lu, 2010) analyzed slot purchase strategy in containership liner service fleets and proposed a mathematical programming model to solve fleet deployment problem and slot allocation problem. Studies on slot exchange are quite scarce. The probably first relevant study is Lu (Lu, 2010), where the characteristics of slot exchange was studied and two integer programming models considering slot exchange alone and the integration of slot exchange and slot purchase respectively were proposed to maximize the concerned revenues.

International sea transportation has been proved to be a market suffering drastic volatility. There are great uncertainties in both transportation demands and revenues of liner services due to changes in global economy and oil prices. To deal with the uncertainties, this paper adopts the *fuzzy theory* which was first introduced by Zadeh (Zadeh, 1965). In this paper, *fuzzy chance-constrained programming* is adopted to formulate our model. *Fuzzy chance-constrained programming* was introduced by Liu (Liu, 1998).To the best of our knowledge, there is little research on chance-constrained slot allocation problem in fuzzy environment.

To conclude, the majority of relevant studies focus on slot allocation problem. Although some scholars have begun studying the problem of slot exchange (Lu, 2010), their research is confined under the assumption of deterministic environments and in the view of a single carrier. This paper considers the problem in an alliance's view and extends the problem into a fuzzy environment.

2 Preliminaries

In this paper, we adopt the concepts of *fuzzy chance-constrained programming theory* to help formulate the model with fuzzy variables. This section presents some basic knowledge about *fuzzy theory* and *credibility-based fuzzy chance-constrained programming*.

Let ξ be a fuzzy variable with *membership function* μ, and u and r be real numbers.

Definition 2.1 The *possibility* of a fuzzy event, characterized by $\xi \le r$, is defined by:

$$\text{Pos}\{\xi \le r\} = \sup_{u \le r} \mu(u)$$

Definition 2.2 While the *necessity* of $\xi \le r$ is defined by:

$$\text{Nec}\{\xi \le r\} = 1 - \text{Pos}\{\xi > r\} = 1 - \sup_{u > r} \mu(u)$$

Definition 2.3 The *credibility* of $\xi \le r$ is defined by:

$$\text{Cr}\{\xi \le r\} = \frac{1}{2}(\text{Pos}\{\xi \le r\} + \text{Nec}\{\xi \le r\})$$

Definition 2.4 The *credibility-based fuzzy chance-constrained programming model* maximizing the objective is given as follows:

$$\begin{cases} \max \ \overline{f} \\ s.t. \\ \quad \text{Cr}\{\text{f}(x,\xi) \ge \overline{f}\} \ge \beta \\ \quad \text{Cr}\{\text{g}_j(x,\xi) \le 0, j = 1,2,...,p\} \ge \alpha, \end{cases}$$

where α and β are *confidence level* given by the decision makers.

Lemma 2.1 Let $\xi_k = (r_{k1}, r_{k2}, r_{k3}, r_{k4})$, $k = 1,2,...,t.$ be a *trapezoidal fuzzy variable* and let function $\text{g}(x,\xi)$ be shown as follows:

$$g(x,\xi) = h_1(x)\xi_1 + h_2(x)\xi_2 + ... + h_t(x)\xi_t + h_0(x) \quad .$$

Let $h_k^+(x) = h_k(x) \vee 0$ and $h_k^-(x) = -h_k(x) \wedge 0$, $k = 1, 2, ..., t$.

The *Crisp Equivalent* of credibility-based fuzzy chance-constrained equation $\text{Cr}\{g(x,\xi) \le 0\} \ge \alpha$ is given by:

If $\alpha < 0.5$, $\text{Cr}\{g(x,\xi) \le 0\} \ge \alpha \Leftrightarrow (1-2\alpha)\sum_{k=1}^{t}[r_{k1}h_k^+(x) - r_{k4}h_k^-(x)] + 2\alpha\sum_{k=1}^{t}[r_{k2}h_k^+(x) - r_{k3}h_k^-(x)] + h_0(x) \le 0$

and if $\alpha \ge 0.5$, $Cr\{g(\text{x},\xi) \le 0\} \ge \alpha \Leftrightarrow (2-2\alpha)\sum_{k=1}^{t}[r_{k3}h_k^+(x) - r_{k2}h_k^-(x)] + (2\alpha\text{-}1)\sum_{k=1}^{t}[r_{k4}h_k^+(x) - r_{k1}h_k^-(x)] + h_0(x) \le 0$.

3 Problem description and formulation

We consider the problem in *Short sea cycle routes* which are a common route structure of short sea liner services. In cycle routes, cargoes are shipped by vessels at fixed freight rate, in fixed routes, among fixed ports and in a fixed cycle sequence, all of which should be listed in a *Shipping Schedule* published by carriers. Slot exchange deals with the mutual exchange of slot capacity among alliance participants. When adopting slot exchange strategy, slots can be exchange in and out by a carrier in different routes. In this paper, we measure the value of a slot in a certain route by the duration of a complete voyage of the route. For a liner alliance, its slot exchange and allocation decision can be stated as a two-stage process: first, each participant of the alliance should decide whether to exchange slots (both in and out) with its partners and the specific amount in each of its operating routes; second, the alliance should decide how to assign its slots so as to satisfy transportation demands and obtain the overall maximum revenue in all of its operating routes. As in containership liner services, the fixed cost is relatively high and constant, therefore, the objective to maximize the overall revenue of an alliance equals to maximizing the overall marginal revenue.

Assume a liner service alliance adopts slot exchange strategy in a shipping sector which includes several call ports. Without loss of generality, symbols for variables and parameters used in the formulated models are introduced and interpreted as follows.

S: set for carriers in the alliance; *R*: set for routes operated by the alliance; *P*: set for call ports; *T*: set for trade port pairs, $T=\{(i\to j)|i,j\in P,i\ne j\}$; L_r : set for legs in route *r*; ξ_{ij}^{kr} : a fuzzy variable, marginal revenue of shipment between port pairs $(i \to j)$ for carrier *k* in route *r*, $k \in S$; q^{kr} : voyage duration for carrier *k* in route *r*; M^{kr} : number of slots in TEUs hold by carrier *k* in route *r*; c_{ij} : contract transportation demands that must be satisfied between port pair $(i \to j)$; η_{ij} : a fuzzy variable, total transportation demands(including contract demands) between port pairs $(i\to j)$. Clearly, we have $Cr\{\text{c}_{ij} \le \eta_{ij}\}=1, \forall(i \to j) \in T$; *N* is a big number. μ_{ij}^r : μ_{ij}^r =1, if route *r* incudes trade pair $(i \to j)$ μ_{ij}^r = 0, otherwise; γ_{ijl}^r : γ_{ijl}^r =1, if the delivery passage of consignments of port pair $(i \to j)$ passing the sailing leg *l* of route *r*, γ_{ijl}^r =0, otherwise.

The decision variables are listed as follows. x_{ij}^{kr} : number of slots carrier *k* deploys in route *r* to ship cargoes between port pair $(i \to j)$; d^{kr} : number of slots company *k* exchange in from partners in route *r*; e^{kr} : number of slots carrier *k* exchange out to partners in route r. $h^{kr}: h^{kr}=1$, if company k exchange in slots in route r, $h^{kr}=0$, otherwise.

Based on the *fuzzy chance-constrained programming theory* the model maximizing the overall revenue can be formulated as follows:

$$\max \overline{f} \tag{1}$$

$$s.t. \quad Cr\{\sum_k \sum_r \sum_{(i\to j)} \xi_{ij}^{kr} x_{ij}^{kr} \geq \overline{f}\} \geq \beta \tag{2}$$

$$Cr\{\sum_k \sum_r x_{ij}^{kr} \leq \eta_{ij}\} \geq \alpha \qquad \forall (i \to j) \tag{3}$$

$$\sum_k \sum_r x_{ij}^{kr} \geq c_{ij} \qquad \forall (i \to j) \tag{4}$$

$$x_{ij}^{kr} \leq \mu_{ij}^{r} N \qquad \forall (i \to j), k, r \tag{5}$$

$$\sum_{(i\to j)} \gamma_{ijl}^{r} x_{ij}^{kr} - e^{kr} + d^{kr} \leq M^{kr} \qquad \forall k, r, l \tag{6}$$

$$\sum_k e^{kr} = \sum_k d^{kr} \qquad \forall r \tag{7}$$

$$e^{kr} \leq h^{kr} N \qquad \forall k, r \tag{8}$$

$$d^{kr} \leq (1-\beta^{kr})\, N \qquad \forall k, r \tag{9}$$

$$\sum_r q^{kr} e^{kr} = \sum_r q^{kr} d^{kr} \qquad \forall k \tag{10}$$

$$x_{ij}^{kr},\ e^{kr},\ d^{kr} \in N \cup \{0\} \qquad \forall (i \to j), r \tag{11}$$

$$\beta^{kr} \in \{0,1\} \qquad \forall k, r \tag{12}$$

In the model, the objective function in (1) maximizes the total transportation revenue of the alliance. Equation (2) means the alliance can obtain the maximal revenue at confidence level β. Equation (3) enforces that the distributed slots to ship cargos between port pair $(i \to j)$ should not exceed the corresponding transportation demand at confidence level α. Equation (4) means the contract demands must be satisfied. Equation (5) enforces that cargoes must be consigned through a certain route. Equation (6) constrains the sum of distributed slots on each sailing leg cannot exceed the available capacities which including the originally controllable slots plus the exchanged results. Equation (7) enforces the numbers of exchanged slots in TEU-days for both sides are consistent in each route. Equations (8) and (9) enforce that a carrier cannot exchange in and exchange out slots at the same time in the same route. Equation (10) enforces the slot exchange equity for each carrier. Equations (11) and (12) are nonnegative and integral constrains for decision variables.

Assume ξ_{ij}^{kr} and η_{ij} are both *trapezoidal fuzzy variables,* such that $\xi_{ij}^{kr} = (r1_{ij}^{kr}, r2_{ij}^{kr}, r3_{ij}^{kr}, r4_{ij}^{kr})$ and $\eta_{ij} = (t1_{ij}, t2_{ij}, t3_{ij}, t4_{ij})$, where r and t are both real numbers.

According to Lemma 2.1**,** equations (2) and (3) can be replaced by their crisp forms, where $\alpha > 0.5$, $\beta > 0.5$ and $x_{ij}^{kr} \geq 0$:

$$-(2-2\beta)\sum_k \sum_r \sum_{(i\to j)} r2_{ij}^{kr} x_{ij}^{kr} - (2\beta-1)\sum_k \sum_r \sum_{(i\to j)} r1_{ij}^{kr} x_{ij}^{kr} + \overline{f} \leq 0 \tag{13}$$

$$-(2-2\alpha)\, t2_{ij} - (2\alpha-1)\, t1_{ij} + \sum_{k\in S} \sum_{r\in R} x_{ij}^{kr} \leq 0 \qquad \forall (i \to j) \in T \tag{14}$$

Therefore the above model can be transformed into a *crisp mixed integer programming model* and can be solved by *Cplex* to obtain the optimal solution.

4 Numerical Experiment

We consider an alliance that consists of three carriers (K1, K2 and K3). The alliance operates three routes, namely R1, R2 and R3 between sectors A and B. Further, we assume consignments within the same sector are forbidden due to policies like *Cabotage Reservation*. The route structure and operation details are shown in figure 1 and table 1:

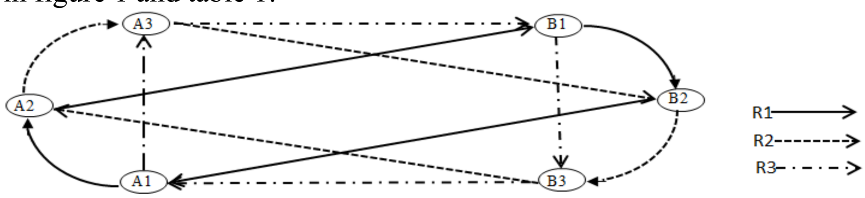

Figure 1. Route structure

Table 1. Operation details

Route（Carriers）	R1（S1, S2）	R2（S2,S3）	R3（S1,S3）
Structure	A1→A2→B1→B2→A1	A2→A3→B2→B3→A2	A1→A3→B1→B3→A1
Capacity（TEU）	K1:2000, K2:2100	K2:2550, K3:2500	K1:2500, K3:2600
Duration（Day）	K1:14 K2:14	K2:14 K3:14	K1:14 K3:14

Table 2 and table 3 show details of the demand and revenue in different routes operated by the alliance in fuzzy environments.

Table 2. Fuzzy demands of different port pairs

K2	Exchange-in	2000	Exchange-out	2550	Exchange-in	550
K3	None	0	Exchange-in	2550	Exchange-out	2550
Total revenue($)			3456644			

Table 5. Slot allocation result

	Carrier	A1-B1	A1-B2	A2-B1	A2-B2	B1-A1	B1-A2	B2-A1	B2-A2
R1	K1	0	0	0	0	0	0	0	0
	K2	483	510	500	615	1022	500	470	0
	K3	0	0	0	0	0	0	0	0
	Carrier	A2-B2	A2-B3	A3-B2	A3-B3	B2-A2	B2-A3	B3-A2	B3-A3
R2	K1	0	0	0	0	0	0	0	0
	K2	0	0	0	0	0	0	0	0
	K3	0	875	270	949	1802	764	390	0
	Carrier	A1-B1	A1-B3	A3-B1	A3-B3	B1-A1	B1-A3	B3-A1	B3-A3
R3	K1	827	1196	0	0	0	726	1051	700
	K2	0	0	315	0	0	0	235	0
	K3	0	0	50	0	0	0	0	0

After adopting slot exchange strategy, the total revenue of the alliance is 3.46 million dollars. The revenue without slot exchange is 3.33 million dollars which is obtained by setting variables d^{kr} =0 and e^{kr} =0. Therefore, by adoption slot exchange, the alliance can increase its revenue by 3.7% without increasing capacities.

5 Conclusions

This paper studied slot exchange and allocation problem in containership liner services in fuzzy environments in an alliance's view, proposed a fuzzy chance-constrained programming model and transformed it into a crisp programming model. The result of the numerical experiment shows slot exchange can significantly increase the overall revenue of liner alliances. Here we may draw the following conclusions. (1) Slot exchange ensures the equity and convenience among alliance participants and at the same time, enables participating carriers to optimize slot allocation in an alliance level so as to enhance the profitability of capacities. (2) *Fuzzy theory* or *fuzzy chance-constrained programming* can be successfully adopted in analyzing, formulating and solving slot exchange and allocation problem in liner alliances in fuzzy environments.

Cohesion of Urban Rail Transit and Other Transportation

Zhichao Huang; Xilin Peng; and Liming Lu

Key Laboratory for Conveyance and Equipment, Ministry of Education, East China Jiaotong University, Nanchang, Jiangxi 330013, China. E-mail: hzcosu@163.com

Abstract: A period of construction developed rapidly has already came up in urban public transport system, and in which urban rail transit is the backbone. Urban rail transit consists of light rail with large capacity and subway. The trend of urban transportation's development is the division of labor and cooperation of all modes of transportation. Then a development model of traffic integration could be formed. The joins between various transportation modes and rail transit are important links. Joins and coordinators of urban rail traffic system and other means of transportation include two points, that is the links between paths and transfers between stations. This paper mainly conducted studies in aspects of rail link modes, transfer time and transfer distance. And the influence factors and planning objectives of urban rail transit are also analyzed. Taking the subway under construction in Nanchang for example and concrete analysis and evaluation about links of urban rail transit was obtained.

Keywords: Urban rail transport; Connection modes; Transfer time; Transfer distance; Planning goals.

1 Introduction

The development of economy and the change of industrial structure, bringing the expansion of city scale and sharply increase of urban populations. According to relevant statistic, the number of urban population in China reached 731 millions in 2013, the urbanization rate reached 53.7%, it leads to enormous pressure to urban traffic. Furthermore, the number of motor vehicle in China also in growth, in 2014 the number of domestic cars is about 140 millions. The number of cars in China has grown from 24 millions to 137 millions, which is 5.7 times of that in 2003.Traffic demand expand rapidly, while the road traffic infrastructures are outdated. That leads to the sharply contradiction of city traffic between supply and demand, meanwhile, traffic congestion situation happens.

People, vehicle and rode are three important elements in traffic, deal with the contradiction between three elements are very important in solve city traffic problems. Construction of the urban traffic is a decision-making engineering system. Lacking of scientific and comprehensive transportation strategy should be responsible for current traffic problems. The governments' disorder works make investment very large, but without returns. The wrong understanding of city functions will cause traffic intersect and overlap as well as over-expansion of passengers and logistics, then will certain cause traffic jams. The goal of city traffic development is establish a comprehensive transportation system. The traffic in big city should combined with construction planning to set up a network system, the urban traffic also need convenient public transportation, trams, taxi and necessary urban rail transit (Lv, 2005).

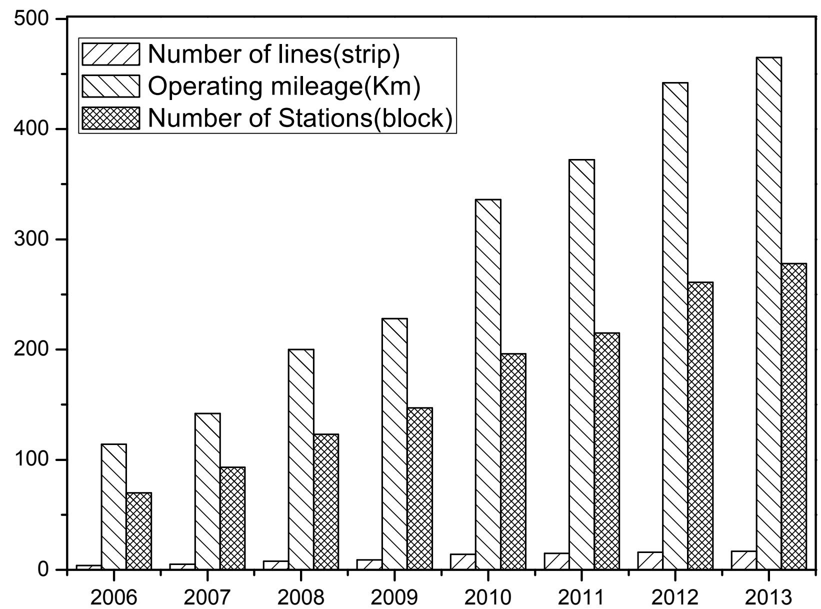

Figure 1. Beijing rail transit network situation

In city, urban rail transit system is a kind of public passenger transport, it has many advantages such as large capacity, fast, safe, energy-saving, comfortable and low pollution. Among the compositions of urban transport system, rapid rail transit system hold the dominant and backbone position. However in order to try best use of the traffic potentiality, transportations must combine with good feeder system and cohesion system (Wang, 2009). Thus the reasonable planning, designing and construction of transportation hub play a key role in the increase of economic benefits of urban integrated passenger traffic system, reducing residents' travel time and determine the public transportation.

2 Analysis of rail traffic connection mode

2.1 The city rail convergence

Urban rail transit mainly comprise of light rail with large capacity, subway and other transportations. There are many means of the convergence between urban rail transit and other transport modes. It can be divided into city traffic and city outskirts traffic. Convergence of city outside traffic includes rail, aviation and ports. Convergence of city inside traffic includes rail, buses, cars, bicycles and walking.

Railway is an important part of comprehensive transportation system, it contains railway transportation and city traffic. Passengers who take trains always use buses and other public transportations to go to railway station. Adding urban rail transit into railway station could evacuate passengers quickly and efficiently. There are many connected modes between railway station and rail transit. The common ways are: (1) Construct rail transit station in front of railway station square and channel intersection set in station square, then through station square to form cohesion with the railway station. (2) Rail station export channel directly lead to the hub of station hall, after outbound, passengers will be able to enter station's waiting room or ticket office. (3) The hall layer of rail station leads to the platform of the passenger station directly, and connected with it through stairs or escalators. (4) Rail transit united with railway to set stations.

Air transport is a main method of high-speed transportation, with many advantages such as fast speed, long transport distance, comfortable, safety, mobility, less investment, short construction period and so on. Air transport is suitable for the goods freight which have the following features, long distance, small volume, time requirement or high freight etc. Due to high requirement of the clearance of space, the airport always apart from city center areas. Due to high requirement for time, the rail transportation with the characteristics of rapid, convenient and large capacity is more suitable than the conventional bus for air transport connection system.

Large passenger port is the hub of urban passenger traffic. Conventional bus, taxi, rail transportation and other public transportation could all be used in harbor transportation system. While rail transit needs the turning radius and high vertical requirement of construction, its application in urban rail transit has yet to be further perfected.

2.2 The outskirts rail convergence

Bus rapid transit combined with modern bus technology, intelligent traffic and operations management to set up bus special lane and build the new form of bus station. The cohesion of bus rapid transit and rail transit can transfer through the station or use one-stop tickets as well as near distance transfer (Figure 1). One-stop tickets make the seamless connection of Bus Rapid Transit and rail transit come ture. Reasonable cohesion can expand the service scope of urban public transportation system effectively and improve the operation efficiency of city traffic rapidly (Lv, 2005).

(a) With the transfer station (b) Iso-station transfer

Figure 2. Transfer modes

Conventional bus is a common transport of city public traffic, and its characters are wide coverage and accessibility. The connection of conventional bus and rail transit use more midway stops and rail transit stations for near distance transfer. Introducing station line in public transport hub station could guide the transfer between conventional bus and rail transport. In particular, the walking facilities between public transport hub station and fore and aft of bus station do good to the transfer.

Set up a special station in the planning of the linkage between taxi and rail transit. In order to cooperate with footwork system the transfer area can be in the same position or be scattered layout. The location of taxi station should be farther than public station and trams station. The areas of taxi turnover, passenger stream areas, the waiting areas and the queue areas should separate from bus and trams routes, thus could reduce the interference of bus and trams travel (Li, 2005).

The growth of private motor vehicles is a major pressure of city road. Building car parking around the urban rapid rail transit station, and then forming a transfer station between car and urban rapid rail transit(Jiang, 2001). This kind of convergence means driving from residence to high-capacity rail transit station then taking rail transit to their destination. This transfer mode need attract vehicle and reduce the load of roads. Meanwhile, the reduced traffic on the relevant roads could drop crowds and improve travel speed and comfort of vehicle (Gan, 2006).

Bicycles play a significant role in city traffic. Therefore, in the connected planning of Urban Rail Transit, government could propose to set certain size parking in residential areas and the city’s main intersection. This setting of bicycle parking should take the land and buildings around the station into consideration. In the downtown area where land valued can use underground space to set parking lot. It would facilitates passengers realize their transfer at the short distances and save transfer time.

Walking is an indispensable part of public transportation. Improve walking conditions will be help to lift transit service levels. In public transportation system, walking plays a role in short distance transfer, and it is a convenient transfer transportation for subway riders. Pedestrian crossing facilities include pedestrian platform bridge and underground passageway. Reasonably pedestrian facilities, transfer security and transfer patency are the key points to improve the walking transfer.

3 The influence factor of urban rail transit cohesion

There are many factors that affect urban rail transit cohesion, generally can be divided into residents travel habits, urban character and guidance policy.

(a) the factors of residents' travel habits include: travel behaviors, easy of transfer, travel time and comfort of travel and so on(Shi, 2012). Affecting by city traffic situation and city scale, acceptable transferring times is one of the reference factors of the convergence of rail transit and other transportation. Such as, residents can through one transportation modes reach majority of the urban areas if the traffic situation is good. Residents have high requirement of connection, rarely choose bus, cars, bicycle as their transfer transport modes, therefore complete the connection work between pedestrian traffic and rail traffic is very important. Travel time is also an important factor in transit linking system. The same time for different transportation modes have different travel distance. Subject to travel time, residents will choose the efficient one.

(b)the factors of urban areas characters include: topography, climate and other aspects of urban features. The influence of topography on urban transport is mainly reflected in travel mode, the roads' slope is large in those cities where have lots of mountainous and hilly. So citizens would prefer to choose public transportation rather than bicycle or pedestrian travel and government should pay more attention public transportation; Cities in plain areas should focus on bicycle and pedestrian traffic.

The impact of climate mainly was the proportion of residents who travel use bicycle, motorcycle or on foot decreased on cold day. In the city where climate pleasant, residence are more likely choose bicycle or walking as their travel tools. Therefore these cities should focus on the convergence of pedestrian and bicycle traffic.

Urban construction area is wide, cities that have fewer building always have higher motorization lever, so they should concentrated on the connection of motor vehicle and rail transit. Cities with more buildings means with high travel proportions, meanwhile they are more suitable for residents who travel by bike, bus or other transportation which occupy less land resource. Therefore, cities should pay more attention on the convergence of rail transit and these transportations.

(c)factors of urban guidance policy include: development policies of cars and buses etc. Cars development policies are the main way to guide the city traffic development. Such as Shanghai, Beijing and other cities adopt rules such as restrict new vehicle licensing, inhibit motor vehicle quantities and raising parking fees in central area to guide private cars application. Simultaneously, those cities should improve the convergence of rail transit and private car and encourage transfer private cars to transportation(Shi, 2012).

4 The analysis of the connected of Nanchang rail transit under construction

4.1 Forecast planning of Nanchang city's rail transit

Nanchang track traffic is the first underground subway transport system in Jiangxi province metropolitan areas. The line is divided into two stages. The first stage was composition of the first phase of line 1, line 2, line 3 subway; the second stage includes line 4, line 5 subway and the second phase of line 1, line 2, line 3 subway. The two stages constitute of a complete rail transit network and achieve the overall goal of network planning.

4.2 Advice on connection mode

According to the survey, the urban motorized numbers were 2.44 millions passengers/day in 2010, vehicle turnover numbers were 22.84 millions passengers*km/day, numbers was respectively 2.58 times, 6 times than those in 2002. In addition, according to the geographical environment, Nanchang Located in the subtropical regions have humid and monsoon climate. In there the humid climate is mild, sunshine abundant, summer and winter long while spring and fall short. Nanchang is a typical city where summer hot and winter cold. If you choose a bike for your trip, you will get a sweat body in summer and stiff arms in the winter, hence residents are more likely to choose motor vehicles, such as buses or private cars as their travel tools.

(a)Based on function features in different areas, we should have different attitude for them and choose different convergence as the key point. Such as: the central area gathered many works, so the morning rush hour attract a lot lf traffic and the evening rush hour arise many traffic. City center was strain on the land resources and have a large number of buildings, so central areas should focus on the convergence of tramp or bus with rail transit. T he convergence facilities should mainly serve commercial and finance areas, administrative office and other areas where jobs gathered. In city neighboring areas, the morning rush hour arise much traffic, the evening rush hour attract much traffic. Peripheral areas are living areas, so they should focus on the convergence of buses, cars, or cars with rail transit. Their convergence facilities should mainly serve residential areas. Mixed areas of commercial and residence split by residential and employment, and located in middle areas of center region and peripheral region in city. Both the morning rush hour and the evening rush hour will attract a lot of traffic. Due to the multiple functions, they should focus on the convergence of walking, buses, taxis with rail transit. Similarly, the convergence facilities should serve both employees and residents. The peak time in tourist areas are different from urban areas. Its peak time always arise during holidays. Different tourism projects also meet different peak time. Tourist areas should pay more attention on the convergence of walking or buses with rail transit. The convergence facilities should reached the entrance of tourist areas.

(b)Diversification of convergence modes means the various forms of convergence. As for Nanchang rail transit, the core area should focus on the convergence of buses, private cars and rail transit, and supplement with the convergence of walking, taxis with rail transit.

Walking is suitable for short-distance travel. In core areas of Nanchang, if you travel on foot, the average time is about 10min and the average distance about 0.8km. So the coverage of convergence facilities, where rail transit transfer by walking, should within 1km. Bus is suitable for long distance travel, and the travel distance about 1 km to 4km. So the coverage of the convergence facilities, where rail transit transfer by the bus, should be between 1km and 4km. Car and taxi is suitable for longer distance travel, with which the acceptable travel speed is higher than 15km/h and the travel distance about 3km to 10km. Therefore, the coverage of the convergence facilities, where rail transit transfer by cars or taxis, should be between 3km and 10km.

5 Conclusion

Modern city need modern transportation system, which adapt to modern life. In order to ease and improve the heavy traffic, city should form a comprehensive traffic pattern that highly coordinate with the urban develop. In order to improve its attractiveness and realize its functions of rail transit, rail transit should closely connected with other transportations, their transfer should be easy and their work should be interoperable. Through the integration of space and time implement “seamless and zero transfer”.

Abstract: In recent years, with rapid development of the comprehensive transportation system, the contradiction between transportation and energy has become more and more serious; energy has become a constraint to the sustainable development of China's comprehensive transportation system. How to optimize the comprehensive transport system structure effectively and promote the comprehensive transportation system sustained development has become an important problem that urgent to be solved. This paper considers the "energy consumption" as constraints, establish decomposition model to analysis the variation of energy consumption. Research shows that, when considering the constraints, it increases the proportion of rail transport and waterway transport in a comprehensive transport system. Therefore, under the constraints of energy consumption, the system should make planning to realize the coordination of transport modes. Especially, should greatly develop railway and waterway which have low energy consumption and little effect on environment.

Keywords: Comprehensive transportation; Energy consumption; Decomposition model; Environmental protection.

1 Introduction

This paper establishes the complete decomposition model to analysis the variation of energy consumption of comprehensive transportation. On the basis of the analysis of energy consumption of different period corresponds to the comprehensive transportation system structure, we parsing the relationship between them. A calculation example is gave based on the statistical data of 1995-2011.The resulting in optimizing the structure of the comprehensive transport system.

2 Modeling

By establishing a complete decomposition of the following model will divided the influencing factors of energy consumption into three parts, traffic volume, energy consumption intensity and system structure of comprehensive transportation.

Decomposition model is show as follow:

$$E(t)=VA(t)\times\frac{\sum_{i=1}^{n}E_i(t)}{VA(t)}=VA(t)\times\frac{\sum_{i=1}^{n}VA(t)\times SV_i(t)\times EI_i(t)}{VA(t)}=VA(t)\times\left[\sum_{i=1}^{n}SV_i(t)\times EI_i(t)\right] \quad (1)$$

$$\Delta E(t)=VA(t)\times\left[\sum_{i=1}^{n}SV_i(t)\times EI_i(t)\right]-VA(0)\times\left[\sum_{i=1}^{n}SV_i(0)\times EI_i(0)\right]$$

$$=\left[VA(0)+\Delta VA(t)\right]\times\left\{\sum_{i=1}^{n}\left[SV_i(0)+\Delta SV_i(t)\right]\times\left[EI_i(0)+\Delta EI_i(t)\right]\right\}-VA(0)\times\left[\sum_{i=1}^{n}SV_i(0)\times EI_i(0)\right]$$

$$=\left[VA(0)+\Delta VA(t)\right]\times\left\{\sum_{i=1}^{n}\left[SV_i(0)\times EI_i(0)+\Delta SV_i(t)\times EI_i(0)+SV_i(0)\times\Delta EI_i(t)+\Delta SV_i(t)\times\Delta EI_i(t)\right]\right\} \quad (2)$$

$$-VA(0)\times\left[\sum_{i=1}^{n}SV_i(0)\times EI_i(0)\right]$$

$$=VA(0)\times\sum_{i=1}^{n}\left[\Delta SV_i(t)\times EI_i(0)+SV_i(0)\times\Delta EI_i(t)+\Delta SV_i(t)\times\Delta EI_i(t)\right]$$

$$+\Delta VA(t)\times\left\{\sum_{i=1}^{n}\left[SV_i(0)\times EI_i(0)+\Delta SV_i(t)\times EI_i(0)+SV_i(0)\times\Delta EI_i(t)+\Delta SV_i(t)\times\Delta EI_i(t)\right]\right\}$$

Where t is time period t; i is kinds of modes of transport;

$E(t)$ —The total energy consumption of the transport sector (tones of oil equivalent)

$\Delta E(t)$ —Relative to the reference periods, increased amount of total energy consumption in the transport sector;

$E_i(t)$ —transportation energy consumption of mode i;

$EI_i(t)$ —transportation energy consumption intensity of mode i;

$EI_i(0)$ —transportation energy consumption intensity of mode i in reference period;

$\Delta EI_i(t)$ —relative to the reference periods, the increases of energy consumption intensity of mode i;

$VA(t)$ —turnover of all modes of transport;

$VA(0)$ —turnover of all modes of transport in reference period;

$\Delta VA(t)$ —Relative to the reference periods, the increase of turnover in period t.

$SV_i(t)$ —in period t，percentage of turnover by transport i of total.

$SV_i(0)$ —percentage of turnover by transport i of total in reference period;

$\Delta SV_i(t)$ —Relative to the reference periods，the increase of percentage that turnover by transport i of total in period t.

According to theory of "jointly created and equally distributed", we can obtained the contribution value of $VA(t)$、$SV(t)$ and $EI(t)$. The influence analyses are as followed:

(1)Effect of $VA(t)$ on $\Delta E_{VA}(t)$.

$$\Delta E_{VA}(t)=\Delta VA(t)\times\left\{\sum_{i=1}^{n}\left[SV_i(0)\times EI_i(0)+\frac{1}{2}\times\Delta SV_i(t)\times EI_i(0)+\frac{1}{2}\times SV_i(0)\times\Delta EI_i(t)+\frac{1}{3}\times\Delta SV_i(t)\times\Delta EI_i(t)\right]\right\} \quad (3)$$

(2)Effect of $SV(t)$ on $\Delta E_{SV}(t)$.

$$\begin{aligned}\Delta E_{SV}(t) &= VA(0)\times\sum_{i=1}^{n}\left[\Delta SV_i(t)\times EI_i(0)+\frac{1}{2}\times\Delta SV_i(t)\times\Delta EI_i(t)\right] \\ &+\Delta VA(t)\times\left\{\sum_{i=1}^{n}\left[\frac{1}{2}\times\Delta SV_i(t)\times EI_i(0)+\frac{1}{3}\times\Delta SV_i(t)\times\Delta EI_i(t)\right]\right\}\end{aligned} \quad (4)$$

(3)Effect of (EI) on $\Delta E_{EI}(t)$.

$$\begin{aligned}\Delta E_{EI}(t) &= VA(0)\times\sum_{i=1}^{n}\left[SV_i(0)\times\Delta EI_i(t)+\frac{1}{2}\times\Delta SV_i(t)\times\Delta EI_i(t)\right] \\ &+\Delta VA(t)\times\left\{\sum_{i=1}^{n}\left[\frac{1}{2}\times SV_i(0)\times\Delta EI_i(t)+\frac{1}{3}\times\Delta SV_i(t)\times\Delta EI_i(t)\right]\right\}\end{aligned} \quad (5)$$

(4)The relationship between（3）and（5）

$$\Delta E(t)=\Delta E_{VA}(t)+\Delta E_{SV}(t)+\Delta E_{EI}(t) \quad (6)$$

By analyzing the decomposition results, combine the data of transportation volume and energy consumption of comprehensive transport systems, we can find the variation of energy consumption.

3 Case studies

3.1 Data and method

Supported by the available literatures, the conversion coefficient is determined as follows: Railway is 1, Highway is 0.1, Water transport is 0.33, and Aviation is

0.072.Data of turnover is from China Statistical Yearbook and data of energy consumption is from energy balance of IEA.

3.2 Results and discussion

The Converted turnover of comprehensive transportation, structure, energy consumption intensity is shown in Table 1; the decomposition result is shown in Table 2.

Table 1. Converted traffic turnover, structure and energy intensity of comprehensive transportation system in China from 1995-2011

Years	1995	2000	2005	2010	2011
Converted turnover (*VA*)	40020.66	49621.89	87418.87	152416.34	170963.17
Structure(*SV*)	(%)				
Railway	41.5	36.9	31.6	24.9	23.9
Highway	13.9	14.7	11.3	29.5	31.7
Water transport	44.4	47.9	56.8	44.9	44.1
Aviation	0.2	0.2	0.3	0.3	0.3
Energy intensity (*EI*)	(Kilogram oil equivalent/KMS)				
Railway	0.0077	0.0079	0.0075	0.0072	0.0069
Highway	0.0721	0.0703	0.0672	0.0631	0.0616
Water transport	0.0076	0.0068	0.0067	0.0065	0.004
Aviation	1.0326	1.0103	0.9061	0.7513	0.6512

Table 2. Contribution of different factors on energy consumption of comprehensive transportation (10^5tons of oil)

Years	1995-2000	2000-2005	2005-2010	2010-2011
$\Delta VA(t)$	9601.23	37796.98	64997.47	18546.83
$\sum SV_i \cdot EI_i$	0.0179	0.0178	0.0162	0.0255
$\sum SV_i * \Delta EI_i$	-0.0005458	-0.0003561	-0.001121	-0.001937
$\sum \Delta SV_i * EI_i$	0.0006223	-0.0007803	0.0113134	0.0010989
$\sum \Delta SV_i * \Delta EI_i$	-0.0000593	-0.0000042	-0.0007611	-0.0000195
Turnover contribution（Iva）	172.1	651.2	1367.7	465.1

Structure contribution（*Isv*）	26.6	-59.3	1307.9	176.3
Energy intensity contribution（*Iei*）	-25.8	-21.5	-184.3	-315
Total	172.9	570.4	2491.3	326.4

The results show that the contribution to the energy consumption of structure has become more and more important. As the Fig 1 shown, the contribution of structure from 1995-2000 was just 15.4%, but it increase to 52.5% from 2005-2010, what more it reach 54% in 2010-2011.

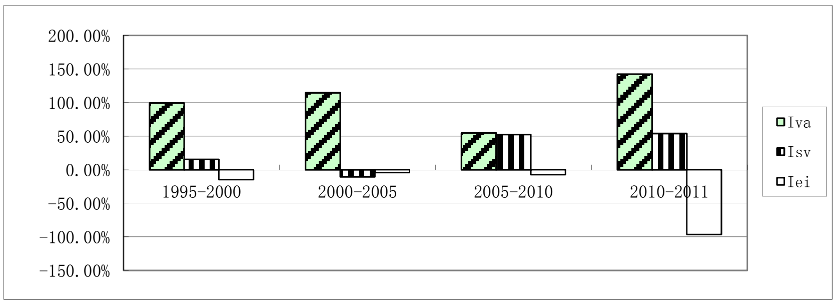

Fig 1. Contribution rate of three factors of comprehensive transportation system in China from 1995-2011

The contribution rates from 2000-2005 was -10.4%, it looks like unreasonable, but when combine the data of turnover (Fig.2) with it, we found that it due to the percentage of turnover of water transport increased in 2003-2005.Beacuse of the low energy consumption of water transport, when its share increases, led to the structure had negative effect on energy consumption growth, it also reflects the importance of an comprehensive transport system structure influence on energy consumption.

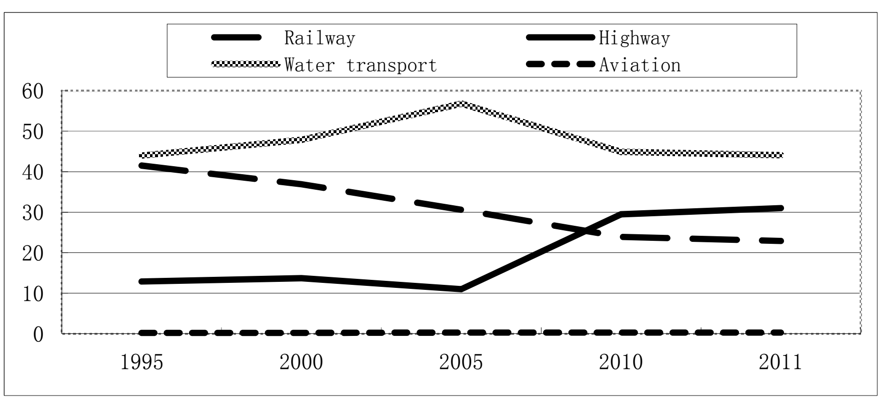

Fig 2. Structure of comprehensive transportation system from 1995-2011

4 Conclusions

Research shows that, when considering the energy constraints, the proportion of waterway and railway increased obviously because of the excellent performance in energy consumption. In the long run, when the traffic volumes grow inevitably, we can optimize the structure of integrated transportation system to save resources by improving the structure of comprehensive transport system. Therefore, the system should make planning to realize the coordination of transport modes. Especially, should greatly develop railway and waterway which have low energy consumption and little effect on environment.

Abstract: Based on the study of development and technical features of piggyback transport abroad, this paper analyzes the necessity and feasibility of developing piggyback transport in china under the new situation of promoting comprehensive transportation system, and focuses on the key problems concerning policies and regulations, vehicles and transportation organization, yard facilities, technical personnel and so on.
Keywords: Piggyback; Comprehensive transportation; Demand; Problem.

1 Introduction

Characterized by safe, convenience, large capacity, all-weather, energy-saving and environmental protection, piggyback transport is an integrated transportation for goods, which can play the advantages of long distance trunk railway transportation and also achieve superiority of road logistics for 'door to door' service. It's truly seamless between railway and road logistics.

At present, to develop piggyback transport, we need to solve barriers on laws and regulations and a series of technical problems such as equipment, yard facilities, operation and management and information platform construction. Meanwhile related standard system needs building and revising.

2 Overview of Foreign Piggyback Transport

Dating back to 1940s, the piggyback transport in North America has been more than 70 years of history. Its application in Europe can also track back to 1980s. Therefore, after years of development, the piggyback transport in foreign countries has formed a mature operating pattern and management system.

2.1 Piggyback Transport in North America

The piggyback transport is one of the ways of railway express transport in North America. Over 160 cities was involved in its transport network, which is almost covering the whole region. To meet the needs of the market and be accepted by the customers, North America strengthens the combination of railway, road, airway and water transport to offer inter-modal services, so as to achieve 'door to door' logistics by one-stop service in the whole journey. In this region, the economic transport distance on railway for piggyback transport is about 900km and beyond. At present, highway semi-trailers are used as its main transport objects. Due to a relatively-high railway clearance, the type of common rail container flat car can actually achieve piggyback transport. For semi-trailers, the way of lifting is necessary when loading and uploading. Hence, the forklift or front loaders will be well-equipped in the rail station.

2.2 Piggyback Transport in Europe

In Europe, the flexible road logistics had big advantages before due to the short transport distance brought by the narrow lands of European countries. However, with dense population and high motorization rate, the traffic congestion has become more and more severe. Adding the continuous improving standards on environmental protection, the suitability of road logistics is reducing. In view that the piggyback transport could efficiently solve the above-mentioned issues, like over-congestion, it has made great progress in Europe, especially under the push of France and Germany. The traditional piggyback transport objects in Europe are highway truck, trailer, highway semi-trailer, container trailer, cars, etc. Flat cars are commonly used as carrying tools, most of which are specialized flat cars with low center of gravity (Lin Jieliang,2014). Besides, restricted by the height of clearance, the concave bottom structure is applied into piggyback vehicle to suit the height.

2.3 Key Features of Foreign Piggyback Transport

(1)Techniques on specialized railway vehicles in foreign countries have been very mature and reliable. The lifting way in piggyback transport will be constantly replaced by self load-and-upload to improve efficiency, which will be the direction of piggyback vehicles.

(2)The infrastructures are dedicated to supporting the use of the specialized railway vehicles, which forming a complete standard system on 'collecting and distributing'. The integral train with fixed-point and routing operation has high efficiency and good benefits.

(3)With the rapid development of highway semi-trailers, the piggyback transport has made further progress in economic benefit and efficiency. Hence, the highway semi-trailer is also the future direction.

3 Demands of Piggyback Transport for Comprehensive Transportation

The comprehensive transportation system, as a new trend and direction to develop modern transport, requires to coordinate each way of transport to operate reasonably and orderly, to optimize transport structure, so as to play their respective advantages to realize coexistence and complementary (Hong yan,2013). On one hand, the development of piggyback transport can make railway and road logistics inseparable; on the other hand, to ensure the safety of the whole process, the following demands for comprehensive transportation need satisfaction.

3.1 Policy and Regulation

(1)License Management

At present, the trailers and semi-trailers can make free combination, which breaking the limits in manufacturing and administrative sector. However, due to the implementing differences, the original system is still playing a role to some extent to restrict the development of drop and pull transport. In our country, the license management should be a priority issue to be solved to develop piggyback transport with semi-trailers.

(2)Insurance

In piggyback transport, the highway truck is the carrier of freight transport, and also a part of railway carrying goods in the perspective of goods weight and package. Therefore, once traffic accident happening, it is easy to generate problem on responsibility and cause economic dispute. Based on this situation, the issues concerning insurance should be taken into consideration when implementing related transport systems.

(3)Annual Inspection

The highway truck or semi-trailer will obviously reduce damage when applying to piggyback transport. Therefore, to improve efficiency, the annual inspection time should be extended appropriately.

(4)Rate Policy and Charge Standard

In China, the piggyback transport is still in the initial stage without any organization pattern being used successfully. Hence, to make it healthy, a new freight rate policy and charge standard should be studied and formulated in accordance with the features of piggyback transport.

3.2 Highway Trucks

(1)Dimension Specification

The dimension of the highway truck (lengthen, breadth and height) should get through the limits of detecting equipment installed in the railway station to accept related tests in accordance with *Regulations for Railway Freight Traffic* and *Railway Cargo Loading Reinforcement Rules*. The ones whose dimension cannot reach the standard should be strictly prohibited in piggyback transport. It is suggested that the van truck would be a good choice in the preliminary stage of piggyback transport.

(2)Loading Weight Specification

The weight of the highway truck should pass the test of the electronic weighing machine equipped in the station. For the ones with overloading or unbalance loading, a relevant reorganizing is necessity. After compliance, the piggyback transport is allowed to continue. Once the total weight exceeds 55t, the piggyback transport should be forbidden.

(3)Loading Reinforcement Specification

It is necessary for non-vans to make reinforcement after loading goods. Moreover, the reinforcement should conform the related rules. If not, the piggyback transport should be prohibited.

(4)Technology State Specification

Due to the huge differences of highway trucks on technology state, some of them with poor state are actually incapable of meeting the requirements of piggyback transport. Therefore, the related technical standard should be set to help improve the highway trucks applied in. To be more adaptive, new structures and new technologies should be strengthened on highway trucks.

3.3 Station Infrastructures

The piggyback transport has high demands on railway station and railway clearance. Based on the structural features and operating modes of the piggyback transport, the railway station involved in must have the following conditions so as to make sure the highway trucks could up-and-off the piggyback vehicles by themselves.

(1)Specification on Operation Area and Hardened Ground

A special operation area for the piggyback transport should be laid off within the large marshaling yards or freight yards to meet the needs of complete train-load (straight line better). Besides, the ground here should be hardened and in line with the height of track. A certain breadth should be given as well, taking vehicle steering, safe operation and temporary parking into consideration.

(2)Specification on Freight Detecting Equipment

Before loading onto the piggyback vehicle, it is necessary to carry out security check to the goods loaded in the trucks so as to conform the regulations for railway freight transport.

(3)Specification on Limits and Weighing Machine

The limit testing device and weighing machine must be installed in the station to avoid the situation of over-limit and overloading.

(4)Ground Power Supply

The ground power should be provided in the railway station to support the lifting and rotating of the piggyback vehicles. Meanwhile, issues concerning water feeding and trash cleaning should be solved as well.

3.4 Personnel

In China, it is still blank in transporting freight trucks by railway. Because of large dimension and weight of freight trucks, this kind of transport can be classified into transportation of special goods. Hence, it is necessary to train on-site operation workers in the perspective of combined transport and transportation of special goods (Zhang Guoping,2009).

(1)Driver

In the piggyback transport, the highway truck needs up-and-off the specialized railway vehicle by itself. In accordance with the structural features of the specialized railway vehicle, some highway trucks need back into the vehicle. Therefore, the drivers must possess high skills in backup. To avoid unnecessary collisions between highway truck and piggyback vehicle, the drivers should accept the professional training to meet the loading requirements.

(2)On-site Operation Workers

In accordance with the structural features of the specialized railway vehicle, the on-site operation workers need help finish a series of actions like lifting and rotating, so that the highway truck could on-and-off it by itself. Hence, it is necessary to carry out special training for on-site workers to make the loading successful and to meet the needs.

4 Key Problems of Development of Piggyback Transport in China

(1)Establishing Coordination and Communication Mechanism

The piggyback transport is one of the modes of combined transport between railway and road logistics. It depends on several factors whether this combined transport could enjoy a rapid development or not, especially depending on the coordination and cooperation of the two sides. Therefore, the related regulations should be implemented and mechanism established to ensure its rapid development based on the features of the piggyback transport.

For example, we should establish freight timeliness safeguard mechanism. Time freight has high added value, but high demand on time. Many freight owners request not only fastness and punctuality, but also arriving then leaving. To ensure the interests of the consumers, it is suggested to set up corresponding transport contracts. For those based on contracts, once meeting commitments failure, the consumers have the right to claim for compensation. The contract guarantees not only the severe quality management and supervision on time freight, but also the commitments of timeliness and other services.

(2)Standard Operating

The drop and pull transport is the most advanced transport modes, but it is still in the initial stage in China. At present, many difficulties need overcoming and solving to develop this kind of transport in our country, including laws and regulations and technical issues concerning transport equipment, station infrastructures, operating organization and management and information platform construction. Meanwhile, related standard system needs building and revising.

As a relatively novel combined transport, the piggyback transport needs a complete set of feasible operating standards. Therefore, to ensure the safety, it is necessary to refine standards and establish severe system in each side, such as vehicle type, flat car type, loading machine, loading mode and so on.

(3)Integrating and Transforming Freight Station

Transport is the part and parcel of logistics. The realization of express freight transport not only depends on the speeding up of transport itself, but also requires the time compression through the whole process from consignor to consignee. Therefore, in accordance with railway development plan, the optimal configuration of freight stations should be carried on to integrate existing ones, namely closing small ones and developing large ones, so as to move towards scale expansion and intensification, with station layout adjustment as its core.

At the same time, the related equipment should be updated and transformed. In view of high demands on railway station and clearance, the current technologies may not meet the needs of piggyback transport. So, the relevant checking and redesigning are inescapable (Zhang Guoping,2009).

(4)Optimizing the Allocation of Resources

The freight operating entities present the characteristics of "small, loose and weak" in China. The individual transportation even accounts for 90% or so. Their demands are diversified, hence bringing some difficulties in allocation of railway resources. Under such background, information integration and unifying allocation of resources need intensifying. To carry out piggyback transport, it is necessary to collect demands from freight transport agents to make use of it to allocate resources.

To enhance efficiency, the railway should identify transport routes and numbers of trains in accordance with highway freight resources. Meanwhile, the road logistics should optimize its allocation of resources so as to maximally reduce the empty-loading ratio in piggyback transport to save cost. In sum, it is necessary to make reasonable planning on routes and numbers of trains based on the allocation of resources.

(5)Vehicle Supporting

Capability expansion and equipment improvement are strategic cores of great-leap-forward development of Chinese railways. In regard to the status of Chinese railways, it is our strategic needs to develop specialized piggyback vehicles to enhance comprehensive operating capabilities, which is also in line with the recent development plan of Chinese railways (Wang Aiming,2007). Therefore, China should learn from the foreign mature technologies on piggyback transport to develop the advanced and practical specialized piggyback vehicles adapted to the Chinese national condition.

Meanwhile, the piggyback transport in China is still in the initial stage. The infrastructures supporting piggyback vehicles haven't been developed yet. Therefore, the design of piggyback vehicles should be adapt to the existing stations as far as possible. In this way, the existing stations only need slight adjustments, then could meet the needs of developing piggyback transport.

In sum, the piggyback transport of complete highway truck should be the priorities in our country so as to meet the current logistics demand. When it is qualified to develop the drop and pull transport, this kind of way should take dominance in piggyback transport, supplemented by complete highway trucks.

5 Conclusions

(1)Comparing with traditional road logistics, the piggyback transport has the characteristics of safe, convenience, large capacity, all-weather, energy-saving and environmental protection. It should occupy a corresponding proportion in the comprehensive transportation system in our country.

(2)With the rapid development of high-speed railway construction and the continuous expansion of network in our country, the in-depth advancing of the railway freight organization reform and the brisk market demand of express freight and 'door to door' transportation, piggyback transport in China has been provided a broad space for development.

(3)China should learn from the foreign mature technologies on piggyback transport to implement related policies and standards as well as to develop specialized piggyback vehicles adapted to the Chinese national condition.

(4)In accordance with the status of Chinese road logistics, it is suggested that complete highway trucks should be used in the near future to develop piggyback transport; and highway semi-trailers should be chosen in the long term. Moreover, it is suggested that vans could be a good choice in the initial stage.

Attraction Area Model for Urban Rail Transit Stations Compared with Different Traffic Tools

Yong Liu; Weidan Liu; and Weixiong Zha

Institute of Transportation and Economics, Humanities and Social Sciences Research Base of Jiangxi Province, East China Jiaotong University, Nanchang 330013, China.

Abstract: Based on prospect theory to analyze walking time, travel time and time sensitivity. Preference survey investigation was used to quantify the affects factors of path choice to build the generalized cost calculation function. According to the cumulative prospect theory to explore the attraction area of urban rail transit compared with other traffic tools. On the surveyed data of a rail transit station. Through a comparison between the traditional walking areas and surveyed data, it is clear that the model is effective and reasonable, and could provide references for the planning, selection and evaluation of urban rail transit.
Keywords: Cumulative prospect theory; Walking attraction area; Travel mode choice.

1 Introduction

Attraction area of urban rail transit is an important factor to ensure the traffic sources. Current research usually takes the experience when it comes to this kind of problem and the quantitative calculation is not too much. (Zhang, 2012) use Logit model to calculations the attraction area of urban rail transit stations in connection with the pedestrian access way. (Wang, 2010) use the aggregate effect theory model build the roads bus passenger range model, (Wu, 2014) calculated the attraction area according to the uniform accessibility principle and the algorithm is also presented. Such methods is accurate for those have been investigated urban rail transit station because it have a strong dependence on the sample, besides, they did not take travel behaviors factors into account.

To solve the above problem, this article from the angle of travelers' psychological point, considering it presences different ways to travel in a trip, and the prospect value is difference, by calculating the prospect value of each travel modes. When the value is equivalent study the attraction area compared with other traffic tools.

2 Cumulative Prospect Theory

In the actual road network system, the road network is a complex dynamic system subject to many external factors influence, the passage time is a random variable, under this condition, the passage of time and the probability distribution of the path has become the traveler's choice basis. In order to facilitate the calculation, we assume that travelers choose the travel path bases on the utility obtained.

We use the $x_{\max}$ represent the maximum benefit that travelers can get at the destination, and is integrated travel fee. So the utility is

$$x_i = x_{\max} - c_i \tag{1}$$

Travelers will choose all feasible paths to arrive their destination, when in the choice of the travel route, each one of the feasible path has actual travel utility variables x and probability functions p .

2.1 Value function

Value function is subjective utility based on the practical utility of various paths, which characterization the effects of the actual level of utility for travelers psychology, is a concave function when travelers gains and is a convex function when losses. As shown in Figure 1 and is defined as follows:

$$v(x_k) = \begin{cases} x_k^{\alpha}, x_k \geq 0 \\ -\lambda(-x_k)^{\beta}, x_k < 0 \end{cases} \tag{2}$$

In the formula, x_k represent the behavioral outcomes with respect to the reference point of the pros and cons, α, β is risk attitude coefficient and $0 < \alpha, \beta < 1$, λ is Loss aversion parameter and $\lambda \geq 1$. Generally $\alpha = \beta = 0.88, \lambda = 2.25$

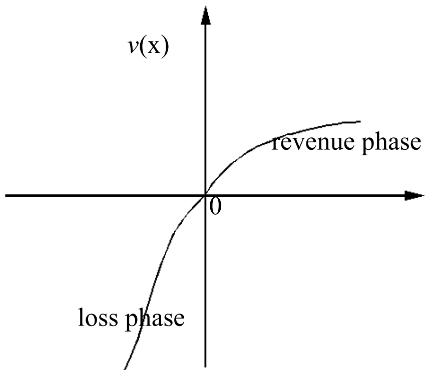

Figure 1. Value function curve

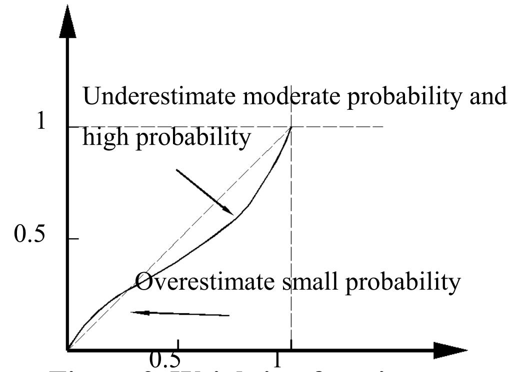

Figure 2. Weighting function curve

2.2 Weighting function

Weighting function is a monotonically increasing function, as shown in Figure 2. In this paper, we use the weight function manifestations based on Kahneman (1979). The actual probability of events is p, the perceived probability is $w(p)$. When it will gains, $w^{+}(p)=\frac{p^{\gamma}}{[p^{\gamma}+(1-p)^{\gamma}]^{1/\gamma}}$ and when it will loss $w^{-}(p)=\frac{p^{\delta}}{[p^{\delta}+(1-p)^{\delta}]^{1/\delta}}$. And $\gamma=0.61$, $\delta=0.69$.

2.3 Cumulative prospect theory and its values

Assuming uncertain prospect f is reflect by a series of combinations (x_i, p_i), w^{+} and w^{-} is entitled to and loss of weight function. The decision weights π_i^{+} and π_i^{-} is:

$$\pi_i^{+}=w^{+}(p_i+\cdots+p_n)-w^{+}(p_{i+1}+\cdots+p_n) \quad (3)$$

$$\pi_i^{-}=w^{-}(p_{-m}+\cdots+p_i)-w^{-}(p_{-m}+\cdots+p_{i-1}) \quad (4)$$

Prospect value (f) can be calculated by the following:

$$f=\sum_{i=1}^{n}\pi_i^{+}v(x_i)+\sum_{i=-m}^{n}\pi_i^{-}v(x_i) \quad (5)$$

3 Perceived Value of Arrival Time

3.1 Travel time costs

Travel time costs (TTC) mainly refers to the time that travelers use transportation costs and walking time in a trip, the value of walking time (t_{walk}) is 1.5 times of the value of travel time (t_{way}) (Chen, 2011). We use $\varphi(t_A)$ represent travel time costs, and x is revenue of per unit (0.14Yuan/min). So the travel time costs is defined as the follows:

$$\varphi(t_A) = (1.5t_{walk} + 0.5t_{way}) \cdot x \tag{6}$$

The sensitivity of different travelers on travel time cost is different, sensitivity coefficients is when taking the travel time and travel costs of economic (c_a) into account, the costs of travel time sensitivity. The value is 0.751 (Yin, 2012).

3.2 Subjective perception of costs

Travelers using different modes of transportation to reach the destination, if travelers arrive time t_A earlier than the actual work time t_w, will have time cost for early arrival. Conversely, travelers will have time cost for late. We assume the $\theta_i (i = 1,2,3)$ represent the cost of travel time, early arrival costs and the late arrival costs of per unit time, $\theta_2 = 0.5\theta_1$, $\theta_3 = 1.5\theta_1$ (Zhao, 2006), when $\theta_1 = 1$ $\eta = 0,1$, the subjective perception of costs is:

$$C_t = 0.751\varphi(t_A) + 0.249c_a + \eta\theta_2(t_w - t_A) + (1-\eta)\theta_3(t_A - t_w) \tag{7}$$

4 Examples

In order to study the situation of different travel models change with time walking, we choose the data of Riverside Road - Longgang Road intersection to Wenjin Road - Road intersection Sungang in Shenzhen as the research object for numerical example. There are four kinds of travel modes can be selected: car, taxi, bus, and rail transit. According to the data obtained by the traffic survey, the travel time probability distribution of each travel modes shown in the following table:

Table 1. Travel time probability distribution

Travel Modes	Probability Distribution（Time/min, Probability /%）

Car (C)	（25,55）；（28,30）；（32,15）
Taxi (T)	（28,60）；（35,30）；（40,10）
Bus (B)	（40,50）；（45,30）；（50,15）；（55， 5）
Rail Transit (R)	（30,85）；（35,10）；（40,5）

Assuming travelers working time is 08:45 am, for those who travel by public transport, the psychological expected travel time earlier than cars and taxi. The time is 08:00 am when traveler departure by bus or rail transit, and the time is 08:10 and 08:15 by taxi and car. As can be seen from Table 1, the traveler may encounter a trip in 13 cases, we select the expectations cost of all travel cases as the reference point. The prospects value (PV) changes over the walking time can be seen in the table 2.

Table 2. Prospects value changes over walking time

PV	0	2	4	6	8	10	12	14
Car	-0.0163	0.1459	0.3016	0.4564	0.7176	0.8790	1.0404	1.2018
taxi	-0.3821	-0.2533	-0.1111	0.0091	0.1630	0.2870	0.4110	0.5350
rail	0.7752	0.6220	0.4687	0.3155	0.1543	-0.0042	-0.1618	-0.3194
bus	0.9215	0.7411	0.5607	0.3802	0.2197	0.0402	-0.1402	-0.3206

As can be seen from the table 2, the prospects value for cars and taxis increase with the walking time increases, originally it was loss phase and then turn into revenue phase. Conversely, the prospects value for bus and rail transit increase with the walking time increases, revenue phase turn into loss phase. That means the walking time will have a greater impact on travelers when choose transportation mode.

From the figure 3, we can see that when the walking time is less than 5.1min, the prospects value for the use of public transport travel mode is much greater than the value of cars and taxis, and at this point the state is revenue. If the walking speed is 6km/h, means when the walking distance less than 500m, travelers prefer to choose rail transit. When the time of travel time reach to 8.5min, the prospects value of taxi, bus and rail transit are flat. That is when walking distance is about 850m, the probability travelers choose public transport as a way to travel will decrease. When the travel time reach to 13min, the rail transit travel mode will be at the loss phase, that is, when walking distance approaching to 1300m, the attractiveness of rail transit decreased rapidly, therefore, the largest urban rail transit attraction area should not exceed 1300m.

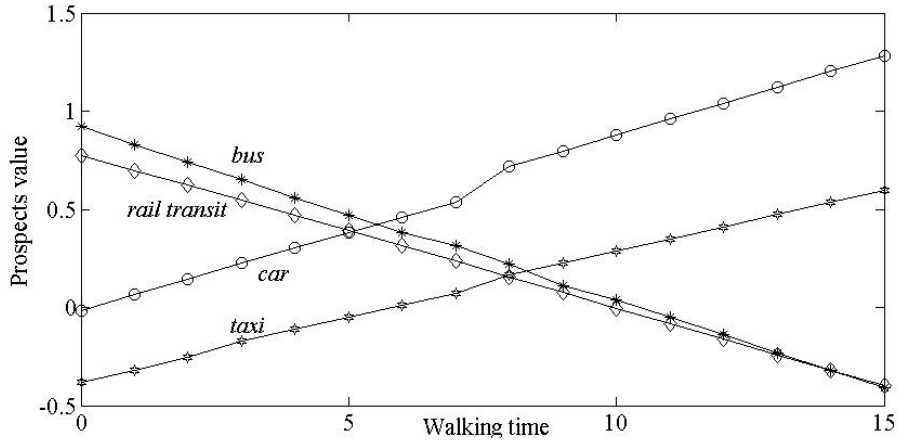

Figure 3. Prospects value changes over walking time

5 Conclusions

We obtain subjective perception cost function by analyzing the way to travel based on traveler psychological, according to the cumulative prospect theory, select the appropriate reference points to calculate each transportation modes based on the walking time. It shows that in the choice of travelers transport, the sensitivity of the economic costs and time sensitivity will be taken into account by traveler. Therefore, in order to improve the utilization of urban rail transit and determine a reasonable attraction area of urban rail transport services, not only will the travel distance into account, but also the economic level around the site should be investigated.

Abstract: How to reasonably determine the freight modal split model has always been a hot topic of research at home and abroad. In recent years, while a lot of researches have been made both at home and abroad on the passenger transport modal split mode, researches on the freight modal split model are scarce. Due to the sharp increase of freight demands as well as the theoretical need of the planning for the comprehensive transportation system, the freight modal split model have attracted the attention of experts and scholars. In this study, the expression of the functional relation between various freight volumes and transportation distance is constructed through analyzing a large number of aggregate data regarding different freight volumes and transportation distances among Chinese cities, and the change law of freight modal split with different transportation distance in the comprehensive transportation system is analyzed, so as to provide a reference and basis for the rational allocation of transportation resources and the optimization of transportation structure.
Keywords: Transportation distance; Freight; Transportation modes; Modal split model; Aggregate data.

1 Introduction

China will witness a continuous rise in freight demand in the future. According to the prediction, at the end of the "Twelfth Five Years", the highway freight volume in China will reach 30 billion tons, the cargo throughput of coastal ports will reach 7.8 billion tons, the inland waterway freight volume will reach 3.85 billion tons, and the airway freight volume will reach 9 million tons (2012). Whether the freight system, as an important part of the comprehensive transportation system, can adapt to the development of the regional freight demand and run conveniently, safely, economically and efficiently will significantly influence the construction and development of China's comprehensive transportation system. A grasp of the freight modal split model, namely, the proportions of transports by highway, railway, waterway, airway and pipeline in the whole freight system, can provide not only as the basis for analyzing the characteristics of various transportation modes, their mutual connections and restrictions, but also as the foundation of the optimization of the freight-mode structure and the rational allocation of transportation resources.

With regard to the freight modal split model, domestic researches are still at a preliminary stage, and foreign researches mainly focus on the improvement of traditional algorithms according to the characteristics of the problems existing in the comprehensive transportation system. The domestic and foreign researches on the freight modal split model are carried out mainly from the following three perspectives:

(1) A research on the freight modal split model is carried out from the perspective of evaluation. Such researches consider from the perspective of evaluation and present different evaluation index systems. For instance, (Duan Aiyuan, 2007) established an evaluation index system of quantitative research chosen by the tools of freight transportation and solved the decision-making of the comprehensive and optimal transportation modes in the decision-making of freight transportation. (Bo Hongxiang, 2007) comprehensively evaluated the decision-making of selecting transportation modes, built the decision-making model of selecting transportation modes. (Liberatore, 1995) built a bistratal analytic hierarchy model of the total cost of transportation network and corresponding customer service level based on every transportation mode, considered service cost and quality, compared and determined modes of cargo transportation and selected the optimal scheme.

(2) A research on the freight modal split model is carried out from the perspective of cost. Such researches conduct an analysis from the perspective of cost and build correlation models by taking the minimum total cost and the lowest generalized cost as the goal. For example, (Hu Junhong, 2013) adopted a quantitative method to combine the generalized cost outside of transportation modes with the local actual situation of traffic and transportation, took Jiangsu Province as an example and raised three transportation modes including highway transportation first and railway transportation second, the combination of highway and railway transportation and giving consideration to the development of railway transportation. (Sheer Yosef, 2000) determined the influence factors of the total cost of freight transportation and storage and inventory, started from the charges of freight transportation, refined the factors like the actual situation of the starting point and terminal point of transportation, analyzed them, obtained the best solution and carried out case researches. (M.Beuthe, 2001) analyzed the multimode models of freight transportation in Belgium, obtained three modes of freight transportation, namely, railway transportation, highway transportation and inland waterway transportation in the

Balkan region and the demand elasticity of 10 types of cargos, adopted the method of the minimum cost to establish the allocation model of transportation demands and determined different transportation modes and the freight volumes of transportation routes.

(3) A research on the freight modal split model is carried out from the perspective of decision-making. For instance, (Jung Dazhi, 2009) built a multi-target grey situation decision-making model, determined the selection of transportation modes in comprehensive transportation and carried out empirical studies. (Reza Banai-Kashani, 1989) selected and used analytic hierarchy process, analyzed different levels of transportation modes in target cities through models and made an optimal decision. (G.P.Kiesmulle, 2005) suggested choosing the modes of freight transportation after packaging freight, calculated a lot of data and proved the feasibility of delaying decision-making in the aspect of economy, especially for low-value cargos.

Domestic scholars still haven't conducted systematic studies on the freight modal split model with insufficient quantitative researches and usually establish inadequate model calibrations due to the limited data they collect. For instance, they complete calibrations only by manners of the data of a specific transportation corridor, which leads to the poor universality of models. The study will research the freight modal split model based on transportation distance and analyze the change law of the freight modal split model with the change of transportation distance.

2 Data and Method

2.1 Data

The research on the freight modal split model in the study includes highway transportation, railway transportation, waterway transportation and airway transportation and leaves out pipeline transportation for the moment.

Through collecting and calculating the data of "The Inter-regional Freight Volumes of Various Transportation Modes in China in 2008". The freight volumes and corresponding distances of various modes in the different administrative regions of China can be obtained. Through classifies, summarizes and computes them and the corresponding freight volumes of various transportation modes at different distances can be gained. The distance here refers to intercity straight-line distance. As not all modes of freight transportation exist in every region or reach the same development level, every 50 kilometers are taken as a node in order to make various transportation modes of comparable at different distances. Here is an example about the concrete method, which selects 0, 50, 100, …, and 3,500 as the horizontal axis, regards the intercity freight volumes with distance from 0 to 50 as one class, accumulates the freight volumes of this class of cities and takes the median 25 as the corresponding transportation distance of the class of freight volumes. Freight modal split equal to the freight volumes of various transportation modes at a given distance dividing by the total freight volumes of four transportation modes at this distance. On this basis, the function and curve of the freight modal split model at different distances are fitted.

Therein, the study arranged and summarized 811 pieces of data about highway freight volume among different cities, 907 pieces of data about railway freight volume among different cities, 240 pieces of data about waterway freight volume among different cities, and 240 pieces of data about airway freight volume among different cities. In 2008, among the total freight volume of 25.87413 billion in our country, the highway freight volume was 19.16759 billion tons, occupying 74.080% of the total freight volume with average freight distance of 171 km; the railway freight volume was 3.30354 billion tons, occupying 12.770% of the total freight volume with average freight distance of 760 km; the waterway freight volume was 2.9451 billion tons, occupying 11.380% of the total freight volume with average freight distance of 1,707 km; the airway freight volume was 4.08 million tons, occupying 0.016% of the total freight volume with average freight distance of 2,934 km; the pipeline freight volume was 453.82 million tons, occupying 1.754% of the total freight volume with average freight distance of 428 km.

2.2 Method

Models were built by the method of ordinary least squares (OLS). Computation was conducted by SPSS statistical analysis software. Specific steps are as follows:

(1) Make a scatter plot of data

(2) Conduct model estimation

During establishment of the model, different alternative models such as polynomial model, exponential function model, logarithmic function model and linear regression model could be set up according to data fitting. During model establishment, the method of ordinary least squares was adopted, namely that proper parameters were selected to minimize the residual sum of squares of all the sample values.

Hence, the paper needed to solve $y = f(x, a_1, a_2, ..., a_n)$, where, $a_1, a_2, ..., a_n$ are undetermined constants and (x_i, y_i) is corresponding to each piece of data. In this way, $\sum_{i=1}^{k}[f(x_i, a_1, a_2, \cdots, a_n) - y_i]^2$ was minimized for the parameter estimation.

(3) Verification and Determination of Model

Reference standards are necessary for model evaluation and model comparison. The study mainly adopted the following two standards. The first standard is the goodness of fit. The basic idea of regression analysis is that explanatory variables contained in the model are used to explain changes of dependent variables as much as possible. In practice, the degree of fitting can be measured by a corrected coefficient of determination which sign as R^2. Higher R^2 indicates a better model. The second standard is that the model shall pass the significance test. Respectively, the study conducted F test, which refers to significance test of equation. And T test can be conducted, which refers to significance test of model variables. If the model can pass both the F test and the T test, the model is deemed to be acceptable. According to these two standards, the optimal model was determined among the multiple models established above.

3. Results

According to results of comparison and optimization of the models, the original fitting function of each freight modal split model is shown in Fig.1 and listed as follows:

Highway: $y_1 = -0.141\ln x + 1.383$ (1)

Railway: $y_2 = -0.004x^{0.648}$ (2)

Waterway: $y_3 = 8.850 \times 10^{-18}x^5 + 6.790 \times 10^{-14}x^4 - 1.270 \times 10^{-10}x^3 - 1.110 \times 10^{-7}x^2 + 3.260 \times 10^{-4}x + 0.116$ (3)

Airway: $y_4 = 2.093 \times 10^{-10}x^2 + 1.017 \times 10^{-6}x - 0.289 \times 10^{-4}$ (4)

Where:

y_i refers to sharing rate; $i = 1, 2, 3, 4$ respectively stand for highway, railway, waterway and airway; $0 \le Y_i \le 1$, unit: %;

x indicates transportation distance, unit: km.

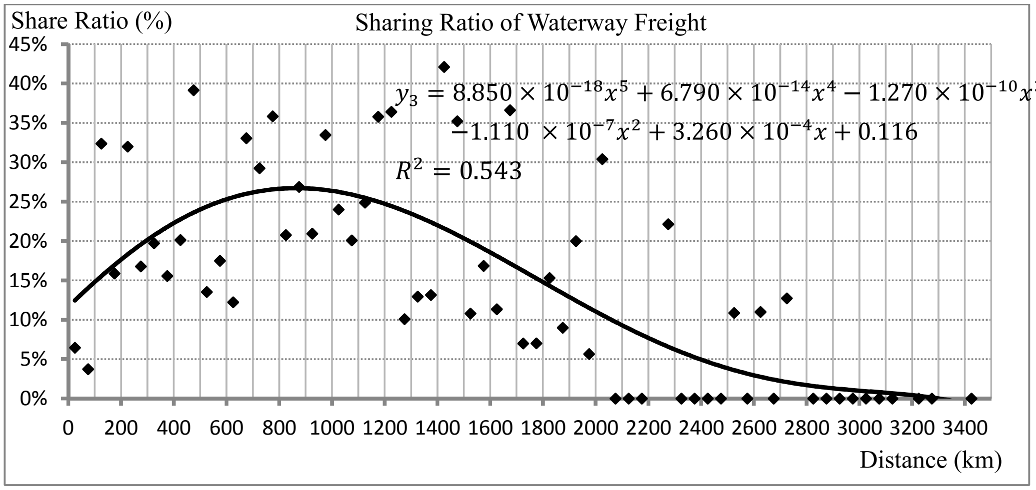

Figure 1. (c) Fitting Share Ratio Curve of Waterway Freight Mode

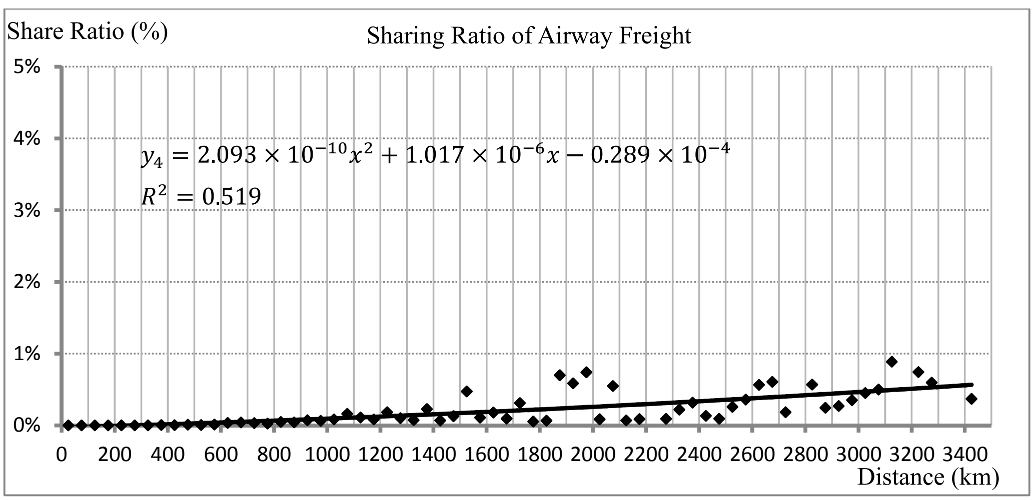

Figure 1. (d) Fitting Sharing Ratio Curve of Airway Freight Mode

According to analysis results of SPSS, the goodness of fit R^2 of highway, railway, waterway and airway is respectively: 0.66, 0.81, 0.52 and 0.52; and all the established models (Formulas 1-4) passed the F test and the T test. Hence, the model is acceptable. The freight modal split models are shown in Fig.2.

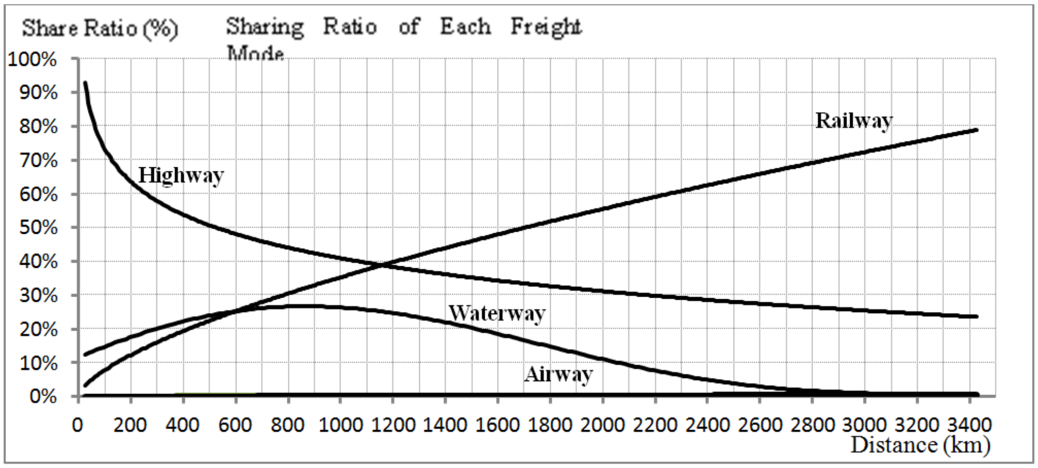

Figure 2. Curves of Fitting Sharing rate of Four Freight Modes

4. Conclusion

The goodness of fit of the model established in this study is not very high, but still satisfying. The reason for this result lies in that data used for fitting was the freight data of various administrative regions in our country all through the year; various freight modes in different administrative regions of our country have not developed in a balanced mode; various freight modes in some regions are highly developed; in other regions, one or two freight modes develop to a low level or are even absent. Hence, as for direct fitting of such kind of macroscopic data, the current goodness of fit of the model is acceptable and valuable in applications to a certain extent.

By establishing the above models, freight modal split in our country, which change with the transportation distances, can be obtained; and the advantageous distance of each freight mode can also be deduced. By virtue of the research results, laws about changing of various freight modes along with the distances can be further understood; the rational utilization scope of each transportation mode under different distances can also be analyzed. These results have certain theoretical values and practical significance to planning and construction of a freight transportation system which is suitable for regional freight demands. Meanwhile, only by knowing the current sharing rate of freight modes in our country, the future freight mode structure can be optimized, the freight structure can be matched with freight traffic demands, resources in the whole comprehensive transportation network can be integrated more easily, transportation efficiency of cargo can be increased, and social comprehensive benefits of freight transportation can be realized.

Abstract: With the development of transportation technology, increasing the degree of intelligent transportation, intelligent transportation affected staff travel is also growing. Fast time-space conversion to personnel changes have an important psychological impact, Especially in intelligent transportation area, the difference of languages and understanding ways between different countries makes a great deal of obstacles. Foreign language teaching is a second language teaching, its goal is to train students for the language skills of the target language and language communication ability. This paper established the architecture and application mode of saptio-temporal metaphor system in transportation engineering teaching internationalization process.
Keywords: Intelligent transportation; Time-space conversion; Psychological metaphor; Architecture; Application mode.

1 Introduction

Generally speaking, there are different methods of classifying metaphor. Based on different source domains from cognitive perspective, Lakoff &Johnson (1980) classified metaphor into three types – structural metaphor, ontological metaphor, and orientational (spatial) metaphor. Structural metaphor is to form a concept by using the structure of another concept or to refer to a concept by using a system of words belonging to another concept. Ontological metaphors allow us to view events, activities, emotions etc. as entities and substances. Orientational metaphor, or spatial metaphor, refers to the metaphor with mapping from spatial orientation as source domain to non-space domain (usually abstract domain) as target domain.

The spatial domain is important not only in its own, but because it is commonly mapped onto other more abstract domains, giving rise to spatial conceptualization of those more abstract domains in a metaphorical fashion, as Levinson (1996) has commented. In a word, a special metaphor called "spatio-temporal metaphor", belongs to the range of orientational (or spatial) metaphor and is a kind of spatial metaphor used to represent time. It is a mapping from the concrete spatial domain onto the abstract temporal domain.

In English, two dominant spatial metaphors – ego-moving metaphor and time-moving metaphor- are used to sequence events in time. They are indeed two space→time metaphoric systems which are also called two spatio-temporal metaphors..

2 Instruments Preparation

There were 3 instruments used in the study, including Pretest, Cross Modal Experiment and Students' Scores in CET4. Pretest was intended to find out 3 pairs of time-moving metaphors and 3 pairs of ego-moving metaphors with very similar accuracy and response time, which formed the test sentences in the following Cross Modal Experiment. Cross Modal Experiment was to test the effects of English metaphor consistency. Meanwhile, subjects' reaction time and accuracy for the two spatial-temporal metaphors in Pretest and Cross Modal Experiment were recorded. Students' scores in CET4 were the indicators of their proficiency in English to a large extent because CET4 has been implemented in China for more than ten years and its validity has already been proved. Both the Pretest and Cross Modal Experiment were conducted in the Autonomous Learning Center in Southwest Jiaotong University.

3 Pretest

The first test was indeed a pretest, so its name was Pretest. The Pretest consisted of 50 spatio-temporal metaphorical sentences of which 25 sentences were time-moving metaphors and 25 sentences were ego-moving metaphors. All the 50 sentences were chosen from Evidence for System-mappings in Understanding Space-time Metaphors, Spatial Metaphors in Temporal Reasoning, As Time Goes by: Evidence for Two Systems in Processing Space → Time Metaphors, Back (or forward?) to the Future: the Role of Perspective in Ttemporal Language Comprehension, Does language shape thought?: English and Mandarin speakers' conceptions of time, Metaphoric Structuring: Understanding Time through Spatial Metaphors. The sentences in Pretest were all conventional metaphors and used simple English words so that Chinese learners had no difficulty comprehending them.

To ensure that subjects fully processed the sentences, we made the task more interactive by asking subjects to place an event on a time line. Subjects were instructed to respond by pressing one of two keys to indicate whether the first event (E1) in the sentence took place in the past (A) or future (B) relative to the second event (E2).

4 Cross Modal Experiment

The second instrument was named Cross Modal Experiment. The Cross Modal

Experiment was a 2 (Metaphor Type)×2 (Consistency) between-subject design in which there were 4 between-subject conditions, consisting of 4 possible combinations of setting sentences and test sentences. Condition 1: time-moving setting – time-moving test; Condition 2: ego-moving setting – ego-moving test; Condition 3: ego-moving setting – time-moving test.; and Condition 4: time-moving setting – ego-moving test. Condition 1 and Condition 2 were consistent conditions and Condition 3 and Condition 4 were inconsistent conditions. In the consistent condition, the setting (prime) sentences and the test (target) sentence belonged to the same spatio-temporal metaphoric system. In the inconsistent condition, the setting sentences and the test sentence belonged to different spatio-temporal metaphoric system. The critical measure was the effect of consistency on the response time to the very similar test sentence by the same subject. A sample set of materials appears in Table 1.

Table 1. Sample stimuli for cross modal experiment

Consistent Condition
Setting sentences, time-moving
I will take the Math exam before the English exam.
My birthday is ahead of John's birthday.
I will take two months vacation after graduation.
Test sentence, time-moving
Dinner will be served preceding the session.
Inconsistent Condition
Setting sentences, ego-moving
I am looking forward to the concert.
In the weeks ahead of him, he wanted to finish this project.
We are coming into troubled times.
Test sentence, time-moving
Dinner will be served preceding the session.

Totally, every condition has 12 （4 sentences×3 groups）sentences and every subject would finish 48 sentences. Three setting sentences were followed by a test sentence. All the sentences were chosen from the spatio-temporal metaphors in Pretest. Just like Pretest, a sentence on the time-line with A/B choice-making would appear one at a time in the middle of the computer screen, as depicted in Figure3.1. Subjects were instructed to respond by pressing one of two keys to indicate whether the first event (E1) in the sentence took place in the past (A) or future (B) relative to the second event (E2). The only one different point from Pretest was the order of the sentences. But the subjects wouldn't be aware of the difference between setting sentence and test sentence.

From table 3.1, it can be shown that in the consistent condition, both the setting sentences and the test sentence belonged to the same spatio-temporal metaphoric type – time-moving metaphors. But in the inconsistent condition, the setting sentences belonged to the ego-moving metaphors while the test sentence was a time-moving metaphor. What the experiment wanted to seek was whether the accuracy and reaction time for the test sentence would be affected by the previous setting sentence in the same or different spatio-temporal metaphoric type.

The order of the sentences was arranged in terms of the following principles. The 6 pairs of metaphors with very similar accuracy and response time either in time-moving or in ego-moving chosen from Pretest would be adopted as the test sentences in Cross Modal experiment. 3 time-moving metaphors and their corresponding time-moving metaphors were used in Condition 1 and 3 respectively; 3 ego-moving metaphors and their corresponding ego-moving metaphors were used in Condition 2 and 4 separately. Verbs indicating "before" and verbs indicating "after" were chosen in the 48 sentences, such as ahead of, follow, precede, behind. The setting sentences were arranged not so strictly only with one consideration that the same verb appearing in the same group at the same time would be avoided as far as possible. A summary table on the English materials was given in the Appendix III.

5 Conclusions and Recommendations

This thesis has made an exploration of English spatio-temporal metaphors for English learners. The results obtained from the two experiments provide evidence for the two distinct psychological systems used in processing event-sequencing statements (ego-moving metaphors and time-moving metaphors). The major findings from the experiment are listed below:

In terms of time-moving metaphor and ego-moving metaphor, the results indicate that subjects take longer to respond to time-moving metaphors than to ego-moving metaphors. It supports the view which is opposite to Tzyyin V. Lai's (2002) primacy of time-moving metaphor in Mandarin for Chinese people and consistent with Zhou Rong's (2001) point of view, i.e., ego-moving seems to be easier to process and ego-moving is primary in Mandarin. So for Chinese English learners, the ego-moving metaphor is easier to comprehend and is therefore the primary conceptualization of time.

Design and Achievement of the Vehicle Information Terminal Based on the Internet of Vehicles

Jie Zeng; Yong Yu; Jinxiu Luo; and Weidong Li

School of Electronics and Information Engineering, Dalian Jiaotong University, P.O. Box 116028, No.794, Huanghe Rd., Dalian. E-mail: zyz@djtu.edu.cn

Abstract: In recent years the Internet of vehicle has been paid much attention as a new development direction of intelligent transportation technology. According to the function requirements of Internet of Vehicle (IOV), a complete set of vehicle's information terminal solution for Internet of Vehicle has been put forward based on GPRS wireless communication, GPS, on-board diagnostic (OBD), digital voice synthesis and other relative technologies. The hardware embedded circuit and software of control has been designed. Finally, to accomplish the test of hardware circuit and software debugging by experiment in laboratory and on vehicle, and to realize functions which include the vehicle position, wireless communication between vehicle and schedule center, path navigation, voice scheduling, fault detection and so on.
Keywords: ITS; Internet of vehicle; GPRS; GPS; On-board diagnosis.

1 Introduction

With the increasing number of vehicle every year in China, it has caused a series of issues, such as traffic congestion, traffic accidents, atmosphere pollution and energy consumption. Thereinto, traffic accidents and traffic congestion have seriously affected people's life and travel. Thereby urban traffic congestion has become a focus problem concerned widely in the course of urbanization. To solve these potential problems, it is imperative to develop urban intelligent transportation. Under the strong impetus of mobile Internet technology, IOV technology emerges as the times required. Currently, it is a better solution to ease urban traffic congestion. The IOV technology can realize information interaction between vehicles and traffic management centers or vehicles. It's convenient for traffic management departments and drivers to obtain running state of vehicle and routes information in the real time. It can optimize the routes and avoid traffic jam and accident effectively, so it is help for improving the efficiency of urban traffic. At the same time it helps to energy saving and emission reduction.

2 Functions of the Vehicle Information Terminal for Internet of Vehicle

Internet of Vehicle (CHENG Gang, 2011) is a new technology in progress, which based on advanced technologies of Internet, computer, communications, path allocation, navigation and sensor. It can realize the functions of routes optimization, real time scheduling, vehicle fault alarm and collision avoidance according to the information of the state of vehicles and traffic.

Through the study of the IOV system, a kind of vehicle information terminal will be designed in this paper, it can realize the following functions:

(1) Vehicle positioning. Get real-time position information of vehicle and send to schedule center.

(2) Path navigation. If the vehicles request for navigation, the schedule center can calculate the optimal route based on real-time traffic conditions in the area, and provides voice navigation for vehicles.

(3) Voice and words prompting. Issue information by modes of voice or words.

(4) Fault code picking-up. Obtain vehicle's fault code information from ECU of vehicles through the CAN bus communication interface, as reference for engineer to locate faults in the future.

(5) Traffic information acquisition. Get road condition and public services information in real-time from the schedule center.

(6) Automatic stop announcement. According to position information obtained by information terminal, it can realize to announce stop information automatically when the bus closes to the bus stop.

3 Hardware Architecture of Vehicle Information Terminal

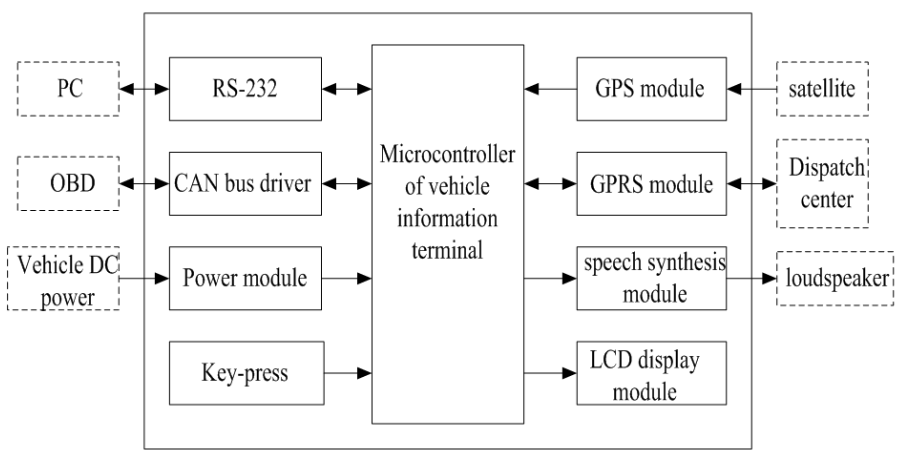

Figure 1.The hardware architecture of vehicle information terminal

The hardware architecture of vehicle information terminal is shown in figure 1. It includes modules of MCU, GPS positioning, GPRS communication, speech synthesis, LCD display, key-press, asynchronous serial ports, CAN driver and system power. Each module of the terminal can realize its functions only under unified control of MCU. With the help of schedule center, the final design goal of IOV system is realized.

3.1 Selection of microcontroller

S9S08DZ60 chip is selected as microcontroller, which is made by Freescale, it has strong anti-interference ability. The microcontroller chip is embedded with CAN bus controller and two independent asynchronous serial communication interfaces. It can communicate with both modules of GPS and GPRS by different serial ports at the same time, thereby to avoid trouble caused by port multiplexing, and to simplify the circuit and program design of asynchronous serial communication. In addition, the microcontroller is also embedded with synchronous serial interfaces, which can provide the communication ports for speech synthesis module. Developed Physical object of vehicle information terminal is shown in figure 2

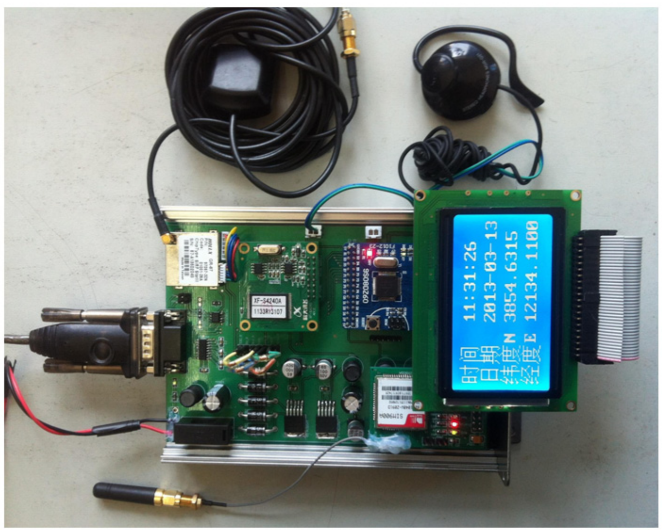

Figure 2.The physical object of vehicle information terminal

3.2 The interface circuit design of GPRS module

To select SIM900A as GPRS module, it's a double frequency GSM/GPRS module. The working frequency of EGSM and DSC is respectively 900MHz and 1800MHz, the operation voltage range is from 3.4V to 4.5V. The GPRS module has electricity-saving technology. Its lowest current is only about 1mA in sleep mode. The figure 3 shows the basic circuit of GPRS module, which includes switch circuit, indicator circuit of network status, indicator circuit of working status, antenna circuit and bypass capacitor circuit. Among these, the bypass capacitor circuit should be put next to pin VBAT as close as possible. Pin DTR, pin RI and pin DCD of the GPRS module connect with pin PTA6, pin PTB0 and pin PTB2 of MCU respectively. Its Pin CTS and RTS are short circuit connection. The pin NRESET and pin STUTAS of GPRS module connect with pin PTA4 and pin PTA0 of MCU respectively. To realize communication between SIM900A and microcontroller, pin TX and pin RX of SIM900A connect with pin TXD1 and pin RXD1 of microcontroller in cross way.

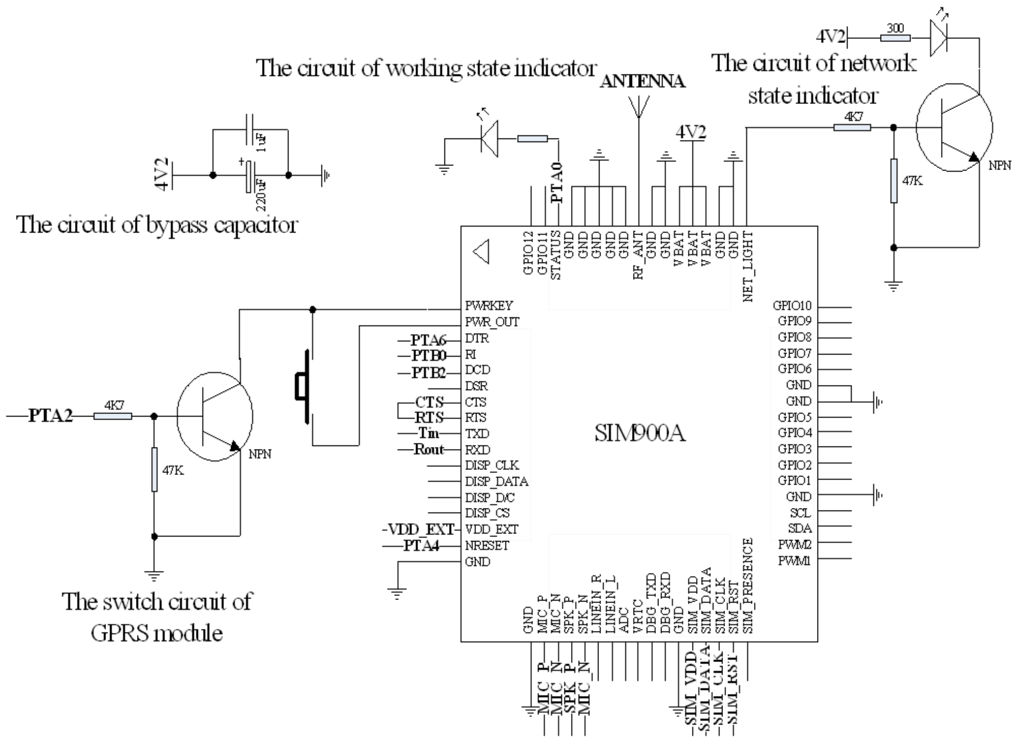

Figure 3.The basic circuit of GPRS module

3.3 The interface circuit design of GPS module

In order to facilitate maintenance and reduce circuit complexity, select model GR-87 as the GPS signal receiver. The basic circuit of GPS module is shown in figure 4. The GPS module use 5V DC power supply. To realize asynchronous serial communication between GR-87 and MCU, pin TX and pin RX of GR-87 connect with pin TXD2 and pin RXD2 of MCU in cross way.

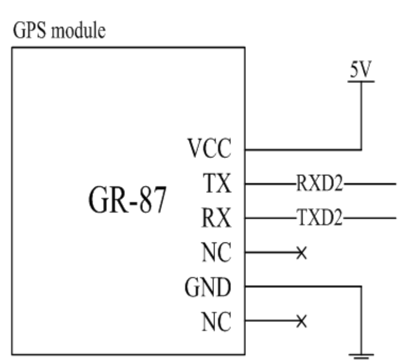

Figure 4.The basic interface circuit of GPS module

3.4 The interface circuit design of speech synthesis module

The model of speech synthesis module uses XF-S4240. It supports a variety of communication ports, such as I^2C, SPI and UART. XF-S4240 has flexible ability of speech synthesis in Chinese text or English alphabets. Considering that two serial ports of MCU have been used by GPS and GPRS module, SPI synchronous serial port of MCU is used to drive the XF-S4240 module, its operation voltage is 3.3V. The basic interface circuit of XF-S4240 is shown in figure 5.

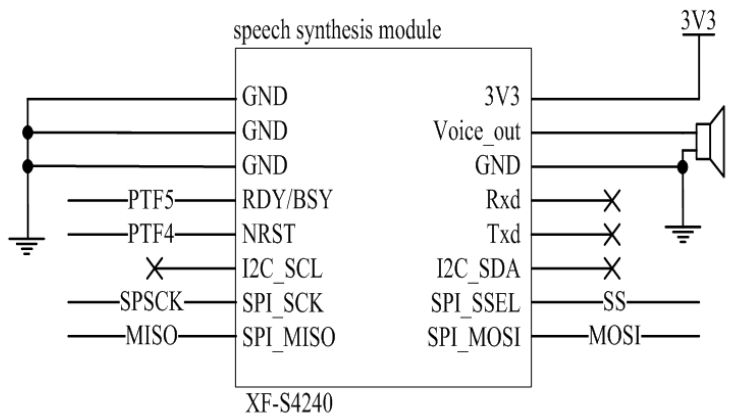

Figure 5.The basic interface circuit of speech synthesis module

4 Software Architecture of Vehicle Information Terminal

As shown in figure 6, software system of the IOV is composed of vehicle information terminal subsystem and schedule center subsystem, through GPRS wireless network, information interaction between the two subsystems can be completed. The software subsystem of vehicle information terminal for IOV (Kevin C. Lee, 2010), as following:

(1) Initializing of each functional modules. Initialize the clock and pins of MCU, and configuring communication interfaces of every modules and MCU.

(2) GPRS wireless communication program. Realize the functions of sending and receiving by AT commands.

(3) GPS satellite positioning data processing program. Receive GPS data by bits, and make extraction, consolidation and analysis to received satellite data through data processing subfunction.

(4) Digital speech synthesis program. Through the SPI communication interface, it can send commands of speech synthesis data frame, wake-up and energy saving, etc.

(5) Fault self-diagnosis and CAN communication program. Extracting the data frame of vehicle fault codes, and send them to schedule center for procession, classification and analysis.

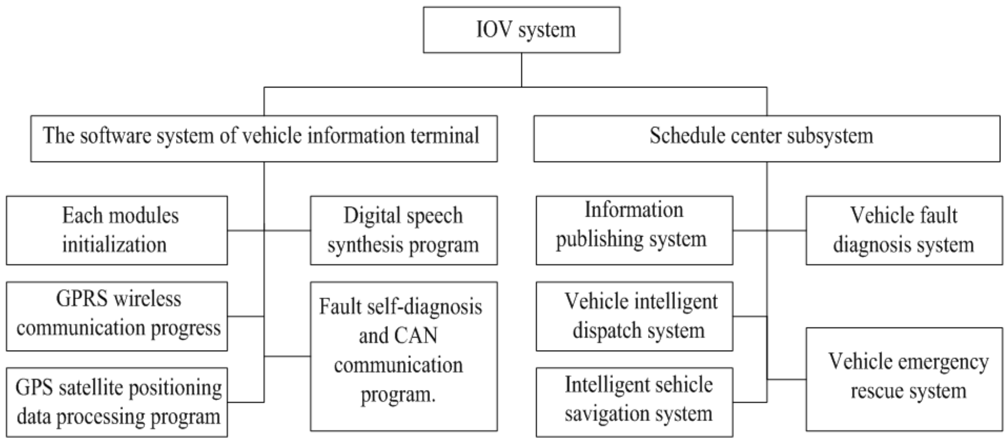

Figure 6.The software framework of vehicle internet information terminal

Software subsystem of schedule center including:

(1) Publishing information system. The system sends public information to vehicles by GPRS wireless network, such as traffic conditions, weather broadcast and public service announcement and so on.

(2) Vehicle intelligent schedule system. The system can realize intelligent schedule and optimize the most efficient and safest route for the vehicles based on vehicle status information and traffic conditions.

(3) Vehicle intelligent navigation system. If the vehicle request for navigation, the schedule center can calculate the optimal route based on real-time traffic conditions in the area, and implement voice navigation for vehicle.

(4) Vehicle fault diagnosis system. The system can get real-time fault codes during vehicle operation, and send them to schedule center for analysis and processing. The system will inform drivers about faults location in advance.

(5) Vehicle emergency rescue system. When the vehicles occur traffic accidents or faults, the system will send emergency signal to schedule center automatically by wireless network, and help to protect life and property safety effectively.

5 The Working Flow of Vehicle Information Terminal

The working flow of vehicle information terminal (LUO Jinxiu, 2013) can be divided into two following parts:

(1) System initialization, it includes MCU initialization, GPRS working state detection, GPRS module boot, and establish GPRS wireless communication connection. The programs run only once after the hardware circuit is powered on, mainly to realize the following functions: configuration clock, communication ports and I/O ports of MCU, and initialization of modules, opening interruption, establish TCP transparent transmission between GPRS module and schedule center server.

(2) Main programs. The system will go into the looping state of the main program after initialization; the system can realize the each function through calling each subprogram, which includes GPS data processing, OBD fault code reception, GPRS wireless communication, speech synthesis and so on. The working flow of vehicle information terminal is shown in figure 7.

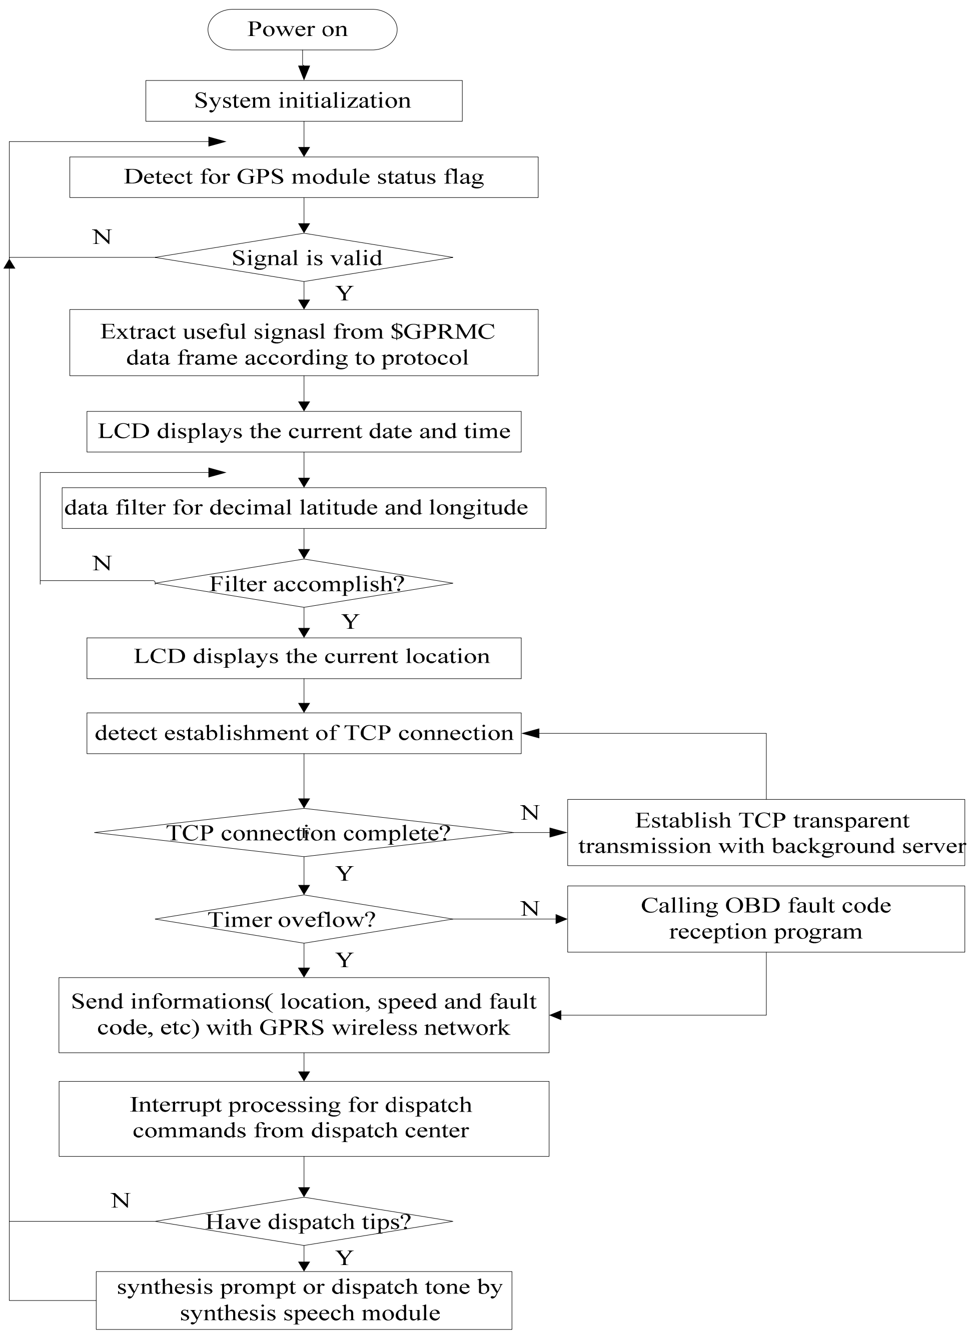

Figure 7.The workflow of vehicle information terminal

6 Experiments on Vehicle

In order to test general functions of vehicle information terminal, to make a road experiments in campus, which includes vehicle positioning, wireless communication, automatic stop announcement, fault code acquisition and schedule information broadcasting and so on. The vehicle for road test is four-wheel drive mini electric vehicle which independently developed by ourselves. The vehicle information terminal uses 24V DC power supply. As shown in figure 8.

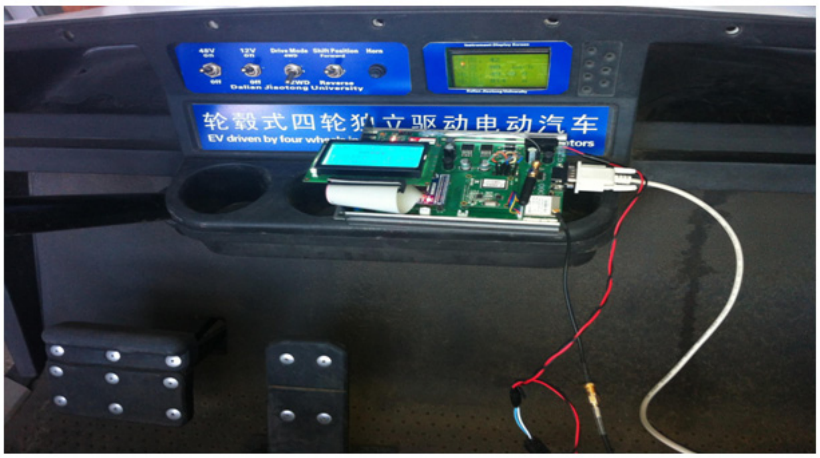

Figure 8.The experiment of vehicle information terminal on an electric car

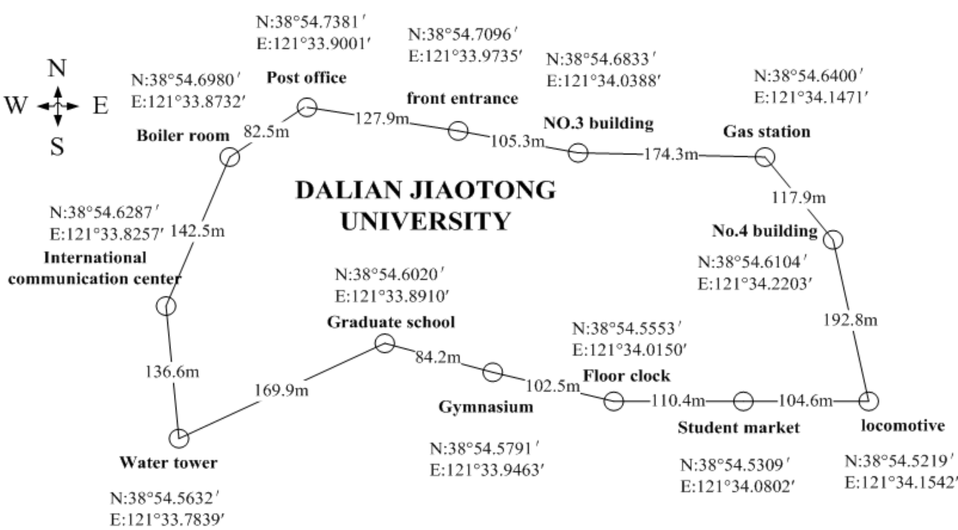

Figure 9.The route map of vehicle terminal experiment

Firstly, to select appropriate route for the test in the campus, then calibrate stops based on geographic information of landmark building, and download geographic information into MCU. Drive the electric vehicle in the setting route to complete actual function tests. The schedule center in the laboratory will analyze the feed-back data from vehicle information terminal to generate actual route trail and simulate fault diagnosis reports, then send schedule information and fault alert to vehicle terminal, by comparison with actual map, the data of latitude or longitude coordinates which is got from vehicle information terminal is basically correct. However, due to the short distance of sites in the campus as well as GPS data errors, the function of automatic bus-stop announcing should be enhance in accuracy. In addition, the experiment about vehicle fault code acquisition based on CAN communication is completed. The route map is shown in figure 9.

7 Conclusions

Through analyzing the basic functions of internet of vehicle system , to build the vehicle information terminal hardware architecture with the aid of the advanced technologies of mobile internet, IOV, computer, communication, position and navigation, automobile electronics. Then based on the mastery of embedded development tools and electronic devices, interface circuits of GPS module, GPRS module, fault diagnosis module, digital voice module and display module with microcontroller are designed and implemented. At same time, to design software architecture and working flow based on its required functions. By experiments on vehicle, the basic functions of vehicle information terminal have been realized. The experimental results show that design of the circuits are reasonable, collaborative work between each function module is normal, the vehicle information terminal can achieve the desired design goal. With the development of mobile internet and internet of things technologies, internet of vehicle is closing to people's life. As an important part of IOV, vehicle information terminal will have bright future.

Distributed Hierarchical Control for an Urban Rail Transit Intelligent Transportation System Based on Multi-Agent

Jingdong Sun

Department of Traffic and Transportation, Southwest Jiaotong University, No. 1, Jingqu Rd., Emeishan, Sichuan 614202, China. E-mail: sun_jdong@163.com

Abstract: Through detailed analysis of control problem of urban rail transit intelligent transportation system, a distributed hierarchical control method was proposed by blending the factitious division of hierarchical system and the natural division of distributed control system. This method is based on the hierarchical control theory of large scale system, and includes three levels: the organization level, the coordination level, and the execution level. The objectives are decreasing the total delay time and increasing the absorption to passengers of the successive trains, a method for train operation adjustment based on Multi-Agent is developed, and the control strategy based on rules is proposed. The distributed hierarchical control method deals with the train planning, the coordination of trains, and the action control of trains in different layers. The simulation results show the effectiveness of the model and the revised algorithm based on Multi-Agent comparing with the traditional control theory.

Keywords: Urban rail transit; Intelligent transportation system; Distributed hierarchical control; Multi-agent; Dispatch.

1 Introduction

A typical intelligent control system uses hierarchical structure to assign control and management task. It emphasizes the function of pursuing objectives of the system, and is prone to analyzing description. However, a distributed control system uses the system structure, which has such characteristics: geographic distribution, disperse control function and centralized management operation (Wang, 2001). The train operation process of intelligent urban rail transit is a complex human-computer cooperation process, which includes the analysis of qualitative and quantitative, time and space, local linear and integral non-linear. The system has several input and output variables, while most parametric variables are non-linear, time-variable, uncertain and spatial distributed (Dong, 2004). To such discrete event dynamic system, the difficulty of the train operation adjustment is huge. It will be hard to recover train behind schedule fleetly, if it uses the traditional control theory, such as optimization method, scheduling rules, simulation method and so on. The distributed hierarchical intelligent control system based on Multi-Agent blends the factitious division of hierarchical system and the natural division of distributed control system can preferably solve the above problems.

2 Model Establishment

The train operation adjustment is a process to reschedule the train timetable and assure most trains running on time by some adjustment measures when the actual train operation status deviate the project train schedule. The train operation adjustment of urban rail transit intelligent transportation system must adopt real-time control mode, which uses the decreasing the total delay time and increasing the absorption to passengers of the successive trains as its performance guidelines according to the characteristics of train operation of urban rail transit.

Suppose there are n stations in line *A-B*, the station set is $S=\{1,2,3,\ldots, n\}$, the corresponding section set is $Q=\{1,2,3,\ldots, n-1\}$, the train set running in the line is $L=\{1,2,3,\ldots, m\}$. The planned arrival time of train l ($l \in L$) at station k ($k \in S$) is $A_{k,l}$, the actual arrival time is $A'_{k,l}$, the planned departure time of train l from station k is $D_{k,l}$, the actual departure time is $D'_{k,l}$. The minimal running time of train l between station k and k+1 is $t^{l}_{k,k+1}$, the additional starting time at station k is τ^{k}_{q}, the additional stopping time at station k is τ^{k}_{t}, the planned stop time for train l at station k is $T_{k,l}$, the actual stop time is $T'_{k,l}$. The minimal train tracking interval time is I, the minimal arrival headway interval time for trains at station k is I^{k}_{d}, the minimal departure interval time for trains at station k is I^{k}_{f}. Define $level(l)$ the level of train l, the smaller the value l, the higher the train level. Define $\omega(j)$ the operation adjustment weight value of level j, and $j=level(l)$, the higher the train level, the bigger the value of $\omega(j)$. The optimization model of train's total delay time is as formula (1) (Wang, 2006); the optimization model of passenger waiting time is as formula (2).

$$\min F = \sum_{k=1}^{n}\sum_{l=1}^{m}\omega(level(l))\left[\left|A'_{k,l} - A_{k,l}\right| + D'_{k,l} - D_{k,l}\right] \tag{1}$$

$$\min P = \sum_{k=1}^{n-1}\sum_{l=1}^{m-1} level(l)\left[\left(A_{k,l+1} - A_{k,l} - T_{k,l}\right) - \left(A'_{k,l+1} - A'_{k,l} - T'_{k,l}\right)\right] \tag{2}$$

$$A'_{k+1,l}\Theta D'_{k,l} \geq t^{i}_{k,k+1} \tag{3}$$

$$D'_{k,i}\Theta A'_{k,l} \geq \delta_{k,l}\left(T_{k,l} + \tau^{k}_{q} + \tau^{k}_{t}\right) \tag{4}$$

$$\left|A'_{k,j} - A'_{k,l}\right| \geq I^{k}_{d} \qquad \left|D'_{k,j} - D'_{k,l}\right| \geq I^{k}_{f} \tag{5}$$

$$A'_{k,j}\Theta A'_{k,l} \geq I^{k}_{d} \qquad D'_{k,j}\Theta D'_{k,l} \geq I^{k}_{f} \tag{6}$$

$$D'_{k,j}\Theta D_{k,l} \geq 0 \tag{7}$$

Formula (3) is the constraint of the section of the train operation. Formula (4) is the constraint of the station working time. Formula (5) is the constraint of the station tracking interval. Formula (6) is the constraint of the train overtaking. Formula (7) is the constraint of the departure time. Formula (8) is the constraint of station's arrival and departure tracks capacity, where $u(x,t)$ is binary step function, $u(x,t)$=1($x \le t$), $u(x,t)$=0($x > t$). Formula (9) is the constraint of the skylight time.

3 Multi-Agent Characteristic and Structure of Train Operation Adjustment

The characteristics of urban rail transit train agent include: autonomy, communication, reaction, oriented-objective, facing-environment and so on. Autonomy indicates that agent possesses control right to its behavior or action, without external interference, autonomously completes its special task; Communication indicates that each agent accepts task assignment or feedbacks the task execution information by intercommunication in organized train group; Reaction indicates that agent should possess the ability of perception environment and reaction. For example, agent confirms the train acceleration according to the sampled environment parameters (such as track parameters: curvature and gradient, the velocity or state of forward train, and so on). Because the parameters of every agent is the environment parameter of the following train agent, every action of agent actually changes the correlative environment parameter of the whole system; Oriented-objective indicates that agent can evaluate its own behavior, and gradually orientate targets; Facing-environment indicates that agent can only works in special environment, which is to realize the safety and reliability of train operation with the communication between one after another agents or agent and dispatcher agent.

According to the above request, Multi-Agent System (MAS) uses compound structure with cognitive process and reactive process, as figure 1. In which the external environment mainly includes dispatching section status information, train operation adjustment decision and so on. Perception receives environment information by sensors, and carries through preprocessing and character identification. Reactor makes judges of the information from perception, directly starts up performer to control train operation towards emergency state or simple state. Towards un-emergency state, it usually starts up the performer after the decider making a decision. The decision of decider depends not only on environment information, but also environment model to forecast the action. Meanwhile, other agents might request to its future action by communication machine, control strategy and might make a strategy of its action beforehand. In this circumstance, the designer might clear up according to conflict resolution knowledge, and determine the corresponding behavior.

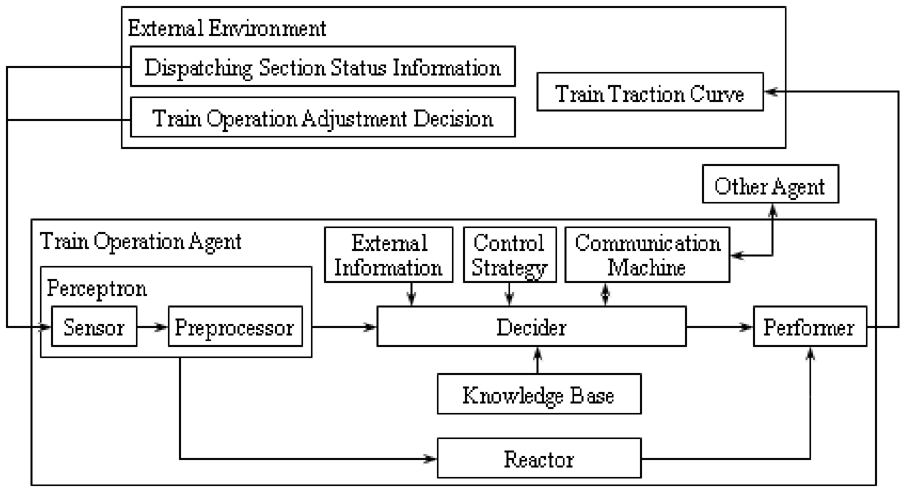

Figure 1. Multi-Agent compound structure of train operation adjustment.

4 Distributed Hierarchical Control Structure of Train Operation Adjustment

The urban rail transit distributed hierarchical intelligent control system, which is based on the Multi-Agent, decomposes the train operation adjustment problem into several sub-problems, and each problem corresponds to a sub-MAS. The agent of each layer follows the rule: the higher the level, the more intelligent the agent, the lower the precision, the longer the information processing time, contrarily, lower level requires high precision, fast information processing. At the same time, the whole system possesses a coordinated organization (Saridis, 1983).

The urban rail transit operation has the requests of high speed, high density, high-punctuality rate and high safety, so consider transport task decomposition and train coordination in different lever by distributed hierarchical control structure, which includes three levels: the organization level, the coordination level and the execution level (see Figure 2). The organization level locates in the high layer of MAS, it receives and translates input instructions and correlated system feedbacks, determines the task, and decompose it into sub-tasks with appropriate execute order, which is realized by administer computer. The coordination level locates in the middle layer of MAS, it receives instructions from organization level and feedback information in each sub-task executing course, and coordinates the executing course with the execution level, which is realized by operating station and monitoring computer. The execution level locates in the bottom layer of MAS, its task usually includes executing certain movement, which requires the knowledge of course mathematical model, course end state and performance criterion or cost function defined by coordinator, which is realized by spot controller.

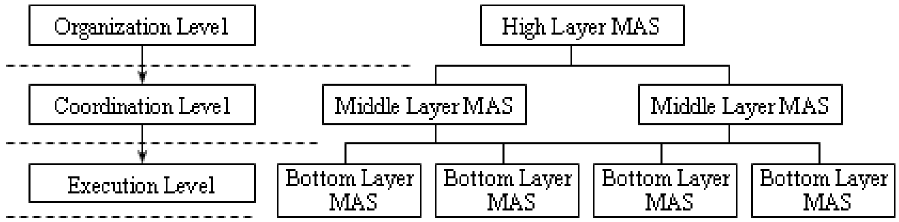

Figure 2. Distributed hierarchical control structure.

5 Model Simulation

In order to verification the validity the algorithm, simulation is made in the Matlab environment. Taking the transport and organization of passenger dedicated the first line of Chengdu subway as an example, the simulation condition is supposed as follows:

The total length is18.5 km, station number n=17, plan to run L=24 trains, which include 12 up-ways and 12 down-ways. the additional stopping time is 1 min, and additional starting time is 1 min, train tracking headways time is 5 min, the weight of trains with different level is (4 3 2 1), population size is 30, crossover probability is 0.8, mutation probability is 0.001, maximum algebra is 200. By combining genetic algorithms, the model is showed in figure 3. The test results show that the distributed hierarchical control method based on Multi-Agent can complete train operation adjustment in disturbing situation efficiently.

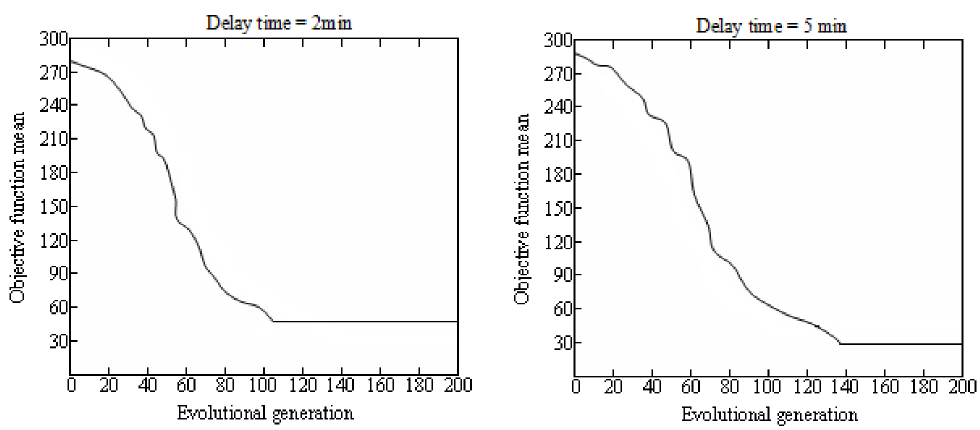

Figure 3. Objective function evolution process.

6 Conclusion

Train is the objection with distributed character in logic and physics, train operation dispatch system is one of the important measures to improve urban rail transport efficiency and keep the safety and punctuality of train transportation. The transport task of urban rail transit intelligent transport system has the characteristics of uncertainty, complexity and spatial distribution, the thought and method of large scale system control is an effective way to solve the system control problem. Multi-Agent technology which possesses autonomy, reaction and oriented-objective characteristic, is used to design train operation adjustment algorithm of urban rail transit based on distributed hierarchical control method. By the method of decomposition and coordination, local adjustment and global adjustment, the cooperation ability and initiative of every part of the control system can be improved, the total delay time of train group can be decreased, the absorption to passengers of the successive trains can be increased, and ultimately improve urban rail train dispatching automation level.

Intelligent Train Dispatching for Urban Rail Transit Based on a Fuzzy Neural Network

Jingdong Sun

Department of Traffic and Transportation, Southwest Jiaotong University, No. 1, Jingqu Rd., Emeishan, Sichuan 614202, China. E-mail: sun_jdong@163.com

Abstract: Through detailed analysis of train operation control procedure of urban rail transit, in view of the present condition of Fuzzy Neural Network (FNN) in train operation control, a new model of train operation adjustment on the FNN is developed, Five levels fuzzy neural network were built and its input and output were designed, the weighing and parameters were revised in order to get different membership function, then corresponding fuzzy rule and could execute fusion decision could be got in the new method. Furthermore, The simulation perception processing of train operation adjustment was completed using Matlab, the mean square error between actual output and experiments output was got The simulation results show that the validity of train operation control procedure of urban rail transit based on FNN.

Keywords: Fuzzy neural network; Urban rail transit; Dispatch; Intelligent transportation; Train operation adjustment.

1 Introduction

An intelligent dispatching system of urban rail transit requires to acquire, transport, process and output correlative information so as to realize the high-efficient incorporate operation of train operation program, dispatching supervision and control, accident settlement, emergent rescue, passenger service and so on (Liu, 2006). In the normal operation condition, the dispatching of train group can be rule processed in the direct of planned train diagram. However, in the abnormal situation, the measures of the adjustment in the train operation are different as a result of the vary factors that influence the trains. The dispatching command confronts a lot of matters, and different kind of matters require different dispatching countermeasures, especially when train is behind schedule or a big disaster or accident is happened, which is a biggish test for the dispatchers. In these situations, they are supposed to react nicety, take effective measures, deal with all kinds of abnormal instances duly and decidedly and recover the normal train operation rapidly. Therefore, the key-point of the intelligence of the dispatching system is that the system should possess intelligent dispatching function in abnormal situations, the main issue of which is to automatically adjust the train operation in the train behind schedule situation.

3 Model Establishment

3.1 Mathematical Model of Train Operation Adjustment

The train operation adjustment of the urban rail transit has many obvious characters, such as excessive restrict conditions and optimize indexes, strong dynamics, high request of real time, combinatorial optimization and so on. Suppose there are $n+1$ stations and n sections in a urban rail line down direction, and the arrival and departure tracks of each station is as $G_i\,(i=1,2,\cdots,n+1)$ that able to receive trains in this direction. There are J trains needed to be adjusted in an adjustment period (commonly 3 to 4 hours), marked as $L=\{l_1,l_2,\cdots,l_j\}$. the weight is ϖ_j ($\varpi_j \in \{0.1,0.2,\cdots,1\}$), which means the characteristics of the train, such as relative priority and so on. When the trains pass each section and station in the dispatching section in order, it will produce y section events with a certain sequence. Each adjusted train has a earliest receiving time h^l, a earliest departing time f^l and a last leaving section time or arriving endpoint time g^l,and should finish the course of this adjustment section in the appointed period (h^l, g^l). Each train has an occupancy time c_i^l and an optional beginning time b_i^l when passing each section. If the finishing time is defined as e_i^l, there exists $e_i^l=b_i^l+c_i^l$, in which b_i^l is constrained by f^l and c_i^l. Samely, trains produce z station events when pass each station of the section. Each train has an occupancy time o_i^l and an optional beginning time b_i^l when passing each station. If the finishing time of occupying the station is defined as v_i^l, then there exists $v_i^l=u_i^l+o_i^l$, in which u_i^l is constrained by h^l and o_i^l. Based on the assumption, the mathematical model of the train operation adjustment in the urban rail line down direction can be defined as formula (1), the adjustment goal is to occupying the least time after being weighted (Jia, 2005).

$$\min z=\sum_{i=1}^{n}\sum_{l=1}^{j}\varpi^l c_i^l+\sum_{i=1}^{n+1}\sum_{l=1}^{j}\varpi^l o_i^l \tag{1}$$

$$e_i^l \leqslant b_j^l \quad i,\ j\in\{1,2,\cdots,n\},\ (\ i< j) \tag{2}$$

$$\left(b_i^a-b_i^b\right)^2 \geqslant I^2,\quad \forall\, a,\ b\in L \tag{3}$$

$$u_i^l \leqslant v_i^l,\ i\in\{1,2,\cdots,n\} \tag{4}$$

$$\sum_{l} L_i^l(t)\, G_i\,, \quad \forall\, t \in T \tag{5}$$

$$b_i^l \geqslant f^l \tag{6}$$

$$u_i^l \geqslant h^l \tag{7}$$

$$\left(u_i^b - v_i^a\right) \geqslant \tau_{发到}, \quad \forall\, a,\ b \in L \tag{8}$$

$$\left(u_i^a - v_i^b\right) \geqslant \tau_{到发}, \quad \forall\, a,\ b \in L \tag{9}$$

Formula (2, 3) is the constraint of the section order of the train operation, which means that trains need to pass each section in turn, and *I* is the interval time of tracking train headways. Formula (4) is the constraint of station occupation condition, which means that train cannot leave before arriving time. Formula (5) is the constraint of station's arrival and departure tracks capacity, which means that in any time *t*, the occupied tracks cannot exceed the capacity of the station. Formula (6) is the constraint of the train's earliest leaving time, which means that trains cannot leave earlier than the daily-shift plan time. Formula (7) is the constraint of the train's earliest occupying station time. Formula (8, 9) means that a station can't transact trains with the same direction at one time, which should have different departure-arrival interval time τ_{da} and arrival- departure interval time τ_{ad}.

3.2 Fuzzy Partition of Input and Output Space

For the train operation adjustment system, the most important part in the control objective function is the train occupancy time ($c_i^l + o_i^l$), which can be indicated from (1). The Root Mean Square (RMS) is used to be the linguistic variable in the control rules, as in (10).

$$d = \text{RMS}\ \left(c_i^l + o_i^l\right) \tag{10}$$

When the control inputs are confirmed, the constraint conditions are equally important. The format expressed by formula (2) - (9) is different from objective function. It must distort each constraint condition to adapt the linguistic variables of fuzzy neural networks. The constraint conditions have only two statuses: satisfied or unsatisfied. Suppose 0 denotes that the constraint condition is satisfied, while 1 denotes unsatisfied, then the most ideal situation can be described as a 9-dimension array with all the members being 0, expressed by C_0. $C(h)$ denotes the satisfied practical operation constraint conditions, the RMS of $C_0 - C(h)$ is used as the linguistic variable of constraint conditions, that is

$$z = \text{RMS}(C_0 - C(h)) \tag{11}$$

The fuzzy set, which is composed by the train occupancy time *d*, constraint conditions *z* and output adjustment *y*, is divided into saturations {*NB*(Negative Big), *NM*(Negative Middle), *NS*(Negative Small), *ZE*(Zero), *PS*(Positive Small), *PM*(Positive Middle), *PB*(Positive Big)}. The control value ϖ denoted by the train weight is divided into saturations, described by *V*={*B*(Big), *M(*Middle), *S*(Small)}.

The Gaussian-type membership function is tally with people's thinking habits and the statistical law, and the maximum value of any membership in the fuzzy subset won't be too small, and it can avoid the dead zone, increase the control performance of the whole train operation adjustment system. Therefore, each fuzzy subset's membership function is Gaussian function $e^{-\left(\frac{x-c}{\delta}\right)^2}$, in which *c* denotes the central point, δ denotes the width and δ=0.03. Take the train occupancy time's linguistic variable *d* as an example, suppose universe is (-3, 3), the unit is *h*, and then the membership function is described as figure 1.

