Calculate results based on survey data and formula (1) (2) (3), as follows, both shipper and consignee are satisfactory to the rail door-to-door service from Figure 4. However neither the value of charge service for shipper nor cargo delivery service for consignee is high according to the survey. The suggestions that rail point Y could amplify charge channel and strengthen normative of cargo delivery.

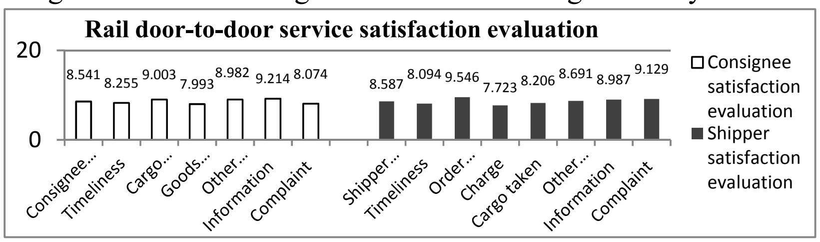

Figure 4.Rail freight point Y satisfaction evaluation values

6 Conclusions

Rail door-to-door service evaluation feature conclude its property, the greatest satisfaction of passengers. It is the development goal and the cause to optimize continually. Acquiring service evaluation indexes system and calculating the rail freight point Y satisfaction value by fuzzy comprehensive evaluation method. It recommends that extend charge channel and enhance normative of cargo delivery. Then verify the method with relevant parameters. Analyzing the changes of customer demand from satisfaction evaluation and rail door-to-door transport experience, so as to guide rail transport development faster and meet society needs better.

Abstract: By analyzing the correlation between road infrastructure construction in different regions of Sichuan Province and poverty, it can be found that when road density is low, the poverty rate is relatively high, then further analysis tells that rural road construction influence the changes of the structure of peasnats' income and improve their viability. On this basis, we make suggestions to increase rural road infrastructure construction in the poverty-stricken areas.
Keywords: Rural roads; Poverty alleviation; Sichuan.

1 Introduction

Transportation which plays a linking role in the economic ties has a vital influence on the division of labor, the trade development, the agricultural production layout and the urban distribution. Rural road is a important basic condition to develop rural economy, to speed up the adjustment of agricultural industrial structure, to increase the income of peasants continuously, and is an important link to promote harmony, to narrow the differences, to promote the integration between urban and rural areas, and is the solid foundation on which to build a new socialist countryside. Relative lag-behind of rural infrastructures, especially underdeveloped road is one of the common characteristics in the poor areas. Rural highway has the widest service recovery and links the poverty areas most frequently, and is also the infrastructure which should be selected to improve in the first place in rural areas.

2 Field Data

Until 2012, in Sichuan province, it has accomplished a investment of 17.3 billion RMB, 22 thousand kilometers newly-built roads and 8967 kilometers newly-expanded roads. All of these programs have brought that 92.26% of the towns are accessible by taking roads and 137 highway bridges, which cover that all newly-built and newly-expanded rural roads (including both concrete roads and asphalt roads) have reached 8471 kilometers, local rural roads have reached more than 9621 kilometers and the roads between neighbors have reached 8471 kilometers. Since 1980s, the state, facing the reality that infrastructure construction in poverty-stricken areas is weak, has enrolled the rural infrastructure construction in the top list of poverty development. As the Sichuan Poverty Alleviation Monitoring

Statistics Yearbook says, the government has invested 9735 million RMB into the preferential poverty counties from 2005 to 2010, including 2310 million RMB to road construction up to 23.8% in and the ratio of 2009 is 34% and 22.2% in 2010. The concrete data is shown in the chart below.

Table 1 The Investments into Road Construction of Si Chuan Preferential Poverty Alleviation Counties(YUAN)

Year	Road Investment	Total Investment for Poverty-alleviation	Ratio(RI/TIP)
2010	507717449	2284305454	22.2
2009	941729918	2751444448	34.2
2008	284711613	1895675962	15
2007	201785900	1251092134	16.1
2006	229472072	778158104	29.5
2005	149093200	774474500	19.3
合计	2314510152	9735150602	23.8

3. Data Analysis

It has been proved that road constructions can improve regional economic growth. (World Bank, 1994, p15). From Chart 2, we can see road construction has a certain relationship with poverty population reduction chronologically. For example, when the Ganzi county's road coverage rate is low, its poverty rate is high; when Chengdu county's road coverage rate is high, its poverty rate is low. The influences of road construction on mitigating poverty are always classified into two kinds, one is direct influence and the other is indirect influence. The direct influences show as saving transportation time, including the time taken on the way to workplace, school, hospital and supermarket and saving money like saving the motor vehicle fuels thing. The indirect influences always mean the increase of income and other benefits brought and various income source and employment stucture by boosting economic growth, which can alleviate the weakness when the economy comes to shocks. (Grootaert，2002)

Table 2 The road density and regional economic condition through the whole province in 2012

Area	Road Density		Per Capita (yuan)	Percentages of Regional GDP（%）			the Proportion of Poverty Families Accounted for the Whole Families（%）
	Calculated on the Territorial Area（KM/Hundred Square KM）	Calculated on Population（KM/Ten Thousand People）		Primary Industry	Secondary Industry	Tertiary Industry

3.1 The influence of rural road construction on income structure

There are two methods that road construction influences on the income of planting industry. One is that, thanks to the accomplished road construction, the peasants save money while they buy and sell agricultural products, so that they have improved the productivity. The other is that the accomplished road can build the relationship between peasants and markets so that they can adjust the planting pattern to increase productivity. What's more, it can stimulate non-agricultural development and offer jobs for non-agricultural population, which would make the income source and labor resource diverse. One of the most important factors that lead town companies to success is that there are the fundamental roads and other infrastructures spread across the rural areas.(World Bank, 1994,p 3)

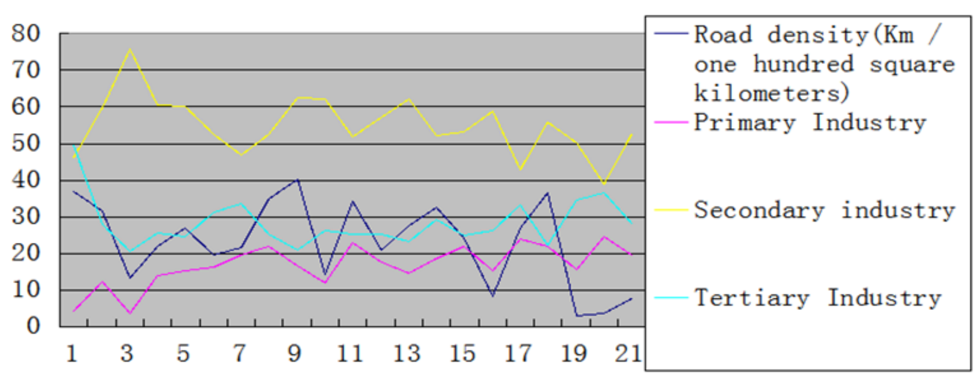

Figure 1.the Relation between Regional Road Density Rate and Industrial Structure

Based on the data of Industrial Structure and road density in the Table 2,plotted discounted diagram shown in Figure 1, we can find the line of Road Density goes the opposite direction against the line of the proportion of Primary Industry's GDP, while keeps the same trends with the line of Tertiary Industry. Then we come to the conclusion that the higher the road density is, the more the proportion of tertiary industry' GDP in regional GDP is and the less ratio of primary industry is, the more easily non-agricultural businesses survive and the more advanced the industrial structure is.

3.2 the influence of road infrastructure construction on raising economic viability of peasants

Road infrastructure construction can make it more convenient for poor people to get education and medical care, make it come true that more professional technicists and teachers come to serve local people, improve the infrastructure quality like hospital and school. And it is also good for poor people to enhance human capital and make it convenient for relatives and friends visiting that raise up social capital. Seen from Figure 2, the correlation between labor training and road density is high, which means road construction is beneficial for labor transfer and employment in poverty-stricken areas and has a positive influence on mitigating poverty.

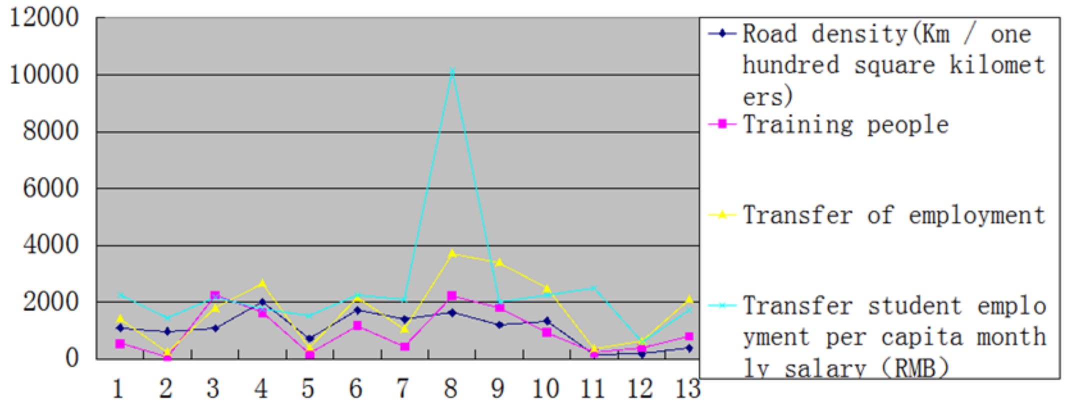

Figure 2. the correlation between road density and the number of training people

Source: Poverty Alleviation Monitoring Statistics Chronology of Sichuan Province (2012)

4 Conclusion and discussion

It is a significant way to increase peasants' income that to construct rural roads. It has been proved that it is a valid approach to get rid of poverty and make moderately prosperous life that to speed up rural roads construction and improve rural traffic conditions. One of the most important reasons that lead to rural economic lagging behind is the weakness of transportation and limited information coming in. However, to speed up rural roads construction not only can break the closing condition, facilitate the exploitation of rural nature resources which turn the soil, mineral, forests, water and tourists resources into productivity, but also can open and expand information and goods channels which bring rural natural products and agricultural products into circulation to increase peasants' income and make well-off life, and drive the rural areas to get rid of poverty eventually.

It is an arduous task for new period poverty-relief that to promote roads construction. The transport agencies in different regions would have to put road-construction as the strategic focus, formulate a practical scheme, take efficient measures to carry out rural roads construction effectively, striving to make contributions to getting rid of poverty and living a well-off life in poverty-stricken areas.

Operation Cost Research of Railway Freight Transportation Enterprise Based on the Advanced Activity-Based Costing Theory

Jianguang Li; Yuxiang Yang; and Jie Li

School of Transportation and Logistics, Southwest Jiaotong University, No. 111 of North Second Ring Rd., Chengdu, Sichuan, China. E-mail: dr.diudiu@gmail.com

Abstract: Based on the theory of activity-based costing, this paper studies the detail cost composition and cost behavior of railway freight transportation enterprise. According to the analysis, this paper purposes an advanced activity-based costing theory. Firstly, it analyzes the exact process of transportation operations. Then, it divides the cost elements into the related cost centers. At last, based on the cost centers, this theory allocates the cost elements into specific processes. Finally, this paper puts forward the calculation steps.
Keywords: Railway transportation enterprise; Operation cost; Cost accumulation; Cost allocation.

1 Introduction

Cost is the monetary expression of resource consumption during the process of products production or manpower supply of an enterprise. It also is an important basis of decision making, budgeting, controlling and performance evaluation. As for a railway transportation enterprise, according to the particularity of its production, there are lots of differences in analysis and calculation of operation cost, comparing with the manufacturing enterprise. Calculating and ensuring the operation cost of a railway transportation enterprise is not only an important constituent part of transportation benefit assessment, but also an obbligato content of decision-making and analysis of profit and loss.

2 Basic conceptions and research status

According to the particularity of its production, the study on railway freight transportation operation cost has to turn some basic conceptions in manufacturing enterprise into transportation field. According to different angles and standards, operation cost could be divided into different types. For examples, there are some classification standards like economic content, economic use, effects during the manufacturing process or the relationship between different cost objects (Li Xingrong, 2007). For the transportation enterprise, the operation cost projects are set as follows: material, fuel, salary, energy, depreciation and other cost.

Cost behavior is the dependence relationship between the variable ultimate cost and portfolio under certain conditions (Zhang Yanan, 2010). Specific to transportation enterprises, their cost behavior means the correlation between the operation cost and the transportation production (generally expressed in tonnage mileage). With the change of output, there are lots of forms of the cost. The same as manufacturing enterprise, the operation cost of transportation costs are divided to fixed cost, variable cost and mixed cost.

Currently, there are more researches on enterprise cost segregation but lacking of theories about railway transportation enterprises. Li studied on the operation processes and expenses dividing of the railway cost in our country, but he didn't take the directed research on the transportation enterprises (Li Dai'an, 2001). Based on the problem of high-speed railway's loss, Ma studied on the calculating methods about high-speed railway cost and put forward the concepts and characteristics about comprehensive transportation cost of high-speed railway (Ma Chongyan, 2014). According to ABC (activity-based costing) theory, Duan had a research on the cost drivers of cost projects in passenger and freight transportation and purposed the BP neural network model for cost forecast (Duan Jie, 2011).

In this paper, the theoretical basis is also the ABC theory. But it analyzes the exact process of transportation operations and divides the cost elements into the related cost centers. Based on the cost centers, this theory allocates the cost elements into specific processes. In a word, it takes both the cost center and the cost processed into considered, when analyzing the cost projects. This advanced theory makes up the lack of calculation in railway freight transportation enterprise cost.

3 Processes of railway freight transportation operation

The production of railway freight transportation is displacement. The whole operation processes are made up with various middle operations. During them, there are both output of production (Total weight of ton-km, Train kilometers) and resource consumption (material, fuel, salary and so on) which leads to cost spending (Liu Yunguo, 2001).

The construction of general transportation enterprises is the same as railway administration. In the structure, there are production departments (e.g. train operation depot, signal depot etc.) and auxiliary departments (e.g. finance, executive office and so on). The processes of railway freight transportation organization are as fig.1.

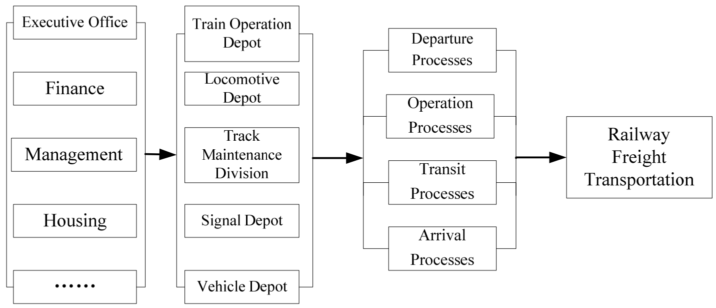

Fig.1 Processes of railway freight transportation organization

4 Accumulation and allocation of cost projects

According to the accounting theory, this paper sets the locomotive depot, train operation depot, vehicle depot, track maintenance division and signal depot as cost centers. As the current research, we briefly divide the cost projects which change with the turnover into variable cost. The cost projects which do not change with the turnover or the variable quantity of which is light are divided into fixed cost. The method of cost accumulation which according to the cost centers is as Tab.1.

Tab.1 Cost accumulation method which according to the cost centers

	Variable Cost Projects	Fixed Cost Projects
Locomotive Depot	Locomotive aided repairing, Locomotive temporary repair, Locomotive repair, Locomotive overhaul, Locomotive servicing work, Fuel and oil of locomotive, Piece rate wage, Piece rate labor cost	Salary bonuses, Labor cost, Wage surcharge, Depreciation cost of locomotives and equipment, Office allowance, Travelling expense, Labor protection cost, Rental expense, Other expenses
Train Operation Depot	Piece rate wage, Piece rate labor cost	Salary bonuses, Labor cost, Wage surcharge, Office allowance, Travelling expense, Labor protection cost, Rental expense, Other expenses, Car use cost
Vehicle Depot	Freight vehicle examination cost	Salary bonuses, Labor cost, Wage surcharge, Depreciation cost of equipment, Device detection cost, spares of means of production, Office allowance, Travelling expense, Labor protection cost, Rental

		expense, Other expenses, Car use cost
Track Maintenance Division		Salary bonuses, Labor cost, Wage surcharge, Depreciation cost of equipment, Maintenance and repair materials cost, Track maintenance machine cost, Office allowance, Travelling expense, Labor protection cost, Rental expense, Other expenses, Car use cost
Signal Depot	Communication expense of stations and lines, Maintenance cost of signal and electrical equipment	Salary bonuses, Labor cost, Wage surcharge

The changes of variable cost are related with some elements (like rotation volume of freight transport), which are called cost drivers. Specifically, cost drivers are the standards or indexes of resource allocation. They are the basic reasons of resource consumption. The cost drivers during the whole railway freight transportation processes are as Tab.2.

Tab.2 Analysis of cost drivers during the railway freight transportation processes

Operation Processes	Detail Processes	Cost Driver	Resource Requirement	Responsible Department
Departure Processes	Freight departure	Sending freight weight	Salaries of freight transportation staff, Cost of stations and related structures	Train Operation Depot, Vehicle Depot
	Shunting operation	Shunting operation hour	Salaries of shunting staff, Maintenance cost of shunting locomotive, Fuel, Oil	Locomotive Depot
Operation	Locomotive	Locomotive	Maintenance cost of	Locomotive

Processes	traction assignment	running kilometers	locomotive, Cost of locomotive oil, Cost of locomotive fuel, Salaries of locomotive crew	Depot
		Engine hours	Depreciation expense of locomotive each hour	
		Total weight of locomotive ton-km	Cost of locomotive servicing	
	Freight vehicle assignment	Freight locomotive hour	Depreciation expense of freight vehicle	Vehicle Depot
		Freight vehicle kilometers	Maintenance cost of freight vehicle, Cost of freight train examination	
	Track assignment	Total weight of train loading	Maintenance cost of tracks, Energy charge in electrified railways, Depreciation expense of maintenance equipment	Track Maintenance Division
	Signal assignment	Train kilometers	Depreciation expense of signal equipment, Maintenance and operation cost of signal equipment	Signal Depot
	Station operation assignment	Train kilometers	Train cost of arriving, departure and passing through	Train Operation Depot
Transit Processes		Transit weight of freight	Transit and loading and unloading cost of freight	Train Operation Depot
Arrival Processes	Freight Arrival	Arriving freight weight	Salaries of freight transportation staff, Cost of stations and related structures	Train Operation Depot, Vehicle Depot
	Shunting operation	Shunting operation hour	Salaries of shunting staff, Maintenance cost of shunting locomotive, Fuel, Oil	Locomotive Depot

Based on the analysis before, we could see that the contents of cost projects were still complex. When dividing them into the operation processes, we ignore or combine the cost projects which take less resources or expenses. The cost allocation of railway freight transportation enterprises is as follows.

Tab.3 Cost allocation of railway freight transportation enterprises

Operation Processes	**Cost Driver（Independent Variable）**	**Variable Cost Projects（Dependent Variable）**
Departure and Arrival Processes	Arriving and Departure freight weight	Freight transportation cost of station
Transit Processes	Transit weight of freight	Transit cost of station
Operation Processes	Locomotive running kilometers、single locomotive running kilometers	Maintenance cost of locomotive, Cost of locomotive oil, Cost of locomotive fuel, Depreciation expense of locomotive, Salaries of locomotive crew
	Engine hours	Depreciation expense of locomotive each hour
	Shunting operation hour	Maintenance cost of shunting locomotive, Salaries, Fuel, Oil
	Freight vehicle kilometers	Maintenance cost of freight vehicle, Cost of freight train examination
	Freight vehicle hours	Depreciation expense of freight vehicle in each freight vehicle hours
	Total weight of locomotive ton-km	Cost of locomotive servicing
	Total weight of train loading	Maintenance cost of tracks, Energy charge in electrified railways, Depreciation expense of maintenance equipment
	Train kilometers	Depreciation expense of signal equipment, Maintenance and operation cost of signal equipment

5 Calculation steps of operation costs

As the discussed above, this paper purposes the division and description of railway transportation enterprise production processes, the analysis of variable cost and fixed cost, the method of accumulation and allocation of cost and the analysis of cost drivers. Based on them, the calculation steps of operation costs are as follows:

(1) Ensure the unit expense, which means finding out the unit expense of a given operation process.

(2) Calculate the operational volume. We have to calculate out the operational volume which is related to the unit expense.

(3) Calculate the variable cost. For a given process, multiply the unit expense and the operational volume. The result is the variable cost of that operation process.

(4) Calculate the whole cost of a freight transportation product. When given a freight transportation product, after calculating out the variable cost, we add up the fixed cost allocation. The result is going to be the whole cost of the product.

6 Conclusions

The calculation of operation cost of railway freight transportation is a key problem of enterprise benefit evaluation. Based on the theory of activity-based costing, this paper studies the division and description of railway transportation enterprise production processes, the analysis of variable cost and fixed cost, the method of accumulation and allocation of cost and the analysis of cost drivers. Then, it gave out the cost calculation steps of a transportation product. The advanced ABC theory could describe the structure of cost projects exactly and provide decision supports of cost structure optimization. However in this paper, the division of cost projects is subjective and it leaves out some cost projects.

Railway Freight Transportation Economic Benefit Cost-Volume-Profit Analysis

Jianguang Li; Jie Li; and Yuxiang Yang

School of Transportation and Logistics, Southwest Jiaotong University, No. 111 of North Second Ring Rd., Chengdu, Sichuan, China. E-mail: 473373626@qq.com

Abstract: Cost-volume-profit model is applied to analyze the railway freight transportation economic benefit, based on the cost data of railway enterprises. Through Cost-volume-profit model, the relationship between transportation costs, freight transportation unit price and freight transport is obtained, then the freight transport and freight transportation unit price at break even point are drawn. Then the key factors affecting transportation profits are clarified and sensitivity coefficients of which are explored. The risk resistance capability of railway enterprise is assessed. This paper can provide adequate data indicators for the railway enterprise managers to make strategic decisions.

Keywords: Cost-volume-profit analysis; Railway transportation; Economic benefit; Sensitivity analysis.

1 Introduction

It is particularly important for railway transportation enterprises to improve the economic benefits. There are strong links between railway transportation economic benefit and effecting factors and it is essential to clarify the relationship and identify the key influencing factors. The existing studies for the railway transportation economic benefit mainly focus on cost accounting and evaluation system, while rare in quantitative relationship between cost, profit, freight transportation unit price and transport.

Li Daian divided railway operations into different sections, calculated variable unit cost of work in each section and got the total cost of railway transportation (Li Daian, 1999). Liu Yunguo applied Activity Based Costing to railway enterprise, analyzing cost divers of operations, accounting the total cost according to the quantity of work (Liu Yunguo, 2001). Zhao Zhiwen established a prediction model of railway transportation cost, based on through PB neural network theory and Activity Based Costing theory (Zhao Zhiwen, 2007).Wen Nuan established an assessment index system, utilizing the analytic hierarchy process to evaluate the economic benefit (Wen Nuan, 2011).Xia Huaiwei made a comprehensive appraisal to railway transportation economic benefit through principal component analysis, identifying the critical factors influencing the economic benefit(Xia Huaiwei, 2001). Zhang Likun evaluated the benefit of Railway PDL by DEA-C^2R evaluation model, in perspective of economic and social efficiency (Zhang Likun, 2010).

Most of the exciting researches assessed railway transportation enterprises economic benefits in macroscopic level, while absent in exploration of mathematical formula of profits. This paper applies CVP model to the study of railway transportation economic benefits, identifying the key factors influencing the economic benefit, assessing the risk resistance capability of enterprise, proposing effective measures to improve the economic benefit.

2 Fundamentals of Railway Transportation Economic Benefit CVP Analysis

Several variables are involved in railway economic benefit CVP model, such as fixed cost of transportation operations (Abbreviated as F), variable cost(Abbreviated as TV), variable unit cost(Abbreviated as V), freight transport (Abbreviated as Q), freight transportation unit price(Abbreviated as P), sales revenue(Abbreviated as S), transportation enterprise profit(Abbreviated as M). The equation between these variables is shown as formula (1).

$$M = S - F - TV = P \times Q - F - V \times Q \tag{1}$$

Formula (1) is the basic mathematical equation of CVP model, which clearly indicates the mathematical relationship between cost, transport and profit. All the CVP analysis derives from the formula.

2.1 Analysis of Freight Transportation Cost Behavior

Cost behavior analysis is the premise of CVP analysis. The product of railway transportation is transport. The transportation cost can be gathered as the fixed costs and variable costs. The fixed costs mainly includes labor cost (which not covers the piece wages), depreciation cost, daily management funds and so on while the variable costs are expenditures varying with operation volume, such as the piece wages, locomotive overhaul fees, locomotive medium-term repairing fees, locomotive servicing fees and so on.

2.2 Analysis of Break Even Point

The freight transports at Break Even Point are these make the sales revenue equals to the transportation total cost. Break Even Point Analysis is helpful for the freight transportation manager to define the relation between freight transport, sales revenue and the profits. The freight transport and sales revenue at Break Even Point (Abbreviated as Q_B and S_B) can be calculated from formula(2)and formula(3).

$$Q_B = F / (P - V) \tag{2}$$

$$S_B = P \times Q_B \tag{3}$$

2.3 Analysis of Profit Target

The volume of freight transport (Abbreviated as Q_W) targeting the profit target (Abbreviated as M_T) can be derived from the formula (1), just by replacing M with M_T in computational formula (4). The variations on variables have influences on target profit, which can be acquired by Profit Target analysis. These are references for the transportation manager as they make decisions.

$$Q_w = M_t + F \big/ (P - V) \tag{4}$$

2.4 Sensitivity Analysis

Railway freight transportation activities are varying constantly. The critical values of freight transportation unit price, transport and fixed cost, which affect the profits of transportation enterprise, can be calculated by formulas, from formula (5) to formula (8), which all derive from formula (2) concerning Break Even Point. Specific to different influencing variable, influence degree each are distinct. The influence degree can be measured by sensitive coefficient, calculated through formula (9). If the sensitive coefficient of a variable is positive, it indicates that the variable has a positive correlation with profit. And vice versa. The larger a sensitive coefficient is, the larger influence degree is.

The minimum allowed unit Price $P_{\min} = V + F / Q$ (5)

The maximum allowed variable unit cost $V_{\max} = P - F / Q$ (6)

The minimum allowed freight transport $Q_{\min} = F / P - V$ (7)

The maximum allowed fixed cost $F_{\max} = (P - V) \times Q$ (8)

The sensitive coefficient $SC_v = \Delta M\% / \Delta v\%$ (9)

In formula (9), SC_v means the sensitive coefficient of a certain variable, $\Delta M\%$ means the percentage change in profit, $\Delta v\%$ means percentage change in the variable.

2.5 Relevant Decision-making Indexes

A series of decisions are necessary in transportation operation, which can determine the development direction of a transportation enterprise in short or long term. The decision-making indexes related to CVP include Contribution Margin (Abbreviated as CM), Safety Margins (Abbreviated as MS) and Degree of Operating Leverage (Abbreviated as DOL). Contribution margin indicates the profit transportation product contributing to transportation enterprise while the Safety Margins reflects the security of transportation enterprise operations. Degree of Operating Leverage, which indicates the impact of changes in sales revenue on profit, is a measure of operation risk. These indexes demonstrate profitability of transportation product and production capacity of transportation enterprise. Transportation operation plan are made based on these indexes. The calculation formulas for these indexes are form formula (10) to formula (14). Q_{MS} means the safety margins transport, $MS\%$ means rate of safety margin, and Q_P means the planned transport.

$$CM\% = \frac{CM}{M} \times 100\% \tag{11}$$

$$Q_{MS} = Q - Q_B \tag{12}$$

$$MS\% = \frac{Q_{MS}}{Q_P} \times 100\% \tag{13}$$

$$DOL = \frac{CM}{CM - F} \tag{14}$$

3 Numerical examples

The paper applies the CVP model to a freight transportation enterprise, estimating the economic benefit in aspects of cost behavior, break even point, profit target, sensitive analysis and DOL, exploring the relationship between freight transport, sales revenue and freight transportation price, identifying the key factors affecting the economic benefit of this transportation enterprise.

3.1 Cost Behavior of railway transportation

The annual volume of the railway is 3000 million tons, while the annual freight transport is 416323 million ton kilometers. The sales revenue is 10511 million yuan throughout the year and the transportation unit price is 252.47 yuan/million ton kilometer. The total costs are gathered as fixed cost and variable cost, shown in table 1. The detail expenditures of transportation operations can be seen in table 2.

Table 1. Cost Items of Freight Transportation Enterprise

Cost behavior	Cost items
Fixed costs	salary, bonus and subsidiary of workers, labor cost (which not covers the piece wages), depreciation cost of locomotive, administrative expenses, travel expense, workers insurance expense, lease rentals and other expenditures
Variable costs	salary, bonus and subsidiary of workers, piece wages, locomotive small-auxiliary-repairing charges, locomotive temporary-repairing fees, locomotive overhaul fees, locomotive medium-term repairing fees, locomotive servicing fees, locomotive fuel oil fees

Table 2. Detailed expenditures of transportation operations

Cost items	Fixed cost	variable cost	Subtotal
1 Cost of labor	18,276,122.00	6,598,959.51	24,875,081.51
2 Direct productive cost	5,631,146.88	20,194,270.07	25,825,416.95
3 Manufacturing service costs	2,486,669.82	-	2,486,669.82
Operation cost summation	26,393,938.70	26,793,229.58	53,187,168.28

3.2 Decision-making Indexes of Railway Transportation

The cost volume profit analysis diagram can be drawn according to the financing data of the transportation enterprise, shown in figure 1. The CVP indexes concerning economic benefit are all in table 3.

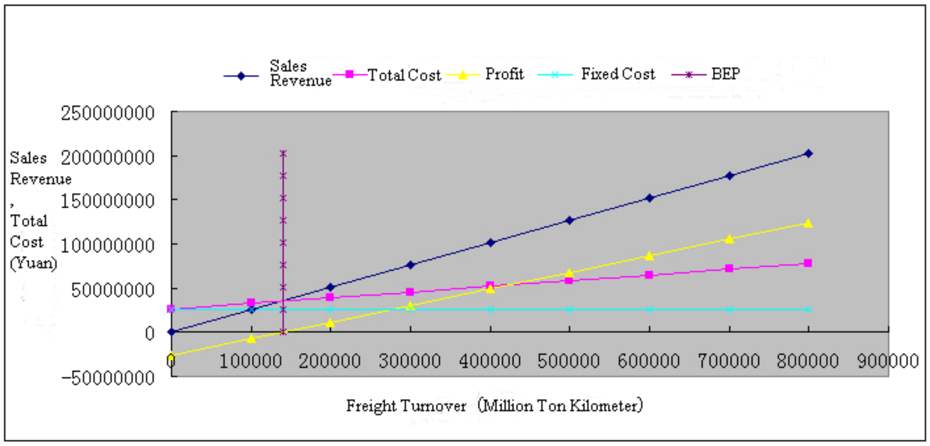

Figure 1. Cost volume profit analysis diagram

Table 3. CVP indexes of transportation enterprise

Items	Indexes	Values
Break Even Point (BEP) Analysis	contribution per unit	188.11 yuan / million ton kilometer
	Rate of contribution margin	74.51%
	Rate of variable cost	25.49%
	Freight transport at BEP	140310.99 million ton kilometers
	sales revenue at BEP	35424315.65 yuan
	safety margin transport	276012.01 million ton kilometers
	Rate of safety margin	66.30%
	completion rate of transport at BEP	33.70%
Transport for target profit	$Q_w = \frac{M_t+F}{P-V} = \frac{M_t+2639.39\times10^4}{252.47-64.36} = \frac{M_t+2639.39\times10^4}{188.11}$	
Sensitivity Analysis (10% Level)	sensitivity coefficient of transportation unit price	2.02
	sensitivity coefficient of variable unit cost	-0.52
	sensitivity coefficient of fixed cost	-0.51
	sensitivity coefficient of transport	1.51
Analysis Of the factors effecting the profits	minimum allowed unit price	127.76 yuan / million ton kilometer
	maximum allowed variable unit cost	189.07 yuan / million ton kilometer
	maximum allowed fixed cost	78314519.53 yuan
	minimum freight transport	140311 yuan / million ton kilometer
	DOL	1.51

3.2.1 Break Even Point of railway transportation

The freight transport at BEP is 140310.99 million ton kilometers, occupying 33.70% of the current freight transport, indicating that the transportation enterprise can achieve balance of profit and loss by competition 33.70% of the current freight transport. The sales revenue at BEP is 35424315.65 yuan while the safety margin ratio is 66.30%. These indexes values demonstrate the transportation operation is in good condition and the enterprise has the certain anti-risk ability. The production capacity is rationally used and the possibility of loss is smaller.

3.2.2 Sensitivity Analysis of Variables Concerning Railway Transportation

Sensitivity analysis rests on the assumption that as the other indexes remain unchanged, the freight transportation price, variable unit cost, fixed cost and freight transport respectively increase by 10%, and the target profit is 5192.06 million yuan (when the freight transport is 416323 million ton kilometers). The sensitivity coefficient of each index is shown in table 3. The sensitive coefficient of freight transportation price ranks the first, about 3 times as that of variable unit price. the sensitive coefficient of freight transport takes the second place while the fixed cost is the last. the freight transport and transportation unit price have a positive effect on the profit and the fixed cost and variable unit cost effects the profit negatively. Improving the transportation price and freight transport are effective ways to promoting profit. On the other hand, reducing the fixed cost and variable unit cost are significative.

3.2.3 Critical Value of Factors Affecting the Profit

The critical values of transportation price, variable unit cost, fixed cost and transport are calculated. As the transportation price reduces to 127.76 yuan (reduces by 49.79%), the sales revenue equals to the total cost. The price leaves no margin of profit. The actual transportation price should higher than it otherwise the enterprise will made a loss. The current price is secure since the critical value price occupies 51.21% of the current price. The enterprise made no profit as the variable unit price increases by 194.75%, from 64.36 yuan to 189.07 yuan. There is equal effective if the fixed cost increases from 26393938.70 yuan to 78314519.53 yuan (increases by 196.71%) or 33.70% of the current freight transports are completed. At present the freight transportation unit price and fixed cost are reasonable, the freight transport is considerable. The enterprise is less likely to suffer a loss based on the analysis of factors influencing the profit.

3.2.4 Degree of Operating Leverage Analysis

The degree of operating leverage of this enterprise is 1.51, means that the earnings before interest and tax (EBIT) will increase by 1.15% as the freight transport increase by 1%, vice versa. It can bring the financial risks as well as the benefit on financial leverage. The larger the Degree of Operating Leverage is given, the higher the operation risk and benefits are. Degree of Operating Leverage is an important reference for the enterprise manager to make strategic decisions.

4 Conclusions

The paper expounds the principles of CVP model and presents the relevant indexes in CPV. Then the CVP model is applied to a transportation enterprise, which can provide some references for the enterprise manager. The cost items of the enterprise are gathered as fixed cost and variable cost. The freight transport at the BEP is calculated, and the sensitivity coefficient of factors effecting profit are drawn. Risk resistance capability of the enterprise is assessed though safety margin and Degree of Operating Leverage.

In conclusion, CVP analysis help the manager to cognize the operation condition and the weaknesses need to improve of the transportation enterprise, providing ideas and approaches for the improvement.

Abstract: With the constant improvement of urban and rural distribution network, "Alliance of Agriculture and Community" has became a highway for agricultural products to flow to the city residents, but there are still a lot of resistances in the process. This paper analyzes the problems of "Alliance of Agriculture and Community" in our country and introduces a new operating model which based on the third-party trading enterprises, then researches its development advantages and suggests the corresponding advice and countermeasures.
Keywords: "Alliance of Agriculture and Community"; Agricultural cooperatives; The third-party trading enterprises; Direct selling.

1 Introduction

As "Medium and long-term plan on development of logistics industry (2014-2020)" published by the state council points out, with the increasing demand for bulk agricultural products logistics and fresh agricultural products cold chain logistics, there is an urgent need for more perfect, convenient, efficient and safe consumer goods logistics distribution system. As an important part of urban and rural distribution, the problem how agricultural products go into the city should gain the corresponding attention. With documents issued by government to support agricultural cooperatives to establish the sales outlets in urban community, "Alliance of Agriculture and Community" do emerge. It's a new sales model of agricultural products after "Alliance of Agriculture and Supermarket" and it implements the farmers and the urban community's directly communication, providing a convenient channel for agricultural products' going into the city and citizens' gaining fresh agricultural products. The direct selling model based on the third-party trading enterprises break the traditional model and introduce professional trading enterprises to improve the sale effect by strengthening professionalism of each link.

2 The Domestic Status of Traditional "Alliance of Agriculture and Community"

The traditional "Alliance of Agriculture and Community" is an agricultural products sales model of building sale stores in the city communities through agricultural cooperatives, making the products directly docking with the community consumers. In recent years, Beijing, Shanghai, Guangdong, Jiangsu and other provinces have tried this pattern positively and have achieved remarkable success in reducing the product price, meeting consumers' demands and improving the level of service. As that this model is still in the early stage, there are many difficulties and problems.

2.1 The main effects of "Alliance of Agriculture and Community"

Firstly, farmers improve their incomes distinctly. The model is, for the most part, a way to expand the sales channels and methods of agricultural cooperatives, achieving the direct supply of agricultural products from the fields to the table, and avoiding the unnecessary circulation. This way saves up to 20%~30% of the circulation costs. A survey found that those agricultural cooperatives which organize "Alliance of Agriculture and Community" improve their incomes distinctly, increasing revenue by 20% and enhancing the farmer's enthusiasm.

Then, citizens gain more convenient life. Agricultural cooperatives build sale stores in the city communities, saving the time of purchase of citizens, and offering protection for freshness of agricultural products. What's more, the product price in the sale stores is generally lower than the supermarket and other external markets (SHI 2014). These community stores supply cheap and healthy agricultural products to citizens, improving the quality of their life.

Lastly, the model may promote the upgradation of agricultural cooperatives. In the past, agricultural cooperatives lacked effective operating standards, and farmers didn't change the traditional product model to meet the market demand in time. "Alliance of Agriculture and Community" provide a good direct marketing platform of agricultural products for agricultural cooperatives, consolidating the development foundation for them. In addition, farmers learned that how to adjust the production structure and realized the importance of the quality of agricultural product according to the sale, cultivating their sense of marketing and quality.

2.2 The protruding problems of "Alliance of Agriculture and Community"

Firstly, the lack of social support. The smooth implementation of "Alliance of Agriculture and Community" involves many aspects of society, it needs the support from relevant departments of commerce and industry, taxation, finance, and so on. At present, the social awareness of this model is not enough, limiting its promotion seriously. For example, some community administrations refuse the stores because they think that these stores are not conducive to their management. Besides, higher taxes or a heavy rent for the land and other issues has seriously reduce the farmers' work enthusiasm.

Then, the lack of funds and equipment. The traditional "Alliance of Agriculture and Community" is dominated by agricultural cooperatives, and the set-up of stores puts forward some requirements for storefront, equipment and personnel. It often takes liquidity, and it bring huge pressure to agricultural cooperatives. Freshness is the key to agricultural products sales, but most agricultural cooperatives are still in the early stage, facilities which include packaging, storage, transportation and test equipment remains to be improved, bringing certain challenges to the product quality and safety.

Lastly, the lack of management ability. Management ability is a big defect of agricultural cooperatives in the process of direct selling. Financial management, e-commerce, logistics distribution all have the certain requirements for labor personnel. Based on the economic power of agricultural cooperatives, they can't provide a higher level of treatment to attract relevant management talent, so it make the lack of talent an important restricting factor of the development of "Alliance of Agriculture and Community" (ZHENG 2013).

3 The Advantage Analysis of the Model Based on the Third-Party Trading Enterprises

3.1 Compared with the model that farmers achieve sales by themselves

As a traditional way to sell agricultural products, this model that farmers achieve sales by themselves avoid the circulation in the middle, and bring agricultural products to consumers directly. This model has large limitation, small scale and single products, it's always very popular in those underdeveloped areas, and farmers are difficult to grasp the market dynamics and adjust production structure timely (WEN 2013). But "Alliance of Agriculture and Community" based on the third-party trading enterprises encourage agricultural cooperatives in different scale to strengthen exchanges and cooperation and form agricultural cooperative federation, and it can rich the type and quantity of agricultural products to meet the market demand. The third-party trading enterprises can receive agricultural products from the planting base directly with professional storage and transportation vehicles, ensuring the freshness of agricultural products in the entire circulation. The enterprises tend to have complete information processing ability to realize the information communication and feedbacks between each link, providing accurate market dynamics and market demand to the farmers.

3.2 Compared with the model of "Alliance of Agriculture and Supermarket"

"Alliance of Agriculture and Supermarket" requires agricultural cooperatives to make a treaty with the supermarket, achieving long-term supply of agricultural products to the supermarket and the win-win between farmers and supermarket. But under this sale model, the supermarket concern the appearance more, freshness of agricultural products, etc. Some farmers cannot meet the high standard and most agricultural cooperatives can't accept the non-cash transactions which widely used in supermarkets. There aren't too high standards of agricultural products under the model based on the third-party trading enterprises, it only needs to pass the quality inspection from the third-party enterprises. Besides, the third-party trading enterprises will be responsible for the store's location, purchasing of cold storage facilities, worker's recruitment and the supply of capital flows, etc. The model solves the lack of capital and management experience of agricultural cooperatives effectively, and achieves a sales platform of agricultural products which is more convenient than the supermarket.

4 The Key for "Alliance of Agriculture and Community" Based on the Third-Party Trading Enterprises

Although that it's the third-party trading enterprises who complete the sale of agricultural products, it doesn't gain any excess circulation, but provide a more professional and efficient agricultural transport condition when compared with the model based on agricultural cooperatives, ensuring the safety of agricultural products. On the other hand, the dominance of trading enterprises lead to the significantly decreasing participation of farmers in sales link. While farmers is a group that is sensitive to sales revenue, in order to maintain the effective connections of each link, it is particularly critical that timely information feedback and the establishment of reasonable interest distribution mechanism. In addition, with the continuous improvement of living standards, community residents give higher expectations to the product variety and quality safety of agricultural products. Only with stable rich supply sources, safe and efficient logistics distribution, and professional store sales, can it gain the expected effect that the model should have and truly realize the optimization and upgradation of traditional "Alliance of Agriculture and Community" operation model. New model based on the third-party trading enterprises is shown in figure 1.

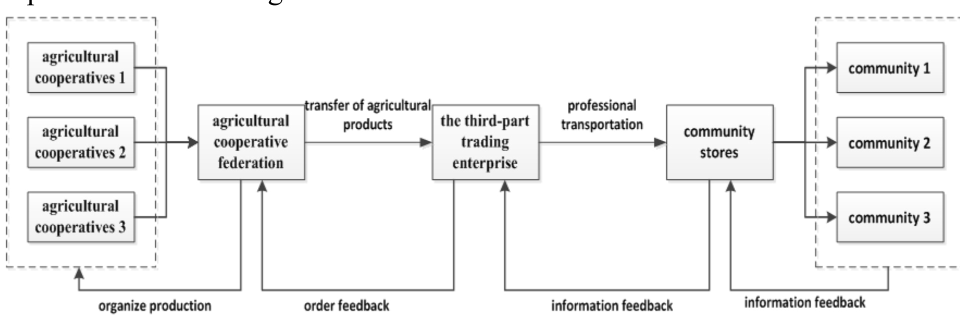

Figure 1. "Alliance of Agriculture and Community" based on the third-party trading enterprises

5 Countermeasures and Suggestions

"Alliance of Agriculture and Community" is a system process involving multiple elements. In order to promote the new model based on the third-party trading enterprises effectively, this paper put forward the following countermeasures and suggestions.

Firstly, deepen the social cognition on "Alliance of Agriculture and

Community". It's a kind of agricultural products sales model which brings many benefits to multiple entities. The government should take effective measures including television, network to promote the advantage of the model and enhance people's understanding of "Alliance of Agriculture and Community". In this way, we can create a good develop environment for it and mobilize the enthusiasm of multiple entities.

Then, strengthen the support from relevant departments to "Alliance of Agriculture and Community". Policy support is an important premise of its rapid promotion (LI 2012). The government should strengthen the capital support, provide the third-party trading enterprises certain preference and support in respect of taxation and land, and offer certain subsidies when enterprises purchase agricultural product storage, transportation facilities. In this way, more trading enterprises will be involved.

Lastly, attach great importance to the government supervision and strengthen cooperation. At present, agricultural cooperatives, the third-party trading enterprises and community market are not mature, so it is important to gain the government's supervision and support. The government can encourage farmers to form agricultural cooperative federation actively and conduct joint sales, find and solve problems through the supervision of the production and management in planting base, the management and construction of community stores and information sharing between farmers and enterprises, and coordinate business cooperation and profit distribution between enterprises and agricultural cooperatives to build the long-term cooperation mechanism.

Abstract: Jiangxi economic development is inseparable from the transportation industry, transportation industry plays an important role in economic development in Jiangxi Province, this paper use 1978-2012 transportation data, analyze the Jiangxi railway transport, road transport, sea transport, air transport, and the use of correlation analysis, gray correlation analysis, elasticity analysis and other analysis of the intrinsic link the province's transportation and economic development; the use of gray prediction model, transportation and economic development in Jiangxi Province were forecast, plan ahead and be prepared to predict the situation in Jiangxi Province in 2013-2020 transportation and economic development in Jiangxi Province, making use of the good momentum of economic development in the country, and to catch up others. To find the problems and the adverse impact on economic development in Jiangxi Province, To build the global economy play a key role in the development of large-capacity channel, the layout of the road network and promote coordinated economic development , to make transportation industry has become a new economic growth point of Jiangxi Province.
Keywords: Correlation analysis; Gray correlation; Elasticity analysis; Gray prediction model.

1 Introduction

In recent years, Jiangxi economy continued to maintain a rapid development momentum. In 2012, the province's GDP reached 1.294888 trillion yuan, an increase of 10.65% over the previous year, for many years to achieve a growth rate of more than 10%. Transportation as a special material production sectors, by specializing in cargo and passenger transportation services business, social production, distribution, exchange and consumption to be normal in all aspects, with social infrastructure, public services and material production, and it is has multiple properties. As a critical infrastructure, it is a prerequisite for the social and economic development and the spread of civilization; as a public good, it is through personnel exchanges, inter-regional exchange of goods to contact the household, spatial displacement of people and things, to support economic sectors building and interpersonal area. By

2012, the annual completion of various modes of transport Cargo traffic 1.2702 billion tons, an increase of 13.8% over the previous year, cargo turnover 344,896,700,000 tons km, an increase of 14.8% over the previous year; passenger transport volume 84,459 million, compared with last year growth of 6.7%, Passenger turnover 97.9844 billion person-kilometers, an increase of 1.8 percent over the previous year. Although transportation industry to continue to develop in Jiangxi, the exact size of the national economy the demand for transportation, and transportation research role in promoting the national economy is still seriously lagging conducted at different stages of development, for the transportation and economic development understanding of the relationship is also largely remain in the sensual rather than rational level, stay on qualitative rather than quantitative level, which will seriously affect the development of Jiangxi, and transport development strategy of science and rationality. If you can not follow the development of transportation and infrastructure for the interaction between the economic development of the national economy to provide the necessary support and protection, it will seriously hinder the development of the national economy. Therefore, the study of transportation and economic development in Jiangxi relationship is of great practical significance.

2 Correlation Analysis

This article is taken from the Statistical Yearbook of Jiangxi,since 1978-2012 years of data, as shown in Table 1:

**.In the .01 level (bilateral) significant correlation.

As seen from Table 3, the highest correlation coefficient is Cargo traffic, followed by passenger traffic and cargo turnover, and finally is the passenger turnover. All the correlation coefficient more than 0.9, has the higher correlation, This shows that economic development is inseparable from the transport industry development of Jiangxi Province, the two are closely related.

3 Grey Relational Analysis

Correlation analysis is based on the probability theory of stochastic processes, by comparison between the array of factors to determine the degree of correlation between variables, is a static study. The Grey Relational Analysis is based on gray system,Compare the time series between the factors to determine which is the dominant factor in high-impact,Is a dynamic process.

Hypothesis the system features action sequences is economic time series behaviorY i = {Yi(n)}, Y i is economic factors, Action sequences related factors is traffic behavior time series Xi={Xi(n)},Xi is transportation factor, n is time, ε_{ij} and r_{if} represent of Yi and Xi Grey Relational and grey relative correlation,Y i and X i Comprehensive Grey Relational is ρ_{ij} (θ is distinguish factor):

$$\rho_{ij} = \theta\varepsilon_{ij} + (1+\theta)r_{if}$$

Now use the data of Jiangxi Province from 1990 to 2012 statistics, Calculates the GDP of Jiangxi Y1, Cargo turnover X1, Passenger turnover X2, Cargo traffic X3, Passenger traffic X4's Comprehensive Grey Relational and sequencing see Table 4(θ = 0.5):

Table 4. Grey Relational table

	X1	X2	X3	X4	
Y1	0.417892344	0.354093	0.36838	0.333333	X1>X3>X2>X4

From the Comprehensive Grey Relational and sequencing, the greatest impact on GDP of Jiangxi Province is Cargo turnover X4, followed by Cargo traffic X3; combining correlation matrix comprehensive analysis, Cargo turnover X4 and Cargo traffic X3 for the gross regional product of Jiangxi Province has significant role in promoting.

4 Elastic analysis

Relative proportions traffic growth rate and economic growth rate, called the transport elasticity coefficient, which reflects the development of the transport sector is to adapt to the development of the national economy,And the degree of adaptation. To maintain a sustained, rapid and coordinated development, transportation must rationalize the relationship.so that the development and growth of the national economy and maintain transportation has proper proportional relationship.

According to GDP of Jiangxi Province is calculated ,to calculate cargo turnover and Cargo traffic turnover elasticity ,various transport and the total shown in Table 5:

Table 5. elasticity coefficient table

Year	Cargo traffic	The people Airlines	Railway	Highway	Water transport
2006	0.56	0.74	0.58	0.52	0.79
2012	1.30	0.67	-0.63	1.47	0.61
Year	Cargo turnover	The people Airlines	Railway	Highway	Water transport
2006	0.40	0.78	0.24	1.07	0.05

From Table 5, the Cargo transportation from 2006 to 2012,the elasticity coefficient from0.56 to 1.30, while cargo turnover from 2006 to 2012, the elasticity coefficient from0.40 to 1.39. In 2012, Cargo transportation turnover volume and elasticity in 2012 is greater than 1, This shows that the traffic is growing faster than economic growth, transportation development presents a balanced development of the national economy, it adapt to the development of transport in general;At the same time, we can see very rapid development in Jiangxi Highway,it is greatly adapt and meet the needs of economic development in Jiangxi Province, it is worth mentioning that the situation in Jiangxi Railway, 2012, Cargo traffic and cargo turnover are negative, This explains Jiangxi railway transportation is very tight, which restricts economic development in Jiangxi Province, to compared 2012 to 2006, Elasticity has been a substantial increase, indicating that transport during the six years has been rapid development,but most of elasticity is still less than 1, This explains the development of the overall transport can not meet the economic development in Jiangxi Province. To further detailed analysis, we can see the development of the four modes of transport fastest is highway transportation, highway Cargo traffic elasticity coefficient from 0.52 to 1.47, its cargo turnover elasticity coefficient from 1.07 to 2.24, We can see highway transport development speed faster than the speed of rail and waterway transport, which shows the development of rail and water transport is far can not meet the needs of economic development.

5 Grey Prediction Model

Gray prediction method is a discrete data as a continuous variable,Discrete values achieved in the change process, showing its regularity. Using Matlab is preferred to achieve gray prediction process. When using Matlab gray prediction program, can be fully in accordance with the prediction model for solving steps, namely

Step1: the original data accumulation;

Step2: Architecture cumulative order matrix and vector;

Step3: Solving gray parameters;

Step4: The parameter data into to predict models to predict.

Using 2005-2012 data with Jiangxi Province transport-related cases, running matlab software, the results are as follows:

Table 6. Transportation predictive value

Year	Z1	Z2	Z3	Y1	X1	X2	X3	X4
2005	2307	62300	5560	4056	8816426	6039555	33270	41722

6. Conclusion

Through correlation analysis, gray correlation analysis, elastic analysis, the transportation and economic development in Jiangxi Province there is a high correlation; compared with 2006, 2012 has been great development, but rail transport also stress, can not meet the economic development. Finally, this paper also made a prediction for the transport of Jiangxi , in 2020, the GDP of Jiangxi Province has 4.952915 trillion yuan.Jiangxi Province transportation will get a larger development.

Abstract: This thesis, based on the characteristics of the taxi industry, to investigate the game model of pricing the taxi industry in relax regulation conditions. By analyzing the relationship, establish in Stackelberg bi-level programming model. Among them, the upper programming for the maximization of social welfare, lower planning is to maximize the interests of Taxi Company. The model considered the taxi operation of actual loading mileage. Considering the solving of bi-level programming model is complex, this Article uses genetic algorithm to solve the upper limit value after relax regulation Then combining case, the pricing game model is studied. The calculation shows that the model can effectively respond to the pricing process. At the same time, the algorithms can effective computational models.

Keywords: Transportation economy; Pricing model; Bi-level programming; Taxi regulation; Generic algorithm.

1 Introduction

Since the 1970s, each country began to relax or relieve economic regulation of the industry to different degrees. At present, China taxi industry is in the strict regulations, there are many regulatory failure phenomena, such as deformity allocation of industry profits between taxi venture and taxi driver, the contradiction of supply and demand between consumers and operators. Taxi fare is an important mean to allocate passengers' resources and coordinate industry participants' Interests and needs. Douglas (1972) analyzed the inverse relationship of the average passenger waiting time and taxi-load rate, and made a model that combine taxi market demand with the average trip costs and waiting time Cairns and Liston Heyes (1996) pointed out that the price of a taxi service regulation is important for produced balance, and notted that only a sub-optimal pricing in travel costs and taxis are forced to be controlled that can be achieved. In recent years, China has also started a taxi fare determined method. Chen Qian and Wang Wei (2005) raised calculation method of the taxi fares under the control of the total amount and related costs formulated by analyzing the taxi supply and demand. Zhen Yangzhong (2006) Using Logit Model PSM function to create a competitive market model under rental prices system, which get a starting price within two kilometers.

These pricing schemes are not taken the problem of regulatory process that how to regulate the price of a taxi problem into account, in view of the method of economics, this article, studies China's urban taxi industry regulation from the point of view of social welfare and industry cost, and establishes price regulation game model through analysis of the process of price regulation that the government and the taxi company's game relationship, so as to provide a theoretical basis for government to determine the regulation of the taxi industry, and provide some ideas and methods for the reform of the taxi industry, which promote taxi industry's healthy development.

2 Basic assumption of pricing model udder Industry deregulation

The government and the taxi company carry out the main-second decision-making relationships Stackelberg game. Between the two game relationship can be described as: regulator (government) act first, than implement appropriate regulatory instruments (price regulation means); taxi company after the operation, according to the regulator’s (government) actions to adjust the company's business strategy.Taxi companies and taxi drivers are for the passenger service, ignoring the internal distribution of benefits between the two conflicts. Consider the two unity gain profits.

Assume that the government's regulation means of the taxi industry are that government subsidies taxi industry by operating mileage q through fiscal tax, set cost per operating kilometer of m, the corresponding transfer payment is mq.

According to the theory of economics, supply and demand balance in the taxi industry and to consider the cost of transfer payments and shadow, the passengers remaining $U(q)$ can be expressed as:

$$U(q) = \int p(q)dq - qp - \lambda mq \tag{1}$$

Where, q is the taxi operating mileage $\int p(q)dq$; as effectiveness of taxi passengers; qp as a taxi passenger travel costs. $\lambda > 1$, λmp as government transfer payments and the resulting shadow costs.

Cost is convex function based on microeconomics, assuming that the costs of taxi companies are:

$$c(q) = c_0 + c_1 q + c_2 q^2 \tag{2}$$

Where: $c_0 > 0, c_1 > 0, c_2 > 0$. c_0 is the taxi company's fixed costs; c_0, c_1, c_2 can be calibrated based on historical data in taxi industry.

Taxi Company's profit is expressed as $\pi(q)$:

$$\pi(q) = pq - c(q) + mq = pq - c_0 - c_1 q - c_2 q^2 + mq \quad (3)$$

The function of Government regulation:

$$\max Z = \int_0^q p(q)dq - qp(q) - \lambda mq + pq - c_0 - c_1 q - c_2 q^2 + mq \quad (4)$$

Taxi company objective function is:

$$\max \pi = pq - c_0 - c_1 q - c_2 q^2 + mq \quad (5)$$

3 Game model analysis of considering taxi actual loading mileage

The game between government and the taxi company is divided into two stages, stage one: regulator adjusts the decision variables m in order to achieve maximum social welfare; Stage two: the taxi company takes action to change their operational programs (operating mileage ***q***) to achieve taxi companies the maximum profits.

In realistic mode, Taxi change between real-load an no-road stages, assuming that demand function related to the real-load and no-load mileage , Passenger demand function is: $Q_i = f(p,k)$. where $k = Q_i / (Q_i + V)$; p represents the price of services of unit operating mileage ; k represents taxi loading rates; Q_i represents the taxi real-load mileage; V_i represents taxi no-load mileage.

According to principles of economics, passenger demand function can be expressed as:

$$Q_i = ap^{\varepsilon} \quad (6)$$

Where, a represents undetermined coefficients; ε represents the price elasticity.

Passengers inverse demand function is:

$$p = (Q_i / a)^{1/\varepsilon} \quad (7)$$

The passenger utility function is:

$$U_i = \int_0^{Q_i} p(Q_i)dQ - P(Q_i)Q_i - mQ_i = \int_0^{Q_i} (\frac{Q_i}{a})^{\frac{1}{\varepsilon}} dQ_i - (\frac{Q_i}{a})^{\frac{1}{\varepsilon}} Q_i - \lambda m Q_i \quad (8)$$

The sum of the passengers' utility:

$$U(q) = \sum_{i=1}^{q} \left[\int_0^{Q_i} (\frac{Q_i}{a})^{\frac{1}{\varepsilon}} dQ_i - (\frac{Q_i}{a})^{\frac{1}{\varepsilon}} Q_i \right] - \lambda m \sum_{i=1}^{q} Q_i \quad (9)$$

Considering the real-load and no-load mileage, the single taxi costs can be expressed as:

$$C_i = \sum_{j=1}^{m} C_j (Q_i + V_i) \tag{10}$$

Where, C_i is the taxi operating costs (yuan); $\sum_{j=1}^{m} C_j$ is the taxi average cost per operators kilometers (yuan / km); m is the number of different cost structure, q is the number of taxi passengers.

The total cost of the taxi company can be expressed as:

$$C = \sum_{i=1}^{q}\sum_{j=1}^{m} C_j (Q_i + V_i) \tag{11}$$

The taxi company's total profit:

$$\pi(q) = \sum_{i=1}^{q} (\frac{Q_i}{a})^{\frac{1}{\varepsilon}} Q_i - \sum_{i=1}^{q}\sum_{j=1}^{m} C_j (Q_i + V_i) + m\sum_{i=1}^{q} Q_i \tag{12}$$

Optimal objective function of Government regulation can be expressed as:

$$\max Z = \sum_{i=1}^{q}\left[\int_0^{Q_i} (\frac{Q_i}{a})^{\frac{1}{\varepsilon}} dQ_i - (\frac{Q_i}{a})^{\frac{1}{\varepsilon}} Q_i\right] + \sum_{i=1}^{q} (\frac{Q_i}{a})^{\frac{1}{\varepsilon}} Q_i - \sum_{i=1}^{q}\sum_{j=1}^{m} C_j (Q_i + V_i) + (1-\lambda) m \sum_{i=1}^{q} Q_i \tag{13}$$

Government and the taxi company master-slave game, assuming the government to consider the social welfare maximization to make optimal decisions on the basis of profit maximization of the taxi company, the game between the Government and the taxi company is expressed by mathematical model as follows:

Upper level (*U1*): is formula (15). $s.t\ Q_i = f(p, m)$

Lower Planning (*L1*):

$$\max \pi(q) = \sum_{i=1}^{q} (\frac{Q_i}{a})^{\frac{1}{\varepsilon}} Q_i - \sum_{i=1}^{q}\sum_{j=1}^{m} C_j (Q_i + V_i) + m\sum_{i=1}^{q} Q_i \tag{14}$$

$$s.t: \pi(q) \ge \pi_0,\ \ Q_i \ge 0, 0 \le k \le 1,\ \ p = (Q_i / a)^{\frac{1}{\varepsilon}}$$

Where, π_0 represents the minimum operating profits of taxi company.

4 Model solutions

For the above model for genetic algorithm design:

(1)Encoding. This process is the first step in the design process of the algorithm, in many cases is encoded in binary form.

(2)The definition of fitness function. Fitness function in relation to the evolution of the population, in algorithmic process fitness is non-negative; the value of the fitness is the bigger the better for algorithm.

(3)The control parameter. Hybridization probability p_c : The p_c higher the population Introduced faster, but the lost speed of received good genes will be increased accordingly, p_c become low that make the search for obstacles. Generally take $p_c = 0.4 \sim 0.99$ .Population size *n*: *n* large, will increase the computational difficulty, ***n*** is small, the search space is limited, the situation may arise not converge. Experts suggest that the scale is $n = 20 \sim 200$. Mutation probability p_m : In order to stabilize the population, after individual variation, it will not have too much difference with the parent; p_m value should be small, generally $p_m = 0.001 \sim 0.1$.

(4)Generating the initial population. Usually generated initial population randomly. The produced needs to check whether it meet constraint, if the constraint is not satisfied need to re-generate the initial population.

(5)Genetic manipulation.

A choice. Select a few larger values of fitness form parent, let not participate in genetic manipulation, used to replace several of the next generation of smaller fitness value. The larger value will be inherited to offspring form remaining Individual. b. hybridization. Hybridization is good genes of parent Inherite to the next generation, and generate new individual contains more complex gene. c. variation. For each generated offspring mutate in a certain p_m 。

(6)Determination of algorithm terminates. When evolution of the group is stable, the process of population evolution ends.

5 Case Studies

Applying the above model to a simple case for analysis. Selected data was generated from the “2007-2009 GuangZhou city taxi monthly cycling operating table ". Basic data are shown in Table 1 and Table 2.

Table 1. Component of unit operating mileage of vehicles

Monthly average operating days	Daily average operating hours	Daily average operating mileage	Daily average passenger mileage	Daily average passenger occupancy rate
28 d	18 h	342.66 km	237.61 km	69.34/%

Table 2. Component of unit cost of vehicles

Type	Component of costs	costs/(yuan / Month)
direct costs	Depreciation, Fuel, Maintenance, Insurance, Intelligent Management System service fees, Accident damages, Driver's social insurance, ect	10608.94
indirect costs	Management salaries, Vehicle license fee for the right to operate, Administrative expenses, utilities, Hospitality, Consumables, Rent, communication expenses, conference fees, advertising fees, intangible assets and long-term assets, insurance, other administrative expenses	2764.98

The corresponding values required by model can be calculated as follows,

When *m*=23, unit cost of vehicles can be obtained, 10608.94 +2764.98 =13373.92 (yuan/ Month)

So, we get unit operating mileage of vehicles , 13373.92/（28*237.61）=2.01（¥/ Month）

According to relevant literature, the value of the price elasticity coefficient ε is from 1.0 to 1.4, here take the middle value 1.25.Generally, the value of the shadow costs is from 1.1 to 1.5, here take the middle value 1.25.Based on the above calculation, the corresponding data can be obtained, as is shown in Table 3.

Table.3 Data required for model calculation

no-load ratio	Operating costs per kilometer	price elasticity coefficient	shadow costs	total number of taxis
30.66%	2.01yuan/ km	1.2	1.25	18858 Vehicles

Algorithm settings are as follows,

(1)The model is binary coded, the optimal storage strategy and roulette way are combined to makes the algorithm convergence.

(2) Groups size, hybrid probability and mutation probability are $n = 50$, $p_c = 0.5$ and $p_m = 0.005$, respectively.

(3)The model chooses forms of two-point crossover, each select two parents to hybridize with probability 0.5.

(4) The algorithm would generate initial individuals 60 randomly, first check whether it can meet the corresponding constraints, if not, then, need to return to re-generate the initial group.

Based on genetic algorithms to calculate the *p* was 2.51 yuan, that is, the average rate per kilometer is 2.51 yuan.

Through the above analysis, we can see the average rate per kilometer is 2.51 yuan. Clearly, it is possible to reach an equilibrium state, which can achieve the regulatory objectives of maximization of the government's social welfare and taxi companies' own interests at the same time.

6 Conclusions

China's taxi industry regulations are too strict, need to relax. Given the current situation of the taxi industry and inadequate competitive market conditions, the government should take reasonable means of price regulation, allowing a degree of competition to protect consumers from price gouging and improve social welfare. Through analysis of price obtained from the bi-level model, it can be concluded that, setting price regulation is a feasible method in today's circumstances where the regulations are too stringent, it also can provide a reference for government policy. Government regulation on prices, in fact, is a long-term process, the paper only discussed a single static problem under price regulation, but did not do further research on dynamic situation, which is the future research directions.

Modeling and Application of an Early Warning System of China's Foreign Trade Container Shipping Market

Jishuang Zhu[1] and Ming Wei[2]

[1]Research Associate, China Waterborne Transport Research Institute, No. 8, Xitucheng Rd., Beijing 100088. E-mail: zjs@wti.ac.cn
[2]Researcher, China Waterborne Transport Research Institute, No. 8, Xitucheng Rd., Beijing 100088. E-mail: weiming@wti.ac.cn

Abstract: To provide effective analysis tools, an early warning system is proposed for China's foreign trade container shipping market. Firstly, by analyzing volatility mechanism of foreign trade container shipping market, a set of monitoring indicators is presented, including container throughput, freight index CCFI and PMI new export orders index et al. The monthly samples of the indicators from 2005 to 2014 are collected. Secondly, the warning threshold and interval of each indicator are determined by the combination method of statistical analysis and expert scoring. According to the design principle of early warning signal system and the indicator state division method, the early warning signal system of China's foreign trade container shipping market is proposed. To monitor the long-term market wave trend, an early warning index model is further proposed by the method of synthetic index, in which the indicator weights are determined by the principal component analysis method. Finally, the comparison results between the system operating and the real market volatility further demonstrate the validity of the proposed system.
Keywords: Foreign trade container; Shipping; Early warning; Signal system; Index; Throughput.

1 Introduction

China's waterborne transport realized the high speed development in the last two decades. Until now, it has not yet formed a complete long-term cycle of fluctuation. Due to lack of enough cyclic statistics, it brings great difficulties for in-depth research on cyclical fluctuation. In 2008, the international financial crisis swept over the world. As a highly internationalized industry, China's foreign trade container shipping market got very big impact with a sharp fall of freight rates and a negative growth of throughput. Since then, the short-term fluctuations of China's foreign trade container shipping market loom large. Experts and scholars began to pay more attention to the study of monitoring and early warning of it.

In the existing literatures, an early warning model of port economics is proposed by the climate index method (Zhu Chao, 2005), in which an early warning indicator system is presented and major monitoring problems are discussed. The literature (Gan Aiping, 2011) investigates the interrelationship of macroeconomic growth and shipping cycle by empirical analysis. The strategies are also proposed to deal with China's future shipping cycle. The literature (Zhu 2011) proposed leading indicators for China's foreign trade container throughput. A composite leading index for China's foreign trade container throughput is proposed by the principal component analysis method (Zhu, 2013). In recent years, some climate indexes are also Su successively released by many research institutes (Table 1). These indexes provide useful quantitative analysis tools for monitoring the short-term market fluctuations in waterborne transport industry.

Overall, the monitoring and early warning of China's waterborne transport industry is still in its infancy stage. The related theoretical analysis and monitoring technology should be further improved. Therefore, an early warning signal system and the index model of China's foreign trade container shipping market is mainly proposed.

Table 1.The existing climate indexes in China's waterborne transport

CSSI and CPSI index	Composite index	July, 2010	Weekly	China Waterborne Transport Research Institute

2 Early Warning indicators and warning thresholds

To effectively monitor container shipping fluctuations, it is not enough to only consider indicators in China's foreign trade container shipping market. The scope should extend to other closely related fields, such as the whole container logistics chain, the macroeconomics at home and abroad, the situation of foreign trade, the upstream and downstream industries and so on. According to analysis of the fluctuation mechanism in china's foreign trade container shipping (Zhu, 2011), the throughput, freight, import and export volumes, supply capacity of container ships and cargo demand are all critically important to monitor the container shipping market. Base on it, the six early warning indicators are chosen, which include the growth rate of China's coastal container throughput (CCCT), China's export container freight index (CCFI), Howe Robinson Containership Index (HRCI), the growth rate of China's import and export volume (CIEV), China's PMI new export order index (NEOI) and American consumer confidence index from the Conference Board (ACCI).

The monthly statistics of these indicators are collected. The sample data ranges from January 2005 to December 2014. On the one hand, the warning thresholds of these indicators are calculated by the statistical characteristics, such as the mean, median, maximum, minimum and variance of the sample data (Abraham, 1983). On the other hand, the expert scoring method is adopted for determining the thresholds. The final warning thresholds are comprehensively derived by these two methods. The thresholds results are shown in Table 2, where the blue, watchet, green, yellow and red light areas respectively denote the different indicator status of overcooling, cooling, normal, heating and overheating.

Table 2. Early warning indicators and warning thresholds

Indicators	Light Area				
	Blue	Watchet	Green	Yellow	Red
CCCT	⩽1.4%	1.4%, 8.0%	8.0%~19.9%	19.9%~24.0%	>24.0%
CCFI	⩽946	946~1028	1028~1124	1124~1157	>1157
HRCI	⩽400	400~600	600~1100	1100~1300	>1300
CIEV	⩽ -9.1%	-9.1%~7.1%	7.1%~24.1%	24.1%~32.6%	>32.6%
NEOI	⩽45.5	45.5~49.5	49.5~53.5	53.5~56.0	>56.0
ACCI	⩽ 52	52~75	75~100	100~107	>107

3 Early Warning signal system and index model

There are five steps to model the early warning signal system of China's foreign trade container shipping market.

Step 1. Selecting Indicators. Generally, about six early warning indicators are selected. The coincident indicators are comprised the majority of the selected indicators. Meanwhile, the leading or lagging indicators are also permitted. The six early warning indicators are selected as shown in Section 2.

Step 2. Determining thresholds. For each indicator, four threshold values are should firstly determined. Then five kinds of status, which include the overcooling,

cooling, normal, heating and overheating intervals, are divided by the four thresholds from high to low. These intervals are represented as the blue, watchet, green, yellow and red light areas, respectively. The warning thresholds of the six proposed indicators in the above section are shown in Table 2. The state of the indicators in 2014 is shown in Figure 1.

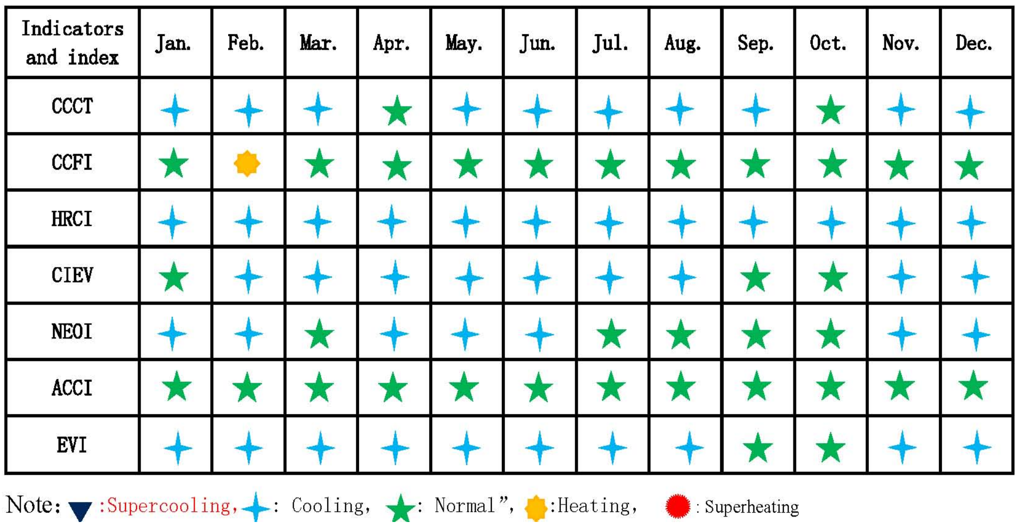

Figure 1. Early warning signals of the indictors and the index EVI.

Step 3. Calculating early warning index. First of all, the blue, watchet, green, yellow and red light areas are set to the values from 1 to 5, respectively. Then, there is a score for each indicator in a month. The value of early warning index is derived by adding up all scores of indicators, in which the indicator weights are determined by the principal component analysis method. Figure 2 shows the curve of early warning index (EWI) of China's foreign trade container shipping.

Step 4. Building signal light system. According to the historical trend and statistics analysis of the EWI, the warning intervals are determined by expert scoring method as shown in Table 3 and Figure 2. Based on it, the state of the index can be shown as different kinds of lights in every month. The last column of Figure 1 depicts the state of EWI in 2014.

Table 3. Early warning indicators and warning thresholds

Index	Light Areas				
	Blue	Watchet	Green	Yellow	Red
EWI	<10.8	10.8~15	15~21.9	21.9~25.5	>25.5

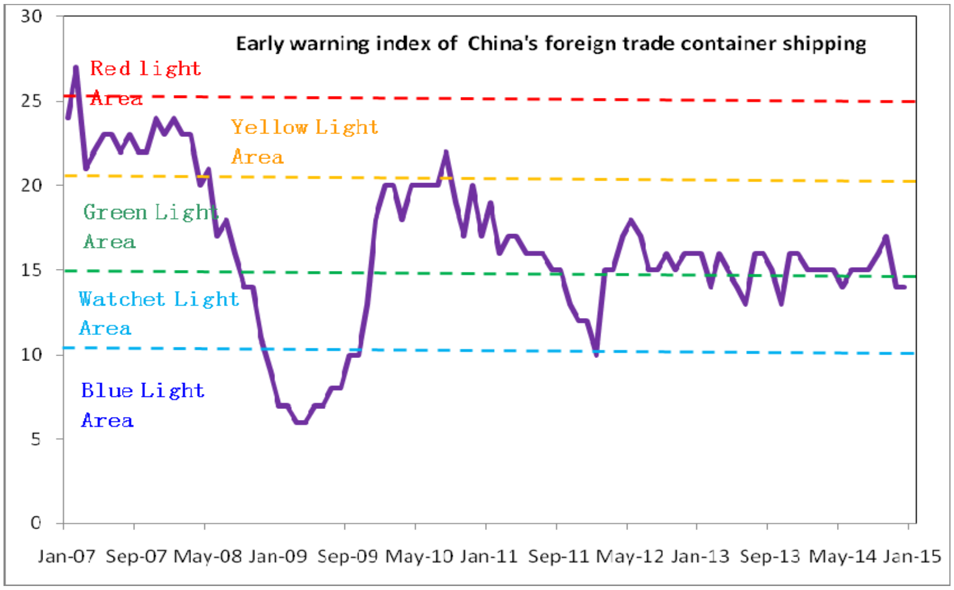

Figure 2. Early warning index of China's foreign trade container shipping

4 Application of EWI

As shown in Figure 2, China's foreign trade container shipping is in the heating state during 2007. The EWI reached the maximum value of 27 and showed the overheating state in February. During this period, China's foreign trade economy developed at a high speed. The growth rate of the import and export volume mostly stayed above 25%. From the container perspective, the growth rate of throughput also stayed above 20%. Moreover, the insufficient container ship capacity resulted in amazing increase of container freight. Soaring charter rate made the HRCI index reached the maximum value of 1407 in September, 2007.

The EWI slowed dramatically with the advent of the international financial crisis of 2008. The china's foreign trade container shipping fell into the overcooling state and the EWI dropped down to the bottom with the minimal value of 7 in February, 2009. China's coastal container throughput decreased with the negative growth, and the CCFI index also fell to below 800 points. The whole container shipping market was at its lowest.

China's container shipping began to rapidly rebound in 2010. The EWI recovered to pre-financial crisis levels in August. However, the shipping market started to fall again since 2011. The EWI slumped into the cooling state once again. In recent two years, China's foreign trade container shipping market is between the state of normal and cooling, and the EWI swing around the value of 15. From the indicators perspective (Figure 1), only two indicators (CCFI and ACCI) are in the norm state. Other four indicators are all in the cooling state in 2014.

From above analysis, the EWI has effectively reflected the fluctuation of China's foreign trade container shipping market in recent years. It can play a warning role in the process of the container shipping market fluctuations.

5 Conclusions

A set of monitoring indicators for China's foreign trade container shipping market is presented. The warning thresholds are given by the export scoring method. Based on it, the EWI and signal system are proposed. The practice of trial operation proves the EWI can truly reflect the fluctuation of China's foreign trade container shipping market. So it is a useful tool to monitor the short-term fluctuation. In further research, the monitoring indicators of other sub-industries, such as dry bulk cargo shipping, crude oil import and inland waterway transport, can also be investigated. Accordingly, the early warning indexes of the sub-industries could also be given. Then, a whole early warning system of China's waterborne transportation can be proposed.

Abstract: Empirical data from related listed companies are then adopted to analyze and test the actual effect of corporate social responsibility on the enterprises' sustainability. Findings show that in each dimension of CSR, the impact on sustainability is fair operation, labor practices, consumer issues, environment, responsibility for governance and community development from high to low in turn. As to economic development and human rights, there is no significant impact on sustainability, and human rights can affect sustainability negatively. Therefore, it is an effective way to promote transportation enterprises' sustainability by enhancing CSR, performing CSR in stages and ensuring the priority of implementation of part enterprises' CSR.
Keywords: Corporate social responsibility; Sustainability; Transportation industry.

1 Introduction

Transportation, the critically basic industry concerning national economy and the people's livelihood, has always played the fundamental and leading role in our national development strategy. For its weightily status, in the 12th Five-Year Plan, our government has put forward the overall goals that on the base of the principal "appropriate advance", we should build convenient, safe, economic and efficient comprehensive system of transport to provide powerful support and guarantee for national economy and social development. And enterprise is the important component part and carrier in transportation, and it is reported that the transportation enterprise has shouldered over eighty percent traffic, which means that the developments of transportation companies directly decide the movement of transportation industry.

To certain extent, the development of transportation enterprises relies on growth of transportation, which doesn't imply that the more rapid, the better. Growing too fast may cause such problems as shortage of funds and generate finance crisis, while growing too slow may also set the enterprise in survival crisis by inefficient use of resources. Taking account of this point, many scholars regarded that companies should gain profit and take other stakeholders' benefit and relevant social responsibilities in to account simultaneously. However, at present such problems as environmental pollution, waste of resources, transportation security problems are looming large. For example, on November 29, 2013 in Dongying, Shandong province, the logistics poisonious parcels cause deaths. All these problems focalize on CSR. How can transportation enterprises, one of the most critical economic arteries of national economy, fulfill their social responsibilities? which are the comparatively important social responsibilities? Figuring out these questions will be of great benefits to instruct making relevant policies, fulfill social responsibilities, and thus promote their sustainability.

2 Literature Review and Research Hypothesis

Corporate social responsibilities (CSR), originated from *Management Philosophy* written by England scholar Sheldon in 1924. In 1971, Committee for Economic Development pointed out that CSR were composed by three concentric circles and formed the CSR Concentric Circles Model. Carroll (1979) put forward CSR four-dimension model, including economic responsibility, legal responsibility, moral obligation and discretional responsibility. Carroll (1991) further revised it as a pyramid model. With the proliferation of stakeholder theory, some study combined it in the model. For instance, Ramanathan (1976) held that CSR could be divided into four parts, i.e. client, personnel, community and vulnerable groups. WBCSD (2003) stated that CSR contained employee benefits, environment protection, community participation, supplier relations and other aspects. Comparing with western countries, researches in our country got behind. By far, the definition and connotation haven't reached a consensus. The domestic CSR researches still judged and expanded on the base of the foreign categories. For example, Xu et al. (2007) considered that Chinese CSR has nine dimensions, i.e. economic responsibility, legal responsibility, environment protection, client orientation, people foremost, public welfares, employment, business morality, society stability and progress.

The measurement adopted in this paper is the sustainable growth rate (SGR) raised in the angle of finance which was also used by Van Horne (1988).

Therefore, it's of great necessity to conclude the relevant researches on the relation between CSR and financial performance. Although the empirical researches on CSR and financial performance starting from 1970s, Margolis and Walsh(2003) have analyzed the 127 empirical researches from 1972 to 2002 and have found out that there are 54 holding the positive relation opinions, 7 of negative relation, 28 of no correlation and 20 of no agreement. Quite a few scholars such as Ruf et al(2001), have discussed the reasons which caused the varied results and all considered that this may boils down to that they haven't taken the industry, scale, quality and others into account and the measurement are too simple or inconsistent. Researches got the results that CSR can drive and constrain sustainability. Li (2006) deemed that CSR, embodying the operation philosophy and value, was a key variable to enterprise sustainability. Hu (2004) analyzed the impact factors of sustainability, the main content of CSR and illuminated CSR's practical significance to sustainability, pointed that CSR is the ethical basis of sustainability finally.

This paper deemed that the sustainability of transportation enterprises should based on the fulfillment of society responsibilities such as responsibility governance, economy development, human rights, labor practice, environment, fair operation, customer problems, community development and so on. For instance, increasing investment on green economy, low carbon, energy saving and staff training will not decease profits but enhance enterprise prestige. Good image is beneficial to elevate customers' evaluations and thus can gain more opportunities, strengthen competitive power and further increase company performance. The CSR in transportation enterprises and their different dimensions are able to influence sustainability positively. On the basis of analyses above, this paper raised the following hypothesis.

H1: transportation enterprises' CSR can influence sustainability positively.

H1a: transportation enterprises' responsibilities for governance can influence sustainability positively.

H1b: transportation enterprises' economic development can influence sustainability positively.

H1c: transportation enterprises' human rights can influence sustainability positively.

H1d: transportation enterprises' labor practices can influence sustainability positively.

H1e: transportation enterprises' environment can influence sustainability positively.

H1f: transportation enterprises' fair operation can influence sustainability positively.

H1g: transportation enterprises' consumer issues can influence sustainability positively.

Hy1h: transportation enterprises' community development can influence sustainability positively.

3 Research Design

3.1 Sample Data Collection

Given that the 2008 global financial crisis may cause some minor errors, data selected in this paper are coming from the *2009-2011 Annual CSR Development Report of Transportation Industry* developed by Kuang (2012) in DLMU CSR and sustainability research center, because this report renders a comprehensive and detailed evaluation and is praised with great authority and reference value.

3.2 Variables and Model Design

3.2.1 CSR

Despite that scholars have defined CSR in different angles, these classification are on account of stakeholder theory. CSR assessment system from the *2009-2011 Annual CSR Development Report of Transportation Industry* are applied in this paper as measurement. This system lists the social expected eight core topics, containing responsibility governance, economic development, human rights, labor practice, environment, fair operation, customer problems and community development. All the results will be in hundred marks and their sum is the final score.

3.2.2 Sustainability

Van Horne(1988) put forward SGR as the following.SGR=(net profit margin ×asset turnover ×equity multiplier ×retained earning rate)/(1-net profit margin ×equity multiplier ×asset turnover ×retained earning rate).This measurement fully disclosed enterprise finance activities and operation activities, manifesting best growing ability under the constraints of current external environments and internal resources.

3.2.3Model Design

In order to test the hypothesis, we set up the following model 1.

$$SGR_{it} = \beta_0 + \beta_1 CSR_{it} + \beta_2 NFPS_{it} + \beta_3 ROA_{it} + \beta_4 GROW_{it} + \beta_5 INDRA_{it} + \beta_6 FIRST_{it} + \beta_7 ZHSHA_{it} + \sum YEAR_{it} + \varepsilon_{it} \quad (1)$$

In this paper, Dependent Variable is SGR and Independent Variables is CSR and its eight dimensions, i.e. the governance of responsibility (ZRZL), economic development (JJFZ), human right (RQ), labor practice (LDSJ), environment (HJ), fair operation (GPYY), consumer issues (XFZWT) and community development

(SQFZ). Besides, in reference to the existing literature, such as Chen et al. (2008) and Tang (2009), we also take other factors reflecting enterprise finance and governance into consideration. Specifically, they are net cash flow per share (NFPS), ROA (return on assets), growth rate of operating profit (GROW), independent director rate (INDRA), share proportion of the largest shareholder (FIRST), stock proportion restriction (ZHSHA) and YEAR.

4 Data Analysis

4.1 Descriptive Analysis of Sample

The listed companies in transportation industry which published CSR reports from 2009 to 2011 as are chosen as research samples, among which there are 27 CSR reports in 2009 and 80 reports come from 2010 and 2011. After deleting 17 data with missing values, 100 complete data are carefully preserved. The minimum value of CSR is 3.65 while the maximum value is 63.04, basically reaching a preferable level of above 60, which reveals the poor situation of CSR on the whole. The deviations of other CSR indexes are also big and the mean value of JJFZ, RQ and GPYY are 0.469, 0.289 and 0.646 respectively, which is consistent with the current reality of CSR.

4.2 Regression Analysis

In table 1, we have a estimation on model 1. In model1, the regression coefficient of CSR is above zero (significance level $P<0.05$), which indicates that the transportation enterprises' CSR can influence sustainability positively and thus hypothesis 1 is verified. Furthermore, we discussed the relations between 8 specific indexes and sustainability, seen in regression 2 and regression 9. Except JJFZ and RQ without obvious regression coefficients, the regression coefficients of ZRZL (significance level $P<0.01$), LDSJ(significance level $P<0.05$), HJ (significance level $P<0.01$), GPYY (significance level $P<0.05$), XFZWT (significance level $P<0.01$) and SQFZ (significance level $P<0.1$) are all above zero. Obviously, in the present fulfillment of CSR, only responsibility for governance, labor practices, environment, fair operation, consumer issues, community development can boost the sustainability efficiently. In the rank of impact factor, they are GPYY (0.054), LDSJ (0.043), XFZWT (0.041), HJ (0.032), ZRZL (0.026) and SQFZ (0.020) from high to low. However, the JJFZ and RQ don't impact evidently on CSR, RQ impacts CSR negatively. Henceforth, the hypotheses 1b and 1c are not verified and hypotheses 1a, 1d, 1e, 1f, 1g and 1h are all verified.

Table 1. Regression Analysis

Dependent variable: SGR									
Variable	Total samples								
	model1	model2	model3	model4	model5	model6	model7	model8	model9
CSR	0.003**								
	2.316								
ZRZL		0.026***							
		3.600							
JJFZ			0.009						
			1.620						
RQ				-0.015					
				-0.879					
LDSJ					0.043**				
					2.361				
HJ						0.032***			
						3.286			
GPYY							0.054**		
							2.068		
XFZWT								0.041***	
								3.084	
SQFZ									0.020*
									1.922
R^2	0.542	0.584	0.487	0.479	0.523	0.563	0.526	0.568	0.500
F	10.890***	10.120***	9.770***	10.320***	9.730***	11.240***	9.450***	10.790***	10.170***
OBS	100	100	100	100	100	100	100	100	100

Notes: (1) T value illustrates T statistic after a Robust standard error correction; (2) * * *, **, * illustrates_respectively 1%, 5% and 10% significance level; (3) In the regression analysis, this paper also concluded such control variables as ROA, GROW, INDRA, FIRST, ZHSHA, CONS and YEAR. Owing to the limited space, they were not listed specifically in the table.

5 Results and Discussion

In terms of different impact of eight dimensions on SGR, CSR can be ranked as fair operation, labor practices consumer issues, environment, responsibilities for governance and community development from top to bottom. However, the economic development and human right do not impact evidently on sustainability, and human right impacts sustainability negatively. This may be due to the macro-environment which affects the economic development and leads to instability of the great economic development from 2009 to 2011. The human right may be paid insufficient attention in transportation industry, which probably generates the negative effect.

Therefore, on account of conclusions mentioned above, this paper believes that good performance on responsibility for governance, labor practices, environment, fair operation, consumer issues, community development will be definitely beneficial to long- term and sustainability, which in turn requires enterprises to infuse such ideas into management system and behaviors to enhance CSR performance. The different dimensions of CSR influence SGR variously. In terms of the impacts, from top to bottom, they can be ranked as fair operation, labor practices, consumer issues, environment, responsibilities for governance and community development. Therefore, in accordance to different phrases and key points, enterprises can perform CSR efficiently and thus boost sustainability.

6 Recommendations for Future Research

Taking into account the difficulties in collecting the data, we only selected the samples up to 2011, the sample is relatively small, future research may collect the latest data to validate the conclusions in this study. In addition, the study was cross-sectional study, a longitudinal study can be considered to be conducted in future study.

Socioeconomic Determinant Analysis of Influencing the Urban Transit Share in China

Runlin Cai[1,2] and Xiaoguang Yang[1]

[1]School of Transportation, Tongji University, No. 4800 Caoan Rd., Jiading District, Shanghai 201804, P.R. China. E-mail: cairunlin@foxmail.com
[2]Shanghai Branch of Urban Transport Institute, China Academy of Urban Planning & Design, No. 5, Lane 168, Linhong Rd., Changning District, Shanghai 200335, P.R. China.

Abstract: In recent years many cities in China are making great progress in developing urban public transportation. Meanwhile the share of public transit is becoming one of the main indexes in evaluating the level of public transport development. Based on the quantitative analysis of different type of cities, this paper reveals the internal relationship between the public transit share and social economic conditions. Firstly the range of factors influencing public transit share or transit usage is determined based on domestic and international literature review. Secondly, the trend of domestic public transit ridership and social economic factors in recent 25 years is examined as the fundamental to build models. Thirdly, the paper chooses 30 cities of different types and scales as the objects of study, and builds structural equation models to quantify the impacts of changes in several determinants on public transit share. In the end the paper illustrates how and to which extent the social and economic factors influence the change of public transit share.
Keywords: Transit share; Socioeconomic determinants; Structural equation model; Factor analysis.

1 Introduction

With the advent of the 21st century, the rapid economic development has led to increasingly serious traffic jams in metropolises, and an effective way to address to the problem is to vigorously develop the urban public transit system.(Yang, 2006) In 2005, General Office of the State Council forwarded the *Advices to Give Priority to the Development of Public Transport (No.46 Document by General Office of the State Council [2005])* released by the Ministry of Housing and Urban-Rural Development of the People's Republic of China and the National Development and Reform Commission, which confirmed the priority of public transit in urban transportation and drew wide attention from cities in China to the development of public transit. In December 2012, the State Council issued the *Guidance of the State Council to the Prior Development of Public Transport (No.64 Document by the State Council [2012])*, in which the State Council clearly pointed out that, "An urban motorized transportation system dominated by the public transport should be constructed by improving the transportation capability, service level, competitiveness and attraction of the public transport. At the same time, the walking and bicycling conditions should be refined…The public transit share should be increased so as to define the dominant role of public transit in urban transportation." These policies have brought precious opportunities for the development of the urban public transportation. One of the major purposes to vigorously development the urban public transport system is to improve the public transit share in the daily transportation so as to alleviate the urban transport pressure. Therefore, it is of vital guiding significance for urban and transportation planning to analyze various socioeconomic factors influencing the public transit share and reveal the internal relationship between the public transit share and the socioeconomic conditions.

Most research into the public transit share appear in foreign literatures. Since the 1990s, there has been a systematic study of the public transit share, focusing on various factors which might influence the public transit efficiency, and the relation between these factors. The previous research could generally be divided into two types, namely research into the endogenous factors and the exogenous factors. The analysis of the endogenous factors mainly focuses on ticket price (Sale, 1976; Kain, 1996), service supply level (Liu, 1993; Kohn, 2000), service quality (Cervero, 1990; Syed, 2000; Avedel, 1995); while the analysis of the exogenous factors focuses on spatial factors, public finance factors and socioeconomic factors. Among them, the analysis of spatial factors and public finance factors mainly features regression analysis. (TCRP, 1996; Crane, 2000; Morral, 1996; Kain, 1996), while the analysis of the socioeconomic factors is mainly conducted through the aggregate model to study the sensibility of public share rate to various factors. For example, Liu (1993) and Chuang (1997) though that the employment rate and the regional development level have the greatest influence on the public transit share. Gomez-Ibanez (1996) found out the elastic coefficient of the employment rate to the public transit share in the downtown area is 1.24~1.75, which is higher than that of the income level, the regional population and other factors to the public transit share. He even deduced that the income level and the suburbanization have a negative influence on the public transit rate, which should be balanced through improving the service level and reducing the ticket price. Liu and Kain (1995 & 1996) studied the interplay between the auto ownership and the public share rate, but their conclusions are relatively vague.

Generally speaking, the research content into the factors influencing the public transit share is diversified and the existing research findings are referential to the formulation of transportation policies to some extent. However, due to the limit of research scope and data acquisition, the existing research findings tend to target at a specific region or city, thus lacking universality. In particular, the foreign urban development characteristics, socioeconomic conditions and transportation system vary greatly from those in China and the importance degree of these factors to China is fundamentally different. Therefore, it is necessary to enhance the quantitative analysis of various influencing factors based on the practical situation in China so as to promote the positive interaction between the formulation of public transit policies and the public transit operation efficiency.

2 Macro-level Trend Analysis of Transit Ridership and Socioeconomic Development

The development of the public transit system has a close bearing on the steady socioeconomic development in the urban area. This part conducts an overview of the urban public transit and socioeconomic development trend in China and analyzes to find the major factors influencing Annual passenger boardings and the public transit efficiency.

2.1 Data source and selection

The data in this part mainly are obtained mainly from *China Statistical Yearbook* issued by National Bureau of Statistics on an annual basis. The statistical data cover the economic and social conditions of various cities in China from 1987 to 2012. Based on these data, this paper calculates and processes relevant indexes.

The urban public transit passenger boardings and the annual per capita transit trips are confirmed as the indexes indicating the urban public transit development level. According to the previous research and the data accessibility, macro factors influencing the public transit development can be classified into three types, socioeconomic development level, public transit system construction level and mechanized development level.

Table 1. Index classification and selection

Classification	Indexes	Unit
Socioeconomic development level	Gross domestic product (GDP)	100 million RMB
	Urban population	10,000 persons
	Urban employees	10,000 persons
	Urban land for construction	km^2
	Population density	10,000 persons/km^2
	Employment density	10,000 persons/km^2
	Per capita income	RMB
Public transit construction level	Standard operating bus vehicles	Set
	Length of operating bus lines	km
	Standard bus vehicle ownership ratio	set/10,000 persons
	Proportion of transit in municipal investment	%
Automatized development level	Road network mileage	km
	Per capita road area	km^2/person

	Private auto ownership	10,000 sets
	Private auto ownership ratio	ets/10,000 persons
	Proportion of road in the municipal investment	%

2.2 Analysis of the public transit and socioeconomic factors development trend

Over the past 25 years, China’s urban socioeconomic level has been greatly improved and the scale of the urban population and land use has kept expanding. The growth of annual passenger boardings is closely related to the expanded scale of urban population and employment. (Figure 1) Though urban population did not show significant growth, the growth curve of urban employment almost coincided with the growth curve of annual passenger boardings. On the other hand, the growth of annual passenger boardings is closely related to the rapid development of the transit system. Also, it can be seen that, as annual passenger boardings increased, standard operating bus vehicles and length of operating bus lines also kept on growing. Especially after 2005, the scale of operating bus lines registered a rapid increase.

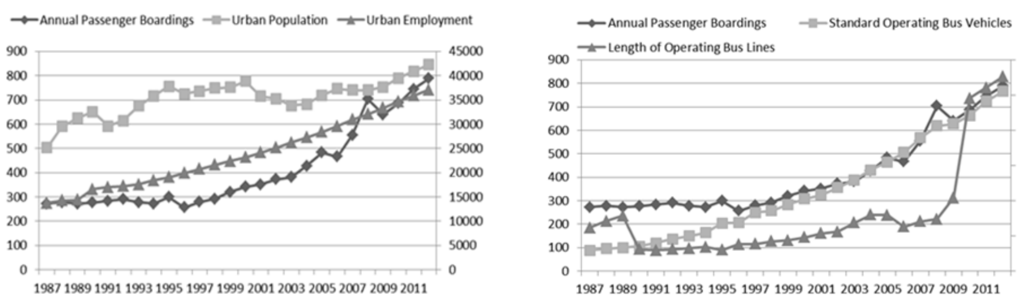

Figure 1. Trend of passenger boardings, population, employment and transit supply

Annual per capita transit trips acts as an index to indicate the public transit service efficiency. Its growth magnitude was not that significant. Around 2000, it even fluctuated, which suggested that, despite the significant growth of socioeconomics and annual passenger boardings, the transit service efficiency still failed to be increased by a large margin and the transit trips still did not hold great attraction to the public. (Figure 2)

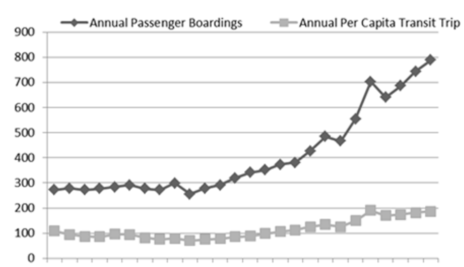

Figure 2. Trend of annual passenger boardings and annual per capita transit trips

From Fig. 3, it can be seen that the development trend of annual per capita transit trips, bus vehicles per 10,000 persons and proportion of transit in municipal investment almost coincided with each other. In some sense, it indicated that, despite of the significant increase of annual passenger boardings, the annual per capita transit trips still developed slowly, which inhibited the competitiveness and attraction of the public transit. And it also can be seen that the density of population and employment is decreasing steadily.

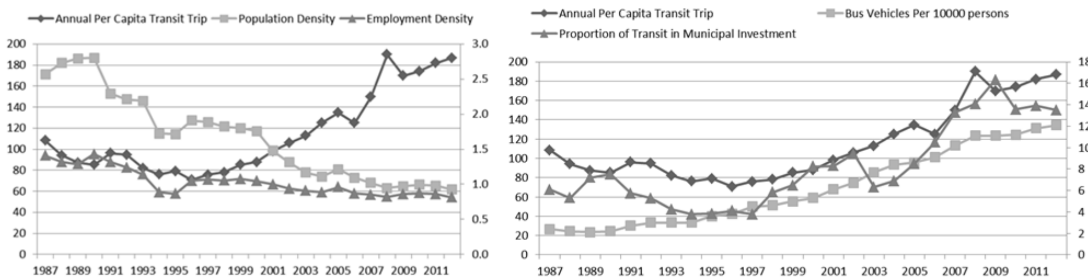

Figure 3. Trend of annual per capita transit trips, population, employment and transit

2.3 Correlation analysis of public transit and socioeconomic development

This part analyzes the correlation between major socioeconomic factors, and annual passenger boardings and annual per capita transit trips, respectively. The first group is to demarcate the correlation coefficient between annual passenger boardings and socioeconomic aggregate indexes and analyze their significance. From Table 4, it can be seen that annual passenger boardings were significantly positively related to GDP, urban population, construction land area, standard operating bus vehicles and length of operating bus lines. This is in line with the general development rules of public transit.

Table 2. Correlation of transit ridership and socioeconomic indexes

		GDP	Population	Construction land	Standard operating bus vehicles	Length of operating bus lines
Transit ridership	Pearson Correlation	.980**	.631**	.930**	.960**	.828**
	Sig. (2-tailed)	.000	.001	.000	.000	.000
**. Correlation is significant at the 0.01 level (2-tailed).						

The second group is to analyze the correlation between annual per capita transit trips. From Table 5, it can be seen that annual per capita transit trips are significantly positively related to standard operating bus vehicles and private cars per 10,000 persons, but are negatively related to employment density and per capita road area. It should be noted that the public transit operating efficiency often has a negative influence on private cars per 10,000 persons, while a positive influence on employment density. From Table 5, it can be seen that variables have a strong correlation to each other, which suggests that the endogenous correlation among the macroscopic data index variables results in the interaction among variables. The discrete study of the urban area will resolve this problem.

Table 3. Correlation of transit ridership per capita and socioeconomic indexes

		Population density	Employment density	Bus vehicles per 10000 persons	Private cars per 10000 persons	Road area per capita
Annual per capita transit trips	Pearson Correlation	-.722**	-.564**	.909**	.913**	.904**
	Sig. (2-tailed)	.000	.003	.000	.000	.000
**. Correlation is significant at the 0.01 level (2-tailed).						

3 Socioeconomic factor analysis

Based on the data of 30 cities related to their socioeconomics, public transportation, mechanized development and residents' trips, an analytical model is established. First, the factor analysis is conducted of all index data. Multiple variables are simplified so as to decompose the original variables and find out the potential types. Those indexes showing strong correlation are classified as one type. The correlation between different types of variables is relatively low. The method has now been widely applied to various fields.

In order to obtain the potential factors influencing the public transit share and further study the relation between various factors and the public transit share, the factor analysis can be conducted to obtain the factors influencing the public transit share.

First, 22 socioeconomic description indexes undergo KMO test (Kaiser-Meyer-Olkin Measure of Sampling Adequacy) and Bartlett's Test of Sphericity. The test results are shown in Table 4:

Table 4. KMO test and Bartlett's Test of Sphericity

Kaiser-Meyer-Olkin Measure of Sampling Adequacy	0.697
Bartlett's Test of Sphericity Approx. Chi-Square	463.2
df	231
Sig.	0.000

KMO value is 0.697, which is close to 0.7. This suggests the result of the factor analysis is good. The value of Bartlett's Test of Sphericity is 463.2 and it reaches a significant level under the degree of freedom (df) of 231 and the significance level of 0.000. This suggests that there are common factors existing in various influencing factors, so the factor analysis is suitable.

Principal component method is the mostly-commonly used method to extract common factors in the factor analysis. Varimax rotation is adopted to rotate the extracted common factors so as to achieve a satisfying explanation. Arrayed according to the eigenvalues, four common factors are extracted. (Table 5)

Table 5. Extraction of socioeconomic factors and their explanation of the original variables

Component	Initial Eigenvalues			Rotation Sums of Squared Loadings		
	Total	%of Variance	Cumulative %	Total	%of Variance	Cumulative %
1	8.465	38.477	38.477	4.564	20.744	20.744
2	3.285	14.933	53.411	3.262	14.828	35.571
3	1.877	8.534	61.944	2.640	11.999	47.571
4	1.504	6.838	68.782	2.586	11.753	59.323

The facto analysis results are shown in Table 6. It can be seen four common factors can be extracted from 22 socioeconomic factors participating in the factor analysis. The first common factor contains five items (including gross road network area, land use scale, length of the road network, auto ownership and bridge and road investment). Its eigenvalue (4.564) and contribution rate (20.744%) are the highest, which suggest that its explanation proportion of the variance of all social factors is the highest and it can be regarded as the road scale factor. The second common factor contains five items (general financial revenue, per capita income, disposable fiscal revenue, GPD and per capita GDP). Its eigenvalue (3.262) and contribution rate (14.828%) are just behind the first common factor. It can be regarded as the urban socioeconomic factor. The third factor contains four items (including bus vehicles ownership per 10,000 persons, length of operating bus lines, scale of standard operating bus vehicles, annual passenger boardings and per capita transit trips). Its contribution rate is 11.999% and it can be regarded as the transit supply factor. The fourth common factor contains three items (including time consumption of private car trips and transit trips and the average time consumption of trips). Its contribution rate is 11.753%, so it can be regarded as a trip time consumption factor.

Table 6. Analysis results of the socioeconomic factors

Socioeconomic factors and factor items	Factor loading	Eigenvalue	Contribution rate (%)
Common Factor 1		**4.564**	**20.744**
Gross road network area	0.930		
Land use scale	0.921		
Length of the road network	0.893		
Auto ownership	0.812		
Bridge and road investment	0.777		
Common Factor 2		**3.262**	**35.571**
General financial revenue	0.750		
Per capita income	0.713		
Disposable fiscal revenue	0.664		
GDP	0.642		
Per capita GDP	0.564		
Common Factor 3		**2.640**	**47.571**
Bus vehicles per ownership per 10,000 persons	0.891		
Length of operating bus lines	0.709		
Scale of standard operating bus vehicles	0.704		
Annual passenger boardings	0.644		
Common Factor 4		**2.586**	**59.323**
Time consumption of private car trips	0.893		
Time consumption of transit trips	0.874		
Average trip time consumption	0.807		

In the following a structural equation model will be established based on the correlation between socioeconomic factors and public transit rate to analyze the influence of various factors on the public transit share and the interaction among various factors.

4 Structural equation model of transit share and socioeconomic factors

4.1 Introduction of the structural equation model

The structural equation model is a statistical approach to analyze the relation among variables through the variable covariance matrix. It is also called covariance structural analysis. The structural equation model is a diversified statistical approach to test the relation between observational variables and latent variables, latent variables and latent variables. Generally speaking, a group of variables are assumed to have the causal relationship. The latent variables can be expressed by a group of explicit variables to stand for the linear combination of certain explicit variable. By testing the covariance among the explicit factors, the coefficient of the linear regression model can be estimated to verify whether the assumed statistical model is feasible to the research process. If it is feasible, the relational expression between the assumed potentials is reasonable.

(1) Model composition

The structural equation model is to test the combination of the factor model and the causal model. Part of the factor model contained is called the measurement equation, which is used to describe the relation between latent variables and indexes. Part of the causal model is called the compositional equation, which is used to describe the relationship between latent variables.

The most common situation of the structural equation model is that both the exogenous variables and the endogenous variables are both latent variables. At the moment, both exogenous variables and the endogenous variables have the measurement equation. The model is shown below:

Measurement equation:

$$y = \Lambda_y \eta + \varepsilon \quad (1)$$

$$x = \Lambda_x \xi + \delta \quad (2)$$

Structural equation:

$$\eta = B\eta + \Gamma\xi + \zeta \quad (3)$$

Where:

x stands for the vectors composed by the exogenous explicit variables;

y stands for the vectors composed by the endogenous explicit variables;

Λ_y stands for the factor loading matrix of y on η;

Λ_x stands for the factor loading matrix of x on ξ;

ε stands for the error items of the endogenous explicit variables;

δ stands for the error items of the exogenous explicit variables;

B stands for the coefficient matrix, which is used to describe the interaction between the endogenous latent variable, η;

Γ stands for the coefficient matrix, which is used to describe the influence of the exogenous variable, ξ, on the endogenous variable, η;

ζ stands for the residual items of the structural equation, which is used to reflect the part of η that cannot be explained.

(2) Model parameter estimation

A complete structural equation model should contain eight parameter matrixes: Λ_y, Λ_x, B, Γ, Φ, ψ, Θ_ε and Θ_δ. Among them, Γ stands for the covariance matrix of the latent variable, $\xi;\psi$ stands for the covariance matrix of the residual item; Θ_ε and Θ_δ stand for the covariance matrix of ε and δ, respectively.

If the theoretical model is proved, $\sum(\theta)$ equals to the general covariance matrix, $\sum$, namely $\sum(\theta)=\sum$, and the variance and covariance of the observational variables (namely indexes of endogenous and exogenous variables) are both the functions of the model parameters. Methods like maximum likelihood (ML) estimation and generalized least squares method (GLS) are usually adopted to estimate the model.

(3) Model evaluation

Model evaluation is related to the data fitting degree of the model. The most commonly-used fitting index to evaluate the model is the chi-square test (χ^2) of the goodness of fit, which can be directly deduced through the value of the fitting unction. The size of the chi-square is related to the sample scale, so the goodness of fit index (GFI), the amended goodness of fit index (AGFI) and the root mean square error of approximation (RMSEA) appeared subsequently. The evaluation index can be chosen according to the data characteristics, sample scale and assumed condition adopted for the test.

4.2 Modeling and effect analysis

The correlation analysis between the socioeconomic factors and the public transit share can be expressed by the relation between the endogenous and exogenous factors of the structural equation and the relation between the latent variables.The path diagram is used to show the structural equation model. The endogenous variables are expressed by ovals and the observational variables are expressed by rectangles. If two latent variables are related to each other, they will be connected by the double-headed arrow. If two latent variables are in a causal relationship, they will be connected by the single-headed arrow. The arrow points to the outcome variable. If a latent variable can be expressed by several observational index variables, the latent variable can be regarded as the observational factor. The single-headed arrow can be used to connect the latent variable and the observational variables to show that the latent variable can directly influence the value of the observational variables.

If there are too many estimation coefficients after all indexes are put into the model, the model might be hardly recognizable. The model relationship is simplified through the stepwise regression method to eliminate the insignificant factors influencing variables to improve the model structure step by step. The model is demarcated in the Amos software. The result is shown in Fig. 2.

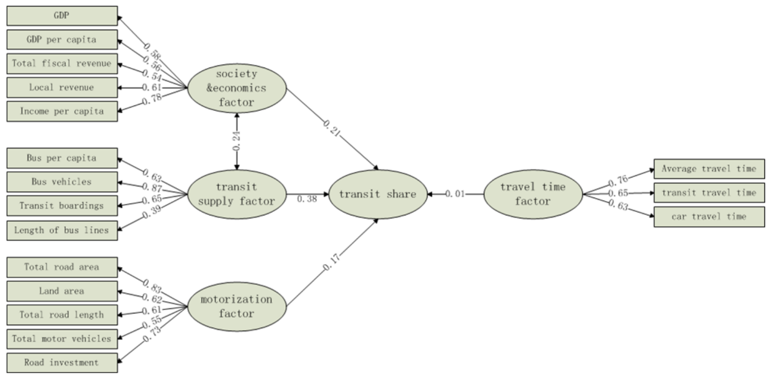

Figure 4. Structural equation demarcated results

Five major characteristics indexes are compared with the ideal value to confirm the fitting precision of the model. The fitting index of the model is shown in Table 7. Through comparison, it can be seen that the fitting index is basically within the ideal scope, which indicates good model fitting degree and certifies that the assumption of the theoretical model is correct. In other words, the socioeconomic factors are correlated to the public transit share.

Table 7. Test of goodness of fit of the model

Evaluation indexes	Model evaluation indexes	Suggested value
Chi-square value/degree of freedom	3.346	Vary with samples
Good of fit index (GFI)	0.843	>0.9
Adjusted goodness of fit index (AGFI)	0.911	>0.9
Root mean square residual (RMR)	0.452	<0.5
Root mean square error of approximation (RMSEA)	0.081	<0.08

The model demarcated results show the interaction between the changes of different factors and the public transit share.

The public transit supply factor has the greatest influence on the public transit share. The correlation coefficient is 0.38, which suggests that the improvement of the public transit bus lines and the expansion of the public transit scale can effectively improve the public transit share. The second influencing factors are urban socioeconomic factor and the road scale factor. Their correlation coefficient of the two to the public transit share is 0.21 and 0.17, respectively. This suggests the urban socioeconomic development level and the road scale can influence the public transit share to some extent, but the influence is not significant. The correlation coefficient between the trip time consumption and the public transit share is 0.01, which suggests that the former is not significantly correlated to the latter.

The correlation coefficient of the urban socioeconomic factors to the public transit supply factor is 0.24. This suggests that socioeconomic development can enhance the development intensity of the urban public transit and increase the public transit scale.

5 Conclusions and prospects

This paper studies the relation between various socioeconomic indexes all over China and in some cities and the public transit share. Through the correlation analysis, factor analysis and establishment of the structural equation model, the following conclusions are obtained:

(1) From the macroscopic perspective, population scale, land use scale and GDP are closely related to the annual passenger boardings; the standard operating bus vehicles, population and employment density are factors closely related to the operation efficiency (per capita transit trips);

(2) As to the social factors influencing the public share, there are three major factors, namely urban socioeconomics, road scale and public transit investment and supply;

(3) Through establishing and demarcating the structural equation model, the factor with the greatest influence on the public transit share is the public transit supply factor, which is followed by the urban socioeconomic factor and the road scale factor.

Due to limited data, the unified model and analysis is just targeted at some domestic cities. The follow-up research should discuss based on cities of different types. Different models should be established to discuss different influence of different factors on cities of different types.

Abstract: In the management process of railway construction, here comes the problems such as involving too many projects, complex business, varying lengths of business cycles, employees and staff capacity varies greatly, which increase the difficulty of management and reduce the efficiency of human resources. It's meaningful to manage the process of railway construction. For the traditional management mode, managers always assign the task directly and manually, which not only increases the administrative burden, but also makes the distribution plan lack of scientificity and rationality, especially for parallel projects, presenting particularly prominent problems. According to "Railway Construction Project Management program guidance" formulated by the former Chinese Railways Construction Management Division it sorted out the management program of railway construction projects and understood the main task type, task attributes etc. meanwhile, studied the existing task allocation algorithm, building a new task allocation model used a multi-dimensional evaluation method and Rough set theory to evaluate the suitability of candidates and fully considered the properties and state of tasks and candidates to improve the scientificity and rationality of distribution plans. On the basis of the above we gave the realization steps of parallel engineering task allocation algorithm for railway.
Keywords: Railway construction; Task allocation; Concurrent engineering; Rough set theory.

1 Introduction

This paper analyzes the process of parallel railway construction project management, finding problems such as managing too many projects, complex business, varying lengths of business cycles, lots of employees and staff capacity varies greatly, etc. Managers always assign the task directly and manually when they distribute tasks in the traditional way, which not only increases the administrative burden, but also makes the distribution plan lack of scientificity and rationality.

To meet the need of modernized management for railway, appropriate task allocation algorithms should be applied to the management of railway construction project, making the task be assigned to appropriate staffs within a predetermined time, so as to improve the efficiency and rationality of task allocation.

This paper analyzed the characteristics of tasks of railway project management, and fully considered the important factors affecting the assignment, and then proposed an allocation algorithm based on multi-dimensional evaluation. It took the expert scoring as the basis for evaluation and applied Equalization method to deal with the original data, Rough set theory to work out the weights of attributes directly affecting task allocation.

2 Railway Project Management Features

2.1 Parallelism and complexity

Large railway construction projects management units always manage many construction projects. So, at the same time, there are always multiple projects need to be managed. The progress requirements of each project are often different and the project management tasks are heavy and complex, increasing the management difficulty greatly.

2.2 Diversity and dynamics of influence factors

Many factors affect task distribution, such as the type and load of tasks, the interests and ability of members, the workload and work experience of the staff. So it’s necessary to consider variety of factors synthetically.

Some factors show their dynamics. In the process of task allocation, new projects always come out at any time, the number and requirements of tasks are constantly changing, the staffs’ joining and leaving is also dynamic. The traditional way to assign the task is essentially static, so it can’t adapt well to dynamic characteristics in the management process. Therefore, it’s is particularly necessary to design a task allocation algorithm of concurrent engineering for railway.

3 Task Assignment Algorithm Designing

The objective of task allocation is to assign the suitable tasks to appropriate staff within a predetermined time. So assignment can be divided into two steps to realize. First, within the stipulated time, select the task with the highest priority. Second, select the most appropriate staff to undertake this task.

When we evaluate the scoring of members and task with subjective scoring, it’ quite necessary to unleash members’ autonomy and reduce subjectivity as possible.

3.1 Scoring designing

According to "Railway Construction Project Management program guidance", the tasks are divided into: document approval, data collection, sending and receiving files, documents signing, document generation, on-site inspection, organizational work, material application, etc. A ~ H can represent the task category in railway construction projects. Meanwhile, select M people with relevant work experience as members of expert group. Task = {t1, t2, ..., tn} represents task items need to be assigned.

Task parameters:

(1) Task load: Define the task workload $Lti = INTti * Fti * Hti$, $INTti$ expresses the intensity of task *I*; *Fti is* the frequency of task *i*; *Hti* represents the time-consuming of task *i*.

(2) Project weights: Tasks of projects belong to key projects and projects with high emergency should be assigned first, so define the project weighting factor pj,

$0 \le pj \le 1.0$.

(3) Assignment Priority: Define the task assignment priority level $D_{pi} = t_{pi} * (1 + pj)$, D_{pi} determines the priority level of task allocation, *tpi* is priority score of the task.

Expert Group was selected to score for task parameters, set a standard scoring range of 0 to 100. Vector [S_{lk1}, S_{lk2},…, S_{lkj}] represents the scoring of expert *l* for the attribute *j* of class *k*. Use the Trimmed Mean to process the vector can obtain the scoring of attribute *j* as follows.

$$\overline{S_{lkj}} = \frac{\sum_{l=na+1}^{n-na} S_{lkj}}{n - 2na} \tag{1}$$

Here, *n* represents the number of scores; *a* represents the coefficient of Trimmed Mean, $0 \le a \le 0.5$; "*Slk*1, *Slk*2,…, *Slkj*" is the array of scoring data in ascending order.

Staff parameters

(1) Personnel load: Define the Personnel load $Li=L0+L_k$, $L0$ shows the current workload of the staff, L_k is the load of task *k* to be assigned.

(2) Staff capacity: Define staff capacity Cap_{ik}, the expert group mark Cap_{ik} for the staffs to be assigned.

(3) Personnel interest: Define Personnel interest Int_{ik}, the staff score for self-interest for each task category.

(4) Staff experience: Define staff experience Exp_{ik}:

$$Exp_{lk} = \frac{\mathrm{NUM}_{lk}}{\sum \mathrm{NUM}_{lk}} * 100 \tag{2}$$

Here NUM_{lk} represents the number of history tasks completed of category k for staff l, SUM_{lk} represents the total number of history tasks completed of category k for all staff to be assigned. Here shows two main tables:

Table 1. Task Attribute Table

Attributes \ tasks	Intensity (*INTti*)	Frequency (*Fti*)	Hours (*Hti*)	Priority (*tpi*)	Project weight (pj)	Task load (*Lti*)	Distribution priority (*Dpi*)
ti	Scoring	Scoring	Scoring	Scoring	Empiric		

Table 2. Staff attribute table

Attributes \ staff	Workload L_0	Capacity Cap_{ik}	Interest Int_{ik}	Experience Exp_{ik}
hi	Scoring	Scoring	Scoring	

3.2 Weight calculation based on Rough set theory

Rough set theory researches incomplete and uncertain knowledge and data .It can learn and conclude from ambiguous and imprecise data. It doesn't need any prior knowledge. Therefore it has been successfully applied into fields such as expert systems, machine learning, pattern recognition, decision analysis, etc.

This paper used rough set theory to calculate the weights of staff properties directly affect task allocation such as staff capacity, personnel interests, staff experience, etc. According to the weights it calculated the assessment value of the staff for the task distribution . Concepts of rough set theory refer to literature (Banerjee M, 1996).

To determine the importance of certain attributes or attribute set, we need to get rid of some other property from the table, and then examine changes of the classification. If the removing of the property will accordingly change classification, so it indicates high importance of the property, on the contrary, indicates low importance of the property. This can use positive region of the rough set to describe.

Consider the task allocation decision table shown in Table 3.

Table 3. Task allocation decision table

U	Workload	Capacity	Interest	Experience	Assign or not
1	light	low	very	general	yes
2	heavy	strong	little	general	yes
3	heavy	general	general	little	no
4	heavy	general	little	little	no
5	light	low	very	little	no
6	heavy	general	little	general	yes

Quantify table 3, and then table 4 can be obtained.

Table 4. Quantized decision table

U	L	C	I	E	d
1	2	0	2	1	1
2	0	2	0	1	1
3	0	1	1	0	0
4	0	1	0	0	0
5	2	0	2	0	0
6	0	1	0	1	1

The universe U composed of elements of NO.1 to NO. 6, the condition attribute set C = {L, C, I, E}, the decision attribute set D = {d}。

U/ind(L,C,I,E)={{1},{2},{3},{4},{5},{6}},U/ind(d)={{3,4,5},{1,2,6}}, $POS_c(D)$={1,2,3,4,5,6}, $r_c(D)$=Card($POS_c(D)$)/Card(U)=6/6=1. Remove attribute L and then $U/ind(C,I,E)$={{1},{2},{3},{4},{5},{6}}, $POS_{c-L}(D)$={1,2,3,4,5,6}, r_{c-L}(D) =6/6=1. After removing C, $U/ind(L,I,E)$ ={{1},{2,6},{3},{4},{5}}, $POS_{c-C}(D)$ = {1,3,4,5}, $r_{c-C}(D)$ =4/6=2/3. After removing I, $U/ind(L,C,E)$ = {{1},{2},{3,4},{5},{6}}, $POS_{c-I}(D)$={1,2,5,6}, $r_{c-I}(D)$= =4/6=2/3. Finally remove E and then $U/ind(L,C,I)$={{1,5},{4,6},{2},{3}}, $POS_{c-E}(D)$={2,3}, $r_{c-E}(D)$=2/6=1/3.

We can conclude that attribute E is the most important because it changes positive region of U/D most, attributes C and I follow, attribute L is redundant. It reflects that we very concern about relevant work experience of the staff, meanwhile the interest and capacity are also taken into account, however the workload tend to be ignored。This paper considered humanity and efficiency and taken the workload into consideration, which was also in line with the actual situation.

Generally, decision-makers always have prior knowledge for each condition attribute and the weight of attributes can be used to measure the relative importance.

The attribute importance in rough set theory can express the influence of the properties to the decision, but it can't reflect the prior knowledge of decision-makers.

This paper combined rough set theory with prior knowledge of decision-makers and then combined synthesis attribute weight gotten from a combination of objective weight with weight from subjective prior knowledge, realized the unity of prior knowledge and objective situation. Normalize the attribute importance of each attribute:

$$q_j = \frac{r_c(\mathrm{D}) - r_{c-j}(D)}{\sum_{j=1}^{n} r_c(\mathrm{D}) - r_{c-j}(D)} \tag{3}$$

Here, $r_c(\mathrm{D})$ represents dependency of decision attribute on condition attribute, $r_c(\mathrm{D})-r_{c-j}(\mathrm{D})$ tells the importance of attribute j, q_j represents the objective weight of j, $q_j \in (0,1.0)$. Use rough set theory can get objective weight and subjective weight can get by expert experience. Suppose the weight of the objective weight is θ.

For Table 3，suppose the subjective weight of each attribute p_i is: p_L=0.2， p_C =0.3, p_I=0.1, p_E=0.4. The attribute importance can be obtained as follows：

$r_c(\mathrm{D})-r_{c-L}(\mathrm{D})$=0; $r_c(\mathrm{D})-r_{c-C}(\mathrm{D})$=1/3; $r_c(\mathrm{D})-r_{c-I}(\mathrm{D})$=1/3; $r_c(\mathrm{D})-r_{c-E}(\mathrm{D})$=2/3

Get the objective weight of each attribute： q_L=0; q_C=0.25; q_I=0.25; q_E=0.5;

So the synthesis weight is：

$P_L=\theta\times0+0.2(1-\theta)\theta=0.2-0.2\theta$, $P_C=\theta\times0.25+0.3(1-\theta)=0.3-0.05\theta$

$P_I=\theta\times0.25+0.1(1-\theta)=0.1+0.15\theta$, $P_E=\theta\times0.5+0.4(1-\theta)=0.4+0.1\theta$

Suppose: θ=0.6, so： P_L=0.08， P_C=0.27， P_I=0.19, P_E=0.46

Here get the synthesis weight of each attribute that directly affect the task allocation.

3.3 Task allocation algorithm

The aim of task distribution is to assign tasks to appropriate staff within stipulated time. Therefore, task allocation can be divided into two steps: first, select a certain task within stipulated time. Second, assign this task to the most appropriate people. So we can determine the assignment order and then assign the task with high priority. Staff that gets the highest score should be assigned firstly.

Task allocation algorithm steps:

step1. Select scoring expert group $Zi:Z1$ is made up of N persons with relevant work experience, taking responsible for the task load scoring; $Z2$ consists of M project manager, taking responsible for staff capacity scoring; $Z3$ is composed of n staff to be assigned and they score for self-interest for each task category.

step2. Select the task items need to be completed from current projects, suppose the task set is T, staff set is H. Score for task load and the staff ability then equalize and normalize the scoring data.

step3. Combine the data from step2 with the project weighting factor *pj* (adjustable) to calculate the allocation apriority score of the task item and choose the task item with the highest score.

step4. According to the relevant data from step2, calculate the task allocation suitability score of the staff for the chosen task item of step2.

step5. Assign the chosen task item from step2 to the staff with the highest suitability score. Then remove the assigned task item from set T and update T and H according the changes of project and staff. Repeat step1 to step 5 until the end.

To consider the one with a heavier workload should have lower task assignment priority, so their fitness to the task is inversely proportional to their workload; likewise, abilities, interests and experience play an active role in the allocation.

Define:

Load matching degree： $LoadFit(i,k) = 100 * 1 / (\mathrm{L}_{ik} * \sum_{l=1}^{n} (1/L_{lk}))$;

$L_{ik} = L_{ik}0 + L_{ik} = (\sum_{t=1}^{m} L_{it}) + L_{ik}$, L_{ik} is the total load if staff i undertake task k ;

Capacity matching degree: $CapFit(i,k) = 100 * Cap_{ik} / (\sum_{l=1}^{n} Cap_{ik})$;

Interest matching degree: $IntFit(i,k) = 100 * Int_{ik} / (\sum_{l=1}^{n} Int_{lk})$;

Experience matching degree: $ExpFit(i,k) = 100 * Exp_{ik} / (\sum_{l=1}^{n} Exp_{lk})$;

Defined the task set T = {t1, t2,..., tn}, staff set H={h1, h2, ..., hm}, task category set S = {a, b, c, d, e},so the synthetic matching degree for task *k* of staff *i* can be defined as:

$$Fit(hi,tk) = LoadFit(i,k)\ P_L + CapFit(i,k)\ P_C + IntFit(i,k)\ P_I + ExpFit(i,k)\ P_E$$

$$= Fit(hi,tk) = LoadFit(i,k)\ P_L + CapFit(i,k)\ P_C + IntFit(i,k)\ P_I + ExpFit(i,k)\ P_E$$

Date of task set T and staff set H is shown in the table blow. Data in the table has been equalized and normalized. Suppose the value of experience matching degree is: 15.27, 20.45, 24.46, 16.49, 23.33.

Table 5. Data table of assigned task

Attributes / tasks	Intensity	Frequency	Hours	Priority	Project weight	Task load	Distribution priority
t1	30	50	10	17.65	0.25	7.32	21.88
t2	10	20	30	23.53	0.10	2.93	25.88
t3	40	20	60	11.76	0.15	23.42	13.52
t4	70	40	20	5.88	0.30	27.32	7.64
t5	100	20	40	41.18	0.20	39.02	49.42

From Table 3, the task set T allocation sequence is: $t5 \to t2 \to t1 \to t3 \to t4$, so t5 should be assigned first, suppose the staffs' load as table6 shows; $P_L = 0.08$, $P_C = 0.27$, $P_I = 0.19$, $P_E = 0.46$. The value of matching degree can work out from the scoring data in table5.

Table 6. Data table of staff

Attri / staff	$L0$	Equalized		Matching degree（normalized）				$Fit(hi,tk)$
		Cap	Exp	$CapFit(i,k)$ 0.27	$IntFit(i,k)$ 0.19	$ExpFit(i,k)$ 0.46	$LoadFit(i,k)$ (0.08)	
a	8000	60	40	16.90	13.79	15.27	24.59	16.17
b	15000	45	55	12.68	18.97	20.45	13.11	17.48
c	20000	75	30	21.12	13.04	24.46	9.84	20.22
d	6000	80	75	22.54	25.86	16.49	32.79	21.21
e	10000	95	90	26.76	28.34	23.33	19.67	24.92

It can be seen from the table that t5 should be preferentially assigned to staff e according to values of synthetic matching degree. Staff e showed obvious advantage in both interest and experience. Meanwhile the synthetic weight of workload was very low so workload affected the value of synthetic matching degree quite lightly. The result of allocation algorithm was in line with the actual principle of task distribution.

4 Conclusions

The parallel railway project management is very important. An efficient and pragmatic task allocation algorithm should be applied into it. This paper considered the difference of projects and the staff property and gave a constructive task assignment strategy for Concurrent Engineering for Railway.

5 Recommendations for Future Research

Personal property directly affects the execution of tasks, so more factors of the staff should be taken into consideration. Meanwhile, the practical situation of the projects always changes, so it's necessary to adjust the related parameters according to the actual situation.

Price Optimization of Express Rail Freight Transportation in a Competitive Context

Yang Chen[1]; Si Ma[2]; and Tieseng Zeng[3]

[1]School of Transportation and Logistics, Southwest Jiaotong University, Chengdu. E-mail: 313810792@qq.com
[2,3]School of Transportation and Logistics, Southwest Jiaotong University, Chengdu.

Abstract: Faced up with the severe competition in the market, the express rail freight transportation management needs appropriate pricing mechanism to improve the efficiency and benefit. The bi-level pricing model is established, including the lower layer model of cargo flow modal split based on the consignors' choices, and the upper layer one aiming at maximizing the benefit of railway enterprises. The improved heuristic algorithm is used in the solution of the bi-level model. The example shows that the express rail freight transportation product has a strong competitive advantage among all the products of other transportation modes with optimum price.
Keywords: Express freight transportation; Pricing; Stochastic user equilibrium; Price sensitivity.

With the gradual deepening of railway express freight system reform, in addition to coal, military supplies and the special transportation outside, railway freight tariffs by government pricing will change into government guidance and limit management. This created the conditions for the research in express cargo freight. With the gradual improvement of the market economy in our country, our express freight transport market has undergone significant changes and be the explosive growth too. Various modes of cargo transport competing has become increasingly intense. So it's time to establish a price making and regulation mechanism in order to meet the fast growing freight market

The literature (Tang, B. 2014) study on the current development of railway freight transport organizations development status and problems, and proposed to optimize express freight organizations, freight market segments and establish freight prices mechanisms to adapt to market competition ; The literature (Hui, S. Q. 2014) have determined the index weights of fast freight pricing factors of weight, thus for the railway enterprises to provide decision-making basis and reference standard in railway freight tariff pricing process, and put forward to improve the railway express freight transport price proposal. The literature (Ma, S., Chen L.J. 2011, and Gao Z. Y. 2001) study on how to pricing for railway freight when various modes of freight transport compete, and establish programming model which taking the maximum benefit of transportation enterprises and the minimum generalized cost of freight transport, then solve that by price sensitivity analysis.

The existing mainly researched from the perspective of qualitative analysis of railway express freight transportation market oriented price making, and there is a lot of achievements and experience about railway passenger pricing. But it has not been able to establish the optimization model of express freight transportation market pricing from the quantitative point of view. So it's going to set a bi-level programming model which is established to optimize fast freight pricing to meet the needs of shippers and maximize the benefits of making the rail freight product at the same time.

1 Probability of cargo owners' selection

Under competitive conditions, there being multiple modes of transport of goods between the two places, fast cargo shippers will choose a transportation way, the generalized cost (not only refers to the tariff, including transportation duration, convenience, reliability and safety and other factors) of which is the smallest. Logit model which is based on random utility theories used to describe the probability of various cargo shippers select modes of transport. Suppose the $n(n = 1, 2, \cdots\cdots, N)$ kinds of goods mode of transport cost function f^n and the utility function V^n are:

$$f^n = w_1 t^n + w_2 u^n - w_3 c^n$$
$$V^n = -\theta f^n \quad (1)$$

Where: t^n、$u^n$and c^n——the n-th mode of transport cargo length, price and ease of transport; w_n——the right of mode of transport time, the price and convenience in the cost function of the weight; θ——conversion parameters between cost function and utility function.

Under the conditions of market economy，when choosing shortcuts cargo transport between the two places, the owners will always choose the way which have the largest utility (generalized minimum cost). Accordingly, the selection probabilities of owners can be derived for each mode of transport for goods:

$$P_n = \frac{expV^n}{\sum_n expV^n} = \frac{\exp(-\theta f^n)}{\sum_n \exp(-\theta f^n)} \quad (2)$$

If the total shortcut freight volume between the origin and destination is Q, then the freight volume of the various transport ways should meet Logit model, namely:

$$q^n = QP_n = Q \cdot \frac{expV^n}{\sum_n expV^n} = Q \cdot \frac{\exp(-\theta f^n)}{\sum_n \exp(-\theta f^n)} \quad (3)$$

2 The distribution mode of cargo flow based on the owners' selection probability

Under normal circumstances, the owner will always choose between two generalized least-cost and efficient transport of goods transport, but after most of owner selected a transport way, with the cargo volume increasing to a certain value, the time of transport will be longer, the quality of service and convenience will decrease, causing the increase of generalized cost, then some owners will give up the road transport and select other methods. Finally, between the different freight transport ways reach a state of stable equilibrium of freight distribution.

This equilibrium can be described as follows: in all the options of fast freight transport modes between the two places, various generalized cost of transportation that have been adopted by goods shippers are generally equal, and not greater than the owner has not been used in the fast freight travel mode.

Based on this theory, a mathematical programming model is used here to describe a variety of cargo transport methods between the two places under the conditions of coexistence, the cargo distribution model based on the selection probability of consignor is ($M1$):

$$\min Z(q) = \sum_{n} \int_{0}^{q_n} f(x)\, dx$$

$$\text{s.t.} \ \sum_n q^n = Q, \ n \in N \qquad (4)$$

This function f(x) means the generalized cost function of cargo transport modes between the two places .And we use the negative utility to express the generalized cost of cargo transport modes. The utility value includes the random utility value and the determined utility value (V^n), so the generalized cost function can use a logarithmic form:

$$f(q^n) = \frac{1}{U} ln q^n - V^n \qquad (5)$$

Also need to prove the equivalence and the uniqueness of solution between the model ($M1$) and the user equilibrium condition. The Lagrange function of the model is:

$$L(q_n, \ \mu) = Z(q_n) + \mu(Q - \sum_{n \in N} q_n) \qquad (6)$$

And the original model's (M1) first-order condition is equivalent to the Lagrange function $L(q_n, \mu)$ on the conditions of minimal, i.e.

$$\frac{\partial L}{\partial q_n} = -\frac{1}{U} ln q_n + V_n - \mu = 0$$

According to the constraint condition is:

$$q_n = \frac{\exp\{U(\mu+V_n\}}{\sum_m \exp\{U(\mu+V_n\}} \cdot \mathrm{Q} = \frac{\exp\,(UV_n)}{\sum_m \exp\,(UV_n)} \cdot \mathrm{Q},\ \ \mathrm{m} \in \mathrm{M} \qquad (7)$$

So, the solution of the model (M1) satisfies the Logit separation function. So the proof of equivalence is finished. In addition, the objective function and the constraint set is convex, so this model is a convex programming problem, there will be a unique solution.

3 The bi-level programming model based on the benefit of transportation enterprises

Model (M1) describes the problem about the cargo traffic distribution between the different ways of express freight transportation, but that only considered the cargo owners. On that basis, we constructed a bi-level programming to reach a predetermined target and seek the optimal freight prices of railway express freight transportation. In this paper, we assume that the target is the largest freight income of the railway express freight transportation enterprises.

Here, a bi-level programming model is constructed as follows (M2) to describe the freight price optimization problems between the different cargo transport modes.

(M2) $\quad (\mathbf{U})\ \max F_1 = q^1 u^1 \mathrm{L}_{ij}$

$$s.t.\ \ u^{1(\min)} \le u^1 \le u^{1(\max)}$$

Type q^n from the lower model (flow assignment model that front):

$$(\mathbf{L})\ \min Z(q) = \sum_n \int_0^{\mathrm{q}^n} f(x)\, dx$$

$$\mathrm{s.t.} \sum_n q^n = Q,\ \ n \in N$$

$$\mathrm{q}^n \ge 0,\ \ n \in N$$

Note that this is non-convex bilayer programming problem, it is difficult to get a global model of the optimal solution, but it can get better solutions, in order to make the calculation simple, this paper uses heuristic algorithm for solving bilayer programming.

4 The algorithm steps of the bi level programming model about price's optimization

In solving the bi level programming model, the key problem is to find the response function of q^n which contacts the upper and lower of the model .Here we through the assumption of the initial cargo transport price values:$u^{n(0)}$, and get the volume of freight transport $q^n(u^{n(0)})$ by solving the lower model, finally conclude the derivative relations between cargo flow and freight price about the n's transport ,thus the reaction function can be linear approximation to:

$$q^n(u^n) = q^n\left(u^{n(0)}\right) + \frac{\partial q^n}{\partial u^n}(u^n - u^{n(0)}) \tag{8}$$

Through this type into the upper model, converting it into a linear optimization problem is to get the optimal solution of the upper model with traditional optimization methods .Once again taking the optimal solution into the lower model ,we get a new cargo allocation scheme .Repeating the above steps until convergence in the bi level programming model ,then we get a optimal solution.

5 Case Study

This numerical example is given to show the application of railway express freight price optimization model and algorithm in multi model transportation environment. When several different cargo transport modes exist in A and B under the competition, how to through the quantitative analysis of reasonable of China Railway Express freight transport price formulation in order to make the railway freight transport efficiency at the same time the goods transportation more bearing.

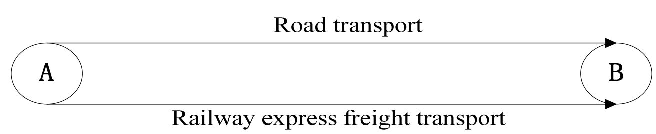

Figure 1. Analysis of examples

There are two kinds of mode of transportation mainly existing in the express freight market with high added value from A to B; here is the railway and highway transportation. Through the front analysis we know, different modes of transport the generalized transport cost function using the following exponential form:

$$f(q^n) = a(q^n)^b - V^n, n = 1,2$$

In the formula, V^n represents the utility value of the cargo transport mode determined .Here a and b respectively values 3 and 0.4. At the front has been the utility function of different modes of transport can be described by the formula (1) to be said:

$$V^n = -\alpha_1 t^n - \alpha_2 u^n + \alpha_3 c^n, n = 1,2$$

Assuming that in the operation process of the freight transport market, the transportation time of railway and highway, convenient and safety remains unchanged, and the volume of high value-added fast freight between A and B is known as 25000 tons. Here the railway freight unit price for (Yuan / ton - km), so the total freight range (17.3, 40) yuan / ton, respectively in table 1-1:

Table 1. Parameters of mode of transport

Cargo transport mode	Transportation cost（YUAN）	Transportation time/h	α_1	α_2	α_3	c^n	L_{ij}/km
Railway	$u^n \cdot L_{ij}$	1.7	3.00	3.75	2.00	6.053	340
Highway	30	1.5	3.00	3.75	2.00	6.053	---

(1) Initializing. Set the initial price between A to B of railway express freight transportation values of $u^{1(0)} \cdot L$ for 20 yuan, and set i to be 0;

(2) In all modes of transport, the freight, time and convenience as established under the premise, substituting it into the lower cargo traffic assignment model, get the cargo traffic in the equilibrium condition of Railway Express Freight Transport bearing: $q^{1(0)} = 14922.0312$;

(3) Draw the derivative relations between cargo traffic and Cargo transport prices under the multi model transport conditions between A and B.$q^1 = 23888.7792 - 448.3374 \cdot u^1$;

(4) Take the reaction function into the target function of the upper model, and solve the upper programming problem: $y^{1(0)} = 26.934$yuan；

(5) Get the iteration step with one-dimensional search method. $\alpha^{(0)} = 0.9605$; Updated, and get a new railway freight transport price $u^{1(1)} \cdot L = 26.6604$yuan;

(6) The convergence judgment. Assuming the iterative precision ($\delta = 0.01$), to determine the existence of$\left(u^{1(1)} - u^{1(0)}\right) \cdot L \leq \delta$. If not, makes the$i = i + 1$, and go to the second step to continue operation.

Though the initial prices of the freight transport are different, finally get the optimal railway express freight transport price and cargo traffic distribution scheme: optimal transport prices is 26.66yuan, cargo traffic by rail transport is 11952.73ton, and railway freight transport income 318549.78 yuan.

The calculation results show that, though the initial railway freight different the final optimal solution is approximate. And this optimal solution can effectively guarantee the railway express freight benefit, also can get higher cargo sharing rate is 47.808%.

6 Conclusion

This article has taken the interests of the two aspects of cargo owner and freight transportation enterprise in consideration, and gives a bi level programming model to describe how to formulate a reasonable railway express freight price when various cargo transport modes between the two places to compete. In this model, we not only consider the security of cargo owners' minimum generalized freight cost, but also consider the railway express freight department can make to achieve greater economic benefits in the express freight transportation market.

The results show that: the selection probability of the cargo transport modes that the owners made is sensitive to the generalized transport cost. In the range of railway express freight transportation price reasonable, through the change of cargo transport price can adjust the cargo traffic distribution structure between A and B. So that the railway express transportation can be effectively adopt to the changes of the freight market. It can also enhance their market competitiveness and ensure a certain profit.

Characteristics of Resident Trips and Countermeasures of Transport Development in Nanchang, China

Yulong Chen[1] and Weixiong Zha[2]

[1]Institute of Transportation and Economics, Humanities and Social Sciences Research Base of Jiangxi Province, East China Jiaotong University, Nanchang 330013. E-mail: chenyulong81009@126.com
[2]Institute of Transportation and Economics, Humanities and Social Sciences Research Base of Jiangxi Province, East China Jiaotong University, Nanchang 330013. E-mail: 1033723954@qq.com

Abstract: Based on the analysis about the indexes of trip time, trip distance and trip times, trips mode, trip purpose with the survey data of Nanchang city and other cities in China, the patterns and characteristics and causes of resident travels are summarized in this paper. The transport development policies are also suggested based on the resident travel characteristics such as development trend.
Keywords: City residents; Trip characteristics; Analysis and comparison; Transportation development policies; Nanchang city.

1 Introduction

With the acceleration of urbanization, the urban residents expand their trip areas; extend the trip time, and also the trip activities getting more and more diversified and complicated. In recent years, the rapid socio-economic development in Nanchang city and building with each passing day, the urban population increasing, all above resulting in urban traffic contradiction is sharpened. As of 2010, the resident population of Nanchang is 5.043 million, the quantity of automobile achieved 0.57million.

2 Analysis on the resident trip characteristics

2.1 Number of trips

The number of trips is residents' daily travel times, which reflects the residents who participate in the activities for the demand for travel in their daily life. The per capita number of travel is the ratio of total trips throughout the day and the total number of residents surveyed, it is an important indicator used to measure the status of urban trips. Per capita travel times data of Nanchang city and part of other domestic cities as shown in table 1.

Generally speaking, the bigger the scale of city, the lower of the average trip times. Nanchang residents average trip times in line with the stage of development characteristics, along with the rapid economic and social development in recent years of Nanchang, residents' trip demand shows a significant growth (Luo, P. C., 2002).

Tab.1 Per capita trip times of partial cities' residents

Name of city	Per capita trip	Survey year
Nanchang	2.61	2012
	2.59	2010
Beijing	2.64	—
Shanghai	1.79	1986
Guangzhou	2.55	2003
Jinan	1.68	1988
Wuhan	1.80	—
Qingdao	1.97	1993
Chengdu	2.16	1987
	2.43	2000
Changsha	2.33	—
Shenzhen	2.41	2003
Hefei	2.75	2007
Nanjing	2.75	2010

2.2 Trip purpose

Resident trip purpose structure usually represents the distribution of the trip purpose The time and mode of travel to different purposes tend to be specific. Therefore, the purpose of the trip can be used to infer the distribution of urban trip demand patterns and behavior patterns. Structure diagram of each trip purpose of different scale city is shown in figure 1.

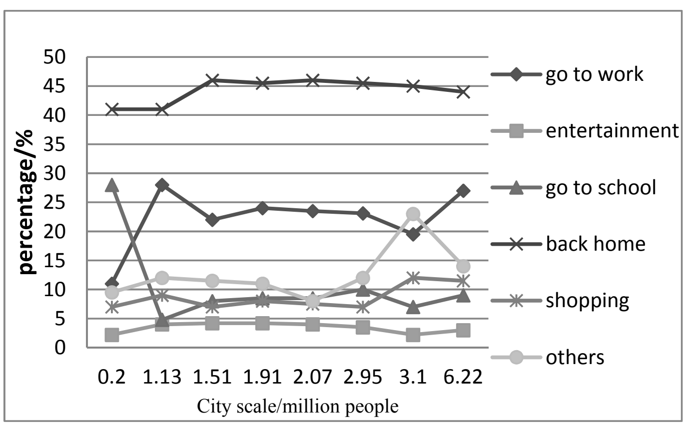

Fig.1 Structure diagram of each trip purpose of different scale city

Investigation data shows that, work, school and other commuter travel is still the main trip activities of residents in Nanchang, whose proportion is about 34.4%. In addition, for the purpose of life shopping trip accounts for 8.08% of the total number, agriculture as the main purpose of travel proportion about 1.41%. Different trip purposes structure map as shown in figure 2.

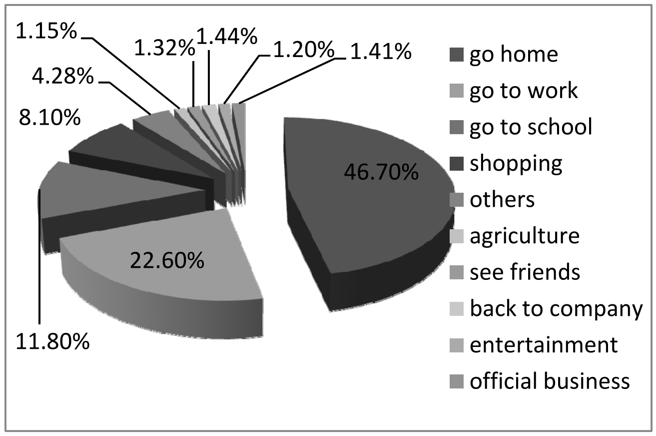

Fig.2 Structure diagram of trip purpose of Nanchang in 2012(total methods)

2.3 Trip time distribution

By the end of 2012, Nanchang civilian vehicle ownership was 0.57 million, 43400 more than last year (excluding scrap vehicles), the annual rate of 8.24%. Resident trip quantity distribution in different time period objectively reflects the pace of life in urban areas and the distribution of traffic demand in time, it is an important reference to analyze and solve the problem of peak hour traffic (Ou, Z., 2012).

Survey data show that residents travel show "twin peaks" (Pendyala, R. M., 2004) in the day time distribution, the morning rush hour ratio is 14.9% higher than 14.65% in 2002. Resident trip at noon also has two small peaks, time from 11:00 to 12:00 and 13:00 to 14:00 respectively and corresponding proportion is 7.47% and 6.81%. Figure 3 below is the residents travel time distribution map of Nanchang (Statistic Bureau of Jiangxi, 2008).

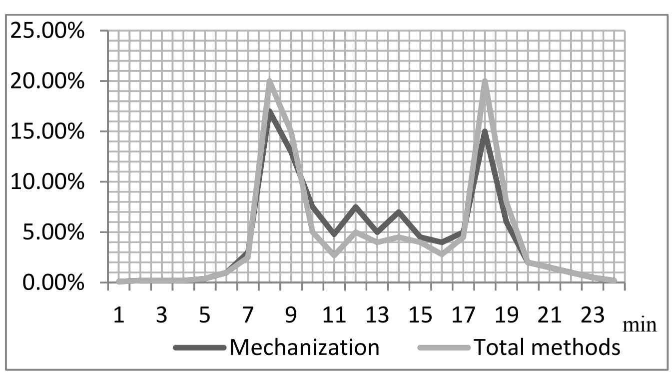

Fig.3. Resident travel time distribution map

2.4 Trip time cost

Urban resident one-way journey time from the starting point to the destination point is resident trip time, the average trip time is an important indicator of measuring a city the overall layout and travel range of rationality and efficiency of traffic (Yang,T., 2008). Traffic mode of its own characteristics, such as direct, flexibility, speed and path, directly determines the size of trip time. It can be seen from the statistical data that, the larger the city, the different purposes of resident trip time consuming smaller. As shown in Figure 4 and Figure 5.

Nanchang resident average trip time is about 25.3 minutes /time, compared with other city, average trip time less than Changsha, Wuhan, Hefei，higher than Shenzhen, as show in figure6(Zhou, Z. Y.,2008). Trip time of Nanchang city residents mainly focus on the short distance trip which usually takes 6-15 minutes or 16-30 minutes.

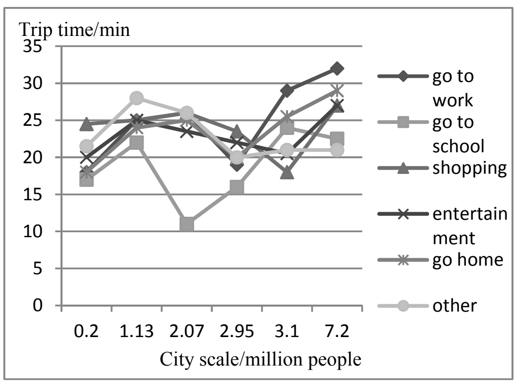

Fig.4 Residents travel time-consuming analysis diagram of different travel destinations

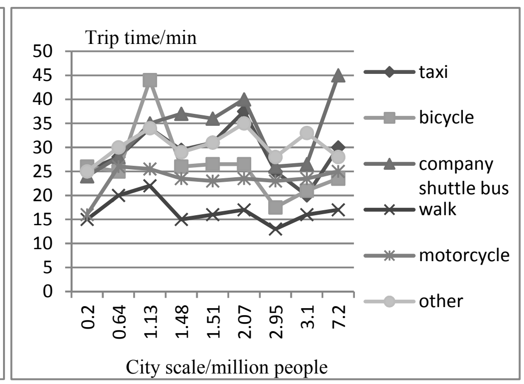

Fig.5 Residents travel time-consuming analysis diagram of different way to travel

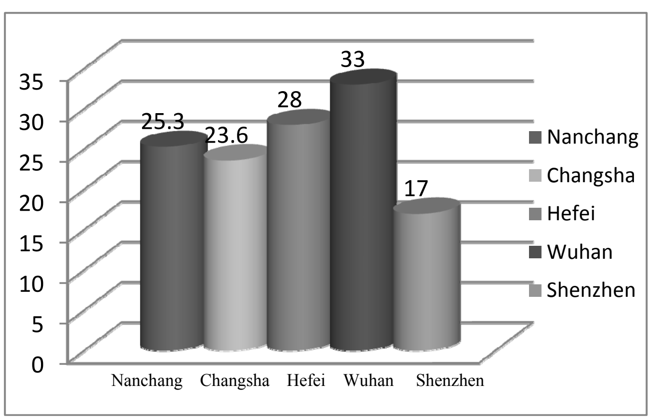

Fig.6 Nanchang city compared with the average travel time of other cities

2.5 Trip Mode Structure

Trip mode structure，generally refers to a collection of proportion used in a variety of means of transport which urban residents use, is an important symbol to reflect the development level of urban traffic(Deng, M. Y.,2000). Resident trip mode in general can be divided into public transport, bicycle, walking, motorcycles, taxis, cars and other units.

Nanchang resident trip motorization degree was 30.19%, which accounted for 7.5% of the motorcycle travel, car travel accounted for 6.26%, buses accounted for 13.8%; non motorized travel accounted for 57.44%, walking and bicycle accounted for 45.9% and 11.54%. Figure 7 below is the various transport modes sharing ratio diagram of Nanchang city residents.

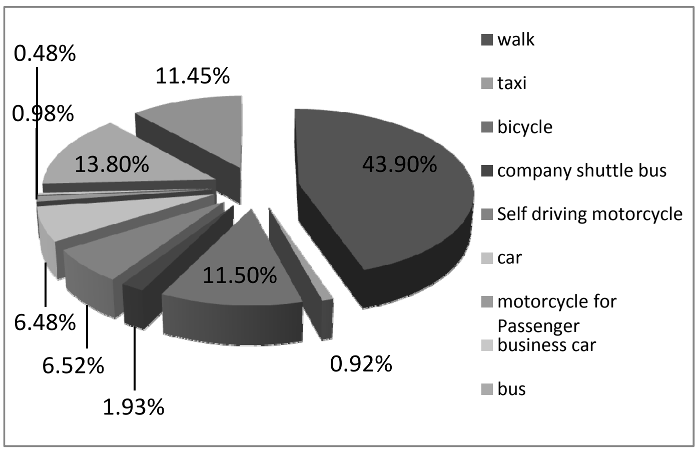

Fig.7 Structure diagram of residents travel mode

3 Analysis of the Main Reasons for the Changes of Resident Trip

(1) City infrastructure construction accelerated and people's trip environment improved. Traffic construction, focusing on the backbone road, transport infrastructure investment continues to a higher level. City infrastructure investment reached 26.94 billion yuan, the total road length up to 1581.57 km, a year-on-year increase of 192.76 km, city road, highway, transportation and other infrastructure scale has been effectively extended, the level of traffic supply further improved. Road construction focuses on the backbone road such as Chaoyang Bridge, Luoyang road tunnel, Jiuzhou elevated, Nanchang bridge overpass etc, at the same time, accelerate the construction of Nanchang West Railway Station, Longtou Gang port and city slow traffic project.

(2) The rapid development of public transport industry creates a good space for citizens to trip. 2012 year the relevant departments comprehensive launched a rail transit network update, urban transportation system planning, Gangkou Avenue project planning, traffic improvement and planning of surrounding Hongcheng big

market etc.

(3) The development of motor vehicle. Especially individual passenger car develop fast, traffic demand growth remains strong. 2012 Nanchang motor vehicle ownership continues to maintain rapid growth, by the end of 2012 motor vehicle ownership reached 0.526 million units, 43400 higher than the previous year, the average growth volume of car is 130 /day. Unceasing enhancement of Urbanization and motorization level, and the rapid development of economy, objectively stimulated the growth of traffic demand.

4 Traffic Development Countermeasure and Suggestion

Through analysis of the present situation of the trip characteristics of residents of Nanchang city and the future development trend, the next few years to improve the urban residents of traffic environment, guide and promote the formation of scientific and rational resident trip mode, the following three main countermeasures and measures need to taken, they are planning, infrastructure construction and management. Details are blow.

(1) To further implement the "Nanchang overall urban planning" (2001 - 2020), strictly control the total increment of center of urban construction, speed up the constructions of metro.

(2) Promoting the construction of urban road network in particular center city road microcirculation system construction, improve the density of roads network. To optimize the existing mode of transit network, continue to add new bus lines in the main passenger corridor and make the bus lines connected

(3)According to the domestic and foreign transportation demand management experience, combined with the traffic characteristics of Nanchang City, applying short-term and long-term combination principle to implement and improve traffic limit line measures. Giver the disordered condition of residents, non motor vehicles, electric vehicles and other slow traffic crossing the intersection, it is necessary to carry out long-term special work

Acknowledgement

I am most indebted to my teacher ZHA Weixiong, who has spent much of her precious time in offering valuable advice and guidance in my writing, and whose intellectual insights have contributed greatly to the completion of this paper. I also want to give my thanks to the experts of traffic whose views deeply inspired me.

Abstract: Based on the characteristics of small and medium-sized cities, this paper establishes a coordination degree evaluation index system of the public transit system and the urban form. The coordination degree is obtained with the values of the sequential variables from the principal component analysis, by using the coordination degree calculation model. Sample data was obtained from different years of Danyang, Suzhou and Tongling. By comparing the analysis of the coordination degrees of different years in different cities, the number of bus routes, coverage percentage of the public transport station, downtown area and population as well as the road mileage was found as the main influencing factors of the coordination degree of the public transit system and the urban form of small and medium-sized cities.

Keywords: Small and medium-sized cities; Public transit system; Urban form; The evaluation index system; Coordination degree.

1 Introduction

The suitable public transportation mode for different forms of urban development is also different. With the accelerating process of urbanization process in china, the synergetic analysis of public transit system and urban form for small and medium-sized cities is very necessary. This paper takes public transportation development and urban form of the small and medium-sized cities as researching object, selects representative indicators to build the evaluation index system, analysis the mutual relationship of the two systems, estimates their coordination degrees. Some recommendations are given according to the results to guide the coordinated development of public transport and urban form.

2 Coordination degree evaluation index system

The evaluation index system should be able to measure changes in different periods of development level of a city, and can evaluate differences in the levels of different cities during the same period.

2.1 The evaluation index system of urban form

Unlike the multi-centered character of most metropolitan, small and medium-sized cities are mostly monocentric, and the land-use characteristics identifies to be determinants of transit demand were the size of downtown. With the continuous development of our country and the acceleration of urbanization and economy, the rapid development of industrial needs more labor and the countryside surplus labor force gradually flocked to the cities, the urban population has been increasing, leading to the expand of the scale of urban land and the development of urban roads and more traffic demand. According to all this characteristics, the evaluation indexes are chosen and shown in the following table.

Table 1.The evaluation index system of urban form

Objective	Index	
Urban form development level index	c_1-city area(km^2)	c_2-downtown area(km^2)
	c_3-center population(Million)	c_4-city population(Million)
	c_5-GDP(billion)	c_6-the proportion of the second industry GDP
	c_7-road mileage(km)	

2.2 The evaluation index system of public transport system

Compared with some metropolitan, the development of public transit system in small and medium-sized city is relatively slow, and has its own characteristics. (1) The public transit network layout is unreasonable, bus lines tend to focus on a few main streets of the city center, and the non-linear rate coefficient is higher due to the development status of small and medium-sized cities. (2) The service of public transit is circumscribed and inconvenient compared with electric bicycles. (3) The input number of bus and per capita is less. (4) Lacking of bus terminals, and basically priority is given to roadside parking. (5) Public transit trip contribution rate is low, and the trip time consume is longer. According to all this characteristics, the evaluation indexes are chosen and shown in the following table.

Table 2. The evaluation index system of public transport system

Objective	Index	
The public transport system development level index	x_1-urban bus lines	x_2- urban and rural bus lines
	x_3- bus lines total mileage(km)	x_4-public transit network density (km/km^2）
	x_5-repetition coefficient of transit network	x_6-coverage percentage of the public transport station(300m)
	x_7-coverage percentage of the public transport station(500m)	x_8-million people have bus number
	x_9-parking area per bus(m^2)	x_{10}-day bus passenger flow volume
	x_{11}-public transit trip contribution rate (%)	x_{12}- bus trip time consume(min)

3 Coordination degree evaluation model

Referencing the capacity coupling coefficient model in physics, the coupling degree model of urban form and transit system is as follows:

$$U = \sqrt{\frac{F(x)G(y)}{\left[F(x)+G(y)\right]^2}} \tag{1}$$

With $\mathrm{F}(\mathrm{x}) = \sum_{i=1}^{n} a_i x_i^{'}$, $\mathrm{G}(\mathrm{y}) = \sum_{j=1}^{m} b_j y_j^{'}$

$F(x)$ is the evaluation function of public transit system, $G(y)$ is the evaluation function of urban form system. The coefficient a_i and b_j are the values of the sequential variables obtained from the principal component analysis using the sample data. The scope of the coupling degree U is $[0,1]$. Coordination degree model based on the coupling degree model can better evaluation the interaction of two systems, its formula is:

$$\Phi = \sqrt{U * T} \tag{2}$$

With $T = \alpha F(x) + \beta G(y)$, α and β are the undetermined coefficient.

Through the above steps, the coordination degree of small and medium-sized city public transportation and urban form can be obtained. Then contrasting table 3, comprehensive evaluation is reached.

Table 3. Hierarchy of coordination degree

Coordination degree	0-0.1	0.1-0.2	0.2-0.3	0.3-0.4	0.4-0.5
evaluation	Extreme imbalance	serious imbalance	Severe imbalance	Mild imbalance	Closed to imbalance
Coordination degree	0.5-0.6	0.6-0.7	0.7-0.8	0.8-0.9	0.9-1
evaluation	Reluctant coordination	Primary coordination	Intermediate coordination	Good coordination	Quality coordination

4 sample data analysis

Danyang, Suzhou, Tongling, which are Chinese typical small and medium-sized cities, are currently in the accelerating period of urbanization. This article selects the relevant data of Danyang in 2006, 2010, 2014, Suzhou in 2006, 2013, and Tongling in 2011, 2012 as sample data, the coordination degree between the urban form and public transit system are computed and analyzed by the coordination degree model constructed before. The sample data as shown in table 4:

Table 4. The sample data

index	Danyang 2006	Danyang 2010	Danyang 2014	Suzhou 2006	Suzhou 2013	Tongling 2011	Tongling 2012
x_1	3	6	17	18	15	23	27

c_7	1989	2084	2140	10789	12612	1109	1258

4.1 Calculation steps and calibration of model parameters

(1) In order to eliminate the influence of different dimensions, the sample data is standardized into [0-1].

(2) Using SPSS software to do the principal components analysis. Taking public transit system as an example, the result is as following table:

Table 5. Eigenvalues of public transit system

component	Initial Eigenvalues			Extraction of sum of squares loaded		
	eigenvalue	variance	cumulative	eigenvalue	variance	cumulative
1	6.38730	53.2275	53.22751	6.38730	53.2275	53.22751
2	2.76350	23.0292	76.25674	2.76350	23.0292	76.25674
3	1.75361	14.6134	90.87016	1.75361	14.6132	90.87016
4	0.81905	6.82543	97.69559			
5	0.23314	1.94287	99.63846			
6	0.04338	0.36153	100			

Table 5 is the eigenvalues of public transit system output of the SPSS software. As can be seen from the table: the variance contribution of the first principal component ratio is 53.23%, the accumulative variance contribution rate of the first three principal components reached 90.87%, so the three main components are appropriate.

(3) Then according to the sample eigenvector table of correlation matrix output of the SPSS, the first principal component of public transit system is obtained:

$$F_1(\mathrm{x}) = 0.989x_1 + 0.306x_2 + 0.925x_3 + 0.518x_4 + 0.790x_5 + 0.615x_6 + 0.775x_7 + 0.762x_8 + 0.573x_9 + 0.862x_{10} + 0.834x_{11} + 0.550x_{12}$$

The second principal component is:

$$F_2(\mathrm{x}) = -0.086x_1 - 0.173x_2 - 0.201x_3 + 0.731x_4 - 0.151x_5 + 0.748x_6 + 0.598x_7 - 0.501x_8 - 0.021x_9 - 0.445x_{10} - 0.444x_{11} + 0.480x_{12}$$

The third principal component is:

$$F_3(\mathrm{x}) = 0.019x_1 + 0.892x_2 - 0.193x_3 - 0.283x_4 - 0.498x_5 + 0.132x_6 - 0.0739x_7 - 0.384x_8 + 0.811x_9 + 0.191x_{10} + 0.020x_{11} + 0.157x_{12}$$

According to the variance contribution of each principal component, the evaluation function of public transportation development level of small and medium-sized city is:

$$\mathrm{F}(\mathrm{x}) = 0.511x_1 + 0.282x_2 + 0.424x_3 + 0.379x_4 + 0.309x_5 + 0.505x_6 + 0.526x_7 + 0.242x_8 + 0.451x_9 + 0.406x_{10} + 0.362x_{11} + 0.420x_{12} \quad (3)$$

Similarly, the evaluation function can be obtained for the urban form:

$$\mathrm{G}(\mathrm{c}) = 0.585c_1 + 0.575c_2 + 0.607c_3 + 0.582c_4 + 0.218c_5 - 0.364c_6 + 0.584c_7 \quad (4)$$

(4) Taking the standardized data into the evaluation function just got above of both systems (formula 3, 4), the quantitative evaluation results would be calculated, as following table:

Table 6. Quantitative evaluation results

years / index	DY 2006	DY 2010	DY 2014	SZ 2006	SZ 2013	TL 2011	TL 2012
Public transit system	0.061	0.989	2.520	3.121	2.659	3.235	3.359
Urban form	0.160	0.227	0.355	1.999	2.998	0.315	0.445
DY represents Danyang, SZ represents Suzhou, TL represents Tongling							

(5) To use the coordination degree model, the value of α and β should be determined firstly. In practical application, keeping the values range of T $[0,1]$ to ensure the coordination degree is between $[0,1]$. With this qualification, the inequalities are as followed:

$$\begin{cases} 0 < 0.061*\alpha + 0.160*\beta < 1 \\ 0 < 0.989*\alpha + 0.027*\beta < 1 \\ 0 < 2.520*\alpha + 0.355*\beta < 1 \\ 0 < 3.121*\alpha + 1.999*\beta < 1 \\ 0 < 2.659*\alpha + 2.998*\beta < 1 \\ 0 < 3.235*\alpha + 0.315*\beta < 1 \\ 0 < 3.359*\alpha + 0.445*\beta < 1 \end{cases} \quad (5)$$

To obtain the optimal solution, namely the $\Phi = \sqrt{U * T}$ has the maximum value, write a program using MATLAB software, and the result was reached- $\alpha = 0.2918$, $\beta = 0.0447$, $T = 0.2918F(x) + 0.0447G(y)$.

(6) Lastly, coordination degrees were calculated according to the formula (2), compared to table 3, the evaluation of coordination degrees were obtained, as in the following table:

Table 7. Coordination degrees

	DY2006	DY2010	DY2014
Φ	0.11	0.34	0.50
evaluation	Extreme imbalance	Mild imbalance	Reluctant coordination
SZ2006	SZ2013	TL2011	TL2012
0.70	0.67	0.52	0.57
Primary coordination	Primary coordination	Reluctant coordination	Reluctant coordination

4.2 results analysis

By the calculated results and the contradistinctive analysis between different years and different cities, it is found that:

The largest weight influences index accounted for Small and medium-sized city public transportation system is urban bus lines, the second is coverage percentage of the public transport station. Urban bus lines index is the most straightforward indicator for public transit system, and the coverage percentage of the public transport station index is the most direct indicator for the public transport system and city form. In figure 1, the two indexes and the quantitative evaluation results of both two systems and the coordination degree have similar trends. It can be inferred that reasonable increase of bus lines and the reasonable layout of bus stops to increase site coverage can effectively improve the coordination degree of two systems in small and medium-sized cites.

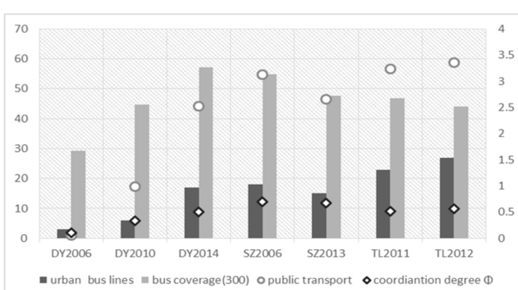

Figure 1. Results contrast

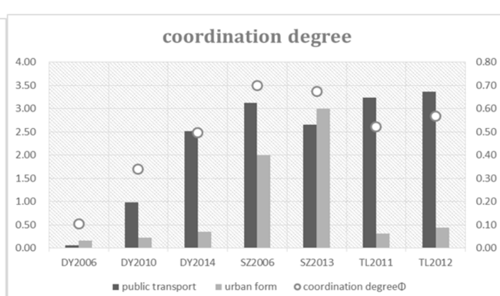

Figure 2. Coordination degree contrast

From table 7 and figure 2, it is found that, on the whole, small and medium-sized cities in our country, as well as the public transport system is constantly moving forward, however the two development is not in coordination. In this situation, consummating public transit system and setting up the integration of urban and rural public transportation system are recommended to guide city development from single-center to multi-center development model.

5 Conclusions

This paper establishes a calculating method and model of coordination degree between urban form and public transit system. The sample data analysis proves the model is effective for small and medium-sized cities. The number of bus routes, coverage percentage of the public transport station, downtown area and population as well as the road mileage was found as the main influencing factors of the coordination degree of the public transit system and the urban form of small and medium-sized cities. From these aspects, improvement strategies can be given.

6 Recommendations for Future Research

The coordinating development of public transit and urban form is important, the synergetic analysis of public transit system and urban form for small and medium-sized cities means a lot. However, due to the limited sample data, this paper has its limitations on representativeness. In future research, more indexes and more sample data may be chosen.

Abstract: Charging the road users basing on vehicle miles of travel (VMT) is seen by many analysts and policy makers as a potentially viable way to generate revenues while maintaining the idea that users should pay for the system. In 2009，American issued the National Cooperative Highway Research Program (NCHRP), aiming at exploring proposals that might be implemented more quickly, possibly enabling nationwide adoption of direct usage-based charges by 2015. After finishing the oil taxes reform in 2009, China also entered the Era of Fuel Tax. With technological progress and the reform accelerating, China will inevitably encounter many problems in the fuel taxes, which are used in highway financing. This paper primarily introduces China financing model, and expects we can learn from American experiences to improve China's highway financing model.
Keywords: VMT fee; Fuel taxes; Highway financing.

1 Introduction

Chinese oil taxes reform was implemented beginning on January 1, 2009, it raised unit tax amount of refined oil consumption tax. This reform can have a dramatic effect on the structure of highway financing in China. Since then, China has already entered the Era of Fuel Tax. Meanwhile, according to the requirements of the American Association of State Highway and Transportation Officials (AASHTO), also as part of the National Cooperative Highway Research Program (NCHRP) Project 20-24(69),the government planned to charge the road users directly based on vehicle miles of travel (VMT) --the United States is beginning the Era of VMT Charging.

At present, China is in the early stages of the Era of Fuel Tax, there will be a long way to enter the Era of VMT Charging. America's advanced technologies and the development concepts, in the process of implementation of fuel tax, wiill have significance for China. China may learn from its experience and avoid the same difficulties and bottlenecks in its development. More importantly, the relevant research associated with VMT can constantly improving and refining china's highway financing means.

2 VMT charging mode in the United States

In the past century, Vehicle fuel consumption tax had been the main mechanism of generating revenue in the United States federal and state. Although it had many remarkable advantages, but utility they play was limited by the structural and political factors over the coming decades. This led to an idea arising through highway service system instead of the fuel tax. The idea implements through modern traffic electronic toll collection technology, and bases on vehicle mils of travel (VMT). VMT charge can overcome challenge about income from fuel charge, but also provides a solution to implement other policy goals.

2.1 The decline in fuel tax

In the United States federal and many state, vehicle fuel taxes are levied on a per gallon. The unit tax should be raise on a regular basis so as to reduce the impact of inflation and burn up lower. Furthermore, as an anti-tax thought spread in public, U.S. officials have become more cautious on the work, which is unwelcome in politics. At the same time, the frequency and magnitude of the recent raising price has been not enough to maintain comparable purchasing power according to the real income per mile.

2.2 Attraction of VMT charges

VMT charge is based on miles of travel rather than fuel consumption quantity or type, such a system will eliminate the concerns of the fuel consumption lower or the new energy vehicles widely used. In addition, if the system can determine where the vehicle has travelled, the revenue stream from it will be able to accurately split into multiple administrative jurisdictions. Other potential benefits may include reducing traffic congestion, mitigating the adverse effects of pollutants on the health, and reducing the potential threat from climate change. For example, improving mileage charge price on the busy route can inhibit the traffic congestion, the same measurement for the larger polluting vehicles can effectively protect the environment.

2.3 fuel tax vs. VMT charges

Table 1 shows the trend of the growth percentage of VMT and fuel consumption since 1997. As reflected in the table, fuel consumption growth tends to decline gradually, and VMT is falling shortly, but there has been a rising trend. If the trend continues, as many people had expected, the effectiveness of the fuel tax to meet transportation financing will continue to decline in the coming days. It also suggests it is necessary to implement the VMT charge.

3 Cases Of VMT fees In the United States

According to the requirements of the American Association of State Highway and Transportation Officials(AASHTO), American introduced an implementation strategy report in 2009 that sources of funding for transport can be direct usage-based charges, the government plans to charge the road users directly based on vehicle miles of travel (VMT).

3.1 Type of VMT

(1) Press mileage charges. This kind of VMT charging model mainly involves light vehicles (such as car), it can also apply to the truck.

(2) Heavy long-distance truck toll. Similar to the first type in concept, the major

difference is that it only applies to charging for heavy goods vehicle and it takes different charging standards according to the different degree of road wear caused by different weight of the vehicles.

(3) Pay premiums and rental fees by mileage. Vehicle insurance and rental costs tend to be fixed during a fixed period (such as $ 1000 a year on premiums). The charge principle of paying premiums and rental fee by mileage is to calculate the cost on the basis of mileage, that is, less driving, less pay.

With regard to three types of VMT fees, that is, universal fees based-on mileage, heavy long-distance freight fees and paying insurance expenses and rental fees based-on mileage, lots of areas have successfully implemented and obtained good results in American.

Table 1. Growth percentage of VMT and fuel consumption

Years	VMT	Fuel consumption
1997	--	--
1998	3.0%	2.9%
1999	5.4%	6.5%
2000	7.6%	7.5%
2001	9.5%	7.2%
2002	11.9%	11.9%
2003	13.3%	13.4%
2004	16.1%	16.1%
2005	17.2%	16.5%
2006	18.1%	13.9%
2007	18.7%	14.6%
2008	16.5%	11.2%
2009	15.9%	9.4%
2010	16.2%	--

Source: American Highway Statistics 1997-2010

3.2 Universal Charging Based-on Mileage: Oregon Transportation Department pilot project

According to the state legislature's instructions, Oregon department of transportation planed and implemented mileage charge and a wide range of congestion charge study. During the period of 12 months, from 2006 to 2007, the pilot project involves 285 cars, 299 drivers, and two gas stations. The OBU is connected to the GPS receiver to detect whether the vehicles drive in these two areas, and odometer is used for the measuring of distance. Then mileage data is transmitted to the two gas stations by radio, thus, the gap between fuel tax the mileage fee is calculated. After the conventional fuel taxes has been paid, vehicle drivers are divided into two parts to test different pricing concept.

In a certain area, Some drivers need to pay the fixed costs 1.2 cents per mile. While the other drivers need to pay 10 cents per mile in the "traffic congestion areas" in rush hours, yet in other driving time it reduces to 0.43 cents per mile. The owners of vehicles don't need to pay the new fees at gas stations, but they will receive payment account document at the end of the research. In this study, both of the two groups will reduce their total VMT, and the technical effect is remarkable.

3.3 Heavy Long-distance Freight Fees: Austria administration project

Austria administration has implemented the freight charge project successfully in January, 2014, which is managed by Europpass company (subsidiary of the Italian highway). This project applies the mileage charge to the vehicles whose permitted loaded mass is more than 3.5 tons, charge grades depend on the varied weight class and the axle number. In order to participate in this project and avoid the inconvenience of artificial paid, each vehicle need to install the particular DSRC (dedicated short-range communication) vehicle-loaded device, which transmit data through different elevated stations set in the highway system. When the vehicle passes through one of the 420 benches distributed across the network, mileage charge is motivated. If the bench did not perceive a vehicle- loaded receiver, the vehicle will be marked with suspected fee evasion.

3.4 Paying Insurance Expenses Based-on Mileage: Massachusetts project

In April 2008, Massachusetts has introduced the vehicle insurance, with characteristics of bidding. Before that the rate of insurance fees was set by state itself. The insurance company provides discount for the owners of vehicle who drive few miles. For annual mileage between 0 and 5000 miles, there is a discount of 10 percent. However, if annual mileage is between 5000 and 7000 miles, the discount reduces to 5 percent. Their Mileage will be verified by the department of motor vehicle registration in Massachusetts.

4 Highway Financing in China

4.1 Highway Financing In China before 2009

Before the fuel tax reform, China implemented a kind of highway financing mode, which is loans to build and tolls to pay. Although this approach plays an important role in easing the lacking funds for construction and maintenance of china's highway, it also exists many problems.

Table 2 is the related data of china highway financing from 2004 to 2008. The national budget funds rose in 2008, other years are in decline, and each year at about 2%, this shows that the Chinese government in the highway financing support needs to be improved.

Domestic lending has always been an important means of financing, such high bank loans will lead to higher risk of financing, which is not a long-term solution to solve the problem of financing.

Utilization of foreign capital accounts for only around 1%, which shows it is unable to mostly rely on foreign investment in highway construction and maintenance.

Table 2. China's highway financing structure

Year	budgetary funds	Vehicle purchase tax	Domestic loans	foreign capital	Self-raised funds	Last year balance
2004	3.1%	11.0%	40.5%	1.3%	39.3%	4.8%
2005	2.4%	10.3%	38.2%	1.3%	43.1%	4.7%
2006	1.5%	9.0%	40.7%	0.9%	42.5%	5.4%
2007	1.4%	12.1%	38.0%	0.8%	43.8%	3.9%
2008	2.5%	11.8%	36.4%	1.0%	43.7%	4.6%

Source：2004-2008 Statistical bulletin on road and waterway industry transportation development

4.2 Highway Financing In China after 2009

After finishing the oil taxes reform, the traditional "loan to build roads, charge to repay loan" is in the role of decreasing in the ordinary highway financing system. The positive phenomenon brought by the fuel tax reform will be also gradually revealed.

Fuel taxes will be as the main source of funds of ordinary highway construction and maintenance, the reform leads to greatly reduce dependent on domestic lending and state investment, and gradually realize the virtuous cycle of investment and financing environment.

5 Revelation of VMT charging mode

China is at the beginning of the "era of fuel tax", there is still a long way to go to the "VMT charge era". According to the existing situation in china, when to implement VMT fee is still unknown. But along with the rapid development of economy and technology, it is possible to develop the fuel tax.

United States has the problems in the process of implementation of fuel tax, such as due to the effects of inflation, it is still suffering from the threat of loss of purchasing power with fuel tax rate gradually increase. Saving fuel cars and new energy vehicles make people use less fuel, china could also meet the same problems.

Therefore, China should draw lessons about development technology and the development idea in the process of implementation of fuel tax from United States. Meanwhile, it is necessary to prepare VMT records of relevant data and implement plan research in advance.

(1)Building research institute, which increasing devotion of manpower and material resources of VMT research to find out feasible solutions.

(2)Introducing foreign advanced technology and ideas, making some experiment for the foreign VMT measurement method with the domestic situation, recording the domestic vehicle VMT data.

(3)Making the vehicle-mounted device research effort. According to the region classification, planning and registering the existing vehicles.

(4)Increasing public awareness and education, which make the public aware of the meaning of VMT measurement in the long term.

Analysis for Deciding Intercity Rail Fares

Jiawei Chen; Canjun Lu; and Wei Wang

School of Transportation and Logistics, Southwest Jiaotong University, Chengdu 610031. E-mail: 729580673@qq.com

Abstract: With the deepening of concept of urban agglomerations and the gradual development of the China's urbanization, China's urban intercity railway is also planning to enter the big construction phase. And with the development of inter-city railway the contradictory between immature pricing theory and rapid formation of intercity railway network has also increasingly been prominent. Ticket revenue is the main source of income for intercity railway and the income is mainly determined by the price and number of passengers. What we want is the best price so the price is the only variable quantity in this paper. The number of passengers is determined by the share rate. Therefore, this paper introduce random utility theory to solve the intercity rail passenger share rate. Share rate is affected by these five factors: price, speed, convenience, comfort and safety. This paper will use AHP to solve weights in random utility. At last the intercity railway benefits will be represented by a function where the intercity rail fare rate is only variable quantity. When this function takes the maximum value we can obtain the best price.
Keywords: Intercity rail; Ticket; Pricing; Random utility theory; Maximum benefit.

1 Introduction

With the gradual development of urbanization in China and the concept of urban agglomeration will be accepted by more people especially from 2008.With four trillion RMB invested into infrastructure, the planning and construction of intercity rail is going to a new high level. Today, almost provinces have developed a large-scale inter-city rail network planning. Meanwhile almost every province has already started construction of intercity rail even completed. For example the intercity rail between Wuhan and Xianning and is completed and the intercity rail between Changsha, Zhuzhou and Xiangtan will be completed. For such an emerging model of transport which has huge investment in intercity rail and costs a lot in the latter. If the operator can not make their own sound competition policy to fight for promoting their share of the transport market, the intercity rail may not be able to succeed in competition with other modes of transport. Intercity rail is generally short-distance transport in urban agglomerations but the main transport in urban agglomerations is short-distance intercity bus in previously time. So Intercity bus will be set as the main competitor intercity railway in this article, thus analyzing how to develop intercity rail fares.

1.1 Literature survey

Chang Myong-Hun proposed a tariff computing model which is based on utility theory.However the specific function expression and parameters are different from practical so this model is rarely used in the real life. Leon and Harold analyze the impact of high-speed rail to other transport modes and change other factors into time scale.Then they analyze transportation choice mode in passenger corridor.Ye Pei used system dynamics optimization model for studying high-speed rail fares.Based on the principles of effectiveness in economic Wei Anqing used efficiency guideline of transport fare to analyze the baes fare in Chengdu-Chongqing high-speed rail.

Through literature analysis we can find out models are difficult and we should collect a lot of data.The innovation of thsi paper is not to obtain the maximun benefit but through the derivation of intercity bus benefit model to obtain the best fare.

2 Establish intercity rail efficiency model

Intercity rail benefits are mainly from turnover and turnover is determined by the number of people aboard and fares so we can establish intercity rail revenue model.

The main function:

$$Z_s = F^{AB} \times P_s \times (\overline{u_s} - \overline{C}_s) \times d_s{}^{AB} \qquad (1)$$

It is the objective function to be solved.Because in this function the only variable quantity is $\overline{u}_s$ so we can obtain the maximun value of $\overline{u}_s$ which is the best fare of the intercity rail through the derivation of formula (1).

Constraints:

$$Z_s \geq o \qquad (2)$$

Transportation revenue must not be negative.Because the transportation company does not lose money intentionally.

$$F^{AB} \times P_s \leq G_s \qquad (3)$$

The actual traffic does not exceed the maximum transport capacity.If the actual traffic exceed the maximum the transport company will be overload.It is dangerous for passengers.

$$\sum_{s=1}^{y} p_s = 1 \tag{4}$$

Each passenger is bound to select a given way to travel.In this paper there are only two ways which are bus and intercity rail.

z_s :The benefit of transporter s;

F^{AB} :The population of district A who want to go district B;

p_s :Share rate of transport s;

$\overline{u_s}$:Average fare rate of transport s which is the only unknown quantity;

$\overline{C_s}$:Cost per kilometer of transport s ;

d_s^{AB} :Distance of transport s;

G_s :Maximum transport capacity of the transports.

2.1 How to calculate p_s

In this article we use random utility to calculate p_s .

According to Logit model, we propose the concept of generalized income-' δ_s '.generalized income does not refer to a specific income but it is comprehensive benefits.In the generalized income function,we selected economy,fast,comfort, secure and convenience of these five factors to determine the p_s .The expression of δ_s is:

$$\delta_s = \frac{\theta_1 \times U_s + z_{fxs} \times \theta_2 + z_{fos} \times \theta_3 + z_{fls} \times \theta_4}{\varphi_f \times \theta_5} + \psi \tag{5}$$

ψ :Undetermined coefficients;

θ_i :Weight factors.

Then using utility theory immediately(Jiang Jinliang,2012)We can get the relationship between p_s and δ_s .

$$p_s = \frac{\exp(-0.01\delta_s)}{\sum_{f=1} \exp(-0.01\delta_s)} \tag{6}$$

Next we will quantify these five factors

(1)Economy.Generally speaking the lower fare the more likely passengers will chose this way to travel.

$$U_s = \overline{u_s} \times d_s \tag{7}$$

U_s :The price of transport s.

(2)Fast.People will chose the way to travel that costs less time.

$$z_{fxs} = \frac{d_s}{X_s} \times \overline{T_f} \tag{8}$$

z_{fxs} :Earnings of quickness of passenger;

X_s :Average speed of transport s;

$\overline{T_f}$:Value of unit time.

$$\overline{T_f} = \frac{GDP}{N_p \times N_t} \tag{9}$$

N_p :The total population of the country;

N_t :Working hours a year.

(3)Comfort.Comfort is a major factor that people should consider especially the higher income people.

$$z_{fos} = O_s(t) \times \overline{T_f} \tag{10}$$

$$O_s(t) = E / \left[1 + \alpha_s \times e^{\left(-\beta_s \times \frac{d_s}{X_s}\right)} \right] \tag{11}$$

z_{fos} :Earnings of comfort of passenger;

$O_s(t)$:Fatigue recovery time of passenger in travel;

E :Limit time required for recovery;

α_s , β_s :Undetermined coefficients.

According to existing research,E=15, α_s =59, β_s =0.29(YI Fujun,2009).

(4)Secure

From existing research about passenger transport safety, most scholars have tended to use ‘safe credibility’ to measure a transportation security.And the ‘safe credibility’ φ_f of intercity rail is 1(Pietro Zitoa, Giuseppe Salvoa, Luigi La Francaa,2011).

(5)Convenience.Ease of access to services is increasingly becoming an important factor when people consider how to travel.When there is no transfer between the transportation and the subway the transportation will attract many people.

$$z_{fls} = L_s \times \overline{T}_f \quad (12)$$

z_{fls} :Earings of convenience of passenger;

L_s :Time from the residential area to the station.

2.2 Factors weight analysis

Accoeding to the classification of passenger the factors affect passenger share rate of intercity may be simplified following factors:Fare, speed, comfort, safety and convenience.The research will focus on five factors.

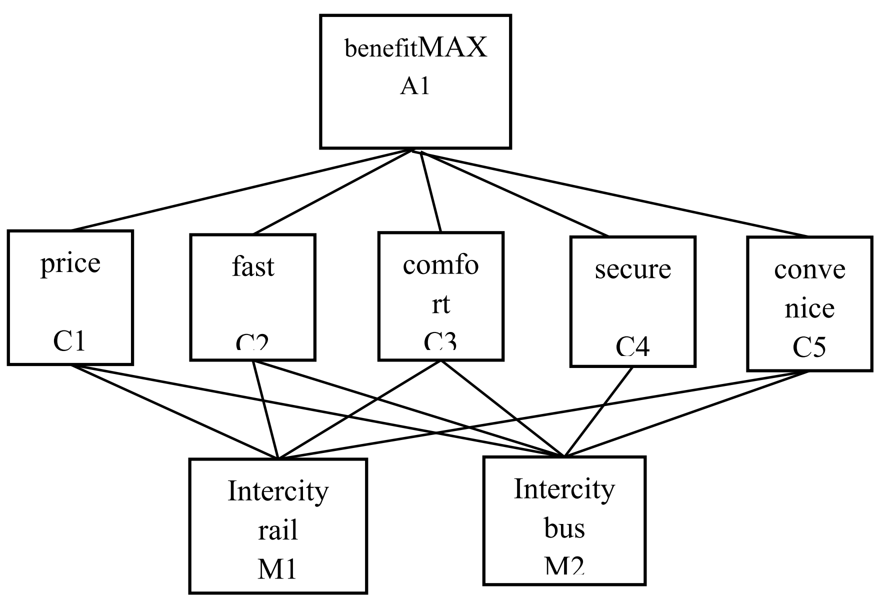

Figure 1.Analytical Hierarchy Figure

According to this multilayer structure,We can more clearly aware of the competition between the operators and passengers and relatonship between the factors and decisions.Based on this model many scholars have proposed the corresponding calculation approach to solute weight(Guo Chunjiang,2010)This article will use the AHP so that we can easily obtain accurate weights.

Table 1.The importance of the meaning of the scale(Nicole Adler,2001)

Significant scale	Meaning
1	Two factors are the same important
3	Former is slightly important than latter
5	Former is significantly important than latter
7	Former is strongly important than latter
9	Former is extremly important than latter
2,4,6,8	Indicating that the intermediate value of these judgments

According to the hierarchy chart,comparing these two factors based on the importance of scaling standard.As follows:

Table2.A-C judgment matrix

A	C1	C2	C3	C4	C5
C1	1	3	5	1/2	4
C2	1/3	1	3	1/3	5
C3	1/5	1/3	1	1/4	1/3
C4	2	3	4	1	5
C5	1/4	1/5	3	1/5	1

M2	1/2	1

Table6.C5-M judgment matrix

C1	M1	M2
M1	1	1/3
M2	3	1

Using mediation method to Calculate Weight Vectors.Specific formula is:

$$w_i = \frac{1}{n}\sum_{j=1}^{n}\frac{a_{ij}}{\sum_{k=1}^{n}a_{kl}} \tag{13}$$

$W_{A-C} = (0.2910, 0.1761, 0.0582, 0.3882, 0.0886)$;

$W_{C1-M} = (0.6667, 0.3333)$;

$W_{C2-M} = (0.2000, 0.8000)$;

$W_{C3-M} = (0.8333, 0.1667)$;

$W_{C4-M} = (0.6667, 0.3333)$;

$W_{C5-M} = (0.2500, 0.7500)$.

3 Examples

In this paper we use intercity rail between Chang,Zhuzhou,Xiangtan as the example to verificate our model.

3.1 Background

The rapid development of ChangSha,ZhunZhou,XiangTan transportation are incompatible with development of economic.Transport infrastructure still has some weak links.Cities are mainly connected with highway and the national road.The structure of intercity transportation is single and this single is not conducive to passenger to travel.So the three cities need the intercity rail.

3.2 Model Solution

Through reviewing the relevant literature we can determine the relevant parameters.

Table7.Parameter calibration

θ_i	d_s^{AB}	X_S	$\overline{T_f}$	L_s	E	α_s	β_s	ψ	$\overline{c_s}$
0.2910, 0.1761, 0.0582, 0.3882, 0.0886.	96km	160km/h	17.379yuan/h	0.5h	15h	59	0.29	1035.14	0.33

Derivating the main function(1)and we can see from the simplified expression the function has a maximun.Ordering derivative value to zero we can obtain $\overline{u_s} = 0.52$ .That is the best rail fare rate and we can obtain the best rail fare.

4 Conclusions

This paper describes the causes and the importance of optimizing intercity rail fares.The analysis shows that the share of passenger intercity rail rate is mainly affected by the fare, travel speed, transfer convenience,comfort and safety.So we introduce Logit mode and random utility theory and analytic hierarchy process to seek contribution rate.And using this model to build a revenue model for intercity railway.The innovation of thsi paper is not to obtain the maximun benefit but through the derivation of intercity bus benefit model to obtain the best fare.The first disadvantage of this article is that we only compare intercity rail and intercity buses.A second drawback of this paper is that when we use random utility model to obtain contribution rate we calculate the weight factor analytic hierarchy process.So the results will not be objective enough.

Abstract: This study focuses on recognizing the travel modes and activity types in personal travel trajectory. Firstly the paper proposes a concept of trip-activity chain pattern to describe the general form of travel trajectory, and analyzes the structure and features of this pattern and its sub-patterns: trip sub-pattern and activity sub-pattern. Then normalized Euclidean distance measurement method is adopted to decompose the travel trajectory into trip and activity parts. Finally we apply RBFNN to solve the pattern recognition problem, which obtains an accuracy of 88.5% of travel mode recognition and 74.4% of activity type recognition.
Keywords: Travel trajectory; Trip activity chain; Travel analysis; Pattern recognition.

1 Introduction

Activity chain and trip chain are effective tools to research the resident's travel behavior and demands. The information of trip-activity chain can be acquired by face to face interview and GPS trajectory survey. For GPS track investigation, how to automatically identify and extract the travel path information, and match with the trip-activity chain, is the key problem to be solved.

Research on urban travel information recognition automatically started in recent decades. Wolf proposed a new theory on using GPS data to replace travel diaries in data collection (Wolf 2000). Stopher et al. developed and deployed a new kind of wearable GPS device for transport applications which offered new thinking on passive personal transportation data collection (Stopher et al. 2005). An integrated GPS-GIS system had be developed to extract person travel survey data by Tsui and Shalaby, which also designed an interactive analysis interface (Tsui and Shalaby 2006). Herrera et al. demonstrated that the cell-phone device is an alternative traffic sensing infrastructure (Herrera et al. 2010). Stenneth declared that cell-phones with GPS sensors can acquire transportation modes (Stenneth et al. 2011). Travel mode recognition can be found in the article of Widhalm(Widhalm et al. 2012), and Liao attempted to solve the recognition of activities(Liao 2006). Our former researches focused on travel mode recognition by adopting Neural Networks(Wang and Zuo 2014) and Support Vector Machines(Wang et al. 2014), and attained comparatively good accuracy.

The purpose of this study is to propose an approach to recognize the travel mode and activity type within one's travel by analyzing the travel trajectory collected by smart-phone devices (as shown in Figure 1). We summarized a concept of trip-activity chain pattern to describe the structure of the trip-activity chain, decomposed the pattern into trip sub-pattern and activity sub-pattern, used Euclidean distance to detect the activity parts and trip parts in trajectory data, and applied the method of Pattern Recognition to achieve the target of identifying travel modes and activity types.

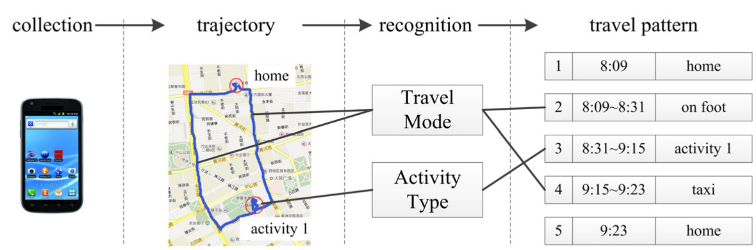

Figure 1. Target of this research

2 Trip-Activity Chain Pattern

Trip-activity chain is a chain structure which is constructed by trip and activity those link each other, which contains enormous travel information. Trip-activity chain pattern is the characteristic of the elements, structure and feature that can specify the trip-activity chain, in order to adopt the Pattern Recognition approach to recognize the information within this pattern automatically.

2.1 Elements of Trip-Activity Chain Pattern

(1) Trip. Trip is the process that traveler move from one place to another.

(2) Stop. Stop is defined as the parts of a whole travel that displacement almost not happens within a certain space and time range. We divide Stop into three categories: a) Activity, b) transfer and c) origin / destination point.

2.2 Structure of Trip-Activity Chain Pattern

(1) Spatial structure

The spatial structure of trip-activity chain is similar to digraph, in which a trip is represented by directed link and an activity is expressed as a node. The activities are connected by trips like the nodes are connected by links, as shown in Figure 2.

(2) Time structure

The time structure of trip-activity chain can be shown as two aspects. The displacement of the traveler is time-varying which is shown in Figure 3, and the parameters those are recorded by the sensors are also changing with time as shown in Figure 4.

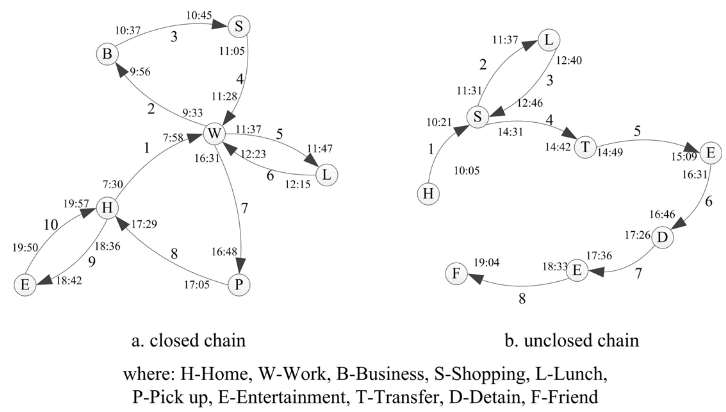

Figure 2. Spatial structure of Trip-Activity Chain

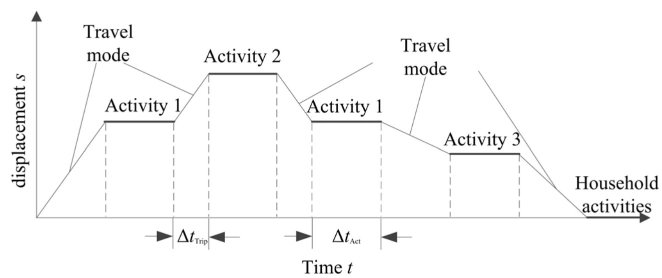

Figure 3. Time structure of Trip-Activity Chain

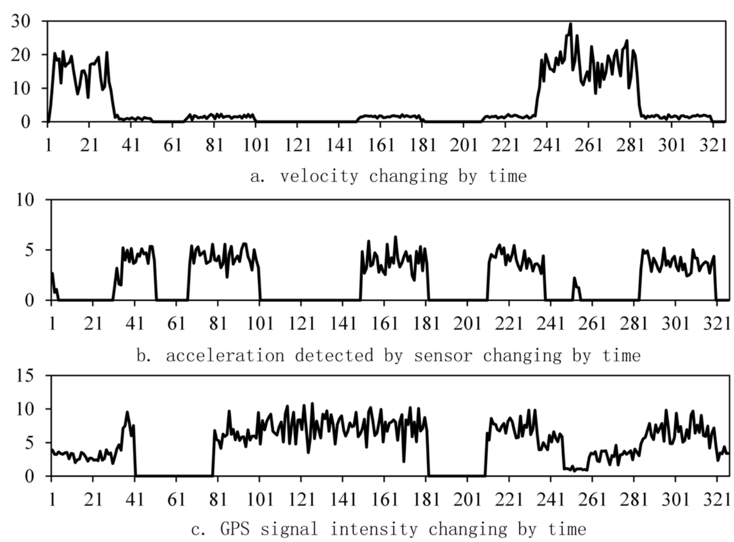

Figure 4. Time feature of parameter

2.3 Features of Trip-Activity Chain Pattern

Though trip-activity chain is relatively complicated with the scope of time-spatial structure, we can decompose the pattern into two sub-patterns:

(1) Trip sub-pattern

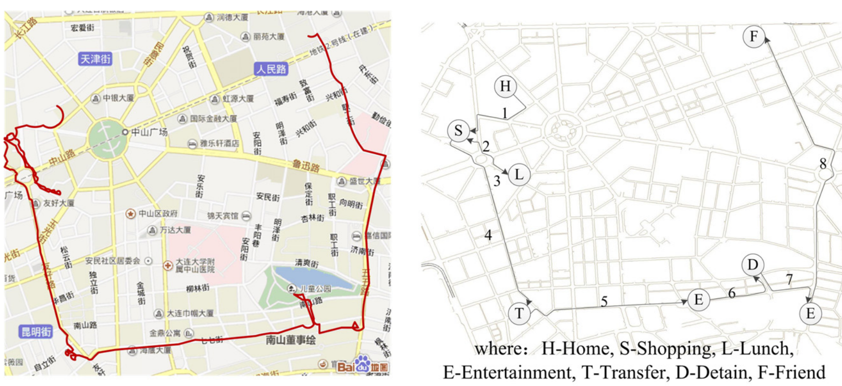
The key point to recognize trip sub-pattern is to identify the travel mode. Travel mode divisibility can be reflected by the following characteristics: a) Velocity. b) Acceleration detected by sensor. c) Moving distance. d) Radius of displacement. e) GPS signal intensity. f) Ratio of missing time. g) Pre-stop-time. h) Origin-destination out of the rode. i) Line compatibility with public transit. j) Traveler’s personal property.

(2) Activity sub-pattern

There are following features of activity sub-pattern: a) Activity location. b) Activity duration. c) Range of activity. d) Trip distance. e) Radius of trip. f) Period in one day. g) Workdays or weekends. h) Visit frequency. i) Time difference and range difference from the former activity / to the later activity. j) Travel mode to arrive and leave. k) Values of sensor during activities. l) Traveler’s personal property.

3 Travel Trajectory Collections

Travel trajectory is a set of time-serial data records that compiles parameters such as position, velocity, and acceleration as a row. A travel trajectory is an instance of the trip-activity chain pattern, while the pattern is the abstract of the trajectory. We can read the trip and activity information from the trajectory data by matching the features of the pattern (see Figure 5.). By applying a smart-phone application, we collected 339 trajectories from16 volunteers (see detail in Table 1.).



a. travel trajectory b. trip-activity chain pattern

Figure 5. Travel trajectory and trip-activity chain pattern

Table 1. Information of trajectory samples

	volunteers	trajectories	frequency	duration
training & validation	16	138	12 per min	1 week
test	16	201	12 per min	1 week

4 Sub-pattern Preparations

Since the trip-activity chain pattern can be divided into two sub-patterns in order to recognize the travel mode and activity type separately, at this step, we need to convert the travel trajectory data into the input vector format to be processed during the travel sub-pattern and activity sub-pattern recognition step.

Travel mode samples and activity samples are decomposed from trajectory samples by normalized Euclidean distance measurement. See formula (1) and (2).

$$b_{ij} = (a_{ij} - \min_j a_{ij}) / (\max_j a_{ij} - \min_j a_{ij}) \quad (1)$$

Formula (1) is the normalization of the feature variables a_i, where a_{ij} is one record of original a_i and b_{ij} is the normalized record of a_{ij}.

$$S_k = \{\{b_{1\cdot j},...,b_{I\cdot j}\} \mid \sqrt{\sum_{i=1}^{I}(b_{ij} - b_{i\cdot j-1})^2} < \varepsilon, I = 1,...,I, j = 1,...,J\} \quad (2)$$

Where, S_k is the data records set of stop k, $\{b_{1\cdot j},...,b_{I\cdot j}\}$ is record j, ε is the threshold of judging stop point, I is the number of feature variables, J is the number of records. Other parts of the trajectory are regarded as the trip records sets. In this research, the maximum Euclidean distance of stop points is below 0.0024 and the minimum of moving poits is above 0.0040, which indicates that stop points and moving points are absolutely separable.

However, points during trip period might stop for a while for signal control or passenger getting on or off. A toleration window τ should be involved to avoid the disturbance of accidental stop points, which means if the continuing τ points are all below ε then they are all stop points otherwise they are trip points.

Figure 6 gives a illustration of dividing trajectories into trip parts and stop parts by the variation of Euclidean distance.

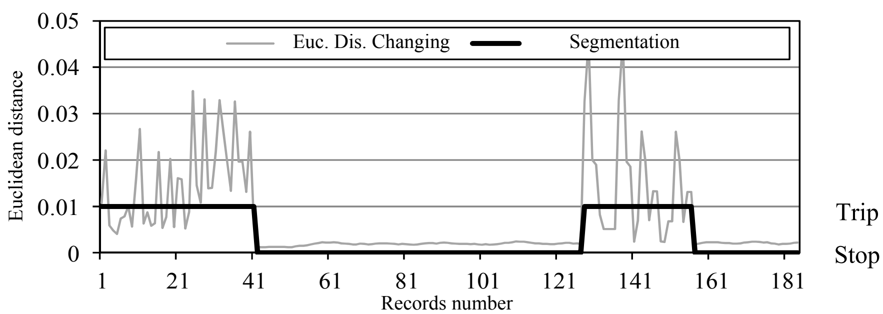


Figure 6. Trajectory segmentation illustration

Results of dividing trajectories are shown in Table 2, and the observation data summary of travel mode and stop type (including activity type, other stop types may be regarded as type other) is shown in Table 3 and Table 4.

5 Trip-Activity Chain Recognition

Since the trajectories are segmented into trips and stops, the trip-activity chain recognition can be conducted separately as trip sub-pattern recognition and activity sub-pattern recognition. Pattern Recognition approaches are the appropriate methods to solve these problems. For travel mode recognition and activity type recognition, we adopted the Radial Basis Function Neural Networks (RBFNN) as the classification method(Wang and Zuo 2014). More about RBFNN see literature(Park and Sandberg 1991).

Giving the feature vector of trip sub-pattern as $CT=(\xi_1,\xi_2,...,\xi_{11})$, and activity sub-pattern as $CA=(\zeta_1,\zeta_2,...,\zeta_{13})$, one real *CT* matches one real trip mode *RT* and one real *CA* matches one real activity type *RA*, which construct mapping of <*CT*, *RT*> and <*CA*, *RA*>. The mapping can be applied to train the RBFNNs where *CT*s match the input neurons and *RT*s match the output neurons of the learning samples, the same as *CA*s and *RA*s. See detail explanation of the variables of *CT* and *CA* in Table 5 and Table 6.

Table 5. Travel mode feature variables

other	9	6	13	7	1	64	64.0%
total							74.4%

6 Conclusions

This paper put forward a research on trip-activity chain pattern recognition by travel trajectory decomposition and classification, which can be applied to improve the efficiency and reduce costs of the study on residents travel behavior and travel demand. In this paper, we define a concept of trip-activity chain to abstract the travel trajectory collected and formatted by smart-phone location services and motion sensors. Then the normalized Euclidean distance measurement implements the segmentation of the trajectory into activity and trip sub-pattern of trip-activity chain pattern, and RBFNN method is applied to solve the classification problem of travel modes and activity types.

This study accomplished an accuracy of 88.5% on identifying the travel modes, but attained a relatively lower accuracy of 74.4% on activity type recognition. The results of our work are fine but not good enough as what other researches have done, which shows a quite broad development space and indicates predictable advancement that can be made.

Analysis of Dynamic Passenger Flow in Urban Rail Transit Based on Data Mining

Xinyu Chen; Yihan Guo; Boyang Li; Miao Ge; and Chunxian Xu

Department of Computer and Communication Engineering, Southwest Jiaotong University, Sichuan, China. E-mail: xian_46Xu@hotmail.com

Abstract: According to the more qualitative methods for urban rail analysis, long cycle of diagramming train schedule chart and large passenger flow, getting the real-time statistics of the passengers' IC card information in AFC system, according to the retention time in each station, a scatterplot of the passengers' density can be drawn, intuitively reflecting the distribution of the passengers' density in every station. To gain the data of the passenger flow in each station and on each route, a more accurate full-time traffic planning can be made by using the reliable traffic data. Due to the multi-routes for passengers, Based on the optimization of Dijkstra, the route in a net can be chosen, then mapping the train schedule chart. At the same time, use the data mining technology in large data era to process the history data and the dynamic information of passenger flow to provide accurate and intuitive reference for the update of the train schedule chart.
Keywords: Current; Train plan; Optimize; Data mining.

Due to the quickness and accuracy of modern computer technology, the use of software programming technology for validation is applied. The WPF technology in Visual Studio is applied, connecting to the MySQL database through ADO.NET, an intuitive, friendly software being completed to realize the simulation of the above content. The train schedule chart usually being updated in a long cycle, according to the real-time dynamic traffic statistics, a traffic planning and schedule chart can be generated in a high frequency and set the reasonable threshold to optimize the existing traffic planning and schedule chart in order to achieve the goal of the analysis dynamic passenger flow.

1 Background

With the city subway network gradually formed, during the holidays or influenced by a certain policy, activities, it will bring big impacts on passenger flow to the subway. Modern metro mostly adopt the method of the long-term prediction, while less actual dynamic analysis after operation, which often caused crowded, trample and low efficiency. Optimization of train operation plan and setting passenger flow analysis solution to reduce the accident rate and efficiency is necessary. (liming Song, 2011)

2 Design principle

2.1 Vulnerability analysis

Subway security model analysis:

The main idea of the famous safety management model called "Reason cheese" model: When multiple layers of tissues defect in a precipitating factor in the accident or initially defect at the same time. The events lose multi-level security and happened. As shown in figure 1,the existing prediction methods, hardware upgrade basis and operating unit management's hidden dangers are potential failure factors.Innovation of the passenger flow analysis method by dynamic analysis of passenger flow optimization, improving the train operation plan and the preparation of train diagrams improve the efficiency and security. （James Reason，1990）

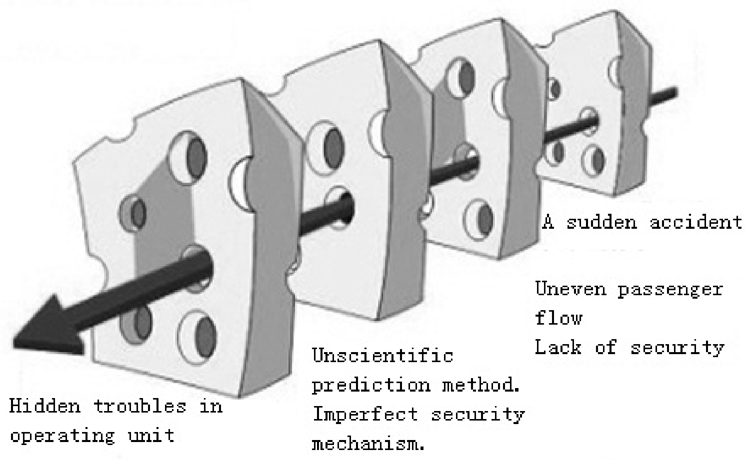

Figure 1. Reason cheese model

2.2 Design ideas

Passenger flow analysis with experimental data and the use of the passenger flow data are more reliable and relatively accurate.At the same time ,using mathematical modeling for the further optimization,then map the train running. The operation of the station passenger density distribution is analyzed, to provide the reference of hardware upgrades and dynamic security arrangements for each station.

2.3 Core architecture

System work process is shown in figure 2：

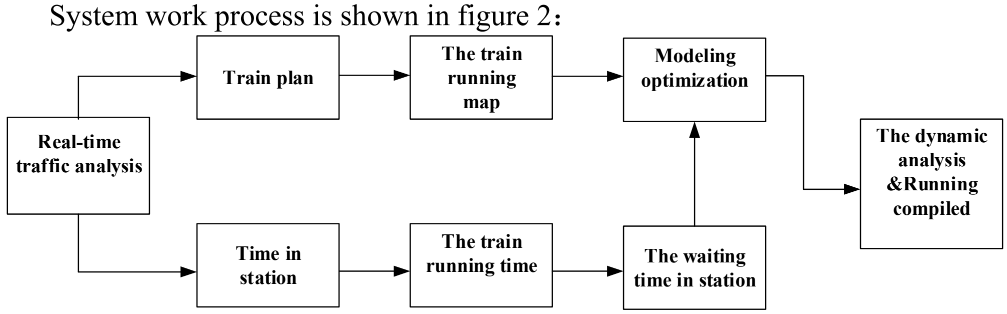

Figure 2. The system work flow chart

2.3.1 To obtain OD Matrix

Defination:OD matrix is the abbreviation of original point - the destination matrix. The matrix of the data is from area A to area B traffic flow.

As larger error exists when use questionnaire to obtain the OD matrix, and the collection is a trouble, so using a computer iteration to obtain the OD matrix iteration must be more accurate.

The principle of the balance of supply and demand is used, which can analyze the inherent law of traffic distribution. And according to the principle of supply and demand balance, a general sense of the traffic distribution can be performed. At this point, The OD matrix system balance model is chosen for passenger flow distribution.

General function of the trip distribution models are as follows（xiangyun Wu canqi Liu，2004）:

$$X_{ij} = T_i \frac{U_j}{f(t_{ij}) + T_i}$$

X_{ij} ——Trip distribution amount intraffic area i to j.

T_i ——The discharge of traffic area i.

U_j ——The charge of traffic area i.

$f(t_{ij})$——The impedance of traffic area i to the traffic area j. t_{ij} represent the the time distance effect parameters from traffic area i to j.

Through related literature query, the $f(t_{ij})$ of subway is often represented as:

$$f(t_{ij}) = t_{ij}^{a_i}$$

Traffic impedance is determined by the walking time of each section, the impedance referred in this article refers to the the time impedance for passengers in the rail transit network from the origin to the destination. (note: due to the difference between different individual's stops the outbound, so in order to study the general impedance, it is determined by the impedance)

The actual survey time data can be obtained by using passengers balance.

Because there are several routes in nanjing subway now ,because of very large amount of calculation and considering some platform traffic traffic was far less than the main station, and by comparing the number of trip distribution models require overlay, together with the influence on the speed of calculation. Some of the big platformare captured.

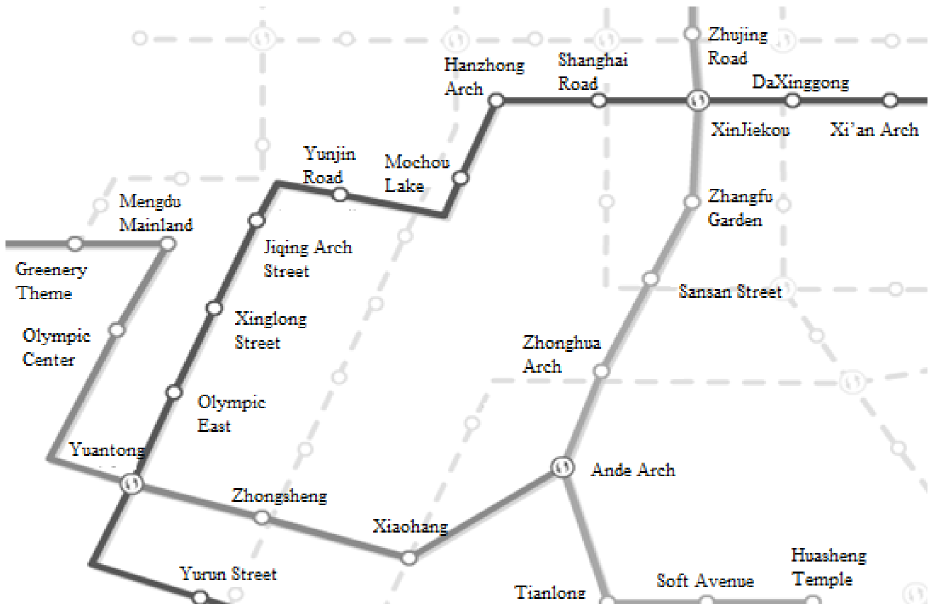

Figure 3. Map of NanJing subway

The survey data shown in the table below:

Table 1.Random traffic statistics

Nunber	Platform	Current/10000	Rate/%
01	Greenery Theme	1.79	0.003815818

Abnormal Vessel Trajectories Detection in a Port Area Based on AIS Data

Feixiang Zhu

Navigation College, Dalian Maritime University, #1 Linghai Rd., Dalian 116026. E-mail: dlmuzhufeixiang@163.com

Abstract: Vessel trajectories anomaly detection in port areas is concerned with finding deviations from normalcy and it is an increasingly important topic when providing decision support for maritime safety administrations. This study proposes an idea that anomalously behaving vessels can be automatically identified from a large Automatic Identification System (AIS) history data by trajectory anomaly detection algorithm. Firstly, the availability of AIS data with a focus on vessel trajectory detection is analyzed in this study. Second, the framework based data mining for vessel trajectory anomaly detection is proposed. Finally, the trajectory anomaly detection algorithm is adopted in order to find the anomalously behaving vessels. Computer programs for decoding, visualization and detection of AIS data have been developed. Experimental results demonstrate that trajectory anomaly detection algorithm in this paper is able to correctly and effectively detect abnormal trajectories from real vessel trajectory data. Research achievements can be applied to intelligent maritime supervision.

Keywords: Automatic identification system (AIS); Vessel trajectory; Data mining; Anomaly detection.

1 Introduction

In recent years, the design of systems that guarantee a high level of security in highly-crowded and critical areas such as harbors, airports, busy streets, etc., have become an important research subject for both academia and industry. Generally speaking, marine traffic accidents make a very bad impression (safety of life, ocean pollution, etc.). So, dangerous situations and accidents in port areas are increasingly perceived as intolerable. Nowadays, many kinds of sensors such as radar, video and infrared cameras and Automatic Identification System (AIS) are widely deployed for monitoring maritime environments. Especially, AIS was primarily developed to exchange vessel-related data among vessels or AIS base stations by using very-high frequency (VHF) technology to increase safety at sea. The AIS data that are exchanged are divided into three different types (IMO, 2003):

- Static information (e.g., IMO and Maritime Mobile Service Identity (MMSI) number, vessel name, call sign, the dimensions of the vessel, type of vessel)
- Dynamic information (e.g., vessel position, time in UTC (coordinated universal time), course over ground, speed over ground)

- Voyage-related information (e.g., current draught, type of cargo).

AIS dynamic data contains vessel trajectory information. Vessel trajectories anomaly detection is concerned with finding deviations from normalcy. One option to perform these tasks of discovering vessel abnormal trajectories is to design algorithms for them by hand. This is time consuming and difficult. However, we can also use automatic techniques from the fields of data-mining that work with available historical trajectory data directly. This is the approach that we take in this study.

This paper is structured as follows. Section 2 discusses the availability of AIS data with a focus on vessel trajectory detection. The framework based data mining for vessel trajectory anomaly detection is proposed in section 3. A vessel abnormal trajectory data mining method is presented in section 4. Using real vessel trajectory data, we explore the capabilities of our method in section 5. Finally, we give the conclusion in section 6.

2 Analysis of AIS Data

The main goal of this study is to find out vessel abnormal trajectory. So, we only consider dynamic data fields that contain measurements automatically updated by appropriate sensors directly connected to the AIS system. Table 1 shows the data fields of the position reports within this study.

According to the technical characteristics, the reporting interval changes depending on SOG, ROT (rate of turn), and the current state of a vessel (ITU, 2014). Therefore, position reports should be output periodically by mobile stations. Table 2 gives an overview of the reporting intervals for position reports according to these technical characteristics.

Table1. Some position report data fields

Data fields	*Description*
Longitude	*Longitude in 1/10 000 min (±180°, East = positive, West = negative)*
Latitude	*Latitude in 1/10 000 min (±90°, North = positive , South = negative t)*
SOG	*Speed over ground in 1/10 knot steps (0-102.2 knots)*
COG	*Course over ground in 1/10 = (0-3599).*
True heading	*Degrees (0-359) (511 indicates not available = default)*

Table2. Reporting intervals of Class A position reports

Ship's dynamic conditions	*Nominal reporting interval*
Ship at anchor or moored and not moving faster than 3 knots	*3 min*
Ship at anchor or moored and moving faster than 3 knots	*10 s*
Ship 0-14 knots	*10 s*
Ship 0-14 knots and changing	*3 1/3 s*
Ship 14-23 knots	*6 s*
Ship 14-23 knots and changing	*2 s*
Ship 23 knots	*2 s*
Ship 23 knots and changing	*2 s*

From Table 1 and Table 2, we know that position report data is appropriate for vessel trajectory analysis. A large number of AIS data are used as the data source for vessel trajectory analysis in this paper. In next section, we will propose the framework of vessel trajectory anomaly detection based on data mining.

3 Framework of Vessel Trajectory Anomaly Detection Based on Data Mining

Data mining is a technique to discover hidden, previously unknown and useful knowledge from a large database. In particular, our study targets to detect vessel abnormal trajectory possessed by AIS, and combines database management systems, data warehousing and mining algorithm to process and analyze data. The proposed research architecture and processes in Fig.1.

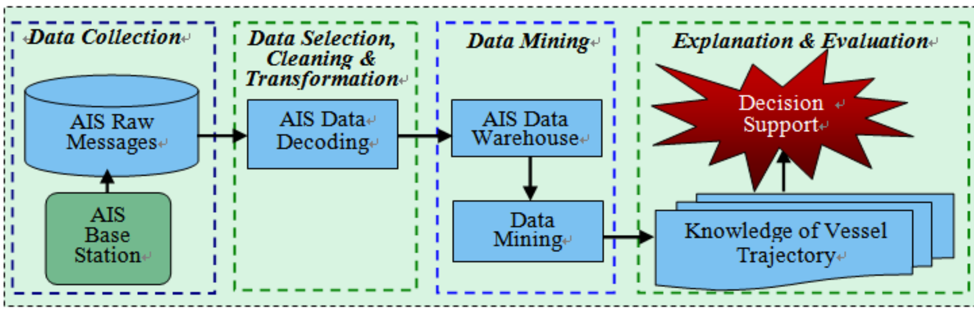

Fig.1 Framework of vessel trajectory anomaly detection

3.1 Data Collection

This study makes use of an AIS base station on the DMU (Dalian Maritime University) campus, about 10km from Dalian port. We use computer programs developed with Visual Studio 2005 C++ to receive AIS original messages and transfer them through the RJ-45 interface to the connected PC's SQL Server 2008 database server (acting as the data storage platform). The total quantity of static and dynamic messages reached 1.0 Gb.

3.2 Data Selection, Cleaning and Transformation

In the AIS technical specification, there are 27 different types of messages (ITU, 2014). In this study, we decode only types 1, 2 and 3 (target vessel position report) and type 5 (dynamic information and voyage related information) messages. Through the use of MMSI as a relational key, each ship's static and dynamic message can be joined together to compose each ship's complete trajectory.

After homogenizing the data and removing redundant information, the data may be deemed "clean". In order that the data mining model can read the information smoothly and perform analysis, we transform the pre-processed data into SQL Server's data warehouse. In this study, several layers of processing and conversion are required from the handling of initial received AIS messages until the end, when the data-mining model can be provided for use.

3.3 Data Mining

This step is based on the research goal of selecting appropriate data mining methods to perform trajectory analysis. In this study, we further describe this step in section 4.

4 Vessel Abnormal Trajectory Data Mining

A number of methods have been proposed where learning is based on estimation of a statistical model for the feature values of individual data points from vessel trajectories. A two-step learning algorithm where feature values of individual data points are first clustered using Self-Organization Map (SOM) and then modelled using Gaussian Mixture Model (GMM) (Kraiman, 2002). A two-level approach based on a combination of GMM and Hidden Markov Model (HMM) for learning and anomaly detection in trajectory data is also proposed (Urban, 2010). However, no details regarding the learning and anomaly detection algorithm are given.

Generally speaking, without considering collision avoidance or other hazardous conditions, vessel will keep course and speed, and make linear motion. The anomaly and danger are more likely to appear, when the vessel is changing speed or course. The abnormal segment may be a portion of the whole vessel trajectory. If we detect the vessel trajectory as a whole, outlying portions of the trajectory may not be able to find out.

Example: TR_3 is not detected as an outlier since its overall behavior is similar to those of neighboring trajectories, shown as in Fig.2. Thus, we miss this possibly important information.

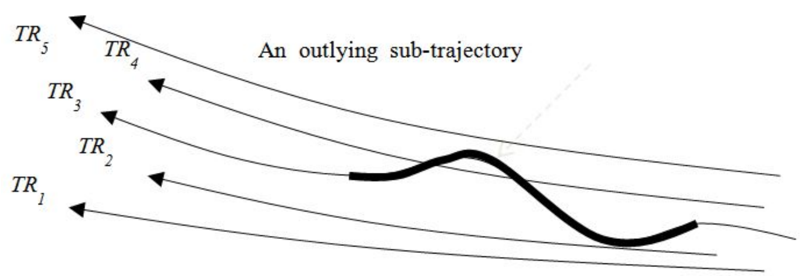

Fig.2 An example of an anomaly sub-trajectory

Therefore, the algorithm for vessel trajectory anomaly detection should be able to detect outlying portions of the trajectories. A trajectory outlier detection algorithm (TRAOD) which was based on partition-and-detect framework was proposed (Lee, 2008). A two-step anomaly detection algorithm is proposed, which first partitions each trajectory into a number of line segments. Next, anomalous trajectory partitions, i.e., line segments, are detected according to a combination of distance-based and density-based analysis.

The TRAOD is based on the partition-and-detect framework. In TROAD, a trajectory is a sequence of multi-dimensional points, which is denoted as $TR_i = p_1p_2p_3 \dots p_j \dots p_{leni}$; a trajectory partition (t-partition for short) is a line segment p_ip_j ($i < j$), where p_i and p_j are the points chosen from the same trajectory.

A t-partition is abnormal if it does not possess a sufficient number of similar neighbors. A trajectory is an outlier if it contains a non-negligible amount of outlying t-partitions. So, there are three parameters in TROAD algorithm: D corresponds to similar, p to sufficient, and F to non-negligible. In this study, we adopt TROAD to detect abnormal trajectory with real vessel trajectory data.

5 Experiment and Result Analysis

In order to detect vessel anomaly trajectories near Dalian port water area, we select a real and original vessel trajectory data set(coverage Dalian Port area: latitude: 38.8ºN~39.0ºN, longitude:121.6ºE~121.8ºE). The data set is extracted from AIS data warehouse as described in section 3. The original vessel trajectory data set is compressed by Douglas-Peucker algorithm (Zhu,2014 and Douglas,1973). We extract the vessel's latitude, longitude from compressed data set. The data set has 465 trajectories and 6293 points.

We conduct all experiments on an i5-2450M CPU @ 2.5 GHz Laptop with 2 G Bytes of main memory, running on Windows 7. We implement our algorithm using Microsoft Visual Studio C++ 2005.

Fig.3 shows the result of the experiment data set. The parameters are set as follows: D = 200, p = 0.95 and F = 0.2. Here, thick yellow lines represent outlying t-partitions, thin yellow lines trajectory outliers with outlying partitions, and thin gray lines normal trajectories. We note that twenty-four trajectory outliers are detected. We can easily see that outlying t-partitions appear if their directions are significantly different from those of neighboring trajectories (such as crossing fairway) in the left-top region and middle region or if they have very few neighboring trajectories. In Fig.3, the outlying t-partitions in the left-bottom region are moving to totally different directions, and the ones in the left region have almost no neighboring trajectory.

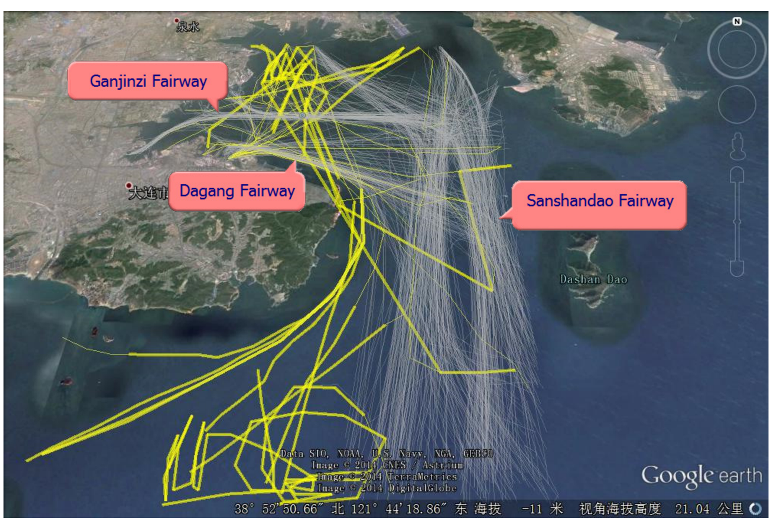

Fig.3 Trajectory outliers for experiment data set

6 Conclusion

Detecting abnormal vessel trajectories from the huge amount of AIS data to improve maritime safety is important for maritime safety administrations. In this paper, we have proposed a framework based on data mining for vessel trajectory anomaly detection. Based on this framework, we have developed trajectory anomaly detection algorithm. The results of experiment show that TRAOD is able to effectively detect trajectory outliers with outlying t-partitions.

This work is just the first step, and there are many challenging issues. First, we consider here only the vessel spatial information. In applications, temporal information and speed information are often associated with spatial information. TRAOD may be not suitable for exploiting multi-dimensional information. Therefore, we should design a new algorithm to vessel trajectory anomaly detection. Second, in order to detect abnormal trajectory real time, it is worthwhile to improve and optimize the related algorithm for AIS big data online analysis.

Study of EMU Process Data and Message Data Communication Technology in UIC Gateway and Simulation

Tong Zhang; Changxian Li; and Haoli Ping

School of EMU Application and Maintenance Engineering, Dalian Jiaotong University, Dalian. E-mail: zhang_tong66@126.com

Abstract: UIC556 standard formulates the mechanism and mode of inauguration, process data and message data communication in the UIC gateway of EMU detailed. As the main EMU communication data stream, process data and message data must be effectively processed and converted with the help of the node monitoring database configuration, then can be transferred to the WTB (MVB) bus correctly. In this paper, comprehensive and detailed analysis of communication theory and software architecture of process data and message data were given in the UIC gateway of EMU. Two important media of process data and message data within the gateway are process data marshalling and UIC mapping server. Process data marshalling mainly achieve filtering and calculation of data between WTB and MVB, marshalling type, operating procedures and marshalling framework were deeply researched. UIC mapping server and TCN protocol stack provide the best path and a variety of services. The transmission mechanism of message data in the gateway and the composition and function of each part of UIC mapping server were detailed analyzed. By semi-physical simulation platform, the theory above is simulated and verified.

Keywords: Process data; Message data; UIC; TCN; UMS; PDM.

1 Introduction

In order to improve operational efficiency and meet the demand of inter-regional and cross-country running, EMU often need to dynamically grouping or decoding. Because our country EMU adopts a number of different manufacturers TCN network equipment, different EMU reconnection grouped together (or decompilation) will inevitably lead to the train network topology changes, change the original static and dynamic properties of many vehicles at the same time, lead to communication barriers after reconnection. Here, TCN bus standard IEC – 61375 which defined the basic data communication mechanism cannot satisfy the interoperability demand of different manufacturer's vehicle (Schaefers, 2000). Equivalent of application layer of TCN standard protocol, UIC556 regards vehicles as the basic unit, defines process and message data frame content, inauguration, process data marshalling (PDM) and a series of related problems (Leaflet,2004). As long as the TCN network equipment of different manufacturers communicate with each other according to the UIC556 standard, use hardware interface consistent with UIC556 communication, or converse interface protocol with UIC gateway simply, then can achieve normal communication of different equipment manufacturers vehicles after interconnection (FEMANDEZ,2007) (JIANG,2011).

At home and abroad in recent years, a more comprehensive study was done in view of MVB and WTB (JIMENEZ,2007), but the principle and design report on UIC communication and gateway was less. Based on the status of EMU operations in our country，it is an urgent task to master the core technology of interconnection, intercommunication and interoperability of EMU.

In this paper, the communication mechanism of process and message data after inauguration in the UIC gateway was researched. First, analyzed the UIC gateway internal software architecture. Then for process data marshalling and UIC mapping server which are two communication medium of process and message data, their structure function and communication mechanism were studied. Finally, the above analysis was simulated and verified on the semi-physical simulation platform.

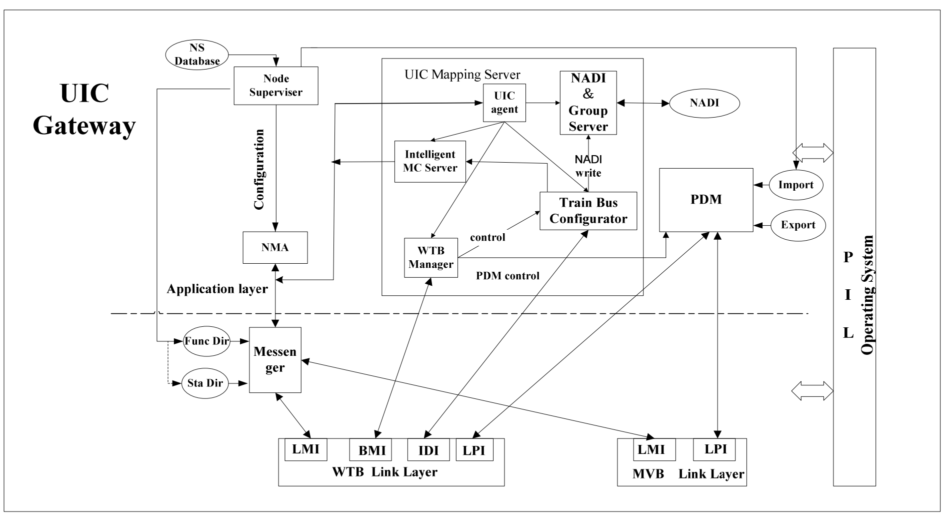

Figure 1. UIC gateway software architecture

UIC gateway and TCN gateway coexist in an entity which, indivisible, with a certain similarity in composition. Application, UIC gateway can fix every process and message data as a frame content which has certain meaning, achieve inauguration and configuration function. The software system architecture is shown in Figure 1. Its software includes TCN protocol stack, UIC mapping server (UMS), process data marshalling (PDM), node monitoring database (NSDB) and real-time operating system (PIL). Among them, LMI is link layer message interface, BMI is bus management interface, IDI is inauguration data interface, and LPI is link layer process data interface.

TCN protocol stack is composed of WTB and MVB link layer, messenger and network management (NMA), can complete TCN inauguration, transfer of process and message data, and have network management functions. UMS mainly accomplishes WTB configuration and control, establish NADI and group serve etc. PDM in charge of marshalling data which between MVB and WTB. In addition to simple data copies, PDM also support the function of process data processing, including and, or, not, maximum, minimum, and so on. NSDB contains all of the vehicles' configuration data, such as PDM, UMS, messenger, WTB configuration, MVB bus management, WTB and MVB communication register. PIL provides a series of system service that is independent of the hardware, and all UMS software components use PIL.

2. Process data transfer mechanism and PDM

2.1 Process data transfer mechanism

As shown in figure 1, if the process data transfer from MVB to WTB, known as exit package. Firstly, move from the MVB physical layer to MVB link layer LPI interface of the UIC and TCN gateway. Then shift up to PDM to filtering and processing, after that the processed data is sent to the LPI interface of WTB link layer and finally reach to the WTB bus physical layer and complete a R frame format conversion. Vice is called entry package.

2.2 PDM

PDM marshalling type is divided into three categories. The marshalling which transmits data from MVB traffic store to the source port of WTB traffic store is called output marshalling. The marshalling which transmits data from WTB traffic store to the configured MVB traffic store is called input marshalling. The marshalling which transmission data is between LVR, MVB or LIO port, is belong to vehicle internal transmission and not through WTB bus, so is called internal marshalling. PDM is composed of many data processing modules, used to implement the data acquisition and preprocessing, functional operation and operation result control etc., and the operation result will eventually copy to the target traffic store. As shown in figure 2.

When R telegram entry package arrives, WTB traffic store first read all variables to PDM memory, and then determine whether is input marshalling. When confirm as input marshalling, check if data's frame type field (FTF) is consistent with NADI's. In the case of FFT correct, execute the marshalling to acquire Pv_Result, otherwise remove the current all WTB data set in PDM memory and all variables becomes invalid. Finally, write the obtained variables from PDM memory to corresponding port of MVB traffic store, shown in Figure 3.

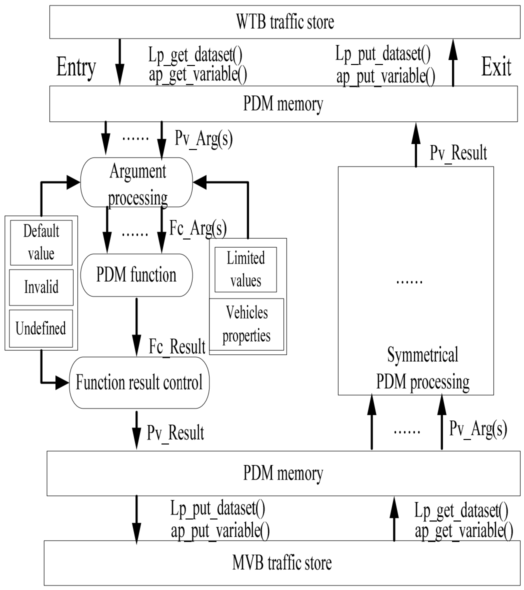

Figure 2. PDM operating procedures

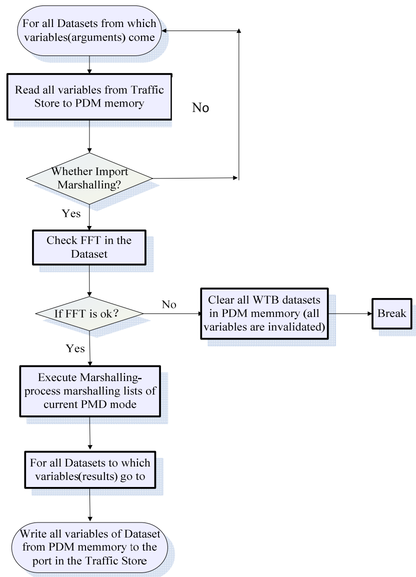

Figure 3. PDM main steps

3 Message data transfer mechanism and UMS

If the message data is transferred from WTB bus to MVB bus and via the TCN ＆UIC gateway, named entry package. The message data from WTB bus will transmit through RTP Real, and afterward get to NMA and UMS for processing, finally reach to MVB bus. NMA module achieves network management through message data. UMS module receives and analyzes E through UAGT modules, and based on the analysis of E telegrams command, determine which sub-module corresponding interface functions should be called to perform operations. Some messages are not transmitted to application and transmitted directly from WTB to MVB bus via messenger. As shown in Figure 4.

UMS is responsible for sending and receiving E telegrams and provide external applications serves, E telegrams from RTP contain remote application service requests submitted. E telegrams are received and analyzed by UAGT sub-module in UMS, then according to different application service requests, functions named UNGS, UWTM, UTBC and UIMCS four sub-modules are called. Among them, UAGT processes result and send reply messages back. UWTM can control inauguration, read the network topology, read node status and other services. UNGS provides NADI and Group database, which stores detailed information about the train, including the inauguration frame version number, R packet data version number, topology, UIC address, train direction, vehicle attributes, additional vehicle information, NADI status, etc. GROUP database holds the information about the vehicle group (LI, 2013). UTBC can deal with leading vehicle request, generate new NADI data and provide redundancy status information and other services. UIMCS is used for changing and grouping information which should be distributed to the corresponding vehicles. Through UIMCS module, distribute above serves as multicast form by TCN protocol.

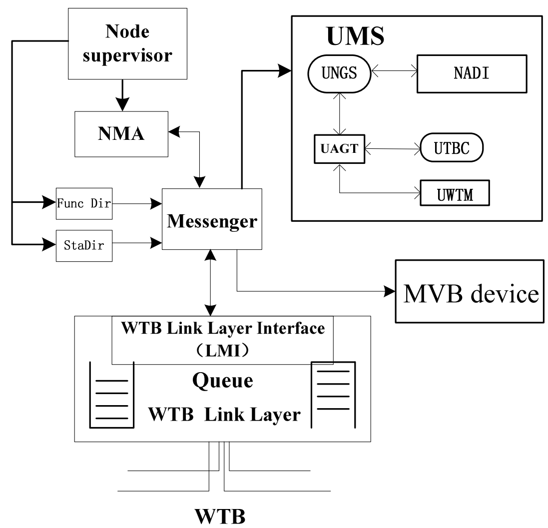

Figure 4. Message data transmission process in the UIC gateway

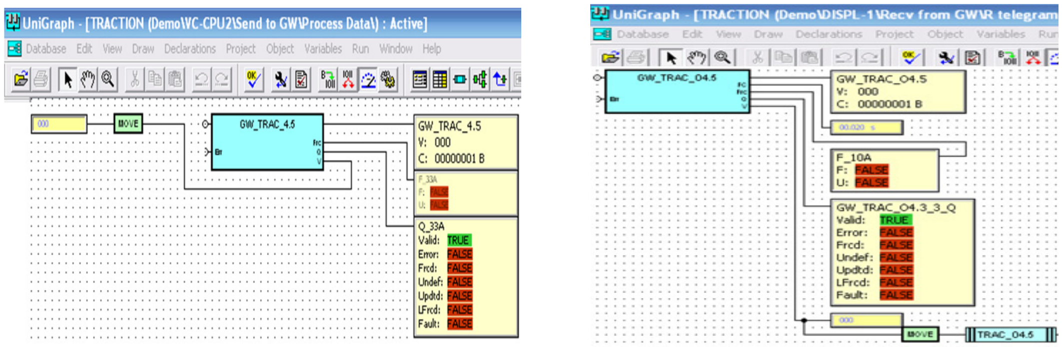
4 Simulation analysis

Semi-physical simulation platform adopted foreign company's TCN＆UIC gateways four set which type was TCN-GW01 / H, 110V power supply, redundant, no I / O interface, for remote shutdown. Additional, equipped with four central processing unit (CCU) and display (HMI) to simulate the corresponding sub-functional units. Used Configuration and Service Station (CSS) software to configure the gateway. Used UIC Train Diagnosis Station (UDS) software to monitor gateway. Each gateway configured one vehicle, and the platform simulated process and message data communication respectively on the train.

4.1 Process data communication simulation

The four sub-function device simulation unit can simulate traction, braking and other equipment of EMU, produce process data and transfer it from MVB bus to UIC gateway. After PDM operation, the data was packaged into R telegram and was sent to other marshalling unit or train. At the same time, UIC gateway received information from other vehicles, and distributed to on-board equipments via MVB bus.

As shown in figure 5, the transmission simulation for train traction of R1 telegram 4.5 (choice of pantograph). First, within the CSS, configured host ports 101 and 104, source ports 201 and 204. Then defined send and receive variables, made variables and defined port match, defined byte offset and checking variables according to the UIC556 standard. Hereafter set up PDM transfer process of process data in gateway, input or output marshalling. Finally, programming with Unicap modular software.



4.2 Message data communication simulation

Select the message telegram 8.2 and 8.2A. If you press the failure Enter key on the display, HMI would send message data request to the leading vehicle simulation unit. After received telegram 8.2, leading vehicle sent 8.2A to HMI. Select index type was function index, code 102 and 103. As shown in Figure 6.

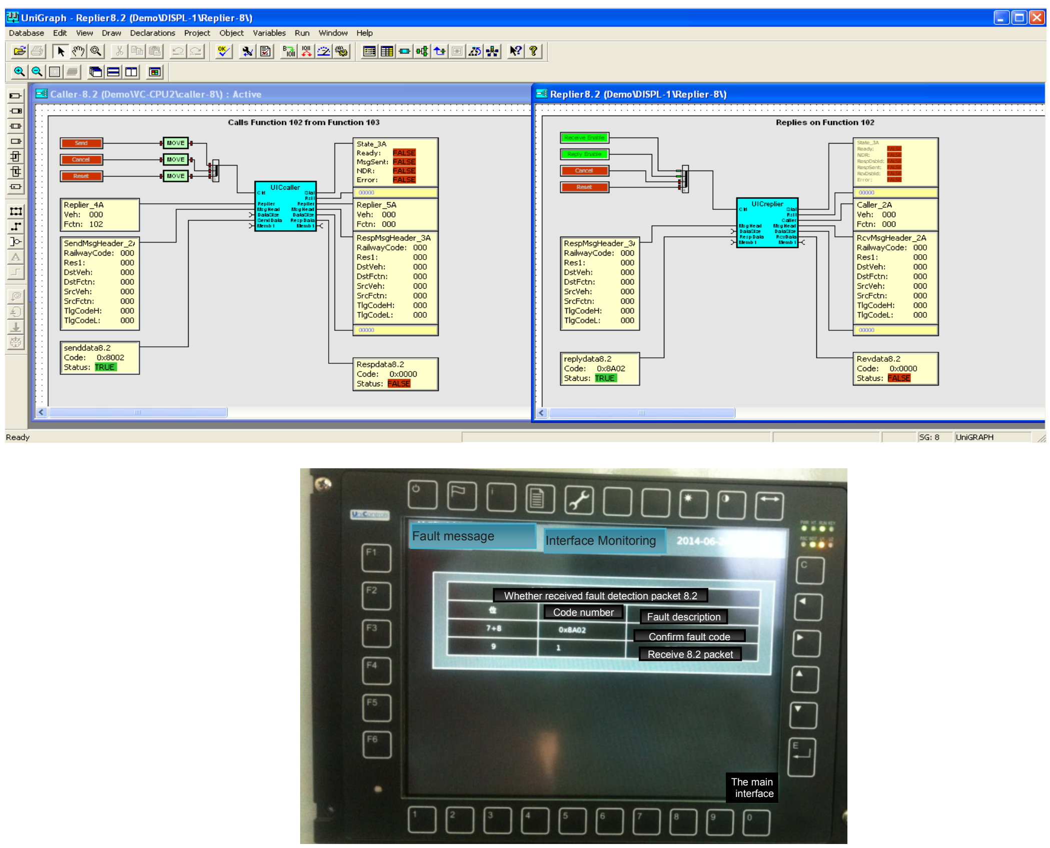


Figure 6. 8.2 and 8.2A telegram transmission simulation

5 Conclusions

UIC gateway is the key equipment to realize interconnection, intercommunication and interoperability between different models of EMU. UIC and TCN protocol stack software is responsible for it.

This paper focused on the transmission mechanism of process and message data and the software composition of PDM and UMS in UIC gateway. This study was conducive to more fully grasp the UIC gateway software technology, and laid the foundation for independent research and development related products. Meanwhile, provided a solution for the interconnection, interoperability and interoperability related technology problems of china EMU.

Abstract: In order to offer the general view and regularity of choosing right transverse position and reduce the uncertainty of choosing lateral position to the ship officers when navigating within the two-way fairway, with the theory of marine traffic engineering and data mining technology, the regularity of transverse distribution of ship' sailing position within the two-way fairway is mined and counted using the shipborne AIS data. The regularity reveals positive effect quantitatively on the safe navigation of different ships caused by the <Regulations for Preventing Collisions at Sea, 1974> and extent of different length of ship complying with rules. The result can be used for choosing the safe and suitable transverse sailing position when the ship goes through two-way fairway and also for marine traffic organization, layout and planning of fairway conducted by the authorities.
Keywords: Two-way fairway; Lateral sailing position; Marine traffic; Regularity of distribution; AIS data.

1 Introduction

Considering the issue of vessel security, arriving and leaving vessel of harbor water must keep suitable lateral position in the limited two-way harbor channel. With the increasing amount of ship, the channel become more busy, thus how to choose the appropriate lateral position when navigating within the channel is big challenge for the navigator and officer.

In the No.9 provision of <International regulations for preventing collisions at sea,1972>,a vessel proceeding along the course of narrow channel or fairway shall keep as near to the outer limit of the channel or fairway which lies on her starboard side as is safe and practicable. This provision means that no matter what kind of condition the ship is in, when navigating along the channel and fairway, the ship should keep navigating along the starboard side of channel and fairway, as the saying of keeping the ship starboard side of channel is deeply in the brain of navigator.

Actually what is the extent and percent of keeping starboard side and how to decide the lateral position are confused, especially how to balance the limited channel and safe navigating is a very important issue. The method of obtaining the lateral distribution of ship sailing position within the channel is seldom covered in the marine related literature.

The AIS(Automatic Identification System) data transmitted by ship can reflect ship' navigational status and marine traffic condition, it also provide reliable data for extraction rule of lateral position of ship when navigating within the channel. With the big amount of AIS data ,this paper use the marine traffic theory and data mining technology to design the algorithm of extracting the lateral position, revealing the lateral position distribution pattern of different type and length of ship. It can offer guide for navigator when choosing the lateral position according to their characteristic and marine traffic organization and management.

2 AIS data Preparation

The AIS data used below is gathered by Vessel information service system based on ECDIS and AIS, according the need of research, the following information is the key research data.

(1)Ship' name and MMSI are used to identify and distinguish ship.

(2)Ship' length and breadth are used to indicate the ship' size.

(3)Longitude, latitude and time express ship' lateral positon within the channel.

(4)COG、SOG determine ship' sailing direction and speed.

2 Algorithm of extracting the lateral ship position distribution within the channel

2.1 Preprocess of AIS

Some AIS data are missing and inaccuracy during the process of transmit and decoding. So it is necessary to do preprocess of AIS data, the main measures are below procedure:

(1)Delete the data which MMSI is 0 .

(2)Delete the data which longitude and latitude exceed reasonable range.

2.2 Design of algorithm

In order to obtain the ship lateral position within channel, this paper set a line of observation which is perpendicular with the direction of main traffic flow. Thus the research issue is obtaining the ship' position distribution on the line.

2.2.1 Search the AIS data around the observation line

The AIS data in database covers all the area around the observation line, but we want to search the ship' position on the observation line. The dynamic AIS data are discrete and updated depending on the ship' speed, the interval is between 2s and 12s. So not all the dynamic position are accurate on the observation line, one way to solve it is searching the data which is nearest to the line, then calculate the intersection point of ship trajectory and observation line.

2.2.2 Calculating the accurate ship position on the observation line

(1) Calculate ship position' distance to the two end of observation line, obtaining the nearest position to the observation line if the sum of two distances is

minimum.

(2) Calculate the vertical distance between nearest position and line.

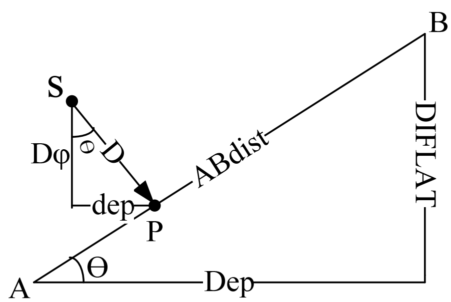

Figure 1. The ship goes across the observation line

As shown in fig 1, A and B is the end of observation line, S is the nearest position of same ship, D is the distance between S and observation line, P is the position when ship passing the observation line, it is also the point we are going to calculate.

(3) Calculate the distance (ABdist), longitude and latitude difference(DIFLONG, DIFLAT) between A and B, and departure(Dep) of A and B. The longitude and latitude difference between P (LatofArrival，LongofArrival) and S(LATITUDE，LONGUTIDE)are Dλ and Dφ. Θ is the angle between line AB and horizontal, Φ_n is the midlatitude of A and B.

(4) The process of calculating the position of P（LatofArrival，LongofArrival):

① Latitude of A and B are $LATITUDE_A$ and $LATITUDE_B$

$\Phi_n=(LATITUDE_A+LATITUDE_B)/2$； （1）

$Dep=DIFLONG*Cos(\Phi_n)$； （2）

② Calculate the sine and cosine of θ：

$Cos(\theta)=Dep/ABdist$； （3）

$Sin(\theta)=DIFLAT/ABdist$； （4）

③ Calculate latitude of P:

$D\varphi=D*Cos(\theta)$ ； （5）

LatofArrival=LATITUDE ± Dφ(+ or – depend on ship position is upward and downward the line) （6）

④ Φ_m is midlatitude of S and P, longitude of P can be calculated:

$\Phi_m=(LATITUDE + LatofArrival)/2$； （7）

$D\lambda=dep*Sec(\Phi_m)=D*Sin(\theta)*Sec(\Phi_m)$； （8）

LongofArrival=LONGUTIDE ± Dλ(+ or – depends on ship position is upward and downward the line) （9）

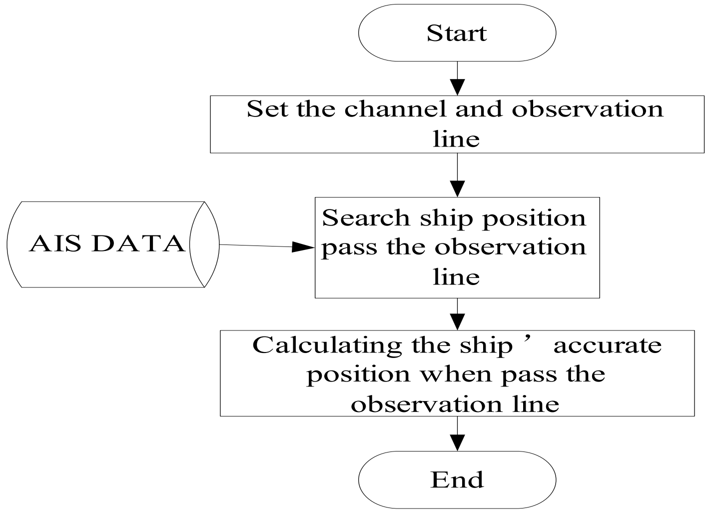

Figure 2. Process of obtaining the position of ship through the observation line

Above algorithm is programed as storage procedure in SQL database, it is very convenient to cope with big data. After the algorithm was carried out, we divide the observation line into small interval, then count the number of ship within each interval which can reflect how to choose the lateral position according to ship' characteristic.

3 Ship lateral position distribution statistics within Xiamen main channel

According to the characteristics of Xiamen channel, choose the channel southeast of gulangyu as our research area. The traffic flow is depicted below, point A and B are selected as the end of observation line.

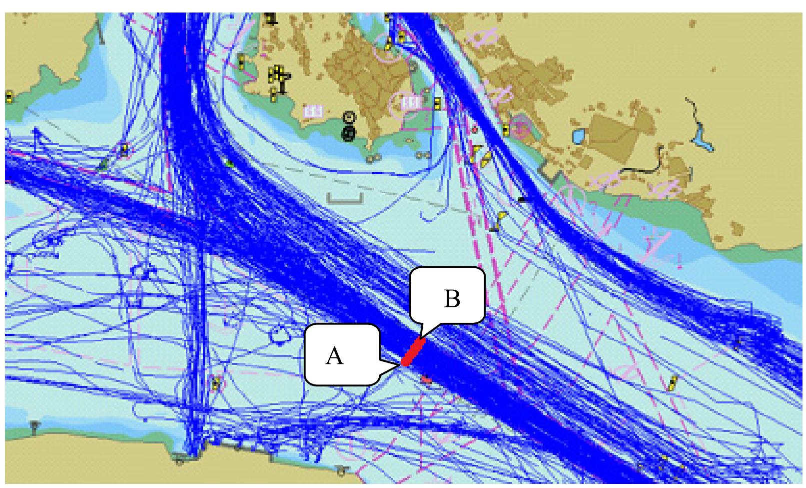

Figure 3. The traffic flow distribution of Xiamen port channel

3.1 Analysis of observation line

As shown in Figure 3, A(24°25.213′N, 118°4.182′E)、B（24°25.35′N，118°04.273′E），we select the AIS data between 2014-7-1 and 2014-7-31.After preprocessing, there are 2703 ship go through the observation line among which 1333 ship going out of port and 1370 ship going into of the port.

3.2 Division of sailing interval

In order to characterize the lateral position ,this paper partition the observation line into 9 intervals according to the distance of observation line end A and B ,as shown below.

Figure 4. Partition of fairway interval

Even though there is no traffic separation schemes set within the Xiamen channel, ship can go through the channel arbitrarily when going in and out of port, actually the ship is affected by the N0.9 scheme of <rules>,the ship is go along the starboard side when going in and out of channel. As shown above left red side is going-out area(interval No.1-5_l) and right green side is going-in area(interval No.5_r-9).

3.3 Statistic of ship lateral position within sailing interval

Ship lateral position distribution and channel space use ratio is characterized by counting the number of ship navigating within the no.1 to no.9 sailing interval using the statistics theory.

3.3.1 Statistic of going-in area

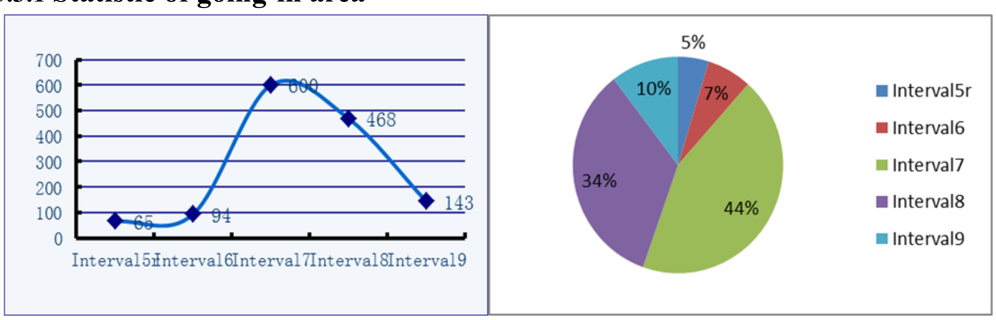

Figure 5. The distribution of arriving ship' sailing position

As shown in Figure5, there are a few percent of ship navigating within the no.5_r and no.6, during which there is 5% ship within the no.5_r and 7% ship within the no.6 sailing interval, these vessels' length is more than 200m, vessel' breadth is more than 30m, these ship choose to navigate almost near the middle of channel for its deep draught need deep water. There are big 44% and 37% within the no.7 and no.8 interval, these ship' length is between 100 and 200, ship' breadth is less than 30m.This means 82% of ship choose to navigate as starboard side of channel, but these ship can’t exceed the bolder of no .8 interval for the outside water’ shallow depth. Within the no.9 interval there 9% ship choose to navigate, these ship’ length is less than 80m and breadth less than 15m for their small tonnage and shallow drought, near outer side of channel can meet their need and safety.

3.3.2 Statistic of going-out area

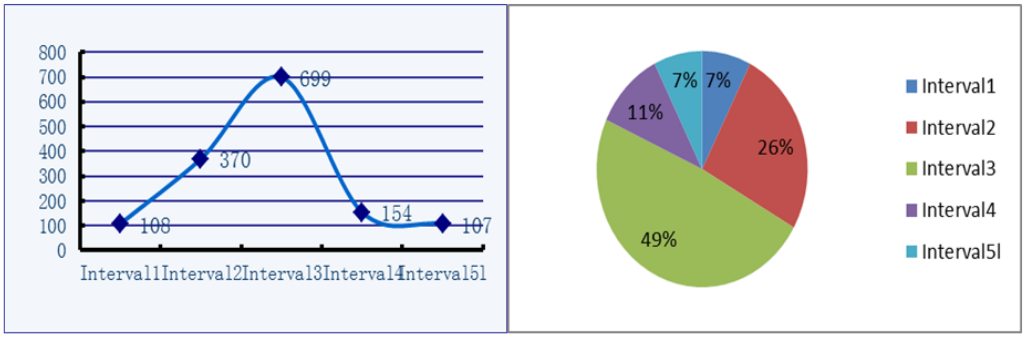

Figure 6. The distribution of leaving ship’ sailing position

As shown in Figure 6, there are a few percent of ship navigating within the no.5_l and no.4, during which there is 6% ship within the no.5_l and 11% ship within the no.6 sailing interval, these vessels’ length is more than 200m, vessels‘ breadth is more than 30m,these ship choose to navigate almost near the middle of channel for its deep draught need deep water. There are big 49% and 26% within the no.2 and no.3 interval, these ship ‘ length is between 100 and 200,ship’ breadth is less than 30m.This means 82% of ship choose to navigate as starboard side of channel, but these ship can’t exceed the bolder of no .2 interval for the outside water ’ shallow depth. Within the no.1 interval there 8% ship choose to navigate , these ship’ length is less than 80m and breadth less than 15m for their small tonnage and shallow drought, near outer side of channel can meet their need and safety.

3.4.3 Statistic of whole channel

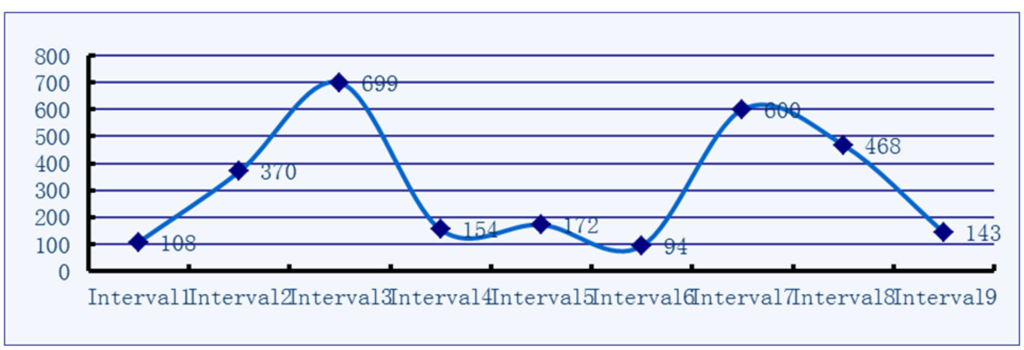

Figure 7. Lateral distribution of ship’ sailing position within the whole fairway

Above shows the ship lateral position distribution within the Xiamen channel, as we see, the amount of ship is increasing from the outer side of channel and reach the top at a quarter width of channel, but there are a few ship at the center of channel. Ship' lateral position is affected by two main reasons, firstly it is affected by the notion of keep the ship as starboard side as possible, this is the reason that there is a few ship choose to sail in the central of channel. On the other hand, navigator must consider ship manoeuvre characteristic and the information of channel, such as the depth of channel and navigational aids. Thus the ship can't navigate too near the starboard side of channel, a quarter width of channel is best choice of mainly middle size ship. Small tonnage ship choose to navigate the outer side of channel, because the shallow water can meet their safe sailing need.

4 Conclusion Analysis

With the theory of marine traffic engineering and data mining technology, the regularity of lateral distribution of ship' sailing position within the Xiamen two-way channel is mined and counted using the shipborne AIS data. This paper characterize the lateral position use ratio of channel, revealing the extent and percent of ship navigating within the two-way channel affect by the <rules>. It proved the navigator' complying attitude toward <rules> and <rules>' good affection on improving the safe navigation within the channel. The result can offer guide to ship operator when choose the lateral based on their ship' characteristic and marine traffic management.

Abstract: For solving problem of heterogeneity data process and low data processing capability in IOT, data in IOT is abstracted as "Context"; taking "Context" as the unified object in IOT big data process, a model of big data process based on Hadoop framework (HDC) is designed. Finally, apply the proposed model to solve problem of vehicle scheduling in petroleum products distribution, capacity of data process is validated by MapReduce distributed parallel computing experiments. Results of the experiments show that HDC has obvious excellence in big data process compared with ordinary computing system.
Keywords: Big data; Hadoop; Internet of things.

1 Introduction

In modern society, distribution is the core business of the whole logistics activities. For oil products logistics, distribution is the procedure of transportation from oil depots to gas stations or to other end-users, which is the last and most important link between oil depots and end users. It plays a key role for business efficiency improvement of oil enterprises [1][2].

In recent years, IOT is applied in more and more fields. In petroleum products distribution, IOT is used in products storage, transportation, and also in clients' inventory and the managing level is improved rapidly. Big data management generated from IOT of petroleum products distribution is a key factor which has restricted the improvement of this filed.

Therefore, there are too many different types of data collecting ends in IOT, data collected from these ends is not only of characteristics of traditional big data, for example, large in volume, high in real time; and also has the unique feature of IOT information, for example, obvious heterogeneity, complex relation, fast data growth and high frequency of data switching and querying [1]. Thus, technical support requirements in IOT data process are much higher in recent years.

Currently, there are already a lot of successful solutions for big data in IOT environment, among which Hadoop distributed system architecture is the most successful solution popularly applied. Hadoop is a distributed software framework which can process large amounts of data through a distributed system and has high reliability and good scalability. Hadoop distributed file system HDFS, distributed computing model MapReduce and distributed database HBase are its three core technologies.

From the existing researches, in (Xue yuan su,2012) ,(Cui Jie,2012) and (Abhishek Verma,2012) architectures of information processing system for massive sensor data in IOT environment are proposed. These models have a high data process capacity, but can't solve problems of heterogeneous data process in IOT. Heterogeneity is one of the main characteristics in the IOT data, so that establishing a unified data model for IOT big data process is in strong demand. In (Abhishek Verma,2012), limitation in query with complex structure is solved in some extent, but data process capacity is still low and needs to be improved.

Since the limitation of existing researches in heterogeneity data process and low data process capacity in IOT environment, a Hadoop big data processing model (HDC) is proposed. In HDC, big data and client requirements are abstracted as “Context” which is the unified object to be processed.

Finally, apply HDC to solve problem of big data process in petroleum products distribution. Results show that the HDC is of high efficiency in data process capacity, response capacity, and data execution capacity.

2 Data Model in IOT

In the IOT, entities include the dominant entity "person", computing entity "machine" and end entities with a sense of ability to identify and control the "objects".Data heterogeneity is obvious in data transferring among different entities. In order to process heterogeneous data uniformly and shield heterogeneity to upper applications, a unified abstraction model for heterogeneous data in IOT is in great demands. In HDC, client service requirements and the collected data are uniformly modeled as "Context".

Data in the IOT environment mainly includes: status, security, transaction processing, etc. In order to encapsulate these information in a unified model, this paper presents a data model for IOT object named as "Context" and is the uniform data and client requests format to be processed in HDC which is defined in Definition 1.

Definition 1: "Context" is composed of five attributes: *Context* = (*id*, *t*, *pos/region*, *mode*, *data*). Meanings of the attributes are:

- *id*: object id. It is the unique object identifier.
- *t:* data collected time.
- *pos*/*region: pos* is the data collected location, and this attribute is for object

monitored by point; *region* is the data collected area, and this attribute is for object monitored by region.

- *mode:* data acquisition manner. For example, perception, input, reasoning, checking, feedback and etc.
- *data:* main information. It is data information to be transferred and processed.

3 Big Data Process System Model

Utilizing "Context" as the unified data object, a Hadoop big data processing model named as HDC is proposed to satisfy distributed processing requirements. HDC is focus on improving data processing capacity of traditional Hadoop framework.

3.1 HDC "CONTEXT" PROCESSING MODEL

HDC mainly includes modules of data collection, data adaption, context generation, context preprocess, context pool, context perceiving, context execution and etc. With sensors as the end devices, context processing model and its data processing procedure are expressed in detail in the Figure 1.

As shown in the Figure 1, data collected from sensors of IOT ends will be encapsulated as the "Context" through "Context Adaptor"; the collected data are often electrical signal, digital signal or a string without specific meaning. Procedure of data mapped from original collected information to "Context" is called as context adaptation (Adaption), which can be expressed as adaptation: S->C. The input S for data adaption is data collected from IOT ends and output C is the "Context Collection" which can be identified by system and will be added into context nodes. The "Context" in context nodes will be handled by preprocess modules, so that valid "Context" will be added to "Context Pool" otherwise to be separated. The "Context Analyzer" fetches the "Context" periodically according to rate of heartbeat, and the advanced "Context" will be generated after analyzing and clustering; advanced "Context" assembles all necessary components for execution and then corresponding operation will be executed; finally, "Context" in execution results needed for feedback will be put back to context nodes for future process.

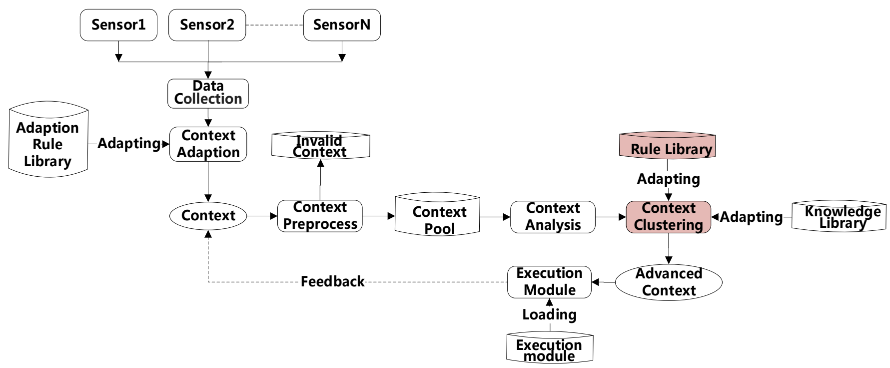

Figure 1. Model of "Context" processing

3.2 DISTRIBUTED PARALLEL PROCESSING MODEL BASED ON CONTEXT QUEUE

The data processing flow shown in the Figure 1 is only a single data processing point in the IOT. In fact, data collection nodes in the IOT are often of characteristics of complex structure, wide distribution and massive quantity, so that single point data processing model can't meet requirements in the IOT environment. Thus, a distributed parallel processing model is required to enhance its practicability.

Based on the single point data processing model, HDC uses Hadoop as basic framework and mainly includes four layers which are computing layer, persistence layer, storage layer and processing layer. In detail, persistence layer manages "Context" access; storage layer stores information of historical "Context" and rules in rule library; computing layer is in charge of data processing and the generated "Context"; process layer listens "Context" in context queue through "Context Listeners" and dispatch them to external interfaces for further process. Considering the limitation of low real-time data processing capacity of Hadoop, the "Context Queue (CQ)" is proposed to be added to HDC as an assistant storage and the improved model structure is shown in the Figure 2.

As shown in the Figure 2, the storage layer is composed of HDFS and HBase. Mass sensor data collected can be stored directly to HDFS or be transformed to "Context" by "Context Adaptor" and then added to the CQ. MapReduce listens "Context" in the CQ and write periodically to HDFS and HBase. As the distributed storage medium for massive sensor information, HDFS and HBase are the base for distributed parallel data processing. MapReduce algorithm in computing layer processes "Context" from context cache pool in parallel, calls the external interfaces for execution and stores results generated to HDFS. "Context Listener", "Context Queue" and external interfaces together formed the "Context Queue Processing Model" (CQPM), which can not only satisfy system distributed and parallel requirements, but also achieve demands of higher system.

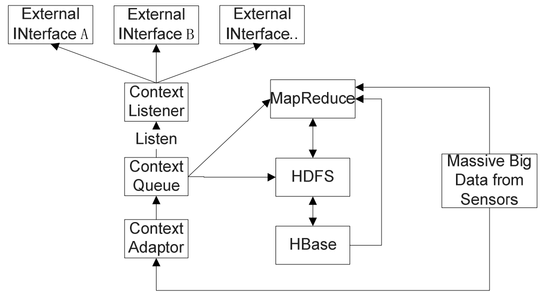

Figure 2. Distributed parallel process model

4 Model Validation and Analysis

Traditional single data process system (SDS) utilizes conventional techniques and consumes expensive computing resources. Simultaneously, SDS uses single server to process data so that data computing capacity is relative. In this section, taking vehicle scheduling in petroleum products distribution as the test case, data process capacity between HDC and SDS is compared and data query ability is also tested.

4.1 TEST CASE

Using the in-transit petroleum products status data collected during distribution procedure as the experiment sample data, which can be defined as vector V_t.

$$V_t = \begin{bmatrix} V_{11t} & \cdots & V_{1nt} \\ \vdots & \ddots & \vdots \\ V_{m1t} & \cdots & V_{mnt} \end{bmatrix} \tag{1}$$

In the vector V_t, row vector V_{it} ($V_{it} = [V_{i1t}, V_{i2t}, V_{i3t}, \ldots, V_{int}]$) is the "Context" information transmitted from some entity at time t. In V_t, m is the number of entities and n is the number of attributes in the one "Context".

The sample data of vehicle information is consisted of two parts: vehicle basic information and vehicle in-transit information. Vehicle sample is defined as vector U_t.

$$U_t = \begin{bmatrix} U_{11t} & \cdots & U_{1nt} \\ \vdots & \ddots & \vdots \\ U_{h1t} & \cdots & U_{hnt} \end{bmatrix} \tag{2}$$

In the vector U_t, U_{jt} ($U_{jt} = [U_{j1t}, U_{j2t}, \ldots, U_{jnt}]$) is the combination of vehicle basic information and current state. The elements in U_{jt} are attributes such as vehicle type, unit transport charge, current state and etc.

Define the best scheduling scheme as one which can not only meet distribution requirements but also achieve a minimum cost. The objective function is defined in formula (8).

$$Min(cost) = d_i(s(V.U)).u_i(s(V.U)) \quad (3)$$

In the formula(3), s(V.U) is the vehicle collection satisfying requirements for distribution. d_i(V.U) is the total distribution distance and u_i(s(V.U)) is the unit price for transportation.

The experiment sample includes distribution status data collected from 10000 (m = 10000) time points and vehicle information data from 100 (h = 100) time points. In map phase, satisfying vehicle collection is got by matching sample data of petroleum product status and vehicle information to meet the distribution requirements; in reduce phase, by analyzing and calculating collections from map phase so that the best scheduling scheme with minimum cost can be obtained.

Hardware configurations of the experiments are shown in the Table1, in which, C_1 is the master server which has relatively better hardware condition. $C_2 \ldots C_{15}$ are the identical slave servers, which are of lower hardware configuration with respect to C_1.

Table 1. Hardware configuration of servers

Name	Configuration	Role
C_1: DELL (Master Server)	Intel(R) i5 CPU 4G Memory 64 Bit Redhat Linux	Datanode, Tasktracker, Jobtracker
C_2 to C_{15}: DELL (Slave Servers)	Intel(R) i3 CPU 2G Memory 32 Bit Redhat Linux	Namenode, Datanode, Secondarynode

We use number after model name to indicate number of servers in experiment environment. For example: experiment environment including five servers in cluster is respectively expressed as "HDC-5" and "SDS-5".

4.2 DATA PROCESSING CAPACITY COMPARISON TEST

As conditions shown in the Table 1, a simulation model is established by MatLab and the objective function value can be calculated by formula (8). Through continuous integrating server resources to experiment environment, nine distributed parallel computing experiments respectively with 1,2,4,6,7,8,10,12,15 servers were carried on. An average data processing capacity (processing capacity is the reciprocal of data processing time) of SDS and HDC are shown in the Figure 3 and data processing time in the Table 2. In the Figure 3, abscissa represents number servers in the cluster.

It can be seen from the Figure 3 and Table 2, in the cluster with 1, 2, 4 servers, SDS has a better performance than HDC (because map and reduce tasks themselves will consume some system resources); with continuous integration of servers, computing capacity of HDC has been rapidly increased. When the number of servers integrated reaches 6, data processing performance of HDC begins to show some advantages than SDS. In the experiment environment with 10 servers, data processing capability of HDC-10 is more than 200 times of SDS-10.

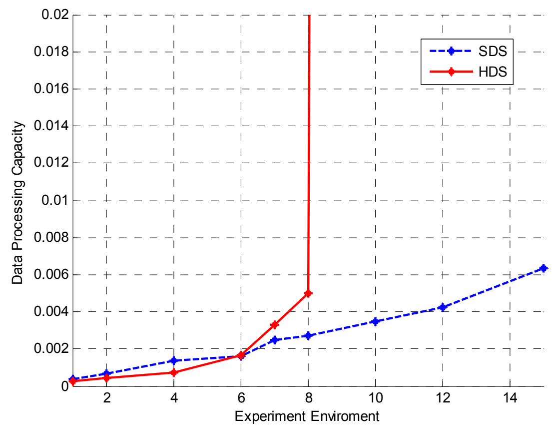

Figure 3. Average process capacity contrast of HDC and SDS

Table 2. Average sample process time contrast of HDC and SDS

Name	Time(ms)	Name	Time (ms)
SDS-1	2568	HDC-1	3469
SDS-2	1484	HDC-2	2377
SDS-4	742	HDC-4	1350
SDS-6	632	HDC-6	598
SDS-7	402	HDC-7	305
SDS-8	371	HDC-8	200.2
SDS-10	287	HDC-10	1.2
SDS-12	235	HDC-12	0.8
SDS-15	157	HDC-15	0.4

4.3 DATA PROCESSING RESPONSE CAPACITY VALIDATION

In this section, still using the case in section 4.1, validation of data processing response capacity is tested.

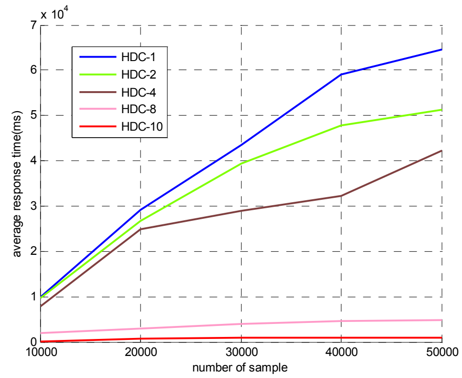

Figure 4. HDC Average response time test

Table 3. HDC average response time (ms) test

Number / Name	10000	20000	30000	40000	50000
HDC-1	10017	29090	43587	58988	64577
HDC-2	9797	26778	39434	47877	51245
HDC-4	7875	24797	28988	32211	42334
HDC-8	2012.5	3012	4013.8	4508.5	4734
HDC-10	417	793	887	921	934

The five distributed parallel computing experiments are processed which respectively includes 10000,20000,30000,40000 and 50000 petroleum sample data and in all experiments, the number of vehicle sample data are all 100. Using the MatLab as the simulation tool, the simulation model was established, and the system response time are shown in the Figure 4 and the Table 3.

It can be seen that data processing performance of HDC is not directly proportional to number of servers in cluster. Especially with relatively more servers integrated to the cluster, the calculation capacity can be greatly enhanced. For example, compared with HDC-8, the HDC-10 is only with two more servers added and the capacity of data processing has been increased by nearly 5 times.

Through the data in above experiments, we can see that in cluster environments with 6 and more servers, HDC has greater advantages in data processing capacity than SDS; at the same time, to improve data process capacity of HDC, it only needs to integrate more servers seamless to the cluster. Especially in a multiple server environment, data processing capacity can be improved rapidly if more servers were added.

5 Conclusion

By analysis of IOT data characteristics, a Hadoop big data processing model (HDC) is proposed. In HDC, big data and client requirements are abstracted as

"Context" which is the unified object to be processed. Based on temporal and spatial characteristics of "Context", definition of CNS is proposed. Uniform Data query operations are also defined upon ideas of CNS. Besides, context & rule matching algorithm and task reorganization algorithm in the CNS is illustrated in detail. Compared with existing researches, HDC is not only able to solve heterogeneous data storage, query, analysis and application in IOT environment but also a good way to improve data processing, data query capability and also data execution effectiveness.

Railway Freight Demand Analysis Based on Multidimensional Association Rules Mining

Yinying Tang[1,2] and Yang Qin[2]

[1]National United Engineering Laboratory of Integrated and Intelligent Transportation, Chengdu 610031, China.
[2]School of Transportation and Logistics, Southwest Jiaotong University, Chengdu 610031, China. E-mail: qinyang740@163.com

Abstract: Railway freight demand are predicted and analyzed by using multidimensional association rule based on Apriori algorithm. At the same time, Three correlation models—goods-weight-transport distance, goods-weight-arrival railroad, goods-weight-arrival province are established by using data mining software Clementine to analysis some railway freight invoice of a railway bureau. Finally, some association rules which are helpful for railway freight demand analysis are obtained. It proved that using multidimensional association rules to analyze the railway freight demand is rational and feasible.
Keywords: Railway freight demand; Data mining; Multidimensional association rule.

1 Introduction

Carrying on an in-depth analysis of the railway freight demand is important for railway department to organize transportation production, to develop the transportation market and to make marketing strategies. Previous researches on the freight demand mostly are concentrated in the mechanism of freight demand, the determination of the influence factors of freight demand and the prediction of freight volume and so on. It couldn't have comprehensive knowledge of freight demand.

This paper use a commonly used data mining technology: the association rule, and establish a multidimensional association rule to analyze a large number of invoice data in practice, in order to find out the relationship between the category of goods, goods weight, transportation distance and other information, and to have a comprehensive knowledge of freight demand, providing the basis and reference for railway enterprises to make decisions.

2 Relevance in the Freight Invoice

Association rule is an important data analysis method in Data mining technology, the purpose is to find out the relationship between different sets of data items in the specified database. Its basis is that if the value of two or more data items in the database repeat and it reaches a certain probability, there is a correlation between them (Ye Xiaoming,2007).

Association rule is put forward by Agrawal et al(Agrawal,1993), which initial application is the analysis of shopping basket in supermarket. After an analysis of store sales record in history, it found that most customers buying milk also will choose to buy bread at a same time, so there is a correlation between milk and bread. Thus the operator may consider bundling the two goods, in order to improve sales.

Freight invoice is the shippers' proof of freight business, which directly reflects the shippers' demands of railway transportation from the category of goods, the weight of goods, transport distance, freight origin destination and so on. Exploring some association rule that cannot be found only by the statistical method through the correlation analysis on the different dimensions of the freight invoice is feasible.

3 Multidimensional Association Rule

According to the selection of data dimension in data mining, association rule can be divided into single dimensional association rule and multidimensional association rule. Single dimensional association rule involves only one dimensional of data. For example, a rule as "grain ⇒ agricultural and sideline products" is obtained by mining the freight invoice. It only involves the attribute dimension of goods category, which indicated that the shippers who send grain mostly also send agricultural and sideline products. If considering multiple dimensions of data, then the mined rules are multidimensional association rule. As the rule "grain∧ Zhengzhou North Station ⇒ Changsha East Station", which involves the attribute dimension of goods category, departure stations, destination station, this shows that the grain is one of the main goods from Zhengzhou North Station to Changsha East station. It can be seen that mining and analyzing freight invoice data with considering only a dimension is difficult to have comprehensive understanding of railway freight demand, so finding the association rule between multidimensional attributes through the multidimensional association mining model, then to analyze railway freight demand is meaningful.

4 Freight Invoice Data Mining Process Based on Multidimensional Association rule

4.1 Association rule mining algorithm

At present, the Apriori algorithm is a commonly used method in mining association rules of data items. The algorithm searches the database successively by using the ideas of iteration, finds all frequent item sets by connecting and pruning, and finally generates association rules from frequent item sets. According to the given minimum support: min_sup, it first find the frequent 1-item set satisfied min_sup, denoted by L_1. Through L_1 connecting to itself, candidate 2–item set is generated, denoted by C_2. By deleting the non-frequent item with pruning in C_2, frequent 2-item set is generated, denoted by L_2. Then L_3 is produced by L_2, so circulates, until L_k is not a frequent k-item set. Finally, the association rules that meet the given minimum confidence: min_conf, are found in all frequent item sets.

4.2 Data preparation

4.2.1 The data source

Some freight invoice data for a station of a railway bureau in January 2015 (export to Excel file, a total of 571 shipping records) are taken as mining object. The data set should be pretreated, converted and discretized and so forth, in order to meet the needs of mining association rules.

4.2.2 Data preprocessing

(1) Data filtering: The redundant field has no significance and reduces the execution efficiency of the algorithm. Therefore, according to research needs, other extra fields are deleted, retaining only the goods category, the name of destination, transport distance and weight for mining analysis.

(2) Data cleaning: When inputting data, wrong operation and other reasons will lead to some of the data or field miss information and format errors, etc. For these cases, the parties need to complete or fix the problem data. An entire record should be deleted if it cannot achieve the prescribed cleaning requirements, lest it has impact on the final mining results.

After the pretreatment, 568 complete records are retained for mining analysis.

4.2.3 Data conversion

(1) The goods category field: Because the goods category is numerous, so the delivery record belong to a category of goods is not much, which will lead to this record's support is not enough, and not conducive to the mining of the association knowledge. Therefore, according to the regulations of *Table of the classification and code of Names of Railway Goods*, All goods category information was merged into 26 categories. Thus the number of cargo records of a certain categories was increased.

(2)The origin-destination field: Similarly, merging the origin-destination information according to the categories also contribute to the discovery of association rules. We can convert the origin-destination information to the two new fields. One is the province that the origins or destinations belong to, so we can know that supply and demand of the goods in different parts. Another is the railway bureaus that the origins or destinations belong to, so that we can know the goods circulation between each railway bureau. Obviously, the meaning of rules according to two fields is different.

4.2.4 Data discretization

In the process of transport of goods, some attribute values are continuous, such as the goods weight, transport distance etc. But Apriori algorithm can only deal with discrete attributes. Therefore, discretization of continuous attributes is necessary.

(1) Discretization of transport distance value: This paper uses the predefined concept hierarchy to discretize transport distance attribute. The discretization of numerical attributes with interval values can be processed like goods category (each distance interval as a class). It is generally believed that 0-500km is the road transport market, while railway transport market is 500-1500km (Lei Dingyou,2003), but as Railway Bureaus operated bulk cargo trains and high-speed railway express trains, transport distance also began to involve 500km inside and 1500km outside. Therefore this paper divides distance information into four classes: I (0-500km), II (500-1000km), III (1000-1500km) and IV (more than 1500km).

(2) Discretization of cargo weight: Local discretization methods are commonly used with equal width interval method, frequency interval method (Zhang Wenyu, 2002). As the goods weight information is dispersive, the above method is not applicable for this research. So this paper uses K-means clustering method to cluster all the weight information into three classes: I (0~0.5 tons), II (0.5~1.5 tons), III (1.5~3 tons). Some clustering results as shown in Table 1.

Table 1. Cargo weight information clustering results

Sequence Number	Weight (tons)	Classes	Sequence Number	Weight (tons)	Classes
1	3.000	III	5	0.410	I
2	2.115	III	6	0.340	I
3	2.250	III	7	1.850	II
4	1.200	II	8	0.580	I

Finally, after processing, the format of freight invoice data table used in the data mining as shown in Table 2.

Table 2. Freight invoice data after preprocessing

Sequence Number	Cargo Category	Cargo Weight	Transport Distance	Arrival-railroad	Arrival-province
1,2, …,	26 classes	I, II, III	I, II, III, IV	18 railroads	34 provincial administrative region

4.3 The establishment of multi-dimensional association rules mining model

Subsequently, those preprocessing freight invoice data are the data source, and three Apriori correlation model are established by software Clementine12.0.

(1) The goods-weight-transport distance correlation model: through the data filtering, the categories and weight of goods are the input, the transport distance are the output, the minimum support and minimum confidence are set to 5%, 25%;

(2) The goods-weight-arrival railroad correlation model: through the data filtering, the categories and weight of goods are the input, the arrival-railroad are the output, the minimum support and minimum confidence are set to 3%, 25%;

(3) The goods-weight-arrival province correlation model: through the data filtering, the categories and weight of goods are the input, the arrival-province are the output, the minimum support and minimum confidence are set to 3%, 25%.

The whole process of data mining is shown in Figure 1.

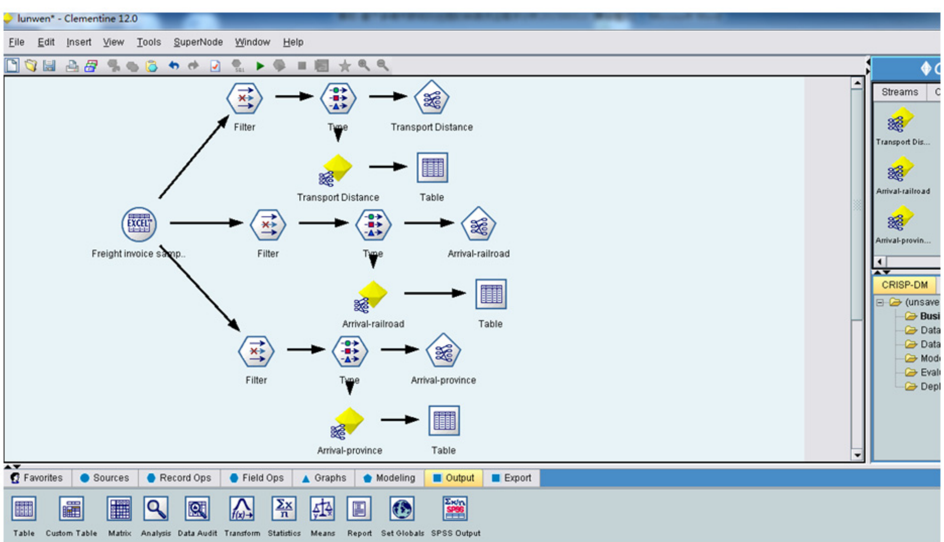

Figure 1.The process of data mining

4.4 The test results

Obtained by data mining, some significant association rules between different attribute fields, which are shown in Table 3, Table 4, and Table 5.

Table 3. Association results of goods-weight-transport distance correlation model

Sequence Number	Association rules	Support %	Confidence%
1	Industrial machinery $\wedge$ Class I weight $\Rightarrow$ Class IV transport distance	5.254	70
2	Pharmaceuticals $\wedge$ Class I weight $\Rightarrow$ Class IV transport distance	5.079	68.966
3	Grain $\wedge$ Class I weight $\Rightarrow$ Class IV transport distance	38.704	59.729
4	Food and tobacco products $\wedge$ Class I weight $\Rightarrow$ Class IV transport distance	6.48	56.757
5	Other goods $\wedge$ Class I weight $\Rightarrow$ Class IV transport distance	6.83	43.59
6	Electronic, electrical machinery $\wedge$ Class I weight $\Rightarrow$ Class II transport distance	5.429	41.935
7	Textiles. Leather, fur and products $\wedge$ Class I weight $\Rightarrow$ Class IV transport distance	5.779	36.364
8	Electronic, electrical machinery $\wedge$ Class I weight $\Rightarrow$ Class IV transport distance	5.429	32.258
9	Textiles. Leather, fur and products $\wedge$ Class I weight $\Rightarrow$ Class III transport distance	5.779	30.303
10	Grain $\wedge$ Class I weight $\Rightarrow$ Class III transport distance	38.704	25.792

Table 4. Association results of goods-weight-arrival railroad correlation model

Sequence Number	Association rules	Support %	Confidence%
1	Electronic, electrical machinery $\wedge$ Class I weight $\Rightarrow$ Inner Mongolia	5.429	41.935
2	Textiles. Leather, fur and products $\wedge$ Class I weight $\Rightarrow$ Liaoning Province	5.779	33.333
3	Other goods $\wedge$ Class I weight $\Rightarrow$ Liaoning Province	6.83	28.205

Table 5. Association results of goods-weight-arrival province correlation model

Sequence Number	Association rules	Support %	Confidence %
1	Electronic, electrical machinery $\wedge$ Class I weight $\Rightarrow$ Harbin railway bureau	5.429	48.387
2	Textiles. Leather, fur and products $\wedge$ Class I weight $\Rightarrow$ Shenyang railway bureau	5.779	33.333
3	Industrial machinery $\wedge$ Class I weight $\Rightarrow$ Shanghai railway bureau	5.254	30.0
4	Food and tobacco products $\wedge$ Class I weight $\Rightarrow$ Shanghai railway bureau	6.48	29.73
5	Other goods $\wedge$ Class I weight $\Rightarrow$ Shenyang railway bureau	6.83	28.205
6	Agricultural and sideline products $\wedge$ Class I weight $\Rightarrow$ Shanghai railway bureau	4.904	25.00

In Table 3, rule 1 indicates that the main demand of distances for industrial machinery is concentrated in 1500 km outside. Rule 3 and 10 show that the demand of distances for many small batch grain in 1000km outside. And through the entire table 3, it can be seen the demand of distances for many kinds of goods are existed in 1500km outside. In the transport market above 1500km, compared with the air transport, railway transport has many advantages, such as great capacity, low cost, safety and not being affected by weather and so on. To further cement and expand transportation market above 1500 km, the railway bureau can consider operating high-speed express for long distance transport

From Table 4, it can be seen that, in the goods sent by this bureau, the main destination of electronics, electrical machinery is Inner Mongolia. Many Textiles. Leather, fur and products, other goods are flowed to Liaoning province. So the bureau should launch marketing work actively in the local, and carry out in-depth cooperation with production enterprises, to understand the enterprise production cycle, which can guarantee enough supply of goods and arrange reasonable transportation production plan.

In Table 5, we can see goods circulation through these rules, which is convenient for the railway bureau to master goods transport demand. And we can get the usage of different types of trucks, which is helpful for operator to arrange for trucks, to improve efficiency, and to reduce the cost of transportation.

5 Conclusions

This paper uses multidimensional association mining technology to analyze freight invoice data, and obtain some illuminating association rules. Compared with statistical and traditional data analysis, it has a more comprehensive understanding of the railway freight demand. But the data value lies in the circulation, if an enterprise only focuses on their own data, it cannot has a great development in the era of big data. Thus, how to exchange data with production enterprises, planting, and even other transportation companies, in order to achieve a win-win situation, is an important problem to study for the railway enterprises in the future.

Discussion about Rail Freight Market Reclassification Based on Freight Production Data

Qinglin Li and Yinying Tang

School of Transportation and Logistics, Southwest Jiaotong University, Chengdu 610031, China. E-mail: yinyingtang@swjtu.cn

Abstract: Nowadays, the information technology has been basically realized during the process of the rail freight production with a large number of freight production data has been accumulated. If these data can be reasonable used, it will provide effective assistance for railway freight marketing. Based on this, the article uses three production indexes (freight turnover growth rate, relative market share rate and the internal freight share rate) to build a model. Combining with the Excel software, we reclassify the existing goods category. Put forward the corresponding marketing strategies about the reclassification category according to actual condition.
Keywords: Production indexes; Goods category; Railway freight market.

1 Introduction

So far, many experts think that market segmentation is an important part of marketing, effective market segmentation helps companies quickly and efficiently identify target markets, develop targeted marketing strategies. Market segmentation is in accordance with the buyer's needs and desires, attitudes purchase, buying practices of different variables, the market is divided into a number of different behaviors buyers groups.

The traditional classification of rail freight is mainly based on single variable for simple classifying, according to the classification of goods stipulated by the government, the goods which rail can transport can be divided into oil, coal, cotton, salt, containers , etc. 28 classes. The reclassification is based on the company's data, using data processing tools to build model. Then find the rule of freight market from the data. So, in this paper, based on marketing theory, there will be a repartition of the existing classification.

2 The Market Reclassification Based on Production Data

2.1 The establishment of the model

During the reclassification, for one kind of goods, the growth rate of turnover volume will be compared with the growth rate of GDP. And it is acceptable to set the average relative market share as 50%. The railway has 25 kinds of goods category. So it is reasonable to set the average interior freight resource occupancy rate as 4%. Based on the present goods classification, this article use the growth rate of turnover volume (L), the relative market share rate (X), and the interior freight resource occupancy rate (N) as three new indexes for reclassification. The model is as following:

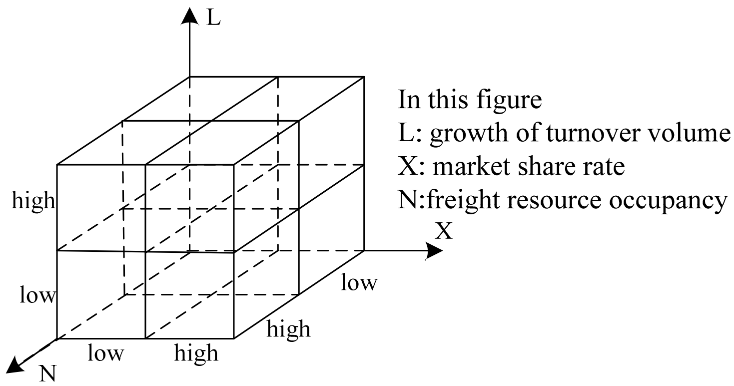

Figure 1 the model of the railway goods reclassification

The three indexes are calculated as following:
The growth rate of turnover volume for i:

$$L_i = \frac{Z_i - Z_i^{'}}{Z_i^{'}} \times 100\% \tag{1}$$

$Z_i, Z_i^{'} \rightarrow i's$ freight turnover volume in this year and last year

The relative market share rate for i:

$$X_i = \frac{q_i}{C_i} \tag{2}$$

$q_i, C_i \rightarrow i's$ volume of freight traffic and $i's$ yearly output in this year

The interior freight resource occupancy rate:

$$N_i = \frac{Z_i}{\sum Z_i} \times 100\% \tag{3}$$

$\sum Z_i \rightarrow$ all kinds of goods's freight turnover volume in this year

2.2 The repartition of the market

According to the three indexes, we can reclassify the market as following:

Table 1. The advance classification of the railway freight market

Market category	Turnover volume's growth	Market share rate	Resource occupancy rate	Market characteristics
I	high	high	high	Good prospect, high market share, more freight resource
II	low	high	high	Bad prospect, high market share, more freight resource
III	high	low	high	Good prospect, low market share, more freight resource
IV	low	low	high	Bad prospect, low market share, more freight resource
V	high	high	low	Good prospect, high market share, less freight resource
VI	high	low	low	Good prospect, low market share, less freight resource
VII	low	high	low	Bad prospect, high market share, less freight resource
VIII	low	low	low	Bad prospect, low market share, less freight resource

3 Processing Data

3.1 Data compilation

From China Statistical Yearbook, we get the recent ten years' data as following:

Table 2. The year 2003—2013 production data of five main kinds of goods

	Year	Coal	Coke	Oil	Steel	Fertilizers	Aggregate
Turnover volume (Million ton kilometers)	2003	505540	63789	102934	165545	72312	1632341
	2004	571298	66151	109964	178964	83276	1810994

3.2 Processing data

We use nonlinear regression analysis to get predictions of the three indexes. The bigger R is, the higher correlation degree is. Based on calculation of regressive analysis, using the trend line fitting function of Excel software, we get the regression curve of the three indexes as follows:

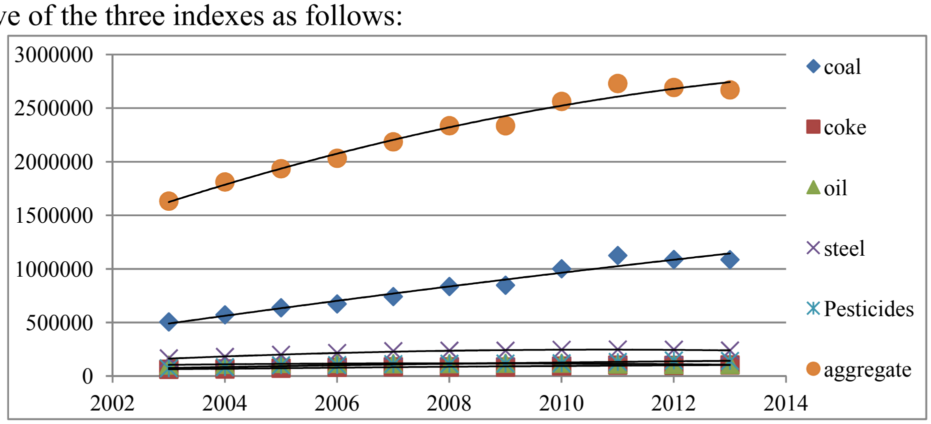

Figure 2.Regression analysis prediction of the turnover volume of the goods

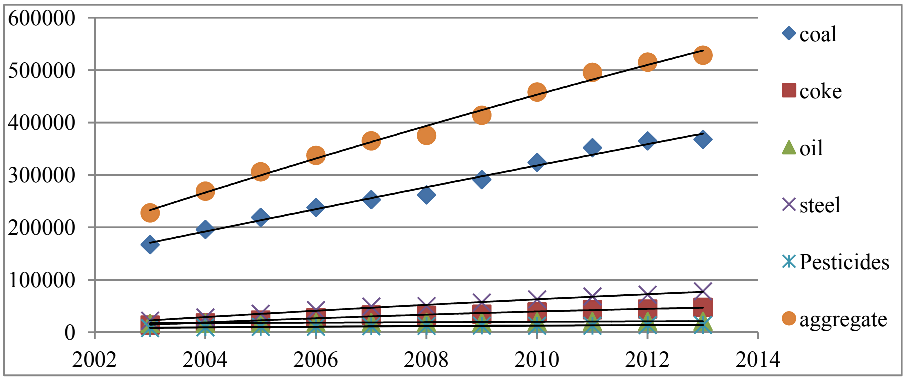

Figure 3.Regression analysis prediction of the yearly output of five goods

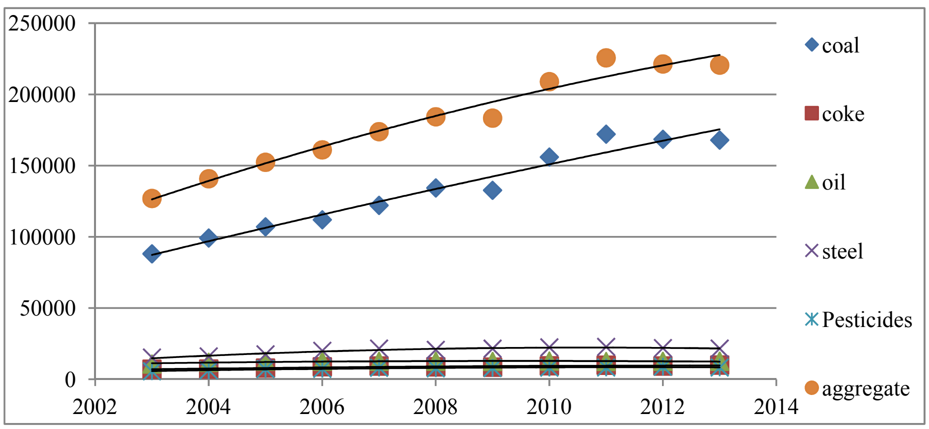

Figure 4.Regression analysis prediction of the freight volume of the five goods

3.3 The consequence

Combining the quadratic regression curve equation, get the table as following:

Table 3.The prediction of the five main kinds of goods in 2014

Category of goods	Coal	Coke	Oil	Steel	Pesticides and fertilizers	Aggregate
Turnover volume (tons kilometer)	1212914	111675	117003	247272	148367	2808359
yearly output (tons)	400000	51840	20900	84012	13654.5	570406
volume of freight traffic (tons)	184583	9346	11870	21292	8319	235410

4 The Market Classification and Marketing Strategy

Using equation (1) (2) (3) to calculate the three indexes in 2014 is as following:

Table 4.Five main goods' three indexes and market reclassification

Goods	Growth rate of turnover volume L_i (%)	relative market share rate X_i (%)	interior freight resource occupancy rate N_i (%)	Market category
Coal	11.67	66.1	43.19	I
Coke	8.04	18	3.98	VI
Oil	8.04	56.79	4.17	I
Steel	3.486	25.3	8.8	IV
Fertilizers	4.89	60.9	5.28	II

Combining with the actual situation, the marketing strategy is as following:

Oil, coal is I market. These two goods have good prospects. Demand of energy is growing with the development of China, so the marketing department should seize this opportunity to seize the energy transport market. Coke is Class VI, this kind of goods has good prospect. Coke is easy to wear and tear, so transit should be reduced during the transport. Steel is Class IV with poor prospects, rail is not its main mode of transport but take more resources. In recent years, domestic infrastructure is slowing down. So for steel, railways should find other sources as soon as possible. Pesticides and fertilizers are Class II with low transport rate. China's production of pesticides and chemical is too high in recent years. In view of this situation, the railway should make proper preparations, actively seeking new sources of supply, do not sit still.

5 Conclusions

Coal, coke, oil steel, pesticides and fertilizers these five very important freight category are important materials for national economic development, to analysis them can provide a reference for freight companies. So, this paper analyzes these five categories of goods freight production data over the past decade. In this process, we use the nonlinear regression method and Excel software to get the reclassification and appropriate marketing strategies. This paper discusses the rail market reclassification based on freight production data. In order to push the pace of rail freight transport data marketing in the actual freight market, we need more data with a more scientific approach.

Abstract: In order to establish and optimize pallet pooling information system, it is the key issue to analyze and mine the related data on the existing pallet pooling system. Here, firstly, the crucial techniques of pallet pooling system and spatial data mining method based on GIS are presented. Then, the functional structure of the pallet pooling system is proposed. Finally by erecting an actual model of spatial data mining system, with the utilization of relevant mining algorithms, a case is studied to dig out the implicit knowledge of spatial database and visualize the output of the spatial data mining result. This system model can not only display the knowledge (the amount of each pallet service station pallet, current on-hand quantity), but can also be found hidden in the pallet pooling system information platform implicit knowledge (in which areas suitable for establishing pallet service station, and where the pallet to more intense). A conclusion is also given to provide auxiliary decision-making to managers.

Keywords: Freight pallet pooling system; GIS; Spatial data mining.

1 Introduction

Pallet pooling system is responsible for pallet leasing, recycling, maintenance and update of social service system (WU 2003).With the increasing scale of pallet pooling system, pallet service stations, pallet rental customer and the increasing number of pallets, data and information derived from the pallet pooling system is increasingly enormous and complex. And spatial data mining based on GIS is to make full use of GIS and computer-related technology, networks, and other resources to manage the pallet pooling system (including hardware and software resources) efficiently in various aspects, such as pallet location, breakage rate, maintenance rate, the number of pallets and other complex information network management of service station. With constant expansion of business, the existing pallet service station cannot meet the demand of customers. Therefore, it is imperative to build the updated pallet service stations to satisfy the growing business needs. According to the result of the data mining analysis, the area where pallet circulation is more concentrated can be analyzed, and the decision to invest a lot of resources can be made accurately. It is the utilization of a series of treatment technologies based on GIS spatial data mining process that can turn the precipitation data into useful knowledge, which can also provide auxiliary decision function.

2 Pallet pooling system functional structure

Pallet pooling system is made up of online public information platform and multiple offline service stations under the reasonable layout. Public information platform is to complete the business flow, information flow, cash flow and electronic commerce related to the pallet pooling business. And pallet service station fulfills the pallet information real-time acquisition and empty pallet of transport, storage, maintenance, and others logistics function (LIU 2012).

In order to integrate the business flow, cash flow, logistics, realize seamless link between pallet rental customer and pallet rental business, promote consistently transportation pallet, such information platform as based on business model and process requirements should be built. By means of information technology, computer technology and network technology, such efficient services can be provided as real-time acquisition, online transactions for rentals business in portal and rental customer support, and the pallet of pallet service recovery, transportation and other business management, as well as other value-added platform services.

3 The method of spatial data mining

There are so many spatial data mining method. According to the found object can be divided into relational database, object-oriented database, spatial database and tense database and text database, multimedia database, heterogeneous database, etc. According to found methods can be divided into machine learning methods(inductive leaning, decision trees, rule induction, based on sample learning, genetic algorithm), the statistical method(regression analysis, discriminant analysis, clustering analysis, the agent simply analysis), neural network(BP algorithm, self-organizing neural network winding), database approach; According to found the task can be divided into the classification, clustering, discovering association rules, time series prediction, evolution, etc. In this paper, it’s will be uses the space clustering algorithm to demonstrate the instance case.

4 Case study

As far as the pallet pooling system in Chengdu is concerned, after a long time of study, it is identified that 200 pallet rental customer business needs of Chengdu, mainly involving the pallet rental customer location coordinates, the number of leasing pallet and the main pallet flow. The k-means clustering algorithm is used to classify the pallet rental customers to determine in which areas some new pallet service stations need to be built.

4.1 Statistical pallet number of pallet service station

Pallet rental customers only need click the "pallet service station" button I that will open a map of Chengdu city, and click what to view in the region pallet service station, the pallet service usage is presented. All pallet service stations, pallet rental customers, such as pallet flow information in the geographical location of Chengdu city, exchange of pallet information and data are stored in pallet pooling system. By means of the statistical analysis of these data, such pallet service information as annual pallet utilization rate, repair rate can be got. Moverover, system management personnel can adopt corresponding decision method to improve service ability.

4.2 Spatial data clustering analysis

As a research branch of clustering, spatial clustering is a process to find the optimal partition. According to the clustering termination conditions, the division is constantly optimized so as to get the optimal solution.

Here, in view of Chengdu 200 pallet rental customers, clustering analysis is presented with the consideration of such data of three dimensions as pallet rental customer location, the number of leasing pallet and pallet data mining on the main flow direction Decisions should be made to determine in which area to erect Chengdu pallet service station and in which key line to support vigorously.

Similar to the traffic OD (Origination to Destination) line, it can be analyzed how much the pallet to lease and where to load goods for a pallet rental customer. Firstly, 200 pallet rental customers from each of the five logistics park of Chengdu are selected. These five areas are Longquan, Shuangliu, Qingbaijiang, bonded logistics center and Xindu respectively. These 200 pallet rental customers are corresponding to the latitude and longitude rental distribution in above five areas. With the operation of the goods, the pallets commute among the five regions. With relevant analysis, it can dig out where communication is more closely, and in which area pallet demand is bigger.

(1) Data source. To be seleced from the transaction data of pallet pooling system, including the number of pallet which pallet rental customers lease, and pallet real-time positioning and flow data.

(2) Data preprocessing. To get the data cleaning and analysis from three dimension: pallet location, the number of pallet leasing and flow direction of the pallet.

(3) Algorithm selection. Using K-means clustering algorithm for mining. K-means algorithm is a typical target algorithm based on the prototype, which is a data point to the prototype of a certain distance as the objective function of optimization, by using the extreme of function as iterative operation adjustment rules. Based on Euclidean distance as the similarity measure, k-means algorithm is a initial

clustering center vector for the number of the optimal classification, makes evaluation index minimum (WU 2011).

Given a certain n of d dimension data set X= {x1,x2,…,xi,…,xn} among them $x^i \in R^d$,as well as to the number of generated data subset k, k-means clustering algorithm to the data object organization for k, C= { c^k， i=1, 2…K} . Each segment stands for a class c^k, each category center is u^i. The similarity and distance judgment criteria are chosen as Euclidean distance calculation at various points within the class to the clustering center distance sum of squares.

$$\mathrm{J}\left(c_k\right) = \sum_{x_{i\in c_k}} \left\|x_i - u_k\right\|^2 \tag{1}$$

The goal of clustering is to make all kinds of total distance sum of square $\mathrm{J}\left(c\right)=\sum_{k=1}^{k} J\left(c_k\right)$is minimal.

$$\mathrm{J}\left(\mathrm{c}\right) = \sum_{k=1}^{k} J\left(c_k\right) = \sum_{k=1}^{k} \sum_{x_{i\in c_k}} \left\|x_i - u_k\right\|^2 = \sum_{k=1}^{k} \sum_{i=1}^{n} d_{ki} \left\|x_i - u_k\right\|^2 \tag{2}$$

Among them, $d_{ki} = \begin{cases} 1, \ x_i \in c_i \\ 0, \ x_i \in / c_i \end{cases}$

From an initial k-means clustering algorithm classification, the data points are assigned to the various categories to minimize the total distance sum of square. As the total distance sum of squares of k-means clustering algorithm increase with the number of category k to reduce (when k=n, J(c) =0), the total distance sum of squares can only under a certain category number k, to obtain the minimum value.

In order to find out whether or not to increase the pallet service station to meet the growing needs of the business. There are five pallet service stations in the original five logistics park. Clustering number is set to 6 that is more effective. So, it should be in the place of clustering 6 to construct a pallet service station, so as to improve the service demand.

Here, R language is used to achieve k-means cluster analysis. Specific operation is as follows.

Firstly, the external data source is collected and saved to excel in the table, then saved as .csv format. In the R language input the following code.

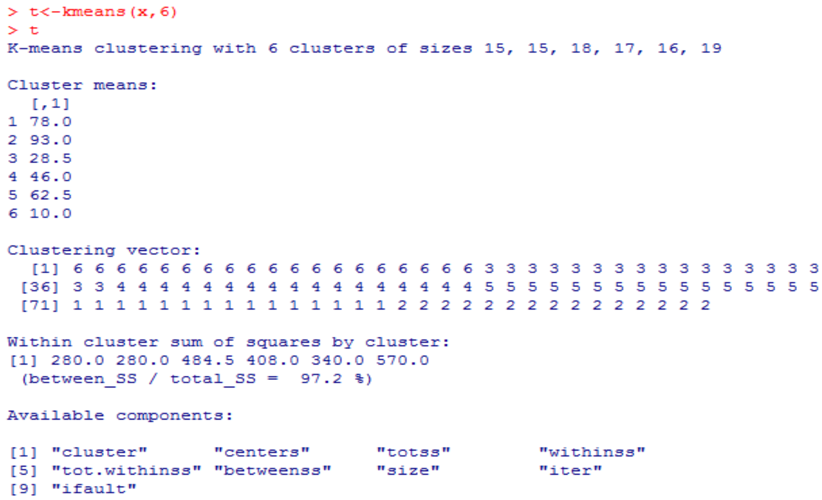
>Read.csv(file= “D:\\work\\data1\\.csv”)

Secondly, the clustering operation is shown as below.

>t<-kmeans(x,6)

>t

The output is as below.



```
> t<-kmeans(x,6)
> t
K-means clustering with 6 clusters of sizes 15, 15, 18, 17, 16, 19

Cluster means:
  [,1]
1 78.0
2 93.0
3 28.5
4 46.0
5 62.5
6 10.0

Clustering vector:
  [1] 6 6 6 6 6 6 6 6 6 6 6 6 6 6 6 6 6 6 3 3 3 3 3 3 3 3 3 3 3 3 3 3 3 3 3
 [36] 3 3 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 4 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5 5
 [71] 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2 2

Within cluster sum of squares by cluster:
[1] 280.0 280.0 484.5 408.0 340.0 570.0
 (between_SS / total_SS =  97.2 %)

Available components:

[1] "cluster"      "centers"      "totss"        "withinss"
[5] "tot.withinss" "betweenss"    "size"         "iter"
[9] "ifault"
```

Figure 1. k-means clustering output

(1) Clustering vector. Each record belongs to clustering (6 on behalf of the sixth clustering, 2 for the second clustering...).

(2)（between ss/total_ss=97.2%）. Set the distance between the sums of squares accounts for 97.2% of the overall distance sum of squares, that is to say, the distance between each cluster achieve to the most.

Then, data are visualized.

>plot cluster(x, t$cluster)

Using word to display the results of data visualization, which is shown in figure 2 as below.

