PUBLISHER'S NOTE

Throughout most of the twentieth century, publication of a new edition of *Architectural Graphic Standards* has been a signal event at John Wiley & Sons. More than a million copies of Ramsey and Sleeper's book have influenced several generations of architects, engineers, and designers of the built environment, as noted by Robert Ivy and Philip Johnson in their respective essay and tribute to this tenth edition. For half of the life of *Architectural Graphic Standards*, Wiley has been proud to have The American Institute of Architects as its publishing partner in this great ongoing endeavor.

The release of the tenth edition of *Architectural Graphic Standards* is an unprecedented event even by the high standards set by this landmark publication. For the first time, revised print and digital versions are being released simultaneously. Also for the first time, both versions are fully integrated and contain the same content, in formats that are tailored to their respective media. This integration culminates a major investment of effort and resources, and ensures that *Architectural Graphic Standards* will continue to be not only a definitive reference but also a valuable design tool.

ROBERT C. GARBER
Publisher
Professional/Trade Publishing
John Wiley & Sons, Inc.

In the fall of 1932, the lowest point of the Great Depression, my father W. Bradford Wiley joined John Wiley & Sons and soon learned that a promising new book had been published in May. Martin Matheson, then manager of marketing, had persuaded Charles George Ramsey, AIA, author of an earlier Wiley textbook, and his younger colleague, Harold Reeve Sleeper, FAIA, to develop their ideas and prepare the plates for what became *Architectural Graphic Standards*. Subsequently, Matheson directed the design and layout of the book and personally oversaw its production and manufacture.

The immediate acceptance and success of *Architectural Graphic Standards* extended far beyond its anticipated audience of architects, builders, draftsmen, engineers, and students. Interior designers, real estate agents and brokers, homeowners, insurance underwriters, and lovers of fine books all came to be among its users and admirers.

Soon after the publication of *Architectural Graphic Standards*, suggestions and requests came from many enthusiastic readers. These called for changes and additions and inevitably the decision was made to publish a second edition in 1936, which was almost 25 percent larger than the first. Recovery from the Great Depression had begun when the second edition came out, and with rising construction activity the demand for *Architectural Graphic Standards* increased. To serve its users' growing needs, work soon began on a third edition which, when published in 1941, was almost twice as large as the original edition.

World War II lengthened the interval between editions; the fourth edition, prepared by Sleeper, appeared in 1951 and had grown to 614 pages. The fifth edition (with 758 pages), Sleeper's last revision, was issued in 1956. The coauthors' achievements in the initial decade, followed by the efforts of Sleeper, provided untold thousands of users with an invaluable resource for almost 30 years.

Harold Sleeper's foresight led to his suggestion, which was heartily supported by John Wiley & Sons, that The American Institute of Architects be asked to assume the editorial responsibility for the sixth and subsequent editions. This was proposed at the June 1964 annual convention of The American Institute of Architects, and within a month a contract between John Wiley & Sons and the Institute led to the fulfillment of Harold Sleeper's wish.

Now, more than 60 years after publication of the first edition, we look back on a remarkable record. Each edition has surpassed its predecessors. The book has grown five-fold in length, immeasurably in depth, and is now packaged in a variety of formats designed for the changing information requirements of architects, their students, and their colleagues in the design and construction fields. The collected editions are a chronicle of twentieth-century architectural practice and reflect as well those times when progress has meant preserving (and hence respecting) our architectural heritage.

John Wiley & Sons takes pride in the part the company has played in the enduring success of *Architectural Graphic Standards* and in the association with The American Institute of Architects. Generations of readers have benefited from this work, and we look forward to meeting the needs of generations to come.

BRADFORD WILEY II
Chairman
John Wiley & Sons, Inc.

FOREWORD

On behalf of The American Institute of Architects (AIA), I am delighted to celebrate with our partners, John Wiley & Sons, the publication of the tenth edition of *Architectural Graphic Standards*. Since 1964, this indispensable tool of the trade has been a resource in helping the AIA carry out its historic commitment to the architectural profession and the public we serve by helping to bring order to this nation's building design standards. What is remarkable about this work and the key, I believe, to its success has been the fact that *Architectural Graphic Standards* is the fruit of a thoughtful, cooperative process that makes every member of our industry an interested stakeholder.

This book has empowered and inspired generations of architects to create a better built environment. The collected editions are a chronicle of the best architectural practices of the twentieth century. Indeed, I would go so far as to make a claim that the very nature of modern practice is encapsulated in the pages of this splendid book. Each chapter, each page, and each detail assists the architect in the design process from programming through construction. Everyone at the AIA and every practicing architect is indebted to the founding authors, Charles George Ramsey, AIA, and Harold Reeve Sleeper, FAIA, for their leadership in creating this catalyst for coherence and coordination in a historically fragmented industry. Without it, modern practice would likely not be as advanced.

In this edition, there are so many contributions from talented AIA members and building design experts that it is impossible to acknowledge all of them here. These men and women gave unselfishly and creatively so that the whole profession will benefit from their knowledge and wisdom. Such generosity is at the heart of what it means to

be a professional. To that list, I would like to add the many individuals, firms, trade associations, professional societies, and manufacturers who have given this publication its authority. Their contributions are credited throughout this book on the appropriate pages.

I would also like to acknowledge and thank three Institute editors: Joseph N. Boaz, AIA (sixth edition); Robert T. Packard, AIA (seventh edition); and John Ray Hoke, Jr., FAIA (eighth, ninth, and tenth editions). John has led this project for the last quarter-century, defining the technical content essential to a new generation of architects. Because of the collective wisdom and dedication of the Institute's editors, the basic principles of service to the industry that were set forth in the original edition continue to be advanced.

I would also like to thank two gifted individuals who have enriched this new edition: Robert Ivy, FAIA, editor in chief of *Architectural Record*, for his inspiring essay, and AIA Gold Medal recipient Philip Cortelyou Johnson, FAIA, for his provocative tribute.

To each and every person associated with this special project I offer the words of Eero Saarinen, FAIA, who wrote in the foreword to the fifth edition: "Just as Vitruvius gives us understanding of the vocabulary of Renaissance architects, so *Architectural Graphic Standards* will show the future the dizzying speed and expanding horizons of architectural developments and practice in our time." (May 1956).

NORMAN L. KOONCE, FAIA
Executive Vice President/CEO
The American Institute of Architects
Washington, DC

PREFACE

The American Institute of Architects and John Wiley & Sons, Inc. are proud to offer to the building design and construction community the tenth edition of *Architectural Graphic Standards (AGS)*, for the first time in simultaneous release with a CD-ROM version. Since *AGS* was first published in 1932, more than a million copies of this comprehensive source of design data and details have helped shape twentieth-century buildings and cities. With the tenth edition, this influential volume, established by Charles George Ramsey, AIA, and Harold Reeve Sleeper, FAIA, will continue into the next millennium as a trusted companion to all who seek its guidance and reference.

Historically, the primary audience of *AGS* has been made up of architects, interns, and construction specifiers as well as civil, structural, and mechanical engineers and students in all these fields. In addition, however, a very important secondary market exists for *AGS*. This group is composed of general contractors, subcontractors, home builders, estimators, specialty contractors, developers, planners, landscape architects, interior designers, building code officials, building owners and building engineers, construction trade associations, historians and preservationists, facility space planners, librarians, homeowners, and lawyers.

Since the publication of the sixth edition in 1971, and under the care of The American Institute of Architects, *AGS* has generally been organized according to the principles of MasterFormat®, which is published by the Construction Specifications Institute. MasterFormat® organizes construction data and information into classifications based on building trade or specialty, reflecting the assembly-line character of the modern construction industry. In the tenth edition, an effort has been made to conform even more carefully to the MasterFormat® system. As a result, most pages have new and improved page titles and section names. Chapters 2 through 16 conform to MasterFormat®, while chapters 1, 17, 18, 19, 20, and 21 contain sections that are compatible with or complementary to MasterFormat®.

The tenth edition of *AGS* is the largest and most improved edition to date in terms of growth and content. It consists of approximately 11,000 illustrations in twenty-one chapters. Much of the core information, or about 50 percent of the book, has remained unchanged. The new edition has increased by 127 pages or about 14 percent. It now has 1,022 content pages, as compared to the 895 content pages in the ninth edition (one of the largest increases in

size for any edition yet). But in terms of real change, with revisions to old pages and new pages added, the book's growth in content is estimated to be about 63 percent. For those who keep records, we have omitted 232 ninth edition pages, revised 224 pages, added 333 new pages, and transferred 465 pages unchanged from the ninth edition.

The 232 ninth edition pages we have omitted constituted about 26 percent of that edition. This process of weeding out has helped enrich the book by making room for new material. Most of the pages that were eliminated were out of date or determined to be of little interest to today's professional. Because of the large number of new pages in this edition, I have not attempted to list them by name. Therefore, I encourage you to open the tenth edition and its CD-ROM product, located in the back cover of the book, and begin your journey.

An important new chapter titled "Accessibility" is based on the design standards of the Americans with Disabilities Act (ADA). Today, both existing buildings and new construction must comply with ADA requirements for accessibility. A special team of experts helped define and develop these new pages. My sincere thanks for their good work and dedication go to Thomas Davies, AIA; Mark J. Mazz, AIA; Lawrence G. Perry, AIA; and Kim Beasley, AIA.

The publication of a major new edition of *Architectural Graphic Standards* requires the time, energy, and expertise of many people. I would like to thank all of the great people at Wiley, but especially Robert C. Garber, publisher; Joel Stein, editorial director; Robert J. Fletcher IV, production manager; Debbie Lynn Davis, new media director; Beth A. Weiselberg, associate editor; and Jim Harper, editorial assistant, for their commitment to this immense and complex project. I would also like to thank two very important players at Wiley who continue to shape the future and the very nature of this important work. One is Stephen Kippur, executive vice president, and president, Professional/Trade Division. The other is Katherine Schowalter, vice president, Professional/Trade Division.

At the AIA, I am delighted with the dedication of our professionals. My special thanks go to three important people who make things happen. They are Janet Rumbarger, managing editor; Pamela James Blumgart, assistant editor; and Richard J. Vitullo, AIA, contributing editor. I am fortunate to have them as my friends and associates over three editions. I also want to thank Fred R. DeLuca, senior vice

president/COO, for his many years of service in the care of one of this Institute's most cherished programs.

I would like to thank two very special people who have joined our AGS celebration—my dear friend Robert Ivy, FAIA, editor in chief of *Architectural Record*, for his insightful essay on the historical context of AGS; and one of this nation's most prominent architects, Philip Cortelyou Johnson, FAIA, for his inspired tribute. We are grateful for their important contributions.

Finally, I want to pay tribute to the memory of the original editors, Charles George Ramsey, AIA, and Harold Reeve Sleeper, FAIA, who created the first five landmark editions. They made a wise decision in entrusting the future of their life's work to The American Institute of Architects, which has nurtured the book with great care and passion for its integrity. As the standard bearer of Ramsey's and Sleeper's original vision, *Graphic Standards* is poised at the beginning

of the new millennium, prepared for service for the next century and beyond.

In conclusion, I want to express my deep appreciation to the AIA members and other contributors for their good efforts in the making of the tenth edition. We honor them by acknowledging their contributions on the relevant page or pages, as well as on the acknowledgments page following the preface. Their valuable and inspired service to the Institute is a fine example of how the profession continues its undaunted support of *Architectural Graphic Standards* year after year.

John Ray Hoke, Jr., FAIA
Editor in Chief
Washington, DC

January 2000

A VIEW OF ARCHITECTURAL GRAPHIC STANDARDS

AT THE BEGINNING OF THE TWENTY-FIRST CENTURY

The tenth edition of *Architectural Graphic Standards* arrives on the cusp of change, as both a century and a millennium tick into memory. It has been a period of extremes—scientific optimism tempered by overwhelming societal trauma, social improvement and two World Wars, Le Corbusier and Albert Speer, Einstein's cosmic vision and atomic weapons, Cold War and commerce.

Two houses built early in the twentieth century in Pasadena, California, illustrate divisions present early in the previous century. The first, Greene and Greene's Gamble house, represents the apotheosis of hand craft, a contemporary wooden temple on a hillside rubbed to near perfection, as open and forthright as the capitalist family it served. Just down the hill, Frank Lloyd Wright sounds a more complex chord at La Minatura, a sophisticated example of modular block construction, advanced for its moment, yet hinting at unresolved psychological forces. The two residences represent radically different ideals, prescient of clashes that would follow in succeeding years.

At the turn of the twenty-first century, our own models seem to be virtual ones, a galaxy of computer-generated, biomorphic shapes developed by architect Frank Gehry and his coterie. The cyber revolution seems to promise endless formal possibilities through easily calculated custom fabrication. We have traveled far from Wright and the Greenes. Bombarded by new information, which assaults us in an electronic torrent, we stand on an invisible divide with the sense that new ways of building are underway. Where can those of us concerned with shaping the built environment turn for help?

Throughout roughly two-thirds of the last hundred years, this encyclopedia of building convention and practice has offered succor and advice. *Architectural Graphic Standards* has been a repository of good ideas and a framework for constructing new ones; its content is singular, based on architecture's specific language, which is drawing. Since 1932, architects, engineers, and a host of others have turned to its pages as they would a knowledgeable mentor.

The representations in *Graphic Standards* are ideal, not specific, meant to embody the best thinking and applications in universal settings, allowing the reader to tailor details to the real world. As a source of ideal principles, the book stands with other seminal antecedents, such as the work of Vitruvius from the first century BC; as a comprehensive resource, it compares to the work of Sir Banister Fletcher almost two thousand years later, with a nod to Diderot and the encyclopedists of eighteenth-century France.

Part of this work's beauty is its organization. Its clear drawings; charts and graphs, and now its digital bits, offer information on a mind-boggling range of issues that mirror the design and building process. It answers the question, "How do you do that?," from site planning to building systems. *Graphic Standards* presupposes the interrelationship of parts to whole projects, a nineteenth-century notion articulated by Wright when he said, "The part is to the whole as the whole is to the part." Here, small details link into larger systems, ultimately joined into entire constructions embracing larger sites, a linked unity of great complexity, divisible into bite-sized chunks.

Physical wisdom is represented in graphic ways. Throughout the millennia, humankind has recognized subtle changes in dimensions that make big kinetic or aesthetic differences. Consider the lowly step. *Graphic Standards* presents tread/riser diagrams that acknowledge the enormous physical changes felt with minor shifts in width to height ratios. It remains to the architect to devise the actual stair, but all can appreciate the underlying facts.

You can read this book as social history as well. Sections on accessibility, ecology, town planning, and historic preservation all arose following specific movements in the larger civilization. Likewise, the exquisite renderings from earlier in this century, with their complicated analyses of shade and shadow, have disappeared: Software has rendered such knowledge almost arcane, as the electronic GPS system eclipsed dead reckoning.

However, the potential unlocked by the computer age only underscores our need for a resource like *Graphic Standards*. When all things are possible, we need to know what things are best. Great freedom on the screen will be well-served by rock-solid craft and a knowledge of materials. The editors and contributors to this body of knowledge have, in a sense, created their own architecture with *Architectural Graphic Standards*. It, and its complementary digital version, form a structure of firmness, commodity, and delight. Accessible and well-crafted, this sturdy and vast treasury of ideas allows us to study, adopt, and modify the accumulated wisdom of the past into our own new ideas. Thus armed, we step forward in time.

ROBERT IVY, FAIA
Editor in Chief
Architectural Record

TIMELINE

The increase in size and complexity of *Architectural Graphic Standards* since its initial publication has mirrored the extraordinary accomplishments of architecture in the 20th century.

<i>Architectural Graphic Standards</i>	Architecture Landmarks
	1910 → <i>Pennsylvania Station</i> , New York (McKim, Mead and White)
John Wiley & Sons publishes <i>Architectural Details</i> , a prototype for <i>Architectural Graphic Standards</i>	1924
	1929 → <i>La Villa Savoye</i> , Poissy, France (Le Corbusier)
	1930 → <i>Chrysler Building</i> , New York (William Van Alen)
Wiley publishes first edition of <i>Architectural Graphic Standards</i>	1932
	1934 → <i>Fallingwater</i> , Bear Run, Pennsylvania (Frank Lloyd Wright)
10,000th copy sold	1936
100,000th copy sold	1947
	1949 → <i>The Glass House</i> , New Canaan, Connecticut (Philip Johnson)
Fourth edition published: changes in building technology trigger 80% increase in length over prior edition	1951
Fifth edition published: last edition prepared by Charles Ramsey and Harold Sleeper	1956
	1958 → <i>Seagram Building</i> , New York (Ludwig Mies van der Rohe)
	1966 → <i>Salk Institute</i> , La Jolla, California (Louis Kahn)
Sixth edition published: first edition edited by The American Institute of Architects; incorporates Unifomat organization	1970 → <i>John Hancock Center</i> , Chicago (Bruce Graham/Skidmore Owings and Merrill)
	1973 → <i>AIA Headquarters</i> , Washington, DC (The Architects Collective)
	1977 → <i>Centre Pompidou</i> , Paris (Richard Rogers and Renzo Piano)

Tenth edition of book and version 3.0 of CD published	2000

A TRIBUTE TO ARCHITECTURAL GRAPHIC STANDARDS

In 1932, the same year Henry-Russell Hitchcock and I collaborated in writing *The International Style*, John Wiley & Sons brought out a little-known book titled *Architectural Graphic Standards*. Both of these books, in different ways, helped usher in the era of Modernism and contributed to my amazing journey in architecture. Sixty-eight years later and ten editions complete, *Architectural Graphic Standards*, or as I like to call it, *Graphic Standards*, has quadrupled in size and immeasurably in depth of content, thanks to the dedicated work of its gifted editors, architects, and contributors. I even understand that it is in digital form on CD-ROM located in the back cover of this book. What's next, a *Graphic Standards* website?

I can't think of another book published this century that has supported, taught, and delighted our profession as much as *Graphic Standards*. These ten editions are a chron-

icle of twentieth-century U.S. architectural practice standards. Furthermore, the book is one of the most unifying and focused reference works available in the world. I have always considered my *Graphic Standards* as important in design as is my pencil.

Every architect loves it, wears it out, and keeps it within arm's length. It is a combination of the *Encyclopedia Britannica* and the telephone book—or maybe it's the *Whole Earth Catalog* of architecture! No architect can be without *Graphic Standards*, and with it every architect is empowered and equipped to practice architecture.

2 Anthropometric Data: Adult

INTRODUCTION TO ANTHROPOMETRIC DATA

The following anthropometric drawings show three values for each measurement: the top figure is for the large person or 97.5 percentile; the middle figure, the average person or 50 percentile; and the lower figure, the small person or 2.5 percentile. The chosen extreme percentiles thus include 95%. The remaining 5% include some who learn to adapt and others, not adequately represented, who are excluded to keep designs for the majority from becoming too complex and expensive. Space and access charts are designed to accept the 97.5 percentile large man and will cover all adults except a few giants. Therefore, use the 97.5 percentile to determine space envelopes, the 2.5 percentile to determine the maximum "kinetospheres" or reach areas by hand or foot, and the 50 percentile to establish control and display heights. To accommodate both men and women, it is useful at times to add a dimension of the large man to the corresponding dimension of the small woman and divide by 2 to obtain data for the average adult. This is the way height standards evolve. Youth data are for combined sex. Although girls and boys do not grow at the same

rate, differences are small when compared with size variations.

Pivot point and link systems make it easy to construct articulating templates and manikins. Links are simplified bones. The spine is shown as a single link; since it can flex, pivot points may be added. All human joints are not simple pivots, though it is convenient to assume so. Some move in complicated patterns like the roving shoulder. Reaches shown are easy and comfortable; additional reach is possible by bending and rotating the trunk and by extending the shoulder. Stooping to reach low is better than stretching to reach high. The dynamic body may need 10% more space than the static posture allows. Shoes have been included in all measurements; allowance may need to be made for heavy clothing. Sight lines and angles of vision given in one place or another apply to all persons.

The metric system of measurement has been included, since it is used in scientific work everywhere and is the most practical system of measurement ever devised. Millimeters have been chosen to avoid use of decimals. Rounding to 5 mm aids mental retention while being within the tolerance of most human measurements.

Disabilities are to be reckoned as follows: 3.5% of men and 0.2% of women are color blind; 4.5% of adults are hard of hearing; over 30% wear glasses; 15 to 20% are handicapped, and 1% are illiterate. Left-handed people have increased in number to more than 10%.

SAFETY INFORMATION

Maximum safe temperature of metal handles is 50°C (122°F) and of nonmetallic handles, 62°C (144°F); maximum air temperature for warm air hand dryers is 60°C (140°F); water temperatures over 46.1°C (115°F) are destructive to human tissue. Environmental temperature range is 17.2 to 23.9°C (63 to 75°F). Weights lifted without discomfort or excessive strain are 22.7 kg (50 lb) for 90% of men and 15.9 kg (35 lb) for women; limit weight to 9.07 kg (20 lb) if carried by one hand for long distances. Push and pull forces, like moving carts, are 258 N (58 lbf) and 236 N (53 lbf) initially, but 129 N (29.1 lbf) and 142 N (32 lbf) if sustained. Noise above the following values can cause permanent deafness: 90 dB for 8 hr, 95 dB for 4 hr, 100 dB for 2 hr, 105 dB for 1 hr, and 110 dB for 0.5 hr.

Weight Kg & Lb (Includes Avg. Clothes). Data Are For Load Computations, Not Health Purposes.

Standing Slump Can Be 30 1.2 For Men Or Women. C.G. Is Within Pelvic Link.

8 Occupant Load Calculations

GENERAL

The information for determining occupant load shown in the table on this page comes from three model building codes in use in the United States:

1. BOCA National Building Code (BOCA), 1996 edition, with permission of the Building Officials and Code Administrators International, Inc., publisher.
2. Standard Building Code (SBC), 1997 edition, with permission of the Southern Building Code Congress International, Inc., publisher, with all rights reserved.
3. Uniform Building Code (UBC), 1997 edition, with permission of the International Conference of Building Officials, publisher.

Occupant load generally is defined as the maximum capacity of a building or room given as the total number of people present at any one time. For occupant loads, it is generally assumed that all areas of a building will be occupied at the same time, with some exceptions noted in specific codes. For example, the UBC states, "Accessory use areas, which ordinarily are used only by persons who occupy the main

areas of an occupancy, shall be provided with exits as though they are completely occupied, but their occupant load need not be included in computing the total occupant load of the building" [UBC Sec. 3302 (a)].

Most codes require that to determine multiple use building or area occupancies, the occupant load (OL) must be based on the use that produces the most occupants. For example, the occupant load for a school multiple use room, which will be used for classroom activities (OL factor 20) as well as assembly space (OL factor 15), is calculated using the 15 sq ft per occupant factor.

If buildings or areas contain two or more separate occupancies, the overall occupant load is determined by computing occupant loads for various areas and adding them together for an aggregate occupant load.

When calculating occupant load for areas with fixed seating in benches or pews, the number of occupants is based on one seat for each 18 in. of bench or pew space. In dining areas with booth seating, the number of seats is based on 24 in. for each seat.

EXITS

All three major codes use occupant loads to determine the size and number of required exits. Based on occupant loads and area uses, it is possible to determine the required number of exits and the arrangement and sizes of exit components.

All three codes (BOCA, SBC, and UBC) consider an exit to be more than merely a door. Although specific definitions vary with each code, exits usually are considered to be continuous and unobstructed means of egress to a public way and may include such building elements as doors, corridors, stairs, balconies, lobbies, exit courts, etc. Elevators are not considered exits. Requirements for arrangement, size, and operation of exits vary; consult applicable codes for specific information.

OCCUPANT LOADS

1. Both BOCA and SBC use net and gross floor areas to determine occupant load. UBC does not differentiate between net and gross areas.
2. Occupant loads for assembly areas with fixed seats are determined by the actual number of installed seats.
3. Occupant load calculations for bowling alleys under BOCA and SBC use 5 persons per alley in addition to the tabular values indicated.
4. Stages are considered assembly areas—less concentrated use (15 sq ft per occupant) in UBC, not separately classified in BOCA or SBC.
5. UBC classifies business areas as office occupancy.
6. UBC classifies industrial areas as manufacturing areas.