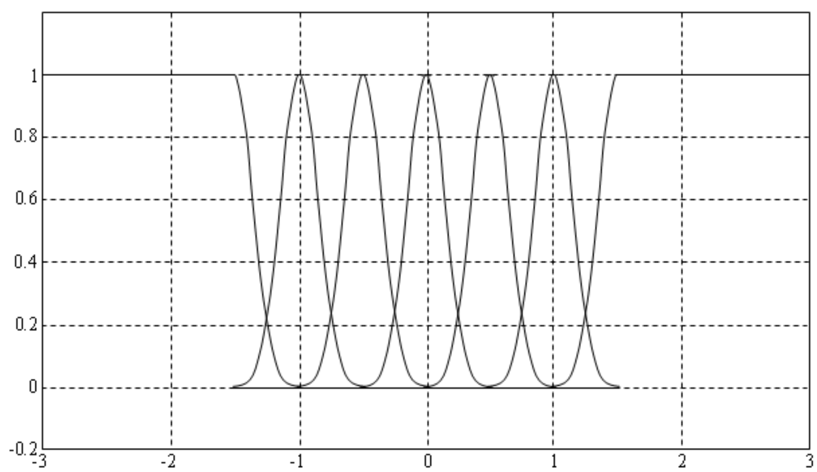

Figure.1 Membership function

3.3 Establishment of Fuzzy Control Rules

The choice of fuzzy control rule affects the effect and precision of the system control directly. The fuzzy rules library is composed of implicit knowledge and explicit knowledge. For example, the operation experience of dispatcher is explicit knowledge, while the rule produced by the input and output of an ideal train operation dispatch course is implicit knowledge. By linguistic rules, it can be denoted as follows: if DE is Ai, DEC is Bi, and U is Ci, then Y will be Di.

There into, DE, DEC and U delegate the linguistic variables of the train's occupying time, constraint condition and control quantities, and Y is the linguistic variable of operation adjustment result. The fuzzy subsets of their linguistic value in correspond universe are Ai, Bi, Ci and Di.

In order to get quantization results of fuzzy control, the fuzzy variables can be coded. For example, {*NB*，*NM*，*NS*，*ZE*，*PS*，*PM*，*PB*} can be denoted by {0,1,2,3,4,5,6}. After accidence establishment, the system rules can be optimized by persistent learning and training of the network. The control course of trains' operation adjustment is showed by Figure 2.

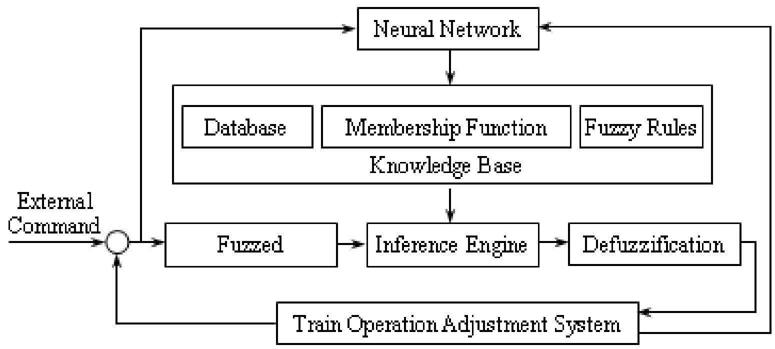

Figure.2 Process of train operation adjustment based on the FNN

3.4 Fuzzy Neural Network Structure

According to the above analysis, fuzzy neural network with 5 layer nodal point can be established, which are input layer, fuzzy layer, regulation layer, normalization layer and output layer.

The first layer: it includes 3 original input variables d，z， ω. Fist establish Gaussian-type membership function to d，z， ω. In the design, 2 neural weighted methods are chosen to simulate hyperbolic Tangent Function, which is also the input activation function.

The second layer: each input component corresponds to a group of nodal points, the number of which corresponds to the number of fuzzy grades of input values, there into, each nodal point delegates a fuzzy linguistic variable. Each nodal point delegates a linguistic variable value, the function of which is to calculate the subjection function belonging to linguistic variables fuzzy set of each input component. To 3 linguistic variables d，z and ω, 7,7 and 3 fuzzy subsets are carved up, and 7×7×3=147 control rules are received.

The third layer: each nodal point delegates a fuzzy rule to accomplish the match of rules, and the outputs corresponding applicability of rules. For a given input, the linguistic variables around input points can have bigger subjection values, while the far-away variables has small subjection values or the value is zero. Therefore, most nodal points' output is zero, which is similar as local approximation network. The algebras algorithm of input value subjection function is used when computing.

The forth layer: the number of nodal points is the same as the third layer. Each rule's application is normalized. In this layer, only a few nodal points have big output value, while most nodal points' output is zero.

The fifth layer: it realizes the clear calculation of system.

4 Model Simulation

In order to verification the validity of the algorithm, simulation experiments is done in the Matlab environment by using anfis function to accomplish the training work of self-adaptive neural network fuzzy inference system. The network structure parameters are: 3 input variables, 2 output variables and 147 regular nodal points. In the condition of the actual train operation status deviate the project train schedule, choose 400 sample data, in which 300 data is used as learning samples, and the 100 remained data is used as testing samples to test the network. During the training, the change of the Mean Square Error is tracked. After the network training restrains, all samples will be identified fuzzily. The testing results show that, with the increase of the training period, MSE decreased gradually, the network converged gradually, the network output basically inosculate the experiments output, and neural network reflect the control rules well, when the error in the network training course is controlled in the range of expected error.

5 Conclusion

Fuzzy Neural Network theory is a relatively new kind of software calculating method, and it can effectively analyze and process imperfect information. The international science field thinks highly of this theory, and it has been widely and successfully used in many science and technology fields such as the mode identifying, machine learning, decision supporting, process controlling, model predicting and establishing and so on. Aiming at the characteristics of the urban rail transit and its construction, this paper uses this theory on solving the problem of decision making in the train operation adjustment, and provides a new method and thought in realizing the high-efficiency, modernization, intelligence in the operation dispatching.

Abstract: In ICT environment, more and more information can be obtained. On the basis of analysis of lane changing action, this paper establishes the vehicle lane changing model based on discrete dynamic game. In this paper, the game stages are divided by the lane width, then the stage process between two vehicles and action strategy of each vehicle are described more reasonable by discretizing acceleration of the vehicles, and PICUD is used as the expected return of the income matrix .This paper use the model to analyze the high-speed road vehicles' lane-changing processes and to determine its revenue, to indicate the effectiveness of this model.
Keywords: Discrete dynamic game; Lane changing model; Intelligent transportation system; ICT environment.

1 Introduction

Lane changing behavior of vehicles is a complicated process, affected by many factors. Many scholars have conducted a detailed study, and proposed the corresponding lane changing models, including vehicles repeated game theory based on dynamic lane changing model and so on.

Considering reasons of changing lane, behaviors can be divided into two types: (1) Forced lane changing. It mainly due to the presence of an accident on the road, construction, control measures or path selection (left turn in front of the intersection) and so on; (2) Independent lane changing. Vehicles due to the current speed or road space can not meet the needs. This paper does not consider specific reason, assumes that the vehicles have the motivation, and has already begun to change lane.

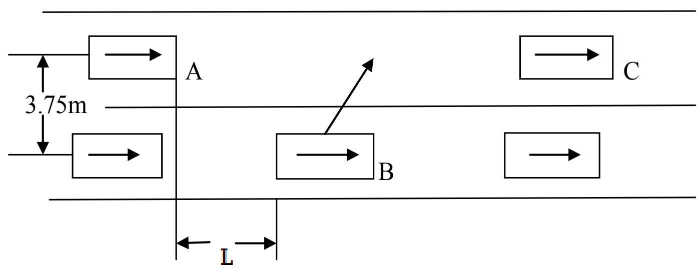

Figure 1. Process of lane changing

Process of lane changing is shown in figure 1. The target of vehicle B is to improve its satisfaction with the current traveling speed and space by changing lane. But vehicle A is likely to take measures to stop B, because the lane changing of B will decreases the distance between A and vehicles in front, and will bring adversely influences on traveling speed or space of vehicle A.

Through the above analysis we can find the fact that there is just competition between the vehicle A and B. As the target vehicle, vehicle B is going to change lane, so its vertical speed is V_B, its vertical acceleration is α_B and its rampant acceleration is α_{Bh}. Vehicle A has vertical speed set as $V_A$and vertical acceleration set as α_A. The lateral distance between the two vehicles is 3.75m which is the width a lane and the longitudinal distance L. Now the lateral distance between vehicles is divided into five equal portions, and every 0.75m is set as a stage of dynamic game theory in this paper.

2 Dynamic Game in The Process of Lane Changing

Game can be divided into static game and dynamic game, and repeated game is a very special kind of discrete dynamic game. Generally, in a repeated game, each participant is to take action at the same time, which is more similar to the static game, but is different from static game. All participants are to take actions at the same time in repeated games, but in the static game, participants are only to take actions at beginning.

In a repeated game, the game that is repeatedly performed is called stage game. In every game stage, the game strategy spaces and payoff functions are the same. If a game which contains a finite number of stages and each participant can observe other participants' actions in the past stages at the beginning of the game, this game is called a limited time repeated game. Game theory contains three important elements:

(1)In the actions of a countermeasure, participants who have the right to determine their own countermeasure actions are known as the players. Although the players in this model are the vehicle A and B, vehicle B has longitudinal acceleration and lateral acceleration in the process of lane changing. These two acceleration have no effect on each other, so the vehicle B's decisions can be divided into longitudinal decision B and transverse decision B_h.The players of this model can represented as $I = \{A, B, B_h\}$.

(2) In a game, practical actions for players to choose are called strategies. Every player $i(i \in I)$ has its own set of strategies S_i . In this model, decision of players is accelerating or decelerating. In order to make expected revenue more accurate, the acceleration is discrete and each decision is set as follows: S_A ={-5,-3,-1,0,1,3,5}, S_B ={-5,-3,-1,0,1,3,5},S_{Bh} ={-0.5,-0.3,-0.1,0,0.1,0.3,0.5}. A negative value indicates deceleration, 0 means neither accelerating nor decelerating, and positive value indicates accelerating, and the unit is $\mathrm{m/s^2}$.

Vehicle A can have 7 decisions each stage, and vehicle B can have 7*7=49 decisions each stage. Each policy group the players selected form a strategy called a situation, the set S of all situations in this model can be expressed as

$S = \{S_A, S_B, S_{Bh}\}$

(3) The expected revenue set of each participant under the strategy combination of specific participants is $R = \{R_A, R_B\}$.

3 Lane Changing Model

Every stage B will observe behavior of A at the same time. By the definition of repeated games, at the beginning of each stage of the repeated game, each participant can observe other participant's actions of past stage. So in the corresponding actual process of drivers' changing lane we can get the following data: the vertical distance between A and B is L_m. Relative distance variation in the last stage is ΔL_{m-1}. The speed of A was $V_{A(m-1)}$ and longitudinal acceleration was $\alpha_{A(m-1)}$. A can also get the corresponding data of the vehicle B to make appropriate judgments and actions at each stage.

A will assume that in the later stages B will have the longitudinal speed V_{Bm} acceleration α_{Bm},and transverse velocity V_{Bmh} and acceleration α_{Bmh}. It assumes that A will has the speed $V_{Am}$and acceleration α_{Am},so we can calculate the distance L_{mf}between the two vehicles after the completion of the vehicle lane changing, at the same time vehicle B has the speed of V_{Bmf} and vehicle A has the speed of V_{Amf}. m represents the number of stage, $m = 1,2,3,4,5$.

The horizontal distance between two vehicles is 3.75 m. vehicle B will have lateral movement of 0.75 m every stage. So the actual time t_m in stage m can be concluded by the equation (1).

$$V_{Bhm} + 0.5\alpha_{Bhm}t_m^2 = 0.75 \tag{1}$$

Then the distance of vehicle A and B, speed of A, lateral speed and longitudinal speed of B at the beginning of stage m+1 can be calculated by the equation (2).

$$\begin{cases} l_{m+1} = l_m + V_{Bm} t_m + 0.5\alpha_{Bm} t_m^2 - V_{Am} t_m - 0.5\alpha_{Am} t_m^2 \\ V_{B(\mathrm{m+1})} = V_{Bm} + \alpha_{Bm} t_m \\ V_{Bh(\mathrm{m+1})} = V_{Bhm} + \alpha_{Bhm} t_m \\ V_{A(\mathrm{m+1})} = V_{Am} + \alpha_{Am} t_m \end{cases} \tag{2}$$

At the end of the stage m, it is assumed that the vehicle A and B will complete the lane changing at the current motion state,. So the total time of lane changing process and ultimately speed and acceleration of vehicle A and B are available through the equation (3).

$$\begin{cases} 0.5\alpha_{Bhm} t_{mf}^2 = 0.75(6 - \mathrm{m}) \\ V_{Bmf} = V_{Bm} + \alpha_{Bm} t_{mf} \\ V_{Amf} = V_{Am} + \alpha_{Am} t_{mf} \\ l_{if} = l_m + V_{Bm} t_{mf} + 0.5\alpha_{Bmf} t_{mf}^2 - V_{Am} t_{mf} - 0.5\alpha_{Amf} t_{mf}^2 \end{cases} \tag{3}$$

4 The Expected Revenue

PICUD is introduced as evaluation of expected revenue and it means the difference between the distance of two vehicles and the stopping distance of avoiding collision. It is calculated as shown in equation (4).

$$PICUD = l_{mf} - \frac{v_{Bmf}^2}{2\alpha_{B\max}} + \frac{v_{Amf}^2}{2\alpha_{A\max}} - v_{Amf} t_r \tag{4}$$

α_{Amax} and α_{Bmax} are the maximum decelerations of vehicles A and B. l_{mf} is the distance between the vehicle A car and B, after lane changing is complete in the situation. t_r is the driver reaction time and vehicle braking system response time and its desirable value is 1s.

A. When PICID≥0, it indicates that there is a certain safety margin. Two vehicles can slow down within a given distance, even vehicle A has higher speed. The value of R_A is -10 and the value of R_B is 10.

B. When PICID<0, there is the same conflict between the two vehicles and there is no certain distance between two vehicles to keep safe. It is very dangerous for vehicle A and B, because collision situation that is not allowed will happen. So the value of R_A is -10 and the value of R_B is -10.

5 Conclusions

At present, our country's intelligent transportation is increasingly developed. We can get the exact vehicle location, speed, acceleration and other data by GPS, mobile positioning technology. Therefore, using of advanced positioning technology can help better control of the vehicle lane. In ICT, this paper establishes the vehicle lane changing model based on discrete dynamic game to help vehicles determine lane changing behavior and protect the safety of the vehicles.

This paper uses the method of dynamic game theory to analyze the behavior of lane changing. Based on one lane width 3.75m, the whole process is divided into five stages, and each stage can be calculated qualitative analysis to ensure the accuracy of the model. The decisions in each stage are discretize and quantized with a high accuracy. But on the analysis of the lane changing model, although there is a competitive relationship between vehicle A and B, in fact, there is more impact on them with other vehicles. So analysis in this model is simplified. In future studies, it needs to consider the influences and the game relations between the vehicles and establish a more scientific and complex model.

Abstract: The real-time traveling information collecting and distributing systems are important parts of intelligent traffic system. However, the existing information collecting and distributing technology have been unable to meet people's personalized needs. The wearable technology that rises gradually has been widely used in the fields of medical, military and fashion. This paper applies the wearable technology to the real-time traveling information collecting and distributing systems. The real-time traveling information can be collected by the intelligent steering wheel cover, and is transmitted by wireless communication technology. At last, the information is distributed to users by intelligent watches. So, users can easily obtain the real-time traveling information.
Keywords: Real-time traveling information; Wearable technology; Information collection; Information distribution.

1. Introduction

Intelligent Transportation System (ITS) includes multiple subsystems. Traffic information collection system is an important part of ITS. With higher demands levels for transportation, it requests the collected traffic information to be real-time. The collected real-time traffic information is the foundation of advanced dynamic traffic guidance, traffic management system and traffic information system. Therefore, information collection system requires advanced traffic information detection technology to collect. The management effects and control effects of road traffic system are directly related to reliability, accuracy and real-time performance of traffic information detection (LIU X, 2011).

With the development of technology, tablet PCs and intelligent phones rapidly spread. Travelers easily get real-time traffic information by personal information terminals (such as in-vehicle information terminal, variable message boards, computer terminals and handheld devices, etc.) However, it's difficult to satisfy travelers' demands for comprehensive traffic information service and personalized real-time dynamic service because of the existing information service system and its manner of publication.

Wearable technology refers to a technology that users use wearable clothing (such as watches, glasses, etc.) which is embedded multimedia, sensors and wireless communications technologies to get access to health-related signs. It can support a variety of interactive modes such as gestures and eye movements operation. It can easily integrate and connect with users' daily needs tools and equipment. Wearable technology now is used in medical, military, fashion, computers, etc. With its convenient and smart features, this technology is applied to real-time traffic information collection and distribution system, developing into intelligent transportation.

2. The development of Wearable technology

Wearable technology in the medical field can be widely used in home health care, clinical control, emergency ambulance, sleep analysis, special populations care, aerospace, heart evaluation, physical training and other aspects. The so-called wearable applications in the medical field is a detection system which can be "put" on the body, that is, using daily clothing and accessories to collect the physical information of people's bodies. The specific approach is making integration of medical researchers' sensor rings, watches, clothing and other apparels, which makes people feel comfortable, get their own signs monitoring parameters and their health status (ZHENG J W, 2008). Now, the concept, forms and functions of wearable devices are all in constant evolution and the product has become increasingly diverse belonging to the product of "human unity" concept (ZHU Y H, XU B Y, WANG X F, 2013).

With the development of technology, the formal technology products of wearable technology mainly include intelligent glasses, intelligent watch, intelligent bracelet, GPS tracker, BrainLink idiodynamic headband and other products.

Tab 1.The technology and function of wearable technology products

Products	Technology	Function
intelligent glasses	Micro-display screen on the upper right side of Google glasses, 720p camera on the right side of the glasses, the touchpad, speakers, a microphone, a gyro sensor and in-built battery able to support 6 hours installed	It combines sound control, navigation, photography and video chatting functions with all the features of mainstream smart phone, communications and data services.
intelligent watch	iOS system installed, supporting Facetime, WiFi, Bluetooth, Airplay, Retina touchscreen capabilities, 16GB of storage space,	It displays part of the message can be presented on the smartphone, such as phone calls, text messages, maps and weibo by display screen.
intelligent bracelet	GPS, gyroscope, accelerometer needles and other sensors that can measure the wearer's physical	It records human movements, sleep, diet and other health-related data by matching software to help

	activity, calorie consumption and so on	consumers adjust rest rules, enhance health and achieve a healthy life.
GPS tracker	GPS chip	It trackers lost equipment according to the GPS chip and achieves GPS positioning with the software and real-time transmission of information to the user.
BrainLink idiodynamic headband	Smartphone, tablet PCs, laptops, smart TVs and other devices linked by Bluetooth with the appropriate application software	It helps phone or tablet know the status of user's brain timely, for example, whether user is focused, tense, relax or fatigue. User can also adjust the focus degree and relaxation degree to give instructions to Mobile Phone Tablet.

3. Wearable technologies in Transit

Urban traffic information system provides varieties of traffic information system for travelers, able to reflect latest real-time traffic information because travelers always develop travel plans based on real-time traffic information before the travel or at the process of changing travel plans. Each traveler's demands for traffic information are different also limited, but all the information demands of all travelers get together to be a lot. So, urban traffic information system should provide travelers with a lot of comprehensive traffic information.

Traffic Information is various. According to the different characteristics of travelers' demands, information can be divided into dynamic traffic information, static traffic information and related traffic information. Dynamic traffic information changes over time and space, including the basic information of traffic jam, car incidents, travel time, location and driving routes, traffic guidance information, traffic control signals. Static traffic information may remain unchanged or changed very little over a period of time information status, including the distribution of transportation, parking, transfer points, ticket selling stations, the charged prices, traffic restrictions, construction and maintenance information, road conditions, etc. Related traffic information refers to other information related to traffic travel, such as travel, hotels, entertainment, shopping, weather, sports, etc. ([YANG L Q,ZHANG N,TAO Z X, 2007). In addition, the vehicles' own information includes fuel consumption, vehicle mileage and inspection notification.

Urban traffic information system includes three subsystems of information collection, information processing and information distribution. Wearable technology can be applied to the information collection and information receiving terminal. The system consists of three parts: the intelligent steering wheel covers, urban traffic information center and the users' intelligent watches system as is shown in Figure 1.

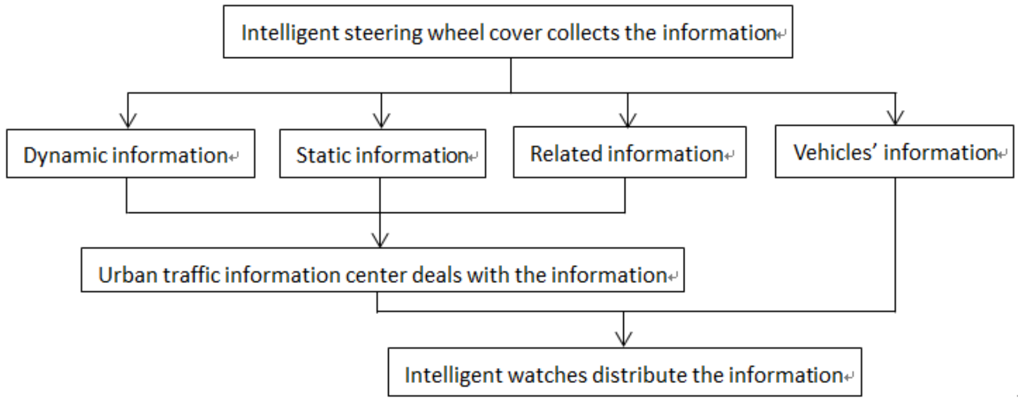

Fig.1 The structure of wearable real-time traveling information system

3.1Wireless Communication Technology

Nowadays, information transmission sends information mainly through cable transmission or wireless transmission. People's traveling mainly relies on travel motor and non-motor vehicles. Movability is a major character of travel, so the information terminal system can only receive information through wireless communication. With the development of technology, GPRS and CDMA networks have almost universal coverage. By the two networks, we can achieve real-time remote transmission of data. Therefore, wireless communication technology among the systems uses CDMA networks (YU C Q, 2002). In addition, when the distance between the intelligent steering wheel cover and the intelligent watch is near, Bluetooth wireless communication can be used. But Bluetooth communication distance is limited. When the user is away from the vehicle, unable searching the Bluetooth signal, it automatically changes into CDMA transmission network. Wireless communication function can be added into the design of intelligent steering wheel cover.

3.2Power supply Mode

Wearable system is a kind of mobile terminals. Power is the key of wearable function. High-performance but low-power batteries and related supply methods are mainly used. Intelligent steering wheel cover is powered by the vehicle terminal and intelligent watch is powered by small lithium batteries.

4. Functional Design

4.1 Intelligent steering wheel cover designs

Intelligent steering wheel cover is an intelligent vehicle signal acquisition sets with sensors and electronics devices. Seemly to be an ordinary steering wheel cover, it can collect dynamic, static, related traffic information and transmit i to the urban traffic information center through the CDMA network. Also, it collects vehicles' information and transmits it via the Bluetooth network or CDMA network to the users' intelligent watches.

Intelligent steering wheel cover can achieve the functions of information collection, driving recording, drunk driving test and so on. Its main functions are shown in Table 2.

Tab 2.The functions intelligent steering wheel cover can realize

Functions	Details
information collection	It can get the information of the current vehicle speed, location, direction, travel distance and so on.
driving recording	It is the part of the driving tracker. It records, stores, displays and prints the information of vehicle speed, time, mileage, operation conditions and other information which is transmitted to the smart watches to record.
drunk driving test	It can detect whether the driver is drunk. If driver is drunk, the vehicle will shut of the engine automatically.

The details of function achieving are as follows:

(1) Location information collection mainly obtains location information via the VPS. Now it mainly relies on GPS satellite positioning technology to track the location of a vehicle. When the GPS acquisition module is embedded in intelligent steering wheel cover, users can directly read the current location information from the GPS acquisition module.

(2) It directly reads the information of vehicle speed, trip information, fuel consumption and other information from the vehicle's own vehicle speedometer, odometer and oil gauge. Information then will be transmitted to intelligent steering wheel cover via the CAN bus (fieldbus).

(3) Traveling direction may be determined by the Grating encoder and other angle sensors. Grating encoder output signals can be directly input into timer part of processor, confirming the angle turned by a counter technique.

(4) Testing drunk driving can be achieved by sensors embedded in the intelligent steering wheel cover. If the driver's alcohol level reaches a certain amount, steering wheel sensor detects the alcohol from the sweat of palm. Vehicle will shut off the engine automatically, unable to start up.

4.2 Intelligent watches design

Since more and more people use mobile phones, people who used to wear a watch become less and less for phones can completely replace the watches' timekeeping function. Watches become an ornament or a symbol of noble status. With the development of technology, watches also gradually step into the intelligent era. With the emergence of intelligent watches, it can not only achieve the function of timing, but also help users experience the more new features of watches.

The main function of the intelligent watches is receiving the data sent by the intelligent steering wheel cover and urban traffic information center.

Achievable functions are as follows:

(1) Alarming. Intelligent watches receive the speed information from steering wheel cover when vehicle moves on the roads with speed limits. If the vehicle is overspeed, it will tell owners by vibrations. Also, intelligent watches can show the remaining oil and remind the owners of refueling with vibrations. Owners can also check remaining oil in advance avoiding the embarrassment of not finding a gas station when away from home. If there is a road traffic accident or a traffic jam ahead, the watch will vibrate to warning the user. Then the driver can select the travel route again with the real-time information. In addition, people usually forget where vehicle is parked after shopping. At this time, simply clicking on the intelligent watch, users can accurately get their vehicles' location via GPS. When it comes to the vehicle inspection time, intelligent watches will remind owners in advance.

(2) Inspection. After parking for a long time, owners begin to suspect that they have not locked the central locking, but it's far away from the vehicle. Owners just tap on the wrist watches border to light up the screen and see whether the door is locked instead of getting back to the vehicle.

(3) Customization. There are three user-defined function keys in the left side of the watch. The owner can set the function buttons according to their needs, such as navigation, multimedia remote control, sending text messages or looking around nearby. In addition, based on GIS maps, the system uses the vehicle location technology getting users' locations and showing the surrounding location information .Besides, the system can constantly update information when users move. They can check the information including photos near the monitoring point, highway entrances and exits, toll stations and other information.

5. Conclusions

This paper introduces real-time traffic information collection system and distribution system based on wearable technology, which uses intelligent steering wheel cover to get the basic real-time traffic information, transmits information to the urban traffic information center through wireless communication technology and finally distributes information through the users' intelligent watches. Users can know their vehicle conditions, road conditions, traffic conditions and any surrounding traffic information by intelligent watches.

The application of wearable technology in traffic is in two forms, intelligent steering wheel cover and intelligent watches. The technology of intelligent watches has become matured, with only some improvements on functions to do. Intelligent steering wheel cover needs building in-sensors and electronics technology which are able to achieve with today's science and technology development. With the use of wearable technology in traffic, it can be more convenient, smart and fast for travelers getting access to real-time traffic information so that the ways of real-time traffic information collecting and distributing will updated. With the development of technology and the popularity of the wearable products, wearable technology in traffic will go further in application and development.

Abstract: Travel time variability has been considered as an important quantitative measure of bus service reliability. It deteriorates reliability by increasing in-vehicle travel time and passenger waiting time. Less attention has been paid to it due to the lack of reliable data. The problem is being addressed by the use of advanced public transport systems. The paper mainly used the GPS data to explore the form and the extent of travel time variability at different times of the day. The process of data cleaning was built for the characteristics of bus GPS data in Chengdu. The appropriate measures of travel time variability based on the travel time distributions were adopted by the study to make the best use of the abounding data. At last, the paper briefly discussed the factors which might affect the travel time and proposed aims for the further research.
Keywords: Travel time variability; Data analysis; GPS data; Travel time distribution.

1 Introduction

Bus service reliability can be defined as the ability of the service to provide a consistent service over a period time. (Avishai, 1977) For passengers, it means the accessibility of transit system, the stability of travel time, and the predictability of the arrival time. For operators, the high quality of service reliability will make the operation of bus system efficient and the service satisfaction high.

Reliability is a compound concept and can be described by several factors. (Seung-Young, 2005) Among which, travel time variability is one of the quantitative measures of reliability.

The high variability of travel time makes passengers anxiety about the waiting time and in-vehicle time. It also brings difficulty to operators to maintain the regular headway and normal schedule. Therefore, the use of run time variation as a reliability indicator is the most appropriate for routes that cover longer distances with many signalized intersection and in cases in which traffic delays and passenger loads are irregular from day to day. (Strathman et al)

Despite its importance, less in-depth attention has been paid to travel time variability, mainly due to the difficulty in collecting complete and reliable run time data. This problem is being solved by the use of advanced public transport systems which collect and record operational data automatically.

The paper used GPS data from automatic vehicle location system combination with smart card data to get complete trips of route 8 in Chengdu. Day-to-day travel time variability is selected as the quantitative measure of service reliability. And the study explored the form and extent of travel time variability at different times of the day.

2 Literature review

Due to the different aspects of reliability, it is defined in a variety of ways. Turnquist and Blume suggest it is “the ability of the transit system to adhere to schedule or maintain regular headways and a consistent travel time.” (Turnquist& Blume，1980) Abkowitz offers a broader definition: the invariability of transit service attributes that affects the decisions of both the user and operations. (Abkowitz, 1978) The complex meaning of reliability leads to a variety of quantitative indicators.

Many papers studied the measure of service reliability. Some indicators are based on the operational level. Avishai considered travel time variability as an indicator of reliability and fitted a beta distribution for travel time. (Avishai, 1977) Strathman et al analyzed the service reliability on selected routes which used a new bus dispatching in Portland, focusing on running times, headways, and on-time performance. (Strathman et al) Seung-Young et al considered different definitions of punctuality in different situations and calculated punctuality indexes for different types of bus routes. (Seung-Young, 2005)

Although many researches discussed the indicators of bus service reliability on operational level, some of them suggested that the reliability perceived by operators and passengers is different. Therefore, the passenger-centered reliability awareness is appeared to grow. Some researchers studied the customer-oriented service standards and scheduling. (Peat et al, 1980; Furth&Muller, 2007) And others developed the customer-driven metrics which could be useful and meaningful for both customers and operators. (Schil, 2011)

From the previous studies, the indicators of service reliability on operational level mainly were about two aspects: travel time variability and punctuality. The metrics of passenger-centered reliability focused on the time consumed by a travel. However, any indicators described reliability should be chosen to be consistent with the operation environment. In some countries, the service frequency of bus is low, so the passengers’ behavior is affected by the schedule and the punctuality is meaningful for the operation. The situation is different for many large cities in China. Due to the high passenger volume, the scheduled frequencies are high even during off-peak and there is no such a timetable which sets the scheduled time at each stops. For this operation environment, the calculation of passenger-driven metrics is complex and the meaning of punctuality lessens. Therefore, more attention should be paid to the travel time variability.

Carrion and Levinson state that travel time variability is caused in general by predictable (e.g. peak hour congestion) and unpredictable (e.g. incidents) variations. The paper is aimed to explore the extent and form of variability at different times of day.

Travel time variability can be mainly viewed from 3 perspectives including vehicle-to-vehicle variability, period-to-period variability, and day-to-day variability. The paper focuses on day-to-day variability which can be defined as the variation of travel time of the same journeys made at the same time on different days.

3. Data

The GPS data and smart card data collected by advanced public transport system are gradually used by a variety of researches. Although data acquired in this way should be richer and more reliable compared to the manual survey, much work would be conducted to improve the quality of data and get the useful information. (Hounsell, 2011) The high quality of data is premise for next analysis. This section briefly introduces the basic information about the data as well as quality issues of the data used by the study and data cleaning methods.

This paper used the GPS data of route 8 in Chengdu. The route runs from HUA Longmen Station in west of Chengdu to the SHL Lidian Station in east of Chengdu. The length of the route is consistent with the length of the town and it connects to two subway station at its midway point. It is one of the busiest bus routes in Chengdu with an average ridership of 60,000 on weekdays, proving a typical route for conducting travel time variability. The route operates with 2.5 to 12 minutes scheduled headways in both directions. The data available for this application includes GPS data and smart card data of route 8 for the 16 weekdays of November, 2014. Table 1 is a list of the major characteristics for route 8.

Table 1.Characteristics of route 8

Characteristics	Direction	
	Eastbound	Westbound
Length(km)	20.9	21.9
Traffic signals	39	40
Number of stops	35	36
Average stop spacing(m)	615	626

The original GPS data includes two types of data. The first type of GPS data records the operation information of vehicle which transmission interval is less than 15s. The second type of GPS data only records the information when vehicle arrive at each stop or depart from each stop.

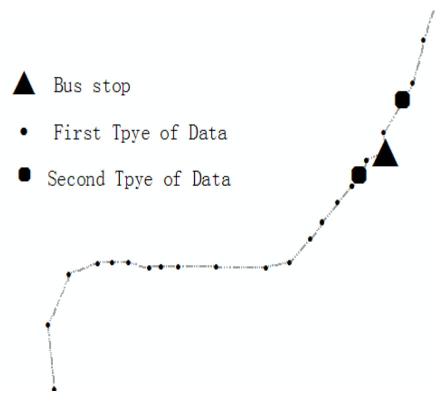

Figure 1. Two types of data

The figure 1 shows the relationship of two types of data. Taking into account the purpose of the study and characteristics of data, the paper tended to use the second type of data to analyze the travel time variability. Useful fields extracted from original data including recording time, speed of vehicle, vehicle ID, stop ID, longitude, and latitude.

In general, the special geographical environment such as tunnels, boulevards, etc may cause the loss or delay of GPS positioning signal even recording errors. Specifically, there are three kinds of problem for GPS data in Chengdu including duplicate data, irregular data and missing data. The paper establishes data cleaning process which mainly consists of two steps to get the reliable trips from the original data. In the first step, the original data were divided into distinguishable trips. Figure 2 is a flow chart for the first step. The second step is to identify the problems may exist in the initial trips and to deal with them. In final, the paper marked 97,859 duplicate records, 4,307 missing record, and 465 irregular records.

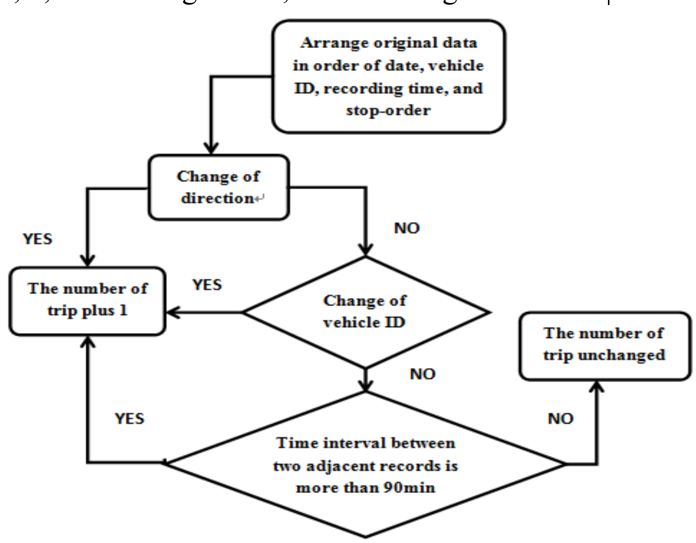

Figure 2. Flow chart for data cleaning

4. The analysis of travel time variability

After data cleaning, 7537 trips were used for travel time variability analysis. The run time for the whole route was calculated from the departure at the first stop until the arrival time at the last stop. Furthermore, the run time within the First Ring Road of Chengdu, the run time from the First Ring Road to the Second Ring Road, and the run time outside the Second Ring Road were calculated by the same way for deeper analysis.

Travel time distributions are an important area for this study because they describe the nature and pattern of variability and exploring the causes of travel time unreliability. This section aims to investigate the form and extent of travel time variability by exploring the shape of travel time distribution in different 15min interval.

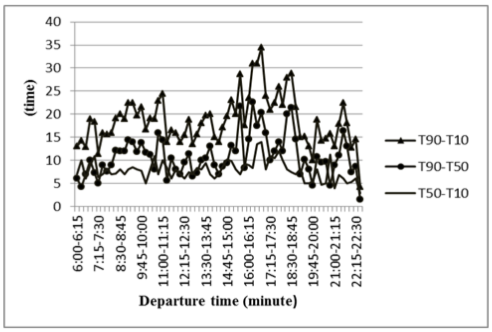
Table 2 shows a series of key descriptive statics for run time. The skewness is a measure of asymmetry of a distribution, while the kurtosis measures the weight of tails in relation to the rest of a distribution. The distribution of run time for the whole route as well as run time within the First Ring Road is close to the normal distribution because of the low value of the skewness and the kurtosis. However, the run time from the First Ring Road to the Second Ring Road and the run time outside the Second Ring Road are skewed distributions which have longer tails than those in a normal distribution for the high value of kurtosis and the observations cluster more.

Table 2. Descriptive statistics of run time

Statistical items	Mean value(min)	SD	Skewness	Kurtosis
Run time for the whole route	98.5	4.5	0.49	0.80
Run time within the First Ring	46.2	9.2	0.42	0.47
Run time from the First Ring to the Second Ring	19.5	3.6	2.57	38.2
Run time outside the Second Ring	32.9	5.4	1.86	8.17

The analysis of travel time variability is based on the percentiles for the travel time. The value of T90 shows that 90% of travel time values are less than this value, while the value of T10 indicates that 10% of travel time values are less than it.

There are four measures of travel time variability for further analysis. T90-T10 illustrates the width of the distribution. The higher value of it means more variable travel time. (T90-T10)/T50 is the width of the distribution relative to the median. T50-T10 is a measure of how early trips relate to the median. And T90- T50 is a measure of how late trips relate to the median. Figure 3, Figure 4, and Figure 5 presents these four measures in different 15 min intervals over the day for both directions. The T90-T10 measure peaks in the evening peak for both directions, while it shows significant increase in morning peak only for the eastbound. And the trend of the T90-T50 is almost parallel with the T90-T10, while the T50-T10 has a gentler trend and shows slight increase in peak hours.



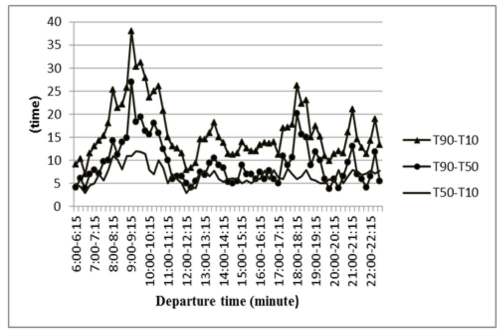


Figure 3. TT percentiles of eastbound **Figure 4. TT percentiles of westbound**

It can be concluded that the travel time of eastbound experiences a more significant variation in the morning compared to the evening peak and has a slighter variation in the afternoon and evening. The situation of westbound is quite different for the slight increase in the morning peak and the irregular increase in the afternoon. In addition, the lateness is responsible for higher values of T90-T10 for both directions.

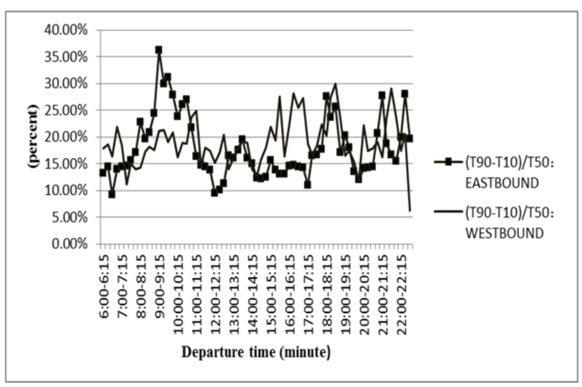

Figure 5. TT percentiles for both directions

It is proved that day-to-day variability is caused by fluctuations in travel demand, variation in driving behavior changes in the amount of roadside activity, accident and other reasons. (Ehsan et al, 2010) Travel time variability is mainly affected by the demand of commuter passengers and traffic condition in the peak hours, so it can be considered that the eastbound is the main direction of commuter traffic cause the high value of the T90-T10 in peak hours. However, the situation of westbound is more complex.

For the further analysis, the paper studied the form of travel time variability for the different sections of the route. The paper presents the (T90-T10)/T50 which is a relative measure of travel time variability for both directions in Figure 6 and Figure 7. It can be seen that the form of travel time variability within the First Ring Road is more significance in peak hour for the eastbound. For the westbound, the travel time variability is gentle and has a slight increase in peak hour which is different from the whole route. The more intense variability for the First Ring Road may be caused by more congested traffic and higher passenger volume. It is proved that the eastbound is still the main direction of commuter traffic for the First Ring Road. However, the variability of the westbound for the Second Ring Road has a large fluctuation, and the maximum value of the measure is higher than the value of eastbound in the peak hour. In a sense, it can be concluded that the irregular variability for the whole route in the afternoon is largely due to the high variability outside the Second Ring Road.

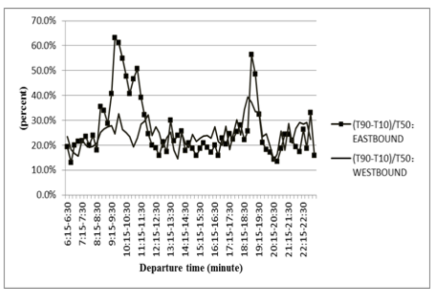

Figure 6. **TT percentiles within the Frist Ring Road**

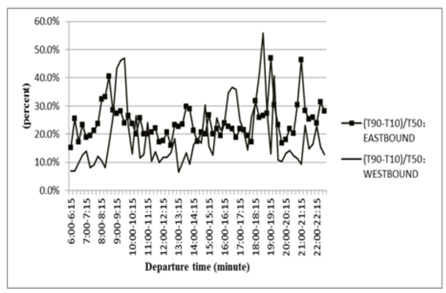

Figure 7. **TT percentiles outside the Second Ring Road**

In addition, the paper tried to explore the factors which may have an effect on the travel time. The whole route was divided into six sections in order to develop the model using a linear regression analysis. Several factors including section length, number of traffic signals, number of stops, number of boarding, and time period is considered in the model by using 8475 records. The result shows that the factor of section length has the highest positive coefficient value (0.65). The number of stops and the number of traffic signals are both significant. The conclusion is almost consistent with the previous studies. However, further analysis should be conducted based on more records.

5. Conclusion

Despite of the importance of travel time variability for public transport, limited research has been conducted on it partly because of the difficulties in collecting the travel time data of operation. This paper explores the approach to analyze the travel time variability using GPS data of certain route in Chengdu.

First, the paper explains why the travel time variability could be considered as the most appropriate measure for the service reliability of bus system based on previous studies and domestic operation environment. Second, the paper illustrates the characteristics of the data used by the study and builds up the process of data cleaning to acquire the reliable data from the original GPS data. Travel time percentiles are selected as the measure of travel time variability to analyze the form and the extent of the variability. The results show that different directions as well as different sections of the certain route have different features in travel time variability. The variability in peak hours may be caused by the higher passenger demand and more congested traffic. However, the irregular large variability in off-peak hours may be due to the complex reasons related to the characteristics of a certain route which should be further investigated.

Although the approach of studying bus GPS data in this paper provided a valuable method for analyzing GPS data, there is much scope to broaden the range of application of the data from advanced public transportation system. And the deep meaning of travel time variability should be mined in the environment of big data.

The next step for the study would combine the analysis of travel time variability with headway to see how travel time variability deteriorates the headway. The features of travel time variability for routes with different characteristics could be further explored. And deeper research should propose some measures to improve the service reliability of bus system.

Abstract: At present, the level of our nation's information of traffic dispatching system is low. Some dispatching departments did not form a complete and unified dispatching system .This will result in security risks, reduce the quality of services and transport efficiency. Been unable to meet the railway sector under market conditions demand for dispatching, the new dispatching system development is imminent.

In this paper, we contrary to the current status of China's dispatching system, for a brief analysis of its shortcomings and possible impact. Meanwhile, according to market needs, proposed the concept of intelligent dispatching system, combined with China's specific conditions and customer needs, the existing dispatching system is divided into eight sub again. By introducing RITS overall research program means, Through the demand for internal railway system users dispatching system analysis, and then，complete the intelligent traffic service dispatching system logic architecture and function architecture. Make the system tends to be more complete, and provide some idea of the intelligent railway traffic control system innovation.

Keywords: Intelligent railway; Intelligent dispatching system; The overall scheme.

1 Intelligent Dispatching System Vision

One obvious drawbacks of our existing freight traffic dispatching system is less degree of information, among dispatching department information can not be comprehensive, and timely interaction. It did not form a complete, unified dispatching system, result in safety hazards, reduce the quality of services and transport efficiency. Based on the rapid development of China's current status of railway intelligent technology, and after the rail transport market, the competition with other transportation industry intensified unprecedented. I put the new era of intelligent vision dispatching system.

The new era of intelligent railway traffic control system need first to solve the scheduling department information exchange each other difficult, and the question there is no unified dispatch system. By relying on intelligent transportation technologies, combined with the current demand for railway dispatching system, overall layout. This paper based on the dispatching system and new demands. Divided the system into planning scheduling, locomotive scheduling, vehicle scheduling, freight scheduling, train dispatching, construction scheduling, power scheduling and comprehensive maintenance scheduling eight parts. By building a interconnected unified whole, to guarantee dispatching various aspects of information interoperability, timeliness and accuracy. Scheduling process to achieve the various departments, real-time sharing of information among all sectors. Meet the transport train conductor production and meticulous management requirements, so dispatching efficacy can be fully realized.

2 RITS overall technical scheme of step

RITS overall technical scheme of the steps shown in Figure 1.

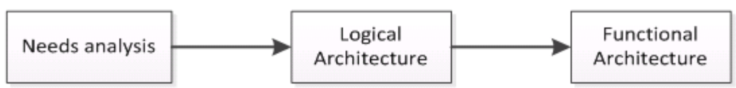

Figure 1: RITS overall technical scheme of step

Step 1:System Requirements Analysis

The system will be faced with specific management issues and transportation services for system development requires research.To fully elucidated the question of this system "what to do" ,to build the railway to make intelligent transport systems tend to be more intelligent and Information Technology. To ensure the security of cargo, to achieve timely delivery, better lay the foundation for customer service.

Step 2:Determine the content of the service architecture

On the basis of the analysis of business requirements, classify, merger, and consolidation,form RITS service architecture content based on the formation of intelligent scheduling needs of cargo transport. We can clear that what kind of service can be provided each RITS.

Step 3:Clear all business platform features

Business platform capabilities need to start from the service architecture, determine the system should have the main function. Corresponding with service, function of the system can be completed by some combination of a particular service. And analyze the interaction, the interactive content between internal logical structure business.

3 Intelligent Dispatching System Requirements Analysis

The purpose of the intelligent traffic dispatching system needs analysis, Aimed at breaking the "information silos" and "fragmentation" of the state of the existing railway. Adoption "system construction integration" of research ideas, starting from the entire intelligence freight services process. Analyze business requirements and its subsidiaries manage demand, in order to build a comprehensive information structure unit as a whole.

Specific analysis of the implementation process to follow, "drill down, from outside to inside, combined with near and far" method in accordance with the RITS system requirements. To build intelligent railway system based on time fundamental needs as the starting point. For intelligent railway transport tasks to be completed by the business process needs analysis. While the overall system as the foundation, gradually raise the goal of building subsystems, obtained division of structural units. Through information exchange technology aggregated into an organic whole, ensure linkage and purpose of each segment structural units of business processes are the same. Finally, we use goal-driven method develop services, making the system practical guidance and can boot the system the forward way.

3.1 Planning and scheduling needs

We need to establish a system of traffic projections，it can project the distribution of real-time traffic that day and the next day and the traffic trends. On the basis of the traffic projections and the basic diagram, achieve planning and scheduling can collaborative preparation boundary handover of heavy vehicles and emptying plan; marshalling scheduling and planning and scheduling collaborative preparation the marshalling starting train plan, make integrated scheduling system and subsystem can share information.

You can get the train automatically attribute information, real-time automatic updates actual train running time, train marshalling content, achieve access, produce summary statistics of the traffic service and traffic forecasting, early warning. Station technical working train diagram can display the number of lines to send and automatic correction; You can also automate statistical analysis plan to honor rate, the actual transfer of the station boundary columns, number of trains, motorcycles reentry frequency, and the time; Through the system to the train dispatching and locomotive scheduling issued freight trains daily plan and adjust the plan and adjust the plan; According the station train, in-transit vehicles, and daily demand plan. Projections with air required by the stage, classes plans should be submitted at the same time generate with empty plans. Traffic condition according to the set focus, related traffic tracking tips; Automatic generation locomotives, and technical capabilities warning.

3.2 Locomotive scheduling needs

Locomotive locomotive scheduling service primarily for the establishment of a dynamic tracking database,by TDCS, the station reports, and reports to track locomotive depot in transit, at the station and the information in paragraph,track locomotive, locomotive repair tips, labor crew super alarm.According the trains daily plan, automatically generate locomotive diagram, and the crew plans to send classes,conduct analysis locomotive.The locomotive diagram reached maintenance department.Monitor the actual implementation of locomotive working diagram,surveillance crew over labor conditions and help deal with locomotive accident.

3.3 Vehicle scheduling needs

Vehicle scheduling needs according to each depot maintenance vehicles numbers and standard,the median standard depot repair station,median standard of repair station,day disabled train repair,plant repair,planned completion date of the number ,the actual number of completed,depot repair, temporary repair to be scrapped, identification car, car accident, car assembly segment repair case,provides vehicle maintenance generated statistical reports,dynamic update trucks use state.We need to within the jurisdiction of passenger and cargo vehicles loopback overhaul plan and key requirements,in the station, in-transit vehicle breakdown, repair dynamic distribution, provide transportation and loopback generate hang plan to achieve dynamic control.

3.4 Freight scheduling needs

Freight dispatcher responsible for loading and unloading trucks each station plan,responsible for approving the work,shippers schedule loading date.Office of the cargo transfer system requests based on traffic projections and the priority automatic approval empty.Auto arrange trucks plan based on the situation and recognize the train unloading.The loading and unloading trucks plan broken down into the various stations and issued stop execution,the station automatically returns the actual loading and unloading trucks.In the long-term system.Intelligent cargo tone will change from passive to active,analysis of transport demand shippers,initiative for the owner to arrange trucks plan,determine transporting cargo plan.Estimated sub-periods pipe weight distribution and the expected arrival time of the service.

3.5 Traffic scheduling needs

Traffic scheduling needs based on actual daily plan and driving,planning phase,and analysis and adjustment the late trains;Safety information monitoring and safety information release,safety precautions promptly reached under various stations ;Daily plan text commands automatically form,accepted plan dispatcher stage plan,automatic on the diagram;Warning to form the focus of the train operating conditions during system running,Train collision check;Achieve a set of commands between each command and the feedback on the implementation form mechanism of mutual control information.On receipt of the case can automatically check and prompt,order to achieve a preview before release,command can be queried by construction plans,you can query by construction plans and other services.

3.6 Construction scheduling needs

Construction scheduling needs preparation of annual and monthly construction plans,receive applications for the construction of various departments, organize the construction approval;Increase in construction plans on the day shift plan diagram;Issued construction scheduling order,Supervise the construction process;Analysis of planned and actual construction.

3.7 Power scheduling needs

Power plan execution,complete stop transmission operation;Monitoring and management operation of the power supply system;According to the need for timely adjustment of power plan;When the power supply equipment failure,Processing power equipment failure;Management of power supply system overhaul plan and maintenance operations.

3.8 Comprehensive maintenance scheduling needs

Comprehensive maintenance scheduling needs organize and direct the implementation of a comprehensive maintenance plan,manage the maintenance operations;Grasp the system of monitoring and analysis;According to the maintenance,proposed speed train proposa;Responsible for organizing the infrastructure,repair equipment;Master affect the safe operation of the train disaster situations.Centralized monitoring of communications,signal and working condition of information system equipment;Tissue repair communication signals.

4 Intelligent Railway Traffic Control System services and functions architecture design

Intelligent Railroad transportation of goods traffic scheduling system is a complex information system involves multi-disciplinary, multi-disciplinary fields.Its architecture is a service to provide services functional architecture,it answers the system can provide what services, and how to provide services.Using a reasonable model to describe the system requirements, structure, data, and linkages,make complex information easy to understand.Facilitate the entire intelligent traffic scheduling system forming a comprehensive understanding.

Through a comprehensive analysis of the needs of freight intelligent dispatching system,should have the corresponding functions.The purpose of this system is that services framework to integrate a variety of business needs,formation of various subsystems in order to meet the demand of users.Collate the results of needs analysis,merging those requirements and the nature of similar.Obtain services framework of the system.

And then,build a whole dispatching by planning and scheduling subsystem,locomotive scheduling subsystem,vehicle scheduling subsystem,freight scheduling subsystem,dispatching subsystem,Construction scheduling subsystem,power scheduling subsystem and comprehensive maintenance scheduling subsystem.These subsystems were driving task dispatching the corresponding item,including the collection of appropriate information, the preparation of the plan, issued the order and the information release.The following figure shows the service architecture and functional architecture.

5. In conclusion

Firstly, through needs analysis，discusses the intelligent railway dispatching system overall technical program.Clearly intelligent railway dispatching system overall technical program role and gives specific research ideas and overall program implementation steps.Second, determine the contents of the system's service architecture based on demand analysis.And then design the railway traffic control system intelligent overall technical program.Analysis and summarized the various business platforms internal logic structure and function,making it an effective overall.Compared with existing scheduling system,mainly to solve several problems in the following areas:

1.Integration of current relative dispersion of traffic dispatching system,form a more unified dispatching system.

2.Increases the likelihood that figure by running lane,reduce operating by dispatch personnel.Thereby reducing the impact of individual factors on traffic scheduling scheme,improves security,ensure the timely implementation of transportation.

3.Strengthening the information level of dispatching system,We can change the situation of scheduling department manually transfer information.

Operation Effects of a Factory Rail Line on a Traffic Artery

Ping Han; Lijie Wang; and Xiaoqiong Jin

Traffic & Transportation School, Dalian Jiaotong University, No. 794 Huanghe Rd., Dalian, Shahekou 116028. E-mail: jtgc@djtu.edu.cn

Abstract: With the enlargement and the development of urban areas, the road intersecting with rail line of the factories has become the artery in the city. As the result, the operation of factory rail line has a great impact on the road traffic. In this paper, based on the field data of the railway crossing through Yellow River Road, Fiveone Road and Southwest Road in Dalian, the factories railway line's influence on road traffic under different operation conditions was analyzed; the relation model between operating parameters and traffic efficiency was established and discussed.

Keywords: Traffic influence; Factories railway line queue length; Blocking time.

1 Introduction

The safety and economic loss due to vehicle delays were considered on the evaluation of at-grade rail-road intersection (Victoria Gitelman, 2006). The parameters, such as capacity, volume, velocity and delay, have been used to research the effects of bus stop and on-street parking on the traffic flow (Ge Hongwei, 2006; Guo Hongwei, 2011). The traffic jam at the intersection on traffic artery caused by the factory rail line is becoming more serious with the increasing volume and should be noticed now. Based on the field data on Yellow River Road, Fiveone Road and Southwest Road in Dalian, the paper analyzes the characteristic of traffic flow and operation of crossing section between artery and railway. The blocking time and queue length are the parameters to measure the operation of such crossing sections. According to the relation among the operational parameters and influence factors, the influence of the rail line on the traffic artery is discussed.

2 Influence factors of railway on the traffic flow

2.1Operational Parameters of traffic flow

The crossing section between the railway and road is like a signalized intersection. When the train is passing, the traffic flow stops just as red light on. The difference is that train's passing time is longer than the red light time in general, so the time of car passing, which includes the more queue waiting time and the more dissipation time, becomes longer. So the paper chooses the queue length and the blocking time including queue time and dissipation time as the operational parameters.

2.2Influence factors of railway on the traffic flow

When the train is passing, the traffic flow stops and queues. The longer the train runs, the more vehicles queues and the longer queue length becomes. The more traffic volumes queue, the longer time the traffic flow dissipates. So the passing time of train is the main factor that influences traffic flow. The passing time depends on the train length and width of road.

The dissipation time not only depends on the road volume, but also depends on the vehicle's speed through the rail. The fewer volume pass the crossing section, the less dissipation time is needed; the higher speed the vehicle has, the more capacity could result, and then less dissipation time is needed. So both the road volume and vehicle's speed are the influence factors.

3 Data Analysis

3.1Field data

The Yellow River Road, Fiveone Road and Southwest Road in Dalian become the traffic artery, the traffic jam is serious. The long queue can be caused when the train is passing. Sometimes the queue even extends to the next intersection. Field data was collected on these three roads by using video and manual method. The volume, speed, passing time of train, road width, queue length and blocking time are all observed.

3.2 Volume on these three Roads

The railway crossing the Yellow River Road and Southwest Road is used to convey the coal to the power plant, so the length of train consisting of 10 or 20 rolling stocks is long. The railway crossing the Fiveone road, also crossing the signalized intersection between Fiveone Road and Nansha Street is used to convey the oil to an oil deport, the train consists of 10 rolling stocks.

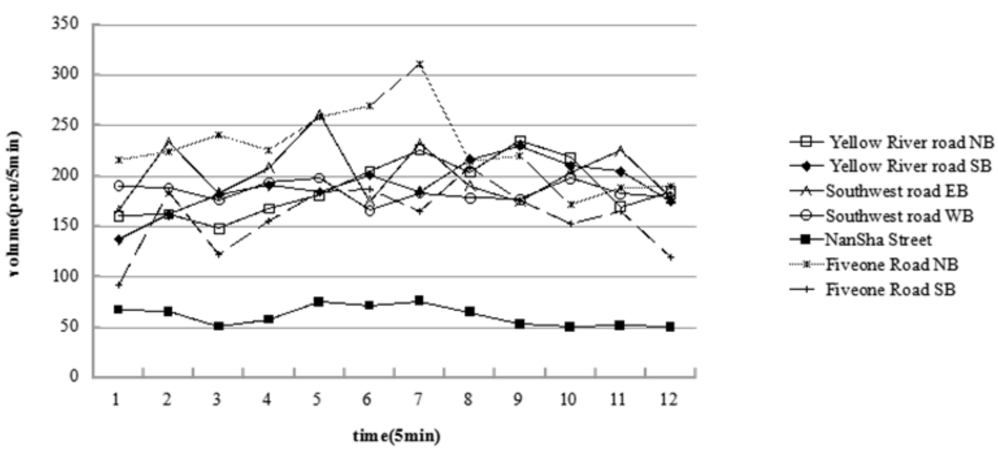

Figure 1.Volume on crossing section

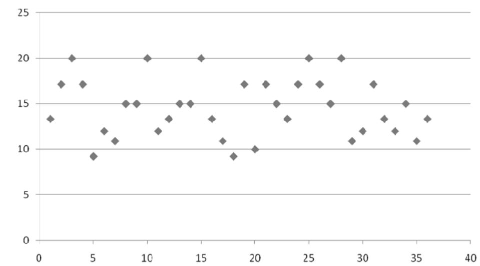
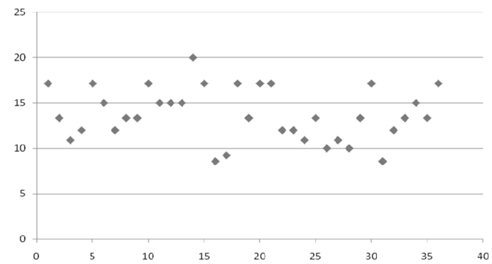
The volume accumulates while the train is passing, and decreases when the train passed (Figure1) in general. The volume variety at signalized intersection is different from the road.

3.3 Speed at the crossing section

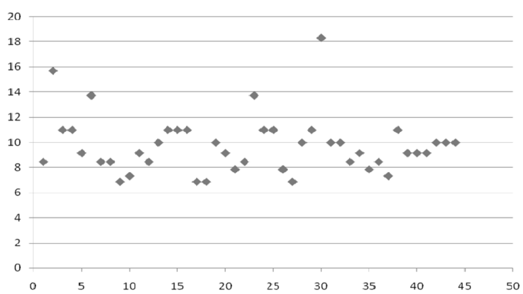
The speed through the crossing section is observed (Figure 2). The speed at the road is higher than that at the intersection. The speeds of Southwest Road are different because of the road slope. The speeds of Fiveone Road are different because of the road alignment.



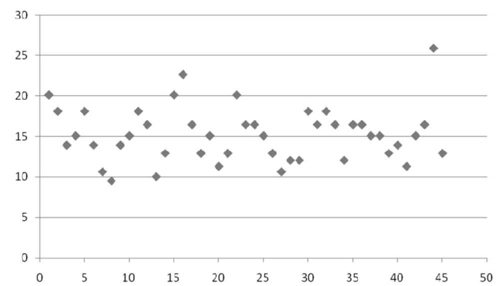
a:Yellow River Road NB



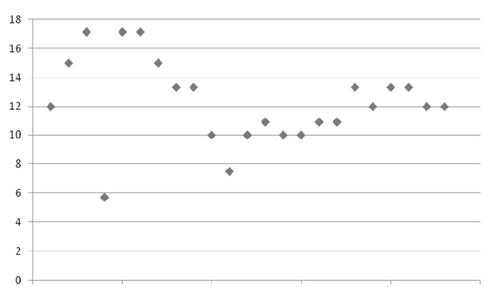
b:**Yellow River Road SB**



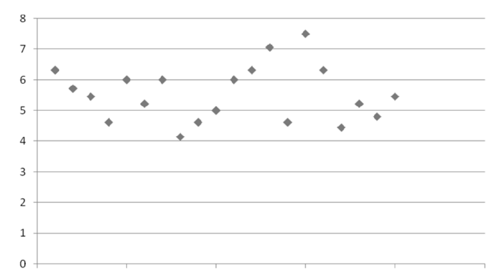
c:Southwest Road WB



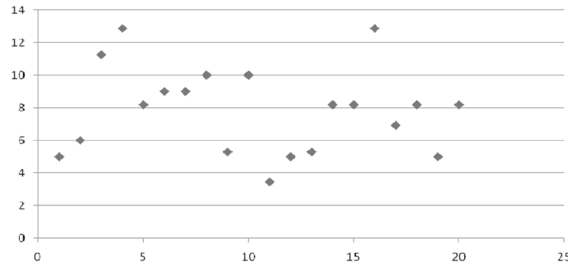
d:**Southwest Road EB**



e:Fiveone Road SB



f:**Fiveone Road NB**



g:Nansha Street

Figure 2. the Scatter of speed through the rail line

3.4 Time on the crossing section

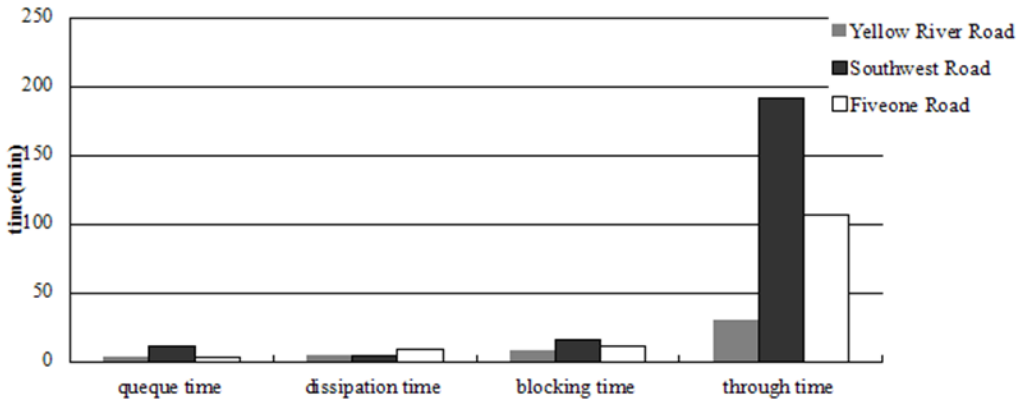


Figure 3. Time of the queue , dissipation ,blocking and passing time of train

The blocking time of traffic flow varies disproportionately with the passing time of train. The more passing time, the more blocking time. The dissipation time at the signalized intersection is more than that on the road. (Figure 3).

3.5 Queue length on the crossing section

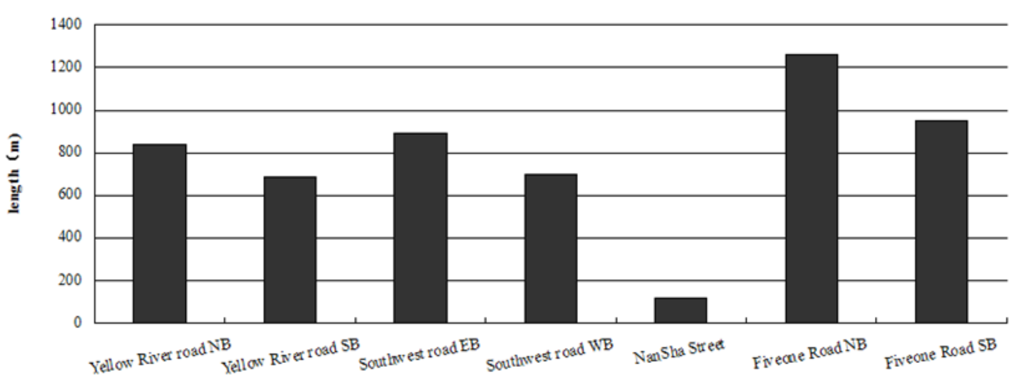

Figure 4. Queue length on the road when train is passing

The queue length is more than 500m with an exception on Nansha Street, which is a branch. The max queue length is 1260m, extending to the next intersection on the traffic artery (Figure 4).

4 Discussions of Results

4.1 Relationship between the queue length and influence factors

The queue length depends mainly on the volume, the passing time. The passing time depends partly on the road width and train length. Table 1 shows the queue length and influence factors on the different section. We found the relationship:

$$Y=0.4101X_1+111.3731X_2+5.6473X_3-117.6710X_4-277.6459 \quad (1)$$

While Y ----queue length (m)

X_1----volume on the road (pcu/h)

X_2----road width (m)

X_3----passing time of train(s)

X_4----train length (veh)

Table 1. The queue length and influence factors (one hour data)

Section	Queue length(m)	Volume (pcu/h)	Road width(m)	passing time of train(s)	Train length(veh)
Southwest EB	894	2432	12.5	192	20
Southwest WB	701	2211	12.5	192	20
Yellow River NB	680	2278	10	30	10
Yellow River SB	840	2263	10	30	10
Nansha Street	120	736	6	107	10
Fiveone NB	1260	2731	9	107	10
Fiveone SB	950	1915	9	107	10

4.2 Relationship between the blocking time and influence factors

The blocking time is the sum of queue time and dissipation time. The queue time depends on the passing time, while the dissipation time depends on the speed passing the section and queue volume. Table 2 shows the blocking time and influence factors on the different section. We found the relationship:

$$Z=0.0079Y+0.2403X_5+0.0469X_3-4.1227 \quad (2)$$

While Z ----blocking time (m)

X_5----speed (m/s)

Table 2. The blocking time and influence factors (one hour data)

Section	Blocking time(min)	Queue length(m)	Speed (m/s)	passing time of train(s)
Southwest EB	14	894	14.55	192
Southwest WB	16	701	9.32	192
Yellow River NB	7.33	680	13.1	30
Yellow River SB	7.83	840	13.9	30
Nansha Street	2	120	7	107
Fiveone NB	12	1260	5.4	107
Fiveone SB	9	950	11.5	107

5 Conclusions

From the table1 and formula 1, no more factors are more significant than others. From the table2 and formula 2, the vehicle's speed passing the railway line is more significant than other factors, and is main influence factor.

Here we may draw the following conclusions:

(1) While the train is passing the crossing section on traffic artery, the operation would be affected, and the phenomenon such as the queue and blocking emerges.

(2) It is also observed that a more passing time could cause the blocking time to increase, but the high vehicle's speed would reduce the impact.

(3) The queue length is the complex combination of all factors. The more passing time could cause the longer queue on the big volume road.

6 Recommendations for Future Research

Obviously, factory railway influences the traffic flow of artery. The influence factors and degree should be known. The more important thing is to know how to reduce the influence. The reasonable threshold of various parameters and factors should be researched. It can provide a reference to operation plan of factories' railway line and organization of traffic flow in order to reduce the influence.

Abstract: According to the incomplete and uncertain factors contained in the real-time information of traffic incidents, the automatic optimization model of incident response plan was developed based on loop learning Bayesian Network (BN) to support for the intelligent decision-making of network traffic emergency management. The first layer (structure learning) adopted the combination of expert knowledge and the K2 algorithm data training method, the second layer (parameter learning) adopted maximum likelihood estimate of the network parameter optimization methods. Firstly, item data were extracted to transform 19 discrete variables with different factors levels. Secondly, consulting some experts in the field of freeway incident management was applied to representing all the key factors that affect the successful operation of incident. Thirdly, this initial model was built with the method of GTT-K2 (Greedy Thick Thinning). Finally, BNs was optimized and modified according to expert knowledge. The core of the proposed model is a loop learning Bayesian network that quantifies the causal dependencies between incident information and response decisions. The model was validated using incidents data to indicate that the proposed algorithm is reliable and accurate.
Keywords: Traffic incidents; Emergency response; Decision-making optimization; Bayesian network.

1 Introduction

Bayesian network is a graphical model which represents the joint probability distribution of a collection of variables by using graph theory, proposed in 1986 by Pearl according to the probability relationship between the variables. It provides a way to represent causal information naturally so that the potential relationships between the data can be identified. In this network, nodes represent variables while directed edges representing dependencies of variables. The characteristics of Bayesian network are as follows: (1) Bayesian theory gives the trust function calculation method in mathematics which contributes to its solid mathematical foundation. Meanwhile, Bayesian theory characterizes the consistency between trust and evidence and the incremental learning characteristic that trust varies with the evidence; (2) In the process of data mining, Bayesian network can deal with incomplete and noisy data set, and describe the correlation of data through probability measure weights, so that the problem of data's inconsistency and even independent have been solved. (3) Graphical method is used to describe the relationship between data, which is semantic clear and easy to understand, so it's helpful for using the causal relationship between data to conduct predictive analysis.

1.1 The basic point of Bayesian methods

The characteristic of Bayesian analysis method is using probability to represent all forms of uncertainties. Learning and other forms of reasoning are all realized by probability rules. The results of Bayesian learning is expressed as a probability distribution of random variable, it can be interpreted as the confidence in the different possibilities. Bayesian School started in two works: Bayes' theorem and Bayesian hypothesis.

Suppose that the joint distribution density of the random variable x,θ is $p(x,\theta)$, and the marginal densities of x,θ are $p(x), p(\theta)$ .Let x be the observation vector, and θ is the unknown parameter vector, so the unknown parameter vector can be estimated through observation vector. The Bayes' theorem is:

$$p(\theta \mid x) = \frac{\pi(\theta) \times p(x \mid \theta)}{p(x)} = \frac{\pi(\theta) \times p(x \mid \theta)}{\int \pi(\theta) \times p(x \mid \theta) d\theta}$$

$\pi(\theta)$ is the prior distribution of θ.

1.2 The Bayesian network of emergency response optimization

Suppose that a joint probability distribution is $P(X_1, X_2, \cdots, X_n)$ and a sort of variables is d . X_1 starts as the root node. And the priori probability distribution of X_1 is $P(X_1)$. X_2 represents a node. If X_2 is related to X_1, then we establish a link from X_1 to X_2 and make $P(X_2 \mid X_1)$ representing the coupling strength. If X_2 has nothing to do with X_1, then the priori probability distribution of X_2 is $P(X_2)$. Then we draw a direction line linking to X_i from it's parent node set $\prod_{X_i}$ in the first stage, ($\prod_{X_i} \subseteq \{X_1, X_2, \cdots, X_{i-1}\}$) and being conditional probability represented by $P(X_i \mid \prod_{X_i})$ quantitatively. As a result, we can obtain a directed acyclic graph which can be used to represent many independent relations embodied in $P(X_1, X_2, \cdots, X_n)$, and this graph is called Bayesian networks. In turn, $P(X_i \mid \prod_{X_i})$ contains all the information necessary to reconstruct the original distribution function. There is a following relationship in sort d .

$$P(X_1, X_2, \cdots, X_n) = P(X_n \mid X_{n-1}, X_{n-2}, \cdots, X_1) \cdot P(X_{n-1} \mid X_{n-2}, \cdots, X_1) \cdots P(X_3 \mid X_1, X_2) \cdot P(X_2 \mid X_1) P(X_1) = \prod_i P(X_i \mid \prod_{X_i})$$

2 Construction of loop learning Bayesian network

There are generally three ways of modeling Bayesian network: 1) modeling based on expert knowledge; 2) learning from the data; 3) creating from knowledge base. The network structure will inevitably involve subjective color if it simply relies on expert knowledge to build. The knowledge of an expert is difficult to fully reflect the objective facts even the expert has enough experience. Historical data contains a wealth of information and experience in hiding. Although you can dig deep level of information simply by learning from data, the redundant information and no logical related information cannot be avoided. Therefore, this article integrated these methods in the actual process of modeling, taking experts knowledge as the guidance while database and knowledge base as the auxiliary, developing advantages and avoiding disadvantages, so as to ensure the efficiency and accuracy of the modeling.

2.1 Bayesian network structure learning based on dependent test K2

The K2 algorithm is to choose the problem by using the greedy search processing model. Firstly, we define a scoring function which can evaluate a network structure, and then start with a network, according to the predetermined number of maximum father node and the order of nodes, select node with the highest score as a parent node of the node. This algorithm use a posteriori probability as the scoring function:

$$p(D \mid B_s) = \prod_{i=1}^{n} score(i, pa_i)$$

Among them, $score(i, pa_i) = \prod_{j=1}^{q_i} [\frac{\Gamma(\partial_{ij})}{\Gamma(\partial_{ij} + N_{ij})} \prod_{k=1}^{r_i} \frac{\Gamma(\partial_{ijk} + N_{ijk})}{\Gamma(\partial_{ijk})}]$

2.2 Parameter learning based on maximum likelihood estimation

In the maximum likelihood estimation method, when giving the value of father node set, we calculate the frequencies of occurrence of different nodes' values and put the frequencies as the conditional probability parameters of that node. The basic principle of maximum likelihood estimation is trying to find the parameter which makes the likelihood function maximum.

When we judge whether it is suitable to put θ^* as the estimation of θ, we should consider its' fitting degree with data. The fitting degree between some possible value of parameter θ and data D can be measured by the conditional probability $P(D \mid \theta = \theta_0)$. And the bigger the probability is, the higher the fitting degree between θ_0 and data D is. The conditional probability $P(D \mid \theta)$ of data D is called the likelihood of θ, denoted as: $L(\theta \mid D) = P(D \mid \theta)$.

If we fix D and let θ change in its definition domain, then $L(\theta \mid D)$ is a function of θ, calling the likelihood function of θ. The maximum likelihood estimation of the parameters θ is to make $L(\theta \mid D)$ achieve the largest value θ^*, which means if $l(\theta \mid D) = \log L(\theta \mid D)$ uses the logarithm of likelihood function $L(\theta \mid D)$ then the likelihood function $l(\theta \mid D) = \log L(\theta \mid D)$ can be obtained. Obviously, the maximum value of $l(\theta \mid D)$ is the maximum point of $L(\theta \mid D)$.

For any fixed *i* and *j*, because $\sum_{k=1}^{r_i} \theta_{ijk} = 1$, when θ_{ijk} takes the value as follows, then

$$\theta^*_{ijk} = \begin{cases} \dfrac{m_{ijk}}{\sum_{k=1}^{r_i} m_{ijk}}, \sum_{k=1}^{r_i} m_{ijk} > 0) \\ \dfrac{1}{r_i} \end{cases}$$

If the value of expression $\sum_{k=1}^{r_i} m_{ijk} \log\theta_{ijk}$ reaches the maximum, $l(\theta \mid D)$ reaches the maximum. Therefore, θ^*_{ijk} which the above formula gives is the maximum likelihood estimation of θ_{ijk}.

3 Case Studies

3.1 Bayesian network structure learning

We determine the Bayesian network structure model of traffic events response decision-making by using the actual data sample learning and comprehensive structure learning method combined with the expert experience. Firstly we express the historical event recording information digitally and extract 19 main variables and dispose them levelly (Table 1). Then, according to the correlation analysis between different variables, several experts find out the variable combination of which the influencing factors are more obvious and the correlation are stronger, and then screen the main variables and construct the basic structure relation. The related variable selection results of structure background based on expert knowledge. Thirdly, the initial Bayesian network structure was constructed based on the GTT-K2 method. Finally, we optimize and correct Bayesian network structure according to the expert knowledge. We can find 8 new correlation edges if we compare the background structure and the training structure. Among them, the correlation edges of ambulances and trailer and the number of people who are stuck in the car and tire repair vehicle don't have clear logical relationship according to the expert knowledge, so we do not consider them (Table 2) . Therefore, according to these four steps, the definitive training result of Bayesian structure based on expert knowledge is as shown in Figure 1.

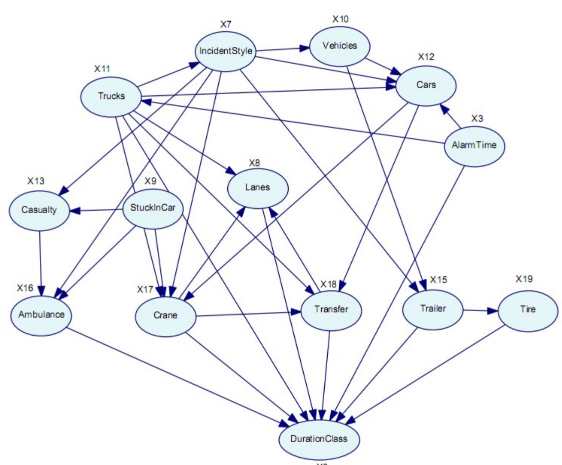

Figure 1.Training results of Bayesian structure based on expert knowledge

Table 2.Illustration of new variables' related factors based on K2 structure training

No	Related factors	Trade-off	Illustration of related factors
1	StuckInCar→Crane	√	The traffic accident with people stuck in the car usually caused more serious damage, so a crane is needed to clear up obstacles.
2	IncidentStyle→Crane	√	More serious accident need a crane to clean up the scene
3	Trucks→IncidentStyle	√	Traffic incidents involving trucks are usually more serious traffic accident
4	Trucks→Vehicles	√	Trucks are also the part of the vehicles involved in the incident
5	IncidentStyle→Trailer	√	Traffic accidents generally need a trailer for clearing the obstacles
6	Ambulance→Trailer	×	There is no clearly logical relationship, so will not be considered
7	StuckInCar→Tire	×	There is no clearly logical relationship, so will not be considered
8	Trailer→Tire	√	Trailer and tire repair vehicle usually joint operate

3.2 Bayesian network parameter learning

The network structure has been established, followed by the network parameter learning. The calculations of Bayesian network parameter mainly include batch learning and sequential learning. Batch learning is that usually at the beginning of the establishment of the network structure, we use the sample data to get the parameter estimation at a time; sequential learning is that in a period of time after training the history data, we use the new accumulated data to estimate the parameters again so as to ensure integrating the experience information of historical data and use the real-time fresh information of the new conditions. Batch learning usually uses the parameters calculation method of the maximum likelihood estimation, and sequential learning usually uses the Bayesian estimation method of which the parameter update is carried out on the basis of existing knowledge. This paper uses the batch learning of maximum likelihood estimation as an example and carries out the Bayesian network parameter learning.

On the basis of the Bayesian network structure based on expert knowledge, for the node X_i, assuming that its parent nodes set π_i is the j th possible value, we need to calculate the probability that node X_i is the kth value. We take node X_8 (the number of lane occupied by incident) as an example and use the maximum likelihood estimation to calculate the node parameter of $\theta_{8jk} = P(X_8^k \mid \pi_8^j)$, as shown in Table 3.

Table 3.Node parameter calculation of Bayesian network

3.3 Bayesian network inference

Emergency response of freeway incident is a traffic management under abnormality. The previous rule reasoning, trigger condition reasoning and case-based reasoning is to reason in the condition of gaining explicit information and according to a prearranged rule or discriminant conditions, and which cannot meet the management requirements of real-time response to the incident. Along with the progress of events, information of incident tends to complete and accurate. And the reasoning process of Bayesian network can respond to the requirements of incomplete incident information and uncertain factors' changing and provide real-time emergency response intelligent decision support. The Bayesian network of traffic incident response decision obtained through loop learning is as shown in Figure 2.

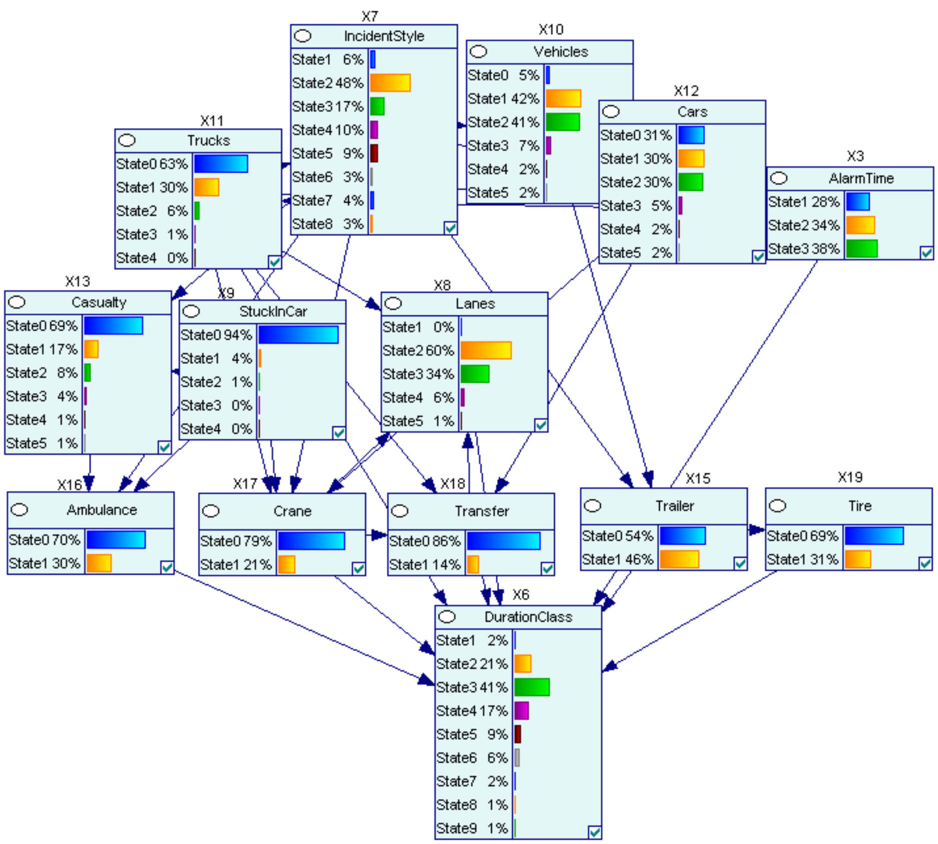

Figure 2.Loop learning Bayesian network of incident response plan

For traffic incident management, casualties caused by incident and expected duration are two very important aspects of incident management and index of reflecting the severity of the incident. Therefore, the prediction of the reasoning process from cause to effect of double learning Bayesian networks facing incident severity is as follows: firstly, we add the other parent node of the predicted nodes to the predicted nodes, keeping the conditions unchanged, and adds all states of new nodes. Then, we expand each item of sum formula by using the Bayesian rule, and will obtain the conditional probability $\theta_{ijk} = P(X_i^k \mid \pi_i^j)$ of predicted nodes.

Then we will illustrate a Bayesian network reasoning process of the incident's severity through a case analysis. The case description is: A rear-ends accident involving a car and a truck happened at night, causing 2 casualties and 2 lanes occupied. According to a series of processes of event detection, scene, disposal, we carry out a real-time analysis and reasoning as follows.

Discovery stage of the incident is: alarm time X3=3 night, incident style X7=1 rear-end collision, the number of vehicles involved in the incident X10=2, the number of trucks involved in the incident X11=1, the number of cars involved in the incident X12=1. At this point, X3, X7, X10, X11, X12 is the evidence variables, and other variables is predictor variables. We can reason that the probability of the number of casualties due to the incident being 2 is 16.2% and the probability of the number of people stuck in the car being 0 is 94.5% and probability of occupying two lanes is 50.6% and the probability of the expected duration of this stage being 60~90 minutes is 44.2% according to Bayesian network.

To-the-scene stage of the incident is: from receiving the alarm to arriving at the scene, under the conditions of the original evidence variables (we give tacit consent to that the original evidence variables are accurate and can amend the original evidence variables according to the site condition), we obtain the new real-time information, that is, casualties caused by the incident X13=2, the number of the people stuck in car X9=0, the number of lanes occupied by incident X8=2. At this point, X3, X7~X13 are evidence variables and other variables are predictor variables. We can reason that the probability of needing an ambulance is 91.4% and the probability of needing a crane is 27.4% and the probability of needing transfer is 25.6% and the probability of needing a trailer is 100% and the probability of needing a tire repair vehicle is 36.5% and the probability of the expected duration of this stage being 120~150 minutes is 60.9% according to Bayesian network.

Clean-up stage of the incident is: under the condition of having known the number of casualties, vehicle involved and the blocking lanes, we need the ambulance, crane, transfer and trailer for rescue and clearing. Therefore, we will get further real time information under the conditions of keeping the original evidence variables. The value of X15~X18 is 1, which means the ambulance, crane, transfer and trailers are needed and the tire repair vehicle X19=0 is not needed. The probability of the expected duration of this stage being 150~180 minutes is 40%. And the duration of this incident is 162 minutes, just falling in the interval. The Bayesian network reasoning results of the total expected duration of this incident's three stages are as shown in Table 4.

Table 4.Bayesian network reasoning results

Expected duration	Discovery stage	To-the-scene stage	Clean-up stage
State1: (0,30]	0.005	0	0
State2: (30,60]	0.195	0.029	0
State3: (60,90]	0.442	0.073	0

Abstract: With the development of high-speed railway and the advancement of railway informatization, the inconformity of time has an impact on the railway operation management and security management. Following the principle of safety, advanced, practicability, reliability, easy maintenance and expansion, this paper designs the framework of railway time management system based on Beidou/GPS satellite navigation system, In-depth analysis of the internal configuration structure of timing node in Ministry of Railways, rail bureau and train deeply, And designs the main technical solution to provide technical support for the time unification of railway departments.
Keywords: BDS; Railway; Timing; Time management.

1 Introduction

At present, there are multiple information systems in China's railway and time system of each is individual, without unified management system. Systems are physical isolation, although a few system uses GPS to timing, there is still a larger error between layers. The inconformity of time brings a certain effect to the normal operation of railway, for example, which will lead to "fly line", "stay" in drawing the actual operation diagram, disorders of train number in statistics report of 18 O'clock, great difficulties in finding out the exact cause of fault when the accident occurs and so on.

In railway time management, some experts and scholars researched on the railway time synchronized net, the system of synchronous timing with satellite and time correcting with network, distributed timing synchronous clock and so on. Tang Jun and Liang Feng (2003) proposed using GPS system as a collecting source of railway time. Liu wei, and Dong Decun (2005) designed and developed a kind of letters type of distributed timing synchronous clock system with free adjustment based on GPS technology. Tang Huaidun and Zhou Shengyang (2007) introduces application of GPS satellite timing in railway time synchronized net. Gao Qing and Ma Xu (2006) studied the application of positioning with the information integration of "Beidou" satellite navigation system and railway transport system in the intelligent transportation construction of railway transportation. Fu Bin (2006) pointed out that the clock quantity traceability in the railway transportation system is related to the safety and accurate command and put forward the project of time unification in railway system by analyzing the principle of timing equipment and the present using situation of clock equipment in railway system. Liu Tianping (2007) introduced how to take the global positioning system (GPS) as a time reference to make sure the synchronization of time information in the driving clock among railway TMIS, railways DMIS, railways HMIS, voice recording computer network system and dispatch and command system. Wang Li and Wang Qian (2008) put forward to establish railway network time synchronized net on basis of Network Time Protocol （NTP） in a comprehensive dispatch system. Qu Bo (2010) reseached a kind of railway time synchronized net which consist of satellite receiving equipment, master clock equipment, time display devices, network management of equipment, and transmission channel. Dong Xueyuan and Gao Shibin (2006) proposed a clock synchronization solution based on the Precision Time Protocol (IEEE1588) by analyzing the demand of fault location and clock synchronization using electric traction line.

To sum up, among the current research achievements, the main time source in the railway timing system is GPS, and very few literature study on the “Beidou” timing system. It’s very necessary to research on the “Beidou” timing application in railways considering the national strategic security. As a result, this paper designs the framework of railway time management system based on Beidou/GPS satellite navigation system according to the principle of safety, advanced, practicability, reliability, easy maintenance and expansion, In-depth analysis of the internal configuration structure of timing node in Ministry of Railways, rail bureau and train deeply, And designs the main technical solution.

2 Designation of system framework

Referencing the time management mode in existing system at home and abroad and considering safety and reliability factors, the railway time management system is composed of space-base and ground-base, namely, the space-time-base rely mainly on Beidou while take GPS as secondary reliance and the ground-time-base is made up of a high accuracy and stable frequency source. Among them, the ground time management system consists of ministerial timing node setting in the dispatching center of railways ministry, bureau timing node setting in the dispatching station of railways bureau or passenger dedicated line and station timing node setting in station or depotor segment. The train time management system is set up in the train. Each of the ground time management system is mainly composed of satellite receiving equipment, atomic clock, time servicer and transmission channel and each of the train time management system consists of satellite receiver, punctual device of crystal oscillator and time servicer, having the functions, such as, time input, time output, time regulation, time calibration monitoring and management functions and so on. As shown in figure 1.

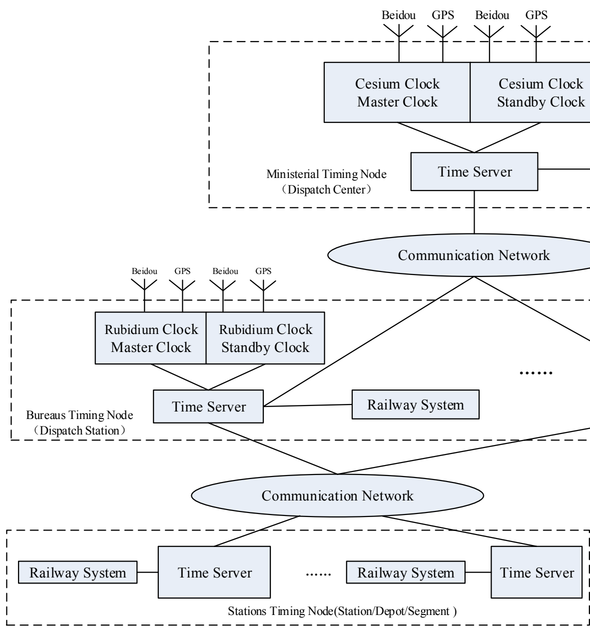

Figure 1. the Framework of Railway Time Management System

Timing center of railways ministry should set up Beidou/GPS satellite timing cesium atomic clocks with double redundancy (master/standby) and add external time server, when timing for systems such as TDCS/CTC, TMIS, freight transportation services, passenger transportation service and so on through interface RS422, the system can take use of the protocol NTP or PTP timing for the other system through network, and reserve extended interface. The time server of railway ministry should is connected with time server of each railway bureau through the transmission equipment such as network and so on. At ordinary times, the system timing for external by cesium atomic clocks in the standard clock timing device, and check the time for once an hour (later, adjust the frequency for time checking according to the actual need). If the difference between the cesium atomic clocks in the standard clock timing device and the clock of Beidou/GPS system is in excess of the prescribed deviation, the system will take Beidou/GPS clock as a standard clock, receive it, transmission it down, and correct the time for cesium atomic clocks in the standard clock timing device.

Timing center of railway bureau should set up Beidou/GPS satellite timing rubidium atomic clocks with double redundancy and add external time server, when timing for systems such as TDCS/CTC, TMIS, freight transportation services, passenger transportation service RBC、TSRS and so on through interface RS422, the system can take use of the protocol NTP timing for the other system through network, and reserve extended interface. The time server of railway bureau should is connected with time server of stations, such as traffic, maintenance, engineering, electricity, power supply and vehicle, through the professional transmission equipment, such as network. The time server of station timing for other system through interface RS422 or general protocol NTP.

Generally, the timing center of railway bureau timing for external by rubidium atomic clocks in the standard clock timing device, and check the time for once an hour (later, adjust the frequency for time checking according to the actual need). If the difference between the rubidium atomic clocks in the standard clock timing device and the clock of Beidou/GPS system is in excess of the prescribed deviation, the system will take Beidou/GPS clock as a standard clock, receive it, transmission it down, and correct the time for rubidium atomic clocks in the standard clock timing device. In addition, the timing center of railway bureau would compare the time with the timing center of railway ministry by rail private network, in order to verify if their own equipment and transmission system is normal, when the difference is more than a certain deviation or there is a breakdown, it will alarm and checking the time automatically or apply for manual intervention.

3 Technological Scheme Design

3.1 Way of guiding the time signal

The time service unit of the business systems of railway transportation should be able to get time signals from the ministerial or bureau time synchronization equipments through a variety of time interfaces, and can provide time services to many business network management systems and network equipments, and will use time keeping function of its business systems, when it can not receive the time synchronization signal of the server.

The time display device can get time signals from the corresponding ministerial , bureau and station time synchronization equipment through a variety of time interfaces, and should be able to display time information under the time signal output driven by the server. We can configure one or more time allocation unit at each level to provide time services for business network at the corresponding level (each service network can set their own VPN or firewall). The principle of guiding time signal of the time display device is guiding to the nearest, which means that the time display device access to the nearest time synchronized server equipment at all levels.

To guide the time source, business systems of railway transportation adopt centralized and decentralized way.

The time signal link of the server equipment at the corresponding level to business system of railway transportation and time display device can transmit time signal over coaxial cable, shielded control cable, audio communication cables and fiber.

3.2 Time synchronization monitoring system

You need to build a timing monitoring system to examine the performance of the railway time synchronization system. The time synchronization monitoring system deploy a lock monitoring device TMU at the center of all levels, the device can be connected to different time signal and clock information on the site through a variety of interface board by modular design. TMU achieves major time precision monitoring functions by comparing timing reference signals of a variety of time signal and core clock, and reports the information to the monitoring center through data networks, and will also report the body clock device working status and other information. The monitoring center takes a unified analysis and post-processing for the monitoring information reported form corresponding time monitoring device through a dedicated monitoring platform software, and provides a good man-machine interface management in a variety of forms. Monitoring system comprising the composition of structural elements, as shown in Figure 2.

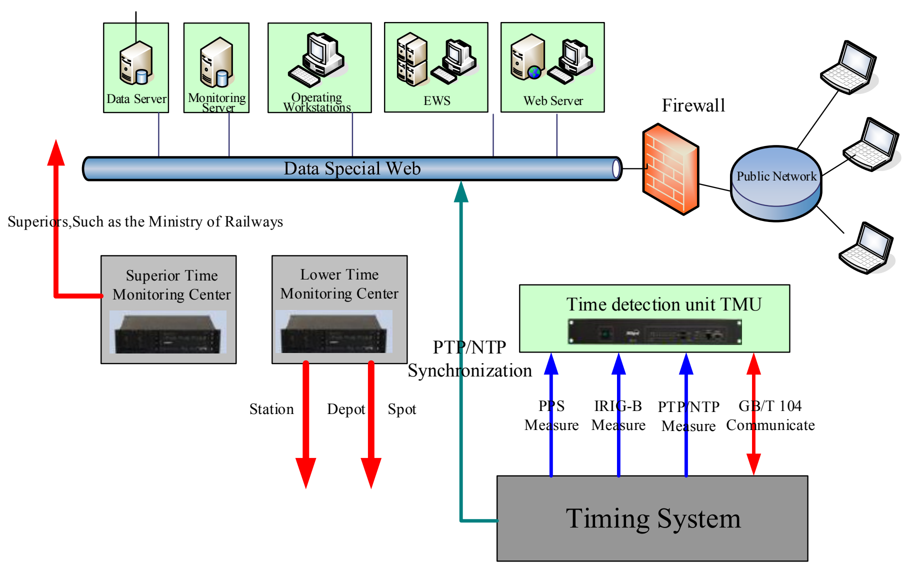

Figure 2. Diagram of Control Center of the Timing System

4 Conclusion

Compared with traditional methods, the railway time management system proposed by this paper has the following characteristics: First, the reliability, when the signal of Beidou/GPS is missing, the system takes the cesium / rubidium atomic clock as the standard time source of time servers, which improves the reliability of the time management system; Second, the security, the system adopts multilevel tree-model, is suitable for hierarchical distributed wide area network system, each layer connects through professional transmission equipment and plays a role of redundancy backup, and can automatically exclude information from wrong server to guarantee the security and practicability of the system; the third is easy to maintain and expandability, multiple subsystems in the railway system is physically isolated, it adopts the satellite timing, whose change is relatively small to the original system, besides, the system takes modular design and provides extended interface, which guarantees that the system is easy to maintain and extend; Fourth, transparency of management, we can observe the operation conditions of the time system , which can increase the stability and reliability of the system .

Abstract: With rapid development of the high-speed railway and mobile communication technology, the high-speed railway passengers have an increasing demand for mobile information service. The mobile communication network is available in the high-speed railway today, where the mobile network is very unstable especially in the tunnel. With slow downloading speed, the passengers can not enjoy good communication and network service. Therefore, how to provide stable and high-efficient communication and network service in high-speed railway has become an urgent issue to be dealt with today. This paper has made a series research of the network access project in high-speed railway carriage. Through a great number of experiments on chengdu-chongqing motor car, the network access project with the main communication device and the extended communication device (referred to as the main device and the extended device hereinafter) in the double-carriage proposed in this paper can enable Received Signal Strength Indication (RSSI) to achieve a better result and cost saving.

Keywords: High-speed railway carriage; Network access; RSSI; Communication device.

1 Introduction

After our railway was sped up for six times and the high-speed railway entered into the era of rapid development , the railway hardware facilities are significantly improved, especially leading in the high-speed railway worldwide, setting a great example for global high-speed development. But the corresponding and affiliated passenger service system has lagged behind in construction, with one of its main parts demonstrated in the mobile information service in the high-speed railway *(Lu Jiajia,2008)*. As the survey published the 34th time by Chinese Network Information Center (CNNIC) showed, until today, the number of net citizen in China has reached 632 million, the mobile net citizens of which have reached 527 million in number, increasing by 26.99 million compared with that by the end of 2013. The scale of mobile net citizens has surpassed that of traditional PC net citizens for the first time(*Ren Yan, 2006*). The passengers (especially the passengers on the medium-and-long-distance railway) have an urgent demand for high-speed mobile communication and network service in the railway, such as surfing internet, watching movies, playing games, etc. Although China Mobile, China Unicom and China Telecom have covered the full range of communication area with 3G, yet the mobile network is still unstable in the high-speed railway and tunnel with slow downloading speed, resulting in unsatisfactory communication and network service*(Wang Zhilin,2010)* for the passengers.

In order to solve the mobile information service in the high-speed railway, we need to first solve how to get access to the high-speed network*(Qi Hongfeng,2012)* in the railway carriage. Therefore, the paper will make a research of the network access in the railway carriage by studying the common carriage network access methods to test various parameters and indicators*(Qin Huafeng,2012)* of WIFI for determining the network access project in the high-speed railway carriage*(Zhang Hesheng, 2006)*.

2 Research of network access solution in high-speed railway carriage

At present, many companies have put forward the mobile network access projects for the high-speed railway. But the main communication device deployed in single carriage is commonly used by deploying network device in single carriage of neighboring carriages to provide mobile network access service. This method can maximize the effect of the main device in communicating ability and connecting scale(Jiang Xinhua, 2007). But through testing and analysis, the method may have blind sport in network coverage, resulting in ineffective mobile network access or bad network signal in some areas of the neighboring carriages. In order to solve this problem, this paper has proposed a network access method by deploying the main device and the extended device in neighboring carriages at the same time, aiming to eliminate the network blind spot of neighboring carriages and realize an effective mobile network access by means of networking bridge. We have also made study and testing of the two deployment methods with the main testing parameters including Received Signal Strength Indication, RSSI of mobile information network. The bigger the value of RSSI, the better the wireless mobile network signal and the faster of the mobile device network used by the passenger; vice versa.

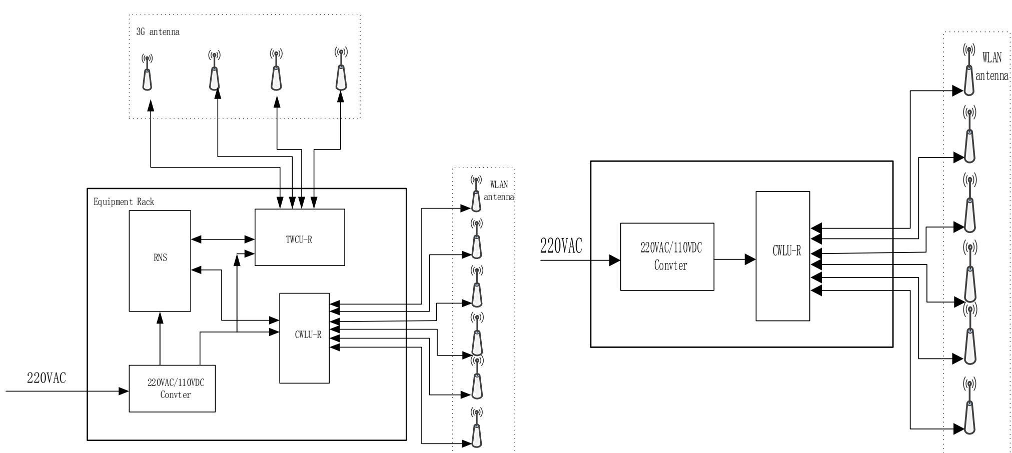
3 Environment deployment of network access solution in high-speed railway

The tested object is CRH1 motor car with 16 carriages located at one end of the railway, adjacent to the driver's cab. In the single-carriage testing mode, the main communicating device of the system is located in the middle of carriage 16 (with the location shooting picture seen in Fig.1); in the double-carriage testing mode, the main communicating device of the system is located in the middle of carriage 16, while the extended communicating network device of the system is located in the middle of carriage 15. The main device and the extended device are connected by means of 5.8G wireless signal. The device with RSSI strength adopts Trinity system device for testing.

a location map of main device b location map of main device

Fig 1. Location map of testing device

The three main devices of the system are located in the built-in erecting fixture in 6U height. The connecting relation between the three devices and the outside include power input and antenna connection. The electricity source is 220 VAC, which is supplied to the device after being transferred by AC/DC in the erecting fixture. The antennas include WLAN antenna and 3G antenna. WLAN antenna is located in the erecting fixture. The device is located in the part of the first carriage which is adjacent to the driver's cab, the electricity source socket with 220VAC is located above the rear part of the last seat. The WLAN extended coverage device of the system is located in the sanitary appliance cupboard between carriage one and carriage two. But we need to open the side gate of the sanitary appliance to facilitate putting the antenna outside the sanitary appliance cupboard.

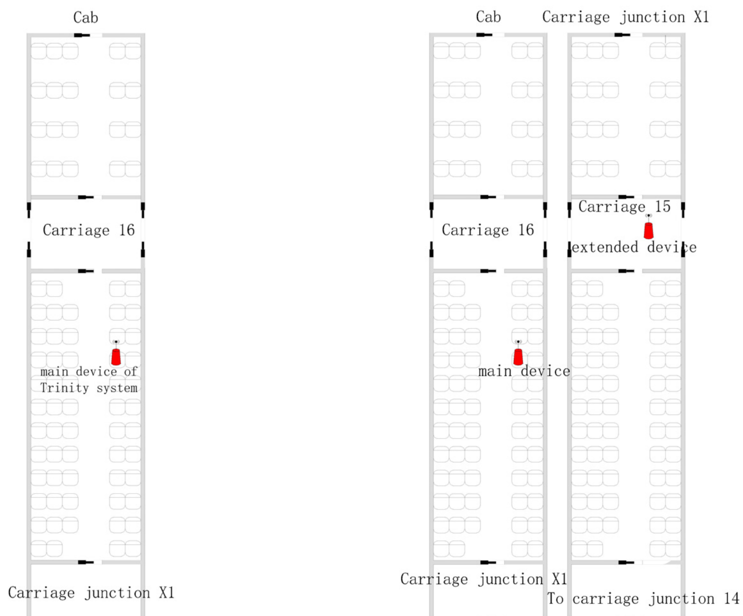


a Sketch map of main device installation b Sketch map of extended device installation

Figure 2. Sketch map of device installation

4 Testing of network access project in high-speed railway

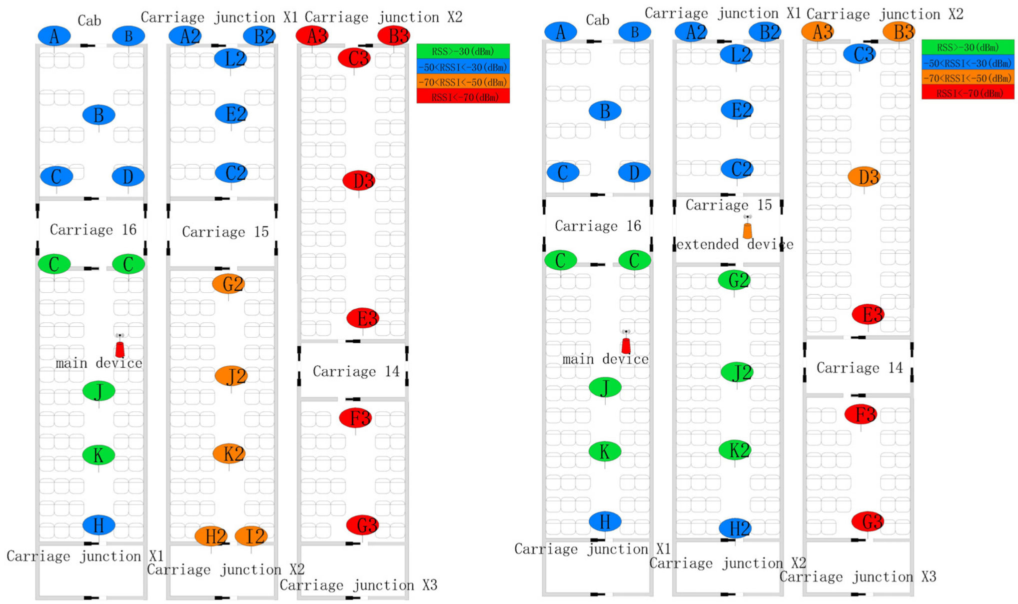
For the network access testing in the high-speed railway, this paper mainly makes the comparative testing between the network device deployed in single-carriage and the main device as well as the extended device deployed in double-carriage. The sketch maps of the two network access projects are shown in Fig. 3.



a Model map of single-carrigae system layout b Modle map of double-carriage system layout

Fig 3. Model map of network access project layout

For the two network access projects, their values of RSSI should be tested. The four kinds of colors stand for four different values of RSSI (the upper right of the following Figure). In the double-carriage testing mode, the main device of the system is located in the middle of carriage 16, while the extended device of the system is located in the middle of carriage 15. The main device and the extended device should be connected through 5.8G wireless signal. The results of the testing are as followed in Fig.4:



a RSSI sketch of single-carriage b RSSI sketch of double-carriage

Fig 4. Carriage location- signal strength coverage map

In the upper left of the coverage map, the green means that RSSI ＞-30(dBm), the blue means that -50(dBm)＜RSSI ＜-30(dBm), the orange means -70(dBm)＜RSSI ＜-50(dBm), the red means that RSSI ＜-70(dBm). The bigger the value of RSSI is, the better the wireless signal is and the faster of the mobile device network used by the passengers; vice versa. The relation of the carriage testing time and RSSI is shown in Fig.5 in the following:

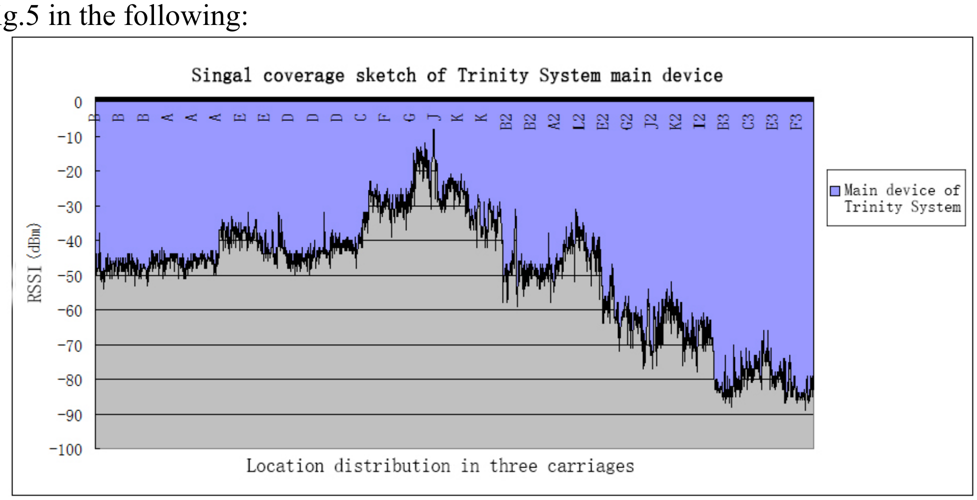


Fig 5. Testing time in carriage-RSSI

The detailed RSSI statistics corresponding to the figure of carriage location-RSSI map is as followed in Table 1:

Tab 1. WLAN strength coverage value statistics in single-carrigage and double-carriage

Carriage	Testing point	single-carriage RSSI [dBm]	double-carriage RSSI [dBm]
Carriage 16	B	-47.5	-47.5
	A	-46.0	-46.0
	E	-39.3	-39.3
	D	-43.4	-43.4
	C	-41.3	-41.3
	F	-29.8	-29.8
	G	-22.6	-22.6
	J (installation point of device)	-18.4	-18.4
	K	-28.9	-28.9
	H	-34.9	-34.9
Carriage 15	B2	-48.9	-48.9
	A2	-48.1	-48.1
	L2	-39.7	-39.7
	E2	-49.2	-49.2
	G2	-62.6	-19.5
	J2	-66.9	-24.3
	K2	-59.7	-27.7
	H2	-66.9	-37.6
Carriage 14	A3	-82.4	-60.2
	B3	-82.2	-46.7
	C3	-77.9	-62.6
	D3	-74.4	-65.7
	E3	-79.5	-73.4
	F3	-82.3	-72.5
	G3	-83.9	-70.9

From the coverage of the main device in the single-carriage, when the device is installed in the middle of the carriage, the maximum RSSI is -18.4dBm and the minimum RSSI is -47.5dBm in that carriage, matching perfectly with the requirements. When the main device is installed in the middle of the first carriage, the part adjacent to the first carriage in the second carriage such as the blue area is meeting the requirement, where the signal strength is between -39dBm and -49dBm. When the main device is installed in the middle of the first carriage, the part connecting the door of the second carriage with the third carriage such as the orange area is not meeting completely the requirements, where the signal strength is between -59dBm and -67dBm. In the double-carriage mode, the RSSI in the two carriages is between -18dBm and -49dBm, meeting the requirement.

With the testing results above, we can conclude: through a great number of testing results in the single-carriage mode and the double-carriage mode on chengdu-chongqing motor car, we can find out that the single-carriage mode uses one main device for coverage, but the mislocated layout of the main device results in unsatisfactory RSSI value in some areas of the carriage; while the double carriage modes deploy the main device and the extended device at the same time. In the testing, we find out that wherever the main device and the extended device are located, RSSI in two carriages can be more reliable compared with single carriage. With this method, we can provide an efficient and effective mobile network access for the passengers in any part of neighboring carriages, eliminating the blind spots of the carriage.

5 Conclusion

In order to provide better service for the high-speed railway passengers in terms of mobile information, this paper has made a research of network access in the railway carriage and its impact over the electromagnetic environment in the carriage. Through a great number of experimental tests on chengdu-chongqing motor car, it shows that the main device and the extended device network access projects proposed in this paper can enable RSSI to reach better results and cost saving. In addition, wireless signal in two carriages can be more reliable and stonger compared with single carriage wherever the devices are located.The researches above have laid a solid base for employing various mobile information services further in the high-speed railway.

New Challenges in Managing Staff Competency for a Driverless Urban Rail Transit System

Xiaofan Xu

School of Transportation & Logistics, Southwest Jiaotong University, Chengdu, China.
E-mail: cdzy13@126.com

Abstract: In order to fully realize the potential of Urban Rail Transit (URT) system in maintaining the viability of major cities, one of the key elements-- the competency of staff operating the URT system--must be managed effectively. As driverless URT systems have the ability to achieve higher efficiency while still maintaining the required safety standard, more driverless URT systems are being built and operated. When an URT becomes driverless, the operating concept of the URT will become significantly different from that of an URT with drivers as well. This has resulted in new challenges to the management of staff competency for a driverless URT system. This paper started off with discussions of the Competency Curve and then used the driverless Singapore North East Line (NEL) as a study case to examine the two main challenges faced when managing staff competency in a driverless URT context: the manual driving of a driverless train, and the driverless train control in the Operating Control Center (OCC). Strategies towards the handling of the above-mentioned new challenges were proposed based on the experiences gained on the ground.
Keywords: Urban rail transit; Driverless; Staff competency management.

1 Introduction

A driverless URT system can be defined as an URT with its trains being able to operate without a driver onboard. Driverless rail transit is not new, but there is a new trend that more and more driverless urban rail transit are being built or to be built in the near future, with the aim of reducing the operational costs and improving the frequency of service. Here are some examples.

(1) The Dubai Metro

As part of the driverless, fully automated metro network in the United Arab Emirates city of Dubai, the first section of the Red Line, covering 10 stations, was ceremonially inaugurated at 9:09:09 PM on September 9, 2009. With the line opening to the public at 6 AM on September 10, the Dubai Metro is the first urban train network in the Arabian Peninsula. The Green Line is under construction, and further lines are planned.

(2) The SkyTrain in Metro Vancouver

It is an urban rapid transit system in Metro Vancouver, British Columbia, Canada which uses fully automated trains running mostly on elevated tracks. The Expo Line was built in time for the Expo 86 World's Fair, the Millennium Line opened in 2002, and the Canada Line opened in 2009 in advance of the 2010 Winter Olympics.

(3) The San Pablo metro

June 16, 2010, a new driverless underground railway began operating in the network of San Pablo.

(4) The Singapore's Driverless Mass Rapid Transit (MRT)

The North East MRT Line (NEL) is the world's first fully-underground, automated and driverless, heavy rapid transit line and was opened on 20 June 2003 with 16 stations. The Circle Line (CCL) is also fully automated driverles metro line. Stage 3, a 5 kilometer five-station segment stretching from Bartley to Marymount, was the first section of the line opened on 28 May 2009. Stages 1 and 2 started operations on 17 April 2010.

(5) The Shanghai's Line 10

The trains on the Shanghai's Line 10 are designed to operate without drivers, but drivers are on board at the moment, since its official opening for restricted service on April 10, 2010.

2 Competency Curve

It has been understood that in general the following curve could well describe the stages that a person experiences when developing and maintaining his competency in a natural environment.

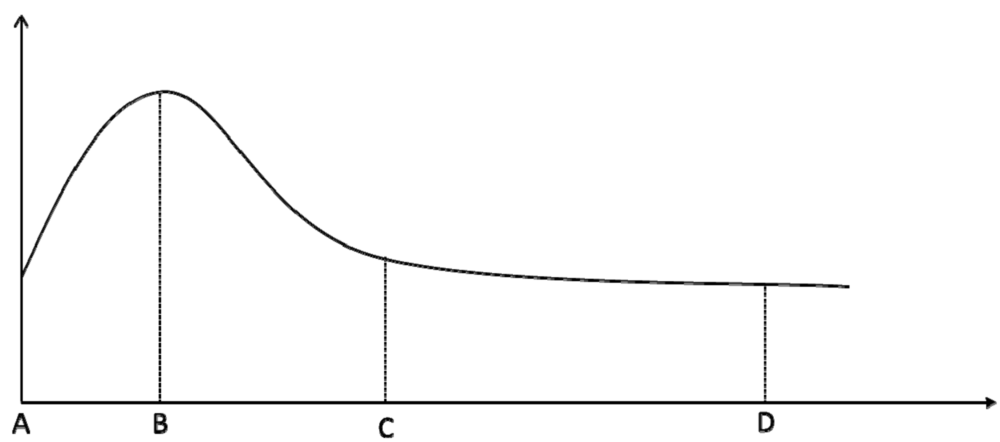

Figure 1. Person experiences stages

Stage (A-B): a person's competency quickly increases and reaches the required level through proper training.

Stage (B-C): his competency level drops when he starts to practice ONLY some skills that are normally required and no more training is provided.

Stage (C-D): his competency stabilizes at a level corresponding to the skills that he regularly practices.

It is obvious that the drop of competency level is a foot note to the old saying “if you do not use it, you will lose it.” And this drop creates a gap between the required Competence Level and his actual competence level. This implies that the staff is no longer competent in terms of some skills, good examples of which are handling rare equipment faults and other rare incidents like fire.

3 North East Line (NEL)

Trains in NEL are operated by computers on board and at wayside.

Based on the predefined Train Working Timetable, a central control computer Automatic Train Supervision (ATS) will trigger train Wake Up signal when the time comes. This signal will travel through various communication equipment including waveguide IAGO and eventually reach a designated sleeping train. A train in sleeping has one live device onboard to receive the train Wake Up signal and turn on the onboard computer and other train equipment.

After the train successfully completes its self-test, the train will be launched to mainline station for passenger service. This process and the subsequent movement/stopping along the mainline do not require any involvement of human driver under normal circumstance, although Traffic Controller (TC) in Operations Control Center (OCC) will monitor the whole process and take action when necessary. Train travel time between stations and dwell time at stations are also controlled by central computer.

Stand-by drivers are deployed inside trains as Customer Service Officers (CSO) with the main task of serving passengers in need such as wheelchair bound passengers. When necessary the stand-by driver is able to operate the train manually and/or handle certain equipment faults.

4 The New Challenges

Two major new challenges are faced when maintaining competency of operations staff of a driverless URT system. One of them relates to standby drivers.

As stand-by drivers seldom drive, their competency level and confidence level tend to drop, especially when manual train driving is concerned because: 1, usually a driverless train is not designed for manual driving, so driver’s comfort like driver’s seat is naturally not taken into account in design, as can be seen from the following picture. 2, no driving compartment is provisioned which means that a driver will have to drive in the presence of passengers close to him. This will inevitably affect the driver’s concentration which is essential to train driving task. 3, to stop a train accurately in manual requires skills and experiences that can only be obtained through practice.

Figure 2.Driving area of a driverless train

The other challenge involves traffic controllers. Unlike URT systems with train drivers readily available at driving console, TC of a driverless URT system will need longer time to find out what really went wrong on board the train and will in general need longer time to get a driver to the scene if a driver is needed.

5 The Strategy to take on the Challenges

The key is refresher training and the success requires that the refresher training is an integrated one which include actual driving, computer based simulation, table top exercise and drills at night when passengers service has stopped and the system is available for training.

Train drivers. Although refresher training through actual driving in Main line is the best and must not be skipped, this type of refresher training may cause train service delay due to the difficulties encountered in stopping a train accurately at stations, leading to the possible failure to achieve service performance requirement. Driving in depot without passengers can be used as compensation. Train driving simulator is good but could be too costly to be justified.

For refresher of train defect handling, Computer Based Simulation (CBS) can be very effective if defect handling exercises using actual train is provided in conjunction.

Traffic Controllers. As the key function of a Traffic Controller is coordination, scenario based table top exercise and drills using the real system at night involving various parties like driver and station staff have been proven to be very effective. Not only participants could regain their familiarity with the operating features of the system, the relevant rules and procedures, gaps among rules and procedures can be identified and filled up as a byproduct. Computer Based Simulation can be deployed for Traffic Controller's refresher training also.

6 Conclusions

Staff competence is one of the key elements needed for safe and efficient operations of an Urban Rail Transit system. However Stand-by drivers of a driverless urban rail transit will see their driving skills drop after the initial training due to the lack of driving practice. On the other hand, as train faults and other incidents are not every day events, both Stand-by driver and Traffic Controller have little chance to practice their incident handling knowledge and skills. In order to ensure they are always "Combat Ready", an "integrated refresher" strategy which includes actual train driving, Computer Based Simulation, table top exercise and drills at night must be adopted.

Simulation of the Optimal Allocation of Self- Service Check-In Kiosks at the Airport

Guihong Zhao; Xing Zheng; and Jun Zhang

Economic and Management College, CAUC, Tianjin 300300, China. E-mail: hcaiczhao@163.com

Abstract: Passengers usually chose the traditional manual check-in or self-service check-in provided by the airport. Then, to confirm the optimal allocation of self-service check-in kiosks, the paper briefly introduced the current situation of self-service check-in and offered literature review of the research method of self-service check-in. Second, based on the method called ExtendSim simulation, the paper put forward assumptions, simulated process and the quantitatively allocated ways of appropriate number of self-CUSS. Third, taking some airport for example, the paper carried out a study on the passengers' arrival on some day and poached the passengers by adopting traditional ways and self-service ways. Finally, the article arrived at the conclusion which contained the briefly average queuing time in the different period of time, the most adaptive numbers of self-service kiosks on the highly utilized rate as well as the appropriate number of self-service kiosks in this airport. And the average value could be regarded as the proper number of self-service kiosks that should be equipped in the airport.
Keywords: Airport; Self-CUSS; ExtendSim simulation; Allocation of check-in.

1 Introduction

1.1 The present condition of Self-Service Check-in

The utilized rate of self-service check-in has been increasing by years (self-service check-in includes: check-in through online, phone and self-service kiosks), due to the more preferences from travelers.

However, there existed some questions relating to institution and standards for the development of self-service. Fast Travel meant a set of self-support process, which was not built on one day. Then, the diversification of self-service check-in only played a part in the whole process of Fast Travel, which required us to gain a better understanding of relevant questions. Through making massive investigations, analysis, conclusions, clear-up and practicing, the article proposed excellent, efficient, workable measures for the problems relating to the present operating mode. With the perpetual optimization, the implementation of Fast Travel could be put into effect. The problems of self-service check-in in our country could be listed in the following:

(1) The irrationality of the configured number of self-service kiosks

Just as Shang yao Y., Chin-Hui T., Miawjane C(2004) put, at present, the passengers still showed great preferences for artificial check-in, particularly for the travelers with registered luggage. However, due to the mere number of both types, if the peak period came, both of them could not meet the demands of passengers.

(2)In contrast, the number of domestic check-in kiosks was inferior to the foreign and most travelers are not guided, just like Yan S, Tang C.-H, Chen M(2004) put.

The majority of passengers remained low for the self-service kiosks, partly because of the inconvenience brought by registering luggage; partly on account of the anxiety; and partly due to the unfamiliarity with self-service kiosks.

(3)The insufficiency of uniform industry standards, as Liu Changyou, Deng Zhenning, Zhang Jinjing(2007) described.

For instance, the self-service check-in varied from different airports or airlines. For customers or enterprises, it would be a waste of resources brought by overlapping investment. Given the deficiency of relevant criterions, it leaded to the mixed self-service and did not accomplish the established target.

The article made explosive study on the dynamic configuration number of self-service kiosks, selected the configured mode of self-CUSS of airports as a major research object and obtained experience from the foreign, in order to solve practical problems.

1.2 The methodology on the allocated number of self-service check-in

1.2.1 The analysis of foreign research

In 1980s, the computer simulated technology, particularly the dispersed simulation, was applied into the airport information system by some space agency of Europe and America. And then, a great number of findings have been made. Some were listed in the following:

(1) On account of the travelers' behavior, Ahn SB and Park Y(2003) built the assigned optimization model for check-in counter. Specifically, by passengers' survey, the study determined to build a model according to the departure time and the arrival time. After that, deploying the passengers' arrival time distributions, it counted the most appropriate amounts of kiosks that should be open as well as the opening period of every counter. The model, not only provided a more economical way for airlines and enhanced customer experience, but also offered applied systems for the effective execution of the kiosks' actual-time assignment. What is more, it also provided effective long-term methods for settling the problem relating to the crowd of airport terminal caused by flight delays.

(2)When making study on the configuration and controlling of check-in kiosks, Nico M. van Dijk and Erik van der Sluis(2006) first computed the minimum number of kiosks needed for every flight. Then, given the constraint condition that the kiosks for the same flight should be adjacent, the study got the minimum amounts of counters for every period and the total open time of kiosks, with the adoption of 0-1 programming.

(3)Ueda, Keiich, and Setsuya Kurahashi.(2014) intended to propose "Self-Service Technology Adoption Model" by utilizing the knowledge and experiences of front line experts. The study also suggests the efficient practice of air–travel passenger handling with self-service kiosks in an international passenger terminal by the simulation of the proposed agent-based model. Through conducting the experiments, the scenario and the key factor are indicated, which may possibly accelerate the self-service usage rate with cost effective way and less impact for customer services.

1.2.2 The analysis of domestic research

(1)Zhu Jinfu, in the book called *Air Transportation Programming*, introduced suggestions for IATA (IATA: International Air Transportation Association) and derived the simplified calculation method based on the Queuing Theory, which were available for measuring the open amounts of check-in kiosks.

(2)Liu Changyou, Deng Zhenning and Zhang Jinjing(2007) made study on the influence of the arrival modes for the check-in service, with the application of Queuing Theory. Definitely, the due amounts of check-in kiosks, for the single flight, were presented for both the uniform arrival and non-uniform arrival of travelers. Then, for the minimum allocation of kiosks for multiple flights, the study, with practical flight data, made simulations for verifying the model and obtained the solutions by the Integer Programming.

(3)Tay-Lin Hwang, Chi-Ruey Jeng and Sin-Siang Wang(2012) established the operating pattern for airport check-in counter assignments by minimising the operational cost from incurred by the airline and maximising passenger service level with considering the use of kiosk machine and full/part-time duty counter staff. According to the experimental results and sensitivity analyses of actual airline operations data, employing part-time counter staff and using kiosk machines would significantly reduce counter operation cost and improve passenger service quality.

Simulation referred to a process for the experimental study of system, which operated with the construction of practical system model. It is worth noting that simulation technology and comprehensive simulation system stayed dispensable in analyzing, designing, evaluating, decision making and training. Especially for the configured number of self-service kiosks, simulation system had advantages that could not be ignored.

3 The construction of model: the configured number of self-service check-in

3.1 The hypothesis of simulation

The course of building a model was to make analysis, hypothesis, and induction for the system. Then, the most important was to make practical factors rational with some reasonable assumptions. According to check-in queuing system, the article carried out the following assumptions:

(1)Initially, both staff and kiosks were in the state of readiness, with no passengers in the system;

(2)All the facility worked normally in the simulation operation, and no breaks left to the staff at the interval;

(3)All the counters could be shared by users;

(4)The arrival time interval of travelers' from varied period complied with the Uniform distribution;

(5)During the permissible period, all the passengers finished the procedure for the check-in;

(6)The queuing rule referred to FIFO;

(7)The average check-in time was replaced by the check-in time; ($A = B + C$; A: the average check-in time; B: the mean time for check-in formalities; C: the mean time to for registering luggage)

(8)Every kiosk shared same traits and only could service one user at a time. The mean servicing time was employed to represent the service time of reception desk;

(9)In accordance with the combination of departure time and ahead of the arrival time, the data about passengers would be actually presented in the system;

(10)During the queuing period, passengers were not allowed to leave or switch the line;

(11)There existed no flight delays under the condition of all departure flights operating punctually for the schedule.

(12)The study did not divide the passengers into distinctive classes, such as first class, business class, and economic class. And it did not include transfer travelers.

3.2 The procedure of simulation

3.2.1 The introduction of simulation software: ExtendSim

For probing into the allocated number of self-service check-in kiosks at the airport, the discrete event simulation is employed for the article. For example, computer network, traffic management, social economic system and other communication system are parts of the discrete event system. Both time and space, relating to events of this system, are disperse. Normally, due the strong randomness of the event, it is difficult to study with conventional methods.

The simulation software is adopted by the paper, called ExtendSim. The ExtendSim is a part of computer simulation tools, which is used to construct models involving multiple kinds of production, service and system. What's more, through repeated argumentation and analysis, ExtendSim is the most appropriate for simulation.

The applied cases have been found in the foreign airports, for the registered luggage system being embedded into the self-service check-in kiosks. Nowadays, in the domestic airports, only T3 of Beijing Capital International Airport offered this kind of service. Its kiosks were to integrate the work of check-in counters into the self-service check-in. Afterwards, by self-support (Specifically, it meant integrating the luggage code printer into the self-service check-in and made data interaction with ELV system of airport.), the kiosks could provide solutions required for the passengers with baggage. In consequence, in the course of designing the simulation, the study neglected individual differences and took shape integration of check-in procedure and luggage transportation, in order to employ the mean time to check-in. Then, the process of simulation is demonstrated in the following, just like the figure 1.

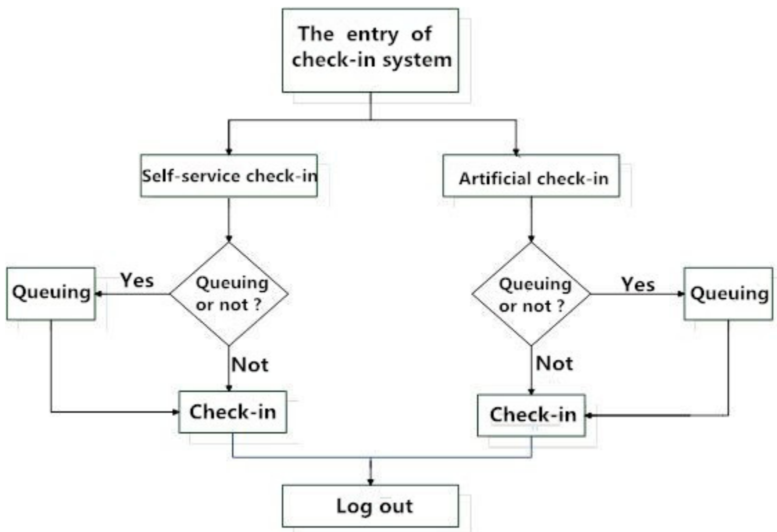

Figure 1. The procedure of simulation

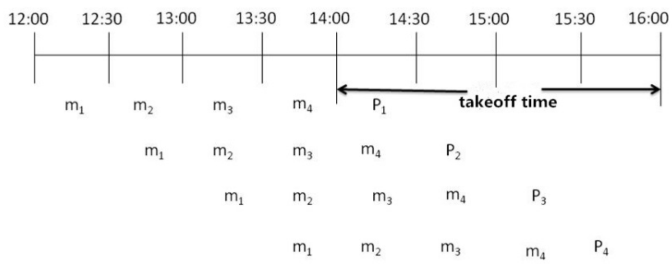
When the departure travelers entered into the check-in system, decisions on the ways of check-in were dependent on the personal preference or practical situation. After choosing, if leaving vacant kiosks, the passengers who selected the self-service would be in the state of check-in directly until logging out; if leaving no spare facility, the state of travelers would be in the state of queuing spontaneously, with the queuing rule called FIFO, until receiving service and then logging out. In the same way, it also could be applied to the artificial check-in.

4 The simulation of some airport terminal's self-service check-in kiosks

4.1 The arrival pattern of passengers

For the passengers, the arrival pattern was more dependent on the travelers' habits. And in the same period, the arrival amounts would vary on the basis of certain flight schedule and arrival rule. Therefore, according to the Arrival Pattern, how to calculate the actual numbers of passengers in some period would be one of the determinant factor for the allocated amounts of kiosks. But the arrival rule could not possibly comply with some specific distribution.

