The historic storefront should be secured by boarding up windows and installing alarm systems prior to and during rehabilitation. Unsecured doors and broken windows permit interior features and finishes to be damaged by weather or vandalism.

Damaged historic features such as cracked display windows, deteriorated wooden panels below windows, and rusted metal structural members should be repaired wherever possible rather than replaced.

Repairs are best made using historic materials; however, substitute materials may be appropriate if they convey the same visual appearance as the surviving components of the storefront.

Only if an entire storefront is missing or is too deteriorated to repair should total replacement be considered. The form and detailing should replicate the historic storefront.

Restoration should be based on historical and pictorial evidence rather than on conjectural designs or the availability of elements from neighboring buildings. When insufficient documentation exists for an accurate restoration, the replacement storefront may be a new design that is consistent with the size, scale, material, and color of the historic building.

Alterations to storefronts for the purpose of providing access to persons with disabilities should not result in the destruction of significant historic materials. For example, if paired door panels are each less than 32 in. wide or if historic decorative hardware is not the "lever-action type," doors and hardware should be retained and automatic door openers considered as a preservation solution.

Whenever possible, high thresholds or one step up should be modified with a ramp. Full sets of steps on a primary facade are often architectural features that cannot be altered without threatening or destroying the building's historical significance; secondary entrances should be considered in such situations.

STOREFRONT DETAILS

INTRODUCTION

Structural systems in architecture are composed of structural elements (such as beams, piers, and trusses) and building materials (wood, steel, and masonry) that together form the walls, floors, and roofing of buildings.

If features of the structural system are exposed, such as load-bearing brick walls, cast iron columns, roof trusses, posts and beams, vigas, or stone foundation walls, they may be important in defining the building's overall historic character.

The types of structural systems found in America include, but certainly are not limited to, the following: wooden frame construction (17th century), balloon frame construction (19th century), load-bearing masonry construction (18th century), brick cavity wall construction (19th century), heavy timber post and beam industrial construction (19th century), fireproof iron beam construction (19th century), heavy masonry and steel construction (19th century), skeletal steel construction (19th century), and concrete slab and post construction (20th century).

PRESERVATION APPROACHES

A significant structural system or distinctive structural features should be identified prior to any work. To accommodate new uses within a historic building, structural upgrading should be done in a sensitive manner. Installing equipment or mechanical systems that result in numerous cuts, splices, or alterations to historic structural members should always be avoided.

If excavations or regrading—either adjacent to or within a historic building—are being planned, studies should be

done first to ascertain potential damage to archeological resources and to the historic building itself. If significant archeological resources will be disturbed, appropriate mitigation measures need to be incorporated into the project. Inappropriate excavations can cause the historic foundation to settle, shift, or fail.

Structural problems, such as deflection of beams, racking of structural members, or cracking and bowing of walls, should be treated—not cosmetically covered over. A deteriorated load-bearing masonry wall should be reinforced and retained wherever possible, not replaced with a new wall that is veneered using old brick.

Structural deterioration can be the result of subsurface ground movement, vegetation growing too close to

foundation walls, improper grading, uncontrolled moisture, poor maintenance of exterior materials, leaking roofs, insect infestation, fungal rot, poor interior ventilation that results in condensation, inadequate attention to the effects of moisture in original structural detailing, and general deterioration of materials over time. Cyclical maintenance and annual inspections should be routine for historic buildings.

The structural system should be repaired by augmenting or upgrading individual parts or features. For example, weakened structural members such as floor framing can be paired with a new member sistered, braced, or otherwise supplemented and reinforced.

Permanent structural upgrading should never be undertaken in a manner that diminishes the historic character of the building, such as installing exterior strapping channels.

In instances where seismic upgrading is necessary, it is best to use grouted bolts as opposed to exposed plates and to locate diaphragms on unornamented surfaces or to consider other options that reduce the visual and physical impact of the code-required change.

If exposed elements of the structural system are beyond repair, the replacements need to convey the same form, design, and overall visual appearance as the historic feature, to equal the load-bearing capabilities of the historic material, and to be physically and chemically compatible.

INTRODUCTION

An interior floor plan, the arrangement and sequence of spaces, and built-in features and applied finishes are individually and collectively important in defining the historic character of the building. Their identification, retention, protection, and repair should be given prime consideration in every rehabilitation project.

In evaluating historic interiors prior to rehabilitation, it should be kept in mind that interiors are comprised of a series of primary and secondary spaces. This is applicable to all buildings, from courthouses to cathedrals to cottages and office buildings. Primary spaces, including entrance halls, parlors, living rooms, assembly rooms, and lobbies, are defined not only by their features and finishes, but by the size and proportion of the rooms themselves—purposely created to be the visual attraction or functioning “core” of the building. Care should be taken to retain the essential proportions of primary interior spaces and not to damage, obscure, or destroy distinctive features and finishes.

Secondary spaces include areas and rooms that “service” the primary spaces and may include kitchens, bathrooms, mail rooms, utility spaces, secondary hallways, firestairs, and office cubicles in a commercial or office space. Extensive changes can often be made in these less important areas without having a detrimental effect on the overall historic character.

PRESERVATION APPROACHES

Distinctive interior spaces, features, and finishes should be identified, then carefully retained and preserved in any work project. Examples include columns, cornices, baseboards, fireplaces and mantels, paneling, light fixtures, hardware, flooring, and wallpaper, plaster, paint, and finishes such as stenciling, marbling, and graining.

Distinctive interior spaces should not be altered by inserting a floor, cutting through the floor, lowering ceilings, or adding or removing walls.

Historically finished surfaces such as paint, plaster, or other finishes should not be stripped (e.g., removing plaster to expose masonry surfaces such as brick walls or a chimney piece). It is also inappropriate to strip painted wood to a bare wood surface, then apply a clear finish or stain to create a “natural, new look.” Distinctive finishes such as marbling or graining on doors or paneling should be repaired, not covered over or removed. Conversely, paint, plaster, or other finishes should not be applied to surfaces that have been historically unfinished to create a new appearance.

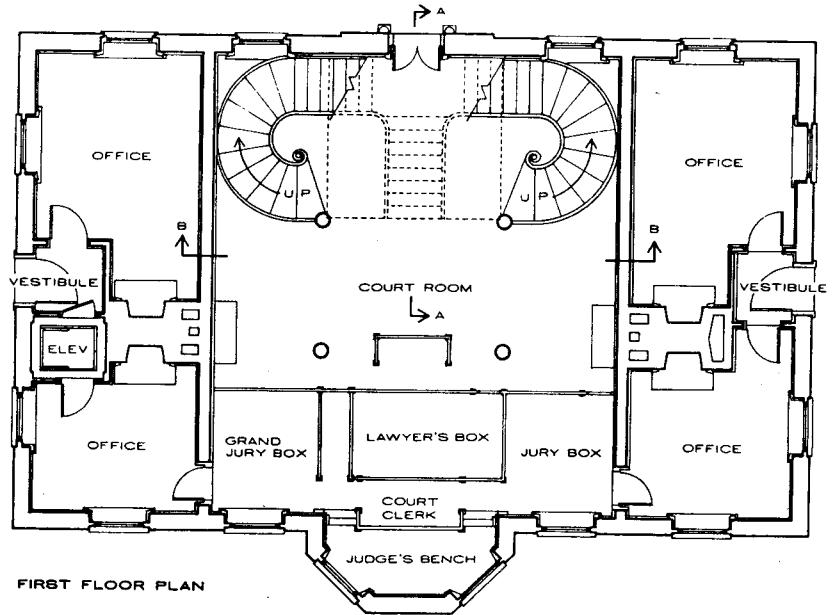

Code-required fire suppression systems (such as a sprinkler system for a wood-frame mill building) should be sensitively designed so that character-defining features are not covered.

Interior features should be protected against gouging, scratching, and denting during project work by covering them with heavy canvas or plastic sheets. Destructive methods of paint removal such as propane or butane torches or sandblasting should never be used because they can irreversibly damage the historic materials that comprise interior features.

Interior features and finishes can often be repaired and preserved by reinforcing the historic materials. Repair may involve the limited replacement in kind of those extensively deteriorated or missing parts of repeated fea-

tures when there are surviving prototypes such as stairs. Examples include balustrades, wood paneling, columns, or decorative wall coverings or ornamental tin or plaster ceilings. If an interior feature or finish is too deteriorated to repair or is missing, its replacement should be based on historical and pictorial evidence rather than on conjectural designs or the availability of elements from neighboring buildings.

In cases where insufficient documentation exists for an accurate restoration of an interior feature or finish, the replacement should be compatible in scale, design, materials, color, and texture with the surviving interior features and finishes. A new design element should be distinguishable from the old and not create a false historic appearance.

*W—wall; F—fixture

NOTES

1. A full bathroom can be divided into three areas of activity: the lavatory/grooming, toilet/bidet, and bathing/showing centers. A powder room is a bathroom with only the lavatory/grooming and toilet/bidet centers. In some large bathroom designs, the lavatory/grooming center may be included as part of the bedroom suite.
2. The standard bathtub height is 14 in., with some special tubs ranging up to 24 in. high. The optimum width for a bathtub rim is about 2 1/2 in.
3. Most standard lavatories and pedestal lavatories are mounted from 30 to 32 in. above the finished floor. However,

ever, a more comfortable lavatory mounting height for most activities is 34 to 38 in. above the finished floor. This may be accommodated in a bathroom when a second lavatory is installed.

4. In bathrooms used by more than one person, opening of the entry door should not interrupt another person's use of the lavatory or toilet. Bifold or pocket doors may be a preferred solution to save space.
5. Typical bathroom accessories include a medicine cabinet, mirror, soap dish, toilet paper holder, towel bar, and linen storage space. A general guideline is to allow between 24 and 36 in. of towel bar space for each family member using the bathroom.

6. Convenient electrical outlets for electric toothbrushes, razors, and hair dryers should be provided. These should be grounded with ground fault circuit interrupters (GFCI) and mounted ±36 in. above the finished floor.

7. Bathroom ventilation may be achieved by natural means (window or operable skylight) or with a mechanical exhaust fan. Consult local building codes for requirements.

8. Soundproofing of the more public powder room (typically used by house guests) is important. Locate powder rooms off the entry hall, utility area, or bedroom hallway, rather than off the living, dining, or family room.

TYPICAL POWDER ROOM LAYOUTS

TYPICAL BATHROOM LAYOUTS

GENERAL

An ideal home kitchen design depends on a number of factors, in particular the living habits and possessions of the kitchen users. A design that is considered excellent for one user may be unsuitable for another.

The following recommendations are not based on any criteria relating to the square footage of the house because the cooking and socializing preferences of the users are a more significant factor in determining kitchen size than the size of the house. On these two AGS pages on kitchens, a small kitchen is defined as 150 sq ft (13.94 sq m) or less and an average size kitchen as greater than 150 sq ft. Unless specified, the kitchen plans shown are designed for one cook.

The major components of a well-planned kitchen are traffic and workflow, cabinets and storage, appliance placement and use/clearance space, counter surface and landing space, and room, appliance, and equipment controls.

NOTES

- Any doorway leading into a kitchen should be at least 2 ft 8 in. (810 mm) wide and not more than 2 ft 0 in. (610 mm) deep in the direction of travel.
- No entry door, appliance door, or cabinet door should interfere with another door.
- All major appliances used for surface cooking should have a ventilation system, with a fan rated at 150 CFM minimum.
- No two primary work centers (the primary sink, refrigerator, preparation, or cooktop/range center) should be separated by a full-height, full-depth tall cabinet (cabinet measured from floor to top of wall cabinets).
- Work aisles (passages between vertical objects, both of which are work counters or appliances) should be at least 42 in. (1070 mm) wide in one-cook kitchens, at least 48 in. (1220 mm) wide in multiple-cook kitchens.
- Open countertop corners should be clipped or radiused; countertop edges should be eased to eliminate sharp edges.
- Controls, handles, and door/drawer pulls should be operable with one hand, require only a minimal amount of strength for operation, and not require tight grasping, pinching, or twisting of the wrist.
- Wall-mounted room controls (i.e., receptacles, switches, thermostats, telephones, etc.) should be located 15 to 48 in. (380 to 1220 mm) above the finished floor.
- Ground fault circuit interrupters should be specified on all receptacles in a kitchen.
- A fire extinguisher should be visibly located in the kitchen, away from cooking equipment and 15 to 48 in. above the floor; smoke alarms should be included near the kitchen.
- Window/skylight area should equal at least 10% of the total square footage of a separate kitchen or of a total living space that includes a kitchen.
- Every work surface in a kitchen should be well-lit by appropriate task and/or general lighting.

PLAN

NOTE

When side-by-side refrigerators are specified, it is preferable to design the space so a person using the fresh food section can access the countertop easily.

REFRIGERATOR WORK AREA

SURFACE COOKING AT ENCLOSED CONFIGURATION

SURFACE COOKING AT OPEN (ISLAND) CONFIGURATION

NOTE

In an enclosed configuration, at least a 3 in. (80 mm) clearance space should be considered to the side wall, which should be protected with flame retardant surfacing material. For safety, the cooking surface and the counter area adjacent to it should be the same height.

SURFACE COOKING WORK AREA

LINEAR COUNTER FRONTAGE

SINK ADJACENT TO CORNER

NOTES

- A measurement of 15 in. (380 mm) minimum from the adjacent counter to the centerline of the sink makes possible a clear floor space of 30 x 48 in. (760 x 1220 mm) centered on the sink.
- If the kitchen has only one sink, it should be located between or across from the cooking surface, preparation area, or refrigerator.

SINK WORK AREA

CENTERS OF ACTIVITY

Although the kitchen has evolved around three basic appliances—the sink, the range, and the refrigerator—a kitchen usually has many more centers of activity. A contemporary kitchen may include some or all of the activity center types listed here:

The **PRIMARY CLEANUP SINK CENTER** houses a recycling center, dishwasher, and food waste disposer.

A **SECONDARY SINK CENTER** may serve cleanup functions as well but is generally associated with a food preparation center.

A **PREPARATION CENTER** is a long, uninterrupted counter that may be placed between the sink and the cooking surface or the sink and the refrigerator. In a kitchen for multiple cooks, there will be more than one preparation area.

The **COOKING CENTER** revolves around the cooking surface. A separate built-in oven need not be a part of this center unless it includes a microwave oven.

A **MICROWAVE OVEN CENTER**, because it is used so frequently, must be close to the major areas of activity.

A **PANTRY CENTER** is included in many kitchen plans. This often has storage cabinetry from floor to soffit or floor to ceiling for storing food stuff near the preparation area. This type of tall cabinet may also be used in the serving or dining area.

A **SERVING CENTER** is used to store serving items. It may be in the kitchen or closer to the dining area.

A **DINING AREA** of some sort is typically included in contemporary kitchens.

The **LAUNDRY AREA** is often found in the basement or garage, but it can also be located in the kitchen.

A **HOME OFFICE CENTER** makes space for a telephone, cookbooks, and household records and is an important part of a kitchen.

A **MEDIA CENTER** with a radio and/or television is part of many kitchens today. This center must be located so the TV can be viewed by the cook and other family members in the kitchen.

A **SOCIALIZING CENTER** in the kitchen is as important as some of the more functional areas. A casual furniture setting or an additional seating area for visiting the cook can accommodate this use of the kitchen.

PREPARATION AREA—ONE PERSON

PREPARATION AREA—TWO PERSONS

NOTE

The preparation area should be immediately adjacent to a sink.

PREPARATION CENTER

- NOTES**
1. The single-wall kitchen type is only acceptable in small apartments or efficiency units.
 2. A corridor kitchen offers one cook the advantage of an efficient, close grouping of work centers on parallel walls. Disadvantages are that household traffic may cross back and forth through the area and that the shape is typically too small for two cooks.
 3. With work centers on two adjacent walls, an L-shaped kitchen forms a natural triangle that allows traffic to pass by the work area. The L shape gives the cook a generous amount of continuous counter space, although generally less than a U-shaped area or an L-shape with an island.
 4. If an L shape is combined with a freestanding central structure, all of the benefits of a U-shaped kitchen are available, with a more open, free-flowing plan. The island invites interaction between the cook and visitors and helps as more than one person can work around this open counter.
 5. The U-shaped kitchen is usually considered the most efficient plan; steps are saved because the cook is surrounded on three sides with a continuous countertop and storage system. Traffic is also naturally directed around the work area.
 6. Kitchen layouts may be customized to suit the needs of each user, and endless variations are possible.

NOTE

Walkways are passages between vertical objects that are greater than 24 in. (610 mm) deep in the direction of travel of which not more than one is a work counter or appliance. Walkways should be at least 36 in. (910 mm) wide and should not cross through the work triangle.

TRAFFIC FLOW ADJACENT TO WORK TRIANGLE

NOTE

If two or more people cook simultaneously, a work triangle should be placed for each cook. One leg of the primary and secondary triangles may be shared, but the two should not cross one another. Appliances may be shared or separate.

WORK TRIANGLE—TWO COOKS

KITCHEN TYPES

WORK TRIANGLE—ONE COOK

NOTE

Flexibility within the triangle shape is required because of the multiple centers found in many kitchens. The work triangle is the shortest walking distance between the refrigerator, primary food prep sink, and primary cooking surface measured from the center front of each. The following size recommendations are suggested:

1. Each leg of a triangle should be between 4 and 9 ft (1220 to 2740 mm) long.
2. The total of all three legs of the triangle should be less than or equal to 26 ft (7920 mm).
3. Family traffic patterns should not interfere with the primary triangle.
4. Cabinetry should not intersect any one triangle leg by more than 12 in. (300 mm).

LAUNDRY EQUIPMENT CLEARANCES

LAUNDRY EQUIPMENT ACCESSIBILITY

NOTE
Provide a chase from the floor to the top of the machines to allow a fit flush with the wall. Provide 4 to 6 in. of clearance for conditions without chase.

ONE-WALL LAUNDRY

"L" LAUNDRY

NOTE
For wheelchair users, having laundry facilities close to the kitchen combines several time-consuming activities with a minimum of movement from place to place.

LAUNDRY WITH KITCHEN

LAUNDRIES FOR WHEELCHAIR USERS

The basic necessities for an accessible laundry facility are front-loading automatic washer, dryer, storage shelving for supplies, lightweight steam iron, ironing board, and a surface for folding.

Locate laundry equipment controls within high forward or side reach range. Controls should operate with one hand without tight grasping, pinching, or twisting of the wrist.

For an accessible laundry area, provide storage for supplies within high forward or side reach range; all working surfaces should be at a comfortable seated work height of 29 in. with knee clearance below.

APARTMENT HOUSE LAUNDRIES

In apartment houses, locate laundry rooms in the basement or on the ground floor of the building near necessary mechanical equipment, piping, and ventilation. Locate laundry rooms on grade to provide surfaces to absorb vibrations from operation and to avoid disturbing the apartment dwellers. Provide convenient access from dwelling units to the laundry room.

Incorporate tables for folding and vending machines for soap, bleach, and other laundry powders into the laundry room design.

Provide for visual inspection of the laundry room for the security of the users. Also, provide an area to accommodate the social aspect of laundry room use in large apartment buildings.

When a laundry is situated above an occupied space, it is best to have a waterproof basin sloped to a drain under the washing machine. This will catch overflow and divert it from the space below.

TWO-CAR GARAGES

ONE-CAR

NOTES

1. The width and length of automobiles and other vehicles change every year. See the table of design vehicle dimensions (below) or consult manufacturers for exact dimensions.
2. Design considerations include circulation, visual safety for backing out, and whether the garage will be in public view.
3. Spaces for workshops, photography darkrooms, laundry rooms, and storage areas are often included in the design of garages.
4. Garages may be attached directly to the house or be connected by a covered passageway. The connection with the house is usually at or near the kitchen or a utility area off the kitchen.
5. The design of concealed storage in garages should accommodate the door swing of cupboards.

DESIGN VEHICLE DIMENSIONS

VEHICLE	LENGTH (FT-IN.)	WIDTH (FT-IN.)
Small car	15-0	5-7
Composite passenger vehicle*	16-9	6-4
Light truck	17-9	6-6
Van	16-9	6-3
Sport/utility vehicle	16-0	6-4

* A composite passenger vehicle is a design vehicle that encompasses passenger cars, light trucks, vans, and sport/utility vehicles. It is the vehicle for which a parking facility should be designed.

SECTIONAL DOOR SIZES

DOOR WIDTH (FT-IN.)	NUMBER OF PANELS ACROSS
To 8-11	2
9-0 to 11-11	3
12-0 to 14-11	4
15-0 to 17-11	5

NOTE

GENERAL

Conference rooms should be located for proximity to user groups within a building and for accessibility to outside guests. Since a conference room typically serves to communicate a firm's "image" to others, finishes are usually selected from higher quality materials to suggest a prominent and visible location. When a conference room functions as a multiuser or multigroup space, the position of access doors is altered and acoustical folding partitions or movable walls may be used. The designer should note the additional requirements imposed by building codes for assembly occupancy for larger rooms.

FINISHES

Carpeted floors, acoustical wall panels, or fabric wall coverings and acoustic ceilings should be used. Avoid using "attention-getting" patterns and colors on walls which may decrease focal emphasis of tables, seating,

and speaker or projection area. All finishes should be carefully examined for flame spread and smoke-generated ratings.

LIGHTING

Parabolic lens fluorescent fixtures provide good general lighting with less glare. Directional fixtures such as track lighting may be used for presentation areas. Use dimming switches.

MECHANICAL

Provide a minimum of eight air changes per hour plus a minimum of 10 cu ft/min of outside air per person for odor-free air and good ventilation. Provide an exhaust system to be manually controlled from the room. Careful attention should be given to sound attenuation of diffusers.

TELECONFERENCING

The space and furniture requirements for teleconferencing are different from the typical conference room. All aspects are geared toward video camera requirements. Typically, the conference is held between groups in separate locations linked by video satellite. The standard layout includes two ceiling-mounted video cameras to cover the participants and an optional direct downward-aimed document camera, a projection television monitor (front or rear projecting) for the remote participants, and a control console which interfaces the video cameras, telephone, and satellite linkage. The room arrangement is such that all participants may view and be viewed simultaneously. Mixing presentation media (projection, boards, flip charts, etc.) becomes more difficult in teleconferencing, while the requirements for acoustics and ventilation remain unchanged from the typical conference room. Lighting must be in accordance with the requirements of the video system used.

SECTION

TYPICAL CONFERENCE ROOM (25 - 30 PERSONS)

J. Kevin Lloyd, AIA; Barge, Waggoner, Sumner & Cannon; Nashville, Tennessee

GENERAL PLANNING NOTES

During the early stages of planning, consult with regional Postmaster General for regulations concerning postal facilities in office buildings.

PLATFORM

A dock area that provides off-the-street loading and unloading of mail.

MAILROOM

A security type room located at platform level, which has its own access door to the platform for off-hour service. Platform door should be 48 in. wide, security type. If window or lockbox service is provided, the mailroom should be located at the principal building entrance level. Standard interior treatment should apply in this space. Provide heavy-duty wall and corner guards.

SERVICES

The size of mailroom and services provided by the post office vary with size and occupancy of the building. The U.S. Postal Service recognizes for its staffing and servicing two types of mailrooms for small, medium, and large office buildings.

- LOCKBOX SERVICE:** Buildings up to 200,000 sq ft of leasable space or with a maximum of 75 tenants. Provide one receptacle for each tenant and rear loading for 11 or more tenants. A building directory must be maintained.

The vertical distance from floor to tenant locks on top tier of receptacles is 66 in. maximum; to bottom lowest tier 10 in. minimum, preferably 30 in. Install only at one entrance. Allow a minimum of 3 ft of clear working space behind units. Provide

CASE AND TABLE

80 sq ft of working space for each additional carrier. Allow 1 sq ft of working space for every 1000 sq ft of leasable office space. Specifications for construction of mail receptacles shall be identical to those for Type II, horizontal apartment house receptacles as prescribed in USPS Publication 17, except that the minimum inside dimensions shall be 5 3/4 in. high, 10 1/2 in. wide, and 16 in. deep.

- CALL WINDOW SERVICE:** Buildings with 75 or more tenants, one carrier for each 100,000 sq ft of leasable office space up to 500,000 sq ft, plus one carrier for each additional 200,000 sq ft of office building. Allow 1.5 sq ft for every 1000 sq ft of leasable space; the minimum call window service space is 100 sq ft.

LOCKBOX

CALL WINDOW

POSTAL SERVICES

PLAN

CENTRAL MAILROOM

Buildings larger than 200,000 sq ft and up to 2,000,000 sq ft of leasable space can be served on each floor from a central mailroom using a containerized mechanical system. Allow a minimum of 400 sq ft for first 50 tenants plus 135 sq ft for each additional 50 tenants, or 2 sq ft for each 1000 sq ft of leasable space.

Service mailrooms shall be provided on each multitenant floor, unless containers are conveyed mechanically to tenant offices. Allow 5 x 7 ft minimum floor area for service mailroom. Mechanical systems accommodating 8 to 19 containers may require a minimum area of 7 x 8 ft. Minimum inside container dimensions are 12 x 16 x 6 in.

Existing mechanical systems often are disbanded. U.S. Postal Service recommends a central mailroom with rear-loading lock boxes and parcel lockers. For high mail and parcel volumes, nutting trucks and BMC containers as shown may be used for transport to mailroom floor (48 in. wide security doors required).

NOTES

- Centralized mail delivery: Neighborhood Delivery & Collection Box Units (NDCBU) are popular in home and office complex developments. USPS can help plan centralized mail delivery (Pub. 265, August 1983).

SERVICE MAILROOM PLAN

- USPS lobby layouts in postal buildings designate specific vending machine areas, customer service lobby, and box lobby with parcel lockers having a lock system similar to public lockers, and customer leased box lockers. See USPS guidelines, "New Directions in Lobby Design Practices." Some equipment and features are applicable to office buildings.
- Rehabilitating existing buildings: the form of mail handling should not change, i.e., an original central mailroom installation may not be changed to mail delivery on each floor. Same applies to mail chute installations. Relocation may be necessary, but discontinuation or introduction of a new installation needs approval. In all cases, early consultation with the local Postmaster should be initiated.

CENTRAL MAILROOM

BASKET CARTS EQUIPMENT

- Receiving boxes: Must be placed near the building's main entrance or near the loading, unloading area for USPS mail collection. Using the shortest line, receiving boxes may not be placed more than 100 ft from the entrance used by the collection person. Locations require local Postmaster approval. Receiving boxes must be placed on the same floor the collection person uses to enter the building. Doors must operate freely. Door openings must be at least 12 x 20 in. and not more than 18 x 30 in.
- Auxiliary boxes: Located near receiving box when receiving box is too small to accommodate first class mail volume. Openings must be large enough to receive tied bundles of first class mail.
- Bundle drops: Receiving boxes must have bundle drops with an opening for a bundle at least 6 1/2 in. wide by 11 1/2 in. long and 4 in. high. To prevent removal of mail through it, the deposit opening must be fully protected by inside baffle plates. Inlet doors must be inscribed "Letters" and "Letter Mail Tied in Bundles." Bottom of the opening must be at least 61 in. above floor level.

Reference: USPS Publication 16, August 1989

NOTES

- All installations must comply with USPS requirements and are subject to inspection.
- Floor penetrations may need firestopping methods.
- USPS provides listing of approved manufacturers.

MAIL CHUTE - PLAN

NOTES

- May be recessed.
- Use wide chutes for 8 x 10 in. envelopes.
- Tempered glass at least 3/16 in. thick, or heavy, shatterproof plate glass at least 3/4 in. thick, or transparent, fire-resistant plastic material of equal or greater strength than 3/16 in. tempered glass.

MAIL CHUTES AND RECEIVING BOXES

- Chutes: Used in buildings of at least four stories for first class mail only. The chute cross section must be approximately 2 x 8 in. and extend in a continuously vertical line from beginning point to receiving box or mailroom. Chute interior must be accessible its entire length. Chutes in pairs have a divider and dual receiving boxes.

MAIL CHUTES AND RECEIVING BOXES

1/2 by Hart Associates, AIA; White Plains, New York

GENERAL NOTES

Coatrooms should be adjacent to and have line-of-sight connections with lobby or with circulation path between building entry and destination (auditorium, gallery, etc). Care should be taken to provide ample space for orderly queuing out of the mainstream of circulation. This is of particular importance in theaters, concert halls, and similar facilities where check in and out of massive numbers of people occurs in a very brief period of time. In galleries, museums, and restaurants, the flow of people is more even, resulting in a diminished need for queuing space and a smaller staffing requirement for the check-room itself.

For general planning purposes, allow between 1.1 and 1.5 in. of rack space per garment, depending on climate. Hats, umbrellas, and packages should be stored with the garment rather than segregating items by type. Most racks contain from one to three overhead shelves for this purpose. For ease of access, these shelves should not extend above 6 ft 8 in.

For small to medium size facilities, conventional coatrooms are adequate. In large facilities where hundreds of garments will be accommodated, the designer should consider using automated conveyors. These systems save a great deal of time by eliminating the need to access aisles searching for a garment. In addition, the aisles are eliminated, resulting in a more efficient use of space. These systems function as follows:

The coatroom attendant hangs incoming garments on a conveyor in prenumbered slots that correspond to the claim check number. Hats and other items are placed in bins over the patron's garments. When departing patrons present their claim check, the attendant keys in the number on a control panel, and the conveyor revolves until it automatically stops at the correct number.

COATROOM AREA REQUIREMENTS

CAPACITY	AREA, CONVENTIONAL	AREA, AUTOMATED
100	75	N.A.
200	140	100
300	200	130
400	240	150
500	310	180
1000	575	320
1500	760	460
2000	1025	600

COATROOM EQUIPMENT

Blythe + Nazdin Architects, Ltd.; Bethesda, Maryland

GENERAL

Round tables are usually recommended for seating four or more persons.

Dimension "A" depends on the perimeter length necessary for food. Dimension "A" depends on the perimeter length necessary for food. Dimension "A" depends on the perimeter length necessary for food. For cocktails, 1 ft-6 in. is sufficient.

Tables 3 ft 0 in. and wider will seat at least one person at each end.

Smaller sizes are satisfactory for drink service; larger sizes for food. Tables with center bases accommodate coupled table arrangements better than four-legged tables.

The type and style of service affect tables and arrangements. Consider the use of service carts, high chairs, as well as accessibility for the disabled. See the Americans with Disabilities Act (ADA) requirements below.

TYPICAL DIMENSIONS

BOOTH DIMENSIONS

- A = Seat back to seat back: 5' - 6" to 6' - 2"
- B = One person per side: 2' - 0" to 2' - 6"
- Two persons per side: 3' - 6" to 4' - 6"
- Three persons per side: 5' - 0" to 6' - 2"
- C = 3' - 0" to 4' - 0"
- D = 2' - 6"
- E = 1' - 6"
- F = 2" to 4"
- G = 1' - 6" ±
- H = 2' - 0" to 2' - 6"

NOTES

1. Local building codes may determine actual booth sizes. Tables are often 2 in. shorter in length than seats and may have rounded ends. Circular booths have overall diameter of approximately 6 ft 4 in.
2. Eliminate one booth and replace with table to provide access for wheelchair.

BOOTHS

BAR DIMENSIONS

- A = 8' - 4" to 11' - 7"
- B = 1' - 6" to 2' - 0"
- C = 2' - 4" to 3' - 2"
- D = 2' - 6" to 3' - 0"
- E = 2' - 0" to 2' - 6"
- F = 6" to 7"
- G = 1' - 10" to 2' - 2"
- H = 2' - 6" to 2' - 10"
- I = 11" to 1' - 10"
- J = 7" to 9"
- K = 6" to 9"
- L = 2' - 6"
- M = 3' - 6" to 3' - 9"
- N = 3' - 0" to 3' - 6"
- O = 5' - 0" to 5' - 9"

NOTE

Ratio of counter seating to servers is 10 : 1 to 12 : 1.

LOW COUNTER DIMENSIONS

- A = 4' - 11" to 5' - 6"
- B = 3' - 1" to 3' - 3"
- C = 1' - 10" to 2' - 0"
- D = 1' - 7" minimum
- E = 1' - 6" to 2' - 0"
- F = 2' - 4" to 2' - 8"
- G = 2' - 3" minimum
- H = 4" to 8"
- I = 5' - 0" minimum

NOTE

A continental bar with low seating is one means of achieving accessibility. The bartender's area can be lowered or the seating area can be on a raised platform accessed by ramp.

BARS AND COUNTERS

NOTE
A raised leaf is one retrofit option.

ACCESSIBLE FURNITURE

SQUARE TABLES

PERSONS	A OR B
2	2' - 0" to 2' - 6"
4	3' - 0" to 3' - 6"

RECTANGULAR TABLES

PERSONS	A	B
2 (on one side)	3' - 6" to 4' - 0"	
6 (3 on each side)	5' - 10" to 7' - 0"	2' - 6" to 3' - 0"
8 (4 on each side)	7' - 6" to 9' - 0"	

ROUND TABLES

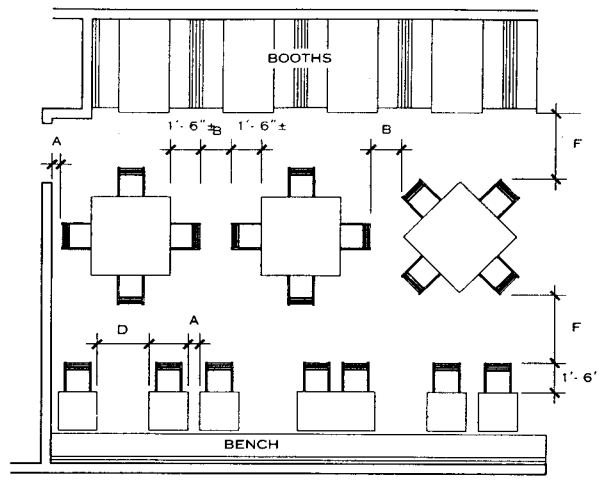

PERSONS	A
4 - 5	3' - 0" to 3' - 6"
6 - 7	3' - 6" to 4' - 6"
7 - 8	4' - 6" to 5' - 0"
8 - 10	5' - 0" to 6' - 0"

TABLES

Janet B. Rankin, AIA; Rippeteau Architects; Washington, D.C.
Cini-Little International, Inc., Food Service Consultants; Washington, D.C.

CLEARANCES:

- A = 6" minimum (no passage)
- B = 1' - 6" (limited passage)
- C = 1' - 7"
- D = 2' - 6"
- E = 3' - 0"
- F = 3' - 6"
- G = 4' - 0"
- H = 4' - 6"
- I = 6' - 0"

NOTE

All dimensions are minimum clearances. Seating layouts show general configurations and are not intended to depict any specific type of operation. Tables may be converted from square to round to generally enlarge seating capacity. Booth seating makes effective use of corner space.

A wheelchair accessible route, at least 36 in. wide, is required to connect the entrance, accessible fixed seating, and restrooms.

TYPICAL SEATING ARRANGEMENTS

SEATING ARRANGEMENTS FOR PERSONS USING WHEELCHAIRS

GENERAL DESIGN CRITERIA

SERVICE AISLES

1. For square seating, allow 72 in. minimum between tables (30 in. aisle plus two chairs back to back).
2. For diagonal seating, allow 36 in. minimum between corners of tables.
3. For wall seating, allow 30 in. minimum between wall and seat back.
4. Allow a minimum of 30 in. for bus carts and service carts.

CUSTOMER AISLES

1. Refer to local codes for restrictions on requirements.
2. For wheelchair access, allow 36-44 in. aisle.
3. For wall seating, allow 30 in. minimum between walls and table.
4. Clear floor space must be provided for table access. Such clear floor space shall not overlap kneespace by more than 19 in.

TABLE PLACEMENT

1. Allow circulation space adjacent to doors and food service areas.
2. Restaurants should offer a variety of seating options.

ACCESSIBLE SEATING

1. If fixed or built-in seating areas are provided, make at least 5%, or a minimum of one fixed/built-in seating area, accessible. Review ADA requirements.
2. Accessible seating should be integrated within the dining area, and should accommodate both large and small groups.
3. Raised and sunken areas must be accessible. Mezzanines must also be accessible unless certain conditions are met (see ADAAG 5.4).

TABLE AND COUNTER CRITERIA

1. Tables average 29 in. high.
2. The tops of accessible tables and counters should be 28 in. to 34 in. high. A portable raised leaf may be provided to adapt lower tables.
3. If seating for people in wheelchairs is provided at tables or counters, kneespace at least 27 in. high, 30 in. wide, and 19 in. deep shall be provided.
4. Where food and drink are served at counters exceeding 34 in. in height, a portion of the main counter, 60 in. in length, should be made accessible, or accessible tables shall be located in the same area.
5. Corners and edges of table and countertops should be rounded for safety.

SEATING CRITERIA

1. Chair seat height is usually 18 in. Seat heights should be slightly higher at wheelchair accessible tables.
2. Seats should be a minimum of 16 in. deep and 16 in. wide.
3. Padding and cushions should be firm.
4. Seat backs should be slightly inclined.
5. Armrests should be provided to aid in rising.
6. Table or counter supports should not interfere with seat kneespace so the feet can be positioned for rising.

DINING SPACE AVERAGES

TYPE OF ROOM	SQUARE FEET PER PERSON
Banquet	10 - 12
Cafeteria	12 - 18
Tearoom	10 - 16
Lunchroom/coffee shop	12 - 16
Dining room/restaurant	13 - 16
Specialty/formal dining	17 - 22

NOTE

Area figures represent the average minimum. Seating requirements may vary widely to suit individual operations.

Janet B. Rankin, AIA; Rippeteau Architects; Washington, D.C.
Cini-Little International, Inc., Food Service Consultants; Washington, D.C.

NOTE

Educational facilities with time constraints should have 10 shower heads for the first 30 persons and one shower head for every four additional persons. In recreational facilities one shower head for each 10 dressing lockers is a minimum. Temperature controls are necessary to keep water from exceeding 110° F. Both individual and master controls are needed for group showers.

GROUP SHOWERS

SHOWER PLAN

DRESSING ROOM PLAN

TYPICAL DIMENSIONS

	MINIMUM	OPTIMUM
Showers	3'-0" x 3'-6"	3'-6" x 3'-6"
Dressing Rooms	3'-0" x 3'-6"	3'-6" x 4'-0"

NOTE

Individual dressing rooms and showers can be combined in a variety of configurations to obtain 1:1, 2:1, 3:1, and 4:1 ratios.

INDIVIDUAL SHOWERS AND DRESSING ROOMS

NOTE

The drying room should have about the same area as the shower room. Provision for drainage should be made. Heavy duty towel rails, approximately 4 ft from the floor, are recommended. A foot drying ledge, 18 in. high and 8 in. wide as shown in the drawing, is desirable. An adjacent wet toilet is suggested. Avoid curbs between drying room and adjacent space. Size of towel service area (which can be used for distributing uniforms) varies. Size of area varies with material to be stored; 200 sq ft is usually sufficient.

DRYING ROOM AND WET TOILET

NOTE

Bench should be minimally 8 in. wide and 16 in. high. Traffic breaks of 3 ft minimum width should occur at maximum intervals of 12 ft. Main traffic aisle should be wider. Avoid lockers that meet at 90° corner.

	A	B	C
Recreation	2'-2"	1'-8"	3'-6"
School	2'-6"	2'-6"	4'-0"

LOCKER ROOM

NOTE

Basket racks vary from 7 to 10 tiers in height. Wide baskets require 1 ft shelf space, small baskets 10 in. shelf space; both fit 1 ft to 1 1/2 ft deep shelf. Back-to-back shelving is 2 ft 3 in. wide. Height is 9 1/4 in.

BASKET ROOM AND BASKET RACK

CABANA

STORAGE

DRESSING

STANDARD SIZES (IN.)

	9	12	15	18
Width				
Depth	12	15	18	
Height	60	72 (overall)		

NOTE

For schools, standard storage locker is 9 in. or 12 in. x 12 in. x 12 in. to 24 in. Standard dressing lockers are 12 in. x 12 in. x 60 in. or 72 in. Number of dressing lockers should be equal to the peak period load plus 10 to 15% for expansion.

LOCKER TYPES

RECOMMENDED MOUNTING HEIGHTS

Richard J. Vitullo, AIA, Oak Leaf Studio; Crownsville, Maryland
BFS Architectural Consulting and Interior Design, YMCA of the USA; Chicago, Illinois

LOCKER ROOM FACILITIES CHECKLIST

1. Fixed benches 16 in. high.
2. Lockers on raised base.
3. Locker numbering system.
4. Hair dryers—one per 20 lockers.
5. Mirrors at lavatory.
6. Makeup mirror and shelf.
7. Drinking fountain (height as required).
8. Bulletin board.
9. Dressing booths, if required.
10. Full - length mirror.
11. Clock.
12. Door signs.
13. Sound system speaker, if required.
14. Lighting at mirrors for grooming.
15. Lighting located over aisles and passages.
16. Adequate ventilation for storage lockers.
17. Windows located with regard to height and arrangement of lockers.
18. Visual supervision from adjacent office.

GENERAL NOTES

1. The most widely used arrangement of lockers is the bay system, with a minimum 4 ft circulation aisle at each end of the bays. Ordinarily, the maximum number of lockers in a bay is 16. Locate dry (shoe) traffic at one end of the bays and wet (barefoot) traffic at the other end. For long bays with a single bench, make 3 ft breaks at 15 ft intervals.
2. Supervision of school lockers is the easiest if they are located in single banks along the two walls, providing one or more bays that run the length of the room.
3. The number of lockers in a locker room depends on the anticipated number of members and/or size of classes. For large numbers separate locker areas should be encouraged. In small buildings interconnecting doors provide flexibility and allow for the handling of peak loads.
4. Individual dressing and shower compartments and a shower stall for the handicapped may be required.
5. Basket storage, if included, generally is self-service. Maximum height is 8 tiers. A dehumidifying system should be provided to dry out basket contents overnight. Separate auxiliary locker rooms for teams, part-time instructors, faculty, or volunteer leaders may be required. A small room for the coach's use may be desirable.
6. The shower room should be directly accessible to the drying room and locker room that it serves. When a shower room is designed to serve a swimming pool, the room should be located so that all must pass through showers before reaching the pool deck.
7. Separate wet and dry toilet areas are recommended. Wet toilets should be easily accessible from the shower room. When designed for use with a swimming pool, wet toilets should be located so that users must pass through the shower room after use of toilets.
8. Locker room entrance and exit doors should have vision barriers.
9. All facilities should be barrier-free.
10. Floors should be of impervious material, such as ceramic or quarry tile, with a Carborundum impregnated surface, and should slope toward the drains. Concrete floors (nonslip surface), if used, should be treated with a hardener to avoid the penetration of odors and moisture.
11. Walls should be of materials resistant to moisture and should have surfaces that are easily cleaned. All exterior corners in the locker rooms should be rounded.
12. Heavy duty, moisture resistant doors at locker room entrances and exits should be of sufficient size to handle the traffic flow and form natural vision barriers. Entrance/exit doors for the lockers should be equipped with corrosion resistant hardware.
13. Ceilings in shower areas should be of ceramic tile or other material impervious to moisture. Locker room ceilings should be acoustically treated with a material impervious to moisture and breakage. Floor drains should be kept out of the line of traffic, where possible.

GYMNASIUM AND POOL LOCKER ROOM

POOL LOCKER ROOM

GYMNASIUM LOCKER ROOM

LOCATION WITHIN THE BUILDING

The courtroom is often the major space in the building and should be centrally located, with primary access to its support spaces (e.g., judge's chamber, jury rooms, witness rooms, court officer's spaces), the public lobby, and toilet facilities.

REQUIRED SPACES

Courtrooms require 3 main areas or zones

1. The public space
2. The courtroom, including the jury box
3. The judge's bench and witness stand

The public space is open to the public for observation of the trial proceedings. Defendants and attorneys also use this space as a waiting area before their trial. The public space should have access to the public corridor and good access to public toilet facilities. It is usually divided from the courtroom space by a low divider rail with swinging gates.

The courtroom space is a restricted access space. Access to this space should be from private corridors, jury rooms, court officer offices, or the gates to the public space. This space contains the majority of courtroom activity. The jury, attorneys, defendants, and sometimes the press occupy this space. The jury box, part of the courtroom space, usually has a raised floor to provide better visibility of the trial proceedings. The jury box should have direct access to the jury room(s) or to a private corridor leading to the jury room(s). The courtroom space should not be accessible from any public corridor.

The judge's bench and witness stand have the most restricted access. They are usually divided from the courtroom space by a divider rail. The floor of the judge's bench is usually raised above the raised floor level of the jury box and witness stand to provide the judge(s) the most prominent position in the courtroom space. The judge's bench has direct access to the judge's chamber or to a private corridor leading to the judge's chamber. The witness stand is located adjacent to the judge's bench and is accessible only from the courtroom space. The witness stand has a raised floor, usually at the same level as the jury box.

SPACE RELATIONSHIPS

The jury should have direct access to the jury room without crossing the courtroom or any public space. A separate entrance to the jury room should be provided from the building corridor. Private toilet facilities should be provided, with direct access to the jury room. The judge should have direct access to the courtroom from his office. The size of the courtroom and its support spaces varies considerably, depending on the volume of court proceedings. For example, in a small municipal or magistrate's courtroom, 50 seats in the public space and 6 seats for jury members are adequate, whereas in a federal district court or state circuit court, 80-100 seats should be provided for the public, 12-14 for jury members (includes 2 alternates), 3 for judges, 1 for clerk of court, and 1 for court reporter. Seating for the press reporters should be provided in or near the courtroom space. All areas must be accessible to persons with disabilities.

CONSTRUCTION

The courtroom does not require natural lighting. A lighting level of 50 fc at the attorneys' table and judge's bench and a lighting level of approximately 30 fc in the public space should be adequate. All perimeter walls should be insulated to reduce sound transmission (STC 47 minimum). Resilient floor covering should be used in the public space and carpet may be used in the courtroom itself.

AREA REQUIREMENTS FOR SUPPORT SPACES

The jury room should be approximately 200 sq ft for municipal court and 350 sq ft for federal district court. Multiple jury rooms are often required for busy court facilities. A judge's chamber should be 150-350 sq ft. If pretrial hearings are held in the judge's chamber, the area should be increased to approximately 750 sq ft. A clerk of court's office should be 150-350 sq ft.

TYPES OF COURTS

Municipal or magistrate's courtrooms are usually small courtrooms located in City Hall or other municipal buildings. Municipal courts handle traffic and minor criminal cases. Magistrate's courts handle small civil and minor criminal cases.

State circuit courtrooms are usually large courtrooms located in the county courthouse of each county. State circuit courts handle all state trial proceedings, both civil and criminal.

Federal district courtrooms are usually large courtrooms located in federal governmental buildings serving each federal judicial district. Federal district courts handle all federal trial proceedings, both civil and criminal.

T. John Gilmore, AIA; O'Cain Forrester Gilmore Architects; Spartanburg, South Carolina

GENERAL ACUTE CARE

Patient rooms must be accessible, easily maintained, and spacious enough to contain high-tech life support and monitoring equipment. Entry doors should be a minimum of 48 in. wide. Wider openings are sometimes required to accommodate large equipment and surgical teams during emergency situations. A clear area of 48 in. should be maintained at the foot of patient beds. Equip patient rooms with basic amenities such as a patient chair, visitor chair, television set (VCR optional), wardrobe for full-length garments and luggage, drawers for clothing and personal items, and a countertop for flowers and cards. Patient rooms include toilet facilities, though central bathing areas may be provided in lieu of individual showers. Doors to accessible toilet rooms must provide a clear opening of 32 in. minimum. If doors swing in, equip them with hardware that permits emergency access. Universal precautions require a lavatory in, or near the entrance to, each patient room and a place to store gloves, masks, and gowns. Space for electronic equipment, such as a patient data terminal and printer, may be required. Semiprivate patient rooms should contain cubicle curtains for visual privacy.

INTENSIVE CARE

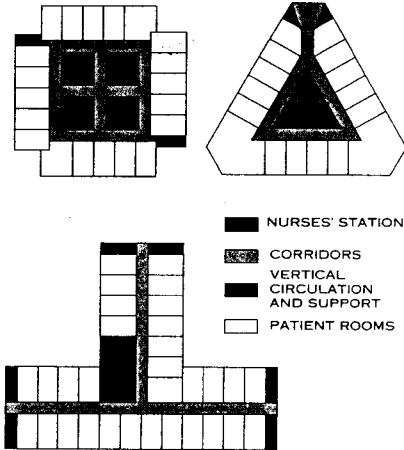

Patients in an intensive care unit are under continuous observation. Each room should be visible from the nurse station or a staffed corridor workstation. Each unit must contain equipment for continuous monitoring. Provide a nurse call at each bed for summoning assistance. Beds should be within view of an exterior window, preferably an operable window. Provide bedside space for visitors and a curtain for visual privacy. Doors should be a minimum of 48 in. wide. Sliding doors may be used for access to rooms or cubicles within a suite. Provide at least one private room or cubicle in each ICU for patients requiring isolation and/or separation. Toilet units can be provided in each bed area, along with a sink, countertop for preparing medications, and universal precautions storage. IV tracks and exam lights are typically placed above each bed. Because of the acuity of illness of these patients, rolling life-support equipment often occupies space at the side and foot of the bed. Maintain a minimum of 48 in. on three sides of each bed. Utility columns allow 360 degree access around the patient.

FINISHES AND HEADWALLS

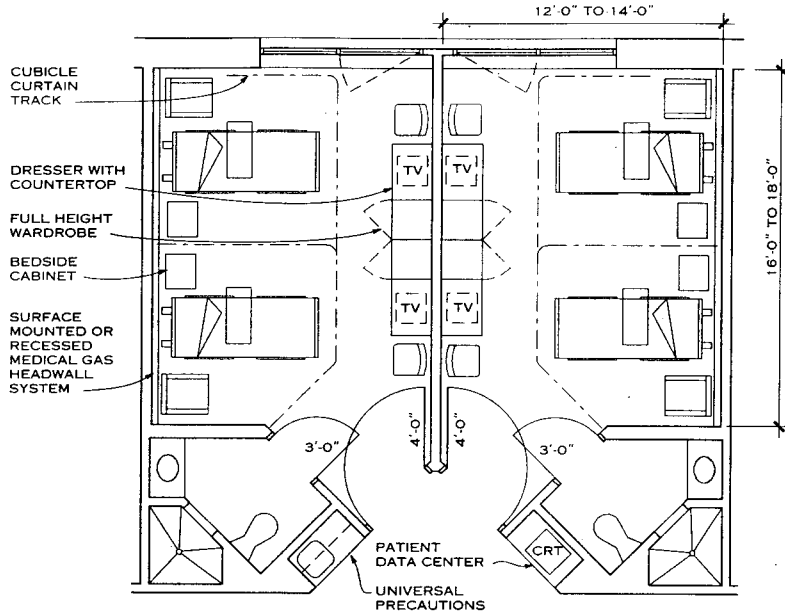

Finishes in patient rooms should be durable and easy to maintain: vinyl flooring, vinyl wall coverings, or painted gypsum board partitions, etc. are typically used. Epoxy paint is sometimes used at wet or medication preparation areas. Some hospitals contain less "institutional" patient rooms with carpeted floors and other homelike finishes. Consult local codes for restrictions on finishes in patient rooms.

Depending on the room type, bed headwalls may include a nurse call button, reading light, room light switches, television controls, electrical outlets, central monitoring capabilities, suction, vacuum, and various medical gas outlets. Headwalls are available as prefabricated units or can be built into the partition. Wall thicknesses may vary depending on the type of equipment used.

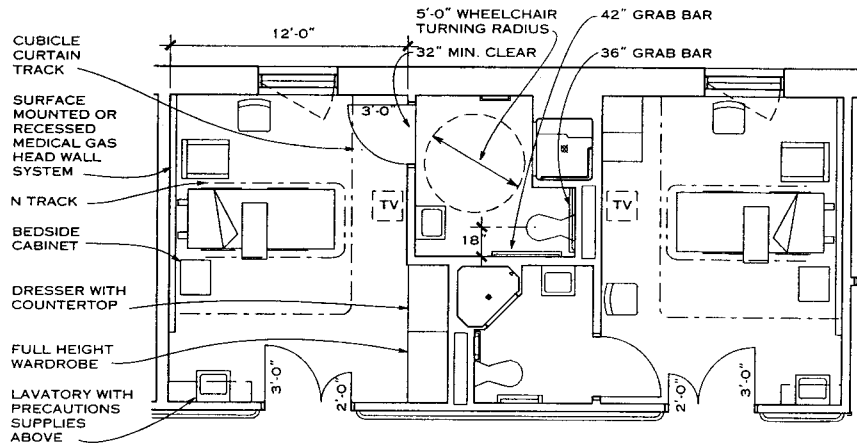

Consult the Americans with Disabilities Act (ADA) for specific accessibility guidelines.

TYPICAL UNIT CONFIGURATION

SEMIPRIVATE PATIENT ROOM

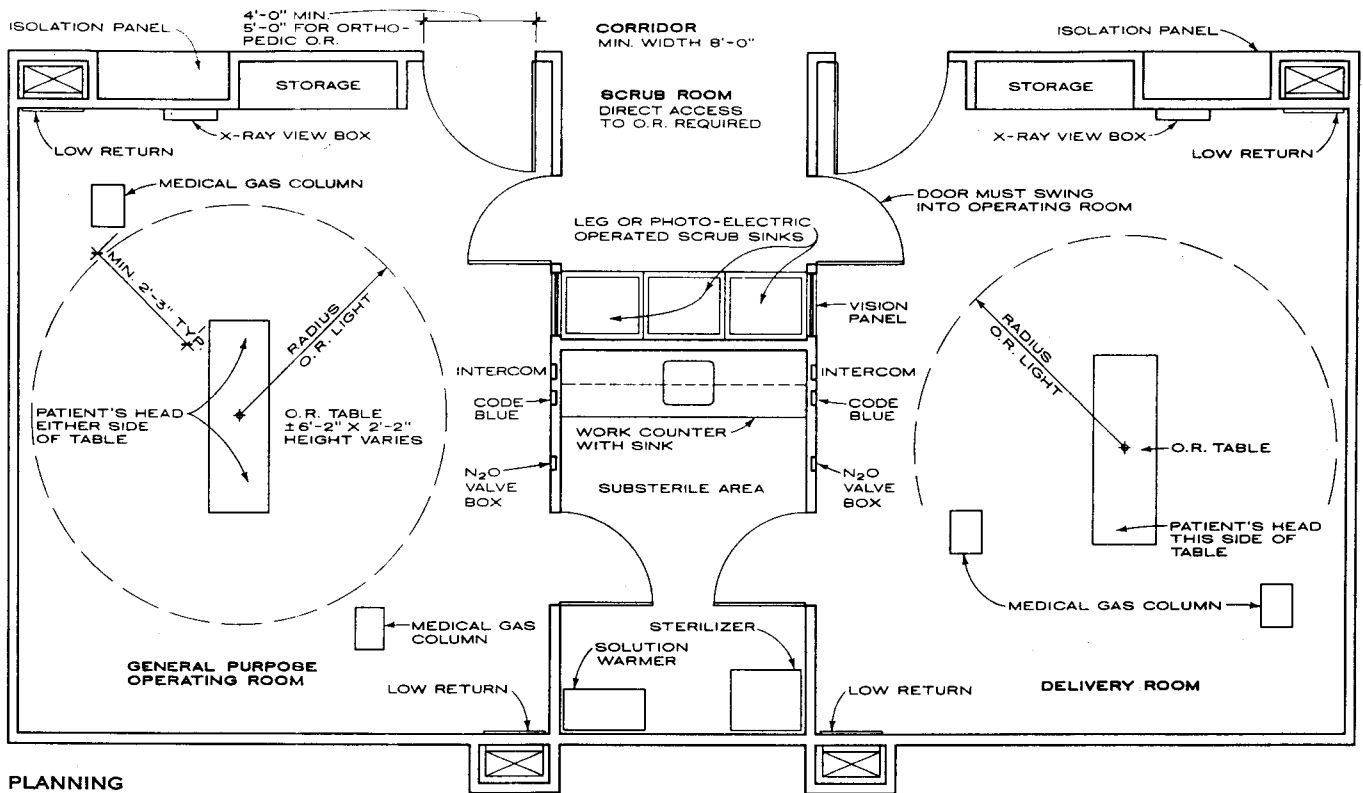

PRIVATE PATIENT ROOM

INTENSIVE CARE UNIT PATIENT ROOM

Timothy J. Cowan; Burt Hill Kosar Rittelmann Associates; Pittsburgh, Pennsylvania

PLANNING ENCLOSURE

General purpose operating rooms must be extremely flexible due to widely varying spatial requirements of surgical procedures and personal preferences of the surgical staff. Public health codes limit the minimum size of these operating rooms to 360 sq ft, exclusive of casework. Certain procedures can require significantly more space. Operating rooms should be roughly square in plan and free of columns, with the operating room table located in the approximate center of the room to allow for maximum flexibility in positioning of equipment and personnel. Delivery rooms may be a minimum of 300 sq ft, exclusive of casework, for noncesarian births and 360 sq ft for cesarian. In delivery rooms, the operating room table is typically shifted from the center of the room to provide more space at the foot end. Endoscopy operators may be as small as 250 sq ft, while orthopedic rooms should be at least 450 sq ft. Operating room finished ceiling height should be no lower than 9 ft 0 in., with an ample ceiling cavity for service space above.

FINISHES

The primary concern in surgical room finishes is cleanliness. Flooring materials should be seamless and have an

integral base for ease of maintenance. Walls should be finished with a scrubable epoxy base paint or with vitreous ceramic tile and bacteria-resistant grout. Ceiling finishes should be either plaster or gypsum board. Built-in casework, countertops, sinks, and similar items should be stainless steel.

In operating rooms where flammable gases will be used an antistatic flooring surface must be specified to avoid sparks that could cause an explosion. Finishes throughout the operating room should be of light, neutral colors to avoid any distortion in skin color.

ENVIRONMENTAL CONTROLS

Temperature and humidity in operating rooms must be strictly regulated to maintain a suitable environment for surgery. Positive air pressure must be maintained with respect to other areas to avoid infiltration of contaminants from outside the operating room. Air should be supplied at low velocities, with diffusers positioned to avoid formation of air eddies. Return registers should be near floor level, adjacent to medical gas columns, and at furthest points from each other for evacuation of an-

esthetic gases, dust, and microbes. In areas where flammable gases will be used, electrical outlets must be explosion-proof or be placed 5 ft 0 in. above finished floor; high-hazard fire protection systems should be installed.

EQUIPMENT

Medical gas columns typically contain a variety of gases, vacuum lines, and power used by the anesthesiologist during surgical procedures. They should be located adjacent to the anesthesiologist, who is positioned near the head of the patient. These columns are ceiling mounted and typically extend down to approximately 5 ft 6 in. above the floor. Retractable columns are also available. Depending on the anticipated use of the facility, a great variety of additional, highly specialized equipment will also be required.

Because of the extreme complexity of these areas, extensive participation by doctors, technicians, equipment manufacturers, and engineers is required throughout the design process.

TYPICAL SURGICAL SUITE

DENTAL EQUIPMENT KEY

1. Dental chair
2. Dual operating room light track
3. Medical gas console
4. Counter (cabinets below)
5. Overhead storage
6. Cutout in counter for waste
7. Stainless steel sink with foot control
8. Film illuminators (2)

PLANNING

The dental chair base is equipped with hot and cold water, wet suction, compressed air, drainage if required for cuspidor, and power. In addition, a chair-mounted operating light may be used in lieu of a ceiling-mounted fixture.

The wall-mounted medical gas console typically includes nitrogen, oxygen, and nitrous oxide. If nitrous oxide gas is included, a scavenging system should be provided. Medical gases can be supplied by tanks on movable carts.

While room finishes are not as critical in dental operatories as in operating rooms, all surfaces should be washable.

DENTAL OPERATORIES

Deborah Hershowitz and Frank Giese; Rogers, Burgun, Shahine and Deschler Architects; New York, New York
Blythe + Nazdin Architects, Ltd.; Bethesda, Maryland

GENERAL

The capacity of each refrigeration machine is equal to 50% of the peak cooling load. Each water pump provides the flow requirement of one refrigeration machine. Therefore, one pair of condenser and chilled water pumps is needed for each machine.

The cooling tower may be located on the roof of the refrigeration equipment room or on the ground adjacent to the equipment room. When located on ground, the condenser water outlet(s) on the cooling tower must be not less than 5 ft above the equipment room floor elevation for proper functioning of condenser water pumps.

See ASHRAE Standard 15-1992, "Safety Code for Mechanical Refrigeration," for required ventilation of chiller plant and monitoring of toxic refrigerants.

EXPANSION OF EQUIPMENT

For operational flexibility of a refrigeration plant, the size of the future refrigeration machine is generally planned to be the same as of the present machines. It may be economically advantageous to oversize some portions of the chilled and condenser waterpipes to handle the future flow rates.

Provision must also be made for expansion of the cooling tower capacity when the future refrigeration machine is installed.

REFRIGERATION EQUIPMENT ROOM SPACE REQUIREMENTS

EQUIPMENT (TONS)	DIMENSIONS								MINIMUM ROOM HEIGHT
	L	W	HEIGHT	T	A	B	C	D	
RECIPROCATING MACHINES									
Up to 50	10'-0"	3'-0"	6'-0"	8'-6"	3'-6"	3'-6"	4'-0"	3'-0"	11'-0"

450 to 550	23'-6"	9'-6"	12'-0"	23'-0"	3'-6"	3'-6"	6'-0"	5'-6"	15'-0"
550 to 750	26'-0"	10'-6"	13'-0"	25'-6"	3'-6"	3'-6"	6'-0"	5'-6"	16'-0"
750 to 1000	30'-0"	11'-0"	14'-0"	29'-6"	3'-6"	3'-6"	7'-0"	6'-0"	17'-6"

Note: Direct-fired absorption machines are roughly the same size as steam absorption machines.

REFRIGERATION ROOM LAYOUT

BOILER ROOM SPACE REQUIREMENTS

BOILER HP	15-40	50-100	125-200	250-350	400-800
Dimension A	5'-9"	6'-6"	6'-10"	7'-9"	8'-6"
Dimension B	7'-5"	8'-9"	9'-7"	11'-9"	14'-3"

NOTE: Above requirements apply to both steam and hot water boilers.

BOILER ROOM LAYOUT FOR STEAM BOILERS

ROOM DIMENSIONS

Dimension A allows for a minimum 3 ft 6 in. aisle between the water column on the boiler and the wall. Dimension B between boilers allows for a clear aisle of:

- 3'-6" - 15-200 hp
- 4'-0" - 250-350 hp
- 5'-0" - 400-800 hp

The shortest boiler room length is obtained by allowing for possible future tube replacement (from front or rear of boiler) through a window or doorway. Allowance is only made for minimum door swing at each end of the boiler.