7. BOCA and SBC classify areas within institutional occupancies; UBC classifies by occupancy description only.
8. UBC classifies mercantile areas as store-retail sales rooms.
9. UBC considers storage and stockroom areas as storage occupancy (300 sq ft per occupant).
10. BOCA and SBC do not separate hotel/apartment and dwelling occupancies.
11. BOCA does not classify skating rinks separately from other assembly areas of less concentrated use (15 sq ft per occupant). SBC does not separate areas within skating rinks.

GENERAL

Stairways are an essential component in the circulation and egress systems of most buildings. They are also the site of accidents resulting in approximately 4000 deaths and one million injuries requiring hospital treatment annually in the United States. For these reasons, stairway design is strictly controlled by building regulations.

The information on this and the following page on stair design summarizes most common building code and access regulation requirements. Be sure to check local regulations as well.

MINIMUM REQUIREMENTS: Consult the table below on building code stairway requirements to determine dimensional limits for treads, risers, and stair width. Verify that local codes are not more restrictive.

TREAD AND RISER SIZES: Use the stair proportioning graph on the associated AGS stair design page to find the number of risers, riser height, and optimum tread depth.

STAIR WIDTH: In addition to the minimums shown on this page, stair widths must also meet occupant load requirements based on use group and floor area. Consult the local building code.

LANDINGS: Landings at least as wide as the stair itself are required at the top and bottom of the stair and at intermediate points if necessary to ensure that no single flight has a rise greater than 12 ft (3658 mm).

STAIR LAYOUT: A sample stairway plan and section are shown on the following page on stair design. Some tips for stair layout follow:

1. Maintain minimum headroom of 6 ft 8 in. (2032 mm) for non-residential and 6 ft 6 in. (1981 mm) for residential stairs.
2. Avoid flights with fewer than three risers to minimize tripping hazards.
3. The use of door alcoves is recommended to prevent stairway doors from obstructing the egress travel path.
4. For prefabricated stairs, the stairwell enclosure should be oversized by several inches for ease of stair installation and to avoid structural conflicts.

TREAD AND RISER PROPORTIONING

Most interior stairs are designed to the steepest limits permitted by code so as to occupy the least amount of space. However, tread and riser combinations that are less steep may be considered for exterior stairs, grand stairs, or stairs of just a few risers. The most common rule for the comfortable proportioning of stairs in these cases is 2 x riser height + tread depth = 25 in. (635 mm). Consider testing life-size mock-ups of stairs of unusual proportions to verify their ease of use.

HANDRAILS

The accompanying diagrams summarize most handrail requirements for nonresidential stairs. For residential stairs not covered by ADA, most codes permit handrails on only one side of the stair, without top and bottom extensions. In some cases a greater range of heights is also permitted. The ADA recommends (but does not require) additional handrails at lower heights where stairs are used by children.

GUARDRAILS

Guardrails 42 in. (1067 mm) in height are typically required on the open sides of nonresidential stairs. When handrails are used in combination with a guardrail, handrail heights

up to 42 in. (1067 mm) are permitted by some building codes. Intermediate rails or balusters must be spaced so that a sphere of either 4 or 6 in. (102 or 152 mm), depending on the code and use group, cannot pass through any part of the guard. Guardrail designs with horizontal rails that are easily climbed are not recommended and, in some cases, are restricted. For residential stairs, guardrails 36 in. (914 mm) in height are usually permitted.

STAIR DETAILS

Treads and risers within a flight must be uniform in size within close tolerances. Treads must be slip resistant. The shape of nosings and risers must meet the requirements shown below. Carpeting or other stair coverings should be applied securely and should not create a nosing radius greater than permitted. Handrails, guardrails, and stairways themselves must meet structural load requirements.

Access regulations in some localities require floor material strips of contrasting color located at the top approach to a stair and at the lowest tread. These markings are intended to aid the visually impaired in identifying the limits of the stair. The application of such markings may be appropriate even where not required, particularly where a high proportion of elderly or visually impaired users are anticipated.

SPECIAL STAIR CONFIGURATIONS

Winders (radiating risers) in stairs normally are permitted only in single-family residences. Minimum tread depth requirements at the inside of the winders may limit the inside radius of the stair. Spiral stairs typically are permitted in single-family residences and for access to mezzanines of limited area in other building types. With certain tread depth restrictions, circular stairways are permitted in most buildings. Alternating tread stairways are permitted for some mezzanines and for access to rooftops. The use of fixed ladders is limited to access to restricted areas, such as rooftops and elevator pits.

ACCEPTABLE NOSINGS AND RISERS

UNACCEPTABLE NOSINGS AND RISERS

SECTION

PLAN

ELEVATION

NOTES

1. When considering metal pipe rails, do not confuse the nominal size by which pipes are specified with the actual outside diameter of the pipe. The outside diameter is larger than the nominal size.
2. Handrails must be continuous on both sides of a stair. Ends of handrails must extend beyond the stair as shown above.
3. The gripping portion of a handrail must be equivalent to a 1 1/4 to 1 1/2 in. (32 to 38 mm) diameter round rail.

STAIR PROPORTIONING GRAPH

STAIR DESIGN AND BUILDING CODES

Building codes are updated regularly, so it is best to consult the current copy of the applicable building code (the BOCA National Building Code, the Standard Building Code, or the Uniform Building Code) for tread and riser dimensions. The International Building Code will also offer a standard for these dimensions when it is published in 2000.

STAIR DESIGN EXAMPLE 1

An exit stairway in a theater rises a total of 20 ft 3 in. This dimension is off the graph shown at left, which means that at least one landing must be inserted in the stair. Select two flights of 10 ft 1 1/2 in. rise each. Looking for the highest possible riser, read across to the 18-riser sloping line (before crossing the 7 in. maximum riser height line), then upward to read a riser height of 6.75 in. Reading downward to the bottom horizontal axis, the optimum tread dimension is 11 1/2 in. This figure can be rounded down to the legal minimum of 11 in. to make the stair as compact as possible.

STAIR DESIGN EXAMPLE 2

A stairway in a single-family house rises 8 ft 10 in. and needs to be as compact as possible according to CABO requirements. Read across to the 13-riser sloping line, then upward to read a riser of 8.15 in.

NOTES

1. Stairs should be laid out in both plan and section. The dimensions shown on this page are samples only.
2. Landings must be at least as wide as the stair.
3. No single flight may rise more than 12 ft 0 in. (3658 mm) vertically.
4. In each flight, there is one more riser than tread.
5. Handrails may project up to 3 1/2 in. (89 mm) into the required stairway width. They must be continuous or the ends must extend beyond the top and bottom of the stair. Stairs serving areas of rescue assistance must have 4 ft clear between handrails.
6. Stairway doors must swing with the direction of egress travel and must not obstruct more than half of the required landing width at any point in the swing. When fully open doors must not strike handrails (including extensions) and not project more than 7 in. (178 mm) into the travel path.
7. See AGS page on areas of rescue assistance for more restrictive stair dimensioning requirements.

PLAN—RIGHT-HAND UP PLAN—LEFT-HAND UP
NOTES

- For spiral stairs, larger diameters increase perceived comfort, ease of use, and safety.
- Tread and platform materials: The most common materials are steel (regular and galvanized), aluminum, and wood. Steel and aluminum can be smooth plate, checker plate, pan type, and bar. A variety of hardwoods can be used, although many manufacturers use steel substructures to support the wood finish surface.
- Refer to local and national codes for dimension and construction requirements and allowable uses.

ELEVATION

PLAN
NOTE

Design considerations for circular stairs are similar to those for spiral stairs. A fabricated steel tube serves as a one-piece stringer to which treads are bolted or welded. Risers can be open or closed. Numerous finishes are available, and treads can be made of laminated wood.

30° TREAD SPIRAL STAIRS

David W. Johnson; Washington, D.C.

TREADS AND RISER SIZES

Riser and tread dimensions must be uniform for the length of the stair. ANSI specifications recommend a minimum tread dimension of 11 in., nosing-to-nosing and a riser height of 7 in., maximum. Open risers are not permitted on stairs accessible to persons with disabilities.

TREAD COVERING

OSHA standards require finishes to be "reasonably slip resistant" by using nosings of slip-resistant finish. Treads without nosings are acceptable provided that the tread is serrated or is of a definite slip-resistant design. Uniform color and texture are recommended for clear delineation of edges.

NOSING DESIGN

ANSI specifications recommend nosings without abrupt edges that project no more than 1 1/2 in. beyond the edge of the riser. A safe stair uses a 1/2 in. radius abrasive nosing firmly anchored to the tread, with no overhangs and a clearly visible edge.

RISER DESIGN

NOTE

Abrasive materials are used as treads, nosings, or inlay strips for new work and as surface-mounted replacement treads for existing work. A homogeneous epoxy abrasive is cured on an extruded aluminum base for a smoother surface, or it is used as a filler between aluminum ribs.

INTRODUCTION

Combining a wide range of common building technologies, the building systems presented on this and the following pages reflect basic approaches to design, construction, and use of materials in response to a variety of occupancy requirements. Such building systems embody key integration issues that arise when components and subsystems are merged to produce complete buildings.

Each example includes a summary of the unique system features, a description of the system's most appropriate or particularly advantageous uses, and a discussion of the main opportunities and challenges for systems integration. The drawings stress the essential interconnectedness among design decisions, illustrating the design process as a fusion of the knowledge of many disciplines, each with an understanding of the value and import of the others' contributions.

The examples encompass structural, envelope, mechanical, and interior systems. In most examples one system (usually structural) or a pair of systems tends to dominate the integration potentials and priorities, clearly circumscribing the prudent and possible uses of the other systems. The examples represent common and reasonable combinations and variations, but they are not the only possibilities within a given building vocabulary.

STRUCTURAL

- Roof: Steel decking and open web steel joists (C)
- Floor: Slab on grade (M)
- Walls: Concrete masonry bearing wall and concrete footing (H)

Principal advantages and characteristics: Bearing wall and bar joist roof building systems employ masonry walls bearing on a turndown slab on grade or conventional spread footings. The walls support a roof structure of open web steel bar joists, through which mechanical distribution systems are threaded. Spans for J- and H-series open web joists generally may not exceed more than 20 times the joist depth, or more than 50 to 60 ft. Long-span joists are available, as are a wide variety of special shapes. By nature, open web joists spaced at even intervals are best suited to relatively light, uniform loads; joists may be doubled or tripled to accommodate heavier, concentrated loads or may be combined with other steel framing for roof openings and rooftop mechanical equipment. The roof deck may be precast concrete plank, tongue and groove wood decking, or, more commonly, steel decking. Small openings in the roof area can be framed between joists by means of specially designed headers.

In buildings with masonry bearing walls, each joist should be anchored to the masonry by means of a joist anchor embedded in the masonry. Steel joists can be designed to cantilever beyond the edges of the bearing walls. Continuous horizontal bracing of both top and bottom joist chords is possible with spot-welded connections at each joist and with the ends of the bracing members anchored to a bearing wall; this type of system is well suited to seismic risk zones.

ENVELOPE

- Roof: Built-up roofing and rigid insulation (B)
- Walls: Window assembly (N), exterior insulation and finish system (EIFS) (D), and canopy assembly (K)
- Floor: Vapor barrier and dampproofing (L)

Principal advantages and characteristics: The concrete masonry unit (CMU) bearing walls are insulated on the exterior to take better advantage of the wall's thermal mass by placing it toward the occupied side. Long-span open web steel joist roofs can deflect substantially, and the camber of the joists alone is often not sufficient to maintain the necessary slope to roof drains.

MECHANICAL

- HVAC: Rooftop unit (A) and ductwork (G)
- Electrical: Surface-mounted conduit or behind furred-out walls
- Plumbing: In partition walls, then through roof
- Fire safety: Sprinkler system suspended from structure in ceiling plenum (E)

Principal advantages and characteristics: If ductwork is to be housed within the depth of the joist, headers or branches must be fed through the joist webs, perpendicular to the spanning direction. The webs of joists must be aligned, and bearing walls with projections must be worked around. Because beams running transverse to the joists may block the threading of piping, ductwork, and wiring, care must be taken that variations in the configuration of

STEEL BAR JOIST WITH BEARING WALL

perimeter walls do not disrupt the regular pattern of the joist web elements, interfering with straight runs for mechanical components. If the building owners will also be tenants, relatively fixed interior lighting and mechanical systems may be planned. Otherwise, overhead and in-floor systems should be laid out for maximum flexibility. If the joist depth is insufficient to carry the ductwork, such equipment can be suspended from the bottom chord of the steel joist.

INTERIOR

- Ceilings: Suspended acoustical tile (E)
- Floors: Resilient tile (J)
- Walls: Glazed interior face on CMU (I)
- Lighting: Fluorescent light fixture in ceiling (F) and natural light (N)
- Furnishings: Movable displays

Principal advantages and characteristics: Suspended interior ceilings are nearly always preferred to directly attached interior ceilings. Finished ceilings attached directly to the joist bottom chord are not only difficult to alter but must be designed to accommodate the high degree of deflection the roof assembly will experience.

SYSTEM SUMMARY

Steel open web joist and bearing wall construction yields buildings that have relatively large interior clear spans and flexible interior layouts. The open webbing of the joists provides a lightweight structure that is easily penetrated by mechanical systems. The bottom chords of the joists are used for suspension of interior finishes, lighting fixtures, and air diffusers in finished areas, although they may be left uncovered. Masonry bearing walls and metal joist roofs are among the simplest and easiest to design and build. The relatively low cost of the system makes it attractive for speculative projects, as does the fact that contractors find this construction method familiar and easy to erect. Retail commercial facilities usually require flexibility in lighting, partitioning, and mechanical systems and large expanses of column- and wall-free space; the envelope and structural systems chosen often reflect these demands.

The height to which masonry bearing walls can be built without resorting to lateral bracing is limited, so they are used most frequently in one-story structures. Roof spans up to 60 ft can generally be accommodated. The spacing and depth of joists is related to the spanning capability of the roof decking material and the requirements for loads on the roof structure.

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland
Based on Richard D. Rush, AIA, *The Building Systems Integration Handbook* (John Wiley & Sons, 1986).

STRUCTURAL

Frame:	Steel, with welded and bolted connections (F)
Roof:	Steel decking welded to frame (A)
Floors, upper:	Steel decking welded to primary frame members, with cast-in-place concrete topping (M)
Floors,	Slab on grade, with concrete foundation (O)
Core:	Central service core of cast-in-place concrete

Principal advantages and characteristics: Core shear walls add rigidity to frame; composite action of structural steel framing and a steel and concrete floor diaphragm result in relatively long, uninterrupted clear spans with smaller depth of construction. Heights can range from one to more than 100 stories. System allows for off-site fabrication of frame components, easy shipping to site, and rapid assembly; corrugated steel deck becomes a working surface as soon as it is placed and provides formwork for concrete topping.

ENVELOPE

Roof:	Built-up roofing or single-ply membrane on rigid insulation (B)
Walls:	Curtain wall units of glass/frame assemblies (E) and insulated spandrel panels (I), attached to structural frame
Basement:	Waterproofing and protective board, with foundation drain (N); vapor barrier under slab (P)

Principal advantages and characteristics: The envelope is structurally independent of the steel frame, providing flexibility in weight, size, and configuration of the envelope system. Curtain wall units preassembled at the factory must be designed with shipping, storage, installation, and general handling in mind, emphasizing protection from damage at all stages.

MECHANICAL

HVAC:	Ducts, with diffusers, either suspended from structure in ceiling plenum or placed in floor plenum beneath access floor (D)
Electrical and	Electrical wires and cables placed mainly in access floor plenum and structural/electrified floor (H); can also be located in ceiling plenum, for lighting, and in interior wall at spandrel panel
Plumbing:	Most plumbing functions placed in core area for efficient vertical circulation of systems
Fire safety:	Sprinkler system suspended from structure in ceiling plenum

Principal advantages and characteristics: Mechanical systems, hidden in floor or ceiling plenums or both, can be accessed through removable panels in ceiling or floor systems.

INTERIOR

Ceilings:	Suspended acoustical tile (C)
Floors:	Carpeted access floor system (L) and structural electrified floor (H)
Walls:	Gypsum wallboard (J)
Lighting:	Fluorescent light fixture in ceiling (G) and natural light (E)
Furnishings:	Open office furniture (K)

Principal advantages and characteristics: Suspended ceiling provides space for distribution of internal services, but it tends to be used principally for overhead lighting and ductwork. Structural/electrified floors and access floor systems keep all wires and cables in space below finish floor, easily accessible by removable floor panels, allowing high degree of flexibility for interior environment. Buildup of static electricity and the ensuing risk of equipment damage and shocks need to be considered. Access floors are not suited to situations involving heavy point loads or shifting heavy equipment. Stringerless systems are among the most flexible and least costly varieties, but they lack the stability of fully gridded systems and depend on perimeter walls for restraint. Use of access floors as air plenum, requiring tight and uniform joints between access panels, may hinder access to wires, cables, and pipes; ductwork in floor plenums may eliminate the advantages of access floors by blocking the path for wiring, cables, and pipes.

**STEEL FRAME WITH ACCESS FLOOR AND CURTAIN WALL****SYSTEM SUMMARY**

Steel frame and curtain wall construction allows for off-site fabrication of frame and envelope components, easy shipping to the site, and rapid assembly at the site. The steel and concrete in the floors are designed to act as a composite diaphragm, providing a thin, lightweight structural element with or without an access floor. The access floor

shown is advantageous in office environments that need especially flexible interior layouts. This system keeps all wires and cables in the space below the finish floor (generally not less than 4 in. deep) and out of wall cavities. Although access floors may add to overall floor-to-floor heights, the access floor conceals the most visually obtrusive distribution elements.

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland
Based on Richard D. Rush, AIA, *The Building Systems Integration Handbook* (John Wiley & Sons, 1986).

STRUCTURAL

- Frame: Staggered story-high steel trusses (D) on steel columns (I) support floor slabs on both top and bottom chords
- Roof: Precast hollow-core concrete plank deck (C)
- Floors, upper: Precast hollow-core concrete plank deck (C)
- Floor, lowest: Slab on grade, with concrete foundation (M)
- Walls: Precast shear panels (H) and precast stiffener beams (O) stabilize structure

Principal advantages and characteristics: This system is best suited to multunit residential or hotel buildings of 7 to 30 stories with repetitive floor plans. Floor-height Pratt trusses are placed atop every other column in a staggered pattern, strengthening the structural system while reducing overall weight; precast hollow-core concrete planks serve as the floor without a topping slab, allowing for bays of approximately 60 x 60 ft (twice the truss spacing). A fire-resistant membrane, such as drywall, is usually added to each side of a truss to provide protection; these walls also serve to divide individual units. Lower floors in this system can be finished and trimmed while upper-level structural members are still being laid; the structure becomes rigid as soon as the precast exterior wall panels and the outer concrete deck elements have been installed.

ENVELOPE

- Roof: Rigid insulation, single-ply roofing and ballast (A)
- Walls: Window assembly (G), precast concrete panels (L), precast stiffener beams (O), and precast shear panels (H)
- Basement: Vapor barrier, and waterproofing and protective board (N)

Principal advantages and characteristics: Precast concrete wall members act as an envelope system as well as a structural system.

MECHANICAL

- HVAC: Ducts, with diffusers, and sprinkler system (B); separate unit-by-unit HVAC systems can be used
- Electrical: Conduit fed through vertical chases at outer walls (J)
- Plumbing: Pipes fed through vertical interior chases
- Fire safety: Sprinkler system supply at central corridor (B)

Principal advantages and characteristics: Because the Pratt-type trusses extend from floor to ceiling, with openings for corridors and elevator doors only, horizontal running of pipes, wiring, and ductwork can be difficult. For this reason separate unit-by-unit heating and air conditioning systems are often preferable; also, unitary HVAC systems offer economic and maintenance advantages in multifamily residential construction. Utilities are typically fed upward through chases and risers on outer walls, with service or supply units placed to either side on each floor; end wall stair enclosures are also used for this purpose. Most sprinkler systems are laid out in this fashion as well.

INTERIOR

- Ceilings: Underside of concrete planks is either painted or covered with acoustical ceiling tile; corridors may have suspended ceiling tile (B)
- Floors: Joints at floor planks are grouted and tops carpeted (K) or tiled (E)
- Walls: Gypsum wallboard (F)
- Lighting: Surface-mounted fixtures or suspended fluorescent fixtures at corridor (B)

Principal advantages and characteristics: The smooth surface of concrete deck planks can provide interior ceiling finishes, if desired.

**STAGGERED STEEL TRUSS****SYSTEM SUMMARY**

Staggered truss construction is most often used for double-loaded residential-type occupancies, including hotels, high-rise apartments, nursing homes, and hospitals. Such building types usually have highly repetitive floor plans and can benefit from systems that integrate objectives regarding structure, interior unit separations, fire-compartmentalization, and acoustical privacy. The system is not generally

considered economical for low-rise buildings due to the manufacturing costs of the jigs for the trusses and the forms for the spandrel precasting. The system easily allows for long structural bays, permitting a high degree of flexibility in unit interiors. The ground floor is free of trusses and interior columns and thus suitable for parking or retail commercial use. The system's light weight reduces foundation size.

Richard J. Vitullo, AIA: Oak Leaf Studio; Crownsville, Maryland
Based on Richard D. Rush, AIA, *The Building Systems Integration Handbook* (John Wiley & Sons, 1986).

STRUCTURAL

Roof:	Metal roof frame (C-stud brace, C-rafter, C-channel, C-joist) (C), with plywood sheathing
Floor, upper:	Metal floor frame (C-joist), steel deck, and concrete topping (L)
Floor, ground:	Slab on grade with concrete foundation (P)
Walls:	C-stud assembly (M)

Principal advantages and characteristics: The lightweight cold-formed steel members are load bearing, and beams, columns, channels, headers, and other elements can be built up from standard steel shapes and sections. The frame's rigidity depends on cross bracing, the distance from exterior corner to exterior corner, and the type and layout of fasteners used. Sheathing both sides of the frame also provides some lateral stability. Steel studs used for masonry backup should be cross braced with steel straps. Horizontal and diagonal bracing increases the frame's rigidity. Welded connections are stronger than self-tapping screws. The method of attachment can affect costs substantially. The positioning and types of fasteners for affixing both interior and exterior sheathing should be carefully specified, because these factors significantly affect lateral stability.

Cold-rolled steel framing is detailed and fastened quite differently than wood framing, and special noncarpentry tools and equipment are required. Advantages of cold-formed steel framing include its light weight, dimensional stability, speed and ease of assembly, resistance to moisture and decay, and, in some cases, readier availability than wood framing members. Also, steel framing members are frequently made from recycled scrap and can themselves be endlessly recycled.

ENVELOPE

Roof:	Shingles and roofing felt (B)
Grade:	Dampproofing (O) and vapor barrier under slab
Walls:	Batt insulation (K), window assembly (H), and brick veneer (G)

Principal advantages and characteristics: Deflection in lightweight steel frame construction can be several times greater than deflection in exterior masonry veneer; such differentials must be accommodated in anchoring details or overcome by adding structural rigidity to the wall frame. The masonry ties that anchor the veneer to the steel frame should permit free and independent movement of the two materials. Where the veneer depends on the steel frame for lateral stability, anchors should be flexible and should not resist shear; wire ties that allow independent movement are recommended. The framing design and method of fastening windows and doors should account for the differences in movement. In general, fenestration components should be attached to either the framing or the veneer, but not attached rigidly to both. When filled with batt insulation and fully sheathed, the lightweight steel frame wall is thermally isolated from the single wythe of masonry veneer. This results in greater differential thermal movement in the veneer than would occur with solid double-wythe masonry construction; the interior heat is not transferred as readily to the exterior masonry.

MECHANICAL

HVAC:	Ducts, with diffusers (D)
Electrical:	Wiring threaded through C-stud wall assembly (M)
Plumbing:	In partition walls, then through roof

Principal advantages and characteristics: Prepunched holes in the studs provide easy routing of plumbing and electrical lines. Most codes require the use of electrical conduit or sheathing of the prepunched stud opening to avoid stripping the insulation as wires are drawn through. Electrolytic action between framing members and nonferrous plumbing pipes must also be considered, and pipes on exterior walls must be adequately insulated.