Hence, "Sliding Window" would be adopted as the calculating method, which divided time into the unit programming period and split the problems up into the set of sub-problem, in order to decrease the complexity of solution and avoid taking the large scale of sample assembled by passenger traffic into account. In detail, the study selected the interval, 14:00-16:00, as the programming period. P_i（i=1,2,3…n）was regarded as the amounts of departure passengers in the programming period, that's to say, the numbers of departure travelers at 14:00-14:30, 14:30-15:00, 15:00-15:30 and 15:30-16:00 would be replaced by P_1、P_2、P_3、P_4. Besides, from 30 minutes to 180 minutes before takeoff, the passengers would arrive at the airport, whose arrival time obey some distribution. Assuming that the amounts of passengers who arrive 180-120 minutes early would be m_1; 120-90 minutes early would be m_2; 90-60 minutes early would be m_3; 60-30 minutes early would be m_4; and m_i（i=1,2,3…n）refers to the percentage, so the study made the provision: $\sum_{i=1}^{n} m_i = 1$. In the next, for the programming period, the percentage of passengers arriving at the airport, performing in the matrix form, would be presented in the following:



M is the distributed matrix of passengers' arrival time and P is the vector of departure travelers in varied periods. And the time frame could be divided by different needs. If setting 30 minutes as a time slot, then M refers to a 7×4 matrix while P refers to a 4×4 matrix. The practical arrival amounts of departure passengers in programming period would be described by $W = M \times P$. So the passenger assignment model, performing in the matrix form, would be listed in the following:

$$M = \begin{bmatrix} m_1 & m_2 & m_3 & m_4 & 0 & 0 & 0 \\ 0 & m_1 & m_2 & m_3 & m_4 & 0 & 0 \\ 0 & 0 & m_1 & m_2 & m_3 & m_4 & 0 \\ 0 & 0 & 0 & m_1 & m_2 & m_3 & m_4 \end{bmatrix}$$

$$P = \begin{bmatrix} P_1 & 0 & 0 & 0 \\ 0 & P_2 & 0 & 0 \\ 0 & 0 & P_3 & 0 \\ 0 & 0 & 0 & P_4 \end{bmatrix}$$

$$W = M \times P$$

$$W=\begin{bmatrix} m_1P_1 & m_2P_1 & m_3P_1 & m_4P_1 & 0 & 0 & 0 \\ 0 & m_1p_2 & m_2p_2 & m_3p_2 & m_4p_2 & 0 & 0 \\ 0 & 0 & m_1p_3 & m_2p_3 & m_3p_3 & m_4p_3 & 0 \\ 0 & 0 & 0 & m_1p_4 & m_2p_4 & m_3p_4 & m_4p_4 \end{bmatrix}=(W_1\ W_2\ W_3\ W_4\ W_5\ W_6\ W_7)$$

Among it, $\sum_{j=1}^{4} W_j = W$ depicted the concrete arrival amounts of departure passengers in the programming period. By field survey and given the actual requirements, the study confirmed the m_i and P_i which would be put into effect. After that, the article obtained the estimated amounts of arrival passengers.

4.2 The settings of simulation

The beginning time of queuing system was at zero clock, January 1, 2013. And the unit of time was set to the seconds. In the initial state, both staff and kiosks were in the state of readiness, with no travelers being serviced. What's more, the simulation for queuing was measured by one hour. On the basis of departure flight schedule, combined with investigative analysis, the article would obtain the time distribution of passengers who arrived at ahead of time. Then, employing the calculation method called "Sliding Window" to ensure the average arrival interval of every passenger, the actual data about passengers would be generated through the Create module, as shown in the Figure 2.

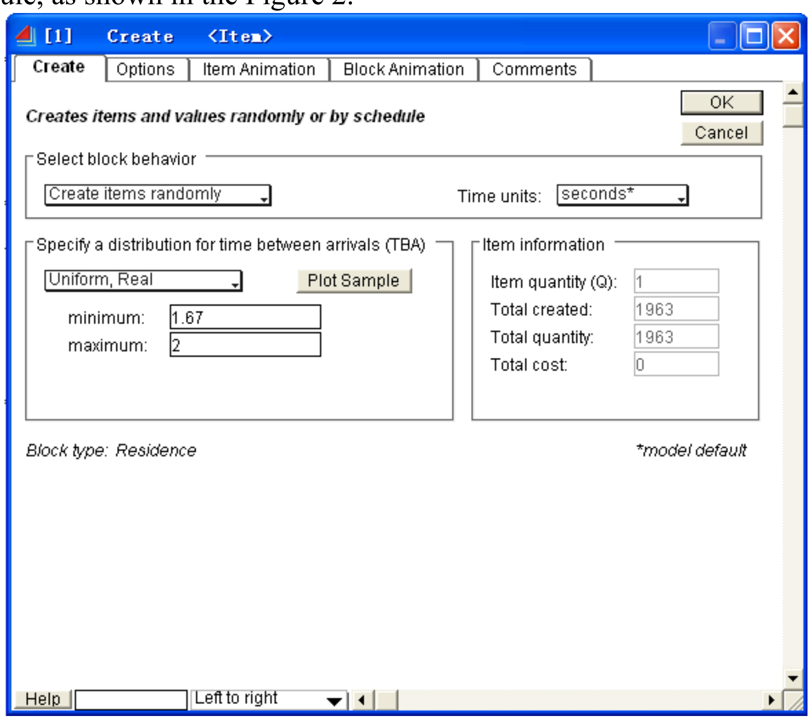


Figure 2. The settings of Create module

After that, to confirm the configured number of self-CUSS, in light of the allocated ratio of self-CUSS, the system would filter out the passengers employing the self-service from the whole travelers. And it required that the allocated ratio of both ways should be input the Probability where the apportionment of self-CUSS was 27%, the sharing ratio of manual check-in was 64%, and the other ways were 9%. Next, in the routing selection, the 27% of passengers generated by the system were arranged to use the self-CUSS; the 64% of travelers would employ self-CUSS; and the remaining selected other ways. The routing selection was presented in the following, just like figure 3.

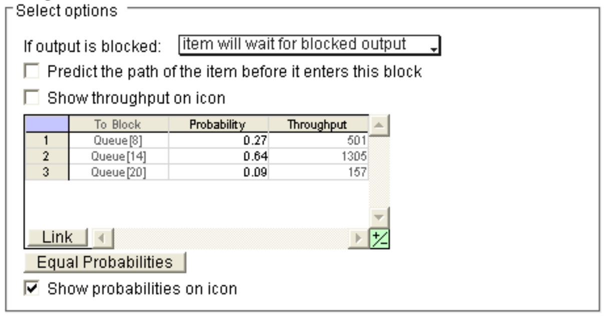

Figure 3. The setting of routing selection

The module of Queue was set to the ordered queue, and the queuing rule complied with FIFO.

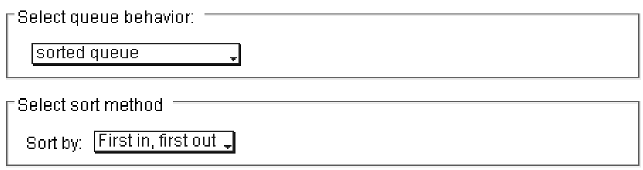

Figure 4. The module of Queue

The average time of check-in was adopted to describe the servicing time of self-CUSS and artificial check-in, which was relatively rigid. In the simulation, the processing time of self-CUSS was 180 seconds. That's to say, every passenger was allowed to spend 180 seconds for check-in, when time is over, it would let the users log out.

It was necessary to set the maximum items in activity to the number which is greater than one, on account of the similar kiosks operating parallelly in reality. Furthermore, the definite values would be adjusted by the parameters output by the simulation. After finishing the settings, the system would run multiple times, in order to gain the range of results. Eventually, the possible results would be appropriate for analyzing the model and observing the result of assessment.

The data of this article was derived from the departure flight, from August 29 to September 4 in 2013, due to the fact that the amounts of actual arriving passengers from varied periods could not be counted and that the alteration of scheduled departure flight in every day could not be neglected. After that, the paper would gain the practical numbers of departure travelers at varied periods, based on the percentage distribution of passengers who arrived ahead of time.

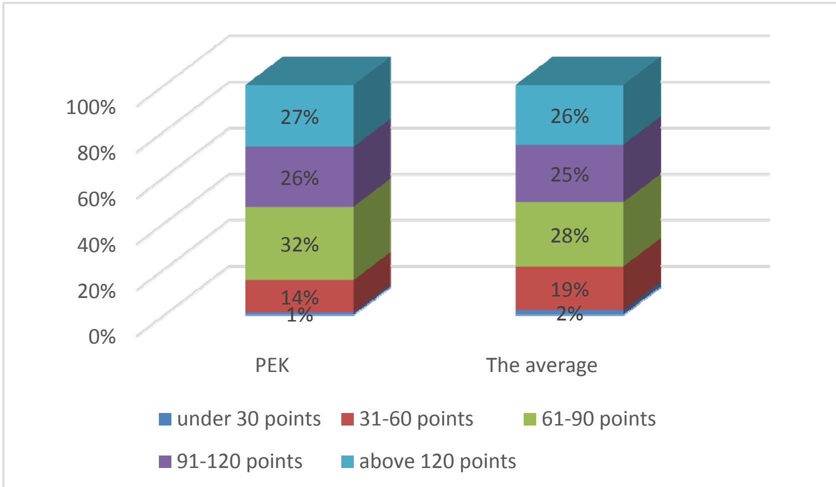

Figure 5. The arriving time distributions of departure passengers ahead of time The data source: PEK 2013 Total Traffic Report

Just as indicated in the figure 5, during 120 minutes, the percentage of arriving passengers, ahead of schedule, was around 73%. Additionally, above 120 minutes, the travelers who arrived ahead of time accounted for 27% of the total. Then, by the Sliding Window, at varied periods, the study would obtain the real-time number of arriving passengers from the foreign and domestic check-in area of T3.

Table 1. The actual amounts of departure passengers at varied periods

Time Quantum	Foreign check-in area	Time Quantum	Domestic check-in area
00:00-01:00	0	00:00-01:00	203
01:00-06:00	429	01:00-06:00	1,424

23:00-24:00	108	23:00-24:00	296
Total	19,449	Total	40,368

The explanatory note: Foreign check-in area refers to the number of passengers in the foreign check-in area; Domestic check-in area refers to the number of passengers in the domestic check-in area.

In the fifth figure, it was acquired that around twenty-seven percent of passengers chose self-CUSS. About forty-five percent of passengers selected the artificial check-in. The percentage of travelers who chose the Bag Drop Off Desk was nineteen. Thus, it was about sixty-four percent of passengers who elected the check-in counters. (Notably, the Bag Drop Off Desk is a part of check-in counters.) In sum, the number of passengers using the self-service check-in versus the number of travelers using the artificial check-in is 3:7.

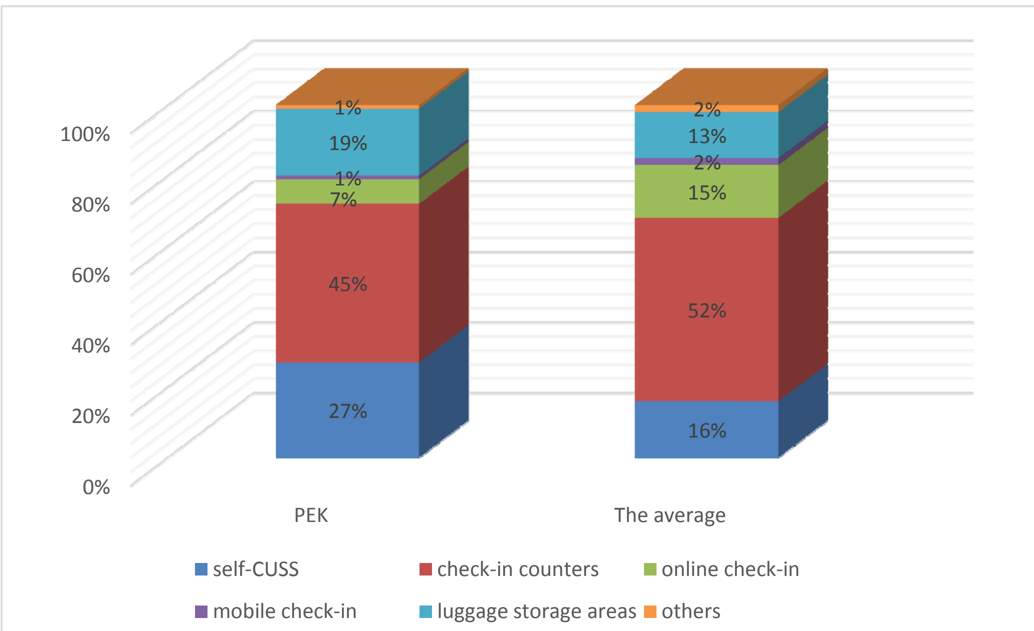

Figure 6. The percentage distribution of the modes of check-in
The data source: PEK 2013 Total Traffic Report

The sojourn time of check-in counters, servicing for the ninety-five percent of international routes, shouldn't be over twenty minutes, based on the Passenger Service Commitment. Meanwhile, the residence time of check-in counters, servicing for the ninety-five percent of domestic routes, shouldn't be over ten minutes. What's more, it must be ensured that the sojourn time for the passengers who adopt the self-CUSS, should not be beyond eight minutes. However, the commitment should be adjusted: the percentage of both international routes and domestic routes, serviced by the check-in counters, should be altered to a hundred. Meanwhile, the others stay invariant. The reason to make these adjustments is because of the limits of the simulation software. Then, the mean time of check-in would be presented through the data offered by some airport and on-the-spot investigation, just as illustrated in the second table.

Table 2. The mean time of check-in from varied passengers

Travelers / Check-in ways	International routes	Domestic routes
Artificial check-in	53 seconds	35 seconds
Self-CUSS	180 seconds	180 seconds

In the study, the article required to keep the utilized rate of self-service check-in and artificial check-in stay at the reasonable range and comply with the adjusted service commitment of Air China. And, by the incessant adjustments of parameters, the optimal dynamic amounts of self-service check-in kiosks would be acquired. Then, it was demonstrated as shown in the third and fourth table.

Table 3. The dynamic index of self-CUSS at varied periods from the domestic

Time Buckets	Opening numbers	The mean length of line	The longest line	The average time for waiting(Seconds)	The maximum time for waiting(Seconds)	The availability
00:00-01:00	3	0.18	3.9	37.21	206.26	0.81
01:00-06:00	21	0.44	7	4.32	64.05	0.83
06:00-07:00	64	2.29	18	6.91	46.54	0.91
07:00-08:00	40	3.87	16	17.96	76.75	0.95
08:00-09:00	23	0.64	7	5.52	61.80	0.90
09:00-10:00	34	0.72	10	4.17	50.02	0.89
10:00-11:00	34	3.91	20	10.51	102.25	0.93
11:00-12:00	34	3.74	26	19.26	136.82	0.93
12:00-13:00	43	1.14	10	5.08	36.51	0.89
13:00-14:00	31	3.52	16	20.85	87.87	0.95
14:00-15:00	36	5.97	19	29.81	83.58	0.96
15:00-16:00	36	7.98	34	38.15	162.67	0.94
16:00-17:00	31	5.18	17	30.08	90.75	0.96
17:00-18:00	31	1.85	14	11.42	81.25	0.93
18:00-19:00	31	5.95	20	34.52	114.64	0.97
19:00-20:00	31	2.04	13	12.41	67.19	0.93
20:00-21:00	18	3.48	13	36.28	121.20	0.93

21:00-22:00	10	1.00	7	20.27	134.82	0.86
22:00-23:00	4	1.08	6	51.06	238.57	0.87
23:00-24:00	4	3.38	10	162.41	414.40	0.90

From the above table, for the domestic routes, it acquired that the peak period of check-in zone arose from six o'clock to seven o'clock in the morning. According to the simulation results, it requires that sixty-four self-service check-in kiosks should be equipped, the utility rate would be nine-one percent, the average queuing length would be two point twenty-nine, the maximum queuing length would surmount to eighteen, the average queuing time would reach six point ninety-one seconds, and simultaneously the maximum queuing time would rise to forty-six point forty-four seconds. In the next, the detailed simulation would be presented, just as shown in the seventh figure.

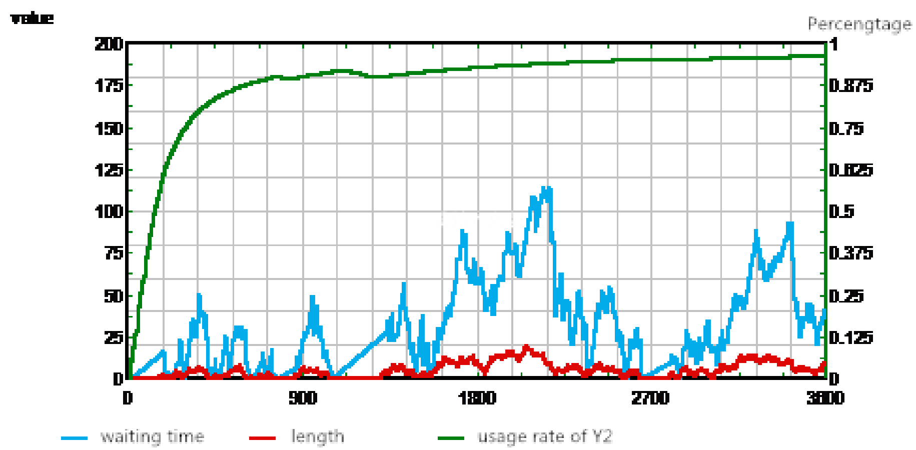

Figure 7. The usage of self-CUSS for domestic flights at 6:00-7:00

Figure 7: the utilized situation of self-CUSS for the domestic flights from 6:00 to 7:00. The fifth table: the dynamic and unrestricted indicators of self-CUSS in the international flights.

Table 4. The dynamic index of self-CUSS for international flights

Time Interval	Open Amounts	Average Queuing Lengths	Largest Queuing Lengths	Maximum Waiting Time(s)	Maximum Waiting Time(s)	Utilized Rate
00:00-01:00	0	0	0	0	0	0
01:00-06:00	1	0.51	2	100.04	243.49	0.88
06:00-07:00	28	3.77	19	24.57	100.85	0.96
07:00-08:00	20	0.52	7	5.32	61.10	0.86

09:00-10:00	12	3.43	14	51.60	215.15	0.89
10:00-11:00	20	1.38	8	13.24	70.20	0.90
11:00-12:00	20	2.81	12	27.29	115.20	0.91
12:00-13:00	20	0.58	8	6.06	80.75	0.83
13:00-14:00	20	1.08	8	10.70	67.97	0.88
14:00-15:00	20	1.50	10	15.33	79.85	0.85
15:00-16:00	20	7.60	22	68.50	193.98	0.93
16:00-17:00	18	1.45	11	16.22	105.36	0.87
17:00-18:00	18	1.58	11	17.66	88.89	0.87
18:00-19:00	18	1.52	11	16.50	110.52	0.90
19:00-20:00	18	1.16	8	12.52	102.44	0.87
20:00-21:00	7	4.17	12	107.72	295.13	0.95
21:00-22:00	7	1.82	8	49.45	207.44	0.92
22:00-23:00	2	0.88	5	70.75	229.42	0.88
23:00-24:00	2	1.22	5	104.71	427.64	0.88

For the international routes, it acquired that the peak period of check-in zone arose from six o'clock to seven o'clock in the morning. According to the simulation results, it required that twenty-eight self-service check-in kiosks should be equipped, the utility rate would be nine-six percent, the average queuing length would be three seventy-seven, the maximum queuing length would surmount to eighteen, the average queuing time would reach six point ninety-one seconds, and simultaneously the maximum queuing time would rise to forty-six point forty-four seconds. In the next, the detailed simulation would be presented, just as shown in the eighth figure.

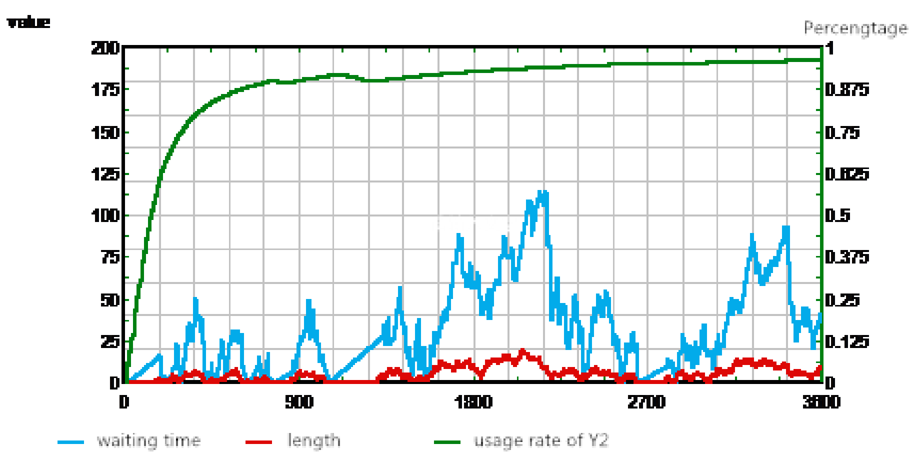

Figure 8. The usage of self-CUSS for international flights at 6:00-7:00

5 Conclusions

Given the fact that the queuing time should be cut down as much as possible and the utilized rate should be improved, the average values were employed as the number of self-service check-in kiosks, based on the amounts of kiosks described by the above. Besides, if both the international and the domestic check-in kiosks area were sliding into the state of heavy load, keeping the counters being in the condition of overloaded operation for a long time, it would lead to severe loss of facilities and then make evil impacts on the quality of travelers' service. Therefore, in order to ensure the service quality, it demands that the self-service check-in kiosks should be reasonably added especially in the peak period, on account of the fluctuation of flights and the increase of passengers' traffic. What's more, it is the ExtendSim simulation that may possibly improve the utilized rate of self-service check-in kiosks with cost effective way and less impact for customer services.

Abstract: Public transport is widely acknowledged as a high capacity transport mode which helps mitigate traffic congestion in urban road networks, reduce fuel consumption and improve air quality. In this paper, a review of the application of internet of things technologies, such as Radio Frequency Identification (RFID), GPS/GIS and GPRS/3G/4G, in public transport system is presented. Thereafter, a newly developed intelligent public transport system with application of Internet of things technologies in Chengdu city is analyzed. The effectiveness of the system is quantitatively analyzed. Results show that application of Internet of things technologies in Chengdu public transport system highly improves operational efficiency and level of service, and reduces total costs of operation and management.
Keywords: Public transport; Internet of things; RFID; GPS/GIS; Level of service.

1 Introduction

In big cities, urban roads become more and more congested, especially at rush hours. In order to mitigate traffic congestions, different traffic management measures have been or are being applied, such as congestion pricing, ITS measures, limit issuance of new car license plates, traffic restrictions based on the last digit of license plate numbers, etc. However, when car traffic demand highly exceeds road supply, the improvement of traffic conditions by applying some traditional traffic management measures appears marginal. In the past decades, more attention has been paid to develop public transport around the world. In China, public transport operators and authorities are trying to increase the public transport mode share by performing fare reform, improving public transport operational efficiency and level of service. In recent years, with the application of Internet of Things technologies in ITS, e.g., RFID technology, sensing technologies, GPS/GIS, GPRS/3G/4G, etc., more advanced public transport systems are being developed.

RFID is non-contact automatic identification technology that uses radio waves to identify and track groups or individual objects at distance. The application of RFID technology in public transport systems started in recent years. In the US and some European countries, the RFID enabled smart card is widely used in the transport field to perform revenue collection. It is perceived as a secure method of user validation and fare payment(Pelletier et al., 2011). Apart from fare collection, the data collected by RFID smart cards can be used for long-term network planning, travel behavior analysis, demand forecasting, schedule adjustment, and longitudinal and individual trip patterns(Pelletier et al., 2011). RFID technology can be applied for Automatic Vehicle Location (AVL) as well. In Beijing, RFID technology was applied for bus signal priority since 2008(Jiang et al., 2011). When a bus equipped with a RFID tag approaches the intersection, a roadside RFID reader captures the bus information and sends it to the traffic signaling system to control the traffic light(Lee et al., 2009). A simulation study conducted in (Wang et al., 2011) shows that the RFID enabled bus priority system has the potential to improve public bus service level by reducing congestion of bus traffic flow.

GPS/GIS and GSM/GPRS/3G technologies have been extensively applied in road transport systems for vehicle monitoring purpose. In the public transport context, data collected by GPS equipped buses can be used for bus fleet tracking and scheduling. In (Medagama et al., 2008) , a GPS/GIS/GPRS and web based system framework for large fleet (including bus fleet) tracking is proposed. In (Liao, 2011), a data driven tool was developed to fuse GPS data and fare collection data. Sun et al. (Sun et al., 2007) Proposed a method to predict bus arrival time at individual bus stops based on the bus location and speed data collected by GPS enabled buses. Besides, The GPS equipped AVL is commonly implemented along with signal priority systems for buses (Hounsell et al., 2005; Liao et al., 2006).

In this paper, Internet of Things technologies applied in public transport systems are reviewed in the next section. Then, intelligent public transport system of Chengdu city, which is composed of four subsystems with application of Internet of things technologies, is presented in section 3. In section 4, the effectiveness of the system is discussed. The last section concludes the paper.

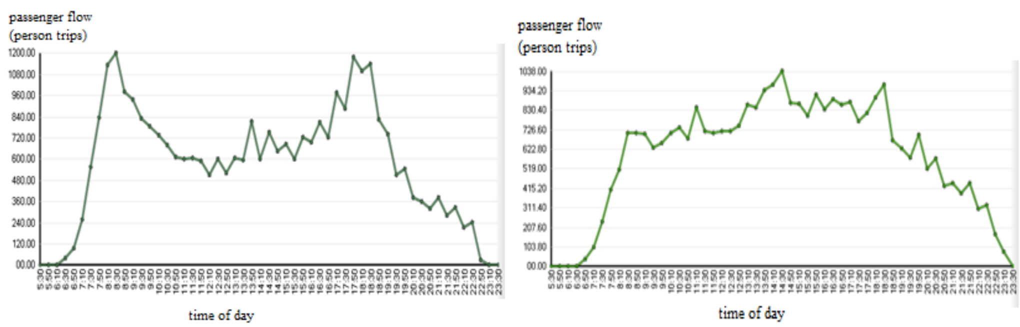
2 Intelligent public transport system in Chengdu

2.1 Background

Chengdu city is located in the southwest of China with a population of more than fourteen million. By the end of 2013, the car ownership in Chengdu is about three million, which ranks three among all cities in China. Traffic demand increases year by year, which leads to severe congestion, especially during rush hours. In the past five years, developing an intelligent public transport system is on the agenda of Chengdu municipality. The system started in 2008, and it is now in full operation. This system is composed of four parts: smart card system, bus monitoring system, bus scheduling system and bus information system. In the following, detailed information about these subsystems will be presented.

2.2 Smart card system

The smart card system (IC card system), has been implemented in Chengdu public transport system since 2004. Up to 2014, more than 7000 buses are equipped with contactless smart card readers that are linked to a GPS device. The preliminary purpose of this system is to realize no cash fare collection. The value stored on a smart card is mainly in the form of eCash and number of rides. Passengers who are onboard in the same bus or transfer less than three times within two hours pay a fixed amount of fare, independent of time of the day and trip distance. Therefore, unlike some systems, where passengers need to tap-on when get in the bus and tap-out when get out of the bus, this system requires passengers to 'tap-on' only when get onboard the bus and no 'tap-out' is required. On average, 75% of passengers use a smart card when traveling with public transport. This percentage goes up to 95% during peak hours. Apart from the role of effective revenue collection, ridership, boarding location and time can be collected as well. Figure 1 (a) illustrates ridership of bus line 47 at different periods of a weekday. Two peaks which are a morning peak between 7:30 and 9:30 and an afternoon peak between 17:00 and 19:00 can be clearly observed. Figure 1 (b) shows ridership of a weekend day, where passenger volumes are more evenly distributed along the day and no peaks can be observed.



(a) weekday (2nd, March 2011) (b) weekend (5th, March 2011)

Figure 1. Ridership of bus line 47 (aggregated in 20min)

The passenger flow data collected by a smart card system can be used to optimize bus line networks, scheduling plans and to improve bus operational efficiency. However, the smart card system now in use in Chengdu public transport company can only collect boarding information of passengers and no alighting information is available. Recently, a new card called "double-chip" (CPU chip and RFID chip) card has been developed. With this double-chip smart card system, passengers only need to tap on when they get onboard the bus, and the boarding information and fare can be collected. No tap out is needed since the alighting information is collected automatically by a RFID reader installed at the back door of the bus. The detailed ridership information collected can be used for long-term bus line network planning and scheduling adjustment. FIGURE 2 shows the structure of a RFID equipped smart card system and the data flow among components of the system.

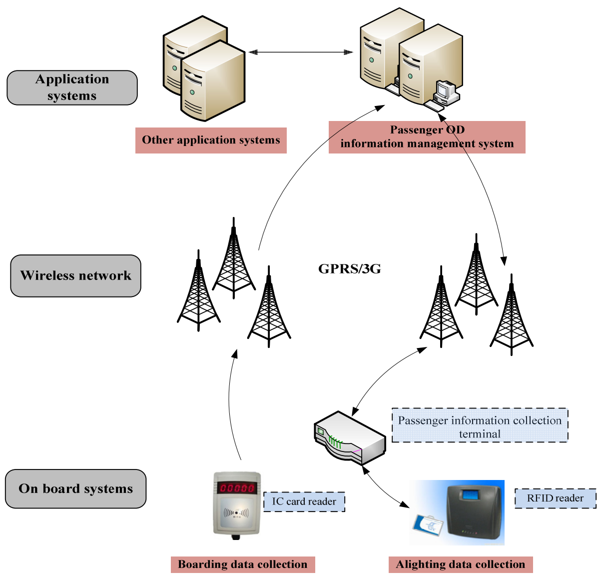


Figure 2. Simple representation of the 'double- chip' smart card system structure and data flow

2.3 Bus monitoring system

In Chengdu, the development of the bus monitoring system started since 2009. Some integrated sensing technologies such as RFID, GPS, GIS, 3G and video have been applied to monitor bus operations. The status of a bus running in the road network can be tracked by applying GPS/GIS/GPRS technologies. In Chengdu, more than 7000 buses are equipped with GPS receivers. The information of bus locations and speeds are sent to the bus monitoring center every 15s through GPRS network. Every bus has a mobile data terminal that allows drivers to send and receive messages and trigger alarms. If a bus driver does not take the right bus line or drives over the speed limit, a warning message will be sent to the driver by the monitoring center.

2.4 Bus scheduling system

A GPS based communication technology, together with GIS and GPRS/CDMA technologies are used to improve real-time tracking and scheduling of buses. On one hand, bus traveling distance collected by GPS is directly linked to the bonus of each bus driver, which helps improve working efficiency of bus drivers. On the other hand, the collected GPS data and passenger data collected by the IC card system are used for estimating ridership of each bus line. According to the estimated ridership, four categories of bus lines are identified as shown in Table 1.

Table 1. Categories of bus lines

Types of bus lines	A	B	C	D
Ridership (person trips/month)	≥ 1200,000	between 800,000 and 1200,000	between 300,000 and 800,000	≤ 300,000

2.5 Bus information system

This system helps travelers make better trip plan with public transport. Before trips, users can get access to the bus information website from computers or web-enabled wireless devices. The system is also combined with GPS based AVL system to provide information of bus arriving at or departing from a bus stop to travelers. Besides, more than 1200 Variable message signs have been installed at bus stops within the third ring road of Chengdu city. The bus arrival time information is displayed in the variable message sign. Recently, Chengdu public transport company has developed an 'app' for smartphones. The 'app' gives real-time bus arrival information for the user's selected bus stops or bus routes. Another new function of this 'app', which is the customized service of buses, has been provided to users.

3 Discussion

TABLE 2 compares the quantitative indexes of bus operation, safety and service before (in 2008) and after (in 2013) implementation of the intelligent public transport system. It is clear that the operational efficiency has been improved substantially in 2013 compared with that in 2008. The number of accidents and the number of bus drivers who drive over speed limit have decreased greatly in 2013 compared with those in 2008. Besides, the level of service has been improved as well after implementation of the system. TABLE 3 indicates operational cost savings after implementation of the system.

Table 2. Comparison of indexes between 2008 and 2013

Operation Indexes	2008	2013
Fare collected per thousand buses per kilometer (RMB)	3772	4260
Percentage of buses in operation during peak hours (%)	62%	93%
Safety Indexes	**2008**	**2013**
Number of over-speed limit (per month)	2136	695
Number of accidents (per month)	277	59
Service Indexes	**2008**	**2013**
Number of complaints (per 600,000 person trips)	207	0.793
Average Waiting time during peak hours (min)	9	3

Table 3. Cost savings after implementation of the system

Type of cost	Labor cost	Bus purchase cost	Invalid bus travel distance (converted to cost)	In total
Reduced amount of cost (10,000 RMB)	14,000	70,000	8,400	92,400

5 Conclusions

In big cities with large population, an efficient way to reduce traffic congestion and enhance efficiency of transportation systems is to develop public transport system as a priority. In this paper, application of Internet of Things technologies in Chengdu public transport system is presented. The comparison results between before and after development of the system show that the operational efficiency and the level of service are improved, and operational costs are reduced substantially. The public transport mode share increased by 7.5% since 2010 when the system started to perform its function.

Abstract: In order to solve the serious problem of traffic congestion, many cities in China are developing urban public transportation systems and focusing on modern trams with the advantages of workload, cost performance and transportation efficiency. Based on analysis of the status quo, problems of tram signal control and operation efficiency, this paper tries to study signal priority control methods for trams under the condition of mixed traffic at intersections, proposed priority control principles of signals based on information perception as well as interaction at intersections, and achieve connection between signal control for trams and the existing urban signal control for other motor vehicles. Through the example application of 17 signal intersections along Suzhou tram lines 1 and 78 around the tramline, the result shows that coordinated priority strategy increases tram operation efficiency and reduces waiting time at intersections. It will provide reference for the reforming of Road Traffic Signal Controller and Road Traffic Signals, which are national mandatory standards in China.
Keywords: Modern tram; Signal control; Signal priority; Intersection.

1 Development situation of trams in the world

In the past ten years, more than 50 countries and 400 cities in Europe and the United States have developed modern trams for urban public transportation. European countries have adopted the system of Communication Based Train Control (CBTC) or Europe Train Control System (ETCS) to control them. In Europe, the CBTC system has independent tram operation control centers, such as SACEM of France and Siemens LZB of Germany, which are ideal for city areas with high volume of passenger flow. ETCS system for trams focuses on network connecting between tramways and railways around cities, so trams are controlled by the railway operation control center directly.

1.1 Trams construction and application status in China

In order to solve the urban traffic congestion and meet the increasing demand of public transportation, many cities in China set off an upsurge of modern tram construction. At present, 11 lines of trams in 7 cities have been put into operation, including: Changchun and Dalian city in which trams are transformed from the original traditional streetcars, and Shenyang, Suzhou, Nanjing, Guangzhou and Qingdao city, in which in which trams have been operating for nearly two years. Trams are under construction in ten cities, such as Shenzhen, Huaian, Zhuhai, and Foshan. More than 40 cities have planned more than 100 tram lines.

In the respect of signal control, both the traditional streetcar operating in Dalian and Changchun and the modern tram running in Binhai New District, Tianjin and Zhangjiang District, Shanghai use driver manual control mode, and travel by road traffic signals at intersections. The trams which have been put into operation in the past two years are designed with reference to technical standards of metro and light rail. Therefore, trams adopt CBTC with expensive cost and complex functions, such as automatic train supervision (ATS), automatic train protection (ATP), intersection priority system, and distributed control system (DCS).

1.2 Existing problems of trams in China

(1) Lack of regulations and standards of trams and unreasonable tram plans. According to the current classification code of motor vehicles and driving licenses, trams and trolleybuses are both classified as motor vehicles, but metros and light rail trains aren't. So tram driver must apply for Class P motor vehicle driving licenses. Trams in many cities are planned, designed and operated as metros or light rail transit. Operating routes, stops and other facilities of trams are designed with focus on the performance of tramcars and control centers rather than to features of mixed traffic conditions.

(2) Signal control is coordinated poorly at intersections and signal priority has not been realized. The technical standards of urban traffic control system (UTCS), built and operated by the department of traffic police, are different from the technical standards of CBTC and ETCS for metro and light rail. During tramline planning and construction, the compatibility with existing UTCS hasn't been considered, resulting in great difficulty in realization of tram signal priority. For this reason, trams opened in Shanghai, Shenyang and Nanjing didn't realize tram signal priority control.

(3) Trams operating efficiency is low and does not meet the design objectives. During plan-step of operating routes and stops, the planning department didn't consider mutual interference with other motor vehicles and pedestrians, collaboration and matching of trams with existing UTCS in these cities, and they designed some impractical and unreasonable principles, such as absolute signal priority.

2 Research on tram signal priority control

2.1 Selection of control strategies

Signal priority control strategies for trams are classified into absolute priority, exclusive phase, conditional priority and coordinated priority.

(1)Absolute priority strategy. When the arrival of a tram is detected, the road signal controller will interpose an exclusive signal phase, turn the current signal phase to a tram travel signal phase. After the tram is detected to have passed the intersection, the road signal controller will switch to the next signal phase. This strategy ensures that each tram will not be delayed for any reason when passing intersection. In spite of this, it has a serious impact on other flows and is very likely to bring traffic jams at intersections.

(2) Exclusive phase strategy. Setting up the exclusive phase for trams will depend on the average travel speed, the departure frequency, the location of stops and so on. It requires channelization and control at intersections to reduce the potential conflict of trams with other motor vehicles. This strategy doesn't need any tram detectors or other additional devices. Nevertheless, the delayed tram will waste the green light.

(3) Conditional priority strategy. By setting some conditions, UTCS provides priority signal only to selected trams. First, according to the tram running schedule, UTCS provides priority signals only to the punctual or delayed trams and not to the advanced trams. Second, UTCS provides priority signals only for trams at rush hours rather than those during flat-peak period. This strategy requires additional control parameters to be added in the existing UTCS.

(4) Coordinated priority strategy. Typically there are two basic control methods. One is turning off the red signal in advance- if the current phase is a red signal and a tram is approaching, the road signal controller will reduce the red signal time and turn the on green signal several seconds in advance. The other one is extending the green signal time- if the current green light is about to turn off and a tram is arriving, the road signal controller will extend the green signal time so that the tram can pass through intersection safely. However, it will lead to excessive adjustment of the signal phase and interfere with other traffic flows when trams come frequently.

We have compared four control strategies in terms of operating efficiency, cost and the influence to other vehicles, as shown in Table 1.

Table 1. The comparison on signal priority control strategies of urban tram

Control Strategy	Operation Efficiency	Cost	Influence to Other Vehicles	Applicable Conditions
Absolute Priority	Highest Efficiency with no delay	High cost, detectors needed	Huge influence to traffic flows and easy to congestion	Applied in the intersections with low traffic volume
Exclusive Phase	Low efficiency with severe delay	Lowest cost, no detectors needed	Relatively fixed signal phase with little influence to other vehicles	Applied in the intersections with low traffic volume
Conditional Priority	High efficiency with relatively low delay	Highest cost	Low influence to traffic flows	Under the coordinated signal control in adjacent intersections
Coordinated Priority	High efficiency with delay in particular	High cost, detectors needed	Low influence to traffic flows and frequent phase	Applicable to trams with less frequent schedule

	intersections		adjustment	

Judging from Table 1, it is obvious that four control strategies have their own merits and defects. In practice, it is needed to calculate the traffic volume of the intersections and investigate the traffic management level as well as the investment in the first place. Then, select an appropriate control strategy for each intersection. In the project of Suzhou Urban Tram, the selected control strategy is coordinated priority after considering that the majority of urban trams can receive priority with little influence to lateral traffic flow.

2.2 Coordinated signal priority control based on interaction

(1) Configuration of sensing equipment

To implement signal control with absolute priority and coordinated priority strategies, it is crucial to sense the arrival and departure of trams at intersections. Highly accurate and sensitive detectors are required for coordinated control and reliable operation. In application of Suzhou tram line 1, four sensing cycle detectors are used to detect and calculate the position of the tram (Figure 1). Specific positions of the tram detector shall determine the tram running speed, the crossing time, the safety braking distance and other factors.

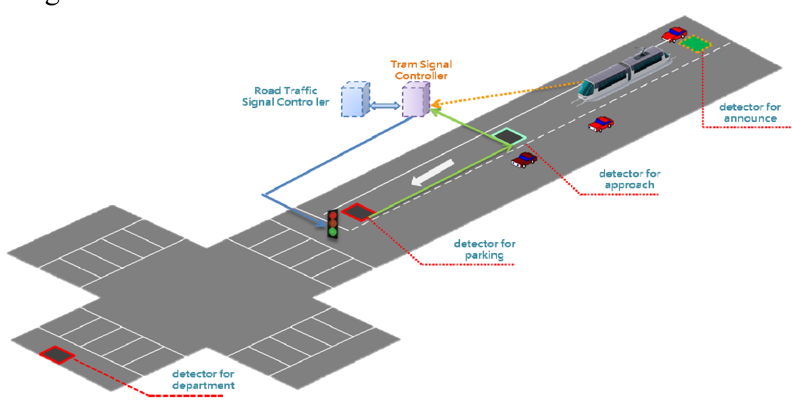

Figure 1. Tram detector layout example

(2)Coordinated control between road signal controller and tram signal controller

We communicate real-time information between the tram signal controller and road signal controller at the level of intersection to coordinate control. The road signal controller exchanges information with the tram signal controller, and the tram sends and receives the signals from signal controller via ports to control the tram signal (Figure 2). After a tram request signal triggers a priority phase, the road signal controller will make five basic responses as follows:

- Request in "front end" of green light: accept request and proceed with the priority phase
- Request in "back end" of green light: accept request and extend the priority phase

➢ Request in red light: accept request and terminate the non-priority phase in advance
➢ Mandatory request: interpose a priority phase
➢ Response lockout period (determined by strategy): do not accept request and wait for a priority phase

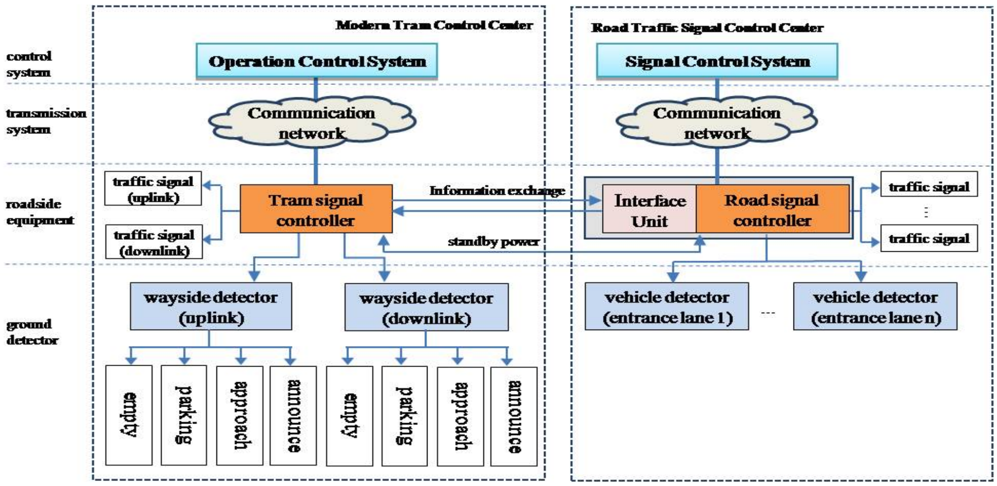

Figure 2. Communication between road signal controller and tram signal controller

2.3 Coordinated control for associated areas with tram signal priority

All intersections passing tram are designed as critical intersections. Considering that the reduction of phase green time for other motor vehicles as a result of tram priority may cause traffic flow queue-spillback upstream, it is necessary to implement signal control on the upstream intersection and select the "control arriving flow slowly and let departure flow quickly" strategy of arterial street coordinated control(Figure 3). Additionally, we implement coordinated control, such as “red-wave” and “green-wave” for main traffic flow on the lateral road.

Figure 3. Coordinate control for intersections in associated areas

(1) Red wave control in upstream intersections

Set the priority intersection as terminal point, establish red-wave band in the upstream intersections, which can make vehicles stop in the priority intersection and close partial traffic flow significantly. The fundamental principle is to close traffic flow and use existing system resources to alleviate the over-saturated traffic flow.

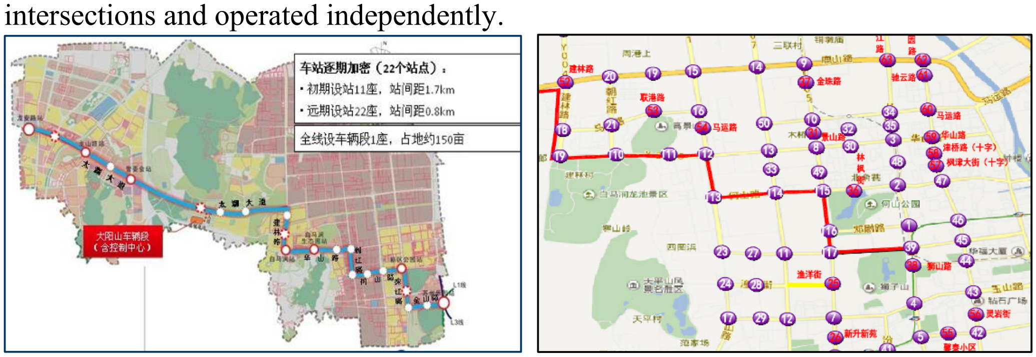
(2) Green wave control in downstream intersections

Set the priority intersection as the starting point, establish the green wave band in downstream intersections, which allows other vehicles in the priority intersections to pass the intersection with low stop ratio and alleviate the queuing in the target intersections. The fundamental principle is to allow fast passing and use existing resources to improve operating ratio.

3 Empirical application of modern tram signal control

The tram network in High-tech Zone, Suzhou, has 6 lines planned with a total length of about 80km. Tram Line 1 was opened in October 2014, and tram line 2 and line 3 are under construction now. Tram Line 1 is the first modern tram line approved by the National Development and Reform Commission in China. It has 22 stop-sites and a total length of 18km. Around tram line 1, there are 104 intersections with road traffic signal controllers installed, with HT-UTCS system provided by Wuxi HT Company, and 17 intersections installed tram signal controllers with CBTC system provided by Bombardier Company.

Coordinated priority Control strategies and proposals discussed above are applied to 17 signal control intersections of tram line 1 and 78 related grouped intersections for empirical study of the region's coordinated control. Before the construction of the tram， some road signal controllers are installed at some intersections and operated independently.



(a) Signal intersections along tram line 1 (b) Signal intersections at related area

Figure 4. Area for empirical application of modern tram

Measuring at morning peak and off-peak for two weeks, we compare operation effects before and after implementation of tram signal priority (Table 2 and 3). The result shows that the average travel speed increased from 21.7km/h to 25.6km/h and the congestion at related grouped intersections was improved after use of coordinated priority control strategy.

Table 2. Priority control effect evaluation of Suzhou Tram Line 1

Evaluation index	Before implementation of signal priority	After implementation of signal priority	Improvement percentage
Average number of parking	10	5	-50.0%
Total average stop delay	8′03″	4′46″	-40.8%
Average travel time, min	49	41	-16.3%
Average speed, km/h	21.7	25.6	+17.9%

Table 3. Coordinated control effect evaluation of related roads

Evaluation Item		Peak hour			Off-peak hour		
Road name	Average index	Before	After	Improve	Before	After	Improve
Zhujiang Rd. [Fenjin St. to Mayun Rd.]	travel time, min	2′40″	2′10″	12.5%	2′15″	1′40″	16.3%
	speed, km/h	25	29	14.3%	28	43	53.6%
Zhujiang Rd. [Yuyan St. to Xinshen Rd.]	travel time, min	3′42″	3′20″	14.9%	2′11″	1′50″	10%
	speed, km/h	21	25	17.5%	23	28	21.7%
Xiangjiang Rd. [Mayun Rd. to Majian Rd.]	travel time, min	5′08″	3′48″	23.6%	4′08″	3′17″	12.5%
	speed, km/h	25	36	45.1%	30	42	38.7%

4 Conclusion

Here we may draw the following conclusions.

(1) Coordinate priority strategy will significantly enhance operation efficiency of modern trams, and effectively reduce stop delays at intersections.

(2) Information exchange in real-time between tram signal controllers and road signal controllers at intersections can realize coordinated traffic control between CBTC and UTCS.

(3) In order to reduce the influence of tram operation vehicles to other motor vehicles, UTCS shall have good function of arterial street coordinated traffic control.

5 Recommendations for Future Research

UHF RFID labels will be used on modern trams and motor vehicles as sensors in 2015 with the hope to enhance the sensor ability of road controllers to the arrival of trams.

Some technical requirements of tram-related signal priority control functions and communication protocol will be added in modification of national standards for road traffic signal controllers and urban traffic control systems. We also suggest that tram-related laws and regulations about tramcar registration and safety inspection, driver training and testing should be established as soon as possible.

Abstract: In the field of traffic management, the development of traffic information technology has provided the technical support for ITS and has become an important means to the traffic manager, which does improve the government's administrative ability. This paper will analyze the intelligent transportation development mode of some representative cities in our country on the basis of the necessity of research of intelligent transportation system based on the public service of the big cities in our country, such as Peking Shanghai and Guangzhou through the method of systematic analysis, and advance some research methods for the big cities, and offer reference for the development of ITS in big cities in our country.
Keywords: Public service; Intelligent transportation; Development model; Systematic analysis.

1 Introduction

With the boom of global urbanization and the rapid development of our country's economy, the big cities of our country such as Peking, Shanghai, Guangzhou and Shenzhen have been deeply troubled by the traffic problems.

Sales growth rate in China's auto market in 2014 is 6.86% less than the data 8% to 10% forecast by the Automobile Association in early 2014 growth. From the data, the growth of passenger cars is still a major force in the overall growth of the automobile industry in 2014.But in all segments of the passenger car, the sales of the best selling car were accounting for 12,376,700, an increase of only 3.1 %; the sales of the SUV vehicle reached 4.08 million, an increase of 46.4%; the number of sales of the MPV is 1,914,300, a highest increase of 46.79%. Automobile Association expects the sales of China's auto will reach about 25.13 million, an increase of about 7%. The domestic sales of cars is about 24.27 million, exports is about 860,000 cars, among which the passenger car sales growth is about 8%; commercial vehicle sales increase is about 2.4 percent. It's obvious that it will cause great pressure for current road conditions in our country.

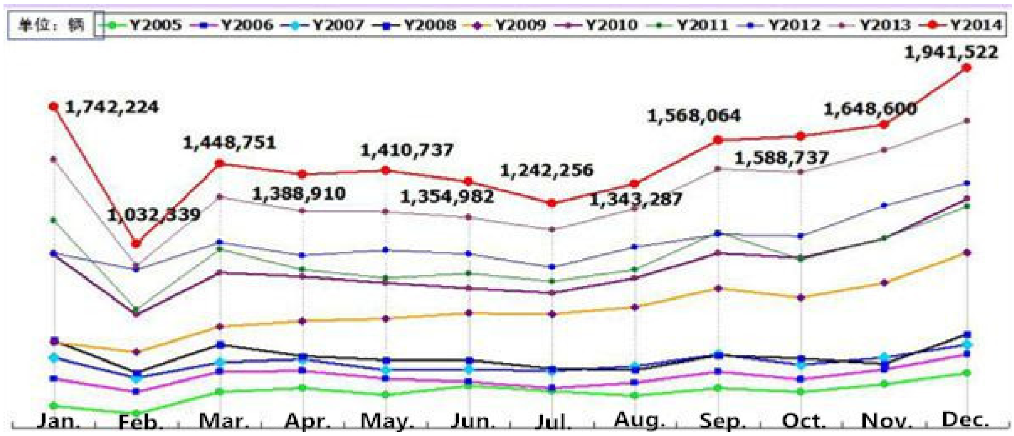

Figure 1. 2005-2014 domestic narrow passenger car monthly sales charts

2012, the ministry of transport released the "intelligent transportation development strategy (2012-2020) in the transportation industry", which pointed out: the development of intelligent transportation will not only support the transportation management,but also pay more attention to the services of public traveling and modern logistics. It will provide services for the car traveling, at the same time, pay more attention to the services of public transportation; it will focus on improving efficiency,at the same time, pay more attention to safety and healthy development; it will draw lessons of tracking technology from abroad and make full use of the new generation of information technology so as to advance the research,development and integrated application of intelligent transportation technology and product with independent intellectual property rights; it will encourage and guide the folk capital investment, as well as promote interagency and cross-industry cooperation, etc. Although intelligent transportation research is only in its infancy in China, it is bound to cause great attention from the related management departments as it is the trans-century economic growth engine and the inevitable choice of transport system construction.

2 Status at Home and Abroad

2.1Foreign research status

Governments in developed countries like the United States, Japan, Europe have put a lot of efforts and resources to the construction of intelligent traffic information services and applications, which has been regarded as a valid means of solving traffic congestion caused by urban sprawl.Dynamic traffic information service is developing into the direction of integration and platformization in order to provide better public services and improve the administrative efficiency of the government.

The United States points out seven major areas of intelligent transportation systems and 29 user services in National Intelligent Transportation System Project Planning, and develops quickly in navigation and safety monitoring system, vehicle toll collection systems, vehicle management systems.The VICS in Japan uses a variety of platform to release dynamic real-time traffic information, mainly used in navigation systems,security monitoring systems, traffic control systems and vehicle management system.The coverage of the intelligent transportation research in Europe is wider, which is currently involved in 11 countries and regions;the advanced traveler information service (ATIS), advanced vehicle control system (AVCS) and so in Europe are playing an irreplaceable role.

2.2Domestic research status

The study of intelligent transportation construction has increasingly become the focus of research scholars.The domestic first-tier cities and the SAR have developed a number of applications, which have facilitated the public to travel and got public recognition to a certain extent. These applications,however,are mainly conducted for the business of departments, which will result in phenomenons as follows.The content of information services will be confined within its business scope and the degree of information sharing is not high; the services of content, quality and range of various existing applications will need to improve and develop continuously; personalized information service approach is still in deficiency, in particular the lack of dynamic traffic information services and the main means of publication are websites and SMS.

3 Field Data

Big cities, which have a population of more than 5 million such as Beijing, Shanghai, Guangzhou , have the preliminary achievements in the field of intelligent transportation development.Analysis of development mode of these cities will provide reference to the development of other cities in the future.

Because of the economic development, which is a powerful driving force, car ownership in cities such as Beijing, Shanghai, Guangzhou is growing at an alarming rate each year.As a result, the traffic problem is increasingly complex, such as serious congestion during the peak, severe air pollution caused by automobile exhaust emissions and short supply of parking space.

As one of the cities that are the first batch of intelligent transport demonstrative cities, Guangzhou mainly exists these problems in traffic fields: lack of industrial regulatory means, inadequacy of infrastructure and regulation to drivers. For a decade,the traffic informatization in Guangzhou has realized the rapid development and a large number of traffic information infrastructure and business systems are widely used through the joint efforts from various departments, which are all the important supports for transportation industry management, enterprise production and management,as well as the travel service.

As a modern metropolis,Shanghai has set international economic, trade, financial and shipping all in one,which has also built urban traffic management control system based on the "cloud service" platform,such as Shanghai Traffic Information Center, road traffic information collection system infrastructure within the city, passenger transport services and management systems, urban traffic electronic toll collection system, the downtown parking, information services and management systems, traffic safety and emergency response management systems, and building intelligent traffic engineering research center in Shanghai.Although the development of intelligent transportation offers lots of convenience for traffic management department of Shanghai ,there still exists some shortcoming, mainly presented as the phenomenon of information island.

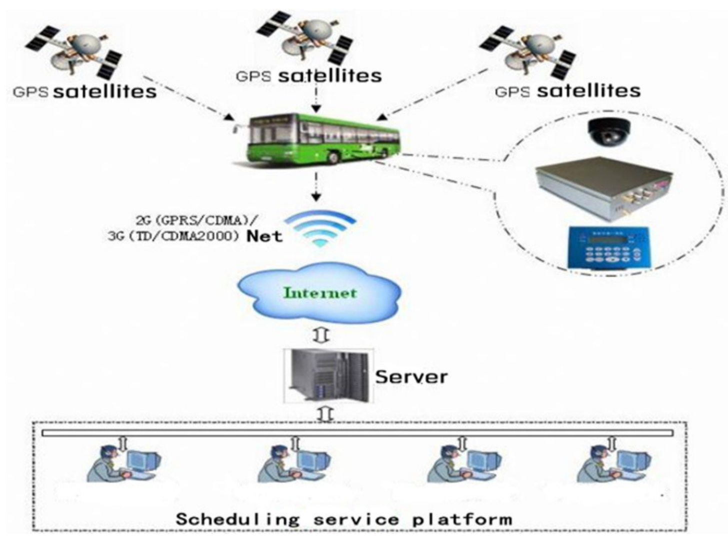

Figure 2. Urban Traffic Management Control System based on the "cloud service" platform

In Beijing, the capital of China,the vehicle ownership has constantly ranked the first around the whole country for many years. Beijing Traffic Development Outline, which has been promulgated,determines to focus on the building of the integrated information platform,aiming to improve scheduling command system, use intelligent transportation technology to build the new Beijing traffic system and realize intelligent road traffic.And this goal has been achieved to a certain degree: the completion of intelligent road traffic control management system; establishment of unified city highway information center;the opening of a municipal transportation card system construction within the city.At present, Beijing has almost built a complete intelligent transportation system, realized various operation such as gathering information intelligently, intelligent supervision, the optimal allocation of resources, which reduce the travel consumption of residents and the administrative burden of traffic department.

4 Data Analysis

Although China's major cities already have their own ITS frameworks, the use of traffic information technology is of low degree in fact. We must take the characteristics of these regions into account and use strict methods and measures to optimize the system in accordance with the government-oriented, business-oriented, market mechanisms operating mode,so as to ensure the government to deliver the optimal service.

4.1 Project needs analysis

ITS is an innovative traffic pattern developed on the basis of digital traffic and intelligent transportation, which is aiming at solving the problem of China's major cities are facing with. Therefore, it is necessary for our management department to provide the overall framework of ITS that is on the basis of public services and planned rationally in order to lay a solid foundation for the development of large cities.

4.2 Technical level to be achieved

The expected technical level is to build a management system that incorporates integrated command platform, traffic signal control system, series traffic check venting system, traffic information service system, traffic business management system as a whole.

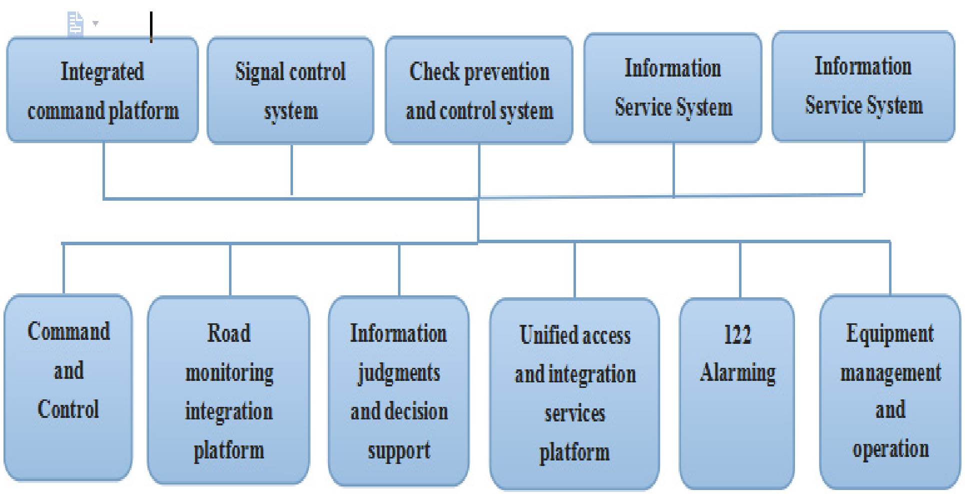

Figure 3. Intelligent traffic management system based on the metropolitan public service theory

4.3 Basic conditions for implementation of the system

(1)Foundation of preliminary work

In the foregoing, we detail the role of ITS in the public service and analyze the current development of ITS in Beijing, Shanghai, Guangzhou, which lays a foundation for the study of late.

(2) Existing study conditions

1) Policy support

Ministry of Transport in 2012 issued Intelligent Transportation Development Strategy In 2012-2020;Guangzhou in 2011 enacted Intelligent Transportation System Twelve Five-Year Development Plan (2011-2015); the Shanghai municipal government issued Action Plan To Promote The Construction Of Smart City In 2011-2013;Beijing promulgated the Beijing Transportation Development Program. All these major strategic plans are important milestones in the development of intelligent transportation. The development of intelligent transportation is genuinely related to people's lives and has a great impact for enhancing national life satisfaction. We ought to believe that the introduction of these government policies will support ITS to make considerable progress in our country, especially in the economically more developed cities.

2) Support from present situation

The development of ITS in our country started late,but with the progress of economy,science and technology,the researches on this system have made substantial progress and achievement.In early 2014, the major Internet giants made a crossover to internet of vehicles and arranged the transportation market. Our country initially established institutional mechanisms adapted to the integrated transport system,such as acceleration of the process of ETC national network, formally implement of new standards of electronic police GAT496-2014 and so on.

In March 2014, the official website of the Ministry of Transport announced that the adjustment related to responsibilities and organization in Ministry of Transport has been basically put in place, forming a large pattern of transport management department where the Ministry of Transport is responsible for managing the National Railway Bureau, China Civil Aviation Administration and the State Post Bureau. As a result,it will promote the effective convergence of various modes of transport and the integration of service.

3) Technology support

With the rapid development of internet of vehicles, cloud computing, car networking and etc,it has no problem to establish transportation systems that is closely linked by information in big cities in the future. Higher Institute of many large cities in China will also provide a steady stream of talent to support the development of this technology.

5 The Optimization Measures

According to the characteristics of the cities, here are specific project implementation plans, technical routes, the organizations and the task decomposition schemes as follows:

a.It has an advantage of low cost if using the program of combining self-developed high-speed MCU with embedded DSP network cameras .

The main chip can be made of just three dollars under the circumstance where performance parameters of HD 720p and H.264 encoding are supported to be unchanged, which is the low-cost advantage that the normal network cameras can not match .

b.Two image sensor lens share a webcam Motherboard

For the characteristic that general parking are arranged in parallel parking lane,we use the dual-lens design——one towards the left ,another towards the right,each HD lens regulators two parking spaces,further reducing the cost.

c. Abandon CCD, ues CMOS sensor

In general, industrial network cameras use CCD more, because its dynamic effect is good and it is not prone to motion image smear.However,CCD is more expensive, the general cost of the CCD network cameras is over a thousand dollars. For parking, the vehicle must be stopped, and thus can use lower-cost CMOS image sensor. CMOS has a huge amount of users in electronics market like digital cameras, so there exists an advantage of cost.

d.The recognition algorithm of camera embedded within the Slow car's license plate

In addition to the embodiment of the video detection terminal (webcam), you must also equipped with a multi-channel video processor (PC) every 25 video terminals to recognize license plate.It is no doubt that it will increase the cost of PC hardware and network cabling hardware. In this regard, for the characteristics that vehicles must stop when they are in traffic lights parking , we propose innovatively that the technical solutions to achieve slow car's license recognition in micro-controllers can complete one frame license plate recognition as long as 10 to 20 seconds, which can meet the requirements of parking license plate recognition and save the cost of PC,and network cabling.

It's no need to use Fast Gigabit Ethernet when there is no immediate transmission of HD video, but you can use WIFI wireless network,which can upload the recognized license plate information to the server.Further,it has no wiring, which is a greatly facilitate to the construction and maintenance.

e.Released real-time road information to car owner's mobile to let them master the relevant traffic situation ahead of time and avoid serious congestion.

6 Conclusions

In summary, the ITS research towards metropolis is a difficult and macroscopic systems engineering,which requires comprehensive planning and unity from the central to local and universities to enterprises.In this process, it's make great sense of leading and driving from government. Meantime, the new technology and management methods should be updated and applied continually.Lastly,it's necessary for private enterprises to enter this field. Only by this way,can we build, operate and manage traffic problems effectively, and get rid of the constraints of intelligent transportation industry development.

Detecting the Synergy between Talent Accumulation and the Effect of Intelligent Transportation Systems

Yu Liu[1,2]; Wenbin Li[1]; and Xinsong Wu[1]

[1]School of Political Science and Public Administration, University of Electronic Science and Technology of China (UESTC), Chengdu 611731, China.
[2]Information Research Center of Regional Public Administration, Key Research Institutes of Philosophy and Social Sciences of Sichuan Province, Chengdu 611731, China.

Abstract: Talent accumulation plays a vital role in improving the comprehensive benefit of Intelligent Transportation System (ITS). Based on literature reviewing, this research analyzes the synergistic mechanism between talent accumulation and the effect of ITS. According to the synergistic model, the degree of synergy between talent accumulation and the effect of ITS has been tested by using related statistical data. The results reveals the developing tendency and the level of synergy between talent accumulation and the effect of ITS. In addition, the results have both theoretical and practical implications for strengthening the effect of talent accumulation and improving the comprehensive benefit of ITS effectively.
Keywords: Talent accumulation; Intelligent transportation system (ITS); Synergy.

1 Introduction

With the development of information technology, transportation has shown the trend of intelligent improvement. In many countries, Intelligent Transportation System (ITS) has been playing a very significant role in the growth of economy and society. Intelligent transportation is of the characteristics of high intelligence, high talent accumulation and high innovation, so talent accumulation is quite important for the sustainable development of intelligent transportation. In recent years, the research around the coordination relationship between talent accumulation and ITS has become the hotspot in the field of management and economics.

Talent accumulation is a kind of special situation in the process of human resource flowing. The term of talent accumulation can be defined as a process that the talent flows from one area or industry to another because of some affection（Zha, 2014）. Under the effect of talent accumulation, the economic output will exceed the summation of the output made by single talent (Niu, 2012).

As for ITS, it is a kind of advanced transportation system based on the development of information technology. ITS cannot only properly resolve the problems of transportation for people and goods, but also drive the development of relevant information services and information industries (Yang, 2006).

Since talent accumulation and ITS are very significant for the growth of economy, the harmonious synergy between them can also bring great improvement for the effect of both talent accumulation and ITS. This research will detect the mechanism of synergy between talent accumulation and ITS based on the theory of synergy. By establishing the synergy model, this research will evaluate the synergetic levels and the trend of talent accumulation and ITS, so as to taking proper measures to improve the effect of talent accumulation and ITS in the future.

2 Model Construction

The synergetic relationship in this research means the level of the synergy between talent accumulation and ITS. In the theory of synergy, the degree of order of each variable devotes greatly to the synergy relationship of systems. Hence, the first step is to construct the model for the degree of order of each variable. In this research, the two systems of talent accumulation and ITS can be shown as $S_i,\ i \in (1,2)$. The variables of the two systems are shown as $X_{ij},\ i = 1,2, j = 1,2, \ldots \ldots n$. n is the number of variables. The model for the degree of order of variables can be shown as:

$$u_{ij} = \begin{cases} (X_{ij} - \beta_{ij})/(\alpha_{ij} - \beta_{ij}) \\ (\alpha_{ij} - X_{ij})/(\alpha_{ij} - \beta_{ij}) \end{cases} \quad (1)$$

In this model, α_{ij} and β_{ij} are the upper limit value and lower limit value of each variable, and $X_{ij} \in (\alpha_{ij}, \beta_{ij})$.

The second step is to calculate the devotion of each variable to the synergetic relationship of systems. The formula is shown as:

$$u_i = \sum_{j=1}^{n} \lambda_{ij} \times u_{ij} \quad (2)$$

In this formula, λ_{ij} stands for the weight of variables.

The third step is to construct the model for the synergetic relationship between talent accumulation and ITS. The formula is shown as:

$$C_t = f(u_{1t}, u_{2t}) = 2\{(u_{1t} * u_{2t})/[(u_{1t} + u_{2t})(u_{1t} + u_{2t})]\}^{1/2} \quad (3)$$

The value of C_t reflects the level of synergy between talent accumulation and ITS in the year of *t (t*=1, 2, 3…T*)*. In this formula, $u_i \in [0,1]$, u_{1t} and u_{2t} stand for the devotion of each variable to the systems of talent accumulation and ITS.

3 Empirical Study

3.1 Variables and Data Resource

In order to comprehensively evaluate the effect of talent accumulation and ITS, this research chooses 6 variables to describe the two systems. As for talent accumulation, the number of employee in the industry of transportation, fixed-investment for transportation and the number of patent in the industry of transportation have been selected out as the indexes to measure talent accumulation in transportation (Niu, 2012; Zha, 2014). Meanwhile, length of city road, casualty in traffic accident (negative index) and greening rate in city are used to measure the effect of ITS (He, 2010). All these variables have been extensively used in former researches. They have also been tested to be effective in reflecting the two systems.

All the data applied in this research are from the statistical yearbook of both Sichuan province and the city of Chengdu from the year of 2005 to 2013. By taking the method of principal component analysis (PCA), the weight of every variable is shown in Table 1.

Table 1. Weight of variables

Talent accumulation	Weight	ITS	Weight
The number of employee in the industry of transportation	0.333528	Length of city road	0.333196
Fixed-investment for transportation	0.333225	Casualty in traffic accident	0.333436
The number of patent in the industry of transportation	0.333247	Greening rate in city	0.333368

3.2 Results Analysis

In order to judge the developing level of talent accumulation and ITS, and the synergetic level of talent accumulation and ITS, this research divided the degrees of evaluation and synergy into four levels. See Table 2.

Table 2. Evaluation and synergy levels

Statistical values	Evaluation levels
$u_{it}, C_t \in (0,0.25]$	Low
$u_{it}, C_t \in (0.25,0.5]$	Primary
$u_{it}, C_t \in (0.5,0.75]$	Medium
$u_{it}, C_t \in (0.75,1]$	Senior

Based on the category in Table 2 and the statistical results in Table 3, we can find that the effect of talent accumulation from 2005 to 2009 was at the low level, while in 2010 and 2011, it rose up the primary level. In the year of 2012, the effect of talent accumulation in Chengdu was at the level of medium. Since 2013, it rose up to the senior level. However, the developing level of talent accumulation in Chengdu has much more space to improve.

As to the effect of ITS, the level was low in 2005 and 2006. In the year of 2007 and 2008, the level of ITS effect was at the primary stage. After 2009, the level of ITS effect rose up to the senior level. All in all, ITS effect of Chengdu has been at the high level in recent years.

Although the developing level of talent accumulation was low from 2005 to 2008, the synergetic relationship between talent accumulation and ITS was at the level of primary and medium. Since 2009, the level of synergy for both of the two systems was senior. Hence, the synergetic level of talent accumulation and ITS in Chengdu has shown a good condition in recent years.

Table 3. Evaluation and synergy of systems

Years	Evaluation of talent accumulation	Evaluation of ITS	Synergy
2005	0.00	0.182912	0.00
2006	0.039541	0.202186	0.739781
2007	0.060391	0.290406	0.755027
2008	0.084399	0.500612	0.702723
2009	0.195863	0.666472	0.837956
2010	0.318956	0.756068	0.913603
2011	0.388546	0.799626	0.938243
2012	0.544546	0.908976	0.968059
2013	1.00	0.955014	0.999735

Figure 1 shows us the trend of evaluation for talent accumulation and ITS in nine years. From this figure, we can find that the developing level of ITS is higher than that of talent accumulation in Chengdu, though both of them show fast improvement during the last few years. Meanwhile, this figure shows that the synergetic level of both systems has been high enough at almost senior stages since 2006.

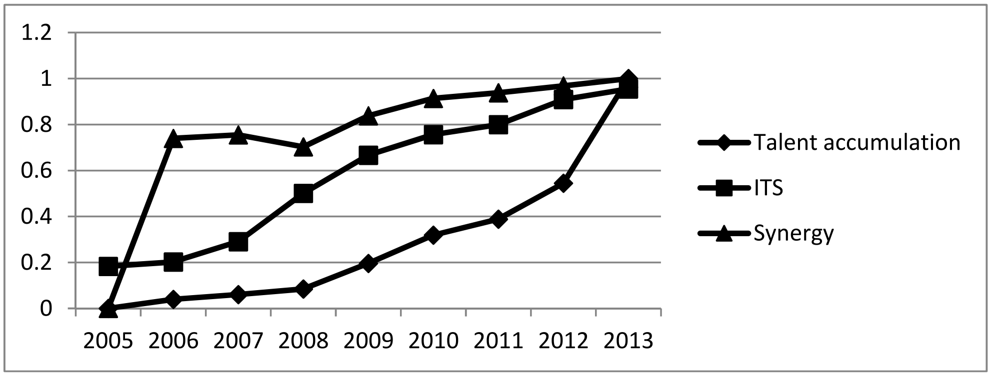

Figure 1. Trend of evaluation and synergy of systems

4 Conclusions

According to former studies, this research selected 6 indexes to describe talent accumulation and ITS. By using the model of synergy, the data which stem from the city of Chengdu from the year of 2005 to 2013 were used to evaluate the developing level to talent accumulation and ITS. The synergetic relationship between the two systems has also been detected in this research. The results clearly show that the level of synergetic relationship between the two systems was at the senior stage from 2006 to 2013. However, the underdeveloped talent accumulation in Chengdu will attract more attention to propose effective measures for improving the effect of talent in the industry of transportation.

Abstract: Traffic flow parameters detection is one of the most critical parts of the intelligent traffic management system in currently. With the continuous development of computer vision and image processing analysis technology constantly development, video detection technology in the traffic parameters testing is more and more attention. Video automatic detection technology utilization of computer vision, image processing and analysis, pattern recognition technology, compared with traditional detection technology induction loop detector, microwave radar detector and magnetometer detector, etc. The video automatic detection has many advantages, such as simple installation, convenient maintenance, not to harm the roadbed, low cost, high accuracy, and wide monitoring area. Firstly, the image sequence can be acquired through the video automatic detection equipment mounted over the road, and then two 2D spatial-temporal images, a panoramic view image and an epipolar plane image, are formed for each lane in this article. By using the methods of constructing a general epipolar plane image model, to reflect the vehicle surface characteristics and movement characteristics of the driveway. Then put forward the texture Canny texture edge detection algorithm of image based on Gabor filter, according to the texture edge detection of three steps: normalization processing, filtering processing and edge texture detection, analyzes the edge texture detection algorithm of epipolar plane image, and provides normalized epipolar plane image, presented the specific calculation method and formula of Canny texture edge detection based on Gabor filter. Finally, according to the graphics after processing, examines traffic flow parameters detection for traffic volume, vehicle speeds and lane occupancy and analyzes summary of the whole algorithm.
Keywords: Computer vision; Epipolar plane image; Traffic flow parameters; Canny edge detection.

1 Introduction

The traffic parameters mainly consist of traffic flow、traffic density ,velocity and the queuing length, etc. The detection of traffic parameters is a key segment of traffic control and management. Through detecting, analysis and controlling the traffic flow parameters, it can enhance the road transportation capacity, reduce the traffic accidents and adjust the traffic distribution of the road network (PG Michalopoulos, 1991; Brian Carlson, 1997).

There are lots of detection measures of the traffic parameters, such as ultrasonic, infrared detection, annular induction coils and computer vision. Ultrasonic detector is in low accuracy, easily influenced by vehicle barrier and pedestrian, and with short detecting distance (not more than 12 m in general); infrared detector is easily affected by heat source of the vehicle itself, and has low accuracy and resistance to the noise; annular induction coils detector has high accuracy, but it has to be set in the roadbed which will damage the roadbed and is inconvenient to the installation and construction. It also needs lots of loops; computer vision detector will use the technology of image processing, artificial intelligence, pattern recognition, etc. To collect the information of vehicle and traffic parameters from the video digital image.

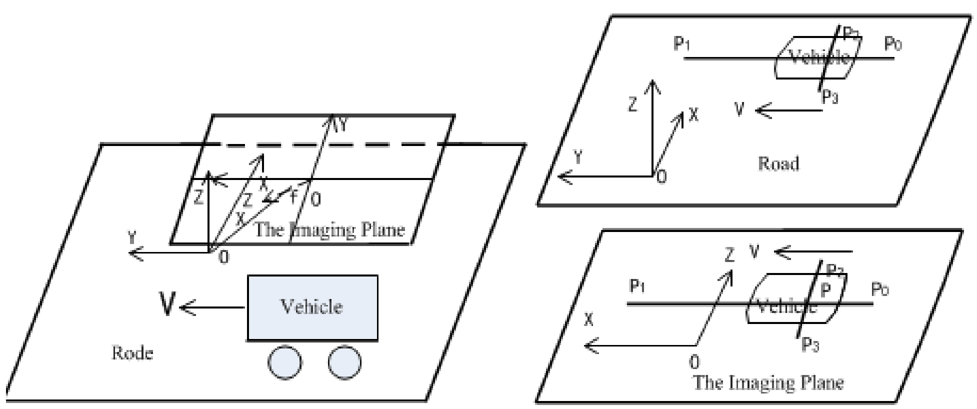
Traffic monitoring system based on video normally use the videos set on the roadside or above the road to acquire the relatively stable traffic scene images in a long distance, detection, vehicle tracking, and traffic flow parameters detection, etc. The vehicle detection methods based on video mainly have streamer method (PG Michalopoulos, 1991), adjacent frame differential method (Brian Carlson, 1997), background subtraction method (Barron J, 1994). Each method has the advantages and disadvantages. Streamer method has very good accuracy and large calculated amount; adjacent frame differential method can detect moving object under the variable background, but may easily lost the detection of slowly moving vehicles, and make one vehicle into several parts; background subtraction method is a commonly used method under the regular background. Its detective effect depends on background updates algorithm, so when background updates has high reliability, it has good effects. As it has characteristics in small calculated amount and high reliability, it has a good instantaneity and practical applicability. In some papers, the method of neural network and SVM (support vector machine) have been used to the traffic video detection field, such as Sun (Lipton A, 1998) use Gabor filter to collect various image characteristics and train SVM grader to realize the vehicle detection. But in these kind of the methods, as it first need to train the traffic image, the processing is complex and instantaneity is not good.

The vision detecting technique has been a hot spot of research in ITS with the particular advantages such as broad view, low cost and intelligence. In traffic monitoring system based on vision, the videos are set on the roadside or above roads to get the relatively stable traffic scene image in a long distance, which then are used image processing technique to conduct vehicle detection, vehicle tracking, and traffic flow parameters detection, etc. As the detection and track in the vision traffic monitoring is at the low level of the whole traffic monitoring system, it needs to collect vehicle information from video sequences image in real-time, constantly track them and provide the basis for the analysis of the traffic information in further. The most important part of the process is how to get good traffic background image from the vehicle operating. It is the key segment to gain the real-time traffic background image in the traffic vision monitoring system. And selecting the adaptive algorithm of background extraction is the most important part of the visual detection research.

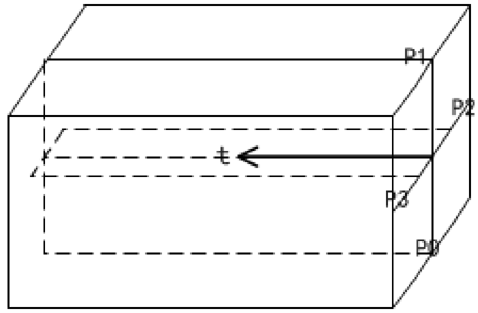
2 Acquisition of Epipolar plane image model of the vehicle motion

2.1 Epipolar plane image model under ideal conditions

The ideal imaging geometric model of the epipolar plane image is shown as Figure 1, in which the projection axis of surface X-axis and Y-axis in the image plane, respectively, is Y direction and X direction. Through stable image, a complex movement of vehicles can be effectively separated with complex background. Because the camera is stationary with the road, it can get a stable image, in which vehicles move or stay along the straight road. Suppose the vehicle is at $X=X_1$, and moves along Y-axis. As the projection of line $X=X_1$ at the image plane is $y=y_1$,the line segment on the vehicle along the Y direction at $X=X_1$ is the projection of the line plane. As in Figure 1(b), the vehicle on the road moves from point P_0 along P_0P_1. Suppose the image plane is paralleled with the road surface, so that on the image plane, the vehicle will travel along P_0P_1, and on the timer shaft, then to take the segment P_0P_1 paralleled with X-axis plane to produced the epipolar plane image. This is an ideal model between the road surface and he image plan. As in this model, the vision must be perpendicular to the road surface and need the higher installation accuracy, it is not often used.



(a) The vehicle motion model **(b) The relationship between the road plane and imaging plane**

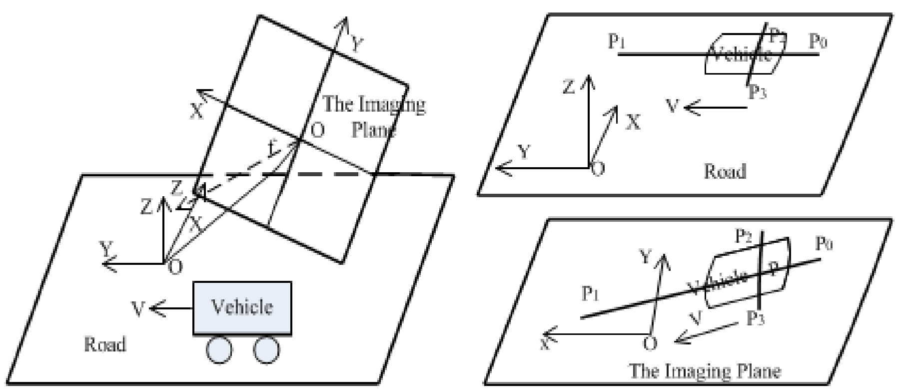


(c) The epipolar plane image of vehicle

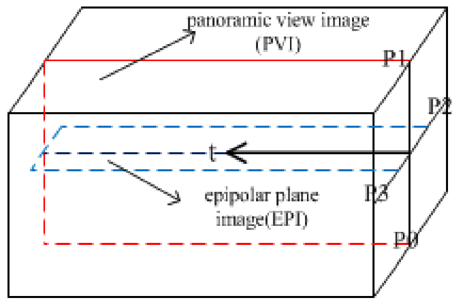
Figure 1.The imaging geometry of epipolar plane image under ideal conditions

2.2 Epipolar plane image model under actual conditions

In this paper, a detection model of road traffic parameter used for a real traffic scene is presented as Figure 2. Suppose the coordinates of the rode surface is XYZ, in which X, Y direction is on road surface. X-axis is perpendicular to the lane. Y direction is paralleled with the lane, Z direction is perpendicular to the road surface, as in Figure 2(a). As the vehicle usually drives along with the lane, this model is suitable for the traffic parameter detection of various flows. In the road coordinate system, as P_0P_1 along the lane, the projections of P_0P_1 and P_2P_3 on the image plane are P_0P_1, P_2P_3, but P_0P_1 is not paralleled to the X-axis(Figure 2(b) below). Suppose the vehicle on the road drives from point P_0 to point P_1 along P_0P_1, then on the image plane, the vehicle will drive along P_0P_1. And on the timer shaft the line segment P_0P_1 takes shape epipolar plane image (Figure 2(c) below). This is a general relationship model of the road plane and image plane. In order to prevent the blocking of vehicle, the video should be installed at a certain height above the lanes.



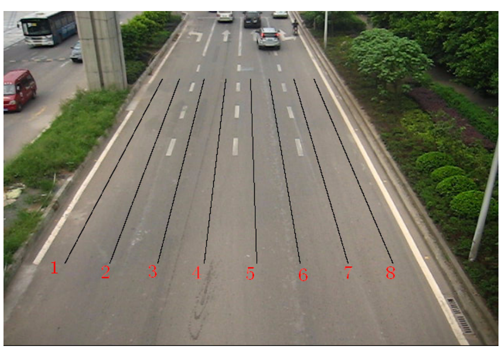
(a) The vehicle motion model **(b) The relationship between the road plane and imaging plane**



(c) The epipolar plane image of vehicle

Figure 2.The imaging geometry of epipolar plane image under actual conditions

In this paper, an example in Wuhan is taken. The video is installed above the road surface 6.5m. The taken image sequences of Four-lanes one-way are in 1280×720.In the middle of each lane, it is taken two line segment-t sections in a group. With about 1.5m, eight epipolar plane images are made up as Figure 3.Two epipolar plane images constructed by any straight segment-t section can detect the traffic parameters of one lane. Every epipolar plane image is plane projection of the contour of the vehicle on a line segment and camera projection center. The vehicles motion and the airspace feature of road surface formed directional texture. It basically reflects the characteristics of the surface and the movement of vehicle in each lane.



(a) The position of line-t section **(b) The epipolar plane image**

Figure 3.The panoramic view image and epipolar plane image of vehicle motion

3 Texture edge detection of epipolar plane image

Texture detection is active field in the research of the computer vision. In general, there are 6 characteristics of texture distribution: sparse, contrast, directional, contiguous, constant and roughness. Based on these characteristics, the existing texture segmentation method can be generally divided into the following categories: the measure methods based on the symbiotic, the method based on markov, the method based on Gabor filter and the method based on fractal. The first three image texture segmentation methods were based on the structural properties and the statistical properties. It is shown by Pentland (Jain R, 1984) that the fractal model effectively covers all the second order change information of the image. Fractal model can have more than three kinds of model ability in theory. There are two fractal characteristics commonly used: Fractal Dimension, FD and Lacunarity. The first one measures the vision roughness of texture to some degrees. The second one contains some information of the texture element.

The basic process in texture edge detection is divided into three steps: normalization dispose, filtering, and texture detection.

3.1 Normalization

The function of normalization can make gray value reach to a predetermined mean value and variance and also to strengthen the effect of the whole image contrast. The function which the normalization adopted is:

$$\mathrm{N(i,j)}=\begin{cases} M_0+\sqrt{\dfrac{V_0(I(i,j)-M)^2}{V}}, if\ \mathrm{I(i,j)>M} \\ M_0-\sqrt{\dfrac{V_0(I(i,j)-M)^2}{V}}, if\ \mathrm{I(i,j)\le M} \end{cases} \tag{1}$$

In which $I(i,j)$ for the gray value of the pixel M_0, for the average of the expected V_0, for the variance of the expected, M for the estimated means of the gray value of $I(i,j)$, V for the estimated variance of the gray value $I(i,j)$, and $N(i,j)$ for the gray value of the pixel spot $I(i,j)$ after normalization.

3.2Canny operator texture edge detection

Here Canny operator is used to detect the texture characteristic of epipolar plane image, which can make the color epipolar plane image to do the gray-scale and the normalized, as shown in Figure 4 show.

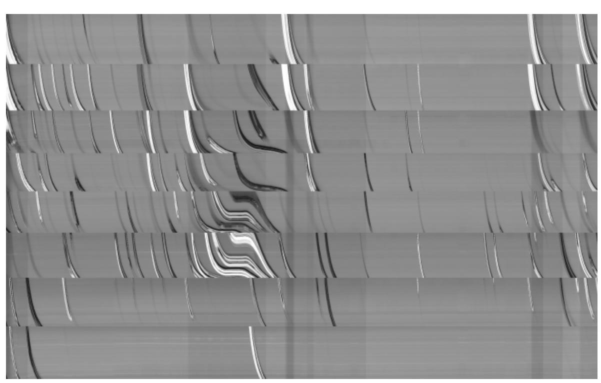


Figure 4.The epipolar plane image after gradation processing

To the epipolar plane image after gradation processing, after the texture is detected by Canny operator, Gabor filter is used to remove the noise points, then the field method is used to keep the edge of the high strength, and connectedness is used to eliminate the particles and the islands to obtain the binarization of epipolar plane image, as shown in Figure 5. This is used as the input graph of the traffic parameter detection and the standard graph of the traffic parameter detection follow-up.

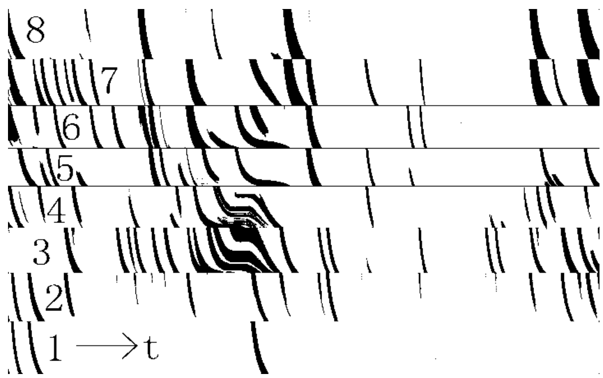

Figure 5.The input graph of the traffic parameter detection

3.3 Canny texture edge detection based on Gabor filter

Gabor transformation uses Gaussian function, $g(t) = \frac{1}{2\pi a} e^{-t^2/4a}$, in which $a > 0$ is contained as window function, Gabor transformation is:

$$G\left[f(b,v)\right] = \int_{-\infty}^{\infty} f(t) g^*(t-b) e^{-jwt} dt = \frac{1}{2\pi a} \int_{-\infty}^{\infty} f(t) e^{-(t-b)^2/4a} e^{-jwt} dt \qquad (2)$$

In the plane, Gabor transform is dense. Gabor wavelet has been widely used in the field of image processing and pattern recognition, especially in the feature extraction of texture image. Gabor wavelet is a plural sine function of rotating Gaussian modulation (Sun ZH, 2002). Commonly used even symmetric Gabor wavelet in two dimensions shown as type (1):

$$g(u,v,\theta) = \frac{1}{2\pi\sigma_u\sigma_v} \exp\left\{-\frac{1}{2}\left[\frac{u^2}{\sigma_u^2} + \frac{v^2}{\sigma_v^2}\right]\right\} \times \cos(\omega u) \qquad (3)$$

with $u = x\cos\theta + y\sin\theta$, $v = -x\sin\theta + y\cos\theta$

In which, θ for the parameters of the small wave direction angle; (x, y) and (u, v) for the original coordinate system and the transformed coordinate system; σ_u and σ_v respectively for Gaussian envelope constant; ω for The frequency of a small wave. In this paper, improved Canny operator, improved texture edge detection process shown in Figure 6.

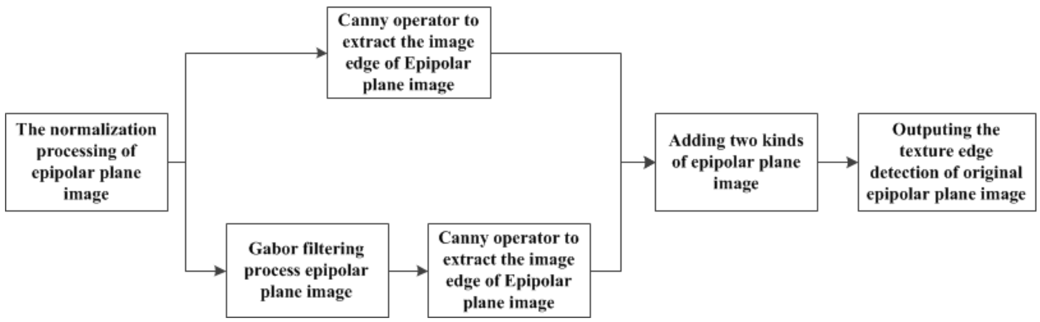

Figure 6.The processing of canny texture edge detection based on Gabor filter

In general, a planar Gabor wavelet consists of a band-pass filter at the direction of μ, and a low pass filter at the direction of ν (perpendicular to μ).The bigger σ_u and σ_v; the more slow attenuation of Gabor wavelet respectively on the direction of μ and ν. By type(1),it is known that the nature of the coordinate transformation from (x, y) to (u, v) is the original coordinate system rotated about $\theta + \pi / 2$ .This is because when vehicles is passing across the testing lines, it generally has a certain speed ,so that it leaves a outline texture on the epipolar plane image within $(0, \pi / 2)$. If $\theta = 45°$, $\sigma_u = 4$, $\sigma_v = 4$,the results of Gabor wavelet transform can be got as shown in Figure 7.

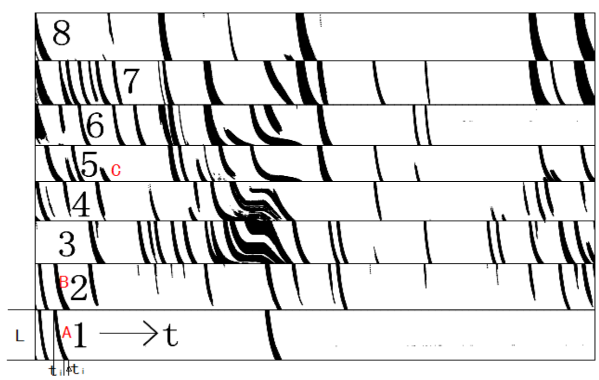

Figure 7.The input graph analyses of the traffic parameter detection

4 Traffic Flow Parameters Detection

The input graph of traffic parameter detection is shown as Figure 5 where every black curve shows that a vehicle is passing by a detection line of epipolar plane image. A part of the curve in the figure is not traversing the whole detection line of epipolar plane image, because the vehicle is deviate from the detection line of epipolar plane image sometime. According to Figure 7, the corresponding technical means are used to analysis various data of traffic detection. The traffic parameters analysis results are as follow:

4.1Model of vehicle detection

Because traffic is the important information in the acquisition of traffic data, the number of traffic section can be determined through detecting the vehicles exist and calculating it. It is shown from Figure 7 that, on a lane, a short black line shows the existing of vehicle. If there are two detection lines, the vehicle could be deviate from the lane, then there will be a half of short line on the detection line, or the repetitive lines on the corresponding lane. It needs filter to determine the number of vehicles. As shown in Figure 7, because C line in the fifth lane is only a short section, it can be deleted in statistics. Only when the length of line l≥l0, we consider it to be a existed vehicle, in which l0 is the shortest line as the statistical vehicle. In meantime, the two detection lines in the adjacent lane is close, the vehicle could be deviated from the lane. When the vehicle is driving in two lanes at the same time, it could be shown that there are two vehicles driving in two lanes while there is only one actually. In statistics, the repeated vehicle should be deleted. For example In Figure 7, the starting points of A in the first lane and B in the second lane are at the same time position, and their end points are at the same time position, and the widths of the two line are very close as well. It is shown that when there is only one vehicle, so in the statistics, it should get rid of the repeated one in the adjacent lane. Finally after calculating the total number of the lines in each lane, eliminating the repeated one and the one beyond the reach of the requirement, the remaining number will be the number of vehicle passing by.

4.2 The detection model of the speed

The speed of vehicle is the important data of the traffic data acquisition as well. Through the analysis of the input graph of the data detection, the speed at which the vehicle is passing by the detected area can also be detected. It can get the time of which the vehicle is passing by the detected area from Figure 7. Then get the speed of vehicle from the length of the detection line. As the A segment in the first lane, it shows there is a vehicle passing by. The time interval of the start point and end point of the segment is t_i. And the length of the detection line is *L*, then the speed of the vehicle is $V_i = L / t_i$.

4.3 The detection model of the time occupancy

The time occupancy is the percentage that the cumulative time of the vehicle passing by a certain section divided by the minute in the unit minute. It is known from the figure that if the time of the vehicle passing by a certain section is Δt_i, the statistic of traffic flow during t is n, the time occupancy can be obtained in.

$$R_s = \frac{1}{t}\sum_{i=1}^{n} \Delta t_i \left(\%\right) \tag{4}$$

In which, R_s :the time occupancy,%; t -the unit minute, s; Δt_i :the time s of the first car I passing by a certain section; n :the number of the vehicle through the observation section within the unit minute.

5 Conclusions

This paper presents a new traffic flow parameters based detection methods in computer vision-traffic flow parameters outside the pole face detection method based on image, the main idea is: first build to reflect each lane of the vehicle by the surface characteristics and kinematics Construction of the outer pole face image, the paper outside the Vehicle motion pole face image model gives a detailed analysis. Then, by its normalization process with improved Canny operator for texture detection, Canny improved operator to overcome the traditional Canny operator to detect the presence of the edge of the rough edges, noise-sensitive shortcomings. The calculation method is given Gabor texture edge detection operator. Finally illustrate the rationality and the specific implementation method based on detection of traffic flow parameters outside the vehicle treated pole face images. The practical application proved that the new method proposed in this paper not only has all the advantages of video detection technology, also has a fine edge extraction, strong noise immunity, etc., is a new traffic flow parameters.

Traffic Guidance Strategy of Urban Freeways Based on Model Predictive Control

Kaifan Dong; Jiayue Gu; Hongtong Qiu; and Ye Yuan

Traffic Management Research Institute of Ministry of Public Security, Jiangsu Province Collaborative Innovation Center of Modern Urban Traffic Technologies, Wuxi, Jiangsu 214000. E-mail: dongkaifan@163.com

Abstract: Urban freeway, as the important carrier of urban transportation, played the role of skeleton in the urban traffic network. It was of vital importance for the entire road network to induce traffic flow of urban freeway reasonably. Firstly, the traffic guidance strategy of urban freeway based on Model Predictive Control was explored. The strategy aimed at minimizing the total time spend. A dynamic expressway network traffic flow model was adopted as the process model. Finally, a simulation case study was presented under different scenarios .The results indicated that the traffic guidance strategy of urban freeway based on Model Predictive Control reduced the total time spent and improved the operational state with good stability and operability.
Keywords: Urban freeway; Model predictive control; Total time spend; Simulation case; Stability.

1 Introduction

Since the beginning of the 21st century, with the acceleration of urbanization and the rapid development of China's social economy, the city's size, population and vehicle fleet have showed significant growth trend. The main contradiction of urban transport is that the limited road resources can't meet the increasing traffic demand. There are more and more traffic congestion and accidents. This series of questions have restricted the sustainable development of cities seriously.

The guidance strategy of urban freeway is mainly by regulating traffic distribution in the network nodes to change the distribution of traffic from the perspective of space. Previous studies used accurate traffic flow model, taking the open-loop control strategy, allowing the system to maintain the optimal operating condition from the overall perspective. However, the volatility of this strategy is great, destabilizing the system. It is difficult to achieve in the actual guidance strategy. Based on this practical problem, this paper presents the guidance strategy of urban freeway based on model predictive control. It will induce strategy into the sliding window operation to increase the stability of the system. Model predictive control is the current research frontier. There are few studies abroad in the transport sector. The article describes the basic principles and mathematical model of model predictive control, process models, and so on. Finally, it studies the stability of model predictive control by analyzing the simulation results.

2 Mathematical models of model predictive control

The control is applied in a rolling horizon scheme: at each time instant k a new optimization is performed over the prediction horizon [k, . . ., k + Np - 1], and only the first value of the resulting control signal (the control signal for time instant k) is applied to the process. The next time instant k + 1 this procedure is repeated. To reduce complexity and improve stability often a control horizon Nc ($\leq$Np) is introduced, and after the control horizon has been passed the control signal is taken to be constant(Bellemans,2006). So there are two loops: the rolling horizon loop and the optimization loop inside the controller. The loop inside the controller of Figure1 is executed as many times as needed to find the optimal control signals at time instant k, for given Np, Nc, traffic state and expected demand. The loop connecting the controller and the traffic system is performed once for each k and provides the state feedback to the controller. Recall that this feedback is necessary to correct for (the ever present) prediction errors, and disturbance rejection (compensation for unexpected traffic demand variations). The advantage of this rolling horizon approach is that it results in an on-line adaptive control scheme that allows us to take changes in the system or in the system parameters into account by regularly updating the model of the system. In conventional MPC heuristic tuning rules have been developed to select appropriate values for Np and Nc(GAN Hongcheng,2011).

One of the main parameters of MPC is the length of the prediction horizon Np, the number of samples for which the behavior model is predicted (Hegyi, 2005). One should choose Np long enough to include all relevant system dynamics in the prediction.

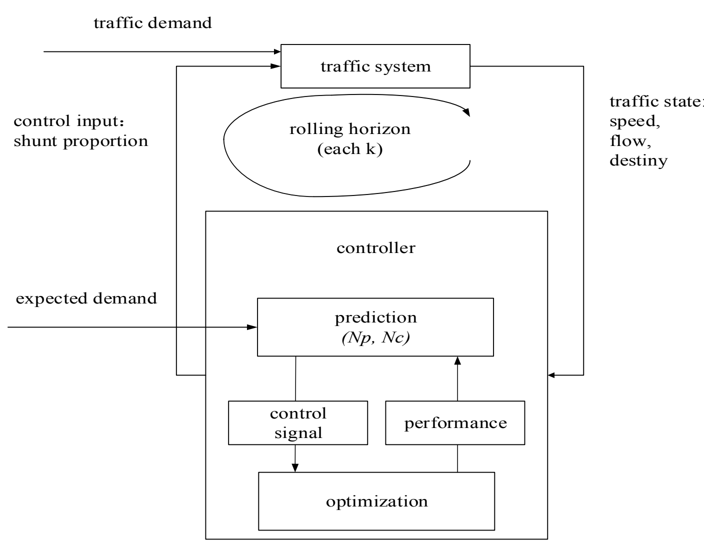

Figure 1. Schematic view of the model predictive control (MPC) structure.

3 Simulation

The benchmark network for the experiments is chosen as simple as possible (see Figure 2), since we want to focus on the relevant points of the approach presented in this paper. The network consists of a main-stream freeway with two origins and two destinations. There are two paths for drives to choose at node ②. "②-④-⑤"is defined as the main path L1. "②-④-⑤" is defined as the secondary path L2.Simulation time(see Figure 3) is chosen from 7: 00 am to 10: 00 am.

Dynamic expressway network traffic flow model (METANET)is adopted as the process model (Messmer, 1990; Papageorgiou, 1998).TTS, total time spend ,includes the total travel time and the total waiting time(Messmer, 1998; Sanwal,1993).

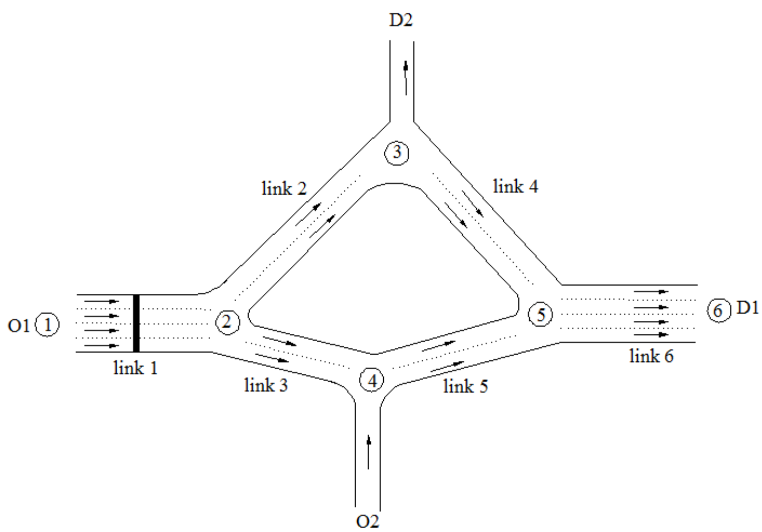

Figure 2. Benchmark network

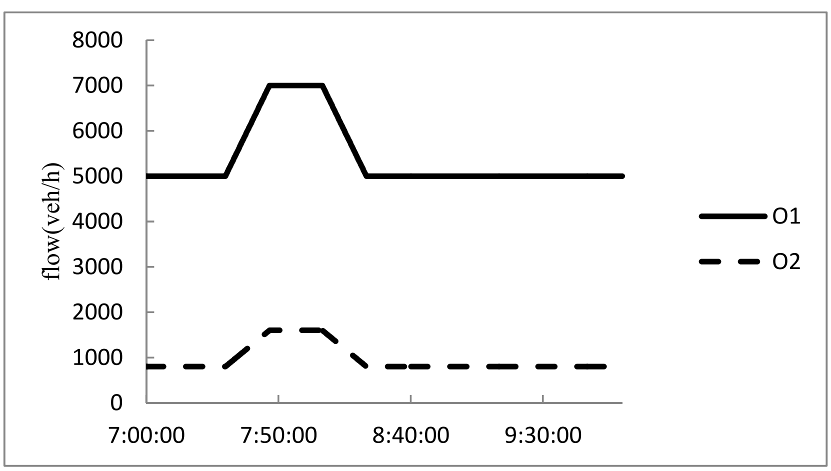

Figure 3. The demand scenario considered in the simulation experiments

3.1 Uncontrolled case

At the start of time, due to the low traffic demand, the road network is running in a smooth state. Traffic demand is increasing gradually. Downstream of the confluence node ④ appears congestion firstly. Traffic can not flow out of the road network successfully. Congestion begins to spread to the upstream. Since then, traffic demand begins to reduce and congestion begins to eliminate. Road network returns to smooth state gradually. The TTS in the uncontrolled case is 4778.0 veh * h.

3.2 Open-loop control case

Taking the urban freeway network as an example, traffic guidance strategy is divided into open-loop control strategy and model predictive control strategy. The strategy aims at minimizing the total time spend. For the node ②, we set shunt proportion $\beta_{D1}^{L1}(k)$ as the control variable, it stands for the proportion of traffic that select main path L1 at node ②, then $\beta_{D1}^{L2}(\mathrm{k}) = 1 - \beta_{D1}^{L1}(k)$. Optimization trajectory of shunt proportion is as follows.

$$\beta_{D1}^{L1}(k) = \{\beta_{D1}^{L1}(0), \beta_{D1}^{L1}(1), \beta_{D1}^{L1}(2), \ldots\ldots, \beta_{D1}^{L1}(K-1)\}$$

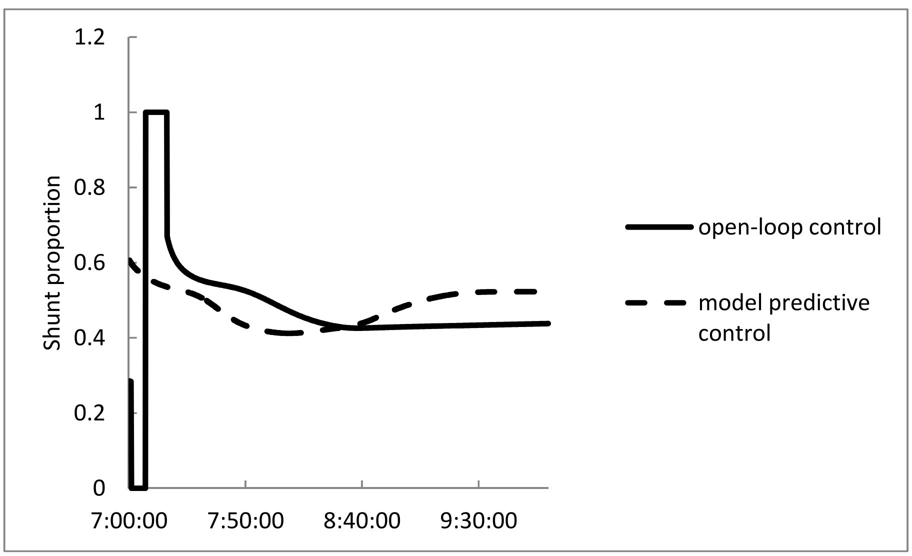

Figure 4. Optimization trajectory

As shown in Figure 4 , optimization trajectory of shunt proportion for open-loop control curves abrupt relatively and has large volatility. Under the open-loop control, in the 7:01: 00-7: 07 time period, shunt proportion is 0. At this point, all the drivers at node ② select the secondary path L2.The traffic of link 3 is zero. The traffic of O1 all flow into link 2.In the 7:07: 10-7: 16:10 time period, shunt proportion is 1.

Compared with the previous period, traffic distribution on the road network appears an opposite trend at this time. All the drivers at node ② select the main path.Traffic, including O1 and O2, loads on the main path fully. Secondary path, including link 2 and link 4, is idle. Shunt proportion is reducing gradually over the time. In the 7:50:00-8:05:40 time period, shunt proportion is 0.5.It indicates the equal probability for drivers to select the main path or the secondary path at node ②.The two paths share the traffic demand from O1 averagely.Finally, the shunt proportion maintains 0.43.Under the open-loop control, the shunt proportion changes from 0 to 1 suddenly, indicating the poor stability and difficulty of achieving. The TTS in the open-loop control case is 4100.5 veh*h, which is an improvement of 14.2%.

3.3 Model predictive control case

In the model predictive control case, the optimization trajectory of shunt proportion is as follows.

$$\beta_{D1}^{L1}(k) = \{\beta_{D1}^{L1}(0), \beta_{D1}^{L1}(0) \ldots \beta_{D1}^{L1}(k_s - 1), \beta_{D1}^{L1}(k_s), \beta_{D1}^{L1}(k_s) \ldots, \beta_{D1}^{L1}(2k_s - 1) \ldots \beta_{D1}^{L1}(K - 1)\}$$

As shown in Figure 4, compared with open-loop control, the shunt proportion of model predictive control changes gently, with less volatility, good continuity and operability. Trajectory curve shows the tendency of rise after the first drop. Finally, shunt proportion is 0.5, indicating the same possibility of two paths. The TTS in the open-loop control case is 4337.7 veh*h, which is an improvement of 9.2%.

In summary, the two traffic guidance strategies both reduce the TTS at varying degrees, improving the utilization efficiency of the road network in time and space. However, the open-loop control only considers the optimal control strategy in the current time. It achieves the best results in theory. But it is none of possibility to realize in reality. The model predictive control, as the real-time feedback control method, has more practical significance, though the improvement is reducing. During the model predictive control period, traffic flow changes smoothly.

4 Conclusions

This paper proposes the urban freeway guidance strategy based on model predictive control to solve the practical problems. The simulation results show that MPC eases road congestion effectively, with good stability and prospect.

5 Recommendations for Future Research

We will study artificial intelligence algorithms and robustness of MPC, aiming at providing theoretical basis and technical guidance for the management of urban freeway.

Model and Algorithm of Urban Road Discrete Network Design Based on CO Emissions

Jian Li; Weixiong Zha; and Tingting Zhu

Institute of Transportation and Economics, Humanities and Social Sciences Research Base of Jiangxi Province, East China Jiaotong University, Nanchang 330013, China.

Abstract: Network design is to optimize traffic network system performance by choosing to build or improve road sections under the given constraint conditions. This paper established a bi-level programming model of discrete traffic network design with optimization of environment protection and user goals, and designed a global optimization algorithm for solving the model based on the genetic optimization algorithm. This algorithm is simple and easy to implement, and the corresponding algorithm procedures have been developed in MATLAB platform. The validity of model and algorithm has been tested by Sioux Falls network and the results showed that the model and algorithm can be well applied to medium-sized network.

Keywords: CO emissions; Discrete network design; Bi-level programming; Genetic algorithm.

1 Introduction

Urban road network is the skeleton and infrastructure of a city, so a good network can relief the contradiction of supply and demand of urban traffic and promote sustainable and rapid development of urban social economy. The urban road network design problem (Network Design Problem, NDP) is an optimal investment problem: given certain constraints, by improving the capacity of existing roads or building new roads to make specific traffic system performance optimization. This paper presents a bi-level programming model with the upper model based on the minimization of co emissions and aggregate travel time of network system and the lower model based on user equilibrium traffic assignment. Basing on low-carbon urban road network design, with the combination of environment and network design, will not carry an important theoretical value but also a practical significance in solving problems of social and traffic.

2 Models and Algorithm

2.1 Models

Upper model in this paper is double objective programming model, as shown in formula 1. The objective of model is the minimization of CO emissions and a total travel time of network system under the constraints of investment budget, through the selection of road to widen or newly build by decision-makers.

$$\underset{y}{Min}\ E_S = w_1 \sum_a (167.154 - 5.2911 v_a + 0.0662 v_a{}^2 - 0.0003 v_a{}^3) \cdot l_a \cdot x_a + w_2 \bullet t_a \bullet x_a \quad (1)$$

$$\text{s.t.} \ \sum_a \tau_a \bullet y_a \le B \quad (2)$$

$$y_a \in (0,1), \forall a \in A \quad (3)$$

$x = x(\mathrm{y})$ can be obtained by the lower programming model. Lower model is user equilibrium traffic assignment model, as shown in formula 4.

$$\underset{x}{Min}\ Z(x) = \sum_a \int_0^{x_a} t_a(\omega) d\omega \quad (4)$$

$$\text{s.t.} \ \sum_k f_k^{rs} = q_{rs}, \forall r \in R, s \in S, k \in P \quad (5)$$

$$f_k^{rs} \ge 0, \forall r \in R, s \in S, k \in P \quad (6)$$

$$x_a = \sum_r \sum_s \sum_k f_k^{rs} \bullet \delta_{a,k}^{rs} \ge 0, \forall a \in A \quad (7)$$

$$t_a(x_a) = t_a \bullet [1 + 0.15(x_a / (c_a + y_a \bullet (pc_a - c_a)))^4] \quad (8)$$

Define:

w_1、w_2—weight of total CO emissions and total travel time, denotes degree of importance attached to different targets of network systems;

E_s、Z—objective function of upper model and lower model;

τ_a—construction cost of widening or building new road;

y_a—decision vector of whether to widen or newly build road;

B—investment budget in upper model;

R、S—sets of origin and destination in road network;

P—all of path sets in road network;

A—all of node sets in road network;

x_a—link flow of section a ;

l_a—link length of section a;

t_a—traffic impedance of section a, travel time;

$t_a(x_a)$—travel time function of section a;

c_a—traffic capacity of section a at present;

pc_a—traffic capacity of section a in the future;

f_k^{rs}—traffic flow of the k-th path between origin and destination of rs;

q_{rs}—traffic flow between origin and destination of rs;

$\delta_{a,k}^{rs}$—relation variables of section and path.

2.2 Algorithm

2.2.1 Algorithm Process

The road network in this upper model is established using GA, and it distributes UE traffic assignment in lower model to get traffic flow of each road according to the OD demand and the network obtained by upper model. Finally it puts the traffic flow into the upper model to determine fitness, as shown in figure 1:

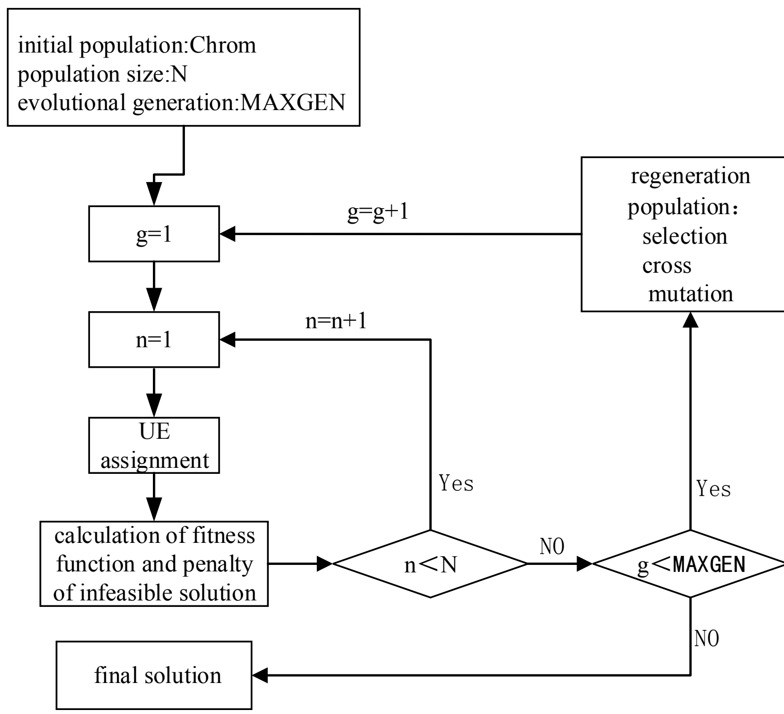

Figure 1. The Flowchart of NDP Model

2.2.2 Algorithm Steps

1. Road Network Coding. The original solution to the problem is mapped to chromosome, using the binary coding. If there are six roads in the road network, then use a variable of 0 or 1 with length of 6 to represent a chromosome, such as (110010). Number 1 indicates that the corresponding roads of 1, 2 and 5 will be newly built or expanded and Number 0 represents the corresponding roads status of 3, 4 and 6 will be maintained.

2. Initialize control parameters. Firstly it generates 40 chromosomes randomly as the initial population with binary encoding method, setting number of evolutionary generation as 100, value of cross probability as 0.9 and value of mutation probability as 0.01.Then the model with 40, 50 and 60 populations, cross probability of 0.8 and 0.9, and mutation probability of 0.01 are calculated again. Finally it comparatively analyze the results and adjust parameters reasonably.

3. UE assignment. According to the road network population obtained, we distribute algorithm of UE traffic assignment. The algorithm is discussed in Reference 3

4. Fitness evaluation. Calculate the objective function in the upper model after get road flow obtained in step 3. The larger the fitness value, the more superior individual, and the greater the probability that the individual is selected genetically to the next generation.

5. Constraint processing. Infeasible solutions not to meet the constraints will be deal with a penalty function, which can change a constraint problem into an unconstrained problem.

6. Selection strategy. Select the best individual and directly inherit to the next generation and then select the other individual using roulette method, which is based on the proportion of fitness selection strategy.

7. Cross operation. Select two individuals randomly from the population and get new fine individuals using double-cut point crossover method.

8. Mutation. Select individuals randomly from a population and change the coding by 0.01 mutation probability in order to maintain the diversity of population and avoid local optimum.

9. Algorithm terminates. Optimal solution cannot be determined by traditional methods, so we set the number of iterations as 100. When the program runs to 100, algorithm terminates; otherwise, returns to step 3.

3 Numerical Examples

3.1 Test Data

In this paper, Sioux Falls network (LeBlanc, 1975) is presented as a case study. There are 24 nodes (assuming that all nodes are occur-attraction spot), 76 sections (66 sections have been built and need expansion in the future, 10 sections need to be built) and 576 OD pairs (traffic demand of 48 OD pairs is 0) in the road network. The network structure is shown in Figure 2, where the solid line represents the existing road, blue dashed line represents the road need to be built.

All the basic parameters of Sioux Falls network can be obtained, referring to reference 1. Because the OD demand given by LeBlanc is for the daytime, it needs to be converted for peak hour. It's found that the 8th traffic flow of 24 hours in descending order is more stable and can be used as basic data for the control of traffic lights by long-term studies in US. So the traffic volume of peak hour is about 8.475% of a day.

3.2 Results and Analysis

Different values of the weight coefficients of w1 and w2 show the degree of deviation between the total travel time and urban traffic environment by planners and policy makers. Therefore, five different sets of weights were compared and different operation parameters in each group were taken in this paper. Each time the program running takes about 14 minutes and the results are as follows:

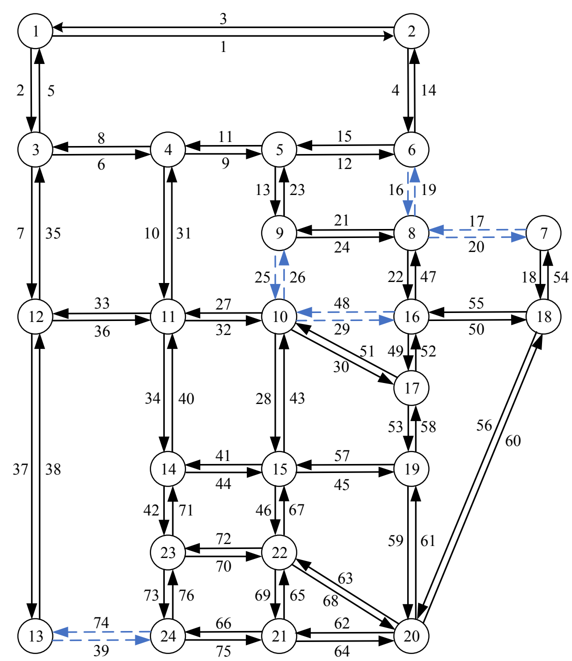

Figure 2. Test Network of Sioux Falls

Table 1. Road Network Design under Different Combination of Weights

Weight	Solution	Investment cost	Cross probability	population size	New Roads	Rebuilding Roads
w1=0, w2=1	3647	19500	0.9	60	16,7,19,25,26,39,48,74,	2,4,6,7,9,12,14,15,18,22,24,27,28,30,31,32,33,34,36,37,40,42,43,46,49,50,51,52,53,55,56,57,58,60,65,67,69,70,71,72,75
w1=0.2,w2=0.8	1045412	19800	0.9	60	16,17,19,25,26,39,74	2,5,6,7,12,15,21,22,23,27,28,30,32,33,34,35,36,37,38,40,41,42,43,44,46,47,49,50,51,52,53,57,58,59,61,63,65,67,71,72,73,75,76
w1=0.4,w2=0.6	2101638	18400	0.8	60	16,19,20,25,26,39,48	3,4,11,12,14,15,22,23,27,28,30,31,32,33,34,36,37,38,40,41,42,46,47,49,50,51,52,53,55,58,60,63,65,67,70,71,72,73,

						75,76
w1=0.6 ,w2=0. 4	3192 829	19700	0.9	60	16,17,1 9,20,25 ,26,29, 39,74	1,2,3,4,6,10,12,14,15,18,22,2 3,27,30,31,32,33,34,35,36,37 ,40,42,44,49,51,52,53,55,57, 58,59,61,62,64,66,67,69,72,7 4
w1=0.8 ,w2=0. 2	4201 091	19900	0.8	60	16,17,1 9,20,25 ,26,29, 39,74	1,2,3,8,12,13,15,22,27,30,31, 32,33,34,35,36,37,40,41,42,4 4,46,47,49,51,52,53,54,57,61 ,62,63,65,66,68,69,71,72,73, 74,75,76
w1=1, w2=0	5317 588	20000	0.9	40	16,17,1 9,20,25 ,26,29, 39,74	1,2,5,6,7,9,10,11,12,15,22,27 ,3031,33,34,36,37,40,42,44,4 5,46,4749,50,51,52,53,54,55, 57,58,59,61,63,64,65,66,67,6 8,72,75,76

From the above table it can be seen that it is easier to get a better result when the cross probability is 0.9 and the population size is 60. Some roads were always selected under different conditions, such as new roads 16, 19, 25, 26, 39 and rebuilt roads 12, 15, 27, 30, 33, 34, 40, 42, 49, 51, 52, 53. This shows that these selected roads are important to improve the system performance and should be the primary consideration in transportation planning.

4 Conclusions

A bi-level programming model for urban road network design problem based on environmental goals is established in this paper. The upper model aims at minimizing the CO exhaust emissions and total travel time to reduce traffic pollution and traffic congestion. The model is solved by GA and Frank-Wolfe algorithm and Sioux Falls network is taken as a numerical example to demonstrate the validity and effectiveness of the algorithm. The results showed that the algorithm has good convergence and the model and algorithm can provide a reference for traffic planning in practice.

[2]School of Economics & Management, Tongji University, No. 1239, Siping Rd., Shanghai, China.

Abstract: An effective solution to traffic jam is to develop public traffic. According to GPS vehicle positioning system we get the bus operation data. Then on the basis of the analysis of the current research, we build a more accurate calculation model with extreme value theory, which is used to evaluate the bus running between adjacent sites based on the AVL data and data mining. The effectiveness of the model is evaluated by a computational example using the AVL data of Shanghai's No.49 bus. At last, we analyze the important role of this index for users and managers, and give some suggestions.
Keywords: Public transit; Punctuality; AVL.

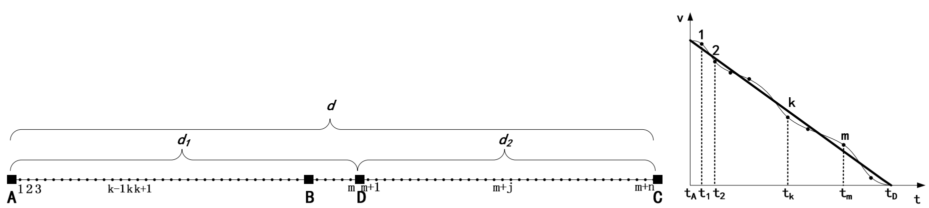
1 Introduction

Bus On-time Performance plays an important role in evaluation system of customers' satisfaction for public transport. In 2003, the Transport Research Institution in the US state of Texas introduced the Planning Time Index for evaluating the bus on-time performance in the Monitoring Report of American Transport Efficiency in 2003 compiled by federal agency. Professor Seung-Young Kho concluded that on-time performance was the most important evaluation index taking the bus operating conditions in Seoul, South Korea for example and put forward the concept of BMS-Bus Operation Management System. Early scholars mainly used the artificial survey data to study the bus service evaluation index, which had larger error. With the development of technology and the universal of the technique like GPS, more and more scholars begin to study the intelligent transport system. Chen put forward the Bus service reliability prediction simulation model based on the AVL-APC data; Joshua Greenfeld systematically elaborated various aspects in APTS which should be thought by the bus operators in his research, especially the Bus On-time Performance, and emphasized its importance; Ranhee Jeong, and Laurence R. Rilett put forward the method of predicting the bus arrival time based on the Artificial neural network model. Domestic scholars also had deeper research in this field. The research group of Professor Xiaoguang Yang systematically studied the deviation of bus intermediate arrival time and the concept and computational method of bus On-time Performance, and respectively analyzed the relationships between the both and passengers association; Professor Zhihua Xiong restructured the stochastic model of road network based on the APTS to evaluate the bus on-time performance and he put forward solving method by combining Frank-Wolfe Method and MSA-Method of Successive Average.

On the basis of understanding various scholars' researches, we found that most scholars only used mathematics method to study, fewer scholars applied the data mining technology to the field of bus research and early scholars only used travel time to study reliability index while reliability was a relatively large evaluation index. Therefore, this thesis bases on the reliability engineering thought, according to the Chinese recent condition of obtaining real-time transport data and its future development trend, using data collected by existing equipment to study bus on-time performance index. We classify and integrate the information of traffic database, on the basis of APTS technique and using the method of data mining, to get data for convenient study. Then taking 49 bus in Shanghai city for example, we fit certain operating road to validate the distribution model of travel time and establish evaluation model of bus on-time performance. At last, we analyze the important role of this index for users to improve travel efficiency and managers to make decisions according to the background of practical application and give some suggestions.

2 Model Develop

It is obvious that the data not get the accurate information about bus in-out site. In fact, only some nebulous statistics could be collected. Therefore it is necessary to calculate the actual information of stopping and leaving time at the site with the model and AVL data.



(a) (b)

Fig.1

In figure 1, D is the actual bus stop theoretically: d_1 indicates the actual pulling in distance; d_2 indicates the actual outbound distance; d is the total distance of into and out of sites; m and n respectively indicate that m pieces of information are returned from bus since pulling in to stopping and n pieces of information since restarting to leaving; k and j are respectively for the number k and j data point. A piece of information returned from GPS includes time (moment), speed, accumulated travel mileage. From this, its speed at point A and C, as well as the distance (d) between A and C can be informed.

This paper sets every two data points as a micro-element, so that the move between every two data points can be approximately treated as uniform variable move. Take the pulling in process for example, as shown in figure 1(b).

The formula to calculate stop time t_D is as follow:

$$\begin{cases} d_1 = \int_{t_A}^{t_D} v \cdot dt \approx v_A \cdot \frac{t_1 - t_A}{2} + \sum_{k=1}^{k=m-1} v_k \cdot \frac{t_{k+1} - t_{k-1}}{2} + v_m \cdot \frac{t_D - t_{m-1}}{2} \\ d_2 = \int_{t_D}^{t_C} v \cdot dt \approx v_D \cdot \frac{t_{m+1} - t_D}{2} + \sum_{j=1}^{j=n-1} v_{m+j} \cdot \frac{t_{m+j+1} - t_{m+j-1}}{2} + v_C \cdot \frac{t_C - t_n}{2} \\ d_1 + d_2 = d \end{cases} \tag{1}$$

Where,

d_1——actual pulling-in distance;

d_2——actual leaving distance;

d——total distance of pulling in and leaving;

v——actual speed;

t_A——pulling in time returned from the system;

t_B——stop time returned from the system;

t_C——leaving time returned from the system;

t_D——actual stop time;

m, n——amount of AVL data returned from bus from pulling in to stop and from restarting to leaving;

t_i——the time when No. i data point returned.

According to Eq. (1), there is

$$t_D = \frac{2\left(d - \sum_{k=1}^{k=m-1} v_k \cdot \frac{t_{k+1} - t_{k-1}}{2} - \sum_{j=1}^{j=n-1} v_{m+j} \cdot \frac{t_{m+j+1} - t_{m+j-1}}{2}\right) - v_A \cdot (t_1 - t_A) - v_C \cdot (t_C - t_n)}{v_m} + t_{m+1} \tag{2}$$

In general, there are obvious differences of bus travel time between periods of time. Therefore, it's not enough to force on the full bus travel time when evaluating the punctuality rate. For passengers, the punctuality rate between sites is more important, which is not a specific value, but a interval. The smaller the interval is, the more accurate the evaluation is.

For a better description for public transportation's punctuality situation, the paper introduces the concepts of Adjacent Sites Punctuality Rate on time (ASPR).

According to the above discussion, the travel time between every pair of neighboring stands can be calculated. Supposing $(t_1, t_2, \ldots\ldots, t_p)^T$ stands for the whole of the P elements. The No. j piece of data in the No. i section is recorded as $T_{ij} = (t_{ij1}, t_{ij2}, \ldots\ldots, t_{ijp})^T$, $T_i = (T_{i1}, T_{i2}, \ldots\ldots, T_{ip})^T$ is a $p \times n$ matrix. The No. k (k=1,2, ..., p) line of T_i respectively indicates the No. n_i travel time data of the No. k pair of neighboring sites, recorded as $T_{ik} = (t_{i1k}, t_{i2k}, \ldots\ldots, t_{in_ik})^T$.Then,

$$T_i = (T_{i1}, T_{i2}, \ldots\ldots, T_{ip})^T = \begin{pmatrix} t_{i1k} & \cdots & t_{in_ik} \\ \vdots & \ddots & \vdots \\ t_{i1p} & \cdots & t_{in_ip} \end{pmatrix} \tag{3}$$

Assume that ASPR of the No. k pair of adjacent sites in the No. i section is calculated by Eq.(5).

$$ASPR_{\mathrm{ik}} = P\left\{\overline{T_{ik}} - S_{ik} \le ti_{jk} \le \overline{T_{ik}} + S_{ik}\right\} \tag{4}$$

Where $\overline{T_{ik}}$ is the average value of the travel time and $\mathrm{S_{ik}}$ is the standard deviation. Thus among the n_i dates, there are m_i dates in the marked time range above. It could be thought that the $ASTT$ obeys binomial distribution. Assume the prior distribution of $ASPR$ is $\beta(a,b)$, and it is able to be inferred that the posterior distribution is $\pi(\mathrm{ASPR}|m) \sim \beta(m+a, n-m+b)\beta(a,b)$. With a given $1-\alpha$, there is

$$P(R_1 \le ASPR \le R_2 |\mathrm{m}) = \int_{R_1}^{R_2} \pi(\mathrm{ASPR}|m)\, daspr = F(R_2) - F(R_1) = 1-\alpha \tag{6}$$

Where $F(r), f(r)$ are distribution function and distribution density of $\beta(m+a, n-m+b)$. $[R_1, R_2]$ is the $1-\alpha$ confidence internal , and $L = R_2 - R_1$ is burst length. In order to get the shortest confidence interval, it is needed to get R_1^*, R_2^* in the following condition:

$$\begin{cases} \min L = R_2 - R_1 \\ \int_{R_1}^{R_2} \pi\left(\text{ASPR}\,|\,m\right) daspr = F\left(R_2\right) - F\left(R_1\right) \end{cases} \tag{6}$$

Considering the relationship of β distribution and binomial distribution, the result of Eq. (6) is equivalent to Eq. (7).

$$\begin{cases} \min L = R_2 - R_1 \\ \sum_{l=a+m}^{N} C_N^l R_2^{\,l} (1-R_2)^{N-l} - \sum_{l=a+m}^{N} C_N^l R_1^{\,l} (1-R_1)^{N-l} = 1-\alpha \\ R_1,\ R_2 \in (0,1) \\ R_2 \geq R_1 \end{cases} \tag{7}$$

Where， $N = a + b + n - 1$

It can be proved that this model has only one result (the the certification procedure is omitted). With MATLAB, the shortest interval $\left[R_1^*, R_2^*\right]$ can be got. The punctuality rate interval from this model is much more accurate than the one assumed, which is better for evaluating the bus running condition between adjacent stops.

3 Model verification

The intelligent transport information used in this thesis is real-time information data of all 49 buses in Shanghai. The basic information of 49 bus is as follows: The upside is from Shanghai Stadium to Hankou Road, the downside is from Hankou Road to Shanghai Stadium, there are 20 stations in all and departure interval is 5min.

The ASPR of all sites when $i = 1$ are shown in table 1.

Tab. 1 ASPR of all sites when $i = 1$

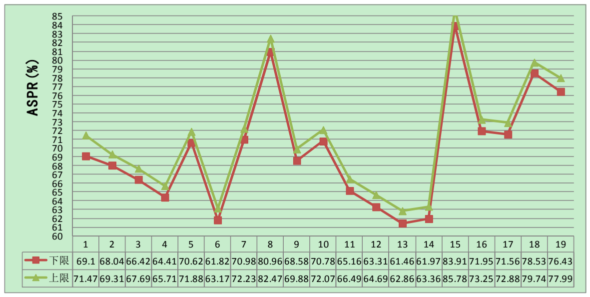


Table 1 indicates that: in morning peak, the punctuality rate is higher between the sites of Huashan Road-Changshu Road and NO.2 Company- Tumour Hospital while it is lower between the sites of North Shanxi Road-Tongren Road, Zhongshan Hospital-Fenglin Road and Fenglin Road-NO.2 Company. The result reflects the bus operation. Table 2 reflects the traffic road circumstance of sites above.