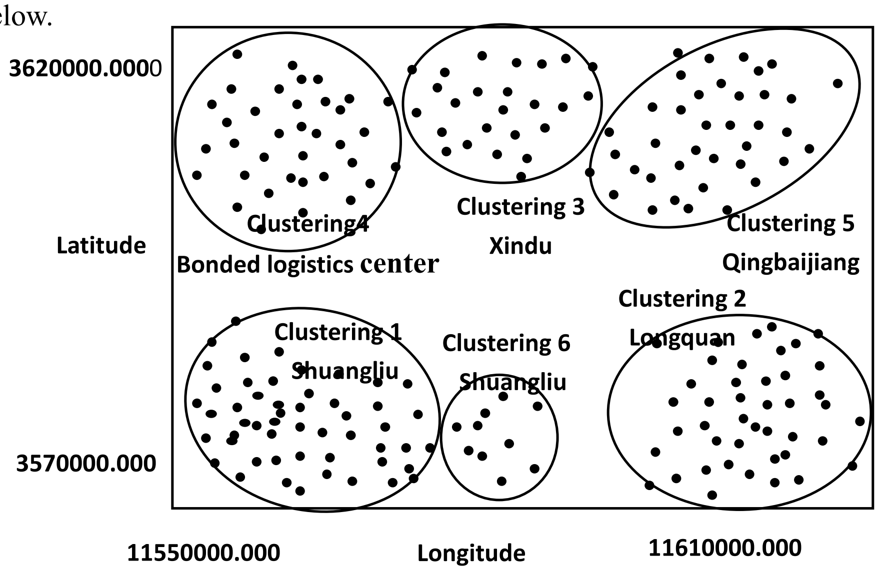


Figure 2. k-means clustering visualization

Finally, the result is analyzed. From above process it clearly seen that 200 pallet rental customers distributed in five area of Chengdu, which gather in these six clustering. The number of clustering 1 and clustering 2 are in majority, which means that the pallet demand in Shuangliu and Longquan is in major, and closely with each other .As the key area of pallet application and circulation, more resources should be put to the side. Clustering 1 and 6 are original in Shuangliu region, and now divided into two clustering, which shows that the gap between these two clustering is relatively large based on space. So, it should be considered whether to build a new pallet service station in order to meet the needs of the grow customers in Shuangliu area, so as to provide better services to pallet rental customers, which will be helpful for the transfer and use of the whole pallet system as well as improvement of customer satisfaction.

5 Conclusion

With the integration of Pallet pooling system and GIS spatial data mining system, a mode of spatial data mining system is proposed, which can not only dig out the explicit knowledge (the number of service stations, each pallet breakage rate, repair rate), but also find implicit knowledge (whether to increase the pallet stations), and the data mining results visualization output in the pallet pooling system (LV 2010). At present, Chengdu will be one of the second batch of pilot cities. In view of the urban joint distribution logistics standard, the pallet standardization can drive forklift, shelves, and all chain standardization. By use of the pallet pooling system and the application of GIS spatial data mining, the efficiency of the pallet on the social circulation, as well as the modern logistics level of Chengdu can be greatly improved, and which will be of important significance to save the cost of logistics.

Abstract: Nowadays, with the rapid development of logistics, the pallet plays a crucial role as a basic carrier for containized unitization. Here, a new commercial mode of the Pallet Pooling System is put forward. There are three aspects to be analyzed such as market analysis, business model, cost structure and revenue model. Firstly, the value provided by the Pallet Pooling system is presented as well as the target market and the marketing tools. Then, there is a discussion about the participants and business processing. Finally, the cost structure, revenue sources of the pallet exchanging platform and the pallet pricing are studied.
Keywords: Containerization; Pallet pooling system; Business mode.

1 Introduction

It is well-known that the application level of pallets is becoming one of the most important symbols of logistics modernization. Combined with forklifts pallets can integrate the scattered cargoes， which forms an effective handling system to greatly enhance the efficiency of loading and unloading. Nevertheless, the statistics of pallet Professional Committee shows that most of pallets are used within the factory rather than recycling in the whole society, which increases the handling work and the cost of logistics.

Pallet Pooling System integrates the pallet resource to recycle in the whole society, so that cargoes need not leave the pallets when transferred among different companies, what have to be changed is only the renter of the pallets. This mode will greatly improve logistics efficiency and reduce the waste of social resources.

Therefore, a new commercial mode of Pallet Pooling System based on the pallet sharing union is put forward, and more details are studied in three aspects including market analysis, business model and revenue model.

2 Market Analysis

Market analysis is the initial step to establish the Pallet Pooling System, which analyzes the market and how to open up the market. This section involves three aspects such as value proposition, target market and marketing strategies.

2.1 Value Proposition

Value proposition is the value which the operator provides to consumers via its products and service. The value that the Pallet Pooling System provides to customers can be described in three aspects.

The first aspect is the realization of the pallet sharing. The Pallet Pooling System integrates the pallet resources to make the pallets shared in the whole supply chain, thereby contributing to the implementation of pallet consistent application. The second one is to provide different rental models which are adaptable to different demands of customers, make the pallets sharing more flexible and wider range of applications. The last one is the participants in the Pallet Pooling System can get certain benefits, including economic benefits and social benefits.

2.2 Target Market

Target market is the company targeted consumer groups. These groups have some commonalities that enable the company to create value for these commonalities. The characteristics of the target market are described in four aspects such as the geographical factors, the object of factors, consumer behavior factors and consumer psychological factors.

Table 1.The target Market of the Pallet Pooling System

factors	Target market		Feature
Geographical factors	Developed cities and moderately developed city		traffic and economic situation more developed
Object factors	Industry	Manufacturing enterprises	The origin of the supply chain which has large demand for pallets
	Company scale	Large or Medium-sized enterprises	Doing a large scale of business which means a large demand of pallets
	Technical level	High technical level	Equipped with more technical facilities
consumer psychological factors	The purpose	Improving efficiency Getting value-added services	Hoping to improve the handling efficiency, and get value-added service
consumer behavior factors	Time point to get into market	Early experience person and Public users	Having advanced ideas and adapting to pallet sharing mode
	Loyalty	Brand loyalists	Willing to give most or even all of their orders to the platform

2.3 Marketing

The pallet exchanging platform provides a kind of service whose main contents are to help the owners of pallet to rent and be responsible for holding delivering and recycling after renting. There are two ways to market for the pallet providers. One is direct marketing, which is to find the potential rental to marketing services. Another is indirect marketing, which is marketing throng the service stations that are distributed in different areas. Therefore, according to different ways of marketing and the feature of the pallet pooling system, four marketing plans are put forward. .

(1)Pre-business promotion on the basis of the early research on the pallet manufacturer.

(2)During the study period of the platform, academic achievements can be published in professional journals and conferences, forming an extremely professional way to promote the platform.

(3)Promoting through the pallet-related associations such as the National Federation of Logistics and Purchasing and some local government departments or business organizations.

(4)Promoting in the industry related professional website.

3 Business model of the pallet pooling system

Business model is a problem which should be solved in the mid-term of Pallet Pooling System development, which includes the Pallet Pooling System, its related business activities and business processing.

3.1 Participants in the pallet pooling system

There are four participants in the pallet pooling system, including the pallet exchanging platform, pallet providers, pallet lessee and service station. Among them, the platform is the core part, and the three other parts join the pallet pooling system to form the confederation.

(1)Pallet exchanging platform consists of network information platform and operating company. Network information platform is responsible for online information publishing and receiving orders. And the operating company is responsible for order scheduling and the capital settlement management.

(2)The pallet providers are the companies which own the certain amount of empty pallets that can be rented. They can register as members of the platform and publish the relevant information of pallets. They can make profits by renting pallets without caring the process of distribution, recycling and transition.

(3)The pallet lessees are the companies which look for the pallets that can meet their needs to rent and pay a certain amount of rent.

(4)The service station cooperates with the platform and provides pallet service such as holding, distributing, recycling and maintenance so as to earn a certain amount of logistics cost.

3.2 Business activities of pallet pooling system

There are four stages in the business process including information dissemination stage, order processing stage, pallets transferring stage and funding segmentation stage. More details are analyzed in the business process to form these four stages. A transaction flow diagram is also given in figure 1 as below.

(1)Information dissemination stage. After registering as a member of the platform, the pallet provider can publish the pallet information in the platform.

(2)Order processing stage. Pallet provider submits orders to the pallet exchanging platform in accordance with the needs of the pallet type, quantity, location, and etc. After receiving the orders, the platform will assign them to the appropriate service station based on the order information. Service station will finish the off-line business.

(3)The pallet transferring stage. After receiving the order, the service station will pick up pallets and delivery them to the right place in the right time according to the order. The pallets will turnover between the different companies with cargoes that loads until the cargoes are off the pallet, and then they will be returned to the local service station by the last lesser.

(4)Funding segmentation stage. After the pallets finish a transferring process, the pallet lesser should pay rent to the platform. And then, the platform will divide the profit to the pallet providers, service station and the platform itself according to a certain rate.

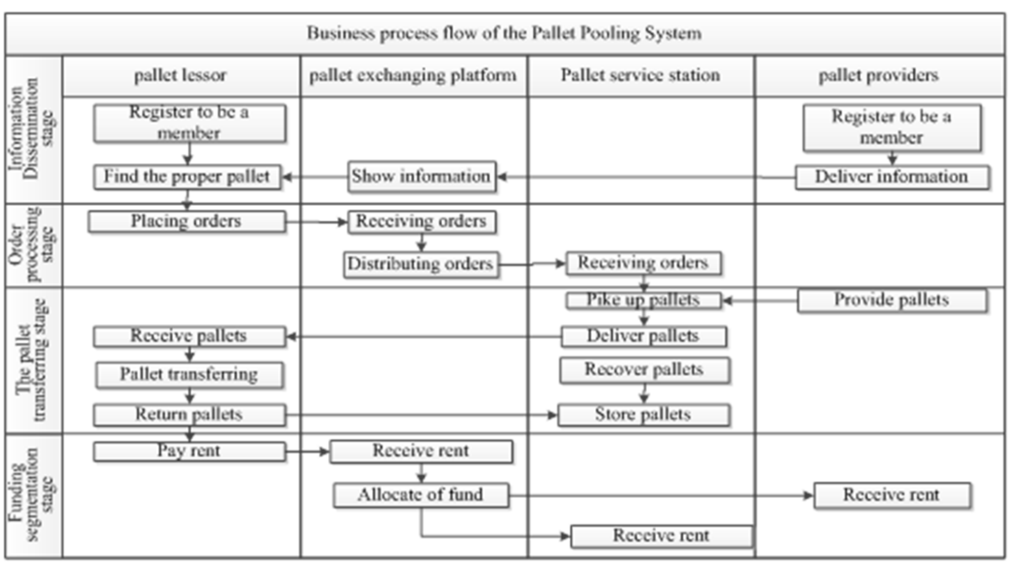

Figure 1. Business process flow of the Pallet Pooling System

The business processing of the Pallet Pooling System shows the complete value chain, which includes all the value-added business in the operation process. Such business processing can lay the foundation of the establishment of the revenue model of pallet pooling system.

4 Cost structure and revenue model of pallet pooling system

The Pallet Pooling System is a for-profit organization whose ultimate goal is to obtain a profit. So it is important to analyze cost structure and profit model of the Pallet Pooling System.

4.1 Cost structure

The cost of pallet pooling system is divided into four parts such as construction costs, marketing costs, daily cost and after-sales cost.

(1)The construction costs include the human cost and infrastructure cost for the software development

(2)Marketing cost includes advertising costs, publicity department staff salaries, travel allowance of business promotion, etc.

(3)The daily cost is incurred in usually operations, which includes a lot of aspects, such as water bills, electric bills, staff salaries, online banking service, and etc.. These expenses are necessary to maintain the normal operation of the platform.

(4)In the provision of services, there will always be some customers who have some doubts incomplete service, which causes the after-sale cost of the pallet exchanging platform. After-sale costs include customer service costs; pallets damaged costs and bad debts.

4.2 Revenue model

The revenue model is a key component of the business model. It is a framework for generating revenues and identifies what revenue source to pursue, and how to price the value.

4.2.1 The source of revenue

There are five sources for the platform to get revenue which are trading commissions, interest of shop margin, technical service revenue, advertising promotion revenue and value-added service revenue.

(1)Trading commissions. The platform will set aside a certain percentage of their commission to pay for their labor in leasing process, which is the main income of the platform.

(2)Interest of shop margin. Use the interest which is got from the shop margin to do financing or venture capital to make profits.

(3)Technical Service Annual Fee. Pallet platform provider can provide rental shop with some technical services, such as shop decoration, periodic notifications of the pallet status, rent settlement notice and etc. to make profit.

(4)Advertising promotion revenue. The platform can set some advertising sectors in the home page for renting to make profit.

(5)When the platform development maturity, it can launch a series of value-added services, such as item tracking and data mining and etc. to make profit.

4.2.2 Price the pallet

Pallet rental price is composed of the platform commission revenues, costs and pallet market share decision, which is calculated as follows.

$$\text{Price} = \frac{\text{annual commission revenue} - \text{annual cost}}{\text{annual circulation volume of pallet}}$$

(1)Annual commission revenue. If the platform wants to recover the initial investment of establishment during the payback period, it should obtain certain annual revenue to ensure. So the annual net revenue should be the ratio of the construction cost to the investment, with the consideration of the VAT (17%) and sales tax (5%). The commission revenue is to take a certain percentage of the whole revenue. Therefore, commission revenue is calculated as the platform.

$$\text{annual commission revenue} = \frac{construction\ investment}{payback\ period \times (1-17\%) \times (1-5\%)} \times a\ certain\ rate$$

(2)Annual cost. It refers to the variable costs of daily operations of platform, including the marketing costs, daily cost and after sales cost.

(3)Annual circulation volume of pallet. The product of quantity of pallet in whole society, market share of the platform and the annual average circulation times of pallet

5 Conclusion

The business mode of the pallet pooling system is studied with certain theoretical and practical significance under the circumstances of contemporary logistics of China. The details of the three stages during the establishment of the Pallet Pooling System are presented, which proposed solutions in aspects of marketing, operation and profiting, and offered the guarantee and theoretical evidence for opening market, operating smoothly, and getting profit.

The Trend of Urban Freight Regulatory Path under the Cloud

Xiaoxia Wang

School of Traffic and Transportation, Beijing Jiaotong University, Beijing 100044, P.R. China. E-mail: xxwang@bjtu.edu.cn

Abstract: The vigorous development of cloud computing and mobile internet provides a new opportunity for the collection, storage, development and utilization of traffic data. By literature investigation, considering the transformation trend of the functions of government agencies in China, this paper reviewed to effectively identify the traffic state of urban road based on the cloud due to Internet of Things (IoT), put forward employing the cloud cooperation applications to dynamic optimization urban freight activities such as consolidation and parking, finally summarized that the cloud logistics mode has promoted as a new logistics service mode. This study improves understanding of how this technology may diffuse within the supply chain.
Keywords: Cloud computing; Urban freight; Logistics service.

1 Introduction

Urban freight, as part of supply chains, is characterized by multiple firms providing their resources and processes to meet customer demand in an efficient manner. It has been acknowledged that the autonomy of the supply chain participants-and their business objectives-as well as the contractual relations between participants have to be maintained when designing an inherent coordination mechanism. Often, new mechanisms are triggered by innovation in the Information and Communication Technology (ICT) industry.

As a key competitive factor, logistics companies depend on tremendous advanced ICT solutions for information processing and sharing. Cloud computing is a great candidate for complementing weaknesses of logistics information systems(heterogeneous processes, geographically scattered and seamed connectivity, etc.) and for supporting innovative activities of logistics(Jung and Kim 2014) Moreover, not only the largest companies can afford advanced systems but also small and medium logistics companies have IT-competence promoting cooperation between them, which in turn reduce transaction costs. For instance, Zagarskikh et al. (2014) focused on the use of shared cloud-computing technologies for data processing and resource-intensive modeling, GIS-technologies for visualization of incoming data and computational results, and tools for the creation of a control with graphical user interface and human-computer interaction. Meanwhile, the number of social network users has recently grown at a rapid pace, which is all the more remarkable. Chen et al. (2012) exploited the use of a cloud services platform for information exchange in combination with the contemporary popular community sites, while developing the site architecture based on the socio-technical system's theory as an indicator.

This paper organized as following structure: (1)government traffic and transport departments has been launched ITS for many years and accumulated vast historical data, and with widely distributed Internet of Things(IoT), advanced cloud computing and universally accessible smart devices, all of these contribute to the optimization of the travel decision of urban freight participators; (2) logistics enterprises especially middle and small ones employing cloud computing will not only cut their operation cost but also benefit from business process or activities up-to-date.

2 IoT and ITS in Urban Area for Carpooling and Parking

Thanks to advances in IoT and smart mobile devices, urban systems collect the abundance of geospatial data. The surveillance of urban traffic systems depends on the effective handling of near real-time traffic observation data. Figure 1 identify traffic state methods based on cloud computing with extracting the traffic information on-line real-time and historical database to deliver decision support for traffic management. (Wei-ning Liu et al. 2010)

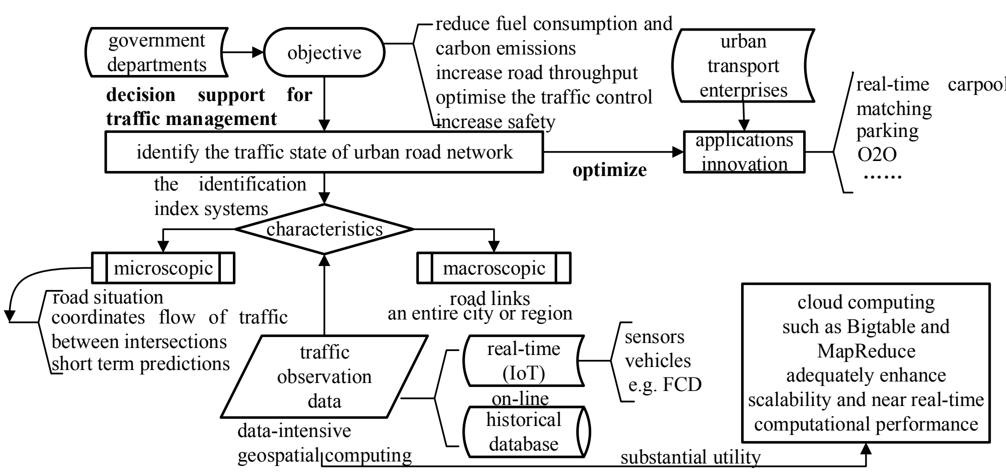

Figure 1. The relationship of urban freight decision support and traffic states in cloud

Firstly, government traffic and transport departments facilitate identify the traffic state of municipal road network in cloud computing environments. The system's optimisation objective is performed on several planning planes simultaneously. One side is the microscopic characteristics of urban road network traffic flow. For instance, the intersection Control Service responsible for coordinating flow of traffic between intersections. Jaworski et al. (2011) treated the vehicles are as cloud services and geographical multicast addressing are used to target all vehicles in the specified areas. On the other side are macroscopic characteristics of urban road network traffic flow, which greatly contributes to monthly or weekly pattern recognize and guide the proper travel decision made. Massive floating car data (FCD) is prevailing methods, Li et al. (2011) investigated the processing of the FCD query, FCD map matching, and speed computation for road links for traffic surveillance with cloud-computing technologies such as Bigtable and MapReduce.

If properly publish and tap those identified pattern, urban transport enterprises could develop all kinds of business innovation applications with the trend of smart mobile devices. For example, Chih-Hsiang Lin et al. (2012) proposed an intelligent real-time carpool system called BlueNet as Figure 2.

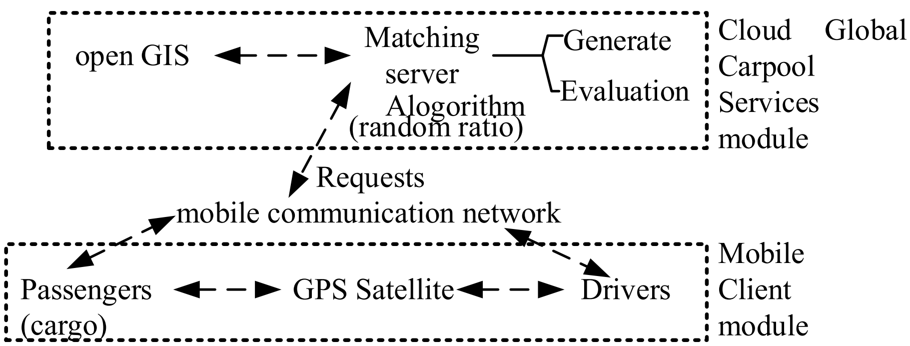

Figure 2. Carpooling and matching

Users can use their smart phones or other devices to find carpool matches by utilizing the Cloud Global Carpool Services(CGCS) module via the mobile communication network. The CGCS module is used to deal with carpool requests and generate suitable carpool match results through the proposed real-time carpool-matching algorithm, which integrated the open GIS system with abundant global geographical information. This also fits cargo consolidation in an urban area. For example, Grzybowska et al. (2013) detailed the use of mobile solutions in the supply chain, and presents the electronic freight and warehouse exchanges as a type of hybrid cloud supply chains. He et al. (2014) presented a multilayered vehicular data cloud platform, namely, an intelligent parking cloud service and a vehicular data mining cloud service, for vehicle warranty analysis in the IoT environment, along with a Naive Bayes model and a Logistic Regression model for the vehicular data mining cloud service.

3 Urban Freight Applications Innovations under Cloud

3.1Cloud especially for SMLSPs

Cloud computing is changing the ways software developed and managed in enterprises, which is changing the way of doing business in that dynamically scalable and virtualized resources are regarded as services over the Internet. Traditional manufacturing systems are typically developed case by case. In cloud-computing-based systems, distributed resources are encapsulated into cloud services and centrally managed. The integration between physical resources and cloud services can be enhanced by combining IoT technology and Software-as-a-Service (SaaS) technology.

In nature, the demand has become increasingly clear in the optimization of the modern supply chain management for the virtual structure of the supply chain business contact. (Zhang 2014) As an enabler of electronic supply chain management systems, to build logistics service platform the decision to adopt cloud computing is based upon complex circumstances as Figure 3(Sun et al. 2012), which affected by information processing requirements and information processing capability proved by Cegielski (2012) with organizational information processing theory. Drawing on the innovation diffusion theory, Subramanian et al. (2014) noted that Chinese small and medium-sized logistics service providers(SMLSPs) are attracted by cloud computing.

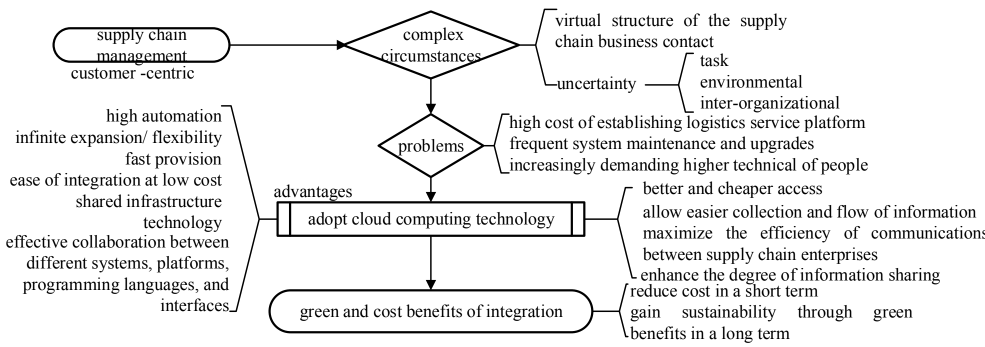

Figure 3. Why is cloud in supply chain management

3.2Logistics companies under cloud

With cloud computing, Kawa (2012) proposed an idea of the SMART model based on agent technology, Kawa and Ratajczak-Mrozek (2013) described the creation of the multi-modal platform designed for cooperating logistics service providers and their customers. In Europe, LOGICAL(http://www.project-logical.eu)'s objective is to enhance the interoperability of logistics businesses of different sizes, to improve the competitiveness of Central European logistics hubs through a decrease of transaction costs, and to promote collective (sustainable) modes of transport.

3.3Develop supply chains management systems under cloud

Chen et al. (2014) proposed an approach for improving cloud-based manufacturing systems based on a four-layer SaaS model. Leukel et al. (2011) proposed representing supply chains as a set of service offerings and customer demand as service requests; coordination is then a problem of determining optimal service compositions. Li et al. (2013) studied the resource virtualization and service encapsulation of a logistics center. After the resources of a logistics center are encapsulated in web services, consider service selection as an optimization problem and create a Particle Swarm Optimization-based web service selection model with quality of service constraints. Sun et al. (2012) described the basic framework of logistics service platform built on cloud computing. And proposed a security framework by research on the security of the framework.

4 Conclusions and Discussion

As an emerging technology, cloud computing is changing the form and function of information technology infrastructures. With the ever-increasing popularity of cloud computing and IoT, the cloud logistics mode has promoted as a modern logistics service mode. This provides a feasibly cost-effective design framework to meet the logistic economy, which will improve the competitiveness of enterprises. This study improves understanding of how this technology may diffuse within the supply chain.

Cloud backup scheme adopting the necessary redundancy strategy may provide relevant data security in one way. Spares and repairmen as two decision parameters in the system are considered to maintain regulated service quality for the cloud users. Jiang et al. (2012) developed for evaluating the profit patterns using the finite-source queuing theory.

And the ICT innovations are always on the way. For instance, Zhao et al. (2012) proposed a method for locating the objects of interest, e. g. traffic signs or road lamps, by computing object-based saliency given a cloud of 3D laser points of an urban scene. Much more convenient mobile customized services for related groups of urban freight transportation benefit are coming. All these facilitate freight service enterprises to provide safer, greener, more efficient transportation service for municipal units and residents.

Abstract: The study of traffic flow data mining technology is meaningful to traffic flow induction, dynamic traffic allocation, traffic management and control. In this paper, we applied the combined model algorithm, traffic flow jam mining algorithm and traffic flow distribution pattern mining algorithm to an integrative Intelligent Transportation System based on data mining technique and also provide an efficient tool for the traffic management.
Keywords: Road traffic; Data mining technology; Intelligent transportation system.

1 Introduction

At present, ITS has accumulated a large number of basic data and become an important application in our country and people's livelihood (CAI, 2003). Therefore, it is very urgent and necessary to research on data mining technology in ITS. The system is committed to achieving traffic data cleaning、traffic accident correlation analysis、traffic flow congestion incident mining、intersection short-time traffic flow forecasting demand and so on, providing an effective tool for auxiliary traffic management and rational allocation of traffic resources(WANG, 2013). The system working process is shown in figure 1.

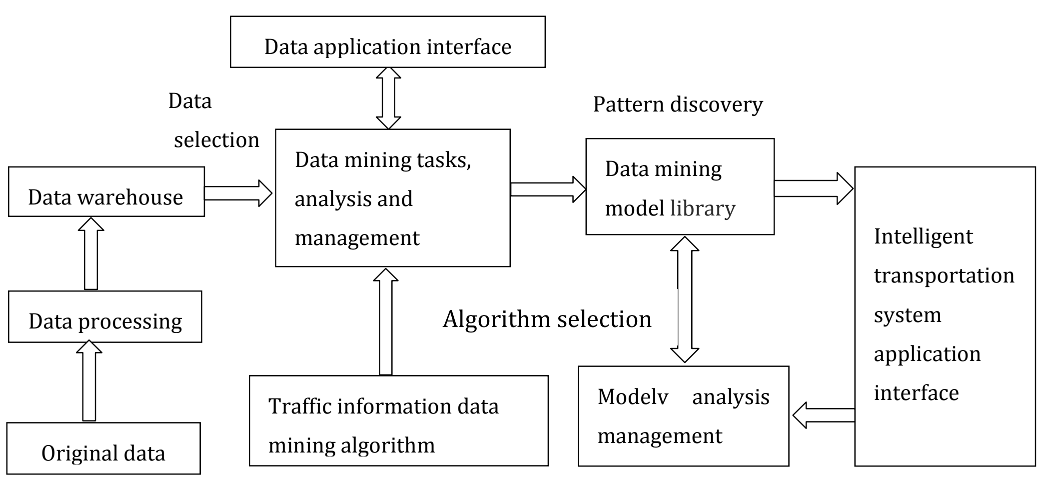

Figure.1. System working flow chart

2 System's Architectural Framework

Integrative ITS based on data mining technology adopts four-layer architectural framework of intelligent transportation mining application platform (LI, 2008). This application platform is convenient for the establishment of data mining algorithm analysis function, data mining system development and configuration. Therefore, users can adopt data mining technology according to their actual demands. Integrative intelligent transportation system is divided into four layers: traffic data layer, data mining layer, analysis logic layer and application system layer.

The system architectural framework is based on data mining algorithm tool, increases analysis logic layer between data mining layer and application system layer, extracts specific analysis model on analysis logic layer, maps to the appropriate data mining algorithm and analysis process, makes the data mining technology and concrete applications combined closely.

(1)Traffic data layer

After the access to external data, external data becomes internal data through format conversion, data cleaning and other processes, providing support for data mining analysis (ZHANG, 2014). Traffic data sources widely and contains large amounts of traffic information, so it's necessary to convert traffic data into appropriate formats before data analysis. The data warehouse provides a unified storage and analysis platform for different data frameworks. Building up traffic data warehouse is the core of traffic data layer, through three parts of data collection and ETL, data warehouse management system and metadata management system. In the process of modeling, considering the wide range in ITS field, therefore the traffic data warehouse is required to have a strong scalability: not only integrate traffic information collected by each application system, but also establish on the basis of its working database for a specific application system.

(2)Data mining layer

Data mining layer contains data mining algorithm tool, visualization method and other auxiliary tools, focusing on data mining algorithm and related tools, such as statistical methods and auxiliary tools. In the algorithm design, we need to give users more choices so as to allow users to set and adjust parameters. In data mining layer, there should be auxiliary tools related to data mining algorithm. For example, similarity measure is the core issue of cluster quality in clustering algorithm. Different similarity measures are for different data, and these similarity measures are also a part of data mining layer.

In present data mining set, we need to achieve basic data mining algorithms, such as: K-means clustering algorithm, hierarchical clustering algorithm, decision tree classification algorithm and so on (ZHANG, 2013).

(3)Analysis logic layer

Analysis model is an independent entity. Application system layer can be realized according to the actual needs corresponding to analysis logical layer. During of intelligent transportation system's data mining, analysis function of extraction and corresponding data mining algorithm need to combine integrated traffic system domain knowledge and data mining technology closely. Analysis model contained in the analysis logical layer is extracted from the actual demand analysis, being able to accomplish a certain number of independent analysis functions. The building up of data mining model in ITS is shown in figure 2.

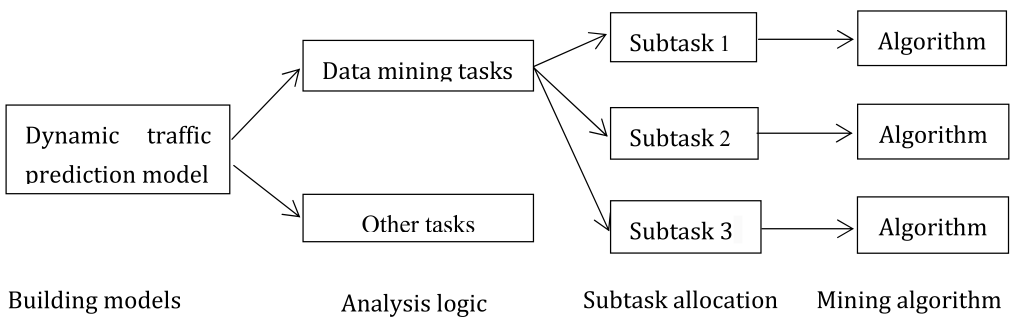

Figure.2. Data mining task analysis logic

(4)Application system layer

Application system layer is set up by users and is the corresponding entry of analysis logic layer by adopting a flexible manner, such as B/S and C/S. Use multilayer structure to meet different demands and finally be applied in the network environment according to the characteristics of ITS.

3 Data Integration and Fusion

There are many different kinds of intelligent traffic data, and the data are distributed among various traffic application systems. Data warehouse provides effective data processing platform for data mining. As a result, intelligent transportation system needs all kinds of traffic data extracted from database operation. After data cleaning and a series of process, traffic data is integrated into the transportation information data warehouse. Due to the urban traffic management decision data regards existing traffic management computer system as data source, traffic information data warehouse shall meet the following requirements:

(1) Get data from traffic management system and application system according to business demands, so the original data can be collected and updated automatically;

(2) Provide flexible and convenient extraction method, new data will be put into the system through friendly user interface;

(3) Provide flexible on-line analytical ability and a multi-angle, deep analysis on original data;

(4) Meet the requirements of future development, scalability and expansibility, ensure technical sophistication;

(5)Serve decision support system effectively, making the decision support system achieve better effect. Decision support system can use many tools to access converted, clean and professional data;

Due to an integrative intelligent transportation system includes many different types of traffic information collection systems, and the data collected by different traffic information collection technologies includes different contents and structures. At the same time, there are errors, omissions and imprecise problems in data more or less. Therefore, we need to do fusion calculation for different sources of data; meanwhile, merge different judgment results on the same traffic event, forming a consistent traffic state.

4 System's Linkage

Linkage is the implementation process of event or state, its trigger condition is the appearance of one or more events' combination in the monitored objects. Linkage system is function modules in comprehensive monitoring system platform handling dangerous information (SUN, 2013). When emergency incident happens, linkage system collects each subsystem's danger information uniformly, then manages and records. At the same time, linkage system completes the related equipment control. When there is a linkage, system platform operates automatically or prompts managers to perform an action based on event situation combining the design plan in advance system. Finally, make rapid and efficient emergency respond to realize the unity of the various application resources (as shown in figure 3).

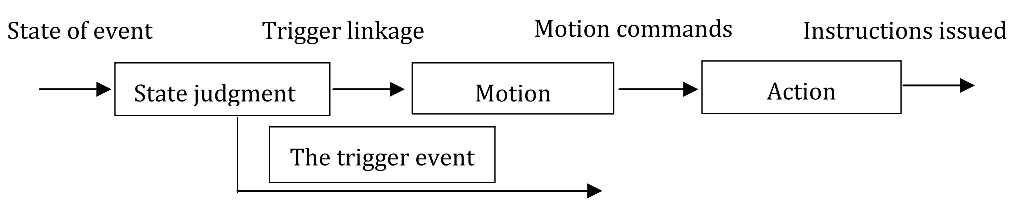

Figure3. System linkage execution graph

Trigger source is the combination of some trigger conditions. When its trigger condition is true, one event is produced and published to linkage system. When it becomes false from true, the trigger condition is restored and another event is published. Trigger condition is generally classified into two types: trigger source based on time and trigger source based on alarm condition according to different trigger conditions.

5 System Functions

Integrative intelligent transportation system based on data mining technology displays a role of traffic mining business functions by application platform. For other functions in intelligent transportation system, such as traffic signal control, traffic data collection, the model can realize these functions through the application of platform. Among them, functions related with traffic flow data mining technology are as follows:

(1)Real-time traffic state judgment

Judge road traffic condition with the evaluation of classification: smooth, mild crowded, crowded, congestion and severe congestion according to the judgment of traffic flow data collected by devices. Get real-time traffic state of road, showing relevant sections with green, light green, yellow, orange, red on the map. After establishing traffic flow pattern warehouse, system calls the mining algorithm to deal with each traffic flow data, give the current state of traffic flow, and display traffic status on the map, so as to show the road traffic state information intuitively.

When system detects that the traffic state is changing, system will generate new traffic state diagram via system linkage function and send new information to the intersection traffic induction device, so as to lead traffic flow and ease traffic congestion.

(2)Regional correlation mining

In view of serial case, mine collected traffic monitoring data, analysis vehicle's information in the near, do regional correlation mining according to the present frequency of suspected car, screen related information of suspected car, and predict possible area of the vehicle.

(3)Vehicle relevance mining

In criminal cases, most of the suspects use vehicle to escape, especially in the vehicle rob case. Therefore, after determining the suspected specific vehicle, analyze its activity rule in this case, find associated vehicles through the way of data mining.

(4)Deck vehicles mining

Regard the thicker traffic flow collection device sections as the center, divide the whole monitoring area into multiple mining areas, do data mining analysis in these areas of traffic flow. If suspected deck car appears, user may inform the intersection officers to intercept suspected deck car.

(5)Abnormal vehicle mining

Moving vehicles in a certain area pass through different traffic information site, the information site will keep track of the vehicle's location, state, pass time, etc. After a period of time, vehicles in the area will leave related activity records in system database basically. Through mining algorithm, all the vehicle's active records are analyzed for a certain period of time combining car registration, calculate the normal vehicle and abnormal vehicle operation.

6 Conclusions

This paper designs an integrative intelligent transportation system based on data mining technology. Describe the system levels, system framework, traffic data mining function module. The system uses road traffic data algorithm with rich analysis functions, do data mining in intelligent transportation system, build up traffic task of data mining model warehouse, providing an effective tool for road traffic management.

A Method of Data Cleaning Based on IC Card and GPS Data in Chengdu

Yi Qian; Ling Xu*; and Pengyao Ye

School of Transportation and Logistics, Southwest Jiaotong University, Chengdu 610031.
*Corresponding author. E-mail: xl_xnjd@163.com

Abstract: It is feasible to infer passengers' boarding and alighting station by using IC card data and GPS data. However, in most cases, the data collected has some problems, such as replicated data and missing data because of the drawbacks of transit system and the influence coming from the external environment. Furthermore, data users cannot explain the data reasonably because they do not know how data is collected. This paper, taking Chengdu transit system as an example, focus on the data cleaning method in data preparation phase. It presents some methods of data cleaning about the data quality problems in IC card and GPS data, and then discusses the triggering distance of buses in Chengdu.
Keywords: Data cleaning; GPS; IC card.

1 Introduction

Data cleaning is the process of detecting and correcting (or removing) corrupt or inaccurate records from a record set. Using the IC card data and GPS data for what decides what kind of method should be used to conduct data cleaning. This paper study on the data cleaning methods that contribute to using the IC card and GPS data to infer passengers' boarding and alighting station, and the fields needed in the two data set of Chengdu transit system are as Figure1 and Figure2 shows: the field CONSUMEDATE in IC card record means the boarding time of a passenger; the field ACTDATETIME in GPS record means the arrival or departure time of a bus on a station; the field STATIONNUM is an unique id of a station.

(1)IC card data

LINENO	BUSNO	CARDNO	CONSUMEDATE	CONSUMETYPE	BALANCE
20	011060	000103293340	2014-11-09 07:38:33	2	(null)
20	011060	000103885324	2014-11-09 07:38:41	2	(null)
20	011060	000115274017	2014-11-09 11:00:59	11	(null)

Figure 1. Sample of IC card data

(2)GPS data

LINENO	BUSNO	ACTDATETIME	GPSSPEED	STATIONNUM
1	046006	2014-11-03 06:52:14	8.53	30463
1	046006	2014-11-03 06:53:33	5.09	30461
1	046006	2014-11-03 06:56:06	5.71	20308

Figure 2. Sample of GPS data

It is necessary to give a brief introduction about the basic rules of inferring boarding station. If a passenger's CONSUMEDATE is between a stop's arrival ACTDATETIME and departure ACTDATETIME, the current STATIONNUM in GPS record is regarded as the boarding station. If a passenger's CONSUMEDATE occurs before the first stop's arrival ACTDATETIME, the first station is choose. If a passenger's CONSUMEDATE occurs after the final stop's departure ACTDATETIME, the passenger's boarding station is unknown (Marie-Pier Pelletier, 2011; Jason B. Gordon, 2012).

This paper describes the data quality problems in Chengdu transit system and proposes a solution for each of them. The rest of paper is organized as follows: in section 2, literature review focuses on the data cleaning of IC card and GPS data; in section 3, the replicated data in both two data set and the abnormal data in IC card data set is discussed and some methods of data cleaning are proposed; section 4 is an analysis about the value of triggering distance in Chengdu transit system; the last section contains the conclusions of this paper.

2 Literature review

Many researches about inferring passengers' boarding and alighting station using IC card and GPS data were made, but little attention was paid to data cleaning in the data preparation phase. Jason B.Gordon proposed a solution for the problem that the timestamp of swiping card was truncated to the minute in London transit system (Jason B.Gordon, 2012). N.B.Hounsell discussed the data consistency in AVL data, and the selection of timing point of a measurement of GPS data (N.B.Hounsell, 2012). Some data quality problems, such as missing data, wrong data and the consistency problem, were presented and a methodology was also used to process these dad data, but more details about the methodology was not available (ZHANG Yu, 2010).

Different from those aforementioned researches, a paper of Guo Shuxia, taking the IC card and GPS data in BeiJing as an example, discussed the problems of data quality in IC card and GPS data set, and designed a methodology to clean the both data set. Steve Robinson found out the data quality problems coming from software, hardware, data and user four aspects, and then developed relevant methodology to process bad data, but that paper didn't refer to the data cleaning of GPS (Steve Robinson, 2014). In fact, it is also very crucial to understand the mechanism of GPS data collecting for us to conducting data cleaning and further research, but surprisingly very little literature was found which investigates the mechanism of GPS data collection, except N.B.Hounsell, in which a simple introduction was made (N.B.Hounsell, 2012).

3 Replicated data and abnormal IC card data

Many factors may lead to replicated data during the process of data collecting, data transmission and data storage, such as equipment trouble, storage trouble and so on (Cheng Shaohui, 2012), and there are also some abnormal data in IC card data set. Fig 3 is a method to process replicated and abnormal data, and more detail is given in three independent parts. The 3.1 discuss the replicate record in IC card data set and 3.2 discuss the replicate record in GPS data set and 3.3 discuss the abnormal data in IC card data set.

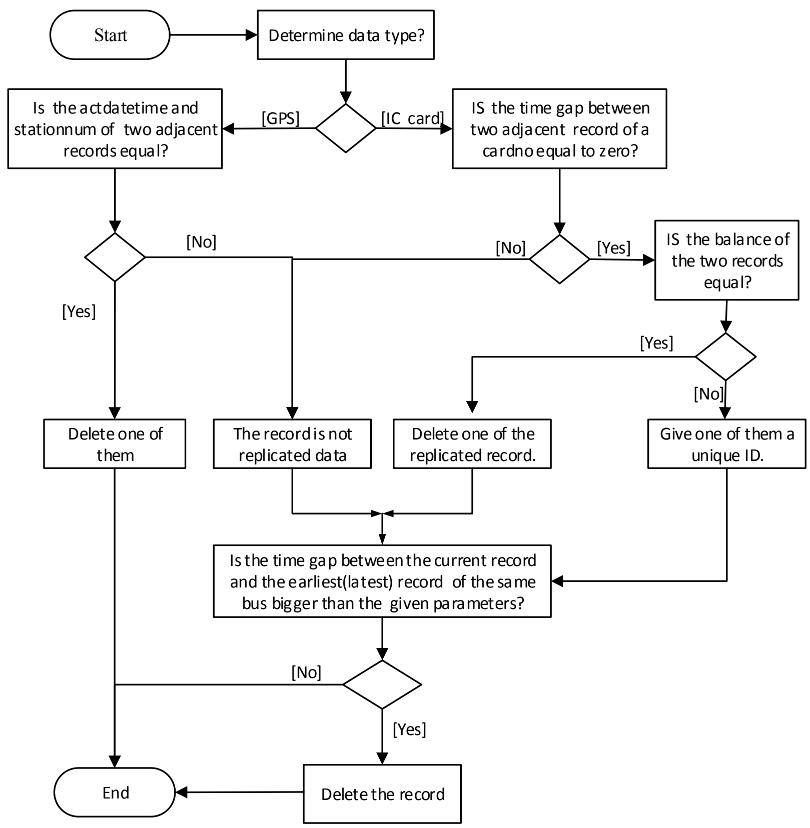

Figure 3. Process of cleaning replicated and abnormal data

3.1 IC card replicated data

In an ideal case, an IC card can has only one record at a specific time, but there exist two kinds of replicated data in the IC card data set: the former is that two records have same CONSUMEDATE, CARDNO, and balance; the latter, just as Figure 4 shows, is that two records have same CARDNO, CONSUMEDATE but different balance, which means that the two records are both valid data. This kind of "replicated data" may result from the fact that people can swipe a card for two times during a boarding event, but the card reader fails to distinguish the difference of ACTDATETIME between them. For the former, the best solution is to delete them from the data set. For the latter, we can give each "replicated data" a different id or simply treat two replicated data as two single record and do nothing with them.

LINENO	BUSNO	CARDNO	CONSUMEDATE	CONSUMETYPE	BALANCE
64	028928	000100001987	2014-11-07 11:12:56	11	(null)
64	028928	000100001987	2014-11-07 11:12:56	1	41.4
309	146009	000100003313	2014-11-05 17:51:50	1	18.35
309	146009	000100003313	2014-11-05 17:51:50	1	16.55
332	119067	000100004136	2014-11-04 16:46:58	1	48.4
332	119067	000100004136	2014-11-04 16:46:58	1	46.6

Figure 4. Sample of replicated IC card data

3.2 GPS replicated data

Just as IC card data, there are also two types of replicated data in the GPS data set: one is that many records have the same ACTDATETIME and PRODUCTID, which may result from the trouble of GPS clock or data management, another is that one arriving (leaving) station event has two or more records, which may result from the swinging of bus during it's running process. As Figure 5 shows, the station #50637 has two records of leaving station event. For the former, it is necessary to delete them from GPS data set directly, and for the latter, it is reasonable to remain the first record of arriving event data and the last one of leaving event data order by ACTDATETIME increasingly, which keeps a longer in-station time of a bus avoiding the phenomenon that many passengers' CONSUMEDATE is not between the arrival time and departure time.

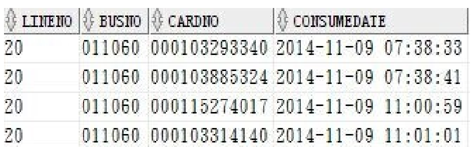
ROUTEID	PRODUCTID	ACTDATETIME	ISARRLFT	LEADIS...	LAGISARRLFT	STATIONNUM
204	011013	2014-11-03 08:12:07	1	1	2	50637
204	011013	2014-11-03 08:12:10	2	1	2	50637
204	011013	2014-11-03 08:12:10	2	2	1	50637
204	011013	2014-11-03 08:13:23	1	2	2	50453

Figure 5. Sample of replicated GPS data

3.3 Abnormal IC card data

In transit system, a bus arrives at a specific station, open the door and then passengers swipe their card one by one, and after these processes, the bus closes its door and leaves for the station. The IC card data in a day should present consistent generally. The abnormal IC card data is these records, whose ACTDATETIME is earlier than the ACTDATETIME of the first record of same bus and same date, or far behind the last record's ACTDATETIME. Just as Figure 6 shows, in (a), there is a large gap between the record at 2014-11-09 07:38:41 and the record at 2014-11-09

11:00:59, and at the same time, the earliest record in GPS data turns up at 2014-11-09 11:00:44, which means that the first two IC card records are invalid; in (b), the latest record in GPS data turns up at 10:18:22, while the latest record in IC card data turns up at 17:04:37,which means that the record at 17:04:37 is invalid. As for the data showed in (a) and (b), it is reasonable to delete these invalid data, but the problem is how to distinguish them from a sea of data. A practicable method is joining IC card and GPS data by time at first, and then add two fields meaning the earliest and latest time of a bus in GPS data for each day, and at last we can distinguish these invalid data by comparing the CONSUMEDATE and the earliest or latest time.



LINENO	BUSNO	CARDNO	CONSUMEDATE

Figure 6. Sample of abnormal IC card data

5 Triggering distance

The GPS data records the information of arrival and departure. When a bus runs close to a station, an arrival event is triggered and when bus leaves for a station, a departure event is triggered. But we do not know how long the triggering distance is, in other words, how far is between the bus and the station when an arrival event or departure event is triggered? In the process of inferring boarding and alighting station, triggering distance is important for us to decide some parameters' value.

In Chengdu transit system, GPS equipment sends a record per ten seconds, and when arrival or departure event is triggered, a record is sent to the data management center. We can get the triggering distance by calculating the distance between the bus and the station when an arrival or departure event is triggered using the latitude and longitude of the station and the record sent by the bus. Each arrival or departure event has a triggering distance. First, taking the line #146 as an example, we calculate the triggering distance of all buses on November 3, 2014 and then get the statistical frequency of triggering distance using an interval 5 meter, and the result is as Figure 7 shows: the 0 on X axis means triggering distance is between 0 and 5 meters and 1 means that between 5 and 10 meters. It is obvious that an large part of triggering distance are between 35 meters and 50 meters with an average value 40 meters, but there are also some cases which have a very long triggering distance and that will be analyzed in the following section.

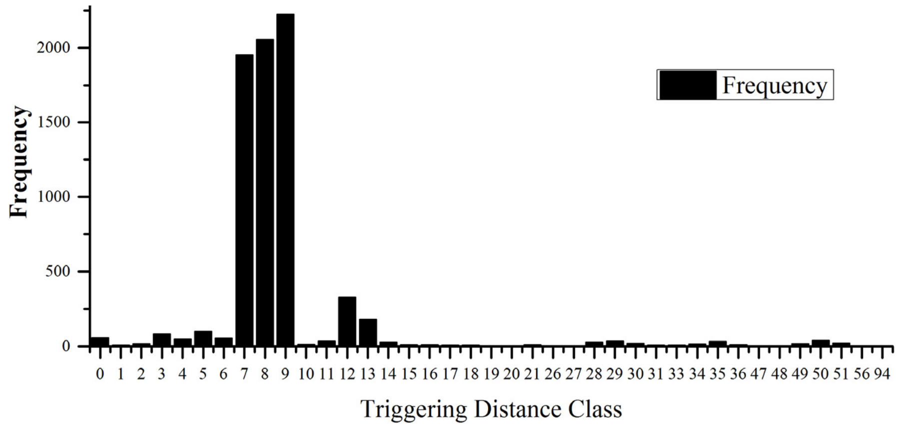

Figure 7. Frequency distribution of triggering distance

Having the aforementioned result, it is necessary to analyze the triggering distance of a specific bus at every station during one turn. Here, we choose one bus on line #146, and then calculate its triggering distance of first turn on November 3, 2014. As Figure 8 shows, the triggering distance of each station during a turn is also between 35 and 50 meters except for the XiangXieLi with a large value of 250 meters.

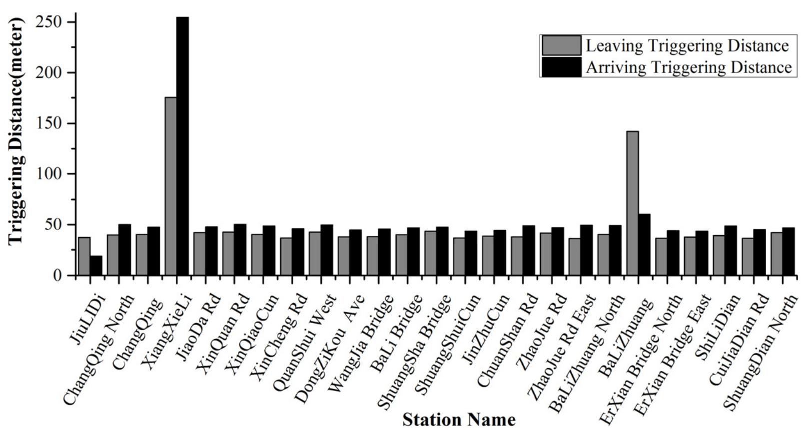

Figure 8. the triggering distance of a single bus during its first turn

As for the XiangXieLi, it is important to find what factors lead its large triggering distance and there are two methods can be taken for that question. First, the average triggering distance grouping by station during a day can tell us whether the latitude and longitude of relevant station leads to its large triggering distance or not. So we calculate the average triggering distance of all buses on line #101 on November 3, 2014 for each direction and station. As Figure 9 shows, being in compliance with the result in Figure 8, the triggering distance in different direction of each station is also between 35 meter and 50 meter largely except for the XiangXieLi, which to a great extent means that the latitude and longitude of XiangXieLi leads to its large triggering distance.

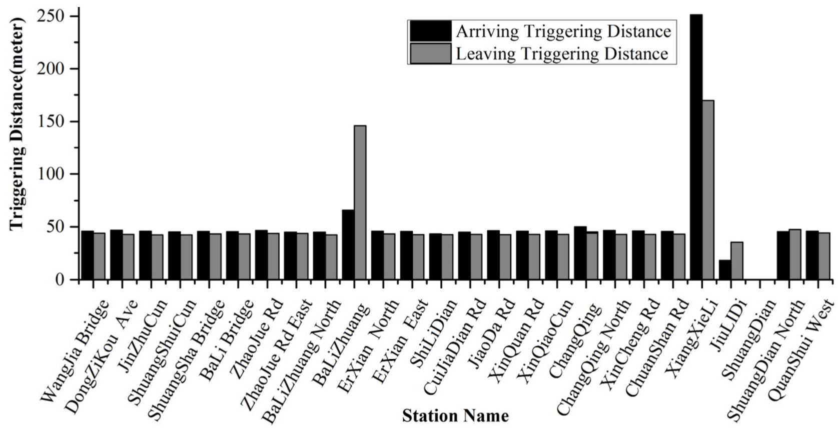

Figure 9. the average triggering distance of each station in the up direction

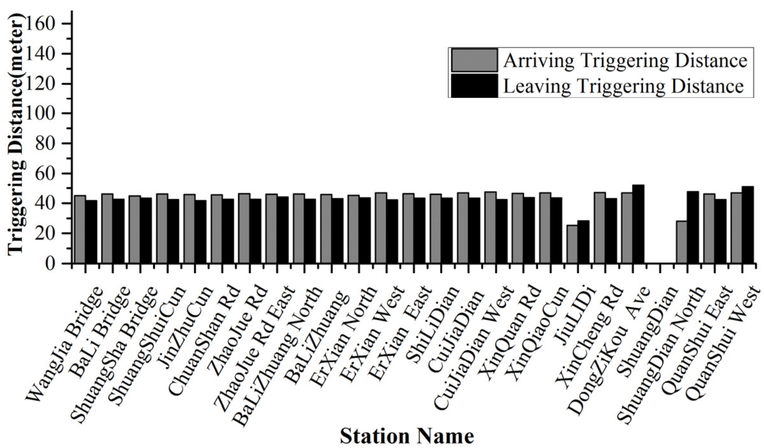

Figure 10. the average triggering distance of each station in the down direction

In order to further validate that conclusion, we consider the relation of time in both two data set: one is the passengers' swiping-card time, namely CONSUMEDATE; the other is the bus's arrival and departure time of each station. In figure 11, the station ChangQing and JiaoDa Rd looks normal, because CONSUMEDATE is between the arrival time and departure time, which is in compliance with the boarding behavior in transit system, while at the XiangXieLi, the CONSUMEDATE falls behind the departure time of the bus, which is not reasonable. Furthermore, we can find that the bus triggers both the arrival and departure events before arriving at the XiangXieLi by putting the latitude and longitude of the XiangXieLi and that sent by the bus when it triggers arrival and departure event at XiangXieLi on map. This phenomenon to a great extent results from the failure in updating the change of the location of the XiangXieLi. Now, it is clear that the triggering distance is largely between 35 and 50 meters in normal sense, but caused by the change of the location of station there are also some stations have large triggering distance.

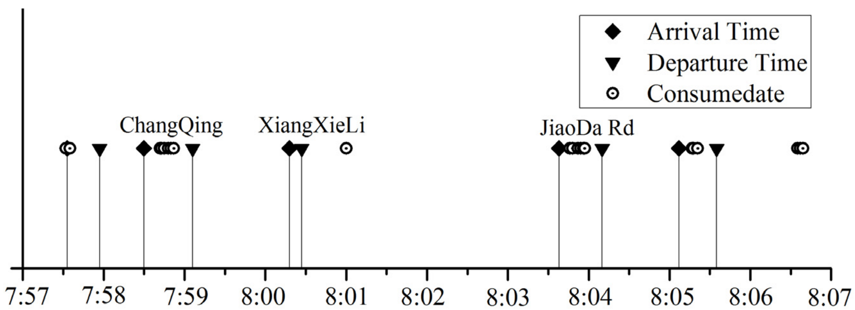

Figure 11. the CONSUMEDATE of IC card and Arrival (Departure) Time of bus

For the latter situation, some measures should be taken to avoid the phenomenon that the passengers boarding at the next or last station, are considered to board at the current station, for example XiangXieLi. One method is to update the latitude and longitude of stations that have changed location, but it proves difficult to get the exact latitude and longitude data if you do not have professional skills and equipment. The other is to change the CONSUMEDATE of records that board at the next and the last station of current one that has changed location information, and make it fall somewhere between the arrival time and departure time. So the first step is inferring boarding station using methods proposed in section *Introduction* and then calculate the difference between the departure(arrival) time of bus and the CONSUMEDATE of passengers'. Let's take XiangXieLi as an example, if a passenger is inferred that he or she boards at a station with large triggering distance and the difference is far less than the given parameter whose value depends on the average difference between the ACTDATETIME in GPS data set and CONSUMEDATE in IC card data, the passenger boards at the station ChangQing, and if more than the given parameters, the passenger boards at the station JiaoDa Rd.

6 Conclusion

Data cleaning is a very important process for further research, during which we should not only exclude the useless data but also find out how data is collected. According to the research above, some methods of data cleaning were proposed about different data quality problems, which make the IC card and GPS data is suitable for inferring the boarding and alighting station. The triggering distance is largely between 35 and 50 meters and there are some stations have a large triggering distance, for which the solution has also been proposed, which helps us to make the rules of inferring boarding and alighting station more reasonably.

Abstract: This article takes three bicycle sharing systems as the research object , the Citi Bike of New York City , the Capital Bike share of Washington and the Divvy of Chicago. Adopting the method of Data mining, the corresponding long-term historic credit card data, bicycle sharing system location data and the land-use properties coming from three bicycle sharing systems are compared and analyzed to get bicycle sharing system in seasonal, spatial and temporal distribution, site symmetry aspects of trip characteristics, which provides support for bicycle sharing system Operational decisions.
Keywords: Public bicycle; Data mining; Travel characteristics.

1 Introduction

Public bikes have become more and more popular in many cities, mainly because they “provide the missing link between existing points of public transportation and desired destinations” (Midgley, 2009).In addition, public bikes offer a mode of transportation that is not only environmental friendly ,but also can be a mode of healthy exercise.

As access to public or shared transport systems becomes increasingly digitised, new data-sets have emerged offering opportunities to research travel behaviour in a continuous large-scale and non-invasive way (Blythe and Bryan 2007).

This paper conducts comparison on three bicycle sharing systems (Citi, Capital Bikeshare, Divvy) vertically to search for similarities and differences on the travel characteristics of public bicycles, and provide effective support for operational decisions.

In here , we mainly concentrate on following points :The first part mainly shows the resource of the rules of data pretreatment; The second part introduces the conditions of three bicycle sharing systems; The third part emphatically analyses the rules of the frequency at weekend and working day trips in time distribution; The fourth part makes a study on the temporal distribution on frequency of pubic bicycle trips. The fifth part studies the features of frequency distribution on public bicycle trip duration. The sixth part analyzes the relationship between the frequency of trip and the ratio of public bicycle borrows and returns. The seventh part explores the influence of the features of seasonal temperature changes on public bicycle trips.

2 The Citi Bike, Capital Bike share and Divvy system

The Citi in New York City is the nation's largest bicycle sharing system, which has 332 bike rental sites and 6,000 public bikes, mainly located in the Manhattan North and Brooklyn South region. In May 2013, officially opened to the public since Citi public bicycle system popularity, by September 2014, the number of systems in use has more than 7 million times, more than 100,000 people have paid a member annual fees.

Capital Bike share was United States first bicycle sharing system, you can choose any of the over 300 stations across Washington, D.C., Arlington and Alexandria, VA and Montgomery County, MD and return it to any station near your destination. In Washington, DC, Capital Bike share has about 24,000 members, annual fee and monthly members.

Chicago Divide was launched a bike sharing system, which is called "Divide & Share" in the summer of 2013. The system includes more than 400 bike access stations (including planning and under construction), a total of 4,000 bikes covering the downtown subway stations, commercial centers and tourist attractions in the surrounding areas.

3 Data

3.1 Data acquisition

This data comes from New York, Washington, Chicago, public bike system Web site, which includes Credit card data and each rental Systems' latitude and longitude. The samples' time interval is from August 2013 to July 2014 in New York, August 2013 to August 2014 in Washington and July 2013 to June 2014 in Chicago. Such as New York Citi bicycle sharing system, its Credit card data contains records of travel time, the terminus name and number, user types (Ordinary or VIP), arrival and departure time, bike number , age and gender. As shown in the following table1.

Table 1. Citi Bike trip data

trip duration	start time	stop time	start station id	start station name	end station id	end station name	bike id	user type	birth year	gender

3.2 Data Preprocessing

When Public bike system records in large travel information, existing part of the error message and data. Before analyzing the entire data sources, we should carry out data cleansing, rectify and delete data failed, specific principles of data cleaning as the following

1. The departure time is later than the arrival of time recorded data will be excluded;

2. Duplication of ID data, and keep only one ;

3. Each record shall be recorded starting station and terminal information, travel records will be excluded if anyone is missing;

4. The data of use of time and arrival time is within 2 minutes will be excluded;

5. Travel time is less than 1 minute and starting station and the Terminal is same site , this kind of data will be excluded;

6. Travel time 10 hours (600 minutes) over as exception data will be excluded.

7. The sample data which travel time is more than 24 hours will be excluded;

8. Management vehicle trip data generated by their exclusion from it. (Patrick Vogela, 2011)

4 Time distribution of trip frequency of public bicycles

We have figured the trip frequency of public bicycles at each period of a day at hourly intervals. As shown in the figure 1, the trips distribution at working days feature has two high peaks, namely 8:00 to 9:00am and 17:00 to 18:00pm, while the high peak occurs at 14:00 to 16:00 at weekends. Besides, public bicycle's card reader times at working days of the 24 hour a day is 2 to 3 times of that at weekends and the using rate is 3 to 4 times of that at high peaks at weekends usually, it is more focused on the outdoor trip at afternoon.

The reason public bicycles show different characteristics at working days and weekends is that they are most frequently used at rush hours at working days with typical commuting feature while bicycles on weekends are usually used for shopping, travailing and leisure,etc.

Public bicycles can not only serve as a convenient vehicle but also a good mean to do city sightseeing. Trip frequency of public bicycles system can be efficiently improved through a special road network linking the sights in the city.

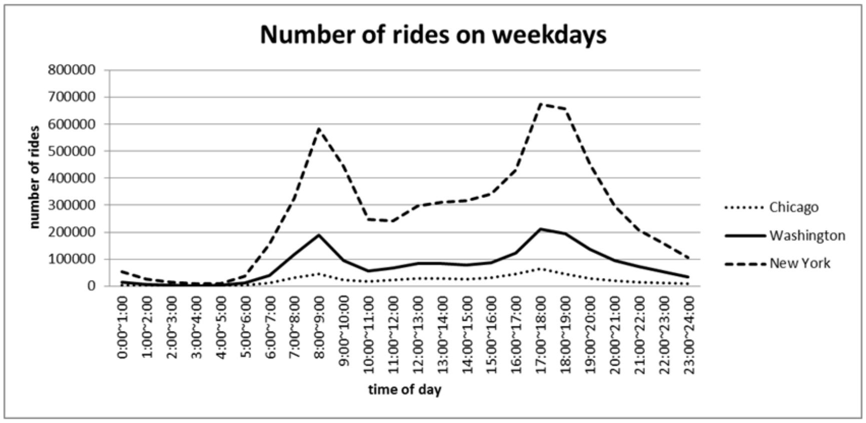

Figure 1. Number of rides per hour on weekdays

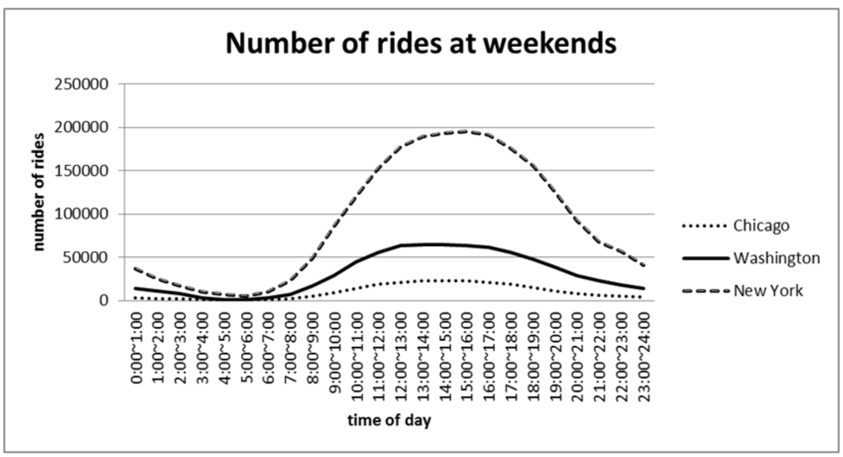

Figure 2. Number of rides per hour at weekends

5 The frequency distribution of travel time

The function of the public bike system is conducting the residents of "last mile" of travel demand and travel time is one of the most important considerations in public bike system. You can see from Figure 5, 90% or more in three different cities travel time are concentrated in less than 30 minutes. In three cities, it is all free when travel time is less than 30 minutes , which is the most important reason for travel are all less than half an hour.

In addition, travel time in maximum frequency values is seen at about 10 minutes in three cities, calculated in accordance with biking in general average speed

15km/h, coupled with road vehicle disturbance and traffic light wait time reduction, more than half of the public bicycle travel radius should be about 2 km.

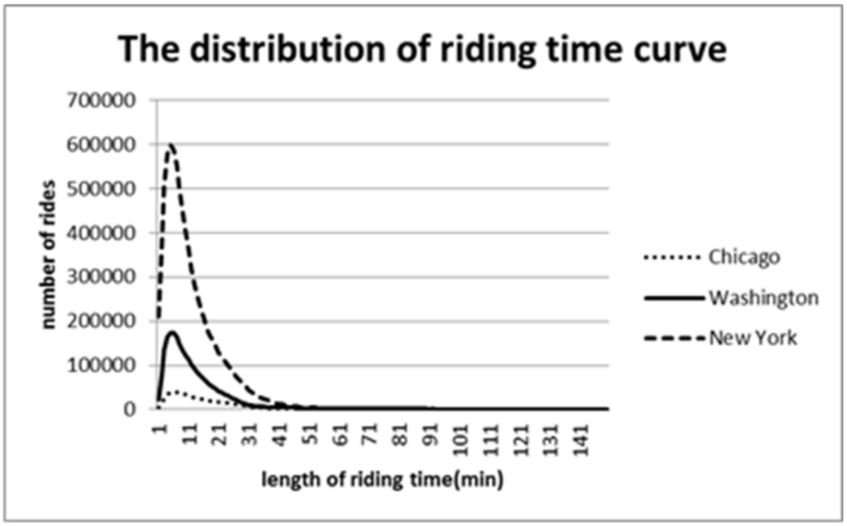

Figure 3. The distribution of travel time curve

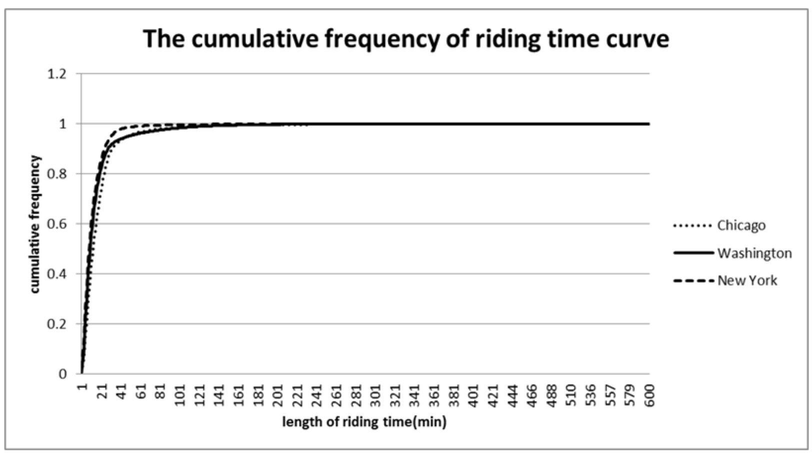

Figure 4. The cumulative frequency of travel time curve

6 The relationship between the frequency of trip and the ratio of public bicycle borrow and return

A public bicycle rental point can be both a starting point and a terminal, only if the number of loaned bike as a starting point and the number of returned bike as the terminus in a certain time period can achieve balance, the site is running properly, otherwise operators should adjust each sites' bike numbers. In Public bicycle operation, due to the differences properties of surrounding land-use of the site, bike borrows and return is imbalance in the same point, In order to ensure the normal operation of the system, we need to schedule a certain amount of vehicles. For operators, vehicle scheduling is one of the highest operational costs, how to achieve the balance of borrow and return for a certain period is significance for optimization of the operating system.

This section focuses on the site lending ratio and frequency of use, as shown in the figure, Longitudinal axis is the ratio of bike loan amount and return amount for the site . Closer to 1 shows better the balance of the site, the horizontal axis for each site's amount of trip swing card in whole year.

Through the comparison on three bicycle sharing system, we can see, each city's law is different. In Washington's public bike system, the frequency of use , the higher the site circulation ratio is closer to 1, while New York and Chicago, there is no obvious relevance. This suggests that circulation associated with the frequency of use is up to which city as your sample .

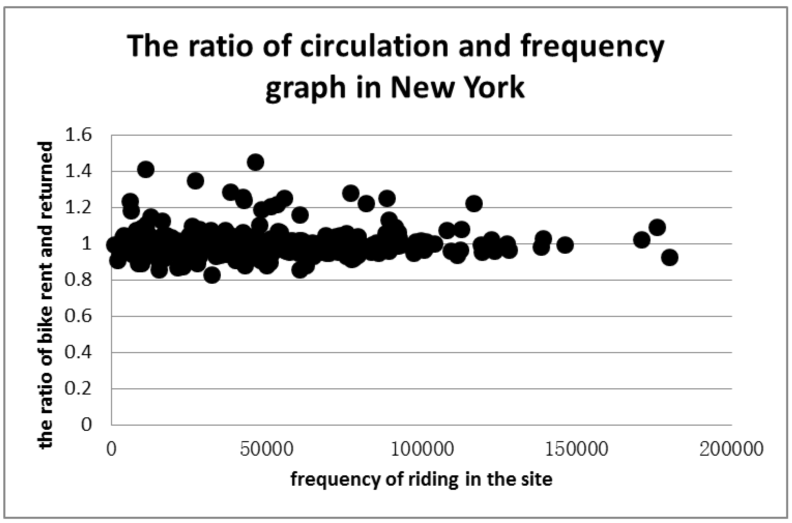

Figure 5. The ratio of circulation and frequency in New York

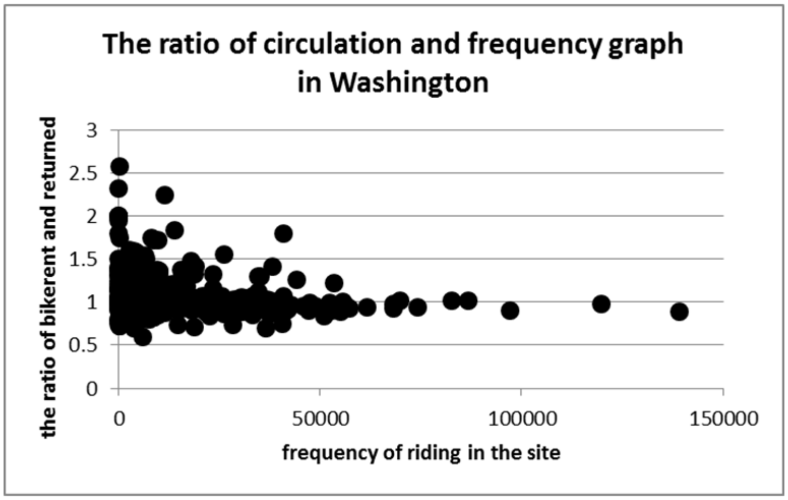

Figure 6. The ratio of circulation and frequency in Washington

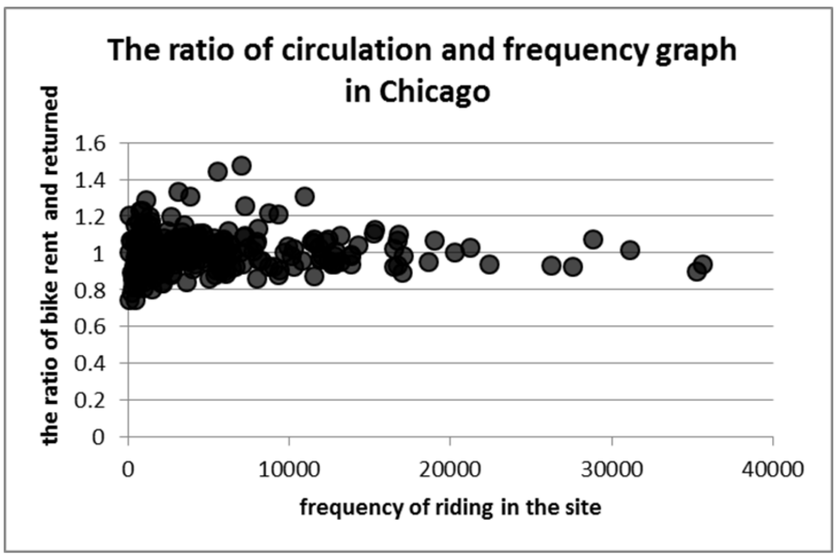

Figure 7. The ratio of circulation and frequency in Chicago

7 The effect of climate on the use frequency of public bicycle

Climate (long-term, seasonal changes) and weather (short-term and daily changes) have a significant impact on cycling and it may be expected that they also influence the level of bike-and-ride (Karel Martens,2004). Cold temperatures, rain, and high humidity levels reduce both the likelihood of using bike share and the duration of trips(Kyle Gebharta,2013).

We could conclude that, from chart 8, climate has a great influence on the use of system of public bicycle. Varied from the big gap on the swing card curve in New York, the change tendency between Chicago and Washington is quite flat. But the common issue is that the lowest usage rate concentrates on January and February of winter, the coldest season of the year. The use of public bicycle in the spring begins to rejuvenate and shows growing tendency but it becomes slow in summer gradually and maintains relatively high level in the end. The summit rate of three curves happens in September and October of Autumn and pleasantly cool weather makes it possible to reach the top for the use of public bicycle.

The use of public bicycle system is remarkably influenced by the change of seasonal temperature. People tend to choose other transportation to go out in cold winter compared to unshelled bicycle. So it is a tough issue for operators to contemplate on how to improve the use frequency of public bicycle on bad weather conditions, such as cold winter.

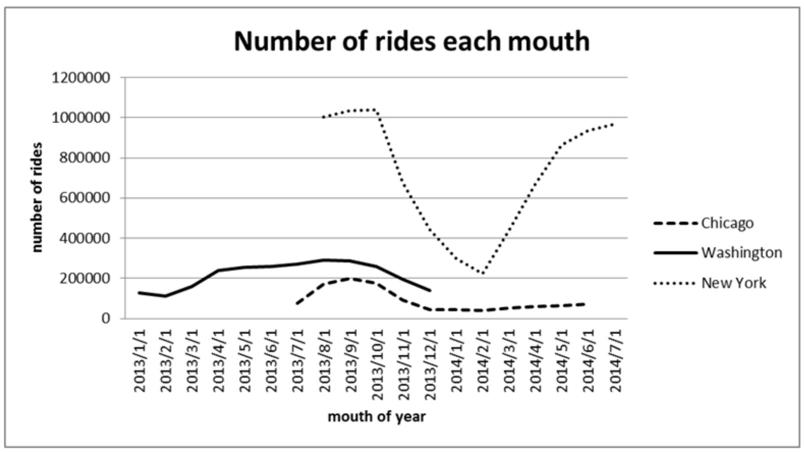

Figure 8. Number of rides in the mouth of year

5 Conclusions

Through data mining methods, we analyze public bicycle system in New York, Washington, Chicago comprehensively and get a lot of findings. . Public bike trips on weekdays is much more than on weekends, each other distributed in time are also completely different, the former showed significant commuter characteristics, which indicates that commuting is one of the most major public bicycle trip purpose. Because of its inherent limitations, Public bike has a significant feature in travel distance and time, the public bike system in three cities are free to use in less than 30 minutes, which led to more than 90% of trips concentrated within this period. The price mechanism for the development of the frequency of use of public bike has an important impact. By comparing the different cities, we also found that the site lending ratio and frequency of use are not necessarily linked. High and low temperatures for the use of public bicycle has an important impact, we found a relatively low winter temperatures will lead to a substantial decline in public bicycle usage.

Abstract: Train diagram planning is the fundamental transportation organization planning, whose quality is related directly to passenger's experience of riding and the revenue of railway interests. By analyzing the characteristics of high speed railway train diagram planning in China, and combing the big data analysis technics, this article offers a way to optimize high speed railway train diagram planning in order to provide passengers with more comfortable environment and convenient riding.
Keywords: Train diagram; Planning; Big data; Optimization.

1 Introduction

High speed railway adapts well to urban transportation with high-density and has great impact on stimulating economic growth. High speed railway in China has led national fast passenger transportation to a new dimension. Currently, a Beijing-centric eight-hour transportation circle has basically formed and the passenger train graph executed in 10 Dec. 2014 includes 2673.5 pairs of passenger trains, among which 1556.5 pairs are motor train unit, accounting for 58.2%. From the beginning, passengers generally didn't like choose high speed railway to go out, but now, most of them turn to high speed railway, which accounts for the increasing recognition of it. This high recognition results from the desire of railway interest to meet the multiple demands of passenger, and their efforts to increase their competitive power depending on the scientific and technological progress. Also, it results from their utilization of new concepts and technology in operation management. The object of railway interests is offering a more convenient and comfortable riding experience to passengers. As an enterprise, meanwhile, they also spare no efforts to get more interests.

Currently, various modes of transportation are facing passengers. Each mode of transportation varies in passenger capacity and the volume of passenger transportation. When confronted with increasingly fierce competition, it's important to offer service in high quality and efficiency for the purpose of appealing to passengers. The quality of train diagram planning influence passengers on choosing trip mode. There are two aspects to judge the quality of train diagram planning. One is judging though service satisfaction from passengers, the other is judging from whether the income and expense are reaching to the equilibrium according to the planning (Shi Feng2004, Cha Weixiong 2000).

The object of passenger train service is people, thus, it's a prerequisite to consider thoroughly about multiple travel demand, and to offer satisfactory products to most of people. Based primarily on the first aspect, this article provides train diagram planning with decision basis according to the demand and satisfaction of passengers, and establishes a planning that meets the demand of market in high quality.

2 The method and difficulties of train diagram planning

1.1 The method of train diagram planning

From the macroscopic scheme to microscopic implement, railway passenger transportation plan can be classified worldwide as: railway network, train diagram planning, train working diagram, utilization of steward and rolling stock, real time scheduling of train movement ; In each phase, according to the characters of different transportation plan, optimization theory and method of train diagram planning correspondingly is "strategy level" in the aspects of enactment timing, focus and timeliness of transportation mission. As for the subsequent "operation level", determine the origin-destination of train, train lines passing, station, frequency of service, train class, marshalling, according to feature of passenger flow is the fundament to carrying out plan.

The enactment and modulation of train diagram planning can be divided into 5 steps (Fu Huiling 2009):

Step1: Microscopic analysis of passenger flow. Enact project of railway network, transportation infrastructure and mobile devices configuration according to passenger transportation demand; Predicting the total passenger flow volume of railway by using prediction technique.

Step2: OD generation of railway network passenger flow. Before formulate train diagram planning, transform total passenger flow volume into OD distribution of railway network passenger flow, which can also be viewed as "distribution of railway physical network".

Step3: The generation of alternative set of train diagram planning. "The alternative set of train diagram planning" is a reasonable universe set of all possible trains within planning. When optimizing train diagram planning, some workable train combinations within alternative set will be chosen to be the final plan. The generation of alternative set is based on the OD distribution of the railway net passenger flow, and it will offer origin-destination of train, operation pathway between them, the frequency of service and range of number of marshalling.

Step4: Optimization of train diagram planning. If there is no constraint of transportation capacity and operation cost, the trains within the alternative set can well meet the demands. However, the scarcity of transportation resource require downsizing of the alternative set by optimizing thereby making the objective function feasible within the constraint of passenger flow and transportation capacity.

Step5: The modulation of train diagram planning. Simulate passenger's selecting behavior for train service before applying, and evaluate, as well as modulate the planning so as to meet well the demand and reasonably utilize transportation resource.

1.2 The difficulties of the establishing of train diagram planning

Based on the procedure of train diagram planning summed above, passenger flow of railway network is the basis of enacting train diagram planning. The number of passenger flow decides the quantity of trains about to work. The distribution of OD determines the section of train operation. Meanwhile, the analysis of passenger travel behavior, mainly including: demand for travel time, ticket price, ways of transfer etc. is considered another factor. According to the factors stated above, it can be determined the class, number, marshalling, speed of train, also, starting station, terminal station, operation pathway and stop-schedule plan. Generally speaking, main difficulties are as follows:

(1)The investigation and prediction about passenger flow

The investigation contains the research contents, location, time, designing the survey, selecting and using of the research equipment, method of research as well as collecting and rearranging of the investigation data, calculating the index and analysis of the results, etc.

The frequently-used method are comprehensive passenger flow investigation, sample survey of passenger condition, passenger flow of, holidays and festival passenger flow investigation, investigation of outburst passenger flow. By using these methods, do statistical analysis of number of passenger, passenger flow of section, number of station, average riding distance.

The methods mentioned above have their advantages and disadvantages, Comprehensive passenger flow investigation: long time, high workload, requiring many investigators, but in high accuracy. Sample survey: often by questionnaire, the type and amount of sample influence greatly the accuracy. Investigation of section of passenger flow: conduct sample survey to passenger flow, usually research on maximum section of passenger, and observe directly the number of passengers in train. Holidays and festival passenger flow investigation: mainly conduct a survey about passenger flow in spring festival, national day and other significant holidays and festivals by questionnaire. Investigation of outburst passenger flow: conduct survey at public places like stadium, gym, cinema, etc. Main reasons of the existence of prediction errors are: the deficiencies of the prediction models itself, dynamic changes of the premise conditions, inadequacy of sample data, only retain high prediction data rather than low, etc.

(2) Analysis of passenger travel behavior

In order to study the traits of travel behavior more accurately, we should consider the traits of passenger (like gender, age, career), traits of travel behavior (like travel objection, departure etc.), attraction area of passenger flow of station, degree of acceptance of travel cost (like first-class seats, second-class seats, hard sleeper, hard seat etc.)

Meanwhile, the analysis of passenger's individual consuming behavior is also a must so as to provide personalized service.

(3) Analysis of passenger satisfaction to train diagram planning

Passengers are the direct service objects of the train diagram planning, so, it is important for railway interest to make subsequent optimization according to feedback of passengers. As far as I know, for the new trains, railway interests will establish train diagram planning according to the passenger flow they predict, and then put new trains into operation. After that for a period, adjust the planning again according to revenue of tickets, seat occupation rate and other data, whose main source are ticket system, rather than passenger. Thus, it results in waste of resources.

3 The analysis and prediction of passenger travel based on big data.

Big data is the fundament of the proliferation of complex web science and human dynamics. The excavation technology of big data has been applied widespread to research on transportation field, especially in prediction of demand.(Wang Pu 2013) Owing to the high cost of traditional OD diagnoses in manpower and material resources, a new research direction, analyzing and acquiring OD flow by utilizing various information resources to dig data, has come into being.

The advent of big data technology provides problems stated previously with a good solution. The main contents of the problem that big data technology is able to solve are as follows:

1.3 Collection of big data

Collection of big data generally is split into 2 layers: IntelliSense layer, and basic support layer.

IntelliSense layer: include data sensing system, network communication system, sensing and adapting system, intelligent identification system and accessing system of hardware software resources. It can realize the intelligent identification, locating, tracking, accessing, transmitting, and transferring of signals, monitoring, preliminary processing and management of mass data in structuring, semi-structuring, and non-structuring. It requires the emphasis on the technology, such as the intelligent identification, sensing, adapting, transmission, accessing of big data resources.

Basic support layer: provide big data service platform with basic support environment. For instance: virtual service, database in the form of structuring, semi-structuring, and non-structuring, and resources of Internet of Things.

1.4 Preprocessing of big data

We may not necessarily get what we are concerned about from the data collected by big data collecting technology, due to the error of data, which disturbs the analyzing. Thus, preprocessing of big data is the prerequisite before storing them.

Preprocessing of big data consists of discriminating, extracting, cleaning data. The first is due to the various structures and type of data, extracting process can help us transform these complicated data into single or easy-to-process configuration, in order to analyze and process quickly. The second is filter worthless and erroneous data from those useful ones.

1.5 Storing and managing of big data

It requires the storing of data by reservoir, and the establishing, managing, calling of corresponding database. Also, it mainly solve complex technological problem of structuring, semi-structuring, and non-structuring big data managing and processing, and make big data storable, denotable, disposable, reliable, besides, make possible the effective transmission of it.

Currently, although hardware performance is increasingly enhancing, the speed of reading and writing profile through hardware is discordantly low. In particular, field of modern intelligent transportation asks for high requirement for speed of data-processing and precision, whereas traditional database can hardly meet demand, which brought about a new generation of database: NoSQL. The main representative database systems are MongoDB, HBase etc. Yahoo established a distributed calculating platform Hadoop for managing, storing and analyzing a great volume of data. Hadoop is a batching system with the merits of enormous cargo handling capacity and automatic tolerance of errors, which is applied extensively in mass data processing. However, there are some shortcomings when it is processing real time data, thus, some real time processing platform emerged in succession, like S4, Storm, who have great advantages in processing uninterrupted stream data.

1.6 Analytical processing of big data

The data processing platform of Hadoop is the core of transportation prediction and analysis system. Combined with data storage layer, it adopts Hadoop system computing framework in order to realize the processing of batching data in database.

Processing program is developed to apply in Hadoop processing platform, high-speed data processing, in order to get a more credible traffic demand analysis and forecast results. The design algorithm of the data processing, will directly affect the final demand analysis results. When conducting mining process about data for the first time, it's a prerequisite to verify model sufficiently, in order to ensure the accuracy of the basic data for subsequent. Combined with the classical traffic demand analysis model, aiming at large data characteristics, design practical data analysis algorithm can guarantee the reliability of the results of the analysis of the final demand.

3.5 Analysis of big data about travel & designing of prediction system framework

The architecture designed to analyze and forecast passenger travel are shown as bellow. It falls into four tiers, data collection layer, calculating layer, data storage layer and the interface layer.

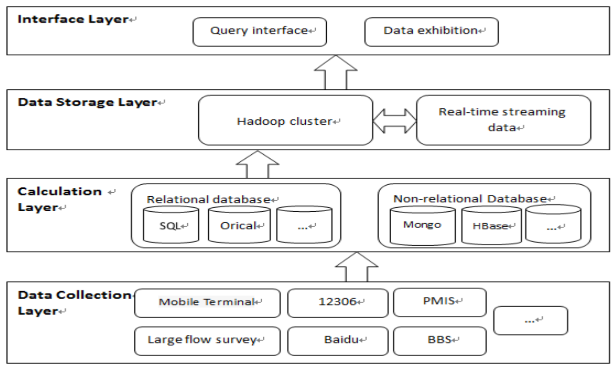

Figure 1. Framework of Data Collecting and Processing System of Big Data

The data collection layer functions as collecting traveler requirement data, which includes:

1) Large flow survey: Collecting data concerning the holiday and school time of colleges and universities, the number of students and their distribution, the cluster of migrant workers, and major events of government, large and medium-sized enterprises and institutions.

2) 12306, PMIS: Recording users' query data on the 12306 website. Each query represents a demand. 12306 has provided favorable conditions, which could record every demand of a user (travel time, change trains, preferable train types) and extract information of sold tickets, both historical and current.

3) Mobile terminal: As the number of cell phones has outweighed that of PCs, applications based on cell phone systems are becoming more diversified. With the help of APPs, data of traveler demands can be easily collected.

4) BBS: Obtaining traveler demand information and feedback through BBS.

5) Other ways: Tourism websites like CTRIP and Qunar, search engine like Baidu could be of important use. By now Baidu has provided big data prediction to forecast passenger flow volume OD.

Calculation layer: Establish corresponding data preprocessing models and algorithm model, input the data from the data collection layer and get the result data including OD, customer behavior, etc.

Data storage layer: For mass data storage, storing and retrieving data should not be restricted to a single database. Considering the trait of the traffic data, multiple database storage containing relational and non-relational databases is employed. In this layer, data sources offered by databases need to be screened in order to provide a reliable and complete access service to the databases. Often, the format of data collected by different system varies. It is necessary to process heterogeneous data in the way that, store them in different sets, design data processing algorithm for them separately and finally, integrate valid data.

Interface layer: Mainly responsible for providing data query and the presentation, providing data support for the compilation of train plan.

4 The compilation of train plan based on big data analysis

Based on the above analysis platform, the compilation process of train plan can be determined as figure 2 based on analysis of large data.

Make compilation of train plan according to the result of big data analysis, figure out several plans in the process of compiling, obtain evaluations after announcement, and adjust the result from the feedback so that we form a closed-loop with feedback. When the evaluation index reaches a set value, it will be determined as the ultimate solution to the train plan.

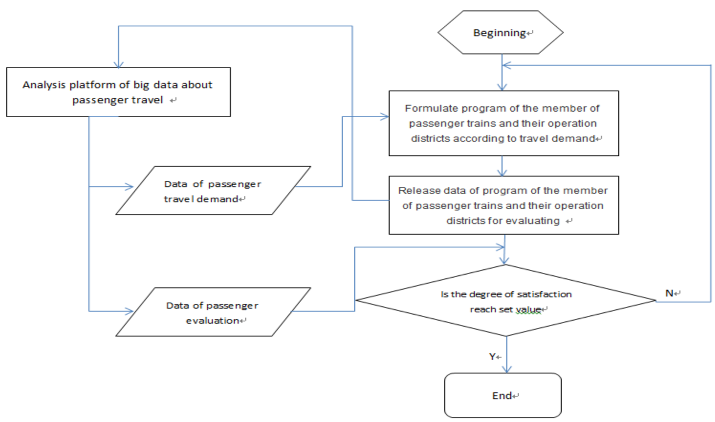

Figure 2. Train Diagram planning flow based the big data analysis

5 Conclusion

This article could not deeply discuss forecast algorithms and models, barely arguing about processing procedure of the big data analysis, roughly designing a system structure based on the technology of big data. In the days to come, how to process transportation requirement analysis according to characteristics of the big data of transportation, and combine classic mathematic models, design reasonable requirement forecasting and analytical algorithms, and make use of advantages the transportation big data is a keynote of the coming research.

[2]School of Transportation and Logistics, Southwest Jiaotong University, Chengdu 610031, China. E-mail: 358189412@qq.com

Abstract: Since the concept of big data was put forward by McKinsey, it has become a frequently cited phrase across all sectors in recent years. Logistics industry is a major beneficiary in the era of big data. Taking the logistics pattern of Cainiao network as an example, this paper analyses the application of the big data in the logistics industry, and studies the influence of big data in the logistics industry.
Keywords: Big data; Logistics.

1 Introduction

In May 2013, Alibaba Group, Intime Group, a joint Fosun Group, Fuchun Holdings, SF Group, tee one up (Shen Tong, Yuantong, Zhongtong, Yunda), ZJS Express, Huitong, and related financial institutions jointly launched the "China smart logistics backbone "(referred to as CSN) project, and the Cainiao network Technology Co., Ltd. "was established.

Cainiao network uses its own technology and resources, cooperates with industry partners, shares data with each other and creates the first domestic logistics of large data sharing platform. It helps logistics express enterprises strengthen information technology and service capabilities and reduce duplication of information systems industry. The platform enables e market analysis, quality indices service, customer mining, and data prediction function.

With the rapid development of information technology, especially in cloud computing, networking technology matures and facilitates big data applications in the logistics industry.

2 Improve the logistics processes and the efficiency of logistics

The most basic application of big data analysis techniques in logistics industry is to summarize, classify and integrate various data of the logistics chain, and then analyze and refine by technological means, help the logistics chain improvements and upgrading and allow logistics to be more intelligent, to achieve the goal of improving operating efficiencies and reducing cost.

3 Customer-centric, shifts from price competition to value competition

The core competitiveness of logistics enterprises is the quality of service, which has been improved by shifting from price competition to value competition. "Data mining" and other big data technologies which can analyze customer consuming information and grasp the consumer behavior characteristic help logistics enterprises to improve customer relationships and enhance the quality of logistics services. Logistics express enterprises should accelerate the introduction of big data and cloud computing technologies.

4 Promote the formation of "big logistics" system - Cainiao network

The arrival of the era of big data has effectively promoted the formation of the "big logistics" system and brought significant changes to the logistics industry. The so-called "big logistics" refers to the enterprise's own logistics (personnel, fleet, warehouses, etc.) and third-party logistics and distribution companies to share information and resources in order to achieve a greater level of use of various resources and reduce logistics costs. Cainiao network, a new company which established "Chinese intelligent backbone" focuses on creating a network of Chinese smart logistics backbone network that uses advanced networking technology, cloud computing and other Internet technologies, to establish an open, transparent, shared data application platform. This platform provides quality services for logistics companies, e-commerce businesses, warehousing companies, third-party logistics service providers, supply chain service providers and other types of enterprises. Cainiao network helps the logistics industry further develop to high value-added areas.

Applications of big data in Cainiao network mainly lie in the following two aspects. ① Data mining techniques to predict consumer information. For example, the network has mastered the consumer and product information in the "double 11" to guide participation of the business, logistics and express companies, consumers logistics information linkage, Cainiao network based on historical consume data, volume and other information prepared comprehensive data analysis and forecasting, to guide businesses stocking. A data mining team has been put in to analysis consumer information. ② "Logistics Data Radar" service to improve order management. "Logistics Data Radar" can provide detailed forecasting of regional and network, not only to monitor the transfer station, but also to monitor the administrative and service outlets county. These data will help courier companies to make decisions. Through line prediction it will help major courier companies to allocate warehouse explosion, and improve the last mile delivery service quality. Through radar data, businesses can clearly realize the logistics order management. Businesses can also take corresponding measures for different situations, such as care of long-term orders, the after service of orders, active follow-up and coordination of treatment and other users express abnormal situations.

With the development and application of big data technology, logistics industry will undergo enormous changes.

Firstly, big data can improve logistics resource utilization ratio. From the viewpoint of the supply chain, every step of goods distribution requires fast and efficient connection. At the same time, each node generates and needs great amount of information. An open, transparent and shared social logistics information exchange platform created through Big Data technologies can combine large data with warehousing and distribution and other logistics capabilities. Information platform can dig and analyze customer source, allow real-time tracking and analyze customer behavior by taking advantage of Intelligence and massive data analysis and processing capabilities. It allows enterprises in the system to keep abreast of logistics information and customer information. When logistics resources are insufficient, these enterprises can find internal and external idle resources through data analysis. With this technical support, scheduling or logistics can fulfill more logistics services，which will increase supply chain surplus.

Secondly, big data can reduce the cost of the logistics industry. In the traditional logistics industry, information lag, high distribution costs and other problems are prevalent. Big Data break the traditional methods of fixed personnel and fixed-line distribution. It uses minimum allocation resources to meet the largest needs of the distribution and furthest reduce logistics costs. Cainiao's information network platform collects items, personnel, vehicles, traffic and other information and stores in the database. Before delivery, based on available information, the platform fully maximizes the vehicle load, and design distribution plan and distribution lines accordingly. In the course of the flow of goods, companies can know and analyze real-time items, vehicles, traffic and other information to optimize the line in time, thus maximally saving time and costs.

Thirdly, big data changes the service mode in logistics industry. Big data provides professional information processing and value mining for logistics industry and encourages enterprises in the system to change from the behindhand service mode to advanced service mode， focus on data, and increase the level of automation and information. Through the collection, collation and analysis of the logistics industry data, we can unearth the potential customer demand, forecast the quantity and quality of commodity distribution, analyze the market trends and configure the appropriate logistics resources in the special period, in order to meet the needs of market development. In addition, the results of analysis can provide personalized service for every customer. From the enterprise's own management situation, according to the daily operation data, the platform can analyze which business is a high-profit business and recommend enterprises to develop the business by investing resources and energy. Reducing the investment in unnecessary operations and processes or giving up the business part with low profit will increase business income. In addition, enterprises can also adjust the current business structure, transfer the extra resources, and optimize the business structure of the enterprise.

Fourthly, big data can improve the management of the logistics industry. Transparent data and intelligent analysis make information of operating status and business situation of any spot in the corporate network easy to obtain. Also, big data can be used to manage, analyze, and determine the behavior of business operations, so that problems can be identified timely. This technology provides important support and guidance for corporate strategic planning, operations management and daily operations, and continuously improves the management level and services quality.

Today is an era of rapid development. The development of the logistics industry is inseparable from the use of big data, it has become a trend. Rational use of big data technology plays a positive role in management, decision, customer relationship maintenance, and allocation of resources in logistics enterprises. Eventually logistics companies become data-driven enterprises, which is a necessary condition for the enterprise in the era of big data for further development.

Structure Sensitivity of the CRH3 EMU Based on FEM

Jun Zhang; Min Zhao; Suming Xie; Jianhua Wang; and Wenzhong Zhao

College of Traffic and Transportation Engineering, Dalian JiaoTong University, Dalian 116028, China. E-mail: zhj@djtu.edu.cn

Abstract: The bodywork structure sensitivities can provide modification direction information in structure design and optimization. This research focuses on the CRH3 bodywork, in which the finite element model is established by implementation of Hypermesh software, meanwhile the modals are performed by use of finite element method. The chassis, side wall, top plate, end wall and other part thicknesses are used as the design variables, and consequently the sensitivities of the CRH3 bodywork modal frequencies to the design variables are achieved by use of numerical differential method. Results show that the sensitivities of the modal frequencies to the chassis and the side wall are maximum and to the top plates are lesser. For the end wall and the chassis front end, the sensitivities are negative.

Keywords: High-speed train; Finite element analysis; Sensitivity; Modal frequency.

1 Introduction

The highest running speed of the CRH3 has reached 350Km/h. In order to reduce its structural weight and increase the reliability, the bodywork has been widely manufactured using aluminum profile (Chang, S.M., 2004). Aluminum alloy profile bodywork carry the loads as a whole structure, so chassis, side wall and top plates could all absorb loads. The design goal of the bodywork is to satisfy the requirements of strength and stiffness under the condition of minimum weight (Tong, W.L., 2009). The bodywork stiffness is to meet the demands of the modal frequency, which is regulated by the railway industry standards of "Test methods for dynamic performance of locomotive and rolling stock on testing (TB/T 3115 2005)". The standard requires that the first-order bending modal frequency of servicing bodywork is not less than 10 Hz, and the ratio between this value and the natural frequency of vertical vibration of the framework should be greater than 1.4. During the process of optimization design, if the weight of the aluminum alloy bodywork is reduced, the strength is generally easy to be satisfied, however this sometimes leads to a fact that the modal frequency does not satisfy the requirement (Chen, X.H., 2000).

In the process of structural modifications, the structure sensitivities are needed, sensitivities are the derivative of responses to the structural parameters, the structural modifications direction can be achieved by sensitivities information (Xie, S.M., 2004), and in structure optimization design the structure sensitivities are essential (Tang, M.P., 2003). In this article a finite elements model of CRH3 emu bodywork is established, the sensitivities of modal frequency with respect to structure parameters are calculated using numerical differential method.

2 The Basic Theory of Structural Sensitivity

The sensitivities of the modal frequency to the structural parameters can be obtained directly by the differential of both sides of the modal equations. Undamped structure free vibration equation is expressed as follows

$$([K]-\lambda_i[M])\{\phi_i\}=0 \tag{1}$$

where $[K]$ and $[M]$ are structural stiffness matrix and mass matrix , respectively; λ_i is the i[th] modal frequency of the structure, $\{\phi_i\}$ is the i[th] modal vector. If the j[th] design variable is x_j, then the following equation could be achieved.

$$([K]-\lambda_i[M])\frac{\partial\{\phi_i\}}{\partial x_j}+(\frac{\partial[K]}{\partial x_j}-\lambda_i\frac{\partial[M]}{\partial x_j})\{\phi_i\}=\frac{\partial\lambda_i}{\partial x_j}[M]\{\phi_i\} \tag{2}$$

By the left multiplication $\{\phi_i\}^T$ for Formula (2), we reach the following Formula (3).

$$\{\phi_i\}^T([K]-\lambda_i[M])\frac{\partial\{\phi_i\}}{\partial x_j}=0 \tag{3}$$

Combining Formula (2)&(3), Formula (4) is obtained as follows.

$$\frac{\partial\lambda_i}{\partial x_j}=\frac{\{\phi_i\}^T(\frac{\partial[K]}{\partial x_j}-\lambda_i\frac{\partial[M]}{\partial x_j})\{\phi_i\}}{\{\phi_i\}^T[M]\{\phi_i\}} \tag{4}$$

Where $\frac{\partial[K]}{\partial x_j}$ and $\frac{\partial[M]}{\partial x_j}$ are the derivatives of structural stiffness matrix and mass matrix with respect to design variables, respectively. To accurately solve $\frac{\partial[K]}{\partial x_j}$ and $\frac{\partial[M]}{\partial x_j}$,we need to know the specific form of elements stiffness matrix and mass matrix, which is usually solved by finite difference method.

3 The Modal Analysis

3.1 Finite element model

The theoretical analysis shows that the sensitivity analysis is based on the finite element method, so in the first place we should establish the finite element model. The finite element method has become the basic method of structural analysis and is also the basic for the structural sensitivity as well as the optimization design. The finite element model of CRH3 emu T02 bodywork is shown in Figure 1. The car bodywork uses shell elements, whereas the main transformer, air equipment and other facilities utilize lumped mass to simulate.

Figure 1. Car bodywok finite element model

3.2 Modal analysis

Modal calculation uses the full vehicle model. The first-order bending modal vibration mode is shown in Figure 2. The first six orders modal frequencies are listed in Table 1.

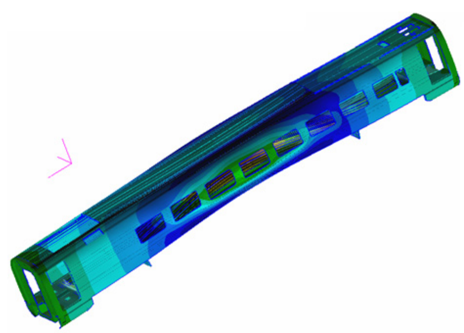

Figure 2. First-order bending modal vibration mode

Table 1. Modal vibration modes and frequencies

Modal orders	Vibration mode	Modal frequency
1	First-order diamond	7.99
2	First-order bending	8.66
3	Second-order bending	10.78
4	First-order torsion	11.51

5	Chassis second-order bending	13.53
6	Third-order bending	14.87

4 Results of The Sensitivity Calculation

4.1 Design variables

In order to research the effects of the chassis, side wall, top plate, end wall and other positions on the modal frequency, the design variables are shown in Table 2. The design variables on the outside of the middle chassis are shown in Figure 3. The only chosen design variable is the shell thickness.

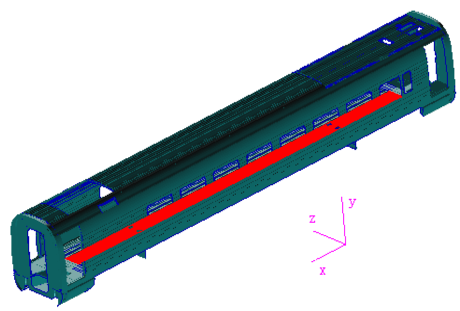

Figure 3. Design variables of the middle chassis

Table 2. Design variables

Serial number	Design variables	Thickness (mm)
1	Top plate S3	3
2	Flat plate S8	8
3	Side wall S3	3
4	Floor S3	8
5	End wall S8	5
6	End wall S5	4
7	End wall S4	6
8	End wall S6	10
9	Door S10	8
10	Front chassis S8	5
11	Chassis carling S5	7
12	Chassis lateral plate S7	32
13	Chassis coupler end grider S32	16
14	Chassis coupler carling S16	6
15	Chassis end cant beam S6	3

4.2 Modal frequency sensitivity

The sensitivities of the first six orders modal frequencies with respect to the design variables are shown in Figure 4. Figure 4 shows that, the sensitivities of each modal frequency to the side wall and to the floor are greater than to others. The maximum is modal 5th sensitivity to design variable 4 (floor), the maximum value is 0.1Hz/mm. On the contrary, for design variable 5(end wall), the sensitivity values are negative, meaning that when the thickness of design variable 5 increases, the modal frequencies will decrease.

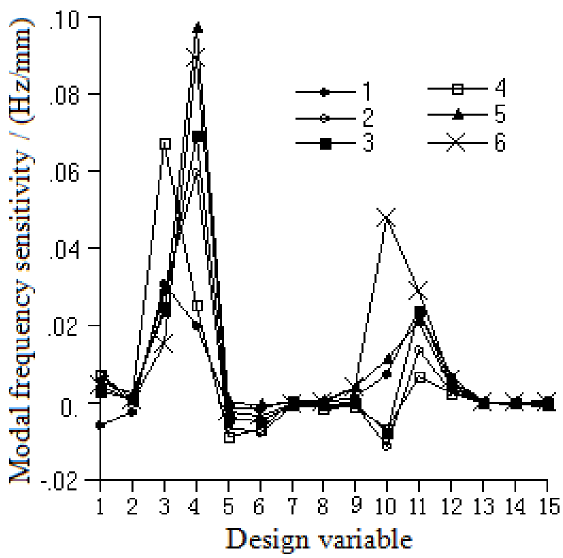

Figure 4. Sensitivities of the modal frequency

This indicates that the increase of those thicknesses have rather small or negligible contributions to the car body strength, but the impact on the bodywork's mass is greater than that on its stiffness. Generally, with the increase of the modal frequencies, its sensitivities will increase too. The rising of the most panel's thickness will lead to the rise of the bodywork's modal frequency.

5 Conclusions

This article established the finite elements model of CRH3 emu bodywork and calculated the bodywork's modal. By implementing the numerical differentiation, we calculated the sensitivities of modal frequencies with respect to each panel thickness of different parts. The results show that with the increase of modal frequencies, the sensitivities increase too. The bodywork's modal frequencies increase with increase of thicknesses of most panels. The bodyworks modal frequencies are most sensitive the chassis and side wall thickness. In general, the contribution of increase of panel thicknesses to the car body stiffness is greater than to the total mass. The research in this paper can quantitatively express rate of change of the modal frequency along with the change of the car body panel thickness, which provided a quantitative means for the bodywork structural modification.

Abstract: The proportion of loading and unload machines in the logistics industry improves constantly, rational selection and handling technology of loading and unloading machine has become an important factor in determining efficient logistics operation method. In terms of domestic railway transportation requirements, the development of mechanization of loading and unloading the is overall slow, the equipment configuration is not suitable for the handling goods category and capacity of freight yards, especially the requirements derived from the regional differences and the diverse needs of customers on the freight transportation cannot be met. Aimed at practical handling operations of freight transportation in Kunming Railway Bureau, this paper puts forward the "three-phase method" for model selection of handling machines, establishes the binomial distribution model for reasonable configuration of handling machines. And the forklift configuration of public freight yards in Kunming East Railway Station is taken as an example for analysis and solution, the results has certain operability.
Keywords: Railway freight transport; Handling machine; Model selection; Quantity configuration; Optimization.

1 Introduction

Railway loading or unloading operation is the first or last working stage of freight transport working procedure, which is throughout the whole process of freight transport. Any kinds of freight transport can't be finished without handling operations. The configuration allocation of handling equipments has direct influence on the efficiency, quality and safety of railway freight transport.

Kunming Railway Bureau (KRB) is particular in the national railway network, in which exist standard gauge tracks and meter tracks at the same time. The operation conditions are unique, many stations have different drawbacks in their freight transport. The phenomena, such as over-term service, poor technical condition and obsolete equipment still in use, exist to varying degrees. In the scope of management, there are various kinds of goods, the conditions for loading and unloading them are different, and the workload varies considerably. For some kind of goods there may be several kinds of machines suitable for handling operation, various configuration schemes of handling machines may be adopted. Thus it would be necessary to compare and select various possible types and quantity schemes of handling machines in conjunction with the freight transport practices of Kunming Railway Bureau, especially with the requirements to promote logistics center construction and the ratio targets of mechanization and equipment integrity, so as to determine the optimal configuration scheme of handling machines for the freight transport of Kunming Railway Bureau.

2 Analysis on the present handling operations of freight transport in KRB

Kunming Railway Bureau administrates the railways distributed in Yunnan, Sichuan and Guizhou provinces. The railways includes three kinds of tracks with standard gauge (1435mm), metre gauge (1000mm) and cun gauge (a Chinese unit of length, 600mm). The cun gauge tracks ceased operations in 1990, so Kunming Railway Bureau becomes the unique one with standard gauge and meter tracks in operation at the same time. The operating station layout of freight transport in Kunming Railway Bureau is as shown in Figure 1.

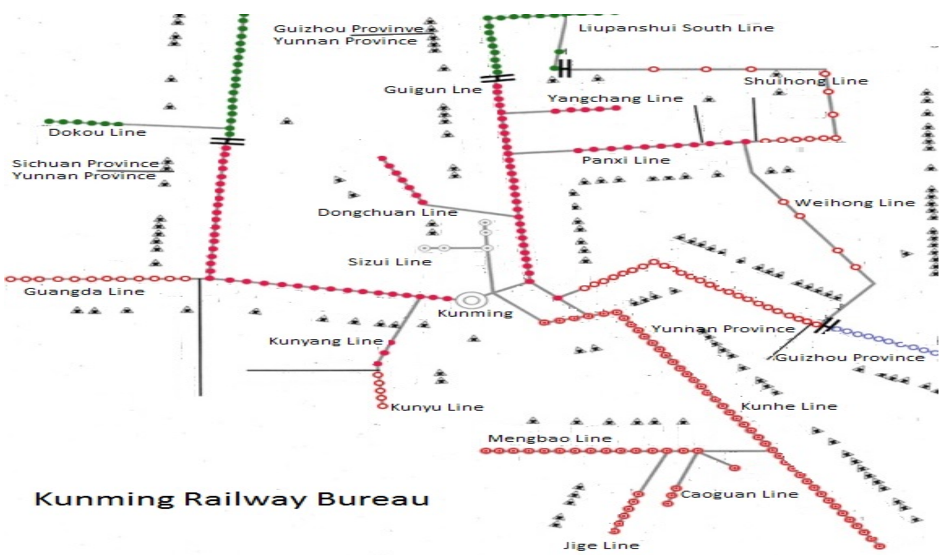

Figure 1. Sketch map of operating stations of freight transport in KRB

With the development of Yunnan Province and its association with surrounding countries, as well as Southeast Asia and South Asia becoming more open, the regional geographic environment and the location of environmental economy of Yunnan are unique and significant. The problem of insufficient for the external obsolete equipment still in use, exist to varying degrees. In the scope of management, there are various kinds of goods, the conditions for loading and unloading them are different, and the workload varies considerably. For some kind of goods there may be several kinds of machines suitable for handling operation, various configuration schemes of handling machines may be adopted. Thus it would be necessary to compare and select various possible types and quantity schemes of handling machines in conjunction with the freight transport practices of Kunming Railway Bureau, especially with the requirements to promote logistics center construction and the ratio targets of mechanization and equipment integrity, so as to determine the optimal configuration scheme of handling machines for the freight transport of Kunming Railway Bureau.

2 Analysis on the present handling operations of freight transport in KRB

Kunming Railway Bureau administrates the railways distributed in Yunnan, Sichuan and Guizhou provinces. The railways includes three kinds of tracks with standard gauge (1435 mm), metre gauge (1000 mm) and cun gauge (a Chinese unit of length, 600 mm). The cun gauge tracks ceased operations in 1990, so Kunming Railway Bureau becomes the unique one with standard gauge and meter tracks in operation at the same time. The operating station layout of freight transport in Kunming Railway Bureau is as shown in Figure 1.

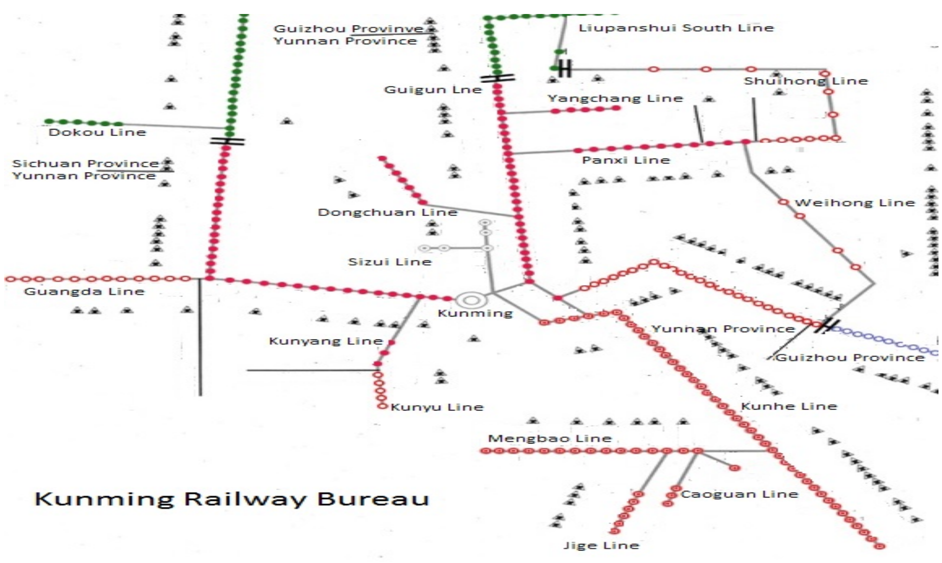

Figure 1. Sketch map of operating stations of freight transport in KRB

With the development of Yunnan Province and its association with surrounding countries, as well as Southeast Asia and South Asia becoming more open, the regional geographic environment and the location of environmental economy of Yunnan are unique and significant. The problem of insufficient for the external passage, especially international railway passage becomes more serious. The transport volume trends of major goods in KRB are represented as Figure 2 (Kunming Railway Bureau and Southwest Jiaotong University, 2014).

At present, there exist some problems in the configuration or allocation of handling machines for the freight transport in KRB as the following:

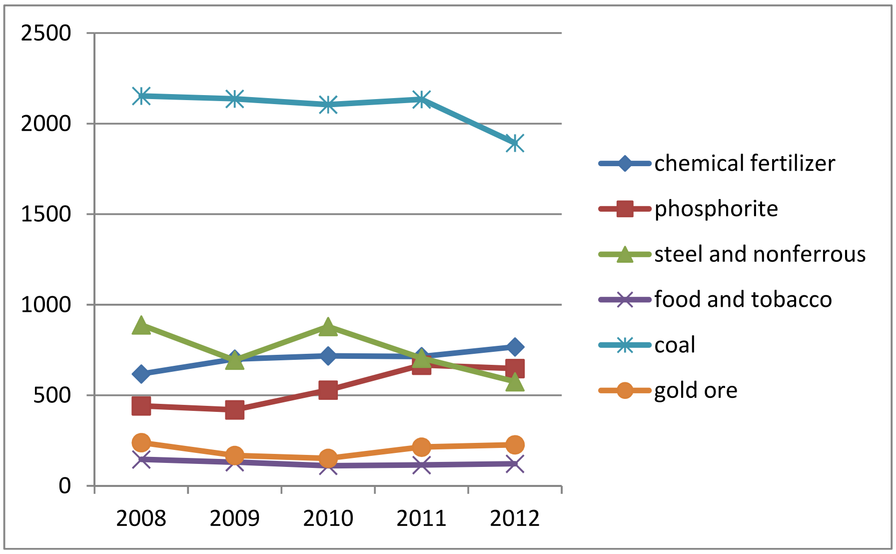

Figure 2. Transport volume trends of major goods in KRB

(1) The equipments are in overtime service, the degree of aging becomes more and more and the performance has been degrading. For example, the 20T gantry in Qujing Station has been in service since 1988.

(2) Because of the repeated installation of handling resources in some areas it is difficult for the scale effect to come true, such as Baita Village station and nearby small stations.

(3) The equipment quantity is insufficient, the loading and unloading are carried out fundamentally by manual labor in some public freight yards, such as Yuanmou station.

(4) Special equipments and universal ones are mixed use, the configuration or allocation of handling machines does not adapted to goods category and yard capacity.

(5) In the model selection there is either blindly novelty seeking, or yield to the temptation of low prices. So scientific criteria are absent and model selection is improper.

3 Model selection method of handling machinery

Aimed at the freight handling practices in KRB, the “Three Phase Method” for the choice of handling machinery types in KRB as the following:

Phase 1——Preliminary Filtering

The basic principles in this stage are：

(1) Based on the characteristics of freight category.

(2) Adapting to the operation property of railway freight yard.

(3) Considering time requirements.

(4) The equipments selected have smooth functioning and work cooperatively.

(5) Various rigging could be adopted to extend the operation scope for a kind of handling machinery.

(6) Standardization, energy conservation and environment protection.

Phase 2——Property Matching

By means of analyzing respective characteristics of handling equipments and tasks (e.g. works of train loading and unloading area, horizontal transport and goods stacking area respectively.), the matching among the handling equipment, goods and conditions can be achieved to determine reasonable handling equipment.

Phase 3——Comprehensive Comparing and Selecting

Through the above two phases the model selection of handling machinery have mainly finished for the great majority of railway freight yards. For some loading and unloading equipments whose operation characteristics are similar and each performance has its own merits, the choice is difficult, so it is necessary to make further comparison and selection in consideration of technical performance, utilization of yard and handling cost so as to make a explicit and scientific decision.

4 Quantity optimization of handling machinery

As the loading and unloading operations in railway yards requires multiple machines working cooperatively, the problem of handling equipment allocation ratio emerges.

4.1 Ratio control

Select 3 kinds of loading and unloading machine commonly used in container center stations as the research object: rail-mounted gantry cranes, front-handling mobile cranes (reach stacker, positive hanging) and container trucks. And suppose the following hypotheses:

(1) The rail-mounted gantry cranes and reach stackers work in uniform motion.

(2) The waiting time cost is ignored.

One-third containers in the trains are transported to auxiliary container yards, so there must be some intervals for the container trucks to reach the handling tracks. The rail-mounted gantry cranes, reach stacker and container trucks work cooperatively to accomplish the handling and transporting tasks of the containers. That is

$$\frac{NT_G}{Z_G} = \frac{N_J T_J}{Z_J} = \frac{N_Z T_Z}{Z_Z} \tag{1}$$

where N, N_J and N_Z is the handling volume of container trains (TEU), transporting volume of trucks (TEU) and handling volume of reach stackers (TEU) respectively, Z_G, Z_J and Z_Z is the quantity of rail-mounted gantry cranes, container trucks and reach stackers respectively, T_G, T_J and T_Z is the average cycle working time of rail-mounted gantry cranes, container trucks and reach stackers respectively.

This model objective is to minimize the waiting and spare time in the process of loading and unloading in which the containers are loaded or unloaded to/from trains and transported from/to the origins/destinations, that is, the quantity ratio among the rail-mounted gantry cranes, container trucks and reach stackers is to be optimized.

4.2 Reasonable amount determination

Relative researches indicate that there is a certain relationship among the handling machinery amount, attendance number and serviceability rate in a railway freight yard. Suppose there is a freight station equipped with *n* handling machines whose serviceability rate is α. When *m* handling machines are required to be on duty, they must be selected from *n* ones, and each choice has two results: in good condition or not. So the number on duty, express as *x*, is binomial distribution (Chen Chuanshi and Li Deyuan, 1988) on *n* and α, which can be written as

$$P\{x = m\} = C_n^m \alpha^m (1-\alpha)^{n-m} \qquad (m = 0,1,2,...,n;\ \ 0 < \alpha < 1) \tag{2}$$

Then let $P_k (0 < k \le n)$ stand for the attendance rate of guarantee that means the probability of *k* machines can be selected at least from *n* ones. Thus there is

$$P_k = \sum_{m=k}^{n} P_n(m) = \sum_{m=k}^{n} C_n^m \alpha^m (1-\alpha)^{n-m} \qquad (k = 0,1,2,...,n) \tag{3}$$

And the mathematical expectation of the rate (A_k) can be obtained by multiplying the number on duty and the attendance rate of guarantee of handling machines, that is,

$$A_k = k \cdot P_k = k \sum_{m=k}^{n} C_n^m \alpha^m (1-\alpha)^{n-m} \tag{4}$$

In response to different *k*, there will be a series of P_k and A_k, the most A_k of which corresponds to the optimum number on duty k^*. In this way there will also be a series of n, α and k^* corresponding each other, which can be transformed into a table. Given α and k^* the reasonable amount of handling machines in possession n can be looked up in the table.

5 Application of Kunming Railway East Station

Kunming Railway East Station (KRES) equips with various types of loading and unloading machines, the problem of reasonable amount determination is discussed in the case of forklifts in the public freight yard of KRES as follows.

There are 40 forklifts distributed in the south, east and west public yards. Their serviceability rate is 95%. According to statistical data, the numbers of forklifts on duty and its frequency in the public yard of Kunming Railway East Station are listed in Table 1 and their cumulative frequency distribution is shown as Figure 3.

Table 1. Numbers of forklifts on duty and its frequency

Number on duty	Occurrence number	Frequency
12	8	0.022
25	16	0.044
28	25	0.069
29	30	0.082
30	38	0.104
32	52	0.142
33	69	0.189
34	78	0.214
35	43	0.118
36	4	0.011
38	2	0.005

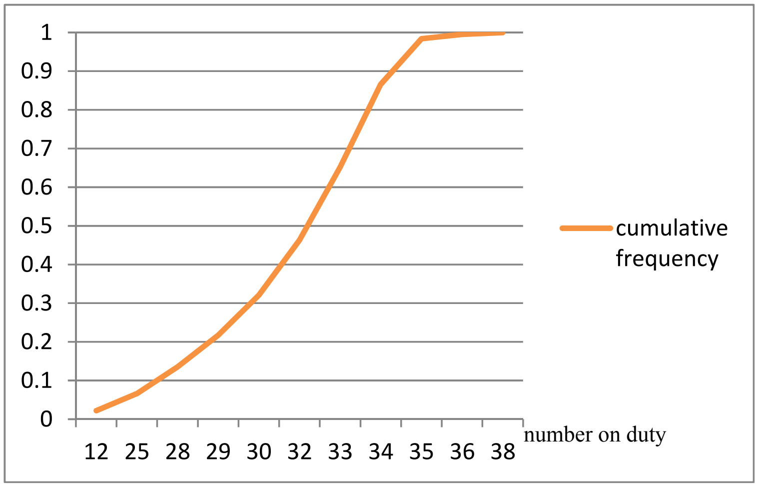

Figure 3. Cumulative frequency distribution of the forklifts on duty

By assigning different values, n and α vary in a certain range. The k^* varying accordingly may be obtained based on the above models with the help of MATLAB compiling and computing. Then a set of n, α and k^* corresponding each other are transformed into the Table 2 as below. The k^* in it stands for practical number of forklifts on duty to ensure normal production, thus n stands for the reasonable number of forklifts in possession.

6 Conclusions

In short, the selection of handling equipment cannot justly distinguish good and bad, but should be combined with practical operational needs, thus the main operation mode and optimal quantity can be determined according to different regions. Finally developing vision problems, along with the changes in the loading and unloading conditions, selected machinery will also change.

Table 2. Query table of reasonable number of forklifts in possession

α / n / k^*	95%	90%	85%	80%
20	17	16	15	14
26	23	21	19	18
30	26	24	23	22
36	32	29	27	25
40	35	33	30	28

46	41	38	35	32
50	44	41	38	35
55	49	45	42	39
60	53	50	46	43

Strength Analysis of Mounting Brackets and Connecting Bolts on an EMU Inner End Door

Yana Li; Yongming Li; and Shengjian Huang

School of Traffic and Transportation Engineering, Dalian Jiao Tong University, Dalian 116028, China.

Abstract: The strength of the key parts and associated coupling bolts on the high-speed car body, which have direct related to the safe operation, is an important content of vehicle design. Nonlinear static strength analysis of mounting bracket on EMU inner end door was calculated on 8 working conditions with ANSYS software and very part was assessed. Then, sliding coefficients of hanging bracket on the most dangerous condition were analyzed. Results show that contact surface sliding coefficients were less than 1, the hanging bracket is safe and is not prone to sliding. Finally the influence of the sliding coefficient and bolt strength based on different preload was studied. With the preload becoming increasingly, the sliding coefficient became smaller and the bolt stress became larger. Taking the both influence into consideration, a proper range of the preload meeting the design requirements was obtained to provide some technology reference on the structural design and selection of bolts for engineers.

Keywords: Bolt; Contact nonlinear; Strength; Sliding coefficient.

1 Introduction

In order to meet the strength requirements, confirm weakness and provide reference for improvement and determine of the connecting parts on high-speed train, detailed strength analysis is needed. The bolt coupling has been widely used among the key components of high-speed train. Compared to other connections, bolts are easily assembled and repaired. This connection type can increase the preload to prevent loosening and cannot cause a phase change of material component. At present, there are two main calculation methods about bolts strength at home and abroad. One is the traditional theoretical calculation which is generally based on the "Mechanical Design Handbook" or few based on "VDI 2230", the other one is FEA. Taking the mounting bracket on EMU inner end door as object, the 3D model and contact relationship were built with ANSYS software to conduct contact nonlinear strength analysis and sliding coefficients calculation. Under different preload conditions, bolt stress regulation and hanger sliding coefficients change were studied to provide a strong technical support for similar structure design in the EMU.

2 Contact nonlinear finite element method

Overall, the solution method of contact problem can be divided into two categories, one is finite element method, the other is mathematical programming method. Contact force and deformation meet boundary condition through the iterations and the introduction of the penalty function and Lagrange multiplier method etc. In this paper, Lagrange multiplier method is used. Taking the smooth contact for example, the satisfied constraint conditions are:

$$\begin{cases} g_n = U_n - U'_n - \delta^0{}_n \ge 0 \\ (U_n - U'_n - \delta^0{}_n)P_n = 0 \\ P_n \le 0 \end{cases} \tag{1}$$

U_n、U'_n、$\delta^0{}_n$ are respectively for the normal displacement, initial spacing at any contact point on the boundary objects Ω and Ω'. P_n is the normal force.

The common finite element formula is below.

$$[K]\{U\} = \{F\} \tag{2}$$

The equation can be obtained by the energy functional variation.

For example, the potential energy functional of a deformable body can be expressed as:

$$\Pi_p = \frac{1}{2}\{U\}^T[K]\{U\} - \{U\}^T\{F\} \tag{3}$$

According to the principle of minimum potential energy, for the displacement of deformable body satisfying the boundary conditions, the potential energy Π_p is minimum and satisfies the stress boundary conditions. That is:

$$\delta\Pi_p = 0 \tag{4}$$

The functional is written as with Lagrange multiplier method:

$$\Pi_L = \Pi_p + \{\lambda\}^T\{g_n\} \tag{5}$$

$\{\lambda\}$ is the introduced multiplier. The formula (4) can be rewritten as:

$$\delta\Pi_L = 0 \tag{6}$$

In which displacement $\{U\}$ and Lagrange multiplier $\{\lambda\}$ are unknowns. Π_p is the quadratic term of displacement $\{U\}$. After formula (6) variation, the elements of main diagonal corresponding $\{U\}$ are not zero and corresponding the multipliers $\{\lambda\}$ are zero in the total stiffness matrix which cannot be solved due to singularity. For this reason, a perturbation Lagrange multiplier method is created. The formula (6) through $\varepsilon > 0$ introduction is written as:

$$\Pi_c = \Pi_p + \{\lambda\}^T \{g_n\} - \frac{1}{2\varepsilon}\{\lambda\}^T \{\lambda\} \tag{7}$$

Compared with Π_L, Π_c has a quadratic term $\{\lambda\}$. The main diagonal elements are no longer zero corresponding to $\{\lambda\}$ and the total stiffness matrix is no longer singular matrix. When $\varepsilon \to \infty$, the formula (7) is reduced to the equation (6).

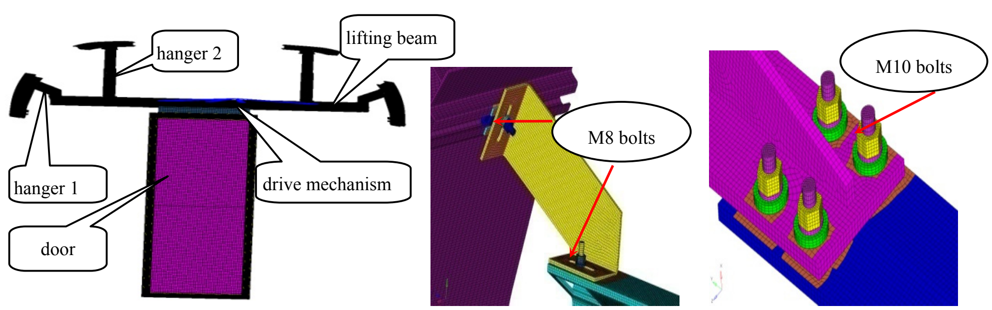
3 The finite element model

3.1 Geometry

The mounting bracket structure was comprised of hanger, lifting beam, bolts, door and drive mechanism etc (as shown in Fig. 1). Hanger 1 was connected with the roof and lifting beam by two M8 bolts respectively. Hanger 2 was connected with itself by eight M10 bolts, with roof by four M10, and with lifting beam by eight M8 bolts. Inner end door weight was about 60 kg and drive mechanism weight was 20 kg.

3.2 Finite Element Model

The finite model was meshed with hexahedral elements (solid 185) and driving mechanism was meshed with mass element (mass 21). According to contact location, the relationships of all parts between bolt, bolt gasket, hanger and lifting beam were defined and there were 104 contact pairs in total. The whole finite element model was 670,664 elements and 922,426 nodes.



(a) overall view (b) local view 1 (c) local view 2

Fig 1. Finite element model

3.3 Calculation Conditions

(1) Preload calculation

There were two types of bolts M10 (tightening torque 36 N•M) and M8 (tightening torque 12 N•M) in the model. The preload was calculated with Eq. 8 in "Mechanical Design Handbook" .

$$F = T/(0.2d) \tag{8}$$

Where d was the bolt diameter, T was tightening torque, F was the preload. According Eq. 8, the preload of M10 bolt was 18000 N and M8 bolt was 7500 N.

(2) The loading cases

According to EN12663-2010 standard, the acceleration values of the device and its components were shown in Table 1.

Table 1. Load case

Case	Longitudinal	Lateral	Vertical	Case	Longitudinal	Lateral	Vertical
1	3*g	1*g	(1 + c) *g	5	3*g	1*g	(1 - c) *g
2	3*g	-1*g	(1 + c) *g	6	3*g	-1*g	(1 - c) *g
3	-3*g	1*g	(1 + c) *g	7	-3*g	1*g	(1 - c) *g
4	-3*g	-1*g	(1 + c) * g	8	-3*g	-1*g	(1 - c) *g

Note: C was 2 depending on the position of the inner end door.

(3) Displacement constraints

Roof and side wall profiles on both sides were full restraints, x = 0, y = 0, z = 0.

4 Nonlinear static strength calculation results

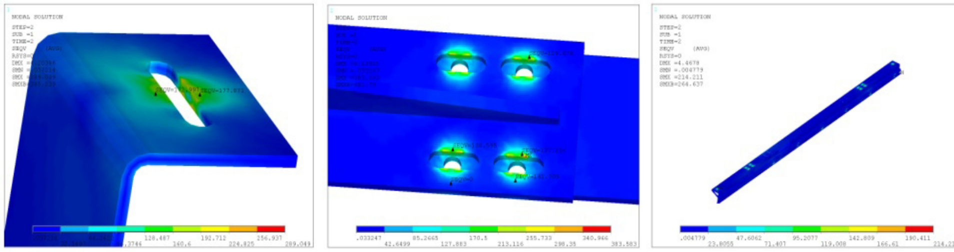
4.1 Component strength calculation

After contact nonlinear finite element analysis, the maximum static strength results of the components under 8 working conditions were shown in Table 2 and stress cloud were shown in Fig. 2.

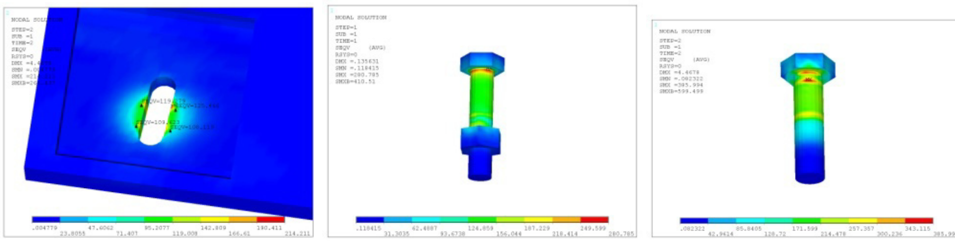
Table 2. Strength results

Unit: MPa

Parts	Case	Maximum stress	Yield stress
Hanger 1	7	178	205
Hanger 2	1	142	215
Lifting Beam	4	126	145
M8 Bolt	preload	281	450
M10 Bolt	3	386	450



(a) local hanger 1 (b) local hanger 2 (c) lifting beam



(a) local lifting beam (b) M8 bolt (c) M10 bolt

Fig 2. Stress results

Table 2 and Fig.2 showed that hangers, lifting beam and bolts were satisfied with the strength requirements.

4.2 Hanger sliding coefficients

(1) Calculation Method

If two objects under the external force only have sliding tendency and no the relative sliding (as shown in Fig. 3), the force between contact surface preventing their relative sliding is called static friction force. There is a maximum value changed with external force. The maximum static friction force is calculated as:

$$f_{\max} = N \times \mu \tag{9}$$

Where μ is the friction coefficient, N is the maximum positive pressure.

If a object relative to another object has relative movement tendency, the static friction force increases with external force, but not infinitely increases and when external force increases to exceed the maximum static friction force, object can move. With the principle mentioned above the sliding contact surfaces are analyzed.

(2) Sliding coefficients analysis process

Reading the ANSYS calculation results;

a) Finding a contact pair;

b) Extracting pressure and friction force between the contact surface on current case;

c) According to the ratio of contact friction force and maximum static friction force(sliding coefficient), judge contact surface sliding conditions. If the ratio is 1, the object may be slid.

(3) The calculation result

Fig. 4 showed the number and location of the contact surface of hanger 2. The sliding coefficients on the most dangerous condition (case 3) were given in Table 3.

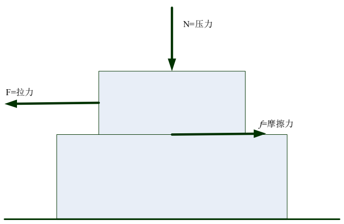


Fig 3. Friction force sketch

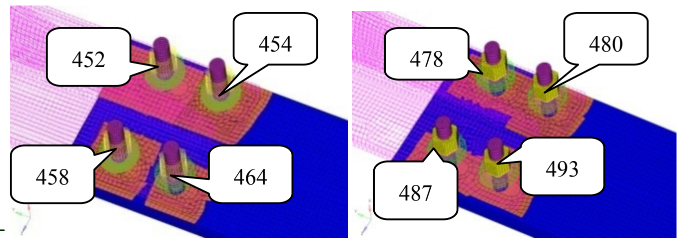

Fig 4. Contact surfaces number sketch

Table 3. Sliding result data

Element number	Pressure N (N)	Maximum static friction force (F_{max} =N*0.15) (N)	Contact friction force f (N)	Sliding coefficient (f/F_{max})
452	15756.0	2363.4	434.5	0.184
454	16552.3	2482.8	324.4	0.131
458	16881.2	2532.2	693.2	0.274
464	18016.7	2702.5	817.4	0.302
478	16451.0	2467.6	314.1	0.127
480	15753.1	2363.0	437.6	0.185
487	16935.3	2540.3	689.8	0.272
493	18303.8	2745.6	959.1	0.349

Note: friction coefficient μ is 0.15.

From Table 3, in the most dangerous condition, the sliding coefficients of the contact surface around the hanger bolt were relatively small, less than 1, indicating that the hanger 2 was not prone to slid.

5. Preload influence on sliding coefficient and bolt strength

5.1 Preload influence on sliding coefficient

With the change of M10 bolt preload, hanger sliding coefficient changed gradually. Taking the contact surface NO493 for example, relationship between the preload and the sliding coefficient was shown in Table 4.

Table 4 . Sliding coefficient variation

Preload F (N)	Sliding coefficient	Preload F (N)	Sliding coefficient
10000	0.705	16000	0.399
11000	0.623	17000	0.361
12000	0.579	18000	0.349
13000	0.539	19000	0.303
14000	0.49	20000	0.282
15000	0.442	21000	0.265

As shown in table 4, with the increase of the preload, the hanger sliding coefficient decreased. When the coefficient was 1, the hanger would be slid. If the sliding coefficient was considered only, preload could be selected in the range of 10000 ~ 21000N.

5.2 Preload influence on bolt strength

With the change of M10 bolt preload, bolt stress changed gradually. The relationship between the bolt preload and bolt stress was shown in Table 5.

Table 5. Bolt stress variation

Preload F (N)	Bolt stress σ_s （Mpa）	Safety factor	Preload F (N)	Bolt stress σ_s（Mpa）	Safety factor
10000	222	2.03	16000	354	1.27
11000	244	1.84	17000	376	1.20
12000	266	1.69	18000	386	1.17
13000	288	1.56	19000	420	1.07
14000	310	1.45	20000	442	1.02
15000	332	1.36	21000	464	0.97

As shown in table 4, with the increase of the preload, bolts stress increased gradually. When preload increased to 20000 N, bolt stress reached to 442 MPa closely to its yield strength 450 MPa. If continue to increase preload, bolt stress could be larger than 450 MPa. Taking bolt safety factor (1.2-1.5) on static load into consideration, bolt preload should be selected in the range of 13167 N~17000 N.

6. Conclusions

1) The analysis showed that the static strength of hangers, lifting beam, bolts and other parts of mounting bracket meet the design requirements in working condition and hanger 2 would not prone to slide;

2) The preload had a critical impact on bolt strength and sliding coefficient. With the preload increased, the sliding coefficient decreased and bolt stress increased. When the preload exceeded 20000 N, bolt stress would exceed its yield strength.

3) If the sliding coefficient was less than 1, considering common bolt safety factor (1.2-1.5) under working conditions, the corresponding bolt preload selection should be in the range 13167 N~17000 N. In this range, bolt safety and reliability could be guaranteed and they provide a good reference for engineers on bolt preload selection.

Abstract: Taking a high-speed EMU as the research object, the noise samples of vehicle at different speeds are collected, the subjective evaluation experiments of sound quality preference are conducted using paired comparison method. After calculation and analysis of the main psychoacoustic parameters of each sample, it can be found that the sound quality preference in EMU decreases with the increasing of speed. SPSS are used to analysis the multivariate linear relationship of preference and objective parameters in EMU. It can be found that the relationship between preference and objective parameters are linear negatively. The preference has obvious strong linear relationship with loudness and sharpness, which show that sound quality in EMU is closely related to loudness and sharpness. The mathematical fitting model between subjective assessment of preference and objective parameters is established by calculating loudness and sharpness. Then through the comparative analysis of the sound quality preference curve from evaluation model and experiment, the evaluation results of the overall sample has strong consistency with the evaluation results of the traditional method of paired comparison. It can be used to predict and calculate the interior sound quality of EMU.
Keywords: High-speed EMU; Sound quality preference; Subjective and objective evaluation; Correlation.

1 Introduction

Foreign researchers found that the interior sound quality of EMU comes from the evaluator's general auditory properties, which is depended on the relevant features of EMU. The preference reflects the occupants' auditory perception to sound, which could be used to describe the preference degree of occupants to sound. Domestic researchers have done a lot of work on how to select the psychoacoustic parameters that is in line with Chinese people's characteristics (Sahin, 2008), and how to obtain a more accurate subjective sensation of the evaluators. According to analysis of evaluation results, the evaluation model is built to measure sound quality preference objectively, which is important to analyze, control and evaluate the interior noise of EMU.

Subjective evaluation of sound quality involves many fields, such as the experimental preparation before work, experimental method and experimental data processing and analysis of inspection, etc. German HEAD Acoustics noise and vibration measurement and analysis system, including the SQLab II multi channel data acquisition recorder and HMS III binaural information collector and Artemis measurement analysis software is used to collected sound samples in this experiment. Acquisition of the sound samples are play backed in laboratory and objectively analyzed, excluding samples from outside interference or unstable operating conditions of the sample, the original signal sampling to select the length truncation and loudness equalization processing, and 12 effective noise samples is obtained, the length is 5 seconds, the subjective evaluation was performed using the paired comparison method. The words selected to describe sound quality are all preference, and according to calculation of main psychological acoustical objective parameters of the noise sample and analysis of the relationship between the subjective evaluation and objective parameters, the prediction model of the interior sound quality of EMU is proposed based on the theory of regression analysis (Zhao Linfeng, 2012).

2 Subjective evaluation experiments and analysis

2.1 Experimental design of paired comparison

2.1.1 Evaluation body

Reference to foreign experience to form the jury and the actual situation of this study, in this paper, the experimental evaluation of a total of 20 selected officers are college students with normal hearing, aged 21 years to 28 years old, mean age 24 years, of which 10 were boys and girls 10, in good health and no hearing impairment, 18 people ride over EMU (Zhang Xiaojuan, 2013).

2.1.2 Experimental Design and Process

The subjective evaluation was chosen in a semi-anechoic room, shown in Figure 1, the room temperature is about 21°C, humidity between 30% to 45%, well ventilated no smell, hearing guaranteed environment. On the basis of the evaluation does not affect the validity of the experiment, in order to reduce the workload, the single-byte matrix is used, 12 sound samples through permutations and combinations, pairwise comparison, a total of 84 pairs. Each sound sample is about 5 seconds, the interval between two sound samples is 2 seconds, then the evaluation time of each pair is about 12 seconds, the time required to complete the evaluation of a group is about 18 minutes, which can fit the foreign evaluation experience of sound quality.

Figure 1. Subjective evaluation experiment in semi-anechoic room

2.2 Data processing and inspection

According to statistical knowledge, the subjective evaluation data can not be directly used as the final result of the analysis parameters, experimental data error may occur due to the influence of subjective and objective factors. In order to ensure the authenticity and reliability of the statistical results obtained, the error and reliability must be tested, and the invalid data should be eliminated. In this paper, the data inspection method of Professor Mao Dongxing of Tongji University is used to eliminate error and ensure the validity of data (Mao Dongxing, 2005).

In order to determine whether the data are reliable, the paper adopts the method of weighted error rate of the proposed by Kendall to carry out the reliability(Kendall MG,1940). Through calculation, the weighted consistency coefficient of evaluation are calculated as shown in Table 1. From table 1, it can be simply find that except tp01 is 85.50%, tp09 is 87.90%, the weighted consistency coefficient of remaining 18 evaluators are more than 90%, and the average weighted consistency coefficient is 96.1%, which indicates that the entire evaluation of experimental data has a higher reliability.

Table 1. Weighting consistency coefficient

Evaluator	Tp1	Tp2	Tp3	Tp4	Tp5	Tp6	Tp7	Tp8	Tp9	Tp10
weighting consistency coefficient	0.855	0.974	0.978	0.905	0.946	0.968	0.975	0.974	0.879	0.953
Evaluator	Tp11	Tp12	Tp13	Tp14	Tp15	Tp16	Tp17	Tp18	Tp19	Tp20
weighting consistency coefficient	0.995	0.952	0.903	0.917	0.971	0.964	0.989	0.944	0.966	0.967

2.3 Calculation and analysis of the preference value

According to the result of weighted consistency, the evaluation data evaluation personnel of Tp1 and Tp9 should be eliminated for its low reliability. Excluding the two reviewers' misjudged data, the average number of remaining with one voice all the evaluators to sample a sound preference scores that samples are selected evaluators all valid, the value calculated by Matlab is the final preference value, which is shown in Table 2. The greater the preference value, the better the sound sample sounds.

Table 2. preference level and parameters values

	Preference	linear	A Weighting	loudness	sharpness	roughness	fluctuation
S1	4.80	106.6	68.7	26.5	1.38	2.17	0.0828
S2	3.90	108.3	70.6	28.7	1.47	2.19	0.0709
S3	3.10	105.5	69.4	27.9	1.41	2.16	0.0864
S4	3.70	104.7	69.6	27.1	1.42	2.13	0.0546
S5	0.80	109.6	71.9	32.2	1.65	2.51	0.0728
S6	1.40	107.1	73.1	35.8	1.58	2.55	0.0661
S7	7.90	104.5	64.2	17.7	1.17	1.07	0.0796
S8	8.90	104.8	63.1	18.1	1.26	1.16	0.1005
S9	7.80	104.3	64.7	20.3	1.29	1.48	0.0817
S10	8.20	106.2	64.6	20.4	1.28	1.44	0.0842
S11	7.10	106.7	65.3	21.6	1.34	1.69	0.0537
S12	8.20	106.9	66.2	22.8	1.36	1.67	0.0501

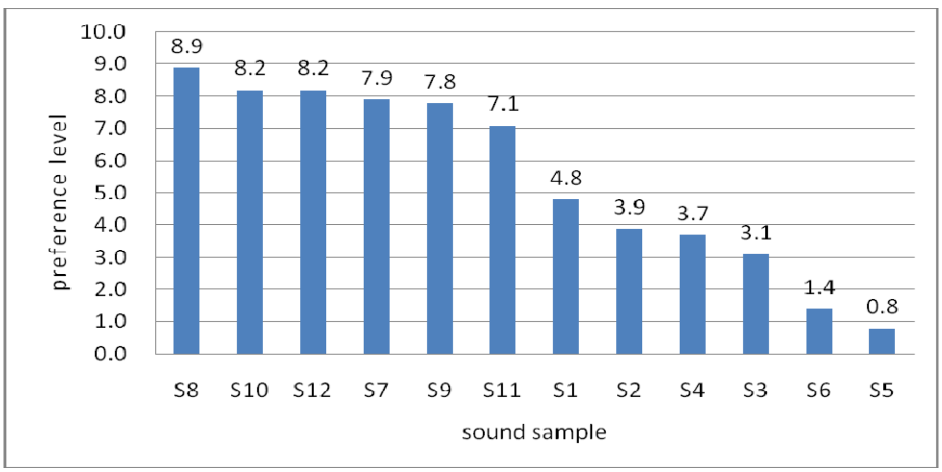

Figure 2. preference level of the sample

It can be seen from Figure 2, the sound preference value of sample 8 is the highest, and it is generally believed that the subjective feeling of sample 8 is the best. In contrast, the sound preference value of sample 5 is the smallest, and its loudness and sharpness are the largest, which shows that the vast majority of evaluators' evaluations to sample 5 are poor.

2.4 The correlation analysis of subjective evaluation and objective of sound

2.4.1 Correlation between subjective and objective

The main purpose of correlation analysis is to research the relationship among these variables. The correlation coefficient r is the main parameter to indicate the relationship among variables, which is in the range [-1,1]. The absolute value of the correlation coefficient r is closer to 1, the relationship among variables is more closely; the absolute value of the correlation coefficient r is closer to 0, the relationship among variables is more estrange (Blauert J, 1997).

Pearson correlation coefficient is used to measure whether the two daters in a line. The formula is:

$$r = \frac{n\sum x_i y_i - \sum x_i \sum y_i}{\sqrt{n\sum x_i^2 - (\sum x_i)^2}\sqrt{n\sum y_i^2 - (\sum y_i)^2}} \quad (1)$$

Pearson correlation coefficients can be obtained from software SPSS19, as shown in Table. It can be seen from Table 3, the relationship between preference and objective parameters of the sound samples is highly negative, the higher the value of each parameter, the worse the preference value. The correlation relationship between Loudness and A-weighted sound pressure level and preference is high, which is more than 0.96, but the attenuation characteristic of A-weighted sound pressure level is low. So, if loudness is selected as a dependent variable of preference, the correlation coefficient of preference and loudness is 0.964, which is the strongest(Kang Runcheng,2011).

Table 3. Pearson correlation coefficient between preference level and objective parameters

	Preference	A Weighting	linear	loudness	sharpness	roughness	fluctuation
Preference	1	-.961**	-.578	-.964**	-.957**	-.943**	.192
A Weighting	-.961**	1	.606*	.988**	.927**	.955**	-.274
linear	-.578	.606*	1	.658*	.675*	.662*	-.251
loudness	-.964**	.988**	.658*	1	.948**	.976**	-.286
sharpness	-.957**	.927**	.675*	.948**	1	.968**	-.307
roughness	-.943**	.955**	.662*	.976**	.968**	1	-.345
fluctuation	.192	-.274	-.251	-.286	-.307	-.345	1

Note: "**" denotes when confidence coefficient (double side) is 0.01, the correlation is significant. "*" denotes when confidence coefficient (double side) is 0.05, the correlation is significant. "-" denotes negative correlation.

In order to reveal the correlation between subjective evaluation results of preference and psychoacoustic objective parameter obviously, Scatter plot was used to analyze the correlation between subjective and objective evaluation, which can be used to determine the relationship between subjective preference and psychoacoustic parameters , as shown in Figure 3-4.

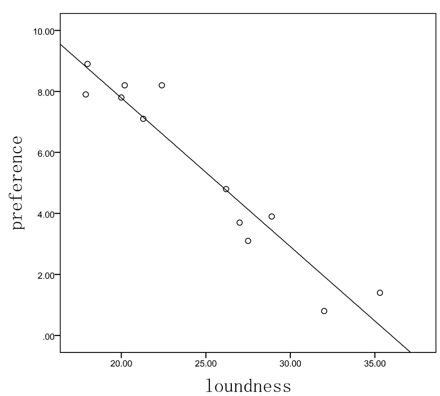

Figure 3.Relationship between preference level and loundness

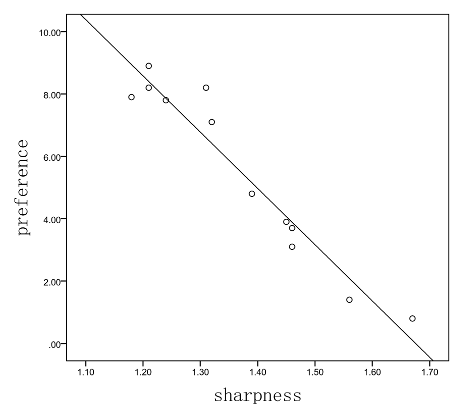

Figure 4. Relationship between preference level and sharpness

From Figure 3-4, it can be found that the relationship between preference and objective parameters are linear negatively, the preference has obvious strong linear relationship with loudness and sharpness, colinearity index is more than 0.91, which shows that sound quality in EMU is closely related to loudness and sharpness.

2.4.2 Multiple linear regression analysis of preference and objective parameters

The statistical analysis software SPSS19 is used for multivariate linear regression analysis (Jiao Fenglei, 2004), the results are shown in Table 4.

Table 4. Multiple linear regression coefficient Table

model	Non standardized coefficient		standardized coefficient	t	Sig.
	B	standard error	Beta		
(constant)	25.523	3.41	-	7.379	0.000
loudness	-0.212	0.119	-0.405	-1.665	0.133
sharpness	-10.700	4.528	-0.586	-2.401	0.042

As can be seen from Table 4, the final variable into the regression equation is loudness and sharpness, and the corresponding regression coefficients are -0.212 and -10.700, from which the mathematical fitting model of sound quality subjective evaluation preference and objective parameters can be obtained as follows:

$$SQ=25.523-0.212L_d-10.7S_p \quad (2)$$

In the formula, SQ is the sound quality preference of EMU, L_d is the loudness and Sp is sharpness (Hempel T, 1990).

Equation (2) shows that the sound quality preference can be described objectively by loudness and sharpness, therefore, in order to improve the sound quality preference in EMU, loudness and sharpness should be controlled seriously. In addition, the absolute values of standardized coefficient of loudness and sharpness are 0.405 and 0.586, which shows that sharpness has slightly larger influence than loudness to sound quality preference in EMU under the conditions of the experiment.

2.4.3 Data **Verification**

A total of 12 sound samples are used, the sound quality preference obtained by subjective evaluation and the sound quality preference obtained by model are compared, the results are shown in table 5:

Table 5. Model calculation value compared with the subjective evaluation value

Sample No.	**1**	**2**	**3**	**4**	**5**	**6**
Subjective evaluation value	4.80	3.90	3.10	3.70	0.80	1.40
Model calculated value	5.01	3.78	3.37	4.06	0.78	1.35
Relative Error	4.3%	3.1%	8.7%	9.7%	2.5%	3.6%
Sample No.	**7**	**8**	**9**	**10**	**11**	**12**
Subjective evaluation value	7.90	8.90	7.80	8.20	7.10	8.20
Model calculated value	8.25	8.66	7.92	8.19	6.82	8.07
Relative Error	4.4%	2.4%	1.5%	0.1%	3.9%	1.6%

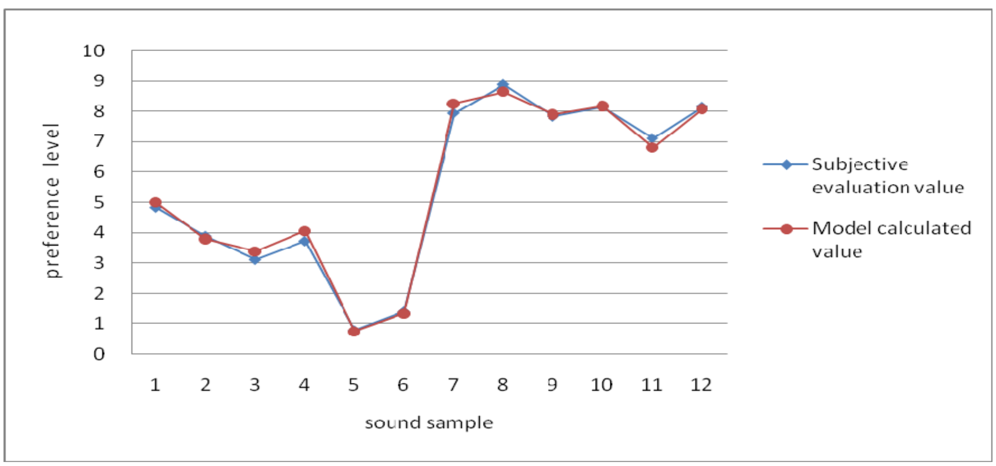

Figure 5. Model calculation value compared with the subjective evaluation value

Compared the two results get from the model and the subjective evaluation, the difference between them is small, the dispersion of error is small, and the error is mainly in the range of 10%. The calculated values and evaluation values are almost the same, such as sample 5, 6, 8 etc, which shows that evaluation model has high accuracy and it can be used to predict sound quality.

3 Conclusions

(1) The paired comparison method is used to conduct subjective evaluation experiments, and it can be obtained that the sound quality preference in EMU has inverse proportion to speed. When the speed is 370 km/h, the preference value in ordinary compartment is of 0.8 (minimum), and when the speed is 330 km/h, the preference value in ordinary compartment is of 8.9 (maximum).

(2) The paired comparison method is used to analyze the correlation of subjective and objective, and it can be concluded that sound quality preference has a high negative correlation with A-weighted sound pressure level and loudness, and its Pearson correlation coefficients are -0.961 and -0.964.

(3) By analyzing the calculated fitting result of the model between sound quality preferences and objective parameters and subjective evaluation value curve analysis,, the curves are basically the same, this shows that the evaluation model has high accuracy and can be used to predict the sound quality, which is important to analyze and control the interior noise of EMU.

Analysis for the Harmonics of an Air-Gap Magnetic Field in Asynchronous Magnetic Coupling

Yanjun Ge[1]; Peng Wang[1]; and Daolei Sun[2]

[1]School of Mechanical Engineering, Dalian Jiaotong University, Dalian 116028, China. E-mail: yjge@djtu.edu.cn
[2]Dalian Tianyun Electric Company, Dalian 116028.

Abstract: Harmonics of Air-gap Magnetic Field has great influence on the working performance of Asynchronous Magnetic Coupling (AMC). Without properly handled, a great deal of vibration and noise problems would happen. Therefore, these harmonics should be analyzed in-depth. Based on the Laplacian/Poissonian equation, the analytical model of Air-gap Magnetic Field was obtained by the boundary condition about permanent magnets and air-gaps. And the harmonics in Air-gap Magnetic Field is analyzed using the result of this model. Furthermore, a method that changing permanent magnetic rotor's pole-arc coefficient is proposed to weaken the influence exerted by harmonics on electromagnetic torque and cogging torque of AMC.
Keywords: Asynchronous Magnetic Coupling (AMC); Air-gap Magnetic field; Harmonics.

1 Introduction

Asynchronous Magnetic Coupling (AMC) has become a research focus for its compact dimension, low weight, environmental-friendly feature, excellent execution efficiency and precise adjustment of both output speed and output torque, etc. (Richard, 2002), (Wallace, 2000).

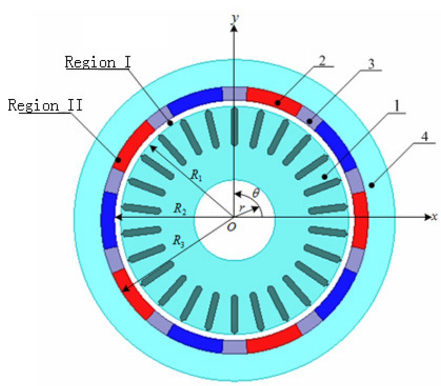
Harmonics in AMC has great influence on the value and ripple of electromagnetic torque, so the main purpose of studying harmonics is to analyze the electromagnetic torque and copping torque in-depth. By taking the derivative of magnetic energy, literature (Noboru, 2012) and (Wang, 2003) gave the mathematical relationship between copping torque and excitation system, which makes parametric analysis on copping torque of permanent magnetic gear and permanent magnet motor respectively. However, the models established in these two papers wasn't relate to air-gap magnetic flux density, so that it can't discover the fundamental cause of influences on the copping torque that are exerted by excitation system parameters.

Taking a scalar magnetic potential as variables, literature (Ge, 2012) used 2D Laplacian/Poissonian equation to derive a analytical model of air-gap magnetic field for a permanent magnet gear, which obtained the analytical result of the field by introducing Neumann boundary condition and was validated by 2D FEM. Taking a vector magnetic potential as variables, literature (Nie, 2012) combined magnetic field with magnetic circuit to put forward a 3-D analytical approach for the calculation of the field and torque of a magnetic gear. Taking into account the slotting effect and the armature reaction magnetic field, literature (Lubin, 2010) establish model based on the resolution of the two-dimensional Laplace's and Poisson's equations in polar coordinates. However, there are some disadvantages in literature (Ge, 2012) and (Nie, 2012). Firstly, the effect of yoke iron on the field is ignored when boundary conditions is set up in these three literatures. Secondly, in literature (Ge, 2012) and (Nie, 2012), pole-arc coefficient was equal to 1 during the analyzing of Permanent Magnet (PM) magnetization, which didn't take into account the effect of PMs' distribution.

In this paper, taking vector magnetic potential as variable, the relative mathematical model of magnetic field in AMC is set up. After solving the model, the analytical solution of harmonics in air-gap magnetic field is decomposed based on its specialty, which can help to analyzed the copping torque of AMC well. Based on these analyzing, changing the pole-arc coefficient, as an effective approach, is proposed to weaken the influence exerted by harmonics on electromagnetic torque of AMC.

2 Calculation of Air-Gap Magnetic Field

Fig. 1 shows the mechanical structure of AMC. The cage rotor and the permanent magnet rotor rotated around the common axis. And their radii are R_1, R_2 and R_3 respectively. θ is circumferential angle, and r is radial vector which starts from point O as shown in Figure 1. Region I is the air-gap between the cage rotor and the permanent magnet rotor. Region II is the annular area of PMs.



1 cage rotor 2 permanent magnet 3 non-magnetizer material 4 yoke iron

Figure 1. Mechanical structure of AMC

All the PMs in this paper are tile-shaped and magnetized radially.

Supposed M is magnetization intensity, M_r is its radial component. As the orientation of M is radial well-distributed, the circumferential component of M is zero, and the M_r can be written as:

$$\mathbf{M}_r(\theta) = \pm M(\theta)\mathbf{r} \qquad (1)$$

In (1), $M(\theta)$ is the constant of PMs, and it can be expressed as $M(\theta) = \frac{B_r}{\mu_0}$,where B_r is remanence and μ_0 is permeability in vacuum.

While the segments of PMs in the permanent magnet rotor are separated by non-magnetizer materials, the relationship between $M(\theta)$ and θ can be illustrated from Fig. 2. In Fig. 2, p is the number of pole pairs of permanent magnet rotor, α_p is pole-arc coefficient and T is the cycle length.

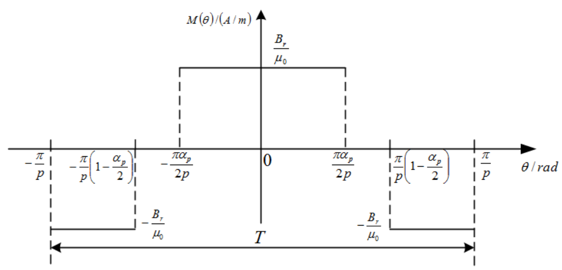


Figure 2. Relationship between $M(\theta)$ and θ

In the light of Fourier expansion method, we get that

$$M(\theta)=\sum_{n=1}^{\infty}\left(\frac{4B_r}{n\pi\mu_0}\sin\left(\frac{\pi n\alpha_p}{2}\right)\cos(np\theta)\right)=\sum_{n=1}^{\infty}M_n\cos(np\theta) \qquad (2)$$

In (2), M_n is the Fourier coefficient, $n=1,2...$

Supposed A_K ($K=1,2$) whose direction are along Z axis is the vector magnetic potential in region I and region II, and its corresponding magnetic flux density is B. B_{Kr}, $B_{K\theta}$ （$K=1,2$）are radial and tangential components of B respectively. Based on the definition of vector magnetic potential and Laplacian/Poissonian equation, B_{Kr} and $B_{K\theta}$ can be calculated as follows

$$B_{Kr}=\frac{1}{r}\frac{\partial A_K}{\partial\theta},\quad B_{K\theta}=-\frac{\partial A_K}{\partial r} \quad (3) \qquad A_1=\sum_{n=1}^{\infty}(A_{n1}r^{np}+B_{n1}r^{-np})\sin(np\theta) \quad (4)$$

$$A_2=\sum_{n=1}^{\infty}(A_{n2}r^{np}+B_{n2}r^{-np})\sin(np\theta)+\sum_{n=1}^{\infty}\frac{np\mu_0M_n}{(np)^2-1}r\sin(np\theta) \qquad (5)$$

where ∇^2 is the Laplace operator, A_{n1}, A_{n2}, B_{n1} and B_{n2} are undetermined coefficients of general solutions in (4) and (5).

Supposed permeability of the yoke in Fig. 1 is infinite. According to the continuous boundary condition in magnetic field and equations (4) to (5),The matrix among A_{n1}, A_{n2}, B_{n1} and B_{n2} can be gained:

$$\begin{bmatrix} R_1^{np-1} & -R_1^{-np-1} & 0 & 0 \\ 0 & 0 & R_3^{np-1} & -R_3^{-np-1} \\ R_2^{np} & R_2^{-np} & -R_2^{np} & -R_2^{-np} \\ \mu_r R_2^{np-1} & -\mu_r R_2^{-np-1} & -R_2^{np-1} & R_2^{-np-1} \end{bmatrix}\begin{bmatrix} A_{n1} \\ B_{n1} \\ A_{n2} \\ B_{n2} \end{bmatrix}=\begin{bmatrix} 0 \\ -\frac{\mu_0 M_n}{(np)^2-1} \\ \frac{np\mu_0 M_n R_2}{(np)^2-1} \\ \frac{\mu_0 M_n}{(np)^2-1} \end{bmatrix} \qquad (6)$$

In (6), μ_r is the relative permeability of PMs. From equation (6), we can get A_{n1} and B_{n1}, A_1 can be obtained by substituting A_{n1}, B_{n1} into (4). Then substituting A_1 into (3), it yields $B_{1r}(r,\theta)$ and $B_{1\theta}(r,\theta)$ respectively as follows:

$$B_{1r}(r,\theta)=\sum_{n=1}^{\infty} np\left(A_{n1}r^{np-1}+B_{n1}r^{-np-1}\right)\cos(np\theta) \quad (7)$$

$$B_{1\theta}(r,\theta)=-\sum_{n=1}^{\infty} np\left(A_{n1}r^{np-1}-B_{n1}r^{-np-1}\right)\sin(np\theta) \quad (8)$$

2 Analyzation for Harmonic of Magnetic Field

In order to analysis the harmonics of air-gap magnetic flux density, Matlab is employed to calculate and draw its distribution.

Fig. 3 and Fig. 4 show radial and tangential component of air-gap magnetic flux density at r respectively when all PMs are magnetized along radial orientation.

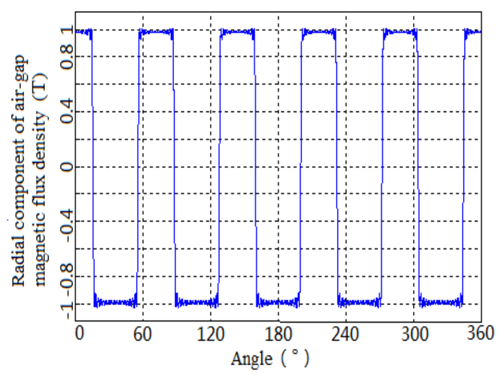

Figure 3. Curve of the radial component magnetic field in Air-gap

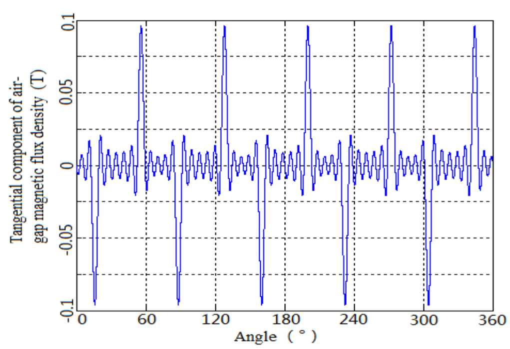

Figure 4. Curve of the tangential of component of magnetic field in Air-gap

As can be seen from fig. 3, the curve of radial component of air-gap magnetic flux density is similar to rectangular wave. It is because that remanence along radial direction are equal everywhere due to the assumption that the magnetizing intensity is evenly distributed. From Fig. 4, tangential component of air-gap magnetic flux density is approximately zero. The reason is that the distribution of air-gap magnetic flux density in the excitation structure shown in Fig. 1 is mainly along the normal direction while the tangential component is insignificant. Overall, the magnetic field in AMC is mainly formed by the radial component, while tangential component can be ignored. So all the following air-gap magnetic field refer to radial-magnetic field.

Equation (7), replacing n with different consecutive integers, can be expressed as curves in figure 5 by employing Matlab.

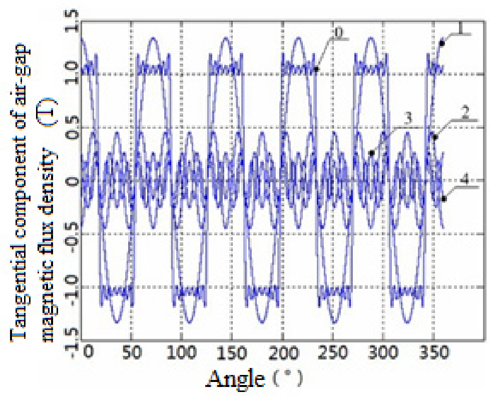

Figure 5. The curve of harmonic distribution of magnetic field in Air-gap

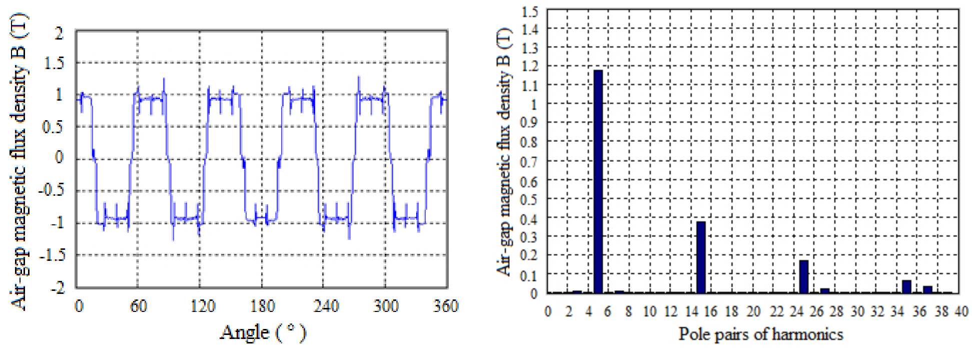
From fig. 5, the waveform of magnetic field in fig. 3 consists of a series of odd sine waves. Among these waves, whose pole pairs and value of amplitude are similar to the ideal sine wave is called fundamental wave, others are harmonics. In fig. 5, number 0 marks actual wave (rectangular wave); number 1 is fundamental wave and its p is 5; while number 2, 3, and 4 mark third, fifth and seventh harmonics and their p are 15, 25 and 35 respectively.

The curves in fig. 6, drawn by FEM software, consist of the main waveform and harmonics of the air-gap magnetic flux density. From fig. 6(a), we find that the air-gap magnetic field density, produced by five PMs in AMC, was constituted by five wave crests and troughs. This curve is in good agreement with that of fig. 3. From fig. 6(b), we find: $p = 5$ refer to fundamental wave, $p = 15$, 25 and 37 refer to third, fifth and seventh harmonics respectively. The curves shown by figure 6 are in good agreement with that of figure 5. Therefore, the analytical model in this paper is correct.



(a) Air-gap magnetic flux density waveform （b） Air-gap magnetic flux harmonic wave

Figure 6. Harmonic analysis of air gap flux density of AMC

3 Magnetic Harmonics Influence on Torque

From fig. 5, we find: the pole pairs p of fundamental wave is 5, while $p=15$, $p=25$ and $p=35$ are corresponding to 3rd, 5th and 7th harmonics respectively. When rotate speed of magnetic field is n_1, the rotate speed of fundamental wave is n_1 due to its pole pair is equal to that of the synthetic magnetic wave. Taking example for 3rd harmonic whose $p=15$ and rotate speed is $\frac{1}{3}n_1$. When the 3rd harmonic rotate more slowly than the inner rotor, the relative inductive current of 3rd harmonic in squirrel-cage bars moves inversely to fundamental wave. As a result, a slight decrease of the electromagnetic torque will happen. Similarly, the electromagnetic torque rise slightly when the rotate speed of 3rd harmonic is faster than that of inner rotor. Both the rise and decrease trends, increasing the copping torque, magnify the ripple of both electromagnetic torque and rotate speed due to the different cycles between fundamental wave and harmonics.

The above phenomenon also applies to other harmonics. Therefore, the magnetic flux density of harmonics should be minimized as far as possible during the design process of excitation system of AMC.

From (7), we find: values of harmonics change with different α_p and δ. Therefore, the effects of α_p and δ should be taken into consideration when design the excitation system.

Curves of harmonics magnetic flux density changing with α_p is shown in fig. 7. In these curves, each one does not experience the linear variation with the increase of α_p. The red curve demonstrates minimum sums of all the harmonics with corresponding α_p.

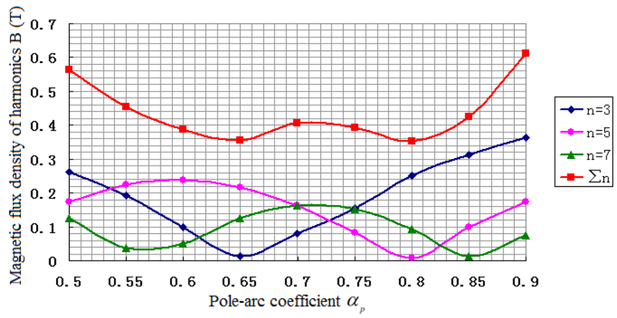


Figure 7. Curves of harmonics magnetic flux density changing with α_p

Literature (Richard Killen, 2002) put forward a method to identify the harmonic that has the most impact on the copping torque.

$$N = \left[\frac{nZ}{2P}\right]_{\min} \tag{9}$$

In (9), n is harmonic order; Z is the number of rotor slots.

In table (1), $p=5$, $Z=32$, the most impact on copping torque is exerted by 5th harmonic. Overall, taking both the value of electromagnetic torque and the degree of torque ripple into account, the pole-arc coefficient should be 0.8.

Fig. 8 shows the ripple of electromagnetic torque when the pole-arc coefficient is 0.8. In fig. 8, the electromagnetic torque ripple remain basically stable (the ripple is 1% approximately).

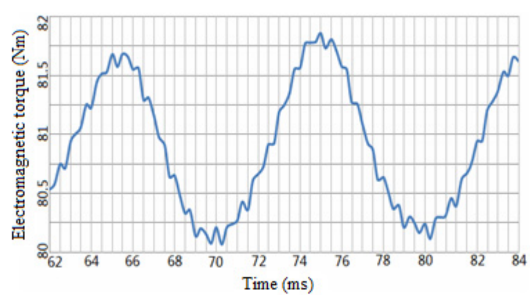

Figure 8.Electromagnetic torque ripple

4 Conclusions

(1) The PMs that are radially magnetized in AMC distributes mainly along the radial direction. The waveform of air-gap magnetic flux density is similar to the rectangular wave, and the radial component of magnetic is made up of fundamental wave and harmonics mainly.

(2) A series of odd harmonics in air-gap magnetic flux density have great influence on the value and ripple of electromagnetic torque in AMC. Different pole-arc coefficients influencing these odd harmonic can be chosen to minimize the electromagnetic torque ripple. Namely, the chosen pole-arc coefficient should not only ensure the sum of all the harmonics to be the minimum but make the value of

nth harmonic as small as possible.

Fine Modelling and Strength Analysis of Metro Car Body Structures

Jian Wang; Jie Gao; and Yana Li

Traffic & Transportation School, Dalian Jiaotong University, No. 794, Huanghe Rd., Dalian Shahekou District, Liaoning 116028, China. E-mail: wangjian_126@163.com

Abstract: Fine modelling is realized on the metro car body. The total element number of the car body model is more than 200 million, and the model is highly similar to the prototype of the car body. The loads are applied according to the EN12663, and 15 load cases are applied to this model. Calculation results showed that car strength is satisfied the design demands. Compression and tension cases are the most serious in all load cases. In all load cases, stress major focused on the corners of the doors and windows, and designers should pay more attentions on these places. Some nodal stress data are extracted from test results. The test data are used to verify the simulation results.

Keywords: Fine modeling; Strength analysis; Metro car body; Test verification.

1. Introduction

Metro car possesses many advantages, such as safety, quick speed, environment protection, energy saving, save space and so on. Currently, the world is seeking to develop metro to address the growing problem of traffic, environment and energy issues. In our country, there are more than 20 cities have opened or opening metro transport services.

Rapid development of the metro is based on safety. As the main body of the conveyance, car body's security is the most important consideration. Some papers have discussed the related questions, such as the effects of materials (Cheng, 2006; Kezhong, 2003), research on the simulation methods (Gong, 2011; Xiong, 2006), and the simulations from different car types (Wang, 2001; Feng, 2010) and so on. But mostly previous results are based on a simplified model. It maybe misses some details. In this paper, based on a B-type metro car body, a fine finite element model is built. The fine finite element model is highly similar to the prototype. Metro car body's strength is calculated. The simulation results are verified by experimental results, and the simulation data match the experimental data very well.

2. Fine finite element model of the car body

The main bearing structure of the car body is made of aluminum alloy materials. The length of the metro car body is 19000 mm, the fixed distance is 2600 mm, the body width is 2800 mm, and the body height is 3470 mm. Some other technical parameters are listed in Tab. 1 and Tab. 2

Tab. 1 Car body's mass parameters

No.	Items	Mass (t)
1	Kerb mass (exclude bogies)	21.0
2	One bogie	7.0
3	Bearing structure	7.9
4	Overload	20.6

Tab. 2 Some material properties

Aluminum Material	Thickness (mm)	Young's Modulus (MPa)	Passion Ratio	Density (t/m^3)	Yield limit (MPa)	
					Base	Weld
6005A	t≤5	69	0.33	2.7	225	115
	5<t≤10				215	115
6082	t≤6				260	125
	6<t≤12.5				255	125
Q690D/E	--	206	0.3	7.82	690	627.3

This fine finite element model is built based on the large-scale commercial processing software HyperMesh and finite element analysis software ANSYS. The model is highly approximated to the metro car body. Four-node thin shell element is the mainly element type for the simulation accuracy. Total number of the element is 2344614, and the node number is 1928048. Fig. 1 is the finite element model mesh.

c. End wall d. Coupler-set structure

Fig. 1 Finite element model

According to the EN12663 standard and task documents, 15 load cases, including AW0, AW3, compression and tension on coupler-set, compression and tension on the end wall, support on 3 points etc., are calculated in this fine model.

3. Calculation results

Analyze the results of 15 load cases, the compression and tension on coupler-set are the most serious cases. The loads on these two cases are: vertical load on the car body 408 kN, longitudinal compression force on coupler-set 800 kN, longitudinal tension force on coupler-set 640 kN. Fig. 2 shows constraints and loads of the two serious cases. Fig. 3 shows some stress concentration points of compression and tension cases. The maximum stress is located at coupler-set. Bolster, corners of door and windows are also the dangerous places. Car body strength is satisfied demands in other load cases.

4. Test verification

To verify the simulation's accuracy of the fine finite element model, a sample metro car is loaded by the 15 load cases, and some stress data are extracted to be compared with simulation results. Verification results show that the fine finite element model can get a more accurate results. The simulation results are similar to the test data. The error is less than 11%.

Tab. 3 Compression load case verifications (Stress unit: MPa)

No.	Test Stress	Calculation Stress	Error Ratio
D01	-160.0	-156.1	2.44%
D02	231.0	223.7	3.16%
D03	222.4	219.3	1.39%
D04	167.0	149.3	10.60%
D06	-100.1	-100.4	0.30%
D07	215.6	211.6	1.86%

Tab. 4 Tension load case verifications (Stress unit: MPa)

No.	Test Stress	Calculation Stress	Error Ratio
D02	187.9	195.2	3.89%
D03	178.7	180.0	0.73%
D05	-118.5	-113.4	4.30%
D06	93.5	90.2	3.53%
D07	170.7	167.8	1.70%
D17	91.4	95.8	4.81%

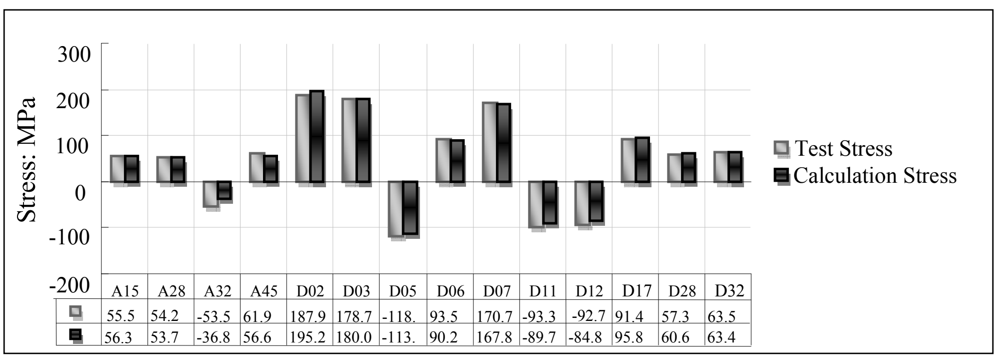

Fig. 5 Tension load case verification figure

5. Conclusions

A fine finite element model is built based on the HyperMesh and ANSYS in this paper. The model includes 15 load cases according the standard EN12663. The simulation results show the compression and tension load cases are the most serious load cases, and the maximum stress is 383MPa lies on coupler-set. Except coupler-set places, door corner, window corner etc. are also the stress concentration places. Compared to the simulation results to the test data, the most nodal stress error is under 11%. The fine modelling and analysis processing are benefit to promote the simulation accuracy. The experience can be used to guide related research work.

Abstract: A field measurement of vibration was performed on the Shanghai Maglev Train Line in China. In the paper, according to the data measured, characteristics of vertical vibration attenuation of the elevated maglev transportation are analyzed. Variations of vertical acceleration level of ground vibration in relation with train speed are investigated. And the differences of vibration between elevated maglev transportation and elevated rail transit are compared. The results show that when the maglev vehicle speed is 150-250 km/h the vibration level away from centerline of 30 m attenuates under the limited value of environmental requirement. With the increasing distance from the track centerline, the difference of vertical acceleration level with different train speed is decreasing. Comparing with elevated rail transit, vertical vibration of elevated maglev transportation attenuates with distance more obviously.

Keywords: Elevated maglev line; Vibration characteristic; z-level vibration.

1 Introduction

Maglev trains, a new rapid transport system, have attracted more attention around the world because of their fast speed and low power consumption. However, vibration induced by the maglev train–guideway interaction may cause a serious environmental problem.

Vibration, as a new kind of city pollution, impacts on people's work and life in many aspects. The vibration frequency range in 1-80Hz is sensitive to the human body, and the feeling of different vibration direction is discrepant. In addition, the vibration affect the accuracy of precise instrument, machine tool and household appliances. Besides, vibration makes negative effects on buildings.

With the development of environmental requirement, the vibration along rail transit becomes a major concern. Many scholars have carried out a series of theoretical analysis and actual measurement to investigate the vibration caused by elevated maglev transportation and elevated rail transit. The effective frequency range of the vibration acceleration sensors used in the test is 0.25-80 Hz (Zhai,2015) .

The vertical vibration level reduces with increase in distance, and there is a rebound 15m away from the track centerline (Chen,2011). Ground vibration enhances about 10 dB as the vehicle speed increases from 125 km/h to 430 km/h (Zhao,2010). These studies have achieved many results and obtained a lot of meaningful conclusions. But these studies are lack of researches on the vibration attenuation of the elevated maglev line and the comparison of the vibration of elevated maglev transportation and rail transportation, which the paper focuses on.

The SMT employing Transrapid Maglev System Technology is the world's first high-speed maglev commercial commuting system. The 30 km elevated double-track project with prototype concrete guideway connects Shanghai Pudong International Airport (SPIA) and the Longyang Road Station. The test was conducted at the NO.499 Beam A Rail. Measuring points are arranged at top of the pier, and horizontal distance aground 0m, 5m, 15m, 22.5m, 30m. The accelerometer (DH103) used in the ground vibration test is produced by Donghua Testing Technology Co., LTD in Jiangsu province of China. The vibration signal acquisition instrument adopted is named DH5920.This test records the vertical acceleration signals of maglev train with the speeds of150km/h, 200km/h, 250km/h, and the background vertical acceleration signals. During the skylight time of Shanghai Maglev Transportation System, the test train ran at three different speeds on the A rail without the interference. The measuring points were installed at the steel stents, which were embedded about 30cm in concrete. The location of measuring points are shown in Fig. 1.

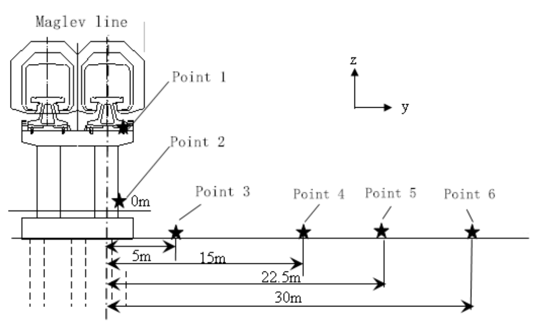

Figure1. Arrangement of measuring points

2 Vibration attenuation with distance

According to "Standard of environmental vibration in urban area"(GB10070-88) and "Measurement method of environmental vibration of urban area"(GB10071-88) we used vertical vibration level as fundamental measure. In addition, the definition of z-level vibration: ISO2631/1-1985 regulates that vibration makes the revision by weighed factor to get vibration level, denoted as VL_Z, in decibels (dB). The standard is applicable to the steady vibration, shock vibration and random vibration. For the occurrence of shock and vibration several times a day, the maximum does not allow to exceed the standard value of 10dB during the day and 3dB at night.

According to GB10070-88 and GB10071-88, from the weak vibration that human just feels (vibration acceleration is about $10^{-3}m/s^2$) to the strong vibration which the body cannot stand (vibration acceleration is about $10^3m/s^2$), vibration acceleration change up to a million times. It makes the measurement, the expression and the operation inconvenient. For the convenience, the national and international standards about vibration use the vibration level instead of vibration acceleration.

Vibration level is defined by the type 1

$$V_a L = 20\lg \frac{a}{a_0} \tag{1}$$

In the formula：

V_aL—vibration level（dB）

a —measured vibration acceleration (m/s^2)

a_o — referential vibration acceleration (m/s^2)

In order to simplify the measurement, we use a single value to represent the effect of vibration on man, which is called the frequency weighed vibration level (VLz). The frequency-weighted ground vibration makes the resonance phenomenon more prominent, because the frequency weighted method considers the perception of human body to ground vibration. According to the weighted method used in ISO2631-1-1997, the higher the center frequency is, the greater decline of the weighted vibration level in the corresponding 1/3 octave band is. Thus, the weighted vibration level depends on the vibration energy in the octave band and the corresponding center frequency. All of the signals at 1-80Hz frequency range are weighted to get the weighted vibration level. VL_Z is defined by the type 2.

$$VL_Z = 10\log \sum (V_a L_i + \alpha_i)/10 \tag{2}$$

In the formula：

VL_Z—weighted vibration level（dB）。

V_aL_i —measured vibration level of each band (m/s^2)

α_i — weighted factor of each band (m/s^2)

It can be seen in Fig.2 that at 250km/h, vibration level of the pier is 103dB, and attenuate to 77dB after transferring to the bottom of the pier. Transferring on the ground along the lateral direction it attenuates with distance: 1dB (5m), 5dB (15m), 9dB (22.5m), 11dB (30m), and at a distance 30m eventually attenuates to 66dB. The vibration produced by of maglev train attenuates very obvious. The vibration of maglev transportation can satisfy vibration requirement on the maglev line at 30m away except in vibration requirement of special residential areas (less than 65dB), which embodies the green character of maglev transportation.

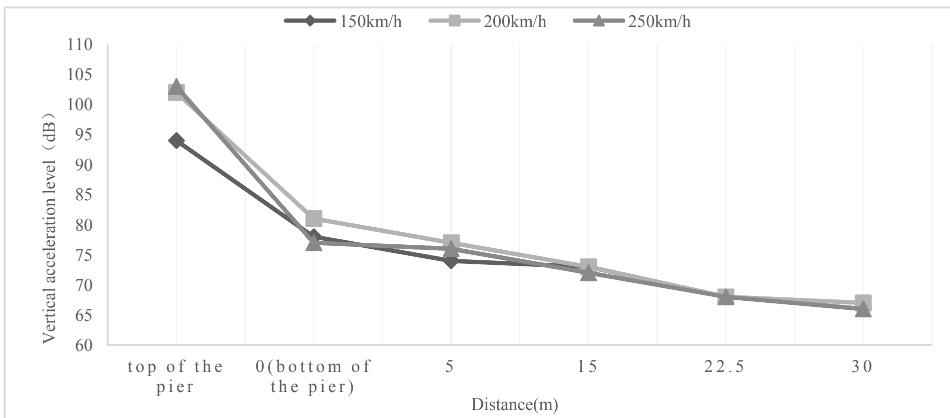

Figure2. The attenuation of z-level vibration 1/3 octave band (0~80Hz) with distance

3 Variation of vibration level with train speed

According to the test results, variation of vibration level with train speed is analyzed. Background vibration level is tested and calculated at the same location when no train passes by. In the Fig.3, when the maglev train passed at 150-250 km/h in the test section, the vibration level at the top of pier (measure point 1) was different obviously from the background vibration level. And away from centerline of 0-30m, when a train passes by, the vibration level is about 10 dB higher than the background vibration level. It shows that the maglev train passing by will have a clear incentive to the vibration of pier.

Difference between measuring point 1 and other measuring points increases with the the distance away from the centerline. By the curve in Fig.3 can be seen, at each measuring point, the variation of maglev train speed influences on the top of pier obviously. And the speed is higher, the attenuation is more obvious. Along with the increase of distance, vibration under different speeds gradually converges. Away from centerline of 15-30m, the vibration level changes little with the velocity.

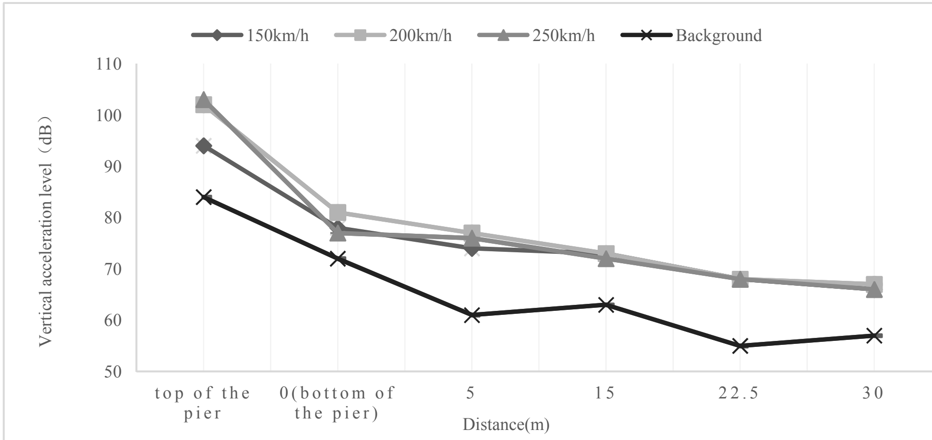

Figure 3. Weighted vertical acceleration level with different speeds

4 Comparison of vibration of maglev transportation and rail transit

This test about elevated rail transit system is at a distance of 80m away from the platform of the Jinsha River Road Station of Shanghai Metro Line 3. The measuring points arrange at the top of the pier, 0m (the bottom of the pier), and 5m, 15m, 22.5m. As can be seen from Fig.4, although the maglev transportation is much faster than the rail transit, the vibration level of maglev transportation and rail transit is not very different. Comparing with the rail transit elevated line, vibration source data of the maglev elevated line is about 6dB higher. But after transmitting from structure to the interface, vibration level of the elevated maglev transportation is about 5~9dB lower than the elevated rail transit on the interface. This suggests that the vibration attenuation of elevated maglev line is more obvious than the vibration attenuation of elevated rail transit.

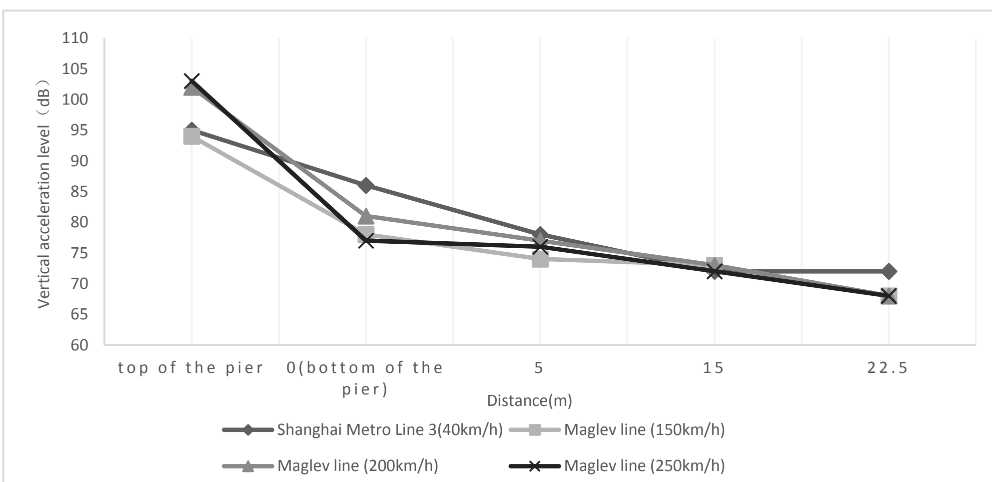

Figure 4. Attenuation of vertical acceleration level for rail transit line and maglev line

5 Conclusion

By measuring and analyzing vibration characteristic of maglev elevated line system, the followings can be concluded:

(1)The vibration of maglev transportation can satisfy vibration requirement (except in vibration requirement of special residential areas) away from centerline of 30 m, which embodies the environmentally friendly characteristic of maglev transportation.

(2)On the track beam, the difference of vibration effect with different speeds is obvious. The farther the measuring point from the track centerline is, the less the influence of the train speed on ground vibration level is. And the variation of the vibration level with different speeds is little 15m away from the track centerline.

(3)The vibration attenuation of elevated maglev line is much faster than the vibration attenuation of elevated rail transit line, and the vibration level of elevated maglev line lower than the vibration level of elevated metro line 15m away from the track centerline.

Abstract: The urban rail transit system in Chinese metropolis is developing into the network operation and structure optimization stage. With the high frequency of Critical equipment failure, equipment intelligent maintenance management needs highlighted. The paper puts forward a method of the evaluation of critical equipment health status in urban rail transit signal system with the needs of overhaul line in Shanghai urban rail transit. The method introduces the equipment service safety concept and defines the health status. Then the paper builds the multi-layer hierarchical structure model of equipment health status combining with considering the multi-dimensional influence factors of signal system equipment such as physical characteristics, economic characteristics and technical characteristics. Finally, the technical process of the fuzzy comprehensive evaluation of equipment health status is put forward. While take the switch which is the critical equipment of urban rail traffic signal system as an example to validate the proposed approach. The results show that the assessment consequence of the proposed method is consistent with the realistic expectations. The method can provide the reference for the diagnosis of hazard factors in service safety while quantitatively analyzing the equipment serving safety level.

Keywords: Urban rail transit; Critical equipment; Health status; Fuzz comprehensive evaluation.

1 Introduction

In nearly 10 years, the rapid development of the urban metro scale in Shanghai has entered the stage of network operation and structure optimization development. Shanghai metro line 10 accident shows that the high load of rail transit system operation leads to the problem of the critical equipment service life. At the same time, the equipment maintenance mode has been developed from after maintenance, planned maintenance to preventive and predictive maintenance, which puts forward new challenges for the management and maintenance of key equipment: how to judge equipment status and evaluate equipment service life scientifically, strengthen the maintenance and management of quick-wear parts, prolong the service life of signal system has become a problem which urgently to be solved.

At home and abroad the research on health monitoring, fault diagnosis and forecasts is mainly focused on mechanical system and electrical system in electrical industry and so on. With reference to the development trajectory of the equipment management study in these industries. By using the system quantitative analysis based on the data of critical equipment in the urban rail transit system instead of single quantitative analysis of equipment life and scientific assessment method instead of single standard, which becomes the inevitable trend of rail transit equipment intelligent management in our country. The evaluation theory and method based on the equipment real-time status detection is the common used equipment management method. But at the most time the equipment real-time status is observed the variation of equipment instantaneous status only from the perspective of performance or functional and unable to track the evolution of equipment performance systematically. It is difficult to describe the system health status and service security accurately by only using the equipment real-time status with comprehensively considering the effect of the physical characteristics, environmental conditions, technical characteristics and many other influence factors in the critical equipment in rail transit system.

In view of the operating unit attaches importance to construction and despises management, the thinkable operating data sample of the critical equipment is limited and cannot support the modeling of fine evaluation method. Relying on the rich expert experience and the part of observable real- time status in operating stage, this paper introduces a concept of equipment health status and puts forward a fuzzy comprehensive evaluation method for critical equipment health status to manage the health status of the critical equipment in the whole life cycle effectively.

2 Division of health status

Health is defined that a person keeps well in the physical, mental and social aspects and can activate normally. The equipment health status is often associated with the equipment service life in the practice of the equipment management. The better the equipment health status is, the longer the remaining service life is and the less possibility of an accident is happened. Following the concept and technique of health status monitoring in the literatures, the definition of the equipment health status in this paper qualitatively describes the ability level of the critical equipment that realized the corresponding technical indexes and functional structure in the specific operation conditions. The paper adopts "health value (HV)" to characterize the equipment health status quantitatively. The classification criteria of the four equipment health status is shown in table 1. It makes the health value as the evaluation index and classifies the equipment state as health, sub-health, sick, serious sick.

Table 1. Division of equipment health status

Status	Value	Feature
Health	$0.75 \leq HV \leq 1$	At the beginning of the equipment life, the health status is perfect.
Sub-health	$0.5 \leq HV < 0.75$	At the middle of the equipment life, there are some risk during the running.
Sickness	$0.25 \leq HV < 0.5$	At the end of the equipment life, there are some serious problems in running.
Serious sickness	$0 \leq HV < 0.25$	The equipment life has been exhausted and cannot run.

The health status of critical equipment in urban rail transit system rail transit system is influenced by multidimensional factors, and the system evaluation has many characteristics, such as multi-objective, multi-criterion and multi-change etc. It is impossible to qualitative analysis the health status of equipment only using logic judgment based on the experience of evaluators. Based on fuzzy mathematics, comprehensive fuzzy evaluation using the principle of fuzzy synthesis to quantitative analysis some factors of fuzzy boundaries, and evaluate the evaluation criterion comprehensively from down to up according to the membership grade of multiple factors to the evaluated things. In the condition of the lacking of current data, comprehensive fuzzy evaluation can effectively simulate human fuzzy language information to process nonlinear and uncertainty system, and describe the engineering experience accumulated by experts, realizing the decision inference. And comprehensive fuzzy evaluation has been widely used in the field of rail traffic safety assessment. This paper uses the comprehensive fuzzy evaluation to conduct a comprehensive assessment of the equipment health status, and draw inspiration from the relative quantitative evaluation can be obtained in two rough comparison, using analytic hierarchy process to determine the comprehensive weight of each index.

3 Modeling for fuzzy comprehensive evaluation

3.1 Hierarchical structure model

Comprehensive evaluation method based on a large number of equipment running status data. However, the internal structure of key equipment is complex and the running environment is varied, and the running state is affected by many factors and the relationship between them is complicated. So only by establishing scientific index system can achieve the effective management of data. To solve the evaluation of complex system, the multi-layer hierarchical structure are often used to simplify things. Typical model of hierarchical structure is shown in figure 1, including the object level, criterion layer and influencing factors layer. Firstly, according to the demand of the evaluation objects, evaluation target is formulated. Then, by the system characteristics as the guidance, the evaluation criterion of equipment performance is divided, and each criterion contains a number of influence factors. At last, according to the main influencing factors of different criterions, the tree structures from top to bottom are used to hierarchically describe the relationship between the criterion and its influencing factors.

To the key equipment of rail transit system, the evaluation target is the health status (health value) of equipment. Literature in the references points out the main influence factors of equipment health value, including reliability, maintainability, detection, security, efficiency, technical performance and so on six aspects. On this basis, this paper merges the reliability, maintainability, detection and security related with RAMS into safety performance criteria, and considers the equipment operating status, operation conditions and the influence of the inherent equipment, adding physical performance criteria. The adjusted performance criteria of health status include: safety performance criteria, physical performance criteria, technical performance criteria and economic performance criteria. The analysis of the relevant criteria and influence factors can be found in the references.

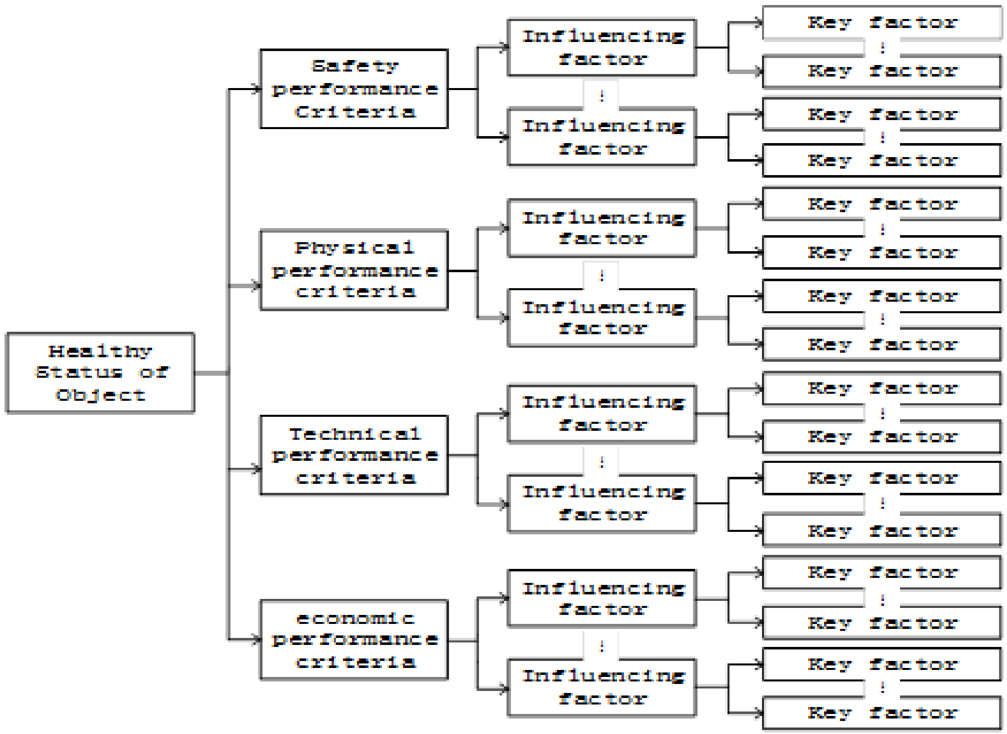

Figure 1. Hierarchical structure model of equipment health status

3.2 Comprehensive Fuzzy Evaluation

The steps of fuzzy comprehensive evaluation are as follows:

Step1: Determine the Influencing factor set U of evaluation object;

$U = \{u_1, u_2, \cdots, u_m\}$, m represents the Influencing factors of the evaluation object.

Step2: Determine the evaluation set V of levels and membership function;

$V = \{v_1, v_2, \cdots, v_n\}$, v_j represents the i^{th} evaluation subset, n represent the total number of evaluation result. This research use four evaluation subsets of A, B, C and D represent health, sub-health, sickness and serious sickness of health status.

Step2: Fuzzily evaluate the Single influencing factor to build fuzz relationship matrix R.

According to the characteristics value of the factor u_i and the membership function, the object must be evaluate/calculate the membership under the influence of u_i. That means to consideration the membership r_{ij} of fuzz evaluation subset in single factor condition.

$$r_i = \left(r_{i1}, r_{i2}, \cdots, r_{im}\right)$$

Step4: Get the fuzz relationship matrix;

The membership of every factors need to quantify for getting a fuzz relation matrix:

$$\mathrm{R} = \begin{pmatrix} r_{11} & r_{12} & \cdots & r_{1n} \\ r_{21} & r_{22} & \cdots & r_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ r_{m1} & r_{m2} & \cdots & r_{mn} \end{pmatrix}$$

Step5: Determine the weight vector A of the facts;

According to the hierarchical structure model, the comprehensive importance vector of model are determined by AHP.

$$A = \left(a_1, a_2, \cdots, a_m\right)$$

Step6: Calculate the result vector B by fuzzy evaluation with multiple factors.

$$\mathrm{B} = \mathrm{A} \times \mathrm{R} = \left(a_1, a_2, \cdots, a_m\right) \begin{pmatrix} r_{11} & r_{12} & \cdots & r_{1n} \\ r_{21} & r_{22} & \cdots & r_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ r_{m1} & r_{m2} & \cdots & r_{mn} \end{pmatrix} = \left(b_1, b_2, \cdots, b_n\right)$$

Step7: Comprehensive evaluation

1) Normalize the results of fuzz comprehensive evaluation to analysis:
2)

$$b_i = \frac{b_i}{\sum b_i}$$

2) Calculate the comprehensive evaluation operator d by each scale scalar which belong to every level.

$$C = \left(C_1, C_2, \cdots, C_n\right)$$

$$d = cB^T$$

3.3 Evaluation process

In conclusion, the overall technical process of comprehensive fuzzy evaluation for health status of key equipment is shown in figure 2, and the structure of model can be optimized according to the results of assessment. Meanwhile, in order to analyze the key influence factors of the overall hierarchy fuzzy, the comprehensive weight w_{ij} and fuzzy membership evaluation r_{ij} are considered comprehensively, and the relative importance U_{ij} is defined, as shown in the following formula, or comprehensively evaluate the relative importance of various influence factors.

$$U_{ij} = w_{ij} \cdot r_{ij}$$

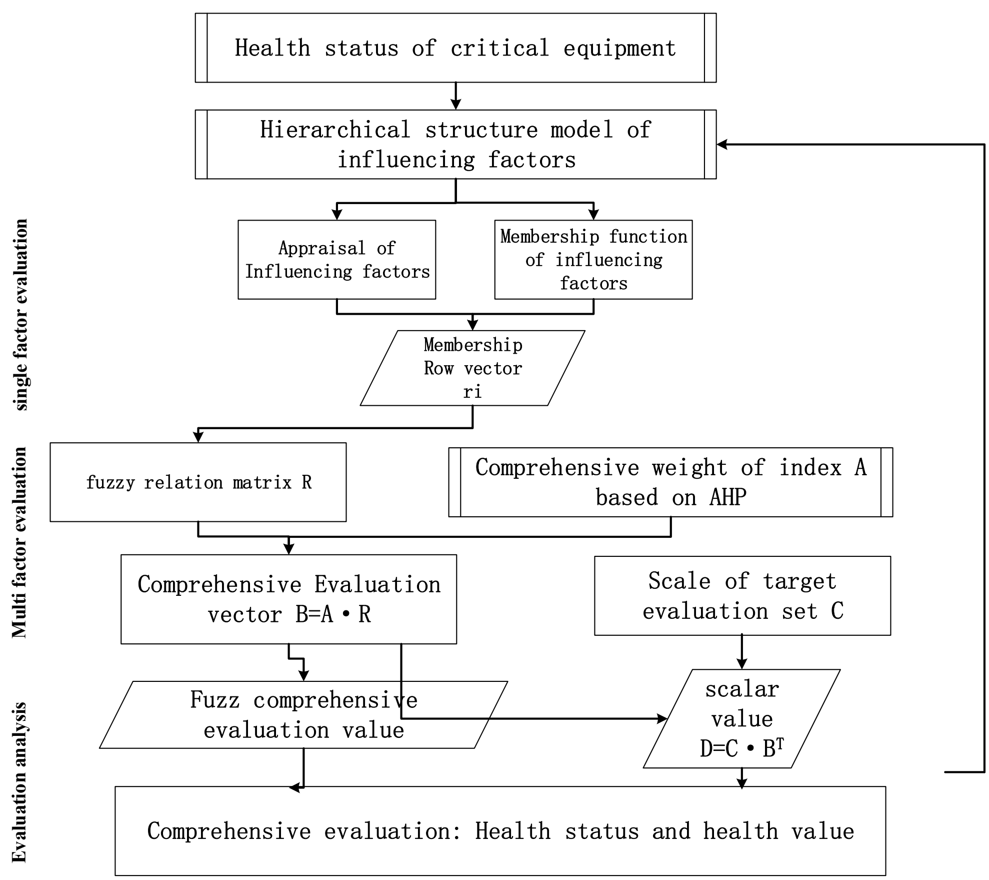

Figure 2. The technical process of fuzz comprehensive evaluation for equipment health status

4 Application

Switch is an important connection and cross devices of rail transit system. Due to the switch has the characteristics of quantity, complex structure and short service life, there is a big risk when rolling stock through, which will seriously impact the traffic safety. So a lot of resources are needed for maintenance. Taking the switch equipment of a certain line of Shanghai metro as an example, the proposed method is applied to evaluate the health status of switch equipment.

(1) Hierarchical structure model

The primary influencing factors of railway switch devices life and health value mainly include economic factors, physical life and technical life. Economic life means the time during which the user fee within reasonable bounds. Physical life means the duration from the time when a device was completely new until the time when the device can't continue to be used technically. Technical life of one device will change as the improvement of technical factors. The five-level hierarchical structural model of switch which is discussed by exports and combined the real using feature is shown in table 2:

Table 2. Five-level hierarchical structure model of switch

(2)Basic data collection

This paper uses the expert scoring method based on questionnaire to collect two kinds of basic data: the index weight and index evaluation of all kinds of influencing factors. In order to evaluate the object scientifically, the expert team should be professional, technical and scientific. At the beginning of the study, 20 questionnaires were sent out to five types of experts, including maintenance personnel, engineers, technicians, managers and researchers. The judgment matrix is established through index weight data questionnaire by comparing the relative importance among index at the same level. The evaluation data is scored by experts according to the actual usage. There are four fuzzy judgment, A, B, C and D. The questionnaire data is shown in table 3:

Table 3. Example: relative importance of the evaluation criteria

A	B1	B2	B3
Economic life	1	1/5	1/7
Physic life	5	1	1/3
Technical life	7	3	1

Table 4. Example: evaluation scoring of influence factors by exports

Influence factor	Fuzzy Evaluation A	B	C	D
Cost per year			√	
Maintenance cost				√
Running cost			√	

(3)Calculation the comprehensive weight of index

Affected by the difference of experts' knowledge, the scoring results of each expert are also different. So the original data should be preprocessed as follows: 1) To eliminate the abnormal data. 2) To eliminate data which is not meet the need of consistency check of level analysis. 3) For the reasonable data sets, to describe the scoring result by geometric mean. Then, the summation method of analytic hierarchy process is used to calculate the index factor weight v_n^j of each level in the hierarchy model, and the consistency inspection is done. Finally, according to the relative weight of factors in each level, the comprehensive weight a_n' relative to the evaluation target is calculated from top to bottom. The calculation principle is shown in the following formula, in which j represents number of upper father index of lower index n.

$$a_n' = \sum_j a_j \cdot v_n^j$$

(4)Fuzz comprehensive evaluation

According to the expert evaluation data of investigation, the frequency of influence factors in the evaluation of subset (A, B, C, D) are used to directly estimate the membership of the single influence factor fuzzy evaluation, and the membership of index is calculated in formula (). In the formula, - represents the membership of the j^{th} evaluation subset of the i^{th} influence factors, and C_{ij} represents the number of times of the j^{th} evaluation subset of the i^{th} influence factors under investigation.

$$r_j^i = \frac{C_j^i}{\sum_{j=1}^{4} C_j^i}$$

Then, on the basis of the comprehensive fuzzy evaluation process, the fuzzy relationship matrix between different hierarchical indexes is structured, according to the order from down to up of the hierarchical structural model. Combining the index weight marked by AHP, the comprehensive fuzzy evaluation is applied in turn to the upper index, and the final results are as follows:

$$B = A\begin{bmatrix} B_{B1} \\ B_{B2} \\ B_{B3} \end{bmatrix} = \begin{bmatrix} 0.157 & 0.562 & 0.281 \end{bmatrix}\begin{bmatrix} 0.27 & 0.6 & 0.13 & 0 \\ 0.330844 & 0.441804 & 0.183917 & 0.042528 \\ 0.27 & 0 & 0 & 0.73 \end{bmatrix}$$
$$= \{0.304195 \quad 0.342494 \quad 0.123771 \quad 0.229031\}$$

(5)Comprehensive analysis

The results show that the fuzzy membership of health status A, B, C, and D of the level one switch equipment is 0.304, 0.342, 0.124, and 0.230, respectively. If the maximum membership principle is adopted simply, the level one switch equipment is still in health status. According to the threshold of health status of equipment in table 1, the integrated health value of level one switch equipment is:

$$\text{HV} = 0.304 \times 1 + 0.342 \times 0.75 + 0.124 \times 0.5 + 0.230 \times 0.25 = 0.68$$

So the health status of equipment is sub-health, and the current some significant influence factors should be observed and maintained in the daily maintenance and management. The result shows that the fuzzy membership of the devices under different health status is 0.304, 0.342, 0.124, 0.230. As the maximum membership principle, the level one switch devices are still in a healthy status. According to the threshold of device health status, the integrated health value of level one switch is shown as following:

Table 5. Fuzz comprehensive evaluation result of influencing factors

Influencing factor	A	B	C	D	Comprehensive weight	Uij	Level
Ballast bed	0.07	0.67	0.24	0	0.1	0.024	D
Material	0.13	0.27	0.6	0	0.032	0.019	D
Maintenance cost	0.27	0.6	0.13	0	0.072	0.093	D
Technical life	0.27	0	0	0.73	0.281	0.205	C
Reform	0.91	0	0	0.09	0.084	0.008	C

5 Conclusions

This paper introduces the health status indicators of key devices, and builds the general multi-level hierarchical structure model of device health status according to the usage characteristics of key devices in railway system. The fuzzy comprehensive evaluation method of device health status is proposed. The evaluation of level one switch is verified in actual operation. The main conclusions are as follows:

(1) The evaluation result of level one switch accords with the reality of the actual situation of device management. This method is able to consider the experts' knowledge and real-time monitoring device status. By defining health state and quantifying health value, it is able to quantitatively analyze the health status of devices, which will provide decision support to device condition maintenance management.

(2) The system importance index considers the weight and fuzzy membership of index factors. It will comprehensively represent the importance of key factors, which has great implications for deciding maintenance management strategy and searching the significance, weakness and blind spot.

(3) The proposed fuzzy comprehensive evaluation of device health status has good universality. For the key devices of different level such as system level, device level and part level, users only need to define the multi-level hierarchical structure model according to the device characteristics, so as to quantitatively analyze the device health status.

(4) Fuzzy comprehensive evaluation method is significantly influenced by experts' knowledge, so the proper selection of experts will directly determine the credibility of evaluation method. In the process of practical application, a scientific evaluation manual should be established. It will guide the whole process of evaluation. The evaluation objects should be evaluated by experts for several rounds to ensure the rationality and consistency.

Abstract: Aiming at the existence of convergence is very slow and there are many local minima problems of BP neural network, put forward an improved generalized congruence neural network (GCNN). Improved GCNN neural network has better generalization ability, learning speed, small relative error, easy to operate. The GCNN applied to fault diagnosis examples of high-speed train gearbox, experiments show that: GCNN neural network can achieve the status of intelligent gearbox fault diagnosis effectively, recognize and classify the pattern effectively, complete fault intelligent diagnosis.
Keywords: Generalized congruence neural networks; Gearbox; Fault diagnosis.

1 Introduction

Fault diagnosis of high-speed train has very important significance. The status quo at home and abroad shows that development and research on fault diagnosis technology have importance and urgency.

Due to mass ratio fixed, transmission torque, compact structure, etc., gearbox is used to change the speed and transmit power most commonly used transmission parts, is an important part of high-speed EMU machinery and equipment, but also prone to a fault component, which runs the state has a great influence on the performance of EMU. The damage and failure of gearbox often leads to transmission system or machine malfunction, leading to major accidents. So study on Fault diagnosis technology of gearbox has a very important significance. To further enhance the accuracy and rapid of fault diagnosis, this paper based on the generalized congruence neural networks, research EMU gear operating characteristics during operation, and its fault diagnosis.

2 Generalized congruence neural network (GCNN)

So far, the ANN structure cooperating institutions combining feedforward multilayer (especially three) neural network based summation - product type neurons with back propagation (back propagation, BP) learning algorithm access to the most wide range of applications. It has proven that BP network has a multilayer neural network S-type nonlinear function can approximate any continuous function with arbitrary precision. However, BP algorithm on the performance stillexist some areas for improvement, such as the existence of convergence is very slow and there are many local minimum problems, especially in practical applications in order to ensure network capacity applicable. Not only need more massive training sample set, but also if the sample data differences, the convergence of the network will be more difficult and will reduce diagnostic accuracy.

Aiming at BP neural network exist that the convergence is very slow and there are many local minimum problems, this paper presents an improved generalized congruence neural network (Generalized Congruence Neural Networks, GCNN), apply to the high-speed train Gearbox Fault Diagnosis. Experimental results show that: Improved GCNN neural network can be effective for gearbox fault pattern recognition and classification, complete intelligent fault diagnosis.

2.1 Generalized congruence function

Improved generalized congruence excitation function is defined as follows:

$$\mathrm{a} \equiv \begin{cases} n & (\mathrm{Gmod}\ m) \qquad [|\,n/m\,|]\text{is an even} \\ m-n & (\mathrm{Gmod}\ m) \qquad [|\,n/m\,|]\text{is an old number, } a\text{nd } n \geq 0 \\ -m-n & (\mathrm{Gmod}\ m) \qquad [|\,n/m\,|]\text{is an old number, } a\text{nd } n < 0 \end{cases} \tag{1}$$

Where, a is the independent variable (input), n is the dependent variable (output), m is mold, usually m> 0; $|\cdot|$ is the absolute value of the symbol; $[\cdot]$ is the rounding function.

2.2 Bayesian regularization

This paper introduces a Bayesian regularization to improve the generalization of GCNN network. Regularization method can improve its marketing capabilities through correcting the training correction performance function of neural networks. Regularization method is an eliminating over-fitting method by limit the network weights appropriately. Regularization algorithm modifies neural network error function by setting certain constraints out the sample data, in the form of regular items added human error function. General neural network training performance function uses squared error function ED, namely

$$E_D = \sum_{i=1}^{N} (t_i - a_i)^2 \tag{2}$$

Wherein t_i and a_i are the target value and the output value of the N training samples in the i-th training time. Introduces a penalty function in Bayesian regularization method, network training performance function becomes

$$F = \alpha E_W + \beta E_D \tag{3}$$

Wherein α and β are regularization coefficient. Square summation $E_W = \sum_{j=1}^{N} \omega_j^2, \omega_j$ of all network weights is the new network weights. Regularization term added in the objective function is to make the role of the smaller connection weight tends to zero as possible, to ensure that the network meets the fitting under the premise of accuracy, ease of cutting off connection weights and the redundant neurons, thereby reducing the complexity of the network to obtain good generalization performance.

3. Gearbox GCNN network model design and training

3.1 Gearbox fault diagnosis model

The GCNN network applies to fault diagnosis of gear boxes, mainly for the accurate calculation of the amount of wear classification and gearbox wear state. The established pattern recognition GCNN network structure of gearbox wear status is shown in Figure 1.

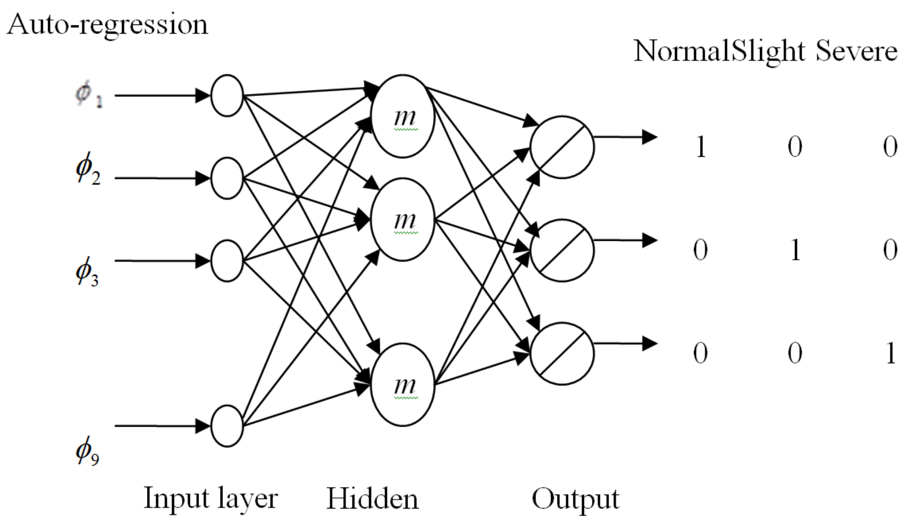

Figure 1. GCNN network structure gearbox fault diagnosis model

In this paper uses three-forward network structure: input layer, hidden layer and output layer each one. Hidden layer and output layer node three GCNN earliest definition has modulus. So, when determine the output layer node modulus, make sure its output is greater than all of the desired output of the neural network, and therefore becomes difficult to determine the value of the mold. The excitation function set in this paper, is different with the original use of network structures. Improved GCNN network structure has the modulus only in hidden layer nodes. Output layer node is the linear summer (Linear function is the simplest function of neurons can be, it's just as simple to neuronal input to the output after passing through the threshold value adjustment) in place of original generalized congruence function. Therefore, in the case of the neural network can not predict all of the desired output, linear summation is to avoid considering the output node modulus value problem. This can increase the learning ability and generalization ability of the network.

The key of troubleshooting is Gearbox vibration signal analysis and feature extraction. Applying vibration sensors mounted on the gearbox vibration signal acquisition, using the researching methods on wavelet packet autoregressive spectral, analysis out the resulting that frequency band signals can reflect changes in the amount of wear of the gearbox, and establishing nine autoregressive model based on features band signals, after wavelet packet autoregressive spectral analysis, conclude: Wavelet Packet autoregressive parameters can accurately reflect the state of the gearbox wear. This article will rank 9 gearbox wear of the situation since the regression coefficient as the original data, so the network input feature vector dimension is 9.

The error of reverse error propagation algorithm in the use of GCNN is spread through the output layer to the input layer. The more layers, the error of reverse propagation becomes more unreliable when close to the input layer. The results of the correction weights also become unreliable. As well increasing the hidden layer will cause GCNN network is too complex, greatly reduces the convergence rate GCNN. A three-tier GCNN network is sufficient to achieve arbitrary dimension n to m-dimensional hint. Therefore, we determine the number of hidden layer 1.

After determining the number of hidden layers, is how to determine the number of nodes in the hidden layer problem. Too few hidden layer nodes, patterns into the rough, may led to the network can not learn the characteristics of training sample, which will not achieve the role of feature extraction. The number of nodes being excessive, the pattern space into too small, will often result in "over-fitting" phenomenon, the network is easy to learn the details of the sample does not matter, grasp the main features. In the specific structure, the numbers of hidden layer nodes in the network are out of trial and error. Reference approximate formula, as well as several tests and commissioning, this article finally determines the hidden layer neurons 15 in this system.

Output of the network for wear state of the gearbox, mainly divides into three kinds of cases in which the normal situation, mild wear, severe wear. So, the output of the network nodes is set to 3. Expressed using the following output: normal (1,0,0), mild (0,1,0) and severe (0,0,1).

In summary, this paper has a hidden layer of the three-tier network GCNN. Use 9-15-3 GCNN network structure. Hidden layer activation function is improved generalized congruence function. Modulus value is set to 0.5. Output layer activation function chose purely linear function.

3.2 Network training and testing

The maximum number of steps in the training is set to 100, the performance parameters are 0.001, the error reverse propagation learning algorithm is 0.02.

In this paper, the sample data at different gearbox wear autoregression coefficient calculated in two parts. As a part of the training data, accounts 75% of the total amount of data. Another part of the data to test the trained network, accounts 25% of the total amount of data. During the 50 times experiment, the training results obtained are shown in Table 1 Statistics.

Table 1. Improved GCNN network straining results statistics

The number of experiments	Network structure	The minimum number of iterations	The average number of iterations	The maximum number of iterations	Success rate(%)
50	9-15-3	12	32	57	98

One training error curve in improved GCNN network training process is shown in Figure 2.

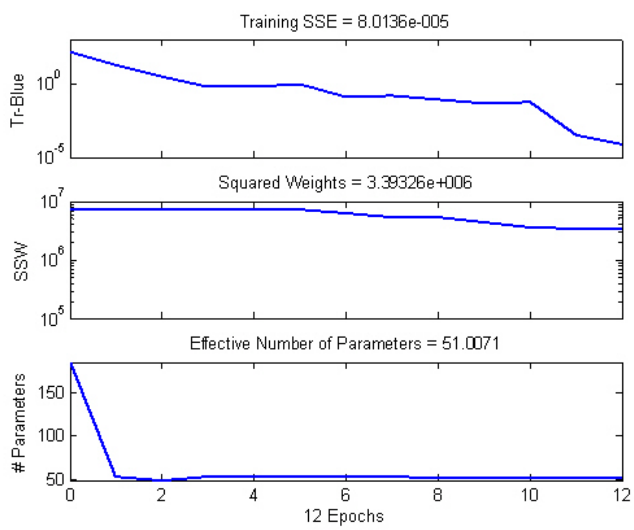

Figure 2. Training error curve in improved network of GCNN

Under the working conditions, the test sample set input trained GCNN network, analysis and diagnosis the state of wear, its desired output and the actual output results are shown in Table 2.

Table 2. Desired output and the actual output of GCNN network detected data

Fault type	Desired output			Actual outputs		
Normal conditions	1	0	0	0.8923	0.0011	0.0002
	1	0	0	0.9667	0.0003	-0.0032
Slight abrasion	0	1	0	-0.0000	0.9998	0.0085
	0	1	0	0.0079	1.0017	0.0021
Severe abrasion	0	0	1	0.0101	0.0115	0.9976
	0	0	1	-0.0012	0.0009	0.9999

As can be seen from Table 2, the improved GCNN network on the recognition result of gearbox fault condition is very accurate, i.e., the rate of diagnosis can be improved greatly. GCNN neural network being used for identify the state of the gearbox fault, modeling speed and recognition speed is very fast. it has a certain significance to solve practical problems.

4 Conclusions

Through experiments, make the following conclusions: GCNN neural network can achieve Intelligent Diagnosis of high-speed train gearbox failure effectively. GCNN network as a gearbox fault state classifiers, can be effective for pattern recognition and classification, complete intelligent fault diagnosis.

Through the experiment, but also proved the superiority of the proposed improved GCNN neural network technology. The improved network has highly prediction accuracy, simple, optimized GCNN neural network has better generalization ability. It has the advantages of that predicted speed is fast, the relative error is small, easy to operate. Examples of the analysis show that the improved GCNN neural network approach is satisfactory.

Numerical Analysis on Welding Deformation and Residual Stress of an Aluminum Alloy Floor of EMU Bodywork

Jun Zhang[1]; Siqun Ma[1]; Min Zhao[1]; Jianhua Wang[1]; and Wenzhong Zhao[1]

[1]College of Traffic and Transportation Engineering, Dalian Jiaotong University, Dalian 116028, China. E-mail: zhj@djtu.edu.cn

Abstract: Numerical simulation of welding of hollow aluminum alloy profile for EMU bodywork floor was performed by using a software SYSWELD. The sparse and close finite model was used for enhancing computation efficiency and precision, the heat source model of double elliptical were utilized to simulate MIG welding, the welding deformations and residual stresses were achieved, the four schemes of weld orders are analyzed an compared, a good weld orders is obtained for reducing the welding deformations and residual stresses. The results show that a reasonable arrange of weld orders can remarkably reducing weld distortions and residual stresses.

Keywords: Weld order; Deformation; Residual stresses; Aluminum alloy floor.

1 Introduction

The EMU bodywork is widely manufactured by using hollow aluminum alloy profile for reducing weight, cost saving and easy to machining, the length of aluminum alloy profile can extend to 25m, and be widely used for making side wall, top plate and floor for EMU(Wang, P., 2012; Xu, Z.W., 2013). The manufacture processes of bodywork of EMU are largely predigested by using aluminum alloy profile, the main manufacture technique is weld jointing that it joins several aluminum alloy profiles to construct a part of bodywork of EMU, for example , a floor of EMU bodywork is make of six aluminum alloy profiles. Therefore, the weld technology and welding process are significant for reducing weld deformation and residual stress, by applying a good welding process the weld deformation and residual stress can largely be decreased and controled, and bodywork performance can be enhanced.(Han, D.H., 2013).

The weld deformation and residual stress relate to various factors, a main factor is the arrange of weld orders. There are many weld seams at the floor of EMU bodywork, a good the weld orders of weld seams can be achieved by a numerical simulation (Xue, J., 2012), the numerical simulation may only consider a local model and a content results can be recovered , this has a significance to improve the weld process. In this paper, a local FE model of floor of EMU bodywork is established, the weld numerical simulations are performed considering four weld orders of weld seams, a reasonable weld orders were achieved, which have the least weld deformation and residual stress.

2 The weld heat source model

A continuum medium with volume V and surface S, its differential equation for heat conduction can be expressed as follows

$$-\frac{\partial}{\partial x_i}(\lambda_{ij}\frac{\partial T}{\partial x_i})+Q-\rho c\frac{\partial T}{\partial t}=0 \qquad (1)$$

where T is temperature,^{0}C; $\frac{\partial T}{\partial x_i}$ is the temperature grads; λ_{ij} is heat conduction tensor, W•m^{-1}•^{0}C^{-1}; Q is heat production rate for unit volume, W•m^{-3}; ρ is density, Kg•m^{-3}; c is specific heat, J•Kg^{-1}•$^0C^{-1}$; t is time, s.

The heat input in weld process is high and concentrate near the welding local location, the heat source model of double elliptical can well simulate this kind of weld process in existing heat source models(Li, Y.N., 2010; Deng, D., 2008), the simulation results basing on this model can achieved a approving accordance with the practice weld process, it is that the shape and size of dissolving pool of the simulation is consistent with the actual weld seam. There are two parts including front and back in this heat source model, the heat distributing function for front part and back part can be expressed as follows, respectively,

$$Q_f[x,y,z]=\exp[-[\frac{x^2}{a_f^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}]] \qquad (2)$$

$$Q_b[x,y,z]=\exp[-[\frac{x^2}{a_b^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}]] \qquad (3)$$

Where Q_f and Q_b is the energy input of front heat source and back heat source, respectively; a_f and a_b is the length of front half elliptical and back half elliptical, respectively; b is a influence parameter of dissolving pool width; c is a influence parameter of dissolving pool depth.

3 The FE model and weld orders

3.1 Finite element model

A finite element model of local chassis of CRH3 EMU bodywork is established with a length of 0.5m and a half the chassis width , each weld seam position has 2 weld seams including up seam and down seam, therefore this model comprises 6 weld seams that join 3 aluminum alloy profile and side beam into a whole structure with 142402 elements and 96696 nodes, the x, y and z displacement components are constrained in on middle symmetry line labeled by ab and cd, the line labeled ef and gh which are joined to side wall are constrained at y displacement component. The finite element model is shown in Figure 1. The parameters of weld technology are as follows: the weld method is MIG weld, the weld voltage and electric current are 20~22V and 200~210A, respectively, the weld speed is 10 mm/s.

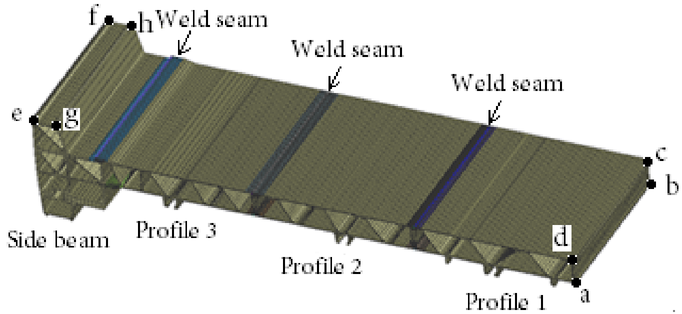

Figure 1. Finite element model

3.2 Heat source parameters

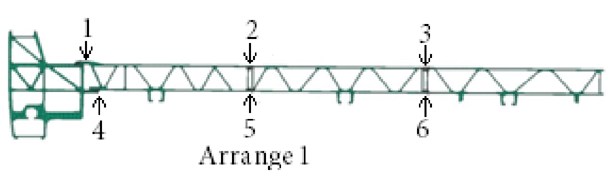
The heat source parameters mentioned above can be adjusted and obtained by using the verifying procedure of heat source in SYSWELD software when the shape and size of welded structure, heat physics properties of material and parameters of welding process are inputted into SYSWELD software. The heat source 1 is a overlap weld seam heat source with 8mm plate thickness which is used to join the side beam and profile 3, and the heat source 2 is a butt weld seam heat source with 2.8mm plate thickness which is used to join two profile. The heat source parameters are listed in Table 1.

Table 1. Heat source parameters

Parameters	Heat source 1	Heat source 2
a_f	1	6
a_b	4	80
b	4	2
c	4	3
Q_f	28.5	2.7
Q_b	23.7	5.1

3.3 Weld orders of seams

In order to research effect of the weld orders on weld deformations and residual stresses, 4 various arranges of weld orders are simulated and analyzed, which is shown in Figure 2, the 1,2,3,4,5,and 6 express the weld order, for example, in arrange 1 the 3 weld seams on the up surface are firstly welded from 1 to 3, then the down 3 weld seams are again welded from 4 to 6.



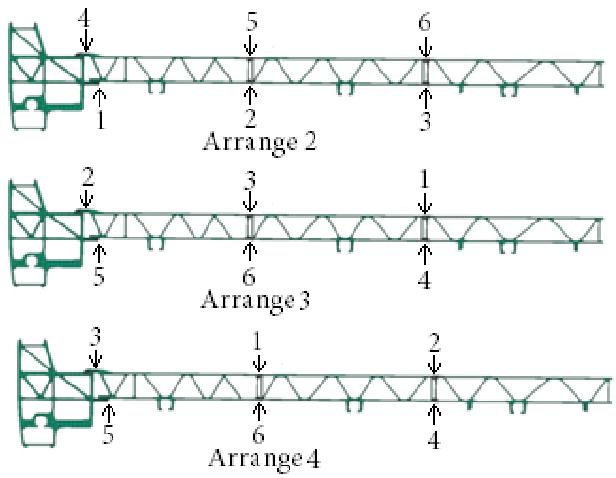


Figure 2. Arranges of weld orders

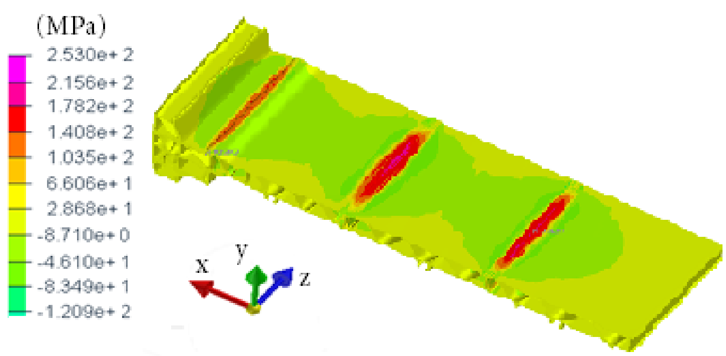
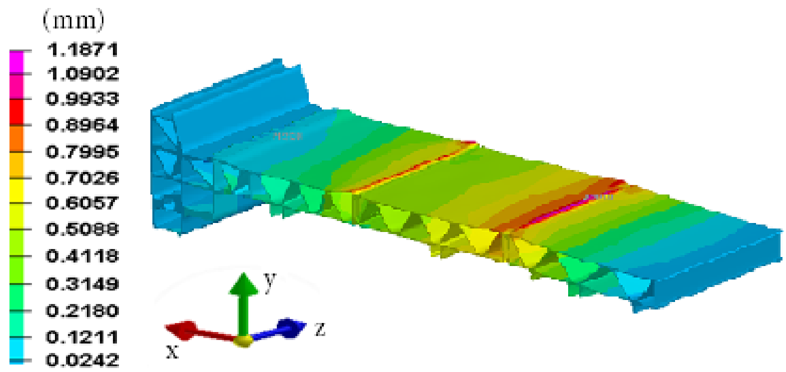
4 Simulation results

4.1 Weld deformation and residual stresses

The weld deformation and residual stresses of arrange 1 of weld orders are shown at Figure 3. Figure 3.(a) shows that there is the maximal residual stress of 178.2 MPa in the weld seam 2, and in the weld seam region hereabout tensile stresses are primary stress pattern, and away from the weld seam region compression stresses are obvious stress pattern.



(a) The residual stresses at longitudinal direction



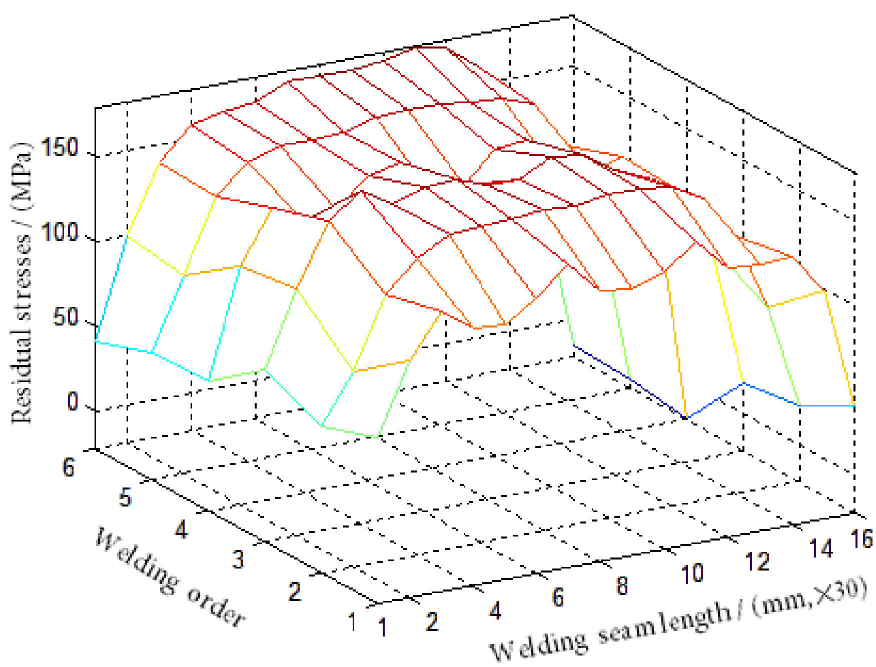
(a) The deformation at y direction

Figure 3. The weld deformation and residual stresses

Figure 3.(b) shows that a maximal weld deformations of 1.187mm are brought at weld seam 2 and 4, the primary model of deformation is buckling deformation.

4.2 Residual stresses change with weld seam length

The changes of the residual stresses of arrange 1 with weld seam length are shown in Figure 4., the maximal residual stress is produced in weld seam 6 at the center back of length direction, which is lasted one welded, and moreover the values of the residual stresses have a gradually increasing trends with the welding orders of from 1 to 6, this expresses that the residual stresses can be reduced by a good arrange of weld orders.



4.3 Compare on various arranges of weld orders

The maximal deformations and residual stresses of various weld order arranges expressed in Figure 2 are listed Table 2., the Table 2 shows that the arrange 2 has the least deformation and lowest residual stress, it is that the outer surface of EMU bodywork floor should be firstly welded, this is because of some reinforcing ribs exist on the outer surface, and therefore the outer surface has the higher rigidness.

Table 2. Maximal deformations and residual stresses

Arrange	Y direction maximal deformation / (mm)	Maximal stress / (Mpa)
1	1.187	290.059
2	0.581	281.005
3	1.181	302.524
4	1.143	291.107

5 Conclusions

This article established the finite elements model of welding simulation of EMU bodywork floor, the weld deformations and residual stresses are obtained. The results show that the weld deformations of aluminum alloy floor of EMU bodywork are primary buckling deformation , the maximal values of residual stresses exist in middle of a weld seam, and in general there exist the maximal residual stresses at the lattermost welded seam. The good arranges of weld orders can reduce the weld deformations and residual stresses, especially the weld deformations can be obviously reduced by firstly welding outer surface of EMU floor, about a half of original deformation is achieved by firstly welding surface of EMU floor.

Solutions for Plane Strain Consolidation of a Saturated Medium

Jiang Wang; Binglong Wang; Shunhua Zhou; and Yaochen Li

The Key Laboratory of Road and Traffic Engineering, Ministry of Education, Tongji University, Cao'an Rd. 4800, Shanghai. E-mail: wnetease2006@126.com

Abstract: The eigenvalue approach, Fourier transforms, and two-step backward finite difference method, has been employed to study the plane strain consolidation of an isotropic porous elastic medium, saturated by one-phase incompressible fluid. The solutions of displacements, stresses and pore pressure has been obtained by the presented method. A model has been used to study the feasibility of the solutions. The results indicate the solutions is effective.
Keywords: Plane strain; Finite difference; Fourier transform; Eigenvalue.

1 Introduction

In engineering, many can simplify to plane problems, such as embankment, wall etc. So, it is important to study the plane strain problems.

The process of consolidation was first investigated by Terzaghi for one-dimensional conditions. Subsequently, Biot extended Terzaghi's theory to three dimensional situations. However, exact solutions to problems involving the consolidation of a soil mass under three-dimensional conditions are not easy to obtain. Several exact and approximate analytical solutions have to be confined to plane strain problems. Mcnamee and Gibson expressed the stress and the pore pressure in porous medium which liquid diffusing in terms of two displacement functions, and plane strain problems of the semi-infinite body to the surface of which a uniform pressure is applied along an infinite strip is discussed. Booker and Small used the transformation of consolidation governing equations by Fourier transform to analyze the consolidation behavior of a horizontally layered soil which subjected to strip, circular, and rectangular surface loads under plane conditions. Some other authors studied the nonlinear and elasto-plastic consolidation. Zhi-yong AI used Laplace-Fourier transforms to study a plane strain consolidation of a porous elastic soil by taking into account the anisotropy of permeability. Selim and Ahmed employed the eigenvalue approach, Laplace and Fourier transforms found the analytical expressions for displacements and stresses at any point, of an inclined line load and , of an initially stressed orthotropic elastic media of a plane strain problem. Shamta Chugh *et al.* continued Selim's work obtained the displacements and stresses for an unstressed elastic media. But the pore pressure has been neglected. Nader Abbasi *et al.* developed a finite difference approach for the solution of non-linear of compressibility and permeability of clay. In their works they limited the analysis of pore pressure, displacement or stress to loading process, the features of these field variables after the load removed partially or absolutely.

In the present paper, eigenvalue approach, Fourier transform and two-step backward finite difference method have been employed to develop a semi-analytical solutions for the consolidation under plane strain conditions. And a simple model has been used to study the feasibilities of the solutions. The results was satisfactory.

2 Basic equations

Consider a homogenous and isotropic porous elastic medium saturated with a single phase incompressible fluid and subject to a small deformation. The governing equations can express as follows:

Equilibrium equations (the body force ignored)

$$\sigma_{ij,j} = 0 \tag{1}$$

Strain-displacement relations

$$\varepsilon_{ij} = \tfrac{1}{2}\left(u_{i,j} + u_{j,i}\right) \tag{2}$$

Effective Stress-strain relations

$$\sigma'_{ij} = \lambda \varepsilon_v \delta_{ij} + 2G\varepsilon_{ij} \tag{3}$$

Darcy's law

$$v_i = \frac{k}{\gamma_w} p_{,i} \tag{4}$$

Continuity equation

$$\dot{\varepsilon}_v = p_{i,i} \tag{5}$$

These equations are written in indexical notations, its meaning can refer to Y.C Li.

Based on equations (1)-(5) the equations, and utilize the conditions of plane strain consolidation, we can get the governing equations of plain strain consolidation as

$$(\lambda + 2G)\frac{\partial^2 u}{\partial x^2} + (\lambda + G)\frac{\partial^2 w}{\partial x \partial z} + G\frac{\partial^2 u}{\partial z^2} - \frac{\partial p}{\partial x} = 0 \tag{6a}$$

$$G\frac{\partial^2 w}{\partial x^2} + (\lambda + G)\frac{\partial^2 u}{\partial x \partial z} + (\lambda + 2G)\frac{\partial^2 w}{\partial z^2} - \frac{\partial p}{\partial z} = 0 \tag{6b}$$

$$-K\left(\frac{\partial^2 p}{\partial x^2} + \frac{\partial^2 p}{\partial z^2}\right) + \frac{\partial}{\partial t}\left(\frac{\partial u}{\partial x} + \frac{\partial w}{\partial z}\right) = 0 \tag{6c}$$

In these equations (6), u and w are the horizontal and vertical displacement, p is pore pressure, k is the permeability coefficient, E and ν are modulus and Poisson ratio, G is shear modulus and λ is Lame coefficient, γ_w is the density of water.

3 Transformed equations

Two-step backward finite equation with variable time increments to approximate the time derivative in equation (6c) i.e.[17]:

$$\frac{\partial u}{\partial t}=a_0u+a_{-1}u_{-1}+a_{-2}u_{-2},\ \frac{\partial w}{\partial t}=a_0w+a_{-1}w_{-1}+a_{-2}w_{-2} \tag{7}$$

Where

$$a_0=\frac{2\Delta_{-1}+\Delta_{-2}}{\Delta_{-1}\left(\Delta_{-1}+\Delta_{-2}\right)},a_{-1}=-\frac{\Delta_{-1}+\Delta_{-2}}{\Delta_{-1}\Delta_{-2}},a_{-2}=\frac{\Delta_{-1}}{\Delta_{-2}\left(\Delta_{-1}+\Delta_{-2}\right)} \tag{8}$$

Are three coefficients depending on the two-backward time increments Δ_{-1} and Δ_{-2}. Subscripts -1 and -2 denote the values of the field quantities at time $t-\Delta_{-1}$ and $t-\Delta_{-1}-\Delta_{-2}$, respectively.

We define Fourier transform $\overline{f}\left(\xi,z\right)$ and $f\left(x,z\right)$ as:

$$\overline{f}\left(\xi,z\right)=F\left[f\left(x,z\right)\right]=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}f\left(x,z\right)e^{i\xi x}dx \tag{9a}$$

$$f\left(x,z\right)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}\overline{f}\left(\xi,z\right)e^{-i\xi x}d\xi \tag{9b}$$

It was known that

$$F\left[\frac{\partial}{\partial x}f\left(x,z\right)\right]=\left(-i\xi\right)\overline{f}\left(\xi,z\right),F\left[\frac{\partial^2}{\partial x^2}f\left(x,z\right)\right]=-\xi^2\overline{f}\left(\xi,z\right) \tag{10}$$

In equations (9) and (10), the ξ is parameter of Fourier transform.

Substituting equations (7)-(10) into equations (6), gives the transformed equations:

$$-\xi^2\left(\lambda+2G\right)\overline{u}\left(\xi,z\right)-i\xi\left(\lambda+G\right)\overline{w}'\left(\xi,z\right)+G\cdot\overline{u}''\left(\xi,z\right)+i\xi\overline{p}\left(\xi,z\right)=0 \tag{11a}$$

$$-\xi^2G\overline{w}\left(\xi,z\right)-i\xi\left(\lambda+G\right)\overline{u}'\left(\xi,z\right)+\left(\lambda+2G\right)\overline{w}''\left(\xi,z\right)-\overline{p}'\left(\xi,z\right)=0 \tag{11b}$$

$$-K\left[\left(-\xi^2\right)\overline{p}\left(\xi,z\right)+\overline{p}''\left(\xi,z\right)\right]+a_0\left[\left(-i\xi\right)\overline{u}\left(\xi,z\right)+\overline{w}'\left(\xi,z\right)\right]=\overline{q}\left(\xi,z\right) \tag{11c}$$

Where

$$\bar{q}(\xi,z) = -a_{-1}\left[(-i\xi)\bar{u}_{-1}(\xi,z) + \bar{w}'_{-1}(\xi,z)\right] - a_{-2}\left[(-i\xi)\bar{u}_{-2}(\xi,z) + \bar{w}'_{-2}(\xi,z)\right] \quad (12)$$

And the symbols '' ' and '" ' denotes the function's one-order and two-order differentiate respect to variable ' z ', respectively. The equations (11) are the transformed equations of a saturated soil under conditions of plane strain.

4 Solve for transformed equation

Equations (12) is a second order nonhomogeneous ordinary differential equation. In order to obtain its general solutions, we should solve the homogeneous ordinary equation corresponding to equations (12), therefore we introducing the expression:

$$\bar{u}'(\xi,z) = \bar{u}_1(\xi,z), \bar{w}'(\xi,z) = \bar{w}_1(\xi,z), \bar{p}'(\xi,z) = \bar{p}_1(\xi,z) \quad (13)$$

Rationally, we have

$$\bar{u}_1'(\xi,z) = \bar{u}''(\xi,z), \bar{w}_1'(\xi,z) = \bar{w}''(\xi,z), \bar{p}_1'(\xi,z) = \bar{p}''(\xi,z) \quad (14)$$

We use the expression, $f(\xi,z) = f$, so the equations (12) can express as:

$$\bar{u}' = \bar{u} \quad (15a)$$

$$\bar{w}' = \bar{w}_1 \quad (15b)$$

$$\bar{p}' = \bar{p}_1 \quad (15c)$$

$$\bar{u}_1' = \frac{(\lambda+2G)\xi^2}{G}\bar{u} + \frac{i\xi(\lambda+G)}{G}\bar{w}_1 - \frac{i\xi}{G}\bar{p} \quad (15d)$$

$$\bar{w}_1' = \frac{i\xi(\lambda+G)}{(\lambda+2G)}\bar{u}_1 + \frac{G\xi^2}{(\lambda+2G)}\bar{w} + \frac{1}{(\lambda+2G)}\bar{p}_1 \quad (15e)$$

$$\bar{p}_1' = -\frac{a_0 i\xi}{K}\bar{u} + \frac{a_0}{K}\bar{w}_1 + \xi^2\bar{p} \quad (15f)$$

Writing equations (16) in the vector-matrix differential equation form:

$$\bar{\mathbf{X}}' = \mathbf{A}\bar{\mathbf{X}} \quad (16)$$

Where

$$\bar{\mathbf{X}} = [\bar{u}, \bar{w}, \bar{p}, \bar{u}_1, \bar{w}_1, \bar{p}_1]^T$$

$$\mathbf{A}=\begin{bmatrix} 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ \frac{(\lambda+2G)\xi^2}{G} & 0 & -\frac{i\xi}{G} & 0 & \frac{i\xi(\lambda+G)}{G} & 0 \\ 0 & \frac{G\xi^2}{(\lambda+2G)} & 0 & \frac{i\xi(\lambda+G)}{(\lambda+2G)} & 0 & \frac{1}{(\lambda+2G)} \\ -\frac{a_0 i\xi}{K} & 0 & \xi^2 & 0 & \frac{a_0}{K} & 0 \end{bmatrix}$$

So, the characteristic equation can express as follow:

$$\det(\mathbf{A}-r\mathbf{I})=\alpha_6 r^6+\alpha_4 r^4+\alpha_2 r^2+\alpha_0=0 \tag{17}$$

Where I is unit matrix and

$$\alpha_6=1,\alpha_4=-\left(\frac{a_0}{K(\lambda+2G)}+3\xi^2\right),$$

$$\alpha_2=\frac{2a_0}{K(\lambda+2G)}\xi^2+3\xi^4,\alpha_0=-\left(\frac{a_0}{K(\lambda+2G)}\xi^4+\xi^6\right)$$

The solution of equation (17) gives the eigenvalues as:

$$r_1=r_2=\xi,r_3=r_4=-\xi,r_5=\sqrt{\frac{a_0}{K(\lambda+2G)}+\xi^2},r_6=-\sqrt{\frac{a_0}{K(\lambda+2G)}+\xi^2}.$$

Let us use the expression, $r(\xi)=\sqrt{\frac{a_0}{K(\lambda+2G)}+\xi^2}$.

Using the eigenvalue method to solve the first order vector differential equation (16), the solution have the form

$$\bar{X}(z,\xi)=X(\xi)e^{r\xi} \tag{18}$$

We observe that eigenvalues $r_1=r_2=\xi$ and $r_3=r_4=-\xi$ are both of multiplicity 2. We use the following method to obtain the eigenvector for the repeated eigenvalue corresponding to $r_1=r_2=\xi$.

By using elementary row transforms to matrix $(A-\xi I)^2$, we can obtain the basic solution set of $(A-\xi I)^2\mathbf{b_0}=\mathbf{0}$ that:

$$\mathbf{b}_0^{(1)} = [-i, 1, 0, -i\xi, \xi, 0]^T, \mathbf{b}_0^{(2)} = [0, 1/\xi, 2G, -i, 0, 2G\xi]^T \tag{19}$$

The other eigenvector can obtain by

$$\mathbf{b}_1^{(1)} = (A - \xi I)\mathbf{b}_0^{(1)} = [0,0,0,0,0,0]^T, \mathbf{b}_1^{(2)} = (A - \xi I)\mathbf{b}_0^{(2)} = [-i, 1, 0, -i\xi, \xi, 0]^T \tag{20}$$

Hence, eigenvector X_1 and X_2 can express as

$$X_1 = \mathbf{b}_0^{(1)} + z\mathbf{b}_1^{(1)} = [-i, 1, 0, -i\xi, \xi, 0]^T \tag{21a}$$

$$X_2 = \mathbf{b}_0^{(2)} + z\mathbf{b}_1^{(2)} = \left[-zi, z - \frac{1}{\xi}, 2G, -i\xi\left(z + \frac{1}{\xi}\right), z\xi, 2G\xi\right]^T \tag{21b}$$

Similarly, eigenvector X_3 and X_4 can express as

$$X_3 = [i, 1, 0, -i\xi, -\xi, 0]^T \tag{21c}$$

$$X_4 = \left[zi, \left(z + \frac{1}{\xi}\right), 2G, -i\xi\left(z - \frac{1}{\xi}\right), -z\xi, -2G\xi\right]^T \tag{21d}$$

The eigenvector corresponding to eigenvalues $r_5 = r(\xi)$ and $r_6 = -r(\xi)$ can obtain by using elementary row transforms to matrix equation $A - r_5 I = 0$ and $A - r_6 I = 0$, so the eigenvector X_5 and X_6 are

$$X_5 = \left[-Ki\xi, Kr(\xi), a_0, -Ki\xi r(\xi), \frac{a_0}{(\lambda + 2G)} + K\xi^2, a_0 r(\xi)\right]^T \tag{21e}$$

$$X_6 = \left[Ki\xi, Kr(\xi), -a_0, -Ki\xi r(\xi), -\frac{a_0}{(\lambda + 2G)} + K\xi^2, a_0 r(\xi)\right]^T \tag{21f}$$

Therefore, the solution of equation (17) can be written as

$$X = (C_1 X_1 + C_2 X_2)e^{\xi z} + (C_3 X_3 + C_4 X_4)e^{-\xi z} + C_5 X_5 e^{r(\xi)z} + C_6 X_6 e^{-r(\xi)z} \tag{22}$$

Writing (23) in vector-matrix form

$$\bar{\mathbf{X}} = \mathbf{B} \cdot \mathbf{C} \tag{23}$$

Where

$$\bar{\mathbf{X}} = \left[\bar{u}, \bar{w}, \bar{p}, \frac{\partial \bar{u}}{\partial z}, \frac{\partial \bar{w}}{\partial z}, \frac{\partial \bar{p}}{\partial z}\right]^T, \mathbf{C} = [C_1, C_2, C_3, C_4, C_5, C_6]^T$$

$$\mathbf{B}=\begin{bmatrix} -ie^{\xi z} & -zie^{\xi z} & ie^{-\xi z} & zie^{-\xi z} & -Ki\xi e^{zr(\xi)} & Ki\xi e^{-zr(\xi)} \\ e^{\xi z} & \left(z-\frac{1}{\xi}\right)e^{\xi z} & e^{-\xi z} & \left(z+\frac{1}{\xi}\right)e^{-\xi z} & Kr(\xi)e^{zr(\xi)} & Kr(\xi)e^{-zr(\xi)} \\ 0 & 2Ge^{\xi z} & 0 & 2Ge^{-\xi z} & a_0 e^{zr(\xi)} & -a_0 e^{-zr(\xi)} \\ -i\xi e^{\xi z} & -i\xi\left(z+\frac{1}{\xi}\right)e^{\xi z} & -i\xi e^{-\xi z} & -i\xi\left(z-\frac{1}{\xi}\right)e^{-\xi z} & -Ki\xi r(\xi)e^{zr(\xi)} & -Ki\xi r(\xi)e^{-zr(\xi)} \\ \xi e^{\xi z} & z\xi e^{\xi z} & -\xi e^{-\xi z} & -z\xi e^{-\xi z} & \left(\frac{a_0}{(\lambda+2G)}+K\xi^2\right)e^{zr(\xi)} & -\left(\frac{a_0}{(\lambda+2G)}+K\xi^2\right)e^{-zr(\xi)} \\ 0 & 2G\xi e^{\xi z} & 0 & -2G\xi e^{-\xi z} & a_0 r(\xi)e^{zr(\xi)} & a_0 r(\xi)e^{-zr(\xi)} \end{bmatrix}$$

The parameters $C_1, C_2, C_3, C_4, C_5, C_6$ are constants defined by boundary conditions.

The expression (23) is the solution of the homogeneous equations corresponding to the nonhomogeneous ordinary differential equations (11). In the following procedure, the method of variation of constants has been employed to obtain the solution of (11), therefore, the expression of (15f) should be

$$\overline{p}_1' = -\frac{a_0 i\xi}{K}\overline{u} + \frac{a_0}{K}\overline{w}_1 + \xi^2\overline{p} - \frac{\overline{q}}{K} \tag{24}$$

Assuming C is function respect to z, utilize the (15), (23) and (24), and differentiate (24) to z, gives the equation

$$\mathbf{B}\cdot\mathbf{C}' = \mathbf{S} \tag{25}$$

Where

$$\mathbf{C}' = \left[C_1'(z), C_2'(z), C_3'(z), C_4'(z), C_5'(z), C_6'(z)\right]^T, \mathbf{S} = \left[0,0,0,0,0,\frac{-\overline{q}(\xi,z)}{K}\right]^T$$

Solving the equation (25), we found

$$C_1'(z) = \frac{1}{2a_0}\overline{q}(\xi,z)e^{-\xi z}, C_2'(z) = 0,$$

$$C_3'(z) = \frac{1}{2a_0}\overline{q}(\xi,z)e^{\xi z}, C_4'(z) = 0 \; C_5'(z) = -\frac{1}{2Ka_0 r(\xi)}\overline{q}(\xi,z)e^{-zr(\xi)},$$

$$C_6'(z) = -\frac{1}{2Ka_0 r(\xi)}\overline{q}(\xi,z)e^{zr(\xi)} \tag{26}$$

Integrating (26), gives

$$C_1(z) = \frac{1}{2a_0}\int_0^z \overline{q}(\xi,z_1)e^{-\xi z_1}dz_1, C_2(z) = 1, C_3(z) = \frac{1}{2a_0}\int_0^z \overline{q}(\xi,z_1)e^{\xi z_1}dz_1,$$

$$C_4(z) = 1 \; C_5(z) = -\frac{1}{2Ka_0 r(\xi)}\int_0^z \overline{q}(\xi,z_1)e^{-z_1 r(\xi)}dz_1,$$

$$C_6(z) = -\frac{1}{2Ka_0 r(\xi)}\int_0^z \overline{q}(\xi, z_1) e^{z_1 r(\xi)} dz_1 \qquad (27)$$

So, the particular solution of equation (11) can express as

$$\tilde{\overline{\mathbf{X}}} = \mathbf{BC}(\mathbf{z}) \tag{28}$$

Where

$\mathbf{C}(\mathbf{z}) = \left[C_1(z), C_2(z), C_3(z), C_4(z), C_5(z), C_6(z)\right]^T$

Hence, the general solution of equation (11) are

$$\overline{\mathbf{X}} = \mathbf{B}\left[\mathbf{C} + \mathbf{C}(\mathbf{z})\right] \tag{29}$$

From (29), we can express the displacements and pore pressure in the transformed domain, $\overline{u}$, $\overline{w}$, $\overline{p}$. Using inverse Fourier transform, we obtain

$$u = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} \overline{u} e^{-i\xi x} d\xi \tag{30a}$$

$$w = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} \overline{w} e^{-i\xi x} d\xi \tag{30b}$$

$$p = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} \overline{p} e^{-i\xi x} d\xi \tag{30c}$$

Furthermore, let us use Fourier transform to the stress-strain relationships, gives

$$\overline{\sigma}_x = -i\xi(\lambda + 2G)\overline{u} + \lambda\frac{\partial \overline{w}}{\partial z} - \overline{p} \tag{31a}$$

$$\overline{\sigma}_z = (\lambda + 2G)\frac{\partial \overline{w}}{\partial z} - i\xi\lambda\overline{u} - \overline{p} \tag{31b}$$

$$\overline{\tau}_{xz} = G\left(\frac{\partial \overline{u}}{\partial z} - i\xi\overline{w}\right) \tag{31c}$$

In (29), we know that $\frac{\partial \overline{u}}{\partial z}$, $\frac{\partial \overline{w}}{\partial z}$ .Substituting it into (31), we can obtain the stress in the transformed domain. Using inverse Fourier transform to (31), the stress under plain strain conditions can be expressed as

$$\sigma_x = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} \overline{\sigma}_x e^{-i\xi x} d\xi \tag{32a}$$

$$\sigma_z = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} \overline{\sigma}_z e^{-i\xi x} d\xi \tag{32b}$$

$$\tau_{xz} = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} \overline{\tau}_{xz} e^{-i\xi x} d\xi \tag{32c}$$

The expressions (30) and (32) are the displacements, pore pressure and stresses of plain strain consolidation.

5 Example

The example used to illustrate the foregoing solutions is shown schematically in Figure 1. An isotropic, homogenous layer of soil occupies the region $0 \le z \le h$. The layer is loaded along its upper surface *z*=0 by a uniform strip loading *q* with occupies the area $-l/2 \le x \le l/2$ and may be assumed to have been applied at time $t=0^+$, and thereafter held constant. Free drainage is allowed across the upper surface of the layer. Movement is either totally restricted along the base.

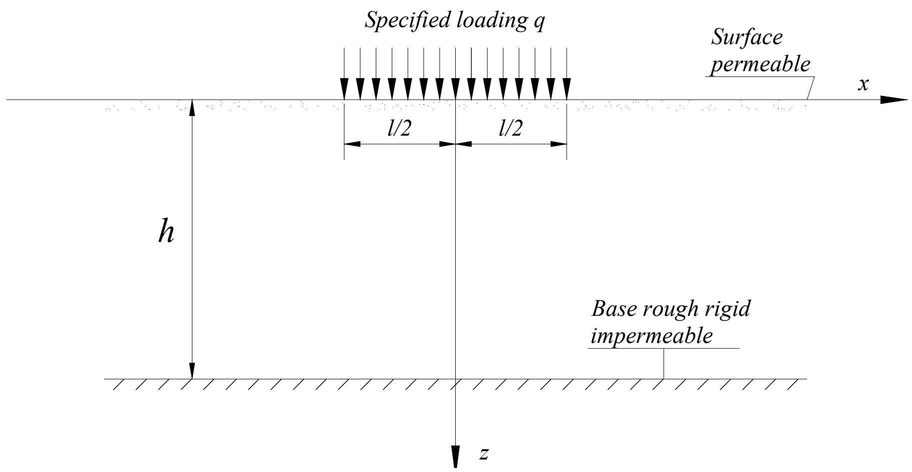

Figure 1. The schematic of the model

The details of the boundary conditions then takes the form shown in Table 1.

Table1 The boundary conditions

Surface *z*=0	Permeable	$p=0$
	Specified surface load	$\sigma_z = -q\left(-\frac{l}{2} \le x \le \frac{l}{2}\right)$,other $\sigma_z = 0$
		$\tau_{xz} = 0$
Base *z*=*h*	Impermeable	$\frac{\partial p}{\partial z} = 0$
	Rough rigid	$u=0$
		$w=0$

Obtaining the solution to such a problem involves evaluating an integral such as that given in (30) and (32). We can use two point Gaussian integrand and Simpson integrand method to approximate the integrals.

Figure 2 shows the variation of excess pore water pressure with time along the center line *x*=0 for this problem. The results show that the curve in good term to other reports, such as Booker and Small etc..

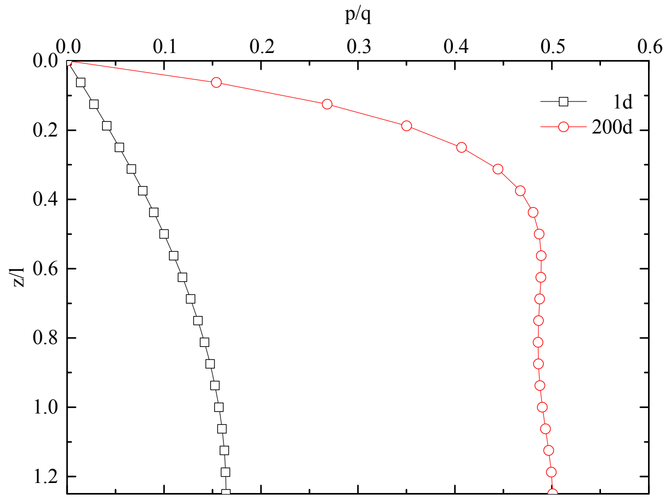

Figure 2. Pore pressure distribution at various time

6 Conclusion

The solutions of the plain strain consolidation we have been presented in this paper are effective. Using these solution some consolidation problem of other boundary conditions are available also. The success of the method can easily obtained by using numerical method.

Abstract: This article introduced respectively the equivalent structural stress method which is based on the American ASME standard and the Miner cumulative fatigue damage theory. The Miner theory uses the S-N curve of welded joints provided in the IIW standard. These two methods are applied to the specific engineering cases of the aluminum alloy car body. The comparison shows that the equivalent structural stress method should be popularized widely.
Keywords: Fatigue life prediction and evaluation; Welded structure; IIW standard; The equivalent stress method.

1 Introduction

In general, the fatigue failure of car body usually occurs in the welding joint. So the fatigue life of welded joint is the most important in the fatigue assessment of car body structure. In this paper, the fatigue life prediction of the aluminum alloy car body is carried out by the equivalent structural stress method and the IIW standard weld fatigue assessment methods. The comparison of these two methods shows that the equivalent structural stress method is more general and accurate.

2 Miner linear cumulative fatigue damage theory

In Miner's linear damage theory, the material fatigue damage is caused by the continuous cyclic load. The level of the fatigue damage is proportional to the stress cycle times. Supposing N_1 is the cycle number of the fatigue damage under a specific stress. At this time, the total network is W. When the cycle number is n_1, the absorbed network W_1 can be gotten

$$\frac{W_1}{W} = \frac{n_1}{N_1} \qquad (2\text{-}1)$$

If the number of loading conditions is m, the material fatigue damage can be expressed as

$$D = \frac{n_1}{N_1} + \frac{n_2}{N_2} + \cdots + \frac{n_m}{N_m} = \sum_{i=1}^{m} \frac{n_i}{N_i} \quad (i = 1, 2, \cdots, m) \tag{2-2}$$

Where n_i the stress cycle number at the level of is stress i; N_i is the cycle number of the fatigue damage under this stress; D is accumulative fatigue damage. If D = 1, material is damage.

The following, the life mileage of the vehicle L_L and the life period L_T are introduced. L_k is the life mileage under load spectrum k (k=1, 2 … m), β_k is the total cycle number per mile, L_y is the running mileage per year.

$$L_L = \frac{1}{\sum_{k=1}^{m} \frac{1}{L_k}} \tag{2-3}$$

$$L_T = L_L / L_Y \tag{2-4}$$

Where $L_k = 1/[\beta_k(\sum_{i=1}^{m} D_i)]$.

3 Equivalent structural stress method

The equivalent structural stress method is based on the stress transfer techniques in fracture mechanics. The equivalent structural stress is used as the controlling parameter of the fatigue stress. It requires much more stringent theoretical consideration of various fatigue influencing factors, such as plate geometry, loading effects and welding gaps etc. Besides, as the nodal force is much less sensitive than the stress in the analysis of the finite element. So, the joint force method is applied to the stress calculation. The insensitivity is the obvious advantage than the IIW standard method.The equivalent structural stress method is not restricted by the difficulty of precisely determining the concentrated stress at the welding points. Because of the insensitivity to computational mesh in structure stress calculation and the equivalent structure stress transfer technique, the method is superior to other methods in many aspects, such as flexibility in the finite element grid, reliability in stress calculation at welding points and the high accuracy forecast in fatigue stress etc.

Based on the ASME standards, the formula for fatigue life of the welded structures is,

$$\Delta S_S = Cd \cdot N^{h} \tag{3-1}$$

The equivalent structural stress can be gotten by

$$\Delta S_S = \frac{\Delta\sigma_S}{t^{(2-m)/2m} \cdot I(r)^{1/m}} \tag{3-2}$$

In which, $\Delta\sigma_S$ is the structural stress which reflects the influence of stress concentration, t is the plate thickness, I(r) represents the influence of load types. The constant m=3.6, Cd and h are the constants of S - N curve (table 3-1), N is cycle-index.

Table 3-1. The parameters of S-N curve

Statistics	C_d	h
mid-value	3495.13	
+2σ	5273.48	
-2σ	2316.48	-0.28
+3σ	6477.60	
-3σ	1885.87	

4 The fatigue resistance S-N curves of the IIW standard

IIW (The International Institute of welding) standard is for evaluating the fatigue life of the welded structures. IIW standard provides the fatigue strength S-N curves measured for the various welded joins in the laboratories. These curves consider the local stress concentration, weld size, and weld shape, stress direction, residual stress and metallurgical conditions. Therefore, these S-N curves are very practical and authoritative. According to the standard, the fatigue life can be considered as infinite under a certain stress range.

As shown in Figure 4-1, the S-N curves are expressed with stress range and the cycle number. The fatigue strength of various welded joints is expressed by the fatigue level (FAT). It represents the constant stress range after 2 million loading cycles.

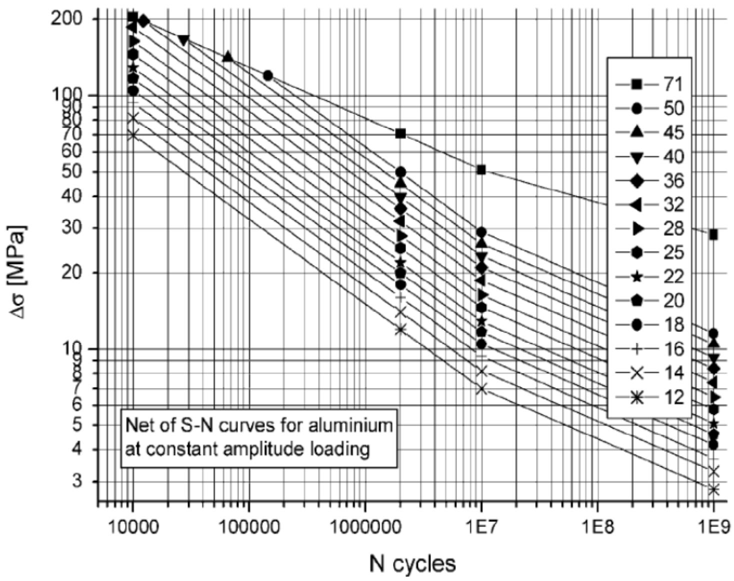

Figure 4-1. The S-N curve of IIW standard

The S-N curves of the IIW standard in the double logarithmic coordinate system are not straight line but are dual-slope lines with the inflection point being at $Nc=1\times10^7$. The fatigue strength corresponding to $Nc= N=2\times10^6$ is the FAT level. In addition, the cut-off cycle-index of the S-N curves is $N_{cut}=1\times10^9$. This means that, in fatigue experiments, the fatigue loading cycles can reach 10^9 times. So these S-N curves are high accuracy.

Figure 4-2 in the IIW standard listed the joint details of steel and aluminum alloy and the fatigue strength grade (FAT) value. These weld joint details are derived from actual engineering structures.

Firstly, select the joint geometry that corresponds to the design requirement and mechanical characteristics from these tables. Secondly, mark down fatigue strength grade FAT values in the table. Then, determine the parameters from Figure 4-2. Finally, S-N curve can be drawn according to these parameters.

Stress ranges		Values of constant C: $N=C/\Delta\sigma^m$ or $N=C/\Delta\tau^m$		
FAT class [MPa]	Stress at knee point $\Delta\sigma_{L,R,k}$ [MPa]	For stress ranges above knee point	For stress ranges below knee point Constant C: $N=C/\Delta\sigma^m$	
Δσ at 2E+6 cycles	**Δσ at 1E+7 cycles**	**m=3**	constant amplitude **m=22**	variable amplitude **m=5**
125	73.1	3.906E+12	1.014E+48	2.091e+16
112	65.5	2.810E+12	9.064E+46	1.207E+16

Figure 4-2. Fatigue parameters of the IIW standard

The life prediction algorithm of IIW standard is based on Miner's theory of damage accumulation. There are some assumptions. For a constant amplitude fatigue load spectrum, the damage increments caused by each cyclic loading are equal and independently additive. The damage increments caused by all levels of cyclic loadings are independently additive. The critical material damage is a constant, which depends only on the material properties. Let n_i be the cycle-index of the stress range $\varDelta\sigma_i$ in load spectrum, and N_i be the total cycle-index which will be damaged in the stress range, then the fatigue damage will occur when

$$D = \sum_i \frac{n_i}{N_i} = 1 \qquad (4\text{-}1)$$

In the IIW standard, damage ratio is defined as,

$$\frac{n_i}{N_i} = \begin{cases} \dfrac{n_i(\varDelta\sigma_i)^m}{C_1} & (\varDelta\sigma_i > \varDelta\sigma_1) \\ \dfrac{n_i(\varDelta\sigma_i)^{m+2}}{C_2} & (\varDelta\sigma_2 \le \varDelta\sigma_i \le \varDelta\sigma_1) \end{cases} \qquad (4\text{-}2)$$

Where, $\Delta\sigma_1$ and $\Delta\sigma_2$ are the inflection points of S-N curve, C_1 and C_2 are constant coefficients and m is the slope of S-N curve.

5 Application examples

5.1 The strength analysis by finite element

In this paper, a simplified finite element model of 160 km emus (district) aluminum alloy B car was built. ANSYS software is adopted to the static strength analysis and determine the evaluation points of dynamic stress range spectrum. The car body finite element model is shown in Figure 5-1.

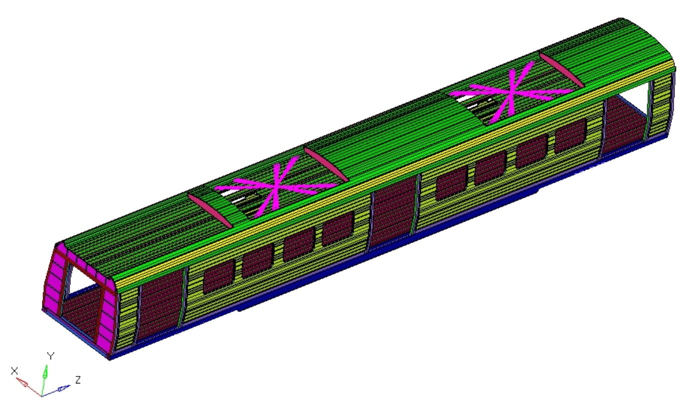

Figure 5-1. Finite element model of aluminum alloy car body

5.2 Fatigue loading conditions

The fatigue loading is applied according to "BS EN 12663-1:2010". The stress concentration and fatigue life prediction are analyzed. This means, a ±0.15g acceleration is applied vertically, longitudinally and transversely to the car body, respectively. The fatigue load conditions are as shown in Table 5-1.

Table 5-1. The load cases for fatigue strength calculation

Working condition	Describe the working conditions	X axle	Y axle	Z axle
1	longitudinal acceleration	0.3×g		
2	transverse acceleration		0.3×g	
3	vertical acceleration			0.3×g

Boundary condition and vertical constraints were imposed on the air spring seat pad, longitudinal and transverse constraints were imposed on the center pin plate.

5.3 The position of the important weld joint

In accordance with the requirements of the specification, 85 importance weld joints in the car body were identified. In this paper, two weld joints that are most concerned in the design were selected for investigation. Their positions are as shown in Figure 5-2 and Table 5-2.

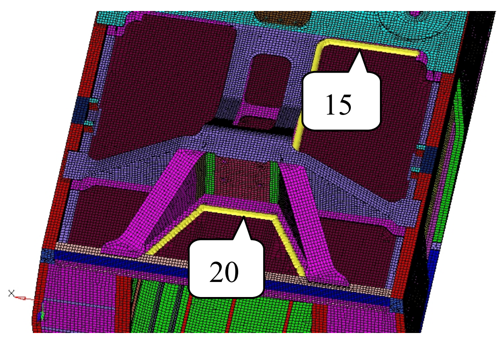

Figure 5-2. The important weld joint position

Table 5-2. The position of important weld joint

No.	Location
15	Weld joint between a side sleeper beam cover plate surface and under the chassis surface
20	Weld joint between coupler seat reinforcement on the cover plate and surface under the chassis

5.4 Analysis results

5.4.1 The result obtained by the equivalent structural stress method

By the master S-N curve method, the finite element strength analysis was carried out on the car body under the three kinds of fatigue strength condition. The fatigue analysis software FE-WELD and the Miner's linear damage theory are used to evaluate the fatigue life of the two weld joints. The equivalent structural stress curve of two welds are shown as Figure 5-3 and Figure 5-4.

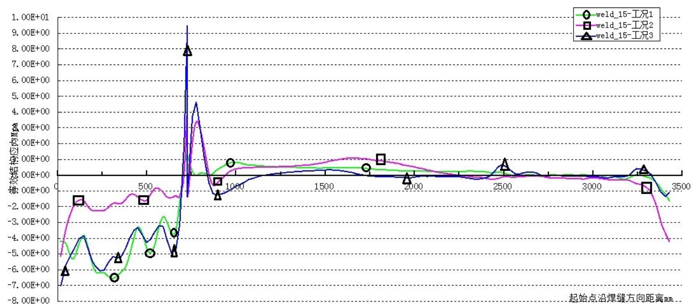

Figure 5-3. Structural stress curve changed with the weld length change of No.15 weld joint under three working conditions

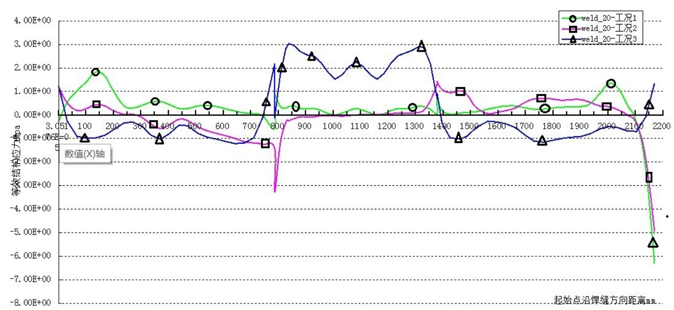

Figure 5-4. Structural stress curve changed with the weld length change of No.20 weld joint under three working conditions

Based on the calculated structural stress and the equivalent structural stress of the two weld joints, the cumulative fatigue damage ratios within 10^7 stress range are gotten by the Miner linear damage theory. The results are shown in Table 5-3.

Table 5-3. The ratio on cumulative fatigue damage of two weld joints

Weld joints	Computational item	Condition 1	Condition 2	Condition 3	Cumulative damage

Weld joints	Computational item	Condition 1	Condition 2	Condition 3	Cumulative damage
15	damage ratio	3.44344E-010	8.17131E-010	1.67102E-009	2.83249E-009
20	damage ratio	5.43717E-010	2.28139E-010	2.06180E-012	7.73918E-010

5.4.2 The result by the nominal stress method of IIW standard

Based on the joint states of the weld seams, the points with maximum stress variation range are chosen as the evaluation points. Miner cumulative damage theory is used to predict fatigue life for the two weld joints with the fatigue characteristic parameters selected in the IIW standard. The cumulative damage ratios of the two weld joints were calculated respectively under three working conditions, shown in Table 5-4.

Table 5-4. The ratio on cumulative fatigue damage of two weld joints

Weld joint	FAT Level	Condition	Variation of stresses（MPa）	Damage ratio	Cumulative damage
15	22	1	2.696473	4.04E-04	0.001630063
	22	2	3.139867	8.64E-04	
	22	3	2.638359	3.62E-04	
20	22	1	0.254468	3.02E-09	1.38887E-08
	22	2	0.282917	5.13E-09	
	22	3	0.289244	5.73E-09	

The comparison of the cumulative damage ratios between Master S-N curve and resistance to fatigue S-N curve in the IIW standard is shown in Table 5-5.

Table 5-5. The result comparison of two methods

	The equivalent structural stress method	Resistance to fatigue S - N curve in the IIW standard
NO.	cumulative damage value	cumulative damage value
15	2.83249E-009	0.001630063
20	7.73918E-010	1.38887E-08

From the table 5-5, we can see the results of fatigue life prediction based on the equivalent structural stress are lower than that on the IIW standard.

6 Conclusion

1) The results of cumulative fatigue damage is much smaller than 1 under the vertical, longitudinally or transversely loading conditions. Compared with the IIW standard weld fatigue assessment methods, the equivalent structural stress method is more accurate. The cumulative damage ratio from the equivalent structural stress method takes into account the stress concentration. This method does not need to specify the joint types, so it's more general.

2) The equivalent structural stress method fully considers the effects of the weld toe gap, the thickness of the welded joint plate and the influence of load model. It can replace the other S-N curves of various joints with a single master S-N curve. So, it can make the results more accurate.

3) The evaluation of car body fatigue life can find out the weak parts of the product. So the computation can improve the quality of the product in the design stage. The results presented in this paper are benefit to the further improvement of car body design.

Structural Optimization for Head Cars of High-Speed Trains in Light of Aerodynamics

Bingzhi Chen; Cheng Chen; Wei Shao; and Wenzhong Zhao

School of Traffic and Transportation Engineering, Dalian Jiaotong University, Dalian 116028, China. E-mail: chenbingzhi06@hotmail.com

Abstract: With the increase of train speed, aerodynamic drag as a part of running resistance becomes increasingly important for train. In order to reduce the aerodynamic drag, configuration optimization is required for train heads, especially for high-speed trains. A simulation based configuration optimization for train heads is developed in this paper on the basis of computational fluid dynamics theory. Both manual and Sculptor-software-integration curve-driven arbitrary deformation are used and compared. The optimization results state that the optimal head configuration can be obtained by combining three software; ISIGHT, Sculptor, and Fluent. Therefore, this study provides a method for optimization and design of train heads.

Keywords: Surface reconstruction; Aerodynamic performance; Numerical simulation; Optimization; ISIGHT.

1 Introduction

With the increase of train speed, the interaction between trains and air become more intensive. The aerodynamics performances of trains draw increasingly attention. Research of train aerodynamics generally involves of air resistance, pressure wave, train wind, pressure pulse resulted from train meeting, pressure wave in tunnel, aerodynamic noise and so on. Study shows that the air resistance accounts for more than 90% of total running resistance when the running speed of train reaches 350km/h in open air. Aerodynamic drag is increased with the square of train speed and the required power is increased with the cube of train speed. In the design of high-speed train, the train configuration is generally designed to be a streamline in order to effectively reduce the air resistance and improve the running efficiency. The configurations of train head and tail seriously affect the pressure drag of trains. They are closely related with the aerodynamic performance of train and are extremely important parts in the configuration design of trains. Therefore, it is an important research subject to optimize the curves of train heads and effectively reduce the influence of the aerodynamic phenomena to trains and the surrounding for the aerodynamic configuration design of high-speed trains.

There are two main methods for studying the configuration optimization of high-speed trains in the world which are experiment method and numerical simulation method. A lot of research on the above -mentioned aerodynamic problems are performed by Japanese and Germans. In their research, wind tunnel model is used as the main pattern in the simulation tests and the numerical simulation of flow field is used as a main calculation method. In the earlier research, different configurations of train heads have been analyzed using the experiment method of wind tunnel model by Japanese. Analysis results show that the train crossing pressure wave can be reduced and the effect of pressure variation caused by the train operation to the environment can also be decreased effectively, when two-dimensional configuration is used in the train head design. There are mainly two head types for German high-speed trains which are wedge shape and ellipsoid shape, respectively. Research results show that three types of train head configurations are developed based on two-dimensional ICE2 head configuration and are propitious to improve the train performance. They are the configuration of long head in which the bevel of head top is lengthened, the configuration of long and the thin head in which the head side is narrowed and the bevel of head top is lengthened, and the configuration of low roof. By using these three types of configurations, the aerodynamic drag of head car under outside-crosswind load is decreased by 5%. The aerodynamic force and rolling moment, which affect the lateral stability of head car, also can be reduced effectively. Among these three configurations, the improvement result for the configuration of low roof is the best. At present, some researchers in China give their contributions to this project. Wind tunnel experiments are performed using the method of adjusting the parameters for the configuration lines of train heads by Tian Hongqi et al. Optimal design for the streamlined configuration of train heads is achieved through adjusting the control parameters after the relationship between control parameters and aerodynamic performance is analyzed in the light of experiment results. A part of head structures and positions are changed and the improved models are analyzed using the numerical calculation software named CFX by Zhang Jingqiang and Liang Xifeng. The optimal design model is then obtained through the comparisons and analyses of the calculation results. The optimization for head configurations of high-speed trains is implemented by Zhang Xiaogang using three-dimensional turbulent flow of blunt bodies. The relationship between geometric parameters and aerodynamic drag is analyzed and verified by the experiments of wind tunnel. The optimal range of each parameter is then obtained and the optimal configuration of train head is designed according to the optimal ranges.

The study of this paper is mainly focused on the design for curve configurations of train heads based on the computational fluid dynamics. 350km high-speed train is adopted as the basic model and its curves of train head are modified using the automatic mesh deformation software named Sculptor. The flow field and the body pressure distribution are acquired by the numerical simulation and calculation. Two means of optimizations are employed. In the first method, the curve variation is driven by manual adjustment, the configuration of train head is then changed, and optimum driving scheme is explored. In the second method, software named Sculptor and software named Fluent are integrated by a multi-disciplinary optimization software ISIGHT. Automatic solving a specific optimization problem is realized through automatic accessing the fluid analysis and structure analysis and setting the constraint conditions by users. The optimization design for the configuration curves of train heads is gained. At last, the optimal configuration of train head and a new design method for the optimization design of train head are acquired through comparing and analyzing these two kinds of methods.

2 Theory and Method

2.1 Fluid field theory

The train is slender object with a large length-width ratio and has a complex configuration. Thus, the air flow around train is a complete three-dimensional motion. There is a strong vortex in the end of the train and the flow field of train is the turbulent flow. The fluid used in this paper is the uncompressible fluid, the mathematical model of calculation is the standard $k-\varepsilon$ turbulence model, and can be expressed by the control equations as follows:

$$\frac{\partial}{\partial t}(\rho k)+\frac{\partial}{\partial x_i}(\rho k u_i)=\frac{\partial}{\partial x_j}\left[\left(\mu+\frac{\mu_t}{\sigma_k}\right)\frac{\partial k}{\partial x_j}\right] +G_k+G_b-\rho\varepsilon-Y_M+S_k \quad (1)$$

$$\frac{\partial}{\partial t}(\rho \varepsilon)+\frac{\partial}{\partial x_i}(\rho \varepsilon u_i)=\frac{\partial}{\partial x_j}\left[\left(\mu+\frac{\mu_t}{\sigma_\varepsilon}\right)\frac{\partial \varepsilon}{\partial x_j}\right] +G_{1\varepsilon}\frac{\varepsilon}{k}(G_k+C_{3\varepsilon}G_b)-C_{2\varepsilon}\rho\frac{\varepsilon^2}{k}+S_\varepsilon \quad (2)$$

Where G_k is the secondary generation term of the turbulence energy, k caused by the gradient of average velocity; G_b is the secondary generation term of the turbulence energy k caused by the floatation. For the incompressible fluid, G_b equals to zero, i.e., $G_b = 0$; Y_M represents the effect of ripple expansion of compressible turbulent to the total dissipation rate. For the incompressible fluid, Y_M equals to zero, i.e., $Y_M = 0$.

Turbulent kinetic energy is resolved by formula (2.1) and. The turbulent dissipation rate is resolved by formula (2.2).

Turbulent viscosity μ_t can be expressed as the function of k and ε. It can be described as:

$$\mu_t=\rho C_\mu\frac{k^2}{\varepsilon} \quad (3)$$

Where C_μ is the empirical constant.

The continuity equation can be written as:

$$\frac{\partial\rho}{\partial t}+\frac{\partial}{\partial x_i}(\rho u_i)=0 \quad (4)$$

Where u_i represents the velocity of flow field surrounding the multiple units; ρ is the air density; x_i represents three coordinate components.

The momentum conservation equation can be introduced as:

$$\frac{\partial}{\partial t}(\rho u_i)+\frac{\partial}{\partial x_j}(\rho u_i u_j)=-\frac{\partial P}{\partial x_i}$$
$$+\frac{\partial}{\partial x_j}\left[u\left(\frac{\partial u_i}{\partial x_j}+\frac{\partial u_j}{\partial x_i}+\frac{2}{3}\delta_{ij}\frac{\partial u_i}{\partial x_i}\right)\right] \quad (5)$$

Where u_i or u_j is the velocity of fluid field; x_i or x_j is three coordinates; p is the pressure; δ_{ij} is Kronecker symbol; δ_{ij} has the expression of δ_{ij}=1.0 when $i=j$ and has the expression of δ_{ij}=0 when $i\neq j$; u is the aerodynamic viscosity.

Energy equation can be written as:

$$\frac{\partial(\rho T)}{\partial t}+div(\rho\mu T)=div\left(\frac{k}{c_p}gradT\right)+S_T \quad (6)$$

Where c_p represents the specific heat capacity; T represents the temperature; k is the heat transfer coefficient of fluid; S_T represents the head resource in the fluid and the thermal energy transferred from the mechanical energy of fluid due to the viscous effect. Sometimes, S_T is defined as the viscous dissipation item.

2.2 Surface reconstruction technology used in the design of high-speed train heads

The shape of the high speed train head is provided with a plurality of surface organic composition of interconnected as a whole, the correlation characteristics of these surfaces bring the phenomenon that one surface is changed and other surfaces are alternated correlatively. Streamlined train head configuration usually adopts the three-dimensional free surface which is developed based on the shape of half a free fall drop.

2.2.1 Surface reconstruction technology

Surface reconstruction technology is adopted to complete the geometric reconstruction of entities through reconstructing the contour surface. It is also one of geometric modeling technologies. Non-Uniform Rational B-Spline(NURBS) surface reconstruction method is developed based on Be'zier method and B-Spline method is widely used now. Its mathematical description can be written as:

$$P(u,v)=\frac{\sum_{i=0}^{n}\sum_{j=0}^{m}W_{i,j}P_{i,j}N_{i,k}(u)N_{j,l}(v)}{\sum_{i=0}^{n}\sum_{j=0}^{m}W_{i,j}N_{i,k}(u)N_{j,l}(v)} \quad (7)$$

Where $N_{i,k}(u)$ and $N_{j,l}(v)$ are the primary functions of B-Spline in the directions of u and v, respectively; k is the degree for the primary functions of B-Spline in the direction of u; l is the degree for the primary functions of B-Spline in the direction of v; W is the power factor sequence; note vector in the direction of u can be written as $U = [u_1, u_2, \ldots u_{n+k+1}]$ and note vector in the direction of v can be written as $V = [v_1, v_2, \ldots v_{m+l+1}]$.

2.2.2 Modeling the curve configuration of train head

The surface structure for the head of high-speed trains is extremely complex. In this paper, head surface is created through controlling lines which involving of control lines and assistant control lines. Several control lines are drawn in the horizontal section, transverse section and longitudinal section since NURBS curves are easy to be controlled and modified. These three dimensional control lines are intertwined to outline the basic contour of the train head. Smooth contour can be obtained using NURBS surface reconstruction method. Control lines used in this paper are illustrated from Figure 1 to Figure 2, respectively.

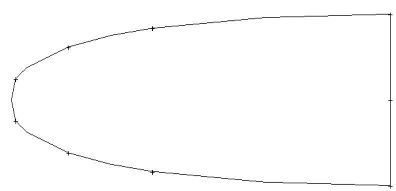

Figure 1. Configuration in the horizontal section

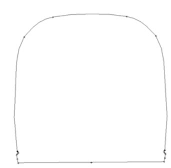

Figure 2. Configuration in the cross section

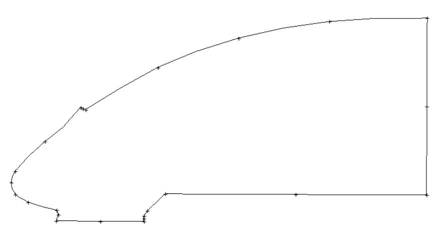

Figure 3. Configuration in the longitudinal cross section

Staggered grid lines are achieved through dominating the control lines and assistant control lines. Smooth model for head of high-speed train, as shown in Figure 4, is created using the surfaces reconstruction technology of CAD.

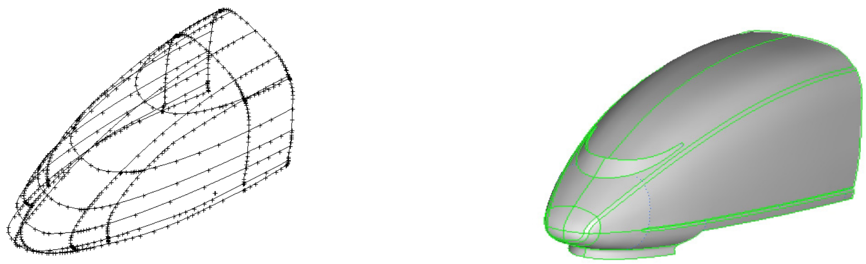

Figure 4. Staggered grid line and geometric model of train head

2.3 Optimzation model of train configuration structure

In order to reduce the aerodynamic drag of train operation and improve the aerodynamic performance when trains are running in the air, the contour surface of train head is optimized with two constraint conditions in which the head length and the maximum cross section are same as those of original train. The optimization model is introduced as follows:

design variable: $Y = \left[y_1, y_2 ......y_n \right]^T \in R_n$

objective function: min $F\left(y\right)$

constraint condition：G

Where variable Y is the coordinate of control point for the surface driving model. Only 6 control points are used in this paper; F (y) is the aerodynamic resistance value of train operation; constraint condition G includes the design variable Y which is the variation range of control point coordinate and is about 0.5m. G also involves of the length of original train head and the maximum transverse section of original train head. The essence of optimization problem is to minimize the aerodynamic resistance value of train head with certain constraints, which is realized by the curve-driven arbitrary deformation controlled by the variation of control points.

3 Optimal design for head configuration of high-speed train

3.1 Creating the finite element models of train head

The model of train head studied in this paper is symmetrical about the maximum longitudinal section and a half of train head is adopted in this paper. Since the outer space of train is infinite and cannot be simulated by computer, the finite region is substituted for the infinite region in this paper and results of the finite computational region is made to be approaching to those of infinite computational region. The computational region is defined as a hexahedron of 40m×6.2m×15m according to the size of train head where the upper calculation space is 1.5 times larger than the length of train head and the lower calculation space is 3 times larger than the length of train head. The train head and computational region are then meshed using the software named HyperMesh. The regions near the train head are meshed using the radial grid, i.e., mesh near the train head is dense and mesh is become sparse gradually from the head to the region in the distance. Mesh of train head region is shown in Figure 5.

Boundary conditions are defined as that the inlet is the velocity inlet and its inlet velocity value is 97.2 m/s. The outlet is the pressure outlet and the train wall is fixed.

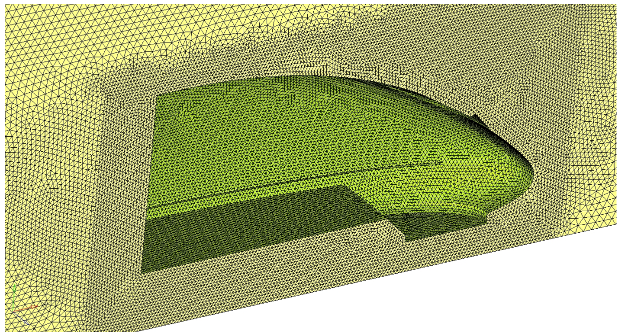

Figure 5. Finite element model of train head zone

3.2 Curve-driven modeling of train head based on software Sculptor

The design requirement for the curves of train head in this paper is to ensure the head length and the maximum cross section of the original train unchanged. In order to clarify the effect of each part of the train head on the aerodynamic drag of train, the train head surface is divided into three parts in the longitudinal direction which are the surface of nose tip, the surface of cab observation window, the transition surface between the train head and the train body. In the configuration design of train head, the train shape appearance should be beautiful and the inside region of train should have the enough space in addition to satisfying the running requirement of aerodynamic characteristics. Thus, the configuration optimization of train has a certain constraints. For example, the transition surface between the train head and train body cannot be changed. A control region is appended to the calculation model of train head using the software named Sculptor. The train head surface is changed simply and conveniently by altering the position of the control point in the control region. The automatic arbitrary deformation of model mesh can be realized, the mesh quality of reconstruction is high, and the model after reconstruction can be used to perform the numerical simulation calculation directly. The surface driving model of train head which is developed in this paper is shown in Figure 6.

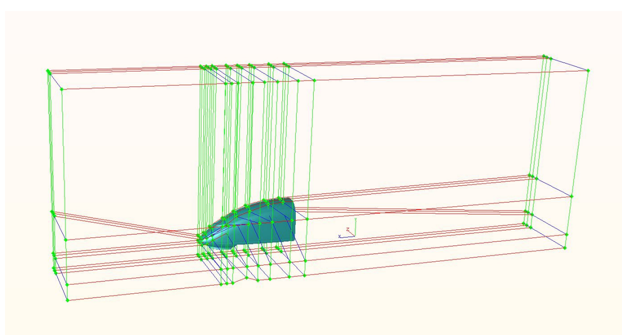

Figure 6. Curve-driven modeling of train head surface and the distribution of controlling points

3.3 Optimization process

Two methods for optimizing the configuration of train head are used in this paper. One is the mesh variation driven by the manual adjustment. Its advantage is that the head configuration could be varied randomly according to the subjective requirements and the optimal configuration model of train head can be obtained. Its drawback is that a lot of work might be needed to find the optimal model. Another is creating the work flow for the optimization design of train head with the help of intelligent optimization software named ISIGT. The optimization model is achieved by the intelligent solution of computer.

3.3.1 Optimization process in manual mode

Two head surface driving schemes are realized by using the first optimization method and are shown in Figure 7 and Figure 8 In the first scheme, the surface height of cab observation window is elevated. In the second scheme, the surface height of cab observation window is depressed.

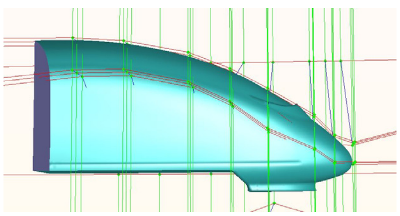

Figure 7. Curve model of original train head

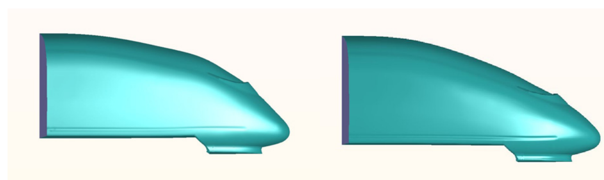

Scheme One **Scheme Two**

Figure 8. Curve models of two schemes

Finite element models of two schemes are imported into the software named Fluent and the flow field analyses are then implemented. Aerodynamic drag and the pressure field analysis of two driving schemes of train head configurations are compared to find the scheme with better aerodynamic performance and obtain the optimum model.

3.3.2 Optimization process of software integration based on the ISIGHT

The automation and multidisciplinary objective optimization of the simulation process is realized by the software ISIGHT. The data model and the calculation results of software named Sculptor and Fluent T are also integrated and transmitted by the software ISIGHT. The optimization target is determined and the optimum solution is sought by its optimization algorithm.

In the optimization and analysis of head configuration, the position height (variable y) of control point on the head surface is selected as the optimization variable. While the aerodynamic drag (variable F) of train head operation is chose as the optimization object. The optimization process is realized using the software ISIGHT in which the design variables, the optimization object, and the scope of variable values are defined. The mixed integer optimization algorithm named MOST is adopted in this paper to seek the optimum solution in which the initial value of the design variable is set to be 0 and the variation range of variable y is set as $-0.5m \leq y \leq 0.5m$. The optimum solution is obtained using the integrated optimization method

ISIGHT and can be expressed as y1=-0.1738； y2=-0.1832； y3=-0.3751； y4=-0.1938； y5=-0.5； y6=-0.5.The program is stopped when the number of iteration step is 112.

4 Optimization result and analysis

After the optimizing the train head configuration by two means, each scheme is realized through changing the train head configuration. The pressure distribution contours of the flow field for the optimization models are achieved through analyzing the effect of each method on the aerodynamic drag and comparing the aerodynamic performance of each scheme. The pressure and velocity vector distribution contours of train heads for the original model and the each scheme after the optimization are illustrated as follows:

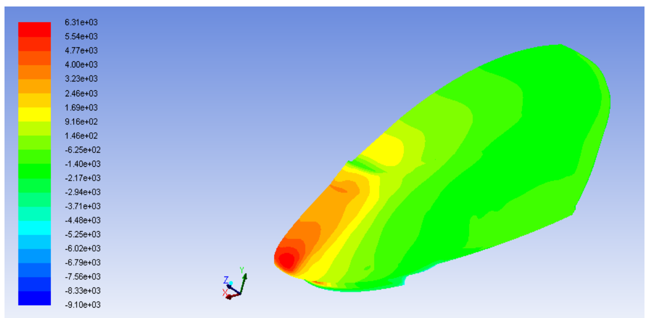

Figure 9. Pressure distribution for train head surface of original model

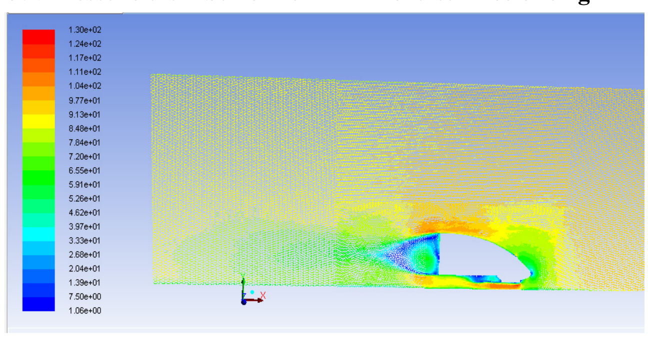

Figure 10. Velocity vector distribution on the symmetry plan of original model

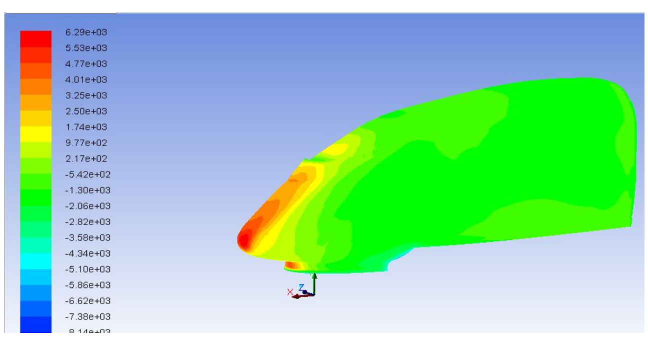

Figure 11. Pressure distribution for train head surface of scheme One

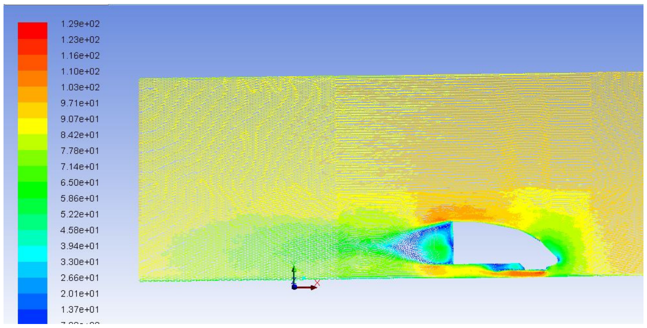

Figure 12. Velocity vector distribution on the symmetry surface of scheme One

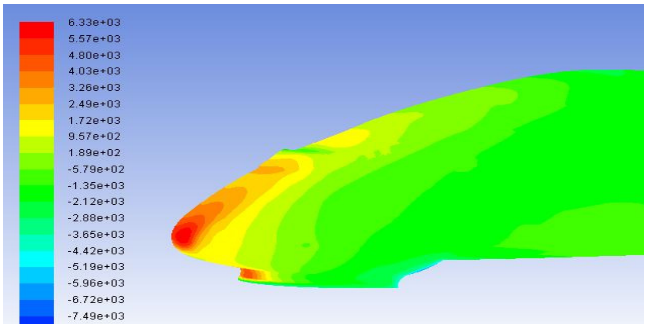

Figure 13. Pressure distribution for train head surface of scheme Two

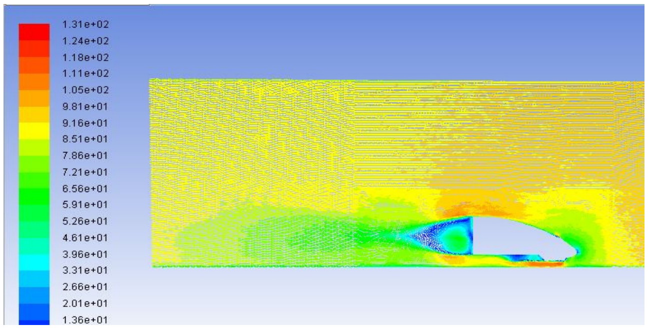

Figure 14. Velocity vector distribution on the symmetry surface of scheme Two

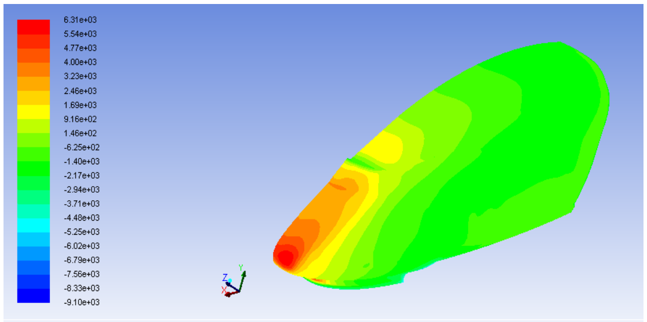

Figure 15. Pressure distribution for train head surface after optimization integration

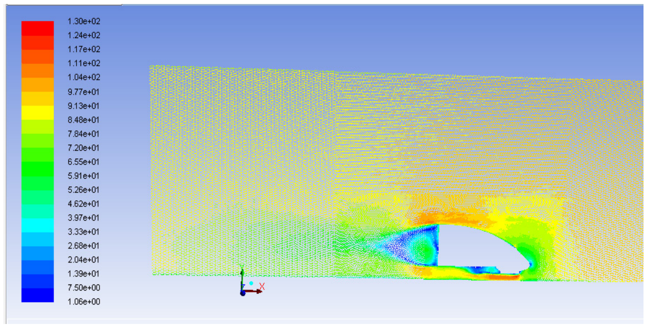

Figure 16. Velocity vector distribution on the symmetry surface after optimization integration

After analyzing the pressure distribution contour of train head, it is found that the flow field around the windward side of train head is in a state of the positive pressure due to the air compression loaded on the train head when the train is running. The pressure at the nose tip of train head is the highest. After passing the nose tip of train head, the speed of air flow is increased, the pressure is decreased, and a negative pressure zone is generated at the bottom of cab observation window. A positive pressure zone is generated at the transition part between the head of driver cab and the air deflector of train roof. The aerodynamic drag of train head is increased due to the positive pressure.

It can be seen from the distribution contour of velocity vector for the symmetry of train head, the flow is separated at the nose tip of train head. One portion of the gas stream flows upward to the roof and another portion of the gas stream flows down to the bottom of train head. The upper airflow is accelerated at the top of the nose tip, is separated at the tail, and forms a turbulent region. The lower airflow must traverse through the region between the bottom of train body and the pavement. It is converged with the upper airflow finally on the upper surface of train head. The turbulent flow is formed and the drag is generated.

The comparison between aerodynamic drag of each scheme is listed in Table1. In Scheme Two, the aerodynamic drag is reduced by abating the surface height of cab observation window. In the optimization results obtained by software ISIGHT, surface height of cab observation window is debased significantly.

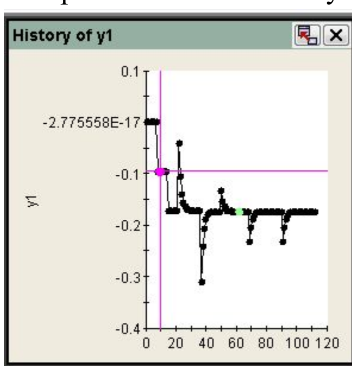
Table 1.Comparision table of aerodynamic drag for two schemes(unit：N)

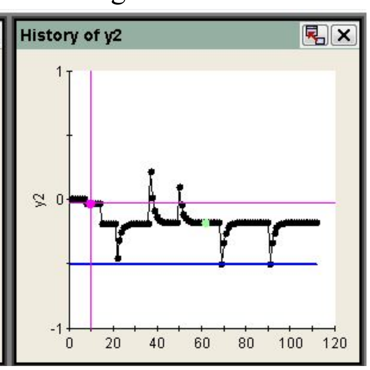
		Pressure drag	Air fraction resistance	Total drag
Train of original configuration		-2378.37	-617.48	-2995.85
Manual driving optimization	Scheme One	-2390.99	-624.89	-3015.88
	Scheme Two	-2339.644	-606.91	-2946.55

Integration optimization using ISIGHT	-2306.58	-604.98	-2911.56

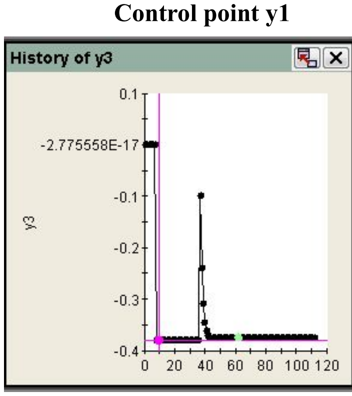
As shown in Table 1, the value of aerodynamic drag for the original model is -2995.85N. The aerodynamic drag of Scheme One is increased and the aerodynamic drag of Scheme Two is decreased by the manual driving surface method. The aerodynamic drag of train head is effectively reduced using the integrated optimization method of the software ISIGHT. It can also be seen from Table 1, the variation of pressure difference is relatively large and the variation of air friction drag is not obvious. Therefore, the aerodynamic drag of train head is reduced through affecting the pressure difference in the optimization of surface configuration of train heads.

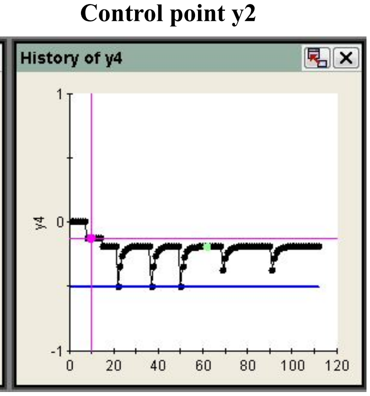
For optimizing the configuration of train heads, the integrated method using the software ISIGHT is more convenient and effective than the manual adjustment method. The monitoring means of visualization are provided in the software ISIGHT. They include the variation history diagram of each variable parameter in the integration and optimization process and the main effect chart of each design variable based on the gradient analysis. As shown in Figure 17 and Figure 18, the effects of design variables on the aerodynamic drag are illustrated. The aerodynamic drag of train head can be effectively reduced through decreasing the height of nose tip and the surface height of the cab observation window. The effect of surface variation of other positions on the aerodynamic drag is small.