AIR SUPPLY

Two permanent air supply openings on opposite walls of the boiler room are recommended. These openings should be located below a height of 7 ft with a total clear area of at least 1 sq ft. Air supply openings can be louvered for weather protection. Check applicable codes for minimum supply air requirements.

Size the openings by using the following formula:

$$\text{area (sq ft)} = \frac{\text{CFM}}{\text{FPM}}$$

Amount of air required (CFM):

- Combustion air - max. boiler HP x 2 CMF/BHP
- Ventilation air - max. boiler HP x 2 CFM/BHP

NOTE: a total of 10 CFM/BHP applies up to 1000 ft elevation. Add 3% more per 1000 ft of added elevation.

Air velocity required (FPM):

- Up to 7 ft height - 250 FPM
- Above 7 ft height - 500 FPM
- Supply air duct to boiler - 1000 FPM

If chillers and boilers are located in the same room, combustion air supply must be ducted to boilers (see ASHRAE 15-1992).

FIGURE 2 EQUIPMENT ROOM PLAN

FIGURE 1 EQUIPMENT ROOM PLAN

EQUIPMENT ROOM SECTION A-A

NOTES

1. The air-handling equipment room should be located centrally to reduce distances conditioned air must travel from the equipment room to the farthest air-conditioned space. Fan noise transmission to adjacent spaces also must be considered. If the equipment room is located near conference rooms, sleeping quarters, broadcasting studios, or other sound sensitive areas, special treatment of the equipment room area will be required to provide adequate sound and vibration isolation from surrounding areas.
2. Adequate access space must be provided to maintain and replace heating coils, cooling coils, filters, damper motors and linkage, control valves, bearings, fan motors, fans, belts, pulleys, and other parts.
3. Figure 1 shows a typical equipment room plan with one floor-mounted air-conditioning unit and one suspended return air fan. The air-conditioning unit shown is a horizontal draw-through type consisting of fan, cooling coil, preheat coil, filters, return air plenum, outdoor air intake plenum, and access sections on either side of the coils.
4. The outdoor air intake louver and exhaust air louver are located on different walls. Where both intake and exhaust louver must be located on the same wall, they must be as far apart as possible, but not less than 10 ft. in order to reduce the short circuiting between the exhaust and intake air.
5. Figure 2 shows the same system without a return fan, but with exhaust capability via a remote fan.
6. When a horizontal blow-through unit is used, the length of the unit essentially is the same as shown for the draw-through unit.

7. Where higher headroom is available, a vertical unit, which can be only the draw-through type, may be used to reduce the unit's length. Depending on the size of the unit, this reduction in length will range from 2 ft. to 3 ft. 6 in.
8. Figure 1 shows an axial fan for returning air from the conditioned space. The return air fan may not be required where the air-conditioning system is not designed to operate under economizer cycle (cooling by cold outdoor air) mode.
9. A floor-mounted centrifugal single width, single inlet type fan or double width, double inlet type fan, may be used instead of the suspended axial fan shown; however, this generally increases equipment room width.
10. Outside air intake louvers are weatherproof with 50 percent to 60 percent free area. Louver size for conventional intake and exhaust air systems can be determined by allowing 800 ft. to 1,000 ft. per minute velocity through the free area.
11. The quantity of outside air drawn into a system depends on the ventilation criteria of the space being served and the amount of make-up air needed to balance any exhaust air drawn from the same space. The ratio of outside air to the total amount being supplied to a space may be very small. An office may need 10 percent to 20 percent outside air; a laboratory may require 100 percent outside air because of its non-recirculating aspect.
12. The total air quantity supplied to any individual space may vary from 0.5 CFM per sq. ft. for light occupancy (public circulation type office space) to 2 to 3 CFM per sq. ft. for laboratories, restaurants, ballrooms, and similar areas with large internal or external cooling loads.

EQUIPMENT ROOM SPACE REQUIREMENTS

CFM RANGE	APPROXIMATE OVERALL DIMENSION OF SUPPLY AIR UNITS			RECOMMENDED ROOM DIMENSIONS		
	W	H	L	W	H	L
1,000- 1,800	4'-9"	2'-9"	14'-9"	12'-6"	9'-0"	18'-9"
1,801- 3,000	5'-0"	3'-6"	16'-0"	13'-9"	9'-0"	20'-0"
3,001- 4,000	6'-9"	4'-6"	16'-0"	17'-6"	9'-0"	20'-0"
4,001- 6,000	7'-6"	4'-6"	16'-9"	18'-0"	9'-0"	20'-9"
6,001- 7,000	7'-6"	4'-9"	18'-3"	18'-6"	9'-6"	22'-3"
7,001- 9,000	8'-0"	5'-0"	18'-9"	19'-0"	10'-0"	22'-9"
9,001-12,000	10'-0"	5'-6"	21'-0"	23'-0"	11'-0"	25'-0"
12,001-16,000	10'-3"	6'-0"	22'-0"	23'-6"	12'-6"	26'-0"

19,001-22,000	11'-9"	7'-3"	25'-0"	26'-9"	15'-0"	29'-0"
22,001-27,000	11'-9"	8'-6"	26'-0"	27'-0"	16'-0"	30'-0"
27,001-32,000	13'-0"	9'-9"	27'-9"	29'-0"	18'-0"	31'-9"

AIR HANDLING EQUIPMENT ROOM REQUIREMENTS

AIR FILTRATION AND ODOR REMOVAL

Air filter selection is determined by the degree of cleanliness required. The initial cost, ease of maintenance, improvement of housekeeping, health benefits, and product quality are considerations. Size and quantity of dust and contaminants are also factors.

Filters most often are located at the air inlet of the heating, ventilating, and air-conditioning equipment, providing protection to the equipment and the area served. Filters are located at the equipment discharge and at entry of air into clean rooms, operating rooms, critical health care rooms, and various industrial process areas. Filters located in return air and exhaust air limit the contamination of other areas and the atmosphere.

AIR FILTER types are dry media, viscous (sticky) media, renewable media, and electronic. Filter performance tests and ratings have been established by ASHRAE, NBS, and AFI. The three operating characteristics that distinguish the various types of air cleaners are efficiency, air flow resistance, and dust holding capacity. Efficiency measures the ability of the air cleaner to remove particulate matter from an air stream. Average efficiency over the life of the filter is the most important consideration. Airflow resistance is the static pressure drop across the filter at a given airflow rate. Dust holding capacity defines the amount of a particular type of dust that an air cleaner can hold when operated at a specified airflow rate to some

maximum resistance value, or before its efficiency is seriously reduced as a result of the collected dust. Filter efficiency comparisons should always be based on the same test conditions.

PREFILTERS are required to extend the life of costlier high efficiency filters. High efficiency particulate filters (HEPA), and their integral frames, should be tested and certified in place. Filter pressure

drop gauges are recommended as an aid to economical replacement scheduling for all types of filters.

ODOR REMOVAL is best controlled by limiting the source. Dilution of odors by direct exhaust ventilation is the most common control method. Air washer and carbon filters are usually used for reclaiming odorous air. Ozone treatment and aerosol masking of odors are sometimes used.

AIR FILTER CHARACTERISTICS

MEDIA AND TYPE	PERCENT EFFICIENCY RANGE		DUST HOLDING CAPACITY	AIRFLOW RESISTANCE (IN. WATER)
	ATMOSPHERIC DUST	SMALL PARTICLES		
Dry panel throwaway	15-30	NA	Excellent	0.1-0.5
Viscous panel throwaway	20-35	NA	Good	0.1-0.5
Dry panel cleanable	15-20	NA	Superior	0.08-0.5
Viscous panel cleanable	15-25	NA	Superior	0.08-0.5

Electrostatic with mat	80-98	NA	Varies	0.15-1.25

John O. Samuel; Joseph R. Loring & Associates, Inc., Consulting Engineers; New York, New York

PURPOSE OF CHILD CARE CENTERS

Child care centers designed specifically to meet the needs of working parents with pre-school age children are a relatively new institution in the United States. Centers can serve as few as 20 children; however, they are usually sized to accommodate 60 to 150 children. Larger centers are overwhelming to young children and should be subdivided into smaller groupings. Centers provide care for children as young as 6 weeks old, to children of kindergarten age. Some centers also provide before- and after-school care for older children. Centers are expected to provide a rich variety of learning experiences, provide a secure environment, and meet the children's physical needs.

For children, all activities are learning experiences, and the key to good design is providing design elements that enhance the child's self-esteem and relate to the children through scale. Developmentally appropriate environments should be stressed. Materials, interiors, and equipment should be selected to create a non-institutional setting, and include such humanizing elements as soft textures, non-poisonous plants, and animals.

CRITICAL DESIGN DETERMINANTS

Major issues that will influence the ultimate design include: the number of classrooms required, and the total number and age of the children in each classroom. State and possibly local regulations pertaining to the requirements for the licensing of child care centers (in addition to building and life safety codes) will be the defining factor in many of these issues. The operator and staff of the center will also provide valuable input.

Many children enrolled in child care centers are too young to walk, talk, or follow directions; therefore, evacuation of the children during an emergency is critical. Cribs are generally used to evacuate infants. Centers, especially those serving infants, should be located only on the ground floor level, and each classroom and napping area should have an exit leading directly to the exterior at grade. Centers should also be designed to meet the requirements of the American National Standards Institute for Accessibility and Usability for Physically Handicapped People.

MULTI-PURPOSE AREA

This area should accommodate a wide variety of activities: group games, play in inclement weather, holiday activities, parent meetings, etc. The area should be a minimum of 400 square feet, and provided with adjacent storage space to accommodate the furniture and equipment that will be used at various times in the space. Toilets should be located adjacent to this area. If a before/after school program is provided, it may be located in this space.

SITE REQUIREMENTS

In addition to the building, there are numerous special site features that should be considered.

Centers should be located in friendly environments, away from natural and constructed hazards. The best location is a residential neighborhood; also utilized but less desirable locations are employment areas and major commuter routes.

A parking area for the parents to drop off and pick up the children should be located close to the building entrance; parents and children should be able to enter the center without crossing vehicular circulation areas. The main entrance to the center should be controlled to prevent unauthorized visitors. On-site parking for staff and visitors should be provided; however, parking should be divided into several small areas, and screened to support an inviting appearance. Deliveries and trash pickup should occur at a screened service entrance.

Outdoor play should be divided into a minimum of two separate spaces, one for older children and one for younger children. Each area should include developmentally appropriate equipment and activities and be provided with specifically selected landscaping materials.

SIZES FOR PLANNING PURPOSES

Child care regulations generally require classrooms of 20-40 net square feet (NSF) per child, with 35 NSF being the average minimum. Support functions will increase the total square footage required. Small classrooms, designed to accommodate two teachers and the related number of children as required by the licensing regulations, are recommended.

TYPICAL SIZES

No. of children	60-150
Building size	80-100 sq ft/child
Total building	6000-12,000 sq ft
Outdoor play	75-100 sq ft/child
Overall lot size	1/2-2 acres

MAJOR FUNCTIONS

Classrooms are the focal point of a child care center; however, there are many other functions necessary to ensure the smooth operation of the center.

Administrative areas, including reception areas, offices, and a staff lounge are essential to center operations. The staff lounge provides a refuge for teachers from the hectic activities and the demands of the children and provides a space to accomplish paperwork. Conference rooms may also be desirable. Staff and visitors should be provided with toilet facilities separate from the children's toilet rooms.

An isolation area should be provided for children who become sick during the day and need to be separated from

the other children. This area must be provided with adult supervision, whether located in a separate, but nearby space or in a space shared with an office function. This area should be near a toilet, and have adequate space for a cot/crib.

The size of the kitchen and related storage area will vary depending on the kinds of food to be prepared and whether food is prepared at the center, supplied by the parents, or catered. Most centers will provide, at a minimum, snacks, milk, and juice. Many centers rely on paper products, so that dishwashing is not a major concern. However, trash accumulation from these products, as well as from disposable diapers, can be significant; a separate trash area should be provided.

A central storage area is required to store extra furniture, seasonal decorations, toys, educational materials, paper products, and office supplies.

MULTI-PURPOSE AREA, LIBRARY, ART, AND MEDIA CENTERS

Depending on the operational needs of the center, and the budget, additional activity areas for the children outside of the classroom may be desired.

A multi-purpose area should accommodate a wide variety of activities: group games, play in inclement weather, holiday activities, and parent meetings. If a before and after school program is provided, it may be located here. The area should be a minimum of 400 square feet, and be provided with adjacent storage space and toilets. Art, media, and library functions are usually found within the classrooms. However, they could be located in separate spaces, providing specialized instruction and an opportunity for the children to be in a different space.

CLASSROOM ACTIVITIES

Classrooms should be divided into clearly defined activity areas, using child-scaled furniture and equipment pertinent to each activity. Activity areas should be separated from traffic patterns and segregated by noise level. Classrooms should be designed for easy rearrangement of furniture and equipment to provide flexibility. Most daily activities including napping, eating, and learning should occur within the classroom to promote continuity and develop feelings of security in the children.

Older children, over two, require individual, small group and large group activity spaces. Cubbies should be provided for storage of children's clothing and belongings. Storage areas for cots, paints, and other supplies should be located within each classroom; however, they should be accessible only to the teachers.

Toilet rooms, art and handwashing sinks should be provided within the classroom to improve sanitation and develop healthy habits, independence, and self-reliance. Fixtures should be child-scaled. One toilet and lavatory fixture should be provided for each 10-15 children, depending on regulations and available budget.

INFANT AREAS

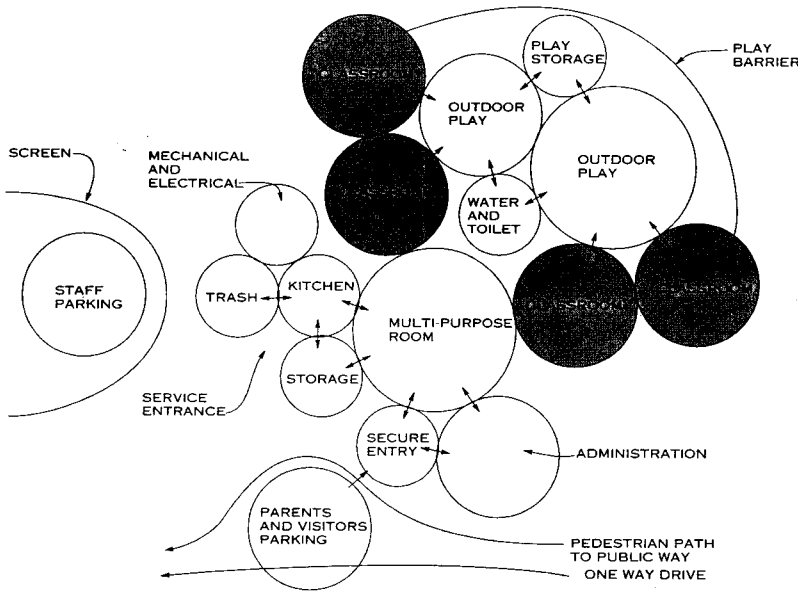

Most regulatory agencies define infants as children under the age of two. Their physical and developmental needs are very different from those of older children, and the infants should be physically separated from the older children. Infant classrooms should be the smallest groups of children at the center, accommodating 6-12 children, depending on the child/teacher ratios.

Physical needs include frequent and irregular feeding and sleeping patterns. Diapering areas designed to ensure that diapering is a safe, sanitary procedure should be provided in each infant area. All the items that the teacher requires in changing the child including wipes, diapers, water, paper towels, a trash receptacle, etc. should be within easy reach of the changing table. Some jurisdictions require that toilets be provided near the diapering area.

Infant areas require more space because of the need for cribs; one crib should be provided for each infant. Cribs should be permanently located in separate areas adjacent to the classroom so that the infants can sleep on their own schedule and in a quiet area. The amount of physical separation from other activities will be determined by applicable child care regulations, and by the staffing patterns. Napping areas will generally require an additional 20-30 square feet/child, depending on the crib size and the child care regulations for separation between cribs.

Because eating in the infant area occurs frequently and at irregular intervals, a small kitchen area should be provided in each infant classroom. The area requires storage, a sink, refrigerator, and either a microwave or a stove for warming food and milk.

A small laundry area should be provided to wash soiled linens and clothes. Close proximity to the infant area is recommended.

SITE RELATIONSHIPS

Linda Clark, AIA; Archi-tots, Inc.; Silver Spring, Maryland

HVAC, PLUMBING, ACOUSTICAL AND ELECTRICAL REQUIREMENTS

Design temperatures should range between 68-78 °F, measured at the children's level, 1 to 3 ft. above the floor. Additional humidification should be provided. Buildings that are too hot or cold can create problems at an otherwise smoothly running center. An adequate ventilation system, with provisions for fresh and exhaust air, is critical to the health of the children. Stagnant air filled with bacteria can contribute to the spread of illness, which is one of the major problems associated with child care centers.

Hot and cold water should be provided in each classroom; however, hot water to child accessible fixtures should not exceed 110°F. Drinking water should also be provided in each classroom.

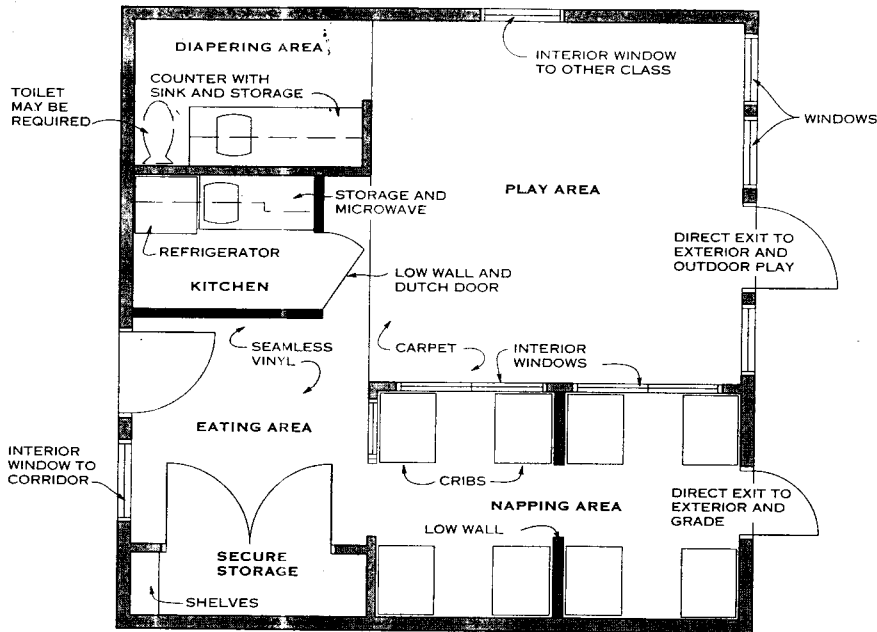

Noise is a major concern. Classrooms, infant napping areas, and offices should be sound insulated from one another. Finishes that absorb sound should be selected.

Lighting should be a combination of natural, fluorescent and incandescent to provide developing eyes with a full spectrum of light. Windows, both to the exterior and to other classrooms are necessary to help the children learn about the world. Receptacles should be either installed above the children's reach, or be of a type which can only be activated when turned or twisted.

SCALE AND FINISHES

All furniture, fixtures, and equipment should be sized to accommodate the children and to promote self-esteem, learning, and independence. Building materials should be selected to relate to the children's scale, i.e., small panes of glass instead of picture windows.

Finishes are important and variety in their selection encourages interest and promotes learning. Basic colors should be neutral to offset the intense and often hectic activities of the children, their equipment, and their artwork. However, accent colors could be provided. Finishes should also be selected for their acoustical properties and ease of maintenance. Both carpeting and seamless vinyl flooring should be provided in the classrooms to support different activities.

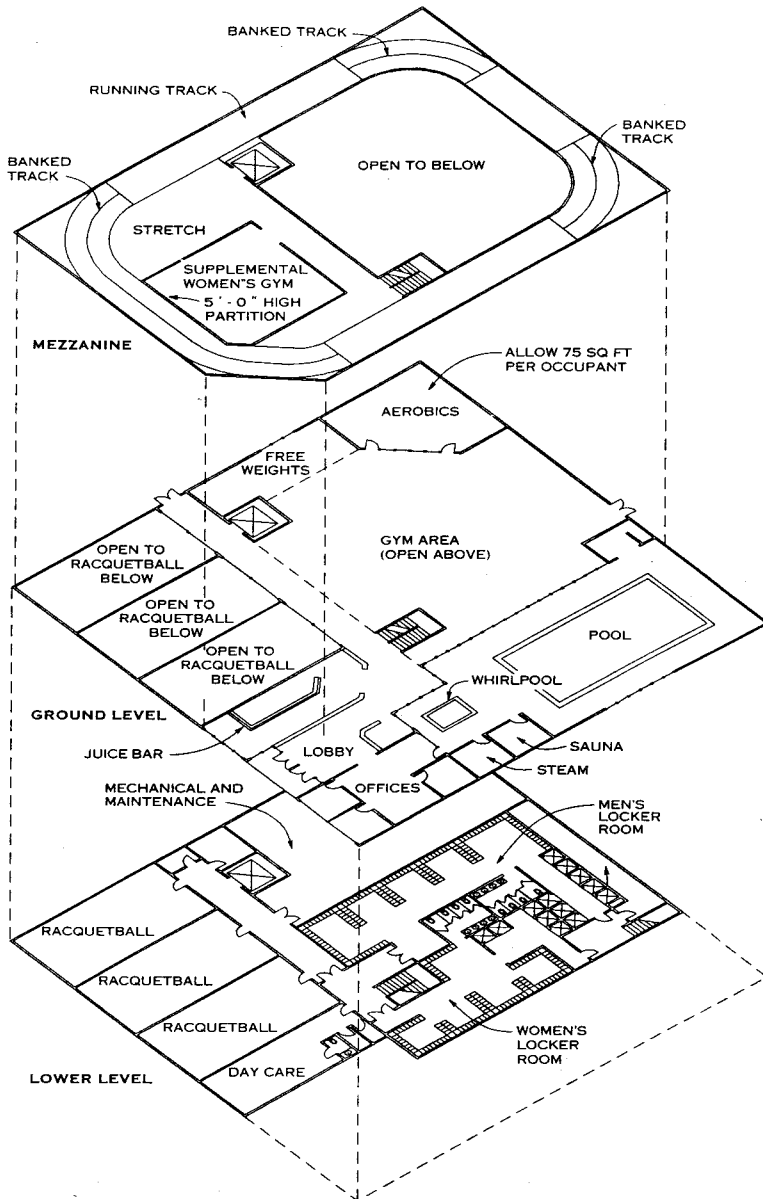

CLASSROOM FOR EIGHT INFANTS

CLASSROOM FOR TWENTY, THREE- TO FIVE-YEAR-OLDS

Linda Clark, AIA; Archi-tots, Inc.; Silver Spring, Maryland

GENERAL

Health clubs combine many activities, services, and equipment types under one roof. The areas for each activity are usually open to each other. This promotes interaction and incentive for individuals to continue their participation. This layout visually exposes each member to other activities in which they may want to participate. The visual center of the plan is where the fitness and aerobic machines are located. Some uses are separated for privacy (e.g. locker rooms, supplemental women's gym, etc.) and for particularly high noise activities like aerobics and racquetball. Restaurants, juice bars, and lounges are also incorporated and are usually connected to the common areas.

Planning criteria for health clubs can be broken down into the following four main categories:

1. Aerobic/Cardiovascular
 - a. Running track
 - b. Treadmill/stair climbing machines
 - c. Stationary bicycle
 - d. Rowing machine
 - e. Swimming pool
 - f. Racquetball/squash
 - g. Aerobic exercises
2. Anaerobic/Muscular Development
 - a. Resistance and repetition fitness machines (includes weight, electronic, or air compression resistance)
 - b. Free weights
3. Muscle and Blood Circulation Stimulation
 - a. Whirlpool (hydrotherapy)
 - b. Steam room (heat therapy)
 - c. Sauna (heat therapy)
 - d. Massage (direct muscle therapy)
4. Services and Support
 - a. Fitness profile (check of weight, blood pressure, percentage of body fat, flexibility, grip strength, and cardiovascular endurance)
 - b. Locker and shower rooms
 - c. Restaurant and lounge
 - d. Administration
 - e. Day care
 - f. Mechanical and maintenance

NOTES

1. Wet areas such as pools and saunas should be segregated from dry areas such as weight rooms.
2. Heavy traffic and wet areas should be finished with impervious floor materials such as ceramic tile. Wet areas should have a nonslip surface and slope to drains.
3. Open gym areas should be finished in a durable carpet with shock resistant padding.
4. Sound isolation systems should be used in all walls, ceilings, and floors that border occupied spaces. Of particular concern is impact noise from aerobic exercise, running, and free-weight training. Resiliency and mass should be built into the structure to reduce sound transmission.
5. Intense human activity, shower facilities, and the pool and sauna areas all contribute major concentrations of moisture that must be vented to the outside.
6. Lighting quality is an important issue for each activity. A diffuse or indirect system is preferred. However, moods can be created through the use of spot lighting, which can highlight activities. Use water resistant lighting in such areas as pools and steam rooms.

TYPICAL HEALTH CLUB LAYOUT

NOTE
Used in pool areas, locker rooms, etc.

FLOORING FOR WET AREAS

NOTE
Used in weight rooms and for aerobic classes.

FLOORING FOR HIGH-IMPACT AREAS

NOTE
Used on running tracks.

DIFFERENT TYPES OF MUSEUMS

The defining characteristic of any museum is its collection. Without a collection, an institution should not ordinarily be called a museum. For instance, a scientific public institution that has interpretive and interactive galleries demonstrating scientific principles and perhaps an Imax theater, but no collections, would be referred to as a science center, not a museum. Similarly, an institution that has an art school and an active art exhibition and lecture program, but no collections, would be called an art center, not an art museum.

Museums are as varied as their collections and their exhibitions. Each has its own special character and special requirements. Nevertheless, all museums do have certain things in common, which is the basis for this section of Graphic Standards.

Listed here are a few of the more common kinds of museums:

1. Art museums: paintings and sculpture, decorative arts, folk art, and textiles
2. Children's museums
3. College and university museums
4. History museums: historic houses, historical society museums, archives, military museums, maritime and naval museums and historic ships
5. Nature centers
6. Park museums and visitor centers
7. Science museums: anthropology; ethnology; aquariums and oceanariums; archaeology; entomology; geology, mineralogy and paleontology; herpetology; medical; natural history and natural science; physical science
8. Specialized museums: aeronautics and space, agriculture, architecture, circus, costume, firefighting, forestry, guns, horology, and military

Following are some of the most basic museum design considerations.

SITE CONSIDERATIONS

PUBLIC PARKING. Urban museum sites generally rely on nearby public parking, while suburban and rural sites require off-street parking convenient to the main public entrance. Typically, daily parking requirements are relatively modest. Maximum requirements will be for special opening events and "blockbuster" exhibitions. Consider sharing parking with nearby churches or businesses that have different peak hours. Valet and remote, bussed parking may be possible for a few events.

STAFF PARKING. This should be convenient to the staff entrance, which will be near shipping and receiving and will have special security measures.

SCULPTURE GARDENS. Such gardens must be either inside or outside the museum security envelope. If inside, they must be enclosed and secure (e.g., MOMA in N.Y.). If they are outside, they must be inaccessible from within the galleries (e.g., the Hirschorn in Washington, D.C.).

SHIPPING AND SERVICE FACILITIES. It is critically impor-

SCULPTURE GARDENS

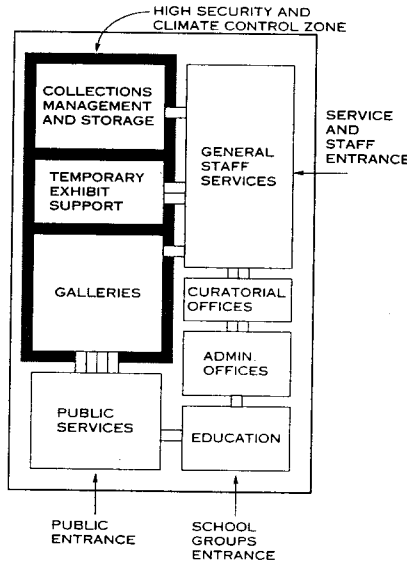

tant for any museum to be able to receive and send large crated and uncrated museum objects safely and efficiently, receive construction and other kinds of materials, and to dispose of trash in a slightly and efficient manner. Requirements vary according to the kinds of objects the museum will house and exhibit, but for most museums the service drive, service yard, and shipping dock must be built to accommodate full-sized over-the-road semi-trailer trucks. Provision also must be made for trash dumpsters and temporary parking for other smaller delivery and service vehicles. A 4 ft high dock will accommodate high-bed trucks but will be very awkward for low-bed trucks and vans. A 2 ft dock will be best for low trucks, but a portable ramp will be required for use with high bed trucks. Two separate docks, one at 2 ft and the other at 4 ft, is ideal. A dock leveler is an alternative. Convenient and attractive accommodation for transformers, emergency generators, chilled water machines, and similar pieces of mechanical equipment should be considered at the beginning of the design process.

LOADING DOCKS

PLANNING RELATIONSHIPS AND TYPICAL MUSEUM SPACES

Museums consist of several discrete blocks of space that must be kept separate for secure and efficient operations. Museums consist of several discrete blocks of space that must be kept separate for secure and efficient operations. Usually the main departments include: public services, educational facilities, galleries, temporary exhibitions support facilities, general staff services, collections management, collections storage, and curatorial and administrative offices. The following diagram illustrates how these relate to each other.

OVERALL SPACE RELATIONSHIPS

PROGRAMMING

The importance of developing a thorough program for museum planning cannot be overemphasized. Museums are composed of many different spaces, each accommodating a particular function. Different kinds of museums require very different spaces, so each anticipated function must be analyzed and accommodated individually. The two most common program mistakes are

1. Emphasizing public spaces and slighting staff support spaces (which often comprise half the museum).
2. Failing to design for future growth.

The following are the main elements that could be found in most museums, although they vary widely, depending on size, type, location, collecting goals, educational mission, etc.

PUBLIC SERVICES

These public non-gallery spaces should be located together near the public entrance. They include vestibule, public lobby, information desk, coat and parcel checkroom, museum shop, auditorium, meeting rooms, A/V presentation/orientation room, public toilets, drinking fountains, and phones.

PUBLIC LOBBY

Generally thought of as a monumental space, this lobby has many practical functions: orientation and access to all public service functions (not just the galleries) and a setting for social functions. This is the one space where windows and skylights can be effective. Size is often governed by the capacity needed for banquet dinners (at 10-12 sq ft per person plus entry and circulation space) and/or receptions (at 8-10 sq ft per person plus entry and circulation space). During receptions visitors may be dispersed throughout the galleries as well, depending on the kinds of events being held.

MEETING ROOMS AND AUDITORIUMS

These will vary widely according to the expected events program. Smaller museums usually have either a sloped floor auditorium or a multi-purpose room. Larger museums may have both. Rooms may be used for museum events, or rented to other public and private groups. The museum board should develop a policy about the use of these rooms before they are designed. For security and operating economy, auditoriums and meeting rooms must be accessible when the galleries are closed.

MUSEUM SHOP AND BOOKSTORE

This sales function is increasingly important both as an educational program and as a source of income. The retail shop should open to the lobby where it will be especially visible and attractive as visitors leave the museum. An adjacent office and inventory space are essential. Size will be determined by the intended marketing and sales program.

PUBLIC TOILETS

Toilets should be sized to accommodate the largest anticipated exhibition openings or auditorium audiences. Plumbing codes often overstate fixture requirements for gallery spaces. Galleries are never crowded all of the time. Interpretations should be clarified with appropriate building code officials.

PUBLIC SERVICE RELATIONSHIPS

John D. Hilberry, AIA; John Hilberry & Associates Inc., Architects and Museum Planners; Detroit, Michigan

GALLERIES

Galleries vary widely according to the objects being exhibited. Gallery sizes and proportions as well as floor, wall, and ceiling materials and lighting must be appropriate for the specific kinds of objects exhibited. Discussed here are some of the most common gallery types:

ART GALLERIES generally are well-finished rooms where objects are displayed to aesthetic advantage but with relatively little interpretive material. Art collections include paintings, sculpture, furniture, decorative arts, murals, architectural fragments and reconstructions, prints, drawings, and photographs.

INTERPRETIVE GALLERIES are simpler architecturally, but the environment is dominated by interpretive materials (historical reconstructions, photomurals, graphics, explanatory text, etc.). Interpretive exhibits cover subjects such as history and natural history and use techniques such as dioramas, period rooms, and dark rides.

SCIENCE CENTER GALLERIES may have no museum objects at all, but may feature educational interactive devices that illustrate scientific principles. These rooms may resemble classrooms or even play areas rather than traditional gallery spaces.

VISIBLE STORAGE GALLERIES contain dense presentations of large numbers of museum objects from the collection with little interpretation but with reference materials available for study.

CHANGING EXHIBITION GALLERIES are flexible galleries used for a wide variety of exhibitions, each installed for a limited period.

COMBINATION GALLERIES integrate several gallery types. Most galleries should be capable of being deinstalled and used for special exhibitions from time to time.

SECTION

PLAN

TRADITIONAL ART GALLERY

SECTION

PLAN

FLEXIBLE OPEN-PLAN GALLERY

GALLERY CHARACTERISTICS

DISCRETE ROOMS: Galleries should be isolated spaces conducive to concentrating on the objects exhibited. The museum-viewing experience is a private one and should not be interrupted by other people moving on balconies, peaking in windows, etc. When the museum is closed, the galleries should become secure dark vaults.

GALLERY FLEXIBILITY: Even "permanent" exhibitions change over time, and all galleries must provide an appropriate amount of flexibility. Traditional art museums achieve this by providing a variety of well designed, proportioned, and organized gallery rooms of different sizes and characters. This arrangement provides the ability to locate different exhibitions in different rooms at different times. A more modernist approach has been to provide open floor space, a modular ceiling system, and movable exhibition walls, so the space can be reconfigured at will. This solution offers the ultimate in plan flexibility, but sacrifices spatial variety and richness in favor of anonymous continuity. The former may be better for permanent galleries and the latter for contemporary art and changing exhibition galleries. A middle ground is to provide some level of physical changeability within the context of fixed gallery rooms.

GALLERY PROPORTIONS: Galleries with pleasing proportions provide the best exhibit spaces. Generally a rectangular floor plan is best. Ceiling heights should be proportional to the plan size of the room and to the objects to be exhibited. Generally 11 to 14 ft is appropriate. Lower ceilings may be acceptable in certain intimate galleries such as those exhibiting old master prints, photographs, or other especially small objects. Ceilings higher than 16 ft are useful occasionally, but generally they are difficult to work with and tend to dwarf the objects being exhibited.

GALLERY FINISH MATERIALS: Galleries must be finished as attractive working exhibit spaces. Floors, wall, and (ideally) ceilings all should be capable of having fasteners secured to them that can support considerable weight. Floors and walls should have securely attached 3/4 in. tongue and groove plywood substrate. Suitable flooring materials are tongue and groove hardwood strip flooring or carpet. Suitable wall materials are thin (1/4 or 3/8 in.) drywall or stretched fabric. Wall carpet sometimes is appropriate. Ceilings can be plain painted drywall or an acoustical grid. If the floor is hard, an acoustical ceiling is especially useful. Ceiling grids should be simple, orderly, and unobtrusive. Recessed lighting tracks are less obtrusive than surface-mounted tracks.

GALLERY SUPPORT SPACES: Storage space for track lighting fixtures and bulbs, pedestals, vitrines, cases, movable exhibition partitions and panels, and other items should be immediately accessible to the galleries. If necessary, this space can be provided in a remote location, but nearby is much more convenient.

INDIVIDUAL GALLERY SIZES AND CEILING HEIGHTS

GALLERY TYPE	FLOOR AREA (SQ FT)	CEILING HEIGHT (FT)
Intimate Galleries	300 - 900	9 - 11
Old Master prints & drawings		
Archival documents		
Jewelry		
Small decorative arts		
Small artifacts		
Miniature dioramas		
Gems & minerals		
Insects, small animals		
Medium Galleries	1,000 - 2,000	11 - 14
14-19 C. paintings		
Traditional sculpture		
Furniture		
Decorative arts		
Small historical exhibits		
Medium-sized artifacts		
Most scientific exhibits		
Interactive galleries		
Most temporary exhibits		
Large Galleries	2,000 - 5,000	14 - 20
Central gallery among smaller galleries		
Large Baroque paintings		
20th C. paintings & sculpture		
Temporary exhibitions		
Industrial history		
Architectural reconstructions		
Historical reconstructions		
Large dioramas		
Large natural history exhibits (dinosaurs, whales, etc.)		

TEMPORARY EXHIBITION STORAGE AND STAGING

Adequate spaces must be provided for receiving and handling exhibition materials, which usually arrive by truck in crates. These materials consist of museum objects borrowed from other institutions and/or individuals, which means that conservation-standard climate control and security must be provided in order to avoid liability for damage and to meet the strict requirements sophisticated modern lenders often impose on borrowing institutions. The main temporary exhibition support facilities are discussed here:

SHIPPING AND RECEIVING FACILITIES: Receiving and sending major traveling exhibitions require first-rate facilities. A good shipping and receiving room has an appropriate loading dock with a large shipping door and immediate access to the crating/uncrating room and to the freight elevator. Very close monitoring of this space by security personnel is essential.

CRATING/UNCRATING ROOM: A large room must be provided as a work space for crating and uncrating borrowed museum objects, for temporarily storing both the objects and their crates, and for examining, photographing, and organizing the objects in preparation for gallery installation. Space may be required to handle several exhibitions simultaneously. The space must be secure and climate controlled to museum conservation standards. This must be a clean room, not a carpentry or paint shop. Appropriate work surfaces, supplies storage, and collection storage equipment must be provided.

TEMPORARY COLLECTIONS STORAGE: After objects are removed from their crates, they must be examined, organized, and safely stored prior to installation. After the exhibition closes, they must be stored and prepared for crating.

TEMPORARY CRATE STORAGE: While the objects are in the museum, the crates must be stored and maintained under proper humidity conditions.

COLLECTIONS MANAGEMENT

These are the facilities that accommodate the handling, care, storage, and conservation of the museum's own collections. Clear unobstructed passageways are essential between the shipping dock to the carpentry shop, crating/uncrating room, galleries, and collections storerooms. Door openings, freight elevators, and passageway heights, widths, and corner configurations must be uniformly large. Placement of ducts and piping must be carefully coordinated to avoid bottlenecks.

The extent of the facilities for collections management will vary widely depending on the extent and nature of the collections and the level of registration, research, and conservation activity that is appropriate or that the institution can afford. Following are discussions of the most important of these facilities.

REGISTRATION: This is one of the most basic museum functions. The registrar generally is responsible for handling all museum objects, keeping track of their location within the museum, and maintaining records about each object, whether owned by the museum or loaned as part of a temporary exhibition. Whenever an object enters or leaves the museum, or even if it is moved around within the museum, the registrar must record that event, make a condition report if necessary, and make sure the movement or removal of the object is appropriate and authorized. These activities require office and work space, facilities for extensive paper files and computer operations, and sometimes space for temporary object storage.

COLLECTIONS STORAGE: The collection storerooms are extremely important and should be located with the other collections management facilities (see Museum Storage).

MATTING AND FRAMING: Any museum that exhibits works of art on paper, photographs, documents, or other two-dimensional paper objects will have an active matting and framing operation. Since paper objects cannot be exhibited for long periods of time without damaging them, they must be constantly taken in and out of frames, and all framed objects must first be matted. This must be a clean room (not a carpentry shop) with work tables and storage for materials. Minor conservation procedures also may take place here if the museum does not have a conservation laboratory.

CONSERVATION LABORATORIES: Most smaller museums do not have conservation labs. Larger museums, however, may have extensive facilities, including separate laboratories for specialized conservation procedures such as those required for paintings, sculpture, 3-D decorative arts, textiles, cars, industrial machinery, fossils, taxidermy, or anthropological artifacts. Each kind of conservation requires special facilities and equipment.

John D. Hilberry, AIA; John Hilberry & Associates Inc., Architects and Museum Planners; Detroit, Michigan

MUSEUM STORAGE

Collections storage and general storage are very different and should not be confused. General storage space can be inexpensive and its location is not critical. Collections storage, however, must meet the most exacting security and climate control requirements and must be correctly located.

GENERAL STORAGE

Museums require large amounts of miscellaneous material that must be stored, either on the premises or in some remote location. On-premises storage is much more convenient. Provision of adequate general storage space is cost-effective, since this space is relatively inexpensive and, if sufficient space is not allowed, general storage items inevitably pre-empt space in more expensive parts of the museum. Storage may be required for grounds and building maintenance equipment and supplies, lifts, ladders, materials-handling equipment, mechanical and electrical equipment and supplies, central office supplies, museum shop inventory, exhibition light fixtures and bulbs, general lighting fluorescent tubes and bulbs, seasonal paraphernalia, volunteer committee supplies, general furniture (tables, desks, chairs, lecterns, etc.), exhibition furniture (pedestals, vitrines, cases, exhibition walls, platforms, etc.), laboratory equipment, audio/visual equipment, and crates (other than those associated with traveling exhibitions). Storage requirements for each of these items should be identified and quantified separately, even if they are to be stored together.

COLLECTIONS STORAGE

Proper care of its collections is one of the main responsibilities of any museum. Location and design of the collections storerooms, therefore, should be a primary planning and design consideration. Since the mission of most museums is to collect continuously, provision for growth is fundamental. Collections storerooms must be clean, dry, secure, well lighted, free of overhead pipes containing liquids, and properly air conditioned to conservation climate control standards. They must be located conveniently near shipping and receiving, curatorial offices, and registration and other collections management facilities. An interior location is ideal. Minimizing the possibility of flooding or other water damage is essential. Whether collections storage is separated into distinct rooms or kept together in large open vaults depends on the nature of the collections and on administrative policies about staff responsibilities.

COLLECTIONS STORAGE EQUIPMENT

Different objects require different kinds of storage equipment. Types and numbers of storage units and the floor area that will be required must be determined by analysis of the collections in close cooperation with the collections management staff. Space must be provided for storage of fork lifts, dollies, and other materials-handling equipment. Some of the more common types of storage equipment are painting screens, painting bins, open steel shelving, closed steel cabinets, wet specimen cabinets, drawer units, flat files, wardrobe units, rolled textile storage racks, hand racks, pallet racks, floor pallets, and oversized objects storage areas. In addition to the storage units, many museum objects are kept in containers, such as acid-free boxes, slander boxes, textile screens, and rolled textile tubes, which are placed in or on the storage units.

COMPACTOR SYSTEMS

A number of companies manufacture systems that permit aisles of shelving units to roll, permitting substantially higher density of objects in storerooms. These systems, though efficient, are costly, less convenient, and may inhibit the ability of fire suppression systems to extinguish flames inside the collections storage units when in the closed position. They require either depressed floor construction for built-in recessed floor tracks or ramps for the surface installation of tracks. Since storage is always at a premium, prudent programming often suggests that adequate storage space be built without compactors, but that provisions be made so they can be added in case of unanticipated collections growth.

SCIENTIFIC RESEARCH LABORATORIES

Science museums often involve significant research programs, which require laboratories of various kinds, including clean, dirty, and wet laboratories, and special storage and equipment rooms. The requirements for each of these rooms must be programmed in close cooperation with the scientists involved.

EDUCATION SPACES

Many museums have active educational programs, ongoing AV presentations, and orientation talks for groups of both children and adults. The following list includes some important education spaces:

1. Holding areas for children's coats, etc.
2. Orientation rooms
3. Studio classrooms
4. Lecture classrooms
5. Staff and docent offices

ADMINISTRATIVE AND CURATORIAL OFFICES AND WORK SPACES

The offices themselves will not be much different from business or academic offices. The appropriate number and size of spaces must be based on projected staff and activities. Generally, museum staffs grow faster than anticipated after new facilities are completed, and ample allowance should be made for "future office" space. These offices can be located with the collections management and general staff areas, or they can be separated. Practical planning considerations often dictate that they be separated. Curators may need larger than usual offices if they will have museum objects in their offices for examination and research. Security and HVAC implications of this possibility must be considered.

GENERAL STAFF SERVICES

Back-of-house facilities required for museums to operate efficiently may include shipping and receiving room(s), shipping clerk's office, sallyport, central security station, maintenance shop, carpentry shop, paint shop, graphics studio, typesetting room, exhibition preparation room, taxidermy shop, isolation room, trash room, compactor room, recycling center, dermatid room, greenhouse, X-ray laboratory, photography studio, darkroom, refrigerated specimen room, flammable liquids storeroom, instrument room, AV storage and work room, and guards' toilets, showers, and dressing rooms. Not all museums will have all of these spaces, and in smaller museums some spaces will be combined. In larger ones, several spaces may be dedicated to one function.

MUSEUM SECURITY

Good museum security results from a combination of good museum planning, good lock and alarm systems, and good professional and security staff practices. A specialized museum security consultant can assist the museum staff and the architect with all of these issues. Planning for security involves understanding the zones that must be kept separate and how public, staff, and objects will move through the facility under different circumstances. When entering and leaving the galleries, the public should be required to pass one easily monitored checkpoint. Non-gallery public functions (such as auditorium, museum shop, or toilets) should not be accessed through the galleries. When closed, galleries should function as secure vaults. Emergency fire exits from galleries should be minimal, alarmed, and located and designed for easy observation of anyone using them.

Staff areas should be clearly separated from galleries and public services. Shipping and receiving and staff entrances must be tightly monitored and easily controlled by the security staff. Collections storerooms should be treated as vaults and should contain no mechanical or electrical equipment that might require access for maintenance or in emergencies. Mechanical ductwork and grilles must be designed to prevent access by burglars to locked galleries and collection storerooms.

Electronic alarm systems should be designed by professionals specializing in museum security systems. Such specialized professionals also should be consulted with regard to locking systems. Often alarm system work is not part of the general A&E contract for reasons of confidentiality. Sometimes alarm company sales personnel design these systems, but this can produce less than ideal results. Because of the liabilities involved, this issue should be discussed carefully with appropriate museum authorities.

Public and staff movement through the museum must be carefully separated. There should be only one public and one staff/shipping entrance to the museum. Public and staff areas will be open at different times, and each should be securable when not open. Public service areas should be easily accessible during open hours. Ideally, there should be only one point of access to the galleries from the public services area. Access from public to staff areas should be strictly limited and easily monitored. Staff should not need to move through galleries when they are closed. The staff entrance and shipping and receiving dock should be together and both easily monitored and controlled by security personnel.

Auditoriums, theaters, and food service facilities present special service access problems because they operate on different schedules from other museum functions and these operations may conflict with the museum's needs for security and cleanliness. Separate service access for these facilities may be appropriate.

In most small and medium sized museums, the central security station should be located at the service entrance with secure windows opening to the outdoors, to the shipping and receiving room, and to a staff entrance sallyport. In large museums, the central station may be in a more secure location away from all entrances, with a shipping clerk's station at the service entrance. The following is a typical security station layout.

GENERAL STAFF RELATIONSHIPS

TYPICAL SECURITY ARRANGEMENT AT SHIPPING AND STAFF ENTRANCE

John D. Hilberry, AIA; John Hilberry & Associates Inc., Architects and Museum Planners; Detroit, Michigan

MUSEUM LIGHTING

Museum lighting presents a fundamental paradox, since the very light that is essential to appreciation of the exhibited objects is also an agent for their destruction. Lighting requirements vary widely from museum to museum and from one part to another of a single museum.

PUBLIC SERVICES. Lighting for public functions should be treated in the most architecturally pleasing way, since these spaces set the tone for the entire institution and intrude on the gallery exhibitions. Public service spaces generally do not contain museum objects, so the use of natural light is acceptable if the galleries are distinctly separate from these spaces. If the separation is less distinct, however, natural lighting in the lobby will have to be strictly limited. In any case, lighting levels in the lobby must not be so high that the galleries seem dark by comparison.

GALLERY LIGHTING. Basic gallery lighting consists of a good track lighting system properly placed in relation to the exhibition walls (see drawing). Line voltage (120V) track offers more flexibility in selection of fixtures (a key consideration), and the fixtures generally produce a softer effect with less glare. Low voltage fixtures can produce more highly focused beams for special effects. Small low voltage fixtures (MR 16) are less intrusive but more expensive and, since the sources are more concentrated, the light quality is harsher. Concealed or shielded lighting sources are desirable (see drawing). General lighting ordinarily is neither required nor desirable. Track lighting can be exposed, shielded, or concealed.

TRACK LIGHTING CONFIGURATIONS

WINDOWS generally are undesirable in galleries because of glare, photochemical degradation, visual competition with the objects exhibited, and security needs. Sculpture galleries are a possible exception, since stone and bronze are essentially unaffected by light.

SKYLIGHTING can be effective, but must be fully understood and very skillfully designed. Many expensive gallery daylighting schemes fail to perform well. Special lighting design consultation is recommended. Risks include photochemical degradation and fading of museum objects due to too high light levels, too much ultraviolet light, too much heat gain, lack of light control for special exhibitions, where natural light may be undesirable, inability to eliminate all light when the galleries are closed, and possible security exposure.

If used, skylighting should be placed in the center of fixed galleries, so that the light generally comes from behind viewers as they look at the exhibition walls. General top lighting in flexible gallery spaces can result in lighting that is too flat and can produce glare. Some of the most successful uses of skylighting have limited the natural light to general diffused reflected light on ceiling surfaces, leaving the actual exhibition lighting to track lighting fixtures. Closets are safer and more easily controlled than horizontal or pitched skylights and can result in satisfactory background light levels. Accent and nighttime lighting still will be required in any case.

The ultraviolet component of gallery lighting is especially dangerous. UV rays can be avoided almost entirely by using incandescent light sources. If natural or other light sources are involved, careful UV filtration is essential. Light reflected from surfaces covered with white titanium dioxide paint contains much less UV than direct light.

The intensity of all forms of light must be carefully controlled. Light intensities should be decreased with a qualified concentration, but the following are commonly recommended maximum lighting levels for various kinds of common museum objects:

MAXIMUM LIGHT LEVELS FOR VARIOUS MUSEUM OBJECTS

TYPE OF OBJECT	MAXIMUM LIGHT LEVEL
Oil paintings	200 lux
Prints and drawings	50 lux
Photographs	50 lux
Textiles	50 lux
Organic materials (painted leather, wood, etc.)	50 lux
Bronze and stone	no limit

TRADITIONAL SKYLIT GALLERY

NOTE
All light above and behind observer

MODERN SKYLIT GALLERY

NOTE
Light above but also in front of observer (glare)

CONTINUOUS SKYLIT GALLERY

LIGHTING IN COLLECTIONS STOREROOMS. Lighting in collections storerooms should provide adequate light for safe handling and examination of objects while protecting them from unnecessary exposure, especially to ultraviolet light. In large storerooms, lighting should be switched so that general light is provided for safe passage in main aisles, and additional light can be switched on when needed in particular areas. This will make for an economical operation and will prevent unnecessary exposure of the objects.

Fluorescent lighting is most common because it is inexpensive, but it must be provided with UV shielding, usually through use of sleeves for individual tubes. Indirect systems that reflect light from a white ceiling painted with titanium dioxide paint will greatly reduce the UV component and result in even light distribution. Light from high pressure sodium bulbs contains almost no ultraviolet light and is excellent from the point of view of conservation. Color discrimination is difficult in this light, however, necessitating separate examining areas with continuous spectrum lighting. Portable lighting also may be used for examination of objects in place.

CLIMATE CONTROL

ZONING. At the outset of any museum project, it must be decided whether the entire building will be maintained at conservation standards or only those areas containing collections items (galleries and collections storerooms). If the conservation standard areas are limited, the rest of the building can be treated like any other public building. Adequate physical separations, including vapor barriers, must be provided, however, between conservation and human comfort zones. In particular, this may mean the galleries will have to be separated from the main public lobby with glass doors (which are also desirable for security reasons). If galleries and collections storerooms are located in interior zones only, many problems and expenses can be avoided.

HUMIDITY CONTROL. Control of relative humidity is the single most critical factor in museum environments. Although ideal conditions vary for different kinds of collections, desirable R.H. for most museum objects is approximately 50%. This level must be held constant, day and night, summer and winter. Fluctuations in R.H. are very destructive, repeatedly stressing the materials of which museum objects are made.

Maintenance of 50% relative humidity throughout the winter months in cold climates tends to produce severe condensation on windows and within the exterior wall construction. Prevention of condensation requires installation of exceptionally good vapor barriers and insulation systems. A completely continuous "zero perm" vapor barrier system is essential in these circumstances. In this context, "zero perm" means a permeability rating of less than 0.1 grams of water per square foot per hour per inch of mercury vapor pressure in accordance with ASTM E 96 test procedure A, B, or BW. The design of wall and roof systems to accommodate such vapor barriers is difficult and should not be undertaken casually.

If, in a cold climate situation, it is determined that installation of zero perm vapor barriers and required mechanical equipment is impossible or impractical, the fall-back position should be to design the wall and roof systems to permit one slow controlled cycle per year, varying from about 25% R.H. in winter to about 50% in summer. Climate control for museums housed in historic buildings reviewed on a case-by-case basis to weigh the importance of protecting the building against the importance of protecting the collection. Hourly, daily, or weekly fluctuations must be avoided under any circumstances.

AIR FILTRATION. Requirements for air filtration vary depending on the quality of the outside air and the conservation demands of the museum objects to be housed. Generally, a good choice would be bag filters with throw-away pre-filters, UL Rating Class 1; particulates removed to 95% efficiency on ASHRAE 52/76. Electrostatic filters must not be used because they produce destructive ozone. Activate carbon filters are effective in removing gaseous pollutants, but they are expensive and require active maintenance.

OPERATING CYCLES. Heating and cooling loads vary greatly between occupied galleries (with lights and people) and unoccupied ones (closed and dark). When unoccupied, systems should be designed to operate at a low maintenance level. Since air volumes are large and pollutant sources nearly non-existent, when a gallery is closed it should be possible to reduce or eliminate outside air in order to improve environmental stability and operating economy.

LOCATION OF PIPING. All piping containing liquids should be kept out of areas containing museum objects. In particular, plumbing should not be located above galleries and collections storerooms.

LOCATION OF OUTLETS, SWITCHES, AND CONTROLS. All convenience outlets, switches, HVAC thermostats, humidistats, and other control devices must be kept off gallery walls. Outlets should be in the base and in the floor. Switches should be remote. Thermostats and humidistats can be located in return air ducts. Gallery walls must be for exhibition purposes only.

John D. Hilberly, AIA, John Hilberly & Associates, Inc., Architects and Museum Planners, Detroit, Michigan

AIRFIELD

The principal component of an airport site is the airfield, which includes the runways, taxiways, and areas for navigational aids. The airfield configuration is the primary factor in determining the layout of the airport site. Basic types of runway configurations are illustrated below. Runways are oriented to take advantage of prevailing winds and to minimize crosswind conditions. Runway length varies for climate conditions (elevation and maximum air temperature) and type of aircraft. The number of runways is a function of the volume of aircraft activity.

SITE LAYOUT

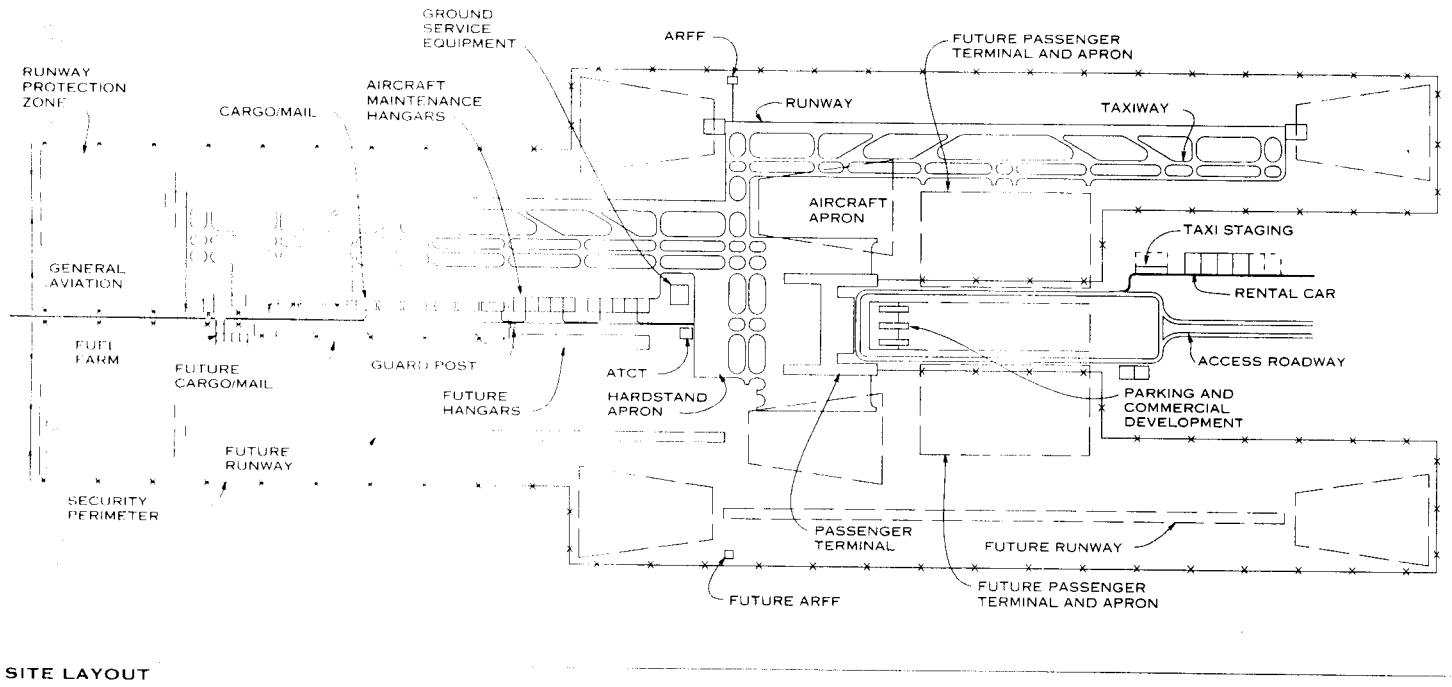

The layout plan illustrates a large airport with a diverse assembly of facilities that are typically required to support the principal aviation function of transporting passengers and cargo. The facilities of the terminal area include the aircraft gates, which should be located to optimize aircraft movement to and from the runways, the terminal itself, and the interface with the ground transportation system, which includes access roadways and parking, and may also include a rail or rapid transit station. Facilities with restrictive location requirements include the air traffic control tower (ATCT), which requires clear sightlines to runways, taxiways, and other areas of aircraft operations, and the aircraft rescue and fire fighting (ARFF) facility, whose site is determined by mandatory response time criteria. Another element of the site layout is the security perimeter, which must encompass all aircraft operating areas. Typically, passenger terminals and cargo buildings are incorporated into the security perimeter. Among the recent trends in airport facilities are the use of automated transit systems (people movers) and the incorporation of large commercial developments (hotels, retail, offices, and conference centers) on the landside of the terminal.

REGULATIONS AND STANDARDS

In the United States, the Federal Aviation Administration (FAA) is principally responsible for the regulations and standards applicable to the design of airports. On a world-wide basis, the International Civil Aviation Organization (ICAO) defines uniform standards and recommended procedures. Enforcement and practice, however, remain within the jurisdiction of individual countries. The reference section lists FAA and ICAO documents that contain useful planning information.

RUNWAY AND TAXIWAY CLEARANCES

The location and height of buildings and other obstacles on or near the airport are regulated by a defined set of imaginary surfaces. The transitional surfaces begin at a prescribed distance from either side of the runway centerline and extend upward at a 7:1 slope. The section illustrates the transitional surface for a precision instrument runway. The approach surfaces extend from beyond the ends of the runway beginning at a 50:1 slope. The runway protection zone, which corresponds to the first part of the approach surface, is usually depicted on site plans. The separation criteria for runway centerlines and taxiway centerlines is based on aircraft wingspan clearances. Clearances illustrated will accommodate a Boeing 747-400.

SITE LAYOUT

Mark Romack; Perkins & Will; Chicago, Illinois

AIRCRAFT DESIGN GROUPS

The FAA groups aircraft into six (6) categories based on wingspan. Representative airplanes of groups I, III, IV, and V are illustrated.

**GROUP I (WINGSPAN UP TO 49')
NOT DEPICTED**

SAAB SF-340

GROUP II (WINGSPAN 49' TO 79')

AIRBUS A320

GROUP III (WINGSPAN 79' TO 118')

MCDONNELL-DOUGLAS MD-11

GROUP IV (WINGSPAN 118' TO 171')

GROUP V (WINGSPAN 171' TO 214')

**GROUP VI (WINGSPAN 214' TO 262')
NOT DEPICTED**

AIRPLANE CLASSIFICATIONS

Mark Romack; Perkins & Will; Chicago, Illinois

TERMINAL CONFIGURATIONS

The most important determinant in the configuration of the terminal is the arrangement of aircraft gates. The four basic types—pier, linear, satellite, and transporter—are illustrated. The pier arrangement results in a compact aircraft apron but creates cul-de-sacs that can restrict aircraft movement. Linear arrangements offer unrestricted aircraft movement but are problematic for hub locations where an

airline with many gates will find its operations spread over considerable distances. Satellite configurations use under-apron pedestrian corridors or automated transit systems to connect terminal processing areas with remote concourse gates. Transporter schemes use buses or mobile lounges to convey passengers between the terminal and noncontact (hardstand) gates. Many airports have some noncontact gates, but few rely on this concept as the principal terminal configuration. Combinations of the four types are often used.

TERMINAL CONFIGURATIONS

TERMINAL PLANNING

The organization of the interior spaces of a terminal chiefly depends on the flow of passengers and their baggage

through a series of processing steps between aircraft and ground transportation, or from aircraft to aircraft in the case of connecting passengers. Typical flows for arrivals and

departures at U.S. airports are diagrammed. Floor plans illustrate the general layout and adjacencies for a small airport serving commuter aircraft and narrow-body jets.