Tab. 2 Analysis of Influencing Factors of ASPR

NO. / Factors	8	15	6	13	14
Bus stop spacing(km)	0.34	0.64	0.55	0.77	0.48
Main road sections					
Intersection number/signal period(s)	2/(180+0)	1/(120)	2/(120+120)	5/(140+75 +75+75+1 20)	1/(120)
Bus lane	√	√	×	×	×
Platform form (A bus way，B not due)	A	A	A,B	A,B	A
Peak hour traffic(pcu/h)	2800	3310	4790	2430	5620
saturation	0.37	0.55	0.79	0.81	0.75

According to table 2, it can be informed that the bus stop spacing, main road sections, intersection number, signal period, bus lane, platform form, peak hour traffic and saturation affect the bus operation, in which bus lane, intersection number, signal period, peak hour traffic and saturation play a much more important role.

4. Conclusions

In this thesis, the study of bus punctuality is mainly discussed and we use GPS system to collect data, GIS technique to analyze data, data mining to handle the derived data. After analyzing the data, we tested that bus travel time basically obeys Beta distribution. Based on that, establish the evaluation model of bus punctuality. After analyzing the bus on-time performance of Shanghai Bus Faw's all 49 buses based on their real-time information data, evaluate it according to the classification table of the service level of bus roads' on-time performance. But this studying method's application has great limitation because of practical constraints; we should find more cost-effective and effective studying method to improve its practical value in the follow-up studies.

Abstract: Vehicle Routing Problem (VRP) is a typical problem of urban distribution, multi-depot vehicle routing problem is a complex extension of vehicle routing problem. Reams of existing research of path optimization problems were assuming different customers have connected directly and using the straight-line distance between two points as the distance between two customers, it is possible in theory, but does not meet the reality of the road network structure, cannot be applied to the actual vehicle schedule.

In this paper, considering both customer's location within a specific service area and the actual road network structure, based on actual customer orders, research the optimal distribution path about multiple distribution centers with different types of vehicles, meet the needs of each customer, taking into account the loading rate of the vehicles, so that the total transport cost is minimal.

Considering the earliness of genetic algorithm, this paper combines simulated annealing algorithm, using an improved genetic algorithm and experimentally verify the feasibility and effectiveness of the algorithm, showing that the algorithm can be directly applied to the actual vehicle schedule.

Keywords: Transport planning; Vehicle routing problem; Road network structure; Multi-depo; Heterogeneous-vehicle.

1 Introduction

MDMTVRP is the extension of Vehicle Routing Problem, means there are many depots equipped a variety of types of vehicles, distribution to multiple clients in the same time, we need to arrange a suitable plan which ensure the needs of all customers are satisfied and lowest total cost of transportation (Yang Yuanfeng,2008). MDMTVSP is closer to reality than the VSP, but also more complex, the scholars (José Brandão, 2006; Teodorovic D, Kikuchi S, 1991; Jacques Renaud (1996) have discussed a series of issues about it. Wang Xiaobo (2009) used hybrid genetic algorithm to solve this kind of problem. Luo Hongbin (2014) used mutation ant colony algorithm to solve this kind of problem. However, the slow convergence of these algorithms make it is difficult to escape from local optimal solution (Li Xiangyong, 2007). Genetic algorithms has good global search ability; simulated annealing algorithm has asymptotic convergence, is a kind of global optimization algorithm converges in probability to a global optimal solution, so combine these two algorithms to solve MDMVVSP to find the optimal solution .

2 The mathematical model of MDMTVRP

MDMTVRP can be described as follows: M depots distribute to N (i = 1,2, ..., N) customers, each depot has K_{ml} units of load of Ql (l = 1,2, ..., L) of the vehicle, distribution cost of per vehicle is related to unit fuel and turnover volume (denoted as C_l), the demand of customer i is g_i and $g_i<Q_l$, the distance between customer i and customer j is d_{ij}, each customer can be distributed by any model of vehicle in any depot, and each customer has only one vehicle for distribution, each vehicle returns to original distribution depot after its task, designing a reasonable scheduling scheme, to meet all customers' requirements, so that the total cost is minimized.

Customer number set for 1, 2, ..., N, yard number is N + 1, N + 2, ..., N + M, define the variable as follows:

$$x_{ij}^{mlk} = \begin{cases} 1 & \text{l type vehicle k from depot m travelling from client i to client j} \\ 0 & \text{else} \end{cases} \tag{1}$$

Mathematical model as follows:

$$\min Z = \sum_{m=1}^{M}\sum_{l=1}^{L}\sum_{k=1}^{K_{ml}}\sum_{i=1}^{N+M}\sum_{j=1}^{N+M} d_{ij}x_{ij}^{mlk}C_l \tag{2}$$

Constraints as follows:

$$\sum_{j=1}^{N+M}\sum_{m=1}^{M}\sum_{k=1}^{K_{ml}}\sum_{l=1}^{L} x_{ij}^{mlk}=1, i\in\{1,2,...,N\} \tag{3}$$

$$\sum_{i=1}^{N+M}\sum_{m=1}^{M}\sum_{k=1}^{K_{ml}}\sum_{l=1}^{L} x_{ij}^{mlk}=1, j\in\{1,2,...,N\} \tag{4}$$

$$\sum_{i=1}^{N}\sum_{k=1}^{K_m} x_{ij}^{mlk} \le K_{ml} \tag{5}$$

$$\sum_{i=1}^{N} x_{ij}^{mlk} = \sum_{j=1}^{N} x_{ij}^{mlk} \le 1, m\in\{N+1, N+2,...,N+M\}, l\in\{1,2,...,L\}, k\in\{1,2,...,K_{ml}\} \tag{6}$$

$$\sum_{i=1}^{N} g_i \sum_{j=1}^{N+M} x_{ij}^{mlk} \le Q_l, m \in \{N+1, N+2, ..., N+M\}, l \in \{1,2,...,L\}, k \in \{1,2,...,K_l\} \quad (7)$$

$$\sum_{i=N+1}^{N+M} x_{ij}^{mlk} = \sum_{j=N+1}^{N+M} x_{ij}^{mlk} = 0, m \in \{N+1, N+2, ..., N+M\}, l \in \{1,2,...,L\}, k \in \{1,2,...,K_{ml}\} \quad (8)$$

In the above formulas, formula (2) is the objective function means the lowest cost of transportation; (3) and (4) ensure that each client can only be served by a vehicle once; formula (5) means vehicles participate in the distribution cannot exceed the total number of each depot; (6) means each vehicle distribute from a depot and return to the depot where it set out; (7) ensures each car's weight must not exceed its load limit; (8) represents the vehicle cannot travel directly from one depot to another.

3 Improved genetic algorithm

3.1 Encoded representation

In this paper, using natural number to code, chromosome structure is (g_1,g_2,…,g_N), g_i is constituted of depot_num and vehicle_num, customer whose number is i is distributed by vehicle vehicle_num in depot depot_num, depot_num and vehicle_num are randomly generated when initializing population. Then the problem is converted into n small-scale problem of TSP.

3.2 Cross reorganization

According to the actual structure of chromosomes, taking two-points crossover method, selecting two chromosomes, exchange genes between two points, and then exchange the head and the tail of each chromosome.

3.3 Mutation

Mutating the chromosomes in the probability of p_m, each gene is constituted of depot_num and vehicle_num, so mutation means changing the depot_num or vehicle_num.

3.4 Algorithm structure

Step 1 Find adjacency matrix of distance based on the actual road network, and use floyd algorithm to solve the shortest distance between any two points;

Step 2 Initialize algorithm: population size is G, the largest number of evolution is g, crossover probability is p_c, mutation probability is p_m, initial annealing temperature is t_0, cooling parameter is γ;

Step 3 Construct chromosomes, generating initial population;

Step 4 Find out the chromosome of largest fitness value in current population, and calculate the fitness value f(B);

Step 5 In the temperature of t_k, randomly select two individuals G_i and G_j with probability of p_c, after cross reorganization, generate two new individuals G_i' and G_j', both calculate fitness value f(i') and f(j'). For G_i', if f（i'）>f(B), accept i' as the new status. Otherwise, if $p_t = e^{-\frac{f(i')-f(B)}{t_k}}$ is bigger than random number belongs to [0,1) , accept B as current state; if not, reserve i as current state. For $G_j^{'}$ as well.

Step 6 Mutate chromosomes with the probability of p_m after crossing, based upon the method in step 4 to decide whether to accept the new state.

Step 7 Judge whether the condition is satisfied, if the optimal solution meet demand, then terminate and output f(B) ; otherwise, $t_{k+1} = \gamma t_k$, turn step 4.

4 Case analysis

In this paper, according to the actual road network, select a section of Chengdu downtown, design a case to test the feasibility and superiority of the algorithm.

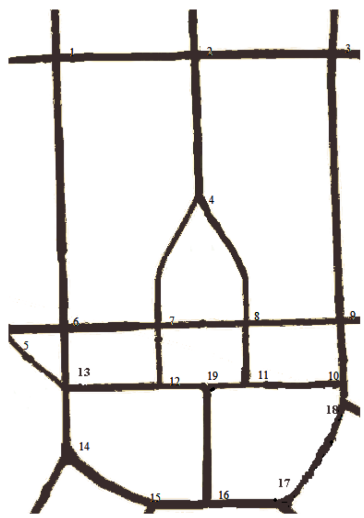

Figure 1. Actual road network

Suppose there are 16 clients and 3 depots, depots are located in positions of no.17, 18 and 19. All delivery is completed by the 3 types of vehicles in all depots, each depot has enough vehicles. Vehicle types and unit cost are in the following tables.

Table 1. Vehicles data

Vehicle	Capacity(t)	Cost of full-load (yuan/km)	Cost of no-load(yuan/km)
1	1	0.8	0.6
2	3	1.25	0.8
3	5	1.5	1.0

First find adjacency matrix of distance based on the actual road network, then use floyd algorithm to solve the shortest distance between any two points.

Table 2. Shortest distances

19	1.69	1.39	1.63	0.88	0.83	0.73	0.39	0.36	0.69	0.5	0.12	0.16	0.5	0.73	0.62	0.42	0.7	0.57	0

Table 3. Customer demands

Customer	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
Demand	0.03	0.44	0.38	0.77	0.80	0.19	0.45	0.65	0.71	0.75	0.28	0.68	0.66	0.16	0.50	0.96

Using MATLAB to program and solve the problem, set population size N=20, predetermined evolution algebra is 100, p_c=0.8, p_m=0.1, initial temperature T=1000, cooling parameter γ=0.9.

By 50 times repeated calculation, get the minimum distribution cost 11.8162 yuan.

The best distribution scheme is:

17 depot：1t vehicle：14；
3t vehicle：15；
5t vehicle：none；
18 depot：1t vehicle：16；4；3 → 2 → 1；
3t vehicle：10 → 11；
5t vehicle：none；
19 depot：1t vehicle：12；13 → 6；

3t vehicle：8 ➔ 9 ➔ 7 ➔ 5；

5t vehicle：none；

The iteration process converges very quickly from Figure 1**:**

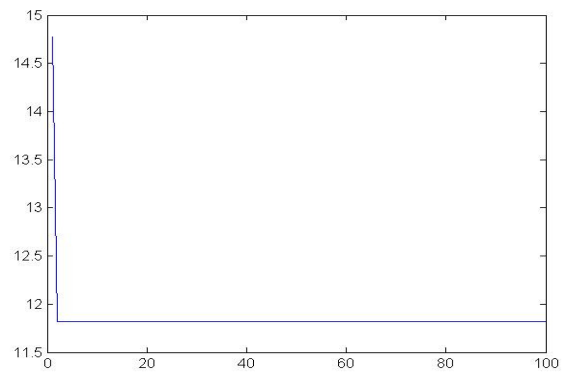

Figure 2. Convergence curve of best fitness

5 Conclusions

In this paper, considering the actual traffic conditions under MDMTVRP, make this kind of problems more practical. This paper combines the advantages of simulated annealing algorithm, improve the local convergence of genetic algorithm, accelerate the convergence rate of the algorithm, and has the ability to break away from local optimal solution. Therefore, the method mentioned in this paper can effectively solve MDMTVRP.

6 Recommendations for Future Research

In the future, time window should be adopted in the study, adjust the distribution route according to the real-time road congestion.

Abstract: Maintenance network planning of RFID facilities is researched considering validity of communication nodes which is a necessary condition for the function of RFID system. Some impacts on the capacity of maintenance network such as number of maintenance resource nodes, coverage radius of maintenance resource nodes and operation expense are considered in this paper. On a certain RFID facilities layout, the maintenance network planning model of minimum the maintenance expense is proposed combining with set covering model constrained as validity of RFID communication nodes. And then the maintenance resource nodes can be determined by heuristic algorithm designed to solve the model. Sensitivity analysis of influencing factors on maintenance capacity is studied by using optimal simulation technology. Experimental simulation results show that the validity of communication nodes had an important impact on the maintenance network planning of RFID facilities. The number and coverage radius of maintenance resource nodes, operation expense of network are more sensitive to maintenance support capacity. Reference approach is offered for the future construction and operation practice of RFID facilities' maintenance network planning.
Keywords: Set covering model; Maintenance network planning; RFID facilities; Validity of communication nodes; Maintenance capacity.

1 Introduction

As the demonstration project, promotion and application of the emerging Internet of Things in the field of public security, civil aviation, transportation, environmental monitoring, smart grid and the agricultural and so on in China, RFID system, which is an essential perception technology of Internet of things, maintains a rapid growth. In 2009, Chinese RFID market share is about 8.03 billion yuans ranking as the third behind England and America. The share of 2012 has reached 12.45 billion yuans and the rate of growth was 18.3%. Just because RFID system play the essential roles in collecting , identifying the valuable information and recognizing environmental events in the various areas of Internet of things, RFID system is firstly promoted development from a single system, integration system into network.

In complex RFID system, the hardware includes tag, reader, communication middleware and backend server. Communication middleware, whose functions are strengthening and transforming signals between the reader and backend server as communication node, is a kind of transmission interface of optical fiber communication. The failure of the communication node may interrupt the information flow and lead to the failure of RFID system. Obviously, for improving performance of RFID system, it is necessary to protect the validity of the communication node from systematic failure. In the field of operation and maintenance of RFID system, planning and designing RFID facilities maintenance network (RFID-F-MN) based on the complex RFID system will be of important practical significance especially for improving reliability of RFID facilities, using maintenance resource effectively and reducing operation expense.

In this paper, we analyze RFID facility network by the complex network analysis method. This network is composed of nodes and edges with functions such as information identification, data collection and information process analysis, etc. Nodes represent different functional entities in the RFID system, such as tags, readers, communication middleware, backend server, etc. Edges represent the connection between the different function entities. The RFID-F-MN is a kind of concept network, whose nodes (i.e., functional entities) are defined as the demand nodes in the maintenance network. Those nodes with functions of maintenance designed as maintenance resources node (MRN) which cover the whole RFID facilities network. Edges refer to the maintenance vehicle path (MVP). The RFID-F-MN is imposed of MRN and MVP which give the maintenance service covering all maintenance demand nodes including communication node (CN), for instance, to detect, repair and maintenance the RFID system etc. In view of the characteristic of CN, once CN is failure, the "edge" which is connected to the CN will be total failure at the same time. Thereby while planning and designing the RFID-F-MN, the validity of the CN must be considered in priority.

RFID-F-MN is proposed to protect the normal system operation of RFID facility network. Xu Yuguo (2012) applied the description and analysis method of complex network to maintenance network planning, and combined with the graph theory to simplify the maintenance network as network with weight including weighted nodes and edges. Its dynamic evolution model was given by analyzing topological structure characteristics of the maintenance network. Su Ying (2012) pointed out that the maintenance network shows the similarity principle with the common network under this theory system of complex network. They are both composed of nodes and edges. Maintenance network is the development and improvement with certain service of common network which can be abstracted as a kind of service network composed of nodes, edges and flow. HAN Zhen & LU Yu (2014) put forward the different evaluation indicators of maintenance network, including node concentration, cluster coefficient and average path length. They tried to provide reference guide for evaluating objectively the structure characteristics and operation performance of maintenance network. Similarly, K.K.Shukla &S.Sah (2013) studied on the construction and maintenance of virtual backbone in wireless networks, and designed node allocation algorithm combined with genetic algorithm to solve the node failure problems. Their key evaluation indictors for maintenance network were selected by covering radius and average path length coming from set covering model.

The literatures above show that complex network analysis method was used for analyzing and planning RFID-F-MN much more practical applications. RFID-F-MN can be abstracted as a functional network including nodes, edges and flow. The clear research approach goes as below: to define and explore the maintenance network based on existed RFID facility network, and to give specific requests and measurement method for concept modeling including the choice of nodes and paths, the analysis of network and operation performance. However, compared with new characteristics of RFID technology, these studies did not indicate that the operation expense of maintenance network is much higher than the construction cost, higher operation expense influence deeply on the overall operation of maintenance network. Therefore, this paper takes operation expense as a decision-making point while planning RFID-F-MN. The validity of CN also should be considered because it directly reflects RFID technology characteristics. Besides, it is a decisive factor for systematic failure of function and good operation of overall network.

2 Formulation of problem

2.1 Modeling idea

Traditional set covering model is to cover all demand nodes satisfied with the minimum number of MRNs and then to allocate these MRNs meeting the demand of all over MDNs.

Set covering model in this paper for RFID-F-MN takes RFID facility network nodes as MDNs with objective function of minimum operation expense. The least quantity of MRNs and the shortest vehicle path are the basic constraints while choosing the MRNs. Coverage rate is used to measure the degree how much the MDNs are covered with MRDs (see formula (1)).

$$e = |\bar{V}| \big/ |V| \times 100\% \qquad (1)$$

$|\bar{V}|$ says the quantity of MDNs which are covered, |V| says the total number of MDNs. When e=100%, the MDNs are covered completely.

Three conditions for modeling are considered as follow:

(1) Classification covering principle is proposed. According to the importance, demand nodes are divided into two categories: communication nodes (CN) and the other support nodes without communication function (SN).

(2) Taking minimum operation expense instead of minimum construction cost as planning objective of RFID-F-MN. In this way, minimum construction cost problem is converted to minimum number of MRNs for this modeling.

(3) Besides, MDNs should be completely covered, at the same time, resource consumption are also considered as constrains in this model, i.e., the actual vehicle consumption for maintenance is combined with shortest path problem.

2.2 Basic assumptions

In the RFID-F-MN, the crossing of path is called node, all nodes are MDNs and can be regarded as alternative MRNs. The set of all nodes is written as V, whose size is m. The set of CNs is written as V_1 and the set of SNs is written as V_2.The set of MRNs is written as V', whose size is n.

e_{ij} says the edge between i and j in the RFID facility network. The set of edges is written as E, whose size is l. L_{ij} says the vehicle path between MRN j and MRN i, the set of paths is written as *Path*.

Assumption 1: The assigned MRNs and MDNs is 1, otherwise 0, see formula (5);

Assumption 2: The demand of all MDNs are same, and each MDN is only covered by the only MRN, there is no MDN is covered repeatedly, see formula (6);

Assumption 3: Cover FN firstly when FN and SN can be covered at the same time, see formula (7);

Assumption 4: MDNs should be covered by MRNs completely, see formula (8);

Assumption 5: Coverage radius is determined by average speed and response time, see formula (9);

Assumption 6: MDNs should be assigned to MRNs which have been selected, and the vehicle path between MRN and MDN should be shorter than coverage radius, see formula (10) and formula (11);

Assumption 7: When MDN i is assigned to MRN j, the path L_{ij} is also assigned to MRN j, see formula (12);

Assumption 8: The quantity of MDNs can be covered by MRN is restrained by its own service capacity, all MRNs have the same capacity, see formula (13).

Assumption 9: C, operation expense of RFID-F-MN, refers to the expense which is paid during the process of maintaining, which is divided into construction cost (C_1), maintenance resources (labor, spare parts, etc.) expense (C_2) and maintenance vehicle fuel cost (C_3).

Assumption 10: C_1, the construction cost of MRNs, is determined by the unit MRN construction cost and quantity. Assume that the construction cost of each MRN is same, C_1, which is one-time investment, is fixed cost.C_1 is only related to the quantity of MRNs, on the premise of meeting the demands of all MDNs, reducing unnecessary resource assignment by controlling the quantity of MRNs to achieve the goal of reducing construction cost.

Assumption 11: C_2, maintenance resource expense, is calculated by standard cost method, the labor cost (LC), vehicle cost (VC) and spare part cost (SPC) used to maintain each MDN can be written as formula (2):

$$C_2' = \sum_i LC_i \cdot Q_{LCi} + \sum_i VC_i \cdot Q_{VCi} + \sum_i SPC_i \cdot Q_{SPCi} \tag{2}$$

LC_i 、 VC_i and SPC_i say the unit labor cost, unit vehicle cost and unit spare part cost respectively (yuan), Q_{LCi} 、 Q_{VCi} and Q_{SPCi} say the quantity of employees, vehicles and spare parts respectively . C_2 is written as formula (3).

$$C_2 = \sum_i Q_i \cdot C_2' \tag{3}$$

Q_i says the quantity of CNs covered by i^{th} MRN.

Assumption 12: C_3, fuel cost, which refers to the cost of vehicles during the process of maintenance, is determined by the unit fuel consumption, distance and the quantity of vehicles. The distance can be converted into average speed and response time. If the road conditions are same, the fuel cost is associated with the actual distance, the cost can be reduced by shortening the distance. Therefore, the minimum cost problem can be converted into the shortest distance problem, namely choosing the shortest vehicle path under the condition that all MDNs be covered.

3 Maintenance network set covering model (MN-SCM)

The objective function of MN-SCM is established as formula (4) in this paper, constraints are written as (5) to (13).

$$MinC = \sum_{j=1}^{l} H_j \cdot p_1 + \sum_{i} Q_i \cdot C_2' + p_2 \cdot \sum Q_{CLi} \cdot \sum_{i=1}^{l} \sum_{j=1}^{l} W_{ji} \cdot L_{ji} \tag{4}$$

S.T.

$$H_j, W_{ji} \in \{0,1\}, \forall i, j \tag{5}$$

$$\sum_{j \in V'} W_{ji} = 1, \forall i \tag{6}$$

$$W_{jx} > W_{jy}, x \in V_1, y \in V_2 \tag{7}$$

$$e = 1 \tag{8}$$

$$R = v \cdot t \tag{9}$$

$$W_{ji} \le H_j, \forall j \tag{10}$$

$$W_{ji} \cdot d_{ji} \le R, \forall i, j \tag{11}$$

$$L_{ji} = W_{ji} \tag{12}$$

$$0 \le Q_i \le Q_{MAX}, \forall i \tag{13}$$

Relevant variables and parameters are defined as follows:

t	Response time of maintenance vehicle (h);
H_j	Choose node *j* as MRN;
W_{ji}	Allocate MDN *i* to MRN *j*;
Q_{MAX}	Maintenance service capacity of MRN;
$A(j)$	Set of nodes which are covered by node
$B(i)$	Set of nodes which can cover node *i*;
R	Coverage radius (km);
d_{ij}	Shortest distance between node *i* and node *j* (km);
p_1	Construction cost of each MRN (yuan/PC);
p_2	Fuel cost of each maintenance vehicle (yuan/ (PC· km));
v	Average speed (km/h);
m	Quantity of MRN (PC);
n	Quantity of edges (PC).

4 Heuristic algorithm designed for maintenance network set covering model

This paper uses heuristic algorithm to solve the MS-SCM, the logic diagram is shown in figure 1. Step 4 in figure 1 (b) is improved based on traditional HA for set covering model. The CNs are assigned prior to SNs, so the demand of CNs can be met.

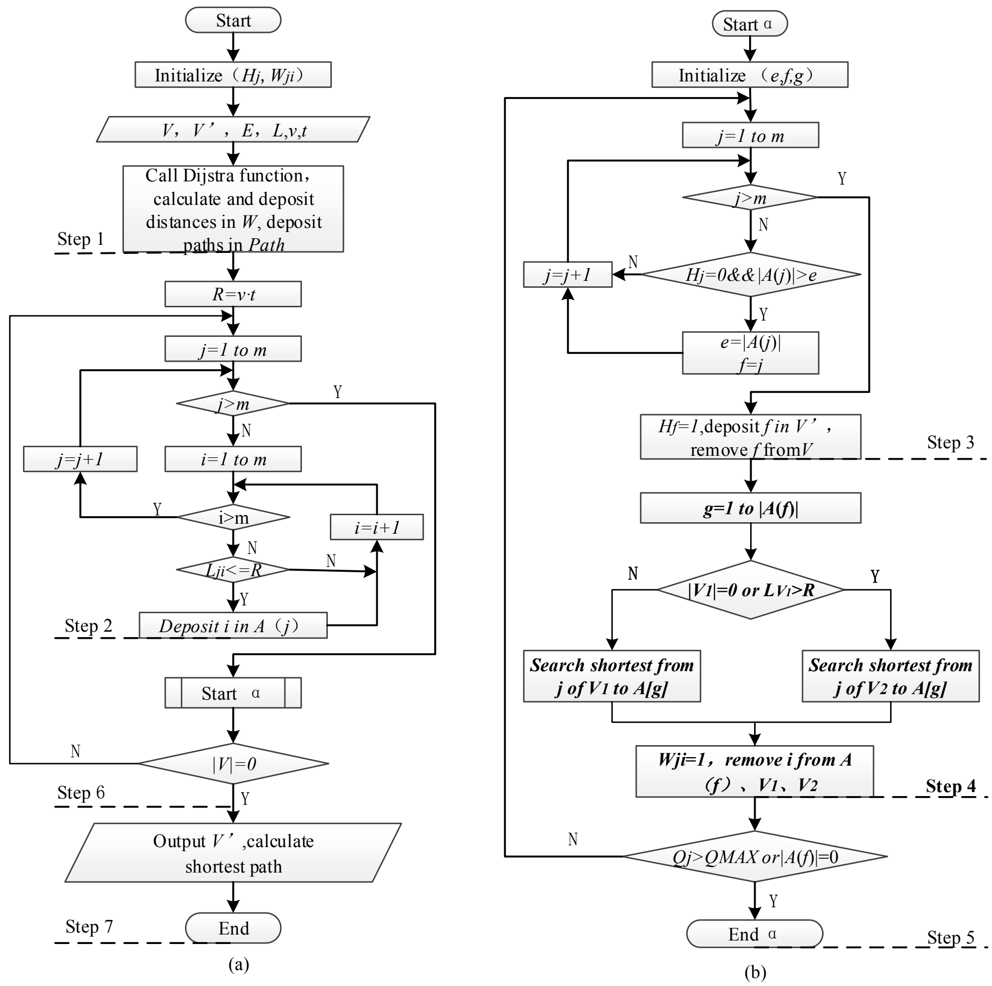

Figure 1. Heuristic algorithm for MS-SCM

Step 1: Initialization. $H_j = 0$, $W_{ji} = 0$.Input node matrix *E*, edge matrix *V*, vehicle speed *v* and response time *t*. Using Dijstra function to calculate the shortest distance between any two nodes, and deposite the distance in matrix *L*, at the same time deposited the paths in the matrix *Path*.

Step 2: Comparing the shortest distance between any two nodes with coverage radius, the serial number of node is deposited in matrix *A*(*j*) if the distance is shorter than coverage radius.

Step 3: Start α.Choose node *j* as MRN if $H_j=0$ and $|A(j)|$ is the max one. Deposited *j* in matrix *V'*, and remove *j* from *V*.

Step 4: Assigning *i*, which is included in *A*(*j*) and the distance between it and *j* is shortest, to *j* if there is undistributed node in V_1, $W_{ji} =1$ and remove *i* from *A*(*j*) and V_1; Otherwise assigning *i,* which is included in *A*(*j*) and the distance between it and *j* is shortest, to *j*, $W_{ji} = 1$ and remove *i* from *A* (*j*) and V_2.

Step 5: Repeat step 4 until $|A(j)|=0$ or $Q_i=0$.End α.

Step 6: Repeat steps 2, 3, 4 and 5 until $|V| = 0$.
Step 7: Output V' and the shortest path.

5 Simulation experiment for model effectiveness

5.1 Simulation network and experiment conditions

In order to verify the validity of the model, simulation experiment data combining with the actual example is analyzed. As shown in figure 2, RFID facility network is given, $|V|= 30$, $|E|= 48$.The quantity of CNs is 15, which is equal to the quantity of SNs. CNs should be covered firstly to ensure the validity of RFID-F-MN.

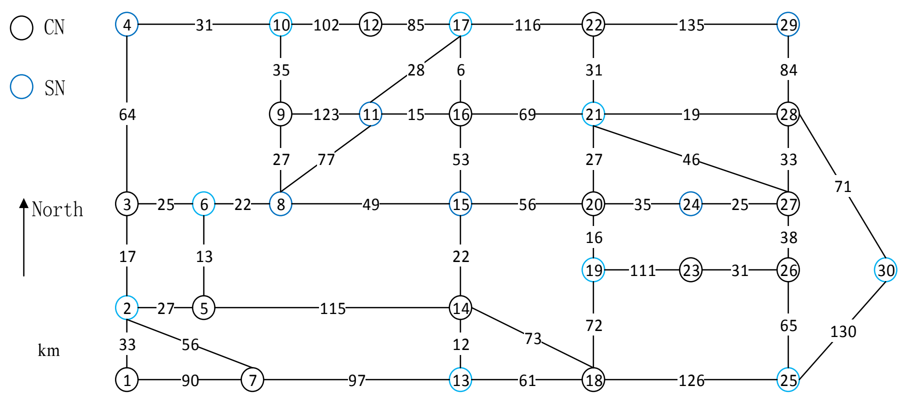

Figure 2. RFID facility maintenance network (RFID-F-MN)

5.2 Analysis of simulation results

R=120km, Q_{MAX} =5.Simulation results is shown in figure 3, the set of MRNs is V= {6, 8, 11, 15, 21, 27, 28 }, and all MDNs are covered, including:

$A(6)=\{4,10,11,13,15\}$; $A(8)=\{1, 2,6,7,8\}$; $A(11)=\{25,29,30\}$;
$A(15)=\{3,5,9,14,18\}$; $A(21)=\{16,20,22,27,28\}$; $A(27)=\{12,17\}$;
$A(28)=\{19,21,23, 24,26\}$。

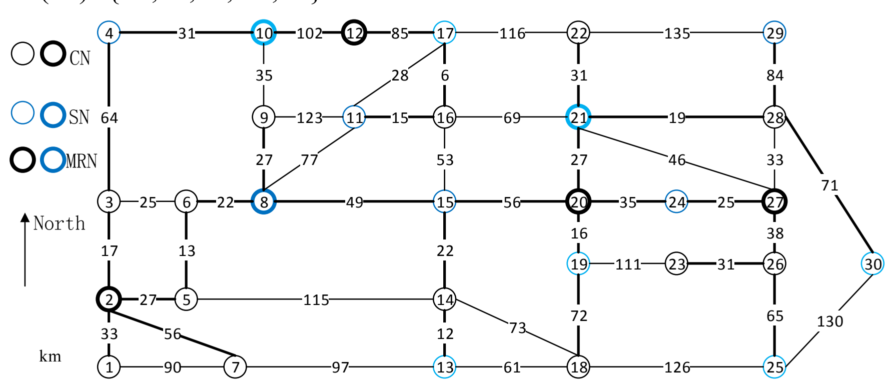

Figure 3. simulation result of MS-SCM

(1) Doesn't consider the validity of CN

R=120km, Q_{MAX}=5. If don't consider the validity of CNs, 7 MRNs are selected, too. V= {1, 8, 10, 20, 21, 23, 27 }, including:

A(1)={**1**,2,**3**,**5**,6}; *A*(8)={**3**,**5**,6,8,**9**}; *A*(10)={4,6,8,9,10};
A(20)={19,**20**,21,24,**28**}; *A*(21)={19,**20**,21,**22**,28}; *A*(23)={**23**,24,25,**26**,**27**};
A(27)={21,24,**26**,**27**,**28**}。

Table 1. Compare results of validity of CNs considered or not

Items	MRNs	MDNs covered	Path length（*km*）	Coverage rate（%）
considered	7	30	1111	100
Not considered	7	19	532	63

When the validity of CNs is considered, the path length is only 532 km, far shorter than 1111 km when not considered. But at the same time, only 19 nodes are covered, its coverage rate is only 63%. Visibly, MDNs are not completely covered by MRNs. There are some nodes are covered repeatedly or uncovered. Repeated cover will cause the waste of resources. Uncovered will lead to partial node unable to be maintained timely when node failure happening. More serious situation comes to extending the failure time of the network.

(2) Sensitivity analysis of coverage radius

In figure 3, coverage radius is 120 km. When coverage radius is changed, the quantity of MRN is also changed. When the coverage radius rank from 100km to 140km, the quantity of MRN is shown in table 2.With coverage radius increasing, the quantity of MRN is reducing gradually. But the path length is reducing with the number increasing firstly, but the length begin to increase when the coverage radius reaches a certain value. Visibly, when choosing the coverage radius, the quantity of MRN and path length should be considered at the same time.

Table 2. Sensitivity analysis of coverage radius

Coverage radius（*vt*，*km*）	MRNs	Serial number of MRNs	Path length（*km*）
100	8	3,6,15,16,20,21,25,28	1069
110	7	2,8,12,14,15,23,28	1061
120	7	2,8,10,12,20,21,27	1111
130	7	2,8,10,12,21,24,27	1219
140	6	9,14,15,16,20,28	1312

(3) Sensitivity analysis of Q_{MAX}

When Q_{MAX} ranking from 3 to 7 or there is no constraint to the service capacity, the quantity of MRN and path length is shown in table 3. For 21th node, if Q_{MAX}=4, due to the 19th MDN is farther than the other MDN, the 21th MRN must abandon it, then the layout of the entire network is affected.

Table 3. Sensitivity analysis of Q_{MAX}

Q_{MAX}	MRNs	Serial number of MRNs	Path length（*km*）
3	10	2,8,10,12,15,16,20,21,27,28	1312
4	8	2,8,10,16,20,21,23,27	1211
5	7	2,8,10,12,20,21,27	1111

6	6	8,10,12,20,21,27	1301
7	6	8,10,12,20,21,25	1145
∞	3	2,15,27	1080

The quantity of MRNs is reducing when the Q_{MAX} is increasing. The path length is reducing firstly, but begins to increase when the Q_{MAX} reaches a certain value. When Q_{MAX}=7, the path length is 1145km. It's only 156km shorter than 1145km when Q_{MAX}=6. But the quantities of MRNs are same 6. Therefore, when identifying Q_{MAX} during the process of planning MSNs, construction cost and operation expense should be in tradeoff together, i.e., we should ensure whether the operation expense reduced by shortening the path length can be made up by the construction cost increased through assigning more resource.

6 Conclusions

We put forward the maintenance network set covering model (MN-SCM) considered validity of CNs with minimum operation expense as objective function in this paper. By simulation experimental example, this model was solved by designing the heuristic algorithm suitable for this decision-making process. Comparative analysis is explored while validity of CNs considered or not is analyzed. Sensitivity analysis of coverage radius and Q_{MAX} to operation expense of RFID-F-MN is analyzed. Conclusions are as follow:

(1) When planning RFID facility maintenance network, the validity of CNs of RFID system should be considered. Main reasons are more clearly: it is indeed decisive factor for systematic failure of overall network function. It affects directly the selection decision of MRNs, and determines coverage rate e. Thereby it finally leads to the technology or function failure of RFID system.

(2) While choosing MRNs and assigning MDNs, on the one hand, the coverage radius should be shorten if the response time is strict. For example, for the emergency maintenance situation, the coverage radius of MRNs prefers to shorter to get quick response. But it will bring about new problems such as more MRNs planned and higher construction cost.

On the other hand, the smaller the Q_{MAX}, the bigger quantity of MRNs. The vehicle path length will be increased at the same time, which leading to operation expense increased.

(3) If the service capacity of MRNs is not considered, to identify MRN by sequence did not influence the quantities of MRNs, but it will cause the path length changed and further lead to the change of operation expense.

All in end, MN-SCM considered the validity of CNs and its heuristic algorithm designed are proved reasonable and valid in this paper. It provides reference in choosing MRNs reasonably and planning maintenance vehicle path efficiently. At the same time, applying the MN-SCM to the RFID-F-MN does not only draw on the experience of maintenance network planning method in military facilities field but more perspective approach goes to maintenance network for wireless network in the field of internet of Things in future.

Abstract: This paper describes the construction of BP neural network model which was used to forecast highway Cargo traffic volume and predicts the highway cargo traffic volume in 2013, it was also used to predict the highway passenger traffic volume, railway cargo traffic volume, passenger traffic volume and their corresponding turn over. The purpose is to provide a scientific and objective reference for the construction of terminal layout and scale of investment of highway and railway traffic routes and stations in Henan province.
Keywords: BP neural network; Passenger and cargo traffic volume; Freight and passenger turnover; Prediction.

1 Introduction

Transportation must go first if the economics develops. This Sentence vividly describes the relationship between transportation and national economy, so we can clear see the important status and role that the transportation industry plays in the national economy. Along with the implementation of "Rise of central China" strategy, Henan province will usher in the golden period of the development of the transport industry (Li, C, 2010).

In order to realize the goal of traffic in the macro, some relevant microscopic traffic planning must be formulated. Traffic volume forecast is the foundation and basis of traffic planning, it has certain reference value for all of the government's planning work, therefore, a scientific and reasonable to predict the future traffic volume and its development trend has very important practical significance and practical value.

There are many forecasting method of traffic volume prediction methods early, such as regression analysis, exponential smoothing method, Markov analysis, elastic coefficient method, neural network model, grey prediction etc. But some of the aforementioned methods used in practice are not so convenient. However, the artificial neural network is a nonlinear system with collective computation, adaptive learning and recognition ability. Compared with the traditional modeling techniques, many scholars have used artificial neural network to build many models in the prediction of traffic and obtained certain achievements recent years.

2 BP Neural Network

BP (Back Propagation) is a kind of according to the error Back Propagation algorithm training of the multilayer feed forward network, is currently one of the most widely used neural network model 1.1 Number of trips. BP network can learn and store a lot of input - output model mapping relationship, without prior to reveal the mathematical equations to describe this mapping(H, L. Q,2007). Its learning rule is to use the steepest descent method, by back propagation to constantly adjust the network weights and threshold, minimize the error sum of squares of the network. Topology structure of BP neural network model includes input layer, hidden layer (input) (hide layer) and the output layer (output layer). Its structure is shown in figure 1. Each layer goes according to order, and finally output by output layers.

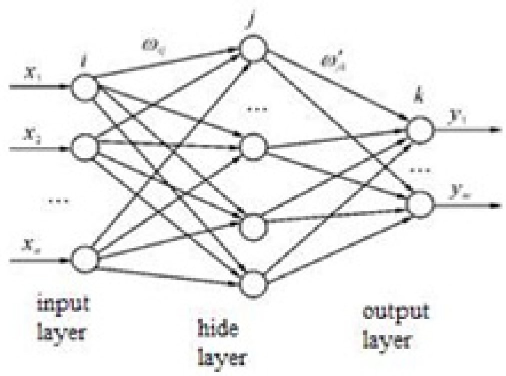

Figure 1.The structure of BP neural network

3 The BP Neural Network Design

Because there is no perfect theory to guide the design of neural network so far, the paper draw lessons from the experience of others on the basis of fully understand the traffic prediction, at the same time combined with heuristics, through continuous improvement and test, finally choose the better design of the BP Neural Network.

3.1 The Preparation of Neural Network Sample Set

Generalization refers to when the data of non sample input to the network is not seen in the training set, the network can output appropriate mapping. It is this ability of using the BP neural network that neural network can be used to predict traffic flow. Due to the increase in the number of samples can improve the generalization ability of the BP neural network, so this paper has collected 2001-2013(Henan Survey Organization National Bureau of Statistics Information Network, 2013), a total of 13 years of highway passenger and cargo traffic volume and turnover and railway passenger traffic volume and turnover, as a sample set table 1.

Table 1. Statistical data of Railway and highway passenger and freight volume and turnover volume from 2001-2013

Year	Highway				Railway			
	Freight transport		Passenger transport		Freight transport		Passenger transport	
	Volume	Turnover	Volume	Turnover	Volume	Turnover	Volume	Turnover
2001	53596	375.78	80259	369.41	4980	1185.36	11196	401.77
2002	55743	398.87	85078	390	5085	1234.77	12148	421

3.2 The Structural Design of BP Network

The structure of the BP neural network design mainly includes the network layer, the number of neurons in each layer. Theoretical analysis has proved that a single hidden layer of BP neural network can be mapped to all continuous functions, only when a number of hidden nodes of hidden layer many still can't improve the network performance, the hidden layer were increased, so the forecast traffic network choose a hidden layer nodes. According to the sample data pare prepared, making the traffic volume and turnover of the previous three years of data as the input layer, transport volume and turnover of fourth years as output. There is no a good analytical formula to calculate the number of hidden neurons so far, at first the number of neurons in hidden layer training network is less, then increase the number of hidden nodes gradually, then use the same sample set for training, through continuous testing, finally choice of the network with smallest error corresponding to the number of hidden nodes.

So the main steps are following:

(1) At first, we should build a BP network structure according to the problem, include the number of layers and nodes.

(2) The selection of initial weight. The selection of initial value too big or too small will influence whether meet local optimum.

(3) The selection of training methods and parameters. According to different applications, BP network provides a variety of training and learning methods, convergence speed of function trainlm is the fastest when meet the tedious computation.

(4) Input the known data and output the unknown data.

4 The Example of Using BP Neural Network

4.1 Forecast of Highway Freight Volume

BP neural network in this paper uses the Matlab software to achieve, the specific steps:

(1) Using the traffic data of every three years to predict next year's data, the basic data for 13 groups, namely using the data from 2001 to 2003 to forecast data of 2004, using the data from 2002 to 2004 to forecast data of 2005, till 2014.

(2) Normalization processing of target vector. Because the output of the BP algorithm is "s" function whose output value between 0 and 1, so the target vector should be normalized before using the neural network model to train the freight volume.

(3) Using net=newff（minmax（p)，[s1，s2］,‘{ tansig’‘, logsig’}) to create the BP neural network. The training function, BP learning algorithm and the performance function use the default function, respectively "trainlm" "learngdm" and "mse".

(4) Using the function "init ()" to initialize the weights and thresholds.

(5) Setting the related parameters, the maximum number of learning for 15000 times, learning speed is 0.1, then the study goal is error sum of squares of 0.01.

(6) Calling the function net=train (net, P, t) to train the created BP neural network.

(7) If the training goals achieved, enter (8), else adjust parameters in step (5) and retrain until the training goals are reached.

(8) Taking simulation and computing the error between the actual value and

simulation value (see table 2).The main Matlab code is as follows (Yu, S. W,2014):

```
pmax=max(p);pmax1=max(pmax);
pmin=min(p);pmin1=min(pmin);
for i=1:9
p1(i,:)=(p(i,:)-pmin1)/(pmax1-pmin1);
end
```

```
t1=(t-pmin1)/(pmax1-pmin1);
t1=t1';
net=newff([01;01;01],[13,1],{'tansig','logsig'},'traingd');
for i=1:9
net.trainparam.epochs=500;
net.trainparam.goal=0.01;
LP.lr=0.1;
net=train(net,p1(i,:)',t1(i));
end
y=sim(net,[                    ]');
y1=y*(pmax1-pmin1)+pmin1;
```

The above program recognition rate stable at around 95%, about 100 times to achieve convergence of training, training curve as shown in figure2.

Table 2. The error of simulation value and actual value

Year	The error between the simulation value and actual value				
2004-2008	0.0006	-0.0013	-0.0009	0.0004	0.0063
2009-2013	0.0002	-0.0007	-0.0185	0.0081	0.0182

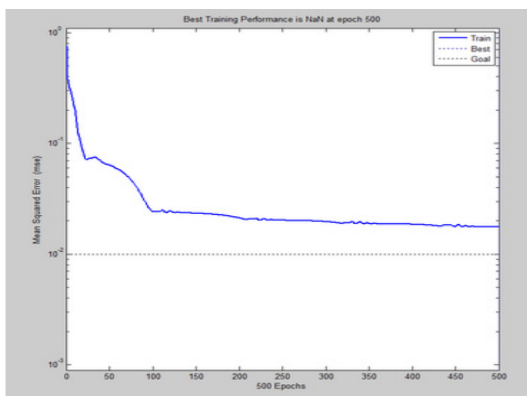

Figure 2.Training performance

(9) Prediction, input data of year 2011, 2012 and 2013 (220122 251772 282970) to calculate the highway freight volume of 2014.

(10) Comparison of actual and predicted values, the results are shown in table 3.

Table 3. Comparison of actual and predicted values，highway freight volume forecast in 2014

Year	Highway freight volume	
	Actual value	predicted values
2004	58147	58002
2005	62684	62127
2006	69898	68920
2007	83537	84001
2008	118198	118235
2009	151343	151301
2010	183291	183536
2011	220122	220185
2012	251772	251998
2013	282970	288116
2014		328452

According to the above steps, the BP neural network model consists of 3 layers, consisting of 15 neurons (1 × 13 ×1), the number of neurons in hidden layer is 13.This is determined by the repeated attempts to get the accuracy of the results (At this time the network convergence speed is the fastest, and the error is the smallest) (Li, Y. M, 2010).

4.2 Prediction of Other Traffic Volume and Turnover

BP neural network is constructed according to the above steps, by adjusting some parameters corresponding to the number of hidden layer neurons to forecast different kind of volume in 2004. The results are shown in following table 4.

Table 4. Highway, railway passenger and cargo volume and turnover volume prediction values in 2013

Year	Highway			Railway			
	Freight turnover	passenger traffic volume	passenger traffic turnover	cargo traffic volume	freight traffic turnover	passenger traffic volume	passenger traffic turnover
	Predictive value	Predictive value	Predictive value	Predictive value	Predictive value	Predictive value	Predictive value
2014	1449.94	231328	1534.40	15165	2166.92	13568	934.18

5 Conclusions

By using the BP neural network model to forecast traffic volume and turnover of passenger and freight volume, the model takes more attention on the simplicity and practicability when building the model under the premise of accurate results. Compared with other complex BP neural network model, it has many advantages. On the one hand, due to the construction of this model calls functions directly from Matlab software, it is simple to operation and easy to learn, on the other hand, the learning ability of this BP neural network is very strong, also after training, the error between target value and actual value is small.

A Comparison Experiment of the Time Benefit between Bus Navigation and Car Navigation

Nian Zhang; Xia Luo; Renjie Du; Xunfei Gao; and Yuxi He

School of Transportation and Logistics, Southwest Jiaotong University, Chengdu 610031, China.

Abstract: In this paper, we carried out an experiment to compare navigation time benefit between bus and car. On the same OD (origin and destination) of 4 kilometers, public transit navigation saved an average of 18 minutes and car navigation saved just 4 minutes, time benefit of public transit navigation is about four times than car navigation. Look from large groups as a whole, and bus navigation time benefit will far exceed the car navigation. This paper illustrated that public transport navigation service should be vigorously encouraged.
Keywords: Experiment; Navigation; Time benefit.

1 Introduction

Satellite navigation and positioning technology for the private has been developed to an advanced level. Current research mainly focuses on bus routing choice, and there are not many studies on navigation time efficiency. Almost all navigation products are to face private car users. At present guidance service for public transport users is primarily through the PC network and station signs, users can only get the static, fixed-line guidance. Users can only be able to get where to travel, how to travel, but they don't know when to start, which bus to take. Especially when passengers meet more than one travel scheme, they may not know which project can save even more time. Because the user could not get dynamic information of the bus, and did not know the delay, did not know where the jam occurred, did not know which bus was full rate. So, it led public transit users to waste time and restricts the public transportation resources allocation effectively.

2 The experiment

We select the second ring road, Dashi street, Qinxi street, Xiaonan street, Chengdu city, as test area. We select 5:30-7:30 as the evening rush hour test period on Wednesday, departure from Huiyuan Building to Orthopaedic Hospital, at a distance of four kilometers. This article conducted experiments in two different conditions that travel with navigation and without navigation, and we organized forty people dividing into four groups, as the Table 1.

Table 1. Experiment groups

Model	Conditions	Number
Car	With navigation	10
	Without navigation	10
Public transport	With navigation	10
	Without navigation	10

2.1 Bus travel

There are three feasible choices for passengers, as the Figure 1 and Table 2.

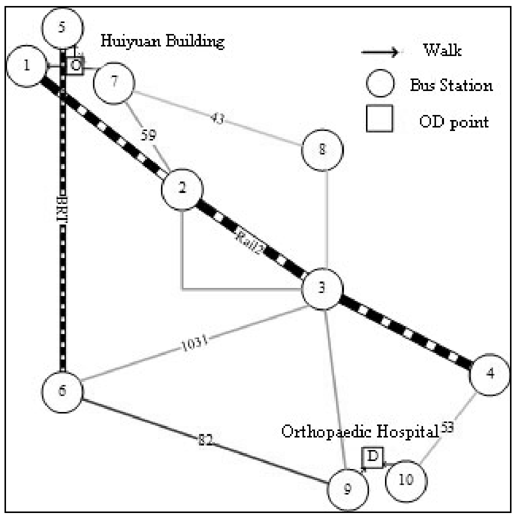

Figure 1. Public transportation routs

Table 2. Bus travel scheme

Project Number	Project（*means transfer point）
1	7-NO.59 Bus-9
2	1-Rail2-2*-NO.59 Bus-9
3	1-Rail2-4*-NO.53 Bus-10

Due to currently technology limit, we cannot get real-time bus dynamic information through user terminal. We used artificial method to obtain number of waiting, load factor, arrival time, and continuously sent them to passengers though mobile phones. Got dynamic bus data, according to saturation and arrival time passengers with navigation can choose the fast bus travel scheme. Meanwhile another group without navigation chose the travel scheme through station signs or internet.

2.2 Car travel

We choose Highmoralmap Navigation which can provides dynamic distance and road bypass scheme for drivers and synchronously record the travel time and route. Meanwhile we arrange the co-pilots recording road saturation.

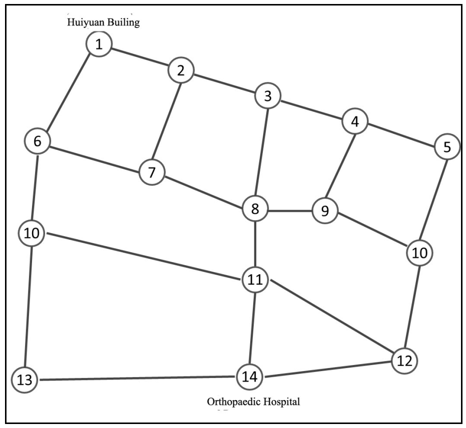

Figure 2. Car driving road network

Table 3. Car travel scheme

Project Number	Project
1	Fuqin Street to 1st Ring Road
2	2nd Ring Road to Dashi Street
3	Fuqin Street to Daqing street to Shudu road to 1st Ring Road
4	Fuqin Street to Yonglin street to Huaishu street to Changsun street to Dashi Street

3 Data Analysis

3.1 Bus data

Without navigation, 10 passengers choose option one, without transfer. Table 4 shows that all of the passenger choose project 1, and spend an average of 40 minutes. In Project 1, passengers can take the NO.59 Bus to reach their destination directly, but due to the high load factor, waiting time and in-vehicle time greatly increased, resulting in the overall travel time longer.

Table 4. Time of bus travel (without navigation)

Project Choice	Departure time	Walking time	Waiting time	Transfer time	Car time	Saturation	Totel time
1	6:05	8	9	0	27	80%	44
1	6:12	7	4	0	29	70%	40
1	6:20	7	7	0	29	90%	43
1	6:21	8	5	0	30	90%	43
1	6:40	7	15	0	35	100%	57
1	6:40	8	15	0	27	100%	50
1	6:40	7	16	0	35	100%	58
1	7:00	7	10	0	30	90%	47
1	7:04	7	6	0	30	90%	43
1	7:15	7	14	0	33	100%	54

With navigation, passengers get dynamic bus information and change travel plan. Table 5 shows that six passengers choose Project 2, three passengers choose Project 3, and according to the information, all of them chose appropriate departure time to make the travel more comfortable and faster.

Table 5. Time of bus travel (with navigation)

Project Choice	Departure time	Walking time	Waiting time	Transfer time	Car time	Saturation	Totel time
2	5:35	7	2	3	14	60%	26
1	5:45	6	2	4	14	55%	26
2	5:45	5	1	3	15	55%	24
2	5:50	5	2	3	15	50%	25
2	6:40	7	2	6	16	55%	31
2	6:45	8	1	5	17	50%	31
3	6:50	7	1	4	20	50%	32
3	6:56	9	0.5	4	16	50%	29.5
3	6:58	7	1	5	14	55%	27
2	7:15	7	1	3	14	65%	25

3.2 Car data

Without navigation, drivers had to choose their paths according experience. Table 6 shows the travel time and saturation of ten drivers.

Table 6. Time of car travel (without navigation)

Departure time	Project	Car time	Saturation
6:15	1	30	80%
6:20	1	29	80%
6:20	2	22	70%
6:30	1	27	95%
6:45	2	24	80%
6:45	1	30	80%
6:50	1	28	85%
6:50	1	27	85%
7:00	1	33	90%
7:00	2	32	80%

Under the conditions of dynamic travel guide, car drivers choose different project, and on the way they can change the paths according to the navigation. But in the course of the experiment, as Table 7 shows, because of the jam of all roads, even drivers change their paths, they could not find a genuine fast way.

Table 7. Time of car travel (with navigation)

Departure time	Project	Car time	Saturation
6:15	2	28	75%
6:19	2	27	80%
6:22	3	24	70%
6:30	3	27	95%
6:45	2	26	80%
7:00	2	23	80%
7:00	1	22	75%
7:10	2	20	70%
7:10	1	21	80%
7:15	3	24	75%

4 Discussion of Results

Because of the dynamic information and the bus lanes, even in rush hour and high network saturation, journey time is mainly under the influence of load factor. Passengers can acquire bus arrival information and load factor to decide when to start and which bus to take, reducing a lot of waiting time and car time, and they can select the bus of the lowest load factor to get the best comfort.

Table 8. Time efficiency comparison of buses

Bus travel	Change time	Waiting time	Car time	Saturation
Without navigation	0	10.1	30.6	91%
Navigation	4	1.35	15.5	55%

Table 9 shows that, private car travel time is mainly controlled by sections of saturation effects, as all roads are saturated, and dynamic navigation effect is very small.

Table 9. Time efficiency comparison of cars

Car travel	Car time	Saturation
Without navigation	28.2	83%
Navigation	24.2	78%

Table 10 shows that in the same OD, it is 18.3 minutes per capita for bus time efficiency, and 2.9 minutes for cars. Public transit navigation time efficiency is much higher than car navigation. Under the conditions of navigation, private cars than under the stochastic conditions saved 4 minutes.

Table 10. Time efficiency comparison between bus and car

	Navigation	Without navigation	Time efficiency
Bus	29.7	48.0	18.3
Car	24.2	28.2	4.0

5 Conclusions

Here we may draw the following conclusions. Relative to the car navigation, bus dynamic navigation will create greater time efficiency both from a personal and societal. It is important to improve the quality of bus navigation and promote it.

6 Recommendations for Future Research

Dynamic transit has not yet universal and related technology is not yet mature. In future work, we will further study of bus navigation technology. It is about that getting each bus driving information, identifying load factor, judging transfer point, and the most important thing is integrating this information and publishing them to user terminal.

Gray Markov Model in the Intersection of Short-Term Traffic Flow Prediction

Canjun Lu; Wei Wang; and Jiawei Chen

School of Transportation and Logistic, Southwest Jiaotong University, Chengdu 610031, China. E-mail: 362873762@qq.com

Abstract: With the rapid development of urbanization, the number of vehicles increased faster than urban roads in our city. The contradiction between supply and demand of urban transportation is increasingly sharp. Intelligent transportation system is an internationally recognized settlement of the best way to solve city traffic congestion. Traffic flow prediction, a key technology of the intelligent system, is the premise and key to traffic flow inducing and controlling. The intersection is the most vulnerable and most likely to appear problem in urban road traffic. Research on intelligent traffic conditions of intersection traffic characteristics, improve the capacity of the intersection is the key and main task of solving the city traffic problem. Short term traffic prediction model of previous research is still not perfect, low computational accuracy, need a large amount of data, the prediction model of complex, operation time is long, and so on. The grey prediction model has the advantages of simple model, less data is needed and short operation time. In this paper, based on the grey prediction model of these advantages combined with the Markov model, to establish a new method of grey model to forecast the short-term traffic flow prediction, and applied to the intersection of overcoming the insufficiency of the two kinds of prediction method, improve the prediction accuracy, carry on the forecast analysis.

Keywords: Intelligent transportation; Grey prediction model; Markov mode; Intersection flow.

1 Introduction

With the rapid development of social economy and the continuous expansion of city size, there's an increased demand for transportation both on its quality and quantity. Compared with the road that is unable to broaden, it's the increasingly crowded vehicles which lead to the worsen traffic situation that persecutes every country (ZHANG Yang,2009). It is a complex and comprehensive trouble to solve the traffic problems, just relying on the construction of roads or control vehicle to address the increasingly serious traffic problems is very difficult, and also it cannot solve traffic problems radically and avoid the growing accident rates. Thus, the Traffic Sensor Networks that is constituted by vehicles and roads that are synthesized by sensors, adopting computer data processing technology to solve the traffic problems of intelligent traffic control network came into being. It can achieve dynamic control signal through short-term forecasting of intersection traffic intersection to control intersection traffic flow more effectively and reduce traffic congestion, improve the safety of driving.

The change process of traffic state is a real, non-linear, non-stationary random one, the randomness and uncertainty of traffic state is growing along with the statistical period shortened. In intelligent traffic control network of traffic flow prediction process, in order to ensure the control efficiency of intelligent transportation and manner to control traffic and command timely, the time required to collect data from sensors in the network is as short as possible.

In other words, in order to ensure rapid completion prediction, we should take the traffic flow data that collected in a short time from the network sensors as predictive parameters. The basic process shown in Figure 1

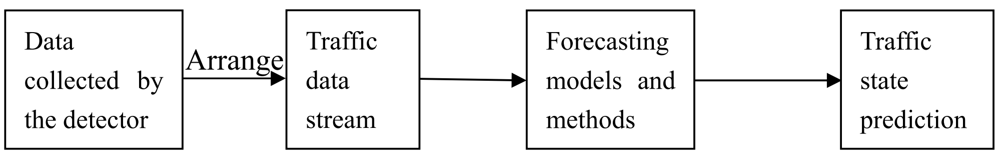

Figure 1.The basic flow of short-term traffic flow forecasting

The equilibrium point of forecasting accuracy and computational efficiency has been always the hotspot of short-term traffic flow prediction algorithm study. Generally the higher the accuracy, the larger the sample data needs to be calculated, and the more calculation time required. The current common short-term traffic flow prediction model as follows: Historical average model, its characteristic is the fast operation speed and modeling simple, but the accuracy is low and cannot solve the burst traffic conditions. Time series model, it simplify the modeling process and can be used to model complex system. If the data is fully, it would have higher prediction accuracy. But the algorithm cannot be transplanted and need the massive historical data to continuous support. Neural network model, with adaptive learning ability, it can make off-line training and on-line real-time forecasting, according to real-time traffic information to update the weights of the neural network. Because of the slow convergence speed, pre training process is complicated and many sample data supporting, it has poor generalization. Nonparametric regression model, the forecast precision is high, the mining information directly from the historical database, algorithm can be transplanted, but the nearest neighbor pattern matching complexity is high, the operation efficiency is low and need enough historical data. This article focuses on gray forecasting model; it has a simple algorithm, high calculation speed and can give good prediction effect of short-term prediction (CAI Yan,2006). The principle is based on the gray sequence generation operator weakens the random, mining potential rules, and the leap of using discrete data sequence dynamic differential equation of successive comes true by the exchange between difference equation and differential equation. Many other researchers conducted their work using Gray model for Short-Term traffic flow forecasting in the past. But separate grey forecasting accuracy is not high. It is difficult to predict with limited within a small range because of the ups and downs and disorder, and the limited number of original data. and leading to its original gray prediction model data under most circumstances is rough. This model also asked the accumulated generating data with index properties so that we can use differential equation fitting. The objects of Markov Prediction have characteristics such as stationary process etc., thus, prediction problem encountered in practice is the random and non-stationary process which shows some certain variation trend with the change of time. Therefore, if Gray model is used to fit these time series data, then identify and predict the development trend of the total sequence, the deficiencies of Markov prediction will be made up as a result. In this paper, combining with the Markova prediction model, and forms a more realistic prediction model, and applied to the intersection traffic flow short-time forecast.

2 Traffic Flow Forecasting Principles

2.1 Grey Prediction Model

Grey system theory is that, although due to the influence of various environmental factors on the system, make the discrete data of the system performance characteristic values exhibit chaos. But the system always has a whole function, it inevitably contains some intrinsic rules. So how to use the scientific method to collate original data and look for the true nature of its knowledge system by the rule of change is worthy of study. The grey system theory with the "generation" method getting a new series randomness weakened and regularity strengthened according to certain requirements for data processing or data transformation. Dig out the inherent characteristics of the original sequence.

Grey prediction model is established by time-series data accumulation generation module. From the process of building of GM (1, 1) forecast model can be seen that GM (1, 1) model is the most commonly used one kind of grey model.

2.1.1 Building of GM (1, 1) forecast model

Set the time series $X^{(0)}$ have n observations, $X^{(0)}=\{x^{(0)}(1), x^{(0)}(2),\ldots, x^{(0)}(n)\}$, Generate a new sequence by summing: $X^{(1)} = \{x^{(1)}(1), x^{(1)}(2),\ldots, x^{(1)}(n)\}$,

$$x^{(1)}(k)=\sum_{i=1}^{k} x^{(0)}(i) \quad (k=1，2，\ldots，n)$$

This sequence $X^{(1)}$ will exhibit certain regularity. Its rules can be obtained by solving the first-order linear differential equations. The definition:

$$\frac{dX^{(1)}}{dt}+aX^{(1)}=u \qquad (1)$$

Where a and u are parameters to be estimated. Set $\hat{\boldsymbol{a}}$ to be a vector of parameters to be estimated.

$$\hat{\boldsymbol{a}}=\begin{bmatrix} a \\ u \end{bmatrix} \quad (2)$$

Using least square method to calculate $\hat{\boldsymbol{a}}=(\boldsymbol{B}^T\boldsymbol{B})^{-1}\boldsymbol{B}^T\boldsymbol{Y}_n$

$$\boldsymbol{B}=\begin{bmatrix} -\frac{1}{2}\left[x^{(1)}(1)+x^{(1)}(2)\right] & 1 \\ -\frac{1}{2}\left[x^{(1)}(2)+x^{(1)}(3)\right] & 1 \\ \vdots & \\ -\frac{1}{2}\left[x^{(1)}(\mathrm{n}-1)+x^{(1)}(\mathrm{n})\right] & 1 \end{bmatrix}$$

$$\boldsymbol{Y}_n=\begin{bmatrix} x^{(0)}(2) \\ x^{(0)}(3) \\ \vdots \\ x^{(0)}(\mathrm{n}) \end{bmatrix}$$

Where $\hat{x}^{(1)}(\mathrm{t})$ is defined as:

$$\hat{x}^{(1)}(\mathrm{t})=\left[x^{(0)}(1)-\frac{u}{a}\right]e^{-at}+\frac{u}{a}$$

Written in a discrete form is:

$$\hat{x}^{(1)}(\mathrm{k}+1)=\left[x^{(0)}(1)-\frac{u}{a}\right]e^{-ak}+\frac{u}{a} \quad (\mathrm{k}=0,1,2\cdots) \quad (3)$$

We can conclude that generating series $\mathrm{X}^{(1)}$ shows the change trend of exponential function by accumulated from (2) and (3).Then can be predicted by the two type of $\mathrm{X}^{(1)}$ model forecast. The changing rule of the original data sequence $\mathrm{X}^{(0)}$ can be generated by the regressive.

$$\hat{x}^{(0)}(\mathrm{k}+1)=\hat{x}^{(1)}(\mathrm{k}+1)-\hat{x}^{(1)}(\mathrm{k})$$

$$=(1-e^{a})\left[x^{(0)}(1)-\frac{u}{a}\right]e^{-ak} \quad (4)$$

That is

$$\hat{Y}(\mathrm{k})=\hat{x}^{(0)}(\mathrm{k}+1) \quad (5)$$

2.1.2 Residual test of the model

The actual value of k time for $x^{(0)}(\mathrm{k})$, Based on the test of time function obtained fitting prediction value is $\hat{x}^{(0)}(\mathrm{k})$(JIANG Zhihua, ZHU Guobao,2004). The residual sequence is defined as follows:

$$q^{(0)}(\mathrm{k})=x^{(0)}(\mathrm{k})-\hat{x}^{(0)}(\mathrm{k}) \quad (6)$$

The relative error:

$$\Delta_k = \frac{q^{(0)}(k)}{x^{(0)}(k)} \times 100\% \quad (7)$$

The average relative error:

$$\bar{\Delta} = \frac{1}{n}\sum_{k=1}^{n}|\Delta_k| \quad (8)$$

Grey prediction model due to the ups and downs and disorder, and the limited number of original data. It is difficult to predict with limited within a small range, and leading to its original gray prediction model data under most circumstances is rough. This model also asked the accumulated generating data with index properties so that we can use differential equation fitting. But the accumulation generation sequence of a nonnegative time sequence is not necessarily with exponential rule, this always leads to the grey model of using the exponential equation to fit is easy to produce very big error (CHEN Youxiao, LIN Xiaoyan,2005). This paper argues that these problems can be solved by improving the results of grey prediction model with Markov chain.

2.2 Markov Prediction Model

Markov Prediction is a method that applies the state transition law found by Russian mathematician Markov in the early 20th century. It analyses the random events in the future development trend and possible results, providing the decision analysis for decision makers.

The basic idea of Markov chain prediction method is a state transition matrix that is obtained through the original data. It estimates the future trend of state transition according to the matrix. One step state transition matrix form is

$$P = \begin{bmatrix} P_{11} & P_{12} & \cdots & P_{1n} \\ P_{21} & P_{22} & \cdots & P_{2n} \\ \vdots & & & \vdots \\ P_{n1} & P_{n2} & \cdots & P_{nn} \end{bmatrix}$$

It describes the probability distribution of n state mutual transfer. P_{ij} shows the probability that transfers form state S_i to state S_j of Markov chain. It's character is

$$0 \le P_{ij} \le 1; \quad \sum_{j=1}^{n} P_{ij} = 1 \qquad i, j = 1,2, \cdots, n$$

It is a key of prediction method of Markov chain to calculate a step transition probability state. The theoretical distribution of one step transition probability is unknown, so we can take the transferring frequency between states as estimation value of probability if we have enough sample data. Assuming that, the times n_i of the state appearance can be known on the basis of sample data. The transition number of times is n_{ij} from one state to another. Then $P_{ij} \approx \frac{n_{ij}}{n_i}$

The objects of Markov Prediction have characteristics such as stationary process etc., thus, prediction problem encountered in practice is the random and non-stationary process which shows some certain variation trend with the change of time. Time series data fluctuates and jumps around this trend due to the influence of random factors, exerting the divergence. Therefore, if GM (1, 1) is used to fit these time series data, then identify and predict the development trend of the total sequence, the deficiencies of Markov prediction will be made up as a result. Consequently,the Grey Markov Prediction model that is combined by two kinds of prediction model can make full use of the information given by historical data to provide a new method for the random and fluctuating data prediction task and improve the accuracy prediction.

Knowing about the status transferring rule is the key to predict development of future by taking the advantage of Markov chain. Therefore, the first step is to divide the state that is to divide the data sequence into a plurality of state to construct the state transition probability matrix. We can take it to be E_1, E_2, $\cdots$, E_n （The state transferring time is t_1, t_2, $\cdots$, t_n ）. The division the state E_n is based on coinciding with non-stationary Markov process and variation tendency. That is, regarding $\widehat{Y}(t) = \hat{x}^{(0)}(t+1)$ as reference curve, making several (determined by the number of state division) parallel to $\widehat{Y}(t)$ to achieve several bar areas of which each strip region represents a state, that is the state area to which it belongs. As shown on the right (JIANG Chengyi,1996).

The transition probability is

$$P_{ij} = \frac{n_{ij}}{n_i}$$

The sequence $\widehat{Y}(t)$ is divided into several States According to the specific situation, and each state (grey number), represented by grey element E_{1i}、E_{2i}:

$$E_i = [E_{1i},\ E_{2i}]$$

$$E_{1i} = \widehat{Y}(t) + A_i$$

$$E_{2i} = \widehat{Y}(t) + B_i \quad (A_i, B_i \text{ are suitable constant,i=1,2,…,n})$$

Thus the most likely predictive value Y(t) of the system future time can be obtained at the midpoint of the desirable for grey interval $[E_{1i},\ E_{2i}]$.

$$Y(t) = \frac{1}{2}(E_{1i} + E_{2i}) = \widehat{Y}(t) + \frac{1}{2}(A_i + B_i) \qquad (9)$$

3 Conclusions

In order to improve the prediction accuracy of short-term traffic of intersection, this paper uses the grey Markov prediction model. It is proved by the analysis of the data that grey Markov model has higher prediction accuracy than a single grey model. Because of the characteristic of the traffic itself, this model is only suitable for short time traffic forecast, and 5 to 10 minutes is better.

Abstract: As a new transaction discipline, grey system theory which is an important branch of the science system, is a new method which researches little data, uncertainty and poor information. The grey system theory is based on incomplete information system .It use the perspective of the system to research the relationship of the information and create models .And by the part of the known information ,it can extract the valuable and meaningful information—how to use known information to reveal the unknown information. Gray model is the most important element of gray system theory. It is an important part both for the system to predict or control, and to establish the correct and accurate mathematical models. This paper will describe the principles of grey system and steps of establishing GM(1,1) model. Gray modeling theory has been widely applied in various fields such as industry, agriculture, social, economic, etc. This paper will use it to forecast the number of the car and analysis the accuracy.
Keywords: Grey forecast; Gray model; GM(1,1) model.

1 The Introduction of Grey Theory

Gray system theory is used to research the uncertain system of "part of the information known, part of information unknown," "little sample", "poor information". Gray was first put forward in field of the control systems, in control theory, people often use color to indicate the clear degree of system information, "black" means that the information is completely unknown, "white" means that the information is completely clear, "gray" means that part of the information known, part of the information is unknown. Accordingly, the information is completely unknown is called black system, information fully aware of the system is called white system, and the part of the information is clear, part of the information is not clear is called gray system.

2 The Principle of Model Establishment

2.1 Set $X^{(0)}$ as non-negative sequence

$$X^{(0)} = (x^{(0)}(1),\ x^{(0)}(2),\ \dots,\ x^{(0)}(n))$$

$X^{(1)}$is the cumulative sequence order of $X^{(0)}$

$$X^{(1)} = (x^{(1)}(1),\ x^{(1)}(2),\ \dots,\ x^{(1)}(n))$$

In the formula, $x^{(1)}(k)$=$\sum_{i=1}^{k} x^{(0)}(i)$(k=1,2, …, n),and $x^{(0)}(k) + ax^{(1)}(k) = b$ is the Original form of GM(1, 1) model.

2.2 Set $Z^{(1)}$ as the average generation sequence of $X^{(1)}$

$$Z^{(1)} = (z^{(1)}(1),\ z^{(1)}(2),\ \dots,\ z^{(1)}(n))$$

In the formula, $z^{(1)}(k) = 0.5(x^{(1)}(k) + x^{(1)}(k-1))$, and$x^{(0)}(k) + az^{(1)}(k) = b$ is the basic form of GM(1, 1) model.

2.3 If $\varphi = [a,\ b]^T$ is the parameters column, B= $\begin{bmatrix} -z^{(1)}(2) & 1 \\ -z^{(1)}(3) & 1 \\ \vdots & \\ -z^{(1)}(n) & 1 \end{bmatrix}$,

Y=$(x^{(0)}(2),\ x^{(0)}(3),\ \dots,\ x^{(0)}(n))^T$,the Least Square estimation of the GM(1, 1) model is this,

$$\emptyset = [B^T B]^{-1} B^T Y$$

2.4 $X^{(0)}$ is the non-negative sequence, $X^{(1)}$is the cumulative sequence, $Z^{(1)}$ is the average generation sequence, $[a,\ b]^T = [B^T B]^{-1} B^T Y$,therefor, the albino equation is as follow:

$$\frac{dx^{(1)}}{dt} + ax^{(1)} = b$$

2.5 The solution of the albino equation is as follow:

$$x^{(1)}(t) = \left(x^{(1)}(1) - \frac{b}{a}\right) e^{-at} + \frac{b}{a}$$

And the solution of the GM(1,1) model is:

$$p^{(1)}(k+1) = \left(x^{(0)}(1) - \frac{b}{a}\right)e^{-ak} + \frac{b}{a} \quad (k=1,\ 2,\ \ldots,\ n)$$

3 The Steps of Model Building

The first step: Accumulate $X^{(0)}$, to generate the $X^{(1)}$

$$X^{(1)} = (x^{(1)}(1),\ x^{(1)}(2),\ \ldots,\ x^{(1)}(n))$$

In the formula , $x^{(1)}(1) = x^{(0)}(1)$, $x^{(1)}(k)$=$\sum_{i=1}^{k} x^{(0)}(i)$(k=1，2，…，n)。

The second step: To get the albino equation

$$\frac{dx^{(1)}(t)}{dt} + ax^{(1)}(t) = b$$

In the formula , "a" is a development factor，"b" is the grey differential equations.

$$x^{(0)}(k) + az^{(1)}(k) = b,\ k=2,\ 3,\ \ldots$$

The third step: Solve parameters a and b. Parameters column $\varphi = [a,\ b]^T$ is identified by the Least Square estimation

$$\emptyset = [B^T B]^{-1} B^T Y$$

The forth step: To get generation data models:

$$p^{(1)}(k) = \left(x^{(0)}(1) - \frac{b}{a}\right)e^{-a(k-1)} + \frac{b}{a} \quad (k=1,\ 2,\ \ldots,\ n)$$

The fifth step: To get original data model:

$$p^{(0)}(k) = p^{(1)}(k) - p^{(1)}(k-1),\ (k=2,\ 3,\ \ldots,\ n)$$

Make k=2，3…，n , you can get the fitted values of the initial data. When k>n, you can get the predictive solution of the grey model

4 The Case

The first step :Structure the original car ownership data of Hangzhou .

$X^{(0)} = (x^{(0)}(1), x^{(0)}(2), \ldots, x^{(0)}(11))$

=（3.96 5.106 6.279 7.962 9.55 10.784 12.025 13.268 13.954 15.789 18.289 20.782）

The second step: Accumulate $X^{(0)}$,getting $X^{(1)}$=（3.96 ，9.066 ，15.345，23.307 ，32.857， 43.641， 55.666，68.934 ，82.888 ，98.677， 116.966 ，137.748）

The third step: Structure matrix B, and data vector Y:

$$B=\begin{bmatrix} -6.513 & 1 \\ -12.206 & 1 \\ -19.326 & 1 \\ -28.082 & 1 \\ -38.249 & 1 \\ -49.654 & 1 \\ -62.300 & 1 \\ -75.911 & 1 \\ -90.783 & 1 \\ -107.821 & 1 \\ -127.357 & 1 \end{bmatrix}$$

Y=
$(5.106\ 6.279\ 7.962\ 9.55\ 10.784\ 12.025\ 13.26813.954\ 15.789\ 18.289\ 20.782)^T$

Solve parameters a, b, $\varphi = [a, b]^T = \begin{bmatrix} -0.1205 \\ 5.3903 \end{bmatrix}$

Then the grey model is : $p^{(0)}(k) = (1 - e^{a})\left(x^{(0)}(1) - \frac{b}{a}\right) e^{-a(k-1)}$

$=5.5277e^{0.1205(k-1)}$

Table 1. Error analysis

Years	Fitted value （100000Veh）	Actual value (100000Veh)	Residual	Fitted relative error(%)
2000	3.96	3.96	0	0
2001	6.2356	5.106	-1.1296	-22.12
2002	7.0341	6.279	-0.7551	-12.03
2003	7.935	7.962	0.027	0.34
2004	8.951	9.55	0.599	6.27
2005	10.0973	10.784	0.6867	6.37
2006	11.3904	12.025	0.6346	5.28
2007	12.8491	13.268	0.4189	3.16
2008	14.4945	13.954	-0.5405	3.87
2009	16.3507	15.789	-0.5617	-3.56
2010	18.4446	18.289	-0.1556	-0.85
2011	20.8066	20.782	-0.0246	-0.12

The above table shows that, in addition to two relative error is greater than 10%, all other fitted relative error is below 10% . It indicates that the model has a better accuracy.

Table 2. The number of prediction

Years	2012	2013	2014	2015
Numbers （10000vel）	234.71	264.77	298.67	336.92

5 Conclusions

When use the GM (1,1) model to do prediction , although it has a lower requirement for original data, the prediction accuracy will be greatly affected by the following elements. First, the smoothness of the original data. The higher the smoothness of the original data, the more accurate prediction results will be. Second, the impact of “a”. “A “mainly affects the scope of the mode, and if it exceed this range, the error will be large, and the expected results will be different.

Abstract: With the popularity of Automated Fare Collection (AFC), transit operators and planners can make use of AFC data to have a better understanding of travelers behaviors, such not only provide meaningful guidance on public transport planning, but also for transit operators provide better services put forward a clear direction. In this paper, the main use of Chengdu on November 2nd to 8th one smart card. Using data mining technology to analysis the spatial and temporal regularity of students. Travel regularity analysis mainly include frequency of use, time of boarding, boarding intensity. This research shows that in a period of time, frequency of use, time of boarding and boarding intensity of student card presents regularity.
Keywords: Smart card; Transit system; Travel behavior; Regularity.

1 Introduction

Automated Fare Collection (AFC) system collects a large number of public transport network transaction of users every day, which includes the card number, type of card, boarding station and so on. Therefore, we can try to use data mining methods to dig out more interesting information in this huge data, such as the use of regular travelers on transit system in time and space, to help planners and operators to understand the behavior of travelers , so as to improving service.

This paper proposes to extract information from smart cards to describe travel behavior of students. The study focus on describing travel habits of students during peak hours on weekdays. The structure of the paper is the following. Firstly, in section 2, literature review focus on studying travel behavior by using smart card data. Then section 3 is a brief description of the data used. Section 4 shows the result of the regularity of student behavior. The last section is the conclusion of the paper and proposes directions for further research.

2 Literature review

This review focuses on analyzing travel behavior by using smart card data. Okamura(2004) analysis passenger boarding time and transfer behavior by using a month of smart card data from an AFC system. They find that boarding time is different from a questionnaire-based person trip survey. The authors also examine transfer wait time at important transfer points and classify cardholders according to some characteristic like boarding frequency, average on-board time. Bagchi & White (2004; 2005) analysis samples of public transit smart card data from Southport, Merseyside and Bradford, in the United Kingdom. The authors use rule-based processing to estimate trip rate per card and the proportion of linked trips by the samples. Tseytin et al.(2006) use the market basket data mining technique to extend the temporal coverage of travelers using weekly magnetic card by matching cards based on a similarity function between the travel patterns of two cards. Utsunomiya et al. (2006) use smart card registration and transaction data to analysis walk access distance from billing address to the first transit entry point, frequency of use, transfer trips, daily travel patterns, variation in transit mode, route and stop choice, and comparison of usage by area of residence. Morency et al. (2007) examine 2 million boarding transactions made within an 11-week period. Travel behavior are analyzed by frequency and time of transit use, fare type, number of boarding, and number of stops used. Bryan & Blythe (2007) use data from concessionary customers in Nottinghamshire County, United Kingdom, to analyze trip rates by user subgroups: elderly, disabled and school children. Mojica (2008) examines changes in travel behavior under deteriorated service conditions with smart card data and subsequently provides a modal shift model using a binary logit formulation. Asakura, Iryo, Nakajima & Kusakabe (2009) estimate change in behavior of train users after a schedule change with smart card data. Morency & Trépanier (2010) use smart card validation data from an extended period to assess loyalty of different segments of cardholders.

3 Data source and method

(1)Data source

From the analytical viewpoint, exploring the regularity of bus travel behaviors by using consecutive and multiple smart card data is very meaningful. This paper used the smart card data of student group as well as the information of the boarding stops in Chengdu from November 2nd to November 8th 2014 as exploratory research to analyze the bus travel behaviors of student group. The full dataset contains 703,014 transactions, collected from 128949 smart cards of students. Table 3-1 show that each transaction record matched with the information of boarding stops has 6 characteristics including card identification, card type, consume date, route identification, bus identification, and stop identification.

Table 3-1. The characteristics of the transaction record

CARD_ID	CARD_TYPE	DATE TIME	ROUTE_ID	BUS_ID	STOP_ID
0061324	4	2014-11-2 7:05:22	59	00700	03012

(2)Method

A transit smart-card fare collection system collects a huge amount of data. In the case of the system in use in Chengdu, for example, about 703,014 entries are collected each week.As the growing number of data generated on an everyday, new developments designed to automatically extract knowledge from that large amount of data have appeared. The term commonly employed to unify them is “data mining”, a technique which uses tools from statistics database management and visualization, as well as new methodologies specifically developed to extract patterns from large data sets.

In following section, the differences in bus travel behaviors of student group between weekdays and weekends as well as the indicators for describing the regularity of the travel behaviors will be explored by using the dataset.

4 The regularity of student travel behaviors

(1)Activity rate on the transit network

The paper defined the H as activity rate, which means the ratio of the number of days used by student card belongings (H_S) with the number of observation days (H_G). In general, the card belongings with high activity rate on the transit network perform relative more regular in travel tracks. Table 4-1 shows the value of the activity rate (H) for the student group in one week. It can be seen that 66% of cards belongings to the experimental sample have been used in the transit network on 60%-100% of the observed days, which reflects the student group is loyal user of transit system.

Table 4-1. The active day distribution of students cards

Activity day	1	2	3	4	5
Number of cards	26171	8568	8578	13322	45678
H	0.26	0.08	0.08	0.13	0.45

(2) Variability of travel behaviors for temporal distribution

Figure 4-1 shows the number of boardings as well as trip rate per card for student group. It can be seen that both the two measures keep a flat trend during the weekdays. However, the number of boardings on weekends is obvious less than it for the weekdays, while the trip rate per card is higher compared to the weekdays.

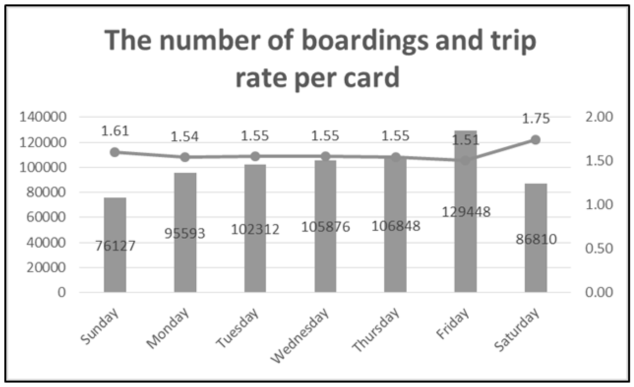

Figure 4-1. the number of boarding and trip rate per card

Figure 4-2 and Figure 4-3 represent the number of boardings for different time intervals for the weekdays and the weekends respectively. Figure 4-2 shows that the boarding time of the student group has a consistent trend for each weekday and has two peak hours including 7:00-8:00 a.m. in morning peak as well as 16:00-18:00 p.m. in evening peak. However, the regularity of the boarding time for the weekends is uncertain because of the flat trend for the different time intervals.

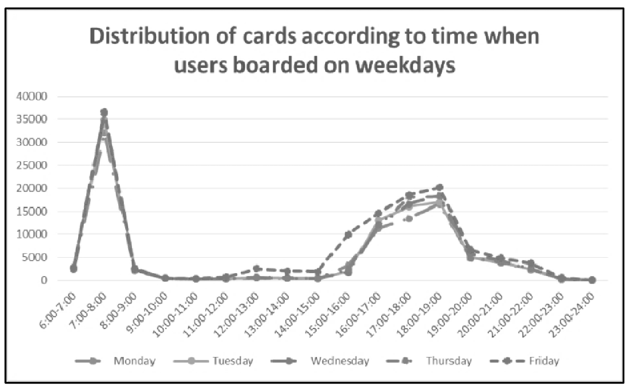

Figure 4-2. Distribution of cards according to time when users boarded on weekdays

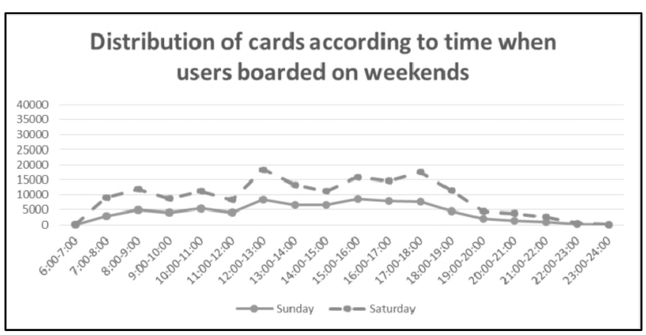

Figure 4-3. Distribution of cards according to time when users boarded on weekends

In addition, the coefficient of variation for the trip rate per card in weekdays is 0.19-0.23, which is lower than it for the weekends (0.33-0.34). It suggests the regularity of travel behaviors for the weekdays is more obvious than it for the weekends.

(3) Regularity of travel behaviors for spatial distribution

It can be seen from Figure 4-2 that the number of boardings is mainly in two time intervals including 7:00-8:00 a.m. and 16:00-18:00 p.m. and the number of boardings for 7:00-8:00 a.m. accounts for the one-third of the total number of the boardings. It dues to most of the students go to school in this period (7:00-8:00 a.m.). As a result of it, this paper selected this time interval (7:00-8:00 a.m.) to study the regularity of student travel behaviors in spatial distribution.

a. The number of the boarding stops

In this study, 7:00-8:00 a.m. interval was divided into four different time intervals for each 15 min to study the number of the boarding stops in every 15 min interval. The following figures (Figure 4-4-Figure 4-7) show the change of the distribution of the boarding stops in every 15 min interval on Monday.

Figure 4-4. 7:00~7:15

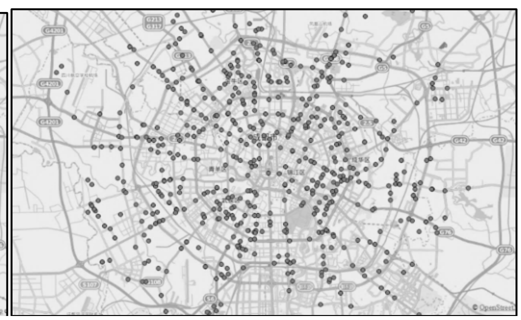

Figure 4-5. 7:15~7:30

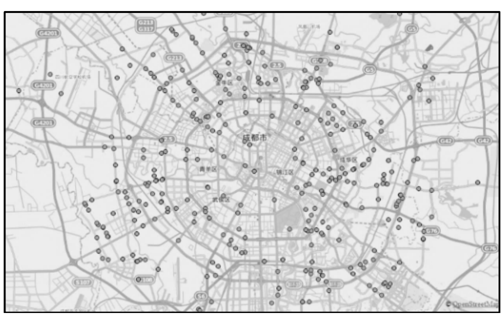

Figure 4-6. 7:30~7:45

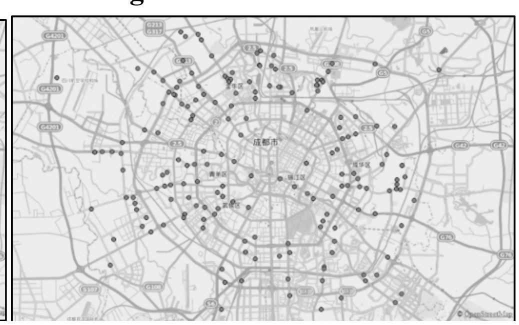

Figure 4-7. 7:45~8:00

Table 4-3. The numbers of boarding stops on weekdays

Time	7:00-7:15	7:15-7:30	7:30-7:45	7:45-8:00
Monday	1939	1842	1636	1272
Tuesday	2006	1894	1664	1318
Wednesday	2002	1924	1654	1299
Thursday	1985	1931	1660	1354
Friday	2015	1931	1679	1307
Decrease	-----	3%-5%	11%-14%	19%-22%

It can be seen from the figures that the number of the boarding stops has a decrease trend over time. Table 4-3 shows that the other weekdays perform the same regularity with the situation on Monday. On the whole, the number of boarding stops in the second interval (7:15-7:30 a.m.) decreases by 3%-5% compared to the first interval (7:00-7:15 a.m.) and the number in the third interval (7:30-7:45 a.m.) decreases by 11%-14% compared to the second interval. The rate of decline for the fourth interval (7:45-8:00 a.m.) compared to the previous interval is highest, which reaches 19%-22%.

b. The boardings of the stops

This paper selected top 30 boarding stops for the number of boardings in four intervals to analyze the boardings of the stops. The intervals include 7:00-7:15 a.m., 7:15-7:30 a.m., 7:30-7:45 a.m., and 7:45-8:00 a.m. There are steady 19,18,13,15 boardings stops in four intervals respectively during the weekdays by the result of data analysis.

Table 4-4 shows the boardings of the steady stops for each time intervals is 69 boardings per 15 min, 42 boardings per 15min, 29 boardings per 15min, and 20 boarding per 15 min respectively. It can be concluded that the boardings of the stops with high volume are relatively steady in the observation time interval for weekdays.

Table 4-4. The boardings of the stops in four intervals

Time	Max boarding	Min boarding	The number of stops	Average boarding intensity
7:00-7:15	148	45	19	69
7:15-7:30	103	30	18	42
7:30-7:45	47	20	13	29
7:45-8:00	27	14	15	20

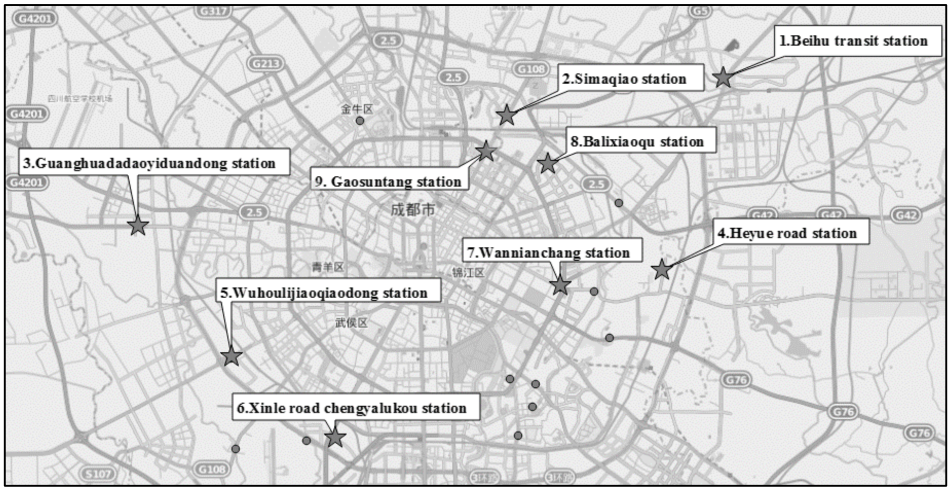

Figure 4-8. 7:00~7:15

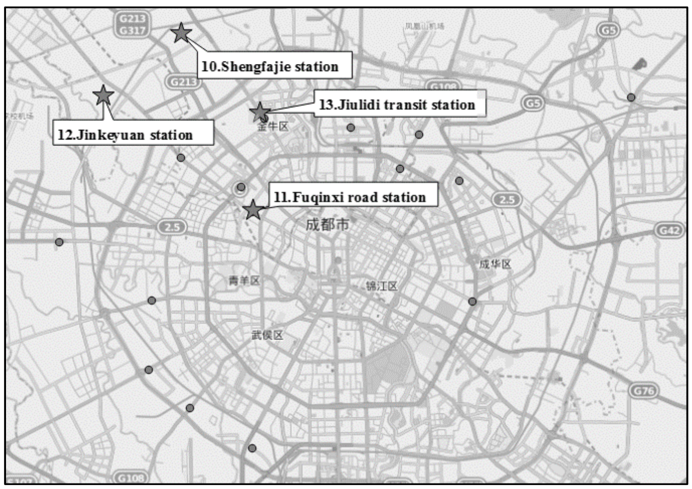

Figure 4-9. 7:15~7:30

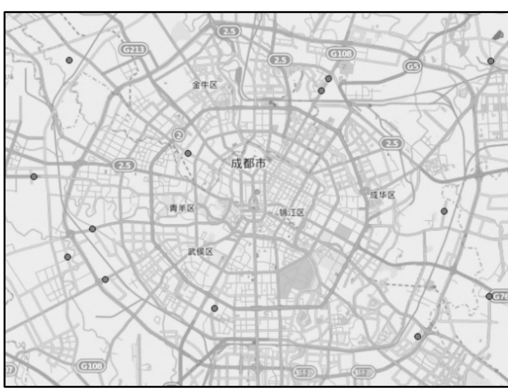

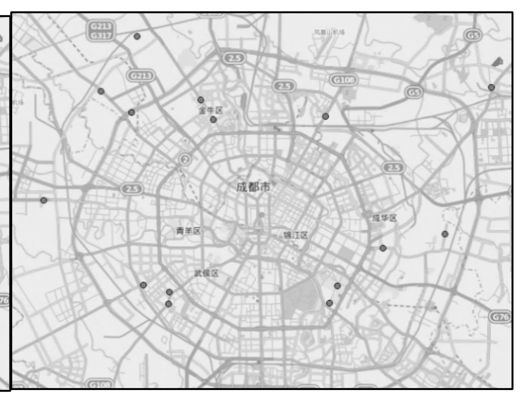

Figure 4-10. 7:30~7:45 Figure 4-11. 7:45~8:00

The above figures (Figure 4-8-Figure 4-11) show the spatial distribution of steady boarding stops in four intervals during weekdays respectively. We find that stop 1-5 with high boardings during 7:00-8:00 a.m. At stop 6-9 during 7:00-7:30 a.m. At stop 10-13 during 7:15-7:45 a.m.

Through analyzing students boarding stops, we find that the number of the boarding stops regularly decrease over time. We also find that most of top 30 boarding stops have stable boardings. It suggests the spatial regularity of travel behaviors.

5 Conclusion

With the popularity of the AFC system, it is reliable to use smart card data to reveal travelers behavior. Because smart card data can record cardholders various attributes in a long period, including boarding time, the stop of boarding and so on. By means of data fusion, smart card data can be combined according to the need of research, can depict the trajectory of travelers and can be found their temporal-spatial regularity.

This paper explain students are transit user with a high degree of loyalty during weekdays by active rate. We research trip rate per card and the number of boarding of students, found that students travel on weekdays higher stability than the weekend, mainly in the 7:00-8:00, 16:00-19:00during the weekdays. Then the number of boarding stops and the boarding of stop during peak hours on weekdays are examined, we found that the number of boarding stops presents an orderly decreasing trend, and the boarding of stop relatively stable. It is suggested that the students travel behavior have temporal-spatial regularity. If we are able to systematically analyze all types of travelers group, we can help transit operators to better understand transit demand. Then transit operators is able to adjust transit supply and provide better service.

Future experiments include the study of using the similar methods to analysis other types of cards and finding their travel regularity.

Acknowledgement

This research was supported by the Special Research Foundation of Science & Technology Department of Sichuan Provincial(Project No.:2014GZ0019-2), the People's Republic of China. It was a subproject of Sichuan Science and Technology Support Program key projects, named "research and application of key technology of urban intelligent traffic information extraction and coordinated control (the theory and application of bus lines optimization based on Dynamic Data Mining)".

Abstract: Intelligent transportation system as a new technology and management system, has been a hotspot and frontier in the traffic research. In addition to the application of intelligent transportation system in road traffic, waterborne, aviation, it also played a huge role in the "high security, high efficiency, high service quality" railway transportation, the railway intelligent transportation system (RTIS). Paper starts from the connotation and essential characteristics of railway intelligent transportation system, and its core technology, development model and strategy, then analyses the main body by the user, the service main body, service framework, logic framework, physical framework and economic and technical evaluation of several parts of the system framework of railway intelligent transportation system theory. Then, we analysis foreign railway intelligent transportation system from the aspects of improving the service quality, enhancing the safety of railway transportation and improving the efficiency of railway transport. After that, the paper introduces the application technology of railway intelligent transportation system in the domestic, such as the Transportation Management Information System, Train Dispatch and Command Management Information System, Automatic Train Identification System and Railway Ticketing and Reservation System. Finally, we combine with the application and development of domestic and foreign railway intelligent transportation system and the analysis of the future vision of rationality in order to meeting the needs of different users and play its biggest role.

Keywords: Railway intelligent transportation system; System framework; Application technology.

1 Summary of railway intelligent transportation system

1.1 The concept and connotation of RITS

Railway Intelligent Transportation System(RITS) on condition that mobile and fixed infrastructure are certain by supporting high-tech information technology, communications technology, sensor technology, intelligent control and decision technology, modern science and technology to achieve information collection, transmission, processing and sharing based on the completion of high efficiency, high safety, high-quality passenger and cargo transport stream generation railway system.

The connotation of Railway Intelligent Transportation System lies in the integration of contemporary advanced science and technology, to realize information sharing, and strengthen the train control system and the safety guarantee system construction on the premise of completed information; At the same time ,making efforts to ensure road safety, to improve transport efficiency and quality of service; Strengthening of comprehensive intelligent decision support system based on management and control of construction, improve the efficiency of the decision-making and scientific.

1.2 Essential characteristics of RITS

RITS focus on enhancing the competitiveness of rail transport market, improve transport efficiency and improve the quality of transport services as the goal, to achieve the transport process through the supervision and management information system to integrate an economic, social, technological the railway system, so it has the essential characteristics as following:

（1） Open system, information sharing.
（2） The application technology, intelligent processing.
（3） According to the demand, dynamic configuration.

1.3 The core technology of RITS

RITS core technology mainly includes support layer perception of the Internet of things (sensor network) technology, support the communication layer of the large capacity of communication technology, support the fusion layer of cloud computing technology and interoperability technology, support implementation layer knowledge reasoning technology and network security technology to protect the safety of the whole system.

2 System framework of the RITS

Railway Intelligent Transportation System framework is used for identifying and describing all the Railway Intelligent Transportation System essential services to users, as well as subsystems to achieve these functions, interfaces and information between the various subsystems and flow between the external environment.

RITS framework consists of user principal, the service principal, the service framework, the logical framework, and economic and technical evaluation of the physical framework of several components.

2.1 The user and the service subject

User main body for service system is a system framework of subject, also putting forward the demand in certain areas of the subject; the main body of the service is to provide service to the user main body. They are the relationship between the service and the service, also in the field of RITS service supply and demand.

2.2 Service framework of RITS

Service framework is the foundation of the whole system framework of RITS. The purpose is to meet various requirements, and the goals are realizing the "high quality service, high safety, high efficiency" intelligent railway transport system. RITS could be divided into seven service system and figure1shows that.

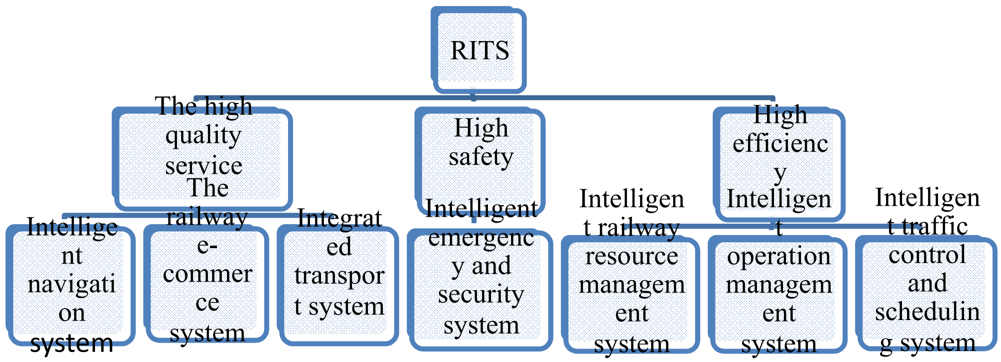

Figure 1. RITS service framework

2.3 Logical framework of RITS

The existence of the logical framework is mainly used to determine the main function of RITS system framework and accomplish the transmission between the information flow and data flow.

2.4 Physical framework of RITS

Physical framework is mainly used to make the each function substantial and modeling. Seven service systems which are divided from service framework as the central management subsystem links railway external user principals through the way of an external WAN wired or wireless communication, and via LAN or WAN, the central management sub the system can be connected to the station subsystem, subsystems and trackside train subsystems.

2.5 Common technology platform of RITS

RITS common technology platform integrates multi-source heterogeneous RITS subsystem information resources according to certain standards and becomes the carrier to collect, transmit, store, process, manage and release all kinds of railway transportation information. Its main function is that sharing data extracted from each business subsystem, and the multiple sources and inconsistent data fusion processing, performing multiple types of dynamic data and static data, time data, spatial data organization, ensuring the correctness of the relationship between the data, consistency and avoiding data redundancy, and provide decision support and information services.

3 Foreign RITS application technology research

3.1 RITS research on improving the service quality

Improve transport services in terms of quality, technology used in different countries vary. Europe via electronic data interchange (EDI) between modes of transport to build a multimodal transport system based on electronic markets, in order to achieve e-freight market positioning, seamless movement of cargo tracking, intermodal convergence operation and automated cargo handling and other stations to reach high efficiency, low consumption, sustainable standard door transport of goods between the integrated transport chain; the United States is also working on the promotion of compatible EDI systems and ITS technologies, and cargo tracking information and treatment, coordination and seamless connectivity between different modes of transport, improve the efficiency and flexibility of operating transport corridor between the public and private between the states; Japan Railway is gradually provide ticket information for travelers by means of e-commerce, service stations along the route, hotel, ticket reservations and other travel information service, at the same time, Japan established e @ train system provides a cheaper, safer, on time information sharing platform to meet the needs of different users.

3.2 RITS research on strengthening the railway transport safety

The research on strengthening the railway transport safety mainly relies on traffic safety inspection system, maintaining of the level crossing safety systems and rail disaster prevention system. First, the traffic safety monitoring is the use of onboard equipment and ground equipment for real-time train running status parameter tracking and detection, fault finding by parametric analysis and troubleshooting, in order to achieve security monitoring. Level crossing safety system is a level crossing in addition to the conventional signal flags, but also the addition of intelligent crossing equipment, real-time monitoring of the crossing, and the timely delivery of information to the crossing near the crossing of trains. Japan's railway disaster prediction and disaster prevention system is divided into two types of disaster monitoring system, the former using scientific methods to predict flooding line, tower defense and other disasters, forecasting, and take appropriate disaster warning and disaster developed under traffic rules to take preventive measures, while the latter is used for detecting those disasters which are difficult to predict, test run of the train to stop in time.

3.3 RITS research on improving the efficiency of railway transport

We must take train lines and operations management into consideration with scientific means to improve the efficiency of rail transport. European Rail Traffic Management System (ERTMS) is a typical foreign representative in improving the efficiency of rail transport. With the developing of European railway, in the late 1980s, European established a unified European Train Control System (ETCS) in order to ensure interoperability train operators, and later established the European Rail Traffic Management Project (ERTMS). ETCS system is the standard of ERTMS, railway communication system (GSM-R) as a platform, European point transponder as the positioning means, wherein ETCS is the most basic level, the use of conventional ground signal system, with fixed closed run, by Ground point transponder will pass the train traffic command, use the track circuit to check the integrity of the train and the train location. Increase traffic in the first stage, based on the command wireless transmission function, the entire range of two-way communications, driving the train from the command passed to the RBC (Radio Block Center), and using balise to position the trains. The third level has completely abolished the ground signal and increased vehicle equipment positioning trains.

4 Domestic RITS application technology

4.1 Transportation Management Information System（TMIS）

In order to improve the quality of services and transport railway transportation efficiency and achieve national railway transport management, information technology, Chinese railway development after decades of the most complex and the most massive, nationwide railway transport management information system (TMIS). TMIS system selects over 2000 main railway stations through a computer network , and collects trains, locomotives, vehicles, containers and cargo dynamic information, to achieve the train, cargo, rolling stock, real-time tracking of container node management, national railway transportation and production personnel at all levels to provide timely and accurate, and complete information and decision management solutions.

4.2 Train dispatch and command management information system（DMIS）

DMIS is a nationwide large-scale computer network signaling system, which uses digital technology, networking, information technology, within the national railway system related to train running, data sharing statistics, operational adjustments and data, and automated processing and inquiry, is a revolutionary breakthrough to the traditional dispatching mode. It greatly reduces the dispatcher's labor intensity and improve the efficiency of transportation and traffic control production level of technology and modernization of Railway Traffic Control.

4.3 Automatic train number identification system（ATIS）

ATIS aims to install an electronic tag on all locomotives and wagons (TAG), in all segments stations, marshalling yard, a large freight station and placed ground stations to identify the boundaries set (AEI), to train and run for accurate vehicle information identification, after computer processing systems to provide for TMIS trains, vehicles, containers real-time tracking information, provide a guarantee for accurate statistical boundaries station wagon, authorities can achieve real-time management of the car now.

4.4 Train railway ticket sale and reserve system（TRS）

TRS is to rely on computer management system, the full realization of the ticket, refund, booking, planning, scheduling, billing, statistics, query and other services for railway customer service provides an effective means of regulation, which marks the beginning of informational Chinese railway. The ultimate goal is to establish a TRS system covering the national railway network computer ticketing, ticket management and sale of work to achieve modernization, so as to facilitate passenger ticket and travel, passenger rail operators to improve the level and quality of service.

5 Recommendations for Future Research

From the departure from the whole railway development in our integrated transportation management system, providing customers with high efficiency, high security, high quality service: in terms of efficiency, to build integrated operational management system, to realize the passenger and cargo transportation efficiently; In terms of safety, should be intelligent construction of emergency rescue and security systems, real-time monitoring and safety evaluation for all kinds of disasters; In terms of service, should focus on building advanced user information system, for the passenger and cargo to provide detailed information and electronic secretary function.

Automatic Train number Identification System plays an important role in the railway intelligent transportation system, and railway freight transportation also plays an important role in the railway transportation. For the past 20 years, the scale and the flow rate of the railway freight trains increased significantly. It is difficult for the rail vehicle management center to make railway vehicle registration, records, statistics, scheduling, maintenance and tracking, and the traditional manual copy train number can't satisfy the demand of a new age. So the Automatic Train number Identification System arises at the historic moment. Imagining, if the Automatic Train number Identification System is not only applied to railway freight train, but throughout the railway train on each piece of goods, thereby it is convenient for railway staff to realize the running track of every piece of goods, and every owner can query logistics situation of their goods constantly. This will avoid the condition of missing goods and raise owner's satisfaction. But, at present still need to solve the problem is that the electronic tag cost highly. If there has a kind of cheap products which can replace the electronic tag and can also be identified by RFID technology . This is the key of the current, and the direction of future research.

Route Optimization of Multimodal Military Logistics Transportation

Jin Zhang

Training Center of Power Command, Department of Watercraft Power Command, Zhenjiang Watercraft College, No. 130, Taohuawu Rd., Zhenjiang. E-mail: zhang_jin_1115@163.com

Abstract: This paper discussed the methods to build up multimodal military logistics transportation networks, defined the topological structures of two-dimensional combined transportation networks without multiple edges and the expression of transportation networks' attribute values. A route optimization model for multimodal transportation based on military supply was established, which turned out to be a high-order model due to the fact that safety attribute was a multiplicative parameter. To solve this problem, this paper proposed two improvement methods, respectively simplifying the original non-linear high- order 0-1 programming model into second-order 0-1 model and linear 0-1 model, which made it far less complicate to get the solutions. For further demonstration, this paper chose a case scenario which involved 74 nodes for simulation analysis, using Lingo 9.0 for programming to get the solutions of the high-order model, the second-order model and the linear model. The consistent results proved the models' correctness and feasibility in getting solutions. It was specially worth noting that the improved linear 0-1 programming model was able to get real-time overall optimum solutions, demonstrating very good real-time performance, stability and solution-getting ability.
Keywords: Military logistics; Multimodal transportation; Non-linear 0-1 programming; Route optimization.

Multimodal military logistics transportation is a transport mode used by army troops to transit personnel, material and equipment. Analysis has showed that applying multimodal transport in military transportation can greatly improve its efficacy, optimize its structure, enhance its rationality and economical efficiency (JIN, Z. H., 2005 and LIU, J., 2011) . Therefore, in order to strength armies' logistics distribution capabilities in an IT-based environment and raise armies' economic benefits, it is of practical significance that we should strength multimodal military logistics transportation, and especially look into its core issue – route optimization.

1 Current Research Review

There have been a few research results on multimodal transportation concerning military logistics, mainly including: ZHANG Jin(ZHANG, J., 2013) proposed a method to convert high-order 0-1 programming models into second-order 0-1 models and validate the method through a simulation case to solve the problem that safety attribute usually results in high-order multimodal military logistics transportation models; YANG Xirui(YANG, X. R., 2008) employed Lagrangian relaxation method into his study, simplified this issue to cargo flow and traffic flow issues, respectively using multiple cargo flow and minimum cost circulation algorithm to get solutions; ZHANG Jiaying(ZHANG, J. Y., 2010) chose cost and time as his optimization objectives, established a model which took into account of time and transport capacity constraints, demonstrated the method to use genetic algorithm for programming and solution; LIU Huaxia(LIU, H. X., 2010) discussed the difficulties in developing multimodal military logistics transportation from organization structure and regulation levels; Akgün(İBRAHIM, A., 2007) proposed a mixed integer programming model for multimodal transport to solve Turkish armies' Deployment Planning Problem (DPP) and discussed the method to use CELPX for solutions; Yıldırım(UĞUR, Z. Y., 2009) also made a analysis study on DPP by applying Discrete-Event Simulation (DES) method.

2 Problem Description and Assumed Conditions

A certain battle zone plans to transport some materials (generalized concept) from a strategic logistics center to a front-line distribution center. Transference is allowed among existing transporting vehicles, but the process of transferring will occur cost and time. Transport capacity of any section should not be smaller than the transport volume. The whole process should comply with specified requirements in terms of time, cost and safety probability. The problem is to choose optimization objectives based upon military demands and decide the best transport route Γ.

In order to clearly clarify and reasonably simplify the problem, assumed conditions are as follows:

(1) If conflicting with civil transportation, military transportation has absolute priority, including the priority to assign transport vehicles and the priority of access;

(2) Sufficient prewar preparation and adequate vehicles (such as automobiles used for transference), which means that there are waiting vehicles during the whole process of unloading;

(3) In the process of transference and transportation, stagnation won't occurred by traffic jam or throughput limits of terminal yards.

3 Multimodal Military Logistics Transportation Network

Modern military transportation has a significant networking feature. Multimodal military logistics transportation network indicates the geographical distribution of all transport routes within a certain battle zone for military materials. It relies on a nation's regional space and is comprised by four types of transport sub-networks, including railway, highway, waterway and air (pipeline is not considered here). It constitutes the basis for military material transport and a fundamental condition for developing rapid reaction and comprehensive support capabilities. It is an ensemble of logistics centers, supporting objects (military clients), supporting pathways (transport routes), supporting facilities (loading and unloading equipment), all kinds of terminal yards (including railway stations, airports, harbors and bus stations).

3.1 The Topological Structure of a Combined Transport Network

Multimodal combined transport network is the basis of a route optimization model. Its topological structure can greatly affect a model's expression form and solution. Typical topological structures for such networks are as follows:

(1) Three-dimensional Combined Transport Network

Such a network puts the transportation nets of multiple transport modes on several parallel two-dimensional combined transport networks, adding transference edges between corresponding nodes (cities), and thus establishes a three-dimensional network which is comprised by many two-dimensional networks(ZHANG, Y. H., 2006). See Graph 1.

(2) Multi-edge Two-dimensional Combined Transport Network

Each node in a network like this indicates a transportation hub which provides many transport modes, and any transference process is completed within this hub. Multiple edges are added between two hubs to indicate that there are more than one transport mode. See Graph 2.

(3) Two-dimensional Combined Transport Network without Multiple Edges

Nodes in such a network indicates logistics centers, military clients and all kinds of terminal yards. Edges are added between linked nodes and a two-dimensional combined transport network without multiple edges is thus created. See Graph 3.

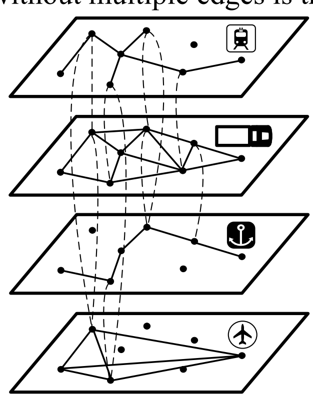

Figure 1. Three-dimensional combined transport network

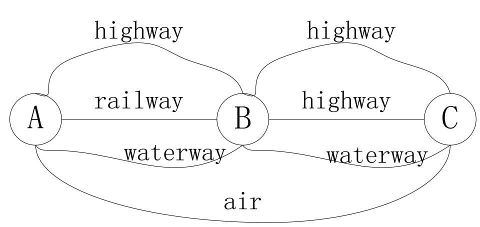

Figure 2. Multi-edge two-dimensional combined transport network unit

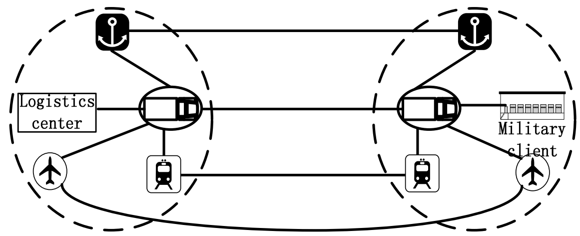

Figure 3. Two-dimensional combined transport network unit without multiple edges

In building up route optimization models, three-dimensional network and multi-edge two-dimensional network need to incorporate 0-1 decision variable $x_{ijk} \in X$, which means that transport mode k is used from city node i to city node j. As a result, the total number of this decision variable will be n×n×4, which is far too more than the number of a network's actual edges. For two-dimensional network without multiple edges, 0-1 decision variable $x_{ij} \in X$ needs to be considered, which means from terminal yard node i to j.The total number of this decision variable equals a network's actual edges.

3.2 The Definition of a Network's Attribute Value

More decision variables will cause the model to be more complicate. It is more advisable to establish a directed graph $G(V, E, T, C, P)$ for a two-dimensional network without multiple edges as the network's topological structure. In this directed graph, V is a point set and its total number is n; $v_i \in V$ indicates a point in the graph, and v_i=[1,2,3,4,5,6] respectively represent logistics center, train station, bus station (i.e. city express way or national highway's exit or entrance), airports, harbor and military client; E is an edge set, $e_{ij} \in E$ means that there are routes linking v_i and v_j; T is E's time attribute matrix, $t_{ij} \in T$ means that the time taken from v_i to v_j is t_{ij}; C is E's cost attribute matrix, $c_{ij} \in C$ means that the cost incurred from v_i to v_j is c_{ij}; P is E's safety attribute matrix, $p_{ij} \in P$ means safety probability in section e_{ij} is p_{ij}.

Establishing edge set attribute matrix T, C, P is fundamental to the establishing of a mathematic model. When $e_{ij} \notin E$, we define $t_{ij}=+\infty$, $c_{ij}=+\infty$, $p_{ij}=1$; when $e_{ij} \in E$, we need to discuss each matrix separately. Before discussion, we need to bring in homogeneity judgment matrix $B=[b_{ij}]_{n\times n}$:

$$b_{ij}=sgn[(v_i-v_j)^2] \quad \forall i,j \in [1,2,\cdots,n] \tag{1}$$

$sgn[]$ is a sign function, during homogeneous transport, $v_i=v_j$, $b_{ij}=0$; during non-homogenous transport, $v_i \neq v_j$, $b_{ij}=1$.

(1) Time Attribute

t_{ij}, as e_{ij}'s time attribute, indicates the time interval between the time when the first transport vehicle arrives at v_i and leaves v_j. During homogeneous transport, time attribute only relates to the time length of transportation, which means:

$$t_{ij} = s_{ij} / \mu_{ij} \tag{2}$$

In this equation, s_{ij} is edge e_{ij}'s mileage. When $e_{ij} \notin E$ *or* $e_{ij} \in E$ is interrupted by attacks, s_{ij} is $+\infty$, and μ_{ij} is e_{ij}'s average running speed.

During homogeneous transportation, transference process is completed via highway transport. Its time attribute includes the time for unloading (the time taken for unloading materials from v_i and transporting to transferring vehicles), the time for transferring, and the time for loading (the time taken for unloading materials from transferring vehicles and transporting to v_j). If unloading speed is faster than loading speed, then,

$$t_{ij} = \alpha_i g_i + s_{ij} / \mu_{ij} + \beta_j \cdot \min\{d_j, M\} \tag{3}$$

In this equation, α_i is v_i's unloading time coefficient (the time used for unloading unit material), and β_j is v_j's loading time coefficient (the time used for loading unit material); g_i represents transferring vehicles' (normally automobiles) standard loading capacity in v_i; M represents the total volume of distributed materials (valuation metric ton). For light goods, the volume will be converted according to relevant standards. d_j is the standard loading capacity of one single transporting vehicle.

If loading speed is faster than unloading speed, then

$$t_{ij} = \alpha_i \cdot \min\{d_j, M\} + s_{ij} / \mu_{ij} + \beta_j \cdot g_i \tag{4}$$

To sum up, the calculation formula for time attribute is:

$$\begin{aligned} t_{ij} = s_{ij} / \mu_{ij} + b_{ij}[\min\{\alpha_i, \beta_j\} \cdot g_i + \\ \max\{\alpha_i, \beta_j\} \cdot \min\{d_j, M\}] \quad \forall i, j \in [1, 2, \cdots, n] \end{aligned} \tag{5}$$

Further explanation for some special situations is as follows:

1) When e_{ij} is non-homogeneous transportation and v_i is a bus station, automobiles don't need to unload materials in v_i and will directly leave v_i for v_j. So α_i becomes 0.

2) When e_{ij} is non-homogeneous transportation and v_j is a bus station, β_j becomes 0.

3) When there is a railway directly linking train station v_i to harbor v_j, to calculate the result for t_{ij}, α_i is 0; to calculate the result for t_{ji}, β_i is 0.

4) When v_j is a military client, β_j is 0, and d_j equals g_i (transporting mission is completed when the first batch of materials arrive at their destination).

(2) Cost Attribute

Cost attribute c_{ij} indicates the direct economic cost incurred during e_{ij}'s transporting, loading and unloading process. It is comprised by transporting cost, loading and unlading cost. Transporting cost includes start-up cost and operation cost (start-up cost is usually ignored by highway and air transport, and operation cost of these two modes are directly determined by distance; start-up cost for shipping is mainly incurred by harbor pierage). During homogeneous transportation, c_{ij} is only about operation cost, and is related to transporting distance and volume. So,

$$c_{ij} = \gamma_{ij} \cdot s_{ij} \cdot M \tag{6}$$

In this equation, γ_{ij} represents operational base price, and its calculation unit is CNY/t*km.

During non-homogeneous transportation, c_{ij} includes transferring cost, loading and unloading cost, and transporting vehicles' start-up cost in v_j. So,

$$c_{ij} = (\eta_i + \gamma_{ij} \cdot s_{ij} + \lambda_j + \theta_j)M \tag{7}$$

In this equation, η_i represents v_i's unloading cost coefficient (CNY/t); λ_j represents v_j's loading cost coefficient; θ_j represents v_j's delivery base price ((CNY/t).

To sum up, the calculation formula for cost attribute is:

$$c_{ij} = [\gamma_{ij} \cdot s_{ij} + b_{ij}(\eta_i + \lambda_j + \theta_j)]M \qquad \forall i, j \in [1, 2, \cdots, n] \tag{8}$$

Further explanation for some special situations is as follows:

1) When e_{ij} is non-homogeneous transportation and v_i is a bus station, automobiles don't need to unload materials in v_i and will directly leave v_i for v_j. So η_i becomes 0.

2) When e_{ij} is non-homogeneous transportation and v_j is a bus station, λ_j becomes 0.

3) When there is a railway directly linking train station v_i to harbor v_j, to calculate the result for c_{ij}, η_i is 0; to calculate the result for c_{ji}, θ_i is 0.

4) When v_j is a military client, θ_j is 0.

(3) Safety Attribute

To define safety attribute p_{ij} for each section within a certain transporting network, it needs experts to make a comprehensive evaluation based on enemies attacking range and precision, surveillance technology and our armies' defense capability and transport facility's disguising level. As a result, this paper won't make too much discussion to define safety attribute's value. The value used in simulation analysis is only applied to prove the realizability of getting a model's solutions.

(4) Transport Capacity Constraints

When e_{ij} is homogeneous transportation, transport capacity constraint is not considered. When e_{ij} is non-homogeneous transportation, which means there will be transference, transport capacity constraint is comprised by three factors:

1) Vehicles' standard load capacity d_j in v_j is no less than the volume of the materials' minimum split cell, which means:

$$d_j \geq m \quad (9)$$

2) Vehicles' physical volume in length/width/Height ($l_j^1/l_j^2/l_j^3$) is larger than that of the materials' minimum split cell ($l_j^1/l_j^2/l_j^3$), which means:

$$\begin{cases} l_j^1 > l^1 \\ l_j^2 > l^2 \\ l_j^3 > l^3 \end{cases} \quad (10)$$

3) Total load capacity D_j of all vehicles in v_j is no less than the materials' total weight M, which means:

$$D_j \geq M \quad (11)$$

4 Route Optimization Model for Multimodal Military Logistics Transportation

A battle zone needs to choose route Γ to transport materials from strategic logistics center v_l to frontline distribution center or military client v_n. The total volume of these materials is M, and the entire process should not consume more *TIME* than W_t. In addition, the total *COST* should not exceed W_c, and safety probability *SAFETY* should not be smaller than W_p.

Optimization objectives vary from different battle fields. In order to keep the study's generality, the paper respectively choose total *TIME*, total COST and the whole SAFETY probability as objective functions to build a multi-objective route optimization model.

$$min \qquad TIME = \sum_{i=1}^{n}\sum_{j=1}^{n} t_{ij}x_{ij} \tag{12}$$

$$min \qquad COST = \sum_{i=1}^{n}\sum_{j=1}^{n} c_{ij}x_{ij} \tag{13}$$

$$max \qquad SAFETY = \prod_{i=1}^{n}\prod_{j=1}^{n} q_{ij} \tag{14}$$

$$s.t \quad x_{ij} = \begin{cases} 0 & represnetse_{ij} \notin \Gamma \\ 1 & representse_{ij} \in \Gamma \end{cases} \forall i, j \in [1,2,\cdots,n] \tag{15}$$

$$\sum_{j=1}^{n} x_{1j} = 1 \qquad \forall j \in [2,3,\cdots,n] \tag{16}$$

$$\sum_{i=1}^{n} x_{in} = 1 \qquad \forall i \in [1,2,\cdots,n-1] \tag{17}$$

$$\sum_{i=1}^{n} x_{ik} = \sum_{j=1}^{n} x_{kj} \qquad \forall k \in [2,3,\cdots,n-1] \tag{18}$$

$$u_i - u_j + n \cdot x_{ij} \le n-1 \quad \forall i, j \in [1,2,\cdots,n] \tag{19}$$

$$v_i \in [1,2,3,4,5,6] \ \forall i \in [1,2,\cdots,n] \tag{20}$$

$$b_{ij} = \operatorname{sgn}\left[(v_i - v_j)^2\right] \forall i, j \in [1,2,\cdots,n] \tag{21}$$

$$t_{ij} = s_{ij} / \mu_{ij} + b_{ij}\Big[\min\{\alpha_i, \beta_j\} \cdot g_i + \max\{\alpha_i, \beta_j\} \cdot \min\{d_j, M\}\Big] \qquad \forall i, j \in [1,2,\cdots,n] \tag{22}$$

$$c_{ij} = \left[\gamma_{ij} \cdot s_{ij} + b_{ij}(\eta_i + \lambda_j + \theta_j)\right] M \ \forall i, j \in [1,2,\cdots,n] \tag{23}$$

$$(m - d_j)\sum_{i=1}^{n}(b_{ij}x_{ij}) \le 0 \qquad \forall j \in [1,2,\cdots,n-1] \tag{24}$$

$$(M - D_j)\sum_{i=1}^{n}(b_{ij}x_{ij}) \le 0 \qquad \forall j \in [1,2,\cdots,n-1] \tag{25}$$

$$(l^k - l_j^k)\sum_{i=1}^{n}(b_{ij}x_{ij}) \le 0 \quad \forall j \in [1,2,\cdots,n-1], \forall k \in [1,2,3] \tag{26}$$

$$q_{ij} = \lfloor (p_{ij} - 1)x_{ij} + 1 \rfloor \quad \forall i, j \in [1, 2, \cdots, n] \tag{27}$$

$$TIME \leq W_t \tag{28}$$

$$COST \leq Wc \tag{29}$$

$$AFETY \geq Wp \tag{30}$$

This model is a 0-1 non-linear programming model, and its decision variable is x_{ij}; equation (15)-(19) specify that feasible solution for this model is the route Γ starting from v_l and ending in v_n, and give out the necessary sufficient condition that this route doesn't include any other sections. u_i can ban any real number(YUAN, X. S., 2006). equation (24)-(26) indicate sections' capacity constraint; in equation (27), q_{ij} represents the mission's safety probability, which means, when $e_{ij} \in \Gamma$, $q_{ij} = p_{ij}$; otherwise, q_{ij}=1.

Equation (14) is the expression of safety probability, which is a multiplicative parameter. It is a high-order equation, causing the whole model to be a far more complicated non-linear one. It will take a great deal of time to get the solution and enhance the uncertainty to obtain the overall optimum solution. To improve this model, we bring in decision variable – phase safety probability p_j, which indicates the safety probability from starting point v_l to v_j on distributing route Γ. It is not hard to find out that:

$$p_l = 1 \tag{31}$$

$$p_j = \sum_{i=1}^{n} p_i p_{ij} x_{ij} \quad \forall j \in [2, 3, \cdots, n] \tag{32}$$

Then ,a new expression equation for *SAFETY* is:

$$SAFETY = \sum_{i=1}^{n} p_i p_{in} x_{in} \tag{33}$$

After replacing equation (14) and (27) with equation (31) to (33), the power value of *SAFETY* equation is reduced from n^2 to 2. The original 0-1 non-linear programming model thus becomes a less complicated 0-1 second-order model.

However, after simplification, this model is still a non-linear one. In order to further simplify it to a linear 0-1 model, given the monotonicity of logarithmic function $ln()$, we replace *SAFETY with* $ln(SAFETY)$ as the optimization objective, and change the mission's equation of safety probability q_{ij}. After replacing equation (14) and (27) in the original model with equation (34) and (35), the model completely becomes a 0-1 programming model.

$$\ln(SAFETY) = \ln\left(\prod_{i=1}^{n}\prod_{j=1}^{n} q_{ij}\right) = \sum_{i=1}^{n}\sum_{j=1}^{n}\left(x_{ij} \ln p_{ij}\right) \tag{34}$$

$$q_{ij} = \exp\left(x_{ij} \cdot \ln p_{ij}\right) \quad \forall i, j \in [1,2,\cdots,n] \tag{35}$$

5 Case Scenario Simulation Analysis

This part will give a case scenario, describe a military logistics network, and discuss its route planning problem. The analysis will choose the improved one-order 0-1 programming model, using calculating software LINGO 9.0 for programming and solution to optimize distribution plans and prove the model's correctness and feasibility.

5.1 Case Mission

Authorities send out the order to make a thorough distribution plan to transport 1000 tons of materials from a strategic logistics center to a frontline distribution center within 40 hours. After successfully delivery, it is required to send special forces to protect essential traffic sections and facilities, repair damaged logistics security facilities, and improve the network's traffic capacity.

5.2 Military Logistics Combined Transport Network

In this network, there are traffic lines between any two harbors and any two airports. To make the graph less complicated, air and maritime lines as well as transferring edges are not marked out. See Figure 4.

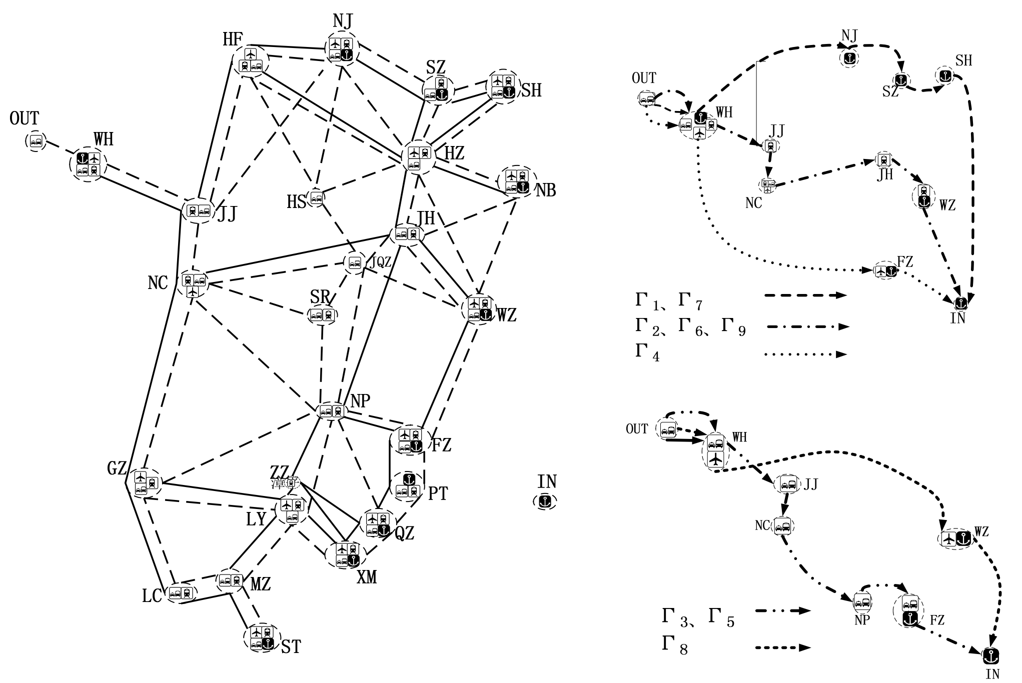

Figure 4. Military logistics supporting network

The military logistics combined transport network involves city nodes WH, NJ, HF, NB, NP, FZ, PT, XM, MZ, LY, SZ, JH, NC, JJ, FT, GZ, HS, JQZ, ZP, HZ, SR, ST, WZ, QZ, SH, LC, a strategic logistics warehouse (starting point/OUT), and a frontline distribution center (finishing point/IN). Each edge's attributes such as mileage, speed and safety probability can be obtained through measurement and statistic study, and attributes such as cost and time can be obtained calculation(LIU, S., 2008). Specific parameters are as follows:

1) Transport capacity

Transport capacity of one train carriage is 60 tons (the exact number of carriages depends on specific situations, but should be no more than 25). Transport capacity of an automobile is 10 tons. A ship can transport 1000 tons of materials and an airplane can transport 100 tons.

2) Time

On railway, transporting speed is 120 km/h, loading and unloading speed is 200 ton/h; On highway, transporting speed is 90 km/h, and transferring speed is 60 km/h; when using ships for transport, operation speed is 25 km/h, and loading and unloading speed is 150 ton/h; when using airplanes for transport, operation speed is 800 km/h, and loading and unloading speed is 100 ton/h.

3) Mileage

Table 1 specifies mileage between every city terminal yards. In the meantime, in order to simplify initial condition, the analysis assumes that transference mileage between any terminal yards within on city is 10 km.

4) Transference

The analysis assumes that automobiles can directly drive into other terminal yards for consecutive transport; that in cities which has the conditions for both railway and waterway transport, all harbors are directly linked with train stations by railways; that transference between railway and airway and that between waterway and airway can be realized through highway transport.