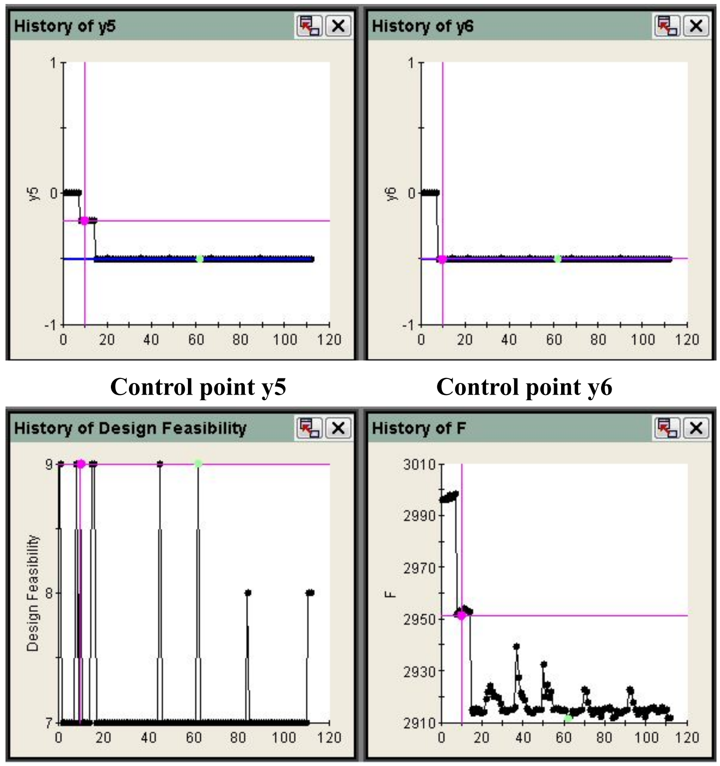


Control point y1 **Control point y2**





Control point y3 **Control point y4**



Control point y5 **Control point y6**

Design feasibility **Aerodynamic drag variable F**

Figure 17. Historical map of parameter variations in ISIGHT optimization process

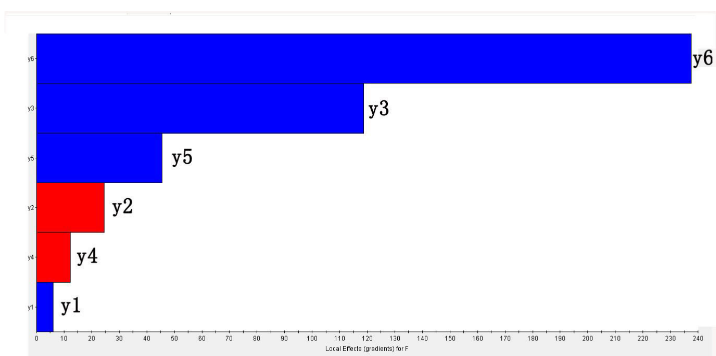


Figure 18. Effect map of design variables on aerodynamic drag

The comparison chart between the integrated optimization model obtained by the software ISIGHT and the original model is shown in Figure 19. It is obvious that using the integrated optimization method to optimize the configuration of train head is feasible. This study provides a theoretical basis for the further research of streamlined train head.

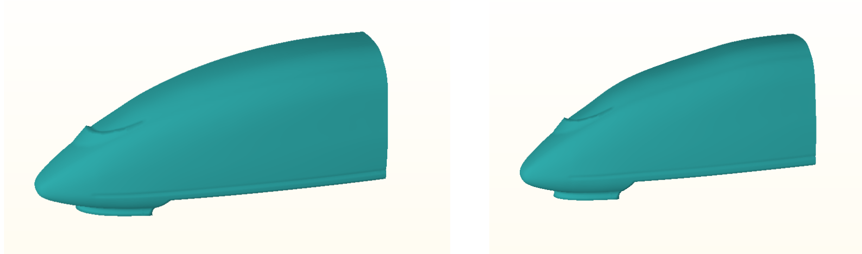

Figure 19. Comparison between the original model and optimized model

5 Conclusions

Both manual and Sculptor-software-integration curve-driven arbitrary deformation methods are used in this paper to conduct the fairness deformation of configuration surface and to improve the aerodynamic drag of train head. Although the two methods are essentially similar, comparison was carried out to investigate the advantages of ISIGHT, Fluent, and Sculptor in the process of optimization design and analysis of train head configuration. The optimization results indicate following results:

(1) The optimal configuration of head of 350-km/h high-speed train presents a better streamlined geometry. The height of nose tip of the train head and the surface height of cab observation window of the optimal configuration are significantly lower.

(2) The aerodynamic drag of the optimal configuration is only reduced by about 3%. Because only the height of a few control points are chose as variables. The results show that the number and location of control points directly affects the optimization result.

(3) Only the aerodynamic drag is considered as optimization goal in this study. More parameters would be considered in the future to achieve the overall optimization.

(4) The optimization methods in this paper are capable for the configuration optimization of high-speed train. This present study could benefit the configuration design of high-speed trains.

Influence of Structure Parameters of Sonar Domes on Sailing Resistance

Liming Du and Shoulong Ni

School of Traffic and Transportation, Dalian Jiaotong University, P.O. Box 395, 794, Huanghe Rd., Dalian. E-mail: dulm@vip.sina.cnom

Abstract: Sailing resistance and underwater acoustic performance are decided by the profile and structure parameters of sonar dome. In the present thesis, influence of some key structure parameters, such as length-width ratio of the maximum water surface line of a sonar dome and width-height ratio of the maximum longitudinal section, on sailing resistance of certain "I" ship was numerically researched. The numerical results show that sailing resistance of the ship installed with the sonar dome whose length-width ratio is about 3.4 ~ 3.6 and width-height ratio is about 1.1 ~1.2 is significantly smaller than installed with other sonar dome. Moreover, the drainage volume of the sonar dome is smaller than others and its comprehensive performance is best compared with other sonar dome. The numerical results agree well with the experimental data.

Keywords: Sonar dome; Structure parameters; Sailing resistance; Numerical simulation.

1 Introduction

Most modern medium and large ships are equipped with the comprehensive sonar equipments at the bottom of them. Whether the ship and submarine sailing or mooring, there are water flowing through the surface of the sonar sensor. In order to improve the signal-to-noise ratio and the detection ability of the sonar, it is necessary to avoid the boundary layer separation lest the sonar dome producing vortex noise affecting the sonar usage. Furthermore, the uneven distribution of pressure leads to the pressure pulsation on the surface of the dome when the ship sailing. To a certain extent, it will increase the sailing resistance. In other words, in addition to the size of sonar equipment, sonar performance and sailing resistance are the main parameters which decide the structure and space of the sonar dome. Sonar performance and sailing resistance are consistent with the requirements of the sonar dome's shape. Therefore, studying the external structure parameters of the sonar dome on the influence of sailing resistance has a great significance to improve the sonar detection performance and reduce the sailing resistance.

Five kinds of domes about the external structure were numerical studied by Yingdong Wang. The results show that the comprehensive performance of the dome profile with its head streamline and tail for semi-circular is the best. Based on the

Reference 5, effects of sonar dome's key structural parameters (the length-width ratio of the maximum water surface line and the width-height ratio of the maximum longitudinal section) on sailing resistance was numerically researched. This research will get the external structure parameters which can let the ship has the lowest sailing resistance. The parameters will provide a reference for the optimal design of the sonar dome.

2 Numerical model and method

2.1 The entity model

This paper studies a certain "I" ocean surveillance ship installed different sized sonar dome about its sailing conditions. The simulated conditions are as follows: full displacement, sea condition less than level 2, wind less than Beaufort level 3, host speed is 1000 r/min, the largest trial speed is 16Kn and economic speed is 14 Kn. The sonar dome is installed at the bottom of the ship between the frame 69# and 75# and coincides with the ships longitudinal center plane shown in Figure 1. The original sonar dome shown in Figure 2 has outline size of 2.52m*1.22m*1m and weight of 2500kg.

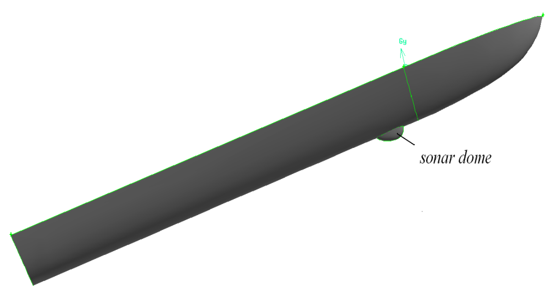

Figure 1. The part of hull under waterline

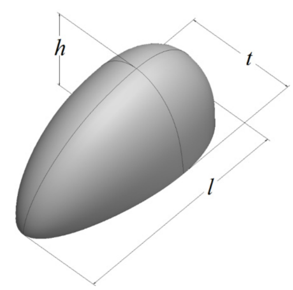

Figure 2. Model of sonar dome

After determined the optimal silhouette of sonar dome and meet the requirements of the installation of sonar equipment, the resistance of sonar dome and the underwater acoustic performance of sonar mainly depend on the key structural parameters and the proportional relationships between them shown in Figure 2. These proportional relationships include the length-width ratio of the maximum water surface line (i.e., the value of l/t) and the width-height ratio of the maximum longitudinal section (i.e., the value of t/h). The paper mainly analyzes the sailing resistance affected by sonar dome, which is based on the research of the two key structural parameters of sonar dome.

2.2 Meshing for the entity model

The boundary of the flow field is rectangular, dividing the flow field into four regions, among which Region 2 is a dynamic region including the hull, and its range constantly changes with the movement of the ship. Due to the complex shape of the ship and the sonar dome, this region is divided by a mixed mesh, generating the unstructured mesh. The other three regions are in a regular shape, and are divided into the hexahedral mesh. The mesh generation of the computing regions is shown in Figure 3.

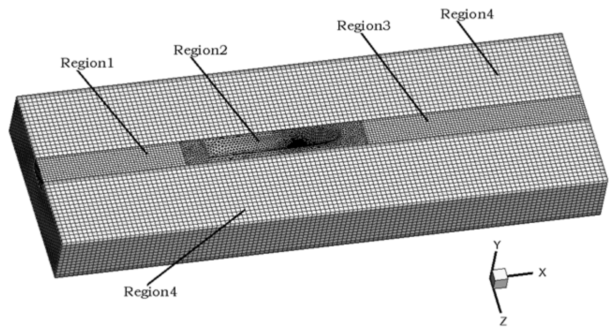

Figure 3. Full grid of the computational domain

2.3 The numerical method and the boundary conditions

According to the sailing speed, we can consider the fluid near the hull in the turbulent state, and it is also the incompressible fluid, complying with the turbulent transport equation, the turbulence model adopts a standard k-ε model. When the ship is sailing, the two phases of air and seawater are involved, so the VOF（Volume of Fluid）multiphase flow model is adopted to simulate the sailing ship. The PISO algorithm is used for the coupling calculation of the speed and pressure. In terms of numerical discrete, the second-order upwind scheme is adopted to improve the calculation accuracy. The flow field around the sailing ship can be considered as the dynamic flow field, and the hull surface is the flow field boundary of the movement, so this paper adopts the dynamic layering model and local re-meshing model of mesh deformation to simulate the ship's sailing process. The setting of boundary conditions are as follows: the outlet adopts the pressure outlet boundary condition, setting the static pressure of the outlet boundary at 0. The hull surface adopts the non-slipping boundary condition.

3 Results and discussion

The relationships between the length-width ratio and width-height ratio of the sonar dome are mainly studies based on reducing the sailing resistance under the condition and meeting the basic requirements of sonar equipment.

Table 1 The size of the sonar dome at the length-width ratio of the maximum water surface (m)

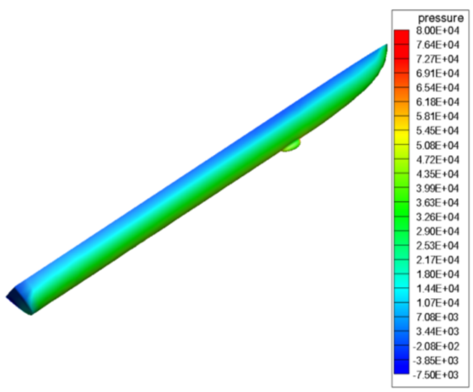
l/t	2.0	2.5	2.7	2.9	3.0	3.2	3.4

l×t×	2.44×1.22×1.05	3.05×1.22×1.05	3.29×1.22×1.05	3.54×1.22×1.05	3.66×1.22×1.05	3.90×1.22×1.05	4.15×1.22×1.05
l/t	3.5	3.6	3.8	4.0	4.2	4.5	5.0
l×t×	4.27×1.22×1.07	4.39×1.22×1.10	4.64×1.22×1.16	4.88×1.22×1.22	5.12×1.22×1.28	5.49×1.22×1.37	6.10×1.22×1.53

3.1 The effects of sonar dome's length-width ratio on sailing resistance

According to Reference 3, suppose the height "*h*" is 0.25*l* (i.e., when the length-width ratio is 4.0, the sonar dome's performance is the best). On this basis, 14 kinds of sonar domes with the length-width ratio *l/t* =2.0~5.0 are analyzed, and their structure sizes are shown in table 1.

The following introduces the ship's sailing resistance at the maximum trial speed 16Kn with the above 14 kinds of schemes.



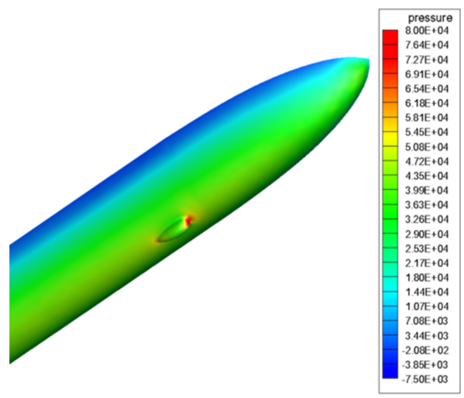


Figure 4. Pressure contours of the hull at the speed of 16Kn

Figure 5. Pressure contours around sonar dome at the speed

Take the simulation result of sonar dome's length-width ratio of 3.0 as an example, and analyze the sailing resistance of the hull and sonar dome. Figure 4 and 5 are the pressure contours around the hull, the bottom of the ship and the sonar dome. From the figures, we can see that the hull pressure is increasing from the top to the down, which corresponds to the water pressure. The bow has a compression effect on water body, which leads to the result that the pressure at the bow is higher than other locations at the same level of the hull. With the ship sailing, the stern has certain negative pressure, and also produces vortex. It is because of the positive and negative pressure difference of the bow and stern, the sailing resistance is formed. Figure 5 shows the pressure around the sonar dome. From the figure, we can see that the front part of the sonar dome also has a compression effect on water when the ship is sailing, which makes the pressure of this part increase significantly, and the rear part of the sonar dome forms certain negative pressure zone. The pressure difference of the front and the rear of the sonar dome lead to the sailing resistance increasing.

The larger the difference is, the greater the sailing resistance is.

Figure 6 shows the velocity contours of the profile when the ship is sailing. From the figure, we can see that the water velocity of the bow, sonar dome and stern increase obviously, and the velocity gradient at the stern is large and produces more vortex, which shows flow separation phenomenon appears here, and causes the increase of sailing resistance. Figure 7 shows how the resistance coefficient changes with time. We can see that the sailing resistance is not stable at the beginning of sailing, and it will basically tend to stable after about 3 seconds, which is completely consistent with the actual situation.

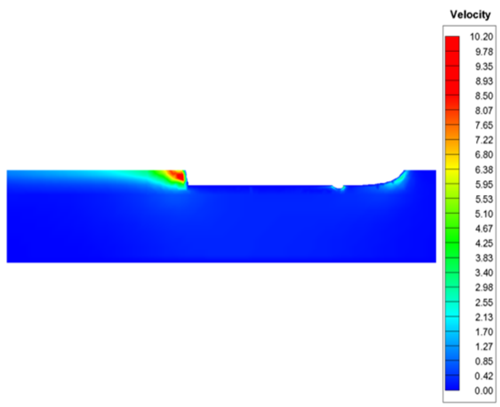

Figure 6. Velocity contours of the profile at the speed 16Kn

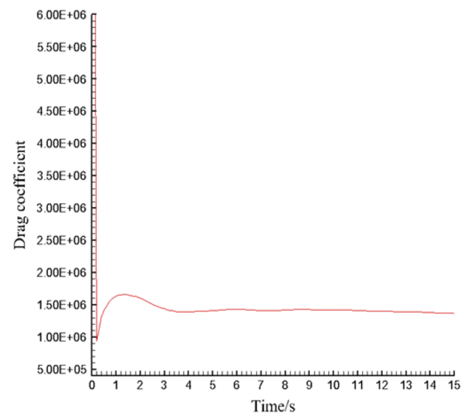

Figure 7. Resistance coefficient curve of the ship at the speed 16Kn

After the statistical analysis of the ship's sailing resistance in a stable sailing with sonar domes of different length-width ratios, the relationship between the sailing resistance and the sonar dome's length-width ratio of the maximum water surface line is shown in Figure 8.

Figure 8. The sailing resistance of the ship installed different length-width sonar dome at the speed 16Kn

According to figure 8, we can see that the sailing resistance first reduces with the increase of the sonar dome's length-width ratio, and when the sonar dome's length-width ratio increases to 3.5, the sailing resistance reaches its minimum, then with the further increase of the length-width ratio, the sailing resistance increases gradually. That is not to say, the longer the sonar dome is, the smaller the sailing resistance is. When the length-width ratio of the sonar dome is between 3.4 and 3.6, the sailing resistance is small, the total drainage volume of the sonar dome is small, and the comprehensive performance is the best. With the further increase of the sonar dome's length-width ratio, the sailing resistance increases first and then reduces, and when the ratio is 4.2, it reaches the maximum. The increase of the length-width ratio will lead to the obvious increase of the drainage volume of the sonar dome, the increase of the manufacture cost and the bad comprehensive performance.

3.2 Effects of sonar dome's width-height ratio on sailing resistance

According to the above simulation results, when the length-width ratio of the water surface line reaches 3.5, the ship's sailing resistance performance is the best, so when analyzing the influence of the sonar dome's width-height ratio of the maximum longitudinal section, we should keep the sonar dome's length-width ratio at 3.5. Take the suggestions of Reference 3, we set 9 simulation schemes of different width-height ratios *t/h* to analyze, the scheme settings are shown in Table 2.

Table 2 The size of the sonar dome at the height-width ratio of the maximum longitudinal surface (m)

t/h	0.90	0.95	1.00	1.05	1.10	1.14	1.20	1.25	1.30
h	1.36	1.28	1.22	1.16	1.11	1.07	1.02	0.98	0.94

For the above sonar domes with 9 different width-height ratios, we simulate and analyze the ship's sailing resistance at the maximum trial speed 16Kn. Take the simulation result when the sonar dome's width-height ratio of the maximum longitudinal section 1.14 as an example, and analyze the resistance when the ship is sailing.

Figure 9 and 10 are the ship's pressure contours around the hull, the bottom of the ship and the sonar dome at the maximum trial speed 16Kn with the sonar dome's width-height ratio of 1.14. From the figures, we can see that the pressure changes around the hull, at the hull bottom and near the sonar dome are basically consistent with Figure 5, but the pressure difference of the maximum positive and negative pressures of the head and tail of the sonar dome reduces obviously. That is to say the sailing resistance reduces obviously. Compared with the sonar dome with the length-width ratio of 3.0 and the width-height ratio of 4.0, the sonar dome with the length-width ratio of 3.5 and the width-height ratio of 1.14 has a smaller sailing resistance. Figure 10 shows the pressure contours near the sonar dome. From the figure we can see that the front of the sonar dome has a compression effect on water, which makes the pressure of this part rise obviously and reach the maximum positive pressure, but the rear of the sonar dome will form certain negative pressure zone. But the sonar dome is at the hull bottom, and the water pressure is large, so the negative pressure of the rear of the sonar dome is offset, forming some positive pressure.

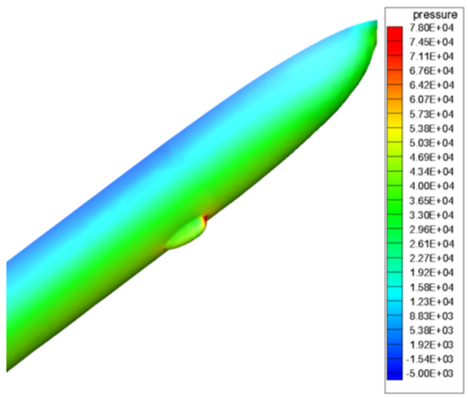

Figure9. Pressure contours of the hull with sonar dome at the width-height ratio

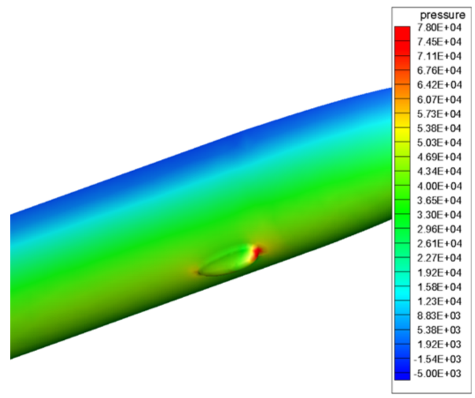

Figure 10. Pressure contours around sonar dome at the width-height ratio

After the statistical analysis of the ship's sailing resistance with sonar domes of different width-height ratios in a stable sailing condition, the relationship between the sailing resistance and the sonar dome's width-height ratio of the maximum longitudinal section is shown in Figure 11.

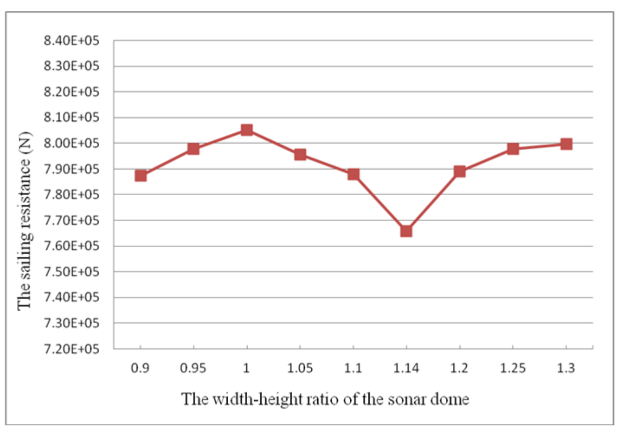

Figure 11. The sailing resistance of the ship installed different width-height sonar dome at the speed 16Kn

From the above figure, we can know that the ship's sailing resistance first gradually increases with the increase of the width-height ratio of the sonar dome, and when the width-height ratio of the sonar dome increases to 1.0, the ship's sailing resistance reaches its maximum, and then with the further increase of the width-height ratio, the sailing resistance will first reduce and then increase. When the width-height ratio reaches 1.14, the ship's sailing resistance will reach its minimum, the height of the sonar dome is 1.07m and the length-height ratio is 4.0, which meets the sonar dome's size requirements of the sonar equipment. As the width-height ratio of the sonar dome exceeds 1.14, the ship's sailing resistance gradually increases , but when the width-height ratio reaches 1.3 and exceeds it, the height of the sonar dome reduces to below 0.94m, and the small internal volume will limit the installation and using of the sonar equipment. So the sonar dome with a width-height ratio of above 1.3 has no use value. When the width-height ratio is below 1.05, the height of the sonar dome is too large, the sailing resistance performance is bad and the manufacture cost increases, so there is no practical significance.

4 Conclusions

(1) The sonar dome's structure parameters have obvious influences on its sailing resistance. Under the condition of meeting the requirements of installing sonar equipment, not the smaller the sonar dome is, the smaller its sailing resistance, but an optimal structure parameter makes its resistance performance and sonar underwater sound performance optimal.

(2) When the length-width ratio of the maximum water surface line of the sonar dome is between 3.4 and 3.6, its sailing resistance is small, and meanwhile it's total drainage volume is small, and the comprehensive performance is the best.

(3) When the width-height ratio of the maximum longitudinal section of the sonar dome is between 1.1 and 1.2, its sailing resistance is small, and meanwhile the size of the sonar dome also meets the size requirements of installing sonar equipment and the comprehensive performance is the best.

Numerical Analysis of the Internal Flow Field of a Marine Centrifugal Compressor and the Structural Optimization of a Vaned Diffuser

Liming Du; Quan Li; and Cheng Li

School of Traffic and Transportation, Dalian Jiaotong University, P.O. Box 395, 794, Huanghe Rd., Dalian. E-mail: dlm@djtu.edu.cn

Abstract: Due to coupling effect and interaction between the impeller and diffuser, internal flow field of a centrifugal compressor is very complicated. In the present thesis, numerical analysis of the internal flow field of a marine centrifugal compressor in multistage environment was carried out. The results indicate that narrow working rang and low efficiency of the prototypical compressor contributes to the eddy between outlet of the impeller and inlet of the diffuser. The coupling relationship between the impeller and diffuser was improved by reducing vane number of the diffuser and shortening the length of the blade trailing edge. The optimal results show that the stable working range of the compressor was broadened and working efficiency and pressure ratio in multistage environment were increased significantly.
Keywords: Centrifugal compressor stage; Internal flow field; Structural optimization; Vaned diffuser.

1 Introduction

Owing to influence of impellers rotating and curvature of impeller surface, whirl breakaway, flow back, secondary flow and flow separation will occur. All the phenomena make the internal flow field of centrifugal compressor very complex. Impeller is one of key components of a centrifugal compressor, by which mechanical work is converted into potential energy and kinetic energy. Boundary improvement of the impeller outlet and diffuser inlet is a feasible measure to improve working performance of a centrifugal compressor. Different from the mechanism of pressure increasing in the impellers, it is by air diffusing for the diffuser to reduce flow velocity and increase static pressure.

It is one of main purposes to recover efficiently kinetic energy which contained in the airflow in centrifugal impeller when designing a high-performance compressor is. In accordance with the principle of conservation of angular momentum, the rest of kinetic energy in the compressor can be further transferred into potential energy and make static pressure increases by the diffuser which making air way area increase or changing the radius of the average flow. However, it may cause a compressor occur flow separating, even leads to stall flutter.

The coupling effect of impellers and diffusers directly affects performance of the whole compressor. Good matching of the two key components can make internal flow fields smooth. While previous design of centrifugal compressor rely designer's experience and on-site test. The traditional design method of centrifugal compressor excessively depend on the previous designing experience and on-site test repeatedly. The method cause enormous waste of time and money, and could not predict the final results and control the developing cost. In the present thesis, numerical method was applied to analyze and optimize the structure of a marine centrifugal compressor. Internal flow field of impeller and diffuser of the compressor was analyzed in different rotating speed and optimize parts of key structure parameters of diffuser depending on the numerical results in order to improve coupling relationship between the impeller and diffuser and increase the performance parameters of the compressor.

2 Numerical model and method

2.1 Numerical model and computational mesh

In present thesis, the impeller of a marine centrifugal compressor has ten main blades and ten splitter, and its diffuser has blades. The inlet radius of the impeller tip is 100mm and the root radius is 50mm. The outlet radius and height of the impeller are respectively150mm and 15mm. Both of the inlet and outlet tip clearance are 0.6mm and impeller's outlet bending angle is 25 degrees. The specific geometric model of the compressor can be seen in Figure 1.

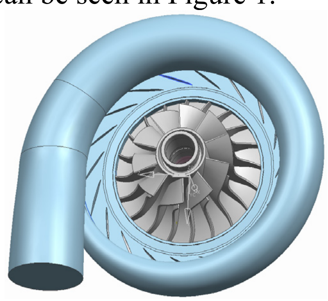

Figure1. Geometric model of the centrifugal compressor

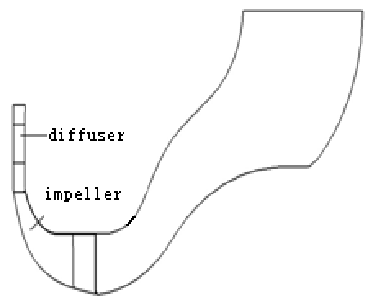

Figure 2. Meridian channel

Due to the complex structure of the compressor, some simplification was done when developing the numerical model of the compressor in the condition of without affecting simulated results. The meridian channel of the compressor was shown in figure 2. In order to reduce calculating cost, numerical grid of impeller is established only for a single channel. At the same time, the import and export of the impeller passages were extended properly, and the wall surface meshes were refined as far as possible to satisfy the y+<10 of wall first grid node. In addition, a butterfly-shaped technology grid was employed to improve the quality of the grid. In order to make the results more comparable, impeller channel grid, diffuser and volute grid of compressor with casing treatment were same as the corresponding computational grid of the solid casing compressor. The total computing grids of the centrifugal compressor is shown as figure 3.

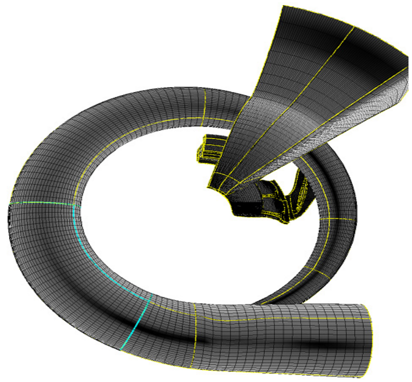

Figure 3. Computing grids of the centrifugal compressor

2.2 Numerical computation method

Compressible ideal gas was chosen as working media. Spalart-Allmaras model is selected to solve turbulence equation, which has strong fault tolerance ability and suits for complex flow for balancing accuracy and efficiency of the computation. Second-order central difference scheme in space discretization and fourth order Runge-Kutta in time discretization were used. In addition, the domain average method is utilized for rotor and stator interface. To facilitate the comparison, the outlet boundary condition was set as the mass flow. The off-design working condition was obtained by reducing gradually the outlet flow rate. The solid boundary is regarded as no-slip and adiabatic walls.

When the curve slope of compressor pressure ratio performance is negative, it is generally believed that the compressor works in unstable condition, namely the compressor falling into rotating stall or surging condition. In the simulating, when the pressure ratio reaches maximum value, convergence error decreases slowly and has obvious cyclical fluctuation, which implicates that stall flutter appears. So when pressure ratio significantly declines and residual concusses with the decreasing of export flow rate, it is believed to approach the stall point, then accurately capture will be executed.

3 Results and discussion

3.1 Analysis of compressor performance

According to experimental data, the efficiency of centrifugal compressor is 78.5% and pressure ration is 2.9 under rated conditions (Mass flow rate is 3.6 kg/s and rotation speed 26700 rpm). Table 1 shows the main performance parameters of the compressor under multiple working condition with rated rotational speed obtained by simulation. According to the table, the error between the numerical results and the experimental data is less than 5%. It indicates that the numerical method and the results in the present thesis are credible. As shown in table 1, the working range of the compressor is narrow and working efficiency and pressure ratio in the condition of big airflow are all lower than expected and it can not meet the design requirements.

Table 1. Performance parameters under variable flow rates with 26700rpm

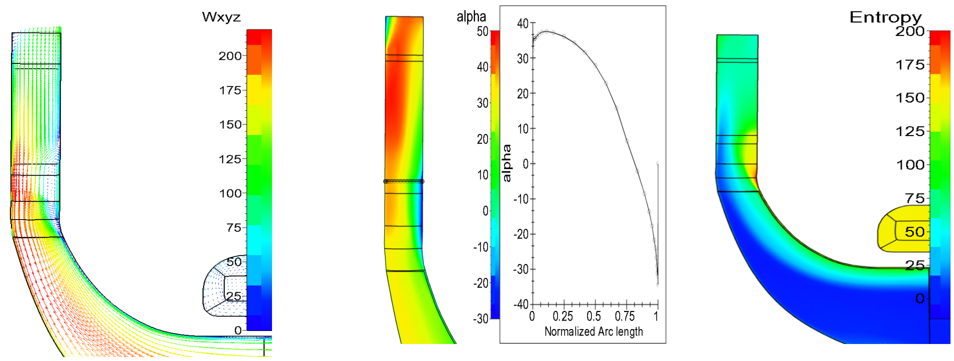
Flow rate G(kg/s)	lumped parameter	
	Pressure ratio π c*	Isentropic efficiency η is（t/t）
3.36	2.872	76.83%
3.60	2.840	77.17%
3.84	2.743	75.67%
3.96	2.632	73.05%
4.20	1.922	50.68%

In order to find the reason why the main performance parameters of centrifugal compressor are low, three research schemes (“impeller” and “impeller + vaned diffuser ” and "impeller + vane diffuser + volute") are set up in the present thesis. Aerodynamic performance of three main components of the compressor were respectively analyzed. According to the numerical results, the performance parameters of the three schemes are obtained as shown in table 2.

Table 2. Performance parameters of different parts

Character / Component	Flow rate G（kg/s）	Pressure ratio π c*	Isentropic efficiency η is（t/t）
Impeller	3.60	3.18	85.89%
Impeller and diffuser	3.60	2.92	79.82%
The compressor stage	3.60	2.84	77.17%

The table indicates that the main energy loss happens between the outlet of the impeller and inlet of the diffuser. In order to find out the main reason that the efficiency is not high enough, it is necessary to analyze respectively internal flow field of the impeller and the vaned diffuser.



(a) Meridian surface streamline of circumferentially-averaged relative velocity

(b) Flow angle distribution

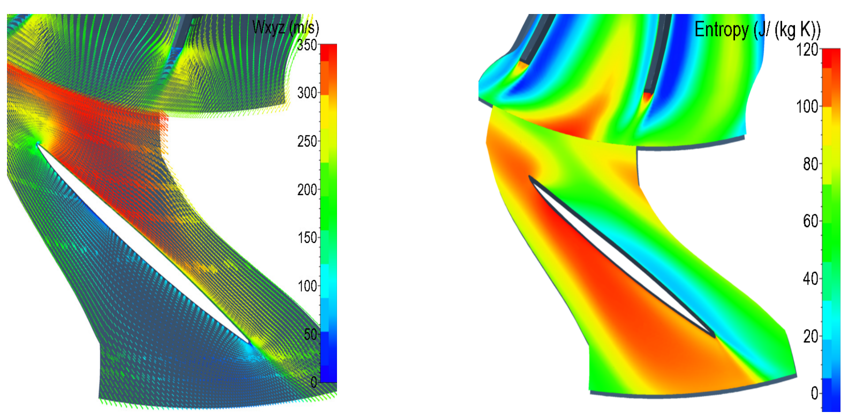
(c) Average cloud of entropy at circumferential

Figure 4. Performance parameters in meridian channel

3.2 Analysis of internal flow

Internal flow field of the compressor was simulated in rated condition in order to analyze the flow field of the impeller. Flow angle contours and circumferentially average streamline of relative velocity and circumferentially average entropy contour are shown in Figure 4. According to figure 4(a), there are some eddy significantly existed in the side of wheel cover between the outlet of the impeller and inlet of the vaned diffuse, which make distribution of flow angle along the blade height direction uneven when air flow into the diffuser, as shown in figure 4(b). It also makes entropy production between the outlet of the impeller and inlet of the diffuser is high, as shown in figure 4(c). Therefore, the efficiency of the compressor decrease quickly.

Figure 5 shows the meridian surface streamline of circumferentially-averaged relative velocity and the average cloud of entropy at circumferential at the height of 50% blade. From the picture, it can conclude that eddy generate between impeller's outlet and diffuser's inlet when centrifugal compressor runs under the rated speed. This part will seriously affect normal work of the front part and the back part. If the zone make wore, it will produce clogging. So the centrifugal compressor can't work normally.



(a) Meridian surface streamline of ıferentially-averaged relative velocity

(b) Average cloud of entropy at circumferential

Figure 5. Height of 50% blade

4 Diffuser structure optimization

4.1 Optimization of the number of diffuser blade

Based on the above analysis, some schemes of the diffuser blade number and the blade length were numerically analyzed in order to increase the whole stage efficiency and pressure ratio of the compressor and improve the coupling relationship between the impeller and the diffuser. Figure 6 shows the efficiency-flow of the compressor with four different diffuser vane numbers.

From Figure 6, it can be seen that reducing the number of the diffuser blade will improve the efficiency and pressure ratio under the large rate of the flow. But if the number of the blade is less, it will make the internal flow field disorder.

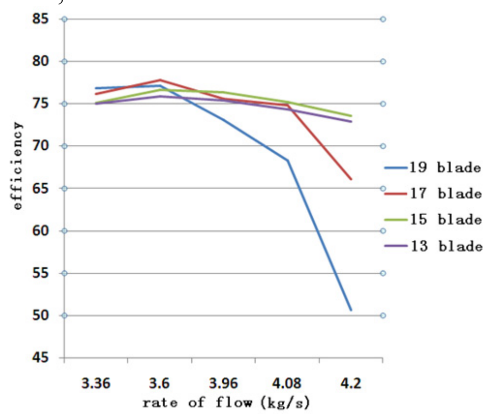


Figure 6. Efficiency-flow

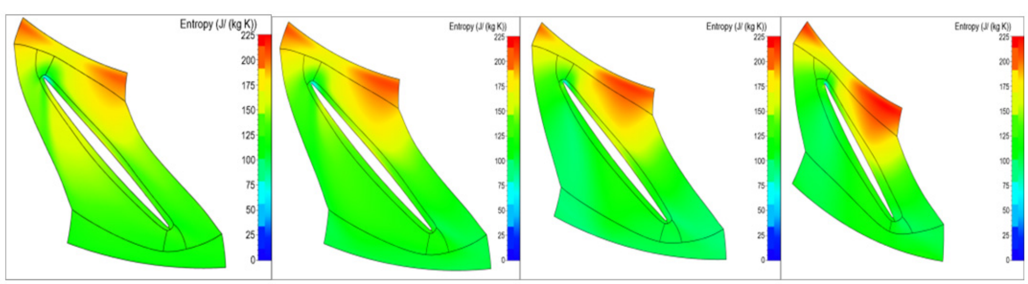
In order to further analyze, the different number of blades entropy are the thesis compared in the figure 7. The blade is high consistency. When the high speed flow pass through the diffuser, there is a great impact on the front of the diffuser, so it may lead to the large loss of the energy, and it will have a great influence on the distribution of entropy in the diffuser. In the figure 7(b) and 7(c), reducing the number of the blade appropriately will improve the energy distribution of flow in each section. And it will make the loss of energy low. But in the figure 7(d), if you reduce the number of the blade much, it can transform kinetic energy into static pressure energy inadequately, it will be badly control the air flow as the preset direction and there is a high entropy section at the suction side of blade, leading to the loss of the energy and making the efficiency and pressure ratio low.



(a)19 blades (b)17blades (c)15blades (d)13blades

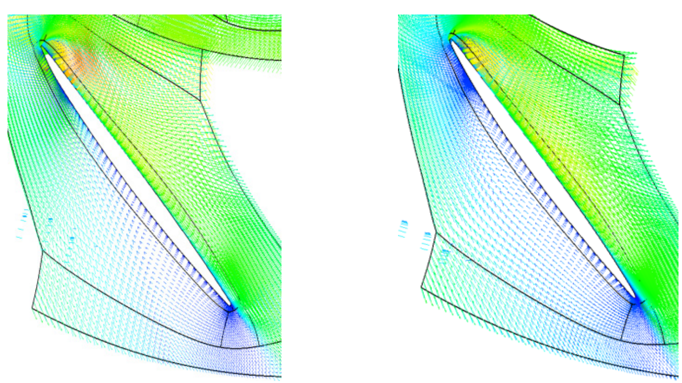
Figure 7. Entropy at the root of blades

Table 3. Performance parameters of different number of diffuser blade

Project	lumped parameter	
	Pressure ratio π c*	Isentropic efficiency η is（t/t）
Before optimization（15 blade）	2.91	75.1%
After optimization（15 blade）	2.94	76.7%

4.2 Optimization of the length of diffuser blade

Through the above analysis, the best number of blades is made, reducing the number of diffuser blade not only make the internal flow field better, but also make the working scope large. But the efficiency and pressure ratio is low at little mass flow. So the paper use the model of Design 3D to optimize the length of diffuser blade. It will improve the loss of energy by the "wake-jet", backflow and so on, and it will make the low speed area and the air flow in the diffuser better. Selecting the length of blade is geometric parameters, changing the diffuser length under the condition of diffuser blade is not distorted. And it will generate the database, then choosing the optimal results in the database as the best result. The table 3 shows that efficiency and pressure ratio under the mass flow of 3.24kg/s.



(a)Before optimization (b)After optimization

Figure 8. Height of 10% blades

In order to compare optimization with others, figure 8 is local vector at the height of 10% blade. From the figure 8, it can be seen that reducing the length of the diffuser blade can make the energy of the air distribution better. In the figure 8(a), the air with high speed and low speed mix together, but the mixture is terrible. In the figure 8(b), the air with low speed along with the suction of the diffuser blade, then it mix with the high speed air. In this case, the internal flow filed is better. If mixture is terrible, it will lead to stall and so on. After optimization, efficiency and pressure ratio is high under the condition of small flow rate. It makes the air interaction better and improves the internal flow field.

5 Conclusions

(1) The present numerical model can correctly simulate operating of the centrifugal compressor under multiple working conditions, and it shows that numerical computation method is reliable.

(2) According to the numerical results of the prototypical model, eddy zone exists between the impeller outlet and diffuser inlet, which makes the efficiency descend quickly and the airflow disorder in the diffuser.

(3) Based on the numerical results of the optimized diffusers, by properly decreasing the diffuser blade number and shorten the length of the blade trailing edge, not only the effect of the eddy zone to the diffuser and impeller can be reduced, but also the flow field of low-velocity zone at the end of the diffuser can be significantly improved, and as a result, the whole level of the parameters such as efficiency and compression ratio can be increased.

Abstract: A total of 29 passenger car side pole impacts were analyzed for this study. Characteristics of passenger car side pole impacts were summarized in depth, including impact velocity, impact angle, impact area, force direction, injuries and deaths, injuries per body region. The passenger injury risk in different impact velocity and angel was analyzed in order to understand the injury mechanism and evaluation index. It hoped to provide reference for the setting of pole side impact standards and C-NCAP.
Keywords: Characteristic; Passenger car side pole impacts; Standards and C-NCAP.

1 Introduction

The severely injured and fatal rate accounted for 25% in vehicle side impact which was the main severely injured and fatal accident type.43%~55% of side accidents were vehicle to vehicle side impacts, and vehicle to pole side impacts accounted for 12%~16%. Side pole impact was a special side impact. Struck time was longer, vehicle body absorbed more energy and injury and death risks of passengers were higher when vehicle impacted with traffic signs pole, tree, bridge pier. Nearly 4800 persons were killed in vehicle side impact in Europe in 2009, of which 1628 persons died in pole side impact, and 3174 deaths in other side impact. The data was (1371, 4872) in America and (204, 1024) in South Korea.

Impact characteristic including impact velocity, impact angle, impact area, force direction, pole diameter, and injury characteristic including injury region, AIS rating were analyzed in-depth in this paper.

2 Statistical Analysis of Side Pole Impacts

7 side pole impacts were taken from the CIDAS database. Each case contained nearly 2000 information items about the human, vehicle, road, and environment. Beginning in July 2011, the CIDAS team surveyed accidents in-depth in Beijing, Changchun, Weihai, Ningbo, Changsha, and Foshan. Other 22 side pole impacts were from crash database of traffic police department.

The injury of which AIS rating was 1 or 2 was defined slight injuries, and the injury of which AIS rating was more than 3 was defined severe injuries.

The calculation formula about fatality rate ($R_{X.fatal}$) of x driving position in passenger car was defined as shown: $R_{X.fatal}= N_{X.Deaths}/(N_{X.Deaths}+ N_{X.Severe\ injuries}+ N_{X.Slight\ injuries}+ N_{X.No\ injured})$

Similarly, the calculation formula about severely injured rate ($R_{X.severely\ injured}$) and slightly injured ($R_{X.sightly\ injured}$) of x driving position in passenger car was defined.

2.1 Impact velocity, angle, pole diameter

29 passenger car side pole impacts were simulated by pc-crash. The average impact velocity and angle were obtained, as shown in figure 1.

Side pole impact velocity was in the range of 40~60km/h, and the average was 54.4km/h. Impact velocity was lower than 39km/h in 50% of slightly injured impacts, and 54km/h in 50% of all injured impacts, and 77km/h in 50% of severely injured impacts, as shown in figure 2. Injury severity increased with impact velocity increased. The average pole diameter was 308mm which could be used in simulation. The average impact angel was 67.6 degrees. There was no correlation found between injury severity and impact angel.

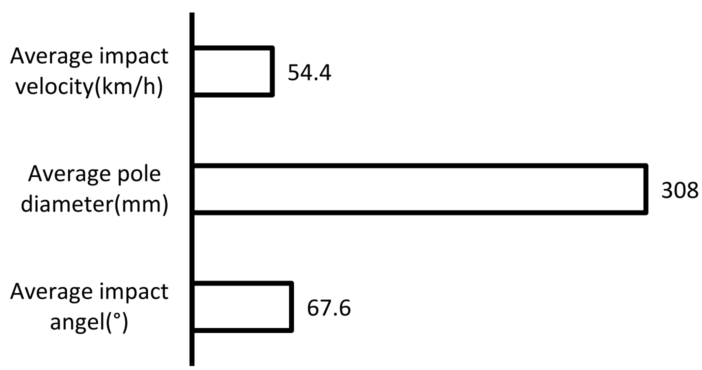

Figure 1. pole side impact parameter

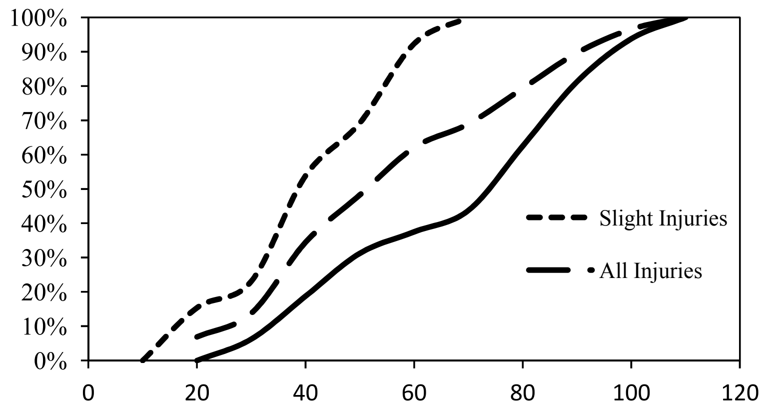

Figure 2. Cumulative impact velocity by injury severity

2.2 Impact area

As shown in figure 3, A was the front area of the car, B was the cab area, C was the area of passenger compartment, D was the rear area of the car. There were 7 impacts in A region, accounted for 24.1% of the total side pole impacts, 17 impacts were in B region accounted for 58.6%, 5 impacts were in C region accounted for 17.3%, none impact was in D region.

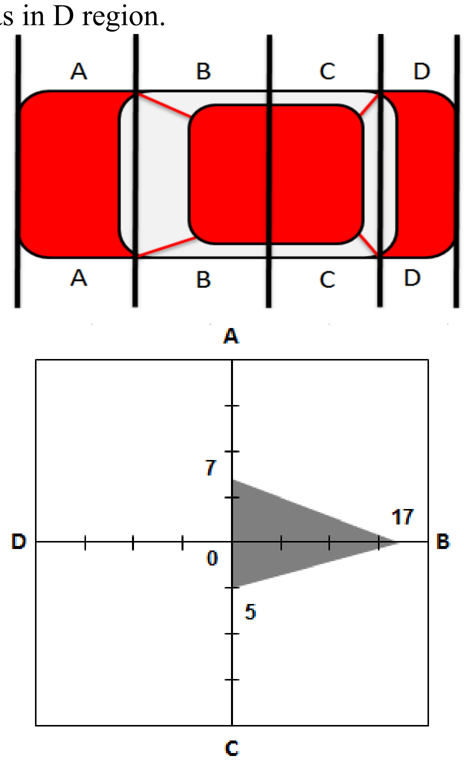

Figure 3. Impact area-Impact number

2.3 Force direction

There were three impact directions named F (forward slope), V (Vertical 90°)

and R (Backward slope) in impact region. 21 impacts on F direction accounted for 72.4% of the total side pole impacts, 8 impacts on V direction accounted for 27.6%, no R direction impact was found, as shown in figure 4.

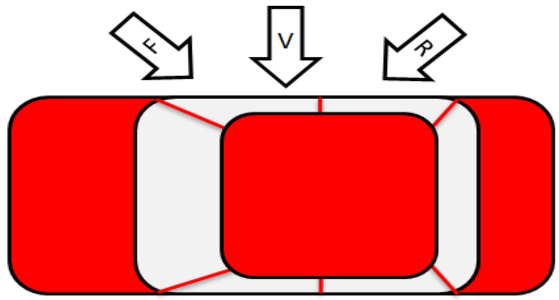

Figure 4. Force direction

Table1 was the force combination of different impact region. The number of impacts and casualties were highest in B-F combination, then A-F, B-V, C-F, A-V, C-V. The slope impact was more common and more serious than vertical 90° impact in real world accidents.

Table 1. Force combination of different region

Combination	A-F	A-V	B-F	B-V	C-F	C-V
Number of Accidents	5	2	12	5	4	1
Slight injuries	2	1	6	1	3	1
Severe injuries	1	0	5	3	1	1
Fatalities	4	2	9	5	2	0

2.4 Injuries and deaths

A total of 29 side pole impacts involved 47 passengers, including 14 slight injuries, 11 severe injuries and 22 fatalities. Side pole impact caused serious passenger casualties, the slightly injured rate was 29.9%, the severely injured rate was 23.4% and the fatality rate was 46.8%, as shown in table 2.

Fatality rate of each position in passenger car was almost same. Driver and back passenger were vulnerable to slight injuries relative to front passenger. 33.3% of front passengers were severely injured, which was higher than driver and back passenger.

Table 2. Injuries and deaths in side pole impacts

	Number of people	Slight injuries	Rate	Severe injuries	Rate	Fatalities	Rate
Driver	29	10	34.5%	6	20.7%	13	44.8%
Front passenger	12	2	16.7%	4	33.3%	6	50.0%
Back passenger	6	2	33.3%	1	16.7%	3	50.0%

2.5 Injuries per body region

In the 29 side pole impacts, the main injured body regions were head and thorax, most of which were severe injuries, accounting for 40.9% and 29.9% respectively. Figure 5 was the injured body region and AIS of people in passenger car side pole impact. Traumatic shock caused by severe traumatic brain injuries and chest collapse in side pole impacts were the main dead reasons according to autopsy reports of 22 deaths.

	Slight Injuries	Severe Injuries
Head	27.5%	40.9%
Face	17.8%	3.9%
Neck	1.6%	2.6%
Thorax	13.9%	29.9%
Upper Extremities	13.6%	6.5%
Spine	2.7%	3.9%
Abdomen	5.8%	2.6%
Pelvis	1.6%	6.5%
Lower Extremities	10.1%	1.3%
Others	5.4%	1.9%

Figure 5. Slight/severe Injuries per body region

3 Summary

The following conclusion can be summarized from this paper:

(1) Side pole impacts were relatively rare accidents compared to other impacts types. But the importance of side pole impacts increased by focusing on severely injuries.

(2) Injury severity increased with impact velocity increased. There was no correlation found between injury severity and impact angel.

(3) The slope impact was more common and serious than vertical 90° impact in real accidents.

(4) Front passengers were vulnerable to slight injuries relative to drivers and back passengers in side pole impacts.

(5) The main severely injured body regions were head and thorax in side pole impacts.

Fault Diagnosis of the Rectifying Circuit of Electric Locomotives

Jiafeng Sun and Yi Guo

College of Traffic and Transportation Engineering, Dalian Jiaotong University, Dalian 116028, China. E-mail: dl_sjf@sina.com

Abstract: The paper conducts the fault diagnosis of three section unequal semi controlled bridge rectifying circuit of electric locomotive in the context of MATLAB/Simulink and suggests the fault analysis method based on the BP Neural Network. Based on the BP Neural Network, it produces failure data by simulation analysis, extracts the character of the faults and constructs the samples of the faults after the normalization processing. This paper also creates network to analyze and recognize the character of the faults and verifies the reliability and practicability of this method by simulation results.
Keywords: Electric locomotives; Three sections of the Bridge Rectifier circuit; Fault diagnosis; BP neural network.

1 Introduction

In order to reduce the harmonic interference, reactive power and increase the power factor of phase-controlled electric locomotives, the main circuits of DC-drive locomotives usually adopt the multi-stage bridge sequence control circuit. Using the fault diagnosis technology is of practical significance and important economic value to the fault exclusion when the faults happen to the power devices in the circuit. This paper using the neural network theory to make fault diagnosis on phased three section of unequal electric locomotive rectifier circuit (Xu, G. C., 2011).

2 The analysis for three section of unequal semi controlled bridge rectifier circuit

The figure of rectifier circuit of ss8-type, ss9-type electric locomotive is shown in Figure 1. During the running of locomotive, the three sections of the bridge sequence control complete the variable voltage speed control to the locomotives (Zheng, L.Q., 2006). There are many kinds of faults among the operation fault of rectifier circuit and this paper only aims at the diagnosis of fault state when the short circuit, open circuit of thyristors and diodes happen. When the half-controlled bridge RM3 working, the open faults of thyristor or diode are divided into 4 categories. When the half-controlled bridge RM3 and the half-controlled bridge RM1 working simultaneously, the open faults of thyristor or diode are divided into 8 categories. When the half-controlled bridge RM1~3 working simultaneously, the open faults of thyristor or diode are divided into 4 categories. The open faults of a thyristor or diode can be divided into 22 categories for the rectifier circuit and the faults are encoded in Table 1 as is shown.

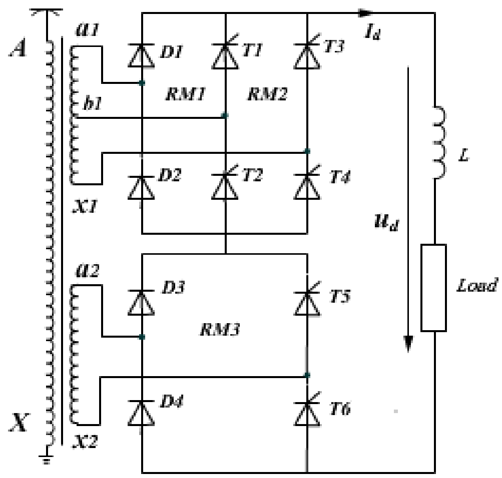

Figure 1. Three stage of unequal semi controlled bridge rectifier circuit

Table 1. Fault type codes

working bridge	fault location	sort	code	working bridge	fault location	sort	code
RM3	D3	①	0010001	RM1 RM2 RM3	D1	①	0110001

	…	…	…		…	…	…
	T5	⑦	0100111		T5	⑨	0111001
	T6	⑧	0101000		T6	⑩	0111010

3 Circuit Simulation

According to the circuit schematic diagram for the three section of unequal semi controlled bridge, it creates a simulation model in the environment of Simulink, as is shown in Figure2. 25KV50HZ single-phase AC power for electricity, single-phase multi-winding saturated transformer is elected as traction transformer.Two trigger signals generated by setting the three-phase bridge trigger can satisfy the demands of trigger and phase-shifted control for single-phase half-controlled bridge. This model adopts RL inductive load to simulate DC motor and smoothing reactor. By measuring the voltage module and oscilloscope display voltage waveform (Sun, Z.R., 2004).

In the simulation process, the phase shifting sequence control to three section bridge is completed by regulating the given control angle of triggers Pulse1~3. Some typical types of output waveforms of fault voltage are shown in Figure 3.

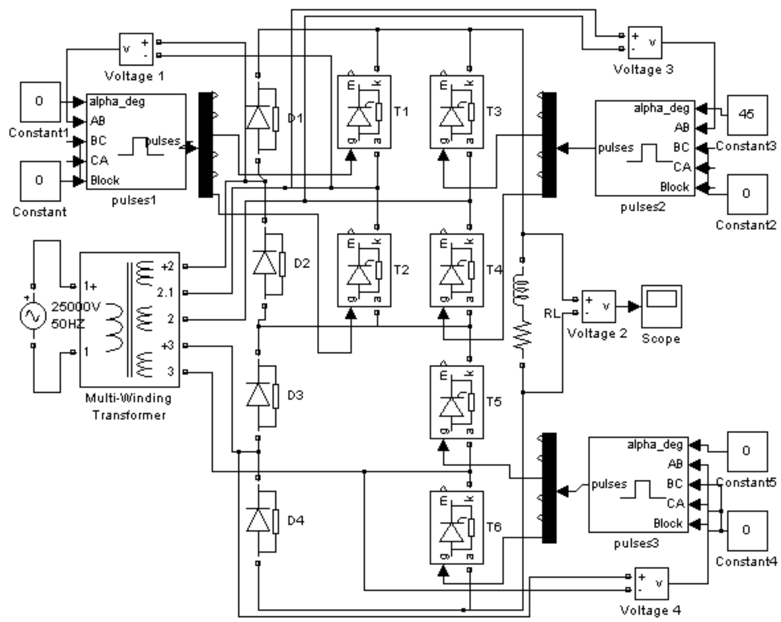

Figure 2. Rectifier circuit simulation model

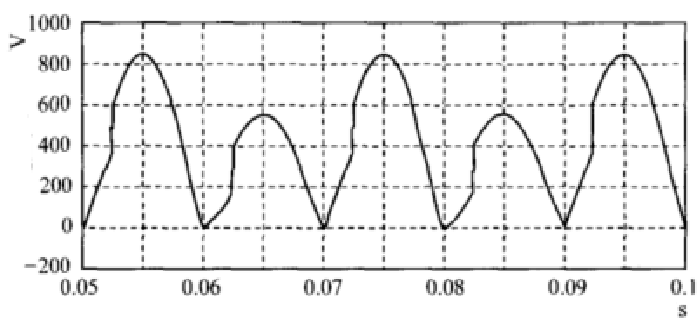

Figure 3. Output voltage of T5 fault when third district trigger angle 45 °

4 Fault analysis based on the neural network

The neural network for fault diagnosis is a kind of multilayer feedforward network (BP Neural Network) trained by back propagation algorithm and its guiding ideology is the correction for network weights and thresholds to make the error function decline in the negative gradient direction and stop the training when the error achieve the desired accuracy. The derivation is detailed in related literatures, not repeat (Gao, J., 2003). And its topology is shown in Figure 4. Input: X1,X2⋯Xn; Output: Y1,Y2,…Yn; the number of hidden nodes: m; W^2_{kj} denotes the correlation between output layer neurons k and hidden layer j; W^1_{ji} denotes the correlation between hidden layer neurons j and input layer neurons i.

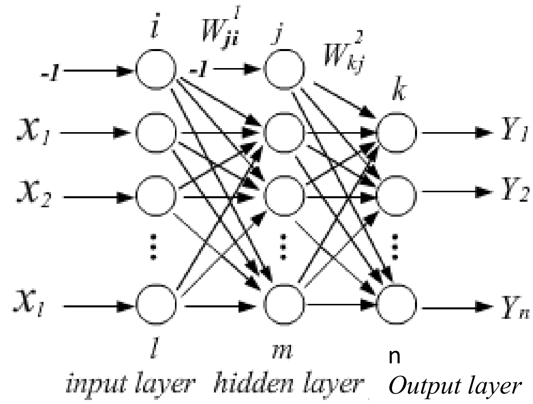

Figure 4. Typical single hidden layer BP algorithm topology

(1) Data preparation

This test simulates the faults of all kinds in the regulating process of three section bridge according with circuit model. It conducts equal interval sampling of output voltage for every faults and obtains the input data of samples. Here, we collect 50 data points per period and scan interval is 0.4ms. And then, it normalizes these data by normalization processing (in the range of[-1,1]) to obtain the input sample of diagnosis system as characteristic quantity to construct the corresponding eigenvectors to correspond the 22 open fault in the circuit. Some samples are shown in Table 2 and these contents conduct as an artificial neural network input sample X[50,22].

Table 2. Training samples

Sample	Fault1	Fault2	Fault3	…	Fault22
X1	0.0296	0.9963	-0.9012	…	-0.8657
X2	0.2671	0.3627	-0.4621	…	-0.7412
X3	0.4766	0.2157	-0.2145	…	-0.2586
…	…	…	…	…	…
X50	-0.9578	-0.1725	0.9635	…	0.4523

(2) Network design

The system adopts 50 input nodes, 15 nodes of hidden layer, 7 output nodes, and uses MATLAB to generate neural networks: net=newff(minmax(X), [15 7], ｛'logsig' ,'logsig'｝, 'trainlm'). It uses the samples in the Table 2 to train the network. So, correspond network parameters are:

net.trainParam.mc=0.85;

net.trainParam.epochs=25000;

net.trainParam.show=2500;
net.trainParam.goal=0.0001;
net.trainParam.lr=0.2.

The output samples of network are taken from the codes of every corresponding faults T[7,22]. The specific eigenvalue are the codes in the Table 1. The neural networks are trained after initialization and its matlab realization is [net.tr]=train(net,X,T). Error analysis for networks are shown in Figure 5.

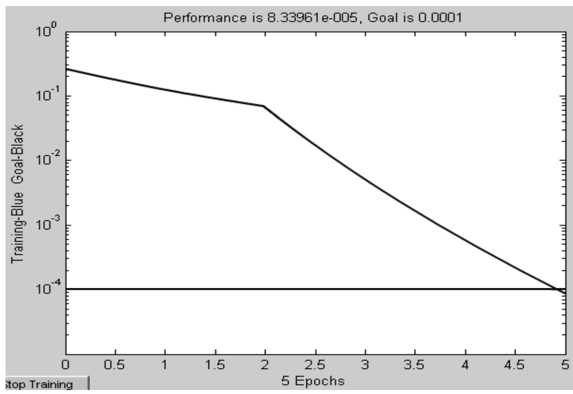

Figure 5. Error curve of training results

(3) Experimental verification

To test reliability and practicability of the program, we conduct an experimental research on three section semi controlled bridge. Break the thyristor T5 of semi controlled bridge RM3, set RM3 firing angle 45° during the third regulator, take 50 sampling points of output fault voltage wave and conduct normalization processing, as is shown in Table 3. Put the data into the trained neural networks: the input fault samples are wrong [50,1], the diagnostic program correspond to the fault samples are result= sim(net, wrong). After the diagnosis, the result data is shown in Table 4. Under the 0.85 threshold condition, we can get the ninth fault of the third regulator district, i.e., the Open circuit result of thyristor T5.

Table 3. Input faults mode

Input nodes	1	2	3	…	49	50
data	0.1766	0.2855	0.3816	…	-0.1850	-0.0986

Table 4. Neural network output nodes

output nodes	1	2	3	4	5	6	7
Point values	0.0180	0.9241	0.8692	0.9104	0.0251	0.0053	0.9173

5 Conclusions

This paper introduces the fault diagnosis of three section bridge rectifying circuit of electric locomotive and create simulation models of rectifying circuit. It analyses the possible failure mode of the switching devices during the regulating process of sequence control for three section bridge and diagnoses the open circuit fault of the devices in the circuit by BP Neural Network. The results show that neural network fault detection can build mappings between the fault voltage and fault type and diagnose the faults accurately. All of these are of great practical significance and certain application potential to the fault diagnosis of AC drive electric locomotive and the main circuit of CHR.

Abstract: With the terrain restrictions, there are quantities of bridge-tunnel connecting sections on mountainous highways, and the traffic accident rate of the bridge-tunnel connecting sections in mountainous highways have always been very high in China. Therefore, the study about safety evaluation of the bridge-tunnel connecting sections of mountainous highways has an important significance for reducing the highway traffic accident rate. Firstly, this study propose a definition about bridge-tunnel connecting sections in mountainous highways. From the aspect of integrated system of bridges and tunnels, this study analyzed the traffic accident characteristics and influencing factors of the bridge-tunnel connecting sections. Based on engineering design data of a typical bridge-tunnel connecting section, a driving simulation test with a model of bridge-tunnel connecting section ("tunnel-bridge-tunnel" type) and simulated foggy weather was carried out using UC-win/Road software. Through the design of appreciate simulation scene and driving simulation experiment, we obtained the drivers' driving speed and heart rate value under the specific connection bridge-tunnel scene. Then the relationship between the driving speed, foggy weather and the driver's heart rate variability is found. Finally, a safety evaluation index of the bridge-tunnel connecting section design on mountains highway is proposed, which is based on characteristics of drivers' heart rate.
Keywords: Bridge-tunnel connecting section; Driving simulation; Safety evaluation; Heart rate; UC-win/Road.

1 Introduction

With the implement of China western development strategy and the rapid growth of economy in the western region of China, the construction of mountainous highways in the western region also is in the period of large-scale expansion. In the design of mountainous highways, it is unavoidable to adopt the form of bridge-tunnel connecting sections which is the chief measure to optimize the road alignment and avoid geological disasters. In recent years, the number and length of bridge and tunnel sections increases continuously and the proportion of bridges and tunnels becomes larger in the mountainous highways in China. Meanwhile, some new problems arise about the traffic safety of the bridge-tunnel connecting section in the mountainous highways. In order to reduce the death rate and the loss of traffic accident, it is very necessary to analyze the driving safety of the bridge-tunnel connecting section of mountainous highways. This article established a driving simulating experiment platform of the bridge-tunnel connecting section by UC-win/road. Then, through the driving simulation experiments, the driver's heart rate index is used for the safety evaluation of the bridge-tunnel connecting section.

2 Literature Review

Until now, expect some studies of driving safety focus on road-bridge and road-tunnel transition sections in common highway, there is few researches about bridge-tunnel connecting section in mountainous highway.

Du et al. (2006) and Lou et al. (2006) established the comprehensive evaluation index system of the tunnel traffic safety evaluation considering the “human, vehicle, road, environment, traffic characteristics”, and used this model to evaluate an operation tunnel in highway through the fuzzy mathematic theory. Xu et al. (2006) studied traffic safety evaluation of mountainous highway using set-valued statistics method of the fuzzy statistical, in order to overcome the problem that it is not accurate to use the grade proportion method and expert score method to evaluate fuzzy and non-quantitative index.

Liu (2009) and Xue (2010) studied the characteristic, safety evaluation and safety improvement measures of the bridge-tunnel connecting section in mountainous highway. Wang and Jia (2006) and Koh et al. (2014) suggested that the main factors affect the safety of mountainous highway are the geometric linear transition, the road surface characteristics transition, luminance transition and the traffic safety facilities. Pan et al. (2012) evaluated the safety driving in the bridge-tunnel connecting section using multiple levels and multiple factors analysis method.

Johansson (1970) and Amundsen and Ranes (2000) studied the visibility of traffic signs under different driving speed according to driver's cognitive ability. Fleyeh (2006) studied the influence of the colors and brightness of traffic signs to the driver reaction time and proposed suggestions about the design and location of traffic signs. Scott-Parker et al. (2015) and Blaszczyk et al. (2014) analyzed the influence factors of the traffic safety of tunnel entrance based on the system of "human, vehicle, road and surrounding environment".

Based on the previous study, road alignment, driving speed, driver's mental and physiological changes, adverse weather influence the occurring of accidents on bridge-tunnel connecting section. And this paper explored the modeling and the driving simulation experiments of bridge-tunnel connecting section.

3 Safety Evaluation of the Bridge-Tunnel Connecting Section of the Mountainous Highway Based on Drivers' Heart Rate

3.1 Mountainous area highway tunnels connecting section definition and classification

Xue (2010) defined the bridge-tunnel connecting section from the construction of bridge-tunnel engineering, however traffic safety of bridge-tunnel connecting section was not considered sufficiently. Zeng (2013) divided bridge-tunnel connecting section in mountainous highway into adjacent interchange connection, the connection between interchange and tunnel, and the connection between tunnel and tunnel. The above point that prescribes the bridge and tunnel is not in complete accord with the fact. So the exact definition of the bridge-tunnel connecting section can be proposed based on the definition of the connecting section in mountainous highway.

From the integrity of traffic system, the bridge-tunnel connecting section in mountainous highway can be classified three classes.

The first form is only connected a bridge and a tunnel directly, which is shown in Figure 1.

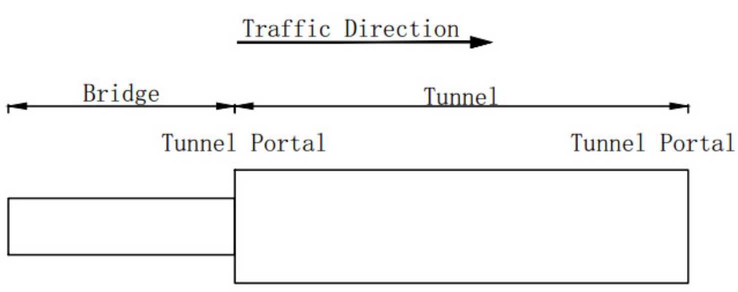

Figure 1 Bridge-tunnel connecting section

The second is the tunnel-bridge-tunnel form and which is shown in Figure 2.

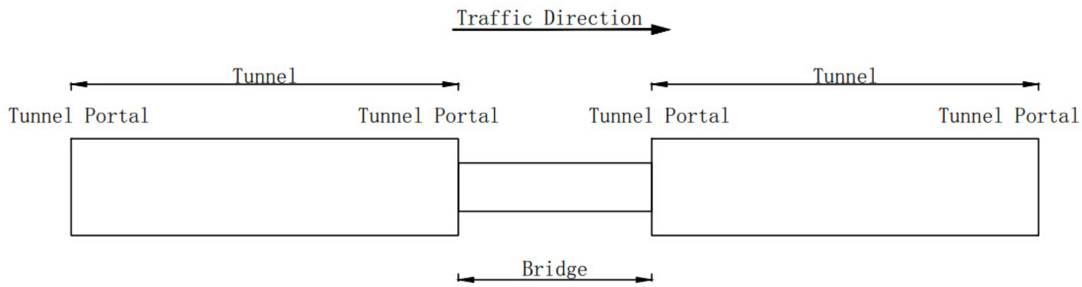

Figure 2 Tunnel-bridge-tunnel connecting section

The last one is the bridge-tunnel-bridge form which is shown in Figure3.

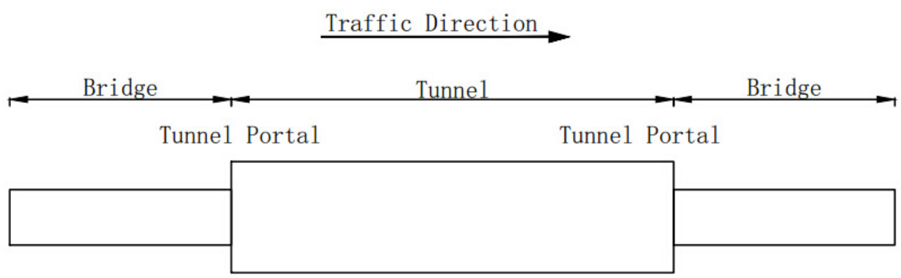

Figure 3 Bridge-tunnel-bridge connecting section

3.2 Driving simulation experiment design and experiment data analyze

Driving simulation is to make the drivers can be in a virtual environment where you can feel the driving experience close to the real effect of visual, auditory and somatosensory. This paper design the scene of Bridge-Tunnel connecting section of mountainous Highways by UC-win/Road.

3.3 Experiment aim and procedures

This experiment simulated single car driving in the bridge-tunnel connecting section of mountainous highway though the UC-win/Road software. The driving speed and heart rate of the drivers were measured during driving in the bridge-tunnel connecting section, then the data was analyzed using the method of statistical analysis.

Experiment procedures

First, UC-win/Road model were debugged, then test personnel got familiar with the driving simulation. Second, test personnel wore heart rate meter, sitting before a driving simulation screen and waiting for the start of the driving simulation test. Third, the test began: the driver simulated driving in the left and right line of bridge-tunnel connecting section respectively by 60 km/h and 80 km/h, and driving speed remains constant as far as possible. Heart rate meter automatically recorded the drivers' heart rate value and video recorder filmed simultaneously. Final, fog scene was added into the driving simulation, then above three steps were repeated.

3.3.1 Driving speed effect on the heart rate changes

In simulated driving tests, in order to determine the influence of the driving speed on drivers' heart rate change, the two groups controlled trials were implemented. Test speed was controlled in 60 km/h and 80 km/h respectively, and the heart rate per second in the process of drivers' driving is recorded. Though everyone has different driving habits and heart rate reference value, the change of heart rate can reflect the psychology when the driver was disturbed by external stimuli. Therefore the index of heart rate variability was used to analyze.

Heart rate variability means the ratio of the driver' heart rate in the process of driving at a time to the driver's average heart rate value stationary state. The following is the calculation equation of the heart rate variability.

$$N_i = \frac{n_i - \bar{n}}{\bar{n}} \times 100\%$$

N_i –*Heart rate* variability *of driver at a time in the process of driving , %*

n_i –*Heart rate value of driver at a time in the process of driving, bpm*

$\bar{n}$ –*The driver's average heart rate value stationary state, bpm*

When ten testers drove the car in the left of the tunnel-bridge-tunnel section and the speed was controlled 60km/h, the heart rate variability is shown in Figure 4.

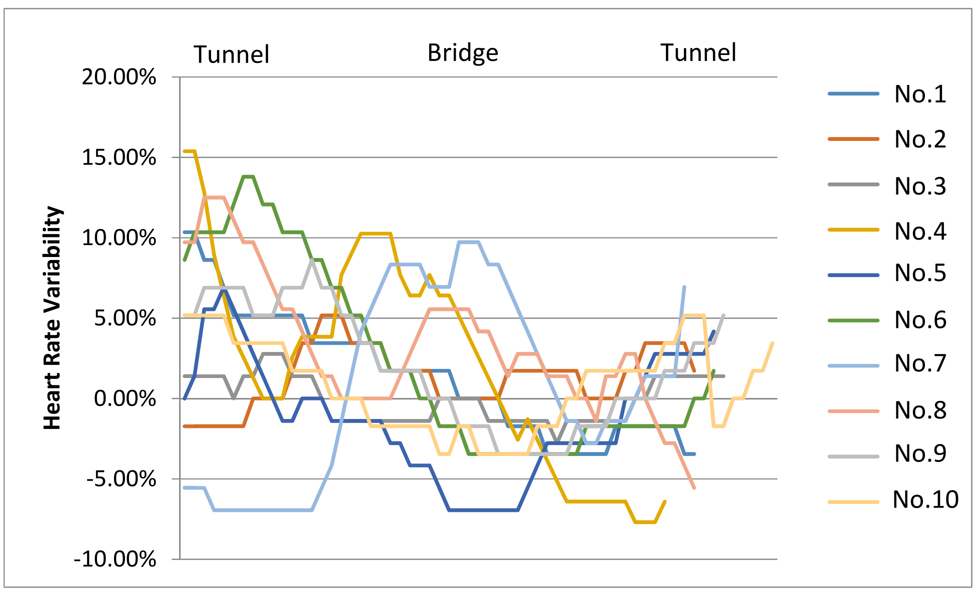

Figure 4 Drivers' heart rate variability (left line of bridge-tunnel connecting section, driving speed 60km/h)

The drivers' heart rate variability for all drivers was averaged and an obvious change trend appeared, which is shown in Figure 5.

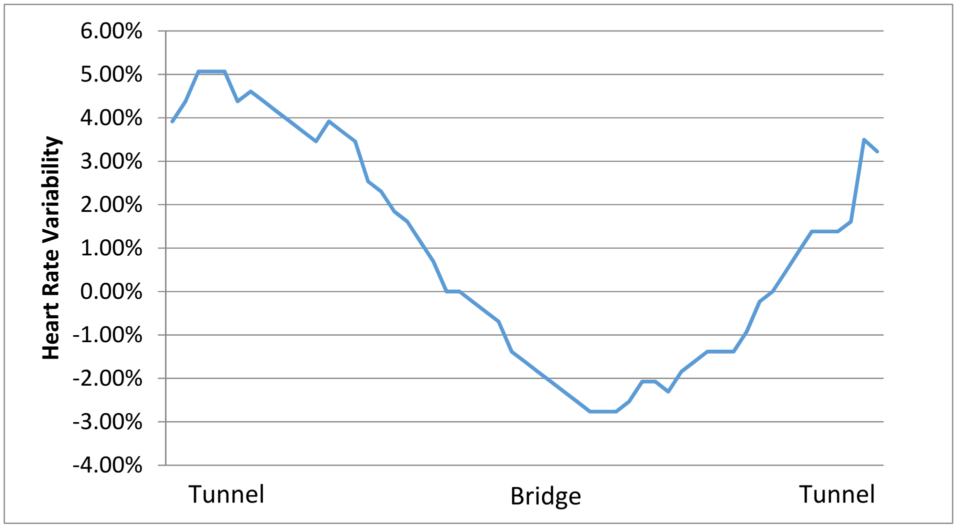

Figure 5 Drivers' average heart rate variability (left line of bridge-tunnel connecting section, the speed 60km/h)

According to Figure 4 and Figure 5, it indicated that the driver was unconformable and nervous, when the car began to drive into the mountainous tunnel, as a result of changing from normal sections into closed environment of tunnel. Then, after the driver adapt to the tunnel environment gradually, the change of heart rate tended to calm slowly. Driving in the bridge section, due to well road conditions and open driving vision the heart rate variability would stay in the range of -3% ~ 3%. When the driver drove into the tunnel second time, the heart rate variability was lesser than that of the first one due to the driver had got a certain tunnel driving experience.

When the driving speed was controlled 80km/h, the averaged heart rate variability for all drivers is shown in Figure 6.

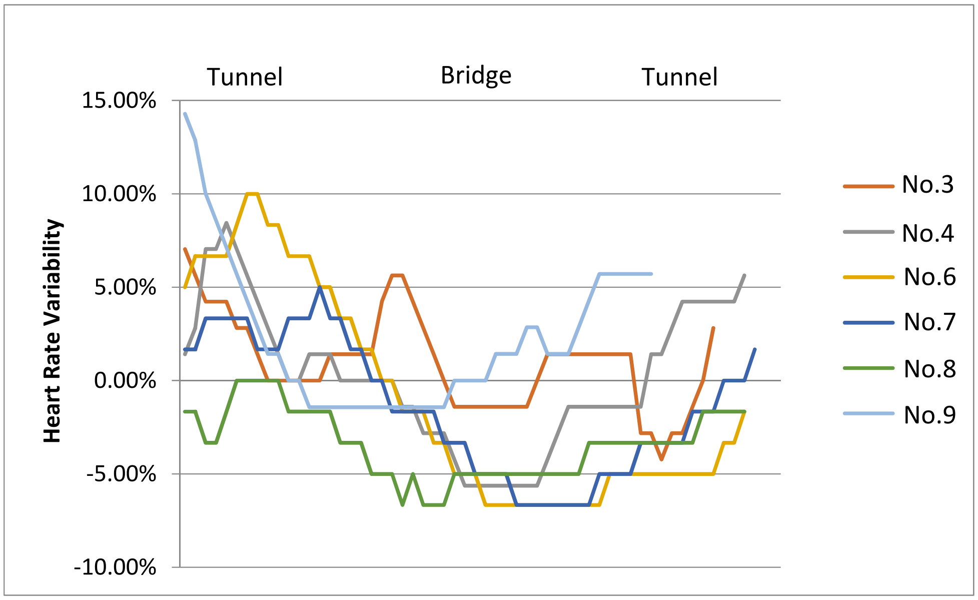

Figure 6 Drivers' heart rate variability (left line of bridge-tunnel connecting section, driving speed 80km/h)

And the driving speed was controlled 80km/h, the average heart rate variability is shown in Figure 7.

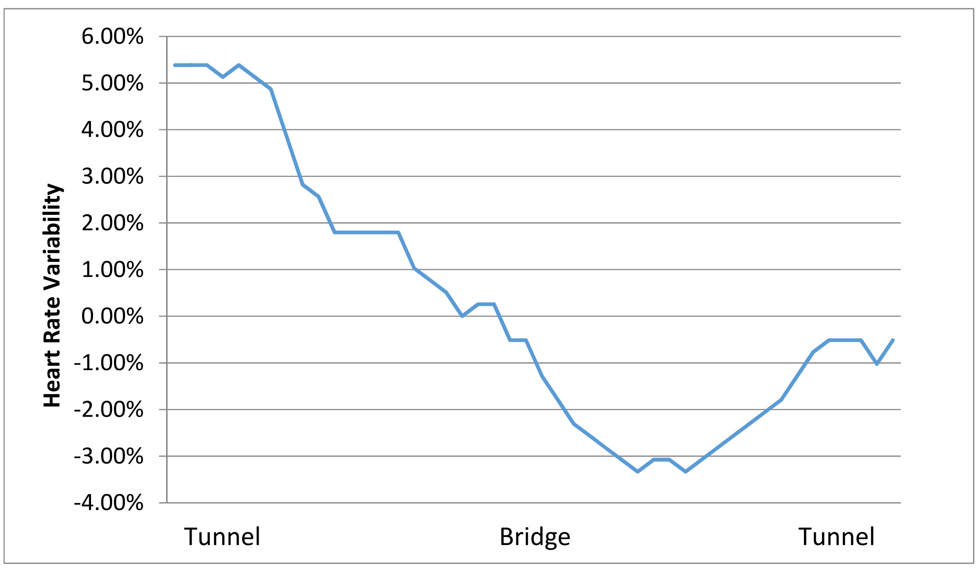

Figure 7 Drivers' average heart rate variability (left line of bridge-tunnel connecting section, driving speed 80km/h)

Compared between Figure 5 and Figure 7, it can be found that the higher the driving speed is, the larger the heart rate variability range driving in the bridge-tunnel connecting section.

3.3.2 The fog effect on the heart rate variability

Adverse weather, such as rainstorm and fog, which often appear in the mountainous area highway, has a serious impact for driving safety. In order to explore the fog impact for safe driving on bridge and tunnel connecting section, scene of bridge section affected by heavy fog was added into the driving simulation experiments, and the influence of the weather for the driving safety can be obtained through comparing to the driver's heart rate variability of the normal weather and that of the fog.

The change curve of heart rate driving in the left line at 60km/h in the fog was shown in Figure 8.

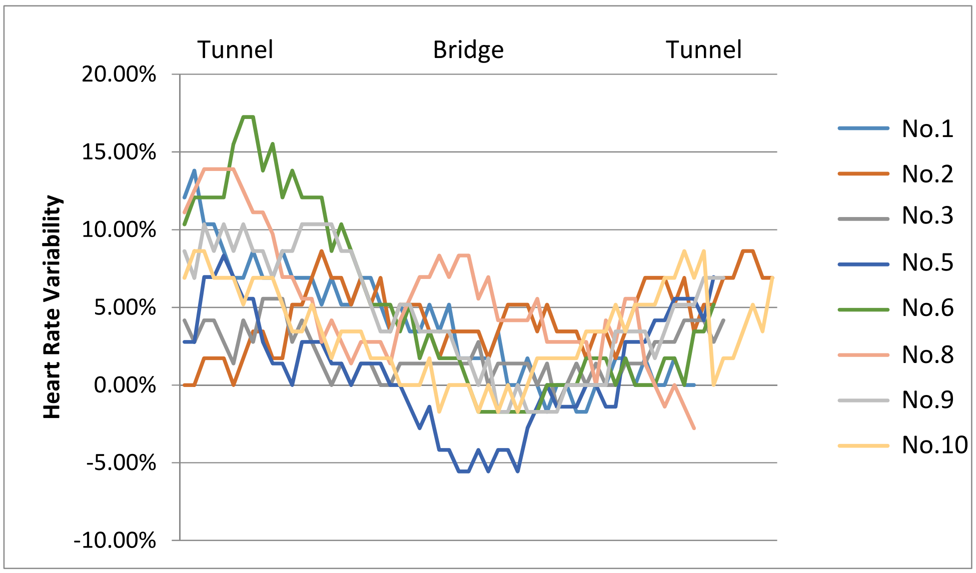

Figure 8 Drivers' heart rate variability under foggy weather conditions (left line of bridge-tunnel connecting section, the speed 60km/h)

Figure 9 is a control group data in normal weather.

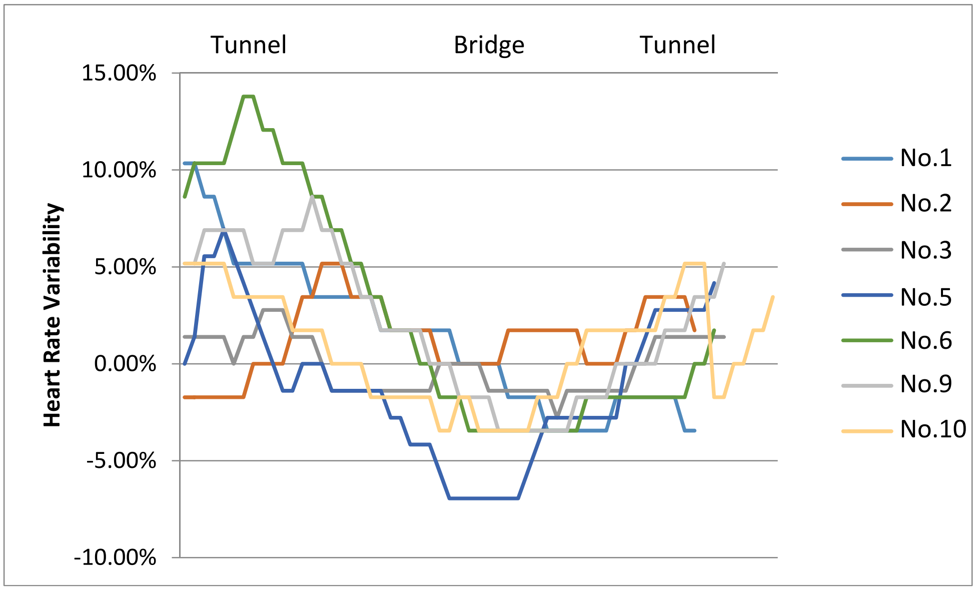

Figure 9 Drivers' heart rate variability under normal weather conditions (left line of bridge-tunnel connecting section, the speed 60km/h)

Compared Figure 8 with Figure 9, it is obvious that heavy fog weather brought great influence on driving in the bridge section and driver's heart rate variability increased significantly. During driving in the tunnel the driver wanted to drive out and expected the highway condition to improve out of the tunnel, while the fog weather made the visibility low and gave the driver with a high psychology dropout. Therefore the change of the heart rate variability is more significant than normal weather.

Thus, through the driving simulation, the relationship between the driving speed and the drivers' heart rate variability of the connection in the tunnels was analyzed.

3.4 Research of evaluation index of the bridge-tunnel connecting section based on drivers' heart rate

Safety evaluation methods can be roughly divided into two categories: firstly, direct evaluation method based on accident data; secondly, indirect evaluation method that is through the relationship establishment among road conditions, driving speed, drivers' psychological and physiological indexes, Building the relationship between intermediate targets and the traffic safety, we indirectly get the relation between road condition and traffic safety. This paper uses the heart rate variability as the connection section of the safety of mountain area highway tunnels intermediate targets, the connection section of the safety evaluation of tunnels.

Zhao (2012) established the relationship of heart rate and curve segment lateral force coefficient and proposed comfortable threshold of driver's heart rate variability driving on the curves with radius 100m-400m. The analysis of driver's comfortable threshold is showed in Table 1.

Table 1 Comfortable threshold of heart rate variability

Grow rate of heart rate	Driving condition on the curve segment
＜4.5	Driver feel no curve, and no any tension
6.5	Driver feel along the curve, slightly and smooth, but feel no any uncomfortable
8.5	Drivers obviously feel drive along the curve and a little unstable
10.5	40% of drivers feel uncomfortable driving on the curve
12.5	All drivers through the curve feel uncomfortable
14.5	Driver feels curve existent and unstable, tension is increased
＞16.5	Driver felt very unstable, and the risk of rollovers exists

Based on the above research result and the conclusion, the index of bridge-tunnel connecting section evaluation were presented in the Table 2.

Table 2 Evaluation index based on heart rate variability

Safety level	Mutation rate of heart rate n/%	Evaluation standard description
Excellent	$\vert n\vert<4.5$	High security level of bridge-tunnel and the length of the structures and plane geometry alignment combination is well.
Good	$4.5\ll\vert n\vert<8.5$	Security level of bridge-tunnel is acceptable and the length of the structures and plane geometry alignment combination is general.
Fair	$8.5\ll\vert n\vert<12.5$	Security level of bridge-tunnel are poor and the length of the structures and flat vertical linear combination should be modified.
Poor	$12.5\ll\vert n\vert<16.5$	Security level of bridge-tunnel are very poor and the length of the structures and flat vertical linear combination should be improved.
Danger	$\vert n\vert\gg16.5$	Driving in bridge-tunnel is dangerous and may lead to accident.

Thus, the safety evaluation process of bridge-tunnel connecting section can be presented as follow:

(1) Based on the modeling of bridge-tunnel connecting section, the simulation drive test was organized (the driving speed was controlled in design driving speed) and the driver’s heart rate was recorded in the driving process.

(2) The mean of the driver's heart rate at the bridge-tunnel connecting section can be calculated using mathematical methods. Then, the curve of heart rate variability is depicted.

(3) According to the evaluation criteria in Table 2, the safety level of the bridge-tunnel connecting section is evaluated.

(4) According to the evaluation results the corresponding safety advice is put forward.

3.5 Suggestion of the safeguard measures about the bridge-tunnel connecting section

Mountainous area highway transportation system which is composed of the people, vehicles, road and surrounding environment is a complex system. Below, from people, vehicles, road and surrounding environment aspects, the proposal to protect the safe operation of the bridge and tunnel connecting segment can be explained as following.

(1) Setup of the guided guardrail

The bridge cross-section is composed of driveway, passing lane and emergency stop road, and the tunnel cross-section is only composed of driveway and passing lane because of limited investment cost. So the cross-section wide of tunnel is narrower than that of bridge, and the traffic accident will perhaps occur in transition section of bridge and tunnel cross-section. Therefore, in order to guide the driver’s sight and make the bridge and tunnel section naturally connected, adding the guided guardrail within a certain distance in front of the tunnel entrance can be considered (Figure 10 and Figure 11).

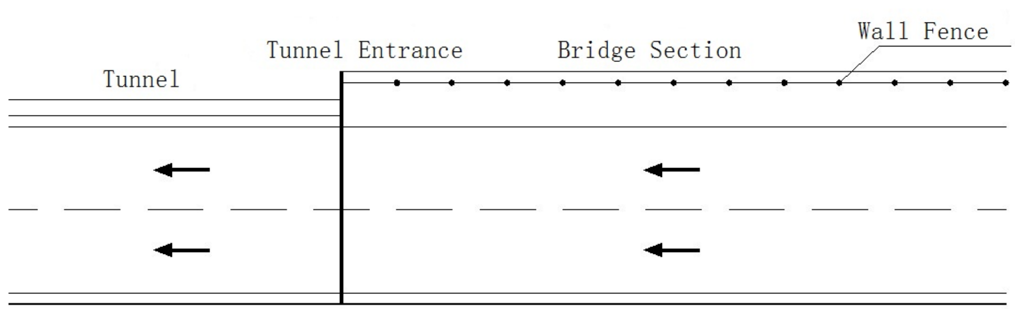

Figure 10 The guardrail position at tunnel entrance before improvement

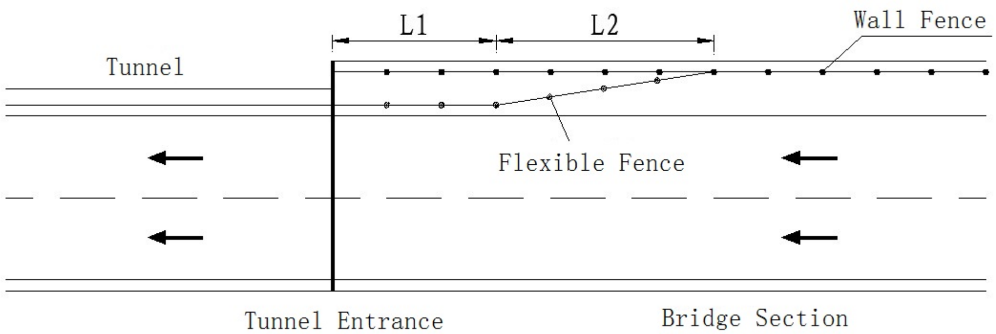

Figure 11 The guardrail position at tunnel entrance after improvement

(2) Setup of tunnel inducing facilities and variable information board

In order to avoid the vehicle crashing into the road shoulder of tunnel, inducing facilities within the tunnel should be setup (LED induction lamp, etc., as shown in Figure 12), and hanging variable information board (as shown in Figure 13) should be setup in a certain distance from the tunnel exit, warming the driver the weather conditions outside the bridge road and tunnel.

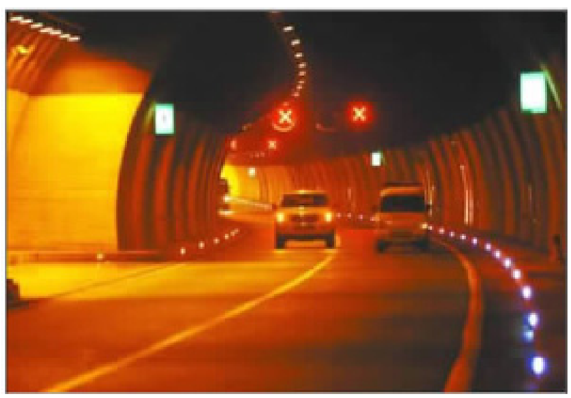

Figure 12 Effective vision inducing facilities in tunnel

Figure 13 The variable information board in tunnel

(3) Setup of lighting processing and deceleration zone in entrance and exit of tunnel

In order to avoid drivers' vision black hole phenomenon when entering the tunnel in daytime, the tunnel lighting should be fully guaranteed during the day and a sign at the entrance of tunnel should be setup to remind the driver to open the headlights in tunnel. Meanwhile, to reduce the drivers' uncomfortable when driving out of tunnel in dark night, tunnel lighting intensity should be weakened.

From the engineering angle, deceleration shock marking should be setup in the tunnel entrance to reduce the driving speed. The setting programs are showed in Figure 14-17.

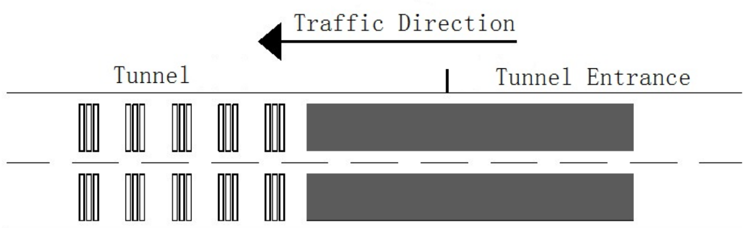

Figure 14 Uphill road of tunnel entrance vibration and deceleration marking settings

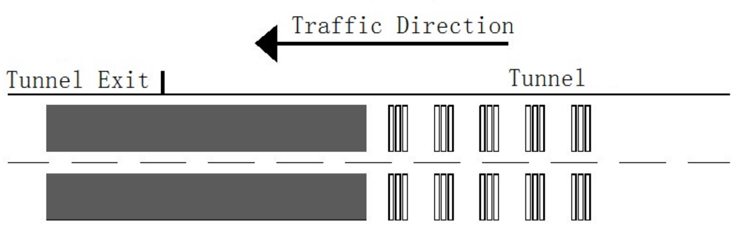

Figure 15 Uphill road of tunnel exit vibration and deceleration marking settings

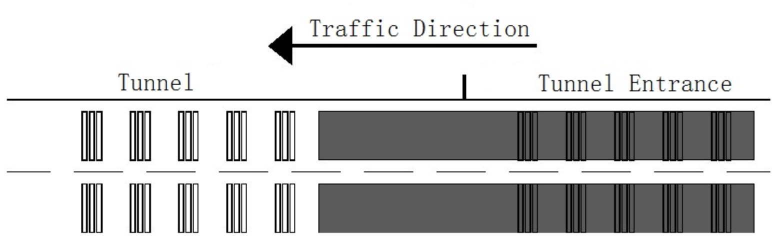

Figure 16 Downhill road of tunnel entrance vibration and deceleration marking settings

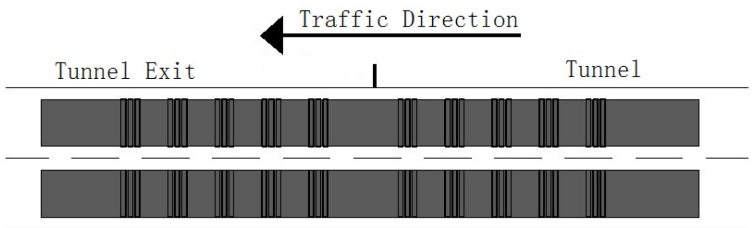

Figure 17 Downhill road of tunnel exit vibration and deceleration marking settings

Conclusions

Based on the mountainous area highway as the research object, a virtual modeling driving simulation is realized.

(1) A clear definition of the connection section of mountainous highway tunnels was put forward, and the bridge-tunnel connecting sections were classified based on the integrity of the bridge and tunnel system.

(2) Based on engineering design data of a typical bridge-tunnel connecting section, a driving simulation test with a model of bridge-tunnel connecting section ("tunnel-bridge-tunnel" type) and simulated foggy weather was carried out using UC-win/Road software.

(3) Based on the model of bridge-tunnel connecting section, the driving simulation was realized. Through analyzing the data of drivers' heart rate measured in experiment, the relationship between the drivers' heart rate variability and driving speed and the fog weather can be put forward. And the safety evaluation criteria based on the drivers' heart rate variability in the bridge-tunnel connecting section were set up.

Abstract: The existing research of the electric power steering (EPS) system less focuses on the safe and reliable operation. Especially the application of fault-tolerant theory to EPS of electric vehicles (EV) actually. In this paper, EPS is built based on sensor fault-tolerant control for EV. Then, the riccati equation is introduced constantly correcting weight matrix Q and R. Finally, a co-simulation analysis is conducted in MATLAB to evaluate the proposed fault-tolerant controller. It is shown that the design had a positive effect in that it could effectively improve performance due to sensor failure. And, a rapid control prototype is built based on dSPACE, a hardware-in-the-loop simulation platform, in order to conduct a real EV test. The results of test are consistent to the simulation and verified the correctness of simulation. The proposed research ensures the steering safety, enhances the EPS stability, and improves the driving comfort.
Keywords: Electric power steering; Fault-tolerant control; Electric vehicles; Sensor failure.

1 Introduction

Electrified vehicles, including electric vehicles (EV) and hybrid electric vehicles (HEV), powered by batteries can achieve quieter and pollution-free operation, which has offered a solution to next generation vehicles. Unlike internal combustion engine vehicles, EV is zero emission but needed to improve the safety and save the fuel consumption (S. W. Yoon, M. D. Glover, K. Shiozaki, 2013).

For advanced vehicles today, many technologies embedded in the micro-controller unit (MCU) enhance the vehicle stability and handling performance in critically dynamic situations. For example, the antilock braking system (ABS) (C. B. Patil, R. G. Longoria, J. Limroth, 2003), electronic differential

(ED) (M. C. Tsai, J. S. Hu, 2007, 2008), and so on, are all solutions implemented to improve both safety and handling. As a necessary part of EV, EPS system has been developing rapidly and becomes one of the safe-critical systems. To compare with the hybrid-power assisted steering system, EPS system promises weight reduction, fuel savings and package flexibility, at no cost penalty(W.Zhao, G.Shi, Y.Lin, etc, 2011).

Although there are many benefits for the EPS car, the research considering practice for safe and reliable operation is still less and there is no more retrievable information at present, so it is urgent to develop the EPS system with steering performance and achieving safe handing(C.Tian, C.Zong, X.Wang, etc, 2009).

The sensor failures such as deadlocking, gain change and so on, might result in severely consequences.So, it is significant value for high reliability design of EPS that the fault-tolerant control is introduced.(G.Xie, D.Tian, G.Yin, 2006) When one or more than one component of system fails, the system does not need to be reconstructed with fault-tolerant control. It makes full use of the remained parts to keep the system stable operation and the prescriptive performance or performance index decreasing slightly (but it is acceptable) to fulfill the tasks safely.

Vehicle reliability and a"limp home" functionality are important considerations for the automotive industry, within the electrified vehicles field this topic is covered in the fault tolerance strategies. A fault-tolerant operation method for a dynamic electric vehicle propulsion system using variable torque versus speed characteristics is also presented. The electrically powered vehicle can continue driving with a minimum performance reduction, and without the need for redundant systems on machine or electronics level.(T.Gerrits, C.G.E.Wijnands, J.J.H.Paulides, etc, 2012).

In this study, EPS is built based on sensor fault-tolerant control for EV. Then, the matrix of the vehicle steering dynamics is introduced. Finally, a co-simulation analysis is conducted in MATLAB to evaluate the proposed fault-tolerant controller. It is shown that the design had a positive effect in that it could effectively improve performance due to sensor failure. And, a rapid control prototype was built based on dSPACE, a hardware-in-the-loop simulation platform, in order to conduct a real EV test. The test results were consistent with the simulation results, thus verifying the simulation.

2 Fault-Tolerant Control

2.1 Problem description

Considering linear continuous system as follows:

$$\dot{x}(t) = Ax(t) + Bu(t) \tag{1}$$

$$Y(t) = Cx(t) + Du(t) \tag{2}$$

Where,x(t)is state variable; u(t) is input; A, B, C, and D is coefficient matrix;(A,B) is controllable matrix.

The state feedback control :

$$u = -Kx \tag{3}$$

For the sensor faults that are probably appeared**,** switch matrix F is introduced, the form is as following:

$$F = diag(f_1, f_2, \cdots, f_n)\,,\; f_i = \begin{cases} 1 & \text{(normal)} \\ \gamma(0<\gamma<1) & \text{(partial failure)} \\ 0 & \text{(complete failure)} \end{cases} \tag{4}$$

When considering sensor faults, closed-loop system is expressed as the following equation:

$$\dot{x}(t) = [A - BKF]x(t) \tag{5}$$

The design problem can be described as: when sensor faults occur, it will look for proper state feedback control matrix K which can make closed-loop system (5) remain stable for all possible as shown in figure 1.

2.2Design of fault-tolerant controller

Fault-tolerant control based on riccati equation can constantly correct weight matrix Q and R by means of an iterative, which makes the solution of riccati equation satisfy special condition(sensor is normal or fault).Then, the feedback control matrix K is gained to improve the reliability of system by adopting, as follows:

For above linear system, state feedback matrix is designed as follows:

$$K = R^{-1}B^{T}P \tag{6}$$

Where, P is symmetric positive definite solution of algebraic riccati equation

$$(\alpha I + A)^T P + P(\alpha I + A) - PBR^{-1}B^T P = -Q \tag{7}$$

For the nominal system as Eq.(1),state feedback control as Eq.(3) can minimize quadratic performance index function

$$J = \int_0^\infty e^{2\alpha t}(x^T Q x + u^T R u)dt \tag{8}$$

In which, weight matrix Q is non-singular matrix, R is diagonal matrix.

When,

$$\mathrm{Re}\{\lambda(A - BKF_i)\} < -\alpha \tag{9}$$

The closed-loop control system has fault-tolerant ability to each kind of sensor fault mode as $F_i \in F$;Where, $\lambda(A - BKF_i)$ represents the system poles of closed-loop under any fault mode ,α is stability margin of system.

3 Road Test and Result

3.1 Test Device and System

The tests were performed using the control system. It comprises a rapid control module, an actuator system, and a sensor system. The SC unit is used for communication between the sensor system and the main controller unit. The PU is used for communication between the actuators and the main controller unit. The 1401/1505/1507 MicroAutoBox is used as the main controller unit. In the actuator and dSPACE system, the input power of 12 V is obtained from the car battery. The entire control loop is closed by the driver in the real EV.

3.2 Road test and analysis

To prove the validity of the control, a parking steering as well as various S-shaped working conditions are adopted to perform joint simulation at torque sensor failures for fault-tolerant control (FC) and not fault-tolerant control (NFC), respectively. This car equipped with the original passive suspension system and the active suspension system with the chaos control, respectively. The primary variables measured during the simulation are the steering wheel turning angle, the steering wheel torque and the moving velocity of the vehicle.

3.2.1 Parking Steering Working Conditions

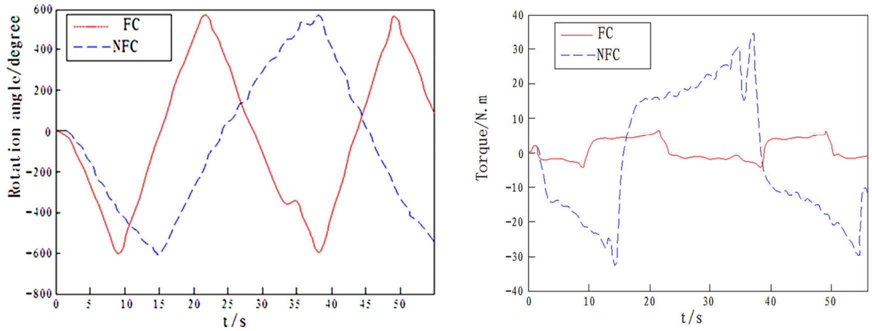
The test analysis on the parking steering working conditions can be employed to illustrate the improvement status for the EPS established over the steering performance for the vehicle.

3.2.2 The S-shaped Working Condition Simulation

The state standards "Vehicle Handling and Stability Test Methods Experiments on Turning Convenience" regulates to carry out simulation on the road surfaces with vehicle speed of 30±2km/h.

3.3 Discussion

Fig. 1(a, b) and Fig. 2(a, b) show that the fault-tolerant controller (FC)applied on the EPS effectively reduces the steering torque. It has better results than a traditional EPS without fault-tolerant control(NFC) especially on an Parking Steering and S-shaped Input. When torque sensor faults occur, the maximum steering wheel angle does not change. But the maximum torque and average torque of traditional EPS are more higher than EPS with fault-tolerant control as shown in Tables. 1 and 2.From the results presented above, it has indicated that the proposed control method can suppress the sensor faults effectively.

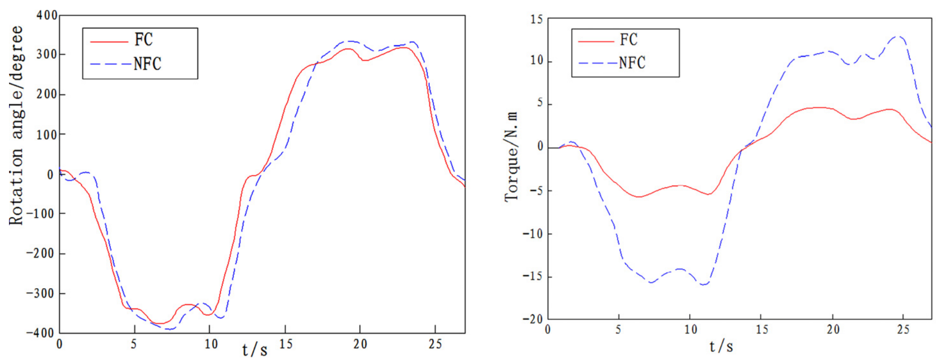


(a)steering wheel angle (b) steering torque

Figure 1 .Comparison chart of Parking Steering

Table 1. Results of Parking Steering

performance indexes	NFC	FC
Maximum wheel angle/°	600	600
Maximum torque /N.m	34.71	6.58
average torque/N.m	16.47	2.79



(a) steering wheel angle **(b) steering torque**

Figure 2. Comparison chart of S-shaped Input

Table 2. Results of S-shaped Input

performance indexes	NFC	FC
maximum wheel angle/°	389.3	376.6
maximum torque/N.m	15.99	5.77
average torque/N.m	9.34	4.44

4. Conclusions and future work

In this study, we focus on fault-tolerant technology which is the key technologies for EPS in EV. Linear system is described, on the basis of which the riccati equation of fault-tolerant controller is introduced. Co-simulation and road test are carried out on some conditions of sensor failures. Result shows that EPS with fault-tolerant could maintain stability. But there are some shortcomings such as fast response, no gain change and non-oscillation, the problems, and so on. In the future work, we will continue to improve control precision and performance robustness further.

Abstract: In order to evaluate the reliability of freeway guidance-system accurately, the indicators about it were studied quantitatively. Firstly, the indicators system, which consists of time reliability, information integrity, information accuracy, coverage area, compliance rate to the guidance-system, was constructed. The meanings of all indicators were illustrated and the relationships among indicators were analyzed. Secondly, the model for calculating the guidance-system reliability of the freeway section was set up by using the probability theory and the structure system reliability method. The statistical method to calculate the guidance-system reliability of freeway networks with the same-service-level sections or different-service-level sections was presented. The probability model of the compliance rate (E_5) which was the strongest random event was proposed. Finally, a freeway guidance-system was employed as an example, $P(E_5)$ was selected as the whole system reliability after monitoring and analyzing the guidance-system. The consequence was verified by the traditional vehicle-statistics theory, the differences between forecast and actual outcome are in [0.06, 0.14]. The result shows the model has higher credibility.

Keywords: Freeway; The guidance-system; Reliability; Evaluation; Probability theory.

1 Introduction

Stable and reliable freeway guidance system can balance the traffic flow, improve traffic conditions, increase the utilization rate and ensure safety of freeway. But the existing traffic guidance system is vulnerable to the influence of traffic dynamic randomness and it is difficult to evaluate accurately by specified indicators. As a very important probability measure indicators (Marvin Rausand,2010),reliability can be used to evaluate the running quality of the guidance system .It is significant to the traffic control, capacity and traffic demand balance, emergency rescue and other management of freeway.

Reliability degree is the characteristic value of reliabilityand it is also an important indicators to measure system performance(GAO S S, ZHANG L X, 2002). The study on reliability degree began in 1930s, the aircraft security research was the mainly point at that time (Marvin Rausand,2010). But in road transportation, the network reliability concept was first proposed by Japan 's Mine and Kawai Mine H, in 1982 (Kawai H,1982), Asakura and Kashiwadani proposed the concept of run-time reliability in 1991(Asakura Y, Kashiwadani M,1991). Anthony Chen proposed the concept of the capacity of the road network reliability(Chen A, Lo H K, Yang H, et al,1999,2000). Recently, reliability has been initially applied in road transportation system and public transport system. Chinese scholars studied the reliability of urban roadway network from the capacity, travel time, connectivity and accessibility, and made a lot of achievements. For example, Dai Shuai, from running time, waiting time, service quality, studied the reliability of public transport systems(DAI S, CHEN Y Y, RONG J, LIU X M,2006). Xiao Dianliang analysed the reliability of freeway emergency rescue system(XIAO D L,2008). But few studies are on the reliability of freeway guidance system.

This paper discussed evaluation indexes and calculation methods for the reliability of freeway guidance system, expecting to play a positive role in this field.

2 Evaluation indicators of guidance-system reliability

2.1 Guidance system

Based on guidance system facilities, freeway guidance systems centre on participants and balancing the freeway network traffic flow. It can reduce the travel time and travel distance, avoid some special events (accident, etc.), and improve the efficiency of freeway transportation (ZHANG X J,2008). Freeway guidance system is divided into static and dynamic guidance system.

This paper is emphasized on the dynamic guidance system, and defined it as a technical system. Including: system, system boundary, the output (consists of two parts: (1) the specified output, (2) non-specified output), the input(①the specified input ② non-specified input), boundary conditions.

2.2 Evaluation indicators

The reliability of freeway guidance system is the ability to fulfill the guidance tasks for traffic or transport under the certain service-level and dynamic traffic conditions. The quantitative evaluation indexes system which consists of time reliability, information integrity, information accuracy, coverage area, compliance rate to the guidance system, was constructed in the paper.

Defining the comprehensive guidance-system-reliability is a function of all above reliability indicators. The function can be expressed as $GSRI_i = f(T_i, F_i, R_i, C_i, O_i)$

where: T_i is the time reliability，it is the ability of the guidance information to transmitted timely, it can be expressed as:

$$T_i = \frac{t}{t_i} \times 100\% \tag{1}$$

Where t is the time threshold from information detected to published under given conditions; t_i represents the real time from information gathered to published in time i. The greater T_i, the higher reliability.

F_i : Information integrity, is the ability that the information loss rate is not greater than the time threshold during information transfer. Formula is:

$$F_i = \frac{f_i}{f} \times 100\% \tag{2}$$

Where f_i is the amount of information transferred to the objective guidance terminal in time i (expressed with the number of transferred data packet)under given conditions. f is the amount of information should be transmitted to guidance terminal under given conditions and within the specified time. The greater proportion means the higher reliability of information integrity.

R_i: The information accuracy reliability, is the ability that the ratio of the correct information transferred to the objective of guidance terminal to the total amount of information (number of packets) is not less than the given time threshold during information transfer. Formula is:

$$R_i = \frac{r_i}{r} \times 100\% \tag{3}$$

Where r_i and r respectively is the amount of correct information sent to each guidance terminal in time i (expressed with the number of data packets) , the amount of all the correct information in real time monitoring under given conditions and within the specified time.

C_i: Coverage reliability, is the ability that the rate of the information coverage area transferred to the guidance terminal to the normal cover area is not less than the given value. Formula is:

$$C_i = \frac{s_i}{s} \times 100\% \tag{4}$$

Where s_i and s respectively is the area of guidance information covered in time i and normal cover area under given conditions, within the specified time.

O_i:Compliance reliability of guidance-system. It refers to the ability that the rate of traffic participants received guidance information to all traffic participants in the coverage area of guidance-system is not less than a given value. Formula is:

$$O_i = \frac{o_i}{o} \times 100\% \tag{5}$$

Where o_i is the number of traffic participants which choose to receive guidance information in time i, o is all traffic participants in the coverage area of guidance-system. The Freeway traffic guidance-information is not mandatory, but suggestive, it can be followed or not by drivers, so O_i can evaluate the operation quality of freeway guidance-system and influence the traffic flow of freeway.

3 Reliability Calculation

3.1 Calculation Method

3.1.1 Calculation method of highway-section Guidance-system

Each parameter of the guidance-system represents the running state of a subsystem, one indicators' invalidation leads to poor running state of the subsystem, and then other related subsystems' running states are badly affected. Viewed from system theory point, once one parameter fails, the entire system will lose its guidance ability, so it is reasonable to establish a system model made up of sub-units in series, and to predict the guidance reliability of highway-section system according to the series system.

(1) The reliability calculated according to series system

Let the event of time reliability as E_1, and the corresponding reliable probability as $P(E_1)$, the reliability of information integrity, information accuracy , coverage area, compliance rate in the corresponding time as E_2, E_3, E_4, E_5 respectively, and the reliable probability as $P(E_2), P(E_3), P(E_4), P(E_5)$. If one of the five indicators fails, the whole system fails, it means the logic gate is in line with the "or gate", that is to say any failure of any event E_i in system can cause the failure of the whole system, which can be shown in Fig.1.

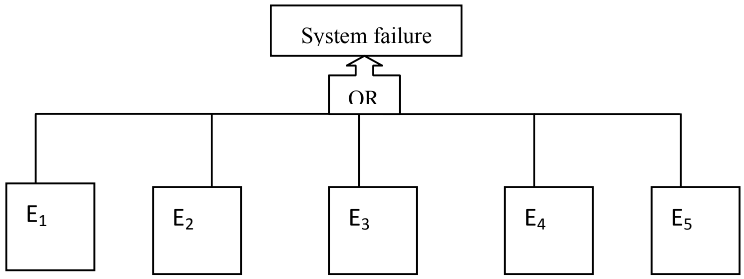

Figure 1. The diagram of Logic gate

According to probability theory, the reliability events of series system E_f can be written as:

$$E_f = E_1 \cap E_2 \cap E_3 \cap E_4 \cap E_5$$

If and only if all the elements of the system work properly, the series system can work normally. System reliability $P\left(E_f\right)$ is the product of the probability of all the events, namely

$$P\left(E_f\right) = P(E_1 \cap E_2 \cap E_3 \cap E_4 \cap E_5)$$

In the case of these events statistical independence mutually, according to the multiplication rule, it can be simplified as:

$$P(E_1 E_2 E_3 E_4 E_5) = \prod_{i=1}^{5} [P\left(E_i\right)]$$

And the system reliability is:

$$R_S = \prod_{i=1}^{5} [P\left(E_i\right)]\left(0 \le P\left(E_i\right) \le 1\right) \tag{6}$$

From the above equation we know the reliable probability is less than 1.0, which was made even less with the product. The method is suitable for the guidance-system whose subsystems have high degree of reliability, and in this case the results won't be seriously downsized.

(2) calculating system reliability with the minimum parameter

Theoretically, system reliability should be the product of five units' reliability, but when all the reliabilities of indicators in the selected guidance-system are low, in order to avoid the excessive downsizing of the results, the unit with the smallest reliability in the series system can be chose to serve as internal reliability of the system, i.e.

$$R_S = \min\{P(E_i), \ 0 \le P(E_i) \le 1\} \quad (7)$$

3.1.2 Calculation for Guidance-system Reliability of Freeway Networks

Guidance-system reliability of the freeway network can be calculated with statistical methods, namely, it is the weighted average of regional sections' guidance-system reliability.

(1) The guidance reliability of freeway network with same-service-level subsystem

When the service levels are in same, the network can be looked as a whole, making the weighted average of the guidance range of each local guidance-system, and the reliability of the whole freeway system in certain time under certain service level R_s is showed as following:

$$R_s = \frac{\sum_{i=1}^{n} R_{s_i} \bullet s_i}{\sum_{i=1}^{n} s_i} (i = 1, 2, \ldots n) \quad (8)$$

Where: s_i is the coverage area of i section's guidance information in certain time; n is the number of the sections in the whole freeway network under the same service level; R_{s_i} is the traffic guidance-system reliability of section i in certain time.

(2) The guidance reliability of freeway network with different-service-level subsystem

When the freeway network has different-service-level subsystems, it is also considered as a whole. Assumed that the freeway network has 6 different-service -levels, the guidance reliability of the whole freeway network R_s is showed as following:

$$R_s = \sum_{m=1}^{6} \frac{\sum_{i=1}^{n} R_{s_i} \bullet s_i}{\sum_{i=1}^{n} s_i} \bullet \partial_m (i = 1, 2, \ldots n; m = 1, 2, 3, 4, 5, 6) \quad (9)$$

Where: ∂_m is the weighted average for grade m (contributions made by different service levels to guiding vehicles), which can be determined by the value of $P(E_5)$; s_i refers to the guidance-information-coverage area of section i in certain time; R_{s_i} refers to the traffic guidance-system reliability of section i in certain time; n is the number of the sections in the whole freeway network under the same-service-level; m is the service level of a certain freeway.

As the freeway guidance-system reliability belongs to the probability problem, it is related closely to the survey cycle, survey times and survey accuracy. Therefore, in practice, increasing the survey times can improve the survey accuracy.

3.2 Calculation Model of $P(E_5)$

The calculations are given as following:

If participants received guidance information over sixty percent of all traffic participants, then event E_5 will effective. Assume the service level of freeway system is A, namely, vehicles run freely, use event B to present arriving x cars, event C to present cars accepted guidance information. B and C are independent to each other. Arriving vehicles follow the Poisson distribution which the arrival rate is λ, that is

$$P(x) = \frac{(\lambda t)^x e^{-\lambda t}}{x!},\ (x = 0,1,...,n) \tag{10}$$

The occurrence probability of event C is $P(c)$, X presents the number of cars accepted service less than forty percent of x, and event C only has two choices: to accept information or not . So $P_b = 1/2$, that is $X \sim C(n, P_b)$, and here we get:

$$\sum_{i=0}^{0.4x} p_b = \sum_{i=0}^{0.4x} c_x^i {p_b}^i (1-p_b)^{x-i} = P(C) \tag{11}$$

$$P(BC) = P(B)P(C) = P(x) = \frac{(\lambda t)^x e^{-\lambda t}}{x!} \bullet \sum_{i=0}^{0.4x} c_x^i {p_b}^i (1-p_b)^{x-i} = 1 - P(E_5) \tag{12}$$

$$P(E_5) = 1 - P(BC) \tag{13}$$

4 Examples

The instance freeway is two-way four-lane, the research length is 6km, and design speed is 100km / h, the direction nonuniform coefficient is 0.6 (uplink direction as the main driving direction), traffic volume of each lane less than 1000pcu/h. Vehicle detectors, meteorological monitoring devices, out-field cameras, variable message signs, etc. are all equipped.

The detection showed that E_5 is not as stable as E_1, E_2, E_3, E_4 in the detecting period , also these parameters value is low. To avoid the excessive downsizing the system's reliability, this paper choose the minimum value of evaluation parameter. Finally to verify the value with the percentage of vehicles accepted guidance service to all vehicles in the freeway network under certain conditions . Formula is showed as:

$$R_s = \frac{\sum q_c}{Q} \times 100\% \tag{14}$$

R_s is the integrated reliability of the guidance-system; q_c refers to the number of vehicles accepted right guidance , Q is the average number of vehicles running on the freeway network in survey period. Comparing the calculation, the results are shown in table 1.

Table 1. results contrast

classes	Up link1	Down link1	Up link2	Down link2	Up link3	Down link3	Up link4	Down link4	Up link5	Down link5
actual-survey value	0.32	0.38	0.32	0.31	0.32	0.29	0.34	0.29	0.29	0.3
Predicted value	0.4	0.44	0.21	0.21	0.18	0.2	0.21	0.18	0.2	0.4
difference	0.08	0.06	0.11	0.1	0.14	0.09	0.12	0.11	0.09	0.1

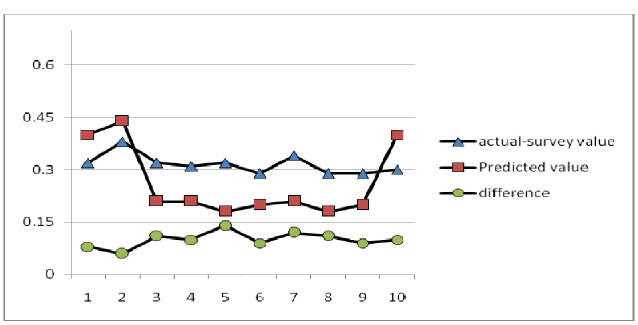

Figure 2. Actual survey and predicted comparison chart

The result shows, differences between the survey data and the predicted results are in the range of [0.06, 0.14]. The results of down line are much closer to the survey data, while the results of up line are much more stable. The predicted value differs greatly at the beginning and the end. It is because that the traffic volume of the freeway is small, but direction distribution are obvious difference, so, the predicted result difference of the uplink and downstream is relatively large. The down line traffic volume is smaller than the up line's, and inter-affects of cars are small, better information guidance effect is gained at the same time, so the predicted result of down line is much closer to the actual value. The traffic flow of the up line is much larger and more steady, so the reliability of it is more stable. Traffic incidents occur in the beginning and the end of the survey, so there are high fluctuations in the predicated values. Overall, the reliability of the freeway guidance-system varies in the range of [0.29,0.38], and the reliability is relatively low. Further construction and adjustment to the guidance-system is needed.

The boundary conditions, inputs and outputs of guidance-systems of different freeway sections are different, the reliability indicators are different, so the evaluation method for the reliability is determined by specific situations, and the minimum method of evaluation indicators can not be selected blindly. Since to obtain the information of large freeway network guidance-system is difficult, no instance analysis for its reliability is studied in this paper.

5 Conclusions

Based on the reliability theory, the reliability on the traffic guidance-system of freeway was discussed and the evaluation model was established in this paper. The example shows the model to calculate $P(E_5)$ is reasonable and conform to the actual situation.

The further studied directions can be summarized as follows:

(1)With the development of science and technology of transportation, and the changes of participants' demand, the improvement of guidance-system, the evaluation method of the guidance reliability must be updated and improved.

(2)Traffic guidance-system is a huge system, in order to increase the success rate and reduce unnecessary loss of property during the system construction ,the viable testing methods for the appropriate scale of system is imperative.

(3)The evaluation method of the guidance reliability for large freeway-network-guidance-systems is an important research direction.

Abstract: Elastic and plastic finite element analyses of the press-assembly process are performed by using the finite element analysis software named ABAQUS for the sealed cowling of freight car bearing. A conclusion that the insufficient press-assembly depth is one of reasons of sealed cowling prolapse is obtained. Reasonable press-assembly depth of the sealed cowling is obtained by the finite element analysis. Related experiment is implemented and the experiment result verifies the correctness of finite element analysis result.
Keywords: Sealed cowling prolapsed; Elastic and plastic finite element analyses; Equivalent plastic strain and stress; Pressing depth.

1 Introduction

Since 2006, sealed cowling prolapse has been repeated in 352226X2-2RZ rolling bearings (Gong Hui, 2007). This not only affects the normal traffic order, but also causes the poor lubrication in bearings and then can endanger the traffic safety. It is essential to solve the problem of sealed cowling prolapse. There are many reasons for the prolapse of sealed cowling. Practical experience shows that the insufficient depth of cover pressing is one of main reasons of the prolapse. According to Maintenance and Management Rules of Chinese Railway Wagon Axle Assembly (China Railway Publishing House,2007), after the completion of the press-assembly, the pressure mounting surface of the sealed cowling shall not exceed the end face of the outer ring of bearing. At present, the press-assembly depth using at the actual site is 0.2mm, that is, after the completion of the press-assembly, the pressure mounting surface of the sealed cowling is 0.2mm lower than the end face of the outer ring.

But actual survey results show that when the press-assembly depth is 0.2mm, the prolapse phenomenon is often generated. This is because during the actual press-assembly process, the sealed cowling under the large press-assembly force has undergone the plastic deformation. The sealed cowling cannot fully enter the outer ring thread. In order to obtain the minimum press-assembly depth which can prevent the prolapse of sealed cowling from generating, the elastic and plastic finite element analyses of the press-assembly process are performed by using the finite element analysis software named ABAQUS for the sealed cowling of 352226X2-2RZ rolling bearings in this paper. After acquiring the minimum press-assembly depth by using the finite element analysis, YN-2 type torque measuring machine of sealed cowling press-assembly is then used to check the analysis result. Test result verifies that the theoretical analysis results of this article are correct.

2 Finite Element Analysis

2.1 finite element analysis model

Elastic and plastic analyses of the press-assembly process between the sealed cowling and the outer ring are performed by using the finite element analysis software named ABAQUS. Because both sealed cowling and outer ring are axially symmetric structure, their element types are defined as a Four-Node Quadrilateral Bilinear Nonconforming Axisymmetric Element CAX4I. The revolving axle is Y-axis. Figure 1 shows the finite element analysis model. The material of sealed cowling is 08AlP. Its material properties are as follows: yield strength is 180MPa, tensile strength is $\sigma_b = 420MPa$, elastic modulus is 186GPa, and Poisson's ratio is 0.3 (Mechanical Industry Press,1996). The relationship expression of plastic stress-strain is $\sigma = 553.47 \times e^{0.234} + 180$ (Xia,2007). The material of outer ring is bearing alloy steel with the elastic modulus of 210GPa and Poisson's ratio of 0.3.

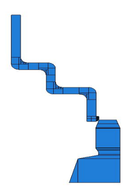

Figure 1. Finite element analysis model

Constraint conditions and loads applied in the model are as follows: the upper end face of sealed cowling with the diameter of $\Phi 179.4^{+0.10}_{-0.15}$ can only move along the direction of the Y-axis. The rest five degrees of freedom are constrained. Six degrees of freedom at the bottom of outer ring are constrained. According to the actual working conditions of the sealed cowling, the downward displacement along the Y-axis is exerted on the upper end face of sealed cowling with the diameter of $\Phi 179.4^{+0.10}_{-0.15}$.

2.2 prolapse reason analysis

The press-assembly process of the sealed cowling is the multi-point frictional contact process between the sealed cowling and outer ring inlet, outer ring thread, and thread groove of outer ring. In order to analyze the prolapse reason intuitively and consider the very violent interaction between the upper and lower end faces of sealed cowling and the outer ring surfaces, three units of the upper and lower end faces of the sealed cowling lug are selected as the feature units and their equivalent plastic strains and stresses are analyzed. The location of the selected feature units is shown as Figure 2.

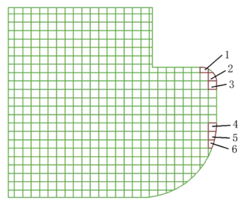

Figure 2. Selected feature units

The variation curves of equivalent plastic strains for six feature units are shown in Figure 3. The variation trends of equivalent plastic strains for feature units 1, 2, and 3 have reached an agreement as shown in Figure 3(a-c). Feature unit 1 is selected as an example to analyze the strain variation. Its values of equivalent plastic strains are given in Table1 and the related variation principle is described as follows: (1) a large plastic strain is produced in the period of outer ring inlet. The value of plastic strain increases from 0 to 0.0058mm, because the violent extrusion and friction are generated between the upper end of sealed cowling lug and the outer ring inlet under the large press-assembly force; (2) the value of equivalent plastic strain keeps increasing and varies from 0.0058mm to 0.0063mm in the period of outer ring thread. But the variation is relatively stable, since the upper end of the sealed cowling lug has already produced a large plastic strain and its interaction with the outer ring is obviously weakened. The plastic strain amplification of the sealed cowling is reduced; and (3) the value of the equivalent plastic strain increases from 0.0063mm to 0.0284mm rapidly and keeps basically unchanged finally in the period of thread groove. The mechanical model of press-assembly part of the outer ring can be equivalent to a cantilever beam. The outer ring inlet is the free end of the cantilever beam and the bottom of thread groove of outer ring can be equivalent to the fixed end of the cantilever beam. The stiffness at the thread groove is much larger than those of inlet and thread. At the moment that sealed cowling enters from the thread into the thread groove, the stiffness of outer ring increases rapidly and the contact area decreases rapidly. The plastic strain of the upper end of sealed cowling lug increases rapidly. When the sealed cowling enters into the thread groove completely, the interaction between them keeps constant. The equivalent plastic strain of the upper end of sealed cowling lug remains unchanged basically.

Figure 3 (d-f) shows that the variation tendencies of the equivalent plastic strain for feature units 4, 5, and 6 are consistent. Feature unit 6 is selected as an example for analysis. Its values of equivalent plastic strains are given in Table 1 and the related variation principle is described as follows: (1) the value of equivalent plastic strain increases from 0 to 0.038mm rapidly in the period of outer ring inlet and outer ring thread. The variation reason is the same as that of feature unit 1; (2) the value of plastic strain increases gradually from 0.038mm to 0.039mm and then remains basically unchanged in the period of thread groove of outer ring. This is because the main interaction produced between the upper end of lug and thread groove of outer ring is relatively weak, when the sealed cowling enters into the thread groove of outer ring. The plastic strain amplification of the sealed cowling is reduced. When the sealed cowling enters into the thread groove of outer ring completely, the interaction between them keeps constant and the plastic strain of the lower end of sealed cowling lug remains basically unchanged.

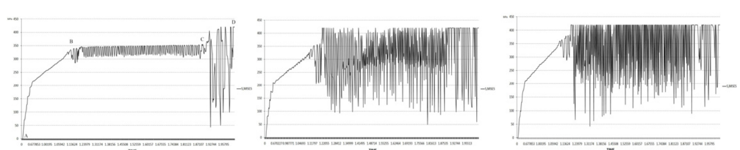
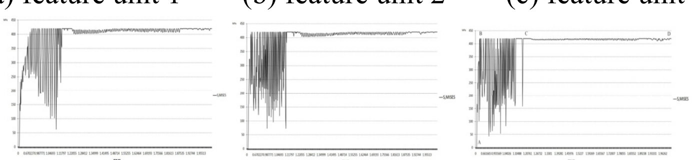
(d) feature unit 4 (e) feature unit 5 (f) feature unit 6

Figure 3. Variation curves of equivalent plastic strains for six feature units

The variation curves of equivalent plastic stresses for six feature units shown in Figure 4 are very similar to those of plastic strains.



(a) feature unit 1 (b) feature unit 2 (c) feature unit 3



(d) feature unit 4 (e) feature unit 5 (f) feature unit 6

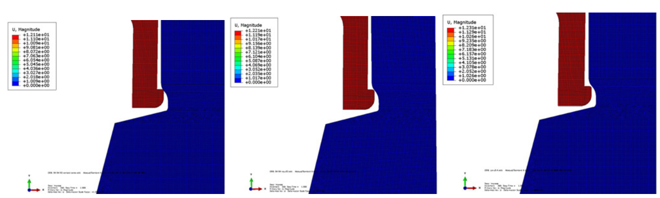
Figure 4. Variation curves of equivalent plastic stresses for six feature units

Table 1. Equivalent stresses and strains of the six feature units

Unit NO.	special position	A	B	C	D
1	Equivalent strain	0	0.0058	0.0063	0.0284
	equivalent stress（MPa）	0	347	351	420
6	Equivalent strain	0	0.023	0.038	0.039
	equivalent stress（MPa）	0	420	420	420

2.3 reasonable press-assembly depth

From the analysis result of the equivalent plastic strain variation principle for the sealed cowling, it can be seen that the large plastic strain is generated during the press-assembly process. As shown in Figure 5(a), when the press-assembly depth of sealed cowling is 0.2mm, the lug of sealed cowling cannot completely enter into the thread groove of the outer ring. The correct occlusion relationship between sealed cowling and bearing outer ring cannot be formed. In order to obtain the reasonable press-assembly depth, the press-assembly processes with the depths of 0.3mm and 0.4mm have been conducted by the finite element simulation, respectively. The final positions of sealed cowling in two kinds of press-assembly depth are shown as Figure5 (b) and (c), respectively.



(a) 0.2mm (b) 0.3mm (c) 0.4mm

Figure 5. Final positions of sealed cowling when press-assembly depth is 0.2mm, 0.3mm and 0.4mm

As shown in Figure 5(b), when the press-assembly depth is 0.3mm, the enter depth of the lug part of sealed cowling into the thread groove of outer ring is increased significantly compared with the case for the depth of 0.2mm. However, the lug has not entered into the thread groove of outer ring completely. As shown in Figure 5(c), when the press-assembly depth is 0.4mm, the lug has entered into the thread groove of outer ring completely. A good matching relationship between the sealed cowling and the outer ring of bearings is generated and the prolapse problem can be improved.

3. Experimental Study

YN-2 type torque measuring machine as shown in Figure 6 is used to check the press-assembly effect of sealed cowling of bearing. According to Chinese Railway Wagon Axle Assembly (China Railway Publishing House, 2007), the torque of

122.5N/m is applied on the sealed cowling in the assembly process. Whether there is the relative rotation between the sealed cowling and outer ring is considered as the criterion to determine the reasonable press-assembly depth of sealed cowlings. The experimental results show that there is the relative rotation between the sealed cowling and outer ring, when the depth of press-assembly is 0.2mm and 0.3mm, respectively. When the depth is 0.4mm, there is no relative rotation between them. Therefore, the reasonable depth should be larger than 0.4mm, which is in agreement with the theoretical analysis result.

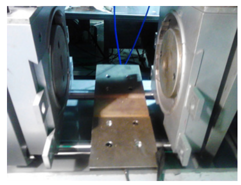


Figure 6. YN-2 type torque measuring machine

4. Conclusions

Elastic and plastic finite element analyses of the press-assembly process for the sealed cowling are performed firstly. The variation curves of equivalent plastic strains for six feature units are acquired. It can be seen from curves that due to the large shearing deformation and plastic strain of the sealed cowling during the press-assembly process, the lug cannot enter into the thread groove of the outer ring completely. The reasonable press-assembly depth should be more than 0.4mm, which is verified through the YN-2 type torque measuring machine. But during the finite element analysis is performed in this paper, the friction coefficient between the sealed cowling and the outer ring is assumed as 0.2, which needs the further experimental verification. At the same time, it needs further optimization analysis when determining the depth of the press-assembly.

Abstract: The common slewing bearings used by large tonnage cranes are bogie slewing bearing and roller slewing bearing. They have different characteristics that affect the lifting capacity. Sliding slewing bearing is a new type of slewing bearing with compact-sized, low barycenter, high stability, large bearing area and good bearing capacity. However, there are some problems need to be studied, such as the rail pressure balance between the slides and the fixed orbits, sliding friction in slewing condition, etc. Polytetrafluoroethylene (PTFE) is a lubricating material with low friction coefficient and high endurance. Contact analytical mode of the sliding slewing bearing and the lubricating layer is established in FEM (Finite Element Method). Frictional resisting moments are analyzed by transient analysis method in two sliding friction condition: steel-steel contact between the slides and the fixed orbits; add lubricating material between the sliding surfaces. The effect of lubricating layer on the rail pressure distribution of the slide in the circumferential direction and the radial direction has been studied. After adding the lubricating layer, there is a significant decrease in the frictional resisting moments of the slewing bearing and the contact regions have been expanded from the below of the reinforcing plate to the whole bearing surface, which makes the rail pressure distribution of the bearing surface more balanced.
Keywords: Slide crane; Slewing bearing; Lubricating layer; Rail pressure; Balance.

1 Introduction

As the offshore exploration and exploitation are being approached from shallow water to deepwater, there are growing demands for crane performance in offshore platform construction and deepwater pipe laying operations (LIU Weihui,2007). Slewing bearing is the vital bearing part of slewing crane whose mechanical property are one of the key factors that determine the lifting capacity, operate safety and stability. There is extremely high requirement for the bearing capacity of slewing bearings in ultra large full-circle slewing cranes.

The early full-circle floating cranes commonly use bogie slewing bearing whose equalizing beams average load to every roller and the wheel pressure distribution is even. However, for large tonnage lifting requirement, the equalizing beam stage and wheel number need to be increased, which makes the structure more complex, high barycenter and bad stability (WANG Yuemin,2009). Ultra large full-circle slewing cranes are commonly adopt roller slewing bearing in present. The device is composed of several rows of roller on the circular track which has the advantages of compact structure, low barycenter, high stability and easy for manufacture and assembly (WANG Shouying,2010). However, some rollers bear too much load while some rollers bear little force due to the complex roller load and the uneven wheel pressure distribution, which affects the safety and lifting capacity of the machine seriously.

Plane strain elements (GUI Zheng,2010) were used to establish the hollow designed bearing roller models used in large crane. The research pointed out that this design can not only increase the radial direction flexibility of the roller, make the load more uniform, but also reduce the wheel stress and improve the bearing capacity. Under different compression stiffness of rubber pads used in rotary bearing (DING Zhendong,2010), uniformity of forces applied on wheels is studied. The results show that rubber pads deformation can reduce the max wheel pressure, the wheel load is uniform. However, oversize deformation would also increase the running resistance, which affects the service life of the rubber pads.

Sliding slewing bearing is a new type of slewing bearing that uses slide instead of roller slewing on the fixed orbits. The structure is more compact, lower center of gravity, higher stability than bogie or roller slewing bearing. The plane-to-plane contact type can increase the bearing capacity effectively (GUO Jitan,2013). However, the sliding friction way increases the contact area of the sliding surface and the frictional resisting moment meanwhile. Under the effect of complex combined loads and imbalanced track beam stiffness distribution, the rail pressure distribution on the sliding surface is imbalance. The region where rail pressure is larger abrades heavily, which affect the safety and service life of the whole machine. Rail pressure balance problem (LI Songfeng,2013) of the slide slewing bearing has been studied and the result shows that adjust the position of the upright or adjust the stiffened plate's distribution can improve the rail pressure balance effectively.

In this article, frictional resisting moments are analyzed by transient analysis method in two sliding friction condition: steel-steel contact between the slide and the fixed orbits; add lubricating material between the sliding surfaces. Lubricating layer has low friction coefficient and weak stiffness. The deformation of the lubricating layer can affect the load distribution on the sliding surface and then affect the rail pressure balance. The effect of lubricating layer on rail pressure distribution of the slide in the circumferential direction and the radial direction has been studied by finite element contact analysis.

2 Calculation model

2.1 Finite element model

Slide slewing bearing is box-like structure and is welded by steel plates. Shell element is used to model the main structure. The slides of the slewing bearing are clinging to the track beam and be divided into outer slide and inner slide. Circular orbits are rigidly fixed on the offshore platform, lubricating layers are fixed on the fixed orbits based on the stiff foundation and are laid between the slides and the fixed orbits to reduce the frictional resistance of the sliding surfaces when slewing bearing rotates. In order to reflect the actual stress states of the slide-lubricating layer-orbit, solid element is used to model the slides and the lubricating layer according to the actual structure. The fixed orbits can be seen as rigid body for whose stiffness is much bigger than the slides. According to test results, young's modulus of PTFE material is 492MPa; density is 2.158 g/mm^3; friction coefficient is 0.05; compressive yield strength is 25MPa.

For comparative purposes, 4 edges of the slides are selected and are named Ⅰ edge, Ⅱedge, Ⅲ edge and Ⅳ edge from outside to inside. Two centerlines of the outer and inner slide are named centerline1 and centerline2. Then we can extract contact pressure of the nodes in each line and compare the circumferential rail pressure distribution and the radial rail pressure distribution through the rail pressure curves. FE model of the slide slewing bearing is shown in Figure 1.

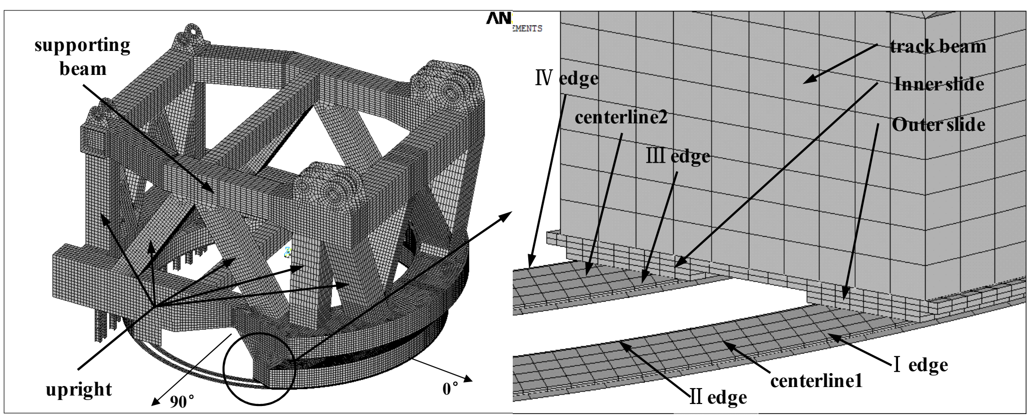

Figure 1.Finite element model

In order to study the effect of lubricating layer on rail pressure, two analytical models were chosen in this article: one with lubricating layer and one with non-lubricating layer. Rigid-flexible contact pairs are established between the slides and the fixed orbits in the model with non-lubricating layer. In the model with lubricating layer, flexible-flexible contact pairs are established between the slides and the lubricating layers and rigid-flexible contact pairs are established between the lubricating layers and the fixed orbits.

2.2 Boundary conditions

In finite element analysis, the slewing of the structure can be seen as the slewing of the fixed orbits accordingly. The fixed orbits can be set as discrete rigid body whose rotation can be controlled by the reference points. Displacement constraints are applied at the position of the drive motor in the meanwhile.

2.3 Load conditions

The effect of the boom and the A-frame on the slide slewing bearing can be seen as external forces and can be applied to the turning joints. The maximum load of the crane is 8000t.

3 Calculation results

3.1 Rail pressure distribution of static load condition

In order to reflect the numerical regularity of rail pressure distribution intuitively and easier to compare and discuss at the same time, we extract contact pressure of the nodes in each sampling lines (Figure 1) and draw the rail pressure curves. Due to the symmetry of the structure and the loads, we only take half of the sliding surface as the research object.

The rail pressure contrast curves of outer slide with and without lubricating layers are shown in Figure 2. The “+” in the legend refers to the FEM model with lubricating layers.

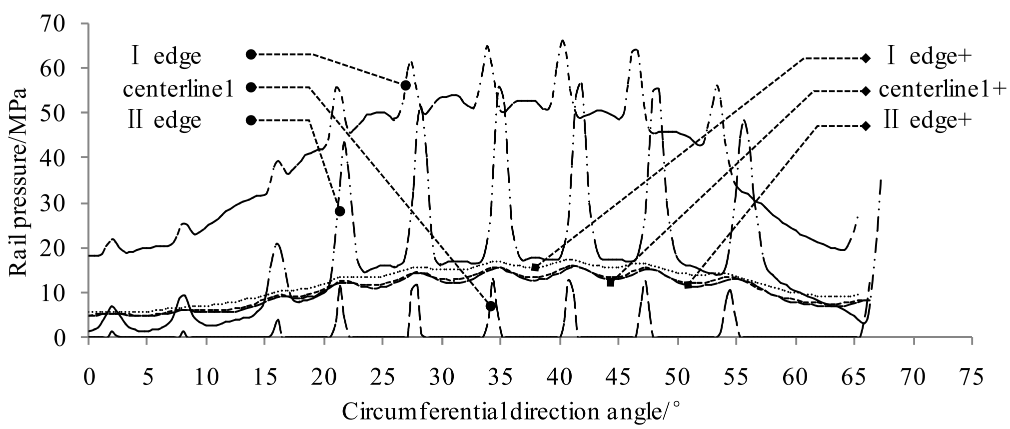

Figure 2.Outer slide rail pressure contrast curve

The rail pressure contrast curves of inner slide with and without lubricating layers are shown in Figure 3. Similarly, the “+” in the legend refers to the FEM model with lubricating layers.

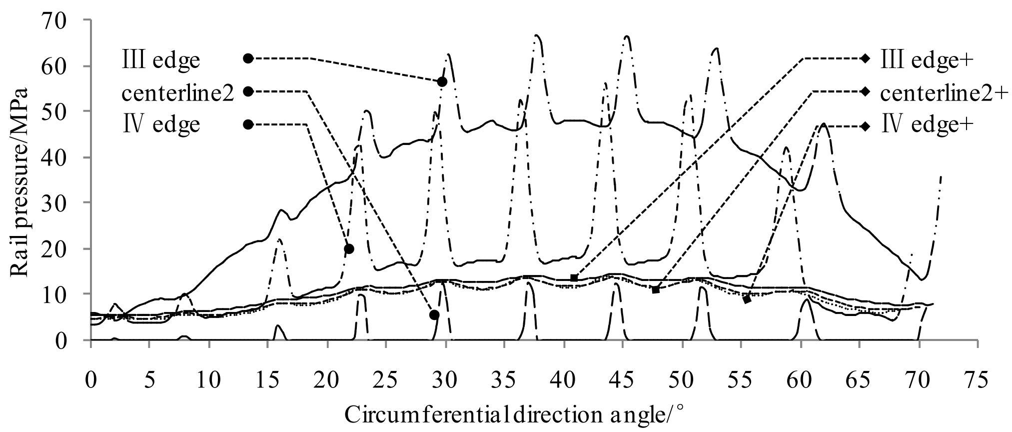

Figure 3.Inner slide rail pressure contrast curve

Along the horizontal axis (circumferential direction) we can see:

(1) With non-lubricating layers, both side of the slide bear load while mid-span area hardly bear load. Rail pressure is great under the upright. Besides that, there are sudden changes occur at the intersection of the web and the rib plate.

(2) With lubricating layer, rail pressure near the mid-span area has increased obviously while it dropped below 20MPa near the 4 edge, cuspidal point of the rail pressure curve disappear, circumferential rail pressure gets a better balance.

Along the vertical axis (radial direction) we can see:

(1) With non-lubricating layer, rail pressure were significant difference to each edge with different values at any angle, radial rail pressure has very uneven distribution which may cause the slide material wear heavily.

(2) With lubricating layer, rail pressure difference reduces significantly. This means that with the deformation of the lubricating layers, mid-span area begins to bear load and share the rail pressure near the edges, radial rail pressure gets a better balance.

3.2 Rail pressure distribution of slewing condition

Both sides of the track beam are near to the uprights where the loads are concentrating. In the mean time, lubricating layer intends to deformation after been pressed. When the sliding slewing bearing is slewing under load, it may cause great stress at the end of the slide in the slewing direction, which can makes the lubricating material wear and tear. This may affect the safety and stability of the crane seriously.

Given the fact that rail pressure of both slides has similar distribution, rail pressure distribution curve of outer slide in slewing condition is given only in Figure 4.

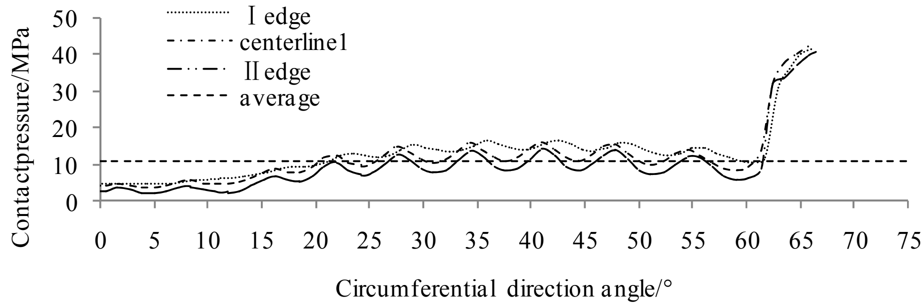

Figure 4.Outer slide rail pressure distribution curve of slewing condition

When slewing bearing slewing, whole rail pressure level remains below 20MPa beside the end of the slide. Rail pressure increases to 40MPa at the end of the slide.

3.3 Frictional resisting moments

The structure of the slewing bearing is ultra large and the load transmitted to the sliding surface is extremely complex. In this article, FEM is used to model the slewing motion of the slewing bearing and then obtain the frictional resisting moments. The result shows that: when bearing 8000t, the frictional resisting moment is 4.0×10^5kN • m with non-lubricating layer and 2.06×10^5kN • m without lubricating layer, which is 51.5% of the non-lubricating layer condition. This means that lubricating layer can reduce the frictional resisting moment and improve the slewing stability effectively.

4 Conclusions

Considering the above analysis, we can draw the conclusions that after adding lubricating layers between the slides and the fixed orbits:

(1) Circumferential rail pressure distribution curves become smooth and the cuspidal point of the rail pressure curve disappear. Circumferential rail pressure gets a better balance.

(2) Due to the fabrication error and week stiffness of the track beam, the rail pressure distribution is imbalance. Lubricating layer intends to deformation after been pressed which makes mid-span area begins to bear load, rail pressure difference reduces significantly from all angles. Radial rail pressure gets a better balance.

(3) Lubricating layers have lower friction coefficient and high endurance which can reduce the frictional resisting moment, improve the slewing stability effectively.

It should also be noted that when structure is slewing, stiffness mutation exists at the end of the slide, rail pressure has a sudden increase at the slide end, the structure need to be further optimized.

Abstract: One reliability prediction method of combining evidence theory interval fusion with Pignistic probability transformation is proposed based on the existing failure rate of similar products. According to the Pignistic probability transformation, the evaluation results of weight evaluated by experts and its confidence lever are converted into gambling probability function. Using evidence theory interval fusion technology conducts synthesis calculation. Interval point estimates are calculated by inverse operation of Pignistic probability transformation and normalized. The weight values of subsystems are obtained and the results of reliability prediction are known. The proposed method is applied on EMU bogie to conduct reliability prediction. The case indicates that the proposed method both considerate the existing failure rates of similar products and combined the evaluation of experts to the subsystems. The reliability prediction results show that this method is more objective.

Keywords: Reliability prediction; Dempster rule; Pignistic probability transformation; EMU bogie.

1 Introduction

Reliability prediction is to predict the system reliability according to data information of the subsystem reliability. The methods (Yalan, 2013; Qingbo, 2012; Jianing, 2014) of reliability prediction include similar products, scoring, stress analysis, mathematical model, Boolean method, and Monte Carlo method and so on. With the development of the EMU, its components have certain product series and inheritance, the most frequently used reliability prediction method is similar products in the EMU bogie design. This method uses specific experience gained from the similar bogies with existing reliability data to determine the new design of bogie reliability. However, due to the incomplete data information, the traditional similar product method is hard to obtain a reasonably expected result. The reliability prediction of bogie is expected to find that the main factors affecting its reliability, and then find out the weak link in the system. Then take some design measures to improve the reliability of the bogie. Therefore, a new method of combining evidence theory fusion range (Deqiang, 2014) with Pignistic probability transformation (Wanqing, 2013) is proposed to estimate reliability of the EMU bogie.

2 Reliability prediction model

2.1 Dempster rules of evidence theory

According to Dempster rules (Jing, 2012), when several experts distribute basic confidence of the same variable, synthesize evaluation results can be expressed as:

$$m(A)=\frac{\sum_{C_i\cap C_j=A} m_1(C_i)m_2(C_j)}{1-\sum_{C_i\cap C_j=\varphi} m_1(C_i)m_2(C_j)} \qquad (1)$$

Specific Dempster rules model is given as below. There are range evaluation results presented by two experts. Use number axis to describe the synthesis evaluation result. A full Dempster interval synthetic rules is shown in Fig. 1.

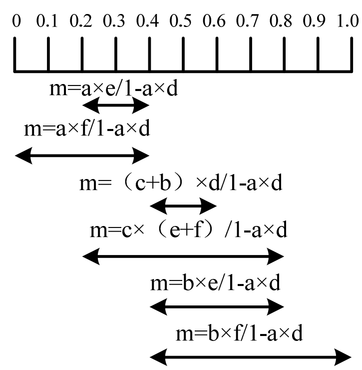

Fig. 1 Assessment result combined two experts

2.2 Pignistic probability transformation

The purpose of Pignistic probability transformation is to reallocate the interval confidence of evaluation system, then get an expected decision-making model. The formula is:

$$BetP(A)=\sum_{B\in U} m(B)\frac{A\cap B}{|B|} \qquad \forall A\in U \qquad (2)$$

Pignistic probability transformation can meet probability calculation with different framework recognition. Dempster rules is an interval fusion arithmetic when the data meet the recognition framework is $\Theta\rightarrow[0,1]$. Uniting Pignistic probability transformation and Dempster rules is used to establish mathematical model to solve the interval fusion problem.

2.3 Determination of subsystem weight

Hired five experts considering affecting factors and their own experience to conduct interval estimation of each subsystem. Give a confidence level of each evaluation result. The procedure proposed for predicting weight is as follows:

Step 1: Convert evaluation results and the given confidence level into gambling function.

Step 2: Use Dempster rules to conduct evidence fusion of the five evaluation results.

Step 3: Use in reverse Pignistic probability transformation model and obtain gambling probability distribution function.

Step 4: Draw a graph of the gambling probability distribution function, and figure out the point estimation of distribution function.

Step 5: Normalize the corresponding point estimation and get the weight of each subsystem.

2.4 Reliability prediction

The relative weight of each subsystem to system reliability is transformed into the weight coefficient of failure rate. Use the reliability data of similar bogie in the production. Find the higher similarity subsystem and the failure rate value. The failure rate value of the system is the ratio between similar subsystem failure rate values and corresponding weight coefficient of similar subsystem.

3 Bogie reliability prediction

Subsystem of Bogie is denoted by S, namely, bogie frame, wheel, axle box, primary suspension, secondary suspension, drive device, brake device. Let $S\{S_1, S_2, S_3, S_4, S_5, S_6, S_7\}$ symbolizes the above subsystems respectively. The five experts is $\{A_1, A_2, A_3, A_4, A_5\}$. The weight results are shown in table 1.

Table 1. Weight results from five experts

	A_1	A_2	A_3	A_4	A_5
S_1	(0.40 0.60)	(0.50 0.60)	(0.30 0.50)	(0.40 0.50)	(0.45 0.55)
S_2	(0.10 0.20)	(0.05 0.15)	(0.10 0.15)	(0.09 0.15)	(0.15 0.25)
S_3	(0.05 0.10)	(0.06 0.10)	(0.03 0.10)	(0.08 0.20)	(0.05 0.20)
S_4	(0.04 0.09)	(0.03 0.09)	(0.03 0.10)	(0.05 0.10)	(0.01 0.10)
S_5	(0.00 0.10)	(0.03 0.05)	(0.03 0.05)	(0.01 0.05)	(0.03 0.10)
S_6	(0.02 0.05)	(0.00 0.05)	(0.02 0.10)	(0.02 0.10)	(0.05 0.10)
S_7	(0.10 0.20)	(0.05 0.15)	(0.05 0.20)	(0.10 0.15)	(0.10 0.20)

Weight evaluation confidences of the five experts from 1 to 5 respectively is: $\{0.95 \quad 0.90 \quad 0.85 \quad 0.80 \quad 0.75\}$.

Bogie frame S_1 as an example is analyzed. Using the established model calculates the point estimation values of weight evaluation. The process is as follows:

(1) First expert's evaluation result for bogie frame S_1 is $[0.4\ 0.6]$. The interval confidence is 0.95. Due to the weight universe is $[0\ 1]$. The gambling function is established in the interval of $[0\ 1]$. The confidence of the evaluation result is reflected in the intervals of $[0.4\ 0.6]$ and $[0\ 1]$. Therefore, the corresponding gambling probability functions are respectively:

$$\frac{0.6-0.4}{1-0}\times m_1[0\quad 1] \qquad \frac{0.6-0.4}{0.6-0.4}\times m_1[0.4\quad 0.6]$$

Then the following equation is established.

$$\begin{cases} m_1[0\quad 1]\times 0.2 + m_1[0.4\quad 0.6] = 0.95 \\ m_1[0\quad 1] + m_1[0.4\quad 0.6] = 1 \end{cases}$$

The solution of equation is ：

$$\begin{cases} m_1[0.4\quad 0.6] = 0.9375 \\ m_1[0\quad 1] = 0.0625 \end{cases}$$

In the same way, the other four experts, evaluation results can be solved as:

$$\begin{cases} m_2[0.5\quad 0.6] = 0.8890 \\ m_2[0\quad 1] = 0.1110 \end{cases} \qquad \begin{cases} m_3[0.3\quad 0.5] = 0.8125 \\ m_3[0\quad 1] = 0.1875 \end{cases}$$

$$\begin{cases} m_4[0.4\quad 0.5] = 0.7780 \\ m_4[0\quad 1] = 0.2220 \end{cases} \qquad \begin{cases} m_5[0.45\quad 0.55] = 0.7222 \\ m_5[0\quad 1] = 0.2778 \end{cases}$$

(2) Fused by Dempster rules of the evidence theory, the distribution function of the basic confidence is:

$$\begin{cases} m[0.45\quad 0.55] = 0.0219 \\ m[0.45\quad 0.5] = 0.1853 \\ m[0.5\quad 0.6] = 0.0684 \\ m[0.4\quad 0.5] = 0.1963 \\ m[0.3\quad 0.5] = 0.0023 \\ m[0.4\quad 0.6] = 0.0081 \\ m[0\quad 1] = 0.0067 \end{cases}$$

(3) Converted the distribution function of the basic confidence by Pignistic probability transformation, the gambling probability distribution function is:

$$\begin{cases} 0.0067x & 0 \le x < 0.3 \\ 0.0182x - 0.0035 & 0.3 \le x < 0.4 \\ 12.2452x - 4.8943 & 0.4 \le x < 0.45 \\ 5.9467x - 2.0599 & 0.45 \le x < 0.5 \\ 0.9502x + 0.4383 & 0.5 \le x < 0.55 \\ 0.7312x + 0.5588 & 0.55 \le x < 0.6 \\ 0.0067x + 0.9935 & 0.6 \le x < 1 \end{cases}$$

(4) The graph of the gambling probability distribution function is shown in Fig. 2.

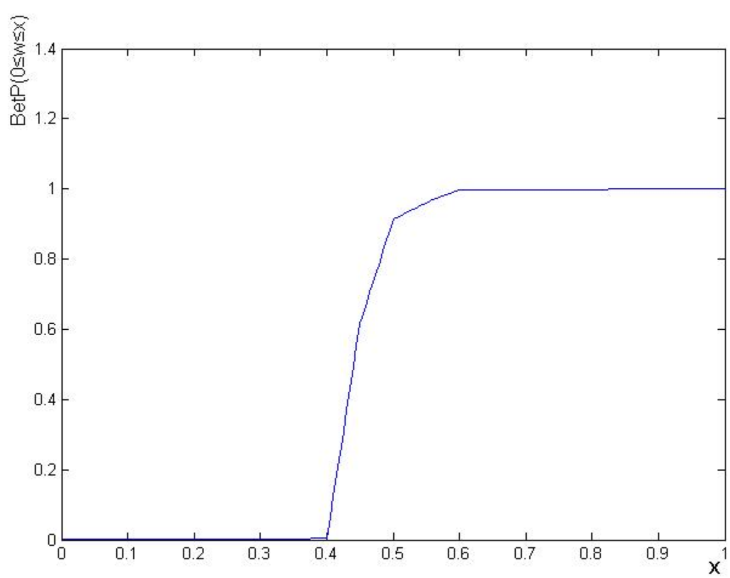

Fig. 2 The gambling probability distribution function

(5) By this measure, the point estimate value of bogie frame is 0.4494.

As the same way, the point estimate value of other subsystem are shown in table 2.

Table 2. Point estimate of assessment result for each system

Subsystem	Frame	Wheel	Axle box	Primary suspension	Secondary suspension	Drive device	Brake device
Point estimate	0.4494	0.1257	0.0878	0.0691	0.0402	0.0353	0.1255

The point estimate value of each subsystem is normalized. The weight of each subsystem is obtained, as shown in table 3.

Table 3. Weight of each subsystem

Subsystem	Frame	Wheel	Axle box	Primary suspension	Secondary suspension	Drive device	Brake device
Weight	0.4816	0.1347	0.0941	0.0741	0.0431	0.0379	0.1345

(6) Reliability prediction

According to the reliability data of the similar EMU bogie, we know that the wheel is subsystem of higher similarity. The failure rate is 0.1938×10^{-5}. The system working time is 12000h. Based on the above weight value of bogie subsystem, the failure rate and reliability of each subsystem are calculated, as shown in table 4.

Table 4. Reliability prediction results for the subsystem of EMU bogie

Reliability index	Frame	Wheel	Axle box	Primary suspension	Secondary suspension	Drive device	Brake device	Total
Failure rate($\times10^{-5}$)	0.0707	0.1938	0.1939	0.2517	0.3042	0.3167	0.1941	1.56
Reliability	0.9915	0.9808	0.9770	0.9702	0.9641	0.9627	0.9770	0.8293

By using the evidence theory synthesis and Pignistic probabilities convert method can predict the reliability level of the bogie quantitatively, and determine whether the result is expected to conform to the requirements of the reliability index, and provide data basis for the implementation of reliability allocation as well.

4 Conclusions

Reliability prediction of EMU bogie is conducted based on combining evidence theory fusion range with Pignistic probability transformation. For reliability prediction, the weight of the each subsystem is determined by the mathematical model that established by means of interval evidence theory fusion based on the Pignistic probability transformation.

The wheel failure rate compared with the existing high similarity bogie system is given. Based on the proposed method in this paper, reliability indexes of the EMU bogie subsystems is calculated. The case has been proved that this method can eliminate the subjective influence of uncertainty factors to some extent and make the results of reliability prediction more objective. At the same time, the reliability prediction results also provide data basis for the implementation of reliability allocation.

Safety Limit Study of the Gravity Center Height for a Loaded Wagon under Cross-Wind

Meiyan Li

School of Transportation and Logistics, Southwest Jiaotong University, Chengdu, Sichuan 610031, China. E-mail: meiyanli_xyc@163.com

Abstract: The application conditions of the safety limit of height of gravity center of loaded wagon in “The railway freight loads and firms regulation” are not described in detail. In this paper, we established the particular three-dimension dynamic model for the container flat car and the container to simulate the dynamic behavior of freight wagon through the curve under cross-wind. We analyzed safety of loaded wagon under different height of gravity center and obtained the safety limit of height of gravity center of loaded wagon under cross-wind. From the analysis of calculation results, we can know that the height of gravity center can reach 2.2 m or higher when the wind speed is lower than 9 grade; when the wind speed is 9 grade, loaded wagon should run with speed limit while the height of gravity center is over 2.2 m; when the wind speed is 10 grade, loaded wagon should run with speed limit while the height of gravity center is over 1.9 m; when the wind grade is 11 or above, loaded wagon should run with speed limit or stop running.

Keywords: Railway freight transportation; Cross-wind load; Limit of height of gravity center; Dynamic model.

1 Introduction

As the running speed of freight train increased, effects of the cross-wind on the safety of railway freight transportation increasing, the requirements of the height of gravity center of loaded railway wagon and offset of gravity center of goods loading under cross-wind are more strictly. At present, the work of loading and firming for railway freight in our country is to calculate and make decision of the safe loading and securing plan, generally according to the rules of “The railway freight loads and firms regulation (the shorter form “loads-regulation”)”, for the actual freight transportation. The height of gravity center of loaded wagon can’t over 2000 mm in “loads-regulation” else the wagon must be running with speed limit. Because of the regulation made on the earlier time, suitable speed level of railway wagon and running environment were not stated. The freight wagon will be affected by cross-wind in the running inevitably. When the wind grade is increasing, the freight wagon will be affected by more cross-wind force, and it can make freight wagon more dangerous. What’s more, the higher the gravity center of a loaded wagon, the greater risk of overturning, and it will cause serious damage. In the study of the safety limit of height of gravity center of loaded railway wagon today, only a few scholars discussed the effects of the height of gravity center of loaded wagon on the safety of railway freight transportation under cross-wind. They usually adopt quasi static method to study, and the model is relatively simple. In this paper, the detailed three-dimension dynamic model was established for the container flat car and the container to simulate the dynamic behavior of freight wagon through the curve under cross-wind. We used safety evaluation indexes of freight wagon, such as derailment coefficient, wheel unloading rate, lateral wheelset force and overturning coefficient, to analyze safety of loaded wagon under different height of gravity center, and obtain the safety limit of height of gravity center of loaded wagon under cross-wind.

2 Modeling of container flat car system

Container flat car system is considered as a complex dynamic system with three parts – bogies, railway flat car body and the container. In order to establish three-dimension dynamic model of container flat car system, we can simplify the whole system to a multi-body system composed of a series of rigid body, force element and constraint. The mathematical model of this system can be described as differential algebra equation.

First, we analyzed the topology of the whole container flat car system, as shown in figure 1. Topological graph can clearly reflect the correlation between every parts of the system, and it is the foundation to establish dynamic model correctly. As shown in figure, we can know that wheelset, bogie frame and bolster are connected by force element, such as spring and friction damper, to form a bogie. The model of container flat car system is composed of bogies, car-body and the container which are connected by force element and joint. And relative to track, wheelset, bogie frame and car-body each have six degrees of freedom. Relative to car-body, the container has no degree of freedom. Relative to car-body, each bolster has three degrees of freedom. Between the wheelset and track are wheel-rail force elements, and guiding frame and rubber bearing are between the wheelset and bogie frame. The central suspension is between bogie frame and bolster which concludes spring and friction wedge unit. The bolster and car-body are connected by side bearings and center plate. Besides, the container and car-body are firmly connected by connecting pin.

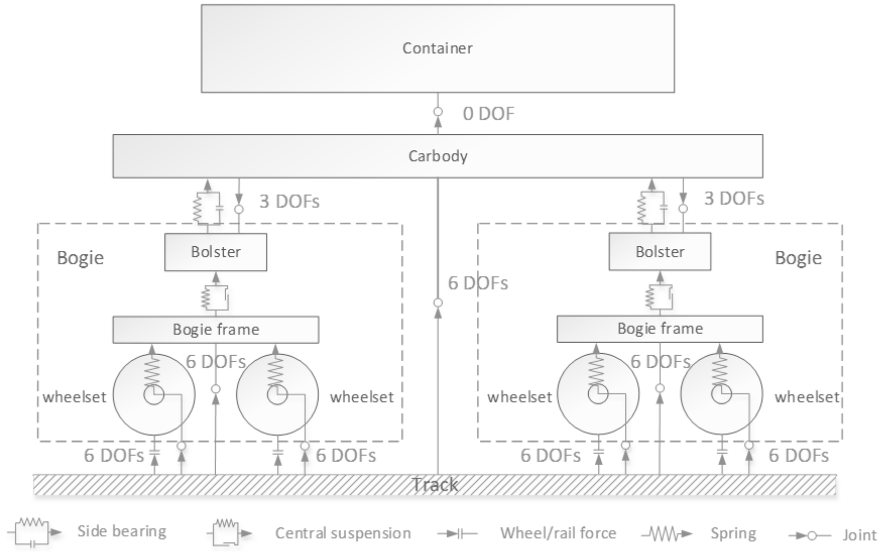

Figure 1. Topological graph of container flat car system

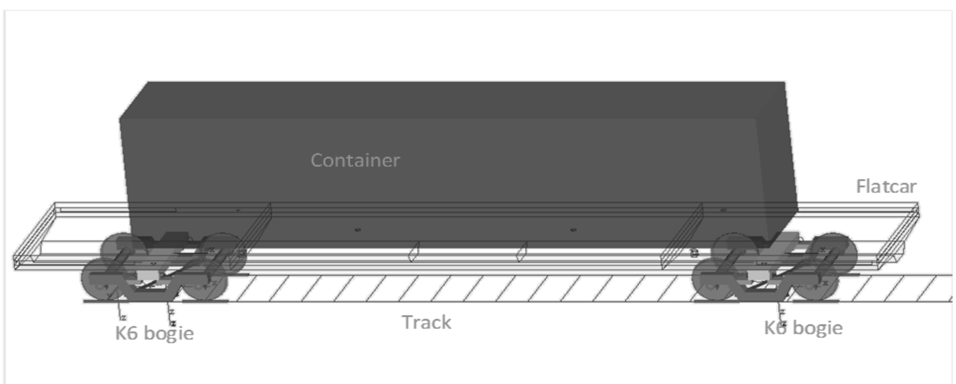

Figure 2. Dynamic model of container flat car system

According to the topological graph of the system, we used dynamic software SIMPACK to establish dynamic model of container flat car system. As shown in figure 2, it includes track, K6 bogie, flat car body and the container. The mathematical model of the system can finally be expressed as the following differential algebraic equations.

$$\begin{cases} \mathbf{M}\ddot{\boldsymbol{q}}+\boldsymbol{\Phi}_{\boldsymbol{q}}^{\mathrm{T}}\boldsymbol{\lambda}=\boldsymbol{F}+\boldsymbol{F}_{\mathrm{wr}}+\boldsymbol{F}_{\mathrm{w}} \\ \boldsymbol{\Phi}(\boldsymbol{q},\mathrm{t})=\boldsymbol{0} \end{cases} \quad (1)$$

Where $\boldsymbol{q}$ is generalized coordinates vector, $\mathbf{M}$ is generalized mass matrix, $\boldsymbol{F}_{\mathrm{wr}}$ is generalized force vector of wheel-rail force, $\boldsymbol{F}_{\mathrm{w}}$ is generalized force vector of cross-wind, $\boldsymbol{F}$ is other generalized force vector, $\boldsymbol{\Phi}$ are constraint algebraic equations,

$\mathbf{\Phi}_q$ Jacobi matrix corresponding to constraint equations.

The whole system has 68 degrees of freedom, and it contains a large number of nonlinear factors such as friction, clearance and piecewise linear spring. All of this increases the difficulty of system solving.

3 Calculation of cross-wind load

According to the force area of the container and relationship between wind pressure and speed, we calculated the wind load on the container flat car system corresponding to different wind grades.

The relationship between wind speed and wind pressure on unit area generated by free-stream can be calculated by the following equation.

$$w=\frac{1}{2}\rho v^2=\frac{\gamma}{2g}v^2 \tag{2}$$

Where w is said wind pressure per unit area, and v is said wind speed. γ is said weight of air per unit volume, and g is said acceleration of gravity. In this paper, we take γ = 0.0129 kN/m³, and g = 9.8 m/s².

We assumed that cross-wind was applied perpendicular to the side of container. The dimensions of 40 ft container are 12192 mm, 2438 mm and 2591 mm, respectively. Side area of the container is 31.59 m^2. Using Eq. 2, we can calculate wind pressure corresponding to wind above 5 grade and maximum of equivalent load of each wind grade. According to the standard CJJ96-2003, wind load used in calculation is equal to maximum of equivalent wind load multiplied by safety coefficient of 1.5. And the calculation results are shown in Table 1.

Table 1. Wind speed, wind pressure and wind load

Wind grade	Wind speed (m/s)		Wind pressure (Pa)		Maximum of equivalent wind load (N)	Wind load used in calculation (N)
	Min.	Max.	Min.	Max.		
5	8.0	10.7	42.12	75.35	2380.40	3570.60
6	10.8	13.8	76.77	125.34	3959.51	5939.27
7	13.9	17.1	127.16	192.45	6079.61	9119.42

The wind load on the side of container is equivalent to concentrated load which applied to the centroid of the side of container. We can use dynamic model of container flat car system and cross-wind load to obtain the safety limit of height of gravity center by simulation and analysis.

4 Evaluation indexes of safety

This article adopts four indexes commonly used for railway vehicles to measure the safety of container flat car. Those are derailment coefficient, wheel unloading rate, lateral wheelset force and overturning coefficient. According to GB5599-85, the definition and limit of four indexes are as follows:

(1) Derailment coefficient is the ratio of lateral wheel-rail force and vertical wheel-rail force, namely Q/P.

The first limit: $Q/P<1.2$, the second limit: $Q/P<1.0$

Where, Q is lateral wheel-rail force generated on the climb rail side, and P is vertical wheel-rail force generated on the climb rail side.

(2) Wheel unloading rate is the ratio of wheel unloading value and average wheel load of wheelset, namely $\Delta P/\overline{P}$.

The first limit: $\Delta P / \overline{P} \le 0.65$, the second limit: $\Delta P / \overline{P} \le 0.6$

Where, ΔP is wheel unloading value, $\overline{P}$ is average wheel load of wheelset. The first limit is the qualified criteria to evaluate vehicle running safety, and the second limit is the criteria which increased safety margin. This paper adopts the first limit as safety evaluation standard.

(3) Lateral wheelset force is the sum of lateral wheel force of both sides, $H = Q_1 + Q_2$. And it should meet the following condition:

$$H \le 0.85(15 + \frac{P_{st1} + P_{st2}}{2}) \tag{3}$$

Where: H is lateral wheelset force, kN. P_{st1}, P_{st2} are static loads of left and right wheel (wheel load), kN. The limit of lateral wheelset force is 70.5 kN according to the Eq. 3.

(4) Overturning coefficient is used to identify whether it will lead wagon to overturn while lateral wind, centrifugal force and inertia force of lateral vibration are applied to the wagon at the same time. The critical condition of overturning is as follows:

$$D = \frac{P_{\mathrm{d}}}{P_{\mathrm{st}}} = 1 \tag{4}$$

Where: D is overturning coefficient, P_{d} is dynamic loads of wheels on the same side of vehicle, kN. P_d is static loads of the corresponding wagon. The limit of D is below 0.8.

5 Dynamic simulation and results analysis

5.1 Working condition of Calculation

Weight of loaded wagon is 55.4 tons, and weight of the container and goods is 25 tons. This article assumes that the total weight of the container and goods remains the same, and different loading just cause the gravity center to change in vertical. In this paper, the height of gravity center is between 1.6 and 2.2 meters, and loaded wagon passes through the curve which radius is 300m with speed of 70km per hour. The curve superelevation is 120mm and the biggest deficient superelevation is 72.7mm. The direction of wind load is from the medial to the lateral of curves, and wind load and centrifugal force are superposed. It is a relatively bad working condition.

5.2 Simulation results analysis

Different wind speed and the height of gravity center are combined to 49 conditions, and the calculation results are shown in the figures below. The first wheelset is the leading wheelset of the leading bogie in the traveling direction and its indexes are the biggest. So we only give derailment coefficient, wheel unloading rate and lateral wheelset force of the first wheelset.

Figure 3 shows derailment coefficient of the first wheelset, and derailment coefficient of left and right wheel are all below the limit of 1.0. As wind speed and gravity center increasing, derailment coefficient of left wheel shows a trend of decrease, mainly because of the increasing of increased load of vertical wheel-rail force in this condition. Derailment coefficient of right wheel is small and the change isn't obvious. Figure 4 shows wheel unloading rate of the first wheelset. Left wheel is the increased load side of wheelset, so wheel unloading rates are small and they are below the limit of 0.65. And right wheel is the reduced load side. As wind speed and gravity center increasing, reduced load is increasing. When the wind speed is lower than 9 grade, wheel unloading rates are all below the limit within the calculated height of gravity center. When the wind speed is 9 grade, wheel unloading rate is on the limit while height of gravity center is 2.2m. When the wind speed is 10 grade, wheel unloading rates are above the limit while height of gravity center is 1.9 m. When the wind speed is 11 grade, wheel unloading rates are all above the limit within all of calculated height of gravity center. So, when the wind speed is 11 grade, the vehicle should reduce speed or stop running. Figure 5 shows lateral wheelset force of the first wheelset, and all of them are below the limit of 70.5kN in the calculated conditions. Figure 6 shows overturning coefficient of the loaded wagon, and its trends are the same with wheel unloading rate of right wheel basically. They are all below the limit of 0.8.

One of four safety indexes is above the limit, and it means that loaded wagon is in an unsafety state. So, according to the results of wheel unloading rate of right wheel, we can obtain the safety limit of height of gravity center under different wind grades.

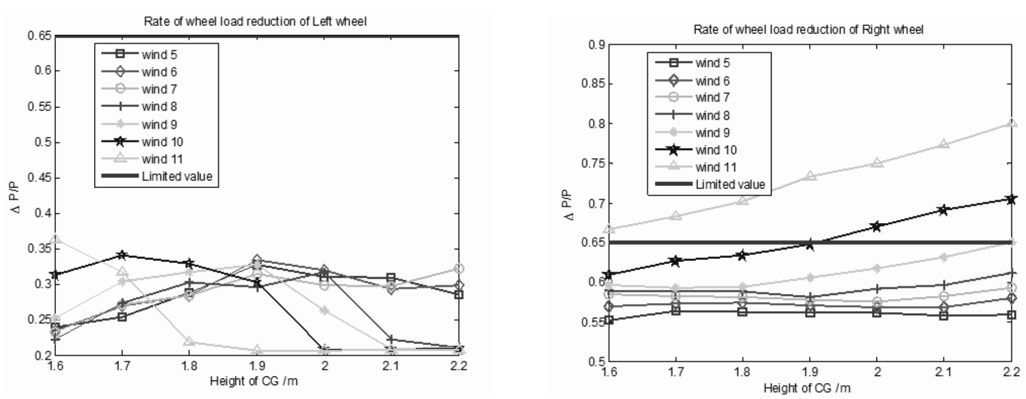
Figure 3. Derailment coefficient of the first wheelset



(a) Wheel unloading rate of left wheel (b) Wheel unloading rate of right wheel

Figure 4. Wheel unloading rate of the first wheelset

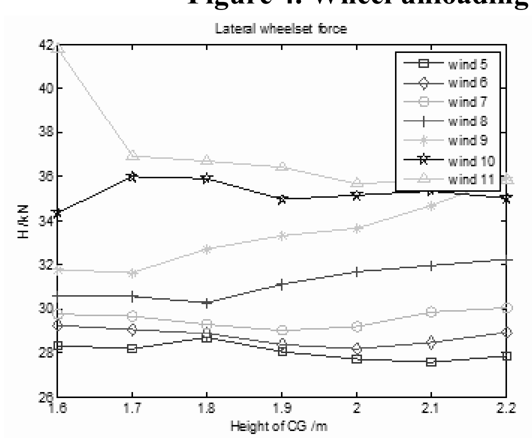


Figure 5. Lateral wheelset force of the first wheelset

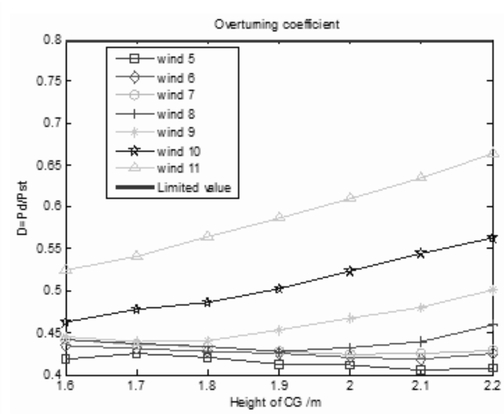

Figure 6. Overturning coefficient of the loaded wagon

6 Conclusions

In this paper, we established detailed dynamic model of container flat car system to simulate the loaded wagon passing through the curve which radius is 300 m. We calculated different working conditions combined 5-11 grades wind with height of gravity center of 1.6-2.2 m, using derailment coefficient, wheel unloading rate, lateral wheelset force and overturning coefficient as safety evaluation indexes of freight wagon, and finally obtained the safety limit of height of gravity center of loaded wagon under different wind speed.

When the wind speed is lower than 9 grade, the height of gravity center can reach 2.2 m or higher; when the wind speed is 9 grade, loaded wagon should run with speed limit while the height of gravity center is over 2.2 m; when the wind speed is 10 grade, loaded wagon should run with speed limit while the height of gravity center is over 1.9 m; when the wind grade is 11 or above, loaded wagon should run with speed limit or stop running.

Elastic-Plastic Analysis on the Contact of Wagon Wheels and Heavy Haul Frogs

He Ma; Jun Zhang; and Xia Li

School of Traffic and Transportation, Dalian Jiaotong University, Dalian 116028, China. E-mail: 1872552215@qq.com

Abstract: The phenomenon of spallings on the frog used in the heavy haul railway occurs easily, which reduced the service life of frog. The worn profiles of No.12 unmovable frog with 75 kg/m rail and wagon wheels used in Datong-Qinhuangdao have been measured. They are used to established an elastic-plastic finite element model to study the contact problem of wheel and frog at different location. The contact patches, the equivalent Von Mises stress and the variation of contact path have been analyzed. The results indicate that the contact patch on the nose rail is near the center line of top surface when the wheel contact with the standard frog and it is on the edge of nose rail when the wheel contact with the worn frog. The equivalent Von Mises stress exceeds the yield limit into the plastic deformation stage. When the wagon passes the standard frog, the wheel contacts with the wing rail, then transits to the nose rail gradually. However, when the wheel runs over the worn frog, the contact point shifts from wing rail to nose rail and then moves to the wing rail again. The contact status of wheel and frog changes between one point contact and two point contact, which causes the variation of equivalent Von Mises stress of the wing and nose rail. Besides, the wheel displacement has a great effect on the equivalent Von Mises stress and therefore it should be taken into consideration when designing the match of wheel and frog. The research provides a theoretical basis for the design of wheel and frog profiles used in the heavy haul railway.
Keywords: Heavy haul frog; Finite element method; Elastic-plastic contact; The equivalent Von Mises stress; Contact patch.

1 Introduction

Switch should have the function of ensuring trains to transfer smoothly on railway. It also should meet the reliability, stability, long service life, low maintenance and repair work under the condition of mass transit (FAN Q. A. 1999). The structure of switch is more complex than other track components. Therefore, switch need more maintenance. The damage mechanism of the wheel and switch are wear, rolling contact fatigue and large accumulated plastic deformation (Kassa E. and Nielsen J. 2008).

Daqin is short of Datong-Qinhuangdao heavy haul railway which is a special line of coal transportation. Its total length is 653 km. It enjoys the reputation of the largest coal cargo and the highest transport efficiency in the world. With the development of the national economy, the demand of coal transportation continues to grow. The transport task of Daqin railway is becoming more and more heavy. There are large capacity, high density and heavy axle load in Daqin, which makes frog more likely produce the phenomenon of falling off and greatly shorten the service life. The wear problem of frog is the most important and major issue to be resolved.

Experts and scholars at home and abroad have done far-ranging research on the wear problem of frog used in Daqin railway. Based on the problems of horizontal crack, vertical crack and vertical abrasion of No. 12 frog with 75 kg/m rail, the finite element models were established by Chen Rong to study the mechanical performance of three-kind frogs under the ultimate load and fatigue load. (CHEN R. and WANG P. 2009). M. Wiest and Martin P. are always studying a finite element model to simulate the wheel passing through the frog. And the dynamic response, the changing rules of the contact stress and the contact spot area are obtained (M. Wiest 2008, Martin P. 2008). As there is inevitably problem which is called "harmful space" in the unmovable frog, the frog with the movable nose rail is considered. While the cost of the movable frog is too high. And the movable frog demands more maintenance and repair and it's difficult to replace. So the movable frog doesn't adapt to the operating condition. Therefore the unmovable frog accounts for the vast majority in the heavy haul railway (ZHAO H. Y. 2010). It's necessary to study the contact situation between the wheel and the unmovable frog.

In this paper the profiles of No.12 unmovable frog with 75 kg/m rail and the worn profiles of wagon wheels used in Daqin have been measured. The finite element models were established to study the changing rules of the contact patch and the equivalent Von Mises stress.

2 Profiles Analysis of the Wheel and the Frog

With the increasing of passages, the profiles of wheel and frog changed with the accumulated wear. A series of tests were carried out to track the evolution of the profile. Some representative worn profiles are utilized in this study. The standard profiles of wheel and frog are used for comparison. The standard profile and representative worn profile of wheel are illustrated in Figure 1. It can be seen that the wear on the tread is severe, whereas the flange wear is mild. This phenomena has great influence on the contact behavior of wheel and rail, which is going to discuss in the next sections.

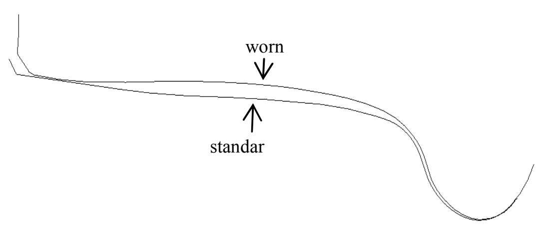

Figure 1. The standard and worn profiles of wagon wheel

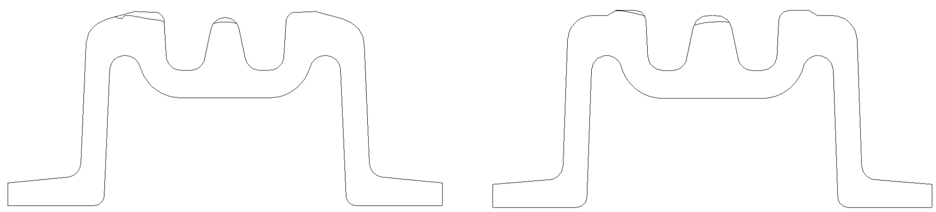
Based on the research results, the frog profiles at the 360 mm and 480 mm distance away from the theoretical nose of crossing wear seriously which are shown in Figure 2. From the figure, it can be seen that the worn wing rail is approximately an oblique line and the curvature of the nose rail top after wearing has become small. The largest vertical abrasion value of the wing rail is 7.483 mm and the one of the nose rail is 4.492 mm at the 360 mm distance away from the theoretical nose of crossing. And at the 480mm the greatest vertical abrasion value of the wing rail is 2.987 mm and the one of the nose rail is 6.570 mm. It can be seen that the wing rail wear more seriously than the nose rail. The wing rail of the standard frog is higher than the nose rail. In the figure the nose and wing rail are all worn. It can be predicted that some wheels contact with both the wing rail and the nose rail. In the facing and trailing moves, vehicles contact with one side of the nose rail respectively. When the vehicle with full load passes the frog, the wheels flange contact with the left of the nose rail which causes the nose rail to wear into the profile shown in Figure 2(b).



(a) 360 mm (b) 480 mm

Figure 2. Standard and worn frog profiles

3 Modeling

In order to investigate the elastic-plastic contact behavior between wheel and frog, the finite element method is employed. The three-dimensional wheel-frog models for different profiles are established. To save calculation time, the model considers half of the wheelset and the track, i.e. a single wheel with the frog on one side, for the symmetric of the wheelset and track systems and load condition.

HX_D2 electric locomotive and C80 wagon under the axle load of 25 t are applied to Daqin railway. As using the single wheel to calculate, half of the axle load 125000N is applied on the axle head. The longitudinal direction is the running direction of the wheel. At the same horizontal plane the lateral direction is perpendicular to the longitudinal direction. The horizontal and vertical displacement of the axle head nodes are restricted to prevent the wheel of the horizontal and vertical rigid displacement. The X, Y and Z directions of linear displacement of nodes on the frog bottom are limited to stop the three directions displacement.

4 Results and Discussion

4.1 Analysis of the contact patch

The elastic-plastic contact calculation between the standard and worn wheel profiles and the standard and worn frog profiles at different positions have been proceeded. It is known that when the wagon wheel contacts the standard frog, the contact patch is long and narrow, the long axis is along the longitudinal direction and the short axis is along the lateral direction. The contact patches are on the head of the nose rail which causing the nose rail head to press and damage. With the wheel running on the facing move, the contact patches expend at the lateral direction. When the wagon wheel contacts the worn frog, the contact patch is longer and more narrow. The contact patches are on the edge of the rail.

The contact area of the worn wagon wheel and the standard frog at the different positions is shown in the Figure 3. From the figure, it could be predicted that when the worn wagon wheel is on the facing move through the standard frog, the wheel contacts the wing rail firstly and the contact area becomes small. At the 480 mm distance away from the theoretical nose of crossing, the wheel contacts with both the wing rail and the nose rail. The contact area is about 50 mm^2. At the 600 mm distance away from the theoretical nose of crossing, the wheel only contacts the nose rail.

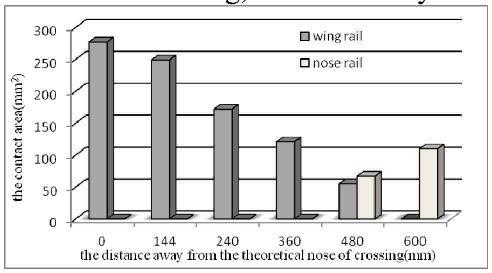


Figure 3. Contact area of wagon worn wheel and standard frog

The contact area of the worn wagon wheel and the worn frog at different positions is shown in Figure 4. When the wheel is on the facing move through the worn frog, the contact area on the wing rail becomes small. At the 480 mm distance away from the theoretical nose of crossing, the frog wears seriously and the lower value of the nose rail top reaches 6.57 mm. Besides, the tread of the worn wagon profile wears seriously. So at the position the wheel contacts the wing rail and then completely transits to the nose rail.

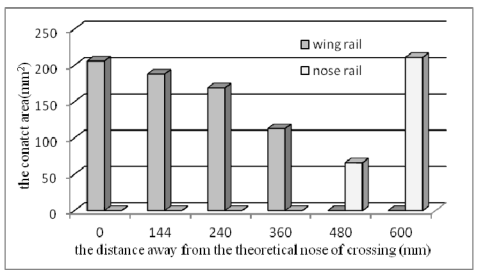

Figure 4. Contact area of wagon worn wheel and worn frog

Every wheelset runs from the throat area of the frog to the theoretical nose of crossing, then rolls onto the nose rail when passing a frog. In the process, the contact state changes between one-point and two-point contact. One is the contact between the nose rail and the wheel flange, the other is the contact between the wing rail and the wheel tread. At last, the wheel only contacts the nose rail. According to above, the contact state of the wheel and the frog is quite complex and is changing constantly. Therefore the contact stress on the wing and nose rail and the basic rail is reallocated.

4.2 Analysis of the equivalent Von Mises stress

4.2.1 Analysis of the equivalent Von Mises stress at the middle position

When wheel runs on the standard or worn frog, the stress is concentrated on the contact region. Table 1 shows the equivalent Von Mises stress of wheel under the 25 t axle load contacting frog at different positions. From Table 1, it could be seen that the equivalent stress exceeds the material yield limit, which causes the plastic flow. And there is no plastic deformation on the surrounding frog material, so it has certain constraint effect on the contact region. When the wheel contacts the standard nose rail, the contact patch is on the top. The nose rail is flattened or damaged. While the wheel contacts the worn frog, the contact patch is on the edge of the wing and nose rail. One side without plastic flow has constraint effect and the other side has large deformation because of no constraints. Where could create "flash" wears seriously.

Table 1. The equivalent Von Mises stress of the wheel and frog/MPa

the distance away from the theoretical nose of crossing (mm)	standard wheel and standard rail	worn wheel and standard rail	standard wheel and worn rail	worn wheel and worn rail
0	908.4	697.4	768.4	673.5
144	1036	703.1	1702	802.2
240	1034	768	1704	1076
360	1033	844.3	1081	1232
480	994.3	1519	1058	1434
600	1146	1349	713.7	691.9

4.2.2 Analysis of the equivalent Von Mises stress with different displacement

Taking the contact between the standard wheel and the standard No.12 frog with 75 kg/m rail at the 360 mm distance away from the theoretical nose of crossing for example, the equivalent Von Mises stress of the wheel and the frog with different displacement is calculated. The effect of contact position on the equivalent Von Mises stress between the wheel and the frog is summarized. The limited position of the wheel on the frog is determined firstly. The distance size chart of the wheel and the frog in the middle position is shown in Figure 5. This position is denoted by 0 mm.

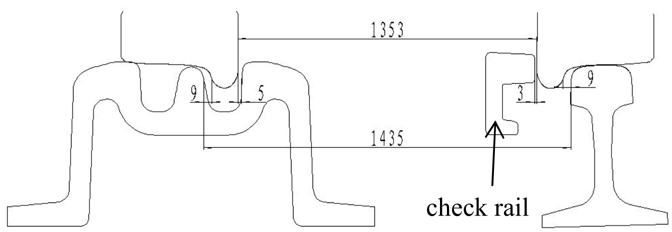

Figure 5. Distance size chart of wheel and frog in the middle position

Because the limited wear value of the check rail is 3mm, the maximum displacement of the wheel near to the frog is 6 mm. The 3 mm and 6 mm displacement of the wheel near to the frog is denoted by -3 mm and -6 mm respectively. The 2.5 mm and 5 mm displacement of the wheel away from the frog is denoted by +2.5 mm and +5 mm respectively. The models of the wheel contacting the frog at five positions are established to analyze the equivalent Von Mises stress, shown in Figure 6.

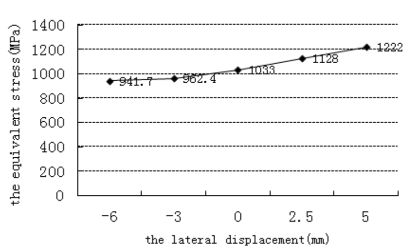

Figure 6. The equivalent Von Mises stress

The maximum equivalent Von Mises stress at the -6 mm displacement on the nose rail is 941.7 MPa which is the smallest one and at the 5 mm displacement is 1222 MPa which is the largest in five values. When the wheel runs away from the frog, the maximum equivalent Von Mises stress gradually increases. This is because the curvature of the nose rail at 360 mm distance away from the theoretical nose of crossing is large and the curvature of the standard wheel profile at the contact point becomes small. With the wheel running away from the frog, the contact area increases. The equivalent stress is small due to the large contact area under the same axle load. The smallest stress also exceeds the material yield limit and the plastic flow happens on the nose rail.

5 Conclusions

The elastic-plastic contact calculation is carried out which is about the standard and worn wheel contacting with the standard and worn No.12 unmovable frog with 75 kg/m rail at different positions under the axle load. The changing rules of the contact patch and the equivalent stress are analyzed. The above facts insist on the following conclusions.

(1) When the wagon wheel runs on the standard frog, the contact positions are the wing rail - the wing and nose rail - the nose rail. While on the worn frog, the wheel contacts the wing rail again after transiting to the nose rail. The wheel jumping between the wing rail and the nose rail makes the frog wear seriously.

(2) The equivalent stress of the wheel and the frog under the 25 t axle load exceeds the material yield limit, which makes the wheel and the frog enter the plastic deformation stage. When the wheel contact the worn frog, the contact patch is on the edge of the wing and nose rail which makes the wing and nose rail “flash”.

(3) The wheel displacement has an effect on the equivalent stress of the wheel and the frog, so it is necessary to take the effect of the displacement into consideration when the wheel and the frog are proceeded the contact calculation.

Monitoring and Simulation Analysis of Composite Foundations on Bearing Characteristics for a High-Speed Railway

Alan Jiang

School of Civil and Safety Engineering, Dalian Jiaotong University, Huanghe Rd. 794, Dalian. E-mail: jiangalan@163.com

Abstract: The methods of geogrid reinforced and CFG pile-supported foundation is a new technique for foundation treatment developed in recent years. It is the first time to be applied in high-speed railway whose design speed is 350 km/h. It consists of rigid piles, geogrids, cushion and soft soil foundation. The unity of pile, geogrid and soil bear the load together. Because of the soil arching effect, tensioned membrane effect and stress concentration. The composite foundation can not only restrict the side deformation of soft soil, but also give full play to the strength an the deformation properties of the soil, in order to effectively improve the strength of the soft soil foundation, reduce settlement of the soft foundation after reinforcement, short construction period and lower construction costs. In this paper, based on the test section of a high-speed railway line, experimental analysis and numerical simulation were used to study the action mechanism, the deformation rules and the stress distribution rules of the pile-net composite foundation.

Keywords: Composite plie-net foundation; Foundation settlement; Pile and soil stress; Geogrid tension.

1 Introduction

With the rapid development of high-speed railway in soft foundation, foundation treatment technology has become mature, the most outstanding is CFG pile composite foundation technique. CFG pile composite foundation is made of cement fly ash gravel pile (CFG pile), pile of soil and sandstone, between sand and gravel several problems such as the medium material composition together constitute layer. It has high bearing of capacity, convenient, low costing, strong adaptability and quality control easier. So it is widely applied and promoted. Under static and dynamic loads, the relations of the high-speed railway CFG pile composite foundation is very complex. Figure 1 shows the Traditional CFG pile composite foundation.

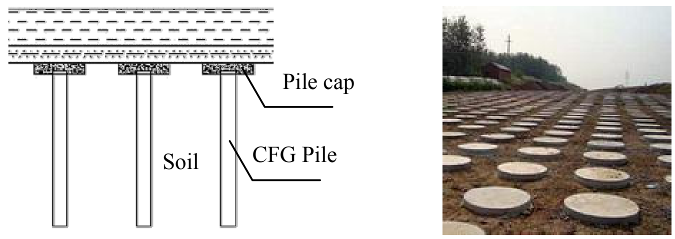

Figure 1. Traditional CFG pile composite foundation

For a high speed railway line in China therefore three different construction methods for a better and safe load transfer, distribution and concentration were carried out: ① Reinforced concrete slab on top of the piles; ② Horizontal geogrid reinforcement on top of the piles (so-called "geosynthetic-reinforced pile-supported embankment"); ③ Cement stabilization of the embankment material.

2 Project and Horizontal Geogrid Reinforcement on Top of the Piles

Between cities the high speed railway are being built. With a design speed of 350 km/h. About 70% of the railway line will run on a structure consisting of single-span and multi-span bridges. The remaining length of the track will run on an embankment. Composite Foundation: Cement Fly-ash Gravel (CFG) Pile + High Strength Geogrids (Ultimate Tensile Strength ≥ 300 kN/m) + Cement Grade Macadam. Figure 2 shows the test geological profile of the high speed railway.

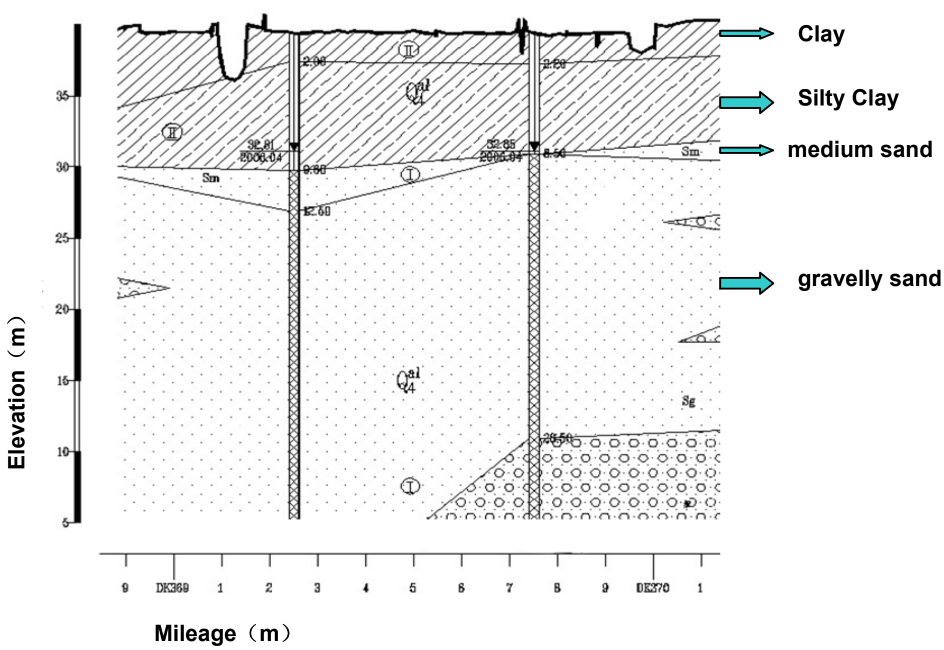

Figure 2. test geological profile

The reinforced method is geosynthetic-reinforced and pile-supported embankment. Normally the Cement Grade Macadam filled with a thickness of about

70 cm on top of the piles for a safe load transfer, distribution and concentration was used. In the Cement Grade Macadam fill, two layers horizontal geogrid reinforcement (300 kN/m) are placed. The diameter of CFG pile is 0.5 meter, and the space between of CFG piles is 1.5 meter. A schematic view of the pile supported embankment is shown in Figure 3 and a picture is given in Figure 4.

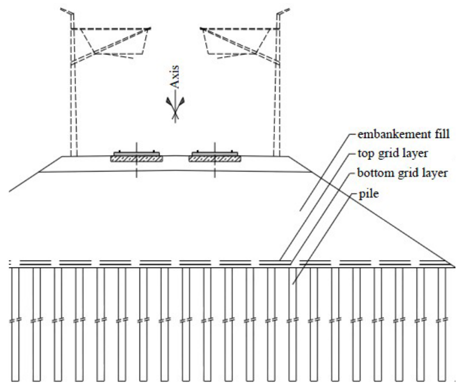

Figure 3. Geosynthetic-reinforced and pile-supported embankment

Figure 4. CFG pile reinforced soft subsoil embankment

The stress relief from the soft soil results from an arching effect in the reinforced embankment over the pile heads and a membrane effect of the geosynthetic reinforcement. Figure 5 shows In the Cement Grade Macadam filled with two layers horizontal geogrid reinforcement on top of the piles. The height of embankment is 8.16 meter (Figure 6).

Figure 5. In the Cement Grade Macadam filled with two layers horizontal geogrid reinforcement on top of the piles

Figure 6. Embankment fill

In order to further understand the intensity of pile-net structure subgrade stability and deformation, pile, requirements of the high-speed railway track bed, it needs to do pile-net structure parameter sensitivity analysis. According to high-speed railway CFG pile composite foundation, the numerical analysis can well solve the coupling effect of piles and soil.

Considering the roadbed symmetry, take half range foundation and embankment structure is analyzed. Calculation scope: vertical take 20 m, transverse take 41 m and longitudinal take a single pile distance. Because of the lower boundary of foundation soil, load has little effect, as no displacement of fixed boundary, the center of each node symmetry and lateral horizontal displacement, the surface is restricted free boundary. Figure 7 shows the finite element calculation model.

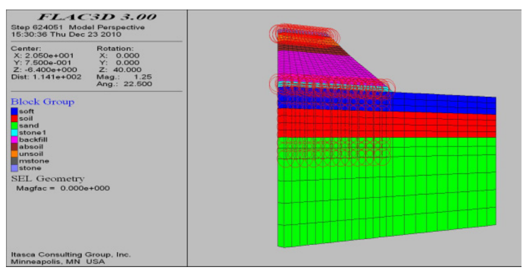

Figure 7. The finite element calculation model

3 Monitoring and Measurement results

3.1 Monitoring of foundation settlement

3.1.1 Monitoring Scheme

The five monitored cross sections, DK369+345、DK369+420、DK369+520、DK369+620、DK369+720, are selected. The different monitored cross sections have distances between 100 m. In the vicinity of K369 +345 section the bridge and embankment are connected, and in the vicinity of K369 +720 section the embankment is connected with the culvert. A large quantity of vertical and horizontal inclinometers and geophones were installed. Additionally, the settlements of the rails were measured. Figure 8 shows the five monitored cross sections.

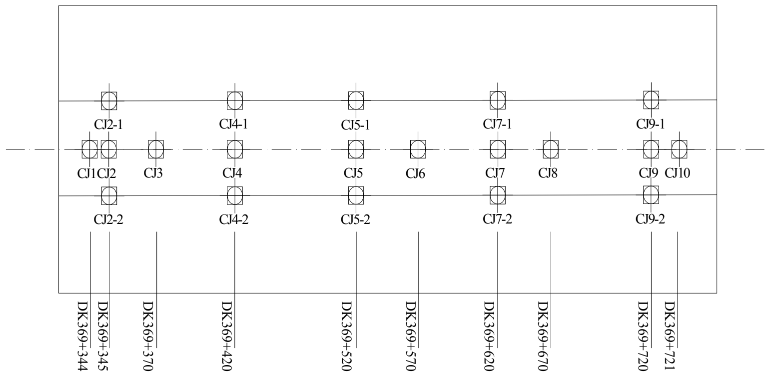

Figure 8. monitored cross sections

In a typical measurement cross section one horizontal inclinometer and up to three settlement plates are used for the examination of the deformation behaviour, see Figure 9. Figure 10 is pictures of the measurement of the settlements.

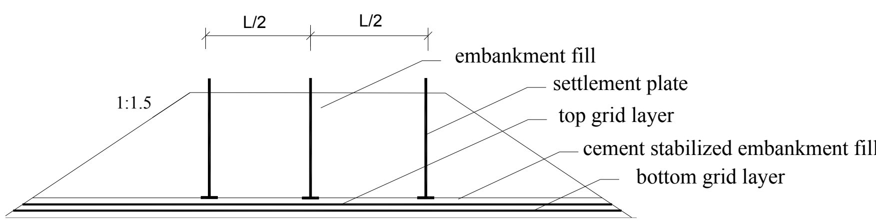

Figure 9. Typical measurement cross section

Figure 10. the measurement of the settlements

3.1.2 Simulation Analysis

This paper has calculated by finite difference FLAC3D program simulated and analyzed. The basic idea is with a differential grid discrete solving domain, difference formula will be ordinary differential equation or partial differential equations turn into difference equation, then combines initial and boundary condition, to solve the linear algebra equations.

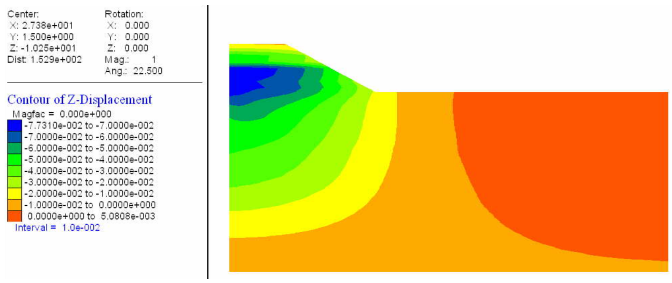

Figure 11. The calculation results

Figure 11 shows that the road embankment foundation surface subsidence center place, reach a maximum. As the center of the distance from the embankment settlement increases gradually reduce, maximum settlement is occurred in the positions shown in figure, the maximum displacement for 30.838 mm on the piles.

3.1.3 Measurement results

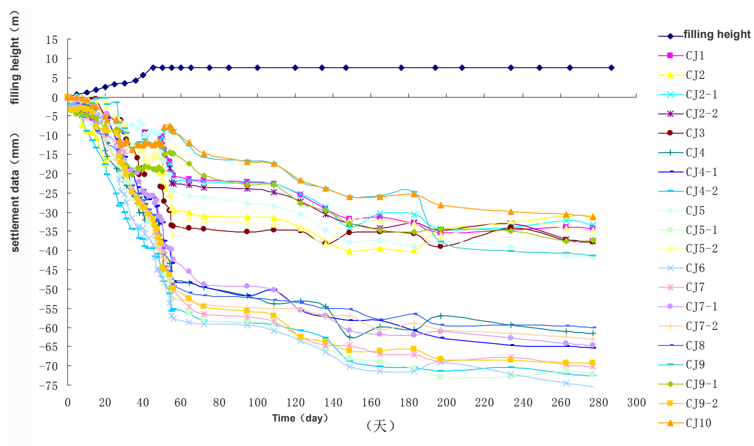

Figure 12. The measurement results

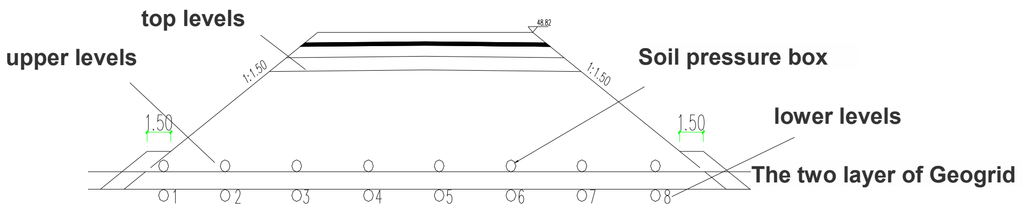
As shown in Figure 12, with the increase of the filling height, roadbed settlement is increasing. The difference between the settlement of pile top and the ones of soil between piles is increasing. Settlement of pile top and soil between piles settlement are obvious stratification. And the settlement of soil between piles is bigger than the settlement of pile top.

During the period of the embankment filling (0～48 days), settlement increase sharply. Foundation settlement rate is proportional to the embankment filling rate, when the filling rate is bigger, the settlement growth rate is larger. When filling to the top of the embankment, settlement curve is an obvious turning point, subsidence increment decreases, and the subsidence rate decreases, the sedimentation stabilized.

3.2 Testing of pile and soil stress

3.2.1 Monitoring Scheme

Test point arrangement is as shown in Figure 13 and the measurement of compressive stress is shown in Figure 14.



1、3、5、7 ： the position between piles; 2、4、6、8 ： the position on piles

Figure 13. test point arrangement

Figure 14. the measurement of compressive stress (Soil pressure box)

3.2.2 Simulation Analysis

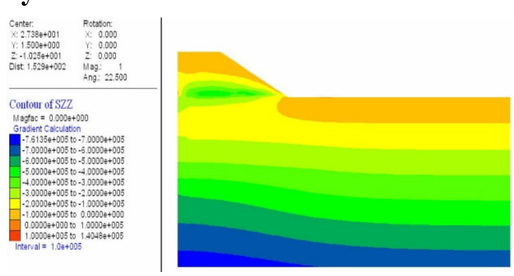


Figure 15. Composite Foundation vertical stress cloud map

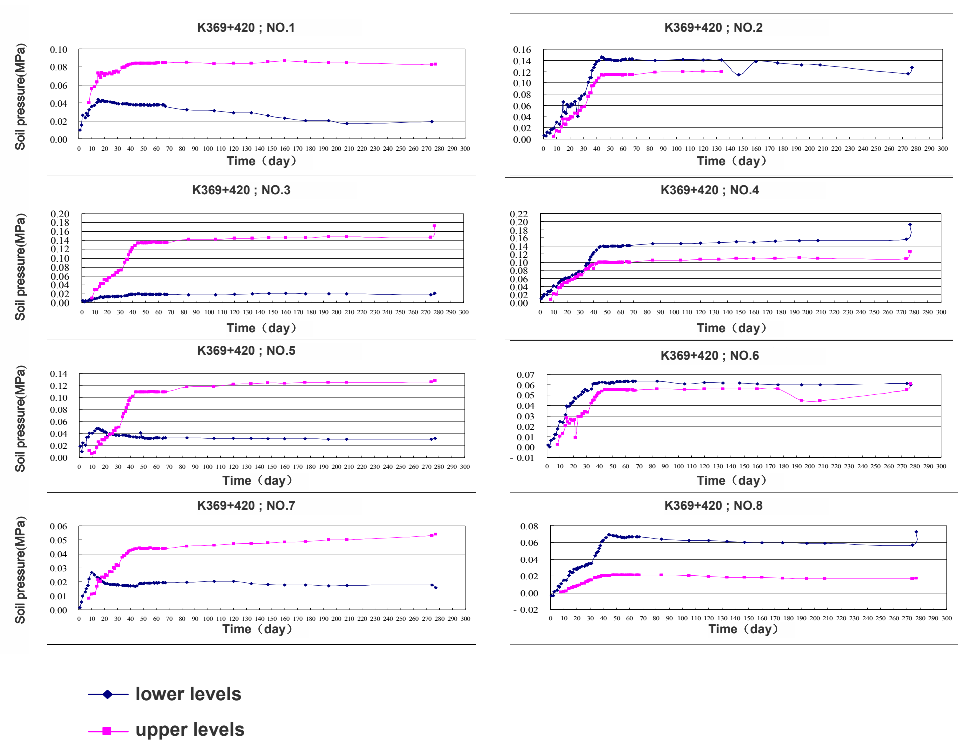
From Figure 15 we can see, there are not centralized stress phenomenon in the foundation. Along with the increase of the depth of foundation, vertical uniform stress increases, the more obvious stratification. This shows that the pile and soil between piles have formed a whole of the pile net composite foundation. Also verified the pile net composite foundation treatment has a good effect. When produced differential settlement between pile and soil, geogrid tension produced, forming a "net" to hold the upper embankment soil body, and makes the its under the vertical stress increase. Reinforced cushion of high strength geogrid due to tensile action, "the film effect" to produce more stress to the CFG pile load sharing.

3.2.3 Measurement results

The arrangement position of soil pressure box is that No.2, No.4, No.6, No.8 locate on the top of CFG pile, contrarily the No.1, No.3, No.5, No.7 locate on the soil between the piles. By analyzing the measured data, the following conclusions are obtained: with the filling height of soil increased, soil pressure curve rise. On the top of the pile, soil pressure at the lower greater than that of the upper. On the contrary, on the soil between piles, upper data of earth pressure is greater than the lower. This shows that the geogrid and cushion layer can be a very good uniform distribution of soil pressure on the top of pile and the between of them. As shown in Figure 16.



(a) the position between piles (b) the position on piles

Figure 16. The test data of soil pressure

3.3 Measuring of geogrid tension

3.3.1 Monitoring Scheme

Test point arrangement is as shown in Figure 17 and the measuring instrument is shown in Figure 18.

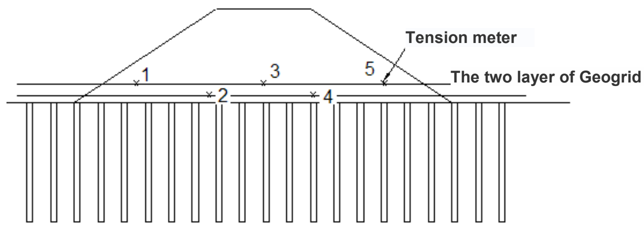


Figure 17. Test point arrangement of geogrid tension

Figure 18. measuring instrument of geogrid tension

3.3.2 Simulation Analysis

It can be seen from Figure 19, on the surface of composite foundation the level stress is minimum, and at the cushion position appeared larger horizontal stress. Because of the existence of the cushion layer of geogrid, under the load function, with the composite foundation pile, soil settlement difference, geogrid tensile stress caused by tensile, constraints of the lateral deformation of the foundation, makes the foundation level of stress redistribution. Pile net composite foundation joined the geogrid in the cushion, geogrid tensile properties can play a very good effect, effectively constraint the lateral displacement of embankment foundation. On the other hand, it makes the surface of compound foundation, namely the top of pile, much less horizontal stress and then protects the piles.

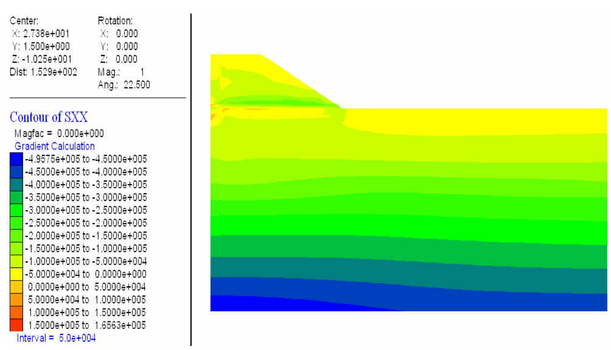

Figure 19. Composite Foundation level stress cloud map

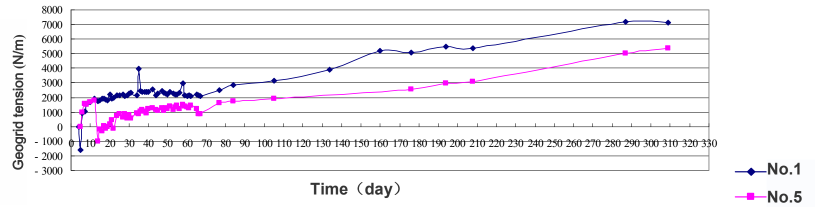
3.3.3 Measurement results



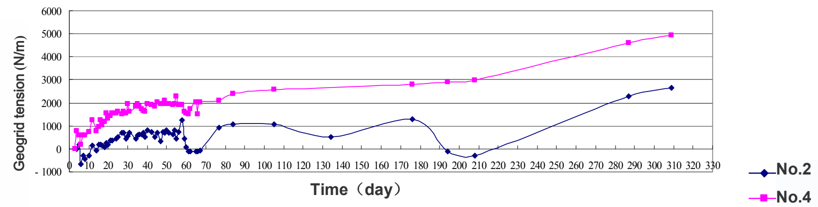


Figure 20. geogrid tension on the section of DK369+520

With the increase of the height of the embankment, geogrid tension increases. After the completion of filling, geogrid tension still rise. Geogrid tension continued to increase after preloading. This shows that the geogrid strength have a time effect.

4 Conclusions

Settlement occurs mainly in embankment construction phase, later, the settlement is lesser and embankment is stabilized. Along the mileage direction differential settlement of embankment is too large, it is necessary to add the temporary load about half a year in order to eliminate eventually the uneven settlement.

The characteristic of High Strength Geogrids is “tensioned membrane effect”. The composite foundation can not only restrict the lateral deformation of soft soil, but also give full play to the strength an the deformation properties of the soil, in order to effectively improve the strength of the soft soil foundation, reduce settlement of the soft foundation after reinforcement, short construction period and lower construction costs.

The pile-net composite foundation deformation rules and stress distribution rules of Mohr - Coulomb model were studied using the numerical simulation software. Studies have shown that: the Reinforced cushion reduced the level of stress and deformation to protect the pile and homogenized vertical stress to reduce the differential settlement. The unity of pile, geogrids and soil bear the load together.

Abstract: An existing cast-in-situ continuous curved bridge was located at the acceleration lane of a new Interchange, widening was needed to meet the width requirements. The original lateral bump walls of the bridge were removed, cantilever sections of beam were cut off about 50cm, and medial bump walls were replaced with corrugated guardrails for balance. With the help of the finite element modeling, conditions of limit and normal state with different load combinations were analyzed. The results, numerical simulations of ultimate flexural capacity and stress of both the top and bottom sides under normal state, showed that the widening project was practicable. On the basis of numerical simulations, vertical deformations between exiting and new beams under using stage were calculated，and by comparison on advantages and disadvantages of different splicing scheme, Polyurethane elastic expansion joint was finally recommended to treat Joints between new and old beams.
Keywords: Existing cast-in-situ continuous curved beams; Numerical analysis; Vertical deformation; Polyurethane elastic expansion joint.

1 Introduction

A new interchange located on the transfer joint of National Expressway No. G94 and No. G45, which was showed in Fig. 1 By the interchange, collinear between G94 and G45 were complied. In 2036, according to the traffic volume forecast, one-way traffic volume on mainstream direction was 34384 pcu/d, while the peak hour traffic volume was 2476 pcu/h, compared with 1942 pcu/d（140 pcu/h, one-way）on the minor direction.

Fig.1 Planar graph of the interchange

In G45 expressway, the bridge was in horizontal curve (R=2500m), intersecting angle was 65°between bridge and local road. Span Arrangement of existing bridge was asymmetric and no bridge pier ([left: 30+(30.676+3×41.5+30.676)+4×30+3×30] and [right:30+(30.676+2×41.5+43.5+28.676)+4×30+3×30]m). The width of (30.676+3×41.5+30.676) and (30.676+2×41.5+43.5+28.676) in upper structure that made up of cast-in-situ continuous beam was 2×20.25m, which the height of beam gradually changed from 2.2 to 2.4m. While the other part, whose girder was 1.7m, was build up by precast box girder. The substructure was partly supported by rectangular pier of 1.4×3.5m,which consisted of a pile cap and 4 pile foundations of φ1.2m,skewed with Tour-Road at its both bump wall and two sides, while the rest was supported by double-column bridge piers of pile foundations (D=1.3~1.5m).

Therefore, the bridge of G45 in the new interchange should be widen, whose piers had to be disposed in the median strip of local road, the method and new or old expansion joint (NEJ or OEJ) were showed in Fig. 2.

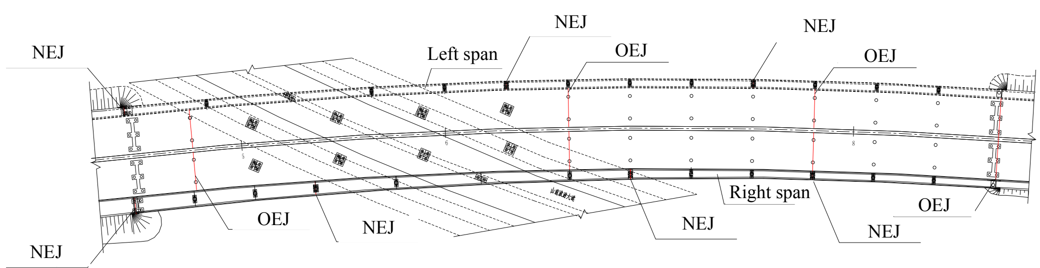

Fig.2 Planar graph of the widen bridge

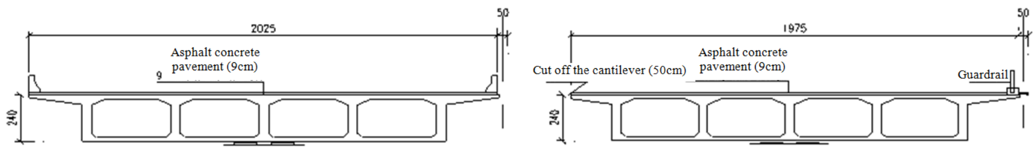
Widen scheme was showed in Fig. 3 The original lateral bump walls of the bridge were removed, cantilever sections of beam were cut off about 50cm, and medial bump walls were replaced with W-typed Beam barriers for balance. Global stress of upper beams was calculated under the scheme.



（a）Original cross-section （b）cross-section after widening

Fig.3 Widening scheme

2 Calculation Parameters

(1)Permanent Load

structure weight:

concrete capacity: 26kN/m3;

bridge deck pavement: 0.09×19.25×26=45kN/m;

W-typed Beam barriers on one side: 4kN/m;

shrinkage and creep: calculated based on JTJ 023-85.

(2) variable load

Basic variable loads:

Vehicle : Super -20t, 5 lane;

Checking load: trailers -120t, 1 lane ;

Vehicle impact: the impact coefficient μ = 0.1.

other variable loads:

changes of global temperature:±25℃

(3) Load combinations

Combination I: Constant load + Vehicle ;

Combination II: Constant load + Vehicle +other variable load;

Combination III: Constant load +trailers

3 Finite Element Model

The whole bridge was divided into 143 Nodes and 117 Space beam elements in MIDAS. Boundary conditions were simulated towards actual structure situation.

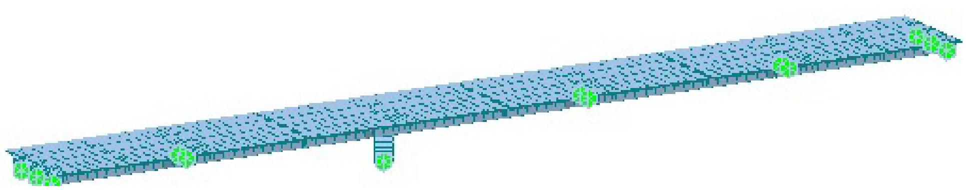


Fig.4 Finite Element Model

In order to analysis the feasibility of widen methods at the same time provide data support for splicing mode, different load combinations as well as their normal and limit state were analyzed(ZHANG Lifang, 2001), deformation value on the vertical direction at joints of bridges were calculated.

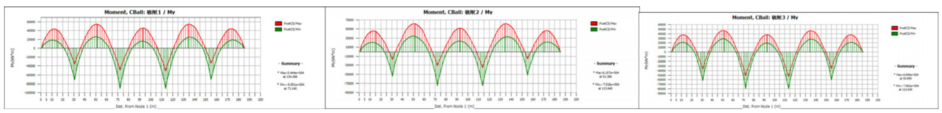
Boundary conditions: Vertical deformation was 0 at the piers, the other boundary are all free.

4 Calculation Results

4.1 Bearing capacity

(1) Limit state

Calculation results of bending moment after widen under limit state were shown in Fig. 5 and Table.1.



I II III

Fig.5 Envelope diagram of bending moment

II	7.197	6.132	21	OK	-0.844	0.077	2.7	OK
III	5.795	5.87	21	OK	-0.053	-0.569	2.7	OK

Table 3. calculation result of principal stress

Type	principle shear compressive stress (MPa)			principle shear tensile stress (MPa)		
	Calculation results	standard value	content or not	Calculation results	standard value	content or not
I	6.462	21	OK	2.422	2.4	NO
II	7.323	22.75	OK	2.598	2.7	OK
III	6.096	22.75	OK	2.39	2.7	OK

(3) Result Analysis

Calculation result showed that all the index content standard value except for that of principle shear tensile stress of Combination I, which proved that the widening methods were feasible.

4.2 vertical deformation after widen

Since deflection of the bridge was basically stable when expansion joint was installed, only vertical displacement at the flange plate of both sides of expansion joint under vehicle load was taken into account(WANG Zonghua,2009; LIN Jing, LIN Guohui,etc,2011; ZOU Zhiping, ZHU Runtian,2013), which was able to provide data support for splicing plan. Calculating result were showed in Table.4, Table.5 and Table.6.

(1) deflection of （30.676+41.5+41.5+43.5+28.676）m continuous box girder in G45under Vehicle load was showed in table 4.

Table 4. Deflection of mid-span in old bridge under vehicle load

Deflection results of mid-span (mm)				
First span	Second span	Third span	Fourth span	Fifth span
-2.94	-5.17	-5.37	-5.41	-2.98

(2) Deformation value of flange plate from inbuilt bridge under vehicle load was 0.68mm.

(3) Deflection of widen bridge under vehicle load

Deflection of (40+40.352+35.5+30) m continuous box girder from right range of widen bridge under vehicle load was showed in table 5.

Table 5. Deflection of mid-span (right) under vehicle load

Deflection results of mid-span (mm)			
First span	Second span	Second span	Second span
−10. 5	−9. 9	−11. 8	−5. 3

Deflection of (40+42+40.352+35.5+30) m continuous box girder from left range of widen bridge under vehicle load was showed in table 6.

Table 6. Deflection of mid-span (left) under vehicle load

Deflection results of mid-span (mm)				
First span	Second span	Third span	Fourth span	Fifth span
−8. 1	−6. 3	−6. 2	−4. 2	−3. 2

(4)As cantilever of flange plate from widen bridge was only 0.75m long under vehicle load that could be neglected.

4.3 Summary

As cantilever of flange plate from widen bridge under vehicle load was so tiny that could be neglected, the maximum vertical displacement of both sides of expansion joint was 11.8+0.68=12.5mm,which meant that expansion joint that could afford 20mm of vertical displacement was optional.

5 Linking measures of vertical expansion joint between the bridges

Based on the experiences(MA Chunsheng, SONG Shenyou,2003), three kinds of expansion joint-which was made of TST elastic broken stone, seamless polymer elastomer and section steel-were chosen in comparison mainly on the aspect of construction difficulties, construction cost and durability. Detailed comparison of upper three kinds of expansion joint on relate aspects were showed in table 7:

Table.7 Comparison of expansion joint

	TST elastic broken stone(asphalt stuff)	Seamless polymeric elastomer Joints	Steel joints
Construction difficulty	technical maturity, convenient construction	technical maturity, convenient construction	technical maturity, convenient construction and higher installation requirement
cost	low （RMB800.00/m）	high （RMB1600.00/m）	moderate （RMB1200.00/m）
performance	Smooth, comfortable	Smooth, comfortable	noisy and low driving comfort because of visible joint
durability	poor fatigue resistance, dustproofing and waterproofing, short life	High fatigue resistance, dustproofing and waterproofing, long life	General fatigue resistance, dustproofing and waterproofing, long life
maintenance	low difficulty but high frequency of replacement, low maintenance cost	low difficulty and frequency of replacement, high maintenance cost	high difficulty but low frequency of replacement, moderate maintenance cost
operation safety	less security threat in virtue of seamless and modified asphalt stuff	less security threat in virtue of seamless and polymer elastomer-polyurethane stuff	more security threat in virtue of visible joint, exposed section steel and cast-in-situ concrete

Though TST elastic broken stone joints had less security threat and low cost, its poor performance of waterproofing and anti-cracking as well as short life span-which was only about two years-lead to regularly maintenance that road traffic was affected. The third one had high technical maturity and long life span, of which it was widely used. However, its strict installation requirement and high difficulty of replacement that brought about more security threat, which did great harm to highway safety. The second one had the highest cost, notwithstanding. Firstly, it had longer life span compared with the first one; secondary, driving become smoother and more comfortable compared with the third one due to no visible joint; what's more, for its low difficulty of installation, replacement as well as designation of joint width and thickness according to deformation, it had great advantages towards the other two kind. So the second one was recommended for designation of connection scheme for the new and the old bridge.

6 Conclusions and suggestions

(1)Results of numerical analysis of working condition corresponding to different load combinations under limit state and normal state proved that widening methods, by which cantilever sections of beam was cut off about 50cm,lateral bump wall was replaced by corrugated guardrails for balance, was feasible.

(2) Analyzed results shown that maximum vertical deformation of using emerged bridge was 20cm, providing data support for selection of expansion device.

(3)By detailed comparison of upper three kinds of expansion joint on relate aspects such as construction difficulty, cost, performance, durability etc., combined with upper analyzed results, expansion made of seamless polymer elastomer was recommended for connection scheme.

(4)Since expansion joint made of seamless polymer elastomer was applied few at home, it was advisable to strengthen construction management for quality ensuring while keep an eye on the service situation during operation, which was of great help to accumulate experience for using.

A Decision-Making Sequencing Model of a Mixed-Model Assembly Line Considering the Leveling of Material and Assembly Switch Cost

Shuling Long; Baofeng Sun; Zhaoyu Lu; and Shoulong Zhang

College of Traffic, Jilin University, Renmin St., Changchun, Jilin 5988, P.R. China. E-mail: sunbf@jlu.edu.cn

Abstract: Sequence model is one of the most important decision of production plan and control for mixed-model assembly line. This paper firstly according to customs' demand and lead time divides the products into four categories: core strategic products I, customer-oriented products II, time-oriented products III, ordinary products IV. And then two principles (customers' demand and material balance) are proposed for every category of product. By using the principle of MPS, two-objective with minimum variations of part usage rate and minimum assembly switch cost sequencing model is given. Finally, the optimal solution set of every categories in a MPS are solved with genetic algorithm (GA), so that decision-making method is clear offered on mixed-model assembly line sequencing problem when with different preference and in structure characteristics of demand. The results show that two-objectives sequencing model above outperforms good shown as four parameters with work-in-process inventory, rate of material balance, assembly switch cost, lead time, etc.

Keywords: Mixed-model assembly line; Sequencing; Material balance; Assembly switch cost.

1 Introduction

To adapt the variation of customer demand, Mass customization gradually replaced the Make-to-Stock mode, and Assembly line also changed from single into mixed. Mixed-Model Assembly Line (MMAL) is known to be a special case of production lines where various and different models of the same product are inter-mixed to be assembled on the same line (Monden, 1983). So, MMAL improve enterprises' ability to response the market changing, and realize the production target: Just-in-Time。

Mixed-model assembly line with multi-product and small batch is of operation characteristics as below: small quantities, complex manufacturing process, high conversion frequency, high-flexibility of the production plan, etc. Sequence model is the one of most important decision of production plan and control for this kind of assembly line. Production plan is influenced by those factors: customer demand changes, material supply reliability, capacity balancing, load balancing of assembly line etc. Sequencing method and model are very important decisions of production planning and control of MMAL.

By existed method of sequencing, major customer demand are given priority to sequencing, then other customs' orders are inserted randomly if there is still spare capacity. This method is conclude the rule of material balance, thereby causes many problems: hardly to implement production plan, inventory excess coexisted with shortage, high assembly switch cost, unguaranteed delivery date and so on.

2 Research Status

Since 1961, Kilbridge and Wester put forward the concept and types of mixed-model assembly line, they began study sequencing problem of MMAL as early as 1963.Sequencing problem firstly need to determine the decision-objective. Monden(1983) defined two goals for the sequencing problem, after then, decision-making target changed at any time. Just like the study of Miltenburg(1990)、Sumichrast(1992)、McMullen（2000). Multi-objective (such as constant rate of usage of resources, maximum efficiency, minimum cost) envoled from single objective.

Some scholars converted above-mentioned goals into other quantifiable objective functions. Bard(1994) developed a model involving two objectives. Chul(1998) addressed three objectives minimizing total utility work, keeping a constant rate of part usage, and minimizing total setup cost. The scholar Yi Dongbo(2003) solved a double- objectives model by Toyota Goal Chasing Algorithm(GCA).Zhang Pengjun(2009) established multi-objective mathematical model considering two objectives: minimize the workstation overload time and idle time, minimize the production cycle.

Leveling of Material derived from Monden(1983),it present as the rate of usage of material, which means the ingredients of production line maintain systematic equilibrium, not only volume of production, but also variety, working time and production load. Song Huaming (2002) discussed the problem of material flow leveling in terms of supply chain, and applied SAA to solve the problem. Liu Wenping(2004) minimizing material consumption variation, switch time incurred by adjustment for model changing, utility work necessitated by overload of workstations, and total assembly cost are formulated. Yang Lin(2013) compared two single objectives: material consumption and the optimization of production time. As a result, GA were proved to be effective in solving sequencing problems.

Mixed-model assembly line sequencing problems have been proved to be a kind of NP-hard by many experts and scholars, besides the selection and optimization of decision-making objectives, they also actively explored in algorithm. There are three kinds of commonly used algorithms : optimal solution algorithm represented by branch and bound method, such as Zhao Xiaobo(1994); heuristic algorithm represented by GCA and variance algorithm, for instance, Yi Dongbo(2003),Jin MZ

& Wu SD(2003); loop improved algorithm including simulated annealing algorithm(SAA), genetic algorithm(GA), tabu search algorithm(TSA),such as Liu Zhaohui(2004) applied SAA in solving the sequencing problem, Mansouri(2005) solved the same problem with improved genetic algorithms，in which elite strategy and niche cubicle was introduced. Dong Jianhua(2003) used GA and hybrid genetic-tabu search algorithm(HGTSA) to solve the problem, result showed that HGTSA is better than GA in global search ability and convergence performance.

In conclusion，manufacturing enterprises should not only meet the customers demand of varieties, quantity, and leading time, but also the improve the internal performance of MMAL.As customization becoming more popular, the leveling of material still has some room for improvement on production plan and control, meanwhile, the influence of switch cost are more sensitive to enterprises benefits. This article divides the products into four categories in chapter 3.And then in chapter 4, two principles (customers' demand and material balance) are proposed for every category of product. By using the principle of Minimal Production Set (MPS), two--objective with minimum variations of part usage rate and minimum assembly switch cost sequencing model is given. The optimal solution set of every categories in a MPS are solved with genetic algorithm (GA). Finally, evaluate the effect of sequencing model proposed before by observing index, which can offer valuable references for determining the ultimate optimal sequencing solution.

3 Products Classification

If it is multi-item small sized production, sequencing of MMAL need to strike a balance between customer requirements and enterprise capacity, Not only the importance of big customer (high demand) and small customer(small demand) , and lead time, but also capacity matching relationship and constraints of material supply.

According to customs' demand and lead time, we divides the products into four categories: core strategic products I, customer-oriented products II, time-oriented products III, ordinary products IV, as shown in figure 1 .

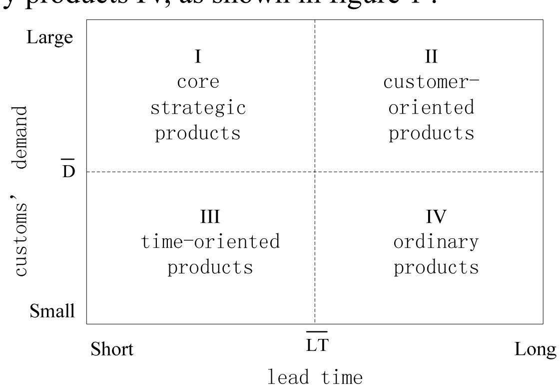

Figure 1. Four categories products

Total customer demand $\overline{D}$, average of maximum and minimum lead time $\overline{LT}$, are the fundamental basis of dividing categories, which need to determined by the actual situation of production line. The details of four categories products as below: Core strategic products (CSP) I: $\mathrm{D} > \overline{\mathrm{D}}$, and $\mathrm{LT} < \overline{\mathrm{LT}}$; Customer-oriented products (COP) II: $\mathrm{D} > \overline{\mathrm{D}}$, and $\mathrm{LT} > \overline{\mathrm{LT}}$;Time-oriented products (TOP) III: $\mathrm{D} < \overline{\mathrm{D}}$, and $\mathrm{LT} < \overline{\mathrm{LT}}$;Ordinary products (OP) IV: $\mathrm{D} < \overline{\mathrm{D}}$, and $\mathrm{LT} > \overline{\mathrm{LT}}$.

The purpose is managing the important products. Therefore, we develop sequencing solutions of I, II, III, IV one by one. It should be pointed out that, in practice, category II and category III are difficult to determine which one should firstly be sequenced, we usually determine it by actual situation with the aid of other indicators.

4 Decision-making Sequencing Model with Two Objectives

Sequencing of MMAL is based on four categories products, solve this problem of every category, two-objective sequencing model is given, namely, The objective function F_1, minimum variations of part usage rate, and objective function F_2, minimum assembly switch cost.

Specifically, we determine production structure by using the principle of Minimal Production Set (MPS), and solve sequencing problem with genetic algorithm (GA) . Sequencing solutions of every category are S_I、S_{II}、S_{III}、S_{IV}.

The superiority of MPS is embodied in determining the production structure of every category quickly, by determining the minimum cycle, finally realize the equalization and synchronization in mixed-model assembly line.

MPS is a vector representing a product mix, such that $(b_1, b_2, \ldots, b_m)$=$(B_1/\omega, B_2/\omega, \ldots, B_m/\omega)$; where m is the total number of product series, B_m is the number of products of series type m that need to be assembled during the entire planning horizon, and ω is the greatest common divisor of $B_1, B_2, \ldots, B_m$. This strategy operates in a cyclical manner. Obviously, ω times the repetition of producing the MPS products can meet the total demand in the planning horizon.

Decision-making sequencing model with two objectives in this paper are as follows:

F_1: Minimum variations of part usage rate. That is to say, at any stage in the production, no matter what the value of k is, the variance of ideal consumption and actual consumption of material is minimal.

F_2: Minimum assembly switch cost. Namely, Multiply switching frequency of different series by single switch cost get F_2.

$$F_1 = min \sum_{h=1}^{r} \sum_{k=1}^{E} (I'_{kh} - I_{kh})^2 \tag{1}$$

$$F_2 = min \sum_{k=1}^{E} \sum_{j=1}^{m} \partial_{jk} C \tag{2}$$

$$I'_{kh} = kN_h/E \tag{3}$$

$$I_{kh} = \sum_{j=1}^{m} n_{jh} * \partial_{jk} \tag{4}$$

$$N_h = \sum_{j=1}^{m} n_{jh} b_j \tag{5}$$

$S.T.$

$$\sum_{j=1}^{m} \partial_{jk} = 1 \tag{6}$$

$$\sum_{k=1}^{E} \partial_{jk} = b_j \tag{7}$$

$$\sum_{j=1}^{m} \partial_{jk} = \sum_{x=1}^{m} \partial_{x(k+1)} \quad k = 1，\cdots\cdots，E-1 \tag{8}$$

$$\sum_{j=1}^{m} \partial_{Ej} = \sum_{x=1}^{m} \partial_{1x} \tag{9}$$

Constraints as follows：

(1) Position constraints: Equation (6) ensures that exactly one product is assigned to each position in a sequence. Equations (8) and (9) ensure that the sequence of products be maintained while repeating the cyclic production.

(2) Demand constraints: Equation (7) guarantees that demand for each series is satisfied.

The parameters of above models and constraints are as follows:

i， the serial number of enterprise's customers, i =1,2,…,n

j， the serial number of the products series, j=1,2,…,m

h， the serial number of varieties of parts, h =1,2,…,r

k， the serial number of production sequencing, k=1,2,…,E

d_{ij}， the demand of m series products of ith customer

D， total demand of m series products

E， in a MPS, the demand of m series products

B_j， the demand of jth series products

b_j， $b_j = B_j/\omega$, in a MPS, the demand of *j*th series products

ω， the greatest common divisor of $B_1, B_2, \ldots, B_m$

n_{jh}， the demand of *h*th parts of *j* series products, n_{jh} is a matrix

N_{h}， the total demand of *h*th parts of *m* series products

∂_{jk}， $\partial_{jk} = 1$， indicate that the *k*th product in a sequence is series *j*; Otherwise, $\partial_{jk} = 0$.

I_{kh}， the actual consumption of *h*th parts after finish the *k*th product

I'_{kh}， the ideal consumption of *h*th parts after finish the *k*th product

C， the switch cost required when series type is changed (Constant)

5 Solution and Results

5.1 Basic Data

The research object of this example is a mixed-model assembly line system of a production enterprise Z in Changchun. This system's production organization pattern is Pull Production. That is to say, monthly production plan is made by customers' monthly order. We assume that takt time and workstations in MMAL are known, four customers A, B, C, D of enterprise need 10000 products which contains four series. Classification based on demand is as shown in Table 1. According to the classification standard in figure 1. we present the demand of every category in Table 2, which devotes B_j of formula(2).

Table 1. The demand for each series of products of each customer

Series / Customer	Lead time	A		B		C		D		sum
Customer1	short	500	300	2500	2000	1000	700	1000	600	5000
	long		200		500		300		700	
Customer2	short	300	200	800	500	500	300	1000	400	2600
	long		100		300		200		300	
Customer3	short	100	50	400	200	300	200	500	300	1300
	long		50		200		100		200	
Customer4	short	100	50	300	200	200	100	500	300	1100

sum		1000		4000		2000		3000		10000

Table 2. The demand of category I to IV, B_j

Series / Category	A	B	C	D	Sum
I CSP	500	2500	1000	1000	5000
II COP	300	800	500	1000	2600
III TOP	100	400	300	600	1400
IV OP	100	300	200	400	1000
Sum	1000	4000	2000	3000	10000

Core components of one product include 11 kinds. The specific demand for all kinds of parts of series A-D product is shown in Table 3., which is the matrix n_{jh}(4*11) in section 4.1, as basis data of MMAL.

Table 3. The demand of components of one product

Series	Quantity	The demand of components										
		n_1	n_2	n_3	n_4	n_5	n_6	n_7	n_8	n_9	n_{10}	n_{11}
A	1	1	1	2	2	2	2	2	2	2	2	1
B	1	1	1	2	0	0	2	2	0	0	2	1
C	1	1	1	2	0	0	2	2	0	0	2	1
D	1	1	1	2	0	0	2	2	0	0	2	1

5.2 Computed Result

Chul(1998), Mansouri(2005), Dong Jianhua(2003), Cao Zhenxin (2005)etc. are using Genetic Algorithm(GA) to solve sequencing problem of MMAL. To solve the above examples, MATLAB 2013a is used to write code to get the model solution, the result show as below.

(1)Situation 1 ： before subdivision

Input the total demand of A, B, C, D series products before subdivided, is $B_1 = 1000$，$B_2 = 4000$，$B_3 = 2000$，$B_4 = 3000$。Run at least 300 times, choose 10 group single optimal solutions, whose $F_2 < 30000$, we get suboptimal solution set S={S_1，S_2，…，S_{10}} of sequencing, just as Table 4.

Table 3. Sequencing solutions before subdivision

Number	Sequencing solutions S	Objective function	
		F_1	F_2
1	Solution =1 2 2 2 2 3 3 4 4 4	2430.4	4500
2	Solution =1 2 2 3 3 2 2 4 4 4	2278.4	6000
3	Solution =1 2 2 2 3 2 3 4 4 4	2316.4	7500
4	Solution =1 2 2 2 3 2 4 3 4 4	2354.4	9000
5	Solution =1 2 2 2 2 3 3 4 4 4	2278.4	10500

6	Solution =1 2 2 2 2 3 4 3 4 4	2316.4	12000
7	Solution =1 3 2 2 2 2 3 4 4 4	2430.4	13500
8	Solution =1 2 2 2 2 4 3 4 4 3	2430.4	15000
9	Solution =1 2 2 2 3 2 4 3 4 4	2354.4	16500
10	Solution =1 2 2 2 2 3 4 4 4 3	2392.4	18000

(2)Situation 1 ： after subdivision

Input four row data of Table 2. successively. We get suboptimal solution sets of four categories are SI={S_{I1}, S_{I2}, …S_{I10}}, SII={ S_{II1}， S_{II2}, ……, S_{II10}}, SIII={ S_{III1}, S_{III2}， ……， S_{III10}}， SIV={ S_{IV1}， S_{IV2}， ……， S_{IV10}}， as Table 5-8.

Table 5. Sequencing solutions of I category product S_I

5.3 Observing Index

(1)Equipment Activation α

Divide the actual operation time by schedule time, and we get equipment activation α, to measure work time utilization. The higher α is, the greater the efficiency of equipment operation are.

$$\alpha = \frac{T-t}{T} = \frac{T-\frac{F_2}{C}\times\omega}{T} = \frac{CT*M}{T} \quad (10)$$

α——Equipment activation.

T——Schedule time. It refers to working time that except the interval, break, and extra work time.

t——Unplanned stoppage time. It is caused by equipment failure, switching operations, and abnormal personnel & materials. In this article, we only consider line stoppage time caused by switching operation, and ignore the rest of the reasons.

CT——Production takt.

M——The total output within schedule time.

(2)Production Capacity Rate β

Production capacity rate is calculated with the ratio of ideal working time and actual operation time, or refers to the operating personnel's capacity in the actual operation time. It is used to measure the time efficiency in operation time, the greater, the better.

$$\beta = \frac{\text{ideal working time}}{\text{actual operation time}}\times 100\% = \frac{CT\times D}{T-\frac{F_2}{C}\times\omega}\times 100\% \quad (11)$$

D——total demand of products.

(3)Leveling Exponent of Material Consumption γ

γ is an index that can measure discrete degree of material consumption in assembly line. The less the value, the better the sequencing solution.

$$\gamma = \sqrt{\frac{\sum_{h=1}^{r}\sum_{k=1}^{E}(I'_{kh}-I_{kh})^2}{E}} = \sqrt{\frac{F_1}{E}} \quad (12)$$

(4) Order Fill Rate б

Order Fill Rate is equal to the ratio of actual finished product and product demand, б expressed as follow.

$$\delta = \frac{\varphi b_j}{B_j} \quad (13)$$

φ——the times that have cycled.

5.4 Example Analysis

This example apply the decision-making sequencing model established before, and get suboptimal solution set with GA, then determine the best sequencing solution by calculate the above indexes and evaluate the effect.

According to section 6.2, two situations' indexes are shown in Table 9. and Table 10. We compare them in following paragraphs.

Table 9. The value of objective function & observing index in situation 1

Sequencing solutions S										ω	Objective function		Observing index		
											F_1	F_2	α	β	γ
1	2	2	2	2	3	3	4	4	4	500	2430.4	4500	93.06%	74.63%	15.59
1	2	2	3	3	2	2	4	4	4		2278.4	6000	90.74%	76.53%	15.09

Table 10. The value of objective function & observing index in situation 2

Sequencing solutions S'								Objective function		Observing index		
I 类		II 类		III 类		IV 类		F_1'	F_2'	α'	β'	γ'
S_I	ω	S_{II}	ω	S_{III}	ω	S_{IV}	ω					
S_{I1}	500	S_{II1}	100	S_{III1}	100	S_{IV1}	100	10182.52	4350	93.29%	74.44%	14.27
S_{I2}		S_{II2}		S_{III2}		S_{IV2}		10357.15	5700	91.20%	76.14%	14.39
S_{I3}		S_{II3}		S_{III3}		S_{IV3}		10283.38	6900	89.35%	77.72%	14.34
S_{I4}		S_{II4}		S_{III4}		S_{IV4}		10404.36	8100	87.50%	79.37%	14.43
S_{I5}		S_{II5}		S_{III5}		S_{IV5}		10492.36	9300	85.65%	81.08%	14.49
S_{I6}		S_{II6}		S_{III6}		S_{IV6}		10385.75	10500	83.80%	82.87%	14.41
S_{I7}		S_{II7}		S_{III7}		S_{IV7}		10350.28	11700	81.94%	84.75%	14.39
S_{I8}		S_{II8}		S_{III8}		S_{IV8}		10409.41	12900	80.09%	86.71%	14.43
S_{I9}		S_{II9}		S_{III9}		S_{IV9}		10333.61	14100	78.24%	88.76%	14.38
S_{I10}		S_{II10}		S_{III10}		S_{IV10}		10467.53	15300	76.39%	90.91%	14.47

S of situation 1 and S' of situation 2 represent different sequencing solutions. For the purposes of drawing expression, we set the number of S and S' as abscissa. Here is the trend graph on observing index α, β, γ (Figure 3).

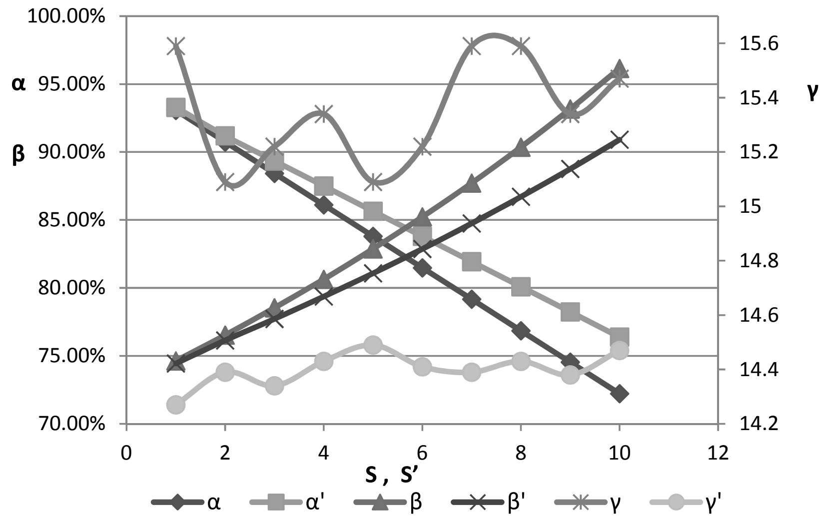

Figure 3. The trend graph on observing index α, β, γ

(1) Equipment Activation α' > α, α of situation 2 after subdivision is more than situation 1, so time utilization and equipment operation efficiency of situation 2 are higher, gross production is more.

(2) Production Capacity Rate β' < β, in the view of β, situation 2 reduce the production capacity rate of assembly line, situation 1 is better.

(3) Leveling Exponent of Material Consumption γ' < γ, γ in two situations both undulate slightly, and meet the demand of the leveling of material. But in comparison, γ of situation 2 is smaller, so we can see by this index that sequencing solutions of situation 2 is superior to situation 1.

(4) For category I product, order fill rate б of different series product are presented in Table 11.

Table 11. Order fill rate б of different series product of category I

the times that have cycled	Situation 1 δ				Situation 2 δ'			
φ	A1	B1	C1	D1	A2	B2	C2	D2
50	10%	8%	10%	15%	10%	10%	10%	10%
100	20%	16%	20%	30%	20%	20%	20%	20%
150	30%	24%	30%	45%	30%	30%	30%	30%
200	40%	32%	40%	60%	40%	40%	40%	40%
250	50%	40%	50%	75%	50%	50%	50%	50%
300	60%	48%	60%	90%	60%	60%	60%	60%
350	70%	56%	70%	105%	70%	70%	70%	70%
400	80%	64%	80%	120%	80%	80%	80%	80%
450	90%	72%	90%	135%	90%	90%	90%	90%
500	100%	80%	100%	150%	100%	100%	100%	100%

After cycled 500 times, order fill rate б of two series product A, C are constant.For instance, in situation 2, after repeating a MPS 500 times, б of series products A, B, C, D are all 100%; however in situation 1, series B is 80%, though series D also meet the demand, it's output beyond 50% than actual demand. So, from the analysis of order fill rate, situation 2 is better than situation 1.

6 Conclusion

In this paper, we sovle the sequencing problem of mixed-model assembly line, two principles (customers' demand and material balance) are proposed for every category of product. And according to customs' importance degree and lead time , we divides the products into four categories. By using the principle of Minimal Production Set (MPS), two--objective with minimum variations of part usage rate and minimum assembly switch cost sequencing model is given. Then get the solution sets of subdivided and un-subdivided, finally, establish the evaluation index system, in order to evaluate the proposed decision-making model, and provide a reference basis for determining the optimal sequencing solution.

(1) Product category reflect the requests of customer order quantity and lead time. Subdivision of series product has remarkable effect for both external demand and internal balance on assembly line. After subdividing product, situation 2 have an advantage over situation 1 considering three indicators α, γ, б.

(2) On the basis of ensuring leveling of material, organizing products' variety, quantity reasonably, can eliminate the workstations' "logistics bottleneck", keep lower work in process(WIP) inventory, and realize smoothly and timely material supply at the assembly line, make product, time, quality, equipment load become comprehensive balanced.

(3) Minimum assembly switch cost is the goal, at the same time, we ensure a constant rate of material consumption, total assembly switch cost of situation 2 decrease an average of 9.5% than situation 1. obviously, it not only reduce the switch time between series, but also improve the efficiency of assembly line, thus the total cost become lower.

(4) How to use suboptimal solution set to determine the optimal sequencing solution. On the one hand, after solving the mathematical model, we choose it with the aid of the system output index of MMAL; on the other hand, we can design indexes on four aspects: equipment efficiency, output capacity, leveling of material, and customer satisfaction, to determine the optimal sequencing solution that meeting demand of operation characteristics of MMAL.

Abstract: Activity-based travel demand forecasting has got great concern in the past decade. In this paper, a nonparametric regression method is presented which can model travel durations by identifying heterogeneity patters that may undermine duration modeling if not detected. The technique utilizes a kernel estimate of the probability density function (PDF) of daily travel durations to compare different activity pattern. The advantage of this method is that it's free of any distributional assumption. The results show that the more complex activity pattern, time spent in travel is more. And it is also found that the distribution of travel duration for the standard-working group and the long-term maintenance group cannot be modeled by a linear or a linearized function. It is indicated that the approach is effective in evaluating covariate effects.
Keywords: Activity; Kernel estimate; Nonparametric regression; Travel duration.

1 Introduction

Activity-based travel demand forecasting approaches have been proposed as an effective method in travel behavior analysis because of their ability to model the derived nature of travel demand (Kuppam and Pendyala, 2001). The timing of activities and travel is an important aspect of activity-travel behavior. Hence, models of activity and/or travel timing are at the core of several activity-based systems that are designed for travel forecasting and evaluating travel demand management policies. The point of activity-based models is to analyzing the activity participation behavior of individuals or households so that travel demand can be predicted. Activity models can be classified into two classes, utility maximization based and micro-simulating method, while the former is complex to find solutions especially when there are many choice branches. Because of improved investigation technology and statistic methodology, simulating activity with probability distribution is more attractive and feasible.

Two broad categories of activity-based travel timing models are simultaneous regression-based models and hazard duration based models (Srinivasan and Guo, 2003). Histogram density estimator and parametric regression are most used methods to simulate the activity pattern. But histogram method is not possible to estimate the probability of unobserved data. The relationship between the dependent variable and its covariates should be pre-assumed to be either linear or a form that may be linearization. Certain distribution features, such as bimodality often cannot be modeled by a theoretical distribution. But the nonparametric approach can leave functional form and distributional assumptions unspecified. And nonparametric density estimation seeks to allow the data to stand on its own by using alternative methods to determine the form of the density function. The major nonparametric approach is the kernel density estimator (KDE).

This paper is to apply nonparametric techniques to model activity pattern and at the same time able to describe the data well. Previous applications of nonparametric techniques in transport contexts include using nonparametrics to specify a model to measure the value of time and using semiparametric to estimate a work trip mode choice model (Fosgerau, 2007; Horowitz, 1993). Relationships between travel time and activity duration are investigated by the bi-variate KDE using travel diary survey data in Seoul, Korea (BAE et al., 2010). A particular strength of some of these techniques is that they allow one to visually inspect various distributions and relationships prior to the imposition of any specific functional form. This paper uses this approach to study the various activity durations distributions of full-time commuters segmented into five individual groups.

2 A Review of Non-Parametric Kernel Density Estimation

2.1 Kernel density estimator (KDE)

The KDE is a completely nonparametric approach for estimating the density function of a continuous random variable. Let $X_i(i=1, 2, \ldots, n)$ denote n independent, identically distributed observations of the random variable X. The PDF for X can be defined as

$$f(x) = \lim_{h\to 0} \frac{\Pr\{x-h < X < x+h\}}{2h}. \tag{1}$$

An approximation for the density function given above may be attained by allowing h to be very small and using the relative frequency proportion at this particular point's neighborhood. A kernel K which is a general function used to weight observations and a bandwidth h which determines the size of the average neighborhood are used here to define the neighborhood. Now by summing the "influence" of each observation placed a kernel, the kernel estimate is defined as

$$\hat{f}(x) = \frac{1}{nh}\sum_{i=1}^{n} K(\frac{x-X_i}{h}). \tag{2}$$

In contrast to the histogram estimator which requires specification of the origin and bin width, the kernel density estimate requires only specification of the bandwidth, h (Kharoufeh and Goulias, 2002).

2.2 Bandwidth selection

The choice of kernel is generally less important as results will not be much affected. Selecting an appropriate bandwidth is, however, an important issue with no easy solution. If the bandwidth is too large then it is over-smoothing. Too much detail disappears and there will be bias. If the bandwidth is too small, then there will be under-smoothing: that is, over-fitting to random fluctuations in data. Thus the choice of bandwidth is about balancing the trade-off between bias and variance. A significant part of the nonparametric literature is devoted to the issue of bandwidth selection but without any single method emerging as a clear winner. More automatic approach is to use cross-validation (Ye, 2003). This is performed using the estimated prediction error $EPE(h) = N^{-1}\sum_n (y_n - m_n(x_n, h))^2$, where the estimate $m_n(x_n, h)$ is computed with bandwidth *h*, unconsidering *n*'th observation. A bandwidth can then be selected by minimizing *EPE*(*h*).

Another approach is to determine an optimal bandwidth from convergence properties of the estimator. This approach relates the bandwidth to the sample size. Thus according to the most used Gaussian kernel which is given by

$$K(t) = (2\pi)^{-1/2} \exp\{-t^2/2\}, \quad -\infty \le t \le \infty, \tag{3}$$

its optimal bandwidth was found to be proportional to $n^{-1/5}$. It will be used throughout this work because it is a unimodal, symmetric distribution, which allows for automatic selection of the smoothing parameter.

3 The activity duration problem

It has been increasingly realized that travel is a derived demand determined by the way how individuals and households organize their time and when and where they go and which travel modes they will use. Past years travel behavior analysis has evolved from being trip-based to activity-based. Researchers have paid considerable attention to the notion of time use while they believe that understanding the mechanisms of activity choice and time allocation will lead to increase reliability in forecasting travel demand and evaluating transportation planning options. Previous theoretical studies emphasized the importance of activity duration as a determinant of activity patterns by suggesting that the value of an activity is positively correlated with the frequency of participation and its duration (Sharman et al., 2012). So activity duration can describe the "intensity" of participation in different activities. That is the reason why activity duration should be measured to find commonalities across various groups of individuals.

The standard activity duration analysis is to use parametric hazard-based models because it regards the duration dependence which means the time at which an activity will be completed depends on the time already spent in the activity (Srinivasan et al., 2003). The hazard function essentially describes the probability that an event will terminate given that it has lasted until time *t*. The hazard function also called failure rate is denoted by $h(t)$ and calculated from

$$h(t) = f(t) \big/ \big(1 - F(t)\big), \tag{4}$$

as $f(t)$ represents the probability density function of a duration, and $F(t)$ represents the corresponding cumulative distribution function. Many existing duration model applications are based on the assumption of proportional hazard functions as follows:

$$h(t) = h_0(t)\exp(-\beta' X + w), \tag{5}$$

where $h_0(t)$ denotes the baseline hazard function, β the vector of parameters to be estimated, X the covariate vector and w represents heterogeneity of individuals. In this approach, it is assumed that hazard rates vary systematically across individuals. The effect of these covariates is modeled by scaling the baseline hazard rate up or down by a multiplicative factor (Srinivasan et al., 2003). Consequently, all individuals have the same hazard situation, although the intensity of hazard function can vary. So it is necessary to propose a more suitable method to describe the distribution of baseline hazard function and take consider of the unobserved heterogeneity.

Define T_{ij} as the continuous random variable denoting the amount of time that individuals in the group $j \in J$ spend on activity $i \in I$. We seek to estimate the probability distribution of T_{ij}. Kernel density estimate of the true pdf for T_{ij} is denoted by $\hat{f}_{ij}$, so the density estimate is given by

$$\hat{f}_{ij}(t) = \frac{1}{n_{ij}h_{ij}} \sum_{k=1}^{n_{ij}} K\left(\frac{t - T_{ijk}}{h_{ij}}\right) \tag{6}$$

where n_{ij} is the number of independent, identically distributed observations for T_{ij}, h_{ij} is the optimal smoothing parameter and T_{ijk} is the kth duration observation for an individual in group j participating in activity i.

Although activity duration times are naturally continuous random variables, we choose to estimate their distributions by discrete approximations. One reason is that in practice we need to obtain the estimation of the density over a finite grid of points to achieve this visualization. Another reason is that most activity duration times are reported in multiples of 5 min. And people in the survey also are intuitive to approximate the times as such. Let $Q_{ij} = \{t : t = 5k, k = 0, 1, \cdots, M\}$ be a finite support for the distribution of T_{ij}, where M is a positive integer chosen large enough so as to contain the sample space of the random variable. Using the kernel density estimates by Eq.(4), a probability mass may be calculated for each $t \in Q_{ij}$. Let $p_{ij}(t)$ denotes the probability given by

$$p_{ij}(t) = pr\{T_{ij} = t\} = \delta^{-1}\hat{f}_{ij}(t), \tag{7}$$

where $\delta = \sum_{t \in Q_{ij}} \hat{f}_{ij}(t)$ normalizes the density so that the massed sum to unity over the finite support. In essence, Eq.(7) constructs a histogram estimator of the duration times in which each cell width is equal to zero. Jones (1989) demonstrates that even when the kernel estimate is discretized, the appropriate optimal bandwidth is still proportional to $n^{-1/5}$. Thus, the effect of discretization is minimal when we use the appropriate smoothing parameter.

4 Data and Results

Data used in this study to estimate the activity duration with nonparametric approach originated from the Shenyang city residents travel survey in 2004. As most travel surveys, the survey typically gathered information on the socio-economic and demographic characteristics of the commuters. The survey collected very detailed revealed preference information on all out-of-home and in-home activities over a 24-hour period. This type of intense data can be used as a basis for exploring trade-offs people may make various activities. Due to article length limitations, the main focus is the full-time commuters' travel duration characteristic of various activity.

With regard to demographic and socio-economic characteristics, the average household size of the sample is about 3.11 persons per household and the average age is close to 40-years-old. Based on a preliminary analysis of the distributions of various activity categories, segmentation of people to five mutually exclusive and exhaustive groups allows for a comparison of the estimated duration densities by means of goodness-of-fit tests. Those are standard-working group (denoted as Q1), high-intensity working group (Q2), low-intensity working group (Q3), short-term maintenance group (Q4) and long-term maintenance group (Q5) (Shao, 2006). The probability distribution of each group contains much more information about the behavior of the qualitative assessment of covariate effects and heterogeneity attained through the shape of the distributions. Table 1 shows the variables and grouping included in the study in addition to the number of individuals (n) in each group.

Table 1. Summary of full-time commuters' segmentation

Group	Description	n
Q1	Main activity is working; working time is less than 9 hours with only 1 travel for working.	8328
Q2	Main activity is working; working time is more than 9 hours with only 1 travel for working.	7916
Q3	Main activity is working; the frequency of travel for working is more than once.	2022
Q4	Main activity is entertainment or maintenance; out-of-home time is not more than 9 hours.	3440
Q5	Main activity is entertainment or maintenance; out-of-home time is more than 9 hours.	686

The data were not segmented and the nonparametric approach mentioned above was used to test for each of the five activity duration variables: subsistence, maintenance, entertainment, staying-at-home, and travel. Travel is the total time spent traveling for any reason during a day. Throughout this work, distribution functions were compared at 60 points (t=0, 5, 10,…300) for which the true distribution is approximated. The distribution of commuters' activity patterns by duration is shown in Table 2.

Table 2. Summary of activity and travel characteristics

Activity type	Average for entire sample (N=22392)	Non-zero observations
Subsistence	7 hr 35 min	17266
Maintenance	3 hr 24 min	4012
Entertainment	3 hr 31 min	3741
Staying-at-home	6 hr 15 min	21365
Travel	2 hr 23 min	20479

Fig. 1 provids sample PDFs generated by the kernel method for travel duration for various groups. Q2, Q3 and Q4 are similarities. Surprisingly, Q5 has the features of the bimodality. The results show that not all commute travels are taken by starting from home and arriving at office. The maintenance and entertainment activities may spend more time on traveling on road. It is important to improve the accessibility especially for the entertainment or leisure activities.

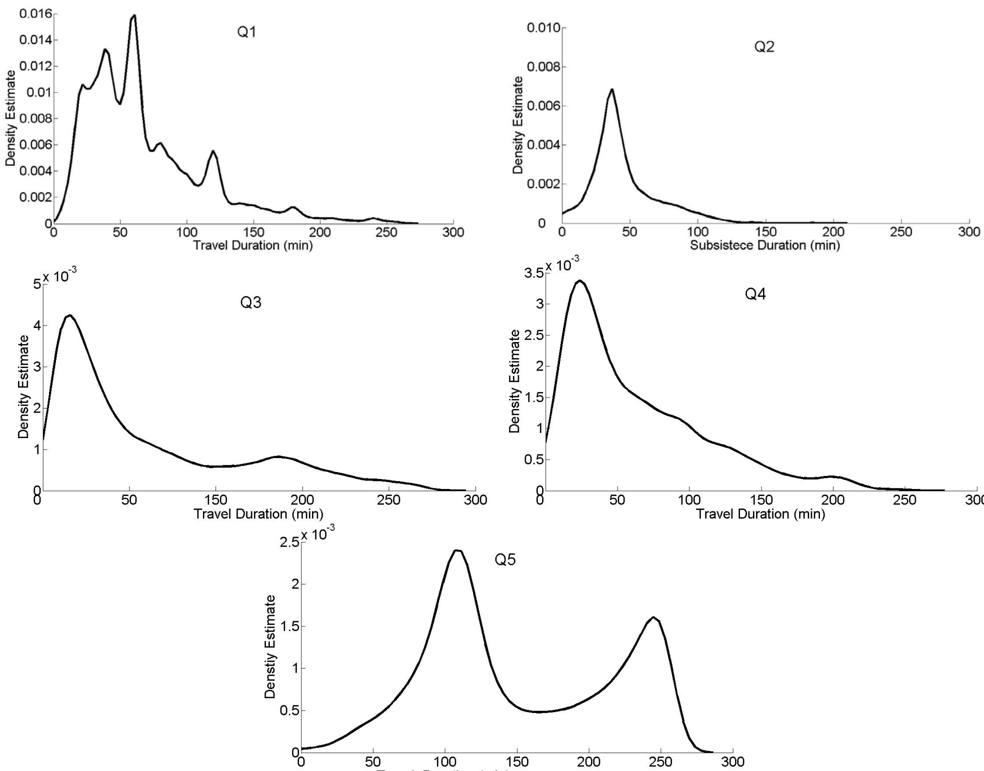

Figure 1. Sample travel density estimates for various groups.

5 Conclusions

This paper presents how to use a nonparametric pattern tool to investigate covariate effects and heterogeneity. A kernel estimate of the PDF is used and distribution functions of groups of individuals are compared. It is not necessary to make a presumption about the distribution of activity duration. And the kernel method is unaffected by potential bimodality in distributions. The kernel technique was tested on five activity durations and contributes to observe the relationship in behavioral visually. So this technique can be an alternative to regression models. This work can be extended in many potential research areas of activity-based travel demand forecasting.

Abstract: Taken Shenyang North subway station as an example, the simulation method of successive event was used to analyze the influence of traffic congestion in subway internal environment. First, the crowd evacuation simulation model in subway station was built. Second, the bottleneck positions and blocking reasons in the process of subway evacuation was analyzed based on the simulation model. At last, the potential safety hazard was eliminated by optimizing the service level and changing the number of service facilities, which can reduce travel time-cost to improve the service quality for passengers.
Keywords: The subway station; Crowd evacuation; The social force model; Pedestrian simulation.

1 Introduction

Subway station is a densely populated place especially at rush hour. Although the interior space of subway is bigger enough, it’s poor connectivity with outside. Particularly in case of an emergency, it’s easier to increase passengers’ psychological panic, which will lead to a large number of casualties and serious economic losses if there are no effective ways to evacuate the passenger flow.

Nowadays, some researchers have been achieved some remarkable results. Dikr Helbing’d (2000) quantified pedestrian behavior reaction into the social force, and reappeared the classic pedestrian evacuation behavior successfully, such as the group effect, he also had explained the phenomenon of "fast is slow" during evacuation. Carl Adam Petri (2000) put forward the concept of Petri nets, which can describe the system structure and the dynamic behavior of the system. American HCM (Fruin, 1985) mainly engaged in the pedestrian movement simulation and macro technology analysis of road capacity. Blue and Adler (1998) had established a series of cellular automaton traffic model. Wang Lida (2006) took Beijing subway line 2 as an example, had researched the aspect of evacuation system、evacuation bottlenecks and evacuation plans.

2 The Analysis of Passenger Flow Organization in Subway Station

2.1 Properties of subway passengers

Personnel evacuation behavior is a kind of group behaviors. Due to the restricted by environment, different positions of evacuation and interaction between individuals, there are many differences between individuals in crowd evacuation. Therefore, we need to separate crowd into independent individuals when building an evacuation model. Subway station passenger process diagram is shown in Figure 1.

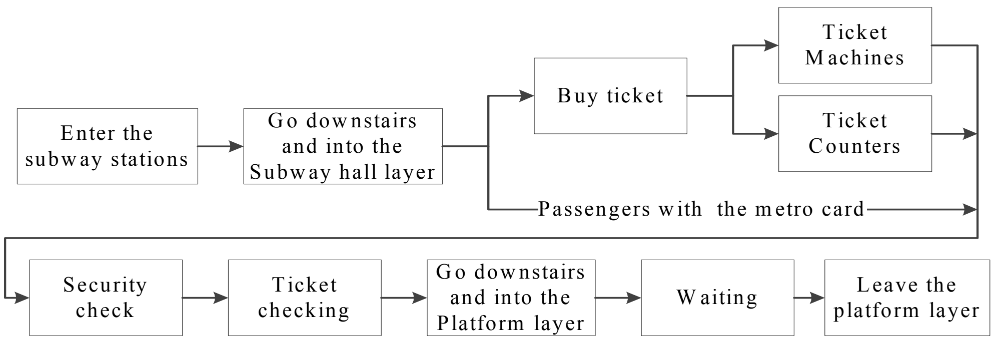

Figure 1. Subway station passenger process diagram

2.2 The subway passenger evacuation modeling method

According to basic theory and research method, the evacuation model can be classified into macroscopic, mesoscopic and microscopic (LIU Zhenyu,2009). The pedestrian movement mode is continuous in the macroscopic model, but it ignores the differences between evacuation individuals, so this kind of method is quite limited.

Pedestrian movement in the microscopic model both interaction and independent, every pedestrian is regarded as a microscopic particle, the particle's social psychological behavior feature is described as the social force. This kind of model makes the pedestrians more like real subway passengers whom can react readily to surroundings. This method is more accurate and widely suitable for most of the evacuation problems.

General mesoscopic method has already detail the units of analysis to the individual. But it haven't considering the interaction between individuals. It's coarser than the Social Force Model.

2.3 The spatial distribution of passenger flow

2.3.1 Passengers queuing phenomenon

When a large number of passengers entered subway station, the through ability would dropped fast and lead to serious crowd congestion. It's necessary to analyze the passengers queuing phenomenon to solve this problem: queue length (the number of passengers in queue); queue time (wait time at service facilities); queue discipline (first come first served); queue system (the number of passengers in station system); queue area (active area of passengers before accepting service).

2.3.2 Passenger traffic conflict

The mechanism of traffic conflict (ZHANG Jianxun,2007) is shown in Figure 2.

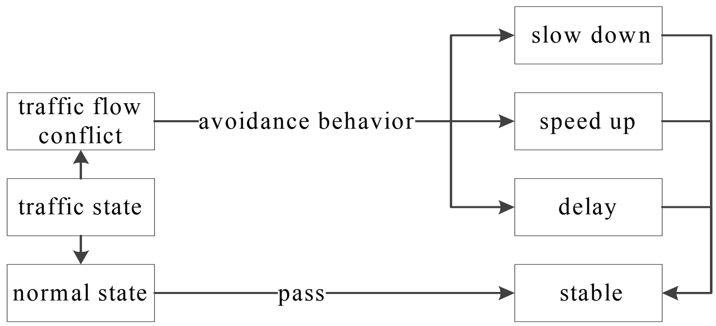

Figure 2. The mechanism of traffic conflict

Firstly, analyze the space structure of the station adequately to determine the direction of passenger flow, and try to find out the potential conflicts spot and the causes of bottlenecks. Then, analyze the influencing factors and put forward an assumption to design the simulation experiment of reducing traffic conflict. Finally, give some reasonable evacuation plans for this problem.

3 Modeling and Simulation of Crowd Evacuation in Subway Station

3.1 Data of the pedestrian traffic characteristics

Shenyang North subway station is located in a heavy traffic urban area, which has the structure of three-tier in the whole Shenyang Metro Line 2. Here are two main kinds of ticketing systems in the station: ticket machines and ticket counters. The service time in ticket machines is around 25.6 seconds, which is longer than ticket counters, 7.5 seconds. The proportion of these two systems is 3:2. The proportion of passengers whether with luggage is 7:3(with luggage: no luggage). Calibration of desired speed in station (WANG Zijia,2013) is shown in Table1.

Table 1. Calibration of desired speed in station(m/s)

Value	Gender		Up Stair	Down Stair
	Male	Female	（Horizontal Direction）	
Max	1.956	1.733	1.194	1.236
Min	0.828	0.697	0.306	0.547
Mean	1.391	1.180	0.700	0.728

3.2 The subway simulation model

The model consists of three layers in total: the ground floor, the subway hall and the platform layer. Considering the complexity of this model, assuming the number of the entrances and the exits of the station as shown in Figure 3.

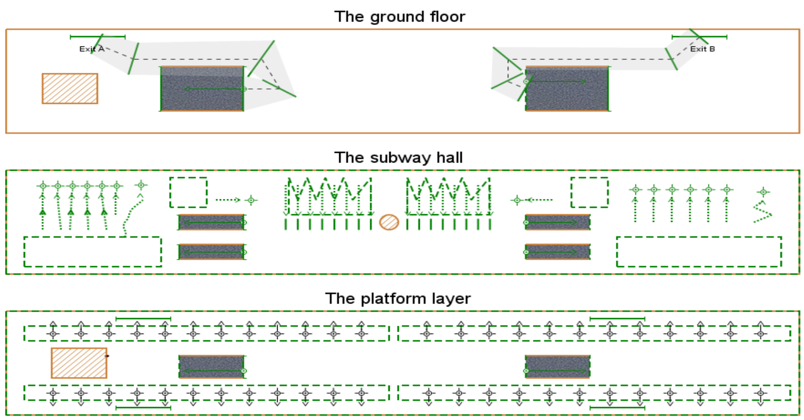

Figure 3. The simulation model plan

Passengers in the system of agent-based have their own thoughts and keep a distance from each other automatically. Diameter of the people obeys uniform (0.4, 0.5) meters. Firstly, passengers enter the ground floor and go downstairs to the subway hall, they have two choices to buy tickets (ticket machines and ticket counters), and the service time obey uniform (20.0, 30.0) seconds and uniform (6.0, 9.0) seconds. Secondly, passengers begin waiting for security checking, the service time obey uniform (4.0, 5.0) seconds. Then, they walk to another waiting area to check tickets, the service time obey uniform (2.0, 3.0) seconds. Finally, passengers go downstairs to wait for subway in the platform layer. About 1-3minutes later, the train draw in and all the passengers get on.

3.3 Model validation

According to the survey data of Shenyang North subway station platform, I had validated the model which established in this paper, the results are shown in table 2.

Table 2. The estimated and actual value of subway station

Test Type	Estimated	Actual Value	Relative Error
Wait Time at TVM (s)	24.5	25.6	-3.52%
Passengers in System (min)	5.6	5.8	-3.45%

The results of the model validation show that both the actual value of "Wait Time at TVM" and "Passengers in System" are higher than the estimated slightly, but the relative errors are in the acceptable range, proving that the pedestrian evacuation model established in this paper is effective.

4 Analysis of Subway Crowd Evacuation Experimental Results

4.1 Analysis of simulation results

Using the computer simulation method can observes the evacuation process and distribution of population intuitively, so as to find out the bottlenecks of the crowd and would also be a reference for optimizing design of the station's layout. Density threshold for platform in the station serve to crowds gathering event (Keith Still,2000) is shown in Table 3.

Table 3. Density threshold for platform in the station serve to crowds gathering event

Danger level	3.59 pedestrians /m^2	
Crowded level	2.15 pedestrians /m^2	
acceptable level	1.08 pedestrians /m^2	

In the simulation, the density map is commonly used to detect the areas with critical densities. Red color indicates the critical density. But in order to make the simulation effect more obvious, the red color is defined as 1.5 pedestrians/m^2, the orange color is 1 pedestrians/m^2, and the green color is 0.5 pedestrians/m^2.

Figure 4 is the simulation result of the ground floor. The densities of entrance and the corner of stairway sometimes were orange during running the model, which means these two places would be easy to form bottlenecks when a large number of passengers coming. In the process of going downstairs, some factors can also lead to traffic congestion such as limited stair capacity、velocity difference and huge flow of people etc.

Figure 5 is the simulation result of the subway hall. Both sides of the stairs and the corner are serious bottlenecks. Both areas of ticket machines and ticket counters are also easily gather lots of passengers and lead to congestion. Meanwhile, it's prone to gather a large crowd when the passengers are waiting in line for security checking. At present, the through capacity of automatic ticket gate is in good condition because of the sufficient number of the gates.

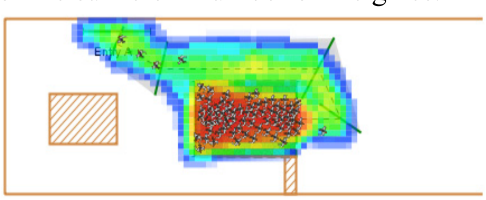

Figure 4. The ground floor

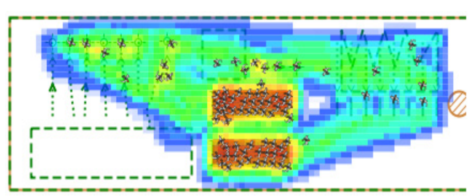

Figure 5. The subway hall

Figure 6 is the simulation result of the platform layer. Stairs are still the most populated areas. Owing to the obvious signs, there is little cross when the passengers select waiting areas. However, it's easily gather a large number of passengers in the waiting areas sometimes, especially at rush hour.

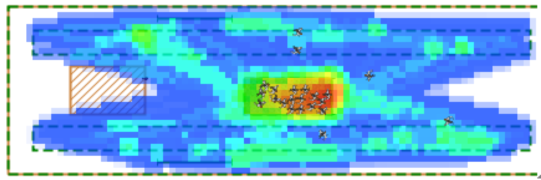

Figure 6. The platform layer

4.2 Optimization program and rationalization proposals

In above，increasing the through capacity of stairs is a good way to solve the potential threat of congestion in both the ground floor and the platform layer. However, the subway hall have the largest number of service facilities、the largest passenger volume and the most complicated structure etc. The passengers stay for a long time in this layer. If there are no effective ways to disperse the crowd when the traffic density is approaching the limit or occur some emergency accidents, the subway hall is more likely to causes congestion and stampede accidents compared with the other two layers.

When the number of passengers increased from 600 pedestrians per hour to 700 pedestrians per hour, there are serious intersection conflict points between the area of ticket counters and the line of security check, as shown in Figure 7. In order to prevent crowd congestion, the station need to reduce the passengers' staying time by opening more ticket machines, setting up some temporary ticket windows, and simplifying the machines' system to improve the efficiency of buying tickets. When the number of passengers increased to 800 pedestrians per hour, lots of passengers gathered in the ground floor, which would causes the pedestrians cannot go downstairs as before and the whole station system would be crashed. So, as long as the passenger arrival rate exceed 700 pedestrians per hour, and station would be ready for avoiding potential danger by opening the mode of early-warning to control the inbound numbers, arranging some professional subway staffs to channel the crowd orderly. At this point, the evacuation signs and emergency broadcasting system can effectively help passengers make the right decision quickly to reduce the time-cost of evacuating, and realize the safety evacuation.

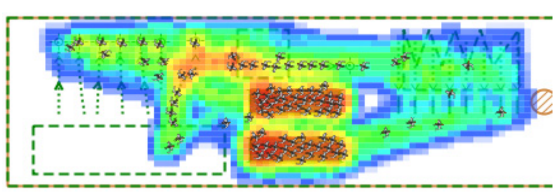

Figure 7. Jam of the subway hall

5 Conclusions

The passenger evacuation model with three-tier structure breaks through the past models with two-tier structure, which has the effectiveness and reference value.

Simulation results show that there is an upper limit for the service ability of subway station. When the inbound pedestrian density exceeds more than 700 pedestrians per hour of each entry would lead to serious congestion even stampede accidents. In order to optimize the quality of the subway service, it's necessary to simplify the ticketing system to reduce pedestrian ticketing time, increase the number of serve machines during the peak time and set some emergency evacuation signs to guide passengers choose the right directions quickly etc. Meanwhile, subway staffs should come to organize passengers to evacuate rapidly if somewhere congestion seriously.

Abstract: The resources of marshalling yard can be divided into physical resources and information resources. For the resources could be used reasonably in marshalling yard, the physical resources and information resources' characteristics were summarized by analyzing the operation process of wagon-flows based on the background of the fact that the integrated automation of marshalling station advances progressively. Moreover, the resources were analyzed by clustering analysis method which is first used in the field of computer. The result shows that it is reliable to use the classify solution to avoid marshalling resources wasting. Compared to the traditional resource, the cluster resource are much wider in space and much longer in time. The foundation can be built for controlling cluster resources based on this research.
Keywords: Marshalling yard; Dispatching system; Cluster resources; Analysis.

1 Introduction

Marshalling station has a series of different types, but it consists of the same multiple subsystems according to the technical process of wagons, like arriving operation subsystem, disintegration subsystem, marshalling subsystem, starting operation subsystem and departure system (There are two sets of such kind system with relative independence and similarity in the Two-way layout of network marshalling station). They connect with each other as a queuing system and they are regarded as a random service system which contains some influence factors. In the random service system, each subsystem has their input streams and service systems which all follow the queuing rule. The queuing system is a waiting system that is serial and insurmountable in the five subsystems. There are different operations and services for different nature of the freight trains which requires different kinds of resources on the station (Wang Ciguang, 2004). So the advantage of all resources should be used fully.

2 Complexity of the Operation in marshalling yard

Because there are so many kinds of work in marshalling yards, we can image how complexly and indeterminacy the station work is.

On one hand, the different station work requires some same resources and facilities. Further, we should take the station work time and operation order into account. The main performance of that is the interaction of the arriving subsystem, break-up subsystem, marshalling subsystem, and departure subsystem. The simulation of the auto-mechanical marshalling yards work process gives us the chance to understand the interaction and the corporation principle of the different station work.

On the other hand, the performance of the indeterminacy includes arriving late trains, fluctuation of working time, equipment bug, running accident.

In conclusion, on the background of automatic marshaling yards, we do research on the optimization of dispatching to dig the dispatching information and the mechanic of integrated control, so that improve the effective of the station work. As a result then make the dispatching system scientific and intelligent. That also can help the railway transportation meet their need, optimizing resource allocation and relieve the bottleneck. In one word, there are many theory and practical meanings on railway transportation (Xue Feng and Luo Jian, 2012).

3 Using of Resources

3.1 Using of physical resources

(1) The different shunting locomotive has different tasks in partitioning in marshalling yards. Each shunting locomotive has specific provision. For example, the duty of shunting locomotive on the hump is to disintegrate trains. The duty of shunting locomotive on the lead tracks is responsible for marshalling. The duty of shunting locomotive on the freight yards is responsible for picking up and delivering wagons (REN Guangwei, 2009). We can see that different locomotive serve different trains' task. The effective use of the locomotive has benefit for the stations.

(2) The locomotive order need to arrange based on the train need. Avoiding mutual interference between the disintegrated and marshalling work is our purpose. When arranging hump operation sequence, the disintegration order of the trains needs to be arranged according to the collocation of wagon-flows situation. For the trains which are in emergency, they should be disintegrated first. The marshalling sequences should be designed according to the train departure time. In one words, the station work should be arranged property. Only in this way can we improve the efficiency of the station work.

(3) The corporation of shunting locomotives. If there are free lines on the lead tracks, marshalling work should be timely arranged for leaving the shunting lines. As a result the wagons have spaces on the shunting lines after their disintegration work on the hump. The locomotives should be arranged separately for the different wagons'

resources. Two locomotives can be arranged to do two kinds of separate work, for example, one for disintegrating the arriving trains, and the other for picking up the local wagons. It means the two shunting locomotives work together at the same time to guarantee the effective of station work. That also can make sure the trains departure in time.

(4) For the stations which have two sets of independent operation of hump, we should use the two independent operation of hump properly. It must be known that the two independent operation of hump can finish work independently in different directions. For the special wagons which need twice work, the hump should be used carefully.

(5) For the arriving and departure lines, their taking up time should be considered. Through analyzing the features of taking up time on the departure lines of different trains, we can take balance advantage of departure lines. Sometime the objective of the use of departure lines is to take them up as least as possible and so on.

Train disintegration sequence and the arrangement of marshalling sequence are similar to the machine scheduling problems. They both have very high requires to scheduling plan, but the machine scheduling problem is relatively simple which only has one goal, so that is to reduce work time. However, sequence problem on marshaling yards is not only to consider to reduce working time, but also to consider the matching between resources and tasks (CHEN Dong, WU Baiqing and GAO Siwei, 2008). Marshalling yard work is much complicated, which involves the time-space problems and so on. Therefore, the disintegration and marshalling sequence problem in marshaling yards have a great difference with the machine scheduling problems in nature.

3.2 Using of information resources

There are many information resources in marshaling yards. Every station work has many information resources. By managing different information in the yard can improve the efficiency and corporation of the station works. Integrated information resources management is the trend of automatic marshalling yards. Through the use and the check of information, dispatchers can cooperate with each other, which can make sure the safety of all station work.

It is important that we should try to collect more and more information. The more we get from the information the better use of the information we can. All the work or task in marshalling yard have relations with each other, so the information resources can help the workers who are responsible for different task know the state of ever station work, for example, shunting. Not only the dispatchers of the shunting can know the process of the work but also others like dispatchers for marshalling can know that. That means all the dispatchers and workers can adjust and do the work very well according the information resources (XUE Feng and WANG Ciguang, 2008).

In one words, all resources should be used and shared reasonably.

4 Integrated Resources in Marshalling Yards

4.1 Purpose of integrated resources

The effective dispatching system is the condition of the better use of the resources and the corporation of locomotive-trains-tracks. Dispatching system makes decisions according to the collecting and analyzing of the information. So the better use of the information the better decisions the dispatching system can make. Also, that can help to improve the efficient and ability of marshalling yards.

Based on the comprehensive point and aim to guarantee the trains running on timetable, the resources are collected as wide as possible. Through effective management and dispatching approach, we can control and use the resources initiatively. Our purpose is to arrange the resource to different work reasonable.

4.2 Classification of integrated resources

Integrated resources in marshalling yards can be classified into four parts based on their statues of being used.

(1) Free resources

Its meaning is that some reality resources can be used now and then. Resource in free means we can use them no limit. Their supply is more than their demand. For example, there are many free dispatching locomotives on the stations waiting for doing work such as for dispatching in marshalling yard. These locomotives can be used free now and then.

(2) Shortage resources

It means they are less than free resources, and we just can use those resources to do limited task in limited time. We know that phase plan is to plan what are the wagons and where are they come from. That plan also develop locomotives plans and tracks plans. As a result the state of all the resources can be predicted and be determined. Shortage resources show that they are used partly or they will be used soon. We also can know how the resources are being used now and how they will be used soon through information resources and phrase plan. So the future state of the resource will be changed because of the change of the phase plan.

(3) Saturation resources

It means the resources (both physical and information resources) are all being used at the moment or because of some rules they cannot be used by any other task. For example, the being used hump which is used for dispatching. They cannot be used by other station work. Saturation resources are very sensitive. If the resources in the saturation state have any emergency problems, they can easily impact the process of station work. There are not any alternative resources in marshalling yard.

(4) Breakdown resources

It means those resources cannot serve for any station work before they are fixed well. The difference between Breakdown resources and Saturation resources are the later one can serve for station and their objects which the resources will serve can change as the result of the change of phase plan.

4.3 Effect of resources classification

We choose cluster analysis to classify the resources in marshalling yard, this approach classify the resources into different classification based on their property. Resources with similar property can be classified into the same class. So we can classify the resources by analyzing their state during a proper time.

Through classifying the resources into different class, we can use them more efficient. That also can help to improve the efficiency of station work. Because all station work need many kinds of resources and the same resource can be used for different station work which can make the resource disorder with each other.

The reasonable using of the resources is the primary condition of effective work on stations. As a result, we can use the resources flexible. The classification of the resources can help us to cope with all them quickly and accuracy. For instance, we can change the phase plan or even change the plan ahead according to the state of the resources. Those can prevent the deadlock of marshalling yards, on the other words, works stop because of the disorder of the resources. It is also a good way to improve the efficiency of station work.

5 Conclusions

(1) Classifying resources can improve the efficiency and corporation of the stations work in marshalling yards. It can make us know the state of the resources quickly and accuracy.

(2) Through the classification, the ability of the marshalling yards can be estimated and predicted. That helps us organize the work efficient and adjust our phase plan in time.

(3) This approach of classification is just a try to analysis resources, and the research on this problem will go on.

Abstract: With the high-speed railways have been put into use in our country, railway transportation capacity achieved liberation. And it make possible of further optimizing program organization and improving the quality of service. Freight demand accepted online began to effect on September 1, 2012, to actively carry out the real-freight system requirement of "open the acceptance of goods, loaded as soon as picked" and to take the customer as the center concept to meet the maximum loading needs of the clients, which put forward higher request for the accuracy and flexibility of the collocation of the transport capacity. Therefore, the capacity coordination of freight stations and railway stations has become a vital and urgent problem. This paper take the freight stations and marshalling yards in railway terminal as main research subjects, through analyzing their working relationship, to summary the capacity coordination connotation of freight stations and railway stations under "real-freight system" and to explore the main factors influencing their capacity coordination. In order to provide feasible and effective theory to improve the capacity coordination situation of freight stations and railway stations as well as to enhance the integrated efficiency of railway.
Keywords: Real-freight system; Capacity coordination; Freight stations; Marshalling yards.

1 Introduction

Depending on the freight of e-commerce system, our country pursues the "real-freight system". This Changes of railway transportation environment, requiring railway transportation system of self-adjustment, to improve the adaptability of the external environment, but also put forward new requirements on the transport capacity of railway hub. The ability of railway transportation hub as a multi-link system capacity, transport capacity will not only restrict any weak links of the system, and will cause the other areas of investment and the ability of the waste, so each link in the system must be coordinated ability. Among them, freight stations and marshalling stations are of railway freight transportation main and basic production unit (DENG Yuncheng,2014). The achievement of capacity coordination of freight station and marshalling yards is closely related to the survival and development of transportation, and meet the needs of railway transport enterprises.

2 The Capacity Coordination Connotation of Freight Station and Marshalling Yards Under "Real-Freight System"

"Coordination" in different areas of the meaning is not the same, but the basic meaning is the same, namely, correct processing system of various internal and external relations, create good conditions and environment for the system to work, promote the system goal. In general, the need for coordination system often contains several contradictory and conflict. Between freight stations and marshalling stations operation mainly includes: the marshalling yard with functions of freight business and freight business in area of marshalling station (LUO Anquan,2009).

2.1 Marshalling yard with functions of freight business

Figure 1 shows the operation flow of marshalling yard with functions of freight business. Shipper with the delivery of goods to the freight car to the freight station Ⅰ, then transported by transship trains to the receiving departure of the marshalling yard Ⅰ. According to the whereabouts of cargo each freight station yard in the disintegration of trucks, trains same fate compiled to form a new train departure, transport, arrived marshalling yard Ⅱ to carry out the same job in the marshalling yard Ⅰ process again. Finally, a small operation will be grouped by train transporting goods to the freight station Ⅱ, Ⅱ freight station pick notify the consignee, the consignee with their own car after unloading the goods shipped to its warehouses or factories.

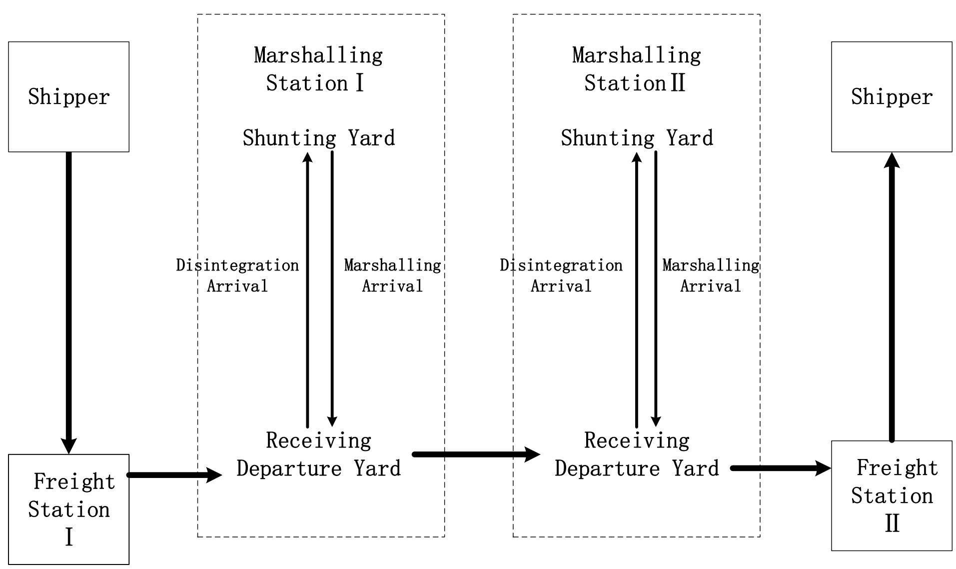

Figure 1. Operation flow of marshalling yard with functions of freight business

2.2 Freight business in area of the marshalling station

Figure 2 shows the operation flow of freight business in area of the marshalling station. Generally in accordance with the freight station nearest freight forwarders, freight station nearby, and then run through transship trains sent goods to disintegration and grouping in marshalling station, the goods will be transported to other places. A choice of direction cargo freight station shown Ⅰ, Ⅱ freight station for loading point, and then sent to the marshalling yard run by small train. Finally disintegrated by the marshalling yard marshalling to arrive to the user.

Similarly, goods from other marshalling yard hubs should also enter the marshalling yard, and then disintegrated by marshalling yard. The marshalling yard put the region's goods to the nearest freight station. And each freight station give the goods to their owner. Self-delivery by the owner and the owner is also responsible for the goods transported by freight station to the demand of the goods.

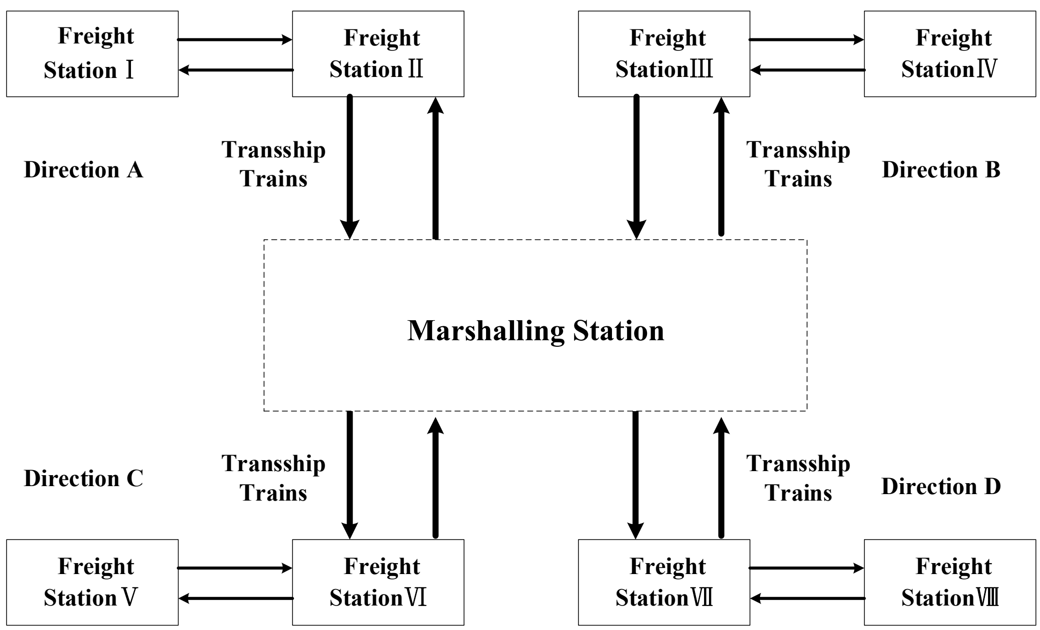

Figure 2. Operation flow of freight business in area of the marshalling station

By operating contact between the two, from different levels and angles , analyze and summarize the meaning of railway freight stations and marshalling yards capacity to coordinate, sum up includes the following four aspects: (1) cargo terminal and Marshalling load capacity on reasonable, balanced (SUN Qi,2010); a reasonable match between (2) freight station and marshalling yard equipment and technology operational capability; (3) the freight station and marshalling yard production order is relatively stable, continue a short time.

3 The Main Influence Factors of the Capacity Coordination Problem Between Freight Station and Marshalling Yards Under "Real-freight System"

(1)Wagon flow organization

Among all the freight stations and marshalling stations in the hub, can form a plurality of traffic flow path (*i.e. transship trains section*), a freight station on the general several each one (LIANG Wangrong,1995). Therefore, a traffic flow on each path independently of wagon flow organization, which can be divided into marshalling station to freight station and freight station to marshalling station, two organizational scheme. And the preparation of freight station and marshalling station organization scheme is more complex. In order to achieve full play in the hub of technical equipment potential, reduce hub station vehicle reorganization work and reduce vehicle maximum repetition adaptation and angle operation. And also make it possible to improve transport efficiency, accelerate the cargo delivery, shorten the residence time of the locomotive and vehicle in the hub and ensure smooth and good transport order.

(2)Handling time

Freight cars loading and unloading part of the residence time of about one-third freight car turnaround time(Cao Xueming,2007), loading and unloading cargo terminal part is finished in the freight station, this part-time compression mainly involves taking reasonable wagons. Cargo operations in vehicle technology job, taking delivery of the car is the most important part of the job. It improves the efficiency of cargo and has a major impact on the compression wagon staying time and wagon transit time.

Through plan to organize delivery in wagon flow organization, tissue material equilibrium arrival station can avoid sending concentrated, but cause blockage of library field. The delivery vehicle in the organization, strengthen the wagon's placing –in and taking-out, directly affect the vacated pick up car line timely and floor smooth. The freight station placing-in a car timely make it possible to the timely completion of cargo handling operation. The freight station taking-out a car timely make it possible to freight cars promptly into the train starting. At the same time, reasonable loading and unloading point of delivery vehicles in order, can effectively use the locomotive and compression wagon staying time.

Therefore the freight station open or not, have a major effect on marshalling station capacity. Freight stations handling equipment capacity tension, causing vehicles cannot be unloaded, which make this part of the vehicle be detained in the marshalling station. As a consequence, it will shunt marshalling station lines and affect the marshalling stations to pick up car and break-up operation of the hump.

(3) Empty car distribution

Shunting yard and special line of empty wagon distribution is mainly realized in a certain shift plan with empty time. According to the specific distribution of empty cargo and effective coordination, and in the condition of considering the dual task, the marshalling yard reasonably determine the flow's directions and flow of the available empty car of the empty station supply point. In order to realize the residence time in the station compression wagon staying time and reduce the empty total transfer cost. China's productivity distribution and regional social and economic development is not balanced, resulting in railway traffic structure presents obvious characteristics. Loaded cars' structure appear in distribution from north to south and from west to East. Otherwise the empty cars and heavy traffic, on the contrary, appear in distribution from south to north and from east to west, and this is the main vehicle evacuation direction. It is because of the need to empty imbalance distribution of the spatial and temporal that provides the need of distribution of empty wagons. The reasonable distribution scheme of the empty wagon, can not only to meet the greater demand for transportation, but also contribute to reducing the empty cars running kilometers, and compression of wagon turnround time.

4 Suggestions

(1)Optimize the organization scheme of car flow. The reasonable organization nonstop of loaded and empty trains, and no adaptation by marshalling stations, which will reduce the reorganization work and save the vehicle hour. The small operation train of the freight station operation section can be a single or a few organized, and marshalling yards excluded nonstop of loaded and empty trains. Then we discuss the organization schemes of the remaining traffic again which include operated on direct and picking and hanging train. Should not only consider the transship trains on the way to run, the residence time of province, and it is more important in marshalling stations short switching time. With the small operation matched with the transit flow, it will realize the train formation plan of the marshalling station according to the provision of cars, create conditions according to the train diagram of crane and shorten the " transit time" scheme.

Therefore, it must reflect the local to the global, to operate a transship train to obey the principle of organization run train. The specific method should be according to the need of the marshalling station transit traffic aggregation, connection and cooperation, to determine the marshalling content of transship train. At the time, according to the railway marshaling stations line train departure time requirements, marshaling stations organize "dispatching a vehicle". It should combine with marshalling station to operate a small freight station train organization schemes, a transship train of locomotive operation scheme and each line, each station, to determine the realization of comprehensive load capacity.

(2)During the wagon staying time, to be delivered in time, to be installed, and other non-production time occupies a large proportion of. In order to shorten the residence time of these nonproduction, collaboration must strengthen the factory, mine, port and railway, forestenterprise department. Combined with labor departments within the organization way, improvement of goods vehicles operating organizations, to avoid disconnection between the working link technology. Therefore, we should combine the characteristics of traffic station and special line of the cargo operation site equipment with operation conditions and the traffic to the law, take the principle of vehicle delivery, cargo handling, train to cooperate closely, to determine a reasonable number of delivery, delivery order and delivery time to each of the work place. The key to shorten cargo stay time, lies in the railway and enterprises can cooperate closely and strongly compressed to be sent, to be installed, to be unloaded and standby and other non-production and residence time of loading and handling time.

(3) Be based on the analysis of factors of empty wagon kilometers influence, we can draw the following basic method for compression of wagon kilometers. ① Adjust the layout of productivity, reducing the imbalance of the empty wagon flow in all directions. ②The optimization of railway empty wagon adjustment plan and empty train formation plan, and making plan of empty wagon distribution reasonable and empty place of transit operation. ③The optimization of wagon flow path. When empty by truck to the loading, the general should be through the shortest path,it must eliminate the same empty at the same radial road and a parallel path of convection. ④Improve the dual task coefficient, the reasonable organization of circulation through train, using empty haul back loading, but to ensure the loading station stop time not exceeding. ⑤Increase the axle load of freight cars, thereby increasing static load, reduce the direction of heavy vehicle number; ⑥Improve the versatility of the truck, and create conditions for the empty substitution of car types. ⑦Strengthen the empty car adjustment plan, and make the distribution of the use of vehicles sensible.

Railway transportation "real-freight system" revolution is an important initiatives by railway transportation administration to face the increasingly potential market competition and under the business philosophy that develop the market by good service. The transportation revolution stress that take the customer as the center concept to meet the maximum loading needs of the clients ,which put forward higher request for the accuracy and flexibility of the collocation of the transport capacity. Therefore, the capacity coordination of freight stations and railway stations has become a vital and urgent problem .This paper explore the main factors influencing their capacity coordination, and to provide the theoretical basis for their optimization method.

Abstract: The departure time domain of passenger trains is mainly to solve the overall layout problem of the passenger trains running line. A reasonable departure time domain of passenger trains can not only construct the skeleton and the core issue of the passenger train working diagram, but also improve the feasibility of the working diagram. The system for optimizing departure time domain and arrival time domain of passenger trains is developed based on the genetic algorithm constraints of the receiving and dispatching trains capacity of railway passenger transportation nodes model in the paper. The goal and function of the system are detailed description. Then the corresponding actual simulation is proposed to validate the effectiveness of the system.
Keywords: Departure time domain; Passenger trains; Genetic algorithm; Optimizing system.

1 Introduction

The originating scheme of passenger trains is mainly to solve the overall layout problem of the passenger trains running line, which is an important prerequisite of the preparation of passenger train working diagram. And as the skeleton and the core issue of the passenger train working diagram, the originating scheme directly affects the feasibility and quality of passenger train working diagram. At the same time, a reasonable originating scheme of passenger trains can not only meet the passenger's requirements of travel time and service quality and enhance the market competitiveness of railway transportation enterprise, but also take full use of existing passenger station facilities and the equipment of passenger car servicing depot, improve the quality and efficiency of operation organization in passenger stations. Meanwhile, with the improvement of transportation efficiency, the railway operating income can be increased and the operating cost be reduced.

As an important part of the passenger train operating organization, the originating scheme establishment of passenger trains is affected by many factors, such as the passenger train plan, passenger station equipment capacity, servicing capacity of passenger car servicing depot, passenger locomotive and rolling number, train safe driving requirements, passenger travel time, etc.. Meanwhile, the originating scheme establishment of passenger trains is a multi-objective, multi-constrained and large-scale combinatorial optimization problem. Taking the maximum degree of passenger travel convenience as the objective function and considering some constraint conditions such as the carrying capacity of arrival and departure tracks and passenger trains must departure and arrive in rational time intervals, an objective programming model for optimizing the departure and arrival time intervals of passenger trains was established (Chen Tuansheng,2006). The departure time domain of passenger trains optimization models for a single node and optimization model for multi-node are established respectively based on the constraints of the receiving and sending capacity of railway passenger transportation nodes. Moreover, the genetic algorithm combined with conflict detection strategy is proposed to solve the problem of the passenger trains' departure time domain for a single node, and a heuristic priority strategy algorithm was put forward for the same problem too(Ni, Shaoquan,2012). Furthermore, the heuristic algorithm combined with conflict detection strategy is designed to solve the problem of the passenger trains' originating scheme for multi-node(Chen Dingjun,2012). There are also many scholars have discussed the scheme of passenger trains from different perspectives.

In the paper, the system for optimizing departure time domain and arrival time domain of passenger trains will be developed based on the genetic algorithm constraints of the receiving and dispatching trains capacity of railway passenger transportation nodes model, and the detailed function of the system will be introduced.

2 Optimization Model and algorithm for Departure Time Domain of Passenger Trains

2.1 Optimization Model for Departure Time Domain of Passenger Trains

We can get the Model of Departure Time Domain of Passenger Trains in paper (Chen Dingjun, 2012), which gives the heuristic priority strategy algorithm.

$$\max f(t) = \alpha \sum_{d=1}^{\sum_{i=1}^{m} f_{0i}} \sum_{t \in T} \delta(d)\mu(x_d(t \oplus w)) + \beta \sum_{a=1}^{\sum_{i=1}^{m} f_{0i}} \sum_{t \in T} \delta(a)\mu(y_a(t \otimes w)) \quad (1)$$

S.t.

$$\sum_{d \in D} x_d(t) \le N_{0t}^{\text{dispatch}} \quad (2)$$

$$\sum_{a\in A} y_a(t) \le N_{0t}^{\text{receive}} \quad (3)$$

$$\sum_{t\in T} x_d(t) = 1 \quad (4)$$

$$\sum_{t\in T} y_a(t) = 1 \quad (5)$$

Where formula (1) expresses let the trains the maximize convenience to passengers; formula (2) expresses the number of trains departure from node at any time can not exceed the dispatching capacity at the period t; formula (3) expresses the number of trains arrival at node at any time t can not exceed the receiving capacity at the period t; formula (4) expresses every train departs from node at only one period of time; formula (5) expresses every train arrives at node at only one period of time.

2.2 Algorithm for Departure Time Domain of Passenger Trains

In the paper (Chen Dingjun,2012), thorough analysis the complexity of the problem, the improved elite group genetic algorithm combined optimization departure time domain of passenger trains and conflicts detecting strategy was designed. Now we developed the optimization system based on the algorithm and combined with the actual application needs.

3 optimizing system for departure time domain of passenger trains

3.1 System Target

Departure time domain of passenger trains is based on the train operation plans which have been draw up ,then the time resources can be preliminary allocated to trains by meeting the travel time and the constraints of the receiving and dispatching trains capacity of railway passenger transportation nodes .

Currently, the method of passenger train departure time domain is a uniform distribution, which can not provide t powerful assist to rain working diagram. With the depth development of transportation products to meet the market demand, the working mode lacking of information means can not help lighten the labor intensity of plan engineering and improve the working efficiency, which has not been able to adapt to the demands of railway development. Therefore, the goal for researching and developing the optimizing system for departure time domain of passenger trains is to improve the intelligent level of train working diagram, achieve plan intelligent generating, and provide the necessary decision-support tools for the working diagram.

The performance of the system have to meet the reliability, practicability, advanced ability to avoid data loss or errors under a long time run. In addition, the system must be simple, practical and simple operation to convenient for the user to master the use of the system.

3.2 System development environment for optimizing departure time domain of passenger trains

In this paper, genetic algorithm based on conflicts detecting is realized by Visual C + +, optimizing system for departure time domain and arrival time domain of passenger trains is developed, and by the computer with Intel Core 2.26GHz and 2GB memory.

3.3 System functions for optimizing departure time domain of passenger trains

(1) Parameters setting function for GA

In the software, parameters such as the size of the population, crossover probability, mutation probability, maximum genetic algebraic can be set and modified (Fig.1).

Figure 1. Software interface for setting GA parameters

(2) Capacity of arrival-departure lines in unit time setting function

According to the actual situation of passenger transportation node, capacity of arrival-departure lines in unit time can be set (Fig. 2.).

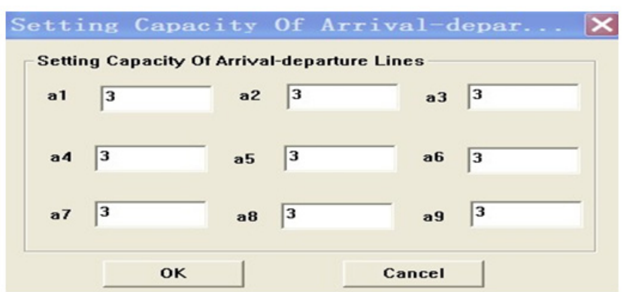

Figure 2. Software interface for setting capacity of arrival-departure lines.