INTERIOR

Ceilings:	Suspended acoustical tile (E)
Floors:	Ceramic floor tile (J), resilient floor tile (N), and carpet (I)
Walls:	Gypsum wallboard (F)

Principal advantages and characteristics: Interior gypsum wallboard, along with exterior sheathing, applied to steel studs provides additional lateral bracing and an interior finish.

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland
Based on Richard D. Rush, AIA, *The Building Systems Integration Handbook* (John Wiley & Sons, 1986).

**LIGHTWEIGHT STEEL FRAME AND BRICK VENEER****SYSTEM SUMMARY**

Lightweight steel frame bearing wall construction is often used in low-rise commercial and residential buildings. The long-term performance of lightweight steel framing in structures over three stories is a concern. To date, its use in medium- and high-rise buildings has been mainly for exterior partitions or as nonbearing backup for exterior veneers.

Speed of construction, noncombustibility, and relative light weight are key advantages of this system. The space between studs eases insulation and accommodates piping

and electrical distribution. Because the framing can be completed independent of the masonry veneer, the interior is out of the weather quickly and can be finished while the exterior brick veneer is laid. In nonresidential construction, which is likely to have fewer bracing walls and longer vertical spans and horizontal runs, added cold-formed bridging or bracing of the frame increases lateral stability. This can also be accomplished by decreasing the stud spacing or increasing the stud gauge.

STRUCTURAL

- Roof: Wood roof truss and plywood sheathing (B)
- Floor, upper: Wood floor truss and plywood subfloor (G)
- Floor, ground: Slab on grade, concrete masonry foundation wall, and concrete footing (K)
- Walls: Wood frame and sheathing (F)

Principal advantages and characteristics: In this example, a standard wood framing system is employed with prefabricated roof and floor trusses and exterior sheathing. The trusses are built at the factory to engineering specifications. The exterior panels act in concert with wall studs as a structural skin and weathering surface. The wood frame system unifies envelope and structure when this external skin acts as a diaphragm over the studs, joists, and rafters. Often built of 2 x 4 elements, the floor trusses also provide a nailing edge nominally 4 in. wide along the top and bottom chords for subflooring and decking, an improvement over the thinner edges presented by dimension lumber. Because trusses are made up from commonly available dimension lumber, there is little chance that supply shortages will delay projects. Assuming proper factory quality control, the variations often seen in dimension lumber from different mill lots should not be a problem. Also, the smaller wood components are more readily available from sustainable forest reserves, as opposed to large dimension lumber sections, which are available only from older growth forests.

Bridging between floor trusses may be eliminated, depending on the depth of the truss and the application and rigidity of subflooring and ceiling finishes. If needed, bridging may be accomplished by running continuous 2 x 4s perpendicular to the truss chords within the open web and nailing them to truss struts. When such bridging is used, it should not block possible transverse duct runs. Most floor truss systems allow for a continuous-edge ribbon at the truss ends in lieu of a header. Before truss units are lifted into place, it is wise to inspect them for uniformity of depth and camber and for general tightness. If substantial field-work is contemplated, it may be desirable to use plywood I-trusses, which can be cut to length and drilled to allow threading of pipes and wires.

ENVELOPE

- Roof: Shingles, roofing felt, with metal flashing (A)
- Grade: Vapor barrier under slab, with dampproofing at foundation
- Walls: Batt insulation (E), window assembly (J), and lapped wood siding (I)

Principal advantages and characteristics: Wood components treated with fire retardants can now be used in many applications for which untreated wood is unsuitable. Some fire-retarding treatments may discolor wood, accelerate corrosion of metal fasteners, or alter the structural properties of the wood. For example, plywood can become delaminated, a particularly difficult problem when the plywood sheathing itself acts as the exterior finish surface.

MECHANICAL

- HVAC: Ducts and diffusers (H), with below-slab perimeter ducts (M)
- Electrical: Wiring threaded through holes drilled through wood studs
- Plumbing: Pipes set in partition walls, then through roof

Principal advantages and characteristics: Open web trusses allow threading of wiring, piping, and ductwork without on-site drilling or cutting, thus greatly speeding and easing the installation of heating, plumbing, and electrical systems.

INTERIOR

- Ceilings: Acoustical tile (C)
- Floors: Carpet (L)
- Walls: Gypsum wallboard (D)

Principal advantages and characteristics: The open web wood trusses permit longer clear spans than conventional timber framing, leaving greater flexibility for the location of interior partition walls that need not be load bearing.

WOOD ROOF TRUSS AND WOOD FLOOR TRUSS

SYSTEM SUMMARY

Prefabricated roof and floor trusses eliminate much field labor, thus speeding on-site construction; help ensure dimensional stability; and may eliminate the need for intermediate load bearing partitions. Longer clear spans are possible with floor trusses than with generally available dimension lumber, and recent advances in manufacturing techniques make it possible to specify many special fea-

tures. Open web trusses are lighter in weight than dimension lumber and can be lifted easily in gangs by a small crane or lift. Trusses are available in standard configurations between 12 and 24 in. deep and allow threading of mechanical systems without cutting the members, speeding installation. The smaller wood components used in these trusses are more readily available from sustainable forests, as opposed to the older growth trees harvested for larger standard lumber sections.

STRUCTURAL

- Columns: Cast-in-place concrete (K)
- Roof: Cast-in-place concrete flat plate (E)
- Floors, upper: Cast-in-place concrete flat plate (E)
- Floors, basement: Slab on grade and concrete pile foundation (N)
- Core: Central service core of cast-in-place concrete

Principal advantages and characteristics: Combines cast-in-place concrete columns with two-way concrete slab plates of uniform thickness. Two-way flat plate concrete floors are among the simplest concrete structures for reinforcing, formwork, and detailing. Exterior precast concrete panels can be attached on lower floors, even with flat plate shoring still in place, while concrete is being poured for upper-floor columns and plates. When crane hoists are used to lift concrete buckets or large equipment, a hole is generally left in a section of each plate to allow for passage of the hoist; this hole is filled later, when large components have been moved and concrete pouring is complete. Elevator shafts are not used for this purpose, as elevators are usually installed before construction work is complete. In this system, precast concrete or composite spandrel units are welded in place to a series of angle clips fastened into the concrete flat plates at their edges.

Flat plate concrete construction permits more stories to be fitted into a given building height than any other system. This is because its floor structure has minimum thickness, especially when post-tensioned. In addition, in many building types the underside of the floor plate can serve as the finish ceiling.

ENVELOPE

- Roof: Rigid insulation and ballast (C), on protected roof membrane (B)
- Walls: Window assembly (D) and precast concrete spandrel panels (M), batt insulation (I)
- Basement: Waterproofing and protective board at foundation, with vapor barrier under slab (O)

Principal advantages and characteristics: Exterior precast concrete panels can be attached on lower floors, even with flat plate shoring still in place, while concrete is being poured for upper-floor columns and plates. Window-framing elements and glazing are installed after the spandrels have been set. Tolerances within the system grow progressively tighter: the concrete structure requires the least attention; placement of steel angles for welding to the spandrels requires greater exactitude; and positioning the spandrels to accommodate framing and glass requires greatest care.

MECHANICAL

- HVAC: Ducts, with diffusers, suspended from structure in ceiling plenum (G)
- Electrical and tele-communications: Power and communication poles (H)
- Plumbing: Most plumbing functions in core area for efficiency in vertical circulation of systems
- Fire safety: Sprinkler system suspended from structure in ceiling plenum
- Conveying system: Elevator equipment in penthouse (A)

Principal advantages and characteristics: Centralized core permits relatively uniform, short horizontal runs for power, plumbing, lighting, and other systems.

INTERIOR

- Ceilings: Suspended acoustical tile (F)
- Floors: Carpeting (L)
- Walls: Gypsum wallboard, metal stud assembly (J)
- Lighting: Fluorescent light fixture in ceiling and natural light (D)

Principal advantages and characteristics: Workstations in unpartitioned interior offices can be serviced unobtrusively by ceiling height power and communications poles, in furred-out areas around columns, and in corridor partition walls. Office workstations require daylight exposure and views. Because the central core is farthest from perimeter zones, usable floor area in the perimeter can be maximized. On constrained urban sites, the central core may be moved against an unfenestrated wall and still retain this advantage.

FLAT PLATE CONCRETE

SYSTEM SUMMARY

This example combines cast-in-place columns and two-way concrete flat plates of uniform thickness, with precast concrete spandrel panels. The system usually has a central core for vertical circulation and services, and it is typically employed for low- to medium-rise construction because of the costs and difficulties associated with placement of materials and labor in higher buildings. The central core also permits consolidation of vertical service risers, increasing

fire protection by reducing or eliminating through-floor penetrations in office areas.

Flat plate concrete construction is especially applicable to apartments, hotels, and dormitories, in which no suspended ceiling is required. Story height can be minimized in these applications by using the undersides of the slabs as finish ceiling.

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland
Based on Richard D. Rush, AIA, *The Building Systems Integration Handbook* (John Wiley & Sons, 1986).

STRUCTURAL

- Frame: Rigid concrete (J)
- Roof: Rigid concrete slab
- Floors, upper: Concrete slab (B)
- Floor, basement: Slab on grade and concrete foundation (L)

Principal advantages and characteristics: Post-tensioning is a highly sensitive integration of the compressive strength of concrete with the tensile strength of steel. Plastic-sheathed, high-strength steel tendons are cast in the slab and, after curing, are placed in the tubes, anchored, and jacked into tension from one end. After stresses are applied, the tendon channels may be grouted to bond the tendons to the slab. For lengths greater than 100 ft, stresses must be applied simultaneously from two ends. Integration of mechanical services is influenced greatly by the positioning of tendons, which controls the locations of through-slab penetrations. Post-tensioning permits the use of shallower beams and slabs, reducing overall building height and permitting longer spans with thinner structural members; structure is quite rigid and less subject to movement and creep, allowing use of masonry infill envelope. Alterations and demolition can be difficult due to potential forces latent in post-tensioned tendons.

ENVELOPE

- Roof: Built-up roofing or single-ply membrane on rigid insulation (A)
- Walls: Window assembly (I), and brick and concrete masonry with rigid insulation (K)
- Basement: Waterproofing and protective board at foundation (N), vapor barrier under slab

Principal advantages and characteristics: Envelope rests on the concrete frame by means of steel shelf angles attached to spandrel beams.

MECHANICAL

- HVAC: Ducts, with diffusers, suspended from structure in ceiling plenum (C)
- Electrical and tele-communications: Wires and cables placed in wall assemblies
- Plumbing: Most plumbing functions placed in centralized locations, avoiding tendons
- Fire safety: Sprinkler system suspended from structure in ceiling plenum

Principal advantages and characteristics: Mechanical systems hidden in ceiling plenums can be accessed through removable panels. This system is optimal for additions to hospitals and other medical facilities, which often require floor-to-floor heights that match those of the existing structure. Although contemporary standards for servicing and mechanical equipment require deeper interstitial spaces than are found in older medical buildings, the shallower slabs and beams of post-tensioned concrete construction can conserve such space.

INTERIOR

- Ceilings: Suspended acoustical tile ceilings (E)
- Floors: Resilient flooring (F)
- Walls: Metal stud and drywall assembly (H)
- Lighting: Fluorescent light fixture in ceiling (D) and natural light (I)
- Specialties: Operable partitions (G)

Principal advantages and characteristics: Suspended ceiling provides space for distribution of internal services but tends to be used only for overhead lighting and ductwork.

SYSTEM SUMMARY

Post-tensioned concrete construction is virtually identical to the flat plate concrete construction described on the preceding page. The major difference lies in the thickness of the concrete slab, which is slightly reduced in this type of construction.

Post-tensioning is a method of reinforcing concrete by stretching steel reinforcing tendons after placement and curing of the concrete structure. This prestressing reduces

POST-TENSIONED CONCRETE

or eliminates tensile stresses on the concrete under use loading and strengthens the slab without increasing its thickness or adding the dead loads introduced by additional steel reinforcing rods. Post-tensioning is useful when the thickness is important to economical or functional design

aspects or when concentrated live loads are high and the building height must be kept to a minimum. It is also effective when project conditions require minimal floor-to-floor heights but maximum ceiling heights with generous space above the ceilings.

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland
Based on Richard D. Rush, AIA, *The Building Systems Integration Handbook* (John Wiley & Sons, 1986).

STRUCTURAL

Frame:	Prestressed precast concrete columns and spandrel beams (D)
Roof:	Prestressed precast concrete double T (B)
Floors, upper:	Prestressed precast concrete double T (B)
Floors, basement:	Slab on grade, with cast-in-place concrete piles (F)
Core:	Cast-in-place concrete vertical circulation (E)

Principal advantages and characteristics: This system is most commonly used for parking garages. Double-T joists are generally 8 or 12 ft wide, at a depth of 18 to 36 in., depending on the spanning requirements; spans of 60 ft are considered maximum, due to the constraints of shipping and lifting the pieces, but longer spans and deeper sections are possible. It is advantageous to use as many similar elements as possible; that is, floors, inverted T girders, and columns should all be of the same length and design. Off-site precasting can conserve time and materials for concrete forming, and on-site erection time is considerably faster than for cast-in-place construction. Cast-in-place core provides lateral stability to frame. Adding final finishes and installation hardware to prestressed components before erection helps reduce on-site construction time. Temporary shoring and bracing may be required during construction, particularly (if the structure is composite) until the toppings have cured to service strength. Lifting loops are generally embedded in the precast pieces and then covered with the topping or cut off after installation.

ENVELOPE

Roof:	Concrete topping slab (A)
Walls:	Spandrel beams act as finish walls (D); no glazing in openings

Principal advantages and characteristics: For parking garages, the most common application of precast concrete frame, a weather-tight condition is not needed; therefore, structural components can be directly exposed to the elements. Some aesthetic treatments can be cast in or applied to surfaces but are not needed for moisture protection.

MECHANICAL

Electrical:	Conduit, exposed at underside of concrete structure
Plumbing:	Pipes from roof and floor drains, exposed to view throughout structure
Conveying system:	Elevator equipment for hydraulic elevator (G)
Fire safety:	Sprinkler heads dropped from supply lines set into channels at upper face of precast floor Ts

Principal advantages and characteristics: In parking structures the requirements for through-floor penetrations are minimal. However, holes or sleeves can be cast in the stems and flanges of the Ts, to allow for passage of conduit and piping. These holes and openings can be as great as one-third of the stem's total depth but must avoid the reinforcing tendons; openings toward the top of the stem in midspan and toward the bottom at the ends are most common. Preplanning of all openings is essential to minimize sitework and to realize the inherent economies of the system. Ts may be notched at the ends to permit passage of conduit along girders or bearing walls. Also, channels can be formed by chamfering mated edges of adjacent Ts at the upper surface, setting the conduit, then pouring a concrete topping slab.

INTERIOR

Floors:	Concrete topping acts as floor finish (A)
Walls:	Concrete structure surface acts as wall finish (D)
Lighting:	Fluorescent light fixtures attached to structure (C), and natural light between spandrel beams
Specialties:	Curbs, handrails, and signage

Principal advantages and characteristics: Most typical interior elements are not needed because of the open air nature of the building type; however, all elements provided are attached directly to the exposed structure. In parking garages, the depth of the structural Ts and concerns for minimizing floor-to-ceiling height present special challenges for the integration of lighting and signs.

**PRECAST CONCRETE FRAME****SYSTEM SUMMARY**

Precast concrete components are usually pretensioned. Pretensioning is a method of prestressing concrete in which steel tendons are stretched prior to placement of concrete and maintained in tension until the concrete is cured. The external tension on the tendons is then released to compress the concrete. This example employs prestressed columns, inverted T girders, ledger girders, and double-T joists, all of the same length and design. Once the

floor and roof Ts are set, the surface is covered with a concrete topping that provides the finished, weather-exposed surface and a horizontal structural diaphragm. The precast components are fabricated off site and lifted in place by crane. A variety of finished surfaces is possible and the unity of materials presents an opportunity for natural visible integration of elements. Thin brick or tile can also be used as a surface material.

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland
Based on Richard D. Rush, AIA, *The Building Systems Integration Handbook* (John Wiley & Sons, 1986).

STRUCTURAL

Frame: Rigid concrete (C)

Floors, upper: Flat plate (K)

Foundation: Slab on grade and concrete (M)

Principal advantages and characteristics: Flying form construction requires almost total regularity in structural bay widths. Flying forms can be used to construct flat slabs, pan-joint slabs, waffle slabs, and various types of beams-in-slab. They are also used to form spandrels of varying configuration. Flat plate or flat slab construction is preferred, as this eases movement of the flying form "table" and minimizes special additional forming. For flying forms to be economical, the building structural layout must be uniform and the beams and spandrels should be very shallow.

There are three principal types of flying forms: adjustable post shoring, manufactured truss forms, and column-supported forms. Adjustable post shoring uses scaffolding that rests on a wood sill and blocking and is raised by jacks. The forms are moved horizontally, usually by means of rollers, and are generally suitable for pours of up to 40 ft in length.

Manufactured truss forms, ranging up to 50 x 100 ft in side dimensions, use 4 to 6 ft deep trusses and are raised by a series of uniformly distributed jacks. The forms are moved by crane from one floor to the next, often in a staggered or stepped sequence. Greater widths in truss forms are made possible by the use of additional longitudinal trusses. Column-supported forms employ adjustable brackets that "climb" columns and are shored after initial positioning. This type is better suited to applications involving relatively close column spacing.

Usually the same work crew sets and strips the flying forms; half of the crew works below the deck level that has been cast, while the other half works above the previously cast area, setting the forms that have been removed. Conventional temporary shoring, separated from the surface forms, is set in place after removal of the flying forms. To speed the process of curing and to enable quicker removal of the forms, early high strength concrete is frequently used.

ENVELOPE

Roof: Built-up roofing and rigid insulation (B); concrete masonry parapet backup (A)

Walls: Window assembly (G) and precast concrete spandrel panels (L)

Basement: Vapor barrier (N)

Principles and characteristics: As in the case of conventionally cast-in-place flat plate concrete construction, the structural and mechanical systems are concealed from view, with the precast concrete envelope spandrel and glazing units connected to the structural frame. Flying form construction, which requires relatively uniform bay widths, can have an effect on visible integration because it produces regularity in the rhythm of structural elements.

MECHANICAL

HVAC: Ducts and diffusers (D)

Electrical and telecommunications: Under-carpet flat cable (J)

Principal advantages and characteristics: In office applications, the high quality of the slab's finished surface lends itself readily to the use of flat wiring for power, lighting, electronics, and communications. Because they are flat, these wiring systems increase the flexibility of open office planning; they are attached to the slab with steel tape prior to the installation of carpet tiles, with direction changes accomplished by folding the flat cable. Extra fire protection measures are unnecessary, as there are no through-slab penetrations to be sealed.

INTERIOR

Ceilings: Suspended acoustical tile ceiling (E)

Floors: Carpet tile (I)

Walls: Metal stud and drywall assembly (H)

Lighting: Fluorescent light fixture and natural light (F)

Principal advantages and characteristics: Flying form construction permits great flexibility in interior layouts and furniture arrangements. The use of flat wiring frees the electrical system from restraints imposed by the structure, permitting the furniture layout and power needs to remain variable until very late in the construction process.

**FLYING FORM****SYSTEM SUMMARY**

Speed of construction, the economies realized through reuses of the forms, and the high quality of finished surfaces are among the most attractive features of this construction method. The systems employed with flying form construction do not differ substantially from those found in other types of reinforced concrete construction; the difference lies in the method of forming slabs and spandrels and in the sequencing of pours. A disadvantage of the flat plate construction system is the relative difficulty of punching through the slab or plate. An important consideration with the use of flying forms is the regularity of bay spacing and the absence of deep beams or spandrels.

During construction the forms are placed and removed in a sequence of related operations, with temporary shoring used after form removal under the slabs until they have cured. The repetitive use of the forms can lead to conservation of both time and, of course, the materials used in forming. Mechanical and interior systems are meshed in the suspended ceiling assembly. The use of flat wiring atop the floor slabs for internal distribution of power, lighting, electronics, and communications dictates the use of removable carpet tiles and yields a set of requirements for interfaces with furnishings and equipment.

Based on Richard D. Rush, AIA, *The Building Systems Integration Handbook* (John Wiley & Sons, 1986).

STRUCTURAL

Frame: Precast concrete panels (H)

Roof: Steel deck and open web steel joists (C)

Floor: Slab on grade and concrete footing (J)

Principal advantages and characteristics: Load-bearing tilt-up wall panels provide a unified vertical envelope, structure, and interior. The panels are precast on-site, generally using the floor slab or grade as the casting surface, and tilted or lifted into position. The floor slab used as a form must be level, smoothly finished, and treated with a bond-breaking agent to permit easy separation of the cast pieces. The wall panels, usually 6 in. in nominal thickness, may extend from one to several stories in height, and must be designed to withstand the bending loads involved in tilting and lifting, as well as loads that will be encountered once in place. They may be plain, reinforced, or prestressed and are often provided with temporary timber or steel "strongbacks" for tilting, particularly when there are large window openings.

The panels must be braced during construction until all wall and roof structural members are in place. Columns are usually cast in place following installation of the panels. In load-bearing tilt-up wall systems the roof and floor members are bolted or welded to plates and angles cast into a continuous ledge beam. Roofing systems may be steel open-web joists, precast concrete T's, or hollow-core planks. Flashing reglets and other roofing connection details can be cast with the panels. Regular inspection of casting and lifting operations is essential.

ENVELOPE

Roof: Built-up roofing and rigid insulation (B); skylights (A)

Walls: Precast concrete panels (H); window assembly (G); dampproofing and protective board (E)

Floor: Concrete slab (F)

Principal advantages and characteristics: Joints between panels should be designed to be concealed; this is easily accomplished where cast-in-place columns are designed to lap the panel edges, or where the panels insert at their edges into a precast column channel. Connections between panels should not be rigid, so caulks and sealants are important.

Foundation and slab detailing are key to preventing water infiltration at the panel bases. It is good practice to design the system so that the slab level is slightly above the bottom edge of the vertical tilt-up panel.

MECHANICAL

HVAC: Ductwork in open-web bar joists (G); radiant heat panels in suspended ceiling (E)

Electrical: Fluorescent light fixtures (F)

Principal advantages and characteristics: Because the slab on which the panels are cast must be smooth, utility raceways, pipes, and conduits that will penetrate the slabs must be stubbed below the finish slab level, covered during wall panel casting, and then uncovered for final connections.

The location and installation of angles, channels, weld plates, conduits, connectors, and other hardware should be carefully planned and detailed, with regular and careful inspections before placing the concrete. Lifting forces and special complications related to openings require exacting structural analysis and special erection hardware.

The suspended ceiling panels incorporate radiant heat panels. Ductwork for cooling and ventilation air is threaded through the open-web bar joists. In the open area, gas-fired heating units are suspended from columns and the structure is left exposed.

INTERIOR

Ceilings: Suspended acoustical tile ceiling (K)

Floors: Resilient tile flooring (I)

Walls: Precast concrete panels (H)

Lighting: Skylights (A) and fluorescent light fixtures (F)

Principal advantages and characteristics: The site-cast panels are the load-bearing elements for the roof members and provide both interior and exterior finish. The building shell can be erected quickly, permitting interior work to proceed along with final joining and sealing of the envelope panels.

The clear spans produced by the bar joist roof structure and option for hung ceiling allow interior partitions to be intro-

**TILT-UP WALL**

duced virtually anywhere, with meshed interior and mechanical systems provided by a ceiling-mounted radiant heat panel.

SYSTEM SUMMARY

Tilt-up walls have been used routinely in a variety of building types and heights, especially for single-story buildings with large, uncomplicated exteriors. The system is also increasingly used for multistory lowrise projects. Significant savings in time and formwork costs can be achieved, and long lead times required for precast or structural steel com-

ponents are often averted. Because most of the forming and erection work is done within the floor slab area, tilt-up systems work well in confined construction sites.

Conservation of time and forming material is realized when there is uniformity in panel design and when the floor surface can be used for forming. Careful planning of the forming, storage, and lifting sequence is essential, and early consultation with manufacturers and contractors is advisable. Regular inspection of casting and lifting operations is essential.