Note: the last letter indicates transport mode (T-Railway, G-Highway, S-Waterway, k-Air), the other letters indicate cities. For instance, WHG means a highway nodes in city WH.

5) Cost

Cost for railway transport is decided in accordance with authority standard issued by the Ministry of Railways. Commodity code is 2334 (quilt/mattress/tent/), delivery base price for carload freight is 10.4 CNY/t, operation base price is 0.0897 CNY//t*km (including railway construction fund), loading and unloading cost is 4.3 CNY/t. Cost for highway transport is decided with the reference of *2008 Xinjiang Commodity Transporting Rate.* Considering price inflation, operation base price is decided as 0.45 CNY//t*km (delivery base price can be ignored), loading price is 2.0 CNY/t, unloading price is 1.5 CNY/t. Cost for waterway transport is decided with the reference of *2008 Jiangxi Waterway Shipping Price Regulation*. Considering price inflation, delivery base price is decided as 5.0 CNY/t (means pierage base price), operation base price is 0.08 CNY//t*km, and according to the data issued by Chinese Harbor Association, loading and unloading cost is 20 CNY/t. Cost for air transport is decided with the reference of *the Rate for Air Transportation from Chongqing to other Cities in China*. Based on the price for transporting 1000 tons of materials from Chongqing to Nanning and from Chongqin to Shanghai, delivery base price is decided as 1097 CNY/t, operation base price is decided as 1.628 CNY//t*km, loading and unloading cost is 500 CNY/t (including fuel fee).

6) Safety probability

Safety probability is directly decided by expert grading method. See Table 1.

5.3 Plan Optimization

BY applying single-route multimodal transport route optimization model, choosing different optimizing objectives, giving different constraint conditions, using LINGO to simulate high-order, second-order and linear models, the solutions we get are consistent. For high-order model, it takes about 10 minutes to get the solution, and for second-order model, it takes about 1 minutes. The linear model is capable of real-time solution. According to the solution status demonstrated by LINGO, all solutions are overall optimum solution.

6 Conclusion

Multimodal combined transport has high reliability, lost cost, good flexibility and high efficiency. It is an important research area for military logistics distribution patterns. This paper focuses on the study of linear 0-1 programming model in multimodal military logistics transportation, finds out a suitable method to solve the non-linear problem caused by safety attribute's multiplicative feature. It simulates and verifies the method through case scenario, and the result of which shows that the improved linear model can greatly increase calculation speed, possessing very good real-time efficiency.

Table 2. Case Scenario Pre-act

Pre-act		Optimizing Objective	Total Mileage (Km)	Cost(ten thousand CNY)	Time (h)	Safety Probability	Constraining Conditions
Γ_1	OUT-WHG-WHS-HFS-NJS-SZS-SHS-IN	Cost	1839	17.95	79.77	0.808	none

Abstract: Logistics Network Assignment Problem is an important research field on logistics optimization. According to User Equilibrium theory, The equilibrium assignment framework of logistics network is a basic problem for it. The framework structure of logistics network consisted of carriers, logistics service providers, the shippers, and the modified Wardrop User Equilibrium of logistics network is proposed. Based on the modified UE condition, the optimum condition/equilibrium status of carriers, logistics service providers and the shippers in the equilibrium situation are analyzed.
Keywords: Logistics network; Modified user equilibrium; Equilibrium assignment framework.

1 Introduction

How to assign the flow rate and price among logistics subjects for maximizing the benefit, minimizing the cost and meeting the logistics needs in a logistics network is an important problem in logistics optimization design sector. The problem could be called Logistics Network Assignment Problem, LNAP.

The Network Assignment Problem, NAP, exists in sectors of economy, traffic, electronic power and information and raises concern of scholars. The Wardrop theory was applied in supply chain network at the first time according to the characters of traffic assignment problem (Nagurney and Dong et al., 2002). Nagurney (2003) provided a method to find out the winner supply chain in a supply chain network consisted of suppliers, manufacturers, retailers and demand markets. The super-network was used to discuss the equivalence problem between the supply chain network equilibrium and traffic network equilibrium (Nagurney, 2006). The supply chain network equilibrium problem with stochastic demand of retails was researched through a supply chain network model consisted of manufacturers and retailers (Dong and Zhang et al., 2004). The supply chain network equilibrium problem with multi-criteria decision maker was still researched (Dong and Zhang et al., 2002). The multi-commodity flow supply chain network equilibrium model with stochastic choice (Xu and Zhu, 2007), the multi-commodity flow supply chain network equilibrium model with random demand (Teng and Yao et al., 2007) and the supply chain network equilibrium model with multiclass multi-criteria stochastic choice (Xu and Zhu, 2008) were researched one by one. Zhang (2004) proposed that the assignment of logistics flow rate in logistics network should be researched via time and cost in the network.

In conclusion, there is a little research on LNAP. But LNAP has important value for recognizing the essence of logistics network and directing the logistics management and engineering in practice. This paper analyzes the equilibrium assignment framework of logistics according to the User Equilibrium theory. This is a basic problem for LNAP.

2 The Framework Structure of Logistics Network

Let the logistics network include 3 layers which are carriers, logistics service providers and shippers. The logistics network framework structure is shown as figure 1.

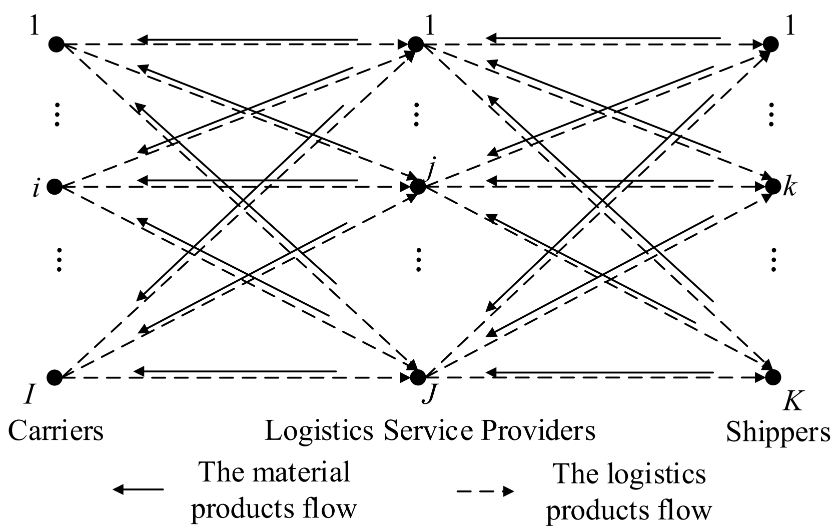

Figure 1. the Logistics Network Framework Structure

The nodes mean logistics activity participants. The directed arcs mean there are connections between the nodes which are connected by the arc. And the arcs also mean there are the flow of material product or the flow of logistics product between them.

Because the participants in the same layer provide the same products or services, there are competition relationships among them. For accomplishing the trade, consuming the logistics products and forming the flow of the material products, there are cooperation relationships among the participants in the adjacent layer. The Nash equilibrium could be used to describe the competition status of the participants in the same layer. They have the equilibrium status or optimum condition if they are in the Nash equilibrium points. The modified Wardrop User Equilibrium could be used to describe the status of whole logistics network, which is *the shippers in logistics network will choose the minimum cost path and make the network to reach the equilibrium status in which the cost of the used paths will be equal and not more than the cost of the unused*. The participants in every layer have the equilibrium status or optimum condition in the equilibrium status according to the equilibrium theory and competition/cooperation situation. The carriers and the logistics service providers pursue the minimum cost and reach the optimum condition. The shippers choose the minimum price of logistics products provided by different logistics service providers and reach the equilibrium status. The whole logistics network reach the equilibrium status if the participants in 3 layers reach the equilibrium status/optimum condition at the same time.

3 The Equilibrium Status/Optimum Condition of Participants in Logistics Network

3.1 The Optimum Condition of Carriers

Assume the carriers obey the rational-economic assumption. Let q_i be logistics product output of the carrier i, then the output of all carriers could be denoted by column vector $q \in R_+^I$, $q = (q_1,\ldots,q_i,\ldots,q_I)^T$. The carrier i will spend product cost f_i for manufacturing logistics products. Because of the competition among the carriers, the product cost function of the carrier i has relationships with output q of all carriers and product time t. then the f_i is

$$f_i = f_i(q,t), \forall i \in I \tag{1}$$

Every carrier would trade with every logistics service provider of the adjacent layer in logistics network. Then there are logistics product volume q_{ij} between the carrier i and the logistics service provider j. carriers must ensure all logistics products could be sold to logistics service providers for the maximum profit. In other word, carriers must ensure flow conservation between them and logistics service providers. That is

$$q_i = \sum_{j=1}^{J} q_{ij} \tag{2}$$

So the logistics product trade volume between all carriers and logistics service providers could be denoted by IJ dimension column vector Q^1, $Q^1 = \left(Q_1^1, \ldots, Q_i^1, \ldots, Q_I^1\right)^T$, $Q_i^1 = \left(q_{i1}, \ldots, q_{ij}, \ldots, q_{iJ}\right)^T$.

The trade cost c_{ij} of the carrier i is

$$c_{ij} = c_{ij}\left(q_{ij}\right) \tag{3}$$

The c_{ij} could be all cost that the carrier i spends for the successful trade with the logistics service provider j.

According to the rational-economic assumption, the objective of the carrier i is the maximum profit. Let P_{1ij} be the product price of the carrier i who sales the product to logistics service provider j, then the optimizing model is

$$\max z_1 = \sum_{j=1}^{J} p_{1ij} q_{ij} - f_i(q, w^1) - \sum_{j=1}^{J} c_{ij}\left(q_{ij}\right) \tag{4}$$

$$\text{s.t.} \quad q_{ij} \geq 0, \forall j \tag{5}$$

Equation (5) shows that the trade volume between the carrier i and the logistics service provider j is non-negative.

3.2 The Optimum Condition of Logistics Service Provider

Logistics service providers trade with carriers and shippers at the same time. They satisfy the demands of carriers and shippers depend on their understanding of the supply and demands in the logistics market. Logistics service providers purchase logistics products from carriers, and sale these things to shippers according to their demands. The logistics service provider j should spend management cost c_j for doing these things. And c_j has relationship with $\sum_{i=1}^{I} q_{ij}$ obviously, then c_j is

$$c_j = c_j(Q^1), \forall j \in J \tag{6}$$

According to the rational-economic assumption, the objective of the logistics service provider j is the maximum profit. Let p_{2j} be product sale price of the logistics service provider j who provides logistics products to shippers, and q_{jk} be logistics product volume between the logistics service provider j and the shipper k, then the optimizing model is

$$\max z_2 = \sum_{k=1}^{K} p_{2j} q_{jk} - c_j(Q^1) - \sum_{i=1}^{I} p_{1ij} q_{ij} \tag{7}$$

$$\text{s.t.} \quad \sum_{k=1}^{K} q_{jk} = \sum_{i=1}^{I} q_{ij} \tag{8}$$

$$q_{ij} \geq 0, q_{jk} \geq 0, \forall i, k \tag{9}$$

Equation (8) shows that the logistics product volume which the logistics service provider j sales to all shippers equal to the volume which is purchased from the carriers. Equation (9) shows that q_{ij}, q_{jk} is non-negative.

3.3 The Equilibrium Status of Shippers

Shippers obtain logistics products with the minimum price by obeying the spatial price equilibrium theory. The shipper k could reach the equilibrium status described by the modified UE equilibrium condition between them and logistics service providers. The condition is *the prices with which the shipper purchases logistics products from the logistics service providers are equal and not more than the prices with which the shipper does not purchase the products if the shipper and all logistics service providers are in the equilibrium status*.

The trading volume of logistics products between all logistics service providers and all shippers could be denoted by JK dimension column vector Q^2, $Q^2 = \left(Q_1^2, ..., Q_j^2, ..., Q_J^2\right)^T$, $Q_j^2 = \left(q_{j1}, ..., q_{jk}, ..., q_{jK}\right)^T$. Let c_{jk} be trade cost which the shipper k spends for logistics products. And c_{jk} has relationship with $\sum_{j=1}^{J} q_{jk}$ obviously, then c_{jk} is

$$c_{jk} = c_{jk}(Q^2), \forall j \in J, \forall k \in K \tag{10}$$

Let p_{3k} be the price which the shipper k is willing to spend for logistics products, set p_3 be the prices which all shippers are willing to spend for, $p_3 = \left(p_{31}, ..., p_{3k}, ..., p_{3K}\right)$, d_k be demands of the shipper k. Because d_k has relationship with the shipper k and all other shippers, d_k is

$$d_k = d_k\left(p_3\right), \forall k \in K \tag{11}$$

If the shipper k is in the equilibrium status, the situation could be denoted by complementarity problems, that is

$$\begin{cases} \left[p_{2j} + c_{jk}\left(Q^2\right) - p_{3k}\right] \times q_{jk} = 0 \\ p_{2j} + c_{jk}\left(Q^2\right) - p_{3k} \geq 0 \\ q_{jk} \geq 0 \end{cases} \tag{12}$$

and

$$\begin{cases} \left[\sum_{j=1}^{J} q_{jk} - d_k \left(p_3 \right) \right] \times p_{3k} = 0 \\ \sum_{j=1}^{J} q_{jk} - d_k \left(p_3 \right) \geq 0 \\ p_{3k} \geq 0 \end{cases} \quad (13)$$

Equation (12) shows that if the shipper *k* chooses the logistics service provider *j* to trade in the equilibrium status, $q_{jk} > 0$ between them, the practice price of the logistics products from the logistics service provider *j* to the shipper *k* is the minimum price, then the sale price of the logistics service provider *j* p_{2j} plus the transaction cost $c_{jk}\left(Q^2\right)$ equal to the price p_{3k} which the shipper *k* is willing to pay for logistics products. On the contrary, if p_{2j} plus $c_{jk}\left(Q^2\right)$ is more than p_{3k}, the shipper *k* does not want to buy logistics products from the logistics service provider *j*, that is q_{jk}=0.

Equation (13) shows that if the shipper *k* chooses the logistics service provider *j* to trade in the equilibrium status, $p_{3k} > 0$ exists, then the trade volume between the shipper *k* and all logistics service providers is the minimum demand of the shipper *k*. Otherwise, if the shipper *k* does not want to pay for logistics products, that is p_{3k}=0, then demands of the shipper *k* is not more than logistics products volume it purchases from all logistics service providers or the logistics products could be treated as free goods. The situation is impossible in practice.

4 Conclusion

The equilibrium assignment framework of logistics network is analyzed in this paper. If logistics network is in the equilibrium status, carriers, logistics service providers must reach the optimum condition and shippers must reach the equilibrium status. Though the equilibrium status/optimum condition is proposed, the equilibrium status of whole logistics network and the model which could describe the state still need to be researched in the future.

Strategy of Constructing a Green Logistics System for the Pearl River Delta

Xiaoping Xu

College of Management, Shenzhen Polytechnic, Liu Xian Ave., Xi Li Nanshan District, Shenzhan 518055, China. E-mail: xuxiaoping@szpt.edu.en

Abstract: The paper focuses on the research of green logistics. It studies on how to constructing a green logistics system in the Pearl River Delta in detailed. It points out that only constructing an effective green logistics system in the Pearl River Delta can improve the overall development level of logistics in this area. This paper gives some suggestions on how to build a green logistics system in the Pearl River Delta in order to improve the development of green logistics. These suggestions may be include as perfecting green logistics legal system, constructing comprehensive transport system, improving green logistics technology and so on.
Keywords: The Pearl River Delta; Green logistics; Strategy; Transport system.

1 Introduction

The paper describes the definition of green logistics firstly. And the paper completely analyses the problems which exist in the development of green logistics in the Pearl River Delta, such as imperfect regional comprehensive transport system, backward green logistics technology and so on secondly. At last the paper points out some measures on how to construct a green logistics system in the Pearl River Delta in order to improve the development of green logistics. These measures may be include as perfecting green logistics legal system, constructing comprehensive transport system, improving green logistics technology and so on.

2 Connotation of Green Logistics

The rapid development of logistics industry has made positive effects on the social economy. But it also brings a series of environmental problems which seriously affected the living environment of human beings. Under this background, the idea and the method of the sustainable development theory, the circulation economic theory, the social responsibility of enterprise theory, the supply chain management theory, the government regulation theory and other basic theory are gradually introduced to the studied field of logistics. So the concept of green logistics was appeared. At present, the concept of green logistics has no uniform definition. The professor WANG (WANG Changqiong) of China defined green logistics as the process of planning, implementing, managing and controlling logistics system through advanced logistics technology and environment oriented management concept with the goals of reducing pollution emissions and resource consumptions.

The connotation of green logistics can be described as the process of establishing the environmental friendly logistics system with the participation of governments, enterprises and all social public, which can reduce consumption and pollution with the method of re-planning, reorganizing, coordinating and controlling the whole life cycle of product. The goal of the system is to improve the further development of circular economy and sustainable development. Based on the theory of corporate social responsibility and government regulation, the system integrates the ecological economy and ecological ethics thoughts into supply chain management practice.

3 Current Situation and Problems of the Development of Green Logistics in the Pearl River Delta

3.1 Current Situation of the Logistics in the Pearl River Delta

The Pearl River Delta Economic Region includes 9 cities, they are Guangzhou, Shenzhen, Zhuhai, Huizhou, Zhaoqing, Foshan, Jiangmen, Zhongshan and Dongguan and with a total area of 41600 square kilometers. The level of the logistics service in the Pearl River Delta is the most advanced among the three major economic regions, including the Pearl River Delta Region, the Yangtze River Delta Region and Bohai Region. The Pearl River Delta is gathered with the nation's largest port group, such as Guangzhou port, Shenzhen port, Zhongshan port, Zhuhai port, Humen port, Huizhou port. And among these ports, Guangzhou port and Shenzhen port are the famous international port. The Pearl River Delta has developed Airport facilities. Taking Guangzhou as the center within 200 km, there are five international airports gathered in this region. They are Guangzhou, Shenzhen, Zhuhai airport. Macau Airport and Hong Kong Airport are adjacent to this region. The Pearl River Delta has widely highway network, such as Guangzhou-Shenzhen highway, Guangzhou-Foshan highway, Foshan-Kaiping highway and so on. The two main railway lines (Beijing-Guangzhou Line and Beijing-Kowloon Line) traverse this region. These two lines are also the transportation artery of China. The Pearl River Delta has formed a comprehensive transportation system which motor and water transport are the main ways of transportation while railway and air transport are the secondary ways of transportation. Logistics enterprises in the Pearl River Delta have grown up, such as Sinotrans Guangdong Branch and PGL and so on. A number of intensive and large scale logistics distribution centers and the third party logistics enterprises have appeared.

The Pearl River Delta logistics industry has improved the regional economic development but it also has caused serious pollution to the environment. The exhaust emissions of motor vehicle, the release of noise and traffic congestion pollute the air. Excessive packaging consumes a large amount of natural resources, resulting in more and more packaging waste remained on the earth. Chemical pesticides used in the process of storage and inflammable and explosive dangerous goods moved in the process of logistics can cause pollution or damage to the surrounding environment. These factors have become invisible killer in the field of the environment.

3.2 Current Situation and Problems of the Development of Green Logistics in the Pearl River Delta

Plan (Program) for Reform and Development of the Pearl River Delta Region (2008-2020) (short for PRD) and the Twelfth Five-Year Plan for National Economic and Social Development of Guangdong Province (short for The Twelfth Five-Year Plan) provide the policy support for the development of green logistics in the Pearl River Delta. But there are still some problems exist in the development of green logistics. The main problems are the following:

(1) Imperfect legal system of green logistics

At present, there has no uniform and systemic law for green logistics in the Pearl River Delta. Each of the nine cities in the Pearl River Delta has its environmental rules, such as Guangzhou Environmental Rules, Shenzhen Environmental Rules and so on. And now there has no green logistics laws for each city, only has some relevant policies for green logistics, such as Rules on Accelerating the Development of Circular Economy for Guangzhou, Rules on Promoting Circular Economy for Shenzhen Special Economic Zone, Rules on Promoting Ecological Civilization Construction for Zhuhai Special Economic Zone and so on. These fragmentary rules can not form an effective constraint mechanism to improve the healthy development of green logistics in the Pearl River Delta.

(2) Imperfect inter-city comprehensive transportation system

The inter-city comprehensive transportation system in the Pearl River Delta is not perfect, and the regional traffic has not formed the unified planning, unified management and overall construction. On the aspect of traffic infrastructure construction, the cities constructed respectively with the result that the transportation network is uncoordinated and imperfect and the construction of the roads is redundant. For instance, the number of port, waterway, railway, air and the other transportation facilities are more than the number of the road facilities in the Pearl River Delta Region. The expressway network has already formed in the Region, but still not perfect, resulting in the partial congestion of Guangzhou-Shenzhen expressway and Guangzhou-Foshan expressway. This reduces the development speed of logistics greatly and increases the cost of logistics. In addition, the construction of transportation hubs is not perfect and the ports facilities do not have complementary advantages either on hardware or on software. This greatly weakened the comprehensive competitiveness of the Pearl River Delta port cluster. It is difficult for the Region to form a coordinated development "win-win" situation between hub ports and feeder ports.

Transportation service system in the Pearl River Delta lacks the coordinated and unified management mechanism, such as non-standard logistics technology and logistics service, poor information transfer and so on. Integration of the regional transport market has not formed. The independent development and the vicious competition between the cities prevent the orderly development of regional traffic integration of Pearl River Delta. Every departments of the comprehensive transportation are managed by different administration agencies. For instance, motor and water transport are administrated by Traffic Authority, rail transport is administrated by the Ministry of Railway, air transport is administrated by the Civil Aviation authority, municipal road, rail transit and public transport are administrated by the local governments. Although these departments are worked with higher enthusiasm, management mechanism of regional integration transportation has not been formed because of the difference on the management system and technical standards.

(3) Backward in green logistics technology

Green logistics technology refers to the greening of logistics equipment, logistics facilities, logistics technology and logistics information. At present, green logistics technology of the Pearl River Delta is backward. Unreasonable and low efficiency of energy consumption is the main problem for motor vehicles, which leads to the higher level of carbon emissions. The standards of equipments of various transport modes are not unified, such as railway containers and shipping containers with different standards, which prevent the development of multimodal transport. The standards between logistics equipment are not matched, as packaging standards and facilities standards are different, which results in the goods cannot be effectively moved in the process of transportation, warehousing, loading and unloading. At the same time, a lower mechanization and automation in logistics activities results in poor environmental performance of logistics equipment.

The current planning and construction of logistics facilities in the Pearl River Delta has less consideration on the environmental protection and sustainable development requirements. In addition, there are some problems such as redundant construction, unreasonable site selection, low efficiency in the process of the construction of ports, stations, distribution centers and other facilities and so on.

Logistics process is refers to the process that organizes each functional elements and between the functional elements of logistics, including transportation, warehousing, packaging etc.. At present, there are some problems exist in the logistics process of the Pearl River Delta, such as empty backhaul transport, repeat construction and unreasonable site selection of warehouse, excessive packaging and so on.

The problems of logistics information technology prevent the development of green logistics in the Pearl River Delta. These problems include low information acquisition speed and high error rate of Bar Code technology, high cost and poor economic performance of RFID (the technology of radio frequency identification), nonstandard format of EDI (the technology of electronic data interchange), unobvious advantages of GPS (the global positioning system) in the goods tracking and scheduling optimization of vehicle etc..

(4) Ineffectively Green supply chain system

There has no unified definition for Green supply chain now. The typical definition of green supply chain management in China is: A comprehensive modern management mode with the consideration of environmental impact and resource efficiency in the entire supply chain, which is based on green manufacturing theory and technology of supply chain management, involving the suppliers, manufacturers, retailers and users, its purpose is to make the products with the lest impact on the environment (negative effects) and the highest resource efficiency in the whole process from the material acquisition, processing, packaging, storage, transport, usage to scrap processing. At present, the greening awareness of the enterprises in the supply chain is weak. Each enterprise focuses on the economic benefits without effective measures to greening the environment. In addition, the green reverse logistics system is not perfect.

4 The Strategy for Constructing a Green Logistics System in the Pearl River Delta

4.1 To Construct the Green Logistics Law System

Perfect law system is helpful to the development of green logistics in the Pearl River Delta. The government at all levels in the Pearl River Delta should construct the green logistics law system in two aspects. One aspect is to construct the regional green logistics law system and perfect constraint mechanism and incentive mechanism. The government should strengthen the comprehensive management and coordination in production, circulation, environmental, ecological and other aspects. Some environmental laws should be promulgated, such as Recovery & Recycling law, Law of Air Pollution Control, Law of Noise Control, Law of Solid Waste Pollution Prevention and Control. The government should strengthen the enforcement of current regulations, such as Comprehensive Utilization of Resources Regulations, Packaging Materials Recycling Approach, the Old Household Appliances and Electronic Products Recovery & Recycling Regulations, Traffic Industry Environmental Protection Regulations, and so on. On the other hand, the region should innovate government administrated mechanism, especially in perfecting mechanism of logistics pollution source, mechanism of environment bearing capacity for logistics, and mechanism of logistics waste material, according to its' advantages and disadvantages, with the domestic and foreign advanced experience. Some measures can be taken in order to innovating government administrated mechanism. For example, the Pollution Levy System and License System can be implemented in the enterprises of the Pearl River Delta. The Pollution

Levy System is the system that the government charging pollution discharge fee for all kinds of enterprises, according to the amount of emission. This system has been successfully implemented in foreign countries with the good results. The License system means that the government ruled the total amount of sewage in a certain period for all enterprises, according to the environmental resources carrying capacity. The ruled total amounts of sewage are assigned to the quota way among enterprises, emission of each enterprise can be assigned to the reserved for their own use, also can be sold in the market. License system is a kind of total quantity control system, which can effectively control the cost of pollution by adopting market mechanism without the governmental intervention behavior. This system has been developed for more than ten years in the developed countries.

4.2 To Construct the Comprehensive Transportation System

The comprehensive transportation system can be constructed for the following steps in the Pearl River Delta. Firstly, the governments should overall plan and improve the infrastructure network of the regional comprehensive transportation. The region should integrate the existing transportation resources and improve the service level of integrated transportation and promote the service ability with reducing the investment. To construct the highway network, rail and intercity rail transit network, the combination of port group in the Pearl River Delta in order to promote the service ability of traffic hub. Secondly, the governments should formulate a unified regional traffic management system and standards to provide institutional guarantee for the implementation of traffic integration. To eliminate administrative barriers and make for Pearl River Delta regional transportation regulations, to break local protectionism and unify punishment standards and market access system in order to form opened transparent and unified regional transportation market. To stipulate technical standards in order to facilitate communication and coordination in the municipalities unified technology platform. For instance, the government can stipulate technical or operational standards of logistics industry in order to form standards system of logistics. Thirdly, the government should construct service system of integrated transportation. To construct international transport channels with the major coastal ports as the center and the international logistics transportation network with the airport as the center. To improve domestic logistics network, the regional distribution and courier service network. Lastly, the government should implement the integrated traffic mechanism. The region should integrate the existing traffic management departments and set up Traffic Bureau (provincial and municipal etc.). The Bureau should be a rational division of labor, well defined power and responsibility, scientific decision-making, effective supervision and implementation of the traffic management system. To form the standardized procedures for deliberation and coordination and establish the permanent coordinating office in the Pearl River Delta Region, which can resolve the problems of the integrated traffic.

4.3 To Construct the Innovation System of Green Logistics Technology

The clean energy engine should be promoted in the Pearl River Delta in order to achieve low carbon emission of the vehicle. The governments can take the following measures for constructing the innovation system of green logistics technology:

(1) To research and develop methanol, ethanol, liquefied petroleum gas (LPG), compressed natural gas (CNG) vehicles in the market.

(2) To develop the multimodal transportation greatly, increase the market coverage of railway transport, water transport and pipeline transport appropriately, reduce the amount of water transport as less as possible.

(3) To overall plan and construct logistics facilities in order to avoid the repeat construction of station, port, logistics centers and other facilities and the reasonable choice for the regional logistics nodes.

(4) To promote the development of greening organizational processes of logistics. Two steps can be taken: the first step is to realizing the greening organizational processes for each functional element of logistics. Such as green transportation, green packaging, green warehousing and so on. The second step is to realizing the greening organizational processes between different functional elements of logistics. These may be include eliminating the barrier between the functional elements of logistics, realizing the seamless connection between the elements, reducing invalid activities, effectively achieving green organization process.

(5) To improve the development of logistics information technology. The governments at all levels should encourage and support enterprises to introduce advanced information technology and management technology in order to improve the service level of logistics enterprises in the Pearl River Delta. The governments should improve the current logistics information technologies as EDI, BC, ERP, RFID, GPS and other information technology in order to solve the problems of the existing system, realize resource sharing, information exchange and data sharing among the Logistics enterprises and promote the development of green logistics in the Pearl River Delta.

4.4 To Construct the System of Green Supply Chain

Green supply chain system can be constructed in the following ways:

The first is to construct the forward green supply chain system. The enterprises should choose the green partners, which can implement the greening process of the whole product life cycle from product design, production, packaging, transport, usage to recovery. The green partners may include green suppliers, green wholesalers, green retailers and green final customers. The enterprises of the green supply chain should implement intensive, high efficiency and pollution-free operation mode. The second is to construct the recycling logistics system. Enterprises should improve the system of reverse logistics and build processing center of reverse logistics. The waste materials which produced in the process of production by the numbers of supply chain can be recovered and transported to the processing center. The recovered materials are classified in the processing center. Harmful and useless goods are eliminated timely. Recyclable goods are reprocessed into new materials which flow from the point of origin to the point of consumption and form the recycling and reuse closed-loop circulation system (as shown in Figure 1).

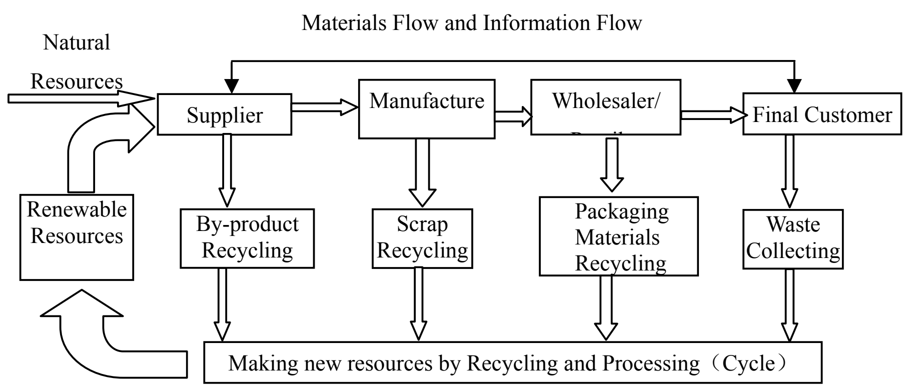

Figure 1. Recycling Logistics System

5 Conclusions

Here we may draw the following conclusions.

The government should play a vital role in improving the development of green logistics in the Pearl River Delta. It needs the joint efforts of governments, enterprises and customers.

(1) To Construct the Green Logistics Law System

(2) To Construct the Comprehensive Transportation System

(3) To Construct the Innovation System of Green Logistics Technology

(4) To Construct the System of Green Supply Chain

A Location Method for a Distribution Center Based on the Gravity Model and the Bi-Level Programming Model

Mingming Zheng[1] and Hongfeng Xu[2]

[1]Lecturer, School of Traffic Engineering, Dalian Jiaotong University, Dalian, Liaoning 116028, China. E-mail: zhengmm1979@126.com
[2]Ph.D., Associate Professor, School of Transportation and Logistics, Dalian University of Technology, Dalian, Liaoning. E-mail: xu_hong_feng@126.com

Abstract: This paper proposes a new method which fully considers the interests of logistics planning department and the clients. This method can define the initial solution of the Bi-level programming model by gravity model, and simplify the calculation of bi-level programming model. The numerical experiment results show that the proposed method are feasible and effective.
Keywords: Distribution center; Location; Gravity model; Bi-level model.

1 Introduction

Distribution center location has a great influence on modern logistics activities. Well located distribution centers can reduce transportation costs and improve operation efficiency. Therefore, locating distribution centers is an important decision-making problem. So far, there have been many methods and models for distribution center location. Aikens proposed 9 basic models after he had generalized the location problem of distribution center. Gravity model which is a typical continuous location model has the advantages of simple modeling and calculation, but it only considers the delivery expense without the variable costs and fixed costs based on distribution center construction and management. And the location of distribution center calculated by gravity model sometimes is unreasonable because of ignoring geographical constraints. Bi-level programming model belongs to discrete location model, it fully considers both logistics planning department and the interests of customers. The result deduced by Bi-level programming is in line with the actual situation because the alternative locations considered geographical constraints. The disadvantages of this model include uncertainty in the initial positions and complex computational procedure.

Considering the advantages and disadvantages of both models, this paper proposes a new method based on gravity model and Bi-level programming model to optimize the location of the distribution centers. The optimization process is summarized as follows:

(1) Investigate and analyze client demands and positions and unit delivery price.

(2) Establish a gravity model with the aim of minimizing total delivery expense and get a theoretical optimal solution.

(3) Considering land use planning and principle of distribution center locating, determine the finite optional positons according to the above result, which are the initial positions of bi-level programming model.

(4) Present a bi-level programming model taking into account the relationships of the distribution center layout and the service expenditure, and get an optimal solution.

2 Gravity model

2.1 Model description

Given there are n clients and client $\mathrm{j}(\mathrm{j}=1,2,\cdots \mathrm{n})$ is located at the location of (x_j, y_j). The distribution center location (x_0, y_0) is unknown, and a gravity model is presented with the aim of minimizing total delivery expense.

$$\min \mathrm{S}=\sum_{j=1}^{n} p_j d_j z_j \tag{1}$$

d_j can be calculated by equation 2.

$$d_j=\sqrt{(x_0-x_j)^2+(y_0-y_j)^2} \tag{2}$$

Where, p_j is the delivery price of per unit amount and unit distance from client j to distribution center; z_j is the demand of client j; d_j is the distance from distribution center to client j.

2.2 Model solution

The specific calculation process is described as follows:

(1) The coordinates of the center of gravity for all users is the initial location of distribution center.

$$x_0^{(0)}=\frac{\sum_{j=1}^{n} p_j z_j x_j}{\sum_{j=1}^{n} p_j z_j}, \quad y_0^{(0)}=\frac{\sum_{j=1}^{n} p_j z_j y_j}{\sum_{j=1}^{n} p_j z_j} \tag{3}$$

(2) Substitute $x_0^{(0)}$ and $y_0^{(0)}$ in equation (1) and (2), and calculate the total delivery cost $S^{(0)}$.

(3) Substitute $x_0^{(0)}$ and $y_0^{(0)}$ in equation (2) and (3), calculate a new distribution center position$(x_0^{(1)}, y_0^{(1)})$.

(4) Substitute $x_0^{(1)}$ and $y_0^{(1)}$ in equation (1) and (2), and calculate the total delivery cost $S^{(1)}$.

(5) Compare the data of $S^{(0)}$ and $S^{(1)}$: if $S^{(1)} > S^{(0)}$, return to step 3, otherwise, stop calculation. Repeat iteration until the optimal solution is found out.

3 Bi-level programming model

3.1 Model description

When determining distribution center locations, the upper-level model takes into account the interests of the decision maker, the cost of the construction of distribution centers is under investment constraint, and the goal is to minimize the general cost. The lower level model is established to minimize the clients' cost.

(1) The upper-level model

From the perspective of policy makers, the first thing is to consider the total cost, which consist of two parts: fixed cost and variable cost. At the same time, it should be considered to attract demand as much as possible.

$$\min F = \sum_{i=1}^{m}\sum_{j=1}^{n} C_{ij}(X_{ij})X_{ij} + \sum_{j=1}^{n} f_j k_j - \theta \sum_{i=1}^{m}\sum_{j=1}^{n} k_j X_{ij}$$

$$\text{s.t.}\begin{cases} \sum_{j=1}^{n} f_j k_j \le B \\ \sum_{j=1}^{n} k_j \ge 1 \\ k_j = 0 \text{ 或 } 1 \end{cases} \tag{4}$$

Where, $C_{ij}(X_{ij})$ is the general service price of per unit amount and unit distance from client i to distribution center j, it increases with the increase of demand, so it is treated as a demand function. X_{ij} is the demand of client i from distribution center j. f_j is the fixed construction cost of distribution center j. B is the total investment budget. $k_j = 1$ represents to construct a distribution center in site j. $k_j = 0$ represents not to construct a distribution center in site j. θ is the coefficient of matching the total cost with customer demand for the unit.

(2) lower-level model

In the real distribution system, the demand of a certain client for a distribution center is influenced by the amount of this distribution center need delivery for all clients. For example, when a distribution center services for multiple clients, then the general service price will increase, and some clients maybe choice another distribution center. In order to describe this phenomenon, a demand function is proposed.

$$X_{ij} = D_{ij}(u_{ij}) \tag{5}$$

Where, u_{ij} is the minimum service cost of distribution center j for client i.

Normally, the form of every client's demand function is same, power function and logarithmic function are the most common forms. But for different client, the parameters are different, which can rely on data statistics.

The lower-level model is as follows:

$$\min T = \sum_{i=1}^{m}\sum_{j=1}^{n}\int_{0}^{X_{ij}} D^{-1}(t)dt$$

$$\text{s.t.}\begin{cases} \sum_{j=1}^{n} X_{ij} = W_{ij}, \quad \forall i = 1,2,\cdots,m \\ \sum_{i=1}^{m} X_{ij} \le s_j, \quad \forall j = 1,2,\cdots,n \\ X_{ij} \le Mk_j, \forall i = 1,2,\cdots,m, j = 1,2,\cdots,n \\ X_{ij} \ge 0 \end{cases} \tag{6}$$

Where: $D^{-1}(t)$ is the negative function of demand function. W_i is the total demand of client i. s_j is the supplying capacity of distribution center j. M is an arbitrarily large positive number.

3.2 Model solution

The constraint $X_{ij} \le Mk_j$ shows the relationship between the demand of clients in each distribution center and the location of the distribution centers in the equilibrium state. If $k_j = 0$ which is determined by the upper-level model, then $X_{ij} = 0$, and if $k_j = 1$, then $X_{ij} \le M$, M is an arbitrarily large positive number, it is certain this constraint can be met, it seems this constraint is unnecessary. But in order to get the reaction function, this constraint can be turned into the following form:

$$X_{ij} = Mk_j - y_{ij} \tag{7}$$

Where, y_{ij} is a slack variable. When $k_j = 0$, it is easy to determine the value of X_{ij} and y_{ij}; when $k_j = 1$, it is necessary to solve upper-level model firstly, get the value of X_{ij} in the equilibrium state, and then the value of y_{ij} is determined, it is y_{ij}^*, so all of reaction functions can be deduced:

$$X_{ij} = Mk_j - y_{ij}^* \qquad i = 1,2,\cdots,m, j = 1,2,\cdots,n \tag{8}$$

Substitute function (8) in the upper-level model, a new distribution center layout scheme is obtained, repeat the above ideas, it will be closer to the optimal solution. The specific procedure is as follows:

(1) Let $s = 0$, s is the number of iterations. Let $k_j^0 = 1, (j = 1,2,\cdots,n)$, it means all the optional positions will construct distribution centers.

(2) Substitute k_j^s in the lower-level model, and to find out the optimal solution for this model, they are X_{ij}^s $(i = 1,2,\cdots,m, j = 1,2,\cdots,n)$.

(3) Calculate the general service price C_{ij}^s according to X_{ij}^s.

(4) Calculate y_{ij}^s, substitute $X_{ij} = Mk_j - y_{ij}^s$ and C_{ij}^s in the upper-level model, and then find out a set of new optimal solutions $k_j^{s+1}, (j = 1,2,\cdots,n)$.

(5) If $|F_{s+1} - F_s| < \varepsilon$, end. Otherwise, let $s = s + 1$, and then turn to step 2. ε is the computing accuracy.

4 A practical example

4.1 Problem description

Select Dalian three largest supermarket chains Enterprise: Carrefour, Wal-Mart and the New Mart supermarket, plan to build distribution centers to the joint distribution of food for them, and the positions of the 11 clients related are shown in figure 1.

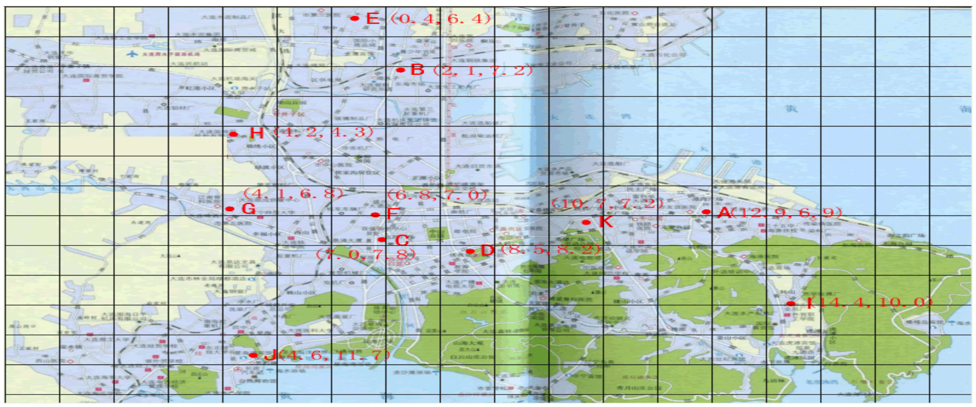

Figure 1. the positions of 11 branches

In this practical example, most of the delivery packaging is carton, the weight of these foods is light, which must be able to meet the load limit of van. But it is necessary to consider the volume of these carton. According to the characteristics of the goods, the pallet can be used in the process of logistics. Because these foods require lower bearing capacity, in order to save cost and convenient for stacking, use four-way double-faced plastic pallet is the best choice, and in order to adapt to van, the size of the pallet is 1200 x1000 (GB/T 2934-1996). Stacking height can reach 1100mm, so the unit volume is 1.32 cubic meters.

The main source of goods is other city, so it doesn't matter without respect to the positions of the upstream suppliers. The clients' demands are stable and predictable. The means of delivery is van, body size is 5300×2270×2400, and the volume is 28.87 cubic meters. Distribution centers have enough supply capacity to satisfy the clients' requirements. There are no other distribution centers have built in this region.

According to statistical data, the demands of clients are as follows (Table 1):

Table 1 the demands and coordinates of clients

NO.	A	B	C	D	E	F
coordinate	(12.9,10.0)	(2.1,7.2)	(7.0,7.8)	(8.5,8.2)	(0.4,6.4)	(6.8,7.0)
demand	13420	25440	12550	13780	16250	17890
NO.	G	H	I	J	K	
coordinate	(4.1,6.8)	(4.2,4.3)	(14.4,10.0)	(4.6,11.7)	(10.7,7.2)	
demand	10200	8600	12750	9360	15230	

4.2 The model and solution of gravity model

$$S = \sum_{j=1}^{n} p_j d_j z_j \tag{9}$$

Where, p_j is the delivery price of per unit volume and unit distance from client j to distribution center; z_j is the demand of client j; d_j is the distance from distribution center to client j.

Obviously, different from the regional distribution planning, the routes are constrained by the urban roads in city distribution, so it is unreasonable to regard straight line distance as the delivery distance. In order to correct this deviation, the delivery distance d_j is defined as linear distance multiplying by 1.41.

$$d_j = 1.41 \times \sqrt{(x_0 - x_1)^2 + (y_0 - y)^2} \tag{10}$$

Let the barycentric coordinates as initial solution based on the coordinates and demands of 11 clients, it is (6.61,7.78). And iterate aided by VB, the results are as follows (table 2):

Table 2 The results of iteration

iteration times	0	1	2	3	4	5	6	7
X	6.607	6.651	6.678	6.696	6.709	6.719	6.726	6.732
Y	7.786	7.713	7.673	7.649	7.632	7.620	7.610	7.603
S		247127	246517	246246	246102	246016	245961	245922

In fact, excessive iteration accuracy has no practical significance, so the iteration precision is 0.001, and then the end result is (6.7,7.6).

As you can see, the optimal location is near to the crossing of Xi'an road and Changjiang road, where is the busiest business district of Dalian, so it is not the suitable position for constructing a large distribution center.

4.3 The determination of optional locations

Combining with the characteristics of Dalian, it is necessary to consider the following aspects:

(1) Distribution centers should close to public transport hub, such as railway stations, highways and ports.

(2) It should be near to the main road of city.

(3) It should comply with the requirements of land use planning in Dalian.

So, four optional locations are proposed:

(1) K1 is near to Dalian locomotive plant, it is close to Shahekou railway and Xiang Lujiao overpass, where is an important transportation hub in Dalian, and there are large areas of land for construction.

(2) .K2 is near to the crossing of Changjiang road and Popular street, where is close to Dalian Port Railway Freight Station, The transportation is convenient, and there are large areas of land for construction.

(3) K3 is located in near the crossing of Xibei road and Yingke road, where is close to Zhou Shuizi Railway Station and international airport, and there are idle lands.

(4) K4 is near to heavy machinery plant, where is close to Xi'nan road, and there are large areas of land for construction.

4.4 Bi-level programming model

The lower-level model: Under the relatively single traffic environment in city, it is reasonable that the demands of clients are only under the influence of transportation cost. So the inverse function of demand function $D^{-1}(t)$ is a constant for every client and distribution centers.

$$D^{-1}(t) = A_{ij}, \quad A_{ij} = d_{ij}p \tag{11}$$

Where, p is the general service price of per unit volume and unit distance from client i to distribution center j.

The lower-level model can be written as:

$$\min T = \sum_{i=1}^{m}\sum_{j=1}^{n}\int_{0}^{X_{ij}} D^{-1}(t)dt = \sum_{i=1}^{m}\sum_{j=1}^{n} A_{ij}X_{ij} \tag{12}$$

Now, the lower-level model is transformed into a linear programming problem, it provides convenience for us to solve the model.

Let $m = 11$, $n = 4$, then calculate A_{ij}, the value is shown in table 3.

Table 3 the value of A_{ij}

A_{ij}	i = 1	2	3	4	5	6	7	8	9	10	11
j = 1	2.837	1.897	0.637	1.036	2.528	0.316	1.092	1.271	3.355	2.339	1.590
2	1.391	4.430	2.540	2.010	5.093	2.574	3.634	3.696	1.448	4.002	1.063
3	4.211	1.829	2.013	2.472	2.061	1.699	1.396	0.425	4.687	3.316	2.858
4	3.190	1.225	0.814	1.382	1.965	0.877	0.691	1.610	3.771	1.352	2.292

Due to assuming the size of distribution centers is enough to meet the demand of all clients, the constraints of lower-level model can be written as follows:

$$\text{s.t.}\begin{cases} EX = W \\ X_{ij} \le Mk_j, \forall j = 1,2,3,4; i = 1,2\cdots,11 \\ X_{ij} \ge 0, \forall j = 1,2,3,4; i = 1,2\cdots,11 \end{cases} \tag{13}$$

Where, E is a 11×44 order matrix, X is a 44×1 matrix, and W is a 11×1matrix.

$$E = \begin{pmatrix} 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & \cdots & 0 & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \cdots & 1 & 1 & 1 & 1 \end{pmatrix}$$

$$X^T = (X_{11,}X_{12,}X_{13,}X_{14,} \cdots, X_{11,4})$$

$$W^T = (13420, 25440, 12550, 13780, 16250, 17890, 10200, 8600, 12750, 9360, 15230)$$

Let $k_1^{(0)} = k_2^{(0)} = k_3^{(0)} = k_4^{(0)} = 1$, and substituted them in the lower-level model, the results are shown in table 4.

Table 4 the results of lower-level model

X_{ij}	i = 1	2	3	4	5	6	7	8	9	10	11
j = 1	3274	5145	1331	2069	3527	1034	1635	1561	3225	1989	3103
2	1605	12015	5309	4014	7106	8424	5441	4539	1393	3402	2075
3	4860	4960	4209	4937	2875	5563	2090	522	4506	2820	5579
4	3681	3321	1701	2760	2741	2869	1034	1978	3626	1149	4473

Then it is able to estimate the clients' distribution costs according to the above data, and the value is shown as follows (table 5):

Table 5 the clients' distribution costs

C_{ij}	i = 1	2	3	4	5	6	7	8	9	10	11
j = 1	9290	9760	847	2144	8916	327	1785	1985	10820	4651	4932
2	2232	53230	13483	8070	36191	21682	19774	16777	2017	13615	2206
3	20465	9071	8475	12206	5926	9454	2917	222	21120	9351	15948
4	11745	4066	1385	3815	5387	2515	714	3185	13675	1553	10253

It's obvious that the construction costs of distribution centers are much more than the distribution costs, according to relevant data, assume that the construction costs of each distribution center are 20000000 yuan, (f_j = 20000000). And substituted f_j = 20000000 in the upper-level model, the results of upper-level model can be obtained: $k_1^{(1)} = 1, k_2^{(1)} = 0, k_3^{(1)} = 0, k_4^{(1)} = 0$.

Because of $|F_1 - F_0| \geq 0.1$, so substitute $k_1^{(1)} = 1, k_2^{(1)} = 0, k_3^{(1)} = 0, k_4^{(1)} = 0$ in the lower-level model, and continue to the second iteration, the results are $k_1^{(2)} = 1, k_2^{(2)} = 0, k_3^{(2)} = 0, k_4^{(2)} = 0$, the iteration is end. The results show that one distribution center will be constructed , the location is K1.

5 Conclusions

This paper proposes a new method which fully considers the interests of logistics planning department and the clients. At the same time, this method can define the initial solution of the Bi-level programming model by gravity model, simplifies the calculation process of bi-level programming model. Through the example, the experiment results show that the method and the model and algorithm proposed by the authors is feasible and effective.

Abstract: The manufacturing enterprise logistics is the most important part of logistics service, therefore it is of great significance to choose a reasonable logistics mode to optimize logistics activities in manufacturing enterprise. According to the results of all index evaluation on alternative logistics modes in semantics given by the experts, this paper proposes a logistics mode evaluation method based on group two-tuple linguistic and grey relational analysis. This method overcomes the defect of information distortion and loss caused in information integration and calculation. Finally, results from numerous examples show that the method presented in this paper is feasible and effective.
Keywords: Grey relational analysis; Two-tuple linguistic; Manufacturing enterprise; Logistics mode.

1 Introduction

Facing the downtrend of total profit, it is strategically decisive that a manufacturing enterprise determine a matching mode after an evaluation of different logistics modes so as to improve the logistics service efficiency. Hou and Zhang (2005) thought that the influence factors affecting selection of logistics mode were generally considered from the perspectives of balance between successful criticality and logistics management ability of the enterprise and balance between logistics service and logistics service. Zhao and others (2009) made a modeling study for three modes including self-support logistics, logistics outsourcing and combination of self-support logistics and logistics outsourcing of the enterprises, and the results indicate that profits of manufacturing enterprises and the third-party logistics enterprises increase as the outsourcing proportion increases. Regarding the selection method of logistics mode, Fei and the others (2012) analyzed factors affecting logistics mode selection of manufacturing enterprises through fuzzy comprehensive evaluation. Zhao and Luo (2013) endowed each objective with weight and found a programming solver for the model by establishing membership functions using maximum and minimum operators.

These researches were mainly on the logistics mode selection of manufacturing enterprises, and rare consideration is given directly to uncertainties in filtering logistics modes. Thus, this paper proposes an evaluation method of logistics mode based on group two-tuple linguistic and grey relational analysis model to provide manufacturing enterprises with a practical and effective guidance and assistance when selecting their logistic modes.

Analysis indicated that research on logistics mode selection of manufacturing enterprises rare consideration is given directly to uncertainties existing in filtering of logistics modes. Thus, this paper proposes an evaluation method of logistics mode based on group two-tuple linguistic and grey relational analysis model to provide practical and effective guidance and assistance in selection of manufacturing enterprises' logistics mode.

2 Factors Affecting Selection of Enterprise Logistics Mode

According to the references, main influence factors discussed in this paper are as below:

(1) Scale and strength of the enterprise. In general, enterprises with large scale and strong power will have self-built logistics systems, and ordinary small and medium-sized enterprises are more likely to select logistics outsourcing.

(2) Logistics cost. Enterprises will select a proper logistics mode to reduce their logistics cost , considering their operational characteristics and capital strength.

(3) Logistics strategic position. If an enterprise does not think its core competitiveness lies in logistics and wants to concentrate its energy and resources on the development of its core business, it will select a mode of third party logistics.

(4) Level of informatization. No matter how consumers or the main body select the mode, manufacturing enterprises themselves will propose new requirements on the application of information technology abreast of the times.

(5) Ability of logistics service. This factor directly affects consumers' comments on logistics companies, and logistics companies would work ceaselessly to improve their services to satisfy consumers' needs.

(6) Scale and strength of the third-party logistics enterprises. Enterprises have to make careful qualification and certification investigations about the scale and strength of the third-party logistics enterprise before outsourcing.

3 Two-tuple linguistic and grey correlation method

The two-tuple semantic methodology was proposed by Herrera, a Spanish scholar, for the first time in 2000. Detailed contents of **Definition1 to Definition 6** (Herrera, 2000; Herrera, 2005; Alcalá, 2007) are given below:

Definition1: If $s_k \in S$ is a language phrase, then function θ can be used to express $s_k \in S$ as corresponding two-tuple semantic form:

$$\theta : S \to S \times [-0.5, 0.5) \quad (1)$$

i.e.

$$\theta(s_k) = (s_k, 0),\ s_k \in S \tag{2}$$

Definition2: Assuming that a certain aggregation method is used to process language evaluation set S and obtain real number $\beta \in [0,T]$, there into, T represents number of elements in S, then β can represent the following two-tuple semantic information by means of function Δ:

$$\Delta: [0,T] \rightarrow S \times [-0.5, 0.5) \tag{3}$$

i.e.

$$\Delta(\beta) = \begin{cases} s_k & k = \text{round}(\beta) \\ a_k = \beta - k & a_k \in [-0.5, 0.5) \end{cases} \tag{4}$$

There into, round represents integral operator taken by rounding-off.

Definition 3: Assuming that (s_k, a_k) represents a two-tuple semantic phrase, s_k represents the k^{th} element in S and $a_k \in [-0.5, 0.5)$, then there must be an inverse function Δ^{-1} which shall be converted into a corresponding numerical value $\beta \in [0,T]$.

$$\Delta^{-1}: S \times [-0.5, 0.5) \rightarrow [0,T] \tag{5}$$

i.e.

$$\Delta^{-1}(s_k, a_k) = k + a_k = \beta \tag{6}$$

Assuming that (s_k, a_k) and (s_l, a_k) represent two-tuple semantic phrase, comparison of (s_k, a_k) and (s_l, a_k) must satisfy the following provisions:

(1) If $k < l$, then $(s_k, a_k) < (s_l, a_k)$;

(2) If $k = l$,

$a_k = a_l$, then $(s_k, a_k) = (s_l, a_k)$;

$a_k < a_l$, then $(s_k, a_k) < (s_l, a_k)$;

$a_k > a_l$, then $(s_k, a_k) > (s_l, a_k)$

Definition 4: Assuming that $\{(s_1,a_1),(s_2,a_2),\cdots,(s_n,a_n)\}$ is a set of two-tuple semantic information, then two-tuple semantic can be expressed as

$$(s,a)=\Delta\left(\frac{1}{n}\sum_{j=1}^{n}\Delta^{-1}(s_j,a_j)\right), s\in S, a\in[-0.5,0.5) \tag{7}$$

Definition 5: Assuming that a set of two-tuple semantic information is expressed as $\{(s_1,a_1),(s_2,a_2),\cdots,(s_n,a_n)\}$ and corresponding two-tuple semantic weight vector is expressed as $\boldsymbol{W}=\{(\omega_1,\beta_1),(\omega_2,\beta_2),\cdots,(\omega_n,\beta_n)\}$, then two-tuple semantic based weighted arithmetic averaging can be expressed as:

$$(s,a)=\Delta\left(\frac{\sum_{j=1}^{n}\Delta^{-1}(\omega_j,\beta_j)\times\Delta^{-1}(s_j,a_j)}{\sum_{j=1}^{n}\Delta^{-1}(\omega_j,\beta_j)}\right), s\in S, a\in[-0.5,0.5) \tag{8}$$

Definition 6: Assuming that (s_α,a_α) and (s_β,a_β) represent two pieces of two-tuple semantic information, then their distance is defined as:

$$d\left((s_\alpha,a_\alpha),(s_\beta,a_\beta)\right)=\Delta\left(\left|\Delta^{-1}(s_\alpha,a_\alpha)-\Delta^{-1}(s_\beta,a_\beta)\right|\right) \tag{9}$$

Assuming that decision maker $\mathrm{EXP}_k\in EXP(k\in T)$ properly measures alternative logistics mode $\mathrm{MO}_i\in MO(i\in M)$ relevant to evaluation indicator $\mathrm{EG}_j\in EG(j\in N)$ and obtains that attribute value of MO_i relevant to EG_j is $r_{ij}^{(k)}\in S$, and then builds language decision-making matrix $\boldsymbol{R}_k=\left[r_{ij}^{(k)}\right]_{m\times n}$ accordingly. Decision maker $\mathrm{EXP}_k\in EXP(k\in T)$ evaluates weight of indicator $\mathrm{EG}_j\in EG(j\in N)$ and estimates that weight of MO_i relevant to EG_j is $\boldsymbol{W}_k=\omega_j^{(k)}(\omega_j^{(k)}\in S)$. According to Definition1, convert matrix $\boldsymbol{R}_k=\left[r_{ij}^{(k)}\right]_{m\times n}$ into corresponding two-tuple semantic decision-making matrix $\boldsymbol{R}_k=\left[r_{ij}^{(k)},0\right]_{m\times n}$, at the same time, convert language weight $\boldsymbol{W}_k=\omega_j^{(k)}(\omega_j^{(k)}\in S)$ into corresponding two-tuple semantic weight $\boldsymbol{W}_k = \left(\omega_j^{(k)}, 0\right)$.

4 Specific Calculating Steps

Step 1: Aggregate evaluation information in two-tuple semantic form into group comprehensive evaluation information. Use equation of two-tuple semantic arithmetic averaging to obtain group comprehensive evaluation matrix $\boldsymbol{MIR} = \left[r_{ij}, a_{ij}\right]_{m\times n}$ and group attribute weight $\boldsymbol{MW} = \left\{(\omega_1, \beta_1), (\omega_2, \beta_2), \cdots, (\omega_n, \beta_n)\right\}$ respectively. Define computational equation of $\boldsymbol{MIR} = \left[r_{ij}, a_{ij}\right]_{m\times n}$ as:

$$\left(r_{ij}, a_{ij}\right) = \Delta\left(\frac{1}{t}\sum_{k=1}^{t}\Delta^{-1}\left(r_{ij}^{(k)}, a_{ij}^{(k)}\right)\right), i \in M;\ j \in N \tag{10}$$

Meanwhile, define computational equation of $\boldsymbol{MW}$ as:

$$\left(\omega_j, \beta_j\right) = \Delta\left(\frac{1}{t}\sum_{k=1}^{t}\Delta^{-1}\left(\omega_j^{(k)}, \beta_j^{(k)}\right)\right), j \in N \tag{11}$$

There into, $\left(r_{ij}, a_{ij}\right)$ represents group comprehensive evaluation value of MO_i relevant to EG_j, and $\left(\omega_j, \beta_j\right)$ represents importance of each individual in the group relevant to EG_j.

Step 2: Estimate a positive ideal solution according to each solution. Express positive ideal solution of each solution as:

$$\left(r^+, a^+\right) = \left(\left(r_1^+, a_1^+\right), \left(r_2^+, a_2^+\right), \cdots, \left(r_n^+, a_n^+\right)\right)^{\mathrm{T}} \tag{12}$$

Thereinto:

$$\left(r_j^+, a_j^+\right) = \max_i \left\{\left(r_{ij}, a_{ij}\right)\right\}, j \in N \tag{13}$$

Step 3: Corresponding to the positive ideal solution, estimate correlation coefficient of each alternative solution. Define the correlation coefficient as

$$\left(\xi_{ij}^+, \eta_{ij}^+\right) = \Delta\left(\frac{\min\limits_i \min\limits_j \left|\Delta^{-1}\left(r_{ij}, a_{ij}\right) - \Delta^{-1}\left(r_j^+, a_j^+\right)\right| + \rho \max\limits_i \max\limits_j \left|\Delta^{-1}\left(r_{ij}, a_{ij}\right) - \Delta^{-1}\left(r_j^+, a_j^+\right)\right|}{\left|\Delta^{-1}\left(r_{ij}, a_{ij}\right) - \Delta^{-1}\left(r_j^+, a_j^+\right)\right| + \rho \max\limits_i \max\limits_j \left|\Delta^{-1}\left(r_{ij}, a_{ij}\right) - \Delta^{-1}\left(r_j^+, a_j^+\right)\right|}\right) \tag{14}$$

Thereinto, $\left(\xi_{ij}^+, \eta_{ij}^+\right)$ represents correlation coefficient between a certain alternative solution and the positive ideal solution, and $\rho\left(\rho \in [0,1]\right)$ represents resolution ratio which is taken as $\rho = 0.5$ in general.

Step 4: Determine degree of correlation of each alternative mode relevant to the positive ideal solution.

$$\left(\xi_i^+,\eta_i^+\right) = \Delta\left(\frac{\sum_{j=1}^{n}\Delta^{-1}\left(\omega_j,\beta_j\right)\times\Delta^{-1}\left(\xi_{ij}^+,\eta_{ij}^+\right)}{\sum_{j=1}^{n}\Delta^{-1}\left(\omega_j,\beta_j\right)}\right), i \in M \tag{15}$$

Step 5: Prioritize the alternative solutions according to the above degree of correlation. Prioritize the alternative solutions according to two-tuple semantic nature: the larger the $\left(\xi_i^+,\eta_i^+\right)$ of a certain solution is, the more precedent the corresponding solution will be.

5 Calculation Example

A large-scale daily consumer goods production enterprise finds that when the uncertainty of customers' demands increases, an enterprise should also speed up its product response accordingly. In order to further improve its logistics management level, the enterprise invites specialists and scholars from relevant sectors to research on selection of logistics mode.

Based on an analytical research of its expert team, the enterprise plans to evaluate and select among self-built logistics mode $\left(\mathrm{MO}_1\right)$, logistics outsourcing mode $\left(\mathrm{MO}_2\right)$ and logistics alliance mode $\left(\mathrm{MO}_3\right)$, and then to establish alternative mode collection $MO = \left\{\mathrm{MO}_1,\ \mathrm{MO}_2,\ \mathrm{MO}_3\right\}$ accordingly. For the purpose of evaluating the above three logistics modes accurately, the enterprise engages five experts $\mathrm{EXP}_k \in EXP\left(k = 1,2,3,4,5\right)$ from product research and development, production and marketing departments, etc., to participate in evaluation of the logistics modes. According to the research conclusions, the following six evaluation attributes are selected: enterprise's scale and strength $\left(\mathrm{EG}_1\right)$, logistics cost $\left(\mathrm{EG}_2\right)$, logistics strategic position $\left(\mathrm{EG}_3\right)$, level of informatization $\left(\mathrm{EG}_4\right)$, ability of logistics service $\left(\mathrm{EG}_5\right)$ and the third-party logistics enterprise's scale and strength

(EG_6), based on which, evaluation attribute collection $EG=\{\mathrm{EG}_1,\ \mathrm{EG}_2,\ \mathrm{EG}_3,\ \mathrm{EG}_4,\ \mathrm{EG}_5,\ \mathrm{EG}_6\}$ is developed, and used by experts as natural language scale with granularity of 7, that is $S^7=\{S_0,S_1,S_2,S_3,S_4,S_5,S_6\}$, Set evaluation criterion used by experts as a set of evaluation language phrase (FC-extremely bad, HC- very bad, C- bad, YB- just so so, Z-important, HZ- very important, FZ- extremely important). Then, expert $\mathrm{EXP}_k \in EXP(k=1,2,\cdots,5)$ properly evaluates weight of $\mathrm{EG}_j\ (j=1,2,\cdots,6)$ first to obtain weight vector of each expert.

$$\boldsymbol{W}_1=(C,HZ,HC,Z,HZ,FZ)^{\mathrm{T}};\quad \boldsymbol{W}_2=(YB,HZ,HC,Z,Z,C)^{\mathrm{T}};$$

$$\boldsymbol{W}_3=(YB,C,YB,Z,YB,Z)^{\mathrm{T}};\quad \boldsymbol{W}_4=(HC,YB,HC,C,YB,Z)^{\mathrm{T}};$$

$$\boldsymbol{W}_5=(C,Z,C,YB,HZ,YB)^{\mathrm{T}}。$$

Carry out two-tuple semantic based evaluation $r_{ij}^{(1)}\ (i=1,2,3,\quad j=1,2,\cdots,6)$ of MO_1, MO_2 and MO_3 relevant to EG_1、EG_2、EG_3、EG_4、EG_5 and EG_6. Build a language evaluation matrix corresponding to EXP_k based on this.

$$\boldsymbol{R}_1=\begin{bmatrix} C & C & HZ & YB & Z & Z \\ FZ & FC & YB & Z & C & FC \\ Z & YB & FC & C & Z & YB \end{bmatrix}$$

Similar to $\boldsymbol{R}_1$, build a language evaluation matrix corresponding to $\mathrm{EXP}_k\ (k=2,3,4,5)$.

$$\boldsymbol{R}_2=\begin{bmatrix} C & HZ & C & Z & YB & Z \\ HZ & YB & HC & Z & Z & YB \\ HZ & FZ & C & YB & YB & C \end{bmatrix}\quad \boldsymbol{R}_3=\begin{bmatrix} YB & YB & HC & FC & Z & HC \\ FZ & FZ & C & YB & Z & FZ \\ HC & HZ & YB & HC & FZ & YB \end{bmatrix}$$

$$\boldsymbol{R}_4=\begin{bmatrix} Z & YB & C & Z & Z & YB \\ HZ & Z & C & HZ & YB & HZ \\ Z & HZ & Z & HZ & C & Z \end{bmatrix} \qquad \boldsymbol{R}_5=\begin{bmatrix} YB & YB & HZ & HC & Z & HC \\ YB & YB & YB & C & HZ & YB \\ FZ & HZ & C & HC & YB & HZ \end{bmatrix}$$

In order to determine the most appropriate logistics mode, the improved grey correlation analysis method mentioned herein will be used for processing and analysis.

Step 1: According to equation (10), determine that group comprehensive evaluation matrix $\boldsymbol{MIR}$ is

$$\boldsymbol{MIR}=\begin{bmatrix} (YB,-0.2) & (YB,0.2) & (YB,0) & (C,0.4) & (Z,-0.2) & (YB,-0.4) \\ (HZ,0) & (YB,0.2) & (C,0.2) & (Z,-0.4) & (Z,-0.4) & (YB,0.4) \\ (Z,0) & (HZ,-0.2) & (C,0.2) & (C,0.4) & (Z,-0.4) & (YB,0.4) \end{bmatrix}$$

According to equation (11), determine that group attribute weight $\boldsymbol{MW}$ is

$$\boldsymbol{MW}=\big((C,0.2),(Z,-0.2),(C,-0.4),(YB,0.4),(Z,0),(Z,-0.2)\big)^{\mathrm{T}}$$

Step 2: Estimate positive ideal solution of each logistics mode according to equation (12)-(13).

$$\left(r^{+},a^{+}\right)=\big((HZ,0),(HZ,-0.2),(YB,0),(Z,-0.4),(Z,-0.2),(YB,0.4)\big)^{\mathrm{T}}$$

Step 3: Estimate degree of correlation between the three alternative logistics modes and the positive ideal solution according to equation (14).

$$\boldsymbol{MRA}=\begin{bmatrix} (FC,0.33) & (FC,0.41) & (HC,0) & (FC,0.48) & (HC,0) & (HC,-0.42) \\ (HC,0) & (FC,0.41) & (HC,-0.42) & (HC,0) & (HC,-0.15) & (HC,0) \\ (HC,-0.48) & (HC,0) & (HC,-0.42) & (FC,0.48) & (HC,-0.15) & (HC,0) \end{bmatrix}$$

Step 4: Prioritize the three logistics modes according to equation (15), the numerical value of $\left(\xi_i^{+},\eta_i^{+}\right)(i=1,2,3)$ as

$$\left(\xi_1^{+},\eta_1^{+}\right)=(HC,-0.3773);$$

$$\left(\xi_2^{+},\eta_2^{+}\right)=(HC,-0.1883);$$

$$\left(\xi_3^{+},\eta_3^{+}\right)=(HC,-0.2186).$$

Step 5: According to numerical value of $\left(\xi_i^{+},\eta_i^{+}\right)(i=1,2,3)$, prioritize the three logistics modes as

$$\mathrm{MO}_2 \succ \mathrm{MO}_3 \succ \mathrm{MO}_1$$

Therefore, the enterprise believes that the third party logistics is the optimal one.

6 Conclusions

Logistics mode is an important driver which ensures effective logistics of manufacturing enterprises. The paper puts forward an logistics evaluation method based on an analysis of group two-tuple linguistic and grey correlation. According to the core idea of traditional analysis method of grey correlation, the paper calculates the grey correlation degree of semantics between each alternative logistics mode and positive ideal point, and determines an optimal scheme according to the size of the correlation, to ensure that the scheme has the greatest degree of correlation. The method can treat the two-tuple linguistic information effectively, and can avoid defects such as information distortion and loss caused in information integration and calculation. The results of numerous experiments show that all the proposed methods are feasible and effective.

Abstract: Suppliers do not always choose the buy-back contract to achieve coordination facing with different return logistics costs. In this paper we discuss the impact of return logistics cost on supply chain coordination and effectiveness of supply chain members based on the classic newsboy model. When the retailer and the supplier have the same return logistics cost, three kinds of buy-back contract models with return logistics cost burdened by the retailer, the supplier and both parties are respectively discussed, and these three cases achieve the supply chain coordination with the same optimal quantity. When the retailer and the supplier have the different return logistics cost, we propose the member of supply chain who has lower return logistics cost undertakes the return delivery to achieve the supply chain coordination.

Keywords: Return logistics cost; Buy-back contract; Coordination.

1 Introduction

Nowadays with rapid development of electronic commerce, customer returns gradually become a kind of effective marketing tools for retailers to attract customers, while a large number of customer returns is likely to lead large retailers returns at the end of selling season. Because of that, suppliers try to change return strategies to deal with growing retailers returns.

In the decentralized supply chain, the purposes of interest among the supply chain members are conflicting, which will lead to reducing the expected profit of the supply chain, while supply chain contract can reduce the total cost of supply chain and increase the overall supply chain efficiency.

Pastemack(1985), Taylor(2001) and Webster (2000) have pointed out that the buy-back contract can encourage retailers to increase order quantity, further increasing the supplier's benefits. Jing Chen, and Ravneet Grewal (2013) show that customer returns policies can be used as competing marketing strategies. YeFei(2007) simply discussed the buyback contract with considering Return Logistics cost.

From the viewpoint of return logistics cost, we discuss its impact of supply chain coordination and effectiveness of supply chain members base on classic newsboy model.

2. Model

In this paper, we analyze retailer's return policy considering return logistics cost through a supply chain consisting of a single supplier and a single retailer. To meet market demand D, the retailer orders Q unit products from the supplier. Suppose the market demand for a non-negative continuous random variables, and.The density function of market demand D is $f(x)$, the distribution function is $F(x)$, $F(x)$ is differentiable, strictly increasing and $F(0)=0$.

Table 1. Model basic parameters

p	retail price per unit
w	supplier's wholesale price of per unit
v	the salvage value per unit
c	product cost per unit
b	the buy-back price per unit, $v<b<w$
l_r	the return logistics cost per unit that the retailer undertakes
l_s	the return logistics cost per unit that the supplier undertakes
π_{sc}	the overall supply chain expected return profit
π_s	supplier 's expected profit
π_r	retailer's expected profit

The supplier as the leader of the game firstly decides the wholesale price w and the buy-back price b, then the retailer determines its order quantity Q and sells the product at p per unit; at last the supplier arranges production based on the retailer's order quantity Q. At the end of the selling season, the supplier will buy back unsold product at b per unit, then there exists $v<b<w$. In this return process, the retailer undertakes $\varphi I(Q)$ unit unsalable product and the supplier undertakes $(1-\varphi)I(Q)$, $0\le\varphi\le 1$, while φ is the distribution rate of unsalable product between the retailer and the supplier.

Base on classic model, we define the expected sales $S(Q)=Q-\int_0^Q F(x)dx$, the expected inventory $I(Q)=Q-S(Q)$ .On the other hand, only when $l_r\varphi I(Q)+l_s(1-\varphi)I(Q)<vI(Q)$ or $l_r\varphi+l_s(1-\varphi)<v$, the supplier will choose the buyback contract, and we do our research in this rage.

The retailer's expected profit is

$$\begin{aligned}\pi_r &= pS(Q)+bI(Q)-l_r\varphi I(Q)-wQ \\ &= (\mathrm{p}-b+\varphi l_r)S(Q)+(b-\varphi l_r-w)Q\end{aligned} \tag{2-1}$$

The supplier's expected profit is

$$\begin{aligned}\pi_s &= (w-c)Q-(b-v)I(Q)-(1-\varphi)l_sI(Q) \\ &= [b-v+(1-\varphi)l_s]S(Q)+[w-c-b+v-(1-\varphi)l_s]Q\end{aligned} \tag{2-2}$$

The expected profit function of supply chain is

$$\begin{aligned}\pi_{sc} &= \pi_r+\pi_s \\ &= [p-v+\varphi l_r+(1-\varphi)l_s]S(Q)+[v-c-\varphi l_r-(1-\varphi)l_s]Q\end{aligned} \tag{2-3}$$

Since $F(x)$ is strictly increasing, π_{sc} is strictly concave. The optimal order quantity of the supply chain satisfies:

$$Q_{sc}^* = F^{-1}\left(\frac{p-c}{p-v+\varphi l_r+(1-\varphi)l_s}\right) \tag{2-4}$$

The retailer's optimal order quantity satisfies:

$$Q_r^* = F^{-1}\left(\frac{p-w}{p-b+\varphi l_r}\right) \tag{2-5}$$

To simplify the model, we suppose the return logistics cost per unit represents the efficiency of logistics system. We discuss the effect of return logistics cost from two cases: the first one is when the retailer and the supplier have the same logistics efficiency, that means $l_r=l_s=l$; the second is they have different logistics efficiency, that is $l_r\neq l_s$ .We will discuss the two situations in the following parts.

3. Return logistics cost is same

In this case, three kinds of buy-back contract models are discussed in coordination with return logistics cost burdened by the retailer, the supplier or partnership. When $\varphi=1$,the retailer undertakes the cost only; When $\varphi=0$, the retailer undertakes the cost only; when $0<\varphi<1$,the retailer and the supplier share the return logistics cost.

3.1 The retailer undertakes the cost only

In this case, the retailer's expected profit:

$$\pi_r^{(1)} = pS(Q) + b_1 I(Q) - lI(Q) - wQ \\ = (p - b_1 + l)S(Q) - (w - b_1 + l)Q \tag{3-1}$$

The supplier's expected profit:

$$\pi_s^{(1)} = (w - c)Q - (b_1 - v)I(Q) \\ = (b_1 - v)S(Q) + (w - c + v - b_1)Q \tag{3-2}$$

Because $\pi_r^{(1)}$ is strictly concave and the retailer's optimal order quantity is unique. Further, $Q_r^{(1)*}$ satisfies:

$$Q_r^{(1)*} = F^{-1}\left(\frac{p - w}{p - b_1 + l}\right) \tag{3-3}$$

It is obvious the retailer's optimal order quantity decreases in the return logistics cost. In order to make the supply chain achieve coordination, it is necessary to make $Q_r^{(1)*}=Q_{sc}^*$, and we can obtain:

$$b_1 = \frac{v(p - w) + (w - c)(p + l)}{p - c} \tag{3-4}$$

When return logistics cost is burdened by the retailer only, the buy-back price increases as the return logistics cost increasing and buy-back contract can coordinate the channel only if parameters satisfy the formula (3-4).We observe the buy-back price is not related to the buy-back contract demands, but depends on the cost structure of the supply chain system.

3.2 The supplier undertakes the cost only

In this case, the retailer's expected profit:

$$\pi_r^{(2)} = (p - b_2)S(Q) - (w - b_2)Q \tag{3-6}$$

The supplier's expected profit:

$$\pi_s^{(2)} = (b_2 - v + l)S(Q) + (w - c - b_2 + v - l)Q \tag{3-7}$$

Because $\pi_r^{(2)}$ is strictly concave and the retailer's optimal order quantity is unique. Further, $Q_r^{(2)*}$ satisfies:

$$Q_r^{(2)*} = F^{-1}\left(\frac{p - w}{p - b_2}\right) \tag{3-8}$$

In order to make the supply chain achieve coordination, it is necessary to make $Q_r^{(2)*}=Q_{sc}^*$, and we obtain:

$$b_2 = \frac{(v - l)(p - w) + p(w - c)}{p - c} \tag{3-9}$$

When return logistics cost is burdened by the supplier, the supply chain cost structure satisfies formula (3-9), it can achieve supply chain coordination, and make the retailer, the supplier and supply chain profits maximized. It is inferred that the buy-back price will increase as the return logistics cost increasing from formula (3-9), and the supplier's expected profit reduces as return logistics costs increases.

3.3 Partnership share the logistics cost

In this case, the retailer's expected profit：

$$\pi_r^{(3)} = (p - b_3 + \varphi l)S(Q) - (w - b_3 + \varphi l)Q \tag{3-11}$$

The supplier's expected profit：

$$\pi_s^{(3)} = [b_3 - v + (1-\varphi)l]S(Q) + [w - c - b_3 + v - (1-\varphi)l]Q \tag{3-12}$$

Because $\pi_r^{(3)}$ is strictly concave and the retailer's optimal order quantity is unique. Further, $Q_r^{(3)*}$ satisfies:

$$Q_r^{(3)*} = F^{-1}\left(\frac{p - w}{p - b_3 + \varphi l}\right) \tag{3-13}$$

In order to make the supply chain to achieve coordination，it is necessary to make $Q_r^{(3)*}=Q_{sc}^*$, and we obtain :

$$b_3 = \frac{v(p-w) + p(w-c) + l(w - c\varphi) + l(p\varphi - p)}{p - c} \tag{3-14}$$

In this case, the overall profit of the supply chain and the profit distribution between the retailer and supplier is not related to logistics costs. While the buy-back price reduces as return logistics cost increasing, but decrease width becomes smaller, which is due to the supplier as a leader who decides the buy-back price, its impact on the buy-back price must be greater than retailers

Through 3.1-3.3, we observe that the three cases will achieve coordination with the same optimal quatity Q_{sc}^*, so we let $Q_r^{(1)*} = Q_r^{(2)*}=Q_{sc}^*$ and $Q_r^{(2)*} = Q_r^{(3)*}=Q_{sc}^*$ to obtain the relationship between b_1, b_2 and b_3.We obtain : $b_2 = b_1 - l$, $b_2 = b_3 - \varphi l$.

When the logistics efficiency is same between the retailer and the supplier, we observe that the supplier can just change the buyback price properly to make the supply chain achieve coordination.

Corollary 1: when the retailer and the supplier have the same return logistics cost, the condition of supply chain coordination is irrelevant to φ, that means no matter who undertakes the return logistics cost ,the supply chain will be coordinated at the same optimal quantity.

4. Return logistics cost is different

When the retailer and the supplier have different logistics efficiency, we analyze the problem from two aspects: the retailer has higher logistics efficiency, that is $l_r > l_s$; the supplier has higher logistics efficiency, that is $l_r < l_s$.

When $l_r < l_s$,that means the retailer has higher logistics efficiency, we analyze the formula (2-4) about Q_{sc}^*, φl_r and $(1-\varphi)l_s$ are both parts of the denominator, Q_{sc}^* will increase as the increase of φ ,we should make the value of φ larger enough and to confirm the maximum Q_{sc}^* which maximize the supply chain profit. On the other hand, we analyze the formula (2-5) and observe that when $l_r < l_s$, the retailer sacrifices some profit to achieve the supply chain coordination. Hence, we let $\varphi = 1\,(0 \le \varphi \le 1)$, the retailer who has higher logistics efficiency but lower return logistics cost undertakes the return delivery only to make the supply chain achieve the optimal.

When $l_r > l_s$,,that means the supplier has higher logistics efficiency,we analyze the formula (2-4) about Q_{sc}^*, φl_r and $(1-\varphi)l_s$ are both parts of the denominator, Q_{sc}^* will decrease as the increase of φ ,we should make the value of φ smaller enough and to confirm the maximum Q_{sc}^* which maximize the supply chain profit. On the other hand, we analyze the formula (2-5),when $l_r > l_s$, φ should be smaller enough to make the value of Q_r^* larger enough to insure the retailer's expected profit maximum. Hence, we let $\varphi = 0\,(0 \le \varphi \le 1)$, the supplier who has higher logistics efficiency but lower return logistics cost undertakes the return delivery only to make the supply chain achieve the optimal at the expense of the supplier's profit.

Corollary 2: When the retailer and the supplier have different logistics efficiency, the supply chain will achieve the maximum profit through regulating the value of φ,that means the member who has higher logistics efficiency or lower return logistics cost will undertake the return delivery.

Conclusions

We discussed the condition that the supplier chooses buyback contract from the viewpoint of the return logistics cost.

Three buy-back contract models of supply chain are discussed in coordination with return logistics cost burdened by the retailer, the supplier or partnership share when the members have the same return logistics cost. In this case, we observe that the supply chain will be coordinated with the same optimal quantity, which is irrelevant with the distribution of the return logistics cost between the members.

In this case, when the retailer undertakes the cost, it will inevitably require suppliers to raise the buy-back price to reduce the loss of profit caused by the return logistics cost. However, because the supplier's profit reduces followed by the return logistics cost increasing, then the supplier compensates for the loss of profits through reducing the buy-back price. As a leader of supply chain, the supplier's impact on the buy-back price is greater than the retailer.

When the retailer has higher logistics efficiency, the supply chain will choose the retailer to undertake the return delivery for reducing the loss caused by the return logistics cost. We observe some examples in the supply chains that cover large or mighty retailers like the Wal-Mart and Su-Ning electronics, in those supply chains, the retailers have systematic logistics systems which insure the high logistics efficiency of the supply chain.

When the supplier has higher logistics efficiency, the supply chain will choose the supplier to undertake the return delivery in order to reduce the loss caused by the return logistics cost. In this case, there are still some examples in the real market trade. Some large-scale suppliers like the automobile-suppliers will undertake the return delivery to confirm the maximum profit and efficiency of the supply chain because of the scale economies effect and their efficient logistics system.

In the end, the models show that no matter who undertakes the return logistics cost, it will make the overall profit of the supply chain reduced as the cost increases, so it is necessary to establish a reasonable and efficient logistics system for the supply chain.

Evaluation and Selection of a Third Party Logistics Supplier in a Chemical Company

Lixin Chen and Na Chen

School of Economics and Management, Dalian Jiaotong University, Mail No. 794, Huanghe Rd., Dalian, Shahekou 116028, China. E-mail: 595010844@qq.com

Abstract: This paper takes Chemical Company an the research subjecet, the purpose of the study is the third party logistics supplier selection of Chemical Company. This paper establishes an evaluation index system of chemical enterprises of third party logistics providers based on the study of logistics provider selection. The index system includes the the enterprise strength,the quality of service,logistics cost and service capability., including 14 detailed indicators. this paper put forward some problems in the cooperation in order to improve the performance of logistics service providers and improve the market competitiveness of Chemical Company.
Keywords: Chemical company; Third party logistics; Evaluation system.

1 Introduction

In recent years, more and more manufacturing companies have outsourced logistics services to the professional third party logistics company, therefore, professional logistics supplier's logistics service quality is directly related to both the enterprise and the customer satisfaction. Nowadays, logistics service providers offer the uneven quality of service. Enterprises need to build a suitable supplier performance evaluation index and methods of its own in the logistics supplier selection, selection and enterprise development goals of logistics service providers, build a win-win cooperation relationship, to realize the reasonable utilization of enterprise resources, so as to improve the enterprise benefits. Enterprises choose logistics service providers in accordance with enterprise development goals, build a win-win cooperation relationship, to realize the reasonable utilization of enterprise resources, so as to improve the efficiency of enterprises.

Along with the enterprise pay more and more attention to the selection of suppliers, research on logistics supplier evaluation and selection is also increasing, but the majority of these studies is to explore for supplier selection and evaluation method. Evaluation method of logistics supplier has been continuously improved, from the early according to experience, to establish quantitative mathematical model of the late selection, supplier evaluation and selection method of combining qualitative and quantitative now. Continuous research and development makes the selection method of logistics service providers become more and more, but also makes the evaluation method of suppliers is partial to theory and complexity, causes the appraisal method of the logistics service provider is not practical when it is difficult to use in practice. A simple method is not convincing, and complex method is difficult to understand and unrealistic, so how to choose an effective logistics supplier performance evaluation and selection method is the key.

2 The selection steps of third party logistics supplier

Specifically, the third party logistics supplier selection has the following steps:

(1) the demand analysis and selection of target.

Enterprises need to analyze the internal demand and the external environment before the third party logistics provider selection. Based on the demand analysis, enterprises will choose to outsource non core business, at the same time choose outsourcing business scope, finally, determine logistics supplier's ability according to the logistics demand of enterprise. The third party logistics supplier selection is not a simple process, good choice can bring a series of benefits for the enterprise, therefore the demand analysis and target selection is the foundation.

(2) the construction of evaluation index system.

The third party logistics supplier evaluation index system is the main basis to evaluate suppliers. The index system is a collection of different levels that it mainly reflects the different attributes of logistics suppliers. According to the principles of index system, this paper set up the third party logistics supplier evaluation system. All sectors of the logistics supplier evaluation index system is not the same, but to sum up, is the basic assessment from several indicators of cost, performance, customer satisfaction, delivery etc.

(3) select the candidate logistics supplier.

The team in charge of third party logistics supplier's evaluation and selection should closely connect with the purchasing, production and other departments, according to the internal and external demand, provide professional service evaluation. Assessment team lists third party logistics supplier candidates, according to the demand analysis, index system and analysis of the survey results. The candidate should be able to meet the enterprise's logistics service requirements, at the same time they should also have the intention to cooperate with enterprises.

(4) issued tenders.

After determining the third party logistics supplier, evaluation team should contact the candidates and determine whether they have the intention to cooperate with enterprises. Companies can issue bidding book to have the intention of cooperation which should indicate the specific requirements of cooperation. The tender should also indicate the service ability, quotation model and other information. Because of limited resource and energy, the candidate should not be too much. According to the actual situation, the enterprise will inspect the bidding enterprises, further understand the tender, in order to choose supplier better.

(5) the evaluation of supplier.

The supplier evaluation is based on the evaluation index system, through the investigation of related information of supplier, evaluate and select the third party logistics supplier using certain evaluation method. After evaluation, if choose success, both sides can carry out cooperation; if the choice is not successful, enterprises need to re-select.

(6) the implementation of cooperation.

The enterprise's demand is changing in the process of cooperation with logistics supplier. If the selection criteria have great change, it should be re-select logistics supplier and the original logistics suppliers should be given some time to adjust.

3. Establish the third party logistics supplier evaluation index system

3.1 selection of evaluation index

According to the actual need, enterprise which decides to outsource logistics business to the professional logistics companies should first choose supplier evaluation index. Supplier evaluation index should be selected to fit with the goal of enterprise development, also can reflect the service ability and level of supplier. Based on the research at home and abroad, combined with the actual situation of chemical industry, this paper selects the strength of enterprises, service quality, service ability and the logistics cost as a chemical industry third party logistics supplier evaluation index. Specific indicators are as follows:

(1) Strength of enterprises

Logistics enterprise's strength being strong or not is the basis of logistics service capabilities and service quality, only with strong fixed asset, financial condition, advanced information technology, it can ensure that the third party logistics companies have the ability to complete the high efficient logistics business. In a period of rapid development, the requirements of enterprise logistics service is more and more high, only powerful logistics suppliers can meet the demand of enterprise logistics.

(2) Service quality

Service quality is a very important assessment index when enterprises choose logistics outsourcing. Logistics companies only provide high quality services that can improve customer satisfaction. Enterprises that choose the high quality logistics suppliers mean that improve the operational efficiency and can improve customer satisfaction which can enhance competitiveness. Service quality is better, the possibility of further cooperation between enterprises and logistics providers is larger. Combined with the actual situation of chemical industry, this paper selects four indicators as accuracy, safety rate, loss rate, response rate.

(3) Logistics cost

Logistics cost is used to measure the service fee of logistics supplier produces in the process. Cost is the logistics supplier's largest expenditure, so reduce the logistics cost is very important. Relevant statistics show that the logistics cost in the total cost accounted for about forty percent that it is the third profit source of enterprises, thus reducing the logistics cost means to reduce the production cost that can manifest the price advantage.

(4) Service ability

The service capacity is third party logistics supplier's service skills and technology that can complete the enterprise's logistics demand. The service capacity is an important influencing factor if Logistics enterprises can complete the shipper's logistics requirements. Chemicals logistics is more dangerous so logistics providers must have stronger service ability. This paper selects four indicators as ability of emergency management, service network, cooperation ability, improvement of service ability

3.2 Test evaluation index importance

Inspection of the third party logistics supplier evaluation index can remove the index which has little influence on the evaluation results. If a certain level have m index in evaluation system, k experts were invited to review, and then analyze its opinion on statistics. Mainly in the following aspects:

（1）concentration degree ： $\tilde{E}_j = \frac{1}{k}\sum_{i=1}^{k} E_j n_{ij}$

Where $\tilde{E}_j$ denotes the concentration degree of expert evaluation for i indexes;

E_j is i index for the j level of importance degree value; n_{ij} denotes j numbers when expert evaluate i index.

（2）Discrete degree： $\delta_j = \sqrt{\frac{1}{k=1}\sum_{j=1}^{5} n_{ij}(E_j - \tilde{E}_j)}$

Where δ_j denotes the discrete degree of expert evaluation for i indexes; Contrary to the centralized degree index, if the more concentrated the expert evaluation, δ_j is relatively small, on the other hand, δ_j is relatively large.

（3） coordination degree:

Where $\tilde{E}_j$ denotes the expert's evaluation of index, the value is bigger, that the index is more important. δ_j is the concentration degree of expert opinions, the smaller the value represents the opinions of experts more concentrated. $\tilde{E}_j$ and δ_j are absolute indicators, the two value represents that the results sometimes are not entirely consistent, then use V_j to judge. The indicator is more important while V_j is smaller.

3.3 Establishment of evaluation index system

According to the actual situation of chemical industry, choose evaluation indexes of the third party logistics provider, then test the selected indicators, finally set up the third party logistics supplier evaluation index system as shown in table 1:

Table 1. Third party logistics supplier evaluation index system

Evaluation target	First level	Second levels
The third party logistics supplier selection	Enterprise Strength	Total assets
		Financial stability
		level of information technology
	Service Quality	accuracy rate
		safety rate
		response rate
		rate of loss
	Logistics Cost	transportation cost
		Warehousing cost
		Order processing cost
	Service Ability	emergency handling ability
		Service network
		cooperation ability
		improvement of service ability

The third party logistics supplier evaluation index system is a multi-level system of indicators. In this paper, the third party logistics supplier evaluation system is divided into three levels, each level indicator is the concrete development of a hierarchical index, a hierarchical index value and also by calculating the next level indicator. In this paper, the third party logistics supplier evaluation system is divided into three levels, each level indicator is the concrete development of a hierarchical index, a hierarchical index value is obtained by the next level index calculation. The third party logistics supplier selection is the object that is the target layer. The strength of the enterprise, service quality, logistics cost and service ability is second level index. The decomposition of these four indicators is third level index

.

4 Conclusions

After selecting the logistics supplier, it is the beginning of the cooperation between the two sides, but not the end. In the process of cooperation, the production enterprises must avoid leakage of internal information to external companies, at the same time in order to cooperation between the two sides can be carried out smoothly, enterprises should establish a contract with third party logistics providers.

(1) signed a valid contract

The contract should be clear formulation of the terms of the contract, try to fill with cooperation regulations in the contract, to avoid in the process of cooperation appear unclear responsibility and the enterprise internal information leakage problem. The risk of some unforeseen circumstances should also make corresponding provisions in the contract, so prevent no chapter when problems arise.

(2) Establish an information sharing mechanism

In the process of cooperation with logistics suppliers, information asymmetry is one of the most common risks that it would lead to a no-smooth cooperative information communication between the two sides. In order to reduce the risk of asymmetric information, cooperation between the two sides should establish information sharing mechanism.Through information sharing, the two sides also master the transportation planning, transportation demand, costs and other information.

Logistics Cost Control Performance Evaluation of Third Party Logistics Enterprises

Lixin Chen and Zhida Guo

School of Economics and Management, Dalian Jiaotong University, Mail No. 794, Huanghe Rd., Dalian, Shahekou 116028, China. E-mail: 595010844@qq.com

Abstract: This paper brings forward the third party logistics cost management performance evaluation system, choose the transport department, storage department, information department and management department as one class index for the performance evaluation, in the foundation of one class index, choosing the appropriate level 2 index, constructing cost performance evaluation system, analyzing the logistics cost management performance.
Keywords: Logistics cost control; Performance evaluation; Third party logistics enterprises.

1 Introduction

The logistics enterprises can get the cost information of enterprise sector, besides, it can get customer cost information of enterprises through the department and customer Activity-Based Costing. The final purpose of any cost accounting method is not only to get a set of cost data. The purpose of department cost information is the internal cost control. The purpose of customer cost information is the foreign customer analysis. Thus, cost performance evaluation is the bridge of internal and external customers cost analysis of cost control. The essence of logistics cost performance evaluation is logistics cost benefit analysis which can provide valuable information for the enterprise management decision. Therefore, after the accounting of the enterprise department cost and customer cost, this article puts forward the evaluation index system based on department cost performance that its purpose is to provide the basis for the department cost control and reduce customer cost through the internal effective cost management.

2 Selection of third party logistics enterprises performance evaluation index

Many domestic and foreign scholars have done a lot of research on the choice of enterprise performance index. Objective evaluation method emphasizes the preset working target, finally compare job performance with the preset goals for comparison, find the gap, then draw a conclusion. Key performance indicators evaluation method is mainly through the clear indicators focus, select a few representative indicators of performance evaluation. The advantages of the balanced scorecard is to appraisal target localization in four dimensions of financial, customer, internal business, learning and growth which is a combination of financial factors and non-financial factors of enterprises. This paper added considerations of the target evaluation method, key performance index evaluation method and the balanced scorecard's charactics when selecting the performance evaluation indicators

(1) the selection of first level index

According to the general logistics department settings and co-ordination principle between departments of objective evaluation method, this selects the transportation department, warehousing department, information departments and administrative department as one class index of the third party logistics enterprise's performance evaluation. Objective assessment method also stressed: to determine the working -performance according to the degree of work target. The determination of target realization degree for transportation, warehousing, information and management department use industry average value for reference.

(2) the selection of second level index

According to the key performance index evaluation method, each department selected a small but representative index when selecting second level index. The thesis is the evaluation of logistics cost performance, therefore, in determining the representative index factors, the main consideration of the two indicators is the sensitive degree of logistics cost.

After determining the first level indicators and second indicators, the establishment of the framework of performance evaluation index system of the third party logistics enterprises, as shown in figure 1:

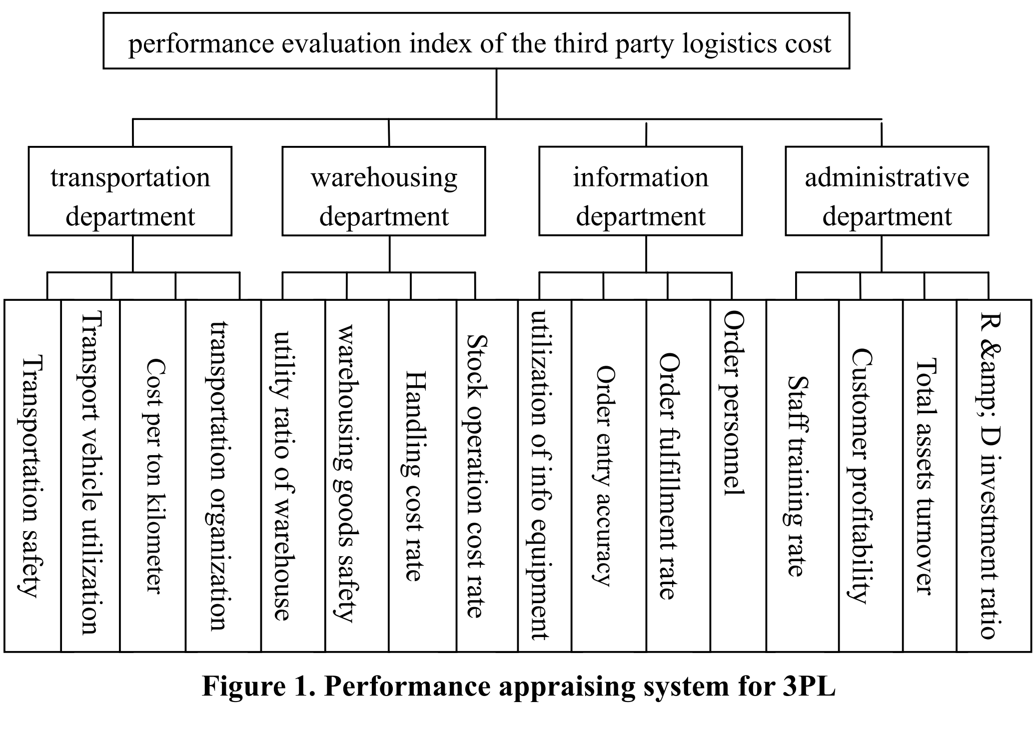

Figure 1. Performance appraising system for 3PL

3.logistics cost performance evaluation of M enterprise

(1) The relative weight of each layer elements and element combination weights are calculated by the comparison judgment matrix:According to factor's important degree judgment value table, performance evaluation index's important degree in the study of logistics experts is given the statistical summary. Construction of two two comparison judgment matrix are as follows:

Table 1. Matrix for internal department performance

department	A	B	C	D
A	1	2	3	4
B	1 / 2	1	2	3
C	1 / 3	1 / 2	1	1
D	1 / 4	1 / 3	1	1

Table 2. Matrix for transportation department performance

A	A_1	A_2	A_3	A_4
A_1	1	1 / 2	1	1
A_2	2	1	2	1
A_3	1	1 / 2	1	1
A_4	1	1	1	1

Table 3. Matrix for storage department performance

B	B_1	B_2	B_3	B_4
B_1	1	1	1	2
B_2	1	1	2	3
B_3	1	1 / 2	1	1
B_4	1 / 2	1 / 3	1	1

Table 4. Matrix for information department performance

C	C_1	C_2	C_3	C_4
C_1	1	3	2	2
C_2	1 / 3	1	1	1
C_3	1 / 2	1	1	1
C_4	1 / 2	1	1	1

Table 5. Matrix for client performance

D	D_1	D_2	D_3	D_4
D_1	1	1	1 / 5	1 / 3
D_2	1	1	1 / 2	1
D_3	5	2	1	1

D_4	3	1	1	1

(2)The relative weight of each layer elements and element combination weights are calculated by the comparison judgment matrix:

Department's comprehensive performance index weight:

W={0.47，0.28，0.14，0.11}

transportation department's comprehensive performance index weight:

WA={0.20，0.35，0.20，0.25}

warehousing department's comprehensive performance index weight:

WB={0.28，0.37，0.20，0.15}

information department's comprehensive performance index weight:

WC={0.43，0.17，0.20，0.20}

administrative department's comprehensive performance index weight:

WD={0.12，0.20，0.39，0.29}

(3)The M enterprise performance evaluation index weight value was determined, then investigate the actual value of various departments performance index. The actual and industry average value of M enterprise's performance index are as follows:

Table 5. Target value for transport department

measured value	Transportation safety	Transport vehicle utilization	Cost per ton kilometer
actual value	37 times / 104 km	83%	0.2
average value	20 times / 104 km	80%	0.15
difference	17 times / 104 km	3%	0.05

The transportation organization mode indicator is currently no quantitative method that can only rely on people to observe and record in practical work to evaluate the enterprises in transport organization efficiency, therefore, this paper is lack of the transport sector index actual value and average value of industry.

Table 6 Target value for storing department

measured value	utility ratio of warehouse	warehousing goods safety	Handling cost rate	Stock operation cost rate
actual value	98%	99%	70%	85%
average value	90%	91%	50%	75%
difference	8%	8%	20%	10%

Table 7. Target value for information department

measured value	utilization of info equipment	Order entry accuracy	Order fulfillment rate	Order personnel productivity
actual value	10%	95%	17	89%
average	30%	90%	10	80%

value				
difference	-20%	5%	7	9%

Table 8. Target value for management department

measured value	Staff training rate	Customer profitability	Total assets turnover	R & D investment ratio
actual value	60%	8	3	20%
average value	50%	13	2	30%
difference	10%	-5	1	-10%

4 Conclusions

(1)Through the investigation on the management department's important degree of second level performance indicators, find that its R&D investment important degree is 0.39 which is the highest in the four indexes. The results show that the investigation of M enterprise, its R & D investment ratio lower than the 10% average in the same industry. Although R & D investment is a cost that the development of the input and output efficiency in the logistics industry is very obvious, therefore, M enterprise's cost control in the future for the logistics management department focuses on R &D investment promotion. The Information Department of the equipment utilization rate is lower than the mean 20% of the same industry. The important degree of equipment utilization rate is 0.20 which is not the highest, but it is lower than the industry average level too high that is the important reason to reduce the information cost benefit. Therefore, consideration should be given to the company information degree when purchase of information equipment is adapt to enterprise's information development level in the future in order to make full use of the function of the equipment, to prevent waste.

Through the investigation on the transport department's important degree of second level performance indicators, find that gap between actual value of transportation safety index and the industry average is the largest of each transport sector index. The industry average level of transport accident is 20 times / 10^4km, while the M enterprise actual transport accident is 37 times / 10^4km. The important degree of transportation safety is 0.35, the highest value of four indicators, so M enterprise's cost control in the future for the transportation department focuses on strengthening the transportation safety management.

(2)According to department's comprehensive performance index weight, we can draw a conclusion that important degree of performance followed by transport department, warehousing department, information department, administration department. If the customer is not as the starting point of the cost management, only from the department, the importance of cost management can refer to the above indexes. The calculation for the weight of two level index corresponding to the various departments provides the basis for the department cost control priority. The important degree of warehousing department is 0.35. According to weight of warehousing department's two level index values, we can draw a conclusion that warehousing department's cost control order: handling, storage goods safety, utilization rate of warehouse and delivery cost of operation.

Abstract: Today, strategic alliance of global logistics is considered as a new device to raise business profit and manage contemporary logistics resource effectively. This paper will give an idea of global logistics strategic alliance in general and point out its roles in contemporary logistics and supply chain.
Keywords: Strategic alliance; Global logistics.

1 Introduction

Today, increasing number of experts and researchers generally consider the research on strategic alliance as a critical part of supply chain relationship research owing to the expansion and extension of supply chain renew contemporary logistics concept. From outsourcing to global strategic fit, there are sufficient evidence show that contemporary logistics is strategic and managerial in nature (Campbell and Reuer, 2001), which means contemporary logistics more terms global logistics management either in operation or in strategy. Therefore, strategic approach becomes the key of global logistics management to achieve competitive advantages (Parnell and Hershey, 2005), accordingly, how to identify strategic alliances and understand its value in global logistics is the focus of contemporary logistics management.

2 Global Logistics Strategic Alliance

2.1 Global logistics strategic alliance identification

In essential, strategic alliance generally refers as long-term and linked arrangements of resources among independent organizations, where the purpose of participators to win-win can be got.

Today, global logistics breaks existing border between countries and expands the process of goods movement from global sourcing to global marketplace. As a result, strategic alliance in global logistics needs to compromise to the consideration about subsidiaries enterprise in different areas and applies specifically external strategic alliance to global supply chain networks (Killing, 1995). Accordingly, strategic alliances in global logistics terms global resources arrangements related to the whole process of goods movement in the worldwide supply chain networks. In nature, such alliances put traditional strategic logistic alliance into the environment of globalization and therefore were endowed with the features that taking advantage of global resources sharing to improve the level of international logistics management (Fitzpatrick and Burke, 2000).

2.2 Requirements of global logistics strategic alliance

According to contemporary author, there are two requirements of strategic alliance: technology and trust base on contracts (Parnell & Hershey, 2005), the strategic alliances in global logistics even more strictly depend on the two dimensions (Lu and Dinwoodie, 2002). Generally, global logistics brings longer transportation line, more frequent partnership relationship and higher risk in transport. In consequence, increasingly complex global logistics operation call on more advanced technology such as EDI, RFID, bar code scanner to support these delicate process and more trust base on contracts to enhance level of cooperation between partners in the global logistics alliances (Fredendall et al., 2005).

2.3 Types of global logistics strategic alliance

Many contemporary scholars believe the typology is a so important way that it directs to the understanding about the theme. Harrison and Hoek (2005) in his book summarize the types of strategic alliances as: partnership, joint ventures and vertical integrations. Specifically, some contemporary researchers in logistics create the typology of strategic alliances in global logistics in terms of the members in global supply chain. From suppliers, intermediates to customers in worldwide countries, Handfield and Nichols (1999) divided the strategic alliances in global logistics into following three types.

2.3.1 Global supplier alliance

Firstly, strategic alliance between global manufacturers/suppliers has been used in the early 1990s to meet the increasing trade tends that need to deliver global products to customers with time efficiency. In nature, Cottrill (1997) views supplier alliance in global logistics as an efficient way to reach logistics management centralization because such alliances between suppliers can decrease the number of discrete distribution or facilities to a more manageable level through sourcing different suppliers and optimizing integrated global suppliers.

2.3.2 Strategic alliance between vendors and global logistics service providers (GLSP)

Strategic alliances between manufactures/suppliers and global logistics service providers (GLSP) is the most remarkable type because it focus on strategic planning and indicates future orientation of global logistics alliances. Contemporary GLSP involve not only global the third-party logistics companies but also carriers and warehouse operators in worldwide countries (Cottrill, 1997), so the alliances with GLSP more perform outside logistics features. Such outside logistics services make each participator concentrating on its core area of competence through expanding the continuum of outsourcing activities between manufactures and GLSP and finally can produce more competitive advantages than "in-house" logistics.

2.3.3 Strategic alliance between global vendors and customers

Strategic alliances between global manufactures/suppliers and customers need to understand each participator`s objectives (Cottrill, 1997). In "Business to Customer (B2C)" or some e-commerce industries, logistics alliance between suppliers and customer is increasingly noted by contemporary logistics research (Swaminathan and Tayur, 2003). A prominent example is that Wal-Mart created logistics strategic alliances with some vendors such as Philips Consumer Electronics, 3M and Procter and Gamble to successfully reduce inventory and other total logistics costs for either the retailers or the vendors (Mentzer et al., 2000).

Certainly, there are some other categories come from different perspectives and standards. For example, earlier in literature, the strategic alliances can be divided in two types: vertical and horizontal alliance. The vertical type is the alliances without equity investment and the horizontal type means the other alliances with equity investment. However, whether how the strategic alliance in global logistics to be sorted, any typology of strategic alliances in global logistics relates to itself value evaluation in nature.

3 Values of Global Logistics Strategic Alliance

3.1 Advantages and disadvantages of Global logistics strategic alliance

Contemporary articles are tending to emphasis the attention of logistics alliances on value of global logistics alliances. Major contemporary researchers commonly believe two things: one is that the advantages of strategic alliances outweigh the disadvantages (Daboub, 2002); the other one is international logistics management is critical for global companies to be successful or fail in global competition (Fredendall et al. 2005). These common grounds give a clue to analyze and understand the worth of logistics alliances in globalization.

At first, the merits of strategic alliances are remarkable. In detail, Daboub (2002) indicated that global strategic alliances promote global enterprise to gain competitive position. The fact is the same, for virtual contemporary global enterprise, global logistics alliance-strategy is a good way to share resources (Rondinelli and Black, 2000), mitigate risk, enhance performance (Parnell and Hershey, 2005), increase profit with cost saving and thereby achieve competitive advantages. Correspondingly, the performance of strategic alliances in global logistics is also prominent. Fitzpatrick and Burke stated in 2000 that global logistics alliances improve the global organization's logistics flexibility and resources efficiency; Halliday in 2002 illustrated that global logistics alliance as a new value-added strategy that can facilitate marketing deliver through change relationship between parties in the logistics alliances. In additional, the linked arrangements from full-orientated outsourcing to integration between worldwide suppliers and customers can lead to decrease the reorder point of inventory, change shipping strategies and in the end, resolve some traditional tradeoffs in global logistics to enhance global logistics performance with cost saving (O`Byrne, 1997).

Furthermore, the strategic alliance in global logistics would change the direction of competitive efforts toward more integrated objectives instead of separate benefits. This standpoint has been regarded as future tendency of global logistics alliance in long term. Gourdin and Clarke (1992) summarize that the success of American Desert Storm in 1991 largely consist in logistics alliance between the Department of US Defense and the American international transportation industry. Logistics alliances can cross different industries in the world is a virtual guide for global enterprise` logistics operation. However, the performance of strategic alliance in global logistics is not always so ideal.

Some contemporary authors provided disadvantages of strategic alliance in global logistics. For instance, some views acclaim that alliance in global logistics contributes poorer performance to small technology-based firms. Recently, MacGregor and Vrazalic (2005) prove this viewpoint again. They argue that in terms of the characteristics of e-commerce in small business, it is hard to utilize strategic alliances properly. As a result, alliances in this area produce negative effects. Moreover, such result is often to bring worse consequence through strategic alliance structure than through single directed unit (Starks, 2004). If considering this shortcoming as constrains of value achievement, the views on the contrary make the research of value about strategic alliance in global logistics clearer and more implicatively. It results in this topic: in what degree the strategic alliances in global logistics can efficiently achieve its value and what is the implication?

3.2 Utility of global logistics strategic alliance

It is clear that the utility of strategic alliances is the key issue in contemporary logistics literature. That means failure or success of global logistics alliances concern to whole supply chain building of global enterprise. It is undoubted that for global firms with limited foreign presence hard to improve performance in short term, strategic alliance in global logistics is the gateway to win strategic advantages in broader supply chain network. In additional, there are so many factors such as government policies, technology, infrastructures of countries , scope of the business, strategic focus and business choice of participators that any deviation of these factors may produce cushioning or aggravating impact on the performance of strategic alliance in global logistics (Baetz et al., 2002; Starks, 2004). Concretely, Kannan and Tan (2004) provide a comparison on attitude between alliance adopters and alliance non-adopters, they proved that changes in the global logistics alliances will result in different results.

Accordingly, members in contemporary logistics alliance have a closer interactional relationship and the intermediaries naturally take an unprecedented significant role. That is why so many contemporary logistics researchers consistently agree that the intermediaries like third-party service providers` performance will impact on the whole global logistics alliance itself (Abrahamsson and Wandel, 1998). This thinking has particularly given much elicitation to senior management of contemporary enterprise.

4 Conclusions

Today global logistics play increasingly significant role in global competitive economic, Strategic alliances in global logistics is an advisable consideration for the enterprise that wants to gain strategic position in global competition. In particular, better understanding about the nature of the strategic logistics alliance can usefully guide that thinking. At the same time, the utility of strategic alliances in global logistics is the issue of value evaluation because properly using global logistics alliances can help to achieve integrated success but any conditional discrepancy will lead to deviation of success.

Therefore, reasonable design and proper utility of strategic alliance in global logistics can develop the full potential of global enterprise, in the meanwhile, it is also a huge challenge for senior management. Better be aware of the advantages and disadvantages of strategic alliances in global logistics contribute to win more competitive advantages in globalization.

Abstract: Briefly, introduce Flexsim and a distribution center. Then, using system modeling and Flexsim to make the analysis of the distribution center. Finally, optimize the system through eliminating bottleneck and improving the equipment configuration and utilization rate.
Keywords: Flexsim; The distribution center; System simulation.

1 Introduction

A distribution center can also be called a warehouse or a package handling center. Distribution center is an economic organization, setting processing, cargo handling, shipping, and many other functions in one logistics base (LIU Lei, 2008) .

Flexsim is simulation software, widely used in the field of logistics engineering and warehousing area. This paper takes one distribution center for example. The distribution center is a storage-distribution center having a larger storage capacity. It makes the analysis using the system modeling and Flexsim to get those purposes: (1) Check the operation of the system and the flow capacity of cargo; (2) Determine its equipment parameter settings; (3) Improvement.

The layout of the distribution center is shown in Figure1. The input area is mainly responsible for receipt, inspection, sorting, etc, to achieve the transport of goods by conveyors; The role of the storage area is to store the pallets full loaded; The distribution processing zone has two districts, I and II, whose functions are same such as labeling and packaging; There are several horizontal carousels and some electronic sorting equipment in the picking area; The delivery area is mainly responsible for shipping work to distribute goods. The main working flow of the distribution center is shown in Figure2. The qualified goods enter into the input area. Later, the defective goods will be unified disposed. Logically, there are three paths for the goods stored in the storage area to directly output, namely, the distribution processing area, the picking area and the dispatch area. The principles about how to choose path are that the goods must pass the distribution processing zone and there is only one frequency. Through secondary processing, the goods are sent to different areas. The goods taken from the storage area are sent back to the storage area and others taken from the picking area are sent to the dispatch area. When receiving the delivery order, the distribution center sends the appropriate goods to the dispatch area, waiting for loading. The goods are in the dispatch area, partly from the storage area and partly from the picking area.

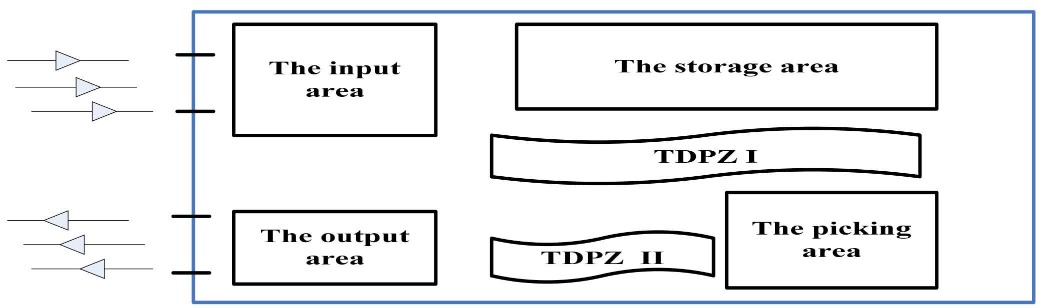

Figure1. The layout of the distribution center

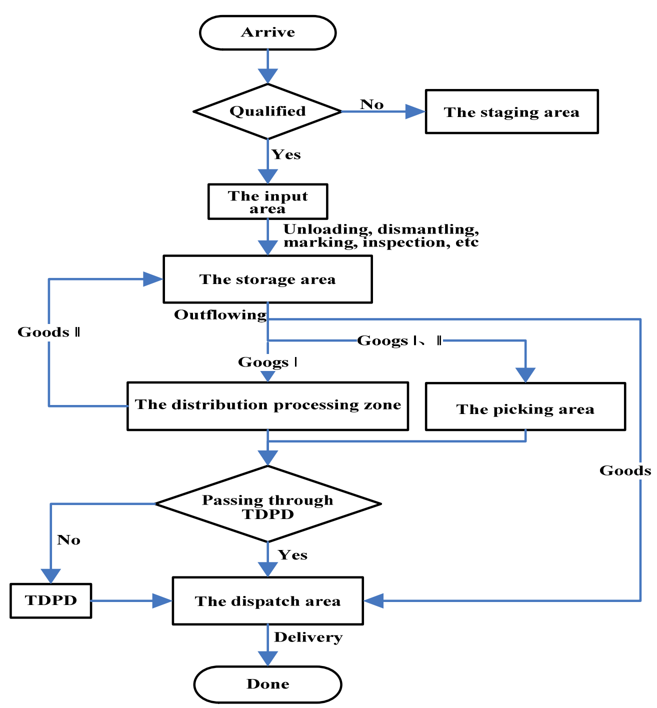

Figure2. The main working flow chart

Note: *TDPD= The distribution processing zone*

2 Building Model

Based on the spatial layout of the distribution center, its 3D model is built using Flexsim, shown in Figure3. In the model, there are many entities. *SOURCE* and *SINK* simulate the arrival and departure of goods, respectively; *CONVEYOR* simulates automatic sorting machine; *COMBINER* simulates packing operation; *PROCESSOR* simulates the delay of some time; *SEPARATOR* simulates the split of tray and so on (MA Xiangguo, 2012).

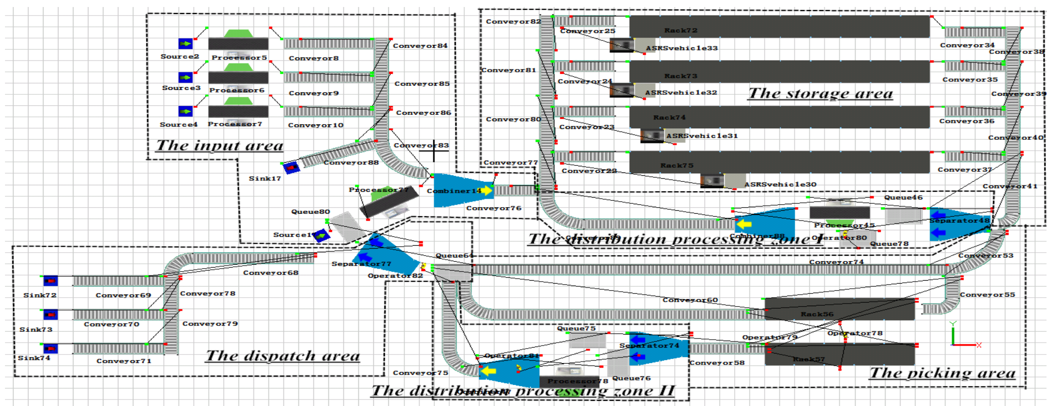

Figure3. Simulation model

Note: *The connection between entities means the logical relationships between related objects.*

The main parameters of the model: *(1)* Receiving: the arrival of goods obeys Poisson distribution, Poisson (55, 1); *(2)* Defective rate is 2.7%; *(3)* The number of trays is 300, which are generated at one time; *(4)* Every pallet loads 4 goods; *(5)* In the distribution processing zone, the operators subject to a Fixed length distribution, mean 60,70, respectively, and random number stream 1,both; *(6)* Using separator to separate the tray and the goods; *(7)* Each rack in the storage area is constituted by 10 levels by 10 bays, placing the pallet from the first available level as well as the first available bay, where the residence time of pallet obeys Poisson distribution, Poisson (7200, 1); Each rack in the distribution processing zone is constituted by 10 levels by 5 bays, placing the pallet into the cross cell of the first available level and the first available bay, where the residence time of pallet obeys Poisson distribution, Poisson (3600, 1); *(8)* The simulation time is set as 10h.

3 Simulation Result Analysis

3.1 Bottleneck analysis

There are three simulation state diagrams at three key moments (the simulation time), shown in Figure 4-6, respectively.

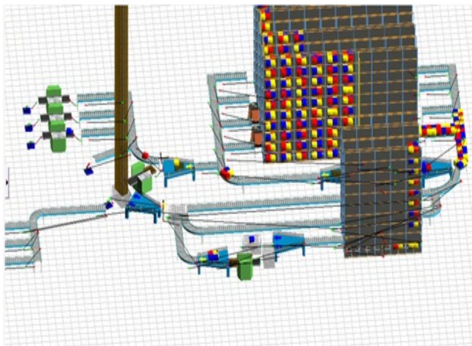

Figure4. System state at 10966.23s

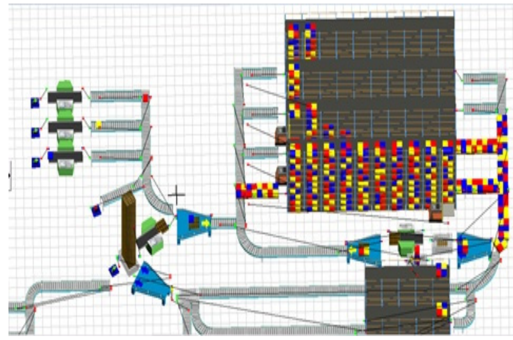

Figure5. System state at 17558.24s

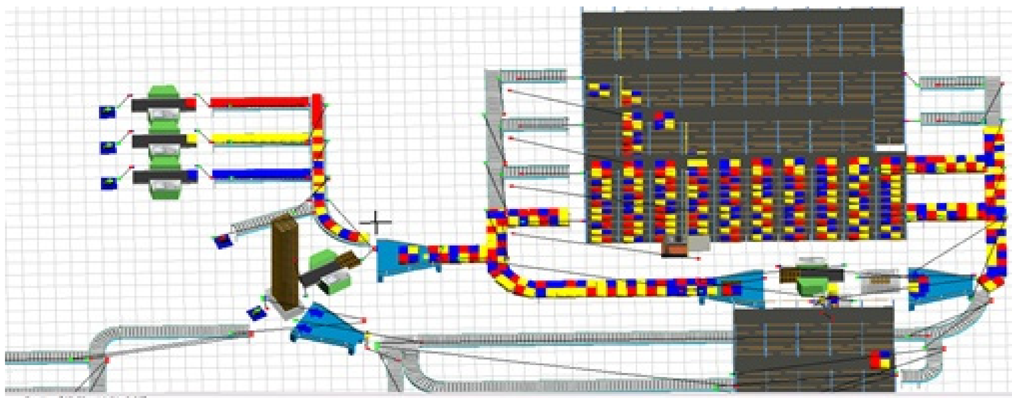

Figure6. System state at 20422.74s

The currency blockage first appears in the link of the storage area and the distribution processing zone I, then spreading to Rack75 and Conveyor22. Finally, the entire input channel is blocked. Thus, the bottleneck is in the distribution processing zone I. In addition, in the distribution processing zone I, Queue78（the Product staging area）: input = 63, output = 53; Queue46（the pallet staging area）: input = 15, output = 15. Therefore, the reason why the blocking appeared is that the goods cannot be packed timely. Namely, the cargo capacity of operator is low.

In Figure6, the entire system is in a paralyzed state. There is an interesting phenomenon at this moment about the racks in the storage area. See the following datum: Rack72: input= 30, output= 24, content= 6; Rack73: input= 28, output= 18, content= 10; Rack74: input= 64, output= 44, content= 20; Rack75: input= 134, output= 34, content = 100. So the utilization ratio of those racks in the storage area is imbalanced. Rack75 is overloaded, which is another reason for the system standstill.

To sum up, the main contradiction: Rack75 supply and operator demand are imbalanced; the secondary contradiction: misallocation of goods in the storage area and the overload operation of Rack75.

(1) Initial optimization

Add a worker, Operator83, to the distribution processing zone I; set it obey the Fixed length distribution, mean 60; set its single-carrying capacity as 2. Additionally, change some conveyors' parameter located in the storage area, shown in Table1.

Table1. The parameter sitting details in the first optimization

Entity Name	Parameter settings
Conveyor77	Set the distribution of the output port, as follows: 80% and 20% correspond to the output port 1 and 2, respectively.
Conveyor80	Set the distribution of the output port, as follows: 70% and 30% correspond to the output port 1 and 2, respectively.

When the simulation stops, the simulation result is shown in Figure7.

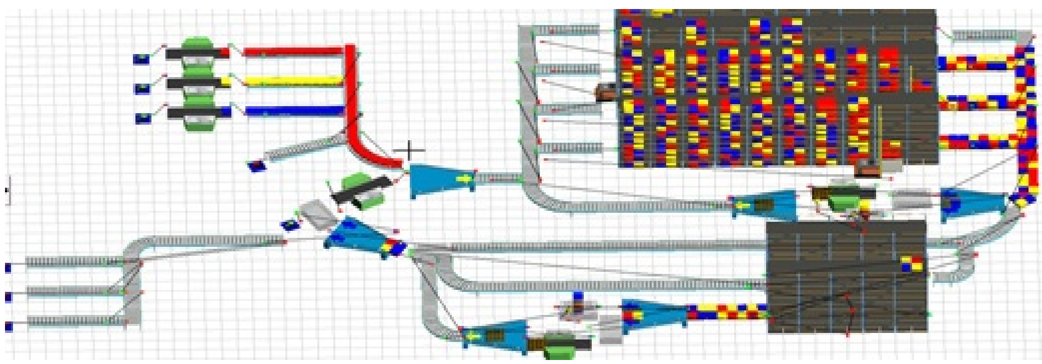

Figure7. The state of the system after the initial optimization

In Figure7, the principal contradiction has been resolved. To some extent, the congestion is alleviated. However, the further optimization has become inevitable. The similar blocking phenomenon exists in the distribution processing zone II. Meanwhile, there is the blockage of products in the storage area. The root reason is the poor secondary treatment efficiency in the distribution processing zone, leading to the consequence that the tray could not be recovered timely. Now, observe the datum, shown in Table2.

Table2. The Rack usage situation

Area	Rack	Input	Percentage	Output	Current
The storage area	Rack72	143	30.17%	126	17
	Rack73	118	24.89%	69	49
	Rack74	119	25.11%	23	96

	Rack75	94	19.83%	10	84
The picking area	Rack56	54	63.53%	48	6
	Rack57	31	36.47%	20	11

In Table2，it is clear that the situation, misallocation of goods in the storage area, has been well improved. However compared to Rack72, Rack73 and Rack74, the goods acceptance rate of Rack75 should be further improved. The distribution of goods between Rack56 and Rack57 is partly imbalanced. In fact, this uneven distribution of local task does not bring about negative effects to the overall cargo storage and the normal operation of the system. Therefore: Continue to improve the low efficiency of the secondary cargo handling in the distribution processing zone.

(2) Second optimization

After a series experiment of optimization, the solution is obtained. In the distribution processing zone, use robots to replace the operators. See Table3:

Table3. The optimization scheme

Area	Original entity	Alternatives	Parameter settings
Distribution processing I	Operator80	Robot80	Set single carrying capacity as 4; allow turning during transport
Distribution Processing II	Operator81	Robot80	Set single carrying capacity as 4, allow turning during transport

When the simulation time is 36000s, the state of system is shown as Figure 8.

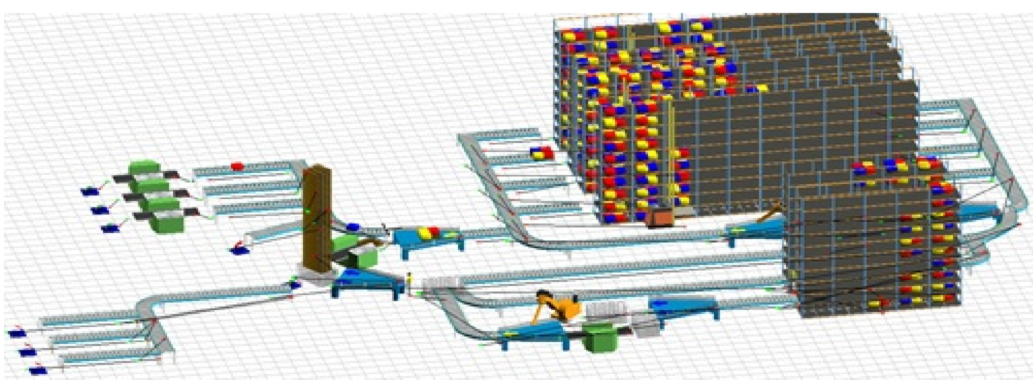

Figure8. The State diagram of the optimization result

By observing, it is clear that the main contradiction, the inefficient in the distribution processing zone, has been resolved.

3.2 Rationality analysis of the tray number

According to the optimization result, the relevant entity datum in current system can be got. The current system: input= 1964, output= 988; Queue80: content = 71, meaning that there remain 71 pallets which are redundant. Opinion: the number of pallets is irrational, which should be significantly reduced. Actually, the average utilization rate of racks in the storage area is 44.25%; the average utilization rate of racks in the picking area is 48%; the tray utilization is 76.33%. To make the distribution center achieve its desired function, the average utilization of racks is relatively low which need to be improved. Therefore, the following conclusion can be drawn: in current system, the utilization rate of racks and pallets is relatively low.

The main reason why the Cargo space utilization is low is the less supply of products. It is necessary to improve the arrival speed of goods. To further ensure the utilization of cargo space, the products minimum stay time and the upper limit of the output port at racks are set as reference variables. In addition, the tray is set to a volatile variable.

Referring to the thought of a linear equation, the premise of optimization is that selecting only one variable to optimize and setting others as constant variables in each process of iteration. After many iterative cycles, the optimal solution is got. The details of the scheme are shown in Table4. (Note: *other parameters' setting remain.*)

Table4. The changed details of the optimal scheme

Entity	Original relative settings	Current relative settings
Source2-4	The arrival of goods obeys Poisson distribution, Poisson (55, 1)	The arrival of goods obeys Poisson distribution, Poisson (50, 1)
Source17	Produce 300 pallets	Produce 320 pallets
Queue80	The maximum size is set as 320	The maximum capacity is set as 340
Rack72-75	The residence time of pallet obeys Poisson distribution, Poisson (7200,1); when the amount of storage reached 80, the Rack shuts down its input port, and while reducing the amount of storage to 20, the Rack opens its input port to restock.	The residence time of pallet obeys Poisson distribution, Poisson (9300,1); when the amount of storage reached 90, the Rack shuts down its input port, and while reducing the amount of storage to 20, the Rack opens its input port to restock.

Based on the optimization result, it can be seen that: the entire system: input= 2152, output= 832; the average utilization rate of racks in the storage area is 66%, improved by 21.75%, compared to the previous rate, 44.25%; the average goods allocation utilization of the picking area is 48%; tray utilization rate is 100%, improved by 23.67%, compared to the previous rate, 76.33%. Pallet utilization has been greatly improved. Through repeated experiments, the situation of tray shortage will not happen. Thus, the number of trays (320) is economical and reasonable.

In summary, the optimization scheme has been proved to be feasible.

4 Summary

The model of the distribution center is built by Flexsim. Based on the two phases of the optimization, the system has been greatly improved. Finally, the goal to improve the efficiency of the distribution center is achieved.

Synchronous Supply Model of the Automotive Components at an Assembly Plant

Min Mao[1,2]; Lin Bo[1]; and Jian Liu[1]

[1]School of Transportation and Logistics, Southwest Jiaotong University, Chengdu 610031, China.
[2]National United Engineering Laboratory of Integrated and Intelligent Transportation, Chengdu 610031, China.

Abstract: The problem of automotive components supply on mixed-model assembly line is more complex due to the diversification of customer demands. The process of automotive components of synchronous supply is analyzed in the paper. This paper presents a synchronous supply model of the automobile mixed-model assembly lines at the assembly plant based on time window, in which the shortest total transport distance is adopted as the objective. Finally the paper gives an example. And the result of the example indicates that this model can realize synchronous supply from material buffer points to the workstations at the assembly plant within the required time. And it is helpful to improve the efficiency of automotive components supply.
Keywords: Mixed model assembly line; Automotive components; Synchronous supply.

1 Introduction

Mixed model assembly lines are widely used in automotive industry because of its greater variety in demand. It can produce different models, different series and different colors cars as per customer's demands. The problem of automotive components supply on mixed-model assembly line is more complex than that of the single-model assembly line, because there are different parts or components in different models on mixed assembly line and the processing times for common tasks may be different. Therefore the automotive components supply on mixed-model assembly line at assembly plant has aroused the attention of scholars at home and abroad. (Choi, 2002) propose a dynamic part-feeding system for an automotive assembly line. (Jiang, 2009) put forward to a workstation distribution scheduling model to minimize the total distribution time at the assembly plant.

Mixed model assembly lines have a strong impact to improve the goal of Just in Time (JIT) and balanced production (Hu, 2011). Just-in-time (JIT) philosophy, first introduced by the Toyota Motor Co. in the late of 1970s, has attracted much interest in its basic underlying concept. (Doran, 2001) explores the differences between just-in-time (JIT) and synchronous supply based on a case study within an automotive context. Synchronous supply can be regarded as the advanced form of

JIT supply (Wang, 2005). Because the synchronous supply results in notable benefits for both buyer and supplier (Doran, 2001; Hu, 2001; Chen, 2009), it has also received considerable attention from both industry and academics.

This paper presents a synchronous supply model of the automotive components at the assembly plant, in which the shortest transport distance is adopted as the objective.