TICKET COUNTER CONFIGURATIONS

SYSTEMS

In addition to conventional mechanical and electrical systems, a large amount of space in an airport terminal will be devoted to systems unique to this building type. The baggage handling system requires space for baggage conveyor routes and floor areas for outbound and inbound systems. The types of handling systems vary widely but all include some means of sorting outbound baggage by flight (either manually or with automated devices) and a method of conveying baggage from check-in to gate (typically by a combination of belt conveyors and tug-and-cart trains). Inbound baggage requires a device for displaying baggage for claim by arriving passengers. Several systems are required to support aircraft at the gates: pre-conditioned (PC) air, ground power (400 Hz), and hydrant fueling, among others. These systems can be supplied from mobile ground service equipment but often are incorporated within the terminal building (or apron, in the case of aviation fuel lines) for reasons of economy and efficiency. Space is required for equipment and distribution runs. Communication requirements tend to be extensive due to the multiple number of systems: public address, flight information and display (FIDS), dynamic signage, ground radio, CCTV and security monitoring, as well as individual or shared information systems for airlines, government agencies, and other tenants.

INTRODUCTION

The U.S. health care delivery system has changed enormously since the early 1980s. The federal government now attempts to control health care costs for patients receiving Medicare and Medicaid benefits by assigning fixed costs to hundreds of standard diagnoses (called Diagnostic Related Groups, or DRGs) and reimbursing health care facilities only this amount for each patient stay. The result has been a substantial shift to outpatient treatment for many diagnoses, including surgery. Consequently, hospitals now face a surplus of inpatient beds and great pressures to revise physical plants to accommodate many more outpatients. At the same time, health insurance companies have cut benefits for inpatient care. All of this has changed the way hospitals are planned and has stimulated new conceptual responses to the new functional challenges. In addition, hospitals are no longer the only building types responding to health care needs. The following sections describe typical U.S. health care facilities in the 1990s.

HOSPITAL BUILDING TYPES

PRIMARY CARE/COMMUNITY

Like the family doctor, the community hospital is the first contact with the health care system for many people. Hospital primary care provides general treatment and diagnostic services within a limited, well-defined geographic area. Such services usually include general surgery, standard radiography and fluoroscopic imaging, routine laboratory tests, and emergency care, as well as general medicine, maternity, and pediatrics. A small unit usually serves as a combined intensive care unit (ICU) and cardiac care unit (CCU). The number of inpatient beds can range from 25-50 for small rural hospitals to 100-150 for facilities in developed areas.

REGIONAL REFERRAL

Compared to primary care hospitals, referral hospitals serve larger, less well defined areas and provide not only basic care but also more specialized care, including orthopedics; eye, ear, nose, and throat (EENT); urology, cardiology; oncology; or neurology. Computerized tomography (CT) scanning, magnetic resonance imaging (MRI), ultrasonography, and nuclear medicine imaging are also present to support these specialties. Cardiac catheterization, open-heart surgery, and cancer treatment programs are sometimes available. The emergency department has a heavier workload because of the specialty capabilities available. The number of inpatient beds can range from 150-200 to 300-350 or more.

TERTIARY CARE/TEACHING

Because many tertiary care/teaching hospitals have world-class reputations and provide extremely special services, they may attract patients from all over the world. Such facilities seek to provide not just health care but also a setting (and patients) for medical research and education. Balancing these objectives is an important consideration in the design of such hospitals. All the specialties are represented, as well as some state-of-the-art diagnostic and treatment modalities frequently still in development. Imaging devices such as positron emission tomography (PET) scan, procedures such as "gamma knife" treatment for cancer, and "clean rooms" for patients recovering from bone marrow transplants must all be housed in specially designed facilities. Tertiary care hospitals may be physically linked to a medical school's basic science and clinical research laboratories, academic offices, classrooms, and very large outpatient facilities. The number of inpatient beds can vary from 400-450 to 800-900 or more.

SPECIALTY (REHABILITATION, PSYCHIATRIC, PEDIATRIC)

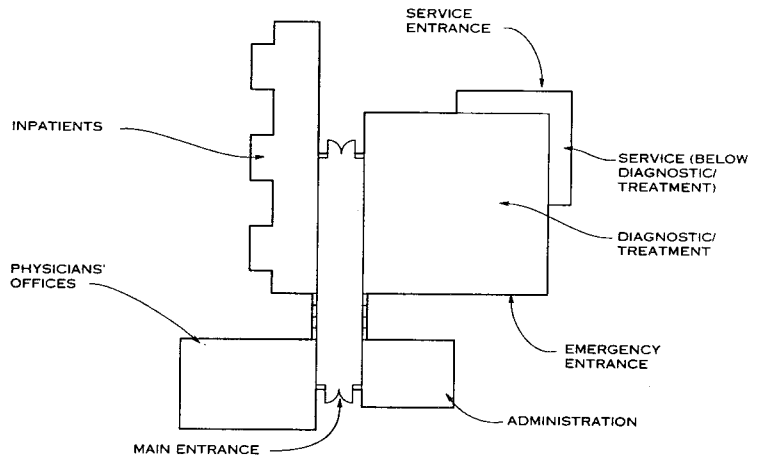

Specialty hospitals treat only one kind of patient. Rehabilitation hospitals treat and provide therapy for patients suffering from illnesses or injuries that have restricted their physical and/or cognitive abilities. Because of such patients' disabilities, fully accessible functional areas with generous clearances and circulation space must be planned. Rehabilitation hospitals may include facilities for cardiac rehabilitation and sports medicine.

Psychiatric hospitals treat patients with mental illness. Since most of these patients are fully mobile physically, patient rooms can be designed like dormitory rooms. Security, access, and unit-to-unit separation must also be considered when planning such facilities.

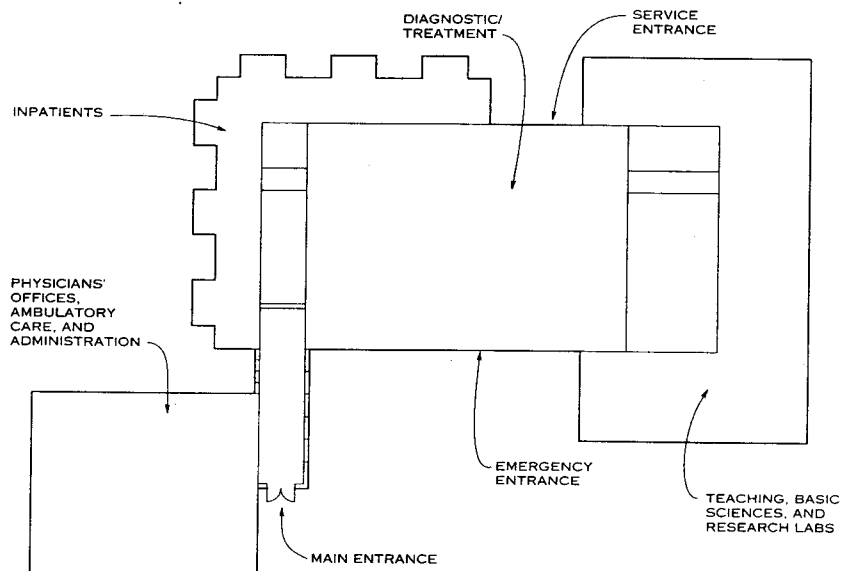

Other specialty hospitals include those devoted to women's and children's health. While they contain most of the treatment and diagnostic areas of a standard hospital, they also have special design needs: patient privacy, appropriate scale, and nonthreatening environments.

PRIMARY CARE/COMMUNITY HOSPITAL

REGIONAL REFERRAL HOSPITAL

TERTIARY CARE/TEACHING HOSPITAL

URGICENTERS

The movement toward outpatient care has stimulated the development of freestanding facilities, not necessarily associated with a hospital, for patients to use as they might a family doctor—frequently on a walk-in basis without an appointment. Urgicenters can relieve overburdened hospital emergency rooms of nonemergency work. To compete with freestanding urgicenters, hospitals are starting urgicenters contiguous to their own emergency department; a triage nurse can direct walk-in patients to appropriate treatment in the hospital, but in a less-intensive, nonemergency setting.

SURGICENTERS

The increase in outpatient surgery has also prompted the development of freestanding surgical facilities, where doctors perform surgery that might otherwise be done in a hospital. State regulations limit patient stays to 24 hours, so the surgery performed must not require the potential support of hospital services. To compete with surgicenters, hospitals are providing outpatient surgery as well: up to 80% of all surgery in some hospitals is outpatient.

SURGICENTER FLOW DIAGRAM

POSTSURGERY RECOVERY CENTERS

The recent development of postsurgery recovery centers brings the freestanding facility idea full circle, back to the "hospital" model. Surgicenters have recognized some patients' need to stay longer than 24 hours and have created a kind of surgical hotel. Because the costs and amenities are similar to those of a very good hotel, such facilities cater to an affluent clientele.

BIRTHING CENTERS

The movement to limit hospital stays combined with women's increasing desire to deliver babies in a less institutional setting, has resulted in the development of freestanding birthing centers. Such centers provide for normal deliveries, which accounted for 75 to 80% of births in the United States in 1990. Complicated and cesarean-section (C-section) deliveries, which require special support, may remain in the hospital setting. Whether in a hospital or freestanding birthing center, the trend is to reduce the average maternity stay to 24 hours, if possible. Consequently, a new planning theory simplifies and accelerates the functional flow of the maternity patient. Labor, delivery, and postpartum stays are now routinely combined in one room (called the LDRP). The design of the LDRP room must balance the needs for special air conditioning, medical gas outlets, and monitoring capability with the desire to create a homelike atmosphere. To compete with birthing centers, hospitals are providing LDRP suites contiguous to C-section operating rooms.

BIRTHING CENTER - TYPICAL LDRP ROOM

AMBULATORY CARE FACILITIES

Increased demand for outpatient care has stimulated the development of freestanding ambulatory care facilities—large outpatient clinics operated by groups of physicians or health maintenance organizations (HMOs). These facilities can combine versions of the urgicenter, surgicenter, and birthing center with full diagnostic support; the resulting functional grouping has been called a "hospital without beds." Ambulatory care planning modules must be flexible. Scheduling each clinic module by hours of use is the most important programming and planning factor in designing functional outpatient clinics. To compete with such centers, hospitals are providing on-site ambulatory care facilities, ranging from contiguous office buildings for physicians to large outpatient clinics.

LONG-TERM CARE FACILITIES

Long-term care facilities manage patients who need supervision of or assistance with long-term, chronic conditions but do not need the treatment and diagnostic support of a hospital. Whereas the number of beds in a typical acute care unit in a hospital is ideally about 25 to 30 per nursing station, as many as 60 beds per station are permitted in long-term care units in some jurisdictions. There are various levels of care within the long-term definition: The skilled nursing facility cares for patients whose chronic conditions require constant nursing support, such as ventilators (assisted breathing). Some hospitals are converting empty bed space to these units, which require a less intense level of staffing. The nursing home traditionally provides care for patients, usually elderly, who need some assistance and supervision. Other levels of care are available in congregate care facilities, eldercare, or assisted living complexes, which offer a variety of living accommodations, ranging from apartments to dormitory-style units to supervised units with nurses on duty.

TYPICAL AMBULATORY CARE/OUTPATIENT CLINIC MODULE

PROGRAMMING

STRATEGIC PLANS

Health care facilities periodically attempt to identify strategies for satisfying probable future needs. Such strategies may involve adding a new treatment or diagnostic service or expanding to capture a larger market share of a particular service and to encourage physicians to use the facilities. A long-range strategic plan documents such goals.

MASTER FACILITY PLANS

Master facility plans are derived from the strategic plan and consist of (1) a projection of future space needs, (2) a comparison of those needs to available existing space, (3) an analysis of existing functional deficiencies, (4) an analysis of existing mechanical and electrical systems and their capacity, (5) block plan diagrams proposing directions for growth and areas of renovation, (6) prioritization and phasing of proposed construction projects, and (7) preliminary construction and project cost estimates based on the proposed phasing.

Note: A reasonable rule of thumb for converting construction cost estimates to project costs is to add 40%. This percentage includes major movable equipment and furnishings, design fees, and design and construction contingencies.

FUNCTIONAL SPACE PROGRAMMING

Functional space programming is often developed in two consecutive levels of detail. The first level is conceptual and is expressed in departmental gross square feet (DGSF). This level of programming is used to develop master facility plans. It consists of a department-by-department calculation of the areas within the overall boundaries of each department, including internal departmental circulation and partitions. DGSF is directly derived from projected departmental workloads or personnel numbers. Earlier popular programming methods, which link the size of a department to the numbers of beds in a hospital, are no longer valid because of the large shift to outpatient workloads.

The conceptual program must be completed by adding estimated mechanical/electrical spaces as DGSF, plus an overall factor (in the range of 1.10 to 1.15) to convert all DGSF to total building gross square feet (BGSF), which adds all general circulation, both vertical and horizontal, and exterior walls.

The second level of detail is a space-by-space program listing, in usable net square feet (NSF), all the functions in the facility. Major mechanical and electrical spaces should also be treated as NSF. These areas can then be factored variously at approximately 1.20 to 1.65 (depending on circulation and partitioning needs) to get DGSF; that result factored by 1.10 to 1.15 yields BGSF. If the assumptions used in the conceptual program are still valid, the DGSF of both conceptual and detailed programs should be approximately the same.

EXAMPLE: A SURGICAL SUITE TO SUPPORT 10,000 PROCEDURES/YR

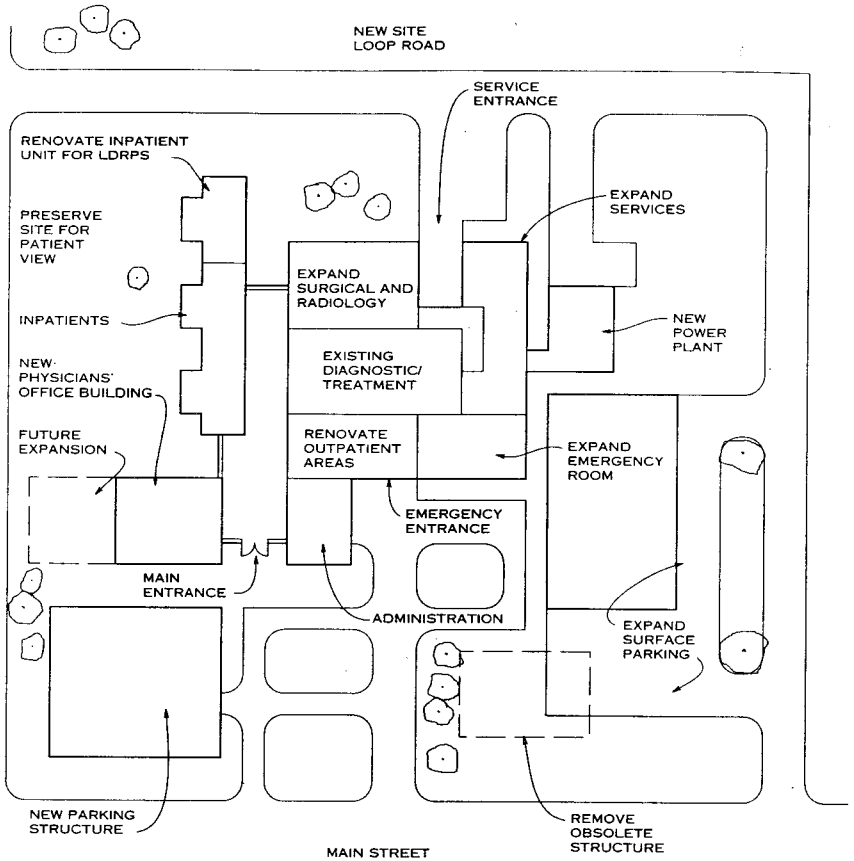

ASSUMPTIONS

- 260 days/yr of scheduled operation. (A small percentage of emergency surgery will not affect the results.)
- 8 hr/day of scheduled operation.
- 25% of the workload is inpatient procedures requiring general anesthesia in a "major" operating room. Each procedure, including cleanup time, ties up a room for an average of 2.5 hr. Therefore, one room can handle 8 hr divided by 2.5, or 3.2 procedures/day.
- 50% of the workload is outpatient procedures requiring general anesthesia in a "major" operating room. Each procedure, including cleanup time, ties up a room for an average of 1.5 hr. One room can therefore handle 5.3 procedures/day.
- 25% of the workload is outpatient procedures requiring local anesthesia in a "minor" procedures room. Each procedure ties up a room for an average of 0.5 hr. One room can therefore handle 16 procedures/day.

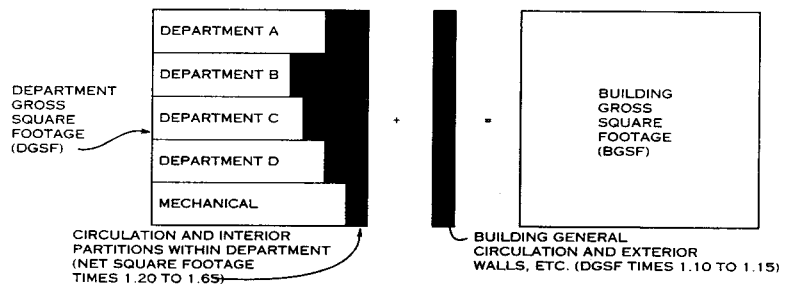

CALCULATIONS

- 10,000 procedures/yr divided by 260 = 38 procedures/day (say 40 procedures/day).
- Inpatients: 10/day at 3.2/room/day requires 3.1 major operating rooms.
- Outpatients with general anesthesia: 20/day at 5.3/room/day requires 3.7 major operating rooms.
- Outpatients with local anesthesia: 10/day at 16/room/day requires 0.6 minor procedures rooms.

Donald W. Velsey, AIA; Ellerbe Becket; Washington, D.C.
Charles F. D. Egbert, AIA; Egbert, Clarens, and Associates, PC Architects; Washington, D.C.

DIAGRAMMATIC MASTER FACILITY PLAN

FUNCTIONAL SPACE PROGRAM

PROJECT COSTS

RESULTS

A total of 6.8 or 7 major operating rooms is required and only 1 minor procedures room is required.

Rule of thumb for programming: The total area (including all appropriate support spaces) of a surgical suite will be approximately 2200 DGSF/operating room or minor proce-

dures room. Therefore this surgical suite would be 8 rooms x 2200 DGSF, or approximately 17,600 DGSF.

NOTE

There are recognized rules of thumb for sizing every department, using workload methodology like this example. See bibliography for more information.

PLANNING THE HEALTH CARE FACILITY

Certain attributes of health care facilities clearly distinguish them from other building types. They resemble small towns or cities in the way city planning and zoning criteria can be applied to planning these facilities. Some representative concerns follow along with specific examples.

1. Functional traffic patterns must be kept separate.
 - a. At loading docks, incoming clean supplies should have no contact with soiled linens, trash, recyclables, and hazardous waste.
 - b. In surgery, restricted areas where scrub suits are worn should be separated from areas where street clothes can be worn.
 - c. In all treatment and diagnostic areas, inpatient stretcher traffic should not mix with ambulatory outpatient or waiting area traffic.
 - d. In elevators, hospital staff and supply traffic should be separated from public and visitor traffic.
 - e. In patient units, those with communicable disease should be separated from others.
2. It is important to respect linear, step-by-step functional flows in certain areas.
 - a. Used surgical instruments move, in order, through decontamination, sterile preparation, terminal sterilization, sterile pack storage, and transportation through a restricted zone back to the operating rooms.
 - b. Outpatient surgery patients move from reception/registration, to undressing, to pre-op holding, to the operating room, to stage 1 recovery, to stage 2 recovery, to dressing, to checkout.
 - c. Radiology film goes from film dispenser, to cassette, to exposure at radiographic table, to film processing and developing, then to quality review, radiologist viewing, and files.
3. The proportion of mechanical and electrical costs to architectural costs is very high, due in part to the following:
 - a. Special, filtered air conditioning systems in surgery, with high volumes of air exchange.
 - b. Extensive medical gas systems: oxygen, medical compressed air, vacuum, nitrous oxide, nitrogen.
 - c. Special exhausts for clinical laboratory fume hoods, nuclear medicine xenon gases, and patient isolation rooms.
 - d. Heavy electrical loads in imaging areas, and isolated power and emergency power requirements in many treatment and diagnostic areas.
 - e. Special transportation devices such as pneumatic tubes, and automated tote-box systems.
 - f. Extensive electronic communications: local computer networks, including provisions for medical information systems; nurse call; intercom; pocket paging; radio communication to emergency services; digital imaging transmission; and television systems for security and for educational and hospital programming.
4. Planning must recognize the need for future flexibility and growth
 - a. Structural modules are derived from the various functional planning units. The ideal grid for inpatient units may be different from that for treatment and diagnostic areas.
 - b. It is important to locate potential high-growth departments where they can expand into new construction or into adjacent renovated soft space.
 - c. When planning large areas with a mix of space sizes, find a common modular dimension to facilitate future changes within a department. For example, program a clinic's exam rooms and utility rooms at 120 NSF. Most partition systems that purport to be easily movable are in fact rarely, if ever, moved; it may be better to plan permanent spaces whose uses can be altered as space demands change.
5. Functional "zoning" determines massing relationships:
 - a. Inpatient units have many of the attributes of hotels and dormitories.
 - b. Treatment and diagnostic areas resemble areas in high-tech buildings, where "process" is important for performing delicate procedures.
 - c. Support and service areas where materials are handled are the health care facility's light industry zones.
 - d. Administrative areas are for business functions and thus are suitable to an office building environment.
 - e. Outpatient processing, registration, and clinic areas—along with the necessary public access, shops, services, and lobbies—can be thought of as retail space. In fact as competition for patients steps up, the phrase "medical mall" has been coined to describe the desired atmosphere of such spaces.

INTRODUCTION

The word "church" simply denotes a space, or group of spaces, that provides a place for devotion, education, and fellowship. Certain images may come to mind when thinking about a church, yet each built form should be a direct response to its particular faith. Belief systems, traditions, and styles of worship may vary widely, even within groups of similar denominations. The architectural vernacular within the region and the neighborhood may impact design decisions. The inclusion and arrangement of liturgical furnishings and symbols should be carefully discussed so that the result reflects the traditions of the group and provides an environment that evokes the appropriate spiritual response.

SITE PLANNING ISSUES

Land capacity: Actual layouts may vary, but typically a site will accommodate 150 to 200 persons per acre at peak usage. Shared parking on adjacent properties increases this number. Allow for more land for outdoor athletic, worship, or cemetery needs. For long-term growth, plan the possibility of acquiring adjacent land.

Parking: Provide one parking space for every 1.6 to 2.2 seats in the main worship area. Consider shared parking on adjacent or nearby properties to reduce the amount of hard surface needed for limited weekly use. Typical parking arrangements accommodate 100 cars per acre.

Site access: Parking should be visible upon approach to the site, and the main entrance to the building needs to be easily identifiable. More than one entrance to the site is advisable. Include service drives for delivery and removing trash from the kitchen and other facilities. Provide adequate sidewalks to the facility.

Building access: Multiple access points to the building will accommodate the rapid influx of people arriving for services. Where possible, include a covered area to protect people being dropped off or picked up. This is especially important for special services, such as weddings and funerals.

ELEMENTS TO CONSIDER

Worship center (nave, sanctuary, or auditorium): Allow 8 to 10 sq ft per person in the seating area. Several basic arrangements for seating are shown here. Consider style of worship, site constraints, seating capacity, and sight lines. Many variations are possible.

Raised platform (sanctuary, chancel, or platform): Allow room for table or altar, pulpit, reading desk, and usually some seating. Observe rules for sight lines.

Music, choir, instruments: Size of choir is typically 10% of the worship center's capacity. Choir seating should be close to the musical instruments and arranged in no more than three rows. Allow room for special performers, handbells, strings, and piano. Consider fixed instruments, such as the organ, in planning the room.

Special considerations: Sacred or liturgical items that have specific functions, such as the tabernacle, baptismal font or baptistry, devotional areas, and statuary will vary among churches. Think of symbols, artwork, seasonal decorations, and furnishings as part of the room. Discuss room acoustics and sound reinforcement systems, which are a critical component. Consider both natural and artificial lighting. Include preparation rooms (sacristies or communion preparation) and, for floral arrangements, spaces with access to a sink, storage, and perhaps refrigeration. Special sinks for consecrated wine or water may be needed. Dressing rooms with toilets may be required for immersion/submersion baptisms.

Gathering space (narthex or commons): Allow 2 to 3 sq ft for each person in the worship center. This is the circulation hub of the church. Include coat hanging and information areas, as well as other storage space.

Administrative offices: Include reception area (25 to 30 sq ft per waiting person), main office (50 to 75 sq ft per clerical staff member), and individual offices (150 to 300 sq ft, depending on function). Provide counseling space where appropriate. Also provide work/storage space for photocopying, filing, and the like. Staff/meeting rooms may be shared as a classroom or library.

Multipurpose rooms (fellowship rooms or parish hall): These are used for dining, meetings, sports, and education. Configurations should be flexible and easy to alter.

Kitchen/serving facilities: Square footage should be 25% of the multipurpose room square footage. Consider whether the kitchen is full service or only for warming or catering. May house commercial or residential equipment. Check local health department rules. Determine whether to design for staff or volunteer help. If the kitchen is adjacent to the multipurpose room, allow secondary access to serve the rest of the facility.

Music support spaces: Provide a seating layout identical to that of the worship center. Design acoustics to match that of the worship center when full. Provide a music storage and retrieval system. Robing rooms, warm-up rooms, music director's office, and practice spaces may need to be included.

Education spaces: These may be designed for licensed day care; check with appropriate authorities. The following age groups need to be considered:

1. Nursery (0 to 6 months): 30 to 35 sq ft per person. Provide a drop-off area with security, storage for infant paraphernalia, changing area with sink, staff toilets, and toy storage.
2. Small children (6 months to 3 years): 30 sq ft per person. Provide changing area with sink, child-sized toilet facilities, storage, and proper lighting and ventilation.
3. Children (ages 4 to 11): 25 sq ft per person. Classrooms are much like an elementary school's. Provide display space, storage, access to toilets, and appropriate surface finishes for crafts.
4. Youth (junior high through college): 18 to 20 sq ft per person. This group typically enjoys a more casual style of space, which can be modified to match its particular image. Incorporate soft furniture, storage, and appropriate finishes for hard use.
5. Adults: 12 to 15 sq ft per person. Depending on style of classes, the furnishings may vary widely, from tables and chairs to lounge-type furniture. May be shared space with parlor, lounge, or library.

PLANNING ISSUES

Including all programmed spaces described above and support facilities such as toilets and mechanical rooms, the complex will be from 55 to 60 sq ft per seat in the worship center. The center of the complex is the gathering space, which acts as a lobby to orient visitors and users alike. Placing the administrative offices near the main entry provides a measure of security. The worship center, the focus of the complex, is easily accessible to the gathering space. Music support spaces are near the performing location in the worship center.

The gathering space may also serve as a lobby for the multipurpose room. The kitchen should serve the multipurpose room as well as other activity spaces. Food delivery and refuse removal need to be accommodated without using public spaces. Nurseries and young children's rooms should be close to the gathering space. Youth classrooms often have a separate entry, removed from the main entry. Clear, wide, and open circulation paths throughout the entire complex will augment its use, as large numbers of people move through the corridors over very short periods of time.

OVERALL SPACE RELATIONSHIPS

SEATING CONFIGURATIONS

David Cooper, AIA; Ware Associates, Inc.; Rockford, Illinois/Chicago/Los Angeles

GENERAL

The following are activity and space requirements for synagogues:

ACTIVITIES

1. Worship for large and small groups
2. Cantorial (all groups), Music (reform)
3. Bar mitzvah and Bas mitzvah
4. Hospitality/reception
5. Study area
6. Child care
7. School
8. Assembly (non-worship)
9. Food services - Oleg Shabbat
10. Maintenance

SPACES

1. Sanctuary (including expansion of 200% for high holidays)
2. Bemah
3. Ark
4. Lectern, reform or conservative
5. Chairs - four for officers
6. Eternal light

AREAS

1. Social hall - 12 sq ft per person dining
2. Administration - 30% of sanctuary space
3. Kitchen - 10% of sanctuary space
4. Education
 - a. 30 sq ft per child in nursery/kindergarten
 - b. 30 sq ft per child in grade 1 to 6
 - c. 20 sq ft per child in grades 7 to 12
 - d. 15 to 20 sq ft per adult
5. Seating - 15 sq ft per person net
6. Aisle dimensions
 - a. Main aisle - 5 ft wide
 - b. Side aisle - 3 ft 6 in.

SPECIAL DESIGN CONSIDERATIONS

SYMBOLIC ELEMENTS: Most Muslim communities, especially those who consider the pluralistic, freedom, and rights-based Western world as their home, want to express their presence through a structure is easily recognizable as a mosque. The common architectural features that give the mosque a unique silhouette are the domes(s) and minarets(s) that culminate with a clearly visible crescent. A formal entrance, an expressed turn of the prayer hall toward the Qibla, a Mihrab that bulges out on the exterior of the Qibla wall, and some carefully placed arched windows can further enhance the recognizability of the mosque.

LOBBY: Some communities require that male and female members of a family separate before entering the mosque, thus requiring two separate entrances. This has important implications for the planning and formal expression of the mosque.

SHOES AND COAT AREA: For men and boys; separate facilities for women, young girls, and children.

WASHROOMS: Provide regular washrooms, possibly including a European bidet or similar arrangement for washing. One washroom should be planned for fifty prayer spaces. Consideration should be given to providing adequate washrooms for women with children.

ABLUTION AREA: Ablution stations are needed for the ritual cleansing of hands, forearms, mouth, sinuses, face, and feet in a prescribed sequence. At least one enclosed shower stall is needed for the ritual shower of Ghusul. Provide a nonskid surface in this area. Some provision should be made for drying feet before entering the prayer area.

PRAYER HALL: Rectangular or square floor area with simple linear arrangement for prayer spaces. The prayer rows are parallel to the Qibla wall and directed toward Qibla as indicated by Mihrab. No shoes are worn in the designated prayer areas. A separate area for women, young girls, and children must be provided. Special acoustically separated but visually connected area for nursing mothers and mothers with very young children is recommended.

AREA FOR NON-MUSLIM VISITORS: Requests to observe the Islamic prayers are common and should be accommodated.

MOSQUE CAPACITY: The mosque should be planned on sound population data and projections. In North America and Europe, construction of a "visible and permanently consecrated" mosque often draws extra people to the congregation.

WOMEN'S ATTENDANCE: Women generally comprise 25 to 33 percent of the total congregation. This will probably increase considerably in the West as women assume a more active role in community affairs.

PARKING: One parking space should be provided for five adult prayer spaces with contingency arrangements for extra parking on high religious holidays.

MOVEMENT THROUGH SPACES: A clear sequence of alternative movement choices from the entrance to the prayer hall should be developed. Areas in which shoes should be removed and stored versus shoeless areas is a planning difficulty. Consult with the client on acceptable situations.

PRAYER AREA: The conventional geometry of a prayer area has been a broadside rectangle with its longer side parallel to the Qibla wall. Religious tradition has established a precedent for longer rows to be closer to the Qibla wall. Floor finishes of the prayer hall should clearly indicate the arrangement of prayer rows at every 48 inches parallel to the Qibla wall. The floor should also be soft enough for the knees, which carry a considerable weight as the body is changes postures. Each prayer module should be 24 x 48 in.

BURIAL PREPARATION: If facilities for the washing and shrouding of the dead are required, follow relevant health regulations.

PROGRAMMING ELEMENTS

1. A marked entrance, gateway
2. A lobby or forecourt with attached facilities
3. Prayer hall and its various sections with clearly marked thresholds of entrances
4. Qibla wall
5. Mihrab
6. Mimbar

Gulzar Haider, Carleton University; Ottawa, Canada

TYPES OF MOSQUES IN THE CONTEMPORARY WEST

NEIGHBORHOOD MOSQUE: Serve those in a community for which the main or the Friday mosque might be beyond convenient transportation.

FRIDAY MOSQUE (often called the main or the central mosque or given a special name like Al-Farooq Mosque): Large enough for Salat al-Juma', capacity usually above 200. Imam's residence and a caretaker's apartment may be attached to the mosque.

ISLAMIC CENTER: Mosque plus facilities for socioreligious gatherings that cannot be performed in the mosque prayer hall, e.g., weddings, anniversaries, lectures, and light sports. Some centers also have facilities for the ritual washing and shrouding of dead bodies in preparation for burials.

CAMPUS CENTER: Caters to the unique setting and requirements of the Muslim population of a university campus.

HEADQUARTERS MOSQUE: Built as a marker of an Islamic diplomatic or organizational presence (e.g., Washington Islamic Center, United Nations Mosque). Mosques that belong to special spiritual orders of Islam may also fall under this category.

NOTES

1. Number of levels for the Mimbar equals 3, 5, or 7 depending on the size of the congregation.
2. Portability of Mimbar is recommended.
3. Coordination of Mimbar and Mihrab design is recommended.
4. When women attendance exceeds 33 percent to total congregation, a separate floor and/or space is recommended.
5. Mihrab design is achieved by relative manipulation of outside and inside surfaces without violating spatial prayer module for Imam.

PLAN

DEFINITIONS

- Salat: Obligatory Islamic ritual prayer to be offered five times a day, preferably in congregation, in the mosque
- Imam: Religious leader of Muslim community
- Salat al-Juma': Obligatory Friday congregational prayer with khutba by the Imam
- Sijdah: Prostration before God in the body position when the forehead, two palms, two knees, and two sets of toes simultaneously touch the earth plane
- Masjid/Mosque: Literally the place where Sijdah is enacted. Place for collective Salat whose crescendo is Sijdah in unison by the whole congregation.
- Jami Masjid: Mosque large enough hold Salat al-Juma'
- Kaa'ba: The cube shaped, black cloth-draped sanctuary erected by Abraham and Ishma'il as "Bait-Allah," the "house of God." Located at the center of the holy precinct in Makkah. The sacred node to which all mosques of the earth are oriented.
- Qibla: Orientation toward Kaa'ba
- Mihrab: Niche identifying the Qibla wall and the place of the Imam who leads the congregational prayer.
- Mimbar: Mosque pulpit, a simple ladder chair for the Imam to rise to a place of higher visibility among a large congregation. Traditionally the symbolic seat of the prophet.

QIBLA ORIENTATION

The following figure and procedure is for cities in the Northern hemisphere west of Makkah. The method can easily be extended to cities over the rest of the globe.

SPHERICAL GEOMETRY

The Qibla orientation for a mosque is calculated by the following equations, using equation 1 to solve for unknown angle p, then substitute the value of angle p into equations 2 to solve angle Q, Qibla orientation:

Equation 1: $\cos p = \cos q \cos m + \sin q \sin m \cos P$

Equation 2: $\sin Q = \frac{\sin q \sin P}{\sin p}$

where:

- C = City Whose Qibla is to be calculated
- Ce = Geometric location of city meridian on equator
- M = Makkah, location of Kaa'ba
- Me = Geometric location of Makkah meridian on equator
- P = Geometric north pole of earth sphere
- O = Geometric center of earth sphere
- G = 0° meridian at equator

- m = Angle COP (known as 90° - latitude of city C)
- q = Angle POM (known as 90° - latitude of Makkah)
- p = Angle COM
- P = Angle CeOm
- Q = Qibla orientation at C, angle between diametric planes CPO and CMO

NOTE

Ablution stall should be separated a minimum of 24 in. with the recommended distance of 30 in.

ABLUTION STALL

SUMMARY

It is recommended that before the architect embark on interpretation and invention of a mosque, they acquaint themselves with the many regional traditions and some recent precedents in the design. The following references are recommended:

Burckhardt, T. Art of Islam: Language and Meaning (London, 1976).
Hoag, J.D. Islamic Architecture (New York, 1977).
Michell, G. (ed). Architecture of the Islamic World (London, 1978).
Papadopol, A. Islam and Muslim Art (Abrams, 1976).
Sevcenko, M.B. (ed). Theories and Principles of Design in the Architecture of Islamic Societies, AKPIA (Cambridge, Mass., 1988).

PLANNING ISSUES

Correctional facility design has experienced a dramatic shift away from the classic cellblock system to a centralized living unit concept. This system provides for greater control of a given number of inmates and economizes on staffing requirements by allowing control of several living units from a centralized location. Living units are sized to provide manageable groups of inmates, maximum flexibility in segregating different groups, and a high degree of fire protection without sacrificing security.

The living unit concept typically groups between 24 and 48 single cells around a communal dayroom, which provides areas for television, reading, conversation, and light activities. Each unit contains its own shower facility, with approximately one shower for every 8 inmates. Units are usually two tiers high, with a two-story dayroom. The inclusion of natural light in both cells and dayrooms is strongly encouraged.

There is a growing trend away from indirect inmate supervision (in which guards are placed in a secure control booth) to direct supervision where guards are in direct contact with the inmates, encouraging an environment of greater interaction.

TYPES OF COURTS

There are many different types of courts in the United States, each with its own characteristics and requirements. Federal courts have several levels of jurisdiction, beginning with the magistrate courts and the U.S. district courts. Courts of appeals hear appeals from the district courts, and the U.S. Supreme Court—the court of last resort—hears appeals from the appeals courts. Tax and bankruptcy courts are also part of the federal judiciary.

Each state has its own judicial system. Some states have special jurisdiction courts, such as juvenile or traffic courts. A good source for information on each state's court system is the National Center for State Courts.

Limited jurisdiction courts can be part of a state system or of a smaller municipal entity. They hear only such matters as misdemeanors and traffic offenses. General jurisdiction courts have trial jurisdiction over all matters and may have some authority to renew appeals from limited jurisdiction courts.

SYMBOLISM AND IMAGE

Historically, the American courthouse has been characterized by its size, siting, and specific architectural elements such as columns, domes, clock towers, and grand entrances. The architectural elements of a courthouse should reflect the dignity of the judiciary and its importance in the community.

PLANNING COURTROOM SPACES

The spaces required in a typical trial courthouse vary considerably from state to state and by level of court. Most contain courtrooms, judicial chambers (offices), jury assembly and deliberation rooms (for courts with jury trials), clerks' offices, records rooms, and prisoner holding cells (in criminal courts). Court clerks, law clerks, court reporters, and administrators need offices, and witness waiting rooms and attorney-client conference rooms are needed. Other offices might include those for the prosecutor (district attorney), public defender, and parole officers. Some courts require special courtrooms, or hearing rooms, for arbitration, mediation, high security criminal cases, and juvenile, family, and traffic cases.

The courthouse must be designed with its special circulation patterns in mind. Separate and distinct circulation paths for the public, judges and their staff, and in-custody defendants help ensure efficiency, safety, and security and are a distinctive feature of modern courthouses.

The public circulation area includes all areas used by the public, attorneys, clients, witnesses, and jurors (before selection), such as the main lobby, corridors, public elevators, public restrooms, waiting areas, and clerk of court counters.

The private circulation area allows judges and trial-related court personnel to move between chambers and courtrooms and jurors to move between courtrooms and jury deliberation rooms. Private circulation usually connects secured, private parking facilities for judges to private elevators and corridors leading to courtrooms and chambers.

Secure circulation provides a path for in-custody defendants, who enter the courthouse through a secure vehicular sally port and are taken to a secure central holding and staging area. A secure prisoner elevator serving holding units between two courtrooms is an easy way to move prisoners to courtrooms without crossing private judicial/juror/staff corridors.

INTERNAL LOCATION OF COURT FUNCTIONS

Clerks' offices, windows for paying fines, and other offices that attract heavy visitor traffic should be located near the main entrance. Courtrooms should be located away from the entrance to minimize noise and distractions. Chambers should also be located away from high-volume public areas. Busier traffic, misdemeanor, and other limited jurisdiction courts belong closer to public entrances, while general jurisdiction courtrooms should be less accessible, perhaps on an upper floor. Jury deliberation rooms, courtroom holding facilities, attorney-client conference rooms, witness waiting rooms, and security officers' stations should be near courtrooms.

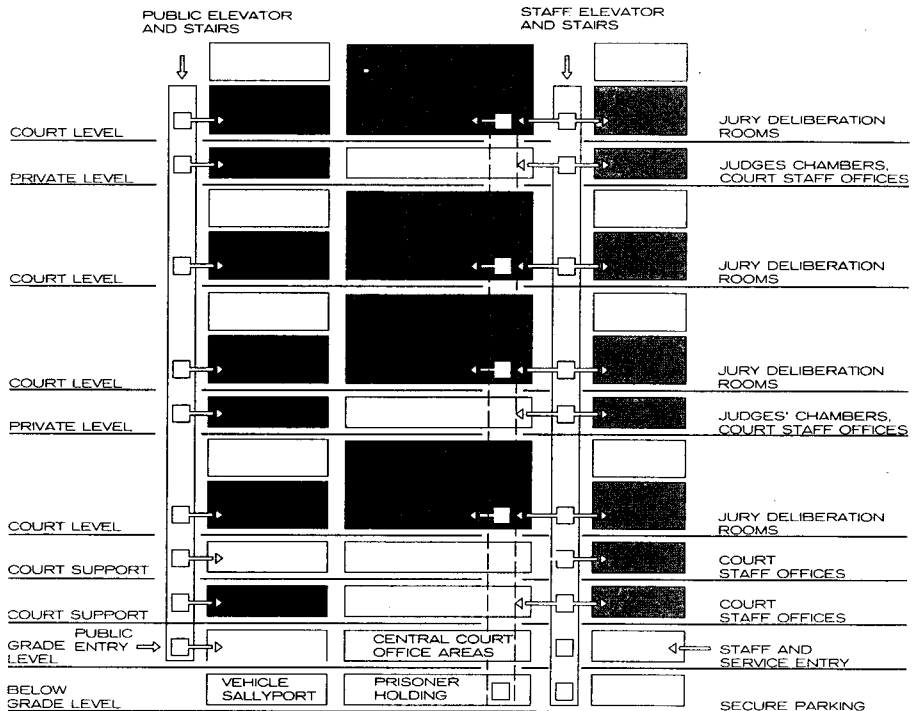

LEGEND

Don Hardenbergh; Courtworks; Williamsburg, Virginia

OVERVIEW OF COURT TYPES

	FEDERAL	STATE	LOCAL
Appellate	Supreme Court, Court of appeals	Supreme Court, intermediate, and appellate court	
General jurisdiction	District courts	Circuit Superior District	
Limited jurisdiction	Magistrate courts	Justice, district, and county courts	Municipal, city, and town courts
Special courts (examples)	Bankruptcy, tax	Juvenile, traffic, and small claims	
Administrative law courts (examples)	Hearing officers, U.S. Atomic Energy Comm., Federal Maritime Comm.	Workers' comp., public utility commissions, admin. law judges	

TYPICAL COURTHOUSE STACKING

COURTHOUSE CIRCULATION AND ZONING SECTION

PRIVATE CIRCULATION

TYPICAL CHAMBER DIAGRAM

PROVISION FOR FUTURE VERTICAL EXPANSION

VERTICAL SECURITY CIRCULATION

COURTROOMS

Courtrooms should be easily accessible to the public. In large multistory facilities, they may be on an upper floor, but in small rural courthouses they may be located near the main entrance. Staff and judges should be able to enter the courtroom through a private corridor, and prisoners should enter directly from a secure holding area adjacent to the courtroom. Prisoners and defendants should not enter the courtroom near the public, jurors, or witnesses. Jurors should not pass near the defendant or the public on their way into the courtroom and should be able to move directly from the courtroom to the deliberation room.

CONVERSION OF ADJACENT SPACE TO COURTROOMS

FINISHING OF SHELL SPACE

PLANNED ADDITION

PROVISIONS FOR FUTURE HORIZONTAL EXPANSION

COURTROOM ACCESS

COURT FLOOR ZONING

Judicial chambers contain the judges' private offices and space for judicial staff such as a secretary, court clerk, and law clerk. Chambers may include a conference room and law library. They should be in a private, quiet, and safe area of the courthouse, usually away from the main entrance or on an upper floor. Judges should have quick and easy access to the courtrooms, while persons meeting with them should pass through a reception or screening area.

Traditionally, judicial chambers are adjacent to the judge's courtroom. While this is convenient for the judge, it makes future organizational changes more difficult. In larger courthouses, it is becoming popular to separate judges' chambers from the courtrooms; sometimes they are even on different floors. Such separation permits sharing of common resources such as the law library, conference areas, and court staff rooms; enhances security; and provides flexibility for later adjustments.

GROSSING AND EFFICIENCY FACTORS

Functional courthouses require more space for circulation and building support functions than most other building types. The departmental gross square footage (DGSF) needed for administrative purposes is reasonably consistent with similar requirements in commercial office or government administration buildings. But highly specialized areas such as courtrooms and holding facilities require considerably more internal circulation.

Basic core functions include major public corridors linking departments; private corridors linking courtrooms, judges' chambers, jury deliberation rooms, and other dedicated support spaces; secure corridors linking courtrooms with prisoner detention facilities; public elevators and elevator lobbies; private and secure elevators; stairs; mechanical, electrical, and plumbing chases; public toilet facilities; and the exterior walls of the building.

Because courthouses have unique security and circulation requirements, individual functional areas must be larger than in an office building. To handle the crowds of disparate people, courthouse lobbies, elevator cores and elevator lobbies, and public corridors must be larger than in a typical office building. An appropriate building gross square foot (BGSF) multiplier for courthouses is typically 1.20 to 1.25 of the DGSF.

TYPICAL COURTHOUSE EFFICIENCY FACTORS

Net area	57 to 65%
Departmental gross area	75 to 85%
Building gross area	100%

SECURITY

Effective courthouse security is maintained by combining structural elements, traffic pattern control, security devices, specific security policies, and security staff. The danger of armed violence requires controlled courthouse access; walk-through metal detectors and X-ray devices at the entrance are necessary in larger urban courthouses. The number of public entrances should be limited and lobbies sized and configured to permit queuing at security checkpoints without making people wait outside.

General court floor security should be controlled by a bailiff station in the public area, with access to private corridors restricted by a proximity card access system. Access to private corridors serving judges' chambers, staff, and jury deliberation rooms may be regulated by closed-circuit television (CCTV) and intercom systems or by a receptionist.

Prisoners should move from a secure sally port into a central holding area. Good sight lines in the courtroom are vital to effective control. Bullet-resistant materials should surround the judge's bench, and duress alarms (linked to a CCTV system) are essential for rapid emergency response. Fine and fee payment windows should have security glazing and duress alarms.

FLEXIBILITY AND EXPANSION

Several measures can prolong the operational life of a courthouse. Floor-to-floor heights and bay sizes may be standardized throughout the building to permit future conversion of noncourtroom space into courtrooms. Locating low-to-medium volume office functions on middle floors makes future modifications easier: As these offices outgrow their space they can be moved to adjacent buildings, allowing court functions to expand upward from the high-volume public floors and downward from the trial courtroom floors. Another strategy is to build shell space (an empty floor or room), which can be fitted out and occupied when needed.

Don Hardenbergh; Courtworks; Williamsburg, Virginia

FUNCTION VS. OPERATION

Courthouses can be organized by function or by type of court. All courtrooms, all chambers, and all clerks' offices are grouped together in a functional organization. An operational arrangement separates different types of courts or departments, such as criminal courts, general jurisdiction trial courts, traffic courts, or family courts. Judges for each court are housed with their clerks and courtrooms on separate floors, or in separate areas, of the building.

COURTROOM DESIGN

Image, symbolism, and functionality are important in courtroom design. The arrangement of the participants and furniture reflects society's view of the relationships between the defendant and judicial authority or, in a civil case, of the relationship between the parties. Furnishings and finishes should reflect the seriousness of the proceedings, yet not be too dark and overbearing.

Courtroom space is needed for the judge, court reporter, clerk, bailiff (security officer), prosecutor or plaintiff and attorney, defendant and attorney, witnesses, jury, and spectators. Other participants include social workers, probation officers, interpreters, police officers, and the press.

The traditional courtroom is rectangular and deeper than it is wide, although some modern courtrooms are round or square. The shape of the courtroom must allow all participants to see and hear one another clearly without having to look back and forth too much.

Functionally, courtrooms are divided into a litigation (well) area and a public (spectator) area, separated by a bar or low railing. The litigation area may be rectangular, with the judge's bench located along the front wall or in the corner of the room.

The depth of the litigation area is determined by whether a jury box is included and the distance needed to separate the judge's bench and attorneys' tables. This separation is necessary both to provide adequate circulation within the litigation area and to give prominence to the judge.

The spectator area in most types of courtrooms should have a minimum seating capacity of 75. Traffic or misdemeanor courts, however, may require a minimum seating of 100 or more depending upon the court's workload.

The height of the courtroom should be proportional to the size of the room and should provide appropriate distance from the ceiling for a judge standing at the bench. The ceiling height over the litigation area may be higher than that over the spectator area.

Acoustics should allow no reverberations or echoes, so that participants are able to hear the proceedings clearly. A public address system is generally recommended.

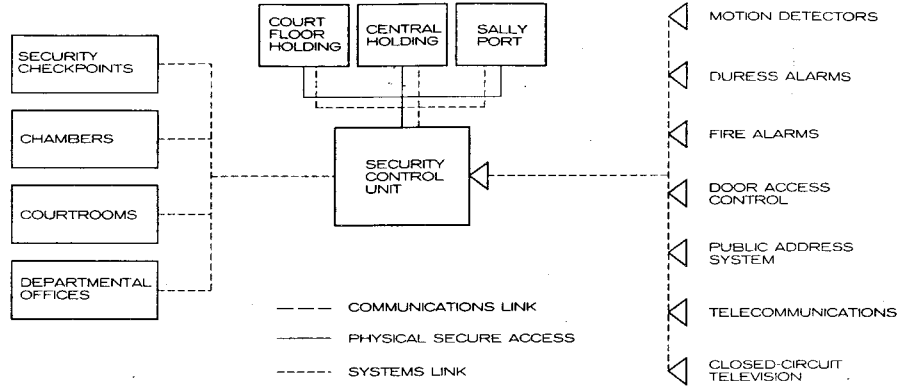

Soundproofing between courtrooms and surrounding spaces (particularly holding cells), double-door vestibules between the public corridors and courtrooms, and carpeting all reduce noise in the courtroom. Generally, the front wall of the courtroom may be constructed of reflective materials to enhance the sound from the litigation area, while the back wall should be covered with sound-absorptive materials to reduce noise.

Courtrooms with exterior windows can suffer from sunlight shadowing and dappling effects, heating and cooling complications, reduced security, exterior noise, and visual distractions. If the location permits, skylights are an excellent source of natural light without the problems presented by windows.

ACCESS FOR PERSONS WITH DISABILITIES

All courtrooms should comply with the Americans with Disabilities Act Accessibility Guidelines for Buildings and Facilities (ADAAG). Areas of the courtroom that need to be accessible are spectator seating, the witness stand, counsel tables, and the jury box. Space should be provided so that all other workstations can be made accessible in the future. The first tier of the jury box may be at floor level, and so may the witness box (the witness box and first tier of the jury box should be the same height).

Allow 48-in.-wide spaces for wheelchairs in the spectator area. The number of wheelchair accessible spaces must meet the seating requirements for assembly areas. All courtrooms with public seating of 51 or more (to a maximum of 300) require four wheelchair locations.

SYSTEM CONTROL LOCATIONS

Sound amplification for the hearing impaired must be installed and available. At least half of each type of courtroom, hearing room, jury deliberation room, and jury assembly room should have an assistive listening (either FM, audio loop, or infrared) device.

SECURITY

Circulation routes for courtroom participants should be clearly separated, and there should be no spaces where a weapon or bomb might be placed or posts or pillars in the courtroom behind which someone might hide. The judge's bench should be shielded with bullet-absorptive material and equipped with duress alarms connected to the central security station.

FURNISHINGS AND FINISHES

The colors and tones of the walls and ceilings should project dignity and calm. Furnishings and finishes should be comfortable, sturdy, durable, vandal-resistant, and easy to clean. Draperies or other window coverings should be used if the courtroom has windows. Seats, benches, and chairs should be comfortable and easy to maintain.

TECHNOLOGICAL APPLICATIONS

Judges, court staff, and attorneys increasingly need access to audiovisual and video equipment, computer terminals, and information databases. While live court reporters will continue taking the record in the immediate future, electronic sound and video recording and playback equipment is becoming more popular and should be available in courtrooms, both for recording the trial and for videoconferencing and hearing remote testimony.

SOUND AND VIDEO EQUIPMENT

Microphones should be located at the bench, clerk's workstation, witness stand, lectern, jury box, and attorneys' tables. Allow space for video display monitors to be installed at the attorneys' tables, lectern, witness stand, and jury box. Camera locations for potential video court reporting, video arraignment, media coverage, or courtroom security surveillance should be identified. Camera coverage of the court proceedings should avoid coverage of the jurors.

SOUND AMPLIFICATION SYSTEMS

All courtrooms should be equipped with sound amplification equipment for assisting the hearing-impaired and for playing back audio exhibits. The master controls should be located at the bench or clerk's station.

COMPUTER TERMINALS AND OTHER EQUIPMENT

Plan on future installation of computer terminals and monitors for the bench, court clerk's station, and court reporter's station in all courtrooms. If possible, recess the clerk's and judge's monitor into the millwork.

Allow for installation of additional electrical outlets at the attorneys' tables, jury box, clerk's station, bench, and public seating area.

THE COURT

CLERK'S WORKSTATION

The court clerk checks case files and records appropriate case dispositions. The clerk frequently passes files to and from the judge and must be close enough to do so easily. The clerk should generally be elevated on one riser so he or she can see the whole courtroom.

The court clerk's work surface should be approximately 30 to 36 in. deep and 4 ft long in order to accommodate case files and computer equipment. The workstation requires the same task lighting as the judge's bench and the clerk's station may have the same duress alarm/intercom link with the central security station as the judge. There should be desk drawers or pigeonholes for paperwork and an inconspicuous, lockable storage area where evidence and trial materials may be stored during recesses.

The court clerk's station should have flush, floor-mounted electrical receptacles, a telephone jack, and cable conduits for computer terminals and a built-in computer monitor. The computer terminal should be equipped with a silent keyboard and laser printer. The control console for the sound amplification system may be located at the court clerk's station, along with a microphone for the clerk.

Don Hardenbergh; Courtworks; Williamsburg, Virginia

JUDGE'S BENCH

The judge's bench should convey dignity and authority. From the bench, the judge should be able to see and hear all courtroom participants, exercise a protective influence over witnesses, address all persons in the courtroom, and pass and receive documents from attorneys, the court clerk, and the court reporter.

The size of the judge's bench should be proportionate to the size of the courtroom. There should be at least 4 ft behind the judge's desk so the judge can move freely for sidebar conferences, reach for reference books, and easily enter and exit the bench.

The bench should include several drawers for supplies and personal items, as well as a bookcase at least six ft wide for legal reference books.

The eye level of the judge should be higher than that of a standing person of average height. Generally, the judge's bench should be elevated 21 in. or at least three risers. A barrier such as an ornamental rail along the front of the bench prevents individuals from approaching too close to the bench or reading documents or notes that are on the judge's bench.

Room lighting should be augmented by task lighting directly above the bench. Lighting controls for the entire courtroom should be located at or near the bench or the clerk's station.

Electrical receptacles flush-mounted in the floor and cable conduits for a built-in video display and computer terminal should be installed. The bench should be equipped with a telephone and a microphone connected to an amplifier controlled by the judge or the clerk.

COURT REPORTER

The court reporter's station should be adjacent to the witness stand so the reporter can clearly view and hear voice testimony. The court reporter should also have an unobstructed view of the entire litigation area, including the judge, witness box, jury box, and attorneys' tables.

The court reporter's station is generally at floor level, which accentuates the prominence of the judge's bench and keeps clear the judge's and attorneys' view of the witness. It should have space and comfortable seating appropriate to the recording methods being used. The workstation should have several electrical outlets and enough space for electronic recording equipment and sound reinforcement equipment should be provided. It also should be made ready for computer equipment and video recording technology. A silent printer in the courtroom may be needed for producing transcripts.

WITNESS STAND

All courtroom participants must be able clearly to hear and see the witness. In addition, because many witnesses testify at a personal sacrifice of time, money, and sometimes safety, they deserve the court's courtesy and protection.

The witness stand is traditionally placed between the jury and the judge, but many courts now use a movable witness box that can face the jury box. The witness stand should be no closer than 4 ft to the jury box so the nearest juror is 7 to 8 ft away. There should be a physical barrier between the witness stand and the judge to prevent the witness from seizing objects from the bench.

The witness stand should be 3 1/2 to 4 ft wide and approximately 5 ft deep to allow for easy entry and exit. Witnesses must frequently receive, examine, and return exhibits; a desk area approximately 15 to 18 in. deep for resting files or evidence may extend from the front or side of the stand.

JUDGE'S BENCH

The exhibit area for screens, chalkboards, and computer and video monitors should be close to the witness stand and visible to jurors and witnesses. The exhibit area could be placed between the witness stand and the jury box.

There should be electrical receptacles and cable conduits for built-in video display of recorded evidence and taped depositions and for review of automated case transcripts. A movable microphone should be mounted in the witness stand so that it is both unobtrusive and able to pick up the testimony of children and soft-spoken witnesses.

JURY BOX

Jurors are temporary "officers of the court" and should be afforded the comfort and courtesies appropriate to their role. The front of the jury box should be shielded with a modesty panel. A 9- or 10-in. shelf should be installed as part of the rail around the jury box, both to allow jurors to examine documents and exhibits and to prevent attorneys from getting too close to the jurors. The first row of seating may be at floor level to permit wheelchair access, with the second tier elevated on one riser. The jury box should accommodate 14 jurors (12 jurors and 2 alternates).

Jurors must be able to hear the judge, witnesses, and attorneys clearly, and they should have unobstructed sight lines to the judge, witness, attorneys, and exhibit area.

The jury box should allow 10 to 12 sq ft per juror. A 14-person jury box needs to be 19 to 21 ft long and approximately 8 ft deep. The jury box should be large enough to accommodate a wheelchair. Audio jacks for earphones for the hearing impaired may be installed at one or two positions. Seats should be fastened to the floor and should swivel and have armrests. Many jury boxes have a footrail.

The jury box should be at least 4 ft from the nearest attorneys' table and 6 ft from the nearest attorney's chair. In addition it should be far enough from the spectator area to inhibit any physical or verbal contact. A bailiff's station may be located between the jurors and the spectators to prevent such communication.

The entrance to the jury box should be near the exit to the jury deliberation rooms. Jurors should not have to cross the courtroom or move through the spectator seating area.

The jury box may be equipped with electrical receptacles, cable conduits, and computer and video terminals for display of recorded and automated evidence, taped depositions, and case transcripts. A microphone may be placed near the jury box.

ATTORNEYS' TABLES

Each table should be at least 7 ft long and should seat up to four people. The tabletop should be 3 to 4 ft wide to accommodate books, documents, and other work materials. The area of each attorneys' table, including chairs and 2-ft circulation space behind the chairs, should be approximately 64 sq ft to allow the parties to move freely around the table. The tables should not have drawers or concealed recesses where a weapon or bomb may be placed.

Attorneys should be able to see and hear all courtroom participants clearly. The litigation area lighting above the attorneys' tables may be augmented with direct task lighting if necessary.

Attorneys and litigants should be able to confer in private. To prevent conversations from being overheard, or documents from being read, attorneys' tables should be 4 ft apart and about 6 ft from the nearest juror or spectator.

The front of the judge's bench should be at least 10 ft from the front of the attorneys' tables. This distance conveys judicial objectivity and dignity.

WITNESS STAND

Electrical receptacles and cable conduits for built-in computer display terminals may be provided for accessing legal databases, reviewing taped depositions, and video display of evidence, exhibits, and transcripts. There should be flush floor-mounted electrical outlets, microphones, and a telephone line so that attorneys may be connected to their office computers by modem.

BAILIFF'S STATION

The bailiff, or deputy sheriff, is responsible for the security of the courtroom and all participants. He or she must have access to an alarm connected to the main security office.

The bailiff generally moves about the courtroom but should be provided with a small table and movable swivel chair, which should occupy no more than 15 sq ft. The area surrounding the bailiff's station should be free of obstacles.

The bailiff should be able to see all areas of the courtroom clearly. The bailiff's station should be located near the defendant's table or by the jury box.

SPECTATOR SEATING

Public bench-type seating at floor level allows access by disabled persons and accentuates the raised litigation area and judge's bench. Aisles should be wide enough to allow wheelchair access.

Public entry into the courtroom should be through a vestibule for security purposes and for noise control. The floor should be carpeted and the surrounding walls acoustically treated.

EVIDENCE DISPLAY AND STORAGE

After exhibits are introduced into evidence and marked, they should be displayed in full view of the court. Hazardous exhibits, such as firearms and other objects that could be used as weapons, drugs, and toxic substances should be placed away from the witness, jury box, and defendant's table. Usually, the clerk's station is the most suitable location. Charts and displays are best presented either between the witness box and the jury box, so the witness may point to them, or across from the jury box if their detail is large enough to be seen at a distance. Increasingly, evidence, including videotapes, physical evidence, computer animations, X-rays, and documents, will be displayed on video monitors.

The courtroom should have an inconspicuous evidence closet where the clerk may secure items during recess. In addition, approximately 40 sq ft should be provided for storing such items as projectors, television monitors, chart boards, easel pads, tripods, chalk and markers, cleaning cloths, pins and tape, and pointers. These may be stored behind the courtroom.

TWO-TIER JURY BOX

Don Hardenbergh; Courtworks; Williamsburg, Virginia

GENERAL

A stadium is a pitch or track for individual athletics or team competition in an arena surrounded by stepped tiers for standing or seated spectators. Some stadiums are covered, but these coverings do not necessarily enclose the structure.

The design of a stadium is largely dictated by the type of activity it will house and by the number of spectators to be accommodated. The specific sports and number of spectators are usually outlined in the program.

POSSIBLE ACTIVITIES FOR STADIUMS

- soccer
- rugby
- football (American)
- baseball
- athletic competition/track and field
- equestrian events: polo, jumping, rodeo
- entertainment concerts
- multi-purpose events

TYPICAL STADIUM CONFIGURATIONS

NBBJ; Research Triangle Park, North Carolina

PRIORITY PLANNING FOR STADIUMS

1. **SAFE** for all spectators and participants: Usually dictated by local codes and regulations, safety issues relate to crowd control, fire safety, evacuation, circulation, etc.
2. **COMPACT** enough to accommodate all spectators within maximum viewing distances to ensure minimum views of all areas of the field of activity.
3. **CONVENIENT** for spectators and participants: Access to amenities within the complex should be available within minimum time standards.
4. **COMFORTABLE**: To ensure feasibility, the comfort of spectators and participants should be accommodated as much as the budget will allow.
5. **FLEXIBLE**: Ensure flexibility in terms of different venues and future growth potential.
6. **ECONOMICAL**: Evaluate initial capital expenditure and recurring maintenance costs.