1

BUILDING SYSTEMS

STRUCTURAL

Frame: Heavy glued laminated wood beams (H); exposed wood frame and plywood sheathing (J)

Roof: Plywood sheathing and wood roof, tongue-and-groove wood decking (C)

Floors: Slab on grade and concrete foundation (N)

Principal advantages and characteristics: Heavy glued and laminated beams and columns, which define the interior of the building, make up the frame in this example. The roof structure is laminated tongue-and-groove decking, nominally 2¼ in. thick, laid over the beams.

Considerable flexibility is available in selecting structural modules and bay sizes in heavy timber construction by varying the depth of beams and increasing the thickness of decking to span between beams. Columns are frequently oversized to give an appropriate appearance; if sized only to carry the loads transferred from above, they may appear too spindly in proportion to other framing elements.

Glued laminated beams, columns, and decking are generally preferred over dimensioned sawcut lumber. Appearance is easier to specify and ensure; a variety of custom shapes, sizes, and presawn joints can be obtained in glued laminated pieces; and they are drier and more resistant to twisting, checking, and shrinkage. All pieces should remain factory-wrapped until in place and out of the weather, as rain and snow will stain them.

If mill-cut lumber is used, it should be cut and dried well in advance and should be specified free of heart centers. Although well suited to pier foundation systems, post and beam framing is often more easily erected atop a perimeter masonry foundation.

Outside air infiltration is increased at endwall joints in tongue-and-groove timber decking and must be controlled through appropriate detailing. When components have been carefully ordered and weather conditions are favorable, erection of the structural system can proceed quickly.

ENVELOPE

Roof: Standing seam roof, roofing felt, and rigid insulation (B)

Walls: Wood siding (G); window assembly (F)

Floor: Vapor barrier under slab (O)

Principal advantages and characteristics: Lower portions of perimeter walls are framed conventionally with wood studs between main timber columns; a vapor barrier is placed toward the occupied side, and the voids are filled with batt or rigid insulation. Drywall covers interior walls; the exterior is sheathed in plywood and finished with diagonal wood siding. The roof deck is covered with a moisture barrier and insulated on top with rigid insulation board between sleepers. A standing seam metal roof is applied over the sleepers, which also provide diagonal bracing.

MECHANICAL

HVAC: Ducts, supply and return system (D)

Electrical: Rigid conduits run through decking (A)

Principal advantages and characteristics: Space heating and cooling is provided by air supply-and-return ducts. Kitchens, lavatories, and other areas requiring both odor removal equipment and greater amounts of fresh air are separated by walls and covered by suspended or furred ceilings.

As in any system with exposed components, cleanliness of details, finishing, and dimensional coordination are very important. If ductwork cannot be fed through voids in the floor structure into interior and exterior wall voids, layout, finishing, and suspension hardware must be skillfully designed and executed for compatibility, as must interior fire sprinkling systems. Overhead electrical service can be located in rigid conduits that run through the decking. During the application of roofing materials, puncturing these hidden conduits must be avoided.

INTERIOR

Floors: Carpeting (I) and clay tile flooring (M)

Walls: Drywall (L)

Lighting: Incandescent light fixtures (E) and natural light

Principal advantages and characteristics: The underside of the laminated tongue-and-groove decking is exposed to interior view and should be specified for appearance grade. Drywall covers interior walls.

LAMINATED WOOD POST AND BEAM

SYSTEM SUMMARY

Although used historically for larger buildings, post and beam construction is now generally confined to buildings of three stories or fewer. Its main advantages are simplicity of elements and details, combined with the potential for visual integration and bold structural and architectural forms.

Structure and interior are unified in post and beam construction. Because the structural elements in this system are exposed to view in the finished buildings, as are portions of the mechanical system, care is required in the visual integration of these components and in the design

and appearance of hardware used for joinery of the wood members. Certain parts of the mechanical system can be meshed within interior partitions and exterior walls, leaving them concealed. The sizing of structural members and joinery details may be influenced more by considerations of visual proportion and appearance than strictly by the loading and stress conditions involved.

Based on Richard D. Rush, AIA, *The Building Systems Integration Handbook* (John Wiley & Sons, 1986).

STRUCTURAL

- Frame: Wood frame and sheathing (J)
- Roof: Glued laminated beams and wood deck (C)
- Floors: Plywood subfloor on lateral steel beams (N)

Principal advantages and characteristics: Modules are tied together through the concealment of joints and mating lines, accomplished by holding the cladding material back from the mating line, and spanning between two units with field-installed components to cover the area left unclad. They are then bolted to the steel frame, in addition to being anchored to the foundation. Stud framing, floor joists, and roof rafters are supported on steel I-beam frames until the unit is placed on its foundation.

ENVELOPE

- Roof: Sheet metal roofing and metal cap flashing (B)
- Walls: Aluminum siding (I) and batt insulation (D)
- Floor: Vapor barrier (O)

Principal advantages and characteristics: Openings in the envelope for doors and windows may present difficulty in mating units, due to differential movement of the units, which are normally placed on separate and less-than-permanent foundations. Entrance doors, for example, should not span between unit mating lines, even when the installation is not considered temporary. Exterior siding can be held back from the mating lines between units and then field-installed to span the joint lines. This technique improves visual integration and also helps tie units together structurally. At the roof, special curb caps are available or may be field-fabricated to span across low parapets on mated units. If a complex must mate some units at all four sides, mechanical system plants may be roof-mounted. Modular units are normally tied down by cable and earth-embedded anchors.

Skirting at the base of the units is often necessary for appearance and security, with field-set steps required at entrances. Plans for roof drainage and water carryoff should be resolved with the manufacturer.

MECHANICAL

- HVAC: Rooftop unit (A) and insulated ducts (E)
- Electrical: Electric baseboard heaters (L)
- Plumbing: Factory installed, hooked up on site (I)
- Fire safety: Fire sprinklers and fire/security systems may be factory installed

Principal advantages and characteristics: Wiring and plumbing, installed at the factory, are easily hooked up at the destination site. Nearly all system components are installed at the factory, including heating, cooling, and ventilation equipment. Site grading, foundation work, connection of utilities and services, landscaping, and interconnection of the modular units are the only on-site activities required. Mechanical systems are meshed within voids in the structure and envelope assembly and are basically self-contained within each unit; even when plans call for the linking together of units to form a complex, mechanical and electrical systems for the individual units remain independent. For occupancies that require substantial interior partitioning, HVAC supply and return registers should be planned for high wall or ceiling locations.

INTERIOR

- Ceilings: Suspended acoustical tile ceiling (F)
- Walls: Drywall (K); window assembly (H)
- Floors: Resilient flooring (M)
- Lighting: Fluorescent light fixtures in ceiling (G) and natural light

Principal advantages and characteristics: An interesting aspect of these low-cost buildings is that except for baseboard-mounted electric heat panels, there are no exposed structural or mechanical elements. The result is maximum interior flexibility.

Ordinarily floor plans are based on the relatively narrow dimension of the module and require great care in planning for interior layouts, although it is possible to obtain large clear-spanned floor areas. Claddings, exterior and interior wall finishes, door and window types, floor finishes, and envelope thermal insulation levels can be specified to order.

LIGHTWEIGHT MOBILE MODULAR SYSTEM SUMMARY

Lightweight mobile modular buildings consist of factory fabricated wooden structures. Although both smaller and larger dimensions are available, the most common size is 12 ft x 60 ft. Speeds of construction and low initial cost are the main advantages of mobile modules. On-site labor requirements are minimal. Where weather, labor, or site problems affect other options, or for emergency or temporary use, mobile modulars are often the appropriate solution. Mobile modular use has increased significantly in areas of rapid growth and development, especially in areas with large influxes of temporary population. Modules can be easily moved, even when assembled as a complex.

Modular units can almost always be combined. Door openings should not be placed at the mating lines between modules; such placement requires field installation of the doors and may result later in binding of the door due to differential movements between the mated modules. When planning the complex, the manufacturer should be apprised of the location of utilities and services on the site; any local building code requirements that differ from major codes; and handicapped access needs. Distance of the site from the manufacturing plant is a major cost factor, and any complications in shipping should be investigated.

Based on Richard D. Rush, AIA, *The Building Systems Integration Handbook* (John Wiley & Sons, 1986).

STRUCTURAL

- Frame: Metal space frame (B)
- Roof: Metal deck (B)
- Floor: Slab on grade and concrete foundation (I)

Principal advantages and characteristics: Space frames serve as both structural and interior systems, while providing a structure for envelope connections and space for meshing of mechanical distribution elements. A metal deck and built-up roof cover the space frame shown. Space frames may appear in horizontal, vertical, domed, vaulted, stepped, sloped, or tower configurations. In this example, the edges of the space frame are glazed to permit perimeter clerestory lighting of interior areas. Tubular high-strength extruded aluminum struts are joined by means of solid aluminum hubs, also designed to accommodate the hardware for fastening of clerestory glazing. The frame can also be cantilevered beyond the continuous perimeter masonry wall, which allows for effective plate structural action.

Space frames are increasingly common as atrium covers and have also been used as structures for entire building envelopes. In perimeter-supported applications, truss depth-to-span ratios of up to 1/30 are practical. Besides, their light weight and economy of materials, space frames have the quality control advantages of factory production.

Recent developments in strut and hub technology make space frames highly durable and well engineered. The lightweight frame components are easily shipped, quickly assembled on site, and then lifted into place. Sometimes the frames are factory assembled and shipped whole or in subsections to the site. Careful coordination and assembly instructions are important to keep pieces in sequence for field assembly. Field bolting is almost always preferred to field welding of frame components, because welding space frames is expensive, and quality control can pose problems.

Where a continuous perimeter wall will not support the space frame, the design of supporting points is crucial. Certain spanning and rigidity advantages are gained by the design of supports that extend the pattern of the space frame above or below the plane of the main truss.

ENVELOPE

- Roof: Built-up roofing and rigid insulation (A)
- Walls: Brick veneer and rigid insulation (G)
- Floor: Vapor barrier (J)

Principal advantages and characteristics: Structure and envelope are connected in this example, with the exposed nature of the space frame requiring a high degree of visible integration between the frame's structural components and parts of the mechanical system. The space frame permits very long column-free spans with minimal amounts of structural material. The visual properties can be destroyed if the frame is coated for fire protection and in many cases coating can be forgone if the frame is placed 20 ft or more above floor level.

MECHANICAL

- HVAC: Ducts suspended from hubs of the frame (C)
- Electrical: Electrical conduits (C)
- Fire safety: Sprinkler piping (C)

Principal advantages and characteristics: Because the space frame is a highly regular structure and is exposed to view in most applications, the coordination of service systems with patterns in the frame is essential for visible integration. Piping can be suspended from the hubs of the frame, but should correspond to the patterns of the frame. Utility runs generally follow the orthogonal grid, while the sprinkling apparatus and electrical conduits may be run diagonally. Fireproofing of space frames generally destroys their appearance, so sprinkling is usually a consideration unless the exposed frame is 20 ft or more above floor level.

INTERIOR

- Ceilings: Metal deck (B)
- Floors: Wood flooring (H)
- Walls: Glass block panel (E) and concrete masonry bearing wall (F)
- Lighting: Incandescent light fixtures (D)

Principal advantages and characteristics: The ceiling unifies interior and structural systems, and meshes them with unified mechanical and interior systems. The solid hubs in the

SPACE FRAME

frame serve to join the struts and can also accommodate mountings for the envelope system and various types of interior equipment.

SYSTEM SUMMARY

The triangulated space frame network is one of the strongest and most efficient structural configurations, permitting long column-free spans with lightweight, highly repetitive elements. Slender structural members make space frames advantageous in cases where high light permeability is sought, yet significant live structural loading may occur.

Typical applications include spans above entries, sports arenas, and convention centers.

The selection of a space frame module is governed by the integration of cladding systems, the spanning characteristics of decking, and the mullion spacing for glazings. A space frame may be enclosed with metal decking, glass, acrylic, membrane, or insulated paneling. Space frames must usually be engineered and fabricated by a specialty engineer and/or fabricator, although strut sections and hubs generally do not need to be specially designed for each application.

Based on Richard D. Rush, AIA, *The Building Systems Integration Handbook* (John Wiley & Sons, 1986).

STRUCTURAL

Frame: Rigid steel frame (C)

Roof: Standing seam metal roof (B); batt insulation (D)

Floors: Slab on grade and concrete foundation (L)

Principal advantages and characteristics: Pre-engineered primary frames and claddings are dominant in warehouse, agricultural, and light industrial buildings, and are increasingly used for office and retail facilities. Their use is generally confined to one-story construction, but there is growing experience with multistory buildings.

Metal frame and skin building systems take advantage of factory assembly techniques and quality control. The structural integration of frame components with the building skin, for strength and rigidity, permits major economies in the size and number of steel framing components. Primary and secondary framing members, fasteners, and panels interact to produce a light, stable building shell. All framing and cladding components are designed, engineered, and fabricated in a plant, then shipped to the site for erection. The same company often designs, engineers, and builds the system. Metal structural components are generally sized and deployed according to exact requirements of an application, permitting economies in materials and speed of construction.

ENVELOPE

Roof: Standing seam metal roof (B)

Walls: Window assembly (H); insulated metal wall panels (I)

Floor: Dampproofing (M) and vapor barrier (N)

Principal advantages and characteristics: The pre-engineered metal building integrates lightweight structural and envelope components, each of which adds strength and rigidity to the overall form. The floor slab, often left uncovered in warehouse and industrial applications, unifies the envelope, structure, and interior systems, and is normally the only major site preparation required for erecting the building. The light weight of the envelope system, which is valuable for shipping, is especially vulnerable to wind uplift and requires great care in design and layout of fastenings. For applications in which privacy or sound isolation is an issue, the thin sheet steel presents an acoustical problem.

The standing seam metal roof system requires less maintenance than other alternatives, and its long-term performance record is excellent. Most standing seam metal roofs provide a free-floating monolithic membrane, connected by a series of slotted clips that allow movement. This method freely accommodates expansion/contraction cycles caused by thermal changes. In addition, a variety of details, colors, and finishes is available.

MECHANICAL

HVAC: Ducts and diffusers (E); heat pump (J); ridge vent (A)

Plumbing: Stacks in roofing panels and seams

Principal advantages and characteristics: Although the structural and envelope systems of metal buildings are usually highly integrated, manufacturers rarely consider the mechanical and interior systems in any detail. When insulating metal sandwich panels are used for interior and exterior finishes, special care is required in detailing the power and signal wiring, and in providing for its protection once in place. The mechanical plant shown in this drawing is located on the ground adjacent to the building, but it could just as easily be roof mounted.

The standing seam metal roof presents several items of concern to architects: the modularity of roof panels and seams, important for locating plumbing stacks, skylights, and other roof apertures; proper expansion details at intersections with flashing, especially upper-roof ridge; and the critical importance of crickets, parapet caps, and other details to avoid buildup of standing water.

INTERIOR

Ceilings: Suspended acoustical tile ceiling (G)

Floors: Carpet (K)

Walls: Insulated metal wall panels (I)

Lighting: Fluorescent light fixtures (F) and natural light

Principal advantages and characteristics: This construction approach is particularly advantageous for applications requiring large interior clear-spans, the support of heavy overhead cranes, or substantial expanses of roof. More

**METAL BUILDING SYSTEMS**

often associated with "standard" buildings components and even "standard" buildings, the metal buildings systems industry is able to respond to highly specialized needs, while still employing standardized structural components and factory fabrication.

SYSTEM SUMMARY

A variety of exterior cladding alternatives is available, ranging from lightweight corrugated metal skins to fully insulated sandwich panels that provide both interior and exterior finishes. Manufacturers also offer door, window, and skylight components that work as integral elements of the envelope and interior systems. Centralization of responsibility for engineering, fabrication, and construction permits close cost control and early assessment of building costs. Architects working with pre-engineered building systems can rely on technical support from the manufacturer,

including the preparation of fabrication and subsystem engineering documents.

The pre-engineered, cold-formed steel componentry is very flexible and can be used for a wide variety of building shapes and sizes. Such buildings can be rapidly dismantled and moved. The rectilinear nature of such systems usually results in buildings that are easily expanded in the longer dimension. Mechanical and interior systems are meshed in the ceilings, but the mechanical plant (here shown on the ground adjacent to the building, but just as easily roof mounted) is normally kept on the exterior, sometimes presenting difficulty with visible integration.

Metal systems are very lightweight. In areas subject to high winds, special care should be taken for wind bracing the structural frame and for fastening and design of exterior cladding details. Building corners and edges are particularly subject to wind-induced uplifting and suction.

1

BUILDING SYSTEMS

STRUCTURAL

Frame: Steel cables in fabric sleeves (A); steel masts (C)

Floors: Slab on grade (E)

Principal advantages and characteristics: Structural, envelope, and interior systems are unified in tension-fabric structures. A fabric membrane, usually configured to follow an optimal structural shape, is anchored by steel cables attached to the fabric and is suspended from steel or aluminum masts to form a roof or total enclosure.

Fabrics for temporary use are typically composed of a polyester substrate with a polyvinyl-chloride-coated outer layer. A more expensive but longer-lasting fabric is either Teflon-coated or silicone-coated fiberglass. Cables are clamped to the fabric, which is cut and sewn according to patterns for the structural shape employed.

The rules of structural geometry that govern the design of tension structures impart a unique and particular form, which does not easily permit deviations. Working with an engineer, the architect often begins the design process with model studies and a computer analysis to verify load expectations and to guide pattern-making for the fabric.

ENVELOPE

Walls and roof: Noncombustible fabric membrane (B)

Floor: Vapor barrier (G)

Principal advantages and characteristics: In general the skin and cables of these structures are in tension, while columns and arches are subject to compression. Under dynamic loading conditions, an efficient tensile structure will adjust and allow slight deformation.

Unique aerodynamic properties assist open tension structures in overcoming the difficulties of wind-driven rain; wind conditions subject most of the fabric to negative pressure, "lifting" rain away from the skin. The use of vegetation or architectural barriers at ground-level openings also reduces wind and rain effects under the canopy.

MECHANICAL

Electrical: Lighting fixtures, receptacles, and sound system mounted on columns and masts (D)

Fire safety: Noncombustible or fire-retardant fabric membrane (B)

Principal advantages and characteristics: Because the fabric transmits light while blocking direct rays of the sun, it also assumes some functions normal to mechanical systems. Electrical lighting and other equipment are difficult to integrate because of the thinness of the structural envelope membrane, and are nearly always attached to the structural masts or placed on independent, freestanding structures.

Acoustical, thermal, and fire-safety considerations are difficult to accommodate in tension structures, although their light weight and dynamic properties under wind loading make them very safe from a structural point of view. If areas of fabric are placed close to the ground or in other easily accessible locations, vandalism becomes a concern, as most materials suitable for tensile structures are easily cut. Fabric-covered structures for the performing arts are generally equipped with electrical systems designed for safety in wet conditions. Sealing of the holes at the peaks of tensile structures where masts protrude is not usually necessary.

Several of the major building codes now contain provisions governing tensile structures, but it is advisable to consult local code officials early in the design process. The treatment of electrical wiring within or affixed to rigid columns and masts, which must be designed to permit some movement, may be a concern. Some fabrics are classified as noncombustible, and some are only fire retardant, so it is important to determine early on which fabrics are acceptable in a specific situation.

INTERIOR

Ceilings and walls: Noncombustible fabric membrane (B)

Floors: Pivoted mast base and concrete footing (F)

Lighting: Incandescent light fixtures (D)

Principal advantages and characteristics: Color is an integral element of fabrics and will have an effect on the quality of natural illumination beneath the canopy. Because the fabric provides both interior and exterior finished surfaces for the envelope, the columns and masts are typically the only

TENSION FABRIC

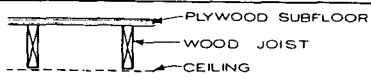

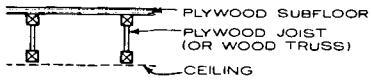

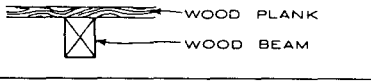

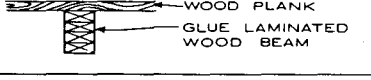

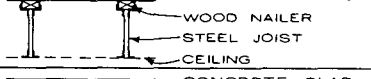

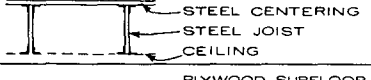

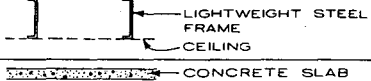

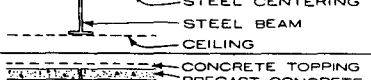

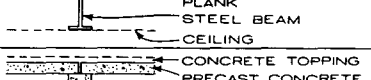

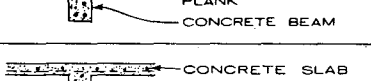

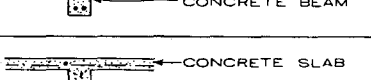

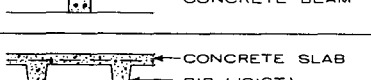

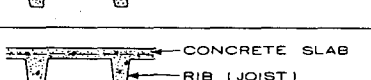

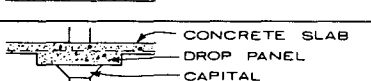

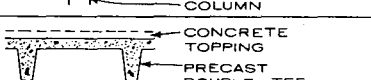

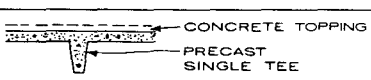

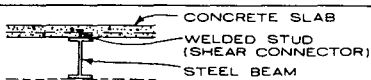

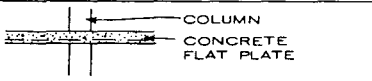

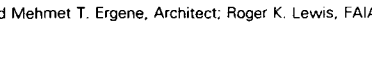

structural members used for mounting such items as lighting fixtures and power receptacles. Gantries hung from columns or masts provide additional service areas.

SYSTEM SUMMARY

Several features give tension structures an advantage over low-cost wood, metal, and concrete shelters. Fabrics can range in service life from a few years to several decades. If a lifetime of around 15 years is acceptable for the facility, a PVC-coated tension structure will suffice at a low initial cost. The usual solution for greater permanence is Teflon coated fiberglass. Clear spans of up to 100 ft are easily obtained with lightweight fabric structures.

Designers can consult with specialists on engineering and shop drawings. Design/build firms will produce complete shop drawings and often fabricate all components or erect the structure on the site. Careful detailing of steel and cable elements, joints, and attachments is critical to overall appearance, as most will be exposed to view. Steel and wire rope manufacturers can assist with detailing.

NOTES

1. Increase when occupancy exceeds this amount.
2. Use weight of actual equipment when greater.
3. American Association of State Highway Officials.
4. Paper storage 50 lb/ft of clear story height.
5. Verify with design criteria.
6. Additional loads—120 lb/linear ft vertical, 24 lb/ft parallel lateral, and 10 lb/ft perpendicular to seat and footboards.

LIVE LOAD

Live load is the weight superimposed by the use and occupancy of the building or other structure, not including the wind, snow, earthquake, or dead load.

The live loads to be assumed in the design of buildings and other structures shall be the greatest loads that probably will be produced by the intended use or occupancy, but in no case less than the minimum uniformly distributed unit load.

THRUSTS AND HANDRAILS

Stairway and balcony railing, both exterior and interior, shall be designed to resist a vertical and a horizontal thrust of 50 lb/linear ft applied at the top of the railing. For one- and two-family dwellings, a thrust of 20 lb/linear ft may be used instead of 50.

CONCENTRATED LOADS

Floors shall be designed to support safely the uniformly distributed live load or the concentrated load in pounds given, whichever produces the greater stresses. Unless otherwise specified, the indicated concentration shall be assumed to occupy an area of 2 1/2 sq ft (6.26 ft²) and shall be located so as to produce the maximum stress conditions in the structural members.

PARTIAL LOADING

The full intensity of the appropriately reduced live loads applied only to a portion of the length of a structure or member shall be considered if it produces a more unfavorable effect than the same intensity applied over the full length of the structure or member.

IMPACT LOADS

The live loads shall be assumed to include adequate allowance for ordinary impact conditions. Provision shall be made in structural design for uses and loads that involve unusual vibration and impact forces.