2 The process of automotive components of synchronous supply

On a just-in-time (JIT) basis, synchronous supply is essentially a system where components supplied are matched exactly to the production requirements of the buyer. Compared with traditional JIT supply, synchronous supply may be limited to the supply of a small number of key components or high value component systems within the short time window available (Doran, 2001).

Normally an automobile assembly plant consists of the main line of body, painting and assembly shops and several sub-lines feeding parts to the main-line as shown in figure1. After press shop, bodies pass several painting processes in paint shop according to the demand of customers. Then, painting body storages enter assembly shop. Some vendors supply components to assembly line based on BOM and sequencing information which are transferred from customers' demand. Vendors are required to sequence components before arriving at material buffer area. There are corresponding relations between workstations and material buffer points. If workstations need some kind of components, sequenced components will be delivered to the right workstations by the conveyance, according to material supply information.

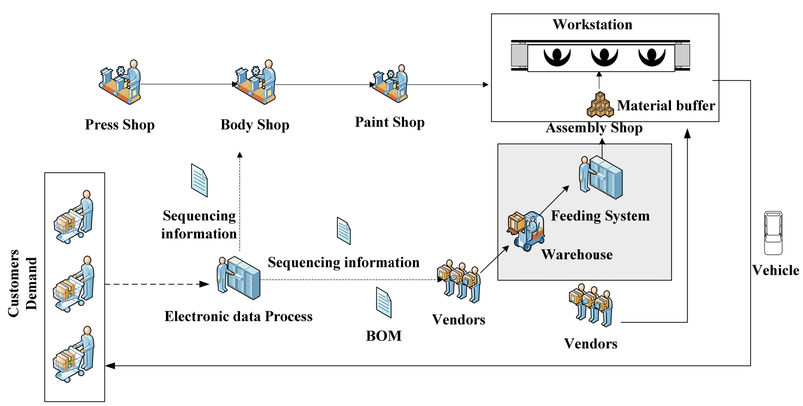

Figure1. The process of automotive components of synchronous supply

3 Components synchronous supply model at the assembly plant

In an automotive context, synchronous supply means automotive components should be supplied exactly at the right workstation of the assembly plant in required time window. The paper presents a synchronous supply model in which the shortest total transport distance is adopted as the objective.

(1) Model assumptions

1) The material buffer area beside assembly lines can meet the demands and components supply shall not exceed supply capacity.

2) The materials in one buffer point can supply one or more workstations.

(2) Definite variables

BT—the best supply time;

L_J、H_J—the lowest and highest supply time available;

T_{ij}—time from material buffer point to work station;

T'_{ij}—time from work station No. i to material buffer point No. j;

u_{ij}—transport speed of conveyance;

z_i—service time of conveyance at material buffer point.

$$x_{ij} = \begin{cases} 1, & Components\ belonged\ work\ station\ i\ stores\ in\ buffer\ poin\ j \\ 0, & or\ else \end{cases}$$

$$y_{iq} = \begin{cases} 1, & q\ conveyance\ supply\ to\ work\ station\ i \\ 0, & or\ else \end{cases}$$

$$x_{ijq} = \begin{cases} 1, & Conveyance\ q\ supply\ components\ from\ work\ station\ i\ to\ buffer\ point\ j \\ 0, & or\ else \end{cases},$$

All above, $i = 1,2, \dots m, j = 1,2, \dots n,\ \ q = 1,2, \dots Q$

(3) Model foundation

The shortest transport distance is adopted as the objective function. The model is like this:

$$\min z = \sum_{i=0}^{M} \sum_{j=1}^{N} T_{ij} \cdot u_{ij} \cdot x_{ij} + \sum_k \sum_{i=0}^{M} \sum_{j=1}^{M} T'_{ij} \cdot u_{ij} \cdot x_{ijk} \quad (1)$$

with

$$\begin{cases} BT_J = \sum_{i=1}^{J} \sum_{j=1}^{N} T_{ij} \cdot x_{ij} \cdot y_{iq'} + \sum_{i=0}^{J-1} \sum_{j=1}^{J} T'_{ij} \cdot x_{ijq'} + \sum_{i=1}^{J} z_i \cdot y_{iq'},\ \ q' = \{q | y_{Jq} = 1\} \\ L_J \le \mathrm{BT}_J \le H_J, J = 1,2, \dots m\ ; \\ T'_{ij} = T_{ij''}, j'' = \{j' | x_{jj'} = 1\} \\ \sum_q y_{iq} = 1, i = 1,2, \dots m\ ; \\ \sum_j x_{ijq} = y_{iq}(i < j); \sum_i x_{ijq} = y_{jq}(i < j); \end{cases}$$

$$x_{im} = 1 \ ; \ x_{nk} = 0$$

The model is modified as：

$$Min\left\{\sum_i \sum_j \overline{T_{ij}} \cdot u_{ij} \cdot x_{ij} - Mx_{im} + Mx_{nk} + \sum_k \sum_{i=0}^{m} \sum_{j=1}^{m} T'_{ij} \cdot u'_{ij} \cdot x_{ijk}\right\} \quad (2)$$

$$\overline{T_{ij}} = T_{ij}, \text{ except } \overline{T_{im}} = \overline{T_{nk}} = 0$$

With constrains 1:

$$\begin{cases} BT_J = \sum_{i=1}^{J}\sum_{j=1}^{N} T_{ij} \cdot x_{ij} \cdot y_{iq'} + \sum_{i=0}^{J-1}\sum_{j=1}^{J} T'_{ij} \cdot x_{ijq'} + \sum_{i=1}^{J} z_i \cdot y_{iq'}, \quad q' = \{q | y_{Jq} = 1\} \\ L_J \le \mathrm{BT}_J \le H_J, J = 1,2, \dots m \ ; \\ T'_{ij} = T_{ij''}, j'' = \{j' | x_{jj'} = 1\} \\ \sum_q y_{iq} = 1, i = 1,2, \dots m \ ; \\ \sum_j x_{ijq} = y_{iq}(i < j); \sum_i x_{ijq} = y_{jq}(i < j); \end{cases}$$

With Constrains 2:

Considering that materials of some workstations must be stored at the fixed material buffer point, the optimal solution should be constrained. If p is the number of $x_{ij} = 1$ and q is the number of $x_{ij} = 0$, the optimal solution in (2) is $opt\left(x^*\right)$. If $\left|\frac{opt\left(x^*\right) - pM}{pM}\right| < \varepsilon$, it means that the optimal solution is the feasible solution. And it's suggested that $\varepsilon = 1/_{2p}$, ε is a small positive number.

4 Analysis of an Example

There are almost 150 workstations in Guangzhou Toyota Motor Co. Ltd. In this example, workstations chosen from interior lines are divided into 6 groups, named from A1 to A6. The corresponding material buffer points are named from B1 to B5. Moreover the materials for workstation of A2 must be stored at material buffer point of B1. Table 1 shows the required time for each workstation and the travel time from material buffer points to workstations. Table 2 is the transport speed of the conveyances from material buffer points to workstations.

Table 1. Required time for each station and travel time from material buffer points to workstations

Travel time(s) / Buffer points	Work station	A1	A2	A3	A4	A5	A6
	Required time	[0,120]	[120,240]	[240,360]	[360,480]	[480,600]	[600,720]
B1		33.00	12.15	112.50	117.18	123.80	11.40
B2		45.38	50.46	113.54	67.34	67.69	77.76
B3		98.42	113.54	57.66	16.80	63.84	70.50
B4		39.00	17.34	57.66	141.14	34.68	29.04
B5		45.38	59.54	121.50	67.34	67.69	73.50

Table 2. The transport speed of conveyance from material buffer points to workstations

Speed m/s	A1	A2	A3	A4	A5	A6
B1	1.00	0.27	1.25	0.84	1.31	0.19
B2	0.55	0.58	0.87	0.67	0.95	0.72
B3	0.81	0.87	0.62	0.32	1.33	0.47
B4	1.00	0.34	0.62	0.97	0.68	0.44
B5	0.55	0.63	0.90	0.67	0.95	0.70

Sources: Based on the website of Guangzhou Toyota Motor Co. Ltd.

Table 3. The supply task from material buffer points to workstations by 2 conveyances

Workstation	A1	A2	A3	A4	A5	A6
Buffer point	B2	B1	B1	B3	B3	B1
Number of conveyance	1	1	1	2	2	1

Table 4. The transport route from material buffer points to workstations by 2 conveyances

Number of conveyance	Transport route	Each section of transport distance (m)	Transport distance(m)	Total transport distance(m)
1	B4-A1-B1-A2-B1-A3-B1-A6-B1	B4-A1: 39 A1-B1: 33 B1-A2: 12.15 A2-B1: 12.15 B1-A3: 112.5 A3-B1: 112.5 B1-A6: 11.4 A6-B1: 11.4	344.1	441.54
2	B3-A4-B3-A5	B3-A4: 16.8 A4-B3: 16.8 B3-A5: 63.84	97.44	

Based on the synchronous supply model in the paper and the data of Table 1 and 2, using Matlab programming, the implement plan from material buffer points to workstations of A1 to A6 by 2 conveyances are formulated (see Table 3 and 4). The conveyance No.1 is in charge of the supply task for workstations of A1, A2, A3, and A6. The transport distance of conveyance No.1 is 344.1 meters in time of 462 seconds with average speed 0.74 m/s. And conveyance No.2 is in charge of the supply task for workstations of A4 and A5. The transport distance of conveyance No.2 is 97.44 meters in time of 152 seconds with average speed 0.64 m/s. The materials for workstations of A1 to A6 are arranged to be stored in different buffer points (see Table 3). The total transport distance is 441.54 m. It indicates that the 2 conveyances can complete the supply task for 6 workstations within required time.

5 Conclusions

Diversification of customer demands brings increase in the number of parts consumed, which causes disturbances in the production and components supply. Synchronous supply should aim at meeting customer demand based on efficient supply chain management and flexible information integration system. The paper proposes a synchronous supply model with the appropriate constrains, in which the shortest total transport distance is adopted as the objective. Finally the example demonstrates the effectiveness of the synchronous supply model at the assembly plant.

Abstract: Aim of the study is to build a VRPTW to improve the recovery of medical waste in China. Both capacity limit and duration time are considered to meet the characteristics of medical waste that it is time-sensitive in the recovery process and enhance recovery efficiency. The model is solved by using improved genetic algorithm (GA), which can avoid dropping into local optimum by adding reverse evolution operation after crossover operation. Finally, the real-world data are collected from 30 medical units and the results show that managers just need to two vehicles to satisfy their demand and the loads and recovery time of each vehicle are 2265kg, 1935kg and 1.5979 h and 3.2532 h respectively. The travel paths of each vehicle are also scheduled.
Keywords: Urban medical waste; Recovery network; Vehicle routing problem with time windows (VRPTW); Improved genetic algorithm.

1 Introduction

With the urbanization speeding up in China, the city size as well as the urban population expanding, urban medical and health industry has developed enormously, which causes a sustainable growth of medical waste. According to the Medical test report announced by Chinese health authorities, viruses and harmful bacteria carried by medical waste is dozens, hundreds even thousands of times as dangerous as household garbage because of their characteristics of space infection, acute infection and latent infection and so on. They will pose a huge threat to the environment and human health if it is not be recycled and disposed properly. How to recycle and dispose the medical waste effectively has become a hot topic for citizens and government.

However, there are still some shortcomings, for China starts relatively late in the management of medical waste and laws and regulations are not perfect. Companies arrange their recovery routes experimental and ignore the characteristic that medical waste is dangerous. If exposed in the crowds for a long time, medical waste may have a high risk of leakage. Therefore, companies need to arrange vehicles and their travel paths to reduce delivery time and risk of leakage.

Vehicle routing problem (VRP) is firstly proposed by (Dantzig,1959). After years of academic research, there emerges a large number of expansion models of VRP, such as vehicle routing problem with time windows (VRPTW) by (Roberto ,1999), etc. At the same time, many heuristic algorithms are also proposed (Beltrami,1974; Tong,2004; Bell,2004). With those, VRP and its' expansion models can be easily solved. However, literatures about how to apply VRP to the optimization of the recovery network of medical waste are scarce in China. Existing studies such as (M. Wang,2012) don't take the characteristics of medical waste that should be delivered on a tight schedule into account and just utilize the simple VRP.

In this paper, we formulate a VRPTW model where time limit is considered. The goal of the model is to minimize the total recovery time, including transportation time and recovery service time, and arrange the number of recovery vehicles and their travel path. At last, we set an example of real world and the results show that the model can be solved effectively.

2 Mathematical Model

2.1 Model description

Urban medical units are relatively geographically concentrated and the recovery and disposal of medical waste are time-sensitive, so it is not necessary to build transfer stations since more layers mean higher risks. In figure 1, we can see that the network of urban medical waste is mainly composed of a disposal center of medical waste and a number of medical units where medical waste is generated. Now, we need to organize several recovery vehicles to collect medical waste, starting from the disposal center and coming back the disposal center when all customers (medical units) are serviced. The total recovery time that every vehicle costs cannot exceed the specified time period (ΔT). The goal is to minimize the total recovery time and organize the number of vehicles and their travel path.

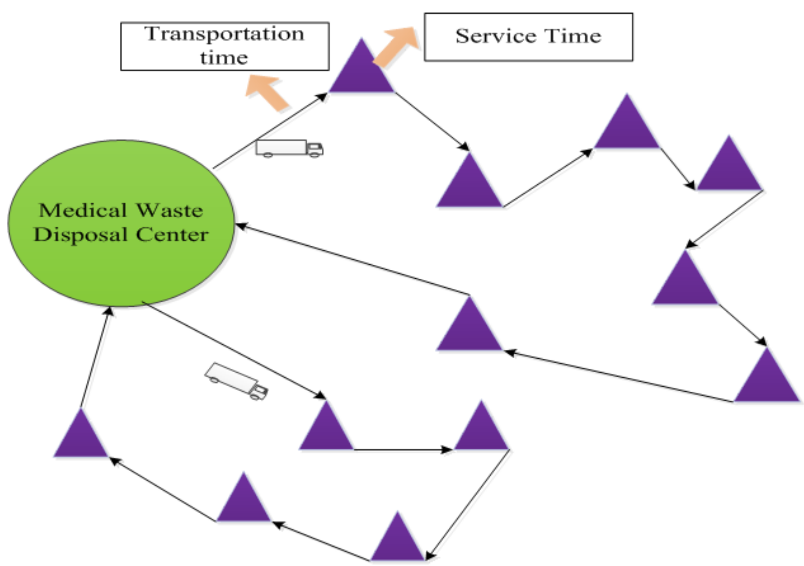

Figure 1. Recovery network of medical waste

2.2 Mathematical formulation.

Before modeling, we assume that the positions of each unit as well as the distance between any two points are known. Every unit is visited just only once by any vehicles.

Denoting the disposal center and medical units by N_0={1,2,..,n}, and the set of recovery vehicles by $K=\{1,2,\ldots,k\}$. The disposal center is located at 0 and the set of all positions is $N = N_0 \cup \{0\}$.The parameter c_{ij} represents the travel time on arc $(i, j) \in A$, where A is the set of arcs between all positions in N_0. The parameters q_i and t_i respectively represent the demand and service time of unit i. Q_k denotes the maximum capacity of vehicle k. Each route has duration limit ΔT. x_{ijk} and y_{ik} are binary variables, x_{ijk} are equal to 1 if and only if vehicle k travels from i to j, y_{ik} are equal to 1 if and only if customer i is serviced by vehicle k. The objective and constraints are defined as follows:

$$Min\ Z = \sum_{i=0}^{N}\sum_{j=0}^{N}\sum_{k=1}^{K} c_{ij}x_{ijk} + \sum_{i=0}^{N} t_i y_{ik} \qquad (1)$$

$$\sum_{i=1}^{N} q_i y_{ik} \le Q_k \qquad \forall k \in K \qquad (2)$$

$$\sum_{i=0}^{N}\sum_{j=0}^{N} c_{ij}x_{ijk} + \sum_{i=0}^{N} t_i y_{ik} \le \Delta T \quad \forall k \in K \qquad (3)$$

$$\sum_{k=1}^{m} y_{ik} = \begin{cases} K & i = 1,2,\ldots,N \\ 1 & i = 0 \end{cases} \qquad (4)$$

$$\sum_{j=0}^{N} x_{ijk} = y_{ik}, \forall i \in N, \forall k \in K \qquad (5)$$

$$\sum_{i=0}^{N} x_{ijk} = y_{jk}, \forall j \in N, \forall k \in K \qquad (6)$$

$$\sum_{i=1}^{N}\sum_{j=1}^{N} x_{ijk} \le |S| - 1 \quad 2 \le |S| \le n-2, S \subseteq \{1,2,\ldots,n\}, \ \forall k \in K \qquad (7)$$

$$x_{ijk} \in \{1,0\}, \forall i \in N, \forall k \in K \qquad (8)$$

$$y_{ik} \in \{1,0\}, \forall (i,j) \in N, \forall k \in K \qquad (9)$$

Equation (1) is to minimize the total recovery time, the first part represents total transportation time and the second means total service time. Constraints (2) guarantee the vehicle capacity limit is not exceeded. Constraints (2) ensure the duration limit on every route. Constraints (4)-(7) state that each vehicle must start and end its route at the disposal center and the flow is conversed at each medical unit. Constraints (8)-(9) define the binary variables.

3. Computational Results

3.1 Data and parameters

There are 30 medical units (Z.G. HE, 2015) and a disposal center, whose latitude and longitude are (30.661431, 104.366613). The capacity limit is $Q_K = 2500$ kg, duration limit ΔT=5 and average speed is 60km/h. Table 1 describes these detailed data. Volume 2 and 6 mean the geographical location (latitude and longitude) and volume 3 and 7 represent the number of beds in each unit (NB, bed number), volume 4 and 8 represent the outpatient production per day (OP, kg/day).

Table 1. Detailed data of medical units

No.	Location	NB	OP	No.	Location	NB	OP
1	30.715275,104.042534	125	500	16	30.703763,104.067945	2200	900

13	30.707014,104.067451	50	40	28	30.704058,104.075439	100	50
14	30.760353,104.116334	30	20	29	30.722949,104.059539	30	50
15	30.688707,104.090282	30	20	30	30.710552,104.079559	30	10

Generally, the medical waste production is estimated experientially. In large and medium-sized cities, it is typically calculated on the sum of production in inpatient department and in outpatient department (X.Y. Ye ,2010). Medical waste generated in outpatient department is 0.09kg per person a day and 0.36kg per bed a day in inpatient department. Service time in medical units is calculated on the basis of their production. Because medical waste are recycled with a special barrel (the capacity is about 40kg). Suppose that handling one recovery barrel need one minute, so the service time can be calculated by follow formula: $t_i = \begin{cases} q_i / 40 & q_i \textit{ is divided exactly by } 40 \\ [q_i / 40] + 1 & \text{else} \end{cases}$. $[q_i / 40]$ means integer part only.

For example, medical waste production (PRO, kg/day) at No.16 in Table 2 is calculated by $2200 \times 0.36 \times 0.8 + 900 \times 0.09 = 715$ kg, and service time (ST, min)by $[715 \div 40] + 1 = 18$ min .

Table 2. Detailed data of medical waste production and service time every day

No.	PRO	ST	No.	PRO	ST	No.	PRO	ST
1	81	3	11	12	1	21	147	5
2	269	7	12	10	1	22	63	4
3	163	5	13	18	1	23	65	2
4	91	3	14	10	1	24	56	2
5	176	5	15	10	1	25	47	2
6	178	5	16	715	18	26	166	2
7	118	3	17	112	3	27	33	5
8	117	3	18	347	9	28	13	1
9	45	2	19	936	24	29	10	1
10	60	2	20	112	3	30	20	1

3.2 Algorithm Design

Vehicle routing problem (VRP), which is proposed by (J.Holland,1975), proves to be a NP-hard problem (Lenstra J.K,1993).GA is a highly parallel, random, and self-adaptive heuristic algorithm that is suitable to solve the problem with large scale. However simple GA drops easily into local optimum and converges slowly. In this paper, we design an improved GA and add the reverse evolution after the cross operation, which can let the search jump out of the inferior solution and seek the better. Figure 2 shows the flow chart of improved GA.

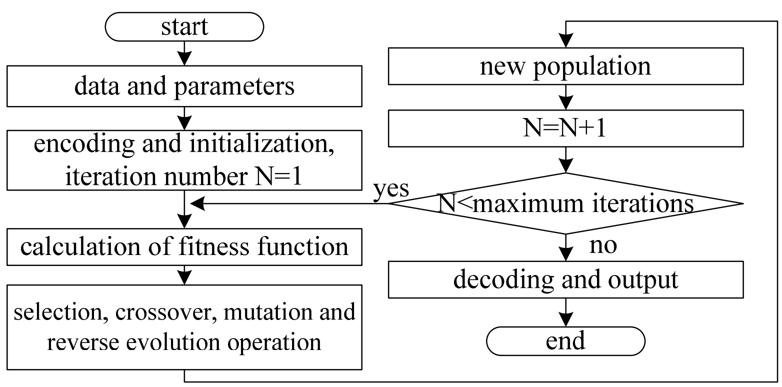

Figure 2. Algorithm iterative diagram

The expression of fitness function is very important in GA. when the capacity limit and duration limit are taken into consideration, the fitness function is formulated as follows:

$$fitness = \frac{1}{Z + F_1 + F_2} \tag{10}$$

Where

$$F_1 = M_1 \sum_K \max(\sum_i q_i y_{ik} - Q_k, 0) \tag{11}$$

$$F_2 = M_2 \sum_K \max\left((\sum_{i=0}^{N} \sum_{j=0}^{N} c_{ij} x_{ijk} + \sum_{i=0}^{N} t_i y_{ik}) - \Delta T, 0 \right) \tag{12}$$

Equation (10) describes the fitness function. Z represents the objective, namely equation (2).Equation (11) and equation (12) are penalty functions which are designed on the basis of the capacity limit and duration limit. M_1 and M_2 can be set as a large positive integer respectively.

3.3 Results

The model is solved by the improved GA. The parameters are set as follows: the max iterations of 350, population size of 80, crossover rate of 0.09 and mutation rate of 0.01.

The total recovery time is minimized to 4.8514 hours and two vehicles are needed to collect all medical waste. The route of vehicle one is 0—7—6—14—5—25—10—1—21—19—29—20—18—28—30—15—0. Its' load is 2265kg and recovery time is 1.5979 h.

The another route is 0—2—4—24—3—9—23—12—17—27—8—22—11—13—16—26—0. The load is 1935kg and recovery time is 3.2532 h.

Figure 3 shows that the total recovery time decreases gradually and stays same at last with the increase of the number of iterations. When iteration number is about 200, the total distance doesn't change anymore.

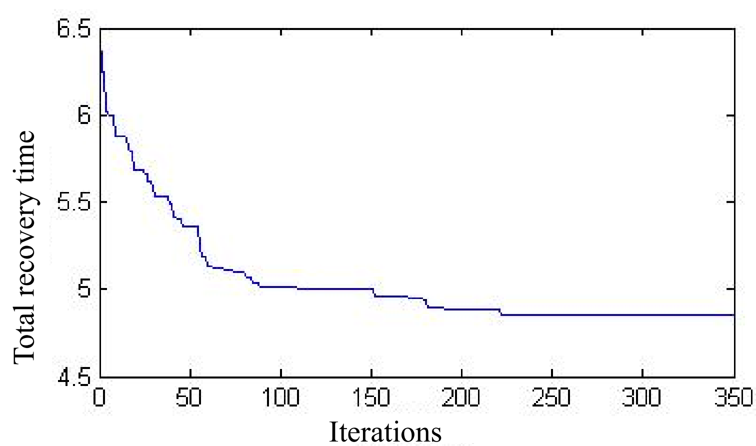

Figure 3. Algorithm iterative diagram

4 Conclusion

We have considered a real-world situation about recovery network of medical waste and formulated a VRPTW model whose goal is to minimize the total recovery time. An improved GA is applied to solve the model and proves to be very effective. The results tell the disposal center how to arrange vehicles for the recovery of medical waste and their travel path. However, the paper discusses the risks qualitatively, which worth doing further study quantitatively.

Abstract: Based on the analysis of the characteristics for fresh agricultural produce supply chain, disruption risks in fresh agricultural produce supply chain are divided into three categories: farmers' production risk, operating risk and demand risk. This paper proposes two main risk managing strategies: horizontal alliance strategy and vertical alliance strategy. Horizontal alliance strategies contain farmers' alliance and operators' alliance, and vertical alliance strategies have four models: farmers' alliance-supermarket, farmers' alliance-wholesale market, base-supermarket and base-operators' alliance. This study is instructional for all members in fresh agricultural produce supply chain in China, and is helpful to improve the ability of defending disruption risks and dealing with disruptions.
Keywords: Fresh agricultural produce; Supply chain; Disruption risk; Strategy.

1 Introduction

With regard to the complex and dynamic environment of supply chains, disruptions in Chinese fresh agricultural produce(FAP) supply chain have been raised as an important concern, such as "Poisonous Banana" in 2007; "Citrus Maggots" in 2008; "Melamine Milk and Eggs" in 2009; "Clenbuterol Issue" in 2010 . These disruptions not only have brought huge losses to the members in supply chain, but also brought casualties and property losses to the community. These issues reflect that there are still lots of problems in Chinese supply chain, and expose the vulnerability of FAP supply chain facing disruptions(Chengli, 2007). The reported dramatic outcomes demonstrate the importance of proactively managing disruption risk in FAP supply chain.

This study intends to contribute to knowledge in this area by addressing two key questions:

—What are the different types of disruption risks or potential risk factors in Chinese FAP supply chain?

—What are the strategies required to manage these disruption risks?

In order to address the above questions, this paper is organized as follows. In Section 2, the relevant literature review on FAP supply chain and supply chain disruption risks are done. In Section 3, the characteristics for Chinese FAP supply chain are analyzed. In Sections 4 and 5, the types of disruption risks and managing strategies are proposed. In Section 6, results and suggestions for future work are discussed.

2 Literature review

There are a large body of literature related to supply chain management, risk analysis and operational strategies. Considering the relevance, we review two streams of recent research: one is focused on FAP supply chain, the other is supply chain disruptions risk.

2.1 Fresh agri-product supply chain

Studying FAP supply chain is becoming a particularly interesting area due to issues related to public health, especially in developing countries. The supply chain of agri-foods, as any other supply chain, is a network of organizations working together in different processes and activities in order to bring products and services to the market, with the purpose of satisfying customers' demands (Christopher, 2005). What differentiate fresh agricultural product supply chain from other supply chains are the characteristics of fresh agricultural product including their short life cycle, their demand and price variability and weather related variability(Ahumada, 2009). In China the supply chain of agricultural products typically involves many players or agents with many farmers at one end and consumers at the other, and is generally too long and fragmented where intermediaries collect a sizable share from the price of the produce paid by consumers. What's more, Chinese agri-product chains consist of the millions of small scale farmers, who are not well structured and organized in the supply chain(Zhang, 2009). These traditional supply chains are tightly linked with social structures (Lokollo, 2004). This makes fresh agricultural product supply chain more complex and harder to manage than that in developed country.

2.2 Supply chain disruption risks

Since the tragedy of 9-11, there has been a rapidly increasing trend in research efforts that study the supply chain risks and disruptions. Supply chain risks have been classified into different categories in papers(Chopra, 2007; Juttner, 2005; Tang, 2006). (Tang,2006) classifies supply chain risks into two, namely operational risks and disruption risks. An operational risk refers to those inherent uncertainties that inevitably exist in supply chains. A disruption risk is referred to as the major disruptions caused by natural and man-made disasters. Most scholars think that disruptions resulted from natural disasters, supplier bankruptcy, labor disputes, war, terrorism and social-economic political instability (Craighead, 2007; Hendricks, 2005; Kleindorfer, 2005). (Oke,2009) argue that supply chain risks fall into two fairly distinct categories—high-likelihood, low-impact risks (or inherent and frequent risks) and low-likelihood, likelihood, high-impact risks (or disruption and infrequent risks). So once the supply chain disruptions, members in supply chain would suffer huge losses.

Strategies to manage supply chain disruption risk were studied by many scholars. (Pochard,2003) discussed an empirical solution based on dual-sourcing to mitigate the likelihood of disruptive events. (Tomlin,2006) suggested two different groups of strategies, mitigation and contingency, prior to a disruption and discussed the values of these two choices for managing a supply chain disruption. (Tang,2006a) proposed robust strategies for mitigating disruption effects. (Marley,2006) discussed lean management, integrative complexity and tight coupling, as well as their relationships with disruption effects. (Chopra,2007) focused on the importance of decoupling recurrent supply risk from disruption risk and of planning appropriate mitigation strategies. (Zegordi,2011) argued that strategies for managing supply chain disruption can be categorized into two main types: preventive and recovery, and preventive solutions can be categorized as follows: robustness strategies; resiliency strategies; security-based strategies; agility strategies.

As can be seen from the above literature, a number of recent papers focus closely on manufacturing supply chain disruptions and discuss the measures that manufacturing companies should use to design better supply chains, or study the different strategies to mitigate the consequences of supply chain disruptions. The studies on disruption risk management of FAP supply chain are much less, especially in developing country.

3 Characteristics of FAP supply chain in China

Compared to general supply chain, FAP supply chain has the following characteristics. On the one hand, there are some special attributes of fresh agri-produce, such as perishability, cyclical growth, regionalism and seasonality. Besides, fresh agri-produce has short life cycle and easily affected by external environment. On the other hand, fresh agri-produce has special nature in supply and demand. The characteristics of Chinese FAP supply chain that are small production and large market, namely "decentralized production, distributed consumption", make the network structure of supply chain more complex and more vulnerable. In summarize, the following are some characteristics about FAP supply chain in China.

3.1 Specificity of the supplier' composition

The suppliers in Chinese FAP supply chain consist of a large number of separate farmers, who have multiple statuses, such as a nature person, a manager, a policymaker. What's more, they have different cultural qualities, financial situations, and behavior models, so that their decisions are rational or irrational. Therefore, it is very difficult to manage these suppliers or farmers. The general theory and methodology of supplier management such as reducing the number of supplier can be not suitable for managing numerous separate farmers. At the same time, compared with other market entities, Chinese farmers have a very weak market force. If there is no "leading enterprise" or other organizations to manage producing and selling of FAP, the farmers' risk would be very large.

3.2 Instability and looseness of supply chain structure

So far, Chinese FAP supply chain has not been integrated. The relationship among members in supply chain is loose and unfriendly. They neither communicate nor trust each other. Most of members only concern about their own interests, and ignore the common interests, which lead to the instability of supply chain structure. Besides, the external environment, such as nature disasters, government policy and market price, will increase the vulnerability of FAP supply chain.

3.3 Members' market force is imbalance

There are 900 million farmers in China. The number of farmers is much more than that of wholesalers or retailers. So agri-produce market is a buyer' market. Buyers have much more market power and more advantage of relative monopoly. Market prices of agri-produce are not the equilibrium price under perfect competition market, but tend to the interests of the buyer. Consequently, compared to other market entity, farmers' market power is much weakest in the whole supply chain. Most of the profits are grabbed by wholesalers or retailers.

3.4 Agricultural products logistics lags behind

FAP has the characteristics of seasonality, regionalism and perishability, which makes it highly dependent on the management of logistics and advanced logistics technology. For example, fresh pork, beef and vegetables need particular containers and equipments when they are delivered. So far, Chinese FAP supply chain has formed an overall system including production, processing, transportation, storage, packing and so on. As a whole, FAP supply chain is lack of management, and the logistics cost is very high.

3.5 Information asymmetry

Because of the diversification of fresh produce's production and consumption, the supply and demand information is scattered. It is hard for farmers to get the right information about market demand. So it often happens that products are either in short supply or unmarketable. In contrast, consumer market is often in the opposite situation.

4 Risk analysis of FAP supply chain disruptions

FAP supply chain is a complex network consisting of farmers, wholesalers, retailers and other brokers. According to the characteristics and process of FAP supply chain, disruption risks of FAP supply chain are divided into three categories, which are farmers' production risk, operating risk and demand risk. See Fig 1.

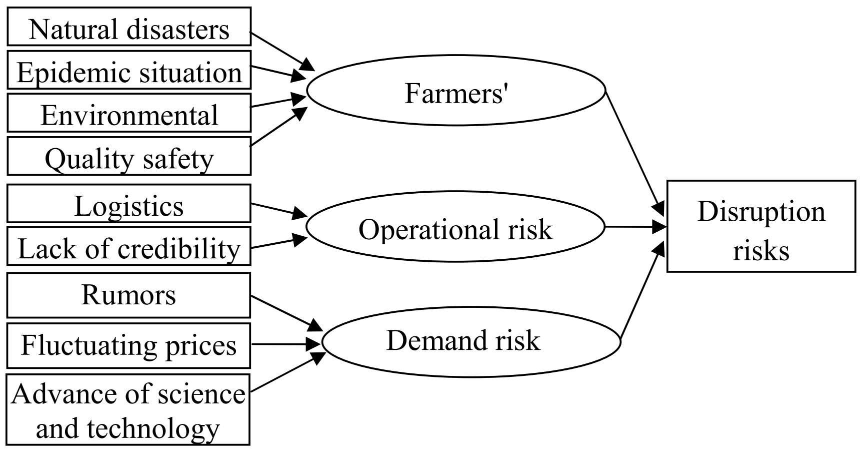

Fig. 1 Disruption risk factors of FAP supply

4.1 Farmers' producing risk

Disruption risk factors of farmers' producing mainly include two aspects. One is from the external environment, such as natural disasters (water logging and drought, earthquake, debris flow, hailstorm, storm and so on), animal or plant epidemic. In 2009, drought, flood, earthquake, typhoon disaster had happened in China. The results were that 47.214 million hectares of crops were affected, 4.918 million hectares of crops were failure, and the direct economic loss was 252.37 billion Yuan(Mei et al., 2010). In recent years, animal or plant epidemic often happens, such as "bird flu", "blue-ear disease", "banana black poison disease". The other risk factor is from farmers themselves, including quality safety (abusing of pesticide, fertilizer, hormone and other production material), environment pollution (land pollution, water pollution), and so on. In order to increase production and incomes, farmers used the forbidden pesticide for their plants, used the forbidden chemicals such as clenbuterol, chloramphenicol for their poultries. The disruptions, for example, "lean meat essence", "melamine milk", "red duck eggs", exposed the vulnerability and the risk in Chinese FAP supply chain.

4.2 Operational risk

Operational risks mainly include logistics risk and operators' lack of credibility. The logistics processes of FAP contain transportation, packing, loading/unloading, storage, distribution and so on. In order to ensure the quality of the products, logistics facilities, logistics technology and logistics management are needed. For example, milk, pork, beef and other fresh products must be stored at a certain temperature. So logistics cost is important part of the total operational cost for operators (wholesalers or retailers). To reduce total costs, operators can use less advanced logistics facilities and technologies. In developed country, the quality of fresh produce is continuously improved from picking to selling. In china, because of lack of logistics management, it is just in opposite. On the other hand, the lack of operators' credibility is also the main reason for the disruption risk. Some operators can use the banned additives and pesticide to ensure the perfect appearance and long guarantee period. For instance, the "turbot" event in 2006 is that wholesalers used illegal drugs "nitro furan".

4.3 Demand risk

Demand risk of FAP supply chain is mainly from sudden changes in customer demand. Major risk factors include price fluctuations, rumors, science and technology progress, and so on. As the consumption of FAP is subjected to the natural conditions and environmental factors, its market fluctuations are more frequent compared with industrial products. The sudden changes of market demand may cause sharp fluctuations in the price of FAP, and eventually lead to breaking off in the entire supply chain. Then, with the rapid development of agricultural science & technology, the new testing technology may detect harmful substances in some produce so that the produce will be unmarketable. Then, rumors are also a kind of key factor for FAP supply chain disruption risk. For instance, poison bananas and citrus born maggots were all actually caused by rumors in 2008.

5 Prevention strategies for disruption risk of FAP

Supply chain management has been widely used in manufacture and retail industry, and has achieved great success. It has not only reduced risk, but also achieved a win-win cooperation for members in supply chain. However, Chinese FAP supply chain lags behind. Because of its particular structure, FAP supply chain operates in a traditional way. When a member confronted a disruption, it had to face it and bear the loss by itself, instead of making good use of the power of the entire supply chain. So this paper proposes the following strategies to cope with the disruptions.

5.1 Horizontal alliance strategy

Horizontal alliance strategy is an alliance strategy which is composed of the same industrial members who are in FAP supply chain for sharing information, technologies, funds and facilities. By this strategy, all node members will achieve scale economy effectively, obtain the complementary sources and ability quickly, and reduce or disperse disruption risks. The horizontal alliances in FAP supply chain are farmers' alliance and operators' alliance.

(1) Farmers' Alliance. Farmers who plant the same kind of agri-produce in the same region could join together to form an alliance. By the alliance, all farmers who plant the same agri-produce could be closely together for sharing the information about marketing and planting, technologies and facilities. The alliance will not only promote scale production of fresh agri-produce, but also help to create competitive edge, increase farmers' bargaining power, and avoid market risks. For example, when facing natural disasters, animal or plant epidemic, farmers could implement the large-scale, standardized, and scientific strategy to deal with risks, and reduce the influence from disruptions.

(2) Operators' alliance. Operators (wholesalers or retailers) in the same region or across region can form wholesalers' alliance or retailers' alliances for sharing the supply-demand information, transportation equipment, preservation facilities and other resources. They may adopt joint purchasing strategy, joint distribution strategy, joint inventory strategy and so on, to reduce logistics cost, improve customer service level and defend the disruption risks jointly. Right now, horizontal alliance emergency strategy for suppliers is widely used in manufacture. For example, in order to reduce the stock level of spare parts and improve service levels, 220 sellers of Caterpiller established a mutual assistance partnership and executed joint inventory strategy. When one of their equipments broke down, they can search the spare parts in retailer's network by DPIS and get them from the nearest spare parts warehouse, so that the equipment would be recovered in the shortest time. But there are few of operators' alliance in Chinese supply chain of FAP, operators have to bear the loss by themselves when a disruption happens. The operators' horizontal alliance will effectively reduce purchasing cost, transportation cost, inventory cost, and other logistics cost by scale effects.

5.2 Vertical alliance strategy

Vertical alliance strategy is formed by farmers or farmers' organization, wholesalers and retailers, for sharing resources and risks. So far, wholesale market still is the core in Chinese FAP supply chain. In this mode, members only concern about their own interests. When a disruption happens for one of members, the other members would resist him instead of giving a hand. Therefore, the effective way to cope with disruptions of fresh agri-produce is to build a vertical alliance, in which all members share resources and risks by contracts or agreements. The following are some modes of vertical alliances.

(1) Mode of "farmers' alliance & supermarkets". Farmers' alliance signs a contract with supermarkets, and farmers' alliance is responsible for quality of the agri-produce. By this kind of mode, the produce will be distributed directly to supermarket. It will not only help to ensure the quality, and reduce the transaction cost, but also effectively prevent disruptions.

(2) Mode of "farmers' alliance & wholesale markets". Farmers' alliances and wholesale markets establish long-term strategic partnership. Wholesale markets are responsible for selling the produce. The advantage of this kind of mode is less intermediate costs. The disadvantage is that supply and demand can not match perfectly.

(3) Mode of "Base & supermarkets". Compared to "farmers' alliance & supermarkets"，the mode of "bases & supermarkets" is pulled by the order of supermarkets. After investigating the market demand for various fresh agri-produces, supermarket can order to the base. Then the base raises agri-produce according to the order, including fertilization, spraying, picking and transportation and so on, in order to ensure the quality. The mode can reduce production risk and quality risk.

(4) Mode of "Base & operators' alliance". If the scale of base is big enough, its supply is more than one supermarket's demand. Then a mode of "base & operators" alliance is appropriate. A base can make agreements with operators' alliance, and supply the agri-produce according to the agreement. The agri-produce will be transported or distributed jointly to every member of operators' alliance.

6 Conclusion

Many recent supply chain events have occurred in China, which is growing in importance with respect to international trade (Olson, 2010). The research on specific supply chain risk factors in China is very important. Based on analyzing the characteristics of FAP supply chain and risk factors of disruptions in China, this paper proposed two risk management strategies, which are horizontal alliances and vertical alliances. In order to increase the ability of resisting the disruption of FAP supply chain, all members in the supply chain should get together, establish a strategic cooperative partnership, share information and resource. It will help to realize scale economics, acquire complementary resource and ability quickly, and reduce or scatter disruption risks effectively. The research can not only enrich the content of FAP supply chain disruption management in the world, but also be very instructional for supply chain members to cope with disruptions in China.

Abstract: With the rapid growth of catering industry, people pay more attention on the food security which have close relation with the management of cold chain. It is vital for the development of cold chain to establish trust mechanism between supply chain numbers, such as farmers, suppliers and catering company. Depending on the analysis of single game, finitely repeated games and infinitely times repeat games between cold chain members, we can draw conclusions as follow. The members of cold chain will choose to keep faith with the aim of ensuring trust mechanism. Suggestion was shown at the end, such as increasing the interests of the trust, default cost and the discount factor, perfecting the information found, making share with information, keeping effective communication and establishing the standard contract.
Keywords: Food cold chain; Trust mechanism; Game theory.

1 Introduction

Food is the first necessity of the people. In our country catering industry keep rapidly develop. The revenue of catering industry is 2556.9 billion, in 2013, which raise 9.0% than last year. O2O, new model of repast, was known by more people. The O2O model, which has been treated as a tendency, has more than 78 million user in 2012. Compared with 2011, the number of user raised 58.1%. We should focus on the issue of food security. There are some issue we should attach great importance in catering industry, such as ensuring pesticides of fruits and vegetables no excessive, meat and poultry no epidemic, aquatic products no pollution.

It is vital for the development of cold chain to establish trust mechanism between supply chain numbers, such as farmers, suppliers and catering company. Food cold chain trust is a kind of belief that partners' promise is reliable and will fulfill their obligations, they have confidence to build good relations of cooperation that have common interests and risk-sharing(Lu Shan,2012). The trust is result of long-term game between cold chain numbers.

2 The trust game between cold chain numbers

2.1 Single game.

Game behavior of cold chain numbers was divided into trustworthiness and breach of contract. In the process of cooperation, considering stakeholders and doing things according to the agreement are trustworthiness. Breach of contract is don't comply with contractual agreements just considering their own interests.

To simplify the model, Hypotheses were listed as follow:

Assumption 1: Game only have two members in food cold chain, there has never been a cooperation among the members of A and B, and it is unknown whether to continue cooperation in the future.

Assumption 2: When A and B both choose to break a contract, or both choose to keep trust, the interests for both side are equal m (break a contract), n (keep trust).

Assumption 3: In case of one party break a contract while the other party keep trust, the interest of non-performance is h and the interest of trustworthiness is g.

Assumption 4: h>n>m>g

Assumption 5: the condition of information is complete.

Because A and B only have a single cooperation, the only Nash Equilibrium is (breach of contract, breach of contract) according to game theory. Due to the value of （n，n）>（m，m）, this balance can't reach Pareto optimality. The two sides get into a "prisoner's dilemma". This shows that, in the course of a single game, members of food cold chain will choose to break a contract in order to get more benefits. Direct result of this is the one-shot deal(Liu Yong Sheng, 2004).

Table 1: Interest matrix of single game

		B	
		trustworthiness	breach of contract
A	trustworthiness	（n，n）	（g，h）
	breach of contract	（h，g）	（m，m）

2.2 Finitely repeated games.

Assuming the number of repeated games is N, a static game is original game. According to game theory, if the original game has a unique pure strategy Nash equilibrium then for any positive integer N, repeated game has a unique subgame perfect Nash equilibrium. That all benefited parties will take the original game of pure Nash equilibrium strategy at each stage. In the process of finitely repeated game, the interests of benefited parties have been raised N times as the original game(Zhang Wei Ying, 1996). Therefore, pure Nash equilibrium strategy of cold chain members still choose (breach of contract, breach of contract).

2.3 Infinitely repeated games.

In this case, members of food cold chain consider gains of long-term cooperation rather than one-time gain of short-term speculation, thus there are more trust.

Hypothesis 1: Taking the time value of money into account, let r as the discount factor and $0<r<1$.

Hypothesis 2: A, B sides have adopted a "trigger strategy", In the process of infinitely repeated game, both sides are trying to use strategy of trustworthiness in the first, if the other party adopt strategy of trustworthiness too, they will always keep to trust. Once found the other party break a contract, they choose to break a contract to retaliate(Wang Xu Hui,2014).

Hypothesis 3: If one party break a contract, the interest of breach of contract is n+x, the interest of trustworthiness is n-y.

If A and B have been chosen to trust, then the total interest for every business is:

$$(1+r+r^2+\cdots)*n\approx 1/(1-r)*n \quad (1)$$

If A and B always choose to break a contract, then the total benefits for each company is:

$$(1+r+r^2+\cdots)*m\approx 1/(1-r)*m \quad (2)$$

Table 2: Interest matrix of infinitely repeated games

		B	
		trustworthiness	breach of contract
A	trustworthiness	（n，n）	（n-y，n+x）
	breach of contract	（n+x，n-y）	（m，m）

According to (1) and (2), we can find that the interest of continuous trustworthiness is greater than break a contract continuously.

$$1/(1-r)*n-1/(1-r)*m=1/(1-r)*(n-m),\ \text{and } n-m>0.$$

If trigger strategy is used, the party who select breach of contract can only have one cheap that is short-term gains x, but long-term loss this time caused is:

$$(r+r^2+\cdots)*n-(r+r^2+\cdots)*m\approx r/(1-r)*(n-m)$$

If short-term gains is less than the long-term loss, no party will choose to break a contract, that is $x<r/(1-r)*(n-m)$ deformed into $r>x/n-m+x$. As long as the discount factor is greater than（x/n-m+x）, no partners will choose to cheat, Pareto optimal for both sides is (trustworthiness, trustworthiness).

In real life, game trust between members of the food cold chain can not be unlimited. Partnership is always present, but before stopping cooperation, there is a long enough duration of the contract and is large enough long-term interests between food cold chain members, they will still choose to trustworthiness. This is because the benefits of trustworthiness outweigh the benefits of opportunism behavior. Once lose the partners' trust, they will hard to make others trust them. Therefore, food cold chain members will choose trustworthy, in order to safeguard the trust mechanism (Ou yang qi, 2014).

3 The countermeasures to improve trust mechanism

3.1 Increase the interests of trust.

If a member of the food cold chain does not want to continue cooperation, he must pay a certain cost, such as losing much of material, manpower, financial resources and credibility; Members of the food cold chain can't consider their own interests, they must act from the perspective of the whole supply chain. For instance, farmers plant vegetables which have excess pesticide, they can't influence the credibility of catering enterprises in order to their own interests; transport enterprises can't reduce cost of cold storage which decrease the quality of vegetables. Only on the basis of this, can we improve the competitiveness of the whole supply chain and obtain greater benefits (Wei Hong Mao,2014).

According to $r>x/(n-m+x)$, we can draw conclusion that the greater the benefits of mutual trust are, the lower the requirements for discount factor will be. When the discount factor is higher, the attitude of enterprises for the current earnings is lower and this could stimulate enterprises to trust each other.

3.2 Improve the information infrastructure.

Each member of the food cold chain should attach importance to establish information infrastructure, it is the important condition to ensure information flow, logistics flow and commerce flow operate smoothly (Zhou Yong, 2004).

The establishment of information network between members of food cold chain that can make the communication become more simply and quickly.

Food cold chain members can use all kinds of information technology to provide each node of the supply chain enterprises with information and collect any type of information which will affect other members of supply chain. As in the following, it will promote the growth of knowledge between enterprises and form learning advantage. Depending on each other, they can adapt to better in the changing environment and improve the consistency and coordination of food cold chain then consolidate trust between members. But each member should grasp the degree of information sharing in order to insure the confidentiality of the core data (Ma Shi Hua, 2005).

3.3 Constant and effective communication.

Communication is a very important way to maintain the trust mechanism between members of the food cold chain.

There are a lot of ways to two-way communications, such as formal or informal talks or trainings on a regular basis and cooperative groups.

Famers, transportations or distribution enterprises can illustrate their problems and tell they need help or what's help they can offer. In this way, it not only increase the trust between supply chain members, but also form the dependence on each other, as a result, the long-term cooperation will be set up(Li Ji Fang, 2014).

3.4 Establish a standardized contract.

First, contract must rely on the government laws and regulations, so it makes penalties clearly and raises the cost of default; Secondly, contract must try its best to be protective to prevent opportunism behaviors; Finally, it is better to do a consultation agreement when accidents happen. For example, distribution center may be delay due to traffic, this requires informal understanding. Valid contract which must be based on the needs of all elements could gives full play to their strengths, so that all members can make a profit and maintain long-term cooperation relationship.

Macroscopic Logistics Cost Accounting from an Environmental Perspective

Chi Zhang and Huadong Li

Institute of Technology, Sichuan Normal University, P.O. Box 122, Chengdu 610101, China. E-mail: czhang2005@126.com

Abstract: Macroscopic logistics costs accounting takes on important significance in enacting scientific and reasonable logistics policies and promoting the quality and efficiency of national economic operation. Current macroscopic logistics costs accounting which does not consider the environmental costs of logistics fails to quantitatively reflect resources and environment losses which have been caused by logistics activities. Based on the idea of sustainable development of logistics and the theory of value of environmental resources, this article, on the basis of China's current accounting mode of macroscopic logistics costs, proposes the composition and accounting method of macroscopic logistics costs from an environmental perspective.

Keywords: Macroscopic logistics costs; Environmental perspective; Accounting.

1 Introduction

The macroscopic logistics costs refer to the analyses of the total expenditures of domestic logistics activities from the perspective of national economic aggregate, and are commonly expressed as the proportion of domestic logistics costs to national benefits. Nonetheless, current macroscopic logistics costs data is insufficient to fully reflect the damage to ecological environment and natural resources which have been caused by logistics activities. Therefore, in the requirements of energy conservation, environmental protection and sustainable development of logistics industry, the improvement of statistics and accounting systems of macroscopic logistics costs appears especially important and urgent.

2 Present Status of Macroscopic Logistics Costs Accounting

2.1 Accounting Modes of Macroscopic Logistics Costs in developed countries

In America, the macroscopic logistics costs consist of carrying inventory costs, transportation costs and logistics administration costs. Among them, the carrying inventory costs contain not only warehouse costs, damage costs, personnel costs, insurance premium and tax expenses, but also the interest on funds held by inventory. And the logistics administration costs, which generally accounts for 4% of total logistics costs, are calculated by multiplying a fixed ratio, which is determined by experts according to American history, and the sum of the carrying inventory costs and the transportation costs.

In Europe, the macroscopic logistics costs are determined primarily based on survey and prediction, including the costs of transportation, storage, packaging and infrastructure investment. And the administration costs, instead of being listed as a separate item, are distributed into storage, packaging, transportation and other items. However, the calculating methods of macroscopic logistics costs in Europe are basically consistent with that in America.

In Japan, the macroscopic logistics costs consist of delivery charges, storage charges and Logistics management fees. The total logistics fees are reckoned mainly on the basis of various data released each year, such as employment statistics, inventory statistics. Besides, with reference to the estimation method of Delaney, some parts of domestic logistics costs in Japan is reckoned from the standpoint of shippers.

2.2 Accounting Mode of Macroscopic Logistics Costs in China

Compared with developed countries, the studies on macroscopic logistics costs accounting started relatively late in China. A relatively well-developed calculation system of macroscopic logistics costs accounting was not available until *Social Logistics Statistical System and Accounting Expressions (Trial)* was promulgated in 2004. In China, total logistics costs refer to all the expenses in all aspects of national economy that have been used for social logistics activities within a certain period of time, including transportation costs, storage costs and management costs (Gao Ziyou , 2005).

In conclusion, due to the lack of environmental costs, current macroscopic logistics costs are insufficient to reflect the real costs of logistics activities. Therefore, it fails to guide modern logistics industry to develop in an environment-friendly, sound and sustainable way.

3 Environmental Value

Five different value theories have appeared successively in the history of economic theories, namely, Marx's labor theory of value, utility theory of value, factors of production theory, Marshall's theory of supply and demand and the existence theory of value [2]. Inevitably, all these theories have certain historical limitations and one-sidedness of the research scope. Today, it has become the consensus of all mankind that resources and environment have value, but the value has been undervalued, even neglected for all the time. Considering our present cognitive level, the following value theory should be more reasonable.

The value of environment derives from not only the usefulness possessed and provided by the natural resources themselves, but also the human labor expenditures for learning about, transforming and protecting the nature. Therefore, the value of environment is in direct proportion to its utility and operation costs, and it is also influenced by supply-demand relations and the scarcity and substitutability of resources and environment (Zhang chi, 2006). Based on the theory of environmental value, using appropriate valuation method, we could quantify the environmental impacts caused by logistics activities, so as to monetize those impacts and reflect them in the logistics costs.

4 Environmental Costs of Logistics Activities

4.1 Environmental Impacts of Logistics Activities

While providing information, services and effectiveness, logistics activities which consist of a series of logistics functional elements also have impacts on the natural environment, such as, pollutant emissions, the consumption of non-renewable resources like oil.

4.2 Approaches to Valuation of Environmental Impacts

There are three approaches to valuating environmental impacts, namely, benefits approach, costs approach and market investigation approach, while each approach contains several specific assessment methods (Yu Liansheng, 2004).

(1) Benefits Approach

Benefits here refer to materials and ecological services provided by environmental resources. Benefits approach generally contains present value method, net price method, user costs method and surrogate market method. Among them, the user costs method which emphasizes the user-compensating principle can be readily combined with the accounting of logistics activities costs both in theory and practice, so it is more applicable to calculate the costs of resource consumption.

According to Weak Benefits Sustain-ability and benefits maintaining principle, the user costs method regards a part of the return of non-renewable natural resources *R* (resource rents), that is, users cost compensation(*R*-*X*), as the depletion value of natural resources. Setting *r* the interest rate (i.e., the discount rate), *R* the annualized return (constant), *X* the annual real income, *n* the remaining years of a certain kind of resources recoverable (limited service years), the user costs is the difference between net income *R* and real income *X*, expressed as the formula,

$$R - X = R \cdot \frac{1}{(1+r)^n} \quad (1)$$

(2) Costs Approach

The maintenance costs method features the simplicity, intelligibility and practicability of its accounting process and the accessibility and accuracy of the data needed. According to statistical materials, we could get the emission load and unit governance costs of pollutants and calculate the environmental degradation costs with the following formula.

$$V_a = \sum V_i = \sum P_i \times Q_i \quad (2)$$

In this formula, V_a represents environmental degradation costs (the total governance cost), V_i represents governance costs of pollutant i, P_i and Q_i represent the unit governance costs and emission load of pollutant i respectively.

4.3 Environmental Costs of Logistics Activities

It is the objective existence which cannot be neglected that logistics activities have impacts on the environment, but these impacts have long been ignored or weakened and never been fully valued by economic means. Therefore, valuating environment impacts of logistics activities is the prerequisite for controlling and effectively managing logistics costs.

The valuation of environment impacts of logistics activities, that is, environmen -tal costs of logistics activities, contains not only the environmental degradation costs which results from logistics activities' consumption of nonrenewable natural resources and discharges of pollutant, but also the expenditures spent on the prevention, treatment and remedy of the environmental degradation costs.

5 Macroscopic Logistics Costs Accounting from an Environmental Perspective

5.1 Definition and Composition of Macroscopic Logistics Costs

Based on current accounting system of logistics Costs in China, in this article, the macroscopic logistics costs is defined as follows.

The macroscopic logistics costs refer to the expenses in all aspects of national economy that have been paid for social logistics activities within a certain period of time, as well as the resources and environmental costs of the whole society that have been caused by logistics activities, including four parts, transportation costs, management costs, storage costs and environmental costs (Feng Gengzhong et al, 2007), as shown in Figure 1.

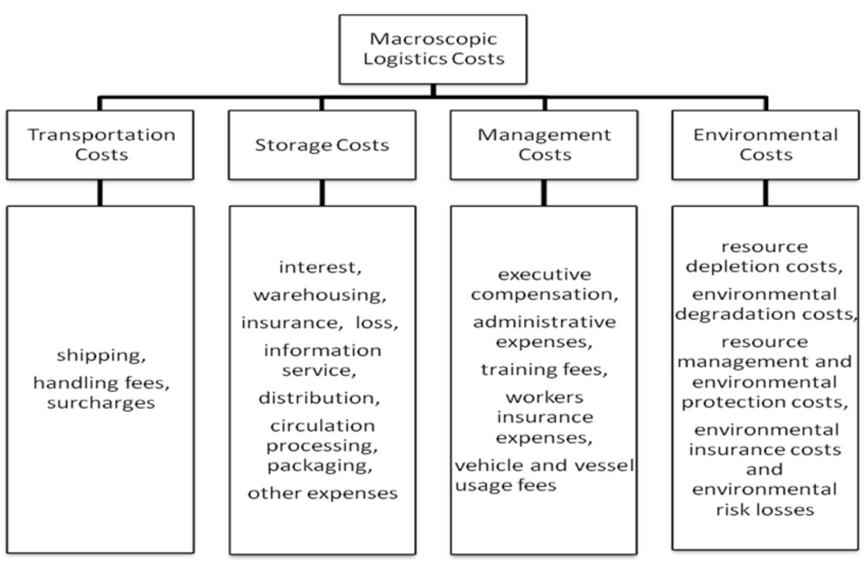

Figure 1. Composition of Macroscopic Logistics Costs

Among them, environmental costs refer to the summation of monetizing damage to the natural environment caused by logistics activities and the expenses on avoiding or reducing damage, including resource depletion costs, environmental degradation costs, resource management and environmental protection costs, environmental insurance costs and environmental risk losses.

5.2 Accounting Methods of Macroscopic Logistics Costs

In order to realize the nationwide uniformity of statistical index, accounting scope and calculating caliber, this article suggests that the accounting of transportation costs, storage costs and management costs remains in line with the current national accounting system, while the accounting of environmental costs is divided into five parts and conducted as follows.

（1）Resource Depletion Costs

The resource depletion costs refer to the permanent reduction of social natural resources which results from the consumption of non-renewable natural resources for goods circulation. And its basic calculation formula is,

Resource Depletion Costs＝∑(the total depletion of each kind of natural resource -s which have been caused by social logistics×the unit uncompensated users cost in each kind of resources)

Wherein, the total depletion of each kind of natural resources caused by social logistics can be drawn from related statistical yearbook, and the unit uncompensated users cost in each kind of resources could be calculated by users costs method.

（2）Environmental Degradation Costs

The environmental degradation costs refer to the damage of ecological environment degradation which has been caused by goods circulation or pollutant discharge in social logistics activities. And its basic calculation formula is,

Environmental Degradation Costs=cargo turnover volume×∑(the unit complete treatment costs of each kind of pollutant×each kind of pollutant which has been discharged by unit turnover volume)

（3）Environmental Insurance Costs

The environmental insurance costs refer to the environmental insurance expenses (dangerous goods) which have been paid to the social insurance department for sharing risks, in order to prevent and reduce the environmental disputes and risk losses caused by environmental accidents. And its basic calculation formula is,

Insurance Costs = social total logistics×the average insurance expense ratio of social logistics

（4）Environmental Risk Losses

Environmental risk losses refer to the risk losses result from environmental acid -ents caused by uncertainties in social logistics activities. And its basic calculation for -mula is,

Environmental Risk Losses = social total Logistics×the average environmental damage costs ratio of social logistics

Wherein, the environmental damage costs ratio of social logistics can be drawn from the investigation data of enterprise logistics and environmental statistical materials, that is, the composite average of the proportion of the environmental damage costs to the total logistics of each department during the delivery of all the goods within the reporting period.

（5）Resource Management and Environmental Protection Costs

Resource management and environmental protection costs refer to the actual expenses of social logistics system which have been paid for maintaining the sustainable utilization of resources, protecting the environment from damage and reducing the damage.

6 Conclusion

This article has carried on the discussion to costs problems of the logistics activities from an environmental perspective, and further improved the concept and statistical modes of macroscopic logistics costs accounting, that is, to quantify environmental damage which results from various logistics functional elements by using the valuation method of resources and environment, and incorporate it into the logistics costs in the form of the environmental costs.

It should be noted that, due to the limitation of valuation method, environmental statistics and other aspects, the logistics environmental costs reflect only the lowest value of the natural resources and environmental assets which have been affected. In addition, the measurement of environmental costs should also pay attention to the problems of boundary definition to avoid omissions and repetitive computation.

Abstract: Site selection for network nodes in closed-loop military supply chain influences many others functional strategies of supply chain network, such as transportation, distribution, inventory, recuperation and recycle. This paper seeks out the proper method of site selection based on the characters analysis of site selection in closed-loop military supply chain network, and proposes an improved TOPSIS method that combined with entropy weight. What's more, through the analysis it could find that the entropy weight calculation manner is simplified to improve the efficiency of site selection in closed-loop military supply chain.
Keywords: Site selection; TOPSIS; Entropy weight; Closed-loop military supply chain.

1 Introduction

As one of the utmost important procedures and steps, site selection plays a fundamental role in the closed-loop supply chain network planning and designing. It's all cleared that site selection influences many others functional strategies in supply chain network construction and operation, such as transportation, distribution, inventory, recuperation and post disposal, which depends on the operation manners, physiology position, and resources available in the supply chain system to great extent. Accordingly, in the planning stage of the closed-loop military supply chain network, the attention firstly focus on the site selection of various nodes in the supply chain network as well.

2 Site Selection Methods

There are various research methods of node site selection in the supply chain logistics system, which can be divided into 3 types: the first type is expert decision making, to investigate and analyze the candidate nodes by using expert professional experiences, and combing with the internal and external operation environment, including Delphi method, expert evaluation method, analytic hierarchy process (AHP); the second type is mathematical analytical method, which is used widely, through abstracting and analyzing the site selection problem, finding the characteristics and the essence of the problem, constructing mathematical model, this method could get the optimal result by solving the model, finally, it adjusts and modifies the optimal solution in accordance with the actual situation, this type involves the center of gravity method, linear programming method, the principal component analysis method, TOPSIS method etc. The third type is the simulation decision analysis method, which abstracts the actual site selection optimization problems, creates the problem background, establishes concept model, and constructs the model of the simulation system, then solves the problem by using logic deduction and some advanced scientific algorithm. This type includes neural network algorithm, genetic algorithm, tab search algorithm, simulated annealing algorithm.

The design and planning of closed-loop military supply chain network are based on the whole military logistics system. Constructing strategic supporting bases and designing essence strategic targets are fundamental for site selection in all levels of network. From the practical perspective, in the pre-selection phase, all levels of existing nodes in the military supply chain have already taken the requirements of military targets and strategic factors into consideration; therefore, most of the work are based on the existing nodes by expanding or modifying the original ones. In other words, site selections in closed-loop supply chain is actually

In other words, the site selection of the closed-loop of military supply chain node is based on the basic roles and functions, location requirements and demand, then, compares all aspects of feasible and discrete alternative sites comprehensively, and makes use of the multi objectives decision making process to choose the best solution as the decision results among the alternative sites.

In view of the above characteristics, this research combined with the actual site selection of the closed-loop military supply chain network nodes, using TOPSIS method to make site-selection decisions, making corresponding improvement to the TOPSIS method, for the sake of multi objective in closed-loop military supply chain network node site selection requirements. Therefore it could ensure that the site selection result is more practical and scientific, suitable to the realistic conditions.

3 Literature Review

Since TOPSIS(technique for order preference by similarity to ideal solution), also known as the approximation ordering method of ideal solution, was initially proposed as a multiple criteria decision making method by Hwang and Yoon(1981), then, it widely applied in many field to solve some decision making problems, such as ranking technologies alternatives(Zavadskas,1986),resource saving decisions making (Zavadskas,1987),construction projects assessment(Zavadskas, E. K., Peldschus, F., Kaklauskas, A.,1994), buildings evaluation(Zavadskas, E. K, Kaklauskas, A.,1996) , optimizing the ways of repairing matched roofs(Ustinovicius,2002), choosing staff in the human resources (Shih,2007),and the finance performance evaluation (Nurgay Ergul,2010, J. Antucheviciene,2012) .

However, in the course of the applying TOPSIS method to solve specific practical and theory problems, some researchers improved this evaluation method through the combination of other algorithm to improve the calculation efficiency. The literatures published recently that relate to make use of TOPSIS and other algorithms could be divided into three categories, which includes fuzzy TOPSIS, AHP and TOPSIS, TOPSIS and entropy as well. Fuzzy TOPSIS mainly used to select partners and contractors (Marzouk,2008), choose suppliers (Boran et al.,2009) and shopping center site selection(Onut et al.,2010) . What's more, fuzzy TOPSIS was used to research the warehouses location decision problem through analyzes the attributes of some specific warehouses as well. While AHP and TOPSIS method, which applied in selecting projects (Amiri,2010), suppliers evaluation (Du,2011),construction planning decision of subway station(Chen t.t.,2012). TOPSIS and entropy represents the entropy weight TOPSIS method, which applied in emergency military logistics' efficiency evaluation (Wang T.hong,2012), selection of supply chain partners (Lu Q.qin,2014). However, the recent papers relate to TOPSIS and entropy method is seldom applied in closed-loop supply chain and logistics, especially in the nodes site selections of supply network.

Despite the AHP-TOPSIS and fuzzy TOPSIS methods are applied in site selection frequently, however, TOPSIS and entropy could be beneficial to the accuracy of evaluation result, improving the reliability and practicability because of its effective calculation procedures and objective criteria. This actually is the application of mathematical inference in practical problem of military closed-loop supply chain node site selection. More importantly, it's also used to evaluate the efficiency, rank alternative solutions, choose suppliers and cooperators, allocate substitutable resources in different regions, and other decision making problems in the field of military warfare and support.

4 Procedures

TOPSIS can be applied to each level of node site selection in military closed-loop supply chain network. The core idea is to construct multi index evaluation criteria in the multi-objective decision process of each level node site selection. Hence it could evaluate each candidate node by using comprehensive evaluation criterion, establishing multi-dimensional evaluation vectors eventually, This vector can be regarded as a specific point $M\ (a_1, a_2, a_3, \cdots a_n)$ in a multi-dimensional space. Each evaluation index in the vector has a best value as well as the worst one, which are also considered as the ideal point and negative ideal point correspondingly. By calculating the distances between candidate point and the ideal point/negative point, ranking alternatives could be found. The point that is far from the negative ideal point meanwhile close to the ideal point could be the optimum site determinant.

In addition, in the TOPSIS site selection method, the entropy weight method can be used to determine the weigh value of each evaluation criterion in military closed loop supply chain node site selection. The criterion could be more important as the weigh value increases. To be specifically, the steps of using entropy weight involved TOPSIS method in the closed loop of military supply chain network node site selection is as follows:

4.1 Establishing the evaluation criteria of node site selection

According to the closed-loop military supply chain network planning and design objectives, the aim of site selection is to realize the closed loop of military supply chain overall strategic target, developing better function of network support efficiency. Therefore, the research begins with studying the whole process of military material supplies when investigating all candidate site point, reviewing various site selection proposals' impact on the overall supply network, as well as on the node functional performance. The candidate nodes assessment could be conducted in the following aspects:

(1)the rationality of geographic location

The rationality of each level node's geographic location refers to the adaptability of all levels of nodes to the overall security pattern in the closed loop of military supply chain network. Specifically, whether the traffic condition, infrastructure, available area could meet each node's support requirements in strategic, operational and tactical level. For the closed-loop military supply chain network node, the geographic location rationality belongs to beneficial evaluating indicator, the greater the value represents the better utilization of network support.

(2)the required cost of node construction

The required cost of node construction refers to the engineering cost and construction spending of establishing or modifying/expanding node construction in accordance with the standard requirements of node function. Node construction cost is a cost orientation index, in a certain range, the smaller the value, the node turns to be closer to the optimal.

(3)the utilization rate of existing facilities

Nodes in each level of closed military supply chain network should utilize the existing security facilities as much as possible, such as warehouses, logistics equipment, goods yard etc. to save the construction funds, as well as to improve efficiency in the use of military resources. Similarly, the utilization rate of existing facilities belongs to beneficial evaluating indicator.

(4)support response level

The ultimate target of setting all levels of supporting node is to meet military force material demand in training and wartime. Therefore, the node's support response level is also a critical evaluation criteria, which mainly refers to the amount of available materials resource, the average distance between the node and military users etc. The plenty of resource amount and the short distance could be beneficial to improve response level effectively. For each node, the higher the support response level, the result could be better, hence it's a beneficial evaluating indicator.

(5)the wartime safety

Wartime safety mainly refers to geographic shelter, safety protection, camouflage protection in all levels of site selections, to hide from the enemy observation, and avoid enemy's fire strike. A better wartime safety job could bring little damage in wartime, which maximizes the support effectiveness. It's a beneficial evaluating indicator.

4.2Construction a standardized matrix of site selection

The five evaluation criteria items of site selection that mentioned above, the assignment range of each index is different in practice. For the convenience of calculation, the present provisions of the value of each index are quantified in the 0 to 1 range, which means the value positioned during 0 to 1 could be seen as legal and efficient. Besides, for the efficiency indexes, bigger value is better, on the contrary, for the cost indexes, the smaller means better.

Thus, it could get an initial evaluation matrix F for each alternative site scheme, namely,

$$F = \begin{vmatrix} F_{11} & F_{12} & \cdots & F_{15} \\ F_{21} & F_{22} & \cdots & F_{25} \\ \vdots & \vdots & \vdots & \vdots \\ F_{n1} & F_{n2} & \cdots & F_{n5} \end{vmatrix}$$

Among them, n represents the number of the alternative site, F_{ij} means the value of evaluation indexes number j $(1 \le j \le 5)$ of alternative site i, $i = 1, 2, 3, \cdots, n$

Then, take advantage of the normalized formula to standardized the initial evaluation matrix,

The normalized formula is

$$x_{ij} = \frac{F_{ij}}{\sqrt{\sum_{i=1}^{n} F_{ij}^2}}, \quad (1 \le i \le n, 1 \le j \le 5)$$

Thus, it could get the standardized evaluation matrix of each alternative site, that is,

$$X = \begin{vmatrix} x_{11} & x_{12} & \cdots & x_{15} \\ x_{21} & x_{22} & \cdots & x_{25} \\ \vdots & \vdots & \vdots & \vdots \\ x_{n1} & x_{n2} & \cdots & x_{n5} \end{vmatrix}$$

4.3Calculating the entropy weight of every index

Entropy method refers to the amount of information that according to the specific values of each evaluation index and attribute provided by objects itself, which is used to determine the weight of each index and attribute. In the site selection of closed-loop military supply chain network, it makes use of standardized evaluation matrix of each alternative site, which contains the data information could be used to calculate the specific weight of each evaluation index.

In general, the values of m evaluation indexes in site selection of each node represent the entropy (information content), which expressed by the standardized matrix: $I = -\frac{1}{\ln(m)} = -(\ln m)^{-1}$

After the normalized processing, each value of evaluation index in the initial evaluation matrix could form an information space, $\Omega = \sum_{j=1}^{m} x_{ij}$

Thus, it could calculate the probability of single evaluation index by the formula of probability,

$$P_j = \frac{x_{ij}}{\sum_{j=1}^{m} x_{ij}}$$

Then, aggregating entropy of each alternative decision in the corresponding evaluation index of every site, the total entropy can be obtained on the evaluation index j $(1 \le j \le 5)$:

$$s_j = -(\ln m)^{-1} \sum_{i=1}^{n} \frac{x_{ij}}{\sum_{j=1}^{5} x_{ij}}$$

Among them, m means the number of evaluation indexes; n represent the number of alternative sites. Finally, it could obtain the entropy of evaluation indexes j $(1 \le j \le 5)$ in site selection:

$$w_j = \frac{1 - s_j}{\sum_{j=1}^{m} (1 - s_j)}$$

In this formula, $1 - s_j$ means the variability of site selection evaluation indexes, through this calculation of the formula, it can get entropy on evaluation index j in closed-loop military supply chain.

4.4calculating matrix with weight of evaluation index

The entropy weights of evaluation index j $(1 \le j \le 5)$ in the closed-loop military supply chain multiples the site selection standardized matrix $X = [x_{ij}]$, then, it can get the matrix with weight of evaluation index $T = [t_{ij}]$, specifically, the matrix with weight is as follows:

$$T = \begin{vmatrix} w_1x_{11} & w_2x_{12} & \cdots & w_5x_{15} \\ w_1x_{21} & w_2x_{22} & \cdots & w_5x_{25} \\ \vdots & \vdots & \vdots & \vdots \\ w_1x_{n1} & w_2x_{n2} & \cdots & w_5x_{n5} \end{vmatrix} = \begin{vmatrix} t_{11} & t_{12} & \cdots & t_{15} \\ t_{21} & t_{22} & \cdots & t_{25} \\ \vdots & \vdots & \vdots & \vdots \\ t_{n1} & t_{n2} & \cdots & t_{n5} \end{vmatrix}$$

4.5establishing positive proper solution and negative proper solution

As for the indexes of efficiency, the positive proper solution means the biggest value. On the contrary, as with the indexes of cost, the positive proper solution means the smallest value. This could illustrates as follows,

$$t_j^+ = \begin{cases} \max(t_{i1}, t_{i2}, \cdots, t_{i5}) & , j \text{ is index of efficiency} \\ m\text{in}(t_{i1}, t_{i2}, \cdots, t_{i5}) & , j \text{ is index of cost} \end{cases}$$

As for negative proper solution, the situation would be contrary. as with the indexes of efficiency, the negative proper solution means the smallest value. When it comes to the indexes of cost, the negative proper solution means the smallest value. This could illustrates as follows,

$$t_j^- = \begin{cases} \min(t_{i1}, t_{i2}, \cdots, t_{i5}) & , j \text{ is index of efficiency} \\ max(t_{i1}, t_{i2}, \cdots, t_{i5}) & , j \text{ is index of cost} \end{cases}$$

Then, it could get the positive proper solution t_j^+ and negative proper solution t_j^-.

4.6calculating the Euclid distance

Calculating the distance between the positive proper solution and negative proper solution, in this paper, it brings in the Euclid distance formula to calculate the gap between the positive proper solution and negative proper solution, which could illustrates as follows,

$$D_i^+ = \sqrt{\sum_{j=1}^{5}(t_{ij} - t_j^+)^2}\ ,\ (1 \le i \le n)\ ,\quad D_i^- = \sqrt{\sum_{j=1}^{5}(t_{ij} - t_j^-)^2}\ ,\ (1 \le i \le n)$$

4.7Ranking all solutions and alternative sites

It takes the Euclid distances that calculated above to investigate the index value of similarity degree, then, ranking the value of index from the biggest one to the smallest one. The formula of similarity degree is $C_i = \frac{D_i^-}{D_i^+ + D_i^-}$

Among the values of the index C_i, if it get more close to 1, then, the corresponding site would be more proper for the node in closed-loop military supply chain network, and would be satisfied the demand of the node. Therefore, in all alternative sites, the largest value of similarity degree C_i in the alternative sites for the closed-loop supply chain network system, the corresponding scheme and site would be the optimal choice and decision.

5 Conclusion

This paper proposes a method with TOPSIS and entropy weight to select site in closed-loop military supply chain network. What is more, it improves the calculation manner of entropy weight to simplify the calculation procedure, besides it keeps the precision of weight at the same time. This would be beneficial to the accuracy of evaluation result, improving the reliability and practicability in closed-loop military supply chain. However, this paper just initially proposes an improved TOPSIS method combined with entropy weight to solve site selection question, but it doesn't provide a specific case or simulation example to verify this method, and the application of this method to solve other decision making problems is still need to consider the specific conditions and different attributes when those problems could be settled efficiently by this method.

Abstract: Port is a major junction in the physical distribution as a base being utilized. It is a contact of maritime and land transport and essential platform in production, trade, distribution and exchange of information as a node of supply chain system crossing each port. Moreover, it has to give competitive advantage to shipping companies and shippers using port which has a significant impact on the national economy of the departure and arrival country. In this paper, using multiple regression analysis, social network analysis (SNA) and data envelopment analysis (DEA), this study examines effect of the network centrality in port and port efficiency on the throughput of Korean and Chinese container port. As a result, network centrality index, relation between degree, betweenness centrality index and throughput were correlated.
Keywords: SNA; DEA; Centrality; Network; Efficiency; Throughput.

1 Introduction

In view of the fact that 80 percent of global trade is carried by sea freight, trade and sea freight have a close relationship. There are node, mode and link in the transport system. The port is a major junction in the physical distribution as a base being utilized. It is a contact of maritime and land transport and an essential platform in production, trade, distribution and exchange of information as a node of supply chain system crossing each port. Moreover, it has to give competitive advantage to shipping companies and shippers using port which has a significant impact on the national economy of the departure and arrival country.

Port throughput is affected by a variety of factors such as national and regional economic growth, trade, import and export, quality of charges and geographic location. However, it is queried that the container throughput is the main or the only criterion of a hub port in specific areas. Therefore, the connectivity degree of a port with other ports for shipping companies in and around the port area becomes the judgment of a hub port.

Because of the increase in the number of ports and the intense competition, it is likely to fail making the port development strategy, according to the port throughput simple, because a port forms a network, which causes the shift of port paradigm. Therefore, future port development strategy needs new ways of identifying not only the competitive factors, but also the understanding of the network.

2 Literature Review

2.1 SNA (Social Network Analysis)

A shipping network such as port system is mainly organized hierarchically by several major shipping ports (center positions). The main regional scales include Caribbean coast (McCalla et al., 2005), Mediterranean (Cisic et al., 2007), and Northeast Asia (Ducruet et al., 2010).

In terms of social network studies, port and air network have been primarily studied in order to understand the phase shift type of port (Ducruet et al., 2010) or air network (Fremont, 2007; Newman, 2011.) until now.

Some of these studies suggest the availability of the network structure through using correlation analysis between port network and port throughput or using correlation analysis among air network analysis index, the number of passengers, the city population and gross regional product (GRP).

Ducreut, C. et al. (2010) constructed a shipping network based on transfer of data between the port and port-based network and suggested location of port to analyze the network index in terms of SNA. They also compared the network centrality degree, the relationship between indicators and port throughput which are connected to the location of the port.

When viewing a previous study, communication and cooperation are the key performance to improving the efficiency of ports. At the same time, measuring port for communication and cooperation between ports and ports of the connection and cooperation can be seen. Network analysis based on cooperation and connection can analyze not only the flow of product, but also the role of ports.

2.2 DEA (Data Envelopment Analysis)

Dan LI et al. (2013) analyzed efficiency of 42 container ports in China in 2010 using DEA. They used terminal length, handling equipment quantity, staff quantity as input variables and container throughput as output variables. In the result of the study, average efficiency of CCR and BCC are 0.689 and 0.577 in 42 ports in China.

Cheng et al. (2009) measured the effect of port improvement and technical development on efficiency of port in 1991 to 2004. They also measured the reason of efficiency changing and the rising and falling of the efficiency using Malmquist productivity index. In the result of the study, scale efficiency is an important factor, but it is not absolutely influent.

Looking at the input variables and output variables in previous studies, they primarily used berth length, total area, number of berths, depth, number of terminal equipment and terminal handling equipment as input variables.

Most of the studies used throughput as output variables. The reason is that, according to Cullinane (2005), throughput is the basis of the evaluating scale of relativity, the scale of investment, or level of activity for intercomparison which is related with freight-related equipment and services directly. Most importantly, it is considered to be an efficient index of container terminals because it is directly related to creating profit of ports.

3. Theoretical consideration

3.1 SNA

A social network is a social structure formed by social relations like an individual organization, friends or trade. This network is expressed by an actor, a node and a tie or a link. SNA is separated by 3 indexes of social relationship and 4 properties of social network.

In this paper, the influence in the field of the sociology of these properties in relation to the concept, as one of the most common indicators, will discuss centrality. In other words, it aims to examine degree centrality, closeness centrality, betweenness centrality and eigenvector centrality in 4 properties of SNA.

(1)Degree centrality

The concept of degree centrality is connected to a node with degree as the center. This is the measurement method on how many other nodes are connected directly to more than one node without going through the connector over two steps.

Degree centrality is defined as follows:

$$C_D(P_k) = \sum_{i=1}^{n} a(P_k P_i) \tag{1}$$

n is the number of the actors,

$$a(P_k P_i) = \begin{cases} 1, \text{connected } P_i \text{ and } P_k \\ 0, \text{connected } P_i \text{ and } P_k \end{cases}$$

Degree centrality is measured on one node, the connectors that have one node in the direction of the incoming and outgoing direction separates into in-degree centrality and out-degree centrality respectively.

In-degree centrality, a number of incoming connections connect directly to the node as follows:

$$C_D(n_i) = \frac{d_I(n_i)}{g-1} \tag{2}$$

At this time, $d_I(n_i)$ is an in-degree centrality of node n_i, g is the number of all nodes in the network, $C_D(n_i)$ is degree centrality.

Out-degree is the number of outgoing connections directly to the node centrality as follows:

$$C_D(n_i) = \frac{d_0(n_i)}{g-1} \tag{3}$$

At this time, $d_0(n_i)$ is an out-degree centrality of node n_i, g is the number of all nodes in the network, $C_D(n_i)$ is degree centrality.

(2)Closeness centrality

Closeness centrality measures a located distance which is from the center of the whole network after calculating a distance from one node to all nodes in measuring centrality of SNA.

In other words, in the case of degree centrality, it is only measured by directly connected nodes, but closeness centrality is linked directly as well as indirectly, all connected in a network, all nodes are calculated by measuring the distance. Because of this, the largest centrality node of the measured closeness centrality is the center with the shortest distance in the whole network. The node in the center is easy to secure and to access all kinds of information; it is influential and has a high social status in networks.

Closeness centrality can be expressed as follows:

$$C_C(P_i) = \frac{n-1}{\left[\sum_{i=1}^{n} d(P_i, P_j)\right]} \tag{4}$$

At this time, $d(P_i, P_j)$ is the number of routes in P_i to P_j.

(3)Betweenness centrality

Betweenness centrality serves as a bridge between the nodes within the network. High betweenness centrality means it is the node to perform intermediary in information exchange or information flow in whole information.

If there is a linked node like A-B-C, because A and C can connect only through B, node B performs regulation role between node A and node C potentially like a bridge.

Betweenness centrality connects port to port by shipping companies. In other words, the higher betweenness centrality port is the higher the transshipment throughput can improve.

This betweenness centrality is defined as follows:

$$C_B(P_k) = \sum_{i=1}^{n}\sum_{j=1}^{n} \frac{g_{ij}(P_k)}{g_{ij}} \tag{5}$$

At this time, g_{ij} is the number of the shortest routes in P_i to P_j, $g_{ij}(P_k)$ is the number of routes in P_i to P_j via P_k.

(4)Eigenvector centrality

Eigenvector centrality measures the importance of nodes in network, namely the centrality of the individual actors and the actors (ego) that are associated with other actors (actors) are considered. It is the concept about evaluating the influence or importance of one node.

In port network, the higher eigenvector centrality port connects with the higher centrality port in the network. To conclude, giving an opportunity to increase the port throughput as partnership and cooperation with highly influential port could be considered.

3.2 DEA

DEA model presented by Charnes, Cooper and Rhodes (1978) is a method for deducting the value of the efficiency considering an objective relationship between multiple output factors and input factors at the same time. It is a non-parametric method fixed existing method of the productivity measure. Also, it is a relative evaluation method in the process of measuring the efficiency values of the subject of appraisal DMUs, not only do not need to require a predetermined weight in each of the output or input factors, but it also provides the information of inefficiency about what occurs in each part.

There are several models depending on the purpose of use in DEA, and common use CCR model and BCC model. These models are DEA techniques evaluating relative efficiency of several DMUs at the same time. There are two models, the biggest difference is that CCR model is used in the case of constant return to scale, and BCC model is used in case of variable return to scale.

4. Results of analysis

4.1 SNA

This study analyzes the centrality of container ports in Korea and China based on Asian sea route of 2014's top 10 container shipping companies. The data for network analysis was based on Containerization International Yearbook 2008-2012.

(1)Results of the degree centrality analysis

High centrality ports in the port network connect a port with a port directly. The results of the top 10 ranked degree centrality are shown in Table 1.

Table 1. Top 10 ranked degree centrality

Rank	2008			2009			2010			2011			2012		
	Port	In	Out	Port	In	Out	Port	In	Out	Port	In	Out	Port	In	Out
1	HK	246	290	HK	362	344	HK	283	276	SZ	310	294	HK	313	294
2	SH	222	184	SH	255	229	SZ	282	267	HK	293	265	SZ	299	257

9	GY	36	35	DL	44	44	GZ	33	32	GY	39	38	GY	41	41
10	DL	32	33	GY	43	43	GY	33	33	GZ	24	24	DL	36	38

* BS: Busan, DL: Dalian, GY: Gwangyang, GZ: Guangzhou, HK: Honk Kong, NB: Ningbo, QD: Qingdao, SZ: Shenzhen, TJ: Tianjin, XM: Xiamen

In terms of the degree centrality Chinese ports ranked high mark consistently (i.e. Hong Kong and Shenzhen), Korean ports (i.e. Busan and Gwangyang) also ranked top 10 continuously. In the case of Tianjin, it appears that in-degree centrality is higher than out-degree centrality. This means that the returning port is more frequent than departure. It seems that most of the shipping companies judged port of Tianjin is suitable in the last port rather than in the calling port of the sea route because of geographical position. Shanghai gradually went down in degree centrality ranking. It is because there is an effect in moving throughput from the port of Shanghai to surroundings ports, but the basic status of the port of Shanghai as a hub port had been continuously increased.

(2) Results of the closeness centrality analysis

The Concept of closeness centrality defined as the logical distance is long or short. In addition, closeness centrality is not only the connection with ports directly, but also the connection between the partners, ports including potential partners directly and indirectly. The ports in the most central location in whole shipping network determined by the choice of shipping companies have an influence because it is easier to access information, power, influence, status, security and gain access to the throughput on the network.

The results of the top 10 ranked closeness centrality are shown in Table 2.

Table 2. Top 10 ranked closeness centrality

(3)Results of the betweenness centrality analysis

Betweenness centrality is defined to be connected with the other networks. This is the rate of all the shortest routes as evaluating function of mediators connecting other nodes.

Table 3. Top 10 ranked betweenness centrality

Rank	2008		2009		2010		2011		2012	
	Port	Degree	Port	Degree	Port	Degree	Port	Degree	Port	Degree
1	HK	0.213	HK	0.142	HK	0.172	HK	0.152	BS	0.141
2	BS	0.100	BS	0.121	SH	0.106	SH	0.133	HK	0.095
3	SZ	0.091	SH	0.102	BS	0.082	SZ	0.086	SZ	0.090
4	SH	0.079	SZ	0.099	SZ	0.060	BS	0.083	SH	0.088
5	QD	0.030	NB	0.051	NB	0.041	NB	0.037	NB	0.029
6	NB	0.025	QD	0.035	QD	0.035	QD	0.032	XM	0.024
7	XM	0.019	DL	0.030	DL	0.025	DL	0.025	QD	0.023
8	GY	0.013	GY	0.013	GZ	0.012	XM	0.011	GZ	0.022
9	SW	0.011	GZ	0.010	XM	0.011	GZ	0.009	DL	0.015
10	TJ	0.010	XM	0.008	TJ	0.008	TJ	0.001	YK	0.008

* BS: Busan, DL: Dalian, GY: Gwangyang, GZ: Guangzhou, HK: Honk Kong, NB: Ningbo, QD: Qingdao, SW: Shanwei, SZ: Shenzhen, TJ: Tianjin, XM: Xiamen, YK: Yinkkou

These ports are located in trunk route in shipping, so it can be seen that they have played a role as a mediator.

Betweenness centrality seems to connect with port to port by shipping companies. In other words, the transshipment traffic volume can be determined by betweenness centrality, so we can judge that a higher betweenness centrality of a port can be a higher transshipment port as well.

(4)Results of the eigenvector centrality analysis

In the port network, a higher eigenvector centrality port, it is much more connected with high centrality ports on the network, therefore cooperation with the ports in high influence can find a chance to increase the port traffic.

Hong Kong, Shenzhen, Busan have achieved high marks in this centrality, the results of the top 10 ranked eigenvector centrality are shown in Table 4.

Table 4. Top 10 ranked eigenvector centrality

* BS: Busan, DL: Dalian, GY: Gwangyang, GZ: Guangzhou, HK: Honk Kong, NB: Ningbo, QD: Qingdao, SZ: Shenzhen, TJ: Tianjin, XM: Xiamen.

In case of the port of Busan eigenvector centrality ranking, it has been increased significantly since 2012 because of the result of the hub port policy of Busan in the Korean government. It is considered that a port operation policy in the future has to increase its centrality itself. In addition, it has to cooperate with ports in high centrality for reinforcing the function of transshipment port more and more.

4.2 DEA

DEA analysis has two forms focusing on maintaining the current output and maximizing the level of input factors called Input-Oriented and focusing on maintaining the current input to maximize the level of output factors called Output-Oriented. Input factors of Output-Oriented is the capital goods, it is the useful DEA model about evaluation of fixed assets like automobile industry, the steel industry and the port industry to input large of capital at once.

This study aims to analyze the efficiency of 10 container ports in Korea and China (Dalian, Guangzhou, Hong Kong, Ningbo, Qingdao, Shanghai, Shenzhen, Tianjin, Busan, and Gwangyang) and its determinants during over a five-year period (from 2008 to 2012) using DEA-CCR.

(1)Results of the port efficiency analysis using DEA-CCR

In an efficiency value more than 1, we can evaluate high efficiency port; a higher efficiency value means higher efficiency port. On the other hand, from this result, a value less than 1 came out; it is relatively inefficient and can be ranked.

The result of the analysis was measured across the Ningbo port efficiently every year. An average of efficiency index in 2008 to 2012 showed 0.761, 0.637, 0.726, 0.864, and 0.902 each year. Busan and Gwangyang ports' overall efficiency appeared to be low, while Chinese ports of Ningbo, Shanghai are relatively efficient.

Table 5. Result of efficiency analysis

Port / Year	2008	2009	2010	2011	2012
Dalian	0.243	0.167	0.241	0.650	0.453
Guangzhou	0.401	0.436	0.391	0.659	0.657
Hong Kong	0.480	0.386	0.347	0.468	0.485
Ningbo	4.037	2.414	4.110	3.118	4.407
Qingdao	0.613	0.494	0.523	1.265	0.637
Shanghai	0.627	0.568	0.528	0.835	0.869
Shenzhen	0.394	0.292	0.312	0.500	0.372
Tianjin	0.466	1.273	0.472	0.738	0.629
Busan	0.206	0.194	0.191	0.270	0.279
Gwangyang	0.139	0.148	0.144	0.142	0.234
Average	0.761	0.637	0.726	0.864	0.902

4.3 Correlation analysis between network centrality and efficiency of ports

This study analyzes multiple regression analysis based on SNA and DEA to find effect of the network centrality in a port and port efficiency on the throughput of the Korean and Chinese container port.

It has chosen its ports based on the top 10 ports in the network centrality in Asian routes, choose 2 Korean ports (Busan, Gwangyang), 8 Chinese ports (Dalian, Guangzhou, Hong Kong, Ningbo, Qingdao, Shanghai, Shenzhen, and Tianjin).

The independent variables used degree, closeness, betweenness, eigenvector index as network centrality in ports, DEA-CCR model as port efficiency index and a dependent variable was used throughput each ports. In addition, for more specific analysis, each country's GDP, total turnover, and total throughput were used as control variables.

(1)Results of the analysis

The effect of the network centrality in a port and the port efficiency on the throughput of the Korean and Chinese container port effects the result of F test in regression equation, F value is significant as 19.038 ($p=0.000$), This factor was responsible for 74.7% of the subject (adjusted R-squared, 0.747).

As a result, there is no correlation between the port efficiency index and the throughput. On the other hand, network centrality index, relationship between degree, betweenness centrality index and throughput were correlation 0.797, 0.740 each other. In other words, the ports of high degree centrality and betweenness centrality have much throughput than others.

That is to say, there is high degree centrality; it can share resources port to port through port network. Furthermore through it, not only knowledge and technology can be shared, but also port operation. In addition, the network serves as information conduits and advances in technology, new insights on the issues can flow between the port information because it spreads knowledge spillover which will be able to benefit from it.

High degree centrality ports in port network have direct relationships with many ports, so it can have influence as the reader in port network. Also, in the case of high betweenness centrality ports connect with port to port. In other words, high betweenness centrality ports expect there is much transshipment traffic because it performs to connect with port to port like a bridge.

Table 6. Result of regression analysis

Dependent variables	Independent variables	Correlation						Adj R^2	F	p-value	β	T	p-value
		Y	X1	X2	X3	X4	X5						
Throughput		1.000						0.747	19.038	0.000			
	Degree	0.797	1.000								0.426	1.967	0.056**
	Closeness	0.602	0.765	1.000							0.108	0.811	0.422
	Betweenness	0.740	0.835	0.751	1.000						0.365	2.349	0.024*
	Eigenvector	0.695	0.909	0.805	0.773	1.000					-0.075	-0.402	0.690
	DEA-CCR	0.033	0.094	0.072	-0.138	0.152	1.000				-0.072	-0.862	0.394

*, ** P<0.05, P<0.10.

5. Conclusion

This study aims (1) to analyze port network analysis for evaluating ports based on calling patterns of shipping companies, examine structural characteristics of port network and search the centrality of ports within the framework of the network; (2) to analyze an efficiency based on drawing high centrality ports through preceding analysis; (3) to analyze multiple regression in 2008 to 2012 port network centrality and efficiency index as independent variables, throughput as dependent variable, factors affecting the throughput expected GDP, total turnover, and total throughput as control variables.

The first analysis used social network analysis (SNA) based on the Asian route of the top 10 container shipping companies in 2014. In the result, most of the centralities were high in Hong Kong, Shanghai and Busan, therefore we can see that the port higher container throughput is has also higher centralities.

The second analysis used data envelopment analysis (DEA) based on 10 ports in having high centralities of SNA continuously. In the result, one of the most efficient ports, port in Ningbo ranked the first position, including the port of Busan, Korean ports appeared inefficient relatively.

Finally, the data analyzed the multiple regression based on the port network centrality and efficiency index. In this analysis, independent variables were used degree, closeness, betweenness, eigenvector index as network centrality in ports, DEA-CCR model as a port efficiency index and a dependent variable was used throughput each ports. In addition, for more specific analysis, the country's GDP, total turnover, and total throughput as control variables were used. As a result, network centrality index, relation between degree, betweenness centrality index and throughput were correlated at 0.797, 0.740 each. In other words, the ports of high degree centrality and betweenness centrality have much throughput than others.

That means there is high degree centrality; it can share resources port to port through the port network. In addition, through it, not only port operation, but knowledge and technology can be shared, as well. Furthermore the network serves as an information conduit and advances in technology, new insights on the issues can flow between the port information because it spreads knowledge spillover which will be able to benefit from it.

High degree centrality ports in the port network have direct relationships with many ports, so it can have influence as the reader in the port network. Also, in the case of high betweenness centrality different ports connect with port to port. In other words, high betweenness centrality ports expect that there is much transshipment traffic because it performs to connect with port to port like a bridge.

This study analyzed only 10 shipping companies, but if extending its scope, accuracy would be able to determine the structure of the network. In addition, it needs not only according to literature quantitative measurement, but also according to qualitative analysis like a question investigation in selecting input factors and output factors as a determining port efficiency.

Spatial Model of City Logistics Nodes and Its Optimizing Algorithm

Yongmei Guo; Xiqiong Chen; Yu Wei; and Guanghui Yan

School of Automobile, Chang'an University, Xi'an, Shaanxi. E-mail: gymei@chd.edu.cn

Abstract: Expounding the problem of urban logistics nodes synthetically, the article proposed a space model for urban logistics nodes aiming at the sales logistics distribution network. The sales logistics distribution was divided into two stages distribution with different characteristics in this model, which reflected the generality and representativeness of the model. On the base of it, the article proposed optimization algorithm according to the two different distributions and discussed the solution.

Keywords: Logistics nodes; Logistics network; Space model; Optimization algorithm.

Introduction

The city, the product of the combination of society, economy, technology, natural condition and so on, is the gathering place of human civilization. In the city, there are some commercial and industrial bases, population size and transport facility, at the same time there are large quantity of transport demand for means of production and living materials. With the rapid development, traffic pressure is on the rise that should not be ignored. The urban freight transport is changing into logistics that is the only way to reduce this pressure. The author took the sales logistics as an example and proposed a space model for spatial logistics nodes and its optimization algorithm.

1. Definition

Logistics node is the origin point or destination of logistics route in logistics network, which is the place of storing, handling, packaging and distribution processing for goods and materials in logistics system. Specifically speaking, it refers to warehouse, port, freight hub or logistics center etc. The space model with logistics nodes largely determines the route, flow direction and process of logistics. There are relative movement on routes and relative pause state in nodes. The process of logistics is composed by move-pause-move-pose. The logistic nodes and routes make a logistics network structure, the space model of nodes and routes forms the logistics system structure.

(1) The role of logistics nodes

Logistics nodes are very important in logistics system. All the logistics activities are ongoing on logistics routes and nodes. The transportation is the main activity in logistics routes, which contains the pickup transportation, trunk transportation, distribution and so on. All other logistics functional elements, such as storage, sortation, handling, distribution processing, logistics information, are completed on logistics nodes.

(2)Classification of logistics nodes

In different kinds of logistics system, the main functions of nodes are different with the changing of aims of systems and positions of nodes. Several types are as follows: Transferring logistics nodes (connecting different modes of transport as the main function), Storing logistics nodes (storing goods as the main function), Dredging logistics nodes (organizing the movement of goods in logistics system as the main function) and Synthesizing logistics nodes (with more than two kinds of functions in system and combining these functions properly).

(3)The difference between the logistics center and distribution center

From the point of space scope and functional level, logistics nodes can be classified into three types: logistics park, logistics center and distribution center. Logistics park is national or regional level, and the logistics center is regional and urban level, and distribution center is village and community level. According to "Logistics terminology standard of the People's Republic of China", logistics center and distribution centers defined as the place or organization of working on logistics activity and distribution business, respectively. Both need perfect information network. Their differences are shown in table 1.

Table 1.The difference between the logistics center and distribution center

Logistic nodes	Service objects	Functions range	radiation range	Feature of flows	Functions
LC	social service	Generalfun ctions	big	small-varietyl arge-group	strong storing and handling capacity
DC	special users	distribution functions	small	multi-varietys mall-group	distribution first, storing second

With the rapid development of urbanization in China, the conflicts between urban traffic and economy development, logistics network layout and urban layout are increasingly serious, which have been the important factors restricting the improving of urban economy. So it is necessary to research and solve the space optimization problem of logistics nodes. This article takes logistics center and distribution center as logistics nodes to discuss.

2. Space model of logistics nodes

The space model of urban logistics nodes can be considered from two aspects: system model of logistics nodes and spatial location of nodes.

2.1Sales logistics system model [1,2]

The process of sales logistics is from producer though logistics center to clients. Producers are origin point sand client sare destinations. First, producer all over the country will send the products that the whole urban needs to logistics center, which is the first echelon transportation. Then logistics center send products to all clients in the urban to complete the distribution, called the second echelon transportation.

The city is a place of consuming, which has a large number of dispersed but relatively intensive clients. Although the needs for every client are small and the difference among the needs is small too, the total quantity of the products for all clients in the city is huge. Thus, the characteristics of first echelon transportation are large-batch, low-frequency, small-variety. The products can be transported by trucks, trains, ships, planes or multi-mode intensively with large batches. The products sending to the logistics center are stored, processed, sorted and delivered by logistics center. The characteristics of second echelon transportation are small-batch, high-frequency and multi-variety. The products can be delivered by small-size vans though urban roads in the second transportation.

For instance, Haier sends large-batch products produced by Qingdao factory or other factories to one logistics center in Beijing, the products are needed by the whole Beijing. Then logistics center will sends the products at ordering time and quantity to supermarkets, malls and end users. Thus the idea of VMI (vendor managed inventory) will be achieved. If the logistics center can successfully complete JIT distribution, the inventory of clients will be eliminated.

2.2 Space model for urban logistics center [3]

According to above-mentioned system model, this article structures space model for sales urban logistics center, showing in figure 1.

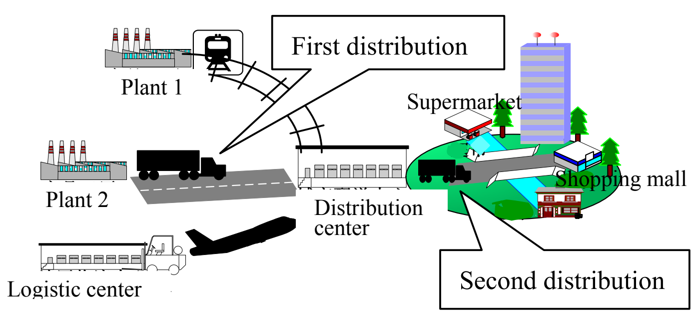

Figure 1. Space model for sales urban logistics center

2.3Extension of mode

Sales logistics belongs to national even worldwide product distribution. Large multinational corporations set branch companies around the world, and the sales networks for their products are worldwide too. For these companies, it is necessary to set up logistics center in the larger sales scope, such as Ning-Hu-Hang metropolitan area, Yangtze River delta economic area, Jing-Jin-Tang economic area even one nation. Distribution centers cooperating with different cities accomplish delivery.

For instance, Dell can send computers to the end users all around the world within 7 days relying on its perfect distribution network, JIT distribution service and supply chain. Analyzing its logistics network in China, logistics network with 3 layers can be described as follows: firstly, transporting products to logistics centers by factories, which has the characteristics of container transportation with large quantity internationally, called products transport in this article. Then regional logistics centers send the products to urban distribution center through the first transportation, and the latter send the products to end users through the second transportation. On these ground, this article builds an extending urban distribution model, showing as figure 2.

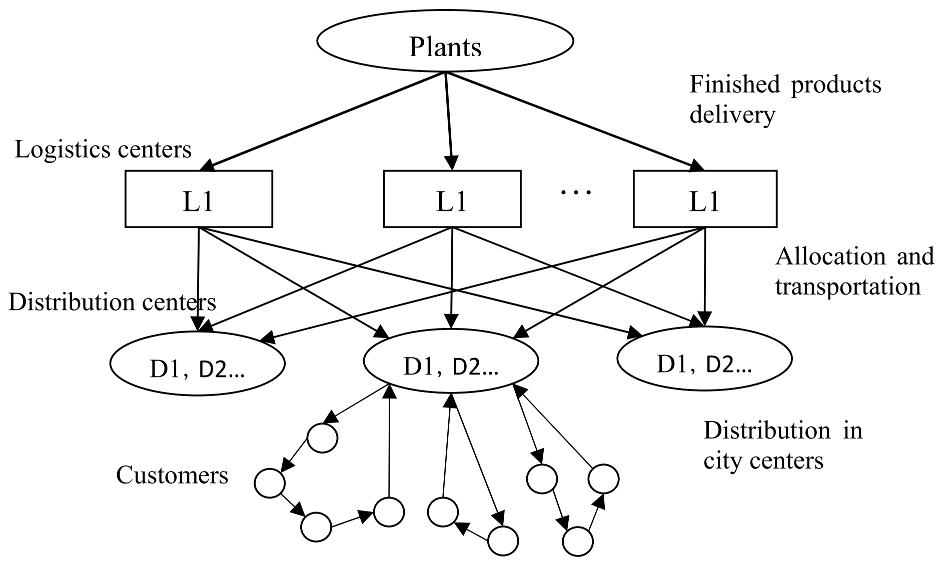

Figure 2. Extension of urban distribution model

2.4Logistics nodes planning

The establishing and processing of logistics nodes have some effect on space environment around the nodes, such as traffic environment, living environment etc. Hence the logistics nodes will be included in the urban traffic planning. Several factors should be considered when confirming the spatial locations of logistics nodes:

- Clients distribution: distribution area of mainly service clients;
- Industrial competition: the surrounding area is whether or not in the occupation scope of the same industry competitors and the distance from the markets;
- Traffic condition: traffic condition as an important factor includes traffic convenience, effective bridging between different carriers and the convenience of customers' arrivals. If ignoring the transportation network situation in the area where the logistics nodes are structured, there would be traffic congestion around the logistics nodes.

- Infrastructure: availability of building lands, feasibility of building, the size and the prize of lands, the distance to clients;
- Environmental factor: if or not there are some effects on the living environment of surrounding residents;
- Development space: the relationship with other nodes, if or not there is enough developing space.

Excepting considering effects of mentioned factors above, the change of land price, recycle problem of fund and invest, water and electricity supply and other base condition, natural condition and policy condition are should considered too. When optimizing the space location of urban logistics nodes, logistics centers and distribution centers with different functions and service clients can be built according to the regional conditions and economic conditions in the area, making use of the advantages of transportation network and hubs, relying on road ,railway modes etc.

3. Logistics distribution network optimization algorithm

3.1 optimization of first echelon transportation

(1) Algorithm description

Supposed that m logistics centers A_i , $i=1,2,\cdots,m$, with maximum inventory $a_i(i=1,2,\cdots,m)$ and n distribution centers $B_j(j=1,2,\cdots,n)$ with the demand $Q_j(j=1,2,\cdots,n)$ .The unit rate (distance) from A_i to B_j is $c_{ij}(i=1,2,\cdots,m; j=1,2,\cdots,n)$ .Then, the transport model that minimizes the total transportation cost z (transportation distance) is as follows:

$$\min z = \sum_{i=1}^{m}\sum_{j=1}^{n} c_{ij}x_{ij}$$

$$\sum_{i=1}^{m} x_{ij} = Q_j \quad j=1,2,\cdots,n$$

$$\sum_{j=1}^{n} x_{ij} = a_i \quad i=1,2,\cdots,m$$

$$x_{ij} \ge 0(i=1,2,\cdots,m;\ j=1,2,\cdots,n)$$

(2) Solving method[4]

The first transportation problem is essentially a linear programming problem in modern mathematics-operational research. The solution can be divided into two main stages: one is the determination of the initial feasible solution (that is, to find initial feasible scheduling scheme); the other is to find the optimal solution from the feasible solution beginning (i.e. find the dispatching scheme that minimizes the total transportation cost based on the initial dispatching plan).

3.2The second distribution optimization[5]

(1)Algorithm description

Logistics distribution route optimization problem can be described as follows: The clients are served with multiple vehicles from distribution center (logistics nodes). The position and the demand of each demand point is certain and the capacity of each vehicle is specific. The goals to reasonably schedule and arrange vehicle routing to minimize the total transportation distance with satisfying the following constraints: The total demand of the customers at each of the distribution path never exceeds vehicle capacity. Each customer demand must be served and be delivered by a vehicle. The algorithm model is as follows:

$$\min VRP(Q_{DC}) = \sum_{k=1}^{m}\sum_{i=0}^{L}\sum_{j=0}^{L} C_{ij} x_{ijk} + \sum_{k=1}^{m} F_k \sum_{j=1}^{L} x_{0jk} \quad (1.0)$$

$$\sum_{i=1}^{L} Q_{Ri} y_{ik} \le q_k, here, \ q_k = q, k \in K \quad (1.1)$$

$$\sum_{k=1}^{m} y_{ik} = 1, i = 1, 2, \cdots, L, \ k \in K \quad (1.2)$$

$$\sum_{i=0}^{L} x_{ijk} = y_{jk}, j = 0, 1, \cdots, L; k \in K \quad (1.3)$$

$$\sum_{j=0}^{L} x_{ijk} = y_{ik}, i = 0, 1, \cdots, L; k \in K \quad (1.4)$$

$$U_{ik} - U_{jk} + LX_{ijk} \le L - 1, \ i, j \in L, k \in K \quad (1.5)$$

$$x_{ijk} = 0 \ or \ 1, \ i, j = 0, 1, \cdots, L; k \in K \quad (1.6)$$

$$y_{ik} = 0 \ or \ 1, \ i = 0, 1, \cdots, L; k \in K \quad (1.7)$$

$$U_{ik} \ge 0, \ i \in 1, \cdots, L, k \in K \quad (1.8)$$

Where:

0 identifies the distribution center and the customers are identified as 1, 2….*i, j* represent distribution center and customers;

k : the tour routing (or delivery vehicles), $k \in K$;

C_{ij} : the distance between *I* and *j*, which can be converted into transportation cost;

x_{ijk} : decision variable, equals to one if arc (*i, j*) is visited by vehicle *k*,0otherwise;

y_{ik} : binary variable, equals to one if customer is served by vehicle k,0 otherwise;

F_k : the fixed use cost of vehicles on the *k* path;

Q_{Ri} : the demand of customers;

q_k : capacity of the vehicles;

U_{ik} : sub-tour elimination constraint vector, represents the sequence that customer *i* is visited in route *k*.

In this formulation, the objective function (1.0) minimizes the total transportation cost (the sum of variable cost and fixed cost). Constraint (1.1) indicates that total amount of loads transported by each vehicle cannot exceed the vehicle capacity. Constraint (1.2) specifies that each node must be visited by only one vehicle. Constraint (1.3) and (1.4) indicates that each customer can be visited only once. Constraint (1.5) relates to the sub-tour elimination. Constraint (1.6) is for binary variables and (1.7) for a limit of y_{ik}. Constraint (1.8) represents that sub-tour elimination constraint vector is a non-negative value.

(2) Summarize for solution

Vehicle scheduling problem in logistics distribution is a NP-hard problem. With the growth of the number of clients, the number of feasible distribution routes solutions is rapidly rising with factorial speed, namely combinational explosion phenomenon. It can be calculated that the TSP (Traveling Salesman Problem) with 20 nodes has about $20!/(2\times 20)\approx 6.08\times 10^{16}$ possible routes, even using computer with 1billion times/s calculation time, it will need 1.93 years to calculate. As a multiple traveling salesman problem with constraints, vehicle scheduling problem in logistics distribution has more complex constraints and distribution routes, comparing with TSP. Hence, the calculated amount is much more than TSP. Generally, precise optimization solution of vehicle scheduling problem in logistics distribution can be obtained in the condition of less quantity of clients and simple transportation network.

The method for solving distribution route optimization problem can be divided into 2 categories: accurate algorithm and heuristic algorithm. The former can calculate the optimal solution, including branch and bound, cutting planes, network flow, dynamic programming method and so on. On account of factorial growth of calculation amount for accurate algorithm with the increasing of the scale of the problem, there are some limits in reality. Therefore, experts focus more on the structure of heuristic algorithm with high quality, such as saving algorithm, scanning method, partition distribution method, scheme evaluation method etc. But every method has its own advantages and disadvantages. Applying synthetic method has been the trend.

For the solution of the second distribution, after designing the accurate solving steps, it can be calculated the optimal vehicle routes of urban distribution only with the help of computers.

4. Conclusion

Logistics distribution network consists of urban logistics nodes and links, the latter represents the movement of goods between nodes. There is multilink between any nodes which represents different transport modes and transport routes. Proper design of space model of logistics nodes can make goods moving smoothly and rationally, reduce the distribution costs and optimize the supply chain.

The space model of sales logistics nodes proposed in this article is suitable for manufacturing industry and trade companies with wide range of market and large quantity of sale. Regional logistics center and urban distribution center can be built by government or several companies together. The distribution optimization of space mode of logistics nodes can be completed by mathematical algorithm, transporting goods through reasonable logistics links and distribution routes could reduce distribution costs and the traffic pressure coming from product distribution.

Reliability Analysis of a Cold Chain Logistics System Based on the Fault Bayesian Network

Qian Guo[1,2]; Yu Huang[2]; and Hongxia Zhao[1]

[1]Department of Traffic and Transportation, Emei Branch of Southwest Jiaotong University, Emei 614202, China.

[2]School of Traffic, Transportation, and Logistics, Southwest Jiaotong University, Chengdu 610031, China.

Abstract: The abstract problem of Cold Chain Logistics System fault is crystallized and its Fault Tree is constructed according to operation features of various functional parts and the causal relationship between events in Cold Chain Logistics System by borrowing ideas from reliability analysis in Reliability Engineering Theory. Bayesian network based on the fault tree has been generated, in order to estimate the operation reliability of Cold Chain Logistics System and reveal the main reasons resulting in the system faults. It could provide a quantitative basis for improving the operation reliability of Cold Chain Logistics System. The expected effect has been achieved via applying the method proposed into the operation and management of a Third-party Cold Chain Logistics enterprise.
Keywords: Cold chain logistics system; Reliability; Fault tree; Bayesian network.

1 Introduction

Cold Chain Logistics System is a complicated system composed of multiple interdependent and interacting functional links accompanied by the complex logistics technology and high logistics cost (Akkerman, R. et al., 2010). There are many uncertain factors in the links of Cold Chain Logistics System, which would affect the normal operation of system, and lead to result that the system cannot perform its required functions for a given period of time.

In Reliability Engineering Theory, System Reliability is defined as the ability of the system to perform specified functions within limited time period. Kong R. and Wang Z. L. (2005) traced back to the formation process of reliability system engineering, and established the framework of theory and technology initially. Zhou Z. B. (2009) proposed a fault diagnosis method of Bayesian network with multi-state fault tree, which has been applied into the Power Supply System. At present, the Fault Bayesian network methods have become the main way to analyze the system reliability (Ding Y. 2008).

Logistics system is an organic whole which has specific function and consists of several logistics elements, such as materials, equipment, conveyance, warehousing facilities, personnel and communication. The reliability of logistics system is a reflection of the ability of the logistics system for working normally to meet the demand of consumer in limited time under certain conditions. Due to the inherently perishable and economic characteristics of fresh products, Cold Chain Logistics System has higher requirement for reliability (Shabani A. 2012). If the system is unreliable, not only will the customers be unsatisfied with the service, but it may also cause great economic loss as the result of return, replacement or payment of compensation.

Fault Tree Analysis is a classic method in Reliability Engineering, which is always used in the analysis of fault happened in designing, estimating and using for complex system(Jin B.H, 2004), such as nuclear power station, civil aviation and manned space flight. Chen X, et al. (2012) established a reliability diagnosis model of logistics service supply chain based on Fault Tree Analysis, calculating the reliability of system to find the key fault of the system. However, the correlation between events had not been revealed, and the bidirection reasoning could not be achieved. Therefore, this paper constructs the fault tree of Cold Chain Logistics System according to the way of top-down and stepwise refinement by using the fault tree for reference. It is more suitable to apply Bayesian Network converted from fault tree for the bidirectional reasoning in order to give the main reasons of failures and the failure probability of the system, which can provide quantitative reference for further improvement in the stability of system.

2 Fault Tree Analysis of Cold Chain Logistics System

Fault Tree Analysis analyzes system failure by going step by step, from top to down, and from simple to complicated. An undesired system fault, namely the top event is taken as the total target of analysis. It is carried out according to the causal logic relationship strictly. All the reasons and the combination resulting the top event are found out to describe how the system fails.

In analyzing Cold Chain Logistics System, the application of fault tree has two parts: The first step is to define the top event which includes the events of unexpected system failure according to the functional requirement of Cold Chain System. The second step is to search for the intermediate events that are the direct reasons leading to the top event, and ranking them under the top event one by one. There are total 3 types of intermediate events. Type 1 is that the food quality does not meet the requirements: the temperature of goods is not maintained in the correct range, or the goods are predisposed to external contamination during the process of logistics. Type 2 is that the quantity and variety do not meet the requirements: the variety of goods do not conform the requirements of order, or the weight is beyond the range of error. Type 3 is that the transportation time does not meet the requirements: the goods are not delivered to the specific place within required time. The intermediate events are connected with top event via logic gate according to the logic relationship among them. The events should be decomposed according to above principles until the events do need to decompose further, namely the bottom events. Thus an inverted tree structure is formed in which the top event, intermediate events and bottom events are connected by logic gate. That is the fault tree of failure of Cold Chain Logistics System.

The occurrence of events that can not satisfy the demands of consumers are taken as the top event, from which there are three direct reason events including “the unqualified quality”, “the wrong number and species” and “the delay in delivery”. Because the occurrence of any one of 3 events can result in the top events directly, these three event should be connected by the logic gate “or”. Then we analyze the lower events gonging on in each function links that can lead to the occurrence of above events, and connect them by proper logic gate according to the logic relationship between them. The downward decomposition step by step won’t stop until the bottom events are determined whose original fault mechanism or probability distribution can be determined by the daily record. A fault tree is established according to the structure of one Cold Chain Logistics System and the operation conditions of each function links, as shown in Figure 1.

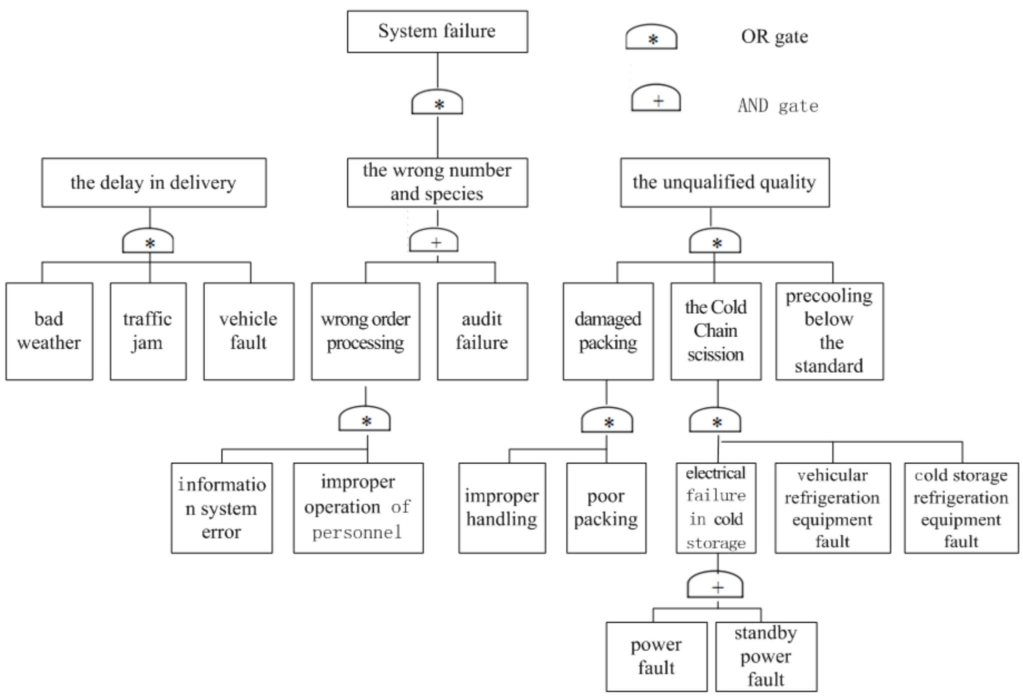

Figure 1. A fault tree of Cold Chain Logistics System

By analyzing the fault events of Cold Chain logistics function links and the logical relationship among the events, we obtain the failure tree of Cold Chain Logistics System that composed of bottom event, result event and logic gate. Although the fault tree is intuitive and succinct in expressing the events resulting in the system failure, the sequential searching algorithm which always use is limited in modeling and analyzing with lower efficiency. If we want to describe the causality among events accurately and reveal the mechanism of system failure, it is necessary for quantitative analysis combined with the Bayesian networks.

3 Reliability analysis of Cold Chain Logistics System based on fault Bayesian network

3.1 Bayesian network

The Bayesian network(Zhang L.W, Guo H.P, 2006) with N nodes is represented as $\boldsymbol{N}=\langle(\boldsymbol{V}, \boldsymbol{R}), \boldsymbol{P}\rangle$. All elements in set $\boldsymbol{V}=\{V_1,\dots,V_N\}$ are random variables which could be the abstract of objects such as the state of components, personnel operation, observed value and so on. The directed edge $(V_i,V_j)\in\boldsymbol{R}$ expresses the correlative relationship between the variable V_i and V_j. V_i is the parent node of V_j, and V_j is the child node of V_j relatively. The nodes without parent node are called root nodes while the nodes without child nodes are called leaf nodes. $\boldsymbol{P}$ is the conditional probability distribution of the nodes in set $\boldsymbol{V}$ and expresses the causal relationship among nodes.

The conditional independence relations among variables and a solid mathematical basis are contained in Bayesian network. If there is $\pi(V_i)$ that belongs to the set $\{V_1,\cdots V_{i-1}\}$ for arbitrary V_i , and V_i is conditional independent with the other variables in set $\{V_1,\cdots V_{i-1}\}$ for given $\pi(V_i)$, then in the joint probability distribution $P(V_1,\dots,V_N)$ that contains N variables are represented as follow

$$\begin{aligned}P(V_1,\cdots V_N) &= P(V_1)P(V_2/V_1)\cdots P(V_n/V_1,V_2,\cdots V_{N-1}) \\ &= \prod_{i=1}^{N} P(V_i/V_1,\cdots,V_{i-1}) \qquad (1)\end{aligned}$$

In which $P(V_i/V_1,\cdots,V_{i-1})$ can be decomposed as

$$P(V_i/V_1,\cdots,V_{i-1}) = \prod_{i=1}^{N} P(V_i/\pi(V_i)) \qquad (2)$$

$P(V_i/V_1,\cdots,V_{i-1})$ will be the marginal distribution $P(V_i)$ When $\pi(V_i)=\varnothing$. Conditional independence simplifies the model. It also decreases the complexity in expressing the model significantly, and improves the reasoning efficiency when the number of variables N is very large. Bayesian network can calculate the occurrence probability of consequences directly by using the joint probability distribution without solving the minimum cut sets of fault tree. It is easy to integrate a variety of evidence, expert experience, and information, which makes the system reliability analysis more intuitive and flexible.

Bayesian network can not only evaluate the system reliability through the network structure and conditional probability distribution of node, but also calculate the probability of other variables via the information of given variables. A given set ***E*** is the subset of ***V*** and the values of variables are known (assumed to be True or False). These given variables are obtained by the method of experience or observation, namely the evidence node. Then probability reasoning is accomplished while the conditional probability P ($\boldsymbol{V_i}$=True/***E***= True) can be calculated according to the Formula (3). That is，when the evidence is given the probability of $\boldsymbol{V_i}$ =True could be obtained. It's a bidirectional reasoning process.

$$P(V_i = \text{True} | E = \text{True}) = \frac{P(V_i = \text{True}, E = \text{True})}{P(E = \text{True})} \quad (3)$$

$P(V_i$=True, ***E***= True) and P(***E***= True) can be acquired through Formula 1 and Formula 2 by using high order joint probability to calculate low order joint probability. Bayesian network achieves the bidirectional reasoning by integrating various uncertain and interdependent factors, thus more abundant decision information are obtained.

Bayesian network can be directly generated based on fault tree under the condition that fault tree has been built. The structures of fault tree are in one-to-one correspondence with the structure of Bayesian network: the events of fault tree are in one-to-one correspondence with event nodes of Bayesian network; the logic gate of fault tree corresponds to a node in Bayesian network which is named by the output event of the logic gate; the connection of events in the fault tree corresponds to the side of Bayesian network, but the connected direction is opposite to the direction of directed edge in Bayesian network; the bottom events that appear repeatedly can be represented as just one random variable in Bayesian network. The fault tree of Cold Chain Logistics System shown in Figure 1 can be transformed into Bayesian network represented as Figure 2 according to above methods.

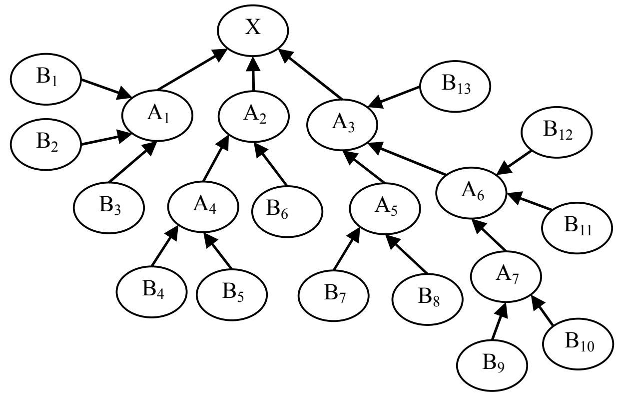

Figure 2 Bayesian network transformed from the fault tree

The universe of each fault event is binary in the fault tree of logistics system, namely there are only two states: occurrence or not, the value of event is 1 when the event occurs. Otherwise the value is 0, which can be represented as :

$$V_i = \begin{cases} 0 \text{ when event } i \text{ does not occur} \\ 1 \text{ when event } i \text{ occurs} \end{cases} \quad i=1,\dots,N \quad (1)$$

The probabilities of bottom events of the fault tree are assigned directly to correspondent nodes in Bayesian network, which is defined by using statistics and expert experience. The conditional probability distribution of logic gate in the fault tree can be determined according to the logical relation. For example, V_1、V_2 and V_3 are the inputs of AND gate, and V_4 is the output, the conditional probability distribution corresponding to Bayesian network is:

$$P(V_4 = 1 / V_1 = 1, V_2 = 1, V_3 = 1) = 1 \quad (2\text{-}1)$$

$$P(V_4 = 1 / \text{else}) = 0 \quad (2\text{-}2)$$

If V_1、V_2 and V_3 are the input of OR gate, and V_4 is the output, then the conditional probability distribution corresponding to Bayesian network is:

$$P(V_4 = 1 / V_1 = 0, V_2 = 0, V_3 = 0) = 0 \quad (3\text{-}1)$$

$$P(V_4 = 1 / \text{else}) = 1 \quad (3\text{-}2)$$

Where “else” represents the means “ in other cases”. Other types of logic gates (such as XOR gate, NAND, voting gate etc.) corresponding to the conditional probability distribution of Bayesian network won’t go into a lot of details(Zhang L W, GUO H P, 2006). The conditional probability distribution corresponds with the nodes of fault Bayesian network shown in Figure 1 are listed in Table 1.

Reasoning by using the fault Bayesian network, the events related with system fault can be found conveniently from top to down analysis, and the probability of system failure can be calculated through the probability distribution and conditional probability distribution of corresponding nodes in fault Bayesian network. Setting T as top event, and E_i ($1 \le i \le M$-1) as intermediate events and bottom events, $e_i \in \{0,1\}$ expresses whether the event E_i occurs or not, and M is the number of nodes in fault Bayesian network, then the occurrence probability of top event T can be represented as :

$$P(T=1) = \sum_{E_1,\cdots,E_{M-1}} P(E_1 = e_1, \cdots, E_{M-1}, T=1) \tag{4}$$

From bottom to top analysis, the influence degree of bottom events on the operation of system can be distinguished. The occurrence probability of other events nodes, namely the posterior probability, can be calculated on the basis of given evidence. It is shown as following:

$$P(E_i = 1 | E_j = 1) = \frac{\sum_{\substack{E_1,\cdots,E_{i-1},E_{i+1},\cdots, \\ E_{j-1},E_{j+1},\cdots,E_M}} P(E_k = e_k, E_i = 1, E_j = 1)}{P(E_j = 1)} \quad (1 \le k \le M, k \ne i, k \ne j) \tag{5}$$

Forward reasoning and backward diagnosis can be achieved on the condition that the information of nodes are known, thus this transformed fault Bayesian network has stronger ability of modeling and analyzing.

Table 2 The probability distribution of nodes in fault Bayesian network

node	Probability distribution	node	Probability distribution
A_1	$P(A_1/B_1,B_2,B_3)$	B_4	$P(B_4)$
A_2	$P(A_2/A_4,B_6)$	B_5	$P(B_5)$
A_3	$P(A_3/A_5,A_6,B_{13})$	B_6	$P(B_6)$
A_4	$P(A_4/B_4,B_5)$	B_7	$P(B_7)$
A_5	$P(A_5/B_7,B_8)$	B_8	$P(B_8)$
A_6	$P(A_6/A_7,B_{11},B_{12})$	B_9	$P(B_9)$
A_7	$P(A_7/B_9,B_{10})$	B_{10}	$P(B_{10})$
B_1	$P(B_1)$	B_{11}	$P(B_{10})$
B_2	$P(B_2)$	B_{12}	$P(B_{12})$
B_3	$P(B_3)$	B_{13}	$P(B_{13})$

4 Application research

Taking the fault tree of Cold Chain Logistics System in Figure 1 as example, we show the application of above method. Two types of data are required to complete reasoning using Bayesian network converted from the fault tree (as shown in Figure 2). The first group is the prior probability of bottom event, that is $P(B_1)$ to $P(B_{13})$, which results from historical records. The occurrence state of bottom events is dimorphic random variable. While the historical data are rich enough, the statistic occurrence frequency can be regarded as the prior probability. Table 3 shows the results. Another group are the conditional probabilities of intermediate events, that is $P(A_1/B_i \ldots B_j)$ to $P(A_7/B_i \ldots B_j)$. The conditional probability distribution table is determined by corresponding logic gate type of fault tree, and there are mature conversion algorithms converting various logic gates to conditional probability distribution of corresponding nodes in Bayesian network. These two types of data are input the Bayesian toolbox of MATLAB to do numerical programming. We obtain the probability of the top event failure P(X=Flase) =0.1970, that is, the probability of Cold Chain Logistics System operating normally is P(X=True) =0.8030. Namely, the reliability of Cold Chain Logistics System is 0.8030.

Table 3 probability distribution data of bottom events

node	name	Prior probability	node	name	Prior probability
B_1	bad weather	0.0236	B_8	poor packing	0.0342
B_2	traffic jam	0.0361	B_9	power fault	0.0050
B_3	vehicle fault	0.0053	B_{10}	standby power fault	0.0625
B_4	information system error	0.0012	B_{11}	vehicular refrigeration equipment fault	0.0297
B_5	improper operation of personnel	0.0225	B_{12}	cold storage refrigeration equipment fault	0.0126
B_6	audit failure	0.0189	B_{13}	precooling below the standard	0.0419
B_7	Improper handling	0.0317			

Then we use Bayesian network to compute the posterior probability. There are seven intermediate events and thirteen mutually independent bottom events in the fault tree, with $A_1 \sim A_7$, $B_1 \sim B_{13}$ respectively. The posterior probability of bottom events can be used to determine the important degree of bottom events acting on top events, namely the influence degree on system reliability when faults appear in the systems. The event with higher prior probability doesn't ensure has higher posterior probability, thus the influence on system is not necessarily large. The bottom events with higher posterior probability have more influence on system reliability, which are the key target for prevention and improvement. The posterior probabilities of bottom events calculated from Bayesian network and the comparison in value of the prior probability are shown in Figure 3.

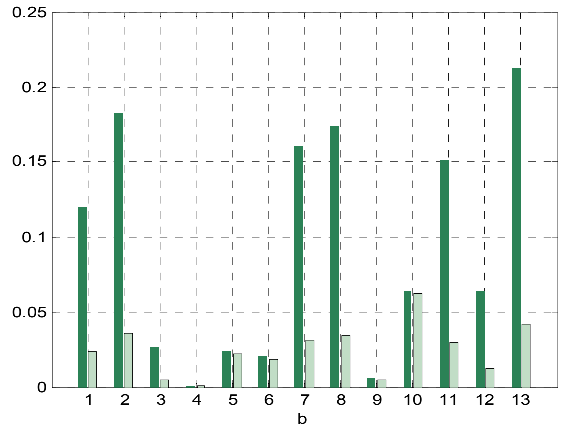

Figure 3. The comparison of prior probability with posterior probability of bottom events

The results showed that the posterior probability of B_{13}, B_2, B_8, B_7, B_{11} and B_1 are higher in all of bottom events, and B_{13} is the event with highest posterior probability. The core temperature of agricultural products after harvest should be decreased quickly until it fits the requirements of warehousing and transportation. This process is called pre-cooling. Delay in pre-cooling operation, uneven or insufficient cooling, is one of the main reasons of failure of Cold Chain Logistics System, which may lead to a loss of several days or weeks on shelf life of perishable products. For the enterprise, it is suggested that the time before the goods entering into cold storage should be shorten as possible, and mobile pre-cooling equipment should be utilized to enhance the pre-cooling effect. For the bottom event B_2, it indicates that the packaging can't fulfill the requirement that goods maintain high-quality before delivered to final consumer. This enterprise should take some measures to solve the problem, such as improving packaging technique, planning the distribution time, as well as routing reasonably and querying the road condition information in time. According to the posterior probability of B_8 and the specific condition of enterprise, it is necessary to improve packaging design to meet the demand of various logistics links on packing. B_7 indicates that methods should be taken during the handling process, and mechanical handling should be used for some packing boxes with huge volume and overweight. The preventive protection plan should be drew up strictly for B_{11} in order to ensure the normal operation of refrigeration equipment of refrigerated vehicles, and ensure the temperature is always maintained at the required settings as well as reduce volatility. After defining the importance degree of basic events affecting on the occurrence of top events, enterprises can take some improvement measures combined with their own resources to prevent the occurrence of top event, namely system failure.