GENERAL STADIUM PLANNING GUIDELINES

The plan of all stadia is determined first by the regulation size of the activity and auxiliary areas, i.e., the pitch or track on which the activity takes place, the necessary surrounding areas for linesmen, and the need to move back the first row of spectators for improved viewing.

If possible, orient the stadium with the long axis running north and south so most spectators face east and west. Attempt to give both teams, as nearly as possible, identical lighting conditions.

STADIUM TERMINOLOGY

- ARENA**: the activity area plus the ancillary area of the stadium.
- ATHLETICS**: track and field events.
- CONTINENTAL SEATING**: a seating arrangement not interrupted by a center aisle.
- CROWN**: the average distance from the eye of the spectator to the top of the head, which is approximately 120mm or 4 3/4 in.
- FOCUS**: the middle of the innermost athletics track or the near touchline in football or soccer.
- HOUSE SEATS**: seats normally reserved for house management or special guests. These are not sold but held out for special use.
- PITCH**: the competition athletic field.
- RAKE**: the angle of rise of seating stands.
- SIGHT LINES**: the lines of vision of the spectators in normal and extreme positions in the facility. Sight lines include upper as well as side views.
- TIER**: one of a series of rows rising one behind and above another.
- VOMITORY**: areaway for circulation within stadium.

LIMIT OF VIEWING

The limit of viewing distance is determined by the ability of the spectator farthest from the activity to distinguish the smallest moving object.

SEATING GUIDELINES

RUGBY

SOCCER

ATHLETICS

OPTIMUM SEATING

STRAIGHT VS. QUADRIC SEATING

Spectator accommodation in rows parallel to the side lines or touch lines and close to the pitch is self-obscuring. A spectator near a corner of the pitch has difficulty seeing the other corner on the same side, since the view is obscured by other spectators. Quadric, or curved, seating can offer unobscured views (see Tiers Comparison).

TIERS

The rake of the tiering is determined either mathematically or graphically in section, where the principal factors are the assumed constant of the crown and these variables: the horizontal distance between consecutive rows, the focus, and the height of the spectator's eye in the first row.

In determining the rake, the lines of sight from the eyes of spectators in each row to the focus should be clear of, or at

A STEPPED TIER SET OUT FROM A TOUCH LINE PRODUCES A PARABOLIC CURVE IN SECTION, WHEN THE LINE OF VISION IS TANGENTIAL TO THE TOP OF THE HEADS OF THE VIEWERS IN FRONT.

CURVED TIERS, HOWEVER, ARE EXPENSIVE AND NOT RECOMMENDED. THE LONG CURVED TIER IN THE DIAGRAM COULD BE REPLACED BY A STRAIGHT TIER OCCUPYING THE SAME VERTICAL DISTANCE IN A SMALLER AREA. THIS COULD BE REPLACED ON ITS OWN AREA WITH A SHALLOW TIER OCCUPYING A SHORTER VERTICAL DISTANCE.

CURVED VS. STRAIGHT

worst tangential to, the top of the head of the spectator in the row in front. This will give a profile that is parabolic, the rake increasing with the viewing distance. Tiers in this profile are not economical to construct and are not safe for crowd movement. The stairs in gangways become unequal and therefore unacceptable.

OVERLAPPING TIERS

Overlapping the seating tiers is an obvious method of substantially reducing the maximum viewing distance—the horizontal (plan) distance—by increasing the vertical distance.

CONCESSIONS

Stands for food, beverages, and souvenirs should be designed to handle peak impact loads. Events with half-times or periods will induce the largest crowds. Patrons should be able to reach concessions within 40 to 60 seconds.

The general recommendation for concessions is 20 to 25 linear feet of counter space for every 1,000 seats if there are no vending machines. If vending is provided, use 13 to 18 linear feet.

DRESSING ROOMS

Dressing rooms should include changing areas with stalls or hangers for clothing, showers, drying rooms, tables for taping, and toilets. Equip stalls with a bench or stool, hangers, a shelf, and possibly a lock box for valuables. There should be a trainer's room for athletes' therapy. Dressing rooms for officials should be separate from those for athletes.

ACCESS CONTROL

There should be one turnstile per 1,000 spectators. Viewers, athletes, and staff should be able to empty a stadium in under eight minutes.

If the field is used for concerts, spectators must have access to toilets and concessions. Admissions control should prevent mixing between those who have purchased floor tickets and those with tickets in less expensive seats.

Other items that should be addressed as part of the program include:

- Broadcasting studios/press boxes
- Emergency medicine/first aid/life safety
- Night lighting
- Public address system
- Restrooms
- Scoreboards/sign boards
- VIP seating/hospitality provisions

CROSS REFERENCE (AGS 10TH ED.)

Grandstand and bleacher details: p. 915
 Playing field construction: p. 768
 Individual sports: polo, soccer, football, baseball, for specific size requirements of playing field and ancillary spaces.

CONSULTANTS

Confer with consultants who specialize in athletic surfaces and equipment, long-span structures, lighting, etc.

STRAIGHT VS. QUADRIC SEATING

THREE STRAIGHT TIERS APPROXIMATELY TANGENTIAL TO THE THEORETICAL CURVE IN A SINGLE TIER IS ECONOMICAL IN COST BUT NOT IN SPACE. SEPARATING AND OVERLAPPING THE TIERS REDUCES PLAN AREA. THE ANGLE OF RAKE MAY NEED TO BE INCREASED BUT SHOULD NOT BE STEEPER THAN 35°.

STACKED VS. STRAIGHT RUN

TIERS COMPARISON

NBBJ, Research Triangle Park, North Carolina

STANDARD SEATS AND SEAT SUPPORTS

SEATING CAPACITY

Allow 18 in. of bleacher length per person per row. Normal aisle width of 36 in. reduces seating capacity by two seats per row x number of rows x number of aisles. See table below.

SAFETY AREAS

1. BASEBALL FIELDS: Minimum 60 ft from seating to foul line or baseline at each side of home plate.
2. SOFTBALL FIELDS: Minimum 25 ft from seating to foul line or baseline at each side of home plate.
3. BASKETBALL COURTS: Minimum 6 ft from seating to court sides, 4 ft minimum to court ends.
4. SWIMMING POOLS: Minimum 5 ft from seating to pool decks. Spectator area must be separate from pool area to avoid mixing dry and wet traffic.

STADIUM SEATING

Concrete risers and treads with seating attached. See typical seats and seat supports above.

FIXED GRANDSTAND

8 in. rise with 24 in. row spacing typical. Available options include front, end, and back rails, crosswalks, ramps, stairs, aisles, vomitories, closed risers, double foot plates, folding seat backs, and waterproof covers of metal or fiberglass for resurfacing existing wooden bleachers.

PORTABLE BLEACHERS

3, 4, or 5 row sections typical. Transportable options include wheels and trailer attachments. Bleachers of up to 25 rows may be assembled of portable sections.

TELESCOPIC BLEACHERS

1. LOWRISE: 9⁵/₈ in. normal rise for most uses. 22 in. minimum row spacing gives maximum seating capacity. 24 in. spacing provides extra passage and leg room space and space for optional folding back rests.
2. HIGHRISE: Models with 11⁵/₈ or 16 in. risers are suggested for pools, balconies, hockey rinks, or similarly difficult viewing situations where seating must be banked more steeply than is normal.

STADIUM SEATING

THEATER DESIGN CRITERIA

The planning of seating areas in places of assembly should involve the following considerations:

- EFFICIENCY:** The floor area efficiency in square feet per seat is a function of the row spacing, the average chair width, and the space allocation per seat for aisles. See following pages for further discussion of these factors.

Efficiency (F) = seat factor + aisle factor

$$F \text{ (sq ft/seat)} = \frac{W_r T}{144} + \frac{I T}{144} \times \frac{1}{S_{avg}}$$

- where W_r = average seat width (in.)
 T = row to row spacing (tread) (in.)
 I = average aisle width (in.) (42 in. width is typical)
 S_{avg} = average number of seats in a row per single aisle: 8 or fewer—inefficient layout; 14 to 16—maximum efficiency (multiple aisle seating); 18 to 50 and more—continental seating.

- CAPACITY AND AUDIENCE AREA:** Audience area = capacity x efficiency.

- 35-75 Classroom
- 75-150 Lecture room, experimental theater
- 150-300 Large lecture room, small theater
- 300-750 Average drama theater in educational setting
- 750-1500 Small commercial theater, repertory theater, recital hall
- 1500-2000 Medium large theater, large commercial theater
- 2000-3000 Average civic theater, concert hall, multiple use hall
- 3000-6000 Very large auditorium
- Over 6000 Special assembly facilities

- PERFORMING AREA:** (not including adjacent support area) (sq ft):

	MINIMUM	AVERAGE	MAXIMUM
Lectures (single speaker)	150	240	500
Revue, nightclub	350	450	700
Legitimate drama	250	550	1000
Dance	700	950	1200
Musicals, folk opera	800	1200	1800
Symphonic concerts	1500	2000	2500
Opera	1000	2500	4000
Pageant	2000	3500	5000

- ORIENTATION OF SEATED SPECTATOR:** Head strain is minimized by orienting chairs or rows of chairs so that spectators face the center of action of the performing area.
- ANGLE OF VISION OF SPECTATOR:** The human eye has a peripheral spread of vision of about 130°. This angle of view from chairs in the front rows will define the outer limits of the maximum sized performing area.

- ANGLE OF ENCOUNTER:** The angle of encounter is defined by the 130° peripheral spread of vision of a single performer standing at the "point of command." Patrons seated outside the spread of this angle will not have simultaneous eye contact with performer. Natural sound communication will also deteriorate for these patrons.

- DISTANCE BETWEEN PERFORMANCE AND LAST ROW OF SPECTATORS:** Achievement of visual and sound communication is enhanced by minimizing this distance while satisfying the preceding parameters.

SCREEN PROJECTION

- The minimum distance between the first row and the screen (D_f) is determined by the maximum allowable angle between the sightline from the first row to the top of the screen and the perpendicular to the screen at that point. A maximum angle of 30 to 35° is recommended.
- The maximum distance between the screen and the most distant viewer (MDV) should not exceed eight times the height of the screen image. An MDV two to three times the screen width is preferred.
- Screen width (W) is determined by the use of the appropriate aspect ratio between the screen image width and height.
- Curvature of screens may reduce the amount of apparent distortion for a larger audience area. Curvature of larger screens may help to keep the whole of the image in focus and may provide a more uniform distribution of luminance.

SCREEN PROJECTION

ZERO ENCIRCLEMENT (PROSCENIUM STAGE, PICTURE FRAME STAGE, END STAGE)

- The angle of audience spread in front of a masking frame is determined by the maximum size of the corner cutoff from a rectangularly shaped performing area that can be tolerated by seats at the side.
- Audience may not fill angle of encounter from point of command.
- Audience farthest from performing area.
- Large range in choice of size of performing area.
- Provisions for a large amount of scenic wall surfaces without masking sightlines.
- Horizontal movement of scenery typically made in both perpendicularly and parallel to centerline.
- Possibility of short differences in arrival time between direct and reflected sound at the spectator. This may be beneficial to music performances.

ZERO ENCIRCLEMENT

90° TO 130° ENCIRCLEMENT (PICTORIAL OPEN STAGE, WIDE FAN, HYBRID, THRUST STAGE)

- Audience spread defined and limited by angle of encounter from point of command.
- Performing area shape trapezoidal, rhombic, or circular.
- Audience closer to performing area than with zero encirclement.
- Picture frame less dominant.
- Range in choice of size of performing area.
- Provision for an amount of scenic wall surfaces possible without obscuring the performing area.
- Horizontal movement of scenery is possible in directions at 45° to and parallel to centerline.
- Shape of seating area places maximum number of seats within the directional limits of the sound of the unaided voice, beneficial for speech performance.

90° TO 130° ENCIRCLEMENT

180° TO 270° ENCIRCLEMENT (GREEK THEATER, PENINSULAR, THREE-SIDED, THRUST STAGE, 3/4 ARENA STAGE, ELIZABETHAN STAGE)

- Audience spread well beyond angle of encounter from point of command in order to bring audience closer to performing area.
- Simultaneous eye contact between performer and all spectators not possible.
- Minimum range of choice in size of performing area.
- Provision of a small amount of scenic wall surfaces possible without masking sightlines.
- Horizontal movement of scenery is possible only parallel to centerline.
- Large encirclement by audience usually demands actor vomitory entrance through or under audience.

180° TO 270° ENCIRCLEMENT

360° ENCIRCLEMENT (ARENA STAGE, THEATER IN THE ROUND, ISLAND STAGE, CENTER STAGE)

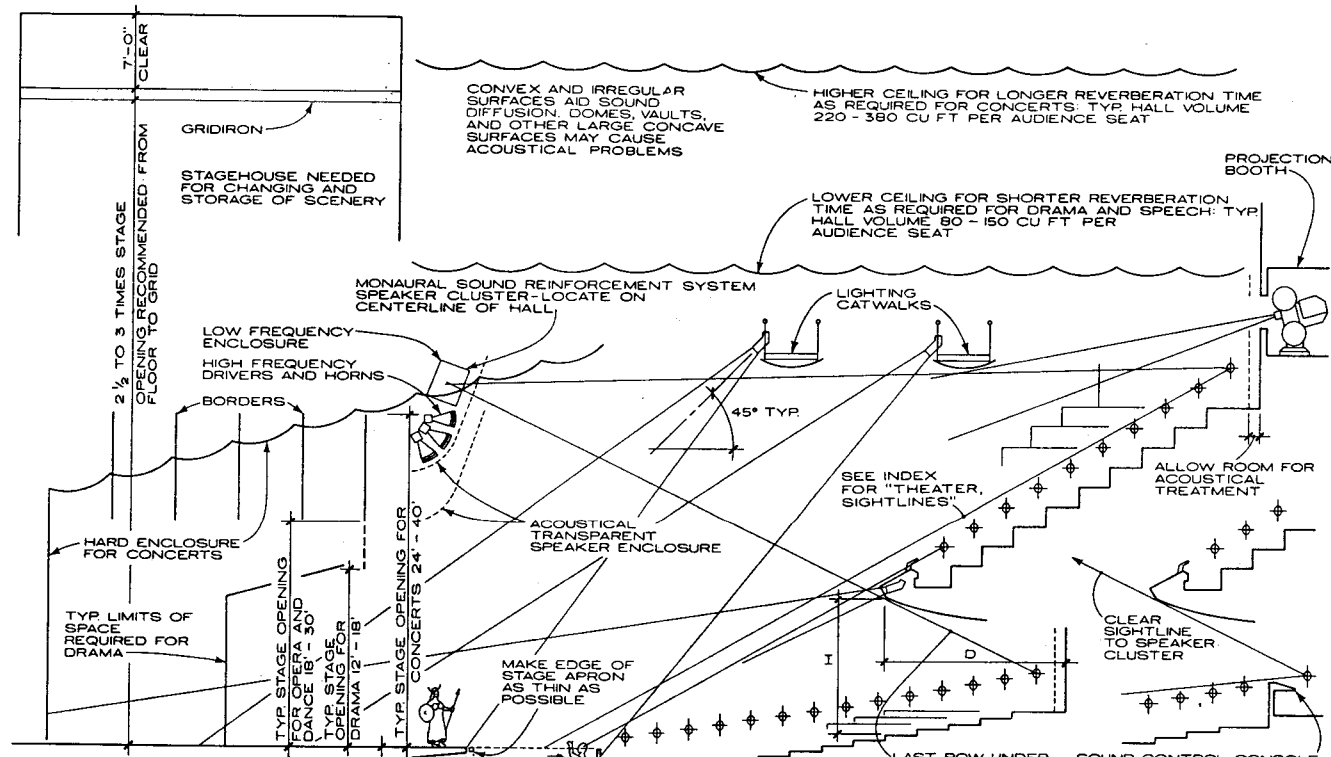

- Performer always seen from rear by some spectators.
- Simultaneous eye contact between performer and all spectators not possible.
- Audience closest to performance.
- No range of choice in size of performing area.
- No scenic wall surfaces possible without obscuring the view of the performing area.
- Horizontal movement of scenery not readily possible.
- Encirclement by audience demands actor vomitory entrance through audience area.

360° ENCIRCLEMENT

$$D_1 = \frac{T}{R-C} [E_1 + (N-1)C]$$

$$E_1 = \frac{D_1}{T} (R-C) - C(N-1)$$

VERTICAL FOCAL PLANE

$$R = \frac{T}{L} [H_E - H_{APS} + (N-1)C] + C$$

$$L = \frac{T}{R-C} [H_E - H_{APS} + (N-1)C]$$

$$H_{APS} = H_E - \frac{L}{T} (R-C) + (N-1)C$$

FLAT FLOOR (R = 0)

VERTICAL FOCAL PLANE

$$L = \frac{T}{C} [H_{APS} - H_E - (N-1)C]$$

$$H_{APS} = H_E + \frac{LC}{T} + (N-1)C$$

FLOOR SLOPE GIVEN AS PERCENTAGE

$$P = \frac{100}{L} [H_E - H_{APS} + (N-1)C] + \frac{100C}{T}$$

$$L = \frac{100T}{PT - 100C} [H_E - H_{APS} + (N-1)C]$$

$$H_{APS} = H_E - \frac{PL}{100} + \frac{LC}{T} + (N-1)C$$

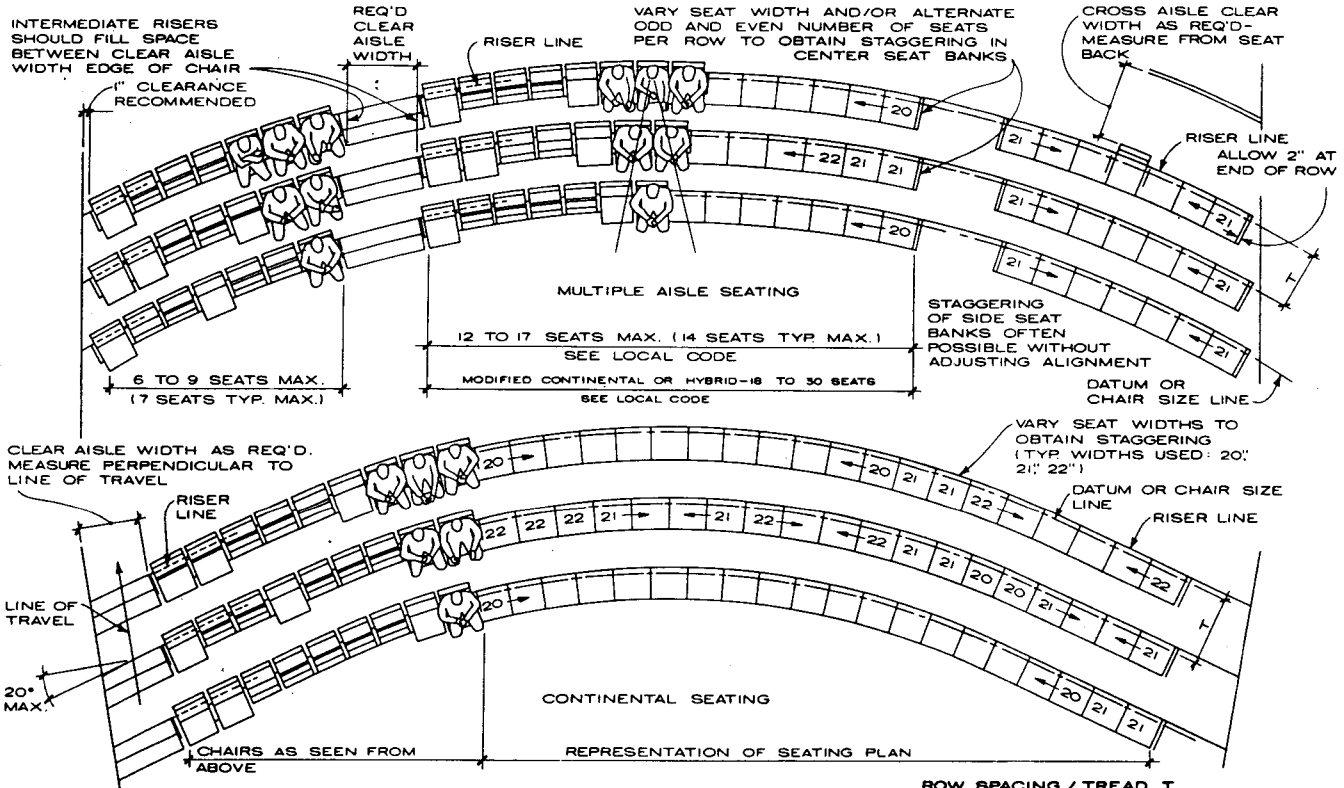

NOTE: WHEN EYE LEVEL AT FIRST ROW IS BELOW APS, E₁ IS NEGATIVE

SLIGHTLY SLOPED FLOOR - VERTICAL FOCAL PLANE

T R 100 P = PERCENT SLOPE

Peter H. Frink; Frink and Beuchat; Architects; Philadelphia, Pennsylvania

CHAIR STANDARDS: Cast iron, steel, riser mounted and floor mounted. Also pedestal mounting using continuous beam support or cantilevered standards. Folding tablet arms usually available.

CHAIR ARMS: Upholstered fabric, wood, plastic, metal.

CHAIR BACKS: Plastic, molded plywood, rolled stamped metal, upholstered front, rear. Higher backs and bottom extension for scuff protection also available.

CHAIR SEATS: Upholstered, plywood, plastic, metal pan, coil or serpentine springs, polyurethane foam.

ROW SPACING / TREAD T

LEGAL CRITERIA: See local code for required minimum spacing. Codes typically stipulate a minimum clear plumbline distance measured between the unoccupied chair and the rear of the chair in front.

32"-33": typical minimum for multiple aisle seating
 34"-37": typical minimum for modified continental seating

38"-42": typical minimum for continental seating

COMFORT FOR THE SEATED PERSON:

32": knees will touch chair back; uncomfortable
 34": minimum spacing for comfort
 36": ideal spacing for maximum comfort
 38" and up: audience cohesiveness may suffer

EASE OF PASSAGE IN FRONT OF SEATED PERSONS:

32"-34": seated person must rise to allow passage
 36"-38": some seated persons will rise
 40" and up: passage in front of seated persons possible

SAFETY: Excessive plumbline distance may entice exiting persons to squeeze ahead and cause jam.

EFFICIENCY: Choice of minimum spacing satisfying criteria above reduces maximum distance to stage.

Peter H. Frink; Frink and Beuchat; Architects; Philadelphia, Pennsylvania

STAGE LIGHTING SYSTEM DESIGN GENERAL COMMENTS

The purpose of a stage lighting system is to provide a flexible arrangement of dimmers, lighting positions, and outlet devices such that stage lighting fixtures may be placed where needed and controlled individually or in groups according to the differing requirements of each production. While it is impossible to develop rules of thumb which will be adequate or appropriate in all cases, several guidelines have been listed below as an aid to determining the proper scope of system required. Several generic cases have been listed. Common terms and equipment components are defined.

CONSIDERATIONS

The planning of a stage lighting system should involve the following considerations:

1. Type of use
2. Size of performing area
3. Size of theater, location of stage lighting positions
4. Budget

Determinations will have to be made about the following subjects:

1. Dimmer-per-circuit or patched circuit system
2. Quantity of dimmers
3. Quantity and distribution of stage lighting circuits
4. Electrical feed size
5. Type of stage lighting outlet devices
6. Type of control console
7. Type and quantity of stage lighting fixtures and accessories

STAGE LIGHTING SYSTEM TERMS AND COMPONENTS DEFINED

DIMMER

A device which controls the intensity of stage lighting fixtures; a remotely controlled electronic device in current practice. Standard sizes are 1.2 kW, 2.4 kW, 6.0 kW, 12.0 kW, at 120 V. Dimmers may be purchased in rack cabinets in large quantities (96 or more) or in small portable packages which can be wall mounted (6, 12, or 18 dimmers).

CIRCUIT

A grounded stage lighting circuit; usually no common neutrals are permitted. Load sizes depend in part on local codes—20 A is average, 15 A is maximum in some areas; some 50 A are often also provided. Circuits are distributed throughout the theater for fixture plug-in and terminate either at a dimmer rack, patch panel, or transfer panel.

DIMMER-PER-CIRCUIT

A configuration whereby every stage lighting circuit home runs to an independent dimmer. This is more economical than a patch panel scheme in most cases.

PATCH PANEL

A custom-made device for interconnecting a large number of stage lighting circuits to a small number of dimmers. This is more expensive than a dimmer-per-circuit configuration in most cases.

TRANSFER PANEL

A custom-made device enabling permanent circuits to be disconnected from the theater's dimming system and connected to a show's touring dimming system. Front-of-house circuits are generally made "transferable" in this way in large multipurpose theaters that must accommodate tours.

FRONT-OF-HOUSE

In a proscenium theater, the audience side of the proscenium. Abbreviated "FOH."

FOLLOWSPOT

A very bright manually operated spotlight used to "follow" a performer around the stage. Light source can be incandescent, carbon arc, xenon, or HMI.

LEKO, FRESNEL, ELLIPSOIDAL, PARCAN, SCOOP, FLOODLIGHT

Theatrical lighting fixtures.

STRIPLIGHT

A continuous fixture containing a number of lamps, used for downlight, backlight, footlight, and cyclorama lighting—usually 6 or 8 ft long with 12 lamps in three or four circuits.

CONTROL CONSOLE

Often called the "light board." A computerized, manual, or hybrid control device for stage lighting dimmers. Generic types include 2, 5, or 10 scene "preset consoles" (manual) and "memory consoles" (computerized). Older installations may have mechanically operated resistance or autotransformer dimmers in which the control console and the dimmer rack are essentially one device.

CONNECTOR STRIP

A type of outlet device for stage lighting circuits; essentially a continuous wireway with outlets or pigtails.

OUTLET BOX

An outlet device for stage lighting circuits. Box size and circuit quantities vary. Surface-mounted or recessed styles available. Circuit numbers must appear on the faceplate (with adhesive labels or engraved).

OUTLET BOX

BOX BOOM

An important front-of-house side wall lighting position in a proscenium theater. See diagram below.

COVE, BEAM, SLOT, TRUSS

A front-of-house lighting position located at the auditorium ceiling. See diagram below.

FOLLOWSPOT BOOTH

Houses the followspots. Enclosed, if possible, and ventilated as per code. Usually at or near the rear of the house, and quite high; 30°–45° to the edge of the stage preferred. Four spots require a booth nominally 24 ft wide x 10 ft deep; two spots require one 12 ft wide x 10 ft deep.

CONTROL BOOTH

Primary location for control console. Good view of stage preferred. Often located on the main level at the rear of the house. House lighting controls should be duplicated here as well as backstage.

DIMMER ROOM

Location for dimmer racks. Can be remote from the stage. Locate for efficiency of load and feed wire conduit runs. Ventilate to accommodate heat load (approximately 5% connected load). Control humidity to protect equipment.

BOOMS, LADDERS, TORMS, TORMENTORS

On-stage side lighting positions. Nonarchitectural; located temporarily for each production as required.

PIPES, BATTENS, ELECTRICS

On-stage overhead lighting positions. Usually rigging pipes or pipe grid members. In a proscenium theater often one or more rigging pipes will be permanently designated as "electrics" and served with connector strips attached directly to the pipe.

CYCLORAMA, CYC

A large seamless white or pale blue backdrop, used scenically to represent the sky or provide a surface on which abstract colors and patterns can be projected with stage lighting fixtures. Usually cloth; some plaster cycs exist, but are difficult (some say impossible) to repair adequately once cracked or marred. Plaster is not recommended.

RECOMMENDED PARAMETERS FOR STAGE LIGHTING SYSTEMS

THEATER TYPE	NUMBER OF SEATS	FEED SIZE*	CIRCUIT QUANTITY	DIMMER QUANTITY
Elementary school	Varies	100	24-36	18-36†
Junior high, or middle school	Varies	300	75-100	75-100
High school	Varies	400	100-150	100-150
Studio theater	75-300	400	150-200	36-200†
Educational drama theater	300-750	800	200-400	200-400
Small professional theater	750-1500	1200	300-500	300-500
Medium size theater	1500-2000	1600	400-600	400-600
Large multipurpose theater, civic theater, road house	Over 2000	2400	600-800	600-800

*Feed size shown in amps, 3 phase, 120/208 V Y.

†A simple patch system where the circuits terminate in male pigtails which can be plugged directly into a small quantity of portable dimmer packs is generally more economical for small installations with limited budgets than a dimmer-per-circuit scheme.

SECTION

PLAN

PROSCENIUM THEATER

STAGE LIGHTING POSITIONS

It is crucial that a theater be provided with adequate, easily accessible stage lighting positions, served with an adequate quantity of circuits. Accessibility is a key issue. Lighting positions in an active theater need to be accessed daily to maintain, focus, and color the fixtures. Safety and ease must be kept in mind, as well as crew size, which is crucial to theater economics. Using a ladder is both time-consuming and dangerous and requires more than one stagehand. A catwalk is much safer, less time-consuming, and only requires one stagehand.

In a proscenium theater lighting is done from a variety of positions and angles. Frontlighting is provided by side wall positions called box booms, the balcony railing, and ceiling positions which can be recessed within the ceiling or exposed as catwalks. Followspots are generally located in a booth at the top rear of the theater (see definitions). On stage, rigging sets with dedicated stage lighting outlet devices (connector strips or drop boxes) and portable vertical floor-mounted pipes called booms provide positions for downlighting, sidelighting, and backlighting. These positions are all important, and every attempt should be made to provide them.

In flexible studio or black-box theaters a pipe grid or a system of catwalks should be provided over the entire

floor area of the theater to which lighting equipment (and scenery) can be attached. This grid should be well served by stage lighting circuits in boxes or connector strips. A two-way grid of 1/2 in. diameter pipe, nominally 4-6 ft o.c. should be adequate in most cases, accessed by ladder from the floor. The catwalk system is preferable, but requires a taller room.

In a thrust or arena theater, a grid or a series of catwalks should be provided over the main stage area to accommodate downlighting, sidelighting, and backlighting. Catwalks, ceiling slots, or ceiling-mounted pipes should be provided for frontlight and low washes, similar to the balcony rail or second cove in a proscenium theater. If there is a conventional stagehouse behind the thrust, it should be served in the same way as a proscenium theater's stagehouse, with overhead pipes and side booms.

THRUST THEATER

SECTION

PLAN

STUDIO THEATER ("BLACK BOX")

GENERAL

The regional enclosed mall is suburbia's answer to the small town main street. Tenants of all types offer a comprehensive and diverse range of products that fit all budgets, attracting many types of shoppers to this type of facility. In fact, in sparsely populated areas, a regional enclosed mall can draw from a radius of 200 miles.

LOCATION

The success of a regional enclosed shopping mall depends on its accessibility to the consumer. Convenient, efficient, and easily recognized access to a facility is essential. Therefore, malls must be located adjacent to several major vehicular routes and within the reach of public transportation. The site must be able to accommodate not only the mall structure itself, but convenient parking for thousands of cars. If a site does not have enough space to meet the parking requirements set forth by the local government, a parking garage may be considered. However, the cost of a garage is enormous and should be avoided if possible.

PARKING

The number of parking spaces required for a regional enclosed mall is generally determined in relation to the area of the anchor store at a typical rate of 5-6 cars per 1000 sq ft. Delineation, organization, and facilitation of vehicular distribution among thousands of parking spaces is accomplished with inner and outer ring roads. The inner ring typically follows the contours of the mall, separating the structure from the parking area, while the outer ring (perimeter road) follows the perimeter of the parking area, property line, or site constraints, connecting adjacent roadways to the parking area.

Between the ring roads the parking spaces are oriented in a fan pattern with each row perpendicular to the mall structure. Orientation in this fashion eliminates the hierarchical pitfalls that result from parking rows situated parallel to the mall. When rows are parallel, shoppers often wait for someone to pull out of the rows they consider more desirable, causing traffic jams near mall entrances.

In a warm or moderate climate, long rows of parking should be interrupted by tree islands to provide shade. However, in a climate where snow is a factor, parking lot segmentation should be avoided. Cost-effective, efficient snow removal requires large unobstructed areas.

Regardless of climate, parking lot drainage is a factor and should be considered. Low points should be located so a shopper's path will not cross a wet or icy drainage area en route from car to mall or vice versa.

ENTRANCES AND EXITS

Opportunities for shoppers to enter the mall must be provided at regular intervals to limit ambulatory travel distance. Anchor stores often furnish several entrances that allow shoppers to enter the store directly. In fact, 40% of all mall shoppers choose to enter malls in this manner, while the remainder use entrances into the mall.

Mall entrances are typically located at the midpoint between anchor stores. However, if anchor stores are particularly far apart, additional mall entrances should be furnished. Keep both horizontal and vertical travel distances between the mall entrance and the parking area to a minimum. Straight pedestrian sidewalks with few steps and/or ramps are appreciated by both the handicapped and other, package-laden shoppers. Ramps and curb-cuts are required for handicapped access.

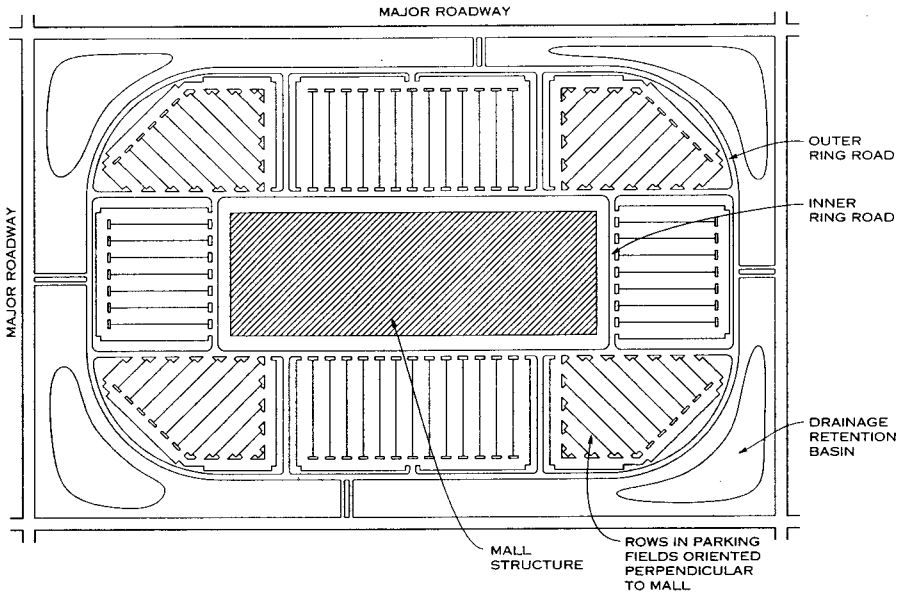

Because of the relative size of the mall structure and the number of entrances, it is imperative that each mall entrance be creatively and independently designated with correlating signage. This practice allows shoppers to easily recall which entrance they used to enter the mall.

While all mall and anchor store entrances double as egress locations, most local building codes require interstitial exits. Typically, an exit is required every 400 ft, so that shoppers need not traverse more than 200 ft to reach the nearest exit. Often, emergency exits from the primary and secondary concourses are permitted to connect to delivery halls behind the tenant spaces, which lead to an exterior door. For required door quantities and travel distance limitations, check local codes.

A—anchor store; F—food court

MALL CONFIGURATION TYPES

SHOPPING MALL SITING/PARKING

NOTE

Parking lots in cold climates must be obstruction free; snow-plows should be able to clear long swaths easily.

SHOPPING MALL PARKING LAYOUTS

Richard M. Roberts, AIA; Omega Design Architects, P.C.; Syracuse, New York

CONCOURSES

Regional enclosed malls must be designed in a way that draw visitors through the massive space, past the attractions of storefront display windows. The design feature used to accomplish this is the node, a point element with gravitational qualities. Careful placement of nodes throughout the common areas of a mall will encourage mall visitors to travel to areas beyond the limit of their view. Since this limit at any given moment in a mall is about 300 ft, it is essential to place a magnetic draw—a node—every 300 ft or less. Concourse intersections, mall entrances, and anchor store entrances constitute nodes.

Nodes at concourse intersections offer opportunities to break up long linear spaces and provide soothing features such as landscaping, fountains, and furniture. Nodes also serve as logical pivot points around which to bend mall concourses should that be necessary or desired. Tenant spaces adjacent to concourse intersections command high lease rates, making it desirable to maximize this type of space in a mall.

A typical regional enclosed mall consists of a primary concourse transected by several secondary concourses. The primary concourse is terminated at both ends with an anchor store. These stores and accompanying signage provide focal points that conduct shoppers through the mall space. Secondary concourses end at anchor stores or mall entrances.

A typical concourse should be between 25 and 80 ft wide, and up to 80% of this width should be effective pedestrian traffic area. The concourse ceiling height should be 60-100% of the concourse width. Ceiling heights outside this range result in spatial proportions that discomfit shoppers, resulting in decreased shopper traffic.

In multiple level malls, floor/ceiling penetrations within concourses are essential to allow shoppers to see what is on other levels. These penetrations, which entice shoppers from one level to another, should be placed and sized so a shopper on one level can see the signage of a store above or below on the opposite side of the concourse.

HORIZONTAL PERCEPTION LIMIT

SIGHT LINES WITHIN MALL CONCOURSE

MALL ENTRANCES AND NODES

TYPICAL MALL LAYOUT

Richard M. Roberts, AIA; Omega Design Architects, P.C.; Syracuse, New York

VERTICAL TRANSPORTATION

In multiple story malls it is necessary to provide escalators, stairs, and elevators to accommodate hundreds or thousands of visitors with varying degrees of mobility.

Escalators are the primary mode of interlevel transport in shopping malls as they can handle the greatest volume of people in a given unit of time and can function as stairs in the event of a power outage. Locate escalators in pairs (up and down) in several convenient locations within the primary concourse and in lengthy secondary concourses. Shoppers should be able to see both the point of departure and the destination before committing to the interlevel travel.

Stairs are the secondary mode of interlevel transport in shopping malls. Locate several stairways in the primary and secondary concourses in much the same manner as the escalators. In addition, provide stairs in accordance with local codes to accommodate exiting shoppers in the event of a fire. Fire stairs are typically located every 400 ft, so the maximum travel distance from any point to a fire stairwell is 200 ft. Check local codes to confirm this distance.

Elevators, the tertiary mode of vertical transportation, are required to accommodate shoppers with limited mobility or a handicap, carrying heavy packages, or pushing strollers. Elevators should be clearly identified and located near both a concourse intersection and a mall entrance.

THEATERS

Regional enclosed malls often include a theater complex with 6 to 24 screens. Generally, the number of screens is based on the market demand as determined by the theater company. Theaters draw large numbers of visitors in hours that do not coincide with the hours of operation of most stores in the mall. As a result, a dead space in front of the theater entrance is often created. For this reason, a theater complex entrance is often located close to a mall entrance in an area that does not command prime lease rates and does not interrupt pedestrian flow.

Theaters require multiple exits that deposit viewers from the screen area to the exterior of the mall. These exits often open into parking or landscaped areas, so it is necessary to plan landscaping, lighting, and connections to the parking areas to provide adequate security.

FOOD COURTS/RESTAURANTS

Food courts draw tremendous numbers of mall visitors. For this reason adjacent tenant spaces are extremely desirable and command prime lease rates. Locate food courts in conjunction with a mall entrance or concourse intersection and

provide direct access to a service hall for food delivery and garbage removal.

The size of a food court and the number of food vendors depends on the size of the mall, the number of out-parcel restaurants nearby, and the developer's vision.

In addition to the many food vendors in the food court, it is typical to see several sit-down restaurants in a regional shopping mall. These restaurants are usually located along exterior walls of the mall near mall entrances and often have their own entrances from the outdoors. A location along outside walls allows these establishments to have windows.

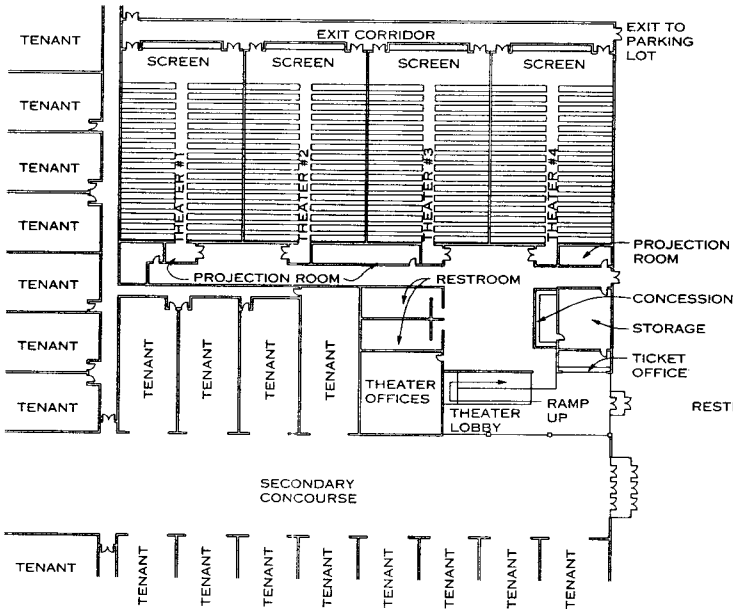

NOTES

1. Each anchor store will have its own receiving area comprising three or more truck bays and a compactor.
2. Interstitial tenants do not occupy enough space or move enough product to warrant individual receiving areas. Instead, several tenants (as many as 25) utilize a common receiving area and loading dock, which usually comprises two truck bays and a compactor. Bay depth should be

great enough to allow a delivery vehicle to remain parked without interrupting vehicular traffic in the parking lot.

3. A network of halls behind individual tenant spaces connects stores to the shared receiving area, and each tenant space has one or more doors that access a support hall. Waste collection is performed through this hall.

MALL GENERAL OFFICES

All regional enclosed malls have general mall offices located somewhere in the building. Generally included are offices for leasing officers, the mall manager, and the operations manager. Because this office space generates no rent, it is commonly situated in an obscure, although not inaccessible, location far from the typical path of a mall visitor. It is common to see community rooms and space available to the public for rent near mall offices.

SECURITY OFFICES

A mall employs several security officers who monitor cameras, traverse the concourses, respond to security emergencies, and provide other security services. These individuals have offices in areas of security risks or low rent generation but not inaccessible to mall visitors. Often security offices are located next to restrooms or adjacent to the mall general offices.

PUBLIC RESTROOMS

Restrooms are equally distributed throughout a mall, generally off a secondary concourse. It is essential, however, not to place the restrooms in a remote location where security could be a problem. It is good practice to locate mall restrooms adjacent to mall offices, security offices, community rooms, and information areas, as these elements offer some security. A struggle or scream from an individual in the restroom should be audible in these adjacent spaces. A large restroom must be located adjacent to the food court.

All mall restrooms must be accessible to the handicapped with proper fixtures, partitions, and doors. All materials used in restrooms should be made of vandal-resistant materials.

ANCHOR STORES

A mall's success relies heavily on the presence of anchor stores, so much so that mall development proceeds only after anchor store leases have been secured. Anchor stores reside at the prime locations in a mall—the termini of primary and secondary concourses. Store signage is located on all visible exterior faces and above the interior mall entrance. Anchor stores generally comprise as much as 60% of the total gross lease area (GLA) of the mall.

Typically an anchor store is between 50,000 and 150,000 sq ft and has one or more levels. If a store has multiple levels, it will have internal vertical transportation via escalators, stairs, and elevators. An anchor store generally incorporates the following spaces:

The SALES FLOOR occupies 70-80% of the total floor area of a store. The floor, which incorporates shopper circulation paths, is divided into departments with stud walls, fixtures, and material variation.

FITTING ROOMS are provided in departments selling wearable items. They are usually built without a ceiling and with walls that end below the ceiling of the store to prevent shoplifters from concealing items in the ceiling.

STOCK/STORAGE AREAS occupy 5-15% of the total floor area of a store. They have no wall, floor, or ceiling finishes and are adjacent to the receiving area.

The RECEIVING AREA/LOADING DOCK is located on an exterior wall adjacent to the stock/storage area.

STORE OFFICES occupy 3-5% of the total floor area of a store. They are usually grouped in a cluster, often adjacent to the restrooms, but several may be scattered around the sales floor, where they are more accessible to the public.

RESTROOMS are often located near store offices and vertical transportation. Multiple restrooms are provided for shoppers, while separate facilities for employees may be placed elsewhere in the store. Restrooms are built with gypsum wall-board ceilings to prevent shoplifters from concealing items.

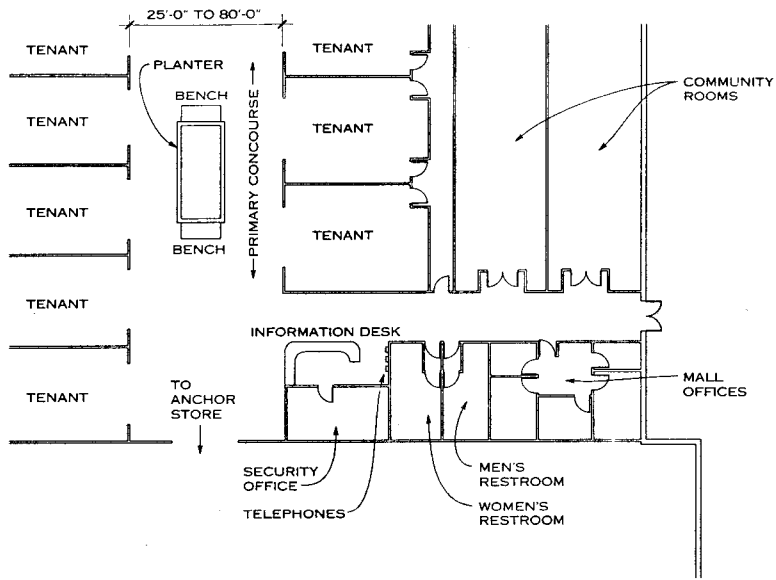

TENANT SPACES

Mall tenants and their requirements differ so greatly it is difficult to typify tenant space. Occupied area can be as small as 500 sq ft (jewelry or specialty stores) or as large as 40,000 sq ft (book or large chain clothing stores). Generally, tenant space is on a single level, but many larger tenants spread their space between levels, with a vertical transportation connection in the space.

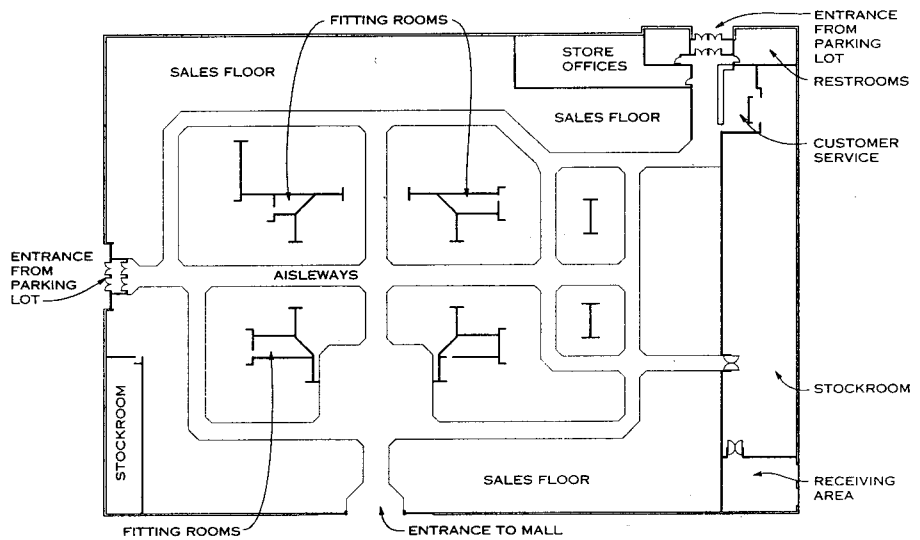

Tenant space generally includes the following:

The SALES FLOOR occupies 80-90% of the total floor area of a tenant space. Most have few, if any, integrated aisles (created with display cases or floor materials), although especially large tenants may use the space more like an anchor store.

Richard M. Roberts, AIA; Omega Design Architects, P.C.; Syracuse, New York

TYPICAL MALL OFFICES, COMMUNITY ROOMS, AND RESTROOMS

TYPICAL ANCHOR STORE

TYPICAL TENANT SPACE (SPECIALTY EYEGLASS SHOP SHOWN)

FITTING ROOMS are often located along rear or side walls of a store and are built without a ceiling and with walls below the ceiling of the store to prevent shoplifters from concealing items in the ceiling.

The STOCK/STORAGE AREA occupies 10-20% of the total floor area in tenant spaces. Located in the rear of the store, it has access to shared receiving areas and delivery halls.

The STORE OFFICE is typically in the rear of the store, where it is used by the store manager. It is not meant to be accessible to the public.

RESTROOMS are provided for employee use only in the stock/storage area. Small stores typically have one unisex restroom, while larger stores have multiple restrooms.

GENERAL

Veterinary clinics are typically divided into three zones—public, procedural and patient—based on use, interior finish, and mechanical zones. The current trend is toward providing full service facilities, including boarding, grooming, and retail areas.

PUBLIC ZONE

It is desirable to have the traffic flow "one way" within the public areas; in one door to reception and waiting and then out another door to the cashier and exit door.

RECEPTION DESK. Allow room for two or three receptionists to work; include space for computer, typewriter, small copier, and files. Files can be accommodated in lateral medical files or an open eggcrate system.

WAITING AREA. Ideally, divide this space into separate dog and cat alcoves with approximately 2 to 3 chairs per exam room. Three-foot clearance in front of each chair, apart from the circulation pattern for pets, is required.

EXAM ROOMS. 1.5 exam rooms per full-time equivalent veterinarian is typical. Exam rooms can be held to a minimum size (rooms exclusively for cats can be as small as 6 ft x 7 ft 6 in.). Two-way traffic flow—a front door for clients and a back door for the veterinarian and for taking animals to treatment—is desirable. One oversized exam room for consultation or for treating large dogs is recommended. Acoustical batt insulation in the walls surrounding exam rooms is suggested. Based on input from the veterinarian, exam rooms should be equipped with undercounter refrigerators and small sinks.

PROCEDURAL ZONE

Includes lab, pharmacy, treatment, X-ray, surgery, and surgery/prep.

LAB/PHARMACY. This facility should be immediately accessible to the exam rooms. Often it forms an acoustical and visual barrier between these rooms and the treatment area.

LAB. In addition to a sink with exhaust fan (a residential range hood is adequate), the lab should include an area for diagnostic equipment (assume 2 ft per piece of equipment minimum), microscope (with kneespace), centrifuge, and workspace.

PHARMACY. This can be a combination of base cabinets with drawers and shelving above (enclosed or open) with risers to make bottles in the back visible. A residential size refrigerator is also necessary.

TREATMENT. Provide one workstation per two exam rooms, with a minimum of two workstations, one dry and one wet, with adjacent layout space for equipment. Workstations can be either peninsular or island. Islands should include a utility column for electrical feed and plumbing vent. Many clinics now include a separate wet workstation for dental procedures. Provide a bank of cages in treatment for intensive care and recovery.

X-RAY. Either an enclosed or open room opening from the treatment area is suitable, depending on local health regulations and the amount of protection desired. Radiation protection needs vary based on the equipment being used, ranging from two layers of gypsum board to lead shielding. A darkroom should be adjacent to the X-ray equipment. Most veterinarians use automatic processors so the old development tanks are no longer necessary. Storage for X-ray films, approximately 14 x 18 in. each, is also required. Wall-mounted X-ray viewers should be provided in exams, treatment, X-ray, and surgery areas.

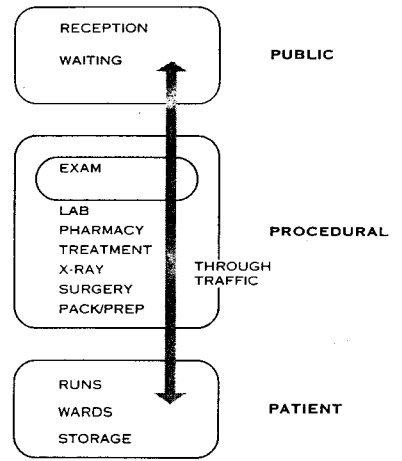

SURGERY/PREP. This should be a small alcove off the treatment area for preparing packs and scrubbing for surgery. A "hands-free" scrub sink, place for an autoclave, and a work area for preparing packs is required. A cabinet-top pass-through to surgery for prepared packs is often requested.

SURGERY. Provide one or two tables and space for parking equipment and carts. High-efficiency particulate airflow filters should be specified on ducts feeding the surgery, which should be a positive pressure room at minimum.

DOCTORS' OFFICE. In addition to a doctor's station adjacent to the treatment area for filling out charts, a small doctor's office is usually required.

TYPICAL ROOM SIZES

ROOM SIZES	MINIMUM	AVERAGE
Reception	8 x 12	12 x 14
Waiting	8 x 16	10 x 20
Retail		12 x 15
Exam	6 x 8	8 x 10
Oversize exam		10 x 12
Laboratory	6 x 12	8 x 12
Pharmacy	6 x 8	7 x 12
Treatment	14 x 20	18 x 24
X-ray	8 x 10	8 x 12
Darkroom	4 x 6	6 x 6
Surgery		
One table	9 x 10	10 x 12
Two table		12 x 16
Wards	minimum 4' aisle	
Runs	4' aisle, 3 x 5 runs	
Office	8 x 10	12 x 16
Handicap bath	5 x 9	
Grooming	8 x 10	12 x 16
Bathing	8 x 10	10 x 12
Food preparation	6 x 6	8 x 10

CONVENTIONAL VETERINARY HOSPITAL BUBBLE DIAGRAM

TYPICAL FLOOR PLAN

Mark R. Hafen, AIA; Gates Hafen, P.C.; Boulder, Colorado

PATIENT ZONE

The patient areas should be acoustically separated from the rest of the facility. The high degree of abuse and constant cleaning requirements of this area make it practical to have painted epoxy concrete block walls, concrete floors, and mylar-faced lay-in acoustical tile ceilings. Ward rooms used for holding small dogs or cats in cages can have walls of drywall.

WARDS. These should have space for no more than 25 animals. Assume approximately 1 to 1.25 cages per linear foot of three-tier caging. Where possible runs or cages should not face each other. Cages are typically placed on 4 in. high built-in curbs. Wards should be provided with natural light when possible and exhaust fans.

RUNS. The number of runs needed depends on the number of larger dogs treated; minimum size is typically 3 x 5 ft each. Drains should be provided in each run. Slope floors a minimum of 1/4 in. per foot. Caging can be either fabricated aluminum, stainless steel, or chain-link available through veterinary or kennel equipment suppliers. Partitions between runs should be a minimum of 6 ft high with the bottom 4 ft solid to avoid cross-contamination. The solid portion can be of galvanized metal, plastic-laminated exterior plywood, or concrete block. Where possible, noise-reducing baffles and panels should be utilized. Hose bibs with hot and cold water should be provided for hosing down the runs.

UTILITY/GROOMING. Room is needed for dry food storage, food preparation, incidental grooming, and washer/dryer. These functions can be separated in larger facilities. The food preparation area should include a double sink, dry food storage bins, work counter, and undercounter refrigerator. A grooming/bathing area should include a raised grooming tub, place for a cage for dog drying, and a small 2 x 4 ft freestanding grooming table. The washer/dryer is used for both washing soiled blankets from the wards and surgery linens. Space is required for a chest-type necropsy freezer. The service entry should be into this room.

MISCELLANEOUS

A small isolation ward, including a small bank of cages and one run, is often required for isolating highly contagious animals. Usually it is located immediately adjacent to the service entry, where it will be accessible without going through other wards or the treatment area.

HEATING, COOLING, AND VENTILATION

Ideally there should be three mechanical zones: public, procedural, and patient. Three truly separate zones help control acoustical and odor problems. These zones should be pressurized so that air is fed to the public areas and exhausted from the patient areas. Additional exhaust fans should be provided in lab and treatment rooms. A large capacity exhaust fan is necessary in the ward and run areas. Where economically feasible, air should be exhausted to the outside in the run areas to avoid spread of diseases and minimize odors. The acceptable temperature and humidity range in the wards and runs can vary beyond the typical comfort zone, but should not be below 50 or above 85 degrees. Air changes in the wards and runs should be 12 to 14 an hour. The surgery should be a positive pressure room with high-efficiency particulate airflow filters.

ELECTRICAL

In addition to the obvious requirements of the X-ray equipment (typically 100 amp), most veterinary clinics utilize a lot of electrical equipment, including autoclaves, dog dryers, and exam and surgery lights. Be careful not to locate too many pieces of equipment on any one circuit.

MATERIALS

Cleanable and durable materials are a high priority. In the public areas flooring can be welded sheet vinyl or quarry tile (with latex epoxy grout). Walls can be covered with flat latex or vinyl. Ceilings can be of gypsum board or lay-in acoustical tile.

In the procedural areas a higher degree of cleanability/durability is required. Floors should be of welded seam homogeneous PVC sheet vinyl, and walls can be washable latex. The surgery should have water-based epoxy walls and a painted gypsum board ceiling. Other ceilings can be lay-in acoustical tile.

In the patient areas durability is most important. All areas exposed to water should have concrete block walls painted with water-based epoxy (other walls should be of epoxy painted gypsum board). Ceilings exposed to water hoses should have mylar-faced acoustical tile. Floors in wards should be of sealed and colored concrete. In the runs it is possible to paint or tile the floors, but the most foolproof solution is sealed and colored concrete.

TYPICAL VETERINARY EQUIPMENT AND SIZES¹

EQUIPMENT	HEIGHT	WIDTH	DEPTH
X-ray control center	53"	21"	12 1/2"
X-ray table	22"	57"	39"
X-ray illuminator	19 3/4"	29"	3 1/8"
X-ray film processor	18 1/2"	23"	38"
Surgical equipment sterilizer	14"	19 1/2"	23 1/2"

Electric lift exam and weight table	10 to 40"	44 1/2"	20"
Pedestal base surgery table	37"	58"	19"
Combination tub/exam table with cabinet ²	38"	60 1/2"	24 5/8"
Combination tub/exam table with legs ²	35"	60 1/2"	24 5/8"
Kennel assemblies ³	48 to 84"	48 to 168"	28 1/4"

NOTES

1. All dimensions are typical and may vary with manufacturer.
2. Combination tub/exam tables can have tub depth of either 6 or 16 in.
3. Kennel assemblies are modular with cage sizes of 24 x 24 in., 24 x 30in., 30 x 30 in., 36 x 30 in., and 48 x 30 in.

SURGERY/PREP PASS-THROUGH UNIT

GROOMING TUB

TYPICAL EXAM ROOM

TYPICAL TREATMENT STATION

Mark R. Hafen; AIA, Gates Hafen, P.C.; Boulder, Colorado

GENERAL

All kennels for boarding dogs must provide for each animal a primary enclosure (usually indoors) for privacy, eating, and resting and a secondary enclosure (usually outdoors) for exercise.

The primary enclosure should consist of solid dividers to separate adjacent runs and provide privacy with a sloped floor to provide for drainage during cleaning. Enclosures should be large enough to allow for normal movements with minimum sizes of 3 x 4 x 4 ft for small breeds and 3 x 6 x 6 ft for larger breeds.

The secondary enclosure is for exercise and should be large enough for the dog to break into a trot with minimum sizes of 3 x 7 x 4 ft for small breeds and 3 x 11 x 6 ft for larger breeds. Separate each run with a barrier to prevent waste from flowing from one to another. Provide hose bibbs to wash down this area.

Cats are boarded in stacked cages of 2 x 3 x 3 1/2 ft with a perch at the rear. The materials can be less durable than those for dogs, since cats are not as destructive and cleaning does not require hose down. Each enclosure should contain a litter box and enough floor space for food and water and lying down. A climbing tree and removable den for hiding can be provided. Cat enclosures are usually vented individually to prevent the spread of diseases.

Cats enjoy interesting views and distractions so good lighting, cheerful colors, music, plants, outside views, caged birds, and fish tanks are recommended. Cats, however, will adapt to boarding faster if they are separated visually from one another. Community play areas are not recommended because of the possible spread of diseases.

VENTILATION

Proper ventilation is important to prevent the spread of diseases. Air should be vented to the outside, unless air cleaners are used. Recommended ventilation standards should be 10 to 15 room air changes per hour.

HEATING AND COOLING

Temperatures should be designed and maintained between 60-80°F, with humidity maintained between 30-70%. Radiant heat in the floor is highly recommended as it provides heat at the level of the animal.

DRAINAGE

The flooring of all runs should be sloped 1/4 in. per foot from the rear to the front. Drainage should be quick and complete, with the floor finish being not so smooth that it becomes slippery when wet or so rough that it is hard to clean and harms the animal. Waste materials should be collected outside the runs or cages and run to minimum 3 in. diameter floor drains.

LIGHTING

All areas should be bright and cheerful with abundant natural light for the health of the animals. Skylights and ample windows located a minimum of 6 ft off the floor are desirable. Windows should be operable and hinged at the sill to tilt inward to prevent escapes.

NOISE CONTROL

Noise control is important to decrease boarding stress and employee health problems such as hearing loss and to meet local noise ordinances. Noise reducing materials should be considered including ceiling and wall baffles.

MATERIALS

All materials used should be durable and easy to clean and maintain. Concrete block sealed or painted is the usual choice. Prefabricated and modular runs are available or chain link fencing can be used. Carpeting is not recommended as a flooring material.