1. ELEVATORS: All elevator loads shall be increased 100% for impact, and the structural supports shall be designed within limits of deflection prescribed by American National Standard Safety Code for elevators and escalators, A17.1 - 1981, and American National Standard Practice for the Inspection of Elevators, Escalators, and Moving Walks (Inspector's Manual) A17.2 - 1979.
2. MACHINERY: For the purpose of design, the weight of machinery and moving loads shall be increased as follows to allow for impact:
 - a. Elevator machinery, 100%.
 - b. Light machinery, shaft or motor driven, 20%.
 - c. Reciprocating machinery or power driven units, 50%.
 - d. Hangers for floors or balconies, 33%.
 All percentages to be increased if so recommended by the manufacturer.
3. CRANEWAYS: All cranes, except those using only manually powered cranes, shall have their design loads increased for impact as follows:
 - a. A vertical force equal to 25% of the maximum wheel load.
 - b. A lateral force equal to 20% of the weight of trolley and lifted load only, applied one - half at the top of each rail.
 - c. A longitudinal force of 10% of the maximum wheel loads of the crane applied at top of rail.
4. PARKING GARAGE GUARDRAILS: Guardrails and walls acting as impact rails in parking structures shall be designed for a minimum horizontal ultimate load of 10,000 lb applied 18 in. above the floor at any point of the guardrail.

MINIMUM ROOF LOADS

1. FLAT, PITCHED, OR CURVED ROOFS: Ordinary roofs - flat, pitched, or curved - shall be designed for the live loads or the snow load, whichever produces the greater stress.
2. PONDING: For roofs, care shall be taken to provide drainage or the load shall be increased to represent all likely accumulations of water. Deflection of roof members will permit ponding of water accompanied by increased deflection and additional ponding.
3. SPECIAL PURPOSE ROOFS: When used for promenade purposes, roofs shall be designed for a maximum live load of 60 psf; 100 psf when designed for roof garden or assembly uses. Roofs used for other special purposes shall be designed for appropriate loads, as directed or approved by the building official.

LIVE LOAD REDUCTION

In general, design live loads should not be in excess of 100 psf on any member, supporting an area of 150 sq ft or more, except for places of public assembly, repair garages, parking structures, and roofs. The reduction shall not exceed the value of R from the following formulas:

$$R = .08(A-150)$$

$$R = 23(1+D/L)$$

where R = reduction (%)
 D = dead load per square foot of area supported by the member
 L = live load per square foot of area supported by the member
 A = area supported by the member

In no case should the reduction exceed 60% for vertical members, nor 40 to 60% for horizontal members.

For live loads in excess of 100 psf, some codes allow a live load reduction of 20% for columns only.

CODES AND STANDARDS

The applicable building code should be referred to for specific uniformly distributed live loads, movable partition load, special and concentrated load requirements.

In addition to specific code requirements, the designer must consider the effects of special loading conditions, such as moving loads, construction loads, roof top planting loads, and concentrated loads from supported or hanging equipment (radiology, computer, heavy filing, or mechanical equipment)

The live loads given in this table are obtained by reference to ASCE, UBC, BOCA, and SBCCI.

Charles W. Vanderlinden, PE; Hansen Lind Meyer, Inc.; Orlando, Florida

GENERAL

When selecting a long span roof system, it is appropriate to consider life safety of equal concern to cost. Egress must be carefully evaluated by simulating the most adverse conditions rather than simply complying with building codes. Fire safety begins by limiting the fire load, as codes rarely require fire protection or sprinkler systems. Auxiliary uses having any fire risk (e.g., food handling) should be carefully fire separated from the rest of the structure.

DESIGN CONSIDERATION FACTORS

Examples of long span structures shown in the table are rated for their ability to address the following design factor conditions.

NATURAL CONDITIONS

- a. Uneven or excessive snow and ice loads: Geometry, equipment, or exterior structure may contribute to snow drifting or ice buildup.
- b. Ponding: Provide positive drainage to remove water from the structure when roof drains clog.
- c. Wind: Evaluate potential of wind induced destructive vibration in members or connections.
- d. Thermal: Diurnal and seasonal temperature cycles can cause significant changes in structural shape and member stresses and may lead to fatigue failure.
- e. Freeze/thaw cycles or corrosive atmosphere: Evaluate long-term effects on structural performance, particularly for exposed concrete structures.

PRIMARY STRESSES

- f. Two or more load paths for all loads should be provided wherever possible. The greater the area a single member supports, the greater should be its safety factor.
- g. Compression failure: Resistance to lateral buckling of long members is crucial. Use members that assure initial and verifiable alignment.
- h. Tension failure: Dynamic stability under wind or other vibration loading should be carefully verified.

SECONDARY STRESSES

- i. Deflection: Changes in orientation of members at joints from loads can increase stresses destructively.
- j. Member interaction: Load flows through structures in such a way as to minimize strength. Check all possible load paths of complex geometric structures.
- k. Nonstructural connections: Assemblies attached to a structure will influence structural load flow and even become part of the load flow if the attachment changes the deflected shape.
- l. Scale: Most systems have a span beyond which self weight becomes a severe limit.
- m. Stress concentration: Check stresses at changes of cross sections, holes, and connections. High-strength materials are particularly sensitive.

TOLERANCES

- n. Erection alignment: True member length and spatial position are crucial for proper alignment and load flow.
- o. Creep: Length changes over time will influence both primary and secondary stresses.
- p. Supports and foundations: Supports must accept movements due to deflections from primary and secondary stresses and differential foundation settlement.

QUALITY CONTROL

- q. Engineering design must not be compromised by time, scheduling, design changes, or building codes. Computerized design must be carefully verified to resolve all primary and secondary stresses.
- r. Construction methods should be selected carefully to safely locate the structural components accurately in space.
- s. Site observation: Only when the structure is properly established in space should it be accepted. Changes in construction should be carefully checked.
- t. Structural building maintenance: Conditions and alignment of various members, especially crucial nonredundant members, should be verified on a regular schedule. Consider using equipment to detect excessive deflection.
- u. Nonstructural building maintenance: Condition of building components should not adversely affect the structure (e.g., keep roof drains open, prevent excessive equipment vibration, and maintain expansion joints).

NOTES

1. Steel is A-36; wood is laminated, sometimes heavy timber; concrete is reinforced with steel; prestressed concrete is prestressed with steel.
2. Cable-stayed system can give auxiliary support to trusses, beams, or frames, greatly reducing span and member sizes, but providing additional tensional strength.
3. Lamella arches provide two-way arch structures and improve redundancy.
4. Domes may also be constructed of aluminum.
5. Pneumatics are fabric roofs, pressurized, and stabilized with steel cables.
6. For each system the following notation applies:
 - is the typical configuration
 - is occasionally used

CONCRETE TOPPED STEEL DECK

STEEL-ENCASED CONCRETE

WOOD AND PLYWOOD COMPOSITE JOISTS

HYBRID STEEL GIRDERS USING STEELS OF DIFFERING STRENGTH

FLITCH BEAMS

Composite construction combines different materials, or different grades of a material, to form a structural member that utilizes the most desirable properties of each. Perhaps the earliest composite structural unit was the mud brick

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

STEEL BEAM WITH STUD IN CONCRETE SLAB

CONCRETE ENCASED STEEL COLUMNS

WOOD AND STEEL TRUSSES

REINFORCED CONCRETE SLAB AND PRECAST JOIST

reinforced with straw. More recently fiberglass-reinforced plastics, wire-reinforced safety glass, and glued laminated plywood and wood beams have been used.

WOOD AND STEEL JOISTS

CASTELLATED BEAMS

NOTES
Individual elements of the composite unit must be securely fastened to prevent slippage, especially at points where load is transferred from one element of the composite member to another.

TYPES OF COMPOSITE ELEMENTS

1. Concrete topped composite steel decks.
2. Steel beams acting compositely with concrete slabs.
3. Steel columns encased by or filled with concrete.
4. Open web joists of wood and steel or joists with plywood webs and wood chords.
5. Trusses combining wood and steel.
6. Hybrid girders utilizing steels of different strengths.
7. Cast-in-place concrete slab on precast concrete joists or beams.

COMPARATIVE DESIGN

A 30 ft beam with a 2.25 kip/ft uniform load carrying 2 1/2 in. concrete fill on a 2 in. metal deck slab uses a W24x55 in a noncomposite design and only a W18x40 with 38 steel studs of 3/4 in. diameter in a composite design.

GENERAL

According to the theory of plate tectonics, the earth's crust is divided into constantly moving plates. Earthquakes occur when, as a result of slowly accumulating pressure, the ground slips abruptly along a geological fault plane on or near a plate boundary. The resulting waves of vibration within the earth create ground motions at the surface, which, in turn, induce movement within buildings. The frequency, magnitude, and duration of the ground motion, physical characteristics of the building, and geology of a site determine how these forces affect a building.

DESIGN JUDGMENT

In an earthquake, buildings designed to the minimum levels required by model codes often sustain damage. Early discussions with an owner should explore the need to limit property loss in an earthquake and the desirability of attempting to ensure continued building operation immediately afterward. To achieve these results, it may be necessary to make design decisions more carefully tuned to the seismic conditions of a site than code requires.

MAIN CAUSES OF FOUNDATION FAILURE

NOTE
The relationship between the period of ground motion and the period of building motion is of great importance. Fundamental periods of motion in structures range from 0.1 second for a one-story building to 4.0 seconds or more for a high-rise building. Ground generally vibrates for a period of between 0.5 and 1.0 second. If the period of ground motion and the natural period of motion in a building coincide, the

building may resonate and the loads will be increased. Theoretically, one part of the seismic design problem is to "tune" the building so that its own period of motion falls outside the estimated range of ground motion frequency. In practice, this tuning is very seldom carried out. Rather, architects rely on increased load effects required by the applicable code to take care of the problem.

FUNDAMENTAL PERIODS

SEISMIC ACCELERATION FOR LOW BUILDINGS EXPRESSED AS A PERCENTAGE OF GRAVITY

William W. Stewart, FAIA; Stewart-Schaberg Architects; Clayton, Missouri
Map courtesy of the U.S. Geological Survey, National Seismic Hazard Mapping Project (June 1996)

SEISMIC CODES

The seismic requirements in the Uniform Building Code have historically been based on Recommended Lateral Force Requirements, generally referred to as "The Blue Book," an earthquake design manual developed by the Structural Engineers Association of California. The seismic requirements in the National Building Code and the Standard Building Code are based on FEMA 222, the National Earthquake Hazards Reduction Program Recommended Provisions for Seismic Regulations for New Buildings. Since the Blue Book and the NEHRP provisions incorporate the expertise of many of the same engineers, and since the anticipated International Building Code will encourage convergence of the requirements, the seismic code development community intends to make the two codes similar.

The following information is based on the requirements expected to appear in the 1997 NEHRP provisions and in subsequent issues of all model codes. Detached one- and two-family dwellings will be exempt from seismic regulations in areas other than those with high seismicity. Seismic codes are constantly evolving, and architects should always consult the relevant code before beginning a project.

A recent, significant change in the seismic codes is the elimination of seismic zones as a basis for establishing design acceleration. Seismic maps have been redrawn (completely for the first time since 1976) to show building response periods as a percentage of gravity.

The map below, based on a building response period of 0.2 second, gives accelerations to be used for low buildings. A similar map based on a building response of 1.0 second is proposed for taller buildings. Before determining what level of ground shaking applies to a project, an architect must find out what type of earth the building will be built on. The maps are based on buildings built on soft rock, but ground motion increases as the soil becomes softer.

TERMS

The seismic community has an extensive set of terms with which to describe common conditions in the field. Following is a short list of these terms and their definitions:

BASE SHEAR (static analysis): calculated total shear force acting at the base of a structure, used in codes as a static representation of lateral earthquake forces; also referred to as "equivalent lateral force."

BASE SHEAR AND DRIFT

DESIGN EARTHQUAKE: earthquake ground motion for which a building is designed.

DRIFT: lateral deflection of a building or structure. Story drift is the relative movement between adjacent floors.

DUCTILITY: the ability of a structural frame to bend but not break. Its ductility is a major factor in establishing the ability of a building to withstand large earthquakes. Ductile materials (steel in particular) fail only after permanent deformation has taken place. Good ductility requires special detailing of the joints.

DYNAMIC ANALYSIS: a structural analysis based on the vibration motion of a building. Dynamic analysis is time-consuming and normally reserved for complex projects.

FORCES, IN-PLANE: forces exerted parallel to a wall or frame.

FORCES, OUT-OF PLANE: forces exerted perpendicular to a wall or frame.

FORCE DIAGRAMS

MAXIMUM CONSIDERED EARTHQUAKE: the greatest ground shaking expected to occur during an earthquake at a site. These values are somewhat higher than those of the design earthquake, particularly in areas where seismic events are very infrequent. The code maps are based on earthquakes of this magnitude.

RE-ENTRANT CORNER: The inside building corner of an L-, H-, X-, or T-shaped plan.

GENERAL

Each building and site lies within a broader context of regional seismicity, localized geology, community vulnerability, and adjacent structures and land uses. Siting decisions, therefore, can have a significant impact on the overall seismic performance of a structure. This page focuses on the following criteria for siting a building:

1. Avoid unstable sites.
2. Avoid nonengineered fill.
3. Avoid or design for sites that can subside or liquefy.
4. Avoid building over surface faulting.
5. Avoid adjacent hazardous buildings.
6. Prevent battering from adjacent buildings.
7. Create safe areas of refuge when redeveloping older buildings.

Decisions on appropriate land uses for a specific site, separation from active ground faulting, site stability, and separation from adjacent buildings are critical to performance. Although many of these factors have traditionally been considered city planning issues, the designer must also incorporate them into the architectural development of a seismically resistant building.

SEISMIC ZONATION TO REDUCE RISK

RELATIVE RISK OF SITE	LAND USE
Low	High-density commercial/retail
	High occupancy and assembly
	Essential services (fire stations, hospitals, emergency operations centers, etc.)
Medium	Hazardous industrial processes
	Medium- and low-density residential
	Low-rise commercial/retail
High	Industrial uses
	Very low-density residential
	Nonhazardous industrial
	Recreation
	Public open space
	Public rights-of-way

NOTE

Land uses should reflect the relative risk of the location.

SITE SECTION

NOTE

On sloping sites, earthquakes can trigger landslides. Also, alluvium and unconsolidated soils can increase the violence and duration of ground shaking. In areas of young soil deposits, design for greater ground shaking. For example, during the 1989 Loma Prieta earthquake, ground shaking in San Francisco's marina district, on nonengineered fill, was more than twice as violent and lasted more than twice as long as ground shaking on adjacent bedrock sites.

UNSTABLE SITES

SITE SECTION

SITE PLAN

NOTE

Within a fault zone, trench to determine the exact location of the fault trace. Development within a fault zone should be restricted to low-density land uses, open space, and other low-occupancy activities

SURFACE FAULTING

SATURATED SAND LAYER CAN LIQUEFY AND SPREAD LATERALLY AND CREATE SAND BOILS ON SURFACE

SITE SECTION (BEFORE LIQUEFACTION)

SITE SECTION (AFTER EARTHQUAKE AND LIQUEFACTION)

NOTE

Avoid sites subject to liquefaction (water saturated sandy soils), design foundation systems to withstand ground failure, drain water from the site, and change the composition of the soil and compact the site.

LOAD PATHS

A load path is the path seismic forces take from the roof to the foundation of a structure. Typically the load travels from the diaphragms through connections to the vertical lateral force-resisting elements and on to the foundation by way of additional connections. This path should be direct and uninterrupted. Seismic design begins with, and codes require, the establishment of a continuous load path.

PREFERRED

NOTE

The base should not be too much larger than the tower above.

The seismic-resistant framing system selected for a structure must meet both architectural and seismic design requirements. Although most buildings can be made seismic resistant, some architectural configurations interrupt the load path or otherwise interfere with the seismic design process. Inappropriate design choices increase construction cost and make the seismic restraint system less effective. The examples on this page contrast configurations that probably would cause problems in areas with high levels of seismicity with variations that should avoid these problems.

PREFERRED

NOTE

While it is best to have uniform stiffness, some variation is acceptable.

PREFERRED NOTE

DISCOURAGED

The lateral force resisting system for a symmetrical building is much easier to design than that for an asymmetrical building. Because the source of an earthquake cannot be known, symmetry in both directions should be considered.

TORSION IN PLAN

PREFERRED

DISCOURAGED

NOTE

This is a variation of the symmetry issue. When the notch gets too big, the building tends to tear at the inside corner.

VERTICAL GEOMETRY IRREGULARITY

PREFERRED

NOTE

Horizontal diaphragms (floors and roofs) can more readily transfer earthquake loads to the vertical force resisting

DISCOURAGED

system when the size and number of holes in the diaphragm are limited.

DIAPHRAGM DISCONTINUITIES

PREFERRED

DISCOURAGED

OUT-OF-PLANE VERTICAL OFFSETS

William W. Stewart, FAIA; Stewart-Schaberg Architects; Clayton, Missouri

RE-ENTRANT CORNERS

PREFERRED

DISCOURAGED

NOTE

While all floors do not have to be the same, it is important that no floor has too much more mass than those adjacent.

MASS IRREGULARITY

PREFERRED

DISCOURAGED

NOTE

When a taller (inherently weaker) first floor is desired, anticipate using much heavier first floor framing to equalize the stiffness with that of the floors above.

SOFT STORY

PREFERRED

DISCOURAGED

NOTE

Although both drawings illustrate shear walls in the same plane, one arrangement is discouraged because the load path is not direct enough.

IN-PLANE DISCONTINUITY

ESTABLISHING SEISMIC FORCES

The equivalent lateral force procedure is the most common method of establishing seismic design forces. In it, the seismic load, V (base shear), is determined by multiplying the weight of the building by a factor C_s ($V=C_sW$). The value of C_s depends on the size of the design earthquake, the type of soil, and the response modification factor (a variable corresponding to the type of lateral force resisting system used). This force is applied at the base of the structure then distributed throughout the building according to the mass and strength of the structure.

DESIGN FOR RESISTING SEISMIC FORCES

Shear walls are load-bearing or nonload-bearing walls that resist seismic forces acting in the plane of the wall. Shear wall design is simpler and more cost-effective than other lateral force resisting systems; however, the architectural design must be able to accommodate the locations of these walls and the small number of openings they permit.

Diaphragms are horizontal or nearly horizontal structural elements (usually a floor or roof) designed to transmit lateral forces to the vertical elements of a seismic resisting system. Diaphragms must be rigid enough and the connections strong enough to transfer the entire load to the lateral force resisting system.

Tall, narrow structures tend to tip over before they slide, while short structures slide rather than tip. Earthquake waves rock buildings, increasing overturning loads, and can act in any direction. Thus, resistance to overturning is best achieved at a building's perimeter rather than at its core.

Building foundations must be designed to resist the lateral forces transmitted through the earth and the forces transmitted from the lateral load resisting system to the earth. In general, softer soils amplify the effects of an earthquake.

BUILDING FRAMES

Braced frames depend on diagonal braces to resist lateral forces. Although cost-effective, most braces limit the number of openings possible in a wall. Eccentric bracing is a configuration that allows for more openings than are normally achievable. K-bracing used to be a common variation of X-bracing, but it was discovered that the forces at the intersection are very great, making the connection difficult.

A moment frame is one in which members and joints are able to resist lateral forces along the axis of the members as well as by bending. It is an alternative to solid shear walls that allows for openness and design flexibility.

SHEAR WALLS AND DIAPHRAGMS

OVERTURNING AND SLIDING

BRACED FRAMES

CONNECTIONS

WOOD CONNECTIONS

Connections are an important element of the lateral force resisting framing system. Wood connections come in a variety of types, many of which are not appropriate for seismic or wind loading conditions. End grain nailing performs poorly and should be avoided, and toe nailing as the sole means of attachment is inadequate. Positive connections using appropriate fasteners are necessary to establish a continuous load path. Shear walls must be fastened securely to the foundation. Diaphragms should be properly attached to the lateral force resisting system. Connector design and detailing should include proper use of connectors to achieve required load capacity and code compliance. Adequate size and placing of nails is necessary to minimize splitting and optimize the load carrying ability of the frame. (See AGS pages on wood seismic design and structural wood fasteners for details.)

BASE ISOLATION

ANCHORAGE

Anchors are either cast-in-place or drilled in after placement of the concrete. When anchors can be precisely located before the concrete is poured, cast-in-place anchors are typically used. Post-installed anchors are usually employed when anchor locations cannot be predetermined with accuracy. Spacing between anchors, the distance to the edge of the concrete, embedment depth, stiffness characteristic, and the type of loading (e.g., dead, live, dynamic, seismic) all must be considered. For structural elements that require seismic design, only anchors tested under dynamic loading should be used. The preferred anchor types for seismic performance include cast-in-place bolts and inserts. Acceptable post-installed anchors are undercut anchors, heavy duty sleeve (torque-controlled expansion) anchors, and chemical anchors. J-bolts and L-bolts cannot be counted to resist much uplift.

ANCHORAGE

BASE ISOLATION

Base isolation is a major seismic design innovation. Analogous to the suspension of an automobile, isolators separate the building from ground motion. Base isolation is most cost-effective for buildings in areas of high seismicity, buildings that must have an irregular shape, large historic buildings, and buildings that must remain in operation immediately after an earthquake.

When using base isolation, it is important to ensure that the isolators are the only place where the building touches the surrounding earth. This is normally accomplished by positioning the building in a large scooped out area and connecting it to the surrounding ground with flexible "bridges." The base isolators are usually located in a sub-basement dedicated to their use.

A recent variation of base isolation is offered by a family of devices that absorb or dissipate energy and change the response of a structure to seismic activity. These systems appear most useful for improving existing structures without the need for an entirely new structural system.

GENERAL

When detailing architectural and mechanical elements for seismic resistance, the architect's primary concerns are to minimize falling hazards and to maintain a normal egress route. Features such as masonry chimneys, parapets, light fixtures, suspended mechanical equipment, large ductwork, and heavy pipes are potential falling hazards. Cabinets and bookcases can block exits if they fall. An additional concern for architects designing for earthquake-prone areas is the need for a building to remain in operation after an earthquake.

Many resources that offer detailed solutions for seismic design only address areas with high seismic activity. However, no single detail is appropriate for all areas. This page is meant to guide architects through the philosophy of seismic design. Readers should use the references listed to develop the right solution for a particular site.

To determine seismic forces on architectural components, an importance factor (I) is introduced into the force equation. I is either 1.0 or 1.5. If the component is essential or might create a hazardous condition when falling or breaking, there is a 50% increase in the design load. The lateral force = 1.6 S_{AS} IW. W is the weight of the part. S_{AS} is the spectral acceleration. In reality the force decreases as the location (height) of the component within the building is lowered. A more complicated formula is available if it is necessary to reduce the loads.

SEISMIC DESIGN CATEGORY FOR STRUCTURES

VALUE OF S _{AS}	SEISMIC USE GROUP		
	I	II	III
S _{AS} ≤ 0.167 g	A	A	A
0.167 g ≤ S _{AS} < 0.33 g	B	B	C
0.33 g ≤ S _{AS} < 0.50 g	C	C	D
0.50 g ≤ S _{AS} < 1.0 g	D	D	D
1.0 g ≤ S _{AS}	E	E	F

NOTES

1. g—weight of object being analyzed; S_{AS}—spectral response acceleration
2. Seismic use group classification is assigned to each building depending on the importance of maintaining function or protecting occupant safety. Buildings in seismic use group III are those that are required to function for post earthquake recovery. Seismic use group II buildings are buildings with relatively large occupant loads. Any remaining buildings fall into group I. The level of seismic detailing is expressed by letters A through F and is based on the relationship between the seismic use group and the level of design ground motion. This level of detailing is known as the seismic design category.

NOTE

This detail must be checked for acceptability when the partition is fire-rated. Partitions that extend to the structure above usually perform well if consideration has been given to potential building racking (i.e., being forced out of plumb).

PARTITION DETAIL FOR SEISMIC AREAS

NOTE

Provide 4-way diagonal bracing and compression struts approximately every 12 ft each way.