5 Conclusions

Cold Chain transportation takes maintaining the quality and improving the efficiency as the center, and Cold Chain Logistics System requires high reliability as guarantee. The method of system reliability analysis in Reliability Engineering theory is taken for inference in this paper. By using it, the abstract problem of the operation failure of Cold Chain Logistics System can be dealt with embodiment, and system fault tree is built according to causality between operation characteristics of functional links and events in Cold Chain Logistics System. Then the fault tree is transformed into Bayesian network, which describes logical relationship among events more accurately, evaluate the system reliability more integrally, and reveals the main reason for system failure. It can provide basis for taking specific measures to improve the operation reliability of Cold Chain Logistics System. The following work will devote the classified research for fruit and vegetable Cold Chain, industrial food Cold Chain, dairy Cold Chain, etc, considering the features and requirements of their temperature control, timeliness, facility, equipment and cost. This research aims at supplying beneficial reference for reducing the delay of Cold Chain logistics links, avoiding the loss of logistics links, and promoting system efficiency in Cold Chain Logistics System.

Abstract: Nowadays, the level of China's theoretical research on pallet pool system is behind its practical operation. Compared with the developed countries' relatively perfect pallet pool system, pallet pool system in China is still on the initial stage. In the subsystems of pallet pool system, order management subsystem as information disclosure and issuing system for platform has the great significance of research. Here, two aspects of order management subsystem are analyzed. Firstly, business requirements of order management system are put forward. Then, it's functional requirements are cleared by UML.

Keywords: Pallet; Order management; Information system.

1 The actual situation of pallet pool system at home and abroad

At present, there are over 7 billion pallets around the world, with a 15% -20% annual increase, but this cargo carrying tools which can greatly improve pallet loading rate and reduce the damage have not be used fully.

CHEP in Australia is the world's first and the largest pallet pool systems company. It has an over-50-year industry experience and a professional team of more than 7700 people. Every day, CHEP manages the business operations of more than 320 million global pallets and containers on average. It has more than 40 pallet rental service centers in China. CHEP has a perfect pallet rental management system. During the pallet rental period, reports can be sent to the customer timely and it can complete the liquidation costs in time. European Pallet Association from Germany and France established the European Railway Association, namely EPAL, and other European Railway Association and work together to maintain the level of quality and inspection of European standard pallets used within Europe. According to users' needs, its service is available around the world. China's first Pallet system appeared in 1965, but due to the operating system, management system, pallet quality standards and other factors it did not succeed. Chinapack Jingli Pallet Pooling System Corporation was established in February in 2010 to fill the vacancy of Pallet respect. China has more than 1 billion pallets, and in order to achieve consistent operation of the tray, establishing pallet pool systems is necessary.

2 The analysis of needs

The main functions of order management system include ordering management, gathering orders management, distributing management, replying management, continuing renting and tracking orders. The main steps of this system are as follows: customers make an order, the system exams the order, the system gathers the orders and sends them to the service station, the workers of the service station distribute the orders, the customers receive the products. Receiving and leasing renewals is the main activity in the service after the expiration of the tray orders, that tray renters have to renew pallets, sublease or not to continue the lease rights. When pallet is in the situation of lease or renewals, the system generates a new order with no relation to the original order and goes to the next order of the process. This is the entire business process of order management system. The most important part of the order management is the order. The research study of the order focuses on the order status.

3 The Analysis of Order Management System Business Process

The main activities of orders are single, setting the single, sub-orders, sending orders, receipt and order tracking.

The first step of the tenant is the Internet, telephone or mail place an order, after the system entry and audit. If the order is placed online, it will be fulfilled by the system. But, if the order is placed in other way, it will be completed by the platform personnel. During the order review process, the main contents of the audit is whether the operators credit rating, designated service station and the designated shop can satisfy the order's basic demand. If the audit is not passed, the system will send the reason of the failure to the tenant. If approved, the system will generate an online documentation, and wait for tenants' confirmation and submission. At this time, the online documentation is in the modified state. When the tenant submitted, the customer service personnel of platform will confirm order information again with the tenant. If confirmed correctly, tenants will submit the online documentation, and the system will generate online orders, At this time, online orders can not be modified. Tenants can only query the situation of the order, and if the platform wants to modify information, they will need to confirm with the tenant. Now, online order is completed. Then, set a single according to the addresses of the tenants and the service station. Platform order scheduling personnel produce service station operation list send a single to service station. When ordered through the audit by the order manager of the service station, the whole order process is in the end state.

The second step is the receipt management. In order management subsystem, signed receipt proves the start of the service, and the pallet which tenant received is not delivered by only one service station. So what the tenant signed was only service station's distribution operation receipt, not the order receipt. Order receipt is produced and put in to the system by the order management personnel platform, then, it will be audited by the system. Through the audit, it can prove the tenant has received the tray successfully. In the receiving process of the tray, if the tray can not meet the requirements of the tenants, the tenant can reject, the service station will redelivery trays at the fastest speed. The order management personnel of platform will feed this situation back to system to modify the order and confirm with the tenant until the tenant is satisfied. After the tenant has been satisfied, the transaction is successful. At this time, the order in the successful transaction state, platform can not modify the order either. When the order receipt has be entered into the system, the customer service personnel of platform will send the information of tray trading to the rental shop to inform the lessor about their tray.

After the expiration of the lease, there will appear two cases. They are recovery and renewal. The recovery of pallet is a work of service station, when the pallet has been recovered to the service station, the system will automatically shut down the order, and the transaction is completed. The specific recovery process and the plan are formulated by the distribution management. Pallet lease or renewal is a process to close the current order and generate a new order. Both the continued lessee and the subtenant need to replace an order, but it is less than the pallet distribution process than before. In the process of tray renewal, firstly, the tenant places an order on the platform Then, the platform distributes leaflets. Finally, the service station will produce the recovery plan of pallet according to then new operation list after getting information. The process of pallet sublet is a process of another tenant to place an order. The tenant will be reviewed according to the step of ordering by the platform, and then, send a single to the specified service station again according to the tenant's address. To transfer the responsibility, the tray tenant and subtenant should confirm new order together with platform. Then, repeat the processes of tray after the expiry of tenant service.

4 The Analysis of Order Management Systems Function

4.1 Use case diagram

According to order management systems business process and the result of the analysis of demand, use case can be got. Figure 1, order management subsystem is divided into single management use cases, receipt management use cases and pallets recovery and management use cases.

（1） Order management use case

To generate online documentation cases, when the order has been reviewed and proved correct, the system will automatically trigger the generation of online documentation cases, the system generates an online documentation, the corresponding order number and date at the time, the online documentation for the operator to examine and verify the next step and submit.

To generate online orders cases. When the tenant and the customer service personnel of the platform confirm again and submitted generated online orders, the tenant cannot modify this document, only according to the system to the query.

The cases of platform sends a single to the service stations. Each generation of an online order, the system will carry on the set list, and orders are split according to orders on the data information, and by the platform of order scheduling personnel review and to the service station to send a single.

The cases of query. The implementation of the platform staff, tenants and rental business can query the situation of order, but tenants and rental business can only query on the related with their orders, not to other tenants order query.

（2） Receipt management use case

Receipt management use case mainly includes the approval management case, returns management cases and query management cases.

The approval management cases. When the tray is transported to the tenant office, tray tenants should carry out the inspection work, in order to ensure the authentication service station work quality and tray quality and quantity, such as to meet their demands, will accept the tray, tray orders signed receipt.

Return management cases. When the service station pallet fails to meet the demand of transport operators, it triggers the turned goods management cases, and tenants have the right to request the service station for the return of this activity, to ensure its own legitimate rights and interests, and to supervise the service of service station. But returned requirements need to be reasonable, otherwise the platform will be processed.

Query management cases. During the non delivery of goods, the operators can order execution status query, but only related with its order of query.

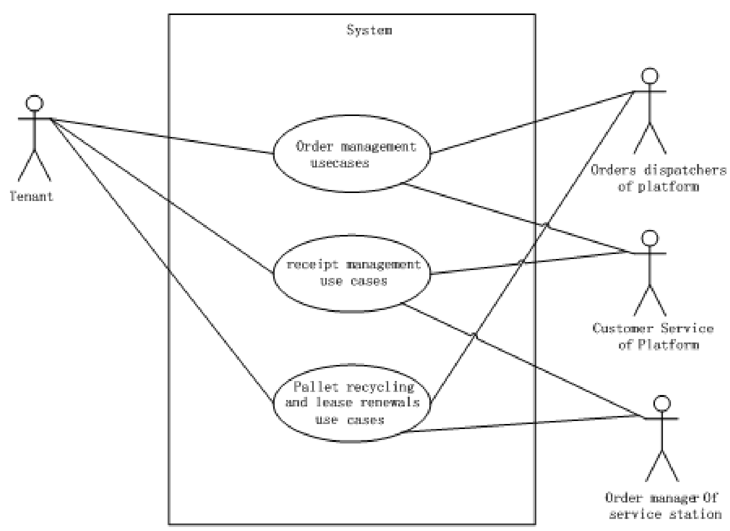

Figure1. Use case

（3） Pallet recycling lease renewals use case.

When the tray in the tenant service expires, it will be recovered and lease tray renewal of case. This process includes pallet recovery case, pallet renewal case and pallet sublet case.

Pallet recovery case. When the tray in the tenant service after the expiration of the period, and the operators are not prepared to renew, also did not happen the situation to sublet, triggered a pallet recovery case. Pallet recycling is in charge of the service station, after the pallet recovery the platform for confirmation, and pallet will go to a new rental activities.

Pallet renewal case. At the end of the period of trays' service in the tenant, if tenants have continued using demand, a tray renewal cases will be triggered. In this case, the operators need to replace an order in the platform, i.e. placing an order before continuing orders again. Generating a contract orders, and combining with the order before going to a new order.

Pallet sublet case. If tenants need transport tray cargo to other locations, the companies which transport enterprises belong to will need to place an order first, and the current tenant will end the current order. Re-orders will activate the order case which was said before. Compared with the prior order case is different. This place, order activity does not need to develop the distribution planning. Distribution activity is completed by transportation enterprises. Do not need to sign the receipt, but still need to pay the rent and deposit. At the same time, to confirm the handover tray activity is confirmed by the original tenant, distribution enterprises and the platform for the information, and to define the demarcation point of responsibility.

4.2 Class diagram

The class diagram to show the static structure of the order management information system, and to analyze the framework of order management subsystem from the view of static structure. According to the use case diagram, we can tease out the relationship between the system as a whole class, attribute, and the operation window class. As shown in Figure 2.

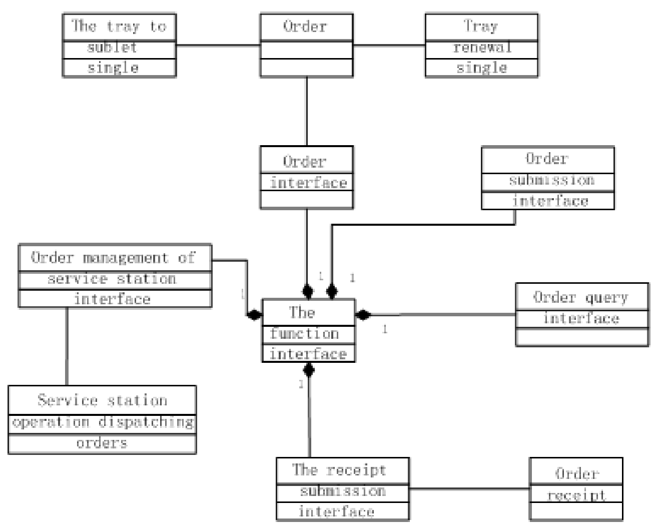

Figure2.The whole system class diagram

4.3 Sequence Diagram

The sequence diagram consists of a group of cooperating objects mutual dynamic collaboration and operation message sending. With two-dimensional sequence diagram showing the order management subsystem within each operating state in lifeline on how to activate and send the message, according to the time order of completing state transformation between object classes to trigger the operation of time. As shown in Figure 3, for the system of the new order of sequence diagrams.

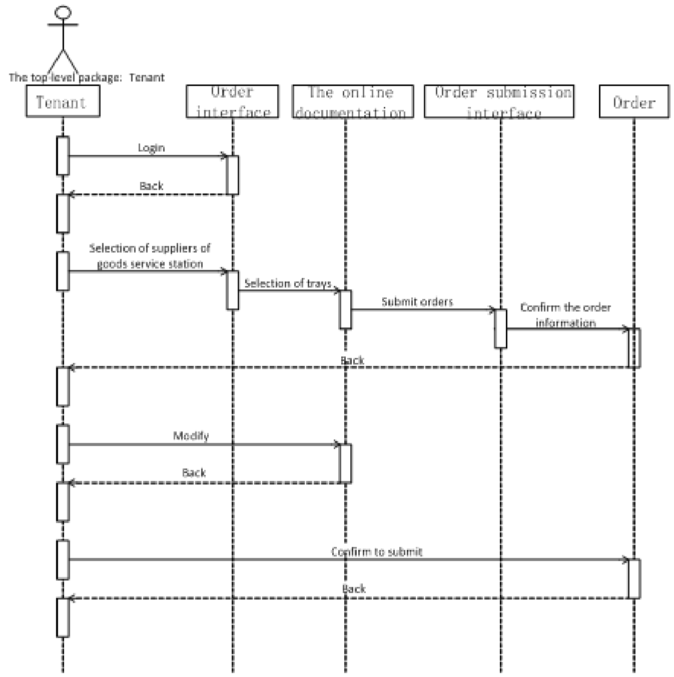

Figure3. New order sequence

5 Conclusion

In our country, pallet pool system in its infancy. The research of China pallet pool system related problems is imminent. The purpose of this paper is to provide a reference for the designers of the pallet pool system, and to provide the basic function and operation mode of order management system to the software developer. It is also convenient to practical development work.

Abstract: As an important part of Mianyang logistics system, Yanting logistics' scientific nodes planning, not only will promote the rapid development of towns and villages' logistics in Yanting, but also will become an important link in connecting urban and rural logistics. In this paper, an optimal logistics nodes assessment framework is presented based on the analytic hierarchy process (AHP) and the fuzzy synthetic evaluation method, on the basis of extensive field study in Yanting. Urban planning logistics system node has a certain theoretical and practical significance. The main contribution of the proposed framework is that it presents a robust method for prioritization of logistics nodes to create a rational planning and to set realistic goals.
Keywords: Logistics nodes; Planning; Analytic hierarchy process.

1 Introduction

Logistics nodes' planning is a common problem faced by logistics decision makers. Reasonable construction of logistics facilities and layout of logistics nodes can improve urban and city's ability to reduce logistics cost. Recently, with the development of urban economy and construction, urban become more and more important for Chinese economy, however, urban logistics construction is relatively lagging. Therefore, the overall consider of logistics nodes planning is important for urban economy development.

The main objectives of this paper are to: (a) indentify key factors for reasonable logistics nodes planning; (b) prioritize alternatives of reasonable logistics nodes planning using fuzzy synthetic evaluation method.

2 Research methodology

This paper will employ analytic hierarchy process (AHP) to help in the selection of not just logistics nodes, but also in the choice and weighing of the selection criteria that go into such a decision making process (Saaty, 1990). AHP method is a relatively perfect evaluation system, which is convenient to calculate and also provides a framework to cope with multiple criteria situations involving intuitive, rational, quantitative and qualitative aspects. The other advantage of this method is that it has capability to check and reduce bias in the decision making process using the geometric mean of the individual judgments (Aminbakhsh et al., 2013). By reducing complicated decisions to a series of simple comparisons and rankings, then synthesizing the results, the AHP not only helps the decision makers to obtain the best decision, but also provides them with a clear rationale for the choices made (Chin et al., 1999).

In china, the initial evaluation of logistics nodes planning is mainly dependent on experience and is mostly influenced by personal ideas, so it always leads the results are unreliable. Thus it is necessary to develop a scientific efficient evaluation method to optimal logistics nodes evaluation.

3 Selection of logistics nodes based on AHP

3.1 Evaluation of selection basis

Qiu (2007) According to the principal and requirements of macro network planning of regional logistics facilities, combined with regional socio-economic development, demand conditions of logistics, the trend of productivity layout., selected ten criteria from the following three aspects: social economy, demand for logistics services, and geographical location. The ten criteria are population, gross domestic product (GDP), and gross industrial and agricultural production, and total social retail goods, volume of regional logistics, required level of logistics service, the importance of economic position, the importance of productivity layout, and the importance of integrated transportation.

3.2 Selection of factors

According to the factors which influence the logistics nodes planning, we choose 5 criteria as the key factors of Yanting's logistics nodes planning, that is, population, per capita income, and output value of enterprises above designated size, arable land, and traffic convenience.

According to the actual situation of the development of the Yanting, we selected 12 alternative sites as a logistics node from the 14 towns, 21 townships, and 1 ethnic township. These alternative sites are listed as following: the center of the Yanting county, Mayang township, Yulong town, Gaodeng town, Jinkong town, Bajiao town, Huangdian town, Fuyi town, Linshan township, Heiping town, Anjia town, Bozi town, and Lianghe town.

3.3 Decision hierarchy and methodology

We build a hierarchy structure model consisting of the goal, criteria on the next levels, and ultimately the 12 finalists on the bottom rung (Figure 1). The goal of our problem is to selecting reasonable logistics nodes. This goal is placed on the top level of the hierarchy. Five criteria are identified to achieve this goal, which located at the next level of the hierarchy. The lowest level of the hierarchy is formed by 12 alternative sites.

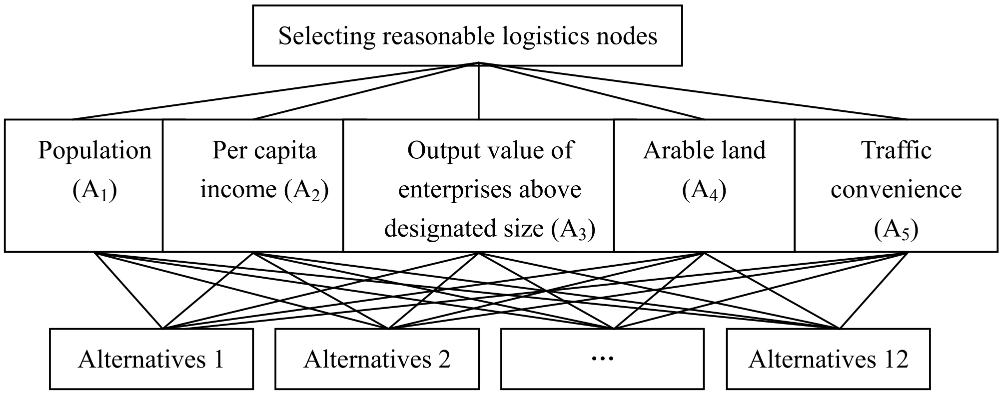

Figure 1. Decision hierarchy

3.4 Construction of pair-wise comparison matrix

After formulating the AHP hierarchy, the next work contains forming a team of experts and developing pair-wise comparison to the criteria using AHP hierarchy. The experts should mark a score (see Table 1) to each pair of *n* elements (A_i, A_j) (Saaty, 1994). A questionnaire is employed in this step. A pair-wise comparison matrix is constructed by an element in the higher level as a criterion element and some elements located at the lower level compared to each other that governed by the criterion. Table 2 shows the pair-wise comparison matrix for the second level criteria.

Table 1. Relatively important of the scale

Importance degree	Definition	Explanations
1	Equal importance	Two activities contribute equally to the goal
3	Weak importance of one over another	Experience and judgment slightly favor one activity over another
5	Strong important	Experience and judgment Strongly favor one activity over another
7	Demonstrated importance	An activity is favored very strongly over another
9	Absolutely important	An activity is favored absolutely important over another
2,4,6,8	Intermediate values between the two adjacent judgment	
Reciprocals ($1/x$)	A value marked when activity A_i is compared with activity A_j then A_j has the reciprocal value when compared with A_i	

Table 2. Pair-wise comparison judgment matrix

	A_1	A_2	A_3	A_4	A_5
A_1	1	5	1	3	1/2
A_2	1/5	1	1/5	1/2	1/5
A_3	1	5	1	3	1/2
A_4	1/3	2	1/3	1	1/4
A_5	2	7	2	4	1

3.5 Calculate weight vector

In reality, the importance of each element which influenced the goal is different. So we should calculate the weight through AHP once more. AHP weights can be calibrated starting from a lot of survey data that collected from Yanting. Finally, we figure out the weight of each element (table 3) and its corresponding eigenvector λ, $\lambda_{\max} = 5.12$.

Table 3. The weight of element

	A_1	A_2	A_3	A_4	A_5
weight	0.2312	0.0527	0.2312	0.0872	0.3977

3.6 Uniform examination

Comparison matrix in pairs is usually not line array, so it is necessary to calculate the consistency level of the estimated vector in AHP. Saaty (1994) use the value of $\lambda - n$ to weigh the inconsistency of comparison matrix in pairs, that is, consistency index (*CI*), $CI = (\lambda_{\max} - n)/n-1$.

In order to find relatively reasonable range of inconsistency of comparison matrix, Saaty (1994) introduced a random consistent index (*RI*), this is the stand to weigh *CI*. And the value of *RI* should look up data. For example, if n=5, then RI=1.12.

When $n \geq 3$ of the comparison matrix, consistency ratio (*CR*) is used to measure the consistency, $CR = CI/RI$, if $CR \leq 0.1$, the weight results are valid.

In this paper, $CI = (5.12-5)/(5-1) = 0.03$, $CR = 0.03/1.12 = 0.027 < 0.1$, so the value of weight is valid.

3.7 Build evaluation matrix

Fuzzy evaluation method for the evaluation object with complex characteristics, evaluators often difficult or impossible to directly give the quantitative results of evaluation object, and the fuzzy synthetic evaluation method can express the essence of information in a natural language way and processing the information in numerical approach, thus providing a unified expression and processing mode for the qualitative and quantitative information.

Specific evaluation steps are as follows:

(1) Determine the comment set

Comment set is a collection of various kinds of evaluation results of the evaluation object. The purpose of the fuzzy comprehensive evaluation is based on consideration of all factors affecting up to evaluate whether the alternative site suitable for the construction of logistics nodes. Therefore, evaluation set V can be established for $\{V_1, V_2, \cdots, V_5\}$ = {very suit, more suitable, suitable, not suitable and absolutely unsuitable}.

(2) Determine the index evaluation set

Index evaluation set is composed of multilayer collection based on the various factors which affect choose the logistics park. It can be divided into 5 sub system, notes for $A = \{A_1, A_2, A_3, A_4, A_5\}$, and it must meet the requirement of $\sum_{i=1}^{5} A_i = A$, the A_i refers to the criteria index that affect the evaluation object, and the n refers to the index number that contained in the i.

(3) Determine weight set

The weight set is a collection that used to describe the index for evaluation objects relative important degree. In the fuzzy hierarchy analysis and evaluation methods, mainly adopts the AHP that has the characteristics of a certain scientific, practical, and simple to determine the weights.

(4) Determining membership matrix

When evaluate the alternative sites of the Yanting's logistics nodes, we should determine the value of the index, that is, calculate the evaluation of membership function, and then build the membership matrix.

3.8 Synthetic evaluation of alternative sites

Firstly, we invited 10 experts to assign relative scores to each town or township. Secondly, reuse the established evaluation index system and fuzzy analytic hierarchy process to evaluate 12 alternative sites. Table 4 to 16 shows the each index's membership degree of each alternative site.

Secondly, reuse the AHP to calculate the each index's weight, W= [0.2312 0.0527 0.2312 0.0872 0.3977]. And then through each index' weight multiply each alternative sites, we can calculate 12 alternative sites' synthetic membership degree (see Table 17).

4 Conclusion

This paper has tried to identify different factors responsible for optimal logistics nodes planning and tried to prioritize them through AHP and the fuzzy synthetic evaluation method. Prioritization is helpful in deciding relative importance of factors while arriving at a rational planning. We use this method to the selection of logistics nodes location, solve the problem of logistics nodes location successfully and give the location where establishment of logistics nodes is suitable.

County logistics planning must have the following characteristics: have transportation materials, people can benefited from the planning, have its' characteristics. Therefore, in the construction of logistics should not only consider the traffic location, but also consider the node and its neighborhood's resources, the existing leading industries, the planning of characteristic industry, the agriculture industrialization base, and explain the main direction and the radiation scope of logistics nodes.

In this paper, we find that the center county of Yanting is very suitable to construct the logistics node, and the Fuyi, Jinkong are more suitable to construct the logistics nodes.

Abstract: In this research paper, a coordination problem has been investigated by considering a single supplier and a single retailer who have different risk attitude in two-stage supply chain. First, we quantify the risk attitude for members of the supply chain with Prospect Theory and establish a supply chain optimal inventory control model with revenue sharing contract. Then we obtain the results of parameters range (revenue-sharing contract) in different risk attitude combinations and use Matlab for numerical example to verify the conclusions. The analysis suggests that revenue sharing contract can coordinate the supply chain and control the supply chain inventory within a reasonable range considering risk attitude.
Keywords: Prospect theory; Risk attitude; Inventory control; Revenue sharing contract.

1 Introduction

Since an inventory cost proportion of total supply chain rises and the impact of participant's behavior on the supply chain is tremendous, we analyze the inventory control problem by considering risk attitude of the members in the supply chain. First, we establish an ordering model for retailer considering risk attitude; then discuss the relationship between supplier risk attitude and production under overall decision-making; and finally analyze the coordination ability of revenue sharing contract using supply chain coordination knowledge and get the result of exact range of parameters (revenue sharing contract) in different risk attitude combinations.

In recent years, many scholars did research on supply chain decision-making considering different risk attitude. (Lau, 1999) mainly used mean-variance method to study supply chain risk which introduces a risk aversion factor, and then analyzed the supply chain return policy when risk aversion factor is different. (Schweitzer, 2000) found that there existed significant decisions bias in newsboy model due to the different risk preferences, and the amount of the order would significantly reduce when there's a decision-making bias.

Prospect theory was proposed by Kahneman and Tversky on the basis of expected utility theory, of which human risk aversion behavior was further quantified.

Utility function $U(W)$ was used in this research. λ denotes risk aversion of decision-maker, and the larger λ, the higher degree of risk aversion. Usually, there always exist $\lambda \geq 1$. Then the specific utility function formula is:

$$U(W) = \begin{cases} W - W_0 & W \geq W_0 \\ \lambda(W - W_0) & W < W_0 \end{cases}$$

2 Model

2.1 Problem Description

We study the supply chain system composed of a single supplier and a single retailer. Assuming c is production cost per unit, the market price of per unit product is p, salvage value of per unit unsold product is v, and there always exists $0 < v < c < p$, and the wholesale price of retailer is $w(w > v)$, the retailer's ordering quantity is Q. Random demand that retailer faced is D, the probability of density function and cumulative distribution function are $f(x)$, $F(x)$ respectively. $F^{-1}(x)$ is the inverse function of *F (x)*. Also we assume that the supplier maximizes profit of the whole supply chain as the coordinator, and we use revenue sharing contract coordinate the retailer and supplier. In other words, supplier is committed to provide the retailer a lower wholesale prices w, while retailer is committed to return a certain percentage (1-φ) of sales revenue to the supplier for making up for the supplier's profit loss due to the lower wholesale prices to retailer.

2.2 The retailer's order strategy

In the revenue-sharing contract (w, φ), the retailer's profit function $\prod_r(Q_r)$ and the expected profit functions $E(\Pi_r)$ are as follows.

$$\prod_r(Q_r) = \begin{cases} \Pi_{r1} = \varphi[pQ_r - (p-m)(Q_r - x)] - wQ_r, & x < Q_r \\ \Pi_{r2} = \varphi p Q_r - wQ_r, & x \geq Q_r \end{cases} \tag{1}$$

$$\begin{aligned} E(\Pi_r) &= \int_0^{Q_r} [\varphi[pQ_r - (p-m)(Q_r - x)] - wQ_r) f(x)dx + \int_{Q_r}^{+\infty} (\varphi p Q_r - wQ_r) f(x)dx \\ &= (\varphi p - w)Q_r - \varphi(p-m)Q_r \int_0^{Q_r} F(x)dx \end{aligned} \tag{2}$$

From (1) and (2), we can find that the retailer's expected profit function is strictly concave with respect to Q_r, and there is an unique order quantity so that the retailer can have the maximum. Then we will analyze from the following two cases.

① When the retailer is risk-neutral

Decision problems retailers faced will turn into:

$$\max_{Q_r} E(\Pi_r) = \max_{Q_r}\left\{(\varphi p - w)Q_r - \varphi(p-m)\int_0^{Q_r} F(x)dx\right\} \tag{3}$$

According to Leibniz theorem, we can conclude from (3): when the retailer is risk-neutral, the optimal order quantity is $Q^*_{r1} = F^{-1}(\frac{\varphi p - w}{\varphi p - \varphi m})$ while the maximum expected profit is $E(\Pi_r(Q^*_{r1}))$.

② When the retailer is risk-averse

According to Prospect Theory, we introduce risk aversion coefficient, then retailer's expect unity will be:

$$\begin{aligned} E[U(\Pi_r)] &= E[U(\Pi_{r1})] + E[U(\Pi_{r2})] \\ &= \lambda_r \int_0^{q_1(Q_r)} \Pi_{r1} f(x)dx + \int_{q_1(Q_r)}^{Q_r} \Pi_{r1} f(x)dx + \int_{Q_r}^{+\infty} \Pi_{r2} f(x)dx \\ &= (\lambda_r - 1)\times\int_o^{q_1(Q_r)} \{\varphi[px + m(Q_r - x)] - wQ_r\} f(x)dx + E(\Pi_r) \end{aligned}$$

So, we can get the optimal order quantity Q_r^* under risk-averse , and Q_r^* will satisfy the following condition:

$$-(\lambda_r - 1)(w - \varphi m)F(q_1(Q_r^*)) + \varphi[p - (p-m)F(Q_r^*)] - w = 0$$

While the maximum expected utility is:

$$E^*[U(\Pi_r)] = (\lambda_r - 1)\times\int_0^{q_1(Q^*)} \left\{\phi[px + m(Q^* - x)] - wQ^*\right\} f(x)dx + (\phi p - w)Q^* - \phi(p-m)\int_0^{Q^*} F(x)dx$$

2.3 The supplier's production strategy

We use the same calculation method as **2.2**, and under revenue sharing contract (w, φ), the profits of the whole supply chain do not depend on the revenue-sharing contract parameters, but the number of production that supplier selects. Afterwards, we can get the profit function of the supply chain and the expected profit function.

① When the supplier is risk-neutral, because supplier only pursues the whole profits of the supply chain, then the optimal production will be $Q^{*}{}_{s1} = F^{-1}(\frac{p-c}{p-m})$,

and the maximum expect profit will be $E(\Pi_s(Q^{*}{}_{s1}))$.

② When the supplier is risk-averse with the introduction of risk aversion, we can get the optimal production under risk-averse. That will be $Q_s{}^{*}$, and Q_s^{*} satisfies the following conditions:

$$-(\lambda_s - 1)(c-m)F(q_2(Q_s^*)) + p - c - (p-m)F(Q_s^*) = 0$$

While the maximum expected utility of the supplier is:

$$E^*[U(\Pi_s)] = (\lambda_s - 1)\times\int_0^{q_1(Q_s^*)} \{[px + m(Q_s^* - x)] - cQ_s^*\} f(x)dx +$$
$$(p-c)Q_s^* - (p-m)\int_0^{Q_s^*} F(x)dx$$

2.4 Parameters Analysis

According to the previous model, in this section we will calculate the sensitivity of loss aversion based on the analysis of the retailer's order quantity, supplier's production and thier expected utility. Through calculating we can obtain that:

$$\frac{dQ_r{}^*}{d\lambda_r} < 0 \qquad \frac{dQ_s{}^*}{d\lambda_s} < 0$$

$$\frac{dE^*[U(\Pi_r)]}{d\lambda_r} < 0 \qquad \frac{dE^*[U(\Pi_s)]}{d\lambda_s} < 0$$

Therefore, the retailer's order quantity, supplier's production and thier expected utility will all decrease with a higher loss aversion.

3 Analysis of Supply Chain Coordination

Supply chain coordination increases the expected utility of each member in the s upply chain by adjusting the parameters of the contract, based on the target to achieve the maximum expected utility of the entire supply chain.

Here, we use a qualitative analysis method to adjust the contact parameters for a certain level and verify the coordination effects of revenue sharing contact. We will analyze from four aspects :

① When retailer is risk-neutral, supplier is also risk-neutral

Based on the previous model, we can get the optimal order quantity of retailer and the optimal production quantity of supplier under risk-neutral attitude. Then we can achieve supply chain coordination using:

$$Q^*_{r1} = F^{-1}(\frac{\varphi p - w}{\varphi p - \varphi m}) = Q^*_{s1} = F^{-1}(\frac{p-c}{p-m})$$

Analyzing the relationship of the parameters, we can draw that the conditions for supply chain coordination will be $m/c < \varphi < 1$, $m < w < c$, $w = \varphi c$.

② When retailer is risk-averse, supplier is risk-neutral

To make the supply chain achieve the coordination, there will be $Q_r^* = Q_{s1}^*$.

Thus,
$$\begin{cases} -(\lambda_r - 1)(w - \varphi m)F(q_1(Q_r^*)) + \varphi[p - (p-m)F(Q_r^*)] - w = 0 \\ Q^*_{s1} = F^{-1}(\frac{p-c}{p-m}) \\ Q_r^* = Q_{s1}^* \end{cases} \quad (4)$$

Solving (4), the conditions to coordinate the supply chain will be:

$$w < \varphi c < c, \quad w/c < \varphi < 1$$

③ When retailer is risk-neutral, supplier is risk-averse

We can use the same method like ②, then the conditions to coordinate supply chain will be: $\varphi c < w < c$, $0 < \varphi < w/c$.

④ When retailer is risk-averse, supplier is risk-averse,

The conditions for supply chain coordination will be:

$$\begin{cases} -(\lambda_r - 1)(w - \varphi m)F(q_1(Q_r^*)) + \varphi[p - (p-m)F(Q_r^*)] - w = 0 \\ -(\lambda_s - 1)(c - m)F(q_2(Q_s^*)) + p - c - (p-m)F(Q_s^*) = 0 \\ Q_s^* = Q_r^* \end{cases}$$

The relationship of w and φ depends on the size of λ_r and λ_s.

4 Examples

Parameter hypothesis: according to the prediction of demand for products, the random demand meets the normal distribution of (1000, 3002), the retailer price is $p = 18$, the production cost is $c = 10$, the revenue sharing coefficient is $\varphi = 0.8$, the wholesale price of supply chain under the dispersive contract is $w_c = 12$, the wholesale price under the revenue sharing contract is $w_\varphi = 8$.

First, the relationship of $Q_r^*, E^*[U(\Pi_r)]$ with λ_r and $Q_s^*, E^*[U(\Pi_s)]$ with λ_s will be shown in the following fig.1.

Concluding from the above figure, we can verify our conclusions that the retailer's order quantity, supplier's production and their expected utility will all decrease with a higher loss aversion.

Second, We will verify the coordination of revenue-sharing contract for the entire supply chain under different risk preference combinations.

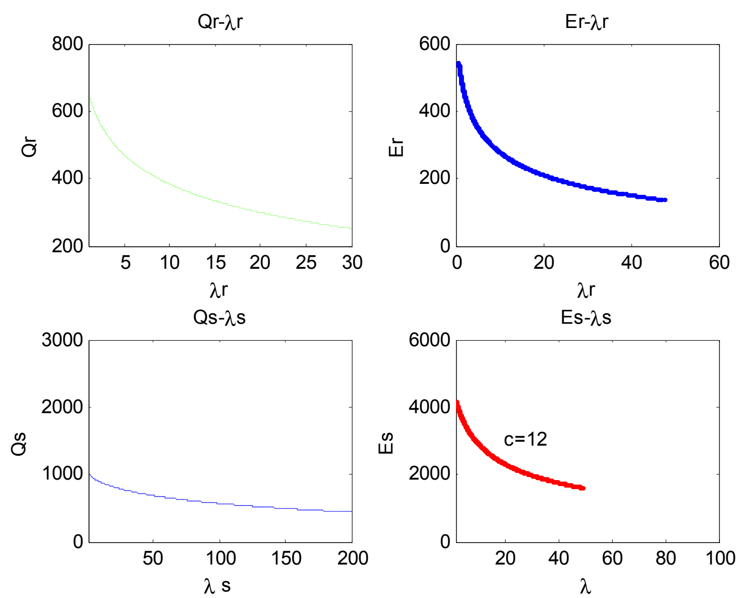

Figure 1. The Sensitivity Analysis of λ

① When retailers and suppliers are all with risk neutral attitude, according to the above formula, we can get the following Table 1.

Table 1. The order, expected profit, total profit of supply chain system (When risk attitude is in combination 1)

System status	Scattered without contract	Revenue sharing contract
The optimal order quantity	900	995
Retailers total profits	4184.4	4868.3
Supplier profits	994.2	1218.6
Supply Chain total profits	5178.6	6086.9

② When the retailer is risk aversion and the supplier is risk neutral or when the retailer is risk neutral while the supplier is risk averse, we can respectively calculate the supply chain data of scattered state and revenue sharing contract conditions, these supply chain data are shown Table2 and Table3:

Table2. The order, expected profit, total profit of supply chain (when risk attitude is in combination 2)

Parameter	Decentralized case				Revenue sharing contract				
λ_r	w_c	Q_c	$\prod_c^r$	$\prod_c^s$	φ_φ	w_φ	Q_φ	$\prod_\varphi^r$	$\prod_\varphi^s$
5	12	794	3713.2	3970	0.81	8	946	6614.4	4883.6
10	12	734	3336.8	3670	0.85	8	895	6528.0	4307.0

5 Conclusions

The inventory control problem considering risk preferences has been solved in this paper. We describe risk preferences with Prospect Theory to find the supplier's optimal production strategy and the retailer's optimal order strategy, then study of the coordinating effect of revenue sharing contract under different combinations of risk attitudes qualitatively. The study shows that revenue sharing contract can coordinate the supply chain when retailer and supplier are in different risk attitude, and we also draw the conclusions that the retailer's order quantity, supplier's production and their expected utility will all decrease with a higher risk-averse.

In this article, only a single supplier and a single retailer was studied in the supply chain, but the situation of multiple competing retailers need a further research.

Abstract: The study investigates the optimal ordering policies of two competitive retailers, one is risk-neutral, another is loss-averse. Because of different scale and credit, Risk-neutral retailers aim for maximum expected profit, while loss-averse retailers targets maximum expected utility. We establish the optimal ordering policies model for the two kinds of retailers whose demand is random and alternative, And proved the existence and uniqueness of the optimal order quantity. Then we carry on the mathematical experimentation with the uniform distribution function, The analysis revealed that when the degree of retailers' lose-averse coefficient increases, their optimal volume of ordering is reducing, while the corresponding risk-neutral competitor's optimal volume of ordering is increasing. But their total volume of ordering is reducing, The scope is becoming slower; when the risk-neutral retailers' wholesale price is falling, their optimal volume of ordering is increasing, while the corresponding the lose-aversion's optimal volume of ordering is just the opposite. But their total volume of ordering is increasing, The growth is becoming slower too.
Keywords: Competition; Perishable commodities; Ordering policy; Substitution; Loss averse utility theory.

1 Introduction

For retailers, The most direct method to reduce business operating costs is the optimal ordering and the inventory strategy. The inventory items we general discussed can usually be applied indefinitely. But some products in the real situation, will rot in a period of storage, or have little value after some time. Such as vegetables, fruits, milk, newspapers, etc. We call perishable commodities, also called seasonal products or short-term-life products. The surplus value of the expired perishable commodities will be lost or very low. This feature will inevitably influence the ordering strategy of retailers. If we order too many products and can't be sold for a long time, This would cause a glut. Such as newspapers, there are less people who want to buy them at night. On the contrary, out-of-stock will cause customer defection and reduced income, the most critical problem of the retailer who selling this kind of perishable goods is the optimal order quantity.

The research of the perishable products order started from Single phase inventory model in the 1950s, namely the newsboy model. There have been plenty of articles dedicated to this problem since 1988. Chen (2004) and Cai *et al.* (2003) studied retailer's ordering policy for substitutable and perishable Commodities. The difference between them is that the former is based on alternative factor to indicate the products which can replace each other, the later has studied the strategies under unilateralism alternative. General researches concentrate on one retailer who sell alternatives, There are two classic articles with retailer competition:1. Parlar et al. (1988) use game theoretic concepts to analyze two retailers' inventory problem of substitutable commodities with stochastic demand. This paper shown that when one of the players acts irrationally for the sole purpose of inflicting maximum damage on the other, the classical single-period inventory strategy will be influenced. 2. Pasternack and Drezner (1991) consider a demand model for two products which have a single-period inventory structure and which can be used as substitutes for each other. They proved that the expected profit function is concave, allowing us to find optimal stocking levels for the two products, They compared optimum inventory levels for the case of single substitution with that where there is no substitution. It is demonstrated for the case of single substitution that total optimum order quantities can actually increase or decrease with the substitution revenue. Su et al. (2006) use practical examples to analysis and simulate the literature of Parlar et al. (1988), determined the specific value of the various parameters in the model, and makes the model more close to reality.

However, these researches all established on the risk-neutral hypothesis, The researches of experimental economists have shown that decision makers are rarely risk neutral. For instance, Fisher and Raman (1996) found that the order of fashion manufacturers are always lower than the risk neutral decision makers. Patsuris (2001) found that, Despite the bad economy, many retail chains continue to add stores, heaping even more unnecessary supply onto the market. An observation by the author in Tai Wei, Hong Kong shows that newspapers in 7-11 shop are rarely unavailable, You can also buy the Sun of the day after 9 p.m. , But newsstands near 7-11 shop are almost out of stock at 7 p.m. and close early. It is clear that 7-11 sell almost all kinds of newspapers and magazines, and customers who buy other commodities in store also have a steady demand for newspapers, It has the ability of anti-risk, in studies we call that giant retailers to withstand risks via product diversification. The newsstands worry that they cannot sell out in the evening, so they would rather reduce the order quantity, There is a completely different attitude toward risk, comparing newsstands with 7-11. Thus only to give up the risk-neutral assumption , considering the risk attitudes of decision makers, can we make the study more realistic. Generally, the measure of risk is probably divided into two categories: One is the change of object function of decision makers, such as the mean variance model; The other is add constraints on the optimization of decision makers, Lau (1980) is the first scholar to discuss this issue, The suppliers and retailers in his study are risk averse, He construct the utility function through mean-variance, Get different results with the news vendor model. Agrawal and Seshadri (2000) studied the supply chain model which multiple risk averse retailers take part. And solved the shortage problem that caused by risk-averse attitude of retailers through introducing a risk neutral distributor. Gan *et al.* (2004&2005) use the Pareto-optimality criterion, used widely in the group decision theory, to define the supply chain coordination involving risk-verse agents. Ye *et al.* (2006) established a two-layer supply chain repurchase lease model which risk averse retailers are involved used the mean variance method. Yu *et al.* (2007) analyses the impact of retailers' risk-defending degree on the optimal order quantity, wholesale prices and supply chain coordination by using the conditional value-at-risk method.

However, the studies ignore the fact that there is nothing fixed about the decision makers' attitudes to risk—that is, simple risk-averse or risk-seeking did not fully reflect the attitude of the decision makers, The decision makers in the prospect theory of Kahneman and Tversky (1979) have following characteristics：(1)The sensitivity to the change of relative wealth is greater than the variation of absolute wealth;(2) Under the condition of the same amount of income, the degree of loss aversion is greater than the extent of pursuit;(3)Earning as risk aversion, while lossing as risk-seeking, namely diminishing sensitivity. That the policy makers have a composite attitude to risk.

Currently, the prospect theory proved can better explain many contradictory appearances of the risk aversion theory, it can describe the behavior of decision makers better, and has been applied in many field such as in economics, marketing, finance, and organizational theory, When analyzing with prospect theory, most scholars assume that decision makers are loss-averse to simplify the problem and obtain some useful conclusions, such as Shen *et al.* (2004) discussed the purchasing decision problem of customized production under the condition of loss aversion, Wang and Webster (2009) uses loss aversion to model manager's decision-making behavior in the single-period newsvendor problem. And on this basis, we use the classical piecewise-linear-value utility function in prospect theory to analyze the order decision problem of perishable product retailers who is different risk preference in a competitive environment.

2 Notation and Assumption

We assume that there are two retailers(R_1 and R_2) who sale highly homogenized perishable products(for example: newspaper)in the market, For the convenience of discussion, we use the following notation:

p_1, p_2: per-unit selling price for two retailers(R_1 and R_2);

w_1, w_2: per-unit wholesale price for two retailers(R_1 and R_2);

x, y: the actual market demand f*or* two retailers(R_1 and R_2);

q_1, q_2: the quantity of goods for two retailers(R_1 and R_2);

π_1, π_2: the profit of two retailers(R_1 and R_2);

q_{1N}, p_{2N}: *the* order quantity with the Nash equilibrium strategy of two retailers(R_1 and R_2);

$f(x), g(y)$: two retailers'(R_1 and R_2) probability density function of the actual market demand, we assumed that they are differentiable and reversible;

$F(x), G(y)$: two retailers'(R_1 and R_2) cumulative distribution function of the actual market demand, we assumed that they are differentiable and reversible;

λ:the degree of R_2's loss-averse coefficient.

In the case of single- phase, the profit of R_1 is

$$\pi_1 = p_1 \min[x, q_1] + p_1 \min[(y - q_2)^+, (q_1 - x)^+] - w_1 q_1 \tag{1}$$

the profit of R_2 is

$$\pi_2 = p_2 \min[y, q_2] + p_2 \min[(x - q_1)^+, (q_2 - y)^+] - w_2 q_2 \tag{2}$$

When $x \le q_1, y \ge q_2$, then we should consider that if R_1's order quantity will be enough to cope with demand which transferred by R_2, the profits are

$$\pi_1 = p_1 x + p_1 \cdot \min[y - q_2, q_1 - x] - w_1 q_1 \qquad \pi_2 = p_2 q_2 - w_2 q_2 \tag{3}$$

When $x \ge q_1, y \le q_2$, then we should consider that if R_2's order quantity will be enough to cope with demand which transferred by R_1, the profits are

$$\pi_1 = p_1 q_1 - w_1 q_1 \qquad \pi_2 = p_2 y + p_2 \cdot \min[x - q_1, q_2 - y] - w_2 q_2 \tag{4}$$

We assume that R_1 is risk neutral, thus, R_1's expected profit is

$$\pi_1(q_1,q_2)=\int_0^{q_1}\int_0^{q_2}(p_1x-w_1q_1)f(x)g(y)dydx+\int_0^{q_1}\int_{q_2}^{\infty}(p_1x+p_1\cdot\min[y-q_2,q_1-x]-w_1q_1)f(x)g(y)dydx$$
$$+\int_{q_1}^{\infty}\int_0^{q_2}(p_1q_1-w_1q_1)f(x)g(y)dydx+\int_{q_1}^{\infty}\int_{q_2}^{\infty}(p_1q_1-w_1q_1)f(x)g(y)dydx \tag{5}$$

We assume that R_2 is loss-averse, and meet the piecewise-linear loss-averse utility function ,as Fig. 1:

$$u(\pi_2(q_1,q_2))=\begin{cases}\pi_2(q_1,q_2) & \pi_2(q_1,q_2)>0\\ \lambda\pi_2(q_1,q_2) & \pi_2(q_1,q_2)<0\end{cases} \tag{6}$$

Where λ is retailer's loss-averse coefficient, It reflect the degree of loss aversion. We assume that $\lambda > 1$, There is a knee in the reference point (to simplify, we set initial wealth to zero), The larger λ, the higher degree of loss aversion. Although the piecewise-linear loss-averse utility function does not reflects the characteristics of the diminishing sensitivity in prospect theory, it widely used in literatures of various fields such as economic, financial and operational management as Kahneman and Tversky (1979) mentioned, because it clearly present the attitude of purchaser to loss.

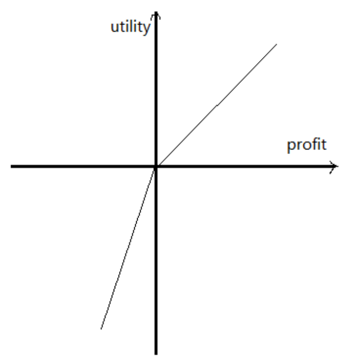

Fig.1. Piecewise-linear loss-averse utility function

When $y < \frac{w_2}{p_2}q_2$ is given by (4), According (4),when $y \le q_2$ and $q_1 < x < \frac{w_2}{p_2}q_2 + q_1 - y$, then the profits of R_2 will be negative.

Thus, we have

$$\pi_2(q_1,q_2)=\int_{\frac{w_2}{p_2}q_2}^{q_2}\int_0^{q_1}(p_2y-w_2q_2)f(x)g(y)dxdy+\lambda\int_0^{\frac{w_2}{p_2}q_2}\int_0^{q_1}(p_2y-w_2q_2)f(x)g(y)dxdy$$
$$+\int_{q_2}^{\infty}(p_2q_2-w_2q_2)g(y)dy+\int_0^{q_2}\int_{q_1+q_2-y}^{\infty}[p_2q_2-w_2q_2]f(x)g(y)dxdy$$
$$+\int_0^{q_2}\int_{\frac{w_2}{p_2}q_2+q_1-y}^{q_1+q_2-y}[p_2y+p_2(x-q_1)-w_2q_2]f(x)g(y)dxdy$$
$$+\lambda\int_0^{q_2}\int_{q_1}^{\frac{w_2}{p_2}q_2+q_1-y}[p_2y+p_2(x-q_1)-w_2q_2]f(x)g(y)dxdy \tag{7}$$

Where the 2nd and 6th indicate negative profits of retailers.

3 Nash strategy of retailers

If retailers does not adopt a cooperative attitude, it is possible that both of them adopt Nash strategy that meet the following conditions

$$\pi_1(q_{1N},q_{2N}) \geq \pi_1(q_1,q_{2N}) \qquad \pi_2(q_{1N},q_{2N}) \geq \pi_2(q_{1N},q_2) \tag{8}$$

Formula (8) shows that if Nash strategy adopted in one side , so does the other side. otherwise the consequences will not get better , Thus the retailer's strategy set (Reflection curves) can be obtained by the first-order derivatives of retailers' profit function.
According to (5), R_1's expected profit is

$$\pi_1(q_1,q_2) = p_1q_1 - w_1q_1 - p_1\int_0^{q_1}\int_{q_2}^{q_1+q_2-x} G(y)f(x)dydx \tag{9}$$

Let

$$I_1(q_1,q_2) = \frac{\partial \pi_1(q_1,q_2)}{\partial q_1} = p_1 - w_1 - p_1\int_0^{q_1}\int_0^{q_1+q_2-x} g(y)f(x)dydx \tag{10}$$

Then

$$\frac{\partial^2 \pi_1(q_1,q_2)}{\partial q_1^2} = -p_1[G(q_2)f(q_1) + \int_0^{q_1} g(q_1+q_2-x)f(x)dx] < 0 \tag{11}$$

Formula (11) shows a strictly concave function of $\pi_1(q_1, q_2)$ with q_1 for any given q_2 .

Lemma 1 $I_1(q_1, q_2) = 0$ is strictly decreasing curve in q_1, q_2 plane.
Proof. See Appendix A.
According to lemma 1 and formula (10), we can know that for any given q_2, The upper bound $\overline{q_1}$ and lower bound $\underline{q_1}$ of R_1's optimal order quantity q_1^* are given by :

$$p_1 - w_1 - p_1\int_0^{\bar{q}_1} G(\bar{q}_1 - x)f(x)dx = 0 \tag{12}$$

$$p_1 - w_1 - p_1\int_0^{\underline{q}_1} f(x)dx = 0 \tag{13}$$

Where $\overline{q_1}$ in (12) can be obtained by letting $q_2 = 0$ in formula(10), Where $\underline{q_1}$ in (13) can be obtained by letting $q_2 = +\infty$ in formula(10).

We could see that when q_2 approaches infinity , The order of R_1 is the classical newsboy model. Thus the optimal order quantity will be greater than the quantity based on classical newsboy model, demonstrating that it is good for retailers when there is substitutable demand.

According to (7), R_2's expected profit is

$$\begin{aligned}
\pi_2(q_1,q_2) &= \int_0^{q_2}\int_0^{q_1}(p_2y-w_2q_2)f(x)g(y)dxdy+\int_{q_2}^{\infty}(p_2q_2-w_2q_2)g(y)dy \\
&+\int_0^{q_2}\int_{q_1}^{q_1+q_2-y}[p_2y+p_2(x-q_1)-w_2q_2]f(x)g(y)dxdy+\int_0^{q_2}\int_{q_1+q_2-y}^{\infty}[p_2q_2-w_2q_2]f(x)g(y)dxdy \\
&+(\lambda-1)\int_0^{\frac{w_2}{p_2}q_2}\int_0^{q_1}(p_2y-w_2q_2)f(x)g(y)dxdy+(\lambda-1)\int_0^{\frac{w_2}{p_2}q_2}\int_{q_1}^{\frac{w_2}{p_2}q_2+q_1-y}[p_2y+p_2(x-q_1)-w_2q_2]f(x)g(y)dxdy \\
&= p_2q_2-w_2q_2-p_2\int_0^{q_2}g(y)dy\int_{q_1}^{q_1+q_2-y}F(x)dx-(\lambda-1)p_2F(q_1)\int_0^{\frac{w_2}{p_2}q_2}G(y)dy \\
&+(\lambda-1)[-p_2F(q_1)\int_0^{\frac{w_2}{p_2}q_2}yg(y)dy-p_2\int_0^{\frac{w_2}{p_2}q_2}g(y)dy\int_{q_1}^{\frac{w_2}{p_2}q_2+q_1-y}F(x)dx+w_2q_2F(q_1)\int_0^{\frac{w_2}{p_2}q_2}g(y)dy]
\end{aligned} \tag{14}$$

Let

$$I_2(q_1,q_2)=\frac{\partial\pi_2(q_1,q_2)}{\partial q_2}=p_2-w_2-p_2\int_0^{q_2}\int_0^{q_1+q_2-y}f(x)dxg(y)dy -(\lambda-1)p_2\int_0^{\frac{w_2}{p_2}q_2}\int_0^{\frac{w_2}{p_2}q_2+q_1-y}f(x)dxg(y)dy \tag{15}$$

Then

$$\frac{\partial^2\pi_2(q_1,q_2)}{\partial q_2^2}=-p_2[F(q_1)g(q_2)+\int_0^{q_2}f(q_2+q_1-y)g(y)dy] -(\lambda-1)w_2[F(q_1)g(\frac{w_2}{p_2}q_2)+\int_0^{\frac{w_2}{p_2}q_2}f(\frac{w_2}{p_2}q_2+q_1-y)g(y)dy] \tag{16}$$

Lemma 2 $I_2(q_1,q_2)=0$ is strictly decreasing curve in q_1, q_2 plane.

Proof. See Appendix A.

According to lemma 2 and formula (15), we can know that for any given q_1, The upper bound $\overline{q_2}$ and lower bound $\underline{q_2}$ of R_2's optimal order quantity q_2^* are given by

$$p_2 - w_2 - p_2\int_0^{\bar{q}_2}\int_0^{\bar{q}_2 - y} f(x)dxg(y)dy - (\lambda-1)p_2\int_0^{\frac{w_2}{p_2}\bar{q}_2}\int_0^{\frac{w_2}{p_2}\bar{q}_2 - y} f(x)dxg(y)dy = 0 \quad (17)$$

$$p_2 - w_2 - p_2\int_0^{\underline{q}_2} g(y)dy - (\lambda-1)p_2\int_0^{\frac{w_2}{p_2}\underline{q}_2} g(y)dy = 0 \quad (18)$$

Where $\overline{q_2}$ in (17) can be obtained by letting $q_1 = 0$ in formula (15), Where $\underline{q_2}$ in (18) can be obtained by letting $q_1 = +\infty$ in formula(15).

Theorem 1 Two retailers have unique Nash equilibrium solution (q_{1N}, q_{2N}).
Proof. See Appendix A.

Thus, in the general case, retailers' Nash equilibrium point (q_{1N}, q_{2N}) can be obtained by$I_1(q_1, q_2) = 0$ and $I_2(q_1, q_2) = 0$. Obviously, we need to know exactly demand density function of retailers and other parameters to find the equilibrium strategy in the actual operation.

4 Properties of the optimal order quantity

The Nash equilibrium point of retailers, that is, the optimal order quantity (q_1^*, q_2^*) is given by :

$$\begin{cases} p_1 - w_1 - p_1\int_0^{q_1}\int_0^{q_1+q_2-x} g(y)f(x)dydx = 0 \\ p_2 - w_2 - p_2\int_0^{q_2}\int_0^{q_1+q_2-y} f(x)dxg(y)dy - (\lambda-1)p_2\int_0^{\frac{w_2}{p_2}q_2}\int_0^{\frac{w_2}{p_2}q_2+q_1-y} f(x)dxg(y)dy = 0 \end{cases} \quad (19)$$

Property 1 R_1's optimal order quantity q_1^* is proportional to R_2's loss-averse coefficient λ, R_2's optimal order quantity q_2^* is inversely proportional to λ.
Proof. See Appendix A.

This conclusion directly demonstrate the order policy while there is a loss aversion between two competing retailers. This property illustrates the reasons why 7-11 could have a big order, At the same time, it offers an important information for R_1 that when the degree of loss-averse coefficient of R_2 is very larger in some cases (such as bad weather), R_1 can order some more products.

5 Numerical Analysis

For simplicity and common, We assume that the stochastic demand subjects to

uniform distribution,
Let

$$f(x_1) = f(x_2) = \frac{1}{\beta - \alpha}$$

Thus we have

$$\frac{\partial \pi_1(q_1, q_2)}{\partial q_1} = p_1 - w_1 - p_1 \int_0^{q_1} \int_0^{q_1 + q_1 - x} \frac{1}{(\beta - \alpha)^2} dy dx = 0$$

Then

$$2(p_1 - w_1)(\beta - \alpha)^2 - 2 p_1 q_1 q_2 - p_1 q_1^2 = 0 \tag{20}$$

$$\frac{\partial \pi_2(q_1, q_2)}{\partial q_2} = p_2 - w_2 - p_2 \int_0^{q_2} \int_0^{q_1 + q_1 - y} \frac{1}{(\beta - \alpha)^2} dx dy - (\lambda - 1) p_2 \int_0^{\frac{w_2}{p_2} q_2} \int_0^{\frac{w_2}{p_2} q_2 + q_1 - y} \frac{1}{(\beta - \alpha)^2} dx dy = 0$$

Then

$$2(p_2 - w_2)(\beta - \alpha)^2 - 2 p_2 q_1 q_2 - p_2 q_2^2 - (\lambda - 1) p_2 (2 \frac{w_2}{p_2} q_1 q_2 + (\frac{w_2}{p_2} q_2)^2) = 0 \tag{21}$$

5.1 The impacts of R_2's loss-averse coefficient on the quantity of goods

In order to discuss the impacts of R_2's loss-averse coefficient on the quantity of goods, we plug $p_1 = 10, w_1 = 5, p_2 = 10, w_2 = 5, \beta = 100, \alpha = 0$ in Equation (20) and (21), So we have

$$10000 - 2 q_1 q_2 - q_1^2 = 0 \tag{22}$$

And

$$10000 - 2 q_1 q_2 - q_2^2 - (\lambda - 1)(q_1 q_2 + \frac{1}{4} q_2^2) = 0 \tag{23}$$

Specify λ=1, λ=2, ..., λ=10, Fig 2 reports the optimal order quantity and the total order of the two retailers.

We can see from Fig. 2 that as R_2's loss-averse coefficient has increased , R_2's optimal order quantity was falling, but R_1's optimal order quantity was increasing. At the same time, the total optimal order quantity is down. The reason is very simple, For given wholesale and retail prices, R_2 will reduce the optimal order quantity to avoid losses, as the newsstand mentioned previously. Once R_1 observe this phenomenon ,he will increase the order quantity to rise profits, From this figure, you can see that the trends of two retailers get gentler and gentler, It may be the following two cases cause this result:(1) R_2's loss-averse coefficient would not increase infinitely, there will always be some customers will visit his shop; (2) If wholesalers found the total order quantity decreased, they would take some measures to decrease the worry of loss, the buyback strategy they usually do is the best example, The graph also confirms the conclusion that lose-aversion's optimal volume of ordering less than the risk-neutral competitor's optimal quantity of ordering

5.2 The influence of R_1's wholesale price w_1 on the order

We assume that the products are highly homogenized, such as newspapers, so they should sell for the same price, but the wholesale price of large and small retailers exist some difference, possibly due to the scale. We plug $p_1 = 10, p_2 = 10, w_2 = 8, \beta = 100, \alpha = 0$ in Equation (20) and (21), So we have

$$20q_1^2 + p_2 q_2^2 + 20q_1 q_2 - 80000 = 0 \tag{24}$$

And

$$5q_1^2 + p_2 q_2^2 + p_2 q_1 q_2 - 40000 = 0 \tag{25}$$

Specify $w_1 = 8, w_1 = 7.5, w_1 = 7, w_1 = 6.5, ..., w_1 = 4$，Fig 3 reports the optimal order quantity and the total order of the two retailers.

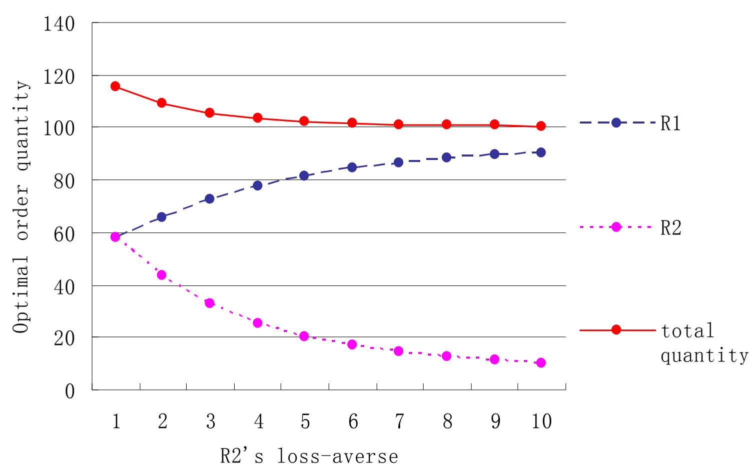

Fig.2. Optimal order quantity with different R2's

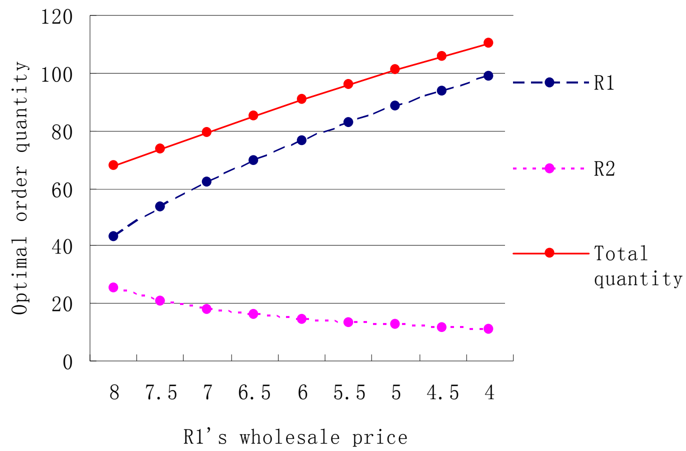

Fig.3. Optimal order quantity with different R1's

We can see from Fig. 3 that as R_1's unit wholesale prices has decreased, R_1's optimal order quantity was increasing. R_2 was just the opposite. At the same time, the total optimal order quantity continue to increase. Apparently, for R_1, decreasing wholesale price means increasing profits, he can raise the quantity of goods appropriately to increase profits, while the trend also get gentler. The reason is simple, For the perishable goods, such as newspapers and magazines, the sales volume may not fluctuate much, The wholesale price of R_2 is high due to his small scale, his wisest strategy against R_1 is just order what he could sells out(under the certain degree of loss-averse coefficient) , Now the wholesalers should be the happiness person, their total sales are increasing, but trend seen slowing, show that it is not wise to share interests with R_1 blindly.

6 Conclusions

This paper studied some characters about two retailers' order quantity of perishable products, there is competition between them. The main conclusion is that When the degree of retailers' lose-averse coefficient increases, their optimal volume of ordering is reducing, while the corresponding risk-neutral competitor's optimal volume of ordering is increasing. But their total volume of ordering is reducing, The scope is becoming slower; when the risk-neutral retailers' wholesale price is falling, their optimal volume of ordering is increasing, while the corresponding the lose-aversion's optimal volume of ordering is just the opposite. But their total volume of ordering is increasing, The growth is becoming slower too.

In the future, adding the internal competition between different products in newsstand is worth investigating, This article focuses on one kind of product, But variety of products in one newsstand can replace each other, For example, Wen Wei Po is similar to Ta Kung Pao , Ming Pao look similar to the Sun(It can be called sub-category) Some customers will seek alternative products when one newsstand is out of stock, but others have turned to other newsstands. Besides, the impact of price on demand is also worth investigating, Although the price of the perishable goods like newspaper is mostly fixed, other types of products like bread will discount after a point in some stores (including large stores). Obviously, Different discount rate could greatly affect consumer demand, adding the strategies about demand and promotion under the influence of price would perfect this model. It is clear that the amount of inventory can impact the degree of loss-averse coefficient. In addition, newspaper vendors' loss-averse coefficient in the morning and at night are obviously different. That is, loss aversion is really relevant to the inventory and time, It will be a dynamic process. Although it is complex, the study will be closer to the actual situation , the result will be more instructive.

Appendix A.

Proof of Lemma 1.

When $I_1(q_1,q_2)=0$,Then

$$\frac{dq_2^1}{dq_1}=\frac{-G(q_2)f(q_1)}{\int_0^{q_1} g(q_1+q_2-x)f(x)dx}-1<0\,.$$

Thus, **Lemma 1** holds.

Proof of Lemma 2.

when $I_2(q_1,q_2)=0$ ， Then

$$\frac{dq_2^2}{dq_1}=-\frac{\int_0^{q_2} f(q_1+q_2-y)g(y)dy+(\lambda-1)\int_0^{\frac{w_2}{p_2}q_2} f(\frac{w_2}{p_2}q_2+q_1-y)g(y)dy}{F(q_1)g(q_2)+\int_0^{q_2} f(q_1+q_2-y)g(y)dy+(\lambda-1)\frac{w_2}{p_2}[F(q_1)g(\frac{w_2}{p_2}q_2)+\int_0^{\frac{w_2}{p_2}q_2} f(\frac{w_2}{p_2}q_2+q_1-y)g(y)dy]}<0$$

Thus, **Lemma 2** holds.

Proof of Theorem 1.

According to (10),we have

$$\frac{\partial^2\pi_1(q_1,q_2)}{\partial q_1\partial q_2}=-\,p_1\int_0^{q_1} g(q_1+q_2-x)f(x)dx<0 \tag{26}$$

According to (15),we have

$$\frac{\partial^2 \pi_2(q_1,q_2)}{\partial q_2 \partial q_1} = -p_2\int_0^{q_2} f(q_2+q_1-y)g(y)dy - (\lambda-1)p_2\int_0^{\frac{w_2}{p_2}q_2} f(\frac{w_2}{p_2}q_2+q_1-y)g(y)dy < 0 \tag{27}$$

According to the Definition 3 of Cachon (2004), Profit function is supermodular, Combined with the theorem 3 of Cachon (2004), We know that in a supermodular game there exists at least one NE.

The response curve of two retailers is decreased strictly (see Fig. 4)

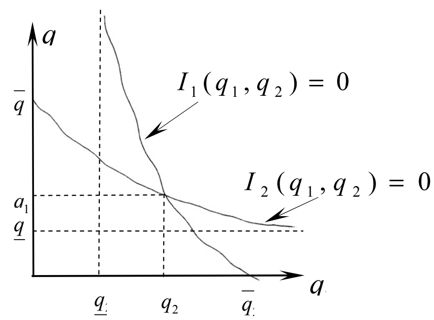

Fig.4. Retailer order quantity

And

$$\frac{dq_2^1}{dq_1} - \frac{dq_2^2}{dq_1} = \frac{-G(q_2)f(q_1)}{\int_0^{q_1} g(q_1+q_2-x)f(x)dx} - 1 +$$

$$\frac{\int_0^{q_2} f(q_1+q_2-y)g(y)dy + (\lambda-1)\int_0^{\frac{w_2}{p_2}q_2} f(\frac{w_2}{p_2}q_2+q_1-y)g(y)dy}{F(q_1)g(q_2) + \int_0^{q_2} f(q_1+q_2-y)g(y)dy + (\lambda-1)\frac{w_2}{p_2}[F(q_1)g(\frac{w_2}{p_2}q_2) + \int_0^{\frac{w_2}{p_2}q_2} f(\frac{w_2}{p_2}q_2+q_1-y)g(y)dy]} < 0 \tag{28}$$

Thus this two curves exist only one intersection point (see Fig. 2), there exists the only one NE holds.

The proof of Property 1.

According (22), we have

$$\begin{cases} [f(q_1)G(q_2) + \int_0^{q_1}(f(x)g(q_1+q_2-x)]\frac{dq_1}{d\lambda} + \int_0^{q_1}(f(x)g(q_1+q_2-x)dx\frac{dq_2}{d\lambda} = 0 \\ (\int_0^{q_2}(g(y)f(q_1+q_2-y)dy + (\lambda-1)\int_0^{\frac{w_2}{p_2}q_2}(g(y)f(\frac{w_2}{p_2}q_2+q_1-y))dy)\frac{dq_1}{d\lambda} \\ (g(q_2)F(q_1) + \int_0^{q_2}(g(y)f(q_1+q_2-y)dy + (\lambda-1)\frac{w_2}{p_2}(g(\frac{w_2}{p_2}q_2)F(q_1) + \int_0^{\frac{w_2}{p_2}q_2}(g(y)f(\frac{w_2}{p_2}q_2+q_1-y))dy))\frac{dq_2}{d\lambda} = -\int_0^{\frac{w_2}{p_2}q_2}\int_0^{\frac{w_2}{p_2}q_2+q_1-y} f(x)dxg(y)dy \end{cases} \tag{29}$$

Let

$$a = G(q_2)f(q_1) + \int_0^{q_1} g(q_1+q_2-x)f(x)dx\ ; \quad b = \int_0^{q_1} g(q_1+q_2-x)f(x)dx$$

$$c = \int_0^{q_2} (g(y) f(q_1 + q_2 - y) dy + (\lambda - 1) \int_0^{\frac{w_2}{p_2} q_2} (g(y) f(\frac{w_2}{p_2} q_2 + q_1 - y)) dy ;$$

$$d = g(q_2) F(q_1) + \int_0^{q_2} (g(y) f(q_1 + q_2 - y) dy + (\lambda - 1)(\frac{w_2}{p_2} g(\frac{w_2}{p_2} q_2) F(q_1) + \int_0^{\frac{w_2}{p_2} q_2} (g(y) f(\frac{w_2}{p_2} q_2 + q_1 - y)) dy)$$

Then

$$\begin{cases} a\dfrac{\partial q_1}{\partial \lambda} + b\dfrac{\partial q_2}{\partial \lambda} = 0 \\ c\dfrac{\partial q_1}{\partial \lambda} + c\dfrac{\partial q_2}{\partial \lambda} = -\int_0^{\frac{w_2}{p_2} q_2} \int_0^{\frac{w_2}{p_2} q_2 + q_1 - y} f(x) dx g(y) dy \end{cases} \tag{30}$$

Thus

$$\begin{cases} \dfrac{\partial q_1}{\partial \lambda} = \dfrac{-b(-p_2 \int_0^{\frac{w_2}{p_2} q_2} \int_0^{\frac{w_2}{p_2} q_2 + q_1 - y} f(x) dx g(y) dy)}{ad - bc} \\ \dfrac{\partial q_2}{\partial \lambda} = \dfrac{a(-p_2 \int_0^{\frac{w_2}{p_2} q_2} \int_0^{\frac{w_2}{p_2} q_2 + q_1 - y} f(x) dx g(y) dy)}{ad - bc} \end{cases} \tag{31}$$

When $a - b = G(q_2) f(q_1) > 0$, $d - c = g(q_2) F(q_1) + (\lambda - 1)\dfrac{w_2}{p_2} g(\dfrac{w_2}{p_2} q_2) F(q_1) > 0$,

We have $ad - bc > 0$ and thus $\dfrac{\partial q_1}{\partial \lambda} > 0, \dfrac{\partial q_2}{\partial \lambda} < 0$ holds.

Abstract: Scraped cars are important renewable resources. In order to improve the recovery rate of Scraped cars, it is necessary to build a Scraped cars reverse supply chain of high efficiency and benefit, and it needs participants of supply chain to realize the organic integration collaborative development of resources, technology and information through the relevant contract mechanism. Interest distribution mechanism is a kind of important contract mechanism. This article builds model of profit distribution of the scraped cars reverse supply chain using improved Shapley value method which considers the risk sharing, which is based on the analysis of the Scraped cars reverse supply chain. Also, this article analyses and verifies the model through a numerical example.
Keywords: Scraped cars; Interests allocation; Reverse supply chain.

1 Introduction

The recycling of scraped cars has great economic value and environmental value. The recycling of scraped cars has positive influence on energy conservation and emissions reduction, as well as promoting the construction of resource saving and environment friendly society. The structure of scraped cars reverse supply chain is shown in figure 1. Every participant in this chain realizes the organic integration of resources, technology, information and business processes and so on through some contract mechanism, and gains collaborative development, as well as greater economic and social benefits. The reasonable design of benefit allocation mechanism is basis of effective operation of supply chain. If distribution of benefit is fair and reasonable, current cooperation relations in the chain will be consolidated and strengthened and the overall efficiency and effectiveness of the chain will be improved. Otherwise it will damage the relations of cooperation among enterprises in the chain, and influence the overall efficiency and performance of the chain, even create collapse of the whole supply chain.

Guo Yajun put forwards a profit model of closed-loop supply chain system under the condition that retailers are responsible for product sales, the third party responsible for waste recycling (Guo Yajun, 2007). Huang Zuqing etc research closed-loop supply chain system under the condition that the third party is responsible to recycle, and put forward the strategy about how the revenue sharing contract realizes win-win among supply chain members (Huang Zuqing etc, 2008). Savaskan compares decision making and earnings among members under four kinds of closed-loop supply chain model in which recycler respectively is retailer, manufacturer, the third party, manufacturer and retailer (Savaskan, 2004). Wang Xu sets up a model of reverse supply chain made up of processors, recyclers and consumers, determines working range between processors and recyclers, designs the profit distribution plan among enterprises in reverse supply chain (Wang Xu, 2009). Wei Xiujian analyses profit distribution problem of supply chain from the perspective of the resources of the supply chain and its contributions to supply chain, and put forwards some ideas and framework of profit distribution among every participant in the chain(Wei Xiujian, 2005).

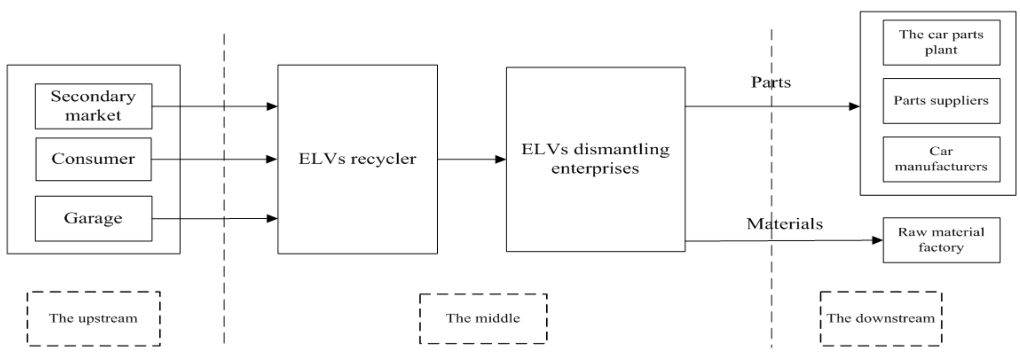

Figure1.Structure of scraped cars reverse supply chain

This paper references related benefit distribution mechanism in scraped cars reverse supply chain at home and abroad, sets up profit distribution model based on Shapley value method, and conducts the corresponding numerical example analysis.

2 Design Background of Profit Distribution Mechanism

In scraped cars reverse supply chain, in order to realize the maximization of economic benefits, the enterprises originally independent optimize and Integrate core competencies, so we can regard the economic activity of the industrial chain as cooperation of many people, profit distribution of enterprises as profit distribution problem of cooperation of many people.

Shapley value method is a kind of mathematical methods to solve the problem of people cooperation countermeasure proposed by Shapley L.S. When n persons engage in an economic activity, it can gain certain benefits about every kind of cooperation formation which consists of some people. When activity of interests among people is non-confrontational, it cannot reduce benefits when the number of people is increasing in the cooperation. So it will come out the biggest benefit because of the cooperation of n persons, and Shapley value method is a kind of plan to distribute this maximum benefit.

Above all, this paper considers the characteristics of scraped cars reverse supply chain, sets a profit distribution model based on the improved Shapley value method which takes the risk into consideration, and conducts the example analysis.

3 Design Content

3.1 Model building

The principle of Shapley value method is as follows: Assuming that collection $I=\{1,2,\ldots,n\}$, if any subset s （any combination within n people）of I has a real function $v(s)$, and:

$$v(\varnothing)=0;\quad v(s_1\cup s_2)\geq v(s_1)+v(s_2), s_1\cap s_2=\varnothing \qquad (s_1\subseteq I, s_2\subseteq I)$$

We call $[I,v]$ cooperation countermeasure of n persons，call v Characteristic function of countermeasures.

We usually call x_i income of member i (from I) from the biggest benefit of cooperation $v(I)$. Under the cooperation I, $x=(x_1,x_2,\ldots,x_n)$ expresses the distribution of cooperation countermeasure, the successful cooperation must meet the following conditions:

$$\sum_{i=1}^{n} x_i = v(I);\qquad x_i \geq v(i), i=1,2,\ldots,n$$

In the Shapley value method, we call the profit distribution of every partner under cooperation I as Shapley value, and record it as: $\Phi(v)=(\phi_1(v),\phi_2(v),\ldots,\phi_n(v))$ .While $\phi_i(v)$ expresses the distribution of member i under the cooperation I, and $\phi_i(v)=\sum_{s\in s_i} w(|s|)\left[v(s)-v(s\setminus i)\right], i=1,2,\ldots,n$;

$w(|s|)=\dfrac{(n-|s|)!(|s|-1)!}{n!}$. Among them:

s_i——All in collection I which contains member i; $|s|$——The number of element in the subset s; n——The number of element in the collection I; $w(|s|)$

——The weighting factor; $v(s)$——Benefits of subset s; $v(s \setminus i)$——Available benefits from s which removes enterprise i.

The Shapley value method above does not consider the risk every enterprise undertakes in the process of cooperation, so we should improve it, and set a benefit-sharing and risk-sharing allocation mechanism.

Enterprises in the Scraped cars Reverse supply chain undertake a lot of risk. This paper mainly considers environmental risk, market risk, dissolution risk, technology risk and cooperation risk (As shown in figure 2).

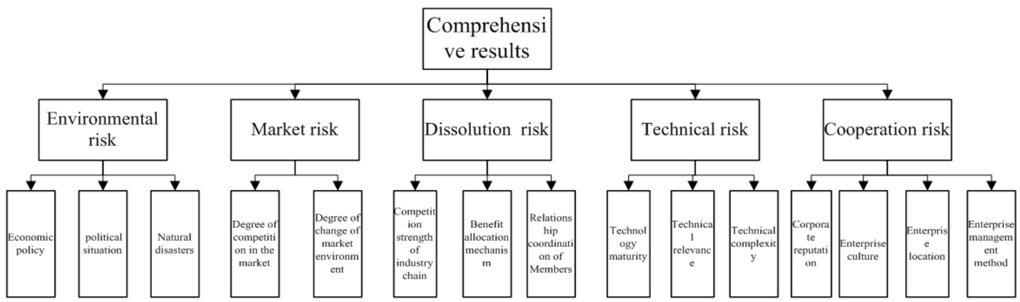

Figure 2.Index evaluation system of risk undertaken by enterprises in the chain

Using total risk coefficient calculation method put forward by Chen Jian and Feng Weidong in the《Construction and management of virtual enterprise》, we gain the total risk coefficient R_i of enterprise in the chain is:

$$R_i = 1-(1-R_{Ei})(1-R_{Mi})(1-R_{Ci})(1-R_{Di})(1-R_{Ti})$$

Among them: R_{Ei}——Environmental risk coefficient of enterprise i; R_{Mi}——Market risk coefficient of enterprise i; R_{Ci}——Cooperation risk coefficient of enterprise i; R_{Di}——Dissolution risk coefficient of enterprise i; R_{Ti}——Technical risk factor coefficient of enterprise i.At the same time, $\frac{\partial \alpha_i}{\partial R_i} > 0$ (α_i is profit distribution proportion of enterprise i).

We calculate all risk coefficient of every enterprise using fuzzy comprehensive evaluation method, so we determine corresponding weight vector W_F for factors under each type of risk. At the same time we also determine evaluation sets $W_E^{'}$ and conduct normalized processing for it, such getting W_E. Then we set a membership degree matrix P for risk factors. Lastly we calculate comprehensive evaluation vector S and comprehensive evaluation value μ, and the computation formula is as follows:

$$S = W_F P，\quad \mu = W_E S^T$$

Clearly，comprehensive evaluation value calculated above is the corresponding risk coefficient, and we can calculate total risk coefficient R_i. Lastly we conduct normalized processing for it, and that is $R = \{r_1, r_2, r_3, \cdots, r_n\}$, as well as $\sum_{i=1}^{n} r_1 = 1$. Risk correction coefficient of enterprise i is:

$$\Delta r_i = r_i - \frac{1}{n}，\quad i = 1,2,\cdots,n$$

Among them: Δr_i——Actual profit distribution correction of enterprise i; $\frac{1}{n}$——Average level of risk undertaken by every enterprise. Therefore, interest $\phi_i(\mathrm{v})'$ of enterprise i is:

$$\phi_i(v)' = \phi_i(v)(1 + \Delta r_i) = \phi_i(v)\left[1 + (r_1 - \frac{1}{n})\right]，\quad i = 1,2,\cdots,n$$

3.2 Example analysis

(1) Model data assumption. There are three main participants in scraped cars reverse supply chain, and they are：car manufacturers A, enterprises B of retrieving and dismantling scraped cars, parts suppliers C. We assume that the investment of three enterprises which is contributed to set joint warehouses, distribution facilities, recycling network and information system and so on separately is 2 million, 3.5 million and 2.5 million. The annual profit of three enterprises separately is 1.2 million, 3 million and 2 million when they conduct separate operation. If A cooperates with B, Its annual profit is 7.5 million Yuan, and if A cooperates with C, Its annual profit is 5.5 million Yuan, and If B cooperates with C, Its annual profit is 6 million Yuan. Lastly, if A cooperates with B and C, Its annual profit is 14.4 million Yuan. Therefore, if the supply chain is made up of three enterprises, the annual profit is 14.4 million Yuan. Investment and earnings is shown in table 1:

Table 1. Investment and earnings of three enterprises (Units: ten thousand Yuan)

	A	B	C	$A \cup B$	$A \cup C$	$C \cup B$	$A \cup B \cup C$
investment	200	350	250	550	450	600	800
profit	120	300	200	750	550	600	1440

(2) Solution of the model. From the model assumption above, we can know that $I = \{1,2,3\}$ （1 is on behalf of car manufacturer A, 2 is on behalf of enterprise B of retrieving and dismantling scraped cars, 3 is on behalf of parts supplier C）, and $v(1) = 120$, $v(2) = 300$, $v(3) = 200$. Cooperative collection which contains car manufacture is $s_1 = \{1,1 \cup 2,1 \cup 3,1 \cup 2 \cup 3\}$, and its corresponding gains is: $v(1 \cup 2) = 750$, $v(1 \cup 3) = 500$, $v(1 \cup 2 \cup 3) = 1440$, and $v(2 \cup 3) = 600$. We can calculate $\phi_1(v)$, $\phi_2(v)$, $\phi_3(v)$ using Shapley value method. Taking car manufacturer A as an example, we can get its calculation process of interests which is shown in table 2:

Table 2. Interest calculation table of car manufacturer A

	1	$1 \cup 2$	$1 \cup 3$	$1 \cup 2 \cup 3$
$v(s)$	120	750	550	1440
$v(s/1)$	0	300	200	600
$v(s) - v(s/1)$	120	450	350	840
$\lvert s \rvert$	1	2	2	3
$w(\lvert s \rvert)$	1/3	1/6	1/6	1/3
$w\lvert s \rvert[v(s) - v(s/1)]$	40	75	350/6	280

So $\phi_1(v) = 40 + 430/6 + 75 + 280 = 466.7$ (Ten thousand).

The same we can get:

$\phi_2(V) = 100 + 105 + 400/6 + 890/3 = 568.3$ (Ten thousand).

$\phi_3(V) = 200/3 + 430/6 + 50 + 230 = 418.3$ (Ten thousand).

We improve the Shapley value above. As an example, we calculate the environmental risk factor of Enterprises of retrieving and dismantling Scraped cars.

(1) Assuming that weight vector of economic policy, natural disasters, political situation is $W_F = (0.5, 0.4, 0.1)$.

(2) Assuming that $W_E' =$ (Good, better, general, poor) = (100,85,70,55), we do normalized processing for it, such getting $W_E = (0.32, 0.27, 0.23, 0.18)$. In addition, the membership degree matrix is:

$$P = \begin{pmatrix} 0.36 & 0.56 & 0.08 & 0 \\ 0.12 & 0.56 & 0.28 & 0.04 \\ 0.2 & 0.6 & 0.2 & 0 \end{pmatrix}$$

(3) Calculating the comprehensive evaluation vector and the comprehensive evaluation value:

$$S = W_F R = (0.5, 0.4, 0.1) \begin{pmatrix} 0.36 & 0.56 & 0.08 & 0 \\ 0.12 & 0.56 & 0.28 & 0.04 \\ 0.2 & 0.6 & 0.2 & 0 \end{pmatrix} = (0.248, 0.564, 0.172, 0.016)$$

$$\mu = W_E S^T = (0.32, 0.27, 0.23, 0.18) \begin{pmatrix} 0.248 \\ 0.564 \\ 0.172 \\ 0.16 \end{pmatrix} = 0.3$$

Therefore, $R_{E2} = 0.3$. At the same time we can get that

$R_{M2} = 0.22$, $R_{C2} = 0.42$, $R_{D2} = 0.12$, $R_{T2} = 0.2$

Therefore, $\mu_2 = (0.3, 0.22, 0.42, 0.12, 0.2)$,

$R_2 = 1 - (1-0.3)(1-0.22)(1-0.42)(1-0.12)(1-0.2) = 0.78$

we can get that total risk coefficient values of carmakers and component suppliers respectively are $R_1 = 0.47$, $R_3 = 0.32$ .We do the normalized processing for total risk coefficient of the three enterprises, such getting $R = (0.3, 0.5, 0.2)$.

Therefore: $\phi_1(v)' = \phi_1(v)\left[1 + (r_1' - \frac{1}{3})\right] = 451.3$ （Ten thousand）

$$\phi_2(v)' = \phi_2(v)\left[1 + (r_1' - \frac{1}{3})\right] = 663.0 \text{ （Ten thousand）}$$

$$\phi_3(v)' = \phi_3(v)\left[1 + (r_1' - \frac{1}{3})\right] = 362.5 \text{ （Ten thousand）}$$

From above, the interests of car manufacturers, enterprises of retrieving and dismantling Scraped cars, as well as parts suppliers respectively are 4.513 million, 6.63 million, 3.625 million.

4 Conclusions

This paper considers the risk problem undertaken by different subjects when designing the benefit distribution mechanism, and verifying the model taking profit distribution among car manufacturers, enterprises of retrieving and dismantling scraped cars, as well as parts suppliers as an example. This benefit allocation mechanism makes the profit distribution of every related subject fair and reasonable, has positive influence on the formation of long-term cooperative relations among them, thus improving the overall efficiency and effectiveness of the industrial chain. This paper only considers five risk factors, and we can improve the indicators of risk evaluation system in the future.

Abstract: The Implementation of green supply chain management (GSCM) is important for the sustainable development of enterprises, while the internal factors affecting the implementation of green supply chain management includes organization structure, resource ability and the performance of enterprises. In order to depict the mechanism that these internal factors affect the diffusion of GSCM within enterprises, this paper built a theoretical diffusion model of GSCM within enterprises. It concluded that: (1) As the network scale grew bigger, diffusion speed between the green supply chain management in the enterprise will reach a steady state with a decline in periodic fluctuations; (2) The increase of the mutual influence of upstream and downstream enterprises of the supply chain is conducive to the spread of the green supply chain management; the more competitive industry is not conducive to the spread of the green supply chain management; (3) The government, the media and non-profit organizations sped up the rate of diffusion of green supply chain management, but did not increase the diffusion steady state; (4) Enterprises under pressure can promote the spread of the green supply chain management.

Keywords: Diffusion model; Green supply chain management; Enterprise interaction.

1 Introduction

Individual enterprise implementation of green supply chain management is the foundation of the green supply chain management diffusion; and whether to implement green supply chain management depends on enterprise internal decision-making mechanism. Whether to implement green supply chain enterprise is also affected by a variety of external environment and internal factors. For example, on basis of statistical analysis in the process of Uzbekistan's enterprises to implement green supply chain management under pressure and dynamic pressure, it can be divided into supply chain environment activity cost, laws and regulations, the current and potential opportunities in four aspects. Christmann and Taylor (2001) pointed out that Uzbekistan's enterprises to improve environmental performance mainly to export new products and become a supplier of foreign companies in Uzbekistan. In order to solve the Uzbekistan's enterprise in the process of implementing green supply chain management provide reference of existing problems, to promote

Uzbekistan's enterprises sustainable development.

We found that the enterprise internal factors affecting the implementation of green supply chain management mainly includes the organization structure, resource ability and the performance of three parts, including the organization including the type of organization, high-level decision-making and staff participation, resources including financial resources, human resources and technical ability, the implementation of performance includes economic performance, environmental performance and operation performance. And the green supply chain management mainly through the spread of "vertical" and "spread" between the two main ways in the enterprise to spread. On the one hand, the green supply chain management through diffusion on the upstream and downstream enterprises in the supply chain partnership, on the other hand, the government's policies and regulations, and the market demands of consumers and other external factors such as organization will promote the dissemination and promotion of green supply chain management in the enterprise between. However, there is lack of implementation of green supply chain management to the enterprise internal factors affecting the relationship and the internal implementation of green supply chain management decision-making model and mechanism research. And also there is lack of green supply chain management diffusion study of influence mechanism between enterprise group and enterprise group of external factors on the interaction between enterprise groups of green supply chain management research on the effects of diffusion.

2 Problem Description and Diffusion Network

In order to articulate the GSCM networks clearly, we define the individual firm as $I(1,...N)$. As for any individual firm, if there are information communication channels between them, we define $X(i,j)=1$; otherwise, $X(i,j)=0$. We define $G=\{X(i,j);i,j\in I\}$ as diffusion in the network enterprise individual and all the relations between them. And the path between the individual firms i,j of network is the collection of individual pairs $\{((i_1,j),..,(i_k,j))\}$ to meet $X(i_1,j)=...=X(i_k,j)$.

The individual network in the enterprise is based on the space distance between connected, here the distance of the said enterprise of the relationship between the individual close degrees.

3 Diffusion model based on complex network

3.1 Enterprises Decision Making and Diffusion Mechanism

A decision to implement green supply chain management depends on enterprise individual attribute, the principle of business decisions, and the relationship between enterprises. We describe the diffusion mechanism as below.

(1)Enterprise individual attributes

A. Enterprise basic attributes

The basic attributes of individual firm means the spread between green supply chain management in enterprise groups. And the influence factors of individual enterprise internal does not change over time, including the enterprise green preferences, the influence of the enterprise's own resources and capabilities, enterprise and enterprise type. The meaning of these factors and values are shown in table 1.

Table 1. The Basic Properties of An Enterprise

Index	Description	Properties
Green Preference(GP_i)	Degree of enterprise environmental protection consciousness, namely the enterprises to implement green supply chain management, and other environmental protection measures.	Normal distribution
Resources(RE_i)	With the implementation of green supply chain management resources, including capital, technology and professional staff, etc.	Normal distribution
Capability(CA_i)	Enterprise implementation of green supply chain management ability, including organization structure, human resources, etc.	Normal distribution
Influence(IF_i)	Enterprise of competitors and degree of influence of upstream and downstream enterprises of the supply chain.	Normal distribution
Enterprise Type(ET_i)	Enterprises in the supply chain upstream and downstream division of different basic types, including suppliers, manufacturers and distributors.	Final product manufacturing enterprises (MA), spare parts supply enterprises (SU), distribution companies (DR)

B. Enterprise update properties

Update attribute of the individual firm means the spread between green supply chain management in enterprise groups, and enterprise individual internal changes over time and update the properties of the factors, including the enterprise to the evaluation of green supply chain management, enterprise implementation of green supply chain management forecast earnings and state enterprises to implement green supply chain management.

(a)Green supply chain management evaluation (GE_i). Evaluation of green supply chain management refers to the enterprise in passing to the external factors of green supply chain management information, the basic understanding of green supply chain management and healthy for the business degree evaluation, due to the differences in the individual attributes of your community. In this study we assumes that the initial value in different enterprise groups individuals obey the normal distribution.

(b)Enterprises to implement green supply chain management forecast earnings (U_i). After enterprise have accepted the external information and basic evaluation of green supply chain management, they will according to the basic attributes of their own and the value of green supply chain management for the implementation of green supply chain management earnings forecast, and the decision whether to implement green supply chain management. Due to the different enterprises by properties and the influence of different green supply chain management evaluation, and therefore this study assumes that the enterprise implementation of green supply chain management forecast earnings for $U_i = BU_i \times GP_i \times RE_i \times CA_i \times GE_i$, including BU average coefficient for the enterprise.

(c) The state that enterprises implement green supply chain management (S_i). After the earnings forecasts of the implementation of green supply chain management, Individual enterprises will compare with expectations of earnings (EU_i). If the predicted value is greater than the expected value ($U_i \geq EU_i$), companies choose to implement ($S_i = 1$) , and vice e ($U_i < EU_i$)Companies are not implemented($S_i = 0$).

(2)Enterprise evolution model

A. Transmission of the information between enterprises

Green supply chain management information transmission between enterprises as shown in figure 1.

B. Update the green supply chain management evaluation

After initial evaluation of green supply chain management, enterprise are associated with the other prompts the target enterprise to update the initial evaluation over time in the network. Update the main green supply chain management evaluation is associated with the evaluation of green supply chain management of enterprises (GE_j), enterprise's influence (IF_j) and the type of role (ET_j). In the period t update individual about green supply chain management evaluation as shown in equation (1),

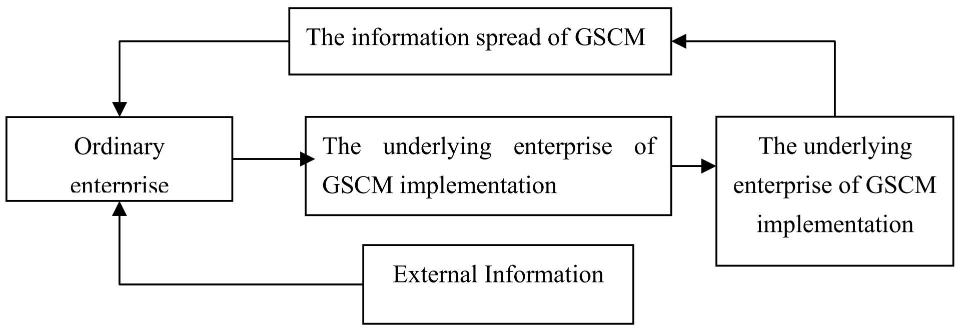

Figure1. GSCM Information Transmitting among Enterprises

$$GE_i^t = \begin{cases} \dfrac{\lambda_1 \times \dfrac{\sum_{j=1}^{n_1} GE_j^{t-1} IF_j^{t-1}}{\sum_{j=1}^{n_1} IF_j^{t-1}} + \lambda_2 \times \dfrac{\sum_{j=1}^{n_2} GE_j^{t-1} IF_j^{t-1}}{\sum_{j=1}^{n_2} IF_j^{t-1}}}{2}, n_1, n_2 \neq 0 \\ \lambda_2 \times \dfrac{\sum_{j=1}^{n_2} GE_j^{t-1} IF_j^{t-1}}{\sum_{j=1}^{n_2} IF_j^{t-1}}, n_1 = 0, n_2 \neq 0 \\ \lambda_1 \times \dfrac{\sum_{j=1}^{n_1} GE_j^{t-1} IF_j^{t-1}}{\sum_{j=1}^{n_1} IF_j^{t-1}}, n_1 \neq 0, n_2 = 0 \end{cases} \quad (1)$$

Among them, this expression (11) said between enterprises of the same type of green supply chain management information to update the influence of the homogeneity enterprise, mainly because of the same type enterprise mutual competition and cooperation relationship to each other. And the size of the said the size of the influence of different types of enterprises, and $\lambda_1 + \lambda_2 = 1$.

C. Individual firm implementation status updates

In each cycle t, the enterprise realize update the implementation of green supply chain management forecast earnings (U_i), and expected return (EU_i) to compare with the enterprise, update the status of implementation of green supply chain management. Because enterprise implementation of green supply chain management includes two aspects: on the one hand, is an enterprise evaluation of green supply chain management, on the other hand is the social standard pressure. As a direct link between potential implementation enterprises groups choose to implement green supply chain increases, the number of companies experience feel pressure with the increase of social norms, and to increase the probability of implementing green supply chain management. Therefore, the enterprise implementation of green supply chain management prediction efficiency update as shown in equation (2),

$$U_i^t = U_i^{t-1} \times \left(1 + \beta \times \frac{w_i^{t-1}}{k_i^{t-1}}\right) \tag{2}$$

Among them, β was the pressure coefficient of social norms, namely the size of the companies affected by the social pressure; k was the connecting enterprise total number; w was the number of connecting enterprise implementation of green supply chain management.

D. Evolution process of enterprise groups

The processes of the enterprise groups with the implementation of green supply chain management of enterprise scale, said when the proportion of the implementation of enterprise implementation cycle change to keep stable, diffusion of green supply chain management to reach steady state. In each cycle t, it will get the cumulative number of implementing green supply chain management enterprise accumulation implement enterprise number, thus the implementation of the overall ratio is

$$R(\mathrm{t}) = \frac{1}{N}\sum_{t=1}^{N} S_i^t, 0 \le t \le T \tag{3}$$

4 Conclusions

This paper used complex network construction of green supply chain management based on distance diffusion enterprise network to analyze the individual firm implementation of the decision making process. We got some useful conclusions.

(1)As the network scale grew bigger, diffusion speed between the green supply chain management in the enterprise will reach a steady state with a decline in periodic fluctuations. Therefore, when the government in formulating the diffusion of policy, policy implications should be considered within the scope of enterprise scale number of the influence of different diffusion to a stable state, especially for different industry or regional policies should consider this point. (2)The increase of the mutual influence of upstream and downstream enterprises of the supply chain is conducive to the spread of the green supply chain management; the more competitive industry is not conducive to the spread of the green supply chain management. Therefore, on the one hand, the government should recognize and promote the larger influence on the supply chain core enterprise implementation of green supply chain management. Government at different levels of competition, on the other hand, should promote the diffusion of green supply chain management industry. In the low level competitive industry, the government should develop appropriate de policies and measures; and in the high level competitive industry, the government should provide more support to the implementation of green supply chain management of enterprises to. (3)The government, the media and non-profit organizations sped up the rate of diffusion of green supply chain management, but did not increase the diffusion steady state. Group of enterprise external propaganda just sped up the green supply chain management information transmission speed, but will not be able to increase the degree of diffusion of green supply chain management in enterprise groups. Therefore, the government and the media should not only spread the green supply chain management of information, but also improve enterprise's own environmental consciousness and promote the spread of green supply chain management. (4)Enterprises under pressure can promote the spread of the green supply chain management. The government should provide enterprises with platform in various industries and internal area communication, and further increase the pressure of social norms for the spread of green supply chain management.

On the Market Access System of Logistics Enterprises—From a View of Comparison between National Road Transport Regulation and Provincial Road Transport Regulation

Li Xue

Law School of Linyi University, P.O. Box 276005, Linyi, Shandong, China. E-mail: Shirley_xue@163.com

Abstract: The unscientific and imperfect market access system of logistics enterprises in China has become a bottleneck for the healthy and fast development of modern logistics industry. Presently, the market access system of logistics enterprises has the characteristics of low level of legislation, lack of operability and reasonability and lack of differentiation in legislation. Through comparison between the National Road Transport Regulation and Provincial Road Transport Regulation, the author holds that the provisions in the Provincial Road Transport Regulation have their reasonability, yet need investigation into their legitimacy, and the National Road Transport Regulation should appropriately elevate the market access threshold for logistics enterprises. Therefore, the article investigates the establishment and consummation of the market access system of logistics enterprises from the aspects of enacting a slip law - Logistics Law, consummating existing rules and regulations and establishing a differentiated market access system.

Keywords: Logistics enterprises; Differentiated market access system; Legal priority; Reasonability.

1 Introduction

The market access system of logistics enterprises is the general term of a series regulation made by the national legislative body or an authorized state administrative organ through legislation as to the preconditions for relevant entities to access the logistics market and conduct activities related to logistics. Forming a scientific and sound market access system for logistics enterprises can facilitate the optimum resource allocation among them, and provide a basis for the state to adjust industrial structure. As there are many types of logistics enterprises, and there are a lot of problems in the market access system of logistics enterprises operating road goods transport, the article only focuses on the investigation into the market access system of logistics enterprises operating road goods transport.

2 Analysis of the Current Status of Market Access System of Logistics Enterprises

At present, the rules and regulations regulating the market access of road goods transport enterprises in China include: The Regulation of the People's Republic of

China on Road Transport (hereinafter referred to as "National Road Transport Regulation"), Provisions on the Administration of Road Freight Transport and Stations (Sites), Measures for the Administration of Road Freight Transport Service Industry, Road Transport Regulations of Shandong Province (hereinafter referred to as "Provincial Road Transport Regulation"), Road Transport Regulations of Guangdong Province and Measures for the Administration of Road Freight Transport Service Industry of Guangdong Province, etc. These rules and regulations have made explicit legal provisions for the road transport enterprises. In view of the current status, the road transport enterprises have the characteristics of small size, weak competitiveness, and narrow scope of service. There is hardly any transport company having influence nationwide. Due to the factor of administrative division, many transport enterprises only operate in its own region, providing similar services and products with simple product structure. Individual private freight vehicles account for over a half of all the freight vehicles, and each goods transport company only has an average of 5 employees. More specifically, the market access system of logistics enterprises in China shows the following characteristics:

2.1 In respect of level of law, the level of the legislation is relatively low

To date, there are only rules and regulations regulating the market access of road goods transport enterprises in China, not reaching the level of law. The directly operable rules and regulations are mostly enacted by the State Council, various ministries and commissions and the local governments, and the majority of them are in the form of "Regulations", "Measures" and "Notice", with low legal effectiveness and lacking authority and general applicability. Inevitably, the result is inability to effectively regulate the market access of logistics enterprises, causing the confusion in the actual operations in various regions.

2.2 In respect of legal necessity, the legislation lacks reasonability

From the aspect of legal necessity, the market access system of logistics enterprises should be designed scientifically. The threshold should not be set up too low, otherwise many cutthroat competitions will be caused, resulting in the unnecessary waste of the limited resources in the market; on the other hand, the threshold should not be too high, otherwise the competition will be limited, affecting the activeness of market economy. Currently, as the market access threshold of road logistics enterprises is relatively low, logistics enterprises in China are mostly consignment departments, and their vehicles are always affiliated or temporarily rented, so there are very few vehicles under their ownership[1]. Logistics enterprises

1According to research, even some logistics enterprises with relatively high volume of business have few vehicles under their ownership. The reason is that the vehicles are owned by individual carriers. The majority of them own one to two vehicles. They just transport goods, and do not operate logistics enterprises. This oversupplied market makes the owners of vehicles have to affiliate with logistics enterprises or provide their vehicles to the logistics enterprises under lease. However, under such circumstances, the vehicles cannot be properly managed, repaired and maintained, and the economic strength and guarantee capacity of the logistics enterprises are reduced, making it hard to ensure the safety and quality of transport.

operating multimodal transport and international transport are scarce. The numerous consignment departments compete with each other fiercely, but are unable to compete with large international logistics enterprises. In order to get orders, some consignment departments arbitrarily lower the charging standard, even offering junk prices. As a result, there have been many cases where the consignment department collected a large amount of payment for goods and then ran off with the money or sold the goods privately. Therefore, by inspecting the existing market access system of logistics enterprises, we can find very serious problem of reasonability.

2.3 In respect of legal subject, the legislation lacks differentiation

There are different business areas in the logistics industry, so different market access conditions should be designed for different market entities, in order to differentiate different types of logistics enterprises. This differentiation does not violate the principle of equality. However, the existing market access system of logistics enterprises has a problem of seriously insufficient differentiation of logistics enterprises, which directly caused the great unbalance among different business segments in the logistics industry.

3 Comparisons between National Road Transport Regulation and Provincial Road Transport Regulation

In the following paragraphs, the articles of the National Road Transport Regulation and Provincial Road Transport Regulation are analyzed, with an emphasis on their differences in respect of provisions concerning the market access system of road goods transport enterprises.

As an administrative regulation, National Road Transport Regulation made the following provisions in its Article 22 concerning the preconditions for operating freight transport business: "Applicants for the freight transport business shall meet the following conditions:(1) Have vehicles suitable for its business and qualified after tests;(2) Have drivers who satisfy the conditions provided in Article 23 hereof;(3) Have a sound transport safety management system."Article 24 makes the following provisions: "Applicants for freight transport business of hazardous goods shall also meet the following conditions: (1)Have more than 5 qualified special vehicles and equipment for transporting hazardous goods;(2)Have drivers, loaders and supercargoes who passed the examination organized by the traffic administration of the municipal people's government and obtained certificates;(3)The special vehicles for transporting hazardous goods are equipped with necessary communication tools;(4)Have a sound transport safety management system."

However, as a local regulation, the Provincial Road Transport Regulation made provisions different from that in the National Road Transport Regulation. Article 30 of the Provincial Road Transport Regulation provides: "In order to get business license for road transport of normal goods and special goods, the applicant shall apply to the road transport administration higher that county level and shall satisfy the following conditions(1)Has the amount of capital appropriate for its business;(2)Has more than 5 qualified vehicles;(3)Has drivers meeting the provided conditions;(4Has a sound transport safety management system and service quality guarantee measures;(5)Has a fixed office place and parking lot appropriate for its scope and scale of business."

By comparing the abovementioned administrative regulation and local regulation, we can find the following differences between the National Road Transport Regulation and Provincial Road Transport Regulation:

(1) National Road Transport Regulation makes separate provisions for the market access system of logistics enterprises operating normal goods transport and hazardous goods transport in Article 22 and Article 24, respectively; yet the Provincial Road Transport Regulation combined the two types of logistics enterprises, making uniform provisions for these enterprises in Article 30 of the regulation.

(2) The provisions in the National Road Transport Regulation are relatively in principle and vague, yet the provisions in the Provincial Road Transport Regulation are more specific, and greatly elevate the market access threshold. The former provides that road transport enterprises shall meet the requirements in respect of qualification of vehicles and drivers, transport management system and necessary communication tools. On the basis of these requirements, the latter adds requirements in respect of capital, service quality guarantee measure, office place and parking lot.

In view of the different provisions in these two regulations, the author holds that the provisions in the Provincial Road Transport Regulation have their reasonability, yet need investigation into their legitimacy.

(1) probably violate the legal priority principle

Legal priority can be simply construed as the prior application of law. The Provincial Road Transport Regulation by nature is a local regulation enacted by the Standing Committee of Shandong Provincial People's Congress, yet the National Road Transport Regulation by nature is an administrative regulation enacted by the State Council. In China, the legal force of laws and administrative regulations are higher than local regulations, and local regulations shall not conflict with the Constitution, laws and administrative regulations. In case the laws and administrative regulations have made provisions for a matter and local regulations need to make detailed provisions, they shall be made within the scope of provisions made by the laws and administrative regulations. Therefore, the access conditions and basis explicitly provided by the administrative regulations shall be complied with by local regulation, rather than changing them. That is to say, the Provincial Road Transport Regulation shall not conflict with the National Road Transport Regulation.

However, although the Provincial Road Transport Regulation shall not conflict with the National Road Transport Regulation, the former does not have to copy the provisions made by the latter. The former can make detailed provisions within the scope of the latter's provisions. The author holds that the Provincial Road Transport Regulation can make requirements for the amount of vehicles according to its authority and in connection with the actual situation of the region. After all, the level of economic development, market status as well as quality and financing capacity of enterprises in different regions and industries of China are different, so the scale and development level of logistics industry in various regions are greatly different. Besides establishing the nationwide logistics market access laws and regulations, the local governments shall also enact the logistics regulations appropriate for their own economic basis and conditions.

(2) Probably violate the reasonability principle

The reasonability principle means that the files and activities of administrative organs should be objective, appropriate and reasonable. In particular, subjectively, the files published and measures taken by administrative organs shall treat the same situation equally and different situations differently; objectively, the measures and approaches taken by administrative organs shall be necessary and appropriate; when implementing administration, administrative organs may take different approaches to realize the goals of administration, and shall avoid the approaches that may impair the interests of relevant parties.

By inspection Article 22 and Article 24 of the National Road Transport Regulation, we can discover that in comparison with requirements for applicants operating normal goods transport business, the regulation gives higher requirements for applicants operating hazardous goods transport business. This is mainly embodied by the more strict requirements on vehicles and persons, and also added the requirement on necessary communication tools. However, this differentiated treatment is unified in the Provincial Road Transport Regulation. To say the least, even if it is appropriate to treat normal goods transport enterprises and hazardous goods transport enterprises without differentiation, the normal goods transport enterprises have different levels and capabilities. They may be a limited company, a joint stock company, partnership or individual proprietorship, so using a single standard for these logistics enterprises with different actual conditions can hardly be deemed as appropriate and feasible. The author holds that the Provincial Road Transport Regulation was enacted for the purpose of elevating the access conditions for logistics enterprises, but besides the precondition of legitimacy, such more strict access conditions should also be reasonable. They should be appropriate for the actual needs of enterprises of different types and levels, in order to ensure the actual feasibility and vitality of the access conditions.

However, if the provisions in the National Road Transport Regulation concerning the market access system of logistics enterprises are scientific and sound? In the phrase "Have vehicles suitable for its business and qualified after tests", it is very vague whether the term "have" means "own" or "rent" or "affiliate"; besides, there is no minimum requirement for the capital, thus the debt paying ability of logistics enterprises cannot be ensured; the service quality guarantee measure are not mentioned; and there is no requirement for the qualification of staff. There necessary requirement are omitted, showing the roughness of legislation, yet the Provincial Road Transport Regulation make some considerations in these respects.

4 Suggestions for consummating the market access system of logistics enterprises

On the basis of the abovementioned analyses and investigation, aiming at the existing market access system of road transport logistics enterprises, the author gives the following reasonable suggestions:

4.1 Enact a slip law – Logistics Law

Currently, China lacks a basic legislation in respect of logistics. As a special civil and commercial area that relates to national interest and people's livelihood, the logistics industry needs an independent slip law to adjust and regulate the legal relations in this industry. Furthermore, viewing from the aspect of comparison, many countries adopting the continental law system have their logistics law, such as Japan. The Logistics Law can elevate the legal level of the market access system of logistics enterprises and enhance the general applicability of the law. In this way, the National Road Transport Regulation and Provincial Road Transport Regulation will be governed by the Logistics Law, and the constitutional conflict between the two regulations in respect of the access conditions of logistics enterprises will be properly solved on the level of law.

4.2 Consummate the existing rules and regulations

The existing rules and regulations concerning logistics are confused, and the market access system of logistics enterprises are not coordinated and unified. In order to maintain the suitability and stability of the Logistics Law, the legislative body should pay close attention to clearing obsolete regulations, integrating repeated or conflicting rules, revising the legal system and repairing legal loopholes. At the same time, in view of the great different among the scale and development level of the logistics industry in various regions caused by the extreme unbalanced economic development in these regions, besides establishing a nationwide market access system of logistics enterprises, market access rules and regulations that correspond to the needs of local logistics industry development shall be enacted according to the actual situations of various regions.

4.3 Strengthen the Construction of Provincial Regulations

China is in the primary stage of socialism with the long-term. The prominent characteristic of the stage is extreme imbalances of regional economic development. The imbalances of economic development in different regions result in big differences of the logistics development scale and level. Therefore, while the national market access system of logistics enterprises is constructed, the regional market access system shall be also formulated according to the reality of the situation in order to meet the needs of local development of logistics industry. "Provincial Road Transport Regulation" as a provincial local regulation shall abide by the "Legislative Law" and "Administrative Licensing Law", and in accordance with the law order rules, is formulated within the framework of "National Road Transport Regulation". The market access system of logistics enterprises enacted by "Provincial Road Transport Regulation" in some aspects is in violation of the law and regulation with upper order, although it has the merits and rationality from the view of meeting the requirement of local logistics industry development. So the local legislator shall carefully examine the legality and coordination of provincial regulation with the host law.

4.4Establish a differentiated market access system

It has become an inevitable requirement to establish different market access systems for different types of logistics enterprises. The author believes that, according to the different types of civil subjects, the following regulations can be made concerning the market access conditions of logistics enterprises in China:

4.4.1 Market access of normal goods road transport logistics enterprises

As a special industry that relates to national interest and people's livelihood, the normal goods road transport industry has its own industrial characteristics and market attributes. The provisions in Article 22 of the National Road Transport Regulation are special requirements as to the access conditions of logistics enterprises, but the access threshold can be appropriately elevated. Especially regarding the provisions for vehicles, the owned, affiliated and rented vehicles should be differentiated, and the logistics enterprises should be encouraged to hold the title to the majority of their vehicles. Furthermore, the author suggests that the legislative body refers to the Classification and Evaluation Indices of Logistics Enterprise, and make more specific provisions for logistics enterprises of different organizational forms such as Joint Stock Company, limited company, partnership and individual proprietorship enterprise in respect of capital, equipment and facilities, management and service, quality of staff and level of informatization. Of course, it may also set up a range, and let the local regulations to make detailed provisions within the range and according to the actual situation of the province. Another principle is to encourage logistics enterprises to operate multiple businesses such as transport, storage, processing, packaging, handling, loading/unloading, distribution and information processing, etc., and encourage them to operate multimodal transport and international transport. The requirements on logistics enterprises operating multiple logistics businesses, multimodal transport and international transport shall be eased, in order to support more logistics enterprises to engage in modern logistics.

4.4.2 Market access of special goods road transport logistics enterprises

Special goods road transport logistics enterprises means the logistics enterprises operating special logistics businesses, and should only be registered after being approved by relevant administration. As the freight activities conducted by these enterprises are very dangerous, and are prone to cause personal injury and property loss, they are a special type of road goods transport enterprises, therefore the qualifications and conditions for these enterprises to access the market should be more strict than that for normal logistics enterprises. The provisions in Article 24 of the National Road Transport Regulation are made aiming at hazardous goods transport enterprises, which are relatively reasonable, but may set up a too low threshold for the market entities to access the market. For instance, the article provides that hazardous goods transport enterprises with 5 qualified vehicles can apply for registration. In practice, there are many cases where logistics enterprises report the affiliated or rented vehicles as their own vehicles. Due to the private law nature of the Logistics Law, according to the principle of private autonomy, what is not explicitly prohibited by law is legitimate, so the said situation is legitimate. However, this conduct is very harmful in practice, as if it is widespread, the capacity of duties of many logistics will be weakened unlimitedly, thus impairing the security and stability of market transactions. Therefore, it must be explicated provided that affiliated and rented vehicles shall not be reported as the vehicles owned by logistics enterprises, namely a logistics company shall have ownership over the 5 vehicles.

What needs reminding is that due to influence by the traditional views, the reform of management system always fall behind the reform of economic system. The logistics industry of China still adopts a scattered or diversified management system, which involves specialized departments of railway, traffic, water transport, civil aviation and trade, as well as comprehensive departments such as National Development and Reform Committee and State Economic and Trade Commission. There are divisions and intersections among the works of various departments, causing the barriers between higher and lower levels or between different departments and regions in the management of logistics industry, which directly affects the establishment of an unified market access system of logistics enterprises, and increases the difficulty for logistics enterprises wishing to engage in multimodal transport, international transport and comprehensive logistics businesses to access the market. Plus, the existing market access conditions of logistics enterprises are neither clear nor easily operable, so need research and revision. The author wishes to use the article as a modest spur to induce others to come forward with their valuable contributions.

Abstract: The construction industry is one of the Chinese pillars of national economic development industry. Construction materials is known as the foundation of the construction industry, and the supply chain costs of construction materials account for a large proportion in the whole construction project, so reducing the supply chain cost of construction materials has become an inevitable trend in the reform and development of construction industry. This paper adopts the method of the supply chain operations reference model and is guided by the vendor managed inventory (VMI) philosophy to model the construction materials supply chain based on each kind of construction materials, include stock, standard and customized construction materials. Comparing with the traditional inventory management in construction industry which means every enterprises in the supply chain only cares and manages the inventory of its own, under the VMI the flow of information is more clear and direct, and suppliers in the whole supply chain, combining with the actual needs can develop more efficient inventory procurement and delivery plans resulted in saving the unnecessary waste and duplication. This study can provide basis for future developing information system in construction industry.
Keywords: VMI; Construction materials supply chain; SCOR.

1 Introduction

Initially, there was an opposite relationship based on the pure business interest of each enterprise in the supply chain. With the rapid development of current economics and the wide application of information network technology, this relationship has gradually developed as the common interests partnership, which also pushes the emergence of the key and advanced inventory management concepts and techniques in the supply chain. The supply chain inventory management is a kind of new, efficient modern supply chain inventory management ideas spawned under the new environment of the supply chain (Huang, 2006).

Vendor managed inventory (VMI) refers to a newly management mode in the supply chain, which is that based on sales information and inventory volume from downstream enterprises in the supply chain downstream enterprises in the same supply chain hold a proactive attitude to manage and control downstream inventory held by other enterprises, through highly sharing of the information resources from the upstream supply chain (Liu, 2011).

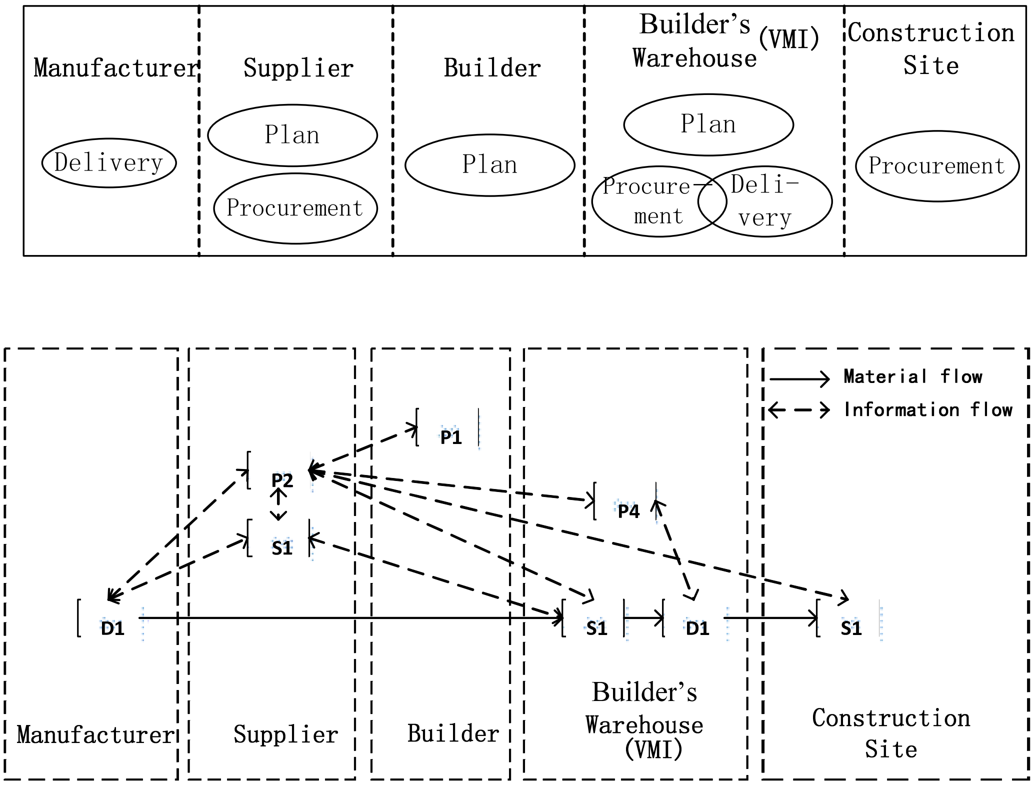
This inventory management strategy breaks the traditional pattern of inventory management which means that every enterprise only manages its own inventory. It is a cooperation strategy between the partners of supply chain strategy embodying a kind of integrated supply chain methodology, and is a kind of inventory decision agent model (Sun, 2009). VMI takes the idea of collaboration and system to manage inventory and enables the whole supply chain collaboratively operate which reflects the integrated supply chain management ideas and adapts to the changing market requirements (Chen, 2009).

The main operation flow of implementation of VMI for a construction project can be expressed as: the builder of this construction project provides market information and demand to the chosen suppliers; the supplier is responsible for replenishing inventory in the warehouses appointed by the builder and pass the demand forecast feedback to the builder; and both parties make decisions in order and maintain mutual coordination and cooperation. The suppliers control the whole supply chain logistics and information flow, and combining with the information from the builder, the chosen manufacturers, develop procurement and delivery plans to coordinate the supply chain as a whole. This paper following the study of Cheng et. al. (2010) will use the vendor management inventory (VMI) to guide modeling construction materials supply chain based on SCOR method. This study can provide basis for future developing information system in construction industry.

2 Stock Construction Material Supply Chain under VMI

Creation of a model of a stock construction materials supply chain under the VMI mode mainly relates to the five parties, including a construction site, warehouses appointed by a builder, a builder, suppliers and manufacturers. According to the level 1 and level 2 model of the SCOR method, a supply chain model of such kind of products is built (refer to Fig. 1). The dotted line and the solid line show the flow of information and the flow of construction materials respectively.

The builder, based on the progress of the construction project specific requirements, develops a supply chain plan for these kinds of stock construction materials. Under the vendor managed inventory, suppliers make decision on a purchasing plan considering these situations of upstream and downstream enterprises and the whole supply chain. The suppliers guided by the supply chain plan provided by the builder develop supply chain procurement plans, which then are transferred to manufacturers, the warehouse appointed by the builder, and the construction site. Immediately receiving the procurement plans, the manufacturers will directly deliver the ordered construction materials to the appointed warehouse, and the warehouse makes a product delivery plan. According to the plan the warehouse will deliver reasonable the stock construction materials to the construction site.



P1:Supply plan; P2: Purchasing Plan; P4: Delivery Plan;
S1: Purchasing Stock Materials; D1: Delivery Stock Material

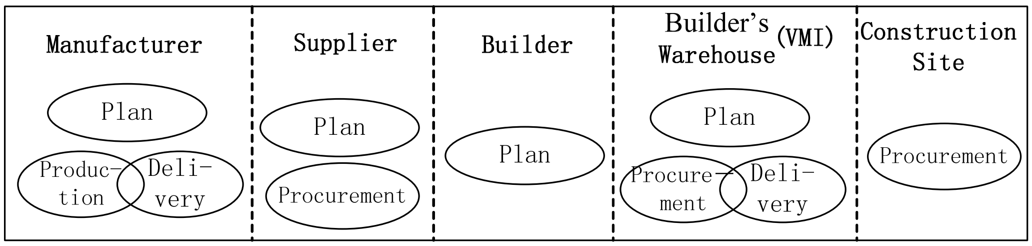
Figure1. Stock Construction Material Supply Chain Under VMI

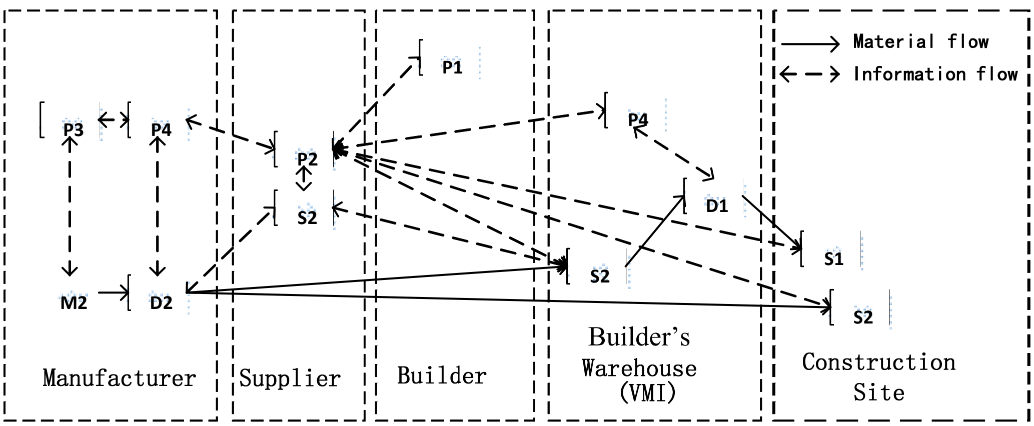
3 Standard Construction Material Supply Chain under VMI

Creation of a model of a standard construction materials supply chain under the VMI mode mainly relates to the five parties, including a construction site, warehouses appointed by builder, a builder, suppliers and manufacturers. According to the level 1 and level 2 model of the SCOR method, a supply chain model of such kind of products is built (refer to Fig. 2). The dotted line and the solid line show the flow of information and the flow of construction materials respectively.

The builder according to the progress requirement of a construction project sets up a supply chain plan, which is then transferred to the suppliers. Based on the information on the supply chain plan, the suppliers make procurement plans for standard construction materials. The procurement plans are shared with the warehouses appointed by the builder, the construction site and the manufacturers. The manufacturers according to the superior purchasing plan make the required construction materials production plan and an appropriate delivery plan. After finishing producing the ordered construction materials, manufacturers directly distribute a part of the materials to the construction site in order to timely meet the demand from the construction site, and the rest part is delivered to the warehouses appointed by the builder, and then is distributed by the decision of the warehouses.

According to the procurement plan information and the physical products, the warehouses considering the upstream procurement plan and the manufacturer's distribution plan, construction schedule and construction site arrangement, draw the final delivery plan to the construction site.





P1:Supply plan; P2: Purchasing Plan; P3: Production Plan; P4: Delivery Plan; S1: Purchasing Stock Materials; S2: Purchasing Standard Materials; M2: Production Standard Materials; D1: Delivery Stock Materials; D2: Delivery Standard Materials

Figure2. Standard Construction Material Supply Chain Under VMI

4 Customized Construction Material Supply Chain under VMI

Creation of a model of a customized construction materials supply chain under the VMI mode mainly relates to the five parties, including a construction site, warehouses appointed by builder, a builder, factories and manufacturers. According to the level 1 and level 2 model of the SCOR method, a supply chain model of such kind of products is built (refer to Fig. 2). The dotted line and the solid line show the flow of information and the flow of construction materials respectively.

For the information flow of the customized construction materials model, the builder according to the actual demands of the construction project, develops the supply chain plan and transfers the information to the upstream factory. The factory according to the received plan develops the procurement plan and procurement of specific products, and then transfers the purchasing plan to the manufacturer. The manufacturer based on the obtained information sets up a customized construction materials production plan and an appropriate delivery plan. At the same time, the factory passes the purchase plan to the warehouses appointed by the builder and the construction site, and then the warehouses develop the delivery plan to the construction site according to the information obtained from the factory.

After each party receiving the corresponding plans, the production process starts. The manufacturers deliver the raw materials used to manufacture customized construction materials to the factory. The factory, after receiving raw materials, starts to make the production and processing according to the specific requirements of the construction project, outputs the customized products, and makes the delivery. There are two the case for the delivery: the first case is that the ordered construction materials, the factor directly distributes a part of the materials to the construction site in order to timely meet the demand from the construction site; the second case is that the rest part is delivered to the warehouses appointed by the builder, and then is distributed by the decision of the warehouses.

5 Conclusions

This paper adopts the method of the supply chain operations reference model and is guided by the VMI philosophy to model the construction materials supply chain based on each kind of construction materials, include stock, standard and customized construction materials. Comparing with the traditional inventory management in construction industry which means every enterprises in the supply chain only cares and manages the inventory of its own, under the VMI the flow of information is more clear and direct, and suppliers in the whole supply chain, combining with the actual needs can develop more efficient inventory procurement and delivery plans resulted in saving the unnecessary waste and duplication. This study can provide basis for future developing information system in construction industry.

Abstract: Elaborating a distribution model type which is “station-to-door” or “door-to-station” under the background that market of express delivery is developing rapidly and the reform of the rail cargo. Then we analysis the advantages of independent management distribution model and collaborative business distribution model. And determining the distribution model for CRE based on the comprehensive evaluation method and entropy method. The paper also analysis what the corporation needs when the corporation chooses collaborative business distribution model. Finally, the paper analysis income-distribution of each collaborative logistics companies based on Nash income distribution model.
Keywords: Logistics; Comprehensive evaluation method; Entropy law; Nash allocation model; Income distribution.

1 Introduction

The statistics of the China’s express delivery business volume show that the rapid growth of the China’s express delivery volume in 2003-2013(WU Zhongkai, 2014). The experts expect the growth rate of the express will reach 40% in 2014. The growth rate of the domestic express business volume will exceed 20%. The ratio of the road transportation is 80%，the air transportation is 15%, and the railway transportation is less than 5% (LI Ding, 2011). No matter the large or small pieces of cargo transportation, the rail market share decreased year by year. This situation makes the China’s express delivery business faced serious challenges. At present the zero single volume of daily average of the railway express freight transportation is about 1.5 million. But only 30% businesses provide "door to door" service. At present the logistics distribution business point of the railway express freight transport just concentrate on the urban areas which along the railway. Its "tentacles" just come into contact the limited range. This situation has significant limitations on the edge area of the logistics distribution. Compared with the other third-party logistics enterprises, the railway express freight transportation loss the competitiveness. Both ends of the logistics distribution of the service level and efficiency will directly impact on the overall effectiveness of the rail freight. In order to enhance service levels at both ends, the railway express freight transportation will choose the autonomous business model or the collaborative business model has been a debatable question. This situation has important guiding significance for the cargo transport organization mode in the future.

2. The selecting condition research of the delivery mode

Under normal circumstances，the railway sites always related to the first-tier and the second-tier cities(CHEN Xiaojuan,2012). In these cities, the logistics distribute only need autonomous delivery which can meet the requirements. The three-tier and the four-tier cities and the rural villages always adopt the appropriate coordination delivery which can save the logistics costs.

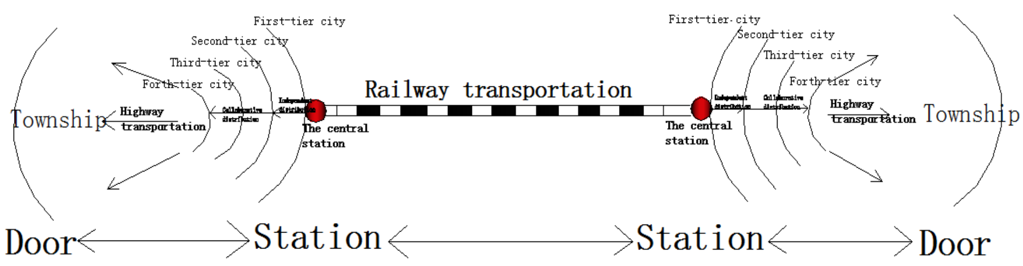

Figure1. logistics distribution mode of the railway express freight transport

2.1 The choice of the distribution mode which based on the comprehensive evaluation method

The comprehensive evaluation method can effectively reflect the various indicators , and reflect a comprehensive, holistic and hierarchical distribution model. (GONG Huang, 2007)The most important is that the comprehensive evaluation method determines the index weights. For the determining of the index weight by the article reference usually determined the entropy method. Therefore the relevant personages combine the comprehensive evaluation method and the entropy method to help the decision makers choose the distribution model(WU Fengying, 2011).