(3) Data management function

Travel time data of passenger trains can be managed, including data reading, data storage, data modification.

(4) Results output function

Results, including fitness value of each generation, optimal solution, fitness value of optimal solution, etc, can be output (Fig.3.).

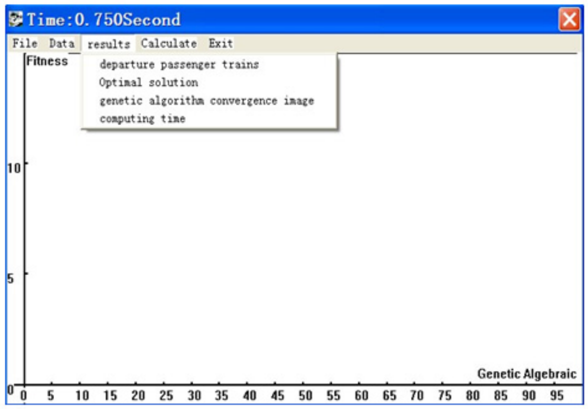

Figure3. Interface for results output

(5) Result statistics function

Statistical results, including the number of departure passenger trains, genetic algorithm convergence image, computing time, etc.

4 Simulation analyses

Parts of passenger departure trains data of Chengdu station are adopted to validate the effectiveness of the model and the algorithm. There are 12 arrival-departure lines, 6 up going available lines and 6 down going available lines, 4 platforms, 2 tunnels, one bridge. According to the station capacity and departure and arrival trains situation, time domain [6,24]can be divided into 9 time periods by 2 hours, and, suppose, maximum number of trains departure from the station at each time period is 9.

(1) Genetic algorithm parameters setting

TABLE 1

GENETIC ALGORITHM PARAMETERS SETTING BASED ON CONFLICTS DETECTING

Parameters	size of the population	crossover probability	mutation probability	maximum genetic generation
Value	30	0.8	0.1	200

(2) Computing Results

The computing results are listed in the TABLE 2, in which only partial results are given because of space constraints.

TABLE 2

Computing Results

5 Conclusions

In this paper, the system for optimizing departure time domain and arrival time domain of passenger trains is developed based on the genetic algorithm constraints of the receiving and dispatching trains capacity of railway passenger transportation nodes model in the paper. The goal and function of the system are detailed description. Then the corresponding actual simulation is proposed to validate the effectiveness of the system. The detailed timetable of the trains in the whole railway net will be research in our future work.

Models and Heuristics for the Split Delivery Vehicle Routing Problem

Jianli Shi

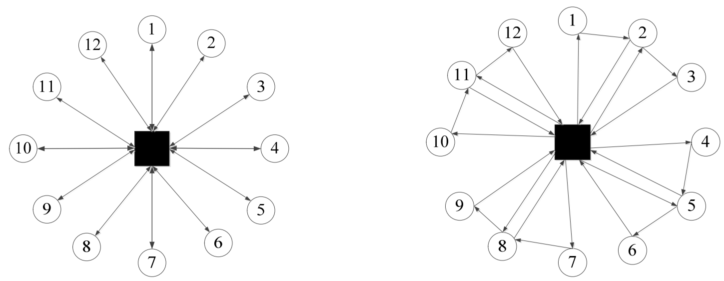
School of Transportation and Logistics, Southwest Jiaotong University, Chengdu, Sichuan 610031, China. E-mail: shjl20043528@163.com

Abstract: Split delivery vehicle routing problem (SDVRP) is a variation of vehicle routing problem, where some customers may be served by more than one vehicle. This paper is a survey on the models and solution approaches for SDVRP. Some models is reviewed. Heuristic and exact solution approaches for the SDVRP are presented. Finally, future work about SDVRP are given.

Keywords: Split delivery; Vehicle routing problem; Heuristic; Exact solution approaches.

1 Introduction

The split delivery vehicle routing problem (SDVRP) (Dror, 1989), is an variation of vehicle routing problem. The difference between SDVRP and VRP is that, the demand of some customers may be larger than the capacity of a vehicle, and can be serviced by more than one vehicle. At this time, the amount deliveried by a vehicle to a split customer becomes a variable. Fig.1 shows the difference between the solutions of VRP and SDVRP.



(a) (b)

Fig.1 the difference between the solutions of VRP and SDVRP(a for solution of VRP, b for solution of SDVRP; capacity of vehicle 6, customer demand 4)

More recently, the literature addresses more complicated problems, such as SDVRP with time windows, SDVRP with pickup and delivery, SDVRP with inventory and production, SDVRP with minimum fraction served, and SDVRP under stochastic environment, SDVRP motivated by applications etc. There are also papers such as (Dror, 1989; Archetti, 2005) etc., which consider the properties of SDVRP and the maximum saving that can be achieved by split deliveries. Most studies develop heuristic and exact algorithms to solve the proposed models.

This paper is a survey on the models and heuristic/exact algorithms to solve SDVRP. In section 2, the mathematical programming formulation of SDVRP is presented. Sections 3 and 4 review the heuristics and the exact approaches proposed for the SDVRP. Finally, Section 5 provides further research on SDVRP.

2 Formulation of SDVRP

The formulation of Dror's is a basic model for SDVRP, which is a mixed-integer program model.

SDVRP is defined over an undirected graph $G=(N,A)$, where $N=\{0,1,\cdots,n\}$ is the vertex set with the depot 0. $A=\{(i,j):i,j\in A,i\neq j\}$ is the set of edge. The cost of an edge $(i,j)\in A$, c_{ij}, is non-negative. There are m vehicles in the depot, each with capacity Q_v, which is different from each other. The demand of customer i is given by q_i, which satisfies $q_i\leq \max_v\{Q_v\}$ 。

x_{ijv} ($i\neq j$) is a binary variable that takes value 1 if vehicle v travels directly from i to j, and 0 otherwise;

y_{iv} is the percent of the demand of i delivered by the vehicle v.

The SDVRP can be formulated as follows:

$$\min\sum_{i=0}^{n}\sum_{j=0}^{n}\sum_{v=1}^{m}c_{ij}x_{ijv} \tag{1}$$

S.T.

$$\sum_{i=0}^{n}x_{ikv}-\sum_{j=0}^{n}x_{kjv}=0 \quad (k=0,1,\cdots,n;v=1,\cdots,m) \tag{2}$$

$$\sum_{v=1}^{m}y_{iv}=1 \quad (i=0,1,\cdots,n) \tag{3}$$

$$\sum_{i=1}^{n}q_iy_{iv}\leq Q_v \quad (v=1,\cdots,m) \tag{4}$$

$$\sum_{j=0}^{n}x_{ijv}\geq y_{iv} \quad (i=1,\cdots,n;v=1,\cdots,m) \tag{5}$$

$$x_{ijv}\in\{0,1\} \quad (i,j=0,\cdots,n;v=1,\cdots,m) \tag{6}$$

$$0\leq y_{iv}\leq 1 \quad (i=1,\cdots,n;v=1,\cdots,m) \tag{7}$$

$$\sum_{v=1}^{m}\sum_{j=0}^{n}x_{ijv}\geq 1 \quad (i=1,\cdots,n) \tag{8}$$

$$\sum_{v=1}^{m}\sum_{i\in S,j\in\bar{S}}x_{ijv}\geq V(S) \quad (S\subseteq N\setminus\{0\};|S|\geq 2) \quad \text{or}$$

$$\sum_{v=1}^{m}\sum_{i,j\in S} x_{ijv} \le |S|-1 \quad (S \subseteq N\setminus\{0\}; |S|\ge 2) \tag{9}$$

Constraints (2) are flow conservation conditions. Constraints (3) specify that the demand of any customers is entirely satisfied. Constraints (4) ensure that vehicle capacities are never exceeded, while constraints (5) guarantee that if some customer is visited by some vehicle, then the same vehicle leaves that customer. Constraints (8) impose that each vertex is visited at least once. Constraints (9) are subtour elimination constraints. The former is for the situation in which the total demand of all customers is larger than the vehicle capacity; the last is for the situation in which the edge satisfies the triangle inequality.

The varieties and extended models are all based on (Dror's,1989), and the most important one is SDVRP with time windows and with homogeneous fleet. The main results are shown in Tab1.

Tab 1 papers on variety and extended models for SDVRP

papers	model type	Remark
Frizzell(1995)	mixed-integer program	SDVRP with hard time windows, heterogeneous fleet
Belfiore(2009)	mixed-integer program	SDVRP with time windows, heterogeneous/unlimited fleet
Ho(2004)	mixed-integer program	SDVRP with time windows, homogeneous fleet
Belenguer(2010)	mixed-integer program	Split delivery capacitated arc routing problem, homogeneous fleet
Lei(2012)	stochastic programming model	SDVRP with stochastic demands, homogeneous fleet
Desaulniers(2010)	mixed-integer program	SDVRP, homogeneous fleet
Archetti(2014)	flow formulation	SDVRP with time windows, homogeneous fleet
Huang(2012)	integer program	SDVRP, homogeneous fleet

3 Heuristics

Heuristics can solve large-scale problem, and are widely applied on VRP. Most of the heuristics for solving VRP can be used to solving SDVRP, including tabu search, genetic algorithm, memetic algorithm, scatter search, simulated annealing method etc., and hybrid heuristic algorithms. The key point of solving SDVRP by heuristics is how to deal with the split customers. Several ways have been proposed to deal with split delivery, such as splitting the last customer of a route, whose demand can't be satisfied fully; delivering part of all customers' demand firstly, then servicing the remainder etc. The main results researching on heuristics for solving SDVRP are shown in table2.

Tab 2 papers on solving SDVRP using heuristics

papers	Algorithm	Remark
Dror(1989,1990)	Local search algorithm	consider only the case with each demand less than the capacity of the vehicle
Archetti(2006)	Tabu search	proved to be much more effective than Dror and Trudeau's(1989) algorithm
Boudia(2007)	Memetic algorithm with population management	proved to beat the tabu search(Archetti, 2006)in many cases
Archetti(2008)	hybrid heuristic based on tabu search	results improve the ones produced by the tabu search (Archetti, 2006) in many cases
Jin(2008)	limited-search-with-bounds algorithm	tested on the set of 12 instances proposed by Belenguer (2000), improve the lower bound on 10 instances and the upper bound on six instances.
Xie(2012)	ant algorithm	Stable results, difference between the best and the worst solution is small
Tan(2008)	ant algorithm	Split delivery result to the reduction of the number of vehicle used and the total route length
Xie(2006)	tabu search/genetic algorithm	put forward an operator to solve the tendency of over-split
Liu(2011,2012)	Two-stage algorithm Clustering algorithm	effective than tabu search(Xie, 2006)
Mota(2007)	Scatter search	minimum possible number of vehicles
Belfiore(2009)	Scatter search	SDVRP with time windows
Aleman(2010a)	adaptive memory algorithm	minimum possible number of vehicles is imposed
Aleman(2010b)	Tabu search with vocabulary building approach	minimum possible number of vehicles; remarkably improve the results of the previous adaptive memory algorithm(Aleman, 2009)
Huang(2012)	greedy randomized adaptive search procedure	delivering part of all customers' demand firstly, then servicing the remainder
Derigs(2009)	local search-based metaheuristic	minimum possible number of vehicles
Lei(2012)	Adaptive large neighborhood search	SDVRP with stochastic demands
Berbotto(2013)	tabu search with granular neighborhood	minimum possible number of vehicles; most results are better than ever results
Wilck IV(2012)	Genetic algorithm	minimum possible number of vehicles; faster than the column generation approach and two-stage algorithm

Summarizing form the literatures listed above, most approach for solving SDVRP are constructive heuristics, such as local search, tabu search, adaptive large neighborhood search algorithm, greedy randomized adaptive search procedure etc. But researches on heuristics based on population is rare. This kind of algorithm, such as particle swarm optimization, genetic algorithm etc. has been proved very effective to solve many difficult problem, specially for VRP, and whether these algorithms can be applied well to SDVRP need to be verified further. And literature of this kind in Chinese is rare.

4 Exact Algorithms

Like the heuristics, the exact algorithms for solving VRP all can be used to solve SDVRP, including column generation approach, cut plane algorithm, branch-price-cut algorithm, branch and bound algorithm, dynamic programming etc. The main results on exact algorithms for solving SDVRP are shown in table 3.

Tab 3 papers on solving SDVRP using exact algorithms

papers	Algorithm	number of customer	remark
Dror(1994)	Local search	20	improve previous lower bounds
Belenguer(2000)	Cut plane algorithm	51	a new family of valid inequalitie
Lee(2006)	labeling algorithm	7	minimum possible number of vehicles
Yu(2007)	Lagrangian relaxation approach	200	inventory routing problem
Jin(2008)	column generation	22	minimum possible number of vehicles
Archetti(2009)	branch-and-price-and-cut algorithm	144	in most cases, improve previous lower bounds and found some new best feasible solutions.
Desaulniers(2010)	branch-and-price-and-cut algorithm	100	SDVRP with time windows
Moreno(2010)	lower bounding procedure based on column and cut generation	100	in most cases, improve the previous lower bounds
Archetti(2011b)	Improved branch-and-price-and -cut algorithm	100	SDVRP with time windows
Archetti(2014)	Branch and cut algorithm	100	present two exact branch-and-cut algorithms

Summarizing form the literatures listed above, researches on dynamic programming to solve SDVRP is rare.

5 Results And Further Research

Since SDVRP has been introduced, it has received increasing attention over time. Heuristic and exact solution algorithms have been proposed. But there are many other issues in SDVRP that need to be considered, including more complicated SDVRP and designing more effective algorithm. In terms of more complicated SDVRP, it is clearly important to consider the situation close to practical application, such as SDVRP in stochastic environment, SDVRP in urban distribution, SDVRP combined with urban transportation etc. Another area of further research is to design more effective algorithm for SDVRP. One way is to present improved algorithm based on the heuristics and the exact algorithms; another way is to apply some existing algorithms to SDVRP, such as particle swarm optimization, dynamic programming etc., which has been verified very effective for VRP. And also, one can design hybrid algorithms to solve SDVRP

Abstract: The main difference between optimization model of train operation plan under the condition which grading passengers and trains level and traditional optimization model is: the mismatch between the passengers level and the trains level will generate additional time consumption, passengers at different levels trains need to transfer. On the basis of existing research, it constructs the hierarchical transfer network; the analysis of the characteristics of a single network showed that there is no transfer arc and network cost in this network, traffic assignment problem is equivalent to the minimum stops problem. This reasearch construct a complete network flow assignment process which is considering the complexity of hybrid network, combined with the passenger travel characteristics and a single network characteristics, using layered flow assignment method to simplify the process of flow assignment. Finally, taking the Beijing-Shanghai high-speed railway as an example, calculate forecasting passenger flow and operation plan in 2015 respectively by traffic assignment method before and after simplification.

Keywords: Passenger railway line; Level classification of passengers and trains; Operation plan; Network flow assignment.

1 Introduction

The transportation organization mode for the high-speed dedicated passenger railway in our country is trains with several speed levels running on the same line. In order to meet different kinds of passenger's transportation demands, high-speed dedicated passenger railway usually designs at least two kinds of passenger transportation product to get more social benefit and enterprise benefit. The existing research did not consider passenger's demand level, for reasons of refining market, it is necessary to study transportation products and optimization problems of train operation plan in the high-speed dedicated passenger railway under the situation of classifying passenger demands.

2 Optimization Model of Train Operation Plan

A complete optimization process of train operation plan in the high-speed dedicated passenger railway can be described as a bi-level programming problem. the upper level programming is to solve the benefit maximization problem in operation plan , the lower level programming is to assign specific operation plan of passenger flow.

The existing research can reach a typical optimization model of train operation plan in the high-speed dedicated passenger railway. the passengers are divided into two levels: high demand level and middle demand level,the trains are also divided into two grades: high grade and middle grade. After grading,the difference of the optimization model is mainly reflected in that for the same OD travel, conversion of high, mid-range passenger hour consumption are different, it can be described as:

$$\min T = \sum_{i,j,k} (x_{ijk}^1 t_{ijk}^1 + x_{ijk}^0 t_{ijk}^0) \tag{i}$$

S.t.

$$\sum_{i,j,k} x_{ijk} = N \tag{1}$$

$$\sum_{k} x_{ijk} = N_{ij} \tag{2}$$

$$n_h \le C_h \tag{3}$$

$$n_h A_0 S \le \sum_{i,j,k} x_{ijk} w_{kh} \le n_h A_0 \tag{4}$$

$$x_{ijk}^0, x_{ijk}^1 \in \overline{z^-} \tag{5}$$

$$w_{kh} \in \{0,1\} \tag{6}$$

From formula (i): $\min T$ is the objective function; x_{ijk}^1, x_{ijk}^0 is the number of passengers in high and middle grade who select travel scheme *k* (origin -destination is station *i,station j*); t_{ijk}^1, t_{ijk}^0 is equated hour consumption in high and middle grade passengers who select travel scheme *k*(origin -destination is station *i,station j*); N is the total number of passengers to send; N_{ij} is the amount of passengers in origin -destination; n_h is the number of trains in interval *h*; C_h is the carrying capacity in interval *h*; A_0 is rated carrying passengers number; S is break-even attendance; w_{kh} is 0-1 variable(when the Kth operation plan include interval h, w_{kh}=1,or w_{kh}=0)

After grading passengers and trains level,the key influence factor is the mismatch between the passengers level and the trains level generating additional time consumption, it can be simply describe as αt_{ijk}^0 or βt_{ijk}^1, the number of α and β is determined on the basis of the condition of the line.

3 Transfer Network And Traffic Assignment Process

3.1 Construction of transfer network

For the specific operation scheme, it can be constructed as a single source and single sink, non-node-cost transfer network and assign flow by minimum path algorithm. After grading passengers and trains level, changes in the network are as follows:

(1)Trains at different levels run in the same interval can not be combined, it will largely increase the number of transfer arc;

(2)Consumption parameter at running arc is a two dimensional vector, its component correspond to the equated hours that high, mid-range passenger spend in taking trains.

Obviously, after grading passengers and trains level, the scale of transfer network greatly increase. Considering the the problem of computational efficiency, it is necessary to deal with a simplified flow assignment process.

3.2 Simplify the design of the whole process of the flow assignment

It is difficult to accept the extra expense from the mismatch of trains and passengers,so the first step should come to the single network construction, then put the passengers into the corresponding level network by assigning flow.

In a complex network consisting of two levels trains, high-grade passenger's travel behavior is divided into four cases: using high-grade trains to transport derectly, using high-grade trains to interchange, coordinating high-grade and low-grade trains to transport, using high-grade trains to transport derectly or interchange. From high-grade passengers' properties, scheme of using high-grade trains to transport derectly is clearly superior to other schemes, so the high-level passengers can assign priority to high-grade network, the high-level passengers can also assign priority to low-grade network.

Giving priority to assign a certain level of passenger flow to the corresponding level of traffic in a single network greatly simplifies the problem:

(1)In a single network, for the same OD flow, passengers need not consider the transfer, there is no transfer arc.

(2)All kinds of direct transportation schemes have the same origin build-up time, it can not be considered.

(3)If the trains are at the same levels, it means the passengers' travel time and the fare are same, the fare on the running arc can also no be considered.

In summary, when carried out directly with the flow in a single network, the shortest path corresponds to the minimum stoppings and the problem is greatly simplified.

The multi-level flow assignment process is as follows:

(1)Construct a high-level trains' single operation network and carry on through flow assignment to high-level passengers;

(2)Construct a low-level trains' single operation network and carry on through flow assignment to low-level passengers;

(3)Delete the through passenger and full loading trains,modify the trains' corresponding capacity which is failure to meet the requirements of train capacity.

(4)Construct a complex transfer network to assign remaining passengers again.

Sequencing problem should be considered in the network flow assignment.

Long-distance passengers flow should be given priority in allocation, it can reduce train loss and allocate passenger flow into trains as much as possible. After it, trains or operation schemes can be adjusted according to the presence situation of the loss section. then it comes to re-assign flow. Thus, during the whole flow assignment process, it need to carry on human external control to flow assignment progress to prevent it entry into the "dead cycle".

In the network flow assignment, specific flow assignment process as shown in Figure 1.

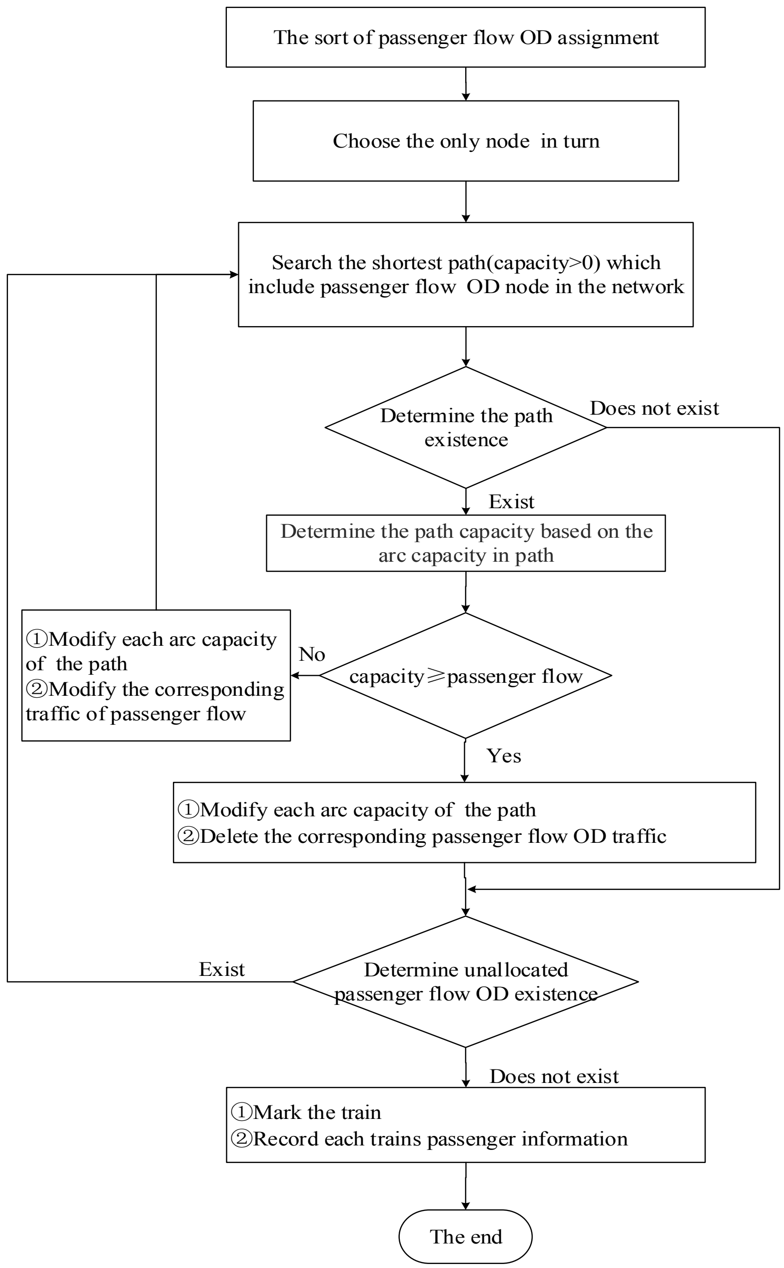

Figure 1. Network traffic assignment process diagram

4 Calculation Of Actual Case

Taking the Beijing-Shanghai high-speed railway as an example, the predicted passenger flow and operation scheme are shown in table 1.

Use self-developed software to carry on the distribution of passenger flow respectively through the non-simplified complex network and simplified transfer network(α=β=1.2), the main indicators are shown in table 2.

Table 1 The Beijing-Shanghai high-speed railway predicted passenger flow and operation scheme in 2015

Predicted passenger flow volume		Operation scheme	
300km/h	200km/h	High speed train	Middle speed train
3982 million/Single direction	742 million/Single direction	94 pairs	20 pairs

Table 2 The main indicators comparison of the flow assignment simplification before and after

	Flow assignment time	Seat utilization	Passengers' time consumption per day
Before flow assignment	7min30s	86.56%	685384.81h
After flow assignment	1min25s	85.7%	673126.83h

Table 2 shows that, the simplified flow assignment results did not produce significant changes, while greatly reducing the computation time.

5 Conclusion

This research had put forward the discussion and the example verification for the flow assignment after classifying the level of passengers and trains, but it didn't carry on the thorough analysis and exploration to optimization and adjustment of trains or operation plan after producing waste section during flow assignment, human external control method in flow assignment process. These two aspects is very important for the flow assignment and the optimization's effect, and it is the focused research direction for the next phase.

Effects of a Single Price Coefficient Change on the Test Number in a Transportation Problem

Lanrong Pan[1] and Haifeng Yan[2]

Southwest Jiaotong University, School of Transportation and Logistics, Chengdu 610031. E-mail: [1]ttoz_187829@sohu.com; [2]yanhaifengjy@home.swjtu.edu.cn

Abstract: Price coefficient changes will affect optimal solution of transportation problem. This paper regards using potential method to solve balanced transportation problem as the research target, focusing on the study of the effects on the optimal solution in the case of single price coefficient change. The study found that the change of non-base variable and base variable price coefficient will cause the change rule of potential and test number, and proved a series of theorems and corollaries. On this basis, the paper gives a simple algorithm to count new test number aimed at single price coefficient change. At the same time provided mathematical analysis.
Keywords: Transportation problem; Price coefficient; Potential method; Test number.

1 Introduction

The transportation problem (Wang Guangmin, 2011) is described below. Yield of each production sites $A_i (i = 1,2,\cdots,m)$ is a_i, and sales volume of each sales locations $B_j (j = 1,2,\cdots,n)$ is b_j. The unit price from A_i to B_j comes to c_{ij}. Then how can we get the scheduling scheme $X^* = \{x_{ij}^*\}_{m\times n}$ to minimize the total freight. It can be described as

$$z = \min\left\{\sum_{i=1}^{m}\sum_{j=1}^{n} c_{ij}x_{ij} \middle| \left(\sum_{j=1}^{n} x_{ij} = a_i\right) \cap \left(\sum_{i=1}^{m} x_{ij} = b_j\right) \cap (x_{ij} \geq 0)\right\} \quad (1)$$

After we get optimum solution of the transportation problem, because of the change of c_{ij}, we need to recalculate the optimal solution. It will take a lot of time if the order of price coefficient matrix is large. When c_{ij} changes little, it will greatly simplify the calculation if we can using the characteristics of original optimal solution to quickly judge the change in the optimal solution.

Through the virtual place of origin or sell, all the transportation problem can be turned into balanced transportation problem. This paper focused on the study of the effects on the optimal solution in the case of single c_{ij} change when using potential method to solve balanced transportation problem. For the linear programming problem (Zeng Meiqing, 2010), we have got a mature theory (Le Xiaoyang, 1990 Wang Huanxiong, 1984). Transportation exhibits a special problem of linear programming. When this occurs, we can get a similar theory.

2 Analysis on change of non-base variable price coefficient

When using the potential method to solve the balanced transportation problem, we can get u_i, v_j according to $\sigma_{ij}^B = c_{ij}^B - (u_i^B + v_j^B) = 0$ (Li Weizheng, 2005), when c_{ij}^N corresponding to the non-base variable changes, because c_{ij}^B is invariant, all the u_i and v_j will not change. Then

Property **1:** In balanced transportation problem, if price coefficient c_{st} of non-base variable changes into c'_{st}, test number σ_{st} will change into $\sigma'_{st} = c'_{st} - (u_s + v_t)$, the rest test number stay unchanged.

So, when a certain c_{ij}^N changes, we can use property 1 to recalculate the corresponding test number of non-base variable. If the test number is still not negative, the optimal solution is unchanged, otherwise, we can use closed-loop method take the non-base variable as in-variable to adjust.

3 Analysis on change of base variable price coefficient

In order to describe convenience, definite as follows:

Definition: For A and B, if A changes into A±a, and B also changes into B±a, then call A is the same change with B. If A changes into A±a, but B changes into B∓a, then call A is the opposite change with B.

Through the research of price coefficient change, we can get the following theorem and corollary:

Theorem **1**: When using potential method to solve standard transportation problem, only if the price coefficient c_{pq} of base variable changes, then

(1)If there is only one base variable x_{pq} in the *q* column and $u_p = 0$, then v_q is the same change with c_{pq}, the rest u_i and v_j are unchanged.

(2)If there is only one base variable x_{pq} in the *p* line and $v_q = 0$, then u_p is the same change with c_{pq}, the rest u_i and v_j are unchanged.

Proof: Because x_{pq} is a base variable, $\sigma_{pq} = 0 = c_{pq} - (u_p + v_q) \Rightarrow c_{pq} = u_p + v_q$ and $u_p = 0 \Rightarrow c_{pq} = v_q$.Based on $\sigma_{ij}^B = c_{ij}^B - (u_i^B + v_j^B) = 0$, we get (*m*+*n*-1) equations. Only one base variable x_{pq} in the *q* column means except $c_{pq} = v_q$ the rest (*m*+*n*-2) equations exclude v_q.Then according to the (*m*+*n*-2) equations and $u_p = 0$,we can get the unique solution of (*m*+*n*-1) potentials exclude v_q.The solution is nothing about v_q. So, theorem 1(1) is proofed. Similarly to theorem 1(2).

Corollary **1:** When using potential method to solve standard transportation problem, in the table of optimal solution, if there is only one base variable x_{pq} in the *q* column and its price coefficient c_{pq} changes into $c'_{pq} = c_{pq} + a_1$, only test number of non-base variable in the *q* column will change and be the opposite change with c_{pq}.

Proof: Make $u_p = 0$.According to the theorem 1 we find that when $c'_{pq} = c_{pq} + a_1$, then $v'_q = v_q + a_1$, the rest potentials will be unaltered. According to the equation $\sigma_{ij} = c_{ij} - \left(u_i + v_j\right)$, we find that $\sigma'_{ij} = c_{ij} - (u_i + v'_j) = c_{ij} - (u_i + v_j) = \sigma_{ij}(j \neq q)$ and $\sigma'_{iq} = c_{iq} - (u_i + v'_q) = c_{iq} - (u_i + v_q + a_1) = \sigma_{iq} - a_1$. So, corollary 1 is proofed.

***Theorem* 2**: When using potential method to solve standard transportation problem, only if the price coefficient c_{pq} of base variable changes, then

(1)Let $u_p = 0$, then v_q is the same change with c_{pq}. If there are (*b*+1) base variables in the *q* column respectively in the line $p, p_1, p_2, \cdots, p_b$, then u_{p_i} are the opposite change with c_{pq}. And if there is only one base variable in the $p_i (i = 1, 2, \cdots, b)$ line, then the rest potentials will be unaltered except u_{p_i} and v_q.

(2)Let $v_q = 0$, then u_p is the same change with c_{pq}. If there are (*b*+1) base variables in the *p* line respectively in the column $q, q_1, q_2, \cdots, q_b$, then v_{q_j} are the opposite change with c_{pq}. And if there is only one base variable in the $q_j (j = 1, 2, \cdots, b)$ column, then the rest potentials will be unaltered except u_p and v_{q_j}.

Proof: Because x_{pq} is a base variable, $\sigma_{pq} = 0 = c_{pq} - (u_p + v_q) \Rightarrow c_{pq} = u_p + v_q$ and $u_p = 0 \Rightarrow c_{pq} = v_q$. If c_{pq} changes into $c'_{pq} = c_{pq} + a_1$, $v'_q = v_q + a_1$, According to $c'_{p_i,q} - (u'_{p_i} + v'_q) = 0$, then $u'_{p_i} = c'_{p_i,q} - v'_q = c_{p_i,q} - v_q - a_1 = u_{p_i} - a_1$ .So u_{p_i} is the opposite change with c_{pq}. Based on $\sigma^B_{ij} = c^B_{ij} - (u^B_i + v^B_j) = 0$, we get (*m*+*n*-1) equations. Only one base variable in the $p_i (i = 1, 2, \cdots, b)$ line means among the (*m*+*n*-1) equations there will be (*m*+*n*-*b*-2) equations exclude u_{p_i} and v_q .Then according to the (*m*+*n*-*b*-2) equations and $u_p = 0$,we can get the unique solution of (*m*+*n*-*b*-1) potentials exclude u_{p_i} and v_q .The solution is nothing about u_{p_i} and v_q. So, theorem 2(1) is proofed. Similarly to theorem 2(2).

***Corollary* 2**: When using potential method to solve standard transportation problem, in the table of optimal solution, if there are (*b*+1) base variables in the *q* column respectively in the line $p, p_1, p_2, \cdots, p_b$ and only one base variable in the $p_i (i = 1, 2, \cdots, b)$ line, only c_{pq} changes, then only test number of non-base variable in the *q* column and the $p_i (i = 1, 2, \cdots, b)$ line will change, ones in the *q* column is the opposite change with c_{pq},and others in the p_i line is the same change with c_{pq}.

Proof: Make $u_p = 0$.According to the theorem 2(1) we find that when $c'_{pq} = c_{pq} + a_1$, then $v'_q = v_q + a_1$, $u'_{p_i} = u_{p_i} - a_1$ and the rest potentials will be unaltered. According to the equation $\sigma_{ij} = c_{ij} - \left(u_i + v_j\right)$, we find that $\sigma'_{ij} = c_{ij} - (u_i + v'_j) = c_{ij} - (u_i + v_j) = \sigma_{ij}$ ($i \neq p_i, j \neq q$), $\sigma'_{iq} = c_{iq} - (u_i + v'_q) = c_{iq} - (u_i + v_q + a_1) = \sigma_{iq} - a_1 (i \neq p_i)$,

$\sigma'_{p_i,j} = c_{p_i,j} - (u'_{p_i} + v_j) = c_{p_i,j} - (u_{p_i} - a_1 + v_j) = \sigma_{p_i,j} + a_1 (j \neq q)$.So, corollary 2 is proofed.

4 Simple algorithm

Using the above theorem, under the enlightenment of Hungarian Algorithm in assignment problem, we get a simple algorithm to calculate new test number when a single price coefficient changes.

Suppose x_{pq} is a variable and its price coefficient c_{pq} changes, make $u_p = 0$.Based on the original table of test number, take x_{pq} as the starting point and take the steps as follows:

STEP-1: Marking

① Mark √ at v_q, mark out the q column;

② In the lined column, if there are variables without marking out the rows , mark Δ at u_i in the rows for the base variables, mark out the rows, turn into③. If not, come to the end.

③ In the lined rows, if there are variables without marking out the columns, mark √ at v_j in the columns for the base variables, mark out the columns, turn back to ②. If not, come to the end.

STEP-2: Calculating new potential

All the v_j marked √ are the same change with c_{pq}, and all the u_i marked Δ are the opposite change with c_{pq}.

STEP-3: Calculating the test number of non-base variable

All the test number of non-base variable just marked out by vertical line are the opposite change with c_{pq}. All the test number of non-base variable just marked out by horizontal line are the same change with c_{pq}.The rest test number remain the same.

Usually when using potential method to solve transportation problem, we will suppose $u_1 = 0$. In order to facilitate the use of the above algorithm, it provides property 2.

***Property* 2:** When using the potential method to solve the balanced transportation problem, in the same group of base variable, sign the potential as u_i, v_j when making $u_1 = 0$, u'_i, v'_j when making $u_p = 0 (p \neq 1)$, u''_i, v''_j when making $v_q = 0$,then

(1)If $u_p = a_1$ when making $u_1 = 0$, then there will be $u'_i = u_i - a_1$ and $v'_j = v_j + a_1 (\forall i, j)$ when making $u_p = 0$;

(2)If $v_q = a_1$ when making $u_1 = 0$, then there will be $u''_i = u_i + a_1$ and $v''_j = v_j - a_1 (\forall i, j)$ when making $v_q = 0$.

5 Example

A transportation problem is showed as follows in table 1, using table working method we get the table of test number and optimal solution as in table 2. Suppose price coefficient of base variable x_{43} changes into $c'_{43} = 5$.

Table 1.production and sales volume and unit tariff

Terminal / Origin	B_1	B_2	B_3	B_4	B_5	B_6	Sales Volume
A_1	10	20	5	9	10	0	6
A_2	2	10	8	30	6	0	5
A_3	1	20	7	10	4	0	2
A_4	8	6	3	7	5	0	9
Yield	4	4	6	2	4	2	22

Table 2.table of test number and optimal solution

Terminal / Origin	B_1	B_2	B_3	B_4	B_5	B_6	u_i
A_1	7	12	0 ④	0	3	0	0
A_2	0 ④	3	4	22	0 ①	1	-1
A_3	1	15	5	4	0 ②	3	-3
A_4	7	0 ④	0 ②	0 ②	0 ①	2	-2
v_j	3	8	5	9	7	0	—

Note: The circle number at the upright means optimal solution

(1)According to the property 2, we can calculate the change of test number in table 2 when making $u_4 = 0$, then we get table 3.

Table 3. table of test number making $u_4 = 0$

Terminal / Origin	B_1	B_2	B_3	B_4	B_5	B_6	u_i
A_1	7	12	0	0	3	0	2
A_2	0	3	4	22	0	1	1
A_3	1	15	5	4	0	3	-1
A_4	7	0	0	0	0	2	0
v_j	1	6	3	7	5	-2	—

(2)Circle x_{43} means taking this as the starting point for marking, then we get table 4.

Table 4. table of optimal solution after marking

Terminal / Origin	B_1	B_2	B_3	B_4	B_5	B_6	u_i
A_1	-	-	4	-	-	2	Δ
A_2	4	-	-	-	1	-	-
A_3	-	-	-	-	2	-	-
A_4	-	4	②	2	1	-	-
v_j	-	-	√	-	-	√	—

(3)According to the simple algorithm, u_1 which marked Δ should reduce 2 and v_3, v_6 which marked √ should add 2.Then test number $\sigma_{23}, \sigma_{33}, \sigma_{26}, \sigma_{36}, \sigma_{46}$ should reduce 2 and $\sigma_{11}, \sigma_{12}, \sigma_{14}, \sigma_{15}$ should add 2.The table of new test number as in table 5.

Table 5. table of new test number

Origin \ Terminal	B_1	B_2	B_3	B_4	B_5	B_6	u_i
A_1	9	14	0	2	5	0	0
A_2	0	3	2	22	0	-1	1
A_3	1	15	3	4	0	1	-1
A_4	7	0	0	0	0	0	0
v_j	1	6	5	7	5	0	—

(4)Because table 5 exists a negative σ_{26} , the optimal solution will change.

(5)Take x_{26} as in-variable, using closed-loop method to continue calculating until get the optimal solution.

6 Conclusions

In real life, the scale of transportation problem is large, and price coefficient changes frequently. If we already get optimum solution, we can use simple algorithm easily get the table of new test number in the new price coefficient, then judge whether the optimal solution is changed or not.

However, the simple algorithm in this paper is aimed at single price coefficient, and it does not consider the condition that several price coefficients change together. So this will be the future research direction.

Abstract: M_3 scheduling problem is one of the most difficult problems in the world in the field of operational research. Analysis of the problem suggests that all the processing time is equal to both the processing time of all parts and floor time on the third sets of machine tools. Correspondingly the minor floor time on the third machine tools matches the fewest total time. According to such thoughts to reduce the floor time of the third machine as much as possible, we design a general algorithm for M_3 scheduling problem, and give the algorithm steps. Finally, through examples we tested and verified the feasibility of the algorithm.
Keywords: Scheduling problem; 3 sets of machine tools; Algorithm; Example.

1 Problem Description

The issue of job-shop scheduling can be simply described as: n workpieces (J_1,J_2,…,J_n) are operated on m machine tools(M_1,M_2,…M_m)at the same time,each workpiece(J_i) has n operations O_{i1},O_{i2},…,O_{in}, and the processing time is v_{ij} when the operation O_{ij} comes; workstages should operate at row and work out once where one machine tool can only processs one product and one product cannot be processed on two or more machines at the same time. In the condition that mentioned above, how can shorten the time when the last workpiece completed?

2 Literature review

General, the subclass of this issue---having the same workstages among the workpieces, which be called scheduling problem. The complexity about this problem is NP-Hard, because if n or m is bigger, it cannot be solved by Exhaustive Method[1]. In 1954 Johnson solved the problem of M_2 scheduling problem by putting forward the optimal algorithm of two machines(m=2) processing n of workpieces[2]. However, the problem of scheduling problem when M_k(k≥3) hasn't be reached, which is the puzzle in the world in the field of operational research.

This paper tries to take Matrices Method to explore optimal algorithm of M_3 scheduling problem.

3 Algorithm Steps

In order to conveniently research, hypothetically n of workpieces are processed on the machine tools A,B,C at row. And the processing time needed on the A respectively are a_1,a_2,…,a_n, and that needed on the B respectively are b_1,b_2,…,b_n, and that needed on the C respectively are c_1,c_2,…,c_n. We define the matrix operation time as $V=\{v_{ij}\}_{n\times 3}$, and $v_{i1}=a_i$, $v_{i2}=b_i$, $v_{i3}=c_i$.

Analyzing this problem can get : all the processing time needed to finish all parts is equal to sum of the time spended on the machine tool C to process all parts and the floor time on it; the less floor time on machine C , the less time needed in whole stages. Therefore, the whole time can be cut to the least if we take the method to reduce the floor time on the machine C.

Following the idea, the arithmetic of M3 scheduling problem can be described as below.

STEP1: Initialization,let p=0.

Define set $T^p = \phi$,express none workpiece has been selected; $P^p = \{1,2,\cdots,n\}$, express n workpieces hasn't been selected. Computing matrix $M^p = \{m_{ij}^p\}_{n\times 6}$,line i express workpiece J_i; column 1(2) express start(end) time when J_i is operated on machine tool A, column 3(4) express start(end) time when J_i is operated on machine tool B, column 5(6) express start(end) time when J_i is operated on machine tool C;and $\forall i = 0 \bigcup \forall j = 0 \Rightarrow m_{ij}^p = 0$,

$$m_{ij}^p = \begin{cases} m_{i,j-1}^p & (j=1, 3, 5) \\ m_{i,j\text{-}1}^p + v_{i,j/2} & (j=2, 4, 6) \end{cases} \tag{1}$$

STEP2: Determine the state variables.

Define the state variables $r_p = y_{p\text{-}1}$,and $y_{\text{-}1}=0$;waiting time $\min\{m_{i5}^p - m_{r6}^p\} = t_{y_p}$,if t_{y_p} not only, determined in accordance with the following rules:

(1) $\min\{|m_{i4}^p - m_{r6}^p|\} = t_{y_p}$,if t_{y_p} still not only,turn to (2);

(2) $\max\{m_{i6}^p\} = t_{y_p}$, if t_{y_p} still not only,choose anyone of them.

STEP3: Matrix calculation,let $p= p+1$.

$T^p = T^{p-1} \bigcup \{r_p\}$, $P^p = P^{p-1} \wedge \{r_p\}$, element of M^p

$$m_{ij}^p = \begin{cases} m_{ij}^{p-1} & (i \in T^p) \\ \max\{m_{i,j-1}^p,\ \ m_{r,j+1}^p\} & (i \notin T^p) \bigcap (j=1, 3, 5) \\ m_{i,j\text{-}1}^p + \mathrm{v}_{i,j/2} & (i \notin T^p) \bigcap (j=2, 4, 6) \end{cases} \tag{2}$$

STEP4: Matrix iterative.

Judge ?$(P^p = \phi)$;yes, turn to STEP5;no,turn to STEP2.

STEP5: Output result.

Output the optimal processing sequence： $(J_{y_0}, J_{y_1}, J_{y_2}, \cdots, J_{y_{n-1}})$,the total time: $\sum_{i=1}^{n} \mathrm{c}_i + \sum_{p=0}^{n\text{-}1} t_{y_p} = m_{y_{n\text{-}1}6}^{n\text{-}1}$.

The computational steps of M_3 scheduling problem is shown in Figure 1.

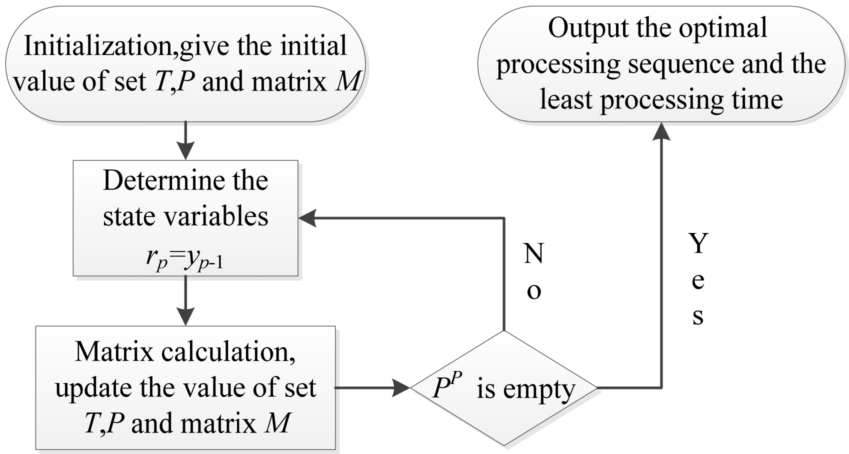

Figure 1. computational steps of M₃ scheduling problem

4 Example

The processing time of workpieces J_1,J_2, J_3, J_4, J_5, J_6 on machine tools A,B,C can form a time matrix as

$$V=\begin{pmatrix}3&7&6\\6&7&3\\6&5&9\\2&6&2\\8&3&5\\9&4&4\end{pmatrix}。$$

(7) p=0, $r_0=y_{-1}=0$, $T^0=\phi$, $P^0=\{1,2,3,4,5,6\}$,

$$M^0=\begin{pmatrix}0&3&3&10&10&16\\0&6&6&13&13&16\\0&6&6&11&11&20\\0&2&2&8&8&10\\0&8&8&11&11&16\\0&9&9&13&13&17\end{pmatrix},\quad \min\{m_{i5}^0-m_{06}^0\}=t_{y_0}=t_4=8;$$

(2) p=1, $r_1=y_0=4$, $T^1=T^0\bigcup\{r_1\}=\{4\}$, $P^1=P^0\wedge\{r_1\}=\{1,2,3,5,6\}$,

$$M^1=\begin{pmatrix}2&5&8&15&15&21\\2&8&8&15&15&18\\2&8&8&13&13&22\\0&2&2&8&8&10\\2&10&10&13&13&18\\2&11&11&15&15&19\end{pmatrix},\quad \min\{m_{i5}^1-m_{46}^1\}=t_{y_1}=t_3=5;$$

(3) p=2, $r_2=y_1=3$, $T^2=T^1\bigcup\{r_2\}=\{4,3\}$, $P^2=P^1\wedge\{r_2\}=\{1,2,5,6\}$,

$$M^2=\begin{pmatrix}8&11&13&20&22&28\\8&14&14&21&22&25\\2&8&8&13&13&22\\0&2&2&8&8&10\\8&16&16&19&22&27\\8&17&17&21&22&25\end{pmatrix},\quad \min\{m_{i5}^2-m_{36}^2\}=t_{y_2}=t_2=0;$$

(4) p=3, $r_3=y_2=2$, $T^3=T^2\cup\{r_3\}=\{4,3,2\}$, $P^3=P^2\wedge\{r_3\}=\{1,5,6\}$,

$$M^3=\begin{pmatrix}14&17&21&28&28&34\\8&14&14&21&22&25\\2&8&8&13&13&22\\0&2&2&8&8&10\\14&22&22&25&25&30\\14&23&23&27&27&31\end{pmatrix},\quad \min\{m_{i5}^3-m_{26}^3\}=t_{y_3}=t_5=0;$$

(5) p=4, $r_4=y_3=5$, $T^4=T^3\cup\{r_4\}=\{4,3,2,5\}$, $P^4=P^3\wedge\{r_4\}=\{1,6\}$,

$$M^4=\begin{pmatrix}22&25&25&32&32&38\\8&14&14&21&22&25\\2&8&8&13&13&22\\0&2&2&8&8&10\\14&22&22&25&25&30\\22&31&31&35&35&39\end{pmatrix},\quad \min\{m_{i5}^4-m_{56}^4\}=t_{y_4}=t_1=2;$$

(6) p=5, $r_5=y_4=1$, $T^5=T^4\cup\{r_5\}=\{4,3,2,5,1\}$, $P^5=P^4\wedge\{r_5\}=\{6\}$,

$$M^5=\begin{pmatrix}22&25&25&32&32&38\\8&14&14&21&22&25\\2&8&8&13&13&22\\0&2&2&8&8&10\\14&22&22&25&25&30\\25&34&34&38&38&42\end{pmatrix},\quad \min\{m_{i5}^5-m_{16}^5\}=t_{y_5}=t_6=0;$$

(7) p=6, $r_6=y_5=6$, $T^6=T^5\cup\{r_6\}=\{4,3,2,5,1,6\}$, $P^6=P^5\wedge\{r_6\}=\phi$, algorithm finished. Output the optimal processing sequence:(J_4,J_3,J_2,J_5,J_1,J_6) ,the total time: $\sum_{i=1}^{6}c_i+\sum_{p=0}^{5}t_{y_p}=m_{66}^5=42$.

5 Conclusion

Although in this paper the example get an optimal solution, the strict proof about this cannot be offered, so this arithmetic is not the optimal algorithm technically. Through the steps of algorithm, it can be seen that this algorithm is able to apply to the job-shop scheduling problem of M_k（k>3）. Compared with the traditional critical path, the effectiveness of this algorithm remains to be improve.

Train Combination Model of a Passenger Train Plan for a High-Speed Railway

Rui Yang; Weidong Chen; and Hao Wen

School of Transportation and Logistics, Southwest Jiaotong University, P.O. Box 610031, Chengdu. [1]E-mail: yangrui1980@126.com

Abstract: According to the idea of combined train plan, this paper optimizes the train plan through the mathematic modeling. It aims to adjusting the sub problems of the problem, which transforms the problem of how to make the qualified trains combine to reduce the number of train and improve the train attendance into a solution problem for bi-objective programming model. Finally, an example is given to prove the feasibility and validity of the model and the algorithm, providing effective support for intelligent development of train scheme optimization for high-speed railway.
Keywords: High-speed railway; Train plan; Plan optimization; Train combination.

1 Introduction

The operation scheme of high-speed railway station is directly related to the level of high-speed railway transport services and the obtained economic benefits, reflecting the railway passenger transportation management strategy and service strategy. The reasonable train operation scheme helps to improve the economic benefit of transportation enterprises, but also facilitate passenger travel, and enhance the competitiveness of the high-speed railway market, so it is necessary to make the in-depth study on the problem of optimizing scheme of high-speed railway train.

According to the Japanese Shinkansen high-speed train plan, they propose the idea of merging-type passenger train plan, and deeply analyze the impact of high-speed railway transportation organization. It is concluded that the combined train scheme has obvious advantage, also the negative influence can be controlled by taking the relevant measures. Therefore, along this idea, enriching the merging connotation of trains at the same time, and further researching on the train combination problem in the process of optimizing train scheme of high-speed railway, this paper puts forward to the mathematical model of solving the problem and designs the special algorithm which is easy to realize on a computer.

2 Assumptions and related definitions

2.1 Assumptions

(1)The assumption on initial train scheme

This paper studies only the combined problems in the process of optimizing train scheme of high-speed railway, so the initial plan of needing be optimized high-speed railway train has been completed by other means, including train species number contained in the proposal, various types of train route, stop scheme, number of the train and direction, which all have been informed.

(2) An uncertainty hypothesis on passenger assignment result

This hypothesis on the initial train operation scheme as the optimization object has completed the passenger flow distribution link and detailed information of each passenger train services needed are known, including the branch number of service passenger flow, OD and the number of passengers etc.

(3)Train personnel quota assumption

Following the "thought of simplified", the train in the assumptions uses unified train personnel, and train personnel value has been informed through other means.

(4) Deterministic hypothesisof passenger choice

This assumption of all the passengers travel choice have been determined by the passenger flow assignment results, and the merger would not cause any train passenger selection changes.

(5) Closed system hypothesis

This paper's studies are not related to the macro effects of the high-speed railway passenger train plan, so the system formed by the research problem is closed, namely the state change of the system will not have any influence on the environment, especially not to attract outside passenger flow and not cause passenger flowing from the system to the outside world.

2.2 Parameter description

N representsthe train number of initial operation scheme of high-speed railway train; n_i represents the number of stationon the train running path, the collection $S_i = \{1, 2, \cdots, n_i\}$ shows the collection of the station on the train running path, among which, the element of 1 corresponds to the start station of the train, n_i corresponds to the end station of the train,other elements stand for intermediate station the train pass by; L_m^{ij} represents the line length between m station and m+1station on the operation path after train i and train j are merged. P represents unified train personnel quota; f_{OD}^i shows the passengers number of riding the train i starting from the O station and arriving at the D station; h_m^i shows the number of carried passengers that the train i runs between m station and m+1 station.

2.3 Variable definition

Definite0-1 variables,the meaning is as follows:

$$x_{ij} = \begin{cases} 1 & combine\ train\ i\ and\ j \\ 0 & other \end{cases} \tag{1}$$

Among which, $i, j = 1, 2, \cdots, \mathrm{N}$, and $i \neq j$, respectively corresponding to initial train scheme in a column that contains detailed information of the train flow.

2.4 Operator definition

(1)First, definite a unary operator $\left| \bullet \right|$,calculate the number of elements of collection S, such as $|S|$.

(2)Second,denifite two unary operator,the algorithm is as follows:

$$S_i \oplus S_j = \begin{cases} 1 & \text{The direction of the train is consistent with the other train} \\ 0 & other \end{cases} \quad (2)$$

Among which, i *and* j are respectively the ordered set of the train path station, $i, j = 1, 2, \cdots, \mathrm{N}$.

In general, the related station on the high-speed railwayis only. The arrangement of station on the line can determine a sequence and form S of a totally ordered station set. The train operation cannot be divorced from the high-speed railway line, so the elements of the collection S_i or S_j must be the elements of S. According to the sequence of elements in S_i and S_j, in contrast with the sequence of elements in S, we can determine whether the array direction of elements is consistent, and then determine whether the running direction of train i and j is consistent.

3 The establishment of the model

3.1 Determination of the target function

1.With the aim of maximizing number of combined train

By merging all the train which meet the combination condition,the result is get that maximizes reducing the number of high-speed line train,reducing the daily operation organization difficulty, improving the efficiency of the high speed train of hanging line at the same time, and indirectly creating favorable conditions for reducing the number of train. Otherwise the idea of combined type passenger train plan will bemeaningless.So the target function is as follows:

$$\max Z_1 = \sum_{i=1}^{\mathrm{N}-1} \sum_{j=i+1}^{\mathrm{N}} x_{ij} \quad (3)$$

2. With the target of minimizing empty train degree

The degree of emptiness to train directly corresponds to the train attendance, reflecting the use ofmobile equipment transportation capacity and the rationality of trainoperation, its value can directly reflect the degree of passenger flow demand on train operation section. With the imaginary degree minimum as the objective to merge the trains, the transport capacity of mobile devices can be made full use, in the premise of completing the same transport task, the trains can more reasonably operate, minimizing the use of quantity and train running kilometers, thus minimizing the daily operating costs of transportation enterprises of high-speed railway and increasing the economic benefit of enterprises.So the target function is as follows:

$$\min Z_2 = \sum_{i=1}^{N-1}\sum_{j=i+1}^{N}\sum_{m,m+1\in\left(S_i\cup S_j\right)} x_{ij}\left(\mathrm{P}-h_m^i-h_m^j\right)L_m^{ij} \tag{4}$$

3.2 Determination of the constraint conditions

1.The constraints of passengers carried between train station

The change of the number of train passengers would only occur at the station, but the number of train passengers is a fixed value in the process of running between stations.Its value should satisfy the following constraint:

$$h_m^i = \sum_{O=1}^{m}\sum_{D=m+1}^{n_i} f_{OD}^i \qquad \left(m=1,2,\cdots,n_i-1; i=1,2,\cdots,\mathrm{N}\right) \tag{5}$$

2. The constraint of train continuity

The running path of two short haul trains must overlap or connect,otherwise it may cause the merged train idling running between part of stations.

$$x_{ij} \le \left|S_i \cap S_j\right| \left(i,j=1,2,\cdots,\mathrm{N} \text{ and } i\neq j\right) \tag{6}$$

3. The directional constraints of train combining

The running direction of two row short haul trains must be consistent, otherwise it is unable to determine the direction of train operation after merging.

$$x_{ij} \le S_i \oplus S_j \left(i,j=1,2,\cdots,\mathrm{N} \text{ and } i\neq j\right) \tag{7}$$

4. Constraints of the capacity of combined trains

The sum of carried passenger between station on overlapping path of the two short haul train cannot be more than the train personnel quota, otherwise the combined train won’t be able to complete all the transportation of the two short haul train.

$$\left(h_m^i+h_m^j\right)x_{ij} \le \mathrm{P} \left(i,j=1,2,\cdots,\mathrm{N} \text{ and } \mathrm{i}\neq\mathrm{j}; m,m+1\in\left(S_i\cap S_j\right)\right) \tag{8}$$

4 Algorithm Design

The combined train model proposed in this article belongs to the double objective programming model category. The traditional approach to solve a double objective programming problem starts off by converting it to a single objective programming problem. We usually consider the calculation of satisfaction value as a single objective programming model by ignoring objective 1, since objective function 2 contains objective function 1 and is more practical to a certain degree. Due to the existence of constraint condition 3, we still cannot solve this problem using currently existing algorithms. Here we propose a newly developed quick and easy solution for satisfaction value calculation as follows, (1)Calculate and store the number of passengers of each adjacent stations for all the trains according to the passenger assignment information in the initial train operation scheme.

(2)Calculate the ordered set (***S***) for all trains according to the direction of study, then sort all the trains according to the departure station and the sequence of the elements in set ***S***.

(3)Take out No. ***l*** *trains* by order If there are trains without tag *; the algorithm ends if all trains are tagged with *.

(4)Determine if there are trains without tag**after train No. ***l+1***. If such trains exist, take out train No. ***k (k>l)*** for feasibility test of combination; if not, tag the No. ***l*** train with *and cancel out all the ** tags, then switch back to step 3.

(5)If the initial station of train No. ***k*** is ahead of or the same as the terminals of train No. ***l***, switch to step 7 for volume check; if not, then tag train No. ***k*** with ** and move on to the next step.

(6)Carry out feasibility test of combination in step 5 with the train without ** tag after train No. ***k***; if no such train exist, tag the train No. ***l*** with * and cancel out all the train tagged with **, then switch to step 3.

(7)Replace train No. ***l*** (no * tag) with the combination train No. ***k*** and train No. ***l*** if the passengers carried between the initial station of train No. ***k*** and the terminal station of train No. ***l*** do not exceed the train seating capacity, then delete train No. k, cancel out all ** tags and switch to step 3; otherwise tag the train No. ***k*** with ** then switch to step 6.

5 Application Examples

In this paper, the high speed railway train as an important part of the research of optimization scheme. By combining with other related research results, we can complete the adjustment and optimization of the specified initial scheme.

The author used the computer programming technology to achieve a complete program for high speed railway train operation plan optimization adjustment. Selecting the 2005 Beijing Shanghai High-speed Railway train plan as the initial scheme, the relevant parameters are as follows: Train staff (1060), attendance (75%), high class passenger time value (0.7) and the corresponding price coefficient(0.3), Intermediate passenger time value (0.3) and the corresponding price coefficient(0.7). after simulating, create a new train plan which contains some data as shown in Fig.1. Some parts index numbers as shown in table 1.

After comparison and optimization of methodology and index, we observed statistical significant improvement of efficiency with the reduction of 7 pairs of trains in operation, in which 6 less pairs of trains required in operation distance between 200 and 500 km, 4 less pairs of trains required in operation distance between 500 and 1000 km, 2 less pairs of trains required in operation distance between 1000 and 1500 km, however 5 more pairs of trains required if the operation distance exceeds 1500 km, On the other hand, the overall efficiency of seats utilization increases from 72.25%to 87.06%, in which the efficiency increases from 71.63% to 89.77% in high-speed trains while the efficiency increases from 73.13% to 75.81% in low-speed trains. We demonstrated that the new model proposed can significantly improve the efficiency of train operation by reducing the void time which leads to increase revenue of railway companies, it works even better on those with high speed trains with higher ticket price.

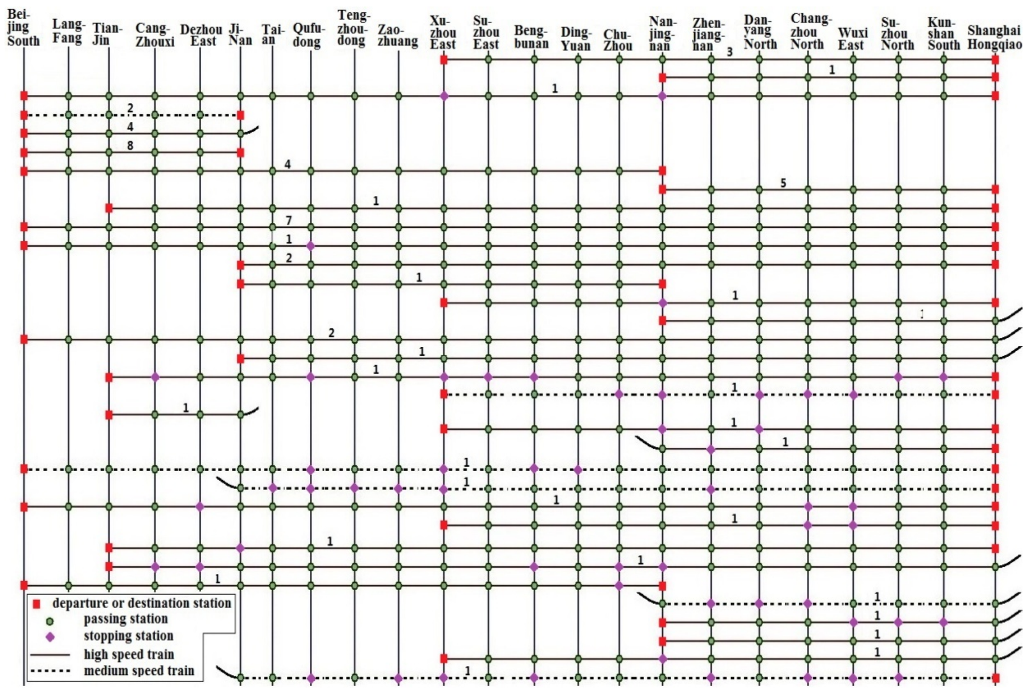

Figure 1. Part of the new train plan

Table 1. The index of operation scheme

The number of trains in operation		
	Before optimization	After optimization
Medium speed train	20	21
High speed train	102	92
The train operation in high speed railway line	102	90
Running distance		
200~500km	25	19
500~1000km	36	31
1000~1500km	53	50
more than 1500km	8	13

6 Conclusions

In this paper, by creating a model and algorithm, using the computer programming to realize the optimization and adjustment of a operation plan. Through the example of calculation, it almost certainly that the model and algorithm are feasible and easy to implement, basically achieve the consolidation purposes.So it improving the high-speed railway train operation plan optimization theory and Promoting the development of intelligent transportation organization.

Abstract: Passenger transfer volume size determines the construction scale and transfer mode of urban comprehensive hub. From the factors which influence passengers to transfer to analysis the transfer requirements of large-scale comprehensive passenger transport hub, the main factors influencing the passenger transfer mode selection characteristics can be summarized as traffic modes, the traveler characteristics and travel characteristics from three aspects. This paper compares the traditional urban comprehensive passenger transport hub with a new mode of urban comprehensive passenger transport hub in transfer type, concluded the transfer mode of comprehensive passenger transport hub and function are more diverse. The transfer between the internal and external transportation hub is actually the choice of transportation problem, it's the key point of hub transfer volume prediction. This paper considers the transfer influence factors of different people and present a simple prediction function.
Keywords: Comprehensive passenger transport hub; Transfer volume; Prediction method.

1 Introduction

Comprehensive passenger transport hub is treated as a hub which collecting a variety of passenger transport and transfer ways, the passenger transfer flow among transfer ways determines the scale and transfer mode of the hub in the very great degree. In the regard of planning and choosing a large passenger transportation hub construction scale and transfer model, not only needs to meet the needs of recent passenger distribution and transfer, but also needs to meet the development requirements of the future passenger transport. Therefore, based on analyzing the current scale of passenger transport hub passenger flow and the way of transfer characteristics to choose the reasonable method to change to the passenger volume prediction has an important guiding significance to the operation of the passenger transport hub.

At present, there are usually two kinds of transfer volume prediction at home and abroad: the four stages predict disaggregate models based on traditional; The disaggregate models based on utility theory (Wu, et al., 2013). Disaggregate models, such as Li et al. (2002) established gravity model by introducing traffic distribution principle; Tan (2013), Sun et al. (2008) established the maximum entropy model, etc. For the disaggregate model, such as Luo (2009) used Logit model calculates the trip distribution hub for passengers; Ou et al. (2010) take Hainan station transport hub as an example, using the Logit model to predict large passenger inside hub transfer behavior; Jia et al. (2009) used the disaggregate Logit model to set up and calibration transfer impedance function and set up the comprehensive passenger transport hub transfer quantity prediction model which based on the double restraint gravitational model.

Although many scholars at home and abroad had studied to comprehensive passenger transport hub transfer volume prediction method deeply, but some problems still exist. Such as the model adaptability is not strong, the transfer ways of cross transfer prediction research are not comprehensive, prediction method is complex, etc. On the basis of combining the reality of comprehensive passenger transport hub, considering the transportation need among varieties of transfer ways comprehensively, this paper proposes a simple change to the amount of prediction method.

2 Influence Factors of Passenger Transfer Mode Selection

It is actually a multi-objective decision-making process when passengers choose their mode of transportation in the center transfer. And it considers a combination of factors like rapid, convenient, economic, safe, comfortable and reliable. These factors can be divided into three aspects: transport characteristics, traveler characteristics and travel characteristics (Luo,2009). *M* expresses the final results that transfer passengers choose. And x, y, z respectively express three aspects of factors influencing transfer passengers' selection. The following function shows the factors influencing passenger transfer.

$$M(x,y,z)=\left\{(x_1,x_2\cdots,x_i),(y_1,y_2\cdots,y_j),(z_1,z_2\cdots,z_k)\right\} \tag{1}$$

Type, x_i express the factors relating to transport characteristics, such as timeliness, service level, transportation security, price, etc. y_j represents the subjective factors of travel choice, such as economic conditions, preference for travel mode, age, gender, etc. z_k represents the objective factors of travel choice, such as travel purpose, travel distance, etc.

In general, in the above factors, speed and ticket price are the two aspects that passengers mainly consider. But sometimes other factors also play a decisive role, such as passengers on official business or business travel generally do not consider fares, but more concerned with fast, convenient and comfortable. Passengers have very time requirements often consider the difference between expected arrival time and actual arrival time, so as to choose the minimum differential mode of transportation, it involves many factors such as speed, service frequency, reliability (Zhai, 2005; Feng, 2006).

Different people choose different travel ways. For some areas have poor transportation, passengers often consider accessibility and safety at first. Passengers have strong economic ability tend to first consider convenience, safety and comfort, and for low-income passengers, economy often comes to the first consideration.

3 Urban Comprehensive Passenger Transport Hub Transfer Type

Urban comprehensive passenger transport hub is a transfer node which assembled the external transport, urban public transport , private transport mode and many other mode of transport (as shown in figure 1), the transfer form is more diverse than traditional external passenger transport hub, the city public transport hub and so on. In order to get the transfer volume prediction which consistent with actual situation and scientific, we must have a fully correct understanding about transfer mode.

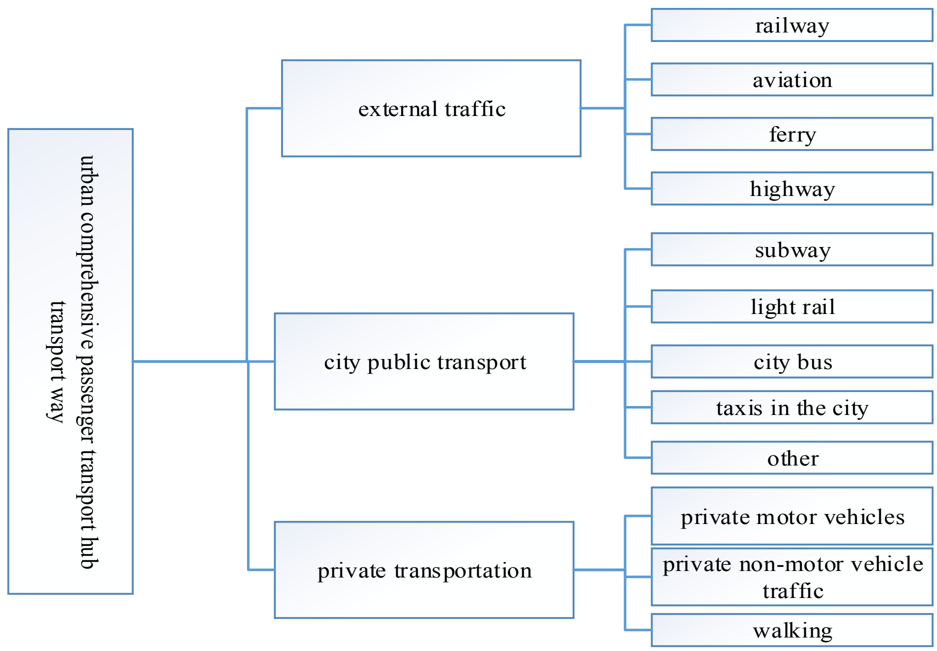

Figure 1. Transportation Mode of Urban Comprehensive Passenger Transport Hub

Table 1 compares urban comprehensive passenger transport hub with traditional passenger transport hub in the transfer form. Traditional passenger transport hub achieves the internal transfer between urban external traffic mainly in transfer function, transfer mode is relatively single. And new type comprehensive passenger transport hub not only contains the transfer which between city and outside of city, the transfer between inner cities, but also requires to achieve two or more external transfer modes.

Table 1 Comparison in Major Transfer Forms of Urban Passenger Hub

Hub	Major Transfer Mode	Diversity of Function
Traditional Passenger Hub	traffic transfer between inside and outside of city	single
Comprehensive Passenger Transport Hub	traffic transfer between inside and outside of city Transfer between external traffic Transfer between internal traffic of city	diverse

4 Transfer Volume Prediction Model

4.1 Description of Problem

Transfers between internal and external traffic in hub is a convergence problem between urban traffic and external traffic, it actually is a problem of transportation choice. According to distributed traffic of the outbound traffic in hub, by predicting various traffic sharing rates to get the transfer volume between the various transportation modes. Because of the passenger traffic within the city is relatively stable, according to a large number of daily passenger transfer passenger data and analyzing the date to get its recent transfer volume. We can know that the transfer forecast of internal and external traffic is the key issues of transfer volume prediction in hub.

4.2 Creation of Model

To passenger volume of one transportation, it can be obtained by classified and counted passenger ticketing system of hub; To the share rate of one transportation, it can also be analyzed by a lot of actual data, but this kind of data tend to lack in our country, so when we analyze transfer volume prediction of the passenger hub, methods of establish transfer model between the various transportation modes are often adopted.

According to the division principle of urban comprehensive passenger transportation hub's transportation modes, using the disaggregate Logit model[10] of transportation mode selection to establish transfer volume prediction model. For comprehensive passenger transport hub, passengers can choose a variety transportation modes when they enter and go out hub, this is a multiple choice question.

Assume that passenger travel mode choice suitable their travel characteristics; all certainty factors which influence passenger change transportation by i to transportation mode j are expressed by X_{ij}, and uncertainty factors are expressed by β, then the reliability which passenger change transportation mode i to transportation mode j can be represented as:

$$K = X_{ij} + \beta \qquad (2)$$

Assume that β obeys double exponential distribution (Gumbel Distribution), use p_{ij} to express the apportion rate of passenger change transportation mode i to transportation mod j , the mathematical expressions of multiple selection probabilities model can be pushed to as follows:

$$p_{ij} = p(K) = \frac{exp(X_j + \beta)}{\sum_{j=1}^{n} exp(X_{ij} + \beta)} = \frac{1}{1 + \sum_{i \neq j}^{n} exp(X_{ij} - X_j)} \quad (3)$$

On the basis of the type (3), assuming that S_i is expressed to be the passenger volume of transportation mode i, the passenger volume of different transportation modes can be predicted by the following function:

$$Q_{ij} = \sum_{i=1}^{m} \sum_{j=1}^{n} S_i \cdot p_{ij} \quad (4)$$

Type, Q_{ij} means the transfer volume of transportation mode i transfer to transportation mode j .

The total transfer volume of all kinds of transportation mode is as follows:

$$Q = \sum_{i=1}^{m} \sum_{j=1}^{n} Q_{ij} \quad (5)$$

5 Adaptability Analysis of Model

Urban comprehensive passenger transport hub is a complex including a variety of modes of transportation and a variety of transportation equipment, it is very important to coordinate its internal subsystems each other. Based on using the disaggregate Logit model to calculate the transfer assessment rate, the transfer volume prediction model is established by fully considering the cross transfer of various transfer ways and predicted the transfer volume of various transfer ways, it also covered the passenger transfer characteristics between various transfer ways.

By analyzing the characteristics of the model parameters, we can obtain the mechanism which all influence factors influence passengers to make the travel decision of choice. By analysis the calculation of transfer modes assessment rate, travelers can be analyzed the difference and the influence on the decision-making behavior with the difference in travel purpose, the different requirements in timeliness, comfort, security, etc, the results can provide scientific basis for all kinds of traffic operation scheduling and improve the connection between transportation coordination.

6 Conclusions

It is a complex work for large comprehensive passenger transport center to forecast the transfer demand. It involves in many fields, such as social, human, economic and system analysis. At present, though there are many scholars and experts studied systematically, there is no mature prediction method for reference. On the basis of above theoretical analysis, this paper proposes a simple and feasible method for transfer demand predicting, providing reference for the demand predicting in the domestic similar comprehensive passenger transport center transfer.

Abstract: Nowadays, as one of the most important procedures of the organization of express freight transportation, the traditional manual programming can not keep up with the change of the transportation market. Therefore, it's important to design the express freight train diagram programming system. Firstly, the background of the research is explained. Then, the system requirements are analyzed .Furthermore, the system functions are designed. Finally, the significance and strength of the system are summarized.
Keywords: Express freight train; Train diagram; System design.

1 Introduction

It is well-known that the express freight transportation is a kind of freight organization form, which is with simple procedure, high loading efficiency and high transportation speed (Lan 2009). It's conducive to the realization of multimodal transport, "door to door" transportation and bulk cargo direct transportation, high value added goods are the main objects of express freight transportation(Peng etal.2011,Yang 2000). Express freight transportation has become one of the development trend of railway transportation because of its necessity and the feasibility reasons (Dai etal. 2013, Zhang etal. 1999).

2 Analysis of Express freight train diagram programming system requirements

2.1 The influence factors of express freight train diagram programming

Before the part of system design, the influence factors of express freight train diagram programming have been analyzed according to the features of express freight train. By analyzing, it mainly includes these factors: train diagram elements, application and capacity of equipment, coordinated operation and transport demand.

2.2 Transport demand

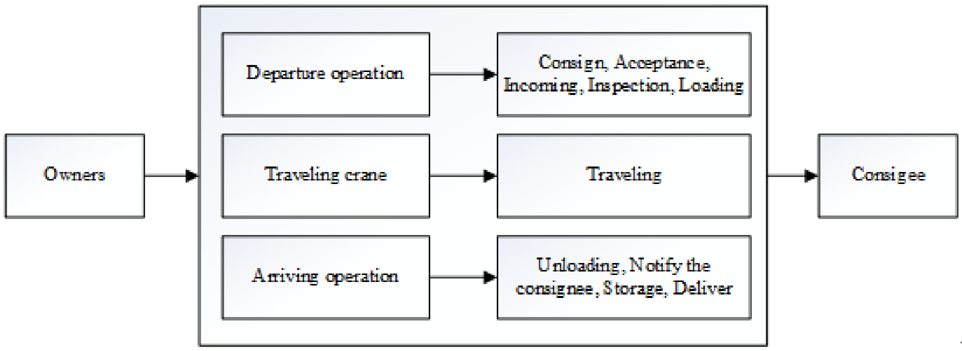

Figure 1. The express freight transportation process

From the express freight transportation process (Figure 1.), the demands of express freight trains' transport could be embodied in the following four aspects: quickness, accuracy, convenience and safety.

The transportation demand of through freight train could be embodied in three levels: the transport business facilitation needs, the whole time demand and the personalized needs of transport service.

2.3 The definition of user agent and service provider

2.3.1 User agent

The user agent is the main service object of a system, which describes and understands that the systems are the bases of system requirements analysis and system design (Hao etal. 2001).The user agent of express freight train diagram programming system mainly includes: external users (the owners and other coordination departments) and inside users (the operations department, transport security department and information service department).

2.3.2 Service provider

Service provider of system means inside users, and mainly includes the operations department, transport security department and the information service department. All of these departments cooperate with each other meet external users' demands.

The service providers mainly include: transportation management, transport security and information service management.

2.4 Requirement analysis of users of the system

2.4.1 Requirement analysis of user agent

From the express freight transportation process, the system satisfies the following demands:

(1) Information service and express freight transport real-time schedule;

(2) Real-time position of express freight trains;

(3) The owners' proposed and evaluation to system as one of the improved data;

(4) Demands of fast freight train and through freight train;

(5) Demands for convenience, which mainly includes convenient delivery (Table 1.). The owners can choose a variety of express freight train to finish transportation flexibly;

Table 1. Express freight handing ways

Delivery type	Handing ways
Telephone	Call the phone number of the freight stations
	Call the phone number of China railway customer service center
Internet	www.12306.cn
	the freight stations
The scene	The railway workers door-to-door service

(6) Demands for accuracy;

(7) Safety requirements. The system shall ensure both safety in train running and the quality of goods;

(8) When freight trains go through technical stations without being marshalled, minimize the stopping time; system should prevent mutual interference between train paths.

2.4.2 Requirement analysis of service provider

(1) Transportation management department

Freight management department: Collecting freight data, analyzing the information of supplied goods, trying to simplify the procedures of fast freight transportation, determine a reasonable plan of cargo transport and express freight train scheme, and provide express freight transport supply ability to the society.

Fixed equipment management department: Providing the information sharing platform for the system.

Mobile device management department: It is responsible for allocating locomotives rationally, reducing waiting time, improving cargo delivery speed.

(2) Dispatching centre

Train diagram programming

Express freight train diagram programming management

(3) Transport security department

Ensuring the coordination between the various departments, the rational allocation of locomotives; the reduction of waiting time, the improvement of cargo delivery speed.

(4) Information service

It mainly includes: data collection, data sharing, data analysis management and maintenance.

3 Express freight train diagram programming system functions design

3.1 Brief introduction to the main functions of the system

According to the analysis of the previous four chapters, system functions could be divided into six parts: online enquiry, data collection and processing, diagram programming, information query, information publishing, information feedback.

3.2 The online query function for express freight trains

This part of function mainly provides services for the external users. Users could search all of the express freight trains in operation at present, as well as information displayed in tabular form, such as the train loading station, frequency, transfer station, marshalling content and so on.

3.3 Data collection and processing function

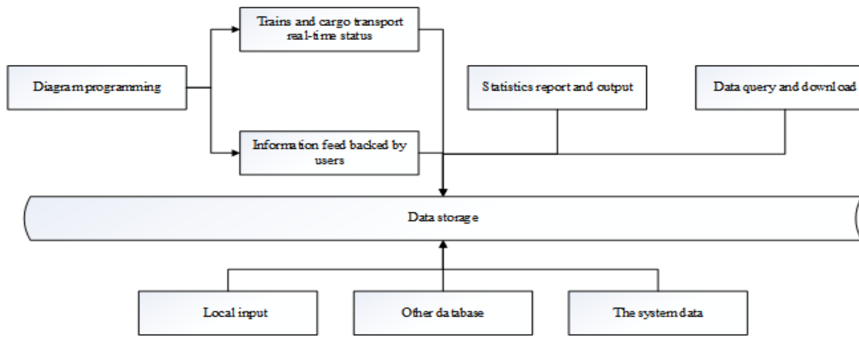

Figure 2. Data processing function

As is shown in Figure 2, the express freight train diagram programming system should have the functions of data collection, processing and management, including data operation, data inspection and storage, statistical data output, data report, search and download etc.

3.4 Diagram programming function

Express freight train diagram programming system includes the following three subsystems: input function of passenger trains' running line; initial point scheme of express freight train diagram; diagram programming and output. The three subsystems coordinate with each other to accomplish the programming of express freight train diagram. The specific process is illustrated in Figure 3.

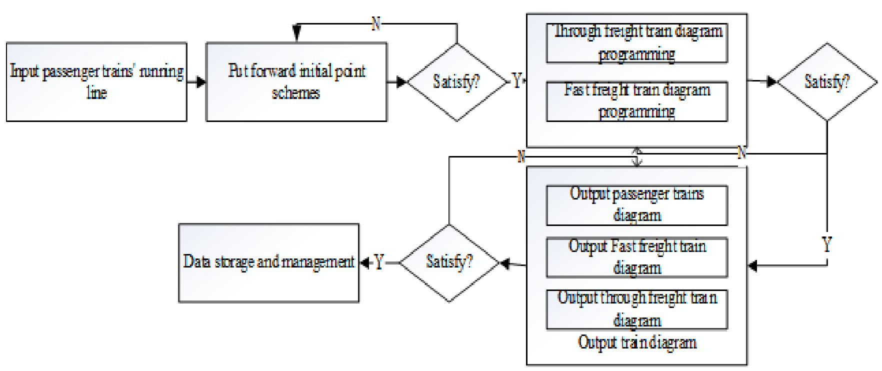

Figure 3. Diagram programming and output

3.5 Information publishing and query functions

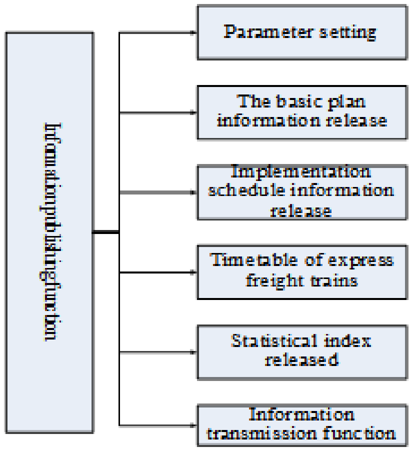

Figure 4. Information publishing

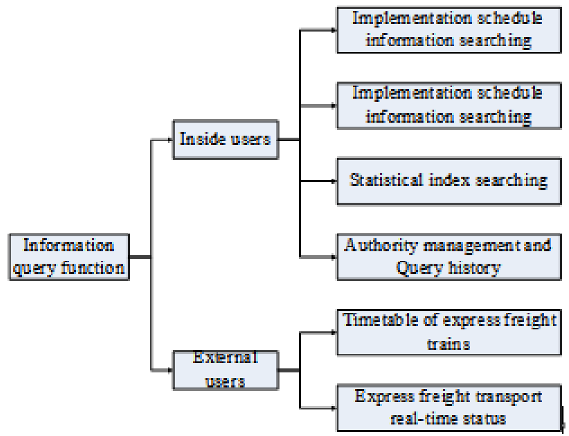

Figure 5. Information query

As is shown in Figure 4 and 5, the system has information publishing function and query function. All kinds of data are released by the system automatically, which could be inquired by users.

3.6 Information feedback function

The system has an information feedback platform, which can collect and deal with the feedback information of users, and establish optimization models.

4 Conclusions

Based on the research background and research situation of express freight train diagram programming system, the paper gives a detailed analysis of factors influencing factors of express freight train diagram programming, then it discusses about all aspects of system requirements and system functions. First of all, the background is introduced. Then, the system requirements are analyzed. Then it design the system functions , such as the data collecting and processing, diagram programming, information query and feedback functions, which embody the humanization and intelligent of the system, and is in line with the requirements of human-computer interaction.

Discussion about the Product Structure of Bulk and Direct Freight Based on Transport Benefits

Jianhua Wang and Yinying Tang

School of Transportation and Logistics, Southwest Jiaotong University, Chengdu 610031, China. E-mail: yinyingtang@swjtu.cn

Abstract: This paper summarizes the product development of domestic bulk and direct freight. Based on the needs of goods category, the bulk and direct freight demand is divided into upper, center and lower three levels. From two angles of economic and social benefits analyzes the transport benefit of bulk and direct freight. Based on the maximization of business income, establishing bulk and direct freight optimization model, and by adjusting the freight volume, designing different levels of freight product structure to achieve optimal transport benefit.
Keywords: Bulk and direct freight; Transport benefit; Freight volume; Product structure.

1 General situation about Chinese through bulk and direct freight product

For a long time, Railway freight transportation as the backbone of the transportation has made a contribution to the national economic development. With the development of economy, the demand of coal and steel is getting smaller, and the competition of transportation market is changing fiercer. 2004-2013, the growth of volume of railway freight is 6.6%, but the volume of rail freight traffic and tonnage mileage in the whole transportation market is changing less as the average speed of 0.55% and 1.1%. Through freight product is the main constituent part of rail freight, in 2012 the proportion of the through freight product in the whole road is about 30%. In order to meet the market demand better, China has taken a series of measures to improve the development of through bulk and direct freight product as following:

Table 1. The event list of Chinese through bulk and direct freight product

Year	Event
2002	Quondam railway ministry designed 54 point to point crossing board through lines in order to guarantee the electricity-coal transportation.
2004	Using the fifth speeding-up, designed 181 point to point originating direct operating lines, and optimized railway freight product project.
2005	Improved the quality of through project by standardizing through line's project etc. methods.
2006	Brought the supply of goods that annual shipments are over 40 tons with the same departure and arrival station into.
2011	The number of through bulk freight lines has grown to 723, and the scope of

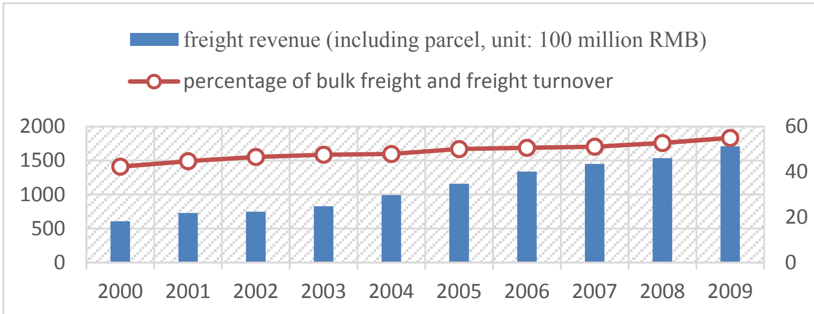
	operation has also been extended.
2012	Pay attention to the big channel and block, design the bulk and direct freight product by different level.

At present, the bulk and direct freight product (the Transport Bureau of Railways Ministry, 2006) is based on coal, oil, ore, steel, coke, grain and other bulk materials category, According to the characteristics of these products, we can design different product based on the category of goods, operation mode, handling mode, timeliness, and transportation organization (Wang Jiankuang, 2014). Many scholars from freight marketing, product structure, capacity allocation, freight organization point of view, for the bulk and direct freight product depth research, has made some achievements in scientific research. In this paper, based on the needs of the different categories of goods, the bulk of through freight demand is divided into three levels: the upper, middle and lower. Upper freight demand products mainly refers to key materials related to people's livelihood, such as coal, mining, petroleum, food, etc., and the needs of the military transport, emergency relief supplies, mainly playing an important manifestation of railway public property and safeguard the basic needs of society; the middle Freight transport demand is for the quality of timeliness, safety and other services required for high value-added products; lower freight product demand mainly contain some low value-added products, and actively tap the market in easing the situation to start marketing capacity, which is in order to better adapt to market competition performance. But when the railway capacity is short and the product under the premise of freight is limited, freight product structure design should in order of meeting the upper, middle, lower transportation needs. Combine with freight demand to design freight product, and with the goal of maximum of enterprise income, establish the bulk and direct freight structure optimization model. Through different levels of demand for freight cargo adjusts freight product to achieve the best overall transport efficiency.

2 The analysis of transport benefit for bulk and direct freight

2.1 Economic benefit

The key to improve transport revenue is the addition of economic benefit and the reduction of transportation costs. Bulk and direct freight advantages of scale to reduce production costs. Construction of large trucks point sources to achieve centralized, organizational focus, is to create efficient, safe conditions for direct freight. By reducing the sorting and marshalling operation, shortening the turnaround time of goods, bulk and direct freight relieves the capacity of technical station and interval, and increases production efficiency. As shown in Figure 1. Accounting to the railway freight revenue and bulk cargo for rail cargo turnover percentage point, some of the bulk cargo turnover always account for about 50% in railway freight transport, and with the increase of bulk cargo turnover, the rail freight revenue increased significantly.

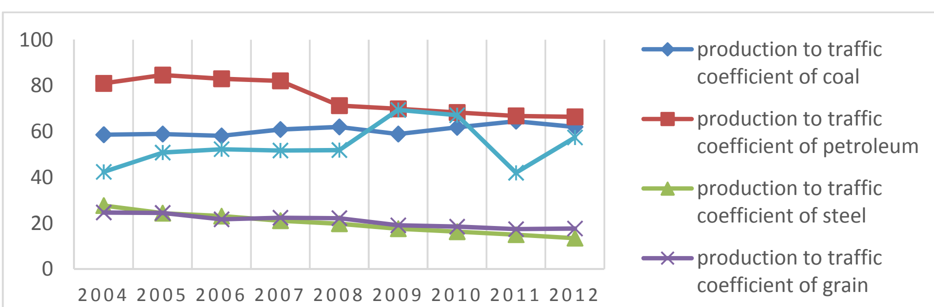


Note: Data from the 2001-2010 "China Statistical Yearbook"

Figure 1. Percentage of railway freight revenue and bulk cargo turnover

2.2 Social benefit

Direct transport bulk cargo object mostly is the key materials in petroleum, likes coal, grain, agricultural and other livelihood. In order to meet the community needs and ensure the state's key materials transportation, railway organizes bulk and direct freight for oil, ore, coal and others, which provides strong guarantee for social and economic development. As shown in Figure 2, China's railway transport of goods in bulk is always dominant from the variation of main product's produced and transported coefficient. In addition, the direct goods transport not only to reduce the total time and save the transit time, but also compress corresponding amount of enterprise stock and production cost, accelerate cash flow. The service, which includes an entrustment, once paid, a vote in the end, responsible for the whole process, is provided from bulk and direct freight to shipper, can decrease the number of intermediate links and improve convenience. Compared with other modes of transport, railway direct transport in bulk goods also has a strong competitive and advantage on scale, security, reliability and all-weather transport (Zong Yan, 2014).



Note: Data from 2005-2013, "China Railway Yearbook"

Figure 2. China produced and transported coefficient of main products

3 The structure optimization model of bulk and direct freight products based on transport benefit

The benefits of bulk and direct freight products include economic benefits and social benefits. On the premise of maximizing bulk and direct freight product revenue, the public property in the social development and national stability should be considered more. So the structure optimization of bulk and direct freight products must be based on meeting social demand, calculating the sum of the product freight revenue after the distribution of bulk and direct freight products by the difference of origin-destination (OD), freight transport demand and product categories. Optimizing the structure of bulk and direct freight products and realizing the optimal transportation benefits by solving the number of different product volume.

3.1 The assumptions of the model

Structure optimization of bulk and direct freight products based on transport benefit affected by many factors, so it is a complex problem. In order to achieve structure optimization of transportation products only taking on freight volume as variable, model assumption is as follows:

Hypothesis Ⅰ: Each freight rate of bulk and direct freight products that operated by railway are known; **Hypothesis Ⅱ**: The wagon flow paths of bulk and direct freight are known; **Hypothesis Ⅲ**: Because of market volatility, assuming different levels of rail freight demand is determined in a certain period. **Hypothesis Ⅳ**: Ignoring the influence of locomotive and car application and passenger organizations on freight products.

3.2 The establishment of the model

$$\max Z = \sum_{O=1}^{X} \sum_{D=1}^{Y} \sum_{s=1}^{S} \sum_{l=1}^{L} (P_1^{ls} + P_2^{ls} * D_{OD}^{ls})\ Q_{OD}^{ls}$$

$s.t.$

$$\begin{cases} \sum_{O=1}^{X} \sum_{D=1}^{Y} \sum_{s=1}^{S} \sum_{l=1}^{L} Q_{OD}^{ls} \le \omega_a & (1) \\ \sum_{D=1}^{Y} \sum_{s=1}^{S} \sum_{l=1}^{L} Q_{OD}^{ls} \le F_X & (2) \\ \sum_{O=1}^{X} \sum_{s=1}^{S} \sum_{l=1}^{L} Q_{OD}^{ls} \le D_Y & (3) \\ \sum_{s=1}^{S} \delta_{OD}^{ls} Q_{OD}^{ls} = R_{OD}^{l} & (4) \end{cases}$$

In the formula:

OD expresses the beginning and the end of the train in network, $O=1,2,\ldots,X$, $O \in X$; $D=1,2,\ldots,Y$, $D \in Y$; l expresses demand level, $l \in L$; s

expresses species of freight products, $s \in S$; P_1^{ls} 、 P_2^{ls} express the base price of the l-layer and s-kind freight product; D_{OD}^{ls} expresses the transport price distance of the l-layer and s-kind freight product between any OD; Q_{OD}^{ls} expresses the freight volume of the l-layer and s-kind freight product between any OD; ω_a expresses the carrying capacity of the line in limit section a, $a = 1, 2, \ldots, A$; R_{OD}^{l} expresses the freight demand of the l-layer between any OD; F_X expresses the capacity constraints of starting station; D_Y expresses the capacity constraints of ending station; δ_{OD}^{ls} expresses the coefficients of satisfaction of the l-layer and s-kind freight product between any OD, $\delta_{OD}^{ls} \in [0,1]$; If l_1、l_2、l_3 express the upper, middle and lower demand, then $\delta_{OD}^{l_1 s} > \delta_{OD}^{l_2 s} > \delta_{OD}^{l_3 s}$.

The objective function is the product of price and freight volume of bulk and direct freight products in different OD and demand level. In the situation of a fixed price, as different freight products volume according to the distribution of constraints, achieving the enterprise income maximization, which reflects the best enterprise economic benefit.

The constraints condition (1) is the capacity constraint in the section, for freight products in several origin-destination of the road network may pass through the same section, which lead to insufficient capacity; The constraints condition (2), (3) represent capacity constraint of starting station and ending station respectively, in case of insufficient capacity caused by different freight product concentrating in freight station. The constraint condition (4) is the satisfaction constraint of different levels of freight transport product. When distribute amount of freight products, upper, middle, lower demand are considering, so the best social benefits is reflected.

3.3 Algorithm design

The railway freight product structure design model using capacity constraint and satisfaction constraint of freight transport product to combine and screen freight volume of different demand levels, getting a series of freight volume conforms to the basic requirements, to which the structure optimization of bulk and direct freight products is according. Algorithm process is as follows:

Step1: Setting the volume initial value of each freight product from freight product portfolio to 0, namely not running train, turn step2; **Step2**: Increasing the volume of each freight product from freight product portfolio in turn, turn to step 3; **Step3**: Checking whether each freight product volume combination satisfies capacity constraint of the interval or the station, if satisfied, turn step4, otherwise, turn step5;

Step4: Checking whether each freight product volume combination satisfies demand satisfaction constraint of different levels of freight volume, if satisfied, keeping the freight product portfolio, otherwise, deleting it, turn step2; **Step5**: Calculating the economic benefits of the current freight volume of different levels demand, to get the optimal combination.

4 Conclusions

Due to the lack of actual data, failed to verify the feasibility of the model and algorithms by examples, this is worthy of further study beyond. Through model analysis, the Q_{OD}^{ls} , ω_a , F_X , and D_Y are positive correlation. There is a relationship between Q_{OD}^{ls} and δ_{OD}^{ls} . The larger the market demand，the more freight product is, so as social benefit. Combined with the above conclusions, the suggestion following is summarized on freight product design.

(1) When passenger and freight run separately, railway companies should vigorously develop the middle and lower freight products, and increase product proportion of high added value, high quality requirements goods before releasing of transport capacity and meeting the needs of the upper products. Through combinations of transport, design intercity and fast freight, high speed rail freight to attract potential sources. (2) Based on improvement of the rolling stock technology, increases heavy haul train proportion in the product of bulk and direct freight on busy road. (3) Model only through different demand levels of freight volume as variable to optimize the product structure. After the railway into the market competition, considering the freight and freight volume is the key to achieve business benefit. Therefore, freight floating should be coordinated to the product structure optimizing.

Abstract: Locomotive scheduling and train scheduling are important parts of the railway operation planning, locomotive scheduling should be cooperated with train scheduling, which could be benefit railroad operation efficiency and make railroad operation be more productive. This paper discuss the Cooperation design for locomotive scheduling and train scheduling based on Train Working Diagram System (TWDS). First, analyzing the business work flow between locomotive scheduling and train scheduling, and coordination process in TWDS. Then, according to the data flow and business requirements, design the mode of data sharing and data synchronizing. Finally, cooperation function and cooperation mode were designed for functions cooperation between locomotive scheduling and train scheduling.
Keywords: Locomotive scheduling; Train scheduling; Train working diagram system; Cooperation.

1 Introduction

Locomotive scheduling and train scheduling are both important railroad operation plan, they should be formulated together, and their cooperation could make the scheduling to be more feasible and close to real. Traditionally, the locomotive operation planner and train operation planner worked separately, but now with the development of information technology, locomotive scheduling system and train scheduling system were developed for railroad industry, which were general used by almost all railroad company. Then, the cooperation between Locomotive Scheduling System and Train Scheduling System become available.

In China, there is a integrated decision support system that both locomotive scheduling system and train scheduling system included, which is named as Train Working Diagram System (TWDS). Besides the two system, TWDS include railroad infrastructure data system, passenger transportation plan system, train tractive effort calculating system, train operation simulation system, train GIS etc. The system structure of TWDS could be shown as Fig.1.

In TWDS, all the subsystem share the railroad infrastructure data, included rail line data, station data, section data, track data etc, and with the share data, all of subsystem would be consistency while data transfer, further more the data manage would be more easier. As parts of TWDS, the locomotive scheduling system and train scheduling system could be cooperated more convenience and closely combined, also, with the C/S network platform of TWDS, the two system could exchange information immediately. This paper will discuss the cooperation model for locomotive scheduling system working with train scheduling system based on the system introduced above.

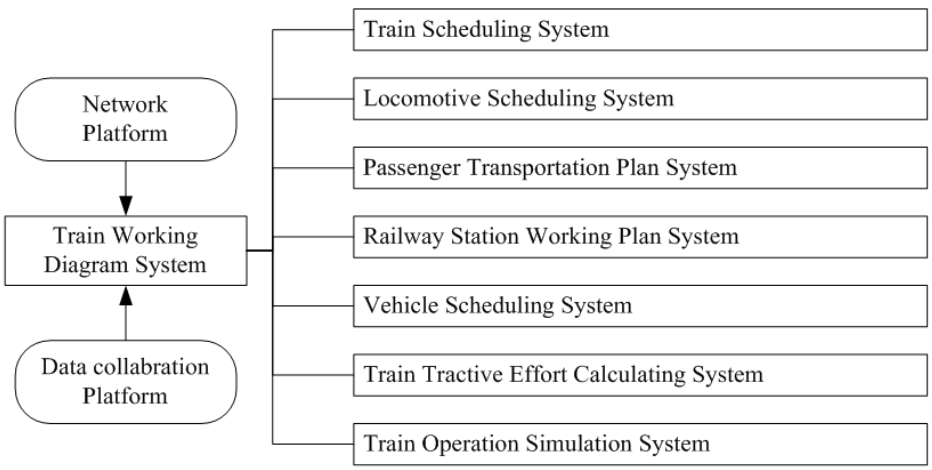

Figure 1. System structure of Train Working Diagram System

2 Cooperation Process Description

Locomotive scheduling should be built in company with train scheduling, they are depend on each other mutually and restrain each other. Train scheduling is a comprehensive transportation resource allocation plan, so much factors should be considered, moreover, locomotive diagram is prepared in accordance with the train line, therefore, it is a coordinated feedback relationship between Locomotive Diagram and train diagram: In the train scheduling preparing stage, some locomotive turn-round factors should be considered, such as locomotive hanging dwell time, locomotive turn-around time standard. Furthermore, In train scheduling sketching stage, locomotive diagram sketch should be formulated, then locomotive indicators should be checked, if locomotive technical working time and crew working time standard were not meet, or certain locomotive efficiency indicators were unreasonable, by analyzing the structure of train diagram, a workable regulatory timetable adjustment feedback plan should be programmed. Therefore, the cooperation process between locomotive scheduling and train scheduling can be expressed as shown in Fig.2.

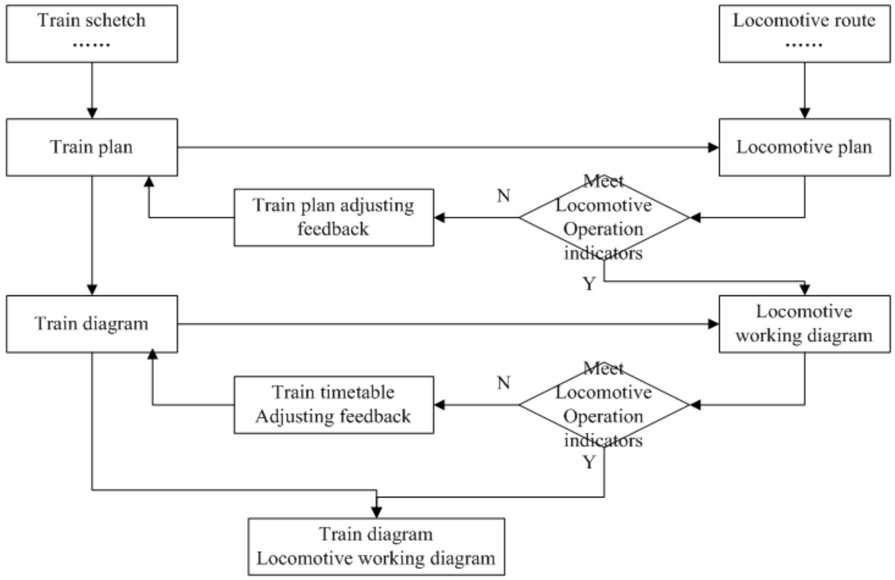

Figure 2. Locomotive scheduling and train scheduling cooperation flow chart

As shown in the locomotive scheduling and train scheduling cooperation process, the locomotive scheduling is carried out after train scheduling, and then train timetable rescheduled after locomotive scheduling for timetable adjustment plan, that is a circular process. which including the cooperation about data, business functions, and the time and space aspect of cooperation involved.

In TWDS, all the subsystem share public data and work on the network platform, so the model for cooperation between locomotive scheduling and train scheduling could be discuss in the aspect of data cooperation, function cooperation and user interface.

3 Data Cooperation Design

In TWDS, according to the data flow and business requirements, the data can be divided into public infrastructure data and business data. The public infrastructure data include railroad network data, infrastructure data, organizations and other basic data, regulations and standards. business data include a lot of different types of data supported for independent business functions of each department. In TWDS, data associated with train scheduling and locomotive scheduling could be listed as follows:

Table 1 Locomotive scheduling and train scheduling data systematization

Data Type	Business Type	Data Description
Public Data	Railroad Network	Rail lines, Stations, Sections, Tracks
	Infrastructure and Equipment	Locomotive type, Train type
	Business Management	Railway corporations, Departments
Business Data	Train Scheduling	Trains, Routes, Maintenance time, Train plan
	Locomotive Scheduling	Locomotive route, Locomotive routing connection, Crew turn-around route

In TWDS, there are cooperation on different departments and different majors, and cooperation on different clients, business cooperation is in cooperated with data transfer and data synchronization. Then, by data sharing and data synchronizing, all subsystem could avoid repeating operation and data inconsistent. Finally, all the data in TWDS were integral and consistent, which make the system be more efficient than separated subsystem. In this section, data sharing and data synchronizing would be discussed.

3.1 Data synchronizing requirement analyze

(1) Public data synchronizing requirement analyze

Public data are the key data of TWDS, it is the basis of data transfer and data interface for all the subsystem, and it is also the standards data. Once the public data modified, all the data refer to the public data should be renewed. The public data included: railroad network data (rail line data, station data, section data), business data (railway company data, department data, train type data).

(2) Business data synchronizing requirement analyze

Business data are the data depend on the subsystem, the business data synchronization between locomotive scheduling system and train scheduling system are their data transfer on work flow process. For business data, some data are the basis or reference of other business, and some data are only for inner business process. For the first situation, refer data should be renewed immediately. For the second situation, no synchronization process should be carried out. The business data should be synchronized included: train data and train timetable in train scheduling system, locomotive route data, trains on routes in locomotive scheduling system.

3.2 Data synchronization mode

The common data synchronization mode could be list as follows:

(1) Message droved mode

(2) Timer droved mode

(3) Request mode

(4) Real time interface mode

Above is the data synchronization mode, and implement mode also should be considered, there are synchronization implement mode and a synchronization implement mode, which depends on data requirement, data flow and data transfer frequency.

3.3 Data synchronization design.

For TWDS, there are desktop mode and network mode. For desktop mode, data synchronization is implemented by data logistic consistent functions which based on integrated data platform for all subsystem. For network mode, based on network platform and message droved mode, all clients of locomotive scheduling system and train scheduling system could implement data synchronization. The whole data synchronization process could be designed as follows:

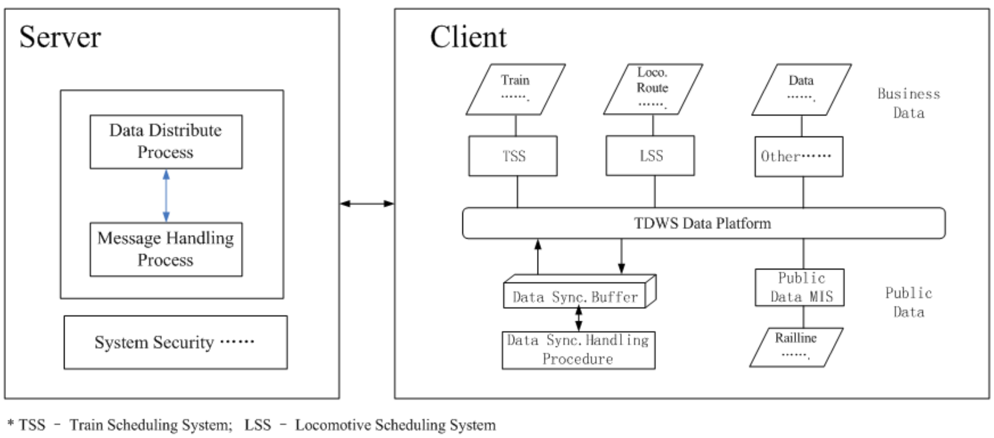

Figure 3. Locomotive scheduling and train scheduling data synchronization process

4 Business Cooperation Design

As shown in section 2, cooperation between locomotive scheduling and train scheduling is a cyclic process, in TWDS, supported by the networking platform, the business functions could be designed for the cooperation, and the cooperation work flow could be expressed as follows.

For functions cooperation between locomotive scheduling and train scheduling, it could be discuss from the aspect of cooperation function design and cooperation mode design.

4.1 Cooperation functions design

Train scheduling involves more departments, which is restricted by more operation rules, and it is the basis of locomotive scheduling, therefore, the cooperation design should be focus on how locomotive scheduling system provide related functions for train scheduling system to dispatch. According to the cooperative process, functions could be designed as follows:

(1) Automatic locomotive scheduling

Automatic Locomotive scheduling function should be designed parameterized to meet all kinds of facilities and complex locomotive operation rules, such as locomotive route, train type, hanging dwell time standards, and whether locomotive running across multiple railway bureau. Moreover, optimized algorithms should be designed, the locomotive indicator could be calculated. The function could be used for not only one locomotive turn-around station, but also whole section, or whole locomotive working diagram.

(2) Technical working time checking

In the process of locomotive scheduling, sometimes locomotive operation changed such as the locomotive hang station changed or crew shift station changed, the technical working time at the working station maybe changed, so the train dwell time and locomotive turn-around time should be checked. This function should be designed to check whether the locomotive turn-around time at turn-around station and train dwell time at crew shift station meet standards according to locomotive routing and crew routing.

(3) Working overtime check

According crew mode and crew route, the function should be designed to check whether the crew working time is over working time standard.

(4) Locomotive indicators setup

Before locomotive scheduling, design a function setting up designated locomotive indicators to check the quality of locomotive working diagram and train diagram, indicators including locomotive numbers, train travel time etc.

(5) Train timetable adjustment feedback plan

With the setting up indicators, design a function to formulate train timetable adjustment feedback plan which base on optimized locomotive operation.

4.2 Cooperation mode design

There are two mode for the function cooperation between locomotive scheduling and train scheduling. The first mode is the user interface mode by commands from planner, which could make use of the knowledge and professional experience of planners, in TWDS, the function should use this mode including: technical working time check, working overtime checking, automatic locomotive scheduling. The second mode is the integrated dispatch mode by inner function call from system, which could make the cooperating process be more simplified, according the business rules and presetting arguments, system could carry out the cooperation automatically, then the scheduling efficiency improved, in TWDS, the function should use this mode including: locomotive indicators setup, train timetable adjustment feedback planning.

5 Conclusions

Based on Train Working Diagram System, this paper discuss the cooperation design for locomotive scheduling and train scheduling, data synchronization and business function cooperation were mainly considered, the resolution would be benefit for the system development and other cooperation system. However, cooperation between two system is more complicated, the other aspect such as system security, interface structure should be involved, it is worth further study on these topics for cooperation design.

Selection and Application of Organization Modes of Container Drop-and-Pull Transport Based on Different Service Objects

Hui Mao[1,2]; Yimiao Ma[1]; and Li Rong[1]

[1]School of Transportation and Logistic, Southwest Jiaotong University, Chengdu, Sichuan. E-mail: 839029841@qq.com
[2]National United Engineering Laboratory of Integrated and Intelligent Transportation, Chengdu 610031, China.

Abstract: As an advanced way of transport organization, container transport with dumping trailers should be considered as a kind of low-carbon and energy-saving mode for the popularization with Green logistics developing vigorously in our country. Since container transport is implemented later in China, and its organizational mode is simply between two points. Therefore its radiation range is often limited by the selected business routes. As a result of the simple organization mode, the efficiency of container drop-and-pull transport has been greatly limited. In order to solve the problems above, this paper analyzes the selection and application of organization modes of container drop-and-pull transport, according to different application objects and circumstances. The results from the thesis are of great practical value and can be used as a guide for transportation enterprise to choose an efficient and scientific organization mode of container drop-and-pull transport.
Keywords: Drop-and-pull transport; Organization modes; Selection; Application.

Container drop-and-pull transport is mainly used in the situation of point to point transportation within large enterprises or factories, fixed-point container transport on trunk lines, interregional transportation and multimodal transport in port area. Because of the difference of transport mileage, arrangement of loading and unloading working points and transportation cost, varied organization modes are required. Furthermore, new types of multi-mode drop-and-pull transport group are needed.

1 Fixed-point container drop-and-pull transport on trunk lines

Trunk line transport is a vital important form of transportation, which transferred goods in long distance with using of large-capacity trunk road transport. Container transport on trunk lines between fixed points, such as logistics transport on intercity direct lines and transport between interregional logistics parks, is definitely suitable for container drop-and-pull transport in the organization mode of “Two Point One Line”, for the character of steady transportation task, sufficient supplies and fixed freight location.

According to statistics, actual loading rate of fixed-point container drop-and-pull transport on trunk lines can reach to 80%. In practice, transport enterprises should build a solid, long-term cooperation between consignor and consignee, or even set business points in separated cities, to ensure the condition of supply organization steady, and to delivery and management turnover trailers effectively. Depending on freight traffic and load distance, turnover trailers can be equipped in delivery point and receiving point. And drop-and-pull transport is arranged in the way of "Two Points One Line, drop-and-pull transport in terminal(s)", which is shown in Figure 1.

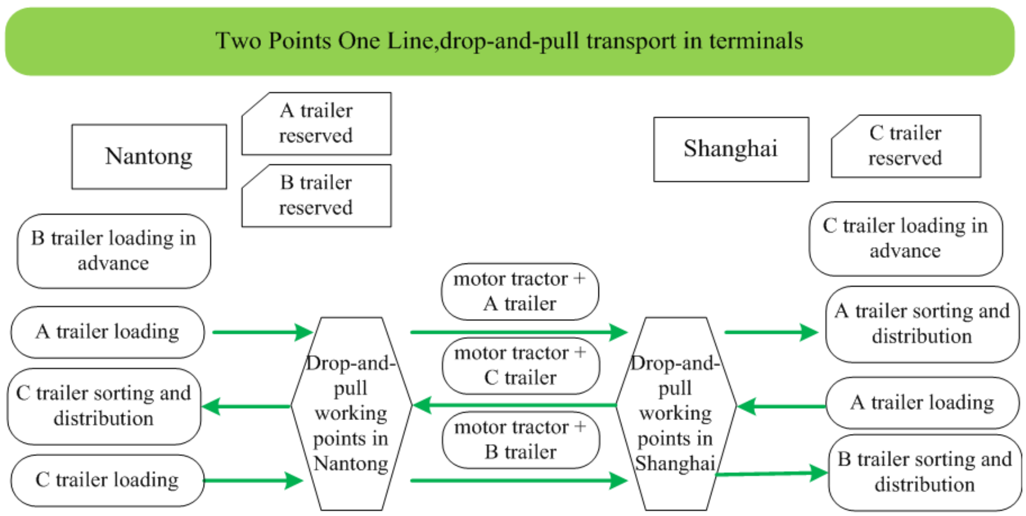

Figure.1. Illustrated of "Two Points One Line" drop-and-pull transport on trunk lines

Figure 2 illustrates a practical case that a logistics enterprise runs a drop-and-pull transport assignment on trunk lines between Guangzhou and Qingdao. The organization mode of "Two Points One Line, drop-and-pull transport in terminals" is selected, for sufficient supplies of container freight traffic and fixed freight location in these two cities. Load distance between two cities is 2250 kilometers, and transit time needs 30 hours. In circumstances of the traditional regular transportation, motor tractor takes 72-76 hours to fulfill a round-trip task, while loading and unloading time needs almost 12-16 hours. That means loading and unloading time accounts for about 20% of total time. It just costs 60 hours to complete a round-trip task by using drop-and-pull transport. It is obviously that efficiency of the tractor organization and operation has improved significantly.

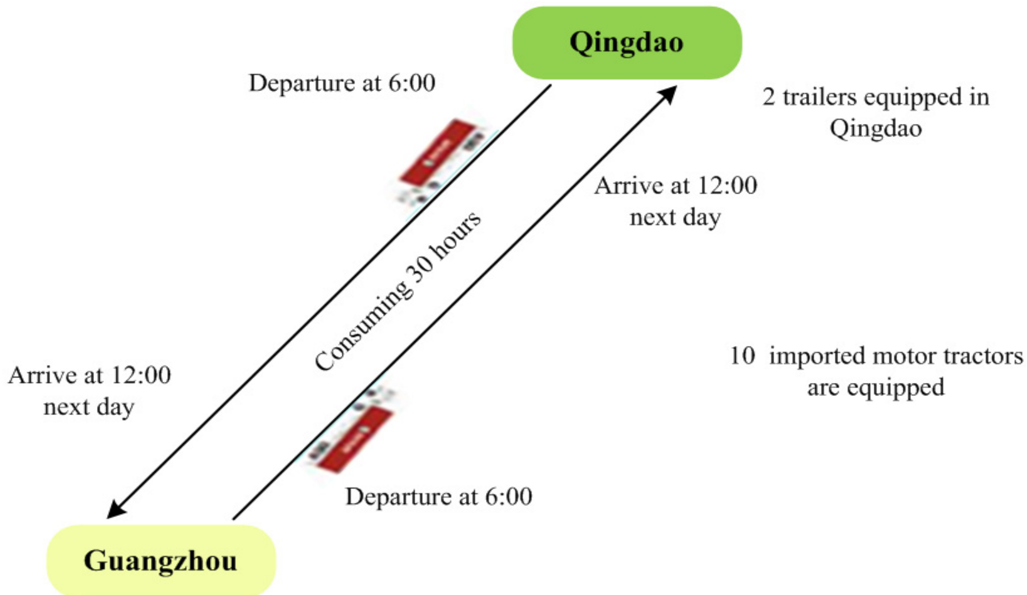

Figure.2. Map for the organization mode of
"Two Points One Line, drop-and-pull transport in terminals"

2 Interregional container drop-and-pull transport

Container drop-and-pull transport are now making great efforts to broaden the operation network, expand the scope of the market, strengthen the business cooperation between enterprises, and it is a general trend. Depending on "Two Points One Line" and advantages of the networked sufficient supplies, source of trailer, station and goods can be shared by building drop-and-pull transport coalition with other enterprises. As shown in Figure 3, the organization mode of "Circle Drop and Pull" or "Several Points One Line, Drop and Pull in Turn" should be selected between transport enterprises and manufacturing enterprises, so as to the ports, harbors and storage yards in the certain related regions. As a result, it can take full advantage of motor tractors and trailers. Therefore drop-and-pull transport can expand from inner-enterprise operation to outer-enterprise operation, from the mode of "Two Points One Line" to "Circle Drop and Pull", thereby efficiency of regional transport operation and level of the organization are raising and promoting.

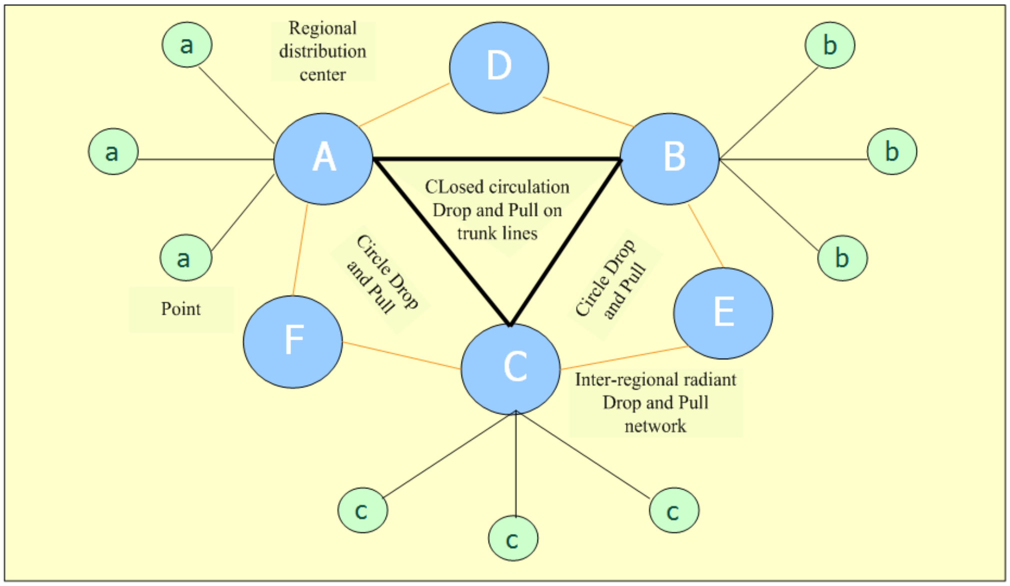

Figure.3. Interregional Container "Circle Drop and Pull"

In reality, each fixed loading and unloading point on closed circulation loop should equip a set number of trailers and turnover containers. When a motor tractor reach to a fixed point, it drops all the containers and trailers, and then keep on traveling after pulling all prepared containers and trailers. As we can see, interregional container transport in the way of "Circle Drop and Pull" can reduce the average cost of one-way freight effectively, raise actual loading rate of round-trip transport infinitely. Besides container drop-and-pull transport in the mode of "Circle Drop and Pull" calls for a fully configured system of inter-regional loading and unloading points and large transportation enterprises. Furthermore, objectively speaking, freight transport promotes from traditional point and linear transport lines to network transport routes. At the same time, regional drop-and-pull transport requires the enterprise the ability of organization of freight source, and to be organized and informationalized. Thus the company keeps on technological innovation, to be intensification, large-scale, networking, and normalization.

Seven provinces, including Shandong, Heilongjiang, Liaoning, Jilin, Neimenggu, Hebei and Tianjin, build the Around Bohai bay drop-and-pull transport coalition, with the advantage of the location around Bohai bay. Drop-and-pull transport can cooperate at a regional scale, the benefits of drop-and-pull transport can be highlighted, and container drop-and-pull transport can be promoted. A company in Shandong shows a good example for it. Initially the traditional operation mode was used. Vehicles reached the operating points for unloading and loading, then went back to distributing center. The return time for vehicles back to distributing center is limited, to ensure the loading and unloading of freight in distribution center. Otherwise the goods cannot be delivered to the receiving point on time in the next day. It is obviously that working hours in the point is very tense, when the load distance and travel time is long. What is more, if delay occurs, the whole system will break down. After equipping motor tractors and trailers as 1:2, drop-and-pull transport can be implemented smoothly all along the working points. Working time of motor tractors in working station is significantly shorter. Organizational problems of system operation caused by the time of operating procedures in working point, can be solved effectively. In consequence, on-time rate of operation is increasing, service time is reducing, and the stability and reliability of the whole system is enhancing, as shown in Table 1 and Table 2.

Table 1.Operation Timetable in Traditional Way

Motor Tractor	Beijing	Tianjin	Jinan	Tianjin	Beijing
Departure Time	12:30	18:30	04:00	13:30	
Arrival Time		15:30	01:00	10:30	16:30

Table 2.Operation Timetable in the Way of Drop-and-Pull

Motor Tractor	Beijing	Tianjin	Jinan	Tianjin	Beijing
Departure Time	12:30	17:00	01:00	09:00	
Arrival Time		15:30	23:30	07:30	12:00

3 Container drop-and-pull transport in port area

3.1 Multimodal drop-and-pull transport for collecting and distributing

Transport enterprises, relying on port, carry out multimodal drop-and-pull transport for collecting and distributing on freight rolling transport, in order to improve transport efficiency and save the cost. Motor tractors take trailers carried containers to the harbor, then trailers take a long-distance transport by ship. After arriving the destination, motor tractors take trailers again to the enterprise or storage yard. As shown in Figure 4, multimodal drop-and-pull transport for collecting and distributing reduces the waiting time of motor tractor, saves the capacity of transport resource, improves the capacity of utilization and ship handling efficiency.

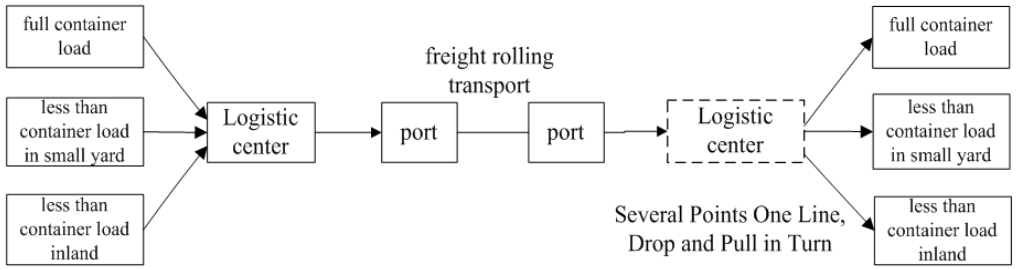

Figure 4.Rolling Shipment Container Drop-and-Pull Transport

Multimodal transport is radially distributed about a port as central part in the view of network configuration of drop-and-pull transport. Due to the containers concentrated in port, a large number of containers will pile up. So we need to build a logistics center between harbor and enterprise, which will become a transit point by selecting an organization mode of "Several Points One Line, Drop and Pull in Turn". All the goods are delivered from enterprises to the logistics center rapidly, and then transported to the port rapidly in form of container by motor tractors in the harbor according to the schedule. The application of logistics center can make the containers deliver from enterprises to harbor rapidly come true, settle the problem such as small footprint of storage yard and lack of handling capacity effectively, improve the responsiveness of port services chain links, maximize the efficiency of port and enhance the service ability of port.

3.2 Container double drop-and-pull transport in dry port

Dry port is a logistics center built in the inland country, with service function of harbor such as customs declaration, applying for inspection and signing and issuing bills of lading, with the purpose of enhancing radiation intensity of port to the inland hinterland. Container double drop-and-pull transport makes container return to operating points of dry port from enterprises and factories import nearby, and transport the containers needed to export from client nearby to storage yard in the harbor.

As double drop-and-pull transport services more outlets, there are round-trip transportation needs and sufficient supplies between customer base and port. For selection of the mode of "Circle Drop and Pull" between harbor and factories, dry port and storage yard, its profit is triple of traditional mode. For high efficiency of this transport organization mode, it has been widely used in foreign countries. What is more, it has been promoted in our country in recent years.

Conclusion

As a kind of low-carbon and energy-saving mode of transport organization, container transport with dumping trailers should be promoted with Green logistics developing vigorously in our country. While container drop-and-pull transport requires the conditions of a higher degree of organization in order to carry out better. So selection of container drop-and-pull transport discussed in this paper must think about type of sources, layout of loading and unloading points, form of transportation management, type of operation lines, form of transportation network in practice. After analyzing the right to choose the prefect container transport organization mode, drop-and-pull transport can get the best economic benefits

Abstract: In order to solve the key issues of urban rail train routing problem, which were considered as to determine running section and turn-back stations, combined with practice experience, a multi-objective 0-1 mixed integer programming model about urban rail train routing problem is established in this paper. This model manages to pursue best matching between train routing strategy and space distribution characteristics of passenger flow demand, when considering capacity limitation of the railway lines and stations as well as facility transportation organization and passenger convenience. Then, the model was simplified according to its features aiming to be solvable by optimizing soft wares directly. Finally, taking Chongqing urban rail line 1 as an example, the practical application of the model has proved its feasibility and efficiency.
Keywords: Urban rail transit; Train routing plan; Multi-objective 0-1 mixed integer programming.

1 Introduction

Urban rail train routing plan fixed the operation section and turn-back station of the trains based on line section of passenger flow distribution and the train makeup. In a more common way, it also includes train interval solutions, diurnal time section and car configuration plan. Better train routing scheme can improve the efficiency of vehicle utilization, make full use of limited resources, and convenient passengers. Therefore, starting from the characteristics of time and space distribution of traffic demand, to seek the best match of train routing and traffic demand space and time characteristics by making the rain routing scheme was a common interests of both passenger and operation partners.

GUO Kai (2005) analyzed routing comparison respectively in Shanghai, Chongqing, Nanjing, Guangzhou and other cities. ZHOU Gang, LU Jing.(2010) used analytic hierarchy process (AHP) to construct a more general operating path optimization model. XU Ruihua, CHEN Jingjing, DU Shimin (2005) is putting forward lower rail capacity and car configuration mathematical model by "running cycle analysis calculation", then choose routing scheme for the operating unit. SUN Yan,SHI Qizhou,ZHAO Yuan(2004) and TIAN Fu-sheng, LU Hong-xia, LI Zhi-hong(2006) also are given from the aspect of transportation enterprise as several car use lower bounds, and established mathematical optimization model formula of the maximum load rate and diurnal time section at the same time. a number of decision variables: makeup length, operation frequency and operation period was defined, from the aspect of transportation efficiency and the traffic demand at the same time in DENG Lianbo，ZENG Qiang，GAO Wei，BIN Song.(2010), established a multi-objective model of urban rail transit train plan. And according to the model, based on the experience of the operation plan formulation method, a three stage method was designed.

In conclusion, the existing literature used pattern comparison or optimization of train operation plan. However, there is a lack of unified and clear rules, the latter have not deeply involved in a variety of special combination of the route collections. While Urban development brings the change of population distribution, however, that a single delivery way already cannot adapt to the passenger flow distribution characteristics of continuous change. Match the space-time characteristics of passenger flow with a complex train routing scheme of urban rail transit is one of the breakthrough point to solve the problem of traffic demand in a long period. This paper will based on traffic demand characteristics of space and time, in order to reach the best match between train route and traffic demand characteristics of space and time as the goal, at the same time considering transportation enterprise benefit and passenger convenience, to solve the routing scheme.

2 Problem description

Urban rail transit train routing can be classified as single route、long-short route、section nested route, cross route and combination in several forms. Combination route is the combination of more than the other two styles, operating organization is very complicated. At present, the vast majority of rail transit operation organization using simple single route mode. However, with the updating of urban development concept, some cities began to show obvious characteristics of multicenter, in turn, affects the population distribution and travel demand, only a single rail route cannot handed well to adapt to the continuous change of passenger flow distribution. more flexible train routing scheme should be adopted in urban rail transit only can it match the passenger flow characteristics of time and space, and undertake the mission of public transport backbone.

The influencing factors of urban rail transit train routing scheme mainly from the perspective of long-term planning, include: passenger section flow distribution characteristics, characteristics of passenger flow between OD, train makeup plan and the station conditions, etc.

The establishment of Routing scheme should be first based on the section passenger flow distribution of time and space. According to the flow amount, time distribution can be divided into two categories: peak and flat period, two periods can be regarded as independent of each other according to the traffic optimization respectively in making Routing scheme. And spatial distribution of passenger flow in a single line without transfer can be reflected by the OD passenger demand. At the same time, the station line conditions, combined with train plan determines the supply capacity, of which the train makeup plan make the most direct way to develop relationship with routing scheme. Based on the following two assumptions, this paper constructs the train operation section and turn-back station mathematical programming model:

(1)the urban rail transit lines use one form of the train makeup, fixed and unified;

(2)this paper builds the model of downside direction only;

3 Train routing model

3.1 parameters

There is a urban rail straight line of n stations, n-1 sections. The Routes set is J, $J=\{ J(i) | i=1 \cdots m\}$, with m routes, each route has its turn-back station and running sections. Thus the *ith* route can be described as：$J(i)=\{A(i), B(i), S(i), L(i)\}$。

In which, $A(i), B(i)$ are the turn-back stations of the *ith* route. $S(i)$ is the station sets the ith route contains. L (i) is the sections the ith route contains.

0-1decision variables are defined as:

$x_{ij} = \begin{cases} 1, j \in L(i) \\ 0, j \notin L(i) \end{cases}, y_{ik} = \begin{cases} 1, k \in S(i) \\ 0, k \notin S(i) \end{cases}$,

x_{ij} equals to 1 if route *i* contains section *j*, or else equals to 0. y_{ik} equals to 1 if route *i* contains station *k*, or else equals to 0.

3.2objective function

The primary goals of urban rail transportation organization from the point of view of system optimization for the routing scheme is to determine the spatial characteristics of transport capacity and traffic demand the best match, but as routing plan is made before the frequency of train services, the difference between uneven coefficient of passenger and coverage rate of route in section is taken to measure the matching between spatial characteristics of demand and the route.

The uneven coefficient of passenger is the ratio of passenger flow in each section j and the minimum one. Let passenger follow of section j be pj, j∈[1,n-1], in which the minimum one is minjpj，then the uneven coefficient of passenger is pj/minjpj。the coverage rate of route is ratio of the amount of routes that contains section j and the lowest bound., let the amount of routes that contains section j be $\sum_i^m x_{ij}$, the lowest bound be minJ, then the coverage rate of route is $\sum_i^m x_{ij}$ /minJ .

Objective function one can be presented as:

$$\min z_1 = \sum_j^{n-1} \left| p_j/\min_j p_j - \sum_i^m x_{ij}/\text{minJ} \right| \quad (1)$$

The second objective function considered the least transfer flow. Let passenger flow between station *o* to *d* be p_{od}, *o,d*∈[*1,n*], a function was designed to describe if station *o* and *d* be connected by one route, in other words, if the passenger flow between station *o* and *d* need transfer or not. That is $\sum_i^m y_{io}\, y_{id} > 0$, $\partial(\sum_i^m y_{io}\, y_{id}) = 1$; or$\sum_i^m y_{io}\, y_{id} = 0$, $\partial(\sum_i^m y_{io}\, y_{id}) = 0$。

Objective function two can be presented as:

$$\min z_2 = \sum_o^{n-1} \sum_{d=o+1}^{n} p_{od} (1 - \partial(\sum_i^m y_{io}\, y_{id})) \quad (2)$$

Taking the operating enterprise efficiency into consideration, income depends on ticket prices and operation cost which is directly related to the car configuration. The shorter the length of route, the faster the car turnover, so as to complete the same transport task takes fewer cars. As a result, the length of route can be taken to measure the cost in routing scheme. The distance between station *f* and *k* is ω_{fk}, *f,*∈[*1,n*]; Then $\omega_{fk} \sum_i^m y_{if}\, y_{ik}$ are the lengths of routes between station *f* and *k*.

Another Objective function can be presented as:

$$\min z_3 = \sum_f^n \sum_k^n \omega_{fk} \sum_i^m y_{if}\, y_{ik} \quad (3)$$

3.3 constrains

As a result of the limitation of urban rail transit lines, station capacity and the requirements of convenience transport organization, several constraint conditions should be satisfied.

(1)any turn-back station on both ends of the route must be the station has turn-back capacity.

$$A(i), B(i) \in \{S_r\},\ S_r \text{ is set of stations has turn-back capacity}, \quad (4)$$

(2)the routes contain all the sections between turn-back station on both ends.

$$xij=1,\quad j\in[A(i),B(i)-1] \quad (5)$$

(3)the routes contain all the stations between turn-back station on both ends.

$$y_{ik}=1,\ k\in[A(i), B(i)] \quad (6)$$

(4)the upper bound of route amounts be satisfied

$$m\leq M,\ \text{M is the upper bound of route amounts} \quad (7)$$

(5) any section coveraged by at least lower bound.

$$\min j \leq \sum_i^m x_{ij},\ j \in [1, \mathrm{n}-1], \quad (8)$$

(6) any station coveraged by at least lower bound.

$$\min j \leq \sum_i^m y_{ik},\ k \in [1, \mathrm{n}], \quad (9)$$

In addition, decision variables still need to meet the station-line connection, namely:

$$x_{ij}= y_{ij}\ y_{i(j+1)},\ i\in[1,m],\ j\in[1,n-1], \quad (10)$$

4 Model simplification

Urban rail transit train routing planning model is confirmed by (1) - (10). The Model has two sets of 0-1 decision variables x_{ij}, y_{ik} and integer variables m, $A(i), B(i)$. The Model has three optimization objectives, the objective function (1) has an absolute value, (2) has nonlinear term partial $\partial(\sum_i^m y_{io}\, y_{id})$. In conclusion, the upper model of urban rail transit train routing planning is a multi-objective nonlinear 0-1 mixed integer programming model, which must be simplified in order to facilitate solving.

4.1 simplifications of the decision variables

The relationship between the decision variables are represented by constraint (5), (6) and (10). The key to determine the routing scheme is to determine each route turn-back station on both ends. Therefore, after the turn-back station set is given, with two turn-back station a and b to mark each route, new 0-1 variables c_{ab} and constant e_{jab}, t_{kab} are defined to replace the original decision variables. c_{ab} value 1 if route J of turn-back station a and b on both ends be selected, otherwise 0, $a,b\in[1,|S_r|]$,$|S_r|$ is turn-back station number. e_{jab} value 1 if section j belong to a and b, otherwise 0, $j\in[1,n-1]$, t_{kab} value 1 if station k belong to a and b, otherwise 0, $k\in[1,n]$. So $x_{ij}=c_{ab}e_{jab}$, $y_{ik}=c_{ab}t_{kab}$.

4.2 simplifications of objective function

Replace xij, yik with cab ,then objective function one turn into:

$$\min z_1 = \sum_j^{n-1} \left| p_j/\min_j p_j - \sum_a^{|S_r|} \sum_b^{|S_r|} c_{ab} \mathrm{e}_{jab} \right| \quad (11)$$

Objective function two turn into:

$$\min z_2 = \sum_o^{n-1} \sum_{d=o+1}^{n} p_{od} (1 - \partial (\sum_i^m c_{ab} t_{oab} t_{dab})) \tag{12}$$

Objective function three turn into:

$$\min z_3 = \sum_a^{|S_r|} \sum_b^{|S_r|} c_{ab} \omega_{ab} \tag{13}$$

There are a lot of methods to solve the multi-objective programming. Almost all of them are turning the problem of multiple objectives into single objective programming problem. In this paper, the first target is to optimizing transport organization system which is the main objective. There is contradiction in the relationship between the other two objectives. Goal two is seeking route length to be considerably long while objective three target at minimum the total route length. Therefore, in order to satisfy the two goals at the same time, optimal routing length should be limited in a reasonable range. Here measured it through passenger average travel length. With $\bar{l}$ as passenger average travel length, the objective function two and three are combined to be:

$$\min z_{2,3} = \sum_a^{|S_r|} \sum_b^{|S_r|} \left| c_{ab} \omega_{ab} - \bar{l} \right| \tag{14}$$

the finally objective function represented as:

$$\min z = \gamma_1 \sum_j^{n-1} \left| p_j / \min_j p_j - \sum_a^{|S_r|} \sum_b^{|S_r|} c_{ab} e_{jab} \right| + \gamma_2 \sum_a^{|S_r|} \sum_b^{|S_r|} \left| c_{ab} \omega_{ab} - \bar{l} \right| \tag{15}$$

In which, γ_1, γ_2 are the Weight coefficients.

4.3 simplifications of constrains

only constrains(8)、(9)are needed after Replace x_{ij}, y_{ik} with c_{ab} ,then constrains(8)、(9)turn into:

$$1 \le \sum_a^{|S_r|} \sum_b^{|S_r|} c_{ab} e_{jab} \le \min j, j \in [1, n-1] \tag{16}$$

$$1 \le \sum_a^{|S_r|} \sum_b^{|S_r|} c_{ab} t_{kab} \le \min j, k \in [1, n] \tag{17}$$

After the simplification, the urban rail transit train routing planning model is made by (7), (15) - (17), which greatly simplifies the decision variable in type and amount, reduced the number of constraints, made the mixed 0-1 integer programming to be 0-1 programming.

Considering the capacity constraints of general urban rail transit station turn-back equipment, more than one train are not allowed to operate at the same time, or it will influence each other and enlarge the turn back time, as shown in the literature [8]. At the same time too many routes will increase the complexity of passengers. At present, RER line - B in Paris, for example have four routes at flat peak period, five at the peak period. Therefore, take total maximum routes amount M for 2-5. After simplification processing, the model can be solved in the optimization software LINGO11.0 programming, when using LINGO default branch and bound method to solve.

5 Case study

Taking train routing scheme of chongqing rail line 1 for example to validate the effectiveness of the model. chongqing rail line 1 opened 27 stations (ChaoTianMen - wall mount), 49 km line length in Long-term operating. Turn-back station set {1,2,14,19,27}. different routes Can be chosen between turn-back station is $C_5^2 = 10$. predict passenger flow in the peak hour of each section is shown in table 1, OD flow forecast data is also needed.

Table 1. prediction of section passenger flow during peak hour for line 1

section	1	2	3	4	5	6	7	8	9	10	11	12	13
p_j	4384	13448	20467	23651	27639	29395	35791	34806	34347	30015	28252	26527	23169
section	14	15	16	17	18	19	20	21	22	23	24	25	26
p_j	17487	15003	13002	11833	10454	7902	7270	8673	7835	6968	4730	4303	2781

The calculation results are shown in table 2 and figure1-4.

Table 2. calculation results

M	minj	γ_1	γ_2	iterations	time(s)	Z	Z_1	$Z_{2,3}$	Z_2	Z_3
2	2	0.5	0.5	47	2	62.41861	114.3635	10.47368	0	51
3	3	0.5	0.5	104	2	53.63167	97.21072	10.05263	0	69
4	4	0.5	0.5	71	2	45.11821	80.69256	9.543860	0	86
5	5	0.5	0.5	68	2	39.17948	70.46422	7.894737	0	106

(1) M=2, minj =2, c=(0, 0, 0, 1, 0, 0, 1, 0, 0, 0)

(2) M=3, minj =3, c=(0, 0, 1, 1, 0, 0, 0, 1, 0, 0)

(3) M=4, minj =4, c =(0, 0, 1, 1, 0, 1, 1, 0, 0, 0)

(4) M=5, minj =5, c=(0, 0, 1, 1, 1, 1, 1, 0, 0, 0)

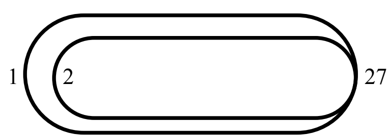

Fig. 1 train routing plan 1

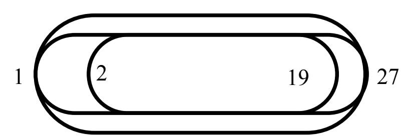

Fig. 2 train routing plan 2

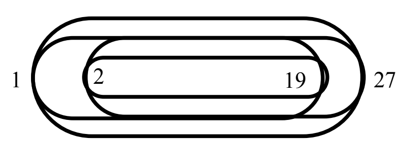

Fig. 3 train routing plan 3

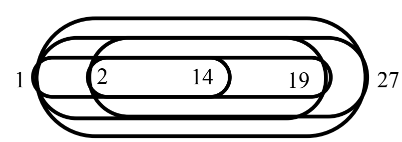

Fig. 4 train routing plan 4

When M=2-5, a throughout route has grew up in the final plan, no passenger need to transfer, so the z2=0. The equivalent of z2 is preferred to be satisfied. With the increase of upper limit M, the objective function z1 and z2,3 continues to decline, show that the total objective function decreases with the increase of route number. But as z3 increases with the larger M, because it will make total route length increased.

6 Conclusions

Taking the core problem in urban rail transit train routing scheme as the decision variables, considering the reasonable demand, transport capacity, transportation organization then the mathematical programming model was established. And the model is simplified based on the characteristics of train routing scheme. The simplified model is integer programming and can be solved quickly through optimization software with high efficiency and quality of solution.

Application of chongqing urban rail transit line 1 and the analysis of calculation results show that satisfy section passenger flow distribution is the primary goal of the routing scheme and transfer flow can be solved throughout route. Train running section and turn-back station is the foundation of the urban rail transit transport organization plan, providing the basis for the establishment of for train operation interval solutions, configuration plan and train stops. Although the research object defined as a single straight line, it also laid the foundation for urban network level rail routing scheme more of complex and practical value in further research.

Abstract: A method of business process reengineering of railway freight transport based on supply chain was discussed. The disadvantage and development of business process reengineering of railway freight transport based on supply chain were introduced. Based on Petri Net and the characters of supply chain, the method model of business process reengineering of railway freight transport was proposed. Every step of the model as a whole was studied. Two steps of the business process reengineering of railway freight based on supply chain were proposed. Lastly, the optimized freight service process was given.
Keywords: Business process reengineering; Supply chain; Petri Net; Railway freight transport.

1 Introduction

As the artery of national economy, railway undertakes the main procurement of people's livelihood supplies and capacity is extremely tense. The goal of Chinese railway cargo transport organization optimization only consider from inside the railway which obeys the principles of economy and benefit maximization while ignore the interests of the cargo owner. Railway cargo business process optimization is based on supply chain, the railway cargo business process as the organic composition of logistics system, pay more attention to cooperate with other logistics service function implement effective connection, thus and logistics systems in the upstream and downstream enterprises established stable cooperative partnership (KONG, 2006).

2 Analysis of railway freight business process based on supply train

2.1 Main problems in business process of railway freight transport

(1) Using tandem mode in business processes, which is time consuming and inefficiency.

Most of business process in railway system is tandem which is time consuming for customers. In addition, several apartments are in low condition thus inhibiting the increasing of overall efficiency.

(2) Lacking in consideration from customer's perspective with tedious procedure and single business.

In the consideration of pursuing high efficiency, railway department could not meet customers' variant need because of its single business and service which do not conform to requirement of outer service-oriented enterprise.

(3) Coordination degree of each operation link is insufficient, and the waiting time during middle processes is too long.

Each department of freight stations is uncoordinated though connected in the procedure of business in some degree due to the distribution of department functions.

2.2 Effects of supply chain thought on business process reengineering of railway freight transport

Railway freight is no longer facing on the original transport market, but a integral supply chain network with all kinds of logistical function including multimodal transport, warehouse management, distribution management, etc. Customers' requirements on transportation and distribution are effected by mercurial market which means transport service provider should keep high efficiency to make sure the procedure more quickly, accurate and stable from place an order to get cargo. However, traditional railway transportation mode could not handle this contradiction. In order to meet customers' need effectively, we should optimize railway freight transport process based on the whole supply train management (ZHANG, 2008).

3 The modeling method of business process reengineering based on Petri Net

Extend the analysis on railway freight transport process before based on Petri Net theory, abstract the flow diagram, and draw a business process model.

Define a four dimensional array $\sum$ as follow:

$$\sum = \left(P, T; A, M_{ij}\right)$$

The transforming relationship between railway freight transport processes and elements in Petri Net was showed in table 1.

Table 1. Correspondence between rail freight transport processes and Petri Net

Railway freight transport process	Petri Net
Processes or tasks of transport demand	P
Implement of processes	T
Resource constraints or capacity	M_0
Time or cost index in processes	A

First of all, main links of freight transport process is modeling on the whole. Each link is represented symbolically by P, T from the register on e-commerce platform to delivery cargos through a series of operations including freight submission, cargo loading, payment of charges, transportation, etc. And finally build a main process network model as chart 1 shows. Submission of transport requirement in sending end and delivery in receiving end are complex which need a more detailed description thus regarding them as sub-procedure symbolized as detailing and modeling submission sub-procedures of freight transport and logistic needs as chart 2and3. Meanings of P and T in model charts are showed in table 2, 3 and 4.

4 Railway freight business process reengineering of the vehicle

4.1 Design ideas and solutions of rail freight business process optimization

(1) To shorten the time of each part is consumed, on the basis of without changing the business process

Through the full use of electronic commerce platform has been shortened documents, delivery time, to make the Railway Bureau, railway freight station and customer can be shared information in time. On the basis of this measure, reasonable arrangement the connection of different modes of transport, to make different business department can be coordination and cooperation and finally to realize seamless connection.

(2) Optimization the process from the structure of business process

Series behavior as much as possible instead of parallel behavior, in this way it can save some time. Then it is a good way to reduce the process which can not bring profit. At last it should consider the relationship of customer and the Railway Bureau.

4.2 The design and optimization in the first phase of the business process

(1) The optimization of railway freight vehicle business process

① Make the tickets and shipping processes in parallel, that is to amend of p4 to p8 process, to improve the efficiency of process make the series structure to parallel.

② in the T6 send train forecast to the customer, notice customers ready to take goods in advance to improve the efficiency of station.

(2)Optimization of the process for T1, T9 process

① improve the efficiency of the system automatically audit order accuracy and remove artificial audit order process, eliminate subnet 1 and 2 in the conflict;

② after the shuttle bus schedule on that day, in advance to remind customers to pay the cost of freight and logistics, namely to modify c11.

③ calculated through actual investigation and take delivery way, resolve the conflict c13 / c14.

④ through actual investigation and calculation way, solve the z1 / z3 conflict.

4.3 The second phase of the business process design and optimization

The second phase of the business process design and optimization under e-commerce environment is mainly focused on the logistic need submission, acceptance and implementation in sending end and receiving end with the goal of synchronous submission, acceptance and implementation of freight transport and logistic need (ZHANG, 2013).

(1)Optimization of logistic demand submission

①Service type: Dividing railway freight transport service into five types according to customers' requirement: Through agent service, door to door service, door to station service, station to door service and station to station service. Customers in sending end fill in logistic demand information and report logistic service demand according to their own needs. Customers in receiving end directly report detailed logistic service after receive the delivery message.

②Service content: Railway logistics value-added services is compared with traditional freight, stretch around freight service chain, promoting the value of freight products and provides all the logistics services.

(2)Optimization of logistic demand acceptance

In terms of how to distribute logistic orders to companies, this article puts forward a method which introduces a score of service area and content (MA, 2008).

(3)Optimization of logistic service implementation and logistic cost payment

Logistic service implementation under e-commerce environment is no longer dispersedly operated, but complete together by railway departments use the way such as strategic cooperative joint operators, with the aid of e-commerce platform, integration of logistics enterprise resources.

In conclusion, we can reach the freight logistic service process in sending end and receiving end based on full logistic thought, supply chain theory and Petri Net model as chart4 and 5(XU, 2002).

The operations of rail freight develop logistics value-added services are on the basis of railway logistics resources integration of the railway corporation, the railway administration and railway logistics companies. As a system, railway logistics are in the influence of the internal and external motivation and resistance. However, from the study of mechanism of railway logistics resources integration we know, whatever motivation or resistance, the overall efficiency and competitiveness will continually increase when integrate all kinds of resource.

5 Conclusion

This article expounded the emergence and development of business process reengineering under supply chain environment, raised a reengineering model and optimized current railway freight service process in two phases. However, this article only generally introduced the business process reengineering model based on supply chain, and lacked a detailed description which should be completed in next phase. Due to the limited level, the proposed model is not perfect enough. It should be modified according to specific situations.

Abstract: This paper intends to establish a production control and safety management system for the passenger transportation depot to improve the level of information. First of all this paper analyzes the necessity and significance of the system. On the bases, describes the design objectives and design range of the system. And then this paper designs the overall structure of the system, proposes the logical architecture and technical architecture program of the system, and then designs the system network solution. Finally this paper carries out a detailed functional design of the system, and the system is divided into two subsystems, the command center subsystems and safety management subsystem, and both of the two subsystems' functional modules are designed in detail.
Keywords: Passenger transportation depot; Production organization; Safety management; System design; Functional analysis.

1 Introduction

The production organization and safety management system of railway passenger transportation depot plays a role of platform for information exchanging between the various departments and types of work within the railway passenger depot, and it is also an information system for leaders of various level to implement dispatch and safety management to various basic units uniformly.

The production organization and safety management system, as one of the internal systems of railway bureau's passenger transportation depot, and an important part of quick response system, its information construction level plays a decisive role in the realization of transportation production of "Efficient command, exchange information and scientific decision-making". And the construction of the system plays a significant role in railway safety production. The main role of the system includes the following aspects.

(1)The system is the main channel of information collection. It provides information support for the production management of the passenger transportation depot to ensure the timely and accurate transmission of information.

(2)The system helps to achieve the production planning management of the passenger transportation depot.

(3) The system is able to implement emergency dispatching disposal facing the sudden events. And it can make a rapid response to ensure the smooth flow of rail transport.

(4) Assistant decision-making.

(5)Coordinate various departments of the passenger transportation depot, achieving smooth communication between the upper and lower levels.

The production organization and safety management system of railway passenger transportation depot should meet the needs of the daily dispatching and production management of the passenger transportation depot, and it should establish a networking, information, intelligence safety management systems to realize sources sharing and to meet the demand for the innovation development of production arrangement and safeguards in the new period. The system plays a positive role in the safety management of railway field, optimization of transportation organization as well as the improvement of work efficiency under this new situation.

2 Research status at home and abroad

2.1 Relevant foreign research

The relevant foreign research mainly focus on the automatic establishment of the crew routing plan, but there are less research on the overall production control and security management system.

The scholar Dennis Huisman studied the implementing procedure of the crew routine plan and the crew dispatching plan of the Nederlandse Spoorwegen in detail. The scholar Alberto Caprara described the development of a new crew planning system set up by Ferrovie dello Stato SpA (the Italian railway company) in cooperation with the University of Bologna. The system divided the procedure into three phases, namely pairing generation, pairing optimization and rostering optimization. The scholar Ernst A.T proposed an integrated optimization model to solve both crew scheduling and crew rostering. The integrated optimization model can adapt to the actual situation of railway operations in Australia.

2.2 Relevant domestic research

The scholar Qu Zhiheng developed the “management system for the passenger train in transit” to strengthen the security monitoring and management for the operations of the passenger train in transit. Including the conductor inspection tour subsystem, vehicle terminal subsystem and data processing center subsystem.

On the basis of the existing “management system for the passenger train in transit”, the scholar Qu Zhiheng integrated the functions and upgraded the hardware configurations of the existing system, and developed the “integrated management system of dispatching of the passenger depot". The system consisted of six subsystems, including the train in transit subsystem, management of cadres' plan of participation in crew work, production scheduling subsystem, video management subsystem, safety information subsystem and train office subsystem.

Xi'an railway bureau completed tasks of constructing the two-level production safety command center of railway administration and the station segment. The command center can realize daily production plan online approval, real-time online monitoring of key aspects of the operation, emergency command online, implementation of operating standards inquiry and efficiency and effectiveness index analysis.

A conclusion can be drawn from analysis of the research status home and abroa d that the current research mainly concentrate on one or a few aspects and lack the comprehensive information architecture. This paper covers comprehensively the entire process of production organization and safety management of passenger depot. And the overall system has been divided into the command center subsystem and safety management subsystem, and its functional architecture has been designed clearly and comprehensively.

3 System design objectives and design range

3.1 System design objectives

Adopt advanced GPS global positioning technology, video surveillance technology, fingerprint recognition technology, computer network technology, information processing and integration technology, building a unified production organization and safety management system which covering the entire process of transportation production within the railway passenger transportation depot.

The system will be in the crew organization, safety monitoring, production safety risk management, railway morale quality assessment as the core, combining computer science, and give full play to the posts initiative of the staff. Control and monitor the production situation and the service quality of the passenger transportation depot accurately and real-timely, raising the level of decision-making management, comprehensively promoting the informatization management of passenger transportation depot.

The design objectives of the system including the following aspects:

(1) Control of real-time information of safety in production and service quality

(2) Implement emergency command processing

(3) Realize the routing of the safety risk management

(4) Improve the efficiency of production scheduling dispatch

(5) Realize the dynamic management of passenger transportation depot personnel

(6) Full and accurate statistical analysis

3.2 System design range

The construction scope of the system covers the management of the passenger transportation depot and its subordinate units, including the departments directly under the passenger transportation depot, team dispatching departments, car team, passenger service workshop, and carriage servicing workshop located around, also including the management of the train on the way, and the construction of the team dispatching video monitoring. The construction range of the system as is shown in the figure 1.

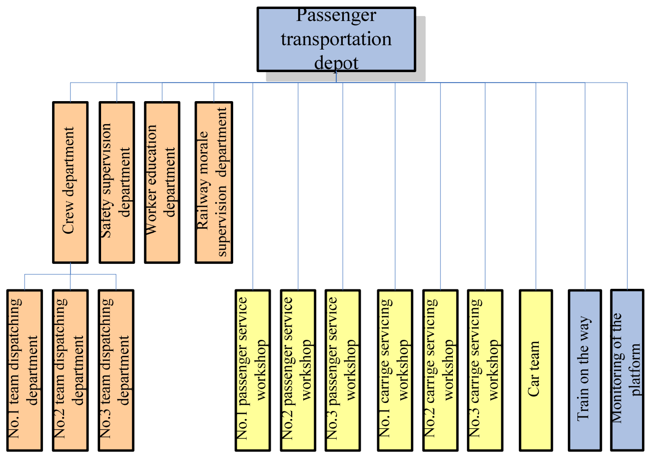

Figure 1.The design range of the system

4 System general designs

4.1 Logical architectural of the system

The logical architectural of the system mainly oriented to the users including the managers of the passenger transportation depot, each team dispatching department, the train on the way, and the train attendants, to provide them a set of convenient and comfortable operating environment, which can realize the real-time organization management, monitoring, and query of the transportation production of the passenger transportation depot. The whole system is divided into user layer, service layer and basic information layer. The logical architectural of the system as is shown in the figure 2.

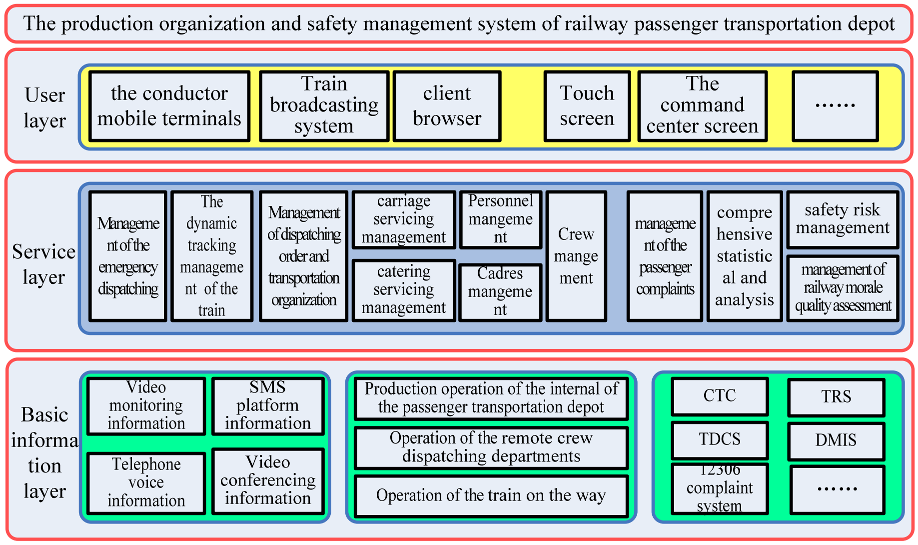

Figure 2.The logical architectural of the production organization and safety management system of railway passenger transportation depot

(1)User layer

User layer provides the users of the system with operation interface, preliminary check the integrity of the user input information, verify the identity of the users. Different users such as the railway bureau, passenger transportation depot, team dispatching departments, and the train on the way can access the production organization and safety management system of railway passenger transportation depot via by devices such as the client browser, the conductor mobile terminals, touch screen, and the command center screen to implement different types of related work and decision analysis of the passenger transportation depot management.

(2) Service layer

Service layer act as the bridge between the user layer and the basic information layer, concentrated the business logic processing of the system. The service layer respond to the requests conveyed from the user interface layer. And perform the corresponding tasks. The service layer extracts relevant data from the data layer, and transmits the necessary data to the user interface layer.

System service layer complete business processes through the unified basic information, and maintain the consistency and integrity of the basic data in the information processing. Business layer contains multiple business services and functional modules. Realize business functions such as statistical, analysis, decision-making, publishing, monitoring, supervision and sharing and exchange data and other business functions. And address the different needs of users directly.

(3) Basic information layer

Basic information layer integrated the operating data of the internal of the passenger transportation, remote crew dispatching departments and the train on the way. And the basic information layer introduces various types of video and audio information. And share the related information from existing systems such as KMIS, TDCS, CTC, TRS, DMIS and 12306. The basic information layer provides basic data and information support to achieve the requests of the service layer.

4.2 Technology structure of the system

Taking into account of the high reliability, scalability, availability, integrity and manageability, the technology structure of the system adopt the Browser/Server structure. Server is responsible for data management; users transact business through the client browser, guarantee the security, integrity of the system data. The system is designed as the typical three-tier architecture, including the presentation layer, business logic layer, and data access layer.

The system separates different business logic and application, and provides the service program that allows the underlying data access, data encapsulation, data transmission, to achieve the application that in accord with the customer application logic. The system accesses between every layer through interfaces to avoid that one layer logic leads to business changes have an impact on other layers.

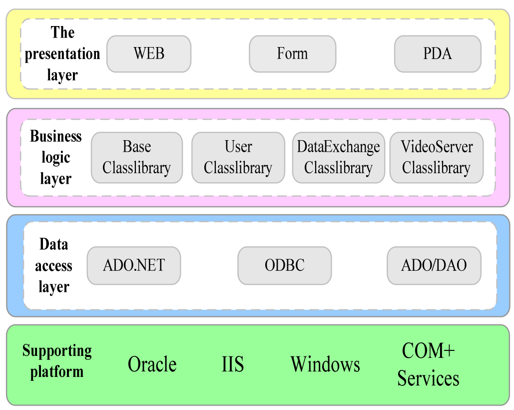

Figure 3.The technology structure of the production organization and safety management system of railway passenger transportation depot

5 Network structure design of the system

The system based on the existing railway network environment, on the premise of reliable, safe and efficient, guarantee the fluency of the network between the system and other related railway production management systems.

The network of the system needs to cover the railway bureau, passenger transportation depot, remote crew dispatching departments, and the train on the way. The network structure of the system as is shown in the figure 4.

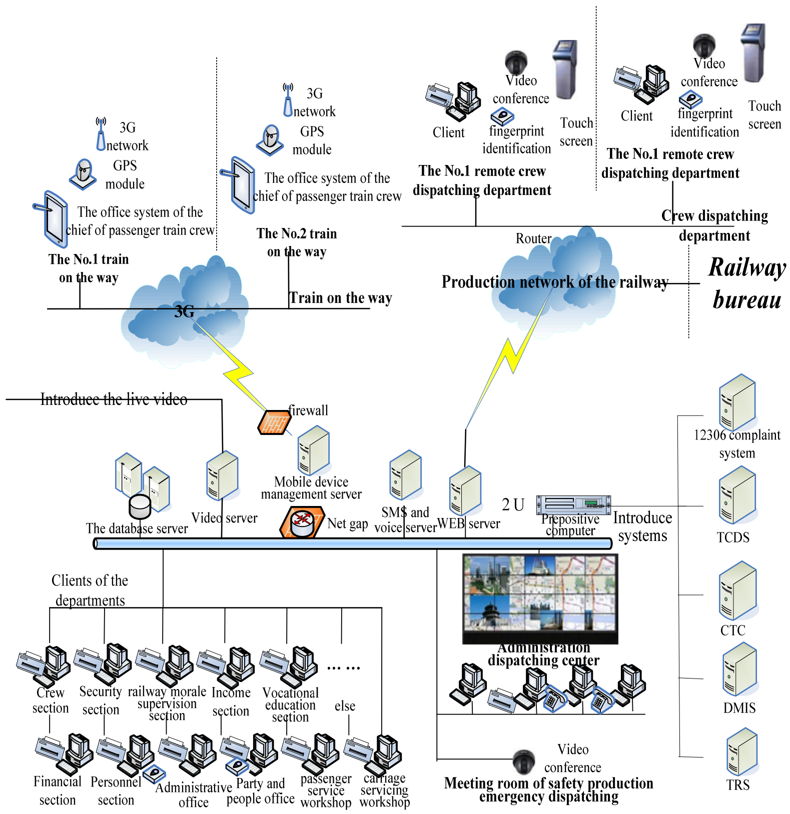

Figure 4.The network structure of the production organization and safety management system of railway passenger transportation depot

6 Functional structure design of the system

6.1 Overall functional structure design of the system

The production organization and safety management system of railway passenger transportation depot is designed based on the modularization. And it integrates production command and safety management these two aspects to design the function. The system consists of two subsystems, the command center subsystem and safety management subsystem. The overall functional structure as is shown in the figure 5.

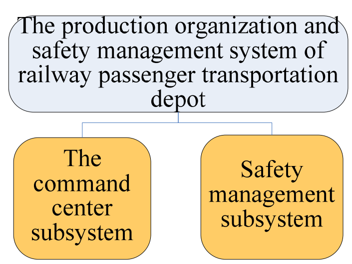

Figure 5.Overall functional structure design of the system

The command center subsystem mainly realizes the commanding and coordinating of the production business and urgent incident. And the safety management subsystem mainly realizes the management of the passenger transportation depot's production management information. Two subsystems complement each other; meet the demands of production organization and safety management of the passenger transportation depot in common. Design function of these two subsystems respectively in the following.

6.2 The command center subsystem

The command center subsystem supposed to have five functions including production scheduling, security monitoring, integrated query, emergency handling and dynamic management of cadres. To realize the function of the command center subsystem, we need to start from hardware and software both of the two aspects for construction. And strengthen the construction in terms of personnel, institutions and systems in order to guarantee the normal operation of the system function.

The command center subsystem focuses on the organization of production, and it via the tracking technology including video conferencing, telephone voice, SMS, and GPS to fully grasp the situation of the train on the road. And the subsystem dispatches the crew team real-timely by taking the form of video commanding and multi part call. And communication and collaboration with the higher authorities through video conferencing, teleconferencing. And implement the treatment of the emergency events.

The main functional modules of the command center subsystem include:

The dynamic tracking management and monitoring of the chief of passenger train crew, management of crew routine, management of the dispatching command and production organization, construction of video surveillance, platform of the SMS sending and receiving, telephone voice call center, management of the emergency dispatching, video conference of the emergency dispatching, and mobile terminals of the chief of passenger train crew. Each modules perform different functions, and combine with each other, formed a perfect platform for production organization which is informatization, networking, real-time and efficient.

The functional structure of the command center subsystem as is shown in the figure 6.

6.3 Safety management subsystem of the passenger transportation depot

The safety management subsystem mainly realizes the management of the passenger transportation depot's production safety information.

The main functional modules of the safety management subsystem include:

Personnel management, crew management, management of railway morale quality assessment, management of cadres, safety risk management, management of the passenger complaints, carriage servicing management, touching screen management, and comprehensive statistical and inquiry. Each modules perform different functions, and combine with each other, formed a perfect informatization, networking, real-time and efficient safety production information management subsystem.

The functional structure of the safety management subsystem as is shown in the figure 6.

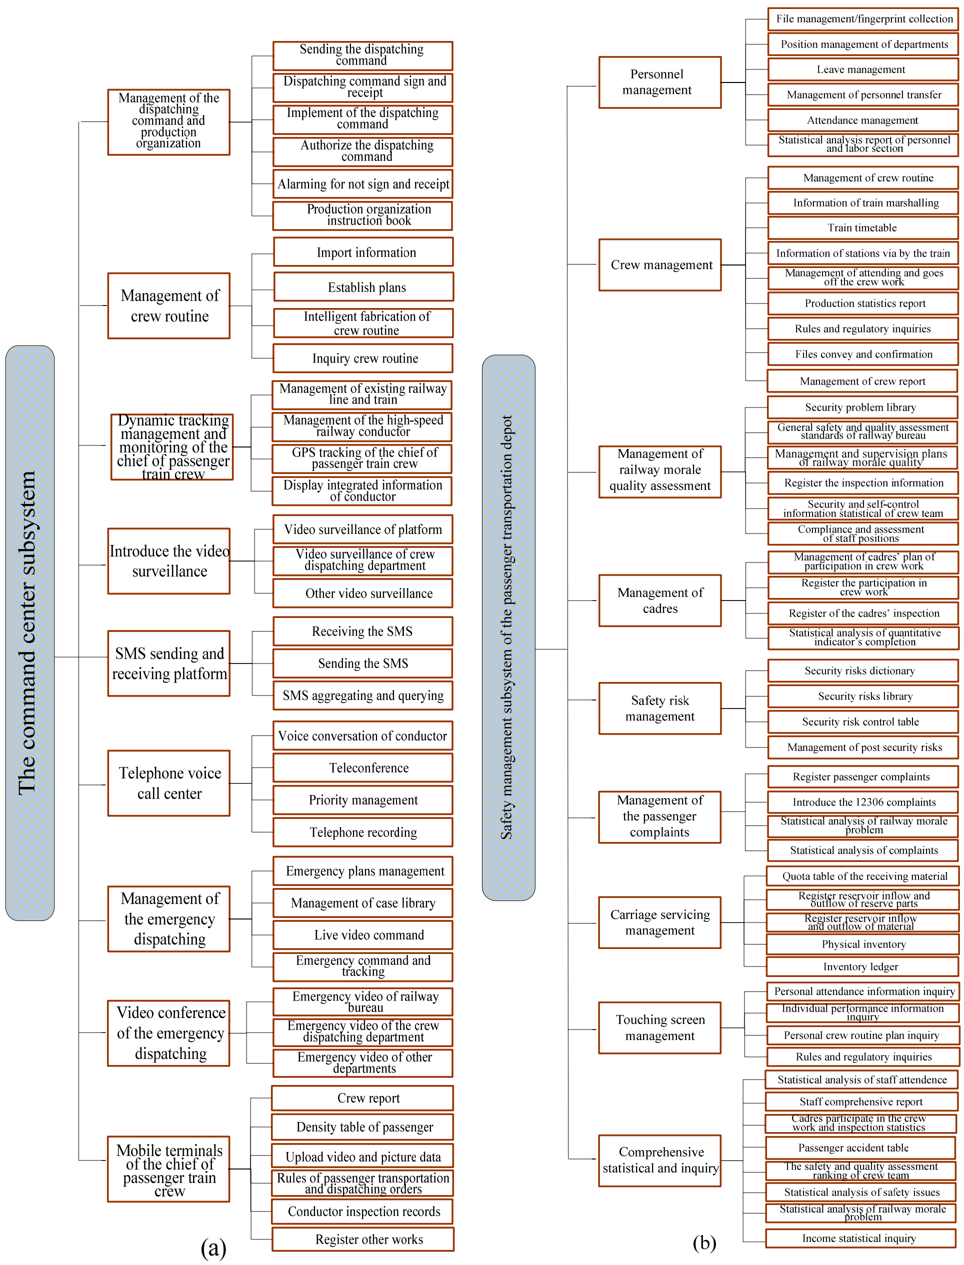

Figure 6. Functional structure design of the command center subsystem and the Safety management subsystem

7 Conclusions

The organization management of the passenger transportation depot relate to the efficiency and patency of the whole transportation organization. Because there are lots of complex links inside the passenger transportation depot, shall make plenty of information. In order to meet the requirement of the development, we need to improve the informatization level of the passenger transportation depot.

The paper designs the production organization and safety management system of railway passenger transportation depot in detail, and puts forward the design scheme of the key parts. The system has reasonable structure and complete functions, has a certain practical value for the organization management. And the system will play a positive role in promoting information construction of the passenger transportation depot.

Abstract: This paper focuses on the schedule design problem for liner shipping to hedge against uncertainties. As a complement of Robust Optimization, a new optimization method – Wave Optimization (WO) is proposed, which is more suitable for socioeconomic systems. Then a mixed-integer nonlinear programming model based on WO is presented to solve the vessel schedule design problem. A real-life case study is investigated and proves that the proposed model could be solved effectively and efficiently for the realistic scale problem.
Keywords: Liner shipping; Schedule design; Wave optimization; Mixed-integer nonlinear programming.

1 Introduction

Not like tramp shipping, liner shipping services have fixed sequences of ports of call and fixed schedules for a period of time (usually 3 to 6 months), mainly involves the transportation of containers (Karlaftis et al., 2009; Norstad et al., 2011; Rakke et al., 2011; Øvstebø et al., 2011). However, there are many uncertainties (disruptions) in liner shipping services, such as bad weather, strike in ports, congestions in passageways and ports, and mechanical failures (Brouer et al., 2013). The various disruptions could make a decrease in schedule reliability. According to Notteboom (2006) approximately 70-80% of vessel round trips experience delays in at least one port. Furthermore, schedule unreliability would have a negative effect on many actors in the supply chain. E.g., Vernimmen et al. (2007) present a case study to illustrate the impact of schedule unreliability on the level of safety stock that should be kept by a manufacturer who sources spare parts from overseas, and it is concluded that an improvement in schedule reliability can lead to significant cost savings for the company under consideration.

There are mainly two ways to handle disruptions in liner shipping services. One is through reactive scheduling (disruption management), and the other one through proactive scheduling (design robust schedules). Only one published journal paper is found in literature devoted to disruption management in liner shipping. Brouer et al. (2013) proposed a vessel schedule recovery problem to evaluate a given disruption scenario and to select a recovery action balancing the trade-off between increased bunker consumption and the impact on cargo in the remaining network and the customer service level.

The literature on schedule design problem in liner shipping is also limited however a trend of increasing. One category of the studies addresses the schedule design problem in a deterministic environment. Mourão et al. (2001) examined two possible schedules for the feeder route in the model they proposed. Ting and Tzeng (2003) presented a dynamic programming model for scheduling a single ship route under berth time-window constraints. Wang et al. (2014) and Alharbi et al. (2014) also proposed the schedule design problem with port time windows, what different is, Wang et al. (2014) focused on a single ship route but Alharbi et al. (2014) focused on a liner shipping network with many ship routes. Wang and Meng (2011) investigated the schedule design problem and the container-routing problem simultaneously which objective is to minimize the sum of the total transshipment cost and penalty cost associated with longer transit time than the market-level transit time, minus the bonus for shorter transit time. The second category of the studies considers uncertain factors when designing the schedules of liner services. In the work of Wang and Meng (2012a), the uncertain port time and sea time contingencies were captured when designing the optimal schedules. They formulated a stochastic MINLP and proposed a cutting-plane based algorithm. Qi and Song (2012) designed an optimal vessel schedule in the liner shipping route to minimize the total expected fuel consumption considering uncertain port times (treated as a random variable). Wang and Meng (2012b) designed robust schedules that can hedge against the uncertainties in port operations, including the uncertain wait time and uncertain container handling time.

This paper focuses on the schedule design problem for liner shipping to hedge against uncertainties whatever occurred on sea or at ports, based on a new optimization theory we proposed – Wave Optimization (WO), which would be introduced in the next section.

2 Wave Optimization

As is known, robust optimization (RO) is one of the most common methods to handle uncertainties in a system and have made great development in the last decade (see Gabrel et al., 2014, for reviews). However, there are some inherent drawbacks of RO, such as: (1) Seeks to obtain a solution that will be feasible for the realization of the worst-case, however, complete protection from adverse realizations often comes at the expense of a severe deterioration in the objective (Gabrel et al., 2014); (2) Usually uses a finite number of scenarios to compute the worst case, but cases beyond the set could happen in real-life which would make the solution not effective anymore; (3) No consideration of resilience in case of the deterioration of the system state. These shortcomings above mentioned limit the application scope of RO in socioeconomic system, though it is fit for some engineering applications of robustness, such as robust control theory, as the engineering failures would produce high-profile repercussions (Gabrel et al., 2014). To remedy the disadvantages of RO, we propose a new optimization method – WO, which is more suitable for the socioeconomic system. Firstly, we introduce the related concepts of WO, see in subsection 2.1.

2.1 Concepts

Wave is the basic representation form of the world, such as mechanical wave, electromagnetic wave and so on and the state curve of something also can be seen as wave (e.g. one's mood, the performance of a basketball player, et al.). The former wave category can be called substantial wave, and the later one virtual wave. We often use the word volatility to describe the bad effect of wave, but few to notice the good side of it. Actually, there is great wisdom in the pattern of wave which is illustrated below with the help of a graph, see Figure 1.

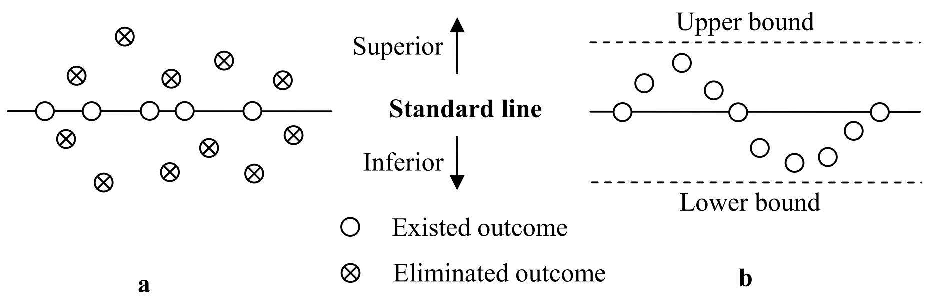

Figure 1. Two different survival modes

In Figure 1a (line form), it only allows of existence of the outcomes which accord with the standard line rigidly, while others would be eliminated. However, in Figure 1b (wave form), it allows the outcomes to fluctuate around the standard line within a certain limit, so more outcomes could be survived than those in Figure 1a. It is obvious that in the form of wave, there's a property of inclusivity which supply the space for various possibility and diversity (uncertainties). Besides, if it reach the crest of the wave, there's always a fall towards the balancing status in the following period of time, and if it get the trough, there would be a rise towards the balancing status as well. This property of wave can be called as recoverability. In this paper, we define the good properties, i.e. *inclusivity* and *recoverability*, as "**waviness**" as integrity of which the adjective form is "**wavy**". Further, in the basic framework of WO, we come up with two index systems to measure waviness: *tolerance* and *resilience*, refers to *inclusivity* and *recoverability* respectively. Then we present the general model of WO consists of the two main index systems, see in subsection 2.2.

2.2 General model

The general model of WO is inspired by the mathematical expression of simple harmonic wave in physics, which can be described by sine function (or cosine function), see Eq. (1).

$$y = A\sin(\omega x + \varphi) \quad (1)$$

In Eq. (1), A is amplitude, ω is angular frequency, and φ is initial phase. In the theory of WO, the parameter φ makes no difference and therefore is set as 0; and the parameter B which is the displacement of equilibrium position in the y direction is needed. So Eq. (1) is converted to Eq. (2).

$$y = A\sin(\omega x) + B \quad (2)$$

The sketch map of Eq. (2) is shown in Figure 2.

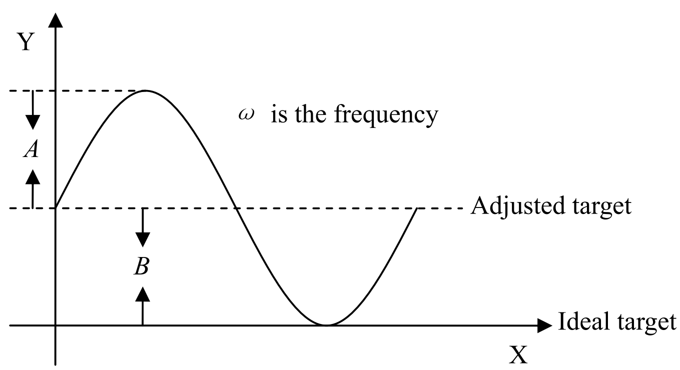

Figure 2. Sketch map of Eq. (2)

In the theory of WO, x-axis equals the ideal target of the system while the real equilibrium position is the adjusted target, A refers to the flexible range of the target, B indicates the buffer put into the system while ω accounts to the resilience of the system. Parameters A and B belong to the index system of tolerance, the greater is the value of A and B, the more space for uncertainties. While ω belongs to the index system of resilience, the greater is the value of ω, the faster bounce back to the schedule target from disrupted status. Our goal is to maximize the waviness of the system, i.e. the sum of A, B and ω, while minimize the operation cost. The objective function of the general model of WO tries to balance the trade-off between the operation cost and waviness benefit of the system, which can be expressed as below.

$$[\text{WO}] \quad \min Z = \mathrm{C}(X) - (A + B + \omega)\cdot M \quad (3)$$

$C(X)$ is the operation cost function, X is vector of decision variables; M is the waviness benefit coefficient. Here no longer mention the constraints of the general model. Moreover, it should be pointed out that the purpose of WO is to make the system possess the waviness (own the potential to perform as wave form) instead of keeping the wave pattern all the time. The general model of WO looks simple and tractable, but whether it is effective or not, we will apply it to the schedule design problem for liner shipping to verify, see the following sections.

3 Problem Description

When designing the vessel schedule for a liner ship route, the ports of call are predetermined and are visited in a fixed sequence. Define a set $I = \{1, \ldots, N\}$ to represent the total ports of call, and the ith leg is defined as the voyage from the ith port of call to the $(i+1)$th port of call, i=1,2, …, N-1, and the Nth leg is from the Nth port of call to the 1st port of call. We let t_i^{ber} (time unit: hour, the same below) be the estimated time of berthing of the vessel at the ith port of call (t_1^{ber}=0, as the time point 0), t_{N+1}^{ber} be the berthing time when the vessel returns to the 1st port of call. We assume a weekly service frequency and m ships are deployed on the route, so there's an equation relation as below shows:

$$t_{N+1}^{\text{ber}} - t_1^{\text{ber}} = 24 \times 7 \times m = 168m \qquad (4)$$

We use the estimated time of berthing other than the estimated time of arrival because shippers/consignees are more concerned about the actual start handling (discharging and loading of containers) time, it makes no difference for shippers/consignees whether a ship has arrived at a port but has to wait for berth (Wang and Meng, 2012b). Therefore, the pilot in time t_i^{in} and pilot out time t_i^{out} of the vessel at the ith port of call are also incorporated in the model.

A_i represents the flexible range of berthing time of the vessel at the ith port of call. We define t_i^{ber} as the published target point of berthing, while [t_i^{ber}, $t_i^{\text{ber}}+A_i$] as the published target window of berthing. If the vessel berths in the target window, it will be announced that the vessel is on schedule. B_i is the buffer time assigned to the ith leg. Let v_i be the sailing speed on the ith leg, subject to the range of $[V^{\min}, V^{\max}]$, and p_i be the productivity (quantity of containers handling per crane per hour) at the ith port of call, subject to the range of $[P_i^{\min}, P_i^{\max}]$. Then the resilience index ω_i including two parts in this paper can be expressed as following: (1) the room for improvement of productivity at the ith port of call (i.e. $P_i^{\max} - p_i$), and (2) the room for speeding up on the ith leg (i.e. $V^{\max} - v_i$). Assume Q_i is the predicted quantity of containers handling at the ith port of call, so the port time t_i^{port} can be formulated as below (assume usually two cranes serve one ship):

$$t_i^{\text{port}} = Q_i / (2 p_i) \quad \forall i \in I \qquad (5)$$

As mentioned earlier, the usage of target window of berthing bring flexible space for liner companies, but from the perspective of port, the vessel berths later than the target point will bring inconvenience since it may disrupt the operation schedule of container terminals. So we define an inconvenience penalty function $F_i(A_i)$ which is shown as below:

$$F_i(A_i)=\begin{cases}0, A_i \le Q_i/(2p_i)-Q_i/(2P_i^{\max}) \\ \varepsilon_i[A_i-(Q_i/(2p_i)-Q_i/(2P_i^{\max}))], A_i > Q_i/(2p_i)-Q_i/(2P_i^{\max})\end{cases} \forall i\in I \quad (6)$$

Eq. (6) indicates that if the time period of A_i can be recovered by improving the productivity p_i to the maximum, no penalty would occur. Otherwise, there's a linear function of penalty. We further define vector:

$$\lambda = (m, t_i^{\text{ber}}, t_i^{\text{port}}, v_i, p_i, A_i, B_i)_{i\in I} \quad (7)$$

The schedule design problem based on WO aims to determine the vector λ to balance the trade-off between ship operating cost, bunker cost, inconvenience penalty and waviness benefit.

4 Mathematical Model

Let t_i^{dep} be the departure time of the vessel at the ith port of call, L_i (n mile) be the length of the ith leg, C^{ship} (USD/week) represent the fixed operating cost of a ship deployed on the ship route, α (USD/ton) be the bunker price, and $g_i(v_i)$ be the bunker consumption rate (ton/n mile) at the speed v_i on the ith leg. As the daily fuel consumption of ships increases approximately proportional to the sailing speed cubed (Ronen, 2011), we can write $g_i(v_i)=\mu(v_i)^2$ since $g_i(v_i)$ is expressed in terms of tons per nautical mile (Wang and Meng, 2012b).

The schedule design problem based on WO can be formulated as a mixed-integer nonlinear programming (MINLP) model:

$$\min Z = C^{\text{ship}}m + \alpha\sum_{i\in I} L_i g_i(v_i) + \sum_{i\in I} F_i(A_i) - \sum_{i\in I}(A_i + B_i + \omega_i)\cdot M \quad (8)$$

Subject to:

$$t_1^{\text{ber}} = 0 \quad (9)$$

$$t_i^{\text{ber}} = t_{i-1}^{\text{dep}} + t_{i-1}^{\text{out}} + L_{i-1}/v_{i-1} + B_{i-1} + t_i^{in},\ i = 2,\ldots,N \quad (10)$$

$$t_{N+1}^{\text{ber}} = t_N^{\text{dep}} + t_N^{\text{out}} + L_N/v_N + B_N + t_1^{in} \quad (11)$$

$$t_{N+1}^{\text{ber}} - t_1^{\text{ber}} = 168m \tag{12}$$

$$t_i^{\text{dep}} = t_i^{\text{ber}} + t_i^{\text{port}}, \forall i \in I \tag{13}$$

$$t_i^{\text{port}} = Q_i / (2p_i), \forall i \in I \tag{14}$$

$$V^{\min} \le v_i \le V^{\max}, \forall i \in I \tag{15}$$

$$P_i^{\min} \le p_i \le P_i^{\max}, \forall i \in I \tag{16}$$

$$A_i \le 24, \ \forall i \in I \tag{17}$$

$$\omega_i = (P_i^{\max} - p_i) + (V^{\max} - v_i), \forall i \in I \tag{18}$$

$$m, A_i, t_i^{\text{ber}}, t_i^{\text{port}} \text{ nonnegative integers}, \ \forall i \in I \tag{19}$$

The first term in the objective function (8) is the ship operating costs, the second term is the bunker costs, the third term is the inconvenience penalty costs and the fourth term is the waviness benefits. Eqs. (9) – (11) answer the berthing time of the vessel at each port of call. Eq. (12) imposes the weekly service frequency constraint. Eqs. (13) – (14) define the departure time and port time of the vessel at each port of call, respectively. Eqs. (15) – (16) limit the varying ranges of sailing speed at each leg and productivity at each port of call, respectively. Eq. (17) enforce that A_i has to be less than or equal to 24 hours. Eq. (18) gives the expression of ω_i. Eq. (19) is for non-negative integer variables.

5 A Real-life Case Study

We carry out a real-life case study to validate the effectiveness of WO and the model we proposed. The MINLP model is solved by LINGO 11.0 running on a 3.2 GHz Dual Core PC with 2GB of RAM.

The case is based on the AWE2 ship route from a global liner company. The sequence of ports of call and the length of each voyage leg are as follows: Qingdao (1: 400) – Shanghai (2: 130) – Ningbo (3: 1100) – Yokohama (4:7800) – Panama (5: 1975) – New York (6: 380) – Boston (7: 559) – Norfolk (8: 1785) – Panama (9: 8800) – Qingdao (1). Other related data are: 4500TEU ships with speed range [10, 24.5] knots are deployed on the ship route; C^{ship} =450000, μ =0.0004, α =560, $\varepsilon_i = 20000, \forall i \in I$, M=2000; pilot in time at the ports of call respectively are {2, 1, 3, 2, 1, 3, 2, 3, 1}, and pilot out time are {2, 1, 3, 2, 0.5, 3, 2, 3, 1}, respectively; productivity range of each port of call all is [30, 60]; the predicted container handling quantity at the ports of call are {1600, 1500, 1000, 500, 1100, 1800, 1400, 900, 1100}, respectively, where the data of the port Panama is virtual since Panama is a canal, no container handling there.

The global optimal solution can be found within 12 minutes when the strategies of *Quadratic Recognition* and *SLP Direction* in "Options" settings are chosen. Since the schedule design problem is a tactical planning problem, the solving time is highly efficient. The computational result of the case is as follows: m=9; the berthing time t_1^{ber} to t_9^{ber} are {0, 55, 95, 181, 625, 759, 819, 882, 1004}, respectively, and t_{9+1}^{ber} is 1512; the port time t_1^{port} to t_9^{port} are {26, 25, 16, 8, 18, 30, 23, 15, 18}, respectively; the sailing speed v_1 to v_9 are {15.38, 11.82, 16.92, 18.01, 17.56, 15.20, 15.97, 17.33, 18.03}, respectively; the productivity p_1 to p_9 are {30.77, 30, 31.25, 31.25, 30.56, 30, 30.43, 30, 30.56}, respectively; A_1 to A_9 are {12, 12, 7, 3, 8, 15, 11, 7, 8}, respectively; B_1 to B_9 are {0, 0, 0, 0, 0, 0, 0, 0, 0}, respectively.

As can be seen, all the values of B are zero, but when we limit the speed at high level and in a tight range, e.g. [22, 24], positive values of B would be generated. This provides inspiring managerial insights that there's no need to assign buffer time to sailing legs in liner shipping since the speed varying range is wide and we can lower the speed to increase resilience while saving the fuel cost. However, in the realized schedule designed by the company, there's buffer time assigned to some legs and therefore ten ships have to be deployed on the ship route which would increase huge ship operating cost. Apparently, the optimized schedule is more reasonable and more cost-efficient than the realized schedule.

6 Conclusions and Future Work

This paper focuses on the schedule design problem for liner shipping to hedge against uncertainties. First, we propose a new optimization method – Wave Optimization (WO), which is flexible and more suitable for the socioeconomic system compared to Robust Optimization. Second, a MINLP model based on WO is presented to solve the problem. At last, the novel method and the mathematical model are verified through a real-life case study, and the global optimal solution can be found within promising time using the business software LINGO 11.0. Useful managerial insights are acquired from the computational result.

The future work may extend to the following directions: (1) further improve the WO theory, and (2) apply the method of WO to other industries, e.g. airline, railway, logistics and supply chain.

Passenger Flow Organization of Large Passenger Stations during the Period of Spring Festival Transport

Xuezhen Chen and Weixiong Zha

Institute of Transportation and Economic, Humanities and Social Science Research Base of Jiangxi Province, East China Jiaotong University, Nanchang 330013, China. E-mail: 1225024038@qq.com

Abstract: With the continuous development of railway passenger transportation enterprise, passenger traffic of railway station is rising, so the difficulty of passenger flow organization is increased. In order to organize the passengers transport during the Spring Festival accurately and efficiently, it is necessary to study passenger flow organization in the peak, to adapt the characteristics of single direction of passenger flow during peak passenger flow and complex passenger flow component , then realize passenger transport safety and orderly. This article firstly introduces the characteristics of passenger flow and its organization during the Spring Festival in China; then introduces the process of passenger in and out of the large railway station in the Spring Festival and according it to analyze the way of passenger flow organization , summarize the existing problems and put forward the suggestions to solve them; followed by Nanchang railway station for example, analyze the cause of passenger transport in the Spring Festival, for the status quo of passenger flow organization in the Spring Festival, analyze the existing problems of the Nanchang Railway Station about passenger flow organization in the Spring Festival and put forward the suggestions to solve them, finally predict the Nanchang railway station travel traffic in 2015.
Keywords: Large passenger station; Passenger flow organization; The Spring Festival transport.

The Spring Festival transport refers to the freight and passenger transport during the Spring Festival. It is specific phenomenon in our social and economic life and a product of the combination of customs and habits inherited from thousands of year in China and the planned economic. Analysis and research of passenger flow of the Spring Festival transport is the objective requirement of the socialist market and has an important reference value for passenger flow planning recent and network construction, arrangement of transportation, transport policy in the future.

Many domestic and foreign scholars have deeply researched on passenger station layout, passenger organization method, streamline design etc. Passenger flows of the Spring Festival transport in large passenger station are the main factors that seriously affect the capacity of the hub and this paper studies on how to or organize them.

1 The characteristics of passenger flow during the Spring Festival transport in China

To study the passenger flows organization method, first of all we must know affecting factors and characteristics of passenger flows of the Spring Festival transport, then analyze passenger transport organization combined with characteristics.

1.1 Causes and composition for passenger flow

Passenger flow of the Spring Festival transport belongs to the peak passenger flow which exhibit that far beyond the daily passenger flow in quantity. It has the general characteristics of passenger flow, the great quantity and the particularity of its period. The forming reason mainly has the following several points:

From economy: after the reform and opening up, with economic development, per capita travel times increased. From traditional culture: China is a country with an ancient civilization. Values, religious beliefs and customs largely contributed to the formation of large passenger flow. From national policy: passenger flow fluctuation and change of policy are almost synchronous. In addition, the disequilibrium of regional economic development causes the frequent labor force flow.

The passenger flow include student passenger flow, tourist flow, visiting flow, migrant workers flow.

1.2 Characteristics of passenger flow

After years of statistical analysis, the passenger flow of the Spring Festival transport has the following characteristics:

1) The passenger flow structure's unbalance: through passenger flow growth larger than the tube. 2)Imbalance of area distribution and flow : preganglionic passenger flow distribution in the economically developed southeast coastal area, the flow is mainly from the southeast coastal areas to the central and western underdeveloped area, postganglionic conversely. 3)The passenger flow's unbalance in time : passenger flow focus on when students leave school and back to and migrant workers go home and back to work. 4)The passenger flow composition's unbalance: from the travel purpose, visiting and tourist flow is the main part of the peak passenger flow, but from identity occupation, office workers, migrant workers and students constitute the main passenger. In addition, each of the above characteristics mutual influence.

2 Passenger flow organization analysis of large passenger station

2.1 Procedures of passenger flow into and out of the station in large passenger station

Large passenger station is the main place of railway passenger transportation, the passenger organization level depends on the passenger station space and streamline layout, the facilities' layout and utilization, the procedures and working methods of the passenger flow organization.

The procedures: for in of station, they are the ticket、pull in station、security-check、go to the corresponding waiting room、ticket check、through the tunnel or bridge into the platform and get on the train; for out of station, they are get off the train、through the tunnel or bridge and ticket check.

2.2 Organization analysis of passenger flow during the Spring Festival transport

2.2.1 Analysis of Facility capability

1) Analysis of waiting equipment ability: the waiting room should have comfortable waiting environment and convenient link with the main entrance and wicket and be near the station. The layout of waiting room has two forms:①

Centralized waiting mode, this arrangement have advantages of flexible use, high utilization, but waiting passengers difficult to maintain order;②Scattered waiting mode: The layout features are opposite with the centralized waiting's.

2) Analysis of inlet and exit capacity of the passengers: single inlet and exit ticket check capacity is an important factor affecting the passenger capacity and limited. So it's the key to set sufficient number of wicket ticket.

3) Booking capability analysis: ticket sale capability relates with ticket types, methods, speed of booking and per capita purchasing of passengers.

2.2.2 Streamline analysis

(1) The classification of passenger station streamline

Generally, from the direction of flow: Streamline can be divided in and out of the station. From the properties of flow: divided into passenger, luggage and vehicles streamline. When the passenger flow peak, streamline analysis should start from station square, meanwhile, streamline can be divided into passenger and vehicle streamline.

(2) Streamline of the peak analysis

1) Passenger Streamline: to convenient for station management and passenger travel, passenger streamline usually are divided into the following types:

①Into the station streamline: it includes ordinary passenger streamline which is the main streamline, has the largest number of passengers and need wait longer time; Transit passenger streamline which the passengers can directly transfer the corresponding when time isn't enough; Suburban passenger streamline which can immediately check ticket and get on the when arrive the station; VIP streamline which apart from others' streamline and has a few passengers; Groups of passenger and special passenger streamline which includes passengers of travel group, maternal and child, the weak or etc. and apart from other's streamline.②Out of the station streamline：its' passengers have the characteristics of concentration and short residence time. This streamline should be smooth and passengers should be evacuated as soon as possible to not affect the efficiency of passenger transport organization.③Tickets streamline: nowadays, although most passengers choose to buy tickets through internet in advance, some passengers still buy tickets in the station because of the contradiction between supply and demand and others' factors. We can see that tickets streamline is quite large.

2) Vehicle streamline: it includes streamlines of bus, postal vehicle, parcel special vehicle, taxis and other social vehicle. Planning various vehicles' stop in the station square well and reasonable organization of various vehicles' routes are very important.

3 Organization analysis of passenger flow of Nanchang Railway Station.

3.1 Overview of Nanchang Railway Station

Nanchang Railway Station is located in Nanchang City, capital of Jiangxi Province. It is the only provincial station in the Beijing Kowloon line. It focus on long-term development, forge ahead and now has developed into a modern railway station with traffic command, ticketing, baggage and parcel transportation, passenger service and commercial, catering, accommodation, entertainment function, etc.

3.2 The causes of large passenger flow during the Spring Festival transport in Nanchang

(1) From regional perspective: Nanchang, the capital city of Jiangxi province and the historical and cultural city, has a vast territory, abundant resources and natural landscape and important geographical position. It not only gave birth to the big local population, but also attracted many domestic and foreign tourists and workers etc. This is the basic cause.

(2) From culture and custom perspective: The Spring Festival is the most important festival for Chinese and also the concentrated period for visiting relatives and friends. People's travel frequency increases greatly during the period.

(3) From social economic development perspective: The development of social economy and transportation industry complement each other. Since Nanchang implemented the policy of economic reform and opening up, the city's GDP increase by 11.75% per year. Nanchang's Economic development will inevitably bring the rapid increase of demand for railway transport.

3.3 Passenger flow organization of Nanchang Railway Station

3.3.1 The present situation of passenger flow organization

The situation of passenger flow organization are as follows: 1) The grid type: EMU train, direct express train, express train, inter Bureau express train, HKMA express train and temporary passenger train.2) Security check: security work will be more strict during the Spring Festival.3) Tickets on sale: provide many methods for passengers to ticket, such as the telephone and internet booking, and ticketing through window, ticket vending machines and temporary ticket car.4) Waiting: Nanchang Railway Station set waiting shed in station square besides waiting room indoor.5) Ticket check: At present, the station check ticket by artificial way.6) Out of the station and transfer: passengers get out station and transfer according to the instructions.7)

Instruction and identification: Provide passenger information of tickets on sale, station layout and other' supplementary information.

3.3.2 The problems of passenger transport organization

The problems as follows: 1) Large passenger flow; lack of security check points; too much time for security check.2) Ticket booth deficiency; passengers get on the train without tickets; some people sell fake tickets to passengers.3) When passengers line in S shape in station square, the queuing disorder and exist security risks; low efficiency of ticket check by artificial; ticket checking tedious.4) The exit disorder; little of traffic for passengers to transfer; long distance after getting off train to transfer; instructions for getting out the station and transfer in the station aren't obvious.

3.3.3 Suggestions for solving the problems

The suggestions as follows: 1) Increase security inspection equipment and patrols; improve the efficiency of security.2) Increase ticket booth and ticket vending machines and arrange staffs to instruct passengers to ticket.3) Strengthen the management of the order in station square; adopt automatic checking method; simplify ticket check procedures.4) Arrange supervision personnel in the exit; clear the indicators.

4 Passenger flow prediction of Nanchang Railway Station during the Spring Festival transport

4.1 The concept of prediction

Prediction is that estimating trend of things possible evolvement in advance by scientific judgment method and econometric analysis. In recent years, the number of passengers of the Spring Festival transport increases dramatically, which brings great pressure to passenger station. If relatively accurate prediction can be made, passenger station will arrange work in advance. At present, about 15~20 prediction methods are really used in practice widely, such as the method of regression analysis, trend extrapolation, MarKoV, Deiphi.

4.2 Variation rule of passengers to send of Nanchang Railway Station

The Spring Festival transport time is generally 40 days, including 15 days before the holiday and festival 25 days. Before the Spring Festival, migrant workers return home concentrated in December 18~22 in lunar calendar, while visiting and travelling in December 26~New Year's eve. If the school holiday early, the peak can be alleviated relatively. After the Spring Festival, two peak flows appear in January 5~11 and 16~21 in lunar calendar.

Through the above analysis, we can conclude that the peak of passenger flow almost appear in the same time, passenger flow have roughly the same changing direction and amplitude every year and the time takes periodic fluctuation. The characteristics conforms to the required conditions by seasonal variation prediction method.

4.3 Prediction of number of passenger flow of Nanchang Railway Station

Nanchang Railway Station is a distribution station of large numbers of passenger and under great pressure of passenger organization of the Spring Festival transport. We can establish model to predict number of passenger flow for dealing with the problem in advance. The number of passengers to send during the Spring Festival belongs to the time series of the seasonal changes and the irregular changes which is suitable for seasonal level model.

Through characteristics of the passenger flow, we can establish seasonal level model, which as follows: $Y_t = Y * f_t$; f_t =the average of passengers the same day/general average of passengers in some year; Y is the daily average the year before predicted year; f_t is the seasonal index or coefficient.

According to the data, 2011～2014 passengers of the Spring Festival transport of Nanchang Railway Station is shown in table 1 as follows:

Table 1 2011～2014 passengers of Nanchang Railway Station during the Spring Festival

year	2011	2012	2013	2014
Passengers （10 thousand person）	294	282.8	283	325

2010～2013 annual average daily passengers of Nanchang Railway Station:

Table 2 2010～2013 annual average daily passengers of Nanchang Railway Station

year	2010	2011	2012	2013
Annual average daily passengers (person)	50986	48328	54187	53916

Using model: $Y = (50986 + 48328 + 54187 + 53916) \div 4 = 51854.25$ *(person)*

$f_{t_1} = 294/50986$; $f_{t_2} = 282.8/48328$; $f_{t_3} = 283/54187$; $f_{t_4} = 325/53916$;

$f_t = (f_{t_1} + f_{t_2} + f_{t_3} + f_{t_4})/4 \approx 0.0057$

The predicted passengers of Nanchang Railway Station during the Spring Festival in 2015 are $Y_t = Y * f_t = 51854.25 \times 0.0057 \approx 295.57$ *(10 thousand person)*

5 Conclusions

Passenger organization is a very complex system engineering especially in the Spring Festival. This paper summarize the existing problems and provide direction for optimization of passenger organization and suggestions on organization work through the analysis of the passenger flow organization of large passenger station during the Spring Festival. In addition, it builds model to predict the passengers of Nanchang Railway Station during the Spring Festival so that can take response measures early.

Security Analysis about a Train Control Center Based on a Bayesian Network

Xiqiang Zhou[1] and Yadong Zhang[2]

[1]School of Information Science and Technology, Southwest Jiaotong University, Chengdu 611756, China. E-mail: 957016618@qq.com
[2]School of Information Science and Technology, Southwest Jiaotong University, Chengdu 611756, China. E-mail: ydzhang@home.swjtu.edu.cn

Abstract: In this paper, by the study of the train control center, we will build a Bayesian networks model on the train control center in GeNIe, then we can use Bayesian networks structure learning algorithm combined with the corresponding original network optimization[1]; at the same time based on multiple fuzzy expert root node evaluation prior probability of Bayesian networks analysis algorithms we can get the root of its initial probability distribution, and through parameter learning of the Bayesian networks we can do quantitative safety analysis on the train control center. By the safety analysis model of the train control center based on Bayesian networks we can not only appropriate security risk quantification calculations train control center, but so analysis and diagnose the main factors which lead to different consequences and posterior probabilities.
Keywords: The train control center; Bayesian networks; Safety analysis.

1 Introduction

Train Control Center as a core part of the ground train control system directly affect the safety and reliability of high-speed train safety, therefore it is necessary to do further signaling system safety analysis, risk management and control of train control center in-depth study of great significance. Conduct research and analysis of security theory train control centers, research hazard identification technology train control center, train control center risk management and control technology research, to guide China's railway signaling system safety assessment is important.

2 Bayesian network's infrastructure

Bayesian network is a probabilistic network, which is based on probabilistic inference of graphical network, and Bayesian formula is the basis of the probability of the network. Bayesian network is a mathematical model based on probabilistic reasoning, it is to address the uncertainty and incompleteness issues raised, it has a great advantage on causes uncertainty and relevance to solving complex equipment the fault, is widely used in many fields.

BN is represented as a directed acyclic graph G = (V, E,θ), where a set of nodes $V = \{x_1, x_2, \cdots, x_n\}$ represent variables, there are set to edge E represents a direct dependency between variables, model parameter θ represents the conditional probability of each state of nodes, that each node $x_i \in X$ has a conditional distribution $(x_i|Pa(x_i))$, $Pa(x_i)$ represents the set of variables x_i in the parent node, thus, the joint probability distribution can be expressed as

$$P(x_1, x_2, ..., x_n) = \prod_{i=1}^{n} P(x_i \mid Pa(x_i)) \quad (1)$$

3 Analysis and modeling of train control center

Train control center is a huge and complex security systems engineering, therefore it is important to clarify the relationship between the central train control systems division level. This chapter describes overall the train control system from the system components, different angles functional level, the implementation process and the status of the transfer. This article focuses on the detailed modeling and analysis from a functional point of Train Control Center.

3.1 Train Control Center Architecture Reference Model

According to the technical specifications train control center and the interface diagram of the train control center combined with other devices, we can describe the static composition intuitive control center column system and its boundaries. The figure below shows the structure of the reference model train control center, as shown in Figure 1

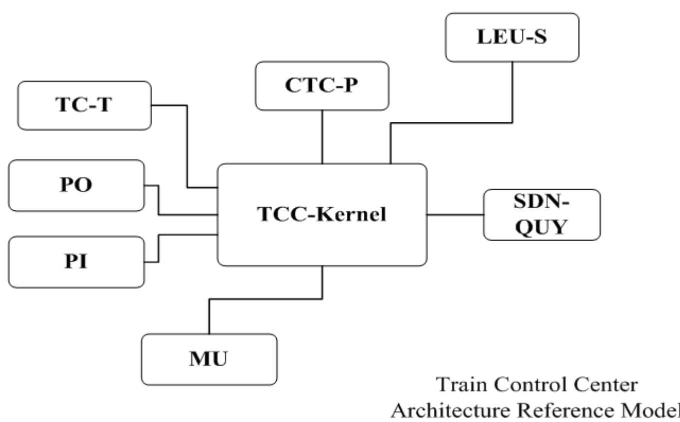

Figure 1.Train Control Center Architecture Reference Model

3.2 Train Control Center features layered model

According to the thoughts of constructing a hierarchical model, and referring to "train control center technical specifications", We can build a hierarchical model of functional architecture reference model train control center of each component unit, and have a detailed description of the function of each unit. Table 1 shows part of the train control center features a layered model

Table 1.Control center TCC-Kernel subsystem features layered model

Code	Functions	Sub-code	Sub-functions
TCCK-4	Track circuits coding	TCCK-4-1	Station track circuit coding
		TCCK-4-2	Interval track circuit coding
		TCCK-4-3	No wiring station track circuits coding
TCCK-5	Track circuit transmit code direction control	TCCK-5-1	Station track circuit transmit code direction control
		TCCK-5-2	Interval track circuit transmit code direction control

3.3 State transition model of train control center

According to Train Control Center Architecture Reference Model, and referring to "train control center technical specifications" of the state of the train control center for analysis and sorting, we can define system shutdown, offline, start the self-test, the communication is established, communication failures, initialization, initialization exception handling, running, trouble-free operation status transfer between processes and conditions

3.4 Sequence diagram model of train control center

Binding function hierarchical model we can conduct a detailed analysis and study of the implementation process state transition model for each state function. Figure 2 shows the station track circuit coding sequence diagram model.

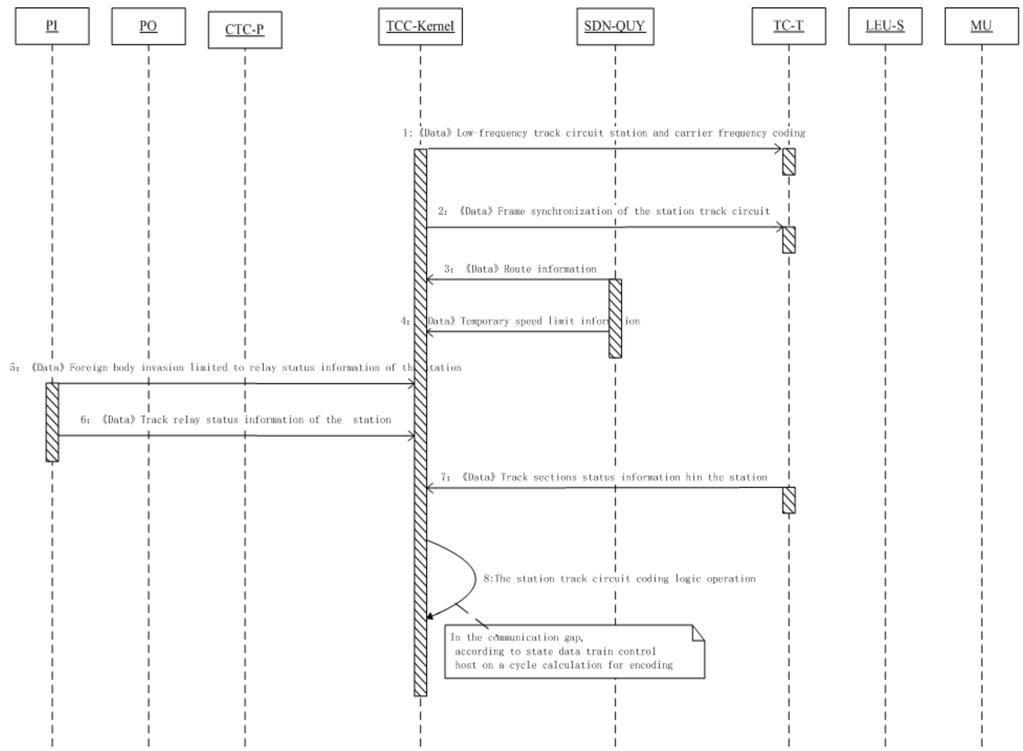

Figure 2. the station track circuit coding sequence diagram model

4 Bayesian network construction and analysis

4.1 Bayesian network building

In fully Bayesian network learning and research, combined with the above for the train control center analysis and modeling, we can build a Bayesian network model about the train control center on the track circuit coding function, and it can be detailed safety analysis. Bayesian network structure is shown in Figure 3.

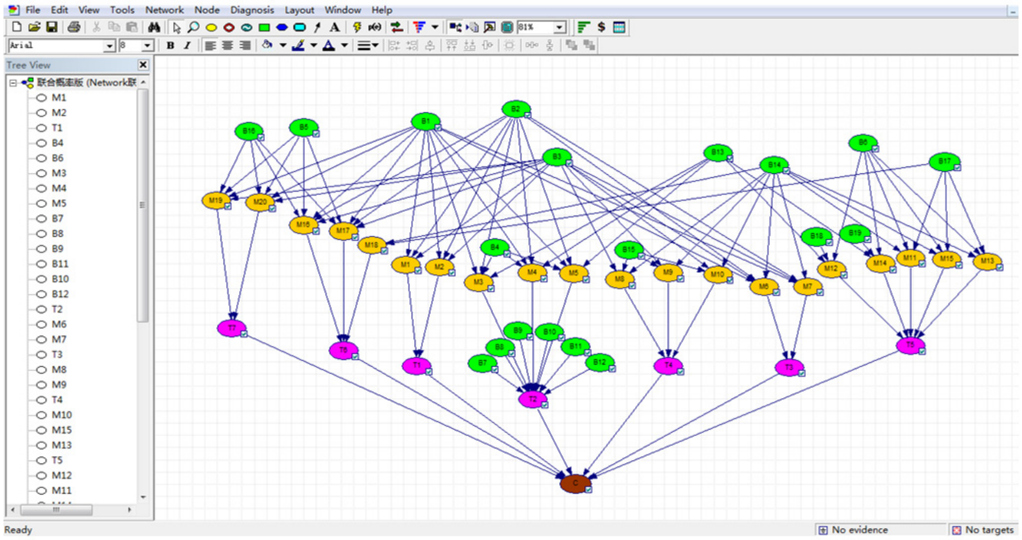

Figure 3.track circuit coding function model based on Bayesian network model

The determining of the Bayesian network model parameters

(1) Non-root conditional probability

Combined with expert opinion, we can determine the conditional probability distribution of nodes based on the logical relationship of each node in the model. For example, the node T6's conditional probability table:

Table 2. the node T6's conditional probability

M16	NORMAL	NORMAL	NORMAL	NORMAL	FOULT	FOULT	FOULT	FOULT
M17	NORMAL	NORMAL	NORMAL	NORMAL	FOULT	FOULT	FOULT	FOULT
M18	NORMAL	NORMAL	NORMAL	NORMAL	FOULT	FOULT	FOULT	FOULT
T6	NORMAL	FOULT	FOULT	FOULT	FOULT	FOULT	FOULT	FOULT

(2) Priori probability of the root node

Because of the high-speed railway development time is short, the statistical data related to the train control system is less and difficult to obtain, we can't be directly determined a priori probability of the root node. In terms of the prior probability of the root, it will be built on the experience and judgment of experts to determine.

We defined incident frequency of 10 levels, and give its value and description .Due to the level of language to describe fuzzy uncertainty, we according to the definition of fuzzy sets and fuzzy Numbers, define its corresponding failure probability and fuzzy number, based on the frequency distribution. Experts judge the frequency of the root node and give its language value, then according to the definition of fuzzy numbers it is translated into the corresponding fuzzy numbers and determined the λ- cut set. The results in the following table .

Table 3. Root node B1 expert judgment data

expert	Frequency of judgment	Failure probability of fuzzy numbers	λ- cut set
1	Seldom	$(6.27\times10^{-8}, 6.27\times10^{-7}, 6.27\times10^{-6})$	$[5.643\times10^{-7}\lambda+6.27\times10^{-8}, 6.27\times10^{-6}-5.643\times10^{-6}\lambda]$
2	Minimum	$(6.27\times10^{-9}, 6.27\times10^{-8}, 6.27\times10^{-7})$	$[5.643\times10^{-8}\lambda+6.27\times10^{-9}, 6.27\times10^{-7}-5.643\times10^{-7}\lambda]$
3	Seldom	$(6.27\times10^{-8}, 6.27\times10^{-7}, 6.27\times10^{-6})$	$[5.643\times10^{-7}\lambda+6.27\times10^{-8}, 6.27\times10^{-6}-5.643\times10^{-6}\lambda]$
4	Rare	$(6.27\times10^{-10}, 6.27\times10^{-9}, 6.27\times10^{-8})$	$[5.643\times10^{-9}\lambda+6.27\times10^{-10}, 6.27\times10^{-8}-5.643\times10^{-8}\lambda]$
5	Minimum	$(6.27\times10^{-9}, 6.27\times10^{-8}, 6.27\times10^{-7})$	$[5.643\times10^{-8}\lambda+6.27\times10^{-9}, 6.27\times10^{-7}-5.643\times10^{-7}\lambda]$

Then use the following formula to collect the expert evaluation data.

$$(\tilde{f}_j)_\lambda = \frac{1}{n}\sum_{i=1,2\cdots,n}(\tilde{f}_{ij})_\lambda \quad (2)$$

According to the following formula

$$I(\tilde{f}_j) = (1-\varepsilon)I_R(\tilde{f}_j) + \varepsilon I_L(\tilde{f}_j) \quad (3)$$

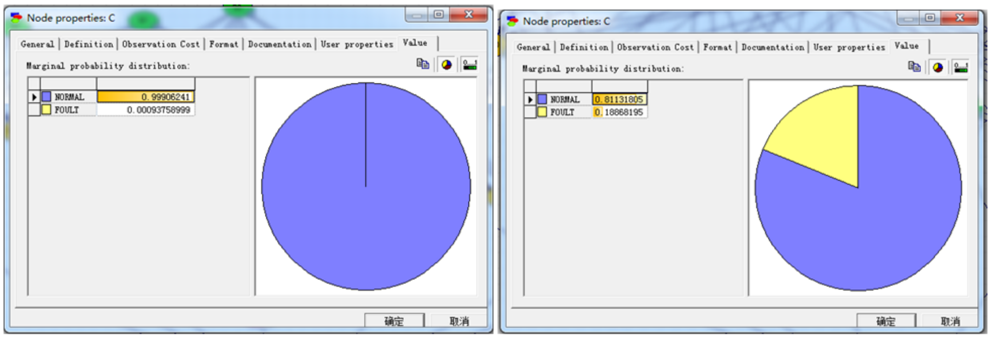
$$I_R(\tilde{f}_j) = |\frac{1}{2}\sum_{\lambda=0.1}^{1}(\tilde{f}_j)_\lambda^R \Delta\lambda + \sum_{\lambda=0}^{0.91}(\tilde{f}_j)_\lambda^R \Delta\lambda| \quad (4)$$

$$I_L(\tilde{f}_j) = |\frac{1}{2}\sum_{\lambda=0.1}^{1}(\tilde{f}_j)_\lambda^L \Delta\lambda + \sum_{\lambda=0}^{0.91}(\tilde{f}_j)_\lambda^L \Delta\lambda| \quad (5)$$

Using the integral method to blur, it is concluded that the root node of the prior probability. Finally the prior probability of B1 is 8.723×10^{-5}, when $\varepsilon = 0.5$.

4.2 Bayesian networks inference

Bayesian networks have two-way reasoning ability. Forecast analysis is as known reason push conclusion reasoning, is a kind of reasoning from the top down. When making causal inference, we can calculate the probability of any node occurs through between the conditional probability distribution of each node. We can use the GeNIe software based on the clustering algorithm in top-down causal analysis. Get track circuit functions of normal and fault probability under the given conditions. The figure below shows the results of Figure node C and non-root node in the probability conditional probability given root node.



In the case of B nodes normal, the probability of node C

In the case of B3 node failure, the probability of node C

Figure 4. Forecast analysis results in Fig.

Diagnostic analysis, also known as the diagnostic reasoning, is known to seek the reasons for the conclusions of reasoning, is a bottom-up reasoning. When making diagnosis reasoning when making diagnosis reasoning, Given the corresponding node observations (evidence of a node), We can learn that the probability of the cause of the result and reason.

The table is about the possibility of sorting class B and class T node failure, when C is under fault conditions

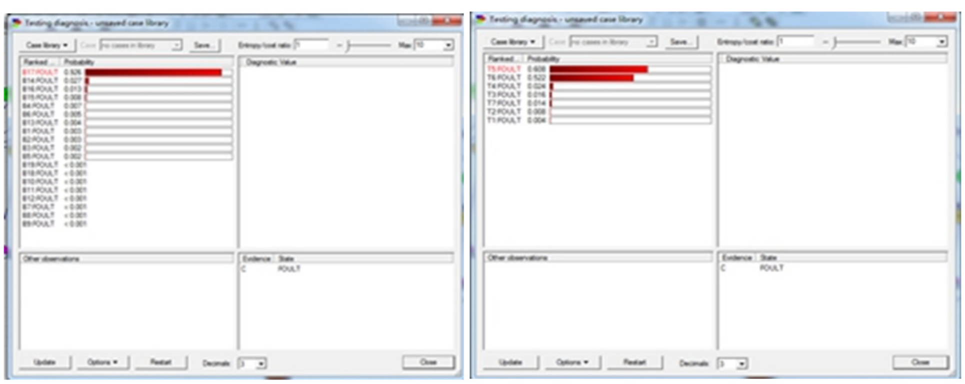


Figure 5. Diagnostic analysis results

When analyzing the chart we can conclude each intermediate node and the root of the failure probability while C fails. According that we can find and analyze the cause of the fault, and provide support for accurately and rapidly determine the cause of the accident!

5 Conclusions

High speed railway in our country this year has been rapid development, which put forward higher request to us. In this paper, on the basis of to learn the train control center, we can do hierarchical analysis model of the train control center, then use Bayesian network technology to build models in view of the train control center of a function, make full use of Bayesian network's uncertainty knowledge expression and the uncertainty reasoning ability, to deal with complex huge logical relationship and carry on the reasonable forecast and diagnostic analysis system.

Abstract: robustness is one of the key requests for train timetable. Generally, the train is determined to operate according to the given time on timetable, but in practical cases, however, the ideal timetable calls for a robust time that capable of absorbing, as much as possible, delays or disturbances on daily operation. Which reflected on train timetable formation is add extra time beyond the given section running time and station stop time. Spontaneously, there are two main sections for each train path to add this extra robust time: operating period between station and station stay period. This paper mainly studied the two different strategies` characteristics, and researched the effect of train timetable structure under same extra time add which the extra time is added on section and stop period, and pointed train timetable extra time limitation factors under different strategies, discussed the two strategies advantages and disadvantages.
Keywords: Train time table; Time table robustness; Extra time; Timetable structure.

1 Introduction

Train diagram is the core file for railway transport organization, it determines each train`s arrive and departure time of the track sector. However, train operation is open to the environment and could be affected by numerous of influences. Usually those influences will force the train to delay or early compared with the supposed time determined by train diagram, thus the train diagram should has the ability to absorb those influences in order to make the train operation safety and punctually. Salido (2008) presented the robustness problem from the point of view of railway operators an. D`Ariano (2007) adopted a detailed alternative graph model for the train dispatching problem, and solve the conflicts between different trains. Zwaneveld (1996) considered the problem of routing trains through railway stations and built a bi-level model to solve the problem then evaluated it. Vansteenwegen (2006) calculated the ideal buffer time according to the arriving train late and different kinds of passengers` time consummation, then designed a linear programing to improve the service level of the railway net. Those researches focus on the railway operation mentioned that the buffer time is very importation for train punctuality and the stableness of train diagram. However, many researches put the buffer time in the track sector and use the settled buffer time to absorb the disturbances the train received. These propose is practicable when the disturbance is little and the number of train operated in the track sector is not very much. While the train stop time could be used as buffer time as well, but few researched on the buffer time set during train stop time. This paper analyzed the buffer time set strategy and compared the buffer time influence on train diagram. The construction of this paper is as follows: in sector 2, the principle of ideal running time and buffer time is given. In sector 3, the buffer time set in track sector is analyzed. In sector 4, the buffer time set in station is analyzed. In sector 5, the two buffer time set strategy is compared and in sector 6, a conclusion is given.

2 Train Ideal Running Time and Buffer Time

Train`s operating speed is limited by the track speed limited, locomotive speed limited and vehicle speed limited. The ideal running time is the time that a train will take according to the distance of the track sector and the train operating speed. It is the smallest possible running time for the arriving train, from its previous station to the connection station. However, the train operating circumstances varies a lot and it is almost impossible for the train to operating at the top speed limit all along. So a buffer time is determined in order to assure the train will arrive on time influenced by all kinds of disturbances. The buffer time setting is shown in Fig.1

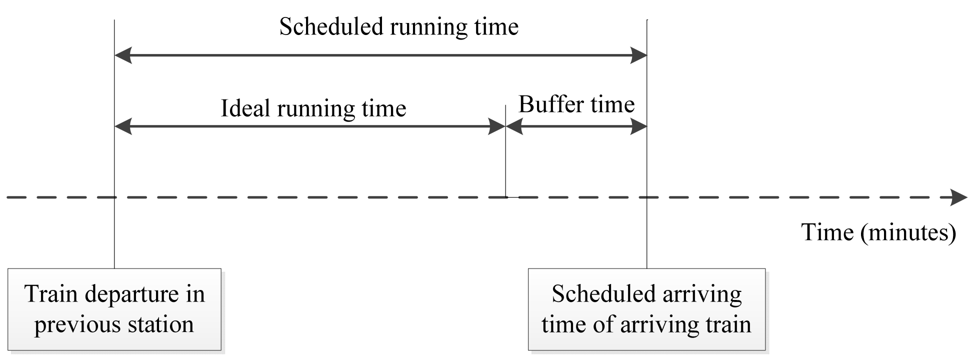

Fig.1 Buffer time setting

The buffer time is very important for train operating, since the trains` operating in the rail could be affected by many uncontrollable influences, it is impossible for the train driver and dispatcher to organize the train according to the set time strictly. The buffer time could allow the train operating deviate from the schedule in tolerance interval.

A train line will pass many track sectors and stations. Accordingly, the buffer time could be set on track sector or on station stop time. The different buffer time set strategy could have different features and affect the train diagram construction differently.

3 Buffer Time Set in Track Sector

If we set the buffer time on tract sector, the scheduled running time during the track sector is added by the buffer time, this make the schedule running time longer than the ideal running time and will cause the sector capacity waste. The buffer time set on track sector is shown in Fig.2.

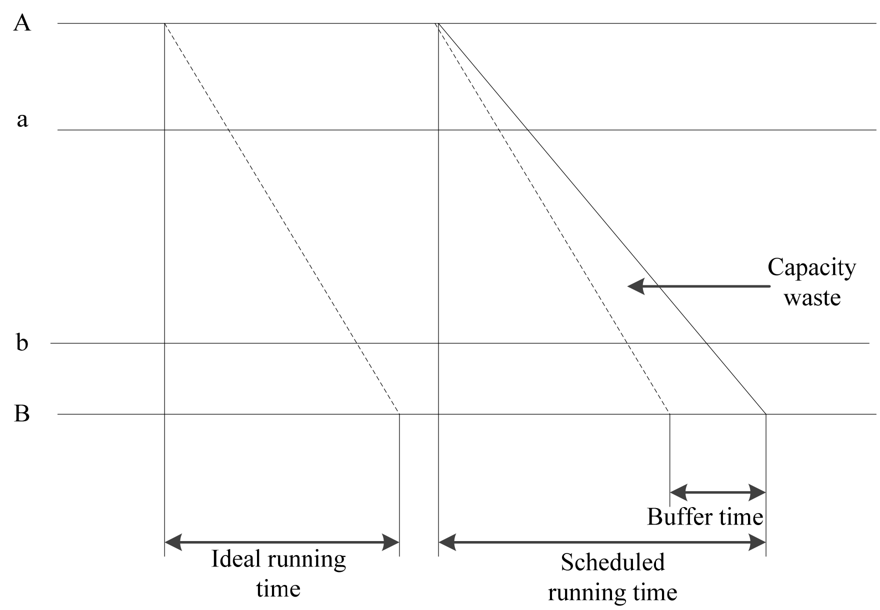

Fig.2 Buffer time set in track sector

From Fig.2 we can see, because of the buffer time set in track sector, the train scheduled running time was prolonged. This prolonged time could be used to absorb the disturbances the train suffered during operating. But however, this extra time period also occupied some track operating time available for the trains. This will cause the capacity waste, especially if the buffer time was set too much for each train in a density track sector, the capacity waste will be remarkable.

4 Buffer Time Set in Station

If we set the buffer time in station, the stop time in station will be prolonged and provide the buffer time to make sure the train will departure on time, this will make the train stop time longer than schedule and might cause the arrive late of the train. The buffer time set in station sector is shown in Fig.3.

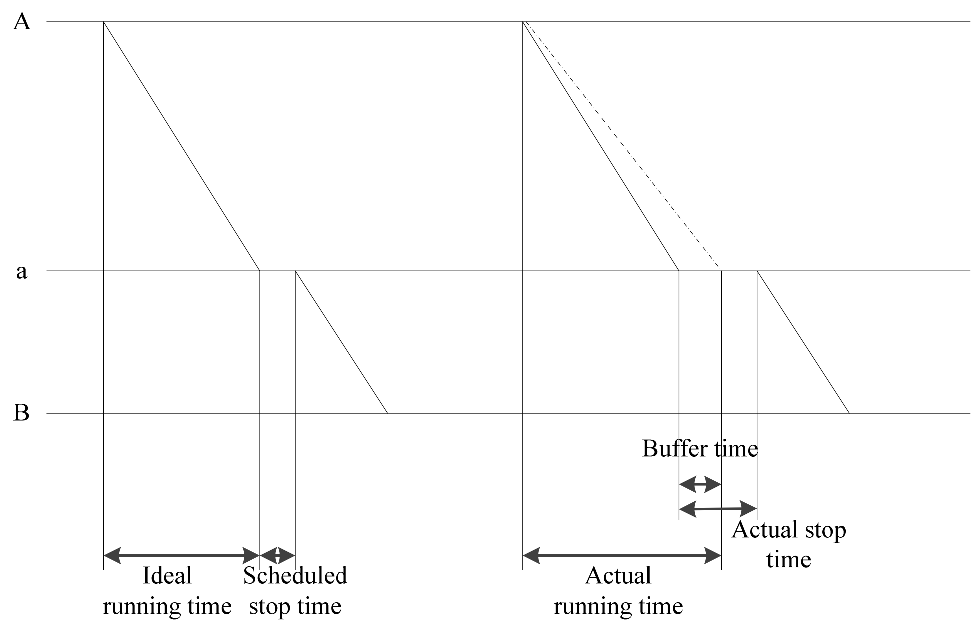

Fig.3 Buffer Time Set in Station

From Fig.3 we can see, because the train running time between the stations is set as the ideal running time, once the train operating is disturbed, the train will arrive at station later than the scheduled time. As the buffer time set in station, the disturbances will be absorbed during the train stop time in station and make sure the train will departure on time. In this situation, the buffer time could cause arrive late of the train or extra stop time for the train.

5 Strategy Compare of Buffer Time Set

According to the analyze in sector 3 and sector 4, we can find that the two buffer time set strategies has different influences on train diagram and both has advantages and disadvantages.

The buffer time set in track sector makes the train path more independent from each other, which means once the one train`s operating schedule is disturbed, the following train path will not be affected, especially for the train diagram density is high. This could make sure the train diagram has a strong robustness and make sure the train could arrive on time during certain disturbances. But the buffer time set in track sector will take some operating time available in the sector, this may cause the track capacity lost.

The buffer time set in station allows the track capacity to be fully utilized by drawing more train paths. And as the stop time is prolonged, the train may benefit it by a high possibility to departure on time, especially for some extreme busy sector where not allow too many buffer time set in track sector. But in this strategy, the train`s arrive punctuality might be effected as the buffer time set during train stop.

There are also other differences for the two strategies on train operating complexity. If we set the buffer time in track sector, the operating speed of each train is differ from each other, this requires a higher driving skill and dispatching management for the train operation; while if we set the buffer time in station, it is possibly each train could operating with the same speed, and the dispatching work force will decrease, this may benefit for the auto-control of train.

The compare of different aspects for the two strategies is shown in table.1.

Table 1. Compare of the two strategies

Buffer time set location	Track sector	station
Restrict feature	Sector capacity	Station line capacity
Drive complexity	high	low
Dispatch complexity	high	low
Range if a train delayed	narrow	wide

From the compare we can see:

1. The track sector buffer time set strategy has a better punctual affection than station set strategy. Precisely, if the track sector capacity is highly utilized, once train delayed, the track sector buffer time set has a narrow affect range; this makes the train diagram more robust.

2. The station buffer time set strategy has a lower complexity on driving and dispatch work. This makes it easier for the application of auto-drive and automatic train operation. However, this strategy may cause wildly arrive late once the train operation is disturbed, also, if the train density is high, the influences between train might cause large effect range once one train is delayed.

Thus, the buffer time set should consider the train density, track sector capacity, station line capacity and drivers` and dispatchers` work skill, set the appropriate buffer time both in track sector and station. The ratio of the buffer time set will be studied in the future work.

Abstract: Recent years, in order to improve the quality of freight transportation, railway transport enterprise has done a lot of research on optimization of freight train working plan on thought of customer first. And it makes a great effect on improving the competitiveness of freight transportation. At first, this paper analyzes the current situation of direct freight train plan. Then, it points out some current drawbacks of direct freight train working plan and emphasizes the importance of logistics costs in freight marketing. At last, it discusses the optimization of direct freight train working plan in loading place on logistics cost and builds the structure of costs in the system.
Keywords: Direct freight train; Logistics cost; Restrictive relationships; Car flow organization.

1 The Current Situation of Freight Train Plan

Strong social demand, stable and concentrated flow of goods and maturing freight network provide support and ensurement for the direct transport of coal, even the whole bulk cargo. Simultaneously, heavy tasks have put forward higher requirements upon rail transport organization. In order to alleviate contradictions between growing demand and capacity tense of freight transport, with expansion of railway station at the same time, the effective approach is to improve the technical equipment and the existing transport organization further and organize direct transport in loading space rationally so that car flow can pass these tight-capacity marshallings without adaptation. And it is an important way of railway transportation of bulk cargo in our country at the present stage.

2 Drawbacks of Freight Train Plan

Reform on freight transport shows the change from commitment of single railway transportation to the entire process of logistics services. Transportation is an important part of logistics and total logistics is now the freight transport social market needs. Nowadays, on one hand, various transport modes are all actively adapt to the demand of social development, on the other hand, development of freight business processes in this area is relatively inadequate.

2.1 Complicated acceptance business

Time and expense customers consume on several formalities in the handling department of freight and yards can be calculated based on traditional freight handling process. Therefore, optimization and new service system should be pulled in so as to improve the quality and efficiency of accepting service.

2.2 Long residence time in the station

According to statistics, freight train spend 70 percentage of travel time on staying in station. On the way, there is no fixed time point and a great complexity in production process. And this leads to time wasting and low efficiency.

2.3 Complexity of delivery procedures

From the freight delivery business processes you can see that process of goods delivery contacts a number of departments, so transfer of information and data needs different people from different departments. Due to the time of arrival can't be confirmed, consignees are not allowed to receive the goods until get notification from station. However, there are a great number of delivery procedures before receiving the goods in many departments.

3 Logistics of Rail Freight Transport Organization

As rail transport market is deepening with each passing day, direct transportation organization service should be enhanced in continued competitive environment. On the other hand, the rapid development of information technology make information resources have greater openness and create a new railway transport organizational environment. Original boundaries between related enterprises have been broken and enterprises have built a win-win partnership instead of working alone. So, considering interests of shipper, consignee and transportation enterprise, rail transit organization plan must proceed from market multi-demand. Only in this way, transportation cost will reduce, customer satisfaction will improve and comprehensive optimization will be done.

3.1 Thought of the logistics system

As a form of system, logistics system has all the features of the system. It is the environment flow of goods and transport organization rely and dominant factor of transportation organization optimization. The system is consisted of interconnected and interacting organism with the overall function. So, logistics system is also consisted of interest groups and they are organically combined rather than accumulated simply. Additionally, there may be mutual restraint or other kinds of relationships between stakeholders. However, all these stakeholders are in same system. Each of them will obey the whole and pursue the overall goal instead of seeking the best interest of one stakeholder

3.2 Internal relationship of logistics system

Logistics system consists of a variety of stakeholders and there are restrictive relationships among different stakeholder. It means there is a contradiction between win and loss of active interest entities logistics system. That is to say optimization of one stakeholder may lead to a loss of interest of another one. And it is the relationship of shifting that exists commonly among stakeholders in logistics system.

① Restrictive relationships between level of service and logistics costs

Improvement of service-level always accompanies increase of logistics costs, and this phenomenon may cause game of stakeholder interest. For example, in order to reduce inventory and use freight system of small quantities, delivery times and transportation costs will increase greatly.

② Restrictive relationships among sectors of logistics

Goods will go through many sectors which are connected closely in moving process. The entire system will not work normally unless there is not a problem on each sector.

③ Restrictive relationships among different functional subsystems of service capabilities

If capacity of each subsystem does not match with each other, overall capacity of the logistics system will be affected. For example, strong handling capacity with low transportation force will bring waste of equipment and manpower.

④ Restrictive relationships among different functional subsystems of logistics costs

For example, to reduce the cost of inventory, small orders will be taken, but it increases transportation times, even costs of transport subsystem.

3.3 Connection with railway system and logistics system

According to restrictive relationships in logistics system, any unilateral approach would undermine the other parts of system more and is not conducive to achieving overall system goal. This theory can apply on transportation problem as well.

Market competition bring more opportunities and challenges to transport companies. In the competition, owners are looking for a more convenient, cost-effective mode of transport to reduce cost. This means that transportation companies should reallocate supply. On one hand, transport companies which are able to provide higher level service will get more supply, on the other hand, transport companies which are not able to meet the requirements will result in loss of supply. Transport companies and shippers must be closely linked together to achieve mutual benefit in this environment.

With reform of the railway transport system, transport organization research considering multi-stakeholder from perspective of logistics system have emerged. Rail transport systems belong to the logistics system as well. As possessing the characteristics of the logistics system, car flow organization can not get rid of the interests of stakeholders and exist in isolation. Therefore, it is necessary and feasible to optimize direct train organization in loading space by thought of connection with railway system and logistics system.

4 Optimization for Freight Train Plan on Logistics Cost

As important part of direct rail transport organization, direct freight train organization in the loading place show its inherent advantages gradually with increase of market demand and rapid improvement of hardware and software technology in rail transport systems. Direct freight train organization in the loading place is no longer unilateral thing for transport enterprises but related to interests of shippers and receivers. At Present, there are potential defects in optimization problems from only considering the interests of the railway transport enterprises. Such as it can not adapt to the market's high demand for transport or does not do good to improve competitiveness of rail transport. Thus, based on the entire logistics system, organizational problems should be optimized by considering various interests and targeting the total cost of the system.

4.1 Division of interests entities in car flow organization

In the logistics system, from loading space to unloading space, goods will undergo three sectors in direct transport mode, shipping sector, accepting sector and receiving sector. Each sector will involve its interests of stakeholders. In addition, as deepening and competition of the market economy, interest conditionality among three sectors has become closer. So, we divide interest entities associated with direct train organizational problems into three parts according to circulation of goods in logistics system and restrictive relationships in railway transport market, and they are shippers, transport companies and consignees respectively. Circulation of freight and division of interests entities are shown in Figure 1.

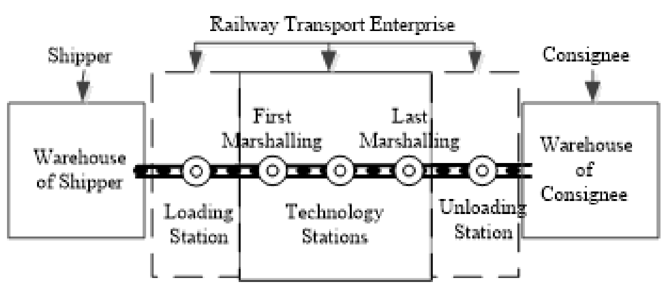

Figure 1. Related parts in the transportation process in logistics system

Based on Figure 1, we can make structure of optimization goal clear under logistics system. It consists of sub-goal of shipper, sub-goal of railway transport enterprise and sub-goal of consignee. Each sub-goal has its own typical interest elements. Restrictive relationships exist among various sub-goals and are shown as conflicts and discords among representing interest elements.

4.2 Mutual restrictive relationships among entities of different interests

Mutual relationships among costs of different interest entities are concrete embodiment of mutual relationships among interests of different entities. No matter inventory cost of shipper and consignee or organizational cost of transport railway transport enterprises is function of single transport order. However, single transport order is determined by organization of car flow. So, mutual interacting restrictive relationships exist in different interest entities because of influence of traffic organization. Inventory cost will increase with increasing single transport order. On the contrary, cost of transport organization have rendered opposite trend with increasing single transport order. With changes in quantity of transportation, trend curves of inventory cost, transportation cost and sum of them are shown in Figure 2.

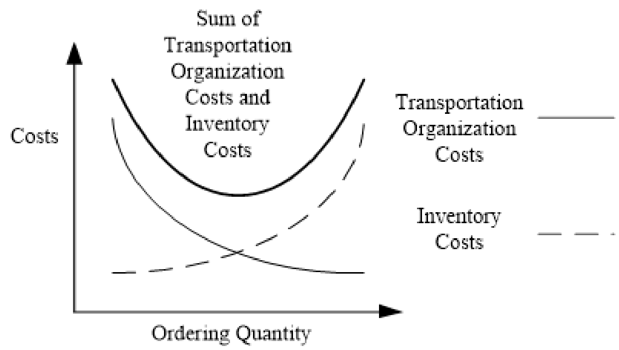

Figure 2.Changing trend of inventory and transport cost with ordering quantity

Minimum total cost point of system is neither on point of minimum transportation cost nor point of minimum inventory cost. There is an important phenomenon of "Interest Swap" in transportation and inventory. Reducing cost of any part unilaterally will pay the price of increasing cost of another. In a word, seeking optimization of integrated interest between transportation cost and inventory cost is optimization objective of car flow organization issue in loading space under logistics system.

4.3 Constitution of logistics costs for direct freight train in loading place

When it comes to optimization of car flow organization in loading space under logistics system, decision makers of transportation organization should break through the narrow thought of seeking interests only for its own but establish an idea for interest of the whole system. So that, it can optimize transportation organization of direct train in loading space and realize our dream of making cost of the whole system the lowest. Summarizing contents of each part above, structure of costs in the system is established as follow in Figure 3.

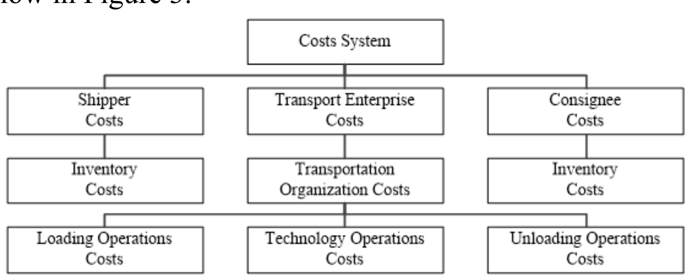

Figure 3. Structure of costs in the system

The figure of structure shows factors which constitute the cost of transportation organization. It is the transition of analysis from qualitative to quantitative, also, the basis of establishing cost function model. Based on the figure, considering all factors such as costs of transportation organization and inventory costs, cost function targeting the lowest cost of system can be set up. We can acquire optimization of freight train plan by analyzing and solving this cost function model.

5 Conclusion

Modern logistics break through the concept that transport capacity is the most important, and put the idea of customer first forward. Considering interests of customers, it seeks optimization of the production and organization under the whole system instead of railway system only. Furthermore, it makes costs of transportation service associated with other costs organically come true. According to this theory, in order to lay the foundation of transition from qualitative analysis to quantitative analysis, this paper focuses on restrictive relationships among different factors and establishing the structure of costs in whole system.

Analysis of the Demand and Supply of Regular Buses

Weidan Liu and Weixiong Zha

Institute of Transportation and Economics, Humanities and Social Sciences Research Base of Jiangxi Province, East China Jiaotong University, Nanchang 330013, China.

Abstract: Basing on the mechanism of supply and demand in bus-market and starting from its actual situation, we make an analysis according to survey data of 211. The analysis mainly includes two parts. Firstly, by analyzing index such as section volume, characteristics of passenger traffic on different times, traffic distribution of kernel density estimation, we know the demand situation. Secondly, on supply side, we dissect the index of capacity, traffic volume and departure interval. At the end, considering profit between bus-company and passengers, a departure interval optimization model can be established. Through this model, rationality and innovative of data analysis be verified and some suggestions can be put forward, thus achieve the purpose of equilibrium.

Keywords: Bus market; Demand; Supply; Departure interval.

1 Introduction

Regular-bus is one of main mode transportation in city public transports. It is the most used public transit for people and responsible for most travel demand. Imbalance contradiction between supply and demand is becoming prominently under high speed process of urbanization and motorization, causing quality of bus service and passenger satisfaction are low. Researches about balance mechanism of supply and demand is important for development of public traffic and residents travel (Wang, 2014).There are a lot of research about supply and demand in transportation, focusing on relationship of supply and demand and equilibrium problems in transport system network (Li,2010; Li, 2007), lacking case study and deep research in single bus line. In this paper, we will analyze survey data of Nanchang 211 bus referred to 211 bus as following and study its demand and supply situation.

2 Bus supply and demand mechanism

2.1 Research of bus supply mechanism

Transport supply is the number of variety transportation products that producers willing and able to provide at a time and in a variety of possible price levels (Wei, 2010). In bus supply analysis, we use "S" to represent supply level:

$$S=J(A_0,Q) \tag{1}$$

Where S is level of bus supply, J is supply function and A_0 is specific social environment.

Studies show departure frequency is an important indicator in bus supply. The smaller grid, the less waiting time, lower congestion and higher passenger comfort.

2.2 Research of bus demand mechanism

Transportation demand is a need for the ability to pay about displacement of people and goods in space (Feng, 2010). When influencing factors such as economic development and traffic environment are given, demand is mainly decided by service level (maximum waiting time of passengers, ride comfort, etc.). The shorter waiting time and higher comfort required, the higher supply level required, or, lower. So in certain cases, bus demand can be showed: We use trips "Q" to represent bus demand:

$$Q = D(A_0, T, R) \tag{2}$$

Where D is demand function, T is maximum waiting time of passengers, A_0 is specific social environment of bus and R is ride comfort (Yang, 2002).

3 Analysis about the demand and supply of 211 bus in Nachang

3.1 Demand analysis

Only adapting demand characteristics, can bus companies improve their interests and serve better. So demand analysis is an important aspect to study balance.

3.1.1 Section volume

Section volume is an important indicator representing passenger demand. It is the number of passengers cross a section in a certain time and single direction, including up section volume and down section volume. By analyzing the existing data we can get passenger distribution of 211bus in Figure 1. Figure 1 shows, Passenger demand in whole line are large, maximum on up and down reach 9000, 7500 (per) respectively.

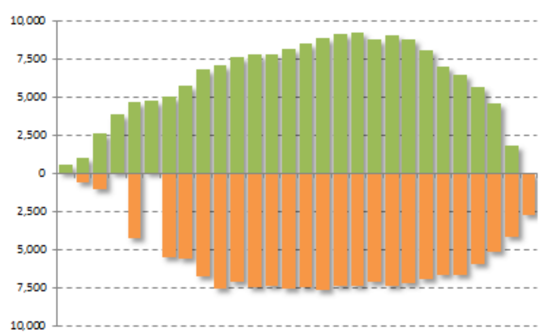

Figure1. Section volume on up and down of 211 bus

3.1.2 Traffic characteristic in different periods

To analyze differences of passenger demand, we divide 211-day times into three sessions: morning peak (7: 00-10: 00), flat peak (10: 00-15: 00) and night peak (15: 00-19: 00). In this paper, we use numbers of boarding index in unit time (1 hour) to analysis passenger traffic. Draw figure 2 of 211 bus boarding amount in unit time of each period by analyzing surveyed data.

Figure 2 shows, average boarding number is volatile, morning peak has the biggest number. Boundary of flat and night peak is obvious. Prior to Nantianyangguang boarding number in flat peak is more than night peak, after it night peak is higher. Charting trend is consistent with actual situation. 211 bus belongs to suburban lines, in morning peak residents go into urban working and learning. In night peak, residents have different needs and the flow shows one-way.

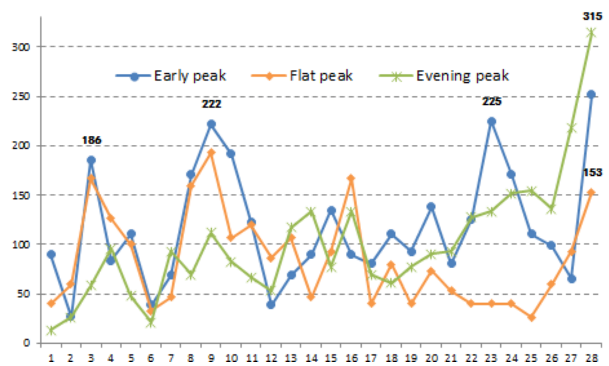

Figure2. Each section of passenger volume on per time of 211(p/hour)

3.1.3 Traffic characteristic in different periods

Kernel density estimation is a non-parametric method, which can use raw data to infer distribution curve, know value of probability density of each frequency in each site (Yang and Meng 2014). In this paper, we take passenger volume of each frequency in each site for a sample, chose Epanechnikov kernel function, use Eviews to estimate density curve of 211 bus.

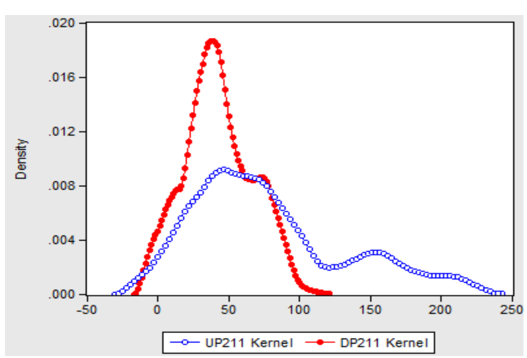

Figure3. Density curve of passenger volume on up and down about 211

Figure 3 shows density curve of up is right skewed and peaks at 50 people. It shows passengers number of a frequency at each site are mostly 50 people. Besides, the up ranges span, showing passenger demand in different frequency and site is unstable. Curve of down shows a narrow peak distribution, peaking at 25 people. It has smaller range span. Passengers demand of up is greater than down, value of probability density are all less than 0.1, showing large changes of passenger demand.

3.2 Supply analysis

3.2.1 Transport capacity analysis

Transport capacity is supply capacity of bus. In this paper, we represent it as product of rated capacity (76 passengers) multiply by actual departure times in all day. Based on surveyed data, we calculate 211 bus transport capacity and show in Table 1.

Table1. Transport capacity of 211 (persons)

Lines	Full day	Morning peak	Flat peak	Night peak
211	20267	5472	7600	7296

3.2.2 Other operating metrics of bus line

Other metrics include grid spacing, volume, non-equilibrium factor of section. By consulting bus companies, we know the departure frequency. Traffic volume is a sum of boarding numbers all day. Non-equilibrium factor of section is result of maximum section traffic divide average cross-section (one-way), which is suitable around 1.2.

Table2. Operation indicators of 211

operating metrics	Full day	Morning peak	Flat peak	Night peak
Grid spacing(min)	5.4	5	6	5
Traffic volume(person)	33168	9873	11967	11328
non-equilibrium factor of section	1.46	1.72	2.44	2.21

Table 2 shows: 211 bus has little change in grid spacing. Traffic volume is greater than transport capacity (33168>20267), indicating transport capacity is insufficient. Non-equilibrium factor of section of full-day is 1.46>1.2, which is appropriate. But flat and night peak are 2.44 and 2.21, indicating the two periods are overcrowding.

3.3 Comparative analysis of supply and demand

3.3.1 Cross-section saturation

Cross-section saturation is a ratio of actual flow to traffic capacity. That is the ratio of demand to supply. If this value is low, capacity is insufficient and supply is greater than necessary. Documentations show the ratio is suitable in scope of 0.5-0.7, by now the bus company can meet needs of residents and would not result in a waste.

Analyzing surveyed data, we can draw a graph of cross-section section saturation at all sites. Figure 4 shows saturation of 211 bus in all sites are high, part of have reached more than 0.75. It states this line is very crowded. In this case the comfortable and satisfaction of passenger is influenced badly.

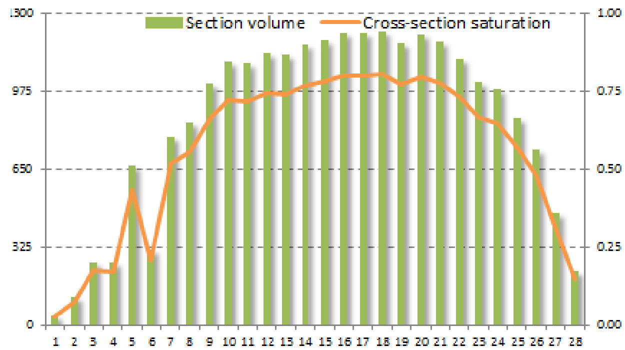

Figure4. The cross-section saturation of 211

3.3.2 Optimization model of departure interval

211 bus has the following characteristics: big passenger flows, high cross-section saturation, less supply, overcrowding and bad service. In order to achieve a balance and meet both passengers and bus companies, we must adjust supply amount. Multi-objective optimization mode can optimize grid spacing, draw a plan appropriate of departure, balance the interests of passengers and bus companies (Chen, 2014).

(1) Model assumptions

[1]Passenger traffic situation and section volume of up and down are known.

[2]Buses are the same, arrive and leave on time (Yu and Zhou 2004).

[3]Grid spacing are the same in one period.

[4]Unified fare in line.

(2) Variable definitions

l is amount of hours the line divided. $T_j(\min)$ is time span of j time bucket. n_j is departure times of j time bucket. $t_j(\min)$ is departure interval of j time bucket. m is number of sites in one-way across line. p_{kj} is passenger capacity throughput in k section of j time bucket. pu_{ij} is boarding number unit time in i site of j times bucket. pp is total traffic in all day. np is rated capacity of each vehicle. lr is minimum load factor. hr is maximum load factor. tr is load factor limitation accepted by passengers. mp_j is the maximum section volume of j time bucket. mt_j is the maximum grid spacing of j time bucket. ht_j is upper limit of waiting time accepted by passengers. c_1(yuan) is buses traveling expenses in one-way. c_2(yuan) is ticket price. bp is number of passengers complaining waiting, $bp=\sum_j\sum_i pu_{ij}$ if $t_j > ht_j$ bl is length of crowded road complained by passengers, $bl=\sum_k\sum_j p_{kj}$, if $p_{kj} > n_j * np * tr$. Among them i is the site, i=1,2⋯m. j is the time bucket of j, j=1,2⋯l.

(3) Model building

This paper selects three 3 goals: benefit cost ratio of enterprises, percentage of waiting complaint, percentage of crowded mileage. The model of optimization to grid frequency is as followed:

$$\min W=\min[-\lambda_1 *(c_2 * pp - c_1 * \sum_j n_j)/(c_1 * \sum_j n_j) * 100\% + \lambda_2 * bp / pp * 100\% + \lambda_3 * bl(\sum_k \sum_j p_{kj} * ml_k) * 100\%] \quad (3)$$

In order to ensure feasibility of the equation, we establish the following constraints:

① Average load factor is greater than minimum load factor: $\sum_{k-1}^{m-1} p_{kj} / n_j * np \ge lr$ (4)

② Passenger waiting time at the site does not exceed a certain time: $t_j \le mt_j$ (5)

③ There is no passengers stranded: $n_j * hr * np \le mp_j$ (6)

(4) Model solution

Calculation process focus on four major stations: Shuanggangdonglukou, East China Jiaotong University Institute of Technology, construction northbound and Changleng. The model simplify a scheduling problem of four sites, m=4. Full-day traffic volume in model use boarding passenger data in all day instead of four sites and the rest do not need to adjust (Yao and lv 2009). All parameter values are as follows: $T_j=[180\ 300\ 240]$, $np=76$, $lr=0.5$, $hr=1.2$, $tr=0.9$, $m_j=[5;\ 10;\ 6]$, $ht_j=[4;\ 8;\ 6]$, $c_1=120$, $c_2=1$, $\lambda_1=0.1$, $\lambda_1=0.5$, $\lambda_3=0.4$. Results shows in Table3.

Table3. Results of scheduling optimization

Line name	time bucket	Uplink		Downlink	
		Departure times	Grid spacing	Departure times	Grid spacing
211 bus	7:00-10:00	61(36)	2.9min(5.0)	47(36)	3.8min(5.0)
	10:00-15:00	55(50)	5.5min(6.0)	51(50)	5.9min(6.0)
	15:00-19:00	48(48)	5.0min(5.0)	56(48)	4.3min(5.0)

Remarks: Data in parentheses represent the actual departure times or grid spacing.

Model result agree with the previous conclusion. That is for different period we should implement different schedule to meet different passenger demand at each periods. So demand in different times has different size, we should implement unequal interval schedule in all day.

4 Conclusions

Based on demand and supply mechanism of bus market, this paper analysis the survey date of 211 bus, then make an analysis about the balance situation of this line. By analyzing, we know passenger demand are different at different times or different directions. On the supply side if you do not consider the difference in demand, it may lead to an imbalance between supply and demand. In order to achieve a balance, bus companies should be combined supply with demand, allocating resources rationally. Then meet the travel needs of residents.

Method of Making Trains Diagram with Computers

Cenfang Jing[1] and Tian Gao[2]

[1]School of Transportation and Logistics, Southwest Jiaotong University, Chengdu 610031, China.
[2]School of Transportation and Logistics, Southwest Jiaotong University, Chengdu 610031, China.

Abstract: With the development of economy and culture, Chinese railway met with great market shock. The train diagram plays a basic role in the preparation for the train working. For a long term, the train diagram in china was prepared manually, and it need many human and material resources. Fortunately, in recent years, the experts and the professionals in traffic and transportation area had taken the work for preparing the train diagram with computer, and the achievement is salient, for an example, the passenger train diagram of all the road net is in practice. The train diagram is introduced firstly in this paper. Then some theories about train diagram, including the base element, the types and the evaluating indexes, are analyzed in details. And on the basis of them, three methods for making train diagram are shown: The first is called time-and-space rolling method. It's a mature method, and it has been implemented; the second one is called generic algorithm. The implementation of coding, permutation and aberrance in train diagram algorithm is the emphasis; The third method makes use of Common KADS Methodology, mainly its planning module and schedule module for the original train diagram and its adjustment. At last, through the research on the method of making train diagram with computer, I will take some suggestions for the development strategy of making train diagram with computer.
Keywords: Train diagram; Optimization algorithm; Common KADS; Development strategy.

1 Introduction

In the production process of organizing the passenger and freight transport, train running is a very complex part, it is to use a variety of railway technology and equipment, and requiring coordination and cooperation among all departments, all types of work and the various jobs to ensure traffic safety and improve transport efficiency. Railway departments complete the process of complex operation and management mainly through train diagram of the preparation and execution to achieve. However, the preparation of train diagram is an extremely arduous, complex and painstaking work, totally dependent on artificial Train Graph. With the rapid development of computer technology, many experts and scholars have been actively exploring the use of computer Train Diagram methods and techniques.

The Train Diagram with computer generally began in the late fifties at abroad. The US GRS in 1958 has been prepared in a simulation program trains and the single track sections of 160 kilometers were tested. Britain in 1965 in not too long a single line automatic block sections by computer simulation test train. Japan in 1960 began to study the use of computer preparation train schedules, and in 1964 worked out practical value can train schedule. In addition, Germany, Belgium, Czechoslovakia, Romania and other countries also have conducted a study of Computerized Train Graph, to varying degrees, with some success and experience.

In China, in 1962, Academy of Railway Sciences and Institute of Transport and Economy began to study the use of non-parallel computer shop drawing a single line diagram, in 1980, the Harbin Railway Bureau used the method of mathematical models, and made the computer a trial cargo train diagram by a two-lane section. In 1991, the Department of Transportation of the Southwest Jiaotong University and the Jinan Railway Transportation developed a two-train diagram preparation computer system in co-operation. After entering the new century, the Transportation of Southwest Jiaotong University has developed the whole railway passenger train operations preparation system by its own research, and used in the fifth railway speed transfer map work, and basically reached a practical level, this is an event of China railway operation in the history.

2 The definition and characteristics of train diagram

2.1 Definitions

Train diagram is the train technical documents that is used to indicate that the train moving time in the section and the arrival or through time in the station, which sets out the program of various train occupied sections, the arrival and departure (or through) time of the train arrived station, the train in the interval running time, the time of the train stops at the station and locomotive routing, etc. Therefore, it is the basis for the organization of railway traffic .

Train diagram provides a coordinated use of railway lines, stations, locomotives, vehicles and other equipment, the production process of railway transportation will strictly enforce the provisions of the program diagram (required by the road map), therefore, the train diagram is a comprehensive plan of production process of the railway transportation, it has a very important significance to ensure the safety of the railway, improve transport efficiency and improve the use of technical equipment and speed railway rolling stock turnover. In addition, the train diagram is an effective form that rail transport companies provide transportation capacity to the community. In this sense, the railway passenger train timetables for social and "Five fix" freight trains running program is the catalog of rail transport services in fact. Therefore, train diagram is a comprehensive plan of railway transportation production and product supply, and it is the link between production and rail transport links production factories and social life.

2.2 features

According to the definition of train diagram, the characteristics as following:

1) Train diagram is a graphical representation use the principle of the coordinates to the relationships of train running time and spatial, therefore, it is actually operation to the process of space-time. On the train diagram, the process of train operation diagram temporal can have two different forms. One is in the horizontal axis represents time and the vertical axis represents the distance, then the train diagram horizontal line indicates the centerline of the station, the spacing between the horizontal line represents the distance between the station, the vertical line indicates the time, which is currently used by China Railway representation. The other is the distance in the abscissa, the ordinate represents time. At this time, the horizontal line on the train represents time, the vertical line represents the centerline distance between stations, and the distance between the vertical lines represents the distance between stations.

2) Although the train diagram has a different kind of representation, they contain the following basic elements in common, namely: The train moving time in the railway section; The pausing time of trains at stages; The pausing time standard of the train in basic section and return section; The work procedure and work time standard of the train in the tech-station, the passenger transport station and the freight station; The interval time in station; The interval time of tracing train. Intermediate computing division distance in train stations in Figure 2-1.

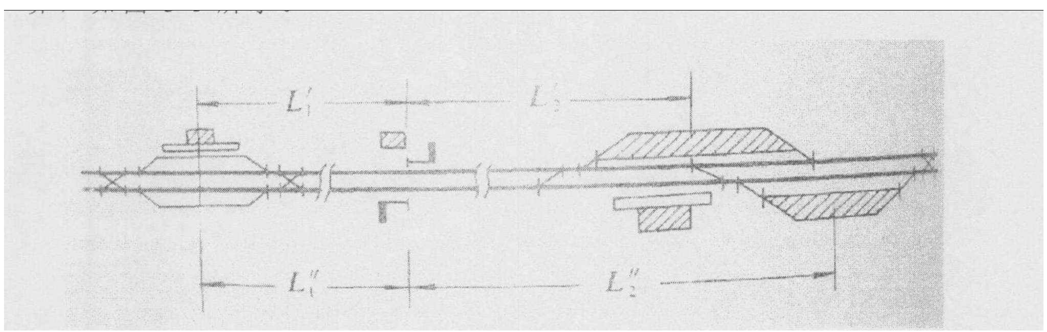

Figure 2-1 calculate the distance between the train station maps

3) Measure technical indicators of train diagram have two parts: the number indicators and quality indicators. For our train diagram, the main consideration is the following indicators: average technical speed of passenger train or freight trains, passenger trains average straight speed, average travel speed of freight trains, freight trains speed factor. These indicators are put into practice before running the figure given by direct plans to run the calculation. We can say that they are static analysis of the train diagram. Objectively speaking, this condition in the actual map compilation work is basically non-existent. Measure the quality of train diagram produced only by rail and concrete practice test to be concluded.

4) evaluate the quality of the preparation of a train running chart indicators in

addition to the merits of those involved in the previous section, another very important indicator is the balance of the overnight train line distribution, especially the balance of the train in the technology station, it will directly affect the through ability and work process of train, the impact of travel speed and the use of equipment and the use of the train station in the section of the locomotive and other quality indicators.

In addition, in order to meet the station's operation process, coordinating the work of vehicles, machines, labor, electricity, vehicles and other departments, railway department for train operation diagram prepared to run the line can achieve a balanced distribution. Because the ability of station is limited, if there is a large number of trains running figure dense arrive or depart in a period of time, it will give the station pressure, and even unable to cope, the result is a serious impact to the train locomotive traveling speed and quality indicators used in the sector or direction. Therefore, the evaluation of train operation diagram, in addition to these indicators, we must also analyze their balance and flexibility.

In summary, according to the definition and characteristics of train diagram, researching and developing a series of practical and feasible computer diagram system, the key is the accuracy of the algorithm used in map compilation and mathematical models.

3 The method of Computerized Train Diagram

3.1 The compilation of methods of computerized train diagram

Looking at the research of domestic and international for history of computerized train diagram, methods used are the following:

1) Simulation method

Simulation run into analog trains and modeling methods such as artificial shop painting. These methods are mainly based on the principles of artificial map compilation and experience to develop and generate computer criterion map compilation and execution of the program in order to achieve the whole process of manually compiled diagram

2) Move the train departure point

The method is generally used in the preparation of two-lane section of train diagram. At the first of all, figure given by a certain time interval train departure point, achieve recursive shop painting headway examination and a running line of treatment, and then check the spacing midnight between trains.

3) Recurrence interval by painting shop

This method is mainly used for single-line section of train operation diagram shop painting. Starts from one end of the section, in accordance with the order of the range appears to be checked and drawn.

4) Mathematical model approach

Use logic algebra, linear programming, graph theory and dynamic programming methods to achieve solving by computer programming. Looking at the results from the present study, due to train diagram involving a wide range of factors affecting complex, difficult to describe with a specific model, some of these factors is difficult to express with mathematical formulas, even among some of the factors in itself is contradictory and mutually conditioned.

5) Artificial intelligence expert systems approach

This is a use of intelligent programming language, the physical condition of the train diagram preparation and knowledge of the rules of artificial experience as fitness expert system to generate the map compilation, and in accordance with the order Traveling trains were running the experiment combinations. This article will introduce Common KADS application methods described in the preparation of the train running figure that belong to this class.

6) Range bound search tree method

The approach is to train diagram as a combination of the regional train order, and to bring the running time instead of running the shop painting line, which runs the establishment figure as a search problem to solve

As can be seen from the above analysis, the use of computerized Train diagram is a requirement for a combination of theory and practice, the technical difficulty of the work is very large, domestic and foreign scholars have done a lot of research work, tried many solutions, but they at the same time made some achievements, but there are all kinds of problems, but the root cause of these problems lies in the way they are used in the preparation of the issue of train operation diagram as a structured decision-making to deal with the problem all by computer. In fact, as discussed above, as the process of the preparation of train diagram is in limited rail transportation equipment and labor conditions, the trains run programs developed by the strategic plan into concrete layer train operation plan to implement the process. In this process, both structured decision-making problems, but also unstructured decision problem cannot be generalized processing. To this end, combined with China's actual situation, proposed the use of man-machine dialogue passenger train diagram preparation methods.

3.2 Several algorithm run establishment figure

The last section of the preparation method has been carried out train diagram representation. Here are some typical algorithms can be used to train diagram preparation.

1) Time-and-space rolling method

Time-and-space rolling method is calculated from Peng Qiyuan teacher of the Southwest Jiaotong University proposed a series graph algorithms. It is built on a 0-1 integer programming model will train diagram in time and space division, reduce the number of calculations to the extent you can use the computer operation.

2) Generic algorithm

This method is a mathematical model. Genetic algorithm is a probabilistic search algorithm, a method based on the theory of evolution and genetics. Because of the genetic algorithm to explore the space without limiting constraint is not necessary to solve the space has continuity, conductivity and its inherent parallelism and other properties. At present, although the algorithm has not been fully proven mathematically .

In summary, the first method is one of the methods currently used, while the second method is still not mature, but with the development of computer hardware and software technology, this approach will also be prepared to run the computer efficiently map one of the ways. The following section describes the simulation of artificial expert system used in the system.

3.3 The application of Common KADS Method in the preparation of the diagram

3.3.1 Introduction of Common KADS

Common KADS is a series of crystallization of international research and knowledge engineering projects, these studies can be traced back to 1983. After so many years, according to the results of the staff and scientists feedback, this method continue to be expanded. Common KADS indicate actual use, many systems project failed because of a technology-driven method is called cause. Only a clear system of color and its potential impact on the organization, and before the system development and system development during the two reached a high degree of consistency, an organization in order to successfully apply information and knowledge technologies. The purpose of the organization is to establish the analysis of an application-driven approach. This approach to users, clients and project stakeholders to ensure that the new system is able to solve practical problems or take advantage of real opportunities within the organization. Other useful features of this approach include the ability to solve complex modeling human-computer interaction, problem solving introducing new specification techniques to solve the problem definition of flexibility and can be configured to define risk-driven life cycle management approach, which replaces the waterfall model for information system projects.

3.3.2 Discussion Common KADS used in the preparation of the system diagram

Common KADS have developed own language, in the design and implementation of the system, we use the common run graph algorithms, using Visual C ten achieve. Through Common KADS system development process can be divided into three, namely: building a knowledge model, establish communication model and build design models. Methods listed below four main steps:

1) Operationalize requirements (operationalize (requirements-> hard-requirements + soft requirements)): This process analysis requirements, and can be converted into the desired representation. This process usually generates two kinds of requirements (constraints), i.e. hard and soft request requirements.

2) Generating a possible architecture system architecture (generate

(requirements-> possible-system-structure)): In this step, to generate all possible system architecture, which is the system has a static knowledge of potential system configuration.

3) Selecting the correct architecture of system configuration (select-subset (possible-system-structure+ hard-requirement-> valid-system-structures): In this step, the hardware requirements and constraints may be applied to a system configuration to filter out the correct system configuration. These constraints are usually designed based on experience or knowledge of the laws of physics, such as the station to the hair line constraints will drive the interval time.

4) In order of preference for the system to sort (sort (valid-system-structure + soft-requirements -> system-structure-list): Under normal circumstances, efficient design space is still very large. Therefore, the standard should be applied to reduce the set preference. In general, we use two preference level to be assessed.

As can be seen, the algorithm thought we described in the previous sections in common KADS method templates are reflected more or less, particularly in the inference of knowledge and knowledge of the task, they use methods of thinking with some of our algorithm ideas is consistent.

4 Development Strategy of computerized train diagram

For a long time, train diagram preparation has been the traditional way backward to complete the job by hand. Due to the preparation process of the diagram to solve complex problems, each whole road map compilation work often requires the completion of hundreds of people together to participate. Map compilation personnel at different skill levels, map compilation heavy workload but must split the case in hand, out of the running figure compiled by the quality varies greatly. Edited on computer research and development strategy map, the study said:

1) The current research should focus on further optimization of solving tensions single, double compilation graph algorithms;

2) promote the use of a computer programmed map depends largely on the quality level of computer software, map compilation, therefore, to do good success in translational research and development work to improve the commercialization of the standard map compilation software system;

3) above inter-bureau bus 2min unified grid map prepared by the Railway Company; tube passenger train diagram prepared by the railway branch, priority is to develop a more complete map compilation passenger train the whole way software systems and railways Bureau train diagram compiled based mapping software system.

5 Conclusions

Development of train operation diagram system is a huge project. At present, some foreign management information systems of diagram, such as Germany and

Japan, have been more mature. This is partly due to the development of advanced technologies, on the other hand due to road network conditions in different foreign and Chinese railway, which is China's railway system cannot directly reference this reason.

Although the peak of world railway construction has been going, but China's railway construction boom was still in full swing. Especially with the railway started to constantly reinvent the old line, the new production line construction and future passenger rail line construction, and an ever-changing and complex interwoven railway network, and it will presented greater challenges for train diagram. Making train diagram with computer is not just a technology, but a project. From the point of view that we need to look at engineering and systems and deal with such issues.

Calculation Method of the Carrying Capacity of High-Speed Railways Considering the Characteristics of Time Using

Yuxiang Zhang and Yuxiang Yang

School of Transportation and Logistics, Southwest Jiaotong University, P.O. No. 111 of North Second Ring Rd., Chengdu, Sichuan, China. E-mail: 259384235@qq.com

Abstract: There are mainly two computing methods of the capacity of high-speed railway, named "Deduction coefficient method" and "tracking interval method". The two methods usually treat the time period which the train could use as an integral whole, and calculate a whole capacity of high-speed railway. Without considering the time period's characteristics, these methods have some disadvantages. For example, the preferences for choosing the time period of passengers will lead to creating some peak hours, in which there are some shortages of the capacity and some off-peak hours, in which there are some overage of the capacity. Based on the disadvantages, this paper considers subdividing the whole capacity hours into lots of time buckets and finds out a new calculation of the capacity of high-speed railway, according to the travel characteristics of passengers and the locations of the high-speed train sections.

Keywords: Characteristics of time using; High-speed railway; Capacity.

1 Preface

After the operation of high-speed railway in our country, comparing with the existing line, it has the advantages of high speed, large capacity, high punctuality rate and other characteristics. Thus, they two have a lot of differences on the transport organization. However, for dispatching, especially in the capacity calculating, high-speed rail still uses the traditional calculation method of the existing line. Thus, there is a problem that it's difficult to deal with the drawing of train path in the actual process of drawing train path when the practical calculated value can be satisfied it.

The reason why it happens is that in capacity of the high-speed rail calculation process, we consider all the time integration of a cycle（usually 24 h, besides the skylight time）but ignoring the time characteristics of available capacity. For example, the preferences of passengers for choosing the travel time will create some unoccupied hours. Passengers prefer choosing the same periods to take the trains, which would lead to the capacity loss in the free hours. Secondly, there also exists unoccupied hours between two multiple unit train depots, because of three elements: the set of maintennance-skylight, the locations of multiple unit train depots and the regulation periods of passenger trains (departing at 6:00 to 24 o'clock, and arriving at

7:00 to 23:00). So, it will cause a difference between the calculation results and the practical values.

2 Analysis of the characteristics of passengers' travel time

The characteristics of railway passengers are one of the foundations of high-speed railway carrying capacity calculation. Based on the analysis of the behavioral characteristics of passengers and the demands of passenger flows, we could find out the practical willing of them and start the research about the distribution characteristics of passenger flows with time and space(Xu Pan, 2012). Then we could also calculate out the carrying capacity of high-speed railway which is based on the passenger characteristics.

The time distribution of high-speed railway passenger flow is also known as the distribution in each time period of passenger flow volume in a day. The characteristics of passenger flows changes with the different spans of time periods. According to the length of cycle, the time distribution could be divided into three parts: day- distribution, week- distribution (namely the weekdays and weekends distribution) and holiday-distribution. This paper just discusses the general calculation of carrying capacity, thus it only takes the day-distribution (also called cycle-distribution) of passenger flows into consideration.

The distributions of passenger flow in a day means the value of passenger flow in every hour. Current studies typically divided the distributions into four types: single-peak type, double-peak type, full-peak type and spurt-peak type.

Meanwhile, according to the current studies, the passengers' travel time of high-speed railway is also related to the operation time of high-speed railway (Chen Xichun, 2013). Due to the initial operational stage of the high-speed railway in country, the skylight repair time is generally arranged in 0: 00-6: 00. Thus, the high-speed railway trains do not operate at that time period. General operating hours are 6: 00 to 24: 00 (Now, there are some trains operate overnight. This paper does not take them into consideration).

The changing regulations are usually influenced by trip purposes, layout of lines, structure of railway network and other elements. Mainly it has the following characteristics: preferring to take a trip on the morning (about 7:00 to 12:00); having relatively fixed high-peak of travel periods; having spare travel time periods.

3 The unoccupied time of high-speed railway train diagram caused by the set of multiple unit train depots and points

Unoccupied time is a parameter that could reflect the unavailable degrees of some equipment or some programs during the operation of railway. We all know that, the arriving and departing of a train have to be on the location of multiple unit train depots and points. Due to this limitation and the fixed skylight repair time, it would produce an unoccupied time period between two depots (Li Jun, 2013).

Schematic is shown by Figure 1 (Wuhan to Changsha section of Beijing-Guangzhou High-speed Railway). In order to ensure the normal operation between the two depots, a train could not depart for Changsha during the **time 1** of this diagram. Similarly, trains would not arrive at Changsha during **time 2** of this diagram. However, Changsha station could send out trains during **time 2**. Thus, the unoccupied time would be offset.

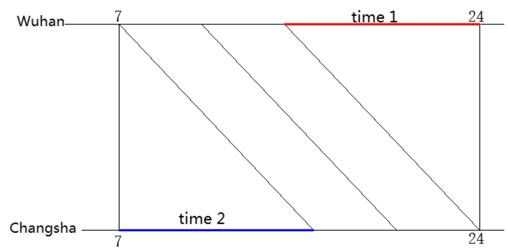

Figure 1. Schematic of travel lines between Wuhan-Changsha section

In summary, the set of depots and points would produce a period of unoccupied time at the last of the time cycle (usually before 24 o'clock). What's more, the length of unoccupied time is influenced by the operating speed of high speed trains, the stops and stop time of trains between the two depots and points and the distance between two depots and points.

There are three factors should be considered if we want to research on the values of unoccupied time: (1) the operating speeds of high speed trains; (2) the stops and stop time between the origins and destinations; (3) the distance between two depots and points. But the current calculations do not consider the lose time caused by the set of multiple unit train depots which causes that the calculated values are oversize than the practical values.

Assuming the unoccupied time which caused by the set of depots and points is T_l, the calculation formula is

$$T_l = \frac{L}{v_t}$$

L——the distance between two depots and points

v_t——the travel speed between two depots and points

According to the analysis of the practical data of the Beijing-Guangzhou, Beijing-Shanghai, Zhengzhou-Xi'an and Ha'erbin-Dalian high-speed railway, we figure out the unoccupied time which caused by the set of main depots and points and they are showed in Table 1.

Table 1. The unoccupied time caused by the set of multiple unit train depots and points

section	distance（km）	Time（min）
Beijing-Shijiazhuang	278	77
Shijiazhuang-Zhengzhou	414	112

Changchun-Harbin	240	66

3 The train diagram unoccupied caused by travel time characteristics of high-speed railway passengers

The carrying capacity of existing lines can be fully used. Because in a period of time, even if the passenger flows are less, which means the passenger trains are less too, the rest of the carrying capacity can be filled by freight trains. But for the high-speed railway, the calculation has to take the preferences of passengers for choosing the travel time into consideration. If the Railway operates trains at a no or low passenger flow, it would get a result of low attendance, wasting of capacity and increasing operation cost.

Therefore for the high-speed railway, we have to take the unoccupied coefficients caused by passenger flows into consideration when we calculate the carrying capacity with the minimum tracking interval method. This paper counts up the practical train plans of every high-speed line (regarded Wuhan-Guangzhou Railway as Beijing-Guangzhou high-speed Railway before 2012) and calculates the unoccupied coefficients of each time periods (divided by 1 hour). Because trains operate in pairs, the data just includes the down-line direction. Due to the large amount of data, this paper just lists Wuhan-Changsha section of Beijing-Guangzhou high-speed line as Example and shows in Table 2.

Table 2.The unoccupied coefficients caused by passengers' travel time between Wuhan and Changsha

section	Time period	2011	2012	2013	2014
Wuhan-Changsha	6-7	1.0000	1.0000	1.0000	0.9167
	7-8	0.6667	0.6667	0.6667	0.5833
	8-9	0.7500	0.7500	0.8333	0.8333
	9-10	0.6667	0.5833	0.5833	0.6667
	10-11	0.6667	0.7500	0.6667	0.6667
	11-12	0.5833	0.8333	0.6667	0.7500
	12-13	0.6667	0.7500	0.5000	0.5833
	13-14	0.6667	0.7500	0.5000	0.3333
	14-15	0.6667	0.6667	0.6667	0.5000
	15-16	0.5833	0.5833	0.5833	0.5000
	16-17	0.7500	0.6667	0.5833	0.5000
	17-18	0.5833	0.7500	0.5000	0.5000
	18-19	0.8333	0.8333	0.6667	0.5833
	19-20	0.8333	0.7500	0.8333	0.8333
	20-21	0.9167	1.0000	0.8333	0.8333
	21-22	1.0000	1.0000	1.0000	1.0000
	22-23	1.0000	1.0000	1.0000	1.0000
	23-24	1.0000	1.0000	1.0000	1.0000

Analyzing large amounts of statistical data and considering the regulation of the preferences of passengers for choosing the travel time, this paper draws a conclusion of the theoretical values of the every depots and sets the Beijing-Guangzhou high-speed railway as example. According to the unoccupied coefficients in 2014, every section could be divided into several time periods shown in the following table. In each time period, we choose the average value when the unoccupied coefficients are relatively similar in each unit hour. The results are shown in table 3.

Table 3.Average unoccupied coefficients between every depots of Beijing-Guangzhou high-speed railway in 2014

<table>
<tr><th>Time period</th><th>Beijing - Shijiazhuang</th><th>Shijiazhuang -Zhengzhou</th><th>Zhengzhou -Wuhan</th><th>Wuhan -Changsha</th><th>Changsha -Guangzhou</th></tr>
<tr><td>6-7</td><td>1.0000</td><td rowspan="2">1.0000</td><td rowspan="4">0.9167</td><td>0.9167</td><td>1.0000</td></tr>
<tr><td>7-8</td><td rowspan="4">0.4792</td><td rowspan="5">0.7000</td><td rowspan="6">0.5938</td></tr>
<tr><td>8-9</td><td rowspan="4">0.6667</td></tr>
<tr><td>9-10</td></tr>
<tr><td>10-11</td><td rowspan="3">0.6389</td></tr>
<tr><td>11-12</td><td rowspan="2">0.6667</td></tr>
<tr><td>12-13</td><td>0.7500</td><td>0.5000</td></tr>
</table>

13-14					
14-15	0.4792				
15-16					0.3500
16-17		0.6042	0.7708		
17-18					
18-19	0.6944				
19-20				0.8333	
20-21		0.9375	0.9583		0.7917
21-22	0.9444			1.0000	
22-23					1.0000
23-24					

According to the table above, we could see that the value of average unoccupied coefficients between every depots have transmissibility, which means the high-peak hour of a section front would have a delay and be showed on the next section. The value of the delay is related to the mileage of this section. This characteristic is consistent with the theory research.

4 Calculation methods for high speed railway available carrying capacity, considering the characteristics of time using period

The thoughts about the calculation method are as follows: Based on the minimum tracking interval method and considering the characteristics of time using period which is caused by the preferences of passengers for choosing the travel time, we put the carrying capacity utilization (1- unoccupied coefficients) of each time period which is based on the passenger flows into the calculation formula. Secondly, we make the result take away the unoccupied coefficients which caused by the setting of multiple unit train depot.

The improved section calculation formula is as follows:

$$\mathrm{N} = \left\{\sum_{i=6}^{23}\left[\frac{60}{I}\cdot(1-\Delta\gamma_i)\right]\right\} - \frac{T_l}{I}\cdot\Delta\gamma_l$$

In the formula, N——the carrying capacity of high speed railway section

i——the operation time of high speed trains, taking 6 -24

I——the minimum dispatch tracking interval on a high speed railway station

$\Delta\gamma_i$——the unoccupied coefficients of section carrying capacity based on the characteristics of passengers' travel time, taking high-peak value, flat-peak value and low-peak value aiming at different sections as Table 3 above

T_l——the unoccupied time caused by the setting of depot and point, values shown in Table 1

$\Delta\gamma_l$——the carrying capacity unoccupied coefficients of the time period of T_l. Because of the sharp cutoff of passenger flows after 21 o'clock, the unoccupied coefficients of T_l would acquire a large value. Thus we take 0.2(reserve capacity) for this coefficient.

5 Conclusions

This paper considers dividing a whole available operation cycle of high-speed railway trains into tiny time periods, based on the preferences of passengers for choosing the travel time, the locations of multiple unit train depot and other elements. On the basis of the minimum tracking interval method, this paper puts forward a new calculation method and calculation formula of carrying capacity utilization which considering the characteristics of time using period. However, with the development of high-speed railway network in our country, the counter change and connection of different lines would make up the unoccupied carrying capacity. Thus the calculation method in this paper is more available for single railways but insufficient for whole network.

Abstract: To solve the contradictions of operation and maintenance in the net of passenger dedicated line, the problem of optimizing passenger train operation scheme and comprehensive maintenance gap was addressed by taking into account the reasonable operation time of passenger train and the importance degree of key train. Aiming at minimize the importance degree of total passenger line influencing by maintenance gap , a collaborative optimization model was proposed, and a corresponding algorithm was designed. Computational results show that the best maintenance gap period is received, which is the train reasonable operation time with least importance degree of the key train. And with the increase of maintenance gap, the number of key train and importance degree has a tendency to increase.
Keywords: Net of passenger dedicated line; Operation scheme; Comprehensive maintenance gap; Collaborative optimization.

As a large-scale infrastructure project, the railway project mainly composes roadbeds, rails, bridges, stations, power supply units, communication signals, etc. In order to keep all equipment in good condition and to ensure the safety, smoothness and comfort of railway transport, daily routine maintenance and overhaul are essential for public works, power supply, electrical services and other equipment. During this period, no train, or some reduced trains are drawn in operation diagram. The time slot reserved for construction and maintenance is called maintenance gap. Comprehensive maintenance gap for passenger dedicated line principally refers to routine repair and maintenance for tracks, power supply, communication signals and other equipment in the network of passenger dedicated line. Since the completion of passenger dedicated railway network, trains are density in a high-level capacity. Not only the original-destination trains, but also a great number of cross-line trains run between large stations in the network. Day or night, there are operation requirements. It makes the passenger dedicated network relatively complex and leads to the serious contradictions of passenger train operation scheme and comprehensive maintenance gap. Therefore, setting comprehensive maintenance gap for passenger dedicated network must consider the traffic demands and operation characteristics, as well as maintenance. Hence, collaborative optimization is required.

(LUO,2007) Proposed that the main content of collaborative optimization is to optimize the time relationship between comprehensive maintenance gap and passenger trains. A probabilistic relational model of maintenance gap and operation schema is built to search for theoretical best gap time, during which period trains with lowest probability frequency are operated appropriately. (YUE,2007)Built a mathematical model to study the relationship between gap setting and train operation and to find optimal combination schema. (MIN,2008)Discussed gap setting method in Beijing-Shanghai high-speed railway from aspects of different methods and time for gap maintenance and the impact of transport organization and device configuration. (HAN,2009)Analyzed the characteristics of various form of maintenance gap, and hence studied appropriate forms of comprehensive maintenance gap for high-speed passenger dedicated line, the intercity rail and the fast track for mainly passenger and also cargo. (ZHAO,2002)Studied how to determine the method of comprehensive maintenance gap setting in Beijing-Shanghai high-speed railway, in order to ensure the organic coordination between comprehensive maintenance planning and organization of train operation. (XU,2010)Researched on rectangular gap and segmented rectangular gap's adaptability and capacity for evening-morning trains. From the point of operation characteristics and considering the maintenance gap setting in foreign countries, (ZHANG,2006)proposed maintenance gap setting schema for passenger dedicated line in regard with gag features of existing line, the characteristics of technic equipment and traffic demands. Given the operation schema of cross-line trains in Beijing-Shanghai high-speed railway, (HU,2011)applied analytic calculation method and graphic method to analyze and calculate the reasonable time period of evening-morning trains. It studied the collaborative relation between gap duration and trains, and ultimately determined the operation schema in different conditions of gap duration.

The collaborative optimization between passenger train operation scheme and comprehensive maintenance gap in the net of passenger dedicated line is an issue requiring further study. As a part of railway network, passenger dedicated network connects with existing lines. Passenger dedicated network runs not only trains between passenger dedicated lines, but also trains between passengers dedicated lines and existing lines, which makes it more complicate. Therefore, merely studying the quantity and ignoring the importance of different trains will lead to a result with limitation or to a possibility of several optimal solution, even to a large deviation between optimal solution and actual situation. Considering operation schemas for various types of passenger trains, this paper studies the collaborative optimization between passenger train operation scheme and comprehensive maintenance gap in the net of passenger dedicated line, according to the different importance degree of each type of trains.

1 Appropriate departure time domain for passenger train operation schema in the network of passenger dedicated line

Considering the convenience for passengers as a principle and the combination of various urban transportation vehicles, trains in passenger dedicated line are usually not earlier than 7h nor not later than 24h. Trains arrive at stations from 7h to 24h. With regard to this rule, assuming t the total travel time, D the one-way running days,

$D = \left\lfloor \frac{t}{24} \right\rfloor$. Therefore, the appropriate departure time domain for passenger trains is calculated as follows:

$$X = \begin{cases} [7, 23 - t + 24D], & 24D \le t < 7 + 24D \\ [7, 23 - t + 24D] \cup [31 - t + 24D, 24], & 7 + 24D \le t \le 16 + 24D \\ [31 - t + 24D, 24], & 16 + 24D < t \le 24 + 24D \end{cases} \quad (1)$$

2 Importance degree of passenger trains in the network of passenger dedicated line

The importance degree quantitatively embodies the importance of each unit in the system. The calculation of importance degree is, in certain physical sense, to order each unit of the system according to their importance.

Divided into proper-line trains and cross-line trains, the large number of passenger trains runs at speed of 200-300 km/h and 300km/h or above. They are distinguished from normal trains by initial letters. G means high-speed trains, D means multiple unit train, K means fast trains. For trains belong to the same type, for example trains initialed by G, the importance degrees are set into different value according to the political and economic influence of the cities they pass by. As for departure time, it is more attractive for business persons to travel in morning peak hour than at noon. These trains in peak hour have higher importance degrees. For trains with different OD in segments, the number of trains effects on their importance degrees. If only one train runs in certain segment, it has a higher importance degree than that a number of trains run in the segment.

The determination for classifying trains in passenger dedicated line by importance degrees is a kind of comprehensive evaluation. Since analytic hierarchy process (AHP) is currently a simple, flexible and practical comprehensive evaluation for qualitative problem, this paper use AHP to determine the importance degree of trains in passenger dedicated line, and to provide basis for the collaborative optimization between passenger train operation scheme and comprehensive maintenance gap in the net of passenger dedicated line.

Firstly classify the trains in passenger dedicated line by different level of running speed, next apply the AHP and Delphi method to compare the importance of pairwise trains, then build the judgment matrix $R = [r_{ij}]$ where $r_{ij} > 0$, $r_{ij} = \frac{1}{r_{ji}}$, $r_{ii} = 1$, r_{ij} is the scale value of relative importance of various types of trains. The judge scales are 1-9 as it is often applied in AHP.

$$R = \begin{bmatrix} r_{11} & r_{12} & \cdots & r_{1j} \\ r_{21} & r_{22} & \cdots & r_{2j} \\ \vdots & \vdots & & \vdots \\ r_{i1} & r_{i2} & \cdots & r_{ij} \end{bmatrix} \quad (2)$$

Calculate the maximum characteristic root $\lambda_{\max}$ in judgment matrix and its proper vector W .Take consistency check for judgment matrix. Normalize each column of the judgment matrix, as follows:

$$\overline{r_{ij}} = \frac{r_{ij}}{\sum_{i=1}^{n} r_{ij}} \qquad i, j = 1, 2, \cdots n \quad (3)$$

Here n is the total number of types of passenger trains in the network of passenger dedicated line.

Calculated the following equation after the normalization of judgment matrix:

$$\begin{cases} \overline{w_i} = \sum_{j=1}^{n} \overline{r_{ij}}, & i, j = 1, 2, \cdots n \\ w_i = \frac{\overline{w_i}}{\sum_{i=1}^{n} \overline{w_i}}, & i, j = 1, 2, \cdots n \end{cases} \quad (4)$$

Get W_i as the weight of importance degree. Finally calculate the maximum characteristic root of judgment matrix, as follows:

$$\lambda_{\max} = \frac{1}{n} \sum_{i=1}^{n} \frac{(BW)_i}{W_i} \quad (5)$$

Check the consistency of the matrix, calculate the deviation consistency index of judgment matrix $C.I.$. $C.I. = \frac{\lambda_{\max} - 1}{n - 1}$, find the consistency index in the average random consistency table, and then calculate the random consistency rate $C.R.$. $C.R. = \frac{C.I.}{R.I.}$, compare the random consistency rate $C.R.$ with 0.1 to determine whether the model is consistent and robust.

3 Problem description and formulation

Operation and maintenance are two determined problems concerning the passenger dedicated line. In order to meet the passengers' departure and arrival demand, the maintenance gap are set generally from 0:00 a.m. to 6:00 a.m. The paper explores the relation between the train operation and the maintenance without the constraint of fixed maintenance gap.

3.1 Assumption

The train operation and adjustment interfere with each other. Within the maintenance, the number of operational train shouldn't surpass the section capacity. The maintenance has little effect on sunset-departure and sunrise-arrival trains. In order to simplify the problem and make the model more realistic, the model established in the paper ignores the interference between trains, and concentrate the relationship between maintenance gap and train operation. Namely, the train within the network are independent. They aren't affected by the changes of the other trains.
Within the maintenance gap, the railway capacity is the constraint for the number of operational trains. Adjustment of the departure time for all trains are the key of the model, and it also satisfies the assumption.

3.2 Model description

The trains of different speed run on the passenger dedicated railway network. These trains are of different importance, and they have different operation planning. Due to the connection between the operation plan and the maintenance, a cooperative model is needed. Firstly, the appropriate departure time scale needs to be set, namely to calculate the impact on all trains from the maintenance $\sum_{i=1}^{n} W_i$, based on the maintenance gap $[m,n]$.The minimize value of $\sum_{i=1}^{n} W_i$ is the optimal maintenance gap scale and operation planning. The other trains aren't affected by the maintenance gap, or they can be adopted to avoid the impact.

3.3 Model formulation

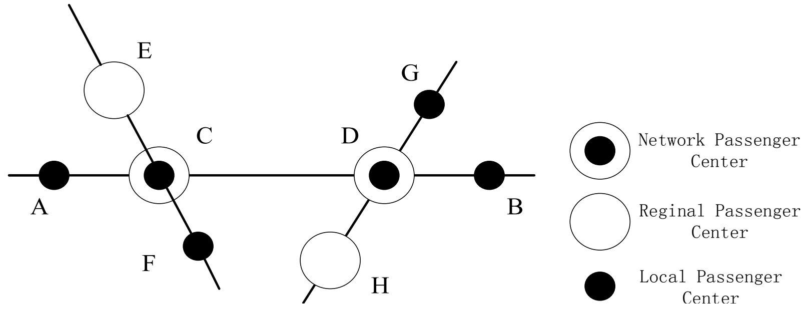

Figure 1. Network Simulation

As shown in the Figure 1, in the passenger dedicated railway network, Line AB is a busy main railway line, and section CD is the section of this main line. The passenger dedicated railway line is of two directions, in our paper, only one direction is calculated, and the other direction can be done in the same way.

The arrival time for all trains on the section CD are calculated based on appropriate passenger departure time scale. As shown in Figure 1, the departure station for i^{th} train is station E, and the arrival station is station H. The appropriate departure time scale at station E is $[c,d]$. The arrival time is y_i, and the arrival time scale is $[c+y_i, d+y_i]$, namely $[c_i, d_i]$.The maintenance gap is set as $[m,n]$. Generally, the relationship between maintenance and arrival time of passenger are listed in figure 2.

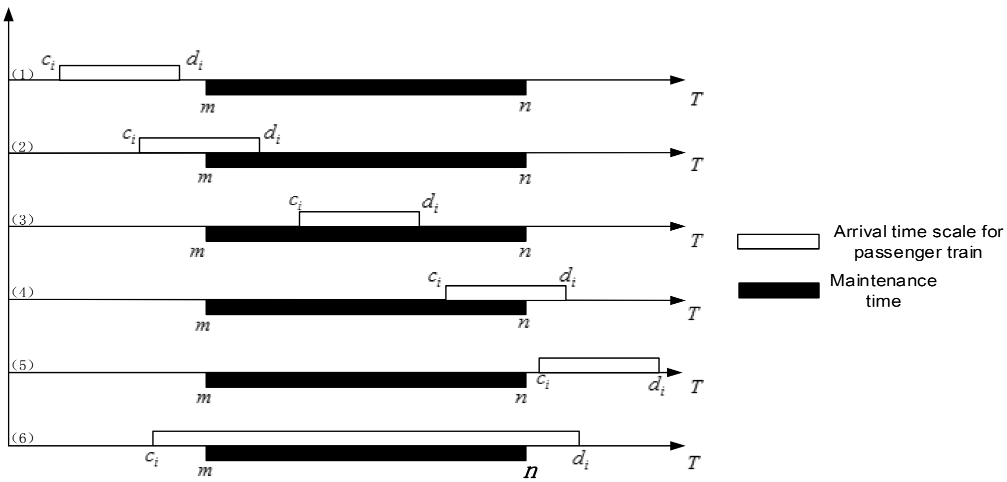

Figure 2. Relationship between maintenance gap and train arrival time

Then another parameter, the pass-through time is needed to determine whether the first and the second type train can pass through the section before the maintenance gap, namely whether the train is affected by the maintenance; the arrival time for the third type of train falls in the maintenance gap, and it's certainly affected by the maintenance; the arrival time of the fourth and sixth train overlapped the maintenance gap. It indicates that the conflicts exits, while the conflicts can be avoided by adjusting the operation planning; the arrival time of the fifth train doesn't overlap the maintenance, and it indicates the departure time aren't affected by the maintenance.

Now we'll discuss the first 3 cases concerning $[c_i, d_i]$ and $[m,n]$:

The first and second type train under the maintenance influence must satisfy the following condition:

$$\begin{cases} m \le c_i + t \\ n \ge d_i \end{cases} \tag{6}$$

The third type train must satisfy the following condition:

$$\begin{cases} m \le c_i \\ n \ge d_i \end{cases} \tag{7}$$

If the pass-through time for train on section CD is t, the train arrival scale is p, then $d_i = c_i + p$, the maintenance gap is q, then $n = m + q$. By (6) and (7), we obtain:

$$\begin{cases} m \le c_i + t \\ m + q \ge c_i + p \end{cases} \tag{8}$$

From the equation above, we can see for the train affected by the maintenance, the minus between maintenance starting time and departure and arrival time of passenger train is inferior the pass-through time. And this minus is superior the minus between train running time and maintenance gap. The train that meet the above condition can't be adjusted.

Under the influence of period of 24 hours, the equation (8) can be rewritten as bellow:

$$\begin{cases} m - t \ge 0 \\ m \le c_i + t \\ m + q \ge c_i + p \end{cases} \cup \begin{cases} m - t < 0 \\ m + 24 \le c_i + t \\ m + q \ge c_i + p - 24 \end{cases} \cup \begin{cases} m - t < 0 \\ \\ m + q \ge c_i + p \end{cases} \tag{9}$$

And m , t , $c_i \in [0, 24)$.

As a result, for every train of the section, if it meets the equation mentioned above, it's affected by the maintenance, and its influence is noted as W_i.For given pass-through time t, train departure time and maintenance gap, $\sum_{i=1}^{n} W_i$ can be calculated. We can obtain the value scale of m with the minimum $\sum_{i=1}^{n} W_i$. This is therefore the optimal starting time for maintenance. Therefore, the operation planning can be adjusted.

3.4 Calculation designing

STEP 0：Calculate the appropriate train arrival time on section CD, $[c_i, d_i]$ and make the order from the smallest to the largest. The total number of trains is set as N. And the rearranged train arrival time scale is set as $[c_n, d_n]$.

STEP 1：Set p_n as the arrival time scale for the k^{th} train, namely $d_n = c_n + p_n$, and calculate the p_n for all trains;

STEP 2：Set t_n as the running time for k^{th} train on section CD, Q as the number of affected trains, W as the importance and its initial value is 0. For a given q, calculate the value scale for c_n, t_n, p_n *and* m. If the passenger train satisfy the equation 6-9, then $Q = Q + 1, W = W + w_i$;

STEP 3：Calculate the minimum value for Q and W when $m \in [0, 24)$. When W reaches the minimum value, we obtain the optimal maintenance plan. When all trains are of the same importance, then the plan with the minimum Q is the most optimal plan;

STEP 4: Find out all the key trains based on the value scale of *m*. We can adjust the operation and maintenance gap based on *m*.

We should note that for trains with several departure scale, we have to calculate the departure time separately. If the train within several solution is always affected by maintenance plan, then this train is the key train. If not, the train can be adjusted to avoid the maintenance influence or it's not affected at all.

4 Experimental Study

According to the information found in literature, the basic information of Beijing-Shanghai high-speed railway is as follows:

(1) Setting mode of the comprehensive maintenance maintenance gap of Beijing-Shanghai high-speed railway is segmented vertical rectangular maintenance gap.

(2) Setting time of the comprehensive maintenance maintenance gap of Beijing-shanghai high-speed railway is 0:00 to 06:00.

(3) The evening-morning train running on the Beijing-shanghai high-speed railway departs generally between 18:00 and 23:00 in the evening, and arrives between 6:00 to 9:00 in the morning. The whole running time is between 7 to 15 hours.

According to case 3, a rational departure and arrival time range of evening-morning train running on the Beijing-shanghai high-speed railway can be calculated. Setting aside for a period of time between 0:00 and 06:00 as maintenance gap is necessary according to case 2. Since the running train of Beijing-Shanghai high-speed railway runs during the day and has no night driving demand. Thus, only the cross-line train can be influenced by the maintenance gap time. According to passenger flow OD, passenger flow density, layout of maintenance facilities, maintenance area and cross-line point's setting, dividing Beijing-shanghai high-speed railway into six running section (Referred to as section): Beijing-Tianjin, Beijing-Tianjin, Tianjin-Dezhou, Dezhou-Jinan, Jinan-Xuzhou, Xuzhou-Nanjing and Nanjing–Shanghai. According to the running section structure table of the cross-line train operation plan of Beijing-shanghai high-speed railway in 2015, which include 169 pairs of high-speed cross-line trains with a planning operation speed of 300km/h and above, 62 pairs of high-speed cross-line trains with a planning operation speed of 200km/h and above.

This paper selects Xuzhou-Nanjing section of Beijing-Shanghai high-speed railway as an example to verify the validity of the method. First, for the high-speed trains with a speed of 300km/h and above, and of 200-300km/h, respectively conduct importance assignment order (G>D>T>Normal) according to the initial letter of train. Based on the method for determining the importance degree of train grades in the text, obtained the importance degree of High-speed cross-line train with a speed of 300km/h and above is 0.75, the train with a speed of 200km/h and above is 0.25. The passenger train operation plan of Beijing-Shanghai high-speed railway in the above document 2015, the reasonable time period of its passenger train arriving at each section were calculated in accordance with the formula (1), according to the requirements of open time of different maintenance gap, depending on the maintenance gap, taking respectively 2.5 hours, 3 hours and 4 hours for example, using a computer program to calculate the sum of importance degree of the key train at different time range of maintenance gaps, as shown below.

After calculation, between 0:00 to 06:00, the reasonable arrival time range of evening-morning train with different weights to the section of Xuzhou-Nanjing section of Beijing-Shanghai high-speed railway is shown in Figure 3, where the high-speed cross-line trains with a speed of 300km/h and above is represented by red lines, speed of 200km/h and above is represented by the blue line.

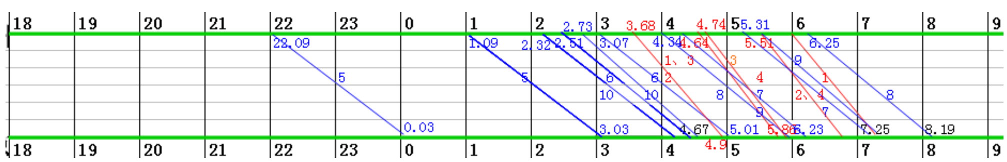

Figure 3. Reasonable arrival time range of evening-morning train to the section of Xuzhou-Nanjing section of Beijing-Shanghai high-speed railway

1. When maintenance gap time q=2.5h

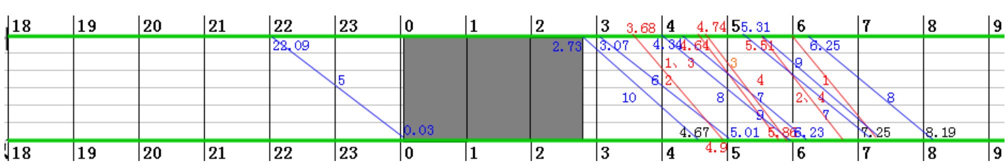

Figure 4. Case q=2.5h

The above figure shows that train No.5, No.6 and No.10 may be influenced by the maintenance gap when q=2.5h. After adjusting for the above three kinds of trains within the scope of $[c_i, d_i]$, they can completely avoid the influence of the maintenance gap set, namely, when q=2.5h, no train will be affected by the maintenance gap set. Thus, when q=2.5h, Q=0, W=0, we can obtain m=0.03, n=3.07, the open time range of maintenance gap is [0.03,0.07].

2. When maintenance gap time q=3h

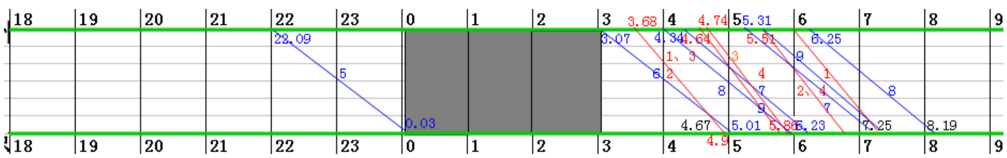

Figure 5. Case q=3h

The above figure shows that train No.5 and No.6 may be influenced by the maintenance gap when q=3h. After adjusting for the above two kinds of trains within the scope of $[c_i, d_i]$, No.5 and No.6 can completely avoid the influence of the maintenance gap set, but the arrival time range of No.10 fall entirely in the time set of maintenance gap, within the range of rational departure time, No.10 can not avoid the influence of maintenance gap set. Thus, when q=3h, Q=1, W=0.25, we can obtain m=0.03, n=3.07, the open time range of maintenance gap is [0.03,3.07].

3. When maintenance gap time q=4h

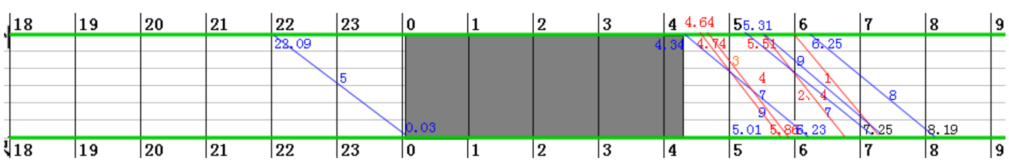

Figure 6. Case q=4h

The above figure shows that train No.1, No.2, No.3, No.5 and No.8 may be influenced by the maintenance gap when q=4h. After adjusting for the above two kinds of trains within the scope of $[c_i, d_i]$, No.5 can completely avoid the influence of the maintenance gap set, but the arrival time range of No.6 and No.10 fall entirely in the time set of maintenance gap, within the range of rational departure time, they can not avoid the influence of maintenance gap set. Thus, when q=4h, Q=2, W=0.5, we can obtain m=0.03, n=4.34, the open time range of maintenance gap is [0.03,4.34].

The main conclusions is as follows through the above analysis:

(1) The existing research results, in which the number of key trains are determined by optimal time set of comprehensive maintenance maintenance gap set,

but this paper uses the sum of importance degree of key trains to find the optimal time of comprehensive maintenance maintenance gap set, to reach collaborative optimization of train operation plan and the comprehensive maintenance maintenance gap, when the key train has the same degree of importance, the model is changed to take the minimum number of key train as the goal, which consistent with the conclusions of existing research results. Therefore, compared with the existing research results, this paper is possible to obtain an opposite conclusion with the previous results.

(2) Through research analysis, with the increase of maintenance gap time q, the key train number and the important degree also have a tendency to increase, as shown in figure 7.

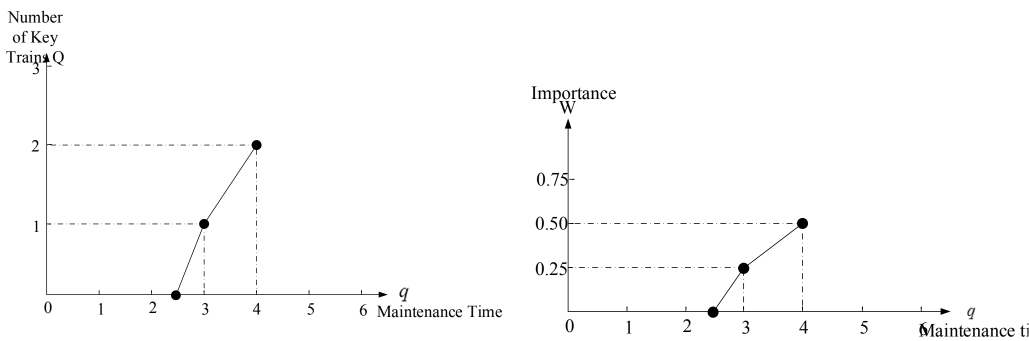

Figure 7. The Change trend chart of sum of number and importance of key train

5 Conclusion

For the problem of collaborative optimization of passenger train operation plan and comprehensive maintenance maintenance gap, this paper put forward the concept of the importance degree of passenger train and key train, and on this basis, established optimization adjustment model for passenger train operation plan of passenger dedicated line network based on comprehensive maintenance maintenance gap optimization settings, conduct algorithm design for the solving of model, and finally demonstrated the effectiveness of the method with numerical examples. This paper only considers the mutual influence between the passenger train operation plan and the comprehensive maintenance of maintenance gap, the next step is to research collaborative optimization model for passenger train operation plan of passenger dedicated line and the comprehensive maintenance maintenance gap under the condition that mutual influence of trains and time-phased reflect the importance of differences.

Abstract: In order to better describe the level of the middle reaches of the Yangtze River port of scale and promote the future development of the middle reaches of the Yangtze River port. The thesis analyses the Scale Structure of six major ports on the Yangtze River via port of first degree, rank - size rule and fractal theory method, while we calculate the rating scale of peacekeeping through the data of the middle Yangtze port from 2004 to 2011. The results show that: the middle reaches of the Yangtze River port size distribution has obvious fractal characteristics, using fractal theory is suitable for analysis of Scale Structure of ports in the region, the first role of the high times port is weak, ports tend to be independent, grade scale spatial layout is more balanced.
Keywords: The middle reaches of the Yangtze River port; Grading scale; Rank - size rule; Fractal theory; Structural optimization.

1 Introduction

The more common use of rank - size rule and fractal theory is in the study of urban rating scale, such as Chentao, Liujisheng. (1994) briefly describes the basic fractal theory, focusing on the fractal characteristics of urban systems, and discusses the urban system spatial distribution of the random diffusion and regularity size distribution. J. Friedmann (1986) studied the level of network system of the city, pointing out that the city hierarchy system will become multinational division reflecting the longitudinal production area. The innovation of this paper is to be applied to the rating scale analysis of the port, and finally verifying the rank - size rule and fractal theory to port rating scale analysis is reasonable through the results. Therefore, we can use the rank - size rule and fractal theory to study the characteristics of the scale structure of the port, to develop a reasonable development strategy of the port, thus contributing to regional economic development. By using this model to calculate, you can get the specific characteristics of the Yangtze River port rating scale, compared with other models, this model has a high practical significance.

2 The Theory Selected

2.1 rank - size rule

Gaochao. (2011) describes that Hausdauf fractal dimension is the fractal dimension of the most commonly used method estimates. Assuming the relationship between total n ports within a certain region, the size of the ports in descending order, If given a throughput metric scale r, the relationship between the port throughput that is greater than r which is N(r) and scale r to meet:

$$N(r) \propto r^{-D} \tag{1}$$

Where D is the Hausdauf dimension.

Taking the logarithm on both sides, we can get

$$\ln N(r) = A - D \ln r \tag{2}$$

Where A is a constant.

In general, the size of the port city obedience rank - size distribution pattern, the most common urban rank - size distribution model is G.K Zipf formula:

$$\ln \mathrm{P}_r = \ln P_1 - q \ln_r \tag{3}$$

Where r is port rank,P_r is r-bit port throughput,P_1 is theoretical maximum throughput of the port,q is a constant. What D means is as follows:

Table 1. What D means

The range of D	Port rating scale morphology
$D = 1$	Port rating scale to achieve the ideal state, port development in good condition, constrained rank - size distribution
$D < 1$	Port rating scale distribution of scattered, port development is not mature enough, the first port is a strong monopoly
$D > 1$	Port grade size distribution is more concentrated and more mature
$D \to 0$	The only port in the region
$D \to \infty$	Port rating scale is indifference

Each port of the middle reaches of the Yangtze River fell by rank and scale to the double logarithmic graph, we can make an objective division to rating scale of ports by a scatter plot. Then subjected to $y = bx + a$ form of regression analysis, according to one of the parameters on the rank port to judge the size of the type.

2.2 The fractal theory

Xujianhua. (2002) describes that fractal theory is a new theory of natural science, social science and scientific thinking across the mid-1970s. Allen P M.(1997) describes that fractal theory is that those very irregular and fragmented external geometry (or phenomena) has its own inherent regularity and self-similarity. The concept of fractal is an American mathematician Mandelbrot (B. B. Mandelbort) first proposed. In 1967 he published in the American Journal of authority of the "science" entitled "How long is the coastline of Britain?" We can not distinguish from the shape and structure of this part of the coast and that part of the coast of what is essentially different, and this is almost the same degree of irregularity and complexity instructions the morphology of the coastline is self-similar. That is the local morphology and the overall shape is similar. In 1975, Mandelbrot founded the fractal geometry. On this basis, the formation of the fractal nature of scientific research and its application, called fractal theory.

3 The Middle Reaches of the Yangtze River Port Rating Scale and Fractal

3.1 The middle reaches of the Yangtze River port rating scale studies

There are a large number of ports on the middle reaches of the Yangtze River, the paper we focus on selected six representative ports to be studied. According to 2012 "Yearbook of Chinese ports," we got the tables which include port cargo throughput and container throughput, specific data is shown in Table 2.

Table 2. 2011 middle reaches of the Yangtze River port throughput

port	cargo (10^3t)	Container (10^3TEU)
Wuhan port	7602	71
Yueyang port	9036	15.5
Yichang port	4635.87	6.11
Jiujiagn port	3907	14.22
Jingzhou port	2147.88	6.4
Huangshi port	1780.54	2.1

Source: 2012 "Yearbook of Chinese ports."