WALL ATTACHMENT DETAIL NOTE

For ceiling grids, pull-out capacity at the joints is a key to good seismic performance. Vertical (compression) struts prevent failure from wave-like or galloping motion. Solutions for all levels of seismic activity are addressed in the Ceilings and Interior Systems Construction Association standards.

CEILING DETAILS FOR SEISMIC AREAS

LIGHT FIXTURES

There are two ways to handle light fixtures that could shake free from the ceiling grid and create a falling hazard. One is to suspend the light fixture from the structure above with two to four wires (if two wires, they should be in opposite corners). The second method (not used in areas with high seismicity) is to brace the ceiling and clip the light fixtures to the grid. Pendant-mounted fixtures should be designed so they cannot swing and hit other building components.

EXTERIOR CLADDING

Exterior cladding must be secured to the building to prevent it from falling. Heavier veneers require more anchorage. When cladding is anchored to the structural frame, consideration must be given to how movement of the frame will affect movement in the cladding. A major concern is the difference in movement between floors and/or floor and roof (story drift), which is addressed with connections that permit the cladding to move independently of the structural frame. Commonly used are push-pull connections, caulked joints, slip joints, and covers that collapse.

SPRINKLER SYSTEMS

To brace sprinkler systems, architects must address three main problems: the falling hazard of heavy mains, separation of the mains at the joints (property loss is critical here), and breaking of the pipes where the heads pass through the ceiling. The latter problem is solved by enlarging the hole (with up to 1 in. clearance) and covering it with a large escutcheon plate. An alternative is to detail a swing joint in the sprinkler drop that will provide 1 in. movement in all directions. Another solution is to detail the grid and sprinkler drops as one integral unit. (See NFPA 13 for information on sprinkler bracing.)

WATER HEATERS

When a water heater overturns, a gas line can rupture. Depending on the level of seismicity, the common solution for residential water heaters is to use a flexible gas connection and/or a simple steel strap wrapped around the tank and securely anchored to a stud or solid wall.

LIGHTING FIXTURE DETAIL FOR SEISMIC AREAS

NOTE

Fill space between water heater and wall with 2x blocking with cushioned face.

WATER HEATER SEISMIC REINFORCING

SHELVING AND CABINETS

Shelves and racks can overturn during seismic activity, injuring building occupants or blocking exits. The hazard increases with the occupancy density and the height of the equipment. Fixtures should be bolted onto heavy-gauge studs above their center of gravity.

ELEVATORS

Traction elevators cause the most concern in regard to seismic activity. The main problem is that the counterweights may come loose and strike the cab. Current elevator standards address this problem, but older elevators may need to be upgraded.

HVAC, ELECTRICAL, AND PLUMBING COMPONENTS

HVAC equipment is often heavy, with large inertial forces; securely attaching such equipment greatly reduces damage. Piping systems generally perform well during seismic activity but are vulnerable at equipment connections.

Heavy electrical equipment such as switchgear, transformers, and batteries are the parts of the electrical system most vulnerable to seismic activity. Emergency systems depend on electrical power for fuel or control and so may fail even though the equipment remains functional.

Plumbing distribution systems are relatively flexible and can withstand a fair amount of shaking. Piping and equipment should be anchored so it will move with the structure, limiting differential movement at the joints.

GENERAL

The greatest hazard in major earthquakes stems from older buildings that were designed under early seismic codes or before such codes were introduced. Seismic rehabilitation (or seismic retrofit) refers to design and construction intended to improve the seismic performance of an existing building.

Some cities have established seismic rehabilitation programs to reduce the risk caused by unreinforced masonry (URM) buildings, which are particularly hazardous in earthquakes. The City of Los Angeles, for example, passed an URM ordinance in 1981 that required all of the 8000 URM buildings in the city to be strengthened or demolished. San Francisco has a similar ordinance. Many buildings also have been voluntarily rehabilitated.

REHABILITATION PROCESS

The first steps in rehabilitation are to identify the seismic deficiencies and determine a method of rehabilitation. Other steps involve budgeting, preparing contract documents, and selecting a contractor.

EVALUATION PROCEDURES

Two procedures exist for evaluating buildings for seismic rehabilitation. The first, called rapid visual screening (RVS), is used to assess the rehabilitation needs of a number of buildings: a whole city, a few city blocks, a college campus, etc. RVS involves surveying the exterior of a building and recording its major features in a way that allows it to be rated for possible seismic risk. The evaluation takes about 30 minutes per building. The intent is not to provide a definitive seismic rating but rather to indicate which buildings should undergo a more detailed evaluation. This procedure is described in Federal Emergency Management Agency (FEMA) Publication 154.

The second, more detailed seismic evaluation process is described in FEMA Publication 178. The evaluation begins with collecting information about a structure and classifying it according to one of fifteen model building types. This qualitative investigation determines whether the building exhibits any of the defined life-threatening performance characteristics that similar structures have demonstrated in previous earthquakes. If such characteristics are identified, a detailed evaluation is recommended and permissible capacity/demand ratios are suggested. Although the detailed procedure generally takes several days to complete, it provides an evaluation of the building's threat to life and a list of the particular structural and nonstructural features that must be addressed.

Another aspect of the evaluation is establishing the benefit-cost ratio for seismic rehabilitation. FEMA Publication 227 describes such a procedure and provides computer software to perform the evaluation.

HAZARDOUS BUILDING TYPES

Any building may be hazardous in an earthquake if it is not designed according to seismic codes and, perhaps more significant, the designer does not understand or have experience with seismic design. Many old buildings, designed before seismic codes existed, are well designed seismically and have stood the test of time. Other, newer buildings are unsafe because they were designed according to an obsolete code and without an understanding of seismic design issues.

A number of typical building types have been identified as hazardous because of their generally poor performance in earthquakes:

1. URMs: bearing wall buildings with unreinforced masonry walls, usually brick.
2. Nonductile concrete frame: typical of buildings constructed in the United States before about 1975, when new codes came into effect that recognized the problems caused by underreinforced concrete frame structures subject to brittle failure. (Ductility refers to the ability of structures, usually steel structures, to deform greatly under load without collapsing.)
3. Concrete or steel frame with unreinforced masonry walls (often hollow tile): popular for buildings constructed from the early 20th century until World War II.
4. Precast concrete tilt-up construction: common industrial building type that relies on the exterior concrete walls to act as shear walls against earthquake forces. Unless correctly detailed, the roofs are likely to pull away from the walls and collapse during earthquakes.

REHABILITATION STRATEGIES

Although the unique characteristics of each building must be considered when devising a rehabilitation strategy, some fundamental concepts have been developed from experience:

1. Add strength.
2. Alter building stiffness.
3. Create structural continuity.
4. Add structural containment.
5. Rationalize existing capacity.
6. Isolate the building from the ground.
7. Add energy-dissipating details.

In addition to purely structural issues, architectural concerns influence rehabilitation design. For historic buildings, rehabilitation measures must be devised that respect the original architecture, and the addition of external strengthening components is not an option. For other buildings this may not be a concern, and affordable cost, safety, and preservation of building function may be the paramount objectives.

FEMA publication 172 provides conceptual design guidance on methods of rehabilitating all 15 model building types described in FEMA 178.

CODES AND REGULATIONS

At present a general code for seismic rehabilitation of buildings does not exist. For URM buildings, the City of Los Angeles Section 88 Code may be appropriate; for certain types of historic URM buildings, the Uniform Code of Building Conservation may be used. Following the Northridge earthquake, Los Angeles developed criteria for rehabilitating tilt-up buildings and nonductile reinforced concrete frame buildings.

The Building Seismic Safety Council/National Earthquake Hazard Reduction Program is developing the first comprehensive criteria (available about 1998) for the rehabilitation of all building types in any geographic region.

1

SEISMIC DESIGN

GENERAL

Empirical rules and formulas for the design of masonry structures resulted from the long history of masonry use and thus predate engineering and analysis. Empirical design is a method of sizing and proportioning masonry elements that depends on centering gravity loads over bearing walls, neglecting the effect of steel reinforcing.

For most masonry work, empirical design is conservative. It is generally appropriate for smaller buildings with interior masonry partitions and stiff floors, as well as buildings in

lower seismic exposure areas and walls not part of the lateral resisting system (even when other walls are engineered). Buildings that are in higher exposure areas or have walls that are part of the lateral resistance system require engineering design that conforms to local codes.

There are specific limits on masonry as to height, wind or other horizontal loads, and seismic loads. In many cases, design for wind and industry recommendations for crack control due to shrinkage or expansion may govern building reinforcement in areas with lower seismic activity.

NOTE

Standard construction practice for masonry crack control requires W1.7 at 16 in. o.c., which would cover seismic

requirements as well. W1.7 steel reinforcement at 8 in. o.c. should be used in parapet locations.

WALL REINFORCING FOR MASONRY WALL (EMPIRICAL DESIGN FOR MODERATE SEISMIC AREAS)

INTERSECTING WALL DETAIL

Edgar Glock, Masonry Institute of St. Louis; St. Louis, Missouri

NOTE

This detail allows transfer of out-of-plane forces but isolates in-plane forces from the structure.

NONBEARING WALL ISOLATION DETAILS

SHEAR WALL SPACING RATIO—EMPIRICAL DESIGN

Bearing walls	Solid units	$l/t < 20$
	Fully grouted	$l/t < 20$
Others	$l/t < 18$	
Nonbearing walls	Exterior	$l/t < 18$
	Interior	$l/t < 36$

l —wall length; t —wall thickness

NOTE

Preformed, hot-dipped galvanized tees (W1.7 wire at 8 in. o.c., vertical for bearing; 16 in. o.c. for nonbearing) are used for reinforcing intersecting walls.

ALTERNATE DIAPHRAGM CONNECTION FOR WOOD JOIST/RAFTER

DIAPHRAGM CONNECTION FOR STEEL JOISTS PARALLEL TO WALL

DIAPHRAGM CONNECTION FOR STEEL JOISTS PERPENDICULAR TO WALL

NOTE

For moderate seismic areas

ROOF TIE DETAILS FOR MODERATE SEISMIC AREAS

NOTE

Empirical design for masonry parapets should be used only in areas with low seismicity. Engineering analysis is required when the height-to-thickness ratio of three-to-one is exceeded and in areas of higher seismicity.

MASONRY PARAPET DETAIL FOR SEISMIC AREAS

GENERAL

Wood frame structures with a variety of solid wood and engineered wood products can be designed to resist seismic forces using many of the same principles used to resist wind forces. Wind-resistant design involves resolving loads assumed to be applied to the structure in one direction for a short time (monotonic loads). Wind load can induce shear that is both perpendicular and parallel with the structure, resulting in an overturning motion as well as uplift on the structure. Seismic loads, on the other hand, are cyclical, moving in different directions over a short period.

Seismic loading conditions on conventional construction are referenced in four main sources, which also provide information about the capacity of various materials: American Society of Civil Engineers 7-95, Section A9.9.10; the Building Code, Section 2326; the Standard Building Code, Sections 2308.2.2 and 2310; and the National Building Code, Section 2305.8. In general, these provisions are limited to buildings with bearing walls not exceeding 10 ft in height and gravity dead loads not exceeding 15 psf for floors and exterior walls and 10 psf for floors and partitions. Sheathing for braced walls must be at least 48 in. wide over studs spaced not more than 24 in. o.c.

Wood construction standards for all seismic areas include the following: wall anchorage must use a minimum of 1 o.c., maximum. Walls must be capped with double top plates. Uniform with end joints offset by at least 4 ft. Bottom plates must be 1 1/2 in. thick (2 in. nominal) and at least the width of the studs.

Forces must be transferred from the roof and floor(s) to braced walls and from the braced walls in upper stories to the braced walls in the story below, then into the foundation. Transfer must be accomplished with toe nails using three 8d nails per joist or rafter where not more than 2 ft o.c. or with metal framing devices capable of transmitting the lateral force. Roof to wall connections must be made at the exterior walls when the building is 50 ft or less in length. A combination of exterior and interior bearing walls is necessary when the building length exceeds 50 ft.

Connections designed for both lateral and vertical (uplift or overturning) loads must be used in conventional wood frame structures designed for seismic areas. Traditional nailing schedules are often adequate to handle lateral forces. Vertical forces can be addressed by lapping structural sheathing and/or strapping the roof, walls, and floors together at appropriate intervals. In addition, the overturning loads in walls must be restrained by anchoring the ends of the shear panels (whether traditional or perforated) to the structural wall below.

Nontraditional materials such as LVL, I joists, and structural composite lumber can be used in seismic design; the capacities and applicable connection types of these products are available from the manufacturers.

NOTE

Each diaphragm in a building must resist the seismic effects in both directions of all the mass above it as well as of its own mass. The seismic loads caused by the roof mass must be transferred to the wall, and the wall must be designed to resist both the effect of the mass of the roof and the mass of the wall. These combined loads must then be transferred to the floor below, which must be designed to resist the effect of both its mass and the load applied by the wall above. In turn, walls below must resist these loads, until the force reaches the foundation, which must be able to resist the combined loads from the rest of the building.

SEISMIC LOAD TRANSFER

David S. Collins, FAIA; American Forest & Paper Association; Cincinnati, Ohio

TYPICAL WALL SECTION FOR CONVENTIONAL WOOD FRAMING

SPACING FOR BLOCKED DIAPHRAGM*

BOUNDARY PANELS (IN.)	OTHER PANELS (IN.)	CAPACITIES (LB/FT)
6	6	320
4	6	425
2 1/2	4	640
2	3	730

*1 1/2-in. panel sheathing; 10d nails into 2X framing (Douglas fir, larch, southern pine).

NOTES

1. Use 1 1/2 in. sheathing for the outside of shear panels, with 10d nails in 2x framing.
2. Capacities are based on structural I panels of Douglas fir, larch, or southern pine. For additional thicknesses or alternative wood species, consult the American Plywood Association.
3. The aspect ratio (the ratio of the longer dimension to the shorter) of a floor or roof diaphragm is limited to $L_2/L_1 \leq 4$. Openings in the diaphragm are limited to either 12 ft or half the length of the diaphragm, whichever is smaller.

FLOOR AND ROOF DIAPHRAGM

NOTES

1. Diaphragms (the roof, floor(s), and shear panels in walls) must be designed to resist forces created by the dead load mass of the structure and applied seismic loads. In wood frame construction, a diaphragm is typically a structural "panel" made of a skin (sheathing) stretched over and fastened to ribs (wood members such as 2x4s). The resulting construction is stiff and strong enough to transmit forces to resisting systems such as the foundation. Connections must be designed to transfer lateral forces and restrain overturning motion. Lateral forces can be either perpendicular or parallel to the structure. The load from each part of a building that is created as the building shifts from the movement of the earth must be transferred to adjoining elements (roof sheathing to rafters to top plates to wall sheathing and studs to bottom plates to floor sheathing and framing and so on, until the lowest level of floor framing, from which the load moves to the foundation; in slab-on-grade construction, the load moves finally from the wall sheathing and studs to the bottom plates).
2. The roof diaphragm comprises roof sheathing, roof framing (rafters, top chord of truss, etc.), and blocking.
3. The ceiling diaphragm comprises ceiling finish material (for example, gypsum wallboard) and ceiling framing (joists, lower chord of trusses, etc.).
4. Roof-to-wall anchorage consists of hold-down anchors to resist uplift forces and nailing to resist shear forces.
5. The wall diaphragm comprises wall sheathing, wall framing, and sheathing fasteners.
6. The floor diaphragm comprises floor sheathing, floor framing (joists, trusses, etc.), blocking, etc.
7. Wall-to-floor-to-wall anchorage consists of hold-down anchors and shear connectors (for example, nails).
8. Floor-to-foundation anchorage consists of hold-down anchors to resist overturning forces and anchor bolts (1/2 in. diameter at 6 ft o.c.) to resist shear forces.

BRACED WALL SPACING

SEISMIC PERFORMANCE CATEGORY	DISTANCE BETWEEN BRACED WALLS	MAXIMUM NUMBER OF STORIES
A	35 ft	3
B	35 ft	3
C	25 ft	2
D	25 ft	1*

*Two stories for detached one- and two-family dwellings

NOTE

The bracing element is typically a shear panel that is anchored against both shear and overturning.

BRACED WALL SPACING

NOTES

1. Shear panels that consist of framing members and sheathing panel(s) or diagonal sheathing members provide the principal lateral resistance to shear loads. Sheathing panels are made of plywood and OSB (for structural panels), gypsum sheathing, or fiberboard. Diagonal wood sheathing boards or strapping can also be used. The shear capacity of the material depends on the quality of the framing and sheathing materials and on the connections. Building codes require a minimum aspect ratio of $H/L \leq 2$ or $3\frac{1}{2}$ for the panel. Sheathing both sides with the same material doubles the capacity of the shear panel. Tests have shown that sheathing each side with a different material adds capacity, although this concept is not accepted by all codes.
2. Use 10d nails at all edges and in field (center area) as follows: for edge nailing, 6 in. o.c. for 280 lb/lin. ft; 4 in. o.c. for 430 lb/lin. ft; 3 in. o.c. for 550 lb/lin. ft; 2 in. o.c. for 730 lb/lin. ft; and 12 in. o.c. for field nailing.
3. This drawing is based on use of structural I panels of Douglas fir, larch, or southern pine. For additional thicknesses or alternative wood species, consult the American Plywood Association.

WOOD WALL SHEAR PANEL

NOTES

1. In traditional shear wall design, parts of the wall that are sheathed from top to bottom without openings are considered individually as shear panels. Hold-down anchors are required at both ends of each of these panels. Each segment must be restrained against the overturning motion and the shear to which it will be exposed.
2. The capacity of a traditional shear wall is the sum of the capacities of the individual shear wall segments, which are determined by multiplying the length of each segment by the capacity of the sheathing (lb/lin. ft). Example: Use $1\frac{5}{32}$ in. sheathing for the outside of the shear panel, with 10d nails spaced 6 in. o.c. for 280 lb/lin. ft. The capacity of this shear wall would be equal to $280 \times (A + B + C)$; $280 \times H =$ uplift (hold-down capacity).

TRADITIONAL SHEAR WALLS

MINIMUM LENGTH OF BRACED WALL

STORY	SHEATHING TYPE*	LOW RISK	HIGH RISK		
			12'-0"	16'-0"	20'-0"
Top or only	G-P	8'-0"	12'-0"	16'-0"	20'-0"
	SW	4'-0"	8'-0"	8'-0"	12'-0"
Story below top	G-P	12'-0"	16'-0"	20'-0"	—
	SW	8'-0"	8'-0"	12'-0"	29'-0"
Bottom of 3 stories	G-P	16'-0"	—	—	—
	SW	8'-0"	Not permitted as conventional		

*G-P—gypsum; SW—structural wood

NOTES

1. For perforated shear walls, the whole wall is considered as a single shear panel without regard to wall openings. Hold-down anchors are required only at the ends of the wall. To determine the capacity of the wall, the lengths of the full-height sheathed areas are added together and the sum multiplied by the capacity of the sheathing.
2. Perforated shear walls may require higher capacity sheathing than traditional shear walls to compensate for the lack of intermediate hold-down anchors.
3. The sheathed walls above and below the openings in a perforated shear wall increase the capacity of the wall. The capacity of the shear wall must be adjusted by a factor derived from two variables: the maximum opening height and the percentage of full-height sheathing on the shear panel. In the following example, a factor of 0.49 is applied. The Wood Frame Construction Manual gives more examples. Example: Use $1\frac{5}{32}$ in. sheathing for the outside of the shear panel, with 10d nails spaced 6 in. o.c. for 280 lb/lin. ft. Shear = $280 \times (A + B + C) \times 0.49$; $280 \times 8 = 2240$ lb uplift (hold-down capacity).

PERFORATED SHEAR WALLS

LUMBER DESIGN VALUES FOR SEISMIC CONDITIONS

DESIGN VALUE*	2 x 8	ADJUSTMENT FACTORS			ADJUSTED DESIGN VALUE (PSI)

	SPF no. 1/no. 2; 1100 psi	1.05 $F_{c } = 1320$	—	1850	1850
	Southern pine no. 2; 1550 psi	—	—	2480	2480

*Additional design values for other species and grades of lumber can be obtained from the Supplement to the AF&PA National Design Specification.

NOTE

Design values for traditional solid wood products and connections are available in the American Forest and Paper

Association's National Design Specification. The values published for wood products must be adjusted by various factors, including size (except for southern pine), to determine the appropriate design values for a particular application. Repetitive members, consisting of three members spaced not more than 2 ft o.c. and sharing a load, must be increased by a factor of 1.15, while the adjustment for

seismic and wind conditions is a factor of 1.6. These factors are applicable only to solid wood products and glued laminated timbers. Connections have similar adjustment factors.

David S. Collins, FAIA; American Forest & Paper Association; Cincinnati, Ohio

1 SEISMIC DESIGN

GENERAL

Lighting design involves selecting lighting fixtures (luminaires) and determining their locations and control devices to realize the desired effects. Basic lighting designs are fairly generic and require but a modest level of effort to achieve a workable result. Attractive and/or complex lighting designs, on the other hand, can require significantly more design work and detail in specifying products and locations. Typical steps in the process are these:

1. Establish project criteria: Determine the quantity and quality of illumination, color of light, and luminaire type (style, appearance) wanted. Check applicable codes and standards, and find out the cost and power limits.
2. Create design concepts: Select the types of luminaires to be used, outline desired controls, and propose locations. Test cost and power budgets.
3. Refine the design: Make calculations and adjustments, sketch details, draft specifications, and coordinate mechanical and structural work.
4. Prepare working drawings: Draw lighting plans, make fixture schedules, and plan layout and circuit controls. Determine emergency, life safety, and egress lighting.

As with all creative processes, it is not unusual to repeat steps until an acceptable result is achieved. With increasing enforcement of energy codes, traditional designs (especially those using incandescent lighting) will not meet energy code requirements. Reiterations involving different light sources or luminaires will often be necessary.

SETTING DESIGN CRITERIA

Lighting design requires the definition of the following criteria for each application: quantity of illumination, quality of illumination, color of light, and suitable luminaire styles.

QUANTITY OF ILLUMINATION

Standards for illumination are set by the Illuminating Engineering Society of North America (IESNA). Illumination is generally measured in the horizontal plane 30 in. above the floor. The units of illumination are footcandles (lumens per square foot) and lux (lumens per square meter). IESNA-recommended levels are summarized on the following page (Lighting and Lighting Systems)—more detailed and specific information is given in the IESNA Lighting Handbook and in other IESNA publications.

Specific lighting levels may be set by codes, such as life safety codes and health codes. For instance, NFPA 101 (National Fire Protection Association Life Safety Standard) recommends an average illumination of 1 footcandle (10 lux) along a path of emergency egress with an emergency power source. Some owners establish their own lighting level requirements for specific areas.

Choosing lighting levels involves thoughtful application of IESNA recommendations to meet the goals of the project. Too much light will lead to excessive energy use and failure to meet energy code limits. Use of high lighting levels (more than 200 footcandles) is rare and usually is associated with special purpose lighting systems like surgical lights.

The IESNA recommends exterior lighting levels for specific applications such as street lighting, sports lighting, and parking lot lighting. Although the IESNA makes some recommendations for exterior lighting applications that are more artistic, such as building facades or statuary, most of these are left to the designer's discretion.