NOTES

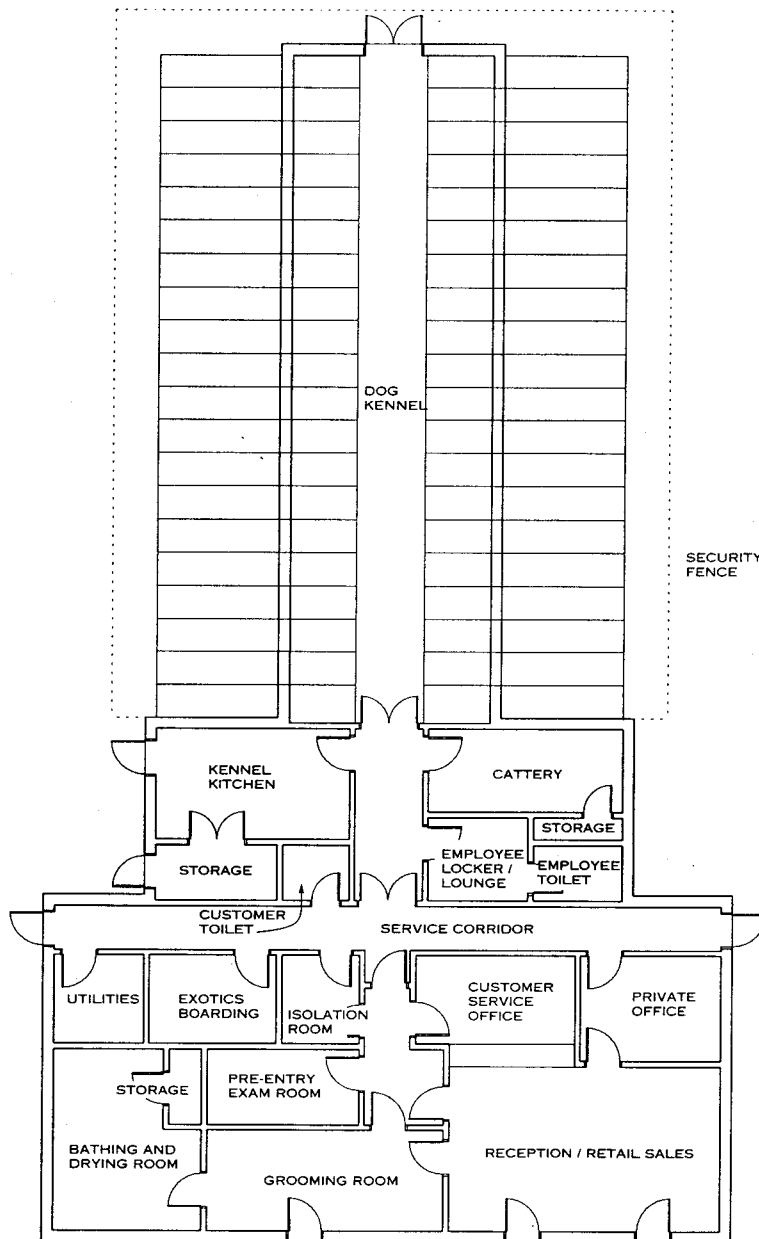

Kennels for the care and boarding of animals are typically defined as breeding, commercial, private, research, and veterinary/medical. The size, type, quantity, and layout of the equipment is related to the function of the kennel and amount and type of patronage.

The schematic drawing (right) is not meant to dictate a design standard but rather to familiarize the reader with typical characteristics of commercial kennels.

Barns: masonry and glue-laminated construction for fire-resistance. Stalls: furred out, finished with red oak, hardwood, or 1/4 in. rubber matting. Casting rails: 2 in. x 6 in. red oak, edges rounded, sealed with boiled linseed oil. Countersink fastener heads, plug. Stall corners: rounded or 45° walls to casting rail. Ventilation: high open slots with optional sliding wood shutter. Windows: safety glass only, minimum of 8 ft above floor. Floor: 3 in. porous asphalt (percolation of one gallon in ten seconds) over 18 in. crushed stone with a porous drainpipe pitched to take effluent away from barn areas. Check local codes on septic requirements. Floors: rough cor crete or skid-resistant brick pavers with a central floor drain to catch basin. Grates: cast iron or precast concrete centered in stall with perforations no larger than 1 in. diameter or 1 in. sq. Floor: sloped to center drain. Provide optional infrared heaters in all horse wash areas at maximum 10 ft above floor. Aisle floors: porous asphalt, paving bricks set in 2 in. sand, or diamond shaped concrete with trench drains to each side.

Tack room area varies with the type of stable. Riding stables have at least one bridle and saddle per horse or pony. Saddle and bridle racks can be fastened in rows, one over another. Additional space is needed for groom equipment, sometimes stored in tack trunks. In broodmare stables, tack is mainly halters and grooming supplies. Tack room and foaling stall must be heated. Foaling stall heat: controllable to raise it as quickly as possible to 75° minimum and to maintain it. Foaling stall floor: seamless, rubberized material, minimum 1 in. thick, textured, and pitched to a separate drain and catch basin (not connected to main barn drainage). Rubberized flooring turned up the walls, minimum of 24 in. Foaling stall adjoined by the situp room (also heated) with a one-way unbreakable glass panel and/or slide shutter for the groom to observe.

All feed and grain storage bins are lined with galvanized steel for vermin control. Feed amounts vary widely. As a guideline, a horse under medium to heavy workload is fed 15 lb of grain plus hay per day. All hay and bedding must be stored in a separate dry barn due to fire risk. As horses are grazing animals, hay managers are not recommended; place hay in a corner of the stall floor. All roofs should have a minimum 7/12 pitch and continuous full length vents under the eaves and at ridges. Sliding doors are preferable. All swinging dutch doors or full doors should have a 180° swing to wall and fasten. Stalls should have heavy duty slide bolts, kick over bolts, and/or locking pins. All hardware should be smooth with no sharp protrusions and inaccessible to horses at the stalls. All light fixtures should be guarded and/or waterproofed. Light switches: located in a central panel away from wet areas. Lighting levels vary. Depending on the program, stalls are lighted with a single floodlight over the inside stall door at the ceiling or 10 to 12 ft. above finished floor. Aisles can be lighted by incandescent or fluorescent lamps. Broodmares and stallions require brighter light and lighting programs to keep fertility levels maximized (approximately 100 footcandles should be achieved at 5 ft 0 in. above finished floor per stall). Aisles may have lower light levels of 40 footcandles, except examination or display areas, which must have additional light available on demand.

INTRODUCTION

Developments in ventilation, glazing, and horticulture have helped achieve satisfactory plant growth in greenhouses to make the practice economical. Site selection considerations include: topography (flat is advisable), drainage, quantity and quality of water supply, air quality, direction and average wind speed, and, most important, the amount of available light. Orientation for optimal solar gain is east-west except in conditions where shadow casting obstructions outweigh the orientation rule. Once a site has been selected, development of a plan for growth (even if only one greenhouse is built at first) is essential, factoring in access, mechanical room locations, and circulation of materials and labor. Heating and cooling needs will vary with latitude, plant type, skin or glazing, and growth period.

NOTE

Use of an uneven span greenhouse allows for optimal solar orientation. Slope of glass is determined by latitude.

OPTIMAL SOLAR ORIENTATION

WHERE
A = MIN. ANGLE OF SPAN
H = HEIGHT
Y = CENTERLINE OF HIGHEST POINT TO PROPOSED GREENHOUSE

SOLVE FOR Y
 $TAN A^\circ = HY$

SPACING OF STRUCTURES

BENCHING

GENERAL

Reduction of summer heat gain is achieved through shading systems, and natural and fan ventilation systems. Shading is most often achieved with the use of paint on the interior glass, lath rolled on the structure's exterior, or cloth of varying density on the structure's interior.

EVAPORATIVE COOLING

Mechanical refrigeration is generally cost prohibitive cooling with the exception of pad systems, or "swamp coolers," involving pulling air through a wet pad the length of the greenhouse wall with a fan mounted high on the opposite wall.

NOTE

Fan and pad water pump are hooked up to the same thermostat.

SWAMP COOLER

EXHAUST FANS

Fan placement depends on greenhouse orientation; optimal placement is the side opposite the normal wind direction. Fans from adjacent greenhouses should be placed opposite each other, spaced at not more than 25 ft. Stratification is desired in summer cooling, where only 15 to 60% of total air volume is moved mechanically.

STRATIFICATION

COOLING SYSTEMS

Air exchange is necessary to moderate interior temperature and humidity. High humidity promotes plant disease and inhibits soil drying. The most common means of ventilation are natural venting, tube ventilation, and fan-jet ventilation.

NATURAL VENTILATION

TUBE SYSTEM

FAN JET SYSTEM

VENTILATION SYSTEMS

GENERIC GREENHOUSE

When properly maintained, a glass greenhouse will last 40 to 50 years. Structural design of a greenhouse is similar to curtain wall design with live loads of wind, snow, piping, and hanging basket plants.

FRAME TYPES

MATERIAL	FEATURES
Pipe frame	Economy/simple connections
Steel frame	50' span (installation by professionals)
Aluminum frame	No rust, deeper sections than steel
Wood frame	Pressure treated lifespan: 10-15 yrs.

GLASS-SHEATHED GREENHOUSE

Rigid or flexible plastic greenhouses feature economy, ease of fabrication, and flexibility of form making. Plastic's liabilities are its poor durability, reduced light transmission over time, and discoloration or brittleness.

PLASTIC TYPE MATERIAL

Flexible	Polyethylene, mylar
Rigid	PVC, acrylic, fiberglass

NOTE

The size of a plastic greenhouse is limited only by the width of a single sheet of plastic.

PLASTIC-SHEATHED GREENHOUSE

HEATING SYSTEMS

Heat distribution is achieved through use of solar, hot air, or radiant pipe systems. Solar heating will usually need the augmentation of the two latter systems at the coolest or windiest part of the year.

RADIANT/HOT WATER PIPE

Systems use a boiler to heat and distribute water. Pipes located at the greenhouse perimeter are the most convenient and efficient method of achieving uniform temperature.

INSULATION

Insulation augments heating systems and helps reduce heat loss from convection and radiation. Three basic systems are most widely used: movable night curtains, plastic covering over glass, and permanent reflective insulation of north wall and roof.

HOT AIR

Systems burn various fossil fuels and distribute the warmed air with fans.

PUBLIC ACCESS TO STREAM PRESERVED

SITE ANALYSIS AND SCHEMATIC SITE PLAN

GENERAL

Residential site planning requires balance among a large number of complex and often competing priorities.

ORIENTATION

No unit should be without sun for at least part of a winter day; south-facing units are premium. Prevailing winds, both regional and local, should be studied so that no building is entirely masked. At the same time, harsh winds should be buffered by plantings, and if buildings are differentiated by side, bedroom and service sides should face the harsh wind.

USE AND ENHANCEMENT OF NATURAL AMENITIES

Too frequently, housing projects are named for amenities that are destroyed during development. Promontories, mature trees, and water features should be incorporated into the design and, if possible, enhanced.

PROVISION FOR VIEWS

Spectacular views can drive the design of a housing project, but every project should strive to provide reasonable views from all units. Although no unit should have a parking area as its only view, many people enjoy views of streets and roadways. Views of green space are important, especially in urban projects.

CONTEXT

The designer must strive to identify valuable off-site resources and influences so that they are recognized in the design.

Such resources include the following:

1. Geometries and alignments
2. Slopes and soils
3. Views of singular objects and natural amenities
4. Recreational facilities
5. Topography and drainage
6. Surrounding and adjoining uses
7. Available infrastructure
8. Market and location

CLEAR DELINEATION OF PRIVATE AND PUBLIC AREAS

Beyond unit design considerations, the site should be organized so that all territory can be clearly allocated to either private custody or public care and maintenance. It is frequently desirable for each unit to control some private open space. However, in higher density developments such space is often limited or filled in unique ways.

REGULATORY REQUIREMENTS

Land available for housing and related uses may face restrictions, including the following:

1. Rights of way for future uses
2. Area required for storm water management and sediment control
3. Mandated unusable areas between projects (called buffers)
4. Building restriction lines: setbacks, build-to lines, height limits, viewsheds, watersheds, separations, rights of way, easements
5. Roadways and parking areas
6. Protection of environmentally sensitive and natural resource areas such as forests, streams, and animal habitats

DENSITY AND BUILDING TYPES

These factors are the most critical to the developed character of the site and are prescribed by zoning and by developer preference—as informed by the architect and others. Zoning density is expressed numerically along with limitations that are often intended to suggest unit type. But any prescribed density can be reached by combining building types with associated parking arrangements. The permitted density may ultimately be reduced through restrictions of various sorts and is rarely achievable on small or irregular sites.

UNITY AND VARIETY

In site design, monotony and excessive repetition are as undesirable as meaningless variation, which can be disorienting and appear chaotic.

ARBITRARY VARIATION AND MONOTONOUS REPETITION

EMERGENCY ACCESS

Size and turning radius of emergency equipment, especially fire engines, can mandate street width, turning radius, and access patterns. Access to buildings becomes an issue at higher densities; installation of sprinkler systems can often balance equipment access around buildings. Always consult the fire marshal in the early stages of design.

SECURITY

Because projects are produced and marketed as discrete places, security considerations can reinforce their hermetic character and prevent integration into the larger community. At higher densities, this phenomenon can produce gated communities with limited or single access, card-accessed parking areas, and private police.

Conventional urban patterns can replace costly and artificial surveillance systems: building placement, window location, and resident awareness, together with architectural limitations on free circulation, can enhance neighborhood security.

ACCESS

Although singular access is frequently desired for marketing and control, redundant access from existing automotive and pedestrian networks provides choice and convenience while reducing concentrations of traffic.

MULTIPLE ACCESS AND SINGLE ACCESS

Ralph Bennett; Bennett Frank McCarthy Architects, Inc.; Silver Spring, Maryland

GENERAL

Numerical definition of density is the most important planning index in housing but it can also be the most misleading. Density numbers frequently become inflammatory in planning debates, so it is important that the architect provide specific images of the actual appearance of planned settlements.

Density appears in two forms: gross and net. Gross density is the index applied to large areas—15 to 20 acres or more—and includes private as well as public improvements such as roads, schools, parks, and residentially oriented retail uses.

Net density is used in relation to project-sized areas—smaller than 15 to 20 acres—and consists of the number of proposed dwelling units divided by the site area. Net density is usually expressed in acres and includes access drives, parking areas, common and buffer areas, and community facilities.

FACTORS AFFECTING DENSITY

1. Dwelling unit size and arrangement.
2. Parking: on grade, in garages, in units, structured in large groups.
3. Passive and active open space.
4. Land use restrictions such as buffers, easements, and setbacks.
5. Land price: the owner's objectives are ultimately formed by this factor, in conjunction with market projections.

TYPICAL DENSITIES

1. **SINGLE-FAMILY DETACHED HOUSES:** The density in developments of this type is generally 6 dwelling units or fewer per acre. In the example illustrated, the density is 4.5 dwelling units per acre, with on-site parking but no garages and 7,500-sq-ft lots.
2. **SINGLE-FAMILY ATTACHED TOWN HOUSES (parking on grade):** The density in a development of this type is up to 14 dwelling units per acre.
3. **SINGLE-FAMILY ATTACHED TOWN HOUSES WITH GARAGE:** Up to 20 dwelling units per acre will fit in a development of this sort.
4. **TWO-STORY ATTACHED HOUSES:** With carports, these houses are designed at a density of around 10 units per acre.
5. **GARDEN APARTMENTS:** Parking on grade is provided in a garden apartment complex, which contains up to 18 dwelling units per acre. In the example shown, each apartment building has 36 units, for a density of 18 units per acre.
6. **WALK-UP APARTMENTS:** Built over one parking level, a walk-up apartment complex could accommodate up to 30 dwelling units per acre.
7. **ELEVATOR BUILDINGS:** Elevator buildings with structured parking can be built at a density of up to 100 dwelling units per acre. The example shown is a double-loaded corridor slab building with 200 units. With surface parking, it offers a density of 45 units per acre.
8. **MIXED NEIGHBORHOODS:** A mixed neighborhood encompasses a variety of dwelling types and, correspondingly, a variety of housing unit densities. The example shown includes an 8-unit walk-up apartment building on a 16,000-sq-ft lot, with a density of 16 units per acre, and single-family detached houses with garages on 8,000-sq-ft lots, with a density of 4 units per acre. The overall density in this example is 6.4 units per acre.

SITE PLAN CONSIDERATIONS

ACCESS

1. Where possible, access should connect and align with existing systems.
2. Marketing and security considerations frequently dictate single access, but redundant circulation gives choice and improved service.

PEDESTRIAN CIRCULATION

1. Rarely provided at lower densities, pedestrian access is essential at higher densities.
2. Pedestrian walkways usually parallel streets.
3. Connections to mass transit are appropriate.

PARKING

1. Parking arrangements have a significant impact on density and appearance.
2. On-street parking for guests is desirable at lower densities and essential at higher densities.

RELATION TO TOPOGRAPHY

1. ADA and subdivision regulations dictate street and walk grades and mandate site reformation at all but the lowest densities.

SERVICE

1. Trash pickup, mail service, and deliveries depend on street access to individual units.
2. Fire apparatus usually dictates road standards.

STREET ACCESS

TECHNOLOGY

STRUCTURE

1. Typically wood frame.
2. Fire separation is required for incorporated parking (garage).

MECHANICAL

1. Air, water.
2. Oil, gas heat, or heat pump.
3. Compression refrigeration or heat pump cooling.
4. Exterior condenser for heat pump or air-conditioning. This type has greatest flexibility for solar and other alternative energy systems.
5. Sprinklers are required in some jurisdictions.

SHOWN AT 2 UNITS PER ACRE ON 100' X 200' LOTS
LARGE LOT SINGLE-FAMILY HOUSES

SHOWN AT 5 UNITS PER ACRE ON 75' X 100' LOTS
SMALL LOT SINGLE-FAMILY HOUSES

SHOWN AT 10 UNITS PER ACRE ON 40' X 90' LOTS
ZERO LOT SINGLE-FAMILY HOUSES

DENSITY CONFIGURATIONS

DETACHED HOUSING CHARACTERISTICS

TYPE	LOT SIZE (SQ FT)	DENSITY RANGE (D.U./ACRE)*	CHARACTERISTICS
Large lot	20,000 and up	0.5-5	Flexibility in orientation. Building restriction lines not significant. Expansion simple. Site character can be exploited.
Small lot	5000-10,000	4-8	Aggregation becomes important. Community planning important. Services important (fire, mail, rubbish). Pedestrian circulation possible and required. Urban design principles apply. Building restriction lines become important. Public sewer and water needed. Clear delineation between public and private space needed.
Zero lot	3000-5000	8-11.5	Eliminates one-sided setback. Shallower lots possible. Other side yard usable as private space. Windows on property line reduced or eliminated.
Z-lot	3000-5000	8-13	Similar to zero lot. Allows more flexible allocation of land. Lot line views over neighboring ownership must be avoided.
Alternating-width lots	3000-5000	8-11.5	Gives variety along street.

* D.U.—Dwelling units

Ralph Bennett; Bennett Frank McCarthy Architects, Inc.; Silver Spring, Maryland

SITE PLAN CONSIDERATIONS

ACCESS

1. Where possible, should connect and align with existing systems.
2. Many arrangements are possible, including alleys, on-site parking, pooled parking and on-street parking.

PEDESTRIAN CIRCULATION

1. Necessary to connect dwellings to common facilities and off-site facilities.
2. Usually parallels streets.

PARKING

1. Has significant impact on density and appearance.
2. If not pooled, on-street essential for guests and overflow.

RELATION TO TOPOGRAPHY

1. ADA, Fair Housing, and subdivision regulations dictate street and walk grades and mandate site reformation at all but the lowest densities.

SERVICE

1. Trash pickup, mail service, and deliveries rely on access from street to individual units.
2. Fire apparatus usually dictates road standards.

STREET ACCESS

MASSING

Variety and richness can be achieved by massing buildings so that individual units are not diagrammatically identifiable. Scale is given by secondary elements, room sized or smaller. Basic combinations are manipulated to produce complex unit configurations; the resulting composition is very different from basic types.

THREE-UNIT BUILDING OF COMBINED TYPES (MANOR)

TECHNOLOGY

STRUCTURE

1. Typically wood frame.
2. Gypsum board walls between units (party walls), 2-hour rating. Some jurisdictions require masonry.
3. Parking must have rated separation if sharing wall or ceiling with unit.

MECHANICAL

1. Air, gas heat, electric baseboard heat, or heat pump.
2. Compression refrigeration or heat pump cooling.
3. Exterior condenser for heat pump or air-conditioning.
4. Sprinklers required in many jurisdictions.

GARAGE UNDER HOUSE—FRONT ENTRY

GARAGE UNDER HOUSE—REAR ENTRY

GARAGE IN FRONT OF HOUSE

GARAGE BEHIND HOUSE

NOTE

Attached houses achieve the highest density possible with individual structured parking (garages). Combining this housing type with parking produces many rich variations.

PARKING

TOWN HOUSES OVER FLATS

TOWN HOUSES OVER TOWN HOUSES

NOTE

Town houses can be stacked upon themselves or on one-story units (flats). Density is increased and fire separations are required horizontally as well as vertically. Individual entries are usually provided.

MULTISTORY VARIANTS

Ralph Bennett; Bennett Frank McCarthy Architects, Inc.; Silver Spring, Maryland

HIGH-RISE BUILDING NOTES

1. In high-rise, single-entry buildings, the views of most residents are distant from public areas.

LOW-RISE BUILDING

2. Low-rise, multiple-entry buildings facilitate close supervision of public areas.

NOTE

Architectural and landscape devices help demarcate private and public spaces between a house front and the street.

SUPERVISION OF PUBLIC AREAS

GENERAL

Clear delineation of usable exterior space is essential to the success of any housing design. Proper planning of exterior space improves security, reduces maintenance, enhances appearance, and permits residents to act as responsible citizens.

DESIGN

On traditional city streets, public and private realms are clearly defined.

The street is in the public realm. Semipublic areas—the entry and foyer—open onto the street from a short distance. The semiprivate areas of the house—living, dining, and/or cooking areas—look out onto the public realm but are screened. The private areas of the house—the bedrooms—are a floor or more above the street, looking out but secluded from view. Semiprivate outdoor areas are at the back of the house, visible to neighbors but secluded from the street.

In multifamily buildings, the provision of a supervised public realm is more complicated than in the attached house. In this case, buildings need to be arranged so that unit windows and common circulation space overlook the public areas of the project. This can be accomplished by

1. Keeping buildings in the two- to six-story height range
2. Clustering the dwelling units so their entrances are distributed rather than concentrated
3. Arranging unit windows so no portion of the ground surface is invisible to dwelling units

PUBLIC AND PRIVATE ZONES IN A ROW HOUSE

BUILDING LOCATION

Separation of buildings from parking and minimum distances between buildings are often mandated by zoning and by building codes.

To avoid involuntary eye contact, vertical walls containing windows and balconies should be at least 60 ft apart. This dimension is often reduced; if so, attention must be paid to elements that can provide elective privacy, such as

1. Curtains and blinds
2. Balcony walls with adjustable opacity
3. Deformation of the wall to provide bays and oblique, rather than frontal, views

ADJACENT USES

Location of certain site activities near unit windows can cause conflict. Although common practice often places back-to-back garden apartments overlooking parking, this setup is not optimum. This arrangement can be improved if the parking area is planted, illumination is at a low level, and the building design provides other views.

Recreational uses such as basketball, tennis, and other noisy, large-muscle activities should be kept away from unit windows and balconies.

Play areas for small children ideally are located where they can be seen from dwelling unit windows.

LANDSCAPE DESIGN

The provision of green space is essential for housing, even in intensely urban areas. Street trees and planted courtyards add value to the densest housing site.

Where space permits, passive green space without specific programmatic purpose can be an attractive addition. Such space should not be so large as to be unsupervisable from the dwellings, and dwellings should be located to take advantage of the amenity it provides.

DIVISION OF PUBLIC AND PRIVATE SPACE

COMMUNITY FACILITIES

Two houses make a community and offer opportunities for elective socialization and joint use.

In small developments, the ordinary activities of daily life offer opportunities for community focus. These activities include picking up mail, putting out trash, doing laundry, and working on cars.

In larger projects, the following activities may provide opportunity for community activity and physical focus:

1. Marketing and management
2. Activities requiring shelter, such as meeting, fitness, day care, and convenience retail
3. Outdoor recreation, such as swimming, tennis, handball, and racquetball

DETAILS

Architectural devices mark and enhance the public and private realms. These devices include fences; walls; changes of level provided by stairs and ramps; zones of planting; and porches, stoops, and terraces.

ADJACENT HOUSE ENTRANCES

Ralph Bennett; Bennett Frank McCarthy Architects, Inc.; Silver Spring, Maryland

GENERAL

The regulatory climate for housing is complex and ever-changing. Therefore, designers should consult regulatory agencies at all levels of government before initiating planning or detailed design of any housing project.

Information on this page is related to site design, building arrangement, and design of the exterior path to the dwelling unit and other common facilities. Further information related to housing can be found in Chapters 1, 11, and 20 of the ninth edition of *Architectural Graphic Standards*.

FAIR HOUSING AMENDMENTS ACT

The Fair Housing Amendments Act (FHAA) was passed in 1988 and applies to all housing scheduled for first occupancy after March 13, 1991. The act is unusual in that it is a civil rights law, not a building code or standard. Although the U.S. Department of Housing and Urban Development (HUD) developed and promulgates the guidelines, HUD has no plans to review its role and will enforce FHAA primarily based on complaints. Compliance will be achieved through complaints by affected individuals and by professional testers.

FAIR HOUSING ACCESSIBILITY GUIDELINES

The most comprehensive instructions for compliance with the construction provisions of the FHAA are provided by the Fair Housing Accessibility Guidelines (FHAG), which were released in their final form in March 1991.

WHAT PROJECTS ARE COVERED

Any multifamily project with four or more dwelling units is covered by the legislation, but not all parts of all dwelling units in all covered projects must be accessible.

Other standards that supplement or supersede the FHAG are the following:

1. SPACES FOR COMMON USE: ANSI standard A117.1-1986
2. SPACES FOR PUBLIC USE (if any): Americans with Disabilities Act (ADA) Guidelines
3. ANY SPACE: Any local building code standard that HUD deems more restrictive

In buildings equipped with passenger elevators, all units must be accessible. Multistory dwelling units (except loft units) not located in elevator buildings are exempt from this requirement.

In walk-up multistory buildings, FHAA requires all ground floor units to be accessible where practical, based on site considerations. A minimum of 20% of the units must be accessible. FHAA definition of the ground floor in walk-up buildings is unclear, but the intention of the legislation was to avoid the installation of elevators in buildings not otherwise needing them. Because interpretations of the law vary, guidance should be sought.

NOTE

The FHAA does not clearly define "ground floor" in requiring that all ground floor units be accessible when practical. For situations such as that shown here, it may be wise to seek guidance regarding accessibility requirements for ground floor units on the lowest level.

GROUND FLOOR UNIT ACCESSIBILITY

NOTE

FHAG permits use of both level changes and lofts in dwelling units as long as common areas are accessible.

DESIGN FEATURES PERMITTED IN ACCESSIBLE UNITS

SITE PLANNING ISSUES

Site accessibility for housing is defined as the existence of a continuous accessible route of travel from a suitable automobile or transit drop-off point (called the arrival point) to the dwelling unit. Such a route may include parking access aisles, curb ramps, walks, ramps, and lifts and must meet the requirements of ANSI A117.1-1986.

Sloped walkways, when included, are defined as being no steeper than 5%. Steeper walkways are defined as ramps and must have a maximum slope of 8.5%; ramps require handrails.

All community facilities must be connected to all covered dwelling units by an accessible route. In certain circumstances, use of a private automobile may be considered part of such a route.

SITE PRACTICALITY TESTS

The designer may use either of two tests to determine whether accessibility is practical at a particular site:

1. INDIVIDUAL BUILDING TEST: Locate an arrival point and entrance for each building or entry, and estimate the slope between them. If a line connecting these two points is steeper than 10%, access is deemed impractical. This test must be conducted both before and after regrading.
2. SLOPE ANALYSIS TEST: Calculate the percentage of the site sloped at grades steeper than 10%. This percentage is the percentage of ground floor units (with a minimum of 20%) that must be accessible.

DWELLING UNIT DESIGN

Dwelling units covered by the FHAA must be designed according to the FHAG. The difference between these requirements and the ANSI A117.1-1986 standard is substantial. Under the FHAG, the unit must be usable and include adaptable features but does not have to be fully accessible according to the ANSI standard. Planning decisions such as door and corridor widths and bathroom and kitchen layouts must meet certain standards, some not as restrictive as the ANSI standard. Items such as accessible plumbing fixtures and counters can be provided as required by specific owners and users.

Units covered by the law must have the following characteristics:

1. Usable doors to enter all rooms
2. An accessible route into and throughout the dwelling unit
3. Switches and controls mounted in accessible locations
4. Usable bathrooms with concealed reinforcing installed in the walls
5. Usable kitchens that permit wheelchair access

Certain design features, including level changes, are permitted. Intermediate levels (lofts) are permitted, although they are not precisely defined. In buildings equipped with elevators, multistory units must include a toilet on the accessible (ground) floor.

Changes in floor level are permitted if they can be defined as "design features" that do not interrupt the accessible route through the remainder of the dwelling.

ITEMS THAT TYPICALLY ARE NOT AFFECTED BY FHAG

1. Windows
2. Interior door hardware
3. Doors not used for passage
4. Fireplaces
5. Stairs
6. Upper floor levels
7. Lower floor levels
8. Closet shelving
9. Circuit breakers
10. Mechanical equipment
11. Individual garages
12. Lofts
13. Basements

NOTE

The number of sides exposed to light and air and whether they are adjacent can be used to describe all dwelling units.

UNIT DESIGN—POSSIBLE EXPOSURES

GENERAL

Before design of a housing project begins, a unit density and mix of types that suit the site must be determined. Units composing the mix are designed according to standards related to the sales price or monthly rental of the dwelling unit. Unit characteristics can be summarized as follows:

MINIMAL HOUSING: No foyer; combined living and dining; small bedrooms (80 sq ft); one bath.

AFFORDABLE HOUSING: Small foyer; combined living and dining; large bedroom may have private bath; other bedrooms share bath with common rooms; minimal storage.

LUXURY HOUSING: Foyer; living, dining, and family (or great) rooms; circulation in hall, some semiprivate rooms (study/sitting); ample to lavish master bedroom suite; other bedrooms share one or two baths; two- or three-car garage.

CUSTOM HOUSING: Large foyer; separate living, dining, and family rooms; porch; large kitchen and pantry; grand circulation; frequent redundant circulation (H&V); many semiprivate rooms; large bedrooms; multiple bathrooms; ample storage; staff service space.

IDENTITY FROM EXTERIOR

With the possible exception of deeply subsidized housing, all housing must survive in the market. This means the project must not deviate greatly from the demonstrated preferences of its market, although it must also offer an identifiable image or appearance.

This image, often called "curb appeal," is frequently defined for the architect by advertising and marketing specialists. In single-family houses, the house itself constitutes a statement. Attached houses also make individual statements, as well as developing community imagery for the potential tenant or buyer. In multifamily housing, the identity of the dwelling is submerged within the group and the individual unit is distinguished by its internal arrangement. Thus, group and individual identity must be defined and developed.

SIDEDNESS

Dwelling units always benefit when buildings are designed with a clear front or public side and a back or semiprivate side. Sidedness enables the cultivation of other contrasting characteristics such as ceremonial/intimate, open/closed, noisy/quiet, ornamented/plain, and urban/pastoral.

NOTE

Housing design should distinguish between public and semiprivate sides of the dwelling unit.

SIDEDNESS

BUILDING MASSING

DWELLING UNIT PLANNING

Dwellings of all sizes have common elements and sequences that must be identifiable.

ENTRANCE

Marketing concerns usually demand a dramatic spatial event at the moment of entry, whether a double-height foyer in a luxury house or a sweep of the living and dining areas in an apartment. However, the architectural organization of this event may require a transitional space, perhaps somewhat enclosed, as compression before expansion into the major semipublic areas of the unit.

CIRCULATION AND ROOMS

In large houses it is possible to separate circulation from the rooms served using devices such as corridors, passageways, foyers, vestibules, and the like. Circulation in smaller units occurs through rooms, most often living and dining rooms.

PLAN BALANCE

In dwelling unit design, all aspects of the plan must be proportional and consistent. A many-bedroom dwelling with living areas too small to accommodate all the occupants is problematic. So is the house with enormous living and dining areas but too few or too small bedrooms. Kitchens, general storage, and circulation must also be sized according to the number of occupants.

FOCUS

All good dwellings offer a hierarchy of experience culminating in a focus, which is commonly the living or living/dining area or family room/kitchen. This spatial focus is often enhanced by spatial definition and/or greater height and by features such as fireplaces (the hearth, of course, is the traditional center of the house), stairs, or access to outdoors.

NOTE

In small plans, circulation should occur through no more than two adjacent corners of living and dining rooms. After accounting for circulation, sufficient space should remain for reasonable furniture arrangements.

CIRCULATION

NOTE

Spaces defined by walls can be reinforced by articulation of the ceiling. Even in small units, ceiling drops and soffits can provide reinforcement of activity areas and spaces.

ARTICULATION OF SPACE

ACCESS TO EXTERIOR

Contemporary living requires connection to outdoor space by circulation where possible or at least by view. In apartments, where this connection may take the form of a balcony, it is usually made at the living room. But since a balcony reduces view and light, it may be placed at the bedroom instead, with access from the living room. Bedroom balconies are a luxury amenity.

UNIT PLAN AND BUILDING MASSING

Plan arrangement is related to building massing; by projecting and recessing adjacent rooms or parts of rooms, building mass can be broken down. Similarly, continuous alignment of exterior walls leads to large-scale massing and elevations in which surface elements such as windows and textured and colored surface areas can be used to compose and adjust scale.

Components such as balconies, storage closets, and fireplaces are often useful for composing elevations and massing, particularly when simplified plan geometries produce large, basic massing.

Ralph Bennett; Bennett Frank McCarthy Architects, Inc.; Silver Spring, Maryland

SITE PLAN CONSIDERATIONS

ACCESS

1. Where possible, points of access should connect and align with existing systems.
2. Many arrangements are possible with streets, courts, and freestanding buildings

PEDESTRIAN CIRCULATION

1. Pedestrian connections are necessary between apartments and common facilities and off-site facilities.
2. Usually parallels streets except where site plan offers rustic walks.

PARKING

1. Parking sites must be pooled or in structures.

RELATION TO TOPOGRAPHY

1. ADA and subdivision regulations dictate street and walk grades and mandate site reformation at all but the lowest densities.
2. Breaks between stairwell groups allow adjustment to the terrain.

COMMON FACILITIES

1. Rental and management offices are common for 50 units or more.
2. Pools and recreation facilities are common in complexes of more than 100 units.
3. Maintenance and storage facilities are common in larger projects.
4. Tot lots and play areas are required for complexes of 20 units or more in many jurisdictions.
5. RV and boat storage are offered in some areas.

SERVICE

1. Mail service and deliveries to stairwells or larger group boxes; trash to Dumpsters distributed in parking lots or other central locations.
2. Fire apparatus usually dictates road standards; sprinklers may permit reduced equipment access.

SITE PLAN

TECHNOLOGY

STRUCTURE

1. Wood frame.
2. Walls between stairwell groups must be masonry or heavy gypsum (2-hr rating).
3. Unit wall must be gypsum board on wood or steel studs (1-hr rating).
4. Second stair must be in rated enclosure.

MECHANICAL

1. Forced air, gas heat, or heat pump.
2. Compression refrigeration or heat pump cooling.
3. Larger units (two bedrooms or more) have centrally located furnaces with ducts and exterior condensers for heat pumps and refrigeration; smaller units may have through-the-wall units with no exterior condenser.
4. Sprinklers required in many jurisdictions.

Ralph Bennett; Bennett Frank McCarthy Architects, Inc.; Silver Spring, Maryland

WALK-UP HOUSING CHARACTERISTICS

TYPE	DENSITY RANGE (D.U./ACRE)*	CHARACTERISTICS
Through unit	Up to 17 (including off-street parking)	Permits sided site planning. Two exposures for each unit. Bedrooms or living areas can be oriented toward parking or view.
Back-to-back unit	Up to 20 (including off-street parking)	Efficient: 4 units per floor. As usually deployed, 50% of units face parking, 50% face view and green.

* D.U. = Dwelling units

THROUGH UNIT

BACK-TO-BACK UNIT

SINGLE-LOADED GALLERY ACCESS

DOUBLE-LOADED GALLERY ACCESS

WALK-UP APARTMENT CONFIGURATIONS

CONFIGURATION

Walk-up apartments are ubiquitous in the United States and come in many varieties. Their appeal lies in the great efficiency of their circulation. Two-story buildings are common and generally require only one stair. Three-story buildings generally require two stairs, one of which must be rated. Buildings higher than three stories present market problems but do exist. Combination walk-up buildings, with elevators going to higher stories, are common in Europe but are uncommon in the United States due to the higher proportional cost of elevators.

SITE PLAN CONSIDERATIONS

ACCESS

1. Entrances should, where possible, connect and align with existing systems.
2. Many arrangements are possible, including alleys, on-site parking, pooled parking, and on-street parking.

PEDESTRIAN CIRCULATION

1. Necessary to connect dwellings to common facilities and off-site facilities.
2. Usually parallels streets.

PARKING

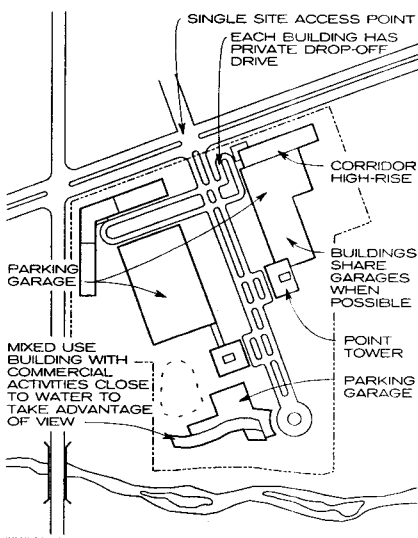

1. Has significant impact on density and appearance.
2. If not pooled, on-street essential for guests, overflow.

RELATION TO TOPOGRAPHY

1. ADA and subdivision regulations dictate street and walk grades, and mandate site reformation at all but the lowest densities.

SERVICE

1. Trash through chutes to compactor in trash room in basement or ground floor; mail to mail room on ground floor; delivery to units or security guard.
2. Fire marshal may request access around building depending on building height and sprinkler system.

SITE PLAN

TECHNOLOGY

STRUCTURE

1. Masonry or concrete, occasionally fire-protected steel.
2. A full range of high-rise building safety measures are required, especially for structures taller than nine stories, which is generally the maximum reach for rescue equipment.

MECHANICAL

1. Decentralized air, gas heat, or heat pump.
2. Compression refrigeration or heat pump cooling.
3. Larger units (two bedrooms or more) have centrally located furnaces with ducts and exterior condensers for heat pumps and refrigeration; smaller units may have through-the-wall units with no exterior condenser.
4. Large and/or luxury buildings may have central systems with boilers, central chillers, and a condenser and two- or four-pipe systems.
5. Sprinklers are required in many jurisdictions.

GROUND FLOOR PLANNING

Ground floors in elevator buildings are significantly different from ground floors in other housing structures because larger numbers of people pass through on the way to their dwellings and because the ground floor is a smaller proportion of the area of the building. Urban versions of the type offer opportunities for retail and commercial uses that can be accessed directly from the street.

DOUBLE-LOADED CORRIDOR SLAB

POINT TOWER

SLAB TOWER EXAMPLES

SLAB TOWER PLAN VARIATIONS

ELEVATOR APARTMENT CHARACTERISTICS

TYPE	CHARACTERISTICS
Double-loaded corridor (slab)	Units have only one exposure. Corridors are interior spaces. Units can be shallow and wide (lengthening corridors, but bringing much light into unit) or narrow and deep (shortening corridors but making a dark zone on the interior). Stairs are required at ends of corridors (limited dead ends allowed).
Single-loaded corridor (slab)	Less efficient than double-loaded corridor. Useful when oriented east-west because all units can face south. Corridor can be naturally illuminated.
Point tower	Efficient circulation because of small number of units/floor; scissors egress stairs can make circulation more efficient. Units can have two exposures. Casts minimal shadow on lower buildings.

Frequently, therefore, the ground floor of elevator buildings is set aside for common spaces and uses. Lobby and security; mail; meeting space; management offices; trash; and mechanical, electrical, and fire equipment frequently are located at grade. In urban situations, retail and commercial uses are appropriate.

If dwelling units are located on the ground floor, they can offer direct access to outdoors.

CIRCULATION VARIATIONS

In the great majority of elevator buildings, the double-loaded corridor is used, which produces a corridor on each floor. By using multifloor units, or by adding stairwell circulation up and down from elevator landings, the number of floors with corridors can be reduced by two-thirds and up to two-thirds of units can have two exposures. Fair Housing Accessibility Guidelines may prohibit some of these variations, especially the skip-stop.

CROSS-SECTION OF VARIATIONS IN CIRCULATION

Ralph Bennett; Bennett Frank McCarthy Architects, Inc.; Silver Spring, Maryland

GENERAL

Special populations require housing forms suited to their needs. Most significantly, small groups of people with special requirements tend to live together so that their needs can be met in a concentrated and efficient way. Facility size is often dictated by financial and operating considerations; the larger the facility, the more difficulty the designer has in making a residentially scaled environment.

Group residences are available for elderly persons, for persons in transition from addiction and psychiatric programs and from incarceration, for persons with terminal illnesses (hospices), and for those who may share another kind of common need.

These facilities typically provide a number of small, simple rooms along with common spaces that include living, dining, and food preparation areas, as well as recreational and administrative facilities.

A more complex group-housing arrangement recently imported from Scandinavia is co-housing—a form of group living that usually features more elaborate individual accommodations along with the common areas found in group homes.

SITE CONSIDERATIONS

1. Direct but controlled access is required from parking and transit facilities to a clearly identifiable entrance.
2. Views from unit windows become especially important in developments where residents spend considerable time in their unit.
3. A variety of views is desirable, from active streets to quiet landscapes. This gives tenants choice in otherwise uniform accommodations.
4. Solar orientation becomes important for such facilities: no unit should be without direct sun at some time during a winter day.
5. Since direct access to outdoors is rarely practical in such housing, exterior access from common spaces becomes more important. Such space should be agreeable for sedentary occupation—sunny but with shade and sheltered from the wind.

TECHNOLOGY

STRUCTURE

1. Single-story buildings can be wood frame in most jurisdictions if properly protected. Two-story or higher buildings must be masonry or protected steel in most jurisdictions.

MECHANICAL

1. Decentralized air, gas heat, or heat pump.
2. Compression refrigeration or heat pump cooling incorporated into through-the-wall units is often used.
3. Common areas have centrally located furnaces with ducts and exterior condensers for heat pumps and refrigeration.
4. Buildings such as hospices, where temperature and humidity control are crucial, use central systems with boilers, central chillers and condenser, and two- or four-pipe systems.
5. Buildings serving persons with special medical needs may require specialized HVAC systems for isolations.
6. Sprinklers are required in most jurisdictions.

SAFETY

1. Systems to announce and report emergencies as well as accommodations for egress are strongly related to the level of assistance required to allow residents to exit the building. The more assistance required, the more extensive the measures required.
2. Building code and fire safety requirements for special needs housing are complex and changing. Protected construction, sprinklers, and supervised fire and smoke alarm systems are generally required.
3. Precautions above this level are dictated by the occupants' ability to perceive danger and act to remove themselves from it. Corridor widths, exit requirements including horizontal exits, separations between dwelling and corridor, and resident staff requirements are all subject to negotiation with local authorities, using model codes as the basis.
4. Local building code authorities should be consulted early in the design process.

NOTE

This 14-unit facility is divided into two clusters of seven rooms, each cluster is served by a lounge and a spa (a room for bathing and personal care). Common facilities include a large living room, kitchen with snack bar, and administration and staff facilities including a residence for the manager. Rooms offer varying aspects from a busy road to a semi-enclosed garden off the common living room to distant landscape views.

HOSPICE RESIDENCE, MONTGOMERY HOSPICE, INC.; OLNEY, MARYLAND
BENNETT FRANK MCCARTHY ARCHITECTS.

NOTE

This 36-room group home is designed for elderly persons suffering from Alzheimer's disease and dementia. Each group and subgroup of units has its own vivid and distinct visual identity. Easily accessed outdoor space is controlled to limit wandering. The plan is organized to permit supervision by limited staff.

EXAMPLES OF SPECIAL NEEDS HOUSING

Ralph Bennett; Bennett Frank McCarthy Architects, Inc.; Silver Spring, Maryland

INTRODUCTION

Solid waste disposal has become a critical issue for society. Landfills and other waste disposal facilities are reaching capacity and siting new facilities is difficult due to environmental and health concerns, including water pollution, loss of wetlands, poisoning of the soil, and the breeding of vermin. As a result, traditional methods of handling solid waste are becoming more costly. Reducing landfill waste extends the life of existing facilities and lessens the need to build new facilities.

Much of what we have called "waste" is not waste, but marketable materials that can be reused to make new products. Reusing materials already extracted from the earth enables sustainable use as raw resources are depleted. Products require great amounts of energy to be produced from raw natural materials. By recycling we are recapturing energy embodied in a material during initial manufacturing processes. Sorting and recycling waste often reduces operating and disposal costs while conserving natural resources and energy.

Most states and municipalities have laws and programs to encourage waste reduction and recycling, including mandatory quotas, deposit/return arrangements, and disposal bans. Buildings should include the spaces necessary to carry out recycling and waste management programs. Once the waste and recyclable materials generation of a building's users are determined, spaces can be designed for sorting, storage, and removal.

RECYCLABLE MATERIALS

Separating materials by category or product is the first step in recycling (see table at right). Materials are sorted into like kinds to prevent contamination. Contaminated materials are less readily recyclable and therefore less marketable. Sorting is particularly important for paper and glass. Cleaning food packaging of organic material is usually necessary. Some recyclers will accept "commingled" or mixed waste and will sort and clean materials by hand or by mechanical means. (Paper is easily contaminated and can never be recycled this way; it must always be separated from other waste materials.) Communities that pick up commingled recyclable materials have enjoyed a greater participation rate since it requires little, if any, change in waste disposing habits. However, sorting of recyclable materials at their generation point is less labor intensive and produces higher quality, less contaminated reprocessed materials.

SYMBOLS

The recycling symbol signifies the three steps of the recycling loop: collecting materials, manufacturing new products, and selling and using recycled products.

In the marketplace, the recycling symbol is marked on products in the following way:

This conformation of the symbol is used to identify items made from materials that can be recycled.

This conformation of the symbol is used to identify products made entirely or primarily from recycled materials.

PLANNING AND DESIGN

When planning a project, make a waste analysis based on the building type or building users and address the following issues:

1. Source generation: identify types and quantities of waste material likely to be generated.
2. Collection and sorting: determine space and equipment needed for the collection and/or separation of waste materials.
3. Disposal: determine the frequency and means of the remover or recycler to collect the waste.

Richard J. Vitullo, AIA: Oak Leaf Studio; Crownsville, Maryland
Tom Lokey: Northeast Maryland Waste Disposal Authority; Baltimore, Maryland

RECYCLABLE MATERIALS

CATEGORY	PRODUCT	MATERIAL DESCRIPTION (RECYCLING LABEL)	CONVERSION OF VOLUME TO WEIGHT
Paper	Ledger paper, white letterhead	SWL - sorted white ledger (high-grade white paper)	Uncompacted - 1 cu yd = 500 lb Compacted - 1 cu yd = 750 lb
	Computer paper	CPO - computer printout	Uncompacted - 1 cu yd = 500 - 600 lb Compacted - 1 cu yd = 1000 - 1200 lb
	Colored paper	SCL - sorted color paper	Uncompacted - 1 cu yd = 500 lb Compacted - 1 cu yd = 750 lb
	Newspaper	Mix - newsprint	Uncompacted - 1 cu yd = 350 - 500 lb Compacted - 1 cu yd = 750 - 1000 lb
	Magazines	Mix - clay-coated paper	Not available
	Telephone books	Mix - mixed papers/adhesives	1 book = 1 - 3 lb
	Cereal boxes	Mix - coated paperboard	Not available
Glass	Shipping boxes	OCC - old corrugated cardboard	Uncompacted - 1 cu yd = 285 lb Compacted - 1 cu yd = 500 lb
	Food jars, beverage bottles	1. Amber glass 2. Green glass 3. Clear glass	Loose, whole - 1 cu yd = 600 lb Manually crushed - 1 cu yd = 1000 lb Mechanically crushed - 1 cu yd = 1800 lb
Plastic	Beverage containers	PET - polyethylene terephthalate	Whole - 1 cu yd = 30 lb
	Milk containers	HDPE - high-density polyethylene	Whole - 1 cu yd = 25 lb Crushed - 1 cu yd = 50 lb Compacted - 1 cu yd = 600 lb
	"Clamshell" containers	Polystyrene plastic foam	Not available
	Film plastic	LDPE - low-density polyethylene	Not available
Metals	Beverage cans	Aluminum/bi-metal	Whole - 1 cu yd = 50 - 70 lb Crushed - 1 cu yd = 300 - 450 lb
	Food and beverage cans	Steel with tin finish	Whole - 1 cu yd = 125 - 150 lb Crushed - 1 cu yd = 500 - 850 lb
Miscellaneous	Pallets	Wood	Not available
	Food waste	Organic solids and liquids	55 gallon drum - 415 lb
	Yard waste	Organic solids	Leaves, uncompacted - 1 cu yd = 250 lb Leaves, compacted - 1 cu yd = 450 lb Wood chips - 1 cu yd = 500 lb Grass clippings - 1 cu yd = 400 lb
	Used motor oil	Petroleum product	1 gallon = 71 lb
	Tires	Rubber	1 passenger car = 20 lb 1 truck = 90 lb

NOTE

No building or facility will need space for sorting and storing all or even most of the recyclable materials on this list. Generally paper products should be separated from other

wastes. The number of products to be sorted within a category should be limited for most users; sorting more than two products may result in contamination.

An effective recycling system in the home, school, or workplace integrates materials sorting with the regular collection of waste. Convenience of use is essential. Recycling systems should be as easy to use as a conventional waste basket (and be usable by the elderly and persons with disabilities). Provide extra space alongside regular waste containers for separating and storing recyclable materials. Conveying systems like waste chutes may also be provided. Collection bins should be clearly distinguished by using different-sized containers and effective graphics; differentiation will encourage proper use and reduce contamination, a serious recycling problem.

NONRESIDENTIAL BUILDINGS

In most commercial and educational buildings, paper is the predominant recyclable waste product (70%+). Paper is readily recyclable into consumable form. High-grade paper, like bond, is used in great volumes and is a generally marketable recycling commodity. Since paper can be easily contaminated, its separation from other waste is critical.

In health care facilities, biomedical waste must be separated from all other wastes and is generally collected and incinerated by waste disposal specialists. Biomedical waste collection spaces should be provided apart from general waste and recycling spaces.

The design of recyclable waste collection rooms used by individual employees, visitors, students, etc. should adequately accommodate the volume of waste generated. Larger waste collection rooms require less frequent removal resulting in lower labor costs. Collection bin sizes should be based on the material weight-to-volume ratio. For example, office paper has a high weight-to-volume ratio; a 96-gallon container, or equivalent, may be the largest one practicable. Collection containers should be placed adjacent to areas where waste materials are generated. Place bins for recycling paper in copy and computer rooms; place bins for glass, metal, and plastic in kitchens, vending rooms, lounges, etc. If waste chutes are used, they should be similarly placed. Manual crushers should be mounted near bins

for low weight-to-volume materials (such as aluminum cans and plastic bottles) to help reduce space requirements. Most collection areas should be neat and ordered in appearance as befits most office environments.

In some high-rise office buildings, the service core near the maintenance closet and freight elevator can house a secondary waste storage or chute area. Tenants or service personnel deposit waste and recyclable materials there regularly. Since this is a holding area accessible only to a few building occupants, the space can be utilitarian in appearance.

Consult local building codes regarding fire separation or sprinkler requirements for storage rooms, especially for combustibles like paper.

Once you determine the quantities, number of separations, etc. of a building's waste, design the central storage/disposal space. See illustrations for a typical layout of a large office building space and loading dock area. These layouts can be used for other building types that handle a similar volume of waste. Waste chutes and compactor/balers are used where the building configuration, removal service, and/or waste volume warrant it.

MINIMUM EXTERIOR TRASH AND RECYCLING AREAS FOR NON-RESIDENTIAL BUILDINGS

BUILDING SIZE (SQ FT)	TRASH (SQ FT)	RECYCLABLE MATERIALS (SQ FT)
0 - 5,000	12	12
5,001 - 10,000	24	24
10,001 - 25,000	48	48
25,000 +	Each additional 25,000 sq ft requires 48 sq ft each for trash and recyclable materials	

SOURCE GENERATION*

CLASSIFICATION	BUILDING TYPES	QUANTITIES OF WASTE GENERATED	TYPES OF WASTE GENERATED
Residential	Studio or one bedroom apartment	1 - 1 1/2 cu yd per unit per month (200 - 250 lb)	Newspaper (38/43) ¹ Plastic (18/7) ¹ Miscellaneous (13/18) ¹ Metals (14/9) ¹ Yard waste/compost (10/15) ¹ Glass (2/8) ¹
	Two or three bedroom apartment or single family house	1 1/2 - 2 cu yd per unit per month (250 - 400 lb)	
Commercial	Office, general	1 1/2 lb per employee per day or 1 cu yd per 10,000 sq ft per day (includes 1/2 lb of high-grade paper per person per day)	Plastics, compost, used oil, metals, and glass (30%) ² High-grade paper (29%) ² Mixed papers (23%) ² Newspapers (10%) ² Corrugated cardboard (8%) ²
	Department store	1 cu yd per 2500 sq ft per day	Corrugated cardboard, compost, wood pallets, high grade paper, and plastic film ³
	Wholesale/retail store	Varies with type of tenant	
	Shopping center	Varies with type of tenant	
	Supermarket	1 cu yd per 1250 sq ft per day	Corrugated cardboard, compost, and wood pallets ³
	Restaurants/entertainment	Varies with number of meals served and type of food	Compost (38%) ² Corrugated cardboard (11%) ² Newsprint (5%) ² High-grade paper (4%) ²
	Drugstore	1 cu yd per 2000 sq ft per day	Corrugated cardboard and high grade paper ³
	Bank/insurance company	Survey required (3/4 lb high-grade paper per person per day)	High-grade paper, mixed paper, and corrugated cardboard ³
Hotel and motel	High occupancy	1/2 cu yd per room per week (plus restaurants)	Glass, aluminum, plastic, high-grade paper, newspaper, and corrugated cardboard ³
	Average occupancy	1/4 cu yd per room per week (plus restaurants)	
Institutional	Hospital	1 cu yd per 5 occupied beds per day	Compost, high-grade paper, biomedical waste, corrugated cardboard, glass, and plastics ³
	Nursing home	1 cu yd per 15 persons per day	
	Retirement home	1 cu yd per 20 persons per day	
Educational	Grade school	1 cu yd per 8 rooms per day	High-grade paper, mixed paper, newspaper, corrugated cardboard, compost, plastic, glass, and metals ³
	High school	1 cu yd per 10 rooms per day	
	University	Survey required	

NOTES

1. Percentage by volume/percentage by weight.
2. Percentage by volume.
3. Percentages not available.

4. This table approximates by building type the quantity and type of waste generated; the information should be used as a guideline only. Volume (using varying weights per cubic yard) is derived from nationwide U.S. averages of noncompacted waste.

MULTIFAMILY HOUSING

Diverse types of waste are generated in the home; this waste is compounded in multifamily apartment buildings. Waste and recyclable materials often contain organic materials that can attract rodents and insects and produce odors that must be controlled or segregated from the surrounding area. Resident's glass, metal, and plastic materials need to be washed or sealed in containers before placing in collection bins. Consult local health, fire, and building codes regarding these storage areas; sprinklers may be required.

A two-part system is recommended for an effective recycling program in high-rise residential projects. First, provide space in the home kitchen area to collect recyclable and waste products. For multifamily housing, each dwelling unit should have a total of 5 cu ft minimum set aside for waste storage (2.5 cu ft for trash and 2.5 cu ft for recyclable materials). Second, provide convenient space on each floor for sorting and/or deposit of materials. Freight elevator bays or maintenance rooms are usually good locations. In low-rise multifamily buildings or complexes, a central interior space may be desirable. The closer it is to the regular waste drop-off point the better.

In some situations, waste chutes provided on each floor can be effective, especially if deposit space is limited. Two waste chute systems are available. One consists of multiple, separate chutes for trash, metal, plastic, and newspapers. The other is a single waste chute that handles all of the waste, which is "sorted" by a computerized revolving bin in a central storage room. Corrugated cardboard and glass usually cannot be accommodated by the chute system because of jamming and breakage, respectively. Glass also requires color separation and is best handled by other collection methods.

Central storage spaces for recyclable and waste materials may be placed in a variety of locations depending on the layout of the building or complex. When no secondary spaces are possible or practicable for waste drop-off, residents must drop off recyclable and waste materials at a central site. The options for this site are as follows:

SINGLE EXTERIOR SITE

Place compartmentalized recycling dumpsters or 90 gallon carts in one central location. This system, easiest for the maintenance staff and the remover, is the least expensive method. However, this is the least convenient arrangement for residents, and a large area on the site may be required.

MULTIPLE EXTERIOR SITES

For larger building complexes, place recycling bins or compartmentalized dumpsters adjacent to a conventional waste disposal site. Keep bins separate and clearly marked. Minimum maintenance is required for this layout, designed to be convenient to residents by providing multiple locations. Removal costs may be somewhat higher than a single collection site.

Exterior storage areas are generally prohibited in required front yards, street sideyards, or required parking and landscaped areas. Check local zoning, fire, and building codes.

SINGLE INTERIOR SITE

A recycling area can be set up at an interior location using separate containers on wheels - 32-gallon containers, 55- or 90-gallon drums - to collect and store waste and recyclable materials. This central collection area should be convenient to residents, near elevator lobbies, mailrooms, chuterrooms, ends of hallways, or in other common areas like laundry rooms, lounges, or lobbies. If no space is available in any of these locations, use a single storage room that meets code requirements.

MINIMUM INTERIOR OR EXTERIOR TRASH AND RECYCLING AREAS FOR MULTIFAMILY HOUSING

NUMBER OF UNITS	TRASH (SQ FT)	RECYCLABLE MATERIALS (SQ FT)
2 - 6	12	12
7 - 15	24	24
16 - 25	48	48
25 +	Each additional 25 dwelling units require an additional 48 sq ft for both trash and recyclable materials	

SINGLE-FAMILY HOUSING

Generally, issues regarding collection of recyclable and waste materials in the single-family home are similar to those within an apartment. Sorting of recyclable materials is often accommodated in kitchen base cabinets, especially under the sink, in a trash cabinet "island," or in a nearby utility closet. Most cabinet manufacturers offer a specially designed base cabinet to handle recyclable and waste materials. If organic materials are collected for composting, odors and vermin must be addressed as well as the ability to clean the collection bins. Garages may include recycling storage areas or closets; if adjacent to kitchens, a pass-through system with closable doors can be built.

BALER/COMPACTOR

NOTES

1. All baler dimensions are approximate and vary depending upon the manufacturer. Typical bale sizes (in inches) are: 18 x 18 x 18, 20 x 24 x 18, 30 x 24 x 20, 48 x 30 x 42, 60 x 30 x 48, and 72 x 30 x 48
2. To determine whether a baler is needed, consult a recycler to analyze probable waste quantities. Balers can make recycling more efficient by saving space. For example, if the volume of cardboard boxes is high in a certain building, balers can greatly reduce the amount of storage space needed. The baling of such waste as metal cans, plastic bottles, paper, or cardboard may make the recyclable materials more marketable by increasing trailer payloads.
3. Some balers expand by linking bins together to accommodate a variable recycling program. A sliding ram mechanism will service each bin.

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland
Tom Lokey; Northeast Maryland Waste Disposal Authority; Baltimore, Maryland

DISPOSAL

To determine waste and recyclable material removal arrangements for a project, contact the municipal or county environmental office for local regulations or guidelines for collection programs. If private arrangements must be made, contact local removal and recycling companies that could service the building. The container type and size compatible with collection vehicles should be noted and provided for in the design. Since recycling is an industry in its infancy, provide extra storage space in or near the building to accommodate future needs.

Some building types, such as grocery stores, generate a large amount of bulky corrugated cardboard, requiring compacting and/or baling. Materials of large volume to weight ratios, such as metal cans and plastic bottles, if not crushed manually at their generation point, may be compacted at a central storage room. The volume of material collected and the number of trips the remover needs to make will generally indicate the cost-effectiveness of a crusher or baler.

GENERAL

Distribution facilities are highly efficient operations in which products are stored and from which orders are filled and shipped to meet customer demand. Distribution facilities house raw materials, parts, or finished products, most commonly at the manufacturing or distribution level. This storage, all along the supply chain, from raw material to product delivery, adds cost, which can be reduced by efficient distribution practices and facilities.

Distribution facilities are designed from the inside out. That is, the size and shape of the product determines how the facility will be operated and what form the building will take. Storage volume can be increased much more cheaply by increasing the height of a building than by increasing its footprint. Column layouts must accommodate a combination of rack types and allow for changes in rack type. Mixed rack types may be placed together in one storage area.

In addition to storage areas, distribution facilities require a battery charging area, a maintenance area, shipping and receiving offices, other business offices, utility equipment spaces, and truck and rail docks.

Truck loading docks are high traffic areas and should be segregated from pedestrian traffic. Railroad access is less commonly required than in previous decades, but when rail sidings are included, the track elevation and geometry control the warehouse location and elevation of the floor.

Most new facilities are built so it will be easy to double the storage area at a later date. Expansion requirements usually direct the organization of storage areas, as it is difficult to expand through a loading dock and disruptive and expensive to expand through utility spaces or offices.

NOTE

Identical items are usually packed together to form a case. Typically, cases of only one SKU are stored on a pallet to make a unit load. Heights vary according to gross weight, product durability, and manageable size. The pallet illustrated is used by the Grocery Manufacturers Association.

TYPICAL GMA PALLET

STORAGE BASICS

The stored product is the module that determines an efficient warehouse size. To provide uniformity in the industry, a common unit load format has developed using a pallet as the tool for shipping, storing, and receiving product. The palletized unit load is now the modular building block from which 90 percent of warehouse dimensions are derived.

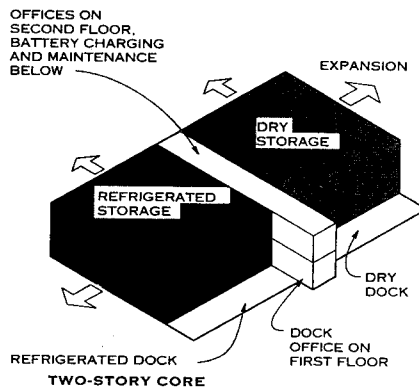

The most common method of handling products uses a standardized Grocery Manufacturers Association pallet. Different product combinations can be packed on a single pallet. For identification, each product is called a stock keeping unit (SKU), although the same product in different packaging, or with different cost structures, can be identified as a distinct SKU.

When a unit load is stackable and large amounts of the same SKU are stored in one place (typical at a manufacturing facility), unit loads can be stacked on the floor. Typically, these stacks are no higher than 3 ft in lanes no deeper than 12 unit loads from front to back. Unit loads are also stored in pallet racks. Typically made of steel (cold-rolled or formed), racks are available in numerous types. The type of pallet rack appropriate for any application depends on the variety, quantity, and movement (velocity) of the unit loads being stored and retrieved.