In order to weight the two indicators of this paper selected, we must first eliminate the influence of dimensionless, so we can use number two index values in the column divide the maximum dimensionless get two columns of data x_1 and x_2 through expert counseling and AHP to determine the weight of the two above-mentioned index weight, the result is:

$$W=(0.75, 0.25)$$

And the overall size of the final port is:

$$x = 0.75x_1 + 0.25x_2$$

Table 3. Comprehensive scale of 2011 middle reaches of the Yangtze River port

port	x_1	x_2	x
Wuhan port	0.84	1	0.88
Yueyang port	1	0.22	0.80
Yichang port	0.51	0.09	0.41
Jiujiagn port	0.43	0.20	0.37
Jingzhou port	0.24	0.09	0.20
Huangshi port	0.20	0.03	0.16

According to Mark • Jefferson's City first degree theory, we will apply it to the level of scale division ports, the ports can be drawn first index, the index is generally considered the first port should include two port index, 4 port and 11 port index index.

$$S_2 = P_1 / P_2$$
$$S_4 = P_1 / \left(P_2 + P_3 + P_4\right) \quad (4)$$

Formula: S_2 - represents 2 port index .

S_4 - represents 4 port index .

P_x - represented ranked No. x overall size of the port by port rating scale. x=1,2,3,4

According to city rank - size rule, 2 port index is 2,4 port index is 1 is the ideal state for a port structure. However, the analysis shows that the index was less than the standard, and from the point of S_2, the first port of monopoly is not strong, and has weak impact on the whole Yangtze River region rating scale; from the point of S_4, the middle rank of the harbor is relatively developed, and evenly distributed, no significant differences in the size of the structure, the values are shown in Table 4.

Table 4. The middle reaches of the Yangtze River port 2011 rating scale index

first degree	2011
2 port index	1.095
4 port index	0.556

To illustrate the role of the middle reaches of the Yangtze River port of first degree whether the strong better, we are out of the list of ports 2004-2010 first-degree value, National Bureau of Statistics. (2013) provides the data wo need, as is shown in Table 5.

Table 5. Middle reaches of the Yangtze River port of 2004-2010 first-degree

years	first degree
2004	2.187
2005	2.021
2006	2.533
2007	1.631
2008	1.161
2009	1.397
2010	1.572

Through the data were analyzed on the table, from 2004 to 2006, the first of the role of the port of Wuhan port is strong, among the years later, the first degree of effect is obviously insufficient, therefore, as a hub port on the middle reaches of the Yangtze River, Wuhan port should strengthen its own port construction and play a good role in its promoting.

3.2 The middle reaches of the Yangtze River port fractal characteristics

Here, we chose port's cargo throughput to represent the rating scale, according to the city rank - size rule, we obtained rank - size regression equation of 2011 the middle reaches of the Yangtze River port and calculate the fractal dimension.

Several groups of coordinates will be needed when painting graphics:

(0,-0.13),(0.7,-0.22),(1.1,-0.89),(1.4,-0.99),(1.6,-1.61),(1.8,-1.83)

Paint simulation using MATLAB, we can get the regression equation:

$$y = -0.9782x + 0.1310$$

The image shown the regression in Figure 1:

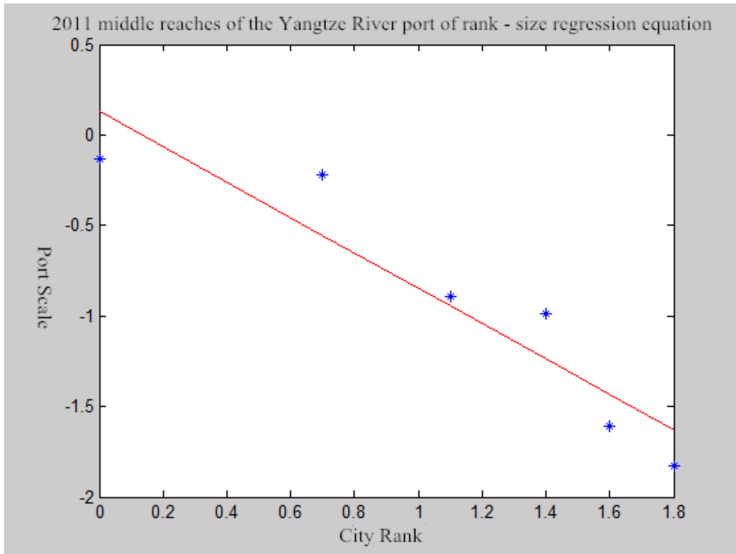

Figure 1. 2011 middle reaches of the Yangtze River port of rank - size regression

From the results obtained in the above MATLAB run can know, the absolute value of the slope of the regression line is 0.9782, the value of D is 1.022, more than 1, indicating the middle reaches of the Yangtze River port size distribution is a relatively balanced distribution type, the size of the high secondary port is not very prominent, close to the port distribution rank - size rule. After obtaining the regression equation, we can calculate the deviation between the theoretical value and the actual value, as shown in Table 6.

Table 6. The deviation of port scale between the theoretical and the actual value

port	deviation
Wuhan port	0.001
Yueyang port	-0.334
Yichang port	-0.055
Jiujiang port	-0.248
Jingzhou port	0.176
Huangshi port	0.200

From the above table, we can know that the actual size of Wuhan port, Jingzhou port and Huangshi port is smaller than their theory scale. Judging from the background of the port area, they have considerable development prospects. The actual size of Yueyang port, Yichang port and Jiujiang port is bigger than their theory scale which indicates port has a high development speed.

Using the same method, we can calculate the Yangtze River port 2004-2011 rating scale fractal dimension, the calculation results are summarized in Table 7.

Table 7. Yangtze River ports rating scale fractal dimension Results（2004-2011）

year	Formula	D	R^2
2004	$y = -1.2918x + 0.0977$	0.7741	0.9801
2005	$y = -0.9127x + 0.0323$	1.0957	0.9592
2006	$y = -0.8718x - 0.1243$	1.1471	0.9800
2007	$y = -0.9673x + 0.0607$	1.0338	0.9903
2008	$y = -0.9636x + 0.1083$	1.0378	0.9594
2009	$y = -1.1382x + 0.1820$	0.8786	0.9710
2010	$y = -1.1818x + 0.1433$	0.8462	0.9732
2011	$y = -0.9782x + 0.1310$	1.0223	0.9326

4 Conclusions

Data can be obtained in the above table, the correlation coefficients were greater than 0.93, indicating good correlation, indicating that the size distribution of the middle reaches of the Yangtze River port has obvious fractal characteristics, using fractal theory for analysis and research in the area Scale Structure of the port, which has a positive significance . Based on this, we should enhance the influence and the economic effect of the first ports to promote the development of all ports on the middle reaches of the Yangtze River, to create a thriving situation of the middle reaches of the Yangtze River ports. Specifically, we should focus on our attention to improve the economic effect of the port of Wuhan port and Yueyang port, make efforts to improve the first degree level of the two ports, make use of their advantages to promote the development of other ports in the middle reaches of the Yangtze River, to achieve a comprehensive and balanced development of the middle reaches of the Yangtze River port.

Abstract: Large passenger transfer hub tends to have complex architectural spaces, wayfinding system plays a positive role in improving the service level of transfer and encouraging travelers to choose public transport. Based on the complexity of building space features and requirements of hub management function, the design of pedestrian-oriented signage system essentially can be summarized as complex decision problems. However, there are few researches on the determination of the locations and the content in order to make an acceptable wayfinding to all participants, especially considering the public transport priority and the sustainable finance. Aiming at this problem, the technique of multi-objective optimization is used as the core tool. The method converted this complex system decision problem into mathematical models based on three objectives (maximizing the level of space-guided, minimizing the financial investment, and minimizing the guidance distance).

Keywords: Design of pedestrian-oriented signage system; Transfer hub; Public transport priority; Sustainable finance.

1 INTRODUCTION

Contacting inside and outside, large passenger transfer hub is an integral part of a modern city. Transfer is the core function of a hub, which tends to have complex architectural spaces and uncertain visual conditions. The complex transfer conditions make travelers more easily confused. S. C. Wirasinghe (W.H.K. Lam, 2003) mentioned that most of travelers rely on pedestrian-oriented signage system except to ask people in wayfinding process. Signage system can ensure travelers have a clear guided in space and orientation in hub.

Design, content and location are key factors influencing whether people can effectively use pedestrian-oriented signage system (Arthur P, 1992). Existing theory has maturely study typesetting, fronts, and colors. As an important part, they have played an active role. But the wayfinding process has its logic including decision-making, implementation and final confirmation to reach the target point.

The process is completed collaboratively by many signage, which emplaced in different locations in transfer hub. The contents of each signage are also largely determined by their position.

As urban traffic congestion problem in China is getting worse, experts and government officials generally considered that a priority development of public transport is an effective way to solve traffic problems (Yanjie Ji, 2004; Xiaoyan Yan, 2007). Public transport in the city as a lever to reduce the amount of traffic demand can achieve the balance between transport infrastructure development and the growth of traffic demand. How to make the strategy of public transport priority to the level of signage system designing is lack of effective quantitative methods.

Both the strategy of public transport priority and sustainable finance to take into account to the design of signage system is a complex joint decision-making problem. From the point of existing research abroad, only little research has addressed the holistic research of oriented signage system, especially in the aspect of using mathematical methods to solve the determination of location and content. Subjective experience of designers, conceptual framework, and specific strategies are marked as a basic to design, which lack of quantitative analysis. Aiming at this problem, this paper develops a mathematical model to research the design of signage system in large passenger transfer hub from the overall perspective. The two core elements involving contents and location are optimized. The paper is organized as follows. Section 2 gives a literature review on holistic study in past and recent years. A multi-objective optimization model of the system design is presented in Section 3. The conclusions and suggestions for future research are given in Section 4.

2 RELATED LITERATURES

The research of signage system focuses on three aspects in the followings: design of signage, relationship between signage and wayfinding process, and assessment of oriented system. The design of signage includes their own attributes and the use of holistic design. The research in this paper belongs to the later, which considers public transport priority and sustainable finance.

Over the years, there is an in-depth research in the standardization of signage itself properties (Manual on Uniform Traffic Control Devices, 2009; BS 8502-2003, 2003), and China also developed the industry standard according to its own national conditions (GB/T 20501-2006, 2006). Wang (Zhe Wang, 2011) proposed that the ideal typesetting of information on the sign is not more than 3-4 lines, and the similar information should be summarized to a group.

But the more important is location and content when we study the use of holistic design. On the view of Arthur and Passini (Kevin Lynch, 1960; Passini R., 1996), wayfinding is the behavior to reach the destination in the space. The behavior can be used to determine location, content, and other design elements. Due to the different structure of the building, the flat is divided into different functional areas. Literatures

(J.R. Carpman, 1991; Xu H. & Kazuhiko N, 2002; Alice Beneicke, 2003; Caves, R.E., 2001; Seunghae Lee, 2014) conducted a detail study of the pedestrian-oriented signage system in libraries, museums, hospitals, terminal and other pedestrian distribution spaces. Series theory of the oriented signage system design based on wayfinding behavior and path selection was developed, and there were detailed design plans and steps according to needs of different places. Obviously, the wayfinding behavior provides an experimental method in the design of oriented signage system.

Meanwhile, scholars focused on the point of optimal decision to determine the layout of signage. Tam (Mei Ling Tam, 2011) attempt to tackle the problem of determining the appropriate locations for placing directional signs in airport terminals or other enclosed environments, with an objective of maximizing the visibility index (VI). Professor Zhang (Dongqing Han, 2008; Yanxin Han, 2010) carried out the initial pedestrian-oriented signage system design and optimization studies in Beijing South Railway Station. The model took the maximum of guidance levels as the objective, then used intelligent algorithms, which include genetic algorithms and simulated annealing algorithm to optimize the location choice in internal space. The model has a good exploration to solve the location problem in the design of oriented signage system. But in fact, the optimization of location faces different objectives, and the model using single target may get poor results in the other standards. People are more willing to accept the program that takes all aspects into account rather than pursuit the strictly optimal solution in only one objective. On these basis, Ling (Yu Ling, 2013) develops the optimization model which contains two optimization objectives, i.e., maximizing the level of space-guided and minimizing the guidance distance, and design an Infeasibility Degree Selection Operation which is inducted into Non-dominated Sorting Genetic Algorithm Ⅱ. However, the above models did not take both the strategy of public transport priority and sustainable finance into account. Still, these researches provide impressive suggestions to the design of pedestrian-oriented signage system, which inspired the model to be established below.

3 METHODOLOGIES

3.1 Description of the Problem

There are series alternative locations and several destinations in a large passenger transfer hub (**FIGURE 1**). The setting principles of alternative locations as follows: a. nodes in the conversion, b. based on the requirements of the continuity of guidance and psychological effects on the pedestrians, an alternative location set every i meters in a continuous sidewalk. Generally i values 30. An alternative location refers to positions in the space that may be set signage. Destinations refers to positions in the space that pedestrian may go to, such as the metro entrance, bus terminals, coach station entrances. All alternative locations compose the initial position set.

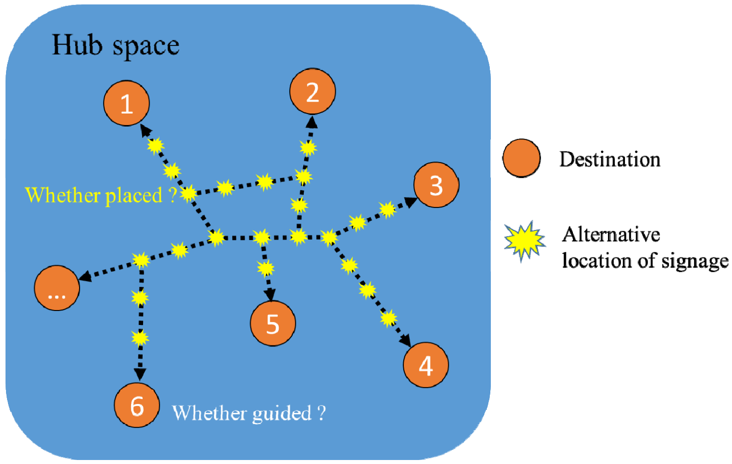

Figure 1. The conceptual model of pedestrian oriented signage system in hub

We can use two variables in Table 0-1 to express decision-making, which contains the location and the content.

$$X_a = \begin{cases} 1, & \text{set signage at the a alternative location} \\ 0, & \text{do not set signage at the a alternative location} \end{cases} \quad (1)$$

$$Y_{ab} = \begin{cases} 1, & \text{imformation in signage} \\ & \text{at the a alternative location contains the destination point b} \\ 0, & \text{imformation in signage at the a} \\ & \text{alternative location does not contain the destination point b} \end{cases} \quad (2)$$

Where a represents the alternative location, $a = 1,2,3,\cdots,m$. b represents the destination of travelers in the large passenger transfer hub, $b = 1,2,3,\cdots,n$, the hub here refers to building functional areas with a certain boundary which has a significance to set signage system.

In the actual the project, there will be a variety of signage with different functions such as comprehensive signage, grade one signage, grade two signage. Each signage can contain a different number of destinations. In order to count funding investment, the model does not consider the hierarchical functional differences among signage. This principle of simplification of signage in every alternative location as follows: a. for each alternative location, the number of signage do not exceed j, generally j values 4, b. for each signage, the number of destination that can accommodate up to k. The number of signage at each alternative location can be expressed by the formula below.

$$Z_a = \left\lceil \sum_{b=1}^{b=n} Y_{ab} \Big/ k \right\rceil \quad (3)$$

The optimization of pedestrian-oriented signage system can be described: according to the optimization objectives, select set A from the alternative locations, which the total number is m. While for each $a_0 \in A$, select set B_{a0} from the destinations which the total number is n.

3.2 Mathematical Model

(1) Multi-objective function

There are several management agencies and departments affecting the decision-making in the design of pedestrian-oriented signage system. The precondition of the overall objective is congruence, but various departments and agencies have their own separate or conflicting objectives. There are three departments affecting optimal decision in Shanghai South Railway Station Program: Shanghai South Railway Station Management Committee (management department), Construction and Transportation Committee of the Shanghai Xuhui District (investment department), travelers (pedestrian).

Management Department What the management department concerned is the efficiency of passenger transfer hub and the reflection of public transport priority. Due to limitations of ability for pedestrian to capture oriented information at an alternate location (too much setting of signage can cause pedestrian to stop to search for information, resulting in obstruction and congestion), the level of guidance cannot be improved by increasing the amount of information density and enlarging the distribution density. So the level of guidance is the average value of each location that is determined to emplace. The essential function of signage system is also here. We can use the function expressed as:

$$maxS_1 = \sum_{a=1}^{a=m} \sum_{b=1}^{b=n} (X_a * Y_{ab}) \Big/ \sum_{a=1}^{a=m} X_a \tag{4}$$

Meanwhile, another important goal for management department is to encouraging more travelers to choose public transport, i.e. the level of public transport priority. That is different destinations in the same space achieve different social value, and the importance for meeting the social needs of public transport to each destination is different. To each destination, we can use a coefficient to represent the degree of importance for implementation of public transport priority. Here we called it public transport priority factor T_b. The first objective function is to give:

$$\max S_2 = \sum_{a=1}^{a=m} \sum_{b=1}^{b=n} (X_a * Y_{ab} * T_b) \Big/ \sum_{a=1}^{a=m} X_a \tag{5}$$

Where T_b is the public transport priority factor, the principle of its value is as follow.

$$T_b = \begin{cases} 1, & \text{the destination } b \text{ is not public transport} \\ 1.5, & \text{the destination } b \text{ is public transport} \end{cases} \tag{6}$$

Investment Department Investment departments hope to achieve a minimum total construction costs, i.e. the number of signage in the entire hub is minimum. The objective function is:

$$\min S_3 = \sum_{a=1}^{a=m} \left\lceil \sum_{b=1}^{b=n} Y_{ab} \Big/ k \right\rceil * h \tag{7}$$

Where h as the price of each signage.

Travelers For travelers, the goal of oriented signage system is to guide the minimum distance. An alternate location do itself best to contain its nearest destination-oriented information. Without considering the importance of the destination, the nearer one needs to be firstly included in the content for an alternate location. This is because when people see pedestrian-oriented information, the destination guided is psychologically regarded as close to themselves that has been widely recognized in the actual emplace of oriented signage. A maximize functions can be used to represent as follows:

$$\max S_4 = \sum_{a=1}^{a=m} \sum_{b=1}^{b=n} (X_a * Y_{ab} * 500) \Big/ L_{ab} \tag{8}$$

Where $L_{ab}(a = 1，2，\cdots，m；b = 1，2，\cdots，n)$ is represents the distance between an alternative location *a* and the destination point *b*. Because there is a gross floor area of destination, it can be seen as the shortest linear distance between the alternative location and the boundary of destination. Large transfer hub often have vertical transfer bottleneck. When calculating L_{ab}, the research uses the model of pedestrian traffic flow - analysis of per capita space according to the literature (Highway Capacity Manual, 2000). The stairs facilities and escalators facilities can be converted to distance calculated by walking according to the design capacity.

(2) Constraint conditions

1) Each destination must appear at least once.

$$\sum_{a=1}^{a=m} \sum_{b=1}^{b=n} (X_a * Y_{ab}) > 0 \tag{9}$$

Formula (9) constrained the worst scenario that pedestrian find a destination. For each destination, it must be appears at least once in all of the signage. Otherwise, pedestrians will not be able to find the destination through the oriented signage.

2) Inherent relationship Constraints are:

$$\sum_{b=1}^{b=n} Y_{ab} = 0\,, \qquad X_a = 0 \tag{10}$$

$$\sum_{b=1}^{b=n} Y_{ab} > 0\,, \qquad X_a = 1 \tag{11}$$

$$\left\lceil \sum_{b=1}^{b=n} Y_{ab} \Big/ k \right\rceil < j \tag{12}$$

Formula (10), (11) constraints natural properties among the location, the content and the quantity. When an alternative location is not to be selected as an emplaced location, it cannot include the information of any destination. When an alternative location is to be selected as an emplaced location, it contains at least one destination. Formula (12) constraints the number of signage at each alternative location which described in the foregoing.

4 CONCLUSIONS AND FUTURE RESEARCH

This study provides a scientific method on how to emplace the location and the content of pedestrian-oriented signage system in large passenger transfer hub. The method converted this complex system decision problem into mathematical models based on three objectives (maximizing the level of space-guided, minimizing the financial investment, and minimizing the guidance distance).

However, the model ignoring the different function of signage is a weakness of this study. In addition, signage setting and the guiding route are closely related. Determining an optimal line in multiple routes to reach the destination in the hub must consider the pedestrian traffic flow and channel capacity. And another is to find an efficient algorithm for the optimization model to verify their logical in the design. These factors should be taken into account in future studies.

Abstract: Based on the analysis of drivers' gap acceptance process of roundabout, the video was used to record drivers' choice behavior when the vehicle entered roundabouts. Through the statistics and analysis of survey data, the results indicated that the gap acceptance behavior can be described by binary choice model—model. The calculation method of critical time headway was given which related with space headway and speed of the rear vehicle on major road. A conclusion was derived that the critical space headway would increase when the vehicles' speed on the major road increased from the calculation results by use of SPSS software.

Keywords: Roundabouts; Critical gap; Binary Logit model; Time headway; Space headway.

1 Introduction

The minimum time headway on the major road is critical gap when a vehicle on minor road enters the priority-controlled intersection. Critical gap is an important parameter which affects the capacity and delay. For roundabouts, it is the minimum value which entry vehicle can enter the circular lane using circular vehicles' time headway. The entry is minor road and the circle lane is major road on roundabouts.

A lot of research about critical gap has been introduced. Plus thought that critical gap decreased when drivers' waiting time increased and their relation curve looked like S shape. The experimental model of critical gap was built. Hammed et al. found the distribution type of time headways on major road vehicles was related to waiting time, drivers' social and economic circumstance, following-up headway, travel objective and so on. The average critical gap is related to conflict flow rate, lane amount of entry, the proportion of turn-left and the velocity of major road vehicles. They built the multiple regression model of critical gap. Based on the hypothesis of negative exponential distribution of time headway on major road and normal distribution of critical gap and accepted gap, Ashworth's method analyzed the distribution character of accepted gap, the average critical gap and variance. Miller derived calculation equation of critical gap based on Ashworth's method when critical gap followed γ distribution. Raff regarded the point of intersection between accumulative accepted gap curve and accumulative rejected gap curve. Raff's method was used in many countries. Brilon et al. pointed the siegloch's method could be only used in saturated flow condition.

Most of the methods were suitable of unsaturated condition. Lag method can be only the theoretical reference value. Logit process method used the similar process to the logit method of traffic planning. Probit method is partial when only considering normal distribution of critical gap because there is remarkable error for normal distribution of critical gap. Hewitt method is the further method of Probit process which calculation software is GAPTIM and PROBIT. The maximum likelihood method has a symphysis that all of accepted gap, maximum rejected gap and critical gap follow normal distribution, and estimate the average value and variance by use of the maximum likelihood method of probability theory.

2 Gap acceptance model of roundabouts

Every vehicle on the minor road needs to choose whether entering the intersection or not. So the gap acceptance operation can be described by Logit model.

$$\begin{cases} P_a = \dfrac{1}{1 + exp - (b_0 + \sum_{i=1}^{k} b_i x_i)} \\ P_r = 1 - P_a \end{cases} \tag{1}$$

Where P_a is accepted probability, P_r is rejected probability, x_i is influencing factor.

Factors which influence gap acceptance operation include space headway, time headway and velocity of rear vehicle on major road of roundabouts.

3 Evaluation of model parameters

The survey result only included rejection or acceptation of vehicles on minor road.

$$\begin{cases} y_i = 1 & \text{the vehicle rejected to enter the roundabout } i \text{ th time} \\ y_i = 0 & \text{the vehicle entered the roundabout } i \text{ th time} \end{cases}$$

For the ith gap acceptance operation, space headway, time headway and velocity of rear vehicle should be recorded.

The likelihood function can be derived by equation (1)

$$L^* = \prod_{i=1}^{N} P_a^{y_i} P_r^{1-y_i} \tag{2}$$

The equation (2) was taken the logarithm. It can be derived as follow

$$L = \mathrm{Ln}(L^*) = \sum_{i=1}^{N}[y_i \mathrm{Ln}(1 - P_a) + (1 - y_i)\,\mathrm{Ln}\,P_r] \qquad (3)$$

4 Application example

Fuming Square is a roundabout in Shahekou Distribution, Dalian and it was chosen as survey object. Vehicles flow were unsaturated flow for not rush-time, which can avoid disturbance to survey data. Survey data are is displayed as Tab.1.

Tab. 1 Survey data of Fuming Square (part)

time headway(s)	Space headway(m)	velocity of rear vehicle(m/s)	acceptance(1) /reject(0)
2	11	4.4	0
4.89	20	3.6	1
3.96	7	2.85	0
2.12	7	3.1	0
3.89	12	2.85	0
3	22	2.6	1
3.12	10	2.5	0
3.86	18	2.4	1
3.24	17	5	1
4.23	12	3.6	1

Tab. 2 Estimated values of parameters

parameter	Estimated value
β_0	-2.815
β_1	-0.382
β_2	1.188
β_3	0.111

The result can be found that drivers were inclined to accept larger space headway and enter the roundabout when the rear vehicle traveled slower. The follow model can be derived based on estimated values.

$$\begin{cases} P_a(s,v,t) = 1/\{1+\exp[2.815-1.188t+0.382v-0.111s]\} \\ \mathrm{P_r}(s,v,t) = 1-P_a(s,v,t) \end{cases} \quad (4)$$

Where, s is the space headway, v is the velocity of the rear vehicle on major road or roundabout, t is the time headway

The analysis result can be applied in the determination of the critical gap of roundabouts because the survey involved minor road drivers' choice whether to enter the roundabout.

For a fixed choosing probability ∂，$(0<\partial<1)$，the follow equation can be derived from equation (4)

$$P_a(s,v,t) = 1-\partial \quad (5)$$

The critical time headway is as follow when the velocity of the rear vehicle was determined.

$$t_a = \{\ln[(1-\partial)/\partial]+2.815+0.382v-0.111s\}/1.188 \quad (6)$$

When ∂=0.5,

$$t_a = (2.815+0.382v-0.111s)/1.188 \quad (7)$$

The results were as Tab. 3 for different velocities.

Tab. 3 Critical gap for different velocities

Velocity (km/h)	T1 (s)	T2 (s)	T3 (s)
22	3.83	3.36	2.89
24	4.05	3.58	3.12
26	4.22	3.75	3.29
28	4.40	3.93	3.46
30	4.58	4.11	3.64
32	4.76	4.29	3.82
34	4.93	4.47	4.00
36	5.11	4.65	4.18
38	5.29	4.82	4.36
40	5.47	5.00	4.54

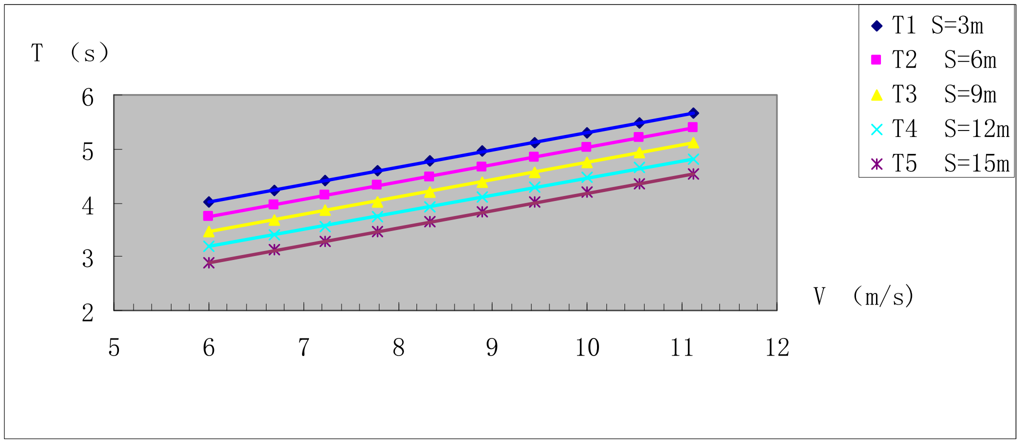

Figure 1. When the space headway is same, the critical gap for the different velocities

According to the Figure 1, when the space headway is same, the critical gap became lager with the increase of rear vehicle velocity. The increase of the critical gap shows that the branch entry the roundabouts become more difficult. In Figure 1 the five lines represent the critical time headway when the space headway is 3 m, 6 m, 9 m, 12 m, 15 m. It shows that in the same vehicle velocity, the critical gap will decrease with the increase of the space headway. What can be also interpreted that the increase of the space headway make the branch flow into roundabouts more easier, so the critical gap will be reduced.

The critical time headway is as follow when the space headway was determined. The results were as Tab. 4 for different space headway.

Tab. 4 Critical gap for different space headway

Space (m)	T1(s)	T2(s)	T3(s)	T4(s)	T5(s)
5	3.83	4.15	4.47	4.79	5.11
6	3.73	4.05	4.38	4.70	5.02
7	3.64	3.96	4.28	4.60	4.93
8	3.55	3.87	4.19	4.51	4.83
9	3.45	3.77	4.10	4.42	4.74
10	3.36	3.68	4.00	4.32	4.65
11	3.27	3.59	3.91	4.23	4.52
12	3.17	3.49	3.82	4.14	4.46
13	3.08	3.40	3.72	4.04	4.37
14	2.99	3.31	3.63	3.95	4.27

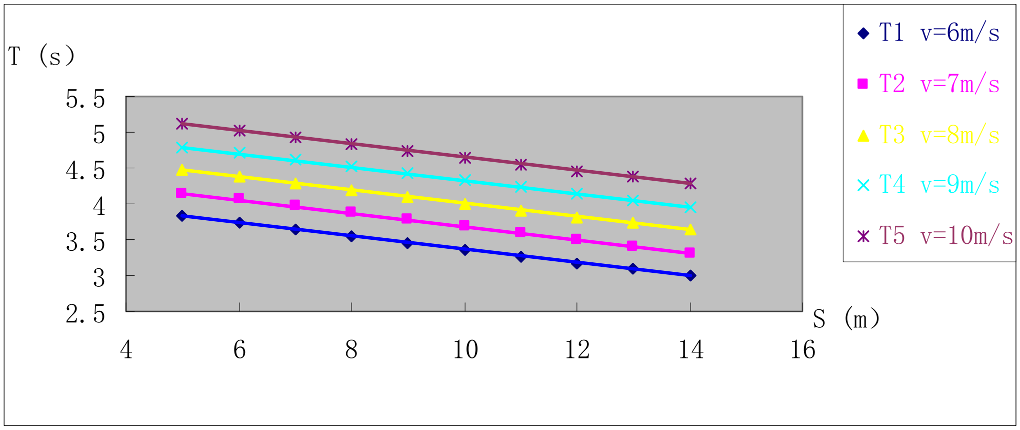

Figure 2. Under the condition of the same vehicle velocity space headway, the critical gap acceptance for the different space headway

Figure 2 is established on the rear vehicle velocity been given. Although, the graphical line in Figure 1 and Figure 2 are different, we can have the same conclusion. Drivers' operation of minor road was influenced by travel distance. The important parameter is critical gap. Regression analysis can be applied to obtain the gap acceptance model of roundabouts. Different parameters' influence to entering probability can be derived by numerical simulation. The critical gap became larger with the increase of rear vehicle velocity, which meant drivers on the minor road were inclined to reject the gap. In general the safety space headway for vehicle through the roundabout is 10 m. So the critical gap lied in the range of 3.36-4.65 s when the velocity is from 6 m/s to 10 m/s with the safety space headway.

5 Conclusions

Conclusions can be obtained that influence parameters to gap acceptance involve space headway and velocity of the rear vehicle on roundabouts. Drivers were inclined to enter roundabouts when space headway or time headway increased. The critical gap will increase when the velocity of major road increased. Drivers' estimations were different for different velocity because different drivers' operational characters.

The Present Situation, Problems, and Prospects of the Nanchang Bus Special Service Corporation

Shuli Deng

School of Economy and Management, East China Jiaotong University, P.O. Box 330013, Jiangxi, China. E-mail: dengshuli@ecjtu.jx.cn

Abstract: With the development of transportation, the car has become an indispensable traffic tools in daily work and life. Bus special service problem is one of the hot issues of concern. Because of its fast speed and low cost, more and more large enterprises realized the importance that they can reduce production cost through the use of special service. With the tailored charter services for the enterprise, the bus special service corporation can provide the enterprise with low production cost and safe service. It is very conducive to achieve the development goals of the enterprise. In January 1, 2013, Nanchang Bus Special Service Corporation formally established that is the supplement and improvement of city public traffic. At the same time, it also marks the Nanchang bus special car will enter into standard unified management that was defected from the operating company of decentralized management. The author mainly analyzes the present situation, problems and Prospect of Nanchang bus special Service Corporation, through the use of comparative data on the detailed explanation to put forward some suggestions that can provide reference for the development of other city's Bus Special Service Corporation.

Keywords: Bus special service; Transportation way; Nanchang Bus Special Service Corporation; Prospect.

1 Introduction

With the diversification of transport vehicle and complicated transport network, there is a difficult problem how to transit special service to make their own innovation and characteristics. If the bus special service is a choice buy, it will directly affect the enterprise cost and enterprise benefit. Bus special service has become a trend and a basic way of existence that modern enterprise save the cost of production. More and more enterprises treat it as an approach and means to reduce the cost of production. Bus special service become a breakthrough in the bus company for marketing innovation, it is a tailored bus service to meet some special people's needs. On the other hand, the bus special service is changing the traditional way of travel. It can bring great convenience for the development of large enterprises and has become a new transportation way of general approval of enterprise. In order to conform to the trend of The Times, Nanchang Bus Special Service Corporation formally established that is the supplement and improvement of city public traffic in

January 1, 2013. At the same time, it also marks the Nanchang bus special car will enter into standard unified management that was defected from the operating company of decentralized management. The author mainly analyzes the present situation, problems and prospect of Nanchang Bus Special Service Corporation, through the use of comparative data on the detailed explanation to put forward some suggestions that can provide reference for the development of other city's Bus Special Service Corporation .

2 Current Status Analysis of Nanchang Bus Special Service Corporation

2.1 The current status of Nanchang Bus Special Service Corporation

With the development of the city public transportation, the special bus appears. It is in the charge of the operating company that is the subordinate company of the General Corporation of Public Transport. In recent years, there is an expansion trend of development in Nanchang city and has formed the suburbs, the industrial zones, campus etc. At the same time, it is hard for the coverage of city bus network. With the establishment of bus special service corporation, we will overcome some shortcomings including original process of special bus, bad service and so on. What's more, we can strengthen the management of the special bus and standardize the demand of the market in order to form the service of special bus.

In order to adapt to the changing of market situation and development needs, the company provides customers with all kinds of low and medium high-grade car and differentiated services to meet the social needs. Meanwhile, to meet the needs of different groups, the company makes a variety of business plans according to customers' requirements. There are nine special services in the Nanchang Bus Special Service Corporation, including services for large conferences and big activities designated by government departments; charter services for Large and medium-sized enterprises; charter services for All kinds of schools(spring and autumn activity, exams etc.) ; fixed bus services for large supermarkets; directional bus services for holiday celebration, conference and exhibition; services for cultural and sports activities; charter services for the public with a variety of cars; services for wedding. It is reported that the company provide special services for the Provincial Department of land resources, the city intermediate people's Court of Jiangxi Province, Xinhua printing factory, Transformer Co. Ltd.and so on. It is proved that the Nanchang Bus Special Service Corporation can provide high quality charter services for the society.

As we all know, special bus need a professional vehicle operation management team. To ensure the safety of operation, the corporation provide every car with GPS intelligent monitoring equipment in order to monitor the real-time speed, ensure the safe operation of the vehicle and avoid operating vehicle safety risk for the customer. At the same time, the special bus driver can receive professional training to get rich driving experience. In order to unify the construction of a specification of the special team, the company will always adhere to the "fine management, scientific development" business philosophy. Taking internal quality, outside image, scale operation, professional management, professional team, quality service and high-end technology resources advantage into consideration, we can create a new corporate image and make unremitting efforts for the overall development of Nanchang Bus Special Service Corporation.

2.2 The analysis of operating income of Nanchang Bus Special Service Corporation

Comparing with the cost of plan, the three kinds of consumption cost exceed frequently. According to the data, we find the main reason is that most of the bus before handover to the special company vehicle mechanical problems, even some vehicles have been unable to run normally, need to change battery, tires, but the company's operation kilometers cost plan has been to the operation of the company, so the company of the cost of maintenance repairs and tires than plan will increase.

According to the relevant statements of the company in 2014, there are four parts of operating costs. The first part includes the wages and bonuses of the drivers and management staff accounting for about 51%; the second part includes three big consumption(fuel, maintenance fee, tire) accounting for about 34% of operating costs; the third part includes the vehicle depreciation accounting for about 11% of operating costs; last part accounts for 4%. Comparing with the plan costs, the second part exceeded. The main reason is that many buses have mechanical problems, even some vehicles have been unable to run normally that need to change battery and tires before they were moved to the corporation. But the operating cost plan of the general corporation was put to the operating corporation. The cost of maintenance and tire will increase.

In addition, the annual plan income was 25 million yuan(including tax) issued by the general corporation in 2014. Until November in 2014, the actual income of Nanchang Bus Special Service Corporation was about 21 million yuan. Comparing with the annual plan, they completed the 95% plan. Comparing with the same period in 2013, the operating income increased 14 million yuan by 200%. Finally, the actual profit was the lost of 0.64 million yuan that reduced 1.23 million yuan with the adjusted plan.

2.3 The marketing of Nanchang Bus Special Service Corporation

There were 19 new special kinds of rental customers in the first half of 2014 units, which added 13 in the first quarter, second quarter increased by six, 41 new special cars. Nanchang Bus Special Service Company is actively negotiating with Nanchang Brewery, Taihao Anime, the people's bank of China and so on. The quantity of these institutions is relatively large and the average is about 5 or more.

Recently, the corporation aimed at Jiangling Group, Nanchang Jingsheng Cigarette Factories, Photo-voltaic, Aviation Group, RT-mart and other large transport unit, through various channels to be completed, but the effects were not significant. You can't image how complex the relation is!

In August 2014, expanding the scope of the"Huang Biao" limit line of Nanchang city, Nanchang Bus Special Service Corporation took this opportunity to seize the "yellow marked vehicle market". On September 1, 2014 in Jiangxi province, in order to strengthen the management of school bus safety, all middle school, primary school, nursery school shall use standard vehicles prescribed by the state. With the two points, there is new market opportunity for bus special service.

3. The Problems Existing in the Nanchang Bus Special Service Corporation

3.1 Shortage of drivers

As the city scale expands unceasingly, people travel demand for bus is becoming more and more big, but the bus driver is very scarce, even become the bottleneck of the public transport development. Those drivers work hard but they are not easy to get social recognition. On the other hand, it is very hard to get the driving license of A2. It resulted that there was in the shortage of special bus drivers.

Through the active efforts to develop the market, the volume increase gradually, but the driver's serious vacancies to keep pace with the development of the business. The Nanchang Bus Special Service Corporation is in a very passive situation.

3.2 The mobilization of drivers frequently

For safety operation and good services, the corporation made strict appraisal system that lead to some drivers who voluntarily apply for the redeployment of operating company. Because they thought that they got low wages but should obey strict rules. On the other hand, the operating corporation made promise to offer good wages and good promotions. A large number of drivers left that made serious influence to the operation of Nanchang Bus Special Service Corporation. To make matters worse, many drivers are not willing to renew contract.

3.3 Driver's self-management and self-discipline ability is poor

Because most drivers don't get higher education and ignore the importance of safety operation, they have some weakness including illegal behavior and violations. The driver's safety awareness has direct contact with safety of operation. The management of the corporation and all staff should pay much attention to it and take some actions to solve this problem.

4. Countermeasures of Nanchang Bus Special Service Corporation

4.1 Revision of relevant assessment system

Every driver is equipped with one car in the corporation. According to the rule of the General Corporation, if the driver has the red light violation behavior, he or she will be published that he or she must learn and stop driving for one month. In fact, there are not enough drivers for special bus service. Therefore the corporation revised the relevant management system, adjusted the assessment methods and made economic punishment according to the actual situation.

4.2 Strengthen the collection of funds

As we all know, it is very important work to collect funds for the corporation. Now, there are some people that are responsible for collection of special car business and scattered charter business. At the same time, the management of the corporation made the timetable of charter fund and the inspection regulations.

4.3 Adjustment of the salary rationally and stablement of driver team

According to different special line, the corporation made study on workload and the work difficulty. It took some drivers long time to go back to the corporation if they stop the bus in rental company. There are mangy plugging point for some special lines. How to solve these problems? In order to ensure the rationality of the salary structure, the Nanchang Bus Special Service Corporation try their best to collect the data to adjust the structure o the salary in order to stabilize the driver's team.

4.4 Strengthen the driver safety monitoring

According to the characteristics of operation of the wide regional special car line and he vehicle more scattered distribution, Nanchang Bus Special Service Corporation made many efforts to strengthen control of traffic situation. According to the non violation, illegal driving, mixed sections, they made such as early, lately inspection, and increased the strength of the inspection to the parking lot with cross examination and branch checks. Meanwhile, they made strict assessment of the vehicle and the driver for not complying with the provisions and the existing problem of the park.

4.5 Strengthen the driver safety training and education

Nanchang Bus special Service Corporation will continue to carry out "safety month" activities issued by the General corporation, to increase the "safety month" campaign, to analyze and explain the various types of accident case recently happened in the General corporation and the Nanchang Bus special Service Corporation.

5 Conclusions

The gold will shine. Nanchang Bus special Service Corporation will show the charm of its own in the city transportation. We need to explore its own path of development and to adopt a pragmatic, trial-and-error approach for its service program. We can learn from foreign bus company. On the other hand, we will try our best to provide different passengers with service diversification, private custom and so on. Finally, we will gain a foothold in the fierce competition in the city transportation market.

Energy-Efficient Train Control: Analysis of Local and Global Optimization

Chuan Li; Yun Pu; and Liwei Duan

School of Transportation and Logistics, Southwest Jiaotong University, Chengdu 610031, China. E-mail: chuan@my.swjtu.edu.cn

Abstract: In view of the hold phase in front of and behind the uphill or downhill of a track, the optimal switch point with Local optimal algorithm is not the one with the least cost. This paper finds its deficiencies, and presents an improved method to be applied in the global optimization to minimize the energy costs.
Keywords: Optimal train control; Energy efficient.

1 Introduction

Because of the rising energy prices and environmental concerns, the energy efficiency of transportation system becomes more and more important. Many people have taken part in the optimal train control to minimize the energy consumption (Howlett, 1995; Cheng, 1999; Khmelnitsky, 2000; Liu, 2003; etc).

The problem is to minimize the energy required to drive a train from one station to the next within a given time. The optimal strategy is essentially a *power-speed hold-coast-brake* strategy. The main energy cost is at *power* and *speed hold phase*. For long distance when *speed hold*, the control strategy will be interrupted by some uphill sections or downhill sections. Hence the optimal strategy becomes an optimal switching strategy. Considering the necessary conditions for optimal switching with Pontryagin analysis, Howlett et al. have shown that the switching points can be determined for each steep section by minimizing an associated local energy functional (Albrecht, 2011; Howlett, 2009; Zhou 2010).

They all deemed that for each feasible journey time, optimal strategy is unique, and using the local optimization to find switching points, the global optimal strategy could be obtained.

In view of the cost of hold phase, we find its deficiencies. The algorithm could not simply be applied in the local and global optimal strategy.

2 Model description and review

For a point mass train the equation of motion can be written as (Howlett, 1995):

$$vv' = \frac{p}{v} - q - r(v) + g(x) \quad (1)$$

where: x is the position of the train, $v=v(x)$ is the speed, $p=p(x)$ is the controlled power per unit mass, $q=q(x)$ is the controlled braking force per unit mass, $g(x)$

is the component of gravitational acceleration due to the track gradient at point x, $r(v)=a+bv+cv^2$ is the resistance force per unit mass. The total time taken is:

$$t(x)=\int_0^x \frac{1}{v}\,\mathrm{d}\,x \tag{2}$$

where: $v = v(x)$ is the solution of the equation of motion.

The cost is usually taken to be the total fuel consumed by the train. We assume that power per unit mass is directly proportion to the rate of fuel supply. The cost $J = J(x)$ is

$$J(x)=\int_0^x \frac{p}{v}\,\mathrm{d}\,x \tag{3}$$

The power per unit mass $p(x)$ is bounded with $0 \le p \le P_{max}$. The braking force per unit mass $q(x)$ is bounded with $0 \le q \le Q_{max}$. The cost of braking is generally ignored.

Write $\varphi(v) = v \cdot r(v)$, where $\varphi(v)$ is strictly convex with $v \ge 0$. Write $\psi(v) = v^2 \cdot r'(v)$, where $\psi(v)$ is strictly increasing with $v \ge 0$. Write $L_V = \varphi(V) + \varphi'(V)(v-V)$. V is the constant speed at hold phase.

3 Local optimal algorithm

The Hamiltonian is defined by

$$H=\frac{\beta-p}{v}+\frac{\alpha}{v^2}\cdot[p-qv-\varphi(v)+gv] \tag{4}$$

The adjoint variables $\alpha=\alpha(x)$, $\beta=\beta(x)$ are solutions to the differential equations:

$$\alpha'=\frac{\beta-p}{v^2}+\frac{\alpha}{v^3}\cdot[2p-qv-\varphi(v)+\varphi(v)+gv] \tag{5}$$

$$\beta'=0 \tag{6}$$

It is known that, on level track, the optimal strategy is *power-hold-coast-brake.* But, on steep track, the *hold phase* is interrupted by one or more *power phases* on the steep uphill section and one or more *coast phases* on the steep downhill section. Then, we expect that the optimal control should switch form *hold* to *power* at some point $x = a$ before the steep section and from *power* to *hold* at some $x = d$ beyond the steep section. It is shown in Figure 1. We define $\eta = \alpha/v-1$ and assume the optimal profile $v(x)$, then

$$\eta' - \frac{\psi(v)+p}{v^3}\cdot\eta=\frac{\psi(v)-\psi(V)}{v^3}$$

with $\eta(x) > 0$ for $a < x < d$, $\eta(a) = \eta(d) = 0$.The switch point is at a, $v(a) = v(d) = V$ and $\eta'(a) = \eta'(d) = 0$.

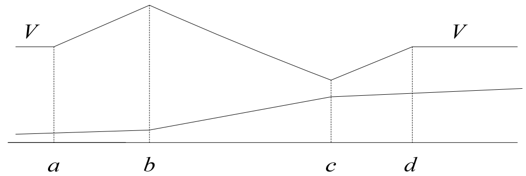

Figure 1. Optimal speed profile on steep uphill

Howlett (2009) and Zhou (2010) designed a function $J_e(v)$ to find the switch point. Consider a track with piecewise constant gradient with $x_0 < x_1 < x_2 <\ldots< x_{n+1}$ and $g(x) = g_j(x)$ for $x_j < x< x_{j+1}$, and where we suppose there is a steep uphill section (b,c), with $x_1<b<c<x_n$, and the switch points a, b, with $x_0 < a < x_1$, $x_n < d< x_{n+1}$.

$$J_e(v)=\int_V^{v(x_1)}\frac{[\varphi(v)-L_V(v)]v}{p-\varphi(v)+g_0 v}\,dv+\int_{v(x_n)}^{V}\frac{[\varphi(v)-L_V(v)]v}{p-\varphi(v)+g_n v}\,dv+\sum_{j=1}^{n-1}\int_{v(x_j)}^{v(x_{j+1})}\frac{[\varphi(v)-L_V(v)]v}{p-\varphi(v)+g_0 v}\,dv$$

$$x(v_{j+1})-x(v_j)=\int_{v(x_j)}^{v(x_{j+1})}\frac{v^2\,dv}{p-\varphi(v)+g_j v},\ j=1,2,\ldots n-1$$

We get the Lagrangian function:

$$F=J_e+\sum_{j=1}^{n-1}\lambda_j[(x_{j+1}-x_j)-\int_{v(x_j)}^{v(x_{j+1})}\frac{v^2\,dv}{p-\varphi(v)+g_0 v}]$$

$$=\int_V^{v(x_1)}\eta_0\cdot v\,dv+\sum_{j=1}^{n-1}\eta_j\cdot v\,dv+\int_{v(x_n)}^{V}\eta_n\cdot v\,dv+\sum_{j=1}^{n-1}\lambda_j[(x_{j+1}-x_j)$$

Where we set $\lambda_0 = \lambda_n = 0$, $\lambda_j \geq 0$, and define

$$\eta_j=\frac{\varphi(v)-L_V(v)-\lambda_j v}{p-\varphi(v)+g_j v}$$

To minimize J_e, we solve the equation $\frac{\partial F}{\partial v(x_j)}=0$.

The constrains are, for each j = 0, 1,2,…n:

$$\eta_{j-1}(v(x_j))=\eta_j(v(x_j))$$

$$\lambda_j=\lambda_{j-1}-(g_j-g_{j-1})\cdot\eta_j(v(x_j))$$

3 Simulation of the Local optimal algorithm

There is a track with steep uphill section from x = 5000 m to x = 6800 m. The train is passing with hold speed V= 20 ms^{-1}. Let x_1 = 5000 m, x_2 = 5600 m, x_3 = 6000 m, x_4 = 6500 m, x_5 = 6800 m with constant gradient accelerations by g_0= -0.075 ms^{-2} for $x < x_1$, g_1= -0.220 ms^{-2} for $x\in(x_1,x_2)$, g_2= -0.270 ms^{-2} for $x\in(x_2,x_3)$, g_3= -0.150

ms^{-2} for x∈(x_3,x_4), g_4= -0.200 ms^{-2} for x∈(x_4,x_5), g_5= -0.090 ms^{-2} for x > x_5. Here we have the power rating P = 3 m^2 s^{-3}, and a = 0.00675, b = 0, c = 0.00005 for $r(v)=a+bv+cv^2$.

We use an adaptive Runge-Kutta Scheme to solve the equations with matlab. Firstly, we set the *power phase* starting at (x,v) = (3399,20), then terminating at (x,v) = (8171,20), with η = 0. Secondly, we set (x,v) = (2500,20), then terminating at (x,v) = (8075,20), with $\eta > 0$. Thirdly, we set (x,v) = (4400,20), then terminating at (x,v) = (8293,20), with $\eta < 0$. The speed profiles are shown in Figure 2. The corresponding profiles for the adjoint variable η are shown in Figure 3.

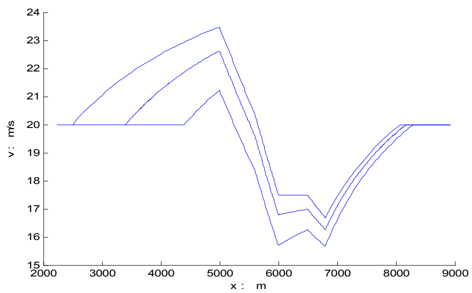

Figure 2. the speed profiles

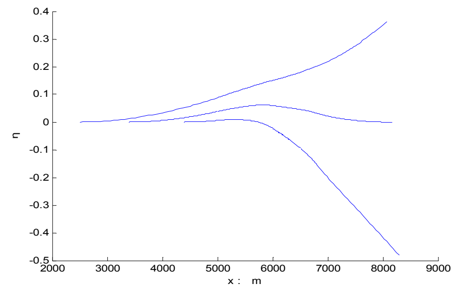

Figure 3. adjoint variable profiles

Now we can find the optimal profile with η (a) = η(d) = 0 and the switch point is at x = a = 3399 m where the optimal control should switch from *hold phase* to *power*.

4 Deficiencies of the Local optimal algorithm

While the point of train is at x < a or x > d, the train is at *hold phase*. From (1), we can obtain:

$$0=\frac{p}{v}-r(v)+g(x)$$

$$P_1 = v\,r(v) - vg(x) = 2.035 \text{ m}^2\text{ s}^{-3}, \quad \text{for} \quad x < a;$$

$$P_2 = v\,r(v) - vg(x) = 2.335 \text{ m}^2\text{ s}^{-3}, \quad \text{for} \quad x > d.$$

From the simulation, we compare the three occasions from 2500 m to 8293 m. The details are given in Table 1 and Figure 4.

Table 1: Compare of J_e, time and cost

occa-sion	η(d)	switch point	termi-nation	power time	J_e	hold phase	hold time	total time	total cost
1	= 0	3399	8171	196.6	3.2563	2500-3399 8171-8293	45.0 6.1	247.6	695.6
2	> 0	2500	8075	211.5	3.8278	8075-8293	10.9	222.4	660.0
3	< 0	4400	8293	172.2	4.2005	2500-4400	95.0	267.2	710.0

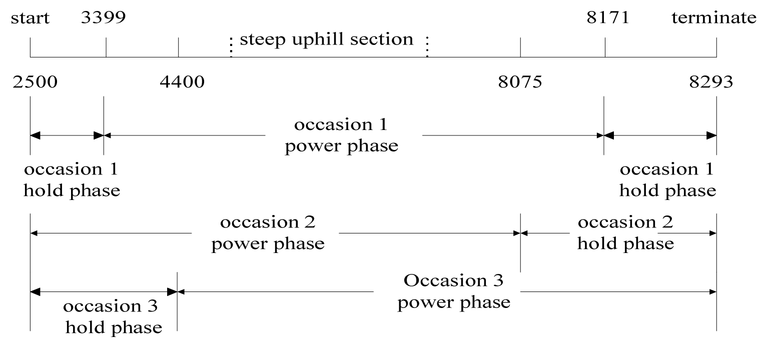

Figure 4. compare power phase with hold phase

Occasion1: a=3399 m, d=8171m, η(a) =η(d)=0, J_e=3.2563. From 2500 m to 3399 m and from 8171 m to 8293 m, the train is at hold phase.

Occasion2: a=2500 m, d=8075 m, η(a)=0, η(d)>0, J_e=3. 8278. From 8075 m to 8293 m, the train is at hold phase.

Occasion3: a=4400 m, d=8293 m, η(a) =0, η(d)<0, J_e = 3.2563. From 2500 m to 4400 m, the train is at hold phase.

The total time is power time plus hold time. The total cost is power cost plus hold cost.

From the Table 1 and the Figure 4, in occasion 1, η(a) =η(d)=0, it's J_e is the least of the three occasions, but in the global optimization from 2500 m to 8293 m, it's total cost is not the least again. Nevertheless, in occasion 2, η(a) =0, η(d)>0, it's J_e is not the least, but in the global optimization, it's total cost is the least yet.

On the analysis, we know that there are deficiencies with the Local optimal algorithm. It is not applied perfectly in the global optimization. However, the idea is valid. It could be improved and applied in some occasions well.

5 the improved Local optimal algorithm to global optimization

The simulation is as the same as the section 4, but the termination is at 8350 m.

The details are given in Table 2.

Table 2 Compare of J_e, time and cost with long distance

occa-sion	η(d)	switch point	termi-nation	power time	J_e	hold phase	hold time	total time	total cost
4	> 0	2800	8110	207.2	3.5198	2500-2800 8110-8350	15.0 12.0	234.2	680.1
5	> 0	3000	8130	203.9	3.3764	2500-3000 8130-8350	25.0 11.0	239.9	688.3
6	<0	4600	8320	165.9	4.6652	2500-4600 8320-8350	105 1.5	272.4	714.5
7	< 0	4800	8350	159.1	5.2472	2500-4800	115.0	274.1	711.2

Occasion4: a=2800 m, d=8110 m, η(a) =0, η(d)>0, J_e= 3.5198. From 2500 m to 2800 m and from 8110 m to 8350 m, the train is at hold phase.

Occasion5: a=3000 m, d= 8130 m, η(a)=0, η(d)>0, J_e= 3. 3764. From 2500 m to 3000 m and from 8130 m to 8350 m, the train is at hold phase.

Occasion6: a=4600 m, d=8320, η(a) =0,η(d)<0, J_e= 4.6652. From 2500 m to 4600 m and from 8320 m to 8350 m, the train is at hold phase.

Occasion7: a=4800 m, d=8350 m, η(a) =0,η(d)<0, J_e= 5.2472. From 2500 m to 4800 m, the train is at hold phase.

From Table 2, the least total coast is occasion 4, η(d) > 0, although J_e is not the least. Simultaneously, the total time is the least.

On the analysis, the switch point is more near to the train in the front, the total cost is less, and the total time is less. Moreover, in this example, the *hold phase* with constant gradient acceleration g_0= -0.075, P_1= 2.035 for x < x_1, and g_5= -0.090, P_2= 2.335 for x > x_5, $P_2 > P_1$. Of course, η(d) > 0.

So, we can get the improved optimal algorithm. The total cost and time are:

$$J = \min\left(\frac{x(a)-x_0}{V}\cdot p_1 + P_{\max}T_{power} + \frac{x_{n+1}-x(b)}{V}\cdot p_2\right)$$

$$T = \frac{x(a)-x_0}{V} + T_{power} + \frac{x_{n+1}-x(b)}{V}$$

The constrains are,

$p_1 = v\,r(v) - vg(x)$, $g(x) = g_0$, for hold phase;

$p_2 = v\,r(v) - vg(x)$, $g(x) = g_{n+1}$, for hold phase;

$vv' = \frac{p}{v} - q - r(v) + g(x)$, for power phase;

$T_{power} = \sum_{j=1}^{n-1}\int_{x_j}^{x_{j+1}} \frac{1}{v(x)}\,\mathrm{d}x$, x_1=a, x_n=b, for power phase.

The optimal control switch point should be searched according to the total energy cost, total time cost, the train, the line and other conditions.

6 Conclusions

The local optimal algorithm could be used to an independent tack with uphill section or downhill section. In view of the hold phase, and total cost, it does not work. Meanwhile, for global optimization, the improved optimal algorithm is valid.

Abstract: Briefly introduced the concept and development status of P&R (Park-and-Ride). Analysis the importance and necessity about developing urban rail transit to the improvement of traffic congestion and realizing green traffic and low carbon travel. First, the problem research mainly discusses the permanent residents who live outside the urban central area with private cars and takes characteristics of the differences of service level of different travel modes as starting point. Then, establish logit travel mode choice model and figure out the utility of travelers from residence to urban central area by three travel modes such as urban rail transit for whole range, private cars for whole range and P&R. And determine the choice probability of travelers towards these travel modes according to this. At last, establish the site selection model of urban rail transit P&R based on choice behavior of residence. The goal of the model is to meet the demand of parking and riding of residence and reduce the number of private cars entering the urban central area and traffic corridor in the maximal degree. At the same time, it takes constraint conditions such as investment upper limit of facilities and the reasonable parking number of a single facility into consideration. This model provides a solution for site selection of urban rail transit P&R facilities.

Keywords: Urban rail transit; Park-and-ride; Mode Choice; Site selection model.

1 Introduction

P&R is a kind of management policy of traffic demand presented in the 1970s, which means providing a parking facility in order to realize a conversion of low carrying rates into the high carrying rates (Zhu Shunying, 2008). The conversion can be private cars, motorbikes and bikes to the ground public traffic, urban rail transit and so on. Internationally there are mainly two types of P&R at present. The one of them improves traveling efficiency and saves the cost of transit development and operating by using P&R. Because of the spread of the city in low density, the low density population and high operating cost of public transportation, which is typical in America and Canada. Another leads people from private cars to public transportation by using P&R because of the heavy load traffic results in high density development in downtown, hopping to reduce the number of motor vehicle, which is typical in Germany, Singapore and Korea. The research of P&R in these countries is comparatively earlier and mature.

With the acceleration of urbanization processes in China, the demand of vehicles keeps growing fast. We have 130 million vehicle population in China as of 2014, which further highlights the problem of environment and energy. What's more, the big city keeps expanding the surrounding though, there still are a number of citizen who live in the ambient area have to shuttle between their houses and city center because of the perfect facilities there. And the travelers driving their private vehicle among them increase the traffic load as a result. Considering the transport situations in our country, especially the development of urban rail transit, we try to attract the citizen who live in the ambient area and drive their private vehicle to the urban rail transit, which has a strong realistic significance in the improvement of traffic congestion and realizing green traffic and low carbon travel (XIE Xiaoqian,2012). This paper mainly discussed the model selection of urban rail transit P&R.

2 Analysis of the factors affecting the Site Selection

There are many factors which influence site selections of P&R facilities. To make research direction more concentrated and concise, this article mainly considers the following five factors which are more directly influential.

(1)Demand. The number of travelers who choose P&R directly influences the locations and the scale of facilities. Travelers can decide whether they choose the method of P&R according to the height of effectiveness in different travel modes. This article aims at travelers all with self-driving cars, so we can divide their travel modes in the round trip of central areas into three kinds (CHEN Rugang, 2012). The first one is all self-driving, the second one is walking to the stations of urban rail transit and choose it, the third one is driving to P&R Facilities of urban rail transit to park and choose urban rail transit.

(2)The Number of Berths. The number of berths is affected by both the demand and the construction conditions limit of berths (WANG Xianguang, 2013). The number of berths should satisfy the demand of travelers as much as possible. If the low demand leads to over decentralization of the berth number, we may not construct berths when being limited by the minimum berths to construct P&R Facilities. Conversely, we may just construct berths according to the upper limit of berth number if the demand is so large that even exceeds the upper limit of the berth number.

(3)Attracting Scope. P&R Facilities have some attracting scope and there is potential demand in the scope. In addition, attracting scope of different P&R Facilities should avoid reciprocal chiasmata so as not to cause competition and resource waste. Therefore, the study should focus on the special attracting scope of P&R Facilities, as well as ensure enough spatial distance among each other at the same time.

(4)Resource Constrained. The planning and site selections of P&R Facilities should be restrained by some resource constraint, as well as not exceed the investment upper limit.

(5)Benefit Goal. The goal which sites selection of P&R Facilities pursue is not only to satisfy and guide as many travelers as possible, but also guarantee travelers to complete P&R as soon as possible. It is the assurance of reducing vehicles entering city center and traffic jams of traffic corridors.

3 Establishment of the travel mode choice and site selection model

3.1 Model hypothesis

In order to simplify the calculation process, we make the following hypothesis:

(1)The selected P&R facility places are all in the urban rail transit stations.

(2)The potential P&R demand within the every P&R facility's attracting scope is known, namely the number of travelers who drive private vehicle and shuttle between their houses and city center is known.

(3)All of the P&R demand which was calculated from travel mode selection probability should be converted to actual P&R demand.

(4)Travelers are supposed to arrive the destination if they arrive the city center by vehicle or urban rail transit.

(5)We neglect the influence of traveler's characteristics when calculating the traveling utility because the targeted traveler's characteristics in this model are single.

3.2 Establishment of the travel mode choice model

We have mentioned in previous paper that there are three types that the potential P&R demand person can select to arrive at city center, namely driving in the whole range, riding the urban rail transit the whole range and P&R. According to the random utility theory of economics, travelers will pursue utility maximization. We can suppose that the travelers will select traveling modes according to the utility. The traveling mode selection model is shown in formula (1).

$$P_{ri}^{p\&r} = \frac{U_{ri}^{p\&r}}{U_{ri}^{p\&r} + U_{ri}^{metro} + U_{ri}^{car}} \quad (1)$$

Where $P_{ri}^{p\&r}$ is the probability that travelers select P&R at the i_{th} station of line No. r. U_{ri}^{car}, U_{ri}^{metro} and $U_{ri}^{p\&r}$ are the utility we can gain from the travelers driving the whole range, using urban rail transit the whole range or using P&R within the facility's attracting scope that is built at the i_{th} station of line No .r. The three utility functions can be described as formula (2)-(4).

$$U_{ri}^{car}=\alpha t^{car}(d'_{ri})+c^{car}(d'_{ri})+p^{car} \tag{2}$$

$$U_{ri}^{metro}=\alpha[(t^{walk}(d''_{ri})+t^{metro}(d_{ri})]+c^{metro}(d_{ri}) \tag{3}$$

$$U_{ri}^{p\&r}=\alpha[(t^{car}(d''_{ri})+t^{metro}(d_{ri})]+c^{car}(d''_{ri})+c^{metro}(d_{ri})+p_{ri}^{p\&r} \tag{4}$$

Where d_{ri} is the distance between city center and i_{th} station of line No. r. d'_{ri} is the average distance between city center and private cars within P&R facility's attracting scope at the i_{th} station of line No. r. d''_{ri} is the average distance between private cars and P&R facility within attracting scope of i_{th} station of line No. r. $t^{car}(x)$, $t^{walk}(x)$and $t^{metro}(x)$ are private cars, walking and metro time function taking distance as independent variable. $c^{car}(x)$ and $c^{metro}(x)$ are the fuel surcharge and the fare function of car and metro taking distance as independent variable. p^{car} is the parking fee in the city center. $p^{p\&r}$ is the parking fee in the i_{th} station of line No. r. α is the VOT coefficient which convert time to fees.

3.3 Establishment of the site selection model

Based on previous analysis and traveling mode selection model, we can establish a further site selection model, the objective function reflects the aim that meeting the demand of park and ride for more people and completing the park and ride in the downtown as soon as possible. The model is shown as formula (5)-(9).

$$\max Z=\sum_r\sum_i Q_{ri}^{p\&r}d_{ri}X_{ri} \tag{5}$$

$$s.t.\begin{cases}\sum_r\sum_i X_{ri}\le P \quad \forall r,i & (6)\\ X_{ri}=\begin{cases}0 & x_{ri}^b=0\\ 0\ or\ 1 & x_{ri}^b\ne 0\end{cases} & (7)\\ Q_{ri}^{p\&r}=Q_{ri}P_{ri}^{p\&r}=\dfrac{Q_{ri}U_{ri}^{p\&r}}{U_{ri}^{p\&r}+U_{ri}^{metro}+U_{ri}^{car}} \quad \forall r,i & (8)\\ \left|d_{ri}\text{-}d_{gj}\right|\ge 2D \quad \forall r,g\ \&\ i\ne j & (9)\end{cases}$$

Where $Q_{ri}^{p\&r}$ is the potential P&R demand at i_{th} station of line No. r. X_{ri}=0 means not to build any P&R facilities at i_{th} station of line No. r. X_{ri}=1 means build one. P is the upper limit of the amount of facilities. D is the radius of facility's attracting scope. x_{ri}^{b} is the amount of parking berth at i_{th} station of line No. r, which can be decided by Formula (10).

$$x_{ri}^{b}=\begin{cases}0 & Q_{ri}^{p\&r}<x_{\min}\\ Q_{ri}^{p\&r} & x_{\min}\le Q_{ri}^{p\&r}\le x_{\max}\\ x_{\max} & Q_{ri}^{p\&r}>x_{\max}\end{cases} \tag{10}$$

Where $x_{\min}$ is the minimum amount requirement of parking berth building a single P&R facility. $x_{\max}$ is the maximum parking berth amount building a single P&R facility. When the demand is not more than $x_{\min}$, we don't take building into consideration. When demand is more than $x_{\max}$, the amount will be $x_{\max}$. When demand is more than $x_{\min}$ and not more than $x_{\max}$, the amount will just be the demand.

As there are judging conditions in the site selection model constraint and it's a nonconvex programming problem which is relatively complex, we have to solve this kind of problem with a suitable algorithm. Such as Branch-and-Bound Method, Genetic Algorithm etc.

4 Conclusions

Among the factors that affect P&R site selection, there are some that are difficult to be quantified can also affect the results. Such as network configuration of the rail transit, Comprehensive traffic survey and urban development planning, etc. The influence remains to be further explored. What's more, we cannot realize the goal of improving traffic construction with P&R and realizing green traffic and low carbon travel simply considering site selection. The investment, construction mode and running mode of P&R all have an effect on its result. It's necessary to do an integration research in the further work.

Abstract: In central business district, the conditions caused by a lot of car travel have resulted in the severe negative effect upon passing on sidewalks, environment of the city, and traffic on roads. The local governments have implemented many related strategies in order to solve these problems. However, the car travel problem cannot be solved sufficiently. The reason is that many types of travel behavior including travel mode choice involve social interaction effect, leading society to deadlock in inferior equilibrium state (social dilemma). The previous travel behavior models, used to be bases for policy evaluation, assumed that individual behavior is independent of others and therefore it resulted in the constrained performances. In view of the above, this study designates the CBD of Dalian City as the study area where the data are collected to build the travel mode choice behavior model into which social interaction effect is incorporated.

Keywords: Travel mode choice behavior; Social interaction; Parking fee; Walking distance.

1 Introduction

In recent years, in large and medium cities, rush hour traffic jams have become a norm. Traffic congestion not only increases the travel time of all travelers, but also cause air pollution, resulting in the improvement of the external costs of people travel.

In the choice of travel modes, travelers are not just rational considerations of personal utility, where he will refer to other members' travel choice in the group, and this behavior is called social interaction. Due to the effect of social interaction, people often can observe the tendency of individuals to comply with the majority of action, which is likely to lead to a stalemate in the inferior social equilibrium, also known as "social dilemma" (Fukuda, 2007). Therefore, policy measures to solve traffic congestion, if only affect individuals and their statistical results for policy evaluation is not sufficient. The current mainstream of traffic behavior model tend to individual behavior independent of the behavior of others, this makes the effect of transport policy affected.

This article explores the city center area commuters travel choice behavior. If there is social interaction, set the transportation mode choice traveler behavior is not specific to the impact of most other travelers, and therefore belong to the whole domain of interaction. In the domain-wide interactive mode, we use the average behavior of the reference group as an alternative variables to describe the impact of interaction. In this paper, the average behavior of the reference group as explanatory variables of individual behavior, indicating that the formation mechanism of collective behavior characteristics.

In this paper, the interaction behavior of car commuters in the city center will be analysis based on the theory of social interaction proposed by Brock and Durlauf.

2 The Binary Choice Model Considering The Social Interaction

This study established a binary choice models based on expected utility theory. Individual decision-making process, in addition to considering individual utility, but also affected the population selection behavior of other members. As follows:

The choice behavior of individual i represented as binary variables w_i. If individual i choose plan A, w_i=1, if individual i choose plan B, w_i=-1. The utility of individual choice can be expressed as $V(w_i)$.

$$V(w_i)= u(w_i)+ S(w_i,\ \overline{m}_i^e)+\varepsilon(w_i) \quad (1)$$

$u(w_i)$:Observed individual utility

$S(w_i,\ \overline{m}_i^e)$:The social utility

$\varepsilon(w_i)$:Unobserved random utility

To reflect the multiplicative interaction between individual choice and group behaviors, The social utility can be expressed as follows:

$$S(w_i,\ \overline{m}_i^e)= Jw_i\overline{m}_i^e \quad (2)$$

$\overline{m}_i^e$: Individual's subjective expectations for the average collective choice, and its range is [-1,1], the formula can be expressed as:

$$\overline{m}_i^e = \frac{\sum_{j\neq i} m_{i,j}^e}{I-1} \quad (3)$$

I: the number of individuals in the group

$m_{i,j}^e$: the subjective expectations of individual i for individual j.

J is the numerical parameters measuring the extent of interdependence between individuals, it can be calculated as:

$$J = \frac{\partial^2 S(w_i, \overline{m}_i^e)}{\partial w_i \partial \overline{m}_i^e} \qquad (4)$$

We assumed that $U(w_i)=u(w_i)+S(w_i, \overline{m}_i^e)$, the probability of individual choice "plan A" can be expressed as:

$$\begin{aligned} Prob[V(1) \geq V(-1)] &= Prob[U(1)+\varepsilon(1) \geq U(-1)+\varepsilon(-1)] \\ &= Prob[\varepsilon(-1)-\varepsilon(1) \leq U(1)-U(-1)] \end{aligned} \qquad (5)$$

Assumed that unobserved random utility $\varepsilon(w_i)$ obey Gumbel distribution, the random utility of "plan B" and "plan A" is $\varepsilon(-1)$ and $\varepsilon(1)$ respectively, then $\varepsilon(-1)$-$\varepsilon(1)$ would be Logit distribution.

$$\begin{aligned} Prob[V(1) \geq V(-1)] &= \frac{1}{1+\exp(-\theta(U(1)-U(-1)))} \\ &= \frac{1}{1+\exp(-\theta(U(1))\times\exp(U(-1))} \\ &= \frac{\exp(\theta U(1))}{\exp(\theta U(1))+\exp(\theta U(-1))} \end{aligned} \qquad (6)$$

Equation (2) is substituted into equation (6) results in Equation (7). θ is the scale parameter of the random utility.

$$\Pr ob(w_i) = \frac{\exp[\theta(u(w_i)+Jw_i\overline{m}_i^e)]}{\sum_{v_i \in [1,-1]} \exp[\theta(u(v_i)+Jv_i\overline{m}_i^e)]} \qquad (7)$$

3 Variable Settings

In this paper, we used questionnaires to collect information needed for empirical analysis in downtown Dalian.

3.1 Options

The travel mode choice behavior was set to binary choice model, They are: commuting by public transport (bus or rail trips, is a cooperative behavior, $w_i = 1$), commuting by car (which is non-cooperative behavior $w_i = -1$).

3.2 The explanatory variables of individual utility

There are two part in the explanatory variables of individual utility, the individual specific variables(X) and the specific variable of reference groups(Y).

For the individual specific variables(X), because of commuter travel characteristics variables may affect the travel mode of choice, this article included the travel characteristics variables in the analysis model. For example, the travel distance, the work system, and the number of stops in commuting process.

Commuter travel decisions, not only affected by the individual's social-economic attributes and the travel characteristics, but also affected by travelers' mental states. Fujii proved that psychological factors plays a very important role in "cooperative behavior" in social dilemmas through a series of empirical studies. Therefore, this paper put "moral sense", "risk attitude" and "self-serving belief" and other psychological factors into the analysis model.

Specific variable of reference group is exogenous characteristics influence reference group choice behavior. This paper using parking fee and walking distance after stopping to assess the impact of policy variables

3.3 The explanatory variables of social utility

This paper set $\bar{m}^e$ as the individual's subjective expectation of reference groups choose public transport average level, referred to as select group average level. Since the model and questionnaire needs different types of data, the variables must be converted between the average level of choice ([-1,1]) and selection ratio ([0,1]). In other words, during the survey, in order to make it easy to imagine for a given situation, we used the proportion of group selection ($\bar{p}^e$) in data collection. When you import the model, you need to use ($\bar{m}^e = 2\bar{p}^e - 1$), the $\bar{p}^e$ is converted to average level of group selection.

Table 1 The explain variable's names and definitions

Variable name			Variable definitions
The individual specific variables (X_i)	Travel characteristic variable	Travel distance	$T_d \geq 10$km set as 1； $T_d \leq 10$km set as 0
		Number of stops	If parking in commuting set as 1， otherwise, 0
		Work system	Fixed working hours set as 1， otherwise, 0
	Psychological factors	moral sense	Factor analysis
		risk attitude	Factor analysis
		Self belief	Factor analysis
The specific variable of reference groups (Y)	Parking fee		10￥，20￥，40￥，60￥
	Walking distance		50m, 150m, 250m, 350m
The average level of collective choice（$\bar{m}^e$）			100%, 90%, 60%, 30%

4 Travel Mode Choice Model Considering Social Interaction

In this part, we used of a questionnaire survey to collect data, constructed the empirical model by introducing social interaction effect into travel mode choice behavior, and on this basis, to analyze the influencing variables of the travel mode choice behavior.

4.1 Model Estimation Results

The model is a binary choice model, we specify all the explanatory variables are the specific variables of "choice of public transport" to determine the impact of the program. In this case, the variable parameter is positive, indicating that the variables have positive impact on individual choice probabilities on public transport, on the contrary, have a negative sign indicates a negative impact. In addition, there were 192 effective respondents surveyed in this article. Because of each respondent need to answer four questions, there are 768 samples could be used to estimate the model.

This paper established four models, the estimated results were shown in Table 2. Model 1 did not consider personal property, Model 2 did not consider psychological factors, Model 3 considered all the factors, and Model 4 removed all insignificant variables.

Table 2. The travel mode choice model estimation results

				Model 1		Model 2		Model 3		Model 4	
The variable name			Parameter	Parameter value	t value	Parameter value	t value	parameter value	t value	parameter value	t value
Specific variables of individual (X_i)	Travel characteristic variables	Travel distance (x_{1i})	c'	——	——	-0.2050	-1.17	-0.2489	-1.4	——	——
		The number of stops (x_{2i})		——	——	-0.3296*	-1.90	-0.3133*	-1.77	-0.3416**	-1.98
		Working system (x_{3i})		——	——	0.5436***	1.96	0.4360*	1.91	0.4036*	1.84
	Psychological factor	MS (x_{4i})		——	——	——	——	0.3918*	1.79	0.3681**	2.36
		RA (x_{5i})		——	——	——	——	0.4270*	2.18	0.4563**	2.56
		SB (x_{6i})		——	——	——	——	-0.1224	-0.46	——	——
Specific variables of the reference group (Y)		Parking fee (y_1)	d'	0.0055***	6.83	0.0056***	6.88	0.0057***	6.94	0.0056***	6.99
		Walking distance (y_2)		0.0921***	7.37	0.0941***	7.43	0.0963***	7.48	0.0951***	7.55
$\overline{m}^e$			J	1.0824***	6.70	1.0983***	6.71	1.0552***	6.35	1.0510***	6.37
Constant			b	2.3834***	8.91	2.8478***	9.16	0.6001	0.75	——	——

Samples	768	768	768	768
$LL(0)$	-532.337	-532.337	-532.337	-532.337
$LL(\beta)$	-422.469	-413.994	-405.601	-406.783
ρ^2	0.206	0.222	0.238	0.236
$\bar{\rho}^2$	0.197	0.207	0.217	0.221

Note：*significant level at 0.1, **significant level at 0.05, ***significant level at 0.01.

Table 2 shows that the explanatory power of the model 1 is not good, $\bar{\rho}^2$（The adjusted likelihood ratio index）did not reach the model adaptation good standards (0.2). Compared with the model 1, the logarithm likelihood values (*LL* (*β*)) of model 2 produced a significant change (using the likelihood ratio test to determine: $16.9>\chi^2_{3,\ 0.05}=7.8$). The model 3 had a good explanation ability, but insignificant explanatory variables still exist in the model 3. After the analysis of the results, this paper took the model 4 as the analysis model.

4.2 Model Variables Impact Analysis

Specific variables of individual（x1i~x6i）shows the effect of various personal attributes. Among them, the "working system" of the parameter symbol shown that the fixed duty commuters will opt for "public transport". This may be due to the cumulative parking fee generated by repeatedly parked. Fixed duty of travelers are very understanding on public transport trips, routes and transfer information, so they are more inclined to choose public transport. The parameter symbol of "The number of stops" tells us that the more travelers' number of stops, the more inclined to commute by car. Probably because the car was very convenience, destination easy to adjust, thus, in this case people prefer to travel by car.

On the psychological factors, the parameter symbol displayed that travelers who have high moral consciousness inclined to choose public transportation, to avoid damage to the interests of others or the public interest. Compared with the risk-lovers, the risk-averts more inclined to public transport, in order to avoid the risk of driving such as traffic accidents, traffic violations and late for work.

Specific variable reference group shows: with the increase in walking distance and parking fee car travel, the tend of travel by car will decrease. Therefore, these variables can assess traffic policy, in other words, by improving parking fee and walking distance to increase the proportion of travelers commuting by public transport.

The average level of group selection has a significant positive effect on travel mode choice behavior. It is worth noting, the parameter J is used to measure the dependence degree of individual behavior, the value is greater than 1, description: strong social interaction (J>1) existing in the group, so the commuters exhibit a tendency to follow the behavior of others. The average level of the behavior choice (collective behavior) may exist multiple equilibria. These findings plays an important role for policy intervening travel mode choice behavior.

Finally, we discuss the deleted insignificant variables in model 3. Since the level of significant is not up to the standard, "travel distance", are not included in model 4. The parameters of model 2 and model 3 value symbol displayed if travel more than 10 km of distance, travelers more inclined to choose car travel. This may be when long-distance travel, people pay more attention to comfort and quickness. But other travelers thought that long-distance travel by car costs too high, preferred to take the low fares public transport. Self-serving belief facet mainly involves punctuality, economy and vanity factor. Bus travel has advantages in terms of economy, but travel by car has an advantage in terms of time savings, making it difficult to determine which option is more selfish.

5 Conclusions

In this article, we prove that psychological factors influence choice behavior to a certain extent, and it could enhance the explanatory power of the model. In addition, the model estimation results show that travelers have a tendency to follow other travelers' travel behaviors, and the strength of social interaction makes it possible that the collective behavior existing multiple equilibria. Therefore, in terms of policy intervention, it is necessary to analyze how to achieve a balanced transfer of collective behavior, in order to reduce social dilemma.

Abstract: Electric vehicle charging station is an important link of electric vehicle industry, and the construction mode of charging station is closely related to the development of electric vehicle. This paper put forward electric vehicle charging station's planning principle, ideas, process and established the charging station network layout planning method combining the centroid method and central place theory. Finally, carry on the instance analysis for the layout of electric vehicle charging station planning in Chengdu and verify the practicability of planning system.
Keywords: Electric vehicle; Charging station; Calculation mode.

1 Introduction

Due to the development of electric vehicle is at the primary stage, so the layout of electric vehicle charging station is still at the discussion stage. However, considering that electric vehicle charging station, gas station, LPG station are all vehicle refueling service facilities belonging to the city, and they have similar characteristics on refueling service function, so the electric vehicle charging station location problem can refer to the layout principle of gas station and LPG station.

Chiara Bersania established hydrogenated load forecasting model based on the historical oil demand data about gas station, optimized LPG station location from the perspective of cost-benefit analysis, put forward planning model suiting the LPG station; Martin Frick pointed out that in order to make the LPG become the large-scale market vehicle refuel, the common benefit analysis method must be used in LPG station layout to find the most optimal location of LPG station scheme; Michael put forward hydrogen station location optimization model based on vehicle maximum flow and made the preliminary hydrogenation infrastructure strategic planning with this model; Ren yulong established multi-objective optimization model by applying the idea of dynamic traffic network based on hard time window constraints. The model regarded the minimum charging cost of chargers and charging station investors as the optimization goal, put forward the two-phase heuristic algorithm to solve the model.

In this paper, we established the charging station network layout planning method combining the centroid method and central place theory for users' convenience and service level, and took Chengdu city as an example, providing reference for the urban planning of electric vehicle charging stations.

2 Standard Charging Station Planning

Determine the construction scale of standard charging station referring to the construction scale of gas station. Gas stations are divided into three types: the covering area is $2500m^2$, and the number of oil gun is 16; the covering area is $1500m^2$, and the number of oil gun is 12; the covering area is $1000m^2$, and the number of oil gun is 8. The construction principle of charging stations is "quick switching, and secondly quick charging", therefore the number of standard charging station's charging pile is 12 in total, including 2 quick charging piles and 10 fast switching piles.

Assuming that battery replacement time is 15 min and the charging station works for 24 h, so a quick service desk can serve 4 vehicles per hour at most. The largest service capacity of standard charging stations is calculated as follows:

$$C_{\text{standard}} = M_{\text{quick switching}} \times \mu_{\text{quick switching}} \times t \quad (1)$$

where, C_{standard}: the maximum service capacity of standard charging stations, vehicles/month;

$M_{\text{quick switching}}$: the number of quick switching pile, set for ten；

$\mu_{\text{quick switching}}$: the service rate of quick switching pile, set for 4 vehicles/h;

t: the service time of standard charging station, set for 24 h;

The maximum service capacity of standard charging station is 960 vehicles per day according to the formula (1). However, the charging station is not in the busy state at every time, and the service desk may appear empty demurrage. The empty demurrage includes the waiting time before customer's arrival and the invalid time. During 10 p.m. of yesterday to 8 a.m. of the next day, the empty demurrage is 8 h in total. Assuming that the invalid service time is 5 min per vehicle, so the design service capacity of charging station can be calculated as follows:

$$C_{\text{standard}} = M_{\text{quick switching}} \times \mu_{\text{quick switching}} \times t \times k \quad (2)$$

where, C_{standard}: the design service capacity of standard charging stations, vehicles/month;

$\mu_{\text{quick switching}}$: the service rate of quick switching pile, set for 3 vehicles/h;

k: the effective coefficient of charging station every day, usually ranging from 0.6-1.0.

The design service capacity of standard charging station is 480 vehicles per day according to formula (2). Details are shown in table 1.

Table1. Service Capacity of Standard Charging Station

Charging modes	Quick charging pile	Quick switching pile	Maximum service capacity (vehicles/day)	Design service capacity (vehicles/day)
Number of standard charging station	2	10	960	480

If the number and scale of charging station is too big, the resources may be in idle and wasted. If the number and scale is too small, the charging infrastructure can't meet users' demands, which leads to the long charging time of vehicle queue, affecting the normal travel of residents.

3 Location Theory Basis

3.1 Central Place Theory

Central place theory concretely discusses how to provide effective supply for urban production and service, how to configure different scale's cities, so as to form city system and market system with multiple levels. Electric vehicle charging station provides vehicle charging service for vehicle users and convenience for normal travel of residents. Due to the electric vehicle facility's location characteristics meet the requirements of central place theory, so this theory can provides a good method for the paper.

3.2 Centroid Method

Centroid method is usually used in the choice of single facility. The main factor of this method is to consider the distance between facilities and requirements of demands, so as to make the selected facility be close to the high demand's area as far as possible and acquire the center of the region's actual location. Based on this analysis, we can use this method to determine the charging station location optimization solution with the shortest mileage. However, this method doesn't consider economy, the possibility of site, and the actual optimal address is often difficult carry out, so we need to combine central place theory to determine the final solution.

4 Charging Station Location Choice Model

First, we use the network layout of central place theory to form service area, select location site within each service area using the centroid method. Second, due to the location site produced by centroid method may not achieve effect in reality, so choose *n* feasible coordinate solutions as alternative address, and determine the final address in the *n* feasible coordinate solutions by using location model.

4.1 Determine Service Scope in Central Place Theory

The essence of confirming service range is to obtain the maximum service radius of charging stations. The determination of service radius for electric vehicle charging station is based on the purpose of users' convenience. At the same time, we need to consider the profit situation of charging stations. At the primary stage, the number of pure electric vehicles is small. At this time, in order to promote using electric vehicles, the service scope of charging station can be slightly bigger. The electric vehicle charging station service radius will gradually be shorten with the rising number of electric vehicles, and the number of charging station will increase to meet users' demands. The upper limit of charging station service range is the longest charging service distance that consumers are willing to get to. Assuming that the maximum time which the driver spends on finding the charging station is 10 minutes, when the driver finds the insufficient battery, the driver will search the nearest charging station in 10 min to get the vehicle recharged

The construction of charging station should meet the customer's charging demands as far as possible, aiming at the customer's convenience. Therefore, we can determine the maximum service radius of charging station from the perspective of the biggest finding time that the customer can bear. Therefore, considering road condition near charging station, road traffic condition and the customer's biggest searching time, the service radius of charging station can be calculated as follows:

$$\mathrm{r} = \frac{V \times t}{\lambda} \tag{3}$$

where, V: vehicle driving speed, km/h;

t: the biggest searching time, min;

λ: road curvature coefficient, λ equals to the ratio between actual transport distance and the linear distance.

In generally, there are three types of road network forms: traditional checker-board type, freestyle type with limited connectivity and the combined type based on the first two. The connectivity of traditional check-board type is better, but the actual distance is 45% longer than the corresponding space distance.

Assuming that the average speed of urban road network traffic flow is 30 km/h and the vehicle can find the charging station within 10 min. On the basis of traditional check-board type network, set the road curvature coefficient 1.4, we can obtain that the maximum service radius of charging station is 5.5km according to formula (3) and the service area of charging station is 33.14km^2 according to the central place theory.

4.2 Primary Address of Centroid Method Model

Assuming that the charging demand distribution is known, the demand of one demand point is Q, its location coordinate is（x , y）, so the location coordinate of shortest charging station theoretically is:

$$\mathrm{X} = \frac{\sum_{i=1}^{m} Q_i \times x_i}{\sum_{i=1}^{m} Q_i} \quad \mathrm{Y} = \frac{\sum_{i=1}^{m} Q_i \times y_i}{\sum_{i=1}^{m} Q_i} \tag{4}$$

where, m: the number of charging station service demand point;

x_i, y_i: coordinates of demand point *i*;

4.3Determine the Final Solution

Location problem in each service community is a single facility location, aiming at making T_c from demand point *i* to facility point *j* be minimum value, the mathematical form of this model is as follows:

$$\min T_c = \sum_{i=1}^{m} E_{ij} d_{ij} \qquad (j=1,2\ldots.n) \tag{5}$$

where, *n*: number of alternative facility point;

m: number of demand point;

E_{ij}: demand intensity from demand point *i* to facility point *j*;

d_{ij}: distance from demand point *i* to facility point *j*.

5 Electric Vehicle Charging Facility Layout Planning in Chengdu City

Choose the per capita GDP、urban population、urban built area and virtual variable that stimulate to buy electric vehicles（1 for yes, 0 for no）as the independent variables, electric vehicle ownership in Chengdu as the dependent variable. Multiple linear regression model is set up as follows:

$$\mathrm{y} = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \beta_4 x_4 + \varepsilon \tag{6}$$

where, y: electric vehicle ownership in Chengdu;

x_1: per capita GDP in Chengdu;

x_2: urban population in Chengdu;

x_3: urban built area in Chengdu;
x_4: virtual variable that stimulate to buy electric vehicles;

Use SPSS and carry on heteroscedasticity testing, autocorrelation testing, find that the four independent variables have a significant impact on the dependent variable. The higher the per capita GDP is, the greater the electric vehicle ownership is. With the increasing of urban population, the electric vehicle ownership will also increase. The increasing of urban built area will promote the electric vehicle ownership. Do statistical analysis with data from 2000 to 2015 as samples, and forecast the electric vehicle markets and the number of charging infrastructure in Chengdu. The prediction result is as follows:

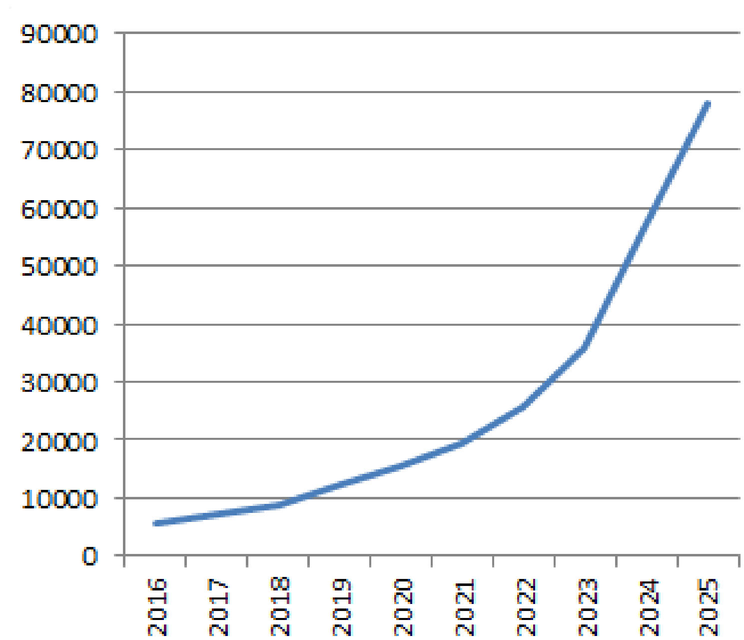

Figure1.Electric Vehicle Ownership in the Future Market

Under the action of market, the distribution of center area is based on the convenience for sales and service. With the development of electric vehicles, vehicle charging demand constantly increases. According to the distribution mode of central place theory, we can get the electric vehicles charging station planning chart combining service radius based on customer's convenience, as shown in figure 2.

Figure2. Electric Vehicles Charging Station Planning Chart in Chengdu

6 Conclusions

This paper studies the solution to the problem of electric vehicle charging station layout planning, uses centroid method and central place method to establish electric vehicle facility selecting model from the perspective of improving service level and users' convenience. Finally, carry on the instance analysis for the layout of electric vehicle charging infrastructure planning in Chengdu and verify the practicability of planning system.

Abstract: The study of reasonable highway network scale is directly related to the network planning, construction and the achievement of social and economic benefits. Based on the analysis of influence factors, different types of highway development partition were proposed and the focus of highway development was discussed. After analyzing the shortcomings and characteristics of traditional methods such as territory coefficient method and connectivity method, the reasonable scale value was predicted by three appropriate methods and adjusted with the gini coefficient. Combining qualitative and quantitative analysis, a reasonable network scale of highway development and construction in Wenzhou was determined, which provides a theoretical basis for the highway network planning adjustment and gives a scientific guide to highway development.
Keywords: Highway; Highway network scale; Prediction method; Gini coefficient.

1 Introduction

This paper studies the reasonable highway network scale of Wenzhou, which reflects the difference and ensures the fairness in each region. First, influencing factors of the regional highway network scale are analyzed. Second, four different types of highway development subareas are proposed and the corresponding focus of development is discussed. Thirdly, after analyzing the applicability of traditional methods, the reasonable highway scale value of each region is predicted. Finally, the predicted value is checked with gini coefficient and adjusted with Lorenz curve, which reach the definitive conclusions.

2 Influencing Factors

The influencing factors of reasonable road network scale can be divided into three categories. The first category is demand factors such as population and its distribution, economic scale and industry layout, mainly reflects the road network supply capacity requirements for economic and social development. The next is the constraint factors, such as land resources, geographical characteristics, which reflects the restriction of resource endowment on road network development scale. The last category is the transportation development mode such as traffic composition and transportation development concepts, which reflects the road network functions to play and the demand to assume in transportation system, and the expected service status etc. The counties of Wenzhou are very different in topographic, geographic, social and economic aspects. So the influencing factors of counties are respectively analyzed in the following.

(1)Population and its distribution

Wenzhou downtown area (WDA), Ruian, Yueqing, Dongtou, Pingyang, Cangnan are mainly town concentrated area with a high population density over 800 persons per sq.km. Yongjia, Taishun, Wencheng of inland area are town dot-development area with a relatively low density between 200~400 persons/ sq. km, in which population and industry develop in places. According to the relevant planning, in 2020 Wenzhou city will have an urban population of 580~610 million, the urbanization level reaches 69~71%; the total population will increase in WDA, Ruian, Yueqing, Dongtou, remain in Yongjia, Pingyang and Cangnan, decrease in Wencheng, Taishun.

(2)Economy and industry

WDA, Dongtou, Pingyang, Cangnan, Ruian, Yueqing are national-level development area. Small commodity, electric, automobile and motorcycle industries locates in WDA, Ruian and Yueqing. It leads to the fact that he total value of GDP and per capita GDP of these counties are significantly higher than those counties. Dongtou, Yongjia, Pingyang, Cangnan belong to the medium level of development. Wencheng and Taishun are provincial-level ecological function areas, which need to limit economic development, so the economic indicators are the lowest.

(3)Geographical features

The overall terrain of Wenzhou is high in northeast and low in southwest, containing coastlines, hills, valleys, rivers, seas.Wencheng and Taishun locates in southwest and Yongjia in northwest ,where the mountain area accounts over 80% of the total area. WDA, Ruian, Yueqing, Pingyang, Cangnan are coastal areas, with hills, valleys, plains, river and other different physiognomy. Dongtou has island hilly terrain, no river, no typical river valley landform, many natural harbors and beaches, there are many navigable channels between each island.

(4) Traffic demand

The traffic demand is the direct factor influencing the regional highway network scale. Through the analysis of retaining volume of motor vehicles and statistical highway and waterway passenger traffic volume. The indicators are the highest level in WDA, while Dongtou, Wen Cheng, Taishun is much lower than the general level, the rest counties' statistical volumes differ in the medium level. Freight traffic volume is similar with passenger traffic volume, but the Dongtou because of its special nature as a harbor district, with the higher level of freight traffic than passenger traffic.

Four different types of highway development partition are proposed here based on the difference of the influencing factors. The first kind combines WDA, Yueqing, Ruian, Pingyang, Cangnan, where has a greater demand for highway development and suitable conditions for the highway development and construction. Secondly, Yongjia has contradiction of highway demand and supply because of its hilly topography. Wencheng and Taishun is the third type with a low highway demand and mountainous area as highway development constraints. Dongtou has a special demand of freight transport as the harbor function.

3 Highway network scale prediction

According to the difference of study ideas, the existing research methods can be divided into four categories: the first category (connectivity analysis): starting from the highway network layout, consider the degree of connectivity of nodes in road network, calculate the scale of road network based on minimum tree in graph theory, including connectivity method, efficiency curve method (Hu, 2012); The second category (time series) : analyze the trend of the development of highway network, including growth curve method (Pei, 1995; Zhou, 2003); the third category (factor analysis), after a comprehensive analysis of factors affecting road network scale of one or more, set up relevant influence factors and the related model to forecast the reasonable road network scale, including territory coefficient method, the production function method, highway volume analysis method, the economic index model method, elasticity coefficient method and multifactor regression analysis (Magnanti, 1984; Meyer, 2000; Gu, 2004, Wang, 2006; Yu, 2006); The fourth category (analogy), on the basis of factors analysis, select highway network in some areas similar with the target area in social and economic development, qualitatively analyze or establish a road network scale model with related influencing factors and the quantitative relationship to determine the regional highway scale, namely the analogy method.

Table 1 analyses the advantages and disadvantages of various methods. It's difficult to find out analogical objects familiar or same with Wenzhou because Wenzhou has a unique geographical conditions named ”seven mountain two water one field” and locates in the intersection of Yangtze river delta economic zone and channel west bank economic zone. From two aspects of the operability and accuracy, connectivity method, the coefficient method, the growth curve method are selected to calculate the regional reasonable road network scale in Wenzhou.

Table 1. Analysis of prediction methods

method	model	advantages	disadvantages	applicability
connectivity method	$L = C \cdot \varepsilon \cdot \sqrt{A \cdot N}$	can reflect the layout of highway network	nodes, connectivity, network deformation coefficient are not easy to determine in large or complex terrain	Small areas or areas without topographic change
efficiency curve method	$\sum Z = f(\sum L)$	Analyze the node importance based on connectivity method, more objective	data requirements are very high	the same as above
growth curve method	$L = K \cdot a^{b^t}$ or $L = \frac{1}{K + a \cdot b^t}$	consistent with the laws of development of things	Lack of consideration of other factors of population, economic development, also has high requirement to the data	Applicable to the prediction of highway network recently
territory coefficient method	$L = K_n\sqrt{P \cdot A}$	Consideration of land area, population, per capita GDP in most of these main factor	no consideration of other influencing factors, may reduce the accuracy of the prediction	applicable to most situations
elasticity coefficient method	$L_R = e \times E$	Built the relation model between highway construction growth rate and the economy growth rate	Hard to find out the relationship with the influence factors and determine the trend of development	More suitable for long term forecast of regional highway network
Highway volume analysis	$L = Q/(S \cdot C)$	directly establish the mathematical model between	Without considering the adaptation degree	Applicable to the prediction of

method		the traffic demand and supply	between the traffic supply and demand,	highway network recently
Analogy method	$L = f(I, P, A)$	The factors considered comprehensively, more close to the actual	analogical object and principle hard to grasp, weight variable factor of analogical various hard to determine	the results depends on the analogy process

4 Highway network scale correction

The gini coefficient were commonly used to evaluate regional unbalanced development in many aspects such as resources, income. It has been proved reliable to evaluate the highway infrastructure distribution in a specific area. The paper proposed that the highway network scale should be adjusted with gini coefficient in the reasonable range.

The reasonable value range of the highway network scale was got from the comprehensive analysis of the prediction results of the growth curve method, territory coefficient method and connectivity method (Table 2).The median value of the reasonable range is choose to be tested and amended as initial value with population gini coefficient, area gini coefficient and economy gini coefficient.(Wang,2006).

Table 2. Prediction of highway network scale

	growth curve method (km)	territory coefficient method (km)	connectivity method (km)	reasonable value range in 2020 (km)
WDA	1377	1371	1414	1371-1414
Ruian	2156	2142	2341	2142-2341
Yueqing	1360	1389	1550	1360-1550
Dongtou	220	196	135	135-220
Yongjia	2884	2869	2682	2682-2884
Pingyang	1875	1804	1960	1804-1960
Cangnan	1886	1679	1818	1679-1886
Wencheng	2011	1961	1802	1802-2011
Taishun	2286	2090	2041	2041-2286

Refer to the gini coefficient evaluation standard(Table 3), the network equilibrium is analyzed with the evaluation conclusion of the prediction value. When the conclusion indicates the highway resource allocation in equilibrium, the tested value can be accepted as a final reasonable result. Otherwise, the initial value adjusts modestly with Lorenz curve in the reasonable range to get the result accepted.

Table 3. gini coefficient evaluation standard

interval	0-0.2	0.2-0.3	0.3-0.4	0.4-0.5	0.5-1.0
conclusion	absolute equilibrium	very balanced	relatively reasonable	unbalanced	Very unbalanced

Table 4 shows the final result corrected with gini coefficient. Table 5 shows that the prediction method concerns the difference in each counties so the gini coefficient in 2020 is bigger than the recent status. But the gini coefficients still keep close to the absolute equilibrium criterion.

Table 4. Correction of highway network scale

	reasonable value range in 2020(km)	Initial value (km)	Corrected value (km)
WDA	1371-1414	1393	1403
Ruian	2142-2341	2242	2188
Yueqing	1360-1550	1455	1421
Dongtou	135-220	178	200
Yongjia	2682-2884	2783	2682
Pingyang	1804-1960	1882	1845
Cangnan	1679-1886	1783	1717
Wencheng	1802-2011	1907	2007
Taishun	2041-2286	2164	2137

Table 5.evaluation of corrected highway network scale

	Population gini coefficient		Area gini coefficient		Economy gini coefficient	
	Data	Conclusion	Data	Conclusion	Data	Conclusion
Recent value	0.160	absolute equilibrium	0.064	absolute equilibrium	0.210	very balanced
Corrected value	0.178	absolute equilibrium	0.051	absolute equilibrium	0.218	very balanced

5 Conclusions

After the prediction and correction，it is the conclusion that the total reasonable highway scale of Wenzhou is 15600 km and the rational scale of each different counties is proposed in Table 4.The paper concerns the influencing factors of each counties which has a different level of highway development and predicts the reasonable highway scale. Using the gini coefficient, on the basis of the differentiation configuration it ensures the equilibrium configuration of highway infrastructure in Wenzhou, which helps the residents of different districts enjoy the fairness of the highway basic service and promotes the economic development of transport infrastructure lagging regions.

Preliminary Exploration in Choice Behavior of a Parking Lot in a S/M City with a Logit Model

Yanjin Li

School of Transportation and Logistics, Southwest Jiaotong University, Sichuan, China. E-mail: 291188963@qq.com

Abstract: In recent years, along with the amount of our country's vehicle increasing year by year, the downtown areas or CBDs in many S/M Cities have appeared parking problems. To provide some effective decision-making reference for traffic management, this article tries to help S/M City find a method to solve its urban parking problem by studying persons' parking choice behavior. We have made the parking behavior surveys about 3 ground parking lots and 2 underground parking lots in Dazhou city, a S/M City in the east of Sicuan Province, and analyzed surveys data to regard the Saturation of Berth as a leading indicator, the distance to destination and the parking fee as two main factors that affect parking choice behavior. On basis of research we established the Binary Logit (BL) models to quantitatively depict the parking behavior. And according to the coefficients in model and the symbols of **t** value view, under the premise that the confidence level of **t** is 95%, the BL model owned a high precision. Finally, based on the qualitative analysis of parking fee, the article got a preliminary threshold of parking fee: the basic fee is 7 yuan/h, and when the parking fee exceeds the value, it has significant effect on adjusting the ground and underground parking lot choice behavior in Dazhou urban area.

Keywords: Choice behavior of parking lot; Logit model; S/M city; The threshold of parking fee.

1 Introduction

Currently, the analysis about the choice behavior of parking lot, as a research direction in the field of urban transportation planning, is playing a more important role increasingly. Yoram (1997) utilized parking behavior data to build a model to analyze people reflection. Rachel (2001) built 6 models that owned multiple different variables to identify significant behavior patterns of persons. Moshe (2004) has defined a mixed model after referring to the formers' achievement in research, and has realized it with MNL. However becautilize of cultural and economical difference, researches from abroad can't always work in our C/M City all time. So, this article tries to find a viable method to study parking choice behavior in our cities. The paper is engaged in parking choice behavior investigation in Dazhou City, and on the basis of analyzing data we utilize BL model and calibration model parameters. Finally we explore the threshold of parking fee which can affect the choice behavior of parking lot and provide a viable method for traffic management about parking problems in the city.

2 Survey overview

In order to grasp regular pattern about the choice behavior of parking lot in S/M City, this article finished 2 surveys on September 1st 2014 (Monday) and September 6th 2014 (Saturday), which tried to get information about the choice behavior of parking lots in Dazhou City, a S/M City in Sicuan Province.

The objects of the investigation are 3 ground parking lots and 2 underground parking lots in the main areas of Dazhou City. Considering that there are differences between persons' choice behavior of parking lot on weekday and weekend, the surveys were carried out on Monday and Saturday. We recovered 555 efficacious questionnaires and made the sampling rate of samples is 90%. The table is divided into 3 parts: instructions of table, information of respondents and survey content. The investigation objects are traveler in parking lot, and the investigation purpose is to obtain persons' reasons of parking choice behavior. Finally, the results are shown in Table 1 and Fig.1.

Table 1 the Overview of Parking Lot and the Saturation of Berth

Number	Name	Type	Fee	the Saturation of berth	
				Mon	Sat
1	Dongyu Parking lot	Ground	5 yuan/h	0.464	0.81
2	Moer Parking lot	Ground	6 yuan /h	0.601	0.827
3	Binjiang Parking lot	Ground	7 yuan /h	0.393	0.727
Average				0.486	0.788
4	Xinshang Parking lot	Underground	4 yuan /h	0.17	0.53
5	Shiji Parking lot	Underground	4 yuan /h	0.134	0.59
Average				0.152	0.56

(the Saturation of berth = the Average number of parking/the Total number of parking).

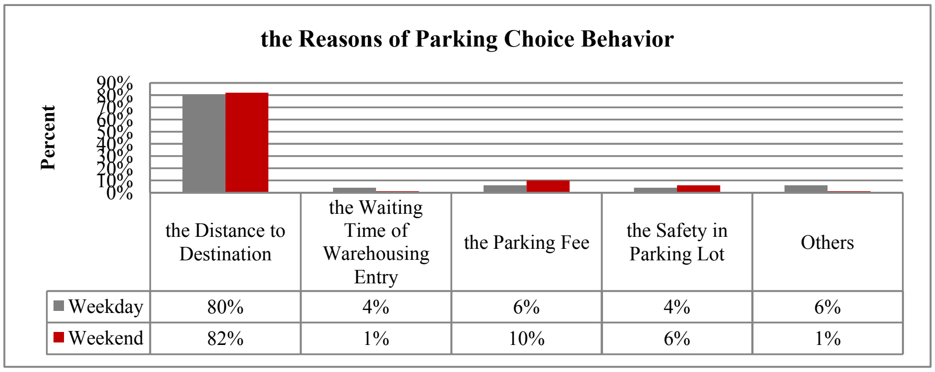

Fig.1 the Reasons of Parking Choice Behavior

3 Building logit models

In order to study on the affecting factors about persons' parking choice behavior, the paper utilize Binary Logit (BL) Model to analyze its problems.

3.1 Selecting model variables

According to Table 1, compared with the ground parking lots ,the Saturation of Berth in the underground parking lots is much lower not only on weekday but also on weekend, which makes their parking distribution unbalanced. So, the Saturation of Parking Berth should be a primary target for models and we should try our best to seek its maximum effectiveness.

On the other hand, according to Fig.1, among the factors with affecting parking choice behavior there are two factors, the Distance to Destination and the Parking Fee, which should become the most important ones(specifically the Distance to Destination, whose percent in Fig.1 is larger than 80%). Therefore, this paper utilizes the Distance to Destination and the Parking Fee as the arguments of BL model and regards whether chooses the ground parking lots or the underground parking lots as binary results (Guang Z.H,2000). The preliminary model structure is shown as following Table 2.

Table 2 the Model of the Parking Choice

Selecting results	Inherent dummy	the Distance to Destination	Parking Fee
Ground parking lot	1	X_{1n1}	X_{1n2}
Underground parking lot	0	X_{2n1}	X_{2n2}
Parameters	θ_1	θ_2	θ_3

3.2 Calibration model parameters

Selecting 500 samples from 555 questionnaires, we respectively build models on weekday and weekend. And the composition of samples is shown on Table 3. What's more, we utilize the Spss to calibration the model parameters with these samples. The results are shown on Table 4.

Table 3 the Composition of Samples

	Ground parking lot	Underground parking lot	Sum
Weekday	90	100	190
Weekend	166	144	310
Sum	255	245	500

Table 4 the Parking Choice Model 1 on Weekday and Weekend

Model 1	θ_1	t_1	θ_2	t_2	θ_3	t_3	H.R	ρ_2	$\overline{\rho^2}$
Weekday	-1.49	-3.77	-0.01	-7.41	0.11	0.22	0.34	0.36	0.35
Weekend	-0.36	-1.39	-0.01	-8.95	0.01	0.25	0.28	0.27	0.25

θ_i （$i = 1,2,3$）is the coefficient of the i^{th} variable, t_i （$i = 1,2,3$）is the t test value of the i^{th} variable, H.R is the Hit Ratio, ρ_2 and $\overline{\rho^2}$ are sensitivity coefficient and adjusted sensitivity coefficient.

From Table 4, it shows that the coefficient of factor parking fee is 0.11 on weekday or 0.01 on weekend, which is larger than zero (>0). This result reflects that when the parking fee is higher, the effectiveness of BL model is more notable, which is unreasonable and goes against the practical experience. And the H.Rs are also a little lower (<0.5).

However, if we abandon the parking fee from BL model, it can't reflect the impact of fee on persons' parking choice behavior. Therefore this article thinks that it is essential to calculate the threshold of parking fee which can make the fee do the deed.

4 Calculating the threshold

The threshold of parking fee is defined that when parking fee is larger than it, the parking fee will affect person's parking choice behavior observably.

According to Table 1, the fees of 5 parking lots all fall in the region [4, 7]. But now, the article will make the parking fee of underground parking lot constant, which is 4 yuan/h, and change the fee of ground parking lot from 0yuan/h to 10 yuan/h. And we utilize the ***Matlab*** to draw their effectiveness curves separately on weekday and weekend. The results of curves are shown in Fig.2.

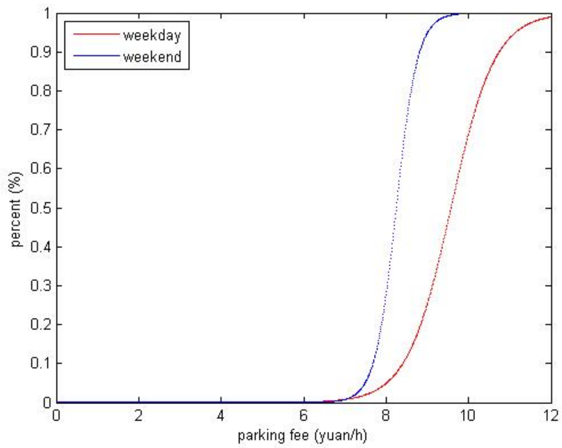

Fig. 2 the Effectiveness Curves of Parking Fee on Weekday and Weekend

According to the above figures., the threshold falls in the region [6,8], which is approximately 7yuan/h, which means that if we get a new parking fee of ground parking lot that is larger than 7yuan/h, the influence of parking fee on the person's parking choice behavior will be notable. So, let's make that the parking fee of ground parking lot is 8yuan/h and 10yuan/h separately (which are larger than 7), and utilize the Spss to calibration model parameters again. The results are shown in following Table 5.

Table 5 the Adjusted Parking Choice Model 2and Model 3 on Weekday and Weekend

Model 2	θ_1	t_1	θ_2	t_2	θ_3	t_3	H.R	ρ_2	$\overline{\rho^2}$
Weekday	-0.99	-3.19	-0.01	-6.12	-0.04	-1.83	0.56	0.31	0.30
Weekend	-0.60	-2.31	-0.01	-7.46	-0.05	-1.97	0.53	0.23	0.22
Model 3	θ_1	t_1	θ_2	t_2	θ_3	t_3	H.R	ρ_2	$\overline{\rho^2}$
Weekday	-1.03	-3.07	-0.01	-6.13	-0.03	-2.35	0.63	0.31	0.30
Weekend	-0.55	-2.10	-0.01	-7.49	-0.02	-2.41	0.58	0.23	0.22

Model 2 is a model whose parking fee of ground parking lot is 8yuan/h;

Model 3 is a model whose parking fee of ground parking lot is 10yuan/h.

5 Conclusions

From Table 5 the effectiveness of BL models will be notable if the parking fee exceeds 7yuan/h. All coefficients of the models are lower than zero (<0), which is coincided with reality. And studying from H.R, ρ_2 and $\overline{\rho^2}$, the accuracy of models is very high. So finally this article can make the conclusions that the threshold of parking fee in ground parking fee is approximately 7yuan/h and if the fee is larger than 7, it can help adjust the Saturation of Berth between the ground parking lots and the underground parking lots to a balanced level in Dazhou City.

Rational Allocation of Passenger Transportation Structures in a Metropolitan Area

Huapu Lu[1]; Luhong Yu[1]; and Shengyu Qi[2]

[1]Institute of Transportation Engineering, Department of Civil Engineering, Tsinghua University, Beijing 100084, China. E-mail: 649558464@qq.com
[2]School of Traffic and Transportation, Beijing Jiaotong University, Beijing 100084, China. E-mail: 782526500@qq.com

Abstract: In light of the rapid development of urbanization, this essay mainly studies the new type of metropolitan area during city evolution and researches about the rational allocation of intercity passenger transportation in metropolitan areas. Based on analyzing the mode and the demand characteristics of the metropolitan transportation, in terms of both sides of transportation supply and demand, establishes the objective function, maximizing the passenger transport efficiency and minimizing residents' cost of travelling, and builds the Multi-objective programming model using restraining variables such as economy, environment, efficiency and service in the passenger transport system. To solve the question above, we apply genetic algorithm (GA) and get the most reasonable transportation structure in metropolitan in sustainable development. Given the same city transportation capacity, different travelling mode split can result in different utilization efficiency, with which we can assess the rationality of the transportation allocation. Finally, we take the Wuhan metropolitan as an example and use the model to allocate the rational transportation structure from Wuhan city to Xiaogan city.
Keywords: Metropolitan area; Transportation structure; Multi-objective programming; Genetic algorithm (GA).

1 Introduction

With the fast development of urbanization in China, it is inevitable for metropolitan to form and grow under the combined effect of aggregation and diffusion. With the same city transport capacity, different travelling mode results in different utilization efficiency. That is to say, a rational transportation structure not only brings the infrastructure to its fullest, but also has a great impact on the total transportation capacity. Also, how to construct a rational transportation structure in metropolitan area is a urgent subject nowadays because it is the key to solving many problems against city development, such as sustained population growth, increasing traffic demand, enormous increase of motor vehicles and insufficient road capacity.

2 Passenger Transportation Systems in Metropolitan Area

2.1 Way of thinking in the model and modeling assumptions

The passenger transportation system in the whole metropolitan area can be divided into two parts: one is the supply, the government enterprise is in charge of the funding and the running. Another is the demand, residents choose travel mode. In terms of the supply side, the main purpose of the government providing the public traffic facilities is pursuing the max social effect instead of an economic one, so the objective function is to achieve the maximum transportation efficiency. Meanwhile, in terms of the demand side, residents all wish to choose the best mode to travel. Generally, the best mode means costing the fewest amount of time and money, which we also use as the objective function to build a multi-objective programming model. And the restraining variables are economy, environment, efficiency and resources.

The modeling assumptions：

(1) The transport structure in this model means the reasonable combination of different transportation mode, excluding the route and network.

(2) Generally speaking, residents travelling cost in metropolitan area consists of the ticket price and extra service fee. Residents choose best mode on their own .

(3) The supply side allows all kinds of travelling vehicles meet traveler's needs at the highest frequency in terms of the transport condition and organization.

2.2 Notation Definitions

Table 1. Notation Definitions Schedule

Symbol	Definition
$_{ij}^{k}$	The volume of passenger flow from location i to location in transport mode
t_{ij}^{k}	The time cost from location i to location j in k transport mode
t_{ij}^{min}	The fewest amount of time from location i to location j
Q_{ij}	The traffic demand from location i to location j
pr_{ij}^{k}	The transport system pollutant discharge form location i to location j
E_{ij}	The biggest transport system pollutant discharge the environment can handle from location i to location j (according to the government standard statistic)
l_{ij}^{k}	The dynamic area from location i to location j the k transport method covers
L	The average road area per person from location i to location j
M	The congregation of all the transport mode
B	The amount of investment in transportation construction
minF^{k}	The fewest passenger capacity from location i to location j in the k transport mode
maxF^{k}	The largest passenger capacity from location i to location j in the k transport mode
C_{ij}^{k}	The residents travelling costs from location i to location j in the k transport mode

3 The Allocation Model Formulation of Passenger Transportation Structure

3.1The objective functions

Maximizing efficiency of the passenger transportation system, minimizing the residents travelling costs, also.

$$\max Z = \sum_i \sum_j \sum_k f_{ij}^k \cdot \frac{t_{ij}^{min} \sum_k f_{ij}^k}{\sum_k f_{ij}^k t_{ij}^k} \tag{3-1}$$

$$minZ' = \sum_i \sum_j \sum_k f_{ij}^k \cdot C_{ij}^k \tag{3-2}$$

3.2 The restraining variables

$$\sum_k f_{ij}^k = Q_{ij} \tag{3-3}$$

$$\sum_k f_{ij}^k \cdot pr_{ij}^k < E_{ij} \tag{3-4}$$

$$\frac{\sum_k f_{ij}^k l_{ij}^k}{\sum_k f_{ij}^k} \ll L \tag{3-5}$$

$$\mathrm{minF}^k \ll f_{ij}^k \leq \mathrm{maxF}^k \tag{3-6}$$

$$\sum_i \sum_j \sum_k X_{ij}^k Y \leq B \tag{3-7}$$

$$C_{ij}^k = \propto_1 \cdot p + \sum_\beta \alpha_\beta \cdot C(p, \beta) \tag{3-8}$$

$$\alpha_1 + \sum_\beta \alpha_\beta = 1 \tag{3-9}$$

$$\forall \mathrm{i} \in \mathrm{O}, \forall \mathrm{j} \in \mathrm{D}, \forall \mathrm{k} \in \mathrm{M}$$

Generally speaking, the cost equals the transportation freight rate and other extra expenses, including comfort level and timing values. α_1、 α_β are parameters; p is the average price from location i to location j; $C(p, \beta)$ are other expenses including comfort level and timing values.

3.3 Analyzing the restraining variables and statistic application

(1) Meeting the overall transport demand

Without a doubt, the purpose of the passenger transportation system in metropolitan area is to meet the residents' demand.

Formula (3-3)，which expresses that the sum of passenger in entire traffic mode must meet the demand of residents travel. Besides, the travel demand of planning year can be calculated by the theory of growth rate.

(2) The environment capacity

Nowadays many metropolises are advocating 'green transportation' and 'sustainable development transportation', because of the traffic pollution. Therefore as city planners, we should consider limiting pollutant discharge, mostly in air pollution and noise pollution. In this model, we only consider the air pollution, for which we choose CO_2、NO_X as restraining variables.

Formula(3-4), expressing that the sum of pollutant emissions in all traffic mode cannot exceed environmental restrictions.

(3) Land coverage restriction.

Land use pattern is very closely related to transportation. Once the land use pattern changed, the travel will also be changed.

$\frac{\sum_k f_{ij}^k l_{ij}^k}{\sum_k f_{ij}^k} \ll L$, which represents the dynamic relationship between road traffic capacity and passenger transportation structure in metropolitan, and l_{ij}^k can be caculated by:

$$l_{ij}^k = \mathrm{D}^k \times d^k / b \tag{3-10}$$

D^k : safe lateral clearance of safety driving of k traffic mode(m);

d^k: safe spachead way of k traffic mode(m); b: average passenger volume of each mode(people/car).

(4) Each mode has its own transit capacity

Under the condition of its transportation tools and infrastructure being determined, each traffic mode has its maximum capacity of saturated state.

Formula(3-6), expressing that each mode has its own capacity limit. Lower limit reflects the complementary of different traffic mode and social fair competitiveness. While，upper limit reflects restrictions of social resources, environment capacity and so on.

(5) Investment constraint

Infrastructure and transport tools of each travel mode needs to spend a lot of money, so we must measure each mode, and try to choose a project which could meet the total investment constraints and achieve the maximum efficiency of transportation.

Formula(3-7)，representing that the investment of various has a fixed limit.

4 Algorithms

The model intends to get the solution through genetic algorithm. The basic idea of this model is: To obtain a set of solutions by encoding which can generates an initial, random population of individuals for a fixed size, to evaluate their fitness, to exert selection, crossover or mutation and other genetic manipulations to achieve population search, and to make the population evolved to the stage which includes the approximate optimal solution.

Step1：The model obtains a set of solutions by encoding, which generates an initial population. In the model, the basic operating parameters of Genetic algorithm are set: Population size $size(U) = 100$, Iteration limit $N = 100$, Crossover and mutation probabilities are taken at 0.5 and 0.05; Randomly generate an initial population; Calculate value of the fitness function for each chromosome, determine the minimum function value and the corresponding chromosome at the temperature of t_1, and make the number of iteration as $k = 1$.

Step 2：According to the population "Fitness" to evaluate the current chromosome of the population. Evaluation criteria is the efficiency value of passenger transport system.(The objective function formula(3-1))

Step 3：Use the constraints to modify evaluating value, select the probability according to the proportion of evaluation value, then go on cross, mutation and other genetic operations for iterations to generate a new population $U^{(k+1)}$.

Step 4：Continue to evaluate the current population of chromosomes(as Step 2).

The process of algorithm as shown in Fig.1.

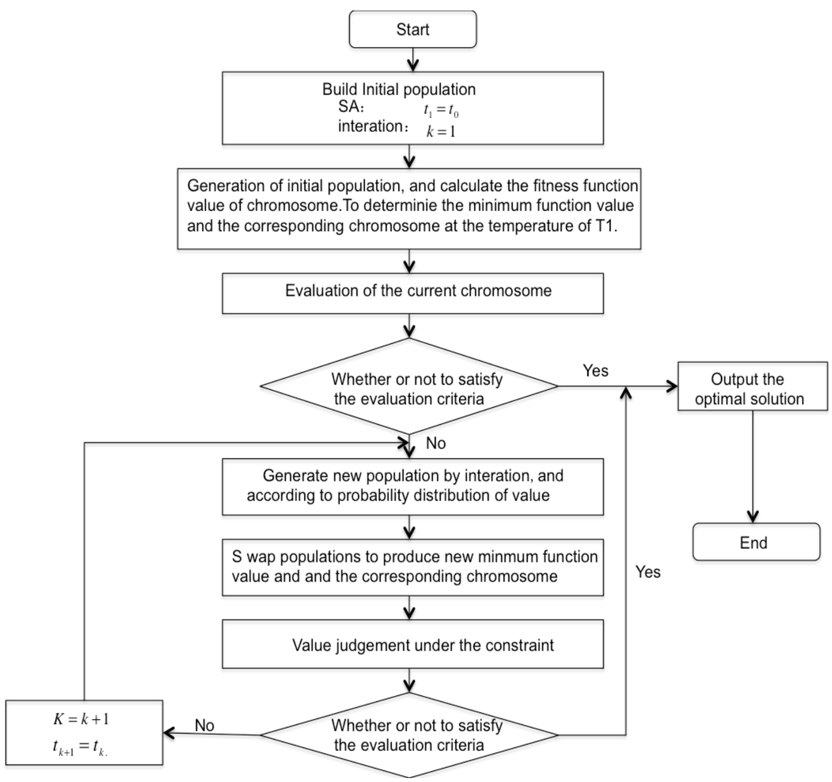

Fig. 1 Flow chart of genetic algorithm

5 The Rational Transportation Structure Allocation of Wuhan Metropolitan

5.1 The "Mode-Path" transportation characteristics from Wuhan to Xiaogan

Taking the central city and a peripheral city –"Wuhan to Xiaogan" in Wuhan metropolitan as an example, it can demonstrate how to allocate the reasonable transportation structure of metropolitan.

The “Mode-Path” in Wuhan-Xiaogan: car-road, car-highway, express, scheduled bus and the developing intercity railway(opened in 2016), as shown in Figure 2.

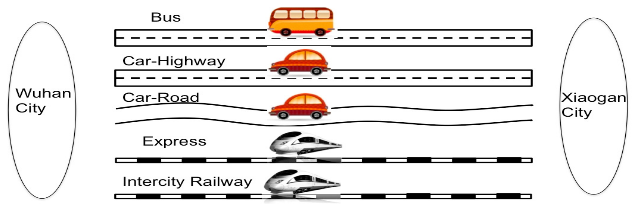

Fig 2. “Mode-Path” transportation from Wuhan to Xiaogan

1) Collecting and preparing data

According to the policy of Hubei Provincial Government, the almanac of Hubei Provincial Government, the planning of Wuhan metropolitan and expert opinions, it is capable of calculating the limit of environment capacity and pollution emission and per capita road area in Wuhan metropolitan. There are some transportation characteristics of 5 kinds of “Mode-Path” in Wuhan-Xiaogan, as shown in Table 2.

2) The total demand of passenger transport

According to the research in Wuhan metropolitan, it is known that the average daily passenger flow between Wuhan to Xiaogan is 3766 person trip(XU Wenxue,2007).We can predict that passenger flow would be 2.128m person trip in 2016, and the average daily demand is 5830 person trip，which is the total passenger travel demand between Wuhan and Xiaogan.

Tab2.Characteristics of intercity passenger transport “mode-path” in Wuhan-Xiaogan

Transportation Mode	Car-highway	Car - Road	Express	Bus	Intercity -Railway
Dynamic area(km^2/per)	50	2.5	0.5	5	0.5
Average price (yuan)	65	45	38.5	23	22
NO_X Emissions (g/ person·km)	6	7.5	0.18	1.5	0.18
CO_2 Emissions (g/ person·km)	1.2	1.4	0.04	0.15	0.04
Travel time(min)	40	55	30	65	30
Transportation capacity(person)	Min: 500 Max: 2915	Min: 500 Max: 2915	Min: 700 Max: 2500	Min: 1000 Max：2500	Min：1500 Max：3500

5.2 The results of the passenger transportation structure allocation model of Wuhan – Xiaogan

1) The results

Solving by the multi-objective programming model of metropolitan transportation structure allocation proposed in Section 3 and using the MATLAB software to run Genetic Algorithm, we can get the rational transportation passenger structure allocation between Wuhan and Xiaogan, as shown in Table 3.

Table 3．Rational passenger volume of transportation structure in Wuhan-Xiaogan

Mode-Path	Car-Highway	Car-Road	Express	Bus	Intercity -Railway
Daily passenger flow(person)	882	630	1275	1004	2089
Share	15%	11%	22%	17%	35%

5.3 The analysis of the solution

According to Tal.3, we know that car shares 26%, railway (express and intercity railway) shares 57% and passenger bus shares 17%.

The share of railway, bus and car travel separately are 12%, 12% and 46% in the passenger flow of Wuhan metropolitan in 2008(Institute of Comprehensive Transportation of National Development and Reform Commission, 2010), which is far more different from the transportation structure allocated by the model in this section.

According to the maximum efficiency of passenger transportation system in the objective function, the utilization of the Wuhan metropolitan's is 55.6% in 2008. However, the utilization is 74.1% after using allocation model in 2016.And there is 33.3% promoted of efficiency after being optimized by this model.

As shown in the Fig.3, from the point of car, the share should be decreased to 26% from 46%. The reduction of the private car's share is beneficial to the environment capacity and the road utilization; from the angle of rail transit, its share should be increased from 12% to 57%. It is chiefly because that the intercity railway from Wuhan to Xiaogan opened in 2016 will help achieve "Long-distance workers" and "Railway as public bus". Whether from the capacity, the frequency and the quality of service, the intercity railway is much better than the scheduled bus.

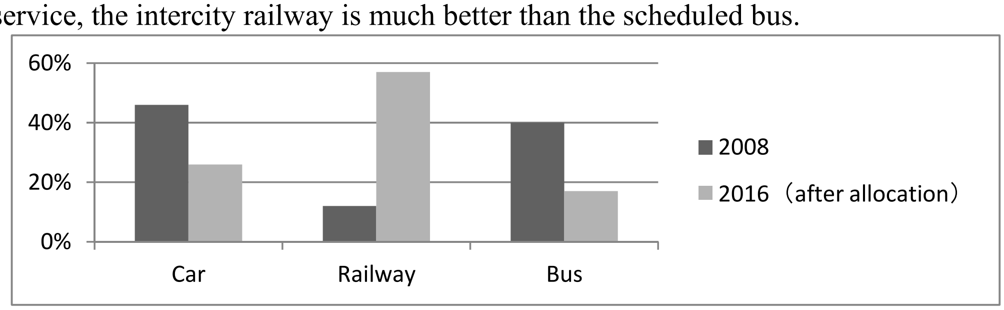

Fig.3 The changes between before and after allocation

6 The Development Suggestion of Transportation from Wuhan to Xiaogan

(1)The rapid development of railway is in line with the status quo of our country which has a high density of population and high aggregation of land. But the transfer between terminals of railway and urban areas also very important, otherwise the residents will reduce the probability of selecting railway.

(2)In order to reduce private transportation split rate, the government can enact the tail number limit and other policies to reduce the trip time of cars.

(3)The reasonable changes in passenger bus. Once operating in the intercity railway between Wuhan and Xiaogan in 2016, the split rate of bus will be transferred to the railways'. It's a challenge to change the operation of intercity bus.

Non-Motorized Vehicle Parking Demand at a Suburban Railway Station

Yingxue Chen[1,2] and Fan Gao[2]

[1]Key Laboratory of the Education, Ministry of Road and Traffic Engineering, Tongji University, Shanghai 200092, China.
[2]College of Urban Railway Transportation, Shanghai University of Engineering Science, Room 1119, Administration Building, No. 333, Longteng Rd., Songjiang District, Shanghai, China. E-mail: chenyingxue04@163.com

Abstract: A survey was made on non-motorized vehicle parking lot scale of line Tsukuba in Tokyo, the influence factors like station passenger flow, distance between station, land development around station, distance from city-center are analyzed, then fuzzy algorithm was built among the four influence factors and non-motorized vehicle parking lot scale. At last, non-motorized vehicle parking demand at suburban stations of metro line 7 was estimated as an example based on the fuzzy algorithm and the influence factors survey data.
Keywords: Suburban station of rail transit; Parking demand of non-motorized vehicle; Line Tsukuba in Tokyo; Fuzzy algorithm.

1 Introduction

Nowadays, with the irrational expansion of city and the problem it caused, great efforts were made to build sub-center or satellite city in China, thus suburban railway system is during rapid development for it is the traffic foundation for suburbs development and bear mass commuter trips. Since entry and exit are usually the weakest parts of thetransport chain, the access traffic system determines the service level and competitiveness of suburban railway to a degree.

For the high house price in city center and the traffic convenience of suburban railway, there are plentiful residential land around the suburban railway station in 3km, and for these residents, railway is usually chosen as a commuter tool. The commuter trip is regular and of high frequency, Non-motorized transportation, which is an important access mode within 3km, and characteristic of flexibility and mobility, has great advantages and potential to be the access mode of suburban railway. But currently, planning and design of non-motorized vehicle parking lot at suburban railway station are not given much consideration to, parking capacity is inadequate, management is poor and facility is simple, which result in share of non-motorized vehicle as access mode for rural railway transit is less than 10%, when in developed country, like Holland and Japan, the figure reached 30% or higher.

Currently, theory of non-motorized vehicle parking around suburban railway station, like parking demand predict, parking lot location, size and layout are lack of specificity and enforceability, The theories available are unable to effectively guide the actual design work, so this paper took Shanghai Railway Transit Line 7 as an example to predict non-motorized vehicle parking demand at suburban railway station.

2 Existing methods

In general, methods available only describe the calculation idea, lacking of a thorough calculation process, and parameters like share of non-motorized vehicle in access trips, transfer impedance can not be got properly for lacks behavior characteristics date. Thus methods available are lack of specificity and enforceability. There are mainly three method:

1) Model of attract rates

This model determines the parking lot scale by calculate the total parking demand in peak time, and this is relevant to land use and density around the station.

$$P_a = \sum_{i=1}^{q} b_i t_i \tag{1}$$

P_a— peak time parking demand（veh）;

t_i — land scale of various land type， km^2;

b_i— average vehicle attract for various land type per km^2。

The problem is that the model calculates parking demand for trip destination but not for transfer, while non-motorized vehicle parking at suburban railway station is usually for transfer to railway.

2) Estimate parking demand through make a survey on non-motorized vehicle share in transfer trip at an exit station

This method neglect problems exist in non-motorized vehicle parking, like inadequate capacity, not standardized management, poor safety guarantee, etc., resulting in the potential non-motorized vehicle transfer demand has been suppressed. It also neglects the difference between suburban and center city in non-motorized vehicle transfer and parking characteristic, trip of non-motorized vehicle to railway station is usually in larger number and of longer distance in suburban area, and parking time is also longer.

3) Logit model

This model need transfer impedance of non-motorized and its competitors to do modal split, but behavior characteristics data of residents around suburban railway station is unavailable and is difficult to get by a small survey. Besides, when using logit model, the assignment is based on the value of the resistance, for example, the impedance of the two lines are 5 and 10, respectively, or 95 and 100, respectively, the assign result is the same. But some factors of impedance can't be quantified like safety, convenience, etc., thus the impedance can't be obtained properly.

3 Comparative analysis

3.1 Parking problem of Shanghai metro line 7

Shanghai railway transit line 7 planned to originate at Baoshan district and destination at Pudong district, the north part of line 7 is a typical suburban railway ,connect a satellite town with center city, assume mass commuter and school trip. So B+R (Bike+ride) mode is suitable for the north part of line 7, especially for the suburban station, for that in suburban area passenger is less, so bus line is rare and the frequency is low, which means long walking distance or waiting time.

Through survey, we found that suburban station of line 7 is deficient in non-motorized vehicle parking facility, induce many illegal taxi and motorcycle. And it is difficult to give the accurate capacity of some exist non-motorized vehicle parking lot, for these parking lots are not experience careful planning and design, and the identification of parking scope is vague. From the quality point of view, non-motorized vehicle parking condition is poor, facility is simple, parking security can't be guarantee. Non-motorized vehicle parking is confusion and sometimes even affect the pedestrian traffic and vehicle traffic. The poor condition of non-motorized vehicle parking lot suppress the true parking demand.

3.2 Parking situation of Tokyo Line Tsukuba

The paper tried to calculate non-motorized vehicle parking demand at suburban railway by learning the advanced experience of foreign countries.

Tokyo and Shanghai are similar in urban characteristics, residents travel characteristics and railway transit scale in future. so the paper decide to make a comparative analysis between Tokyo transit and Shanghai transit.

Tokyo suburban rail transit line Tsukuba approved by Japanese government in non-motorized vehicle feeder organization, is similar with the north part of Shanghai rail transit line No. 7. It is opened in 2005, and the passenger flow is mature and stable now.

The two line are similar in line location, line function, they both connect the city center and the suburban area, and bear a lot of commuter trips.

In traffic theory parking demand is considered to relevant most to land use around, passenger flow, station distance from city center and average distance between stations. Table 1 shows the figures of the parameters of Tokyo Line Tsukuba. And fuzzy algorithm was used to build the relationship between non-motorized vehicleparking demand with the four factors mentioned above.

Figure 1. Location of Tokyo metro line Tsukuba

Figure 2. Location of Shanghai metro line 7

Table1. Non-motorized vehicle parking lot scale and situation of four influence factors of line Tsukuba

Station	average passenger flow (per day)	development level of land use	average distance between station (km)	Station distance from city center (km)	non-motorized vehicle parking capacity (veh)
Tsukuba	15,117	16	2.7	58.3	410
Kenkyū-gakuen	3,691	12	3	55.6	0
Bampaku-kinenkōen	1,684	12	3.25	51.8	300
Midorino	2,360	9	3.75	48.6	0

Kita-Senju	193,976	25	2	7.5	300
Minami-Senju	14,597	6	2.2	5.6	230
Asakusa	8,111	12	2	3.1	80
Shin-Okachimachi	33,754	25	1.55	1.6	350
Akihabara	224,608	25	1.6	0	120

4 Fuzzy algorithm

Fuzzy algorithm is especially applicable to the subject investigated with fuzzy concept and fuzzy logic[8], based on that there is correlation between parking capacity and four factor but the relationship is not clear, fuzzy algorithm is used for design fuzzy inference method by information fusion of influence factors.

First, the issueshould be expressed by fuzzy mathematics model. In the fuzzy reasoning machine, surrounding land developed level M (i), site distance from city center D (j), average station distance S(k), passenger flow volume P (l) wasdefined as input, and non-motorized vehicle parking lot scale PK as output, the domain of each variable are: M(i)=[0,25];D(j)=[0.60];S(k)=[0,6.5];P(l)=[0.15000]

Each variable was divided into 5 grades from 1(low) to 5(high). Design fuzzy inference rules by factors, and designed membership function as shown in figure 3.

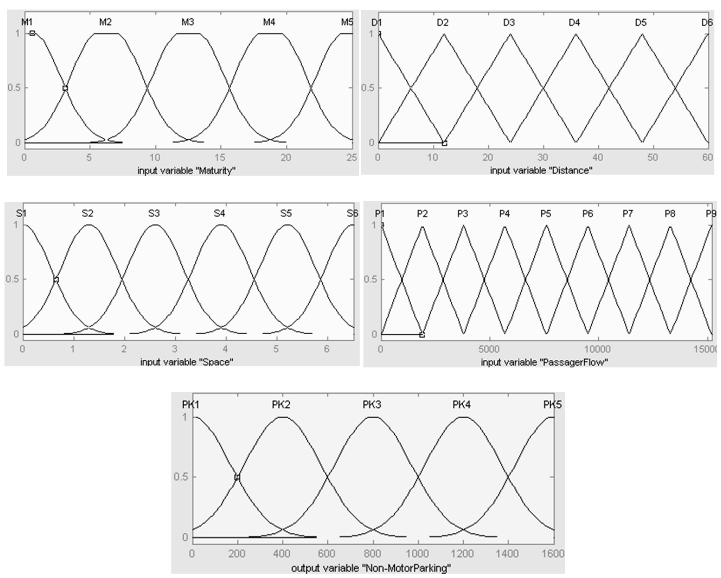

Figure 3. Membership function of each variables

By using the MATLAB fuzzy control toolbox for operation, select the Mamdani method for fuzzy reasoning, and gravity center method for defuzzification process, then we get the fuzzy control rules.

Finally，the model above was used as an example with the statistical station data{M (I), D (J), S (k), P (L)}of Shanghai metro line 7 as the input of fuzzy reasoning machine, to make the estimation of non-motorized vehicle parking capacity more accurate and reliable. The results can be seen in Table 2.

5 Conclusion

Non-motorized vehicle parking demand of south part station of Shanghai metro line 7 was obtained by comparative analysis between Shanghai metro line 7 and

Tokyo metro line TSUKUBA by fuzzy algorithm, but this is only applicable to this case, further study should focus on more general model. For it is difficult to get the predict passenger flow, data used in model is current flow, with the new line built and put into operation, the passenger flow will change , and so will the non-motorized vehicle parking capacity of the station.

Comprehensive Development Scale of a High-Speed Railway Station Based on TOD

Xiaojun Ruan

School of Transportation and Logistics, Southwest Jiaotong University, Chengdu Sichuan 610031, China. E-mail: 642572981@qq.com

Abstract: TOD refers to transit-oriented development. This paper analyses the development scale of foreign high-speed railway stations and the surrounding areas by referencing the successful experience of TOD mode in foreign cities and combining the related information of land development and city development. It comes out that the development scale is different from various kinds of high-speed railway stations and the surrounding areas, and summarizes the differences as well. In the meanwhile, this paper puts forward the calculation basis of the development scale of high-speed railway stations based on TOD mode through analysis, as well as the basic ideas and method of determining the upper and lower bounds.
Keywords: TOD; High-speed railway; Stations; Comprehensive development; Scale.

1. Introduction

TOD refers to transit-oriented development. The concept was first proposed by American architect and planner Peter Calthorpe in order to solve the unrestricted spreading problem of USA cities after World War II, and it takes the public transport as the center to build comprehensive development of urban pedestrian district. The public transportation is mainly included subway, light rail and bus lines, and it takes bus stations as the center, 400~800 m (5~10 minutes' walk) as the radius to establish the center square or city center. Its characteristics lie in that it sets work, business, culture, education, living as a whole to achieve the purpose of "mixed use".

The research on comprehensive development of traffic and land started early in foreign countries. In 1993, Peter Calthorpe put forward that the TOD mode could replace the unrestricted spread development mode in outskirts district in his book *The American Metropolis-Ecology，Community，and the American Dream*, and he worked out a set of detailed rules for the city land use based on TOD strategy. In 1997 Cervero and Kockelman brought forward the "3D" rule of TOD, which is "density", "diversity" and "design".

Li Yan established a combined model of dividing traffic mode and traffic distribution in *Research on Sustainable Development of City Rail Transit Based on TOD*, which was suitable for the characteristics of China's traffic and TOD community.

Zhao Jing discussed the special background and conditions of implementing TOD in *Research On the TOD Programming Method Suitable for Chinese Cities* , and put forward the definition of TOD mode suitable for Chinese city's characteristics by adopting the SWOT analysis method.

The TOD mode of comprehensive development of high-speed railway in our country is still in the exploratory stage, but the successful experience by utilizing TOD mode in foreign urban rail transit provides a reference mode for it. The comprehensive development scale of high-speed railway stations based on TOD mode varies from development patterns and spatial structure.

1.1 Industrial park pattern

Taken Taoyuan, Xinzhu, Tainan, Taichung, Chiayi station in Taiwan as example to analyze this pattern.

The development of high-speed railway station surrounding areas (high-speed railway special district, Fig. 1) in Taiwan is with particular emphasis on the development of the industry, giving full play to the multiplier effect of high-speed railway and the leading industry itself. It develops high-speed rail industrial parks in the high-speed railway station surrounding areas, and these specific areas are divided into station special district and special industrial zone and other contents. For example the special district of Xinzhu station takes the advantages of science and technology park in Xinzhu county to develop the biomedical science and technology; Taichung Station special district combines the advantages of traffic, the surrounding industrial infrastructure and human resources, to develop super scale commerce, entertainment and shopping facilities, administrative center and science and technology industrial park.

Fig.1 Planning map of Taoyuan, Xinzhu high-speed

On the whole, the scale of high-speed rail station surrounding areas in Taiwan are small, from 100 hectares to 400 hectares. The land scale of Taoyuan, Xinzhu, Taichung, Chiayi, Tainan and other sites around the stations are listed in table 1. The sites give full consideration to the needs of stations and industrial development when utilizing land.

Table 1. Area statistics of five station special district in Taiwan

Station	Special district area（hectares）	Function positioning
Taoyuan	490	International business city
Xinzhu	309.22	Biomedical science and technology city
Taichung	273.35	Entertainment and shopping city
Chiayi	135.24	Leisure and Recreation City
Tainan	299.72	study of Ecological City
Total	1507.53	

The spatial structure characteristic of high-speed railway station surrounding areas for industrial park comes that high-speed railway station (hub) +industrial park+ peripheral general city built-up area structure， and the land-use scale mainly depends on the basis of the original city industry and the land-use conditions of high-speed rail station surrounding areas . The better the foundation of the city Industry is, the larger comes the scale. In general the land scale of high-speed railway station surrounding areas for industrial park is relatively large, usually about 1~5 square kilometers.

1.2 City center pattern

Through the case analysis of high-speed railway station surrounding areas in Europe and Japan, it comes out that the high-speed railway station surrounding areas based on TOD has some differences in the scale due to the impact of urban development potential and other factors, ranging from 0.5~1.0. In general, the central area or deputy district scale formed from the high-speed railway station surrounding areas in small city is relatively smaller, around in 0.5~0.8 square kilometers, while the city in larger scale, the scale of its high-speed railway station surrounding areas of the city center or vice center size is relatively large, about in 0.8~1.0 square kilometers. There are also some exceptions that can reach 1.5 square kilometers (table 2).

Table 2. Foreign high-speed railway station surrounding areas

number	name	area（ha）
1	Tokyo station surrounding areas	126
2	Ikebukuro Station surrounding areas	85
3	Shinagawa Station surrounding areas	65
4	Shinjuku Station surrounding areas	114

2 Calculation of comprehensive development scale

2.1 calculation basis

Most high-speed railway cities delimit a large range of area for the development land use of high-speed railway station surrounding area. In the meanwhile, the scale of high-speed railway station surrounding area exists great differences and varies from 2~3 square kilometers to 30~40 square kilometers.

The scale, populations and economic development level of the cities can have direct impact on the passenger flow and traffic flow of high-speed railway stations. Generally speaking, the bigger the city scale is, the larger the passenger flow and traffic flow will be.

As the node of high-speed railway network, high-speed railway station surrounding area has a large volume of passenger flow getting in and out, and these flow needs to be distributed to the station surrounding area, as well as the periphery city space. In the meanwhile, the high-speed railway station and its surrounding area absorb passenger flow from the periphery city space, and deliver these flow to other nodes of high-speed railway station network. The number that needs to be absorbed and distributed requires passenger flow prediction to calculate the exact volume. After obtaining the passenger flow, the composition and proportion of all kinds of passenger flow need to be analyzed based on the survey data and experimental figures. In addition, the demand volume of the functional facility for the development project can be computed out according to the demand.

The above are the general calculation basis for the development scale of high-speed railway station surrounding area. In the specific project, the development scale and proportion should be flexibly adjusted according to the development positioning strategy made by development project of high-speed railway station surrounding area.

2.2 Methodology

Because the comprehensive development of high-speed railway station in the future will bring a large number of passenger flow, which would be superimposed with the existing passenger flow channel. Therefore, the superimposed passenger transport demand will exceed the station load-carrying capacity, or will result in land loss due to over exploitation. Thus the basic ideas and method to determine the upper and lower bounds of comprehensive development of high-speed railway station and its surrounding area based on TOD mode are put forward.

(1) Method to determine the upper bound

The passenger demand that produced by all kinds of land development type and scale cannot exceed the load-carrying capacity of the high-speed railway station. The basic model to determine the upper bound can be expressed as the following formula:

$$r_{sta} = \sum_{i=1}^{m} x_i y_i z_i \tag{1}$$

Where

r_{sta} is the passenger flow getting in and out of the high-speed railway station;

x_i is the *i* kind of land scale of high-speed railway station;

y_i is the *i* kind of land development intensity of high-speed railway station;

z_i is the passenger flow that produced by the *i* kind of unit land construction area of high-speed railway station.

The passenger flow distribution model can be established by taking advantage of the passenger flow getting in and out of the station, as well as its spatial distribution characteristics. The model is shown as (2).

$$D = f\left(r_{sta}\right) \tag{2}$$

Based on this, the one-way traffic volume (r_{seci} (*person time*) , *i=1, 2,…, n*) of each section in rush hour can be worked out.

Set the one-way traffic volume of maximum section in rush hour not exceeding the load-carrying capacity of station as the controlling condition, and determine the upper bound of development. The limit condition can be expressed as (3).

$$r_g = r_{seci}\left(max\right) \le r_{\sec}^{up} \tag{3}$$

Where

r_g is the one-way traffic volume of maximum section in rush hour;

$r_{\sec}^{up}$ is the load-carrying capacity of station.

(2) Method to determine the lower bound

High-speed railway passenger transport is one kind of transport mode with a large capacity, which is involved with huge amount of investment. Once the passenger flow of high-speed railway station is insufficient, great investment waste will be caused, which would make the operator side and investment side encounter with huge losses. Therefore, in order to avoid insufficient passenger flow and to guarantee the transport efficiency, the lower bound of the development scale needs to be controlled.

From the angle of investment and operating efficiency of high-speed railway stations, the passenger flow generated by various types of land development cannot be under the minimum traffic flow that makes assurance of high-speed railway station financial balance (at a given policy subsidy).

The basic model to determine the lower bound of development scale for high-speed railway station surrounding area is shown as (4).

$$f(r_r)+R_c(r_g)+R_s+R_t=f_\beta(r_r)+C_c(r_g)+C_{yy}(r_g)+C_j+C_s+C_{dx} \quad (4)$$

Where

$f(r_r)$ is the operating revenue function whose main calculation basis consists of daily passenger flow volume and other revenues such as advertisement, internal station commercial rent. These commercial revenues would be calculated pro ratio to simplify the model;

$R_c(r_g)$ is the residual value of cars and residual value function; R_s is the residual value of the equipment; R_t is the residual value of building project; $f_\beta(r_r)$ is the tax function; $C_c(r_g)$ is the car purchase fee function; $C_{yy}(r_g)$ is the operation fee function; C_j is construction cost, which mainly consists of building project construction cost, advance fee, reserve funds and other project cost. The construction period of all costs is four years, and the costs should be calculated 25% of every year; C_s is equipment cost which represents purchase equipment fees and equipment replacement cost;

C_{dx} is cost of overhaul.

The calculation method of each cost and profit is as follows:

$$f(r_r) = 365 r_r p_p (1+\alpha)\left(P/A_I, N\right) \tag{5}$$

$$R_c(r_g) = \frac{2r_g l}{DV} YFc_{dj}\left[\left(\beta_c + \beta_c^w\right)/(1+I)^N + \sum_{j=1}^{n_{gz}-1} \beta_c/(1+I)^{jL_c}\right] \tag{6}$$

$$R_s = c_s^d l\left[\left(\beta_S + \beta_S^w\right)/(1+I)^N + \sum_{j=1}^{n_{gz}^s-1} \beta_c/(1+I)^{jL_s}\right] \tag{7}$$

$$R_t = c_t^d l \beta_t/(1+I)^N \tag{8}$$

$$f_\beta(r_r) = 365 r_r p_p (1+\alpha)\beta\left(P/A_I, N\right) \tag{9}$$

$$C_c(r_g) = 0.0731Bc_{cgl}\left[\frac{r_g}{BD} Y\left(2+4h_{cg}+H_p\right)\right]\left(P/A_I, N\right)(1+I) \tag{10}$$

$$C_j = c_j^d l(1-\alpha_b) \tag{11}$$

$$C_s = c_s^d l\left[(1-\alpha_b) + \sum_{j=2}^{n_{gz}^s}\left(P/F_I, (j-1)L_s\right)\right] \tag{12}$$

Where

r_r is daily passenger flow of station, $r_r = \sum r_{sta}/2$; p_p is the ticket fee corresponding to average distance ; α is the proportion that other incomes account for total fees; $\left(P/A_I, N\right)$ is equal value pay series present value factor; I is the social discount rate; N is the cycle of high-speed railway station project; r_g is he one-way traffic volume of maximum section in rush hour; l is the length of track line; D is the specified number of train staff; V is the travelling speed of the train; Y is the capacity reserve coefficient; F is the maintenance and car reserve coefficient; c_{dj} is the unit price of cars; β_c is the car life salvage value rate; β_c^w is the residual value rate of unused cars at the end of project; n_{gz}^s is the purchase number of equipment during the lifetime of project; L_s is the lifetime of equipment; β_t is the residual value coefficient of building construction; β is the ratio of tax; α_b is the government subsidy coefficient; c_{cgl} is the unit price of operating fees; h_{cg} is the second coefficient in rush hour; H_p is the departure pair number in daily normal time.

3 Conclusions

Through the above analysis, the conclusion comes that the scale of high-speed railway station surrounding areas in foreign cities is basically the same. Generally speaking, the high-speed railway station surrounding area of small city is relatively small, while in large scale city it is larger. The scale of surrounding areas in different types of high-speed railway stations is basically various.

Abstract: Due to many uncertainties involved in the transit network optimization evaluation process, many existing methods could not portray different types of uncertainty. So the evaluation results couldn't objectively reflect actual problem. Based on the research results of previous scholars, this paper proposed set pair and entropy analysis in the ranking of transit network optimization schemes and constructed decision-making models. The method was applied to an example. Results showed that the method could solve the problem of non-unity between several indexes and the uncertainty of subjective opinions could be reduced. The calculation process was simple and easy to use. The method provided new ideas for the analysis of uncertainties for the public traffic network optimization.
Keywords: Transit network; Ranking of optimization scheme; Set-pair; Entropy.

1 Introduction

Urban public transit is very important for passenger's travel. Optimal transit network can improve service level of public transit and bring convenience to people. It also can alleviate traffic tension and promote the healthy and sustainable development of public traffic. Hu Qizhou and Zhang Weihua presented the decision making model for the optimization of urban public transport network by using grey related degree (Hu Qizhou and Zhang Weihua, 2007).They also set up the decision making model by quantum analysis and cosine formula(Hu Qizhou and Zhang Weihua, 2008).NI Jie and LIU Zhiqiang analyzed the restraint condition of the public transport optimization and plan the public transport network by using Ant algorithm method (NI Jie and LIU Zhiqiang, 2007). Tang Kefu and Wu Dawei proposed a new optimization model and developed an adapted genetic algorithm to solve the model (Tang Kefu and Wu Dawei, 2004). However, many uncertainties will happen in the process of public transit network optimization evaluation. Some methods cannot characterize different types of uncertainty. So the actual problems maybe not be reflected. In this paper set-pair and entropy is used for the public transit network optimization. The model can analyze the internal connections of the systeminlocal and overall ways. It is easy to use and the process of calculation is simple.

2 Set Pair - Entropy Analysis Method

2.1 Set pair analysis

Set-pair analysis (SPA) is a new system theory which was put forward by Zhao Keqin (Zhao Keqin, 2000). His main point is that certainty and uncertainty can be regarded as one system. Set pair is consisted by two related sets. It can be separated by the relationship of the two set as "Same", "Different", and "Opposite". And the uncertainty caused by fuzziness, random and information shortage can be uniformly processed by SPA.

Under certain conditions, the connection degree can be defined as follows:

$$\mu = a + bi + cj \qquad (1)$$

μ is connection degree of the two sets. i is the difference degree mark. j is opposite degree mark. i and j are both regarded as coefficients, j=-1, $i \in [-1,1]$.

$$a + b + c = 1 \qquad (2)$$

Assuming that the comparison of public transit network optimization schemes does not consider the difference, the relation degree expression is used to highlight the same and opposite degree. The object to be evaluated and the ideal scheme form one set-pair for set-pair analysis.

$$a + b + c = 1, \quad b = 0, \quad c = 1 - a \qquad (3)$$

2.2 Entropy weight coefficient

In order to reduce the subjective factor in decision making, in this paper entropy weight of objective method is adopted to determine the weight vector of the index. The procedure is as follows:

The entropy of the j optimization objective is defined as follows.

$$H_j = -\frac{1}{\ln n}\sum_{i=1}^{n} f_{ij} \ln f_{ij}, j = 1,2,\ldots,m \qquad (4)$$

$$\text{Where, } f_{ij} = \frac{r_{ij}}{\sum_{i=1}^{n} r_{ij}}, i = 1,2,\cdots,n; \; j = 1,2,\cdots,m \qquad (5)$$

And if $r_{ij} = 0$, make $f_{ij} = 0$.

$$w_j = \frac{1 - H_j}{m - \sum_{j=1}^{m} H_{ij}}, j = 1,2,\cdots,m \qquad (6)$$

$$W = \{w_1, w_2, \cdots, w_j\}, j = 1,2,\cdots,m \qquad (7)$$

In multi-objective decision making, the scores of all the schemes by one measurement should be normalized before calculating entropy as the objective weight of this measurement.

2.3 Evaluation method of set pair and entropy

$M_1, M_2, \cdots, M_n$ are the objects to form the set to be evaluated. There are measurements $C_1, C_2, \cdots, C_m$ and every measurement has a measure score $f_{ij}(i=1,2,\cdots,n; j=1,2,\cdots,m)$ .Construct the multi-object evaluation matrix A as follows.

$$A = \begin{bmatrix} f_{11} & f_{12} & \cdots & f_{1m} \\ f_{21} & f_{22} & \cdots & f_{2m} \\ & & \vdots & \\ f_{n1} & f_{n2} & \cdots & f_{nm} \end{bmatrix} \quad (8)$$

$$A_0 = \left(f_{01}, \quad f_{02}, \quad \cdots f_{0i} \cdots \quad f_{0m}\right) \quad (9)$$

Where f_{0i} is the ideal score of the i measurement for the ideal scheme.

Comparing all the scores of the evaluation matrix with the scores of the ideal scheme matrix will get the identical degree of d_{ij} ,If $f_{ij} \prec f_{0j}$ (benefit type) $d_{ij} = \frac{f_{ij}}{f_{0j}}$; If $f_{ij} \succ f_{0j}$ (cost type), $d_{ij} = \frac{f_{0j}}{f_{ij}}$

- **Model one**

The non-weighted connection degree matrix U between the to-be-evaluated object and the ideal scheme is constructed as follows.

$$U = \begin{bmatrix} d_{11} & d_{12} & \cdots & d_{1m} \\ d_{21} & d_{22} & \cdots & d_{2m} \\ & & \vdots & \\ d_{n1} & d_{n2} & \cdots & d_{nm} \end{bmatrix} \quad (10)$$

We calculate the weights of all characteristics following the equation 4-7 to determine the weighted connection degree matrix R of A. The objects to be evaluated and the ideal scheme are defined as follows.

$$R = U \times W = \left(u_1, u_2, \cdots, u_n\right) \quad (11)$$

$$u_i = \sum_{j=1}^{m} w_j d_{ij} \ (i = 1,2,\cdots n, j = 1,2,\cdots m) \quad (12)$$

The ranking of the evaluated objects can be determined by the values of u_j. The bigger the value of u_j, the closer to the ideal scheme, and the better the evaluated object. The object with the biggest connection degree is the optimal line net optimization scheme.

- **Model two**

Firstly we normalize all attribute value of all evaluation index of each evaluation scheme. According to equation 10, we construct the similarity degree matrix for evaluation scheme and ideal scheme U_A and U_C.

$$U_A = \begin{bmatrix} d_{A11} & d_{A12} & \cdots & d_{A1m} \\ d_{A21} & d_{A22} & \cdots & d_{A2m} \\ & & \vdots & \\ d_{An1} & d_{An2} & \cdots & d_{Anm} \end{bmatrix} U_C = \begin{bmatrix} d_{C11} & d_{C12} & \cdots & d_{C1m,} \\ d_{C21} & d_{C22} & \cdots & d_{C2m} \\ & & \vdots & \\ d_{Cn1} & d_{Cn2} & \cdots & d_{Cnn} \end{bmatrix} \quad (13)$$

Where $d_{Aaj} + d_{Cij} = 1$. If d_{ij} is the identical degree, $d_{Aij} = d_{ij}$. If d_{ij} is the opposite degree, $d_{Cij} = d_{ij}$.

Based on the Entropy and Weight method, we calculate the weights of similarity degree matrix U_A and U_C.

$$W_A = \{w_{A1}, w_{A2}, \cdots, w_{Aj}\} W_C = \{w_{C1}, w_{C2}, \cdots, w_{Cj}\}, j = 1,2,\cdots,m \quad (14)$$

Then we will calculate the connection degree matrix of weights of the evaluated objects A and C and the ideal scheme.

$$R_A = U_A \times W_A = (u_{A1}, u_{A2}, \cdots, u_{Am}) \; R_C = U_C \times W_C = (u_{C1}, u_{C2}, \cdots, u_{Cm}) \quad (15)$$

The identical degree is a positive index and the bigger the better. The opposite degree is the negative index and the smaller the better. The ultimate ranking can be achieved by similarity degree and the similarity degree ranking method as follows.

$$R_i = \frac{R_A}{R_A + R_C}, i = 1,2,\cdots m \quad (16)$$

The bigger the value, the closer the scheme is to the ideal scheme. Therefore evaluation can be based on the value of similarity degree.

Model two divides equation (10) into two parts. The uncertainty can be evaluated from the relation between the part and the whole.

3 Example

The above method is applied to the case mentioned in the paper by HU Qizhou and ZHANG Weihua (HU Qizhou and ZHANG Weihua, 2008). The city government requires the transportation department to optimize the current public transit network in order to improve the utilize efficiency of current traffic resource and alleviate the conflict between demand and supply of traffic. Transportation planning and design institute put forward five schemes. The value of constraint is as follows.

Table 1. The value of constraint

Constraint	Scheme 1	Scheme 2	Scheme 3	Scheme 4	Scheme 5
non-linear rate/%	1.29	1.35	1.40	1.37	1.58
flow unevenness coefficient/%	1.32	1.43	1.47	1.48	1.36
average transfer times/ time	1.80	2.20	1.90	2.00	1.90
the efficiency of network load/%	0.73	0.79	0.68	0.72	0.78
line overlap factor /%	2.30	2.80	2.10	2.90	2.70
walking time /min	7.00	6.90	7.50	6.50	5.80
line length /km	12.20	11.90	10.20	11.30	13.60

The five schemes can meet the constraint condition of city public transit network optimization. We set six targets mentioned in Table 2.

Table 2. The objective function value of schemes

Scheme	Economic benefits of Public transportation enterprise / million	Line coverage rate /%	Direct ratio /%	Daily load factor of transit network /%	Passenger travel time /min	Efficiency of transit network /%
1	60.5	159.8	65.5	60.5	35.7	60.1
2	58.5	185.5	58.5	55.5	20.2	40.3
3	69.5	150.2	75.5	45.5	30.5	90.7
4	65.5	165.8	62.5	50.6	25.3	50.6
5	63.5	180.5	77.3	40.5	25.5	80.2

Note: Indexes are benefit type except the total travelling time of passengers is cost type.

The best scheme is required to be selected from the five schemes. So the decision-making matrix is defined as follows.

$$A = \begin{bmatrix} 60.5 & 159.5 & 65.5 & 60.5 & 35.7 & 60.1 \\ 58.5 & 175.5 & 58.5 & 55.5 & 20.2 & 40.3 \\ 69.5 & 150.2 & 75.5 & 45.5 & 30.5 & 90.7 \\ 65.5 & 165.8 & 62.5 & 50.6 & 25.3 & 50.6 \\ 63.5 & 180.5 & 77.5 & 40.5 & 25.5 & 80.2 \end{bmatrix}$$

Connection degree matrix calculated by model one as follows.

$$R = (0.798, 0.826, 0.865, 0.806, 0.866)$$

There is no difference among all the evaluation schemes. And the ranking result is 5, 3, 2, 4 and 1. The fifth one and the third one are so close to differentiate and this method is not precise.

By model two, the similarity degree matrix is calculated as follows.

$$R = (0.788, 0.696, 0.812, 0.734, 0.788)$$

The ranking result is 3, 5, 1, 4 and 2. The third one is the best one. The fifth one came close to the first one.

From the above process, it can be inferred that the optimal scheme is different by different models. We should use the right model according to the conditions. Then the scheme selected is the best one.

4 Conclusions

Based on the set pair and entropy weight theory we construct two decision-making models. The problem of non-standardized dimensions of all measurements has been solved. The subjective uncertainty has been reduced. We have achieved reasonable results. This method can provide new analysis method for public transit network optimization.

Abstract: To further explore the construction of urban rail transit network in the timing of each line, constructed the index system related factors and proposed a multi-objective decision algorithm based on lattice order. Firstly, by constructing a series of rail-building program more objective evaluation system lattice order decision, based on indicators of the type of indicators dimensionless processing, integrated power and data policymakers subjective right to compute the dispersion of objective evaluation of the relative weight of heavy and binding decision matrix, by calculating the difference between the value of comprehensive programs to achieve grid sequence of ordering options, the application of the decision-making method Chengdu alternative rail transit construction to evaluate the timing of the program. The results show that: the usage of multi-objective decision algorithm lattice order determined by the results and the actual timing of the construction is consistent, and the algorithm can effectively avoid over-dependence on the actual objective data and rational decision-makers of the limited nature of defects and other problems, indicating that the model to provide a method for the construction of urban rail transit timing.
Keywords: Urban rail transit; Construction schedule; Multi-objective lattice order decision making; Case verification.

1 Introduction

Relative usage of traffic demands and the limited road resources make urban rail transit development(Jinjian,2006), much attention has been paid to rail transportation network as a backbone of urban public transportation, for the travel characters of different passenger corridor and passenger transportation tasks at the same time also determines the level of a city public transport services. Determine the sequence of rail network construction quality will directly affect the future development trends and the economic benefit of city rail and even affect the expansion of urban spatial axis, so the rail transit network construction of time-series analysis has important affect.

At present, both at home and abroad has do some research for the city rail transit network construction and puts forward some principles of qualitative analysis or quantitative analysis of the algorithm, but too much subjective factors such as quantitative parameter selection weight is differ, too many constraints, lead the model's methods adaptability is not enough. Such as Huang Rui (Huangrui,2012) to the grade of rail transit network, set up based on node important degree - line importance of rail transit construction sequence model, through the construction of comprehensive importance size sequence. The algorithm of node selection is largely based on the overall urban planning, and the node important degree and the surrounding land, traffic also is closely linked, difficulty of quantitative research. Zhang Jiamin (Zhangjiamin,2013) by technical and economic characteristics of urban rail transit project, based on the Monte Carlo simulation to improve the level of analysis algorithm, according to the average accumulative grading evaluation to determine the sort of construction projects. This method is with interval number to represent the weight range, but if the hierarchical values more discrete, weaken the statistical average values represent the real project classification of reliability. To (Chenghua,2010) in qualitative analysis, such as the recent construction on the basis of the fixed number of year, the scale of the recent construction funds, puts forward recent line construction schedule based on cost - benefit optimization algorithms, due to the complex model, constraint condition is more, difficult to apply in the field of engineering.(Chen yuanduo,2010) combined with geographical factors such as Chen flower, traffic conditions, economic factors, such as screening of various track site node and important degree is calculated, and then in combination with geographical factors, determine the construction schedule plan. Node selection on the algorithm is still is too casual, lack of effective quantitative analysis of the shortcomings. GuoYanyong (GuoYanyong, 2013) analysis such as the six influence factors of urban rail transit construction, established the corresponding evaluation index system of timing and based on AHP and entropy weight - an ideal solution of the integrated model, by determining the line decision index and the negative ideal solution of Euclidean distance to determine the construction sequence. Although the algorithm able to objectively according to the statistical index, but it can't effectively avoid reverse problems arising from the algorithm and defect problems brought by the Euclidean distance itself. The above results to rail transit project construction schedule study provide a different way of thinking, but there are some defects with more or less.

In order to arrange the sequence of rail transit construction is more reasonable and efficient is proposed in this paper a kind of based on lattice order decision making is mainly used to solve the total order characterization for complex system of optimal scheduling problem, solutions for different decision preference elements constitute a lattice, lattice order than the total order more truly reflect the preference structure, thus for multi-objective alternative multielement complex system merit, lattice order decision making is total order decision-making more scientific and reasonable(GuoYanyong,2013).

2 The conception the Multi-objective Lattice Order Decision Making

With lattice order decision making method, first, to eliminate the unit of each evaluation index and the dimension of the non uniformity and not commensurability, need dimensionless processing of various index data, after the dimensionless data can be considered as policymakers on each index of different schemes of satisfaction. Decision makers should be taken into consideration when making index weight depicting index data of personal subjective preferences and objective discreteness. On the premise of the above information is complete, will be the effective decision information fusion, constructive solutions set decision matrix, on the basis of selecting the indexes of great sets and the minimal set of positive and negative ideal solution, and are seen as top and bottom element as two virtual solution (using the lattice theory to prove that the introduction of virtual scheme does not change the order relation of the original solution concentration between elements), and extending the decision scheme for the case .Finally, using the Euclidean distance to measure the decision scheme and top elements and bottom elements, the difference between decision principle for the solution and the distance of the top element as small as possible.

3 Rail transit construction sequence index system of influencing factors

As the urban rail transit construction project is a long-term and complex systems engineering, and affected by many factors determine the sequence of construction, the current engineering and academic circles have no a recognized evaluation index system. In view of the above characteristic, this paper finishing excavation with references [7] ~ [9] in the high frequency reference indexes, and indicators of teasing out Pearson correlation analysis, eliminate correlation of high index ($R^2 = 0.9$), the resulting index system as shown in Table 1.

Table1. Urban rail transit construction sequence evaluation index

The target	No.	index	methods	type
Temporal factors affecting rail transit construction	U_1	The length	The statistical	quantitative
	U_2	Line layout is important index	Experts assess	qualitative
	U_3	Passenger turnover	Traffic prediction	quantitative
	U_4	The intensity of load	Traffic prediction	quantitative
	U_5	Uneven coefficient of passenger flow sections	Traffic prediction	quantitative
	U_6	Track of bus passenger traffic	Traffic prediction	quantitative
	U_7	Coordinate with urban land use	Experts assess	qualitative
	U_8	Coordinate with urban traffic system	Experts assess	qualitative
	U_9	The difficulty of engineering	Experts assess	qualitative

4 The construction of the rail transit construction sequence selection index system

The construction of the rail transit construction sequence selection index system should be established based on wire mesh city characteristics, from the operating effect, network structure, social benefits and implementation of strategic development, construction, and urban development, environmental protection coordination of reasonable construction are chosen in the actual project indicators should be considered in three aspects: the evaluation index should be into system, fully reflect the characteristics of the urban rapid rail transit network as much as possible; Considering the index data availability and operability of the evaluation process; As far as possible to reduce the correlation between indicators, to ensure that the evaluation precision.

4. 1 Indicators of dimensionless processing

Due to the different indicators have different units, the lack of male sex, so to index evaluation data points forward, backward, moderate index and interval index dimensionless processing respectively, specific as follows(Ma Chaoqun,2007). Positive for type indicators

$$p'_{ij} = \begin{cases} 1 & p_{ij} > U_i \\ \dfrac{p_{ij}}{B_i} & 0 \le p_{ij} \le U_i \end{cases} \qquad (1)$$

Negative type indicators

$$p'_{ij} = \begin{cases} 1 & p_{ij} < L_i \\ \dfrac{U_i - p_{ij}}{U_i - L_i} & L_i \le p_{ij} \le U_i \\ 0 & p_{ij} > U_i \end{cases} \qquad (2)$$

Moderate type indicators

$$p'_{ij} = \begin{cases} \dfrac{p_{ij} - M_i}{U_i - M_i} & M_i \le p_{ij} < U_i \\ \dfrac{M_i - p_{ij}}{M_i - L_i} & L_i \le p_{ij} \le M_i \\ 0 & p_{ij} \le L_i \text{or} p_{ij} \ge U_\text{j} \end{cases} \qquad (3)$$

Interval type indicator

$$p'_{ij}=\begin{cases}1 & M_j^1 \le p_{ij} < M_j^2 \\ \dfrac{p_{ij}-L_j}{M_j^1-L_j} & L_j \le p_{ij} < M_j^1 \\ \dfrac{U_j-p_{ij}}{U_j-M_j^2} & M_j^2 \le p_{ij} \le U_j \\ 0 & p_{ij} \le L_j \text{or} p_{ij} \ge U_j\end{cases} \quad (4)$$

and: p'_{ij} For value (after dimensionless processing); L_j For the lower limit index; U_j For the lower limit index; B_i Parameters for evaluating indicators; M_j^1 、 M_j^2 、 M_j Intermediate values of indicators.

4. 2 The determination of the weights

Weighting calculation methods at home and abroad mainly include subjective judgment, such as: rail transit network plan is more than the selected target 77 objective analysis of two types of lattice order decision method, subjective judgment method of faults for relies too much on expert experience, and objective analysis, the defect to ignore the expert knowledge and experience, the calculation results and the actual deviation is bigger. In view of the above, this article will be effective the above two kinds of method is to use a set of legal union, is now on its process in detail.

4. 2. 1 Determine the objective of discrete degree of right

Set an objective evaluation indexes weight vector for discrete degrees

$W^*=(w_1^*,w_2^*,\cdots,w_1^*)$

$\sum_{j=1}^{n}(w_j^*)^2=1$

$\lambda_{ij}(w_j^*)$

According to the first item I the first j a evaluation index evaluation scheme With the index the sum of the deviation of the other schemes evaluation,

$$\lambda_{ij}(w_j^*)=\sum_{k=1}^{m} w_j^* \left|p_{ij}-p_{kj}\right| \quad (5)$$

Namely,

$\lambda_{ij}(w_j^*)$ Said in the first j a evaluation index, evaluation of all parties Case the total deviation,

$$\lambda_{ij}(w_j^*) = \sum_{i=1}^{m}\sum_{k=1}^{m} w_j^* \left| p_{ij} - p_{kj} \right| \qquad (6)$$

Namely,

According to the principle of determining the weight of maximizing deviations, the evaluation index weight should make all evaluation indexes of maximum total deviation, and made the $\sum_{j=1}^{n}\lambda_{ij}(w_j^*)$ biggest。Construction goal programming $F(w^*)$ as:

$$\begin{cases} F(w^*) = \sum_{j=1}^{n}\lambda_{ij}(w_j^*) = \sum_{j=1}^{n}\sum_{i=1}^{m}\sum_{k=1}^{m} w_j^* \left| p_{ij} - p_{kj} \right| \\ s.t. \quad \sum_{j=1}^{n}(w_j^*)^2 = 1 \qquad w_j^* \geq 0 \end{cases} \qquad (7)$$

And the normalized processing, objective weight vector for:

$$w^0 = (w_1^0, w_2^0, \cdots, w_n^0)$$

$$w'^0_j = \frac{w_j^*}{\sum_{j=1}^{n} w_j^*} \qquad (8)$$

4. 2. 2 The determination of important degree of subjective rights

Using the AHP analytic hierarchy process (AHP) to qualitative evaluation experts. Processing, the method of AHP hierarchy with reference to relevant processing method, subjective weight vector for after processing $w^s = (w_1^s, w_2^s, \cdots, w_n^s)$

4. 2. 3 The synthesis of total weight

An index of total weight should be related to the subjective weight and objective weight.For this consideration, define total weight vector

$$w = (w_1, w_2, \dots, w_n)$$

$$w_j = \frac{w_j^s w_j^0}{\sum_{j=1}^{n} w_j^s w_j^0} \qquad (9)$$

4. 3 The calculation of decision matrix

Define the operator $d_{ij} = w_j p_{ij}$, The decision matrix

$$D = \begin{bmatrix} d_{11} & d_{12} & \cdots & d_{1n} \\ d_{21} & d_{22} & \cdots & d_{2n} \\ \vdots & & & \vdots \\ d_{m1} & d_{m2} & \cdots & d_{mn} \end{bmatrix} \qquad (10)$$

4. 4 Ranking

On the basis of lattice ordered related theory, positive and negative ideal solution, respectively.

$$\begin{cases} M^+ = \{\max(d_{i1}), \max(d_{i2}), \cdots, \max(d_{in})\} & (11) \\ M^- = \{\min(d_{i1}), \min(d_{i2}), \cdots, \min(d_{in})\} & (12) \end{cases}$$

The Euclidean distance between positive and negative ideal solution:

$$L = \sqrt{\sum_{j=1}^{n} [\max(d_{ij}) - \min(d_{ij})]^2} \qquad (13)$$

Plan I and Euclidean distance between positive and negative ideal solution, respectively.

$$L_i^+ = \sqrt{\sum_{j=1}^{n} [\max(d_{kj}) - d_{ij}]^2} \qquad (14)$$

$$L_i^- = \sqrt{\sum_{j=1}^{n} [d_{ij} - \min(d_{kj})]^2} \qquad (15)$$

Define comprehensive difference value of the I.

$$L_i = q\,\frac{L_i^-}{L} + (1-q)\,\frac{L_i^+}{L} \qquad (16)$$

Q is optimistic coefficient, $0 < q < 1$, can be given by the expert subjective.

5 The example analysis

Recommendation from the vision of the rail transit network of Chengdu (2005 edition) tech-oriented altogether is composed of 7 lines, 255 km line network scale, combining with expert evaluation to obtain the indicators of statistical prediction value, as shown in table 2.

Table 2. statistics of original index of line

Index	U_1	U_2	U_3	U_4	U_5	U_6	U_7	U_8	U_9
1#	30.0	9.8	800.30	4.42	4.85	0.104	9.1	8.9	7.5
2#	50.1	9.5	1175.59	3.16	4.25	0.118	9.5	8.6	8.1
3#	47.6	8.9	1057.60	2.36	3.87	0.088	8.8	8.1	8.8
4#	34.6	8.2	456.08	2.08	3.85	0.057	8.7	7.8	8.3
5#	20.9	7.8	282.03	2.51	2.86	0.041	8.0	7.2	8.0
6#	38.6	7.5	319.80	1.59	2.65	0.048	8.1	7.4	8.1
7#	33.6	8.7	374.90	2.16	3.11	0.057	8.5	8.4	8.5

Using formula (1), (2) of the basic data in table 2, standardizing, easy to know the cost index, the rest are efficiency index. The calculation results are shown in table 3.

Table 3. index standardization processing

index	U_1	U_2	U_3	U_4	U_5	U_6	U_7	U_8	U_9
1#	0.312	1.000	0.580	1.000	1.000	0.818	0.733	1.000	1.000
2#	1.000	0.870	1.000	0.555	0.727	1.000	1.000	0.824	0.538
3#	0.914	0.609	0.868	0.272	0.555	0.610	0.533	0.529	0.000
4#	0.469	0.304	0.195	0.173	0.545	0.208	0.467	0.353	0.385
5#	0.000	0.130	0.000	0.325	0.095	0.000	0.000	0.000	0.615
6#	0.606	0.000	0.042	0.000	0.000	0.091	0.067	0.118	0.538
7#	0.435	0.522	0.104	0.201	0.209	0.208	0.333	0.706	0.231

Formulas (8), (9) are used to get the optimal weight vector formula (10) are used to get the weighted after the standardization of the matrix Z, then using the formula (12) to carry on the coordinate transformation, the origin of coordinates translation to ideal solution, the calculation results such as table 4.

Table 4. the weighted matrix after translation

index	U_1	U_2	U_3	U_4	U_5	U_6	U_7	U_8	U_9
1#	-0.079	0.000	-0.042	0.000	0.000	-0.019	-0.030	0.000	0.000
2#	0.000	-0.014	0.000	-0.050	-0.030	0.000	0.000	-0.020	-0.056
3#	-0.010	-0.043	-0.013	-0.082	-0.050	-0.041	-0.053	-0.052	-0.121

4#	-0.061	-0.077	-0.080	-0.093	-0.051	-0.084	-0.060	-0.072	-0.075
5#	-0.115	-0.096	-0.100	-0.076	-0.101	-0.105	-0.113	-0.111	-0.047
6#	-0.045	-0.111	-0.096	-0.112	-0.111	-0.096	-0.105	-0.098	-0.056
7#	-0.065	-0.053	-0.089	-0.090	-0.088	-0.084	-0.075	-0.033	-0.093

According to the type (13), various solutions to the ideal solution are calculated separately, and the "vertical distance" is: $\mathrm{D}_i = (0.014, 0.010, 0.056, 0.061, 0.099, 0.093, 0.062)^T$ .To each scheme of the vertical distance from small to large in this arrangement, the optimal sorting B line construction can be got. $D_2 < D_1 < D_3 < D_4 < D_7 < D_6 < D_5$ .Through "vertical distance" size relations, each line sequence is: the construction of line 2 and line 1 and line 3 and line 4 to 7 lines, line 6 and line 5.Chengdu metro line 1, in fact, the first phase has been opened to traffic in 2010, south extension line # 1 at the end of 2014 opened; The first phase of line 2 has been open to traffic in 2012, opened in 2013, along the west east along the end of 2014;Metro line 3 and line 4 is opened in 2015, metro line 7 opened in 2016, is expected to line 5 and line 6 are currently conducting project feasibility study, has not yet started construction. As you can see model calculation results are consistent with the actual construction schedule of chengdu basic, from the side to verify the rationality and validity of the model.

6 Conclusion

(1) On the basis of previous literature on the sequence of rail transit construction, tease out a set of factors affecting construction schedule auditions index system, and to create the indexes of Pearson correlation analysis, eliminate the higher correlation index ($R^2 = 0.9$), effectively avoid the effect of the correlation between indicators.

(2) In view of the traditional TOPSIS model in the reverse order, the weight values of strong subjectivity and Euclidean distance their own defects, puts forward the improved algorithm, the algorithm by index transformation will absolutely ideal solution, and establish a decision-making plan to absolute ideal solution and negative ideal solution is absolutely a weighted distance optimization model, using the Lagrange multiplier method to solve the model to get the optimal weight vector, the introduction of "vertical distance" instead of the traditional "Euclidean distance", the methods by measuring vertical distance determines the optimal construction schedule plan.

(3) In this paper, the proposed algorithm was applied to chengdu city rail transit network construction sequence analysis.The results show that the model calculation results are consistent with the actual construction schedule of chengdu basic, from the side to verify the rationality and validity of the model.

(4) This modle is not considered for the construction of the existing line for new

line timing effect, this is the next step to be further discussed.

Abstract: Environmental conditions of urban traffic corridor was not only related to the comfortableness of the around residents living, but also related to problem of lessen fule-comsumption and gas-letout of urban traffic. So it became one of the urban traffic focus recently. This paper first researched attracting scope of urban traffic corridor. This part concluded the universal and accurate method of determining covering scope. Then, based on the relationship between different traffic modes and carbon emissions, a model which contains all traffic modes was established to calculate transport carbon emissions. After that, a bilevel programming model was established to optimize system configuration of traffic corridor, where the upper model minimizes the system carbon emission, while the lower model optimums for the users' trip. And based on Genetic Algorithm, we designed an arithmetic to resolve this bilevel programming model. Finally, this paper used Chengdu to Longquanyi district traffic corridor as an example. By the application of origin and destination data from the dwellers within the covered scope of traffic corridor, this paper completed corridor system optimization configuration, to prove the feasibility of the model in this paper.
Keywords: Attracting scope; Bilevel programming model; Carbon emission; Genetic algorithm.

1 Introduction

Urban transport corridor area undertook most traffic travel in the intensive land use area, where carbon emissions of traffic in this zone is very large. In the view of low-carbon, we should effectively plan urban transport subsystems of transportation corridor, which not only helps to reduce carbon emissions but also provide a more comfortable living environment for residents.

Priority corridor study is to determine the specific configuration coverage of corridor through researching attract features of internal transit corridor and the method to divide the scope of the corridor. Then, on the basis of the residents traffic characteristics in different areas and the relationship between traffic modes and emission, the paper establishs the emission model, including individuals and all modes. Finally, the paper establishes a bilevel programming model to optimize system configuration of traffic corridor, where the upper model minimizes the system carbon emission, while the lower model optimums for the users' trip, which can provide the optimal allocation program of corridor to reduce carbon emissions.

2 Corridor coverage and carbon emission model

2.1 Corridor coverage model

As urban corridors contain various modes of transportation, passed by various land use and contact with the surrounding regions of people flow, traffic, logistics, it is unreasonable to simply draw a rough range to determine the scope of the traffic corridor. Therefore, in consideration of the land use and transportation modes, the steps to determine corridor coverage as follows:

Step 1: Based on the present OD data of transport corridor, forecast the planning OD data and obtain the desired travel pathway map.

Step 2: According the desired travel pathway map, combined with the situation of road network, analysis traffic direction and the maximum section traffic of corridor, determine leading public transport mode.

Step 3: According the person flow direction, the capacity of each road, and the conditions of corridor, determine the corridor coverage.

2.2 Attractive bent law with effect field

As we all know, traffic lines have attracted characteristics, which is similar with that of gravity and effect field theory. While along the corridor area gathered high person flow with its powerful attraction to people and business, and form a cluster effect field.

Take the traffic lines as conductors and the study area as the space medium, then the traffic volum will be took as current. Thus, around the "traffic lines". will generate the magnetic field.

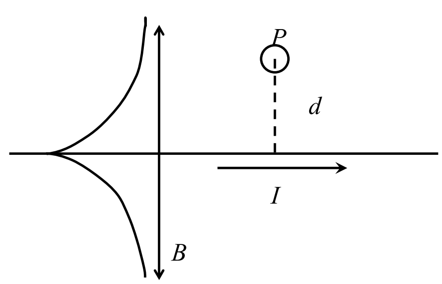

Figure 1. the effect field of current-carrying conductor in Electromagnetic Field

As the Figure. 1, Since the distance d between P point and conductor is much less than the length of the conductor, so we can think that the conductor is infinitely long. According to BisSisL law, the field strength of P point B is:

$$B=\frac{\mu I}{2\pi d} \quad (1)$$

Where, I is the current strength , here it means person flow on traffic lines; d is the distance d between P point and conductor, here it means the distance between passengers and traffic lines; μ is permeability of the point P, reflecting the sensitivity of the lines.

Because the corridor includes multiple lines and can't be ideal straight, add the distance correction factor k to modify the model. Therefore, assume the total number of lines is n and i represent any of lines, and the field strength is converted into corridor effect field. Finally, we can get the formula as follow:

$$E(d)=\int_0^d \frac{\mu I}{2\pi(kd)^a}\mathrm{d}(d)=\frac{\mu I}{2\pi k^a}\int_0^d d^{-a}\mathrm{d}(d)=\frac{\mu I}{2\pi k^a}\bullet\frac{d^{1-a}}{(1-a)} \quad (2)$$

2.3 carbon emission model

The traffic modes in urban corridors can be broadly divided into six kinds, respectively bus, railway, car, motorcycle, taxis, walking. According to the static by US Bureau of Transportation Statistics in 2009, the carbon emission factor (p_i) for different modes are shown as Table. 1. Moreover, through a lot of investigation and relevant data, the average passenger number of different modes as shown in Table. 2:

Table 1. different modes of transport of carbon emission factor (g/(personiskilometers))

Mode of transport	bus	Rail	Private car	Bicycle	taxi	walk
Carbon Emission Factor	30	8	120	0	150	0

Table 2. different modes of transportation average number of passengers (passengers)

Mode of transport	bus	Rail	Private car	motorcycle	taxi	walk
The average number of passengers	29	1368	1.60	1.06	2.31	1

Based on the above two tables, we can see the total carbon emissions of whole city transportation corridor system can be expressed as:

$$C_{total}=\sum_{i=1}^{6}C_i=\sum p_i\cdot x_{a,i}\cdot l_a \quad (i=1,2,...,6) \quad , \; s.t.\; x_{a,i}\le\beta_i\cdot\sigma \tag{3}$$

Where: C_{total} is the total carbon emissions of the urban transport system; C_i is carbon emissions of the i-th mode; p_i is the carbon emission factor of the i-th mode of transport; $x_{a,i}$ is the average passengers number of the i-th mode on the section “a”; β_i is the average passengers number of the i-th mode; l_a is The length of the section “a”.

3 Corridor System Configuration Optimization Model

This paper established system configuration optimization model mainly from system optimal and user optimal two aspects, at the same time, the two levels influenced each other.

3.1The upper model

The upper model involved the transportation corridor total carbon emissions minimum and maximum benefits of investment in infrastructure, etc. this paper defines a comprehensive benefit index, the index measures the total cost including investment and system total benefit. Getting comprehensive benefit goal as follows:

$$\min E=\phi_1 W_n+\phi_2[\sum_i\sum_a p_i x_{a,i} l_a-\sum_i\sum_a p_i x_{a,i}^0 l_a]M+\phi_3[x_a t_a(x_a)-x_a^0 t_a(x_a^0)]S \tag{4}$$

Where W_n is cost of n traffic management strategy(RMB), $n\ge 1$; S is per unit time output of the corresponding urban residents(yuan); $t_a(x_a^0)$ is impedance of road before strategy implementation, usually referred to the travel time.; M refers to the unit mass of carbon emissions on the international market price (RMB). Due to three parts of magnitude is not in the same field, this paper introduced three parameters ϕ_1、ϕ_2、ϕ_3, $\phi_1+\phi_2+\phi_3=1$ and $\forall\phi_i\in(0,1)$.

W_n is relevant with the size of traffic strategy: $W_n=\sum_i U_i\bullet e_i$ .Where, U_i is i.st strategy, e_i is i.st investment costs; $S=\frac{GDP_{ave}}{365*8}$, GDP_{ave} is per capita gross domestic product; $M=56RMB/\text{ton}$.

The upper model pursuits the minimum of traffic corridor carbon emissions and maximum benefits of investment in infrastructure, transportation demand management measures should be limit of government spending, namely: $W_n=\psi(y,q)\le W_{\max}$.

3.2 The lower model

In this paper, the lower model with user optimal angle analysis, considered the generalized cost, including passengers must pay for travel time delay and methods on the transportation cost, as follows:

$$c_p^{ij} = \sum_a st_a \delta_{a,p}^{ij} + w_p^{ij}, \forall i, j, a \tag{5}$$

Where, c_p^{ij} is the cost of travel for any OD points (i, j) to choose the path p ; w_p^{ij} is the cost of price for any OD points (i, j) to choose the path p ;

$$\delta_{a,p}^{ij} = \begin{cases} 1, & \text{if roads } a \text{ is on paths p between of } (i, j); \\ 0, & \text{others.} \end{cases}$$

A_c is the cost of driving: $A_c = l_c \bullet \lambda$ .where, l_c is the driving distance, $l_c = \sum_a \delta_{a,p}^{ij} \theta_{a,c} \varphi_{a,c} l_a$; λ is unit fuel costs of travel distance. A_b is the cost of bus, $A_b = 2$.

A_{r1} is subway fares; A_{r2} is light rail fares; A_r is rail transit fares: $A_r = \xi_{a,r1} \bullet A_{r1} + \xi_{a,r2} \bullet A_{r2}$.

t_a is the time spent on network of either roads a . $t_{间}$ is the public transport departure intervals(frequency). V_n represents the average speed of transportation n , X_a is motor vehicle traffic capacity (veh/ h), C_a is road capacity (veh/ h). According to the American federal highway BPR road resistance function model, analyzing the impedance of different modes of transport, we can get the results as follows: $\alpha = 0.15$, $\beta = 4$,

$$\text{t analysis.} \begin{cases} t_r = \frac{l_a}{V_r} + \frac{t_{间}}{2} \\ t_{brt} = \frac{l_a}{V_{brt}} + \frac{t_{间}}{2} \\ t_{bus} = \frac{l_a}{V_{bus}} \left[1 + \alpha \left(X_a / C_a \right)^{\beta} \right] + \frac{t_{间}}{2} \\ t_c = \frac{l_a}{V_c} \left[1 + \alpha \left(X_a / C_a \right)^{\beta} \right] \end{cases} \tag{6}$$

So we can get t_a : $t_a = \sum_{s=r, brt, bus, c} \theta_{a,s} \varphi_{a,s} t_s$ .Where:

$$X_a = \sum_{i,j} \sum_p f_p^{i,j} \bullet \delta_{a,p}^{i,j} , \quad \sum_p f_p^{i,j} = q_{i,j} , \quad \sum_j q_{i,j} = O_i , \quad \sum_i q_{i,j} = D_j .$$

Travel time affected by OD traffic volume, in turn, would affect the traffic capacity of network. Therefore, the traffic distribution—combination of traffic assignment model is established, to reflect the feedback:

$$\min Z = \sum_p \int_0^{X_a} c_p^{i,j} \, dx + \frac{1}{\gamma} \sum_{ij} q_{ij} (\ln q_{ij} - 1) \tag{7}$$

Due to the lower model involves the user's travel choice problem of the network, the network itself are the restricting conditions of the lower model. According to the urban public transport planning standards, we get bus system of traffic corridor as follows:

$$s.t\begin{cases} t_0 \le \min\left\{T_{\max}, \frac{l_{\max}}{v}\right\} \\ n_a = \left[\frac{x_a}{t_{\text{间}} m}\right], \forall a \\ p \le \sum_a n_a \\ 0 \le n_a \le 5, \forall a \\ 0 \le t_{\text{间}} \le t_{\text{间}\max}, \forall a \end{cases} \tag{8}$$

Where, N is the bus traffic planning route within the research scope; m is the public transport vehicle (column) capacity; $T_{\max}$ is the biggest travel time for different size of the city; $l_{\max}$ is the bus lines maximum length for different scale of the city;; v is the design speed of the urban corridor bus system; n_a is the public transportation line number on the road a; $t_{\text{间}\max}$ is the biggest bus service frequency within the research scope.

4 Example analysis

4.1 Example seletion

The paper selects a traffic corridor from Chengdu urban area to Longquanyi as example, including metro line line 2 east extension line, Yidu avenue, Chenglong avenue and some linking roads, as shown in Fig. 2. This corridor mainly influences the Tongan subdistrict, Damian subdistrict, Longquan subdistrict, Shanquan town, Chadian town and Baihe town, so the paper selects above subdistricts and towns as trip generation points derecting to Chegndu.

According to the corridor coverage model proposed in the 2nd section, considering the place of bus stops, the place of metro stations, travel distance and land use surrounding the corridor, the paper has determined the coverage area of corridor, shown in Fig. 3. Moreover, in the base of some projections, we obtained the OD data of trip generation points, as shown in Table. 3.

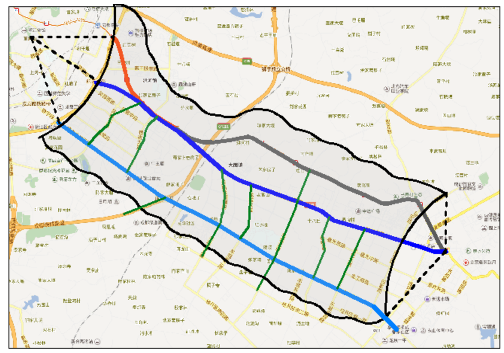

Figure 2. Study area of the traffic corridor Figure 3. The coverage area of corridor

Table 3. the OD data of trip generation points in 2014

towns (subdistricts)	metro	car	Public bus	sum
Tongan subdistrict	253	1133	852	2234
Damian subdistrict	342	1543	1160	3043
Longquan subdistrict	1119	5093	3829	10042
Shanquan town	2126	9675	7275	19078
Chadian town	693	3122	2347	6156
Baihe town	6432	29271	22009	57719

This example does not consider the external passenger traffic demand due to newly built traffic facilities and new strategies of TDM and TSM. The example only analysis the benefits of carbon emission in the base of original passenger traffic demand

4.2 Discussion of Results

Firstly, selec above datas as input of optimal allocation model proposed in chapter 3rd . Then, use the Genetic Algorithm to solve this model. Finally, through programing based on the MATLAB, we obtain the result of this optimal allocation model.

Through the statistical analysis of result, we can see that the number of newly built P&R parking lot berths is 563 and the total investment needs $ 67.5 million RMB. (The example does not consider the investment of builting the metro line line 2 east extension line, so the upper limit of the total investment is $ 67.5 million RMB, called W_{max} .) Furthermore, the changes of carbon emissions, passenger volume and traffic volume are obvious.

1. After the implementation of the program, the carbon emissions of cars and buses are significantly reduced, respectively, 7.327 t and 9.089 t. But, the emissions of metro increase by 3.002 t, as shown Table. 4. Finally, the carbon emissions of the traffic corridor decrease by 13.14%.

2. The passenger volume of metro increase significantly and is 27102 persontime, basically corresponds the actual passenger volume (about 20000

persontime), obtained from the metro department. Specific changes in passenger volume as shown in Table.5.

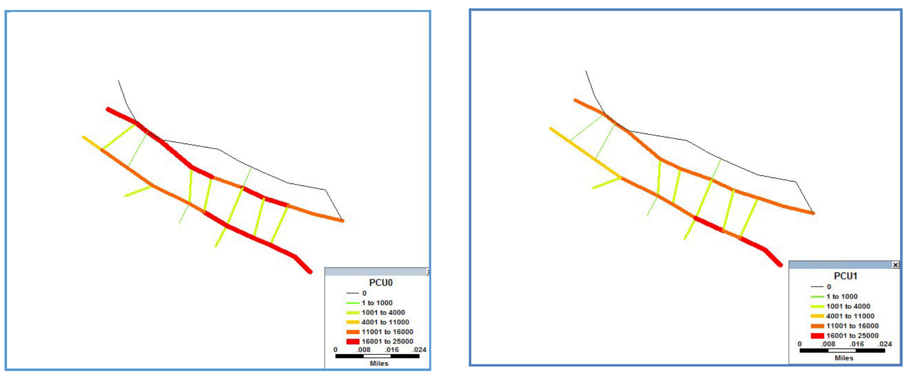
3. The traffic volumes of Yidu avenue and Chenglong avenue respectively decrease by 2000 pcu and 1000 pcu per day, which show that the effect of metro attract Yidu avenue is greater than that of metro attract Chenglong avenue. Specific changes in passenger volume as shown in Fig. 4.

Table 4. Specific changes in carbon emissions

traffic modes	Before the implementation of the program			After the implementation of the program		
	metro	car	Public bus	metro	car	Public bus
carbon emissions	0. 178	83. 551	18. 379	3. 180	76. 224	9. 271

Table 5. Specific changes in passenger volume

traffic modes	Before the implementation of the program			After the implementation of the program		
	metro	car	Public bus	metro	car	Public bus
passenger volume	5726	51293	43937	27102	48293	17313



Before the implementation of the program After the implementation of the program

Figure 4. Specific changes in passenger volume

5 Conclusions

The paper has established a bilevel programming model to optimize system configuration of traffic corridor, where the upper model minimizes the system carbon emission, while the lower model optimums for the users' trip. Through the model, we can see that optimal allocation model not only can effectively reduce carbon emissions, but also improve operational efficiency of corridor system. Finally, the paper use the example to verify this model, which show that the model proposed by this paper has accuracy and practicality with a certain.

Abstract: With the rapid development of urban modern logistics, traffic capacity of freight transport network cannot satisfy the requirement of cargo distribution and delivery. Therefore, it is very urgent to enlarge and optimize the freight transport network. In this thesis, based on the analysis of proposed transport network, the state of the increasing flow, and transport time, transport cost, road congestion and the cost of unit capacity, an optimization model is built to enlarge the capacity of the freight transport network, and then an algorithm is devised to solve it. Eventually, an example is used to verify the validity of the model and the algorithm. This thesis is likely to offer a theoretical method for making decision, optimizing and designing freight transport network.

Keywords: Freight transportation network; Optimization of network capacity; Maximal flow.

1 Introduction

With the rapid development of urban modern logistics, the demand for lane capacity of freight vehicles exceeds the existing capacity. However, traditional way to distribute goods on traffic network is within the scope of lane capacity. It limits the development of urban logistics industry greatly. Therefore, it is urgent to ease the conflicts on the existing roads system between the supply and demand.

At present, control on freight traffic implements include the following policies in most domestic and foreign cities: First, policy to prohibit and restrict management sessions, road or vehicle, such as London of England and Chengdu of China; Second, policy to limit the number of parking spaces to control the road traffic (Lu, 2004), which is mainly used in places near city's CBD; Third, policy to charge some congested roads to control traffic flow; Fourth, policy to use the indicative signs to guide the smooth flow of freight vehicles (Li, 2013); Fifth, policy to control the freight transport demanding, which is used in most cities of Japan. Although these policies ease some of the city's traffic congestion to a certain extent for a period of time, it has also brought a lot of inconvenience to the development of urban economy, especially the development of urban logistics industry. For example, on the one hand, it separates the integration of logistics system, increasing the cost of logistics services, extending time of goods distribution and reducing the overall quality of service of logistics system; On the other hand, it exacerbates the urban traffic congestion and causes other problems to a certain extent (Li, 2013).

Based on the existing control measures on urban transport and its adverse effects on logistics industry, and the existing researches mainly focused on solving urban passenger traffic network capacity optimization, which rarely considered transport time, transport costs and other factors, an optimization decision method will be designed to reduce traffic restrictions on urban logistics development through the expansion of existing transportation network construction to meet the development trend of urban logistics and put forward some ideas of expansion and optimization for freight transport network that cannot meet the requirements in this thesis.

2 Freight traffic volume survey method

Freight traffic volume means the number of traffic that pasted one point or one section on the road in the period time. The main purpose of surveying freight traffic volume is found the problems existing in the current region, provided the basis on the traffic management and planning, mastered various traffic phenomena in the study area, to provide data for predicting freight traffic volume.

At present, the survey methods have artificial counting method and mechanical counting method. Mechanical counter method has pressure tube type detector, the induction coil detector, ultrasonic detector; floating car view method and video observation method; according to the survey duration time divided into investigation of intermittent traffic volume and continuous traffic investigation (Li, 2004). When survey the freight traffic volume can be based on different conditions and requirements, to choose the means of investigation method.

3 Freight traffic volume prediction method

Freight traffic flow prediction means through investigating the status of freight traffic flow and analysis the data, use modern information technology and means to build all kinds of prediction model, the scientific prediction and analysis carried out for the implementation of freight transportation network planning management. Freight traffic flow prediction aims to ease the congestion on freight traffic network, balance the freight traffic distribution in space and time, and provide the basis on the urban transportation network of project management and renovation project. There are a lot of freight demand forecasting methods. The specific methods should be selected depending on the actual situation. The main methods are:

(1) Multiple regression prediction model.

Regression forecast method needs to find out the relationship that between the freight volume forecasting object (the dependent variable) and the effect of various factors of object prediction (independent variables), and establish the corresponding regression equations, then based on the value of independent variables, obtained the value of the dependent variable. Because the predicted freight volume is closely linked with social economy, we can select number n economic indicators as independent variables, study on the relationship between them and the freight volume, calculate the regression equation (He, 2004). In this way, we can predict the shipment volume.

(2) Time series forecasting model

Ahmed and Cook presented time series forecast model in traffic flow field as the first people. Box and Jenkins created ARIMA model that was used widely:

$\hat{x}t(l) = \sum_{j=1}^{\infty} G_{1+j} a_{t-j}$.Time series prediction of $\{x_t\}$ that, if XT is known, need to predict the number of $(t+1)$. This model is especially suitable for the freight traffic flow stability. If the flow condition changes greatly, the amount of computation will be very large, the model will expose serious deficiencies in prediction. In addition, this model does not consider the relationship between upstream and downstream sections of the flow.

(3) Prediction model of elastic coefficient method

Through the study on the transportation elasticity, grasp the development trend of transportation in general. Mathematical model of elastic coefficient method is: $y_t = y_t^1(1+i)^1, i = E(s)q = i^\wedge 1 \,/\, q^\wedge 1 \, * q$. Usually, the economic growth will promote the development of the transport industry, when the economy development is rapid, the transportation industry will become the factors that restrict the development of it. When we use the model, can obtain Freight rate of changing by multiplying the changeable rate of economic and freight volume elasticity, calculate the elasticity coefficient and relevant economic rate and calculate shipping volume (Ji, 2013).

(4) The exponential smoothing forecasting model

Forecasting strategy of exponential smoothing method is a historical observation extrapolated to the future, then according to the adaptive principle, revised the demand pattern that has changed. This method is often used in three kinds of trend changeable conditions that they are level, linear, and two curves.

(5) Model of grey system

Grey prediction method is based on the past and now known or uncertain information, and establishes GM model from the past to the future, in order to determine the system development tendency in the future, and provide a basis for planning and decision making. $GM(1,1)$ is $d_x/d_t + a_x = u$, due to the random quantity or noise are often mixed with original series, in the control system theory, often need to use filtering method to eliminate the noise, the way in the grey prediction of sequence is equivalent to the filtering processing method (Zhang, 2001).

(6) The historical average model

The historical average algorithm is simple because the parameter can use the least square method to estimate, which can solve the problem of traffic flow changes at different time and different period. But it cannot solve the prediction of static, because it can not reflect the basic uncertainty and nonlinear characteristics of dynamic traffic flow, especially cannot overcome the influence of random factors, no way to deal with traffic accidents and other emergencies in the system.

4 Freight transportation network expansion construction

Through the series of cargo survey and forecast, analyzed the demand of the freight traffic volume in a certain period of time. Now there are some researches which have expanded and improved the road network capacity of lowest unit cost (Zhang, 2010) or have taken into account two factors that the unit cost of road expansion and road congestion level to improve freight network to make establishments of the network capacity optimization objective function (Kou, 2012). This paper designs a multi-objective mathematical model below based on minimum transport costs, shortest transportation time, the lowest unit cost of road expansion, the highest level of road congestion.

$$\begin{cases} Min\ P = \sum p_{ij}\,\Delta c_{ij} & \text{(the unit transport cost)} \quad (1) \\ Max\ M = \sum o_{ij} & \text{(the congested road)} \quad (2) \\ Min\ M = \sum m_{ij} & \text{(the unit transport time)} \quad (3) \\ Min\ P = \sum q_{ij} & \text{(the unit transport cost)} \quad (4) \end{cases}$$

where: p_{ij} = the unit cost of expansion project of line (v_i, v_j) ;

Δc_{ij}= the addition of traffic network capacity of line(v_i, v_j);

o_{ij} = crowded conditions of line (v_i, v_j);

m_{ij} = freight vehicles travel time of line (v_i, v_j);

q_{ij}= transportation costs of line (v_i, v_j).

To optimize the network, as while it needs to be meet the following constraints:

1) Freight vehicle transporting time on the road transportation network is not higher than vehicle transporting time of the free traffic;
2) Traffic network expansion is limited to the conditions of road itself which cannot exceed the ceiling of the road capacity;
3) Each section of the actual traffic flow cannot exceed the maximum traffic capacity;
4) Optimization and expansion of freight transportation network is to meet the expected traffic flow.

$$\begin{cases} m_{ij} \le F \\ \Delta c_{ij} \le X \\ 0 \le f_{ij} \le c_{ij} \\ max\ v(f) = Q \end{cases}$$

where: $F =$ vehicle travel time that traffic flow is in the free flow state of line (v_i, v_j);

$X =$ the maximum acceptable expansion of line (v_i, v_j);

f_{ij} = traffic flow of line (v_i, v_j);

c_{ij} = maximum capacity of line (v_i, v_j);

$v(f)$ = maximum traffic network flow;

Q = expected network traffic flow.

This model is a multi-objective decision-making model, it is very difficult to solve directly. General ways to solve this kind of problem, there are two methods. The first one: according to the relevant requirements, decide the weight of each object and make different target weighted linear. The second, make some certain objectives transform into constraints, and make the original problem transform into a double objective decision or single objective decision (Wei, 2005). This paper considers the difficulty to take into account the weight of each target. so the paper chooses the second way to transforms the multi-objective model into a single objective model.

The new model:

The objective function:

$$Min\ P = \sum p_{ij}\ \Delta c_{ij}$$

Constraints:

$$\begin{cases} m_{ij} \geq m_{mn} & \text{(The unit transport time of the expansion road is not less than the other sections)} \\ q_{ij} \geq q_{mn} & \text{(The unit transportation cost of the road expansion is not less than other sections)} \\ o_{ij} \geq o_{mn} & \text{(The expansion road's congestion level is not less than the other sections)} \\ m_{ij} \leq F \\ \Delta c_{ij} \leq X \\ 0 \leq f_{ij} \leq c_{ij} \\ max\ v(f) = Q \end{cases}$$

A multi-objective decision-making model is transformed into a single-objective decision-making model. To find out the optimal solution, it needs an optimization algorithm, with this optimization algorithm to get the program that meets the expansion and optimization of the urban logistics freight transport network.

In this paper, the idea of model optimization algorithm is that using the shortest path algorithm to seek the most ideal expansion road, then gradually getting the quantity added to the expectation of volume. This model determines the expansion section that requires take into account the transport time, transport costs, road expansion unit cost and road congestion level. So this paper decides to use the multiplier of transit time, transportation costs, road expansion unit cost, and road congestion as a total factor.

As the following formula:

$$w_{ij} = q_{ij} \times m_{ij} \times o_{ij} \times \left(p_{ij} \times \Delta c_{ij}\right) \tag{5}$$

Where: w_{ij} = the total factor of line (v_i, v_j);

q_{ij} = unit transport cost of line (v_i, v_j);

m_{ij}= unit freight transport time of line (v_i, v_j);

o_{ij} = crowded conditions of line (v_i, v_j);

p_{ij} = unit expansion project cost of line (v_i, v_j);

Δc_{ij} = traffic quantity added of line (v_i, v_j).

And because unit transport time(m_{ij}) = road length(L_{ij}) / vehicle speed(V_{ij}), vehicle transport costs(q_{ij}) = unit transport cost(c_{ij}) × road length(L_{ij}), crowded conditions(o_{ij}) = traffic capacity(c_{ij}) / traffic flow(f_{ij}). Therefore, the formula (5) can be converted to the following：

$$w_{ij} = \left(C_{ij} \times c_{ij} \times {L_{ij}}^2 \times p_{ij} \times \Delta c_{ij}\right) / \left(V_{ij} \times f_{ij}\right) \quad (6)$$

The total factor w_{ij} of equation (6) is the weight of the shortest path algorithm, while seeking the best expansion sections of freight transport network with Dijkstra shortest path algorithm.

At present, this problem can be solved by precise algorithm and heuristic algorithm. The precise algorithm has branch and bound approach, dynamic programming approach, cutting planes approach, and network flow approach. The heuristic algorithm has constructive algorithm, two phase algorithm, and metaheuristics algorithm.

Based on the above analysis, the paper designs optimization expansion steps, as follows:

step 1: Based on the current traffic network $G = (v, e, c, f, P, O, M, Q)$, each road traffic flow does not change, current flow of the network as initial flow;

step2: In accordance with formula (6), calculate w_{ij} in each section, then mark w_{ij} to a new transport network $= (v, e, w)$;

step3: According to w_{ij}, use Dijkstra shortest path algorithm to find the shortest path from v_s to v_t ;

step4: In the shortest path from step3, the line $v_i v_j$ quantity added $c_{ij}^* = min(f_{ij})$. If $f_{ij} < c_{ij}$, $f_{ij} = c_{ij} - f_{ij}$;If $f_{ij} \geq c_{ij}$,$f_{ij} = c_{ij} + x_{ij} - f_{ij}$. Add the minimum quantity c_{ij}^* to each line in the shortest path of v_s to v_t;

step5: Calculate the maximum flow $\sum f_{sj}$ of the network. If $\sum f_{sj} = Q \leq c + X$,turn to step9. If $\sum f_{sj} < Q \leq c + X$, turn to step6;

step6: In the shortest path from step3, cycle the step4, until $\sum f_{sj} = Q \leq c + X$, turn to step9, or $\sum f_{sj} < Q \leq c + X$,and $c_{ij}^* = 0$ turn to step7.

step7: Calculate the shortest path again that this paths have not been expanded. Cycle the step4 to step5, If $\sum f_{sj} = Q \leq c + X$, turn to step9; If $\sum f_{sj} < Q \leq c + X$, turn to step8.

step8: Cycle step7, if it cannot meet $\sum f_{sj} = Q \leq c + X$, the original freight transport network has no optimal solution, end of the algorithm.

step9: Have found the optimal solution , the algorithm end.

In the above steps, c_{ij}^* represents the flow added of each time, f_{sj} represents the flow that connect v_s.

5 Numerical studies

There is a freight traffic network, the maximum flow of it can reach 15, it has reached 14, near saturation. After survey and prediction, the freight traffic flow will reach 18 in the coming period, so the freight transportation network needs to be expanded. The number on paths represents (c_{ij}, f_{ij}) as the figure1.

It is known the roads weights of freight transportation network, calculate the shortest path from v_s to v_t , obtained the expansion road, expand on it. ((X_{ij}, w_{ij}) represents the expansion restrictions and expansion of the total factors, as the figure 2. Using ideas of this article, Calculated expansion sections are $v_sv_3, v_2v_5, v_5v_t, v_6v_t$, expanding energy is 1,2,1,1 respectively, the total consideration of expansion is 20, shown in Figure 3.

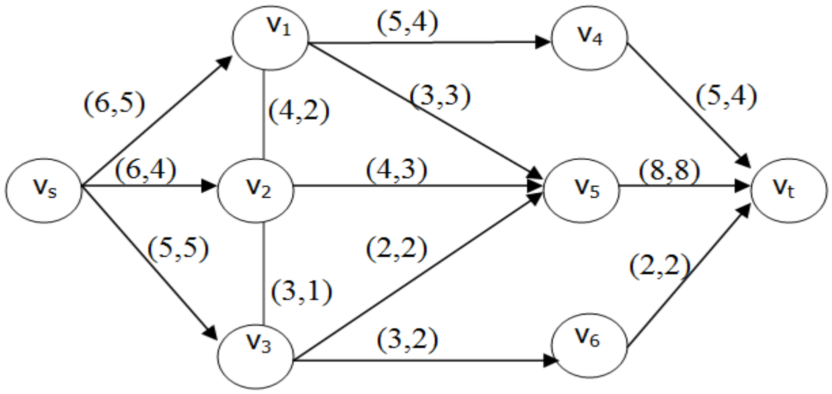

Figure 1. Capacity and flow of a transport network

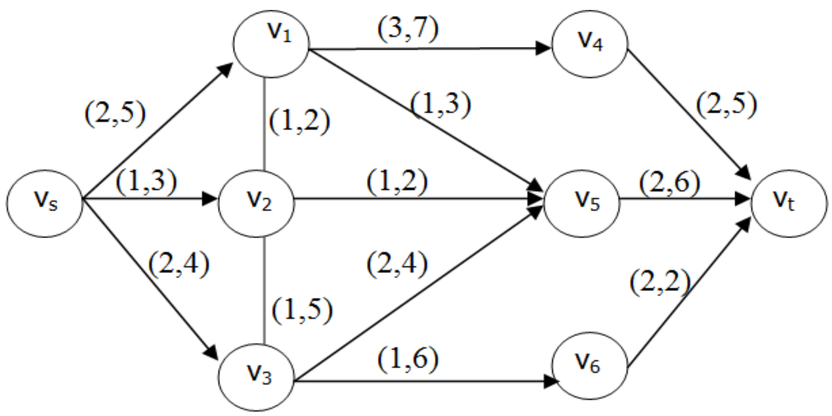

Figure 2. Capacity and flow of a transport network

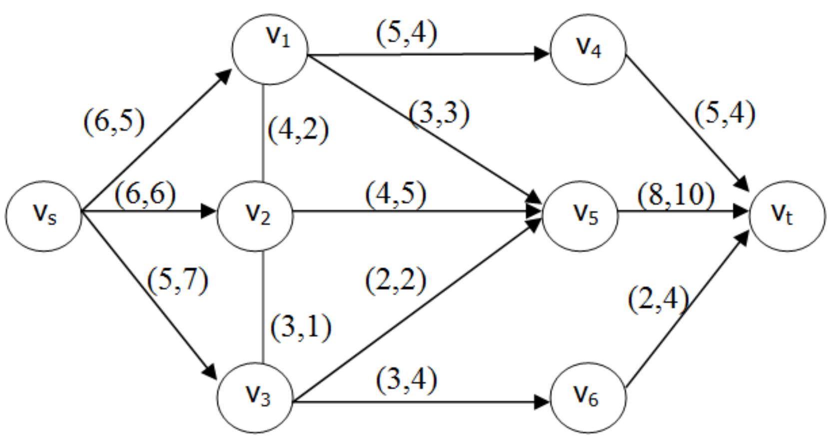

Figure 3. Adjusted transport flow

This is a simplified example of practical problems, mainly in order to illustrate the feasibility of the idea and the construction of freight transport network expansion planning. The actual complex problems can be calculated by MATLAB.

5 Conclusions

This paper studied the urban freight transport network and established an expansion optimization model about urban freight transport network with the shortest transportation time, the lowest transportation costs, the unit capacity cost minimum and the least road congestion status. At last a corresponding algorithm was designed in this thesis. This thesis focused on the urban freight transport network without considering the impact of traffic part of pedestrians and non-motorized vehicles for freight transport network. Therefore, the further study on considering various factors compulsively, and establishing a more rational optimization expansion model will be necessary.

Abstract: Road classification and hierarchy are the fundamental of road network planning and road design, and a set of strict and quantitative hierarchy method can reduce or even eliminate the subjectivity and uncertainty in urban planning. Based on summarizing deficiencies in existing road classification method, this paper focus on the road structure importance in network with complex network analysis techniques, building an index to describe road comprehensive importance and quantified road hierarchy method. The index built here takes both of road structure characteristic and road width into account. Through the case study of Mianyang, we find that, to some extent, there is a good similarity between results of this new method and the traditional method. This new method could help planners classify and rank urban roads more accurately and faster.
Keywords: Urban road network; Road hierarchy; Complex network; Betweenness; Road width.

1 Introduction

Road hierarchy, a usual measure and form of classification of road in which each kind of roads has a ranking with respect to the whole set of kinds, is a vital part of the design of urban road network. The reason is that we can't ensure appropriate management, engineering standards and maintenance practices applied to a certain road until its hierarchy is determined.

The kind method in Highway Functional Classification: Concepts, Criteria, and Procedures (Federal Highway Administration, 2013) is typical of many kinds of road classification and hierarchy in use around the world. In this typical method, functional classification is used to categorize road with the two primary transportation functions of roadways, i.e. mobility and access, and some other factors helping determine the proper category. Roads providing a high level of mobility are called "Arterials", those providing high level of accessibility are called "Locals", and those providing a mix of both of them are called "Collectors".

In China, almost relative design specifications and criteria identify four hierarchy levels of urban road classification, with comprehensive consideration of status (or importance) of road in the urban road network, transportation function and service function to buildings along the road (Ministry of Housing and Urban-Rural Development of the People's Republic of China, 2012). However, no more description has been given about how to determine a road hierarchy in practical work. Existing conventional road classification and hierarchy methods are based on different functions and status of roads, while they are qualitative. As a consequence, planners and engineers probably determine a road hierarchy by their own experience, which is easily affected by subjective factors.

Therefore this paper introduced a quantitative method of urban road hierarchy with building an index used to describe comprehensive importance of urban roads.

The rest of this paper is structured as follows. Section 2 is literature review. In section 3, we mention the methodology used and show how the index is defined and calculated. Calculation hierarchy method introduced in this paper is particularly presented in section 4 with a real case study. Then the result is further analyzed in section 5. Finally section 6 concludes the paper.

2 Literature Review

Official hierarchies of urban networks almost are based on local or national design specifications and criteria, and may reflect features and relations of urban roads in some degree. Those hierarchy methods have been widely discussed (Eppell, McClurg, and Bunker, 2001; Marshall, 2004). Often those conventional and official hierarchy methods are vaguely stated, so planners and designers have to decide by subjective judgment.

Other than conventional hierarchy methods, there're many studies of road hierarchy from different directions. Stevens (Stevens and Coupe, 1978) proposed that people have hierarchy structures organized in their cognition to road networks of some cities, and gave direct evidence for hierarchical structure in cognitive maps. Hirtle (Hirtle and Jonides, 1985) extended Stevens's work to a natural environment that has no predetermined, well-defined hierarchical structure. And how the hierarchies of roads form and grow and are used in our perception and cognition was investigated by Tomko (Tomko, Winter, and Claramunt, 2008).

Many real networks in nature and society share two generic properties, i.e. scale-free and high degree of clustering, and it has been proved that these two features are the consequence of a hierarchical organization (Ravasz and Barabási, 2003). Jiang (2007) studied topological patterns of urban street networks of 40 U.S. cities and found that all the topologies of urban street networks demonstrate a small word structure and a scale-free property for both street length and connectivity degree. Salingaros (2005) and Jiang (2008a) articulated that urban street networks demonstrate an ordered hierarchical structure of connections at the different levels of scale, but they didn't quantify hierarchy levels and provided how to divide each road to a certain hierarchy level.

3 Methodology and Index Definition

3.1 Methodology

In this study, we first tried to define and build a quantitative index to describe the importance degree of road in network, with which all roads can be ranked in order. Then under the process of calculation hierarchy method (section 4) we would get a classification result where each road is divided to a hierarchy level. Finally we compared the result with real classification of city network to demonstrate the reliability of this method.

3.2 Topological structure characteristics and mobility

In urban road network, for one road, there is an inverse correlation between its mobility and accessibility. In general, an arterial road has a more high status and is more important than a collector or local road. So to some extent, mobility is positively related to importance of the road in network. Hence, we could use the structure importance of road to reflect mobility.

An important arterial road with high level of service will not connect many roads directly, while most traffic transfer between collectors or local roads must go through it. In other words, an arterial road plays a role like 'hub'. Betweenness, as a centrality measure of a vertex within a network (Freeman, 1977), could describe degree of the 'hub' effect of a vertex in network (Wasserman and Faust, 1994; Jiang, 2008a). Therefore this paper chose betweenness as an indicator to reflect structure importance of road. Betweenness of the vertex is defined as follows:

$$C_i^b = \sum_{\substack{j,k \\ j \neq k \\ j,k \neq i}} \frac{|\sigma_{jk,i}|}{|\sigma_{jk}|}, \text{ or normalized: } \overline{C}_i^b = \frac{C_i^b}{(|V|-1)(|V|-2)} \qquad (1)$$

We analyzed urban road network and got its topological representation on the basis of strokes (Thomson, 2003; Jiang and Liu, 2008b), which is a dual graph and where vertices represent strokes, then betweenness of each vertex can be calculated by Eq. 1.

3.3 Limit of road width

A stroke is naturally merged urban road segments with a good continuity of direction (Thomson, 2003; Jiang and Liu, 2008b) which is based on the Gestalt principle. Gestalt principles, or gestalt laws, are rules of the organization of perceptual scenes and aim to formulate the regularities according to which the perceptual input is organized into unitary forms (Todorovic, 2008). Because of the influence of urban land use planning, the width of boundary line of each road segment ranges. Some stroke which crosses through the whole city and can be as a traffic corridor has a high betweenness, but one road on this stroke may be narrow so that the hierarchy level of this road wouldn't be too high. In general, narrow road is with bad mobility but good accessibility whose importance is relatively low in real network.

Although other factors such as speed limit and volume can also influence determining road classification and hierarchy, in this paper, we just choose road width as another component of the index we build. The reason is that road width is a stable factor, which will not easily change in a long time, so that the effect of road width to hierarchy is reliable.

3.4 Index calculation

This paper took into account both structure importance and road width to build an index, called *CI* (comprehensive importance), which is used to describe the comprehensive importance of road in network. For the road r_i, betweenness of the stroke which it belongs to is C_i^b and width is w_i, then CI_i should have a relation with them like $CI_i = f(C_i^b, w_i)$. We could compare the comprehensive importance of different roads with the relative values of *CI*, so we just need to express the correlation correctly. We defined the CI as

$$CI_i = g(w_i) \cdot \exp(C_i^b) \qquad (2)$$

where $\exp(C_i^b)$ is to eliminate zero value effects of C_i^b, and $g(w_i)$ is standardization of w_i with $g(w_i) = w_i / \max(w_i)$.

4 Calculation Hierarchy Method

In this section, we chose road network of Mianyang city for our study and introduced how to rank roads and get hierarchy of them, which we called calculation hierarchy method. First we need a GIS file of Mianyang network shown as Figure 1, then process this file to get its topological representation with strokes and compute betweenness using UCINET 6. Betweenness of road equals to the stroke it belongs to, next, we can get CI of each road by Eq. 2. On account of difficulties of getting data about the width of the whole roads, we estimated the width according to the number of lanes.

Table 1. Attributes of partial roads of Mianyang network

LinkID	SID	Length (km)	g(w)	Betweenness	CI
1	1	0.207	0.69	0.032	0.7113
2	2	0.295	0.36	0.177	0.4244
3	3	0.054	0.20	0	0.2
4	4	0.085	0.36	0	0.3556
5	5	0.08	0.18	0.003	0.1783
6	5	0.038	0.36	0.003	0.3566
7	2	0.695	0.36	0.177	0.4244

Table 1 shows attributes of partial roads of Mianyang network, where LinkID is road number and SID is stroke number.

Figure 1. Urban road network map of Mianyang

We ranked all roads in descending order of *CI*, and the higher *CI* road had, the higher level hierarchy road was. *CI* is continuous but road hierarchy is discrete. Thus we must select appropriate threshold values of CI to divide the range of *CI* into three parts. Each hierarchy of roads has a sum of length and a proportion in the network in urban road planning, so we can divide *CI* according to the length and proportion of each hierarchy of road and confirm the thresholds. Table 2 shows length and proportion of each hierarchy of Mianyang network. Under the ranking condition, roads with top *CI* are arterials until the sum of road length is close to 75.8324km, and the lowest *CI* among them is the first threshold. It is notable that in all probability we can't exactly find a road segment in the method to make the total length of some hierarchy level equal to that length in real network. Analogous, we can get collectors and the second threshold, and the remaining road are local roads. The result is shown in Table 3. In this way all roads in network are classified. The structures of road hierarchy in both real network and result of calculation hierarchy method are shown in Figure 2 and Figure 3.

Table 2. Road hierarchy of real network

Hierarchy	Length(km)	Proportion
Arterial	75.8324	18.74%
Collector	138.01	34.11%
Local	190.808	47.15%
Total	404.6504	100%

Table 3. Road hierarchy of calculation hierarchy method

Hierarchy	Length(km)	Proportion
Arterial	75.8194	18.74%
Collector	138.023	34.11%
Local	190.808	47.15%
Total	404.6504	100%

(a) arterial subnet (b) collector subnet (c) local subnet

Figure 2. Subnet of each hierarchy level in real network

(a) arterial subnet (b) collector subnet (c) local subnet

Figure 3. Subnet of each hierarchy level in calculation hierarchy result

By comparison between Figure 2 and Figure 3, it seems that in both cases subnets of each hierarchy have similar structure. But arterial subnet of calculation hierarchy method (Figure 3a) looks more smooth and has fewer short branches than the real (Figure 2a).

5 Discussion of Results

It is hard to compare road hierarchy of both situations effectively just from graphs. In this section we analyzed and compared their similarities and differences from two aspects, sizes and compositions of the same hierarchy in both situations. Size ratio r_s is the ratio of total length of some hierarchy in calculation hierarchy result to the total length of the same hierarchy in real network. And composition ration r_c is the ratio of total length of those roads with same hierarchy in both situations to the total length of that hierarchy in calculation hierarchy result. When they're similar in size, the r_c can reflect the degree of conformity of the result of calculation hierarchy method with the real result.

Table 4. Compositions of each hierarchy level in both situations

Hierarchy	$L^{real}_{arterial}$ (km)	$L^{real}_{collector}$ (km)	L^{real}_{local} (km)	Total	r_c
$L^{calc}_{arterial}$ (km)	69.3474	6.472	0	75.8194	0.9146
$L^{calc}_{arterial}$ (km)	6.485	131.538	0	138.023	0.9530
$L^{calc}_{arterial}$ (km)	0	0	190.808	190.808	1.0000
Total	75.8324	138.01	190.808	404.6504	
r_s	0.9998	1.0000	1.0000		

We could conclude from Table 4 that this calculation hierarchy method is credible. Although affected by subjective factors due to the limits of conventional methods, our planners must design roads and determine road hierarchy correctly in general. In that way, the result of calculation hierarchy method are also credible largely because of high conformity.

6 Conclusions

This paper introduced a new index CI to describe the integral importance of roads in network and a new method to rank and classify road quantitatively. Special focus was on the definition of the index and how to use it classify roads. Through a case study of Mianyang road network, it is indicated that the index can work well and the new hierarchy method is reliable. Applying this index and method to practical work can simplify and accelerate the progress of road classification and hierarchy, meanwhile, can mitigate adverse effects of subjectivity.

7 Recommendations for Future Research

About the definition of the index, we can take other factors into account in addition to road width and study whether the effect of a multiple-factor index is better than the one-factor index. Besides, we will have more case studies of other cities road networks to prove that the index and method have a general applicability.

Abstract: Road traffic safety is a complicated system engineering. This study makes a study on the macro regularity and control strategies of road traffic accidents systematically. Compared with other developed provinces, Jiangxi province lags much behind in road traffic safety construction. A large number of traffic accident data of Jiangxi province are collected and analyzed quantitatively using SPSS software. In this study, the macro regularity of road traffic accidents in Jiangxi province is found out and corresponding control strategies are put forward. As a result, goals of reducing traffic accidents and improving the road traffic safety level in Jiangxi province are reached. The research could meanwhile be of value to related research and formulate policy control of other cities.
Keywords: Road; Traffic accidents; Macro regularity; Control strategies; Safety.

1 Introduction

As the main artery of the national economy and bearing 87.3 percent and 76.3 percent of passenger and freight volumes, road transportation is the significant motivation and power for developing national economy and improving people's living standards. Statistics show that since 1899, over 30 million deaths have been caused by the car crash accidents worldwide. According to statistics data from Traffic Management Bureau, Ministry of Public Security , the number of accidents which caused casualties totals 210821 in 2011, killing 62387 people, which ranks first in the world six years in a row. Through the analysis of traffic accident data, the causes could be found and effective strategies of improving traffic safety could thus be sought out. Jiangxi province is representative in traffic safety problems due to its middle-level economic development and the increasing number of motor vehicles. This research makes a study on the macro regularity of road traffic accidents Jiangxi province systematically. According to the local investigation situation, corresponding control strategy is put forward then.

2 Data and Method

2.1 Data Resource

In this study, data on traffic safety accidents and related influencing factors, 2000-2013, in Jiangxi province are collected. These data come from Jiangxi Statistical Yearbook (2000-2014), Memorabilia: Jiangxi Public Security and Traffic Management, 1987-2007, Jiangxi Road Traffic Safety Accidents Report (2008 -2013). As is shown in table 1and Figure.1.

Table 1. Four indexes of road traffic accidents of Jiangxi province(2000-2013)

year	the number of accidents(accident)	the number of death(person)	the number of injuries(person)	direct property loss(ten thousands yuan)
2000	17591	3222	13988	7225
2001	17696	3355	14754	7150
2002	17772	3163	14669	7456
2003	13998	2818	11542	7783
2004	10531	2760	10004	6370
2005	8585	2428	8370	7698
2006	9449	2332	10759	6496
2007	8080	2060	9250	6261
2008	6350	1945	7370	6160
2009	5872	2161	7148	4564
2010	4126	1603	4938	4184
2011	3411	1733	4135	4857
2012	3145	1579	3479	4542
2013	2915	1492	2977	3738

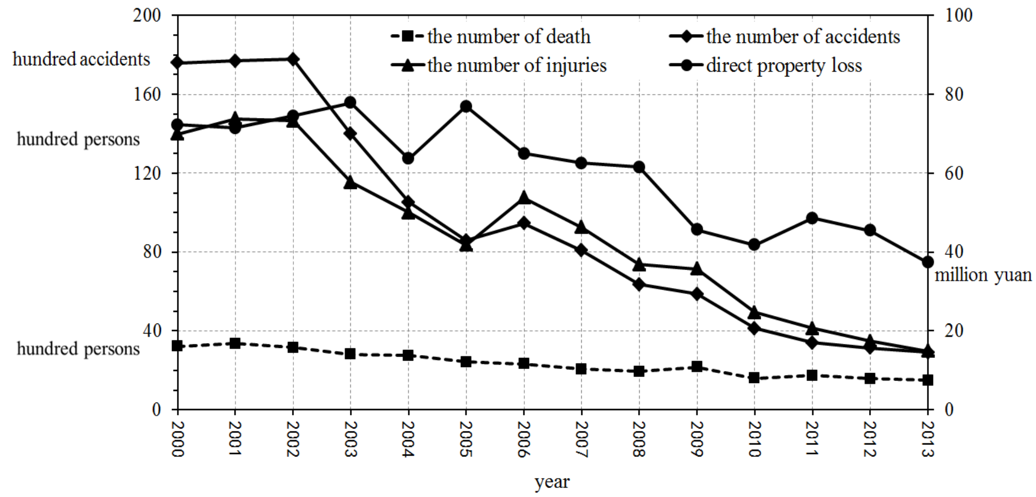

Figure 1. Four indexes of road traffic accidents of Jiangxi province(2000~2013)

Seen from the four indexes in recent years, the traffic safety situation in Jiangxi province is improving and the number of accidents is shrinking. However, severity of death, injury and property loss vary in traffic accidents. Therefore, it is difficult to compare the statistics of death, injury and property damage of different regions and in different years. In this study, the reference standard is that the death, injury and property damages are all converted to total loss of the traffic accidents.

According to the yearly regulations from 2000 to 2013 in Compensation Standards of Traffic Accidents and Personal Injuries in Jiangxi Province:

Death compensation = per capita income in the place where the appellate court is located×20years (1)

Disability compensation = per capita income in the place where the appellate court is located×disability coefficient×compensation period (2)

In the above formula, per capita income could be obtained by statistical yearbook, and disability coefficient and compensation period could be fixed hierarchically according to the accident investigation report from traffic administration departments. Afterwards, the number of deaths and injuries and direct property damages in road traffic accidents in Jiangxi province could be converted into the total loss of traffic accidents. The case of each year is shown in Figure.2.

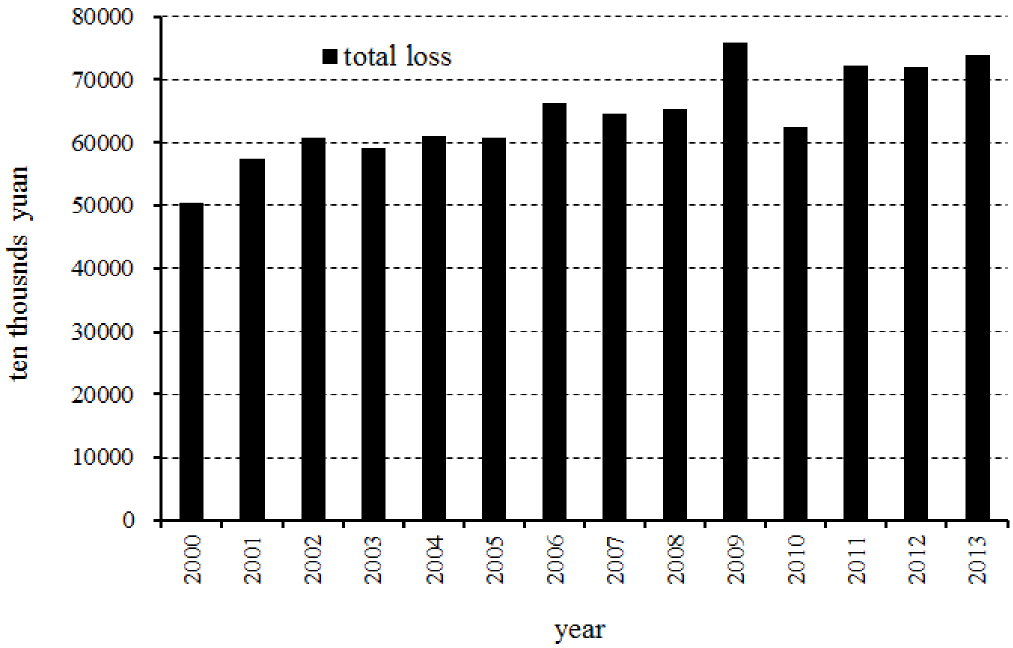

Figure 2. The total loss of road traffic accidents, 2000 to 2013, in Jiangxi province

It could be seen from figure 2 that the total loss of road traffic accidents in Jiangxi province is on the rise and that the traffic safety situation is very grim. Based on relevant theories and research literature of road traffic safety, this study chooses population, urbanization rate, highway mileage, the number of motor vehicles and drivers as influencing factors. The collected data are shown in Table 2.

Table 2. The influencing factors of traffic accidents , 2000 to 2013, in Jiangxi province

year	population （ten thousands persons ）	（%）	road length （hundred kilometre）	the number of vehicles （ten thousands vehicles）	the number of drivers （the thousands persons）
2000	4149	28	603	114	79
2001	4186	30	605	136	91
2002	4222	32	607	154	103
2003	4254	34	612	191	107
2004	4284	36	619	218	110
2005	4311	37	623	302	109

2006	4339	39	1282	352	109
2007	4368	40	1307	399	273
2008	4400	41	1338	446	313
2009	4432	43	1370	505	356
2010	1189	45	1406	569	391
2011	1210	46	1466	631	453
2012	1232	48	1506	684	875
2013	4522	49	1547	752	929

2.2 Method

Fig. 3 shows the model of traffic accidents generating rules analysis.

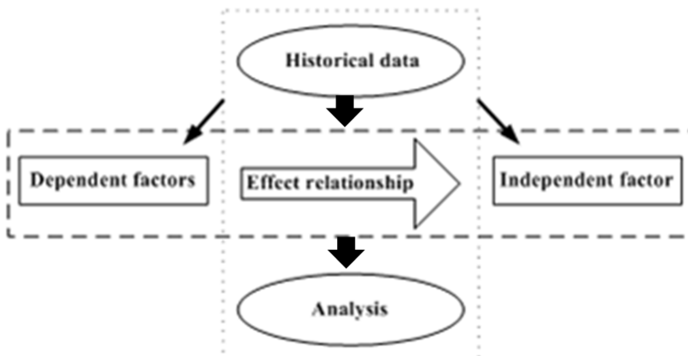

Figure 3. Conceptual model of traffic accidents analysis

The correlation coefficients $\mathbf{r_{lj}}$ are introduced to discuss the relation between road traffic safety accidents and influencing factors in Jiangxi province. Simple correlation coefficients between $\mathbf{y}$ and $\mathbf{x_{li}}$, and between $\mathbf{x_{li}}(\mathbf{l=1,2,\cdots,k})$ and $\mathbf{x_{ji}}(\mathbf{j=1,2,\cdots,k})$ could be calculated separately by the sample values $\mathbf{y_i},\mathbf{x_{1i}},\mathbf{x_{2i}},\cdots,\mathbf{x_{ki}}$, $\mathbf{i=1,2,\cdots,n}$. The formula can be written as follows:

$$r_{xy} = \frac{COV(x,y)}{\sigma_x \, \sigma_y} \tag{3}$$

Where, r_{xy} denotes correlation coefficients between x and y; $COV(x,y)$ denotes covariance between x and y; σ_x denotes standard deviation of x; σ_y denotes standard deviation of y.

Through the simple correlation coefficient of the sample, the size of the correlation coefficient of $\mathbf{y}$, namely dependent variable, and $\mathbf{x_j}$, namely independent variable, could be observed.

In the study, simple correlation coefficients are calculated with the aid of SPSS software. The result of output by SPSS is shown in table 3.

Table 3. Correlation

Correlation	Population	Urbanization rate	Length of highway	Vehicle possession	Number of drivers
Accident of total loss	-.275	.875	.824	.853	.738
Sig	.171	.000	.000	.000	.001

3 Results and Control Strategies

3.1 Results

The results show that strong correlation exists between the urbanization rate, length of highways, the number of motor vehicles and drivers and the total loss caused by traffic accidents. They not only verify the traditional traffic safety theory, but also further throw light on road traffic safety control strategies of Jiangxi province.

Based on the above research and taking into consideration other accident data and field investigations, it is found that the road traffic accidents in Jiangxi province have the following rules:

(1)High traffic accident fatality rate

Traffic accident fatality rate is the ratio of the total number of deaths and injuries in traffic accidents. The rate is about 14 percent to 20 percent in Jiangxi province, while remains between 1 percent and 4 percent in developed countries.

(2) Large proportion of vulnerable road users in accident victims

Vulnerable road users (mainly pedestrians, cyclists and two-wheeled vehicle users) account for more than 50 percent in terms of the number of deaths, injuries, accidents or other indexes of traffic accidents. Among these, the proportion of motorcyclists in the number of deaths and injuries is 23.58 percent and 28.52 percent respectively.

(3)Accident-prone segments

Dangerous and hazardous segments and accident black spots became the worst-hit areas of traffic accidents. For example, K194-K204 road of Daguang Expressway (from Ganzhou to Suichuan) accounts for 9.5 percent of the whole road mileage statistics, while the number of accidents and deaths has accounted for 31 percent and 71 percent.

(4)High proportion of traffic accidents on roads in mixed traffic status, without traffic control and with imperfect traffic facilities

Statistics show that traffic accidents occurring on roads without traffic control account for about 40 percent to 50 percent of those occurred throughout the year in Jiangxi province. The resulting death toll accounts for 55 percent to 65 percent of that in a whole year.

(5) Non-motor vehicle users and pedestrians violation being the main cause of urban road traffic accidents

Around a third of urban road traffic accidents in Jiangxi province are caused by violation of non-motor vehicles and pedestrians.

(6)Relatively high traffic accident rate of operating vehicles

Over the recent 10 years, the number of accidents, deaths and injuries related to operating vehicles accounts for 37.75 percent, 47.13 percent and 35.79 percent respectively of the corresponding index of the total number of traffic accidents.

3.2 Road Traffic Control Strategies

(1) The control of human unsafe factors

First of all, a strict and efficient driver training, appraisal, supervision and management mechanism should be established. Then, the regulation of key illegal behaviors must be strengthened, including both motor vehicle drivers and non-motor vehicles users and pedestrians. For different violations, different treatment schemes should be formulated. Finally, transport enterprises should strictly implement the responsibility system for production safety. What's more, transportation enterprises and the qualifications of drivers should be supervised for strict carry-out of the transport market access system.

(2) Improvement and enhancement of vehicle safety

Gradually increase the security of overall vehicle constitutes. Provincial Development and Reform Commission and Bureau of Quality Supervision should organize experts to participate in the analysis of road accidents. Under the guidance of the motor vehicle industry development policy, supervision of the auto companies should be strengthened from the source of the car manufacturers. At the same time, the motor vehicle inspection system should be strictly enforced and regulations on motor vehicle production, modification, maintenance, inspection and mandatory retirement should be strengthened as well.

(3) Improvement and enhancement of road system safety

Establish an effective of road traffic safety audit system. In addition, the provincial and local governments and transportation departments should effectively increase investment on, reasonably set up and improve the traffic safety facilities.

Comprehensive investigation and remediation should be made on road accident black spot and segments with security risks. Relevant departments should jointly formulate the investigation and remediation norms and standards of accident-prone segments, and identification, monitoring and evaluation system should be established, too. What's more, sound security risks investigation and remediation mechanism should also be formed.

(4) Improvement and enhancement of road traffic safety management

To begin with, set up road traffic safety committee in the charge of the government, leaders as main officials. The members consist of many traffic safety related departments. Make sure that all departments involved work collaboratively on it.

It is necessary to make a reasonable increase in the police force and an introduction of high-level professionals. On the other hand, the police force could be released by means of social forces. For example, part of the traffic safety management work can be carved out of the traffic control department. Funded by the Government, a tender is initiated and the task is then turned over to the successful bidder, a professional business or team.

(5) Enhancement of road traffic safety propaganda and education

Gradually improve the traffic safety propaganda system dominated by the government, in the charge of the road traffic safety committee and participated by other relevant departments. At the same time, establish long-term mechanism of traffic safety propaganda and undertake traffic safety propaganda activities regularly.

Education and traffic police departments could organize the writing of books and periodicals on traffic safety propaganda and education for children and adolescents of different ages. Make traffic safety education part of the legal education in schools at all levels.

(6) Establishment of sound traffic safety policies, laws and regulations

Accelerate the formulation of local regulations, governmental rules and regulations, and regulatory documents supporting the provincial traffic safety administration. Implement them reasonably. For instance, the formulation of Road Construction Designed to Implement Traffic Regulations, Guidance on Road Transport Facilities Installation, Motorcycle and Electric Car Regulations, School Traffic Safety Implementation Outline, The "Four Synchronous" Requireme*nt of Road Transport Facilities Construction* .

4 Conclusions

In the future, rapid development of motorization will be accompanied by increased traffic casualties. In this study, through statistical analysis of accident data, correlation is built between people, vehicles, roads, urbanization rate and traffic accidents. Together with other traffic accident data and research, the macro regularity of road traffic accidents in Jiangxi province is analyzed. Corresponding road traffic control strategy is then proposed, which is aimed at establishing a road traffic safety control system theory and technology system.

Abstract: Simulation software Arena is used to build fishing port system simulation model. According to the actual operation characteristics of the fishing port, the flexible berthing way is to assign a certain length of coastline in accordance with the length of the fishing boat, no fixed berths. Through many simulation experiments, reasonable length of coastline corresponding to different annual throughput is obtained. After analyzing the simulation results, I achieved the formula for calculating the corresponding reasonable length of shoreline, which can be used as a fishing port planning and design.
Keywords: Annual discharged volume for fishing port; Port; Reasonable length of coastline; Flexible berthing; Simulation.

1 Introduction

The fishing port production process can be seen as a service process for random arrived boats. Queuing theory is used to handle random service issues traditionally. Representatives ship needs to be selected. But types are complex, therefore, the use of queuing theory can't accurately describe the service process. With aid of computer, we uses simulation approach to deal with random service problems which has demonstrated good results. However, the preparation of a computer program is too complex to promote. The emergence of management system simulation software leads to the convenience to greatly improve the efficiency and increase the promotion of the use.

2 Analysis of reasonable length of fishing port shoreline by simulation software Arena

2.1 Model Introduction

Arena is a management system software that combines ease of use and flexibility of high-level language emulation emulator. The most basic modeling tools are the modules which connect together to build a variety of different simulation models (David Kelton, 2007). Model is divided into boat subsystems, waiting subsystems, berthing and unberthing subsystem.

Boat subsystem is to determine the arrival time interval of fishing boat, the proportion of ship carrying amount of fish. etc. Subsystem records boats' waiting time, the time for same type of ship is divided into the total waiting time and average waiting time for each boat. Moored subsystem is to record total work time and average working hours. The leave subsystem record the needed time of departures after the work is completed.

Model takes flexible berthing approach. Fixed Berthing approach will lead to some equipment idle in the port, negatively affect the overall operational efficiency, thereby causing unnecessary economic losses. So many fishing ports began to arrange a flexible berthing operating plan based on a certain length of fishing boat, assign shoreline length to substitute fixed number of berths. When fishing boat working, the specific shoreline and its front area stay as a whole, which has no clear distinction with previous design. Flexible berthing method enables the number of fixed berths to exceed original division ones, maximizing the use of quay length, thereby reducing the overall staying time in the port. Meanwhile, this way not only takes full advantage of shorelines, but also improve the unloading equipment utilization, shortening the waiting time in port.

2.2 Model data and results

Control variables in the model is average time interval, the proportion of boat types and shore length. Entity attributes include shoreline occupied by different boats and volume of fish per boat, also statistical data like when fishing boats in and out and working time in port.

This paper simulates the fishing port in the amount of discharge port from 10,000 to 20 0,000 tons, 20 kinds of unloading ports capacities. Different unloading port capacity corresponds to different time intervals, the proportion of boat types, contained volume. Obviously, with the increasing amount of fish volume: the arrival time interval will be shorter, large fishing vessels in the proportion will increase, small fishing vessels will be lower.

According to the queuing theory, when the number of fishing boat obey Poisson distribution (GUI Jinsong, 2000), arrival interval time obeys the negative exponential with the parameter same λ. The probability density for interval time as t is:

$$g(t) = \lambda \cdot e^{-\lambda t} \tag{1}$$

According to related data provided by Zhapo, Fujian Dongshan, Tongling, Dalian Xingshu ports, daily arrival boats are 25 to 69 , 40 to 55 for eighty thousand tons of yearly unloading volume port. Average arrival time can be calculated by the number of daily arrival fishing boats and its volume. Fishing ports in the model calculations presented in this paper and corresponding to the amount of the average time interval is in Table 1 below.

Table 1. Average arrival time interval of fishing boat (various annual throughput)

The quantity of annual fishing [Ten thousands/year]	1	2	3	4	5
The average interval time of fishing boat [h/ships]	4.07	2.04	1.4	1.01	0.82
The quantity of annual fishing [Ten thousands/year]	6	7	8	9	10
The average interval time of fishing boat [h/ships]	0.68	0.59	0.505	0.45	0.4
The quantity of annual fishing [Ten thousands/year]	11	12	13	14	15
The average interval time of fishing boat [h/ships]	0.37	0.34	0.31	0.29	0.27
The quantity of annual fishing [Ten thousands/year]	16	17	18	19	20
The average interval time of fishing boat [h/ships]	0.26	0.24	0.23	0.21	0.2

In view of 12,000 statistical random sampling groups, small-sized fishing boats 45%, medium 34%, and large 21%. Its improvement and uncertainty are taken into account. The proportion of various types of fishing boats are as follows:

Small fishing boats: Medium fishing boats: large fishing vessels=0.4:0.3:0.3;

Small fishing boats: Medium fishing boats: large fishing vessels=0.35:0.35:0.3;

Small fishing boats: Medium fishing boats: large fishing vessels=0.3:0.35:0.35;

Small fishing boats: Medium fishing boats: large fishing vessels=0.25:0.4:0.35.

Through statistical analysis of 12,000 sets of fishing boats, the length of 3 types of standards design are 14.2 m for small boats, 34.32 m for medium-size, 45 m for large. Based on documents (XIN Hongfu, 2000) fishing port berth length is calculated as follow.

$$L = L_b + 0.15L_b \tag{2}$$

with L_b: the length of design standards for fishing ship.

By analyzing *Xingshu fishing port throughput and ship unloading capacity statistics* (one year) and *Zhapo fish market statistic tables* (three years), the amount of fish cargo loading of each model fishing boats are shown in Table 2.

Table2. The amount of fish cargo loading of each model fishing boat

Small fishing boat		Medium-size fishing boat		Large fishing boat	
Deadweight [t/ship]	Membership	Deadweight [t/ship]	Membership	Deadweight [t/ship]	Membership
2	0.3	4.5	0.3	7.5	0.3
3	0.45	6	0.45	8.5	0.4
4.5	0.25	8	0.25	10	0.3
Weighted average [t/ship]	3.45	Weighted average [t/ship]	6.05	Weighted average [t/ship]	8.65

According to the literature (XIN Hongfu, 2000) we know that the efficiency of human-labor is 2~4 t/h, cranes unloading is 5~9t/h, mechanic is 10~15 t/h. Occupied shoreline is 17 m for small fishing boats, berth occupancy time is 1.5 h; medium-size 38 m, 2.8 h; large 52 m, 3.5 h. 365 days is regarded as an operation cycle, the fishing moratorium time is three months. So 275 working days a year and 24 working hours a day. Ensuring fishing port annual throughput unchanged, we change the length of shoreline, so that I can get the corresponding optimal quay length of throughput (Comprehensive minimum charges including the cost of idle boats and the waiting boats for berth). According to the literature (David Kelton, 2007), the ratio of small fishing boat is 2.3:1; the medium-size is 2.9:1; the large is 4.1:1. As follow table 3.

Table3. The simulation results

the annual throughput[ten thousand tons/year]	1	2	3	4	5	6	7	8	9	10
the length of quay [m]	225	300	380	500	550	600	650	700	750	800
the utilization	35	35	37	36	37	37	36	36	37	38

of quay [%]										
the cost of comprehensive[/t]	0.13	0.12	0.11	0.11	0.095	0.085	0.079	0.075	0.071	0.07
the annual throughput[ten thousand tons/year]	11	12	13	14	15	16	17	18	19	20
the length of quay [m]	810	820	830	835	840	840	845	845	850	850
the utilization of quay [%]	38	42	44	42	45	36	51	51	53	56
the cost of comprehensive[/t]	0.065	0.066	0.064	0.058	0.058	0.056	0.056	0.055	0.054	0.054

Table 3 shows that with the increase of fishing port annual throughput the length of quay will increase, the cost of comprehensive will gradually reduce; when the fishing port annual throughput reaches a certain amount the length of quay will increase gradually slow, the cost of comprehensive gradually decrease too; the fishing port annual throughput resches above 150000t, the length of quay will remain the same baisclly, the cost of comprehensive will be similar and remain unchanged basically.

Abtained:

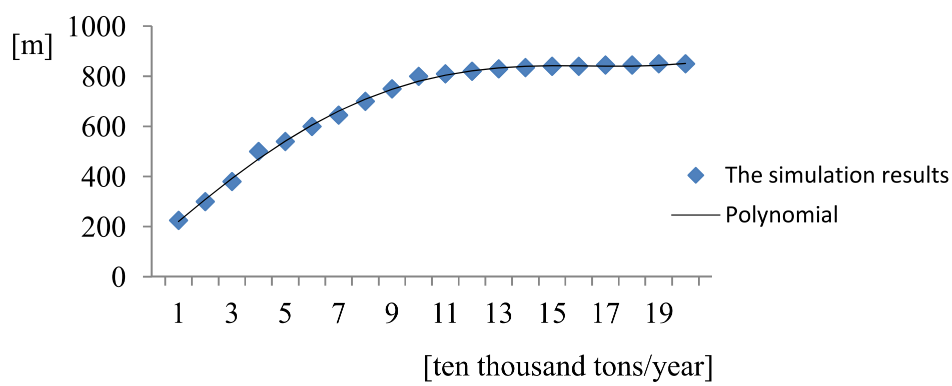

Figure 1. Analsis of simulation results

The picture 1 shows that the points represent the simulation calculation results, the curve represents the fitting result. By the above picture the information can be obtained is that the curve fitting correlation coefficient reached 0.9974, meets the requirement of the fitting.

The formula in the picture is：

$$y = 0.0086x^4 - 0.2635x^3 - 1.0156x^2 + 93.045x + 128.69 \qquad (3)$$

3 Conclusions

Here we may draw the following conclusions.

(1) According to the different requirements of fishing port annual throughput, average arrival interval time under various conditions of an annual throughput can be known;

(2) With the statistics of actual fishing port data, ratio of various fishing boat is obtained;

(3) Using simulation software Arena to simulate the working conditions of fishing port, the fishing port quay length corresponding to different fishing port under annual throughputs are acquired.

(4) The formula to calculate the relationship between the fishing port annual throughput and the length of quay is obtained.

Traffic Safety Evaluation Based on the Inherent Safety Principle

Tingting Gao

Traffic Safety Laboratory, School of Automobile and Transportation, Tianjin University of Technology and Education, Tianjin 300222. E-mail: gaotingting@tute.edu.cn

Abstract: Different from traditional safety studies which focus on the probability of accidents, inherent safety research takes one step further to judge the possibility of the inherent hazards. The method in the paper is necessary to analyze the risk of the urban road, especially it is necessary to avoid the traffic conflict or traffic accident's occurrence on the aspect of the source. This paper built an evaluation index based on the inherent safety principle. The evaluation index consists of inherent people safety, inherent automobile safety, inherent road safety and inherent environment safety, and each aspect contains sub-indexes. Finally, the paper will quantify evaluation index which influence the traffic safety by the extension evaluation model. Based on the evaluation results, it was found that the traffic safety evaluation based on inherent safety is more reasonable and valuable.
Keywords: Traffic safety; Inherent safety; Extension evaluation; AHP.

1 Introduction

Different from traditional safety studies which focus on the probability of accidents, the ultimate goal of inherent safety (IS) is "avoiding hazards rather than keeping them under control" (Kletz 1998). IS mainly applied to the construction of nuclear power plant, coal mining and other dangerous industries, and its purpose is to ban accident extremely. It has two meanings about the traffic safety: on the one side, it avoid the occurrence of traffic accidents, on the other side, it analyze safety evaluation indexes based on IS if there is a traffic accident. The paper analyze the essence of evaluation index about traffic safety from the first aspect to. Now typical evaluation index systems contain: Ed-wards and Lawrence proposed Prototype Index for Inherent Safety (PIIS) in 1993 (Edwards. DW 1993); Heikkila proposed Inherent Safety Index (ISI) in 1996 (Heikkilä A-M 1996); Palaniappan proposed i-Safe index in 2002 (Palaniappan C 2002); M. Gentile proposed evaluation method based on the fuzzy method in 2003 (M. Gentile 2003); Yuan Manrong proposed a intersection safety evaluation model based on extension principle in 2013 (Yuan manrong 2013) Research in this study from point view of the traffic system, the evaluation index which influence the traffic safety consist of the inherent people safety、inherent automobile safety、inherent road safety and inherent environment safety, and each evaluation index contain some second indexes.

2 Extension evaluation principle

2.1 Definition of Matter Element

The theory of the extension evaluation principle is extension set theory. Assuming $R = (\mathrm{N}, \mathrm{c}, \mathrm{v})$ is a multidimensional matter element, c_1、$c_2 ......c_n$ is a characteristic vector , and v_1、$v_2 ......v_n$ is a value vector of c_1、$c_2 ......c_n$, then a multidimensional matter element is using the following formula:

$$R = \begin{pmatrix} N & c_1 & v_1 \\ & c_2 & v_2 \\ & \cdots & \cdots \\ & c_n & v_n \end{pmatrix} = (\mathrm{N}, \mathrm{c}, \mathrm{v}) \qquad (1)$$

2.2 Matter Element Model

Matter element model is a practical method which applied on the evaluation issue. Assuming a comprehensive evaluation issue named N and has a number of impact factors, the matter element model is as following formula. (Yuan manrong 2013)

$$R = (\mathrm{N}, \mathrm{c}_j, \mathrm{v}_j) = \begin{pmatrix} N & c_1 & v_1 \\ & c_2 & v_2 \\ & \cdots & \cdots \\ & c_n & v_n \end{pmatrix} = \begin{pmatrix} N & c_1 & < a_1, b_1 > \\ & c_2 & < a_2, b_2 > \\ & \cdots & .... \\ & c_n & < a_n, b_n > \end{pmatrix} \quad (j = 1, 2....n) \qquad (2)$$

$< a_i, b_i >$ is classical field, in the practical study, a_i is the average index value of evaluation index, and b_i is the design value of evaluation index.

2.2.1 Matter element calibration

Evaluating matter element calibration is an important step. The safety grades, indexes and measure value used in the model, the formula is as follows:

$$R_i = (\mathrm{N}_i, \mathrm{C}, \mathrm{X}) = \begin{pmatrix} N_i & C_1 & x_1 \\ & C_2 & x_2 \\ & \cdots & \cdots \\ & C_n & x_n \end{pmatrix} \quad (3)$$

Where N_i is traffic safety level, which can divide into 5 grades as shown in table1(Yuan li 2010).

Table 1. intersection safety level

Safety degree	very safe	safer	less safer	little safe	dangerous
d	$0 \le d < 0.5$	$0.5 \le d < 0.8$	$0.8 \le d < 1$	$1 \le d < 1.2$	$1.2 \le d$
Safety grades	A	B	C	D	E

$C_i(\mathrm{i}=1,2,\ldots\mathrm{n})$ is the evaluation index, $C_{ij}(\mathrm{i}=1,2,\ldots\mathrm{n};\mathrm{j}=1,2\ldots\mathrm{m})$ is the evaluation sub-index. $x_i(\mathrm{i}=1,2,\ldots\mathrm{n})$ is the actual measured value about C_{ij}.

2.2.2 The weight ratio

General weight ratio can take AHP method to solve, can also take the weighted average method, this paper mainly adopts the latter.

2.2.3 The correlation function

Correlation function usually has many methods to determine, such as bigger and more optimal or smaller and more optimal. For some problems which have more stronger fuzzy, it can also use the method of fuzzy mathematics. This paper apply the smaller and more optimal algorithm because of the selected factors are some unfavorable factors .

$$k(\mathrm{x}_i) = \begin{cases} \dfrac{x_i - a_i}{b_i - a_i}, x_i \text{ are advantage factors} \\ \dfrac{a_i - x_i}{a_i - b_i}, x_i \text{ are disadvantage factors} \end{cases}$$

The explanation of a_i, b_i, x_i is the same as the above.

2.2.4 The degree of safety

d is a comprehensive related final degree, is also safety grade which mentioned in the paper. The concrete is calculated as follows:

$$d = \sum_{i=1}^{n} w_{c_i} \max(\mathrm{w}_i \cdot (\mathrm{k}_i)) \qquad (4)$$

Where d is safety degree, w_{c_i} is evaluation index, not evaluation sub-index, k_i is correlation function of evaluation sub-index.

3 Building traffic safety evaluation system based on inherent safety principle

Traffic system is a complex system consists of people, automobile, road and environment. Each factor of the system has a significant function for the traffic system safety and influence each other. The traffic safety system based on inherent safety is as shown in figure 1.

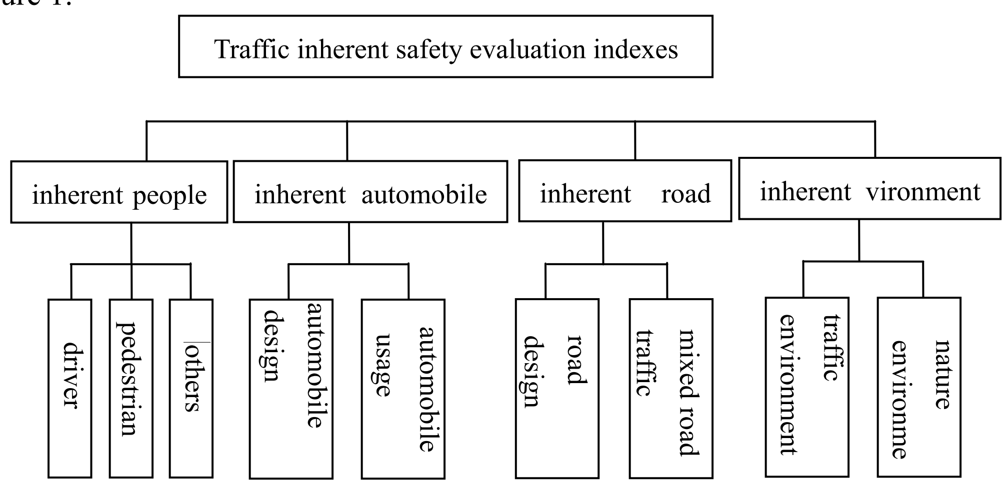

Figure1. traffic safety system based on inherent safety

(1) Inherent people

Inherent people is the main factor which influence the traffic safety, especially the driver's improper behavior, bad mental state and other factors. Moreover, the pedestrian and the people of bicycle is secondary factors which influence the traffic safety of the inherent people. due to lack of the Consciousness.

(2) Inherent automobile

Inherent automobile is key factor which influence the traffic safety, which consist of the automobile design and automobile usage. Active and passive safety devices of the automobile is more and more prevalent. On the other hand, good drive habit of the automobile is equally important.

（3）Inherent road

The people and the automobile act on the road. Physical condition of the road design and mixed traffic condition is belong to inherent road.

（4）Inherent environment

Inherent environment is consist of the traffic environment nature environment. Traffic signal, traffic marking and traffic timing of the traffic environment influence the traffic safety directly. Meanwhile, abnormal weather is equally important.

3. Case study

The case study take Tianjin road traffic safety level as an example, the paper determine the weight ratio by Delphi method and the weighted average method, to determine the correlation ratio by using the minimum optimal principle, so using the above formula can be obtained corresponding data such as shown in table 2.

Table 2. the traffic safety degree based on extension evaluation

		a_i	b_i	x_i	w_{c_i}	w_i	k_i	d_i
inherent people	driver	90	85	80	0.8	0.2125	0.5	0.1063
	pedestrian	25	20	10	0.8	0.025	0.3333	0.0083
	others	25	20	10	0.8	0.0125	0.3333	0.0042
inherent automobile	automobile design	0.05	0.02	0.01	0.02	0.2	0.75	0.15
	automobile usage	0.8	0.4	0.1	0.02	0.05	0.5174	0.0286
inherent road	road design	0.05	0.02	0.01	0.1	0.2	0.75	0.15
	mixed road traffic	85	80	70	0.1	0.05	0.3333	0.0167
inherent environment	traffic environment	70	65	60	0.08	0.05	0.5	0.025
	nature environment	25	20	10	0.08	0.2	0.3333	0.0667

$$d = \sum_{i=1}^{n} w_{c_i} \max(\mathrm{w}_i \cdot (\mathrm{k}_i))$$

$$=0.8\times 0.1063+0.02\times 0.15+0.1\times 0.15+0.08\times 0.0667=0.1084$$

The correlation function of each evaluation index, can be obtained by calculating the influence factors of road traffic safety, it can conclude that human driver is the main influencing reason of the inherent people, car design is the main influencing reason of the inherent automobile, road design is the main influencing reason of the inherent road, natural environment is the main influencing reason of the inherent environment.

This is consistent with the actual road safety evaluation. Finally, ten times magnification of 0.1084, it calculated by the evaluation of traffic safety in the case of road is the D level, and unsafe state.

4 Conclusion and Future Research

The evaluation of the traffic safety which use of extension theory for traffic safety, selection of evaluation factor is based on the inherent safety, the selected method in traffic safety has not been applied, so the strong innovation. The paper also has some deficiencies, especially the evaluation factor values determined subjectivity, how to use fuzzy mathematics association.

Acknowlegement

This research has been financed by the project of Tianjin University of Technology and education ((Project no. KJ14-05), which is greatly appreciated.

Abstract: Recognizing the role of public transit in support of road pricing and vehicle emissions reduction, this paper studies the combined effects of road pricing and rail transit on land use, transportation system, and vehicle emissions under different development scenarios. A comprehensive analysis of the impacts using a quantitative method, which combines the integrated land use and transport interaction model (TRANUS model), the scenario-planning techniques, and the emission factor model-MOBILE 6, has identified a number of important results. First, joint implementation of road pricing and transit-oriented development (TOD) strategy has better effects on land use, transportation system, and vehicle emissions. Specifically, combined implementation of these two strategies can not only alleviate the negative impact of road pricing on population and commercial, but also improve the operating conditions of the entire road network. More importantly, road pricing and TOD strategy can play mutually reinforcing roles in reducing the vehicle emissions of the entire region.
Keywords: Road pricing; Rail transit; Land use; Transportation system; Vehicle emission.

1 Introduction

The implementation of road pricing policy is bound to have a wide range of effects on both land use and transportation system (Zhong et al., 2013, 2015a, 2015b). In particular, the environmental impact of road pricing is an urgent question that needs to be answered. Previous studies on environmental effects of road pricing usually use the method that combines the traffic demand model and the vehicle emissions model. In fact, road pricing could not only stimulate a variety of changes in people' short-term travel behavior, such as route choice, time of travel, travel mode choice, trip frequency. Moreover, in the long-term, road pricing may also affect (re)location decisions of households or firms, such as residential or work locations (Banister, 2002). More importantly, such long-term (re)location decisions have again implications on the short-term travel behavior decisions, in the sense that relocations will influence travel patterns, mode choices, traffic densities, and level of service (LOS) of the transportation network (Tillema et al., 2010), ultimately affecting vehicle emissions and air quality. Therefore, the goal of sustainable development of the city can only be achieved by considering land use, transport, and environmental protection together (Bandeira et al., 2011). Furthermore, public transit, especially large-scale rail transit system, is often recognized as an effective tool to reduce vehicle emissions. However, existing studies have not investigated the joint quantitative impacts of road pricing and rail transit on vehicle emissions. Therefore, the main purpose of this paper is to evaluate the combined impacts of road pricing and rail transit on land use, transportation system, and vehicle emissions, from the land use and transportation integration perspective. What separates this from most previous studies is that it combines the integrated land use and transport model, the scenario-planning techniques, and the emission model to assess the joint effects of road pricing and rail transit.

2 Methodology

Firstly, the integrated land use and transport model (TRANUS) and the scenario-planning techniques are applied to simulate the changes of land use and transportation system under different regional development scenarios and road pricing schemes. Then the traffic flow parameters obtained from TRANUS are inputed into the vehicle emission model (MOBILE 6). Finally, we can estimate the urban traffic related atmospheric pollutant emissions, namely, CO, NOx, TOG under different development scenarios and pricing schemes.

2.1 Study Scenarios and Road Pricing Schemes

Jiangyin is a city in China's Jiangsu province on the Yangtze River. Jiangyin is selected as the study area for this research for several reasons, including available high-quality data on parcels, the land market and the transportation network; a recently completed (2011) comprehensive plan is available. More importantly, as a rapidly developing city, Jiangyin is facing a serious traffic congestion and air pollution problems in the central urban area.

There are several kinds of road pricing applied worldwide. In order to narrow the topic, we mainly investigate cordon pricing, which involves charging a fee to enter or drive within a congested area, usually a city center. In order to test the impacts of toll rates on vehicle emissions, we consider two levels of toll rates. Vehicles entering the downtown between morning and evening peak hours are subject to the payment of a charge of 10 Chinese Yuan (CNY) or 20 CNY.

The future regional development scenarios are subdivided into four categories:

- Scenario A: Business as usual (BAU) scenario, which aims to characterize the future regional development on the assumption that no new land use or transportation policies will be adopted.

- Scenario C: Scenario A plus road pricing.
- Scenario T: Scenario A plus rail transit system. We call this scenario the TOD scenario in which a regional rail transit system is introduced.
- Scenario D: Scenario T plus road pricing.

2.2 Land Use and Transport Modeling

The TRANUS software is adopted as the research platform in the paper. TRANUS is an integrated land use and transport analysis software based on decision theory and input-output analysis. It combines land attributes (location of population, economic activity, land consumption) and transportation model (trip generation, trip distribution, mode split, and trip assignment) (De La Barra et al., 1984). As an integrated land use and transport software, TRANUS is more conducive to the interactions between land use analysis and travel behavior.

In order to establish of Jiangyin integrated model, we need first to select the components of the land use and transport system. The land use system elements in this paper considering fourteen sectors, including industrial employment, retail employment, government employment, entertainment employment, health employment, education employment, population, industrial land, retail land, residential land, office land, health land, education land, and entertainment land. For the establishment of the transport system, we consider five categories of passenger transport modal, including rail transit, bus, car, walk, bike. The transportation network is composed of road network, bus network, and rail transit network.

For the calibration of the Jiangyin integrated model, a piecewise estimation approach is adopted. In a piecewise estimation approach, land use model and transport model are first calibrated individually before the parameters that define the interaction between both models are set (Abraham and Hunt, 2000). Specifically, the Jiangyin application is calibrated using the following three stages: First, calibration of the land use model as a stand-alone application; Second, using the result obtained by the land use model to calibrate the transport model as a stand-alone application; Finally, calibration of the interaction parameters between both models using the complete integrated land use and transport model. Overall, we have calibrated the land use and transportation outputs of TRANUS with observed values for 2010 (for more details, please see Zhong et al., 2015). Comparisons between TRANUS modeled and observed values reveal that the observed and modeled values are close enough to allow the use of TRANUS for forecasting into the future.

2.3 Vehicle Emission Modeling

Using the calibrated Jiangyin integrated model, we can simulate the influences of different regional development scenarios and road pricing schemes on land use and transportation system of the region. In the next step, we further apply the U.S. Environmental Protection Agency's (EPA) emission factor model-MOBILE 6 to estimate vehicle exhaust emissions. Link-based tailpipe emission factors are estimated from basic emission rates (BERs) obtained using the MOBILE6 model, and correction factors. Thus,

$$EF_{Y,f,V} = BER_{Y,f,v} \cdot TECF \cdot HCF \cdot PCF \cdot CCF \cdot SCF_{f,V} \quad (1)$$

where $EF_{Y,f,V}$ is the real-world link-based emission factor (mg/sec) for calendar year Y, facility type f, and link-based average speed V; $BER_{Y,f,v}$ is the basic emission rate (mg/sec) for calendar year Y, facility type f, and average cycle speed v under standard temperature, pressure and humidity; $TECF$ is the temperature correction factor (dimensionless); HCF is the local relative humidity correction factor (dimensionless); PCF is the local pressure correction factor (dimensionless); CCF is the cycle correction factor to convert BER at Federal Test Procedure (FTP) cycle speed to real world link-based emissions at the same average cycle speed; $SCF_{f,V}$ is the speed- and facility-specific correction factor (dimensionless); f is the facility type; v is the standard driving cycle speed (km/h); V is the average speed on roadway link (km/h); Y is the calendar year.

Link-based emissions models are coupled with link-level activity data (obtained using the TRANUS model) to estimate emission inventories. Total emissions for a single link for a given facility type are estimated from Equations 2 and 3 below:

$$t_i = 3600 \cdot L_i / V_i \quad (2)$$

$$TE_{i,f} = EF_{Y,f,V_i} \cdot t_i \cdot vol_i \quad (3)$$

where i mean the link ID; V_i mean speed of vehicles traveling on link i (km/h); L_i is the length of link i (km); t_i mean average travel time on link i (sec); vol_i is the vehicle volume on link i (veh/hr); $TE_{i,f}$ mean total emissions on link i for facility class f (mg/hr).

Summing TE across all links on a network produces an emission inventory estimate. Emission factors are coupled with outputs from the TRANUS to estimate an emission inventory. Finally, the impacts of different regional development scenarios and road pricing schemes on regional vehicle emissions are quantified.

3 Results and discussion

3.1 Land Use Impact Analysis

The key results of the land use impacts of different scenarios and toll rate are provided in Figure 1. We can see that road pricing has a negative (decentralizing) effect on both retail employment and residential density within the pricing cordon area under the BAU scenario. Different from the BAU scenario, the retail employments and population under the TOD scenario increased slightly when the congestion toll is 10 CNY. This indicates that the joint implementation of both road pricing and rail transit can inhibit the dispersion effect of road pricing in a certain extent. When the toll level is 20 CNY, however, both employment and population deconcentration have emerged due to the decentralizing effect of road pricing being greater than the agglomeration effect of rail transit.

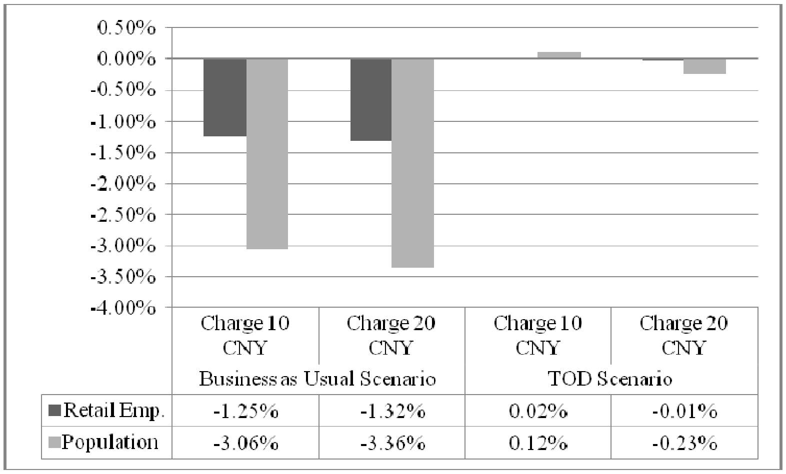

Figure 1. Changes of land use indicators under different scenarios

3.2 Traffic Impact Analysis

The modal splits under different development scenarios are provided in the following table, we can observe that:

- Look at the difference between Scenario A and C, we can find that the proportion of the travelers who use private car decreased dramatically with the increase of toll level. On the contrary, the ridership of walking and public transportation increased with the increase of road pricing level. This indicates that travelers are more likely to choose public transit or foot instead of driving, following the implementation of road pricing. In addition, the number of cycling trips affected little by the road pricing.
- Due to the introduction of a rail transit system, mode share for walking and public transit increased significantly under the TOD scenario. Moreover, the proportion of private car travel under the TOD scenario is much lower in comparison with the BAU scenario. This means that TOD stragety (especially rail transit) is much more effective than road pricing to change the structure of travel choices.

Table 1. Modal splits under different regional development scenarios

Travel Mode	Modal split					
	BAU Scenario			TOD Scenario		
	A	C		T	D	
		Charge 10 CNY	Charge 20 CNY		Charge 10 CNY	Charge 20 CNY
Walk	12.0%	14.0%	15.1%	34.5%	35.3%	35.9%
Bike	30.9%	30.2%	30.2%	15.7%	15.6%	15.7%
Public Transit	9.5%	11.4%	12.1%	24.3%	25.0%	25.3%
Private Car	47.6%	44.4%	42.5%	25.5%	24.0%	23.1%

3.3 Analysis of Vehicle Emissions

Figure 2 demonstrates the impacts of different regional development scenarios and road pricing schemes on regional vehicle emissions, we can see that:

- Compared with the Scenario A, the 10 CNY pricing scheme (Scenario C) can reduce the total amount of all types of exhaust emissions by more than 2%, the 20 CNY scheme (Scenario C) can decrease the vehicle exhaust emissions by about 4%, and the exhaust emissions are reduced by 6%~10% under the Scenario T. This indicates that when considering reducing vehicle emissions of the whole region, TOD strategy is better than road pricing policy. Furthermore, A combined strategy (Joint implementation of road pricing and TOD strategy), as simulated in Scenario D, leads to much better results, it can reduce the emissions by 10%~15%.
- It is also interesting to note that, for the same congestion toll rate, (D-T)/T is larger than (C-A)/A. This means that, for the entire region, road pricing and TOD strategy can play mutually reinforcing roles in reducing vehicle emissions. The underlying mechanism needs further research.

4 Conclusions

The important practical implications on the basis of this study are as follows:

First of all, road pricing may have a negative impact on both retail employment and population. Rail transit can promote the commercial development and population concentration. Therefore, in order to avoid the negative effects of road pricing on land use, road pricing and TOD strategy should be used together. Secondly, the TOD stragety (especially rail transit) is much more effective than road pricing to change the structure of travel choices. Thirdly, the results in this article also show that road pricing and TOD strategy can play mutually reinforcing roles in reducing vehicle emissions of the whole region. The underlying mechanism of this phenomenon is worthwhile of further study.

Abstract: In order to identify risk factors in the process of the railway dangerous goods transport, decrease the risk index, based on the work flow of rail dangerous goods transport, this paper made a deviation analysis according to the three working links of railway dangerous goods transport (sending work, work on the way, arriving work) by using hazard and operability analysis (HAZOP), determined the reasons of the deviation, the consequences and the corresponding measures, at the same time, made an idea to determine the degree of deviation quantitatively. Finally, took yellow phosphorus as an example, analyzed risk factors in the process of transport comprehensively and systematically, provided reference and recommendations for safety management of railway dangerous goods transport.

Keywords: Dangerous goods; Railway transport; Risk factors; Hazard and operability.

1 Introduction

There are so many kinds of dangerous goods which behave different characteristics, serious accident might happen if workers operate carelessly, which could result in loss of security and property. Many of the freight transport accidents are caused by dangerous goods. To make the railway dangerous goods transport safe and dependable, decrease the risk, there is a crying need to discuss the risk situation of railway dangerous goods transport and to analyze the risk factors. Researches (B. Fabiano, 2005) indicated: to evaluate and assess the railway dangerous goods transport had an important significance to safety guarantee. Some scholars offered a proposal to enhance the safety management and the development of railway station by analyzing the problems exiting in the safety management of the railway station (ZHANG Lan, 2005), the other analyzed the necessity and feasibility of the safety monitoring of the railway dangerous goods transport, the safety monitoring is beneficial to safe operation(WANG Zhe, 2010). And some scholars found the main problems in the dangerous goods transport process of handling station in China and puts forward countermeasures (YANG Zhanjun, 2000). Above researches investigated related problems of railway dangerous goods transport such as safety evaluation, operation management, terminal yard study and so on, which have a reference role for subsequent study. But most of the research methods are qualitative, that is to say they are pretty traditional and short of innovation. While the research consequences were not used to practical application, which remain to deepen.

So the author studies deeply on risk factors in every link of the railway dangerous goods transport by using an innovative and cross-domain method. Hazard and operability analysis method (HAZOP) was used in chemical sector widely, it can find all of the risk factors by analyzing every point of technological process and provide reference to improve security. Railway dangerous goods transport is a complicated and dangerous process, which can be regarded as a technological process. So we can add the idea of HZAOP into it and take yellow phosphorus as an example, to avoid risk factors, to ensure operability safety, which has important reference significance to the railway dangerous goods transport.

2 Application of HAZOP in Railway Dangerous Goods Transport

HAZOP was used to railway dangerous goods transport, its meaning should be redefined: it is a kind of structured analysis method which is used to identify equipment problem, technical defects and human error in the process of the railway dangerous goods transport. Its nature is to identify deviation degree of every point, possible accident and influence by analyzing the process of railway dangerous goods transport, partitioning analysis points, choosing guide words, finally achieved the harm identification of risk factors.

The analysis step of HAZOP of railway dangerous goods transport includes partition analysis point, determine and analyze deviation and record consequences, the HAZOP flow chart as shown in Figure1.

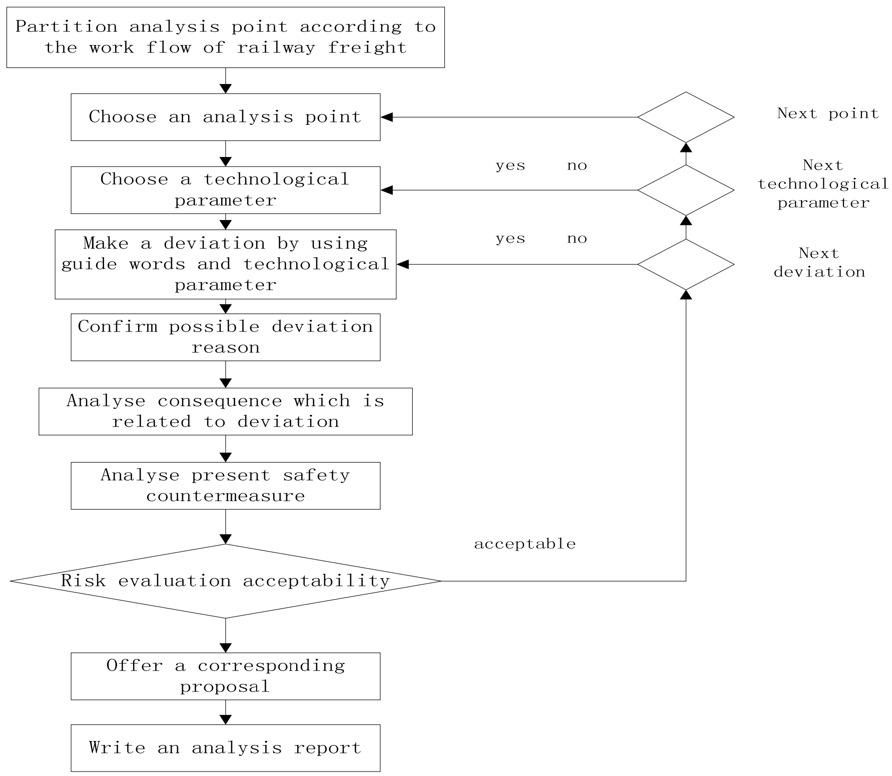

Figure 1. HAZOP flow chart of railway dangerous goods transport

Railway workers of different trades and departments constitute analysis group, analyze the whole process according to the HAZOP analysis method comprehensively. Firstly, partition points and determine deviations according to the process of railway dangerous goods transport. Secondly, analyze points and deviations, deviations are usually combined by guide words and parameters, Finally, analyze reasons, consequences, present measures and suggestions, then record analysis consequences.

3 HAZOP of Railway Dangerous Goods Transport

3.1 The partition of points

The process of railway dangerous goods transport is a continuous safety chain, in which the analysis points refer to key points of operation and equipment. Points partition shown as black, italic and underline in Figure2.

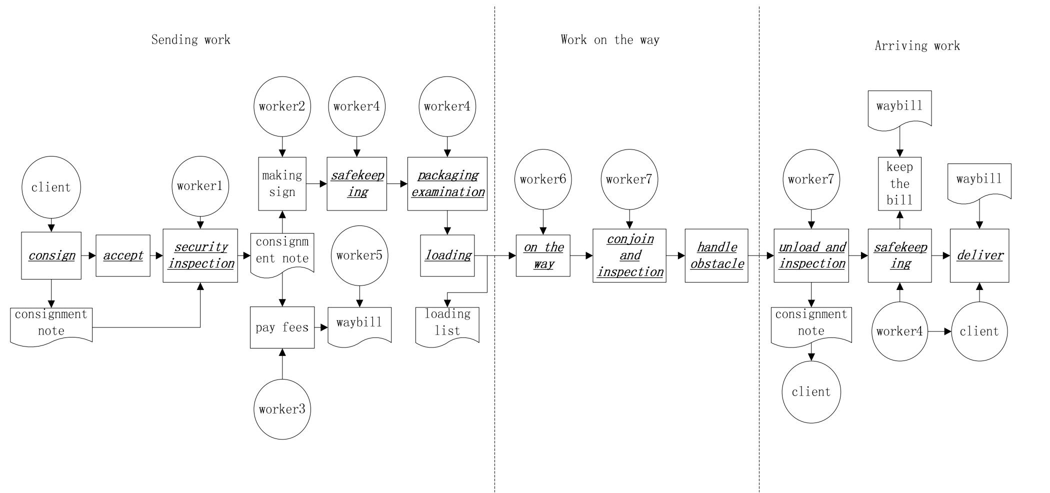

Figure 2. Analysis points of HAZOP

3.2 The analysis of deviations and consequences

The deviations are the main parts of the analysis (ZHANG Lingwan,2012), by analyzing deviations, we can find all of hidden danger in the every analysis point. The HAZOP deviations and their descriptions of the railway dangerous goods transport shown as Table 1.

Table 1. HAZOP deviations and descriptions

Number	Deviation	Description
1	Wrong name	point1)：record goods name wrongly
2	Wrong waybill	point2)：record waybill information wrongly
3	Useless safety check	point3)：security inspection did not avoid hidden danger
4	Damaged goods	point4)：keeping goods carelessly leads to goods damage
5	Useless packaging	point5)：wrong appliance, material and operation lead to packaging useless
6	Damaged packaging	point4) 6) 7) 10) 11)： operate improperly leads to packaging damage in the process such as loading
7	Goods losing	point4) 6) 7) 8) 10) 11) 12)：goods losing happens in the process of keep, deliver and so on
8	Operating fault	point6) 10) 8)：delivery and loading goods improperly
9	Unusual parameter	point7-9)：check and find unusual parameter
10	Handling fault	point9)：handle obstacle improperly
11	Dereliction	point7)：workers neglect duty on the way

For railway dangerous goods transport, the specie of dangerous goods is various, which is divided into 9 big kinds, 25 small classes. Different kinds of dangerous goods have different properties, this paper provides an unified model for analysis, when you analyze one kind of dangerous goods, you should have different emphasis point. For example, when we study on the inflammable and explosive materials, the risk factors may exist in the consign and accept link, except that, we should consider the sealed packing, temperature control and so on.

3.3 The analysis of deviation degree in HAZOP

After we got the deviation analysis consequences (ZHOU Shuai,2014), to make a unified standard for qualitative parameters and quantitative parameters, to make it easy to count data, the author used deviation degree to measure the degree of deviation. It shows that how far do the measured parameters away from the standard parameters. For quantitative parameters, we presume the maximum allowable positive deviation isa_{max}^{+} , and the maximum allowable negative deviation isa_{max}^{-}, so the deviation degree of parameters can be recorded as:

$$f = \frac{|t-s|}{a_{max}^{+}-a_{max}^{-}}\beta \qquad (1)$$

Which the t refers to measured parameters, the s refers to standard parameters, the β refers to risk parameters.

When the positive deviation and negative deviation exist respectively, the β should be calculated as:

$$\beta = 1-\frac{a_{max}^{-}}{a_{max}^{+}} \qquad \beta = 1-\frac{a_{max}^{+}}{a_{max}^{-}} \qquad (2\text{-}3)$$

Thus, the reasonable range of deviation degree for quantitative parameters is [0,1], if f=0， then deviation is 0, if f=1, then it is maximum allowable deviation, if f>1, then the parameter is transfinite。

For qualitative parameters, the deviation degree is divided into 5 levels, the f can be [standard, pretty standard, general, pretty eccentric, eccentric] ≤[0.2，0.4，0.6，0.8，1.0].

4 HAZOP of Yellow Phosphorus Transport by Railway

Yellow phosphorus is a kind of translucent white or yellowish waxy solid, its ignition point is 30 ℃ and melting point is 44.1 ℃. It is stable when it can not contact air, but it will spontaneous combustion in the air, when it is burning, there will be white poisonous smoke(WANG Bowei,2007). So in the process of yellow phosphorus transport by railway, the most key link is the packaging inspection, the concrete analysis process and consequences are shown as Table 2.

Table 2. HAZOP analysis process and consequences

Number	Deviation	Description	Possible reason	Consequence	Present countermeasure	Proposal
1	Wrong name	record goods name wrongly	1misstatement 2mistake	1accidents 2equipment damage 3increased cost	inspect before accept goods	1emphasize and avoid 2strengthen training and inspection power
2	low height of water on yellow phosphorus	the height of water on the yellow phosphorus is lower than 15cm	1original quantity deficiency 2leakage	1yellow phosphorus spontaneous combustion 2hidden trouble of spontaneous combustion	inject water according to the standard	1strengthen safety inspection after injection 2test equipment
3	sealing differential	containers had not been sealed well	1priming negligence2sealing differential on the way	1yellow phosphorus spontaneous combustion2hidden danger	seal rigorously	1seal rigorously 2ensure equipment quality
4	overloading	the weight of yellow phosphorus boxes is more than 10kg	1operation against rules 2negligence	1accident 2equipment damage	limit weight	1limit weight rigorously 2increase punishment
5	temperature of container does not reach the standard	temperature of container does not reach 44.1℃	1did not preheat before priming 2preheated but not enough	1yellow phosphorus condensation 2hidden danger	heating layers and thermometer are design	1preheat before priming 2inject equipment
6	the quantity of nitrogen	the quantity of nitrogen is less than	1negligence 2equipment damage	yellow phosphorus spontaneous combustion	Use container equipment to fill	1periodic inspection 2ensure seal

	is deficiency	0.15Mpa			nitrogen	
7	improper isolation of train vehicle-body	the isolation material is not wet mat	1shortage of professional quality 2negligence	1leakage and accident 2equipment damage	wet mat isolation	1inject after loading 2more advanced material
8	overloading	the number of yellow phosphorus tub is more than 240	1operation against rules 2negligence	1accident 2hidden danger	inject after loading	strengthen training and inspection power

The Table 2 shows the whole process of HAZOP clearly. We took the quantitative parameter: the quantity of nitrogen as an example, calculated the degree of deviation. From Table 2 we can know that the standard parameter s is 0.15Mpa, according to the practical experience we presume the maximum allowable positive deviation a_{max}^{+}, is 0.25Mpa and the maximum allowable negative deviation a_{max}^{-}, is 0.05Mpa, now the measured parameter t is 0.20Mpa,. Then substitute values into formula (1) and (2), the calculation process shown as formula (4) and (5).

$$\beta = 1 - \frac{0.05}{0.25} = 0.80 \tag{4}$$

$$f = \frac{|0.20-0.15|}{0.25-0.05} \bullet 0.80 = 0.20 \tag{5}$$

Thus, the degree of deviation f is 0.20, between the reasonable range [0,1].

5 Conclusions

Here we may draw the following conclusions.

（1）Research shows that HAZOP can get all of the risk factors of railway dangerous goods transport comprehensively, the analysis results can be used in the process of practical operation to avoid the appearance of risk factors, as a result, the safety degree can be promoted and it can promote the development of railway dangerous goods transport. So we can say, the HAZOP is effective for analysis of railway dangerous goods transport. Also, this paper shows the calculation method of deviation degree.

（2）Takes yellow phosphorus as a case to show how to analyze factors by using HAZOP, provides railway dangerous goods transport with a reference

（3）Through HAZOP, railway workers can identify all of the hidden danger in the process of railway dangerous goods transport, increase operability, avoid accident or decrease consequences, finally ensure railway dangerous goods transport operate safely, placidly and economically.

Bayesian Belief Net Model-Based Traffic Safety Analysis on the Freeway Environment

Bo Sun[1,2]; Decun Dong[1]; and Shicai Liu[2]

[1]Key Laboratory of Road Traffic Engineering of the Ministry of Education, Tongji University, Shanghai 201804. E-mail: sdustsb@163.com
[2]Department of Information and Engineering, Shandong University of Science and Technology, Shandong, China.

Abstract: The short-time crash risk measurement on the freeway has been catching much attention of government and management authorities. Due to recent advanced development in information systems and traffic sensor technologies, the real-time crash prediction models are getting more practicality. Critically, crash frequency analysis is the most important step for traffic safety studies. The paper makes two major contributions. Firstly, a multi-level Bayesian framework has been researched to identify risk factors towards the urban expressway by modeling unprocessed traffic data and roadway geometric topology data. Secondly, the paper utilized Bayesian belief net to build the real-time crash prediction model for the basic freeway segments. The objective is to predict the formation probability of a hazardous traffic condition in 4-9minuts in a 250-meter-long freeway road section. Results obtained can be used for the urban freeway management departments to understand the risk factors and take immediate actions in advance to avoid traffic accidents on the freeway.
Keywords: Urban expressway; Risk factors; Real-time crash prediction model; Multi-level Bayesian framework; Bayesian belief net.

1. Introduction

Road safety is a primary priority of transportation engineering. Up until now, lots researches have been carried out at both the macro- and micro-levels. Micro-level traffic safety studies research motor-vehicle crashes in specific locations, such as roadway segment, intersection) with the need of with a small number of occurrences but a great deal of detailed traffic information. Studies in this area concentrate on the aggregate analysis (including crash frequency analysis, crash rate analysis) and disaggregate analysis (including real-time crash prediction).

Conventional road crash predication models employ traffic flow variables, such as speed limits, AADT and others, to identify hazardous locations. According to studies (Sabey and Staughton, 1975; Treat et al., 1977; Oh, C. 2005), road crashes occur due to the interaction of factors, and four major factors include the road geometry and environment, the motor vehicle, the human, and the traffic dynamics. Furthermore, the study (Oh, C. 2001) also indicates that road crashes will regularly occur because of sudden disrupted traffic conditions even on geometrically correct roads and under right driving conditions. Motivated by the above study, some researches began studying road crash predication in real-time with the help of high-resolution detector data (Lee et al., 2006; Pande and Abdel-Aty 2007; Abdel-Aty et al., 2008). However, existing crash predication models have some major shortcomings and are limited to the location of detectors, variable traffic variables and the modeling method efficiency.

In order to solve the above shortcomings and limitations, this paper proposes a Bayesian belief net (BBN) based framework to design a real-time crash prediction model. The research simulates an urban expressway equipped with uniformly but packed detectors, and uses BBN to conduct the evaluation.

2. Simulated Scenario and Data Preparation

The simulated scenario needs to consider quality of detector data, accuracy in reported crash time and sample size. We use VISSIM to simulate one expressway with two lands in each direction, and the expressway has 210 detectors within 25.4 kilometers with an inter detector space about 250 meters. The simulated scenario is used to experiment with different detector combinations and identify optimal detector layout plan for the surveillance of hazardous traffic condition formation in real-time. The data stored in the detectors include speed, vehicle count, occupancy and number of heavy vehicles per lane for each 8 milliseconds round the clock (24 h a day, 365 days a year). Data of all the lanes are collected once every 5mins. The crash data contain date, time in minutes, location (in nearest 10 meters), vehicles involved, type of crash, and others. This study divides the whole road length into 250 meters road sections in such a way that every section harbors one detector. Then, for every crash case, data from two upstream, two downstream and the detector with in the section are extracted from the detector database.

For every crash case, the data point contained information on 5-min cumulative vehicle count, number of heavy vehicle count, average speed and average occupancy from all five detectors. Furthermore, the study also introduces another variable called 'congestion index' (CI) at each detector position to get the combined impact of speed and flow. Diasetal. (2009) argued that level of congestion is a less biased representation of speed as the speed that can be considered low for a specific road section may emerge as too high for another road section due to the road geometry and other physical constrains. Motivated by this theory, this study includes CIatall5 positions to the previously declared variable space. The CI for any detector position can be calculated according to Equation (1):

$$CI = \frac{\text{FreeFlowSpeed-Speed}}{\text{FreeFlowSpeed}} \tag{1}$$

The free flow speed for each of the detector position is calculated based on the speed-flow, the speed-occupancy diagram and the observed value. The final variable space contains 65 predictors. Values for 25 predictors (5 variables for each detector position× 5 detector positions=25) are directly generated by detectors and the rest 40 are calculated via comparing the longitudinal difference of these predictors among different detector positions.

3. The Description of Bayesian Belief Net Method

Bayesian belief net (BBN) is a relatively new method in the artificial intelligence (AI) probability and uncertainty community with multifarious usage (e.g., reason in g under uncertainty, making predictions of highly uncertain phenomena, etc.).BBN based system can help researches understand a phenomenon or make predictions about events. BBN is highly effective in situations where inferences are not warranted logically but probabilistically. As a graphical modeling method, BBN is represented with a graph and a basic equation. The graphical part of the BBN consists of two types of elements–a set of nodes and a set of directed edge. To explain the numerical part, we can define a BBN over a universe of variable U={A1,...,An}. Then the BBN can be specified with a joint probability distribution P(U) that can be obtained according to Equation(2).

$$P(U) = \prod_{i=1}^{n} P(A_i \mid pa(A_i)) \quad (2)$$

Where, $pa(A_i)$ represents the parents of A_i.Now, if new findings e1,..., ek on some variables with in U are obtained and joint probability distribution P(U) has been known, we can re-write Equation(2) as Equation(3):

$$P(U,e) = \prod_{i=1}^{n} P(A_i \mid pa(A_i)) \prod_{i=1}^{n} e_j \quad (3)$$

Via marginalizing $P(U,e)$, we can obtain the probability of any variable A within U, according to Equation (4).

$$P(A \mid e) = \frac{\sum_{U/A} P(U,e)}{P(e)} = \frac{\sum_{U/A} P(U,e)}{\sum_{A} P(A,e)} \quad (4)$$

4. Model Design

In this section, we propose and evaluate the BBN based real-time crash prediction model in three interlinked phases with three datasets. Firstly, the variable selection contains 189 crash data and 6478 traffic condition data. Secondly, the paper constructs and simplifies the model according to parent divorcing technique and then yields the conditional probability tables for each variable. Thirdly, the model performance is evaluated using a separate dataset.

4.1 Data Extraction

Random multinomial log it (RMNL) method was employed on the dataset for variable selection to decide and rate the most important variables. A step-wise iteration method has been followed in which at each step 100 logistic regression trees were grown by randomly selecting 4 variables at a time. Figure 1 represents the top ten most important variables. Figure 2 presents the cumulative importance of detectors in each location which has been calculated by summing the importance of all five variables (e.g., for detector in position 2, d2 is the summation of the importance of d2q, d2p, d2v, d2o, d2i). Figure 3 shows the importance of detector combination based on their spatial variation (e.g., for the spatial variation between positions 2 and 4, d24 is the summation of the importance of d24q, d24p, d24v, d24o and d24i). It should be further noted that in the form $d\alpha X$, d represents the detector, α means the position of the detector (e.g., 24 means the location between 1 and 4), and X is the variable, where "q" means 5-min cumulative vehicle count, "p" means 5-min cumulative count of heavy vehicles, "v" is the average speed over 5mins, and "o" stands for the average occupancy over 5mins. From these three figures, we can draw the following conclusion that detector positions 2 and 4 should be chosen to maximize the prediction success when the real-time crash prediction model employs a combination of detectors in two locations.

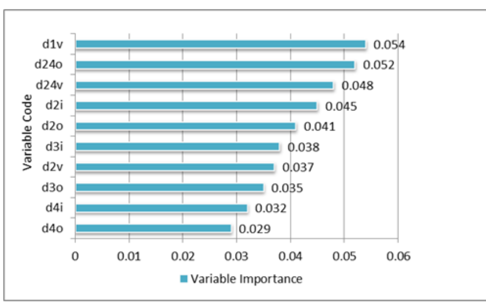

Figure 1. Top Ten Variables within the Variable Space

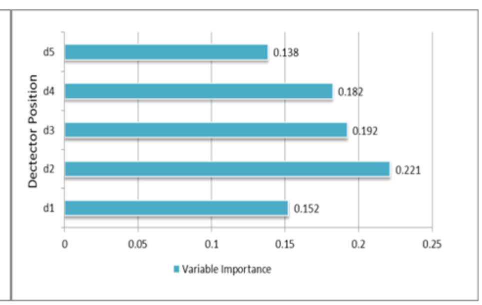

Figure 2. Each Detector Location

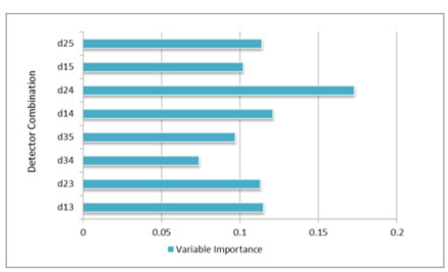

Figure 3. Detector Combinations

4.2 Model Design Principles

Subsequently, we extract data from the combined dataset for all the crash cases with complete information on variables generated by 2 and 4 detector locations. The dataset contains 622 crash cases and corresponding 25,899 normal traffic condition data points. Furthermore, the dataset is further divided into the dataset for the model design purpose and the one for the evaluation purpose. The dataset for model building includes 545 crash cases (including the 119 crashes employed for variable selection) and 22,204 normal traffic condition data. Of these 362(69.5%), 68 (10.1%), 83(13.6%) and 3(<1%) are respectively rear-end, side-swipe, single vehicle and tipping over crashes.

The determination of the BBN graphical structure follows the data extraction. And 'crash' is chosen as a child node to the parent nodes. Furthermore, two new intermediate variables 'risk ratio A' and 'risk ratio B' are introduced in order to decrease the complexity of the conditional probability table for 'crash'. Based on the above methods and corresponding independent variables, we can obtain the probability of potential crash traffic conditions.

In order to establish BBN model, we use the information variables, the outcome variable along with their states and conditional probability tables as input and computes and provides the BBN as output. The resulting model is illustrated by figure 4. From figure 4, we can observe the node d2i suggests that 23.72% of the samples (crash and normal all together) have congestion index at detect or location 2 to be less than 0.04; 7.16% of the samples have congestion index at the same location between 0.04 and 0.06 and soon.

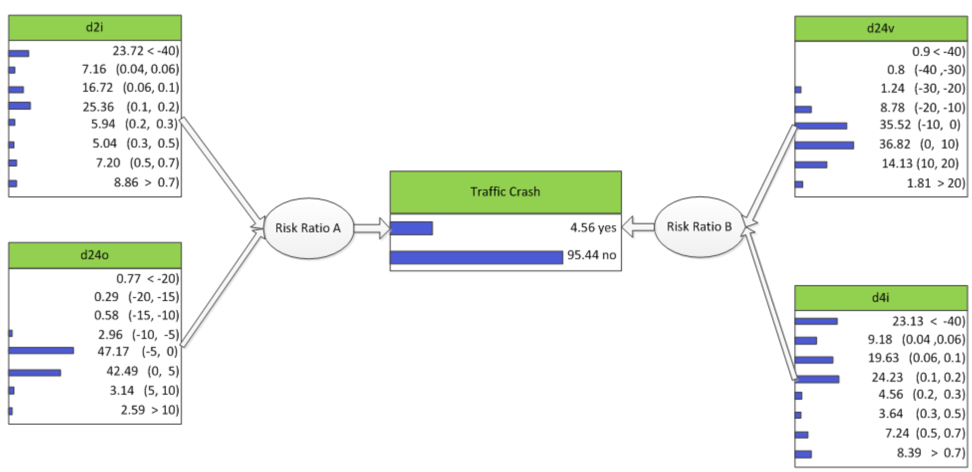

Figure 4. The BBN-based real-time crash prediction mode

4.3 Model Evaluation

The simulated crash data is used for evaluating our proposed BBN model. The dataset contains 90 crash cases and 2795 normal traffic condition cases. Among these normal traffic condition data points, 450 have been randomly selected to evaluate the model. Based upon Figure 4, we can observe that the average probability of the crash traffic condition equals to 4.56% for the unavailability of new evidence entered. We use this value as the minimum threshold for evaluating the performance of the model. The threshold value has been raised up to 15% and the classification accuracy have been fathomed and presented in Figure 5.

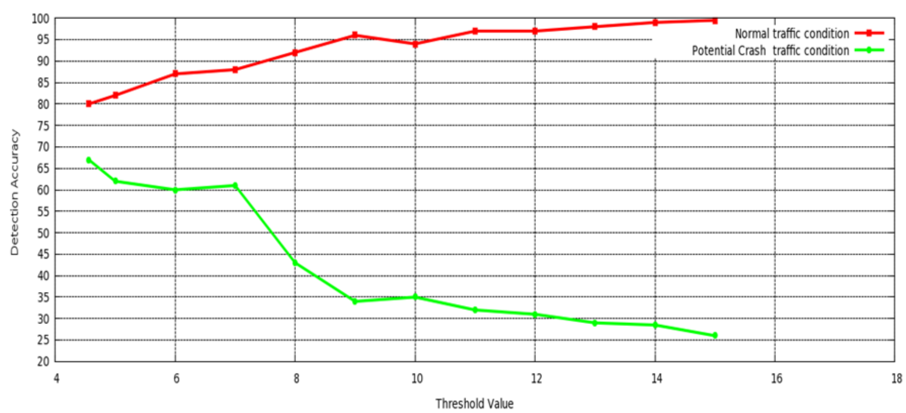

Figure 5. Performance evaluation

The results reflect that at a threshold value of 4.56% the model is able to successful classify 66% of the crashes with a false alarm rate less than 20%. If the threshold value is raised up to7% then the model still can predict 58% crashes and 87% normal traffic conditions with an overall classification accuracy of 82%. And in case of a threshold value as high as 14%, the model classifies 30% of the crash cases with only less than 3% false alarm.

5. Conclusion

The paper offers an improved framework and modeling method to predicate the real-time traffic crashes. The paper also solves the problem of large variable space with small sample size with the introduction of random multinomial logit model to identify and rank the most important variables. Furthermore, the Bayesian belief net (BBN) has been introduced. Simulation results show that the model can predict the chance of a traffic condition of a 250 meter long section under consideration in the basic freeway segment to become hazardous within then ext4–9mins.

Abstract: When reaching the intersection, driving conditions of vehicles always change among acceleration, deceleration, idling, resulting in increasing fuel consumption and emissions dramatically. This paper proposes a vehicle speed guidance system to make consumption and emission become the minimum based on real-time signal state, vehicle location and speed when vehicles through the intersection. A simulation study is implemented for the intersection of Caoan Road and Lvyuan Road in Shanghai and the study results show that there is a significant effect under different traffic flow. Better results can be obtained in high saturation.
Keywords: Speed guide system; Emission; Microscopic simulation.

1 Introduction

With the rapid development of urbanization and motorization, motor vehicle exhaust pollution is more and more serious in cities. Because driving conditions of vehicles always change among acceleration, deceleration, idling at the intersection, fuel consumption and emission will increase dramatically (Cherchas, D.B,1979). Because drivers cannot obtain the information of intersection in the front of vehicles, the driver cannot make judgments in advance and only rely on experience to determine the driving speed. In this case, the fuel consumption and emission are relatively large (Guohua Song, 2010). Therefore, this paper proposes vehicle speed guidance based on real-time signal state vehicle location and speed, so that realizing the target of decreasing exhaust emission.

2 Strategy of Speed Guidance

To sharpen the research problem, we make the following assumptions:

(1) The study area is a single intersection without considering the impact of adjacent intersections.

(2) Assume that vehicles obey speed guidance strictly.

(3) Without considering interference of pedestrians and non-motorized.

(4) Lane speed limit is 60 km/h.

(5) Acceleration is $3.04 m/s^2$ when vehicles accelerate; driver's reaction time is 1s.

(6) Packet loss rate is 0, that is to say, sending and receiving information are accurate.

(7) Delay is in the acceptable range, that is to say, information is passed in a timely manner.

In this paper, a sensing line is disposed at the place that the distance between the sensor line and the stop line is 100m. Speed guidance will start when vehicles pass the sensor line. We will consider when the vehicles are given speed guidance according to speed of the vehicles and remaining green time. We regard the distance that vehicle can drive as judge distance. Vehicles start to accelerate to maximum speed when reaching the sensor line, and vehicles pass intersection at the maximum speed. The equation is given as follows.

$$L = \begin{cases} v + \frac{16.7^2 - v^2}{2*3.04} + 16.7 * (t - \frac{16.7 - v}{3} - 1); \frac{16.7 - v}{3.04} + 1 \leq t \\ v + v(t-1) + 0.5 * 3.04 * (t-1) \wedge 2; \frac{16.7 - v}{3.04} + 1 \geq t \geq 1 \\ vt; t \leq 1 \end{cases} \tag{1}$$

Where V is speed when vehicle pass sensing line, t is the sum of remaining green time and remaining yellow time. L compares with 100, if L is greater than 100, then we calculate the distance S that vehicle can drive at the current speed; if S is greater than 100, the driver is notified to drive at the current speed; otherwise vehicle will increase fuel consumption by accelerating. If S is less than 100, then informing the driver accelerate to 60 km/h through the intersection immediately; if L is less than 100, informing the driver slow down, not only decreasing fuel consumption and emissions, while improving throughput and traffic safety.

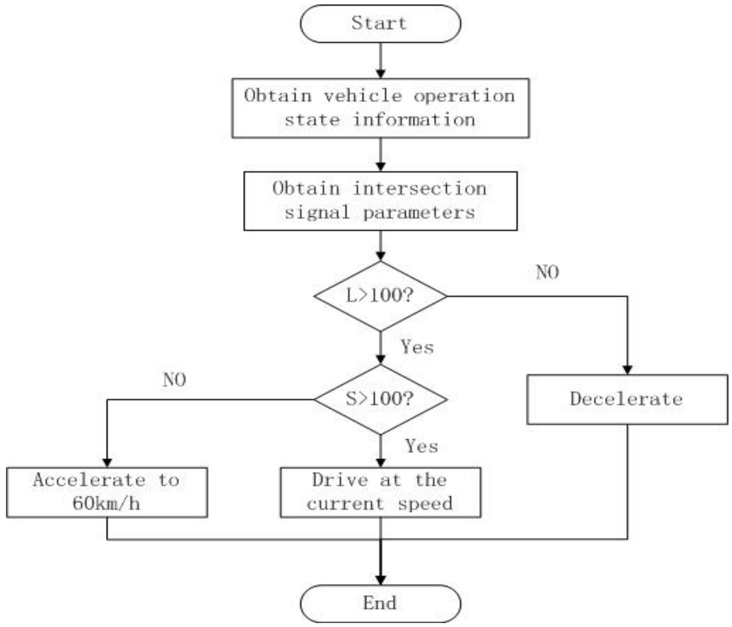

Figure 1. Flow diagram of speed guidance

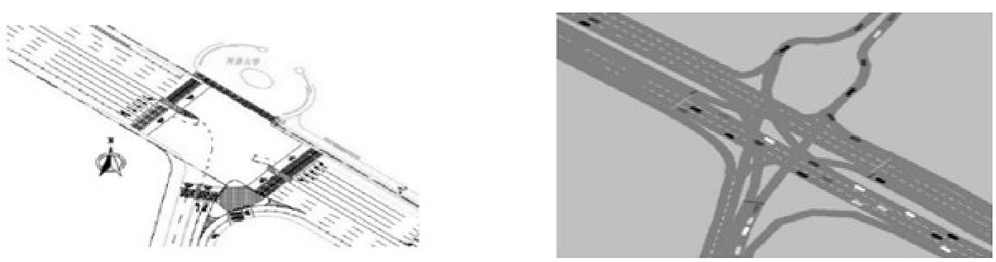
3 Simulations and Analysis

(1) Experimental design

Selecting the intersection between Caoan Road and Lvyuan Road as empirical research, the current situation of road network and CAD diagram are shown in Figure 2. The lane functions are shown in Table 1.



(a) Situation of Intersection (b) Intersection simulation

Figure 2. Situation and Simulation of Intersection between Caoan Road and Lvyuan Road

Table 1. Lane function

	Lane function	Lane number
East entrance	Left-lane	1
	Straight	3
	Right-lane	1
West entrance	Left-lane	1
	Straight	3
	Right-lane	1
South entrance	Left-lane	1
	Straight	1
	Right-lane	1
North entrance	Left-lane	
	Straight	1
	Right-lane	

Considering various factors, West entrance of the intersection is selected as the research object. The signal timing control scheme adopts two phase control. The cycle is 90s and the green ratio is 0.5. And yellow light time is 4s. In order to demonstrate adaptability of speed guide model in various traffic states, we select different traffic conditions, corresponding traffic flow are 300 puc/h, 1500 puc/h and 2700 puc/h, and saturation are 0.1, 0.5 and 0.9. They cover different traffic saturation such as low, medium and high.