The uniformity of lighting levels is also subject to IESNA recommendations. For interior lighting, IESNA generally recommends the following ratios of illumination for comfort:

1. Task proper: 100%.
2. Immediate surround: 33-100%.
3. Distant surround: 10-100%.

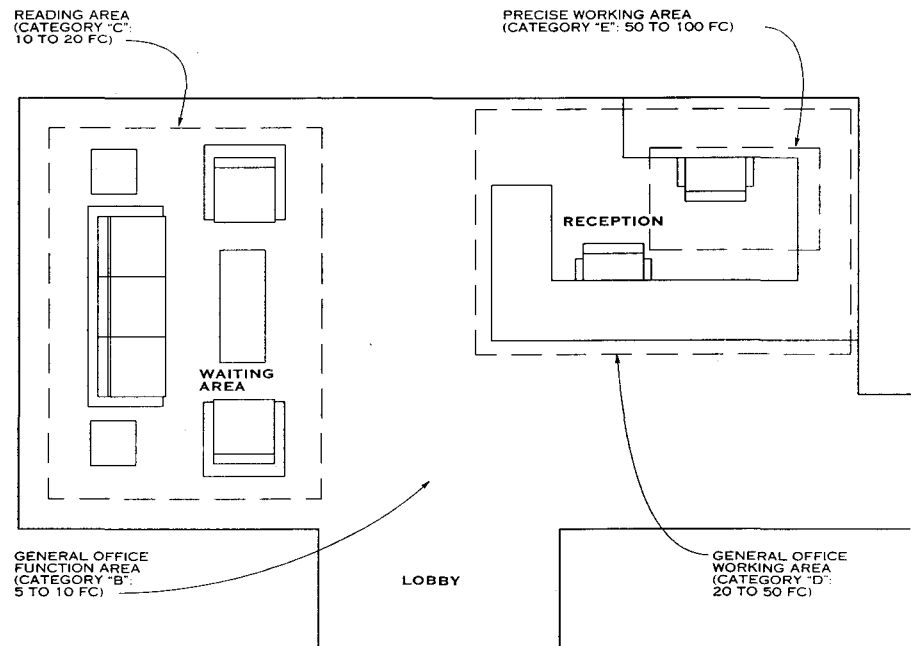

When light is designed to maintain these relationships, the human eye continually adapts to the light level and responds quickly to visual stimulus. However, visual interest is caused by contrast in which ratios between task and surround might be 100:1 or even greater. This is one of the greatest paradoxes of lighting design: The most appealing visual scenes are often uncomfortable.

LIGHT SOURCE SELECTION GUIDE

LAMP CCT ¹ (KELVINS OR K)	APPLICATIONS
<2500	Bulk industrial and security (HPS) lighting
2700-3000	Low light levels in most spaces (<10 FC); general residential lighting; hotels, fine dining and family restaurants, theme parks
2950-3200	Display lighting for retail and galleries; feature lighting
3500-4100	General lighting in offices, schools, stores, industry, medicine; display lighting; sports lighting
4100-5000	Special application lighting when color discrimination is very important; not commonly used for general lighting
5000-7500	Special application lighting when color discrimination is critical; uncommon for general lighting
MINIMUM LAMP CRI ²	
<50	Noncritical industrial, storage, and security lighting
50-70	Industrial and general illumination when color is not important
70-79	Most office, retail, school, medical, and other work and recreational spaces
80-89	Retail, work, and residential spaces when color quality is important
90-100	Retail and work spaces when color rendering is critical

¹ CCT—correlated color temperature

² CRI—color rendering index

NOTE

In this example, choosing the proper amount of light in each area not only meets visual needs but consumes only the minimum necessary energy. Use the high end of the

light level ranges for older people, where finishes are especially dark, or where the work is particularly important or requires great speed.

LIGHTING LEVELS FOR TYPICAL OFFICE RECEPTION AREA

QUALITY OF ILLUMINATION

Quality of illumination remains largely an aesthetic issue. However, a number of specific quality issues can be addressed objectively:

1. Eliminate flicker: Light sources should minimize or eliminate flicker caused by AC power or other influences.
2. Eliminate or minimize glare: Shield lamps from view. Minimize very bright and very dark surfaces. Illuminate walls and ceilings.
3. Use light sources with good color rendering: Halogen, high CRI (color rendering index) full size and compact fluorescent, and high CRI metal halide and white HPS lamps should be used whenever possible.

COLOR OF LIGHT

Both the correlated color temperature (CCT) and color rendering index (CRI) for light sources should be used in choosing light sources. In general, try to match CCT when mixing sources, such as halogen and fluorescent.

SUITABLE LUMINAIRE STYLES

Many design problems have reasonably obvious solutions determined by a combination of budget, energy code, and industry standards. For instance, most office lighting designs utilize recessed troffers because they are cost-effective and energy-efficient and they meet the standard expectations of owners and tenants. Choices among troffers require further consideration, although at that point style is a lesser issue.

Some situations call for uncommon or creative designs. In these cases, the distribution of the luminaire and its physical appearance become critical. In particular, luminaires that enhance the architecture are desired for residences, hotels, restaurants, and other nonwork spaces. Decorative styles range from contemporary to very traditional; lamp options may permit a choice between incandescent and more energy-efficient light sources, such as compact fluorescent or low watt high-intensity discharge (HID) luminaires. In fact, energy-efficient decorative lighting fixtures, both interior and exterior, are one of the fastest growing parts of the lighting fixture industry as the market for attractive luminaires that comply with energy codes grows.

James Robert Benya, PE, FIES, IALD, Pacific Lightworks; Portland, Oregon
Robert Sardinsky, Rising Sun Enterprises; Basalt, Colorado

GENERAL

Most buildings are equipped with electric lighting systems for interior uses. Early in the history of lighting, illumination systems were designed for minimum use of interior space at night. Today, however, electric illumination systems generally are designed to be used in place of natural light.

FUNCTIONS OF LIGHTING

Light is one of many tools available to help in space design. In the beginning of any project, it is wise to recall the functions of lighting and to be certain each has been examined:

1. Performance of tasks: Lighting to perform work, whether it is reading, assembling parts, or seeing a blackboard, is referred to as task lighting. Visual work is a primary reason for providing lighting.
2. Enhancement of space and structure: It is only through the presence of light that spatial volume, planes, ornament, and color are revealed. For centuries, structural systems evolved partly in response to aesthetic as well as functional desires for light of a certain quality. The progress from bearing wall to curtain wall was driven by the push of newly discovered technologies (both in materials and in technique), by evolving cultural desires for certain spatial characteristics, and by a desire to admit light of a particular quality. These developments are reflected in the Gothic church window, the baroque oculus, and the Bauhaus wall of glass. With the advent of electric lighting systems, this connection of structure to light was no longer entirely necessary, but most architects continue to pay homage to this historical tie.
3. Focusing attention: The quality of light in a space profoundly affects people's perception of that space. The timing and the direction of an individual's gaze are often a function of the varying quality and distribution of light through the space. Lighting draws attention to points of interest and helps guide the user of a space.
4. Provision of security: Lighting can enhance visibility and thereby engender a sense of security. Lighting can also be used to illuminate hazards, such as a changing floor plane or moving objects.

BASIC LIGHTING TERMS

LUMINAIRE: a structure that holds an electric lamp and its socket, wiring, and auxiliaries, such as ballasts.

PORTABLE LUMINAIRE (LAMP): a luminaire equipped with a cord and plug and designed to be moved from space to space.

LIGHTING FIXTURE: a luminaire that is permanently attached ("hard wired") to a building.

LIGHTING SYSTEM: the lighting fixtures in a building, sometimes including portable lights, subdivided into smaller systems (e.g., the lighting system in a room or all luminaires of a particular type in a room or building).

ILLUMINANCE: the measure of light striking a surface, in footcandles (lumens per square meter). Illuminance can be measured and predicted using calculations; also illumination.

NOTE

Fixture manufacturers have developed luminaires (mostly fluorescent) that produce a light distribution that tends to reduce direct glare and veiling reflections if used in large, uniform arrays and typical open office geometries. This distribution pattern is called batwing.

LUMINAIRE LIGHT DISTRIBUTION PATTERN

Performance of very special visual tasks of extremely low contrast and small size	I	10000-15000-20000	1000-1500-2000	

NOTE

Standards for lighting and illumination in North America are established by the Illuminating Engineering Society of North America. IESNA recommendations are summarized in the

IESNA Lighting Handbook, 8th edition, from which this table is taken.

LAMP: the electric bulb or tube within a luminaire.

PHOTOMETRY: the measure of light, especially with respect to a luminaire.

PHOTOMETRIC REPORT: a written report that describes the manner in which light is emitted from a luminaire, presented in an industry standard format.

ENERGY EFFICIENCY: the measure of how a lighting system compares to standards, in the context of building size and function.

its lumens downward will have a higher CU (room cavity ratio and reflectance values being equal) than one that distributes light in any other direction. A higher CU is not necessarily a virtue; it only ranks fixtures according to their ability to provide horizontal illumination.

The lumen method/zonal cavity system is limited by the following:

1. It is based on a single number, average value.
2. It assumes a uniform array of lighting fixtures.
3. It assumes all room surfaces have a matte (Lambertian) finish.
4. It assumes the room is devoid of obstruction, at least down to the level of the work plane.

The light loss factor (LLF) is used to calculate the illuminance of a lighting system at a specific point in time under given conditions. It incorporates variations from test conditions in temperature and voltage, dirt accumulation on lighting fixtures and room surfaces, lamp lumen output depreciation, maintenance procedures (mainly frequency of cleaning), and atmospheric conditions. The LLF is also known as the maintenance factor.

To use a CU table, assumptions must first be made about the reflectance of major room surfaces. Then the room cavity ratio (RCR) can be determined according to one of the following formulas:

For rectangular rooms: $RCR = [5 \times H(L + W)] / (L \times W)$, in which H is the cavity height

For odd-shaped rooms: $RCR = 2.5 \text{ wall area/floor area}$

LUMEN METHOD

Lighting design involves determining how many luminaires are needed for a particular application and where to locate them. The most accurate means of determining illumination performance is by computer; a number of point-by-point lighting programs are available with DXF and DWG file interfaces and other features. (See the annual computer issue of Lighting Design and Application, an IESNA publication, for a current list of commercially available programs.) It is also possible to estimate illumination results from a proposed lighting design using the lumen method and photometric report(s) from candidate luminaires.

The lumen method, also known as the zonal cavity system, is a calculation method that can be used to determine the horizontal illuminance that will result from a proposed lighting fixture selection and layout or the number of fixtures required by a proposed fixture selection and its horizontal illuminance value.

The lumen method is based on the definition of average footcandles over an area. The method modifies the fundamental equation of $1 \text{ fc} = 1 \text{ lumen/sq ft}$ to account for room size and proportion; reflectance from walls, ceiling, and floor; fixture efficiency; and reduction in output over time due to dirt accumulation, deterioration of reflecting surfaces, and reduction of lumen output.

The lumen method requires the following information:

1. Room dimensions (to compute wall area and floor area)
2. Height of fixtures above work plane
3. Reflectance levels of major surfaces (ceiling, walls, floor)
4. An estimate of the light loss factor (LLF)
5. Initial lamp lumens
6. A target illuminance level

The coefficient of utilization (CU) is the percentage of total lamp lumens that reaches the work plane. As such, it has nothing to do with the intensity of the fixture but rather with the efficiency of the fixture (lumens emitted from the fixture divided by lamp lumens and the direction of the lamp output—this direction of output is graphically represented by the candlepower distribution curve). For purposes of this procedure, the plane of interest is invariably a horizontal plane (typically either the floor or desk level), therefore a fixture that throws the greatest percentage of

NOTE

Any one of these dimensions may be the cavity height (H), which is the distance from the light fixture to the work plane of interest.

CAVITY HEIGHT DIAGRAM

GENERAL

Lighting can be designed both to use minimum energy and to realize environmental benefits such as reduced air and groundwater pollution. Electric light sources more efficacious than traditional incandescent lamps have been developed to meet most lighting needs. The key to achieving efficient design is knowing how and when to choose efficient sources, luminaires, and controls.

CODES

The U.S. Energy Policy Act of 1992 requires states to develop codes that require efficiency in lighting design. Each code must meet or exceed the requirements of ASHRAE/IES 90.1-1989. In 1996, although in many states compliance was mandatory and enforced, some states had yet to adopt such a code, while others had not yet begun enforcement. For federal government buildings, a version of 90.1 with more stringent values was in force. Progress toward regulating energy efficiency in Canada was similar.

All codes presently calculate allowed watts based on building type and area. Codes generally determine allowed interior lighting watts in one of three ways—room by room, by area (groups of rooms), or for the entire building:

1. Room by room: Determine the specific use of each room and its net area. Multiply the area of each room by the allowed power density (watts/sq ft) adjusted for the room cavity ratio (RCR). Add the wattage for all rooms together.
2. Area: Determine the use of major portions of a building or renovation and the gross lighted area of each. Multiply the gross lighted area by the allowed power density (watts/sq ft) for each group of rooms by type. Add the figures for all areas together.
3. Whole building: Determine the building type and the gross lighted area for the entire building. Multiply the gross lighted area by the allowed power density (watts/sq ft) for the entire building by type.

To find the total allowed watts for the interior of a building, start with the total wattage as determined by one of the three methods above. Then subtract "credit" watts for lighting controlled by advanced automatic devices such as daylighting or motion sensing and add other allowed watts, if any.

An allowed lighting load can also be determined by using a building energy simulation program like DOE-2. However, because the program's algorithm is based on the same power density assumptions as the allowed amount given above, it is unlikely the value for lighting determined in this manner will be significantly different.

Exterior lighting is governed less than interior lighting, and under some codes it may not be governed at all. As well, energy codes in general do not regulate lighting watts in dwelling units.

ADDITIONAL CODE REQUIREMENTS

In addition to limiting lighting power in a building, lighting energy codes also have other requirements. These vary by state but may include the following:

1. Mandatory use of readily accessible switching in all enclosed spaces. (Exceptions are allowed for spaces in which this would be unsafe.)
2. Use of multilamp or electronic fluorescent ballasts whenever possible.
3. Separate switching for daylighted and nondaylighted spaces in building interiors.
4. Ability through switching or dimming to adjust lighting levels in a space exceeding 100 sq ft and 100 watts.
5. Automatic shutoff controls for lights in spaces in larger buildings (usually larger than 5000 sq ft).
6. Automatic shutoff controls for exterior lights.

LIGHTING CONTROLS IN ENERGY-EFFICIENT APPLICATIONS

While most energy codes require switching for all spaces, some switch types control energy use better through automatic switching and/or dimming. "Control credits" are often offered by codes that permit the designer to reduce the watts of all lights connected to certain automatic devices; this arrangement allows the design to employ more lighting watts and still comply with the energy code.

COMPLIANCE STRATEGY

To realize design compliance with local energy codes without significant redesign, observe the following process:

1. Choose a general lighting system that uses one of these sources: fluorescent T-8 with electronic ballasts, high-wattage compact fluorescent with electronic ballast, or metal halide or HPS (high-pressure sodium).
2. Make certain the luminaire and room are reasonably efficient. Use direct lighting for tasks whenever possible, and make room finishes light, especially ceilings.
3. Design to just barely meet IESNA recommendations for each space.
4. For downlighting, wallwashing, and other traditional incandescent applications, use compact fluorescent or HID (high-intensity discharge) sources.
5. Minimize the amount of track lighting by using recessed fixtures or monopoints when possible.
6. Use incandescent and halogen sources sparingly, confining them to necessary decorative lighting.
7. Add advanced controls such as motion sensors and daylighting dimming. These allow the reduction of actual lighting watts and can help bring a design into compliance with energy efficiency requirements.

LINEAR SLIDE CONTROL ROTARY OR PUSH-ON/OFF CONTROL TOUCH-PLATE CONTROL

DIMMING CONTROL DEVICES

TRADEOFFS

Energy codes do not regulate lighting design or the amount of lighting in a particular space. For instance, a designer could slightly reduce the lighting loads throughout an office building by using efficient lighting equipment. With the energy saved, an important space like the main lobby could be illuminated in a less efficient manner, such as with incandescent chandeliers, and the project would still comply with the energy code.

Tradeoffs are allowed among interior spaces in the same building, but they are not allowed between interior and exterior lighting. In addition, tradeoffs are not allowed between buildings, even if they are owned by the same company and stand on the same site.

ENERGY-EFFICIENT LIGHTING CONTROLS

DEVICE OR METHOD	OPERATION	TYPICAL CREDIT*
Time clock (with manual override readily accessible)	Turns lights on and off at scheduled times	0-10%
Dimmer	Reduces lighting power by manual adjustment	0%
Motion sensor	Turns lights on and off based on space use	15% (>250 sq ft) to 30% (<250 sq ft)
Daylighting controls	Reduces interior lighting power based on amount of daylight in space	20% (stepped) to 30% (continuous dimming)
Scene preset dimming	Reduces average power by dimming combinations of lighting systems	10-20%
Tuning	Reduces lighting power by hidden adjustment	10-15%
Lumen maintenance	Reduces interior lighting power based on age of lamps and cleanliness of space	10-15%
Combined systems	Combinations of the above are not directly additive	Up to 45%

*The credit offered varies from code to code and may not be available everywhere.

$$\text{NUMBER OF LUMINAIRES} = \frac{\text{footcandles desired} \times \text{room area}}{\text{CU} \times \text{LLF} \times \text{lamps/luminaire} \times \text{lumens/lamp}}$$

$$\text{AVERAGE FOOTCANDLES} = \frac{\text{lumens/lamp} \times \text{lamps/luminaire} \times \text{CU} \times \text{LLF}}{\text{area of room (sq ft)}}$$

$$\text{POWER DENSITY (W/sq ft)} = \frac{\text{design watts (including ballast)}}{\text{area of room}}$$

where:
 CU = coefficient of utilization (percentage of light that actually reaches task)
 LLF = light loss factor (time-dependent depreciation factors)

NOTE

See manufacturer's photometric tables or the Lighting Handbook of the Illuminating Engineering Society for tables of values for CU, LLF, lumens/lamps, etc

$$\text{NUMBER OF FIXTURES} = \frac{50 \times 25 \times 40}{0.67 \times 0.7 \times 4 \times 2850} = 9.35 \text{ luminaires (use 9 or 10)}$$

$$\text{POWER DENSITY (W/sq ft)} = \frac{9 \times 111}{25 \times 40} \text{ or } \frac{10 \times 111}{25 \times 40} = 0.999 \text{ W/sq ft (9 luminaires) or } 1.111 \text{ W/sq ft (10 luminaires)}$$

TYPICAL EXAMPLES

Room size 25 x 40 ft; ceiling height 9 ft; illumination level 50 footcandles (IESNA category 10); 2 x 4 ft. recessed trofers with four 32-watt T8 lamps (2850 lm) each.

CU = 0.67 (plastic lens)
 Electronic ballast input watts = 111
 LLF = .70

FORMULAS FOR AVERAGE LIGHTING CALCULATIONS

James Robert Benya, PE, FIES, IALD, Pacific Lightworks; Portland, Oregon
 Robert Sardinsky, Rising Sun Enterprises; Basalt, Colorado

DETERMINING THE EFFECT OF PARTITIONS ON LIGHTING LEVELS

The illumination that reaches a desk top in a direct lighting system is a combination of light arriving directly from the lighting fixture and indirectly via reflectance from various room surfaces. A partition not only interferes with this indirect component of light but can drastically reduce the potential direct component.

Consider the example shown in the accompanying diagrams. In diagram "A", the workstation is contained within 42 inch high panels. Extending "sightlines" (as if the desk top could "see" the ceiling) from the center of the station out to the ceiling over the top of the panels, it can be seen that in a 10 by 10 ft workstation, a ceiling area of 4,225 sq ft (65 x 65 ft) has the potential for contributing light to the workstation. If the lighting fixtures are installed 8 ft apart, there would be an average of 66 fixtures [4,225 sq ft ÷ (8 x 8 ft)] that could contribute light directly to the desk top.

If the same 10 x 10 ft workstation had partitions 60 in. tall, the projected lines would enclose a ceiling area of 676 sq ft (26 x 26 ft). This area would include only ten or eleven fixtures [676 sq ft ÷ (8 x 8 ft)]. This 80% decrease in the number of lighting fixtures that could possibly contribute light directly to the desk top does not translate into an 80% drop in light levels at the desk top. However, it will cause a significant decrease, the amount of which is influenced by factors such as the distribution pattern of the lighting fixtures and the finishes of the partitions.

Clearly, task lighting is important to consider when partitions are more than 42 in. high.

LIGHTING CALCULATIONS FOR SPACES WITH PARTITIONS

A rough approximation of the magnitude of the effect of partition height on lighting levels can be calculated using the following technique. (However, do not use this technique for totally direct lighting systems unless several luminaires directly contribute light to the cubicle.)

1. Use the coefficient of utilization (CU) table for the fixture to calculate the average illuminance at the top of the partitions. Use the distance from the luminaires to the top of the partitions as the cavity height, and use actual reflectance values except for the floor; use "0" for the floor cavity reflectance.
2. Determine the transfer coefficient of a virtual ceiling luminaire: Use the distance from the top of the partition to the desk top as the cavity height. Use the cubicle's partition reflectance as the wall reflectance, and use the effective ceiling cavity reflectance of the actual ceiling cavity above the top of the partitions. Use the table below to find the transfer coefficient.
3. Multiply the illuminance from the first step (at the top of the partitions) by the transfer coefficient to find the approximate average illuminance at the desk top.

PANEL HEIGHT COMPARISON

LIGHTING CONTROL CHOICES

Energy codes require readily accessible switching for all electric lights. The National Electric Code requires switching at specific locations in houses. Traditional switches meet these requirements. Other lighting controls choices are discussed here:

SWITCHING

Standard toggle switches are the most commonly used lighting switches. Three-way and four-way switches permit control from several locations. Choices include standard toggle switches and the more modern "decora" or paddle switches. Electronic touch switches are also becoming more common.

DIMMING

Manual dimming is popular in homes and many other spaces. To dim fluorescent lighting, use modern high frequency electronic dimming ballast systems. An energy credit may be available for using manual dimming under some conditions.

SCENE DIMMING

Scene dimming or multichannel preset dimming systems are increasingly being used for spaces with four or more independent dimming channels, such as restaurants, custom-built houses, and boardrooms. Scene dimming systems are like modern theatrical dimming in that there is a cross-fade between scenes, which are combinations of preset dim light levels.

TIME SCHEDULING

Lighting controls that use clocks to switch lights on and off on predictable schedules are the most commonly used form of automatic lighting controls. Some energy codes require automatic controls of this type as a minimum standard. Controls may vary from individual "time clock" switches to programmable timers and large-scale energy management systems.

OCCUPANCY SENSING

Motion sensors can be used to control lights according to space occupancy. Passive infrared sensors are the most commonly used; ultrasonic sensors are also popular and work better in spaces with partitions. Sensors have sensitivity and timeout adjustments. Choose wallbox sensors with internal switches or dimmers for small rooms, ceiling-mounted sensors with remote relays for larger rooms. Multiple sensors can be used in the same room to ensure coverage.

Energy credits for using motion sensor systems are fairly substantial, as these systems save quite a bit of energy in most applications.

DAYLIGHTING AND RELATED CONTROLS

Daylighting systems use dimming or switching to reduce interior lighting when adequate daylight is present. In buildings with windows near the work area, savings can be significant, and most codes permit a substantial controls credit for daylighting.

Lumen-maintenance controls allow lighting to be dimmed automatically when it is new and, through photoelectric sensing, to be increased gradually as lamps age and luminaires get dirty. The equipment for these controls is similar to that for daylighting, and most systems do both.

Adaptation compensation controls (the opposite of daylighting) increase interior light as exterior light increases. Tunnels are classic applications for adaptation compensation, but the same principles can be used to save energy in supermarkets.

DEMAND MANAGEMENT

Lighting can be dimmed 10-20% with little effect on productivity but a profound impact on overall building load. By sensing incoming electric service for peaks, lighting can be dimmed when other building systems are peaking in load. The result is a "flattening" of the energy use curve, which lowers electric energy cost.

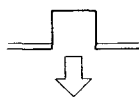

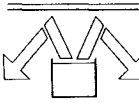

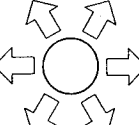

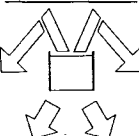

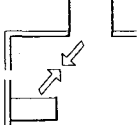

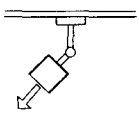

APPLICATIONS FOR LIGHTING CONTROLS

Office buildings, schools	Motion sensors in private offices, classrooms, and conference rooms
	Time scheduling systems for open office areas, corridors, halls, and lobbies
	Motion sensors in toilet rooms and storage
	Daylighting in areas adjacent to windows or skylights
	Combined systems (e.g., motion and daylighting) wherever logical
Retail	Time scheduling for store windows, general and display lighting
	Motion sensing for storage and dressing rooms
	Daylighting and lumen maintenance near skylights
Industrial, institutional	Adaptation compensation for general lighting
	Time scheduling in most areas
	Daylighting near windows and skylights
Outdoor	Motion sensing in restrooms, little used storage areas
	Choices include photoelectric switches, motion sensors, time switches, and manual switches

GENERAL

A luminaire is any device that includes a lampholder, a means of electrification, and a support. Lighting fixtures are luminaires that are permanently attached to a building. Luminaires are characterized by the manner in which light is distributed. Luminaire types are identified in the chart below.