In a typical distribution facility, the contents are rotated ten to twenty times a year. However, depending on many factors, this "inventory turn" number may vary from two turns to 52 turns for perishable products (52 turns means an average product storage time of about a week).

Distribution center management seeks to minimize construction costs by increasing product movement (turns) and choosing storage layouts that minimize the building footprint. It is less expensive to build taller buildings for vertical storage than to increase the building footprint; however, it may be more labor intensive to access very high storage areas. Moving unit loads in and out of pallet racking is very different from selecting cases or individual items from unit loads.

Most distribution centers receive product in full unit loads. Some ship full unit loads, while others ship smaller numbers of cases or less than case quantities. Most distribution centers ship a combination of full unit loads and smaller quantities.

NOTE

Grocery distribution facilities exemplify distribution to retail outlets, demonstrating the complexity involved in storing products with varying requirements. Grocery facilities often require five or more coolers with different temperatures, a freezer, and an ice cream freezer, as well as a heated storage area and special fruit-ripening rooms. The building configuration is determined by the temperature-conditioned space requirements.

Illustrated are four configurations for a grocery distribution facility. In each, the architectural plan has been designed

around the facility operation. The storage rooms, with their varying conditions, complicate the space layout. Also, because each space may expand independently, planning for future expansion must consider each space individually.

Refrigerated space is a specialized single use space and, as such, can double the cost of constructing warehouse space. Refrigerated rooms, particularly freezers, should not open directly into unconditioned environments. Typically a refrigerated dock serves as a buffer between these rooms and nonrefrigerated spaces.

NOTES

1. The rack layout used determines the building column spacing. Often, the column layout accommodates combinations of different rack types.
2. An even number of selection aisles is preferable so the selection path begins and ends on the dock or at the order assembly area.

TYPICAL WAREHOUSE PLAN

TYPICAL GROCERY DISTRIBUTION FACILITIES

St. Onge, Ruff and Associates, Inc., York, Pennsylvania

TYPICAL DISTRIBUTION FACILITY CROSS-SECTION

TYPICAL PALLET STORAGE RACK

TYPICAL DISTRIBUTION FACILITY CROSS-SECTION

The cross-section of a distribution facility is determined by the storage height requirement and the roof slope. Some building codes require a minimum roof slope of 1/4 in./ft.; a roof slope of 1/8 in./ft. is the minimum for most roof systems.

Because internal roof drainage is expensive, it is preferable to drain the roof using downspouts at the building perimeter.

Depending on the combustibility of the stored product, in-rack sprinklers are required for most storage rack systems. Except in refrigerated spaces, ESFR (early suppression fast response) sprinklers installed at the ceiling can be used in lieu of in-rack sprinklers.

ESFR sprinklers impose a height limitation on warehouses where they are used. They limit the roof height to 40 ft and the top of the stored product to 35 ft.

TYPICAL PALLET STORAGE RACK

Although pallet racking design often depends on the height and footprint of a building, it is preferable for this relationship to be the other way around. Distribution centers should be designed "inside out" so the warehousing and material handling needs are free of external constraints. In any case, applicable building codes and fire protection guidelines (NFPA standard 231C) must be followed. Building clearances must allow for lights, steel, etc. but should not be excessive to avoid wasting storage space (measured in cubic volume).

PALLET STORAGE HEIGHT REQUIREMENT

TYPICAL DISTRIBUTION CENTER FLOW CHART

St. Onge, Ruff and Associates, Inc.; York, Pennsylvania

TYPICAL STORAGE ARRANGEMENT TYPES

The storage modes illustrated accommodate a wide range of uses. Floor stacking unit loads is the simplest method because it involves no special equipment except the device used to transport the loads. The unit load racking illustrations demonstrate a gradual increase in storage and move-

NOTE

One-deep (single) or selective racks are the most commonly used. They are typically constructed with two unit loads per storage bay (the space between uprights). When this rack is used, one unit load sits on each side of the aisle.

For product in large groups or lots, two-deep racks may be used to allow for more product in the building footprint. Two deep racks require the use of a vehicle capable of reaching into the rack for the inner unit load. Push-back racks are an alternative arrangement that is similar in plan.

ONE- AND TWO-DEEP LOAD RACK LAYOUTS

NOTE

Drive-in racks, which are one unit load wide, are used to store large quantities of the same unit load. The unit load rests on rails that extend the depth of the rack. Drive-in racks have unit load depths of two or more (3 units are illustrated). To access inner loads, a fork truck must be driven into the rack between the rails that support the unit load.

DRIVE-IN UNIT LOAD RACK LAYOUT

ment philosophy. Rack systems require specialized equipment that can access all levels of storage and work efficiently in the aisles. Building columns, in-rack fire protection, and utility lines must be considered when laying out a storage system. When racking is placed back-to-back in a warehouse, a minimum space of 6 in. may be required between racks for in-rack sprinkler system piping or 18 in. for building columns.

NOTE

VNA rack layout is similar to one-deep racks except the aisle is narrower, which both saves space and places opposite sides of the aisle within reach of a specialized order picker. An employee riding the vehicle can select cases from unit loads on the floor and from each of the overhead storage positions. The narrow aisle also requires special equipment for loading. Allow 16 ft clear at the front of the aisle and 12 ft at the rear for VNA vehicle access.

VERY NARROW AISLE (VNA) RACK LAYOUT

NOTE

Floor stacking of unit loads does not require racks, which can save capital costs. However, floor-stacked product is not easily selected as the stacks can only be reached from the top tier. Unit load characteristics usually limit stacking heights to three high. Floor stacking is most often used when large quantities of the same unit are stored.

THREE-DEEP UNIT LOAD FLOOR STACK LAYOUT

BUILDING AREA (SQ FT) PER PALLET POSITION*

TYPE OF STORAGE	STORAGE HEIGHT BY UNIT LOAD					
	2	3	4	6	8	12
4 deep floor stack	11.5	7.6	-	-	-	-
6 deep floor stack	10.4	7.0	-	-	-	-
Single deep	18.9	12.6	9.5	6.3	-	-
2 deep (MDR)	15.6	10.4	7.8	5.2	-	-
3 deep (MDR)	13.9	9.3	6.9	4.6	-	-
2 deep push back	14.4	9.6	7.2	4.8	-	-
Double deep	14.4	9.6	7.2	4.8	-	-
VNA (turret truck)	-	-	-	5.2	3.9	-
AS/RS (single deep)	-	-	-	-	2.1	1.4

*Storage area only, does not include end aisles or intermediate cross aisles.

NOTE

The square footage in a building footprint occupied by each unit load decreases as stacking height increases, since a vertical stack of unit loads occupies the same floor space as a single load of the same dimension. A reduction in aisle width from the combination of rack usage and equipment type could also reduce building square footage.

NOTE

Unit loads are assembled (or palletized) either manually through case stacking or with an automatic palletizing machine. The tiers of cases in the unit load illustrated are rotated 180 degrees from the adjacent tiers; the interlocked cases stabilize the load.

TYPICAL UNIT LOAD

NOTE

Automated storage and retrieval systems (AS/RS) incorporate an unmanned storage and retrieval machine or SRM (described in AGS chapter 14). Allow 15 ft minimum clear space at the front runout and 25 ft minimum at the rear for crane access. AS/RS systems, which are often 80 ft tall, automate the distribution operation and can store more unit loads in a smaller space than other rack systems. Often, the AS/RS rack system serves as the building structure as well.

AS/RS RACK LAYOUT

St. Onge, Ruff and Associates, Inc.; York, Pennsylvania

GENERAL

Cold storage distribution facilities are differentiated from other distribution facilities because they are refrigerated. In addition to the requirement for mechanical refrigeration to provide a cold environment, the construction of these buildings is very different. The cooler or freezer rooms must be well-insulated to reduce energy costs; gaps in the thermal envelope are not acceptable. The low temperatures also cause a vapor drive toward the refrigerated space, which requires that the thermal envelope have a continuous vapor barrier to prevent condensation or frost in the cold space. Specialized materials and details are needed to construct a hermetically sealed vapor envelope.

NOTES

1. Small coolers and freezers may be constructed with insulated panels inside a weatherproof building shell. Often these are prefabricated units.
2. The least costly way to build coolers and freezers is to use the walls, roof, and floors of the building as the thermal envelope. This envelope must be vapor-tight and have continuous insulation, particularly at the corners and across penetrations of the envelope. To achieve this requires an extensive amount of specialized detailing and craftsmanship.
3. For rooms with temperatures below 32°F, insulation and subfloor heating must be considered.
4. Refrigeration evaporators must be placed with consideration for maintenance access, effective air circulation, noise, and protection from vehicle or product damage.
5. Air units and piping must be protected from damage, especially when ammonia refrigeration is used. The ammonia hazard inside a building can be reduced by locating the ammonia piping and valves above the roof.
6. Dock areas are subject to a great deal of air infiltration because of the openings for trucks. Select dock equipment that will minimize this infiltration. Refrigerating the dock reduces the amount of moisture vapor that reaches the interior freezer.
7. Dock temperatures below 32°F require features that prevent frost accumulation at truck openings. In cold climates, refrigerated docks may also require heating.

SPACE RELATIONSHIPS

GENERAL

Food processing facilities process raw materials into either a single food product or a common line of food products, each processed according to its own specifications. Several types of process facilities are described on this page:

1. Fluid processing of products such as milk, beverages, or concentrates
2. Meat, poultry, and fish processing, ranging from slaughter operations to packing individual meat portions for retail sale
3. Fresh or frozen baked goods
4. Cereals and other grain products
5. Fresh, canned, and frozen vegetables
6. Snack foods and sugar and confectionery products
7. Specialty items and food additives

TYPES OF FOOD PROCESSES

Each food product can be handled and processed in a variety of ways to produce various end products. For example, fresh vegetables can be canned or frozen for easier distribution and longer shelf life. Food processing facilities can be designed to handle each process in several ways:

1. Batch: In a batch operation the product flows through the process in distinct steps or stages. For example, soups may be cooked in a kettle or juice may be mixed in a large tank before it is packaged.
2. Continuous flow: In this operation the product flows through the process in a continuous stream. For example, milk is produced in a continuous fashion from pasteurization to bottling.
3. Combination of batch processing and continuous flow: A product may begin in a batch form and be finished in a continuous flow. For example, cake batters can be mixed as a batch and then transferred to an oven for continuous baking.

Many products can be processed either in a batch or in a continuous flow mode. For example, juice can be produced from concentrate by mixing a batch in a tank or by mixing it with water in a continuous stream. Higher production runs usually can justify the additional expense of complex equipment needed to run a continuous process.

TYPICAL PROCESS FACILITY AREAS

Depending on the food processed and the way it is processed, a typical food manufacturing facility may contain several or all of the following functions:

RECEIVING

1. Raw materials such as milk, flour, and granular or liquid sugars can be received in large quantities, either by truck or rail car, and placed in bulk storage tanks.
2. Raw materials are also received on pallets delivered by trucks to loading docks.
3. Materials can also be received in reusable totes and bulk containers. Packaging supplies usually are received on pallets delivered by truck.

STORAGE

1. Storage of finished products should be minimized to achieve maximum shelf life in retail stores. Many products are processed and loaded directly onto trucks without being stored in the plant.
2. Many food products must be stored frozen to gain maximum shelf life. Ice cream products are usually stored at -20°F. Some finished products, such as milk, must be tested before distribution to confirm regulation compliance.

SHIPPING

Trucks can be loaded with fork trucks or pallet jacks. Some processes lend themselves to staging an entire truckload on the dock and automatically transferring it to the truck.

ADMINISTRATIVE AREAS AND EMPLOYEE AMENITIES

Administrative offices support the operations of the plant. Lockers and toilets should be provided so that workers can properly prepare themselves before entering the processing areas. An access hallway is sometimes required to limit entry to sensitive processing areas. Additional sanitary measures may be required in some process spaces.

Lunchrooms, computer rooms, quality control, research and development, and maintenance are other functions typically located in these areas.

RAW MATERIAL HOLDING

1. Some raw materials need to be quarantined before they are released for processing. This holding period allows the product to be tested for bacteria or impurities before processing.
2. Dry storage areas are provided for packaging goods and raw materials that do not need to be kept cool or frozen.
3. Refrigerated storage areas can be for fresh or frozen products that would spoil if not refrigerated. Refrigerated rooms may need to be divided to prevent cross-contamination of raw materials. For example, raw meat species need to be separated.
4. Tempering rooms are provided to thaw frozen materials before they are sent to production. Some raw materials requiring tempering include meats and frozen fruits.

PROCESS PREPARATION, MIXING, BATCHING, AND BLENDING

1. Most raw materials that are prepared for use in recipes or food processes need to be unboxed, debagged, sorted, weighed, and measured. Raw vegetables must be cleaned and washed. A convenient location needs to be provided to remove trash.
2. To make a food product, several raw ingredients may need to be mixed together. Ingredients such as preservatives and artificial colors and flavors may be weighed separately in a prebatching room.

CUTTING, BAKING, COOKING, AND COOLING

Examples of these functions include:

1. cutting steaks and roasts from larger beef portions.
2. baking cake products in continuous ovens.
3. cooking soups and sauces in batches in large kettles.

PACKAGING

Finish goods can be packaged manually into boxes or be handled by automatic packing equipment.

PROCESS FLOW

A well-designed food processing facility will aid in maintaining sanitary conditions and ensuring production of a safe food product. Typically the facility is wrapped around process functions. The ideal process facility would consist of a process flow that proceeds in linear fashion straight through the facility as shown in the accompanying plans.

A straight-through facility:

1. minimizes cross-traffic.
2. minimizes the potential for cross-contamination of raw and cooked products.
3. eliminates confusion between receiving and shipping functions.

Not all sites lend themselves to a straight-through flow. A U-shaped plan, for example, means the product is received and shipped from the same side of the building.

PROCESS FLOW LAYOUT TYPES

PRECAST CONCRETE

CMU WALL AND STEEL JOIST WITH SUSPENDED CEILING

NOTES

1. In general, sanitary finishes must be hard, durable, smooth, and easy to clean. Food processing rooms should be free of any hidden areas or ledges that may hinder cleaning and sanitizing.
2. Precast concrete tees are often used on process rooms. One disadvantage is that all piping and utilities are exposed and must be cleaned regularly.
3. Precast concrete with a smooth, void-free surface provides a hard surface and is usually sealed to provide good chemical resistance.
4. Monolithic coatings of epoxy and other types of materials are trowel applied in 1/8 to 1/4 in. thickness to provide better resistance to harsh process environments.
5. Fiberglass-reinforced panels or galvanized metal wall panels provide a hard, cleanable surface.
6. Sealed concrete provides minimum protection from processes and clean-up chemicals.
7. Suspended ceilings composed of stainless steel grids and panels provide a cleanable surface. One disadvantage of this type of finish is that the space above must be properly ventilated.
8. Epoxy-painted concrete masonry units (CMUs) provide a resistant surface if "pinholes" are filled to prevent places where bacteria can grow.
9. Ceramic tile or glazed CMU with epoxy joints provides the most durable and long-lasting process room finish.
10. Brick pavers generally provide the best resistance to harsh process and cleanup chemicals. Fill joints with cementitious material or a more chemical and heat resistant material like Furan (a specialized concrete mix).

SANITARY FINISHES ON BUILDING MATERIALS

SANITARY DESIGN

Various government organizations regulate food processing facilities, including the U.S. Department of Agriculture (USDA), the Food and Drug Administration (FDA), and state and local health departments. These organizations attempt to curtail three potential food hazards:

1. Bacteria: Many food products are susceptible to environmental or in-plant contamination. Bacterial cross-contamination of a product can occur when raw products and cooked products are in close proximity. Food processing plants should be arranged to eliminate this possibility.
2. Physical: Process lines should generally be positioned away from overhead piping, walkways, and other features from which contaminants can fall into the product. Metal particles from process pumps and other equipment can also be a physical hazard.
3. Chemical: Pesticides and other chemicals used for rodent control can contaminate processed products. Preservatives and other food additives should be added in proper quantities. Boiler water chemicals and equipment lubricants should be used appropriately.

General sanitary considerations begin with proper landscaping and lighting on the building exterior. Landscape stones placed around the building perimeter help prevent vermin from nesting close to the building. Exterior lights should be located away from doorways because they attract insects at night. On the interior, specify no glass in the process area; unprotected light bulbs could break and fall into the product. There should not be painted surfaces in process rooms; paint can chip and fall into the product.

FACILITY CLEANING

Use a dry process to clean up as much as possible to prevent process wastes from entering the sewer. Provide hose stations and high-pressure, low-flow wash stations.

Some process equipment can be left in place for cleaning. Cleaning and sanitizing solutions are circulated through the process lines. Some equipment should be disassembled and cleaned at a remote site. Foam cleaners, which mix air and foaming chemicals, can be sprayed on processing equipment, tanks, and vessels to help hold detergent on the surface.

PIPING AND UTILITIES

As far as possible, keep utilities and piping to a minimum. Piping runs should not be located over process equipment because pipes can leak and drip condensate into the product. Locate piping away from walls or tight to the wall or other surface and caulk it on both sides. Provide proper insulation and jacketing of all piping.

Typical process utilities include steam and condensate return; process water; hot water; chilled water for cooling jackets; compressed air and control air; gas ovens or hot water heaters; hydraulics for hydraulically operated motors; refrigeration for process or space cooling; electrical; plumbing (no standing water on floors; 400 sq ft/drain); hand-washing and cleanup stations.

PIPING LOCATIONS

Within the processing space, piping should be on pipe racks. To make changes or repairs to piping, the food processing line usually must be shut down to avoid product contamination. An alternative is to locate piping in a crawl space above the process room. This utility service area allows utility drops to occur at the connection point to the processing equipment. Changes and repairs to piping and utilities in the utility service space can usually be made while the food processing line is running.

TEMPERATURE AND LIGHTING OF PROCESS AREAS

Keep temperatures to USDA-specified levels or lower to slow growth of bacteria. Refer to ASHRAE guide for manufacture of particular products. Lighting considerations include proper lighting levels and good color rendition for inspection of products. All fixtures should be enclosed and, possibly, gasketed for wash-down service.

WALK-ON SANITARY CEILING

NOTE

Pipe rack may include food processing piping, utility piping, electrical wiring, and control circuits.

BUILDING CODES AND CIVIL RIGHTS LAWS

Accessible is a design term that was first introduced in the 1950s to describe elements of the physical environment that can be used by people with disabilities. Originally, the term described facilities that could be accessed by wheelchair users, but it has evolved to include designs for a wider group of people with more diverse functional requirements.

Society's need for accessible design has increased as a result of continuing medical advances. For example, the discovery of antibiotics in the 1940s dramatically improved the survival rate for people who sustained spinal cord injuries. Concurrent with the medical advances has been the development of new building technologies, such as residential elevators, wheelchair lifts, and power door operators, that have made the provision of accessible facilities more practical and less expensive. Accessible design will continue to change as medical advances and building technologies continue to evolve.

From an architect's perspective, there is a difference between appropriate accessible design for public facilities and the best approach for private, custom accessible projects. Public accessibility standards establish general design specifications that broadly meet the targeted population's needs. By contrast, custom accessible design should address the specific needs of an individual user. The same design standards, for example, are not always appropriate for paraplegic wheelchair users and wheelchair users with cerebral palsy. Custom accessible design should not, therefore, necessarily follow commercial standards. Rather, it should reflect the individual user's unique capabilities and preferences. Even design details such as the orientation of a bathroom fixture should be evaluated in order to suit the specific client.

Accessible design is a new and still-evolving field. Nonetheless, the proliferation of laws and codes governing its implementation demands that architects educate themselves with regard to both the principles and the legal requirements of accessibility.

THE REGULATORY HISTORY OF ACCESSIBLE DESIGN

The American National Standards Institute (ANSI) published the first national standards for accessible design in 1961. After its initial publication, many state and local jurisdictions began to adopt ANSI A117.1 as their accessibility code, although they often modified selected standards to suit their communities. ANSI A117.1 quickly became the most widely used accessibility standard in the United States.

ANSI has periodically revised the A117.1 standard since it was first published. In 1980 it was expanded to include housing standards focused primarily on the needs of wheelchair users (specifically paraplegics). In an effort to encourage states to adopt the standards and to promote uniformity, the 1986 revision eliminated all "scoping" requirements.

Scoping is the extent to which a standard is applied; for example, a standard may be applied to *all* project elements or only a *fraction* of the elements. The 1980 ANSI standards, for instance, require provision of a "reasonable number" of wheelchair seating spaces in places of assembly but not fewer than 2 spaces. After publication of the 1986 ANSI A117.1 standard, scoping was left to the discretion of the local adopting authority.

The 1968 Architectural Barriers Act was the first federal legislation that required accessible design in federal facilities. To address the absence of federal accessibility standards and the lack of an enforcement mechanism, Congress enacted the 1973 Rehabilitation Act. In addition, the Act required facilities built with federal funds, and facilities built by entities that receive federal funds, to be accessible to persons with disabilities.

Section 502 of the 1973 Rehabilitation Act created a new federal agency, the Architectural and Transportation Barriers Compliance Board (ATBCB) to develop and issue minimum guidelines for design standards to be established by four standard-setting agencies. In 1984 the ATBCB issued the Uniform Federal Accessibility Standards (UFAS), which were established by the Department of Defense (DoD), the Department of Housing and Urban Development (HUD), the General Services Administration (GSA), and the U.S. Postal Service. UFAS is similar to the format and content of ANSI A117.1, 1980.

FHAG: FAIR HOUSING ACCESSIBILITY GUIDELINES

UFAS: UNIFORM FEDERAL ACCESSIBILITY STANDARDS

ADAAG: AMERICANS WITH DISABILITIES ACT ARCHITECTURAL GUIDELINES (TITLE III)

CABO/ANSI: AMERICAN NATIONAL STANDARDS INSTITUTE A117.1

SBCCI: SOUTHERN BUILDING CODE CONGRESS INTERNATIONAL

BOCA: BUILDING OFFICIALS AND CODE ADMINISTRATORS INTERNATIONAL

In 1988 Congress enacted the Fair Housing Amendments Act (FHAA). Although the Act's guidelines include design requirements, it is a civil rights law, not a building code. Because FHAA is federal law, state or local building authorities cannot officially interpret the Fair Housing standards, nor can local building inspectors enforce them. The 1988 Fair Housing Amendments Act was unprecedented as the first federal law to regulate private residential construction.

Two years later, in 1990, President Bush signed the Americans with Disabilities Act (ADA). This landmark legislation provided new civil rights protections for people with disabilities, and its guidelines included new federal accessibility standards. ADA addresses the design and operation of privately owned public accommodations and state and local government facilities and programs. ADA design standards are very similar to the 1986 ANSI standards. ADA did not include housing design requirements because they were addressed in the earlier Fair Housing Amendments Act.

RELATIONSHIP BETWEEN CIVIL RIGHTS LAWS AND BUILDING CODES

Enactment of the 1988 Fair Housing Amendments Act and 1990 Americans with Disabilities Act created a complex relationship between federal laws and the local building codes that already existed throughout the United States. Although many of the accessible design requirements in the civil rights laws and the codes are similar, there are major differences.

Building codes are specific to a legal jurisdiction, such as a state, county, township, or city. These state/local regulations are usually based on national model codes (BOCA, UBC, Southern) that a jurisdiction elects to adopt. The state and local jurisdictions typically modify the model codes and, as part of their review and enforcement process, make administrative rulings and interpretations. Over time, these modifications and interpretations make the design requirements of each municipality unique even though the underlying code is based on a national model.

Building officials use local codes to review architectural and engineering plans before they permit construction. They also perform on-site inspections to verify that the completed construction is in compliance.

Unlike municipal officials, federal agencies do not issue building permits and typically do not inspect construction. As well, the federal government does not issue rulings or interpretations for individual projects. Civil rights law enforcement is a "complaint-based process" that HUD administers for Fair Housing and the Department of Justice administers for ADA. These agencies may choose to act on a citizen complaint, or a complainant may elect to seek direct relief through federal courts. Legal decisions regarding such complaints will gradually refine unclear design and construction components of federal civil rights laws. Architects must therefore monitor federal court rulings made throughout the United States in order to ensure they are apprised of the most current design standard information.

As civil rights laws, Fair Housing and ADA include both provisions for facility design and construction and for facility operation and management. Provisions that address operation and management create new legal responsibilities that are shared between facility designers and facility operators. This arrangement changes the traditional architect-client relationship and alters the way architects must do business. For example, architects should carefully record programming decisions since the intended use of a new space often establishes its accessibility requirements. ADA requirements for an employee work space, for example, are different than those for a public space. If a facility operator later changes the use of a space, compliance becomes the owner's rather than the architect's responsibility. Another change is that architects must now evaluate an owner's project funding sources in order to determine the project's federal accessibility requirements. This precautionary step can prevent an architect's failure to comply with federal laws such as the 1973 Rehabilitation Act as a result of inaccurate funding information.

Terminology common to both civil rights law and building code standards can be confusing because the same words often have different meanings. The term *dwelling*, for example, has a much different meaning in the Fair Housing design guidelines than it does in building codes. Similarly, building use and occupancy categories such as *transient lodging* and *assembly areas* (places of assembly) are not consistent between ADA and the building codes. Because architects must deal with both types of standards, they should carefully review the definitions included in each.

Kim A. Beasley, AIA, and Thomas D. Davies, Jr., AIA; Paralyzed Veterans of America Architecture; Washington, D.C.

ADA AND FHAA DESIGN REQUIREMENTS

The Americans with Disabilities Act (ADA) and the Fair Housing Amendments Act (FHAA) are the two broad federal civil rights laws that address accessible design and construction of both public and private facilities. The Fair Housing Amendments Act covers multifamily housing. The Americans with Disabilities Act is applied to a wide range of public accommodations offered by private entities (Title III) and municipal facilities (Title II). Other federal laws, such as the 1973 Rehabilitation Act, may also apply to some projects. Architects should be aware that, in many aspects, federal civil rights laws are different from building codes. Therefore, receiving a building permit does not indicate that a project design complies with these federal laws.

The Americans with Disabilities Act includes design requirements for new facility construction and for additions to and alterations of existing facilities that are owned, leased, or operated by both private entities and local governments. However, design standards and management responsibilities differ between the two owner groups. Standards and responsibilities are described in the Act in Title III for private entities and in Title II for local governments. ADA Title III includes design standards and scoping for general application and also for certain specific building types, including transient lodging, medical care facilities, and libraries. Regulations issued by DOJ are contained in 28 CFR, Part 36.

Owners and operators of existing private facilities that serve the public have ADA construction responsibilities under what is called "barrier removal." Local governments also have the responsibility of making all their new and existing programs accessible. Meeting this ADA responsibility for municipal programs may sometimes require new construction or physical modifications to existing facilities. ADA also prescribes employer responsibilities for changing their policies or modifying their facilities to accommodate employees with disabilities (Title I).

Several ADA concepts determine design requirements such as "path-of-travel" components for renovation projects and the "elevator exception" for small multistory buildings. It is imperative that architects familiarize themselves with all aspects of the law as well as with the design standards.

ADA Title II requirements are based on the concept of "program accessibility," which is similar to Section 504 of the 1973 Rehabilitation Act for Federal Programs. ADA requires state and local governments to provide access to all their programs for people with disabilities. Local government program responsibility includes policies and operations as well as the built environment. In order to provide access to existing inaccessible programs, state and local governments must develop a "transition plan" that lists the necessary changes. Inaccessible programs can be addressed either by altering policies and procedures or by modifying physical structures or by a combination of both strategies.

The Fair Housing Amendments Act addresses new multifamily housing constructed either by private entities or local governments. Which housing types are covered is not completely clear because of minor scoping overlaps between ADA and FHAA and because of imprecise scoping definitions in both laws. Generally, Fair Housing covers apartments, dormitories, and other lodgings included in projects with four or more total dwelling units that are built for sale or lease. Most townhouses are not covered because they are multistory units. Existing housing structures and any remodeling, conversion, or reuse projects are not covered by FHAA. The law's design standards, drafted with an eye toward single-use apartment projects, include requirements for both individual dwelling units and common use facilities such as lobbies, corridors, and parking.

The Fair Housing guidelines allow the exclusion of certain dwelling units because of site considerations such as steep topography and floodplains. The guidelines include site practicality tests for analyzing site constraints. Several major scoping issues such as multistory dwelling units and multiple ground floor levels are discussed in the supplementary information that precedes the guidelines. Prior to project design, architects should carefully review this material as well as the guidelines themselves.

FEDERAL LEGISLATIVE PROCESS

To help them understand current civil rights law design requirements and monitor the publication of new standards, architects should be familiar with the federal legislative process. Information on federal design standards is available within specific Acts, in the resultant regulations, and in published guidelines. Additional information is available in the legislative history of an Act and in the numerous documents issued during the "rule-making process."

APPLICABLE ACCESSIBILITY STANDARDS FOR SAMPLE PROJECTS

PROJECT DESCRIPTION	FEDERAL LAWS	BUILDING CODES
Federally owned project of any type	1968 Architectural Barriers Act 1973 Rehabilitation Act Other standards as described by the agency	Building codes may or may not be applicable
Project that utilizes federal funds or is built by the recipient of federal funds (private or government)	1968 Architectural Barriers Act 1973 Rehabilitation Act, UFAS Other standards appropriate with ownership use and type	State and/or local building codes may apply
Local government-owned commercial or public facility	ADA Title II 1973 Rehabilitation Act	State and/or local building codes may apply
Local government-owned multifamily housing	ADA Title II 1973 Rehabilitation Act 1988 Fair Housing Amendments Act	State and/or local building codes may apply
Privately owned public accommodation or commercial facility	ADA Title III	State and/or local building codes may apply
Privately owned multifamily housing	1988 Fair Housing Amendments Act (public accommodation spaces must meet ADA)	State and/or local building codes may apply
Privately leased, government-owned public accommodation	ADA Title III-Tenant ADA Title II-Owner	State and/or local building codes may apply
Government-leased, privately owned public accommodation	1973 Rehabilitation Act-Tenant ADA Title II-Tenant ADA Title III-Owner	State and/or local building codes may apply
Church-operated, church-owned facility	None	State and/or local building codes may apply
Privately operated, church-owned facility	ADA Title III-Tenant None-Owner	State and/or local building codes may apply
Church-operated, privately owned facility	None-Tenant ADA Title III-Owner	State and/or local building codes may apply

NOTE

Temporary facilities must meet the same federal standards as similar permanent facilities.

FEDERAL RULE-MAKING PROCESS

The administrative process for implementing federal laws requires public notice (in the *Federal Register*) and a public comment period for any proposed new regulations or guidelines. Architects should monitor this ongoing process in order to track the new standards that are periodically added to the existing accessibility guidelines. The architectural guidelines for laws like ADA are also periodically revised through the same rule-making process.

Technical Assistance Manuals (TAMs) are another design information source. Administering agencies such as the Department of Justice and HUD periodically publish these manuals in order to clarify existing guidelines or standards.

APPLICABLE FEDERAL STANDARDS FOR SPECIFIC PROJECTS

The first step in evaluating the accessibility requirements for a specific project is to determine what laws and regulations apply. Project accessibility requirements may be determined by the following facts:

1. What type of building or structure will be built
 2. Who owns the facility
 3. Where the construction funds originate
 4. What other federal funding the project's owner receives
 5. Who the intended users of a space or component are
- The accompanying table shows the applicable standards for many types of projects.

GENERAL

The flowcharts shown on this and the following AGS page address only the architectural aspects of the following federal laws that govern accessibility: the Architectural Barriers Act of 1968 (ABA), Section 504 of the Rehabilitation Act of 1973 (Section 504), the Fair Housing Amendments Act of 1988 (FHA), and Title II and Title III of the Americans with Disabilities Act (Title II ADA and Title III ADA). Other accessibility laws and standards may apply; consult your client. The charts do not address employee-generated accessibility requirements, auxiliary aids, reasonable accommodations, or human relations issues.

Many conditions apply to the decision points in the flowcharts, and occasionally the appropriate outcome may differ from what is illustrated. Consult relevant standards, regulations (e.g., GSA leasing regulations), and your client to ensure accuracy. As the chart shows, existing noncompliant features may affect your project.

Federal agencies periodically update their accessibility standards; always make sure you are working with the most current copy of any federal law. Listed here are the applicable standards as of August 1999 for the laws specified in the first paragraph above:

ABA: Uniform Federal Accessibility Standards (UFAS)

SECTION 504: UFAS (federal agencies may use amended versions)

FHA: Fair Housing Amendments Accessibility Guidelines (FHAAG)

TITLE II ADA (State and Local Governments): Americans with Disabilities Act Accessibility Guidelines (ADAAG) (without the elevator exception) or UFAS

Title III ADA (Private Entities): ADAAG

TERMS USED IN THE CHARTS

ALTERATION: Any change that affects usability. This includes remodeling, renovation, rearrangements in structural parts, and changes or rearrangement of walls and full-height partitions. Normal maintenance, re-roofing, painting, wallpapering, asbestos removal, and changes to electrical and mechanical systems are not "alterations," unless they affect usability.

COMMERCIAL FACILITIES: This category includes nonresidential facilities whose operations affect commerce but excludes all facilities that are covered or expressly exempted from coverage under the Fair Housing Act.

CONTINUING OBLIGATION: Barriers must be removed whenever it becomes readily achievable to do so until all barriers as defined by ADAAG have been removed.

EXECUTIVE BRANCH: The federal government has three branches, executive, judicial, and legislative. The executive branch contains most of the federal departments and facilities. The General Services Administration (GSA) manages most of the judicial branch facilities, making these facilities subject to the ABA. The Congressional Accountability Act requires the legislative branch to comply with the ADA.

MULTIFAMILY HOUSING: As defined by the ABA, FHA, ADA, and Section 504 of the Rehabilitation Act of 1973, multifamily housing is a "building with four or more dwelling units." Further, they state that "dwelling units within a single structure separated by fire walls do not constitute separate buildings." In other words, according to these standards townhouses are multifamily dwelling units.

PATH OF TRAVEL: This is a continuous route connecting an altered area to the entrance and point of arrival. It can include sidewalks, lobbies, corridors, rooms, and elevators, as well as telephones, restrooms, and drinking fountains serving the altered area.

PLACE OF PUBLIC ACCOMMODATION: This set of facilities has retroactive requirements. There are twelve categories:

1. Places of lodging (e.g., inns, hotels, motels, except for owner-occupied establishments renting fewer than six rooms)
2. Establishments serving food or drink (e.g., restaurants and bars)
3. Places of exhibition or entertainment (e.g., motion picture houses, theaters, concert halls, stadiums)
4. Places of public gathering (e.g., auditoriums, convention centers, lecture halls)
5. Sales or rental establishments (e.g., bakeries, grocery stores, hardware stores, shopping centers)

Continues on next page

21 INTRODUCTION

OWNED OR LEASED BY THE EXECUTIVE BRANCH, FEDERAL GOVERNMENT

OWNED OR LEASED BY A PRIVATE ENTITY

Terms used in the chart (continued)

- 6. Service establishments (e.g., laundromats, dry cleaners, banks, barbershops, beauty shops, travel services, shoe repair services, funeral parlors, gas stations, accounting or law offices, pharmacies, insurance offices, professional offices of health care providers, hospitals)
- 7. Public transportation terminals, depots, or stations (not including facilities relating to air transportation)
- 8. Places of public display or collection (e.g., museums, libraries, galleries)
- 9. Places of recreation (e.g., parks, zoos, amusement parks)
- 10. Places of education (e.g., nursery schools; elementary, secondary, undergraduate, or postgraduate schools)
- 11. Social service center establishments (e.g., day care centers, senior citizen centers, homeless shelters, food banks, adoption agencies)
- 12. Places of exercise or recreation (e.g., gymnasiums, health spas, bowling alleys, golf courses)

PRIMARY FUNCTION: Any area in which a major activity takes place. This includes both customer service areas and work areas in places of public accommodation. It includes all offices and work areas in commercial facilities. It does not include mechanical rooms, boiler rooms, supply storage rooms, employee lounges or locker rooms, janitorial closets, entrances, corridors, or restrooms.

PRIVATE CLUB: To qualify, these organizations must meet the following criteria:

- 1. Members exercise a high degree of control over club operations.
- 2. The membership selection process is highly selective.
- 3. Substantial membership fees are charged.
- 4. The entity is operated on a nonprofit basis.
- 5. The club was not founded specifically to avoid compliance with federal civil rights laws.

READILY ACHIEVABLE: According to the laws, this means "easily accomplishable and able to be carried out without much difficulty or expense." The Department of Justice has 21 examples of what is readily achievable:

- 1. Installing ramps
- 2. Making curb cuts in sidewalks and entrances
- 3. Repositioning shelves
- 4. Rearranging tables, chairs, vending machines, display racks, and other furniture
- 5. Repositioning telephones
- 6. Adding raised markings on elevator control buttons
- 7. Installing flashing alarm lights
- 8. Widening doors
- 9. Installing offset hinges to widen doorways
- 10. Eliminating a turnstile or providing an alternative, accessible path
- 11. Installing accessible door hardware
- 12. Installing grab bars in toilet stalls
- 13. Rearranging toilet partitions to increase maneuvering space
- 14. Insulating lavatory pipes under sinks to prevent burns
- 15. Installing a raised toilet seat
- 16. Installing a full-length bathroom mirror
- 17. Repositioning the paper towel dispenser in a bathroom
- 18. Creating designated accessible parking spaces
- 19. Installing an accessible paper cup dispenser at an existing inaccessible water fountain
- 20. Removing high-pile, low-density carpeting
- 21. Installing vehicle hand controls

TRANSITION PLAN: This type of document identifies all "services, programs, and activities" offered by public entities and outlines either how each is accessible or a plan to make it accessible. Both Section 504 and Title II ADA requires covered entities to provide access to all programs in an integrated setting. Entities may view programs in their entirety when determining access.

OWNED BY A RELIGIOUS ORGANIZATION OR PRIVATE CLUB

OWNED OR LEASED BY A STATE OR LOCAL GOVERNMENT

FORWARD APPROACH—ALCOVE

FORWARD

PARALLEL APPROACH—ALCOVE
MANEUVERING CLEARANCES

PARALLEL

MAXIMUM CLEARANCE

NOTE
Additional space can be provided beneath the table, desk, or other element, but that space is not considered knee and toe clearance.

MINIMUM CLEARANCE

NOTE
Clearances shown are required at specific accessible elements.

SAMPLE MANEUVERING CLEARANCE—DRINKING FOUNTAIN

CIRCULAR

T-SHAPED

TOE CLEARANCE ONLY
KNEE AND TOE CLEARANCES

NOTE

Knee and toe clearance that is included as part of a T-shaped turning space should be provided only at the base of the T or on one arm of the T. In some configurations, the obstruction of part of the T-shape may make it impossible for a wheelchair user to maneuver to the desired location.

WHEELCHAIR TURNING SPACE

GENERAL NOTES

1. Knee and toe clearance must always be at least 30 in. (760 mm) wide.

2. Knee and toe clearance can be included as part of the wheelchair turning space and clear floor space at accessible elements. However, the extent and location of knee and toe clearance can affect the usability of the space.

UNOBSTRUCTED SIDE REACH

MAX. SIDE REACH OVER OBSTRUCTION

OBSTRUCTED HIGH FORWARD REACH

OBSTRUCTED SIDE REACH

CLOSET

OBSTRUCTED HIGH FORWARD REACH

OBSTRUCTED SIDE REACH

SHELVES

PARALLEL/SIDE REACH LIMITS

REACH RANGE

ANSI A117.1-1998 reduced the maximum reach range from 54 in. to 48 in. for unobstructed side reach and made the height limit the same as that for unobstructed forward reach, with the following exceptions:

1. A117.1 provides exception for existing elements located 54 in. maximum above the floor or ground.
2. A117.1 provides exception for elevator car controls, allowing buttons at 54 in. maximum, where the elevator serves more than 16 openings. This exception may be revisited in future editions, when the elevator industry has had an opportunity to develop alternate control configurations.

REACH RANGES

3. A117.1 does not apply the 48 in. restriction to tactile signs. Tactile signs must be installed so the tactile characters are between 48 and 60 in. above the floor. Below this height, tactile characters are difficult to read by standing persons, as the hand must be bent awkwardly or turned over (similar to reading upside down) to read the message.

FHAG requires controls and operating mechanisms in covered dwelling units to be installed at a maximum height of 48 in., with the following exceptions:

1. FHAG allows inaccessible controls in covered dwelling units if "comparable" accessible controls are provided.
2. Floor outlets are permitted if an adequate number of accessible wall outlets is provided.
3. Electric outlets above kitchen counters can be located in corners, provided additional outlets are located within reach.

Accessible controls and operating mechanisms should be operable with one hand and not require tight grasping, pinching, or twisting of the wrist, with the following exception: FHAG does not regulate the operating force or type of operation required for controls and operating mechanisms in dwelling units.

CHILDREN'S REACH RANGES FROM A WHEELCHAIR (IN., MM)

FORWARD OR SIDE REACH	AGES 3 AND 4	AGES 5-8	AGES 9-12
High (maximum)	36 (915)	40 (1015)	44 (1120)
Low (minimum)	20 (510)	18 (455)	16 (405)

SPECIFICATIONS FOR WATER CLOSETS SERVING CHILDREN (IN., MM)

DIMENSION	PRE-K, K (AGES 3 AND 4)	1ST-3RD (AGES 5-8)	4TH-7TH (AGES 9-12)
Water closet centerline	12 (305)	12-15 (305-380)	15-18 (380-455)
Toilet seat height	11-12 (280-305)	12-15 (305-380)	15-17 (380-430)
Grab bar height	18-20 (455-510)	20-25 (510-635)	25-27 (635-685)
Dispenser height	14 (355)	14-17 (355-430)	17-19 (430-485)

OBJECTS MOUNTED ON POSTS OR PYLONS

POSTMOUNTED PROTRUDING OBJECTS

FREESTANDING OBJECTS

PLANTER NOTES

RAILING

CURB

1. Protection from overhead hazards can be provided by permanent, built-in elements or by movable elements such as furniture and potted plants.
2. Thoughtful, informed design can reduce or eliminate most overhead hazards (e.g., low headroom hazards can be avoided by enclosing areas under stairs and escalators).

NOTES

1. Wall sconces, fire alarm appliances, environmental controls, door hardware, signs, and suspended lighting fixtures are examples of protruding objects.
2. Some standards specify the extent to which doorstops and door closers may protrude into the 80 in. (2030 mm) vertical clearance, generally allowing a 2 in. maximum projection.
3. Protruding objects are not permitted to reduce the required width of an accessible route (36 in., except 32 in. width permitted for a 24 in. length).

OVERHEAD HAZARDS—EXAMPLE

OVERHEAD HAZARD PROTECTION—EXAMPLES

90° TURN

TURNS

REQUIREMENTS FOR ACCESSIBLE ROUTES

Accessible routes are generally required as follows:

SITE ARRIVAL POINTS: From each type of site arrival point (public transportation stops, accessible parking spaces, passenger loading zones, and public streets or sidewalks) to an accessible entrance.

Consult the applicable regulation to determine the required number of accessible entrances. Building codes generally require that at least 50% of the entrances, but no less than one, be accessible. Under the Fair Housing Accessibility Guidelines (FHAG), site conditions may allow some buildings to be exempt from this requirement.

WITHIN A SITE: Between accessible buildings, facilities, elements, and spaces on the site.

Intent: The intent of this requirement is not to require accessible routes where no "connection" is otherwise intended between buildings or facilities, but to ensure that, where a connection is intended, an accessible connection is also provided.

FHAG vehicular route exception: FHAG allows a vehicular route to be provided in lieu of an accessible route between covered dwelling units and public and common use site facilities where the slope of the site or other restrictions prevents the use of an accessible route. Accessible parking spaces are required at the covered dwelling units and at the facilities served only by the vehicular route.

Building code vehicular route exception: Recent model building codes also allow the use of a vehicular route in lieu of an accessible route, where the only means of access between two accessible facilities is "a vehicular way, not intended for pedestrian access." This exception is not limited to slope or other site restrictions.

MULTILEVEL BUILDINGS AND FACILITIES: Between all levels, including mezzanines, in multistory buildings, unless exempted.

ADA elevator exception: Buildings with only two floors are exempt from providing an accessible route to the upper or lower level. Buildings with less than 3000 sq ft per floor, regardless of height, are exempt from providing an accessible route to upper or lower floor levels. Neither exception applies to shopping centers, offices of professional health care providers, public transportation terminals, or state and local government facilities.

Building code elevator exception: Model building codes generally exempt a maximum aggregate area of 3000 sq ft, regardless of the number of levels. Similar to the ADA restrictions, this exception cannot be used in offices of health care providers, passenger transportation facilities, or mercantile occupancies with multiple tenants. Consult the applicable local code.

FHAG elevator requirements: For buildings containing dwelling units, and not public or common use spaces, FHAG does not require accessible routes to all levels. Instead, the existence or lack of an elevator determines the extent of units covered (and the floors required to be served by an accessible route). When elevators are provided, they generally must serve all floors; an exception is provided for elevators serving only as a means of access from a garage to a single floor. When elevators are not provided, only the "ground floor" units are subject to the FHAG requirements. In mixed-use construction, an accessible route is required to the first level containing dwelling units, regardless of its location. Consult FHAG for specific requirements.

Levels not containing accessible elements or spaces: For facilities in which only a percentage of the spaces provided are required to be accessible (assembly, residential, institutional, and storage), the model codes do not require an accessible route to serve levels not containing required accessible spaces. For example, an apartment building or a motel would not require an accessible route to upper floors if all required accessible units or rooms were located on the accessible level. Separate requirements for dispersion of accessible elements and spaces may still require multiple accessible levels. Consult the applicable local code.

ACCESSIBLE SPACES AND ELEMENTS: To all spaces and elements that are required to be accessible.

Toilet rooms and bathrooms: ADA generally requires that all toilet and bathing rooms be accessible. This does not trigger a requirement for accessible routes if the floor level is not otherwise required to have an accessible route.

Alterations: ADA and the model building codes generally do not require that altered elements trigger a requirement for accessible routes to the elements, unless covered under specific "primary function" requirements. In alterations involving "primary function" areas, the accessible route obligation is triggered but is subject to specific limitations. Consult ADA and the applicable local code.

COMPONENTS OF ACCESSIBLE ROUTES

Accessible routes are permitted to include the following elements: (1) walking surfaces with a slope of less than 1:20, (2) curb ramps, (3) ramps, (4) elevators, and (5) platform (wheelchair) lifts. (The use of lifts in new construction is limited to locations where they are specifically permitted by the applicable regulations. Lifts are generally permitted to be used as part of an accessible route in alterations.)

Each component has specific technical criteria that must be applied for use as part of an accessible route. Consult the applicable code or regulation.

LOCATION OF ACCESSIBLE ROUTES

Interior routes: Where an accessible route is required between floor levels, and the general circulation path between levels is an interior route, the accessible route should also be an interior route.

Relation to circulation paths: Accessible routes should "coincide with, or be located in the same area as a general circulation path." Avoid making the accessible route a "second class" means of circulation. Consult the applicable regulations for additional specific requirements regarding location of accessible routes.

Directional signs: Where the accessible route departs from the general circulation path, and is not easily identified, directional signs should be provided as necessary to indicate the accessible route. The signs should be located so that a person does not need to "backtrack."

ACCESSIBLE CURB RAMP PLAN

TYPE A

TYPE B

TYPE C

CURB RAMP TYPES

TYPE D

TYPE E

DESIGN CONSIDERATIONS

1. Design storm drain systems to shed water away from curb ramps.
2. The dimensions shown are for new construction. For alterations when these dimensions are impractical, review the Americans with Disabilities Act Accessibility Guidelines (ADAAG) for less strict dimensions.
3. The ADAAG requirement for detectable warnings was suspended by the Architectural and Transportation Barriers Compliance Board, pending revision of the detectable warning detail. FHA and many states continue to require detectable warnings at locations shown on this page but the details specified vary.

CURB RAMP SECTION

NOTE

If the 4 ft 0 in. minimum dimension cannot be met for type F, the 1:10 slope becomes 1:12 maximum.

TYPE F

TYPE G

NOTE

If passenger loading zones are provided, at least one must be accessible, with a 5 ft wide x 20 ft long access aisle. The surface slopes of the vehicle standing space and the access aisle must not exceed 1:50 (2%). The path of travel to and from a vehicle standing stall must have a minimum vehicular clearance of 9 ft 6 in. If there are curbs between the vehicle standing space and the access aisle, a curb ramp must be provided.

TYPE 1

TYPE 2

ACCESSIBLE PASSENGER LOADING ZONE

Mary S. Smith, P.E.; Walker Parking Consultants/Engineers, Inc.; Indianapolis, Indiana
 Mark J. Mazz, AIA, P.A.; Hyattsville, Maryland

GENERAL

The information on this page conforms to the Americans with Disabilities Act Accessibility Guidelines for Buildings and Facilities (36 CFR 1191, July 26, 1991), also known as ADAAG, and Bulletin No. 6: Parking (February 1994), both issued by the Architectural and Transportation Barriers Compliance Board. State and local requirements may differ, but ADA requires that designs conform to the higher requirement.

NOTES

1. Accessible parking stalls should be 8 ft wide with an adjacent 5-ft access aisle. No special clearance is required for these stalls.
2. Van-accessible stalls should be 8 ft wide with an adjacent 8-ft access aisle accessible from the passenger side of the vehicle. (Backing into 90° stalls from a two-way aisle is an acceptable method of achieving this.) Vehicular clearance along the path of travel to and from a van-accessible stall should be 8 ft 2 in. In parking structures, van-accessible stalls may be grouped on a single level.
3. It is permissible for all required accessible stalls to conform with Universal Parking Design guidelines. Since vans may use any accessible stall in this arrangement, universal stalls must have 8 ft 2 in. vehicle clearance.
4. Access aisles should be delineated separately from parking spaces. Access aisles must be at the same level as parking stalls (not above, at sidewalk height). Required curb ramps cannot be located in access aisles. Two spaces may share a single access aisle (except when van stalls require passenger-side access in one-way designs).
5. Parking spaces and access aisles should be level with surface slopes not exceeding 1:50 (2%) in any direction.
6. The stalls required for a specific facility may be relocated to another location if equivalent or greater accessibility in terms of distance, cost, and convenience is ensured.
7. Accessible stalls in the numbers shown in the accompanying table must be included in parking facilities leased or 100% reserved for employees. However, they need not be reserved for accessible parking (i.e., they need not be marked with signs) until or unless an employee with a disability needs the stall in that location.
8. Provide an accessible route from accessible parking stalls to the destination. This should make it possible for persons in wheelchairs to travel without rolling down parking aisles past more than one parked vehicle (other than their own). Crossing a parking aisle at 90° is preferable to rolling down a parking aisle.
9. Provide signs at accessible stalls to reserve the spaces for individuals with disabilities; pavement markings alone are not acceptable. Signs need not be provided for every accessible stall if they clearly delineate the accessible parking spaces.
10. Requirements are per lot, not by total facility parking.

REQUIRED MINIMUM NUMBER OF ACCESSIBLE PARKING SPACES

TOTAL PARKING IN LOT	VANS	CARS	TOTAL
1-25	1	0	1
26-50	1	1	2
51-75	1	2	3
76-100	1	3	4
101-150	1	4	5
151-200	1	5	6
201-300	1	6	7
301-400	1	7	8
401-500	2	7	9
501-800	2	2% min., less 2	2% min.
801-1000	3	2% min., less 2	2% min.
1001-1400	3	17+1 for each 100 over 1000	20+1 for each 100 over 1000
1401 and more	12.5% of total	17+1 for each 100 over 1000	20+1 for each 100 over 1000

NOTES

1. At facilities providing outpatient medical care and other services, 10% of the parking spaces serving visitors and patients must be accessible.
2. At facilities specializing in treatment or services for persons with mobility impairments, 20% of the spaces provided for visitors and patients must be accessible.

NOTE
S—accessible parking sign; SV—van-accessible parking sign.

ACCESSIBLE PARKING LAYOUTS

NOTE
SV—van-accessible parking sign. (All universal spaces are van-accessible.)

UNIVERSAL PARKING DESIGN

3. The information in this table does not apply to valet parking facilities, but such facilities must have an accessible loading zone. One or more self-park van-accessible stalls are recommended for patrons with specially equipped driving controls.
4. Fair Housing requirements match the ADAAG requirements, except as noted below:
 - a. Van-accessible stalls are not required.
 - b. Two percent of total parking must comply.

ACCESSIBLE PARKING IN DEDICATED BAY

- c. Parking stall may be sloped. Maximum slope of access aisle is 5% with a maximum cross-slope of 2%. Preferred maximum slope and cross-slope of stall and aisle is 2%.
- d. There are no requirements for employee-only stalls.
- e. When sidewalks are not provided, ensure that there is an accessible route through the driveways or provide additional compliant parking at each accessible feature on the property.

NOTE
Slope = Y:X, where X is a level plane.

COMPONENTS OF A RAMP

RAMP NOTES

1. Accessible ramps must have running slopes of 1:12 or less; surfaces with a running slope greater than 1:20 are considered ramps. All design parameters shown on this page are based on ANSI A117.1-1998.
2. Design outdoor ramps and approaches so water will not accumulate on surface. Maximum cross slope is 1:48.
3. Landings should be level at top and bottom of ramp run

and at least as wide as the run leading to it. A 60 x 60 in. landing is required where ramp changes direction. Provide level maneuvering clearances if there is a door at the landing.

4. Handrails are required on both sides when rise is greater than 6 in.
5. Edge protection is required at ramps and landings that drop off. Refer to local building codes for guardrail requirements.

RAMP AND LANDINGS—SECTIONS

NOTE
Handrails and ramp edge protection are not shown in this drawing for clarity.

RAMP LANDINGS

Lawrence G. Perry, AIA; Silver Spring, Maryland

21 RAMPS

CIRCULAR

NONCIRCULAR

NOTES

1. Dimensions are based on 1998 ANSI A117.1
2. Provide continuous handrails at both sides of ramps and stairs and at the inside handrail of switchback or dogleg ramps and stairs.
3. If handrails are not continuous at bottom, top, or landings, provide handrail extensions as shown in the ramp and stair example; ends of handrails to be rounded or returned smoothly to floor, wall, or post.
4. Provide handrails of size and configuration shown and gripping surfaces uninterrupted by newel posts or other construction elements; handrails shall not rotate within their fittings.

HANDRAIL DESIGN

CURB

NOTE

Ramp and ramp landing edge protection can be any configuration that will prevent the passage of a 4 in. (100 mm) sphere, where any portion of the sphere is within 4 in. (100 mm) of the ramp or landing surface.

RAMP AND RAMP LANDING EDGE PROTECTION DETAILS

TYPICAL VERTICAL WHEELCHAIR LIFT

PLATFORM (WHEELCHAIR) LIFTS

Wheelchair (platform) lifts are generally permitted to be used as part of an accessible route in new construction only to reach performing areas in assembly occupancies; wheelchair spaces in assembly occupancies; spaces not open to the public with an occupant load of no more than 5; and spaces within a dwelling unit. In some regulations, wheelchair lifts are permitted where site constraints prevent the use of ramps or elevators.

When lifts are used in new construction, accessible means of egress may be required from the spaces served by the lifts. Lifts are not permitted to be used as part of an accessible means of egress; therefore, in nonsprinklered buildings horizontal exits or areas of refuge may be required in spaces served by lifts.

Wheelchair (platform) lifts are generally permitted as part of an accessible route in alterations to existing buildings.

Wheelchair (platform) lifts that are part of an accessible route are required to comply with ASME/ANSI A17.1 and must provide a wheelchair-sized clear floor space, level floor surfaces, and accessible operable parts. Lifts are not permitted to be attendant-operated and must allow for unassisted entry and exit.

A117.1-1998 allows manual doors or gates on lifts with doors or gates on opposite sides (a roll-through configuration). Other lifts must have low-energy, power-operated doors or gates that remain open for at least 20 seconds. Doors/gates located on the ends of lifts must provide 32 in. (815 mm) clear width; doors/gates located on the side of a lift must provide 42 in. (1065 mm) clear width.

A new ASME/ANSI standard, A18, Platform Lift and Stair Chair Lift Safety Standard, replaces the portions of A17.1 that address lifts.

ELEVATOR LOBBY ELEVATORS

Elevator doors must open and close automatically and have a reopening device that will stop and reopen the car and hoistway door if the door is obstructed. Although the device cannot require contact to activate, contact can occur before the door reverses direction. The device must remain effective for at least 20 seconds.

Tactile designations at each jamb of hoistway doors should be 2 in. (50 mm) high, centered at 60 in. (1525 mm) above the floor. Include a five-pointed star at the main entry level.

Hall call buttons should be raised or flush, 35–48 in. (890–1220 mm) above the floor, with the “up” button located above the “down” button.

Audible hall signals should sound once for cars traveling in the up direction and twice for cars traveling down. Check the applicable regulations for required decibel level and frequency of audible signals. In-car signals are permitted in lieu of hall signals, as long as they meet all the requirements for visibility and timing.

DESTINATION-ORIENTED ELEVATOR SYSTEMS

Destination-oriented elevator systems assign passengers to specific cars by requiring them to enter their destination floor at a keypad or by other means, such as use of a coded identification card. A117.1-1998 provides detailed accessibility criteria for this type of elevator system.

Destination-oriented elevator systems must provide both an audible signal/announcement and a visible signal to indicate the car assigned. Therefore, the elevators in the bank must be audibly and visibly differentiated and the signals/announcements provided at the point of input must be the same as those provided at the car upon arrival.

A visible display is required in the car to identify the registered destinations for each trip, and an automatic verbal announcement is required to announce the floor as the car stops. Tactile signs at hoistway jambs are required to identify not only the floor level but also each car.

A117.1-1998 allows use of a telephone-style keypad in lieu of buttons for each floor. Keypads used for destination floor input must have a telephone keypad arrangement, with a tactile dot on the “5” key. Each key must be raised or flush and at least 3/4 in. (19 mm) in its smallest dimension.

ELEVATOR EMERGENCY COMMUNICATIONS

Elevator cars must provide an emergency two-way communication system between the car and a point outside the hoistway. Controls must be located within accessible reach ranges. When the system includes a handset, the cord must be at least 29 in. (735 mm) long. The system must provide both audible and visible signals; it cannot be limited to voice communication.

ELEVATOR CAR POSITION INDICATORS

Within elevator cars, audible and visible signals are required to identify the location of the car. Visible signals at least 1/2 in. (13 mm) high must be provided for each floor the car serves; these signals must illuminate to indicate the floors at which the car stops or passes.

Audible signals for new elevators must be automatic verbal announcements that indicate the floor at each stop. Exceptions allow the use of audible signals for some low-rise hydraulic elevators.

ELEVATOR CAR CONTROL PANELS

A117.1-1998 requires all elevator car controls to be 35 in. (890 mm) minimum and 48 in. (1220 mm) maximum above the floor. An exception is provided for elevator cars serving 16 or more openings, for which controls as high as 54 in. (1370 mm) are allowed. Other standards generally allow controls up to 54 in. (1370 mm) when a side reach is possible.

Buttons must be at least 3/4 in. (19 mm) in diameter and can be raised or flush. Existing recessed buttons are generally permitted to remain. Buttons for floor designations should be located in ascending order. Visual characters, tactile characters, and Braille are required to identify buttons. Tactile characters and Braille should be to the immediate left of each button.

CONTROL PANEL HEIGHT

Lawrence G. Perry, AIA, Silver Spring, Maryland

GENERAL

ANSI A17.1, Elevator Safety Standard, covers general elevator safety and operational requirements. It has been adopted in virtually all jurisdictions. All sizes shown on this page are based on A117.1-1998, which contains extensive accessibility provisions for passenger elevators, destination-oriented elevator systems, limited use/limited application elevators, and private residence elevators. Consult the applicable accessibility regulations for elevator exceptions. Model codes, the Fair Housing Act, the Americans with Disabilities Act, and the Architectural Barriers Act each has a different threshold for requirement of elevators.

EXISTING CAR CONFIGURATION NOTES

1. A $\frac{5}{8}$ -in. (16 mm) tolerance is permitted at 36 in. (915 mm) elevator doors, allowing the use of industry-standard 900 mm clear-width doors.
2. Any other car configuration that provides a 36-in. door and either a 60-in. (1525 mm) diameter or T-shaped wheelchair turning space within the car, with the door in the closed position, is permitted.
3. Inside car dimensions are intended to allow an individual in a wheelchair to enter the car in a forward direction, turn around within the car with the door closed, and exit in a forward direction. A smaller car size is permitted for existing car configurations, requiring a person in a wheelchair to either enter or exit by maneuvering backwards.

CENTERED DOOR LOCATION

OFF-CENTERED DOOR LOCATION

ANY DOOR LOCATION

ANY DOOR LOCATION

INSIDE DIMENSIONS OF ACCESSIBLE ELEVATOR CARS

NEW

EXISTING LIMITED USE/LIMITED APPLICATION (LULA)

NOTES

1. This type of elevator is permitted as part of an accessible route within dwelling units.
2. Car size shown is per A117.1-1998. Verify the car size requirements of applicable accessibility regulations.
3. Controls are located in a side wall 12 in. (300 mm) minimum from an adjacent wall.
4. Doors must be located on the narrow end of the car.
5. Car door/gates are required to be power operated.
6. Cars with openings on only one end require a person in a wheelchair to either enter or exit by moving backwards; therefore, in a single-opening configuration, the hoistway doors/gate must be low-energy, power-operated doors.
7. Cars with openings on each end allow a wheelchair user to roll through (enter and exit in a forward direction); manual, self-closing hoistway doors/gates are permitted.

NOTES

1. Limited use/limited application (LULA) elevators are permitted to be used as part of an accessible route in certain conditions. Check applicable accessibility regulations for permitted installations.
2. LULAs must comply with part XXV of ANSI A17.1.
3. LULA elevators have a smaller car size, requiring a person in a wheelchair to either enter or exit by moving backwards unless the car has openings on each end. Car size is limited by A17.1.

4. LULAs move more slowly than other passenger elevators and may not be appropriate when large numbers of people must be served.
5. Car controls are located on a side wall.
6. Low-energy, power-operated swing doors are permitted at the hoistway entrance, provided they remain open for 20 seconds when activated.

LIMITED USE/LIMITED APPLICATION ELEVATOR

PRIVATE RESIDENCE ELEVATOR

Lawrence G. Perry, AIA; Silver Spring, Maryland

OVERALL VIEW - WHEELCHAIR LIFT

NOTE
Screw driven lift platform is lifted along a threaded rod, which is rotated by the power unit.