(2) Simulation

Taking Vissim4.3 software as simulation platform, and we will have an redevelopment using Visual Basic 2012 and Vissim.COM interface.

The total time of each simulation is 3600s, simulate accuracy is 2-step / s. Speed, trajectory and corresponding time signal status are recorded in 0.5s intervals during simulated process, so that we can facilitate results. Because data exists to large errors at initial stage of simulation, the paper selects 1000-3600s period of simulation to analyze.

4 Vehicle Exhaust Emission Model

We use VSP model to estimate vehicle emission. The paper determines calculation formula of VSP by selecting the relevant parameters accord with the characteristic of vehicles. VSP region is divided by selecting appropriate step size. We get the unit interval emission rate in VSP interval from measured data and emission model, finally establishing vehicle emission model based on VSP.

(1)Vehicle specific power(VSP)

Vehicle specific power is defined as the instantaneous power per unit mass of vehicle, unit is kw/t. VSP is independent of weight; it can describe this variation by combing driving conditions and vehicle emissions.

VSP formula considers several ways of doing work; its value is related to speed and acceleration. The formula is given as follows.

$$VSP = v*(a*(1+\delta)+g*grade+g*f)+0.5\rho*C_D*A*v^3/m \quad (2)$$

Where v is spot speed, unit is m/s ; a is instrument acceleration, unit is m/s^2; δ is factor of merit; g is acceleration of gravity, and generally its value is 9.8 m/s^2 ; $grade$ is road slope, dimensionless; f is coefficient of rolling resistance, dimensionless; ρ is air density, Celsius take 1.2kg / m^2 at 20 degrees; f is drag coefficient, dimensionless; A is front cross-sectional area, unit is m^2; m is vehicle mass, unit is kg.

Here vehicles are divided into light trucks vehicles (cars) and heavy-duty vehicles (buses and trucks). For light trucks, empirical values of the coefficients are given, C_D*A/m takes 0.0005, δ takes 0.1, f takes 0.0135, ignoring wind speed and road gradient. Finally the formula of light vehicles is given as following.

$$VSP = v*(1.1a+0.132)+0.000302v^3 \quad (3)$$

For heavy vehicles, C_D*A/m takes 0.00028, δ takes 0, f takes 0.00938, ignoring wind speed and road gradient. Finally the formula of heavy vehicles is given as following.

$$VSP = v*(a+0.09199)+0.000169v^3 \quad (4)$$

(2)Interval division of VSP

As can be seen from the above equation, VSP is closely related with traffic conditions, it represents the utility of spot speed and acceleration. We can calculate instantaneous VSP for per second according to the formula, but there is a large dispersion of the same VSP value accord with emission rates when we calculate emission based on VSP. In order to ensure a more accurate calculation of emissions based on VSP, VSP value is divided according to certain interval unit. We took average value of instantaneous emission rate as release rate under the Bin, thus it reduced the discreteness of data effectively. Interval division size of VSP Bin is directly related to accuracy of estimated results. At present, there are different ways to divide VSP interval depending on the vehicle type and data acquisition. VSP interval is classified according to the following principle.

$$VSP\ Bin = n,\quad \forall VSP \in [n-0.5, n+0.5) \quad (5)$$

Where n is integer.

(3)VSP interval emission rate

VSP Bin emission rate is determined by calculating VSP Bin emission based on second driving data and emission data. First, we calculate each kind of vehicle emission rate of VSP Bin by collecting a large number of various types of vehicles. Then we calculate emission rate that can represent light vehicles and heavy vehicles according to the proportion of models and other information.

1> Data collection

In this paper, light vehicles are divided into 5 types according to the national emission standards, ie. country 0, country I, country II, country III and country IV. Heavy vehicle includes passenger carriage and goods van, we have obtained data that includes all of the above types in the test. Real-time data includes testing time, speed, acceleration and other indicators.

2> Calculation of VSP interval emission rate

First, we put data into (3) and (4) after performing initial processing of data based on emission data. VSP values of light duty gasoline vehicle ranged from -20 kw / t to 20kw / t by analyzing data. Its emission accounted for more than 98%, while VSP values of heavy-duty diesel vehicle ranged from -15 kw / t to 15kw / t, its emission accounted for more than 98%. We can calculate emission rate according to the formula (6).

$$ER_{in} = EF_{in} / N_n \qquad (6)$$

Where ER_{in} is emission rate of the i-th effluent in the n-th VSP interval, unit is g/s; EF_{in} is total emission of the i-th effluent in the n-th VSP interval, unit is g; N_n is total time in the n-th VSP interval, unit is s.

We will calculate emission rate of light vehicle corresponding VSP interval according to national standards. The proportion of vehicle types l that come from Caoan road and Lvyuan road are foundation that calculates emission rate of light vehicle in VSP interval. According to statistics, National stage 0 emission standard accounted for 3.0% of the total number of road traffic, National stage I emission standard accounted for 6.3%, national stage II emission standard accounted 25.1%, National stage III emission standard accounted 44.1% State, National stage IV emission standard accounted 21.6%. According to the proportion coefficient of vehicle types and vehicle emission rates in each VSP interval, emission rate of light vehicles can be calculated in various VSP interval. The formula is given as following.

$$E_k = \sum_i ER_{ki} * \lambda_i \qquad (7)$$

Where ER_k is interval emission rate of the k-th effluent, unit is g/s; ER_{ki} is interval emission rate of the k-th effluent of the i-th vehicle type, unit is g/s; λ_i is proportion of vehicle type which is the i-th emission standard.

We will put the result into formula (7) according to formula (6), we can get emission rate of CO2, NOx, HC and CO in different VSP interval, they are regarded as basis in the paper.

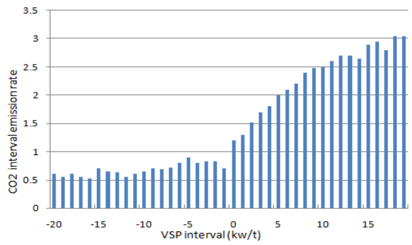


Figure 3. CO2 emission rate of light gasoline in each VSP interval

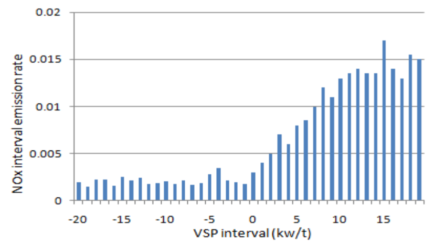

Figure 4. NOx emission rate of light gasoline in each VSP interval

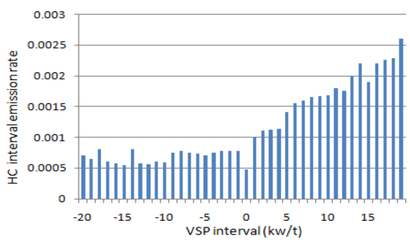

Figure 5. HC emission rate of light gasoline in each VSP interval

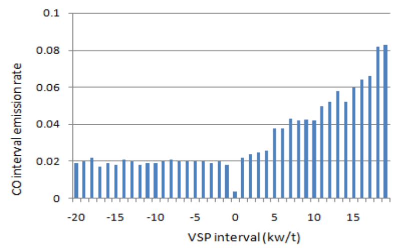

Figure 6. CO emission rate of light gasoline in each VSP interval

5 Impact of Speed Guidance on Vehicle Emission

To facilitate the analysis, all cars are light gasoline vehicles in simulation, and vehicle emission analysis range from the sensor line to stop line of import road. According to the simulation and emission model, results can be obtained as follows.

In the case where saturation is 0.9, average emissions of CO2, NOx, HC and CO were 1208.39 ml, 2.7939 ml, 0.9184 ml and 20.664 ml. In the case of speed guidance average emissions of CO2, NO x, HC and CO were 1064.39 ml, 2.5339 ml, 0.8224 ml and 19.064 ml.

In the case where saturation is 0.5, average emissions of CO2, NOx, HC and CO were 642.77 ml, 1.554 ml, 0.502 ml and 11.53 ml. In the case of speed guidance average emissions of CO2, NOx, HC and CO were 590.17 ml, 1.41 ml, 0.4565 ml and 10.59 ml.

In the case where saturation is 0.1, average emissions of CO2, NOx, HC and CO were 148.3 ml, 0.362 ml, 0.113 ml and 2.732 ml. In the case of speed guidance average emissions of CO2, NOx, HC and CO were 139.4 ml, 0.334 ml, 0.107 ml and 2.502 ml.

6 Conclusions

By analyzing the above results, when speed limit is 60 km/h, average emissions decreased significantly in different saturation with speed guidance, and the higher the saturation, the effect is more evident. When the saturation is 0.9, average emissions decreased by 10%.

Speed guidance will make different effect on emissions because of different speed limited, lane number and signal phase and other factors. These also need further study.

Abstract: Recently, as the rapid development of electronic information and wireless communication technologies, Communication and information shared between the vehicles become possible. In the case of vehicle communication, driver can know the information of vehicle in front of it, so the reaction time will be different with tradition. The vehicle information of this paper includes headway, acceleration and speed. Firstly, the experiment without vehicle information on driving simulator was done to verify the driving simulator. Then, the experiment with vehicle information on driving simulator was done and the data was analyzed. Finally, the results show that the reaction time with vehicle information obviously less than without vehicle information. The difference of reaction time caused by age increases, however the difference of reaction time caused by gender decreases.
Keywords: Vehicle information; Reaction time of car-following; Factor; Model.

1 Introduction

Reaction time is the duration from the front vehicle shifting to the following vehicle begin reacting during car following process(including perception and operational phase). With the development of communication technology, car communications have become achieved which will become the future direction of transport development(YANG Fan,2012). Therefore, the study of reaction time under vehicle information is the basis of car following theory under information environment. Also, it has practical value for safe driving.

There are many factors impacting the reaction time which has been deeply studied. Dabbour and Easa thought the reaction time depends on the task of driving and personal characteristics of driver(Dabbour, E. and Easa, S.,2009). Broen and Chiang thought the reaction time of elderly driver are more than young in some cases (Broen, N., & Chiang, D, 1996). But Lerner found that age has little impact on reaction time (Lerner, N,1994). Green found several causes for different conclusions: sample bias, the elderly who have better driving habits, experience and more practice make up the defects of perceiving and moving slowly(Green, M.,2000). Chang et al. found when the speed increases from 25mph to 40mph, the reaction time reduces 0.5s. But when the speed increases from 40mph to 55mph, the reaction time reduces no longer (Chang, M., Messer, C., and Santiago, A,1985). Atif Mehmood and Said M.

Easa found acceleration and deceleration size of the front vehicle and personal characteristics of driver have significant impacts on reaction time(Mehmood Atif; Easa; Said M, 2009). At home, XU Ting, CAO Shili, MA Zhuanglin and ZHU Tong et al studied the reaction time and headway in car following based on driving simulator (XU Ting, 2013). ZHANG Zhiyong, HUANG Yi, REN Futian found the average reaction time is 0.97s in deceleration following state. Also, the reaction time changes as the speed changes. Fujita Motohiro found response delay is an independent variable of car following. It is affected not only by personal characteristics of driver and traffic situation, but also vehicle type(Zheng Jian, 2013).

But all the study mentioned above is the environment without vehicle information. Although Kong has optimized the model of car following based on the car-road network, the factors of impact on reaction time hasn't been deeply studied.

The reaction time has been divided into reaction time under deceleration and reaction time under acceleration in this article. Firstly, the feasibility of driving simulator has been certified through the experimental data under environment without vehicle information. Then, the traditional factors on reaction time has been analyzed and corresponding computational model has been achieved under environment with vehicle information.

2 Experimental Program

2.1 Experimenters and Equipment

This paper uses world-class driving simulator as an experimental platform which has simulation vehicles with sensor, computers, projectors and audio output device.

Factors on reaction time include personal characteristics of driver and driving conditions. Personal characteristics of driver include age, sex, age of driving and driving strength. Driving conditions include headway, speed and acceleration of front vehicle. Sixty drivers(32 men and 28 ladies) have been selected for this experiment. Their ages range from 22 to 67 years old and have been divided into three grades(22-28, 29-54, 54+). Driving ages begins from getting the license and have been divided into three grades(0-5, 6-20, 20+). Driving strength is measured by driving time weekly and has been divided two grades(0-20, 20+). In order to ensure comparability, the distribution of age and sex is same as the distribution in particle of Atif Mehmood and Said M. Easa. Specific information is mentioned in table 1 and table 2:

Table 1. Information of test people

Sex	Age					
	22-28		29-54		54^+	
	number	proportion	number	proportion	number	proportion
Man	4	6.7%	18	30%	9	15%
woman	4	6.7%	17	28.3%	8	13.3%

Table 2. Levels for categorical variables

Variable	Level and range		
	1	2	3
Age	young(22-28)	wrinkly(29-54)	old people(54+)
Sex	man	woman	
Age of driving	novitiate(0-5)	commonly(6-20)	skilled(20+)
Intensity of driving	commonly(0-20)	strong(20+)	

2.2 Program Design

The experiment road imitates the Beijing Lotus Pond Road. Reaction time is divided into acceleration and deceleration. There are two degrees based on deceleration of vehicle in front in deceleration circumstance. One is normal that the deceleration is ranging from $2.5m/s^2$ to $3.5m/s^2$. Another is urgent that the deceleration is ranging from $4m/s^2$ to $7.5m/s^2$(ZHANG Zhiyong, 2009).

The following vehicle travels at a rate of 60,80 and 100km/h respectively from a starting point in driving simulator. The front vehicle travels at the same rate from a point which is 1.5km away from starting point at a moment under deceleration circumstance. But different spacing between following vehicle and front vehicle are set up under different circumstance. The spacing is 20m, 30m and 40m respectively under normal deceleration. The spacing is 10m, 20m and 30m respectively under urgent deceleration. The front vehicle decelerates at a point which is 2km away from starting point. The front vehicle travels at a rate of 60km/h from a point which is 1.5km away from starting point at a moment under acceleration circumstance. The spacing is 20m under acceleration. The front vehicle accelerates at a point which is 3km away from starting point.

As mentioned above, every driver experiments 9 times respectively under normal and urgent deceleration. However every driver experiments one time under acceleration. Of course the same experiment will be done under circumstance with vehicle information. Therefore every driver experiments 38 times altogether and 2280 sets of experimental data will be obtained. Every driver will be trained one hour before experiment.

2.3Vehicle Information Provided and Data Acquisition

A lot of vehicle information were given for driver through voice and text. The information includes acceleration, speed, spacing and so on. The function achieves through program.

Data acquisition system of driving simulator is very powerful. All the necessary data can be achieved through driving simulator by program. The necessary data include acceleration of front vehicle, speed of following vehicle, reaction time of following vehicle, spacing and so on.

3 Data Analysis

3.1 Circumstance without Vehicle Information

3.1.1 Following under Deceleration

Data analysis software SPSS is used to analyze data received from driving simulator. Histogram of reaction time without vehicle information under different speed and spacing is showed in fig.1. The result in fig.1 shows that reaction time has significant difference between normal and urgent deceleration. The reaction time under normal deceleration is longer than urgent deceleration. The reaction time is longer as spacing increasing at a same rate under the same circumstance.

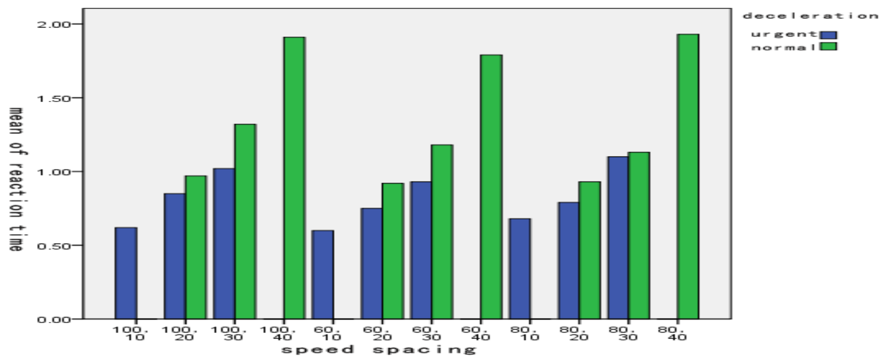

Fig.1 Reaction time under different speed and distance

The relation between reaction time and age, sex, age of driving and intensity of driving are analyzed respectively. The relation between reaction time and sex is showed in fig.2.

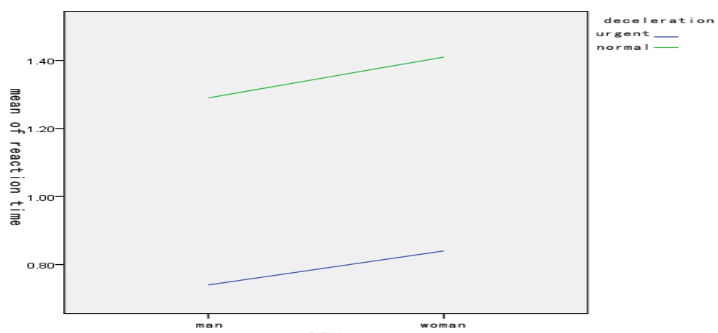

Fig.2 Comparison of Reaction time based on gender

The result in fig.2 shows that the reaction time of man is shorter than woman under two circumstances. The reaction time has little difference caused by age under the same circumstance. This is because that the old people is skillful at driving. The reaction time of novitiate is shortest under normal deceleration. The reaction time of commonly is shortest under urgent deceleration. The impact on reaction time by driving intensity is different under different age and sex.

In summary, the reaction time is taken as dependent variable. Spacing, speed, sex, age, age of driving and driving intensity are taken as independent. The model is achieved by SPSS as following.

$$T_N^{-} = 0.081G\text{-}0.003V + 0.052D \qquad (R^2 = 0.93) \tag{1}$$

$$T_S^{-} = 0.002A\text{+}0.107\text{G+}0.002\text{V+}0.025\text{D} \qquad (R^2 = 0.89) \tag{2}$$

T_N^{-} is reaction time under normal deceleration; T_S^{-} is reaction time under urgent deceleration; G is the sex of driver, man is 0, woman is 1; V (Km/h) is the speed of following vehicle; D (m) is spacing; A is age of driver.

3.1.2 Following under Acceleration

The data are received from driving simulator under acceleration without vehicle information. The reaction time is taken as dependent variable. Age, sex, age of driving and driving intensity are taken as independent variable. The relationship between reaction time and age, sex, age of driving and driving intensity are received by SPSS.

The result shows that reaction time of man is shorter than woman under acceleration. The reaction time is increasing as the age growing. The reaction time is reducing as the driving intensity increasing, but the difference is little obvious. The relationship between reaction time and age of driving is little obvious.

The model is achieved by SPSS as following:

$$T^{+} = 0.026A + 0.27G \quad (R^2 = 0.78) \tag{3}$$

T^{+} is reaction time under acceleration; A is age of driver; G is the sex of driver(man is 0, woman is 1).

The result is conformed to the conclusion of Atif Mehmood and Said M. Easa as mentioned above which certified the driving simulator is feasible(Mehmood Atif; Easa; Said M, 2009).

3.2 Circumstance without Vehicle Information

3.2.1Following under Deceleration

Histogram of reaction time with vehicle information under different speed and spacing is showed in fig.3.

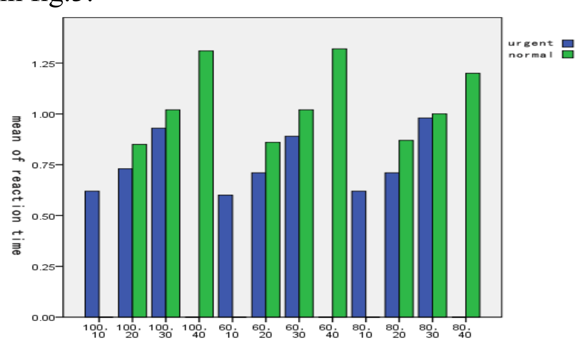

Fig.3 Reaction time for different speed and distance

Comparing the data under deceleration between circumstance with and without vehicle information, then we put forward hypothesis testing: the mean of reaction time under deceleration is same between circumstance with and without vehicle information. The confidence is 0.95. The t test is done by SPSS. The result is showed in table 3.

Table 3. Result of test

	The mean of reaction without vehicle information(s)	The mean of reaction with vehicle information(s)	t	result
Normal	1.23	1.04	-13.2	refuse
urgent	0.79	0.74	-3.2	refuse

T is -13.2 under normal deceleration which is within the range of refusal, so we reject the null hypothesis. The result is that the vehicle information has obvious impact on reaction time. T is -3.2 under urgent deceleration which is within the range of refusal, so we reject the null hypothesis. The reaction time decreases 15.44% under circumstance with vehicle information in normal deceleration. The reaction time decreases 6.33% under circumstance with vehicle information in urgent deceleration.

This is because that the vehicle information has warning function for driver. While the information of deceleration is offered to driver, the driver will have a feel of alertness.

The result in fig.3 shows that reaction time is different between normal and urgent circumstance. The reaction time under normal circumstance is longer than urgent circumstance. However, the difference between normal and urgent circumstance is minor under circumstance with vehicle information. Reaction time is increasing as spacing increasing while driving at the same rate under the same circumstance. However, the growth is minor under circumstance with vehicle information. This is very important for safely driving.

The relation between reaction time and age, sex, age of driving, intensity of driving is analyzed respectively by SPSS. The relationship between reaction time and sex is showed in fig.4.

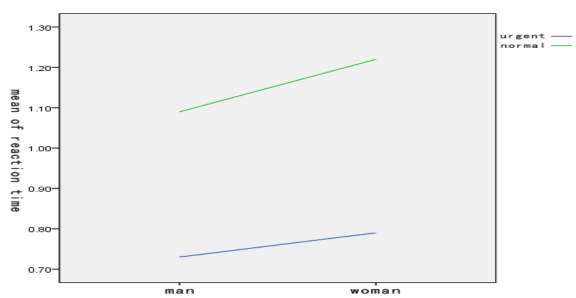

Fig.4 Comparison of Reaction time based on gender

The reaction time of man is shorter than woman under two circumstances showed in fig.4. The reaction time of woman is shorter with vehicle information than without vehicle information under two circumstances. The result shows that the vehicle information is valuable for women. The reaction time is increasing as age growing which is little different with circumstance without vehicle information. There is few impact on reaction time caused by age of driving and driving intensity under circumstance with vehicle information.

In summary, the reaction time is taken as dependent variable. Spacing, speed, sex, age, age of driving and driving intensity are taken as independent. The model is achieved by SPSS as following.

$$T_N^- = 0.003A + 0.056G - 0.001V + 0.031D \quad (R^2 = 0.92) \tag{4}$$

$$T_S^- = 0.001A + 0.105G + 0.002V + 0.019D \quad (R^2 = 0.94) \tag{5}$$

T_N^- is reaction time under normal deceleration with vehicle information; T_S^- is reaction time under urgent deceleration without vehicle information; G is sex of driver(man is 0, woman is 1); V is following speed(Km/h); D is spacing(m); A is age of driver.

3.2.2 following under acceleration

Comparing the data under acceleration between circumstance with and without vehicle information, then we put forward hypothesis testing: the mean of reaction time under acceleration is same between circumstance with and without vehicle information. The confidence is 0.95. The t test is done by SPSS. The result is showed in table 4.

Table 4. Result of test

	The mean of reaction without vehicle information(s)	The mean of reaction with vehicle information(s)	t	result
Acceleration following	1.17	0.92	-17.5	refuse

T is -17.5 under acceleration, so we reject the null hypothesis. The reaction time decreases 21.4% under acceleration with vehicle information. The result is very important for improving the capacity of road.

The relationship between reaction time and age, sex, age of driving, driving intensity are analyzed by SPSS showed in fig.5.

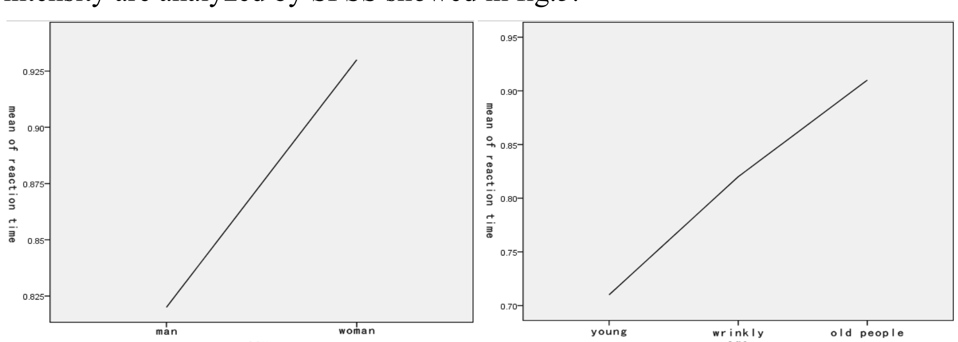

Fig.5 Effect of driver factors on reaction time based on vehicle communication

The reaction time of man is shorter than woman under acceleration. However, the difference is minor under circumstance with vehicle information. The reaction time is increasing as age growing. The reaction time is increasing as age of driving growing which is different from the circumstance without vehicle information.

In summary, the reaction time is taken as dependent variable. Spacing, speed, sex, age, age of driving and driving intensity are taken as independent. The model is achieved by SPSS as following.

$$T^{+} = 0.024A + 0.09G + 0.002E \qquad (\mathrm{R}^2 = 0.84) \tag{6}$$

T^{+} is reaction time under acceleration with vehicle information; A is the age; G is the sex(man is 0, woman is 1); E is the age of driving.

4 Conclusion

This paper do the experiment by driving simulator. We analyze the data received from driving simulator under different circumstances and achieve the conclusion.

(1) No matter under acceleration or deceleration circumstance, the reaction time is different between circumstance with and without vehicle information. However, the difference is more obvious under acceleration circumstance. The reaction time decreases 21.4% under acceleration with vehicle information than without vehicle information. There is 15.44% under normal deceleration and 6.33% under urgent deceleration. This shows that vehicle information is important for improving capacity and safe driving.

(2) The difference caused by sex is minor under vehicle information than without vehicle information. The mean of reaction time of woman is reducing under vehicle information. The result shows that the vehicle information is important for women driver.

(3) The reaction time is little impacted by age of driving under vehicle information.

(4) The reaction time is impacted mainly by age, sex and spacing under vehicle information.

This paper doesn't consider the impact of vehicle information itself. For example, the way of offering information, the amount of information and the content of information. of course the traffic flow doesn't been considered in this paper. So further research is needed to analyze the reaction time under vehicle information.

Abstract: Nowadays the process of urbanization in China is rapid, so the demand of city-to-city transportation or downtown-to-suburb transportation is massively increasing. The traditional ways of passenger transportation cannot meet the passengers' requirements gradually and have some related safety problems. So this paper put forward the concept and the definition of long-distance passenger transportation based on highway network. At the same time this paper analyze the long-distance passenger transportation's advantages and disadvantages qualitatively and quantitatively by the SWOT-AHP method. We also found that the lack of theory support is the main disadvantage of long-distance passenger transportation based on highway network while it also confronts the strong competition of high-speed railway transportation, however the advantages like higher comfort level and higher coverage rate still demonstrate its development potential. The competitiveness of long-distance passenger transportation will be enhanced during its rapid developing if we strengthen its advantages.
Keywords: Long-distance transportation; Highway network; Passenger transportation; The SWOT-AHP method.

1 Introduction

With the economy rapid developing, the urbanization is speeding up in China. At the same time, with improving of the transportation capacity and the developing of the information network, the cooperation between cities to cities becomes more and more important. As a result that the passenger transport demand is constantly increasing. Passenger transport also has effect on the urbanization and the economic integration. So a new environmentally friendly passenger transport mode is asked to meet the demand（Mao, Zhang, Zhou,2004 and Xie, Zong, Wang ,2005）

At the end of the year 2011 long-distance transportation had been applied into to the passenger transport line which is between the Dalian and Lvshun. At year 2012 the intercity passenger transportation became a new mode and had been adopted in many cities like Shanghai, Hangzhou and so on (Ling, 2012). All the fact has shown that the long-distance passenger transportation is a growing trend in China. But the academic research of this type of transportation is not well developed. So establishing research methods for long-distance passenger transportation is very necessary.

Although the long-distance transportation has a good prospect, the studies of long-distance passenger transportation are few. Now many studies focus on the high speed railway passenger transportation, and some of the studies choose the intercity railway as the subjects and find out the problems of operation management (Zeng, 2013）. The studies of the long-distance passenger transportation are main about the rural passenger transportation (Cao, 2011) and intercity passenger transportation (He, Zhang, Bie, Zhou, 2011). So the researches on the long-distance passenger transportation is based on the highway network is significant.

2Long-distance passenger transportation

2.1The problems of traditional transportation modes

The features of the traditional transportation modes in China are high driving speed, overload and so on .The lack of planning and safety management brings so some risks (Li, Zhou, Si ,2008)such as the following problems.

(1)Unsuitable timetable plan. In the traditional long-distance transportation modes the drivers need to drive for a long time so it is easy for the drivers feeling tired and obviously it is not safe.

(2)Driving with high speed and vehicle overload. The drivers drive fast in order to arrive in least time. In addition the vehicle overload will bring some economic profit to the drivers but also bring many safety problems.

(3)There are two or more drivers are responsible for driving so the constraint of each driver is less. Under this condition the driver sometimes stops on the shoulders of highway to pick up the passengers. It is very dangerous.

2.2 Definition of long-distance passenger transportation system

The long-distance passenger transportation system is based on the city road network and highway network. It has been used in the city-to-city passenger transportation system and the long-distance passenger transportation system is consist of bus stations, service area, facilities of the road. The development of economic integration is the background of the long-distance passenger transportation and the target is improving intercity bus public service system of long-distance passenger transportation.

3. The properties of long-distance passenger transportation system

Passenger transportation is a concept which has been put forward in integration of urban and rural public transportation, high speed railway passenger transportation and long-distance passenger transportation. These three systems have the similarities so in table 1 these three systems are compared and the features of long-distance passenger transportation is concluded (Fang, 2011 and Zhou. Li, Yang, 2011)

Table1. The features of long-distance passenger transportation and the differences between urban public transportation, long-distance passenger transportation and high speed railway passenger transportation

NO		urban public transportation	high speed railway passenger transportation	long-distance passenger transportation
1	Service object	Towns and rural residents	The residents who are going out of the city	The residents who are traveling from one economic region to others
2	Passenger type	Visiting relatives, business, work, commuting	Visiting relatives, business, work, commuting and traveling	Visiting relatives, business, work, commuting and traveling
3	Length of route	Less than 20km	Inner city traveling :l80~400km；	Inner city traveling :20~400km；
4	speed	25km/h	200km/h-250km/h	On the highway the speed is 100km/h， on the national road the speed is 60-80km/h
5	Rush time	Morning rush: 7:30am-8:30am Evening peak: 5:15pm-6:15pm	On workday，morning rush is 7:00-8:30， Evening peak of commuting is 6.pm-8.pm，	January, February, May and October； Morning rush: 7am-9am Evening peak: 6pm-8pm
6	Line type	Backbone line and regional line	City to city	City to city
7	Departure interval time	10min-25min	10min-20min	Average 30min

8	Average distance between station to station	800m-1000m	Developed area is 20km-35km; Others are 40km-50km	20km-30km
9	price	2 to 8 RMB	0.4 RMB /km;	0.1 to 0.15 RMB /km
10	Coverage rate	If the urban-rural integration has been come true in all the area, the coverage will be over 95%	Low coverage rate	Higher than the rate of high speed railway, but need the cooperation of urban public transportation

From the table1 we can find out that high speed railway passenger transportation and the long-distance transportation system have the same service range. But the high speed railway passenger transportation is faced with two problems ---high price and low coverage rate. After optimizing the driving routes and stations as shown in the following, the long-distance passenger transportation system will not have these two problems.

4 Analysis of long-distance passenger transportation using the SWOT-AHP method

4.1 SWORT matrix of long-distance passenger transportation.

SWOT analysis, which is also called the situation analysis method, is the basic method of competitiveness research. Using this method to analysis, all the elements can be considered comprehensively and the best solution can be found out through systemic review (Guo,Wang, Jiang, 2009 and Ji,2013). The superiority, weaknesses, opportunities and threats of the long-distance passenger transportation system can be found out using SWOT analysis. AHP (the analytic hierarchy process) is used to find out the main factors, then these factors constitute the ladder hierarchical model and finally determine the total ordering of evaluation object (Han, 2006).

The SWOT analysis method is only qualitative analysis, so its result is only a qualitative description, but the AHP can simulate the procession of thinking and use the quantitative analysis to deal with the data. As a result the combined SWOT-AHP method has both advantages from qualitative analysis and quantitative analysis. Compared with other methods like Boston Consulting Group Matrix, Ansoff Matrix and SPACE Matrix (Strategic Position and Action Evaluation Matrix), SWOT-AHP method can analyse the influencing factors qualitatively and quantitatively (Jiang, Xu, Song,2013).

(1) Superiority (s)

1) Faster---- Because the long-distance passenger transportation system is based on the highway network, the coach is driving with high speed to meet the demand of

passengers

2) Convenient----The long-distance passenger transportation has the characteristics like many transfer stations, high coverage rate and so on. These features make passengers convenient.

3) Standardization----In the long–distance passenger transportation model all the operation of the programs have been planned and the price will not change without limited.

4) Comfortable----The vehicles of this system are air-condition coaches and there are service centers, urban commercial and leisure centers along the each route.

(2) Weaknesses (W)

1）The lack of theoretical analysis----As a result of the lack of theoretical analysis the price will perhaps not be reasonable and transport management perhaps not be well organized. As to the authors' knowledge, there are few researches of the long-distance passenger transportation.

2）The lack of facilities----The traditional transportation modes has few stations so the facilities cannot meet the demand of the new mode. To apply the long-distance passenger transportation system the transfer condition needs to be improved.

3）Management issues----Now the long-distance passenger transportation system are run in small scale and low efficiency. The government invests less because they do not notice the potential.

(3)Opportunity (O)

1）The demand is increasing----Because the urbanization is accelerating rapidly, so the demand of city to city transportation is increasing. The passenger transportation has been studied and applied on the town bus and high speed railway widely.

2）The application of long--distance passenger transportation is increasing. The passenger transportation has been studied some problems have been found out. But the demands for convenient and fast are obvious. If we can solve the problems the long-distance passenger transportation will have a good future.

(4)Threat (T)

1）Competitor—high speed railway transportation system is the main competitor to the long –distance passenger transportation system. The high speed railway network has been enlarged quickly in recent year, at the same time its travel speed and condition is improving. Therefore the long –distance passenger transportation system has much pressure.

2）Traffic fees---based on the regulation during the travel the vehicles need to pay for some kinds of fee. It is as same as the coaches. If we want to ensure the reasonable prices we need to reduce some traffic fees for long-distance coach.

4.2 Application of analytic hierarchy process to quantify the influence factors

(1)Based on the analysis and the degree of effect to construct the matrix (Huang, Wu, Huang, 2007)

Table 2. The analysis of long-distance passenger transportation using SWOT method

Internal conditions		External conditions	
Superiority (s)	Weaknesses (W)	Opportunity (0)	Threat (T)
High speed	The lack of the theory	Demanding is increasing	Competition of high speed railway transportation
high frequency	Facilities are not complete	the need of diversified development	difficulty of unified management
Transit conveniently	The lag of system software	this model has been tried	difficulty of traffic fee decreasing
regulatory management	lack of money		
divers services			

(2) Using the analytic hierarchy process to quantify the influence factors which have been listed in table 1

1）Comparing each factor of SWOR group, which is shown at table 3

Table 3. The comparisons on the weights of each group's elements

	S_1	S_2	S_3	S_4	S_5
S_1	1	1/2	1/2	3	3
S_2	2	1	1/3	2	5
S_3	2	3	1	2	6
S_4	1/3	1/2	1/2	1	3
S_5	1/3	1/5	1/5	1/3	1

	W_1	W_2	W_3	W_4
W_1	1	2	5	3
W_2	1/2	1	2	1/3
W_3	1/5	1	2	1/3
W_4	1/3	3	2	1

	O_1	O_2	O_3
O_1	1	4	2
O_2	1/4	1	1/3
O_3	1/2	3	1

	T_1	T_2	T_3
T_1	1	5	5
T_2	1/5	1	3
T_3	1/5	1/3	1

（2）Comparison of each group

Table 4. The comparisons on the weights of each group

	S	W	O	T
S	1	5	3/5	7/3
W	1/5	1	3/7	1/3
O	5/3	7/3	1	5/2
T	3/7	3	2/5	1

（3）Using the eigenvalue method to sort each group, the results are shown in Table 5

Table 5. The weight analysis of each group

SWOT group	Priority	CR0	SWOT factor	CRi	Priority of each group's factors	Total Priority
S	0.3425	0.0792	S1:high speed	0.0680	0.2013	0.0689
			S2:high frequency		0.2422	0.0830
			S3:Transit conveniently		0.3717	0.1273
			S4: regulatory management		0.1298	0.0444
			S5: divers services		0.0550	0.0188
W	0.0949		W1: the lack of the theory	0.0862	0.4800	0.0455
			W2:facilities are not complete		0.1672	0.0159
			W3: The lag of system sof tware		0.0947	0.0090
			W4: lack of money		0.2581	0.0245
O	0.3822		O1:demand of passengers	0.0176	0.5571	0.2129
			O2: the need of diversified		0.1226	0.0469

		development			
		O3: this model has been tried		0.3202	0.1224
T	0.1804	T1:the competition of high speed railway transportation	0.0176	0.6864	0.1238
		T2: difficulty of unified management		0.2114	0.0381
		T3: difficulty of traffic fee decreasing		0.1022	0.0184

CR is called random consistency ratio. When CR<0.1, the matrix is judged as acceptable consistency. When CR≥0.1, the matrix needs to be adjusted.

From table 5, the Cri<0.1 the matrix is judged as acceptable consistency, therefore the result is acceptable.

4.3 Analysis of the competition tendency.

(1)In the level of S/W/O/T, the opportunity of the long-distance passenger transportation system has the highest priority (0.3822), the priority of the threat and the weakness is relatively low (They are 0.1804 and 0.0949). These results show that the superiorities of the long-distance passenger transportation system such as comfortable, high speed and so on, which provide the opportunities of developing.

(2)The competition of high speed railway transportation system is the main threat. (The total priority is 0.1238). But the superiorities (S3) (The total priority is 0.1273) like high coverage rate, strong adaptability can help the long-distance passenger transportation system to compete with the high speed railway.

(3)In the analysis of weakness and threat, the priority of lack of the theory(W1) and the competition which comes from the high speed railway(T1) is the highest(they are 0.4800 and 0.6864).It means that we need to pay attention to the advantages of high speed railway to improve the competitiveness.

5. Conclusions

This paper compared the long- distance passenger transportation and high speed railway transportation and finds out the advantages and disadvantages of the long-distance passenger transportation system. Combined with analysis of economic integration, traffic integration and service integration, this paper concluded the definition of long-distance transportation. And the SWOT-AHP method was used to analysis the superiority, weakness, opportunity and threats of long-distance passenger transportation and finally confirm its potential. However this paper mentioned little about the operation research of the long-distance transportation system. Actually there are many problems, for example the lack of facilities. All the problems show that the operation of long-distance passenger transportation is still needed to be studied. With more and more facilities completed, the long-distance passenger transportation system will service for the passenger much better.

Abstract: With the implementation of promoting ecological civilization and green transportation construction process, the importance of highway landscape is increasingly recognized and more sustainable and innovative approaches are needed for planning and managing landscapes in China. Based on 3S techniques (Remote Sensing, Geography Information Systems, Global Positioning System),the study proposes a transdisciplinary method combines remote sensing interpretation, field reconnaissance and spatial analysis to delimit the range of visibility for highway and identify landscape resources in Sichuan-Tibet Highway. We also develop a landscape assessment by partitioning the highway landscape and discuss some planning solution to configure the networks of highway landscape and optimize the geographical layout of tourism facilities. We believe that this method proposed in this case can effectively assist highway landscape planning and will contribute to the formation of the tourism synthesis with Sichuan-Tibet highway as development axis and social, economic and ecological construction of Kangding in east Tibet Plateau.
Keywords: Sichuan-Tibet highway; Landscape planning; GIS; GPS; RS; Kangding.

1 Introduction

Over the last few decades, a 4.24 million-km network of highways has been superimposed on the west of China and it is the world's biggest road system.. Transportation planning has traditionally focused on economic and technical problems but not paid enough attention to landscape planning along the highway leading to monotonous design style and insufficiency of the regional features, even causing damages of local picturesque scenery for some highway construction. With the implementation of promoting ecological civilization and green transportation construction process, highway should meet the needs of ecology and the tourism simultaneously. And highway landscape planning plays an increasingly important role in construction of an ecological civilization. Highway landscape planning, taking the highway features, the natural circumstance and the social environment into comprehensive account, is considered to an ‘artistic creation’ for highways displays from the whole to the detail, which emphasizes overall grasp of the highway landscape taste and the tourism services . Xiong(1990) studied highway landscape systematically and put forward the basic theory of highway aesthetics. Zhang(1999) summarized components and characteristics of the highway landscape. Cai(2004) discussed the engineering factors and ecological factors of highway landscape from such perspectives as the alignment design, service area location, highway classification, horizontal and vertical curves, highway facilities, views borrowing, ecological planting landscape, etc. Li et al (2008) explored the theories of ecological restoration and reconstruction. Li and Cai (2011) give a general analogy of ecological landscape design based on the theory of scenic byway of USA. Zhang et al (2012) use CARD_1 software applications in landscape planning and design scheme of visual simulation. Sheng et al (2012) put forward the compensation design method of highway landscape involving the road side slop, the central dividing strip, the intercommunication grade separation and the service area. Marcucci et al (2013) examined the potential benefits and challenges of linking landscape-level green infrastructure planning and implementation with integrated transportation planning and highway project development in the United States policy context. Yang et al (2013) put forward the theoretical basis for highway landscape design method namely "ecological, artistic, secure". The Hawaii Statewide Highway System Sustainable Landscape Master Plan provides comprehensive guidance on how to bring Hawaii’s highway system into alignment with the Hawaiian principle of Pono – of being environmentally sustainable and in harmony with place (Charles et al, 2015). According to the analysis of previous research and relevant information, however， most of researches on highway landscape limits to highway slope ecological restoration, plant community arrangement, plant landscape design and highway environmental pollution and still need to be strengthened in depth and wideness. On the other hand，less researches has been done to focus on highway landscape in landscape planning design terms.. Meanwhile, landscape outside of the scope of the highway was often omitted, and the relationship between highway and highway landscape has not been studied, which causes visual intrusion and ecosystem damage. Generally speaking, theoretical basis for the planning, design and evaluation of the road system have not been established, which would not provide comprehensive guidance to highway landscape construction. Conception of researchers from different disciplines should be upgraded and innovated with the aim of further researches from different perspectives.

“3S”, the combination of Geographic Information System (GIS), Globe Position System (GPS) and Remote Sensing (RS), is a popular technology in the field of geo-statistics and has been gradually applied into landscape planning and design in recent years. RS has incomparable advantage over usage of long-sequence monitoring of land surface changes on multiple scale with cheap cost. GPS have become powerful tools for fieldwork along the highways with the ability to locate precisely. GIS has powerful ability of geospatial analysis, information integration of vector and raster data and map exported, which is superior to the traditional landscape layout methods by CAD mapping (Cai and Lu, 2009; Tian et al (2010). Therefore, “3S” technology can resolve the problems which is difficult to solve for traditional methods in highway landscape studies and develop a new way for highway landscape planning.

We took the impact range of highway as the scope of research and applied “3S” technology into highway landscape design under the guidance of landscape ecology and road ecology theory. We also explored the strategies to help plan Tibet Plateau highway landscape design and tried to suggest a new way of thinking about highway landscape constructions.

2 Profile and Landscape Planning Theme of the Study Highway

Sichuan-Tibet road entersinto Qinghai-Tibet Plateau in Zheduotang, Kangding County and is divided into south and north section in Dongeluo village, Xinduqiao town. What we study here is the Kangding section of Sichuan-Tibet Highway(in the west of Zheduotang), which consists No. 318 national highway in the east and west and No. 215 provincial highway in the south and north in the length of 125.8km.It connects 4 towns, nearly30 natural villages and many scenic regions such as Mount. Zheduo, Waze ecological valley, Xinduqiao, Mount. Gaoersi and Tagong Grassland, which is the main roads of Sichuan tourism west wing line and to travel ecologically on the ring road in Kangding County Meanwhile, it also can be an organic component of ‘2-hour tourism circle surrounding Mount. Gongga’ which is centered on Kangding airport (Figure 1).

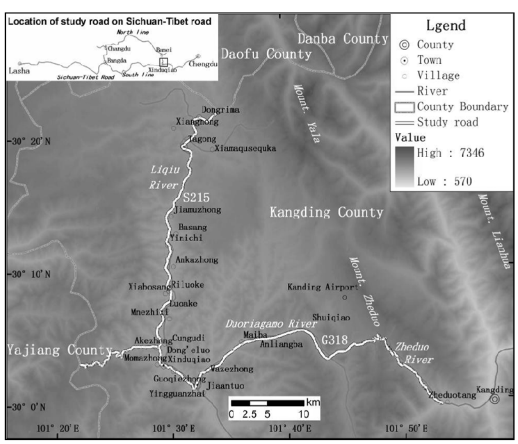

Figure 1. The location of the study road

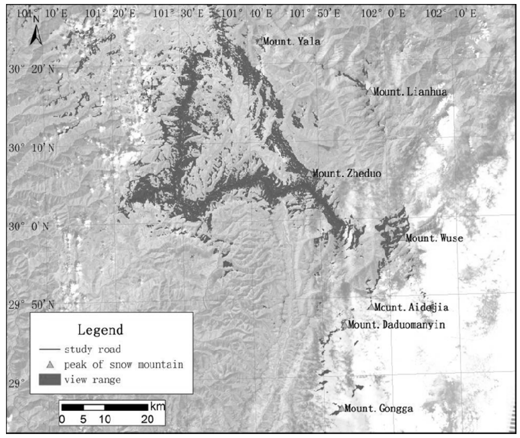

Figure 2. Visible analysis of the study highway

The region of planning section has a continental plateau climate with acute topographic undulation in the altitude interval 3250-4298 m and complex belt spectra of vegetation, but many ecological environmental problems such as weathered soil, degradation of vegetation and water and soil erosion. Meanwhile, the past road constructions fails to focus on ecology protection of slope for highways and spoil ground, the scenery inside the region has been largely affected. . Moreover, past highway constructions doesn't have special landscape design and lacks transformation to landscape outside road boundary line, which leads to obvious discordant phenomenon on landscape along the highway. These landscape defects have already been important factors that restrain the development of local tourism and an overall highway landscape plan needs to be effectuated eagerly

According to the researches on natural and cultural characteristics of Kangding section of Sichuan-Tibet highway, we can find that it is this section's geographical basis to be in the east of Qinghai-Tibet Plateau and at the intersection of south and north sections of Sichuan-Tibet highway. Shangri-la tourism zone and Gongga western slopes circular tour expand its tourist environment, and Muya culture which integrates the culture of Tangut qiang tribesmen and Tibetan constitutes its cultural connotation. Based on analysis on tourism resources and visitors' needs and requirements, this plan proposes two themes: 'Plateau Valley Ecotourism' and 'Muya Tibetan Cultural Tourism' which intend to build an exemplary landscape highway which embodies local characteristics, reflects natural and cultural truth and integrates ecological protection, tourism and socioeconomic performances.

3 Content of Landscape Planning

3.1 Definition of highway visible range and landscape resources investigation

The most significant factor of highway tourism is line-dependent tour, that is, the scenery can be seen on the highway. Therefore, visible area of the highway needs to be confirmed and landscape resources should be filtrated as the basis of landscape planning.

3.1.1 Viewable area of section planning

According to Digital Elevation Model (DEM) provided by International Scientific Data Service Platform, view field of planning section is obtained from ArcGIS platform (Figure 2). We can see that that the viewable region can cover 1167km^2, most of which is both sides of road and sectional high mountains, including Mount. Gongga, Mount. Daduomanyin, Mount. Aidejia, Mount. Wuse, Mount. Zheduo, Mount. Lianhua, Mount. Yala, etc.

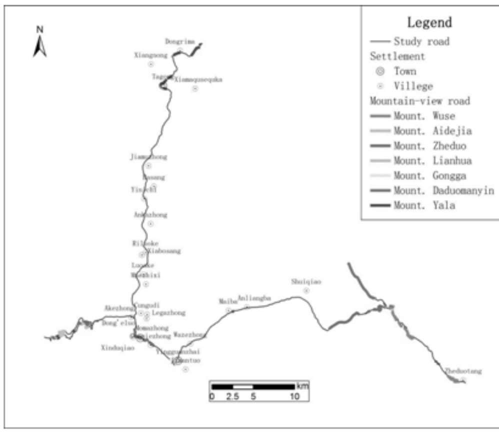

Figure 3. Viewable sections of snow mountain

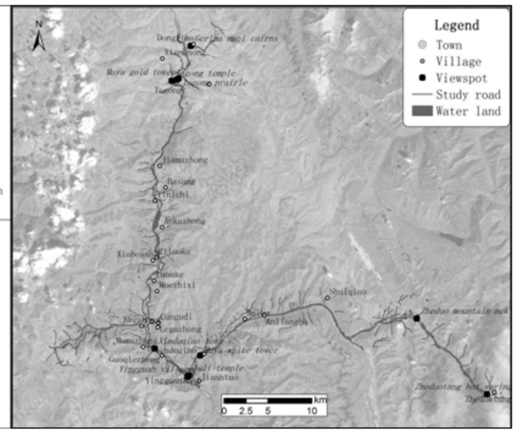

Figure 4. Distribution of villages and existing tourism scenic spots

3.1.2 Distribution of landscape resources

(1) Viewable sections of snow mountain

As the special part of the plateau, snow mountain are of fine scenery and occupy a hallowed status in local religion and customs. Through visible analysis, we get the section distribution of Snow Mountains as the basis of landscape district and arrangement of viewpoints.. The results (figure 3) shows that visible sections of Mount. Yala are distributed on Tagong Grassland and Gaoersi Peak with a length of 8.5km. Visible sections of Mount. Gongga are distributed on Waze Township and Mount. Zheduo with a length of 1.9km, while that of Mount. Zheduo are dispersedly distributed in No.2 section of Gongbuka Bridge and fractional sections of Mount. Gaoersi with a length of 9.0km. Visible sections of Mount. Aidejia peak are distributed on Mount. Zheduonek with a length of 1.5km, and visible sections of Daduomanyin near Xinduqiao town and the nek of Mount. Zheduo with a length of 3.4km. Visible sections of Mount. Lianhua at are distributed on ridge and peak of Mount. Gaoersi with a length 4.8km. Visible sections of Mount. Wuse are distributed from Mount. Zheduo nekto fractional sections of Zheduotang with a length 8.5km.

(2) Distribution of surface water resources

According to Landsat TM remote sensing image and on the basis of ERDAS 9.2, the distributions of surface water resources is decoded within 5 km of both sides of planning landscape through supervised classification. The results show that there are rich water resources near Kangding sections of Sichuan-Tibet Highway except Mount. Zheduo, Mount. Gaoersi and the Peak of Mount. Xiangpi. Nearly all the sections are along rivers. Various kinds of river landscape form the framework of natural scenery of plateau valleys. Meanwhile, there are two areas with wider river and moderate terrain, distributed fromXinduqiao to the middle section of Tagong and the west of Waze Township. These two places are fit for making wetland landscape and wetland view point.

(3) Distribution of villages and existing tourism scenic spots

Residential areas and tourist attractions near 5km of the planning highway are filtrated on the basis of ArcGIS 9.3, including 2 towns, 18 administrative villages, 36 natural villages, 5 road maintenance gang and 8 sight spots. We can see that Tibetan Villages are mainly distributed on the section from Wazezhong toJiamuzhong village which is the center of Muya culture. Road maintenance gang is distributed near Mount. Zheduo, Mount. Gaoersi and Songlingkou, forming unique culture of plateau highway maintenance squad. Meanwhile, existing tourist attractions are mainly distributed on 3 districts: Xinduqiao -Yingguanzhai, Tagong, Zheduotang,which respectively symbolizes Muya Tibetan culture, grassland and Tibetan Buddhism, geological hot springs, three special tourism resources(figure 4).

3.2 Evaluation and Subsection of Highway Landscape

Highway landscape is sequential kind landscape. In the process of driving, tourists can only feel the change of landscape sequence and can hardly feel every detailed feature which forms the scenery. These significant obvious changes are caused by the change of landform and various land-use types. The division of the sequence spaces as a whole should be based on the distribution rule of road landscape types. Boundaries can be put on the intersection of shifting landscape and view changes of every section should have a landscape main axis in which the distribution of scenery is proper, thus tourists can get a good visual effect.. Based on requirements of landscape experience and safety requirements, the length of every section should be among 10-20km to get rid of hypo-wakefulness.

3.2.1 Division of basic investigation unit

The investigation and evaluation of landscape resources are the foundation of highway landscape planning. Firstly, we should take samples of landscape statistics in every section according to the planning section and take the length of the section and the number of statistics into consideration., Basic **investigation** unit should be made at a length of 2km and target sections can be divided into 63 basic survey units, because of which multi-criteria evaluation to every unit can be done.

3.2.2 Analysis of basic investigation unit

(1) Topography

The elevation and slope of each investigation unit can be extracted out using DEM data on GIS platform (figure 5). The results reveals that the altitude of target highways differs greatly and lowest part is Zheduotang, less than 3300m, while both the nek of Mount. Zheduo and the peak of Gaoersi are higher than 4200 m. Other places are mainly among 3400m to 3700m. The slopes of sections near Mount. Zheduo and Mount. Gaoersi are more than 3 degree, and the highest is7 degrees, which is the degree of obvious sky way. The slope of other places are among 1-2 degrees. Therefore, Zheduotang and Mount. Gaoersi should be be listed individually in landscape sections of highways.

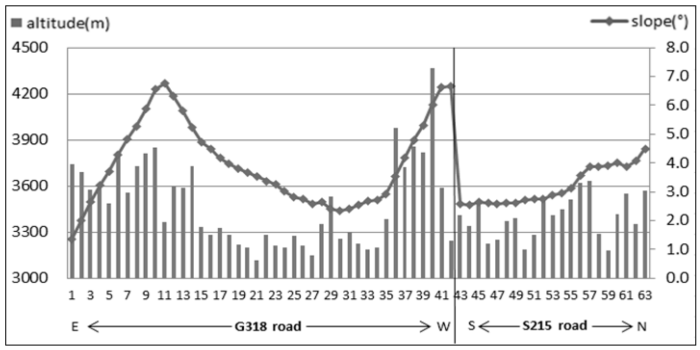

Figure 5. The altitude and slope of each highway section

(2) Land use types

We make artificial visual interpretation and divide planning section into several types: woodland, grassland, building land, water land and unused land on the basis of landsat TM images and ERDAS 9.2 platform (figure 6). The further analyses for proportion of different types of land use within 2km both sides of the planning section on the platform of ArcGIS(figure 6). We can see that that woodland besides both sides of Mount. Zheduo and Mount. Gaoersi occupies a large proportion; woodland and natural land form the majority of the land in 53-57 sections. The land of 31st section (Xinduqiao town) mainly used as building land, while grassland dominates other places. Because highways are built mainly besides the river, the water area is nearly 5 %. Thereby the areas near Xinduqiao and 53-57 sections can be listed as a category in landscape division.

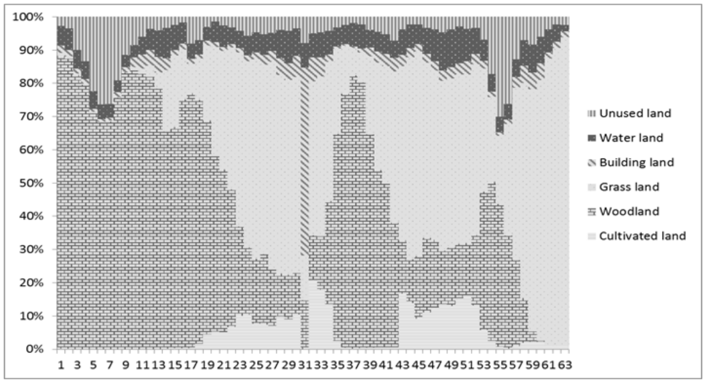

Figure 6. The land use structure of each highway section

(3) General evaluation on field and quality of vision

Visible area of each section is analyzed by viewshed model in ArcGIS and evaluation on field of vision is got through Equal Distance Visual Assessment by Expert Team (EDVAET) (Wu and Li, 2001), on the basis of natural and humane scenery in each section and aesthetic judgment of experts on landscape in real earnest. With figure 7, we can find that the maximum of visible areas occurring at the peaks of Mount. Zheduo and Mount. Gaoersi, while visible area in valley region is the smallest which is less than 30km^2 in each section. Area with the most beautiful scenery is the peak of Mount. Gaoersi and Mount. Zheduo peak and Tagong grassland. Scenery along No. 215 provincial road is better than along No. 318 national highway. In the following landscape section, field of vision and quality of vision should be taken into consideration and sections with large visible area and good scenery should be singled out..

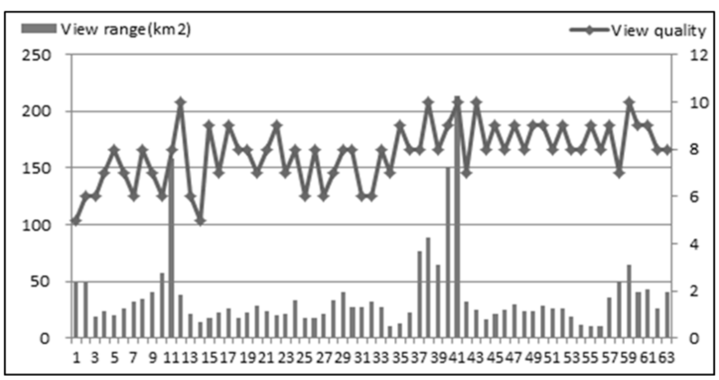

Figure 7. Evaluation of view range and quality in study road

3.2.3 Section of highway landscape

According to analysis to natural, humanistic scenery in basic investigation unit, we can divide the planning highway into 9 landscape sections (figure 8). Among them, No. 318 national highway is divided into 6 sections: Zheduotang valley section, Zheduo mountain meadow section, Waze broad meander valley section, Xinduqiao Muya Tibetain style section, Gaoersi alpine forest section and Gaoersi plateau meadow section. No. 215 provincial highway is divided into 3 sections: Baisang broad meander valley section, Songlinkou canyon torrent section and Tagong snow-capped plateau section.

3.3 Distribution of highway landscape nodes and tourist facilities

Based on the highway landscape section, the interval of landscape appreciation and focus of aesthetic experience is extracted according to the linear features and vision field features of the road, namely the landscape excitement, for satisfying tourists' requirements for appreciation and recreation.

3.3.1 Distribution of highway landscape nodes

There are 21 landscape nodes in this planning, including 16 ordinary viewing decks, 3 wet-land viewing decks and 2 service stations (figure 9). According to the planning, the average interval of the point of landscape service facilities is nearly 6km, relatively even in distribution, and the service stations are located in Mount. Zheduo nek and Tagong Gold Tower. The landscape facilities basically meets the tourists' requirements for rest, viewing and life service.

3.3.2 Distribution of bicycle paths

In order to improve the travel feeling of the road and satisfy the demand of riding backpacker, bicycle paths of three different types with a length of 7.5km are planned according to the terrain and road condition (figure 8), including the rural scenery bicycle path (out of the tree sides, connecting the Dong eluo and Menzhixi viewing deck), Muya elegant bicycle path (in side-ditch and cover-plate form, located near Waze Township) and forest greenroad bicycle path (the form of crossing the forest, near Niudi viewing deck).

3.3.3 Rural tourism-driven project

Due to reflect the support of landscape road to the tourist economy and promote the enthusiasm of local residents in the development of landscape road, the rural tourism-driven project is set for the viewing and tourist facilities. We set respectively the point of tourist facilities as 8km (service station), 5km (large-scale viewing deck), 3km (middle viewing deck), and 2km (small-scale viewing deck). The radius of bicycle path service is 2km. The results show that there are 4 villages including Luzhao Town, Waze Township, Xinduqiao Town, and Tagong Village, 23 administrative villages, 34 natural villages, 10 scenic spots an 7 other units along the bicycle path and all of them located in tourism scope of this planning. Each points of tourist service facilities correspond to 1 to 16 villages, scenic spots or other units (It may overlap), and it can provide basis for the operation in follow-up tourism development.

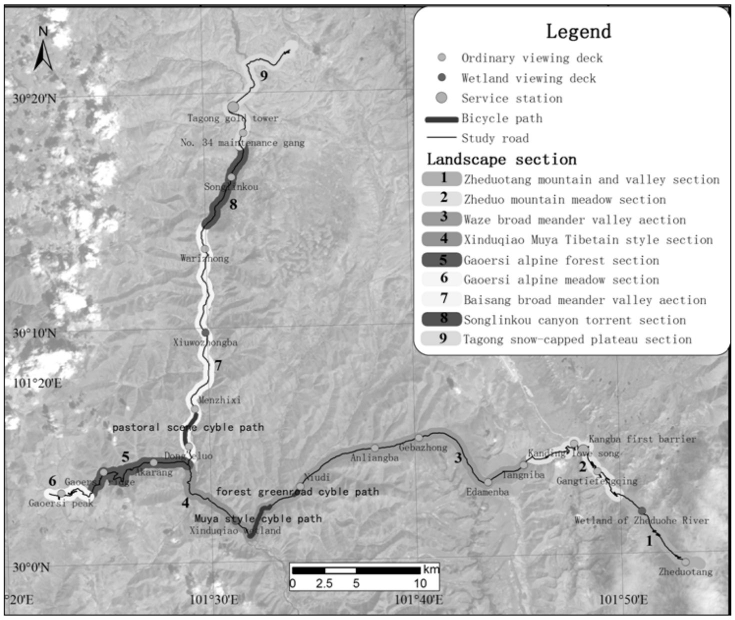

Figure 8. The landscape sections and node of the study road

4 Conclusions

This paper applies the methods of geographical space investigation and analysis represented by RS, GPS and GIS technologies (collectively referred to as "3S") into the landscape planning research of Kangding Section of Sichuan-Tibet Highway, which has yielded good results. Firstly, we employ such methods as visibility analysis, remote sensing interpretation and field reconnaissance to demarcate the visible highway field and study the landscape resources. Secondly, we employ GIS space analysis to make a comprehensive evaluation on the natural geographical characteristics including the elevation, slope, land use types and horizon along the highway and such humanistic landscape characteristics as visual quality. Based on this, we demarcate the highway sections in accordance with the changes of all landscape evaluation indexes. Thirdly, by employing the comprehensive analysis function and map output function of GIS, we formulate the landscape planning projects including landscape facilities layout and tourism-driven project and displays them on the map.

Eventually, the planning highway is divided into 9 landscape sections, and 21 lookouts and service stations of 3 types, 7.5km-long bicycle path of 3 types, the rural tourism-driven project are planned to help the landscape construction and tourism development of region. In addition, based on the landscape characteristics of highway sections, the planning researches into such fields as section planting configuration, slopes and borrow and disposal ground treatment project and ethnic culture displaying project.

By conducting landscape planning research on the Kangding section of Sichuan-Tibet Highway based on “3S”, it verifies the importance of “3S”in the highway landscape planning research and explores new methods of highway landscape planning; on the other hand, it realizes the joint development of the section landscape planning research and the tourism resources along the highway, which will not only make the tourists joyfully appreciate the plateau lakes, snow mountains and meadows and charming sceneries in Muya, Tibet but form an integrated tourism complex mode of ‘highway-scenic spots-tourism supporting-tourism services’, thus greatly promoting the development of the local society, economy and ecology.

Vessel Behavior Analysis on a Narrow Waterway

Yao Yu*; Jian Zheng; and Jihong Chen

College of Transport and Communications, Shanghai Maritime University, Shanghai 201306, China. E-mail: yaoyu@shmtu.edu.cn

Abstract: The drivers are the main receivers and responders of the external environment while the ship navigation as well as the core of the maritime traffic systems. Their behaviors will direct influence the safety of the maritime traffic operation. However, maritime traffic models have only considered open sea without complex narrow channel traffic environment. Whereas the narrow channel performs various traffic characteristics with respect to its high density traffic flow; the narrow channel can efficiency describe the vessel behaviors under encounter situations including vessel following and near head on etc. The simulated area included a junction and a slight approach channel with high maritime traffic density within the YangShan port of Shanghai. According to use vessel handling simulator to gather throttle, rudder, DCPA (distance to closest point of approach), TCPA (time to closest point of approach) and others key parameters under following scenario when the vessels off the harbor. Furthermore, a microcosmic vessel behavior is analyzed combined with dynamic vessel factors (velocity and course) and external influence factors (wind and visibility). Analysis results can be insight into the real vessel behavior for each vessel category, meanwhile can improve current maritime traffic model.
Keywords: Vessel behavior; Narrow waterway; Following behavior.

1 Introduction

With the rapid increase in maritime traffic, maritime safety and capacity become more and more important. For the safety of navigation, the role of driver is essential to analyze. Drivers are the main receivers and responders of the external environment while the vessel navigation. Eighty percent of global maritime accidents were due to human error caused by the decision-making *(Coldwell,1983; Hazel,2007)*. Vessels' behavior research is an important part of the vessel traffic domain study and safety navigation area. By analyzing the behavior of the vessel driving characteristics, the collision avoidance aspects including ways, methods, features and discipline is captured at the microscopic perspective. Apparently, amounts innovative results are discovered *(Mou, 2010; Zhao-Lin W, 1984; Yang, 2013)*. So research on the vessel navigation and manipulation from the macroscopic view is the key to improve traffic safety on the sea, also can provide the data basis of traffic management strategy.

Vessel's behavior is determined by the brain thought, stimulate and judgment at significant degree *(Gerritsen,2010; Borgonovo,2001, Okura,2001)*. Whereas these intrinsic factors are unpredictable, only vessel navigation state can be used to investigate. Errors must be exit if different vessel behaviors were put together to analyze, because complete same states of two vessels has low possibility to occur. Now there are two main data collection methods to gather vessel behavior's data are direct observation and manipulation simulator respectively. Simulation method is easier on the data acquisition which can produce a variety of vessel traffic state according to the set and can be a recurring status. According to manipulate the vessel by bridge teams, simulated behavior data canbe directly collect including speed, distance, rudder etc.

2 Descriptions of Data

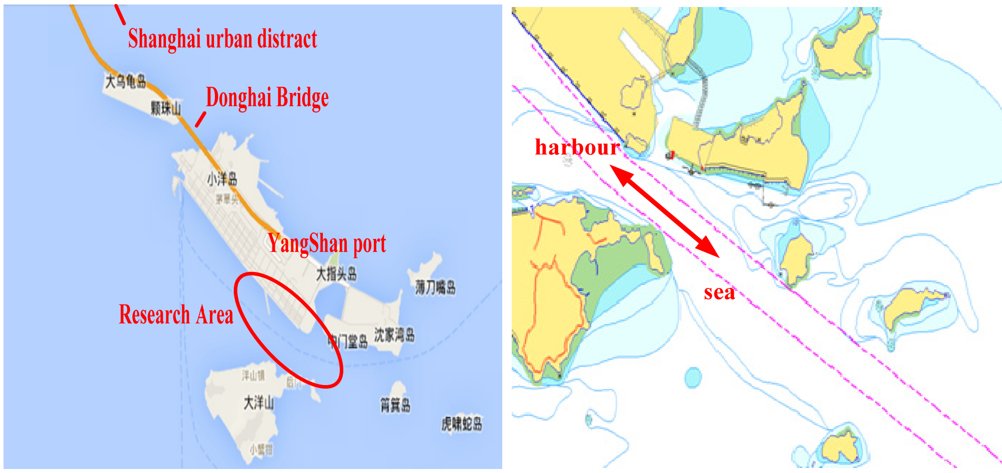
The data were obtained by vessel manipulation simulator, where 3 groups (20 in per group) shipmasters were selected to simulate the actual manipulation under departure port scenario for investigating their driving behavior. The data obtained by vessel manipulation simulator has obvious advantages. First of all, in the selection of the scene, it's easier to set port waters narrow waterway, avoid the observation data inaccuracies because of the higher density of the vessel traffic flow density. Secondly, that can also select the test object targeted, as ship master related by this paper, which can reflect the actual manipulation of the ship leader behavior more targeted

Simulated data is obtained through the Shanghai Maritime University Marine vessel simulator laboratory. The simulator is provided with a 3D scene and can be maximized consist with the actual situation of maritime traffic. Data is composed of 60 different sets of bridge teams on container vessel type. In the research area, the system accumulated simulated messages at 6-s intervals. And most vessels navigate with a speed of 0 to 14 knots (1 knot=1.852 km/h =0.514 m/s). Thus, a good way is needed to extract and compare relative speed, relative distance, DCPA, TCPA between tracks.

3 Data Analysis Method

Yangshan Deep-water Port has most containers handled and it is the largest container port in the world. It is connecting with the Shanghai area by the East China Sea Bridge. Harbor waters showed high traffic density, interference, narrow fairways and so on. Because of the requirements of complex traffic environment and high order, the transport behavior of typical research within the region is extremely important.

Research area as shown in Figure 1; Figure 1b zooms in on the area. The main vessel types are container vessels in the research area. Different container vessels have different vessel behavior because maneuverability and sensitivity to danger will differ. Container vessels have the largest vessel size, the gross tonnage is used to consider.



(a) (b)

Figure 1.Research area of Yangshan port: (a) overview and (b) close-up

The detailed data collection areas are proposed based on maneuvering simulator. Figure 2 shows the navigation direction sea to Yangshan port and Figure 2b shows the opposite navigation for Yangshan port to sea. Width of waterway is 300m, two-ways, and each way width is 150m. That is to say, there is significant influence of the objective vessel by the leading vessel or encounter vessels no matter what navigate from port to sea or sea to port in this narrow waterway.

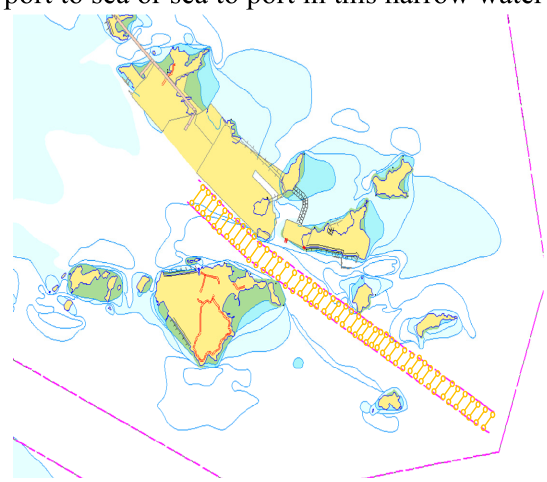


Figure 2. Study area navigation port to sea

4 Vessel Following Behavior

Due to the Yangshan Port hydrological conditions are semidiurnal tide, which means there are twice fluctuations of the tide one day. Vessels are required against stream during departure the berth. So the moment before the tug pull the vessel in channel won't be considered.

Figure 3a shows the probability of relative distance distribution when the vessel navigate from harbor to sea. Here, the x-axis, relative distance between the objective vessel and the former vessel, indicates the longitudinal distance along the consecutive vessel central position. The results show these simulated bridge teams tend to keep the following distance between 600 m to 900 m to maintain a respond arena. The simulated vessel set length is 290m and the draft is 15m. That means the relative distance between the consecutive vessels is about 2-3 times than a single vessel length. Also it apparently that a part of bridge teams choose a larger following distance more than 6 times as a vessel length, which can be pay more caution along the narrow waterway. This means that most ship masters prefer a reasonable following distance less than 3 times vessel length when they off the berth, meanwhile the relative distance is influenced by waterway geometry and vessel size.

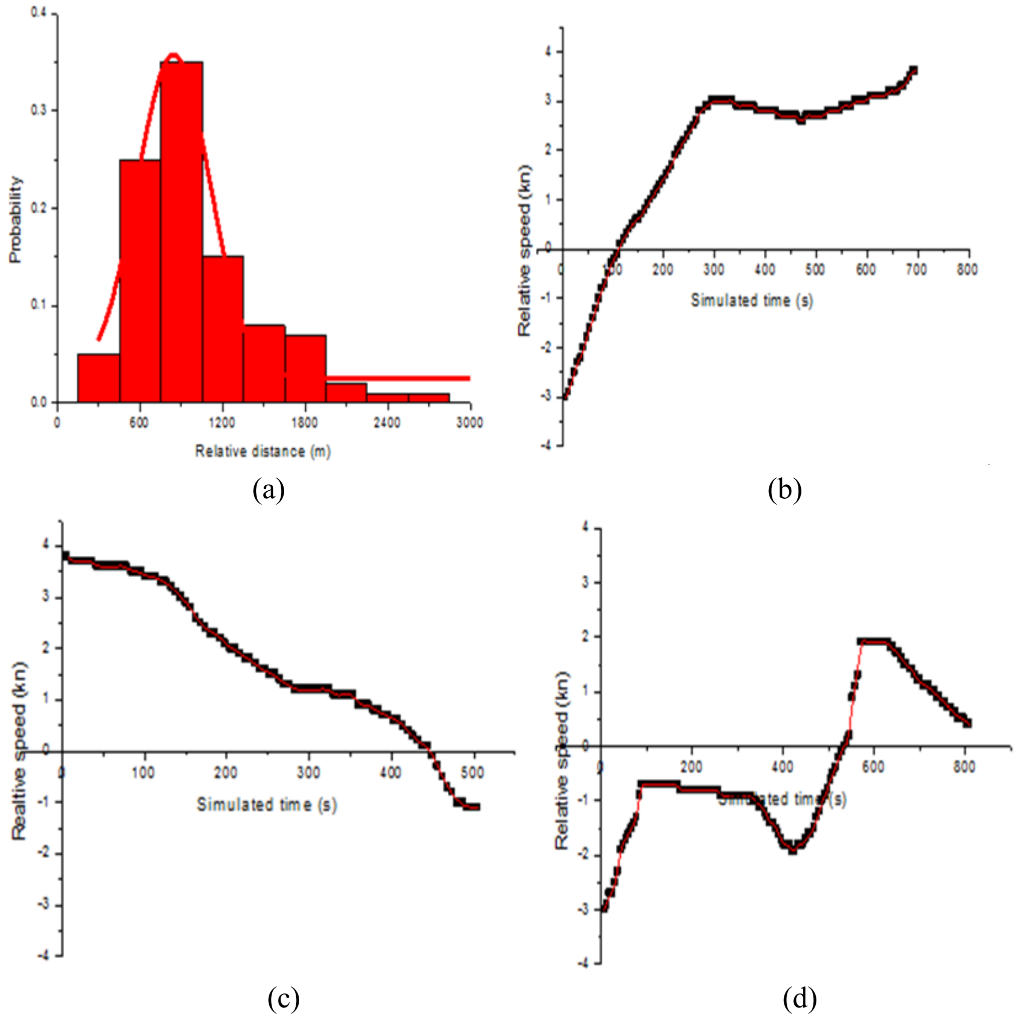

Figure 3.Vessel following behavior: (a) probability of relative distance, (b)-(d) relative speed

For better to describe different vessel behaviors, bridge teams were divided into 3groups, represent by Fig 3b, 3c, and 3d respectively.

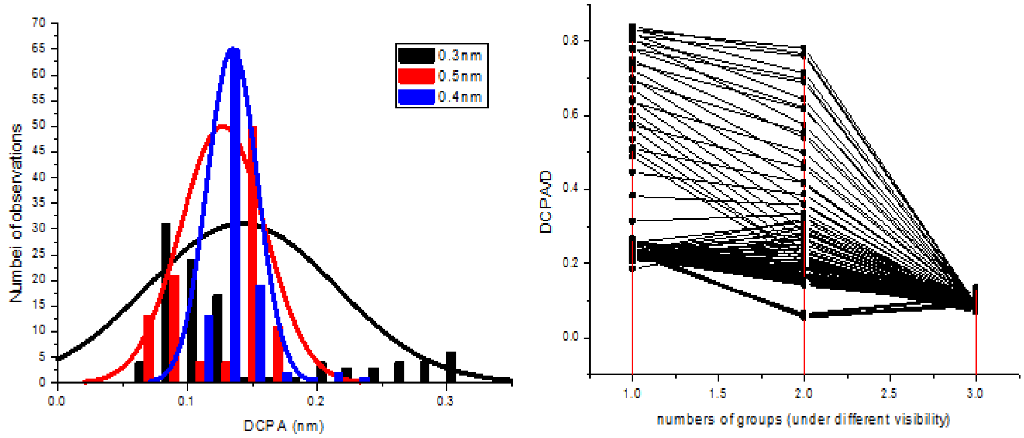
Figure 3b shows the relative speed between the objective vessel and leading vessel is gradually increasing from negative to positive. That indicates the objective vessel is in a accelerated state. This kind of situation demonstrates our objective vessel's speed was lower than the leading one before navigated in waterway. And then the objective chose to accelerate. It was can be seen from the Figure 3b, the objective vessel near the entrance of sea and keep a stable speed interval after simulated 300s while the leading one has already depart from harbor for a while. This figure illustrate that vessel speed is closely related with the leading ones'.

In Figure 3c the objective vessel speed shows a decline tendency which opposite with Fig 3a. It is certain that the objective vessel speed was decreasing from full speed for safety unlike the relative distance is enough large to keep high speed at the beginning. The leading vessel speed was decline due to the uncertain condition at 450s, so the objective one adopt same action to down their speed lower than the leading for keep away from the leading vessel's domain.

Different in Fig 3d, the relative speed appeared three inflection points. A reasonable explanation about objective vessel speed keep changing is that vessels have lower speed in a narrow waterway and adjusting throttle accompanying the leading vessel behavior.

5 Analysis of DCPA under Influence of Visibility

With reference to the literature *(Zhao-Lin, W. 1984)*, the DCPA were calculated. Figure 4a shows the DCPA distribution. Different colors represent different visibility which was set as 0.3nm, 0.4nm and 0.5nm respectively. Mean values of DCPA are 0.200nm, 0.134nm，0.127nm,respectively. It is easier to see that bridge team kept a lesser DCPA from the leading vessel in higher visibility scenario. The value of DCPA is decreasing with the visibility decreasing. And 0.3nm is a significant threshold, which the vessels were influenced under this threshold. It is forbidden to navigate when the visibility lower than 200m in China.



(a) (b)

Figure 4.Effect of visibility: (a) DCPA distribution and (b) DCPA/D distribution

Generally, shipmasters both consider the distance between objective and leading vessel and DCPA in order to judge if take collision avoid action or not. Figure 4b shows the values of DCPA / relative-distance under different visibility. With reference *(Zhao-Lin, W. ,*1984*)*, the smaller the value , the probability of take action to avoid collision is bigger. It's equally in Fig 4b that the third group data of DCPA/D is lesser than other groups, that means the possibility of bridge team tend to take action is increasing.

6 Conclusions and Recommendations

This paper presented the results of an analysis of simulated data for behavior of vessels while navigating from port to sea, and the influence of external factor as visibility in the YangShan port in Shanghai. Vessel behavior was characterized by relative distance, relative speed, and DCPA values.

The results show the different vessel behavior for different groups of ship masters. The safety following distance between the objective vessel and leading vessel usually maintain twice or three times than a vessel length while navigating to sea. That is to ensure the efficient reaction time to manipulate vessel state. Secondly, the speed of objective vessel is closely related with the leading vessel and companying with the changing of the relative distance. At last, the external influence factor was analyzed under different visibility. The experiments show that visibility has a significant impact on vessel relative distance. A bridge team decreases a vessel's speed and increase the following distance when visibility decreases. Meanwhile, values of DCPA are increasing with the visibility decreasing. Consequently, vessel adopt action possibility of collision avoidance is increasing.

Abstract: China is one of the countries with fastest speed of development of urbanization and mechanization in the world. There are many problems, including serious traffic jam, aggravating environmental pollution, increased exhaust emission, lack of resources, increased gap between rich and poor, etc., affecting sustainable development of economy, society and environment. Meanwhile, these universal problems of 21st century have attracted wide attention of international society. Traffic, as the base and guidance of urban development, plays a decisive role in urban development. Consequently, attention has been paid to both urban sustainable development and sustainable development of urban traffic. In the work, evaluation index system of urban traffic sustainable development was built based on urban traffic sustainable development theory, and the weight of each index in evaluation was determined according to theoretical analysis and expert consultation. Extensional matter-element model was established using extension to evaluate urban traffic sustainable development condition, thus achieving the grade and possible development of urban traffic sustainable development in Beijing and providing scientific and rational basis for urban planning and construction department. The results show that urban traffic sustainability is in good condition, however, trending to common condition. Regulation and intervention should be carried out. In addition, evaluation index system and method of urban traffic sustainable development are scientific and rational, thus providing the relevant basis for decision of government department.

Keywords: Urban traffic; Sustainable development; Extension theory; Analytic hierarchy process; Comprehensive evaluation.

1 Introduction

China is one of the countries with fastest speed of development of urbanization and mechanization in the world. There are many problems, including serious traffic jam, aggravating environmental pollution, increased exhaust emission, lack of resources, increased gap between rich and poor, etc., affecting sustainable development of economy, society and environment. Urban traffic system, as a comprehensive system of all kinds of urban traffic modes, is the transport corridor of people flow, logistics and information flow. The development level of urban traffic system directly affects the improvement of residents' life quality, urban function and comprehensive competiveness. So, correct measurement and evaluation of development level of urban traffic system will have realistic meaning for solving traffic jam problems, achieving rapid, safe and efficient operation of traffic system, and promoting urban economic development(1).

Theoretic research of urban traffic sustainable development is focused on establishment of traffic sustainable index system at present (2). There have been a lot of achievements, where representative index systems are STPI in Canada (14 indices: freight volume, road network, travel mode structure, environment, energy, transportation cost, traffic casualties, etc.), COMPASS in German (15 indices: accessibility, transportation infrastructure, environmental impact, renewable energy utilization, transportation equity, etc.). Stockholm in Sweden has established evaluation index system through seven aspects including accessibility, environmental impact, health medical treatment, land use, housing condition, employment condition, etc. England has selected 21 indices including accessibility, crowded degree, infrastructure, travel mode structure, environment, energy, transportation satisfactory degree, transportation cost, etc (3-6).

Ability Evaluation of urban traffic sustainable development is a basic method of discovering and solving urban traffic problems. The point is not evaluation results but providing decision-maker with the information to solve traffic problems. Urban traffic sustainable development level is analyzed and evaluated to determine whether urban traffic system develops in accordance with society, economy, environment and resource, and the problems in the operation process of urban traffic system are revealed. It has an important realistic meaning for exploring limited factors, realizing early warning in bad state and promoting benign development of urban traffic.

Although lots of constructive studies have already been done on the ability measurement of urban traffic sustainable development by many scholars, relatively few studies fully consider its development potential, and point out its development trend to provide early warning and effectively control measures. Therefore, in the work, evaluation index system of urban traffic sustainable development in accordance with Chinese situation is established based on traffic problems, sustainable development and system theory. Combined matter-element analysis (7-12) with AHP, evaluation method of urban traffic sustainable development is researched to provide scientific and rational basis for urban traffic sustainable development in China.

The main chapters in the work are as follows. In Session 1, the meaning and research situation at home and abroad are introduced. In Session 2, combined with the present achievements, evaluation index system of urban traffic sustainable development in accordance with Chinese situation is established according to the actual problems of urban traffic development. In Session 3, the methodology is proposed. In Session 4, the system and method proposed in the work are verified and analyzed to get the conclusions by a case study of Beijing. The achievements in the work can provide scientific and rational direction for metropolitan traffic development in China.

2 Traffic Sustainable Development Measurement Index

2.1 Urban Traffic Sustainable Development

Sustainable development is one of the largest problems in the 21st century. The theory and thinking of sustainable development affects the process of world development and human civilization as an epoch-making thought. Urban traffic system is an organic whole composed of urban road system, traffic flow system and management system. The essence of urban traffic system is the development of urban traffic system in accordance with economy, society, resource and environment (3-6). It can satisfy the requirement of society to freedom of movement, access to opportunity, communication and commodity trade without damaging other basic or ecological value of human at present and in future. Urban traffic sustainable development should contain the following attributes.

(1)Sustainability

Sustainability means that natural resources will be sustainable for human use forever, and not affect the production and life of progeny because of resource exhaustion. It requires that human economy development cannot exceed the bearing capacity of natural resources and ecological environment. Because of limited resources for urban traffic development and certain bearing capacity of ecological environment, the following relations should be satisfied in urban traffic development: Development speed of vehicle should be adaptive to that of road resources; the traffic mode be adaptive to traffic need growth selected; the pollution caused by transportation not exceed self-purification of environment, thus meaning coordination between traffic development speed and bearing capacity of environment.

(2)Development

Development is the premise of sustainable development. To satisfy the growing traffic need of people, urban traffic system should be kept in certain growing speed, and the development quality be gradually improved. The advanced, safe, convenient and fast traffic means with low resource exhaustion should be applied to satisfy urban traffic development. Only in certain level can traffic system be provided with necessary material basis, thus achieving sustainable development and solving the present traffic environment problems.

(3)Equity

Equity contains interpersonal and intergenerational equity. Interpersonal equity is to compensate the welfare loss caused by traffic jam and decrease of ecological environment quality because of vehicle exhaust, noise, vibration, thus ensuring that members of the whole social group can have the fair right of using traffic resources and accepting transportation services. In addition, Intergenerational equity is to ensure the environmental pollution caused by urban traffic cannot exceed the self-purification and self-recovery ability of environment in order to make long-term use of ecological environment and not affect the production and life of progeny.

(4)Coordination

Coordination requires urban traffic system to change as follows: the pure economic growth is changed into the comprehensive development of economy, society and ecology; the present and partial benefits into long-term integral benefits; traditional material resources into nonmaterial and information resources; urban traffic system should focus on improvement of system structure to coordinate each subsystem with network.

2.2 Index Screening and Establishment

The purpose of urban traffic sustainable development is to achieve coordination of economy, society, resources, environment and transportation. In order to comprehensively evaluate the development level, a scientific and rational evaluation index system should be established. The system structure and elements of the object are analyzed, and the corresponding relation between sustainable development target and systematical elements established. Then the corresponding degree between quantitative index and target is researched to determine selection and set of index.

Ecological Impact Index B_4	[D15] Coordination Coefficient of Transportation Fuel Consumption	Impact of Environment and Energy
	[D16] Air Pollution Index (API)	
	[D17] Averages Traffic Noise of Traffic Trunk (dB (A))	
Government Management Index B_5	[D18] Management Capabilities of Urban Traffic System	Regulation Strength

In the work, based on the actual situation of China, the meaning of urban traffic sustainable development and relevant achievements at home and abroad, evaluation index system of urban traffic sustainable development level is divided into five aspects: traffic function index, economic and financial index, social equity index, ecological influence index and government management index. The structure is divided into several layers as follows: Top layer is abstract evaluation target, namely evaluation index of urban traffic sustainable development; second layer is the targets including society, economy, environment, resources, government management, etc.; middle is principle layer; last is index layer. Tab. 1 shows the concrete indices.

2.3 Index quantification

(1) Quantization of transport function index

D1：90%-level trip time consume of residents

Definition: 90%-level trip time consume of residents T (namely the trip time of 90% residents is less than T) is the acceptable maximum. The maximum tolerable (acceptable) trip time consume is different among cities with different scales and people with different trip purposes. People’s maximum tolerable trip time consume is relatively higher in cities of larger scale. Taking into account different sizes of cities, Chinese 90%-level trip time consume of residents should be: 60min in megalopolis; 50min in big cities; 40min in medium-sized cities; 30min in small cities.

D2: Bus number per ten thousand people

Definition: the average number of public transport vehicles of per urban ten thousand people (including temporary population). Bus number per ten thousand people is an index reflecting the level of development of urban public transport and traffic structural condition. Together with share rate of urban public transport, it is also a reference index that determines whether the transport development strategy is clear, and whether preferential policies and measures of public transport are implemented.

D3: 300-meters coverage rate of bus station

Definition: 300-meters coverage rate of bus station refers to the ratio of bus station coverage area (calculated as the radius of 300m) to the built-up area. This index can evaluate the status quo of urban transport systems to judge current situation of sustainable development of urban transport, thus providing a reference for making development plans. Meanwhile, it can also evaluate whether the urban transport planning has achieved requirements of sustainable development.

D4: Traffic congestion coefficient

Definition: traffic congestion coefficient is an evaluation index reflecting urban traffic congestion. According to operating conditions of network, congestion degree is divided into five grades: very smooth, smooth, mild congestion, moderate congestion and severe congestion.

D5: Road network density

Definition: Road network density refers to the ratio of road length to built-up area. (Road refers to that with pavement width of above 3.5m, not including sidewalks).Road network density is an index measuring of the constitutes feature of road network, the basic condition of road traffic management, and also an important index for making strategies of road traffic management, reflecting the construction level of urban transportation.

D6: Line network density of public transport

Definition: line network density of public transport refers to the ratio of total length of road centerline with public transport routes to built-up area, and the length of rail lines is directly included in the public transport line length. According to the sixth specification of the Five Cities Road Traffic Planning Design, the density of routes network of public transport should reach 3-4km/km2 in downtown area and 2-2.5km/km2 in urban fringe areas.

D7: Supply-requirement ratio of center parking area

Definition: supply-requirement ratio of center parking area is the ratio of parking capacity of central area to parking demand.

D8: Average vehicle speed on main roads

Definition: vehicle's average travel speed on the main road of built-up area.

(2) Quantification of economic and financial index

D9: Transportation investment coordinating coefficient

Definition: transportation investment coordinating coefficient, defined as the ratio of urban investment of transportation construction to total urban GDP, reflects the coordination of urban transport investment with economic growth.

D10: Proportion of public transport investment in infrastructure investment

Definition: the proportion of urban transport investments in the total public transport infrastructure investment.

(3) Quantification of social equity index

D11: Road area per capita

Definition: road area per capita refers to the ratio of road area in downtown area (road refers to that with pavement width of above 3.5m, not including sidewalks) to urban population (including agricultural population).

D12: Public transport share rate

Definition: public transport share rate refers to the ratio of public transport (including regular bus and rail) travel volume chosen by urban residents in recent years to the total amount of travel volume.

D13: Mortality per ten thousand vehicles

Definition: mortality per ten thousand vehicles refers to annual average number of traffic deaths per ten thousand vehicles (not including bike conversion). Mortality per ten thousand vehicles, as an important indicator to measure death situation of traffic accident under certain level of motorization, is also the comprehensive reflection of facilities construction of traffic safety and management effectiveness of traffic safety.

D14: Direct economic loss of accident

Definition: direct economic loss of accident refers to average direct economic loss of per million vehicles (excluding bicycles).

(4) Quantification of ecological impact index

D15: Coordination coefficient of transportation fuel consumption

Definition: coordination coefficient of transportation fuel consumption refers to the proportion of the growth of road traffic fuel consumption in travel demand growth.

D16: Air pollution index (Air Quality Index)

Definition: Air pollution index is a quantitative description of air quality. According to “Chinese ambient air quality index (AQI) technical regulations”(HJ 633-2012): air pollution index is divided into sixth gear, including 0 to 50, 51-100, 101-150, 151-200, 200-151 and more than 300. Correspond to the level of six, air quality index is larger, the pollution is more serious, and have the more obvious impact on human health.

D17: Averages traffic noise of traffic trunk

Definition: it refers to the average value of equivalent sound level weighted based on the length of monitoring data of urban traffic trunk road, reflecting the severity of the noise pollution on the environment caused by transport vehicles.

(5) Government management index

D18: Management capabilities of urban traffic system

Definition: it refers to whether comprehensive transportation—led by government leaders and coordinated by related departments—is established. Government should conduct transportation planning, construction and management based on traffic demand, road traffic safety situation and urban development requirements. Strategies for sustainable development should be made, with implementing public transport policy with priority, thus establishing countermeasures of people-oriented transport system.

3 Methodologies

In this stage, Matter-Element Analysis is mainly to describe the matter with three factors: matter, characteristics and magnitude. The three factors are then assembled orderly into one basic element, which is called matter-element. Given the evaluation standards for grades of index parameters of urban traffic sustainable development ability, the ability is judged by calculated values of each index parameters. The essence is an issue of identification. In this work, matter-element was composed of evaluation index, calculated value and grade. Evaluation index weight was determined synthetically with Analytic Hierarchy Process (AHP) and Entropy Method. The sustainable development evaluation model of urban traffic index parameters was established with the Matter-Element Analysis.

3.1 Matter-Element Method

Definition 1**:** In the following formula, R_0 is matter-element of urban traffic sustainable development evaluation; N_0 all of the grades; N_{0j} the j^{st} grade; C_i the i^{st} evaluation index; $(V_{0ij})_{nm}$ matrix of matter-element with same characteristics; N_j the value range of index C_i.

$$R_0 = \begin{bmatrix} N_0 & N_{01} & N_{02} & \cdots & N_{0m} \\ C_1 & V_{011} & V_{012} & \cdots & V_{01m} \\ C_2 & V_{021} & V_{022} & \cdots & V_{02m} \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ C_n & V_{0n1} & V_{0n2} & \cdots & V_{0n3} \end{bmatrix} = \begin{bmatrix} N_0 & N_{01} & N_{02} & \cdots & N_{0m} \\ C_1 & \langle a_{011}, b_{011} \rangle & \langle a_{012}, b_{012} \rangle & \cdots & \langle a_{01m}, b_{01m} \rangle \\ C_2 & \langle a_{021}, b_{021} \rangle & \langle a_{022}, b_{022} \rangle & \cdots & \langle a_{02m}, b_{02m} \rangle \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ C_n & \langle a_{0n1}, b_{0n1} \rangle & \langle a_{0n2}, b_{0n2} \rangle & \cdots & \langle a_{0nm}, b_{0nm} \rangle \end{bmatrix} \tag{1}$$

Definition 2: Assuming that $<a_{pi},b_{pi}>$ means the allowed value scope of index C_i, membership degree of C_i and evaluation grade j can be expressed as $K_j(V_i)$.

$$\text{If } Vi \in [a_{0ij},b_{0ij}], \quad K_j(V_i) = \frac{-\rho(V_i, V_{ij})}{|V_{ij}|} \tag{2}$$

$$\text{Else, } V_i \notin [a_{0ij},b_{0ij}], \quad K_j(V_i) = \begin{cases} \dfrac{\rho(V_i, V_{ij})}{\rho(V_i, V_{pi}) - \rho(V_i, V_{ij})}, \rho(V_{i,} V_{pi}) \neq \rho(V_i, V_{ij}) \\ -\rho(V_i, V_{ij}) - 1, \rho(V_i, V_{pi}) = \rho(V_i, V_{ij}) \end{cases} \tag{3}$$

where

$$\rho(V_i,V_{ij}) = \left| v_i - \frac{1}{2}\left(a_{ij}+b_{ij}\right) \right| - \frac{1}{2}\left(b_{ij}-a_{ij}\right), \rho(V_i,V_{pi}) = \left| v_i - \frac{1}{2}\left(a_{pi}+b_{pi}\right) \right| - \frac{1}{2}\left(b_{pi}-a_{pi}\right)$$

Definition 3: If w_i is the weight coefficient of index i, the correlation of all evaluation indexes and grade j is shown as below.

$$K_j(p) = \sum_{i=1}^{n} w_i K_j(V_i) \tag{4}$$

$$\overline{K_j(p)} = \frac{K_j(p) - \min_j K_j(p)}{\max_j K_j(p) - \min_j K_j(p)} \tag{5}$$

$$j* = \frac{\sum_{j=1}^{m} j * \overline{K_j(p)}}{\sum_{j=1}^{m} \overline{K_j(p)}} \tag{6}$$

According to the principle of maximum correlation, eigenvalues of evaluation grade can be solved. J* is eigenvalues of evaluation grade, meaning the degree of tendency to a certain level of urban traffic sustainable development.

3.2 Weights determination

AHP is an approach for facilitating decision-making by organizing perceptions, feelings, judgments and memories into a multi-level hierarchic structure that exhibits the forces that influence a decision (13, 14). Saaty (14), further suggested AHP is about breaking a problem down and then aggregating the solutions of all the sub problems into a conclusion. AHP is used to determine the weight of controlling factors, and provides a structured framework for setting priorities on each level of the hierarchy using pair wise comparisons that are quantified using 1–9 scales (15).

Step 1: Establish decision matrix

$$A = \left(a_{ij}\right)_{n\times n} \tag{7}$$

Where: $a_{ij}=1$ (i=j), $a_{ji}=1/a_{ij}$. The 9-scale linguistic variables to compare the relative importance between any two dimensions are used. The linguistic variables to describe the importance comparison are shown in Table 5.

Step 2: Order and the consistent matrix

$$b_{ij} = \sqrt[n]{\prod_{k=1}^{n} a_{ik} \cdot a_{kj}} \tag{8}$$

$$B = \left(b_{ij}\right)_{n\times n} \tag{9}$$

Where: $b_{ij}=1(i=j)$, $b_{ji}=1/b_{ij}$, $b_{ij}=b_{ik}b_{kj}$.

Step 3: Calculate the weight

$$w_i = \frac{g_i}{\sum_{k=1}^{n} g_k} \tag{10}$$

Where: $g_i = \sqrt[n]{\prod_{k=1}^{n} b_{ik}}$

3.3 Calculation Procedures

(1) Matter-element of urban traffic sustainable development evaluation should be firstly determined with Formula (1), based on each measurement values evaluation indexes and the corresponding evaluation levels.

(2) Membership degree $K_j(V_i)$ of m evaluation grades corresponding to n evaluation indexes ($D_1, D_2, \ldots\ldots, D_n$) should be calculated, according to Formula (2) and (3).

(3) Weights W_i of C_i can be determined with AHP according to Formula (7-10).

(4) Correlation $K_j(V_i)$ of evaluation indexes and grade j can be calculated based on Formula (4).

(5) Eigenvalues of evaluation grade j and grade variable j^* can be solved with Formula (5) and (6). The grade variable can be used to judge the urban traffic sustainable development level.

4 Case Study

4.1Data

In this work, the relevant index data of Beijing mainly comes from the statistical literatures, such as Beijing statistical yearbook, China transportation yearbook, China urban construction statistics yearbook. With the statistical data, evaluation index values of sustainable development of Beijing urban traffic can be determined (see Table 2).

Table 2. Evaluation Indices of Urban Traffic Sustainable Development in Beijing

Code	Indexes	Situation Value
D1	Trip Time of 90% Residents (min)	42.72
D2	Bus Number per Ten Thousand People (Buses/ Ten Thousand)	21.56
D3	300-meter Coverage Rate of Bus Station (%)	75
D4	Traffic Congestion Coefficient	7.73
D5	Road Network Density (km/ km^2)	5.5
D6	Line Network Density of Public transport (km/km2)	4.1
D7	Supply-requirement Ratio of Center Parking Area	0.71

D8	Average Vehicle Speed on Main Roads (km/h)	19.4
D9	Transportation Investment Coordination Coefficient (%)	3.68
D10	Proportion of Public Transport in Infrastructure Investment (%)	43.6
D11	Road Area per Capita (m^2)	5.6
D12	Public Transport Share Rate (%)	34.5
D13	Mortality per Ten Thousand Vehicles (People/ Ten Thousand vehicles)	3.78
D14	Direct Economic Loss of Accident (Ten Thousand Yuan/ ten thousand Vehicles)	7.3
D15	Coordination Coefficient of Transportation Fuel Consumption	1.45
D16	Air Pollution Index (API)	147
D17	Averages Traffic Noise of Traffic Trunk (dB (A))	69.9
D18	Management Capabilities of Urban Traffic System	5

4.2 Results

Based on the reality of social and economic and historical data of Beijing, matter-element of urban traffic sustainable development evaluation was set up as Table 3, with the evaluation standards of expert research results and provisions of *Urban road traffic planning and design specification GB50220-95* and *Evaluation index system of urban road traffic management (2007 edition)*.

Membership degree $K_j(V_i)$ of m evaluation grades corresponding to evaluation indexes C_i can be calculated and listed in Table 4. Weight of indexes are determined by AHP and listed in Table 5. Grade correlation can be calculated and listed in Table 6. Table 7 shows eigenvalues of evaluation grade of urban traffic sustainable development. The grade of each index can be clarified with the screening of maximum of $K_j(V_i)$ (See Table 6). Combined with the eigenvalues, urban traffic sustainable development can be comprehensively analyzed. The classification can be achieved (See Table 7).

According to the eigenvalue j* evaluating the level of urban-traffic sustainable development, Beijing is in a general level in the sustainable development of urban traffic. However, the urban-traffic sustainable development of Beijing is getting better and better with more efforts from the government. Table 7 explains the current situation of urban-traffic sustainable development in Beijing.

Firstly, it introduces some important indexes belonging to level 1 or level 2, including the number of standard public-buses shared by every ten thousand people, public-transportation investment and sharing rate. It manifests the significant achievements and improvements of public transport reform in Beijing.

Secondly, relevant departments have attached great importance to traffic safety, and developed good management plans regulating static transportation systems. Therefore, there are some other indexes in level 1 or level 2, such as direct economic loss from traffic accidents, supply and demand ratio of parking in center area, mortality rate per ten thousand cars, management capability of urban traffic systems.

However, Table 7 also shows some negative results. For example, some evaluation indexes are in a general level, such as air pollution, noise, road-network density and road area per capita. Thus, more efforts should be made to improve ecological environment and traffic equality in Beijing.

Finally, some level-four indexes include residents travel time, traffic congestion coefficient and average speed of buses on main road. Those indexes indicate that Beijing still has severe traffic congestion and a low citizen-travel efficiency and satisfaction. Considering the overall traffic system, it can be seen that Beijing government has relatively strong control and regulation ability, making significant progress in transportation investment, public transportation development and traffic safety. However, Beijing government still needs to improve its environmental pollution control, citizen travel satisfaction and transportation functions.

Table 3. Matter Element of Urban Traffic Sustainable Development Evaluation

Index	Value	Excellent	Good	Normal	Bad	Worse	Joint Domain
D1	42.72	<0,20>	<20,30>	<30,40>	<40,50>	<50,100>	<0,100>

5 Conclusions And Discussion

The method evaluating urban-traffic sustainable development is developed by matter-element method and AHP. The eigenvalues can be figured out through the level of each evaluation index and the relevancy of evaluation levels. Then, multi-parameter evaluation will be converted to single-factor evaluation to quantitatively work out the overall level of urban-traffic sustainable development. Besides, the advantages and deficiencies of urban-traffic sustainable development can be clearly determined through analyzing the level of each evaluation index, thus providing a scientific and rational basis for promoting the sustainable development of urban transportation.

The accuracy of weighting coefficient is also significant to determine the sustainable development level of urban transportation. With the knowledge and experience from many experts, the work applied AHP to determine the weight of evaluation indexes, objectively and comprehensively reflecting the importance of each evaluation index and the actual situation of existing problems. When evaluating urban-traffic sustainable development, several aspects were paid relatively more attention, such as transportation functions, social equality and ecological environment. It can be seen that Chinese government not only emphasizes on constructing urban traffic but also attaches much importance to the social equality and ecological protection of environment in social and economic development. Such efforts are significant to the sustainable development of urban traffic.

This method was also applied to systematically analyze the sustainable development capability of urban traffic in Beijing. The evaluation results imply that Beijing government has a strong control and regulation ability. Beijing has achieved significant outcomes in the development of public transportation, traffic safety and transportation investment. However, Beijing government should make greater efforts to improve traffic environment management, transportation functions and citizen travel satisfaction. Besides, the analysis manifests the practical situation of urban-traffic sustainable development in Beijing, proving the effectiveness and practicality of this method. However, different cities emphasize on different aspects of urban-traffic sustainable development due to some complex and changeable influential factors. Therefore, government should consider the practical situation of urban development when applying this method in order to reasonably select indexes and scientifically describe the practical situation of urban-traffic sustainable development.

Abstract: By calculating Chengdu carbon emissions of road passenger transport per capita daily from 2008 to 2013, found that the carbon emissions per capita daily increased year by year and began to stabilize. Using LMDI method to analysis the factors of Chengdu road passenger transport carbon emissions, found that trip structure has increasingly become a major factor inhibiting Chengdu road passenger transport carbon emissions, motorized trip rate and residents daily trip distances increased carbon emissions. Chengdu should further improve the relevant policies, inhibiting the growth rate of private car ownership, and develop public transport and bicycles and other public transport modes to further reduce carbon emissions.
Keywords: Road passenger transport; Carbon emission; LMDI; Energy conservation and emissions reduction.

1 Introduction

With the deterioration of the environment and global warming, energy-saving and environmental protection and the development of low-carbon traffic has become the mainstream around the world. State Council issued *2014-2015 energy saving low-carbon development action plan* on May 26, 2014, which requires China 2014-2015 carbon dioxide emissions per unit of GDP fell by 4% and 3.5%.On November 12, 2014, the Asia-Pacific Economic Cooperation Organization meeting, the two countries jointly issued the *U.S.-China Joint Announcement on Climate Change* is mentioned about 2030 China plans to reach a peak of carbon dioxide emissions, and non-fossil energy accounted for an increased to about 20% of the total energy consumption.

In addition to the part of the natural causes of climate change, a big part is caused by human activities, especially the use of fossil fuel energy. According to the projections of the International Energy Agency, 23% of global carbon emissions from energy consumption in 2007 was from the transport sector, and by 2030 this proportion will increase to 41%, traffic has become a focus of carbon emissions in the developed countries to reduce emissions. Currently, most of the documents are given to calculate the total urban carbon emissions of road passenger transport, but ignore the impact of population growth to the carbon emissions.

2 Road passenger transport status of Chengdu

According to *2013 Chengdu Transportation Development Annual Report*, road passenger transport is divided into taxis and private cars, buses, rail transportation, non-motor vehicles and others. In order to facilitate the calculation, non-motor vehicles and other transportation options are collectively referred to as others. Because the carbon emissions of walking and cycling is zero, they are not included into the scope of statistics.

The recent Resident Trip Survey in Chengdu was investigated by Parsons Brinckerhoff Company in 2009. Through the survey to the central city of Chengdu 4700 households, we obtained the travel needs of 22000 residents. Due to various reasons, in recent years, there has been no large-scale resident travel survey in Chengdu. The data of 2008 and 2009 are from Transportation Committee of Chengdu and *Chengdu urban and rural comprehensive transportation planning studies*. The data of taxi, bus and the subway from 2010 to 2013 are from *2012 Chengdu "traffic ahead" strategy Statistical Monitoring Report*, *2013 Chengdu "traffic ahead" strategy Statistical Monitoring Report* and *Chengdu Transportation Development Annual Report 2013*. In the absence of the data of the proportion of private car travel in residential structures from 2010 to 2013, in reference to the car ownership over the years from *2013 Chengdu Transportation Development Annual Report*, based on the car ownership and the proportion of residents' travel structure in 2008 and 2009, we get 2008-2013 Chengdu residents travel structure and per capita daily travel distance (excluding walking) shown in Figure 1.

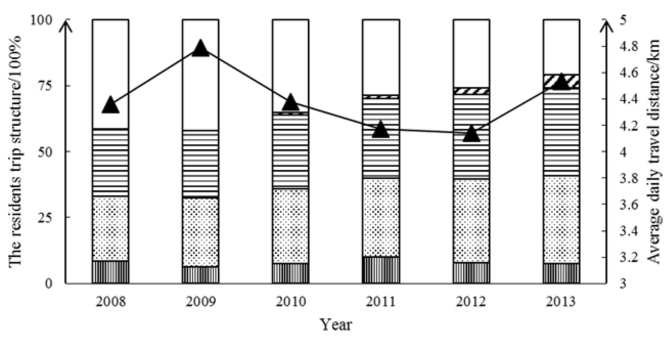

Figure 1. The resident trip structure and the distance of everyday travel in Chengdu from 2008 to 2013 (without walk)

As shown in Figure 1, the travel distance per capita daily began to recovery after experienced a reduction of three years. Bus and rail travel structure ratio increased year by year, and the proportion of cars is steadily. The increasing of the vehicle on the road in the city caused urban congestion, while it also increasing the carbon emissions of urban road passenger transport.

Assume that the average time travel a certain distance, carbon emission factor is calculated with reference to the various modes of transportation standards of the US Energy Foundation, as shown in Table 1:

Table 1. Emission factor standards by US Energy Foundation (g/km· per capita)

	emission factor
Taxi	140.2
Car	116.9
Bus	19.8
Subway	7.5
Others	19.8

3 LMDI model building and decomposition

In order to analyze the factors influencing Chengdu road passenger transport, this paper uses logarithmic mean Divisia index method for carbon decomposition.

Assume that C is the daily road passenger transport carbon emissions per capita in Chengdu, i is the type of transportation (car, taxi, bus, rail transportation and other modes of transport). The daily road passenger transport carbon emissions per capita in Chengdu decomposed into four factors (various carbon intensity of transportation, travel structure, motorized travel rates and average daily travel distance).

$$C=\sum_i C_{it}=\sum_i \frac{C_{it}}{M_{it}\times m}\times\frac{M_{it}\times m}{N_t\times m}\times\frac{N_t\times m}{S_t\times m}\times\frac{S_t\times m}{P_t} \quad (1)$$

C_{it} is the carbon emission of transportation i per day in year t; M_{it} is the amount of passengers of transportation i per day in year t; m is the distance of every travel; N_t is the amount of passengers by motor vehicle per day in year t; is the amount of passengers per day in year t; S_t is the population of Chengdu in year t. Let:

$$e_{it}=\frac{C_{it}}{M_{it}\times m},r_{it}=\frac{M_{it}\times m}{N_t\times m},p_t=\frac{N_t\times m}{S_t\times m},q_t=\frac{S_t\times m}{P} \quad (2)$$

e_{it} is the carbon emission intensity of different modes of transportation, r_{it} is the resident trip structure, p_t is the residents travel motorization rate, q_t is the distance of every travel in year t, then:

$$C=\sum_i e_{it}\times r_{it}\times p_t\times q_t \quad (3)$$

Use LMDI method decompose the factors of formula (3). Let the carbon emissions of period 0 is C_o, C_t is the carbon emissions of year t, then:

$$\Delta C = C_t - C_0 = \Delta C_{ei} + \Delta C_{ri} + \Delta C_p + \Delta C_q \quad (4)$$

ΔC_{ei} is the effect of carbon emissions caused by the carbon emission intensity of different modes of transportation; ΔC_{ri} is the effect of carbon emissions caused by the residents trip structure; ΔC_p is the effect of carbon emissions caused by the residents travel motorization rate; ΔC_q is the effect of carbon emissions caused by the distance of every travel. Then the equation (4) can be showed as below:

$$\Delta C_{ei} = \sum_i \frac{C_i^t - C_i^0}{\text{In}C_i^t - \text{In}C_i^0} \text{In}\left(\frac{e^{it}}{e^{i0}}\right) \quad (5) \qquad \Delta C_{ri} = \sum_i \frac{C_i^t - C_i^0}{\text{In}C_i^t - \text{In}C_i^0} \text{In}\left(\frac{r^{it}}{r^{i0}}\right) \quad (6)$$

$$\Delta C_{p} = \sum_i \frac{C_i^t - C_i^0}{\text{In}C_i^t - \text{In}C_i^0} \text{In}\left(\frac{p^{t}}{p^{0}}\right) \quad (7) \qquad \Delta C_{q} = \sum_i \frac{C_i^t - C_i^0}{\text{In}C_i^t - \text{In}C_i^0} \text{In}\left(\frac{q^{t}}{q^{0}}\right) \quad (8)$$

Assuming the carbon emission intensity of different modes of transportation is constantly, then $\Delta C_{ei} = 0$.

4 Chengdu daily road passenger transport carbon emissions per capita calculation and decomposition analysis

According to the formula mentioned in *Calculation of Urban Passenger Transport Carbon Emissions and Carbon Development Strategy*, which is written by Zheng Dayong (2011), considering the days and the population, the formula of Chengdu daily road passenger transport carbon emissions is:

$$C_t = \sum_{i=1} q^t r_i^t e_i^t \quad (9)$$

q_t is the distance of every travel in year t; r_{it} is the residents trip structure; e_i^t is the carbon emission intensity of different modes of transportation, which is constantly. By calculation, the result is shown in Figure 2:

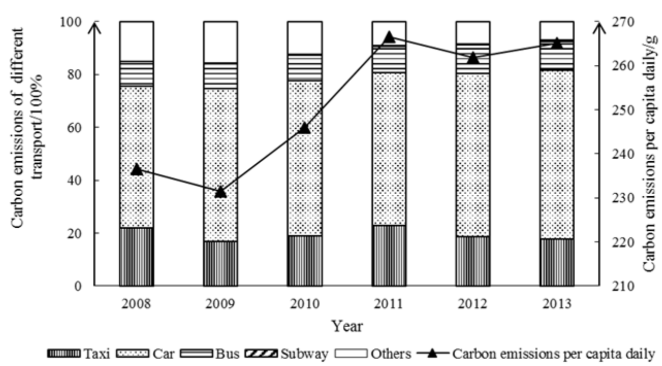

Figure 2. the daily per capita carbon emissions and the proportion of different of transport in total emissions from 2008 to 2013

Combined with Figure 1 and 2, although the proportion of cars in the traffic structure is not the largest, but the largest carbon emission is the car. Based on the data in 2008, decompose the factors, the result is shown in Table 2 and Figure 4.

Table 2. The decomposition results of the factors

	ΔC_{ri}	ΔC_p	ΔC_q	ΔC
2008	0	0	0	0
2009	-24.99	-2.53	22.38	-5.14
2010	12.66	27.34	-25.53	14.47
2011	22.8	9.92	-12.1	20.62
2012	-12.82	10.26	-2.14	-4.7
2013	-37.33	16.9	23.65	3.22

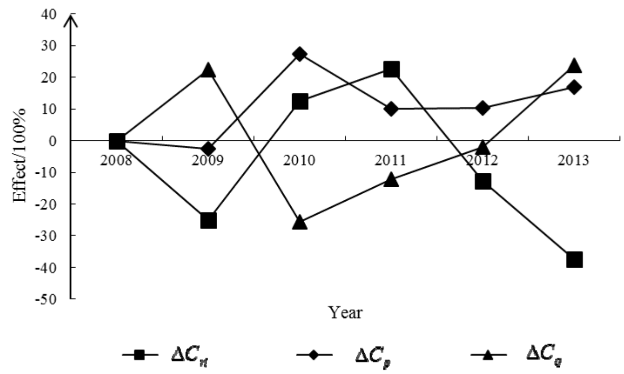

Figure 3. The trends of the contribution of the factors

Because the data of the residents trip structure is without walking, so this three factors are independent of each other. Although Figure 1 shows the factor impact the carbon emissions of Chengdu road passenger transport, we cannot see the relationship between them.

From Table 2 and Figure 3, the main factors of the increasing of the carbon emissions per capita daily are the resident trip structure and the residents travel motorization rate, which the impact of residents travel motorization rate is higher than the resident trip structure. While after 2011, the residents trip structure became the factor inhibited carbon emissions. The daily travel distance gradually became the factor increasing carbon emissions, which is related with the expansion of Chengdu and the construction of Tianfu New Area, Many people's workplace began to move south with the construction of Tianfu New Area and the residents travel distances increase year by year. The residents travel motorization rate from Figure 3 can be seen is an important factor increasing carbon emissions, which suggests that maintain the current level if the motorization rate is difficult to reduce. The resident trip structure in the past two years largely inhibited the growth of carbon emissions, which indicated that with the implementation of the "Traffic Ahead" and the development of public transport played a very important role in reducing carbon emissions. With the continuous growth of car ownership, it is recommended to take draw lots in Beijing to reduce the number of cars increasing. It's also very important to develop public transport and optimize the structure in further.

5 Countermeasures

5.1 Structural reduction

Chengdu should accelerate the development of subway. Deeping the study of modern tramcar at the same time, accelerate the construction of tramcar. Chengdu should also accelerate the planning and construction of bus station, and the integration of two spheres of public transportation, achieving the integration of the central city and suburban transit. By the end of 2013, Chengdu vehicle population reached 124,000, an increase of 10.9% over the previous year. Chengdu should take actions such as take draw lots in Beijing to inhibit the growth of cars.

5.2 Technical reduction

Chengdu should speed up the optimization of intelligent transportation system, start the development of intelligent transportation integrated information service platform, and gradually build a platform which integrated public transportation, real-time traffic and park driving system. Developing renewable energy or other new energy, accelerating the progress of Chengdu taxi “Oil to Gas” project. Meanwhile, optimize the structure of buses, increase the proportion of pure electric vehicles, LNG vehicles and dual-fuel vehicles to reduce carbon emissions radically.

5.3 Policy reduction

Sichuan Provincial Communications Department, Chengdu Municipal Government, Municipal Energy Saving and Reduction Office have released documents about low-carbon city construction or energy saving. Apart from it, we should also enhance the propaganda of low-carbon transport, protect the implementation of the policies.

6 Conclusion

In this paper, using LMDI method to analysis the factors affecting the carbon emissions of Chengdu road passenger transport, the following are conclusions:

(1) From 2008 to 2013, carbon emissions of Chengdu road passenger transport per capita daily increase gradually and being stabilize.

(2) Residents travel structure is becoming a major factor inhibiting the growth of carbon emissions. The development of public transport in Chengdu optimized residents travel structure, effectively easing the growth of urban road passenger transport carbon emissions.

Abstract: The researches and practices of green inland navigation are comprehensively investigated. Based on the national oceanic economic strategy that Zhejiang provincial party committee proposed, the dynamic mechanism of green inland navigation development are made deep research, and the current status and problems of Zhejiang province inland navigation are systematically discussed. The development thoughts and key tasks of Zhejiang province green inland navigation are further studied and the policies of development of Zhejiang province green inland navigation are put forward.
Keywords: Green; Inland navigation; Zhejiang.

1 Introduction

Zhejiang province is famous for water resources. Water is the base of ecology and the source of life. Under China's New Normal，Zhejiang province has been speeding up the building of green inland waterway transport. It is the strategic choice of Zhejiang adjusting and optimizing the structure, energy conservation and emissions reduction and building an upgrade regional economy. In March, 2012, Zhejiang provincial government officially approved "Zhejiang province inland waterways Renaissance action and plan". This indicates that the Zhejiang inland waterways recovery action plan had begun comprehensively. The 4th plenary session of the 13th Zhejiang provincial party committee put forward "five water treatment" in November 2013. "Five water treatment" indicates the treatment of sewage, flood control, drainage, water supply security and water conservation. It is the fundamental policy that Zhejiang provincial government has recently introduced. It is the key to promote the development of a new round of reform in Zhejiang. Water conservancy has been regarded as the breakthrough to promote industrial transformation and upgrading. The 5th plenary session of the 13th Zhejiang Provincial Party Committee introduced the decisions about developing beautiful Zhejiang to create a better life. It is the guidance document that Zhejiang province has been promoting ecological civilization construction and improve people's livelihood in the current and future period. It is the strategic task for the future development of ports and shipping in Zhejiang province of revival of inland waterway transport, guiding the optimization configuration of inland port resource, reasonable adjustment of inland water transportation structure, promoting the green development, low carbon development, cycle development of inland waterway transport, realizing the win-win situation of Inland waterway transport development and improving the water environment in Zhejiang province under China's New Normal.

2 The Current Situation of the Development of Inland Waterway Transport in Zhejiang Province

Zhejiang province is full of rivers with Butiao River, Qiantang River, Caoer River, Yong River, Jiao River, Ou River, Feiyun River, and Ao River from north to south. With abundant water resources, Zhejiang province ranks as the top province of inland water transport. The inland navigation is an engine of economic development in Zhejiang province. In Zhejiang province, the inland waterway has the navigation mileage of 9748 kilometers, with high-grade waterway of the fourth and above rank 1398 kilometers. There are seven important inland ports in Zhejiang province as are Hangzhou port, Huzhou port, Jiaxing inland port, Shaoxing port, Ningbo inland port, Jinhualanxi port and Lishuiqingtian port with 4535 berths. At the end of 2013, Zhejiang province inland port cargo throughput reached 375 million tons, and the container throughput reached 231 thousand TEU. The year navigation ships is 1.74 million.

Table 1. Zhejiang province inland port cargo throughput (Unit:10 thousand ton)

year / port	2013	2012
sum	**37458.7593**	**39171.1994**
Hangzhou port	9381.6092	9097.0459
Jiaxing inland port	11106.9621	10855.5495
Huzhou port	15311.8033	17840.4484
Shaoxing port	1344.5611	1205.1643
Ningbo inland port	52.4946	52.3883
Lanxi port	69	20.2
Lishui port	3.8	3.22
Qingtian port	188.489	97.183

3 Dynamic mechanism of Zhejiang green inland water transport development

3.1 The requirements of the transformation and upgrading of Zhejiang inland waterway transport

Waterway transport is regarded as the green transportation mode. Inland waterway transport has the comparative advantage of large capacity, low cost, less land, small energy consumption, light pollution and high comprehensive efficiency. Enhancing rapid and accurate emergency response capacity and ability to dispose of the sudden water pollution accident of ships, improving supervision and regulatory capability of inland waterway transport water pollution, building smooth, efficient, safe and green inland waterway transport system of Zhejiang province are important contents of implementation of major policy decisions of Zhejiang provincial party committee and provincial government "five water treatment" and "beautiful Zhejiang". Speeding up the building of green inland waterway transport, and realizing the sustainable coordination development between inland waterway transport and ecological environment not only effectively relieve the contradiction between economic development and traffic resources in Zhejiang province, but also are of great significance for construction of Zhejiang Marine ecological civilization demonstration area, transformation of economic development patterns and the transformation and upgrading of inland waterway transport.

3.2 Reversed transmission of the pressure from ecological environment

With the rapid development of inland waterway transport, there is serious lag about shore handling and treatment of inland ships garbage and watercraft oil-contaminated water and water pollution prevention and control of inland waterway transport. Under China's New Normal，Zhejiang inland waterway transport development mode faces many adjustments. Ecological environment problems formed reversed transmission mechanism for the transformation and upgrading of inland waterway transport in Zhejiang province. If Zhejiang transformation and upgrading of inland waterway transport is not in place, not only the goal of promoting the transformation of regional economy of Zhejiang province in short time will not be achieved, but also the sustainable development of Zhejiang economy will be seriously restricted. The transformation and upgrading of Zhejiang inland waterway transport has become the basic needs of "five water treatment" and "beautiful Zhejiang province" in Zhejiang province, as well as the practical basis of the long-term stable development of regional economy in Zhejiang.

4 The path of the development of Zhejiang green inland waterway transport

4.1 To foster green inland waterway transport market subject with positive guidance

It is advisable to make financial support and introduce favorable policies to develop green inland waterway transport. The marketization of shipping resources allocation should be operated. The merger and reorganization of inland port and shipping enterprise should be encouraged. The small and medium-sized enterprises of inland port and shipping should be encouraged to make scale operations. The partnership of inland port and shipping enterprise should be explored. The contract mechanism and equity alliance mechanism, etc should be gradually made to strengthen business market competition.

4.2 To strengthen the construction of ecological channel

Based on the harmony between man and nature, ecology protection, and the characteristics of humanities and the natural environment, ecological environmental and reusable materials should be made use of to the greatest extent in order to reduce the consumption of natural resources and social resources, improve ecology self-healing of channel and network of rivers and capacity of flood discharge along channels. The construction of ecological waterway and arterial waterways greening should be actively explored. The waterway maintenance work should be made further perfection to ensure that the channel intact and clear by enhancing funds in waterway maintenance.

4.3 To strengthen the overall process management

It's suggested to establish the cooperation mechanisms on information sharing and communication, and to form working resultant force of shipping water pollution prevention and control. Vessel inspection departments should strengthen the inland water transport ship anti-fouling structure and equipment design drawing review and inspection. The waterway transportation management department should actively lead water transportation operator to eliminate backward non-environmentally friendly equipments. The structure of inland navigation must be adjusted to meet the demands of economical development.

Ship standardization should be vigorously promoted. Local maritime administrative institutions should enforce better supervision and administration of ship pollution in inland water transport. The environmental protection consciousness of the inland river crew should be enhanced. The port enterprises should, in accordance with the requirements of the laws and regulations, constantly perfect port security facilities under the supervision of port administrative department, and the latter should carry out supervision and inspection on a regular basis.

4.4 To enhance the supervision over dangerous goods transportation in inland navigation

It's to strictly implement reporting system of dangerous goods and ships in port operation. Those who conceal, falsely report and have berthing operation of non-compliances should be sanctioned. The intensity of the cruise should be increased in order to improve navigation order. It's to use the advanced information methods and tools, such as comprehensive supervision system of the ship, AIS and GPS, to regulate inland navigation ships of dangerous goods have dynamically, comprehensively and effectively.

4.5 To strengthen prevention and control of inland port water pollution

The sustainable development of port means to build the port that is of safe transport, quality-beneficial, scientifically and technically pioneering, energy saving and environmental friendly. The existing inland port shoreline resources should be integrated. Those inland ports that are of small scale and causing serious environmental pollution should be relocated, transformed or removed. Inland ports should be aimed at being of large scale, intensified, and modern. According to the types of loading and unloading of goods, inland ports should gradually establish water retaining devices of land frontier and yard spray dedusting facilities. It’s better to build dock depot sewage collection sedimentation facilities. It's to speed up the renovation of ship garbage receiving facilities of the existing port to meet the requirements of environmental protection standard. According to the opinions that the environmental protection department approved, new port project is to carry out the measures of prevention and control of pollution, the same must be designed, constructed and put into use as main body project.

4.6 To speed up the standardization of inland ship

It's to takes enterprise as the main, government guidance as the supplementary to speed up the renewal and reconstruction of the existing nonstandard, old environmental protection facilities of ships by using economic incentives methods and improve technical standards of inland ships. It's to actively promote the use of standard ship. It's to establish and improve the coordination mechanism of ship standardization work.

Newly built ships should be strictly equipped with corresponding oil pollution and garbage prevention facilities, and obtained corresponding vessel inspection certificate. For existing ship, the oil pollution and garbage pollution prevention equipments should be transformed as quickly as possibly. If the ships can not meet the requirements, ship inspection department should mot issue the inspection certificate, the maritime administration department should not issue port entry and exit visas of the ship. According to the requirements of national energy conservation and emissions reduction, the principle of overall planning, a step-by-step implementation, easiest first and steady progress, new energy ships such as LNG is to be actively promoted.

4.7 To strengthen the regulation about receiving ashore of the ship rubbish and oil sewage and the pollutants collection and disposal of ship pollutants

Port and shipping administration departments should enhance the regulation and supervision over the oil sewage recycling place and garbage receiving place. The port enterprises should be supervised to establish the necessary waste receiving place and ship oil sewage receiving place. In conditioned ship anchoring service area and ship visa points, it’s better to set up the public ship waste receiving and oil sewage receiving place. It's to establish and improve the mechanism of ship pollutant collection and treatment and operational management.

4.8 To strengthen the inland navigation supporting and safeguarding system

The four supporting and safeguarding systems of the inland navigation safety, salvage, pollution prevention and emergency treatment should be strengthened. The long-term mechanism on prevention and control of water pollution of inland navigation should be established and improved. First of all, the inland navigation safety-guarding system should be enhanced. A variety of water traffic safety facilities should be built. Provincial and municipal monitoring platform and terminals should be established. Visualization and control of main channels and ships should be fully achieved so as to improve the capacity of water traffic safeguarding. The inland river salvage system should be set up. What’s more, it's to be equipped with the rescue ships, salvage ships, towing ships, fire fighting and other professional equipments as a whole. It's to have a professional and part of the rescue team in order to develop water salvage ability. In addition, the prevention and control system of water pollution in inland navigation should be strengthened. It's to plan and set up emergency rescue base of dangerous goods in the north of Zhejiang province planning and construction. Finally, it's to reasonably reserve pollution prevention emergency supplies, be equipped with specialized clean-up ships. It's to promote shipping water pollution accident emergency rescue capabilities. The emergency treatment system should be set up in order to make the risk assessment of inland shipping area, hazard monitoring and early warning.

4.9 To strengthen rules and regulations of water pollution prevention and control as well as publicity work in inland waterway transport

The rules and regulations of water pollution prevention and control in inland waterway transport should be introduced immediately. The delivery management regulations of garbage and oil water of ships and the plan for the implementation of supervision on ship garbage delivery should be studied and made as soon as possible in order to provide legal safeguard for shipping pollution of water prevention and control. There should be more publicity of water pollution prevention and control of inland navigation. The shipping personnel should be actively guided and supervised to conscientiously implement the relevant laws and regulations, and the ship pollution prevention facilities should be properly equipped with and used. It's high time to raise the water protection consciousness of personnel, port and wharf enterprises. The ship pollution damage liability insurance should be actively carried out. The ship pollution accident should be preceded efficiently and quickly.

5 Conclusion

It is observed that developing green inland navigation will be a complex and systematic project. It needs having a whole list of design issues and taking overall consideration of. It should have the corresponding complete supporting system including mechanism, policy and evaluation. The research proposes the supporting system of the mechanism, path and policy of Zhejiang green inland navigation. It provides access to the transformation and upgrading of Zhejiang inland navigation. It better explore the coordination development path of "five water treatment", beautiful Zhejiang and inland navigation industry. It also provide theoretical support of the policy on a powerful province of marine economy and the sustainable development of Marine economy.

Abstract: The principle of selecting test points is that the number of test points is as less as possible and faults that can be isolated should be as much as possible. Firstly, the structure and function of the system is described by using the logical model. According to the principle, two matrixes with the criteria of the fault detection and the fault isolation are built by combining the Boolean matrix in order to obtain the global testing point sets. Then the global testing point sets is optimized with the evaluation index of the amount of test information and the test cost, and the best global test point sets and the test sequence are obtained. Finally, the onboard power controller of maglev train is taken as an example to validate the model. The result shows that the method is effective and can be used for faults detection and measurability design of analog circuits
Keywords: The test point; Logical model; Boolean matrix; The best global test point set.

1 Introduction

As the fastest ground transportation in our country, the maglev train is a kind of transport system with fully dispersed power. It has many characteristics such as numerous electric equipment, complicated structure, the diversity of electrical characteristics, and a large number of large scale integrated circuit and so on. However, as an imported equipment, maglev trains lack of much information, such as the complexity of circuit data and the schematic diagram, which is unconventional to repair the equipment when faults occur. Therefore, equipment only has to be sent to foreign factories to repair, causing long maintenance time and big cost, which have serious influence to the operation of maglev train. So there is an urgent need to carry out the research of the fault diagnosis methods and the diagnosis system for maglev electrical equipment.

But almost all of the fault diagnosis methods rely on the acquisition of data from the test point samples. Only chose the best test points, it can guarantee the information and representativeness of samples, which can ultimately achieve good diagnosis.

There have made certain achievements at home and abroad in selecting the test point. In the some papers, the optimization of the test point in the different board-level circuits is studied respectively by graph theory and the fault tree method.in order to solve the problem, such as complicated types of signal ,the optimization principles of the biggest fault characteristic information entropy is built based on the correlation matrix model. The validity and feasibility of this method is verified by actual circuit, but the process is complex, large amount of calculation.

However, in the other papers, topology problem of test engineering is studied. The graph theory model is used to describe the topology structure, and the optimization method of the test points is given based on graph theory model from the Angle of the concurrent design engineering requirements; there are many algorithm of selecting the test points in the papers. Varghese come up with a kind method of selecting the test points, which is called "faith level"; Hatchway and Bastian put forward the concept of fuzzy sets; Stenbakken and Souder sit put forward a method , which is used to decompose QR factorization of the circuit sensitivity matrix; Abdurrahman and others generate the test point set with continuous quadratic equation method; Wang Peng and Yang Shaquan describe the fault distinguish ability of the test point by the fault isolation degree and conditional fault isolation degree, and choose the test point according to distinguish ability. These methods above are only local optimization method, can't guarantee the global minimum point sets. Although the exhaustive search algorithm can find global optimal solution, but it is a NP-complete problem, the system with medium size is not applicable.

Therefore, this paper describe the structure and function of the system by using the logical model, and build the matrix with the criteria of the fault detection and the fault isolation combining the Boolean matrix. Then optimize the global testing point sets with the evaluation index of the amount of test information and the test cost, the best global test point sets and the test sequence are obtained.

2 The Optimization Model Of The Test Points Based On Boolean Algorithms And Logic Model

Logical model is put forward by American scholar Ralph De Paul Jr., which can describe the correlation and causation between function modules and test on the basis of through the form of a directed graph to diagnose the reason and have the test analysis.

The logical model is mainly composed of functional flow diagram and correlation chart. The functional flow diagram is built based on the function of the system and the information of the test points, which has an overall description about the dissemination path of the system functions information by directed graph. Directed graph mainly includes the following elements: the functional test point set $T_0 = \{t_1, t_2, \cdots t_b\}$, is the set

mof all test position in a level; the set of fault modules $M = \{m_1, m_2, \cdots m_a\}$, Refers to the set of all the components; the set of the directed edge is represented by $E = \{e_{ij}\}$, where e_{ij} is the edge from m_i to m_j

Because the logical model mainly describes the relationship between the fault mode and the test points, and ignore the testing methods and means, which can't reflect the correlation of the detection and the specific fault mode. Meanwhile, because the fault mode is not clear, the location of the test point is primarily determined. Therefore, On the basis of the logical model, the introduction of Boolean matrix can describe the causal relationship between the fault unit and the test point in detail.

Boolean algorithms can be used for fault detection and fault isolation with the logic "or", "and" as well as "exclusive or".so the test point sets in the guideline of fault detection and fault isolation can be got, which is represented by T_D, T_I .if the global test point set is represented by T:

$$T = \left\{ T_n \middle| T_n \subset T_D, 且 T_I \subset T_D \right\} \quad (1)$$

2.1 The Choice Of the Global Test Point Set

2.1.1 The optimization of the test point set in the Standard that the number of the fault isolated is the most

Generally, assuming that there is only a fault at a certain moment for a system, which is a typical binary pattern recognition problem. Therefore, it is necessary to combine the output of different tests to judge the possibility of faults. m_0 represents the system has no fault, and $M = \{m_i, i = 0,1,\cdots a\}$ represents the state set of the system. So the correlation matrix of the state as follows:

$$MT_{(a+1)\times b} = \begin{matrix} \\ m_0 \\ m_1 \\ \cdots \\ m_a \end{matrix} \begin{matrix} t_1 \quad t_2 \quad \cdots \quad t_b \\ \begin{Bmatrix} h_{01}, h_{02}, \cdots\cdots h_{0b} \\ h_{11}, h_{12}, \cdots\cdots h_{1b} \\ \cdots\cdots\cdots\cdots\cdots\cdots \\ h_{a1}, h_{a2}, \cdots\cdots h_{ab} \end{Bmatrix} \end{matrix} \quad (2)$$

In the correlation matrix above, The element in the first line is special, $h_{0j} = 0$, $j = 1,2,\cdots n$.

The condition that two faults can be isolated is that the corresponding row vector of two faults must be different, and the logical "or" represents the corresponding test can isolate two faults. $T_I(m_i, m_k)$ is used to represented the test point set that can isolate

m_i and m_k :

$$T_I(m_i, m_k) = \sum_{j=1}^{b} \left[(h_{ij} \bullet h_{kj}) t_j \right] \quad (3)$$

In the formula (3), $\bullet$ represents"Exclusive or", and $i \neq k$.

According to the formula (3), the test points that can isolates any two faults can be got. The accumulation of these test combinations is the set that can isolate all faults. Which is represented by $T_I(M)$:

$$T_I(M) = \prod_{i,k=0,i\neq k}^{a} T_I(m_i, m_k) = \prod_{i,k=0,i\neq k}^{a} \left\{ \sum_{j=1}^{b} \left[(h_{ij} \bullet h_{kj}) t_j \right] \right\} \quad (4)$$

However, With the fault modes and the quantity of the test points increasing, T_D is not the only one, which causes that the global test point set is not the only one, $T = \{T_1, T_2, \cdots T_n\}$. Therefore, it is necessary to optimize the test point sets.

2.1.2 The optimization of the test point set in the Standard that the number of the fault test points is the least

First, construct the incidence matrix in accordance with the relationship between fault and the test points:

$$M'T_{a\times b} = \begin{matrix} & t_1 \quad t_2 \quad \dots \quad t_b \\ \begin{matrix} m_1 \\ m_2 \\ \dots \\ m_a \end{matrix} & \left\{ \begin{matrix} h_{11}, h_{12}, \cdots\cdots h_{1b} \\ h_{21}, h_{22}, \cdots\cdots h_{2b} \\ \cdots\cdots\cdots\cdots\cdots\cdots \\ h_{a1}, h_{a2}, \cdots\cdots h_{ab} \end{matrix} \right\} \end{matrix} \quad (5)$$

This matrix is Boolean matrix, $M' = \{m_1, m_2, \cdots m_a\}$ represents the faults set. $T = \{t_1, t_2, \cdots t_b\}$ represents the primary test point. The matrix element h_{ij} represents the correlation between the test point t_j and the fault mode m_i, when t_i can detect m_i, the value of h_{ij} is 1, otherwise the value of h_{ij} is 0.

Assuming that $D(m_i)$ represents the total test point sets that can test the fault m_i:

$$T_D(m_i) = \sum_{j=1}^{b} (h_{ij} \bullet t_i) \quad (6)$$

In the formula (6), $\sum$ represents the accumulation of "Logic plus". When $T_D(m_i) = 0$, there is no test point detecting the fault m_i.

Therefore, $T_D(M')$ is used to represent the test point sets that can simultaneously detect different faults:

$$T_D(M') = \prod_{i=1}^{a} T_D(m_i) \quad (7)$$

In the formula (7), $\prod$ represents the accumulation of "Logic multiply ", which can simultaneously detect different faults.

2.2 The optimization of the global test point set in the guideline that the test cost is the lowest

Each of the test point has the different amount of information, so the test efficiency will be different. At the same time, differences in the location of the test point results in the different test cost. Under the same conditions, it is easier and lower test cost to measure the output test point than the test points in the internal circuit. Therefore, this article will be further screened the best global test point set based on the test cost and the amount of information contained in the test point.

The set $C=\{c_1,\cdots,c_b\}$ represents the test cost of the test points; The failure rate of each fault mode in the circuit is represented by $P=\{p(m_0),p(m_1),\cdots,p(m_b)\}$, and $p(m_0)$ represents the rate of the circuit without fault; The global test point set of the system is $T=\{t_j \mid t_j\in T_0\}$, the test point t_j divides the fault of the system into the detect fault set M_{jp} and undetectable fault set M_{jf}. $M_{jp}=\{m_1,m_2,\cdots m_{jp}\}$， $j\geq 1$。 $M_{jf}=M-M_{jp}$ .The probabilities of detect fault set and undetectable fault set $P(M_{jp})$, $P(M_{jf})$ can be respectively got:

$$P(M_{jp})=\sum\left[1-h_{ij}\right]p(m_{jp}) \quad (8)$$

$$P(M_{jf})=1-P(M_{jp}) \quad (9)$$

The test information $L(M,t_j)$ of the test point t_j can be obtained according to information entropy theory:

$$L(M,t_j)=-\left\{P(M_{jp})Log_2P(M_{jp})+P(M_{jf})Log_2P(M_{jf})\right\} \quad (10)$$

The test efficiency of the test point t_j is α_j, which the ratio of the test information is and the test cost:

$$\alpha_j=\frac{L(M,t_j)}{c_j} \quad (11)$$

The test efficiency of the global test point set as follows:

$$A=\prod_{j=1}^{|T|}\alpha_j=\prod_{j=1}^{|T|}\left(\frac{L(M,t_j)}{c_j}\right) \quad (12)$$

The larger the value of A, the higher the test efficiency of the test point set which has the maximum value is the best global test point set.

Therefore, the flow chart of the preferred fault detection point set as shown in figure 1.

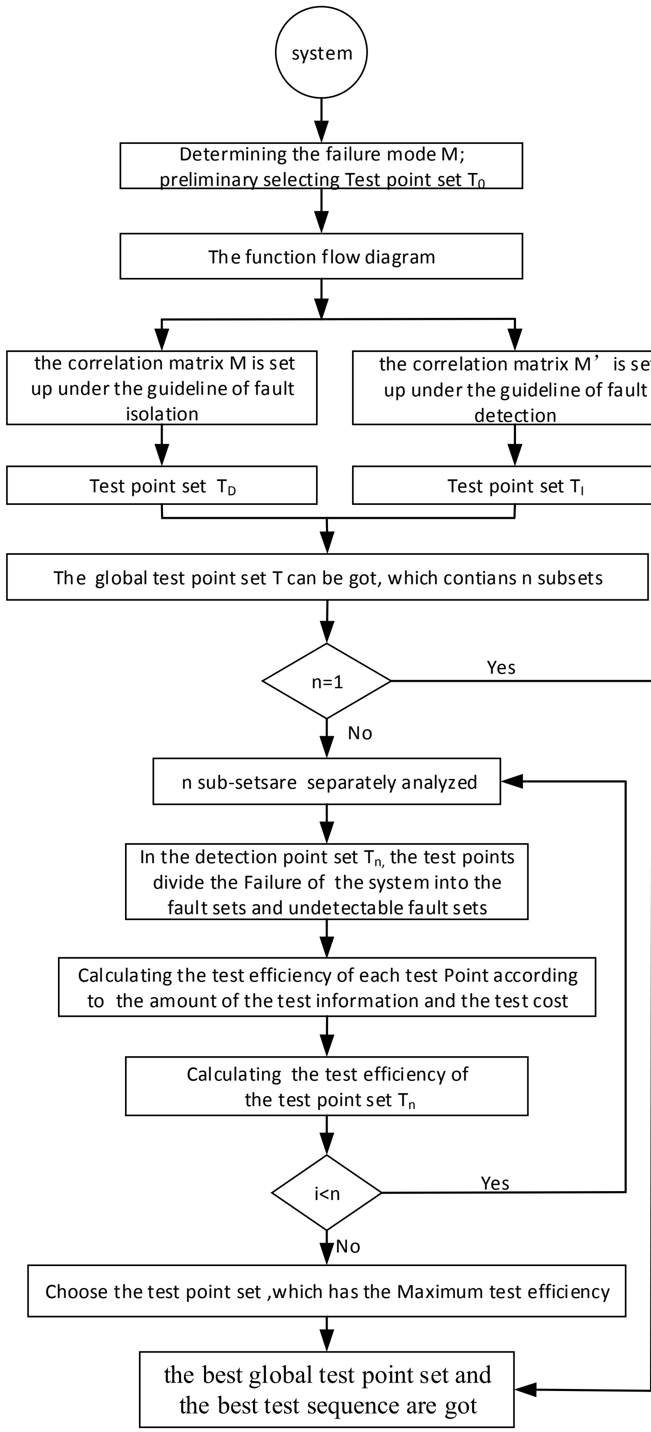

Figure 1. The flow chart of the preferred fault detection point set

3 The Optimization Of The Test Points For The Onboard Power Controller Of Maglev Train

The onboard power controller of Maglev train is referred to as "BNS, which is mainly controlling and monitoring the main vehicle power supply equipment of train. The system contains a large number of integrated circuits, and the analog circuit occupy the main part, as shown in figure 2.

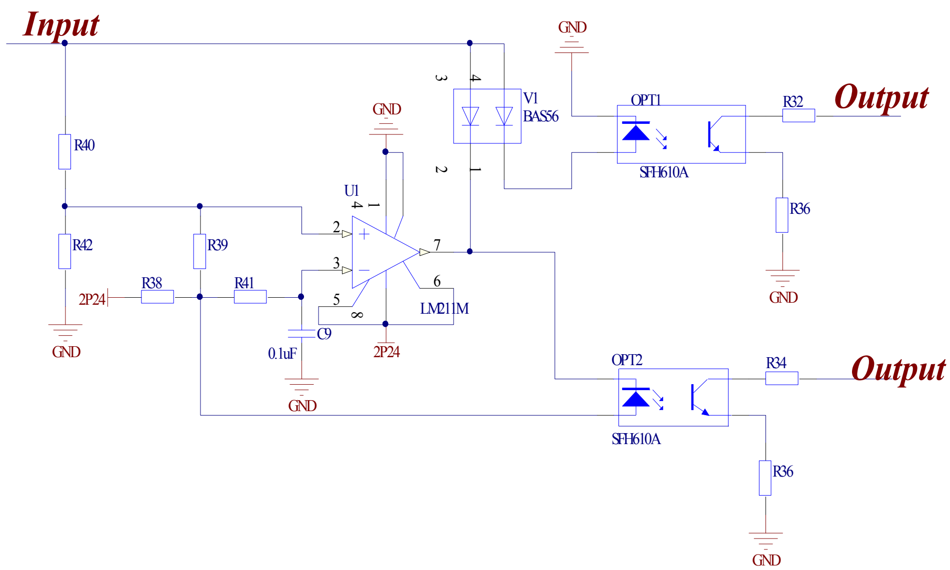

Figure 2. The analog circuit of the onboard power controller of Maglev train

There is introducing the application of the optimization method of the test point in analog circuit, where take the onboard power controller of Maglev train as an example, specific steps are as follows:

(1) The circuit is divided into five modules, as shown in figure 3.

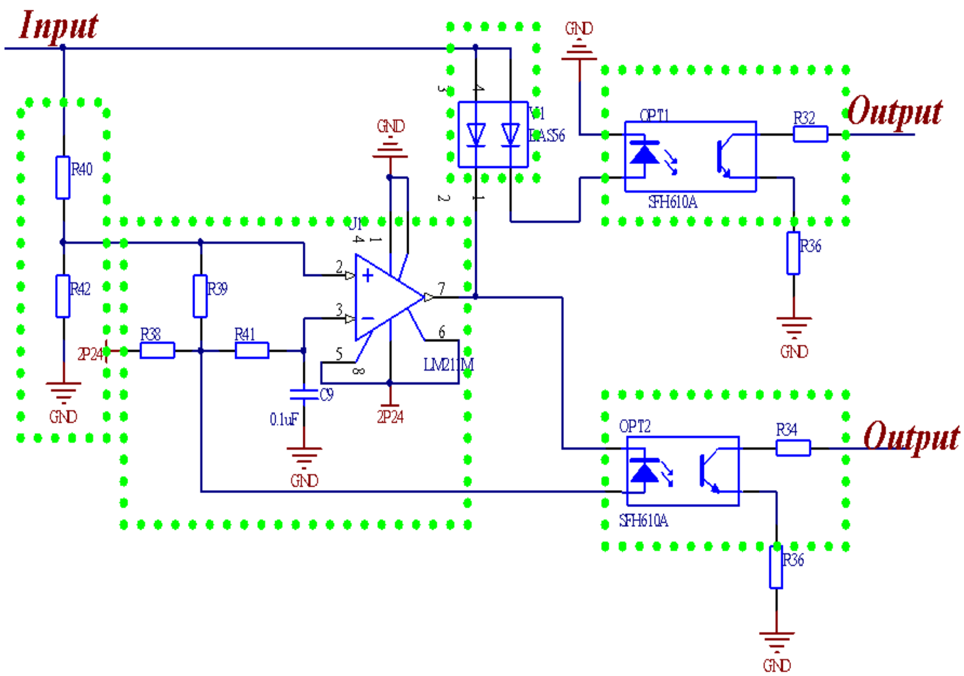

Figure 3. The partition of circuit module

(2) Drawing the function flow diagram of the analog circuit, as shown in figure 4.

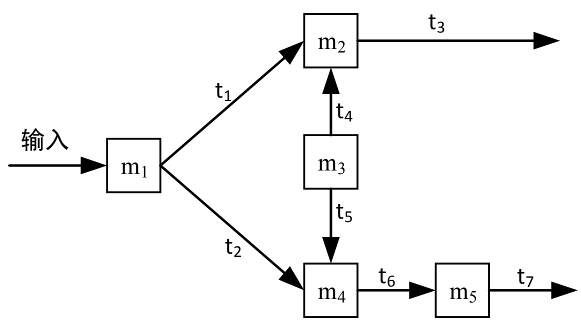

Figure 4. The function flow diagram of the onboard power controller of Maglev train

(3) According to the function flow diagram of analog circuit, the correlation matrix is set up under the guideline of fault isolation. And the corresponding test point set can be obtained according to the formula (3), (4).

$$M'T = \begin{bmatrix} & t_1 & t_2 & t_3 & t_4 & t_5 & t_6 & t_7 \\ m_0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ m_1 & 1 & 1 & 1 & 0 & 0 & 1 & 1 \\ m_2 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ m_3 & 0 & 0 & 1 & 1 & 1 & 0 & 1 \\ m_4 & 0 & 0 & 0 & 0 & 0 & 1 & 1 \\ m_5 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

$T_I(m_0, m_1) = t_1 + t_2 + t_3 + t_6 + t_7$， $T_I(m_0, m_2) = t_3$， $T_I(m_0, m_3) = t_3 + t_4 + t_5 + t_7$

$\ldots\ldots T_I(m_4, m_5) = t_6$

$$T_I(M) = \prod_{i,k=0,i\neq k}^{a} T_I(m_i, m_k) = T_I(m_0, m_1) \bullet T_I(m_0, m_2) \bullet \cdots \bullet T_I(m_4, m_5) = (t_1 + t_2 + t_3 + t_6 + t_7)(t_3)\cdots(t_6)$$

$$= t_3t_4t_6 + t_3t_4t_7 + t_3t_5t_6 + t_3t_6t_7 + t_1t_3t_4t_6 + t_1t_3t_4t_7 + t_1t_3t_5t_6 + t_1t_4t_6t_7 + t_1t_5t_6t_7 + t_2t_3t_4t_6 + t_2t_3t_5t_6 + t_2t_4t_6t_7 + t_3t_4t_5t_6$$
$$+ t_3t_4t_6t_7 + t_3t_5t_6t_7 + t_1t_2t_3t_4t_6 + t_1t_2t_3t_4t_7 + t_1t_2t_3t_5t_6 + t_1t_2t_3t_6t_7 + t_1t_2t_4t_6t_7 + t_1t_3t_4t_5t_6 + t_1t_3t_4t_6t_7 + t_1t_3t_5t_6t_7 +$$
$$t_1t_4t_5t_6t_7 + t_2t_3t_4t_5t_6 + t_2t_3t_4t_6t_7 + t_2t_3t_5t_6t_7 + t_2t_4t_5t_6t_7 + t_3t_4t_5t_6t_7 + t_1t_2t_3t_4t_5t_6 + t_1t_2t_3t_4t_6t_7 + t_1t_2t_3t_5t_6t_7 + t_1t_2t_4t_5t_6t_7$$
$$+ t_1t_3t_4t_5t_6t_7 + t_2t_3t_4t_5t_6t_7 + t_1t_2t_3t_4t_5t_6t_7$$

Therefore, when the guideline is the fault isolation, the test point set is $\{t_3t_4t_6\}$， $\{t_3t_4t_7\}$， $\{t_3t_5t_6\}$， $\{t_3t_6t_7\}$。

(4) According to the function flow diagram of analog circuit, the correlation matrix is set up under the guideline of fault detection. And the corresponding test point set can be obtained according to the formula (6), (7).

$$M'T = \begin{bmatrix} & t_1 & t_2 & t_3 & t_4 & t_5 & t_6 & t_7 \\ m_1 & 1 & 1 & 1 & 0 & 0 & 1 & 1 \\ m_2 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ m_3 & 0 & 0 & 1 & 1 & 1 & 0 & 1 \\ m_4 & 0 & 0 & 0 & 0 & 0 & 1 & 1 \\ m_5 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

$T_D(m_1) = t_1 + t_2 + t_3 + t_6 + t_7$， $T_D(m_2) = t_2$， $T_D(m_3) = t_3 + t_4 + t_5 + t_7$， $T_D(m_4) = t_6 + t_7$

$T_D(m_5) = t_7$

$$T_D(M) = \prod_{i=1}^{a} T_D(m_i) = T_D(m_1) \bullet T_D(m_2) \bullet T_D(m_3) \bullet T_D(m_4) \bullet T_D(m_5)$$
$$= (t_1 + t_2 + t_3 + t_6 + t_7)(t_2)(t_3 + t_4 + t_5 + t_7)(t_6 + t_7)(t_7)$$
$$= t_3t_7 + t_1t_3t_7 + t_2t_3t_7 + t_3t_4t_7 + t_3t_5t_7 + t_3t_6t_7 + t_1t_3t_4t_7 + t_1t_3t_5t_7 + t_1t_3t_6t_7$$
$$+ t_2t_3t_4t_7 + t_2t_3t_5t_7 + t_2t_3t_6t_7 + t_3t_4t_6t_7 + t_2t_3t_4t_6t_7 + t_2t_3t_5t_6t_7$$

Therefore, when the guideline is the fault detection, the test point set is $\{t_3 t_7\}$ 。

(5)The best global test point set can be got by the formula (1),which is $\{t_3,t_4,t_7\}$, $\{t_3,t_6,t_7\}$.

(6) According to the test efficiency, the global test point set t can be optimized, and the best test point set can be got, as well as the test sequence can be determined.

For the test point set $\{t_3,t_4,t_7\}$, the failure mode is divided into pass subsets and failure subsets, "P" is said that the detection pass, "F" said the test is failed. As shown in figure 5.

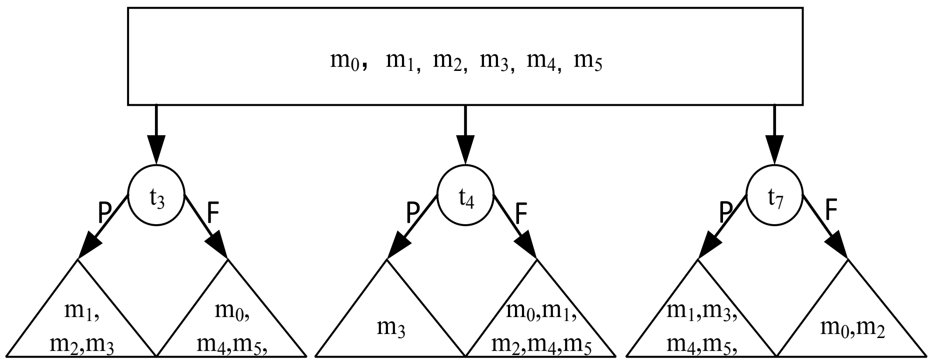

Figure 5. The classification figure 1 of failure mode

There are assumes that the normal probability of the circuit is 0.8, the failure probability is 0.2, five kinds of fault state probability is same, which is 0.04; because t_3 and t_7 are the output test point, which facilitates testing, so There are assumes that the testing cost of the test point t_3 , t_7 is 1, the testing cost of others is 2. The detection efficiency of each testing point can be got by the formula (8), (9), (10), (11), (12), the results are shown in table 1.

Table 1.The detection efficiency of each testing point in the test point set $\{t_3,t_4,t_7\}$

project	t_3	t_4	t_7
M_{jp}	$\{m_1,m_2,m_3\}$	$\{m_3\}$	$\{m_1,m_3,m_4,m_5\}$
$P(M_{jp})$	0.12	0.04	0.16
M_{jf}	$\{m_0,m_4,m_5\}$	$\{m_0,m_1,m_2,m_4,m_5\}$	$\{m_0,m_2\}$
$P(M_{jf})$	0.88	0.96	0.84
$L(M,t_j)$	0.5294	0.2423	0.6343
c_j	1	2	1

$\alpha_j = \dfrac{L(M,t_j)}{c_j}$	0.5294	0.1212	0.6343
$A = \prod_{j=1}^{\vert T\vert} \alpha_j$	0.0407		

In the test point set $\{t_3, t_6, t_7\}$, figure 6 shows the classification figure of the failure mode, table 2 shows the detection efficiency of each testing point in the test point set.

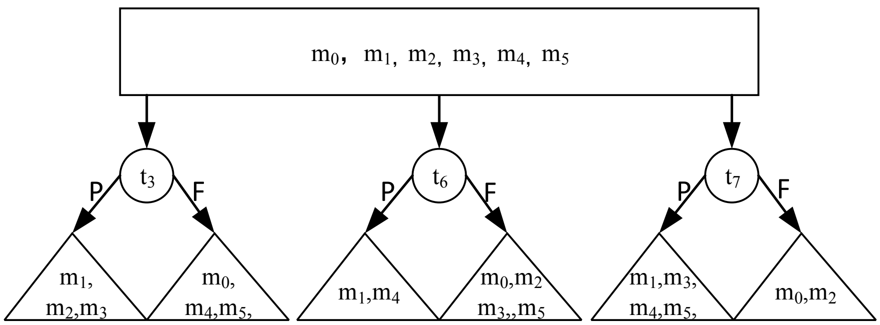

Figure 6. The classification figure 2 of failure mode

Table 2.The detection efficiency of each testing point in the test point set $\{t_3, t_6, t_7\}$

project	t_3	t_6	t_7
M_{jp}	$\{m_1, m_2, m_3\}$	$\{m_1, m_4\}$	$\{m_1, m_3, m_4, m_5\}$
$P(M_{jp})$	0.12	0.08	0.16
M_{jf}	$\{m_0, m_4, m_5\}$	$\{m_0, m_2, m_3, m_5\}$	$\{m_0, m_2\}$
$P(M_{jf})$	0.88	0.92	0.84
$L(M,t_j)$	0.5294	0.4022	0.6343
c_j	1	2	1
$\alpha_j = \dfrac{L(M,t_j)}{c_j}$	0.5294	0.2011	0.6343
$A = \prod_{j=1}^{\vert T\vert} \alpha_j$	0.0675		

Because $A\big|_{\{t_3,t_6,t_7\}} > A\big|_{\{t_3,t_4,t_7\}}$, the best global test point set is $\{t_3, t_6, t_7\}$.

In the best set of the global testing point $\{t_3, t_6, t_7\}$, $\alpha_j\big|_{t_7} > \alpha_j\big|_{t_3} > \alpha_j\big|_{t_6}$, so the best test sequence is t_3, t_6, t_7. As shown in figure7.

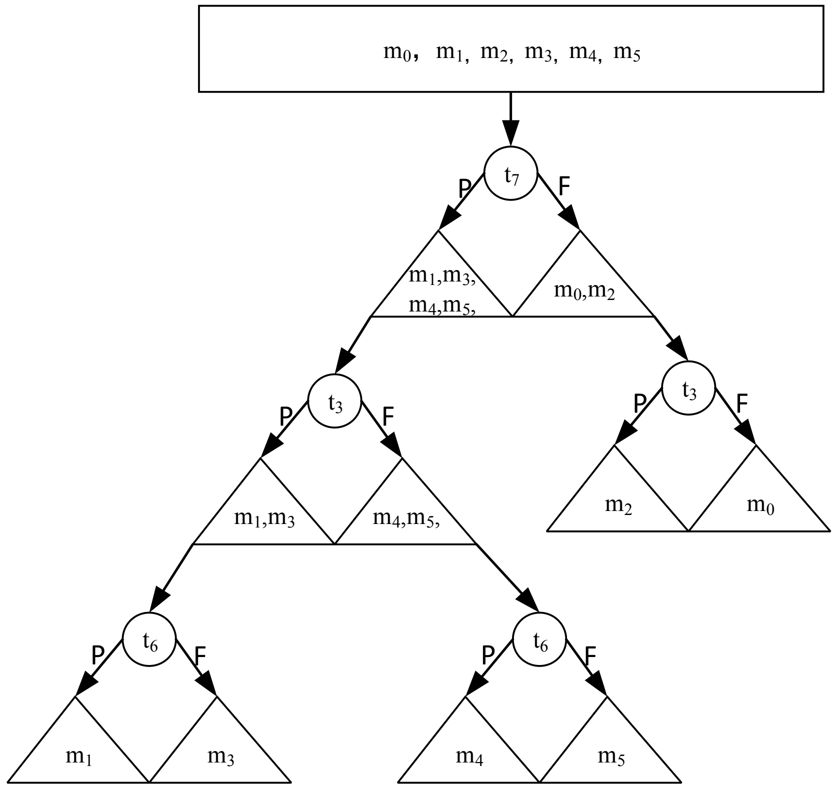

Figure 7. The best test sequence

4 Conclusions

Here we may draw the following conclusions.

(1) The method of selecting test point makes full use of the test cost and failure probability information without exhaustive all fault diagnosis tree, which makes the algorithm simple, fast, and reduces the amount of calculation;

(2) The related model of the strategy takes the test cost of each test point into account, which is more accord with the actual system;

(3) The instance shows that the strategy is effective and can be applied to fault detection of analog circuits.

5 Recommendations For Future Research

In this paper, the method of selecting test point requires the users draw the function flow diagram of the system according to the composition module and information flow of the system. And when the number of the test units is large, there are large amount of calculation, and needs to further selecting test point of complex systems test points.

Abstract: This paper investigates the location-routing problem arising in the context of hazardous waste (HW) management. The problem is to identify the location of recycling center, treatment center and disposal center, and determine the allocation and route plan of HW and waste residue. By incorporating various operational and capacity constraints, especially the link risk tolerance capacity constraints, we formulate the problem as a multi-objective mixed integer linear programming model to minimize the total cost and the total risk simultaneously. An augmented ε-constraint algorithm is customized to approximate the non-dominated frontier to the problem. Finally, a realistic example is used to test the proposed approach. Computational results show that the augmented ε-constraint algorithm is a suitable multi-objective optimization approach to handle the problem.
Keywords: HW management; Location-routing problem; Multi-objective optimization; Augmented ε-constraint approach; Non-dominated solution.

1 Introduction

Hazardous waste (HW) is the waste material which is corrosive, toxic, flammable, reactive or infectious and so on. With the advancement of China's industrialization process, a large amount of HW is produced nowadays. Compared with the conventional waste, the biggest feature of HW is that it is dangerous, if not properly managed; it may be harmful to the ecological environment and human health, and even to the sustainable of economic development. HW management including collection, transportation, recovery, treatment and disposal, and complex decision-making is needed in all process, and all parts together affect the quality and safety of the HW management. This paper discusses the management of hazardous waste location-routing problem (HWLRP), its decision-making process is shown in Figure 1.

HWLRP is a difficult multi-objective combinatorial optimization problem. In the recent twenty-five years, the academic societies conducted a lot of research works for solving this problem. Zografos first proposed the location-routing problem for a single type of HW (Zografos, 1989), the author constructed a multi-objective optimization model which minimizes the risk and time at the same time, and designed a goal programming algorithm. After that, many papers studied a similar problem, and their differences are the location centers, risk assessment methods and multi-objective optimization algorithms. Discussing about the algorithms, Revelle designed a linear weighted sum algorithm (Revelle, 1991), while Giannikos chose a goal programming algorithm (Giannikos, 1998). List first studied the location-routing problem for many types of hazardous materials/wastes (List, 1991), the author built a multi-objective optimization model which contained cost, risk and risk equity objectives at the same time, and presented a linear weighted sum algorithm. After that, Alidi discussed a similar problem, and developed a goal programming algorithm (Alidi, 1992). Alumur first took into account the compatibility constraint between the HW and the treatment technology, and he solved this model with a linear weighted sum algorithm (Alumur, 2007). Shuai extended the cost and risk objectives and built a new multi-objective optimization model by taking recycling center location problem into the decision-making process, and then designed a TOPSIS algorithm to solve the model (Shuai Bin, 2011). Recently, Samanlioglu built the most comprehensive model that encompassed the recycling center, treatment center and disposal center location at the same time, as well as the allocation plan of the wastes and waste residues to the corresponding centers. The author designed a lexicographic weighted Tchebycheff algorithm to solve the model (Samanlioglu, 2013).

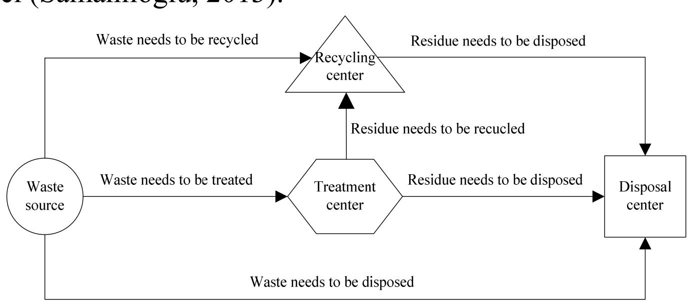

Figure 1. Process of HW management

In summary, the methods of the existing literatures have the following two drawbacks. On the one hand, no literature has considered the link capacity in their approach. On the other hand, HWLRP is a mixed integer multi-objective programming problem, the linear weighted sum algorithm that the existing literatures commonly used is affected severely by the weighting factor, and it is possible to return weakly non-dominated solutions. Therefore, this paper studies multi-objective optimization model and algorithm for HWLRP. On the basis of fully analyzing HW management processes, we build a new multi-objective mixed integer linear programming model which minimizes both systematic cost and risk, and contains link capacity constraint, and then design an augmented ε-constraint approach for the model. Finally, we use an example to test the ability of the proposed algorithm.

2 Model Formulation

2.1 Problem Description

This paper mainly answers the following questions: (1) where to locate HW recycling centers; (2) where to locate HW treatment centers, and what treatment technology to use; (3) where to locate HW disposal centers; (4) how to distribute and transport the recyclable HW (and HW needs to be treated and disposed) among the recycling centers (treatment centers and disposal centers); (5) how to distribute and transport the recyclable residues (and residues need to be disposed) among the recycling centers (and disposal centers); (6) how to distribute and transport the residues which need to be disposed among the recycling centers.

2.2 Model Assumption

Our model is based on the following assumptions:

(1) The research area could be described as a transportation network consisting of nodes and links; (2) transportation cost is linearly related to distance, and location and operation costs are respectively unrelated and linearly related to process amount; (3) transportation risk and location risk are respectively linearly related to transportation amount; and process amount;; (4) a type of HW is compatible with at least one kind of treatment technology; (5) The detail transportation, recycling, treatment and disposal processes of HW and waste residues are not considered.

2.3 Optimization model

The following notations are used in our model.

Sets:

$N(V,E)$: HW transportation network，where V is the set of nodes, and E is the set of links.

$R \subseteq V$,$T \subseteq V$ and $D \subseteq V$: set of candidate recycling centers, treatment centers and disposal centers, indexed by r , t and d ,respectively.

$O \subseteq V$: set of other kinds of nodes.

L : set of treatment technologies, indexed by l .

W : set of the kinds of HWs, indexed by w .

H : set of HWs, indexed by h .

Parameters:

$c_{\text{HR},ij}$ ($r_{\text{HR},ij}$): unit transportation cost (risk) of transporting recyclable HW using link $(i,j) \in E$.

$c_{\text{HT},wij}$ ($r_{\text{HT},wij}$): unit transportation cost (risk) of transporting HW $w \in W$ which needs to be treated using link $(i,j) \in E$.

$c_{\text{HD},ij}$ ($r_{\text{HD},ij}$): unit transportation cost (risk) of transporting HW which needs to be disposed using link $(i,j) \in E$.

$c_{\mathrm{TR},ij}$ ($r_{\mathrm{TR},ij}$): unit transportation cost (risk) of transporting recyclable waste residue from treatment center using link $(i,j)\in E$.

$c_{\mathrm{TD},ij}$ ($r_{\mathrm{TD},ij}$): unit transportation cost (risk) of transporting waste residue which needs to be disposed from treatment center using link $(i,j)\in E$.

$c_{\mathrm{RD},ij}$ ($r_{\mathrm{RD},ij}$): unit transportation cost (risk) of transporting waste residue which needs to be disposed from recycling center using link $(i,j)\in E$.

$f_{\mathrm{R},r}$ ($v_{\mathrm{R},r}$): fixed cost (variable cost) of operating a recycling center at node $r\in R$.

$f_{\mathrm{T},tl}$ ($v_{\mathrm{T},tl}$): fixed cost (variable cost) of operating a treatment center at node $t\in T$ using technology $l\in L$.

$f_{\mathrm{D},d}$ ($v_{\mathrm{D},d}$): fixed cost (variable cost) of operating a disposal center at node $d\in D$.

$s_{\mathrm{R},r}$ ($s_{\mathrm{D},d}$): location risk of operating a recycling (disposal) center at node $r\in R$ ($d\in D$).

$s_{\mathrm{T},tl}$: location risk of operating a treatment center at node $t\in T$ with technology $l\in L$.

o_h , τ_h , q_h : origin node, type and volume of HW $h\in H$.

α_h (β_h , γ_h): percentage of the part needs to be recycled (treated, disposed) of HW $h\in H$.

η_{lw}: percentage of mass variation of HW type $w\in W$ after being treated using technology $l\in L$.

κ_{lw} (σ_{lw}): percentage of the part needs to be recycled (disposed) of HW type $w\in W$ after being treated using technology $l\in L$.

δ_{lw} : 0-1 parameter, if HW type $w\in W$ could be treated using technology $l\in L$, $\delta_{lw}=1$, otherwise, $\delta_{lw}=0$.

λ_r : average recycling proportion of recyclable HW and waste residue at recycling center $r\in R$.

$b_{\mathrm{LR},r}$ ($b_{\mathrm{UR},r}$): minimum (maximum) recycling capacity of operating a recycling center at node $r\in R$.

$b_{\mathrm{LT},tl}$ ($b_{\mathrm{UT},tl}$): minimum (maximum) treatment capacity of operating a treatment center at node $t\in T$ using technology $l\in L$.

$b_{\mathrm{LD},d}$ ($b_{\mathrm{UD},d}$): minimum (maximum) disposal capacity of operating a disposal center at node $d\in D$.

$b_{\mathrm{UE},ij}$: maximum risk allowed on link $(i,j)\in E$, which is pre-determined by the decision maker of government.

θ_{iV} : 1, if $i\in V$. 0, otherwise.

ϑ_{ij} : 1, if node $i\in V$ is the same with node $j\in V$. 0, otherwise.

Variables:

$x_{\mathrm{HR},hij}$ ($x_{\mathrm{HT},hij}$, $x_{\mathrm{HD},hij}$): amount of the part needs to be recycled (treated, disposed) of HW $h \in H$ transporting on link $(i,j) \in E$.

$x_{\mathrm{TR},tij}$ ($x_{\mathrm{TD},tij}$): amount of waste residue needs to be recycled (disposed) from treatment center $t \in T$ transporting link $(i,j) \in E$.

$x_{\mathrm{RD},rij}$: amount of waste residue needs to be disposed from recycling center $r \in R$ transporting link $(i,j) \in E$.

$y_{\mathrm{HR},hi}$: amount of the recyclable part of HW $h \in H$ recycled at node $i \in V$.

$y_{\mathrm{HT},hil}$: amount of the treatable part of HW $h \in H$ treated at node $i \in V$ using technology $l \in L$.

$y_{\mathrm{HD},hi}$: amount of the disposable part of HW $h \in H$ disposed at node $i \in V$.

$y_{\mathrm{TR},ti}$ ($y_{\mathrm{TD},ti}$): amount of recyclable (disposable) part of waste residue from treatment center $t \in T$ recycled (disposed) at node $i \in V$.

$y_{\mathrm{RD},ri}$: amount of disposable part of waste residue from recycling center $r \in R$ disposed at node $i \in V$.

$y_{\mathrm{R},r}$: total amount of waste recycled at recycling center $r \in R$.

$y_{\mathrm{T},tlw}$: total amount of waste of HW type $w \in W$ treated at treatment center $t \in T$ using technology $l \in L$.

$y_{\mathrm{T},tl}$: total amount of waste treated at treatment center $t \in T$ using technology $l \in L$.

$y_{\mathrm{D},d}$: total amount of waste residual disposed at disposal center $d \in D$.

$z_{\mathrm{R},r}$: 0-1 variable, if a recycling center is operated at node $r \in R$, $z_{\mathrm{R},r}=1$, otherwise, $z_{\mathrm{R},r}=0$.

$z_{\mathrm{T},tl}$: 0-1 variable, if a treatment center using technology $l \in L$ is operated at node $t \in T$, $z_{\mathrm{T},tl}=1$, otherwise $z_{\mathrm{T},tl}=0$.

$z_{\mathrm{D},d}$: 0-1 variable, if a disposal center is operated at node $d \in D$, $z_{\mathrm{D},d}=1$, otherwise, $z_{\mathrm{D},d}=0$.

Using the notations, HWLRP can be formulated as the following multi-objective mathematical optimization model [P]:

$$\begin{aligned}\min z_1 = &\sum_{h\in H}\sum_{(i,j)\in E} c_{\mathrm{HR},ij} x_{\mathrm{HR},hij} + \sum_{h\in H}\sum_{(i,j)\in E} c_{\mathrm{HT},\tau_h ij} x_{\mathrm{HT},hij} + \sum_{h\in H}\sum_{(i,j)\in E} c_{\mathrm{HD},ij} x_{\mathrm{HD},hij} \\ &+\sum_{t\in T}\sum_{(i,j)\in E} c_{\mathrm{TR},ij} x_{\mathrm{TR},tij} + \sum_{t\in T}\sum_{(i,j)\in E} c_{\mathrm{TD},ij} x_{\mathrm{TD},tij} + \sum_{r\in R}\sum_{(i,j)\in E} c_{\mathrm{RD},ij} x_{\mathrm{RD},rij} \\ &+\sum_{r\in R}\left(f_{\mathrm{R},r} z_{\mathrm{R},r} + v_{\mathrm{R},r} y_{\mathrm{R},r}\right) + \sum_{t\in T}\sum_{l\in L}\left(f_{\mathrm{T},tl} z_{\mathrm{T},tl} + v_{\mathrm{T},tl} y_{\mathrm{T},tl}\right) \\ &+\sum_{d\in D}\left(f_{\mathrm{D},d} z_{\mathrm{D},d} + v_{\mathrm{D},d} y_{\mathrm{D},d}\right)\end{aligned} \tag{1}$$

$$\begin{aligned}\min z_2 = &\sum_{h\in H}\sum_{(i,j)\in E} r_{\mathrm{HR},ij}x_{\mathrm{HR},hij} + \sum_{h\in H}\sum_{(i,j)\in E} r_{\mathrm{HT},\tau_h ij}x_{\mathrm{HT},hij} + \sum_{h\in H}\sum_{(i,j)\in E} r_{\mathrm{HD},ij}x_{\mathrm{HD},hij} \\ &+\sum_{t\in T}\sum_{(i,j)\in E} r_{\mathrm{TR},ij}x_{\mathrm{TR},tij} + \sum_{t\in T}\sum_{(i,j)\in E} r_{\mathrm{TD},ij}x_{\mathrm{TD},tij} + \sum_{r\in R}\sum_{(i,j)\in E} r_{\mathrm{RD},ij}x_{\mathrm{RD},rij} \\ &+\sum_{r\in R} s_{\mathrm{R},r}y_{\mathrm{R},r} + \sum_{t\in T}\sum_{l\in L} s_{\mathrm{T},tl}y_{\mathrm{T},tl} + \sum_{d\in D} s_{\mathrm{D},d}y_{\mathrm{D},d}\end{aligned} \quad (2)$$

s.t.

$$\sum_{r\in R} y_{\mathrm{HR},hr} = \alpha_h q_h \quad \forall h\in H \quad (3)$$

$$\sum_{(i,j)\in E} x_{\mathrm{HR},hij} - \sum_{(j,i)\in E} x_{\mathrm{HR},hji} + \theta_{iR} y_{\mathrm{HR},hi} = \vartheta_{i,o_h}\alpha_h q_h \quad \forall h\in H, i\in V \quad (4)$$

$$\sum_{h\in H} y_{\mathrm{HD},hd} + \sum_{t\in T} y_{\mathrm{TD},td} + \sum_{r\in R} y_{\mathrm{RD},rd} = y_{\mathrm{D},d} \quad \forall d\in D \quad (18)$$

$$b_{\mathrm{LR},r}z_{\mathrm{R},r} \le y_{\mathrm{R},r} \le b_{\mathrm{UR},r}z_{\mathrm{R},r} \quad \forall r\in R \quad (19)$$

$$b_{\mathrm{LT},tl}z_{\mathrm{T},tl} \le y_{\mathrm{T},tl} \le b_{\mathrm{UT},tl}z_{\mathrm{T},tl} \quad \forall t\in T, l\in L \quad (20)$$

$$b_{\mathrm{LD},d}z_{\mathrm{D},d} \le y_{\mathrm{D},d} \le b_{\mathrm{UD},d}z_{\mathrm{D},d} \quad \forall d\in D \quad (21)$$

$$\sum_{h\in H} r_{\text{HR},ij} x_{\text{HR},hij} + \sum_{h\in H} r_{\text{HT},\tau_h ij} x_{\text{HT},hij} + \sum_{h\in H} r_{\text{HD},ij} x_{\text{HD},hij} + \sum_{t\in T} r_{\text{TR},ij} x_{\text{TR},tij} + \sum_{t\in T} r_{\text{TD},ij} x_{\text{TD},tij} + \sum_{r\in R} r_{\text{RD},ij} x_{\text{RD},rij} \le b_{\text{UE},ij} \quad \forall (i,j)\in E \tag{22}$$

$$y_{\text{HT},htl} \le b_{\text{UT},tl}\delta_{l\tau_h} \quad \forall h\in H, t\in T, l\in L \tag{23}$$

$$y_{\text{T},tlw} \le b_{\text{UT},tl}\delta_{lw} \quad \forall t\in T, l\in L, w\in W \tag{24}$$

In model [P], formulas (1) and (2) are the objectives, minimizing the systematic cost and the systematic risk, respectively. In formula (1), the first three items represent the transportation cost of recyclable, treatable and disposable of HWs from their origins to recycling centers, treatment centers and disposal centers, respectively. The fourth and fifth items correspond to the transportation cost of recyclable and disposable waste residuals from treatment centers to recycling center and disposal centers, respectively. The sixth item is the transportation cost of disposal waste residuals from recycling centers to disposal centers. The seventh to ninth items describe the fixed location cost and variable operating cost of recycling centers, treatment centers and disposal centers, respectively. The systematic risk in formula (2) could be understood following formula (1), but the only difference is location risks in the seventh to ninth items are only related with process amount.

Formulas (3) to (30) are the constraints. Specifically, constraints (3) and (4) represent the volume allocation requirement of the recyclable part of HWs among recycling centers and the associated flow conservation constraints in the transportation network. Similarly, constraints (5) to (8) specify the volume allocation and the flow conservation requirements of the treatable part and the disposable part of HWs, respectively. Constraint (9) determines the amount of HWs treated per technology and per type at treatment centers, while constraint (10) aggregates this amount of HWs per technology. Constraints (11) to (14) are the volume allocation and the flow conservation requirements of waste residuals from treatment centers, and Constraints (15) to (17) are those of waste residuals from recycling centers. Constraint (18) determines the amount of waste residuals coming from the HW origins, treatment centers and recycling centers disposed at disposal centers. Constraints (19) to (21) ensure the minimum and maximum capacity requirements of recycling centers, treatment centers and disposal centers, respectively. Constraint (22) guarantees the risk tolerance capacity of each link in the transportation network. Constraints (23) and (24) are the compatibility constraints between HWs and treatment technologies.

3 Augmented ε-Constraint Algorithm

It is not difficult to prove HWLRP is a NP-hard problem. Fortunately, the proposed model [P] is a multi-objective mixed integer linear programming model, and HWLRP is a tactical problem, it is often not sensitive to the solution time. Hence, we customize the augmented ε-constraint algorithm, a state-of-the-art multi-objective integer programming approach, to solve this problem efficiently.

In order to facilitate the description of the algorithm, we simplify the HWLRP as $\min z(x)=\{z_1(x),z_2(x)\}$ s.t. $x\in X$, where $z_1(x)$ and $z_2(x)$ represent the cost objective (1) and risk objective (2) respectively, and the feasible region X is composed of formulas (3) to (24). Firstly, normalization method are used to eliminate the dimension of objective such as $\overline{z}_i(x)=\left(z_i(x)-z_i^{\min}\right)/\left(z_i^{\max}-z_i^{\min}\right)$, $\forall i=1,2$. Suppose x_1 and x_2 be the optimal solution of minimizing only cost objective $z_1(x)$ and risk objective $z_2(x)$ of the original problem, respectively. Let $z_1^{\min}$ and $z_2^{\min}$ be the minimum value of cost objective $z_1(x)$ and risk objective $z_2(x)$, respectively, $z^{\min}=\left(z_1^{\min},z_2^{\min}\right)$ is named as ideal point, obviously, we have $z_1^{\min}=z_1(x_1)$, $z_2^{\min}=z_2(x_2)$. Let $z_1^{\max}$ and $z_2^{\max}$ be the maximum value of cost objective $z_1(x)$ and risk objective $z_2(x)$, respectively, $z^{\min}=\left(z_1^{\min},z_2^{\min}\right)$ is known as nadir point. There are many methods to determine the nadir point. In this paper, we use a method based on lexicographical order, namely:

$$\begin{cases} z_1^{\max}=\min z_1(x) \text{ s.t. } z_2(x)=z_2^{\min}, x\in X \\ z_2^{\max}=\min z_2(x) \text{ s.t. } z_1(x)=z_1^{\min}, x\in X \end{cases} \tag{25}$$

Now we discuss the augmented ε-constraint algorithm(Mavrotas, 2013). For the original problem, suppose i_2 and r_2 be the iteration number and the varying range of risk objective, where $r_2=z_2^{\max}-z_2^{\min}$. Let g_2 and e_2 be the equalized interval number and the current constraint level of risk objective. Initialize $i_2=1$, and set the constraint level $e_2=z_2^{\max}-i_2\,r_2/g_2$ at the current iteration number i_2. Introduce slack variable $s_2\geq 0$ of risk objective, the non-dominated solution of the original problem can be searched by solving the following model:

$$\begin{aligned} &\min \overline{z}=z_1(x)+\delta s_2/r_2 \\ &\text{s.t.}\begin{cases} z_2(x)+s_2=e_2 \\ s_2\geq 0 \\ x\in X \end{cases} \end{aligned} \tag{26}$$

If model (26) has an optimal solution $\{x^*,s_2^*\}$, then a non-dominated solution $\left(z_1(x^*),z_2(x^*)\right)$ is obtained. Update the iteration number $i_2=i_2+1$, and algorithm continues. If there is no feasible solution, algorithm terminates.

4 Illustrated Example

The illustrated example comes from the HW management practice of Sichuan province in China. Assume administrative cities are the source nodes of HWs, and they are also the candidate points of recycling centers, treatment centers and disposal centers. Let HWs could only be transported by highway, national or provincial road. A HW transportation network of Sichuan province containing 44 nodes and 164 links are constructed as shown in Figure 2, where nodes 1~21 are administrative cities, and other nodes are road intersections. Due to the length limitation of the paper, other parameter settings are not explained in detail.

The proposed algorithm is coded by MATLAB 8.0, and CPLEX 12.5 is used as the underlying optimization solver. All experiments are executed on a PC with Intel Core i5-2400 3.10GHz and RAM 8.00 GB.

For the test example, the solution procedures are as follows. Firstly, ideal point is obtained as (586732547.7, 240752.7) by minimizing the cost objective and the risk objective, respectively. Based on this result, using the lexicographic order method explained above, nadir point is solved as (673215755.1, 307891.5). Then, the augmented ε-constraint algorithm (AECA) is implemented where parameter δ is set as 10^{-3}. The non-dominated frontier with 11 non-dominated solutions is shown in Figure 3. As can be seen from figure 3, all 11 non-dominated solutions are distinguished with each other and uniformly distributed in the frontier, demonstrating AECA is an efficient algorithm to the multi-objective HWLRP.

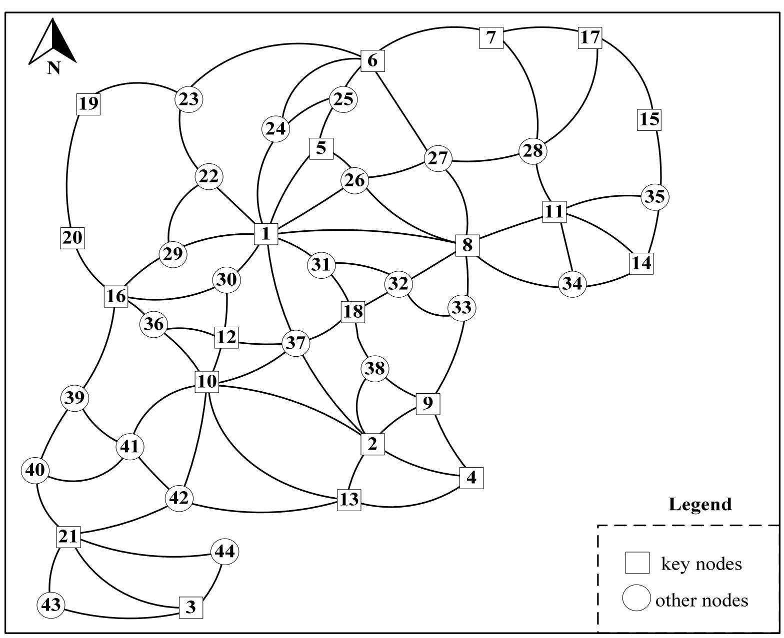

Figure 2. Test HW network

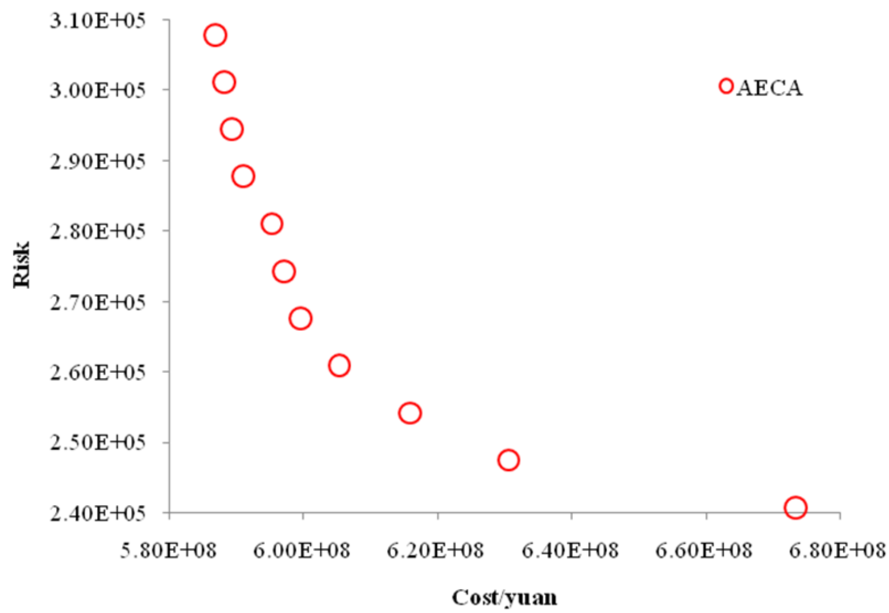

Figure 3. Non-dominated frontier of the test example

5 Conclusions

Location-routing problem is one of the key issues of HW management process, and the nature of the problem is a multi-objective optimization problem. In this paper, we first formulate the original problem as a multi-objective mixed integer linear programming model to minimize cost and risk simultaneously. The structure of the model is compact, and if only one objective exists, the model can be used to solve large-scale practical problems directly using commercial optimization software. In order to find effective non-dominated frontier, a state-of-the-art multi-objective integer programming algorithm, namely augmented ε-constraint algorithm, is customized. Finally, computational tests on a large-scale realistic example show that the augmented ε-constraint algorithm is suitable for solving the multi-objective HWLRP. The algorithm not only can ensure the uniform distribution of non-dominated solutions, but also avoid redundant computations effectively.

Abstract: In order to understand the level of carbon emissions of a port, a calculation model is constructed on the basis of fuel consumption, electricity consumption and consumption of ship activities, and this model has been applied to the estimation of carbon-emission of Ningbo Port. Results show that CO_2 emissions of Ningbo Port have increased by 144 percent from 2005 to 2013. Besides, carbon emissions from ship activities account for more than 50 percent and are still on the rise. Meanwhile CO_2 emissions of electricity and fuel consumption of Ningbo Port are 30 percent and 14 percent respectively, and they show a downward trend. Finally some countermeasures of technical innovation, fine management, regulations of legislation and cultivation of energy-saving concept, are put forward to promote low-carbon development of Ningbo Port.

Keywords: Port; Carbon emissions; Low-carbon development.

1 Introduction

Under the constraints of energy and environment, low-carbon economy is a must. According to China's “12th Five-year Plan”, energy consumption and carbon emissions per unit of GDP must be decreased by 16% and 17% respectively by 2015. In Ningbo-Zhoushan port, the top port throughout the world, large amount of energy is consumed and large amount of carbon dioxide is emitted every year. In Copenhagen meeting in December 2009, China committed to decrease greenhouse gas emissions per unit of GDP to 40%-45% in 2020 lower than that in 2005. Reducing carbon emissions of port is not only beneficial to the development of the whole economy but also conducive to sustainable development of ports. In this paper, the calculation frame of Ningbo Port is constructed for seeking the sources and the trends of carbon emissions in recent ten years, and some countermeasures of low-carbon development are put forward to promote the advancement of Ningbo Port.

2 Researches on carbon emissions

Currently there are mainly three kinds of framework document of carbon emissions. These are the Greenhouse Gas (GHG) Protocol, the Air Quality and Greenhouse Gas Toolbox, and the Carbon footprint guidance document.

Greenhouse Gas (GHG) Protocol is developed by World Resources Institute (WRI) and World Business Council on Sustainable Development (WBCSD). The global standard for how to measure, manage, and report greenhouse gas emissions is set in this document, and hundreds of companies and organizations are using GHG Protocol standards and tools to manage their emissions and become more efficient. Air Quality and Greenhouse Gas Toolbox is a tool system developed by the International Association of Ports, which raises some strategies to reduce carbon emissions and puts forward guidelines of the development of clean and low-carbon air project and climate protection program. Meanwhile, the tool system puts forward the corresponding solutions aimed at the air quality of ports, climate change and other issues. Carbon Footprint Guidance Document is developed jointly by the World Ports Climate Initiative Company and some ports, whose purpose is to provide technical guidance for those ports that commit themselves to designing their own methods to calculate carbon footprint.

The GHG protocol divides carbon emissions of enterprises into three categories, namely, the carbon emissions from production activities, power consumption and others activities of enterprise. As this model is easy to be applied to calculate the port's carbon emissions and is widely adopted throughout the world, it is adopted to construct the carbon emissions model of Ningbo Port in this paper.

3 Measure models of Ningbo Port's carbon emissions

3.1 Overview of Ningbo Port

Ningbo Port is located in Zhejiang Province, and is one of China's important ports of collective and distributive transportation of commodities such as liquid chemical, oil, ore and containers. In 2014, cargo throughput and containers throughput of Ningbo Port respectively amount to 5.26 billion tons and 18.7 million TEUs, growing 6.2 percent and 11.5 percent compared with the data in 2013. At present Ningbo Port's cargo throughput and container throughput respectively rank the first and the fifth in the world.

Since 2005, Ningbo Port's throughput has continued to increase, meanwhile the amount of fuel consumption, power consumption and arrived ships show a rising trend. Table 1 shows the facts, as following.

Table 1.Statistics of fuel, power and ships on Ningbo Port (2005-2013)

Year	Fuel consumption (t)	Power consumption (million kw/h)	ships (unit)
2005	25502.9	12708.4	5955
2006	29186.0	14088.0	6973
2007	31183.5	15571.0	9605
2008	35163.7	15692.7	11220
2009	33897.1	17313.4	12643
2010	37253.5	22528.5	14020

3.2 Model design of the calculation of carbon emissions

3.2.1 Scope definition

This paper measures the carbon emissions of Ningbo port mainly from the following three categories:

(1) Fuel consumption of port

This category includes the consumption of gantry cranes (including door and cantilever type), the traditional rubber tired gantry cranes, forklifts and other mechanical equipment, and fuel consumption of trucks, trailers and other transportation vehicles, except the fuel consumption of ships in port.

(2) Electricity consumption of port

This part includes power consumption of tire cranes, rail cranes, quayside container cranes and other production equipments which consume electricity, such as lighting, office buildings, warehouses, container loading sites, work areas and other places. And it also includes electricity consumed in the process of machine repair, sewage treatment, ventilation, inspection car weighing, as well as electricity consumed in the daily management of port operations and other facilities. (3) Power consumption of ships

This part includes the carbon dioxide emitted from ships burning fuel to generate electricity to provide for their operation in the process of waiting or discharging in the harbor.

3.2.2 Formula of carbon emissions

(1) Carbon emissions of fuel consumption of port

$$E_F = \sum (C_{Fi} \times F_{Fi}) \quad (1)$$

In the above formula, E_F = amount of CO_2 emissions from total fuel consumption (t); C_{Fi} = i-class fuel consumption per year (t); F_{Fi} = i-class fuel emission factors（t CO_2/t）. Referring to the *2006 IPCC Guidelines for National Greenhouse Gas Inventories*, the author decides that the CO_2 emission factors of diesel and gasoline are 3.150 t.CO_2 / t and 3.045 t.CO_2 / t respectively.

(2) Carbon emissions of electrical power consumption of port

$$E_E = (C_E \times F_E) \div 1000 \tag{2}$$

In this formula, E_E = amount of CO_2 emissions from electricity consumption (t); C_E = Port in total power consumption (kw.h); F_E= CO_2 emission factor used electricity (kg CO_2/kw.h). Electricity power of Ningbo Port is mainly thermal power, and the CO_2 emission factor is 1.0523 kg CO_2 / kw. h.

(3) Carbon emissions of ship power consumption

$$E_s = (Q_s \times F_s) \div 1000 \tag{3}$$

In this formula, E_S = annual amount of CO_2 emissions from shipping activities in port (t); Q_S = annual amount of oil consumption of ships in port (L); F_S = factor of CO_2 emissions (kg CO_2 / L). According to the statistical data of Ningbo Port, the average time of ship in port is about 48h, the average tonnage is 30 thousand tons and the consumption of diesel is about 10092 liters / ship.

4 Data Analysis

4.1 Results of calculation

Overall, from 2005 to 2013, the amount of Ningbo Port's CO_2 emissions increases by 1.44 times, and the average annual growth rate reaches 11.8 percent. Meanwhile, the percentage of carbon emissions from fuel and power consumption decrease gradually in recent nine years, and the percentage from ship in port increases. See Table 2 and Figure 1 for the results.

Table 2.Amount of CO_2 emissions in Ningbo Port (2005-2013)

Year	Various sources of carbon emission						Total
	Fuel consumption of port		Electrical power consumption of port		Ship power consumption		
	Ton	Percent	Ton	Percent	Ton	Percent	Ton
2005	80334.4	21.5	133731.1	35.8	159079.0	42.6	373144.5
2006	91936.2	21.6	148248.2	34.8	186273.4	43.7	426457.8
2007	98228.2	18.9	163853.4	31.6	256583.4	49.5	518665.0

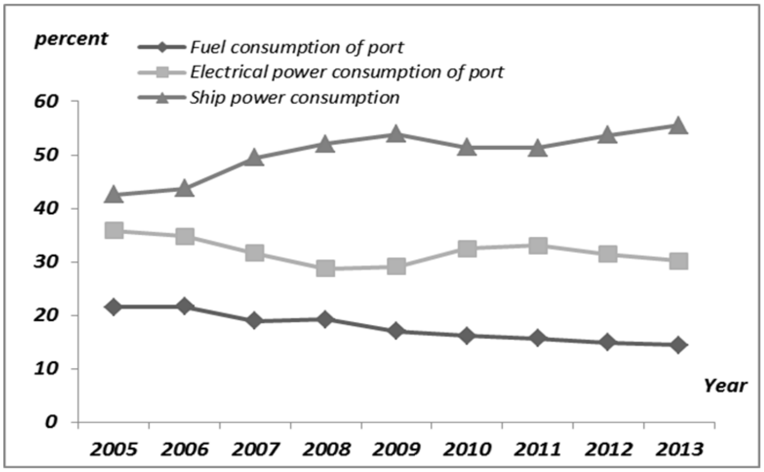

Figure 1.Trends of carbon emissions of Ningbo Port (2005-2013)

4.2 Analysis of results

(1)The proportion of fuel consumption has decreased due to promoting energy saving projects. The growth of CO_2 emissions from fuel consumption is relatively flat, and the proportion of fuel consumption has declined from 21.53 in 2005 to 14.36 in 2013, which is closely related to energy conservation and emissions reduction projects carried out in Ningbo Port. In recent years, the energy structure has been optimized by increasing the use of clean energy and gradually promoting the use of LNG trucks within Ningbo Port. Compared with conventional diesel-powered trucks, LNG trucks can be reduced by nearly 20 percent of energy cost and nearly 30 percent of CO_2 emissions. At the same time, gantry crane are powered by shore power instead of original diesel generator, hence the consumption of fossil energy is reduced. According to statistical data from Ningbo Port, the effect of these energy conservation and emission reduction projects is so significant that the port has saved the equivalents of 9,000 tons of standard coal, and has reduced 2400 tons of exhaust emissions and more than 20000 tons of CO_2 emissions.

(2)The growth speed of carbon emissions from electric power consumption has accelerated, but the proportion in total has declined. From 2005 to 2009, the increase of CO_2 emissions from electric power consumption in Ningbo Port is relatively flat and stable. But from 2009 to 2011, the increase is faster, which is mainly caused by the continuous promotion of the "Oil to Electricity" project. Through the use of cleaner electrical energy to replace fossil energy, CO_2 emissions of fossil fuel have been greatly reduced. Although the shore power consumption shows relatively fast growth, the CO_2 emissions from shore power consumption has decreased from 35.84 percent in 2005 to 14.36 percent in 2013 in total emissions.

(3)The proportion of energy consumption from vessels arriving at Ningbo Port has increased due to the growth of transport business. Over the past decade, owing to the benefits from the location advantages and the economic growth in foreign trade, the number of vessels arriving at Ningbo Port shows a sharp increase, consequently leading to a continuous growth of CO_2 emissions from arrived vesse1s. The proportion of CO_2 emissions from arrived vesse1s has also increased. From 2005 to 2013, the number of vess1s arrived at Ningbo has increased from 5955 to 18,877, in the meantime, the CO_2 emissions of arrived vess1s has increased from 160,000 tons to 500,000 tons. Although the proportion of CO_2 emissions from arrived vesse1s has slightly declined from that in 2009, it has showed a rising trend in general, that is, it has increased from 42.63 percent in 2005 to 55.47 percent in 2013.

5 Countermeasures of promoting low-carbon development of Ningbo Port

Here the author suggests the following countermeasures to reduce the amount of carbon emissions in Ningbo Port.

(1)The enterprises of port should improve the efficiency of port operations, shorten the stay time of vessels in port, and promote the use of shore power instead of ship power, so that the fuel consumption of ships will be reduced.

(2) Clean energy such as solar, wind, gas and other low-carbon energy should be developed through technical innovation. Thus the dependence on fossil energy will be reduced.

(3)Fine management of low-carbon development should be developed，in which the whole target of carbon emissions control should be broken into pieces and distributed to all the management units of the port, which should be controlled through budget. The enterprise should set up the fine management of low carbon development by dividing the whole target of carbon emissions into pieces, and control the amount of carbon emissions of management units through the budget.

(4)The authorities of government should develop standards and future legislation, and periodically evaluate the performance of enterprises’ carbon emissions, rewarding the good and punishing the bad.

(5) Working staff of enterprises should be guided to develop low-carbon awareness and energy-saving behaviors in their daily work and life. In this way the consumption of energy will be reduced and the level of carbon emission will decrease.

6 Recommendations for future research

Low-carbon development is a consensus in the whole world. The index of low-carbon must be included in evaluation of sustainability and quality of port economy. In this paper, a framework of port carbon emissions has been promoted and applied to the practice of Ningbo Port. More practical countermeasures to reduce carbon emissions need to be further proposed in future.

Risk Assessment of Water Traffic Safety on the Wuhu Section of the Yangtze River

Shiyu Zhang; Xue Min; Zhuo Li; and Yueqin Zhu

Department of Transportation Planning and Management, School of Transportation, Wuhan University of Technology, Wuhan, Hubei, China.
E-mail: 172701505@qq.com

Abstract: Systematical, reasonable and feasible water traffic safety evaluation is an important basic work to build a long-term effective mechanism of safety. In this paper, on the base of safety systems engineering, water transportation systems engineering and other theories, and traffic characteristics of Wuhu Section of the Yangtze River, we proposed a reasonable, exercisable and effective comprehensive evaluation method for water traffic risks—AREEAC, which estimates accident rates synthetically, environmental effects and accident consequences in waterways. And a comprehensive evaluation model basing on AREEAC is set up to estimate traffic risks of the busy waterways in the Yangze River apart from an empirical researching on Wuhu section of Yangze River. The researching results consistent with actual situation in general. Besides, the corresponding measures to control risks are proposed according to the results of safety risks assessment.
Keywords: Safety risk; Comprehensive evaluation; Busy waterway; The Yangze River.

1 Introduction

The trunk line of the Yangtze River has become China's largest inland shipping golden waterway. The Yangtze River water traffic safety evaluation is the foundation of the Yangtze River water traffic safety supervision, to strengthen research on traffic safety risk assessment of the Yangtze River, and to set up risk control strategy and corresponding measures, have great practical significance for the healthy development of the Yangtze River. Currently, the study on water traffic safety risk assessment at home and abroad has achieved abundant research results, derived a number of scientific, comprehensive and systematic evaluation methods, such as fault tree analysis, fuzzy mathematical analysis method, gray fuzzy theory, BP artificial neural network, FSA (ZHAO Jiani, 2005) and the like. But the strong comprehensive risk evaluation method(Fujii.Y,1974), that in view of characteristics of a busy section of the Yangtze River traffic flow, and to consider the consequences of environmental factors , the effects of the accident and strong operability is less. According to the characteristics of traffic flow and safety accident of the busy segment of Yangtze River; referring to the domestic and foreign existing research results of risk evaluation method, the article puts forward the comprehensive risk evaluation method based on accident rate, environmental factors and the consequences of the accident，three factors (referred to as AREEAC). A comprehensive evaluation model basing on AREEAC is set up and we will use it to access and analyze the traffic safety risk on Wuhu section.

2 Characteristics of Traffic Flow and Safety Accident on Wuhu

Wuhu maritime bureau covers the jurisdiction of the Five-step of Yangtze river main channel to head of the Old-continent on-line to Tzuhu river and Wujiang river, including the Yangtze trunk line of 13 main channels, 175 kilometers, 8 branch channels,157 km water areas, covering three level administrative area waters as Wuhu, Tongling, Maanshan(WANG Yuhong, 2003). The main characteristic of busy segment is large vessel traffic flow. During 2009 to 2013, daily traffic flow reached more than 1400 on Wuhu, but maintained at the average daily level of 400 on Wuhan and Threegorges. So we take Wuhu segment as typical characteristics to access and analysis the traffic safety risk in main busy segment of the Yangtze River. Combined with accident statistics of Wuhu section and the actual situation, safety accident characteristics of the Yangtze River main busy segment in 2008-2013 are as follows (LI Zhuo, 2013):

（1）From quantitative analysis of the general accident danger accidents, there is no obvious rules to follow. Except for 2001 the water traffic safety situation improved markedly, in the other five years the number of accident danger is 24 pieces or more every year. However, the number of accidents numerical rating shows a declining trend.（2）According to analyze the types of accidents, the largest, the number of ship collision accident is far higher than other types of accidents and collisions, and because of the characteristic of the collision accident, the three indicators, personnel missing death、 economic loss and wreck number caused by accidents, obviously higher than that of other types of water traffic safety accident. The second is the sink .The third category of multiple incidents is contact damage, partly because busy traffic flow of the large segment that frequent accidents section leads to the wreck more prone to loss of touch events.（3）Based on analysis of the circadian time of the accident , the night is the high incidence of accidents , especially between midnight to 6am.（4）From the point of the loss caused by accidents, With the loss of the number of accidents is declining, but the number of the death, missing people and ship wrecks as well as economic losses showed significant upward trend.（5）From the cause aspect of accidents , the crew improper operation , violation of sailing, fatigue driving, adventure sailing, manning missing, negligence lookout and other human factors and so on, these anthropogenic factors are the main causes of the danger accidents . Second factor is the ship, as the ship unseaworthy, electrical equipment aging and ship hull aging, adventure overload e and so on, all easily lead to accidents. Environment factors are the major cause leading to crew error, especially at fog navigation that seriously affecting the observed sight so extremely easy to cause the collision, rocks and g running aground accident。Moreover large traffic flow of the Yangtze River trunk busy segment and wreck accidents have caused the collision of multiple malignant events, the rocks and sank aground events occurred frequently.

3 Comprehensive Risk Assessment Model and Index System

3.1 AREEAC Assessment Model

According to the characteristics safety accidents of the Yangtze River trunk busy segment the paper proposes an integrated water traffic safety evaluation method --AREEAC. The comprehensive risk evaluation method is based on the accident probability, the environmental impact factors and consequences of accidents, the core design philosophy is calculated statistical probability of the accident the busy segment, the relative environmental harmony degree and accident consequence assessment, and then to obtain the value of a comprehensive accident risk assessment in the form of being multiplied by the three factor's value. That is, comprehensive risk evaluation of water traffic value（R_c） can be regarded as product of the accident rate（A_r）, relative environmental harmony degree（E_f）, the accident consequence assessment（A_c）.

$$R_{\mathrm{c}} = A_r \times E_f \times A_c \qquad (1)$$

Note: A_r is considered by the number of accidents and traffic flow; E_f is adjusted value by eight objective indicators of environmental factors considered; A_c is Calculated by four consequences considered. (ZHANG Shengkun, 2003)

AREEAC evaluation method has the following characteristics: （1）The AREEAC draws lessons from the domestic and foreign existing studies of water traffic safety evaluation method, and have been adjusted to make it more suitable for research of this paper. （2）The comprehensive consideration the incidence of the accident and objective environmental factors and the influence of accident consequence of water traffic safety. （3）The influence degree of each index and the evaluation standards are related to the various aspects of the topic research experts survey results. （4）The AREEAC is strong operability, suitable for practical application.

3.2 Accident Rate Evaluation and its Indicators

$$A_r(\mathrm{t}) = X(\mathrm{t})/T(t) \qquad (2)$$

In the format: $X(\mathrm{t})$--The total number of accident dangers in year t; $T(\mathrm{t})$--Traffic flow in year t; $A_{\mathrm{r}}(\mathrm{t})$--The occurrence rate of water traffic accidents in year t.

3.3 Environmental Impact Assessment and Its 1ndicators

Through objective environment and accident analysis of the Yangtze River busy segment, combined with expert opinion, eight kinds of objective danger rating of environmental factors are shown in the table (see Table 1). (HAN Yansheng, 2006)

Table 1. Risk Rating Standard of 8 Kinds of Objective Environmental Factors Danger Rating Criteria

Risk Class	5	4	3	2	1
Traffic flow (vessel/day)	>1000	750~1000	500~750	250~500	<250
Visibility (number of bad days / year)	>40	30~40	20~30	10~20	<10
Wind ((year-standard number of days)	>140	100~140	60~100	20~60	<20
Flow velocity (m/s)	>5	4~5	3~4	2~3	<2
Channel width (B0/B)	<2	2~3	3~5	5~8	>8
Curvature (steering angle)	>50	35~50	20~35	10~20	<10
Water depth (H/d)	<1.3	1.3~1.6	1.6~2.0	2.0~4.0	>4
Perfect rate of beacon Aids to navigation	<70	70~80	80~90	90~95	95~100

Note: This evaluation method selects quantity of ships a day for traffic flow evaluation index; Poor visibility is set within 2km horizon; Annual average standard wind days = (grade 4 ~ 5) the number of l average annual wind days + 1.5 * (level 6 and above) annual average wind days; The evaluation index of the channel width is channel width B0 / shipping maximum width B; Maximum angle of curvature that the ship steering required when through channel is selected as the evaluation index of Curvature; Water depth of risk evaluation indexes is H (channel)/d (ship draft); Navigation AIDS is perfect rate of beacon Aids to navigation as the evaluation standard, that is " the waters area / the whole channel waters area covered by the actual waterway navigation aids ", so as to improve the rate of 100% is denoted as 100. (HUANG Liwen, 2005; Nii Yasuo, 1992).

The risk value F_i of factor i can be regarded as the product of risk score and corresponding weight of environmental factor i, i.e.:

$$\mathrm{F}_i = F_0 \times w_t \qquad (3)$$

Adding risk value of the 8 single factors and get the objective environment risk value on the segment, i.e.:

$$F = \sum_{i=1}^{s} F_i \qquad (4)$$

Then the objective environmental risk value F of the segment /the objective environment risk value F_0 of the basis segment, get the relative environmental adjustment value E_f, i.e.:

$$E_f = F / F_0 \qquad (5)$$

3.4 The Accident Consequence Assessment and Its Indicators

Reference to the accident grading standards in “Statistics Approach of Water Traffic Accident”, as well as expert assessment, the accident consequence assssment standards are shown in the table (see Table 2). (HU Shenping, 2010)

Table 2. The Score Judgment Standard of Water Traffic Safety Accident Consequences Measure Indicators

Consequences measure indicators	Judgment standard	Score
Casualties （C）	Accident caused the death of people more than 30	1
	Accident caused the death of people from 3-30	0.8
	Accident caused the death of 1 or 2 people	0.6
	Accident caused serious injuries	0.4
	No one seriously injured in the accident	0.2
Economic loss （M）	above 100 million Yuan	1
	from 5 million to 100 million Yuan	0.8
	from 3 million to5 million Yuan	0.6
	from 500000 to3 million Yuan	0.4
	less than 500000 Yuan	0.2
Environmental pollution（E）	Widespread, long-term ecosystem destruction in the near waters	1
	Serious environment pollution	0.6
	Small scale, local environment pollution	0.3
Social influence （S）	a great influence both at home and abroad	1
	great influence in China	0.6
	Small effect	0.3

Note : If no casualties , economic loss or environmental pollution, the score is 0.

According to the project , " key security technology research on the golden waterway navigable segments of the Yangtze River " and the opinions of the experts, assessing the consequences of the accident in busy segment is based on comprehensive quantitative evaluation on casualties (C), economic losses (M), the pollution of the environment (E) and social impact (S) four indicators. So when calculating accident consequence assessment , first of all, getting the four measure indicators respectively on the basis of Table 2 ,then summing and then dividing by four we obtain the value of accident consequences , i.e.:

$$A_c = (C + M + E + S)/4 \tag{6}$$

4. Traffic Safety Risk Assessment on Wuhu Section Based on AREEAC

4.1 The Calculation of Accident Rate

This paper will use the evaluation method on Wuhu section of the busy 3 years 2011 to 2013 for traffic safety comprehensive risk evaluation of longitudinal water. First we collected traffic flow and accident data on Wuhu period of the Yangtze River from 2011 to 2013. Traffic flow: 554490 ships in 2011, 529830 ships in 2012, 518885 ships in 2013; accident data: 19 cases in 2011, 24 cases in 2012 and 30 cases in 2013.

According to the data in Table 3 and referring to the formula (2) we obtained accident rate on Wuhu segment for three years from 2011 to 2013: $A_c(2011)$=3.43; $A_c(2012)$=4.53; $A_c(2013)$=5.78 (unit :Thousand ships/year).

4.2 Calculation of Relative Environmental Adjustment Value

Getting score of 8 factors of the objective environment from the analysis of actual situation on Wuhu between 2011 to 2012, and in accordance with many experts studied of the relevant scientific project, scholars and the views of the crew, 8 the value of objective environmental factors of the Yangtze trunk busy segment statistics compiled are shown in the table (see Table3).

Table 3.Grading value and weight of objective environmental factors in the Yangtze Trunk busy part

environment all factor	traffic flow	visibil ity	wind	flow rate	course width	tortuosity	water depth	Aid to navigation
2011	5	2	3	2	1	5	4	3
2012	5	2	3	2	1	5	3	3
2013	5	3	3	2	1	5	3	3
Weight W_i	0.26	0.18	0.05	0.09	0.13	0.10	0.12	0.07

Reference formula (3), (4), (5), we calculate the relative environmental adjusted value on Wuhu for nearly 3 years 2011 to 2013: Environmental risk value (F):3.13 in 2011, 3.19 in 2012 and 3.37 in 2013. Take the objective environment risk value of 2011 as the baseline to calculate the relative environmental adjustment value (E_f):1 in 2011, 0.96 in 2011 and 1.02 in 2011.

4.3 Accident Consequence Assessment

According to the data required for this accident consequence assessment method for evaluating，then statistical sorting water traffic accident consequences detail in Wuhu section of the busy trunk line of the Yangtze River from 2011 to 2013, water traffic accident consequence assessment value calculated referring to the formula (6) of Wuhu section on the Yangtze trunk busy segment in the nearly three years are shown in the table (see Table 4).

Table 4. Water Traffic Accident Consequences Assessed Values of Wuhu Section in the Yangtze River from 2011 to 2013

Year	2011	2012	2013
Casualties C	4.6	4.2	3
Economic loss M	4.8	5.6	7
Environmental pollution E	0.3	1.5	0.3
Social influence S	5.7	8.1	9.6
The accident loss value A_c	3.85	4.85	4.93

4.4 The Analysis of Comprehensive Evaluation's Results

The above results are substituted into the formula (1) to get the water traffic comprehensive risk value on Wuhu section nearly 3 years as shown in the table (see Table 5).As can be seen from table 4, 2011 to 2013, water traffic accident risk appraisal of the busy trunk line of the Yangtze River in Wuhu section of AREFAC values were 13.21, 21.17 and 29.07. Water traffic safety situation nearly three years on Wuhu show the best in 2011, then in 2012, the worst in 2013.

Table 5. Risk Assessment of Water Traffic Based on AREFAC on Wuhu Section of the Yangtze's Busy Trunk Segment from 2011 to 2013

Year	2011	2012	2013
A_r	3.43	4.53	5.78
E_f	1	0.96	1.02
A_c	3.85	4.85	4.93
R_c	13.21	21.17	29.07

Analyzing the evaluation results, the reason is as follows:

(1)From the point of accident rates the maximum traffic flow on Wuhu section in 2011 is 554490, but the water traffic safety accidents number is 19 that at least in three years, all lead to the lowest accident rate in 2011. Traffic flow on Wuhu section in 2013 is the least the last three years, the corresponding water traffic safety accident is the most as 1.5 times the number of accidents in 2011, which all led to water traffic accidents in Wuhu section in 2013 significantly higher than the previous two years.

(2)From the analysis of relative environmental adjustment value, because the relative environmental harmony degree is mainly with large difference in the horizontal risk assessment comparison in different segment, but the relative environmental harmony degree of risk evaluation in the longitudinal in the same segment nearly 3 years has little difference so leading to small influence on the assessment results.

(3)From the analysis of accident consequence assessment in 2013, the number of accidents is largest in 2013 in Wuhu segment and four indicators of accident consequence assessment show as follow: 12 casualties just less than18 casualties in 2011, 5 sunken ships, the economic losses is as high as 630 ten thousand Yuan. All the above made the consequences of the accident to a corresponding maximum value in 2013.

From the above analysis, in combination with the status of water traffic safety supervision and management in the Yangtze River in recent years, it is not difficult to find water traffic safety management in the busy part of the Yangtze River still need to be improved in many aspects: (1)To promote technology innovation of safety navigation: The implementation building of AIS and VTS, CCTV in main busy segment, integrated use of GPS satellite positioning, electronic chart, wireless communication, radar, SMS group sending device and other scientific and technological means in order to explore and enrich the means of stereo Cruise etc. (2) Covering AIS (GPS) system in the busy segment of the Yangtze Rive, construction of the integration mechanism of electronic cruise for help, preparing plans database system, etc. that all can further improve the early warning management and emergency rescue mechanism; (3)Popularization of safety culture education can improve water traffic safety culture and we should improve navigation safety protection system.(XIONG Bing, 2011)

5 Conclusions

The AREEAC evaluation method considering the rate of accident, the consequences of objective environmental factors and the impact of the accident to the water traffic safety, the most obvious characteristics and innovation place are simple, strong operability and suitable for practical application.

While AREEAC risk evaluation method proposed in this paper has considered three aspects as the accident incidence, objective environmental factors and accident consequences and been on the quantitative processing. But the indicators of membership degree and weight given by the many are based on the expert's experience evaluation, which makes the conclusion of the evaluation is too subjective. Therefore using more objective scientific methods will be another main content of the future. That requires the government, research institutions and shipping companies and other multi persistent co-operate to ensure the water traffic's safety of the Yangtze trunk segment.

Lifeline Road Planning Method in Disaster-Prone Areas

Liang Ye and Ying Liu

Transport Planning and Research Institute, Beijing 100028, China. E-mail: yel1231@163.com

Abstract: Road system is one of important part of lifeline systems in disaster-prone areas. It is very significant to do the lifeline road planning in disaster-prone area to mitigate disaster loss and save lives. The paper borrowed ideas from developed countries about lifeline road's definition, planning methods, and planning experiences. After that, the definition of lifeline road in our country has been set. And several affect factors of lifeline road planning were found, they are: natural characteristics, type of disasters, spatial distributions, transportation system, and other lifeline system distributions. The planning object was set up to build a definite function, wide coverage, flexible and reliable, and smooth lifeline road system. According to the object, basic principles were suggested and the planning method was provided. By integrating node layout and dynamic programming with the guidance of planning objects, there are two paths to planning the lifeline road based on evaluating existing road network, the first one is to select critical links of road network, and the second one is to improve the road network structure.
Keywords: Lifeline road; Disaster-prone area; Planning method.

1 Introduction

Natural disasters such as flood, earthquake, debris flow, freezing rain and snow, occur frequently in China, which causes huge loss of life and property. Road system is one of important part of lifeline systems in disaster-prone areas. It is very significant to do the lifeline road planning in disaster-prone area to mitigate disaster loss and save lives. Till now, we do not have specific researches about lifeline road planning method in disaster-prone area. In disaster-prone area, it is not enough to repair road infrastructures after natural disasters occurred. The more important thing is to take preventive measures before natural disasters occurs. So it is necessary to operate the research on lifeline road planning method to strengthen the road network, improve the safety and reliability in disaster-prone area.

2 Literature Review

There are numbers of researches defined lifeline system in past years. Duke and Moran (1975) is one of the pioneering papers on lifeline system, which classified lifeline system as: Energy (Electricity, Gas, Liquid Fuel), Water (Potable Flood, Sewage and Solid Waste), Transportation (Highway, Railway, Airport, Harbor), and Communication (Telephone and Telegraph, Radio and Television, Mail and Press).

Hall (1991) states in his state-of-the-art report, “Within a broad definition lifelines can be defined as those utilities, facilities, structures and equipment that make up much, but not all, of the fabric of our infrastructure, whether it be in a rural or urban setting” . Platt (1995) defined transportation and communication lifelines as: among the critical networks required for moving material, people and information among locations distributed in geographic space. And Chang (2000) pointed out that “performance and recovery of transportation systems appear to play a major role in the development of long-term impacts. This arises in large part because transportation infrastructure often requires substantially lengthier repair times than other lifeline systems. ”

Some of researchers did studies on finding approaches to strengthen or improve lifeline road network. Sakakibara (2004) found that it is critical that individuals in each district have access to vital facilities in their local neighborhood so that no district is isolated. They used a topological index to quantify road network depressiveness/ concentration to evaluate the isolation of district in a city. Miller (2003) stated that many approaches have been used to measure lifeline roads' vulnerability but most can be grouped into two major categories: performance based indicators (network reliability and network performance) and user based indicators (accessibility).

Lifeline road planning is one of important part of disaster prevention in developed countries. In 1998, the American Lifelines Alliance (ALA) established to facilitate the creation, adoption and implementation of design and retrofit guidelines of lifeline system. In New Zealand, Transport Agency published the report titled *Engineering Lifelines and Transport- Should New Zealand be doing it Better?* The report examined New Zealand engineering lifelines activity, its level of integration in road controlling authority management practices, and its relationship to the resilience of roading networks to natural hazards.

3 Definition and Impact Factors of Lifeline Road

Based on definitions of previous researches, the definition of lifeline road in this paper is: critical roads with high resistance against natural disasters which connecting vital facilities inside districts and between districts.

Numbers of factors impact lifeline road planning, they are:

(1) Natural characteristics. Including topography, geology, and climate which are important impact factors of general road network planning;

(2) Type of natural disasters. It is the most important factor which impacts the demand of lifeline roads, road strengthen technologies chosen, and the location of new lifeline roads;

(3) Spatial distributions. The distribution of vital facilities such as residence districts, shopping malls, hospitals, and schools.

(4) Existing road network. Lifeline road planning should be based on existing road network by strengthen existing roads and construct new roads.

(5) Layout of railway, airport and harbors. Lifeline road planning should consider the connection of railway stations, airports and harbors. And they also impact the function of lifeline road when considering of the whole comprehensive transportation system.

(6) Layout of other lifeline systems. Lifeline road is the base and connection of other lifeline systems. Lifeline road planning should also consider the connection of energy system, communication system, water supply and drainage system, and sanitary system.

4 Objectives and principles

4.1Objectives

The planning object was to build a definite function, wide coverage, flexible and reliable, and smooth lifeline road system. Detailed objectives are:

(1) All districts in the region have at least two roads with enough capacity connecting with other regions, make no district is isolated after disaster occurred;

(2) There is at least one road with enough capacity connecting with railway stations, airports and harbors in the region;

(3) There is at least one road with enough capacity connecting with vital facilities including energy system, communication system, water supply and drainage system, and sanitary system.

4.2 Principles

(1) Consider the demand of economic and social development after fully satisfied the demand of personnel and material delivery when disasters occurred;

(2) Choose the road which could serve more people after connected basic nodes;

(3) Choose existing roads first, if there is no existing road, then build a new one;

(4) Fully consider the geography, geology and climate characteristics in disaster-prone areas, make the road construction coordinate with the environment.

5 Lifeline Road Planning Method

There are two paths to planning the lifeline road based on evaluating existing road network, the first one is to select critical links of road network, and the second one is to improve the road network structure.

The planning procedure could be summarized as following:

(1) Confirm planning area and set up planning objectives. It is the first and basic step of lifeline road planning.

(2) Collect related materials and analyze the demand. Related materials including: type, history, distribution and characteristics of natural disasters in the planning area and their impacts to roads; population, industry, and urbanization of planning area; geography, geology and climate characteristics of planning area; and the layout of vital infrastructures such as school, hospital, supply station, transportation system, urban street, metro system and pipelines.

(3) Choose connecting nodes. It is the pivotal step of lifeline road planning. Generally, we choose connecting nodes as residential areas, manufacturing districts, airports, railway stations, bus stations, harbors, energy bases, water bases, communication center, hospitals, and schools.

(4) Evaluate of existing road network about the ability of resistant disasters. The purpose of this step is to find out the pivotal roads and weakness of the road network by physical topology method. The physical topology of road network means the structure of a network, including device location and cable installation.

- The method of identifying critical links of road network. The definition of critical links of road network in the paper is: roads with high probability to make the district isolated after destroyed by disasters. There are some methods and indexes to identify pivotal roads based on previous researches such as the Mincuts Frequency Vector by Bulteau and Rubino (1997). The Mincuts Frequency Vector could compare two different topologies and point out edges make the network more vulnerable.
- The method of identifying weakness of road network. Sometimes we strengthen the road network by constructing new roads. The purpose of identifying weakness of road network is to decide which road contributes most to strengthen the network. The Topological Index (TI) proposed by Hosoya (1971) could be used to quantify road network depressiveness and compare the effect of adding a new road.

(5) Planning lifeline road. Lifeline road comes from two ways: one way is to strengthen critical roads of existing road network; the other way is to construct new roads to strengthen the whole road network. The planning procedure is shown as following:

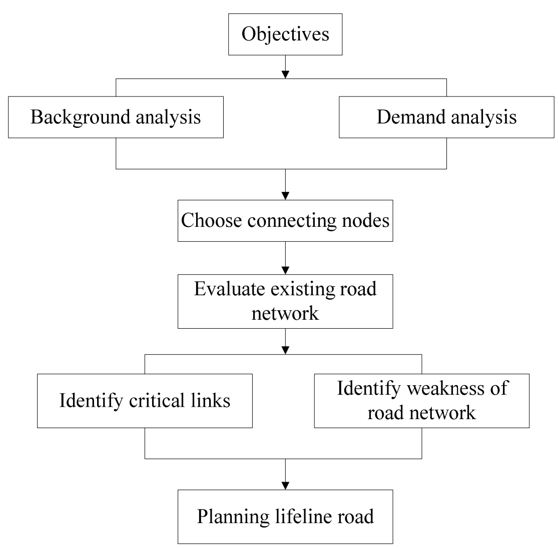

Figure 1. Lifeline road planning procedure

6 Conclusions

Lifeline road planning is more concern about connecting with critical nodes and avoiding isolated which is differing with regular road network planning. It is very significant to do the lifeline road planning in disaster-prone area to mitigate disaster loss and save lives. The paper borrowed ideas from developed countries about lifeline road's definition, planning methods, and planning experiences. After that, the definition of lifeline road in our country has been set. And several affect factors of lifeline road planning were found. The planning objectives were set up and basic planning principles were suggested. We found that there are two paths to planning the lifeline road based on evaluating existing road network. The lifeline road planning procedure was drawing out to guide the lifeline road planning in disaster-prone areas.

Abstract: As having the technical feature of rail transportation model，the urban rail transit is widely regarded as one of the effective ways to improve the current situation of urban public traffic and environmental problems. Especially at the background of adding the Megalopolis type in China, the construction of rail transit and urban space is facing increasing complex and intertwined problems, which relates to the engineering disciplines of traffic planning, traffic operation and management, urban planning and design, architecture and landscape design, as well as other disciplines of economy, anthropology, sociology and so on. So summarizing the Integrative development method of urban rail transit and urban space is of urgent significance. By concluding and reviewing the relating research and project, the research condense the trends of integration of urban rail transit and urban space, and furthermore the new key problems of Integrative development of urban rail transit and urban space.
Keywords: Urban rail transit; Transport planning methodology; Urban space; Integrative development; Review.

1 Introduction

In recent years transportation means have expanded from walking pedestrian routes to cars, buses, taxis and urban rail transit. Updating transportation methods not only directly changes the travel mode, but also has a marked impact on the urban space. Urban rail transit has been treated as a typical representative of the new development of urban public transport modes in recent years. As the urban public three-dimensional passenger transport system featuring in the main rail transport, urban rail transit has been generally accepted and welcomed for its large capacity, time efficiency, low pollution and low energy consumption. It has been widely researched by many countries, especially developing countries, and is generally seen as one of the most effective ways to improve the current situation of urban public transport and mitigate environmental issues.

Compared with other transit modes in the city, the underground rail transit improves the land utilization, and the degree of freedom of the city space layout to a certain extent. Rapidly developing rail transport lines and stations have become a new element in the urban space, leading to new phenomena, new features, new laws and new relations to the urban space under such influence. As rail transit construction and urban space are faced with ever more complicated and intertwined issues, it involves multiple engineering disciplines, such as transportation planning, transportation operation and management, urban planning and design, and architecture and landscape design, as well as integrated disciplines such as economics, anthropology and sociology. In recent years, under the guidance of important theories like the compact city, TOD, transit metropolis and smart growth, research scholars have made fruitful exploration into the theory and practice of rail transit and urban space integrative development from different perspectives. By sorting and reviewing the current situation of studies on the rail transit and urban space integrative development, targeted methodological guidance will be provided to address the practical problems in the process of building a sustainable city.

2 Summation and analysis of research status

After integrating into urban space, rail transit will impose impacts on the urban spatial form, urban transport system, social patterns and economic conditions, and some impacts are overt but some are covert, which take a long time to embody.

2.1 Aspect of city and architecture

As the main arteries through the urban area, the smooth operation of the transportation network is directly related with the urbanization process and effective solution of such issues. At present, there are some conflicts between the development of rail transit and the layout of the city development, but the problems are gradually improved with the overall planning more scientific. Rail transit development and the urbanization process affect and improve each other. The development backgrounds are different in Paris, London, Tokyo, Stockholm and Hong Kong, and the reason why such cities became globally recognized model cities for rail transit development is closely connected with the promotion of urbanization and guidance of orderly and compact city growth by developing the TOD mode（Tiwari R., Cervero R., Schipper L.，2011）.

As an important interface between city and transportation, the rail transit complex is the primary form of transport in the city center integrating into the city, and also an effective way to realize reasonable resource allocation within a limited space, having advantages of multifunctional synthesis, full service, integrative space and three-dimensional expansion. In the high speed development period of rail transit construction, the construction of station complexes became an important implementation method for the research on rail transit and urban space integration on the micro-level.

2.2 Aspect of transportation

Compared with the traditional local public transport system, urban rail transit has a more significant decisive effect on the spatial pattern, and introducing urban rail transit will recombine the accessibility in cities and push change of the urban structure（Huang Zhigang，Jin Zeyu，2010）. The development and construction of rail transit bring significant impact on surroundings along the lines and around the station mainly in aspects of integrated land use and urban spatial evolution, as well as space value and comprehensive benefits brought by stations.（Krause A L，2012）.

Different countries face different problems. Taking China as an example, it mainly faces the problems of poor accessibility to the destination, complicated paths and low space quality for travelers（Sohn K.& Shim H.，2010）. Facing practical problems, the urban builder and administrator put forward specific optimization strategies usually by integrating resources related to rail transit construction, and strictly controlling the nature of land-use and building density of the land along rail transit lines and around stations. Rail transit construction also impacts on the type and development mode of surrounding land by changing location conditions of the area along the lines and around the station.（Ratner K. A.，2013）.

2.3 Aspect of society

In the rapid process of urbanization, the people-oriented social function of urban space cannot be changed, and the social aspects of rail transit become important. This is seen in many cities and is also a key issue in the process of rail transit and urban space integrative development（Ewing R., Handy S.，2009）. It remains highly meaningful for the sound development of cities, improving the attractiveness of public transport, and easing traffic and environmental pressure.

In recent years, the “transfer” problem has gradually become a focus after rail transit integrated into the urban system, and it is also a key link for realizing rail transit and urban space integration. Many studies show that a good connection quality is not only key as to whether rapid transit in large capacity is achieved and encourages more people to transfer to rail transit, but also one of the important foundations for the safety of passengers. From the sociology perspective, the discussion of rail transit and urban space integration at the level of physical perception and behavior pattern of pedestrians is currently very lively.

2.4 Aspect of economy

Benefits generated from rail transit and urban space integrative development are various and remarkable, mainly including space benefits, social benefits, environmental and economic benefits. The influence of rail transit on the real estate market embodies the value of rail transit’s influence on the urban space. A specific influence is to change the original land price distribution by enhancing the accessibility of the surrounding area, reducing travel costs and improving the original urban spatial pattern, but there are different perspectives in studies on the specific influence level（Fang Jing，Chen Rongqing，2013）.

Land use plays an extremely important role in rail transit construction and urban space creation. Good interaction should be kept between them. Studying the influence on land use has important implications for improving the density of land use, researching rail transit and urban space integration and realizing the urban sustainable development（Zhao Yanjing，2007）. At the level of specific implementation, urban rail transit can promote high-density and high-strength development and use of land along the lines, increase the efficiency of land use, and increase the economic and social vitality of the area along the lines（Bian Jingwei，2009）.

3 Trends of research and Practice

(1)Diversification of research disciplines

Statistics show that globally, the highest proportion of studies concentrate on engineering and transportation, and keep increasing, although of course all areas are comprehensively discussed and new fields such as urban studies are developing. In China specifically though the main focus comes from the angles of “resource sharing” and “land utilization” and most discussions are from a macro perspective. From the macro and micro perspective, the ratio of studies on the key link of “transfer” in transportation and urban space integration is low all the time, but having an increasing trend.

(2)Complication of existing problems

Many studies show that problems in rail transit and urban space integration in China at present are getting more and more complicated and are no longer just problems at the level of operations management and transportation planning. As a complex and gigantic system as a whole, the comprehensive effectiveness of cities is closely related to the matching degree of various subsystems. The actual operation efficiency of the rail transit system has to rely on the participation and coordination of subsystems in other relevant cities, and higher rail transit efficiency is crucial for the orderly development of urban space.

(3)Integration of solutions

Since existing problems are complicated, the “transportation-city-building” integration-design theory system and method shall be established by synthesizing problems and integrating multiple disciplines like transportation planning, urban planning, urban design, architectural design and landscape design from a comprehensive perspective. Taking transport efficiency and space quality evaluation in studies on rail transit stations and urban space integration as an example, we will leave out the traditional single simulation for passenger flow around rail transit stations and the evaluation of urban sustainability. Meanwhile, simulation and evaluation of rail transit and urban space integration is an important way to solve transportation and urban problems（Figure 1）.

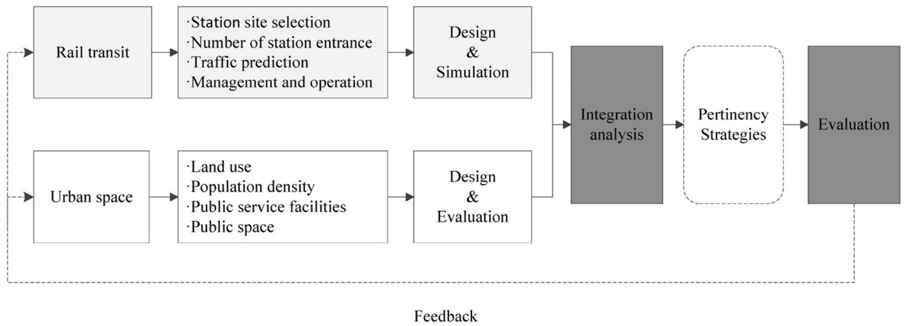

Figure 1.Integrated optimization idea of rail transit and urban space

4 Conclusions

After gradually planted into city built area, urban rail transit lines and stations have been fusing development with original city space, which resulting in a series of new space, new phenomena, new problems, new rules need to research deeply and optimizing. By combining relevant urban practices and research, the following two key conclusions were extracted:

(1) Establishing scientific contact among "Traffic mode - Behavior rules - Urban space". Through studies on rail transit and urban space integration, taking "Behavior rules" on transportation as the medium and link, we can reveal the relating principle. We can break through the limitations of discipline classification, clarify the scientific contact and the coupling properties among the "Traffic mode - Behavior rules - Urban space", find the objective principle of comprehensive connection in Influenced Urban Realm around Station, and provide corresponding theoretical support for precise studies on urban space from an intensive, systematic and synergic perspective.

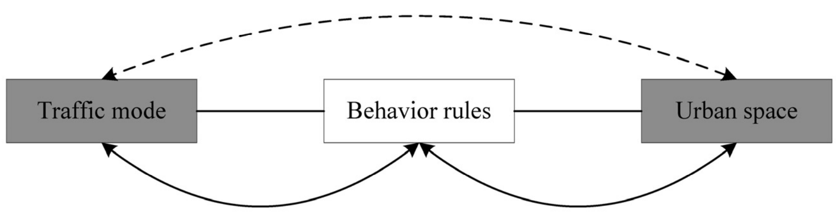

Figure 2.Integrated optimization idea of rail transit and urban space

(2) Forming the "transportation-city-building" integration design theory and method system under the influence of urban rail transit. Based on the solution of key issues at the first level, relevant achievements and academic ideas in fields of transport planning and design, urban planning and design, architectural design, and landscape and public design ought to be integrated effectively, and new theories, new tools and new methods should be sought.

The aim should be to ultimately improve urban transport efficiency, urban living quality and urban space quality, and to deliver results which are both theoretically credible and have practical meaning.

5 Recommendations for Future Research

Firstly，as the carrier of event, precise definition of radiation realm of rail transit station which has the character of complex function, diverse behavior, sensitive ecology and technology complex is very basic to in-depth knowledge and optimization to the space whose health is directly related to the city traffic, travel mode, image of city, city disaster prevention and so on. Secondly，selecting the most suitable method to solve the problems in the radiation realm of rail transit station. Thirdly，building integration development guidance to rail transit and urban space in different levels of point，line and plane in order that lay a solid foundation to progressive solving the problems in different levels and the whole urban environment sustainable development.

Problems and Improvement Measures of Highway Traffic Safety Facilities

Kairan Zhang[1] and Qianqian Qiu[2]

[1]National United Engineering Laboratory of Integrated and Intelligent Transportation, Chengdu 610031. E-mail: krzhang@swjtu.cn
[2]Department of Safety Engineering, School of Transportation and Logistics, Southwest Jiaotong University, Chengdu 610031. E-mail: 325860348@qq.com

Abstract: As to improve road traffic safety and traffic efficiency, this paper focused on the study of highway traffic safety facilities. By investigating the currently basic application of highway traffic safety facilities, combining with the traffic accidents statistics and the setting regulation of highway traffic safety facilities, the problems of each kind of safety facilities were described in detail. Result shows that the main problems existing is caused by the lack of traffic safety facilities and unreasonable traffic safety facilities' setting. Finally, this paper analyses the causes of the problems from the planning, design, construction and maintenance management of highway safety facilities and puts forward the improvement measures.
Keywords: Traffic safety; Traffic safety facilities; Setting problems; Improvement measures.

1 Introduction

With the development of the socio-economic level, the road transport developed rapidly, road accidents' number is also increasing, which becomes the focus of attention. After a lot of research, Treat and Sabey found that people, vehicles, road-related accidents showed as Table 1, where road-related accidents accounted for 28% to 34%, which is an important factor affecting traffic safety.

Table 1. The proportion of people, vehicles, road-related accidents

The reason	Only Road	Only people	only Vehicles	Road & People	People & Vehicles	Vehicles & Road	People , Vehicles & Road
Sabey conclusions /%	2	65	2	24	4	1	3
Treat conclusions /%	3	57	2	37	6	1	3

US had settled up multiple vehicle crash test site, has accumulated a lot of experience in setting fence, has a large number of experiments on the material, form and structure of the fence system from experiment, developed a series of standards in guardrail's design, selection and installation and maintenance (Yan Xinping, 2009). European countries researched the type and structure of highway guardrail, forming a complete experimental system and procedures, and combining the characteristics of each country's road traffic environment to develop a appropriate barrier (He Xinyun, 1999). Japan focus on simple and practical, amended several times, making the road traffic safety facilities' settings is more simple and practical (Cheng Binsheng, 1989). Chinese traffic safety measures were mostly in traffic management, mainly from training of security awareness (Wang, Y. J, 2009), relying on rules and regulations for the management, little research of the engineering technology. In recent years, research on the security facilities has made some results (Shi Maoqing, 2005), but there are still some unreasonable conditions in traffic safety facilities' setting (Fan, X, 2006)).

2 Highway Traffic Safety Facilities

2.1 Fence

Fence is an important part of Traffic safety facilities, plays an important role in preventing traffic accidents. It can effectively prevent the vehicle crossed the median strip to prevent the vehicle left the road, it can absorb energy through the deformation of the fence to lessen the severity of the accident, at the same time, induce a driver's view of the road to make contour and linear be clearly observed.

2.2 Traffic Sign

Traffic sign, with a predetermined pattern, symbol, or text, transfer traffic information to pedestrians, drivers and other traffic participants.

Its role is to organize, manage and guide traffic to run, to provide allowable route to road users, to protect the vehicle safe and smooth operation, but also the specific measures of road traffic organization design implementation.

2.3 Road Marking

Road marking is a kind of transportation facilities installed on the road with in a variety of lines, arrows, text, graphics and facade marks entity tag, protruding signs or outline standard. Its role is to inform users of road traffic passing rules, warning, guidelines and other information. It can be used alone or in conjunction with the sign.

2.4 Glare Facilities

Glare facility is used to improve night driving environment and prevent drivers suffer nighttime glare interference of structures. Glare facilities usually set in the center median strip of road, the main purpose is to eliminate the moving car headlights at night causing the driver glare interference. Setting glare facility can make nighttime driving conditions more favorable, increases driver's line of sight, thus weakening the tension of driver, effectively reducing the probability of road traffic accidents and improve traffic safety.

2.5 Sight Inducing Facility

Sight inducing facility is provided along the road, for identifying the road line shape, direction, roadway and the dangerous road. it can expand through the line of drivers' sight, thereby to make protection of secure driving.

2.6 Other Safety Features

It include isolation facilities, lighting, crash facility, crosswalk, hedge lane, anti-wall, cooling pool, convex reflector and other facilities in order to improve road safety.

3 The Situation of Highway Traffic Safety Facilities

Nearly half of China's traffic accidents occurred on secondary and below roads. The low standard level of these roads, poor road conditions and traffic safety facilities lack or unreasonable, lead to highlighting security risks and easily traffic accidents.

A large number of statistical data shows that about 30% traffic accident is concerned to the vehicle outside the outlet, about 10% caused by the collision of vehicles and roadside hazards (including the bridge pier, railings, tree, lighting fixtures, mark column and other road infrastructure).

Road safety facilities plays an indispensable role in reducing traffic accidents. Table 2 showed the relationship of roadside protection and traffic accidents (LIU Jing-hui., 2011). It can be seen from the table, no protection facilities conditions, traffic accidents has a big number and most serious harm. No protective facilities condition the traffic accident is 4.1 times of the protective facilities, and casualties reached 5 times as much.

Table 2. The Relationship of Roadside Protection and Traffic Accidents

protective facilities	Accidents number		Deaths number		Injured number	
	number	Proportion (%)	number	Proportion (%)	number	Proportion (%)
Waveform guardrail	17990	7.55	8243	12.16	23880	8.68
Collision walls	3613	1.52	1237	1.83	4401	1.60
Protective pier	7151	3.00	2361	3.48	8530	3.10
Other protective facilities	38711	16.24	9037	13.34	43390	15.77
no protective facilities	170886	71.69	46881	69.19	194924	70.85

4 Problems and Analysis of Traffic Safety Facilities

4.1 Plan

Highway traffic safety facilities system in China carried out in recent years. In terms of planning, there is a systematic approach and lack of planning. Safety facilities did not get attention, more not considered together in the plan with other facilities of highway engineering, often tended to consider safety facilities after completion of other engineering facilities, which makes the entire road system poor coordination and influence the highway traffic function (LI Fu-yong, 2006). Evaluation on the safety, reliability and environmental aspects of the planning scheme of safety facilities little to consider even is not involved, due to the lack of planning, traffic safety facilities application cannot form a complete system, thus causing traffic safety facilities system a lot of problems in the overall application.

4.2 Design

In spite of the design in accordance with national standards and foreign examples, consider the characteristics, the geographical information, climate conditions and the factors of highway construction investment of the road, select the appropriate structure and materials, reasonable setting of highway safety facilities. But as a result of the planning of safety facilities system in China on the issue, has not formed on the design norms of traffic safety facilities, lack of safety facilities for the software design, the vast majority of the design of safety facilities are based on personal experience, this caused the subjective factors become the main factors influence in the design, it led to poor safety facilities.

4.3 Construction

Construction safety facilities are usually started after the road construction, there will often be in a not good situation in safety facilities and the main project. The construction unit of safety facilities is most important to guarantee the quality, but in order to shorten the construction period, some construction units had not set the safety facilities with the requirements of the construction.

More seriously, there is a construction unit Jerry situation, it bring that safety facilities set did not adopt the design requirements of the process and materials are not strictly construction, which makes the construction quality of safety facilities not to meet the design requirements, which greatly reduced safety performance, so that the overall decline in road safety.

4.4 Management

The maintenance work of safety facilities is to protect the safety of facilities can play an important role of security protection in normal for a long time. But now the traffic safety facilities maintenance has not been taken that of attention like highway pavement maintenance, which caused that the setting and updating of the highway safety facilities haven't meet the demand of road. The lack of traffic safety facilities maintenance equipment of advanced technology, make the maintenance work more difficult, and impact the capacity of highway traffic. On the other hand, because of the inadequate propaganda and supervision of highway management department, there are many security facilities man-made damage, seriously affecting the normal use of safety facilities.

5 Measures to Improve Road Traffic Safety Facilities

5.1 Technical measures

There are only two traffic-related laws "People's Republic of China on Road Traffic Safety Law" and "People's Republic of China on Road Traffic Safety Law Implementing Rules", although there is some provisions related to traffic safety facilities, but the operability of the law and regulations for the safety facilities' planning and management is not strong. Should make the law of traffic safety facilities through its planning, construction and management, implement safety responsibility, strengthen the planning, construction and management of traffic safety facilities, and make it more authority and operation.

5.2 Management Measures

5.2.1 Material Procurement Supervision

In material procurement, relevant departments should formulate corresponding management mechanism, prevent the materials safety facilities which cannot meet the standard requirements (Xiao Dian-liang, 2007). Rigorous testing of material properties, relevant departments should promptly notify the unqualified safety facilities purchasing department for rectification, accept the safety facilities materials which meet the requirements, and allow it to be input in construction.

5.2.2 Construction Supervision

The safety facilities of construction is carried out by the construction unit, safety facilities construction need to be synchronized with the road engineering to ensure the coordination of safety facilities and road facilities, in order to make the safety facilities to function properly, the traffic management department should supervise the construction unit of the road safety facilities, to ensure the safety of facilities construction is synchronized with the theme of the road engineering, to establish a good management mechanism to ensure the safety facilities engineering construction schedule, to prevent the jerry emergence, and to ensure the quality of safety facilities engineering.

5.2.3 Acceptance Supervision

After the highway safety facilities construction completed, organizing the relevant experts. Experts have to study the setting of safety facilities. If they found unreasonable situation, it means the safety facilities in a bad quality, it should not be accepted, but to inform the construction unit to rearrange the safety facilities, then check again until the entire road safety facilities to be acceptance of all. It should be avoided that road has been opened to traffic while the safety facilities are still setting.

5.2.4 Maintenance Management

There should establish a safety facilities inspection table, if not meet the requirements, the safety facilities should be promptly repair and rectification. In addition, the safety facilities maintenance also should strengthen the propaganda, strengthen the awareness of traffic safety facilities, advocate the masses care of traffic safety facilities, and supervise the destruction of traffic safety facilities, if traffic safety facilities found problems, timely to reflect to the relevant departments.

6 Summary

Through research discovery, lack of traffic safety facilities and unreasonable traffic safety facilities setting are the major problem in currently traffic safety facilities setting. In China, The main reason is the lack of long-term development planning, the lack of scientific design process, not deal construction effect, the relative lack of maintenance and management of the investment, the lack of necessary scientific management mechanism.

For these problems, our country should establish technology system of safety facilities in technology. In the management, our country should strength all aspects of supervision and management work, including materials procurement, construction, acceptance and maintenance management.

Abstract: In order to solve the driving safety problem caused by the complicated terrain conditions and the changeable climate for mountainous freeway, it is necessary to construct assess index system to improve transportation security for mountainous freeway. The method used in this paper is: by taking the advantage of diagnosing and inferring the uncertainty of the knowledge of Bayesian network, we put forward a transportation security assessment model for mountainous freeway based on Netica. We use the model to evaluate a practical mountainous freeway and the result shows: the probability of the freeway section to keep in a safe state is 71.5%, and the safety grade of the road section of mountains freeway is 2.
Keywords: Mountainous freeway; Security assessment; Bayesian network (BN); Diagnostic reasoning.

1 Introduction

The geological and topographical conditions along the mountainous freeway are complicated, the overall geometric factors are poor and horrible weather often occurs, which is not conducive to vehicle operation, so transportation safety for mountainous freeway is a difficult problem in the traffic science research (Chen, 2013).

For improving highway safety, B. Φ .BABU Kov has been committed to research the relationship between the road condition and traffic safety since 1990, and had a study on safety evaluation of freeway section (Kov, 1990). Zheng Heng proposed to a method for roadside safety measurement using Bayesian network (Heng, 2008). Tian Yujia carried out an in-depth study on traffic safety of mountainous expressway bridge-tunnel sections and sets up the safety evaluation system of bridge-tunnel sections on mountainous expressway based on Bayesian network (Yujia, 2010). Yu Rongjie employed Bayesian inference method to evaluate Real-time weather and traffic variables, along with geometric characteristics variables (Rongjie, 2012). Meng Xianghai put forward a traffic safety evaluation method of the mountainous freeway section based on geometric alignment index by analyzing the relation between traffic accidents and geometric alignment (Xianghai, 2014). Up to now, few scholars conducted security assessment for mountainous freeway using the Bayesian network.

This paper presents a transportation security assessment model for mountainous freeway based on Netica. The model can effectively aggregation knowledge and experience of experts to update marginal probability of nodes, as well as flexibly conduct the diagnosis and sensitivity analysis of systems. Thus, the output of the safety assessment model can be used to compare the danger level for mountainous freeway. The model provides references for analysis on the safety hidden danger and making plan for improving the traffic safety for safety designers for mountainous freeway.

2 Bayesian Network

Bayesian Network (BN) has been widely-used approaches in probability theory at all times. A BN is a Directed Acyclic Graph (DAG) consisting of a set of nodes, representing variables with a finite set of states, and edges, which representing the probabilistic causal dependence among the variables (Yu, 2006).

Using Bayesian network method to establish traffic safety analysis model can do not only the accident probability prediction but also making accident diagnosis, thus finding out the weakest link of the system. As a traffic accident could be caused by multiple factors, in this paper, we give several main affecting factors of traffic safety for mountainous freeway; the precision of the model will increase along with other factors to be joined. Besides, other research results of transportation safety can also be used to improve conditional probability model in this paper, which making it more accurate.

3 Assessment Models of Traffic Safety Using BN

3.1 Topology structure of the BN of the traffic safety analysis

Due to the limitation of the special geographical conditions and nature environment of mountainous freeway, the horizontal curve radius, the longitudinal grade, the radius of vertical curve and the sight distance all have effect on traffic safety in the road factors for mountainous expressway. Meanwhile, lighting condition and ADT (average daily traffic) have intimate relationship with the driver's state. In addition, the accident occurrence has greatly close relation with environmental factors, therefore, the paper selects fault casualty number, weather condition as a measurement of the index of mountainous freeway.

In this paper, the analysis for mountainous freeway mainly to the driver's state, the road condition, and the environmental condition three aspects. Then, the paper will select eight observable variables and four latent variables to establish relations with the direct cause and the basic reason of accidents. The eight observable variables are “lighting condition (S_1)”, “ADT (S_2)”, “horizontal curve radius (S_3)”, "longitudinal grade (S_4)", "the radius of vertical curve (S_5)", "sight distance (S_6)", "fault casualty number (S_7)" and "weather condition (S_8)". The four latent variables are "the driver's state (B_1)", "road condition (B_2)", "environmental condition (B_3)" and "accident type (A)". For eight observable variables, this paper aggregates multi-group opinions of experts E (E_1~E_3) in traffic safety field to determine the marginal probability of nodes, and sets up the theory of Bayesian network model of bifurcate connection, as shown in Figure 1.

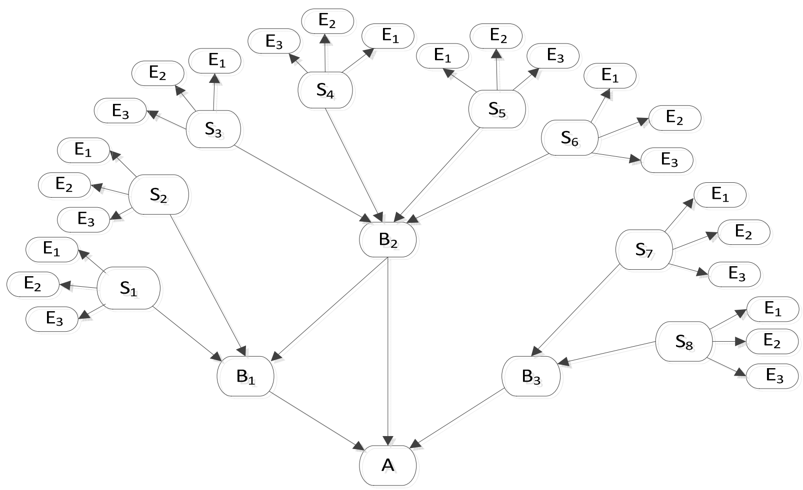

Figure 1.Topology structure of the Bayesian network

3.2 Marginal probability of node for aggregating experts' opinions via BN updating

For getting more objective evaluation results, we need to select a number of traffic safety experts to determine the judgment standard of every index. The 15 experts this article selected are equally distributed into three groups and every group of experts form a judgment standard after a deep discussion. Assuming that when the experts E_m (m=1, 2, 3) for a risk assessment of evaluation united, they would think the index S_i (i=1, 2, ⋯ ,8) as in a certain state E_{mn}, and the probability of the traffic accidents (refers to an accident in a month, the same below) is $P(S_i\!=\!Yes \mid E_{mn})$, where E_{mn} is the evaluation criterion of the expert E_m for index S_i. For the convenience of experts to evaluate index, the paper would use the appraisal interval values, as shown in Table 1, to divide the sensitivity extent of the index, and the medians of the appraisal interval values are used as the representative values to estimate $P(S_i \mid E_{mn})$.

Table 1. Appraisal interval values from the experts

Degree of sensitivity significance	$P(S_i \mid E_{mn})$（High）	$P(S_i \mid E_{mn})$（Low）
Very significant	1.0~0.8（0.9）	0.2~0.0（0.1）
Significant	0.8~0.6（0.7）	0.4~0.2（0.3）

Potentially significant	0.6~0.4（0.5）	0.6~0.4（0.5）
Low significant	0.4~0.2（0.3）	0.8~0.6（0.7）
Very low significant	0.2~0.0（0.1）	1.0~0.8（0.9）

Refer to the appraisal interval in Table 1, the evaluation criteria are listed on some indexes of different experts (Sulin, 2012),(Ahmed, 2011) as shown in Table 2.

Table 2. Assessment criteria of some factors from different experts

Index S_i	Expert 1		Expert 2		Expert 3	
	Criteria $P(S_i = Yes \mid E_{1n})$		Criteria $P(S_i = Yes \mid E_{2n})$		Criteria $P(S_i = Yes \mid E_{3n})$	
Horizontal curve radius S_3/m	(1) <2000	0.5	(1) <1500	0.6	(1) <2500	0.4
	(2) [2000,4000]	0.2	(2) [1500,3000]	0.25	(2) [2500,4000]	0.25
	(3) >4000	0.1	(3) >3000	0.1	(3) >4000	0.1
Sight distance S_6/m	(1) <165	0.4	(1) <165	0.5	(1) <150	0.6
	(2) [165,210]	0.3	(2) [165,300]	0.3	(2) [150,250]	0.3
	(3) >210	0.15	(3) >300	0.1	(3) >250	0.15
Weather condition S_8	(1) good	0.4	(1) good	0.6	(1) good	0.5
	(2) average	0.2	(2) average	0.25	(2) average	0.3
	(3) bad	0.1	(3) bad	0.1	(3) bad	0.15

According to the assessment criteria of index S_i, aggregated from different experts in Table 2, we can update the probability of index into each criterion under the premise of index $S_i = Yes$, and each node of $P(S_i = Yes)$ can be last updated based on the new evidence. Hence, they can be calculated using Bayesian theorem, which is shown as Eq. (1).

In Eq. (1), we can assume that $P(E_{m1})$=$P(E_{m2})$=, … ,=$P(E_{mk})$=1/k, as no information about the variable E_{mn} is provided yet. Then, We can calculate $P(E_{mn} \mid S_i = Yes)$ using Eq. (1), and calculate $P(S_i = Yes \mid E_{1n}, E_{2n}, E_{3n})$ using Eq. (2), so as to complete the modeling process of Bayesian network.

$$P\left(E_{mn} \mid S_i\right) = \frac{P\left(S_i \mid E_{mn}\right)P\left(E_{mn}\right)}{P\left(S_i\right)} = \frac{P\left(S_i \mid E_{mn}\right)P\left(E_{mn}\right)}{\sum_{n=1}^{k} P\left(S_i \mid E_{mn}\right)P\left(E_{mn}\right)} \quad (1)$$

$$P(S_i = Yes \mid E_{1n}, E_{2n}, E_{3n}) = \frac{P(E_{1n}, E_{2n}, E_{3n} \mid S_i = Yes)}{P(E_{1n}, E_{2n}, E_{3n})} \quad (2)$$

3.3 Model of reasoning and safety evaluation

Then we have established the Bayesian network model. For the road section with known influencing factor, we get the marginal probability of the root in the evaluation model by using aggregating experts' opinions via updating BN. Then we do the forward reasoning for the model by using the analysis model established by the BN analysis software packages-Netica, and we get the accident probability $P(A = Yes)$ for mountainous freeway. The paper will use the assessment criteria, as shown in Table 3, to evaluate the safety of mountains freeway using the probability $P(A=Yes)$.

Table 3. Assessment criteria of the mountains freeway safety

$P(A= Yes)$	Safety grade	$P(A= Yes)$	Safety grade
<0.1	1	0.1~0.3	2
0.3~0.5	3	>0.5	4

4 Applications

For a road section of mountains freeway with known influencing factor, the actual numerical values of influencing factor and the marginal probability updating are shown in Table 4.

Table 4. Marginal probability of root node via BN model

Index S_i	Actual numerical values	$P(S_i=Yes \mid E_{mn})$
Horizontal curve radius S_3	3500m	$P(S_3=Yes \mid E_{12},E_{23},E_{32})$=0.397
Sight distance S_6	230m	$P(S_6=Yes \mid E_{13},E_{22},E_{32})$=0.262
Weather condition S_8	average	$P(S_8=Yes \mid E_{12},E_{22},E_{32})$=0.353

We use BN analysis software packages-Netica to Figure 1 reasoning, finally the probability of system node A is "Yes": $P(A=Yes \mid B_1,B_2,B_3)$=0.285, as shown in Figure 2. Therefore, according to Table 3, the safety grade of the road section is 2.

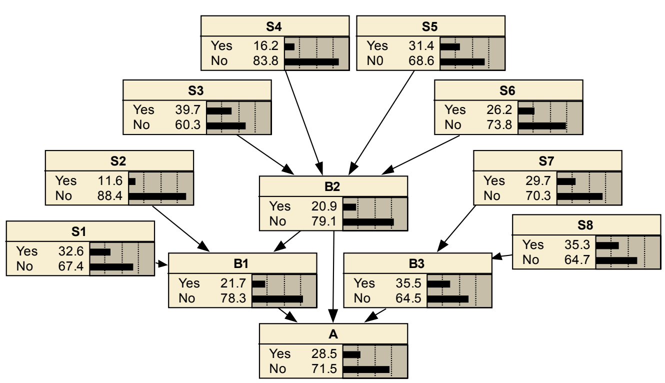

Figure 2. Final results of assessment

5 Conclusions

In this paper, based on past experience and the results of previous studies, the traffic safety analysis model is established using BN. The different views of different experts are reflected on the final results of the evaluation by BN. Meanwhile，we do the forward reasoning for the model by using the analysis model established by the BN analysis software packages-Netica, and we gets the accident probability of system, thus the security assessment for mountains freeway can be accomplished.

Application of Fuzzy Set Pair Analysis in Poor Shunting Early Warning for a Track Circuit

Zicheng Wang; Jin Guo; Rong Luo; and Jinxiu Xiao

School of Information Science and Technology, Southwest Jiaotong University, Chengdu, Sichuan 610031, China. E-mail: wangzc90@my.swjtu.edu.cn

Abstract: Aiming at the problem of poor shunting failures in track circuit which seriously affect transportation safety, this paper proposes an early warning strategy based on fuzzy set pair analysis. For an example of 25 Hz electronic phase detecting track circuit, main influence factors are taken as early warning indexes through the failure mechanism analysis. In consideration of the effect of man-induced subjective factors during the index weight decision by Analytic Hierarchy Process, the grey relational analysis is applied to correct the weight to make the results more reasonable. The concept of fuzzy connection degree is applied to determine the value of discrepancy coefficient in set pair analysis theory. Measured samples and warning grades are used to compose a set pair and the connection degrees of the measured samples and the warning grades are calculated and ranked. Then through the farther same, difference and antagonism set pair analysis the poor shunting early warning for track circuit is achieved. The results and comparisons with other methods show that the fuzzy set pair analysis method is feasible and can provide a scientific basis for track circuit site maintenance.

Keywords: Track circuit; Poor shunting; Early warning; Grey relational analysis; Set pair analysis; Fuzzy connection degree.

1 Introduction

Track circuit is an important equipment in railway signaling system which is used for monitoring the position of the trains on the railway track. The performance of the track circuit which lay on the ballast bed is strongly influenced by its work environment. Especially for oil, coal and other cargo transport railway station the value of ballast resistance is rather changeable. The poor shunting failures frequently happen as a result. The poor shunting failures could lead to the wrong displays of the signal. So it is possible and necessary for us to find some methods for the fault early warning. The traditional method for early warning is achieved by setting several warning lines. It’s greatly influenced by human factors. Therefore, this paper proposes an early warning strategy based on fuzzy set pair analysis.

2 Set Pair Analysis

2.1 Definition of connection degree

The set pair analysis is a new quantitative analysis method about uncertainty theory. Its basic idea is to incorporate certainty and uncertainty into one system and describe the uncertainty of the system by the connection degree.

Given two sets A and B and assumes that the two sets form a set pair $H = (A, B)$. Then analyze the characteristic of the set pair H for a specific issue. Suppose that there are n characteristics in all and s characteristics are common to A and B. There are p characteristics that set A and B is antagonistic to each other. The ratios s/n, f/n (f=n-s-p), p/n are called the same, difference and antagonism degree (denoted as a, b, c for convenience) respectively. Therefore, the connection degree can be expressed as

$$\mu_{(A,B)} = \frac{s}{n} + \frac{f}{n} i + \frac{p}{n} j = a + bi + cj, \quad a + b + c = 1 \tag{1}$$

Where i is the discrepancy coefficient ($i \in [-1, 1]$), j is the antagonism coefficient and its specified value is -1.

In addition, a comprehensive connection degree analysis should be make based on the characteristics weights. Assumes that the connection degree of the index k is μ_k and its weight is ω_k. Then the connection degree of the set pair can be calculated using equation (2).

$$\mu = \sum_{k=1}^{n} \omega_k \mu_k \tag{2}$$

The warning grade of the poor shunting failure can be determined through sorting the connection degrees of the warning index value set and the warning grade set. The corresponding grade of the maximum connection degree is the warning grade of the poor shunting failure.

2.2 Determination of discrepancy coefficient

The determination of the discrepancy coefficient i is the key to calculating the connection degree. This paper applies the concept of fuzzy connection degree to determine the value of discrepancy coefficient i. So the fuzzy connection degree of the warning grades and the index values in the range of the adjacent warning grades should be confirmed. For example, assumes that the index value x is in the range of warning grade Ⅱ, that means $x \in [S_1,S_2]$. The fuzzy connection degree of index value x and the warning grade Ⅰ can be expressed as $\mu_{(x,\, b1)} = a + bi + cj$. Here a is the same degree, b is the difference degree, c is the antagonism degree. The closeness degree of x and S_1 is S_1/x. The closeness degree of x and S_2 is x/S_2. Then take the normalized results of the closeness degrees $S_1S_2 / [(S_1+S_2)x]$ as the same degree a and $x / (S_1+S_2)$ as the antagonism degree c. According to the equation $a + b + c$=1, the difference degree b can be expressed as $(S_1-x)(x-S_2) / [(S_1+S_2)x]$. Therefore, the fuzzy connection degree of x with the range of warning grade Ⅰ can be given by

$$\mu_{(x,b_1)} = \frac{S_1 S_2}{(S_1+S_2)x} + \frac{(S_2-x)(x-S_1)}{(S_1+S_2)x} i + \frac{x}{S_1+S_2} j \quad (3)$$

Substituting (3) into the discrepancy coefficient i in equation (1), it becomes

$$\mu_{(A,B)} = \left(\frac{s}{n} + \frac{f}{n}\frac{S_1 S_2}{(S_1+S_2)x}\right) + \frac{f}{n}\frac{(S_2-x)(x-S_1)}{(S_1+S_2)x} i + \left(\frac{p}{n} + \frac{f}{n}\frac{x}{S_1+S_2}\right) j \quad (4)$$

3 The model of poor shunting early warning for track circuit

3.1 Selection of early warning indexes

The factors affecting the magnitude of the voltage at receiving end of the track circuits include rail impedance, ballast resistance and the length of track circuit. Because the type and the length of track circuit are certain for a specific station, the ballast resistance is the main influence factor. The value of ballast resistance largely depends on the trackside temperature and humidity. Therefore, voltage at receiving end (V), cumulative number of failures (N), trackside temperature (T) and humidity (H) are used as the early warning indexes in this paper.

3.2 Partition of early warning grades

This paper establishes a set of sample data through the field survey data. The sample data set $\boldsymbol{Q} = [Q_1, Q_2, Q_3, Q_4, Q_5, Q_6, Q_7]$ is shown in table 1. In order to make the indexes comparable the sample data are normalized and the results are shown in table 2. In this sample data set the last 2 groups of data are test samples and the rest are reference samples which represent different degrees of fault tendency. According to the reference samples the early warning grades are divided into four grades which are green warning grade, yellow warning grade, orange warning grade and red warning grade. Four groups of early warning ranges are shown in Table 3. Here, S_1, S_2, S_3, S_4 are the threshold values of four warning grades.

Table 1. Sample data set

Serial No	U	H/%	T	N
1	24.2	25	24	1

H	0.273	0.527	0.818	1
T	0.333	0.567	0.833	1
N	0.250	0.500	0.750	1

3.3 Evaluation of index weight

The AHP method is one of the most common methods to determine the index weight. The detailed process of AHP method is shown below.

1) Establish the comparison matrix ***A***. The determining principle of the element $\boldsymbol{a}_{ij}$ can be given by

$$\boldsymbol{a}_{ij} = \begin{cases} 0 & The\ j^{th}\ factor\ is\ important\ than\ the\ i^{th} \\ 1 & The\ j^{th}\ factor\ is\ as\ important\ as\ the\ i^{th} \\ 2 & The\ i^{th}\ factor\ is\ as\ important\ as\ the\ j^{th} \end{cases} \quad (5)$$

2) Calculate the significance index r_i, here

$$r_{max} = max\{r_i\},\quad r_{min} = min\{r_i\},\qquad r_i = \sum_{j=1}^{n} a_{ij} \quad (6)$$

3) Build the judgment matrix ***B*** whose element $\boldsymbol{b}_{ij}$ can be determined by

$$b_{ij} = \begin{cases} \dfrac{r_i - r_j}{r_{\max} - r_{\min}}\left(\dfrac{r_{\max}}{r_{\min}} - 1\right) + 1 & r_i \ge r_j \\ \left[\dfrac{|r_i - r_j|}{r_{\max} - r_{\min}}\left(\dfrac{r_{\max}}{r_{\min}} - 1\right) + 1\right]^{-1} & r_i < r_j \end{cases} \quad (7)$$

4) Establish the optimal transfer matrix ***C*** where

$$c_{ij} = \frac{\sum_{k=1}^{n}\left[lg\left(b_{ik}/b_{jk}\right)\right]}{n} \tag{8}$$

5) Build the consistent matrix ***D*** where .

$$d_{ij} = 10^{c_{ij}} \tag{9}$$

6) Solve the maximum eigenvalue and eigenvector of the consistent matrix ***D***.

In this paper the comparison matrixes are established using (5) based on the experience of three experts and then the AHP method is applied to calculate the index weight. The normalized results of the index weight are shown in table 4.

Table 4. Index weight

Expert	U	H	T	N
1	0.5636	0.2637	0.1177	0.0550
2	0.5898	0.1778	0.1778	0.0546
3	0.5638	0.1178	0.2634	0.0550

But, it's strongly influenced by man-induced subjective factors when determining the index weight using AHP. The grey relational analysis is used to correct the index weight in this paper. ξ_k is the correlation coefficient of index k which can be expressed as

$$\xi_k = \frac{\left(\Delta_{min} + \rho\Delta_{max}\right)}{\left(\Delta_{dk} + \rho\Delta_{max}\right)} \tag{10}$$

Where $\Delta_{\min}$ = minmin $|x_0(k) - x_d(k)|$; $\Delta_{\max}$ = maxmax $|x_0(k) - x_d(k)|$; $\Delta_{dk} = |x_0(k) - x_d(k)|$; ρ is the distinguishing coefficient whose value is 0.5 in this paper; $x_0(k)$ is the value at index k in standard model; $x_d(k)$ is the value at index k in testing model.

The vector X = [0.5898, 0.5898, 0.5898, 0.5898] is constituted by the maximum value of the index weight matrix shown in table 4 and it is used as the standard model. Three weight vectors given by the experts are used as three testing models. Using (10) the correlation coefficient matrix ξ can be denoted by

$$\xi = \begin{bmatrix} 0.7745 & 0.2163 & 0.1601 & 0.1440 \\ 1.0000 & 0.1793 & 0.1793 & 0.1440 \\ 0.7759 & 0.1601 & 0.2161 & 0.1440 \end{bmatrix} \tag{11}$$

Then calculate the correlation degree r_k of each index. r_k can be expressed as

$$r_k = \frac{1}{3}\sum_{j=1}^{3}\xi_{kj}\ (k = 1,2,3,4) \qquad (12)$$

Divide the correlation degree of each index by the sum of all the index correlation degree, and thus, the vector of the corrected index weight can be denoted by $\boldsymbol{\omega}$ = [0.6230, 0.1358, 0.1357, 0.1055].

4 Example verification

According to the above method the connection degree of the test sample Q_7 and each warning grade can be expressed as

$$\begin{aligned} &\mu_{(Q_7,S_1)} = \frac{1}{4}i + \frac{3}{4}j, \mu_{(Q_7,S_2)} = \frac{1}{4} + \frac{1}{2}i + \frac{1}{4}j \\ &\mu_{(Q_7,S_3)} = \frac{1}{2} + \frac{1}{2}i,\ \ \mu_{(Q_7,S_4)} = \frac{1}{4} + \frac{1}{2}i + \frac{1}{4}j \end{aligned} \qquad (13)$$

Take the determination of discrepancy coefficient i in $\mu_{(Q_7,S_2)} = \frac{1}{4} + \frac{1}{4}i + \frac{1}{2}j$ as an example. x_1=0.833， $x_1 \in [S_2,S_3]$， where S_2=0.553， S_3=0.933. Substitute these data into equation (3), it becomes

$$\mu_{(x_1,b_2)} = 0.4072 + 0.0246i + 0.5682j \qquad (14)$$

x_4=0.75， $x_4 \in [S_2,S_3]$， where S_2=0.5， S_3=0.75. Substitute these data into equation (3) too, it becomes

$$\mu_{(x_4,b_2)} = 0.4 + 0i + 0.6j \qquad (15)$$

Based on the vector of the corrected index weight $\boldsymbol{\omega}$=[0.6230,0.1358,0.1357,0.1055], the comprehensive fuzzy connection degree can be given as

$$\mu_{(x,b_2)} = \omega_1\mu_{(x_1,b_2)} + \omega_4\mu_{(x_4,b_2)} = 0.2959 + 0.0153i + 0.4173j \quad (16)$$

Substituting (16) into the discrepancy coefficient i in $\mu_{(Q_7,S_2)} = \frac{1}{4} + \frac{1}{4}i + \frac{1}{2}j$, it becomes

$$\mu_{(Q_7,S_2)} = 0.45865 + 0.00765i + 0.39795j \quad (17)$$

Now all information of the data is utilized and it can satisfy the requirement of the accuracy. Therefore, Substitute i=0，j=-1 into (17), it becomes $\mu_{(Q_7,S_2)} = 0.0607$. Similarly, it can obtain the results: $\mu_{(Q_7,S_1)} = -0.7559$, $\mu_{(Q_7,S_3)} = 0.54769$, $\mu_{(Q_7,S_4)} = -0.0607$.

The computed results of test sample 7 and test sample 6 are shown in table 5 and it can be seen that the maximum value of the connection degree of the 6th group of data is 0.7342 and it's in the range of the green warning grade. That means the track circuit is able to work well. Similarly, the maximum value of the connection degree of the 7th group of data is 0.5477 and it's in the range of the yellow warning grade. That means poor shunting failures are likely to occur and the surveillance for track circuit should be strengthened.

Table 5. Analysis and calculation of connection degree

Data	Expression of μ	Value of i	Calculation method of μ	Value of μ	Results
6	$\mu_{(Q_6,S_1)} = j$	i_a=0, i_b=0, i_c=0	$\mu_{(Q_6,S_1)} = j$	0	Green Warning
	$\mu_{(Q_6,S_2)} = \frac{1}{4}i + \frac{3}{4}j$	i_a=0.0432, i_b=0, i_c=0.0648	$\mu_{(Q_6,S_2)} = 0.0108 + 0i + 0.7662j$	-0.7554	
	$\mu_{(Q_6,S_3)} = \frac{1}{4} + \frac{3}{4}i$	i_a=0.4509, i_b=0.00036, i_c=0.4406	$\mu_{(Q_6,S_3)} = 0.588175 + 0.000272i + 0.33045j$	0.2577	
	$\mu_{(Q_6,S_4)} = \frac{3}{4} + \frac{1}{4}i$	i_a=0.2537, i_b=0.0153, i_c=0.354	$\mu_{(Q_6,S_4)} = 0.75 + 0.01055i + 0.015825j$	**0.7342**	
7	$\mu_{(Q_7,S_1)} = \frac{1}{4}i + \frac{3}{4}j$	i_a=0.0537, i_b=0.0049, i_c=0.0772	$\mu_{(Q_7,S_1)} = 0.0134 + 0.0012i + 0.7693j$	-0.7559	Yellow Warning
	$\mu_{(Q_7,S_2)} = \frac{1}{4} + \frac{1}{2}i + \frac{1}{4}j$	i_a=0.2959, i_b=0.0153, i_c=0.4173	$\mu_{(Q_7,S_2)} = 0.45865 + 0.00765i + 0.39795j$	0.0607	
	$\mu_{(Q_7,S_3)} = \frac{1}{2} + \frac{1}{2}i$	i_a=0.1105, i_b=0.0049, i_c=0.1512	$\mu_{(Q_7,S_3)} = 0.55525 + 0.00245i + 0.00756j$	**0.5477**	
	$\mu_{(Q_7,S_4)} = \frac{1}{4} + \frac{1}{2}i + \frac{1}{4}j$	i_a=0.2959, i_b=0.0153, i_c=0.4173	$\mu_{(Q_7,S_4)} = 0.39795 + 0.00765i + 0.45865j$	-0.0607	

5 Conclusions

This paper proposes a new early warning method for track circuit based on fuzzy set pair analysis. The grey relational analysis is used to correct the index weight determined using AHP, so the results become more reasonable. Compared with Radar Chart method the warning results are identical. It indicates that the method proposed in this paper is feasible. In addition, the Fuzzy Set Pair Analysis method has the advantages of strong operability and simple calculation.

Abstract: Observed records provide clear evidence of global climate change, especially for severe weather events. The study presented addressed strategies for safety management of road infrastructure under Severe Weather Conditions (SWC), aims to consolidate transportation infrastructures' adaptation to severe weather change. On the basis of reviewing security and management strategy, we analyze the impact of Road Transportation Infrastructure (RTI) in severe weathers. Moreover, strategy development for managing highway safety under SWC is discussed based on the risk assessment, the precaution mechanisms, the emergency rescue and the traffic organization. Lastly, we briefly discusses guarantee measures for implementation. The study demonstrated that the reasonable adaptation strategy for safety management of RTI under SWC can effectively enhance the responsiveness of the traffic administrative department, in addition, which is of great social significance to reduce the loss of accidents to SWC, to maintain social stability and the protection of people's life and property safety.
Keywords: Adaptation strategies; Security; Management; Road transportation infrastructures; Severe weather conditions.

1 Introduction

Road Transportation Infrastructure (RTI) such as highways and bridges are exposed to exterior environments. Hence, they are vulnerable to extreme weathers. As modern RTI network extends continuously, the consequences and impacts of major disasters emergency (e.g., such as extreme weather) are becoming aggravate and complicate. In order to reduce the losses caused by traffic accidents, improving RTI management in extreme weather is the urgent need of the traffic safety.

According to the influencing degree of Severe Weather Conditions (SWC) on highway traffic safety, the biggest influence is caused by the heavy fog weather, ice and snow, rain and other weather followed behind. So it is a significant and long-term task to set up perfect major RTI crisis response mechanism, perfecting the traffic infrastructure and safety management strategy in extreme weather, strengthening emergency contingency ability in extreme weather and other major disasters,

According to the empirical findings, climate change related shifts in weather patterns might also cause RTI disruptions (Koetse, M. J., and P. Rietveld, 2009.). However, due to climate change, SWC may change positively or adversely in severity and frequency of occurrence, depending on the respective weather event and the location of its occurrence (Schweighofer, J., 2014.). More generally, it is concerned that the safety of RTI was closely related to the SWC (Eisenberg, D., 2004.; Barnes, P., and R. Oloruntoba, 2005.).

Climate change and SWC have impacted in the global, such as U.S.A (Karl, T. R., J. M. Melillo, et al, 2009.), Northern Canada (Koetse, M. J., and P. Rietveld, 2009.), E.U (Vajda, A., H. Tuomenvirta, et al, 2011.) and so on (Loosemore, M., V. Chow, et al, 2014.), which will affect several economic sectors including the hydroelectric, energy, marine, freshwater, and mining industries as well as RTI (Prowse, T. D., C. Furgal, et al, 2009.). Observations show that warming of the climate is unequivocal and the probability that SWC turns frequently.

Moreover, In response to cope with the climate change and set up management strategies, many local governments are directing agencies to utilize existing and traditional local government tools to adapt to climate change (Hirokawa, K. H., and J. D. Rosenbloom, 2013.). The United States governments and Canada governments (Selin, H., and S. D. VanDeveer, 2005.) have been working for environmental cooperation, in order to build the climate change networks and adaptation planning. Therefore, future RTI should be made more robust to possible changes in climate conditions, which includes three main parts: risk identification, risk ranking, and risk management. This aim implies that users of climate information must also change their practices and decision-making frameworks (Hallegatte, S., 2009.). Therefore, it is very necessary to study traffic risks and management measures of highway on the basis of SWC in order to develop effective early warning plans to improve usage and safety management level of infrastructures and equipment.

2 Analysis on Security Impact Factors of RTI In Extreme Weather

The impact of RTI on traffic safety is mainly reflected in the 3 aspects, such as lack of visibility, reduced road adhesion coefficient, unstable driving for motor Snow, slippery road conditions haze and low visibility weather has become one of the major incentives for traffic accidents (Ministry of Public Security Traffic Management Bureau). As shown (left) in Figure 1.

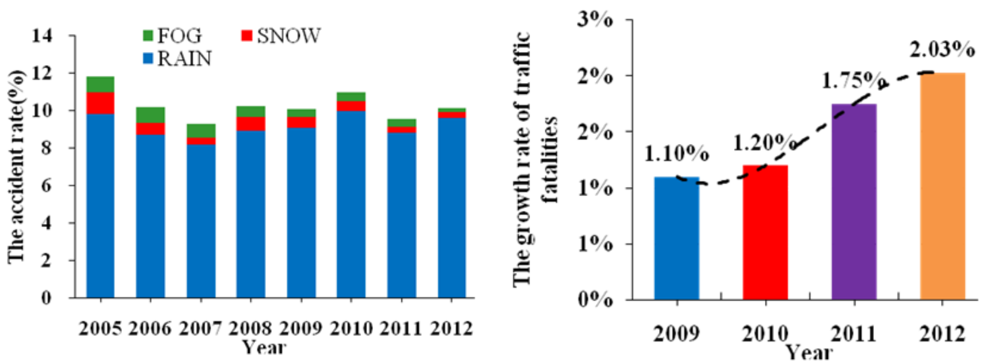

Figure 1. The accident rate statistics and growth rate of traffic fatalities in snow - ice in China

2.1 The Snow - Ice Impact on The Traffic Safety of The RTI

Table 1. The Influence in Ice - Snow and Foggy Condition

The braking distance for different types of speed on ice - snow condition							
Road conditions	Average speed (km/h)						
	50	60	70	80	90	100	110
Dry asphalt pavement	12.3	17.8	24.0	31.5	39.9	49.2	59.5
Ice and snow pavement	49.2	71.0	95.5	126.0	150.0	196.9	238.2

The highway fog speed limit recommended value in foggy condition					
Visibility distance	The maximum safe speed (km/h)				
	I < 1%	1 %≤ I < 2%	2% ≤ I < 3%	3% ≤ I <4%	4% ≤ I <5%
L ≥ 200	111	110	108	107	106
150 ≤ L < 200	92	92	91	90	89
100 ≤ L < 150	71	70	70	69	68
50 ≤ L < 100	44	44	43	43	43

Icy road will make road adhesion coefficient reaches the lowest point, causing the vehicle does not have sufficient capacity to resist lateral forces and unable to maintain a balance, leading the vehicle skidding drift out of control; when driving in snow, drifting snow will affect the driver's sight. Snow has a strong reflection of the sun, which prone to the snow-blind phenomenon (blinding) that damage to the driver's eyes and causing eye fatigue which is extremely detrimental to safe driving.

The braking distance for different types of speed on the ice and snow conditions is shown in Table 1.

According to the climatic conditions and traffic information, statistics in British, when snow falling the highway accident rate is 5 times as the dry road and the accident rate is 8 times as the dry road surface when freezing. The growth rate from 2009 to 2012 of traffic fatality statistics in China's snow and ice weather (right) is shown in Figure 1.

2.2 The Rain Impact on The Traffic Safety of The RTI

Traveling on the highway in rainy day would often have a "water slide" phenomenon. The coefficient of friction is significantly reduced on slippery roads, leading to reduced vehicle braking performance and increased risk of reduced visibility at the same time, which severely affected the sight and pavement marking visible distance. The relationship between surface water status and speed as well as adhesion coefficient is shown in Figure 2. H represents the water film thickness (mm).

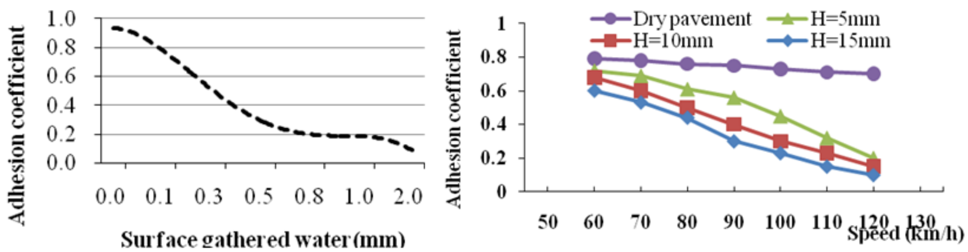

Figure 2. The relationship between surface water and speed as well as adhesion coefficient

According to accident statistics in Japan, Japanese highway fatalities associated with the rainy accounted for 42% (Ministry of internal affairs and communications - statistics bureau of Japan), however the number of rainy days throughout the year accounted for only 27%. The rainy growth rate of traffic fatality statistics from 2009 to 2012 is shown in Figure 3 (left).

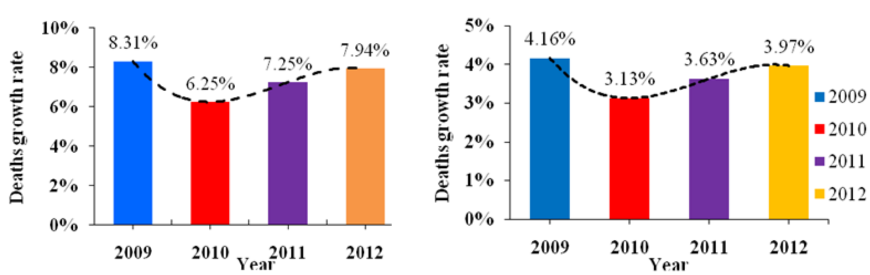

Figure 3. Traffic accident deaths growth statistics in rainy (L) and foggy (R)

2.3 The Fog Impact on The Traffic Safety of The RTI

Fog lead to low visibility and sight disorders and the driver's visual distance will be greatly shortened. Since it is difficult to discern the scene and traffic marking as well as front and rear vehicle, the driver is psychologically stressful and easier to have judge mistakes, which will lead to the front and rear car rear-end. Highway speed limits recommended values in fog condition are shown in Table 1. Due to fouling, dust and mist of water droplets in the air mixed in the water film formed on the road, the coefficient of adhesion between tire and road will become lower.

According to statistics in the annual report on road traffic accidents in 2010, traffic accidents caused by fog accounts for 3.51% of the total number of highway traffic accidents in China. The greater the fog, the more accidents will happen. The growth rate of deaths under accident in foggy weather from 2009 to 2012 is shown in Figure 3 (right).

3 Strategies For Addressing Security Managment

3.1 Risk Assessment

From the perspective of safety system engineering, risk assessment is based on analysis of past data loss, with system identification and security analysis of the safety or danger of the infrastructure, the level of risk is to be measured and graded according to certain standards, specifications, and safety indicators. So that combined with the existing conditions and the level of the security security, measures of the control system of a dangerous nature will be proposed. The flow chart of strategies for addressing security management was shown in Figure 4.

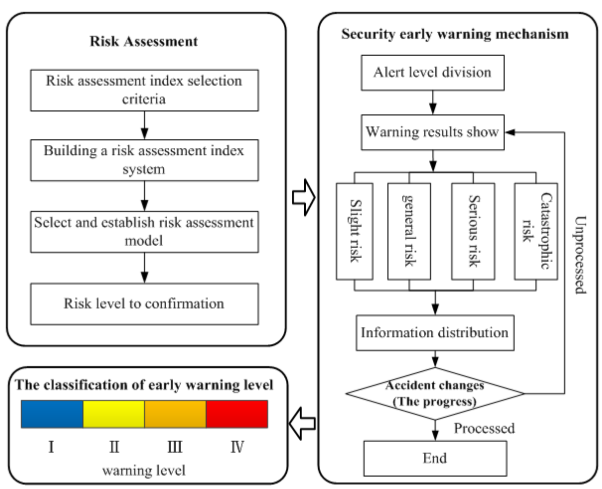

Figure 4. The flow chart of strategies for addressing security management

3.2 The Classification of Early Warning Level

In extreme weather, the warning classification of RTI was an insignificant risk (class I), general risk (class II), serious risk (class III) and catastrophic risks (class IV). In practical work, the precipitation, the disaster severity (the width, recovery difficulty and the length of the damaged roads and bridges), traffic congestion time, the development degree of the regional road network and highway rescue force are the basis of the warning classification. Meanwhile, the early warning level can also take local conditions, economic losses and casualties into consideration.

3.3 Early Warning Management

Development goals of traffic, whether in the meteorological development strategy research in china are: by 2020, the modern transportation meteorological monitoring, alert, early warning, integrated forecasting system will be established and improved; making great efforts in the detection and monitoring of the service conditions of the RTI in extreme weather to provide meteorological support services of international standards for smooth and safety transportation.

3.4 Emergency Rescue

It is a significant and long-term task to set up perfect major RTI crisis response mechanism, perfecting the traffic infrastructure and safety management strategy in extreme weather, strengthening emergency contingency ability in extreme weather and other major disasters, and guaranteeing the emergency response capacity of major disasters caused by extreme weather and other factors, as well as protecting the transport system as the lifeline of the national economy in all kinds of unexpected disasters remains safe operation. It is also an inevitable requirement for modern society to improve government management ability, and maintain social stability.

When extreme weather and other unexpected disasters happened, the following issues must be solved in the emergency rescue: Immediately understand the severity and the extent in extreme weather and other unexpected disaster events; enable the appropriate contingency plans and carry out disaster rescue and personnel evacuation in the shortest possible time according to established good procedures; simple, unified and efficient rescue organizations can reduce the blindness of the rescue by making full use of rescue supplies and time. Therefore, the scientific nature, timeliness and standardization of the emergency rescue are the key to the success of the emergency rescue work. Emergency plans library which has universal characteristics is summarized by traffic engineering prior knowledge, methods, and technology of road management and traffic flow states field. The dedicated plans library has highly pertinence and purpose. On the basis of profound knowledge and understanding of traffic conditions of a regional road network, road structural features, the characteristics and the severity of the traffic incident for managers, the dedicated plans library is summarized by the experience and the accumulation. Information (road infrastructure, traffic flow and other information) distribution, adjustment and release are carried out by the press, radio, variable information panels, variable speed limit signs, road network condition information site.

A reasonable emergency rescue engineering is based on previous crisis experience determine of the appropriate alert level and disposal procedures in accordance with the crisis category, size, extent, and grade. Once the crisis broke out, we can determine the corresponding level through the analysis of the situation immediately, then the appropriate contingency plans can be started and the best decisions can be made in the shortest possible time.

3.5 Traffic Organization Strategy

It is necessary to implement the corresponding management control strategy in order to ensure traffic safety and smooth flow. These management control strategies, which is corresponding to the weather type and its impact degree, should be embodied in the form of a plan or response program.

(1)The Recommendatory Strategy

This kind strategy is mainly used to provide real-time weather and traffic information for road users. The specific implementation method of the proposed strategies publishes information by variable information boards, temporary warning signs, road inspections, and Traffic Radio Ads, which ensure that road users can have immediate access to weather and traffic information.

(2)The Control Strategy

The main purpose of the control strategy is to control the travel speed of the traffic flow and running status on the road in extreme weather conditions. The specific implementation methods of the control strategy include publishing real-time speed limit information by speed limit signs or variable information boards; special sections may set up a temporary speed limit warning signs; publish warning information by the warning lights and Traffic Radio Ads.

(3)The Treatment Strategies

Treatment strategies can improve traffic safety and life safety with the use of rescue resources which the extreme weather and other major disasters required. Treatment strategies are mainly involved in internal and external coordination of the emergency department. Rescue resources required in rainy weather include pumps, steel bridge and others; rescue resources required in ice and snow weather include deicing salt, anti-slip agents, snow removal vehicles and others; rescue resources required in foggy weather conditions include anti-fogging agent, anti-fogging car and others. The primary duties of the treatment strategies for traffic management department prompt early warning notes for the relevant departments in extreme weather conditions.

4 Discussions

Strategic implementation safeguards include policy support and technical support, which can be divided into information gathering technical support, information dissemination, technical support, emergency rescue system, and space resources and data security.

(1)Information Gathering Technical Support

A collection of information includes traffic flow information and meteorological information. The weather information is obtained from meteorological, environmental monitoring equipment. Timely and accurate meteorological monitoring play an important role in developing reasonable response strategy, controlling and guiding vehicle to avoid risk, providing the driver with real-time traffic information and reducing the impact of highway traffic safety in extreme weather. Traffic flow information which is obtained by the information detectors (loop coil, video detector) includes traffic volume, density, speed and other data.

(2)The Emergency Rescue System

The emergency rescue system gives rapid response to traffic accidents and coordinate with all relevant departments to take emergency action through the information about traffic accidents prompt in extreme weather. It minimizes casualties and property losses caused by traffic accidents, restoring highway capacity as soon as possible and reducing traffic demand in the affected area of traffic accidents.

(3)Space Resources and Data Security

When taking a full account of the urban development planning, we should make urban development coordinate with emergency rescue and management development in sudden disasters. The basic conditions of emergency rescue work are applicable RTI. Therefore, the demand of the emergency rescue work should be given full consideration and leaves enough space of development for it in the construction of major transport infrastructure. The establishment of urban disaster risk assessment and disaster information database in line with the urban characteristics in China can provide a theoretical basis for the construction of the emergency rescue management system and data.

(4)The Policy Support

Urban RTI safety management requires a strong policy protection mechanism in extreme weather, especially for the continuity and security policy and financial investment, which are the basic guarantee for long-term development and construction of emergency rescue and management systems.

5 Conclusions

RTI is an important part of the transportation system. "The China's Twelfth Five-Year Guideline in the transportation field" makes great efforts to strengthen infrastructure construction, optimize the layout of the integrated transport infrastructure network and strengthen its traffic safety, which not only reflects the overall level of service of the transportation system, but also reflects the level of urban traffic management capabilities. With the continuous growth of RTI, traffic safety issues become increasingly prominent in china.

This paper reviews traffic accident status of ice, snow, rain and fog and summarizes domestic and international RTI security management strategy. Taking traffic fatalities number as indicators of road traffic safety operation, transportation infrastructure security of ice, snow, rain, and fog is analyzed from the visibility, sight, road adhesion coefficient, safe distance and other factors. The risk state of RTI facing disasters when a traffic accident happens is estimated and assessed. The early warning level together with publishing and management of early warning information are determined according to the analysis results of risk assessment. The emergency rescue system is studied from the accident detection and confirmation, command scheduling, resource optimization and configuration, and information dissemination etc. RTI safety management strategies and required rescue space of the strategy implementation, information database, policy and other strategic security in extreme weather are discussed from the recommended strategy, control strategy and treatment strategy these three aspects. The deficiency of this paper is that we only studied the influence of traffic safety of RTI in the ice, snow, rain, fog weather. However, in addition to the conditions mentioned above, more SWC have an impact on highway safety operations and further research is still needed.

Therefore, it is a difficult task for RTI safety management and security work in extreme weather. This requires formulating an emergency rescue and developed management strategy of appropriate transport infrastructure in sudden disaster, and carrying out the research on risk assessment, disaster warning, emergency response and management system. The safety management strategy of RTI needs to develop a scientific, rational, and sustainable strategic planning. With the dual support of the policy and technical support mechanisms, the expected target is completed in stages. Finally, safety management system of the RTI is established with urban characteristics in China.

Abstract: Bridges differ from surface streets and highways in terms of their physical properties and operational characteristics, which in turn, affect the risk of motor-vehicle crashes. This paper attempts to identify motor-vehicle crash patterns on Sutong Bridge and to compare differences between bridge-related crashes and all crashes. 459 crashes occurring on Sutong Bridge from May in 2008 to June in 2010 were collected and analyzed. Results reveal that bridge segment is involved in more fixed-object crashes and fewer rear-end crashes among total crash experience. And bridge-related crashes result in more serious consequences including higher fatality rate and longer crash duration.
Keywords: Bridge; Motor-vehicle crash; Crash type; Crash severity; Crash duration.

1 Introduction

The roadway system in China includes approximately 735,300 highway bridges (Statistical Report of Transport Development, 2013). Bridges differ from surface streets and highways in terms of their physical properties and operational characteristics. Bridges typically are narrower than approach roads, and often lack some safety features such as shoulders. And bridges as significant travel links over obstacles carry high traffic volume. The unusual physical properties and operational characteristics of bridges affect the risk of motor-vehicle crashes that occur on them (Retting, 2000).

Most existing studies about motor-vehicle crashes on bridges conclude that traffic crashes are more commonly associated with bridges than with comparable other roadways. Agent and Deen (Agent,1976)(Agent,1976) analyzed accident records on interstate routes and parkways from 1972 to 1973 in US and they found that bridge-related accidents were a significant percentage of the total accidents and their severity was generally higher than the severity of all accidents. Similarly, Brinkman and Mak (Brinkman,1986) also considered that bridge-related crashes constituted a high percentage of all crashes and were approximately twice as likely to result in fatality as a typical crash. Retting et al. (Retting,2000) studied 1,381 police-reported crashes of four highway bridges in the New York City and summarized that bridges had higher crash rates than their respective approach roads. However, in China, to date, little information regarding bridge-related crashes has been published. This paper attempts to identify motor-vehicle crash patterns on Sutong Bridge in China and to compare differences between bridge-related crashes and total crash experience.

2 Data Preparation

Sutong Bridge is a two-way and six-lane bridge located between Suzhou city and Nantong city in Jiangsu Province in China. Figure 1 describes a general view of Sutong Bridge. This bridge consists of two parts including bridge segment crossing the river and general highway segment. As a steel stayed-cable bridge with double towers, the bridge segment comprises main bridge, north bridge approach, and south bridge approach. And the general highway segment includes entrance/exit ramp and basic roadway segment. Thus, Sutong Bridge is divided into five parts: main bridge, south bridge approach, north bridge approach, entrance/exit ramp, and basic roadway segment. And main design parameters of the five segments on Sutong Bridge are listed in Table 1.

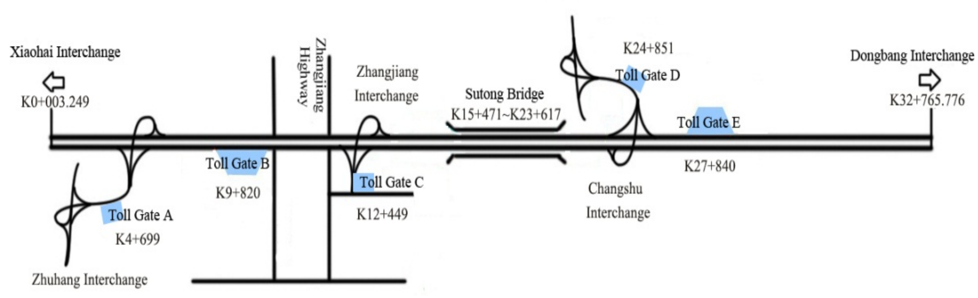

Figure 1. A general view of Sutong Bridge

Table 1. Road Parameters of Sutong Bridge

Segment Name	Length (m)	Minimum Curve Radius (m) and Length (m)	Maximum Slope (%) and Length (m)	Speed Limit (km/h)
Main Bridge	2,088		±1.5 / 2100	100
Bridge Approach (North)	3,485	7000 / 3417	+2.1 / 1795	100
Bridge Approach (South)	2,573	7000 / 3511	-2.4 / 1090	100
Entrance/Exit Ramp	17,080	55 / 226	+3.0 / 352	40
Basic Roadway Segment	24,277	5500 / 1716	-1.4 / 1540	120

There were 459 motor-vehicle crashes collected by Sutong Bridge Co. Ltd. from May in 2008 to June in 2010. Crash data from these crashes are available with specific information related to crash time, crash duration, crash location, weather conditions, crash vehicle, crash type and crash severity. Three distinct crash types plus an "other" category were defined. The three crash types are rear-end, fixed-object, and sideswipe/overtaking (Retting,2000). Regarding crash severity, these crashes were classified as fatal crash, injury crash and property damage-only (PDO) crash.

3 Data Analysis

To identify motor-vehicle crash patterns on Sutong Bridge, crash type, crash severity and crash duration were studied. Table 2 lists the distribution of crash types on Sutong Bridge. The three major crash types including rear-end, fixed-object, and sideswipe/overtaking crash account for more than ninety percent of all crashes. And there are similar conclusions in regard to bridge-related crashes. Moreover, there are eighty crashes occurring on the bridge segment that account for about seventeen percent of all crashes, which shows bridge-related crashes comprise a significant portion of total crash experience. In particular, the bridge segment involves more fixed-object crashes (43.75 percent) and fewer rear-end crashes (23.75 percent) associated with all crashes.

Table 2. Crash Types on Sutong Bridge

Crash Type	All Crashes		Bridge-related Crashes	
	Number	Percent of Crashes	Number	Percent of Crashes
Rear-end	154	33.55%	19	23.75%
Fixed-object	156	33.99%	35	43.75%
Sideswipe/Overtaking	118	25.71%	21	26.25%
Other	31	6.75%	5	6.25%
Total	459	100%	80	100%

Figure 2 illustrates the numbers of fatal, injury, and PDO crashes on Sutong Bridge and corresponding percent. PDO crashes account for almost ninety percent of all crashes, with similar results to bridge-related crashes. And there is no obvious difference in relation to the percent of injury crashes between bridge-related crashes and all crashes. But fatal crashes make up a higher percent of bridge-related crashes relative to all crashes.

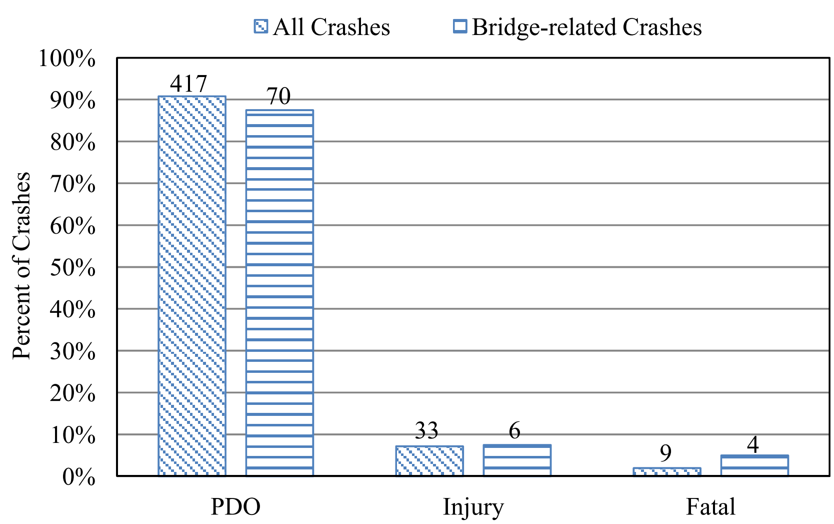

Figure 2. Crashes on Sutong Bridge by severity

In addition, crash duration is also regarded as an important factor to describe crash patterns. With crash duration increasing, negative impacts of crashes are becoming more and more serious. From May in 2008 to June in 2010, bridge-related crashes on Sutong Bridge in total cost 9,048 minutes that are about twenty-eight percent of the duration of all crashes. In Figure 3, a majority of crashes (89.85 percent in all crashes, 86.08 percent in bridge-related crashes) can be rescued and cleared within two hours (120 min). However, with respect to crashes lasting for more than six hours, the frequency of bridge-related crashes is much larger than one of all crashes. That is to say, in general, crashes occurring on bridge segment last more time than all crashes.

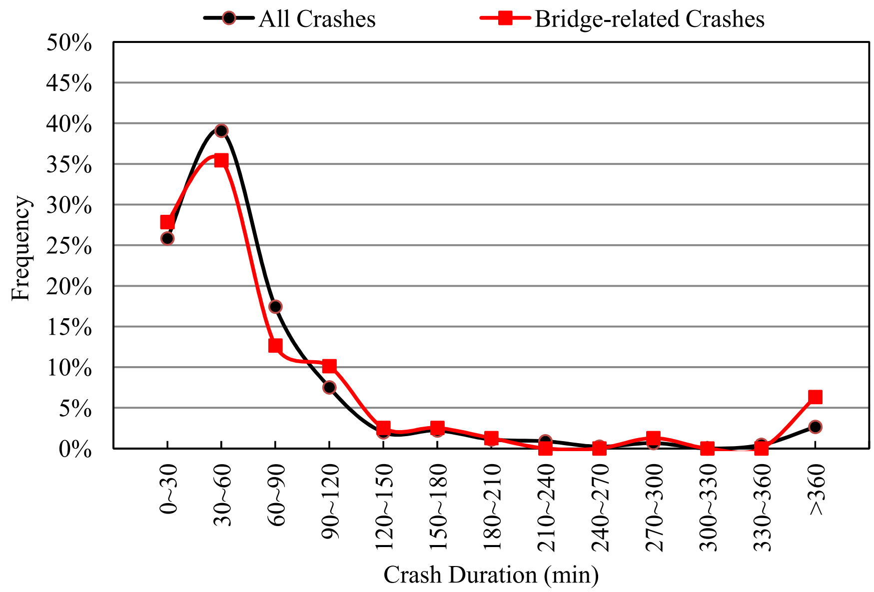

Figure 3. Crashes on Sutong Bridge by duration

4 Conclusions

In regard to Sutong Bridge, bridge-related crashes comprise a significant portion of total crash experience. And the three major types of bridge-related crashes is rear-end, fixed-object, and sideswipe/overtaking. In particular, the bridge segment involves more fixed-object crashes and fewer rear-end crashes than all crashes. Bridge-related crashes comprise a significant portion of severe accidents. Fatal crashes make up a higher percent of bridge-related crashes relative to all crashes. Moreover, although a majority of crashes can be rescued and cleared within two hours, bridge-related crashes take more time to be rescued and cleared than all crashes.

Abstract: With the rapid development of civil aviation, flights have increased dramatically. With the increasing flight density, the control interval has been narrowing constantly. Because of the heavy workload of the air traffic controllers (ATCs) in many regions, the risk of severe consequences due to ATCs fatigue becomes increasingly serious. Based on the analysis of the domestic events caused by ATCs fatigue in recent years, this paper investigates the fatigue of ATCs with using the SHEL model --- 'L' subsystem, 'L -L' subsystem, 'L -H' subsystem, 'L -E' subsystem and 'L-S' subsystem. It establishes the risk evaluation index system of ATCs fatigue. In the new approach, analytic hierarchy process (AHP) is used to determine the weights of evaluation index for ATCs fatigue. The method of decision making trial and evaluation laboratory (DEMATEL) is applied to revise indexes' initial weight at all levels and to effectively reduce the influence among evaluation indexes at all levels, so as to enhance objectivity and scientific degree of the indexes' weight. With the implementing of multilevel fuzzy comprehensive evaluation, each influence on fatigue is collected and corresponding measures are proposed according to the evaluation results to improve the aviation safety.
Keywords: Air traffic controller fatigue; AHP; DEMATEL; Fuzzy comprehensive evaluation; SHEL model; Aviation safety.

1 Introduction

According to the Federal Aviation Administration (FAA) statistics, about 21% of all aviation accidents associated with fatigue (Ji Q et al, 2006). The Confidential Human Factors Incident Reporting Programme (CHIRP) research data shows that 13% of the running error is directly related to controllers' fatigue (Allen, T. 2004). Controllers' responsibility is to prevent the collision of aircraft with aircraft, aircraft with obstacle, to sustain and accelerate the major task of air traffic order, their fatigue greatly increases the incidence of unsafe incidents. Fatigue is the most important factor that causes controllers "error, forgetting and leakage". With the rapid development of civil aviation, unsafe incidents caused by controllers fatigue have the increasing tendency year by year, fatigue has become the most important and unavoidable factor that affects ATC safety .

In general, most researches focused on the analysis of working pressure, control and scheduling system for the effects of fatigue, while ignored the quantitative management of the controllers' fatigue. The SHEL model is one of the most commonly used models that aim to analyze human factors. It can be used to analyze the factors that may affect controllers' fatigue from perspective of the man - machine - environment - management system engineering, so as to build controllers' fatigue risk evaluation index system, then to determine the controller's fatigue level with fuzzy comprehensive evaluation method.

2 To Build Assessment Index System of the Controllers' Fatigue Risk

The SHEL model was originally proposed by Edwards in 1972, and modified by Hawkins in 1987. It is now the research framework of human factor (Hongzhi Wang et al,2012). The controllers' fatigue is a combination of many factors, based on the SHEL model, the fatigue risk's research scope has been defined within the four interfaces of the SHEL model as well as the person's own factors. And the human and software interface mainly refer to some factors of management.

Based on the analysis of the related controllers' fatigue accidents, according to the feasibility of establishing index system, independent, comprehensive and scientific principles, from 'L' subsystem, 'L -L' subsystem, 'L -H' subsystem, 'L -E' subsystem and 'L-S' subsystem, the controllers' fatigue risk assessment index system has been established from the five dimensions based on expert experience (Table 1).

3 Controllers' Fatigue Risk Evaluation Method

3.1 The establishment of evaluation factor set and evaluation set

The factor set is an ordinary set, which is composed of the elements of various factors, usually expressed by $U = \{U_1, U_2, \cdots, U_n\}$. Here, $U_i = \{U_{i1}, U_{i2}, \cdots, U_{ij}\}$ is evaluation factors, it stands for number of single factor of the same hierarchy.

When evaluating sub-factors, determining the comment sets: $V = \{V_1, V_2, \cdots, V_5\}$. Here, V= {' less ', 'small', 'medium', 'high', 'higher'}is evaluation grades standard.

3.2 The determination of the weight sets

The analytic hierarchy process (AHP) is created by the T. L. Saaty professor in early1970s. It is assessing method which combines qualitative analysis , quantitative analysis and practical multi-objective decision analysis methods (Liu Lianxin,2014).

1-9 calibration method (Minhui Yan et al. 2014) is used for expert scoring to draw relevant judgment matrix, and square root method is used to calculate the consistency of judgment matrix. Steps are as follows (Kun P& Maoshan Q,2004):

1) To calculate the geometric mean of all the elements of judgment matrix X of each row: $\overline{W_i} = \sqrt[n]{M_i}$ where $M_i = \prod_{j=1}^{n} a_{ij} \quad i = 1,2,\cdots,n$.

2) To normalize $\overline{W} = \left[\overline{W_1}, \overline{W_2}, \cdots, \overline{W_n}\right]^T$: $W_i = \overline{W_i} \Big/ \sum_{j=1}^{n} \overline{W_j}$, $W = \left[W_1, W_2, \cdots, W_n\right]^T$ is the requested feature vector.

Table 1. evaluation index system of controllers' fatigue risk

Target layer	Index of first level	Index of second level
Controllers fatigue risk assessment	controllers U_1	sleep U_{11}
		Circadian rhythm U_{12}
		Control skills U_{13}
		Experience in control U_{14}
		The body health U_{15}
		Emergency and communication ability U_{16}
		Safety awareness and sense of responsibility U_{17}
	Controllers and Other staff members U_2	Control team U_{21}
		Pilots and other personnel U_{22}
		Members of the family U_{23}
	Controllers and equipment U_3	Equipment failure U_{31}
		Equipment can meet the demand of controllers U_{32}
	Controllers and the environment U_4	The weather conditions U_{41}
		The workplace environment U_{42}
		Sleep and rest environment U_{43}
		The military controls U_{44}
	Controllers and software U_5	Flight flow U_{51}
		Route structure U_{52}
		Business training U_{53}
		Crew resource management U_{54}
		The shift system U_{55}
		staffing U_{56}
		Site management U_{57}
		Operating procedures U_{58}

3) To calculate the largest eigenvalue of judgment matrix: $\lambda_{\max} = \sum_{i=1}^{n} \frac{(X \cdot W)_i}{nW_i}$

4)To determine the consistency index and the consistency ratio: $CI = \frac{\lambda_{\max} - n}{n-1}$, $CR = \frac{CI}{RI}$, where RI is random consistency indicator, its value can be obtained by look-up table (Feng C,2012). If $CR \le 0.1$, generally considered that the judgment matrix assign is reasonable.

3.3 The initial weights DEMATEL method

The DEMATEL is based on digraphs, which can separate involved factors into cause group and effect group (Mohsen Alvandi et al,2012).

1) The establishment of the direct-relation matrix: the direct- relation matrix is set by measuring the relationship between criteria in four levels: 0, 1, 2, 3 , where they respectively represent "no influence", "very low influence ", "low influence ", "high influence ".experts make sets of the pair-wise comparisons in terms of influence and direction between criteria. The direct- relation matrix:

$$A = \begin{bmatrix} 0 & a_{12} & \cdots & a_{1n} \\ a_{21} & 0 & \cdots & a_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix} = \left(a_{ij}\right)_{n\times n}, i = 1,...,n, j = 1,...,n;$$ in which a_{ij} is denoted as the degree to which the criterion i affects the criterion j.

2) To normalize the direct- relation matrix: $Y = A \Big/ \max_{1\le i\le n} \sum_{j=1}^{n} a_{ij} = (y_i)_{n\times n}$.