The specific evaluation model is：

$$Exp = \sum_{i=1}^{m} B_i \times P_i \qquad (1)$$

In the first formula,Exp is the comprehensive benefit evaluation;B_i is the first i index entropy;P_i is dimensionless value of the first i index;m is the number of indicators.Using the extreme value method to process P_i ,the calculation formula is:

$$P_i = \frac{p_{ij} - \min|p_{ij}|}{\max|p_{ij}| - \min|p_{ij}|} \times 10 \qquad (2)$$

In the second formula,P_{ij} is statistical values of this index; $\max|p_{ij}|$ is the maximum in all scenarios; $\min|p_{ij}|$ is the minimum in all scenarios.In this model,B_i can be calculated by the entropy weight method.Next,use of B_i and P_i calculated by Exp,the value of the maximum scheme represents the optimal scheme by comparing different schemes.then you'll use the entropy weight method to calculate the value of B_i.There are n schemes, m indexes will form the original matrix $P=(p)_{ij}$,P_{ij} is the first i index in the first j scheme value.In order to eliminate the influence of each index due to different units,and each statistical values are normalized by equation 2 to distinguish with P_i.

f_{ij} is the proportion of the first i index in the first j scheme, k_i is the first i index of entropy weight,the calculation formulas are

$$f_{ij} = q_{ij} / \sum_{j=1}^{n} q_{ij} \quad , \quad k_i = -c\sum_{j=1}^{n} q_{ij} \cdot \ln(q_{ij}), c = 1/\ln(n) \qquad (3)$$

b_i is the first i index of entropy weight,the calculation formula is:

$$b_i = (1-k_i) \Big/ \sum_{i=1}^{m} (1-k_i) \qquad (4)$$

After determining the choice model, through in-depth study of railway express freight transport enterprises and comparisons of other logistics enterprises, 7 indicators are selected for evaluation. They are the turnover, profit, goods collection time, delivery time, site storage scale, and logistics cost, satisfaction of consignors. In each site, these data of radiation region are collected, and then after using the selection model, the choice of independent operation mode of distribution or collaborative management mode of distribution of the area can be made through calculation.

2.2 The distribution of benefits in the pattern of collaborative management distribution based on Nash model

In the view of resources Possession rate of the market and the whole benefit, the short term dynamic alliance between the synergy and cooperation of logistics enterprises , achieve far greater economic and social benefits than the business model of single logistics enterprise(WU Lang,2009). In order to make one's own resources effectively utilized, make the maximum benefit from the minimum cost of inputs, so that the collaborative logistics enterprises can reach a consensus on "risk sharing, benefit sharing ".

2.2.1 Model hypothesis

Hypothesis1: **t**he scale economy income produced from cooperative management distribution mode between the railway express freight transportation and other logistics enterprises generated value is greater than the economic benefits and value the independent distribution individual enterprises produce.

Hypothesis2: the profit collaborative logistics enterprises are assigned is greater than the enterprise independent logistics distribution generated.

Hypothesis3: only considering the distribution coefficient and income between each collaborative logistics enterprise, does not take into account other factors.

2.2.2 The establishment of the model

Suppose there are N logistics companies in the collaborative management and distribution alliance. The enterprises proposed a coordination scheme of benefits distribution and the corresponding solutions distribution coefficients α_j

$$\alpha_j = \left(\alpha_{1j}, \alpha_{2j}, \alpha_{3j} ... \alpha_{nj}\right), j = 1,2,3,...n$$

α_{ij} is the profit distribution coefficient which the first i cooperative enterprise get from a coordination scheme of benefits distribution by the first j cooperative enterprise, $0 \le \alpha_{ij} \le 1$, $\sum_{i=1}^{n} \alpha_{ij} = 1$,the distribution coefficient matrix of interest distribution scheme is :

$$\alpha_{ij} = \begin{bmatrix} \alpha_{11}, & \alpha_{12}, & ..., & \alpha_{1n} \\ \alpha_{21}, & \alpha_{22}, & ..., & \alpha_{2n} \\ ..., & ..., & ..., & ... \\ \alpha_{31}, & \alpha_{32}, & \alpha_{33}, & \alpha_{3n} \end{bmatrix}$$

During setting the benefit programs ,the collaborative logistics companies set up their own distribution coefficient of the expect interest. We can suppose distribution scheme of the expected revenue as follows:

$$\alpha_i^+ = \left(\alpha_{11}^+, \alpha_{22}^+, \ldots, \alpha_{nn}^+\right), \sum_{i=1}^{n} \alpha_i^+ \geq 1$$

The collaborative logistics companies exist the lower bound of interest distribution coefficient. The lower bound also determines the benchmark coefficient of cooperation and coordination.We can suppose the program as follows:

$$\alpha_i^- = \left(\alpha_1^-, \alpha_2^-, \ldots, \alpha_n^-\right) = \min\left(\alpha_{1j}, \alpha_{2j}, \ldots, \alpha_{nj}\right)^T, j = 1,2,\ldots,n$$

The expected value of interest distribution coefficient of each company is not equal to 1,so the collaborative logistics companies negotiate amendments expected profit value,we set up χ_i as this coefficient. The final interest distribution coefficient is μ_i , $\sum_{i=1}^{n} \mu_i = 1$,and the final interest distribution coefficient is not less than coordinate reference coefficient α_i^-,so:

$$\mu_i = \alpha_i^+ - \chi_i \text{ and } \mu_i \geq \alpha_i^-$$

We can use Nash model to deal with multilateral negotiation problem and we can get the final benefit allocation scheme, next find the best correction coefficient $\chi_i = \left(\chi_1, \chi_2, \ldots, \chi_n\right)$,Nash model is:

$$\max\left\{\left(\alpha_1^+ - \chi_1 - \alpha_1^-\right)^{w_1}, \left(\alpha_2^+ - \chi_2 - \alpha_2^-\right)^{w_2}, \ldots, \left(\alpha_n^+ - \chi_n - \alpha_n^-\right)^{w_n}\right\} \quad (5)$$

$$W_i = \left(\alpha_i^+ - \chi_i\right) \times \Phi \quad (6)$$

$$s.t \begin{cases} \alpha_i^+ - \chi_i \geq \alpha_i^- \text{ , i=1,2......,n} & (7) \\ \sum_{i=1}^{n} \alpha_i^+ \geq 1 & (8) \\ \sum_{i=1}^{n} \left(\alpha_i^+ - \chi_i\right) = 1 & (9) \end{cases}$$

The fifth formula is objective function, $\alpha_i^+ - \chi_i - \alpha_i^-$ is the difference between an enterprise final profit distribution coefficient and coefficient of reference consultation,and it greater than zero. w_i is an important vector in the whole cooperative enterprise in the Alliance, $\sum_{i=1}^{n} w_i = 1$

The sixth formula evinces the final benefits between the collaborative companies.

From the seventh to the ninth formulas are the constraint conditions. The eighth formula represents the profit allocation coefficient can not less than the coordinate reference coefficient. Otherwise, the companies will not cooperate the programs. The ninth formula evinced the total amount of the distribution coefficients of expected revenue is more than1.When the enterprises set the partition coefficient ,they always consider their own interests. The tenth formula evinced that the total amount of the ultimate benefit distribution coefficient is 1.

2.2.3 The solving way of model transformation

According to the Kuhn-Tucker conditions, We can calculate the correction coefficient χ_i

$$\chi_i = \alpha_i^+ - \alpha_i^- - w_i \cdot \left(1 - \sum_{i=1}^{n} \alpha_i^-\right) \tag{10}$$

The final interest distribution coefficient of the first i cooperative enterprise, μ_i is:

$$\mu_i = \alpha_i^- + w_i \cdot \left(1 - \sum_{i=1}^{n} \alpha_i^-\right) \tag{11}$$

The final income and expenses of the first i cooperative enterprise is W_i :

$$W_i = \left[\alpha_i^- + w_i \cdot \left(1 - \sum_{i=1}^{n} \alpha_i^-\right)\right] \times \Phi \tag{12}$$

The final interest distribution coefficient in the twelfth formulas is composed by the coordinate reference coefficient and compensation coefficient, so according to the cooperative alliance overall income and expenses to calculate the final income and expenses of each cooperative enterprise.

3 Model application

There is a logistics and distribution business from Chengdu to Chongqing, A is railway express company, B is transport company, C is warehousing company. And the estimated total revenue is 4 million RMB. According to the proportion of investment in collaborative alliances ,combine with expert's experience and opinion,and the satisfaction of three partner companies for the distribution of income so that get the benefit allocation scheme of initial business:

$$\mu_i^{'} = \left(\mu_1^{'}, \mu_2^{'}, \mu_3^{'}\right) = \left(0.44, 0.31, 0.25\right)$$

Coordinate the initial program according to the actual distribution business,so company A,B and C put forward the corresponding benefit allocation scheme:

$$\alpha_{ij} = \begin{matrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{matrix} \begin{bmatrix} \alpha_{11}, & \alpha_{12}, & \alpha_{13} \\ \alpha_{21}, & \alpha_{22}, & \alpha_{23} \\ \alpha_{31}, & \alpha_{32}, & \alpha_{33} \end{bmatrix} = \begin{bmatrix} 0.45, & 0.30, & 0.25 \\ 0.41, & 0.33, & 0.26 \\ 0.40, & 0.32, & 0.28 \end{bmatrix}$$

we can get the importance of vector of expert whole collaborative alliance based on the expert assessment:

$$w_i = \left(w_1, w_2, w_3\right) = \left(0.50, 0.30, 0.20\right)$$

So the three companies expected revenue distribution scheme is:

$$\alpha_i^{+} = \left(\alpha_{11}^{+}, \alpha_{22}^{+}, \alpha_{33}^{+}\right) = \left(0.45, 0.33, 0.28\right)$$

Three companies benchmark coordination coefficient scheme is:

$$\alpha_i^{-} = \left(\alpha_1^{-}, \alpha_2^{-}, \alpha_3^{-}\right) = \min\left(\alpha_{1j}, \alpha_{2j}, \ldots, \alpha_{nj}\right)^T = \left(0.40, 0.30, 0.25\right)$$

The distribution of benefits in the pattern of collaborative management distribution based on Nash model. Calculate correction coefficient beside on the eleventh formula.So χ_i is :

$$\chi_i = \left(\chi_1, \chi_2, \chi_3\right) = \left(0.025, 0.015, 0.020\right)$$

We can calculate final income distribution coefficient beside on the twelfth formula , μ_i is:

$$\mu_i = (\mu_1, \mu_2, \mu_3) = (0.425, 0.315, 0.260)$$

We can calculate final earnings value of the three companies beside on the seventh formula, W_i (millions) is :

$$W_A = 0.425 \times 4 = 1.7,\quad W_B = 0.315 \times 4 = 1.26,\quad W_C = 0.260 \times 4 = 1.04$$

4 Conclusions

Facing the current logistics market, the "door to door" transportation is quite necessary for the railway express freight company. The option of the both ends of the logistics distribution pattern will affects the efficiency of enterprises in a large extent. The effective utilization of the comprehensive evaluation method makes the appropriate guidance for the railway express freight transportation. In reality according to the distribution capacity of the logistics enterprise service site, the factory can choose the corresponding distribution mode. The logistics companies choose the collaborative distribution model, the logistics companies can allocate the profits by using the advantage of the income allocation model of Nash and the collaborative logistics companies require the higher satisfaction level of the income distribution coefficient and greater acceptance. This situation settles solid foundation for the future logistics enterprise and shares the market resources of the logistics effectively. It has great guiding significance on the business of logistics and distribution in the future.

Abstract: We examine the decision problems for one retailer and one manufacturer in a supply chain under the influence of governmental via carbon tax policy and subsidy financial instruments, in which manufacturer produces two kinds of products to a retailer, and the retailer resells them to the customers with price dependent demand. The two-stage game-based models under three different carbon tax policies are constructed to formulate the aforementioned decision problem in a supply chain. Comparison analysis for pricing decision models under different carbon tax policies is performed and some managerial insights are drawn. At last, a numerical example is given to demonstrate the effectiveness of the proposed models and conduct sensitiveness analysis. The impact of manufacturer's production costs, government carbon tax and green subsidy on the profits of manufacture, retailer and supply chain is analyzed.

Keywords: Emission tax; Green subsidy; Stackelberg game.

1 Introduction

Recently, environment problem is increasingly stressed by individual governments. A rich literature has developed for analyzing supply chain pricing decision with the consideration of carbon emissions. Supply chain pricing decision has been analyzed by many scholars. Santanu and Sarmah (2010) analyzes the coordination and competition issues in a two-stage supply-chain system where two vendors compete to sell differentiated products through a common retailer in the same market. The demand of a product not only depends on its own price, but also on the price of the other. Ruo et al. (2013) develops models for the determination of the retail price and the order quantity for the buyer, as well as the production batch size, wholesale discount and/or the credit period offer for the supplier, under five different scenarios.

This paper is also related to product substitution. Sang and Bell (2011) investigate the impact of demand substitution on production quantity levels for the cases of symmetrical and asymmetrical demand substitution. Chen et al. (2013) consider pricing policies for substitutable products in a supply chain with one manufacturer, who sells a product to an independent retailer and directly to consumers through an Internet channel. Banerjee and Chatterjee (2014) analyze the effect of asymmetric product differentiation on the profit ordering of firms in a sequential game. However, these papers don't consider the product substitution resulted from carbon emissions.

Supply chain decision with carbon emissions is increasingly analyzed by existing researchers. Yang and Zhang (2011) propose some strategies on how to advance cooperation satisfaction among enterprises based on low carbon supply chain management in order to enhance the competence of the whole supply chain. Du(2013) studies the decision model for a emission-dependent supply chain consisting of one single emission dependent manufacturer and one single emission permit supplier in the 'cap-and-trade' system. Ala-Harja and Helo(2014) analyse cases from the food industry, mainly order-picking, transportation, warehousing, and distribution aspects from the greening point of view, and consider three case examples of decisions in supply chain design in the food industry .

Since product substitution and governmental green tax and subsidy policies are very meaningful to supply chain management, we focuses on the decisions for manufacturer and retailer in competitive green supply chains while the government carbon tax on manufacturer or retailer and subsidy to consumers are considered. Manufacturer produces two types of substitutable product, one results in high carbon emission and another one results in low carbon emission.

2 Problem Description

We examine the decision problems for one retailer and one manufacturer in a supply chain under the influence of governmental via tax policy and subsidy financial instruments, in which manufacturer produces product 1 and product 2 sold to a retailer, and the retailer resells them to the customers with price dependent demand . We consider product 1 and product 2 as high carbon emission product and low carbon emission product, respectively. We further assume the government levies carbon emission taxes on manufacturer for producing high carbon emission product or retailer for selling high carbon emission product, and provides subsidies to consumers using low carbon emission product. Furthermore, we consider three different carbon tax policies adopted by the government in the supply chain. The first two polices concern the decentralized supply chain under which retailer and manufacturer make their decision separately: government levies carbon taxes on the retailer for selling high carbon product, government levies carbon taxes on the manufacturer for producing high carbon product. The third policy focuses the centralized supply chain under which retailer and manufacturer make their decision jointly. In this case , government can levy carbon taxes on the retailer or on the manufacturer. Both alternatives of levying carbon taxes lead to the same result.

The following notations are used to develop the mathematical model.q_i: the demand for product i， $i = 1,2$.p_i: retail price for product i， s: unit green subsidy for product 2， τ： unit carbon emission tax for product 1， w_i: wholesale price for product i， c_i： manufacturer cost for product i.

Similar to NirvikarSingh et al.(1984), we suppose the demand for product i is a general linear demand function of its own sale price p_i and the rival's sale price p_j, $j \neq i$. $q_1 = a_1 - b_1p_1 + c(p_2 - s)$, $q_2 = a_2 + cp_1 - b_2(p_2 - s)$ .where $b_i > c > 0$, i =1,2. That $b_i > c$ indicates that the change of p_i is more influential on product 's own demand than that of the product j 's sale price p_j is.

3 Model formulation

A two-stage game-based model under each carbon tax policy is constructed in this section to formulate the aforementioned decision problem in a supply chain. In Stage 1, we present the manufacturer's decision by maximizing its profit to obtain the equilibrium wholesale prices w_1 and w_2 for two types of products given τ and s. Based on the government's influence via τ and s as well as the wholesale prices w_1 and w_2, retailer's sale price p_1 and p_2 are determined in Stage 2. To obtain equilibrium solutions of the two-stage game-based model, this work adopts backward induction starting from Stage 3 under the goal of retailer profit maximization, ending with Stage 1 for the solutions of the government's financial intervention. The details of model formulation associated with these three-stages are presented in the following subsections.

3.1 Decision Model 1: Government Levies Taxes on retailer in Decentralized Supply Chain

In this case , retailer's profit function (Stage 2) can be expressed as

$$\pi_s^1 = \sum_{i=1}^{2} q_i p_i - \sum_{i=1}^{2} q_i w_i - q_1 \tau \tag{1}$$

The retailer is assumed to seek profit maximization. we derive the retailer's optimal retail price for given values of w_1 , w_2 , τ and s by applying the first order conditions of the retailer profit function. From $\frac{\partial \pi_s^1}{\partial p_1} = 0$ and $\frac{\partial \pi_s^1}{\partial p_2} = 0$, the retailer's retail price can be obtained as

$$p_1^{1*} = \frac{w_1+\tau}{2} + \frac{b_2 a_1 + c a_2}{2(b_1 b_2 - c^2)} \quad , \quad p_2^{1*} = \frac{w_2+s}{2} + \frac{c a_1 + b_1 a_2}{2(b_1 b_2 - c^2)} \tag{2}$$

Since $\frac{\partial^2 \pi_s^1}{\partial p_1 \partial p_2} = 2c, \frac{\partial^2 \pi_s^1}{\partial p_1^2} = -2b_1 < 0, \frac{\partial^2 \pi_s^1}{\partial p_2^2} = -2b_2 < 0$, the negative definite Hessian is checked as $\frac{\partial^2 \pi_s^1}{\partial p_1^2}\frac{\partial^2 \pi_s^1}{\partial p_2^2} - \left(\frac{\partial^2 \pi_s^1}{\partial p_1 \partial p_2}\right)^2 = 4(b_1 b_2 - c^2) > 0$. It satisfies the second-order condition for retail profit maximum.

Manufacturer's profit function (Stage 1) can be expressed as

$$\pi_f^1 = \sum_{i=1}^{2} q_i w_i - \sum_{i=1}^{2} q_i c_i \tag{3}$$

Similarly, we can obtain the manufacturer's wholesale price for given values of τ and s. From $\frac{\partial \pi_f^1}{\partial w_1} = 0$ *and* $\frac{\partial \pi_f^1}{\partial w_2} = 0$, manufacturer's wholesale price can be obtained as

$$w_1^{1*} = \frac{b_2 a_1 + c a_2}{2(b_1 b_2 - c^2)} - \frac{\tau - c_1}{2}, \qquad w_2^{1*} = \frac{c a_1 + b_1 a_2}{2(b_1 b_2 - c^2)} + \frac{s + c_2}{2} \tag{4}$$

Since $\frac{\partial^2 \pi_f^1}{\partial w_1^2} = -b_1 < 0$, $\frac{\partial^2 \pi_f^1}{\partial w_2^2} = -b_2 < 0$, $\frac{\partial^2 \pi_f^1}{\partial w_1 \partial w_2} = c$, Hessian Matrix is calculated as $\frac{\partial^2\pi_f^1}{\partial w_1^2}\frac{\partial^2\pi_f^1}{\partial w_2^2}-\left(\frac{\partial^2\pi_f^1}{\partial w_1\partial w_2}\right)^2=b_1b_2-c^2>0$. It satisfies the second-order condition for manufacturer profit maximum.

3.2 Decision Model 2: Government Levies Taxes on manufacturer in Decentralized Supply Chain

In this case , retailer's profit function (Stage 2) can be expressed as

$$\pi_s^2=\sum_{i=1}^2 q_ip_i-\sum_{i=1}^2 q_iw_i \tag{5}$$

Compared with the(1), retailer's profit do not have $-q_1\tau$, because government Levies Taxes on manufacturer。From equation $\frac{\partial\pi_s^2}{\partial p_i}=0$, i=1,2。We have the retailer's retail price can be obtained as

$$p_1^{2*}=\frac{w_1}{2}+\frac{b_2a_1+ca_2}{2(b_1b_2-c^2)}\ ,\ p_2^{2*}=\frac{w_2+s}{2}+\frac{ca_1+b_1a_2}{2(b_1b_2-c^2)} \tag{6}$$

Since $\frac{\partial^2\pi_s^2}{\partial p_1\partial p_2}=2c,\frac{\partial^2\pi_s^2}{\partial p_1^2}=-2b_1<0,\frac{\partial^2\pi_s^2}{\partial p_2^2}=-2b_2<0$as Decision Model 1, the negative definite Hessian is checked as $\frac{\partial^2\pi_s^2}{\partial p_1^2}\frac{\partial^2\pi_s^2}{\partial p_2^2}-\left(\frac{\partial^2\pi_s^2}{\partial p_1\partial p_2}\right)^2=4(b_1b_2-c^2)>0$. It satisfies the second-order condition for retail profit maximum.

Manufacturer's profit function (Stage 1) can be expressed as

$$\pi_f^2=\sum_{i=1}^2 q_iw_i-\sum_{i=1}^2 q_ic_i-q_1\tau \tag{7}$$

Compared with the(4), Manufacturer's profit has been added to $-q_1\tau$. Similarly, we can obtain the manufacturer's wholesale price for given values of τ and s. The manufacturers' wholesale prices can be derived from the first-order conditions of the respective manufacturers' profit maximization problems:$\frac{\partial\pi_f^2}{\partial w_1}=0$ and $\frac{\partial\pi_f^2}{\partial w_2}=0$.We get

$$w_1^{2*}=\frac{b_2a_1+ca_2}{2(b_1b_2-c^2)}+\frac{c_1+\tau}{2}\ ,\qquad w_2^{2*}=\frac{ca_1+b_1a_2}{2(b_1b_2-c^2)}+\frac{c_2+s}{2} \tag{8}$$

Consistent with the Decision Model 1, $\frac{\partial^2\pi_f^2}{\partial w_1^2}=-b_1<0$, $\frac{\partial^2\pi_f^2}{\partial w_2^2}=-b_2<0$, $\frac{\partial^2\pi_f^2}{\partial w_1\partial w_2}=c$, Hessian Matrix is calculated as $\frac{\partial^2\pi_f^2}{\partial w_1^2}\frac{\partial^2\pi_f^2}{\partial w_2^2}-\left(\frac{\partial^2\pi_f^2}{\partial w_1\partial w_2}\right)^2=b_1b_2-c^2>0$. It satisfies the second-order condition for manufacturer profit maximum.

3.3 Decision Model 3: Manufacturer and retailer in collaboration

There is no difference Government Levies Taxes on manufacturer or retailer if Manufacturer associates with retailer completely. The profit of manufacturer and retailer can be obtained as

$$\pi_{sf}=\sum_{i=1}^2 q_ip_i-\sum_{i=1}^2 q_ic_i-q_1\tau \tag{9}$$

We can get $\frac{\partial^2 \pi_{sf}}{\partial p_1^2} = -2b_1 < 0$, $\frac{\partial^2 \pi_{sf}}{\partial p_2^2} = -2b_2 < 0$, $\frac{\partial^2 \pi_{sf}}{\partial p_1 \partial p_2} = 2c$, Hessian Matrix is calculated as $\frac{\partial^2 \pi_{sf}}{\partial p_1^2}\frac{\partial^2 \pi_{sf}}{\partial p_2^2} - \left(\frac{\partial^2 \pi_{sf}}{\partial p_1 \partial p_2}\right)^2 = 4(b_1 b_2 - c^2) > 0$. The retail prices can be derived from $\frac{\partial E\pi_{sf}}{\partial p_1} = 0 and \frac{\partial E\pi_{sf}}{\partial p_2} = 0$ as

$$p_1^{3*} = \frac{c_1+\tau}{2} + \frac{b_2 a_1 + c a_2}{2(b_1 b_2 - c^2)}, \quad p_2^{3*} = \frac{c_2+s}{2} + \frac{c a_1 + b_1 a_2}{2(b_1 b_2 - c^2)} \tag{10}$$

Through the calculation of three models, we can get manufacturer's wholesale price, retailer's retail price and the demand for product.

Table1 Manufacturer's wholesale price, retailer's retail price and the demand for product of three models

Variable	Model 1	Model 2	Model 3
p_1^*	$\frac{\tau + c_1}{4} + \frac{3(b_2 a_1 + c a_2)}{4(b_1 b_2 - c^2)}$	$\frac{c_1 + \tau}{4} + \frac{3(b_2 a_1 + c a_2)}{4(b_1 b_2 - c^2)}$	$\frac{c_1 + \tau}{2} + \frac{b_2 a_1 + c a_2}{2(b_1 b_2 - c^2)}$
p_2^*	$\frac{3s + c_2}{4} + \frac{3(c a_1 + b_1 a_2)}{4(b_1 b_2 - c^2)}$	$\frac{c_2 + 3s}{4} + \frac{3(c a_1 + b_1 a_2)}{4(b_1 b_2 - c^2)}$	$\frac{c_2 + s}{2} + \frac{c a_1 + b_1 a_2}{2(b_1 b_2 - c^2)}$
q_1	$\frac{a_1 - b_1(\tau + c_1) + c(c_2 - s)}{4}$	$\frac{a_1 - b_1(c_1 + \tau) + c(c_2 - s)}{4}$	$\frac{a_1 - b_1(c_1 + \tau) + c(c_2 - s)}{2}$
q_2	$\frac{a_2 - b_2(c_2 - s) + c(\tau + c_1)}{4}$	$\frac{a_2 - b_2(c_2 - s) + c(c_1 + \tau)}{4}$	$\frac{a_2 + c(c_1 + \tau) - b_2(c_2 - s)}{2}$
w_1^*	$\frac{b_2 a_1 + c a_2}{2(b_1 b_2 - c^2)} - \frac{\tau - c_1}{2}$	$\frac{b_2 a_1 + c a_2}{2(b_1 b_2 - c^2)} + \frac{c_1 + \tau}{2}$	-
w_2^*	$\frac{c a_1 + b_1 a_2}{2(b_1 b_2 - c^2)} + \frac{s + c_2}{2}$	$\frac{c a_1 + b_1 a_2}{2(b_1 b_2 - c^2)} + \frac{c_2 + s}{2}$	-

From Table1, we know that is no correlation to p_1^*, p_2^*, q_1, q_2 and w_2^* in Model 1 are same to Model 2 . However w_1^* in Model 1 is smaller than in Model 2. q_1, q_2 in Model 3 are larger than in Model 1 and Model 2.

4 Numerical analysis

In this section, a typical numerical analysis will be emerged. we assume a_1=50, a_2=30, b_1=7, b_2=5, and$c$=2, the manufacturer cost c_1=2, c_2=4, nit carbon emission tax for product 1 $\tau = 3$, unit green subsidy for product 2 $s = 2$. We analysis sensitivity of manufacturer cost for product , unit green subsidy for product 2 and unit carbon emission tax for product 1.

5 Conclusions

This paper addresses the retailer's retail price and the manufacturer's wholesale price based on government levies carbon taxes on the manufacturer or retailer and offers green subsidy to consumers. Our results show that, retail price, the demand for product and wholesale price for product 2 n Model 1 are same to Model 2. Wholesale price for product1 in Model 1 is smaller than in Model 2. The demand for product and The profit of manufacturer and retailer in Model 3 are larger than in Model 1 and Model 2.

In this work, we only consider the supply chain including manufacturer and retailer under the given of green subsidy and carbon emission tax. The government does not optimize the whole profit of society including consumers, and there are only one manufacturer and one retailer. These aspects are the main limitations of our work, which can be further examined in future word.

Abstract: Rational planning and improvement on the operational efficiency of the logistics park depends on the precise of definition of the radiation scope of the logistics park, but there is still a lack of scientific and accurate theoretical method aiming at solving the definition of the radiation scope of the logistics park. Based on the traditional space division model such as potential model in the economic geography as well as giving full consideration to the important role the transport network playing in the logistics activities, the accessibility was introduced into the traditional potential model based on the Euclidean distance metric to modify the distance parameter, and the method of defining the radiation scope of logistics park based on applying the accessibility analysis to potential model was proposed. Finally, on the basis of GIS software, this method was used to define the radiation scope of the five logistics parks of the similar type in Sichuan province. It proved that the application of this method based on GIS software had the advantages of the scientific accuracy as well as the easy acquisition and operation of data, which reflected the higher application value.
Keywords: Potential model; Road accessibility; Logistics park; Radiation scope.

1 Introduction

The radiation scope of the logistics park is the adjacent regions that is located around the logistics park as well as has connections with the logistics activities(including the links such as transport of goods, distribution, warehousing, packaging, handling, distribution processing and related logistics information) of the logistics park. Currently, in the logistics park layout planning, the accurately defining the radiation scope of the logistics park not only has an important impact on its focused business scope and service object, but also plays a vital role in determining the future development type, development strategies and directions. Although the traditional space division theories and methods such as the gravity model (Shao and Xie, 2006) and the breaking-point model (Shao and Xie, 2011)were applied to defining the radiation scope of the logistics park within a certain area, these model simplified the measurement of distance parameter, which resulted in unsatisfactory accuracy in space division. However, the accessibility theory which is widely applied in the planning of the city and its functional areas is the precise method for analyzing the actual space distance. It systematically establishes the links between the regional transportation network and the region, in addition, with the gradual expansion of in-depth of the application of geographic information system (GIS), it further promotes the development of accessibility analysis. Based on the basic principles of the potential model theory and the accessibility theory, defining the radiation scope of the logistics park based on the potential model in which the accessibility analysis is applied is proposed in this study, then the radiation scope of five logistics parks in Sichuan province is defined by integrate quantitative and qualitative scientific means on the basis of GIS technology.

2 Modeling

2.1 Traditional potential model

The potential model which developed from breaking-point theory by P.D. Converse deemed the people movement, cargo movement, information movement and so on between regions resulted from the potential difference in which the cost played a decisive role. Equation (1) is the potential model.

$$F_{ij} = S_j \big/ D_{ij}^{\beta} \; (i \neq j) \qquad (1)$$

Where F_{ij} is the potential energy city j exerts on point i, S_j is the size of city j, D_{ij} is the distance from point i to city j, β is the friction coefficient of the distance.

Initial studies only measured the two parameters such as size of city and the distance respectively by the urban population and the Euclidean distance, however, along with the in-depth research, scholars gradually found the impact that the transport network have on the distance could not be ignored, which means the radiation ability of the object does not simply and smoothly diminish along with the spatial straight line but chooses the direction and path with least resistance to spread. Zhu et al. (2007), Duan et al. (2008) and Shi et al. (2009) studied the distance parameter to some extent and proposed the different measurement method. Therefore, in order to more accurately reflect the impact that the transport network has on the distance parameter, the distance parameter in the potential model is measured based on the concept of accessibility in this study.

2.2 Accessibility

2.2.1 Concept of accessibility

In 1959, Hansen (1959) proposed the concept of accessibility which was defined as the opportunity for the interactions between each node in the transport network, in other simple words, accessibility refers to the convenience the one move from one location to the destination by certain transport systems (Morris et al., 1978) which was also known as reachability and attainability. In the 21st century, with the introduction of GIS spatial analysis method (O'Sullivan et al., 2000), the study of accessibility was further developed. Now it not only plays an important role in the urban transport planning, but also gradually falls within the scope of human geography and regional economics.

2.2.2 Accessibility measurement

With the increasingly closer integration between the accessibility analysis and the GIS technology, measuring the accessibility based on the quantitative methods by GIS has become the commonly used method by the scholars, for instance, Eck et al. (1999) defined the influential scope of the store by GIS technology based on the accessibility concept. In this study, on the basis of GIS raster data, the tool of Cost Distance is used to measure the shortest travel time from any point to the logistics park, which is considered as the accessibility, shown in Equation (2).

$$A_{ij} = \min(C_{ij}^1, C_{ij}^2, C_{ij}^3, \ldots, C_{ij}^n) \qquad (2)$$

Where A_{ij} is the accessibility from point i to logistics park j, C_{ij}^n is the travel time from point i to logistics park j in transport path n, n is the total of all possible transport path from point i to logistics park j.

2.3 Potential model based on the accessibility analysis

The potential model based on the accessibility is established to define the radiation scope of the logistics park by introducing the accessibility to modify the distance parameter in the potential model, shown in Equation (3).

$$F_{ij} = P_j \big/ A_{ij}^{\beta} \; (i \neq j) \qquad (3)$$

Where F_{ij} is the potential energy logistics park j exerts on point i, P_j is the comprehensive strength of logistics park j, A_{ij} is the accessibility from point i to logistics park j, β is the friction coefficient of the distance.

However, due to difficult determination of the dimension obtained in Equation (3), Huff probability model is usually used to effect dimensionless, shown in Equation (4).

$$F_{ij} = {P_j / A_{ij}^{\beta}} \Big/ {\sum_K \left(P_K / A_{iK}^{\beta}\right)} \qquad (4)$$

Where F_{ij} is the probability that area i belongs to logistics park j, A_{ij} is the accessibility from point i to logistics park j, β is the friction coefficient of the distance (usually taken as $\beta = 2$), If the number of the logistics parks is k, the ownership of point i can be determined by comparing to obtain the greatest F_{ik}.

3 Application examples

This study takes the five logistics parks including Xinjin logistics park, Jiazhou logistics park, Ya'an logistics park, Qingbaijiang logistics park and Western China modern logistics park which are of the similar type in *Chengdu-Chongqing Economic Zone Regional Planning* as an example, the potential model based on the accessibility analysis is used to define the radiation scope of the five logistics parks. The geographical location of five logistics parks and the regional road network are shown in Figure 1.

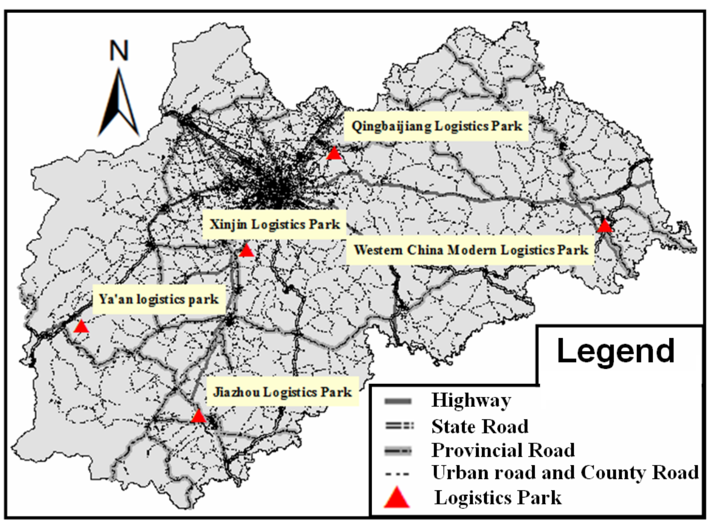

Figure 1. Location of the five logistics parks and the regional road networks

3.1 Determination of the comprehensive strength of the logistics parks

Based on the scientific, comprehensive, representative and operational principles in selecting the indexes as well as combined with the knowledge of social demography, urban economics and urban geography, 11 refinement indexes from the perspective of the logistics park scale as well as the equipment and facility of the logistics service are established to evaluate the comprehensive strength of the logistics park, as shown in Table 1.

After enquiring the relevant statistical data and being estimated by expert, the original data are obtained, as shown in Table 2. Then SPSS software is used to implement principal component analysis to get the comprehensive scores of the five logistics parks. Finally, the minimum-maximum standardized method is used to carry out data conversion to get the comprehensive strengths of the five logistics parks, as shown in Table 3.

Table 1. Index of evaluating the comprehensive strengths of the logistics parks

Influencing factors	Refinement index
Logistics park scale	Regional GDP（X_1）（$10^9\ RMB$）
	Investment intensity（X_2）（$10^9\ RMB/acre$）
	Settled company qualification（X_3）
	Whether it has bonded area（X_4）
	Preferential policy（X_5）
Equipment and facility of the logistics	Quality of equipment and facility（X_6）
	Information network level（X_7）
	Multi-modal transport level（X_8）
	Supporting services level（X_9）
	Environmental level（X_{10}）
	Service price level（X_{11}）

Table 2. The original data of the evaluating indexes of the five logistics parks

Logistics parks \ Index	X_1	X_2	X_3	X_4	X_5	X_6	X_7	X_8	X_9	X_{10}	X_{11}
Xinjin logistics park	200	0.005	4	2	4	4	5	2	4	3	3
Jiazhou logistics park	60	0.004	3	1	3	3	4	2	3	4	2
Qingbaijiang logistics park	233	0.005	4	1	4	4	5	3	4	3	3
Ya'an logistics park	25	0.01	3	2	4	4	4	2	4	4	3
Western China modern logistics park	500	0.01	4	1	4	4	5	3	4	4	2

Table 3. Comprehensive strengths of the five logistics parks

Logistics parks	Comprehensive score	Comprehensive strength（P_i）
Xinjin logistics park	0.735	4.04
Jiazhou logistics park	-2.305	1
Qingbaijiang logistics park	0.476	3.781

Ya'an logistics park	0.61	3.915
Western China modern logistics park	0.483	3.788

3.2 Determination of the logistics park accessibility

In this study, ArcMap GIS software is used to analyze the logistics park accessibility. Based on the 4 kinds of roads of different speed, such as the highway, the state road, the provincial road, the urban roads and county road, "Cost Distance" tool is utilized to generate the accessibility grids, as shown in figure 2.

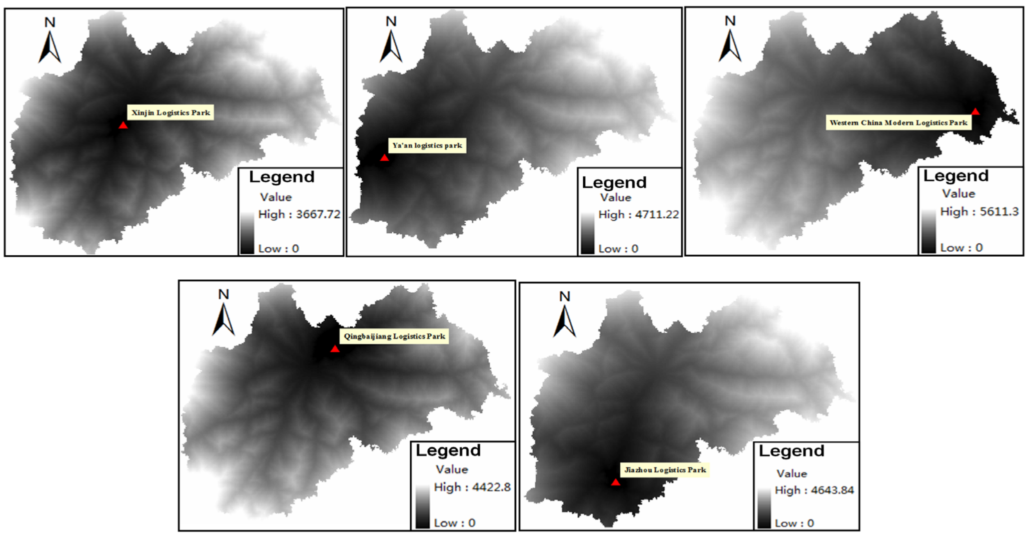

Figure 2. Accessibility grids of the five logistics parks

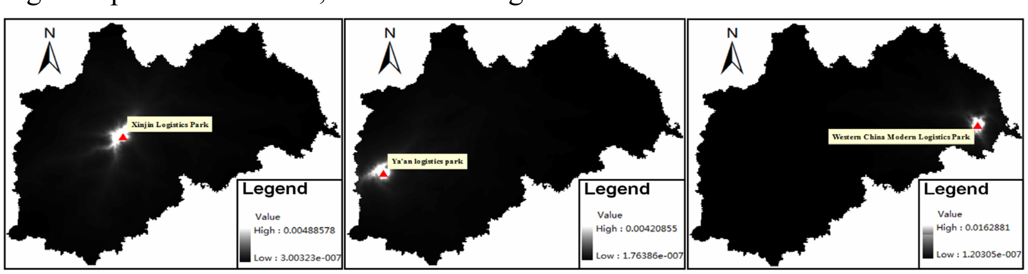
3.3 Definition of the Radiation Scope of the Logistics Park

The comprehensive strengths of the five logistics parks obtained in part 3.1 and the accessibility grids generated in part 3.2 are substituted into Equation（3）to generate their potential value charts by the raster calculator tool, as shown in Figure 3. Then the *Highest Position* tool is used to compare the potential value F_j in the same grid to determine the ownership of the grid, thus the radiation scope of the five logistics parks are defined, as shown in Figure 4.



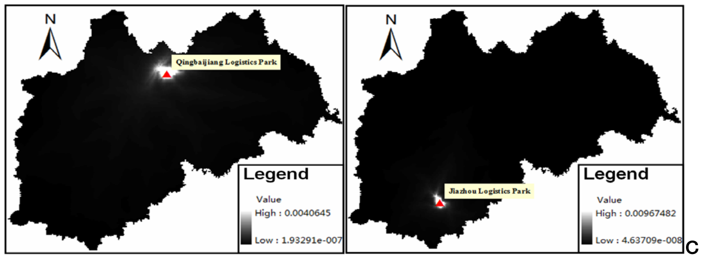


Figure 3. Potential value charts of the five logistics parks

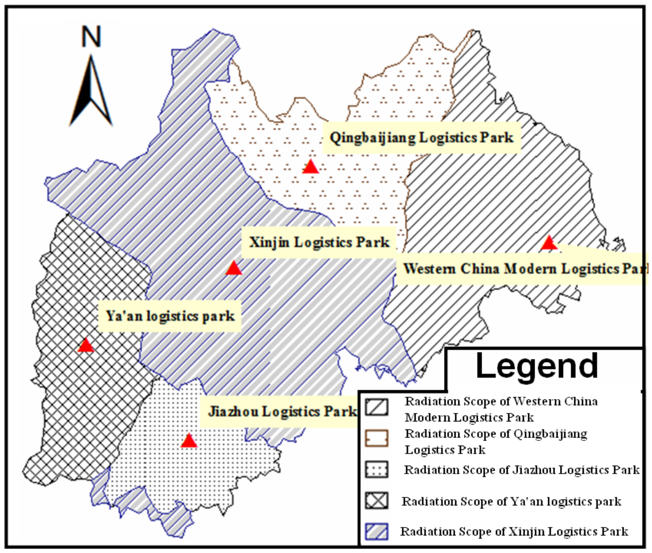

Figure 4. The radiation scope of the five logistics parks

4 Conclusions

The premise of the existence of the logistics park is the cargo transport as well as the cargo transport is based on the transport network, so it determines the definition of the radiation scope of logistics parks must not simply use the potential model based on Euclidean distance. Therefore, the accessibility is introduced into the potential model to modify the distance parameter to propose the potential model based on the accessibility analysis to define the radiation scope of the logistics park, which is a more rational and scientific method for defining the radiation scope of logistics park. This method more accurately reflects the essence of the distance parameter in the potential model as well as overcomes the inaccuracy caused by Euclidean distance in the traditional potential model, and it can be proved in the example analysis that when both the comprehensive strength is huge enough and the accessibility is good enough, the radiation scope of the logistics park defined based this model can across the closed barrier region formed by the other logistics parks, which is also in line with people's general awareness for this issue.

5 Recommendations for Future Research

Some improvements can be done based on in this study, for example, this study focused on the accessibility only based on road network, in which the other modes of transport network was neglected, so analysis result of the accessibility is incomplete. In addition, the reasonability of the index system to evaluate the comprehensive strength of the logistics park need to be further proved.

Location-Allocation Model of Maritime Emergency Supplies Repertory under Joint of Government and Enterprise

Yunfei Ai; Jing Lu; and Lili Zhang

School of Transportation Management, Dalian Maritime University, Dalian, Liaoning 116026. E-mail: fair126aiyf@126.com

Abstract: It studies the location-allocation problem of maritime emergency supplies repertories under the joint of government and enterprises. A bi-level optimization model with the objective of minimizing cost is proposed, the first level model solves the location-allocation problem of maritime emergency supplies repertories; the second level model solves the distribution of emergency supplies in the alliance based on the results of first level model. In view of the model, it designs a genetic algorithm with elite reserve strategy. The numerical example results indicate that the model and the algorithm are feasible.

Keywords: Joint of government and enterprise; Maritime emergency supplies repertory; Location–allocation; Genetic algorithm.

1 Introduction

Emergency management becomes a hot topic with water emergencies occur frequently, where reasonable configuration of emergency resources will ensure the timely and effective rescue after the emergency occurs. In comparison with the traditional emergency system, maritime emergency system has big difference and is more complicated with the influence of maritime natural conditions. (Li, 2006) studied the location model of rescue vessel on the sea based on the large number of data sets acquired from the Canadian Coast Guard Search and Rescue branch. (Azofra, 2007) studied the placement of sea rescue resources and they formalized a general methodology based on gravitational models which allowed us to define individual and zonal distribution models. (Goerlandt, 2012) described recent advances in modeling the sea rescue services using discrete-event simulation and the Monte Carlo technique. (Lehikoinen,2013) developed a Bayesian Network to examine the recovery efficiency and optimal disposition of the Finnish oil combating vessels in the Gulf of Finland, Eastern Baltic Sea. (Venäläinen, 2014) studied the evaluation of emergency response in the Gulf of Finland and studied the influence of water and wind to the speed of rescue vessels.

To meet the emergency demands caused by frequent natural disasters and large-scale emergencies, the government should fully utilize the power in society and establish socialized emergency storage system which combines national and civil inventories. In recent years, China advocated the government and enterprises to establish multi-level and multi-mode of the storage mode to save cost and improve efficiency. (Chen, 2012) built the system of China relief reserve, the system of national emergency supplies reserve consists of two parts: the national reserves and corporate in-kind agreement reserves. (Ma,2011) proposed that when given the real situation of China and in the process of establishing the socialized relief storage system, attentions should be focused on relief classification and storage mode selection, pricing problem in government-enterprise cooperation and location-allocation problem with multiple storage modes. (Ma,2014) used mathematical model to establish a cooperative game premise condition, then analyses the emergency material storage cooperative game between the government and the enterprise and establishes binding cost apportionment and punishment measures to get a stable cooperation, so that both sides obtain the biggest benefit.

Based on above literatures, we study the pre-occurrence location-allocation problem of maritime emergency supplies repertories under the joint of government and enterprises, which determines the location of water emergency supplies repertories, the cooperation enterprises and the emergency supplies in them. Within the scope of the study defined above, the proposed model and approach is unique with the following distinctive features:

(1) The coverage radius of maritime emergency supplies repertory is determined by the actual speed of salvage vessel, the emergency response time and the natural conditions such as wind, water current. (2) Probability distribution of emergency demand is used. Based on the gravity model, it puts forward the allocation method of demand between the repertories. (3) We establish the bi-level optimization model under the joint of government and enterprises with the objective of minimizing cost. (4) In view of the model, a genetic algorithm with elite reserve strategy is designed and a case studies is given.

2 Problem description

A general overview of pre-occurrence location of emergency resources can be described in figure 1.

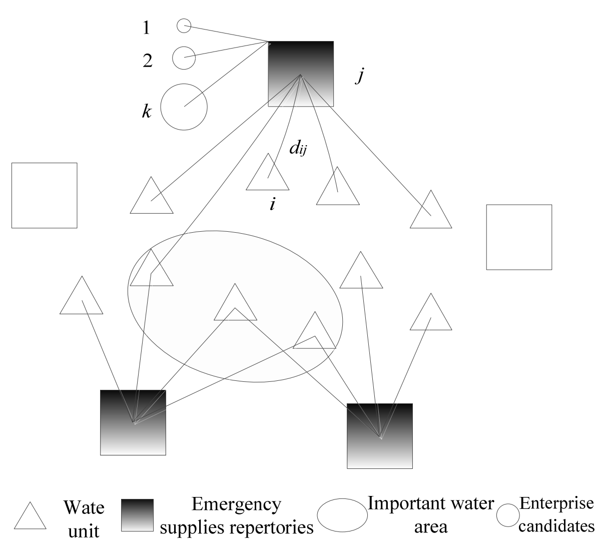

Figure 1. Water emergency supplies repertory location-allocation

The water area is divided into several water units and each unit is represented by its center, $i = 1,2,\cdots I$ is the index of water units. Some water units are in the important water area and they should be covered by at least two times. There are several candidates of maritime emergency supplies repertories, $j = 1,2,\cdots J$ is the index of candidates. d_{ij} is the distance between water unit i and candidate j. There are a number of enterprise candidate points, $k = 1,2,\cdots K$, each candidate can only cooperate with an emergency supplies repertory and a material repertory can cooperate with multiple enterprises.

2.1 Coverage radius of emergency supplies repertory

Maritime emergency supplies are transported by salvage vessels. So the coverage radius of emergency supplies repertory is equal to the maximum distance that the salvage vessel can achieve under the wind, water current and other natural conditions within the emergency response time(We assume that the travel path is rectilinear). So the actual sailing speed of salvage vessel is a result of the vector superposition, as shown in figure 2.

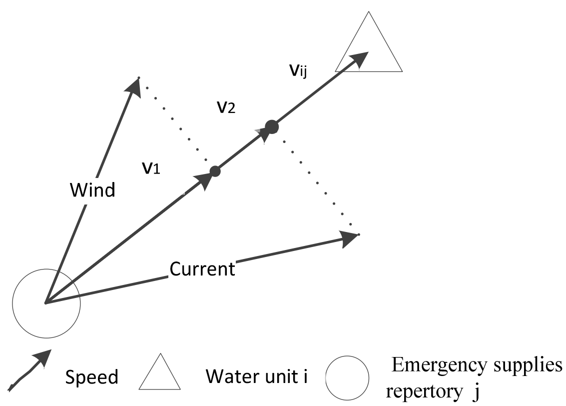

Figure 2. The velocity vector superposition

$$v'_{ij} = v_{ij} + v_1 + v_2 \quad (1)$$

v_{ij} is the sailing speed of salvage vessel from emergency supplies repertory j to water unit i without the influence of natural conditions; v_1 is the influence of wind; v_2 is the influence of water current; v'_{ij} is the actual sailing speed of salvage vessel considering the influence of wind and water current. Here we use the constant wind and constant water current from the meteorological statistics.

$$r_{ij} = v'_{ij} t \quad (2)$$

r_{ij} is the coverage radius of repertory j towards water unit i. If the distance between the water unit and the candidate is larger than the coverage radius of the candidate, we consider that the candidate will not provide emergency service for this water unit, if $d_{ij} \le r_{ij}$, then water unit i can be covered by the candidate j .

2.2 Allocation of demand between emergency supplies repertory

If a water unit is covered by several repertories, its demand for emergency resources should be allocated to them. Most of the literatures consider the allocation of emergency resources using all-or-nothing assignment. Emergency event has great uncertainty and the probability distribution of demand is more suitable. Based on the gravity model, we put forward the improved probability distribution method.

$$u_{ij} = \eta_{ij} w_j^2 V_{ij} \big/ d_{ij} \tag{3}$$

u_{ij} is the attraction that water unit i can fell from emergency supplies repertory j . w_j^2 is the service quality of emergency supplies repertory j , w_j^2 is known as a priori. If water unit i could not be covered by emergency supplies repertory j , then it cannot fell the attraction of emergency supplies repertory j , the parameter η_{ij} can achieve that goal. η_{ij} is a binary variable, for water unit i and emergency supplies repertory j , if $d_{ij} \le r_{ij}$, then $\eta_{ij} = 1$, otherwise $\eta_{ij} = 0$.

$$M_{ij} = q_i u_{ij} \Big/ \sum_{j \in N_i} u_{ij} \tag{4}$$

q_i is the demand for emergency supplies of water unit i . M_{ij} is the proportion of water unit's demand occupied by emergency supplies repertory j .

2.3 Joint of government and enterprises

The corporate in-kind agreement reserves are divided into production-oriented enterprises reserve (combined of production capacity reserves and physical reserve) and sales-oriented enterprise reserves (mainly physical reserves) such as large supermarkets (Chen, 2012). In our study, we focus on the sales-oriented enterprise reserves. After the allocation of emergency reserves, the government physical reserve is first considered. If the capacity of government physical reserve cannot satisfy the demand, the enterprise reserve is considered. In this paper government gives subsidies to the cooperation enterprises for their participation.

3 Model formulations

3.1 Model assumptions

(1) Salvage vessels do not involve round-trip transportation; (2) The travel path of salvage vessel is rectilinear; (3) The readiness is equal for all vessels; (4) Government gives subsidies to cooperation enterprises for their participation.

3.2 Parameters

$i = 1,2,\cdots I$ is the index of water units; $j = 1,2,\cdots J$ is the index of candidates; $k = 1,2,\cdots K_j$ is the set of enterprise candidates corresponding repertory j ; r_{ij} is the coverage radius of repertory j towards i; d_{ij} is the distance between water unit i and candidate j; $N_i = \{j | d_{ij} \le r_{ij}^k\}$ is the set of emergency supplies repertories that can cover water unit i; η_{ij} is a binary variable; y is a binary variable, if the candidate j is selected, then $y_j = 1$, otherwise $y_j = 0$; w_i^1 is the importance of water unit i; w is the threshold of w_i^1, if $w_i^1 \ge w$, then water unit i should be covered more than once; w_j^2 is the service quality of emergency supplies repertory j; u_{ij} is the attraction that water unit i fells from emergency supplies repertory j; q_i is the demand for emergency supplies of water unit i; M_{ij} is the proportion of water unit's demand occupied by emergency supplies repertory j; Q_j^1 is the maximum capacity of emergency resources reserve j; Q_k^j is the maximum inventory of enterprise k can provides; C_j is the fixed construction cost of emergency supplies repertory j; c_j is the unit reserve cost of emergency supplies repertory j; x_k^j is the supplies that k enterprise reserves for j emergency repertory; a_k^j is the subsidies that j emergency repertory gives to k enterprise for unit emergency supplies.

3.3 Model

Based on the previous analysis, we establish the bi-level optimization model. The first level model is:

$$\min \mathrm{Z} = \sum_{j=1}^{J} y_j C_j + \sum_{j=1}^{J}\sum_{i=1}^{I} M_{ij} c_j + \mathrm{Z}_1 \quad (5)$$

$$\sum_{j \in N_i} y_j \ge 1 \quad (6)$$

$$\sum_{j \in N_i, w_i^1 \ge w} y_j \ge 2 \quad (7)$$

$$u_{ij} = \eta_{ij} * w_j^2 * v'_{ij} / d_{ij} \quad (8)$$

$$M_{ij} = q_i u_{ij} \Big/ \sum_{j \in N_i}^{J} u_{ij} \quad (9)$$

Objective (5) is the total cost, the first part is the fixed construction cost of emergency supplies repertories, the second part is the reserve cost of the emergency supplies, the third part is the cost of subsidies that government gives to enterprises. It is necessary to take into account the fairness and efficiency when configure the emergency resources, so we propose that the location of maritime emergency supplies repertories should not only achieve the full coverage of the water units, but also achieve the multi-coverage of the key water units. Constraint (6), (7) can achieve that. Constraint (8), (9), we have introduced in section 2.2.

The second level model is:

$$\min Z_1 = \sum_{j=1}^{J}\sum_{k=1}^{K_j} a_k^j x_k^j \quad (10)$$

$$\sum_{j=1}^{J} M_{ij} - Q_j \geq 0 \quad (11)$$

$$\sum_{k=1}^{K_j} x_k^j = \sum_{j=1}^{J}\sum_{i=1}^{I} M_{ij} - Q_j \quad (12)$$

$$x_k^j \leq Q_k^j, x_k^j \geq 0 \quad (13)$$

Objective (10) is the total subsidies that government gives to enterprises; constraint (11) achieves that when the allocation amount of emergency supplies is greater the capacity of emergency repertory, we choose the joint of government and enterprises; constraint (12) achieves that amount of enterprise reserve is equal to the shortage of demand of emergency repertory. Constraint (13) is the constraint of x_k^j.

4 Heuristic algorithm

The bi-level programming model is difficult to solve, the first level model is a nonlinear programming problems and the second level model is a linear programming problem. Genetic algorithm is one of the best heuristic algorithms that can achieve global search (Goerigk,2014, Zegordi,2009, Gelareh,2011). So we design a genetic algorithm (GA) to solve the first level model and use *linprog* function in MATLAB to solve the second level model.

4.1 Genetic algorithm

(1) The chromosome coding, initial population and fitness function

The genetic algorithm uses binary encoding, if the candidate is selected, then the genetic is 1, otherwise 0. The initial population is generated randomly. If the chromosome is feasible, it will be kept in the population. When the number of the chromosomes reaches the population, we get the initial population. $f = I - Z$, f is the fitness value of the chromosome, Z is the objective function value of the chromosome, I is a relatively large constant.

(2) Elitist individuals

In each generation, the algorithm selects top-ranking individuals as the elite individuals which will be kept separately. Then carry on selection, crossover and mutation. The elite individuals replace the individuals with the relatively low fitness value, and go into the next generation.

(3) Penalty function

If the individual is infeasible, then a penalty function is used. $f' = f - P$, P is a constant variable, f' is the new fitness of the chromosome.

(4)Genetic operators and termination condition

The algorithm uses the roulette method to choose the individuals that can enter the next generation. Use single-point crossover and two-point mutation operation. When the iteration reaches the maximum number (when the fitness of the algorithm is stable), the calculation finishes.

4.2 Linear programming function

We use the function *(x，fval)= linprog (c,A,b,Aeq,beq,lb,ub,options)* to solve the second level model. The calculation results return to the genetic algorithm.

5 Model application

The water area is divided into 20 water units, there are 10 candidates of maritime emergency supplies repertories and each repertory have 3 candidate enterprises, as shown in Table 1-3. We assume that the speed matrix of salvage vessels sailing to each water units from the emergency supplies repertory candidates is known, as shown in Table 4.We assume other parameters, as $w = 5$, $T = 4$ minutes.

Table 1. The data of waters of units

Numerical experiments are carried out in MATLAB on a desktop PC with 2.93 GHz dual-core processor, 4GB RAM and 32-bit Microsoft Windows 7 ultimate operating system. The population of GA is 50, the length of the chromosome is 10, the crossover probability is 0.9, the mutation probability is 0.1, the largest iteration is 200. The program was run 50 times, the results were stable and the average computing time is 194 seconds.

The candidates 1,5,7,9 are selected to construct maritime emergency reserves bases, actual capacity are 36,51,47,41, total cost is 175.5, enterprise 1,13,15,19,25 are selected, the actual reserves are 6,10,11,17,11.We can figure out that the final location results can achieve the full coverage of the water units and the multi-coverage of the key water units, as shown in Tab.5

Table 5. The coverage of water unites

6 Conclusions

We study the location-allocation problem of maritime emergency supplies repertories under joint of government and enterprises. We establish the bi-level optimization model under the joint of government and enterprises with the objective of minimizing cost and design a genetic algorithm with elite reserve strategy. The numerical example results indicate that the model and the algorithm are feasible. We assume that the subsidies given to the cooperation enterprises is known as a priori, but the computation of subsidies is very important and we will study in next.

Abstract: Express logistics by means of high-speed railway faces challenges, such as the lack of infrastructural facilities, freight transportation limits, low efficiency of upstream-downstream industries and the furious competition of logistics industry. Considering the factors of regional differences, misallocation of resources and income levels, we designed the follow three operation modes for high-speed railway logistics: completely-opened mode, agent-cooperated mode and self-employed mode. The fuzzy synthetic evaluation based on set-valued statistics was applied for evaluating and choosing the three modes. This led us to the conclusions. First, the completely-opened mode is suitable in the areas where logistics market saturation and maturity are high. Second, outsourcing the distribution business is the best choice in the areas where its' distribution resources are insufficient, high-speed railway organization should cooperate with the local logistics agencies. At last, the self-employed mode is suitable only in this case that business outlets, transportation network, logistics center and logistics information system and other resources of high-speed railway organization are extremely sufficient.

Keywords: High-speed railway; Express logistic; Operation mode; Fuzzy synthetic judgment.

1 Introduction

In express industry, high-speed railway is one of most effective and ideal way to transport express items. High-speed railway is rather punctual, because it is not influenced by traffic jams and air traffic control. Specifically, it has the following advantages: cost advantage, high reliability, wide spectrum of services and high speed. In the meantime, there are many disadvantages and challenges. First, lack of infrastructure is a serious difficulty. Second, transportation is limited to small batch of goods. Thirdly, the service level of upstream and downstream is relatively low. Determining how to evade these risks and how to choose reasonable operation modes are significant for high-speed railway organization to increase competitiveness.

2 Analysis of affecting factors and dimension

2.1 The affecting factors

(1) Demands of express

The express demand for high-speed railway are the service needs of high quality and high efficiency. In addition, it is necessary to promote synergies in the development of manufacturing industry, business industry and logistics industry, because a large volume of import and export trade is one major factor for express demands.

(2) Logistics resource

It is very important that express enterprises establish logistics facilities at each node city in the whole high-speed railway network. Besides, the quantity and location of logistics distribution center, the saturated degree of express market, the talented person's comprehensive quality, and logistics enterprise's managerial skill in one area all above will influence the forms and patterns of the development of high-speed railway express.

(3) Average disposable income of local residents

The average disposable income of local residents determines the consumption level, so it could be used as a important indicator of the economic development in a region.

2.2 The dimensions of logistics business

(1) Ownership and control power

The organization could control wholly or partly logistics activities in a region. Of course, it is possible for out of control situations to occur, then the organization just provides the high quality transportation resources.

(2) The dominance of logistics activities

When high-speed railway organization controls the express logistics business partly, the dominance of logistics activities reflect its status in the whole express logistics system of market, business and management.

(3) The regional span

It should not take the identical general development mode among central city, terminal type city, and non-node cities of the high-speed railway network. The most fundamental reason is that the regional spans are different.

Considering the factors all above, we designed the follow three modes for high-speed railway organization to operate logistics express.

3 Three models of operation mode

3.1 The completely-opened mode

In this mode high-speed railway organization should open fully its high-quality resources of railway transportation for the society, and just provide transit services between initial station and destination. All of the logistics process will be handle by courier companies. The mode is shown in Figure 1.

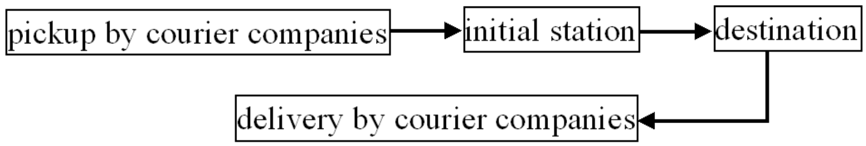

Figure 1. The completely-opened mode

3.2 The agent-cooperated mode

In this mode high-speed railway organization will completely outsource its delivery business to logistics agency. This mode is shown in Figure 2.

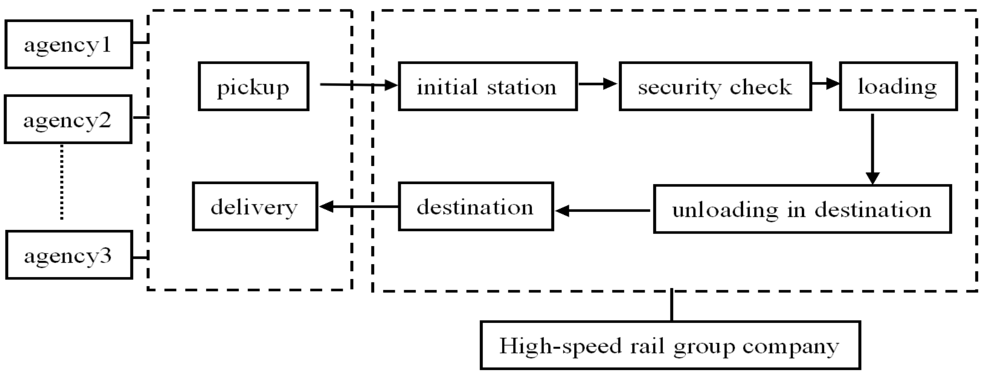

Figure 2. The agent-cooperated mode

3.3 The self-employed mode

In this mode high-speed railway organization can provide integrative logistics services or even customized logistics services for manufacturers, trading companies and E-commercial enterprises. The prerequisites for these is that high-speed railway organization must have enough operations and distribution centers, integrated high-speed railway network and professional logistics information system around the country. This mode is shown in Figure 3.

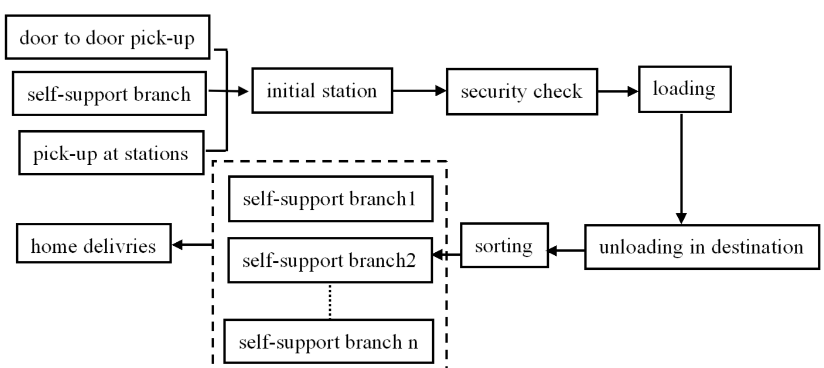

Figure 3. The self-employed mode

4 Fuzzy synthetic evaluation based on set-valued statistics

4.1 Description of the model

Considering the factors of no determinacy, randomness and fuzziness in the process of evaluation, we used the fuzzy synthetic evaluation based on set-valued statistics to evaluate three operation modes. The results of each probabilistic test is a definite point in the phase space, but the results of set-valued statistics is a subset. We assume the sample assembly is A, the set of evaluation indexes is C, the set of experts is D.

Firstly, the statistical estimation of arbitrary index c_i ($c_i \in$ C, i= 1, 2,…,m) from a expert will be denoted as a_i, the statistical estimation of number j (j = 1, 2,…,n) expert we denote as $[u_{i1}{}^{(j)}, u_{i2}{}^{(j)}]$, and $[u_{i1}{}^{(j)}, u_{i2}{}^{(j)}] \subseteq a_i$. The superposition of n intervals can be described as formula1.

$$\overline{i_{ai}}(u) = \frac{1}{n}\sum_{j=1}^{n} i\left[u_{i1}^{(j)}, u_{i2}^{(j)}\right](u) \qquad (1)$$

$$i\left[u_{i1}^{(j)}, u_{i2}^{(j)}\right](u) = \begin{cases} 1, & u_{i1}^{(j)} \le u \le u_{i2}^{(j)} \\ 0, & else \end{cases} \qquad (2)$$

Secondly, the average estimation of arbitrary index c_i from n experts can be denote as:

$$\overline{u_i} = \frac{\int_{u_i^{'}}^{u_i^{''}} u\overline{i_{a_i}}(u)du}{\int_{u_i^{'}}^{u_i^{''}} \overline{i_{a_i}}(u)du} \qquad (3)$$

In the formula, $u_i^{'} = \min\left(u_{i1}^{(1)}, u_{i1}^{(2)}, ..., u_{i1}^{(n)}\right)$, $u_i^{''} = \min\left(u_{i2}^{(1)}, u_{i2}^{(2)}, ..., u_{i2}^{(n)}\right)$.

So, we found:

$$\int_{u_i^{'}}^{u_i^{''}} u\overline{i_{a_i}}(u)du = \frac{1}{2n}\sum_{j=1}^{n}\left[(u_{i2}^{(j)})^2 - (u_{i1}^{(j)})^2\right] \qquad (4)$$

$$\overline{u_i} = \frac{1}{2}\cdot\frac{\sum_{j=1}^{n}\left[(u_{i2}^{(j)})^2 - (u_{i1}^{(j)})^2\right]}{\sum_{j=1}^{n}\left[u_{i2}^{(j)} - u_{i1}^{(j)}\right]} \qquad (5)$$

Thirdly, we can calculate the synthetic determination of arbitrary sample from all the specialists.

$$\overline{u} = \left[\overline{u_1}, \overline{u_2}, ..., \overline{u_n}\right] \quad (6)$$

Finally, we can get the scores of fuzzy synthetic determination through reasonable function.

4.2 The index system

When the high-speed railway enterprises choose their operating mode for express logistics, the following factors should be taken into account. These factors includes: the characteristics of the customer, economic development of the area, the demand of express logistics, the logistics resources and express logistics business dimension. We combine a number of experts in the table of operating mode selection assessment to evaluate the indicators, and sums up the indicator set of the following evaluation system, it is shown in table 1.

Table 1. The evaluation indicators system

Level 1 indicators	Level 2 indicators	Weight
X_1 Economic status indicators （0.1）	Y_1 Overall economic development level of the area	0.05
	Y_2 Per capita income level of the area	0.05
X_2 Express logistics demand （0.25）	Y_3 The popularity of the Internet and Online shopping intention indicators	0.075
	Y_4 The development of E-commerce logistics	0.062
	Y_5 Import and export trade factors	0.063
	Y_6 The logistics industry and manufacturing, business and other multi-industry linkage	0.05
X_3Logistics resource （0.40）	Y_7 Transportation infrastructure factors	0.064
	Y_8 The construction of the nodes in the high speed rail network	0.064
	Y_9 The number and layout of logistics distribution center	0.064
	Y_{10} Logistics express delivery market saturation of the area	0.056
	Y_{11} Express logistics information resources integration level	0.056
	Y_{12} Express business operation and management level of the area	0.048
	Y_{13} Logistics talent resources	0.048
X_4 Logistics business dimensions （0.25）	Y_{14} Regional span	0.037
	Y_{15} Control level of logistics activities	0.075
	Y_{16} Dominance level	0.033
	Y_{17} The ownership	0.10

4.3 Analysis of statistical data

We select three representative cities (or area), Ⅰ is a highly developed coastal cities, Ⅱ is a relatively developed inland provincial capital city, Ⅲ is a less developed cities. We evaluate the various indicators of these three cities with the opinions of five experts, then we calculate the comprehensive evaluation value based on formula (5). Finally we get the comprehensive evaluation values statistically, it is shown in table 2.

Table 2. Comprehensive evaluation values of Ⅰ, Ⅱ and Ⅲ city

Indicator \ City	Ⅰ	Ⅱ	Ⅲ
Y_1	0. 9200	0. 8100	0. 7100
Y_2	0. 8768	0. 7568	0. 6420
Y_3	0. 8540	0. 7750	0. 7230
Y_4	0. 8830	0. 7250	0. 6180
Y_5	0. 9326	0. 8107	0. 7125
Y_6	0. 8764	0. 7795	0. 6256
Y_7	0. 8859	0. 7596	0. 6896
Y_8	0. 8527	0. 7708	0. 6970
Y_9	0. 8650	0. 7705	0. 6605
Y_{10}	0. 8580	0. 7404	0. 6340
Y_{11}	0. 8423	0. 7333	0. 6352
Y_{12}	0. 8674	0. 7750	0. 6503
Y_{13}	0. 8912	0. 7821	0. 6924
Y_{14}	0. 9012	0. 7942	0. 7836
Y_{15}	0. 7125	0. 8365	0. 8328
Y_{16}	0. 7016	0. 7821	0. 7789
Y_{17}	0. 7013	0. 8050	0. 8102

4.4 Calculation and selection of the judge function

We used the average-weighted type of comprehensive evaluation function to calculate the result. We assumed that the normalized weight vector $W = (w_1, w_2, ..., w_m) \in I^m$, that means the expression of the comprehensive evaluation could be $f(\overline{u_1}, \overline{u_2}, ..., \overline{u_m}) = \sum_{i=1}^{m} w_i \overline{u_i} \times 100$. We put the comprehensive evaluation values of every indicator in the functional respectively, then we can figure out the comprehensive evaluation value of the three cities: 86.28, 75.49 and 66.34.

5 Conclusions

Here we could draw the following conclusions.

(1) The score of comprehensive evaluation is proportional to the level of economic development, stage of industrialization and income per head. This show that the market capacity of high-speed railway express logistics demands is bigger in developed areas.

(2) In city Ⅰ, because of the market saturation is higher and express enterprises are more mature, the control level of high-speed railway organization is weaker here. It shows that areas like city Ⅰ suit to the completely-opened mode.

(3) Though most indexes are different, but the dimensions of logistics business is resemblance between city Ⅱ and Ⅲ. The reason is that high-speed railway organization don't have its own terminal distribution network all over the whole country. So, outsourcing the distribution business is the best choice for high-speed railway in the areas where its' distribution resources are insufficient, therefore, high-speed railway organization should cooperate with the local logistics business.

(4) The self-employed mode is suitable only in the case that business outlets, transportation network, logistics center and logistics information system all resources of high-speed railway organization are highly intensive.

Abstract: In order to reduce the logistics cost of manufacturing enterprises and improve the utilization efficiency of warehousing and customer satisfaction, this paper researched enterprise's sales and delivery process according to the related theory of process optimization. In this paper, the existing business processes of the company and work flow chart are demonstrated. Problems in this process are brought up including forklift's whilst distance increased and unbalanced utilization rate because of lacking of loading platforms by using value chain analysis method. ECRSI optimization approach is employed to improve this problem, instead of existing separated loading port, the U-shaped loading platform have been added to assist sales and delivery process. Extendsim is used to contrast and evaluate simulated pre and post optimization sales and delivery processes. The results show that cargo area's average waiting time, average queue length, maximum waiting time and maximum queue length are greatly reduced compared with existing process; The backlog of goods and congestion in cargo area has improved significantly; forklift's utilization rate is more balanced and the total efficiency improved significantly. The optimized sales and delivery process will help to improve enterprise's comprehensive competitiveness.

Keywords: Business process; Value chain; Loading platform; Simulation; Optimization.

1 Introduction

Every advanced management mode just provides advanced management concept and methods for enterprises, but every enterprise has different background and culture, and cannot imitate blindly. Regardless of the enterprise management mode, all need process to support it. Every advanced management mode is inseparable from the excellent process, and excellent process provides support and assistance for advanced management mode. The organizational structure of the vast majority of enterprises in our country are based on the theory of division of labor pattern, therefore, enterprise's operating process is divided into relatively independent departments by function (WEN, 2010). Process optimization changes these processes in the organization and management, makes these processes are fragmented again and banded together to become a continuous process, through the process of integration and optimization, to achieve customer service, cost and efficiency of global optimization.

Marketing is the starting point of business activity, have a decisive effect on the business of technology, production, finance, personnel and other management, only successful marketing strategies can pull in front of all aspects of implementation of the strategy, the delivery part of the enterprise value chain is particularly important. However, most projects are concentrated in personnel, payroll and warehouse management, delivery management rarely involved. This situation occurs mainly because of long-standing delivery management work is not being taken seriously, but at the same time, delivery is tedious work and gets indirect benefits, it is also an important factor (SHANG, 2009).

Factors affecting the sales delivery efficiency are complex; there are both external and internal factors. External factors from the market factors, the internal cause are the human resources, technology ability restriction problem. Some are the direct factors, some are the indirect factors. Multi-factor effect is difficult to quantitative calculation, it is difficult to establish accurately mathematical model. Through simulation, the method of multiple statuses of return flow and the dynamic change the allocation of resources; can achieve the purpose of optimizing the process efficiency. Reproducing the status quo to run multiple processes and modifying the allocation of resources dynamically through the simulation method, to optimize the process efficiency. Through the comparison of multiple process simulation software, this article chooses Extendsim as the platform to simulate the sales and delivery process.

2 Analysis of the existing problems and optimization design

2.1 Analysis of the existing problems of sales and delivery process

S company in Xian is a large private manufacturing enterprise, S company has developed rapidly in recent years, and sales of the annual growth rate are over 20%. However, at the same time of rapid growth, some problems stand out in company. On the one hand, the phenomenon of damage and shortage is serious, on the other hand, the low efficiency and low utilization rate of equipments cause the high cost of the enterprise.

S company’s current sales delivery process is when an order is received and need to delivery, firstly, the main planner and administrator notify the transport group (outsourcing) to arrange the vehicles, then warehouse keeper load goods, the system operator determines whether it’s the finished goods or not, when customers accept goods, they feedback to the company, finally, it is the financial settlement.

Business operation’s objective is to input resources into customer value. Value activities are the basic way of survival and development. Value chain analysis with its unique perspective and framework is playing an increasingly important role in the strategy making at all levels of the enterprise. This paper will apply the value chain analysis method to analyze the company's sales and delivery process, to identify critical control point and put forward the scheme to reduce the non value added links.

(1) The performance indicators of sales and delivery process

S company's transportation outsources to a third party logistics company, so the company is mainly responsible for inspection before receiving and delivering. This paper analyzes the key performance indicators of sales and delivery process, Table 1 shows the key indicators as the control targets of sales and delivery process.

Table 1. The performance indicators of sales and delivery process

Category	Indicators	Definition
Quality	Product loss rate	The ratio of product loss's number to the actual distributions
	The qualified rate of products	The ratio of qualified product quantity to the actual number distribution products
	The accuracy of the product's quantity	The ratio of the actual delivery products to plan delivery products
Timeliness	Punctuality	The goods delivery on time to the total number of delivery
Service	The professionalism of the service	Professional processing abnormal situation
	Traceability of responsibility	The convenience of investigation for responsibility when found the goods damaged, not qualified

(2) The key point of sales and delivery process

Table 2 shows the main inputs and outputs of controlling the activities.

Table 2. The key point and main control method of sales and delivery process

The key points of the inlet and outlet	Input	Output	The main controlling method
Vehicle scheduling	Inform the shipping company to arrange vehicles, fill in the outbound order, feedback the cargo's volume weight, destination and time requirements	Vehicle selection, positioning	The real-time track transportation, KPI index evaluation, formulate the measures for vehicle scheduling management
Loading	The number of inventory, damage detection. Packing	Send information feedback, traveling real-time monitoring	Assign responsibilities , GPS applications, determine the feedback mechanism
Customer acceptance	Feedback after receiving, customer acceptance	Send the receiving report, feedback, back problems	Determine the accountability measures

Sometimes, customers will find sub-quality goods when they received, some are caused by the company itself in the design, production, packaging, loading and unloading, some are due to the third party logistics company's transportation. For now, if the customer asks to return money or to have re-delivery, S company takes a loss completely for two situations.

In addition, S company lacks of loading platforms, leading to large-scale outbound activities inconvenient and inefficient, also forklifts whilst distance increased, not only waste the space-time resources, but also caused an increase in the company's operating cost.

2.2 Optimization of sales and delivery process

MTO enterprises have a variety of line optimization way, such as improving the equipments' running speed, increasing equipments and working shifts, optimizing order process. Generally speaking, the enterprises will be from costs, expenses and implementation complexity to consider optimization (ZHANG, 2010).

At present, the main methods of process optimization are ESIA, ECRSI and SDCA (WANG, 2014). In the practice, enterprises need to do everything to reduce the non-value added activities, adjust the core value-added activities, the basic principle is ESIA. The main role of ECRSI is to analyze processes and judge whether the process can be eliminated, combined, rearranged, simplified and increased, to make the process more reasonable, more simple, more time- saving. SDCA balances the process, then checks the process to ensure its accuracy, and finally makes a reasonable analysis and adjustment, so the process can meet the requirements.

Extendsim itself provides "Optimizer" block as a tool to optimize the model, from the perspective of scientific data provides a reference for decision makers. In this paper, due to the randomness of the orders and the date of delivery constraints, the optimization solution only is considered to improve equipment running speed, increase equipments. Thus, this paper puts forward the following optimization.

① Set up pre-delivery inspection area. This paper uses the Increase program in ECRSI to set up pre-delivery inspection area. Thus, the company can move outbound goods into pre-delivery inspection area before transporting, the goods confirmed on site by third party logistics company attendants and the company's technical staff, and took photos as evidence. If no external damage, at this case the cargo's security responsibilities transfer to third party logistics company and goods are packaged and loaded by the third-party logistics company. If the damage occurring after the transport (except for technical issues), the third party logistics company is fully liable.

② Transform loading platform. At present, S company only has two loading platforms, which leads to the peak period of the exit and entry is not convenient. In order to reduce the backlog of goods and vehicles waiting time during peak-hour, this paper proposes an improved scheme to transform original H-shaped loading platform (separated loading port) into U-shaped loading platform after considering the costs, expenses, implementation complexity and other factors. Thus, in the U-shaped loading platform, forklift 1 unloads at Port a, forklift 2 loads at Port b. If forklift a is empty and forklift 2 leaves filled with goods, but Truck B hasn't unloaded yet, at this time forklift 1 can be directly drive to the loading Port b to load Truck B through the 2nd forklift's road and sent goods into warehouse staging area, while forklift 2 can operate into the U-shaped loading platform to do next loading activity through 1st forklift's road. Comparison diagram as shown in Figure 1 and Figure 2.

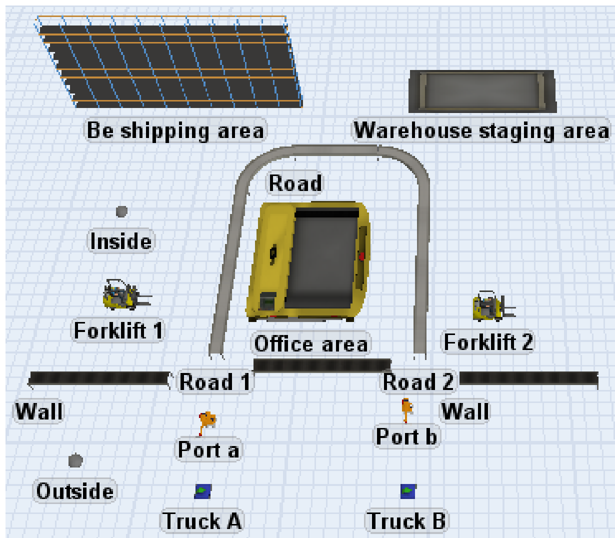

Figure 1. H-shaped loading platform

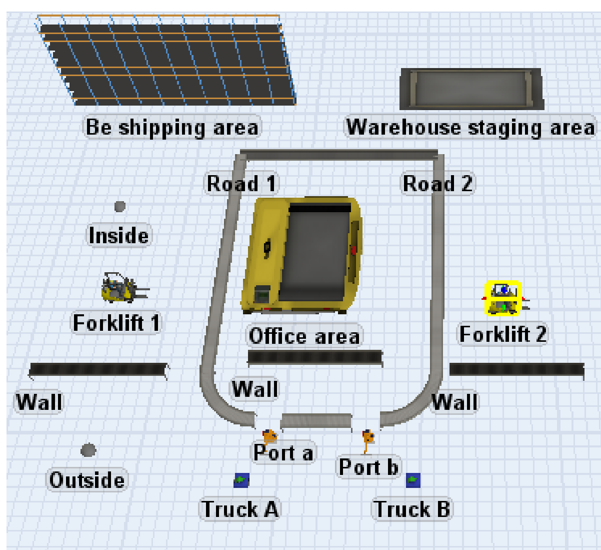

Figure 2. U-shaped loading platform

3 Simulation of sales and delivery process with Extendsim

The model of sales and delivery includes a variety of objects, among them, trucks, forklifts, transport channels are important objects, and they are also the key in the process of modeling.

3.1 Extendsim and its modeling

Extendsim simulation is developed by the Imagine That Company in the United States; it entered the market in 1988. It uses C language to write it's program and develops a certain number of blocks for different functions, and be packaged to form Extendsim block library for different business processes. According to the characteristics of enterprise business processes and workflow, Extendsim build a special logistics block library with it's reusability. Extendsim forms logistics business simulation environment under the combined effect of these two types of block library. In practice, Extendsim forms the simulation results and outputs it when we input the corresponding parameters combining with the assessment objectives (QIN, 2011).

The block of create that from Item library; its main function is to produce items and record amount of logistics entered into the delivery process. The block of Queue that from Item library, its main function is to allocate scratch space and store items momentarily. The block of Activity is used to process items. The block of Select Item 0ut from Item library, its main function is to output items selectively and generates a random number that obeys distribution. The block of Exit that from Item library, its main function is to end the simulation and record shipments.

3.2 The simulation under H-shaped loading platform

This paper sets up the Number of running is 1, the End time is 2880, namely the running time of the whole model for 2 days, the Global time units is minutes.

In Extendsim7, the block of Activity is used to simulate goods, the goods created from Create library are allocated according to the ratio of 4:6 through the block of Select Item 0ut, that is 40% of goods are stored, 60% of goods are delivered. For storage goods, in order to compare the goods backlog before and after optimization facility, we set up the parameters of the Queue block is unlimited. Forklift 1 that from the block of Activity were assigned to finish product stocking randomly, and set up total time is 5 min, the maximum capacity is 1, which means that this task can only deal with a forklift. Similarly, for delivery goods, we set up the same parameters as the model of goods inbound. According to the company's existing sales and delivery process, this paper builds the model of sales and delivery process, as shown in Figure 3.

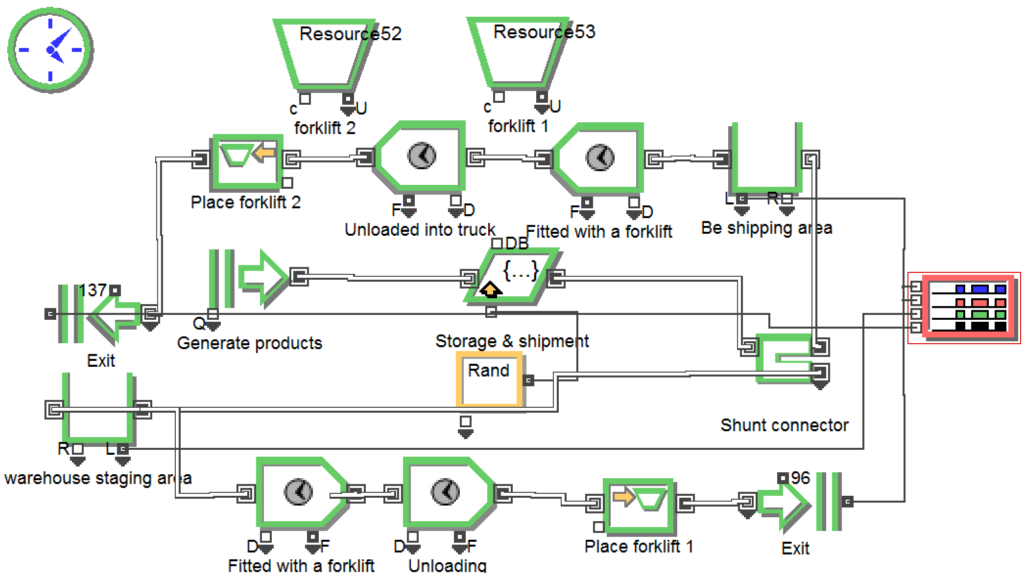

Figure 3. The simulation model of H-shaped loading platform

3.3 Data analysis

The block of Plotter and Discrete event that from Plotter library is used for statistics for the simulation results. This paper analyzes the block of Exit, Resource pool and Queue, the specific simulation results as shown in Table 3.

Table 3. The simulation results of H-shaped loading platform

Block	Attribute	Arrival	Leave	utilization	The average length of the queue	The average waiting time	Maximum waiting time	Maximum queue length
Be shipping area	Queue	158	151	0.9098158	4.8429105	48.51859	136.72568	15
warehouse staging area	Queue	78	78	0.1896133	0.2566219	4.8215217	21.02486	4
forklift 2	Resource Pool	×	×	0.9895042	×	×	×	×
forklift 1	Resource Pool	×	×	0.4986752	×	×	×	×

Table 3 shows that a total of 236 products entered into emulation platform, a total of 78 products are stored and a total of 142 products are delivered, the simulation completed a total of 220 pieces. In the delivery process that is the busiest periods, the emulation platform is congested with goods, and there are 16 products were not finished until 2880 minutes. In the above counts modules, the highest utilization rate is forklift 2, but the utilization rate of forklift 1 still has much room for improvement. Both average waiting time and the maximum waiting time of shipping area are the longest. So the company should improve the efficiency of delivery and shorten the processing time.

3.4 The results of U-shaped loading platform

In the U-shaped loading platform, what is different from the H-shaped loading platform is that forklift 1 and forklift 2 can carry on the handling operation flexibly through the U-shaped channel. So in the model of U-shaped loading platform, we set up the maximum capacity is 2, which means that this task can deal with two forklifts. The specific simulation results as shown in Table 4.

Table 4. The simulation results of U-shaped loading platform

Block	Attribute	Arrival	Leave	utilization	The average length of the queue	The average waiting time	Maximum waiting time	Maximum queue length
Be shipping area	Queue	156	156	0.092435	0.1101608	1.0672624	11.601423	3
warehouse staging area	Queue	90	90	0.065018	0.0810674	1.2824765	14.986176	4
forklift 2	Resource Pool	×	×	0.810396	×	×	×	×
forklift 1	Resource Pool	×	×	0.8397846	×	×	×	×

Table 4 shows that a total of 246 products enter into emulation platform, the simulation completed a total of 245 pieces. In the delivery process that is the busiest periods, the emulation platform runs smoothly and there is no congestion almost, and there are only one product were not fully finished until 2880 minutes. In the above counts modules, the utilization frequency of blocks still is forklift 2, and the utilization frequency of forklift 1 is improved greatly. Both the average waiting time and the maximum waiting time of be shipping areas are reduced sharply. Judging from the statistics module, the processing efficiency of the process has improved.

3.5 Discussion of results

We can draw the following conclusions by comparing Table 3 and Table 4.

① During the 2880 minutes, the U-shaped loading platform processing total number is 245, it increased by 11.36% comparing with 220 pieces that disposed in the H-shaped loading platform.

② Be shipping area's average waiting time, the average length of the queue, the maximum waiting time, maximum queue length In the U-shaped loading platform were significantly reduced than before. The average waiting time is reduced from 48.51859 to 1.0672624, decreased by 47.451328 minutes.

③ The average length of the queue is reduced from 4.8429105 to 0.1101608, decreased by 4.7327497.

④ The maximum waiting time is reduced from 136.72568 to 11.601423, decreased by 125.12444.

⑤ The maximum queue length is reduced from 15 to 3, decreased by 12.

Through the above analysis, it can be seen that the situation of backlog has improved significantly in the U-shaped loading platform, the utilization rate of forklift 1 increases to 83.97846%, utilization rate of forklift 2 falls to 81.0396%, two forklifts' utilization rate is more balanced and the total efficiency improved significantly. It shows that the U-shaped loading platform is superior to the H-shaped loading platform.

4 Conclusions

This paper analyzes the S company's current existing problems and applies ECRSI method to optimize the process. Finally, this paper simulates the before and after the optimization of the process by Extendsim, then gets a new simulation results and analysis, it proves the feasibility of the optimization scheme, it also has a certain significance for enterprises in the same industry.

Abstract: The material input and output dynamic process of iron and steel enterprises is made up of the procurement process, the production process and the sale process, and the procurement process running success or not will directly affect the enterprise final product pricing and the whole profit of the supply chain. This paper is based on the basic principle of ABC method, procedure, standard and analysis process. On the base of a detailed investigation of a certain iron and steel group logistics management process, I explore and find problems that exist in the current iron and steel enterprises procurement process. To solve these problems, the article uses ABC method to reconstruct the purchasing process of iron and steel enterprise, and chooses the performance evaluation method to evaluate the re-engineering of purchasing process, next step analyze the economic benefit of iron and steel enterprise. The results shows that the re-engineering of procurement process based on ABC method can improve the flexibility and robustness of the iron and steel enterprise, and ensure the timeliness and the quality of the supplying raw material, improve the ability of the enterprise internal work together. It also can significantly enhance the core competitiveness of the enterprise.
Keywords: ABC method; Procurement; Process re-engineering; Performance evaluation.

1 Introduction

Material purchasing is an important part of the iron and steel enterprise production and management, the mission of material procurement department is to provide quality and economy productions by production quality, quantity, timely and economically for the manufacture, engineering, maintenance, labor insurance, etc, so it will guarantee the production and construction of the iron and steel enterprise go on wheels; To check and ratify the needed materials according to the predetermined plan on production and construction; To choose suppliers, organize purchase and import at home and abroad through formulating purchase plan, and also to arrange reasonable reserve; For the sake of improving planning accuracy, reducing reserves possession, accelerating the capital turnover, reducing the purchasing cost by making organization for the material supply management system. Traditional way of purchasing is opaque, and vulgar. Due to the factor such as system or mechanism, traditional purchasing mode has many places incompatible with modern purchasing, which affected the efficiency and effectiveness of procurement; meanwhile it also resulted in the high purchase and transportation cost. Enterprise material purchasing is involved in the enterprise itself, and at the same time is significantly related to the relationship between enterprise and suppliers, so how to optimize the iron and steel enterprise procurement logistics processes to reduce costs, improve enterprise competitiveness is the current problem that urgently need to be addressed (WU, 2014).

We can use time efficiency, SCM and ABC method to reengineer the purchasing process of iron and steel enterprise. Compared with other methods, it is more appropriate to use ABC method which is abbreviation of activity-based costing. Activity-based costing of theoretical framework is proposed by GeorgeJ Staubus, who is a professor in the United States. In recent years, our country mainly combine with case analysis in the research of activity-based costing or discuss its application in a particular industry (YU, 2007). To restructure purchasing management business process for steel enterprise by using ABC method can make the loss and waste of enterprise in the process of purchasing be in the lower limit, raise the sciences and effectiveness nature of the decision-making, planning, control, and promote the continuous improvement of enterprise management level .

2 The purchasing process by some iron and steel enterprises and problems in it

For most of the iron and steel enterprise before a group has its own set of material supply management system, organization structure and business processes, and there are certain differences between each other. But the main business process is roughly same, it includes making the procurement plan based on the requirements, selecting suppliers and signing procurement contracts, registration, checking incoming materials to the warehouse, settlement and payment delivery. Material supply department is not only responsible for purchasing goods, but also is responsible for the warehousing distribution, namely buy, pipe, tube recycle, save tube (ZHOU, 2009). The procurement business processes is as shown in Figure 1.

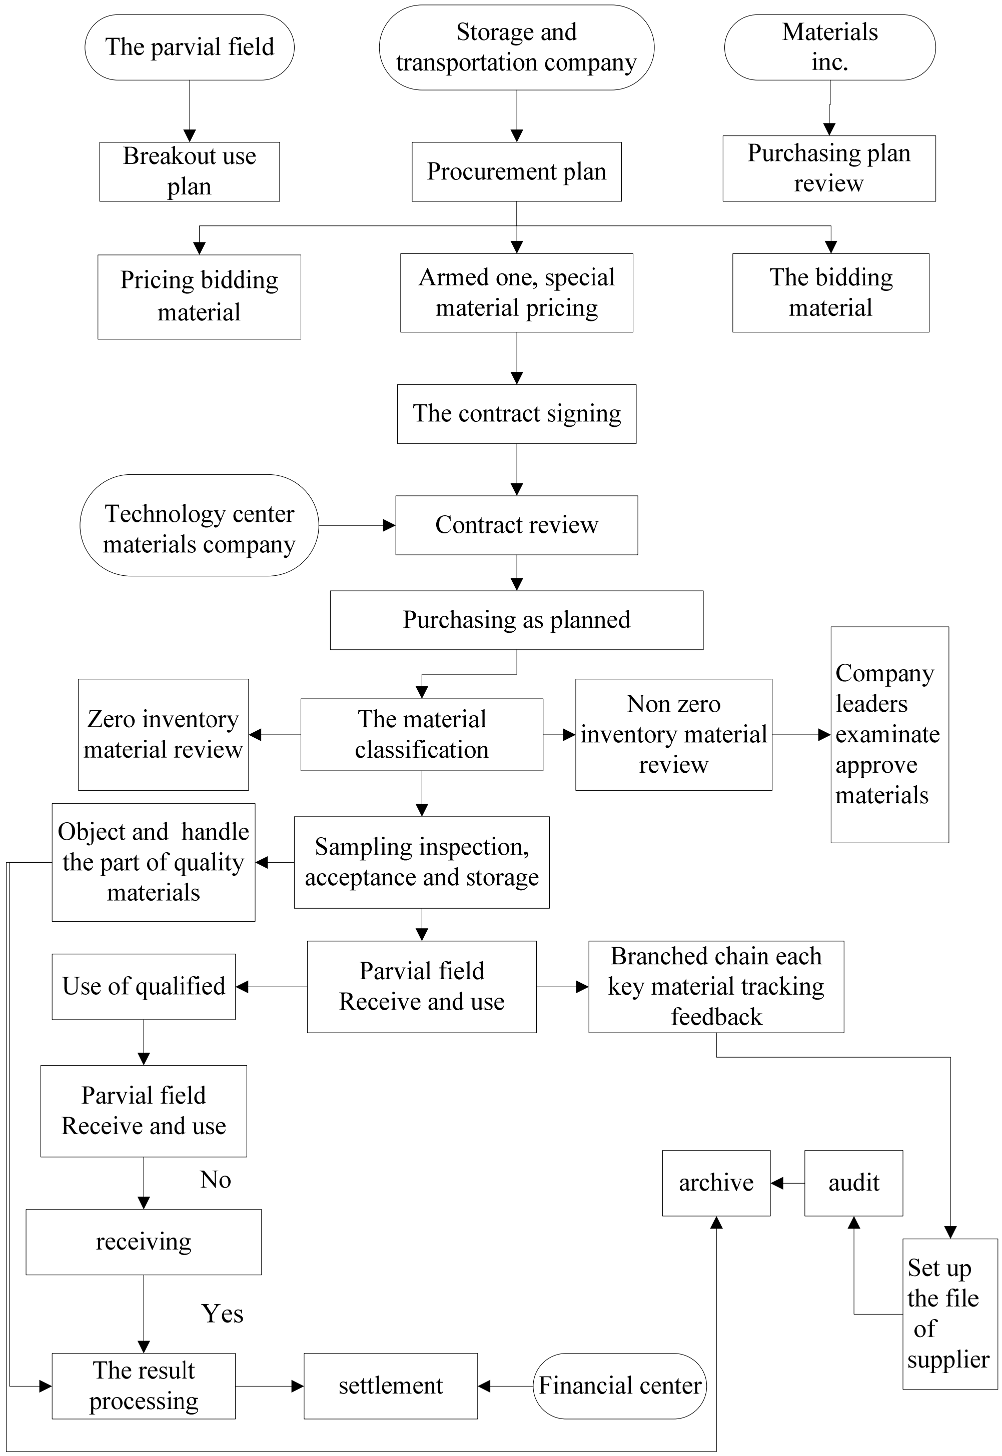

Figure 1. The current procurement flow chart

Traditional way of enterprise purchasing is opaque and vulgar, Due to the factor such as system or mechanism, traditional purchasing mode has many places incompatible with modern purchasing, which affected the efficiency and effectiveness of procurement, at the same time it also led to the high purchase and transportation cost. Enterprise supplies Procurement is involved in the enterprise itself, meanwhile it also has a major impact on relationship with suppliers. Specific analysis is as follows:

1) Each stock company has decentralized procurement, and is short of economies scale.

In case of decentralized management, Each company independently participates in carving up such companies external resources as supply and sales market resources, thus to form a number of the supply chain competition. The joint-stock company takes decentralized procurement, it causes that the company is unable to form Into scale, so after restructuring, unified purchasing process and supplier resources, implementing the centralized group Purchasing is the primary problem of group purchasing management to solve (MA, 2003).

2) The information cannot be shared.

Because the private information between Purchaser and supplier, enterprise purchasing department and related departments, management and implementers, is without integration, purchasing information does not implement effective sharing . as a result, it can't track procurement accurately, including purchase requisition, purchase vouchers, inquiry quotation; transport Processing, the goods processing, quality control and so on (LI, 2003).

3) Lack of restriction, easy to cause the black-box operation.

Purchase transaction authorization, issuance, approval, implementation and recording is without reasonable division of labor according to position, Purchase behavior lacks of restriction and transparency is insufficient. Enterprise makes the necessary separation for quality testing and payment right, which is respectively in charge of the quality inspection department and the financial department, but there is no separation in the pricing power, materials purchase price is lack of centralized management control. Purchase price is mainly determined by the buyer who negotiate with suppliers by using historical comparison information, enterprise purchase price is lack of monitoring, which brings about the materials procurement back with high price but poor quality, has the serious influence to the enterprise cost management and the quality of the product. The choice of suppliers and the signing of contract are completed by the buyer; the procurement in charge by special People, in the choice of suppliers, the subjectivity, optional gender and randomness is big, and the procurement process may be driven by interests, then appear black-box operation, giving up good for second-rate, and further situation.

4) Acceptance inspection is an important later check of purchasing department,

quality control is difficult.

Quality and delivery time is another two important factors for purchaser to consider, but in the current procurement mode, it is difficult for purchaser to participate in the supplier's production and quality control activities, to solve the quality and delivery of the goods period only through afterwards control method, and the control is very difficult. The union between purchaser and supplier is limited to temporary procurement, production organization and quality control activities related to each other is not transparent. So you need to make examination and acceptance through all sorts of relevant standards, such as international standards, industry standards. The cooperation lacking of the quality control will cause that the increasing difficulty to goods quality control of the purchasing department, to invest a lot of Time and energy, to pay the too big cost of various management.

5) Pyramid organization has disadvantages.

The traditional special steel enterprise's organization is set up according to the function, vertical organization is overmuch, the institutions is relatively, generally overstaffed, in central business processes to produce such problems as too much increment of the intermediate links and low efficiency, which does not accord with the requirement of supply chain management flat. The enterprise manage mode based on the theory of "division of labor theory", its organization form is the level of the pyramid, top-down hierarchical control structure. This organization institutions are the productions that determined by the planned economy and the backward management technology, it is function-centered, while don't care the process. The organizational structure determines the management process and information transmission channel; it caused the information transmission slowly, and in the statistical report process of each link, makes information distortion due to the influence of selfish departmentalism. These non value-added operations not only consume resources, but also affect the decision-making speed and even lead to policy mistakes (LU, 2005).

3 The application of the ABC method in a certain iron and steel enterprises procurement process reengineering

On the basis of procurement logistics process analysis for a certain iron and steel group, using ABC method to make procurement logistics process reengineering and to analysis, the results are shown in Table 1.

Table 1. The current procurement process analysis

Serial number	Business process description	Job classification	Whether it is necessary
(1)	Breakout plan was proposed	Non value-added homework	Necessary activities
(2)	Summary procurement plan	Non value-added homework	Necessary activities
(3)	Materials purchasing plan by the company	Non value-added homework	Non-essential activities
(4)	Determine the material purchasing plan	Non value-added homework	Non-essential activities
(5)	Sign the contract	Non value-added homework	Necessary activities
(6)	Review the contract	Non value-added homework	Necessary activities
(7)	Perform purchasing plan	Non value-added homework	Necessary activities
(8)	Material classification audit	Non value-added homework	Necessary activities
(9)	Non zero inventory material for examination and approval of leadership	Non value-added homework	Non-essential activities
(10)	Sampling inspection, acceptance and storage	Non value-added homework	Non-essential activities
(11)	The quality objection handling	Non value-added homework	Non-essential activities
(12)	receiving	Non value-added homework	Necessary activities
(13)	Finance settlement center	Non value-added homework	Necessary activities

There much control phenomenon after the event in the process of making procurement plans, such as after making procurement plan of storage and transportation company, the manager of the material company office have to check for acceptance, in fact, it should be made purchasing plan by the material and supply company according to the sales and inventory. Eliminating the process such as procurement staff to clean up, to Carries on the statistical, to contact the relevant unit staff, to understand inventory, delivery time, quality and technical requirements and so on, to put forward to implement Examination and approval opinions, and then reported to the branch leadership and a series of unnecessary return process after the procurement staff received purchasing plan. So we should strengthen procurement planning of beforehand and matter controls, synchronize the information, coordination of transmission, improve the efficiency of process operation. The investigation questionnaire for material purchasing process showed that the audit, material pricing and contract review of the purchasing plan whose execution of required number is 7, 9, 5, and 6 respectively, accounting for 75% of the total number of the whole process. In addition, pricing for supplies needs for a long time, generally 1 to 2 days, contracting review is 3 to 10 days, quality objection processing is about 15 days, signing a contract with suppliers is to 1 (province) to 15 (province) days, and the information passing basically do not have the way of application of information processing, which affects the efficiency and effectiveness of the procurement, leads to the procurement costs rise.

Therefore, the purchasing logistics reengineering is according to the following steps:

Activity Elimination. It means to eliminate the job without additional value assignment. Take effective measures to eliminate for the job that have been made sure have no additional value assignment.

Activity Selection. It means to select the best among the multiple different assignments chain, and different strategies often produce different assignments.

Activity Reduction. It is a way to improve enterprise management cost and resources, that is to say, to improve the work efficiency of the necessary or improve the work without additional value that cannot be eliminated in a short time Homework.

Activity Sharing. It is the use of improving efficiency of necessary work by Economies of Scale, that is, improving the operation of input-output ratio, so it can reduce operation reason distribution rate and the cost shared by a product (CHENG, 2012).

Through the above analysis, we can make reengineering as the follows, the information of the current procurement logistics process (1) and (3) is passed to the storage and transportation company through the meter Computer, materials sourcing companies received purchasing plan from the internet, then they will inform upstream suppliers about the purchase plan, suppliers need to prepare the goods as required, negotiate pricing, then the two sides sign a purchase contract, the buyer is responsible for purchasing, manufacturing department is responsible to prepare the goods, at the same time, notify the financial center for financial settlement. The purchase logistics process after reconstruction is as shown in Figure 2.

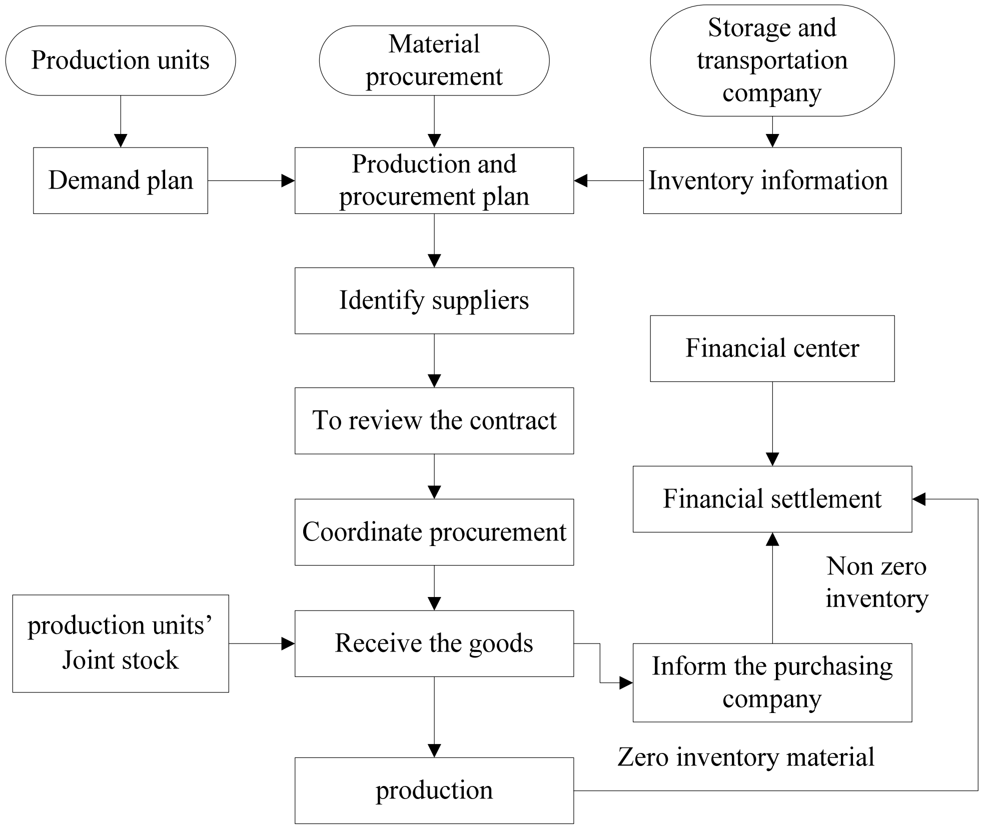

Figure 2. Procurement logistics flow chart after reconstruction

Using information technology to reduce the time for making purchasing plan, audit, material pricing, as well as the contract review time, in this way, it can improve the efficiency and effectiveness of procurement, and the materials directly into the production department t, reduce the purchasing department work pressure and avoid the activity process that do not add value, it is useful to achieve fine operation. Through the reconstruction of purchasing process, it can reduce the non value-added work, can save the time of purchase, simplify the working process of the purchase, and thus reduce the purchasing cost.

4 Reviewing for a certain iron and steel enterprises after the procurement process reconstruction

In the program of iron and steel enterprise management, effective performance evaluation and management is indispensable, the performance evaluation is to evaluate enterprise's production and operation activities by regularly or not regularly, based on facts, it can help the enterprise find weak link in enterprise management, put forward the improvement measures and goals, make the enterprise to progress for long. After reconstructing the purchasing process by using ABC method, it has the following four aspects carries on the analysis of performance appraisal.

1) The evaluation of lead time. Lead time is a kind of effective comprehensive indicator of considering the whole organization structure and operation. How to reduce procurement lead time involves many aspects, such as too long setup time, frequent downtime, not coordinate schedule, not reliable suppliers, too long transportation time, and a series of problems such as mass inventory may result in the long purchasing lead time. Long lead time show that the transport cycle performance, processing cycle, long storage period in the supply chain is long, and lead to the high cost. Due to process reengineering, the information of the current procurement logistics process (1) and (3) is passed to the storage and transportation company through the meter Computer, materials sourcing company received the purchasing plan from the internet, thus information transmission speed faster, which can reduce the time that required to interview, therefore it will shorten the lead time. Cost drivers, and the concept of value added/non-value added work is put forward by homework cost method, which recognizes the cost of production of measurement should be based on the decomposed into cost drivers homework, so as to give prominence to the key assignments/operation process resources. According to the requirement, reduce the value increment non-essential activities, it can save a series of unnecessary roundtrip process of procurement staff such as to clean up, statistics, contact the relevant unit staff, understand the inventory, delivery time, quality and technical requirements, etc., put forward suggestion on, examination and approval and submitted to the branch leadership after receiving purchasing plan; At the same time, the materials directly into the production department can shorten the storage period. Thus greatly reduce the procurement lead time.

2) The evaluation of flexibility. Flexibility refers to the system can adjust range of ability to external or internal interference caused by the change. Simple understanding of the supply chain flexibility refers to the abilities that it can rapidly and economically process uncertain situation that happened in the production and business operation of the environment or caused by environment uncertainty, it is generally composed of buffer, adaptation and innovation ability. Due to the operation of the supply chain is under uncertainty environment, when the customer demands change; the flexibility of supplier becomes the key factor for its survival. High flexibility can improve customer satisfaction, increase the strain capacity on demand, reduce the overdue orders and the possibility of missed opportunities, but also enhance the ability to develop new markets and products (HAO, 2004).

Through the analysis of the procurement lead time, as a result of the purchasing lead time greatly shortened, procurement staff have the production plan in timely and accurate information, so they'll have plenty of time to focus on value analysis and selecting sources, research, negotiation strategy and understanding the production problems. Therefore, when something changes, there are more full time in relatively to adjust reaction, at the same time, using information technology can increase flexibility and the core competitiveness of enterprises.

3) The evaluation of robustness, robustness is namely Conservatism; it refers to the robustness and strong degree in the process of change. For the supplier, robustness means that even if the client demand changes to a certain extent, the supplier will still be able to guarantee the product quality, delivery, normal operation, so as to guarantee the stability of the whole supply chain operation in the cooperation between suppliers with the clients (WANG, 2004).

4) The evaluation of cost. From the perspective of supply chain operation, the cost of purchasing supply system used to be reflected with supply chain assembly commonly, including supply chain communication cost, inventory cost and supply chain total transportation cost of external costs, reflecting the cost of the supply chain operation efficiency. it will reduce the non value-added homework, reduce waste throughout the supply chain, reduce the transportation cost through refactoring; By reducing the order to delivery cycle, production and logistics process can be finished in a short time, all entities in the supply chain can run more efficiently, Thus finally to reduce inventory; To improve the corresponding cash turnover by reducing order delivery cycle.

5 Conclusions

For iron and steel enterprises, the process that to product for sale and to purchase for the production is an interlocking input/output dynamic process of materials, which in turn makes up the procurement process, production process and marketing process. From a logistics point of view, the success of the initial procurement process operation will directly affect the enterprise production and sales pricing of the final product and the entire final profit of supply chain. It increases the flexibility and robustness, avoids the situation that it appears the suspension of equipment production, smelting process because of the lack of material which can cause huge economic losses, and ensures the continuous production of iron and steel enterprises through the implementation of ABC method for the reconstruction of the procurement process. Considering the strategic cooperation with suppliers, the characteristics such as the intensive capital of iron and steel enterprise, raw material fuel capital takes up big volume and the large transportation, so as to guarantee the quality of raw materials and timeliness in the process of implementing ABC method. Through the implementation of ABC method, which is beneficial to make a detailed and specific analysis and control on how to use the resources step by step, and to optimize operation chain, value chain and the combination of production quantity and variety, so as to optimize the allocation of resources, to give play to various synergy among various departments and technology and production process, finally to improve the core competitiveness of the enterprise.

Third-Party Cold Chain Logistics Cost Accounting Based on Activity-Based Costing

Ting Wang; Xiuli Li; Mei Huang; and Teng Ma

School of Automobile, Chang'an University, P.O. Box 710064, Xi'an, Shaanxi. E-mail: wtingwater@163.com

Abstract: Compared to the general logistics, the cold chain logistics is more expensive and the cost structure is more complex. It plays an important role in logistics. The importance of the logistic cost determines that it must be as accurate as possible, which requires higher requirements for accounting methods. In order to carry out cost accounting better, this paper uses activity-based costing and multistage mode, assembling the indirect cost into operations according to resource driver, forming the ABC library. The cost allocation rates are determined by the activity driver. The cost in the ABC library is assigned to various cold chain logistics service according to the cost allocation rates. In this way, we can obtain the cost object, which is the indirect cost of the third-party cold chain logistics services. Based on activity-based costing, this paper establishes a cost accounting model for the third-party cold chain logistics enterprises. Apply this model to one of the third-party cold chain logistics enterprises and analysis the cost accounting. Research results show that cost accounting based on activity-based costing is more accurate, truthful and objective compared to traditional cost accounting methods for indirect cost. The cost method is conducive to control cost effectively and to make better decisions for enterprises.

Keywords: Cold chain logistics; Activity-based costing; Cost accounting; Multistage mode.

1 Introduction

With the increasing demand for fresh food and frozen food, the cold chain markets have good development prospects. However, cold chain logistics faces enormous pressures and challenges. High logistics costs seriously affect the economic efficiency of the third-party cold chain logistics enterprises.

The third-party cold chain logistics enterprises combine cold chain process, cold chain storage, cold chain transportation and cold chain distribution to meet the demands of the customers. By reducing costs, the third-party cold chain logistics enterprises improve work efficiency and service level, which enhance its competitiveness.

As the third profit headspring, logistics costs control is directly related to the profit of the third-party cold chain logistics enterprises. How to reduce costs and increase profits is the key for a third-party cold chain logistics enterprise. In this way, it is necessary to find ways to control logistics costs.

2 The problems of the third-party cold chain logistics enterprises applying the traditional cost management.

From the perspective of functional forms, the costs of cold chain logistics include the costs of distribution processing, packing, storage, transport and handling. From the perspective of payment forms, the costs of cold chain logistics include the costs of materials, labor, equipment, and the costs of integrated management. Some costs can be shown from statistics directly, which are the direct costs. The other costs cannot be calculated directly, which are indirect costs. Indirect costs can be estimated in a certain proportion according to experiences.

The traditional cost management is applicable for the enterprises which have less operating varieties, less intermediate operation, low proportion of indirect costs. The traditional cost management is difficult to assign indirect costs accurately, so it is not applicable for the third-party cold chain logistics enterprises. For higher indirect costs of the third-party cold chain logistics enterprises, the single cost distribution standard has warped the costs information of logistics enterprises. Traditional cost management allocates indirect costs to business subjectively on the basis of production or working hours.

3 The multistage mode of activity-based costing

Activity-based costing method is centered on activity. In the cost accounting process ABC focus on activity. Compared to the traditional method, activity-based costing method in cost accounting has more thorough changes.

Activity-based costing recognizes and measures the cost, dynamically reflecting all the activities. It provides useful information for strategy, planning and control to eliminate worthless-added activity, improve “value-added” activity and minimize wastes. In this way, the management can be improved. Activity-based costing is based on “activity consumes resources, product consumes activity”. Therefore, it includes resources, activity, product, service, motivation and activity motivation.

An enterprise's resources include direct labor, direct material, production and maintenance costs (wage costs such as purchasing personnel), indirect manufacturing costs and production costs (such as advertising). Resources enter into the activity which is the unit of work with a certain correlation. Activities COST pools are the cost collection of of resources consumed in homogeneous assignments. The cost objects are the final point and sufferers of costing businesses. Cost drivers are the facts leading cost. Cost drivers can be divided into two categories which include resource drivers and activity driver by Activity-Based Accounting.

In multi-stage model, activities are not directly consumed by the cost object, but consumed by other activities. Other activities are consumed by the cost objects.

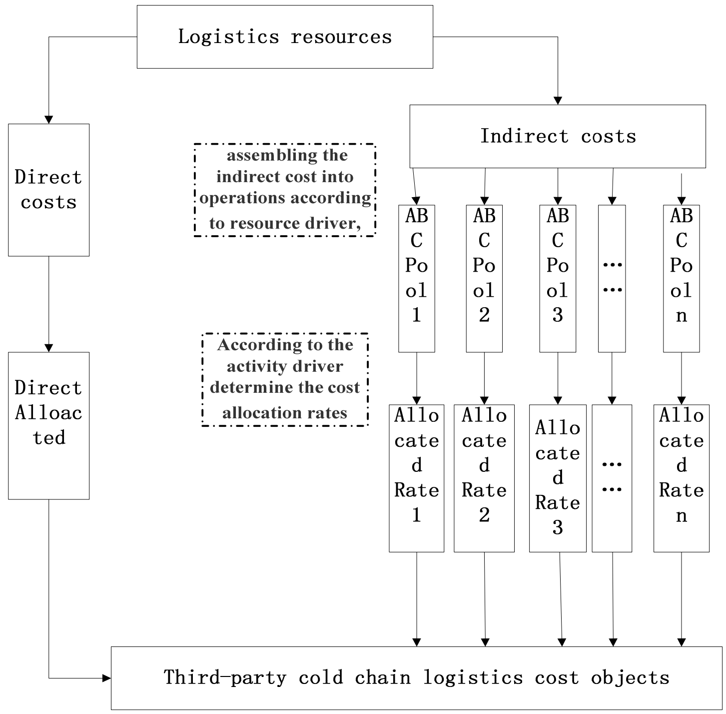

Figure 1. Multi-stage Model of ABC

4 The implementation of activity-based costing in cost accounting of the third-party cold chain logistics enterprises

Take the example of one third-party cold chain logistics enterprise W. The operation mode of company W is mainly achieved through the cold chain logistics services contract signed. The income and the balance of the project costs are the project's profit. Total costs directly derived from the financial statements of the company. However, we cannot accurately calculate the costs of every project. So, logistics enterprise cannot set reasonable price. Now we account the costs of company W using activity-based costing.

Company A and company B have the same requirements for frozen processing activity and packaging activity. But for the refrigerated distribution activity, they have different demands. Company A requests 1300 of product distributed to 130 every three days. Company B requests 1300 of product distributed to 87 every two days.

In order to meet the requirements of company A and B, 300 square meters in the warehouse are used to store company A's products, and 200 square meters in the warehouse are used to store company B's products（assuming that company A and company B have the same distance to W and every link has not caused damage and no penalty cost）.

The costs of the third-party cold chain logistics are made up of the costs of direct materials, the costs of direct labor and special cold chain costs. Special cold chain costs refer to the penalty cost for damage or improper distribution time. The cold chain logistics costs are relatively easy to be collected directly to specific services. Based on the activity driver determines the cost allocation rates, activity-based costing is used to allocate huge indirect costs. The cost in the ABC library is assigned to various cold chain logistics service according to the cost allocation rates. In this way, we can obtain the cost object, which is the indirect cost of the third-party cold chain logistics services.

4.1 Analysis of third-party cold chain logistics activities

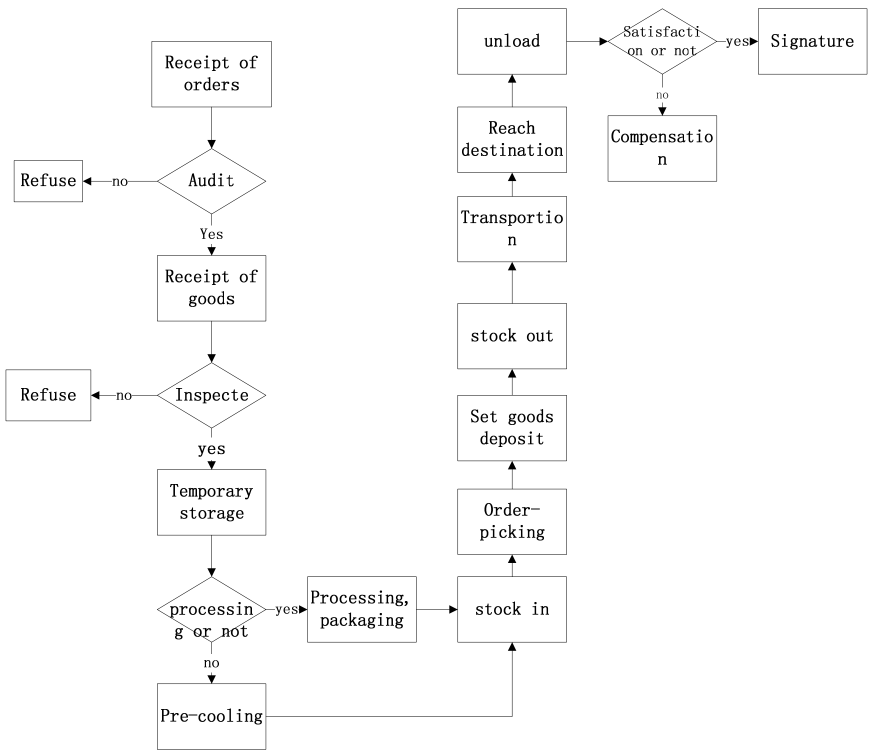

Figure 2. Business process diagrams of W

From the figure1 we can get that the activity of the third-party cold chain logistics can be named: Contract processing activity, frozen processing activity, Packaging activity, Purchase materials activity, Stock in activity, frozen storage activity, Stock out activity and Refrigerated distribution activity.

4.2 Identify resources

Major resource projects include: the costs of resources, the labor costs, electric power changes, fuel costs, depreciation costs and office expense. The costs of resources: material fees of purchasing an appropriate packing. It belongs to direct costs and can be collected directly to the cost object.

The labor cost: the calculation of labor costs is the number of employees involved in logistics operations and corresponding salary multiplied by. Manager salary to direct costs, and can be collected directly to the cost object.

Electric power changes: the amount of electricity can be determined by a company's meter directly. The quantity multiplied by the units of electricity is electric power changes. The power consumption is considerable including the normal office, electricity consumption frozen (reservoir), cold storage and cold-chain equipment.

Fuel costs: fuel fees are mostly spent on frozen processing machinery, material handling equipment and the vehicles of refrigerated transportation. Fuel fees can be obtained directly from the financial statements.

Depreciation costs: It mainly refers to the depreciation of the plant, machinery, equipment, warehouse and fixed assets. Depreciation cost allocation mainly accord to the fixed assets calculated using time limit in the company.

Office expenses: It mainly refers to the cost, which the company spends in the project contract processing, warehouse management, project management, and other project.

4.3 Allocation of resources to the various logistics activities

Table 1. The costs of resources of W company

materials Costs	Labor costs	Electricity tariffs	Fuel costs	Depreciation costs	Office expenses	total
7320	109300	12532	12788	3343	880	132843

(There are 600 Yuan in labor cost that is responsible for the wages of company A's and company B's manager. This belongs to the direct costs of direct labor, and it can be collected directly. Labor cost is involved in indirect distribution: 109300-6000=103300 Yuan.)

(1) The allocation of labor costs

Resource driver of labor cost is the number of employees. The rate of resource driver is average of salary. Hence, the resource cost is the salary levels and the number of employees multiplied by.

Table 2. The allocation of labor costs of W company

The activity name	Resource driver	The number of resource driver	The rate of resource driver	Resource c osts（Yuan）
Contract processing activity	The number of e mployees	2	2500 Yuan/person	5000
Frozen processing activity		7	2400 Yuan/person	16800
Packaging activity		7	2400	16800

			Yuan/person	
Purchase materials activity		4	2500 Yuan/person	10000
Stock in activity		7	2400 Yuan/person	16800
Frozen storage activity		5	2300 Yuan/person	11500
Stock out activity		4	2400 Yuan/person	9600
Refrigerated distrib u-tion activity		7	2400 Yuan/person	16800
total		43		103300

（2）The allocation of electric power changes

Resources driver is the kilowatt-hour. The rate of resource driver is the unit price. Electric power changes of W company are the kilowatt-hour and the unit price multiplied by.

Table 3. The allocation of electric power changes of W company

The activity name	Resource driver	The number of resource driver	The rate of resource driver	Resource costs （Yuan）
Frozen processing activity	kilowatt-hour	2250kilowatt-hour	1Yuan/ kilowatt-hour	2250
Packaging activity		1337kilowatt-hour		1337
Stock in activity		490kilowatt-hour		490
Frozen storage activity		6740kilowatt-hour		6740
Stock out activity		690kilowatt-hour		690
Refrigerated distribu -tion activity		1025kilowatt-hou r		1025
total		12532		12532

（3）The allocation of costs of fuel costs

Fuel costs of company W are mostly spent on frozen processing machinery, material handling equipment and the vehicles of refrigerated transportation. Resource driver is working hours. The rate of resource driver is devices per hour fuel consumption costs (Assuming that frozen processing machinery and material handling equipment have the same fuel consumption costs).

Table 4. The allocation of costs of fuel costs of W company

The activity name	Resource driver	The number of resource driver	The rate of resource driver	Resource costs （Yuan）
Packaging activity	Working hours	12 hours	12788/192=66.6	799.4
Tock activity		49 hours		3263.6
Stock activity		52 hours		3463.4
Refrigerated distribution activity		79 hours		5261.6
total		192 hours		12788

(4) Depreciation costs of company W

Depreciation costs of fixed assets are mainly calculated based on the length of procurement of equipment or plant's life. This belongs to the direct costs, and it can be collected directly.

Table 5. The allocation of depreciation costs of W company

The activity name	Resource costs（Yuan）
Frozen processing activity	1050
Packaging activity	260
Stock activity	295
Frozen storage activity	790
Stock activity	385
Refrigerated distribution activity	563
total	3343

(5) The allocation of office expense of company W

Office expenses are exclusive costs, which can be obtained directly from the financial statements, and assigned directly to the related logistics jobs.

Table 6. The allocation of office expense of W company

The activity name	Resource costs（Yuan）
Contract processing activity	205
Packaging activity	296
Refrigerated distribution activity	379
total	880

Summarily, we can get the cost of every activity:

Table 7. Activity cost of each logistics operation of W company

The activity name	Labor c osts	Electricity tariffs	Fuel costs	Depreciation costs	Office expenses	total
Contract process -ing activity	5000	——	——	——	205	5205
Frozen processing activity	16800	2250	——	1050	——	20100
Packaging activity	16800	1337	——	260	——	18397
Purchase materials activity	10000	——	799.4	——	296	11095.4
Stock in activity	16800	490	3263.6	295	——	20848.6
Frozen storage activity	11500	6740	——	790	——	19030
Stock out activity	9600	690	3463.4	385	——	14138.4
Refrigerated distrib ution activity	16800	1025	5261.6	563	379	24028.6
total	103300	12532	12788	3343	880	132843

4.4 Assignment costs to each cost object

Firstly, we need to determine the activity driver of each cost object:

Table 8. The activity driver of logistics operation of W company

The activity name	Activity driver
Contract processing activity	Contract number
Frozen processing activity	Number of products
Packaging activity	Number of products
Purchase materials activity	Number of products
Stock in activity	The number of stock in
Frozen storage activity	Warehouse area
Stock out activity	The number of stock out
Refrigerated distribution activity	The number of distribution

Table 9. The quantity of activity driver of each logistics operation of W company

Activity driver	total	The number of resource driver	
		A	B
Contract number	2	1	1
Number of products	2600	1300	1300
The number of stock in	20	10	10
Warehouse area	500	300	200
The number of stock out	25	10	15

The number of distribution	25	10	15

The rate of activity driver= the costs of activity / the total number of resource driver. We can get the rate of resource driver.

Table 10. The activity driver rate of each logistics operation of W company

The activity name	The costs of activity	The total number of resource driver	The rate of resource driver
Contract processing activity	5205	2	2602.5
Frozen processing activity	20100	2600	7.73
Packaging activity	18397	2600	7.07
Purchase materials activity	11095.4	2600	4.27
Stock in activity	20848.6	20	1042.43
Frozen storage activity	19030	500	38.06
Stock out activity	14138.4	25	565.54
Refrigerated distribution activity	24028.6	25	961.14

When we get the rate of resource driver and the total number of resource driver of contract A and B, we can obtain the indirect costs of contract A and contract B.

Table 11. The logistics costs assigned to cost object A and B

The activity name	The rate of resource driver	Contract A		Contract B	
		The number of resource driver	Assigned amo unt	The number of resource driver	Assigned am ount
Contract processing activity	2602.5	1	2602.5	1	2602.5
Frozen processing activity	7.73	1300	10050	1300	10050
Packaging activity	7.07	1300	9198.5	1300	9198.5
Purchase materials activity	4.27	1300	5547.7	1300	5547.7
Stock in activity	1042.43	10	10424.3	10	10424.3
Frozen storage activity	38.06	300	11418	200	7612
Stock out activity	565.54	10	5655.4	15	8483.1
Refrigerated distribution activity	961.14	10	9611.4	15	14417.1
Total	64507.8			68344.2	

The costs of the third-party cold chain logistics are made up of two parts: direct costs and indirect costs. Direct costs include direct material costs, direct labor costs and special cold chain costs. Direct costs are assigned to cost objects according to the number of products. In this case, A and B have the same contract numbers. Direct material costs is 7320，so MA=3660，MB=3660 .Direct Labor costs: LA=3000, LB=3000. Special cold chain costs: CA=CB=0. Indirect costs p: IA =64507.8, IB=68344.2.

Costs object A = $M_A + L_A + C_A + I_A$=3660+3000+0+64507.8=71167.8;

Costs object B = $M_B + L_B + C_B + I_B$ =3660+3000+0+68344.2=75004.2.

Company A and Company B has the same contract numbers, which is 1300. So, costs per unit of A contract is 54.7(71167.8/1300) and costs per unit of B contract is 57.7(75004.2/1300).

5 Conclusions

This paper applies this model of ABC to one of the third-party cold chain logistics enterprises and analysis the cost accounting. We can get:

(1) Applying the activity-based costing to third-party cold chain logistics cost, specific resource consuming can be mastered clearly.

(2) Determine the cost of each project of cold chain logistics. Logistics enterprise can get reliable product cost information. They can set reasonable price.

(3) Through accounting, we can get whether the fame of costs is reasonable and workout a reasonable and effective solution to reduce costs, and improve the economic efficiency of enterprises.

Abstract: Considering the financial feature of logistics enterprises, this paper discusses the uniform credit financing mode that allows banks and logistics enterprises to have comprehensive cooperative relations based on the existing inventory financing products. Introducing the idea of "two sides decide the market", the paper analyzes the problem of income distribution in the capital supply chain that consists of commercial banks, logistics enterprises and loan enterprises. In the contract, this paper uses Stackelberg game theory of complete information to analyze the behavior of banks and logistics enterprises, and then applies backward induction method to get the risk bearing rate of logistics enterprises, the loan-to-value ratio and bank lending rate. The result indicates that, under uniform credit financing model which depends on logistics enterprises to determine loan-to-value ratio and banks to determine lending rate accordingly can expand the demand of financing market and create more benefit for all participants. Finally, the sensitivity analysis of small enterprises' compliance rate and pledge' realizability demonstrates that the interest relationship in the model is compatible with the reality.