CUT-AWAY SECTION

TYPICAL PLAN
WHEELCHAIR LIFT

GENERAL

Not all lifts comply with ADAAG and A117.1-1998 requirements. Verify applicable regulations before selecting a specific type of lift.

Wheelchair lifts are suitable for retrofits of buildings that are not barrier free. Bridges are available from manufacturers for installation over stairs. Recommended speed: 10 to 19 fpm. Capacity: 500 to 750 lb.

Lifts operate on standard household current and are suitable for interior or exterior applications.

WHEELCHAIR LIFT REQUIREMENTS

TYPICAL ANSI A17.1, SEC. 2000.1B	PRIVATE RESIDENCE ANSI A17.1, SEC. 2100.1
42 in. door for top and bottom landings, mechanical/electrical interlock, solid construction	36 in. door for top landing; bottom landing can have guard (other requirements similar to 42 in. door)
Platform sides: 42 in. solid construction	Platform 36 in. solid construction
Grab rails	Same
Enclosure or telescoping toe guard	Obstruction switch on platform
Maximum travel 12 ft	Maximum travel 10 ft
	Automatic guard 6 in. at bottom landing in lieu of door
Key operation	Key operation

NOTE
Chair lift power unit may also be located in chair chassis. Chair lift's compact size may make this lift type more feasible than others for residential use.

CHAIR LIFT - SECTION

STAIR LIFT OR PLATFORM (STRAIGHT RUN)

Inclined stair lifts can be adapted to straight run and spiral stairs. Standard types run along guide rails or tubes fastened to solid wall, stairs, or floor structure. Power units may be placed at the top or bottom of the lift run or in the lift chassis, depending on the manufacturer. Some inclined lift systems fold up out of the way for daily stair use.

Where stair width necessitates a more compact lift, as in residential use, chair lifts are available for straight run or spiral stairs. However, many inclined stair lifts come with standard fold-down seats.

Recommended speed, 20 to 25 fpm on straight runs, 10 fpm on curved sections. Capacity, 500 lb. Typical platform size, 30 x 40 in. Check local code capacities.

INCLINED WHEELCHAIR LIFT REQUIREMENTS

TYPICAL RESIDENCE ANSI A17.1, SEC. 2001	PRIVATE RESIDENCE ANSI A17.1, SEC. 2100
42 in. self-closing door: solid construction, mechanical/electrical interlock, lower landing	36 in. self-closing door: solid construction, mechanical/electrical interlock, upper landing
42 in. platform side guard: not used as exit, solid construction	36 in. platform side guard: not used as exit, solid construction
6 in. guard: permitted in lieu of side guard	6 in. guard: permitted in lieu of side guard
6 in. retractable guard: to prevent wheelchair rolling off platform	6 in. retractable guard: to prevent wheelchair rolling off platform
Door required at bottom landing	Underside obstruction switch bottom landing
Travel 3 floors max.	Travel 3 floors max.
Key operation: attendant operation is push button	Key operation: attendant operation is push button and requires door at bottom landing

STAIR LIFT OR PLATFORM SECTION

STAIR LIFT CHAIR OR PLATFORM PLAN WITH TURNS

Eric K. Beach; Rippeteau Architects, PC; Washington, D.C.

NOTES

1. Hardware: Specify hardware that can be operated with one hand, without tight grasping, pinching, or twisting of the wrist.
2. Thresholds: Thresholds are typically limited to 1/2 in. maximum height; however, some standards allow a 3/4 in. height for certain sliding doors.
3. Opening force: Interior doors (other than fire doors) should be able to be operated with 5 lb of force. Exterior doors and fire doors may be regulated by the authority having jurisdiction.

ACCESSIBLE DOOR FEATURES

HINGED DOOR

SLIDING OR FOLDING DOOR

NOTES

1. For a hinged door, the clear width is measured between the face of the door and the door stop with the door open at a 90° angle.
2. For a sliding or folding door, the clear width is measured between the edge of the door and the jamb with the door fully open. Hardware must be accessible with the door in fully open position.
3. Doors in dwelling units covered by FHAG are permitted to have a "nominal" 32 in. clear width. HUD allows a 2 ft 10 in. swing door or a 6-ft exterior sliding door installed in a "typical" manner to satisfy this requirement. ICC/ANSI A117.1-1998 allows a 31 1/4 in. (810 mm) clear width.

SWING—SAME DIRECTION

SWING—OPPOSITE DIRECTION

MANEUVERING CLEARANCE FOR TWO DOORS IN A SERIES

NOTES

1. Maneuvering clearances are also required at power-assisted doors.
2. Maneuvering clearances are not applicable at full-powered automatic doors or low-energy power-operated doors.
3. The floor and ground surface within the required maneuvering clearance of a door must not slope more than 1:48 and must be stable, firm, and slip-resistant.
4. Where doors are recessed more than 8 in. (such as in an alcove or in a very thick wall), the maneuvering clearances for forward approach should be used.
5. For doors within dwelling units covered by Fair Housing Accessibility Guidelines (FHAG), maneuvering clearances are not required.

MANEUVERING CLEARANCE AT SLIDING AND FOLDING DOORS

NOTE

Tactile signs with raised characters and Braille are required on signs provided as permanent designations of rooms and spaces. A117.1-1998 allows either combined tactile/visual characters or separate tactile characters with redundant visual characters. By providing duplicate characters, the tactile characters can be made easier to read by touch, and a wider variety of visual characters can be used. Room numbers, room names, exit stairs, and restrooms are examples of spaces with "permanent" designations. Tactile characters must be located between 48 in. (1220 mm) and 60 in. (1525 mm) above the floor or ground.

Tactile signs at doors must be located so that a person reading the sign will not be hit by a door that is being opened. A117.1-1998 allows door-mounted tactile signs on the push side of doors with closers, which do not have hold-open devices. Tactile signs located on the pull side of doors should be located so that an 18 in. (455 mm) x 18 in. (455 mm) "safe" zone, centered on the sign, is provided beyond the arc of any door swing between the closed position and the 45-degree open position.

Signs that provide directional information to, or information about, permanent spaces are required to comply with specific requirements for visual characters. Minimum character heights are regulated both by the height of the sign above the floor and by the intended viewing distance. Consult the applicable regulations for signs required to identify specific accessible features, spaces, or elements.

SIGNS

FIRE ALARMS

Fire alarm systems are not required by accessibility regulations, but they are required to include accessibility-related features. Visible-alarm notification appliances, intended to alert persons with hearing impairments, are the primary accessibility component of fire alarm systems. Criteria for the placement of visible alarms, the intensity of each appliance, the intensity of the signal throughout the covered area, and the cumulative effect of multiple appliances are all regulated in an attempt to ensure that the signal is immediately noticed, without creating light patterns that could trigger seizures in persons with photosensitivity.

The National Fire Alarm Code, NFPA 72-1996 and later editions, contains the state-of-the-art criteria for visible alarms; provisions in A117.1-1998 are identical.

A117.1-1998 introduces a new approach to visible alarm criteria for dwelling units. While previous editions and the model codes have required visible alarms only in wheelchair-accessible units, the new approach requires that all units be capable of adding visible alarms (on an as-needed basis), with the capability to use a single set of visible notification appliances for notification of both unit smoke detector activation and building fire alarm activation.

TELEPHONES

Lawrence G. Perry, AIA; Silver Spring, Maryland

ELEVATION

NOTE

Detectable warnings are required at passenger transit platforms whose edges border a drop-off where no screen or guard is provided. The detectable warning should be a 24-in. (610 mm) wide strip of truncated domes, contrasting with the adjacent walking surface.

ADAAG requirements for detectable warnings at hazardous vehicular ways and reflecting pools have been suspended.

DETECTABLE WARNINGS

INTERNATIONAL SYMBOL OF ACCESS FOR HEARING LOSS

NOTE

Stadiums, theaters, auditoriums, lecture halls and similar fixed seating assembly areas are required to provide assistive listening systems if they have a capacity of more than 50 persons or if an audio amplification system is provided. Portable systems may be acceptable.

Check the applicable requirements for the number of receivers required, as they vary from just over 1% to 4% of the total capacity of the assembly area. At least 25% of the receivers should be hearing-aid compatible.

Signs should be provided at ticketing areas, or other clearly visible locations, indicating the availability of the assistive listening system. Signs should include the international symbol of access for hearing loss.

ASSISTIVE LISTENING SYSTEMS

AUTOMATIC TELLER MACHINES AND FARE MACHINES

Where ATMs or fare machines are provided, generally at least one machine is required to be accessible. A117.1-1998 provides extensive criteria addressing the input and output requirements of these machines and is intended to make them usable by someone with a vision impairment or a hearing impairment. A117.1-1998 requires operable parts to be not more than 48 in. (1220 mm) above the floor or ground; other standards may allow operable parts as high as 54 in. (1370 mm) where a side reach is possible.

VOLUME-CONTROLLED TELEPHONE

INTERNATIONAL TTY SYMBOL

NOTE

Wheelchair-accessible telephones are required where public telephones are provided. One wheelchair-accessible phone is required on each floor or level where phones are provided; where more than one bank (three or more phones) is provided on a floor or level, at least one phone at each bank must be wheelchair accessible. At least one phone per floor or level must allow forward approach.

A117.1-1998 requires that all operable parts of wheelchair accessible phones be located a maximum of 48 in. (1220 mm) above the floor or ground. Other standards may allow operable parts as high as 54 in. (1370 mm) where a side reach is possible. Federal regulations require all new telephone equipment to be hearing-aid compatible.

VOLUME-CONTROLLED: All wheelchair-accessible telephones, plus an additional 25% of telephones, must provide volume control. Check the applicable standards for required amplification requirements, as they vary. Telephones with volume control must be identified by signs, unless all telephones have volume control.

TEXT TELEPHONES (TTYs): Consult the applicable standards for the required number and location of TTYs. Recent model codes, based on the recommendations of the ADAAG Review Committee, provide for an increased number of TTYs. While the current ADAAG requires only one TTY in many cases, the more recent provisions require additional TTYs based on the number of phones at the site, in the building, on each floor, and at each bank of phones. Additional requirements may apply for hospitals, transportation facilities, highway rest stops, emergency roadside stops, service plazas, stadiums, arenas, hotels, and convention centers.

Public TTYs should be identified by the international TTY symbol. Directional signs to TTYs should be provided at banks of public telephones not providing TTYs. In addition, there may be requirements for shelves and outlets at banks of telephones without TTYs, to allow use of a portable TTY.

WHEELCHAIR-ACCESSIBLE TELEPHONES

CANES USED FOR AMBULATING

1. Canes provide support by shifting some body weight to the user's arm and shoulder and by helping maintain balance.
2. Single-point canes are available in various heights, in adjustable models, and with many different handgrip configurations. Collapsible models also are available.
3. Tripod and quad canes have three or four legs on the base. This configuration increases stability but also increases the weight of the cane.

LONG CANES USED FOR DETECTION

1. Long canes assist persons who are blind or visually impaired to detect obstructions in their path of travel.
2. Long canes are typically 36 to 48 in. long; they may fold, telescope, or be rigid.
3. Long canes may be used in either the "touch" technique (the cane is moved side to side, touching the floor surface 6 to 8 in. outside each shoulder) or the "diagonal" technique (the angled cane is held stationary with the tip just above the ground surface).
4. When using the touch technique, the cane length and the vertical angle formed with the ground plane serve as the basis for accessibility standards regarding protruding objects.

CRUTCH

MISCELLANEOUS CANES

CRUTCHES

1. Crutches reduce body weight stress on lower extremities by transferring force either to the user's shoulders or forearms.
2. Axillary crutches have an underarm support to transmit forces to the user's shoulder.
3. Nonaxillary crutches have handgrips and a forearm or upper arm cuff to distribute weight to the user's forearm.
4. Users must be able to stand with one crutch and simultaneously perform other functions with their free hand, such as opening a door.
5. Crutches used for walking are angled approximately 6 in. away from the body for greater stability, so slightly wider corridors and outdoor walks are desirable.

WALKERS

1. Walkers can provide some support for users but primarily are used to help maintain balance.
2. They are often used for travel in open areas without handrails, furnishings, or other means of support and balance. For many users, walkers help increase their self-confidence and therefore their independence.
3. Walkers are adjustable in height to suit individual users.
4. Walkers are flared for stability. The handgrip width is typically 16 1/2 to 18 in. The base width is typically 24 in.
5. Folding walkers are generally made of lightweight aluminum tubing and collapse to a width of approximately 4 in. They may have small front wheels, front and rear wheels, or four rubber tips.
6. Basket, or rolling, walkers have three or four wheels and various types of hand brakes. They may also have a shopping basket and/or a seat. The width of most rolling models is 27 to 28 in.

WALKER

AXILLARY CRUTCH

AMBULATING CANES

RACING WHEELCHAIR

MANUAL WHEELCHAIRS

1. Manual chairs are hand-propelled using rims mounted on large front or rear drive wheels. They are available in many different models and sizes and with a variety of removable or adjustable accessories, such as footrests and armrests.
2. The most popular U.S. models have large, rear drive wheels and smaller, front castor wheels. Armrests are usually "cutaway" to allow closer access to tables and counters.
3. Lightweight frames, usually of aluminum, may be either collapsible or rigid.
4. The width and length of wheelchairs vary significantly with the user's personal anthropometrics and with the chair's design. The widest standard model is approximately 26 in.; however, special accessories and extra wheel camber can increase this overall width.
5. Manual chair users have different capabilities for maneuvering and propelling their wheelchairs. Most manual chair users with spinal cord injuries can independently transfer from their wheelchair to a close-by toilet seat, bench, bed, automobile seat, or similar furnishing.
6. Specialized wheelchairs are available for daily activities such as bathing and for athletic competitions such as basketball and tennis.

WALKER

LONG CANE

MOBILITY AID PARAMETERS

SHOWER COMMODE WHEELCHAIR

MANUAL WHEELCHAIR

Kim A. Beasley, AIA, and Thomas D. Davies, Jr., AIA; Paralyzed Veterans of America Architecture; Washington, D.C.

THREE-WHEELED

NOTES

1. Individuals with impaired mobility or with stamina insufficient to travel relatively long distances often use electric scooters.
2. Scooters have either three or four wheels. Three-wheeled models are more maneuverable but less stable than four-wheeled models.

FOUR-WHEELED

3. Short wheelbase scooters are more maneuverable but less stable than models with longer wheelbases.
4. Short, three-wheeled models are more suitable for indoor use; longer, four-wheeled models are more suitable for outdoor use.
5. When operated indoors, scooters are often used differently than wheelchairs. Some compact scooters, however, can turn and maneuver within parameters similar to those of wheelchairs.
6. The scooter seat may swivel to facilitate its use in stationary positions such as in front of a desk. Seat heights are typically adjustable to suit the rider.

ELECTRIC SCOOTERS

NOTES

1. Motorized wheelchairs are propelled by electric motors powered by rechargeable batteries below the seat.
2. Motorized wheelchairs are usually controlled by a hand mechanism, or joystick, mounted on the chair arm. The joystick restricts access to tables, desks, etc. Some motorized chairs are controlled by sip-and-puff operators.
3. Motorized wheelchairs are similar in overall size to manual wheelchairs, but they are heavier and generally less maneuverable. The frames are not collapsible, although they can be partially disassembled.
4. With a full battery charge, motorized wheelchairs can climb steeper grades than most users can negotiate in manual chairs.
5. Users often need assistance transferring out of their wheelchairs onto a seat, bed, or toilet fixture.

MOTORIZED WHEELCHAIRS

VEHICLES ADAPTED FOR WHEELCHAIR AND SCOOTER USERS

A variety of private and commercial vehicles can provide transportation for wheelchair and scooter users. These vehicles often require special parking and drop-off arrangements so that users can access the vehicles. Most accessible commercial transit vans and some private vehicles may also require additional vertical clearance to accommodate their increased overall height. For most users, the major factor in private vehicle selection is whether they transfer to the car or van seat in order to drive or whether they drive seated in their wheelchair.

CONVENTIONAL PRIVATE AUTOMOBILES

1. Wheelchair and scooter users who can transfer or who are partially ambulant often elect to use conventional automobiles equipped with hand controls.
2. Some wheelchair users drive two-door automobiles equipped with a split-bench front seat. This arrangement allows the user to transfer onto the driver's seat, dismantle his or her wheelchair, and store it in the back seat.
3. In order for wheelchair users to enter and exit conventional automobiles, a clear access aisle is required beside the vehicle. The aisle width must allow for wheelchair passage and permit the chair to be positioned at an angle for transfer to the driver or passenger seat.
4. Special lifts can be installed on the rear bumper, trunk, or even the roof of conventional automobiles to allow a scooter or wheelchair to be transported.

LIFT- AND RAMP-EQUIPPED PRIVATE VANS

1. Minivans, full-size vans, and conversion vans can be equipped with various types of lifts to allow wheelchair users to enter and exit the vehicle while remaining seated in their chairs. Van floors can also be lowered to allow a driver to remain in a wheelchair while driving the vehicle.
2. The best lift arrangement depends on several factors, including the height of the van doors, the van interior, and the user's personal anthropometrics. If a wheelchair user's seated height is more than approximately 44 in., for example, he or she may need either a full-size van or a minivan with a raised roof.
3. The three most common types of wheelchair lifts are side door- or rear door-mounted platform lifts or side door-mounted rotary lifts.

4. Platform lifts are mechanically raised and lowered with either linear tracks or parallel arms. For designers, the important feature common to all lifts is that the user rolls on or off the platform straight ahead. This procedure requires extra ground space either on the passenger side or behind the van for the chair to roll off the lift.
5. Rotary lifts can be installed at the side door to swing out in an arc that will realign the wheelchair parallel to the van before it is lowered to the ground. A rotary lift significantly reduces the required aisle width.
6. Some minivans can be equipped with automatically deployed ramps that can be lowered to the ground or the sidewalk from the passenger side door.
7. Since the ramp user enters or exits straight ahead, ramp-equipped vehicles also require a generous side access aisle, approximately the same as for a platform lift.

LIFT-EQUIPPED COMMERCIAL TRANSIT VANS

1. Commercial transit vans must meet minimum ADA requirements for lift platform size and interior headroom, which typically are more stringent than those for personal vehicles.
2. Most commercial transit vans have raised roofs to provide interior headroom and opening clearance at the entry door sufficient to accommodate passengers seated in wheelchairs. Extra height must therefore be provided at outdoor canopies and other overhangs that protect passengers during loading and unloading; a minimum height of 9 ft 6 in. is recommended.
3. Most commercial vehicles are equipped with slightly larger platform lifts than private vehicles, necessitating generous access aisles.

RESIDENTIAL BEDS

For wheelchair users who can independently transfer themselves between bed and chair, bed heights should facilitate their movement back and forth in a sitting position. Transfer is easiest for these users if the mattress top approximately matches their wheelchair seat height (typically 18 to 20 in.).

Quadriplegics or other wheelchair users who cannot independently transfer themselves between bed and chair are typically assisted by attendants, who use a portable lift mounted on a metal stand. In order for the lift frame to be positioned underneath the bed, the boxspring must have sufficient clear space beneath it. Depending on the diameter of the lift wheel, a clearance of approximately 8 in. is typically required. Because the overall bed height is not critical for people who use a lift to transfer, it may be acceptable to block the bed up off the floor to provide sufficient space beneath it.

BEDS

CABINETS

CHESTS

DESKS

DIFFICULT TO OPERATE EASY TO OPERATE

DRESSERS, CHESTS, AND CABINETS

Dressers and chests for wheelchair users should be situated so there is a clear access aisle in front of the furniture. This aisle should be wide enough (approximately 42 in.) to allow the drawers to be opened when a wheelchair is positioned parallel to the chest. Dressers and chest drawers should be narrow enough to be opened with one hand using a single pull rather than with simultaneous use of two pulls. Drawer hardware profiles should be appropriate for people with limited hand function. Pulls, for example, should be able to be hooked rather than grasped.

Cabinets, tables, stands, and other furniture with doors should have relatively narrow leaves so the arc of the swing when they are opened is small. This makes the leaf easier to operate without moving the wheelchair as the door is opened.

DESKS, TABLES, AND WORKSTATIONS

Knee space is integral to the use of desks, tables, and workstations. In order to serve wheelchair users, furniture must offer knee space that can accommodate the chair in a position that places the user's legs fully beneath the horizontal surface and his or her upper body close to the front edge of the top. For most wheelchairs, knee space with a clear height of approximately 2 ft 3 in. is sufficient. Higher knee space also raises the working surface and, for most uses, including writing and eating, it is desirable to have the top surface as low as possible. One option is to use a desk or work table that can be adjusted to the height required by an individual user.

The minimum aisle width required to turn (90°) a wheelchair in and out of any knee space depends on the width and depth of the knee space itself. A deep, narrow knee space requires more maneuvering clearance than a wide, shallow knee space. The recommended minimum width for a knee space is 2 ft 6 in. This width requires an aisle of approximately 3 ft 4 in. in order for most wheelchairs to complete a 90° turn without backing and filling. Pedestal tables and pedestal-supported or cantilevered open worktops offer wider knee spaces. Workstations with adjustable height tops can be tailored to a specific user's needs, but the minimum knee space width should be 30 in.

CHAIRS

For ambulatory people who have difficulty maintaining their balance, chairs should be stable in order to provide support. Chairs equipped with armrests help ambulatory users to sit and rise and are generally more comfortable to sit in. Chair leg supports and cross-bracing should not obstruct kick space below the seat. Kick space allows the chair occupant to position his or her feet partially beneath the body in order to rise.

Low chair seats make it more difficult for the occupant to sit and rise. For comfort, the chair seat height (typically 16 to 18 in.) should allow an occupant's feet to rest comfortably on the floor. High stools or chairs should include foot rails or elevator platforms to support the occupant's feet. Chairs that serve tables and desks should be light enough to be easily repositioned.

Ergonomic work chairs allow many aspects of the chair, such as seat height and angle of incline, to be adjusted to suit each individual user. Wheelchair users who wish to sit in conventional chairs typically have individual preferences. People who transfer diagonally can use chairs with armrests, while people who transfer from a parallel position must have clear side access, which is offered by chairs without fixed armrests.

FURNITURE OPERATION FOR ACCESSIBILITY

ADJUSTABLE HEIGHT WORK SURFACE

ACCESSIBLE DRAWER PULL

NOTE

For knee space below a tabletop with a minimum width of 2 ft 6 in. between obstructions (e.g., table legs), the approach clearance should be 3 ft 6 in. A knee space width of 3 ft 0 in. or more should have an approach clearance of 3 ft 0 in.

TABLE CLEARANCES

CHAIR FOR DINING OR DESK

ERGONOMIC WORKSTATION CHAIR

Kim A. Beasley, AIA, and Thomas D. Davies, Jr., AIA; Paralyzed Veterans of America Architecture; Washington, D.C.

- NOTES**
- Depending on the configuration of clear floor space, the maximum height of the controls ranges from 3 ft 8 in. (1120 mm) to 4 ft 6 in. (1420 mm), and the minimum height ranges from 9 in. to 2 ft 10 in. (230 to 865 mm).
 - If the partition is greater than or equal to 2 ft 0 in. (610 mm) deep, urinal clear floor spaces must be 3 ft 0 in. (915 mm) wide. If the partition is less than 1 ft 5 in. (430 mm) deep, urinal clear floor space may be 29 in. (735 mm) wide.

LOCATION OF ACCESSIBLE FIXTURES AND ACCESSORIES

NOTE
These configurations do not comply with UFAS or ADAAG.

OPTIONAL GRAB BAR CONFIGURATIONS

ACCESSIBLE BATHTUB AND SHOWER

Mark J. Mazz, AIA, P.A.; Hyattsville, Maryland

- CONCEALED FLANGE NOTES**
- Size: 1 1/2 or 1 3/4 in. O.D. with 1 1/2 in. clearance at wall.
 - Material: Stainless steel chrome-plated brass with knurled finish (optional).
 - Installation: Concealed or exposed fasteners; return all ends to the wall, intermediate supports at 3 ft maximum. Use heavy-duty bars and methods of installation.
 - Other grab bars are available for particular situations.
 - Consult ANSI and ADAAG requirements, as well as applicable local and federal regulations.

GRAB BAR ATTACHMENT DETAILS

GENERAL NOTES

1. All dimensional criteria on this page are based on ANSI A117.1-1998, and on adult anthropometrics.
2. In new construction, all public and common use toilet rooms are generally required to be accessible.
3. Where multiple single-user toilet rooms or bathing rooms are clustered in a single location, and each serves the same population, only 5%, but not less than one, of the rooms must be accessible. The accessible room(s) must be identified by signs.
4. Single-user toilet and bathing rooms provided within a private office are permitted to be adaptable. Making the room accessible is permitted to involve replacement of the water closet and lavatory, changing the swing of the door, and installing grab bars in previously reinforced walls.
5. In accessible toilet and bathing rooms, at least one of each type of fixture and accessory provided must be accessible.
6. A wheelchair turning space is required within accessible toilet and bathing rooms.
7. Doors are not permitted to swing into the required clear floor space at any fixture, except in single-user rooms, where a clear floor space is provided beyond the swing of the door.

UNISEX TOILET AND BATHING ROOMS

ASSEMBLY AND MERCANTILE OCCUPANCIES

1. Recent model codes require accessible unisex toilet and bathing rooms in certain assembly and mercantile occupancies. These unisex rooms are beneficial for parents with small children and for persons with disabilities who require personal assistance in using toilet facilities, since the assistant may be a person of the opposite sex.
2. This requirement applies when a total of six or more water closets (for water closets and urinals) is provided in the facility.
3. Fixtures provided in unisex rooms are permitted to be included in the number of required plumbing fixtures.
4. Unisex facilities must be located within 500 feet, and within one floor, of separate-sex facilities. In facilities with security checkpoints, such as airport terminals, unisex facilities must be located on the same side of the checkpoint as the separate-sex facilities they serve.
5. Unisex toilet rooms require a single water closet and lavatory. Unisex bathing rooms must also provide an accessible shower or bathtub. An exception allows the use of a room containing two water closets (for one water closet and urinal) in lieu of a dedicated unisex room.
6. Doors to unisex toilet and bathing rooms must be secureable from within the room.

ALTERATIONS

1. Accessible unisex toilet and bathing rooms are permitted in alterations in lieu of altering existing separate-sex facilities in certain conditions.
2. Unisex rooms must be located in the same area and on the same floor as the existing inaccessible facilities.

LAVATORY ON SIDE WALL

TOILET ROOM LAYOUTS

1. Some of the toilet room layouts shown are similar. Variations are in the direction of the door swing and whether the width or depth is the more constraining dimension. Dimensions show comfortable minimums and preferred dimensions.
2. Overall room dimensions include a 2 in. construction tolerance.
3. Each layout shows the required clear floor space for the fixtures and the doors. Frequently, the clear floor space at the fixture is more stringent than the 60-in. diameter or the T-shaped maneuvering space required. Both must be considered.
4. Door maneuvering clearances: see ADAAG (section 4.13.6 and fig. 25) for various requirements and conditions. Variables include direction of swing, direction of approach, size of door, and door hardware.
5. Doors to bathrooms are assumed to be 36 in. wide, with a closer and latch for privacy. Where noted, the overall dimension may decrease if there is no closer.

OUTSWINGING DOOR

INSWINGING DOOR

OUTSWINGING DOOR

LAVATORY ON OPPOSITE WALL

Lawrence G. Perry, AIA; Silver Spring, Maryland

GENERAL

See other pages in this chapter for requirements for accessible residential fixtures. All dimensional criteria are based on ANSI A117.1-1998, unless otherwise indicated.

WATER CLOSETS AND URINALS

1. A117.1-1998 allows water closets to be located 16 to 18 in. (405 to 455 mm) from the side wall. Previous editions of ANSI as well as other regulations require this dimension to be an absolute 18 in. (455 mm).
2. A117.1-1998 requires the water closet clearance to be unobstructed by lavatory or other fixtures. Previous editions and other regulations allow other configurations with a lavatory within the water closet clearance.
3. The dashed area indicates the allowable location of the toilet paper dispenser. Outlet must be within the range shown. Dispensers should allow continuous paper flow and not control delivery.
4. A117.1 does not require an elongated urinal rim; other regulations may.
5. Manually operated flush controls must be located not more than 44 in. (1120 mm) maximum above the floor.

WATER CLOSETS

TOILET COMPARTMENTS

1. Toe clearance 9 in. (230 mm) high and 6 in. (150 mm) deep is required at the front and at least one side of accessible toilet compartments. Toe clearance is not required when the compartment size exceeds the minimum dimension by 6 in. (150 mm) or more.
2. Left- or right-handed configurations are permitted.

LAVATORIES

1. Knee and toe clearance is required below accessible lavatories. The lavatory overflow is permitted to project into the knee clearance.
2. Exposed pipes and water supply pipes located beneath accessible lavatories must be insulated or located so as to protect users from contact with the pipes.
3. Lavatory controls should be within accessible reach range, be operable with one hand, and not require tight grasping, pinching, or twisting of the wrist. Automatic controls are acceptable. Manually activated, self-closing faucets should operate for not less than 10 seconds.

TOILET COMPARTMENTS

BATHTUBS

1. Bathtub controls, other than drain stoppers, must be located on an end wall between the tub rim and grab bar and between the open side of the tub and the midpoint of the tub width.
2. A 59 in. (1500 mm) minimum length shower spray unit is required.
3. Tub enclosures must not obstruct controls or interfere with transfer from a wheelchair to the tub. Enclosures must not have tracks mounted on the tub rim.

SHOWER COMPARTMENTS

1. Shower compartment thresholds are not permitted to exceed 1/2 in. (13 mm). Design should anticipate water escaping from the compartment.
2. A fixed, folding, or removable seat is required in transfer-type compartments. Seats in roll-in showers, where provided, should be located on the wall adjacent to the control wall and should be folding-type seats. Seats can be rectangular or L-shaped; see A117.1 for details.
3. A 59 in. (1500 mm) minimum length shower spray unit is required.
4. Shower enclosures, where provided, must not obstruct controls or interfere with transfer from a wheelchair.

BATHROOM LAYOUTS

ACCESSIBILITY STANDARDS FOR BATHROOMS

Residential bathrooms and single-use toilet rooms can be divided into two general categories—private facilities such as those located in single- or multifamily dwellings and public or institutional facilities such as those located in nursing homes, hospitals, dormitories, or hotels.

Although toilet room and fixture design standards were an important part of the first ANSI A117.1 standards in 1961, wheelchair bathroom standards for private dwellings were not included until the 1981 edition. Four years later, the Uniform Federal Accessibility Standard (UFAS) published nearly identical bathroom standards for dwellings included in federal projects. In most multifamily projects, whether privately or publicly funded, between 1 and 5% of the total dwellings must meet the ANSI or UFAS standards for full wheelchair accessibility. The exact scoping requirement depends on the specific local or federal code.

In 1988 the Fair Housing Amendments Act (FHAA), a federal civil rights law that addressed private multifamily housing design, was enacted. FHAA guidelines included new and different standards for residential bathrooms. Although less strict than those found in ANSI and UFAS, the Fair Housing standards must be much more broadly applied, typically to 30–100% of all project units. The specific project scoping depends on the building configuration and whether or not it is equipped with a passenger elevator. The Fair Housing guidelines include two alternative bathroom design standards. In covered dwellings with two or more full bathrooms, the more strict standards can be used for one bath and more minimal standards can be applied to the second bathroom.

In 1991 the Americans with Disabilities Act (ADA) included new design standards called the Americans with Disability Act Accessibility Guidelines (ADAAG). ADAAG standards are not typically applied to private residential facilities because the previously issued Fair Housing standards already apply. However, bathrooms located in “transient lodging” facilities such as hotels or public institutional facilities such as hospitals may be required to meet both ADA and Fair Housing standards.

Architects should carefully verify which bathroom requirements apply to their projects because accessibility design standards vary significantly, even though many use the same technical language and general concepts.

MANEUVERING SPACE

An accessible bathroom must meet specified plan requirements, depending on the standards used. Each bathroom plan must provide the fixture clearances required by the applicable standard. In addition, some general maneuvering space must be provided, although the amount of space and the measurement rules vary.

Bathrooms that comply with Fair Housing must be “usable” rather than “accessible” and therefore have lower maneuvering space standards. According to Fair Housing, if the entry door swings into the bathroom, there must be enough clear space to position a wheelchair clear of the door swing. This requirement is described as a rectangular space 30 x 48 in. ANSI, UFAS, and ADAAG describe the required bathroom maneuvering space as either a 5-ft diameter circle or a 5-ft T-shaped area. Maneuvering space can include knee and toe space under fixtures and accessories.

All of the standards permit required floor space for fixtures to overlap with required maneuvering space. Current ADAAG standards, however, do not permit the bathroom door (even in single-user facilities) to swing into any fixture clearance. In almost all instances, this requirement effectively demands that the door swing out into the adjacent hall or bedroom.

BATHROOM ENTRY DOORS

Different standards require different size bathroom entry doors. Fair Housing permits a 2 ft 10 in. door to provide a “nominal” 32-in. clear opening. ANSI, UFAS, and ADAAG require installation of at least a 3 ft 0 in. door to provide the full 32-in. clear opening. These three standards also require maneuvering clearances for door operation.

GRAB BARS

Grab bar arrangement can influence the floor plan of an accessible bathroom. Fair Housing grab bar standards are less strict, and this permits the design of smaller bathrooms. For example, the grab bar installed adjacent to a water closet can be shorter than that required by ANSI. In fact, Fair Housing permits the installation of swing-down grab bars, so the water closet does not even have to be located adjacent to a wall. The stricter grab bar requirements of ANSI, UFAS, and ADAAG can become critical factors in water closet and bathroom arrangements and thus will affect the overall bathroom plan.

ADAPTABLE FEATURES

In residential bathroom design, “adaptability” was a new term when introduced in the 1980 ANSI edition. Adaptability in this case is defined as “the capability of certain...elements...to be altered or added so as to accommodate the needs of persons with or without disabilities, or to accommodate the needs of persons with different types or degrees of disabilities.” In accessible bathrooms, adaptable elements might typically include “removable” base cabinets that can be eliminated, when necessary, to provide knee space below vanities and hidden wall reinforcing that will facilitate later installation of grab bars around certain plumbing fixtures. Some codes and civil rights laws require provisions in certain bathrooms for “adaptable” features.

For single-family custom homes or remodeling projects, bathroom designs should be specially tailored to the individual homeowners. If a master bathroom is planned for a wheelchair user, for example, the design should reflect that person’s individual capabilities and preferences. This might include a specific type of bath fixture or a specific fixture orientation to accommodate better body function on the right or left side.

Kim A. Beasley, AIA, and Thomas D. Davies, Jr., AIA; Paralyzed Veterans of America Architecture; Washington, D.C.

WATER CLOSET SPACE REQUIREMENTS

LAVATORY AND SHOWER SPACE REQUIREMENTS

BATHTUB SPACE REQUIREMENTS

PLUMBING FIXTURE REQUIREMENTS

Although fixture requirements vary among the common accessibility standards and guidelines, the most significant differences are found between the Fair Housing Act and ANSI and UFAS. The current ADAAG requirements are similar to the ANSI/UFAS standards except for some very subtle technical differences. Floor space requirements for the different accessibility standards are illustrated in the accompanying plans. For other requirements, such as grab bar installations or faucet specifications, that depend more on a specific fixture, architects should refer to the code(s) or standard(s) that apply to their projects.

WATER CLOSET STANDARDS

Clear floor space requirements for water closets are similar in the Fair Housing, ANSI/UFAS, and ADAAG standards. Several of these include arrows on the floor plans to indicate a wheelchair user's approach direction, although the significance of this is never explained. The major differences between Fair Housing and the other standards are the minimum space required behind the water closet (33 in. as opposed to 36 in. or more) and the configuration of the lavatory or vanity that may be located adjacent to the toilet. In order to meet Fair Housing standards, an adjacent lavatory does not have to include knee space, whereas knee space is an important ANSI/UFAS and ADAAG requirement.

Designers should be aware of other technical requirements such as grab bars, wall reinforcement, and toilet seat heights. For all the standards except Fair Housing, toilet grab bar requirements can significantly affect both the loca-

tion of the water closet and the overall bathroom arrangement. Water closets that meet ANSI/UFAS and ADAAG, for example, must be located adjacent to a long side wall; therefore, they cannot be positioned next to a bathtub or directly inside the entry door. When designing toilets for Fair Housing projects, architects should also reference several other requirements that were added to the 1996 edition of the HUD Fair Housing Act Design Manual.

LAVATORY AND VANITY STANDARDS

The major differences between accessibility standards for lavatories and vanities are related to the need for under-basin knee space. Specifically, Fair Housing does not require knee space but the other standards do. In some instances, the knee space height required by ADAAG is greater than that required by ANSI or UFAS. All accessibility standards except Fair Housing include requirements for a maximum sink depth. ADAAG, ANSI, and UFAS also include requirements for faucets, mirrors, and medicine cabinets. The 1996 Fair Housing Act Design Manual amended the original guidelines to require that a parallel approach vanity sink be centered on the required clear floor space.

BATHTUB AND TUB/SHOWER STANDARDS

The ADAAG, ANSI (pre-1998), and UFAS accessible bathtub standards also have subtle differences. The bathtub clear floor space requirements are similar to those for water closets in that an approach direction is indicated (either perpendicular or parallel). The significance of the approach direction is similarly unclear, particularly when a knee space lavatory will be installed adjacent to the tub. Wheelchair access to the bathtub faucets and controls is available in

either case, although ambulatory bathers' access is compromised by a lavatory installed in this location. Under the Fair Housing guidelines, it is permissible to locate either a water closet or non-knee space lavatory in this position.

Fair Housing offers two different clear space requirements; the designer may choose to comply with either. Of these alternatives, Alternate B is stricter because it requires clear space adjacent to the foot of the tub.

STALL SHOWER AND ROLL-IN UNIT STANDARDS

Accessible showers include both transfer stalls (where a bather moves from a wheelchair to a bench or portable seat) and roll-in stalls (where a bather remains seated in a special shower chair and is either pushed by an attendant or self-propelled into the stall). Stall shower design requirements vary among the different standards. Fair Housing has fewer strict requirements for stall size and requires a smaller clear space in the bathroom outside the shower entrance. ANSI, UFAS, and ADAAG require installation of a built-in stall seat. The standards also address the location and design of the mixing valve, operating controls, and spray head. All accessibility standards require either wall reinforcing or grab bars inside a shower. ANSI, UFAS, and ADAAG include a maximum dam height for stall showers. All the accessibility standards except Fair Housing include specifications for roll-in showers. These stalls are much larger and without a dam in order to permit wheelchair access, making it necessary to lower the floor structure beneath the shower to provide an essentially flush transition with the bathroom floor.

Lawrence G. Perry, AIA; Silver Spring, Maryland

ACCESSIBILITY GUIDELINES

The 1980 American National Standards Institute (ANSI) A117.1 and the 1984 Uniform Federal Accessibility Standards (UFAS) were the first to include kitchen design standards that focused on the needs of wheelchair users. In most multifamily housing, ANSI/UFAS standards must be applied to between 1 and 5% of the total dwelling units, depending on local building codes or federal standards. The kitchen standards in the 1988 Fair Housing Amendments Act, a federal civil rights law, include less specialized wheelchair design features for multifamily housing. Fair Housing standards must be applied to between 20 and 100% of the total project units, depending on the configuration of the buildings, whether they are equipped with a passenger elevator, and the site topography.

Architects should carefully verify which kitchen requirements are appropriate for their specific project because accessibility codes and civil rights laws have very different design standards.

Kitchen designs for single-family custom homes or remodeling projects should be based in part on which family member performs cooking or clean-up chores and also on the capabilities of the wheelchair user. Accessible kitchens should reflect conventional layout principles with regard to proper workflow and functional adjacencies.

FIXTURE AND APPLIANCE REQUIREMENTS

The three general types of wheelchair standards for residential kitchens are: (1) general kitchen maneuvering space; (2) individual fixture and appliance maneuvering space; and (3) other fixture specifications such as basin depths, switch locations, and faucet configurations. ANSI and UFAS standards for appliances and plumbing fixtures are much more restrictive than Fair Housing (see chart on this page). All of them require that sufficient clear floor space be provided at fixtures or appliances to accommodate either a *parallel* or *front* approach, depending on the applicable design standard.

Some clearance standards do not have a functional basis, however. For example, in order to be useful, a parallel approach to a dishwasher must be offset to allow the bottom-hinged door to be fully lowered. An adjacent knee space at either the kitchen sink or an open, end-of-counter location provides optimum wheelchair access to a dishwasher. A parallel approach to a refrigerator is more practical than a front approach because the user's longer horizontal reach will allow full access to the interior.

The 1998 ANSI appliance clearances are more sophisticated than previous standards. For example, oven clearances depend on whether the unit is a self-cleaning model and on whether the door is side- or bottom-hinged. If the kitchen design is based on specific assumptions regarding appliances, the architect should carefully note that fact on the drawings to ensure that the proper model is purchased and to protect against compliance questions.

A critical point regarding clear floor space and kitchen fixtures and appliances is the requirement to precisely center the floor space on the centerline of the appliance or fixture. Although this requirement was not explicitly stated in the Fair Housing guidelines, HUD interprets this to be a Fair Housing kitchen and bathroom requirement. In a kitchen plan, the impact can be significant. In order to provide a parallel approach, for example, fixtures or appliances less than 48 in. wide must be offset from either an end wall or an inside counter corner. A 30 in. refrigerator, for example, must be located 9 in. away from an end wall; a 24 in. dishwasher must be located 12 in. away from an inside counter corner. Kitchen centerline requirements exceed the 1986 ANSI "safe harbor" requirements.

Requirements for general maneuvering space within the kitchen and for counter heights also vary among standards. ANSI and UFAS require a minimum clearance between counters, countertops, appliances, or walls of (1) a 40-in. galley aisle where required fixture or work area knee space is provided or (2) a 60-in. aisle in U-shaped kitchens. The minimum galley aisle required by Fair Housing is unclear, although designs that meet 1986 ANSI technically meet the federal laws. ANSI and UFAS require either adjustable height counters or fixed counters at a height of 34 in. Fair Housing does not address counter heights.

ADAPTABLE FEATURES

The term "adaptability" is defined as "the capability of certain . . . elements . . . to be altered or added so as to accommodate the needs of persons with or without disabilities" For accessible kitchens, "adaptable" elements might include "removable" base cabinets that can be eliminated to provide knee space below countertops, or adjustable height countertop sections that can be raised and lowered.

Lawrence G. Perry, AIA; Silver Spring, Maryland

NOTE

A U-shaped counter arrangement must include a 5 ft 0 in. clearance between the opposing counters (or appliances or walls) in order to comply with ANSI or UFAS standards. FHAA guidelines require a 5 ft 0 in. clearance if a sink, range, or cooktop is installed in the base leg of the U. If the base leg fixture includes a knee space or removable base cabinets, the 5 ft 0 in. clearance is not required.

U-SHAPED KITCHEN PLAN

NOTE

ANSI and UFAS require 40 in. clearance between kitchen cabinets and opposing walls, cabinets, or appliances where the counters provide knee space. In other instances, an accessible route is required. The FHAA guidelines, however, require a 40 in. clearance in all cases. Passage widths between opposing counter sides or walls and counter sides are not specifically addressed in the FHAA guidelines. If this passage's length does not exceed 24 in., ANSI or UFAS permits the width to be a minimum of 32 in.

GALLEY KITCHEN PLAN

FLOOR SPACE AND KNEE SPACE REQUIREMENTS FOR FIXTURES AND APPLIANCES

APPLIANCE	REQUIREMENT	FAIR HOUSING	ANSI/UFAS
Sink	Approach	Parallel	Parallel or front
	Knee space	No	Yes
Range/cooktop	Approach	Parallel	Parallel or front
	Knee space	No	Optional
Work space	Approach	Not required	Front
	Knee space	No	Yes
Refrigerator	Approach	Parallel or front	Parallel or front
	Knee space	No	No
Dishwasher	Approach	Parallel or front	Parallel or front
	Knee space	No	No
Oven (self-cleaning)	Approach	Parallel or front	Front
	Knee space	No	No
Oven (non-self-cleaning)	Approach	Parallel or front	Front
	Knee space	No	Yes (off-set)
Trash compactor	Approach	Parallel or front	Parallel or front
	Knee space	No	No

NOTE

Fair Housing guidelines and most building code standards require a clear floor space at most kitchen fixtures and appliances. This space can permit a parallel or a perpendicular (front) wheelchair approach, depending on the fixture or appliance selected or the decision of the designer. HUD has interpreted its FHAA guidelines to require centering of the clear floor space on the appliance or fixture. This is not a requirement of the building codes, however, and may exceed the 1986 ANSI "safe harbor" for FHAA.

APPROACH DIAGRAM FOR FIXTURES OR APPLIANCES

NOTE

Locating the kitchen sink next to the dishwasher has accessibility benefits as well as functional advantages. The sink knee space provides convenient access for a wheelchair user to the adjacent dishwasher. The sink itself should be a shallow unit with easy-to-operate faucets. A tall spout and a pullout spray attachment are also recommended. Garbage disposals must be offset in order to provide full knee space under the sink.

KITCHEN SINK AND DISHWASHER

NOTE

The design of kitchen storage space for wheelchair users should provide both visual and physical access to wall and base cabinets, drawers, and pantries. Base cabinets, for example, can be specified to include pullout shelves or drawers that will provide easy access to items stored in the back of the cabinets. Similarly, shelf racks on pantry doors make it easier for the user to find and reach stored items.

KITCHEN STORAGE

NOTE

A range or cooktop should have front- or side-mounted controls so the seated user does not need to reach over the heated surfaces. A smooth cooktop surface allows pots to be slid rather than lifted on and off the burners. Separate cooktop and oven units allow the alternative of providing knee space below the cooking surface, although this arrangement can also create safety issues.

STOVES AND COOKTOPS

NOTE

Side-by-side models offer the user both freezer and refrigerator storage at all height levels from the floor to the top shelf. Over-and-under models can also be a satisfactory choice for many wheelchair users. Models with narrower doors are easier to operate and the desired parallel access is easier to provide if the refrigerator doors swing back a full 180 degrees.

DIMENSIONING METHODOLOGY

GENERAL

Provide only critical dimensions on plans so as to keep them as uncluttered as possible. Consider the building trades using the dimensions and the sequencing of their work.

Because tolerances vary in construction, the as-built dimensions do not always coincide with the design dimensions. Dimensioning from established grids or structural elements, such as columns and structural walls, assists the trades that must locate their work prior to that of others.

NOTES

1. Dimensions under 1 ft should be given in inches. Dimensions 1 ft and over should be given in feet.
2. Use a diagonal line to separate the numerator from the denominator in a fraction. Do not use decimal fractions preceded by a zero (e.g., 0.5).
3. Dimension points should be indicated with a short, blunt 45 line, called a hatch mark. Hatch marks are oriented differently for vertical (↖) and horizontal (↘) dimensions. Modular dimension points may be designated with an arrow or a dot.

PARALINE DRAWINGS

Paraline drawings are sometimes referred to as AXONOMETRIC (Greek) or AXIOMETRIC (English) drawings. These drawings are projected pictorial representations of an object which give a three-dimensional quality. They can be classified as orthographic projections in as much as the plan view is rotated and the side view is tilted. The resulting "front" view is projected at a 90° angle to the picture plane (as illustrated in the projected method). These drawings differ from perspective drawings, since the projection lines remain parallel instead of converging to a point on the horizon.

Drawings prepared using the projection method require three views of the object, which tends to be more time-consuming and complex than drawing by the direct measuring method. The following drawings utilize this method; they are simple to draw and represent reasonably accurate proportions.

OBLIQUE

In an oblique drawing one face (either plan or elevation) of the object is drawn directly on the picture plane. Projected lines are drawn at a 30 or 45° angle to the picture plane. The length of the projecting lines is determined as illustrated and varies according to the angle chosen.

DIMETRIC

A dimetric drawing is similar to oblique, with one exception: the object is rotated so that only one of its corners touches the picture plane. The most frequently used angle for the projecting lines is an equal division of 45° on either side of the leading edge. A 15° angle is sometimes used when it is less important to show the "roof view" of the object.

ISOMETRIC

The isometric, a special type of dimetric drawing, is the easiest and most popular paraline drawing. All axes of the object are simultaneously rotated away from the picture plane and kept at the same angle of projection (30° from the picture plane). All legs are equally distorted in length at a given scale and therefore maintain an exact proportion of 1:1.

TRIMETRIC

The trimetric drawing is similar to the dimetric, except that the plan of the object is rotated so that the two exposed sides of the object are not at equal angles to the picture plane. The plan is usually positioned at 30/60° angle to the ground plane. The height of the object is reduced proportionately as illustrated (similar to the 45° dimetric).

SHADES AND SHADOWS

Shades and shadows are easily constructed and can be very effective in paraline drawings. The location of the light source will determine the direction of the shadows cast by the object. The shade line is the line (or the edge) that separates the light area from the shaded areas of the object. Shadows are constructed by drawing a line, representing a light ray, from a corner of the lighted surface at a 45° angle to the ground plane. Shadows cast by a vertical edge of the object will be drawn midway in the angle created by the intersection of the projected line of the object and the ground, or baseline (the baseline represents the intersection of the picture plane). The 45° light ray is extended until it meets the shadow line (as illustrated), and this point determines the length of the shadow for any given vertical height of the object. Shadow lines of all vertical edges of the object are drawn parallel to one another.

TERMS AND CONCEPTS

1. THE OBJECT: Called a building in this example.
2. THE PICTURE PLANE: An imaginary, transparent plane, onto or through which the object is perceived in a perspective rendering. It is:
 - a. Parallel to one face of the drawing paper, if it is a one-point perspective.
 - b. Perpendicular to the ground line and at any angle to the building if it is a two-point perspective.
 - c. Tilted and placed at any angle to the building if it is a three-point perspective.
 - d. A curved plane if it is a wide angle perspective view.
3. HORIZON LINE: A line drawn on the picture plane to represent the horizon. It is usually located at the point where all parallel lines recede away from the viewer and finally converge. This point is aptly designated as the vanishing point. Note that although the horizon is generally thought of as a horizontal line, in certain applications it could be vertical, or even at an angle, to the picture plane. For example, in drawing shades and shadows it appears to be at a 90° angle and in a three-point perspective it appears to be slanted.
4. STATION POINT: The point from which the object is being viewed or, in other words, the point from which the viewer is seeing the building. The location of this point will be the factor that determines the width of the drawing. A 30° cone of vision is drawn from the station point; as the viewer moves away from the object, the cone widens, the object becomes smaller, and more material is included in the area surrounding the object. A common way of determining the distance between the station point and the picture plane is by referring to the following parameters:
 - a. Minimum - 1.73 times the width of the drawing.
 - b. Average - 2.00 times the width of the drawing.
 - c. Maximum - 2.5 times the width of the drawing.
5. VANISHING POINT(S): A specific point or points located on the horizon line, where all parallel lines, drawn in perspective, converge or terminate. The location of the vanishing point varies with the type of perspective drawing. In the two-point perspective, the distance between the vanishing point left and the vanishing point right is estimated as being approximately four times the overall size of the building.
6. VISUAL RAY: An imaginary line drawn from the station point to any specific point lying within the designated scope of the plan layout of the object. The point at which this projected line passes through the picture plane will determine the location of that point in the perspective drawing.
7. GROUND PLANE: The ground on which the viewer is standing. In plan, this is determined at the station point. In perspective, it is the primary plane on which the building is sited. When the lines of this plane are extended to infinity, they become the horizon line. The intersection formed when the picture plane and the ground plane come together is called the ground line. In this way the horizontal dimension of the drawing is determined. The vertical dimension is determined by the vertical distance from the ground line to the horizon line. This should be approximately twice the height of object, in perspective, or a 30° cone in elevation.
8. ONE-POINT INTERIOR PERSPECTIVE: The most frequently used application of a one-point perspective. This is the same method as that used in setting up a one-point exterior perspective, except for the limitations that the confinement of space places on the location of the vanishing point. The vanishing point is usually located at the sitting or standing height of an average person within the space (eye level can be considered to be at 5 ft 4 in. from the floor). In most cases, the vanishing point is located within the confines of the enclosed space being represented in the drawing.
9. TWO-POINT PERSPECTIVE USING THE MEASURING POINT METHOD: This is a simplified alternative to the conventional method of laying out the plan picture plane and projecting the vanishing lines. The measuring point method of drawing a two-point perspective eliminates the necessity of the preliminary layout of the plan. One of the obvious advantages of this method is the ease with which the size of the drawing can be adjusted. A perspective can be made larger by simply increasing the scale of the drawing.

PERSPECTIVE - PROJECTION METHOD

NOTES

Before the drawing can be laid out, the following information must be obtained:

1. An approximation of the overall dimensions of the building.
2. The location of the building in relation to the picture plane.
3. The orientation of the building, either in front of or behind the picture plane.

While the building can be located anywhere in the drawing—in front of, behind, or at any angle to the picture plane—the simplest approach is to place the building at the picture plane. The horizontal lines of the building would be parallel to the picture plane in a one-point perspective or placed at an angle to the picture plane. Usually this will be a 30/60 or 45° angle in a two-point perspective.

ONE-POINT DIRECT MEASURED INTERIOR PERSPECTIVE

Samuel J. De Santo and Associates; New York, New York
 Alvarado Thrun Maeda and Associates; New York, New York; Eric A. Borch; Newburgh, New York

ONE-POINT PERSPECTIVE

The one-point perspective is probably the least complicated of the projected perspective methods. The primary face of the building or object is placed directly on the picture plane. The adjacent planes, generally connected to the primary plane at right angles, converge to the vanishing point - which can be either in front of or behind the picture plane. The vanishing point, located on the horizon line, also determines the height from which the building is viewed.

The conventional method of laying out a one-point exterior perspective is illustrated on the preceding page. A plan view, roof view, and elevation are required for the layout. The size of the object, and therefore the drawing, can be increased or decreased by moving the plan further in front of or behind the picture plane. This method is more flexible but much more complicated and time consuming than the method that follows.

EXTERIOR ONE-POINT PERSPECTIVE

1. Draw the primary elevation of the building to scale.
2. Locate the horizon above the ground line at the desired level (eye level is approximately 5 ft 4 in.). To ensure that the final perspective will fall within the 60° cone of vision, the height should not exceed 2 times the height of the building. The vanishing point is located left or right arbitrarily depending on the view desired.
3. Locate the 45° measuring point (45° MP) on the horizon by drawing a line from the vanishing point to the most remote corner from the vanishing point to the most remote corner from the vanishing point to the most remote corner, to a vertical line drawn down from the VP. From this intersection draw a line upward, at a 60° angle to meet the horizon. This point (45° MP) will be the vanishing point for all lines that are positioned at a 45° angle and parallel to the picture plane.
4. From each corner of the primary elevation, draw a line to the vanishing point.
5. The room depth is determined by starting at point 0 on the ground line and measuring to the right. Connect this point to the 45° MP on the horizon. The back wall is located where this line intersects the vertical base line drawn from the VP to the ground line.
6. The perspective is completed by constructing the back wall at the location established in step 5 and connecting it to the front wall. Note that the lines that are drawn at 45° angle in the drawing remain parallel to each other as they are extended in perspective.

ONE-POINT INTERIOR AND SECTIONAL PERSPECTIVE

1. Draw the primary elevation, or section, to scale. Locate the horizon line and vanishing point within the confines of the interior space.
2. The 45° measuring point (45° MP), which is also the SP in section, is located similar to the exterior one-point perspective. Strike an arc from the most remote corner of the room to a vertical line drawn from the VP. From this intersection draw a line upward at 60° (to the vertical) to meet the horizon. This intersection shall be the 45° MP.
3. The room depth is determined by starting at point 0 on the ground line and measuring to the right. Connect this point to the 45° MP on the horizon. The back wall is located where the line intersects the vertical base line drawn from the VP to the ground line.
4. Complete the back wall as illustrated. Note that all lines occurring at a 45° angle in the elevation remain parallel in perspective. All surfaces that are parallel to the picture plane will remain parallel in perspective.

TWO-POINT PERSPECTIVE

The projection method of constructing a two-point perspective is illustrated on page 197. This is the most widely used and most flexible method of drawing a two-point perspective. It can be taken from any viewpoint by simply turning the plan to the desired position in the preliminary layout. The size of the perspective can also be adjusted by moving the plan in front of the picture plane for a larger drawing and behind the picture plane for a smaller drawing. As in all projected methods, an inordinate amount of time and energy is devoted to the layout. The measured method is equally accurate, less time-consuming, and much easier to construct, since it eliminates the need to lay out the drawing in plan. The desired size of the drawing is determined by drawing the primary elevation at the desired scale.

30°/60° DIRECT MEASURED SYSTEM

1. **SETUP:** Draw a horizon line and locate vanishing point right (VPR) and vanishing point left (VPL) separated at a distance that is approximately 4 to 4.5 times the maximum width of the building. Follow the illustration to locate the station point and leading corner of the building.
2. **LENGTH:** Measure, to scale, the length of the building along length line L. A perpendicular line is drawn from these designated points to the ground line. The vanishing perspective lines are then drawn directly from these points to the appropriate vanishing point (VPL). In this way the correct length of the line can be determined. Note what happens when equally spaced points are projected from the ground line to the vanishing point. The visual distance (length) between them, as they get closer to the vanishing point, is progressively foreshortened.
3. **WIDTH:** The width is measured along the width line (see illustration) at double scale. That is, if the perspective is drawn at a scale of $\frac{1}{8}$ in. = 1 ft and a particular line is to be drawn at 5 ft, measure 5 ft at $\frac{1}{4}$ in. scale starting at the corner and measure to the left of the corner horizontally. A line is drawn from each point on the width line to the appropriate vanishing point (VPR). The intersections of the length and width vanishing lines will define the "plan" in perspective.
4. **HEIGHT:** Since the leading corner of the building is placed directly on the picture plane, the height is measured, to scale, directly on the H line. It is then carried to VPL and VPR as illustrated.

TWO-POINT PERSPECTIVE - 30°/60° DIRECT MEASURED SYSTEM

45° DIRECT MEASURED SYSTEM

1. **SETUP:** Similar to the method used in the 30°/60° setup, the vanishing points are placed on the horizon line and separated by 3 times the diagonal width. Complete the setup as illustrated.
2. **LENGTH:** Measure, to scale, the length of the building along the length line L. Connect the points directly to VPL.
3. **WIDTH:** In this setup, the width is the same as the length scale. Measure the width of the building along the width line W. The length and width lines will form an outline of the "plan" in perspective.
4. **HEIGHT:** The height line is positioned at a 45° angle and marked off to scale. A line representing the leading corner of the building is drawn perpendicular to the ground line. Connect or draw a line from the measurement points along the height line horizontally to the vertical corner line. As in the 30°/60° setup, these points are then carried to VPR and VPL.

TWO-POINT PERSPECTIVE - 45° DIRECT MEASURED SYSTEM

Samuel J. De Santo and Associates; New York, New York
 Alvarado Thrun Maeda and Associates; New York, New York; Eric A. Borch; Newburgh, New York

THREE-POINT PERSPECTIVE

In a one- or two-point perspective, the vertical lines of the object are usually parallel to each other and perpendicular to the ground plane. In reality, however, the vertical lines also converge, depending on the height of the observer (or the station point). If the station point is higher than the roof plane, the vertical lines will converge as they get closer to the ground plane; if the station point is lower than the roof plane, the vertical lines will converge as they move farther away from the ground plane.

The three-point perspective is very similar in method to the two-point one. The plan is rotated at any angle to the picture plane, and the location of the station point (in plan) is determined in the same way. The right and left vanishing points will likewise be located on the horizon line. The side view, however, differs from the two-point perspective in that the picture plane is now tilted forward when viewing the building (or object) from a point lower than the roof plane or backward when viewing the building from a point higher than the roof plane. When the lines of vision are drawn to the station point in plan and a side elevation, the combined projections result in a three-point perspective as viewed from the "front." As in the other projected perspective methods, a plan view, side view, and picture plan are required before the perspective can be constructed.

Vanishing point left and vanishing point right (indicated as points 1 and 2 in the illustration) are located on the horizon line. The distance between these two points is approximately four times the maximum length of the object. Once these two points are determined, the entire framework of the construction can be drawn using the 30/60 and 45° triangles ($75^\circ = 30 + 45$).

LENGTH

The length line is drawn at the same scale as the line connecting points 1 and 2 (which is four times the maximum length of the object). Measured points are projected perpendicularly from the length line L to the ground line (see illustration). From the ground line, the measured points are connected to vanishing point left (or point 1).

WIDTH

At double the original scale, that is, if length (L) is at a $\frac{1}{4}$ in. scale, use $\frac{1}{2}$ in. scale for width (W). Locate the distances along the width line, and connect these points directly to the vanishing point right (or point 2).

HEIGHT

Using the original scale, mark off the measuring points along the height line (H). These points are projected perpendicularly to the line labeled "vertical plane." From these points a line is drawn to vanishing point right (point 2), thereby cutting the vertical lines vanishing to point 2.

45° POINT

This point on the horizon is determined by projecting a line from the upside down station point so that it will meet the horizon line at a 75° angle. All lines occurring at a 45° angle to the picture plane (in viewing) will converge to this point; it is, therefore, often convenient to use this as a reference point when converting exact width to length, or vice versa, in plan.

PROJECTING THE PERSPECTIVE

Samuel J. De Santo and Associates; New York, New York
 Alvarado Thrun Maeda and Associates; New York, New York; Eric A. Borch; Newburgh, New York

GENERAL

Virtually all computer-aided design (CAD) systems support the concept of layers, which allow grouping of graphic information for display or plotting. Intelligent use of layers can reduce drawing time and improve drawing coordination. For example, a single CAD file can be used to produce a floor plan, a reflected ceiling plan, a power plan, and a lighting plan. In addition to increased drawing productivity, use of standardized CAD layers provides these other benefits:

1. Improved coordination between architects, engineers, and consultants
2. Efficient creation of facility management record drawings from construction documents
3. Symbols and details that can be reused without conversion of layers

In 1990 the first industry standard for the use of CAD layers in architecture, engineering, and facility management was introduced with the publication of *CAD Layer Guidelines*. In 1997 the second edition of *CAD Layer Guidelines* was published, expanding the work begun in the first edition in the following ways:

1. Adds discipline designations for interior design, telecommunications, and other fields
2. Expands layer designations for remodeling projects
3. Designates the "long format" as the single approved layer name format
4. Coordinates with the Construction Specification Institute's Uniform Drafting System
5. Defines a standard for naming and organizing CAD files

CONVENTIONS FOR NAMING LAYERS

The CAD layer guidelines are organized using a hierarchical structure that provides for flexibility and expandability. The first level of the hierarchy is the discipline code. Discipline codes follow traditional sheet numbering conventions as shown here:

A	Architectural
C	Civil
E	Electrical
F	Fire protection
G	General
H	Hazardous materials
I	Interiors
L	Landscape
M	Mechanical
P	Plumbing
Q	Equipment
R	Resource
S	Structural
T	Telecommunications
X	Other disciplines
Z	Contractor/shop drawings

Discipline codes are followed by either a hyphen or another letter that designates a specialized discipline. For example, AG is used for architectural graphics.