3) To calculate the total-relation matrix: $Z = Y + Y^2 + \cdots + Y^n = (z_{ij})_{n\times n}$, when $n \to \infty$, $Z = Y(1-Y)^{-1}$

4) To determine the influence weight: $W_b = \sum_{j=1}^{n} z_{ij} W_a \Big/ \sum_{i=1}^{n}\sum_{j=1}^{n} z_{ij} W_a$

5) To determine the new weight: $W = \frac{1}{2}(W_a + W_b)$

3.4 To establish the single-factor evaluation matrix

The ATCs fatigue factor set of risk assessment, from U_i to comment set V are regarded as a fuzzy mapping. The fuzzy evaluation matrix $R_i = \{r_{ijk}\}$ can be determined, where $r_{ijk} = d_{ijk}/d$, d_{ijk} is the number of experts that the evaluation factor U_i in the ij item evaluation index are made as evaluation V_k, d is the total number of experts who participate in the evaluation.

3.5 The fuzzy comprehensive evaluation

The fuzzy comprehensive evaluation method was founded by L. A. Zadeh in 1965, it is built on fuzzy mathematics based on a comprehensive evaluation method, the method is characterized by the use of fuzzy sets, some complex and difficult to quantitative, quantitative factors and then construct the fuzzy matrix, the use of fuzzy operator composite operator, to finalize the evaluation of the object level (Tao, J. C et al,2010).

1) The first level of comprehensive evaluation

According to FUZZY theory, the FUZZY matrix synthesis operation, to evaluate each child respectively to make comprehensive evaluation factor set, U_i of evaluation vector $B_i = W_i \circ R_i = (b_{i1}, b_{i2}, ..., b_{i5})$.

2) The second level of fuzzy comprehensive evaluation

Each child factors set U_i as a factor, B_i was used as the single factor evaluation, namely get factors set U to comment set V a fuzzy mapping. The secondary comprehensive evaluation: $B = W \circ R = (b_1, b_2, ..., b_m)$ .Here, R is fuzzy evaluation matrix. The W stands for weights of objects layer influence factors.

According to the quantitative value of V of the evaluation set , FUZZY comprehensive score of F is obtained by $F = B \cdot V^T$. The evaluation results would be analyzed according to the scores.

4 Controllers' Fatigue Risk Comprehensive Evaluation Example Analysis

Take a control center as an example, based on the evaluation index system and evaluation model, the controllers' fatigue risk instance has been analyzed:

1) To set up the evaluation factor $U = \{U_1, U_2, \cdots, U_5\}$, which $U_1 \sim U_5$ respectively controllers, controllers and other personnel, controllers and hardware, controllers and the environment, controllers and the environment; Second to set up the secondary evaluation factors: $U_i = \{U_{ij}\}(i = 1, 2, ..., 5; j = 1, 2, ..., 8)$.

2) To set evaluation set with the corresponding standards. According to controllers may happen fatigue risk, determine the evaluation sets of five levels: V = {v1, v2, v3 , v4 , v5} = {'less', 'small', 'medium', 'high', 'higher'}. In order to quantify the evaluation results, to make the results easy to understand, it is needed to clear the scale of the grade score interval, and the medium score would be taken as the quantitative score. The specific rating score interval and quantitative score are shown in table 2.

3) To determine the initial weights W_a. Using the expert investigation method, 15 experienced controllers have been consulted according to the rate of 1-9 scaling method to get the corresponding judgment matrix, the initial weight W_a, as shown in table3 has also been got.

Table 2. risk grade and risk level assessment

grade	I	II	III	IV	V
levels	less	small	medium	high	higher
score	[0，20]	(20，40]	(40，60]	(60，80]	(80，100]
score	10	30	50	70	90

4) To modify the initial weights. Through questionnaires to the expert panel, we can get influence matrix between the layers of index, through calculation, affect weight W_b can be set, with integrating the initial weights and improved weight, new weight W can be set .

Table 3. factor sets, evaluation index weights and evaluation results

index	weight			index	weight			Judging matrix data				
	W_a	W_b	W		W_a	W_b	W	V_1	V_2	V_3	V_4	V_5
U_1	0.4390	0.3022	0.3706	U_{11}	0.3135	0.1783	0.2459	0.4	0.4	0.2	0	0
				U_{12}	0.1215	0.1068	0.1142	0	0.3	0.5	0.2	0
				U_{13}	0.0651	0.2488	0.1570	0.1	0.3	0.3	0.2	0.1
				U_{14}	0.0500	0.0986	0.0743	0.1	0.2	0.5	0.2	0
				U_{15}	0.2595	0.1241	0.1918	0.3	0.5	0.2	0	0
				U_{16}	0.0385	0.1516	0.0950	0.3	0.4	0.2	0.1	0
				U_{17}	0.1522	0.0919	0.1220	0	0.1	0.6	0.3	0

				U_{32}	0.6667	0	0.6667	0	0.2	0.5	0.2	0.1
U_4	0.1661	0.2295	0.1978	U_{41}	0.4476	0.3205	0.3840	0	0	0.3	0.3	0.4
				U_{42}	0.1636	0.2265	0.1951	0.4	0.3	0.2	0.1	0
				U_{43}	0.1059	0.4530	0.2795	0.2	0.2	0.3	0.3	0
				U_{44}	0.2829	0	0.1414	0	0.4	0.5	0.1	0
U_5	0.2484	0.1545	0.2015	U_{51}	0.2424	0.0117	0.1270	0	0.4	0.3	0.2	0.1
				U_{52}	0.1216	0	0.0608	0.2	0.4	0.4	0	0
				U_{53}	0.0412	0.1283	0.0847	0	0.3	0.3	0.3	0.1
				U_{54}	0.0655	0.2276	0.1466	0	0	0.3	0.3	0.4
				U_{55}	0.2381	0.0947	0.1664	0	0.2	0.3	0.3	0.2
				U_{56}	0.1259	0.1706	0.1483	0	0.1	0.4	0.3	0.2
				U_{57}	0.0350	0.2340	0.1345	0	0.3	0.3	0.3	0.1
				U_{58}	0.1303	0.1331	0.1317	0.2	0.2	0.4	0.1	0.1

5) To determine the fuzzy evaluation matrix. In accordance with the above comment, 10 control experts are asked to evaluate the indexes to make the fuzzy evaluation matrix (table 3).

6) The first level of comprehensive evaluation.

$$B_1 = W_1 \circ R_1 = \begin{pmatrix}0.2075 & 0.3407 & 0.3211 & 0.1152 & 0.0157\end{pmatrix}$$
$$B_2 = W_2 \circ R_2 = \begin{pmatrix}0.0837 & 0.2703 & 0.4836 & 0.1626 & 0\end{pmatrix}$$
$$B_3 = W_3 \circ R_3 = \begin{pmatrix}0.1666 & 0.2000 & 0.4333 & 0.1333 & 0.0667\end{pmatrix}$$
$$B_4 = W_4 \circ R_4 = \begin{pmatrix}0.1339 & 0.1710 & 0.3088 & 0.2327 & 0.1536\end{pmatrix}$$
$$B_5 = W_5 \circ R_5 = \begin{pmatrix}0.0385 & 0.2153 & 0.3341 & 0.2427 & 0.1694\end{pmatrix}$$

Where "$\circ$" is a compound operator in fuzzy matrix. According to the evaluation factors, we select $M(\bullet,+)$ as the comprehensive evaluation function.

7) The second level of fuzzy comprehensive evaluation.

According to the first level of comprehensive evaluation results, the R can be stated as following matrix:

$$R=\begin{bmatrix}B_1\\B_2\\B_3\\B_4\\B_5\end{bmatrix}=\begin{bmatrix}0.2075 & 0.3407 & 0.3211 & 0.1152 & 0.0157\\0.0837 & 0.2703 & 0.4836 & 0.1626 & 0\\0.1666 & 0.2000 & 0.4333 & 0.1333 & 0.0667\\0.1339 & 0.1710 & 0.3088 & 0.2327 & 0.1536\\0.0385 & 0.2153 & 0.3341 & 0.2427 & 0.1694\end{bmatrix}$$

Make the second level of the fuzzy comprehensive evaluation:

$B=W\circ R=(0.1379 \quad 0.2532 \quad 0.3445 \quad 0.1689 \quad 0.0775)$

The vector B stands for object layer calculation results. Normalized as $B'=(0.1404 \quad 0.2578 \quad 0.3508 \quad 0.1720 \quad 0.0790)$. By fuzzy evaluation vector $V=(10 \quad 30 \quad 50 \quad 70 \quad 90)$ get comprehensive evaluation results:

$F=B'\cdot V^T=45.8251$

In the same way we can get $F_1\sim F_5$ as follows:

$F_1=37.8196$; $F_2=44.4952$; $F_3=44.6676$; $F_4=52.0206$; $F_4=52.0206$.

According to the evaluation results, the evaluation results of risk of fatigue can be stated by the following descriptions:

The grade of controllers' fatigue risk is "medium". The primary index score sorting is $F5>F4>F3>F2>F_1$, in addition to the ATC factor score of 37.8196, in a "small", the other factors in the "medium" level. Among them, the controllers and environmental factors, controllers and software factors score close to 60, namely "high" level, affects the overall score should be paid more attention. For the secondary indicators, among them, the weather conditions, the crew resource management, the shift system, personnel, equipped with 4 factor scores are more than 60, in a "high" level, are the higher rating reasons of the controllers and the environment, controllers and software. For this, the management and training should be strengthened, and the shift system should be optimized. Sleep, body health, emergency and communication ability, equipment failures, workplace environment, complex structure of six factors are in a "small" level; other factors are in the " medium", in which safety awareness and sense of responsibility, the equipment can meet the demand of controllers, business training, site management confusion, preference for 60 points, should be treated seriously to prevent the situation to become worse. Therefore, grading result has pointed out the direction for quantitative fatigue risk management.

5 **Conclusions**

Firstly, to establish the controllers' fatigue risk evaluation index system based on the SHEL model, factors of judgment matrix are obtained by expert grading, the weight of each influence factor is calculated by AHP. Secondly, the weights are modified with using DEMATEL that effectively reduces the interaction between various indicators, thus to improve the objectivity and scientific degree of evaluation index weight. Last, the fatigue quantitatively scores are set with the fuzzy comprehensive evaluation system. With the experiment, through the set model, the controllers' fatigue risk level has been determined as "medium". Verified by the relevant experts, the evaluation result accords with the basic control center's actual situation, which verified the practicability and validity of the evaluation system. At the same time, the various factors scores can provide the basis for fatigue risk management. This method, as a perfect combination of qualitative analysis and quantitative analysis, has provided a new method for the controllers' fatigue quantitative risk management.

6 Recommendations for Future Research

On the basis of the present study, combine with interactive programming software, it can develop tools of fatigue and risk assessment to the airline company's fatigue and risk assessment, provide a great reference of scientific management for the company.

Humanized Transportation Design Research Based on the Sustainable Development of Urban Roads

Zhaoming Zhou[1]; Shengmin Zhou[2]; and Weixiong Zha[3]

[1]College of Civil Engineering, Hunan City University, Yiyang, Hunan 413000.
[2]Xiangtan Technology Research Center of Urban Planning Information, Xiangtan, Hunan 411100.
[3]ECJTU, Institute of Transportation and Economics, Nanchang, Jiangxi 330013.

Abstract: Urban road plays a important task of carrying traffic flow in traffic system. The level of traffic design will directly affect the efficiency exerting of the whole urban traffic. Urban roads humanized transportation design bring humanized design ideas into the urban road traffic design, human centered and scale, to meet people's physiological and psychological needs, material and spiritual needs. In this paper, analyze the connotation of humanized transportation design of urban road. Then explore different levels of goals to humanized transportation design. Finally put forward the specific content of urban roads humanized transportation design, including humanized design of barrier-free facilities, sidewalk, crossing facilities, and temporary park. Through constantly integrate humanized ideas into the urban road design, ultimately achieve the harmony between humankind and nature.

Keywords: Urban roads; Humanized; Transportation design; Sustainable development.

1 Introduction

The sustainable development is the rational regression of think over about human traditional development model, social development translates from purely economic growth into coordinated development of economy, society and environment. Urban traffic sustainable development is the concrete embodiment of the concept of sustainable development in transportation field, and urban roads humanized transportation design is an effective means to achieve sustainable development of urban traffic. Through the use of humanized design ideas in the urban road traffic design, will maximum limit of traffic participants in the passage of time is not one's own internal force through, reduce road conflict between vehicular traffic and pedestrian traffic, protect personal safety of traffic participants, and promote the harmonious coexistence of people-car-road.

2 Connotation of Humanized Transportation Design

Humanized transportation design bring humanized design ideas into the urban road traffic design, optimize the design for transportation system and transportation infrastructure of human centered, to meet people's physical and psychological needs, material and spiritual needs. Through humanized transportation design can maximum limit traffic participants forced through the Places do not have the right of way, reduce the conflict between road traffic and pedestrian traffic, protect the personal safety of traffic participants, promote the harmonious coexistence of people-car-road, conducive to the sustainable development of urban traffic. In the humanized transportation design need to meet the following three requirements:

2.1 Centred round Traffic Participants

Centred round traffic participants, meet the traffic demand of the traffic participants. So-called humane traffic design is the design of traffic required to meet requirements of human. The so-called human traffic design is the traffic design need to satisfy the requirements of humanization. At present the development of urban traffic mode tend to be heavy vehicle light person, urban transportation infrastructure is car traffic system rather than the human system. In fact the ultimate goal of urban traffic is not in order to achieve the transfer of car, but with the help of the various traffic tools to realize transfer of people. In the final analysis is to serve the people.

2.2 Based on Traffic Planning

Taking traffic planning as the basis, play link role between traffic planning and road facilities construction. Traffic design is the intermediate link of traffic planning and road facilities construction. On the one hand through the traffic design makes transport planning concept to be realized, on the other hand road facilities construction need to be guided by the traffic design. Traffic design makes the road facilities construction follow traffic planning concept, to ensure the close linkage between traffic planning and road facilities construction.

2.3 Constrained by Transport Resources

Constrained by transport resources, ensure the effectiveness and feasibility of traffic design. Traffic resources refer to a series of elements of transport activities for the social and economic system, including market resources, technical resources, financial resources and space resources. In the traffic design, it is necessary to give full consideration to the existing transport resources, in order to ensure the effectiveness and feasibility of traffic design.

Humane transportation design based on the above three requirements, finally realize the traffic participants in the general process of traffic demand, included functionality, safety, convenience and comfort. Functionality is the most basic demand of traffic facilities, this is a prerequisite to let traffic participants make use of traffic facilities. Traffic participants in the use of transportation facilities need to consider the safety of transport facilities. After safety is met, traffic participants will pursue the convenience and comfort requirements. Elements of humanistic traffic design as follows.

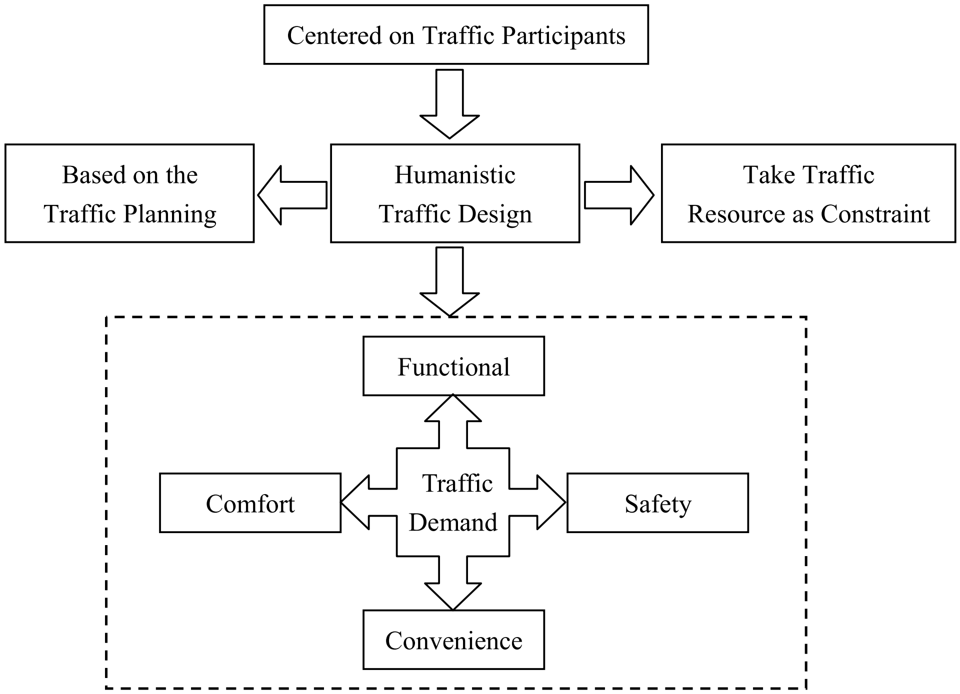

Figure 1. Elements of humanistic traffic design

3 Goals of Humanized Transportation Design

Humane traffic design's goal is to meet the traffic participants in turn different levels of traffic demand, let the traffic participants feel safe, convenient and comfortable in the traffic process. At the beginning of urban development, road system at an early stage, fewer roads and poor traffic quality, at this time traffic design goal is just to meet the basic needs of travel. With the continuous development of urban economy, road facilities gradually increase, traffic accident increased significantly, began to realize the importance of safety. Traffic safety as the main principle in traffic design; strengthen the construction of road safety facilities; ensuring the safety of travel. After the safety of traffic participants are protected, traffic design began to pursue the convenience of transportation. Through the road facilities construction to promote urban road system increasingly perfect. Traffic participants can quickly reach the destination by road infrastructure. When the traffic function, safety, and convenience of goals have been realized, people increasingly high to the requirement of the spiritual life, and humanization design concept more and more attention. Traffic design goal up to traffic comfort, emphasis on human-centered, ultimately achieve the maximum harmonization of people, car, road and environment. The relationship between the various levels goals of traffic humanization design as shown in Figure 2.

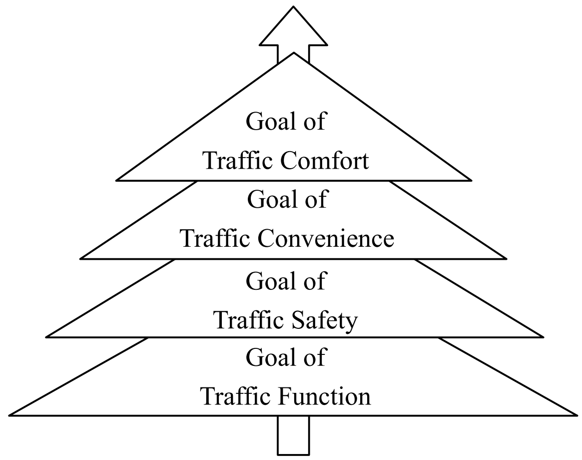

Figure 2. Goals of humanization traffic design

3.1 Goal of Traffic Function

Meet the traffic function is the primary goal of humane traffic design, traffic design if unable to meet the established traffic function, traffic participants would not have to use the traffic facilities, and the presence of the transport infrastructure is redundant. In all goals of humane traffic design, function demand is the most basic and important. Traffic design only meet the function of traffic, traffic participants will pursue a higher level of demand.

3.2 Goal of Traffic Safety

After the traffic design meet the established traffic function, traffic participants will pursue traffic safety in the travel process. Personal safety is the primary factor of traffic participants consider, this is the basic condition for people to survive. Traffic participants in the travel process, safety demand have risen to an irreplaceable position. On the road at any time and any place, people need a protected space. Traffic safety goal should be mentioned in an important position of the human traffic design, and fully consider the traffic participants for the safety of the psychological feeling.

3.3 Goal of Traffic Convenience

Convenience demand refers to traffic participants can easily choose the path in the travel process, eventually passed the road infrastructure to reach the destination. In the traffic design should take full account of this goal, road network is very complicated, when through the network node, traffic participants often encounter the problem of path selection, at this point the need for planning, decision-making, information processing, traffic participants need to have better spatial discrimination and psychological control ability, namely spatial cognition. Now people pay much attention to efficiency, we usually want the most effort, the most energy, the most time, the least cost way to achieve their own needs. So in the city humane traffic design, should fully consider the convenience of traffic participants needs.

3.4 Goal of Traffic Comfort

Comfort goal refers to traffic participants in the travel process of physical and mental pleasure, and enjoy the whole travel process. When the urban traffic design meets the function demand, safety demand and convenience demand of traffic participants, traffic participants becomes to pursuit of comfort goal. Urban traffic to ensure comfortable driving, traffic participants feel happy in the travel process, the quality of life is improved with the increase of, the quality of life increases. Comfort demand is a higher level of demand, can let people to get rid of the traffic negative impact, make the traffic participants physical pleasure in the travel process.

4 Humanized Designs of Urban Roads

4.1 Humanized Design of Barrier-free Facilities

Barrier-free design of urban roads can best reflect the level of humanized, from the blind road layout to curb ramp forms, reflects the love and care for people with disabilities. Currently most of the urban roads have barrier-free facilities, but there are some problems, such as curb ramps and crosswalk mutual dislocation, parking chaos on the blind, blind road brick loose, road barrier-free facilities and surrounding building barrier-free facilities not cohesion. In order to ensure safely travel and use for persons with disabilities, from design, construction to maintenance all needs to be strictly the quality pass. At the same time, the road barrier-free facilities linking to the surrounding entrances, to facilitate travel for the disabled.

4.2 Humanized Design of Sidewalk

Compared with road, city road pedestrian traffic volume is larger, sidewalk is an important part of city roads, establish and improve the pedestrian system is fully reflected humane. In the humanized design of the sidewalk, not only pay attention to the appearance design of pavement, pedestrians on the sidewalk of color and pattern is not very interested, Pedestrians are most concerned about safety and comfort. So traffic design should fully consider the smoothness of sidewalk and paving skid brick as far as possible, ensure that pedestrian can walk safely on the sidewalk.

4.3 Humanized Design of Crossing Facilities

Urban roads occupied large proportion of pedestrians and non-motor vehicles. If not fully consider the demand to across the street in the traffic design, then wait until after the completion of urban roads, they can only to find a suitable way out on their own arrangements, it will be prone to traffic violations such as crossing the road, not only affect the traffic order, and it is easy to cause traffic accidents. Therefore, during the humanized design of pedestrian crossing facilities, shall be detailed investigation of the engineering situation and planning, analysis of pedestrian demand scientifically, clear focus on the general location of crossing the street, and build reasonable crossing facilities.

4.4 Humanized Design of Temporary Park

Motor vehicle in urban road stop disorderly phenomenon is serious. Motor vehicle occupancy lane for parking, likely to cause congestion, reduce the traffic capacity of roads. Combined with urban land resources are very scarce, unable to build a large-scale parking for vehicle parking. In this case, can be wide sidewalks as a temporary parking of motor vehicle, combined with the specific circumstances of each road, sub-sections, sub-time to make scientific and reasonable regulations, formulate feasible charging standards, and increase the daily maintenance of these sections. It can not only make full use of the sidewalk resource, but also can relieve the pressure caused by parking in a certain extent, let parking chaos phenomena become orderly, thus to ensure the stability of the entire traffic order and smooth, thus to ensure the entire traffic order stability and smooth.

5 Conclusions

In summary, with the continuous development of china's national economy and the continuous improvement of people's living standards, urban residents on the construction of urban infrastructure and advance the level of awareness of a higher demand. For urban road, not only on the traffic function, but on the safety, convenience, comfort also has higher requirements. In response to deal with increasingly serious traffic pressure and environmental problems, need to constantly optimize the design of urban roads, integrate humanized ideas in the design, creating humanized space of city, and ultimately promote the sustainable development of society.

Abstract: This article starting from the arterial highway traffic accident analysis, it analyzes "2010 Statistical Yearbook of road traffic accidents" and concludes the distribution law about the arterial traffic accident. Furthermore, the article analyzes the influence factors of arterial roadside accident, comparing the results of the roadside safety problem. According to the latest domestic and foreign roadside design ideas and methods, it analyzes the various design elements and understands the design content, so as to provide a reference to the later proposed improvement measures. Finally, from the side of road safety tolerance design concept and reasonable way the side net perspective, in order to enhance expressway roadside safety, optimize roadside safety facilities. It is of great significance to design roadside and take effective and practical measures to increase the safety level on arterial highway.

Keywords: Arterial highway; Traffic accident; Roadside; Protection; Tolerance design.

1 Introduction

Arterial highway is the main highway in long-distance travel and rapid transportation. But arterial highway traffic easily lead to accidents, due to high speed, complex road condition, complex vehicles and interference factors. Therefore, adopting all kinds of means to reduce off-road accident frequency and off-road accident severity, which has important significance to reduce the loss of people's lives and property and improve the level of road traffic safety.

By analyzing arterial highway accident, we find out the cause and characteristics of the accidents, and summarize the factors influencing arterial highway off-road accidents. Arterial highway roadside design improves road safety conditions and then put forward the main countermeasures of roadside accident.

2 Analysis of roadside accident statistics of arterial highway

This article starting from time, space, conditions and causes four angles, it analyzes "2010 Statistical Yearbook of road traffic accidents" and concludes the distribution law about the arterial traffic accident:

(1) Accident affected by season, from November to January is relative the peak, the number of accidents close to 10 %, while from September to

February's fatal accident rate is relatively high.

(2) The majority of arterial highway accidents occurred during the day, it formed the peak of accidents at 17-20.

(3) Arterial highway accident mainly occurred in the plain areas, accounted for 66%, but from the accident death rate angle, the area of mountain was significantly higher than the plains and hilly area.

(4) Arterial highway accidents mainly distributed in the straight section, the proportion of 90%, but the accident death rate is the lowest.

(5) Arterial highway accident black spot mainly distributed in the road.

(6) Arterial highway without protective measures is easy to cause accident, but inappropriate protective measures will increase the accident death rate.

(7) Arterial highway traffic accident is a collision between motor vehicles. The main form is head-on collision, side collision, following collision and scraping hit pedestrians, which side collision is more than 35%.

(8) The cause of arterial highway is varied, which the main factor is the driver's own, but also there are some objective factors leading to traffic accidents.

3 Analysis of influence factors of arterial highway roadside accident

Transportation system is consisted of people, vehicles and road, traffic accident is also the result of these three factors. The analysis of roadside accident's influence factors are also from the three points.

3.1 Roadside accidents and traffic participants

Traffic participant is driver, passenger and pedestrian, which the driver is the main factor. The driver's physiological; psychology, perception, analysis, judgment and reaction are not identical. While the perceived slow, inaccurate judgment, operational errors in the accident accounted for the majority, which is mostly due to the driver's body, physiological, mental, emotion ,experience and so on.

3.2 Roadside accident and vehicle

The vehicle performance is an important factor affecting traffic safety. Although in many accident statistics, the proportion of roadside accident caused by vehicle fault is not large, but once this kind of accident occurs, the consequences are more serious.

The reason caused by vehicle roadside accident is breaking failure, light failure, mechanical damage, vehicle overloading, goods lashing not solid and other reasons. In addition, because of many parts suffer repeated load, the vehicle will lead to accident after more than a certain number of fatigue.

3.3 Roadside accident and road

Traffic foundation is road. Road must meet its clients' characteristics and demand. The influence factors of road alignment to accident are: radius, curve frequency, corner, steep, linear combination, the horizon. These will affect the driver's driving to a certain extent. Studies have show that widening lane can reduce roadside accident.

Roadside protection measures are important influence factors of roadside accident, but improper protective measures may even lead to the roadside accident.

4 Arterial highway's safety protection design measures

4.1 Safety design concept and elements of arterial highway roadside

Roadside safety design includes tolerant design, flexible design and harmonious design. Tolerance design is the core of roadside safety design (YAO Xianghua, 2010). Based on the tolerant design, road must provide adequate roadside zone to off-road vehicle, in order to ensure the roadside safety and minimize the severity of the accident. The core of roadside tolerance design is the design of roadside zone. During the design of roadside safety facilities, flexible design should consider local economic conditions, the existing facilities, construction materials etc, which to select the most appropriate local scheme from a variety of options. The idea of harmonious design is to protect the local environment, the highway alignment in harmony with environment, giving a comfortable feeling (GAO Hailong, LI Changcheng, 2008).

Highway roadside accident is people, car and road in the traffic system which one or more of the factors' coordinate relationship have been destructed. According to the characteristics of roadside accident, this paper summarized the influence of highway roadside safety and environment factors.

Arterial highway design elements include: highway geometry alignment, road surface recognition, shoulder, side ditch, slope, traffic safety facilities, and other roadside safety facilities and the roadside environment.

4.2 Arterial highway roadside accident active preventive measures

Active guidance is to achieve interaction between driver and road, which install traffic safety facilities and improve road environment. The driver can consciously change operation behavior and driving direction, according to the information conveyed by running environment. Driving environment played an "active" leading role, who prevent vehicle from driving off-road and effectively reduce the possibility of vehicle off-road (LI Yang, 2008).

4.2.1 Line of sight guidance

Line of sight induced facilities set along the lane both of the road, indicating the direction of the road, roadway boundary and dangerous section. It can induce the driver's line of sight in the daytime and night, showing the outline of road and guiding or warning the change of the highway alignment, in order to promote safe operation. At present common sight induced facilities are outline sign, linear induction sign (PENG Wuxiong, 2007) and confluence induced sign. The facility's cost is low and the use is widespread.

Outline sign arrange on the edge of the road, indicating the road alignment outline and the right direction. Arterial highway often has vicious accidents in sharp and continuous steep place, where it is necessary to set up outline sign. The accident black spot should also set up a reflective outline sign or bigger size of reflector. When you set the outline sign, please pay attention to the transition between the straight line and curve, and maintain a smooth continuous line of sight guidance.

Linear induction sign used to show the outline of road and guiding or warning the change of the highway alignment, in order to promote safe operation. Linear inducing divided into the indicative linear inducing sign and warning linear inducing sign.

Confluence induced sign commonly is warning pile. Warning pile is to improve its recognition and warn driver road alignment, which usually are red and white. Warning pile is arranged on the side of roadside with a certain width and good horizon.

4.2.2 Cross-boundary reminder

Cross–boundary reminder has vibration line and shoulder rumble strip. Vibration line's surface spread over refractive index glass beads, which can slow down, prevent slippery and rainy night reflection. At the same time, it also can effectively avoid vehicle off-road according to vibration reminder which serve as a warning to the driver. Setting vibration line needs to have adequate zone providing "tolerance" space to off-road vehicle.

Shoulder rumble strip remind vehicle through the vibration and noise to return the normal lane. Reducing caused by driver fatigue and distraction off-road accident is very effective. It has low maintenance cost and high profit. It also can be used in existing or new pavement.

4.2.3 Pavement skid resistance

Pavement skid resistance mainly set skid resistance sideslip and change the pavement structure. Skid resistance sideslip usually arranged on sharp bends or steep sections, and its cost is low. Changing pavement structure aim to increase pavement skid resistance coefficient and improve pavement skid resistance. It includes changing pavement material, increasing the cover layer, increasing pavement texture, using pavement groove. Due to the high cost, it generally used in high grade highway.

4.2.4 Shoulder hardening

Shoulder hardening can be divided into shoulder widening and shoulder strengthening. In most cases shoulder widening involve widening roadbed. From the financial point of view, it is not very economical, compared with shoulder strengthening is more economical and efficient. Shoulder strengthening is one of the most effective means to increase the width of the road, especially highway pavement width is small in the mountainous area, which can increase traffic capacity and improve traffic safety.

4.2.5 Speed control

Speed control includes the following factors: Advisory, Speed feedback facilities, Deceleration mark, Illusion mark and Deceleration hump.

Advisory speed limit is different from the general speed limit. It does not have the force of law. In China there is not advisory speed limit, but many foreign countries began to use. Advisory speed limit is usually used in dangerous curve recommended together with warning sign.

Speed feedback facilities can detect vehicle speed passing a point and display on the screen. Once the vehicle speeding, it also can send out the alarm to the driver. In arterial highway, speed feedback facilities are suitable to frequent accidents sections caused by excessive speed.

Deceleration mark is used to remind the driver to slow down. It usually set in a small radius curve segment, long downhill, uphill convex vertical curve etc.

The principle of the illusion mark is making driver illusion that feeling the road is more and more narrow, causing the driver's psychological preparedness and involuntarily slowing down.

Deceleration hump is a mandatory deceleration measures which have a certain degree in the road. It usually sets at the chicane steep two-lane highway, the continuous long steep, road through the town or village. Next to the deceleration hump should set up corresponding deceleration sign and mark.

4.2.6 Change the alignment

Changing the alignment includes changing the horizontal curve and geometry. If changing horizontal curve and shoulder widening implemented together, it will greatly help to reduce arterial highway roadside accident. Change horizontal curve common methods are: increasing the horizontal curve radius, setting transition curve and avoiding negative linear combination. Changing road geometric alignment is high investment and long cycle, but is the most fundamental improvement method. Improving methods are the following three points: making the alignment consistency, straighter and eliminating the "dark concave".

4.3 Arterial highway roadside roll over and collision protective measures

Arterial highway roadside roll over and collision protective measures is to set up adequate roadside area and minimize roadside obstacles. It includes rational design of embankment slope, drainage facilities, removal of roadside hazardous materials, roadside hazardous material sign.

Embankment slope can be divided into three types: return slope, non-return slope and dangerous slope. Return slope's safety is best. Off-road vehicle usually can stop or slow back to lane in the return slope. Design had to be not apparent discontinuities dangerous goods and fence. If necessary, it can set the sight induced facilities. In the non-return slope, vehicles usually can not stop or return to lane, but directly ran to the bottom of the slope, so the slope cannot exist dangerous goods. In the dangerous, the vehicle roll over accident possibility is bigger.

Roadside drainage facilities include curb, ditch, culvert and other drainage structures. The design of ditch should not only meet the requirements of drainage, but also as far as possible not lead to off-road vehicle plunged into ditch or collision with the ditch.

Off-road vehicle will collide with roadside obstacles. In order to reduce such accidents, we should try to remove roadside obstacles.

When the roadside dangerous goods can not be removed shift and other means of disposal, it can brush reflective paint on the goods or set warning sign next to the dangerous.

4.4 Arterial highway roadside collision protection measures

Arterial highway roadside collision protection measures mainly are roadside fence, energy dissipating installation and buffer energy dissipation facilities.

Collision avoidance mechanism of roadside barrier is absorbing the energy of collision through barrier and vehicle elastic-plastic deformation, friction and displacement body, in order to protect the driver and passenger safety. Barrier itself is an obstacle, and it should properly handle roadside safety area' obstacle with design of tolerance idea. Its cost is high, but it must use in mountainous road.

In order to ensure the highway roadside safety, it should try to eliminate the potentially dangerous goods in the roadside area. But some facilities are essential, such as traffic sign, road lighting facilities and traffic signal emergency telephone. such facilities' rod has formed the fixed obstacles. When ensure such facilities that can resist wind load and ice load, it can realize yield and disintegration to erased collision through the sliding surface, plastic hinge and frangible element, in order to reduce the severity of accidents.

Buffer energy dissipation facilities usually set at highway horizontal curve, interchange, entrance of service area, bridge parapet ends and bridge piers, playing a warning and buffer role. Its cost is low and the use is widespread.

5 Conclusions

This paper analyzes the law of arterial highway accidents and the influence factors of arterial roadside accident, comparing the results of the roadside safety problem. Then it analyzes the various design elements and understands the design content. Finally it concludes roadside accident active preventive measures, roadside roll over and collision protective measures and roadside collision protection measures. This paper has great theoretical and practical significance.

Abstract: Traffic electronic enforcement facilities were carried out widely in china, but its application effectiveness was lack to system evaluation. The time distribution, types, cause and severity degree of traffic accidents were comparatively studied on the basis of datum which were collected before and after the implementation of traffic electronic enforcement facilities, and the existing problems of traffic safety were concluded at signalized intersection after implementing traffic electronic enforcement. The analysis showed that traffic electronic enforcement could obviously improve the condition of traffic safety at signalized intersection, especially restrain the traffic accidents significantly which were caused by illegal driving that traffic electronic enforcement facilities could detect, but the severity degree of traffic accidents tended to worse. In order to improving the condition of traffic safety in the environment of traffic electronic enforcement, the safeguards should be set up from the aspects of education, engineering and management. The conclusion was helpful to guiding the scientific application of traffic electronic enforcement in china.
Keywords: Electronic enforcement; Safety effectiveness; Safeguards; Traffic accident.

1 Introduction

A number of researching works have been carried out abroad in the aspects of safety effect evaluation and safeguards of traffic electronic enforcement because of their longer application of traffic electronic enforcement facilities, the evaluation methods have been formed. For example, Flannery and Maccubbin used Meta analysis techniques to assess the safety effect of red light running cameras (A Flannery, 2002). Ruby and Hobeika evaluated the effectiveness of red light running cameras from the aspects of traffic violation, traffic accidents and socio-economic, pointed out that warning signs should be established at the upstream position of traffic electronic enforcement facilities (D E Ruby, 2003). Zwahlen and Suravaram analyzed the contribution of driver education, strict issuance of driving licenses and traffic electronic enforcement, pointed out that traffic electronic enforcement was the most efficient way to reduce traffic accidents (H T Zwahlen, 2007). Decina and Thomas systematically evaluated the situation of traffic safety at the sites of traffic electronic enforcement facility (L E Decina,2007). Stokes, Russell and Rys analyzed the feasibility, effectiveness, legitimacy and public acceptability of automated traffic signal enforcement in Kansas(R W Stokes,2003). Tarek and Paul proposed the evaluation method of intersection safety camera program in Canada (S Tarek, 2007) .

Because of significant difference of traffic environment between China and developed countries, moreover the traffic electronic enforcement facilities were carried out widely in China, so it was necessary to assess the situation of traffic safety improvement after its implementation in order to play the advantages, meet the shortfall and promote scientific applications of traffic electronic enforcement.

2 The characteristics of traffic accident

The accident data in this paper was provided by the traffic police department, relying on the national "863" project. The scope of investigation was traffic accidents at forty signalized intersections during three years before and after the implementation of traffic electronic enforcement in Harbin, China. Harbin implementation of traffic electronic enforcement began to be widely used in 2006, so the accident data for consecutive three years was 2002 to 2004 and 2006 to 2008. Statistical analysis of the data used comparison method, and through quantitative and qualitative analysis, the safety effectiveness of traffic electronic enforcement was mainly reflected.

(1) Key indicators comparison of traffic accidents

Table 1 lists the key indicators comparison of traffic accidents at forty signalized intersections before (from 2002 to 2004) and after (from 2006 to 2008) the implementation of traffic electronic enforcement in Harbin, China.

The datum in table 1 showed that the number and total economic loss of traffic accidents reduced obviously after the implementation of traffic electronic enforcement, the condition of traffic safety at signalized intersections had been improved, but death rate, injury rate and economic loss per traffic accident were rising, which death rate per traffic accident increased 0.087, the injury rate per traffic accident increased 1.039. The rising characteristics of traffic accidents were related with the situation that drivers accelerated to pass signalized intersection at the moment of rear yellow time in order to avoiding the punishment by traffic electronic enforcement. If the growth of traffic volume was considered before and after the implementation of traffic electronic enforcement, the accident rate per vehicle would decrease more and more after the application.

Table 1. Accident comparison at signalized intersection before and after the implementation of traffic electronic enforcement

Items	Accident number	Deaths	Injured	Economic loss(RMB)	Death rate per accident	Injury rate per accident	Economic loss per accident (RMB)
Before implementation	168	19	98	698300	0.113	0.583	4157
After implementation	45	9	73	195200	0.200	1.622	4338

(2) Comparison of traffic accident types

Except the number of traffic accidents reduced significantly, there were great differences in traffic accident types before and after the implementation of traffic electronic enforcement. Table 2 lists the types comparison of traffic accidents at forty signalized intersections in Harbin, China.

The datum in Table 2 showed that the number of traffic accidents in head-on collision, side collision, rear-end collision, on to scratch, same to scratch and roll-over reduced greatly at signalized intersection after the implementation of traffic electronic enforcement, which side collision accidents decreased 54, accounting for 32.1 percent of the total number of traffic accidents before the implementation, those were related with the reduction of illegal driving such as red light running. But the number of pedestrian-related traffic accidents increased 5, accounting for 11.1 percent of the total number of traffic accidents after the implementation, those were related with the situation that drivers didn't notice pedestrians enough when they accelerated to pass signalized intersection at the moment of rear yellow time in order to avoiding the punishment by traffic electronic enforcement.

Table 2. Accident types comparison at signalized intersection before and after the implementation of traffic electronic enforcement

Accident types	Accident number			Percentage (%)		
	Before implementation	After implementation	change	Before implementation	After implementation	change
Head-on collision	46	16	-30	27.38	35.56	+8.17
Side collision	70	16	-54	41.67	35.56	-6.11
Rear-end collision	15	2	-13	8.93	4.44	-4.48
On to scratch	11	0	-11	6.55	0.00	-6.55
Same to scratch	16	0	-16	9.52	0.00	-9.52
Scratching pedestrian	1	6	5	0.60	13.33	+12.73
Collision fixture	3	3	0	1.79	6.67	+4.88
Roll-over	1	0	-1	0.60	0.00	-0.60

(3) Time distribution comparison of traffic accidents

Figure 1 describes the time distribution difference of traffic accidents before and after the implementation of traffic electronic enforcement at forty signalized intersections in Harbin, China.

From the perspective of occurring time, traffic accidents mainly happened from 7:00 to 23:00 before the implementation of traffic electronic enforcement, which the number of traffic accidents in the periods of 8:00-10:00,11:00-12:00 and 15:00-18:00 was more than the ones in other time. The traffic easily fallen into congestion in the three time which coincided with the peak hours of traffic volume. At those times, drivers were prone to impatience, which would increase the possibility of illegal driving in the period of rear yellow time and the first part of red time.

Traffic accidents occurred more dispersed after the implementation of traffic electronic enforcement, which was related with the condition that traffic electronic enforcement restrained illegal driving.

(4) The cause comparison of traffic accidents

Figure 2 compares the cause difference of traffic accidents before and after the implementation of traffic electronic enforcement at forty signalized intersections in Harbin, China.

From the perspective of cause of traffic accidents, the number of traffic accidents which were caused by illegal driving that traffic electronic enforcement facilities could detect, such as illegal occupying lane, red light running, illegal U-turn, etc. decreased significantly from 42 to 9, accounting respectively for 25 percent and 20 percent of the total number of traffic accidents before and after the implementation of traffic electronic enforcement. But the number of traffic accidents which were caused by illegal driving that traffic electronic enforcement facilities could not detect was almost same before and after the application of traffic electronic enforcement, only decreased from 29 to 26, accounting respectively for 17.3 percent and 57.8 percent of the total number of traffic accidents before and after. The result showed that traffic electronic enforcement could restrain the traffic accident significantly which was caused by illegal driving that traffic electronic enforcement facilities could detect. The cause of the other traffic accidents mainly was focused on the driver negligence, improper operation, etc.

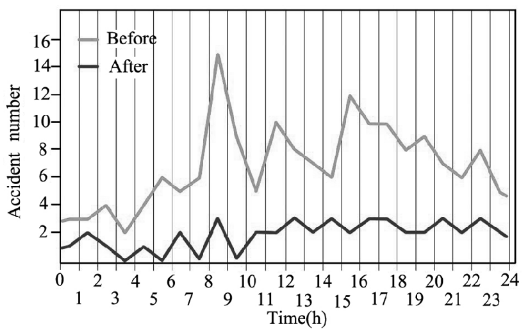

Figure 1. Time distribution of traffic accidents before and after the implementation of traffic electronic enforcement

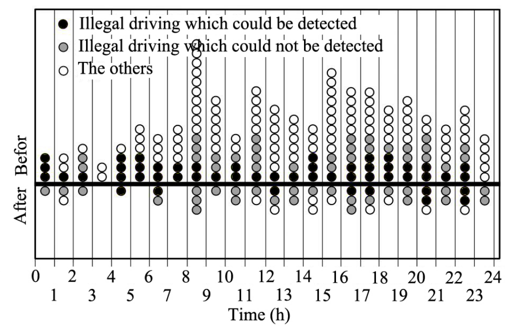

Figure 2. The cause of traffic accidents before and after the implementation of traffic electronic enforcement

(5) Severity degree comparison of traffic accidents

Figure 3 draws the severity degree difference of deaths-related traffic accidents before and after the implementation of traffic electronic enforcement at forty signalized intersections in Harbin, China.

From the perspective of severity degree of traffic accidents, the number of deaths-related traffic accidents decreased from 15 to 8, accounting respectively for 8.9 percent and 17.8 percent of the total number of traffic accidents before and after the implementation of traffic electronic enforcement. But the deaths-related traffic accidents mostly concentrated from 18:00 to 3:00 after the implementation instead of the dispersed deaths-related traffic accidents before the implementation of traffic electronic enforcement, and the rate of deaths-related traffic accidents of the total traffic accidents increased obviously, those were related with the high speed at signalized intersections in order to scrambling the rear yellow time and the low punishment possibility by traffic electronic enforcement at night.

Figure 4 shows the severity degree difference of injured-related traffic accidents before and after the implementation of traffic electronic enforcement at forty signalized intersections in Harbin, China.

The number of injured-related traffic accidents decreased from 76 to 34, accounting respectively for 45.2 percent and 75.6 percent of the total number of traffic accidents before and after the implementation of traffic electronic enforcement. The injured-related traffic accidents occurred relatively dispersed from 6:00 to 21:00

after the implementation instead of centralized injured-related traffic accidents in peak hours before the implementation of traffic electronic enforcement. But the rate of injured-related traffic accidents of the total traffic accidents increased greatly, the reason was same as the one of deaths-related traffic accidents.

The above analysis showed that the severity degree of traffic accidents tended to worse after the implementation of traffic electronic enforcement, so it was needed to strengthen the safeguards of traffic safety at signalized intersections in the period of yellow time in the environment of traffic electronic enforcement.

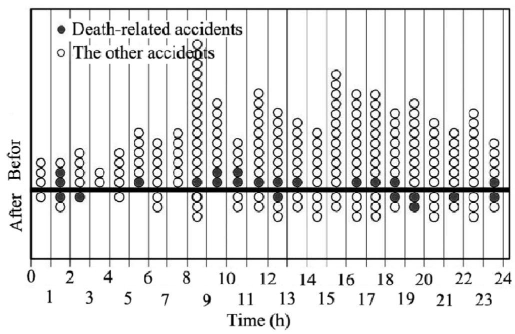

Figure 3. Comparisons of deaths-related traffic accidents before and after the implementation of traffic electronic enforcement

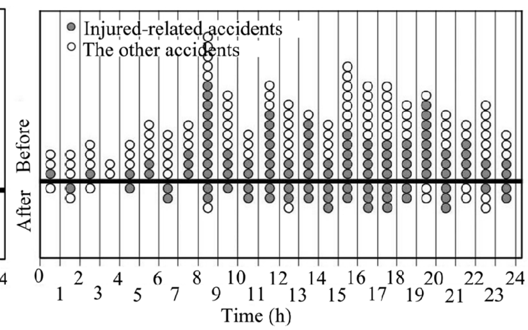

Figure 4. Comparisons of injured-related traffic accidents before and after the implementation of traffic electronic enforcement

3 Safety effectiveness of traffic electronic enforcement

The safety effectiveness which was taken by traffic electronic enforcement was mainly reflected in table 3.

Overall, traffic electronic enforcement was helpful to reduce traffic accidents and deaths or injured, improve the condition of traffic safety at signalized intersections. But some new problems such as pedestrian-related traffic accidents adding, severity degree of traffic accidents tending to worse, etc. must be paid more attention and solved effectively.

4 Safety safeguards in the environment of traffic electronic enforcement

In order to improve the condition of traffic safety at signalized intersections in the environment of traffic electronic enforcement, combining with foreign management experience and actual application situation in China, the following three aspects of safeguards were advised.

(1) Education

① strengthening the propagation of traffic electronic enforcement

The positions and types of traffic electronic enforcement, the serious consequences which were caused by illegal driving should be placard and propagated by broadcast, TV, text, internet and promotional panels, avoiding to occur serious traffic accidents at the location of traffic electronic enforcement because drivers understand deviation.

② improving awareness of traffic safety of traffic participants

Driver was the first factor which affected traffic safety, he should be improved safety awareness by education to fundamentally curb the occurrence of traffic violations and decrease the driving risk. At same time, pedestrians also should be strengthened to educate and propagate to protect them from being collided with vehicles. The educational contents included crossing the street civilization, crossing the street at the prescribed places and crossing the street under the traffic signal and traffic signs.

Table 3. Safety effectiveness conclusion of traffic electronic enforcement

Items	Effects and existing problems	Reasons
Overall effectiveness	Traffic accidents reduced obviously The total loss of traffic accidents reduced significantly	The times of traffic violation reduced The traffic order improved The continuous traffic violations suppressed
Time distribution of accident	Traffic accidents occurred more dispersed The high incidence periods of traffic accidents eliminated	Traffic violations reduced significantly in peak hours
The cause of accident	Traffic accidents which were caused by illegal driving that traffic electronic enforcement facilities could detect reduced obviously Traffic accidents which were caused by illegal driving that traffic electronic enforcement facilities could not detect almost kept same	Illegal driving that traffic electronic enforcement facilities could detect reduced significantly Traffic electronic enforcement facilities could not restrain the illegal driving which could not detect
Severity degree of accident	Death-related traffic accidents reduced, cumulative number of deaths reduced Death-related traffic accidents occurred at night or in the evening	Illegal driving reduced significantly such as red time running Detection accuracy of traffic electronic enforcement decreased at night, the deterrent effect reduced
	Injured-related traffic accidents reduced, cumulative number of injured reduced Average severity degree of injured-related traffic accidents increased	Illegal driving reduced obviously such as red light running High speed at signalized intersection in order to scrambling the rear yellow time
Accident types	Traffic accidents in collision and scratch reduced obviously Pedestrian-related traffic accidents increased	Illegal driving reduced obviously such as red light running High speed at signalized intersection in order to scrambling the rear yellow time

(2) Engineering

① perfecting signs and markings of traffic electronic enforcement

The study showed that traffic electronic enforcement could effectively restrain illegal driving only when there had complete traffic marking (H Ke ,2012). So the marking must be complete in the environment of traffic electronic enforcement to ensure the high level of deterrent effect.

In addition, it was very necessary to add warning signs at the location of traffic electronic enforcement in China. Not only the signs could strengthen the deterrent effect of traffic electronic enforcement, but also its could avoid the improper operation to lead to traffic accident, which was caused by driver tension when he suddenly saw traffic electronic enforcement facilities but there was not warning information in advance to meet psychological reaction time. In abroad, if the place was set up traffic electronic enforcement facilities, not only the location but also the position in front of 50-100 meters all were built warning signs, and the enforcement types such as red light running, over speed, etc. were marked, seeing figure 5.

② adding the stop marking in the period of yellow time

Driver often accelerated to pass signalized intersection to scramble the yellow time in order to escape the punishment by traffic electronic enforcement facilities. At this time, he rarely paid attention to the crossing pedestrians to lead to serious traffic accidents. One traffic marking was proposed to remind driver slowing down to avoid the driving behavior of scrambling yellow time when he didn't pass the marking at the moment of yellow light opening (J Xiancai,2011). The marking was set up in front of the stopping line; the detail position was described by formula (1).

$$L=YV-l \tag{1}$$

where, L was the maximum distance(m) that vehicle completely pass the stopping line under uniform speed when the yellow light lighted, Y was the yellow time(s), V was the maximum limited speed(m/s), l was the length of vehicle(m).

③ setting up protective measures for crossing pedestrians

If there existed significant confliction between vehicles and pedestrians at intersection, it was very necessary to set up protective measures for crossing pedestrians in addition to reminding driver to drive carefully, such as guardrail, safety island, etc. On the one hand those measures protected crossing pedestrians from collision with vehicles; on the other hand they could guide the behaviour of crossing pedestrian. If the turning sight distance was bad at intersections, some traffic safety facilities should be built such as convex mirror, speed lump.

Figure 5 the signs of traffic electronic enforcement

(3) Management

① ensuring scientific placement of traffic electronic enforcement

The placing principle of traffic electronic enforcement was to improve the condition of traffic safety and reduce the traffic violations. The total number and the rate of traffic violation, the traffic accidents should be considered more when the locations of traffic electronic enforcement were selected. The locations and types of traffic electronic enforcement should be published and propagated to improve transparent before application instead of concealed enforcement in order to fine.

In addition, uniformity should be considered to enhance the deterrent effect when traffic electronic enforcement facilities were placed. The situation should be avoided that traffic electronic enforcement facilities were placed intensively in part region but its were lack in other region. The inhomogeneity easily leads to decline the deterrent effect of traffic electronic enforcement, and increase driver's trusting to luck.

② taking mobile traffic electronic enforcement to enhance deterrence effect

It was needed to spend huge to realize the complete coverage of traffic electronic enforcement facilities in city, and it was not scientific solution plan. Mobile electronic enforcement facility could not only restrain illegal driving as fixed traffic electronic enforcement facilities did but also enlarge enforcement coverage in space. One hand it could save cost, on the other hand it also solved the blind spot that fixed traffic electronic enforcement facilities left, was helpful to restrain driver's trusting to luck.

③ improving the management efficiency of traffic violations to strengthen the deterrence degree

The efficient system of traffic electronic enforcement should be built quickly in order to detect rapidly, process fast, and publish immediately illegal driving. In management, traffic violators must be executed punishment to eliminate privileges and relationships; illegal driving must be checked by continuously improving the detection accuracy and range of traffic electronic enforcement facilities, timely maintaining the failure facilities of traffic electronic enforcement; the information of traffic violation must be informed promptly to driver by text, letter, etc. Those measures could enhance the deterrent effect of traffic electronic enforcement, completely dispel the driver's trusting to luck, and avoid the occurrence of continuous and multiple illegal driving in the process of driving.

5 Conclusions

Here we may draw the following conclusions.

(1) Traffic electronic enforcement could restrain the traffic accidents significantly which are caused by illegal driving that traffic electronic enforcement facilities could detect, but it was very limited to restrain the traffic accidents which are caused by illegal driving that traffic electronic enforcement facilities could not detect.

(2) The time distribution, types, cause and severity degree of traffic accidents had been changed greatly before and after the implementation of traffic electronic enforcement. Traffic electronic enforcement was helpful to reduce traffic accidents and deaths or injured, improve the condition of traffic safety at signalized intersections; but the severity degree of traffic accidents tended to worse after the implementation. So it was needed to strengthen the safeguards of traffic safety at signalized intersections in the period of yellow time in the environment of traffic electronic enforcement.

(3) In order to ensure traffic safety at signalized intersections in the environment of traffic electronic enforcement, the safeguards should be set up from the aspects of education, engineering and management. The purpose was to improve the deterrent

effect of traffic electronic enforcement to restrain more illegal driving, realize traffic accidents controllable.

Abstract: Much of the researches show that 75% of the accidents are caused by human factors, among them about 21% are connected with fatigue. The mission of civil aviation air traffic controllers is to prevent the aircraft from colliding and to guarantee the smooth flowing of air traffic. With the development of civil aviation of China, the flight number has increased dramatically; unsafe incidents caused by controllers' fatigue are also increasing. Considering the complicated and ambiguous characteristics related to fatigue, this paper, based on the SHEL model, investigates the air traffic controllers' fatigue from a new perspective with dividing it into 'L' subsystem, 'L-L' subsystem, 'L-H' subsystem, 'L-E' subsystem and 'L-S' subsystem. Some suggestions on reducing the fatigue risk of air traffic controller have been given.

Keywords: Aviation safety; Human factors; Air traffic controller fatigue; SHEL model.

1 Introduction

The purpose of air traffic control is to prevent collisions between civil aircraft and aircraft, civil aircraft and obstacles, and to maintain and expedite an orderly flow of air traffic. In order to prevent collisions, to organize and to expedite the flow of traffic, and to increase aviation safety, controllers need to provide information and other support to pilots. Based on these requirements, the air traffic control must be available 24 hours per day in many airports. Controllers have to work in shifts. Shift work or long hours patterns that disrupt the body's circadian rhythms often result in workers' fatigue. Controllers' fatigue is a threat to aviation safety because it can affect all tasks, whether it is because of impaired judgment, concentration difficulty, or other performance deficiencies.

The role of human error in aviation accidents is well established with previous studies reporting that between 70% -80% of aviation accidents result from some type of human error, 21% of reported aviation incidents are fatigue related (Shappell & Wiegmann, 2004;Jackson & Earl,2006). In recent years, the theory and method about the SHEL model analysis has been widely applied in areas such as medical (Molloy & O'Boyle, 2005; Antunes, Bandeira & Carriço, 2010), petrochemical industry (Mao Jian et al, 2010; Jiang Hongye et al, 2011), shipping (Wang & Zhao, 2012; Zeng & Gao, 2010), highway transportation (Cheng, 2007) and in civil aviation that is particularly prominent. Civil aviation communication error events are analyzed based on SHEL model (Sun & Shi, 2011); the SHEL model was applied to fuzzy comprehensive evaluation for aviation safety (Zhang & Wang, 2006); human factors in the maintenance efficiency is analyzed and the research based on the SHEL model (Li & Feng, 2009); aviation enterprises safety was evaluated and research based on neural network and the SHEL model (Wang, 2010).

On the basis of the traditional SHEL model using, with the analysis and summarization of the existing application and analysis model, controllers' fatigue risk is analyzed and research has been done from the L, L-L, L-H, L-E and L-S five aspects, and policy recommendations have been put forward, solution has been given for air traffic controllers' fatigue risk control.

2 The SHEL Model

SHEL model is firstly put forward by Edwards in 1972, then in 1987 Frank Hawkins had made modification, and now this model is widely used in research framework of artificial factor (Itoh, Mitomo, Matsuoka, & Murohara,2004).SHEL model is a conceptual model of human factors as an acronym of its constituent elements (Software, Hardware, Environment, and Liveware) (figure 1). The liveware is the center of the model and the most important factor of the system. Liveware, software, hardware, environment and the relationship among them, have made the four interfaces of the model: L-S, L-H, L-E and L-L interface. The relationship between each interface is uneven, which means the four interfaces are not made of completely perfect matches. The elements of the system should be considered with much caution, otherwise will lead to system crashes and accidents.

Figure 1. The SHEL model

3 Controllers' Fatigue Risk Analysis Based on the SHEL Model

The air traffic control work is an open, dynamic and multi-variable system in which man-made factors have a crucial role to play. Civil aviation is in a rapid development phase. The air traffic flow is increasing. The airspace is becoming more and more crowded. The workload of ATC is usually too big. The number of accidents caused by controllers' fatigue is growing. Controllers' fatigue, as a kind of human factors, is also combined with the liveware and its software, hardware, environment of interactive interface. Therefore, the SHEL model can scientifically analyze the factors affecting all aspects of controllers fatigue, easily find fatigue cause and take preventive measures from the comprehensive perspective, so as to minimize accidents risk caused by controllers' fatigue.

In the controllers fatigue risk assessment system:

L subsystem: that refers to the personal factors related to controllers' fatigue. Control work's particularity and shifting system can affect controllers' health, and poor health condition results in poor self-adaptive variation and poor adjustment ability. The cumulative fatigue is not easy to deal with. The work efficiency, the workload of the controllers, the controllers' business knowledge, skills and control experience would affect the fatigue. Personal physiological factors, psychological factors and living styles have an effect on fatigue as well as emergency and communication ability, safety awareness and sense of responsibility. Eating habits cannot be ignored.

L-L subsystem: in air traffic control system, that mainly refers to controllers and pilots, adjacent sectors, adjacent control room, the traffic control department coordination communication and control unit. Control team cooperation and interpersonal relationship, not only directly affect the working status and workload of the controllers, but also affect the controllers' psychological status, which make the mental load increased further. Controllers' communication with the related personnel and the degree of language standardization will affect the workload.

L-H subsystem: including radar system, communication system, telegram processing system and other facilities, or controllers and system entities, mainly refer to the relationship between the controller and hardware device. With the progress of modern science and technology in civil aviation, modernization of ATC equipment is widely used. But no perfect coordination can be found to match the controllers' operation habit. For example, the equipment design and fabrication are not consistent with people's physiological and psychological characteristics that will affect the controllers' fatigue the same. Work stability and accuracy of the hardware are also potential impact factors of controllers' fatigue.

L-E subsystem: including the internal environment and external environment. Bad weather will increase control calls and ATC workload. Controllers need to concentrate for a long time, with bad weather; controllers are more likely to get tired.

Family relationship is harmonious or not will affect controllers' psychological condition, that may be a cause of fatigue the same. The working environment such as temperature, humidity and lighting are connected with work efficiency. Unqualified working environment can not only reduce control efficiency, but also cause controllers' long-time accumulated fatigue. Sleep environment is comfortable or not directly affects the controllers' sleep quality and length. In recent years, with the increased number of the military training missions, especially after the implementation of RVSM, controllers' workload is greatly increased with the military coordination, .

L-S subsystem: mainly refers to the management factor, also includes the control program, the computer program, the progress strips use, information display and the other non-physical information. The particularity of the controls work requires controllers work on shift, and shift work disrupts controllers' normal circadian rhythm and affects sleep. That is why the shift system is reasonable or not is still a question. Rules and regulations of the design are reasonable or not, working procedure is standard or not, will increase the workload of the controllers to reduce the working efficiency.

4 Controllers Fatigue Risk Control Decisions and Recommendations

4.1 Controller implementation process of risk control methods

Controllers fatigue control scheme is future-oriented. It is based on the fatigue risk identification and assessment, to take measures to reduce the risk of controllers' fatigue. According to these measures, the concrete fatigue risk control scheme is made. In practice, it can be combined with the real-time control and feedback control.

According to the characteristics of the controllers' fatigue risk, the following fatigue risk control process is designed (as shown in figure 2):

Firstly, the controllers fatigue regulators issues a fatigue risk monitoring instruction; then the whole fatigue risk monitoring system starts. According to the controllers' fatigue risk analysis based on the SHEL model, from L, L - L, L - H - E, L - S, these five aspects, specific analysis has been made on fatigue risk evaluation factors to judge whether the evaluation indexes are in the normal range or not. With this comprehensive evaluation, if the risk of fatigue is in the allowed range, it can come back to monitor by state feedback system; if evaluation result of fatigue risk is beyond the allowed range, analysis needs to be made from the perspective of the overall system to select effective control method to implement risk control. To verify whether the control objectives are achieved or not, the control result needs to be sent to monitor as feedback for validation.

It has to be noticed that the fatigue is not easy to be found. The monitored objects that seem normal from the outside, but some factors have already seriously affected the fatigue state. Therefore, the task of monitoring and control system is very important. It is necessary to carefully monitor, identify and diagnose the indexes' state and always stay vigilant. Security is a relative concept, the index factors may change with the environment then seriously influence the fatigue state to cause accident symptom even accident. The controllers' fatigue risk control methods need continuous circulation monitoring and implementation to detect potential threat factors and control the fatigue within the scope of the permission.

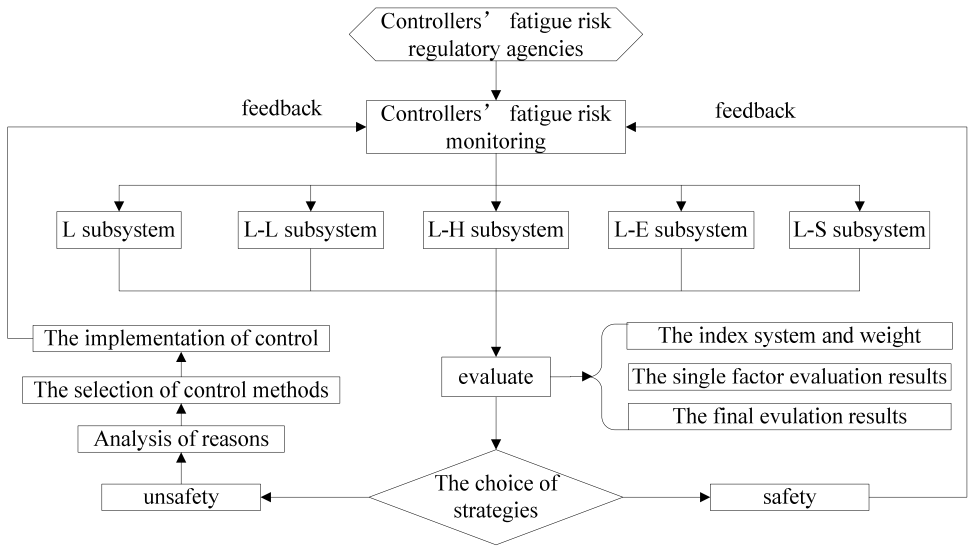

Figure 2. Implementation process controllers' fatigue risk control method

4.2 The controllers fatigue risk control decision-making suggestions

4.2.1 To strengthen education and training

A good education about the risk of fatigue, the cause of sleepiness and the importance of sleep habit is important to solve controllers' fatigue in the control environment. Some life style factors have been proved that would affect people to deal with fatigue well enough. For example, the controller with good health habits, such as physical exercising, eating a balanced diet, good sleep habits and good time management strategy can deal with fatigue more effectively. Managers, scheduling staff and crew all airline personnel should also get education about the effects of fatigue, the influence factors of fatigue and scientifically proved fatigue countermeasures. Finally, controllers, scheduling and management personnel must be aware of sleep and circadian rhythm is important, and to guarantee quality daily sleep as a good way to prevent the fatigue at work.

4.2.2 To strengthen management, maintain good coordination and cooperation among people

To build character complementary control team is important. If in the same team, all controllers are isolated, introverted and quiet, then the high strength workload can cause controllers' fatigue more easily, thus result in false, neglected or wrong control judgments that would end in control accident. On the contrary, if in the same team, all controllers are cheerful, outgoing, willing to chat, they will lead to safety accident due to chat distraction. It is also necessary to establish team intervention mechanism: the leaders should carefully observe the psychological change of the shift members, to find out the problems timely and to apply psychological intervention if necessary. More communication is needed to better understand the difficulty met by the crew. Leaders should help to solve the problems to avoid long time accumulation of mental fatigue that would impact control work. The flow rate and the number of flight conflict need to allocate should be in the control so that it would not surpass the controllers' workload.

4.2.3 To create a good environment for the controllers

Control environment mainly includes the working environment and living environment. Control room should be equipped with comfortable seats that are humanized in design and color. Control room's lighting, noise, humidity should be controlled in a reasonable range. Control room's light distribution should be set to avoid shadow; otherwise it may cause visual fatigue due to the impact of controllers' radar screen observation. That will affect control safety. To set some human-based rest area and exercise facilities in the workplace can make the controller to get relaxed after work. The controllers' family life and daily life stress should also be paid attention to. Family harmony degree will affect controllers' psychological condition. Controllers with psychological pressure will be influenced by the accumulation of mental fatigue, thus may impact control safety. To create a healthy and comfortable control environment can reduce the controllers' bad mood. To keep good mood is advantageous for the controllers to improve work efficiency, to eliminate the unsafe behavior, thereby to reduce or eliminate the happening of the accident.

4.2.4 To improve the organization and management function, to strengthen the construction of software

Shift system directly affects the health of the controllers and the work efficiency because it affects the working hours, rest intervals with the complexity of the work and effort. Therefore, the shift system needs to be optimized, to make it more adaptive with the abilities of human physiological regulation and fatigue recovery. Through the controllers' effect assessment of fatigue, to set controllers' on-duty time and rest time limit and management conditions as soon as possible. Rules, constraints and mutual supervision among the posts can be used to strengthen the supervision mechanism.

5 Conclusions

This paper has analyzed the influencing factors of air traffic controllers' fatigue with using the SHEL model and has built the control strategy of controllers' fatigue. Some suggestions have been given to reduce the air traffic controllers' fatigue.

6 Recommendations for Future Research

On the basis of this study, the future research can be focused on the comprehensive evaluation of air traffic controllers' fatigue in order to provide an effective basis for fatigue risk management. The combination of the comprehensive evaluation of air traffic controllers' fatigue and the control strategy can be used as a management tool of fatigue risk.

Risk Assessment of Rail Transit Financing Mode Using Land Reserve Based on Fuzzy Comprehensive Evaluation Method

Kangzi Chu

School of Transportation and Logistics, Southwest Jiaotong University, No. 111, North Section 1, Second Ring Rd., Chengdu, Sichuan 610031. E-mail: chukangzi@126.com

Abstract: The financing of land plays an important role in the process of the construction of rail transit. Risk assessment of financing is a systematic project, which needs scientific and rational design. This article divides 5 risk sources of financing by land in metro construction and operation, every risk source is divided into several risk factors. Afterwards, the article assesses the financing risk by using bi-level fuzzy comprehensive evaluation model. Finally, this paper analyses the merits and demerits of this method in actual application.
Keywords: Risk assessment; Rail transit financing; Fuzzy comprehensive evaluation.

1 Introduction

With the rapid development of national economy and the rising of people's living standards, the increasing traffic demand and the shortage of road resources has become the main factors restricting the development of the city. Against this background, rail transit become the first choice of the government to solve this problem because it has advantages such as high capacity, high speed, environmentally friendly etc. Yet it is always worth remembering that the investment of construction of rail transit is huge and it is not enough if only depend on the government financial subsidies(CAO Hongfei,2010).For example, the civil engineering cost of Beijing metro line 4 is 194.63 million yuan per kilometer(LI Wenxing, YIN Shuai, 2012). The combined effect of the land near the metro stations is strong and the appreciation space is large, so financing by developing the land near the stations plays an important role in the financing strategy such in Hong Kong, Tokyo(YE Xiafei, HU Zhihui, GU Baonan, 2002).However, the investment project of the metro has long construction period, high running costs, long investment recovery period, and public welfare(SHI Zhiwei,2013),on the other side, whether the financing can meet expected requirement of financing has a big impact on the construction and operation of rail transit network in the future. In conclusion, risk assessment of rail transit financing mode using land reserve is highly relevant.

2 Financing risk analysis

As is well known, various factors influence the risk of rail transit financing. This article divides the risk into 5 risk sources, 16 risk factors.

2.1 National risk source (3 risk factors)

It refers to the risk caused by war, coup or economic collapse. National risk source may cause the rail transit project shut down or destroyed. The risk factors of national risk source are: war risk, political risk and the risk of social instability.

2.2 Engineering risk source(3 risk factors)

Engineering risk means the loss caused by the decision-making mistakes of rail traffic engineering construction. For example, the mistake of route-selection may lead to the increasing cost of construction. The risk factors of engineering risk source are accident risk, engineering technology risk and extension risk.

2.3 Land risk source(3 risk factors)

Land risk is always caused by the difference of land location during land reserve, land developing and land transfer. In some place, the land risk is also closely associated with land properties, the suitability and limitations of land. There are 3 risk factors in land risk source: the risk of land reserve, the risk of land development and the risk of land transfer.

2.4 Industrial market risk source(3 risk factors)

The change of industrial market may lead to the loss of ticket revenue or the income of land transfer under some circumstances. This risk source is also associated with the price fluctuation of the construction materials and facility instruments such as rebar, metro vehicle, signaling system. The risk factors of industrial market risks are ticket price risk, the risk of related industries, the risk of market supply and demand.

2.5 Fiscal and financial risk source(4 risk factors)

During financing period, the distribution of revenue and the operation of land bonds or land funds are very important. We must take revenue distribution risk and operation risk of land bonus or land funds into consideration. Besides, financing by land reserve and development is affected by international financial scene. Above all, the risk factors of fiscal and financial risk source are revenue distribution risk, operation risk of land bonus, operation risk of land funds and international financial scene risk.

3 Model construction

3.1 Hierarchy division

The model required for our purposes is focused on a proper evaluation of the expected frequency of accidents.

Based on the theory of fuzzy mathematics, we divide the risk assessment of rail transit financing mode into 3 layers: objective layer, risk source layer and risk factor layer.

Objective layer: objective layer is recorded as "P" ,it is the evaluation criterion of the risk in this mathematical model. The objective layer can be expressed as:

$$P=\{9,7,5,3,1\}$$

The assignment from 1 to 9 means the financing risk increase gradually.

Risk source layer: there are 5 risk sources in this layer: national risk, engineering risk, land risk, industrial market risk, fiscal and financial risk. These risk sources are recorded as "B_1, B_2, B_3, B_4, B_5" .The weighting factors of these risk sources can be defined as a set named W, each risk factor is recorded as

$$W_i\,(\sum_{i=1}^{n} W_i = 1 \quad (n=5)).$$

Risk factor layer: this layer is the secondary partition of risk source layer, each risk factor is named as B_{ij} , B_{ij} means it belongs to the *i*th risk source (B_i)and the *j*th risk factor of B_i.We are assuming that the *i*th risk source has J_i risk factors. The weighting factor is defined as

$$W_{ij}\,(\sum_{j=1}^{J_i} W_{ij} = 1).$$

3.2 The construction of weight vectors

The risk sources in the second layer have different effect on rail transit financing mode using land reserve, so we have to assign different weights to these risk sources and risk factors in each layer. These weights constitutes weight vectors. Though the weight distribution can't avoid the effect of subjective factors, choosing the suitable method can minimize the impact. In this article, we use *AHP* method to solve this problem because it has consistency check during the calculation. Consistency check can reduce the effect of subjective and the errors due to considering each source or factor separately in certain extent. Each weight factor is named as t_i .The weight vector is called A and $A=\{t_1,\ t_2 \ldots\ldots t_n\}$

3.3 Building a fuzzy evaluation matrix

Fuzzy evaluation matrix can be expressed a set of risk probability based on the judgments of experts. In this model, the risk level is divided into 5 levels: very low, low, medium, high, very high. If the experts' number is Z, the number of expert who think the probability of risk factor B_{ij} is Z_{i1}、Z_{i2}、Z_{i3}、Z_{i4} and Z_{i5} ,so the row vector of fuzzy evaluation matrix is defined as

$$R_{mi} = \{\frac{Z_{i1}}{Z}, \frac{Z_{i2}}{Z}, \frac{Z_{i3}}{Z}, \frac{Z_{i4}}{Z}, \frac{Z_{i5}}{Z}\}$$

Assuming that the *m*th risk sources have *n* kinds of risk factors ,the fuzzy evaluation matrix can be expressed as:

$$R_m = \begin{pmatrix} R_{m1} \\ . \\ R_{mi} \\ . \\ R_{mn} \end{pmatrix} = \begin{bmatrix} \frac{Z_{11}}{Z} & . & . & \frac{Z_{15}}{Z} \\ . & . & & . \\ . & & . & . \\ \frac{Z_{n1}}{Z} & . & . & \frac{Z_{n5}}{Z} \end{bmatrix} = \begin{bmatrix} r_{11} & . & . & r_{15} \\ . & . & & . \\ . & & . & . \\ r_{n1} & . & . & r_{n5} \end{bmatrix}$$

3.4 The choice of fuzzy arithmetic operator

After the construction of fuzzy evaluation matrix, we should make the fuzzy evaluation and get a row vector named C_m, the process of calculation can be expressed as:

$$C_m = A_m \bullet R_m$$

Where:

A_m is the weight vector of risk factors belongs to the *m*th risk sources.

"$\bullet$" is the fuzzy arithmetic operator.

There are 2 kinds of fuzzy arithmetic operator are widely applied in the risk assessment(XIE Lijuan,CHEN Qiao,2012):

(1) （∨—∗）

The operation principle of this arithmetic operator is :

$$C_j = \bigvee_{i=1}^{n} (t_i * r_{ij}) = \max((t_1 * r_{1j}),(t_2 * r_{2j}),(t_3 * r_{3j})\ldots\ldots(t_n * r_{nj}))$$

We can notice that this arithmetic operator taking the impact between t_i and r_{ij} into consideration, but the outermost layer of this arithmetic operator uses *Max-min* algorithm. Generally speaking, *Max-min* algorithm may lose some important information of risk factors especially in the condition of many risk sources or risk factors.

(2)(+—∗)

It is a weighted average arithmetic operator. The operation principle as described below:

$$C_j = \sum_{i=1}^{n} t_i * r_{ij}$$

In this arithmetic operator, the weight factor and membership are taken into consideration. C_j is determined by all risk sources and factors, not only by some specific combinations of weight factor and membership.

Therefor by comparing the characteristics of ∨—∗ and +—∗,we use the second arithmetic operator.

3.5 Fuzzy comprehensive evaluation(first level)

The first level of fuzzy evaluation includes 2 layers: risk source layer and risk factor layer. For any risk source, we figure out it's weight factor by using *AHP* method. As shown in 3.2,risk factor layer's weight vectors is recorded as A_i.The fuzzy evaluation matrix of first level can be expressed as:

$$C_i = A_i \bullet R_i$$

Where

i means *i*th risk source.

3.6 Fuzzy comprehensive evaluation(second level)

After the first level of fuzzy evaluation, we get a set of fuzzy comprehensive evaluation row vectors $C_1 \sim C_5$.The final fuzzy evaluation matrix is recorded as C

$$C = \begin{pmatrix} C_1 \\ C_2 \\ C_3 \\ C_4 \\ C_5 \end{pmatrix}$$

In this step, we use *AHP* method again to get weight vector of risk sources. This weight vector is named as A .This article use arithmetic operator "+ — *" to get risk evaluation matrix R ,

$$R = A \bullet C$$

In the end, we get matrix $\overline{R}$ by normalization matrix R .The risk evaluation result $K = P * \overline{R}^{\mathrm{T}}$

4 The example

In this part, we take a rail transit network for example to calculate this model.

In this network, we assume that the weight vectors from A_1 to A_5 are as follows:

$$A_1 = \begin{pmatrix} 0.1932 & 0.0833 & 0.7235 \end{pmatrix}$$
$$A_2 = \begin{pmatrix} 0.1497 & 0.0991 & 0.7512 \end{pmatrix}$$
$$A_3 = \begin{pmatrix} 0.0915 & 0.2014 & 0.7071 \end{pmatrix}$$
$$A_4 = \begin{pmatrix} 0.2737 & 0.0869 & 0.6394 \end{pmatrix}$$
$$A_5 = \begin{pmatrix} 0.0475 & 0.2830 & 0.1082 & 0.5613 \end{pmatrix}$$

The weight vector of risk sources is defined as A

$$A = \begin{pmatrix} 0.1292 & 0.2210 & 0.5470 & 0.0355 & 0.0673 \end{pmatrix}$$

According to the judgments of experts, we get fuzzy evaluation matrix from R_1 to R_5:

$$R_1 = \begin{bmatrix} 0 & 0 & 0.1 & 0.8 & 0.1 \\ 0 & 0 & 0 & 0.3 & 0.7 \\ 0.3 & 0.5 & 0.2 & 0 & 0 \end{bmatrix}$$

$$R_2 = \begin{bmatrix} 0 & 0.2 & 0 & 0.5 & 0.3 \\ 0.1 & 0 & 0.5 & 0.3 & 0.1 \\ 0 & 0.3 & 0.3 & 0.2 & 0.2 \end{bmatrix}$$

$$R_3 = \begin{bmatrix} 0 & 0 & 0.4 & 0.3 & 0.3 \\ 0.1 & 0.3 & 0.5 & 0 & 0.1 \\ 0.2 & 0.4 & 0.3 & 0.1 & 0 \end{bmatrix}$$

$$R_4 = \begin{bmatrix} 0 & 0.1 & 0.2 & 0.2 & 0.5 \\ 0 & 0 & 0.2 & 0.4 & 0.4 \\ 0 & 0 & 0.3 & 0.4 & 0.3 \end{bmatrix}$$

$$R_5 = \begin{bmatrix} 0 & 0 & 0.1 & 0.5 & 0.4 \\ 0.2 & 0.3 & 0.4 & 0.1 & 0 \\ 0.2 & 0.4 & 0.2 & 0.2 & 0 \\ 0.3 & 0.3 & 0 & 0.2 & 0.2 \end{bmatrix}$$

Fuzzy comprehensive evaluation(first level):

$$C_i = A_i \bullet R_i$$

$$C_1 = (0.2170 \quad 0.3618 \quad 0.1640 \quad 0.1796 \quad 0.0776)$$

$$C_2 = (0.0099 \quad 0.2553 \quad 0.2749 \quad 0.2548 \quad 0.2051)$$

$$C_3 = (0.1616 \quad 0.3433 \quad 0.3494 \quad 0.0982 \quad 0.0475)$$

$$C_4 = (0 \quad 0.0274 \quad 0.2639 \quad 0.3453 \quad 0.3634)$$

$$C_5 = (0.2466 \quad 0.2966 \quad 0.1396 \quad 0.1860 \quad 0.1312)$$

$$C = \begin{pmatrix} C_1 \\ C_2 \\ C_3 \\ C_4 \\ C_5 \end{pmatrix} = \begin{bmatrix} 0.2170 & 0.3618 & 0.1640 & 0.1796 & 0.0776 \\ 0.0099 & 0.2553 & 0.2749 & 0.2548 & 0.2051 \\ 0.1616 & 0.3433 & 0.3494 & 0.0982 & 0.0475 \\ 0 & 0.0274 & 0.2639 & 0.3453 & 0.3634 \\ 0.2466 & 0.2966 & 0.1396 & 0.1860 & 0.1312 \end{bmatrix}$$

Fuzzy comprehensive evaluation(second level):

$$R = (0.1292 \quad 0.2210 \quad 0.5470 \quad 0.0355 \quad 0.0673) \bullet \begin{bmatrix} 0.2170 & 0.3618 & 0.1640 & 0.1796 & 0.0776 \\ 0.0099 & 0.2553 & 0.2749 & 0.2548 & 0.2051 \\ 0.1616 & 0.3433 & 0.3494 & 0.0982 & 0.0475 \\ 0 & 0.0274 & 0.2639 & 0.3453 & 0.3634 \\ 0.2466 & 0.2966 & 0.1396 & 0.1860 & 0.1312 \end{bmatrix}$$

$$= (0.1352 \quad 0.3119 \quad 0.2918 \quad 0.1580 \quad 0.1031)。$$

$$\overline{R} = (0.1352 \quad 0.3119 \quad 0.2918 \quad 0.1580 \quad 0.1031)$$

$$K = P * \overline{R}^{T} = 5.43$$

5 Conclusions

As we all known, risk assessment is hard to quantify, but this article overcomes this problem by using fuzzy comprehensive evaluation method. Furthermore, the model in this article also takes the effect between risk sources and risk factors into consideration. The result of evaluation is relatively objective and the model has quite strong systematically. We can also get the risk assessment result by using computer programming. The algorithm is easy to realize in C# programming language.

However ,the risk assessment method has some disadvantages and the main point is that the assessment result will be influenced by the expert's scoring. When metro-transportation corporation about to make the risk assessment, they should choose the experts with high level of professional standards to guarantee the objectivity of the assessment result.

Study on the Influencing Factors of Recycling Household Electronic Waste Based on Consumer Participation under the EPR System

Rong Wu

School of Business Administration, Nanchang Institute of Technology, Nanchang, Jiangxi 330099, China. E-mail: 37367165@qq.com

Abstract: Based on combining with the domestic and foreign theoretical research about consumer participation in recycling waste household electronic, this paper considered behavioral attitude, subjective norms, environmental knowledge, behavior disorders and behavior motivation, and designed questionnaire and investigated the public, and analyzed the survey results. At last, this paper found the main factors influencing consumers to participate in recycling waste household electronic under extended producer responsibility system.
Keywords: Extended producer responsibility system; Waste household electronic; Take-back models.

1. Introduction

With the implementation of "circular economy promotion law of the People's Republic of China", the modern producers' responsibility already extended to the recycling, utilization and disposal stage of disposed products from the pure production stage. It means that consumers and enterprises all have a responsibility to recycle waste household appliances.

Therefore, under extended producer responsibility system, it is an important aspect what factors will influence on the participation behavior of consumers about the research on recycling waste household electronic.

Based on combining with the domestic and foreign theoretical research about consumer participation in recycling waste household electronic, this paper refined the influencing factors of recycling waste household electronic, including behavioral attitude, subjective norms, environmental knowledge, behavior disorders and behavior motivation. This paper designed questionnaire and investigated the public, and analyzed the survey results. At last, this paper found the main factors influencing consumers to participate in recycling waste household electronic under extended producer responsibility system, and analyzed on the difference in perception of these influence factors between different consumers.

2. Sample extraction conditions

The empirical research used the questionnaire form, the 300 questionnaires were sent out, and collect 280 copies, of which there are 259 valid questionnaires, and effective recovery rate is 86.3%. Questionnaire distribution is shown in table 1.

Table 1. The questionnaire distribution table

Demographic variables		Percent	Demographic variables		Percent
Sex	male	53.7	Age	15-22	38.6
	female	46.3		23-40	38.2
profession	Scientific education and environmental sanitation field	9.7		41-54	14.3
	engineer	13.5		Above 55	8.5
	Management	8.5	Education	The junior high school and above	5.0
	Worker	8.5		High school	12.4
	Service personnel	8.5		College and University	70.3
	housewife	13.9		postgraduate	12.4
	Retire	8.5	Monthly income	Less than 1000 RMB	18.6
	Student	15.8		1001-3000 RMB	45.1
	others	13.1		3001-5000 RMB	24.4
				More than 5001 RMB	11.9

3. Factor analysis

Through factor analysis on the 20 initial variables of the influencing factors, the value of KMO was 0.788 (>0.5), it shows that this group of data is suitable for factor analysis. According to that the characteristics root extraction factor is larger than 1 and the varimax rotation method, six new factors can be extracted as main factor of the 20 initial variables, and the cumulative contribution rate of the 6 major factors was 77.136%, which can reflect that the amount of information about the original 20 variables was 77.136%.The loading matrix of 6 factors is shown in table 2.

Table 2. Orthogonal rotated factor loading matrix of the influencing factors

Participating in recycling is to obtain income	-.058	.038	-.023	-.088	.855	.006
Whether paid recovery is important to me.	.121	.098	.223	.009	.048	-.184
I am satisfied to door-to-door recovery service	.091	.124	.746	.288	.167	-.221
I feel very convenient with door-to-door recovery service	.056	.423	.764	.198	.288	-.062
I am satisfied to door-to-door recovery free service	.015	.163	.725	-.174	.046	.366
It is very important to door-to-door recovery service for me	-.076	.362	.686	-.215	-.017	.220
My family thinks I should participate in the government recovery	.027	.824	.115	.086	.079	.077
My friends and neighbors think I should participate in the government recovery	.132	.881	.179	.126	.085	-.012
Neighbors are very active to participate in the government recovery	.135	.830	.192	.054	.048	.126
characteristics root	4.145	2.467	2.394	2.080	1.867	1.532
the contribution rate	21.098	13.355	12.420	11.549	10.394	8.322

the cumulative contribution rate	21.098	34.452	46.872	58.421	68.814	77.136
Cronbach's alpha	0.9000	0.8554	0.7834	0.8108	0.7680	0.7880

According to the original information and statistical analysis result, six main factors can be redefined as: Y1 is environmental knowledge, Y2 is subjective norm, Y3 is service motivation, Y4 is behavior disorders, Y5 is economic motivation, Y6 is behavior attitude.

4. Regression Analysis

This paper used SPSS20 software as a statistical tool, analyzed survey data, and obtained the following results:

(1) In the regression model, F=16.050, P <0.001, which showed that the regression model has statistically significant and better fitting degree.

(2) All variables were forced into the equation in enter mode, the analysis results are shown in table 3.

Table 3. Regression analysis results

	Not standardized coefficient		standardized coefficient	t	Sig.	R2	Adjusted R2
	B	Std. Error	Beta				
（constant）	4.355	.026		169.210	.000	.239	0.224
environmental knowledge	-.004	.029	-.009	-.154	.878		
subjective norm	.083	.026	.160	3.163	.002		
service motivation	.171	.026	.331	6.649	.000		
behavior disorders	-.068	.027	-.131	-2.510	.013		
economic motivation	.093	.026	.179	3.604	.000		
behavior attitude	.122	.027	.235	4.470	.000		

The results of regression analysis showed that: firstly, about environmental knowledge, P=0.878 (>0.05), which shows that it does not have statistically significance, namely environment knowledge is not significantly influence for consumers to participate in the behavioral intention. Secondly, about service motivation, economic motivation and behavior attitude, $P<0.001$, which has statistically significance, and about subjective norm, $P<0.01$, which has statistically significance, and about behavior disorders, $P<0.05$, which has statistically significance. Thirdly, through the size of the corresponding β value, the influencing degree to consumers' intention of waste household electronic recycling can be judged: service motive>behavior attitude> economic motivation>subjective norms. Fourthly, behavioral disorders have a significant negative impact on recycling behavior intention.

5. The difference analysis

After found five factors that have significant influence on consumers' behavior of participating in recycling waste household appliances, variance analysis is carried out according to the different gender, age, occupation, education and income levels of the consumers. The results of the analysis are shown in table 4.

Table 4. The variance analysis

	sex	Age	occupation	education	income levels
subjective norm	.054	.542	.123	.512	.002
service motivation	.001	.363	.258	.223	.000
behavior disorders	.032	.020	.000	.000	.030
economic motivation	.255	.121	.015	.000	.001
behavior attitude	.388	.787	.566	.116	.123

According to the results of the analysis, it can obtain the following conclusions:

(1)The perception of different sex on subjective norms, economic motivation, behavior attitudes has no significant difference (the corresponding P values are greater than 0.05), however, the perception of different sex on service motivation and behavior disorders has significant difference (the corresponding P values are less than 0.05), It can be concluded through the sample that service motivation and behavior disorders influenced women more than others.

(2) Different age does not exist significant differences on subjective norm, service motivation, economic motivation and behavior attitude (the corresponding P values are greater than 0.05), however, it exists significant differences on behavior disorders ($P<0.05$); further through afterwards Scheffe test, it is found that the perception of consumers of 24 ~ 40 years old on behavior disorder is obvious weaker than the other age groups of consumers.

(3) The perception of different occupation on subjective norm, service motivation and behavior attitude has no significant difference (the corresponding P values are greater than 0.05), however, the perception of different occupation on economic motivation and behavior disorders has significant difference (the

corresponding P values are less than 0.05). Further through afterwards Scheffe test, it is found that the perception of workers and housewives on behavior disorder is obvious weaker than the other groups of consumers. At the same time, the perception of housewives on economic motivation is obvious stronger than the other groups of consumers.

(4) The perception of different degrees on subjective norm, service motivation and behavior attitude has no significant difference (the corresponding P values are greater than 0.05), however, the perception of different degrees on economic motivation and behavior disorders has significant difference (the corresponding P values are less than 0.05). Further through afterwards Scheffe test, it is found that the perception of consumers of the junior high school on behavior disorder is obvious weaker than the other groups of consumers, the perception of the higher education consumers on economic motivation is less obvious.

(5) The perception of different monthly income on behavior attitude has no significant difference (the corresponding P values are greater than 0.05), however, the perception of different monthly income on subjective norm, service motivation, economic motivation and behavior disorders has significant difference (the corresponding P values are less than 0.05). Further through afterwards Scheffe test, it is found that the perception of higher income consumers on subjective norm, service motivation is more obvious, the perception of consumers of income less than 3000 on behavior disorder and economic motivation is obvious stronger than the consumers of income more than 3000.

6. Conclusions

This paper designed questionnaire and investigated the public, and analyzed the survey results. Through the factor analysis, regression analysis and the difference analysis, this paper found the main factors influencing consumers to participate in recycling waste household electronic under extended producer responsibility system, including subjective norm, service motivation, behavior disorders, economic motivation and behavior attitude. At last, this paper analyzed on the difference in perception of these influence factors between different consumers.

Abstract: This paper analyzes accident characteristics from several factors like accident type, reason, environment and crash part by reporting in-depth accident that involved minibus passenger injured of China in-depth accident study program (CIDAS). The paper uses PC-CRASH simulation software, sets the minibus simulation model and gets the equivalent collision speed by simulation. Then the relationship between equivalent collision speed, maximum deformation, collision overlap, passenger injury and frontal structure safety of minibus are analyzed. By analyzing opposite collision vehicle type, deformation characteristic of minibus and structural failure of minibus passenger cabin deformation of frontal collision, the characteristics of structural failure of minibus are studied. Finally, the paper compares the minibus accident cases and China passenger vehicle frontal impact occupant protection regulation of equivalent collision speed and collision overlap, analyzes the different between test factors of regulation and statistics of real accident, and give the improving opinion for passenger vehicle frontal impact occupant protection regulation.
Keywords: Minibus; CIDAS; Frontal structure; Safety.

1 Introduction

There is a unique appearance vehicle that is usually called ‘bread style vehicle’ in China, and it is divided in classification of minibus. The first generation of minibus in China came from Japan, in japan it is called minibus too. After introducing to China, due to low cost, wide application and relatively simple producing progress the minibus was widely used. Minibus is increasingly important in passenger vehicle market of China as the policy of ‘bringing autos to the countryside’ published.

On the one hand, minibus sales are growing rapidly, on the other hand, the road traffic safety of it is not going well. As we all known, the frontal structure of minibus is relatively shorter than other kinds of vehicle. So the passenger compartment of front is easily deformed when head on collision happen. This paper classify the minibus based on character of frontal structure. Then the paper analyze the accident type of frontal collision of minibus based on database of China in-depth accident study (CIDAS), and acquire equivalent energy speed by using PC-CRASH software for accident reconstruction. Finally the correlation of equivalent energy speed and risks of injury are analyzed.

2 Characteristic and Classification of Frontal Structure

The characteristics of minibus can be divided into three types according to the frontal structure, as table 1 showed. Type A of minibus is nearly with no existent frontal deformation zones; Type B of minibus have the frontal deformation zones, but the engine is not installed in the front of deformation zones; Type C is similar to ordinary vehicles, and there is a relatively longer frontal deformation with engine installed in there.

The type a minibus is early introduced from Japan, so there is almost no frontal deformation zones. As the collision regulations and occupant protection laws and regulations are implemented, in order to pass legislation test to sales vehicle in the market, all the OEMs of minibus involved in the research of frontal safety. Most of type a minibus changed into type b minibus through several ways like increase the frontal deformation zones, optimize the structure of front parts stiffness and longitudinal beam size position, etc.

Table 1. Classification of minibus

Type	External characteristic	Structural characteristic
Type A		Without frontal deformation zones
Type B		With frontal deformation zones Without engine installed
Type C		With relatively longer frontal deformation zones With engine installed

3 Data and Accident Type

China in-depth accident study (CIDAS) was started in 2011, and it collects traffic accidents in five cities, Changchun, Beijing, Weihai, Ningbo and Foshan. The investigation engineers worked 24 hours on duty, when the accident occurred, the engineers and police arrived at the scene of the accident at the same time, so they collected the first hand data of the accident. Then the engineers inquired the parties involved in the accident and collected medical injury information, completed the CAD sketch drawing combined with photographs and field measurements. Finally the accident information was input the CIDAS database for in-depth study.

There is a total of 13 frontal collision occurred of minibus from the database of CIDAS, and all accidents resulted in passengers injured or death, table 2 shows the basic information of frontal impact of minibus.

Table 2. Information of frontal collision of minibus

Accident number	Vehicle type	Casualty	Passenger involved
13	Type A：1 Type B：11 Type C：2	42	68

The road distribution of minibus frontal impact is showed in figure 1. Straight road number up to account for 47.8% of the total, followed by the expressway accident accounted for 21.7%, the T-junction and the crossing accident account for 17.4% and 8.7%, the bridge only account for 1 accident, 4.3% of the overall.

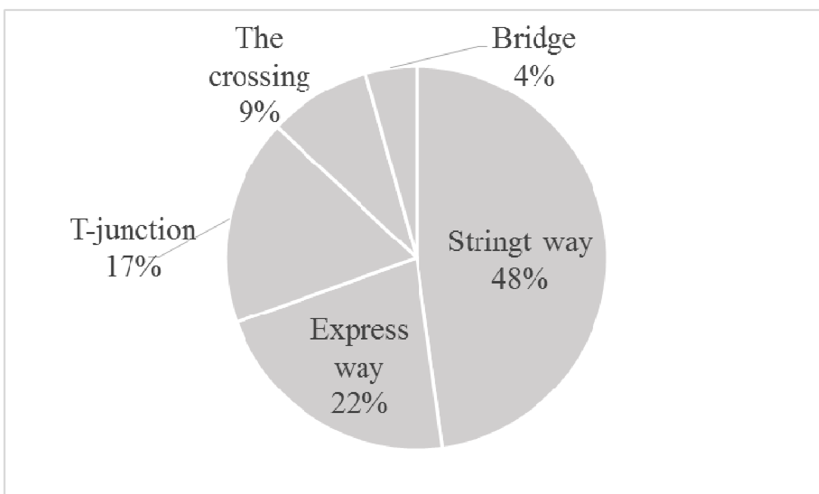

Figure 1. Distribution of accident location

Frontal impact accident occur mostly in straight road, accounts for nearly half of total. The T-junction and the crossing road account for 26% of total, the least is the express way that account for 22% of total.

4 Frontal Structure Analysis

By using the pc-crash software, the equivalent energy speed (EES) is acquired. Figure 2 is the distribution of equivalent energy speed (EES), rate of front collision overlap and the maximum deformation depth. The horizontal axis represents rate of front collision overlap, the vertical axis represents equivalent energy speed and the area of circle represent the size of deformation depth (area is bigger, the deformation depth is longer).

In all cases, there exists passenger compartment deformation when EES exceed 20km/h. to be fair, 20km/h is not a high speed for frontal collision. In this part, small overlap impact factors should be considered, such as the EES of 28.7km/h has caused the minibus passenger compartment deformation for the case of 18.1% overlap. Of course, it should be seen that minibus performance is not good enough for a relatively large overlap rate, such as 73.0% overlap with 30.4km/h EES.

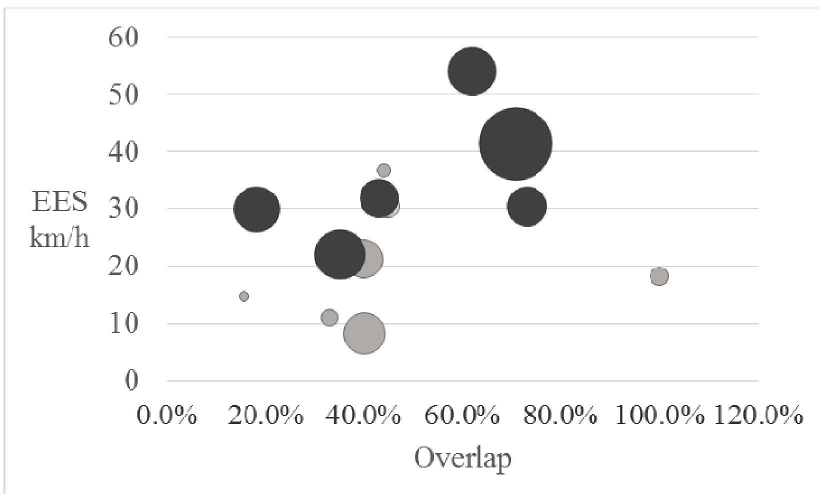

Figure 2. Distribution of EES, overlap and maximum deformation depth

New injury severity score (NISS) was first proposed in 1997, its basic idea is that not to consider the division of parts of the injured body, but with the most three serious AIS score (sum of squares) of multiple injuries as the injury severity score.

Figure 3 represents the correlation of NISS of frontal passenger and maximum deformation depth. The correlation coefficient R^2 value is 0.502. This points out that with the increase of depth of deformation, the wounded NISS values show a rising trend, the correlation is obvious, there is a moderate intensity correlation of deformation depth and passenger injuries.

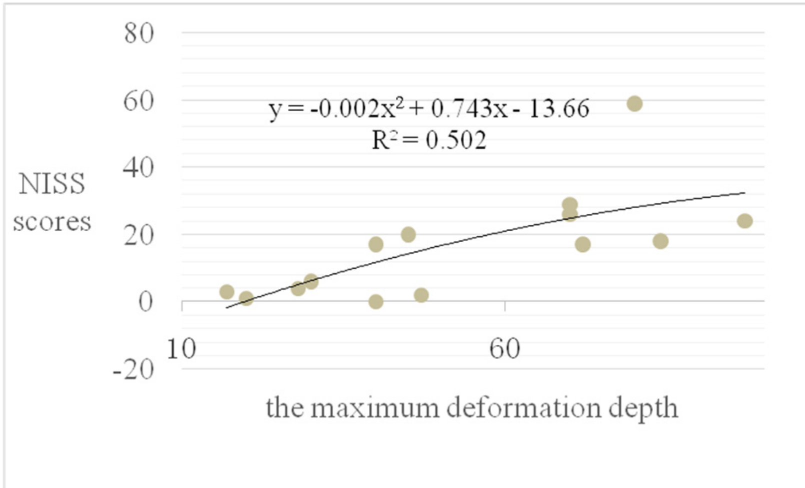

Figure 3. Correlation of NISS and maximum deformation depth

As figure 2 showed that there is a concentration on the overlap of 40%. There are two standards of frontal impact of passenger vehicle. One is GB11551-2003 the protection of the occupant in the event of a frontal collision for passenger car, the other is GB20913-2007 the protection of the occupants in the event of an off-set frontal collision for passenger car, the details information is showed in Table 3.

Table 3. Occupant protection standards of front crash in China

Number	Overlap Rate	Crash Speed	Barrier Type	Standard Type
GB11551-2003	100%	50km/h	Rigid	Compulsory
GB20913-2007	40%	56km/h	Deformable	Recommended

The number of accident of the overlap around 40% is the most (57.1% of total). From the view of quantity, the test for frontal collision of 40% overlap is necessary, from the structure safety view, it's necessary to set the test protocol of 40% overlap frontal collision test from recommended to compulsory test in order to avoid deformation of passenger compartment at relatively lower collision speed by optimizing the frontal structure of minibus.

5 Conclusions

When frontal collision happened, even at a lower EES, the minibus can have a large deformation, and this caused the passenger compartment reduced. Relatively lower (40%) overlap and relatively higher (80%) overlap collision at lower equivalent energy speed (lower than the speed of frontal collision protection standards) are all working not well enough to deal with the deformation. There is a positive (R^2=0.502) correlation between maximum deformation of frontal and New injury severity score, this represents it has a high risk of the front row passenger of minibus to get injured or death when frontal collision happened at a low speed.

Traffic Relief Based on the Construction Characteristics of Urban Roads

Weidan Liu and Weixiong Zha

Institute of Transportation and Economics, Humanities and Social Sciences Research Base of Jiangxi Province, East China Jiaotong University, Nanchang 330013, China.

Abstract

In order to meet the process of urbanization and solve supply and demand contradiction of urban traffic, departments and government put a lot of manpower, material and financial for municipal facilities. In cities, there are many new roads under construction, reconstruction and maintenance. It will bring a huge change to city when those municipal roads completed. However, construction of road will occupy limited resources and make urban traffic more crowded. Construction of subway station and line is also belonging to urban road construction. At present, large-scale subway construction is ongoing in Nanchang. According to this situation, this paper describes basic conditions for traffic relief during subway construction. And proposed urban traffic relief should be combined with different construction schemes to make a reasonable arrangement. Method of construction should also meet requirements of traffic relief plan proposed by traffic management department, taking into account feasibility of construction program and construction risk.

Keywords: Construction of city road; New ideas for traffic relief; Basic conditions for traffic relief; Construction methods; Traffic relief.

1 Overview of urban road construction

Urban road construction projects include various types, it have a great impact on normal operation of urban roads and the construction area in city road network. Generally speaking, it include urban expressways, trunk roads, interchanges, large bridges, rail lines and stations, large square, large pipe networks and so on. According to the influence characteristics to transport system, we put these large projects into point, line and area engineering works (Mao, 2001).

Point project includes: Interchange, large bridges, rail stations, transportation hubs, large square, etc.

Line project includes: Urban freeway, main roads, urban rail transit lines, etc.

Area project includes: Large pipeline construction, etc.

Since Nanchang is constructing rail transit lines and stations, construction of these subway lines and stations pose a serious impact to Nanchang's traffic. Therefore, this paper will focus on city's traffic relief during the construction of subway project belonging to the point and linear project such as rail transit lines and stations.

2 New ideas and methods about traffic relief during subways construction

2.1 Construction optimization program based on traffic relief

Different construction methods have different effects on urban transport, in these methods, the greatest is open-cut method. Construction methods proposed by subway design and construction units are often made from the view of subway project investment, construction period, safety and quality, but lack of traffic. It is necessary to change construction program by comprehensive comparison and meet traffic relief needs when construction program has a great impact on traffic or price of traffic relief is too high to afford. In the optimization program, with co-ordination arrangements technical advantages of owner, designer, constructer and supervisor should be fully utilized to modify construction process and plan, reducing construction fence time, narrowing construction fence area, thereby reduce traffic impaction (Huang, 2009).

2.2 New ideas and methods

Facing of growing traffic pressure, traffic management departments are often more focused on demand of urban traffic and less to consider subway construction when approval the scheme about construction fence relating to subway, such as subway construction period, project investment, security management, etc. So we should change ideas when formulate traffic relief scheme. In order to make subway project plan or construction method rational, operability, traffic workers should make early intervention in subway preliminary design stage. To carry out the plan of traffic relief during subway's construction, we should investigate construction site fully and communicate with design units about program or construction method.

3 Basic conditions for traffic relief reasonably during subways construction

To provide a scientific, operability plan during construction, construction features must be clearly along subway lines, interval and associated road, this is the basis to determine reasonable plan of traffic relief (Liu, 2012).

(1) The alignments of subway line and each range segment
(2) Design of station along with subway and interval
(3) There are three forms of the subway station: underground station, ground station and elevated station; Design Line range also includes underground line, ground line, overhead lines and the transition section line.
(4) The settings situation of entrance along subway station
(5) Construction methods of subway stations. According to the geographical and environmental conditions where the station is located, there are three construction methods: open-cut method, cover excavation method and tunneling method.
(6) Traffic situation on the ground and pipeline layout facilities (Shi, 2010).

From the conditions above we can see: In order to facilitate the analysis of subway construction impact on the surrounding city traffic situation and to give full consideration to the influencing, constraints and other coordination factors around construction site when formulate traffic relief plan .The plan should be based on range of stations along involved, analyze and master the subway construction methods, environmental conditions surrounding the construction site. Technically, the impact of subway construction on traffic mainly refers to the influence of the occupation of road construction, transport facilities demolition within scope of construction, construction methods, management of construction (Zhang, 2008).

4 The construction method of the subway station

Forms of construction fence are closely related to construction methods and the surroundings, so it must consider in conjunction. Generally, Different methods lead to different construction fence forms. Determining construction method and form of construction fence have a significant impact for safety, quality, time and cost. So we should make a reasonable choice based on planning condition along line, engineering geological and hydrogeology conditions. At the same time, role of ground buildings existing and planning should be taken into consideration. After completion of station structure, station structure safety should not be affected by near building structures or other engineering activities. Meanwhile we should consider environmental factors, putting adverse effects on surrounding environment to minimize during and after the construction. There are three methods commonly used in subway construction: Direct excavation-shoring construction, Cover-excavation method, Tunneling method.

4.1 Open cut method

Open cut method is the most economical compared with other methods and it also a method that is safety and reliable. If the conditions allowed, it should have priority.

Direct excavation-shoring construction is often applied to the situation that the ground has condition of open excavation and enough of construction site. It can be combined with ground demolition and widening roads. Using this method, the station can be located in road within or outside. In order to make ground traffic flow to be evacuated, temporarily interrupted of some roads is allowed during construction and using temporary diversion when conditions permitted (Tan, 2005).

4.2 Cover-excavation Method

Cover-excavation method can be divided into the following process: first, excavating from ground down to a certain depth; then, closed the top, constructing the rest of lower part project under closed roof. If the interruption is not allowed due to road traffic and the roof above the pit can't be once formed then a down side cover-excavation method can be a choice. Cover-excavation method generally applies to traffic must not be interrupted, and the roads are narrow areas or the underground station structure have special protection requirements for the surrounding structures.

4.3 Tunneling method

Under the following conditions tunneling method can be used: ground has no condition to carry out unconditionally open cut; engineering geological conditions are good and water table is low, no groundwater and no confined water. When the tunneling method used in subway station construction, it have no effect on ground traffic and has less ground demolition (Chen, 2009).

By analyzing advantages and disadvantages of different construction methods, pointing out their application, we can know that if the ground has enough sites, roads can be occupied in long time and underground pipelines can remove, then direct excavation-shoring construction should be considered firstly. Besides, According to geological conditions of Nanchang, because of poor strata self-stability and in order to control the excessive subsidence on the surface of the earth, ensure proper use of underground pipelines and ground built structures often requiring additional auxiliary construction technology, carrying tunneling construction of large cross-section and large span structures in the quaternary soft soil layer often need additional auxiliary technology. It is clear tunneling method has high cost and risky. Therefore, according to the surrounding environment, the station of subway Line 1 in Nanchang recommend open cut method and cover-excavation method.

5 Examples of verification

These methods will affect traffic in different degrees, but the holding time and degree of road is different. Regardless of which method used in constructing, traffic basically has partial be closed. Theoretically cover-excavation can guarantee ground vehicle traffic during construction, but for the following reasons construction method of station is generally not considered the method of cover-excavation. The reasons are: Firstly, due to construction of temporary roads, pipeline relocation, the construction of retaining wall in the early times, roads also need to be partially closed temporary. Secondly, for various technical reasons in late construction, traffic needs a second partial close again. Thirdly, the temporary road system is expensive.

This paper describes bayi hall subway station in Nanchang which has greater difficulty in construction. Analysis the construction method of open cut method and ground traffic relief during the construction of subway station. Station of bayi hall is located in the intersection of zhongshan road and xiangshan road where is in the commercial center of Nanchang. There are large building density along this station and has little red building retreat. By considering location, engineering geological and hydrogeology conditions, the construction of station mainly use open cut method in stages, partly use the method of cover-excavation– reverse. Details are as follows:

In the first stage, construct the west side of roof blanket of 3rd line and ground subsidiary structure by using open cut method. As can be seen from traffic relief plan that a large defective is it has large area of road closure and serious impact to traffic. So when making traffic relief plan we should take full advantage of surrounding roads, rational organization of transport to realize the rationality of traffic relief. The scheme of traffic relief can be shown specific in figure 1:

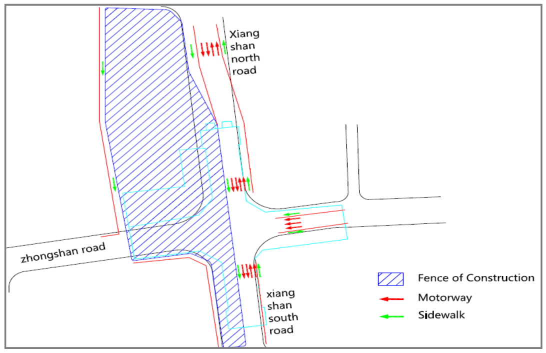

Figure 1. First stage of bayi hall subway station

Corresponding traffic relief plan: Disconnect the traffic of Zhongshan road at xiangshan road, move the traffic of xiangshan north and south road to eastward, Keep the original four lanes and sidewalks that total width is 17.4m.

In second stage, construct the east side of the roof blanket and ground subsidiary structure by using open cut method. Traffic relief scheme can be shown in figure 2.

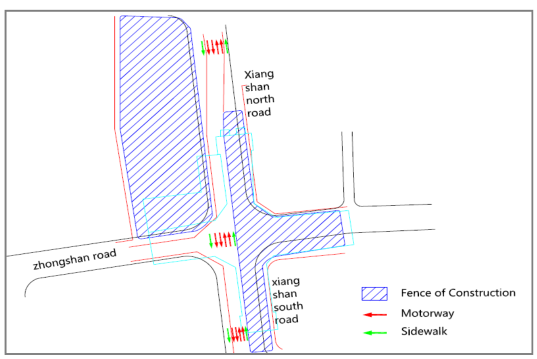

Figure 2. Second stage of bayi hall subway station

Corresponding traffic relief plan: Disconnect the traffic of Zhongshan road at xiangshan road, move the traffic of xiangshan north and south road to eastward, keep the original four lanes and sidewalks that total width is 15.5m. The width of the sidewalk in the zhongshan road is 5.5m.

In the third stage, construct pit in east and west of 1rd line and west side of the northern section of subsidiary pit, using cover-excavation–reverse method to construct the station of 3rd. Bayi hall station is the only one in all 24 stations of Nanchang subway 1rd using cover-excavation– reverse to construct. This method can shorten the time of construction fence as far as possible. It can make road traffic recover as soon as possible. The scheme of traffic relief can be shown specific in figure 3.

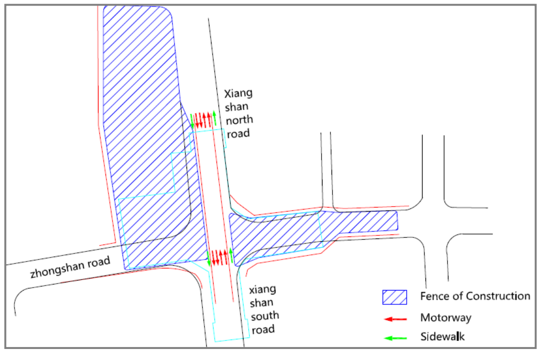

Figure 3. Third stage of bayi hall subway station

Corresponding traffic relief plan: Disconnect the traffic of Zhongshan road at xiangshan road, recover original road traffic of xiangshan north and south road, keep original four lanes and sidewalks that total width is 20m. The width of the sidewalk in zhongshan road is 5.5m.

In the four stages, construct the main structure, subsidiary structure in the east and west end and the main structure of subsidiaries of 3rd station in the west of the northern section by using open cut method. The scheme of traffic relief can be shown specific in figure 4.

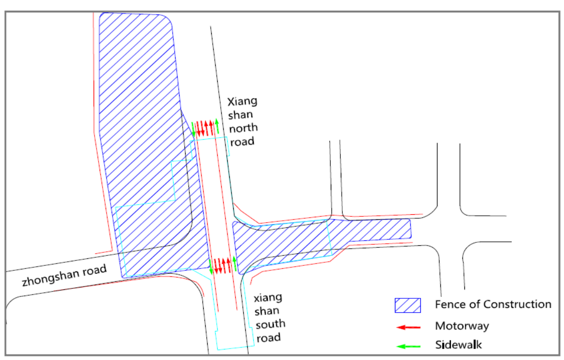

Figure 4. Four stage of bayi hall subway station

Corresponding plan: Disconnect the traffic of Zhongshan road at xiangshan road, recover the original road traffic of xiangshan north and south road, keep the original four lanes and sidewalks that total width is 20m. Set sidewalk in zhongshan road.

6 Conclusions

Traffic relief is a complicated systematic project related to many units such as planning, building, traffic management and construction sector, etc. It requires constant coordination between different departments. In many times it needs to conduct the process "construction conditions - project design- feedback" repeatedly. Due to the unforeseen factors, construction prerequisite, repeated changes of sort plan, so traffic relief plan should have elasticity during construction. So that can we cope with various adverse factors generated during construction.

Analysis of the Safety of the Linchuan Section on Donglin Highway

Yu Xia and Weixiong Zha

Institute of Transportation and Economics, Humanities and Social Sciences Research Base of Jiangxi Province, East China Jiaotong University, Nanchang 330013, China.

Abstract: In order to improve the B road's traffic safety level, take Linchuan section on Donglin highway as an example. According to the traffic accident data from January 2009 to December 2013, analyzed the main law of Linchuan section on Donglin highway traffic accident. Then using the based on the primary element of the grey association degree analysis method to analysis the main reason of Linchuan section on Donglin highway traffic accidents, analyzed the reasons for the formation of accidents from the design and planning of the accident black point, especially analyzed the causes of the two main dangerous intersection. Finally, put forward the traffic accident prevention and control countermeasures from four aspects of people, vehicles, road, environment, to the traffic management departments are proposed.
Keywords: Broad; Traffic accidents; Primary element; Grey association degree.

1 Introduction

There's a lot of researches on road traffic accident in our country, the largest is highway research, however, specifically for distributing function of provincial highway traffic accident cause analysis and countermeasures of prevention and control of research is less. Provincial highway have differences in features of other highway, it always connects cities and counties, the traffic distribution function is obviously, most of the road through the villages and towns, makes sections mixed models, the density of the access is big, feeder roads planning and design is unreasonable, and thus influence the operational efficiency of the thread; especially the Linchuan section on Donglin highway in Fuzhou city, it is located in the urban-rural fringe, throughout three villages and towns, as two or three rounds of motorcycle over the years, the number of two or three rounds of electric vehicles has greatly increased, the driver of the vehicle traffic safety consciousness is low, traffic violations to highlight, coupled with the increase of traffic volume, the provincial highway traffic accidents, serious impact on the provincial highway connecting the full realization of the superiority of the urban and rural areas, threatening the safety of people's life and property.

2 Field Data

In this paper, using grey correlation analysis method based on the primary elements to analysis the road traffic accident of Linchuan section on Donglin highway. At the same time, this paper analyzes the reasons of accident black point design and accident reason and cause dangerous intersection point planning, points out the hidden trouble in security of Linchuan section on Donglin highway and the hidden trouble causing traffic accidents, in carried on the systematic analysis and summary.

Linchuan section on Donglin highway only 13 km，but the access almost 71. Highway design for level 1, level 1 design speed of 90 km/h, mixed traffic. Between January 2009 and December 2013, 700 road traffic accidents happened, 34 people were killed and 279 injured, and caused the economic loss of 10460860 yuan. Investigate its objective reasons, can be divided into the following:

(1) The road traffic, big truck overloading, the car speeding
(2) Of motor vehicles and non-motor vehicles mixed driving
(3) The road damage and destruction
(4) Facilities lack integrity Settings, maintenance is not in place
(5) Flat crossing too much
(6) Models is complex, the speed of the car a span

3 Data Analysis

The grey correlation analysis method based on the main elements macro analysis of the causes of road traffic accidents, can not only consider the influence between the elements of a road traffic system, but can also find out the influence factors of road traffic accidents and the related degree between the size of the effect. Grey correlation analysis process is as follows:

(1) The main element set and the determination of main influence factors

Based on the characteristics of road traffic accident analysis and previous accident statistics of Linchuan section on Donglin highway, combined with the mechanism of traffic accident, determine the main factors that influence the main element and the corresponding subsystems, see table 1.

Table 1. Traffic accident factors and the main influence factors of them

Road subsystem	The main elements	Main factors influencing
Motor vehicle	Motor vehicle status	Normal and abnormal
Motor vehicle drivers	State of the drivers	Normal, overspeed, illegal overtaking each other, not to Change lanes and other regulations to give way, illegal
Motor drivers and	State of non-motor	Normal, illegal

pedestrians	vehicles and pedestrians	
The road	Intersection situation	Flat crossing road, the crossing road
The traffic environment	The weather conditions	Sunny, rain, overcast

(2) Determine the sequence analysis

Road traffic accident has three indicators as the basic statistics, statistics of the corresponding main factors influencing the number of traffic accidents, the number of deaths, injury. Set the reference sequence (also called mother sequence) for $X_0^{'}$; Compare sequence (also known as a sequence) $X_i^{'}$, $i=1,2,\Lambda,n$ .To pose with the sequence of $X_0^{'}$ and $X_i^{'}$ the original data sequence, constructs a matrix with the original data sequence, see type (3.1).

$$\left(X_0^{'}, X_1^{'}, L, X_n^{'}\right)=\begin{bmatrix} x_0^{'}(1) & x_1^{'}(1) & K & x_n^{'}(1) \\ x_0^{'}(2) & x_1^{'}(2) & K & x_n^{'}(2) \\ M & M & O & M \\ x_0^{'}(N) & x_1^{'}(N) & K & x_n^{'}(N) \end{bmatrix}_{N\times(n+1)} \quad (3.1)$$

Among them, $X_i^{'}$ is the main influence factor of the accident, matrix represents a main element.

(3) To the dimensionless variables

Due to various factors in the system data in a column may be due to the different dimensions, comparison, or in more difficult to get the correct conclusion. So the grey correlation analysis, generally must carry on the dimensionless processing of data. Eliminated by dimensionless calculation can achieve different dimensional data value differences between the impact, at the same time also can reflect the main influencing factors on the influence degree of the overall road traffic accident. Using (3.2) to the original data sequence is dimensionless.

$$x_{ij} = \frac{x_{ij}^{'}}{\sum_i x_{ij}^{'}} \quad (3.2)$$

x_{ij} refers to the main impact factor i of the j accident indexes of dimensionless results; $x_{ij}^{'}$ refers to the main impact factor i of the j original accident index; $\sum_i x_{ij}^{'}$ refers to the corresponding to j of the three index of the accident of the original value is the sum of the accident. See the data resulting from the dimensionless sequence type (3.3)

$$(X_0, X_1, L, X_n) = \begin{bmatrix} x_0(1) & x_1(1) & K & x_n(1) \\ x_0(2) & x_1(2) & K & x_n(2) \\ M & M & O & M \\ x_0(N) & x_1(N) & K & x_n(N) \end{bmatrix}_{N\times(n+1)} \quad (3.3)$$

For each of the main elements to select the optimal reference sequence, choose the method of major elements of the optimal sequence of reference type (3.4).

$$X_0 = (x_0(1), x_0(2), K, x_0(2))' \quad (3.4)$$

Among them: $x_0(j) = \max_{1 \le i \le n} \{x_i(j)\}, j = 1, 2, K, N$.

(4) Calculating correlation coefficient

$\xi_{0i}(k)$ is the correlation coefficient of $x_0(k)$ and $x_i(k)$, see type（3.5）

$$\xi_{0i}(k) = \frac{\min_i \min_k |x_0(k) - x_j(k)| + \rho \max_i \max_k |x_0(k) - x_j(k)|}{|x_0(k) - x_i(k)| + \rho \max_i \max_k |x_0(k) - x_j(k)|} \quad (3.5)$$

Remember: $\triangle_{0i}(k) = |x_0(k) - x_i(k)|$,

$$\triangle_{\min} = \min_i \min_k |x_0(k) - x_j(k)| ,$$

$$\triangle_{\max} = \max_i \max_k |x_0(k) - x_j(k)| \quad (i = 1, 2...n; k = 1, 2, ...N)$$

$\triangle_{\min}$ is the smallest range, $\triangle_{\max}$ is the biggest range. $\rho \in (0, \infty)$ is distinguish coefficient, the general values is $0.1 \sim 1$, the smaller ρ can improve can improve the correlation coefficient between the difference, the greater the resolution, specific values can take as the case maybe. When $\rho \le 0.5463$, the resolution is the best, so usually take $\rho = 0.5$.

(5) Computing correlation:

Because of the correlation coefficient is a sequence and reference in each moment the connection degree of (that is, each point in the curve) value, so its number to more than one, and information too scattered is not convenient to compare integrity. So it is necessary to every time (that is, each point in the curve) of the correlation coefficient of concentration of a value, its average, namely as a comparative sequence and the number of correlation degree between the reference sequence, the correlation formula of r_{0i} is as follows:

$$r_{0i} = \frac{1}{n} \sum_{k=1}^{n} \xi_{0i}(k), k = 1, 2, \Lambda, n \quad (3.6)$$

Correlation is adopted generally calculate the average correlation coefficient is computed, but three indicators of traffic accidents in the accident influence degree is different, so can't will severity index of different simple accumulation, this will cause misjudgment. Such analysis that it is necessary to adopt the weighted average method to evaluate correlation, we can use type (3.7) correlation calculation.

$$r_{0i} = \sum_{k=1}^{n} \omega_k \xi_{0i}(k), k = 1, 2, \Lambda, n \tag{3.7}$$

ω_k is the weight of the three indicators for traffic accident (the number of accidents, deaths, and the number of injured),we can using expert scoring method to determine. Expert scoring method to determine the weights of three indexes: the weight is 0.1, the number of accident death toll index weight is 0.6, the number of injured weight of 0.3.

4 Discussion of Results

Take the traffic accident of Linchuan section on Donglin highway during January 2009 to December 2013 into consideration, 700 traffic accidents occurred, 34 people were killed and 279 injured. According to the actual situation of Linchuan section on Donglin highway from the main influence factors, such as: stadia, road slope and road camber, roadside disturbance factor, because most of Linchuan section on Donglin highway the road is straight, no sharp, road slope, it should not, so there is no statistical these factors.

4.1 K231 + 200 accident causes dangerous intersection analysis

K231 + 200 accident is a dangerous crossroads intersections, the east is 7% up to the sun town central primary school and the town of old street branch of the west is 9% of the uphill to the Luohu town and new village branch. The intersection between January 2009 and December 2009, to a maximum of 86 traffic accidents occurred, killed seven people and injured 43 people, accounting for 18% of the total number of flat crossing traffic accident.

(1)Traffic signs obscured, branches and leaves of trees incredibly hides the intersection of the "cross" mark.

(2)Access sights of bad, because of the trees in the shade of buildings, caused by intersection of east and west two line stadia is only 80 meters and 70 meters respectively, is far less than 110 meters of stadia.

(3)After the entrance to the slope is too large, slope is found on both sides of the branch of the main road, the east branch of the uphill slope of 7%, on the west side of the hill slope has reached 9%, lack of mandatory reduction measures in a bar.

(4)Big four intersection traffic, the flat crossing traffic and traffic are larger, at the same time these people's traffic safety consciousness is low, branch vehicles don't come near the main vehicle.

4.2 K236 + 300 accident causes dangerous intersection analysis

K236 + 300 accident is a dangerous crossroads intersections, the east is 6% of the uphill to the Luohu town and the village of east branch, the west is the gateway to a new house in the village of branch. The intersection between January 2009 and December 2009, to a maximum of 63 traffic accidents occurred, killed 3 people and wounded 34 others, accounting for 13.4% of the total number of flat crossing traffic accident.

(1)The lack of traffic signs, the road does not have a road sign.

(2)Poor access sights, as a result of the doers of the word, buildings and slope block, caused by intersection of east and west two line stadia is only 50 meters and 75 meters respectively, stadia is far less than 110 meters.

(3)After the entrance to the slope is too large, the main branch is on the west side of the slope, on the west side of the hill slope of 8%, lack of mandatory reduction measures in a bar.

(4)Four intersection was badly damaged, the crossing overload truck traffic, perennial water caused by the road surface is damaged, the driver in order to choose travel route and reduces the main idea of the vehicle.

5 Conclusions

Respectively from the people, vehicles, road and environment four aspects analyzes the influence of the main causes of traffic accidents, put forward to reduce and prevent the happening of the road traffic accident, to ensure the safety of corresponding measures. Here we may draw the following conclusions.

(1)Strengthen the traffic safety education, to reduce road traffic offence;

(2)Strengthen the vehicle maintenance, improve vehicle safety performance;

(3)To improve road safety facilities, and constantly improve road conditions;

(4)In order to strengthen the management of road traffic, optimize the environment of road traffic safety.

6 Recommendations for Future Research

(1)The system, from the viewpoint of the mechanism of traffic accident qualitative research, to analyze the general process of the traffic accident, but how to quantitatively analysis the law of action between various factors within the system, still need further study.

(2)The secondary roads such low grade road, the traffic safety is often after accidents caused enough attention, thus caused many unnecessary casualties and property losses. So, how to carry out the low level of road traffic safety evaluation, in a timely manner to eliminate potential hidden trouble of road traffic safety is an urgent need to study.

Abstract: Road traffic fatalities account for the maximum portion of total production accident fatalities in China, although they exhibit steady annual reductions in recent years. Road traffic accident forecast is a core component of a target setting which proves to be an effective measure to improve road safety by the best-performing countries. In this paper, a traffic accident prediction model aimed to set road safety targets is proposed. Based on cointegration analysis of Chinese crash and economic data, the model avoids spurious regression and shows a satisfactory precision. The prediction results can be a good reference to policymakers on their target setting.

Keywords: Traffic accident; Death rate forecasting; Cointegration analysis; Error correct model.

1 Introduction

The annual number of road traffic casualties is above 200,000 in China (RIHMT, 2013). With such a high price for motorized road mobility, road traffic safety problems attract great attention of Chinese governments. To combat traffic accidents, the 12th Five-Year Plan of Road Traffic Safety (12th FYPRTS) was published at the end of 2011 (CSCOSPC, 2011). This is the first nation-level special plan for road safety, which offers a nationwide comprehensive framework for reducing road traffic accidents and fatalities. According to the FYPRTS, each local government above the county level is supposed to develop their own road safety plans.

For a road safety plan, the safety target setting is essential. Some models have been developed by domestic researchers to forecast the Chinese road safety tendency such as a multi-level recursive death toll prediction model (Li Xiangyong, 2006), a death toll prediction model based on neural network (Qin Liyan, 2010) and a multiple linear regression model of traffic accidents (Fang Yuerong, 2012). However, the short-term relationship between road safety and economic factors isn't taken into account in these models, which is important for target setting.

This paper aims to build a relatively simple model of traffic accident death rate prediction, revealing how road safety reacts to economic factors. The rest of the paper is organized as follows. Firstly, the methodology used in modeling is explained and the data sources are given. Secondly, the prediction model is built with the help of statistic software Eviews7.2. Thirdly, several main conclusions are summarized.

2 Methodology and Data

2.1 Methodology

Most macro road safety analysis and forecasts are conducted within the framework of linear regression (Yong-Jun Kweon, 2010; George Yannis, 2014). But some attention should be paid to spurious regression phenomenon (Granger, 1974). In a spurious regression, the standard t-statistic indicates that a sound relationship exists between the variables when, in reality, there is no such relationship. This is because the variance of the errors is not consistently estimated. To deal with the problem, the conduct of cointegration analysis is needed. Engle–Granger two-step method (Engle, 1987) can test the cointegration relationship. The first step is to find out integrated order of each time series by Augmented Dickey–Fuller (ADF) test method. If the time series has the same integrated order, the cointegrated regression model can be established as follows.

$$y_t = \hat{b}_0 + \hat{b}_1 x_{1t} + \cdots + \hat{b}_N x_{Nt} + e_t$$

where $\hat{b}_0, \hat{b}_1, \cdots, \hat{b}_N$ is estimated by ordinary least square (OLS) method, and e_t is residual error.

The second step is to test the stationary of $\{e_t\}$. If it is stationary, the series are regarded as cointegrated. Otherwise, they are not cointegrated.

An error correction model (ECM) can be built when the series are cointegrated. ECM is proposed by Davidson et al. (Davidson et al., 1978). It is a useful tool to estimate both long period and short period relationship between cointegrated time series.

For two variables, the structure of the first-order ECM is presented as below.

$$\Delta y_t = a_1 \Delta x_t - \lambda \cdot ECM_{t-1} + u_t$$

$$ECM_{t-1} = y_{t-1} - b_0 - b_1 x_{t-1}$$

where a_1 is short-term coefficient, λ is an adjustment coefficient and u_t is equilibrium error.

2.2 Data sources

The mortality rate per ten thousand vehicles data (Table 1) used in this paper are collected from The People's Republic of China on road traffic accident statistics report 2013 (MPSTMB, 2013). Economic data (Table 2) are obtained from the web of National Bureau of Statistics of the People's Republic of China.

Table 1. The mortality rate per ten thousand vehicles (1978-2013)

Year	Mortality rate	Year	Mortality rate	Year	Mortality rate	Year	Mortality rate
1978	120.20	1988	46.05	1997	17.50	2006	6.16
1980	119.62	1989	38.26	1998	17.30	2007	5.10
1981	104.47	1990	33.38	1999	15.45	2008	4.33
1982	95.85	1991	23.15	2000	15.60	2009	3.63
1983	85.32	1992	20.19	2001	15.46	2010	3.15
1984	84.35	1993	27.24	2002	13.71	2011	2.78
1985	42.99	1994	24.26	2003	10.81	2012	2.50
1986	62.39	1995	22.48	2004	9.93	2013	2.34
1987	61.12	1996	20.41	2005	7.57		

Table 2. Real Gross Domestic Product Per Capita (1978-2013)

Year	GDP Per Capita (yuan)	Year	GDP Per Capita (yuan)	Year	Mortality rate	Year	GDP Per Capita (yuan)
1978	381	1988	862.203	1997	1788.414	2006	3789.807
1980	404.241	1989	883.539	1998	1910.334	2007	4303.776
1981	430.53	1990	904.113	1999	2037.969	2008	4694.301
1982	447.675	1991	973.836	2000	2192.655	2009	5101.59
1983	480.822	1992	1098.804	2001	2357.247	2010	5607.177
1984	525.399	1993	1237.869	2002	2554.224	2011	6099.429
1985	597.408	1994	1384.173	2003	2793.111	2012	6534.531
1986	668.655	1995	1518.666	2004	3056.382	2013	7000.875
1987	717.042	1996	1653.159	2005	3382.137		

3 Model development

3.1 Variable selection

The most common indicator used in Chinese quantitative road safety targets is deaths per 10,000 motor vehicles (DPMV). Therefore, DPMV is selected as explained variable in this paper. Gross domestic product per capita (GDPPC) is chosen as explanatory variable, characterizing economic conditions. To avoid the influence of inflation, real GDP per capita data are adopted.

3.2 Model development

The data between 1978 and 2011 are used to determine the parameters of ECM. The data in 2012, 2013 are used for forecast comparison.

The results of ADF test of two variables and their difference series are summarized in Table 3.

Table 3. The ADF test result for the series

Variables	t-Statistic of ADF test	Critical value (1% level)	Critical value (5% level)	Critical value (10% level)
LnGDPPC	-2.635628	-4.296729	-3.568379	-3.218382
LnDPMV	0.364961	-3.632900	-2.948404	-2.612874
ΔLnGDPPC	-3.732707	-4.309824	-3.574244	-3.221728
ΔLnDPMV	-8.443748	-3.639407	-2.951125	-2.614300

Table 3 shows LnGDPPC and LnDPMV are nonstationary with 1-order integration. Therefore, the cointegrated regression model is estimated as below.

$$LnDPMV_t = \underset{(27.65058)}{12.55957} - \underset{(-21.29609)}{1.301374} \cdot LnGDPPC_t + e_t$$

The equation shows a high fitting degree with R^2=0.985350. The constant term and coefficient term passed through t-test. The ADF result of residual error is shown in Table 4.

Table 4. The ADF test result for residual error

	t-Statistic of ADF test	**Prob**
ADF test statistic	-3.032789	0.0035
Test Critical value (1% level)	-2.636901	
Test Critical value (5% level)	-1.951332	
Test Critical value (10% level)	-1.610747	

According to Table 4, the residual error is stationary. The two variables are proved to be 1-order integrated and cointegrated. The ECM model equation can be built as:

$$\Delta LnDPMV_t = -\underset{(-5.042306)}{1.310458}\Delta LnGDPPC_t - \underset{(-2.983101)}{0.158041}ECM_{t-1}$$

R^2=0.646012, DW=2.159929. The statistical fit of the ECM to the data is satisfactory. The forecasting results of the model are illustrated in Table 5.

Table 5. Forecast result comparison

Year	Predicted value	Real value	Error (%)
2012	2.619222	2.50	4.7689
2013	2.412894	2.30	1.9084

According to Table 5, the model has high precision.

4 Conclusions

Road safety tendency is essential to set proper road safety targets. It is necessary to develop a prediction model especially for this purpose. To avoid spurious regression, cointegration theory is introduced to forecast the fatality rate. The error correction model is built using deaths per 10,000 motor vehicles as explained variable and GDP per capita as explanatory variable. The prediction results show a satisfactory precision and can be a good reference to policymakers.

Abstract: Based on the achievements of key research project of Liaoning Province Transportation Department "Research on Road Safety and Traffic Operation of Expressway", hazardous location of eight-lane expressway are identified adopting quality control method in this article, and comparing with the hazardous location of four-lane and six-lane expressway. The effect of expressway entrance & exit on hazardous location is further analyzed. The preliminary conclusion is achieved that entrance & exit of eight-lane expressway and above is the primary cause of traffic accident. The research results of this article can provide theoretical basis for the design and lane layout of eight-lane expressway and above
Keywords: Multi-lane expressway; Traffic safety; Hazardous location.

1 Introduction

Multi-lane expressway means eight-lane expressway and above. In order to meet the needs of social development and traffic operation, several expressways have been or about to be reconstructed and extended in China recently. Multi-lane expressway is the development trend of expressway in future. The regulations on multi-lane expressway are almost blank, especially on eight-lane expressway and above, the hazardous location identification of eight-lane expressway and above have been seldom researched.

This article adopts a hazardous location identification method combining with the level of safety of service (LOSS), quality control method and probability distribution of accidents. The hazardous location includes sections, expressway tool stations, entrances & exits. Represented by Shenyang-Dalian expressway (eight-lane expressway), the hazardous locations of multi-lane expressway are identified applying this method. By comparing with four-lane and six-lane expressway in Liaoning Province, the cause and characteristic of hazardous locations are analyzed.

2 Hazardous Location Identification

2.1 Hazardous section identification based on LOSS

At the level-four safety service, the expressway traffic safety situation is badly, and the various accident indicators are clearly above than average. Thus, the sections of level-four safety service can be regarded as the traditional hazardous sections. Based on the level of safety of service, 16 hazardous sections of Shenyang-Dalian expressway are identified as follows.

Table 1. Hazardous sections of Shenyang-Dalian expressway based on LOSS

No.	Hazardous Location	No.	Hazardous Location
1	K9-K10	9	K159-K160
2	K19-K20	10	K165-K166
3	K22-K24	11	K264-K265
4	K34-K35	12	K280-K281
5	K41-K42	13	K290-K291
6	K44-K45	14	K297-K298
7	K123-K124	15	K301-K302
8	K144-K145	16	K334-K335

2.2 Hazardous location identification based on quality control method

(1) Hazardous location identification method

The quality control method is based on the probability theory. The critical rate $Rc^{\pm}$ could be obtained after comparing the accident rate of specific location with the average accident rate of similar characteristic location. The quality control method takes into account both the number of accidents and traffic flow, and becomes a classical method of hazardous location identification. The critical rate $Rc^{\pm}$ is computed according to Eq. (1)

$$R_c^{\pm} = A \pm K\sqrt{\frac{A}{M}} \pm \frac{1}{2M} \quad (1)$$

With Rc^{+} is the upper limit value of critical accident rate, Rc^{-} is the lower limit value of critical accident rate, A is the average accident rate of similar characteristic location, K is the statistical parameter, equal to 1.96(95% confidence), M is the traffic volume of specific location during the survey period(100 million vehicle).

The identification criterion of quality control method is as follows:

□ If the actual accident rate is less than the lower limit value of critical accident rate Rc^{-}, the traffic safety situation of this section is quite good;

② If the actual accident rate falls between the lower limit value of critical accident rate Rc^{-} and average accident rate A, the traffic safety situation of this section is good;

③ If the actual accident rate falls between the average accident rate A and the upper limit value of critical accident rate Rc^{+}, the traffic safety situation of this section is bad;

④ If the actual accident rate is more than the upper limit value of critical accident rate Rc^{+}, the traffic safety situation of this section is quiet bad, and could be identified as hazardous location

(2) Results of hazardous section identification

Based on the quality control method, 31 hazardous sections of Shenyang-Dalian expressway are identified as follows.

Table 2. Hazardous sections of Shenyang-Dalian expressway based on quality control method

No.	Hazardous Location	No.	Hazardous Location	No.	Hazardous Location
1	K307-K309	12	K111-K112	23	K264-K265
2	K332-K334	13	K116-K117	24	K280-K281
3	K371-K372	14	K123-K124	25	K290-K291
4	K394-K395	15	K144-K145	26	K301-K302
5	K59-K60	16	K159-K160	27	K307-K308
6	K65-K66	17	K164-K166	28	K311-K312
7	K75-K76	18	K172-K173	29	K322-K323
8	K79-K81	19	K229-K230	30	K327-K329
9	K89-K90	20	K240-K241	31	K334-K335
10	K92-K93	21	K255-K256		
11	K96-K97	22	K260-K261		

2.3 Hazardous toll station identification based on probability distribution of accidents

Based on probability distribution of accidents, if the accident rate of one toll station is more than the sum of average and 1.5 times standard deviation of accident rate, this toll station could be regarded as hazardous toll station. The results of hazardous toll stations identification are shown in table 3.

Table 3. Hazardous toll stations of Shenyang-Dalian expressway

No.	Tool Station Name	Accident Rate(per year per lane)
1	Liaoyang County Station	8.90
2	Jinzhou Station	11.81

2.3 Results of hazardous location identification

Synthesizes LOSS, quality control method and probability distribution of accidents, and combining the suggestion of expressway management, the total number of hazardous location of Shenyang-Dalian expressway is 20, including 5 hazardous sections, 2 hazardous toll stations, 10 hazardous interchange areas. In order to further analyze the cause of multi-lane expressway hazardous locations, the hazardous locations of six-lane expressway(Shenyang-Shanhaiguan expressway), four-lane expressway(Shenyang-Dandong expressway, Changchun-Shenzhen expressway, Shenyang-Kangping expressway, Siping-Kangping expressway) are compared. The specific results are shown in table 4.

Table 4. Summary table of hazardous location identification

No.	Hazardous Location	Type	Expressway Name	No.	Hazardous Location	Type	Expressway Name
1	K306-K307	Toll Station	Shenyang-Shanhaiguan Expressway	25	K76-K77	Interchange Area	Shenyang-Dalian Expressway
2	K661-K662			26	K117-K118		
3	K345-K346	Service Area		27	K270-K271		
4	K395-K396			28	K291-K292

16	K224-K225			40	K138-K140		
17	K295-K297			41	K147-K152		
18	K300-K303			42	K1-K2	Interchange Area	
19	K327-K329			43	K254-K257	Basic Section	Changchun-Shenzhen
20	K334-K336			44	K290-K293		

21	K7-K10	Interchange Area		45	K375-K378		expressway
22	K47-K48			46	K23-K28	Basic Section	Siping-Kangping expressway
23	K52-K53			47	K55-K59		
24	K65-K66			48	K42-K49	Basic Section	Shenyang-Kangping expressway

From the distribution of hazardous locations showed in table 4, we can conclude that hazardous locations of four-lane and six-lane expressway are mainly located at basic sections, a total of 18 hazardous locations are identified on four-lane expressway, including two toll stations and two interchange areas, accounting for 11%. A total of 10 hazardous locations are identified on six-lane expressway, including two toll stations and three interchange areas, accounting for 50%.

To further analyze the location characteristic of eight basic sections, we can find six sections are located front or behind the interchange area, which are shown in table 5.

Table 5. Hazardous section of Shenyang-Dalian expressway front and behind the interchange area

No.	Section Beginning	Section Ending	Accident Rate (100 million-vehicle per kilometer per year)	Direction	Comment
1	K0+000	K1+000	51.64	Dual-way	Expressway entrance， weaving areas
2	K18+800	K19+800	48.35	Dalian	Front Shilihe Interchange
3	K122+300	K124+000	68.63	Shenyang	Front and behind Haipan Interchange
4	K224+000	K225+000	48.74	Shenyang	Front Liguan Interchange
5	K295+000	K297+000	64.74	Dalian	Front Jindao Interchange
6	K300+900	K302+900	61.91	Dalian	Front Haiwan North Interchange

Thus, a total of 20 hazardous locations are identified on eight-lane expressway, and 90% of hazardous locations are located at toll stations, interchange area and front or behind interchange area.

3 Main Safety Problems of Multi-lane Expressway

(1) The conflict of lane changing is primary reason of traffic accident. From the

statistical data of traffic accident, we can conclude that the 90% of accidents are caused by lane changing on eight-lane expressway, while 11% and 50% of accidents are caused by lane changing on six-lane and four-lane expressway respectively.

(2) A fair amount of traffic accidents occurred near the interchange area. From the statistical data of traffic accident, we can conclude that accidents occurred near the interchange area on eight-lane expressway significantly more than six-lane and four-lane expressway. For multi-lane expressway, when the vehicles change lane from interior lane to external lane, it will need more time to drive off expressway. If the drivers are clumsy, they will not complete the operation. The accidents occur easily if the vehicles force to exit. Besides, some vehicles always park at the triangle channelization area to judge path, this situation lead to accidents easily.

(3) The roadside signs are often blocked. According to the traffic regulations and driving habits, most large trucks drive on the external lane. When the traffic volume is large, the large trucks that driving on the external lane will easily block the small vehicles driving on the interior lane, thus the small vehicle drivers are influenced to obtain information from roadside signs, the signs information will be invalidated.

4 Macroscopical Safety Countermeasures of Shenyang-Dalian Expressway

(1) Before the toll station, the sign of “SLOW DOWN” is suggested to be set.

(2) The deceleration marking is suggested to be set on exit ramp to warn driver.

(3) The toll station columns should be coated on reflective material to improve the night vision.

(4) The signs of lane distribution and speed limitation of different types of vehicles are suggested to be set at interchange area.

(5) Before the expressway exit, warning marks should be set to warn drivers weaving section ahead.

(6) Speed-limit signs, warning signs of slow down and speed camera signs are suggested to be set for controlling speed on the downhill pat, small radius curves sections, etc.

(7) The vision induced signs are suggested to be set on small radius curves sections, and the signs of forbid overtaking should be set on poor visibility sections.

Abstract: Sustainable Development takes interest in long-run economical development, emphasizing to satisfy the needs of contemporary people, but not to damage the profit of future generations. As the lifeline of economic development, sustainable development of transportation System makes decision concern. The development of Chengdu Transportation at high Speed is sustainable or not is a vital problem. So we use the DEA (data envelopment analysis) model to conduct a comprehensive analysis about the input and output of the field of traffic Chengdu city nearly ten years, combining sustainable development indicators. We estimate the sustainable development state and get important influence factors to obtain the sustainable development of Chengdu City traffic.
Keywords: Chengdu; Transportation; Sustainable; DEA.

1 Introduction

Along with the continuous development of modern society, especially the further expansion of economies, the scale of city traffic will significantly increase. The contradiction with the limited city resources ecological environment and nervous energy also will be more and more serious. In the current situation, the development of traffic system is no longer adapted to only improve the road network performance, ease the traffic pressure. Then we should focus on promoting the sustained and harmonious development, paying attention to the rationality of road planning, the sanity of traffic management and control. so as to facilitate traffic, for facilitating the traffic environment social and economic development greatly together.

The key of city traffic sustainable development is to make economic development, ecological environment and quality of life have the relative balance. Through the research and implement of the planning program, the city traffic sustainable development planning promote the balanced development between city economy, social environment and city traffic, achieving the traffic economic sustainability, social sustainability and environmental sustainability. There are not too many methods or models Specifically for the sustainable development of city traffic system. The main research methods at home and abroad so far are following: The weighted average method, AHP analysis method, principal component analysis, fuzzy evaluation and data envelopment analysis (DEA) method. The first four methods are not good at Dynamic evaluation, timing evaluation, binding test, and their subjective is strong. Moreover what they only make evaluation but analyzing or adjusting is not conducive to decision makers to make improvement in following work. But DEA Method can not only evaluate The relative effectiveness of the same type of every decision, but also further analysis the reasons of non valid DEA unit and the direction of future improvement of each decision, Providing important information for decision makers. Next in importance, it needn't any weight hypothesis, but getting optimal weights by actual data of input and output, Excluding many subjective factors, which has the very strong objectivity. In addition, as the DEA Method doesn't integrate data directly, we need not non-dimensional data before using the DEA Method to establish mathematical model. So I use the DEA to research sustainable development of Chengdu traffic system.

2 The basic idea and model of the DEA method

2.1 Sketch

DEA Method is short for Data Envelopment Analysis. using DEA can Investigate Scale validity and technological efficiency of city development along the production frontier. In the determination of the relative effectiveness of unit, we optimize every unit, making relative efficiency biggest and weight best. And for the non effective unit, we point out the direction of adjustment index, as well as give the amount of adjustment.

2.2 DEA model

C^2R model among DEA in this thesis:

$$\begin{cases} \min\left[\theta - \varepsilon\left(\sum_{r=1}^{t} S_r^+ + \sum_{i=1}^{m} S_i^-\right)\right], \\ \sum_{j=1}^{n} \lambda_j x_{ij} + S_i^- - \theta x_{ij_0} = 0, \\ \sum_{j=1}^{n} \lambda_j y_{rj} - S_r^+ = y_{rj_0}, \\ \lambda_j \geq 0, \quad j = 1,2,\ldots, \quad n \\ S_i^- \geq 0, \quad S_r^+ \geq 0. \end{cases} \tag{1}$$

In the formula, n is decision making units (DMU), here NMU j means a particular year, x_{ij} represent input of type i from DMU j, y_{rj} represent output of type r from DMU j. ε is Non Archimedes infinitesimal that is generally equal to 10^{-6}; λj is weight variable; S^-_i is a slack variable, S^+_r is the remnant variable. λ_j. S_i^-,S_r^+ and θ are estimating parameters.

1) Usually, when $\theta^*=1$ and $Si^{-*}=Sr^{+*}=0$, DEA of DMU is called effective, the effective frontier formed from it is constant returns to scale, and DMU is scale and technical efficiency..

2) If $\theta^*<1$ or $Si^{-*}\neq0$, $Sr^{+*}\neq0$, DMU is considered DEA invalid, or technique inefficiency, or scale inefficiency, if $Sr^+=Si^-=0$, DMU is considered technique efficiency; Make $K=\frac{1}{\theta}\bullet\sum_{j=1}^{n}\lambda_j^*$, when K=1, DMU is called scale efficiency, and when K>1, it is the increasing return to scale, otherwise it decreases progressively.

3) If DMU is inefficiency, we may improve non-DEA efficiency decision-making unit on relative efficiency plane through DMU, in the context without decreasing the input, the primary input to some extent decreases or in the context without increasing the input, the output to some extent increases ($y0\geq0$),

$$\text{i.e.}\quad \begin{cases} x_0=(1-\theta^*)x_0+S^{-*}\geq0 \\ y_0=S^{+*}\geq0 \end{cases}.$$

4) In DEA dynamic evaluation in consideration of time, make i>0, if $\theta^0(t-i)<\theta^0(t)$, the system remains sustainable development track, at this time, the efficiency of input-output is somewhat improved over time; If $\theta^0(t-i)=\theta^0(t)$, the development track of system is inferior to sustainable development track.

In practical application, each input and output value have definite dimension, it can be proved that the optimal efficiency index of decision-making unit is independent of the selection of dimension of input and output value. The selected DMU should have several features: Same task object, same environment and same input as well as output. Note that the input indicator is not "the smaller, the better", and the output indicator is not "the larger, the better".

3 Data Analysis

3.1 indicators select

We classify the urban traffic large scale system as three sub-systems: the transportation self-development sub-system, energy environment development sub-system, and social and economic development sub-system. In which in the first two sub-systems key indicators are selected as the input, while in the social and economic development sub-system those are selected as the output.

The input indicator in transportation self-development sub-system is: Commercial car ownership, the length of road in urban areas; the input indicator in energy environment development sub-system is: funds for transportation maintenance construction; and the input indicator in social and economic development sub-system is: the number of employees in year-end transportation, the gross value of production of the tertiary industry. Specific input-output data is shown in Table 1.

Data of table 1 comes from "Sichuan Provincial Bureau of Statistics", "Sichuan Province Statistical Yearbook" and "Chengdu City Statistical Yearbook" in 2008~2013.

Table 1.Output and input of Chengdu traffic system in 2008~2013

index \ year	2008	2009	2010	2011	2012	2013
The number of Business vehicles（vehicle）	114010	120605	134989	142121	134464	140819
The urban road length（kilometer）	2418	2645	2610	2704	2797	2706.6
The construction and maintenance funds of urban transportation（ten million yuan）	21.373	16.690	59.195	42.053	35.317	40.764
Number of employed in transportation（million）	1.66	1.93	2.10	2.28	2.44	2.54
The third industry GDP（hundred million yuan）	1814.2	2233.0	2868.4	3383.4	4000.3	4574.2

3.2 Model Solute and analysis

Bring the data of table 1 in C^2R model, I can get the following results in table 2 and table 3 by Matlab 7.0.

Table 2. The results of the model solution

DMU	θ	λ_1	λ_2	λ_3	λ_4	λ_5
2008	0.8702	0.1455	0.1061	0	0	0.5344
2009	1	0	0	0	0	1
2010	0.8621	0.7666	0.0627	0	0	1.0269
2011	0.8985	0.8976	0	0	0	0.3265
2012	1	0	1	0	0	0
2013	1	1	0	0	0	0
DMU	λ_6	S_1	S_2	S_3	S_4	S_5
2008	0	0	0	0	0	469.3442
2009	0	0	0	0	0	0
2010	0	0	0	17.5705	0	888.7313
2011	0	889.1045	0	1.1934	0	722.5748

2012	0	0	0	0	0	0
2013	0	0	0	0	0	0

Table 3.Evaluation results of Chengdu traffic sustainable development ability

year	$\sum \lambda_j$	$K = \frac{1}{\theta} \bullet \sum_{j=1}^{n} \lambda_j^*$	θ	The relative effectiveness
2008	0.786	<1	0.8702	×
2009	1	=1	1	√
2010	1.8562	>1	0.8621	×
2011	1.2241	>1	0.8985	×
2012	1	=1	1	√
2013	1	=1	1	√
year	The Scale validity	The technical efficiency	The sustainable development track	
2008	Decrease	×		
2009	Appropriate	√	On the track	
2010	Increase	×	Inferior to the track	
2011	Increase	×	Inferior to the track	
2012	Appropriate	√	On the track	
2013	Appropriate	√	Weakly Inferior to the track	

From table 3, we can analysis Chengdu traffic development in recent 6 years: the evaluation results of year 2009、2012、2013 are DEA effective, meaning that input and output reached the optimal state. Both scale and technology are effective. Meanwhile reflects Chengdu traffic development have been fully aware of the coordinated development of the whole traffic system, try to improve the efficiency of input and output.

In table 3, non DEA efficient units are all technical inefficiency, illustrate that combination of resources between the various transportation subsystem is not the best, input or output surplus deficit, scales in year 2010~2011 this two are increasing, which is not reasonable. Comprehensive technical invalid I can get that the increasing scale depends on large investment in resource, but the dependence of technology and the efficiency of input and output is not high.

Then we improve and adjust the non DEA efficient units, figure out savings amount of input in table 4, for reference.

Table 4. non DEA efficient units improve and adjust

year	θ	The number of Business vehicles （vehicle）	The urban road length （kilometer）	The construction and maintenance funds （ten million yuan）
2008	0.8702	14798.50	313.86	2.77
2010	0.8621	18614.98	359.92	25.73
2011	0.8985	15314.39	274.46	5.46

Through the improvement and adjustment of non DEA efficient units, we may safely draw the conclusion that increasing scale maybe rely on substantial investment of resources, especially the traffic construction and maintenance funding in 2010.

3.3 Countermeasures and suggestions for the sustainable development of Chengdu traffic system

In the transport sector, the target of sustainable development construction is the basic condition to establish and promote the sustainable development of human settlements. The methods mainly are: the land use in combination with transportation planning; establish traffic less demand mode; the development of public transport; improving the traffic management; to encourage non motorized modes of transport etc..

By establishing and solving the DEA model, I conduct a comprehensive evaluation of the analysis of the sustainable development of Chengdu City traffic system nearly 6 years, face the future sustainable development of Chengdu City traffic system goal, put forward the following suggestions:

1) Development is the premise and basis of the system collaborative development, so the Chengdu economic development is the key and dependence of the city transportation development. At present and in the future several years, vigorously develop the Chengdu City Economic and reasonable industrial layout is very important to promote and adjust the Chengdu City transportation
2) Development mode of city traffic system in order to change the high input, high consumption, high yield. Improve the technology innovation ability of industry and enterprise in city traffic system, increase their added value; further integrate the transport resources, human resources, capital investment, energy and environmental resources, optimize the control, reasonably adjust investment and development mode, vigorously improve the scale effect and technical efficiency.
3) Give full play to talent resource advantage and research strengths of Chengdu City traffic , develop and utilize clean energy in Chengdu traffic system, reasonably control speed and scale of city traffic development, coordinate traffic environment, and gradually improve the effectiveness of collaborative development of traffic system.

Abstract: For supporting analyses of traffic evolutions and traffic situation assessment, a Modified Cell Transmission Model (MCTM) for urban expressways is presented. The calibrated Van Aerde single regime model is used to replace the supposed triangle or trapezoid structural fundamental diagram, which makes the MCTM more adapting to describing expressway traffic flow characteristics. For different link connection types on expressways, rectilinear, merging, diverging and weaving transmissions of traffic flow are formulated using the proposed MCTM model. Using the designed experimental expressway section, three scenarios are simulated using CTM, MCTM, and INTEGRATION respectively, including normal traffic simulation without any incident, traffic simulation with accident, and traffic simulation with accident and managements. Results show that MCTM model can directly show the traffic flow condition and evolution process on expressways.
Keywords: Urban traffic; Modified cell transmission model; Urban expressway; Van Aerde single regime model.

1 Introduction

At present, traffic congestion is inevitable. Recurrent congestions have statistically significant features, and the congestion duration and breadth can be estimated and predicted. Relatively, because the occurrence time and space of traffic incident is random, the influence of non-recurrent congestions cannot be replicated. Therefore, once the traffic event happen, how to estimate the change of traffic status and how to predict the probable duration and breadth is the important basis of implementing traffic management and traffic information service.

Cell Transmission Model (CTM) is one typical method of describing the mechanical properties of a continuous traffic flow, which reveals the macroscopic traffic characteristics of segments, roads, and network under non-congested and congested conditions, including shock waves, queuing, interplay between traffic flows on different links, etc. (Daganzo, 1994; Daganzo, 1995) Due to considering temporal and spatial transfer characteristics of traffic flow, CTM is often used in estimations of urban traffic flow parameters (Hu, 2010), analyses of traffic flow transmission and state evolution rules (Gao, 2011), impact analyses of traffic events

(Jiyang, 2008; Chen, 2009), project designs of traffic control and information service (Shang, 2008; Zeng, 2006), and other aspects. In addition, specialized studies on parameter calibrations and adaptations of traffic models were carried out (Daganzo, 1997; Chen, 2010; Wang, 2010).

On the basis of the existing research methods and results, this paper constructs a modified cells transmission model (MTCM) for urban expressway to estimate state and assess traffic situation, through analyzing physical structures, traffic flow characteristics, and traffic data collections on domestic urban expressways.

2 Methodology

2.1 Fundamental of cell transmission model

The continuous traffic flow on section without on- and off-ramps meets the following conservation relations (Lighthill, 1955; Richards, 1956):

$$\frac{\partial q}{\partial x}+\frac{\partial \rho}{\partial t}=0 \tag{1}$$

where q represents traffic volume; ρ represents traffic density; x and t are respectively spatial and time variables. CTM processes the space and time in the discrete way, and supposes the link be a set of cells with a certain length. So the moving process of traffic flow on links is shown as the following Figure 1.

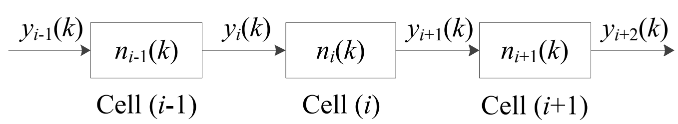

Figure 1. Transmission of traffic flow between cells in CTM

Based on the conservation equations of fluid mechanics, the moving process of vehicles satisfies:

$$n_i\left(k+1\right)=n_i\left(k\right)+y_i\left(k\right)-y_{i+1}\left(k\right) \tag{2}$$

where $n_i\left(k\right)$ is the vehicle number on the ith cell at the kth time interval; $y_i\left(k\right)$ is the vehicle number from the $\left(i-1\right)th$ cell to the ith cell at the kth time interval.

The cell length in CTM is equal to the distance of vehicles running with the free flow speed during one time interval. Therefore, the transmission volume between cells depends on both the existing vehicle number on the upstream cell and the vehicle number that can be accommodated in the remaining space of the downstream cell. Considering the back-transfer characteristics of the crowded traffic wave, $y_i(k)$ can be expressed:

$$y_i(k) = \min\left\{n_{i-1}(k), Q_i, \delta \cdot \left(N_i - n_i(k)\right)\right\} \tag{3}$$

where Q_i is the maximum number of vehicles that can run into the ith cell at one unit interval, and it can be expressed as $Q_i = q_{max,i} \times \varepsilon$; N_i is the maximum capacity of the ith cell, and it can be expressed as $N_i = \rho_{j,i} \times l_i$.

The maximum number of vehicles running out from the upstream cell is defined as the sending capacity, i.e. $S_i(k)$; and the maximum number of vehicles that can be accepted by the downstream cell is defined as the receiving capacity, i.e. $R_i(k)$.

$$\begin{cases} S_i(k) = \min\left\{n_i(k), Q_i\right\} \\ R_i(k) = \min\left\{Q_i, \delta\left(N_i - n_i(k)\right)\right\} \end{cases} \tag{4}$$

Thus, the Equation (3) can be transformed into Equation (5) as follows.

$$y_i(k) = \min\left\{S_{i-1}(k), R_i(k)\right\} \tag{5}$$

2.2 Modified cell transmission model for urban expressway

The traditional CTM assumes the flow-density relationship meet the simple trapezoidal structure, which do not match the actual traffic characteristics on expressways. Based on the detected data of traffic flow on Beijing expressways, the curve fitting result shows that the Van Aerde single-regime model can express the relationships of traffic flow-density (Zhao, 2009). Therefore, the Van Aerde model is introduced in this study to modify the traditional cell transmission model, so as to improve the accuracy of the model for describing traffic flow states on expressways.

According to Equation (4), for any unimodal flow-density relationship (as shown in Figure 2), the sending rate (s_i) and receiving rate (r_i) at each unit interval can be expressed as Equations (6) and (7). ρ_c is the traffic density corresponding to the capacity.

$$\begin{cases} s_i = q_i \\ r_i = q_{\max} \end{cases}, \text{ if } 0 \le \rho_i \le \rho_c \tag{6}$$

$$\begin{cases} s_i = q_{max} \\ r_i = q_i \end{cases}, \text{ if } \rho_c < \rho_i \le \rho_j \tag{7}$$

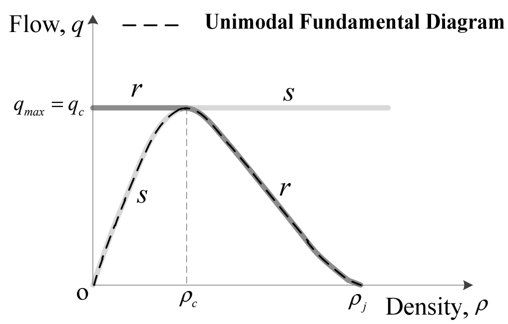

Figure 2. Receiving and sending rates based on unimodal fundamental diagram

Then the follow equation can be derived:

$$\begin{cases} s_i = q_{max} \\ r_i = q_i \end{cases}, \text{ if } \rho_c < \rho_i \le \rho_j \tag{8}$$

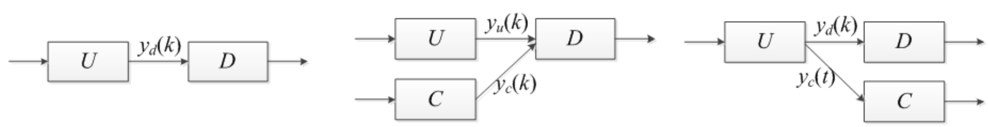
In the Van Aerde single-regime model, the relationship of density-speed is as Equation (9) (Rakha, 2009).

$$\rho = \frac{1}{c_1 + \frac{c_2}{v_f - v} + c_3 v} \tag{9}$$

where ρ and v are traffic density and speed respectively; c_1, c_2, c_3 are three intermediate variables, which can be derived by calibrating four characteristic parameters, i.e. free flow speed v_f, capacity q_c, jam density ρ_j, and speed-at-capacity v_c. Based on the speed-density-flow relationship of $q = \rho v$, the flow-density relationship can be gotten to be used in MCTM .

2.3 Transmission principles of traffic flow on different sections of expressway

According to whether connecting the ramp, expressways can be divided into three type segments, including basic segment, merging segment, and demerging segment, as shown in Figure 3. *U* and *D* respectively represents the upstream and downstream cell on the main road, *C* is the cell on the on-ramp or off-ramp. $y_u(k)$ is the vehicle volume running out from *U*, $y_d(k)$ is the vehicle volume running into *D*, $y_c(k)$ is the traffic volume running out from on-ramp or off-ramp.



(a) Basic segment (b) Merging segment (c) Demerging segment

Figure 3. Three types of segments on expressways

On the basic segment, there is the equation of $y_d(k) = y_u(k)$. The transmission traffic volume depends on the sending capacity of the upstream cell and the receiving capacity of the downstream cell, which can be expressed as follows:

$$y_d(k) = \begin{cases} S_u(k), & if\ S_u(k) \le R_d(k) \\ R_d(k), & if\ S_u(k) < R_d(k) \end{cases} \quad (10)$$

On the merging segment, $y_u(k)$, $y_d(k)$, and $y_c(k)$ satisfied Equation (11).

$$\begin{cases} y_u(k) \le S_u(k) \\ y_c(k) \le S_c(k) \\ y_d(k) = y_u(k) + y_c(k) \le R_d(k) \end{cases} \tag{11}$$

If $R_d(k) \ge S_u(k) + S_c(k)$, then,

$$\begin{cases} y_u(k) = S_u(k) \\ y_c(k) = S_c(k) \\ y_d(k) = y_u(k) + y_c(k) \end{cases} \tag{12}$$

And if $R_d(k) \ge S_u(k) + S_c(k)$, then,

$$\begin{cases} y_u(k) = \text{mid}\{S_u(k), R_d(k) - S_c(k), R_d(k) \cdot p_u(k)\} \\ y_c(k) = \text{mid}\{S_c(k), R_d(k) - S_u(k), R_d(k) \cdot p_c(k)\} \\ y_d(k) = y_u(k) + y_c(k) = R_d(k) \end{cases} \tag{13}$$

where $p_u(k)$ is the flow rate of running straight on main road, and $p_c(k)$ is the flow rate of running through the on-ramp.

On the demerging segment, the flow rate of running straight is $\beta_d(k)$, the flow rate of running through the off-ramps is $\beta_c(k)$, and $\beta_d(k) + \beta_c(k) = 1$. Thus,

$$\begin{cases} y_d(k) = y_u(k) \cdot \beta_d(k) \\ y_c(k) = y_u(k) \cdot \beta_c(k) \end{cases} \tag{14}$$

Due to the relations of $y_u(k) \le S_u(k)$, $y_d(k) \le R_d(k)$, and $y_c(k) \le R_c(k)$, the $y_u(k)$ can be expressed as Equation (15).

$$y_u(k) = \min\{S_u(k), R_d(k)/\beta_d(k), R_c(k)/\beta_c(k)\} \tag{15}$$

3 Case Study

An experimental section is chosen to carry out traffic simulations on the expressway. The length of the section is 3.6 km, which contains twelve main links, one on-ramp, and one off-ramp, as shown in Figure 4. Each link is one cell. Thus the characteristic parameters of the fourteen cells are calibrated, as shown in Table 1.

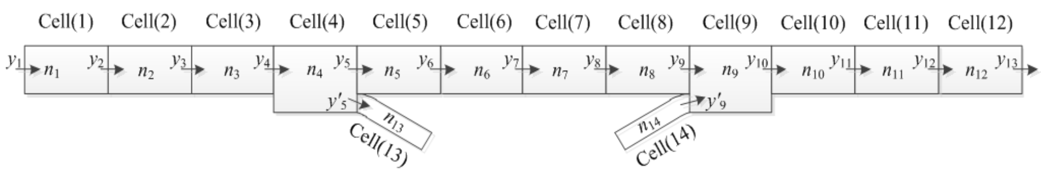


Figure 4. Cell structure design for the experimental expressway

Table 1. Values of traffic flow characteristic parameters for each cell

Cell ID	Num. of Lanes	Length (m)	v_f / (km • h^{-1})	q_c / (veh • h^{-1} • lane^{-1})	v_c / (km • h^{-1})	ρ_j / (veh • km^{-1} • lane^{-1})	N_i / (veh)	Q_i / (veh)
1	3	300	65	1887	45	151	136	16
2	3	300	65	1786	44	151	136	15
3	3	300	65	1778	44	151	136	15
4	4	300	67	1569	42	138	166	15
5	3	300	65	1887	45	151	136	16
6	3	300	65	1887	45	151	136	16
7	3	300	65	1887	45	151	136	16
8	3	300	65	1887	45	151	136	16
9	4	300	67	1569	42	138	166	16
10	3	300	65	1778	44	151	136	15
11	3	300	65	1786	44	151	136	15
12	3	300	65	1887	45	151	136	15
13	1	150	50	900	30	120	18	3
14	1	150	50	900	30	120	18	3

Three scenarios are simulated respectively using the models of CTM, MCTM, and INTEGRATION. INTEGRATION model was developed on the basis of the Van Aerde single-regime model, and it also fuses the microcosmic driving behavior model and the macroscopic traffic stream model to describe the vehicle running status better. On this context, INTEGRATION model is as the platform to derive the data under different traffic states, which are used as the comparative basis.

The three scenarios are expressed as follows: (1) No accident happens on the expressway section. The entrance volume on the main road is 4000 veh/h, and both the volume through the on-ramp and the off-ramp is 500 veh/h. (2) An accident happens on the outside lane of the 10th cell, which continues 15 min. The capacity of this link is 1725 veh/h/lane, the free flow speed is 64 km/h, the speed-at-capacity is 55 km/h, and the jam density is 150 veh/km/lane. (3) The upstream on-ramp (i.e. the 14th cell) is closed in 2 min after the accident. The information notice is also carried out to guide more vehicles leaving the main road. The volume through the off-ramp increases by 70%, i.e. 850 veh/h.

Density contours are drawn using the output data from CTM, MCTM, and INTEGRATION, as shown in Figure 5. Based on the simulation results of INTEGRATION, Mean Absolute Deviation (MAD) and Mean Absolute Relative Error (MARE) are calculated to compare the results of CMT and MCTM. The results of MADs and MAREs are shown in Figure 6.

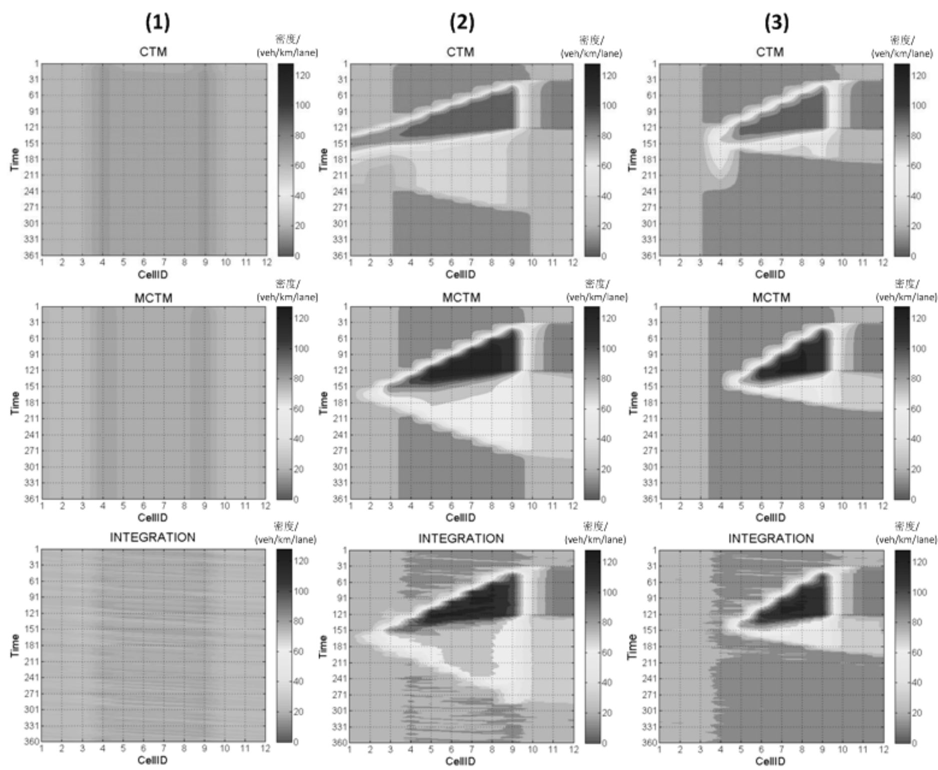

Figure 5. Comparisons of simulated density results

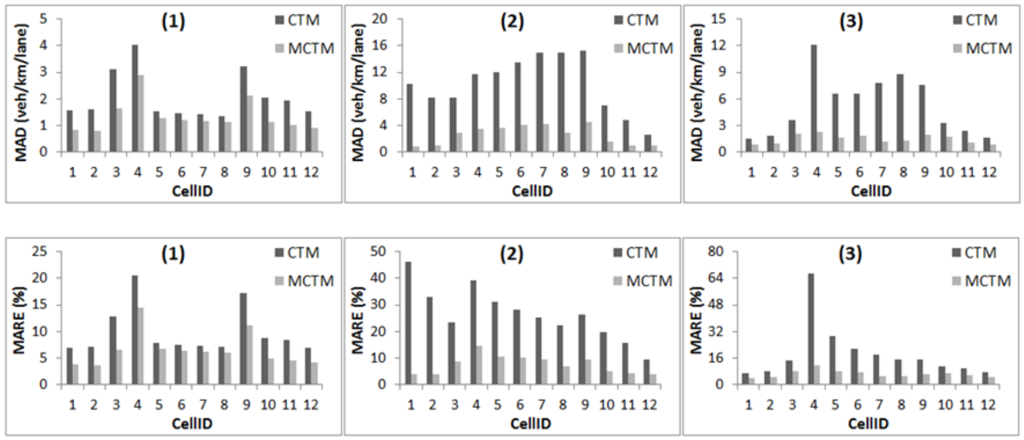

Figure 6. MADs and MAREs of traffic density estimations (CTM vs. MCTM)

For three scenarios, the density results estimated by MCTM are closer to the results of INTEGRATION. The MADs are less than 5 veh/km/lane, and the MARE values are within 10% except that of the 4th cell.

4 Conclusions and Recommendations

Carrying out studies on traffic flow states and evolution rules are fundamental basis of traffic situation assessment, traffic organization and management. This paper grasped the advantages of CTM in describing the shock wave, queuing, and influence of traffic flow, and then built the MCTM which focusing on calibrating the traffic parameters of urban expressways using the Van Aerde single-regime model. Comparing with CTM, MCTM can better describe the complex traffic moving and transmission process on expressways. And comparing with the traditional traffic simulation model, MCTM does not need to build the complex network platform. The structure of MCTM is simple and it can be solving fast.

In addition, considering the deviation and insufficiency of MCTM in estimating traffic flow parameters, it is recommended that further studies be conducted on calibrations of parameters on different cells. It is also recommended that the Noise variables be introduced into MCTM to improve the accuracy of the model.

Relationship between Traffic Accidents and the Road Traffic Operation Index—A Case Study of Beijing

Xunfei Gao; Nian Zhang; Yuxi He; Tong Zou; and Renjie Du

School of Transportation and Logistics, Southwest Jiaotong University, Chengdu 610031, China.

Abstract: Road Traffic Operation Index can comprehensively reflect the traffic state of the urban road network. In order to research the temporal distribution and the incidence relation, various traffic accident and traffic index is selected as the research object. This paper select the traffic accident data (occurrence location, occurrence time, accident category attribute) and traffic index data within the Beijing Fifth Ring Road from January to June 2014, as the basis to identify the monthly distribution and the daily distribution of total traffic accident, and the monthly distribution of various traffic accident. The occurrence location and the occurrence time of traffic accident is used for determining the traffic index value when the accident occurred. Regression analysis and SPSS is used and the results of each method is evaluated by R^2 values and F values. The results show that there is a positive correlation between total traffic accident, vehicle collision, other accident and traffic index. Vehicle breakdown and traffic index does not exist a positive correlation.
Keywords: Traffic accident; Road traffic operation index.

1 Introduction

In recent years, the contradiction between demand and supply of urban transport is increasingly prominent (the motor vehicle population of Beijing at the end of 2013 is 5.437 million). The congested urban traffic operating state, the seriously mixed traffic flow and the chaotic traffic order made the probability of occurrence of road traffic accident increased. On the other hand, traffic accident would destroy the fragile traffic operating state, increase the degree and the duration of congestion. There are some differences in the effect of various traffic accident on the traffic operating status.

Based on the traffic accident data of Xi'an and Jiangsu Province, Professor Chen Kuanmin, Bai Shuan studied the spatial and temporal distribution of traffic accident. Beijing Transportation Research Center studied and established the urban road traffic operating evaluation techniques and application systems. And road traffic operation index (traffic index) is applied to the Beijing road network operational monitoring. Traffic index can make the road operating state indexing and digital. It can comprehensively reflect the traffic situation of road network, and provide the data basis for the relationship study between traffic accident and traffic index.

This paper select the traffic accident data and traffic index data within the Beijing Fifth Ring Road from January to June 2014, as the basis to study the temporal distribution of total traffic accident and various traffic accident. Using the occurrence location and the occurrence time of traffic accident to determine the traffic index value when the accident occurred. And the regression analysis is used to study the relationship between total traffic accident, and various traffic accident and traffic index.

2 Study Object

2.1Traffic accident

Traffic accident is defined as the personal injury or property loss due to the fault or accident on the road in *People's Republic of China Road Traffic Safety Law*. According to the classification rule of traffic accident in *Data Format for Radio Data System-Traffic Message Channel Part 1: Event and Information Codes*, traffic accident is divided into vehicle breakdown, vehicle collision and other accident.

This paper select 2536 traffic accident information from January to June 2014 as the accident data basis. It include 362 vehicle breakdowns, 947vehicle collisions and 1227 other accident.

2.2 Traffic Index

This paper select the traffic index monitoring data of Beijing Transportation Research Center as the data basis. The update frequency of monitoring data is 15 minutes and the number of traffic index is 17376 from January to June 2014.

Traffic index can comprehensively and simply described space, time, intensity and other characteristics of traffic congestion. Using traffic index, travelers can understand the road network traffic congestion in real time. The range of traffic index is shown in Figure 1. It is 0 to 10, and is divided into 5 grades. 0～2, 2～4, 4～6, 6～8, 8～10 is respectively corresponded to smooth, mainly smooth, mild congestion, medium congestion, severe congestion. The higher values indicate more serious traffic congestion.

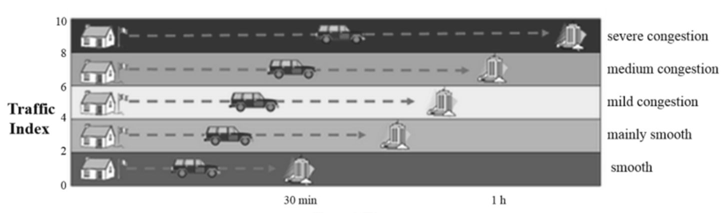

Figure 1. Relationship between traffic index and travel time

3 Temporal Distribution of Traffic Accident

According to the occurrence month and the occurrence hour of traffic accident, the frequency distribution of traffic accident is analyzed. Based on it, the temporal distribution of traffic accident is studied.

3.1 Monthly Distribution

The monthly distribution of total traffic accident and traffic index from January to June 2014 is shown in Figure 2.

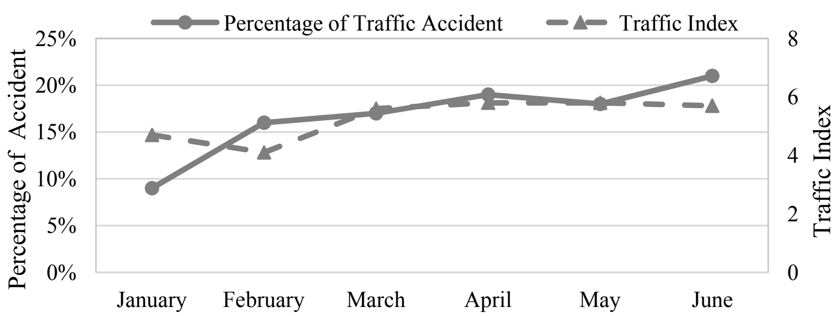

Figure 2. Monthly distribution of total traffic accident and traffic index

Figure 2 shows that the number of accident trend to increase with the increasing of traffic index. Traffic index of January is lower than the average level because of student holidays and a large number of passenger leaving Beijing. In terms of the number of accident, January also is lower than other months. Compared to January and February, traffic index of March, April, May and June have a substantial increase. And the number of accident also show a same increasing trend. But we need to concern about February. Traffic index of February is 4.1 that is the lowest point because of Chinese New Year. However, the number of accident of February is higher than January. It show an opposite trend with other months.

The total number and the monthly number of vehicle breakdown, vehicle collision and other accident is counted. The monthly distribution of various traffic accident is shown in Figure 3.

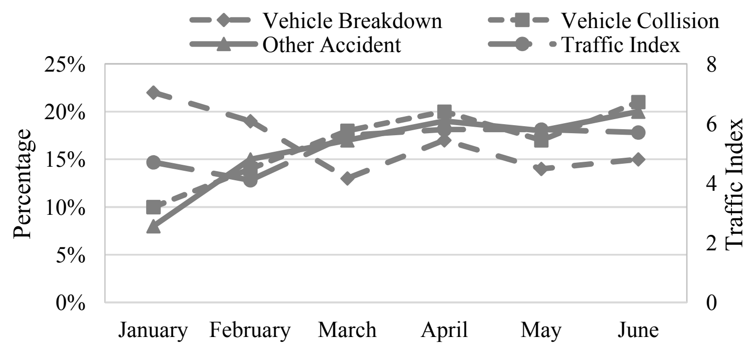

Figure 3. Monthly distribution of total traffic accident and traffic index

The trend of vehicle collision and other accident is same as the trend of total traffic accident. It has a large difference with vehicle breakdown. The number of vehicle breakdown in January and February is higher than other months, because that the low temperature of winter is easy to cause vehicle breakdown. In the monthly distribution of vehicle collision and other accident, the number of accident trend to increase with the increasing of traffic index, and the number of accident in Chinese New Year is relatively high.

3.2 Daily Distribution

We select 30 minutes as the interval to account the number of total traffic accident. Based on it, the percentage of each interval is determined. And the interval of accounting traffic index also is 30 minutes. Traffic index of this period is the mean of two update frequency. The daily distribution of total traffic accident and traffic index is shown in Figure 4.

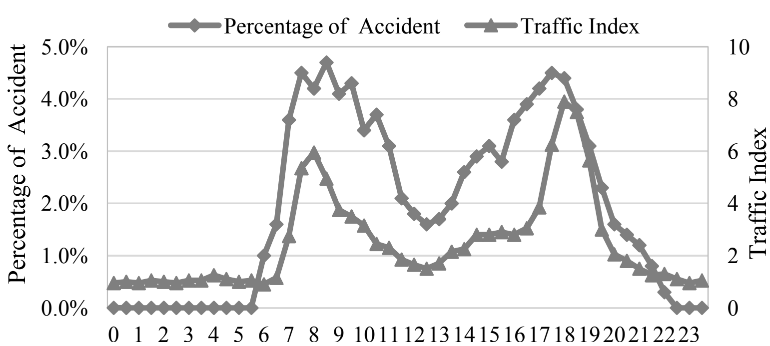

Figure 4. Daily distribution of total traffic accident and traffic index

Like the daily distribution of traffic index, the daily distribution of accident also has morning peak and evening peak. But the morning peak periods of accident is 8：00 to 10：00, and the evening peak periods is 16：00 to 18：30. It has some difference with the daily distribution of accident. In this periods, traffic operating state is congested and traffic system is relatively unstable. Traffic accident is easy to happen.

4 Correlation Analysis of Traffic Accident and Traffic Index

Traffic accident is the result of multiple factors, such as people, vehicle and environment. Simultaneously, the results of monthly distribution and daily distribution indicate that traffic accident and traffic index has a close relationship.

Cluster analysis and regression analysis is used for analyzing traffic index data and accident data, and establishing the relational model of accident and traffic index.

The occurrence location and the occurrence time of traffic accident is used for determining the traffic index value when the accident occurred. The input value is the daily number of accident and the average of index value when the accident occurred.

4.1 Analysis Result

This paper select 173 groups of data as basis. Linear, logarithmic, quadratic and cubic function is used for regression analysis, and the “level of significance” value is 0.95. The fitting curve of regression analysis is shown in Figure 5 to 8. The result of regression analysis is shown in Table 1 to 2. The analysis results is evaluated by R^2 values, and R^2 values can explain the proportion or percentage of the total variation in Y via the regression model. And the analysis result of various traffic accident only use the result of the best method.

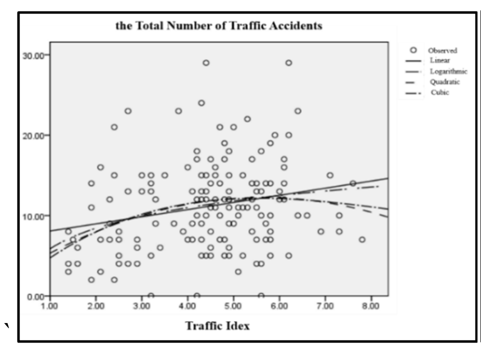

Figure 5. Total accident fitting curve

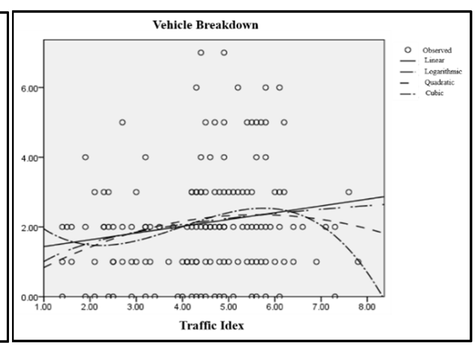

Figure 6. Vehicle breakdown fitting curve

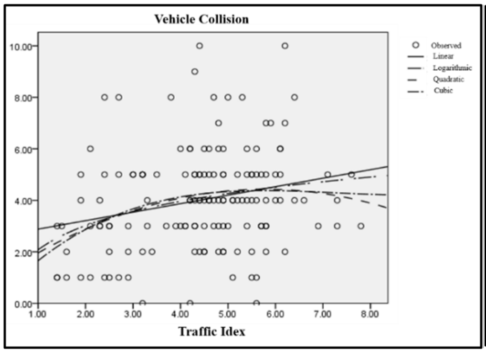

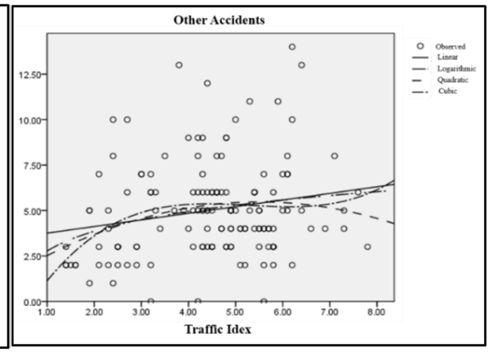

Figure 7. Vehicle collision fitting curve **Figure 8. Other accident fitting curve**

Table 1. Analysis result of total traffic accident

Function	R Square	F	F'	df2	df1	Sig.
Linear	0.103	18.635	3.9	171	1	.002
Logarithmic	0.114	21.983	3.9	171	1	.001
Quadratic	0.122	11.801	3	170	2	.003
Cubic	0.121	7.745	2.6	169	3	.001

Table 2. Analysis result of various traffic accident

Property	Function	R Square	F	F'	df1	df2	Sig.
Vehicle Breakdown	Quadratic	0.029	2.539	3	2	170	.052
Vehicle Collision	Logarithmic	0.139	27.607	3.9	1	171	.001
Other Accident	Cubic	0.118	7.537	2.6	3	169	.003

Table 1 indicates that there is a positive correlation between total traffic accident and traffic index. But the value of R Square only is 0.122, so the correlation is poor and unobvious. F' is the theoretical value of F-test. And all F values are greater than F', so assuming causality of regression analysis is significant. Traffic congestion only is one of factors leading to total traffic accident, and it is not the primary cause.

In table 2, the R Square value of vehicle breakdown only is 0.029 and F value is less than F'. It means that assuming causality of regression analysis isn't significant, so vehicle breakdown and traffic index does not exist a positive correlation. On the contrary, vehicle collision, other accident and traffic index exist a positive correlation. But like total traffic accident, the correlation also is poor and unobvious. The value of R Square only is 0.139 and 0.118.

5 Conclusions

Based on the analysis result of above paper, the distribution of total traffic accident has a temporal feature. Total traffic accident and traffic index exist a positive correlation. The probability of accident is greater when traffic index is higher.

There are some differences between the correlation of various traffic accident, total traffic accident and traffic index. Vehicle breakdown and traffic index does not exist a positive correlation. The number of vehicle breakdown in January and February is higher than other months. Vehicle collision, other accident and traffic index exist a positive correlation. During peak period, traffic congestion is severe and the state of traffic flow is unstable with increasing traffic index. And the probability of accident is increasing. So this paper suggest increasing traffic enforcement and safety management efforts.

How to Evaluate the Road Consistency and Driving Comfort of a Newly-Built Freeway—A Case Study of the Wu-Liu Freeway in Guangxi

Yue Wang and Shuo Liu

Key Laboratory of Road and Traffic Engineering, Ministry of Education, Tongji University, Shanghai 201804, China. E-mail: willingkoa@hotmail.com

Abstract: The freeway from Wuzhou to Liuzhou is a newly built branch in freeway network planning of Guangxi Zhuang Autonomous Region in China, providing more convenient access from Guangxi to the Pearl River Delta area. This study aims at improving safety performance and risk tolerance of this newly built freeway, in which a 40km segment with complex geometric design was investigated. Driving simulation experiments were carried out based on a 3D model constructed with data of regional terrain and geometric design. 20 experienced drivers participated in the simulating experiments. Road consistency was evaluated through driver's speed choice. Data on speed indicators were collected and analyzed, including average speed, standard speed deviation, speed variation coefficient, and speed difference between driving speed and design speed. Evaluation of driving comfort was obtained from driver's heart rate, lateral acceleration and corresponding track deviation. The results show that the overall design of Wu-Liu freeway is of good quality and potential problems lie in S curve, curves with small radius, continuous curves with divergent radiuses and entrances to tunnels.

Keywords: Road consistency; Driving comfort; Speed; Safety; Driving behavior.

1 Introduction

Safety evaluation is necessary and important for improving geometric design of road network, but currently most safety evaluation is based on vehicle's speed and crash rate. Therefore, it is difficult to predict the safety level in advance of the operation of road. Driving simulator has become an ideal surrogate measure on account of its advantages in safety, efficiency, resourceful data, and excellent experimental control (Bella, 2008). Its validity for analysis on driver's behavior was confirmed in some previous studies (Godley et al, 2002, Manser, 2007).

The Wu-Liu freeway connects Wuzhou and Liuzhou, providing a shortcut from Liuzhou, which has expanded to be an industrial base, to Guangzhou, the capital city of Pearl River Delta. Its operation makes the most energetic area in southern China becomes more accessible for residents and enterprises in Guangxi Zhuang Autonomous Region, which encourages the economic development in this area. The 40km target road segment of this two-way four-lane freeway runs from pile K85 to

K125, including two long tunnels and two overpasses. In this project with design speed of 100km/h and the maximum gradient of 4%, the minimum radius is 700m for horizontal curve and 10000m for vertical curve.

2 Method

2.1 Questionnaire

The 40km target segment was divided into 20 sections, with average 2km for each section, while guaranteeing the completeness of bridges and tunnels. The questionnaire was conducted in two aspects: road consistency and driving comfort. Drivers were asked to score road consistency and driving comfort for each section and answer some subjective questions on their speed choice and expected speed limit of the freeway segment. Suggestions on the questionnaire were also made.

2.2 Road consistency evaluation

Road consistency in this paper refers to the consistency of road alignment design. Its change leads to adjustment of driving behavior. If the change of road alignment exceeds driver's expectation, operation error may occur when the driving task is performed. Usually the vehicle runs in the trajectory which the driver believes to be safe (Misaghi and Hassan, 2005). The risk would be very limited if the expected track is consistent with road geometric design. In the case that the driver drives on a track inconsistent with road alignment, the vehicle would deviate from the center of lane and risk would increase. The following indicators were chosen to evaluate road consistency. The criteria of evaluation levels were displayed in Table 1.

(1) Lateral deviation

For the target freeway segment, the lane width is 3.75m, the width of simulation vehicle is 2m and the width of marking is 0.2m. It was calculated that lateral deviation ought to not exceed 0.775m to keep good road consistency. The smoothness of driving track and intercross frequency were also considered.

(2) Lateral acceleration

The lateral acceleration also changes with road alignment. In general, the more fluctuant is lateral acceleration variance, the worse is road safety performance.

(3) Speed consistency

Driving speed is the highest speed the driver would choose according to real-time road condition and traffic environment. The speed consistency was reflected by the difference between driving speed and design speed.

(4) Speed variation coefficient Cv

Cv=Speed standard deviation/Average speed

The variation coefficient overcomes the influence of sample fluctuation in speed analysis and contributes to further study on correlation between speed fluctuation and crash rate.

(5) Section speed difference ΔV

ΔV is the absolute value of speed difference between adjacent road sections. It is an important indicator in road design evaluation.

$\Delta V=|V_{85i}-V_{85i-1}|$

Where V_{85i} is the 85% speed of the target section, V_{85i-1} is the 85% speed of road section ahead of the target section.

Table 1. Evaluation levels of road consistency indicators

Evaluation level	lateral deviation	|driving speed –design speed|	Speed variation coefficient Cv	Section speed difference ΔV
Good	$\leq$0.775m	$\leq$10km/h	$\leq$0.031	Between -10 and 11
Fair	Between 0.875m and 0.775m	Between 20km/h and 10km/h	Between 0.031 and 0.046	Between -15 and -10 or Between 11 and 16
Poor	$\geq$0.875m	$\geq$20km/h	$\geq$0.046	$\leq$-15 or $\geq$ 16

2.3 Driving comfort evaluation

(1) Heart rate change

The driving experience is pleasant only when driver's emotional and physical burden are reasonably controlled. When driver's heart rate increases over 20 beats per minute, senses of oppression, tension and panic would appear and driving safety would be negatively affected or even threatened.

(2) The transverse acceleration

When driving through a curve, the driver experiences the transverse acceleration generated from centrifugal force. Driver and passengers in the vehicle would be uncomfortable if the acceleration is too high or changes too fast.

3 Experimental Setup

3.1 Experiment equipment

The driving simulation experiment was based on a simulator system with eight degrees of freedom. SCANeR, the software applied to simulation, was developed by French Company OKTAL. The simulation vehicle was a Renauh Megane III with engine removed, data collection system installed and rear-view mirror replaced by a LCD screen. It was fixed in the center of a concealed sphere-shaped driving cabin. The projection system of five projectors was built on the roof, providing a 250º view of simulated driving environment. Data was recorded in the experimental driving process, including driving time, trip meter, speed, wheel change, lane deviation, brake force, acceleration, gear shift, etc.

Smart-Eye was used to measure driver's head pose and gaze direction. It comprised four cameras to capture gaze and head movement and another three to record driving environment.

Cardio tachometer 400sd, which was produced by Finish Company POLAR, was used to record driver's heart rate during the experiment.

3.2 Experiment design

20 experienced drivers (24-50 years old) were selected through telephone and internet interviews. Firstly, the working mechanism of the simulator system and how to prepare for the experiment were explained to them, then they were informed of specific instructions on their driving task and invited to complete basic information questionnaire, including personal information and driving experience. Before formal experiment, participants drove for 3-5min in simulator for adaption to the simulating driving environment. Their normal heart rates were recorded in the process.

4 Results

4.1 Questionnaire

The target freeway was divided into 20 sections. The score for each section scaled from 1 to 4 and 3.50 was determined as the minimum threshold value. Sections with score lower than that were investigated. It turns out that section 15 16 and 17 are located at the bottom of continuous downward slopes and in each of them at least one small-radius horizontal curve is included; section 18 consists of curves with divergent radiuses; section 19 and 20 lead to the tunnel entrance.

4.2 Road consistency and driving comfort

After analysis of data obtained from simulator system, sections with potential risk were identified. The relations between curvature and speed (and standard deviation), lateral deviation (and standard deviation), lateral acceleration (and standard deviation), driver's heart rate, the difference between driving speed and design speed were explored respectively and displayed in the figures below.

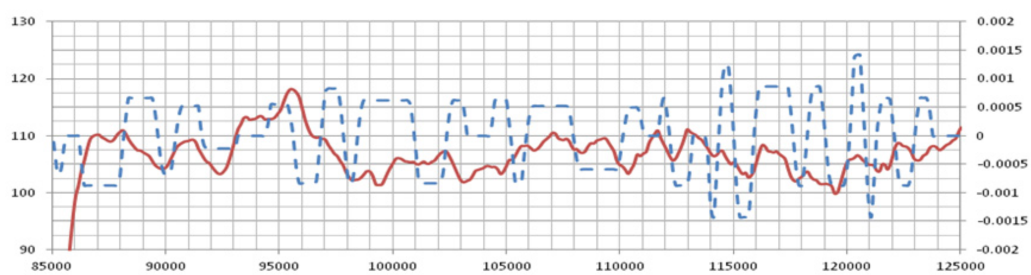

Figure 1. Speed and curvature

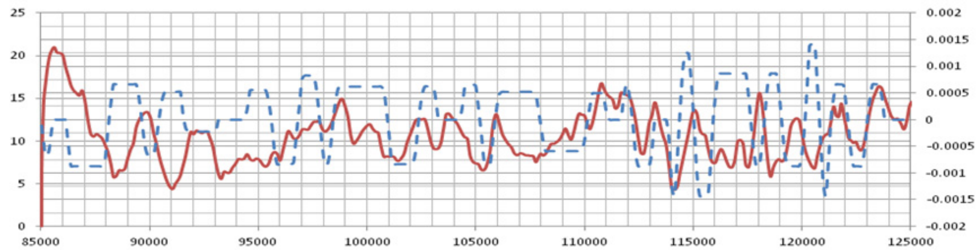

Figure 2. Speed standard deviation and curvature

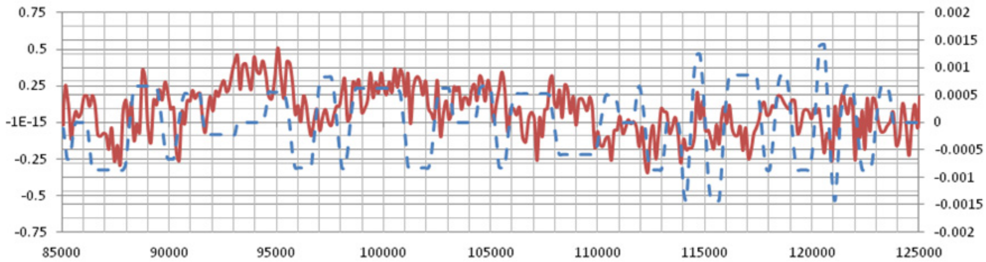

Figure 3. Lateral deviation and curvature

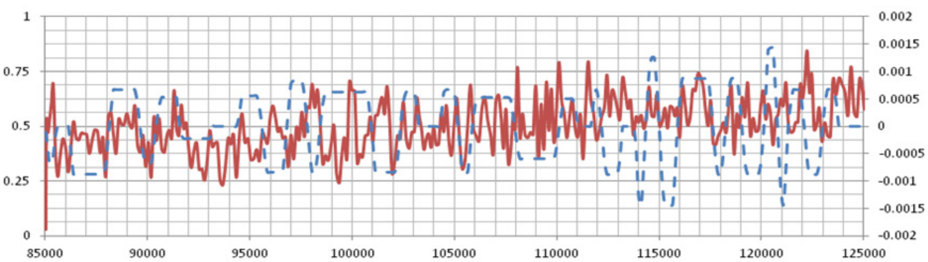

Figure 4. Lateral deviation standard deviation and curvature

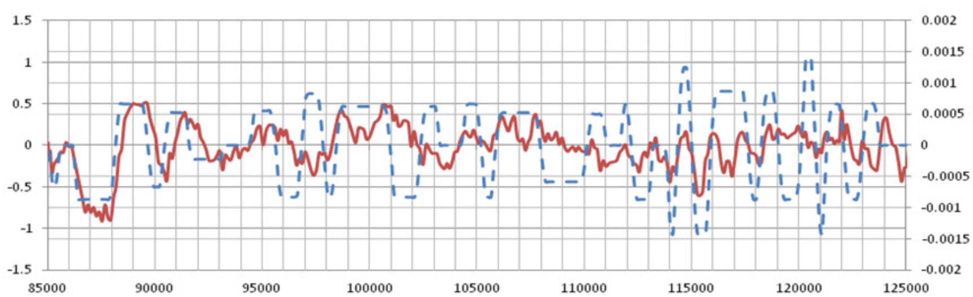

Figure 5. Lateral acceleration and curvature

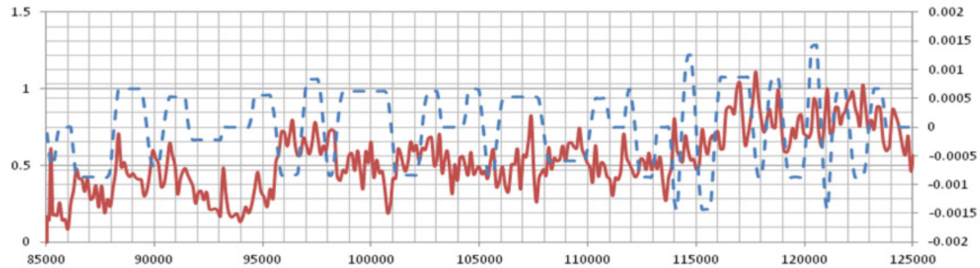

Figure 6. Lateral acceleration standard deviation and curvature

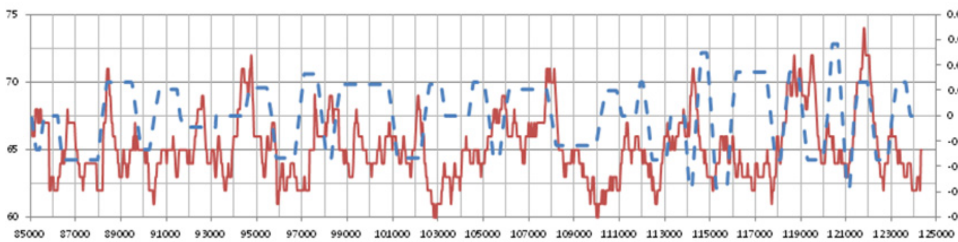

Figure 7. Heart rate and curvature

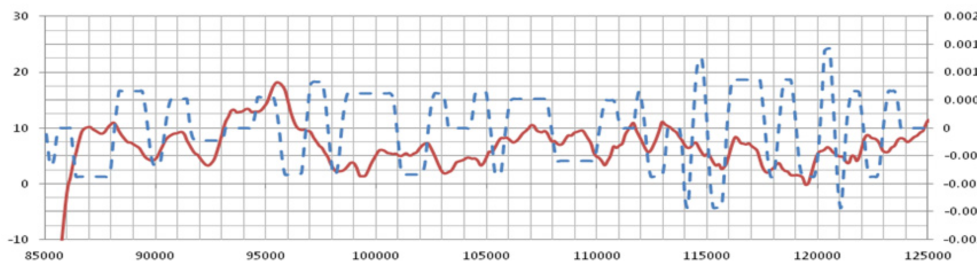

Figure 8. The difference between driving speed and design speed and curvature

It could be learned from these figures that curvature and lateral acceleration are positively correlated. High or highly fluctuant lateral acceleration implies difficulties and risks in performing driving task. In the experiment, drivers choose various speeds in the same section, but they always keep the vehicle running in the lane since lateral offset is kept below 0.775m. Significant relation between heart rate and curvature is shown in Figure 7. As illustrated in Figure 8, driving speed is greater than design speed during most time. This indicates that the overall road alignment is of good quality that the driver could drive safely at a relatively high speed, and drivers are rarely affected by other vehicles in free traffic flow.

5 Conclusions

For the target road segment of Wu-Liu freeway, the overall design is of good quality. Potential problems lie in curves with small radius, continuous curves with divergent radiuses or in opposite directions (S curve), and entrances to tunnels.

Safety evaluation is necessary and important for improving geometric design of road network, but it is inconvenient to conduct for a newly built freeway. This study provides a method of completing the task with driving simulation experiments, in which driving environment of the newly built freeway is constructed in a 3D model and projected in a board front view. Analysis helps road engineers to locate black spots on the road and make improvement designs or compensation measures in corresponding road sections.

Car-Following Model Based on Ahead Acceleration and Velocity Differences

Longhai Yang[1]; Jiekun Gong[2]; and Shun Zhao[3]

Abstract: The traditional car-following theory suppose that drivers' reaction absolutely depend on leading-vehicle behavior. Actually, drivers make decisions based on the information of leading-vehicle and the second leading-vehicle, even more. Recent researches only consider the speeds and locations of multiple leading-vehicles, but the acceleration of leading-vehicle also plays a vital role in the car-following characteristics. Based on the FVD (Full Velocity Difference) model and the OV (Optimal Velocity model) model, the MAAVD (Multiple Ahead Acceleration and Velocity Differences) model which take accelerations and velocities of multiple leading-vehicles into account is established. Linear stabilization and sensitivity of susceptibility of different models are simulated and compared. The result shows that the new model could improve the stability of traffic flow by considering the information of leading-vehicle and second leading-vehicle and could improve the stability better by considering the acceleration of leading-vehicle.
Keywords: Car-following model; Multiple leading vehicles; Stability.

1 Introduction

Driving behaviors of experienced drivers are effected by not only the leading vehicle but also the second leading vehicle. But in the study of traditional following behaviors, in order to simplify the calculation, the effect of leading vehicle was only considered (Wang D H, 2012). As the car-following theory is gradually getting mature, more and more scholars begin to study the car-following behavior which consider the effects of multiple leading vehicles and take more concentrate on finding the reasonable models to simulate the actual following behavior more realistically. At present, the studies of multiple vehicles car-following mainly focus on optimal velocity (OV) (Bando, 1995) model and full velocity difference (FVD)(Jiang R, 2006).

On the basis of OV model, multi-cooperation driving model was established with the consideration of effect of multiple headways on car-following(Ge H X, 2005).On the basis of FVD model, multiple velocity differences (MVD) model was established by introducing multiple velocity differences(Wang T, 2006). The multiple ahead and velocity difference (MAVD) model was presented with consideration of the position and velocity information of multiple vehicles (Sun D H, 2010). Some researchers find that the stability of car-following model which considers the reaction time of driver is improved and the traffic capacity also could be improved in the car-following model (Hu Y, 2014). There are also some researches show that the consideration of the position and velocity information of multiple vehicles also could reduce the adverse impact of the reaction time of driver (Chen J, 2014). Moreover, the number of vehicle which should be considered in car-following also isn't different. It is proved that three leading vehicles should be included in the congestion. However, two leading vehicles is enough in the free (Zhang X, 2014). The models which consider the information of multiple vehicles ignore the effect of acceleration. But the full velocity difference and acceleration (FVDA) model show that the overall consideration of headway, speed difference and acceleration of leading vehicle provides the car-following higher stability than FVD model and provide the vehicle faster acceleration (Yu S, 2013). In conclusion, the acceleration of leading vehicle should be considered in the multiple car-following model.

In this paper, the new model is presented by introducing the headways and speed differences of leading vehicle and second leading vehicle on the basis of MVD model. The new model has considered the effect of acceleration of leading vehicle. The linear stability of the new model is analyzed through the linear stability theory, and mathematical simulations are done to the comparative analysis of different car-following models.

2 Multiple Ahead Acceleration and Velocity Differences Model

MVD model is presented on the basis of FVD model and introduces the velocity difference of multiple leading vehicles (Wang T, 2006). The MVD model is shown as:

$$a_n(t) = \alpha\left[V(\Delta x_n(t)) - x_n(t)\right] + \sum_{l=1}^{m} \lambda_l \Delta v_{n+l-1}(t) \quad (l = 1, 2, \ldots, m; m \ll N) \tag{1}$$

Where α is the sensitive coefficient of drivers for headway. *N* is the total number of vehicles in the road. *m* is the number of multiple leading vehicles. λ_l is the weight coefficient of velocity difference and is less than λ_{l+1}. $V(\Delta x_n(t))$ is the function of optimal velocity. $\Delta v_{n+l-1}(t)$ is velocity difference between leading vehicle and following vehicle.

When $m=0$, MVD model is equivalent to OV model. When $m=1$, MVD model is equivalent to FVD model.

MVD model just considers the influence of multiple velocity differences and ignores the headways of multiple leading vehicles and the acceleration of leading vehicle. But these parameters are important for simulating car-following and could decide the accuracy of simulation. Consequently, based on MVD model, this paper establishes a new model (MAAVD) with the consideration of ahead acceleration and multiple velocity difference. The MAAVD model is shown as

$$\begin{aligned} a_n(t) = \alpha\left\{(1-p)V\left[\Delta x_n(t)\right] + pV\left[\Delta x_{n+1}(t)\right] - v_n(t)\right\} \\ + \lambda\left[(1-q)\Delta v_n(t) + q\Delta v_{n+1}(t)\right] + ka_{n+1}(t) \end{aligned} \quad (2)$$

Where α, λ are the sensitive coefficient of driver for headway and for relative velocity; k is the influence coefficient for acceleration of leading vehicle; *p* and *q* are weights of second leading vehicle for headway and relative velocity; $\Delta x_n(t)$ and $\Delta v_n(t)$ are the headway and the speed difference between the *n*th and the (*n+1*)th vehicle; $a_n(t)$ is the acceleration of the *n*th vehicle.

3 Stability analysis of the MAAVD model

In order to analyze the characteristic of the MAAVD model, especially the stable domain, the linear stability analysis is carried. To assume that the initial state of the fleet is stable, the fleet moves with the headway which is h. The position of *n*th vehicle could be expressed by

$$x_n^0(t) = V(h)t + hn \quad (3)$$

$y_n(t)$ is defined as the tiny disturbance which is applied in *n*th vehicle. Its expression is shown as:

$$y_n(t)=exp(i\theta n+zt) \quad (4)$$

Therefore, the actual position of *n*th vehicle could be presented as:

$$x_n(t) = V(h)t + y_n(t) + hn \tag{5}$$

The new function of optimal velocity which is built through substituting formula (5) into formula (4) is expanded by Taylor method. Subtracting the high order terms, the expression could be got as:

$$V[\Delta x_n(t)] = V(h) + \dot{V}(h)\Delta y_n(t) \tag{6}$$

Substituting Fouries series expansion of the disturbing function and formula (6) into MAAVD model, the following expression could be got.

$$\begin{aligned} z^2 = \alpha\left[(1\text{-}p)\dot{V}(h)\left(e^{i\theta}\text{-}1\right) + p\dot{V}(h)e^{i\theta}\left(e^{i\theta}\text{-}1\right)\text{-}z\right] \\ +\lambda z\left[(1\text{-}\beta)\left(e^{i\theta}\text{-}1\right) + \beta e^{i\theta}\left(e^{i\theta}\text{-}1\right)\right] + kz^2 e^{i\theta} \end{aligned} \tag{7}$$

To assume that $z=\omega i+\gamma$, γ is usually zero. Combining Euler formula $e^{i\theta}=cos\theta+i\bullet sin\theta$ the real part and the imaginary part of formula (7) are taken as zero, we can get the stability equation, which can be solved by elimination and L Hospital rule. The solution can be expressed as

$$\dot{V}(h) = \frac{\frac{\alpha}{2}(1+2p)+\lambda}{1\text{-}k} \tag{8}$$

In order to contrast the three models expediently, λ is chosen as the recommended value $\lambda = 0.2$, k , p are the introduced parameters, $k=0.1$, $p=0.2$ .The critical curves between headway and sensitivity coefficient in different models are shown in Figure 1.

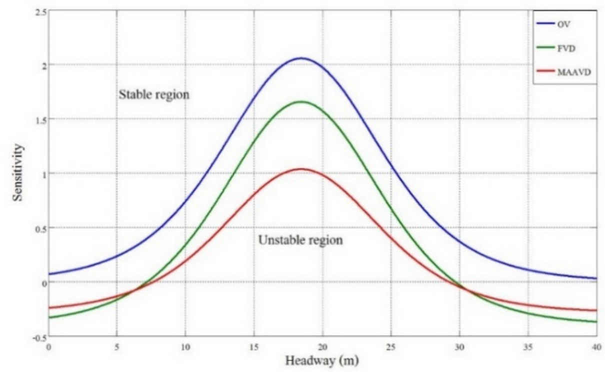

Figure 1.The critical curves between headway and sensitivity coefficient in different models

The critical stability curves of OV Model, FVD Model and MAAVD Model are shown in the Figure 1. Vehicles can be driven smoothly in a certain range (no congestion), which is above the critical curve. As is shown in the figure1, compared to OV Model and FVD Model, the MAAVD model has a larger stable region and a smaller unstable region, which avoids the indefinite time headway in OV Model. We can draw a conclusion that considering the acceleration of the leading vehicle and the second leading vehicle will facilitate the achievement of the stability of traffic flow could be drawn.

4 Mathematical Simulation

Mathematical simulation was taken to OV model, FVD model and MAAVD model in order to figure out the contribution of the MAAVD model. To make the simulation more practical, this paper cites the function of optimal velocity which was tested by Helbing and Tilch through experimental data (Helbing, 1998). Its expression is shown as

$$V\left[\Delta x\right]=V_1+V_2\tanh\left[C_1\left(\Delta x-l_c\right)-C_2\right] \tag{9}$$

Where, $V_1=6.75\,m/s$, $V_2=7.91\,m/s$, $C_1=0.13$, $C_2=1.57$, l_c is the length of vehicle which is 5 meters. Defining vehicle number as 20, initial speed as 11m/s, headway as 10m, $a_1(t)=0.5$ when $100\le t<122$, $a_1(t)=-0.3$ when $222\le t<262$.

Same values was taken for the same parameters in each model, where α=*1.4* , λ=*0.2* , *k=0.1* , *p=0.2* , *q=0.2* . The result of the mathematical simulation are shown from figure 2 to figure 5.

Figure 2 to 4 show that at the beginning of the simulation, the desire speed is less than the initial speed in each model when the headway is 15m, so all vehicles in three models choose to decelerate. The OV model has the biggest amplitude of the deceleration, and the MAAVD model has the smallest amplitude. For the following stage which all vehicles speed up to keep the desire headway and speed, there are overshoot in the OV and FVD model, while vehicles in the MAAVD model accelerate to the desire speed with no overshoot. The result reflects that the MAAVD, considering multiple leading-vehicles, has the ability to predict the behavior of the leading vehicles in detail, which helps make perfect choice.

The headway and speed of vehicles in three model are basically the same when the model goes to the first stable stage, while the next stages when the cars slow down to still and then speed up, the speed curves of three model are quite different. For the MAAVD model, the speed curves of each vehicles are similar to each other, and are smoother as the number increase; while for the OV model and FVD model, the oscillation appears when the number of vehicles go up to 15 for OV model and 10 for FVD model.

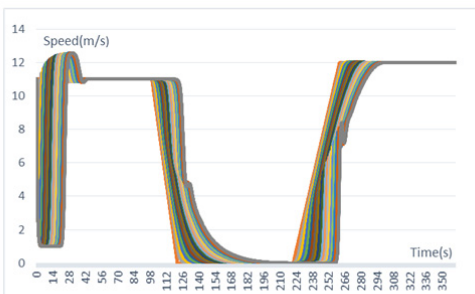

Figure 2.The speed curves of vehicles under OV model

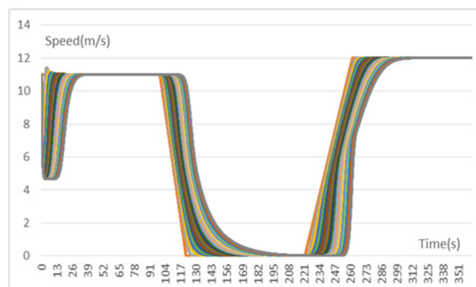

Figure 4.The speed curves of vehicles under MAAVD model

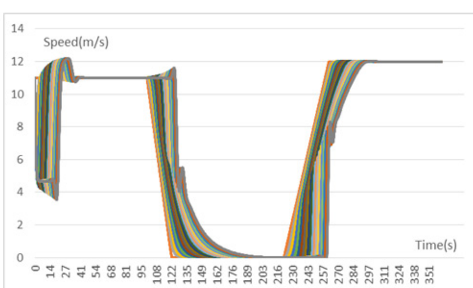

Figure 3.The speed curves of vehicles under FVD model

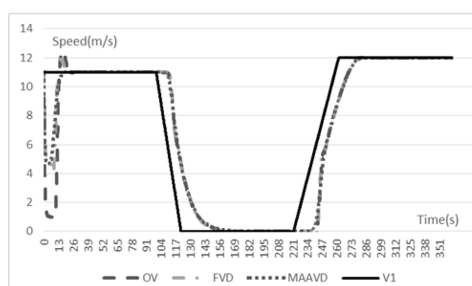

Figure 5.The speed curves of the tenth vehicle under different car-following models

Then we take a look at the speed of the tenth vehicle of each model, as it shown in Figure 5, the three models are mathematically stable when the vehicles are less than10. Figure 5 shows that the variation trend of speed of the tenth vehicle in OV model and FVD model are similar, and both of them have an overshoot which are 25% of the stable speed. It takes 14s for the MAAVD model from the beginning to stable state (|a|<0.5m/s), 21s for the FVD model and 22s for the OV model.

5 Conclusions

In this paper, a MAAVD model is constructed by considering the behaviors of leading-vehicle and the second leading-vehicle. Based on the linear stabilization, the critical stable condition of MAAVD model is obtained. By analyzing simulation results, conclusions are reached as follows.

(1) Comparing with OV model and FVD model by linear stability analysis, MAAVD model has a smaller critical value of sensitivity coefficient, which means a greater stable region of traffic flow.

(2) With the same initial conditions and disturbances, MAAVD model responses to the disturbance faster, contributing to more smooth speed.

Effect of Break Time on an Evaluation Index of Driving Characteristics

Yong Liu and Weixiong Zha

Institute of Transportation and Economics, Humanities and Social Sciences Research Base of Jiangxi Province, East China Jiaotong University, Nanchang 330013,China.

Abstract: Long continuous driving will generate traffic safety hazard due to the driver's own characteristics. In order to study driver perception, judgment and operating characteristics, the study tested and analyzed evaluation indicators and their changing rules under different rest time. Established the relation model between rest time and each evaluation index. According to the relation model, draw the operation driver's driving characteristics change over time and given the appropriate break time for driver.
Keywords: Break time; Driving characteristic; Continuous driving; Traffic safety.

1 Introduction

A long time continuous driving can easily lead to driving fatigue, resulting the decline of the driver's perception, judgment and operating characteristics, which could lead to accidents. In order to ensure driving safety, (D. Wylie, 1996) found that the continuous driving time is the main factor affecting driving fatigue. (Connor J., 2002) found that the driver in the normal resting state, the main driving fatigue are the time and times of continuous driving. Through the sort of importance, (Li, 2003) established the driving fatigue hierarchical structure model, given the impact of sorting which provides a new way of thinking about driving fatigue. (Ma, 2009) select evaluation indicators of driving characteristics, and shows the relationship between the indexes and driving time, gives recommendations require the driver needs to stop resting after 3.5h. On the basis of fatigue cumulative time of long-distance bus driver, (Zhai, 2012) make a break halfway experiment studied.

After driving, the degree of fatigue significantly increased, while the driver’s operating characteristics significantly lowered (Niu, 2014). From the perspective of driving characteristics, we analysis the relationship of break time and evaluation of index, and gives the suggestion about the length of break time after continuous driving.

2 Driving Characteristics and Evaluation Index

Driving characteristics of the driver in the information processing is demonstrated in its own characteristics, based on the expanding of the human behavior classic model S-O-R, the information processing can be classified into three stages, perception, judgment and operating (Ma, 2009).

2.1 Evaluation index of driving characteristics and testing instrument

When study the driving characteristics of perception, judgment and operating after a continuous driving, we should choose the evaluation index which can accurately represent the driving characteristics and the testing equipment easy to measure. After comparative analysis, the final selection of evaluation index and test equipment are shown in Table 1.

Table 1. Evaluation indicators and test equipment

Classifications	Evaluation index	Testing instrument
perception	Depth perception differences, speed perception differences	Depth perception analyzer, Perceptual speed meter
judgment	Choice reaction time, note assign values	Visual response analyzer, Note assignment instrument
operation	Correct operation times, error operation times	Note assignment instrument Action judge Miriam

2.2 Test samples selected

Based on (Ma, 2009) experimentally research in a row after driving 3.5h, test driver perception, judgment and operating indicators variation of the break time. The test index and equipment are shown in Table 1. Stratified random sampling method to select 40 drivers who are in health and have not had an accident before, including 32 males, 8 females; with the average age of 37; 1 to 28 years of driving experience, with an average 18 years of driving experience. Each driver test at least twice, a total of 120 cases to obtain test samples. Choose drivers who are under the same continuous driving time as the research object, at the end of the driving, measured once every five minutes.

3 Relativity between the Length of Break Time and the Evaluation Index

First, the raw data sample screening test to determine the available samples of 108 cases. Analyze the correlation between the rest time and each evaluation index, the correlation test results in Table 2. Rules can be seen as follow:

1) There was a significant negative correlation between the length of time to rest with depth perception differences, differences in the speed of perception, choice reaction time, error operation times and subjective fatigue.

2) There was a significant positive correlation between the length of break time the note assign value and correct operation times.

Table 2. Breaks between each evaluation index

Evaluation index	Correlation coefficient R	P
Choice reaction time	0.821	<0.01
attention assign value	0.869	<0.01
Correct operation times	0.757	<0.01
Speed perception	-0.855	<0.01
Depth perception	-0.892	<0.01
Error operation times	0.902	<0.01
Subjective fatigue	0.859	<0.01

4 Analysis the Effect of Break Time on the Evaluation Index

4.1 Depth perception

Analyze on the difference of depth perception y_1 of the driver with different break time t. The results shown in Figure 1. Between break times with depth perception difference cubic curve equation can be established, the relationship model is as follows:

$$y_1 = 2\times10^{-4}t^3 - 0.0031t^2 - 0.2769t + 8.1205 \quad (1)$$

Seen from Figure 1, the test data were in the confidence interval range, and coefficient of determination was 0.9211, indicating that the establishment of a more reasonable curve equation, with the growth of the break time, the driver's depth perception ability to gradually rise.

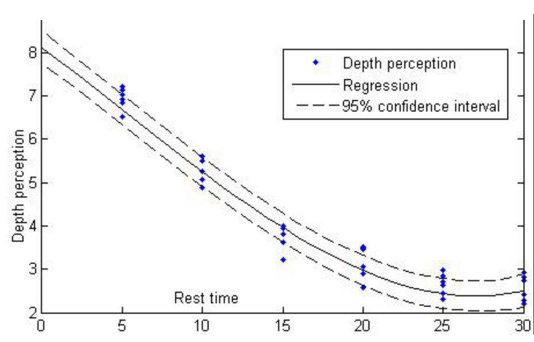

Figure 1. Depth perception

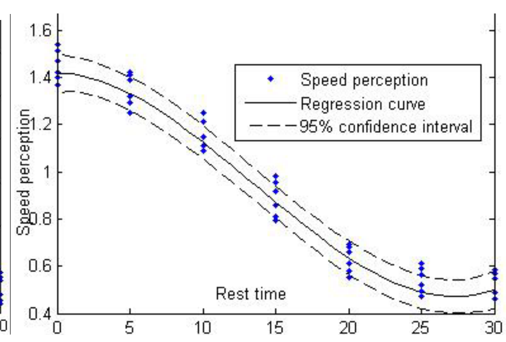

Figure 2. Speed perception

4.2 Speed perception

The relationship between break time and differences of speed perception y_2 is shown in Figure 2.The relationship model is as follow:

$$y_3 = 1\times10^{-4}t^3 - 0.0037t^2 - 0.0015t + 1.4193 \quad (2)$$

Seen from Figure 2, the test data were in the confidence interval range, and coefficient of determination was 0.8929, indicating that the establishment of a reasonable curve equation, and with the growth of the break time, the driver's speed perception differences are on the rise.

4.3 Reaction ability

The relationship between break time and the choice reaction time y_3 is shown in Figure 3. The relationship model is as follow:

$$y_2 = 3.4\times10^{-5}t^3 - 0.0026t^2 - 0.0695t + 1.2565 \quad (3)$$

Seen from Figure 3, the test data were in the confidence interval range, and coefficient of determination was 0.9117, indicating that the establishment of a reasonable curve equation, and the increasing of break time, the driver's choice reaction time decreased and the reaction ability improved.

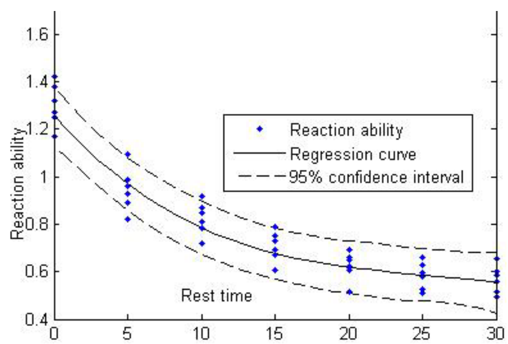

Figure 3. Reaction ability

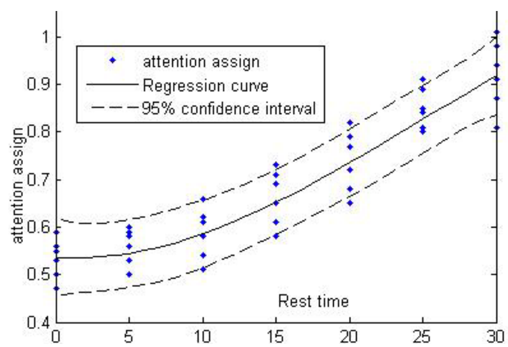

Figure 4. Attention assign

4.4 Attention assign

The relationship between break time and the attention assign value y_4 is shown in Figure 4. Which follows the relational model:

$$y_4 = -1.1\times10^{-4}t^3 - 0.0083t^2 - 0.0023t + 0.5364 \quad (4)$$

Seen from Figure 4, the test data entirely within the confidence interval range, and the coefficient of determination was 0.7835, indicating that the establishment of a more reasonable curve equation, the longer break time, the higher attention assign value, the better attention.

4.5 Correct operation times

The relationship between continuous driving time and the correct operation times y_5 is shown in figure 5. Which follows the relational model:

$$y_5 = -2\times10^{-3}t^3 + 0.0695t^2 + 1.0071t + 95.7619 \quad (5)$$

Seen from Figure 5, the test data entirely within the confidence interval range, and the coefficient of determination was 0.8166, indicating that the establishment of a reasonable curve equation, and the increasing of break time, the operating characteristics also rising, and the correct operation times increased.

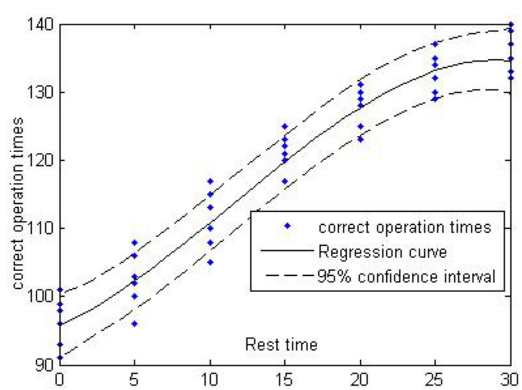

Figure 5. Correct operation times

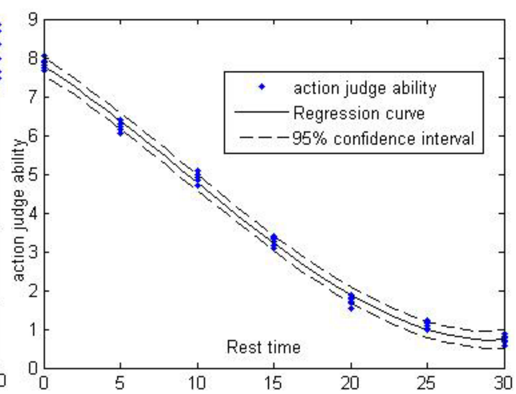

Figure 6. Action judge ability

4.6 Action judge ability

The relationship between rest time and the action judge ability y_6 is shown in Figure 6. Which the relational model as follows:

$$y_6 = 3\times10^{-3}t^3 - 0.0076t^2 - 0.2514t + 7.7762 \quad (6)$$

Figure 6 shows the test data within the confidence interval range, and coefficient of determination was 0.7370, indicating that the establishment of a more reasonable curve equation, and the increasing of break time, the operating characteristics also rising, and the error operation times decreased.

5 Suggestions about the length of break time based on driving characteristics

According to the Ma (2007) and Li (2001), the use of experimental psychology test methods to determine the driving characteristics of the individual evaluation index threshold level, and to determine the driving characteristics of comprehensive evaluation based on fuzzy clustering (Niu, 2014). The results are shown in Table 3.

Table 3. Synthesis Evaluation Classifications of Driving Characteristics

grade	A	B	C	D	E
value	0.91-1.00	0.75-0.90	0.58-0.74	0.45-0.57	0.30-0.44

Different individuals have very different individual indicators, individual indicators in the detection of the driver, with high specificity, it should adopt multi-index portfolio, through a comprehensive evaluation to improve the accuracy of the determination (Ma, 2009). Based on the length of break time on the driving characteristics evaluation index analysis, using the formula (1) to (6) estimated the value of the driver's driving characteristic evaluation index after a period of rest time. Based on the evaluation index threshold of driving characteristics to determine driver's individual evaluation index grade under the appropriate length of break time, while using fuzzy clustering method, to make a comprehensive evaluation of the driver's driving characteristics under the corresponding break time. Calculation results of the analysis are shown in Table 4.

Table 4. Test Results of Driver's Characteristics after a Period of Rest Time

Time	depth perception	speed perception	Choice reaction	Distribution attention	Correct operation times	Error operation times	Grade
0	8.01	1.42	1.27	0.53	96	7.82	E
5	6.93	1.32	0.93	0.56	102	6.21	E
10	5.27	1.15	0.81	0.58	110	4.93	D
15	3.62	0.86	0.69	0.65	121	3.25	D
20	3.05	0.61	0.61	0.72	128	1.72	C
25	2.64	0.52	0.58	0.85	132	1.09	C
30	2.41	0.49	0.56	0.91	135	0.71	B

From Table 4, under the same length of break time, there are obvious differences between the different grades of individual evaluation indexes and comprehensive evaluation grade. Therefore, an integrated evaluation level has a certain rationality. Based on the analysis results in Table 4, the driver at the time of 20min or more break time, driving characteristics of the driver more comprehensive evaluation rating in good state. With the increase of the length of break time, the driving characteristics of the driver of a comprehensive evaluation level gradually rises, when it reaches 30min, driving characteristics at a high state, In this case, the driver's attention ability is good, can accurately determine the speed of perception and the choice reaction time. Therefore, we recommend that when the driver have a continuous driving time for 3. 5 h, needed to have a rest stop at least 20min.

6 Conclusions

Based on ergonomics theory, the driving characteristics can be classified into perception, judgment and operating characteristics, based on the experimental psychology to determine the evaluation indicators of driver's perception, judgment and operating characteristics.

Study on the impact of the length of break time on the driver’s perception, judgment and operating characteristics evaluation index, the results show that with the break time increasing the driving characteristics gradually rising. With the growth of the break time, depth perception difference with speed difference between the estimated value of the driver are decreased, the driver's choice reaction time decreases, attention assign value increased, the number of the correct operation of the driver gradually increases, while the number of error operation of the driver gradually reduced. Based on the relational model of break time with the established evaluation index and driving characteristics between the comprehensive evaluation results, we recommend that when the driver have a continuous driving time for 3. 5 h, needed to have a rest stop at least 20min.

[3]The Key Laboratory of Road and Traffic Engineering, Ministry of Education, Tongji University, Shanghai 201804, China.

Abstract: In recent years, the global climate change has triggered higher occurrence rate of natural disaster, the failure of civil infrastructure function has caused enormous social and economic loss, which reminds people to recognize the importance of risk assessment on civil engineering facilities. This paper takes safety risk assessment of influence of weather factors on urban metro transit facilities by using the methods of FTA, AHP and fuzzy evaluation theory, provides risk assessment index system, calculates the relationship between weights of three weather factors, and establishes a Risk evaluation model based on AHP-Fuzzy Synthetic Evaluation with an example of the section between Beiyuan station and Wangjingxi station in line 13 in Beijing. The results are useful to identify security risks in urban metro transit facilities system, and to improve it.
Keywords: Metro; Risk assessment; The fault tree; Weather effect.

1 Introduction

With the rapid development of urban rail transit, human beings attached increasingly importance to the safety of urban metro transit operation. As urban metro transit facilities system is a vast and complex system engineering, there are many security risks in its operation throughout the process. Weather's effect on metro facilities has a lot to do with metro emergencies. For example, part of subway lines inundated and significant delay was resulted in New York, USA in August, 2007; line 1 exit collapse caused by sustained downpour caused 11 deaths in Hangzhou, China in November, 2008.

There have been some researches on risk assessment of railway, but few of them do with weather factors' affect on urban metro transit facilities. According to a literature review by (Osberghaus, 2010), transport, together with the health sector, is characterized by large uncertainties in conjunction with potentially high adaptation costs in the future. (Nathanail, 2014) proposed a Framework for Monitoring and Assessing Performance Quality of Railway Network Infrastructure. As a result, risk assessment on the effect of weather factors on civil engineering facilities in metro has is of great practical significance towards improving the urban metro transit operation safety level.

This paper takes safety risk assessment of influence of weather factors on urban metro transit facilities by using the methods of FTA, AHP and fuzzy evaluation theory, provides risk assessment index system, calculates the relationship between weights of three weather factors, and establishes a Risk evaluation model based on AHP-Fuzzy Synthetic Evaluation with an example of the section between Beiyuan station and Wangjingxi station in line 13 in Beijing. The results are useful to identify security risks in urban metro transit facilities system, and to improve it.

2 Importance Analysis of Weather Factors

Weather disasters include disasters caused by typhoon, rainstorm(snowstorm), cold wave, strong wind (sandstorm and/ or duststorm), low temperature, high temperature, drought, thunderstorm and lightning, hail, frost and fog. To understand where the risks are and what weather factors have the most significant effect, this article sets up a fault tree. Considering the damage of rail transportation due to the weather cause, the top event indicated that the existing metro facilities cannot operate safely. The total fault tree will be set up relatively based on the four middle events: the subgrade damage, poor construction or maintenance, tree invasion and track damage. Further research will be studied to analyses all kinds of factors aroused risks and therefore the logical relationships will be shown among those factors. The fault tree is shown in figure 1.

We can obtain minimal cut sets based on the structure of the fault tree, then we can calculate the importance degree of each basic event:

$$I_{\phi}(i) = 1 - \prod_{x_i \in k_j}\left(1 - \frac{1}{2^{N_j - 1}}\right) \quad (1)$$

Where Nj is the number of basic events and Kj is the jth minimal cut set. The results are as follows:

X1=X7=0.999≈1，X3=0.937，X8=0.911，X4= X9= X10=0.859，X5= X6= X11= X13=0.75， X2= X12= X14= X15=0.5,

So X1=X7 >X3>X8>X4= X9= X10>X5= X6= X11= X13>X2= X12= X14= X15

Then it can be seen that damaged whether caused by windstorm, especially extreme severe whether like typhoon, has the most serious damage to the rail transportation civil facilities. In addition, accumulated snow and heavy rain damaged rail transportation to a large extent as well.

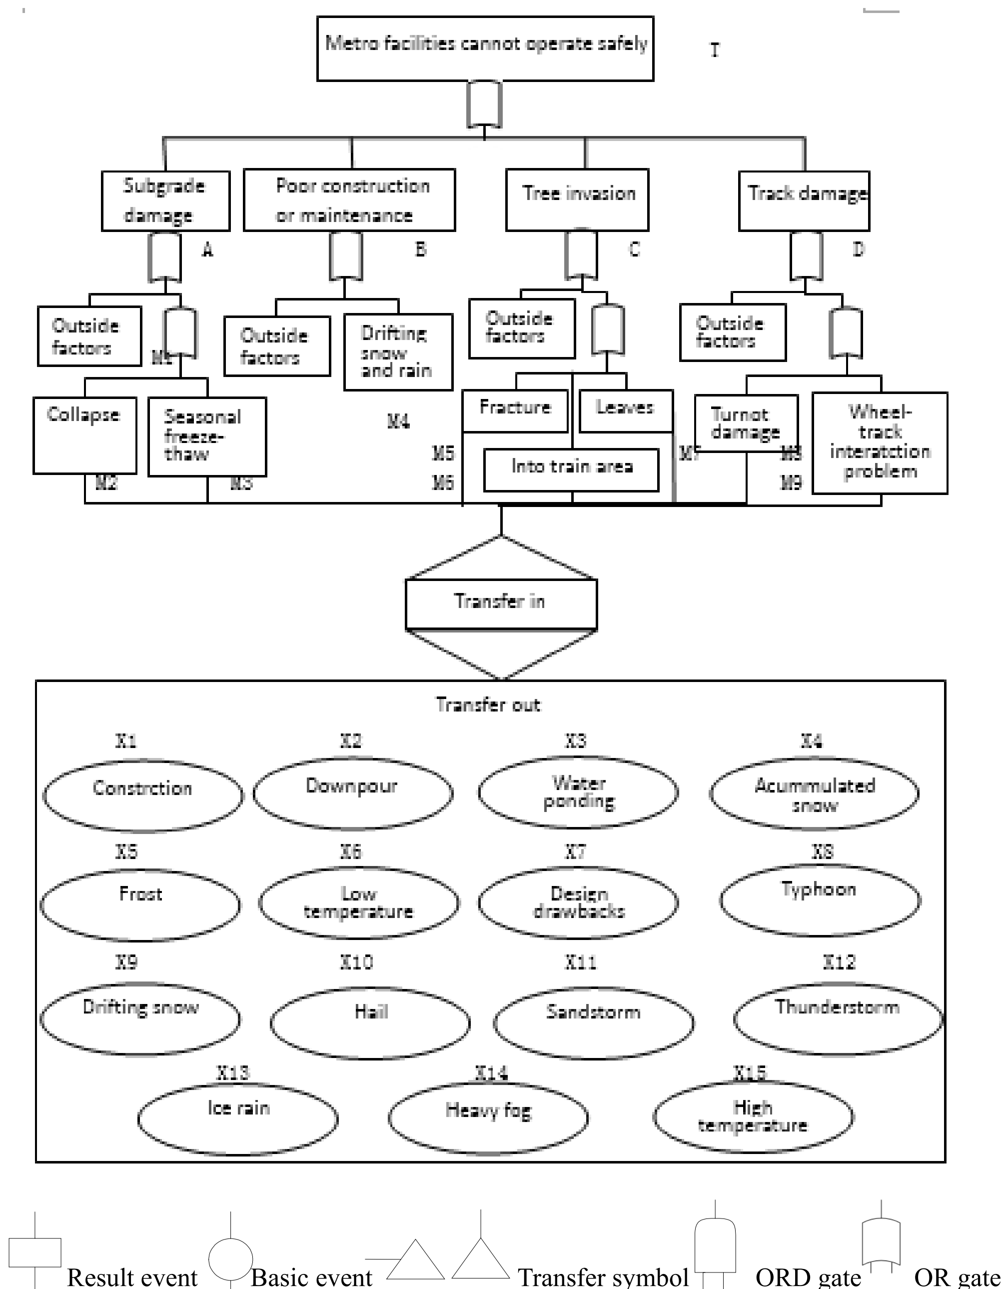

Figure 1. Fault tree

3 Weather Effect Risk Evaluation Index System

According to statistical analysis of data from Beijing subway operating company in recent years and lots of spots investigation, we have the weather effect risk evaluation index system, based on which we can design questionnaire for weather factor on metro facilities as bellow. The membership degree matrix can be obtained by scores form experts. For example, the shadow part of the Table1 is the shadow part.

Table 1. Questionnaire for weather factor on metro facilities

Index \ Grade(score)			Ext. high (8)	Very high (7)	Fairly high (6)	High (5)	Medium (4)	Low (3)	Fairly low (2)	Ext. low (1)
Wind A	A1	Station protection area trees								
	A2	Temporary buildings surrounding the station								
	A3	High-rise buildings outside the protection area	**Judgment matrix of factor wind**							
	A4	Height coefficient of wind pressure								
	A5	Shape factor of wind load								
	A6	Wind barrier								
Rain B	B1	Ground elevation of station entrance / exit								
	B2	Catchment area of station entrance/exit								
	B3	Step number of station entrance /exit	**Judgment matrix of factor rain**							
	B4	Station roof shape								
	B5	Drainage facility capacity								
	B6	Facility service life								
Snow C	C1	Station roof shape								
	C2	Monitoring system	**Judgment matrix of factor snow**							
	C3	Rain and snow tent								
	C4	Turnout snowmelt equipment								
	C5	Snow sweeper								

4 AHP-Fuzzy Synthetic Risk Evaluation

This paper takes the section between Beiyuan Station and Wangjin West Station as case study, which is located in Chaoyang District, Beijing. Beiyuan Station is a station on the 13th line and Wangjing West Station is a transfer station between 13th line and 15th line. Beiyuan Station is located at the west side of the Guangying East

Road, with one exit. Wangjing West Station is located at the west side of Dawangjing village. The platform of the Wangjing West Station is of double island, and there are total 4 tracks, the outside two of which are reserved for the 13th lateral line, including the A and B exit of 13th line and the C exit of 15th line. The total length between Beiyuan Station and Wangjing West Station is 6.8 km, situated between the 4th ring and 6th ring. Both elevated and ground line are used for line laying, and sound barrier are installed at both sides of the track.

4.1 Decide Evaluation Factors

The evaluation factors are the same as in the AHP analysis, including six factors: U_A={Station protection area trees, temporary buildings surrounding the station, high-rise buildings outside the protection area, height coefficient of wind pressure, shape factor of wind load, wind barrier}

4.2 Decide The Evaluation Set

The choice set is described as following: V={Extremely high, very high, fairly high, high, medium, low, fairly low, extremely low}.

4.3 Decide Weight Vectors

The relatively weight vector of each risk factors of wind condition subsystem calculated through the AHP method is shown below:

w_A=(0.339，0.278，0.070，0.137，0.137，0.039)

4.4 Decide Membership Matrix

The membership degree matrix can be obtained based on the judgment matrix (shadow part in table 1) which is calculated by scores form 20 experts.

$$R_A=\begin{bmatrix} 0 & 0.563 & 0.313 & 0.124 & 0 & 0 & 0 & 0 \\ 0 & 0.438 & 0.188 & 0.188 & 0.188 & 0 & 0 & 0 \\ 0 & 0.250 & 0.375 & 0.125 & 0.250 & 0 & 0 & 0 \\ 0 & 0 & 0.313 & 0.313 & 0.375 & 0 & 0 & 0 \\ 0 & 0 & 0.250 & 0.375 & 0.375 & 0 & 0 & 0 \\ 0 & 0.563 & 0.370 & 0.063 & 0 & 0 & 0 & 0 \end{bmatrix}$$

4.5 Calculate The Fuzzy Synthetic Evaluation Set

The Fuzzy Synthetic evaluation set can be achieved by multiplying the weight vector of wind effect factors by the membership degree matrix as shown followed.

$B_A=W_A\times R_A$==（0，0.352，0.276，0.225，0.147，0，0，0）

In the same way, we can get B_B=（0，0.088，0.350，0.318，0.221，0.023，0，0; B_C=0，0，0.068，0.287，0.232，0.234，0.088，0）

4.6 Comprehensive Risk Evaluation

After respective risk evaluation of each weather factor, we can conduct comprehensive risk evaluation . There are three risk factors evaluated according to the weather condition: U={heavy wind, rain, snow }. w=(0.230，0.667，0.103) .

B=W×R= (0.230，0.667，0.103)×
=（0，0.072，0.057，0.334，0.537，0，0，0）

4.7 Results Analysis

$$V = \frac{\sum_{j=1}^{m} b_j v_j}{\sum_{j=1}^{m} b_j} = 4.664$$

So the result of the risk level evaluation is between high and medium, which is allowed to appear and be accepted by controls.

According to the standard in table 2, the section between Beiyuan Station and Wangjing West Station is at level 1 under the effect of wind, at level 2 at level 1 under the effect of rain, at level 2 under the effect of snow, and the comprehensive risk evaluation result under three factors is at level 2.

Table 2. Standard for metro facilities in response to weather disaster in Beijing

Risk level of metro line section	Risk grade
Level 1	Extremely high, very high
Level 2	High, medium,
Level 3	Low, fairly low, extremely low

5 Conclusions

Here we may draw the following conclusions：

(1) Through the analysis on the rail transit construction facilities under the effects of weather factor, it can be concluded that the first three serious weather factors are heavy wind, rain and snow. All of these factors are evaluated by the fault tree analysis from the cases that the facilities are out of order by the weather factors.

(2) Based on the fuzzy synthetic evaluation on section between beiyuan station and wangjing west station in beijing rail transit 13^{th} line, it's evaluated that it is the first class under the effect of heavy wind; it's the second class under both effects of rain and snow condition. Therefore, it can be comprehensively evaluated as the second class.

Abstract: In this paper an accurate of railway vehicles random vibration analysis method and engineering application systems is employed to do random vibration analysis, geometric models of electrical control cabinets of comprehensive inspection train is build. The model is excited by German low interference spectrum and 5 different results are calculated. As the speed increases vertical and lateral acceleration standard deviation are also increase and the lateral acceleration standard deviation of 220-250km/h more sensitive than the vertical. Cabinet installation support lateral acceleration standard deviation relatively large.
Keywords: Comprehensive inspection train; PEM; Random vibration; Cabinets.

1 Introduction

Integrated high-speed detection employ EMU as the carrier, with track inspection, pantograph line supply, wheel/rail dynamics detection, communication, signal detection and other precision measuring equipment, the integration of modern measurement, time and space positioning synchronous, data exchange, real-time image recognition and data processing, and other advanced, in the high-speed operation of track and catenary, isokinetic testing infrastructure such as communication, signal condition, in order to improve the detection efficiency and guide the railway infrastructure on-site maintenance and repair, it is an important technical equipment which ensure the safety of train.

Figure1. High speed inspection testing train

The first 250 km/h high-speed integrated testing train of our country is designed and manufactured by CNR Changchun railway vehicle co., LTD. as shown in Figure 1. The highest detection speed is 250 km/h; the maximum traction power is 5500 kW. Rail detection, catenary inspection, wheel/rail dynamics, communication and signal detection system are carried by the car. At the same time, train special network, positioning synchronous, environment video information collection multimedia display and data processing system also are set up and the integration of the information, share, and comprehensive is analysis by itself (Moretti M, 2004).

High speed inspection testing train which is needed to make sure that the storage of equipment work is in order. Due to the complexity of running environment variable and the structure of the vehicle, car body are motivated by the random vibration in the operation process, the vibrations can pass to the seat of the cabinet which affect the operation of the equipment which may be damaged due to excessive vibration. Therefore understand the rack installation random response of structure design parameter is particularly critical. Traditional vehicle dynamics employ multi-body dynamics to simplify the model. The inside elastic damping and mass distribution relationship of carbody frame and other structures are ignored. For the rough model, the vehicle dynamics proper function is weakened which make modern vehicles design has some deficiencies. The local details information of vibration components cannot be obtained by calculation especially for opposite high frequency, so that the effect on the dynamics indicators of the local structure change is not sensitive. The data can only create the actual kind of car, as measured by field tests. Using traditional methods to analyze, as mentioned in the above, when there is local structure change, it is difficult to solve this problem, this paper uses the research and development of efficient algorithms program of random vibration of railway vehicles using the Mode Decomposition and the pseudo-excitation method (Lin Jiahao，Zhang Yahui, 2004) as the foundation to solve the structure vibration(Zhang Youwei,2013). With different speed cabinet installation support on the random vibration is analyzed then compared the results in order to find out the reasonable design parameters.

2 The structure random vibration analysis of simulation system

Railway vehicles efficient algorithm program involves the theory formulas of random vibration will be introduced in the literature (TONG Wei,2014). Take cabinet installation support calculation data as an example, this paper briefly introduces the analysis process. Figure 2 for vibration analysis flow chart.

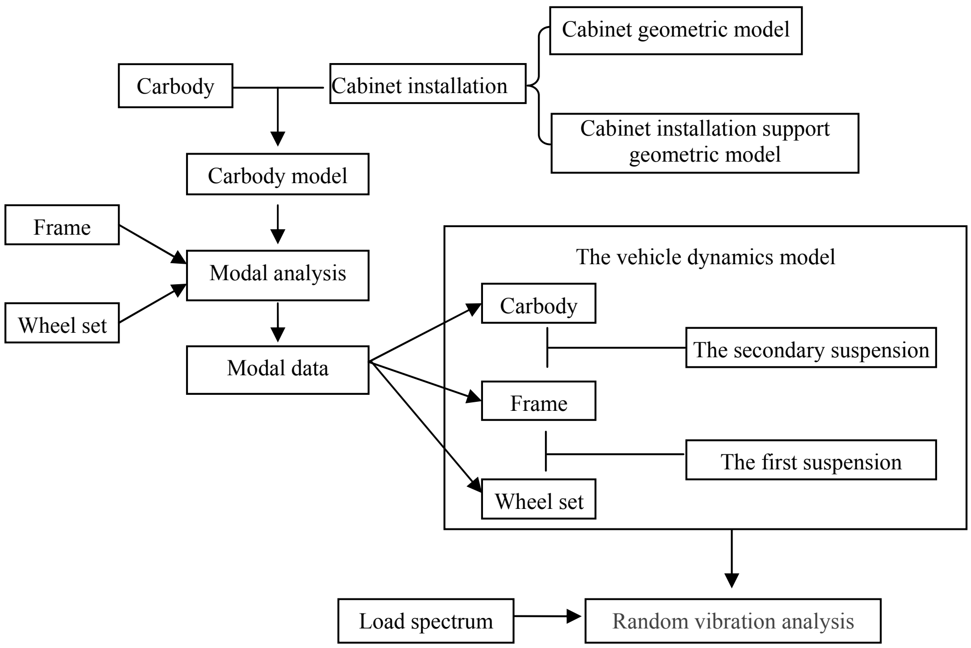

Figure 2. Flow diagram of vibration analysis

3 Calculation model

3.1 Dynamic model of vehicle structure

The quality of high-speed integrated test train cabinet is 300 kg, there are four cabinets are installed on the lower floor is equipped with elastic support, upper with roof chute are connected by bolts. Material parameters are listed in table 1.

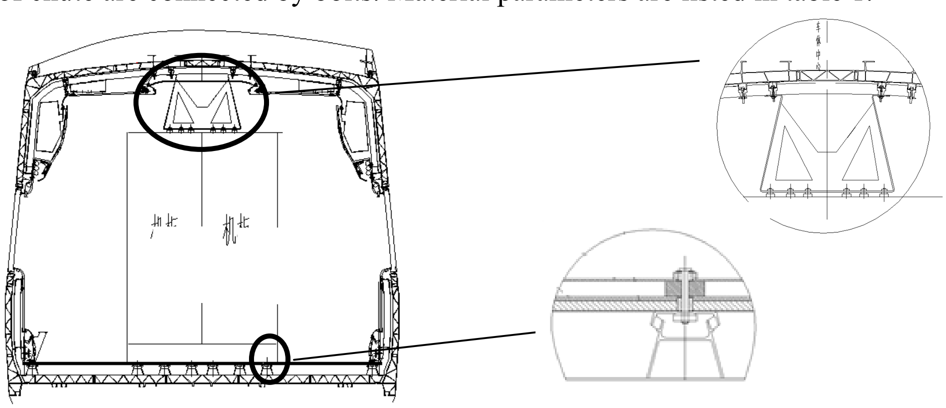

Figure 3.Cabinets installation and partial enlarged detail

Table1. Material parameters

	Density	Modulus of Elasticity	Poisson's ratio
Cabinets (steel)	$7.85g/cm^3$	210Gpa	0.3
Carbody 5-5A02(aluminum)	$2.7g/cm^3$	70Gpa	0.33

The detail of the cabinets' installation is shown in figure3. The structure is rubber, the static displacement is controlled by it and the initial stiffness (Zhang Xiangning,2012) listed in table 2.

Table 2. Initial stiffness of rubber

	Initial stiffness（unit：MN/m）
Longitudinal direction	180
Lateral direction	400
Vertical direction	171.5

Model established in this paper is divided into two parts, the first part is structural model, including installation cabinet, frame, the wheels of the model, as shown in figure 4, the second part is the second spring suspension devices including spring and damping element. The calculation model are 209598 nodes, dynamic degree of freedom are about 1 million. The first 100 order modal include all parts, cutoff frequency is respectively: 40 Hz for carbody, 292 Hz for frame and about 2382 Hz for wheel.

Figure 4. The finite element model

3.2 Load model

Track irregularity power spectrum state of track irregularities is to describe all of the most effective form; it reflects the amplitude-frequency characteristics of track irregularity. Track irregularity power spectrum is important basis of locomotive vehicle and bridge line tunnel design, calculation and evaluation. The size and shape spectra and the level of spectral density are connected with structure and state of the circuit. A large number of measurement and analysis are the fundamental of spectral density. At present, track irregularity power spectrum include PSD of U. S. railways and German high-speed track spectrum is used for analysis, considering the specific load spectrum, the German high-speed track spectrum which divided into high interference and low interference track spectrum, two kinds of spectral function expression of the orbital spectrum. This paper uses German low interference spectrum.

3.3 The computational conditions

The simulation is divided into 5 conditions which is listed in table 3.

Table 3. Introduced of condition

Speed	Introduced of condition
160km/h	The design of the low speed
180km/h	Test low average running speed, compared with the calculation results
200km/h	The average running state, in order to provide more reference
220km/h	The average speed of the test
250km/h	The highest speed of actual operation state

4 The calculation result analysis of random vibration

4.1 The acceleration standard deviation of vehicle structure

The railway vehicle random vibration efficient algorithm program is employed which could get the acceleration standard deviation of cabinets. Standard deviation of each point on the structure of the relative acceleration root mean square value which reflects the structure of each point on the relative acceleration vibration amplitude of the statistical data (The level of curve left the equilibrium position). The maximum lateral and vertical acceleration under different speed standard deviation of carbody is shown in Figure5, with the speed is increasing; the vertical and lateral direction acceleration standard deviations of carbody are also increasing. Vertical acceleration standard deviations were much more than the lateral, but the increase of lateral amplitude from 220 km/h - 250 km/h is larger than vertical. It can be seen that speed range the sensitive of lateral acceleration standard deviation is more sensitive than the vertical.

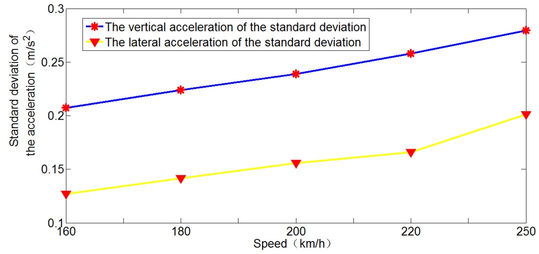

Figure 5. Carbody acceleration standard deviation of different speed

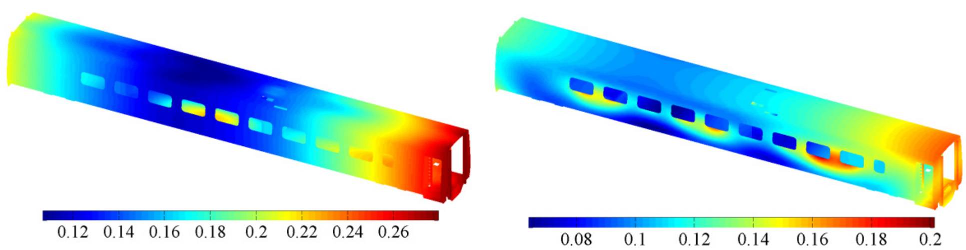
As shown in Figure 6, the car body vertical and lateral acceleration standard deviation of running 250 km/h. The maximum of vertical acceleration standard deviation is $0.28\mathrm{m}/s^2$, which appear at carbody side of the door and central of vehicle chassis. The maximum lateral acceleration standard deviation is $0.2\mathrm{m}/s^2$, in the corner of the window near the side of door. The results are shown that carbody structure is 1/2 symmetric structure. The side of door stiffness is weak. With the speed is increasing, the vibration acceleration of the standard deviation is also increasing.



a) Vertical b) Lateral

Figure 6.Vertical and lateral acceleration power spectrum of 250km/h

4.2 Random vibration analysis of the cabinet installation

According to the different speeds, random vibration analysis was carried out for the cabinet installation; Figure7 shows the maximum vertical and lateral acceleration standard deviation of cabinet installation. As the speed is increasing the vertical and lateral acceleration standard deviation is also increasing, but with the difference of the carbody is given, lateral is always greater than the vertical. This is because the installation on rubber bearing, in the process of traditional analysis for in-car equipment or car lifting equipment is often based on the analysis of the vibration of the car body to unify judgment. However, for in-car equipment which is installed on the elastic support, the results capture traditional analysis is not exact. The study of the vibration detail characteristic is necessary which traditional analysis is very difficult to do. Railway vehicle random vibration efficient algorithm program can analysis the specific location for the further.

When the speed of vehicle is 250km/h, the maximums vertical acceleration standard deviation of the cabinet installation is $0.122\ \mathrm{m}/s^2$ and the lateral is $0.165\ \mathrm{m}/s^2$. In the vertical direction, the cabinet installation of the maximum acceleration standard deviation of the carbody decrease by 56%, this is for the reasonable design and installation location selected is more reasonable and the maximum lateral direction acceleration the carbody decreases by 17.5%. The parameters of the lateral installation design compared to vertical to be weak. It's also due to the installation structure of nature, for in the lateral direction there is only one bolt connect to the carbody, so according to the results, there still have some improvement to do for the structure.

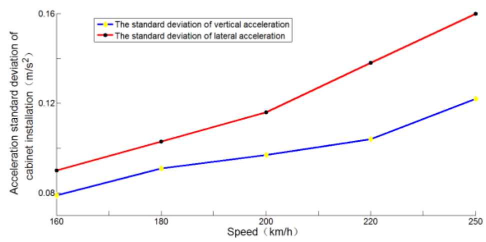


Figure7. Cabinet installation acceleration standard deviation

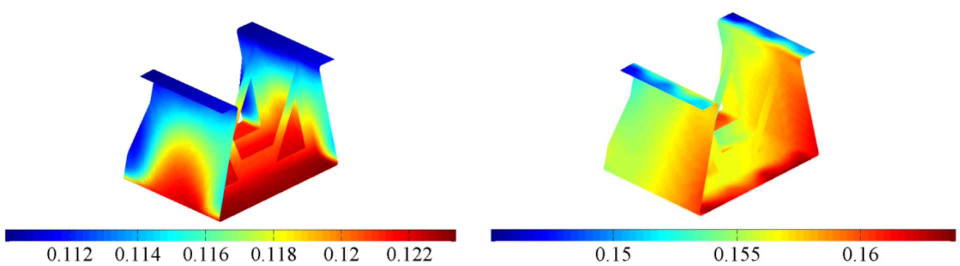

a) Vertical b) Lateral

Figure8.Vertical and lateral acceleration power spectrum of 250km/h

5 Conclusions

In this paper, we established cabinets of comprehensive inspection train structure model and an efficient vehicle random vibration process algorithm is employed to carry out random vibration analysis then we get the following conclusion:

(1) As the speed increases vertical and lateral acceleration standard deviation also increases and between 220-250km/h lateral acceleration standard deviation more sensitive.

(2) When the vehicle speed is 250 km/h, the vertical acceleration standard deviation of the cabinet installation is 0.122 m/s^2 and the lateral is 0.165 m/s^2. Cabinet installation in the vertical direction of the maximum acceleration standard deviation of the carbody vertical decreased by 56%, the maximum lateral direction acceleration of the carbody is decreased by 17.5%.

Risk-Sharing Rationalization of an Intercity Railway PPP Project

Rongdi Zeng[1] and Dan Wu[2]

[1]Department of Traffic and Transportation Emei Campus, Southwest Jiaotong University, No. 1, Jingqu Rd., Emeishan, Sichuan 614202, China. E-mail: sczrd@sina.com
[2]Emei Railway Train Operation Depot, Chengdu Railway Bureau.

Abstract: The critical factor to achieve a PPP project is risk management. we need to analyze the connotation of the intercity railway PPP project first, then summarize the major risk factors of the project in every stage by collecting and studying the investigation. At last, we should build the mathematic model of the risk-sharing for the purpose of maximum satisfaction of the whole project to use game theory to acquire the result of the risk-sharing to sum up general principles in any risk taken by the participants of the biggest residual coefficients.
Keywords: Intercity railway; PPP project; Risk allocation; Game theory.

These years, PPP project has been widely used in the intercity railway construction. Owning to its large number of the participants, extensive covers, complex organization structure and huge difference in all parties' interest demand, the risks of every stage as well as the risk-sharing become highly critical in studying the intercity railway PPP project.

1 The Connotation of the PPP Project Taken by Intercity Railway Construction

Intercity railway is a transportation system with great passenger transporting capacity and connects every city in the urban agglomeration, which mainly helps transport passengers between big cities and the middle cities as well as those in middle and small cities to improve urbanization and the development of regional economic integration. The typical existed intercity railways are Beijing-Tianjin, Shanghai-Ningbo Pearl River Delta and so on.

PPP is the abbreviation of Public-Private-Partnership. Win-win or multi-win is the heart of PPP's cooperation idea. When participating in a project, responsibility won't be shifted to private enterprise, but is taken by both sides. The sectors or representatives of government call for bids to decide partner (private enterprise), set up a project company with the bidding company, and sign the franchising contract. During the franchising time, the project company is responsible for financing, and the government compensates for the private investment in the way of capital, land comprehensive development and so on. In short, the PPP project stresses on complementing each other's advantages, risk sharing and pooling-or-interest.

The PPP project is used essentially to construct the intercity railway by the government and private enterprises and finally come to the long-term cooperation relationship during the business time. Government grants the private enterprises franchise in a certain period and reasonable reward for investment to attract the third party, accelerate the railway construction, improve the service quality and release the traffic pressure. Government changes from the roles of the infrastructure investor or facilitator into the roles of administrator or cooperative to release the investment pressure and increase the public commodity supply. The private enterprise is allowed to join in railway construction, which widens the ways to invest the railway construction and activates the capital market.

2 The Stage Division and Major Risk Factors of the PPP Project

The intercity railway PPP project's operation process can be divided into 4 stages: preparatory phase, determination of the PPP project company, project implementation and project handover. Departments involved and main process are shown in graph 1.

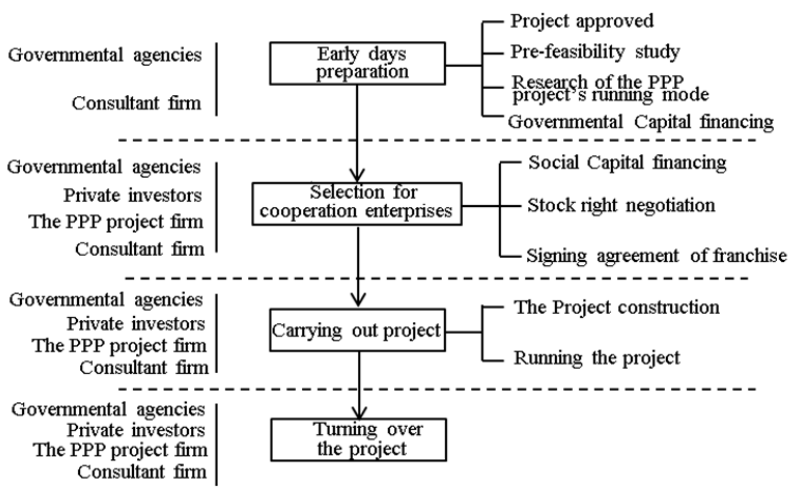

Figure 1. The PPP project's process of conduct

There are six main risks in the project, including: politics, finance, credit, and so on. Risks in every stage are shown in the table 1.

Table 1. The PPP project's risk

Risk sorts		Early days preparation	Selection for cooperation enterprises	Carrying out project	Turning over the project

3 Risk-sharing's Model Building

3.1 Model Building

In the balanced market, profit is in positive correlation with risk, which means the greater the risk is, the higher the profit will be. Before the risk-sharing, the participants of the project have taken varieties of measure against all kinds of risks. Risks to be solved are inevitable, which means that how much profit or how many risks taken by participants is only related with the risks of their own. Assuming risk sharing each participating body is rational, targeting the overall satisfaction with the program risk-sharing schedule, the risk-benefit, cost of risk, the risk of resistance is known, the PPP project model is built.

Given that the project is divided into l stages, , $l \in (1,2,3,\cdots K)$, and i participants who are faced with j kinds of risks, $i \in (1,2,3,\cdots N)$, $j \in (1,2,3,\cdots M)$, we can use x_l^{ij} to represent that participant i undertake risk in stage j, $x_l^{ij} = \begin{cases} 0 & non-risk-sharing \\ 1 & risk-sharing \end{cases}$.

Any party in risk-sharing not only gets the profit but also pays for certain risk cost. Given that participant i's profit is Y_l^i and risk cost is C_l^i in stage l, then the follows are obtained：

$$Y_l^i = F(x_k^{nm}) \tag{1}$$

$$C_l^i = G(x_k^{nm}) \tag{2}$$

It's given that $\lambda = Y_k^i - C_k^i$, which is called risk residual coefficients. Only when $Y_k^i - C_k^i > 0$, activity will be created to cover the risks. The risk residual coefficients is linked with participants' activity and ability to control the risk when the risks occur. Under certain risk, the PPP project is aimed at getting maximum overall satisfaction, which means to get max risk residual coefficients. That is:

$$f(x_l^{ij}) = \max \sum_{l=1}^{K} \sum_{i=1}^{N} \sum_{j=1}^{M} \left[F(x_l^{ij}) - G(x_l^{ij}) \right] \cdot x_l^{ij} \tag{3}$$

Given that $H(x)$ is the function of the ability to undertake the risk, with the different resource taken by every participant and the different ability against risk, D_l^i is used to express that participant i in l stage can take how many risk. Then we get:

$$\sum_{j=1}^{M} H(x_l^{ij}) \le D_l^i \tag{4}$$

Generally speaking, a participant only takes one sort of risk. However, because a few risks are special such as act of god, two or more participants have to go through these risks. Given that the number of these participants are certain, W_l^j is used to express that participant j takes most kinds of risks in stage l, we can get:

$$\sum_{i=1}^{N} x_l^{ij} \le W_l^j \qquad (5)$$

With (3)、(4)、(5), we can get optimized model as follows:

$$f(x_l^{ij}) = \max \sum_{l=1}^{K}\sum_{i=1}^{N}\sum_{j=1}^{M}\left[F(x_l^{ij}) - G(x_l^{ij})\right]\cdot x_l^{ij}$$

$$S.t \quad \sum_{j=1}^{M} H(x_l^{ij}) \le D_l^i \quad i \in (1,2,3,\cdots N),\quad l \in (1,2,3,\cdots K)$$

$$\sum_{i=1}^{N} x_l^{ij} \le W_l^j \qquad j \in (1,2,3,\cdots M), l \in (1,2,3,\cdots K)$$

$$x_l^{ij} = 0,1 \qquad i \in (1,2,3,\cdots N), j \in (1,2,3,\cdots M), l \in (1,2,3,\cdots K),\quad W \in (1,2,3\cdots,N)$$

3.2 Analysis of risk-sharing result

In a PPP project, risk profit cost and ability against risk can be worked out in some ways, and then the reliable result will be obtained by the model. From the model, the existence of the best risk-sharing projects is reasoned in theory. Given that risk residual coefficients function is linear, there is enough power against the risk and a participant at most take one risk, we will find that a risk is taken by a participant with the highest risk residual coefficients and that the overall satisfaction is max. That is, in a certain risk, the lager the risk residence is, the more suitable it is to take this risk.

Considering only officials and private enterprises conducting a project who aim at max overall satisfaction of risk-sharing, government need to keep balance between the economical profit and the social profit by using the game theory to negotiate with the private to come to that state.

(1) When λ of government and the private enterprises is less than 0, in this game, both sides will meet Nash-Equilibrium. However, considering the purpose (to acquire max overall satisfaction), the one whose λ is biggest take this kind of risk.

(2) When government's λ is more than 0 while the private is not, only one can meet the Nash-Equilibrium. Because of the private's weakness in the risk, the government should bear it.

(3) When the private's λ is more than 0 while the government's is not, it is similar to（2）, the private enterprises should bear the risk.

(4) When λ of both of them is less than 0, none of them can meet the Nash-Equilibrium and is unwilling to assume this kind of risk. Once the risk is taken by any side, the party must pay cost. In this situation, they have to negotiate with each other to come to the appointment that they will bear the risk together and decide how much each party should bear.

4 Conclusions

Here we may draw the following conclusions:

(1) The government departments should undertake the risk of legal change, service facilities and other aspects because it has stronger resistance than the private sector. Financing and market risks should be taken by the private sector because they are more powerful in control these problems that are directly related with their profit. In most situations, the private take steps to move their troubles to contractors, suppliers, carriers, banks or insurance firms. Due to lacking of control against act of god, the government department and the private sector must sign the contracts to undertake these risks jointly after negotiation in order to design the risk aversion mechanisms (such as price adjustments, extending the concession period, the buffer fund, etc.) to avoid them.

(2) Varieties of the risks are shared by all participators. Academically, risks should be given to those who are reliable and full of power to bear them, which means that the risk in a stage should be assumed by those whose risk residual coefficients are biggest, so that during the project period the overall satisfaction will reach the maximum. However, in the process of project, risk-sharing is a course of dynamic game among the all parties, which finally leads to Nash-Equilibrium to benefit maximization of all participants and realize Pareto Optimality.

It is firmly convinced that the more deeply the PPP project is studied, the more standardized and reasonable the recognition and allocation of the mechanism for railway PPP project risk are. Therefore, there is no doubt PPP financing mode will play an increasingly critical role in Chinese intercity railway construction.

Forecasting Method for Urban Rail Transit Ridership at the Station-Level Using a Weighted Population Variable and Genetic Algorithm Back Propagation Neural Network

Junfang Li[1,2]; Guanhua Yang[1]; Jun Co[1]; and Li Li[3]

Abstract: Distance-decay affect of contribution rate of population in different distance to ridership has not been considered in current model. As a result, prediction of ridership at station-level is not accurate. Population in near distance to the station contributes more to ridership than that in far distance. So population used to predict should be weighted by corresponding contribution rate. Multivariate correlation analysis is used to analyze relationship between weighted population and ridership, and also to analyze relationship between other predictors and ridership, which can pick out significant predictors affecting ridership. To solve the irrationality of linear prediction model, model of Back Propagation Neural Networks (BP) which can express strong relation between independent and dependent elements and needs no formula in detail has been built. To avoid local solution, Genetic Algorithm (GA) is used to improve the model. Ridership result predicted by GA-BP with weighted population is compared with that predicted by linear model with weighted population, that predicted by GA-BP with total population and that predicted by linear model with total population. The comparation shows model in this essay exceeds others, taking minimum and maximum relative error, average relative error, and root of mean square error into consideration. So, GA-BP model with weighted population is perfect when forecasting ridership of urban railway transit at station-level.
Keywords: Ridership of urban railway transit at station-level; Weighted population; Back propagation neural networks; Genetic algorithm.

Urban Rail Transit (URT) ridership at the station-level is an important component of URT ridership, which is critical for determining the scale of stations and access facilities. There is a strong interrelation between land use within station service area and ridership at station-level whereas change of land use can cause sudden change of ridership. General "four-step" (McNally, 2000; Li, 2009; Wang, 2009; Shi, 2011) and "trip chain" (Dong, 2012; Lan, 2009) methods are not suitable for this timely ridership prediction. Because this two methods rely on complex basic reference of OD and focus on regional all transport modes, which cost a large amount of time and money. They belong to static prediction and can not supply timely ridership varied by land use change within service area of station.

Multivariable regression is able to predict timely ridership according to land use change within service area of station, which takes predictors as independent variable and ridership result as dependant variable. References (Zhao,2003; Kuby,2004; Chu, 2004;Javier,2011) analyze specific main elements affecting ridership, among which inhabitant population and employment are recognized as the important elements. References (Kuby,2004;Chu,2004) take inhabitant population and employment and other element affecting ridership as independent variable and use linear regression to predict daily ridership. There exists two problems in previous research. The first is that total population used in the prediction model which do not comply with distance-decay rule. Taking Aoto Station in Tokyo, Japan as an example, within service area of the station, 0-1km, 1-2km, 2-3km, 3-4km bands population contributes to the ridership at the rate 0.48，0.094，0.013, 0.005(unit: person/person). So population needs to be weighted by corresponding rate according to the distance to the station,

Another problem is irrational using of linear regression. There are so many issues which are not considered clearly in the model, for example, effect of the balance of inhabitant population and employment on ridership is non-linear. However, there are so many expressions for non-linear relationship, which make the specific expression for this prediction difficult to decide. It is necessary to find out one specific model which can express relationship between predictors and the ridership in our essay.

1 Key Predictors Affecting Ridership

Referring to (Zhao,2003;Kuby,2004;Chu,2004;Javier,2011), select preliminary predictor such as weighted population, road density, number of shuttle lines, land use mix within the service area of station, number of unidirectional trains, number of interchange lines, number of park&ride facilities of the station, whether the station is terminal or not, distance from station to city center.

Weighted population means the accumulation of population multiplied by weight corresponding to the distance within the service area of the station. Total population means the accumulation of population within the service area of the station, in another words, weight is 1 for all population in different distance in this situation. The figure illustrating the weight is as follows.

Total population Weighted population

Figure 1. Weight of distance-decay and total population

Weighted population is calculated as follows:

$$P_i = \sum_{k=1}^{m} (p_k w_{ik}) = \sum_{k=1}^{m} (p_k g(d_{ik})) \tag{1}$$

P_i: Weighted population within service area of Station I;

p_k: Population of Traffic Zone k; d_{ik}: Distance from Traffic Zone k to Station i;

w_{ik}: Weight at distance d_{ik} from Station i; $g(d_{ik})$: Expression of weight, which is the function of d_{ik}; Reference (Blainey,2009) puts forward 5 types of expression (power function, normality negative exponential form, common negative exponential form, quadratic function, logistic function)

m: Number of traffic zones within Station i

Road density measures accessibility to the station. Higher road density can cause more ridership. Number of shuttle bus measures convenience to the station by bus; Land use mix is expressed by the following formula:

Higher land use mix (Lin,2008;Qian,2003) can bring high balance between inhabitant population and employment within the service area of station, which means less ridership.

$$P_{mix} = \left| D_{popu} \times \log_{10}(D_{popu}) \right| + \sum_{k=1}^{n} \left| (D_{em})_k \times \log_{10}(D_{em})_k \right| \tag{2}$$

Where:

P_{mix} is land-use mix ratio of service area;

D_{popu} is population density of service area (unit: per/hectare);

D_{em} is density of the k th type employment (unit: per/hectare) of service area;

n is total number of employment types in service area.

Number of unidirectional trains is accumulation of unidirectional trains departing from the station in peaking hour. If there exists a few lines in the station, that is total number of unidirectional trains of all the lines in peak hours. This element measures the attraction of station which affects the ridership.

Number of park&ride facilities measures interchange convenience from shuttle modes to the URT. More park&ride facilities mean more ridership.

Whether the station is terminal or not also measures the attraction of station. It is expressed by bi-variable, If it is, its value is 1, and if it is not, its value is 0.

Identifying key factors is critical. If all the above variables are used to formulate forecasting model, the performance of model will be unsatisfying because of the correlation between these variables.

Partial correlation analysis is used to find key factors to avoid other confounding factors when analyzing relationship between two variables. The formulas are listed as follows:

$$r_{xy} = \frac{\sum_{i=1}^{n}(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i - \bar{x})^2 \sum_{i=1}^{n}(y_i - \bar{y})^2}} \quad (3)$$

$$r_{xy,z_1} = \frac{r_{xy} - r_{xz_1} r_{yz_1}}{\sqrt{(1 - r_{xz_1}{}^2)(1 - r_{yz_1}{}^2)}} \quad (4)$$

$$r_{xy,z_1z_2} = \frac{r_{xy,z_1} - r_{xz_2,z_1} r_{yz_2,z_1}}{\sqrt{(1 - r_{xz_2,z_1}^2)(1 - r_{yz_2,z_1}^2)}} \quad (5)$$

$$r_{xy,z_1\ldots z_n} = \frac{r_{xy,z_1\ldots z_{n-1}} - r_{xz_n,z_1\ldots z_{n-1}} r_{yz_n,z_1\ldots z_{n-1}}}{\sqrt{(1 - r_{xz_n,z_1\ldots z_{n-1}}^2)(1 - r_{yz_n,z_1\ldots z_{n-1}}^2)}} \quad (6)$$

Where,

r_{xy} : Simple correlation coefficient of variable x and y ;

r_{xy,z_1} : Correlation coefficient of variable x and y when controlling z_1 ;

r_{xy,z_1z_2} : Correlation coefficient of variable x and y when controlling z_1 and z_2 ;

$r_{xy,z_1\ldots z_n}$: Correlation coefficient of variable x and y when controlling $z_1 \ldots z_n$;

x_i , $\bar{x}$: The i th value of variable x and the mean value of x ; The meaning of y_i , $\bar{y}$ is same as x_i , $\bar{x}$.

The partial correlation coefficient needs to be tested for significance further. The null hypothesis is that the partial correlation coefficient to be tested is not significantly different from zero. The corresponding T-statistic for the test is shown in Eq. 6.

$$t = \frac{r\sqrt{n-1}}{1-r^2} \tag{7}$$

Where,
t: Statistic value of test;
r : Partial correlation coefficient to be tested;
n :Sample size.

When degree of freedom is $n-1$, the probability value p corresponding to t is obtained to be compared with 0.01 and 0.05. If $p < 0.01$, association between the two variables is strongly significant. If $0.01 < p < 0.05$, association between the two variables is generally significant. If $p > 0.05$, association between the two variables is not significant.

2 Prediction Model of UMT

Liner model for prediction can not actually express the relationship between the key predictors and ridership. For example, in liner model, ridership is proportional to inhabitant population or employment population, which means, more population cause more ridership. However, if inhabitant population balances employment population within the service area of the station, which means inhabitant population do not seek job outside and do not take UMT and the ridership decrease, which is a nonlinear relationship.

Back Propagation Neural Network(BPNN) (Shi,2009) model is a typical type of artificial neural network, which can learn and save large amount of input-output reflection relationship, and needs no specific formula, having extraordinary large-scale processing and information distribution ability, which is generally used in function approaching, mode cognition, category and data compacting is selected as the forecasting model for URT ridership at station-level. Structure of BPNN includes input layer, hidden layer and output layer. The learning algorithm is comprised of upward spread of information and back propagation of errors. For the upward spread of information, nodes in input layer collect outside information and spread it to the nodes in hidden layer. According to information change ability, hidden layer can be designed of single or more layers. Finally, information spread from nodes in hidden layer to output layer can be output after the final processing. If actual output is not coincided with the expected output, back propagation of errors starts. Errors spread from output layer to hidden layer and then the input layer. In this process, weight and bias of layer are adjusted according to gradient descent. Periodical upward spread of information and back propagation of error are the process for weight and bias adjusting, which is also the learning process of BPNN, and the process will not stop until the output can be accepted.

BPNN is adopted to predict the UMT ridership at station-level.

2.1 BPNN Model

The theory shows that three layers BPNN can realize any reflection from input to output. So

Three layers BPNN model is adopted. According to experience, hypothesize that the number of key factors affecting ridership is n, which is also the number of nodes in input layer. In output layer, there is only 1 node: ridership. The number of nodes in hidden layer is $\left|\sqrt{n}\right|$, which is square root of product of number of nodes in input layer and number of nodes in output layer. Formula of BPNN model for forecasting ridership at station-level is constructed as follows:

min

$$E\left(w,b,v,c\right)=\frac{1}{2q}\sum_{p=1}^{q}\sum_{k=1}^{l}\left(O_k(p)-\widehat{O}_k(p)\right)^2 \tag{8}$$

Subject to

For output layer:

$$o_k=f\left(\sum_{j=1}^{m}v_{jk}y_j+c_k\right) \qquad k=1,2,\cdots l;\ j=1,2,...m \tag{9}$$

For hidden layer:

$$y_j=f\left(\sum_{j=1}^{m}w_{ij}x_i+b_j\right) \qquad j=1,2,\cdots m;\ i=1,2,...n \tag{10}$$

In which，transform function $f\left(x\right)=\frac{1}{1+e^{-x}}$

Where,

$E\left(w,b,v,c\right)$: The objective function, minimizing the MSE of the actual and predicted ridership;

w,v are matrix of weights variable;

b,c are bias vector variable ;

$O_k(p)$, $\widehat{O}_k(p)$: The actual and predicted ridership of the k th neurons in output layer of the p th station sample. In our model, there is only one node in output layer and thus $l=1$.

v_{jk}: The weight of the j th node in hidden layer related to the k th node in output layer;

w_{ij}: The weight of the i th node in input layer related to the j th node in hidden layer;

y_j: The output of the j th node in hidden layer;

x_i: The input of the i th node in output layer, that is the value of key variables;

c_k: The k th bias node in output layer;

b_j : The j th bias node in hidden layer;

m : Number of node in hidden layer, which is rounded off of $\sqrt{n}$.

n : Number of node in input layer.

q : Total number of station samples.

2.2 Solution of BPNN

Steepest gradient descent method is adopted to update the weight and bias at the each iteration *(28)*. The detailed solution steps are described as follows:

Step1: Initialization. Values of every weight and bias are randomly given within (-1, 1). Then, it is needed to set prediction accuracy and the maximum number of learning iterations.

Step2: Select input (predictors) /output (actual ridership) of any station randomly. Use BPNN with initial weights and bias to forecast and obtain the predicted ridership. Then, MSE can be obtained by comparing the predicted ridership with actual ridership of the station. Calculate partial derivative $\delta_o = (\hat{o} - o)o(1-o)$ which is from MSE to node in output layer.

Step3: Calculate partial derivative $\delta_h(j) = \delta_o v_j y_j (1-y_j)$ which is from MSE to nodes in hidden layer using v_{jk} , δ_o and y_j .

Step4: Adjust each weight v_{jk} using δ_o and y_j , that is $\Delta v_j = \eta \delta_o y_j$. Adjust each weight w_{ij} using $\delta_h(j)$ and x_i , that is $\Delta w_{ij} = \eta \delta_h(j) x_i$. η is the learning rate of BPNN.

Step5: Use BPNN and weights and bias obtained from Step 4 to forecast ridership of all stations using input (predictors) of these stations. Then, the objective function E , can be obtained by comparing the predicted ridership with actual ridership of all stations and summing the difference up. If E satisfies the prediction accuracy requirement or the maximum number of learning is satisfied, then the optimal value is obtained and the calculation procedures are terminated. Otherwise, select input (predictors) /output (actual ridership) of next station, back to Step2 and go to the next iteration:

2.3 Genetic Algorithm Optimize Initial Parameter of BPNN

Solution of BPNN relies greatly on initial weight and bias whose irrational selection will converge to local solution. However, GA is devoted to obtain the global solution because it only uses evaluated function, not gradient or other complementary information. Even for polymorphic and non-continuous function, it can also converge to nearly global approximation. As a result, GA is used to optimize the initial weight and bias of BPNN, and the optimized weight and bias are taken into BPNN for further solution. The steps are as follows: (1) Initialize iteration, group number, crossover proportion, mutation proportion; (2) Code the group with real value, taking the average error between the actual output and expected output as evaluation function.(in this essay, the evaluation function of GA is the goal function of BPNN); (3)Periodically process selection, crossover and mutation and compute the evaluation until iteration are reached. The chart flow that GA optimizes initial parameter of BPNN is as follows:

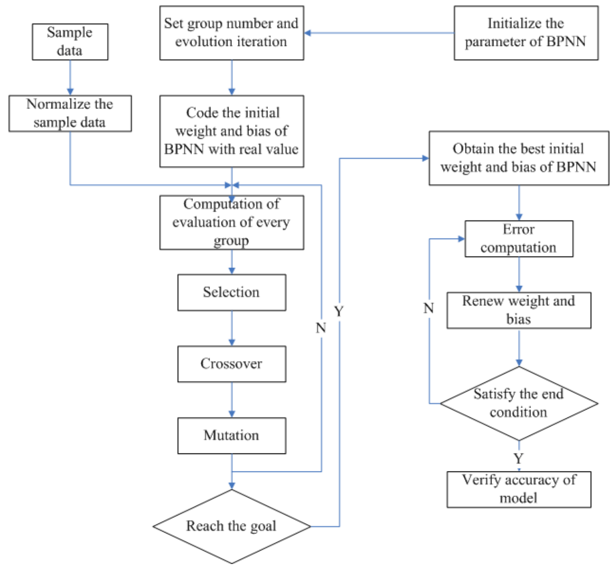

Figure 2. GA optimize BPNN

3 Case Study

3.1 Data source

Case study is the prediction of ridership entering the station in the morning peak hour in Tokyo, Japan, and the number of station selected is 33. The stations selected exist on JR, private railway, subway. Ridership data is referred to as "Total Rail Season Tickets Classified by Departure Stations and Inhabitant Zones of Tokyo" (MLIT of Japan,2010a) at 2010 which gives specific amount of ridership and which inhabitant zone they come from. Population data is referred to as "Day and Night Population Classified by Chomes" (MLIT of Japan,2010b) of Tokyo statistical information. Distance from the inhabitant zone to the station is gauged on google map along the road network. Taking Aoso station in Tokyo, Japan as an example, the code of inhabitant zone which produce the ridership, the specific amount of ridership, chomes in this inhabitant zone, distance from every inhabitant zone to the station and total population in the inhabitant zone are in Table 1.

Table 1. Ridership and population of Aoso Station in morning peaking hour

Code	Chomes	Ridership entering staion In morning peak hour(person)	Population (person)	Distance to station(km)	area(km^2)
12205	Shinjuku 5 - 6 chomes	21	3908	3.4	0.59
12213	Aoto 7 - 8 chomes、Kameari 1 - 2 chomes、Swan 4 chome	2305	10970	1.62	0.77
12218	Ohanajaya 1 - 3 chomes、Swan 1 - 3 chomes、Higashihorikiri 1 - 2 chomes	23	20276	1.91	1.12

12219	Aoto 1 - 6 chomes	8654	17873	0.34	1.17
12220	Okudo 7 - 8 chomes、Takasago 1 chome、Hosoda 2 chomes	1252	5789	1.5	0.81
12223	Menhir 1 chome、Menhir 3 - 4 chomes、Menhir 6 - 8 chomes	2780	16690	1.025	1.06
12224	Takaracho 1 - 2 chomes、Menhir 2 chome、Menhir 5 chome、Yotsugi 5 chome	75	15019	1.76	0.93
12230	Okudo 1 - 6 chomes	207	15933	2.4	1.41
Total		15317	106458		7.86

Road density is total road length divides total area within the service area of station(unit: km/km^2); Taking Aoso Station as an example, its road density is 18 km/km^2.

Data for land use mix within service area of the station refers to "The Number of Enterprises and Employment Classified by Chomes and Industries" (MLIT of Japan,2010c) of Tokyo statistical information, where the 16 types of employment are agriculture-forestry-fisheries, mining, construction, manufacturing, electrical, gas heating and water supply Industry, information and communications, transport, wholesale and retail trade, finance and insurance, real estate, restaurant accommodation, medical welfare, education and learning supported industry, composite services, services not classified, unclassified public services. Accumulate area of all chomes within service area of station, and accumulate population, all types of employment. Land use mix can be calculated according to Formula 2. Taking Aoso Station as an example, the population is 106458 persons and the above types of employment are 0, 0, 2005, 8421，74，192，3260，9061，692，1197，2959，4480，1993，94，4623，768 persons separately. The area is 7.86 km^2. And then the land use mix within service area of Aoso Station is 0.849.

Number of unidirectional trains, number of interchange lines, number of park&ride facilities of the station, whether the station is terminal or not, distance from station to city center all refers to official website of operation companies in Japan.(JR operation company, Keio Electric Railway, Keisei Electric Railway, Odakyu Electric Railway, Tokyo Metropolitan Bureau of Transportation, All Subway)

3.2 Selection of key predictors

3.2.1 Weight population

Weight curve of every station varies. Weight curves of urban stations are different from that of suburban stations. The two are also different from that of out-suburban stations. Because in out-suburban area, distance people would like to accept form their home to the station increases. Population locating at same distance to station contributes more in out-suburban area than that in urban area. As a result, stations are categorized to three types, that is urban area(0-15km), suburban area(15-30km) and out-suburban area(more than 30km). For every type station, draw the curve that contribution rate of population to ridership in different distance, which is weight curve for population.

Select another 48 stations of Odawara Line in Japan for statistic. Range from Shinjuku Station to Tamagawa Station belongs to urban stations, the number of which is 17. Range from Noborito Station to Machida Station belongs to suburban stations, the number of which is 10. Range from Sagamiono Station to Odawara Station belongs to out-suburban station, the number of which is 21. Accumulate total ridership and population at different distance within service area of every station of every type separately. Then fit them with 5 functions mentioned in Reference [11] on MATLAB. Taking residual sum of squares of the data as index, weight curve of three types of station are all normality negative exponential function curve. The specific formula of weight for population at different distance is in Figure 3.

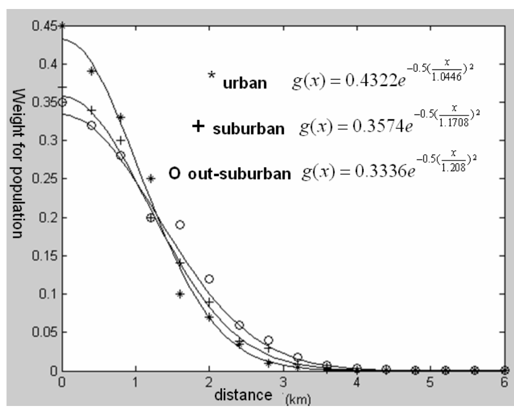

Figure 3. Weight curve of population in different area

Even though there exists unique feature for weight curve of every type of station. However, the above curve concluded can reflect whole trends of weight for population in this area and it is considered reasonable. Taking Aoso Station as an example, it is 9.6km away from the city center, belonging to urban stations, and so weight curve of urban station is chosen. Combining relative data in Table 1, compute the weight population within its service area according to Formula (1) as follows:

$$P = 3908 \times g(3.4) + 10970 \times g(1.62) + 20276 \times g(1.91) + 17873 \times g(0.34) + 5789 \times g(1.5) + 16690 \times g(1.025) + 15019 \times g(1.76) + 15933 \times g(1.41)$$

Which is 17858 persons.

3.2.2 Key predictors

Weighted population of 33 stations can be obtained according to Section 3.2.1. Combining with data statistic in Section 3.1, the value of road density, number of shuttle bus, land use mix, number of unidirectional trains in peak hours, interchange lines of station, number of PR facilities at station, distance to city center can be obtained. Correlation analysis can proceed according to Formula (3)—(7) in Section 1. The result is in Table 2.

Table 2. Correlation analysis between independent variables and ridership

	population		Road density	Number of shuttle bus	Land use mix	Number of unidirectional trains	Number of interchange lines	Number of P&R facilities	Whether it is terminal	Distance to the city center
	total	weighted								
ridership	-0.039	0.455**	0.07*	0.18*	0.164*	0.043*	0.101	0.251	0.028*	0.04

*** express significant**

**** express high significant**

The Figure 2 illustrates that the relative coefficient for total population and ridership is negative and they have no relation. Obviously, it is unreasonable to use total population as predictor. The relative coefficient for total population and ridership is 0.455, whose relation is high significant. The relative coefficient for number of unidirectional trains and number of interchange lines is 0.924 according to Formula (3)—(7), also whose relation is high significant, which means one predictor can be expressed by another one. As a result, combing with Table 2, the number of interchange lines is deleted. The relative coefficient for road density and distance to city center is 0.542, also whose relation is high significant. As a result, distance to city center is deleted. Finally, 6 variables that weighted population, road density, number of shuttle bus, land use mix, number of unidirectional trains and whether the station is terminal or not are selected as key predictors.

3.3 GA-BP model predicting ridership

3.3.1 Prediction model

6 key predictors are selected in Section 3.2, which means number of nodes in input layer is 6. As a result, number of nodes in hidden layer is $\sqrt{6}$, nearly 3. The 6-3-1 BPNN model is constructed, where the total number of weight that 6 nodes in input layer corresponds to 3 nodes in hidden layer is 18, and total number of bias of hidden layer is 3. the total number of weight that 6 nodes in hidden layer corresponds to 3 nodes in output layer is 3, and total number of bias is 1. Total number of value to be solved is 25. 28 stations' data are used to train and the other 5 stations' data are used to test.

3.3.2 GA optimize the parameter and solve the model

GA is used to optimize the initial weight and bias. ①Initialize the iteration of GA 100, group scale 30, mutation proportion 0.3, crossover proportion 0.1; ②Code weight and bias to be solved with real value, which is random value between [-1，1]. One group of code is a chromosome. Built 30 chromosomes randomly; ③Decode 30 chromosomes and put them in BPNN model and compute the goal Function (8) according to (9)—(11), which is also evaluation function of GA. ④Chromosome with minimum evaluation is selected among 30 chromosomes and inherit directly. Other chromosomes crossovers with each other at 0.3 proportion, mutates with each other at 0.1 proportion. As a result, a new generation chromosome come up. Repeat ③until 100 generation.

It shows that minimum evaluation in every generation in the process of optimization in Figure 3. It can be seen that rapid convergence comes up from beginning to 50 generations and then it slows to stability from 80 to 100 generations and the initial weight and bias are obtained.

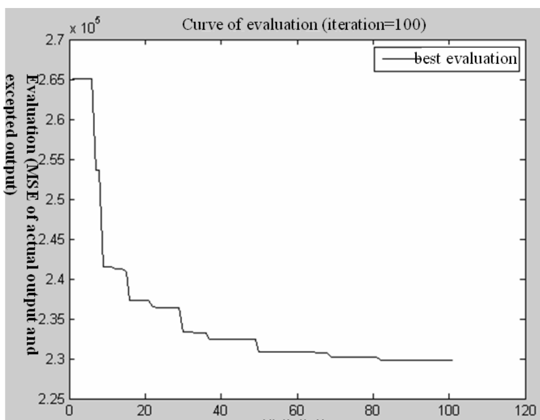

Figure 4. Iteration of initial parameter of BPNN optimized by GA

Put initial weight and bias after optimization into BPNN model, solve the model according to Section 2.2. Set calculation accuracy 0.001, the max number of iteration 30000. When the iteration reaches 25893, the accuracy of goal function is 0.001 and the algorithm stops. The final weight and bias is in Figure 5, where w in turn are weights that 6 variables (road density, number of shuttle bus, land use mix, number of unidirectional trains, whether the station is terminal or not and weighted population) corresponds to nodes in hidden layer. v in turn are weight that nodes in hidden layer corresponds to nodes in output layer. b are bias of nodes in hidden layer and c is bia of node in output layer.

Compare performance of BPNN with parameter which is not optimized with that with parameter which is optimized with GA. It can be obviously seen that BPNN with parameter which is not optimized can easily converge to local solution whose goal function is 0.1 and can not reach the global solution whose goal function is

0.001. That GA-BPNN can converge to the global solution shows its excellence.

$$w=\begin{bmatrix}0.8624 & 0.3358 & -0.4343\\ -0.3238 & 0.2069 & 0.1619\\ -0.331 & -0.0064 & 0.1036\\ -0.7171 & 0.5506 & -0.207\\ 0.041 & 0.4145 & -0.8768\\ -0.9031 & 0.3747 & 0.5604\end{bmatrix},v=\begin{bmatrix}-0.7904\\ -0.7442\\ 0.0991\end{bmatrix},b=\begin{bmatrix}-0.3248\\ 0.2157\\ 0.4825\end{bmatrix},c=-0.214$$

Figure 5.The final weight and bias of GA-BP neural network

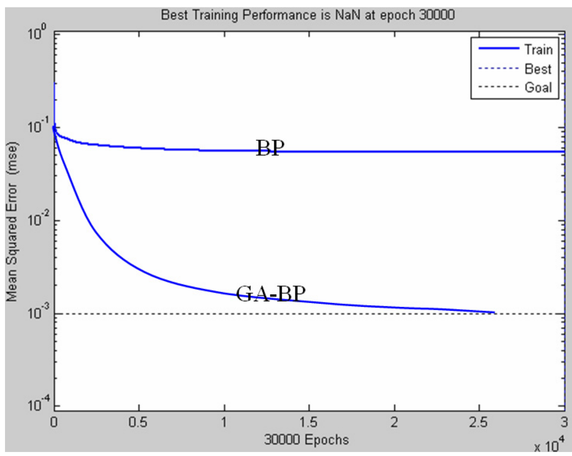

Figure 6. Compare of training performance between GA-BP and BP

3.3.3 Analysis of model result

To verify the excellence of GA-BPNN model with weighted population for prediction, we compare the result of it with the result of GA-BPNN model with total population, the result of linear model with weighted population, the result of linear model with total population. The other 3 models also take the same 28 station data for training and another 5 station data for test. The linear model is based on SPSS software for regression. The compare is in Table 3. Average absolute error and average relative error of GA-BPNN model with weighted population are minimum, which means it can reflect the interrelation between predictors and ridership actually. After this interrelation is decided, ridership can be predicted timely if one predictor changes.

Table 3. Indexes of four kinds of model

station	GA-BPwith weighted population	GA-BP with total population	Linear with weighted population	Linear with Total population	Actual ridership
Hikifune	2278	3049	2899	1049	2406
Horikiri	350	483	259	560	372
Kita-Senju	12302	10566	11265	6783	12503
Gatannno	10854	8259	13225	9096	10736
Nishiarai	17028	13220	18543	27557	16956
Average absolute Error(%)	108	1781	1184	3901	
Average relative error(%)	1.26	20.7	13.8	45.4	

4 Conclusion

(1) The factors affecting the UMT ridership at station-level is analyzed. Weighted population is put forward for the distance-decay rule. To avoid deviation, key predictors should be selected by multivariate correlation analysis.

(2)BPNN model is constructed for prediction. Because solution of BPNN relies on initial weight and bias greatly, GA is used to optimized the parameter.

(3)Relative data of 33 stations in Tokyo, Janpan are used to train and test the model, where the weight curve for population is fit according to the data of Odwara Line in Japan. Relative analysis is used to seek the relationship between factors affecting ridership and ridership. As a result, 6 variables are selected as key predictors, based on which, construct BPNN model with 6 nodes in input layer, 3 nodes in hidden layer and 1node in output layer. Compare of the result of GA-BPNN with weighted population with BPNN with weighted population shows that GA-BPNN can get global solution. Compare of the result of GA-BPNN with weighted population with the other three models(GA-BPNN with total population, linear model with weighted population, linear model with total population) shows the excellence of GA-BPNN model with weighted population.

(4)Case study in this essay is prediction of ridership in morning peak hour. The model put forward by this essay can also be used to predict ridership in dawn peak hours and daily ridership at station-level.

Abstract: It is important to evaluate bus system development level for public transportation system operations management. In his paper, 22 indicators are selected to establish the evaluation target system of the bus system development level. A new combined evaluation method based on structure entropy weight- matter element analysis is proposed. In this method, structure entropy method can make the weight calculation more objective, matter element analysis can ensure the integrity of the qualitative and quantitative information and easier to operate. Finally, case study of Dalian, after analyzing the particularity of bus system in Dalian, it specifically evaluates the development level of the bus system in Dalian used structure entropy weight - matter element analysis method, and gets the level is “medium”, among all of the indicators, the rating of peak hour load factor is “pass”, then it proposes some reference countermeasures to improve the development level of bus system in Dalian for the evaluation results.
Keywords: Urban transportation; Public transit; Evaluation; Structure entropy weight; Matter element analysis.

1 Introduction

The rapid growth of car brings a lot of problems to limited road space, this determines the cities must give priority to the development of public transport system. Now the development level of the public transport system is lagging behind in large and medium-sized cities, especially the regular bus system. Therefore, a whole, objective and impartial evaluation and analysis is particularly important for public transport system, by assessing and analyzing the operate situation of public transport systems, propose a more reasonable, high feasibility of improving program has become more urgent.

In recent years, various combinations of evaluation model are widely used in public transport evaluation system, especially the method which combined AHP and other methods is favored by the majority of scholars (Yang et al. 2014, Guo et al. 2014, Meng et al. 2012). It is worth mentioning that, in addition to the common method AHP, a current method named Structure Entropy method is increasingly used to determine the weight. At the same time, the evaluation model which combined Structure Entropy weights method and other evaluation method is continuous exploring (Xie et al. 2014).

This paper establishes the evaluation system of regular bus system from the facility level, benefit levels, service level. In terms of evaluation method selection, I choose the Structure Entropy weights method which combined qualitative analysis and quantitative analysis to determine the weights. A more concise and easier to operate evaluation methods which named Matter Element Analysis method is combined with Structure Entropy weights method, forming a new combination evaluation model applied in this paper.

2 Evaluation System

The valuation of urban public transport system contents lots and involves broad, Therefore, evaluation of selected factors also should be considered more. This article selected 22 specific indicators from the facility level, efficiency level, service level to build the of regular transit system evaluation system (Ren et al. 2014, Huang et al. 2011) (as shown in Figure 1).

3 Structure Entropy - Matter Element Analysis Introduction

Structure Entropy weight method is a new method to determine the weights which combined qualitative analysis and quantitative analysis. Its basic principle is to combine Delphi expert method and fuzzy analysis method. First of all, it forms a typical sort. Then it uses entropy decisions formula to calculate entropy and analysis blind degree. At the same time, it also statistics and processes the potentially bias data.

Matter-element theory as a modern uncertainty theory of mathematic determines the relevance of the target element by considering the distance and position between every index value and its classical field and segment field, then determine the level according the classical field that the correlation value belongs to. This method can analysis both qualitative and quantitative factors. And its result is in the real number field, to some certain extents, this overcomes the loss and changed of the information. In this paper, a comprehensive evaluation method that combine Structural Entropy weight method and Matter Element Analysis named Structural Entropy - Matter Element Analysis is applied. Its specific steps are shown below(as shown in Figure 2).

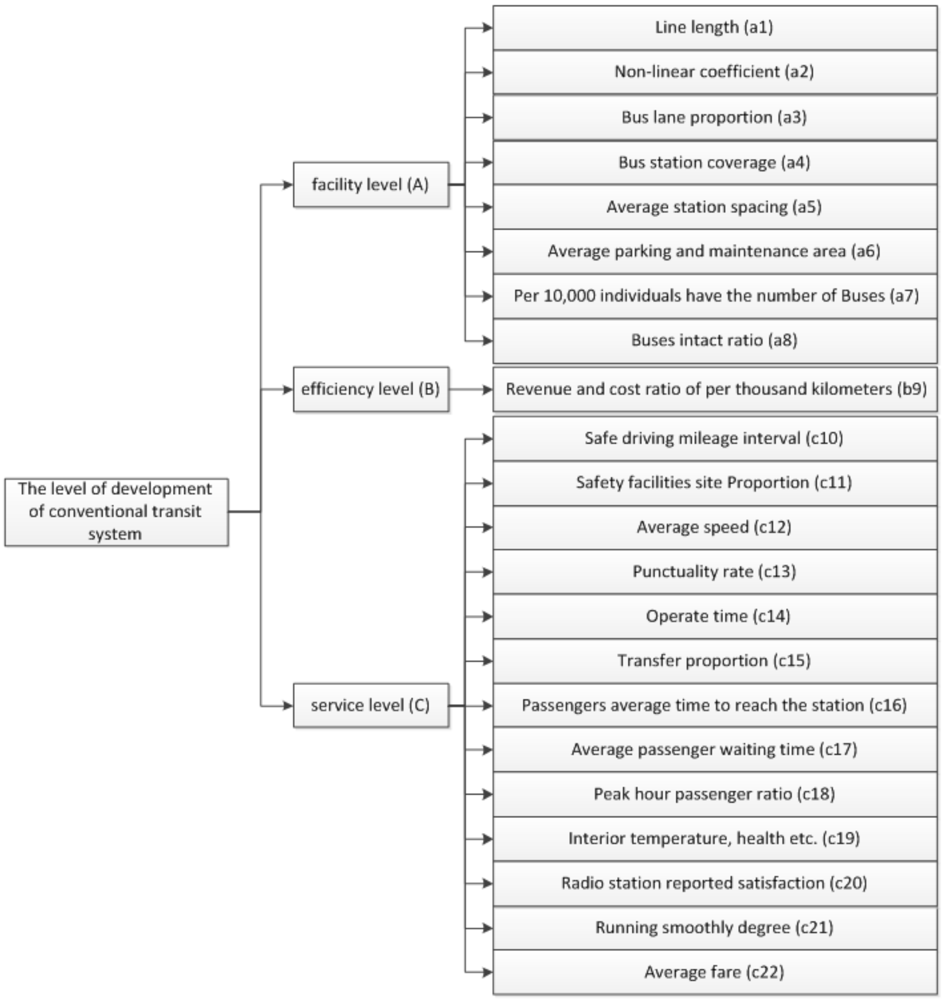

Fig.1 Evaluation index system of bus system

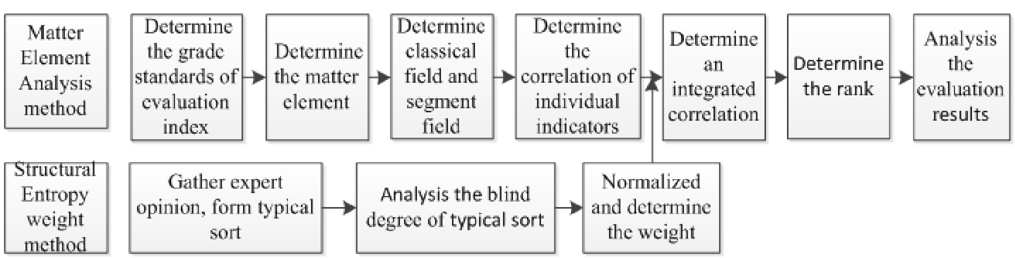

Fig.2 The steps of structure entropy weight - element analysis evaluation model

3.1 Evaluation Grade Standard

After reviewing the relevant literature, this article gives the index evaluation criteria of regular bus system, making the evaluation more fair and objective. The specific evaluation criterion is shown below.

Table 1 Evaluation indicators grade standard recommended value(Wang 2003)

	Index Name	Grade standard				
		A (Excellent)	B (Good)	C (Medium)	D (Passing)	E (Poor)
a1	Line length (km)	[10,15]	[5,10],(15,20]	(20,25]	(25,30]	(30,50]
a2	Non-linear coefficient	[1,1.4]	(1.4,1.9]	(1.9,2.4]	(2.4,2.9]	(2.9,3.5]
a3	Bus lane proportion (%)	(30,100]	(20,30]	(10,20]	(5,10]	[0,5]
a4	Bus station coverage (%)	(95,100]	(85,95]	(75,85]	(65,75]	(0,65]
a5	Average station spacing (m)	(0,300]	(300,500]	(500,700]	(700,900]	(900,2000]
a6	Average parking and maintenance area (km^2)	(200,300]	(180,200]	(160,180]	(140,160]	(0,140]
a7	Per 10,000 individuals have the number of Buses	(30,50]	(25,30]	(20,25]	(15,20]	(0,15]
a8	Buses intact ratio (%)	(95,100]	(90,95]	(85,90]	(80,85]	(50,80]
b9	Revenue and cost ratio of per thousand kilometers	(1.6,10]	(1.4,1.6]	(1.2,1.4]	(1,1.2]	(0,1]
c10	Safe driving mileage interval (million km)	(1.50,5]	(1.3,1.5]	(1.1,1.3]	(0.9,1.1]	(0,0.9]
c11	Safety facilities site Proportion (%)	(90,100]	(80,90]	(70,80]	(60,70]	[0,60]
c12	Average speed (km/h)	(25,50]	(20,25]	(15,20]	(10,15]	(0,10]
c13	Punctuality rate (%)	(90,100]	(80,90]	(70,80]	(60,70]	(0,60]
c14	Operate time (h)	(18,24]	(16,18]	(14,16]	(12,14]	[3,12]
c15	Transfer proportion (%)	(0,22]	(22,30]	(30,40]	(40,50]	(50,100]
c16	Passengers average time to reach the station (min)	(0,5]	(5,10]	(10,15]	(15,20]	(20,40]
c17	Average passenger waiting time (min)	(0,5]	(5,10]	(10,15]	(15,20]	(20,40]

c18	Peak hour passenger ratio (%)	(0,70]	(70,80]	(80,90]	(90,100]	(100,150]
c19	Interior temperature, health etc. (%)	(90,100]	(80,90]	(70,80]	(60,70]	(0,60]
c20	Radio station reported satisfaction (%)	(90,100]	(80,90]	(70,80]	(60,70]	(0,60]
c21	Running smoothly degree (%)	(90,100]	(80,90]	(70,80]	(60,70]	(0,60]
c22	Average fare (yuan)	(0,1]	(1,2]	(2,3]	(3,4]	(4,10]

3.2 Determine Matter Element，Classical Field and Segment Field

The evaluation object denoted thing U, each index as feature $C=(c_1,c_2,\ldots,\ c_n)^T$. the value of Features denoted $X=(x_1,x_2,\ldots,\ x_n)^T$. The three elements with sequence $R=(U,C,X)$ composed the matter-element (Cai 1994) denoted:

$$R=\begin{bmatrix} M & c_1 & x_1 \\ & c_2 & x_2 \\ & \cdots & \cdots \\ & c_n & x_n \end{bmatrix} \tag{1}$$

Among them: x_i is the value of c_i , (i=1, 2,…,n).

The value of c_i is $x_{oji}=[a_{oji},b_{oji}]$ (i=1, 2,…, n)，named classical field (Cai 1994) ，and $X_{oji}=[x_{oj1},x_{oj2},\ldots,\ x_{ojn}]^T$, so the matter element of classical field is shown as below.

$$R_{oj}=\begin{bmatrix} M_{oj} & c_1 & x_{oj1} \\ & c_2 & x_{oj2} \\ & \cdots & \cdots \\ & c_n & x_{ojn} \end{bmatrix}=\begin{bmatrix} M_{oj} & c_1 & [a_{oj1},b_{oj1}] \\ & c_2 & [a_{oj2},b_{0j2}] \\ & \cdots & \cdots \\ & c_n & [a_{ojn},b_{ojn}] \end{bmatrix} \tag{2}$$

Segment Field is denoted by Rp .

$$R_p=\begin{bmatrix} M_p & c_1 & x_{p1} \\ & c_2 & x_{p2} \\ & \cdots & \cdots \\ & c_n & x_{pn} \end{bmatrix}=\begin{bmatrix} M_p & c_1 & [a_{p1},b_{p1}] \\ & c_2 & [a_{p2},b_{p2}] \\ & \cdots & \cdots \\ & c_n & [a_{pn},b_{pn}] \end{bmatrix} \tag{3}$$

3.3 Structure Entropy Method to Determine Weight

(1) Gather experts opinion, form typical sort

If there are 22 indicators, the qualitative ordering number from 1 to 22, 1 represents the most important and 22 represent the most important, the rest is similar. This is typical sort.

(2) Analysis the blind degree of typical sort

To reduce the uncertainty of typical sort, it is necessary to statistical analysis and process the qualitative judgment conclusion as follows.