The second level of the hierarchy is the major group code. This is used to designate a construction system or type of information. For example, a drawing might contain layers with the following discipline and major group codes:

A-WALL	Walls
A-DOOR	Doors
A-GLAZ	Glazing
A-EQPM	Equipment
A-CLNG	Ceiling information
A-ROOF	Roof
E-POWR	Power
S-COLS	Structural columns

Layer names can be further extended with a minor group code and a status code. The minor group is an optional, four-character field used to define subcategories of information. For example, A-WALL-PART indicates architecture, new, wall, partial height. IDEN for identification and PATT for pattern are two commonly used modifiers in the minor group field.

Status codes are four-character designators used to differentiate new construction from demolition, remodeling, and construction that is "existing to remain." They are only needed when a project has phases of work that must be differentiated. Defined values for this field are shown on this page under the heading "Status Field Modifiers."

Layers representing the dominant phase of a project can be named without using a status field. For example, in a small remodeling project, NEWW would indicate new construction, while layers without status fields would indicate parts

of the existing building that will remain. For example, a remodeling plan might contain the following layers:

A-WALL-NEWW	New walls
A-DOOR-NEWW	New doors
A-WALL-DEMO	Walls to be demolished
A-DOOR-DEMO	Doors to be demolished
A-WALL	Existing walls to remain
A-DOOR	Existing doors to remain

Conversely, a remodeling project consisting of mostly new construction might use EXST to indicate layers referring to "existing to remain" construction and layers without status fields to represent new construction.

The status field is always placed as the last field of the layer name. In a simple layer name such as A-WALL, the status field would be the third field (A-WALL-DEMO). In a more detailed layer name, the status field would be the fourth field (A-WALL-FULL-DEMO).

MASTER LAYER LIST

The master layer list identifies all defined layers in the CAD layer guidelines. Users are free to add their own layers, but should identify them as "user-defined." The use of an asterisk (*) indicates a place holder for the discipline code, major group, or minor group. Some layers included in the following list are new or have been revised since the first edition of *CAD Layer Guidelines*.

This list is arranged alphabetically by discipline. Layers within each discipline are arranged by construction system.

ANNOTATION LAYERS

*-ANNO-TEXT	Text
*-ANNO-REDL	Redline

*-ANNO-SYMB	Symbols
*-ANNO-LEGN	Legends and schedules
*-ANNO-DIMS	Dimensions
*-ANNO-TTLB	Border and title block
*-ANNO-NOTE	Notes
*-ANNO-NPLT	Construction lines, nonplotting information
*-ANNO-KEYN	Key notes
*-ANNO-REVS	Revisions

NOTE

Annotation layer names may be appended with a four-character sheet name designator when needed.

COMMON MODIFIERS

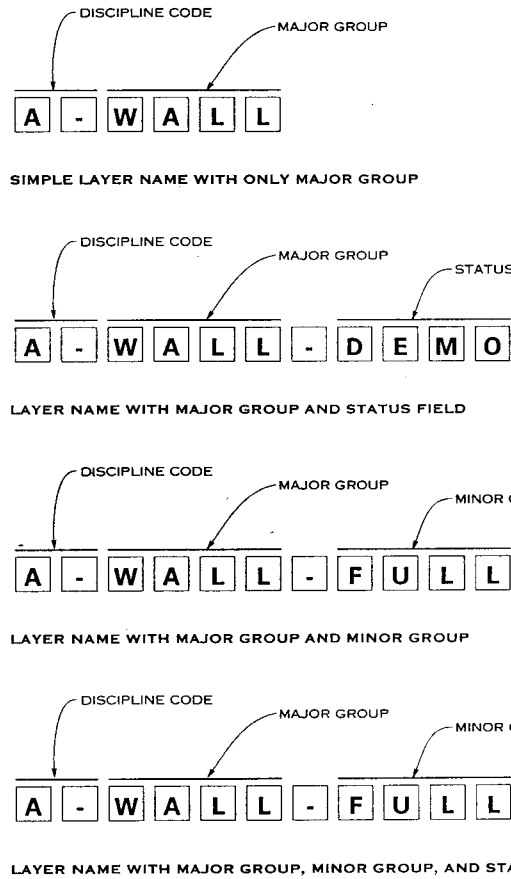

*-****-PATT	Cross-hatching, poché
*-****-IDEN	Identification tags
*-****-ELEV	Elevation (vertical surfaces in 3D)
X-RDME	Read-me layer, not to be plotted

STATUS FIELD MODIFIERS

*-****-NEWW	New work
*-****-EXST	Existing to remain
*-****-DEMO	Demolition
*-****-FUTR	Future work
*-****-TEMP	Temporary work
*-****-MOVE	Items to be moved
*-****-RELO	Relocated items
*-****-NICN	Not in contract
*-****-PHS1-9	Phase numbers (1-9)

NOTE

The status field may also occur as the fourth field, following a minor group.

OPTIONS FOR LAYER NAME FORMATS

GENERATIVE GEOMETRY

The archetypal circle and square can geometrically generate many forms. Ancient cultures recognized these forms and relationships as essential and sacred, a metaphor of universal order. The circle and square in the act of self-division give us three generative roots: the square roots of 2, 3, and 5 (figs. 1a and 1b). These root relationships are all that are necessary to form the five regular (Platonic) solids that are the basis for all volumetric forms (fig. 1c). Also, 2, 3, and 5 are the only numbers required to divide the octave into musical scales.

FIGURE 1A

FIGURE 1B

FIGURE 1C

THE $\sqrt{2}$

In seeming paradox, the half of a square produces its double; this is analogous to biological growth from cell division and the generation of musical tone. In fig. 2a, the diagonal of square ABCD (square 1, fig. 2a) is exactly equal to the side of square ACFG (square 2). The area of square 2 is exactly twice that of square 1. The side of a square is called its root. The side of square 1 = 1; the side of square 2 = the square root of 2. The diagonal of square 2 = 2, exactly twice the side of the primary square. The division of the square by the diagonal yields three seemingly contradictory, yet geometrically true, relationships:

$$\text{root} : \text{root} :: \frac{1}{\sqrt{2}} : \frac{\sqrt{2}}{2} \quad \text{root} : \text{diag} :: \frac{1}{\sqrt{2}} : \frac{\sqrt{2}}{2}$$

$$\text{root} : \text{diag} :: \frac{1}{\sqrt{2}} : \frac{\sqrt{2}}{2}$$

The square root of 2 represents the power of multiplicity through the geometric progression a:b::b:c (fig. 2b). The relationship of the side to the diagonal may be written

$$\frac{1}{\sqrt{2}} : \frac{\sqrt{2}}{2} :: \frac{2}{2\sqrt{2}} : \frac{2\sqrt{2}}{4} :: \frac{4}{4\sqrt{2}} \text{ etc}$$

GENERATIVE GEOMETRY

FIGURE 2A

FIGURE 2B

THE SQUARE ROOT OF 2

FIGURE 3A

FIGURE 3B

FIGURE 3C

THE SQUARE ROOT OF 3

THE VESICA PISCIS AND THE $\sqrt{3}$

The Vesica Piscis is a form generator of the triangle, square, and pentagon—the basic planar elements of the five Platonic solids. The overlapping circles are an excellent representation of a cell or any unity in the midst of becoming dual. Medieval churches and cathedrals incorporated the fish-shaped geometry as a symbol of Christ.

To construct the Vesica Piscis: draw a circle of any radius about center A; at any chosen point on the circumference, draw another circle of equal radius (B). The area and shape defined by the two centers and the overlap of the two circumferences is known as the Vesica Piscis (fig. 3a).

Fig. 3b shows the generation of equilateral triangles.

In fig. 3c, we see that if AB = 1, then DG = 1, CG = 2, and, by the Pythagorean Theorem ($a^2 + b^2 = c^2$), the major axis

$$CD = \sqrt{(CG^2 - DG^2)} = \sqrt{3}$$

FIGURE 4A

FIGURE 4B

FIGURE 4C

THE SQUARE ROOT OF 5

THE $\sqrt{5}$

The square root of 5 may be generated from a 1:2 rectangle (a double square); see fig. 4a. Fig. 4b demonstrates the relationship of the square root of 5, both with the number 5 (as the square of its root) and with the fivefold symmetry of the pentagon. The 3,4,5 "Pythagorean" triangle (fig. 4c) is derived from the crossing of three semidiagonals (square root of 5 divided by 2). The square root of 5 is the proportion that opens the way for the family of relationships called the Golden Proportion.

THE GOLDEN PROPORTION

Grand philosophical, natural, and aesthetic considerations have surrounded this proportion ever since humanity began to reflect on the geometric forms of its world. The Golden Proportion can be found in nature, where it governs plant growth patterns and human proportions. Its presence can be found in the sacred art and architecture of Egypt, India, China, Greece, Islamic countries, and other traditional cultures. It was hidden in Gothic cathedrals, celebrated in Renaissance art, and used by modernist architects such as Le Corbusier and Wright.

Discontinuous proportions contain four terms (a:b::c:d). Geometric relationships are of a three-term proportional type (a:b::b:c). There is only one proportional division that is possible with two terms; this is written a:b::b:(a + b). The unique two-term proportion (designated by the Greek letter ϕ) was called "golden" by the ancients because the original unity is always represented in its division, written

$$\frac{1}{\phi^3} : \frac{1}{\phi^2} :: \frac{1}{\phi} : 1 :: 1 : \phi :: \phi : \phi^2 :: \phi^2 : \phi^3 \text{ etc.}$$

Scott C. McBroom, AIA; Alexandria, Virginia

GOLDEN PROPORTION

Fig. 5a shows the construction of the Golden Proportion from the 1:2 rectangle. Fig. 5b demonstrates the relationship of three squares related by ϕ . Fig. 5c reveals an important pentagonal relationship: the side of a pentagon is in relation to its diagonal as

$$(1 + \sqrt{5}) \div 2 \text{ or } 1:\phi, \text{ the golden section}$$

ϕ represents a coinciding of the processes of addition and multiplication called the Fibonacci Series, which manifests itself in some biological growth patterns. The Fibonacci Series is an additive progression in which the two initial terms are added together to form the third term (1, 1, 2, 3, 5, 8, 13...). Any two successive terms tend to be approximately in relation to one another as 1: ϕ , and any three successive terms are as 1: ϕ : ϕ^2

TRIANGLE
 AREA = 1/2 ANY ALTITUDE X ITS BASE (ALTITUDE IS PERPENDICULAR DISTANCE TO OPPOSITE VERTEX OR CORNER.)
 $A = \frac{1}{2} b \times h$

TRAPEZOID
 AREA = 1/2 SUM OF PARALLEL SIDES X ALTITUDE
 $A = \frac{h(a+b)}{2}$

CIRCLE
 AREA = $\frac{\pi D^2}{4} = \pi R^2$
 CIRCUMFERENCE = $2\pi R = \pi D$
 ($\pi = 3.14159265359$)

REGULAR POLYGON
 AREA = $\frac{nSR}{2}$
 (n = NUMBER OF SIDES)
 ANY SIDE $S = 2\sqrt{R^2 - r^2}$
 $R = \frac{S}{2 \tan \frac{\theta}{2}}$ $r = \frac{S}{2 \sin \frac{\theta}{2}}$

TRAPEZIUM (IRREGULAR QUADRILATERAL)
 AREA = DIVIDE FIGURE INTO TWO TRIANGLES AND FIND AREAS AS ABOVE

PARALLELOGRAM
 AREA = EITHER SIDE X ALTITUDE

CIRCULAR SEGMENT
 AREA = (LENGTH OF ARC θ) X $R - \frac{1}{2}(R-y)$
 CHORD $c = \frac{2\sqrt{2yR - y^2}}{2} = 2R \sin \frac{\theta}{2}$

CIRCULAR SECTOR
 AREA = $\frac{\theta R^2}{2}$
 = AREA OF CIRCLE X $\frac{A^\circ}{360}$
 = $0.0087R^2 A^\circ$
 ARC $\theta = \frac{\pi R A^\circ}{180} = 0.0175 RA^\circ$

ELLIPSE
 AREA = $.7854 Dd$
 APPROX. PERIMETER = $\pi \sqrt{2(x^2 + y^2)}$

PARABOLA
 AREA = $\frac{4hb}{3}$

GEOMETRIC PROPERTIES OF PLANE FIGURES

SPHERE
 VOLUME = $\frac{4\pi R^3}{3} = 0.5236D^3$
 SURFACE = $4\pi R^2 = \pi D^2$

SEGMENT OF SPHERE
 VOLUME = $\frac{\pi b^2(3R-b)}{3}$ (OR SECTOR - CONE)
 SURFACE = $2\pi Rb$ (NOT INCLUDING SURFACE OF CIRCULAR BASE)

SECTOR OF SPHERE
 VOLUME = $\frac{2\pi R^2 b}{3}$
 SURFACE = $\frac{\pi R(4b+c)}{2}$ (OR: SECTOR + CONE)

ELLIPSOID
 VOLUME = $\frac{\pi abc}{6}$
 SURFACE: NO SIMPLE RULE

PARABOLOID OF REVOLUTION
 VOLUME = AREA OF CIRCULAR BASE X 1/2 ALTITUDE.
 SURFACE: NO SIMPLE RULE

CIRCULAR RING OF ANY SECTION
 R = DISTANCE FROM AXIS OF RINGS TO TRUE CENTER OF SECTION
 VOLUME = AREA OF SECTION X $2\pi R$
 SURFACE = PERIMETER OF SECTION X $2\pi R$ (CONSIDER THE SECTION ON ONE SIDE OF AXIS ONLY)

VOLUMES AND SURFACES OF DOUBLE-CURVED SOLIDS

ANY PRISM OR CYLINDER, RIGHT OR OBLIQUE, REGULAR OR IRREGULAR.
 Volume = area of base x altitude

Altitude = distance between parallel bases, measured perpendicular to the bases. When bases are not parallel, then Altitude = perpendicular distance from one base to the center of the other.

ANY PYRAMID OR CONE, RIGHT OR OBLIQUE, REGULAR OR IRREGULAR.
 Volume = area of base x 1/3 altitude

Altitude = distance from base to apex, measured perpendicular to base.

ANY FRUSTUM OR TRUNCATED PORTION OF THE SOLIDS SHOWN

Volume: From the volume of the whole solid, if complete, subtract the volume of the portion cut off.

The altitude of the cut-off part must be measured perpendicular to its own base.

SURFACES OF SOLIDS

The area of the surface is best found by adding together the areas of all the faces.

The area of a right cylindrical surface = perimeter of base x length of elements (average length if other base is oblique).

The area of a right conical surface = perimeter of base x 1/2 length of elements.

There is no simple rule for the area of an oblique conical surface, or for a cylindrical one where neither base is perpendicular to the elements. The best method is to construct a development, as if making a paper model, and measure its area by one of the methods given on the next page.

STRING METHOD
(FOR LARGE SCALE AND FULL SIZE)

CARD METHOD

AUXILIARY CIRCLES METHOD

PARALLELOGRAM METHOD

Either pair of opposite apex points may be used:

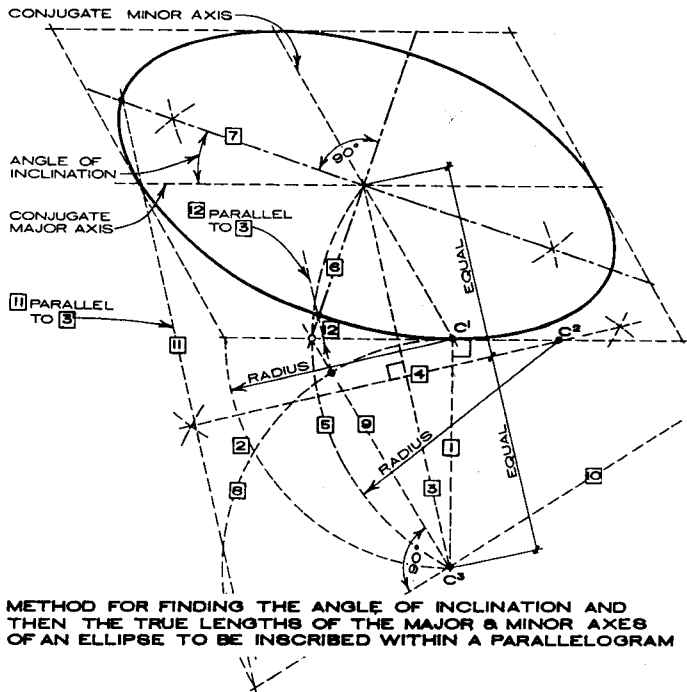

3 CENTER METHOD
(APPROXIMATE)

5 CENTER METHOD

3 and 5 center methods are not true ellipses, but only approximations which are useful for small scale drawings.

METHOD FOR FINDING THE ANGLE OF INCLINATION AND THEN THE TRUE LENGTHS OF THE MAJOR & MINOR AXES OF AN ELLIPSE TO BE INSCRIBED WITHIN A PARALLELOGRAM

NOTE

1. Using the conjugate axes, the ellipse can be drawn directly by using the parallelogram method.
2. Using the true lengths of the axes, the ellipse may be drawn with any one of the methods illustrated on this page.

TO FIND THE AREA OF AN IRREGULAR PLANE FIGURE

1. Divide the figure into parallel strips by equally spaced parallel lines.
2. Measure the length of each of the parallel lines.
3. Obtain a summation of the unit areas by one of these 3 "rules".

TRAPEZOID RULE

Add together the length of the parallels, taking the first and last at $\frac{1}{2}$ value, and multiply by the width of the internal "d". This rule is sufficiently accurate for estimating and other ordinary purposes.

SIMPSON'S RULE

Add the parallels, taking the first and last at full value, second, the fourth, sixth, etc. from each end at 4 times full value, and the third, fifth, seventh, etc. from each end at 2 times the value, then multiply by $\frac{1}{3}d$. This rule works only for an even number of spaces and is accurate for areas bounded by smooth curves.

DURAND'S RULE

Add the parallels taking the first and last at $\frac{5}{12}$ value, the second from each end at $\frac{13}{12}$ value, and all others at full value, then multiply by d. This rule is the most accurate for very irregular shapes.

NOTE

Irregular areas may be directly read off by means of a simple instrument called a Planimeter.

TO FIND THE VOLUME OF AN IRREGULAR FIGURE BY THE PRISMATOID FORMULA

Construct a section midway between the bases. Add 4 to the sum of the areas of the 2 bases and multiply the quantity by the area of the mid-section. Then multiply the total by $\frac{1}{6}$ the perpendicular distance between the bases.

$$V = \left[(\text{area of base}_1 + \text{area of base}_2 + 4) (\text{area of midsection}) \times \frac{1}{6} \text{ perpendicular distance between bases.} \right]$$

This formula is quite accurate for any solid with two parallel bases connected by a surface of straight line elements (upper figure), or smooth simple curves (lower figure).

TO FIND THE VOLUME OF A VERY IRREGULAR FIGURE BY THE SECTIONING METHOD

1. Construct a series of equally spaced sections or profiles.
2. Determine the area of each section by any of the methods shown at left (preferably with a Planimeter).
3. Apply any one of the 3 summation "rules" given at left, to determine the total volume.

This method is in general use for estimating quantities of earthwork, etc.

TO FIND THE VOLUME OF CUT AND FILL DIRECTLY FROM THE CONTOUR PLAN

1. Draw "finish" and "original" contours on same contour map.
2. Measure the differential areas between new and old contours of each contour and enter in columns according to whether cut or fill.
3. Add up each column and multiply by the contour interval to determine the volume in cubic feet.

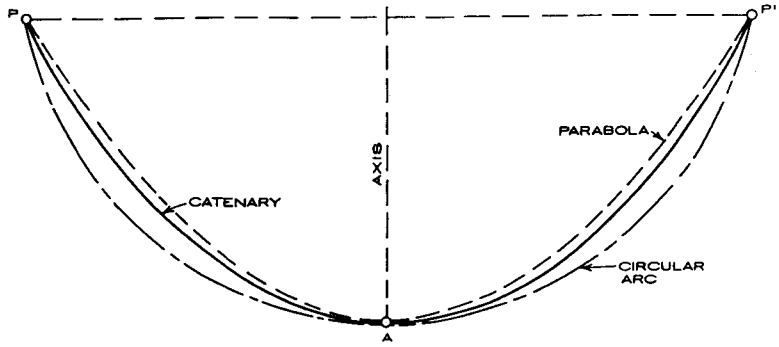

EXAMPLE

CONTOUR	CUT	FILL
85	300	
80	960	
75	2,460 - 2 = 1,230	3,800 - 2 = 1,900
70	20	2,200
	9,200	6,800
	x5	x5
TOTALS	46,000	34,000
	cu. ft.	cu. ft.

NOTE

1. Where a cut or fill ends directly on a contour level use $\frac{1}{2}$ value.
2. The closer the contour interval, the greater the accuracy.

This method is more rapid than the sectioning method, and is sufficiently accurate for simple estimating purposes and for balancing of cut and fill.

CATENARY

A catenary curve lies between a parabola and a circular arc drawn through the same three points, but is closer to the parabola. The catenary is not a conic section. The easiest method of drawing it is to tilt the drafting board and hang a very fine chain on it, and then prick guide points through the links of the chain.

**HYPERBOLA
AUXILIARY CIRCLES METHOD**
GIVEN: Axis, Apex, Asymptotes
(tangents at infinity)

- PROCEDURE:**
1. Draw auxiliary circles with OB and OA as radii: note $\frac{OB}{OA}$ = slope of asymptote.
 2. Erect perpendicular 3 where circle 2 intersects axis.
 3. Draw any line 4 through O, intersecting circle 1 at B and line 3 at C.
 4. Draw line 5 through C parallel to axis.
 5. Draw tangent 6 at D, intersecting axis at E.
 6. Erect perpendicular 7 at E, intersecting 5 at P, a point on hyperbola.

**HYPERBOLA
PARALLELOGRAM METHOD**

- GIVEN:**
Axis, two apices (A and A') and a chord.
1. Draw surrounding parallelogram.
 2. Divide chord in whole number of equal spaces (C_1, C_2, C_3 , etc.).
 3. Divide edge of parallelogram into same integral number of equal spaces (E_1, E_2, E_3 , etc.).
 4. Join A to points E on edge; join A' to points C on chord. Intersection of these rays are points on curve.

This method can be used equally well for any type of orthogonal or perspective projection, as shown by example of ellipse.

**PARABOLA
PARALLELOGRAM METHOD**

This method is comparable to the "Parallelogram Method" shown for the hyperbola above and the ellipse on previous page. The other apex 'A' is at infinity.

**PARABOLA
ENVELOPE OF TANGENTS**

This method does not give points on the curve, but a series of tangents within which the parabola can be drawn.

H. Seymour Howard, Jr.: Oyster Bay, New York

OBULATE SPHEROID

An ellipse rotated about its minor axis.

PROLATE SPHEROID

An ellipse rotated about its major axis.

PARABOLOID OF REVOLUTION

A parabola rotated about its axis.

GENERAL ELLIPSOID

NOTES

1. The dome shapes shown above are SURFACES OF POSITIVE CURVATURE, that is, the centers of both principal radii of curvature are on the same side of the surface.
2. SURFACES OF NEGATIVE CURVATURE (saddle shapes) such as those shown below, are surfaces in which the centers of the two principal radii of curvature are on opposite sides of the surface.

The elliptic paraboloid is similar, but its plan is an ellipse instead of circle, and vertical sections are varying parabolas.

HYPERBOLIC PARABOLOID

(STRAIGHT LINE BOUNDARIES)

This shape and the hyperboloid of one sheet are the only two doubly ruled curved surfaces.

ELEVATION

PROJECTION

PROPERTIES OF PLATONIC AND ARCHIMEDEAN POLYHEDRA

The basic particulars of the Platonic and Archimedean polyhedra are given in the table. The first column of the table gives the names of the polyhedra together with their P-names. The second column lists the numbers of faces, edges, and vertices. For instance, these items for tetrahedron are given as F3:4, E:6, and V:4.

Here, the letter F stands for face and the digit that follows F indicates the number of sides of the face. The letter E stands for edge and the letter V stands for vertex. The items given in the second column for a tetrahedron indicate that it has four triangular faces, six edges, and four vertices. Also, the information given in the second column of the table for P7 (cuboctahedron) indicates that it has 8 triangular faces, 6 square faces, 24 edges, and 12 vertices.

The third column of the table lists the radii of inspheres of the Platonic and Archimedean polyhedra. An insphere is a sphere that is tangent to all the faces of the same type of a polyhedron. A Platonic polyhedron has only one insphere. An Archimedean polyhedron, on the other hand, has either two or three inspheres, depending on whether it has two or three different types of faces. The radius of insphere for an Archimedean polyhedron given in the third column corresponds to the smallest insphere, that is, the insphere that is tangent to the largest faces. Also included at the end of the table are two general formulas for evaluation of the radii of inspheres for Platonic and Archimedean polyhedra. Each value in the third column is given in terms of a parameter L, which represents the edge length of the polyhedron.

The parameter L, representing the edge length, also appears in columns four and five. Columns four and five list the radii of interspheres and circumspheres of the Platonic and Archimedean polyhedra. An intersphere is a sphere that is tangent to all the edges of a polyhedron and a circumsphere is a sphere that passes through all the vertices of a polyhedron. Each Platonic or Archimedean polyhedron has one intersphere and one circumsphere.

The last column of the table lists the dihedral angles of the Platonic and Archimedean polyhedra. A dihedral angle is the angle between two faces of a polyhedron that share an edge. For any Platonic polyhedron, all the dihedral angles are equal. In contrast, an Archimedean polyhedron may have up to three different dihedral angles, as shown in the last column of the table. For an Archimedean polyhedron that has more than one dihedral angle, the faces that correspond to each dihedral angle are specified by the numbers of their sides given in square brackets. For example, in the case of P6 (truncated tetrahedron), the first dihedral angle is preceded by [6-6], indicating that the angle is between two hexagonal faces, and the second dihedral angle is preceded by [6-3], indicating that the angle is between a hexagonal face and a triangular face.

The properties of the Platonic and Archimedean polyhedra, as given in the table, are incorporated into the part of Formian that deals with the processing of polyhedral configurations. The information is built into Formian in terms of the formulas given in the table. The use of formulas will allow the full available accuracy of the computer to be utilized. High accuracy of the basic polyhedral data is essential in many situations. This is the case, for instance, when dealing with complex polyhedral configurations that consist of many thousands of elements, in particular, when the generated geometric details are to be used as a basis for other operations, such as structural analysis.

In regard to the accuracy of the entries in the table, it should be noted that for the snub polyhedra (P15, P16, P19, and P20), the accuracy of the entries for radii of insphere, intersphere, and circumsphere depends on the accuracy of a parameter k. The value of this parameter in the table is given accurate to nine decimal places. The values of the dihedral angles for the snub polyhedra in the table are also given accurate to nine decimal places.

1. $Rc = \sqrt{Rt^2 + L^2/4}$
2. $Rt = \sqrt{Rc^2 + L^2/4}$
3. $Rip = \sqrt{Rc^2 - rp^2}$
4. $Rip = \sqrt{Rt^2 - bp^2}$
5. $L = 2\sqrt{Rc^2 - Rt^2}$
6. $a = 2 \operatorname{asin}(L/2Rc)$
7. $a = 2 \operatorname{acos}(Rt/Rc)$
8. $a = 2 \operatorname{atan}(L/2Rt)$

NOTE
The relations shown above are applicable to every Platonic and Archimedean polyhedron, where:

- L is the edge length.
 - a is the angle subtended by an edge at the center of the polyhedron.
 - Rc is the radius of the circumsphere.
 - Rt is the radius of the intersphere.
 - Rip is the radius of an insphere, that is, a sphere that is tangent to all the faces of type p.
 - rp is the distance between the center and a corner of a face of type p.
 - bp is the distance between the center and the midpoint of a side of a face of type p.
- The radius of insphere for an Archimedean polyhedron given in the third column of the table corresponds to the smallest insphere, that is, the insphere that is tangent to the largest faces.

SCIENTIFIC NOTATION

Scientific notation is used to abbreviate large numerical values in order to simplify calculations.

$$4.2 \times 10^4 = 4.2 \times (10 \times 10 \times 10 \times 10) = 42,000$$

$$1.0 \times 10^1 = 1 \times 10 = 10$$

$$6.0 \times 10^{-4} = 6.0 \times (1 / 10 \times 10 \times 10 \times 10) = 0.0006$$

MULTIPLYING AND DIVIDING POWERS

$$x^n \cdot x^m = x^{n+m} \quad (x^n)^m = x^{nm}$$

$$\frac{x^n}{x^m} = x^{n-m} \quad \frac{1}{x^n} = x^{-n} = \frac{1}{x^n}$$

PYTHAGOREAN THEOREM

$$c^2 = a^2 + b^2$$

BASIC TRIGONOMETRY FUNCTIONS

$$\sin \theta = \frac{\text{opposite}}{\text{hypotenuse}} = \frac{a}{c}$$

$$\cos \theta = \frac{\text{adjacent}}{\text{hypotenuse}} = \frac{b}{c}$$

$$\tan \theta = \frac{\text{opposite}}{\text{adjacent}} = \frac{\sin \theta}{\cos \theta} = \frac{a}{b}$$

$$\cot \theta = \frac{\text{adjacent}}{\text{opposite}} = \frac{1}{\tan \theta} = \frac{b}{a}$$

RADIANS AND DEGREES

A radian is a way of measuring angles in addition to degrees. Radians are the primary unit of angular measurement used in calculations.

$$1 \text{ rad} = \frac{180^\circ}{\pi} = 57.3^\circ \quad (\text{approx})$$

$$1^\circ = \frac{\pi}{180^\circ} = 0.01745 \text{ rad} \quad (\text{approx})$$

LINEAR DISTANCE

The distance *s* which a point *p* on the rim of a rotating wheel covers is called linear distance. The angle θ , the intercepting angle, is measured in radians.

$$s = r\theta$$

LINEAR SPEED

The linear speed *v*, of the point *p* around the rim of a rotating wheel, is the time taken *t* for point to travel the distance *s*.

$$v = \frac{s}{t}$$

ANGULAR SPEED

The angular speed ω , of the point *p* around the rim of a rotating wheel is the time taken, *t*, for the point to travel the angular distance, θ . The angular distance can be measured in degrees, revolutions, or radians. The resulting units of angular speed depend on the units used for angular distance and time.

$$\omega = \frac{\theta}{t}$$

LAW OF REFLECTION

A light ray reflects from a surface such that the angle of reflection equals the angle of incidence.

$$\theta_1 = \theta_2$$

LAW OF REFRACTION

When a light ray traveling through a transparent medium strikes another transparent medium, part of the ray is reflected and part is refracted, entering the second medium. The angle of the refracted ray depends on the angle of incidence and the index of refraction of both mediums.

$$n_1 \sin \theta_1 = n_2 \sin \theta_2$$

TOTAL INTERNAL REFLECTION

When light attempts to move from a medium with a high index of refraction to a medium with a low index of refraction, there is a particular angle of incidence large enough that the angle of refraction reaches 90°. The transmitted light ray moves parallel to the surface of the first medium and no more light is transmitted.

This angle of incidence is called the critical angle and depends on the indexes of refraction of the two mediums. Any angle of incidence larger than the critical angle is reflected back into the first medium.

$$\sin \theta_c = \frac{n_2}{n_1}$$

Speed of Light in Medium

$$C_{\text{medium}} = \frac{C_{\text{vac}}}{n_{\text{medium}}}$$

THERMAL EXPANSION OF LENGTH

An object of initial length *L*₀ at some temperature. With a change in temperature of ΔT the length increases ΔL . The constant α is called the average coefficient of linear expansion for the given material.

$$\Delta L = \alpha L_0 \Delta T$$

THERMAL EXPANSION OF AREA

An object of initial area *A*₀ at some temperature. With a change in temperature of ΔT , the area increases ΔA . The constant γ is the average coefficient of area expansion for the given material.

$$\Delta A = \gamma A_0 \Delta T \quad \gamma = 2\alpha$$

THERMAL EXPANSION OF VOLUME

A mass of initial volume *V*₀ at some temperature. With a change in temperature ΔT , the volume increases ΔV . The constant β is called the average coefficient of volume expansion for a given material.

$$\Delta V = \beta V_0 \Delta T \quad \beta = 3\alpha$$

NOTE

To establish uniform practice among designers, it is desirable to present a list of materials generally used in building construction, together with their proper weights. Many building codes prescribe the minimum weights of only a few building materials. It should be noted that there is a difference of more than 25% in some cases.

ARCHITECTURAL AREA OF BUILDINGS

The architectural area of a building is the sum of the areas of the floors, measured horizontally in plan to the exterior faces of perimeter walls or to the centerline of walls separating buildings. Included are areas occupied by partitions, columns, stairwells, elevator shafts, duct shafts, elevator rooms, pipe spaces, mechanical penthouses, and similar spaces having a headroom of 6 ft and over. Areas of sloping surfaces, such as staircases, bleachers, and tiered terraces, should be measured horizontally in plan. Auditoriums, swimming pools, gymnasiums, foyers, and similar spaces extending through two or more floors should be measured once only, taking the largest area in plan at any level.

Mechanical penthouse rooms, pipe spaces, bulkheads, and similar spaces having a headroom less than 6 ft and balconies projecting beyond exterior walls, covered terraces and walkways, porches, and similar spaces shall have the architectural area multiplied by 0.50 in calculating the building gross area.

Exterior staircases and fire escapes, exterior steps, patios, terraces, open courtyards and lightwells, roof overhangs, cornices and chimneys, unfinished roof and attic areas, pipe trenches, and similar spaces are excluded from the architectural area calculations. Interstitial space in health care facilities is also excluded.

ARCHITECTURAL VOLUME OF BUILDINGS

The architectural volume of a building is the sum of the products of the areas defined in the architectural area times the height from the underside of the lowest floor construction to the average height of the surface of the finished roof above, for the various parts of the building. Included in the architectural volume is the actual space enclosed within the outer surfaces of the exterior or outer walls and contained between the outside of the roof and the bottom of the lowest floor, taken in full: bays, oriels, dormers; penthouses, chimneys; walk tunnels; enclosed porches and balconies, including screened areas.

The following volumes are multiplied by 0.50 in calculating the architectural volume of a building; nonenclosed porches, if recessed into the building and without enclosing sash or screens; nonenclosed porches built as an extension to the building and without sash or screen; areaways and pipe tunnels; and patio areas that have building walls extended on two sides, roof over, and paved surfacing.

Excluded from the architectural volume are outside steps, terraces, courts, garden walls; light shafts, parapets, cornices, roof overhangs; footings, deep foundations, piling caissons, special foundations, and similar features.

NET ASSIGNABLE AREA

The net assignable area is that portion of the area which is available for assignment to an occupant, including every type of space usable by the occupant.

The net assignable area should be measured from the predominant inside finish of enclosing walls in the categories defined below. Areas occupied by exterior walls, partitions, internal structural, or party walls are to be excluded from the groups and are to be included under "construction area."

1. "NET ASSIGNABLE AREA": Total area of all enclosed spaces fulfilling the main functional requirements of the building for occupant use, including custodial and service areas such as guard rooms, workshops, locker rooms, janitors' closets, storerooms, and the total area of all toilet and washroom facilities.
2. "CIRCULATION AREA": Total area of all enclosed spaces which is required for physical access to subdivisions of space such as corridors, elevator shafts, escalators, fire towers or stairs, stairwells,

ARCHITECTURAL AREA DIAGRAM

elevator entrances, public lobbies, and public vestibules.

3. "MECHANICAL AREA": Total area of all enclosed spaces designed to house mechanical and electrical equipment and utility services such as mechanical and electrical equipment rooms, duct shafts, boiler rooms, fuel rooms, and mechanical service shafts.
4. "CONSTRUCTION AREA": The area occupied by exterior walls, partitions, structure, and so on.
5. "GROSS FLOOR OR ARCHITECTURAL AREA": The sum of areas 1, 2, 3, and 4 plus the area of all factored non- and semienclosed areas equal the gross floor area or architectural area of a building.

In commercial buildings constructed for leasing, net areas are to be measured in accordance with the "Standard Method of Floor Measurement," as set by the Building Owners and Managers Association (BOMA).

The net rentable area for offices is to be measured from the inside finish of permanent outer building walls, to the office or occupancy side of corridors and/or other permanent partitions, and to the center of partitions that separate the premises from adjoining rentable areas. No deductions are to be made for columns and projections necessary to the building.

The net rentable area for stores is to be measured from the building line in case of street frontages and from the inside finish of other outer building walls, corridor, and permanent partitions and to the center of partitions that separate the premises from adjoining rentable areas. No deductions are to be made for vestibules inside the building line or for columns and projections necessary to the building. No addition is to be made for projecting bay windows.

If a single occupant is to occupy the total floor in either the office or store categories, the net rentable area would include the accessory area for that floor of corridors, elevator lobbies, toilets, janitors' closets, electrical and telephone closets, air-conditioning rooms and fan rooms, and similar spaces.

The net rentable area for apartments is to be measured from the inside face of exterior walls, and all enclosing walls of the unit.

NOTE

Various governmental agencies have their own methods of calculating the net assignable area of buildings. They should be investigated if federal authority or funding apply to a project. Also, various building codes provide their own definitions of net and gross areas of building for use in quantifying requirements.

FORMULAS NOMENCLATURE

- E Modulus of Elasticity of steel at 29,000 ksi.
- I Moment of Inertia of beam (in.⁴).
- M_{max} Maximum moment (kip in.).
- M₁ Maximum moment in left section of beam (kip in.).
- M₂ Maximum moment in right section of beam (kip in.).
- M₃ Maximum positive moment in beam with combined end moment conditions (kip in.).
- M_x Moment at distance x from end of beam (kip in.).
- P Concentrated load (kips).
- P₁ Concentrated load nearest left reaction (kips).
- P₂ Concentrated load nearest right reaction, and of different magnitude than P₁ (kips).
- R End beam reaction for any condition of symmetrical loading (kips).
- R₁ Left end beam reaction (kips).
- R₂ Right end or intermediate beam reaction (kips).
- R₃ Right end beam reaction (kips).
- V Maximum vertical shear for any condition of symmetrical loading (kips).
- V₁ Maximum vertical shear in left section of beam (kips).
- V₂ Vertical shear at right reaction point, or to left of intermediate reaction point of beam (kips).
- V₃ Vertical shear at right reaction point, or to right of intermediate reaction point of beam (kips).
- V_x Vertical shear at distance x from end of beam (kips).
- W Total load on beam (kips).
- A Measured distance along beam (in.).
- B Measured distance along beam which may be greater or less than "A" (in.).
- L Total length of beam between reaction points (in.).
- W Uniformly distributed load per unit of length (kips per in.).
- W₁ Uniformly distributed load per unit of length nearest left reaction (kips per in.).
- W₂ Uniformly distributed load per unit of length nearest right reaction, and of different magnitude than W₁ (kips per in.).
- X Any distance measured along beam from left reaction (in.).
- X₁ Any distance measured along overhang section of beam from nearest reaction point (in.).
- Δ_{max} Maximum deflection (in.).
- Δ_x Deflection at point of load (in.).
- Δ_x Deflection at any point x distance from left reaction (in.).
- Δ₁ Deflection of overhang section of beam at any distance from nearest reaction point (in.).

GENERAL

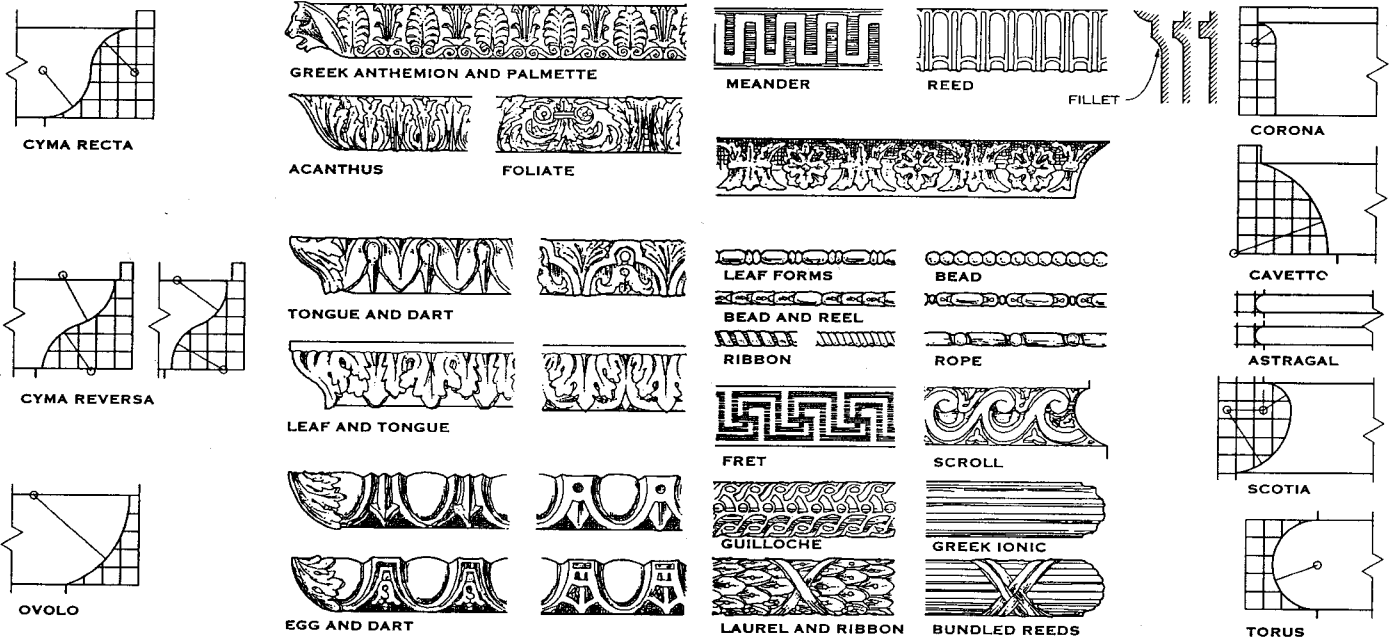

Classical architecture is based on five distinct and formalized systems of columns and horizontal supports, called the orders. A proportional system in which the parts and divisions of each order, measured in multiples or divisions of the diameter of the lowest part of the relevant tapered column shaft, distinguishes each unique order.

NOTE

A parallel comparison based on Vignola proportions in terms of a constant lower diameter.

THE FIVE CLASSICAL ORDERS — RENAISSANCE PROPORTIONS

MOLDINGS — TYPES, PATTERNS, AND DECORATIONS

Scot C. McBroom, AIA, Alexandria, Virginia

DORIC ORDER (MUTULAR)

CORINTHIAN ORDER

Scot C. McBroom, AIA; Alexandria, Virginia

ENTASIS

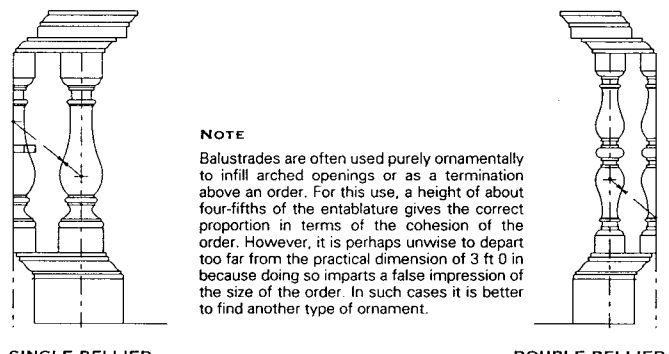

INTERCOLUMNIATION

ARCHED DOORWAY

NOTE
Balustrades are often used purely ornamentally to infill arched openings or as a termination above an order. For this use, a height of about four-fifths of the entablature gives the correct proportion in terms of the cohesion of the order. However, it is perhaps unwise to depart too far from the practical dimension of 3 ft 0 in because doing so imparts a false impression of the size of the order. In such cases it is better to find another type of ornament.

GENERAL

Developed at the time of the French Revolution, the metric system rapidly spread throughout Europe during the Napoleonic wars. It was promoted in the United States by Thomas Jefferson and later by John Quincy Adams, but the federal government did not legalize its use as a measurement system until 1866. In 1893, all standard United States measures were defined in metric units. Today, the United States remains the last industrialized country to commit to metric.

SYSTEM INTERNATIONAL (SI)

The modern metric system, known as "System International" (SI) was established by international agreement in 1960. It is the international standard of measurement and the system mandated by the *Metric Conversion Act* for use in the United States.

THE METRIC CONVERSION ACT

The *Metric Conversion Act of 1975*, as amended by the *Omnibus Trade and Competitiveness Act of 1988*, establishes the metric system as the preferred system of measurement in the United States. It requires that, to the extent feasible, the metric system be used in all federal procurement, grants, and business-related activities after September 30, 1992.

METRIC IN CONSTRUCTION

There has been much speculation about the difficulty of converting to metric in the United States construction industry. The experiences of the British, Australians, South Africans, and Canadians, all of whom converted from the inch-pound system to metric in the past 20 years, showed the following facts.

1. Metric conversion proved much less difficult than anticipated since most work is built in place.
2. There were no appreciable increases in design or construction costs, and conversion costs for most construction industry sectors were minimal or offset by later savings.
3. Architects and engineers liked metric dimensioning because it was less prone to error and easier to use than feet and inches and because engineering calculations were faster and more accurate since there were no unit conversions and no fractions.
4. Metric offered a one-time chance to reduce the many product sizes and shapes that are no longer useful, thus saving production, inventory, and procurement costs.

The following developments should make metric conversion in the United States construction industry easier:

1. The use of computer-aided design and drafting systems continues to increase; almost all engineering and cost calculations are now performed on computers.
2. The codes and construction standards of two of the country's three model building code organizations (BOCA and SBCCI), NFPA, and ASTM contain dual units that specify measurements. Many other standards-writing organizations have added metric measurements to their documents or are preparing to do so.
3. The preliminary results of several recent General Services Administration metric pilot projects in the Philadelphia area indicate no increase in design or construction costs.
4. American design and construction firms report no problems using metric in foreign work.
5. The costs of metric conversion in other industries have been far lower than expected, and the benefits greater. Total conversion costs were less than one percent of original estimates at General Motors, which now is fully metric. Rationalization of fastener sizes at IBM during metric conversion reduced fastener part numbers from 38,000 to 4,000. Some American manufacturers, such as Otis Elevator, are switching to metric to increase their international competitiveness and reduce their parts inventories. Others, such as the wood industry, have shipped exports in metric for many years.

CONVERSION AND ROUNDING

In a "soft" conversion, an exact inch-pound measurement is mathematically converted to its exact (or near exact) metric equivalent. In a "hard" conversion, a new rounded, rationalized metric number is created that is convenient to work with and remember.

When converting numbers from inch-pound to metric, round the metric value to the same number of digits as there were in the inch-pound number. In all cases, use professional rounding to determine the exact value.

With professional rounding, the basic module of metric design is 100 mm. Make every effort to keep design dimensions in this increment. Additional multimodules and sub-modules, in preferred order, are 6000, 3000, 1200, 600, 300, 50, 25, 20, and 10.

Example: 1990 BOCA Article 514.7 requires 36 inches (914 mm) of unobstructed pedestrian walkway width. However, 914 mm is not a clean and rational number. It should be rounded to facilitate the easiest construction possible. Since anything less than 914 mm would not meet the code requirements, the preferred number would be 1000 mm. Submodules will produce a rounding of 950, 925, or 920 mm.

SOFT AND HARD METRIC

Soft metric means "No Physical Change." This implies the product need not be physically modified to be used in a metric project. More than 95% of currently used building products will not change. In the future, as standard international metric product sizes are developed by the International Standards Organization (ISO) or another standards organization, these products may undergo modification to be compatible in the World market. Custom products, often made by computer controlled machinery, can be specified in any size.

Hard metric means "Product Requires Physical Change." The product must be physically modified to be efficiently used in a metric project, which is planned on a metric grid. A handful of current products must undergo hard metric conversion to new metric sizes.

HARD METRIC PRODUCTS

PRODUCT	SIZE (MM)
Brick	90 x 57 x 190 ¹
Concrete masonry unit	190 x 190 x 390
Drywall	1200 x 2400 ²
Raised access flooring	600 x 600
Suspended ceiling tiles and grids	600 x 600 and 600 x 1200
Fluorescent lighting fixtures (lay-in type only)	600 x 600 and 600 x 1200
Air diffusers and grilles (lay-in type only)	600 and 1200 widths

1. Three vertical courses of metric modular brick with a joint of 10 mm equals 201 mm, which is rounded to 200. Three vertical rows of 200 equal 600 mm. 600 x 600 mm is a preferred nominal module for masonry.
2. Drywall thicknesses remain the same to minimize production impact. The standard thicknesses are 12.7 and 15.9 mm. Standard stud spacing is 400mm.

SPECIFICATIONS

Metric specifications should use "mm" for almost all measurements. The use of mm is consistent with the dimensions specified in major codes, such as BOCA and NEC. With the use of mm, the decimal point is used when extreme precision is indicated. Meters may be used only where large, round metric sizes are specified. Centimeters shall not be used in specifications. This is consistent with the recommendations of the AIA and ASTM.

RULES FOR WRITING METRIC SYMBOLS AND NAMES

1. Print the unit symbol in upright type and in lower case except for liter (L) or unless the unit name is derived from a proper name.
2. Print decimal prefixes in lower case for magnitudes 10³ and lower; print the prefixes in upper case for magnitudes 10⁶ and higher.
3. Leave a space between the numeral and symbol (example: 12 mm).
4. Do not use the degree mark with kelvin temperatures.
5. Do not leave a space between a unit symbol and its decimal prefix (example: km).
6. Do not use the plural of unit symbols, but do use the plural of written unit names (example: kg, kilograms).
7. For technical writing, use symbols in conjunction with numerals (example: 10 m²) and write out unit names if numeral is not used (example: square meters).
8. Indicate the product of two or more units in symbolic form by using a dot positioned above the line (example: kg·m·s⁻²).

9. Do not mix names and symbols (example: N meter).
10. Do not use a period after a symbol except when it occurs at the end of a sentence.
11. Always use decimals, not fractions.
12. Use a zero before the decimal marker for values less than one.
13. Use spaces instead of commas to separate blocks of three digits for any number over four digits (example: 45 138 kg or 0.004 46 kg). In the United States, the decimal marker is a period; in other countries a comma usually is used.

COMPARISON OF DRAWING SCALES

INCH-FOOT SCALES	INCH-FOOT RATIO	METRIC SCALE
Full size	1:1	1:1
Half size	1:2	1:2
4" = 1'-0"	1:3	
3" = 1'-0"	1:4	1:5
2" = 1'-0"	1:6	
1-1/2" = 1'-0"	1:8	1:10
1" = 1'-0"	1:12	
3/4" = 1'-0"	1:16	1:20
1/2" = 1'-0"	1:24	1:25
1/4" = 1'-0"	1:48	1:50
1" = 5'-0"	1:60	
1/8" = 1'-0"	1:96	1:100
1" = 10'-0"	1:120	
1/16" = 1'-0"	1:192	1:200
1" = 20'-0"	1:240	1:250
1" = 30'-0"	1:360	
1/32" = 1'-0"	1:384	
1" = 40'-0"	1:480	1:500
1" = 50'-0"	1:600	
1" = 60'-0"	1:720	
1" = 80'-0"	1:960	1:1000

NOTES

1. Metric drawing scales are expressed in nondimensional ratios.
2. Metric scales 1:2, 1:25, and 1:250 have limited use.

DRAWING SHEET DIMENSIONS

SIZE	SHEET SIZE
A0	1189 x 841 mm (46.8 x 33.1 inches)
A1	841 x 594 mm (33.1 x 23.4 inches)
A2	594 x 420 mm (23.4 x 16.5 inches)
A3	420 x 297 mm (16.5 x 11.7 inches)
A4	297 x 210 mm (11.7 x 8.3 inches)

NOTES

1. The ISO's "A" series drawing sizes are preferred metric sizes for design drawings.
2. A0 is the base size with an area of one square meter. Smaller sizes are half the long dimension of the previous size. All "A" sizes have a height-to-width ratio of one to the square root of two. Use a 35 mm microfilm frame to reduce these sizes.

METRIC PREFIXES

MULTIPLES	PREFIXES	SYMBOLS
1 000 000 000 000 = 10 ¹²	tera	T
1 000 000 000 = 10 ⁹	giga	G
1 000 000 = 10 ⁶	mega	M
1 000 = 10 ³	kilo	k*
100 = 10 ²	hecto	h
10 = 10	deka	da
0.1 = 10 ⁻¹	deci	d
0.01 = 10 ⁻²	centi	c
0.001 = 10 ⁻³	milli	m*
0.000 001 = 10 ⁻⁶	micro	μ
0.000 000 001 = 10 ⁻⁹	nano	n
0.000 000 000 001 = 10 ⁻¹²	pico	p

*Commonly used with base units in design and construction

BASE UNITS

PHYSICAL QUALITY	UNIT	SYMBOL
Length	Meter	m
Mass ¹	Kilogram	kg
Time	Second	s
Electric current	Ampere	A
Thermodynamic temperature ²	Kelvin	K
Luminous intensity	Candela	cd
Amount of substance ³	Mole	mol

NOTES

1. "Weight" is often used to mean "mass."
2. Celsius temperature (°C) is more commonly used than kelvin (K), but both have the same temperature gradients. Celsius temperature is simply 273.15 degrees warmer than kelvin.
3. Mole is the amount of molecular substance and is used in physics.
4. Additional common units of measurement are the hectare (ha), liter (L), and metric ton (t). The hectare is used in surveying for land or sea areas and is equal to 10 000 square meters. The liter is a measurement for liquid volume that is equal to 1/1000 of a cubic meter. The metric ton is used to denote large loads such as those used in excavating and is equal to 1000 kilograms.

PLANE AND SOLID ANGLES

The radian (rad) and steradian (sr) denote plane and solid angles. They are used in lighting work and in various engineering calculations. In surveying, the units degree (°), minute (′), and second (″) continue in use.

DERIVED UNITS

QUANTITY	NAME	SYMBOL	EXPRESSION
Frequency	hertz	Hz	Hz = s ⁻¹

THE WOLF RESIDENCE, TORONTO, CANADA, COMPLETED 1974. ARCHITECTS: A.J. DIAMOND AND BARTON MYERS. DESIGNED BY BARTON MYERS

Robert Hill, Barton Myers Associates; Toronto, Canada

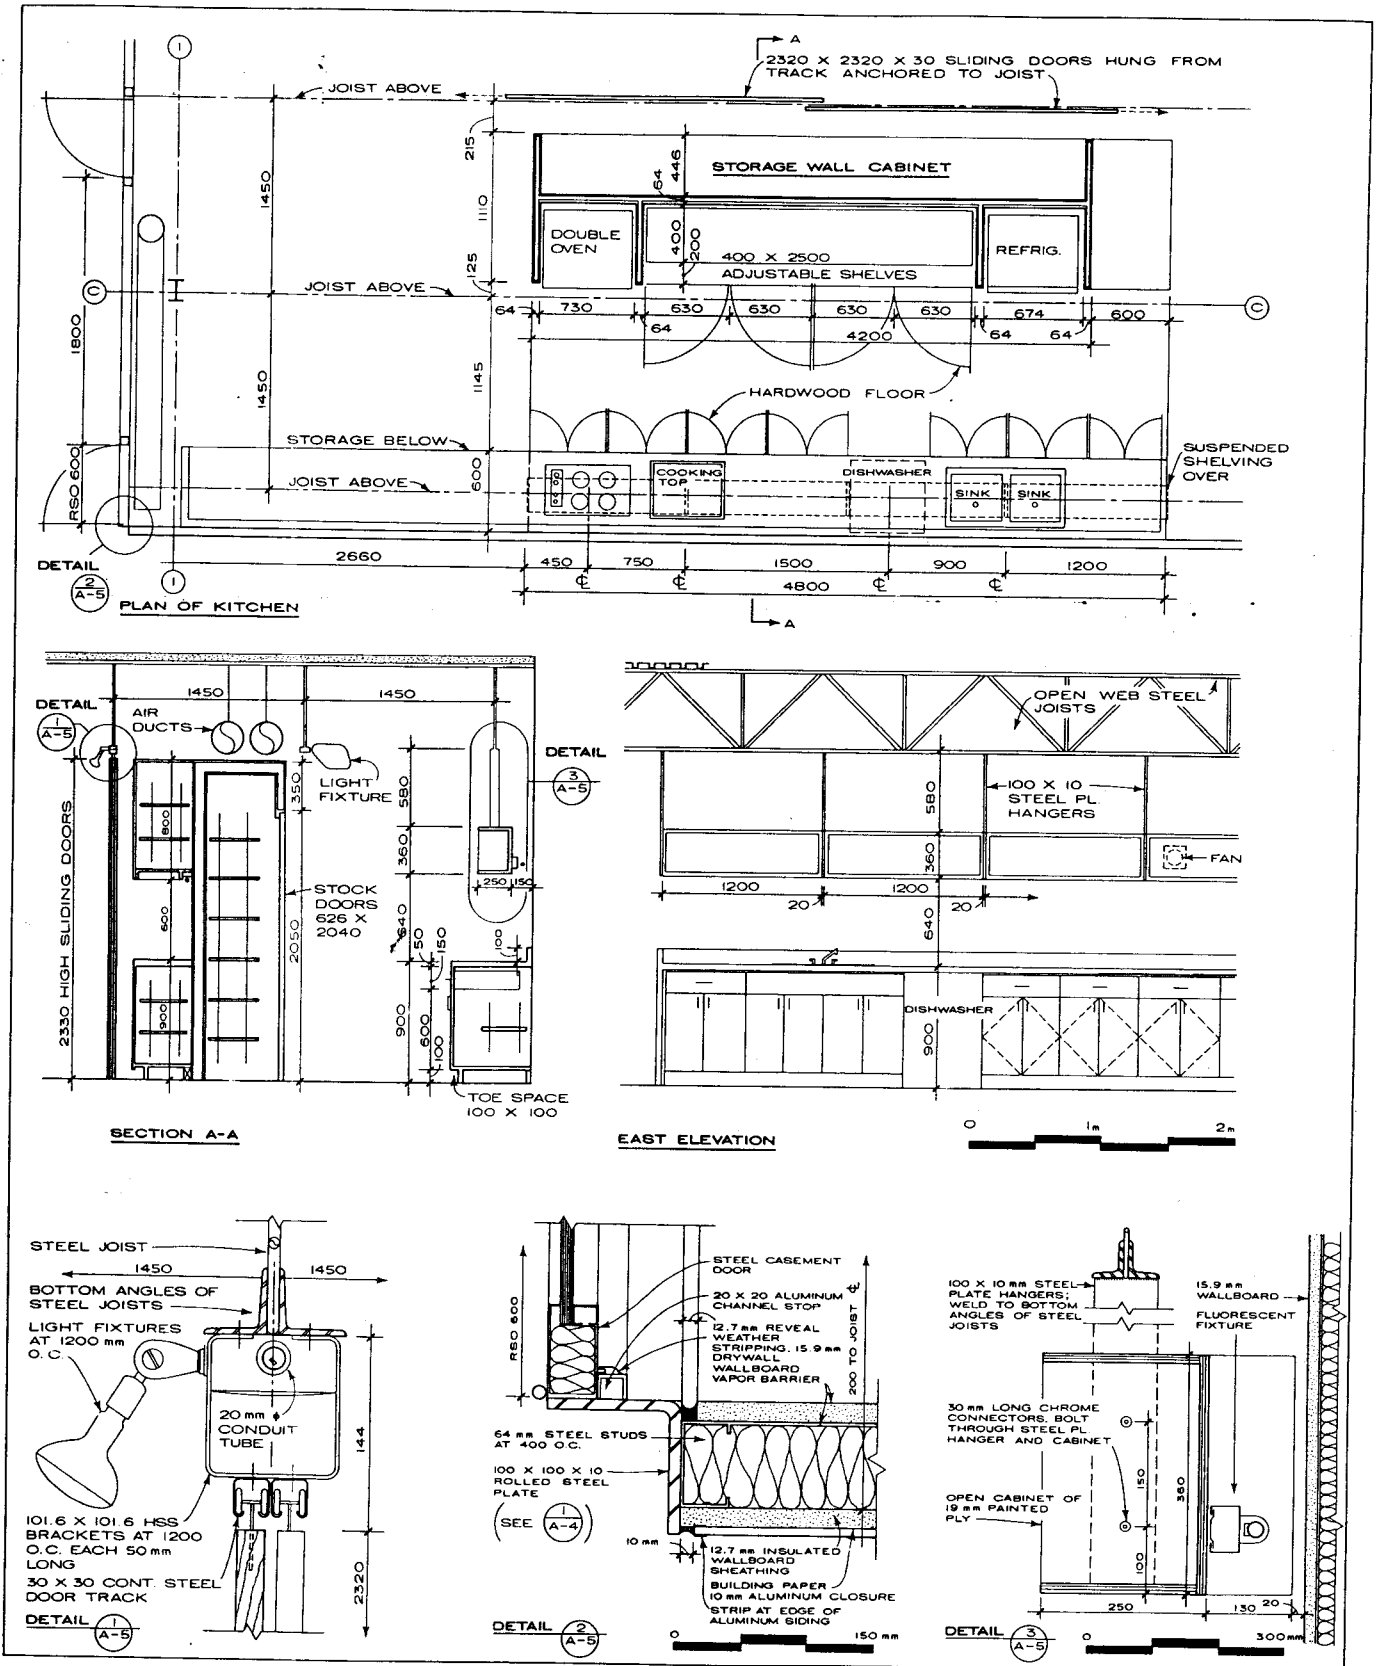

Robert Hill, Barton Myers Associates; Toronto, Canada

A METRIC

NOTES

1. All dimensions shown are in millimetres, using the axial technique of measurement and a grid plan based on a 100 mm plan module.
2. On site plan, sections, and elevations, note that all floor elevations are in metres.
3. All steel sections are dimensioned in millimetres, with weights of lengths in kilograms per metre.
4. Stock lumber dimensions have been "soft converted" to metric equivalents, since lumber will continue to be produced in imperial sizes to meet American Lumber Standards (ALS) requirements.
5. New metric stock door sizes for interior and exterior doors are employed throughout.