There are k experts consult in the investigation, we will get k pieces of consult papers, each one corresponding to an index set, denoted $U=\{u_1,u_2,\ldots, u_n\}$, the Corresponding typical sort denoted $(a_{q1},a_{q2},\ldots,a_{qn})$. So k pieces of consult papers give an indicators sort matrix $A(A=(a_{qi})_{k\times n}, q=1,2,\ldots,k, i=1,2,\ldots,n)$. The a_{qi} represents the evaluation from *q-th* expert to *i-th* indicator, and the value of $a_{q1},a_{q2},\ldots,a_{qn}$ choose from $\{1,2,\ldots,n\}$ (Cheng 2010).

After transforming the qualitative order, we define it is membership function.

$$\zeta(I)=\frac{\ln(m-I)}{\ln(m-1)} \tag{4}$$

I is the number of qualitative order, $\zeta(I)$ is membership function value, I=1,2,⋯,n, n is the number of indicators, m is the conversion parameter, m=n+2. If we put $I=a_{pi}$ to formula (4), we can get $b_{pi}(\zeta(a_{pi})=b_{pi})$, b_{pi} is the membership value, $B=(b_{pi})_{k\times n}$ is the membership matrix.

We think the k experts give same contribution to the same indicator ζ_i, then we denote the k experts' average contribution to ζ_i by b_i.

$$b_i=(b_{1i}+b_{2i}+\ldots+b_{ki})/k \tag{5}$$

We define the *q-th* expert uncertainty cognitive to ζ_i as the blind degree, denoted by Qi.

$$Qi=\left|\left\{\left|\max(b_{1i},b_{2i},\ldots,b_{ki})-b_i\right|+\left|\min(b_{1i},b_{2i},\ldots,b_{ki})-b_i\right|\right\}/2\right| \tag{6}$$

The overall understanding of the k experts to ζ_i is denoted by x_i.

$$x_i = b_i(1-Q_i), x_i > 0 \tag{7}$$

So the evaluation matrix of the k experts give to the all indicators as $X = (x_1, x_2, \ldots, x_n)$.

（3）Normalization

If we make $w_i = x_i / \sum_{i=1}^{m} x_i$ ， then $W = (w_1, w_2, \ldots, w_n)$ is the weight matrix of $U = \{u_1, u_2, \ldots，u_n\}$.

3.4 Determine the Correlation Coefficient

Correlation function is correlation of evaluated level, it means that the similarity between the two grades. Extension Set correlation function can be expressed algebra, making things incompatible quantified (Cai 1994).

Suppose the distance from one point x_i to an interval $x_{oji} = [a_{oji}, b_{oji}]$ is following.

$$\rho(x_i, x_{oji}) = \left| x_i - \frac{a_{oji} + b_{oji}}{2} \right| - \frac{b_{oji} - a_{oji}}{2} \tag{8}$$

Similarly, we can also get the distance from x_i to $x_{pi} = [a_{pi}, b_{pi}]$.

So the correlation function is following.

$$k(x_i) = \begin{cases} \dfrac{-\rho(x_i, x_{oji})}{|x_{oji}|}, & x_i \in x_{oji} \\ \dfrac{\rho(x_i, x_{oji})}{\rho(x_i, x_{pi}) - \rho(x_i, x_{oji})}, & x_i \notin x_{oji} \end{cases} \tag{9}$$

3.5 Determine the Grade Level of Evaluation

If we have the correlation and weight of all indicators, we can get the summing correlation.

$$L(x_i) = \sum_{i=1}^{n} w_i k(x_i) \tag{10}$$

Correlation value indicates the degree of compliance with the grades. The larger the value, the thing is more in line with the grade. This evaluation level is determined based on the principle of maximum degree of membership.

4. Case of Dalian Evaluation

Dalian unique geographical conditions make conventional transit system has a greater degree of influence for the residents. By investing the development level of Dalian bus system, we get the value of each index in the table below.

Table 2 Evaluation indicators values of bus system in Dalian

indicator	value	indicator	value	indicator	value	indicator	value
a1	15.9	a7	22.5	c13	75	c19	80.7
a2	1.72	a8	98.9	c14	15	c20	75.45
a3	15.3	b9	1.25	c15	35	c21	74.95
a4	92	c10	1.48	c16	10.4	c22	1.67
a5	607.2	c11	99.7	c17	4		
a6	168	c12	17.5	c18	94.5		

Combined with the above data, the weight and evaluation result by using the structure entropy method and matter-element analysis method is in the table below.

Table 3 Correlation calculations Fact Sheet

indicator	weight	result	indicator	weight	result	indicator	weight	result
a1	0.044	good	b9	0.053	medium	c17	0.050	excellent
a2	0.051	good	c10	0.047	good	c18	0.056	passing
a3	0.041	medium	c11	0.035	excellent	c19	0.022	good
a4	0.055	good	c12	0.058	medium	c20	0.023	medium
a5	0.052	medium	c13	0.057	medium	c21	0.033	medium
a6	0.036	medium	c14	0.043	medium	c22	0.050	medium
a7	0.057	medium	c15	0.052	medium	summing	1	medium
a8	0.042	good	c16	0.043	medium			

Look at the table 3, we can know that most indicators are in the medium level, few indicators rank excellent, good, passing .We haven't obtained the poor level. The summing results of comprehensive correlation is $k_3 = \max_{j=1,2,3,4,5} L(x_i) = 0.1218$, The results show that the public transport system in Dalian ranks the medium level. Among them, in the evaluation of the results of a single index, the evaluation rating of "passing" is only one---The load factor of peak hours. Therefore, relevant departments should take serious measures towards this index in order to promote the development of public transport system in Dalian. Following recommendations are presented below: Increase the number of buses which are loaded with a higher rate.

Ensure that a bus can be taken during peak hours and reduce the grid spacing, thereby reducing load factor of peak-hour.

5 Conclusions

Now the development level of bus system in a lot of cities has the problem that the bus system cannot meet the need of people travel. Therefore, the operation situation of bus system needs a whole, objective and impartial evaluation and analysis, so that we can propose some targeted and high feasibility improving program. This paper presents an evaluation method that based on structure entropy - Matter Element Analysis. This combination evaluation method can work with the characteristics of qualitative and quantitative factors well. Using Entropy method to determine weight improve the objectivity of the weight calculation. Matter element analysis method can reduce the distortion of information of evaluation. it is also an easy method to operated. In this paper, we use the conventional method to carry out the actual calculation and evaluation of the public transport system in Dalian city. We get a comprehensive evaluation grade of conventional public transport system in Dalian, it ranks intermediate level. These indicate that the conventional public development in Dalian is in general level. This paper takes Dalian as an example to ensure the effectiveness of this combination evaluation method, and I hope this method can provide some reference to the public transport system evaluation of other cities.

Abstract: Through detailed analysis of Conceive, Design, Implement, and Operate (CDIO) engineering education mode, the operation and management of urban rail transit education is innovated in combining basis theory, personal capability and collaboration of team and environment of society. In view of Capability Maturity Model (CMM), a model of operation and management of urban rail transit education reform Based on CDIO is developed, and the program optimizing method called Prepare, Assess, Summary, and Adjust (PASA) based on CDIO is put forward, furthermore, the basic tasks and demands of the method are also discussed in detail. When the CDIO engineering education model with the project as its carrier is build, the Flexible, Module, and Season (FMS) organization mode of teaching is actively promoted, and the requirements of the project implementation arrangements are met. From the method had been implemented since 2010, the system has got the approval of the teachers and students, which stimulates students' interest, and has a better effect in practice.
Keywords: CDIO; Urban rail transit; Education reform; CMM; PASA; FMS.

1 Introduction

Knowledge and ability are two basic concepts in the field of education. The organic combination of the learning of knowledge and nourishment of knowledge based ability is an important and difficult problem. So some problems on their relationship have been valued and explored by many scholars and cooperation-education and problem-based-learning are some fruit of their exploration. There are some defects in these explorations, for they catch one and lose another in solving the problem of the relationship between knowledge and ability. The emerging model of CDIO emphasizes the link between knowledge and ability and provides new ideas and models in combining the learning of knowledge and nourishment of knowledge based ability.

CDIO denotes conceive, design, implement and operate (Gu,2009), it is the newest research result of international engineering education reform in recent years.

The theory of “learning-by-doing” and “project based education and learning” is focus on summary and abstract expression. Innovative talents who have the ability to innovate doesn’t inherent, almost of them are cultivated by acquiring learning and practice. Carrying out the creative education is the most directed and valid way to cultivate innovation ability. How to cultivate innovative engineering and technical talent is hot spot of domestic and abroad higher engineering education reform in recent years.

2 CDIO-Based Engineering Education Modes

CDIO takes the engineering projects (including products, production processes and systems) as the training objectives, R&D and product operation as its carrier and engineering professional practice environment as the engineering teaching environment. so that students can learn in the way of active and practical courses which link to learn engineering. CDIO not only inherits but also develops the idea of European and American engineering education reform more than twenty years. Even more important, it proposed systematic ability cultivation, comprehensive implementation guide, complete implement process and rigorous inspection including twelve standards and has strong operability. CDIO is one of the patterns under the strategy of “learning-by-dong”. It is a kind of education concept which combines abstract education and practical education, and its syllabus competence goals and innovative talents quality fit highly.

CDIO curriculum design is established on the basis of the talent training goal’s comprehensive analysis. It includes four aspects: technical knowledge and reasoning, career skills and quality, interpersonal communication and team coordination ability as well as the CDIO under the enterprise and society environment. That just meets the requirement of business world to innovative engineering talents. Due to the modern engineering system’s more and more dependence on multidisciplinary background knowledge, the students must grasp suitable technical knowledge and have rigorous reasoning ability. Personal and professional skill is the core competencies which is necessary to mature engineers. Students must grasp the interpersonal skills and have good communication ability for working under the environment based on team cooperation. At last, in order to actually accomplish the establishment and operation of products and system, students must have the ability to conceive, design, implement and operate products and system on enterprise and society level(Crawley,2009,Wang,2007).

3 CDIO Operation and management of urban rail transit education Mode Based on CMM

Although CDIO engineering education proposes specific requirements with one vision, four levels of capacity requirement, twelve criterion of teaching concept and five guiding ways, it hasn’t pointed out the further description of how to gradually train and systematically evaluate students' CDIO engineering ability, that is to say, the increasing process of students' CDIO engineering ability is undefined. Therefore, using the basic thought of software capability maturity model (CMM) (Carnegie,1994), this paper constructs CDIO operation and management of urban rail transit education mode based on CMM is established and shown by Fig. 1. Reflect students' CDIO engineering ability's practical and needed improving direction by ability mature grade characteristics, and then make students' DCIO engineering ability matures continuously through orderly growth (Hu,2010).

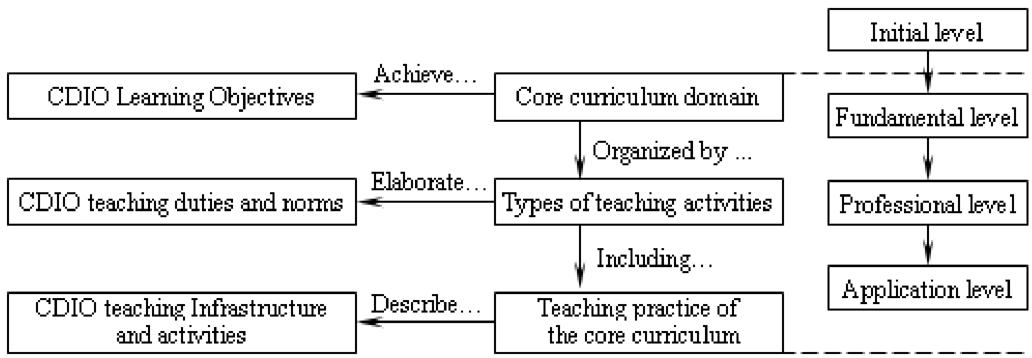

Figure 1.CDIO operation and management of urban rail transit education mode based on CMM

In Fig. 1, except for the initial level, each grade of the rest levels formulates some core curriculum domain. In the professional study process, the students basically start study taking the curriculum as a unit; therefore, teaching curriculum study is the most basic CDIO study process practical activity. Core curriculum domain includes a series of core curriculum teaching practical activities which are organized by teaching activity types and influence CDIO engineering capacity's formation by their execution. When a core curriculum domain's whole core curriculum teaching practice can be implemented according to the requirements, the CDIO learning objectives ought to be achieved by core curriculum domain guide can be realized, that is to say, cyclic iteration incremental training on students' CDIO engineering ability through the execution of core curriculum teaching practice and core curriculum domain.

Each core curriculum domain should contain four teaching activity types: formulate curriculum teaching standard, ascertain curriculum teaching condition, execute curriculum teaching and evaluate teaching results. Practical activity like teaching standard establishment generally describes the teaching standard and strategy of teaching curriculum, for example, formulate curriculum teaching outline standard according to CDIO engineering education idea and CDIO teaching target. Practical activity like ascertaining curriculum teaching condition mainly determines the precondition needed by curriculum teaching, including CDIO teaching infrastructure and pre-study curriculum determination and so on. Practical activity like executing curriculum teaching mainly describes the curriculum teaching's content, form, method and so on, including formulating teaching calendar according to teaching outline, executing teaching according to teaching calendar, recording students' study situation and so on. Practical activity like evaluating teaching results is mainly about ensuring that teaching activity can be conducted according to the established standard, checking the state and effectiveness of the execution process at any time, executing suitable measurement, analysis and comments, for example, visit a class, teaching archives inspection, students comments etc.. while describing the teaching curriculum practice, the CDIO teaching infrastructure and practical activity, which has great influence on the realization and standardized execution of curriculum domain target, generally emphasize what to do other that how to do.

4 CDIO personnel training plan Optimization with PASA method

Education plan's improvement needs the cooperation of educational circles, industrial circles and evaluation organization. Confirm the knowledge, skill and quality should be possessed by engineering undergraduate talents and propose the content and measurement of education plan's improvement to perfect the education plan of education target and requirement. Meantime, on the aspect of curriculum setting, it is necessary to highlight the relevance of curriculum setting to avoid the unnecessary repetitious content so that students can grasp the relationship of knowledge of each curriculum to solve the comprehensive problems. Moreover, we should pay attention to the formation and cultivation of students' CDIO engineering capacity. We should focus on industry internship and engineering training while avoiding the too small and too narrow curriculum setting. The talents education plan's optimization based on CDIO mainly aims at the defect of students' CDIO engineering capacity. It is composed of four sections: preparation, assessment, summary and adjustment, "PASA method" for short. This method's core is the establishment of integrated curriculum plans. The optimization process is shown in Fig.2.

It can be seen in Fig.2, the design process of integrated curriculum plan based on CDIO has two main closed loops: study effect closed loop and integrated curriculum plan closed loop based on CDIO outline. The former is used to improve CDIO, and the latter is for integrated curriculum plan design execution using CDIO. The existing condition is the sum of all the factors influencing the present curriculum plan, including school system, the existing curriculum plan's structure, profession target, educational system, the state's requirement to talents and so on.

4.1 Preparation

The design process of integrated curriculum plan based on CDIO has two main closed loops: study effect closed loop and integrated curriculum plan closed loop based on CDIO outline. The former is used to improve CDIO, and the latter is for integrated curriculum plan design execution using CDIO. The existing condition is the sum of all the factors influencing the present curriculum plan, including school system, the existing curriculum plan's structure, profession target, educational system, the state's requirement to talents and so on.

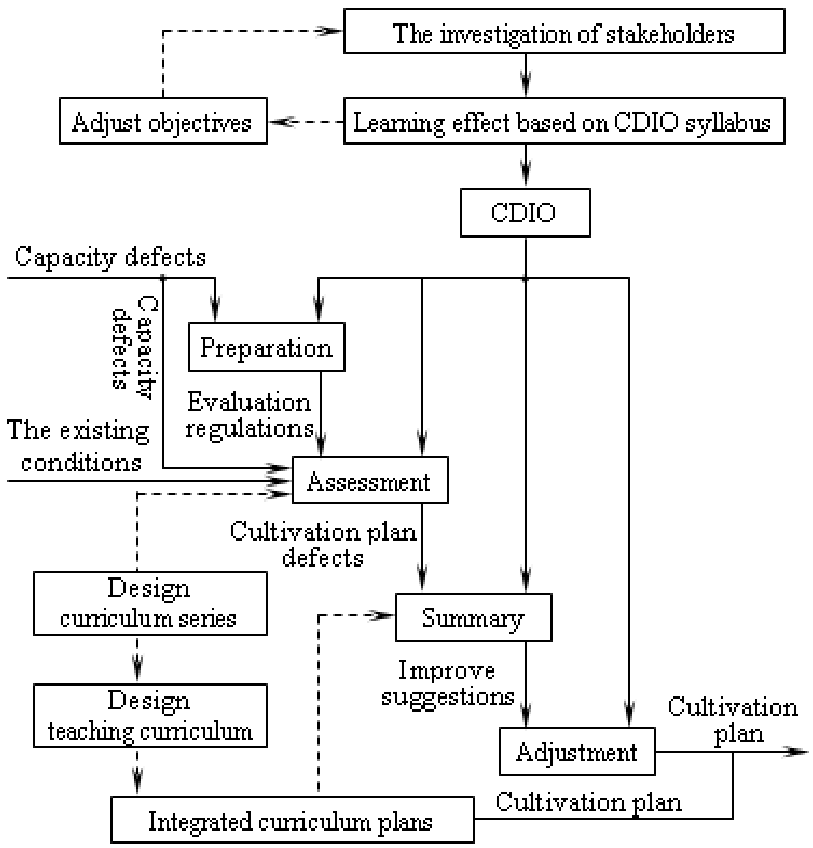

Figure 2.The cultivation plan optimization and the design process of integrated curriculum plans

4.2 Assessment

With contrast to CDIO stand and references on existing condition, find out the defects of the cultivation plan which causes students' CDIO engineering capacity defect according to the evaluation regulation fixed at the preparation phase. At first, cultivation plan execution organization reports the relevant content and implementation status of cultivation plan, expounds the principles and guiding ideology of cultivation plan establishment, explains how to gradually trains student's CDIO engineering capacity and solves the existing problems through implementation cultivation plan, what is the characteristic of the cultivation plan, etc.. Then, the evaluation group picks up the relevant files of cultivation to read, and picks up the relevant files of cultivation plan execution status when its necessary, and analyzes the existing problems of cultivation plan according to CDIO. Aiming at the existing problems of cultivation plan, make clear the relationship between cultivation plan and students' CDIO engineering capacity defect through ways such as students' interviews, teachers' discussion, field survey of cultivation plan execution and so on. Find out the cultivation plan defect which brings about capacity defect through comprehensive analysis.

4.3 Summary

Provide all the scores of cultivation plan indexes according to CDIO standard, and extensively exchange and communicate with students, teachers and teaching management section through evaluation situation announcement according to cultivation defect, moreover, should pay attention to listening the business world engineers' relevant opinions, and then propose the cultivation plan's improvement suggestion. In addition, evaluation organization also needs to compose a final report to fix the modes and methods used by this evaluation, the main content, the results, completion status and existing problems of this evaluation for reference while the cultivation plan implementation organization is executing the evaluation plan.

4.4 Adjustment

With the contrast to CDIO standard, improve the present cultivation plan according to the improve suggestion to eliminate the cultivation plan defect which brings about capacity defect. During the adjustment process of the cultivation plan, we should proceed with extensive lecture and organize discussion with students, teachers and teaching management staff based on the modified plan. Comprehend the cultivation target and requirement of the cultivation plan, familiarize with the various teaching practical activity standard of the curriculum setting plan and try our best to make sure the cultivation plan can be smoothly implemented according to the regulations.

5 CDIO Teaching Organization based on FMS

In order to ensure the implementation of CDIO engineering teaching mode, based on the project teaching' confession and CDIO cognition our school seriously use the successful experience of Department of Industrial Engineering of Tsinghua University and Singapore Nanyang Technological University's project teaching for reference. Aiming at the problems which is came across by the operation and management talents when they face enterprise choice, combining with CDIO relevant standard and China's actual situation, we construct CDIO engineering teaching mode taking the project teaching as the carrier, and positively impel FMS teaching organization mode, namely, flexible, module, season. We proceed with project teaching innovation taking the operation and management of urban rail transit as the practical object and find a set of feasible capacity training plan so that the students' comprehensive vocational ability and sustainable developing capacity can be improved.

5.1 Implement Flexible Teaching Management

In order to adapt to the marketing economy's demand variation to production, make sure the teaching content keep in step with enterprise's production flow, and promote learning with working mode's development so that the example can come from the first production line in time and the project selection can be in accordance with the enterprise's real requirement. Meantime, for the purpose of students' projects' timely inspection in practice, our school change the rigid management into flexible service, flexibly adjust study module according to producing training or the enterprise production's requirement to internship, and adjust school's teaching organization mode in time to make the teaching organization flexible. Especially, at in-post practice phase, we can elastically adjust CDIO four sections according to the students' internship arrangement in batches.

5.2 Design Module Curriculum Group

To implement engineering education, we should dynamically organize module curriculum group mode according to engineer professional role demand. after the curriculum development conducted by school and enterprise based on working process, in order to implement semester project, we should organize and establish curriculum group such as software design engineers taking semester object as the core, embedded system engineers, network engineers, information system integration engineers, e-commerce and so on. A curriculum module is a assembly of professional curriculum, professional quality curriculum and elective curriculum to a task field. And then sort the assembly according to the growth law of the professional ability in order to connect the knowledge among the curriculums.

The students can finally become different roles through studying different knowledge module and grasping tools and skills. The traditional curriculum pays great emphasis on theory completeness and analytical calculation and neglect engineering application. The innovated curriculum takes both classical content and modern technology into consideration, emphasizes on basic theory and pays attention to methods, especially engineering application.

5.3 Realize Season Teaching Organization

In order to make it easier to implement semester object, ensure flexible teaching management, our school firstly carries out season teaching in the operation and management major. In terms of teaching organization, we take 7~8 weeks as a season teaching unit to shorten the teaching cycles and adapt to flexible management. In terms of curriculum arrangement, the curriculum which needs strong continuity should be arranged in a season; the curriculum which trains mind skills normally should be divided into basic part and improving part which should be arranged separately in two seasons; the curriculum about professional quality should be arranged in each season according to the students' quality formation characteristics. In the terms of project execution, we proceed with midterm inspection, project conclusion and evaluation through project-week.

7 Conclusions

At present, the transformation from traditional education to engineering education is becoming the trend of education mode innovation. Many colleges and universities is exploring practical engineering education. Operation and management of urban rail transit education innovation according to CDIO education mode has got obvious effect in practice. Its teaching way has motivated the students' interests, strengthened the ability of solving problems, cultivated team spirit, and upgraded the profession quality. This just realizes the teaching target under CDIO concept and meets the business world's need to innovative engineering talent. However, the profession's teaching innovation is a long-term and comprehensive task. We need to do further research and exploration if we want to gain comprehensive teaching effect.

Abstract: The study focuses on the travel time costs of public traffic, calculates them under different conditions in order to analyze the coordination of them. It's finished by two stages. At the first stage, using generalized travel cost share rate forecasting model to forecast the share rates of different income groups using different travel modes. At the second stage, the share rate is used to determines the travel time cost function. Selecting distance and time as characteristic variables of the function, studying the change of it. Finally, taking Guangzhou as an example to analyze the coordination of the urban rail transit. The results indicate that it's necessary to control the length of the line coincides between the subway and bus within 4km. It improves the accuracy and practicality of the model with consideration of more factors affecting the resident travel mode choice.
Keywords: Transportation economy; Travel time cost; Passenger coordination.

1 Introduction

To make full use of urban rail transport's capacity, it's necessary to consider different travel modes' coordination which means the relationship between them. There are 2 kinds of coordination forms: competition and coexist. The research of urban rail transport's coordination is mainly about studying the relationship between urban rail transport and other travel modes, improving overall passenger capacity of the city by reducing competition or improving coexist of other travel modes. TTC (travel time cost) is the time consumption in one trip. It's a effective way to analyze the travel mode's coordination by calculating the travel mode's TTC.

In recent years, the researches of TTC in developed countries are mainly for city traffic model classification, the total cost of the quantification and basis of the travel cost charge policy. Logit model and its improved model are the most common methods so far. Kaoris establish a travel mode probability prediction model and apply it in the decision making process (M and A 2000). Henshers use disintegration model to establish a joint choice model of residential address and travel mode (D and W 2002). Kwigizies select the personal, social, economic attributes and other factors, apply cross stratified logit model to estimate the probability of residents travel mode (V et al. 2011). The study on the value of travel time in our country begins in the mid-1980s. Zhong Fangs establish a comprehensive model which can calculate the value of travel time by introducing the time factor, it make a improvement to the traditional method (Fang et al. 2009). Zhao Shuzhi puts forward a calculation method to residents' travel time value model in view of different travel modes (Shu-zi and Bei 2011). Xu Tings who regard the travel behavior as a research object use the correlation to analyze the factors closely related to the residents' travel modes (Ting et al. 2013). On account of the utility function determination in logit model depends on the individual travel behavior investigation, the parameter estimation is affected by many uncertain factors. This paper aims to use generalized travel cost to predict the traffic mode share rate, searches for the quantification method of various public travel mode's TTC based on the time value theory. Then enhancing the urban rail transport's coordination by comparing the TTC of urban rail transport with other public travel modes under different conditions.

2 The calculation model of travel time value and travel time cost

2.1 The calculation of different income level Residents' value of travel time

VOT (value of time) is the benefit increment amount produced as time elapsing and the monetary expression of efficiency loss caused by the non productive expenditure of time. Personal saving time value is generally considered equal to the cost of someone that is willing to pay his time saving. Before calculating the residents' VOT, the residents should be classified on the basis of their income level first, it's generally divided into 6 grades from low to high. The range of each grade is decided by the specific economic situation of the city.

This paper adopts the most common production method to calculate different income level residents' travel time value. The production method based on the passengers' travel time is for the production that can create national income or GDP. This method is generally used to calculate the VOT for work. This paper aims to modify the calculating formulas to calculate the VOT according to the residents from different income levels VOTj (Jianzhong 2009), the calculation formula is as follows:

$$VOT_j = \frac{M_j}{(365 - J) \times 8} \tag{1}$$

VOT_j: The value of time according to the residents of income level j;

M_j: Per capita annual income according to the residents of income level j;

J : Annual weekends, statutory holidays (115 d).

2.2 TTC model

TTC (travel time cost) mainly refers to the time consuming that travelers throughout the travel. It can be measured by money which is also called narrow travel expenses including the VOT and travel expenses. Seen from above that travelers from different income levels have different VOT. Although it won't be affected by the travel modes directly, but the type and ratio of travelers that each travel mode attracts are not the same. The VOT of different income levels with its proportion in all travel modes, it's able to get the VOT of this travel mode, and then get the TTC (wei et al. 2010).

$$VOT_i = \sum_j \theta_{ij} \times VOT_j \tag{2}$$

$$TTC_i = (t_{i0} + t_{i1} + t_{i2}) \times VOT_i + r_i \tag{3}$$

VOT_i: The value of time according to the i-th travel mode;
θ_{ij}: The proportion of passengers according to j income level in the i-th travel mode;
TTC_i: The travel time cost according to the i-th travel mode;
t_{i0},t_{i1},t_{i2}: The transfer time, waiting time, travel time according to the i-th travel mode;
γ_i: The expense according to the i-th travel mode.

3 Sharing rate prediction model based on the generalized travel cost

3.1 Generalized travel cost

Generalized travel cost represents the cost of passenger travel process required to pay. The generalized travel cost is the sum of the travel influential citys' average utility of different factors. It's also the point that differs it from TTC. It usually includes the following factors. Economy that refers to the freight paid in passenger trave. Rapid, the time passengers spend in the travel reflects the quality of various travel modes' service. Convenience which refers to the convenience of non-riding stage in the trip. Snug which is generally represented by 8% conversion fee, meaning ease produced fatigue properties in travel. According to the independence and addition principle of service quality characteristics in travel modes, it's able to construct the generalized travel cost function:

$$V_i = E_i + F_i + C_i + S_i = 1.08R_i + (T_i + Y_i) \times VOT \tag{4}$$

E_i, F_i, C_i, S_i: Economy, fast, convenience, snug of the i-th travel mode;
R_i: The average cost of the residents spend on the i-th travel mode;
T_i: The average operating time of the i-th travel mode;
X_i, Y_i: Distributed time, waiting time of the i-th travel mode.

3.2 Share rate forecasting model

In this paper, VOT model is used to predict the share rate of transport (Wei-chao 2013). This model assumes that urban residents choose to travel in a minimum of generalized travel cost way. Affected by economy, residents of different income levels choose a different probability of different travel modes. Based on previous research, it's generally believed that the VOT obeys lognormal function:

$$f_j(VOT)=\begin{cases}\dfrac{1}{2\sigma_j VOT\sqrt{\pi}}\exp\left[-\dfrac{(\ln VOTj-\mu_j)^2}{\sigma_j^{\ 2}}\right] & VOT>0\\ 0 & VOT<0\end{cases} \quad (5)$$

$$\mu_j=\ln VOT \quad (6)$$

$$\sigma_j=\left|\ln VOT-\mu\right| \quad (7)$$

$$\mu=\sum_j \ln VOT\times\alpha_j \quad (8)$$

αi: The proportion of urban residents of different income levels j;
μ: The value of city residents average unit time.

This paper studies the share rate of residents on different income levels on bus, subway and taxi. The generalized travel cost of these travel modes are respectively expressed as V1,V2,V3. For the passengers of different income levels, the difference of the generalized travel cost are modest. Ignoring the effect of income level on the passenger travel cost, the time value model diagram as shown in Figure 3-1:

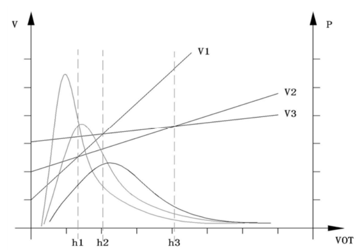

Figure 1.Time-value model that passengers choose three modes of transport

Using the formula function and linear function characteristics of V_1, V_2, V_3, it's possible to calculate the figure of h_1, h_2, h_3. According to the properties of probability distribution function. For the residents of j-th income level, the distribution function that the value of time in different ranges corresponds is the probability of selecting travel modes F_{ji} (Xiao 2012), then it's able to get θ_{ij}.

$$F_{ji}=\int_{si} f_j(x)\mathrm{d}x \quad (9)$$

$$\theta_{ij}=\frac{\alpha_j\times F_{ji}}{\sum_j \alpha_j\times F_{ji}} \quad (10)$$

$F_{j1,\ 2,\ 3}$: The probability passengers of j-th income level select the1, 2, 3-th travel mode;
s1, 2, 3: The integration intervals of 3 travel modes are respectively (0, h_1), (h_1, h_2), (h_2, ∞)

α_j: The proportion of residents in j-th income level;

4 The example analysis

4.1 The value of travel time calculation of residents in Guangzhou

This paper takes Guangzhou city as a example to analyze the coordination of subway line in 2005. Dividing residents into 6 grades by their income level. Grading standards and the proportion refer to the latest data from the recruitment enterprise of Guangzhou. There are also some assumptions in this paper. A. the lognormal standard deviation that the Guangzhou residents' unit time value obeys is as same as the residents' time value in China. B. the per capital GDP in 201l-2015 is increasing by 10% per year in Guangzhou. C. the division of residents' income level in Guangzhou is as same as the division in 'Chinese statistical yearbook 2010'. Calculating the value of residents average equivalent unit time in Guangzhou according to formula (4), it's shown in table 1.

Table 1. The prediction of value of travel time in Guangzhou City

Parameters	The lowest income	Low income	Lower-middle income	Middle income	Higher-middle income	High income	The highest income
Monthly income (yuan)	<2000	2000 ~3000	3000 ~4000	4000 ~5000	5000 ~6000	6000 ~8000	>8000
Proportion (%)	2.9	11.23	17.48	16.4	11.77	16.32	23.9
2015 Predictive value M_j (yuan)	7892.40	10859.81	14073.91	18214.43	24100.27	31024.67	46711.89
VOT_j	3.95	5.43	7.04	9.11	12.05	15.51	23.36
μ_j	1.37	1.69	1.95	2.21	2.49	2.74	3.15
σ_j	1.06	0.74	0.48	0.22	0.06	0.31	0.72

4.2 Residents travel share forecasting

According to the 'city road traffic planning and design specifications', the residents' travel survey data in 2005 Guangzhou and per capita income data in 2011 Guangzhou, annual traffic report data in 2011 Guangzhou, Guangzhou city traffic bureau of Guangzhou city price parking fees and standards, it's possible to get the data. Considering the capacity problem of taxi, assuming each taxi loads 3 passengers during the rush hour. Per expense is 7.6 yuan. Forecasting the generalized travel cost of these travel modes in 2015 by formula (1) , shown in table 2.

Table 2. The commuting parameters and values of Guangzhou city residents

travel modes	T_i(min)	X_i(min)	Y_i(min)	R_i(yuan)	V_i
bus	38	10	7.5	1.79	1.93+0.93VOT
subway	31	10	2	3.22	3.48+0.72VOT
taxi	31	0	0	22.8	8.21+0.52VOT

Using the properties of linear function to calculate the generalized travel cost. The intersections of V_1, V_2, V_3 are respectively 7.6, 15.32 and 23.65. Expressed by h_1, h_2, h_3. According to the properties of probability distribution function, using formula (5) to (7) to calculate the probability residents of different income levels select these travel modes. Then using formula (8) to calculate the proportion of the different income levels residents' in i-th travel mode, shown in table4-4. Combining the value of different income levels residents' time with formula (2) , then getting the VOT of these travel modes, shown as table 3.

Table 3. The VOT of residents in Guangzhou

θ_{ji}	1	2	3	4	5	6	7	VOT_i
1	0.0861	0.3087	0.4029	0.1373	0	0.0073	0.0577	7.56
2	0.0104	0.0546	0.1211	0.2114	0.1911	0.2387	0.1726	13.15
3	0.0094	0.0189	0.0073	0	0	0.1045	0.8599	21.90

4.3 Analysis of passenger coordination based on TTC

On the assumption that the Guangzhou city residents choice travel mode obeying the principle of minimum generalized travel cost, it's able to calculate the VOT of these travel modes. Assuming that a section of route in Guangzhou can be used by these travel modes and the trip distance of them is the same. According to the total transfer time and waiting time in Guangzhou, assuming that the total transfer time and waiting time of bus is respectively 15min and 5min, the total transfer time and the total waiting time of subway is respectively 5min and 3min, the waiting time of taxi is 3min. Finally the TTC function can be got by using formula (3).

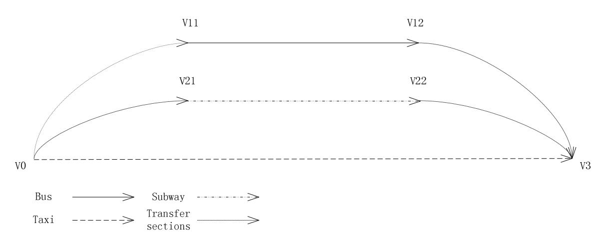

Figure 2. Paths of travel modes

L is travel distance, V_{i2} is the driving speed of i-th travel mode. From above, knowing that TTC is close related to L and V_{i2} which is affected by the road saturation. Under the condition that the road is in good state, it would be okay to assume that the driving speed of travel mode 1, 2, 3 are respectively 20 km/h, 35 km/h, 40 km/h. Considering the fare of tickets in Guangzhou, the TTC-L graph of the various travel modes is plotted as figure 3(Jun et al. 2014).

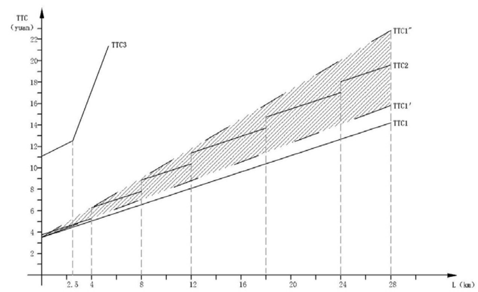

Figure 3. The relationship between L and TTC

This paper mainly focus on the relationship between TTC_1 and TTC_2. Knowing from figure3, when the bus speed is below a certain valueV'_{12}, TTC_1 is higher than TTC'_1. In this case, the presence of L makes TTC_1 higher than TTC_2. When the bus speed is above a certain value V''_{12}, TTC_1 is higher than TTC''_1. At this point, no matter what the value of L is, TTC_1 is rival to TTC_2. Using the nature of linear function, it's easy to calculate that V'_{12} and V''_{12} are respectively 17.28km/h and 11km/h. Assuming that the operating speed dropping to 3/4 of the original in traffic jams, which means the lowest operating speed of bus in Guangzhou is 15km/h. Only when $L \in (1.85,4), \cup (42.18, \infty)$, TTC_1 is higher than TTC_2. Under the assumption that bus and subway have the same travel distance and the waiting time of them are determined, TTC_1 is lower than TTC_2 in Guangzhou. In fact, due to the limit of ground conditions, bus lines are generally longer than the subway line when the staring points ending points are the same, the factors that will further narrow the gap between the two travel modes. As public transports, they undertake the similar purpose passenger flow. Under the above assumptions when the bus and subway travel routes overlaps more than 4km in Guangzhou, the coordination between subway and bus is low. At this time, the passenger competition will be formed between the two kinds of public transportation which will result in unnecessary waste of resources. The results indicate that it's necessary to control the length of the line coincides between the subway and bus within 4km.

5 Conclusions

As one of the city's most important modes of transportation, the coordination between urban rail transport and other travel modes will affect the city's passenger capacity directly. In this paper, we calculates the time value of different income levels by dividing income levels. By constructing predictive traffic share rate mode based on generalized travel cost. Forecasting the proportion of residents on different income levels in kinds of travel modes. Calculating the VOT and TTC of travel modes by weighting VOT. So far, the model is completed. By comparing the TTC of travel modes in different operating speed and travel distance. Finally, we study the coordination between urban rail transport and other travel modes, then determine the suitable travel distance and line layout program.

Abstract: On-board cable in the subway is an essential competent in the whole power system for the electric transmission, power allocation and signal control. The cable insulation condition plays an important role in safe and reliable operation of the subway. Traditional insulation detection devices haven't taken into account the impact of the electromagnetic interference on insulation test detection. Severe electromagnetic interference would impact the unstable operation and the data volatility of the online monitoring system. Therefore, the paper proposes optimal double T filter based new approach to cable insulation detection in the subway, and analysis its transmission characteristic by using mathematic method. From the software simulation and actual measure, the paper concludes that the proposed approach can not only improve the detection accuracy of the cable insulation, but can also fit with 50Hz noise signal interference produced by on-broad machine in the subway. With the proposed approach, stability of equipment operation can be guaranteed.

Key words: *The subway equipment, cable insulation detection, optimalizing double T filter, Electromagnetic interference*

1 The necessity of electric cable insulation measurement in the subway

Today's subway is complete in almost every function, and be equipped with various electrical equipment. Therefore more cables are laid correspondingly. The train body is mainly made of stainless steel and aluminum alloy. Once cables are scratched or broken, electricity leakage will occur and take serious effects for the train operation and passengers' safety. Additionally, when the cable insulation is damaged, the ground fault will occur, lead to the faulty operation of signal circuits and control circuits, or even result in serious consequences such as fire hazard and equipment damage. More seriously, these effects will break the normal operation of the whole system, and even cause casualties.

In urban rail transit systems, many electronic power's frequency are 50Hz, and it's very easy for the power signal to produce noise interference by many ways. These devices include overhead traction wires, leakage coaxial cable, mobile communication modules, etc. Some testing equipment is more sensitive to electromagnetic interference. This device can't work normally or even lead to mis-operation, if affected by electromagnetic interference. It will bring serious consequences to the safe operation of rail transit system.

The traditional design of cable insulation detection concept fails to go through the field noise filter processing. However, because of the complexity of on-board power grid and operating environment in subway train, the noise interference is a necessary considered factor to improve the precision of the cable insulation detection. Based on traditional experiences, there are few researches about precise insulation detection in the complex noise interference the environment of the subway train. Therefore the high precise cable insulation detection approach is particularly important for complex noise interference environment in the subway train.

2 Double T filter based new cable insulation detection hardware design for the subway train

In the subway train operating environment ,there is serious electromagnetic interference produced by working machine which disturbing insulation detection system .In order to eliminate the measurement error produced by 50Hz noise jamming ,we combine double T filter circle with insulation detection system.

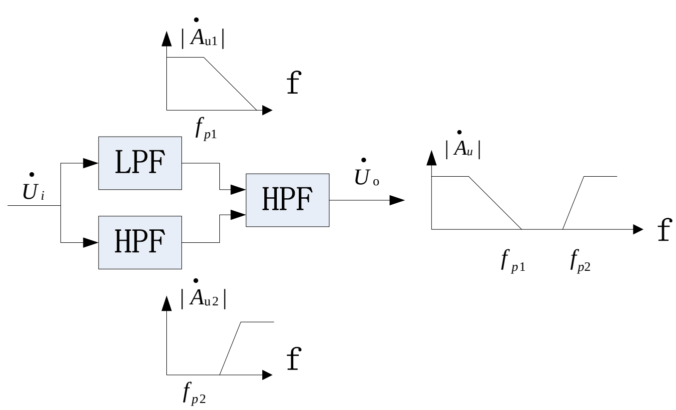

Figure 1. Block diagram of band-stop filter

In the signal processing circuits, it is often to use the band stop filter blocking interference signals fleeing. As shown in figure 1, band-stop filter usually use a low-pass filter (LPF) and a high-pass filter (HPF) in parallel. The cutoff frequency, fp1, of the low pass filter should be lower than the cutoff frequency, fp2, of high-pass filter. The value of the stop band is (fp2 - fp1).Band-stop filter can constitute a noise-squelch circuit which can have very good filtering effect on strong interference signals at certain frequency.

The double T filter makes use of the characteristics of capacitance that the impedance of capacitance changes with fluency. By appropriately selecting the value of capacitors and resistor, the double T filter can effectively select the desired frequency signal and filter out interference signals.

Assume that $\dot{U}_i$ is the input signal of the double T network filter and $\dot{U}_o$ is the output signal of the double T network filter. Using F stands for its frequency characteristic, it follows that.

$$F = \frac{\dot{U}_o}{\dot{U}_i} = \frac{s^2 + w_o^2}{s^2 + 4sRC + w_o^2} \quad (1)$$

Let $s = jw$, we can get:

$$F = \frac{1 - w^2C^2R^2}{(1 - w^2C^2R^2) + j4wRC} \quad (2)$$

Let $w = w_0 = \frac{1}{RC}$, we can get:

$$|F| = \frac{|1 - w^2C^2R^2|}{\sqrt{(1 - w^2C^2R^2)^2 + (4wCR)^2}} \quad (3)$$

From the above equation, it can follow that double T filter presents a good filtering ability for w_0 signal .In order to make use of the double T filter's characteristics filtering out interference signals from source which can have influence on the accuracy of sampling the voltage, double T filter is integrated into the Insulation test voltage sampling circuit.

Cable insulation detection band stop filter is shown in Figure 2 which is composed of RC low pass filter and RC high pass filter. A low pass filter is composed of resistor R15, R16 and capacitor C33.It constitutes a T-network filter; high-pass filter is composed of capacitors C33, C37 and resistor R12 .It constitutes a T-network filter. Two filters are symmetrical T-shaped structure, which is called a symmetrical double-T network band-stop filter.

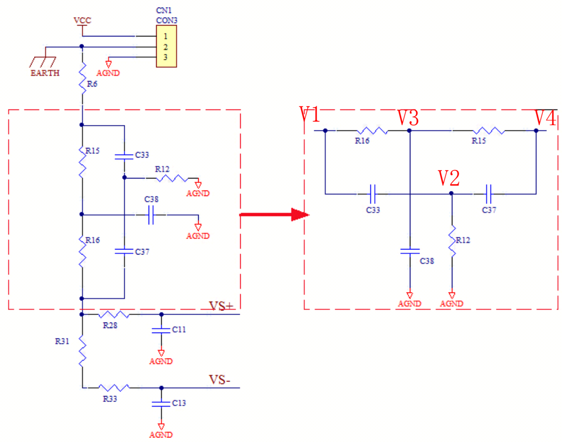

Figure 2. Double T filter

In figure 2 each components must reach following require relationship: C33=C37=C;R16=R15=R;C38=2C;R12=R/2;

Accroding to electronic circuit, we can get the equation：

$$(V_1\text{-}V_2)sC = \frac{2V_2}{R} + (V_2 - V_4)sC \tag{4}$$

$$\frac{V_1 - V_3}{R} = \frac{V_3 - V_4}{R} + 2V_3 sC \tag{5}$$

$$\frac{V_3 - V_4}{R} + (V_2 - V_4)sC = 0 \tag{6}$$

Finally, we can get the relationship as following:

$$w_0 = \frac{1}{CR}, 2\beta = \frac{4}{CR}, Q = \frac{w_0}{2\beta} = \frac{1}{4}$$

3 Positive Feedback Double T filter based new cable insulation detection hardware design for the subway train

The electronic circuit in figure 2 has a shortcoming that the value of Q only be 1/4.So, we can't adjust the Q. If we want to make Q be adjustable, and we want to try ourselves best to increase the filter effect, we must take advantage of positive feedback. The revised electronic circuit was shown in figure3.

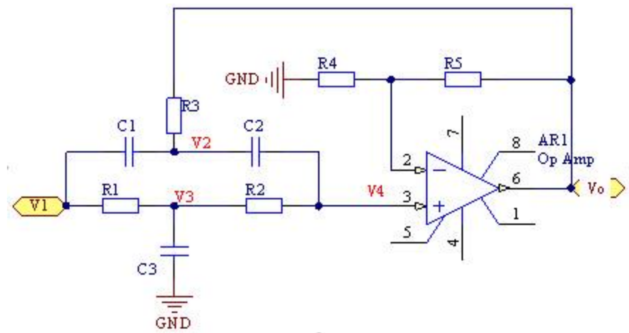

Figure 3. Optimal Double T Filter circuit

$$(V_1 - V_2)sC = \frac{2(V_2 - AV_4)}{R} + (V_2 - V_4)sC \tag{7}$$

$$\frac{V_1 - V_3}{R} = \frac{V_3 - V_4}{R} + 2V_3 sC \tag{8}$$

$$\frac{V_3 - V_4}{R} + (V_2 - V_4)sC = 0 \tag{9}$$

We can get:

$$\frac{V_4}{V_1} = \frac{C^2R^2S^2 + 1}{C^2R^2S^2 + (4-2A)CRs + 1} \tag{10}$$

By calculating, we can get:

$$Q = 1/(4-2A)$$

From the relationship between A and Q, we can know that the more A trends towards 2 the more the Q are. If A>2, the system will be unstability. We can see the difference from the below figure.

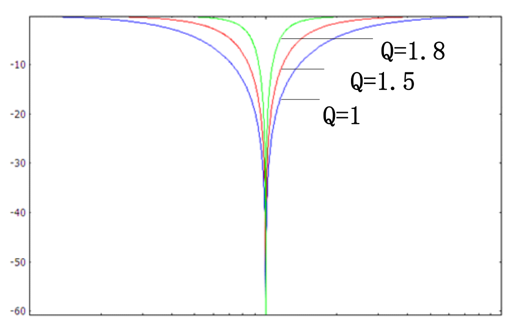

Figure 4. Amplitude-frequency when A=1, A=1.5andA=1.8

Among the figure 4, the blue line stands for the amplitude-frequency when A=1.The red line stands for the amplitude-frequency when A=1.5.The green line stands for the amplitude-frequency when A=1.8.

4 Insulation resistance sampling principle

Figure 5 shows the insulation resistance sampling, this electronic circuit don't use the double T filter with the positive feedback. However, the resistance sampling principle is the same thing , We can catch the principle of insulation resistance sample by the following figure.

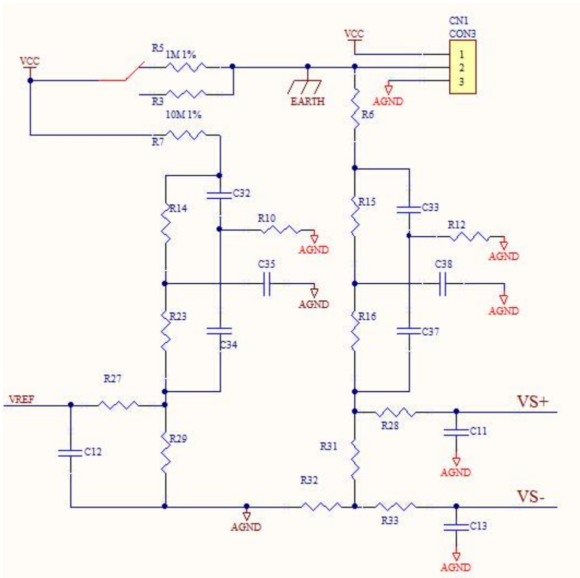

Figure 5. Insulation resistance of the sampling, correction module circuit diagram

VREF is benchmark power of ADC. V + and V - are the ADC input voltage signal (sampling voltage waited for conversion) the principle of insulation resistance measurement is stated as follows:

By controlling relay to connect 1M R5 to insulation resistance sampling circuit, the R5 is measured insulation resistance.

Where, n stands for the resolution of the AD converter,

X_{1M} is the conversion result when the value of insulation resistance is 1M. we can get:

$$\frac{\frac{R_{31}}{R_{29}}*(R_7+R_{14}+R_{23}+R_{29})}{R_5+(R_{15}+R_{24}+R_{31}+R_{32})}=\frac{X_{1M}}{2^n} \tag{11}$$

Let $(R_{15}+R_{24}+R_{31}+R_{32})$ =B and $\frac{R_{31}}{R_{29}}*(R_7+R_{14}+R_{23}+R_{29})$ =A, we can get:

$$\frac{2^n*A}{R_5+B}=X_{1M} \tag{12}$$

A and B are the parameter to be corrected.

In the same way, by controlling relay to connect 10M R6 to insulation resistance sampling circuit. At present the R6 is measured insulation resistance.

Eventually we can obtain equation (13):

$$\frac{2^n*A}{R_6+B}=X_{10M} \tag{13}$$

Where, X_{10M} is the conversion result when the value of insulation resistance is 10M.According to the equation (12) and (13) we can obtain the equations group.

$$\frac{2^n*A}{R_5+B}=X_{1M}\ ;\ \frac{2^n*A}{R_6+B}=X_{10M} \tag{14}$$

Though calculating we can obtain the value of A and B.

A= A_1 、B= B_1

Finally we can get equation (15)

$$\frac{2^n*A_1}{R_x+B_1}=X \tag{15}$$

Where, R_x is the insulation resistance of the cable under test, X is the conversion result produced by AD converter when R_x is the insulation resistance of the cable. Before operating electric cable insulation measurement system, system will start the correction function regularly and get the value of A and B which are needed to calculate the insulation resistance of the cable. After the correction, the correcting circuit switch is disconnected and the electric cable is connected. This algorithm can effectively reduce the influence of floating resistance fluctuating with the external environment, and largely improve the precision of the measurement of insulation resistance.

5 The simulation and the result analysis

5.1 Filter Simulation And Analysis

In order to prove that the double T filter with the positive feedback circuit is able to filter fixed frequency noise and perform better. We conduct an experiment by the Multisim simulation software .

After simulation by Multisim, we can get the simulation results about the amplitude-frequency characteristic curve in figure 6.

The left figure stands for the amplitude-frequency of Positive Feedback Double T Filter, while the right figure stands for normal Double T Filter. By comparing the two figure, we can conclude that Positive Feedback Double T band-stop filter's band-stop filter characteristics perform excellent, and stop band is narrower. Figure 7 is the mixture picture by two curves. It shows that the amplitude amplification of 50Hz signal is -45.972 dB when using the Positive Feedback Double T Filter, while the amplitude amplification of 50Hz signal is -42.772 dB when using single Double T Filter. So Positive Feedback Double T filter based new cable insulation detection can effectively suppress the interference produced by signal whose frequency is 50Hz.

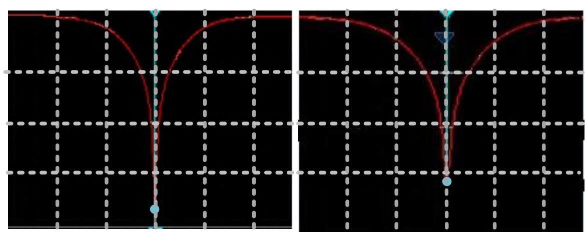

Figure 6. The amplitude frequency characteristics

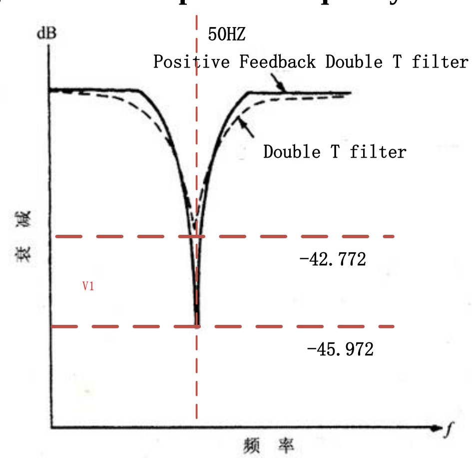

Figure 7. Amplitude frequency characteristics area chart

5.2 The experiment of measuring insulation resistance

In the experiments, we replace the insulation resistance of the cable with testing resistance and use signal generator load interference noise to simulate the interference signal in the subway train when subway train is running.LTC2484 is used in insulation detection circuit. Power supply voltage is 400V. Fluke digital multi-meter whose type is 187 was used in experiment for measuring and calibration standard table and its impedance measurement accuracy is 0.05%. The values of testing resistance were 5.1 K, 10 K, 15 K, 20 K, 25 K, 50 K, 100K, 1 M, 5 M, and 10M. The experimental results are shown in table 1,2and 3.

The experimental results in Table1 was obtained by tradition insulation testing device without filtering. The results in Table 2 were obtained by insulation testing device based on double T filter. The results in Table 3 were obtained by insulation testing device based on double T filter with the positive feedback.

Table 1. Tradition insulation testing

NO.	Grounding resistance nominal value / KΩ	Grounding resistance measured value / KΩ	Means for measuring the value of the / KΩ	Relative error%
1	5.1	5.07	4.91	3.58
2	10	10.03	9.53	4.69
3	15	14.94	13.83	7.77
4	20	20.15	18.92	5.39
5	25	24.85	22.80	8.78
6	50	49.85	45.91	8.17
7	100	99.45	95.73	4.27
8	1000	994.75	908.40	9.16
9	5000	4969.15	4762	4.76
10	10000	9939.05	9445	5.55

Table 2. Insulation testing device based on double T filter

NO.	Grounding resistance nominal value / KΩ	Grounding resistance measured value / KΩ	Means for measuring the value of the / KΩ	Relative error%
1	5.1	5.07	5.00	1.96
2	10	10.03	9.82	1.80
3	15	14.94	14.72	1.86
4	20	20.15	19.6	2.0
5	25	24.85	24.51	1.96

6	50	49.85	49.04	1.91
7	100	99.45	98.19	1.81
8	1000	994.75	981.8	1.82
9	5000	4969.15	4913.5	1.73
10	10000	9939.05	9833	1.67

Table 3. Insulation testing device based on double T filter with the positive feedback

NO.	Grounding resistance nominal value / KΩ	Grounding resistance measured value / KΩ	Means for measuring the value of the / KΩ	Relative error%
1	5.1	5.07	5.03	1.39
2	10	10.03	9.88	1.20
3	15	14.94	14.82	1.20
4	20	20.15	19.75	1.25
5	25	24.85	24.71	1.18
6	50	49.85	49.34	1.03
7	100	99.45	99.09	0.91
8	1000	994.75	986.8	1.32
9	5000	4969.15	4933.5	1.33
10	10000	9939.05	9893	1.07

Through the experiment results, it follows that insulation resistance measurement error measured by tradition detection method is bigger than that measured by double T filter based new cable insulation detection approach and the insulation resistance measurement error measured by double T filter is bigger than measured by double T filter with positive feedback .It is proved that the electromagnetic interference has a great influence on the insulation detection and can easily make the on-line insulation monitoring system unstable . We can see from table 3 that test errors remain below 1.5%, which satisfies the requirement of subway train cable insulation level. We can draw a conclusion that double filter with positive feedback based new cable insulation detection approach can effectively filter electromagnetic interference and makes the equipment working in a stable state in the course of subway running.

7 Conclusion

Traditional insulation detection equipment places great emphasis on the algorithm to improve detection precision, but places little emphasis on eliminating the electromagnetic interference. Although there are many designs about shielding electromagnetic interference for every electrical module in the subway train, the cables for modules connecting are still influenced by electromagnetic interference. This paper puts forward a new scheme which combines cable insulation testing with positive feedback double T filter. The simulation experiment proves that positive feedback double filter based new cable insulation detection approach can effectively filter electromagnetic interference and makes the equipment working in a stable state in the course of subway running and measurement error is less than 1.5% when conducting the sampling measurement for insulation resistance of less than 2M, furthermore, devices can running reliably and steadily and conform to the requirements of the site.

Abstract: The unification and coordination problems of the ticketing system is an important link for realizing the barrier free transfer in the city passenger transportation system. At present, the unification and coordination of the ticketing system between Metro and bus system of the major cities in our country has been basically achieved. But difficulties in the unification and coordination of the ticketing system between the high speed railway of the city region and the city track transportation have still been existed. In the foundation of the elaboration in the kind and system of the subway ticket in the domestic and foreign, it is concluded that: there are 3 kinds of subway ticketing modes, a fixed ticketing mode, multistage ticketing mode and a composite ticketing mode; in China, subway ticketing modes are classified into 2 types, as all public transport mode available and Metro special. On the base of the analysis of the demand and current situation of the unification and coordination of the ticketing system between the Chengdu Metro and Chengguan High-speed Rail, a solution is put forward. To cannel Chengguan High-speed Rail ticket real name system, using the IC card and magnetic ticket ticketing system mode, establishing a unified clearing center, to achieve the initial coordination of Chengdu Metro and Chengguan High-speed Rail ticketing. Finally, puts forward some existing problems corresponding suggestions and measures of the ticketing coordination are put forward.
Keywords: Chengdu Metro; Chengguan high-speed rail; Ticketing mode; Ticketing system.

1 Introduction

As a project of the urban infrastructure construction, the subway has become an effective way to solve traffic problems in big cities, and it has been an important symbol of the modernization of the city's traffic, and its development reflects the level of the city's comprehensive strength in a great extent.

The coordination between the various urban public transport modes in the line network, management systems and ticketing organizations has been the premise to realize the integration operation of urban passenger transport systems. Urban passenger transport systems are composed of the rail transportation system, the rapid bus transit system, the bus system and other passenger transport systems (including the car, non-motor vehicles and so on). Therefore, the realization of the seamless connection between the city rail transit and other transport systems has been the basic element of the establishment of the comprehensive transportation system in modern city. And the unification of the ticketing mode and the integration of the fare system are the keys (ZHAN Xiaoju, 2006).

2 Profiles of the subway ticketing mode and the ticket type

At present, there are no unified ticketing system models in the subway of the foreign big cities. The limited city cards of New York can be used to transfer the subway system or the bus system. And the infinite city card can be used to take the free bus for many times. In Hong Kong, the metro ticket pricing is drawn up by the meter, and they are different from adults and children. Free ride coupon is used in Tokyo metro, it can be used to take all the railway, subway and buses in the 23 district, and the unification of the ticketing system is achieved in the metro, the railway and the bus system (WANG Ke, 2007). In China, the pattern of ticket pricing is not uniform, specifically speaking, the section ticketing system adopts to Guangzhou, while the metered fare ticketing system adopts in Chengdu.

3 The subway ticketing mode form and ticketing types installation

(1) The current ticketing mode

At present, the fixed ticketing mode, the multistage ticketing mode and the composite ticketing mode are used in the domestic and foreign countries. The fixed ticketing mode is namely the single ticketing mode; the multistage ticketing mode contains the timing ticketing mode, the section ticketing mode and the metered ticketing mode; the composite ticketing mode includes the metered combining timing ticketing mode and the times combining timing ticketing mode. Advantages and disadvantages of the single ticketing mode and the multistage ticketing mode are shown in the table 1 (ZENG Qiong, 2011).

Table1. Comparison of advantages and disadvantages of subway ticket mode

Ticketing mode	Advantages	Disadvantages
Single ticketing	Easy to use, less equipment, low cost.	Cannot reflect the relationship between distance and operation cost.
Metered ticketing	Reflect fairness, increase ticket revenue, reduce government subsidies.	Difficult to manage and carry out, require the technical equipment to support.
Section ticketing	Convenient for passengers transfer, reflect the change of the Metro Center station's edge distance.	Difficult to operate in the different charging regional edge, and difficult to determine the charge standard.
Timing ticketing	Improve the subway service level, beneficial for traffic demand management	Fares and riding distance have no direct relation, unfavorable to the high cost transportation system.

(2) Subway tickets in China

The metro ticket in our country can be divided into two types by issuing mechanism: the "one card" issued by the city bus company applicable to the all buses; the "one ticket" issued by the Metro Inc only suitable for subway system. The "one ticket" include the one-way ticket, the stored value ticket and the times ticket. Automatic fare collection system (AFC system) can form some extended ticket types according to the three main kinds of tickets, through the combination of parameters, such as: the round-trip ticket, the section ticket, the regional deadline ticket, the travel ticket, and the emergency ticket.

(3) Chengdu metro ticketing mode setting

Chengdu Metro Line 1 takes the composite ticketing mode combining the timing and metering, the basic fare starting from 2 yuan, the whole section cost 5 yuan valuation for interval single car at the station, passengers for single trip can stay in the station for to 2 hours; the metro ticketing mode in line 2 are the same with the line 1, the free vertical transfer can be realized in the Tianfu Square station, the harmony and unification between Metro and metro are realized. The subway tickets have two kinds, one-way IC card and Tianfu IC card. The one-way ticket issued by Metro Inc is only applicable to subway station and only available on the sale day; Tianfu card issued by the city, including ordinary card, student card and the old card, can be applied to the city bus.

3 Subway ticketing system

The subway ticket system is composed of the AFC system, the ticketing system, the financial system, the management system etc. In the administration of subway operation, the ticketing organization is monitoring, coordinating, commanding and scheduling on the ticket flows, income flows, and the running of AFC system. The quality of ticketing organization is directly related to the operation of the company's income and economic benefit. Therefore, the effective management of the AFC system is the core of metro operation management.

The AFC system is a city rail traffic charging system based on communication network, automatic control, non-contact RF IC card, sensing and other high-techs. It can realize the fare, seat, ticketing management, liquidation, statistics and other functions, and accomplish the automatic meter and timing charging in the passenger's trip process, the efficiency and benefits are effectively improved (CHEN Yu, 2009).

3.1 Subway ticketing system management mode

Metro ticketing system generally adopts the ticket center and station ticket, namely the two level management, the center ticket management mainly takes the plan management, the specific operation to face the passenger are mainly taken by the station ticket management.

The ticket policy is the core of the center ticket management. The ticket policy sets all kinds of business's implementation rules, such as fare revenue, check the financial, settlement. Including: fare formulation principle, the fare scheme, AFC system, settlement system and so on. The fare scheme is formulated the basis fare table, while provides the basic criterion of passengers, such as time, mileage and so.

The station ticket management mainly includes three aspects, namely revenue management, ticket management and ticketing facilities management. Revenue management is mainly completed by the AFC system; ticket management is mainly to realize the ticket recycling and reusing; facilities and equipment management is to repair and maintenance the daily operation and hardware and software upgrade work for AFC system and equipment.

3.2 The station ticketing processing rules

In a one-way ticket for example, passengers should buy a tickets according to the start point and end point of the applicable fare, valid for a single use, and is to be recovered when you are outbound. The specific ticket processing rules are shown in figure 1. The one-way ticket and Tianfu card in Chengdu metro are processed by the similar rules.

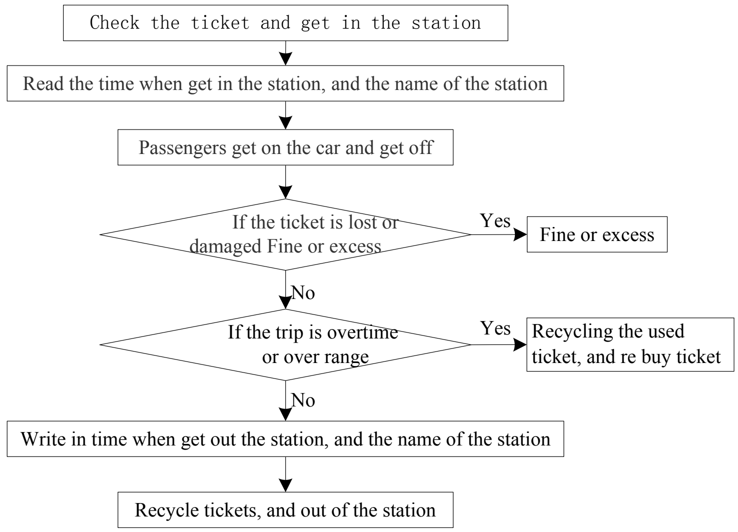

Figure 1. one-way tickets processing rules

4 Analysis of the ticketing system's coordination between Chengdu Metro and the Intercity Railway

4.1 The requirement and current status of the ticketing system's coordination

Chengguan High-speed Rail major services business and commuter passenger flows from Chengdu to Dujiangyan (Pengzhou), and it has very strong public welfare. Chengdu Metro Line 2 is introduced into the Xipu station on Chengguan High-speed Rail, ticketing system compatible for the two ticketing modes needed to be built, to achieve barrier free transfer in one stage.

Chengguan High-speed Rail has the short, the direct and the cross line passenger flows, the short distance passenger flow of XiPu Railway Station is mostly the transfer passenger flow from Metro Line 2. The current tickets use the real name system, divided into ordinary tickets and thermo sensitive magnetic tickets. Tickets are attached to the passenger's name, the identity card number, the travel time, the interval, the seat number and other information. The originating station uses the "check before wait" ticket mode, the other stations along the line use "check after wait" artificial checking or AFC mode (YANG Jie, 2010).

4.2 The solution for the coordination of the ticketing system

Since the railway CRH train tickets use the real name system, the transfer in XiPu station between the Metro Line 2 and Chengguan High-speed Rail is limited. The thermos sensitive magnetic tickets and the paper tickets are used in High-speed Rail, while IC card (Tianfu cards and single trip tickets) is used in Chengdu Metro. There are some difficulties in the realization of unification of the two ticketing systems. Therefore, a proposal to cancel the rail name ticketing system in Chengguan High-speed Rail is raised up.

(1) Cancel the rail name ticketing system in Chengguan High-speed Rail

The real name ticketing system makes the passenger ticket system complicated, making the involving problems complexity, greatly reducing the efficiency of the city bus passenger transport. As for the independent closed operation mode is used in Chengguan High-speed Rail, making passengers must purchase their tickets when out of the station to transfer to other railway in Chengdu Railway Station. If the real name system can be cancelled, it will not affect the operation of the internal other railway lines. In addition, Chengguan High-speed Rail will have big public welfare and others, so that it is more similar to the operating of urban rail transit. Therefore, cancel the real name ticketing system can be considered.

(2) Take the mode that combining the IC card and the magnetic ticket

IC card system is formed by the line ticket center, the station ticketing system and field equipment, and the ticketing mode uses the non-contact IC card, the technical standards, keys and data structures is the same with Chengdu Metro. The line ticket center should be set in Chengdu station of Chengguan High-speed rail, the station ticketing system of the station along the line should be accessed to the line ticket center (YANG Jie, 2010).

Magnetic ticketing system is composed of the regional ticket center, the station ticketing system and the field equipment, the ticket mode takes the original thermal magnetic paper ticket. All stations along Chengguan High-speed Rail ticketing system should be accessed to the area ticket center.

For the two ticketing system, the station ticket center and field equipment need to have the function to be able to identify, control, statistics, analysis.

(3) Establish the unified clearing center.

A rail transportation clearing center is required to be set by Chengguan High-speed Rail and Chengdu Metro in order to meet the need for unified the operational standards, share information in the ticketing system. The ticketing center should take unified management on the two ticketing systems, and adjusting ticketing operation mode, in order to realize distribution statistics and the financial income on both ticketing systems.

By canceling the real name ticketing system in Chengguan High-speed Rail and improving ticketing systems, using paper thermal magnetic tickets and subway IC card, the initial unity and coordination of the subway and intercity railway and between the bus system are realized.

5 Conclusions

Using the above ticketing system, although the harmonization and unification of the intercity railway and the subway are initially realized, there are still some constraints, mainly reflected in the following aspects:

① If the ticket system need integration, a lot of money for reconstruction on the related equipment update will be needed to invest and the cost of construction will be increased;

② The investment and management of ticket clearing center need operators to determine in consultation, more difficult exists in building;

③ The station using magnetic tickets and IC cards, the compatibility of automatic fare collection terminal for two ticketing modes will be needed to set.

④ Ticketing system requires real-time updates to control the number of passengers by the ticket checking system, thus reducing the probability of overcrowding of trains in the High-speed Rail.

Optimization Analysis of the Energy-Absorbing Structures in a Subway Train

Bingzhi Chen and Ruixian Qin

School of Traffic and Transportation, Dalian Jiaotong University, Dalian, Liaoning 116028, China. E-mail: chenbingzhi06@hotmail.com

Abstract: In this paper, energy-absorbing structures at the front end of the subway trains are studied through size optimization and topology optimization. To maximize the energy absorption and minimize peak impact force, the size optimization is conducted by optimization software iSIGHT and collision simulation software PAM-CRASH. Moreover, the topology optimization of energy-absorbing device is obtained by software OptiStruct. The results indicate that combining the two aforementioned optimization techniques is capable to improve the crashworthiness of the energy-absorbing structures and the passive safety of the subway train.
Keywords: Subway train; Energy-absorbing structure; Collision simulation; Optimization design.

1 Introduction

At present, the subway has been vigorously developing in many cities, because of its huge capacity and quick speed. Once a traffic accident occurs, it will cause serious casualties and property losses. Therefore, the development of collision safety technology is very necessary. The technology is divided into active safety and passive safety protection . Active safety technology refers to take positive measures to prevent the occurrence of accident. And passive protection technology is the means through good crashworthiness design and energy absorption protection system to guarantee the life safety of the driver and passengers. With the improvement of train speed, the crashworthiness design of train has become a hot topic in the current rail safety field.

The optimization design of crashworthiness problems are being studied extensively . In 1975, Bylytschko first carried out the finite element analysis on train collision, using the shell element and the explicit time integration technology. By the response surface method, Kurtaran conducted the crashworthiness of the constrained

Optimization of the cylindrical shell and the simplified train body structure. With maximum energy absorption as the optimization objective and impact load as the constraint, Fang and Jiao used the response surface method to optimize the rectangular section of the thin-walled member considering the crashworthiness.

In this paper, the optimization design of the subway train is divided into the following Firstly, considering both the energy absorption maximum and minimum peak impact force, the size of energy absorption structure is optimized using the optimization software iSIGHT and the collision simulation software PAM-CRASH. Secondly, the topology optimization of energy-absorbing device is obtained by the software OptiStruct. At the same time, the crashworthiness of this device is verified.

2 The Theory of Crash Simulation and the Finite Element Model of Train

2.1 The Basic Theory of Crash Simulation

Currently, the main collision analysis software are based on the following formulas:

The momentum equation,

$$\sigma_{ij,j} + \rho f_i = \rho \ddot{x}_i \tag{1}$$

Where ρ is the density, σ_{ij} is the stress, f_i is the volume force and $\ddot{x}_i$ is the acceleration.

The mass conservation equation,

$$\rho \ \gamma = \rho_0 \tag{2}$$

Where γ is the relative volume, ρ_0 is the initial density.

The energy conservation equation,

$$\dot{E} = VS_{ij}\dot{\varepsilon}_{ij} - (p+q)V \tag{3}$$

Where $\dot{E}$ is the current energy, $\dot{\varepsilon}_{ij}$ is the strain rate, q is viscous resistance, S_{ij} is given by $S_{ij} = \sigma_{ij} + (p+q)\sigma_{ij}$, p is the pressure given by $p = -\sigma_{kk}/3 - q$, V is the volume.

So, the equilibrium equation in the Galerkin form is

$$\int_V (\rho\ddot{x}_i - \sigma_{ij,j} - \rho f_i)\delta x_i dV + \int_{S^0} (\sigma_{ij}^{+} - \sigma_{ij}^{-})n_j \delta x_i dS + \int_{S^1} (\sigma_{ij} n_j - t_i)\delta x_i dS = 0 \tag{4}$$

By the divergence theorem, formula (4) can be written as follow:

$$\int_V (\sigma_{ij}\delta x_i)_{,j} dV = \int_{S^0} (\sigma_{ij}^{+} - \sigma_{ij}^{-})n_j \delta x_i dS + \int_{S^1} \sigma_{ij} n_j \delta x_i dS \tag{5}$$

So, the finite element discretization form is

$$M\ddot{x}(t) = P(x,t) - F(x,\dot{x}) \tag{6}$$

In which, M is the mass matrix, $\ddot{x}(t)$ is the node acceleration vector and P is the load vector. The numerical method mostly applies the explicit central difference method.

2.2 The finite element model of train

In this paper, a simplified finite element model was built. The size of element used is 25 mm, and local refinement is needed for interesting part. The length of train is 19000mm, the width is 2650mm, the height is 3785mm and the weight is 32t. The head of the train is divided into 870793 elements. Figure 1 shows the finite element model and the partial enlarged view of the front part.

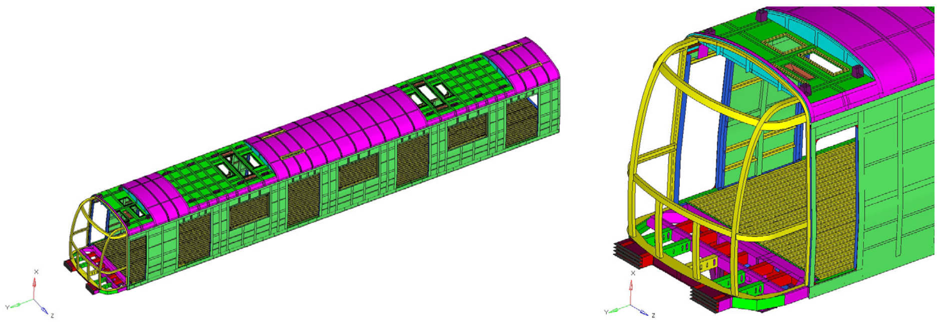

Figure 1. The finite element model

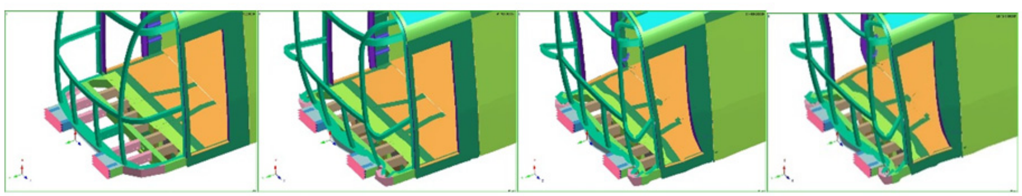
3 The size optimization of the energy absorption structure

3.1 The simulation analysis of collision

Under the working condition of fully loaded head train at a 25km/h speed impacting on a rigid wall, the simulation result of collision is gotten.



0ms 80ms 60ms 250ms

Figure 2. The deformation of front-end at the different time

From Figure 2, we can see the first level of energy-absorbing beam has been completely collapse. But the deformation of the second level is very small. Therefore, this level doesn't work.

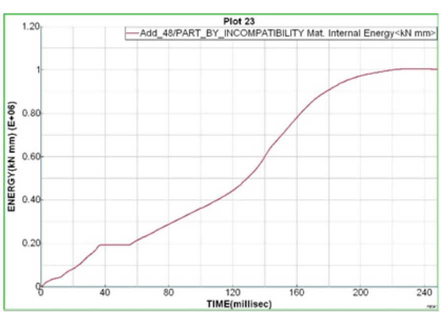


Figure 3. The sum of energy absorption

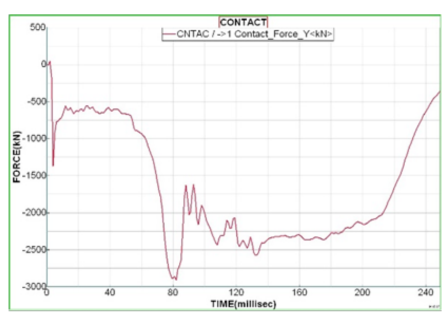

Figure 4. The history of collision force

From Figure 3, the absorbed energy curve shows the total energy absorption is 1005KJ. The peak impact force in Figure 4 is 2908KN.

3.2 The optimization model

In this paper, the following multi-objective optimization model is solved.

$$\begin{aligned} &\max E(T_1,T_2) \\ &\min F(T_1,T_2) \\ &s.t.\ 1.0 \le T_1 \le 4.0 \\ &\qquad 4.0 \le T_2 \le 10.0 \end{aligned} \tag{7}$$

Where, E is the total energy absorption by the energy-absorbing beam, F is the collision force, the design variable T_1 and T_2 are the two level's thickness of energy-absorbing beam.

Figure 5. The iteration of the optimization problem

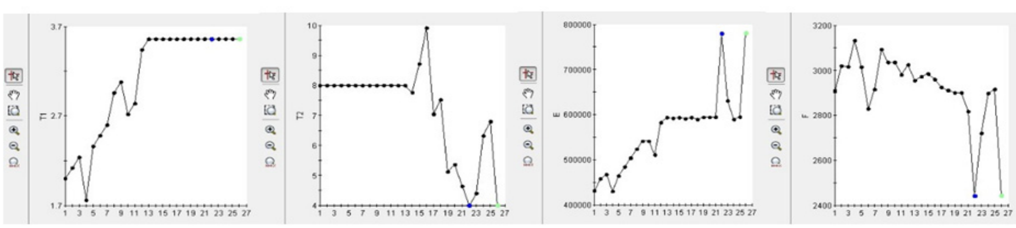

Figure 6. The iteration history of T_1, T_2, E and F

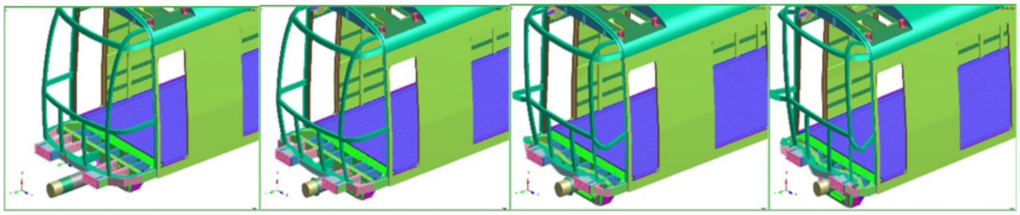
The data and curves optimization history are shown in Figure 5 and Figure 6. For the last iteration, the thickness of the first level energy-absorbing beam is 3.56 mm, the thickness of the second level is 4.0 mm, the total energy absorption is 780630J and the maximum collision force is 2443.4KN.

3.3 The optimization results

For the optimized energy-absorbing beam, the simulation result of collision can be gotten.



T=0ms T=81ms T=162ms
T=250ms

Figure 7. The deformation at different time after size optimization

As it can be seen from Figure 7, until the end of the collision, the floor didn't occur any deformation. The first level of energy-absorbing beam completely collapse, and the second level is only partly damaged. So, the optimized structure can withstand the more powerful impact. The performance of this structure is improved greatly.

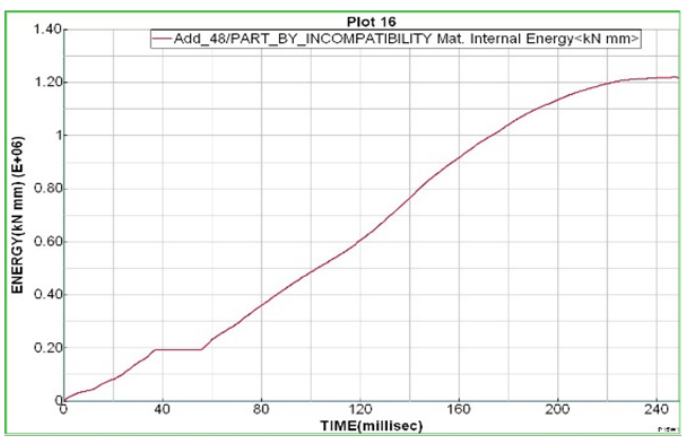


Figure 8. The total energy absorbed by the optimized energy absorption structure

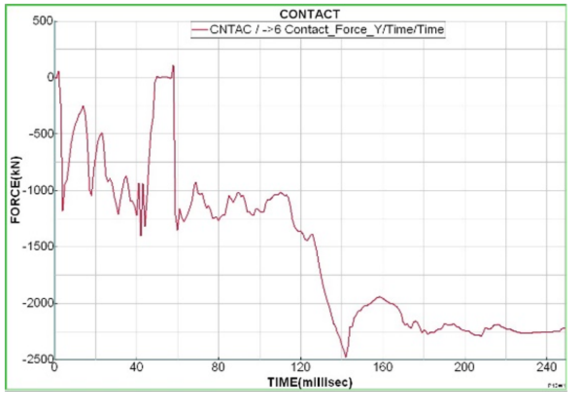

Figure 9. The curve of collision force

Table 1. Structure performance before and after size optimization

	Absorbed energy	Mass of the energy-absorbing	Peak impact force
Before	1005KJ	72.38kg	2908KN
After	1218.5KJ	62.25kg	2477.3KN
Improvement	21.2%	13.9%	14.8%

From the above curves and table, we can see the total absorbed energy is raised to 1218.5KJ and the peak impact force of collision is reduced to 2477.3KN. Furthermore, the mass of the two-level energy-absorbing beams reduced 10.13kg. So, by the size optimization, the performance of crashworthiness is improved and the lightweight design is realized.

4 Topology optimization of the second level energy-absorbing beam

4.1 The design domain and the working condition

The front end of the train is shown in Figure 10. The design domain is the second level energy-absorbing beam. By the topology optimization, the collision resistance of train is improved and the lightweight design is realized. A 3000 KN impact force is applied at anti-creeper position, when the longitudinal displacement constraint is considered.

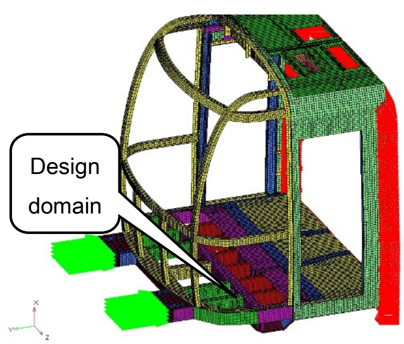

Figure 10. Topology optimization condition

4.2 The result of topology optimization

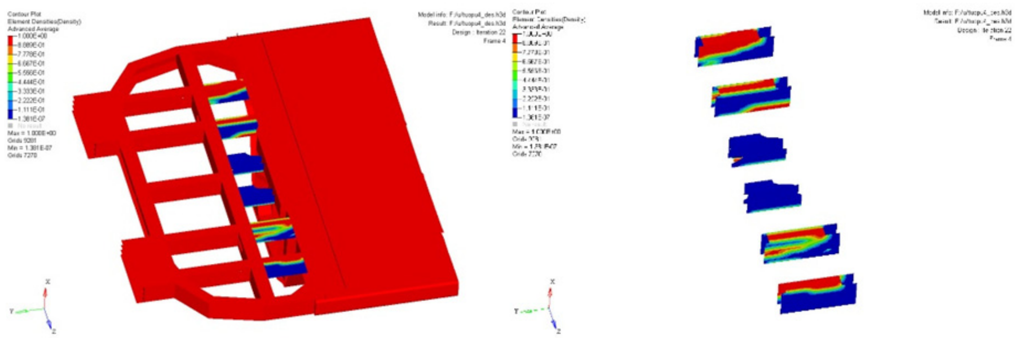

Figure 11. The result of topology optimization

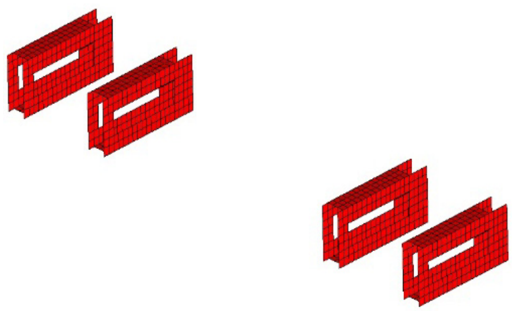

Figure 12. The redesigned energy-absorbing

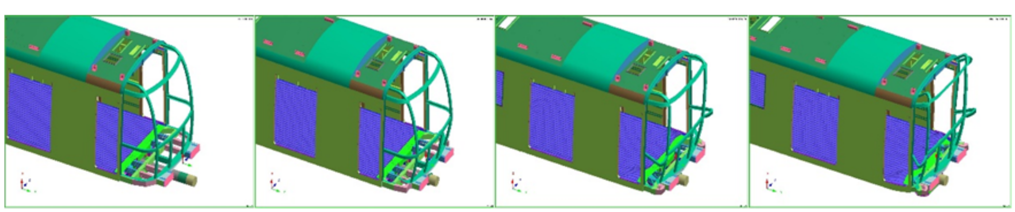
In Figure 11, the red part represent the density is 1, and the blue part represent the density is 0. Other colors represent the density is between 0 and 1. We can see that the stiffness is big enough so that the two beams in the middle can be removed. Moreover, the other four beams can be designed as shown in Figure 12.

4.3 The result analysis of collision considering the redesigned energy-absorbing structure



T=0ms T=80ms T=160ms T=250ms

Figure 13. The deformation at different time after topology optimization

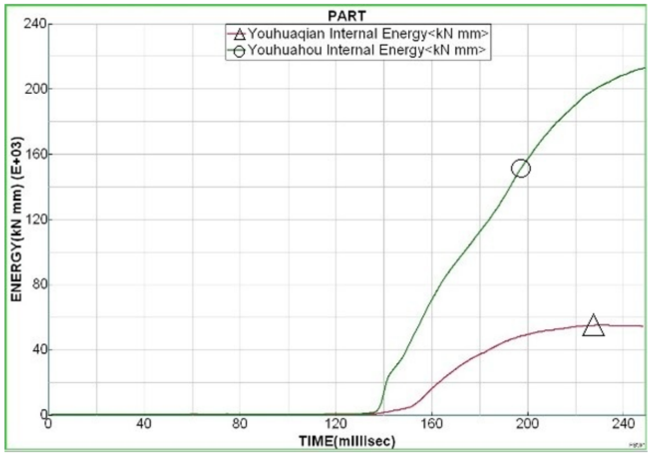


Figure 14. The total energy absorbed by the redesigned energy absorption structure

Figure 15. The curve of collision force

Table 2. Structure performance before and after topology optimization

	The absorption energy of the second level beam	Mass of the energy-absorbing beam	Peak impact force
Before	55KJ	72.38kg	2908KN
After	214.9KJ	50.3kg	2739.1KN
Improveme nt	339.8%	30.5%	5.8%

From Figure 13, we can see the first level of energy-absorbing beam completely collapse and the second level is also damaged. But the second level can absorb more energy if the impact force greater. In table 2, the absorbed energy of second level is raised to 214.9KJ and the peak impact force of collision is reduced to 2739.1KN. Furthermore, the mass of the two-level energy-absorbing beams reduced 22.08kg. So, the performance of energy-absorbing beam is improved and the lightweight design is realized.

5 Conclusion

Combining the optimization software iSIGHT and the collision simulation software PAM - CRASH, multi-objective size optimization of the energy-absorbing beams was realized. Moreover, the topology optimization method is used for the second level energy-absorbing beam by the software OptiStruct. The results show that, the crashworthiness of the energy-absorbing beam is improved and lightweight design is realized. It is suggested that the present optimization design method is capable to improve the passive safety of the railway vehicle collision.

Abstract: This paper constructed efficiency evaluation model which was based on the Data Envelopment Analysis of urban transit systems from the input and output perspective. Meanwhile, this article obtained annual technological and scale efficiency and quested the solutions of urban transit systems' problem discovered in this evaluation studies through evaluating the Peking's efficiency of urban transit systems from 2003 to 2012 with this model. Thereby, this post provide the basis for improving the organization and optimization of urban transit systems furtherly. As a result, the pure technical efficiency of Peking's transit system is higher, but for achieving the best performance, it is necessary to increase investment in technology. Generally, the returns to Peking's transit systems' scale is increasing. And it has a large room to enhance.

Keywords: Urban transit; Efficiency evaluation; DEA model; Peking.

1 Introduction

The urban transit systems is not only the important urban infrastructure but also the Social Welfare Cause that is related to the national interest and people's livelihood. Currently, Public Transportation Priority has become the consensus of the metropolitan transportation development, developing energetically public transit is important channel to settle the urban traffic jam. Under the background of urban traffic congestion, the effective method to improve the urban transit systems' efficiency can be found and the degree of organization and optimization of the urban transit systems can be enhanced with this method through evaluating the transit system's efficiency and analyzing the significant factors influencing the efficiency. Significant research has been conducted by international and domestic academics in recent years, one of the most mature quantitative research methods is Data Envelopment Analysis (DEA). Attah K. Boame(2004) concluded that the average technical efficiency was about o.78 through evaluating the efficiency of Canadian urban transit systems from 1990 to 1998 with the method of DEA and analyzing the change of efficiency with the method of Tobit analysis of regression. Matthew G. Karlaftis(2004) studied the relationship among efficiency effectiveness and economies of scale of 256 transit systems of American over a 5 year time period with the DEA and frontier production functions and obtained the conclusion that efficiency and effectiveness were positively correlated and economies of scale was dependent on output. SHEN Xiaojun et al (2008) obtained the annual technological and scale efficiency and put forward of the corresponding improvement measures with the application of DEA to evaluate the efficiency of urban transit systems of Nanjing from 2000 to 2006. YANG Ming et al (2011) established the evaluation model of public transport operation efficiency with the application of DEA, analyzed the advantage and disadvantage of Changsha by comparing with others through laterally assessing the capital cities' public transport operation efficiency of 17 provinces in 2009 and analyzed its development performance of transit operation mainly through longitudinally evaluating the data of Changsha from 2001 to 2010. In home and overseas study, because of the difference of objects of study selected by scholars, which make the evaluation indicators selected in DEA model diversity and the analysis to the factors which influence the efficiency is weak. As a result, this paper will assess the urban transit systems of Peking with the channel that study and construct DEA model and propose measures purposefully through analyzing the results of assessment.

2 The evaluation model and Indicator system of urban transit systems' efficiency

Currently, there is no unified definition regarding the efficiency of urban transit systems at home and abroad, the conventional definition adopted is derived from which is based on the definition of efficiency. Economic efficiency is the degree meeting the need of people, which is afforded by social production with the usage of available resources. Generally, it often be called the resource utilization rate. Thus it can be seen that efficiency mainly exam the relationship between the input and output. The efficiency of urban transit systems, it also be called the input-output ratio of resource of urban transit systems, is a correlation between the investment to public transit and the satisfaction degree of people's need to public transit generated by the investment to public transit.

Data Envelopment Analysis is a method of efficiency rating that be in the crossing field of operational research, management science and econometrics, which was created by A. Charnes and W. W. Cooper et al (1978) who were the American famous operational research experts. Decision Making Units (DMU) is the department or unit with the multiple input and output. DEA can assess Decision Making Units' comparative validity through making sure the production frontiers and whether the DMU is on the stochastic frontier of production possibility set or not, it's a nonparametric evaluation method without the need of parameter estimates. The evaluation result obtained by picking the DEA model is independent of the effectiveness of any human factors, in other words, it is objective. This paper picks up the CCR model and C^2GS^2 model that are the mostly representative model of DEA models, the CCR model can be used to assess the scale efficiency of DMU and overall effectiveness of technical efficiency, the C^2GS^2 model can be used to assess pure technical efficiency. The C^2GS^2 model can be obtained through increasing the constraints $\sum_{j=1}^{n}\lambda_j = 1$ in the CCR model.

The specific expression of CCR model is as followed:

Assume there are n decision-making units, each decision unit has m inputs and s outputs. The input and output vector corresponding with the decision-making unit j (j=1, 2… n) are $X_j = (x_{1j}, x_{2j}, ..., x_{mj})^T$ and $Y_j = (y_{1j}, y_{2j}, ..., y_{sj})^T$ respectively. x_{ij} is the volume of investment of input i *to* decision-making unit j , $x_{ij} > 0$, $i = 1,2,...,m$, $j = 1,2,...,n$; y_{rj} is the quantity of output r *to* decision-making unit j, $y_{rj} > 0$, $r = 1,2,...,s$, $j = 1,2,...,n$.

Building the DEA validity of linear programming models of decision-making unit j:

$$\min \theta = V_D$$
$$s.t.\begin{cases} \sum_{j=1}^{n}\lambda_j X_j \le \theta X_{j_0} \\ \sum_{j=1}^{n}\lambda_j Y_j \ge Y_{j_0} \\ \lambda_j \ge 0; j = 1,2,...,n \end{cases} \quad (1)$$

After introducing the slack variables ,the model(1) becomes：

$$\min \{\theta\}$$
$$s.t.\begin{cases} \sum_{j=1}^{n}\lambda_j X_j + S^- = \theta X_{j_0} \\ \sum_{j=1}^{n}\lambda_j Y_j - S^+ = Y_{j_0} \\ \lambda_j \ge 0; j = 1,2,...,n \\ S^- \ge 0; S^+ \ge 0 \end{cases} \quad (2)$$

X_{j_0} and Y_{j_0} are respectively the index vector of input j_0 and output j_0; θ is the shrink ratio; λ_j is the linear combination coefficient of decision-making units; S^- and S^+ are slack variables. DMU_{j_0} is the necessary and sufficient condition of DEA effective, the optimal value of linear programming $V_D = 1$,and λ_j, S^-,S^+ have the optimal solution. If $\theta^* = 1$, $S^{-*} = S^{+*} = 0$ then the decision-making unit j_0 is DEA effective; If $\theta^* = 1$, S^- and S^+ exist non-zero value, then the decision-making unit j_0 is DEA weak efficiency; if $\theta^* < 1$, then the decision-making unit j_0 is DEA invalid.

This paper chooses three input indicators and one output indicator through analyzing the physical truth, which is based on the definition of urban public transport system efficiency and the application of DEA model. Input indicators: the urban transit systems includes the common input of person, vehicle, and road elements and so on. However, as the index that characterize the Labor and capital investment, the number of operating vehicles (cars) and operating range (km) directly reflects the resources investment of the public transport system, the number of operating vehicle include all of the operating vehicles of bus, rail transit and taxi, operating range is divided into bus operating mileage and rail transit operating range. Output indicators: the annual passenger traffic is the most direct reflection of the operation effect of public traffic. DEA model's input and output indicators are shown in Table 1.

Table 1. The input and out index of urban public transport system

Type	content	Code
Input indicators	Number of operating vehicles	X1
	Bus operating range(km)	X2
	Rail transit operation range(km)	X3
Output indicators	Annual passenger traffic（100 million ）	Y

3 Evaluation of public transportation efficiency of Peking during 2003-2012

In the use of DEA model, taking every year from 2003 to 2012 as a DMU (DMU1, DMU2… DMU10), then, longitudinal evaluation of efficiency of Beijing public transportation is conducted based on those DMUs. The data of all input-output indexes comes from the annual report of Beijing traffic development, as shown in Table2.

Table 2. The input of Peking public transportation during 2003-2012

Year	Operating vehicles（Car）	Operation mileages of bus（Km）	Operation mileages of rail transit（Km）	Annual passenger traffic（Million visitors）
2003	83788	17908	114	47.8
2004	73252	16823	114	56.9
2005	86715	19206	114	59.0
2006	87089	19360	114	54.2
2007	87125	17353	142	55.2
2008	89821	17857	200	66.2
2009	90330	18270	228	72.7
2010	90611	18743	336	75.9
2011	91078	19460	372	79.2
2012	92431	19547	442	83.2

Based on Table2, taking the DEAP and BBC software to analysis the efficiency of Beijing public transportation, the analysis results (Table 3) mainly contain overall efficiency θ^*, pure technical efficiency σ^* and scale efficiency S^*. Technical efficiency means the output ability of a certain input. Scale efficiency reflects the scale of the development of public transportation.

Table 3. The analysis results of the efficiency of Beijing public transportation during 2003-2012

DMU	Overall efficiency θ^*	Pure technical efficiency σ^*	Scale efficiency S^*	Scale efficiency
DMU1（2003）	0.826	1.000	0.826	Increasing
DMU2（2004）	1.000	1.000	1.000	Steady
DMU3（2005）	1.000	1.000	1.000	Steady
DMU4（2006）	0.919	1.000	0.919	Increasing
DMU5（2007）	0.901	0.969	0.930	Increasing
DMU6（2008）	0.964	0.990	0.974	Increasing
DMU7（2009）	1.000	1.000	1.000	Steady
DMU8（2010）	0.981	0.997	0.984	Increasing

DMU9（2011）	1.000	1.000	1.000	Steady
DMU10（2012）	1.000	1.000	1.000	Steady
Average	0.959	0.996	0.963	

From the analysis results in Tabe3, we found that the efficiency of public transportation of Beijing was 1 in 2004,2005,2009,2011 and 2012; this result proves the input of public transportation was properly exploited and got the maximum output. The overall efficiency was less than 1 in 2003,2006,2007,2008 and 2010 which means DEA invalid; this consequence indicates the efficiency of public transportation is low in those years.

Because of overall efficiency is equal to the multiplying of pure technological efficiency and scale efficiency in the DEA model, the DEA's invalidity in 2003 and 2006 attribute to the scale in-efficiency. It reflects that the scale of public transit is small and the returns to scale is increasing. However, the reasons making the DEA invalid also include the lower pure technological efficiency in the year of 2007, 2008 and 2010, in other words, it fails to obtain the largest output under certain conditions of investment, which concludes that public transit should be allocated reasonably and the efficiency of public transit should be enhanced. Generally, the average efficiency, average pure technological efficiency, and average scale efficiency of Peking's public transit is 0.959, 0.996, and 0.963 respectively. And the returns to scale of urban transit systems is increasing or invariable in general. It indicates that the pure technological efficiency is higher, but increasing the technological investment making the Peking's public transit achieve the best state should be supposed and the scale efficiency has a large room to promote.

4 Conclusions

Data Envelopment Analysis is a very efficient method to study the comparative validity among the departments or units of the same type and it also is a very comprehensive method to deal with the multi-objective decision-making problem in theory. Meanwhile, there is no need to estimate the parameter in advance with the usage of DEA, it is independent of the effectiveness of the unit of index selected and it has the incomparable advantage in the aspect of avoiding the subjective factors and decreasing error.

This paper established the efficiency evaluation model based on DEA and introduced the evaluation index system with the usage of this method to evaluate the efficiency of Peking's urban transit systems. Meanwhile, this article obtained the annual technological and scale efficiency and put forward corresponding improvement countermeasure tentative ideas that have practical guiding significance through comparing the Peking's urban transit systems' efficiency from 2003 to 2012 over a period of ten years. For meeting the need of future urban transit systems' development, enhancing the overall transport capacity and efficiency of urban transit systems and the urban transit systems' organization and optimization, this paper suggests that the reasonable strategies should comprehend the structural contradictions in urban transit systems exactly, coordinate the input and output of every kinds of traffic resource reasonably, integrate the existing urban traffic resources and construct the urban transit systems with high accessibility, high coverage rate and high efficiency through establishing the DEA model and empirical study.

Compiling Operative Plans of Rail Transit Turn-Back Stations

Jingchun Geng

The Third Railway Survey and Design Institute Group Corporation, No. 10, Minjiang Rd., Hebei District, Tianjin 300251, China. E-mail: jingchungeng@163.com

Abstract: It is an important task that compiling operative plans of turn-back stations in surveying, designing and operating urban rail transit projects. The quality of operative plans not only has direct effects on the results of operation management, but also reflects the rationality of turn-back station's layouts. This paper transforms the problem of trains connection in station operative plans into spliced network planning of trains with many constraints and objective functions. Based on the Windows environment, using object-oriented language Visual C++ 6.0, this paper develops the Rail Transit Station Operative Plans Compiling and Simulation System with Trains Traction Calculation. It can achieve the goal that standardized management, fine simulation and optimization, provide technical support and decision-making reference for the surveying, designing and operation departments in urban rail transit.

Keywords: Rail transit; Turn-back station; Operative plans; Spliced network planning.

With the urbanization process in China, passenger flows and traffic demands increase rapidly, especially on holidays and morning and evening rush hours. The urban road congestion problems have severely restricted the sustainable development of cities. Looking at the development of the world's major cities, urban rail transit in major cities has been the preferred solution to solving the problem of traffic congestion and achieving urban sustainable development. Since the Beijing Subway Line 1 project started in 1965 and by the end of 2014, 38 cities that including Beijing, Shanghai, Tianjin, Guangzhou, Shenzhen, Nanjing and other have been approved to construct urban rail transit; among of them 22 cities, including Beijing, Shanghai, Tianjin, have built 95 urban rail transit lines whose operating distance has been over 2900 km and will reach 6956 km by 2020. Thus, Chinese rail transit will enter a new building boom period during the Thirteenth Five years.

In recent years, with more and more rail lines put into operation, rail transit is becoming increasingly important in alleviating urban traffic congestion. Based on practical experiences in rail transit operation, we can infer that there are still some difficulties for rail transit, which are station layouts, rolling stock performance, signal control, operation level and other factors, to deal with passenger flows in morning and evening rush hours, and the turn-back capacity is the key to enhancing system capacity. Consequently, no matter in choosing station layout during the phase of project surveying and designing, or in compiling operative plans during the phase of operation and management, capacity calculations in turn-back stations become the focus, and compiling operative plans is the only way to calculating turn-back capacity. Nowadays whether in surveying and designing department, or in operation and management department, the basic solution to compiling operative plans is under traditional artificial arrangements, and supplemented by train traction calculation or using artificial experience to estimate trains running time, then to diagram station capacity by artificial means. Thus compiling operative plans not only is subject to the makers' ability and experience, but also takes a lot of time, and the accuracy of the calculation would be difficult to be guaranteed, seriously affecting the decision of station layout and operational plans. Therefore, it's of great importance to propose a compiling model for station operative plans and develop simulation software.

1 Simulation Model

The key point of compiling turn-back station operative plans is to figure out succession plans among ahead and rear trains. Thus we can transform this problem into spliced network planning of trains with many constraints and objective functions.

Based on some operation activities like train's movement, running licenses, passengers getting on and off trains and so on, station operative plans regard these operation activities as "tasks" in spliced network. According to different categories of "tasks", station operative plans' spliced network among different "tasks" is divided into "craft relations" (or called as "interlock relations") and "organizational relations." "Craft relations" refers to occupied sequences of trains determined by lines' and stations' layouts and signal designing, mainly including trains' running process from point A to point B and logic relations of signal equipment' successive activities. "Organization relations" refers to the sequence determined by train operations and passenger services, including passengers getting on and off the train and driver's cages veering.

1.1 Station operative plans network

S_i^m is the beginning time for train i to do the task m; F_i^m is the end time for train i to do the task m; D_i^m is the minimum time needed by train i to do the task m; and the set of the task's attributes is $m_i = \left(S_i^m, F_i^m, D_i^m\right)$.

As is shown in Fig.1, to describe the spliced relations between two successive tasks, Time-Interval is defined as the minimum time interval needed to do the two tasks. $F_i^m TS_j^n$ (Finish to Start) is the time interval between the end time for the train i to do the task m and the start time for the next train j to do the task n; $F_i^m TF_j^n$ (Finish to Finish) is the time interval between the end time for the train i to do the task m and the end time for the next train j to do the task n; $S_i^m TS_j^n$ (Start to Start) is the time interval between the start time for the train i to do the task m and the start time for the next train j to do the task n; $S_i^m TF_j^n$ (Start to Finish) is the time interval between the start time for the train i to do the task m and the end time for the next train j to do the task n.

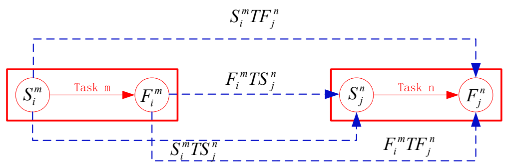

Fig.1 Sketch of spliced network relations

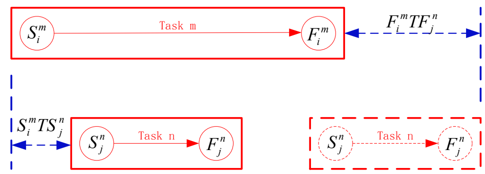

Fig.2 Sketch of mixed spliced network relations

As is shown in Fig.2, Mixed Spliced Relations is defined to describe the relations between two tasks, and it's controlled by $S_i^m TS_j^n$ and $F_i^m TF_j^n$. In other words, the start time between two tasks must keep a certain time interval, and so does the end time.

When compiling station operative plans, there must exist conflicting routes limited by interlocking relations of switches and intersecting between ahead and rear trains, which shows the two tasks can't start or be over at the same time. Thus we can transform conflicting routes of the two tasks into the spliced relations among $S_i^m TS_j^n$, $F_i^m TS_j^n$, $F_i^m TF_j^n$ and $S_i^m TF_j^n$.

1.2 Constraints of compiling station operative plans

(1) Stations must complete all the "tasks" once and only once.

Suppose that station need hand N trains, and each train i needs to do M tasks; χ_i^m represents the task m of train i whether to start or not.

$$\chi_i^m = \begin{cases} 1 & \textit{the work m of train i has started} \\ 0 & \textit{otherwise} \end{cases} \quad (1)$$

$$\gamma_i^m = \begin{cases} 1 & \textit{the work m of train i has ended} \\ 0 & \textit{otherwise} \end{cases} \quad (2)$$

$$\sum_{i=1}^{N}\sum_{m=0}^{M} \chi_i^m \gamma_i^m = 1 \quad \forall i, m \quad (3)$$

(2) Satisfy the requirements of time interval $S_i^m TS_j^n$, in other words, only when the task m of all trains i just ahead starts, can train j begin the task n.

Decision variable β_{ij}^{mn} represents the task m of train i being just ahead of the task n of train j.

$$\chi_j^n = \begin{cases} 1 & \sum_{i=1}^{N} \beta_{ij}^{mn} \chi_i^m = 1 \\ 0 & \textit{otherwise} \end{cases} \quad \forall j, n \quad (4)$$

ES_j^n represents the earliest start time for train j to do the task n. EF_j^n represents the earliest end time for train j to do the task n. Thus the earliest start time for train j to do the task n equals the task m's start time of all trains i just ahead pluses the maximum value of the time interval $S_i^m TS_j^n$. The earliest end time for train j to do the task n equals the task m's earliest start time ES_j^n of all trains just ahead pluses the minimum time needed by task n.

$$ES_j^n = MAX\left(S_i^m + S_i^m TS_j^n \middle| \beta_{ij}^{mn} \chi_i^m = 1 \quad \forall i, m\right) \tag{5}$$

$$EF_j^n = ES_j^n + D_j^n \tag{6}$$

(3) Satisfy the requirements of time interval $S_i^m TF_j^n$, in other words, only when the task m of all trains i just ahead starts, can train j end the task n.

$$\gamma_j^n = \begin{cases} 1 & \sum_{i=1}^{N} \beta_{ij}^{mn} \chi_i^m = 1 \\ 0 & otherwise \end{cases} \quad \forall j, n \tag{7}$$

Thus EF_j^n is the maximum value of the task m's start time of all trains i just ahead pluses the time interval $S_i^m TF_j^n$.

$$EF_j^n = MAX\left(F_i^m + S_i^m TF_j^n \middle| \beta_{ij}^{mn} \chi_i^m = 1 \quad \forall i, m\right) \tag{8}$$

$$ES_j^n = EF_j^n - D_j^n \tag{9}$$

(4) Satisfy the requirements of time interval $F_i^m TS_j^n$, in other words, only when the task m of all trains i just ahead ends, can train j start the task n.

$$\chi_j^n = \begin{cases} 1 & \sum_{i=1}^{N} \beta_{ij}^{mn} \gamma_i^m = 1 \\ 0 & otherwise \end{cases} \quad \forall j, n \tag{10}$$

Thus the earliest start time for train j to do the task n equals the task m's end time of all trains i just ahead pluses the maximum value of the time interval $F_i^m TS_j^n$.

$$ES_j^n = MAX\left(S_i^m + F_i^m TS_j^n \middle| \beta_{ij}^{mn} \gamma_i^m = 1 \quad \forall i, m\right) \tag{11}$$

$$EF_j^n = ES_j^n + D_j^n \tag{12}$$

(5) Satisfy the requirements of time interval $F_i^m TF_j^n$, in other words, only when

the task m of all trains i just ahead ends, can train j end the task n.

$$\gamma_j^n = \begin{cases} 1 & \sum_{i=1}^{N} \beta_{ij}^{mn} \gamma_i^m = 1 \\ 0 & otherwise \end{cases} \quad \forall j,n \tag{13}$$

Thus EF_j^n is the maximum value between the task m's end time of all trains i just ahead and the time interval $S_i^m TF_j^n$.

$$EF_j^n = MAX\left(F_i^m + F_i^m TF_j^n \middle| \beta_{ij}^{mn} \gamma_i^m = 1 \quad \forall i,m\right) \tag{14}$$

$$ES_j^n = EF_j^n - D_j^n \tag{15}$$

(6) To compact all tasks and make the operative capacity in station reach the maximum, the time interval between two successive tasks is expected to be the least. LAG_{ij}^{mn} represents the time interval between the task n's start or end time of train j and the task m's end or start time of the just ahead train i.

$$MIN\left(LAG_{ij}^{mn}\right) = \begin{cases} \left(ES_j^n - ES_i^m\right)\beta_{ij}^{mn} \chi_i^m & \forall S_i^m TS_j^n \\ \left(ES_j^n - EF_i^m\right)\beta_{ij}^{mn} \chi_i^m & \forall S_i^m TF_j^n \\ \left(EF_j^n - ES_i^m\right)\beta_{ij}^{mn} \gamma_i^m & \forall F_i^m TS_j^n \\ \left(EF_j^n - EF_i^m\right)\beta_{ij}^{mn} \gamma_i^m & \forall F_i^m TF_j^n \end{cases} \tag{16}$$

2 The optimal solution of model and the operative capacity of stations

When compiling station operative plan network, some regulations about the operative process of inbound and outbound trains need to be made. Thus suppose that stations first do inbound tasks of trains from adjacent stations or sections, then do the tasks about passenger service, and finally do the task of outbound. Meanwhile we assume the earliest start time of network plans is 0 and no task has been done; in other words, the start time for the first train to do the first task is 0 (that is $S_{i=1}^{m=1} = 0$); and then we plus some time one by one according to the task requirements and spliced relations.

Operative capacity in rail transit stations is closely related to the compiling of operative plan, which is represented by time intervals of two successive trains and divided into arrival time intervals and departure time intervals according to the differences between arriving in and departing from stations. The shorter of time intervals, the more trains handled in a unit time (usually 1 hour), and the larger of the operative capacity of stations.

$CF_{i,j}$ represents the departure time interval between two successive trains, which is the difference between the two last tasks' end time (that is $m = M$) of the former train i and the latter train j; $DD_{i,j}$ represents the arrival time interval between two successive trains, which is the difference between the two first tasks' start time (that is $m=1$).

$$CF_{i,i+1} = F_{i+1}^{m=M} - F_i^{m=M} \tag{17}$$

$$DD_{i,i+1} = S_{i+1}^{m=0} - S_i^{m=0} \tag{18}$$

$CF_{\min}$ is the minimum departure time interval, which is the maximum value among all departure time intervals （$CF_{i,j}$） between two successive trains. $DD_{\min}$ is the minimum arrival time interval, which is the maximum value among all arrival time intervals （$DD_{i,j}$） between two successive trains.

$$CF_{\min} = MAX\left(\overset{N-1}{\underset{i=1}{CF}}{}_{i,i+1}\right) \tag{19}$$

$$DD_{\min} = MAX\left(\overset{N-1}{\underset{i=1}{DD}}{}_{i,i+1}\right) \tag{20}$$

HT（headway of trains）represents the minimum tracking headway of two successive trains, choosing the maximum value among $CF_{\min}$ and $DD_{\min}$. During the compiling of station operative plans, by properly arranging the task start and end time of two successive trains, we can minimize HT namely, we get the optimal solution and also make station capacity get the maximum value.

$$HT = MAX(CF_{\min}, DD_{\min}) \tag{21}$$

HT is defined to represent how many pairs of trains received or sent by station in one hour.

$$N_h = 3600 / HT \tag{22}$$

3 Analysis of Case Simulation

According to the model above, based on the Windows environment, using object-oriented language Visual C++ 6.0, we develop the Rail Transit Station operative plan Compiling and Simulation System with Trains Traction Calculation. As is shown in Fig.3, we take this certain rail transit station as an example and simulate by means of the system. In this case, station layout is a turnaround station with one island platform and dual crossovers before the station; trains consist of 4 motor cars and 2 trail cars and their maximum running speed is 80km/h; the limited speed of switches is 35km/h; the total time for passengers get on and off the train is 90 seconds. Assuming the two turn-back tracks and platform being empty at the beginning, we can use the system to simulate the station operative plans, as is seen in Fig.4.

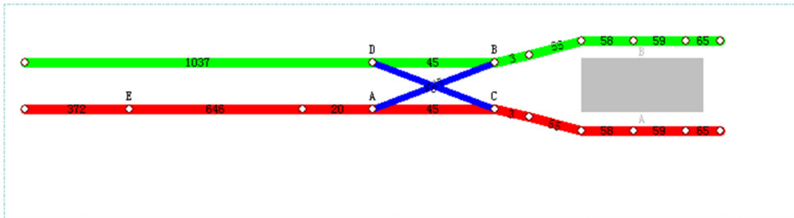

Fig.3 sketch of station yards

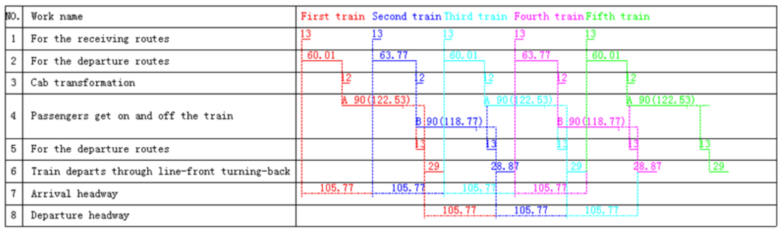

Fig.4 graph of station operative plans

According to the station operative plans obtained by simulation, the optimal operative process for this station layout is described as follows:

Step 1: The first train arrives in the station straightly through Point E and stops at Side A of the station, and then passengers get on and off the train, meanwhile apply for a lateral arrival routing and clear the signals.

Step 2: The second train arrives in through Point E and stops laterally at Side B after one tracing headway, and then passengers get off the train.

Step 3: After the second train stops, convert the switches and clear the signals. When the station dwell time is over, the first train departs laterally and Side A becomes unoccupied.

Step 4: After the first train leaves and the track circuit Point D at the before-station crossover gets unoccupied, convert the switches and clear the signals; then the third train arrives in through Point E straightly and stops at Side A of the station.

Step 5: After the third train stops, convert the switches and clear the signals, when the station dwell time is over, the second train departs straightly and the Side B of the station gets unoccupied.

Step 6: After the second train leaves and the track circuit Point D at the before-station crossover gets unoccupied, convert the switches and clear the signals; then the fourth train arrives in through Point E laterally and stops at Side B of the station.

Step 7: After the fourth train stops, convert the switches and clear the signals, when the station dwell time is over, the third train departs laterally and the Side A of the station gets unoccupied.

Step 8: After the third train leaves and the track circuit Point D at the before-station crossover gets unoccupied, convert the switches and clear the signals; then the fifth train arrive in through Point E straightly and stops at Side A of the station.

From here to Step 5 forms a cycle.

From Fig.4, we can conclude the minimum departure headway ($CF_{\min}$) and arrival headway of this station layout is 105.77s; the minimum tracing headway is $HT = MAX(105.77,105.77) = 105.77$ s; and the number of receiving and sending trains in one hour is $N_h = 3600 / HT = 34$ pairs.

4 Conclusions

The quality of operative plans for turn-back stations directly restricts and influences the choice of turn-back stations' layouts in the survey and design phase and the determination of running plans in the operation and management phase. The paper transforms the problem of compiling station operative plans into spliced network planning with many constraints and objective functions. The Rail Transit Station Operative Plans Compiling and Simulation System with Trains Traction Calculation is developed to achieve the standardization, refinement and optimization of urban turn-back station operative plan compilation. The paper sets a certain turn-back station as an example to simulate and prove the feasibility of the model, providing technical support and decision-making reference for the surveying, designing and operation departments in urban rail transit.

Abstract: Improve urban rail transit system's operation efficiency, guarantee the operation scheme's economical, reasonable and effective has important significance to ensure the city passenger transport system's whole performance work normally. This paper from the view of network level, put train operation process simulation with passenger travel process simulation together, research the microcosmic simulation problem of urban rail transit network passenger transport process, use the unified modeling language to describe the simulation system's analyze, design and realize; and take Suzhou rail transit network planning in 2015 as an example, achieve its' passenger travel process's microcosmic simulation. The microscopic simulation technology, can recur the whole network passenger transport process, achieve elaborate statistical time and efficiency index, and to lay a solid foundation for the operation scheme's analysis, decision-making and evaluation.
Keywords: Urban rail transit; Unified modeling language; Passenger travel process; Microcosmic simulation.

1 Preface

Network operation is the inevitable developing trend of urban rail transit. Lines in the network interconnected by transfer station, make different lines' passenger transportation activities correlative, interact, and variety, therefore, compared with the single line condition, rail transit network operation are more complicated in passenger flow distribution forecast, transportation plan making, event emergency treatment and other aspects. In order to achieve network transport organization's optimal management, it is especially important to grasp the passenger flow's time-space distribution laws, master the interaction relationship between sections, stations, trains and passenger flows in the network from the nerwork level.

This paper suggest to build system entity model, establish the rail transit passenger travel process simulation system, using UML tools to describe the system's analysis, design and development, and take Suzhou rail transit network planning in 2015 as an example, achieve its' passenger travel process's microcosmic simulation. The system can provide effective auxiliary decision-making tools and methods to network passengers' distribution analysis and forecasting, transport scheme's optimization, emergency resources' optimal allocation and etc.

2 Modeling analysis based on UML

Here to describe system analysis by use case diagram and activity diagram, to describe system design by class diagram, sequence diagram and state diagram, to describe system development by component diagram.

2.1 System analysis

The system's user include network basic information administrator and simulation valuator. Basic information administrator is responsible for various data management needed by simulation, such as: network structure basic data, train operation data, station time and passenger flow data, etc. Simulation valuators used the 'simulation parameters management module' to invoke the basic data, after setting up the relevant parameters, start the passenger transport process simulation calculate. Figure 1 show its use case diagram.

'Passenger travel process simulation calculate' is the core use case of the system, its function describe as table 1 shows, other use cases are provide basic data and control parameters for this use case. 'Network basic information manage' use for edit rail network's topological structure, and the line, station, section's attribute information and etc. 'Train operation process calculate' use for calculate various lines' train operation time-distance data under specified operation scheme. 'Station time manage' use for set the passengers' time distribution consumed during the get in, outbound and transfer process. 'Station passenger flow data manage' use for set the station's get in passenger's total number, time distribution and destination stations' distribution.

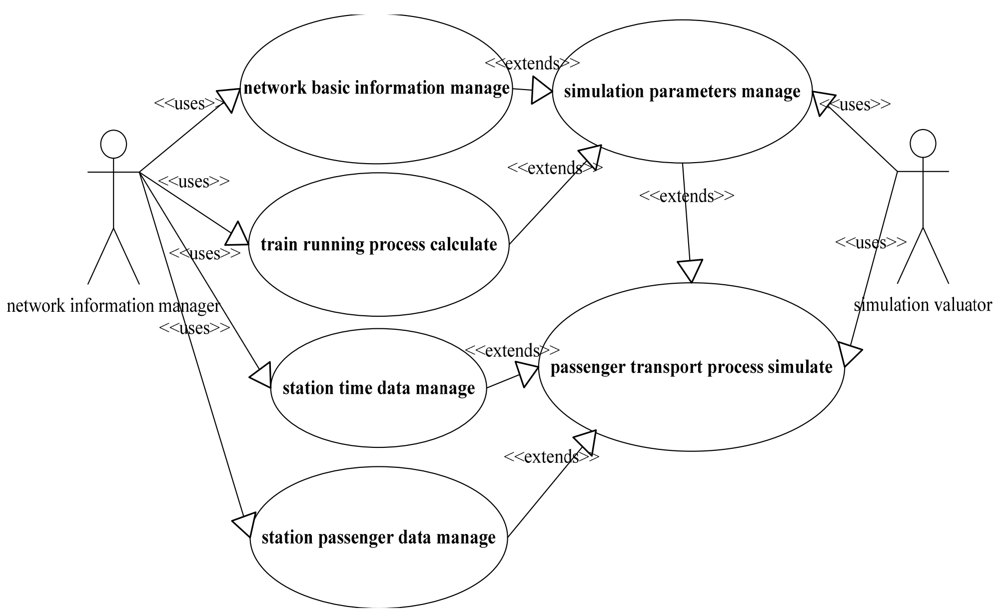

Figure 1. passenger travel process simulation system use case diagram

Table 1. 'passenger travel process simulation calculate' use case's function description

Function	Detail information
describe	Based on the basic data and setting parameters, simulate passenger travel process in network
input	Network basic data, train running time data, station time data, station passenger flow data, simulation control parameters
output	The whole passenger travel process, index statistics about network transportation
precondition	Full data about basic information and control parameters
post-condition	Passenger transport organization scheme's evaluate and optimize
specification	If parameters is full, complete passenger transport process simulation calculate automatically

Figure 2 shows the simulation system's activity diagram, describes the algorithm process of 'passenger travel process simulation calculate'. According to the given simulation parameters and basic data, the system get the simulation start time and end time automatically. Simulate calculate begin from the start time moment, move forward step by step according to the setting time step, until arrived the end time moment and stop simulation.

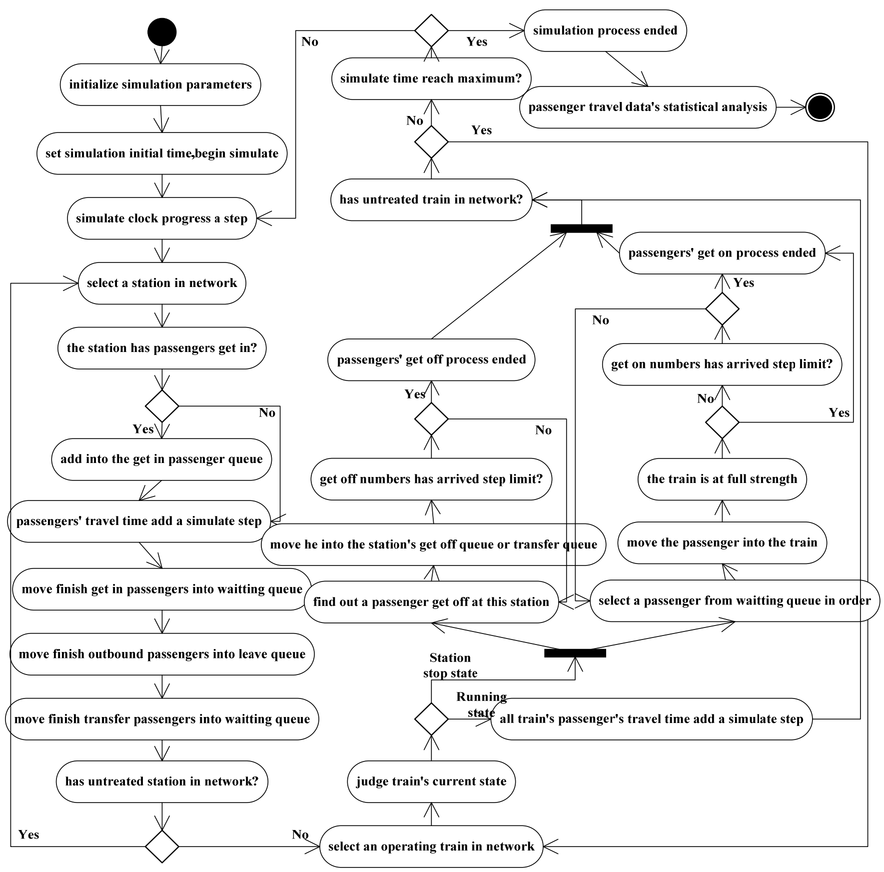

Figure 2. simulation system's activity diagram

The following contents are calculated in each simulation step:

(1) passenger's status update in each station within the network.

With the simulation clock's progress, stations will have new passengers to get in and add to arrival queue. While passengers in stations which are entering, leaving and transferring, their current state may change with time, therefore need to check the update. At the same time, in order to meet later index calculation, station passengers' relevant time need to add a step.

(2) each running train's status update within the network.

According to the time-distance data, train's position and operating mode will change along with the simulation time progress. If train's current mode is running, need to update the passenger's travel time inside the train; if train's state is stop at station, need to exchange passengers with the stop station.

2.2 System design

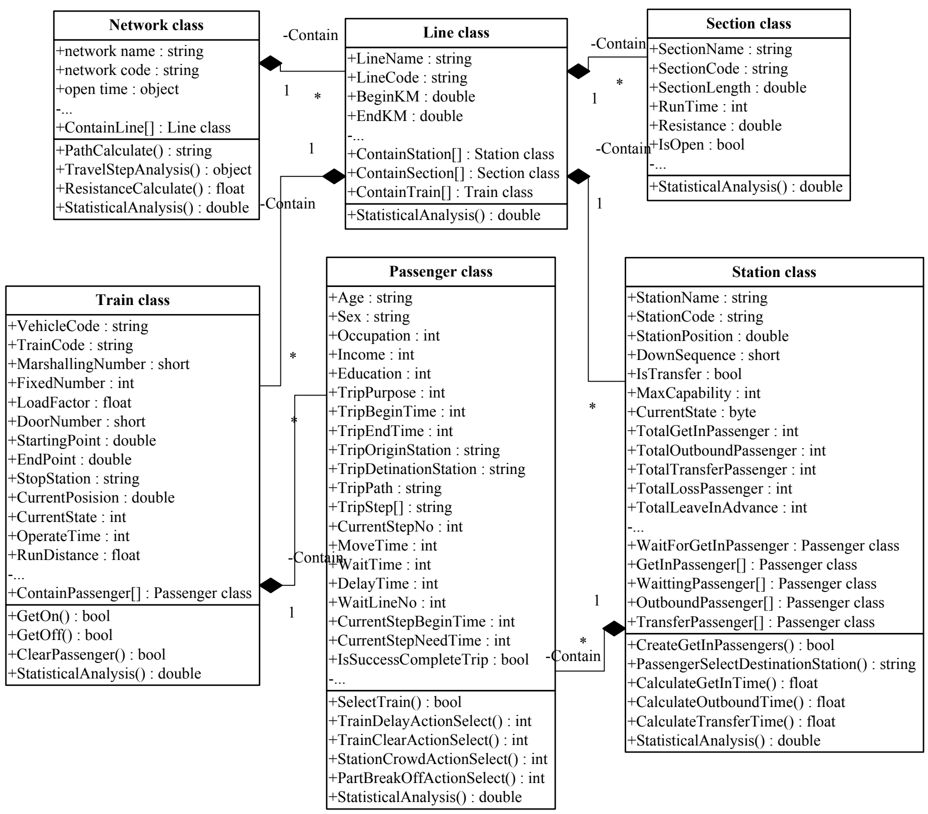

Figure 3. simulation system's class diagram

From the network transport activity's main participants we know, the simulation system's class mainly include: passenger, train, station, section, line and network. According to the passenger transportation process simulation requirements, design the simulation system's class diagram as shown in figure 3. Among them, the passenger class is the core of the system, its design may not only reflect the passenger's individual characteristics, but also meet the requirement of travel process drive and key parameters statistics. Further more, simulation system contains a large number of passenger individual objects, these individual objects have different behavior choice and motion characteristics when confront different situations, this will be reflected by the estimate algorithm inside the class's operation function.

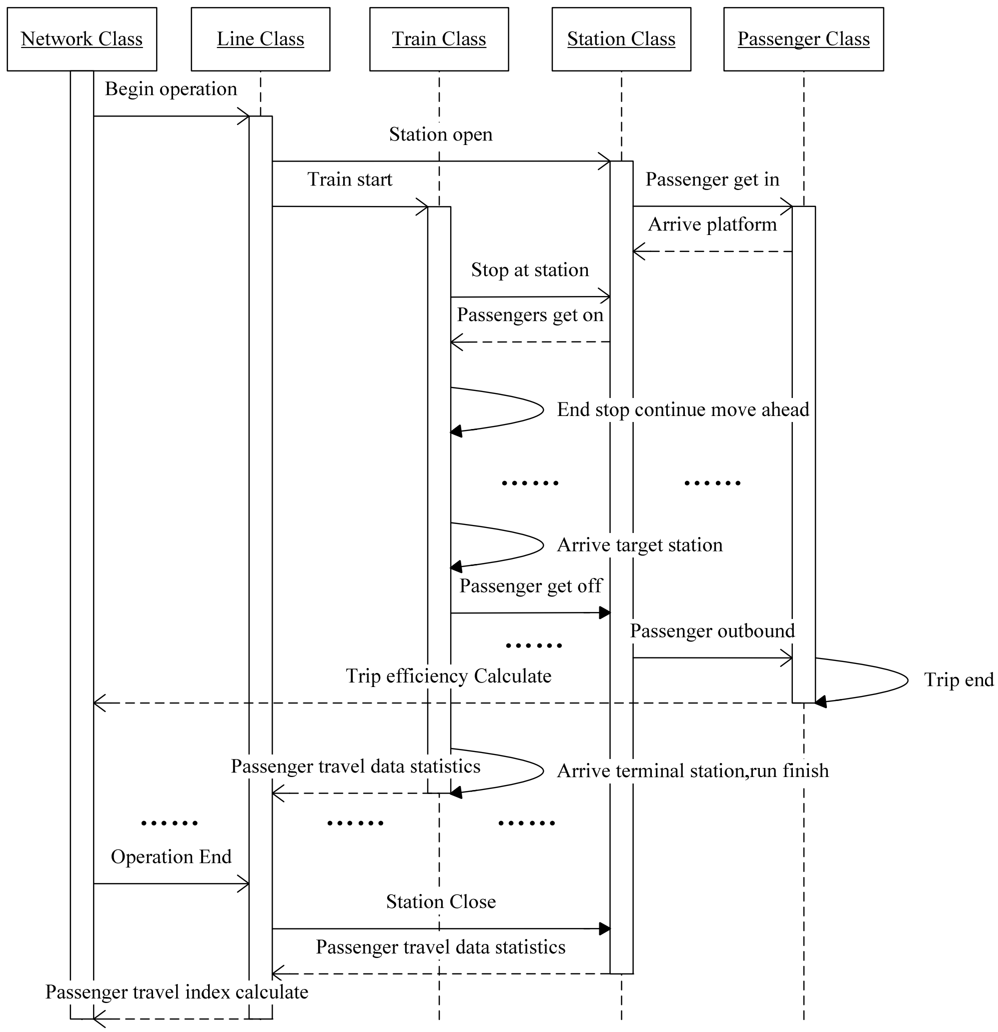

Figure 4. passenger travel process simulation sequence diagram

During the simulation process, the main work is train object and station object's status update and passengers exchange between them, while network object and line object mainly used for general control and statistical analysis, its sequence diagram as shown in figure 4. Train object's life cycle start from origin station depart, end after reach the destination station and complete clear passengers. Passenger object's life cycle start from reach origin station, end after leave rail transit system. Line object and station object create from its opening operation, and logout when its stop operation. Network object's life cycle throughout the whole simulation process, and is the global control object.

Figure 5 is the station object's state variation diagram. Stations are initialized according to the simulation parameters, open in specified simulation time. In each simulation step, statistic the total number of passengers in the station, and set the station's state to temporary closed or limit passenger flow or normal operation according to the statistical result. The cycle continues until the simulation time arrives the operation end time, station closed.

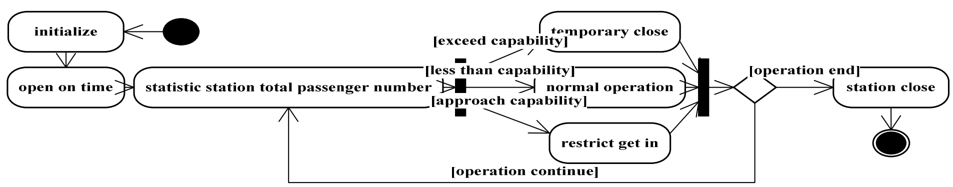

Figure 5. station object's state diagram

Figure 6 is the train object's state variation diagram. When the system clock arrive running time the train object is created, according to time-distance data train runs on the designated route. When train stop at station, execute passengers get off operation first. If the train has not arrive destination station, execute passengers get on operation, then continue run forward. Otherwise train running ended, object logout.

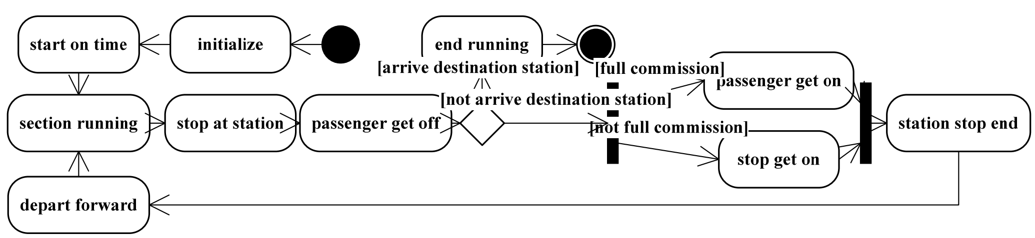

Figure 6. train object's state diagram

Figure 7 is the passenger object's state variation diagram. When passenger begin to travel, passenger object created. Then according to the trip requirement, transfer in sequence between train object and station object, until reach the destination station, outbound and leave, object logout.

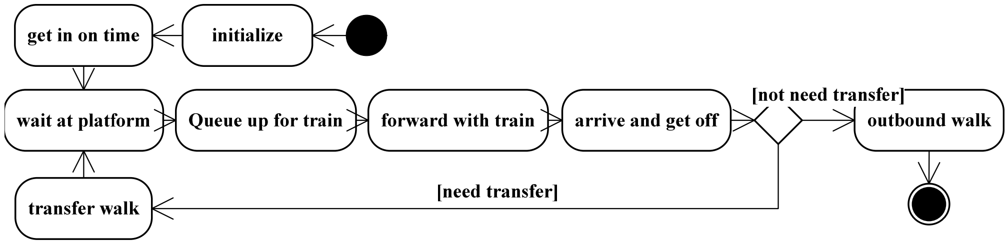

Figure 7. passenger object's state diagram

2.3 System development

As shown in figure 8, the simulation system contains two function module, include seven components. ‘Information management module’ mainly for system administrators use, consist by five components which are network basic information management, OD path and impedance calculation, train running time calculation, station time data management and station passenger flow data management. Each component provides two interfaces: edit interface and retrieve interface, edit interface provide function for manage basic data, retrieve interface provide data for simulation calculate. ‘Simulation calculate module’ mainly for simulation evaluator use, consist by simulation parameters manage component which use for simulation parameters and result's manage and setting, and passenger travel process simulation calculate component which use for execute simulation calculate and result analysis.

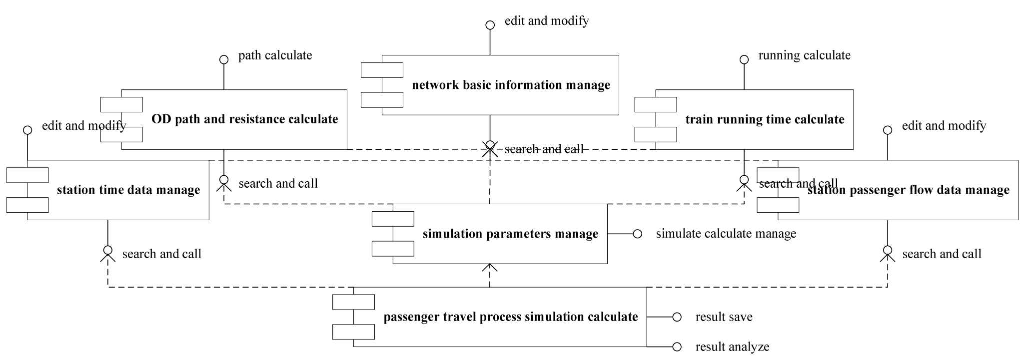

Figure 8. passenger travel process simulation system component diagram

3 Passenger travel process simulation example

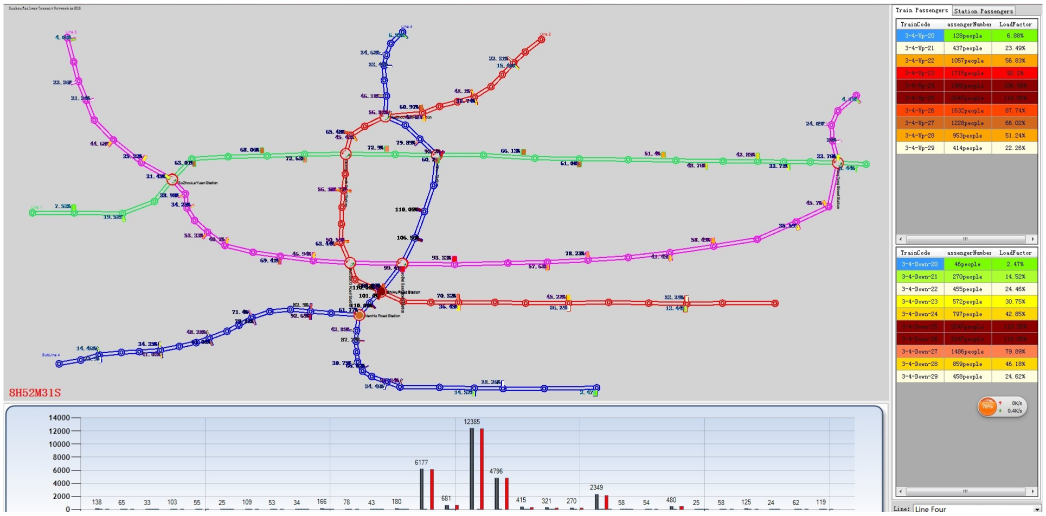

Figure 9. SuZhou 2015 planning network passenger travel process simulation screenshots

Take SuZhou rail transit 2015 planning network for example, through assumption lines basic data and passenger flow data, conduct simulation calculate, the result shows as figure 9 and figure 10. Figure 9 is the network passenger travel process microcosmic simulation's animation screenshots, in which can clearly show each line's train position, each train's load factor, each station's passenger number and other data's changing process. Figure 10 shows a station or a train's passenger number variation along with time. Through microcosmic simulation, can clearly recur network passenger travel process, and has important reference to master passenger flow's network distribution, grasp the system's bottleneck and weakness.

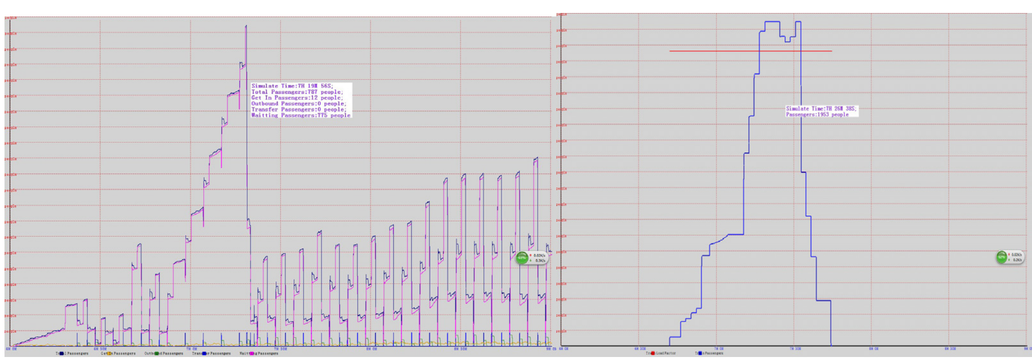

Figure 10. station passenger number change trends graph (left) and train passenger number change trends graph (right).

4 Conclusions

This paper put train operation process simulation with passenger travel process simulation together, build urban rail transit network passenger travel process simulation system, use the unified modeling language to describe the simulation system's analyze, design and realize; and take Suzhou rail transit network planning in 2015 as an example, achieve its' passenger travel process's simulation calculate, verified the system's validity. The system can provide effective aid decision making tool to promote rail transit system's efficiency.

Because the rail transit passenger travel process involve many technologies, the system this paper build although realize the passenger transport process simulation, but simplified dispose in many details, such as station passengers' move process, passengers' get on and off's rule, emergency treatment and so on. These aspects are the objects that need to do further study, in order to make the system's simulation results conform with reality more.

Abstract: In this paper, it analyzed the variation of waiting passengers in transfer station platform, and a model was obtained to calculate the number of waiting passengers, the number of passengers who had got on trains and the remaining passengers in transfer sites when trains arrived and left the transfer station during the coordination period. In the model, the case that passengers could not board on the first arrival train they encountered was considered. Based on the calculation model, an optimization model was established. The optimization model took maximizing the total number of passengers that departed as the target during the coordination period in the transfer station, and took the maximum waiting passengers not exceeding the capacity of each site as the constraints. Using the calculation model and the optimization model, a case was analyzed under the condition that passengers transferred unevenly between two inter-lines. The research can provide a reference for urban railway network coordination.
Keywords: Urban rail transit; Calculation model; Optimization model; Transfer station; Coordination.

1 Introduction

With the increase of urban rail lines, network-oriented operation model is being formed, the corresponding passenger traffic is also showing a leap -growth. As a bridge between lines, the operation of transfer station has an important impact on the operational efficiency and quality of the entire rail network. Therefore, improving the service capability and quality of the transfer station is a very important issue.

Liu (2011) proposed a method to solve the mismatch of transport capacity between lines and the restriction of transfer station capacity through restricting passenger flow and operating with skip-stops. Wang (2011) analyzed the impact of traffic density mismatch between intersecting lines to the number of waiting passengers and stranded passengers and the residence time. Wang (2013) analyzed a calculation method under the condition that different arrival intervals of trains from two different lines corresponded to the different aggregation. Xu (2013) described the changes of waiting passengers in an ordinary station through establishing a probabilistic model. Yan (2008) calculated the operation intervals through balancing the travel satisfaction of passengers against the interests of enterprises. Zhao (2011) analyzed the passenger flow volume variation of ordinary station, and a method was obtained to calculate the maximum number of passengers through analyzing the number of passengers arriving, boarding and alighting.

There are few studies about the impact of transport capacity mismatch between lines and transfer stations in the existing literature. Firstly, in this paper we analyzed the necessity of capacity during peak hours for particular lines coordination. Then we established a model to calculate the number of waiting passengers in the transfer station, and proposed an optimization model of line capacity coordination on this basis. Finally, a case was used to analyze the impact of adjusting operation intervals and carrying capacity to the result of coordination under the condition that passengers transfer unevenly between two inter-lines.

2 Analysis and Research Hypothesis

This paper mainly analyzes the problem that transfer directions are not balanced, caused by the commuters. Taking the morning rush hour for example, a lot of people take suburban rail rushing into the city from suburb, and transfer in the transfer station intersected with the urban ring, while there are less passengers in the opposite direction .In this case, as the main connecting line, the urban ring is greatly impacted. In addition, the operational capacity and the station capacity are limited, and it's easy to be stranded. So it needs further study to avoid congestion in the transfer station.

Describing the variation of passenger flow accurately is the precondition for the coordination of inter-line capacity. In order to analyze the relationship between operational capacity configuration and requirements, this paper ignores the impact of passengers getting off the train and evacuation procedure, only takes the variation of waiting passengers in the transfer station into consideration.

This article discusses the situation that the transfer station is an intermediate station of the intersecting lines. There are four operational directions at the transfer station when two lines intersected. Respectively, l_{11} and l_{12}, l_{21} and l_{22} represent the up and down direction of line l_1 and l_2 .Assume that:

(1)Trains on each line operate balanced.

(2)In the same direction, the transfer passenger flow from outside the station subjects to the same Poisson distribution.

(3)In the same direction, the transfer passenger flow brought in the transfer station subjects to the same Poisson distribution.

(4)No passengers transfer between the up and down directions on the same line.

3 Computing Model for Transfer Station's Waiting Passengers

This paper only analyzes the variation and calculation method of waiting passengers in one station for the reason that each station shares the same calculation method. This paper mainly analyzes the calculation method of line l_{21}.

3.1 Analysis for waiting passengers on the line l_{21}

Depending on the operating characteristics of the train, passengers' arrival and departure regularities on line l_{21} are shown in Figure 1.The arrows above the time axis represent the times that passengers getting off the trains on line l_1 arrive at l_{21} in transfer station, while the arrows below the time axis represent the times passengers taken away from the transfer station on l_{21}. On the line l_2, D_2 is the dwell-time in the transfer station; t_i-D_2 is the times that the i^{th} train reaching the transfer station on line l_{21}, t_i is the leaving time. h_1 and h_2 are the intervals between trains on line l_1 and l_2.

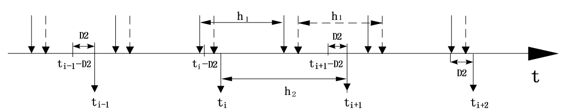

Figure 1. Passenger's arrival and left time in l_{21} platform

The number of passengers inside the station on line l_{21} is increasing during the time period t_{i-1} to t_i-D_2. After the i^{th} train stops and opens the door, the number of passengers in the station is decreasing till this train closes the door and leaves this station, the leaving time is t_i, and then the next cycle starts in the same way. Therefore, the waiting passenger flow in the station on line l_{21} shows a cyclical variation. According to the variation characteristics of passenger flow, the extent of congestion about the transfer station can be reflected by calculating the number of waiting passengers when the train arrives on line l_{21}, and the remaining waiting passengers $SY_i^{l_{21}}$ after this train leaves the transfer station. Furthermore, the operational efficiency can be reflected by calculating the actual number of passengers transported from the transfer station.

3.2 Calculation model of waiting passengers on line l_{21}

Firstly, we gave the relationship between parameters as in formula (1).

$$\begin{cases} PD_{t_i-D_2}^{l_{21}} = SY_{i-1}^{l_{21}} + DD_{(t_{i-1},t_i-D_2)}^{l_{21}} \\ XN_{t_i}^{l_{21}} = PD_{t_i-D_2}^{l_{21}} + DD_{(t_i-D_2,t_i)}^{l_{21}} \\ SJ_i^{l_{21}} = \min\{XN_{t_i}^{l_{21}}, FN_i^{l_{21}}\} \\ SY_i^{l_{21}} = XN_{t_i}^{l_{21}} - SJ_i^{l_{21}} \end{cases} \tag{1}$$

Where $PD_{t_i-D_2}^{l_{21}}$ represents the number of waiting passengers when the ith train arrives at the transfer station on l21; $SY_{i-1}^{l_{21}}$ represents the number of remaining waiting passengers on l21 after the (i-1)th train leaves; $DD_{(t_{i-1},t_i-D_2)}^{l_{21}}$ represents the number of arriving passengers during the dwell time period (ti-1,ti-D2); $XN_{t_i}^{l_{21}}$ represents the total number of passengers that need to take the ith train before it leaves the transfer station; $SJ_i^{l_{21}}$ represents the actual number of passengers aboard during dwell-time period of the ith train; $FN_i^{l_{21}}$ is the operating capacity of the train, which is the number of empty seats after passengers get off the train.

$DD_{(T_a,\tau)}^{l_{21}}$ is calculated by formula (2):

$$DD_{(T_a,\tau)}^{l_{21}} = ZW_{(T_a,\tau)}^{l_{21}} + HC_{(T_a,\tau)}^{l_{21}} \tag{2}$$

Set $[T_a, T_b]$ to be the operational period, $\tau \in [T_a, T_b]$, $ZW_{(T_a,\tau)}^{l_{21}}$ is the random arriving passengers from outside the station on line l_{21} during the time period (T_a,τ); $HC_{(T_a,\tau)}^{l_{21}}$ represents the transfer passengers from line l_1 to l_{21} during (T_a,τ).

Assume that the random arriving passenger flow outside the line l_{21} subjects to Poission flow, the intensity to be $\delta^{l_{21}}$, then it has:

$$E(ZW_{(T_a,\tau)}^{l_{21}}) = (\tau - T_a) \cdot \delta^{l_{21}} \tag{3}$$

And $HC_{(T_a,\tau)}^{l_{21}}$ can be calculated as formula (4):

$$HC_{(T_a,\tau)}^{l_{21}} = HC_{(T_a,\tau)}^{l_{11}\to l_{21}} + HC_{(T_a,\tau)}^{l_{12}\to l_{21}} \tag{4}$$

Where, $HC_{(T_a,\tau)}^{l_{11}\to l_{21}}$ represents passengers transfer from line l_{11} to l_{21}; $HC_{(T_a,\tau)}^{l_{12}\to l_{21}}$ represents passengers transfer from line l_{12} to l_{21}, shown as formula (5) and (6).

$$E(HC_{(T_a,\tau)}^{l_{11}\to l_{21}})=\begin{cases}0 & T_a\le\tau<t_{cs}^{l_{11}}+t_{hc}^{l_{11}\to l_{21}}\\ \lambda^{l_{11}\to l_{21}}\cdot[floor(\frac{\tau-t_{cs}^{l_{11}}-t_{hc}^{l_{11}\to l_{21}}}{h_1})+1] & t_{cs}^{l_{11}}+t_{hc}^{l_{11}\to l_{21}}\le\tau\le T_b\end{cases} \quad (5)$$

$$E(HC_{(T_a,\tau)}^{l_{12}\to l_{21}})=\begin{cases}0 & T_a\le\tau<t_{cs}^{l_{12}}+t_{hc}^{l_{12}\to l_{21}}\\ \lambda^{l_{12}\to l_{21}}\cdot[floor(\frac{\tau-t_{cs}^{l_{12}}-t_{hc}^{l_{12}\to l_{21}}}{h_1})+1] & t_{cs}^{l_{12}}+t_{hc}^{l_{12}\to l_{21}}\le\tau\le T_b\end{cases} \quad (6)$$

Where, $t_{cs}^{l_{11}}$ and $t_{cs}^{l_{12}}$ respectively represents the time that the first train arrives at the transfer station on line l_{11} and l_{12}. $t_{hc}^{l_{11}\to l_{21}}$ and $t_{hc}^{l_{12}\to l_{21}}$ respectively represents the time it takes transfer passengers to reach the transfer station in the corresponding direction. Both of them take average statistics. $\lambda^{l_{11}\to l_{21}}$ and $\lambda^{l_{12}\to l_{21}}$ are the passenger volume intensities transferring from each train in both direction on line l_1 to l_{21}.

The time t_i each train leaves the transfer station on line l_{21} meets the equation (7).

$$t_i = t_{cs}^{l_{21}} + D_2 + (i-1)\cdot h_2 \qquad i=1,2\ldots N \quad (7)$$

Where, $t_{cs}^{l_{21}}$ represents the arrival time of the first train on line l_{21}, N is the number of combined trains on line l_2.

The initial arrival times $t_{cs}^{l_{11}}$ 、 $t_{cs}^{l_{12}}$ 、 $t_{cs}^{l_{21}}$ in each direction satisfy the formula(8).

$$T_a\le t_{cs}^{l_{pq}} \le T_a+h_p \qquad p=1,2;\quad q=1,2 \quad (8)$$

Where, h_p represents the running interval of line l_p.

Based on the analysis above, both the expected value of waiting passengers in the transfer station $E(PD_{t_i-D_2}^{l_{21}})$ and the expected value of actual traveler flow of each train on l_{21} $E(SJ_i^{l_{21}})$ can be obtained using iterated inference. Similarly, the formulae of $E(PD^{l_{pq}}_{t_i-D_2})$ and $E(SJ^{l_{pq}}_i)$ (p=1,2; q=1,2) in other direction can be obtained.

4 Optimization Model of Capacity Coordination Adjustment

For the whole transfer station, the target of the coordination and optimization is to maximize the number of passengers taken away *SJ*, which is tallying up all the values of traveler flow in each direction, shown in formula (9).

$$\text{Obj.}\quad \text{Max}\quad SJ=\sum_{i_1=1}^{N_1}E(SJ^{l_{11}}_{i_1})+\sum_{i_2=1}^{N_2}E(SJ^{l_{12}}_{i_2})+\sum_{i_3=1}^{N_3}E(SJ^{l_{21}}_{i_3})+\sum_{i_4=1}^{N_4}E(SJ^{l_{22}}_{i_4}) \tag{9}$$

Where variable(N_1, N_2, N_3, N_4) is the number of trains on line l_{11},l_{12},l_{21},l_{22} during the study period. Otherwise, the maximum number of waiting passengers $\max(E(PD^{l_{pq}}_{t_i-D_2}))$ (i=1,2…N;p=1,2;q=1,2) must be not exceeding the maximum number the platform can hold, described by (10)~(14).

$$\max(E(PD^{l_{11}}_{t_{i_1}-D_1}))\le C^{l_{11}}_{\max}\qquad i_1=1,2\ldots N_1 \tag{10}$$

$$\max(E(PD^{l_{12}}_{t_{i_2}-D_1}))\le C^{l_{12}}_{\max}\qquad i_2=1,2\ldots N_2 \tag{11}$$

$$\max(E(PD^{l_{21}}_{t_{i_3}-D_2}))\le C^{l_{21}}_{\max}\qquad i_3=1,2\ldots N_3 \tag{12}$$

$$\max(E(PD^{l_{22}}_{t_{i_4}-D_2}))\le C^{l_{21}}_{\max}\qquad i_4=1,2\ldots N_4 \tag{13}$$

$$t_{N_1}\le T_b;\; t_{N_2}\le T_b;\; t_{N_3}\le T_b;\; t_{N_4}\le T_b \tag{14}$$

Where $C^{l_{pq}}_{\max}$ is the maximum number that the platform l_p can hold in the q[th] direction. D_1 is the dwell-time on line l_1 in the transfer station while D_2 is the dwell-time on line l_2 in the transfer station.

Formula (9) ~ (14) describe the coordination optimization model in transfer station of cross lines. But the optimization model is in accordance with constraints (1)~(8); the adjusting parameters are the train headway time interval (h_1,h_2) and the carrying capacity of the i[th] train $E(FN_i^{l_{pq}})$. $E(FN_i^{l_{pq}})=\mu^{l_{pq}}$ (p=1,2;q=1,2) can be derived according to the assumptions. In the following, we discuss the coordination optimization schedule between cross lines by example when the numbers of transfer passengers in opposite directions are seriously imbalanced during the peak-hours.

5 Case Study

We chose the morning peak-hour 7:00~8:00 as the coordination period. The transfer passengers in each direction were shown in table 1 and the data were transfer passengers from the rows transferring to the corresponding columns.

Table 1. Transfer passengers

	l_{11}	l_{12}	l_{21}	l_{22}
l_{11}	--	--	214	231
l_{12}	--	--	252	224
l_{21}	105	132	--	--
l_{22}	121	125	--	--

Two coordination schemes were considered. One was to adjust the train headway time interval h_1 on line l_1, the other one was to adjust the carrying capacity of trains $\mu^{l_{2j}}$ (j=1,2) on l_2. The two schemes were discussed as follows.

5.1 Coordination of headway time interval

According to table 1, trains on l_2 brought passengers away from the transfer station while trains on l_1 brought passengers in the transfer station. Therefore, the smaller h_2 was, the better it is to evacuate passengers. Assuming that h_2 to be 180s, the smallest headway time interval, we considered adjusting h_1, the headway time interval on l_1, to optimize the transfer passengers in the transfer station. Denote the initial time 0 by 7:00, then the coordination period T was 3600s. The initial data were set as follows: Intensities of passengers arriving at the transfer station from each direction $\delta^{l_{ij}}$ = 0.5, $\mu^{l_{ij}}$=500, $t_{cs}^{l_{11}}=t_{cs}^{l_{12}}$=80s, $t_{cs}^{l_{21}}=t_{cs}^{l_{22}}$=120s, $C_{\max}^{l_{ij}}$=700, D_1=D_2=40s, the walking time in transfer station in all directions was 90s.

Through simulation, we could get the variation trend of the maximum number of waiting passengers in the transfer station and the total number of passengers taken away during the period, as shown in figure 2 and figure 3. In figure 2 and figure 3, x-coordinate represented headway time interval h_1(s), while y-coordinate represented waiting passengers. Figure 2 showed that as with h_1 increased, waiting passengers in the two opposite directions on l_1 increased, while waiting passengers in the two opposite directions on l_2 decreased. In order to meet the constraint that the number of waiting passengers must be not exceeding the maximum number the platform can hold in all transfer stations, the headway time interval h_1 was in accordance with constraint (15). hl and hu were shown in figure 2.

$$\text{hl} \le h_1 \le \text{hu} \tag{15}$$

According to the initial parameters, we could calculate that hl was 225s and hu was 260s. As shown in figure 3, when h_1 decreased, the total number of passengers taken away from the transfer station increased within the range of [hl,hu]. Considering a variety of disturbance when the train ran, if h_1 was too small, we should consider the risk that waiting passengers in the transfer station on l_2 may exceed the capacity. Considering all these factors, we could select $h_1$to be 240s, so the number of waiting passengers in each station was: 405(l_1 up-line), 495(l_1 down-line), 663(l_2 up-line), 495(l_2 down-line).

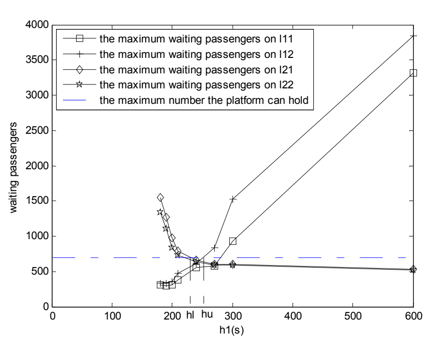

Figure 2. Relationship between waiting passengers and h_1

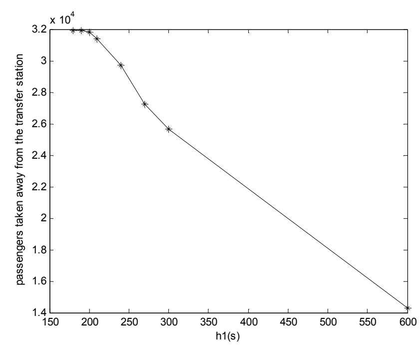

Figure 3. Relationship between depart passengers and h_1

5.2 Coordination of the carrying capacity of trains

As the main transfer direction was from l_1 to l_2, so we could adjust the carrying capacity of trains on l_2. Assuming that h_1=h_2=180s, the other parameters to be invariant. Through simulation, the effect the carrying capacity of trains on l_2 had on the number of waiting passengers could be obtained. For the sake of convenience, list the two parameters in figure 4. The effect that the carrying capacity of trains on l_2 had on the number of passengers taken away from the transfer station was shown in figure 5. In figure 4 and figure 5, x-coordinate represented the carrying capacity after passengers getting off the train $\mu^{l_{21}}, \mu^{l_{22}}$ *(unit)*, while y-coordinate represented the number of waiting passengers. The number of waiting passengers in transfer station on l_1 was not affected, so it was not discussed any more.

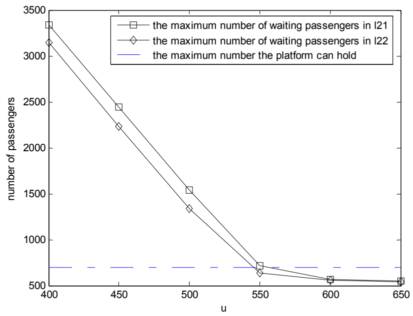

Figure 4. Waiting passengers change with $\mu^{l_{21}}$ 、 $\mu^{l_{22}}$

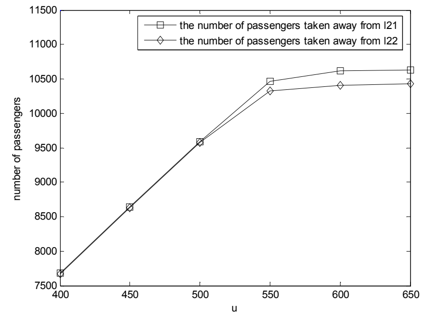

Figure 5. Depart passengers change with $\mu^{l_{21}}$ 、 $\mu^{l_{22}}$

Figure 4 and 5 showed, within some range (as shown in the figures: $\mu^{l_{21}} \leqslant 550, \mu^{l_{22}} \leqslant 550$),the variation of carrying capacity had a great effect on the maximum number of waiting passengers in the corresponding transfer station and the total number of passengers taken away. Therefore, it is an effective method to optimize the number of waiting passengers by increasing the carrying capacity of the trains in the main transfer directions. The coordination of carrying capacity can be achieved by replacing another type of train or changing train marshalling.

6 Conclusions

In this paper, it analyzed the variation trend of waiting passengers in transfer station platform, the interactions of parameters described by formulae, and models to calculate the number of waiting passengers and the passengers taken away from the transfer station are obtained. Based on the calculation model, a coordination optimization model was established. The optimization model took improving the efficiency of the transfer station as the target, and took the maximum waiting numbers in each transfer platform not exceeding the capacity of the platform as constraints. Finally, a case was analyzed under the condition that the number of transfer passengers in opposite directions were imbalanced, so the adjust schemes were provided, and the effect that train headway time interval adjusting and train carrying capacity adjusting had on waiting passengers in the transfer station and the service efficiency was obtained.

Abstract: Communication Based Train Control System (CBTC) is different from the traditional train control system. It controls the train in high-Precision Positioning by the continuous, high- speed and two-way train-wayside data communication. Automatic Train Supervision (ATS) is an important subsystem of CBTC to control the train in high-speed and normal operation. This paper introduces the system structure and functional requirements of the ATS system. Then this paper particularly designs and realizes functions of train working diagram, routing judgment, train route control, automatic generation of train number and train operation adjustment. Such this paper builds Comprehensive experiment simulation platform.
Keywords: Urban rail traffic; Automatic train supervision; Running simulation.

Automatic control system of urban rail transit (ATC) consists of Automatic Train Protection (ATP), Automatic Train Operation (ATO) and Automatic Train Supervision (ATS). Based on the design principle of fail-safe, ATP is responsible for the safety in the process of train running. ATP raises the train running level and Control train automatic driving including arrivals and departures of trains, automatic reentrant. ATS is the command center of the ATC system. The main effect of ATS is to command and supervision of train operation. The three subsystems cooperated to achieve complete functions of ATC system. The relationship between ATS, ATO and ATP shows in figure1.

1 Summary of ATS

According to the train operation plan, the ATS system compiles train schedule and organize train operation in accordance with train diagram. ATS gathers and displays the real time information of train number, actual running time, condition of route, station information and train position. Such ATS gives supports to dispatch and command of Urban Rail Transit.

The ATS simulation system is communication Based Train Control System (CBTC). The ATS simulation system can realize functions of the real time information of train and station, editing train working time schedule, route control, automatic turn-back running, automatic generation of train number, train withholding in station platform and train jump stopping and preservation and print of the simulation data.

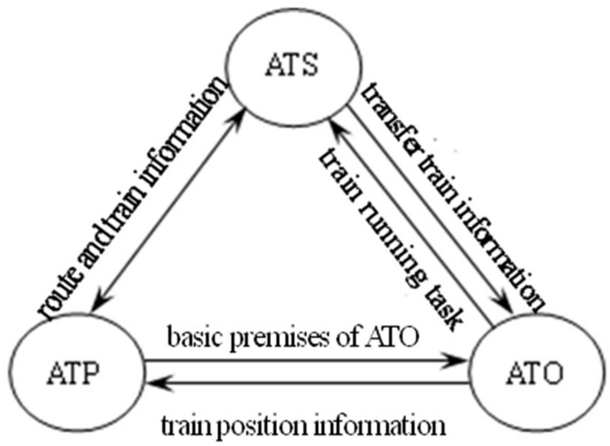

Figure 1. Relationship between subsystem of ATC

2 Drawing Train Working Diagram

Urban Rail Transit train timetable is realized by train working diagram. The train working diagram shows the relationship of time and space of train running. It stipulates the interval occupied order of each train, the train running time in the section, the train arrival and departure time, station dwell time，turnaround time of turn back station, train routing and leaving and arriving car depot. It can directly display the train’s state of running time in the section, stopping and passing of station. Such train working diagram is the base of organization of train operation.

Train working diagram of Urban Rail Transit contains plan operation diagram and actual train diagram. The actual train diagram is produced from the train’s arriving and departing time of automatic searching. The two operation diagram are distinguished by different colors. The plan operation diagram is one minute diagram. The transverse axis is equally divided into one minute. The longitudinal axis is equally divided by the train running time in the section, as Figure2 shows. The elements of drawing train diagram include the train running time in the section， station dwell time, residence time of turn back station, turn-back departure interval, operation time of car depot, time interval between trains spaced by automatic block signals and time interval for two trains despatching in succession in the same direction.

The simplest method of drawing train working diagram is to find out the starting and arrival point. The two points are connected to form a line. The method is simple.

Since there are many stations and running lines, the work load is large. The train running time in the section and station dwell time are relatively fixed in drawing. So the system can directly draw up and down direction line. If the running line is different the generated line, it can be fine adjusted.

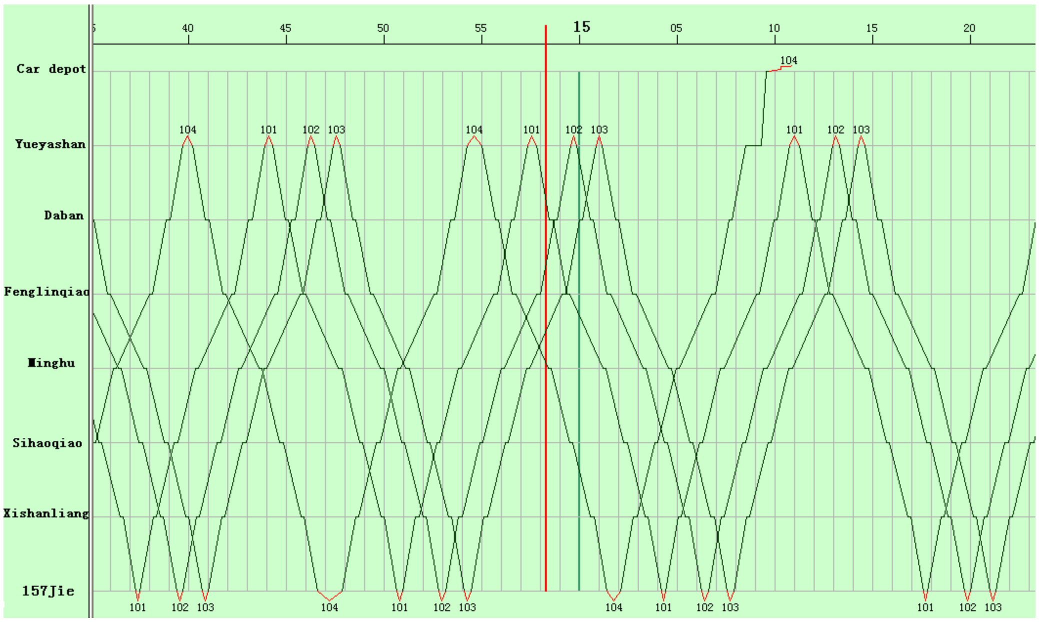

Figure 2.Plan operation and actual train diagram

The drawing process of the train working diagram.First, starting station was determined. Secondly, destination station was determined. The ATS simulation system generates running line according to the predetermined time standard. Last, the line can be adjusted according to the practical operation.

During drawing train working diagram, the destination station should be selected by the train operation plan. The operation routing depends on the destination station. The operation routing contains long locomotive routing and short locomotive routing. The turn-back station of long locomotive routing is the terminal station of the line. The turn-back station of short locomotive routing is the appointed intermediate station of the line. During drawing short locomotive routing running line, the ATS simulation system should judge the conditions of the locomotive routing(Figure3).The form of reentrant contains station-front and station-end turning-back(Figure4,5).

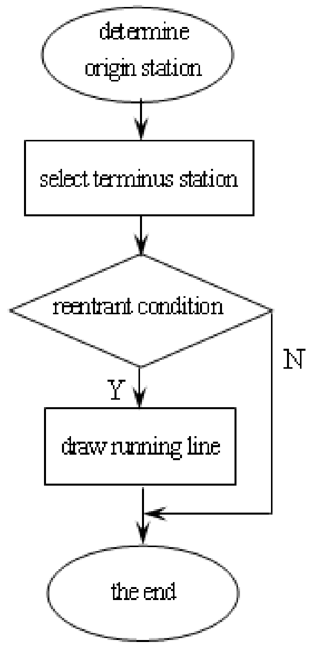

Figure3. Drawing line flowchart

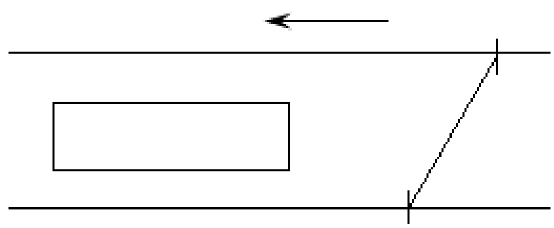

Figure4. Station-front turning-back

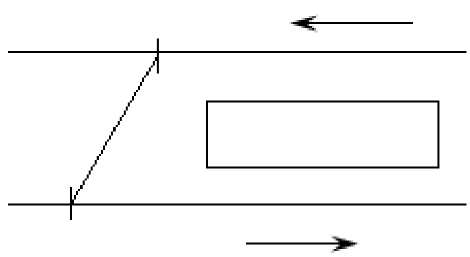

Figure5. Station-end turning-back

3 Train route control

The moving block system is one of development directions of signal system for urban rail transit. The train runs in accordance with train diagram. The train running route includes auto railway route and manual route. Normally, the train route is auto railway route. Its control process shows as Figure6. According to the requirement of work the ATS simulation system can artificially control the switch and route. The artificial control of switch contains conversion of switch normal position and reverse position, individually lock and unlock. The manual route can be controlled by choosing start-stop signal. Also the route can be cancelled and released.

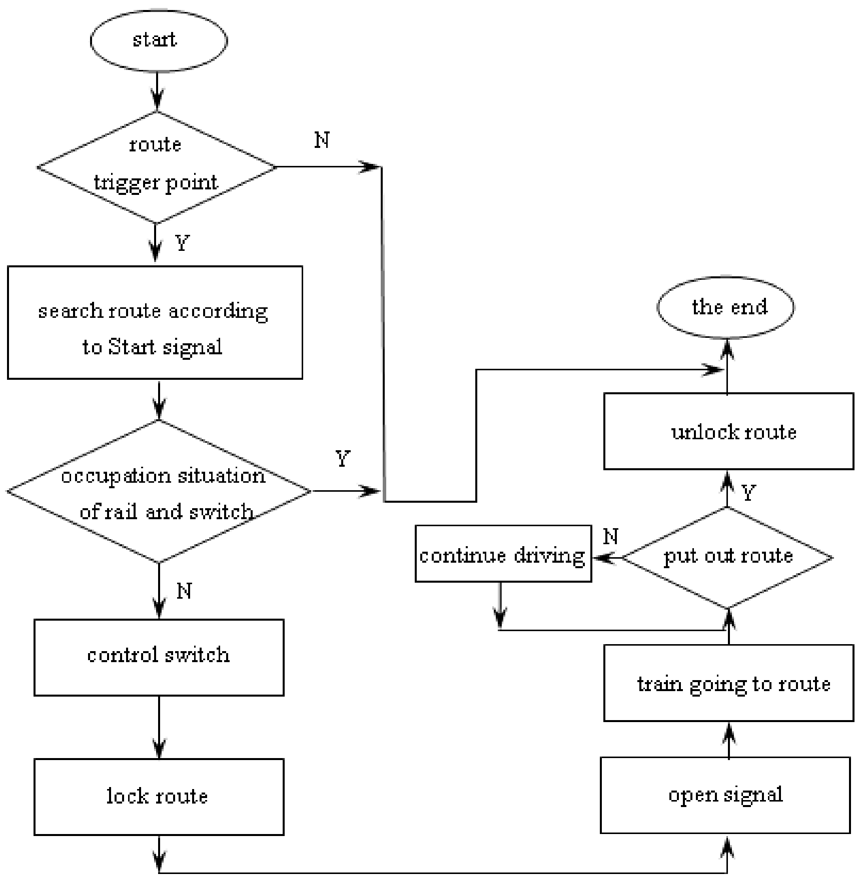

Figure 6. Auto railway route control flow chart

4 Train withholding in station and station jump stopping

The train directly passes through the station without stopping and carrying passengers. The ATS simulation can realize the train withholding in station by selecting the train in the dialog box.

The train jump stopping refers that the train departure from station after increasing the station operation time in order to achieve the purpose of train interval equilibrium. The ATS simulation can realize train jump stopping by selecting the station in the dialog box.

The application of ATS simulation platform meeting the requirements of the laboratory of soft and hard platform interface has stronger practicability. The results can provide some theoretical and implementation reference for the building of Urban rail transit relevant experimental platform.

Abstract: China has entered the booming stage of urban rail transit. Suspended monorail system, which belongs to urban rail transit with low traffic volume, is under development. Adaptability and technical feasibility of suspended monorail are analyzed on the basis of train capacity, technical features and construction cost. Operational features of symmetrical suspended monorail systems in Germany and Japan are introduced. Capacity adaptability of the monorail is calculated under four-parameter combined cases, which are vehicle size, seat layout, train marshalling and capacity principles. The trains with width 2.4m ~2.6 m and marshalling cars 2~3, are suggested in domestic. Compared to modern tram, BRT, and metro, the monorail has unique advantages in technology, engineering construction and cost, and it becomes new development of urban rail transit. Learn from development of mid-low speed maglev traffic, and the monorail will be successfully brought to market.
Keywords: Suspended monorail system; Train capacity; Technical feature; Function orientation; Domestic application.

1 Introduction

Rapid and large-capacity public transport with electric energy power and by wheel/rail running mode is referred to as urban rail transit. Beginning with the opening in 1863 of Metropolitan Railway in London, urban rail transit has developed more than 150 years. 170 cities in 50 countries and regions all over the world have opened rail transit and operating mileage is over 10,000 km.

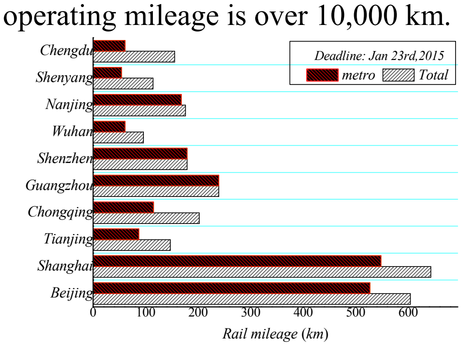

Figure 1. Statistics of urban rail traffic mileage in China

China has entered into a stage of vigorous development of urban rail transit. According to the data from China Association of Metros in early 2015(China Association of Metros), mileage of urban rail transit are counted in Figure 1. Mileages of Beijing and Shanghai rank the first and proportion of metro traffic mileage reaches more than 80%. Modern tram and straddle monorail are operated. Mid-low speed maglev, suspended monorail and automated people mover systems (APM) (Figure 2) are also developed gradually.

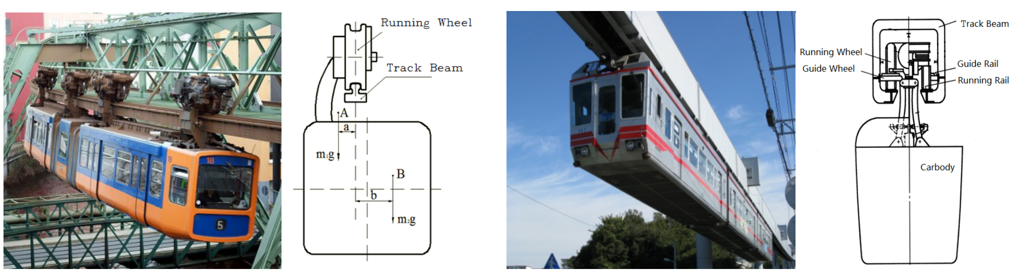
Guangzhou Metro (A-type vehicle) Shenyang Tram Chongqing straddle monorail

Zhuzhou mid-low speed maglev Chiba suspended monorail Guangzhou APM system

Figure 2. A variety of urban rail transit system

2 Presentation of suspended monorail system

On the basis of different design principles, two suspended monorail systems, asymmetric type and symmetric type, are developed (Figure 3).



(1) Asymmetric type (2) Symmetric type

Figure 3. Two types of suspended monorail

Famous monorail lines, Wuppertal line in Germany and Ueno zoo line in Japan, are applied the asymmetric type. Originated from design thoughts of German engineer Eugen Langen in 1894, this type takes advantages of double flange guide technology, moment balance principle and steel wheel/rail contact. Some deficiencies, such as excessive flange wear and passenger unilateral ride, limit its application.

Symmetric type, which is originated from France SAFEGE, uses rubber tires running in an enclosed track beam. It has contributed to reduce operating noise, improve ride comforts and decrease effect of severe weather. This type is promoted heavily by Mitsubishi Heavy in the world's longest suspended monorail line-Chiba monorail. Along with technical progress of rubber tires, advantages of symmetric type gain international acclaim. Therefore, symmetric type is study object of this article.

3 Adaptability and technical feasibility analysis of suspended monorail

3.1 Train capacity analysis

Combined with operating and train features of Japan Chiba and Germany Dusseldorf monorail systems, train capacity is analyzed in Table 1. Capacities of the two systems are not high. The seats are in a symmetrical layout and passengers can move freely. Standing capacity principle of the two system is calculated as being 3~4 person/m^2, which belongs to comfortable standard (SHEN Jingyan,2007). Based on operation schedule of Chiba monorail, passenger flow volume at peak hour for one-way traffic is less than 2500.

Table 1. Train capacities of suspended monorails in Japan and Germany

		Chiba urban monorail in Japan	Duesseldorf Sky Train in Germany
Manufacturer		Mitsubishi Heavy	H-bahn
NO. of Driver's Cab		2	0
NO. of Vehicles		2	2
Vehicle Size length * width*height (m)		14.8*2.58*3.085	8.232*2.334*2.623
Vehicle Capacity (person)	Seating	30	16
	Standing	48	54
	total	78	70
Operation scene			

Table 2. Factors for train capacity analysis

Factor	Classification	Factor	Classification
Vehicle Size length * width (m)	9 *2.2	Number of Vehicles	2
	11*2.4		3
	15*2.6		4
	19*2.8		5
	22*3		
Seat Layout	Metro seat	Capacity principles (person/m^2)	4
	Bus seat		5

Vehicle size, seat layout, train marshalling and capacity principles of urban rail transit in China (Table 2) are introduced to analyze domestic capacity adaptability.

Train capacities under different types of seat layout and standing capacity principles are calculated with the size, such as carbody thickness, door width, wheelchair area, and so on. The train in this paper applies symmetrical design and driver's cab is considered in the lead and tail vehicle. At present, standing principle of 5 person/m2 is applying in some domestic cities for better comfort.

Some results are shown in Figure 4 and Table 3. As vehicle width and numbers increase, so do the train capacity. An excess of vehicle width or numbers will give rise to high cost on engineering construction and maintenance. Narrow track and slender beam column have obvious advantages on decreasing engineering cost and environmental influence.

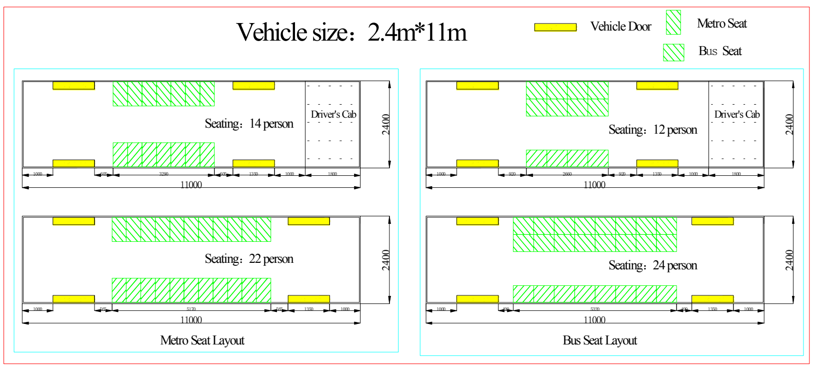


Figure 4. Seat layout of a vehicle (size: 11m length and 2.4m width)

Table 3. Calculation results of train capacity

			Metro seat layout				Bus seat layout			
Case I: 4 person/m^2	Vehicle No.		2	3	4	5	2	3	4	5
	Vehicle width	2.2m	96	159	222	285	96	159	222	285
		2.4m	140	226	312	398	142	227	312	397
		2.6m	228	359	490	621	222	348	474	600
		2.8m	328	510	692	874	318	494	670	846
		3m	420	650	880	1110	406	629	852	1075
Case II: 5 person/m^2			Metro seat layout				Bus seat layout			
	Vehicle No.		2	3	4	5	2	3	4	5
	Vehicle width	2.2m	110	182	254	326	110	182	254	326
		2.4m	162	260	358	456	164	261	358	455
		2.6m	262	412	562	712	246	386	526	666
		2.8m	376	585	794	1003	354	550	746	942
		3m	484	749	1014	1279	454	703	952	1201

Considering length of the station platform of Chiba monorail, which is built for 2~4 vehicles, the capacity is partial to the result for conditions of case II, vehicle width from 2.4m to 2.6m, and vehicle number from 2 to 3. The value for 3 vehicles with 2.4m width is close to that for 2 vehicles with 2.6m width, as shown in gray areas in Table 3. And it is appropriate. On the basis of 14 pairs of train operated from 8:00 to 9:00 am in Chiba line and high population density in China, a hypothesis, that pairs of operating train at peak hour is 20, is made. For the train with 2.4m width and 3 marshalling cars, passenger flow volume at peak hour is about 5000 under the hypothesis.

3.2 Technical features analysis

Urban public traffic develops seven categories: metro system, straddle monorail, suspended monorail, modern tram, maglev system, automated guideway transit and BRT. Modern tram and BRT system have the same capacity with suspended monorail. Technical features of the three systems are compared in Table 4. Suspended monorail has remarkable features of high punctuality, low impact on the environment, good city landscape, litter effect on ground resources and transportation. Due to feature of elevated transit, rescue services for train faults are difficult(ZHOU Meiyan,2014). There are some rescue measures(Figure 5). If train failure appears in a single line and it can’t move any more, a rescue train should be sent to fault location and passengers can be evacuated to the rescue train from the front door, or evacuated to ground by vertical evacuation passageway, such as rope, slide, aerial ladder and so on. If there are double track lines, passengers can be evacuated from the side door.

Table 4. Technology features of suspended monorail, Modern Tram and BRT

		Suspended Monorail	BRT	Modern Tram
Line condition	Grading	10%	6%	6.5%
	Minimum curving radiu(m)	30	24	For steel wheel: 18 For rubber tire: 11
Operation indicators	Running speed (km/h)	20-30	15-30	15-25
	Train punctuality	High，not affected by the ground traffic congestion	High, affected by the weather	Low, affected by ground traffic congestion and weather
	Rescue situation	difficult	easy	easy
Environment effect	Noise(dB)	<65	75	For steel wheel:70 For rubber tire: 65
	Waste gas	No	Serious	No
	Landscape	Elevated running, Good vision and landscape	Ground and elevated running, General vision and landscape	Ground running, limited vision and landscape

Figure 5. Rescue measures of suspended monorail systems

3.3 Engineering construction and cost features analysis

Engineering construction and cost features of suspended monorail, modern tram, and BRT are compared in Table 5(ZHOU Meiyan,2014). Suspended monorail possesses advantages of low construction difficulty. All parts, including track beam, beam column and so on, use batch production and site construction is simple. So construction time is the shortest. Cost per kilometer of suspended monorail is about 120~150 million. Except the station, all parts of monorail require litter ground space. If lines change the route or remove, the parts can be moved easily and previous engineering cost should not be wasted.

Table 5. Construction and cost of suspended monorail, modern tram and BRT

	Suspended Monorail	BRT	Modern Tram	Metro
Construction period	1-2 year	1-2 year	2-3 year	4-5 year
Construction time	Prefabricated structures, Site assembly，< 1 year	Site construction, 1-2 year	Site construction, 2-3 year	Site construction, 4-5 year
Cost (hundred million RMB/ km)	1.2-1.5	0.3-0.5	0.8-1.5	5-8

4 Function orientation of suspended monorail system

Function orientation of suspended monorail system is summarized as follows:

(1) Passenger flow volume at peak hour is about 5000 and it belongs to urban rail transit with low traffic volume.

(2)It can be used as a supplement of urban rail transit in big cities or the main line in medium cities, or a traffic line between the central city and satellite towns.

(3)It can be built as internal transportation tools for airport terminals, large business districts and economic development zones.

(4)It can be designed for city landscape sightseeing.

(5)It is adapted to the district that ground traffic becomes saturated and underground construction condition is special. Cities with rich buried relics, abundant spring water, or special soft soil, are suitable for suspended monorail.

5 Domestic application and development advice of suspended monorail system

A proposal of NPC &CPPCC Sessions 2012, advice to alleviate urban traffic congestion phenomenon by suspended monorail system(Qin Wu,2013), was made. Some cities, such as Tianjing, Shanghai, Hefei, Jinan, Qingdao, Guiyang and Wenzhou, show clear intentions to construct suspended monorail or are carrying out feasibility studies. At present, preliminary planning mileage for suspended monorail transit in China is close to 300 km.

Primary key to promote suspended monorail system in China is to nationalize its design and manufacturing technology. The promotion way can learn from the implementation of mid-low speed maglev traffic in domestic. Firstly, test lines or test running lines are built to prove and master the technology of suspended monorail. And then, tests for homemade equipment are carried out and improved equipment can be manufactured. Further development potential of suspended monorail in domestic cities should be excavated. Then whole-set equipment of suspended monorail system can be brought to the market maturely.

Abstract: Under the background of urban rail transit's rapid development, urban rail transit station， as the only connection of urban space and rail transit， undertakes the responsibility of traffic organization and passenger volume distribution. Influenced urban realm around station becomes the focus of the optimization of the sustainable urban development. Pedestrian Microscopic Simulation method establishes the comprehensive dynamic behavior rules in a part of urban space through simulating the behavior law by digital tools， in which can explain the internal demand and motive mechanism of the development and change of urban space fairly well by digital representing and analyzing relevant laws. After that, the research with the realm as the carrier analyzed the demand of each simulation level and the choice of simulation parameters based on analyzing the walking connection behavior characteristics, and then further established the methodology system of pedestrian microscopic simulation. At last the research taking the study of influenced urban realm around typical station for sample explored the application method of optimizing of urban space and traffic organization based on Anylogic platform.
Keywords: Urban rail transit; Optimization of traffic organization; Influenced urban realm around station; Walking connection behavior; Pedestrian microscopic simulation.

1 Introduction

In transportation design and analysis Pedestrian Microscopic Simulation are common. The different behaviors of pedestrians can be simulated based on different mathematic models. In urban design, by digital simulation of individuals and the interaction between them in the urban area, Pedestrian Microscopic Simulation illustrates the bottom-up dynamic mechanism and process of urban space development and introduces the technology into urban design, optimizing and updating to a great extent, so as to effectively improve the ability of problem-solving of urban design on the micro level. In urban design, the natural conflict between human demands and space requirements are prioritized. Among features related to behavior law has become the key element relating to urban space. It is a key point in future research on urban space features.

Currently, the social force model is perhaps the best known. In 1995, physicists Helbing and Molnar first proposed its embryonic form, and later published a model in the journal Nature in 2000. The social force model can simulate the self-organization process of pedestrians, and thus vividly reflect behavior features of the pedestrian flow. Representative software includes Anylogic, SimWalk and NOMAD, etc.

It is a quite challenging and very urgent problem to organize stations and the surrounding urban space from the micro perspective. Applying the Pedestrian Microscopic Simulation technology to the urban design of Influenced Urban Realm around Station is the current application of self-organization planning. Among various self-organization planning methods abroad, multi-individual simulation centered on Pedestrian Microscopic Simulation is a practical and increasingly mature method. There have been successful examples regarding multi-rail transit and comprehensive development of surrounding urban environment based on the technology in several countries and regions including Hong Kong, Japan and the UK.

2 Research and application foundation

2.1 Simulation requirements of Pedestrian connection behavior

This research focuses on the influence of a station on the urban space based on pedestrian timings. The Influenced Urban Realm around Station refers to a certain urban space around a specific station, in which various behaviors of individuals will be influenced by this station. From the 1950s, the research on pedestrian behavior features shifted from macro features to micro ones. Pedestrian Micro behavior Three-Level Theory proposed by Hoogendoorn and Bovy from Delft University of Technology in the Netherlands divided pedestrian micro behavior into three levels (Hoogendoorn S. P., P.H.L. Bovy, 2004), namely strategy level, tactical level and operational level, corresponding to the psychological decision-making process of pedestrians, and received relatively wide recognition. Referring to the Three-Level Theory, pedestrian behavior features in the micro simulation can also be divided into the perception level, option level and action level (Figure 1). Different levels have different simulation requirements (Hu Mingwei, Shi Qixin, 2009; Jia Hongfei, Yang Lili, Tang Ming, Meng Dan, 2009).

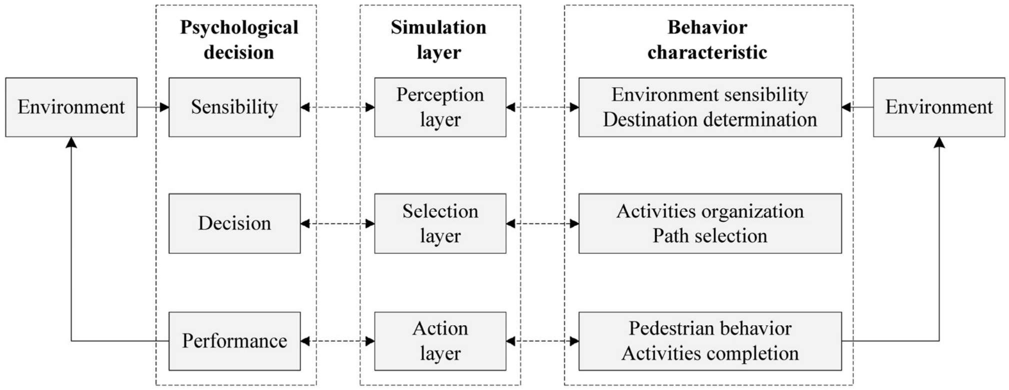

Figure 1. The relationship between psychological decision and behavior simulation

2.2 Characteristic parameters of pedestrian connection behavior

Pedestrian behavior feature parameters can be divided into macro and micro parameters. According to the area of urban design, together with current studies by relevant scholars, the simulation requirements level and the simulation feasibility of every parameter were summed up (Helbing D., Farkas I., Vicsek T, 2000).

In the specific simulation process, it is impossible and not necessary to take all behavior feature parameters into consideration (Zhang Guobin, 2009). Therefore the simulation parameter needs to be simplified to some extent, as long as the major features of pedestrian connection behavior can be demonstrated. As for the requirements of the simulation, some simulation parameters are preserved or eliminated. Finally, walking speed, space requirements, walking influenced scope, accelerated speed, destination, active link, turning actions, queuing, waiting, and facility influence are included in the major parameters of simulation.

3 Applications for pedestrian micro-simulation technology

Exploring the methodology for introducing Pedestrian Microscopic Simulation into the micro process of urban design is a key stage in connecting urban space and rail transit. The application of the technology consists of three stages, namely urban survey, survey statistics and simulation analysis. This research chose Anylogic7.0 as the software platform and used the social force model to conduct the pedestrian micro-simulation study (Figure 2).

Liziba station on the Chongqing light rail network's Line 2, is located by the Jialing River in the city's central Yuzhong District. It is housed within a large residential tower block. The station is on the 6th floor due to the hilly local landscape. Exit B of the station connects to an upper road running along a ridge behind the building at 6th floor level while Exit A is down on the first floor. The station is close to residential areas and bus stops with a large population flow, complicated traffic routes and unusual space.

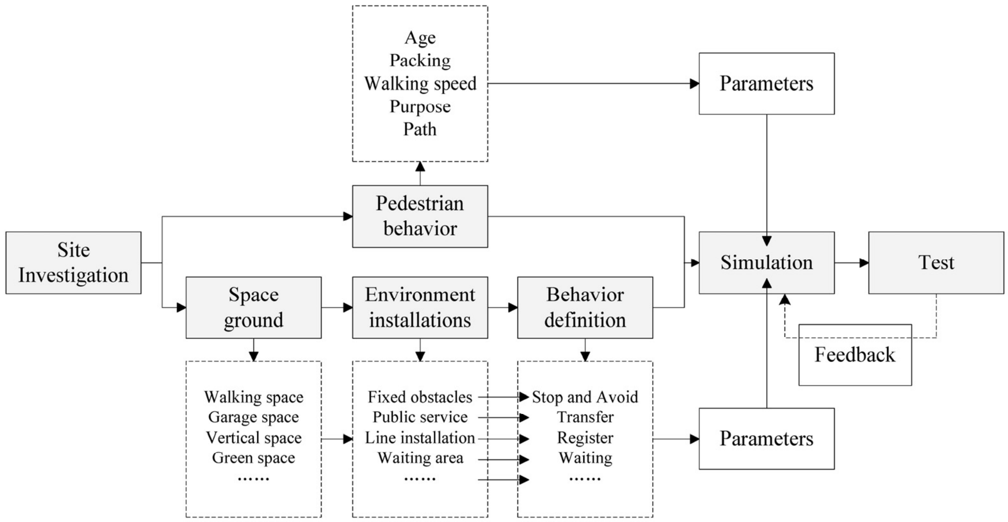

Figure 2. Simulation Process of Anylogic

3.1 Survey of urban information

According to the requirements of the research and software simulation, the survey consists of two major parts: physical environment and pedestrian behavior (Figure 3). There are four major aspects:

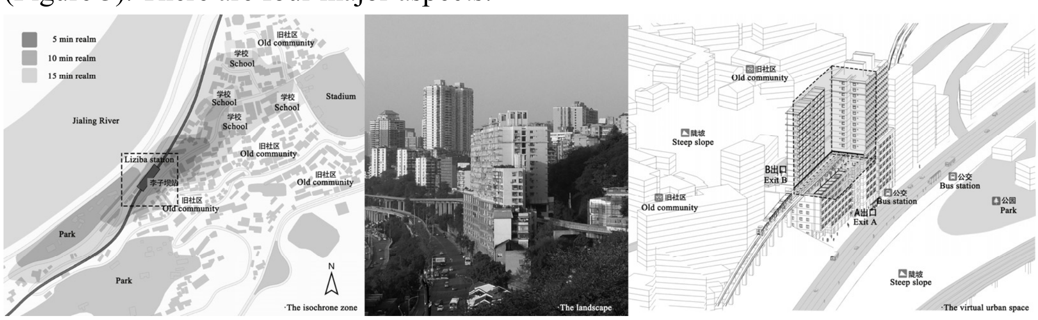

Figure 3. The isochrone zone and landscape of Liziba station

(1) Work out the isochrone zone, so as to identify the simulation scope and the urban elements.

(2) Establish the mathematical model. In this way, the base map of the simulation region is generated and all functional regions are identified.

(3) Calculate the traffic volume and the pedestrian component ratio at every key point in the simulation region according to the record.

(4) Survey the movement, capacity of buses and taxis within the simulation region, so as to identify the operational ability of this transferring method.

3.3 Simulation analysis

Anylogic provides a visualized simulation observation mode, enabling designers to better grasp the micro behavior of pedestrians. However, Anylogic does not provide a section mode. Hence, the section simulation effect of Liziba Station is drawn according to the simulation result, reflecting some problems. Please refer to Figure 4 for the pedestrian flow simulation result of urban design on a micro-level. The following conclusions can be drawn in line with the pedestrian flow figures of Liziba Station and surrounding pedestrian channels (Figure 4).

Figure 4. The pedestrian simulation flow diagram and present situation of Influenced Urban Realm around Liziba Station

Comparing the Anylogic simulation results and real scene images they can be seen to be very close indicating that Anylogic can go on to help improve pedestrian flows. Based on the above analysis of the simulation results, below are several recommendations for the Influenced Urban Realm around Station at Liziba and for further simulation:

(1) Broaden the width of stairways connecting Liziba Station platform and hall.

(2) Given that the function of the station hall is ensured, the collecting and distributing space at the station hall level can be enlarged via the subsidiary room so as to control pedestrian density at Exit A efficiently.

(3) Try best to cut down parking spaces along the street to the north side of Exit B, and enlarge the walking area for pedestrians to improve access for nearby residents.

(4) Creating a platform bridge by making use of the height differences of the station and vertical transportation at Exit A could separate pedestrians from vehicles, and eliminate security risks without adding a new line.

In summary, recommendations from the analysis of the Influenced Urban Realm around Liziba Station can solve the problems established in the first simulation. Should they did not achieve expect, analysis shall be carried out for the new problem with optimization again. This research is only the first exploration of pedestrian simulation method, in the hope that solution of microcosmic problems can facilitate the optimization in the Influenced Urban Realm around Station from macro level.

4 Conclusions

Here we may draw the following conclusions.

(1) The rapid expansion of cities and dramatic increase in complexity is undeniable. What should be ensured is that people's physical condition and behavioral competence will not be altered negatively due to the expansion of cities, nor will they see significant cultural / societal changes. While paying attention to urban macro system question, we shall also pay attention to the minutiae of the quality of people's lives.

(2) By exploring pedestrian micro simulations, the method of "simulation-optimization-re-simulation-re-optimization" was created. It has updated the methodology of urban design, perfected the appraisal system of urban design based on digital tools, and contributed refinements to urban design on a micro level. Meanwhile, by introducing Pedestrian Microscopic Simulation into urban design, this method has been applied in wider aspects, broken through its original traffic auxiliary analysis field, made a marked and positive effect on space comparison and rational decisions regarding urban design.

Influence Law of Urban Rail Transit Delay Propagation under Network Operation

Fengbo Liu

Key Laboratory of Road and Traffic Engineering, Ministry of Education, School of Transportation Engineering, Tongji University, Cao'an Rd. 4800, P.O. Box 201804, Shanghai. E-mail: 6fb@tongji.edu.cn

Abstract: Network operation perplex train delay and passenger flow delay which are the two typical representations of delays. Several train diagram models were set up to analyze train delay propagation characteristics and passenger flow affect. The most prominent characteristics is network dynamic property, and main factors are utilization of carrying capacity, distribution of delay and location of delay. Therefore computer simulation is applied for a case study of Shanghai Metro's Line 2 to find the influence law of these factors. Firstly, the simulation results help summarize several challenges of delay propagation for Urban Rail Transit (URT) Organization. Secondly, it is found that Operation Reliability is an important indicator of Urban Rail Transit Organization. The mutual effect between delay propagation and carrying capacity has been mainly reflected in actual URT Organization. Lastly, this paper provides URT with strategies to deal with these influence relation.
Keywords: Urban rail transit; Train delay; Network operation; Delay propagation; Computer simulation.

1 Introduction

Stochastic events will happen to URT to affect the normal operation，whose results are train delay and passenger flow delay in general. Under the condition of network operation, these delays propagate in its own line and others which has transfer relation to the line, meaning spread in the whole network, due to the complex network scale and structure, various train operation modes and complicated passenger flow distribution. Therefore, networked delay propagate is more complicated and needs more attention.

2 Literature review

Researches about URT train delay at home and abroad can be summed up as four aspects: generation mechanism, propagation characteristics, influence factors, network reliability. Several classic results are as follows:

YUAN J et al. (YUAN J et al., 2007) proposed a stochastic model of train delay propagation in stations to estimate the knock-on delays. The stochastic variations of track occupancy times were modelled with conditional probability distributions. The model can be applied for optimizing the station capacity utilization. XU Ruihua et al.

(XU Ruihua et al., 2006) analyzed several characteristics of train delay propagation and established the train delay simulation model of Urban Mass Transit, then found the related influencing factors of train delay and the spread of delay propagation. WANG Zhiqiang et al. (WANG Zhiqiang et al., 2009) designed a URT network's simulation analysis model and network's connection reliability evaluation index. JIANG Zhibin et al. (JIANG Zhibin et al., 2012) proposed a simulation model and found some passengers may get benefits from the short delay, but large initial train delay may result in not only knock-on train and passenger delays along the same line or the entire rail transit network.

Simulation techniques can be used to study train delay. XU Ming et al. (XU Ming et al., 2004) illustrated the modeling-method, the structure design, the function realization, evaluates parameters of a train operational delay simulation system. Besides, many institutions have researched train delay and the reliability of train diagram, etc. through microscopic simulation, developed some simulation systems (such as RailPlan, RailSys, OpenTrack, RailSim, RECIFE, etc.).

In contrast to the above, this paper takes the network operation into account, and analysis the influence law of URT delay propagation.

3 Delay propagation law in network operation

3.1 Propagation characteristics of train delay

Initial train delay may occur in a station or a section, then it may trigger joint delays to other trains because of connectivity of line and network.

(1) Rapidity and directness

The most lines of URT's only have two main tracks. The interval and buffer time between trains are both small. Therefore, train delay will spread more directly and rapidly, which can be illustrated by figure 1.

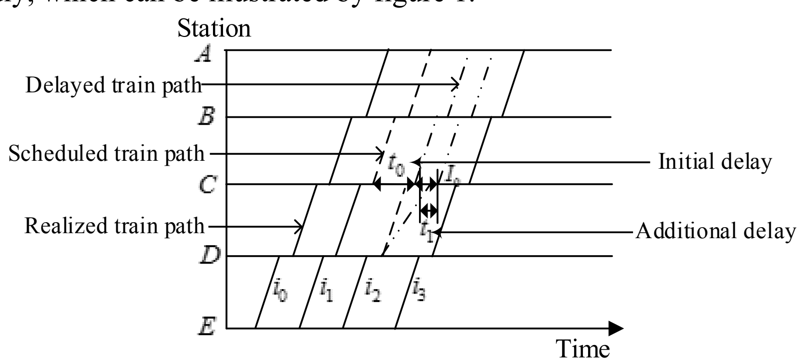

Figure 1. The train delay propagation rapidly and directly

(2) Two directions

1) Propagation forward: When some train delay happens, the forward train may be detained at forward station for a while to reduce the interval between the two trains, which can be illustrated by figure 2(a).

2) Propagation backward: Expect for spreading backward in same direction, train delay may still spread in another direction, because the rolling stock is used by cycling. When a train is delayed in one direction, it may still delayed when it starting at the circulation station unless the delay is eliminated completely by buffer time.

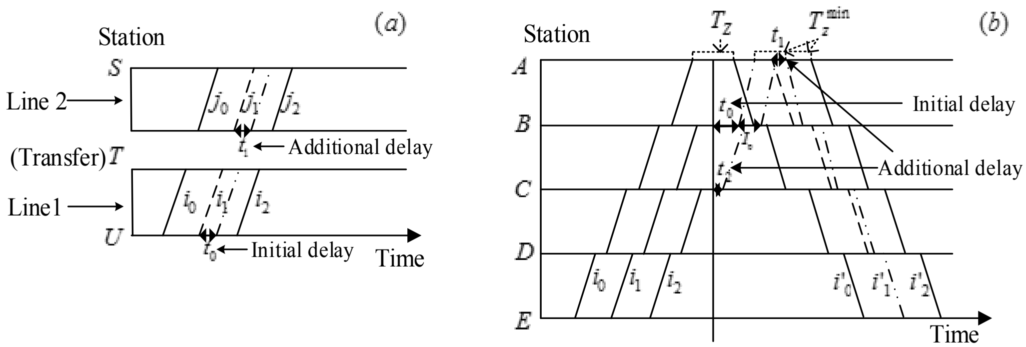

Figure 2. Examples of forward propagation (a) and counter propagation (b)

(3) Network propagation

Lines connect each other through the transfer station in network. When a train is delayed in a line, thus may lead to a lot passengers transferring to other lines to keep away from the delay, if there have delay until so this is a diffusion phenomenon in network.

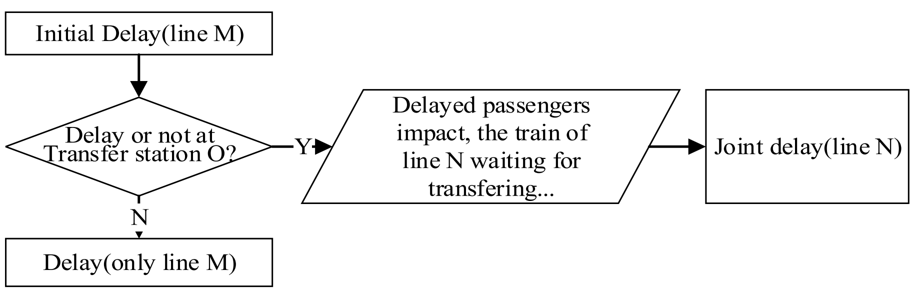

Figure 3. Network propagation process

(4) Network dynamic property

There is a buffer time between two trains in general, the length of buffer time determines the propagation speed and absorbed level of delay. If buffer time is smaller than initial train delay, the delay will spread dynamically in network, which means initial delay will be absorbed gradually, or second delay may be caused by relevant circumstances. 'Adjustment time' can be defined to describe the above adjustment process of delay, it begins with initial delay occurs, end in recovering plan operation.

3.2 Characteristics of passenger flow affected

Passenger flow will be affected by train delay. A travel time (T) including walking time into stations (t_w^i), all of waiting time($\sum t_w$), all of riding time($\sum t_r$), transferring time (t_w^t), and walking time out stations (t_w^o), among which waiting time and riding time are susceptible to train delay.

$$T = t_w^i + \sum t_w + \sum t_r + t_w^t + t_w^o$$

(1) Stage Differences

Riding time delay changes with the train delay, while waiting time delay or not is indicated by arrive time and train departure time.

(2) Dynamic change

The passengers' once waiting time or once riding time delay does not always lead to total travel time delay. For example, a train may accelerate to smooth over the waiting time delay. Besides, a passenger may transfer another train more quickly and reduce waiting time when the former train has a small delay, so he can arrive his destination punctually.

(3) Passive delay

Because of the influence of train delay and delay adjustment measures, the travel time delay is passive for each passenger. Especially, some trains have high load factors at rush hours of URT network, and Transfer stations have large passenger flow, they board the first transfer train hardly and are easy to be delayed. This situation is common in recent years.

4 Delay propagation simulation

4.1 Simulation design

The RailSys software is adopted to simulate Shanghai Metro line 2's train operation environment and operation mode, where stochastic delay is set according to delay analysis parameters (Table 1). 50 times simulation experiments are run to get relative indicators more accurately.

Table 1. Delay analysis parameters

A~Capacity utilization ratio	B~The delay distribution	C~ The initial delay location
A1~ 85.7%	B1~0min:2min:5min:10min = 90:8:2:0	C1~station XJD
A2~ 90.4%	B2~0min:2min:5min:10min = 90:6:2:2	C2~station PPS (busy)

4.2 Simulation results

There are schemes comparison according to the simulation results (Figure 4):

Scheme 1:（A1B1C1 and A2B1C1）the influence of different capacity utilization

For improved capacity utilization ratio in A2B1C1, high train density leads to more serious delay propagation than A1B1C1. We can see that initial delay (arrival delay and departure delay) at station XJD in A2B1C1 is longer. What's more, the train running speed can’t increase and the stop time can’t shorten because train operation interval is short.

Scheme 2:（A1B1C1 and A1B2C1）the influence of different delay distribution

The delay distribution is described by the proportion of various delay time, 0min means there is no delay. For A1B2C1, The delay time growth and the propagation scope increases observably, which means 2% 10min delay has a great influence. Because the long distance between HQA and SHR, the trains keep a higher speed running a long time, so the delay are absorbed greatly. However, the delay becomes severe because of higher train density and shorter section distance since NJX.

Scheme 3:（A1B1C1 and A1B1C2）the influence of different delay location

The initial delay occurs at a busy station (PPS) in A1B1C2, then we can see the delay disappears more slowly than A1B1C1, because there are more trains in these sections during the Adjustment time, so the buffer time is less and not enough to absorb the delay.

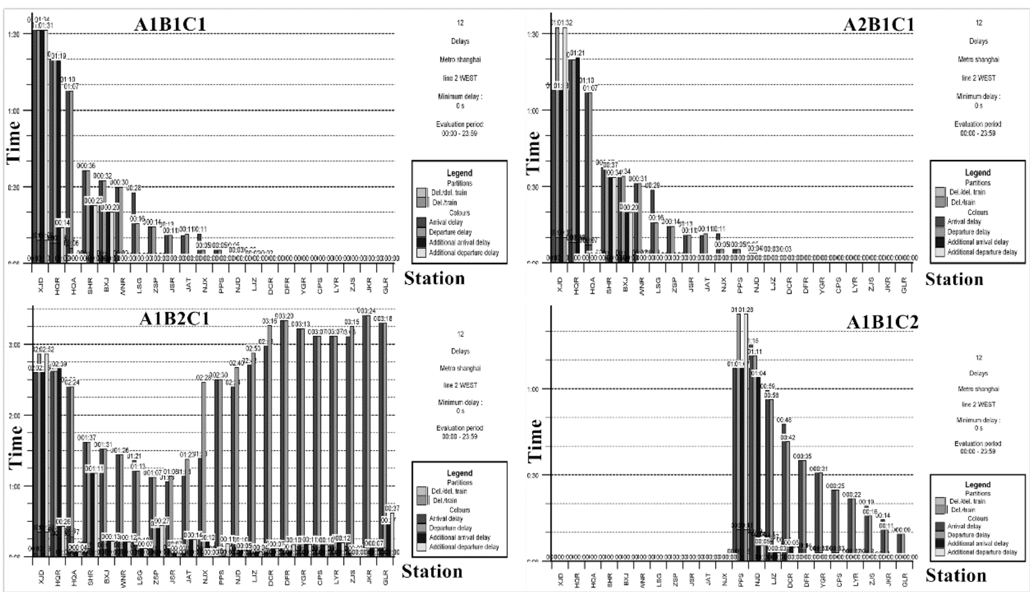

Figure 4. Delay propagation simulation results

5 Conclusions

(1) It is observed that higher capacity utilization ratio means greater challenges. In the event of a train delay, Operation Reliability will be effected. Therefore, capacity utilization ratio should keep within a certain range. The dot in figure 5 expresses the best capacity utilization ratio for reliable operation.

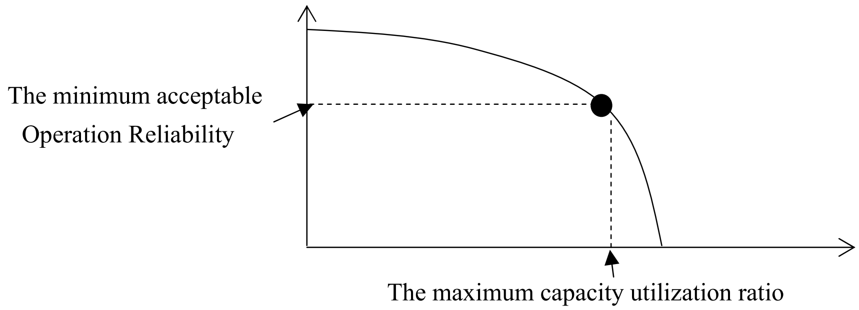

Figure 5. The reliability of capacity utilization and Operation Reliability

(2) It is also observed that large delay has greater influence, so we should avoid it in the process of URT Organization.

(3) There are some strategies to deal with these influence relation: 1) a certain amount of buffer time is necessary for dealing with stochastic delay. 2) Do a good job in prevention of early warning, reduce the possibility of emergency delay. 3) Optimize operation organization work and security the train operation order of busy stations or sections.

6 Recommendations for Future Research

The passengers' route choice behavior is important to future study so that it can be replicated in microscopic simulation models to represent more realistic train operation conditions.

Abstract: According to the design requirements of CBTC simulation platform, the fault injection model of track-side equipment carries out research, at the same time, the circuits are designed and the software are tested on dynamic simulation sand table. In this article, the operation principles, fault characteristics and trigger mechanisms of the track-side equipment such as the responder, emergency shutdown button, signal light and turnout are analyzed and designed. And the feasibility of fault injection model is verified by testing the fault injection. The fault diagnoses and emergency command abilities of Railway operating training staff are trained by the fault injection, at the same time, it also provides some services for the teaching and training.
Keywords: Urban rail; Simulation; Fault simulation; Control system.

1 Introduction

Urban Rail Traffic Control Laboratory is a laboratory construction project of Southwest Jiaotong University Emei Campus Ministry of Education to improve the basic conditions of school. The Urban Rail Traffic Control Laboratory consists of five training platforms, including the urban rail operation simulation platform based on the simulation of the urban rail transit operation sand table, the equipment operation platform which is based on the train operation control system and network traffic technology, the management and control integration simulation training platform based on station signal control system and ISCS underlying hardware and software technology, ATS signal interlock simulation training platform based on train signal supervision system and DCS system, and control system coordination and dispatching training platform based on the simulation environment under abnormal conditions.

The design concept of Urban Rail Operation Simulation Platform is to simulate train track, train reversal, etc. process in urban rail traffic. Through simulating urban rail abnormal operating conditions, train the analyzing and solving capability of students for emergency, emergency plan, and typical case. Currently, the control system of sand table only can do simple control for signal equipment, without detection feedback function. Owing there is no detection feedback function, control system does not know whether the control is in place, all kinds of setting fault in sand table cannot be returned back to the interlock host, and cannot simulate the rail operation under abnormal conditions.

The prerequisite of setting fault on the sand table is reading back signal equipment status. The feature of the control system in the paper is that it can periodically collect the signal equipment status information, deliver the change of status back to the interlock host, and simulate the rail operation under abnormal condition by the fault injection.

2 The control system and interface

The signal equipment such as the signal light, turnout, departure indicator and emergency shutdown button are used on the sand table. The signal equipment on the sand table is mainly concentrated in the station and small part is on the rail line. The most of data is switch signal and the amount of data is small. The design of control system interface should consider the following factors: the rate of information, data format, interference immunity, the wiring convenience of the sand table, real-time, expansibility and other factors. The RS-485 interface uses differential signal and has strong interference immunity, easy networking and cheap price. In addition, the interface can transport between long distance, and the communication speed can meet the need of control and detection. The RS-485 is suitable as a communication interface between the control system and the interlock host. The control system structure is shown in Figure 1.Multiple control system is connected to the interlocking host via RS-485 bus and the interlock host could check the logical relationship of signal equipment and access to the operating control center(OCC) for unified management. The control system consists of three parts, including signal light drive and detection, turnout drive and detection, interface and protocol. Departure indicator and emergency shutdown button can be completed by using signal light drive and detection circuit.

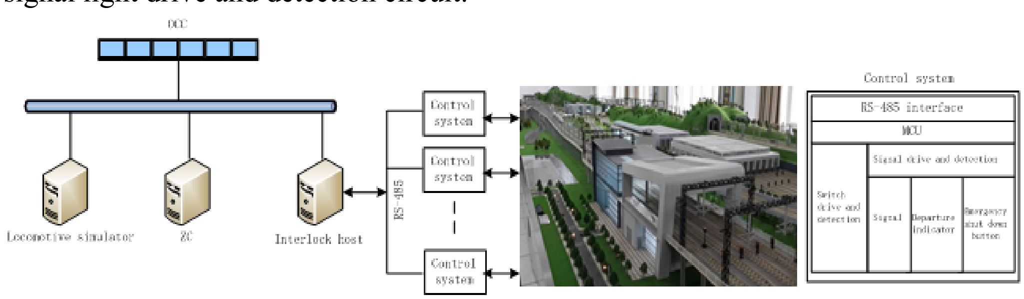

Figure 1. The control system structure

The communication interface and protocol are shown in Figure 2.The differential transceiver SN75LBC184 has transient voltage suppression, does not need external chip protection circuit. The RS-485 network terminal uses 120 ohm resistor terminal. The RS-485 interface of each node is always in the state of receiving data, the interface switches to transmit mode when sending data to the interlock host. The MCU of control system uses STC12C5A60S2, and the RS-485 interface is connected to the UART interface of MCU. When the MCU transmits data to the RS-485, only need to operate the UART interface.

	interlock host ->sand table	sand table ->interlock host
byte 0	SYN(0xAB)	SYN(0xCD)
byte 1	address	address
byte 2	CW	CW
byte 3	data length	data length
byte 4	data 0	data 0
byte 5	data 1	data 1
byte ···	······	······
byte n-1	check	check

Serial data frame format

Figure 2. The communication interface and protocol

RS-485 uses half-duplex communication mode, and the data transmits in serial mode. The structure of data includes synchronization character, address, the data length, data and check. In order to distinguish the direction of data flow, data frame synchronization character from the interlock host to the sand table uses 0xAB, from the sand table to the interlock host uses 0xCD.Address is a unique address curing in control system, stores in the EEROM region of STC MCU. Command word contains reading and writing the address, reading and writing the turnout status, reading and writing the signal status, writing the departure indicator status, and reading the emergency stop button status. The third byte of data frame determines the data length, and the last byte is check word.

3 Signal light drive and fault detection

The number of signal lights on the sand table is large, and the signal light uses various colors of light emitting diodes. The driving circuit is generally connected with a resistor. Signal detection is mainly to detect signal lamp in normal status, short circuit status, open circuit status or the ground status. LED has a different pressure drop when the lighting, red or yellow is between 1.8V and 2.5V, green is between 2.7V and 3.5V. When the signal voltage drop is in the range of LED lighting, you can explain that the signal is lighting and normal. If the signal is not normal, we determine light is in short circuit, open circuit, or ground fault condition.

The input level threshold of flipping CMOS gate circuit is always half of power , and with power fluctuates. According to this feature, when we design for the auxiliary detection circuit, the voltage drop determination signal is converted to a logical value determination. The signal light auxiliary detection circuit is shown in Figure 3(a).Owing the number of lights is particularly much, so we design a signal light driving and detection card for each 32 lights. The card uses the SPI bus cascade as shown in Figure 3(b).The control data is sent from the serial input and parallel output shift register 74HC595, and the test data is looped back from the parallel input and serial output shift register 74HC165.The shift register is fabricated by CMOS process, every two manage a signal light.

(b)signal light control and detection card circuit

Figure 3. Signal light drive and detection circuit

The signal light control and detection card circuit is shown in Figure 3(b).When the signal light L0 is controlled, the control data will be sent to the Q0 terminal of 74HC595.If the Q0 terminal outputs high level, the light will be turned off. And the low level will make light on. When detecting the signal light L0, enter 00B, 01B, 10B and 11B four kinds of logical values to Q0 and Q1 terminal. Then read back the logical value from D0 and D1 terminal. Four kinds of logical values from the low to the high combines into a byte, the byte is equipment state value. As shown in Figure 3(c), the equipment state value of light is different. Through the equipment state value, we can determine the fault condition of signal light. The control method of the remaining signal light is similar to above method, the light x is managed by Q_{2x}, Q_{2x+1}, D_{2x} and D_{2x+1}.

4 Turnout drive and fault detection

The switch machine uses the push-pull electromagnet, electromagnet magnetic will make the switch locking. A switch drive and detection card can manage four switches, the board uses SPI bus. The data of switch drive outputs by parallel port 74HC595, acquisition data and fault data are sent to the 74HC165 parallel port. The turnout control and detection circuit is shown in Figure 4.The turnout drive signal is Q0 pin of 74HC595.Through the control of combinational logic circuit, the coil current of L293D switch machine is in forward, reverse or no current.

The detection of the turnout uses non-contact optoelectronic switch, and the location and anti-location both install one separately. When the turnout is moved, it will drive the turnout linkage mechanism, and when the turnout linkage mechanism reach reliably one side of location (anti-location) detector, the detector will output location (anti-location) pulse signal. The location (anti-location) detection circuit uses firstly inverter 40106, resistors and capacitors to constitute TTL inverter and RC oscillator, and the output square wave signal drives the infrared light emitting diodes. To generate different frequency pulses, the resistor of the location (anti-location) detection circuit will be set different values, therefore, the pulse input of location (anti-location) are distinguished by the frequency. After the infrared receiver diode receives the signals, the signals are modulated and outputted to the MCU to identify, and then the identified turnout states are sent back to the main control card by the D0 port of the 74HC165.

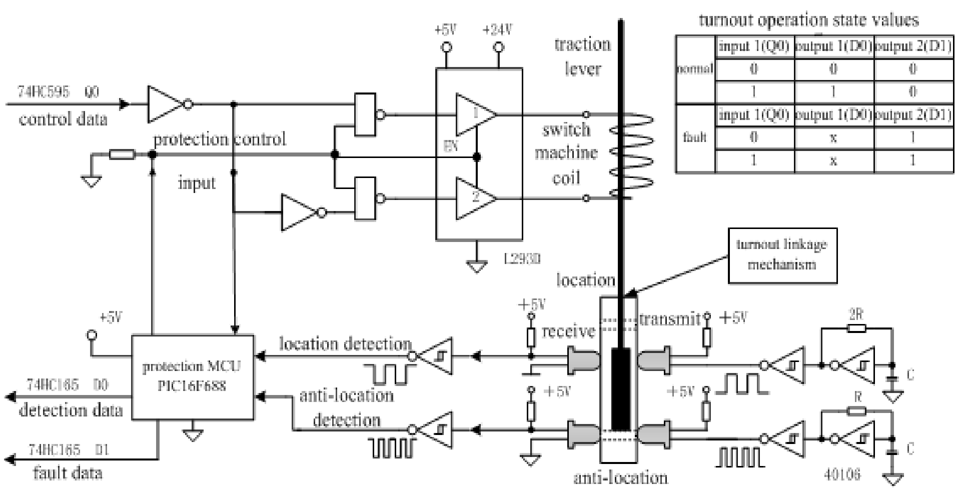

Figure 4. Turnout control and detection circuit

Due to the coil of switch machine is drove by DC power, the coil impedance is small. So the switch machine can not be supplied power for a long time, otherwise it will burn the coil or driver chip L293D.Through the comparison of the control data and the detected data, identify the turnout is in place or not. In order to cut off power of switch machine coil, achieve the purpose of protecting MCU. The detection data and fault data are returned back to the main control card by the D1 port of the 74HC165.

5 The control system fault injection and test

A sand table has many lines, a line has many control systems, they are arranged in a control cabinet. Every control system is connected to the interlock host by the RS-485 bus. A set of control system contains a main control card, many signal machine driving and detecting cards and turnout driving and detecting cards, and manage one station or more adjacent stations. Each control system contains main control card, signal machine driving and detecting card, turnout driving and detecting card, and they are cascade connected through SPI bus. The main control card is responsible for communication, outputting control signals and reading back detection data. And the signal machine driving and detecting card manages signal machine, departure indicator and emergency stop button. The turnout driving and detecting card is responsible for managing the turnout. The physical diagram of control system is shown in Figure 5.

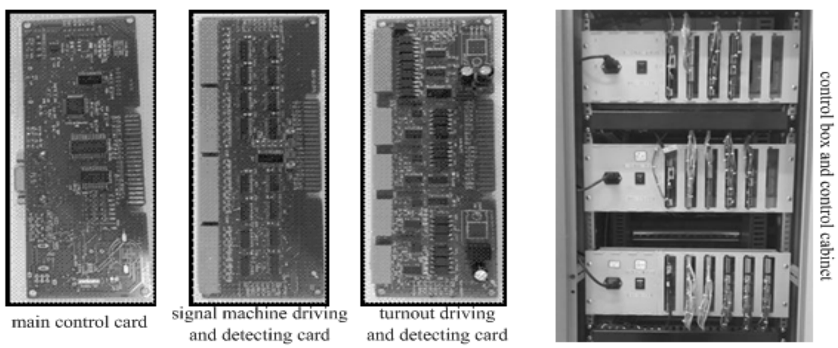

Figure 5. The physical diagram of control system

Through controlling and detecting the signal equipment on the sand table, all aspects of urban rail operation simulation software are reflected truly. The simulation software can make students master all aspects of urban rail operation quickly, and verify the logic relation of interlock parts. The urban rail operation condition is shown in Figure 6. Many groups of students study and practice in the line, prove that the control system is reliable and feasible.

Figure 6. The urban rail operation condition

6 Conclusions

The urban rail simulation laboratory could simulate many kinds of abnormal condition, and provide specific practices for the all professional students. For the students of signal profession, the lab could train many abilities of students, such as interlock logic relationship, the system signal control, communication, equipment failure identification, etc. For the students of operation management profession, it could provide vertical and horizontal linkage training based on various normal and abnormal situations in the positions such as operation coordination, emergency command center, control center, station, train, etc. The control system relies entirely on the self-exploration, self-development, from easy to difficult, in the last it is improved gradually. Compared with the similar laboratory, the laboratory focuses more on training. It is an important reference for training students which study in railway transportation, railway signal or other profession in laboratory construction.

Motion Simulation of a Vessel Based on Standard Environmental Conditions and Dynamic Assessment

Rukai Zhang, Guangshu Dai; and Zeliang Wu

Navigation Department, Tianjin Maritime College, 8 Yashen Rd., Jinnan District, Tianjin. E-mail: kaidesky@163.com

Abstract: The motion simulation of vessel play a very important role in the maritime full mission simulator, which can show the user some kinds of simulation environment in the fixed sea and meteorological conditions. The purpose of this paper is to decide the way of vessels motion in the fixed sea and meteorological conditions by use of the real-time hydrological and meteorological information, and the dynamic assessment of the security situation of vessels can be done at the same time.

Keywords: Vessel motion simulation; Simulator; Sea state; Dynamic assessment.

1 Introduction

With the rapid development of marine economy, marine disasters, caused by heavy weather especially sea wind, fog and the derived bad sea condition (storm surges, waves, current etc.), happen frequently and are more and more prominent to maritime security.

Usually, seaman deals with the bad weather mainly based on experiences, and takes action according to the meteorological information obtained by NAVTEX. The purpose of this paper is to show the ship motion in bad weather by simulator to the user, and decide the security situation of vessels in bad weather by use of the real-time hydrological and meteorological information. So as to provide accurate safety information for the ships.

In china, (Huang, 2001) has done some research on the ship motion in the dynamic environment, and is very helpful for my research.

2 The model of storm force in the state of underway

2.1 model analysis of ship by force

The most serious failure state for the ship underway is to capsize. It is generally believed that the ships are influenced mostly in the horizontal state, so this study is based on the situation of crosswind.

Just as (G Bulian,2004) described, the roll motion of the ship affected by crosswind and wave can be expressed as the equation:

$$(J_{xx} + J_{add}) \cdot \ddot{\emptyset} + D(\dot{\emptyset}) + \Delta \cdot \overline{GZ}(\emptyset) = M_{wind,tot}(\emptyset, t) + M_{waves}(t) \qquad (1)$$

J_{xx}: ship moment of inertia in air, J_{add}: added moment of inertia, $D(\dot{\emptyset})$: general damping moment, Δ: ship displacement, $\overline{GZ}(\emptyset)$: restoring lever, $M_{wind,tot}(\emptyset, t)$: total instantaneous moment due to wind, $M_{waves}(t)$: total instantaneous moment due to waves.

For the sake of calculation convenience, the effects of wind is divided into two parts, the mean wind and the instaneous wind, when the ship is exposed to wind, the constant wind can only reduce the ability of ship against external gust effect; while the gust is the mainly cause of capsizing.

The heeling moment $\overline{M}_{wind}$ due to the wind can be expressed in the formula:

$$\overline{M}_{wind} = \frac{\rho_{air} \cdot \overline{V}_w{}^2 A_L C_y (H_w + H_{yd})}{2} \quad (2)$$

Where, ρ_{air}: air density, $\overline{V}_w$: mean wind speed, Hw: distance from the waterline of the center of aerodynamic pressures, Hyd: distance from the waterline of the center of hydrodynamic pressures, Cy: drag coefficient, AL: lateral projected area.

For the influence of mean wind, we can approximate changes the ship's GZ curves as follow. First of all, the mean wind made the stable position of the ship shifts fromΦ0 to ΦS. In consideration of the changes of stable position, the GZ value at the windward side becomes and the stability vanish angle becomes larger, while in the lee side shows the GZ value and stability vanish angle becomes smaller. The capsizing generally occurs at the lee side, so here only the lee side considered.

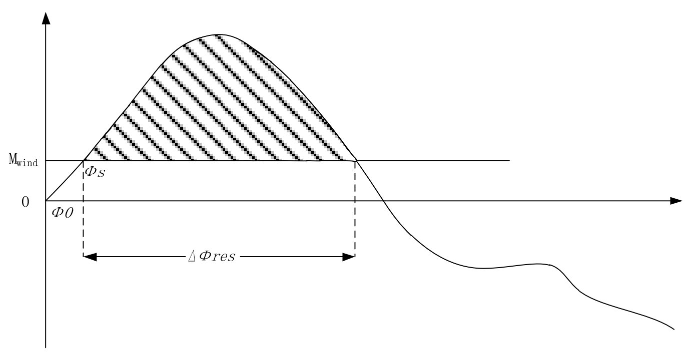

Fig.1 GZ curve schematic diagram and relevant parameters

2.2 Wind spectrum and wave spectrum analysis

The wind and the waves are all irregular random process. The effects of wind and wave on the ship can be most directly exhibited by the wind wave spectrum. This paper assumes that waves are fully developed by the effect of the wind, so the mutual relationship exists between the wind and the waves.

Because the wind direction is steady, this wind spectrum only includes the instaneous wind, and is described by Davenport spectrum:

$$S_{wind}(\omega) = \frac{K\overline{u}_{10}^2}{\omega} \acute{\chi}^2 (1 + \acute{\chi}^2)^{-\frac{4}{3}} \quad (0 \le \omega \le \infty) \quad (3)$$

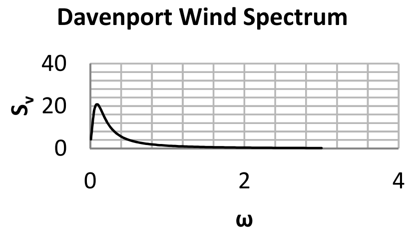

Fig.2 the davenport wind spectrum

Where, K: instaneous wind coefficient, and K=0.003, $\bar{u}_{10}$: mean wind velocity, ω: the frequency of instaneous wind and $\acute{\chi}$=600ω/π$\bar{u}_{10}$.

The sea elevation in metres is modeled using the spectrum recommended by the international towing tank conference（ITTC）as follow：

$$S_{wave}(\omega) = \frac{A}{\omega^5} exp\left(-\frac{B}{\omega^4}\right) \quad (4)$$

Where, A=8.10*10-3g2,B=3.11/$H_{1/3}{}^2$.

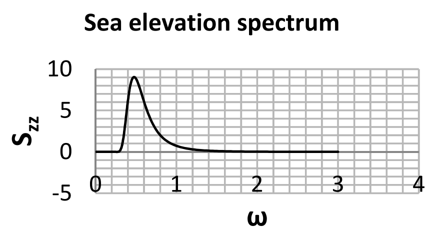

Fig.3 the sea elevation spectrum

3 The model of safety judgement for ship at sea

Through alternating the GZ curve, the mean wind influence upon ship is excluded, the movement of the ship will be irregular at the effect of the irregular waves. According to (Peng,1989). The spectrum of ship motion can be expressed as follow:

$$S(\omega) = \frac{\omega^4}{g^2} \frac{x_\theta{}^2}{(1-\wedge_\theta{}^2)^2 + 4\mu_\theta{}^2 \wedge_\theta{}^2} (S_{wind}(\omega) + S_{wind}(\omega)) \quad (5)$$

Where, ω: the encounter frequency of the ship, here $\omega = \omega_0 \left(1 + \frac{\omega_0}{g} \vartheta cos\theta\right)$, g: acceleration of gravity, x_θ: effective wave slop, $\wedge_\theta$: specific value of the encounter frequency and wave frequency, μ_θ: effective drag coefficient。

The roll angle standard deviation σ_x and the roll velocity standard deviation $\sigma_{\dot{x}}$ can get from the spectrum of ship motion:

$$\sigma_{\dot{x}}^{\ 2} = \int_0^{+\infty} \omega^2 S_x(\omega) d\omega \tag{6}$$

$$\sigma_x^{\ 2} = \int_0^{+\infty} S_x(\omega) d\omega \tag{7}$$

According to the characteristics of the wave spectrum, the motion of the ship around the steady position under the action of beam wind can be considered to be Gauss course. Assume that ship's capsizing accord with Poisson distribution, ship capsizing probability of exposure in a particular environment for a period of time can be got according to the Poisson equation. The capsizing probability of ship can be expressed as follow:

$$P = 1 - exp\left(-\frac{T_{exp}}{2\pi}\frac{\sigma_{\dot{x}}}{\sigma_x} exp\left(-\frac{1}{2}\left(\frac{\Delta\Phi}{\sigma_x}\right)^2\right)\right) \tag{8}$$

The probability of occurrence of different levels for different ship sailing under different wind conditions can be got by calculating.

4 Introduction of the system

4.1 system working principle

System workflow roughly as follows:

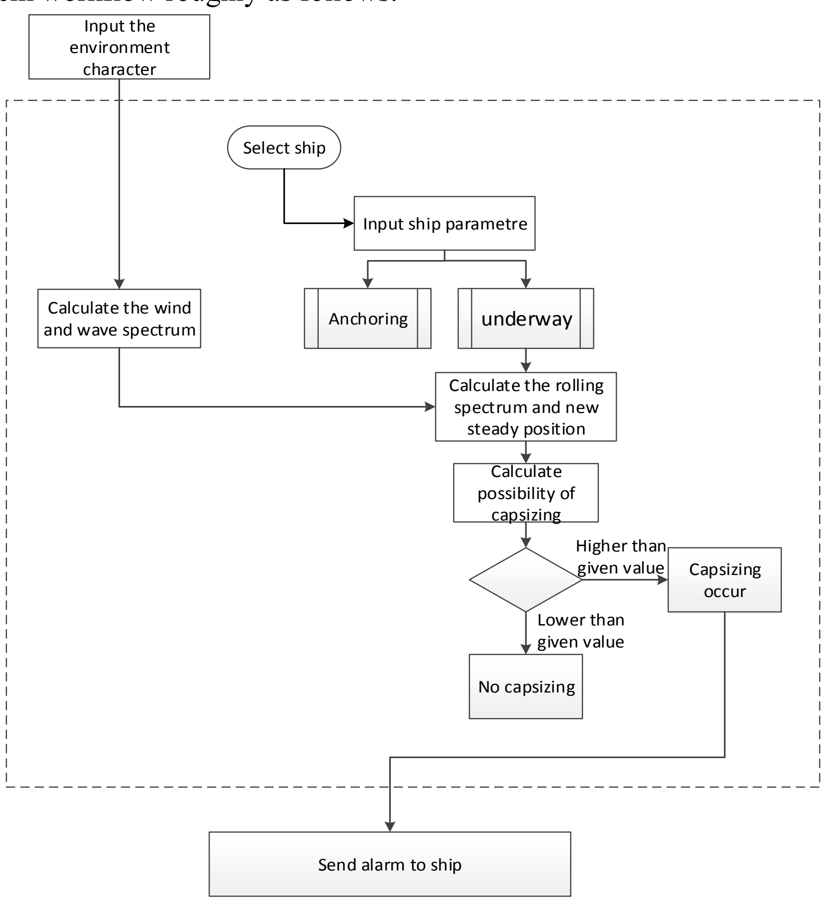

Fig.4 System work flow

Through the information platform and real-time observation we can get the environment information, and the detail of the ship is easy to get. Combining the ship location, ship detail and environment character, the possibility of capsizing can be got, and the danger degree of the ship is easy to judge.

Fig.5 Technical renderings of ship motion in the simulator

4.2 Practical application of the system

This system can be used in maritime supervision department or Shipping Co which often has ship sailing in the heavy sea area. Combining with a communication system, a computer processing, the system can be used alone, for route selection, navigation state monitor, reference for meteorological navigation; And the system can be used, together with the ENC system, radar system, AIS system, as additional calculation unit of ship monitoring or information display system. It is easy to judge ship in danger, and complete safety status monitoring and alarm of a series of ship. According to the calculation result, the safety navigation advice can be given.

5 Result and discussion

The methods of calculating the probability of capsizing of ship navigating in heavy sea area is studied in this paper. When the relevant departments predicts the ship is in danger, safety information can be conveyed to the ship in danger by the public communication network, the VHF or satellite equipment. Damage to the personnel, ship and cargo can be avoided. This system has positive significance to the navigation safety and navigation order of heavy sea area.

Reform of a Load Balancing Mechanism for a Railway Freight Vehicle

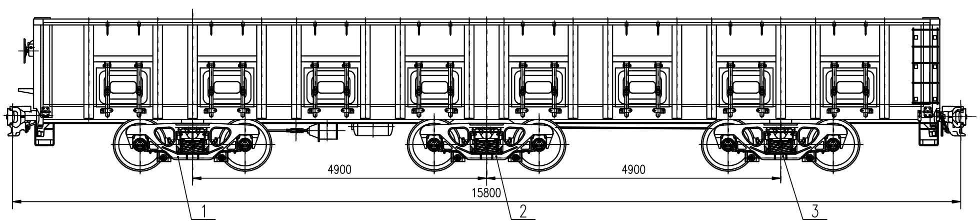
Jiafeng Sun and Li Liu

College of Traffic and Transportation Engineering, Dalian Jiaotong University, Dalian 116028, China. E-mail: dl_sjf@sina.com

Abstract: To achieve uniform distribution of loads over three bogies, we use two sets of load balancing mechanisms at the underframe of car body. The practical tests show that the load balancing mechanism has two problems: low efficiency, the difference between vertical forces at both ends being equalised reaches about 25%; response latency, the force at the passive end is always slightly delayed, which affects the uniform load effect when the vehicle operates at high speeds. This paper gives the principle and stress analysis of the railway freight vehicle load balancing mechanism, and provides the methods to improve the efficiency of the mechanism.
Keywords: Railway; Freight vehicle; Uniform load; Mechanism; Efficiency.

1 Introduction

Generally, the car body of railway freight vehicle is supported by two bogies and each bogie has two wheel set. The structure of the vehicle can be regarded as two-stage simple supported beam with uniform load, i.e., car body-bolster and bolster-wheel set (Zhao, W. H., 2000). To improve the vehicle loading, especially the concentrated loading capacity in the middle, a vehicle is developed with three bogies this year, named three-point support vehicle, as shown in Figure 1(Lin, J., 2003).

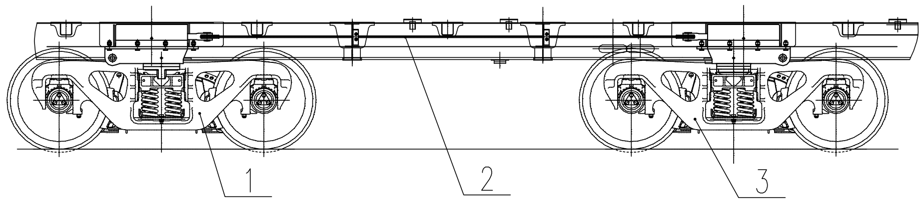


1—The bogie in Position 1, 2—The bogie in Position 2, 3—The bogie in Position 3

Figure 1.Three-point support railway freight vehicle

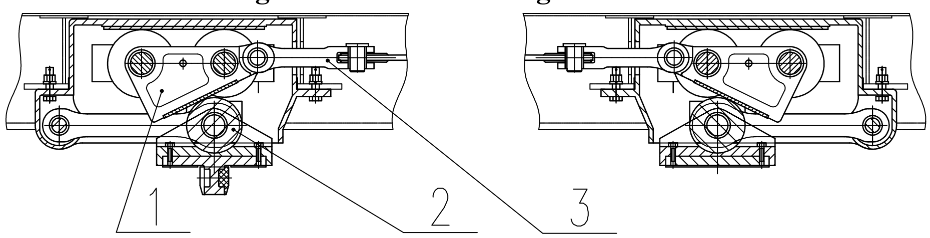
2 The problem in it

In order to achieve uniform distribution of loads over three bogies, the load balancing mechanism can be set at the underframe of car body, distributing even load on the bogie in the middle of the vehicle and the one at one end. There are two sets of load balancing mechanisms and vertical forces act on two side bearers of each bogie respectively. As simple force analysis shows, the bogie in the other end of the vehicle can get the same load as that two bogies. The load balancing mechanism is shown in Figures 2 and 3(Cao, Y., 2007).



1—The bogie in Position 2, 2—Load balancing mechanism, 3—The bogie in Position 3

Figure 2. Load balancing mechanism



1—Inclined wedge, 2—Roller, 3—Brace

Figure 3. Structure of load balancing mechanism

The load balancing mechanism is a kind of mechanism with inclined wedges. Although the load balancing mechanism can achieve uniform distribution of loads theoretically, it has two problems by testing:

(1)low efficiency, the difference between vertical forces at both ends being equalised reaches about 25%;

(2)response latency, the force at the passive end is always slightly delayed, which affects the uniform load effect when the vehicle operates at high speeds (Hu, H. P., 2010).

3 Force analysis of load balancing mechanism

The 1:1 effect of load balancing mechanism based on the present design theory can be obtained, after the detailed analysis of the present load balancing mechanism and the deduction of theoretical formula. However, the system working efficiency in practice manifests that a component of the load must be applied to overcome the friction of wedges and the initial elastic deformation of the braces. Therefore, uneven distribution of loads and latency are the inevitable results (Wang, F.D., 2003).

The equivalent force diagram of load balancing mechanism is shown in Figure 4, and the meanings of the symbols in the figure are shown as follows:

α_1 and α_2- the inclined wedge angle;

β_1 and β_2- the friction angle of the friction surface;

μ-the equivalent friction coefficient (the approximate value is 0.044, β=2.52°);

L_0- the distance between rollers in two horizontal planes;

x1 and x2- the horizontal distance;

L – the length of the brace.

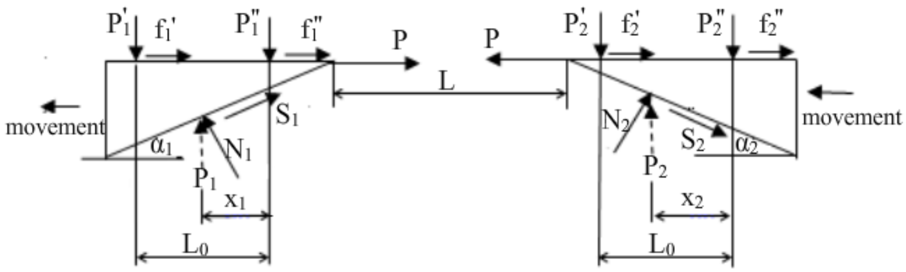


Figure 4.the equivalent model of load balancing mechanism

The end on the left is set to be active here. When dynamic load P_1 is transferred from the side bearers in active end to wedges, N_1 acts on slop, driving the left mechanism to move left. The brace pulls the right mechanism to the left after completing elastic deformation, driving the side bearers at the right end which is also the passive end to move down to complete motion for uniform load, and vice versa.

The following are fundamental formulas:

$$\mu = \tan\beta \tag{1}$$

$$f_i = \mu_2 P_i \tag{2}$$

$$S_i = \mu_1 N_i \tag{3}$$

$$P_i = P_i' + P_i'' \tag{4}$$

$$P = P_1 * \tan(\alpha - \beta_1) - (P_1' + P_1'') * \tan\beta_2 = P_2 * \tan(\alpha + \beta_1) + (P_2' + P_2'') * \tan\beta_2 \tag{5}$$

(1) The brace elastic deformation has the following expression

$$\Delta L = \frac{PL}{EF} \tag{6}$$

The symbolic meanings in the above formulas are as follows:

μ_i - the friction coefficient;

f_i - the equivalent friction in horizontal plane;

S_i - the friction in slop;

N_i - the normal pressure (KN);

P_i - the vertical force acting on a single wedge;

P- the tension of the brace in the process of load balancing(KN);

E - the elasticity modulus (216×109 N/m^2);

F - the cross-sectional area of the brace ($50\times14mm^2$);

ΔL- the anount of brace elastic deformation.

Taking 275(KN) which is the experimental data value of P1 into the formula (5), the tension of the brace can be got: P=109.77(KN).

The brace elastic deformation can be obtained by taking P into the formula (6): ΔL=2.99(mm).

Vertical displacement of the side bearers may be lost, because of the deformation. The displacement: $2.99\times\tan26^\circ=1.46\text{mm}$.

According to the calculation on geometry size of actual product, when the displacement of the passive end is 35.1 mm, the load acting on the corresponding side bearer is 221 KN and, in this case, the equivalent stiffness is:221/35.1=6.3 KN/mm.

That is, the load that is equal to 6.3×1.46=9.19 KN is offset in vertical direction.

(2) The analysis of friction resistance

The friction resistance of the mechanism is from respectively the friction between the roller and the plane and that between the roller and the shaft. By comprehensive consideration, in this scheme, equivalent friction coefficient is taken and the value is larger than that under pure rolling and smaller than that under pure sliding. So, the value 0.04 is taken.

(3) Delay load balancing mechanism of action

The mechanism is complicated and has many links. There exist friction and clearances between the parts of hinge, which influences the response speed. The friction of the damping device and the elastic elements are also the reasons of response latency.

4 The methods to improve the property of load balancing mechanism

Through the above analysis, the following aspects can be changed to improve the efficiency of the load balancing mechanism and reduce lag:

(1) The corresponding lag caused by the elastic deformation can be reduced by increasing the cross-sectional area of the brace;

(2) To reduce equivalent friction coefficient, several methods can be taken such as increasing the diameter of the roller and improving the lubrication conditions between the inner hole of the roller and the shaft;

(3) Because it is hard to change the friction characteristics of materials, we enhance the efficiency by changing the wedge angles. The inclined wedge angle is optimized, the normal pressure is reduced and the resistance is also declined in the process of load balancing.

It is necessary to analyze the relationship between the inclined wedge angle and the efficiency. The ratio of the inclined wedge angle to the forces acting on side bearers at both ends is the function of α, and, to improve load balancing effect, we discuss the influence on the effect resulting from adjusting the wedge α.

According to formula (5), the ratio of P_1 to P_2 is determined by formula:

$$\frac{P_1}{P_2} = f(\alpha) = \frac{\tan(\alpha+\beta_1)+\tan\beta_2}{\tan(\alpha-\beta_1)-\tan\beta_2} \qquad (7)$$

So, the equivalent friction coefficient (sliding and rolling) is 0.044 and the value of the equivalent friction angle is $\beta_1=\beta_2=\beta=2.520°$.

According to formula (7), the monotonicity of the tangent function determines $f(\alpha)>1$. Only under the condition that friction is not taken into account, i.e., $\beta_1=\beta_2=\beta=0$, the equation $f(\alpha)=1$ can be got, that is to say the force is transmitted in accordance with 1:1 and the efficiency equals 1.

With the friction condition given by formula(7), the ratio of the input force to output force acting on the present mechanism is $f(26°)=1.505$. That is to say, the ratio of the output force to input force is its reciprocal: $1/f(26°)=1/1.505=0.664$, i.e., the value of the efficiency is 0.664. The relationship between the wedge angle α and the force ratio $f(\alpha)$ can be got by programming calculation using the MATLAB software shown in Table 1. As α increases, the ratio $f(\alpha)$ reduces and the uniform load rate of the system is improved.

Table 1. The relationship between $f(\alpha)$ and α and η and α（μ=0.044）

α（°）	25.	26.	27.	28.	29.	30.	31.	32.
$f(\alpha)$	1.53	1.505	1.48	1.46	1.45	1.43	1. 42	1.4
η(%)	20.88	20.15	19.47	18.85	18.27	17.74	17.25	16.79
α（°）	33.	34.	35.	36.	37.	38.	39.	40.
$f(\alpha)$	1.39	1.38	1.37	1.36	1.34	1.34	1.34	1.33
η(%)	16.37	15.98	15.61	15.27	14.96	14.67	14.40	14.14

According to Table 1 , when α increases from 26° to 37°, the ratio of the output force to input force rate increases from $P_2/P_1=1/1.505=0.664$ to $1/1.34=0.746$. However, when α increases to 37°, the pressure angle of the roller increases much and the general working efficiency of the system will be lower. Therefore, on the premise of keeping the inclined wedge structure symmetrical, it is hard to meet the requirement for the perfect uniform load only by changing the inclined wedge angle.

As a result, in the three optional measures, the first one and the third one should be combined. Because the third would enlarge the horizontal tension, increasing the load acting on the brace, it is necessary to increase the cross-sectional area appropriately to avoid the influence that the initial elastic deformation has on the systematic response. The choice about whether to use the second measure is made according to the practical situation.

5 Conclusions

As to the problems including low efficiency and response latency existing in the load balancing mechanism of three-bogie railway freight vehicle, the force analysis reveals that the efficiency and the latency are relevant to the inclined wedge angle and the dimensions of the brace and the roller, and that the reasonable design can improve the mechanism efficiency and reduce action delay. In the practical design, to get the optimal comprehensive effect, some factors should be taken into consideration such as the installation space, the internal force in the mechanism and the strength and abrasion loss of every part.

Abstract: Promotion of pure electric vehicle (EV) has become a trend, of which the braking performance is very important. In this paper, by using a family of curves of the relationship between adhesion coefficient and sliding rate of an electric vehicle on different roads, to elect the sliding rate corresponding to the peak value of adhesion coefficient, and then the mathematical models of EV braking process are established and the dynamics differential equation is obtained. According to the optimal control theory, appropriate state vector and control vector based on the dynamic mathematical model of vehicle-road system are selected, and a quadratic performance index of the minimum error between actual output and expected output with the minimum energy consumption of the hydraulic braking system in time domain are proposed as well. Typical working condition parameters are selected as the initial condition to calculate series of control parameters of the optimal control model by Riccati matrix algebra equation. In MATLAB/simulink vehicle anti-lock braking system model is established, and by simulation graphs of wheel velocity response show that, the wheel velocity can satisfy the slide requirements well by using optimal feedback control algorithm for EV with more advanced ECU system.
Keywords: Electric vehicle; Braking performance; Sliding ratio; Optimal control.

1 Introduction

To address the two urgent issues nowadays of protecting the environment and achieving energy sustainability, it is of strategic importance on a global scale to replace oil-dependent vehicles with electric vehicles (Cheng Lin et al.,2014), and the promotion of electric vehicle has become a prevalent trend increasingly. The development of the electric vehicle also focus on the theme of safe, energy saving, and environmental protection. How to apply modern control theory and technology to improve the performance of active safety for electric vehicles has been the research hotspot in automotive filed for several years.

The braking performance is directly related to the safe running of the electric vehicle, automobile anti lock braking system (ABS) can make full use of the adhesion between tire and road surface, so as to shorten the braking distance, improve automobile braking performance, and handling stability, which has become an indispensable part of automobile brake system. Similar to the braking system of traditional vehicle, but more accurate control algorithm should be adopted in electric vehicles because of its more advanced and mature electric control system.

2 Mathematical modeling of ABS

2.1 Tire Modeling

The tire model is a mathematical model which describes mechanical properties of road-tire. In practical application, it is difficult to draw a formula which describe effects of various physical parameters of tire on adhesion coefficient. A tire model called "Magic Formula" proposed by Pacejka is widely used, because almost any tire parametric curves can be fitted by adjusting parameters of "Magic Formula", and it is usually written as equation (1):

$$\varphi(s) = \varphi_0 + D\sin\left\{C\arctan\left[Bs - E\left(Bs - \arctan\left(Bs\right)\right)\right]\right\} \tag{1}$$

Where φ_0 is the static friction coefficient of tire, and commonly $\varphi_0 = 0$, D is the peak factor, C is the curve shape factor, B is the stiffness factor, E is the curvature factor, and s is the slip ratio, $s = 1 - \omega r / u_a$. In this pepper different sets of parameters above are chosen to simulate three kinds of typical working conditions of dry asphalt pavement, mud road, and ice snow covered pavement (Table1).

Table 1. Parameters of different typical working condition

Typical working conditions \ Parameters in Magic Formula	D	C	B	E
Dry Asphalt Pavement	0.8	2.4	4	0.9
Mud Road	0.6	2.4	5	0.9
Ice Snow Covered Pavement	0.15	2.4	6	0.9

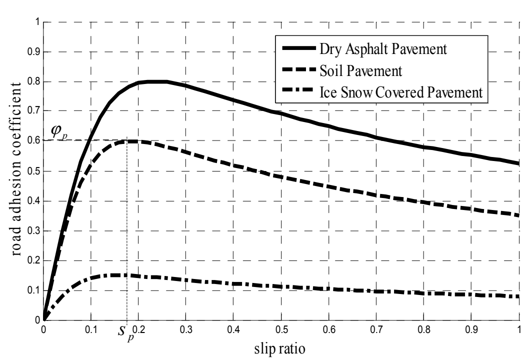

Figure 1. Adhesion coefficient-slip ratio curves of three different road surface

The adhesion coefficient-slip ratio curves (figure 1) shows that tire adhesion coefficients reach the peak value in the sliding rate about 0.2 in three different road conditions. Therefore, the proposed control algorithm should make the slip ratio to maintain at around 0.2 to prevent the wheels from locking to the greatest extent.

2.2 The vehicle dynamics model

If the rolling resistance and aerodynamic resistance are ignored, the vehicle single wheel model after simplified is shown in figure 2. (Yu Fan,2005),of which the mass of the single wheel model is m, the wheel rolling radius is r_d, the moment of inertia of the wheel is I_w, the wheel angular velocity is ω, the vehicular velocity is u_a, the wheel velocity is u_ω, the braking moment is T_b, the rolling resistance moment is T_f ,the ground normal force is F_z, and the ground tangential braking force is F_{xb}.

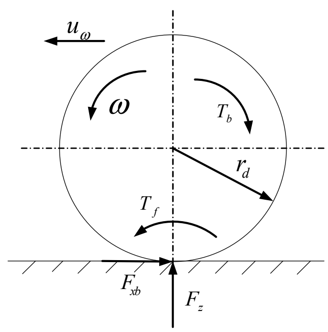

Figure 2. Braking mechanics model of the single wheel

From figure 2 the dynamics equations of vehicle braking can be obtained as follows：

$$m\dot{u}_\omega = -F_z\varphi(s) \tag{2}$$

$$I_w\dot{\omega} = -T_f - T_b + F_z r_d \varphi(s) \tag{3}$$

$$T_b = \alpha P(t) \tag{4}$$

Where $P(t)$ is hydraulic brake pipe pressure, α is a constant value.

3 Design of optimal control algorithm for ABS

In the control system, the wheel angular velocity ω and the wheel angular acceleration $\dot{\omega}$ are chosen as the state variables, the wheel velocity u^* ($u^* = 0.8u_a$) corresponding to the peak value of $\varphi - s$ curve is chosen as expected output. Therefore it is necessary to design tracking system, so that the actual output of control system is the tracking value of expected value, and the tracking follower can be designed as a integral form as follows:

$$I = \int_0^t \left(\omega r - u^*\right)\mathrm{d}t = \int_0^t \left(u_\omega - u^*\right)\mathrm{d}t \tag{5}$$

Where $u_\omega = \omega r$ .What is different from the conventional algorithm(Cui Shengmin, 2008) is that a first-order integrator is substituted for a second-order integrator.

Take derivative of the equation (3), and substitute equation (1) and (4) into it, such equation can be obtained:

$$\ddot{u}_\omega = \frac{F_z r_d^2}{I_w}\dot{\varphi}(s) - \frac{\alpha r}{I_w}\dot{P}(t) \tag{6}$$

Where $$\dot{\varphi}(s) = \frac{48\cos\left[\frac{12}{5}\arctan\left(\frac{2s}{5}+\frac{9\arctan(4s)}{10}\right)\right]\left[\frac{18}{5(16s^2+1)}+\frac{2}{5}\right]}{25\left[\left(\frac{2s}{5}+\frac{9\arctan(4s)}{10}\right)^2+1\right]}$$

it is complicated to solve, in order to increase the computing speed, $\dot{\varphi}(s)$ can be simplified as (LI Gang,2012):

$$\dot{\varphi}(s) = -\frac{\varphi_p}{s_p}\frac{r_d\dot{\omega}}{u_a},(s \le 0.2) \tag{7}$$

Organize all equations above, matrix form of the state space equation of ABS is obtained as follows:

$$\dot{\mathbf{X}} = \mathbf{AX} + \mathbf{B}U + \mathbf{E}d \tag{8}$$
$$\mathbf{Y} = \mathbf{CX} \tag{9}$$

Where

$$\mathbf{A} = \begin{bmatrix} -\frac{\varphi_p}{s_p}\frac{F_z r_d^2}{I_w u_a} & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix},\ \mathbf{B} = \begin{bmatrix} -\frac{\alpha r_d}{I_w} & 0 & 0 \end{bmatrix}^{\mathbf{T}},\ \mathbf{E} = \begin{bmatrix} 0 & 0 & -1 \end{bmatrix}^{\mathbf{T}}$$

$$\mathbf{X} = \begin{bmatrix} \dot{u}_\omega & u_\omega & I \end{bmatrix}^{\mathbf{T}},\ \mathbf{C} = \begin{bmatrix} 0 & 1 & 0 \end{bmatrix}, U = \dot{P}(t), d = u^*,\ \mathbf{Y} = \omega r = u_\omega .$$

In order to control the hydraulic system with minimum energy consumption, and minimize the error between actual output and expected output during the process of braking, quadratic performance index (eq.10) is chosen (B.-C.Chen,2014):

$$J = \int_0^{\infty} \left(\mathbf{X}^{\mathrm{T}} \mathbf{Q} \mathbf{X} + U^{\mathrm{T}} \mathbf{R} U \right) \mathrm{d}t \tag{10}$$

Where $\mathbf{Q}$ and $\mathbf{R}$ are the weighting matrices for state deviations and input effort, respectively.

$$\mathbf{Q} = \begin{bmatrix} 1 & & \\ & 1 & \\ & & 10^5 \end{bmatrix}, \quad \mathbf{R} = 1$$

The optimal control law of this system is as equation(11) according to optimal control theory:

$$U^* = -\mathbf{R}^{-1}\mathbf{B}^{\mathrm{T}}\mathbf{L}\mathbf{X} = -\mathbf{K}\mathbf{X} \tag{11}$$

The $\mathbf{L}$ in feed back gain matrix can be obtained by Riccati formula (eq.12).

$$-\mathbf{L}\mathbf{A} - \mathbf{A}^{\mathrm{T}}\mathbf{L} + \mathbf{L}\mathbf{B}\mathbf{R}^{-1}\mathbf{B}^{\mathrm{T}}\mathbf{L} - \mathbf{Q} = 0 \tag{12}$$

4 Simulation results

With the parameters shown in Table.2, the proposed algorithm is evaluated by using MATLAB/Simulink, and the dynamic responses of electric vehicle are shown in the following Figures.

Table.2 Parameter conditions in control algorithm

F_z	350Kg	α	600
r_d	0.3m	s_p	0.2
I_w	$12\,\mathrm{Kg}\cdot\mathrm{m}^2$	φ_p	0.8

In order to observe the character of wheel velocity u_ω tracking the expected wheel velocity u^* corresponding to the peak value of $\varphi - s$ curve, two typical conditions of speed u_a at 30Km/h and 60Km/h are selected. The response process of u^* and brake oil pressure can be illustrated in Figure 3 and Figure 4, respectively.

In figure 5 illustrates that, the proposed algorithm of using a first-order integrator mainly can not only reduce the computational complexity of solving the Riccati matrix equation significantly, but also have a more rapid response quality than the conventional algorithm of using a second-order integrator.

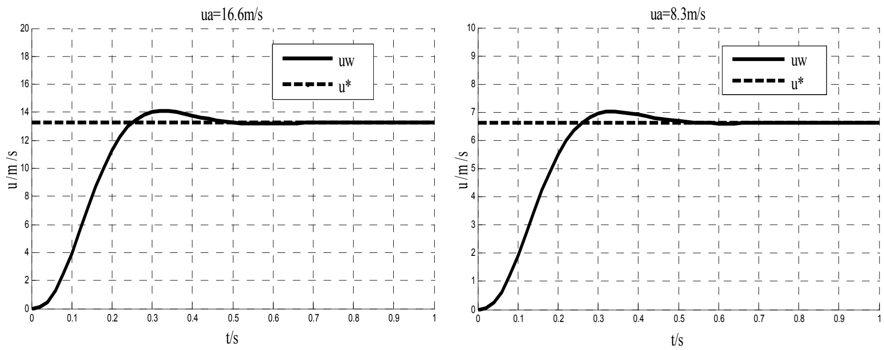

Figure 3. Response of wheel speed

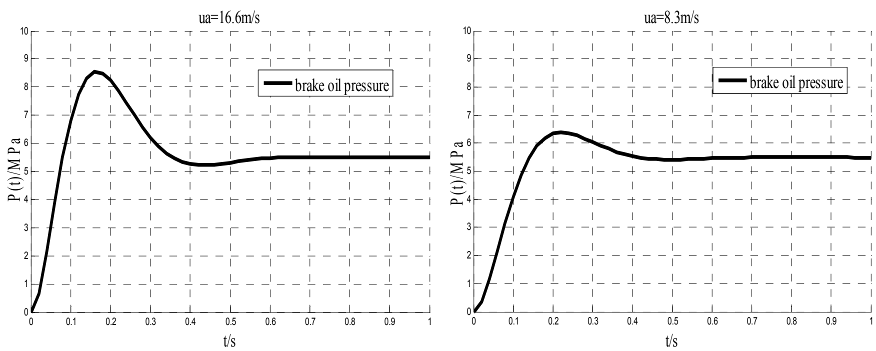

Figure 4. Response of brake oil pressure

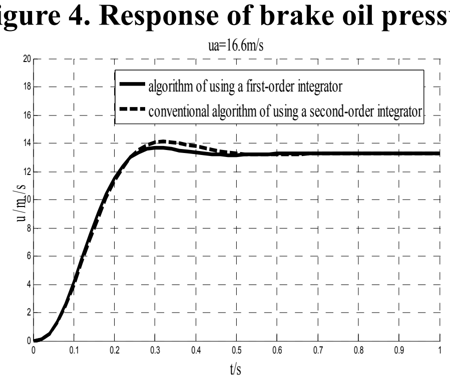

Figure 5. Comparison of effects of two kinds of control algorithm

5 Conclusions

As can be seen from the simulation graph, wheel velocity u_ω can track the expected wheel velocity u^* quickly with reasonable error by controlling the brake oil pressure during driving the EV at one speed. Therefore the slip ratio of wheel is about 0.8, and then larger braking-force coefficient can be obtained for EV.

The proposed algorithm can achieve a good anti-lock braking performance, but mathematical model of ABS is demanded to be as precise as possible and high performance real-time computing system is required. However, compared with the traditional fuel-consumption vehicles, EVs are often equipped with more advanced ECU system, this control algorithm has better practical application value for EV.

[2]Traffic and Transportation School, Dalian Jiaotong University, Dalian 116028, China. E-mail: wyydl@djtu.edu.cn

Abstract: In this paper, two methods are used to deal with air cooling channel's entrance. One method is connecting the Axial-flow fan. The other uses circular cross section of the guide tube as the air inlet. This paper analyzes Axial-flow fan's influence to the numerical calculation results of air cooling channel and puts forward a method to build simplified and reasonable physical model in the simulation calculation of the locomotive traction motor's air cooling channel. Then structure optimization of air cooling channel is proposed to ensure uniform flow distribution of each outlet.

Keywords: Locomotive traction motor; Air cooling channel; Axial-flow fan; Structural optimization.

1 Introduction

As the power source of locomotive, traction motor's good heat dissipation is vital to ensure smooth and safe operation of locomotive. This requires cooling ventilation system to have reasonable structure and layout method. In the simulation calculation of air cooling channel by fluid analysis software FLUENT, selecting the calculation area reasonably is the important premise to realize accurate simulation. A cooling ventilation system for locomotive traction motor takes environmental air into the lead axial-flow fan, after the fan impeller rotating speed, cooling air gets into the entrance of cooling air channel through the guide tube, air flows through three sub channels, then cools three traction motors.

The simulation calculation that connecting the Axial-flow fan to the cooling channel can realize accurate simulation of locomotive traction motor's air cooling channel. But complicated Axial-flow fan structure makes modeling more difficult and the number of elements and nodes increases obviously. So it is necessary to make further study for the selection of the simulation computation area of cooling air channel. This paper compares the results between the whole model with Axial-flow fan and the simplified cooling air channel.

The simulation results show that the flow rate distribution of the original three air outlets are uneven, difference between each outlets exceeds the design requirements due to the unreasonable layout of internal baffles and the seriously blocked channel's corner. Therefore, it is necessary to optimize the structure of the air cooling channel to ensure uniform flow distribution among sub channels without increasing air resistance greatly.

2 Physical model and System parameters

2.1 Physical model

Method 1 is the whole model with Axial-flow fan, as shown in figure 1. Cooling air channel has an inlet and three outlets, above the air inlet are guide tube and Axial-flow fan .Cooling air gets into the system though the entrance of Axial-flow fan and flows out through three air outlets. The Axial-flow fan is cancelled in method 2, using circular cross section of the guide tube as the air inlet.

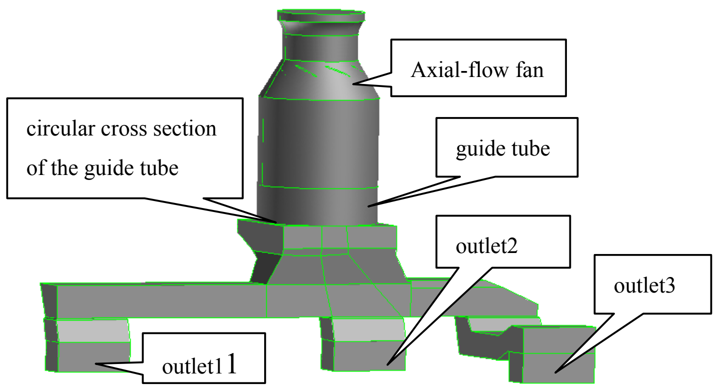

Figure 1. Whole model with Axial-flow fan and cooling channel

The performance parameters of Axial-flow fan: Rotational Speed n=2950 r/min, ventilation rate Q=330 m3/min, pressure P=3600 Pa. performance and structure parameters of air cooling channel: resistance of channel entrance P=400 Pa，size of channel entrance Φ=810 mm, three outlets of air cooling channel face to the motors respectively, each outlet size 220 mm × 520 mm，back pressure 2300 Pa. Size of circular cross section of the guide tube D=810 mm, d=524 mm.

2.2 Meshing

Due to the complexity of the fan model structure, structured grid is difficult to achieve when the flow field area dispersed, this flow field area is divided into tetrahedron and pyramid grid in tgrid method with FLUENT pretreatment software GAMBIT, the air cooling channel area is divided into many blocks, the well-shaped areas are dispersed into structured hexahedron grid. Other areas are dispersed into unstructured tetrahedral grid because of its strong adaptability characteristics. The girds around the blades need to be refined to adapt the complex flow situation. There are 3.9 million elements and 0.8 million nodes in method 1, 0.46 million elements and 0.11 million nodes in method 2. Discrete grid models are shown in figure 2.

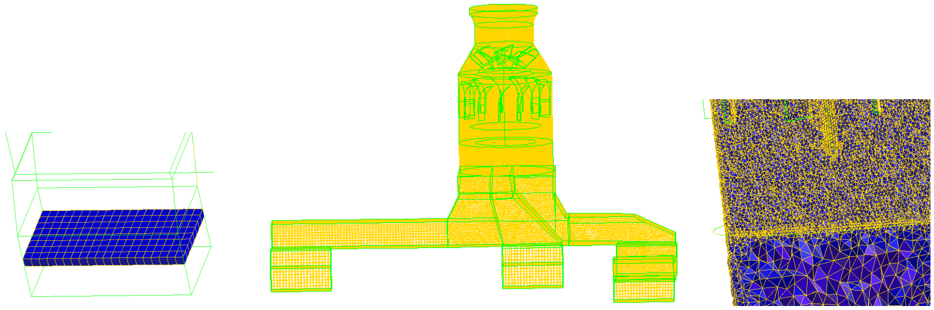

Figure 2. Finite elements of the whole model and Local amplification view

3 Numerical calculation method and boundary conditions settings

3.1 Numerical calculation method

Because of the temperature rise is small between the outlet and inlet and the velocity of fluid is slow, the compressibility of the gas is not obvious, viscous force is dominant, and this traction ventilation system flow field is treated as incompressible viscous fluid. The master equation choices the three-dimensional turbulent navier-stokes equations, using SIMPLE algorithm to solve the equation which can solve the problem of velocity and pressure coupling. Calculation model uses the standard k - epsilon turbulence model, the near wall region is treated as standard wall function method. As it belong to the internal fully developed turbulent flow, turbulence intensity and hydraulic diameter are suitable to be the turbulence parameters.

3.2 Functional zoning and boundary conditions settings

Axial-flow fan is belong to the rotating machinery, the moving fluid near rotating impellers shows the transient features in the fixed reference system. By using the motion reference system for processing, the case of transient flow field can be translated into steady situation. Traction ventilator part adopts the multiple reference frame model (MRF) in the process of calculation. MRF model is often used in this situation that the interaction is not obvious between stator and rotor. The moving fluid near rotating impellers is set as moving area and other areas are static areas in method 1. After importing the mesh model into FLUENT, the wall of rotating impellers is set as moving, rotational speed is 2950r/min, the wall is static relative to the surrounding fluid.

Inlet boundary conditions both in two methods are velocity inlet, and ensured to have the same flow 330 $m^3/\min$, speed direction perpendicular to the entrance surface. The outlets of the cooling air channel in this paper are limited to have the ruled pressure, so they are set as pressure outlet, the value is 2300 Pa.

4 Calculation results analysis

Both the two methods are conducted on the workstation with 32 G of memory, 8 core CPU, faster 2.4 GHz, the calculation results are reached the second order convergence accuracy.

4.1 Comparison and analysis of flow flied

The inlet static pressure and mass flow of each sub duct achieved from two methods are listed in table 1. Figure 3 shows the velocity pathlines from two methods. Figure illustrates that the internal flow states of air channel are basically identical between the two methods. The velocity gradient of airflow changes slowly in the sub duct1, velocity changes evenly, backflow occurs at the corner between the air duct and sub duct 2; the velocity of air in sub duct 2 increases firstly and then decreases; the velocity of air at the entrance changes evenly, but when the gas flow from the vertical to horizontal direction, the section of sub duct 3 becomes smaller suddenly, blocking phenomenon occurs. Table 1 lists the flow distribution situation, the mass flow values of each sub duct achieved from two methods have a little change, but less than 0.1 kg/s.

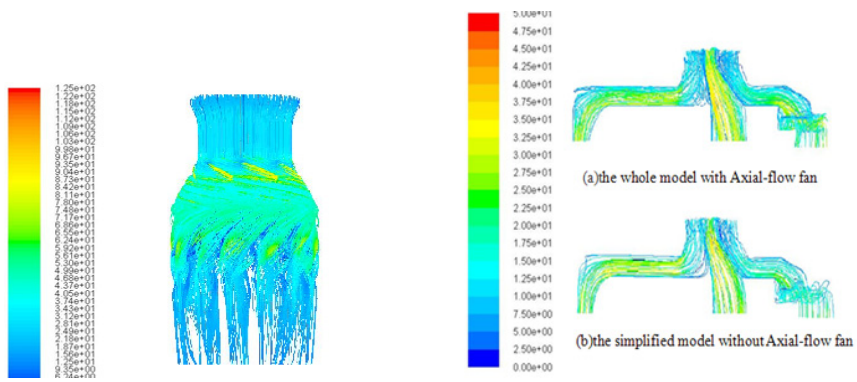

Figure 3. Pathlins of the two methods

Table 1. Static pressure at the inlet and the flow distribution among sub ducts

	Inlet static pressure （Pa）	Mass flow (kg/s)		
		Outlet1	Outlet2	Outlet3
Method1	3190	1.68	3.24	1.82
Method2	3160	1.77	3.18	1.80

4.2 Comparison and analysis of velocity and pressure at the inlet

Figure 4 shows velocity vector of inlet and outlets achieved from two methods, both velocity magnitude and distribution are almost the same, the inlet velocity of sub duct 2 is larger than sub duct1 and sub duct3. On both sides of the entrance of Sub duct 2 appears a small amount of horizontal air flow; Static pressure value and distribution achieved from two methods are almost the same and static pressure value of inlet is listed in table 1.

According to the analysis above, the inside flow of the cooling air channel tends to be consistent between the model connecting the Axial-flow fan and the simplified model using circular cross section of the guide tube as the air inlet. This is because that, the cross section that air flow through increases gradually from the bottom of the guide to the cooling air channel inlet, The gas disturbance, velocity and pressure distribution inequality problems caused by guide vane rotating improved fully through the tube, so there is almost no influence to the air flow in the air cooling channel, Axial-flow fan's influence to the numerical calculation results is little in the simulation calculation of locomotive traction motor's air cooling channel.

5 Structural Optimization of air cooling channel and Calculation results analysis

The simulation results show that the flow rate distribution of the original three air outlets are uneven, difference between each outlets exceeds the design requirements. Because of the sub duct 2 is the shortest, its air flow rate is larger than both outlet1 and outlet 3 apparently, the difference up to 45%. Therefore, it is necessary to optimize the structure of the air cooling channel to ensure uniform flow distribution among sub ducts.

Firstly, enlarging the fillet to make the flow diffused smoothly; secondly, the baffle 1 near the inlet moves to the baffle 2 20 mm, the baffle 3 moves to the baffle 2 30 mm: Then, separating sub duct1 and sub duct2 to enlarge the fillet corner of subduct2; lastly, optimizing the baffle shape between sub duct2 and sub duct3, it means reducing the cross-section of the outlet 2 and increasing the cross-section of the outlet 3. The original model and optimized model are shown in Figure 5.

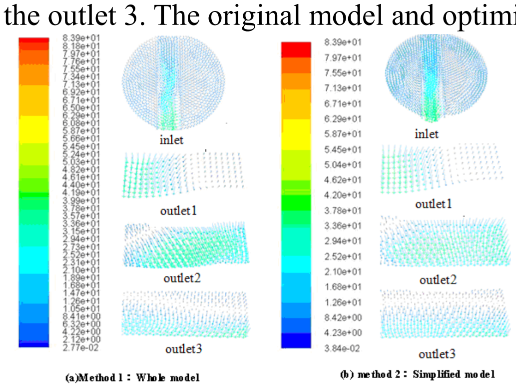

Figure 4. Velocity vector for cooling Channel's inlet and outlets

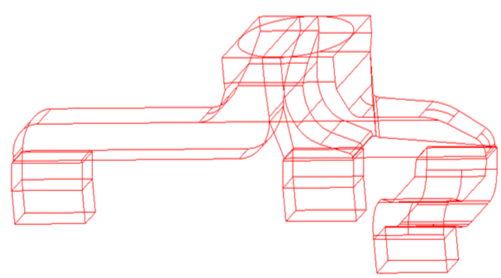

Figure 5. Optimized structure of air cooling channel

Based on the above optimization model, re-establish the grid model and simulate. The grid division method, the mathematical model selection and boundary condition settings are consistent with the original method. Static pressure at the air duct entrance and the flow distribution among sub ducts of original method and optimization method are listed in table 2, the maximum difference of mass flow is

Less than 10% among three outlets of the optimized air cooling channel. Figure 7 shows velocity vector of outlets achieved from the optimization method. The figure shows that flow rate among sub ducts of optimized channel is more uniform and backflow phenomenon is less clear.

Table 2. Contrast of static pressure at the inlet and the flow distribution

	Inlet static pressure （Pa）	mass flow (kg/s)			maximum difference of mass flow
		outlet1	outlet2	outlet3	
Original method	3187	1.7	3.2	1.8	48.%
Optimization method	3312	2.2	2.4	2.16	9%

6 Conclusions

My conclusions are as follows:

(1) In the simulation calculation of locomotive traction motor's air cooling channel with the model that using circular cross section of the guide tube as the air inlet, computational scale, the number of iterations reduce greatly and computation time reduces to 1/5 of the whole model. The inside flow of the cooling air channel tends to be consistent to Axial-flow fan's. So it can be removed to get simplified and can reduce the modeling work, improve the computational efficiency.

(2) By enlarging the fillet, adjusting the baffles, reducing the cross-section of the outlet 2 and increasing the cross-section of the outlet3, the air flow rates of three ducts trend to be identical, the difference is less than 10%, which meets the requirement of air cooling channel design strictly.

Abstract: The FEM of car body steel structure is established on the basis of the structure characteristics analysis for the Multi-function operation car. Since the lifting platform is one of the main equipments of the Multi-function operation car, emphatically analyses the lifting platform's strength. The results show that the original structure design of the lifting platform is not reasonable. Then, a series of improvement schemes are proposed, and each kind of improvement scheme is calculated and analyzed. Finally the lifting platform's strength of the improvement Multi-function operation car meets the requirement.
Keywords: Lifting platform; Strength analysis; Structure improvement.

1 Introduction

The Multi-function operation car is the specialized equipment, used for the repair and maintenance of electrified railway and high-speed passenger special railway catenary. The car is equipped with aerial work bucket, the lifting platform, wire shifting device and the catenary detection system. It can be used for comprehensive testing, inspection and maintenance of high voltage catenary line and line facilities, also can be used for the repair and maintenance of the high-altitude facilities of the railways, bridges and tunnels [1]. The roof's lifting platform is one of the main equipment to achieve the above functions. Since the lifting platform of the Multi-function operation car carrying weight, and revolve radius of the rotating arm is large, so its structure strength safety is especially important. In this paper, the finite element model of whole car is established and the strength of the lifting platform is analyzed. Then according to the calculation results, the lifting platform structure is improved.

2 Introduction of Lifting Platform Structure

Two operation equipments are equipped on the roof of the Multi-function operation car: One is lifting operation equipment on the roof lifting platform which is at the "B" end roof of car ; The other is aerial work bucket mounted on the installation base which is a thin-walled cylindrical tube structure, connecting the roof and under frame, at the "A" end roof of car. The Multi-function operation car body steel structure is shown in Figure 1. The roof lifting platform is mainly composed of 120mm ×103mm transverse and longitudinal channel steels and 8mm thick sealing plates. The transverse channel steels connect with the top side beams, and the longitudinal channel steels are uniformly distributed in the middle of the transverse channel steels; Equipment installation seat is arranged at the central of roof lifting platform, connecting with the transverse and longitudinal channel steels; Sealing plate tiles on the top skins of the operation platform. The partition column which is just under the middle lifting platform connects with the transverse channel steel. Angle steel, Z-sharp steel and channel steel are used to connect the roof lifting platform and other parts of the roof .The structure of roof lifting platform is shown in figure 2.

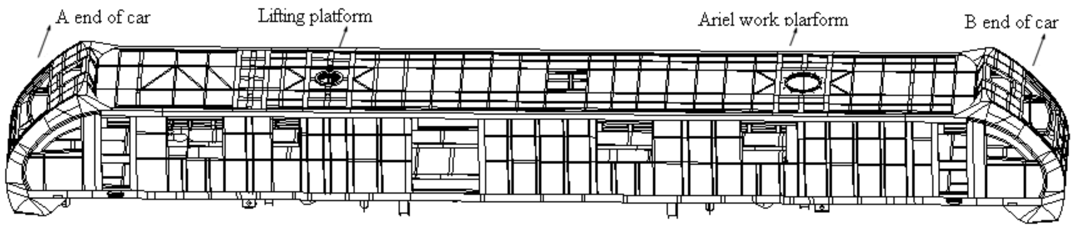

Figure 1.Steel structure of car body

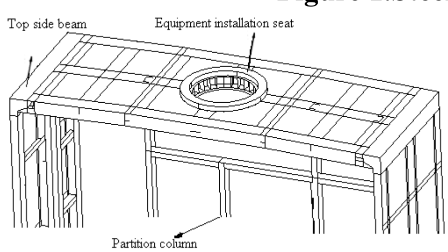

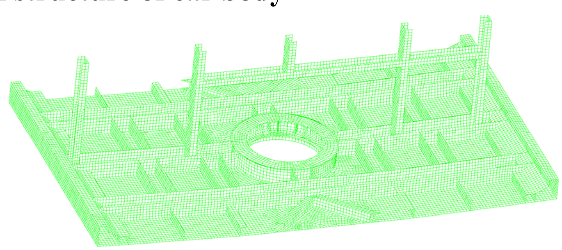

Figure 2.Structure of lifting platform

Figure 3.Local finite element model of lifting platform

3 Finite Element Modeling and Calculation Results Analysis

3.1 Finite element modeling

The FEM model of the carboy is established based on the geometric model. The majority of car structures are meshed by using the shell element, individual structures are meshed by using solid element such as crane blocks, equipment installation seat. The car body is divided into 1.1 million nodes, 1.24 million elements. The local finite element model of roof lifting platform is shown in figure 3.

3.2 Load and constraint conditions

While working the car body suffers the vertical load applied on the rotating arm of the lifting operation equipment and aerial work bucket in addition to the dead weight and weight of load. The operation rotating arm can rotate 360 degrees. From the barycenter of lifting rotation arm to the center of mounting seat surface, the vertical height is 550mm, the radius is 1668mm, and the concentrated load on the barycenter is 25kN; The vertical distance and the horizontal distance between center of gravity of aerial work rotating arm and mounting seat surface are respectively: 2844mm and 970mm, and the concentrated load on barycenter is 59kN. The vertical constraints are applied on the bolster where the cylinder jacks the car.

3.3 Calculation results analysis

The material for Multi-function operation car body is Q345B steel, the material properties are as follows: elastic modulus is 210GPa, Poisson's ratio is 0.3, and the density is $7.85\times10^{-6}\,kg/mm^{-3}$. According to the standard TB/T 1335-1996 *railway vehicle strength design and test standard*, the allowable stress of material is 216 MPa[2]. The lifting platform strength is calculated, and the maximum stress is 450 MPa at the intersection of the transverse channel steel and side beams , as shown in figure 4.

Further analysis of the results is that the maximum stress of the transverse and longitudinal channel steel that nearby the equipment installing seat is 323 MPa on the edges of web plate of steel diagonals. Nearby the aerial work platform, the maximum stress of car body is only 71 MPa. Occurs at the first window corner of the "A" end of car, the stress nephogram is shown in figure 5.

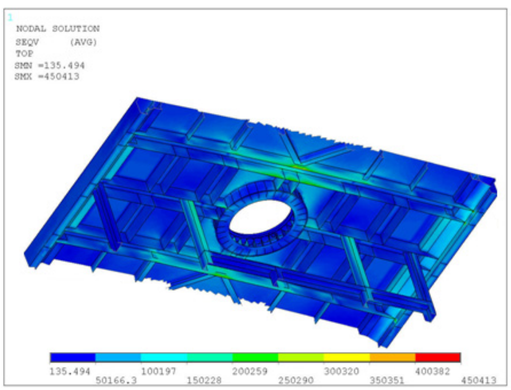

Figure 4.Lifting platform stress nephogram

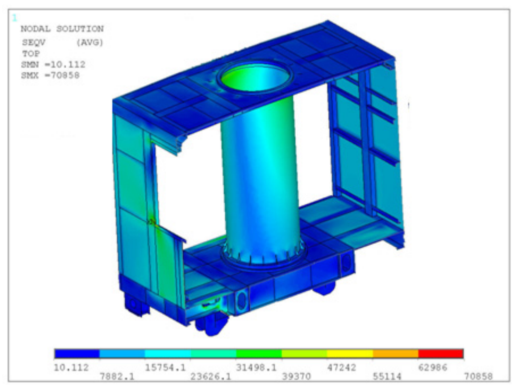

Figure 5.Aerial work platform local stress nephogram

4 Improvement of lifting platform

According to the calculation results, although aerial work platform's rotating arm suffers greater load than the lifting platform, it meets the strength requirements due to using a thin-walled cylindrical tube mounting seat which connects the roof and under frame. If the lifting platform is also using this structure, it is bound to increase the weight of steel structure of car body. Therefore the lifting platform structure should be improved without using a thin-walled cylindrical tube mounting seat. Comprehensive analysis of car body structure's characteristics and stress distribution, specifically identified the following three kinds of improvement projects.

4.1 Improvement scheme 1

Because bending resistant ability of opening channel steel is weak, channel steel connected to the equipment installation seat is changed into rectangular steel. The stress distribution of improvement lifting platform is shown in figure 6. The maximum stress occurs at the intersection of transverse channel steel and side beam, stress value is 330Mpa. Stress values of the rectangular steel around the equipment mounting seat have fallen to below the material allowable stress. But the stress values of the longitudinal channel steel connected with the rectangular steel still exceed the allowable material stress.

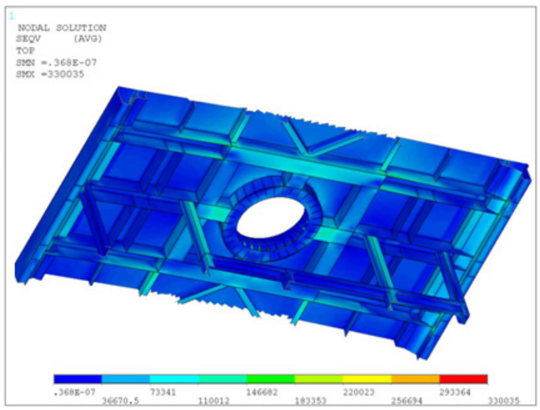

Figure 6.Stress nephogram of lifting platform in scheme 1

4.2 Improvement scheme 2

Compare with the calculation results of the original structure and the improvement scheme1, we can see that the improvement scheme by changing the cross-sectional form of lifting platform is feasible. In addition, the maximum stress of the original structure and improvement scheme1 occurs at the intersection of transverse channel steel and side beam. So the stress concentration here is most serious, the structure should be improved. Improvement schemes are as follows: Replace the open channel steel under lifting platform by the rectangular steel; the lower part of equipment mounting seat closed by 8mm steel plate; Change sealing plate thickness from 8mm to 10mm on the top of equipment mounting seat. Keep the 20mm distance between the horizontal rectangular steel with the top side beam. The improvement lifting platform structure is shown in figure 7. Then the lifting platform strength is calculated and analyzed. Its maximum stress is 262MPa, Occurs at the position where the horizontal rectangular steel connects the bevel edge of side beam. But the other parts of lifting platform stress are lower than the material allowable stress. The improvement structure of lifting platform has relatively high strength, except the position where the horizontal rectangular steel connects the bevel edge of side beam. Finally, we just need to do local improvement.

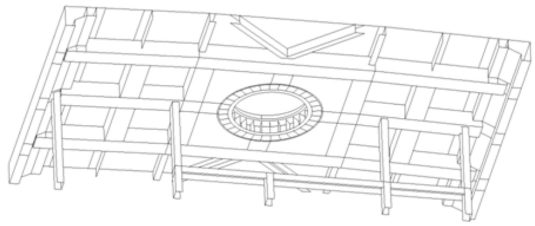

Figure7.Structure of lifting platform in scheme 2

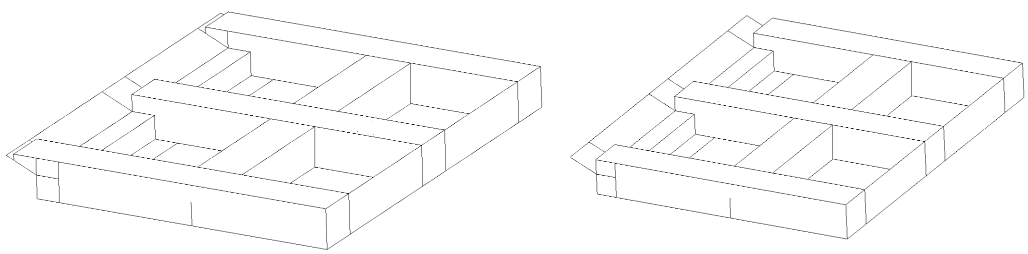
4.3 Improvement scheme 3

For the local position above specific improvements are as follows: Remove part of the horizontal rectangular steel connected to the bevel edge of side beam. The local structure is shown in figure 8. The maximum calculated stress of the improvement lifting platform is only 111MPa, as shown in figure 9. The calculation results show that the lifting structure of improvement scheme 3 is more reasonable and the stress distribution is more uniform. It can greatly reduce the maximum stress value.



(a) Beam structure in scheme 2 **(b) Beam structure in scheme 3**

Figure8.Comparison diagram of local structure of lifting platform

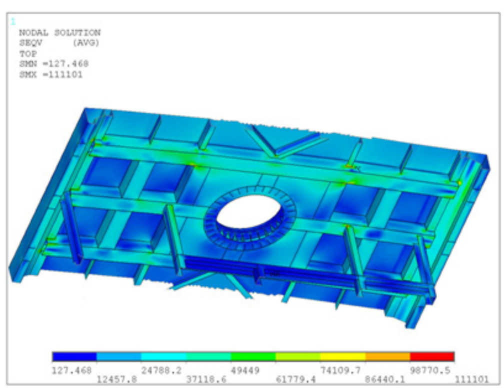


Figure9.Stress nephogram of lifting platform in scheme 3

5 Conclusions

By the analysis of the finite element strength on the lifting platform, the calculation results show that the original lifting platform structure of Multi-function operation car is not reasonable. According to the calculation results, a series of improvement schemes are put forward .Finally a reasonable scheme of lifting platform is proposed which meets the mechanical properties. While in the improvement process, the rules obtained are as follows: Aiming at the stress concentration, the relatively weak local structure should reinforce without changing the overall structure as far as possible; Bending resistance of the open channel steel is weak, if the structure is subjected to a large torque, rectangular steel should be used. The results of this study provide some reference for the design of Multi-function operation car body in future.

Optimization Plan of Refrigerated Container Refueling Strategies in Transit

Tianlun Cheng

Southwest Jiaotong University, Southwest Jiaotong University, No. 111, North 1st Section of Second Ring Rd., Jinniu District, Chengdu, Sichuan, PRC. E-mail: 450347106@qq.com

Abstract：Containerization and multimodal transport are the development direction of railway cold-chain transportation. The increasing market demand also put new requirements on railway cold-chain transportation. The fact that China is a country covering vast territory with backward cold-chain transport equipment restricts the range of railway refrigerated freight transport. Therefore railway cold-chain transportation lost its comparative advantage that combined large freight volume and long transport distance. For solving this problem, railway transportation department uses 45ft integrated diesel-electric refrigerated container as cold-chain carrier, at the same time, adopts stop and refueling strategies in transit to extent continuous refrigerating time. Due to China’s railway cold-chain transportation is still in early stages, the location of gas stations along the route is uncertain and the refueling plan is lack of scientificity, the efficiency of railway refrigerated container transportation can be improved obviously. For extending the depth of railway cold-chain transportation and promoting the development of containerization and multimodal transport, this paper considers the features of railway cold-chain transportation in China and the method of using 45ft integrated diesel-electric refrigerated container. By setting the minimum cost as the objective function and involve other constraint condition in railway cold-chain transportation, this paper gives a optimization plan of refrigerated container refueling strategies in transit based on dynamic programming. Based on the research results on optimization plan, railway transportation department can reduce the time of refueling-stop and number of gas station which are unnecessary to reduce the cost of railway container freight station building, improve the efficiency and quality of railway cold-chain transportation.
Keywords: Refrigerated container; Railway cold-chain; Refueling strategies; Dynamic programming.

1 Introduction

The current container used in railway cold-chain transportation is 45ft integrated diesel-electric refrigerated container adapted to the features of China’s railway transportation. Compared with traditional railway mechanically refrigerated containers, Hobbs J.E, Young L.M.(2000)referred, it is more in line with the characteristics of modern refrigerated logistics, and through container multimodal transportation, can implement no-gap cold-chain transportation, which is good for extending the depth of railway cold-chain transportation, promoting the development of containerization and multimodal transport. However, the continuous cooling time is confined in 10 days during transit due to the limit of diesel-electric refrigerated container fuel tank volume, according to Xie R.H, Liu G.H, Qu R.G.(2007). This can be a important problem in the development of railway cold-chain transportation. When face to long distance transport (4000km and more, for instance) or in intermodal transportation with multiple reloading, require to continuous cooling time is out of reach for current refrigerated containers and traditional train operation organization. Zhou,J (2009) referred that this situation makes railway cold-chain transportation lost its comparative advantage that combined large freight volume and long transport distance. In this situation, establish a thorough refrigerated container refueling strategies in transit become most important. It is necessary to ensure the extension of refrigerated container refrigeration time, to ensure the quality of the goods, but also to control costs and reduce the number of stops to ensure the timeliness of cargo transport.

2 Problem statement

Railway transportation's comparative advantages are low transportation cost, large freight volume, and long transportation distance and low energy consumption. For extend the cooling time of refrigerated container, refueling during transit is necessary and unavoidable.

If we take refueling at every container station as refueling plan, the generalized cost will be large, and the travel speed must be decreased, furthermore, is harm to the efficiency and quality of railway cold-chain transportation. As we all know, different refueling strategies lead to different influence on railway refrigerated container transportation, as figure below shows.

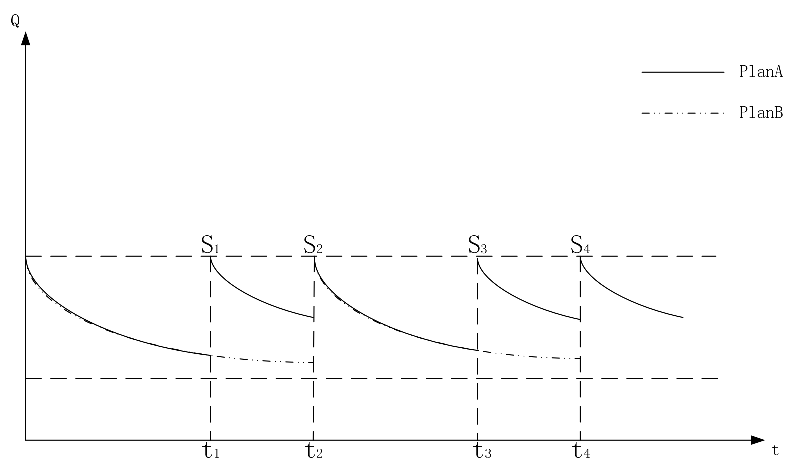

Figure 1. Influences of difference refueling strategies

In Figure 1, the curves describe fuel consumption of refrigerated container during transit. With refueling plan A, we must stop the train 4 times at S_1, S_2, S_3 and S_4, while with plan B, we only need stop twice at S_2 and S_4. The conclusion is obvious that take different strategies will bring change in operation cost and quality.

So in this paper, we focus on making optimization plan of refrigerated container refueling strategies in transit through building a dynamic programming model.

The following chat describes the detailed parameter of the container in research which is extensively used by China railway tielong container logistics co., LTD.

Table 1. Detailed parameter

External dimensions（L×W×H）	13716mm×2438mm×2896mm
Internal dimensions（L×W×H）	12716mm×2294mm×2554mm
Maximum gross weight	30480 kg
Dead weight	7000——7180kg
Container Internal Volume	74.5 m^3
Fuel tank volume	543L
The shortest continuous cooling time	About 240 hour
Charging voltage	380V
Range of temperature control	-29 $^{\circ}C$ ~+27 $^{\circ}C$
Ambient temperature	-40 $^{\circ}C$ ~80 $^{\circ}C$
Airtightness（m^3/hr.）	≤7
Hot leakage rate（KCAL/hr. $^{\circ}C$）	≤41.3

Assumption 1. For better researching, we make train with refrigerated container running route abstracted as a one direction line. The speed of train is *v*, and $\sum l_i$ denotes the transport distance, $\{S, E\}$ denotes the set of sections. The number of container transaction stations that can conduct refueling operation is $r-1$. The origin stop and destination stop are denoted by S_0 and S_r, $S=\{s_i | i=1,2,\ldots,r-1,r\}$

is set of container transaction stations on operation line, $E=\{e_i \mid i=1,2,\ldots,r-1,r\}$ is set of operation sections and $l(e_i)$ is length of section e_i.

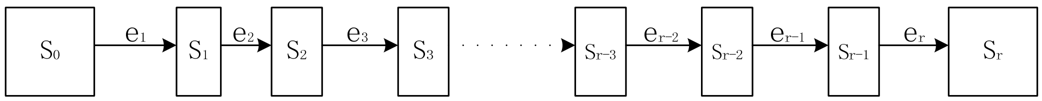

Figure 2. Abstract description of the train operation

Assumption 2. The factors which can influence the cooling effect and energy consumption during the railway cold-chain transportation are complex which involve the temperature difference between day and night, different temperature, humidity, and wind speed when in different regions, etc. However, these are all not the research focus here. Therefore, we see these influence factors as constant and make no influence on refrigerated container transportation.

Assumption 3. Different freights make no different on transportation condition.

Assumption 4. The refueling operation time, additional time for stopping and starting, and other operating time at every container station along operation route are fixed.

3 Dynamic programming models

The refrigerated container refueling strategies in transit can be seen as dynamic programming because it can be a good method to describe the process of transportation which involved many variables changing with different stages. And we take the different sections train running as different stages, the diesel quantity remaining as status variable. The choice of refueling strategies can be a multistage decision process. For observing dynamic programming's principle of optimality, we make minimizing the cost (penalty cost) as our model's objective. As the optimum strategy of whole process, it must observe the following principle: no matter what status or strategy before, for the status resulted from previous strategy, the rest strategies must consist in the optimum strategy.

By making cost as indicator, we can build an indicator recursive equation between adjacent two stages. During status transition, once it reached a certain status of a stage, the later process is only depended on the status at this moment, and independent of the previous statuses or strategies. It observes the ineffectiveness theory.

3.1 Refrigerated container diesel consumption model

In order to study refrigerated container fuel consumption and refueling, we use inventory theory to build refrigerated container diesel consumption model. For sampling the influential factors, we make some assumption as follow.

(1)The refrigerated container in transit consumes diesel at a speed which is a time related function.

(2)The refueling operation time is same at different station.

(3)Precooling and the change of external environment are out of consideration.

(4)Set reasonable minimum diesel storage. When the diesel quantity remaining in fuel tank is less than the minimum diesel storage, the train must refuel.

(5)The refueling strategies use (s,S) strategy, which means we must set q_{min} as minimum diesel storage and q_{max} as maximum diesel storage (it usually uses the 95% of the maximum capacity of the tank, Q).

3.2 Stage division in model

The stages in dynamic model are beginning with the train leave or pass one station, and end up with arriving the next station. Through this way, we can division the train route into a set of separate phases and number them. In different stage, we can make different strategy to control the whole process of transportation. When i=1 , we think the dynamic model is in stage 1, and when i=2 , in stage 2,and so on. The i=r is the last stage.

3.3 Status and status variable

Based on the assumption we made before, the diesel quantity remaining in fuel tank is the only variable which is time-varying. They are various in different stages and make effect on making refueling strategies.

So we make the diesel quantity remaining in fuel tank when a train arrives one station as the status variable and use q_i to denote the status of stage i ,that is the diesel quantity remaining in fuel tank of refrigerated container at station i . $f(t)$ is the diesel consumption function, which is time related.

$$q_0 = q_{max} = Q*0.95 \tag{1}$$

$$q_1 = Q - \int_0^{\frac{l_1}{v}} f(t)dt \tag{2}$$

3.4 Decision variable

$X_i = \{x_{ij} \mid j = 0,1\}$ is allowed decision variable set in stage i ,and $x_{ij} = 0$ denotes the train with refrigerated container will pass the station i without refueling;

$x_{ij} = 1$ denotes the train will be refueled.

$X = \{x_i | i = 1, 2..., r-1, r\}, x_0 = 0$ is a set of every decision variable at every station from origin stop to destination stop. We can know this set of variable is a set of 0-1 discrete variables.

3.5 Quality indicators

Solving dynamic programming problem means finding an optimum strategy under a specific situation. In this model, we take the relevance between around two stages and the actual characteristics of the refrigerated container transportation into consideration, use refuel and stop cost, rate of damaged goods, dwell time, the diesel quantity remaining in fuel tank and consumption in next stage as quality indicators of status transition. These indicators are determined by status variable and decision variable in previous stage. So, they are changing following q_i and x_i, denoted by $d_i(q_i, x_i)$,the function calculator as follow.

$$d_i = \left(q_i - x_i \int_0^{\frac{l_i}{v}} f(t)\,dt - \int_{\frac{l_i}{v}}^{\frac{l_{i+1}}{v}} f(t)\,dt - q_{min} \right) * \mathrm{C}_i * b_i * t_i^{\Delta} \qquad (3)$$

The part in bracket makes there is no possible that the diesel quantity remaining in fuel tank is less than the minimum diesel storage when train is in the next section under present status and decision. The three parts after bracket make sure the cost, rate of damaged goods and dwell time are minimum.

The refueling cost contains two parts, one of them is refueling operation cost c_{oc} and another is oil cost.

$$C_i = c_{oc} + p_{dplp} * (Q - q_i) \qquad (4)$$

p_{dplp} is the diesel price per liter.

3.6 Status transition equation

If q_i describes the status of stage i , and the decision x_i is made, the status of this stage will transit into the next stage. We use status transition equation to describe this process, which explains the relevance among the status q_{i+1} of stage

$i+1$, q_i of stage i and decision variable x_i at stage i. The status transition equation is as follow.

$$q_{i+1} = x_i Q + (1 - x_i) q_i - \int_0^{\frac{l_{i+1}}{v}} f(t)\, dt \tag{5}$$

3.7 Indicators recursion equation

The optimal process indicator in the back of previous stage is needed when calculate the next stage's optimal process indicator, and there is functional relationship between the two indicators, which named indicators recursion equation. The equation is as follow and $h_i(q_i)$ denotes the optimal process indicator.

$$\begin{cases} h_i(q_i) = min\{h_i(q_i, x_i) | x_i \in X\}, i = 1, 2 \ldots r-1, r \\ h_i(q_i, x_i) = d_i(q_i, x_i) + h_{i-1}(q_{i-1}) \\ h_0(q_0) = 0 \end{cases} \tag{6}$$

3.8 Mathematical expression of the dynamic programming model

We give the mathematical expression of the dynamic programming model as follow.

$$\begin{aligned} &(DOP)\ min\, h = \sum_{i=0}^{r} h_i(q_i(x_i), x_i) + h_0 \\ s.t \quad & q_{i+1} = x_i Q + (1 - x_i) q_i - \int_0^{\frac{l_{i+1}}{v}} f(t)\, dt \\ & x_i = 0,1 \end{aligned} \tag{7}$$

Table 2. Variables in dynamic programming

q_{min}	minimum diesel storage
q_{max}	maximum diesel storage
q_i	status of stage i
Q	maximum capacity of the tank
X_i	allowed decision variable set in stage i
X	set of every decision variable at every station
x_{ij}	decision variable
$d_i\left(q_i, x_i\right)$	quality indicators
$f\left(t\right)$	diesel consumption function
C_i	Refueling cost in stage i
b_i	rate of damaged cargo in stage i
t_i^{Δ}	Dwell time in stage i
c_{oc}	refueling operation cost at station i
p_{dplp}	diesel price per liter
$h_i\left(q_i\right)$	optimal process indicator in stage i

4 Integrated assessment model

4.1 Time Constraints

Transit time usually means the average transport time-consuming in transportation of goods from the starting point to the end point. Average transport time-consuming influences transport cost in two different ways.

(1) The loss of value of the goods because of limited pot life (for example, fruits, vegetables, sea food, etc.) and sensitive time value (for example, newspaper, fashionable dress, etc.).

(2) Occupancy cost of capital by the value of goods in transit performance. For goods of high value goods or big freight volume, it is good for improving the rate of capital turnover and utilizes to shorten the cargo transportation time.

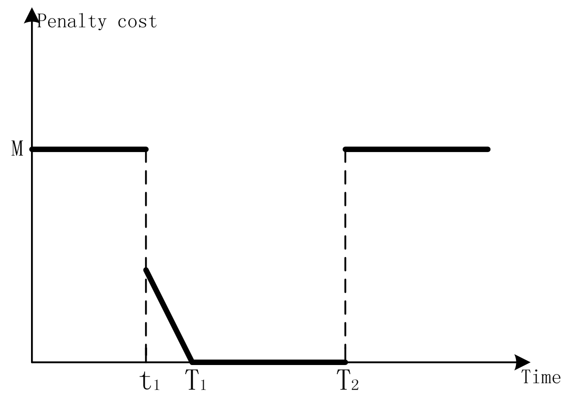

Figure 3. Penalty cost under mixed time window

We adopt the mixed time window limit in this paper. Mixed time window is mixed up with hard and soft time windows in transport service. When the delivery time is within (t_1, T_1), goods can be accepted but the carrier must bear penalty cost. When it is earlier than t_1 or later than T_2,the penalty cost will be an infinite. When the delivery time is within (T_1, T_2),the goods will be accepted without penalty cost.

Under mixed time window, when the arrival time of train with refrigerated containers is within (t_1, T_1), the penalty cost is denoted by f_{pc} in which a function of time related is consisted of the warehousing fee(reefer container electricity costs, container bit administrative expenses,etc.) paid by railway cold-chain transportation department because of early arrival. For an economic results pursuing enterprises, it is obvious uneconomical. The penalty cost function under mixed time window as follow.

$$G(t) = \begin{cases} M, & t < t_1 \\ f_{pc}(t - t_1), & t_1 \le t < T_1 \\ 0, & T_1 \le t \le T_2 \\ M, & t > T_2 \end{cases} \quad (8)$$

The time in this model are consisted of two parts: the running time in section

e_i ,which can be calculated by section length l_i and train speed v; the refueling operation time t_i^{Δ} at station i.

4.2 Rate of damaged cargo constraints

Cold-chain transportation cargo has perishability and special temperature requirements. Thus there would be different levels of cargo damage. In practice, the influential factors of the rate of damaged cargo could be very complex and contain many variables in consideration. For being convenient to study, the rate of damaged cargo is abstracted into a time related unary function $b_i(T_i)$ as fallow.

$$b_i(T_i) = \int_0^{T_i} g(t)dt \tag{9}$$

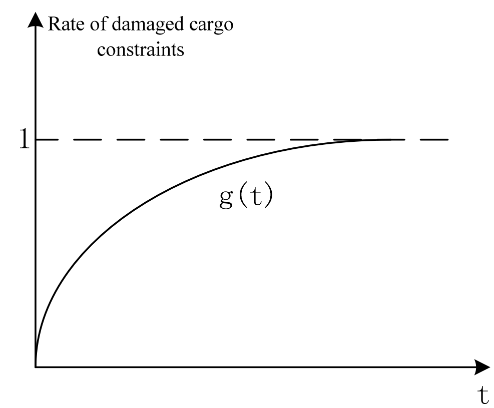

Figure 4. Rate of damaged cargo function

T_i is the travelling time consumed when train arrived the station i. When making railway cold-chain transportation contract, the rate of damaged cargo should be restricted in a specific range. So, when we build the model, the rate of damaged cargo should be taken into consideration—must be or less than a specific ratio β. For value the rate of damaged cargo and the cost in the same way, we define $C\left(\sum_{i=0}^{r} b_i\right)$ as the function to turn cargo damage to penalty cost.

4.3 Objective function

As a profit aimed enterprise, the railway transport sector should make sure that maximum profit and minimum cost. So, based on this principle we build objective function contains transport and refueling cost, which means, under same freight rate, railway transport sector can increase profit by decreasing cost.

The main costs are as follow.

(1)The refueling cost at container transaction stations. In order to facilitate the research, in model, we fix the refrigerated container refueling operation cost at different station, and the refueling cost is depend on refuel quantity. p_{dpl} denotes the diesel prince per liter.

(2)Time penalty cost. It is a function of time related is consisted of the warehousing fee (reefer container electricity costs, container administrative expenses, etc.) paid by railway cold-chain transportation department because of early arrival.

(3)Cargo damage penalty cost. It takes time as variable and converts the rate of damaged cargo into cost for measuring the transport efficiency and quality. Cargo damage penalty cost should be the less the better.

4.4 Integrated assessment model

By using dynamic programming, we have a set of initial refueling-stops strategies $X=\{x_i \,|\, i=1,2...,r-1,r\}$. After that, we need to validate if they can meet the time window' require or the cost limits. If they are all satisfied, then the initial strategies set is the optimized result, otherwise, it must be under modification. By make some through stations to stopping stations or in turn, we try to get another feasible solution and then validate the new solution in the same way and so on. The assessment model can be expressed in mathematical way as follow.

$$\begin{aligned} &min\ F = C\left(\sum_{i=0}^{r} b_i\right) + h_{(DOP)} + G(t) \\ &s.t \qquad t_1 \le \sum_{i=0}^{r} t_i^{\Delta} x_i + \sum_{i=0}^{r} \frac{l_i}{v} \le T_2 \\ &\qquad\quad \int_0^{\sum t_i^{\Delta} x_i + \sum \frac{l_i}{v}} g(t)dt \le \beta \end{aligned} \tag{10}$$

5 Optimization algorithm for refueling strategies

Our final optimization model is combined dynamic programming model and integrated assessment model, its mathematical expression is as follow.

$$
\begin{aligned}
& min\ F = C\left(\sum_{i=0}^{r} b_i\right) + h_{(DOP)} + G(t) \\
s.t \quad & (DOP)\ min\ h = \sum_{i=0}^{r} h_i\left(q_i\left(x_i\right), x_i\right) + h_0 \\
& q_{i+1} = x_i Q + (1 - x_i) q_i - \int_0^{\frac{l_{i+1}}{v}} f(t)\,dt \\
& t_1 \le \sum_{i=0}^{r} t_i^{\Delta} x_i + \sum_{i=0}^{r} \frac{l_i}{v} \le T_2 \\
& \int_0^{\sum t_i^{\Delta} x_i + \sum \frac{l_i}{v}} g(t)dt \le \beta \\
& x_i = 0,1
\end{aligned} \tag{11}
$$

Through iterative analysis calculating, we can get the optimization result. In addition, if an initial solution can't meet the time and cost constrains, the problem is no solution for that the initial solution is already the least time consumption strategy.

Step1: Determine the section length l_i , the train speed v , the initial diesel quality in refrigerated container oil tank Q and diesel storage bound q_{min}, q_{max};

Step2: Solve the dynamic programming problem by sequential method and get a initial solution X^1;

Step3: Put X^1 into assessment model and check if it meets the constraints and calculate F^1;

Step4: If X^1 is feasible, stop calculating and X^1 is the final result and the optimization plan;

Step5: If X^1 can't meet the constrains, find at which station the least $d_i(q_i, x_i)$ appear, then adjust the decision variable x_i (from 0 into 1 or in turn). Turn to step2 and get a new solution X^2;

Step6: Put X^2 into assessment model and turn to step3 till get the final solution.

6 Conclusions and recommendations for future research

This paper built a dynamic programming model based on railway cold-chain transportation and tries to optimize the refueling stopping strategy. For decreasing the cost and time consumption, the method in this paper has a certain value. This model can be used in making refueling plan of railway cold-chain transportation, and reduce unnecessary stopping. However, because of lacking of specific data, the assumption in this paper and the function defined are not accurate in a certain extent, which needs further study in the future.