LUMINAIRE TYPES

TYPE	LIGHT DISTRIBUTION
Direct	Emits light downward. Most recessed lighting types, including downlights and troffers, are direct luminaires. 
Indirect	Emits light upward, so it bounces from a ceiling into the space below. Many styles of suspended luminaires, sconces, and some portable lamps provide indirect lighting. 
Diffuse	Emits light in all directions uniformly. This type includes most bare lamps, globes, and chandeliers and some table and floor lamps. 
Direct/indirect	Emits light upward and downward but not to the side. Many types of suspended luminaires, and some table and floor lamps, offer this type of lighting. These luminaires can offer mostly direct or mostly indirect lighting. 
Asymmetric	For special applications. For instance, asymmetric uplights are indirect luminaires with a stronger distribution in one direction, such as away from a wall. Wall-washers are a form of direct luminaire with stronger distribution to one side to light a wall. 
Adjustable	Usually, direct luminaires that can be adjusted to throw light in directions other than down. Examples are track lights, floodlights, and accent lights. 

CHOOSING LUMINAIRES

DIRECT luminaires tend to be more efficient because they distribute light directly onto the task area. They generally create dark ceilings and upper walls, which can be dramatic but can create discomfort from the high contrast.

INDIRECT luminaires generally create comfortable low-contrast soft light, which psychologically enlarges space. They tend to be less efficient for task lighting.

DIFFUSE luminaires create broad general light that often is considered glaring due to the lack of side shielding. They are generally chosen for ornamental reasons or for utilitarian applications.

DIRECT/INDIRECT luminaires are often a good compromise between the efficiency of direct lighting and the comfort of indirect lighting.

James Robert Benya, PE, FIES, IALD, Pacific Lightworks; Portland, Oregon
Robert Sardinsky, Rising Sun Enterprises; Basalt, Colorado

LUMINAIRE STYLES

Downlights and troffers are discussed below; commercial fluorescent fixtures, indirect and direct/indirect lighting systems, architectural lighting fixtures, and decorative lighting are discussed on the following page.

DOWNLIGHTS

Downlights are often called "cans" or "tophats." They are principally used for general illumination in a wide range of residential and commercial applications, especially in lobbies, halls, corridors, stores, and other finished spaces. Downlights can be equipped with incandescent, halogen, low-voltage, compact fluorescent, or HID (high-intensity discharge) lamps. There are several major types, which accommodate varying source types, ceiling heights, plenum heights, room types, and beamspreads. These include the following:

OPEN CONE: the cone of this type of downlight shields the lamp and develops a beam pattern.

OPEN BAFFLE: ridged baffles shield the lamp and minimize glare.

OPEN ELLIPSOIDAL: an elliptical reflector allows a small aperture only; this beamspread is highly efficient.

LENSED (prismatic or fresnel): generally used outdoors or in wet locations, the lens protects and seals the lamp compartment of this type of downlight.

DIFFUSER: a diffuser distributes light broadly, which is especially useful in closets and showers.

ADJUSTABLE: adjustable downlights can be used as a downlight or as an accent light.

PULLDOWN: this feature allows the light to be used as a downlight or an accent light and permits a wide aim.

DOWNLIGHT RATINGS

Choice of a downlight depends on the applications for which it is listed. The primary rating types are these:

THERMALLY PROTECTED (T) downlights are suitable for all applications except direct concrete pour.

INSULATION-PROTECTED (IP) downlights are used when the fixture may come in contact with insulation. They are designed to prevent fixture overheating.

INSULATED CEILING (IC) fixtures are used when the fixture is intended to be in contact with insulation.

AIRTIGHT INSULATED CEILING (AIC) downlights are for applications in which the fixture is in contact with insulation and air leaks in the ceiling must be prevented.

DAMP LOCATION fixtures can be exposed to moist air but not to direct water spray or rain.

WET LOCATION fixtures can be exposed to direct water spray or rain.

SPA OR SHOWER fixtures are designed to be used in a shower stall or over a spa.

CONCRETE-POUR fixtures are designed to be installed in direct contact with concrete.

EMERGENCY fixtures are equipped with a backup battery to produce light for at least 90 minutes during a power outage (generally available only for compact fluorescent luminaires).

TROFFERS

Troffers are widely used in offices, stores, schools, and other commercial and institutional facilities for general lighting in work and sales areas. They are the most common type of fluorescent luminaire.

OPEN CONE OPEN BAFFLE ELLIPSOIDAL

DOWNLIGHTS

LENSED troffers use a plastic lens to refract light and distribute it in the desired area. The lens cuts off light distribution to minimize glare and protects lamps from breaking in food preparation and service areas. Lenses can contain internal RFI shields for use in hospital operating and laboratory rooms. Lens troffers equipped with highly polished internal reflectors offer very high efficiency.

PARABOLIC troffers have parabolically shaped aluminum or plastic louvers that shield the lamp to improve visual comfort. These troffers offer sharp cutoff, which makes some of them suitable for use in computer work spaces. "Parabolics" generally refer to deep-cell louvers 6 in. or larger across; "paracubes" are shallower troffers with smaller cells. Larger cells are more efficient, but smaller cells make it easier to hide the lamps.

Fixtures meeting IESNA recommendations for computer work spaces are generally identified.

Most troffers are recessed and designed to be laid into acoustic tile ceilings, with the fixture face matching the size of the tile. The most common troffer sizes are 2 x 4 ft, although 2 x 2 ft and 1 x 4 ft are also readily available. Other sizes exist, often to match a specific ceiling (such as 20 x 60 in. fixtures for a 5-ft ceiling grid system). Different mounting types are made, including the following identified by the National Electrical Manufacturers Association:

NEMA "G": for fixtures in a standard exposed inverted T grid.

NEMA "F": for fixtures furnished with a flange and designed to be installed in an opening in plaster or wallboard.

NEMA "SS": for fixtures in a screw-slot inverted T grid.

NEMA "NFSG": for fixtures in a narrow face slot T grid.

NEMA "Z": for fixtures in a concealed Z spline ceiling.

NEMA "MT": for fixtures in a metal pan ceiling system.

Some recessed troffers are also designed to interface with the building HVAC system: "Heat extraction" troffers have vents in the top of the fixture to allow return air to be pulled into the troffer, past the lamps, and into the ceiling plenum. "Air-handling fixtures" have slots around the lens or louvers to supply air to a room (by means of a special boot that can transfer air to the supply air system) or to remove it (by connection to a return duct).

Troffers can also be equipped with emergency battery packs to power some or all of the lamps during a power outage or emergency condition.

TROFFER RATINGS

Most troffers are rated for standard dry indoor applications and must not touch insulation. Some special types include

1. Gasketed: can be damp or even wet rated.
2. Fire-rated: can maintain up to one hour ceiling rating in certain rated ceilings.
3. Vandal-resistant: equipped with vandal-resistant lens.
4. RFI: lens troffers that are shielded from radio frequencies.
5. Specially gasketed: rated for clean room applications.

Troffers can be equipped with most fluorescent technologies, including dimming, magnetic or electronic ballasts, and T-12 or T-8 lamps. Special troffers are made for ceiling systems like the linear metal slat system (4 in. wide). Recessed troffer depth varies from 3 1/2 to more than 7 in., so troffers must be coordinated with other elements above the ceiling.

ALUMINUM LOUVER

PARABOLIC LOUVERED

ACRYLIC LENS

LENSED

TROFFERS

LUMINAIRE STYLES

Downlights and troffers are discussed on the previous page, where the subject of lighting equipment is introduced.

COMMERCIAL FLUORESCENT FIXTURES

Several types of fluorescent direct luminaires appropriate for general and utility lighting are employed as commercial fixtures. Most utilize wraparound lenses or diffusers in which the lamp is surrounded by the lens; either way, the lamp is hidden from direct view while radiating light downward and to the sides. Commercial luminaires are among the lowest cost lighting fixtures and are typically used for general and utility lighting in modest projects.

COMMERCIAL RATINGS

Most commercial fixtures are rated for dry locations. Some have damp labels. Most can be equipped with a battery pack for emergency power.

INDUSTRIAL LIGHTING FIXTURES

These fixtures generally have a utilitarian or functional appearance. Fluorescent industrials have strip lights and open fixtures with simple reflectors that are designed to be surface-mounted or hung by chains or rods. HID (high-intensity discharge) industrials include high bay downlights and low bay downlights. Industrial fixtures are generally used in factories and warehouses and increasingly in schools and retail stores where a less-finished appearance is desired.

INDUSTRIAL RATINGS

Most industrial fixtures are listed for dry locations. Some have finishes such as glass or porcelain that resist corrosion caused by airborne gases or particles; others are made of aluminum or plastic. Certain fixtures are specifically designed for demanding environmental applications ranging from wet or saltwater marine luminaires to explosionproof products for use in petrochemical plants, grain storage, and other unusual locations.

INDIRECT AND DIRECT/INDIRECT LIGHTING SYSTEMS

Most indirect and direct/indirect lighting systems are designed to illuminate offices and similar finished spaces. In almost all cases, the ceiling should be finished in white paint or white acoustical tile, as the reflectance of the ceiling plane is critical.

Indirect lighting systems only produce uplight. Generally they should be mounted at least 15-18 in. below the ceiling; longer suspension lengths can improve uniformity but potentially will decrease efficiency. To maintain adequate clearance, ceilings should be at least 9 ft high.

Direct/indirect lighting systems are intended to produce some indirect lighting for its comfort and balance and some direct lighting for efficient production of task lighting. Similar suspension length and ceiling height considerations apply. The percentage of uplight to downlight varies; generally the higher the ceiling, the greater the downlight percentage should be.

INDIRECT AND DIRECT/INDIRECT LIGHTING SYSTEM RATINGS

Almost all indirect and direct/indirect luminaires are intended for dry, relatively clean indoor locations. Many of these systems are designed to meet IESNA recommendations for lighting computer workspaces and are rated as complying with either IESNA /ANSI RP-1-1993 or IESNA RP-24-1989. These ratings are based on ceiling brightness and uniformity criteria.

ARCHITECTURAL LIGHTING FIXTURES

Like downlights, architectural lighting fixtures are functional and inconspicuous rather than decorative. They are used to illuminate architectural shapes and forms.

WALLWASHERS come in several types. Eyelid wallwashers essentially are downlights with an eyelid-shaped shield on the room side. Recessed lens wallwashers resemble downlights but use an angled lens to throw light more to one side. Surface and semi-recessed lens and open wallwashers, which throw light onto an adjacent wall, generally work best; they can also be mounted to track. Downlight wallwashers are designed to illuminate rather than scallop an adjacent wall, although the light they provide is not good enough for display purposes.

WALL GRAZING FIXTURES, sometimes called "wall slots," are used to illuminate walls in lobbies, corridors, and core areas. They are especially suited for textured or polished surfaces.

ACCENT FIXTURES focus light on art and building surfaces. Recessed accent lights appear as downlights but internally permit rotation and elevation of the light beam. Eyeballs and pull-down accents resemble downlights that cannot be adjusted. Track lighting systems are specifically designed for accent lighting of art and retail displays, with easy relocation of lampholders along the track.

COVE LIGHTS provide uplighting from coves or other architectural elements more efficiently than strip lights and without socket shadows.

TASK LIGHTS are specifically designed to illuminate a desk area while minimizing veiling reflections.

DECORATIVE LIGHTING

Lighting is the "jewelry of architecture" and, in many building types, plays a significant role in building style, period, or motif.

CHANDELIERS are ornate luminaires that generally comprise many small incandescent lamps to simulate the effect of candle flames. Chandeliers are hung from the ceiling and are used for general illumination in dining rooms, foyers, and other formal spaces.

PENDANTS are also ceiling-hung decorative fixtures. In general, the term is used for luminaires that are less formal than chandeliers, such as those used in offices or restaurants. Most pendant luminaires also use incandescent lamps, although modern variations are available with HID and fluorescent sources.

CLOSE-TO-CEILING luminaires are similar to pendants but are mounted close to the ceiling to allow use in rooms with conventional ceiling heights.

SCONCES are ornate or decorative wall-mounted luminaires. Often they match an adjacent chandelier; in other cases, they are the sole decorative lighting element. Sconces generally exhibit the widest range of styles, from crystal sconces with flame-tip lamps to modern designs.

LAMPS are traditional portable luminaires generally used for table or floor mounting. Torchères are floor lamps designed for uplighting. Most portable lighting uses incandescent or halogen sources, although compact fluorescent options should be considered for commercial and hospitality applications.

LANTERNS are outdoor luminaires mounted to ceilings, walls posts, or poles.

DECORATIVE LIGHTING RATINGS

Lanterns are generally rated with wet labels. Most other decorative fixtures are rated for dry indoor use, although a few sconces also have damp or wet labels.

James Robert Benya, PE, FIES, IALD, Pacific Lightworks; Portland, Oregon
Robert Sardinsky, Rising Sun Enterprises; Basalt, Colorado

ILLUMINATION CRITERIA

The lighting levels given are average figures:

1. Typical offices: 40-60 fc (400-600 lux) in an empty room.
2. Offices, mostly computer work: 20-40 fc (200-400 lux) in an empty room with task lighting as needed.
3. Offices, traditional paper tasks: 40-60 fc (400-600 lux) in an empty room with task lighting at work locations to provide 60-120 fc (600-1200 lux) for specific tasks.
4. Conference and meeting rooms: 30-50 fc (300-500 lux) in an empty room.
5. Lobbies and hallways: 10-20 fc (100-200 lux) in an empty room.

OTHER RECOMMENDED CRITERIA

VISUAL COMFORT PROBABILITY (VCP): This figure is only useful for comparing direct (troffer) lighting systems. A minimum of 70 is recommended. (Note that high VCP does not guarantee visual comfort.)

CCT and CRI: Correlated color temperatures (CCT) and the color rendering index (CRI) suitable for common office uses are shown in the accompanying table.

LIGHTING POWER DENSITY: Approximate design targets using T8 lamps and electronic high frequency ballasts (not including task lights) are shown in the accompanying table.

REFLECTED CEILING PLAN

NOTE

In this 10 x 10 ft office, two fixtures produce 50-60 fc on the work area at 1.18 watts/sq ft.

In small offices, maximize comfort and efficiency by having fixtures straddle the work area. Avoid placing a single overhead fixture. Partial symmetry is better than checkerboard or other asymmetrical layouts. Maintain approximately 2-3 ft from fixtures to side walls. Lensed fixtures and indirect lighting systems work best in small rooms.

SMALL OFFICE LIGHTING LAYOUT

REFLECTED CEILING PLAN

NOTE

In this 14 x 16 ft room, four two-lamp fixtures produce 25-35 fc uniformly at 1.08 watts/sq ft. If higher lighting levels are needed, as in a mailroom, use three-lamp fixtures. In meeting rooms, consider adding task lights such as downlights or wall-wash luminaires.

In larger offices and work rooms, arrange fixtures as symmetrically as possible. Vary the spacing if necessary, for example, from the standard 8 x 8 ft to 6 x 8 or 10 x 8 ft. Keep the long sides of fixtures within 2-3 ft of the wall.

LARGE OFFICE LIGHTING LAYOUT

James Robert Benya, PE, FIES, IALD, Pacific Lightworks; Portland, Oregon
Robert Sardinsky, Rising Sun Enterprises; Basalt, Colorado

DESIGN CONSIDERATIONS

LENSED SYSTEMS provide good basic light at the lowest cost, are the easiest to install, and tend to be the most efficient. Most are not suitable for computer work in large open rooms.

PARABOLIC LOUVERED SYSTEMS are more attractive and better for larger rooms where computer work is undertaken. Walls should not be too dark.

INDIRECT LIGHTING SYSTEMS, which provide a comfortable light, must be properly spaced to avoid light stripes on the ceiling. They require ceilings taller than 8 ft and generally require the use of task and/or accent lighting.

DIRECT/INDIRECT LIGHTING SYSTEMS must be properly spaced as well, but they offer a good balance between comfort and efficiency. They require ceilings taller than 8 ft and tend to be more complex and costly than other lighting systems.

Choose luminaires carefully, taking manufacturer's recommendations into account.

REFLECTED CEILING PLAN

NOTE

Using two lamps in every fixture, this layout produces 30-50 fc in an empty room at 1.22 watts/sq ft. Using one lamp, the design produces 15-30 fc at 0.6 watts/sq ft. The spacing between rows can be made wider. At 12 ft, the design delivers around 20-40 fc. Suspension length is critical.

LIGHTING CRITERIA FOR OFFICES

OFFICE TYPE	CCT ¹	CRI ²
Most office space	3500 or 4100K	>70 CRI
Executive office	3000 or 3500K	>70 CRI
Medical/dental office	3500 or 4100K	>80 CRI
Art/graphics, dental operatory	5000K	>90 CRI

LIGHTING POWER DENSITY

General office space	0.8-1.2 watts/sq ft
Executive office	1.1-1.4 watts/sq ft
Medical/dental office	1.0-1.8 watts/sq ft
Drafting/accounting space	1.4-2.0 watts/sq ft
Meeting rooms	1.0-1.6 watts/sq ft
Lobbies and hallways	0.4-0.8 watts/sq ft

¹CCT—correlated color temperature

²CRI—color rendering index

SUSPENDED INDIRECT AND DIRECT/INDIRECT SYSTEMS

REFLECTED CEILING PLAN

NOTE

This layout produces 30-50 fc in an empty room using two F32T8 lamps in a lensed or parabolic luminaire at 0.92 watts/sq ft. With three lamps, it produces 50-75 fc at 1.38

watts/sq ft. Increasing horizontal spacing to 10 ft with three lamps produces 40-60 fc at 1.22 watts/sq ft. Also consider 2 x 2 fixtures with two F32T8/U or four F17T8.

CORRIDOR LIGHTING

In office buildings, corridors require reasonably uniform illumination with minimum glare. Using ordinary troffers is tempting but generally creates too much light beneath the fixtures and not enough evenly distributed light.

Downlighting is easy but tends to create deep shadows and cave-like spaces. Mixing downlights and other lighting sources, such as sconces or wallwashers, creates a more attractive design with a better balance of brightness among walls, ceiling, and floor.

Wall lighting is an alternative to downlights and sconces for use in corridors. It enhances art and graphics and can reveal wall textures, such as those of stone and brick. Grazing lights can highlight polished or shiny surfaces such as granite or wood.

PLAN

NOTE

Fluorescent pendants and sconces produce general light. Compact fluorescent downlights and wallwashers and halogen art accent fixtures provide more specialized lighting that showcases the architecture and artwork and creates an atmosphere.

MAIN AND ELEVATOR LOBBIES

LOBBY LIGHTING

Lobbies offer a primary opportunity for use of creative or decorative lighting. Pendants, ceiling fixtures, and sconces are the primary lighting systems, supplemented by downlights, wallwashers, and other architectural light sources. To most easily meet energy code requirements, use fluorescent, compact fluorescent, and/or low wattage HID (high-intensity discharge) lamps instead of incandescent.

Main lobbies are a most important venue for ornamental and decorative lighting design. Wall lighting is especially useful for providing a sense of spaciousness and cheerfulness. Art objects such as paintings or sculpture may require accent lighting.

Architectural and decorative lighting sources are generally used in combination in lobbies. Incandescent and halogen lamps are often preferred for specific luminaire types, such as art display lights. However, whenever possible, use of more efficacious lighting sources such as fluorescent or HID fixtures is recommended.

LIGHTING FOR CONFERENCE AND MEETING ROOMS

A combination of lighting systems works best in meeting rooms. Uplights from sconces or pendants produce general, ambient light. Downlights illuminate the table. Wallwashers light presentation or art walls. Although the potential combined lighting power is high, preset control systems minimize simultaneous use.

NOTE

In this scheme, each round downlight uses 26 watts of compact fluorescent light (either two 13-watt lamps or one 28-watt lamp). Square downlights use two 16-18-watt

lamps. Designs produce 10-20 footcandles (fc) at 0.6-0.7 watts/sq ft.

NOTE

In this arrangement, sconce quantity can be minimized by maintaining a nominal 8-ft either-or spacing. Sconces and

downlights each have two 13-watt lamps or one 26-watt lamp. Designs produce 10-15 fc at 0.6-0.7 watts/sq ft.

NOTE

Although asymmetric, lighting one wall of a hall or corridor can both provide effective light and be an attractive element, potentially highlighting art or graphics. A wall slot (shown at left) is best for textured or polished surfaces and

creates a floating ceiling; wallwashers (right) are better for lighting art or graphics. While footcandles are about the same as in the two schemes above, power use increases to 1.2-1.5 watts/sq ft to illuminate vertical surfaces.

REFLECTED CEILING PLANS FOR CORRIDOR LIGHTING

AVERAGE CONFERENCE ROOM LIGHTING PLAN

NOTES

1. The lighting load total in this plan of 2.75 watts/sq ft (5.25 watts/sq ft for halogen lamps) is not often reached because, in most cases, not all fixtures are used simultaneously.
2. Wallwashers produce vertical illumination at 30 footcandles (fc) on one short wall, using about 5 watts/sq ft with fluorescent lamps and 1.5 watts/sq ft with halogen lamps.
3. Downlights produce direct light at 10-15 fc that is concentrated downward, usually onto the table surface in a conference room. Compact fluorescent fixtures require 0.5 watts/sq ft, while halogen fixtures require about 1.25 watts/sq ft. The ability to dim lights is a requirement for most conference rooms.
4. Sconces produce indirect light at approximately 10-15 footcandles. Compact fluorescent lamps require 1 watt/sq ft to light a room, while halogen lamps require 2.5 watts/sq ft.
5. Incandescent and halogen light sources are often used in board and other meeting rooms. When a building houses a number of conference rooms, it is best to use fluorescent sources to avoid overspending in the overall building energy budget.

James Robert Benya, PE, FIES, IALD, Pacific Lightworks; Portland, Oregon
Robert Sardinsky, Rising Sun Enterprises, Basalt, Colorado

SPECIAL LIGHTING ISSUES FOR OFFICES

Lighting for computer use, task lighting, and wall lighting are among the specialized lighting issues in office design.

COMPUTER LIGHTING

Lighting for computer workspaces is becoming increasingly specialized. There are four distinct approaches to this sort of design:

1. Parabolic troffers optimized for computer spaces: By meeting specific cutoff and distribution specifications, some parabolic and small-cell louvered direct lighting fixtures provide lighting acceptable for concentrated computer workspace applications. These lighting systems are generally fairly efficient but tend to create spaces with dark upper walls and ceilings.
2. Indirect suspended lighting: Indirect lighting systems that illuminate ceilings uniformly are also considered good for computer workspaces. General indirect lighting tends to be comfortable but bland. Supplemental task lighting is usually necessary.
3. Direct/indirect lighting: Some direct/indirect lighting systems have been optimized for illuminating computer workspaces, providing the advantages of the two lighting systems just described. The greatest disadvantage of these direct/indirect systems is cost.
4. Intensive CADD workspaces: CADD workspaces are the most demanding of all computer workspaces. Neither parabolic nor indirect lighting, even if optimized for computer workspaces, is acceptable. Task-only lighting systems or very low levels of general light are needed. The unusual requirements of these spaces are often resolved by creating a cave-like space and letting employees manipulate lighting levels and types with switches and dimmers.

TASK LIGHTING

For use under cabinets or shelves, continuous fluorescent task lights are generally the best choice. Good task lights offer the ability to dim or alter the distribution of light to minimize veiling reflections.

Table lamps and task lights produce localized task illumination using a portable luminaire. The area of influence is small but proper location can achieve a successful result. Use compact fluorescent lamps whenever possible.

WALL LIGHTING

Office spaces generally require supplemental wall lighting to compensate for the lack of wall lighting provided by most general lighting systems. Wall grazing and wallwashing are two methods used to accomplish this lighting task.

FINAL TOUCHES

Many offices are furnished with partition-style systems furniture. In this case, best results are obtained by coordinating lighting and furniture plans. Try to use fluorescent lamps of consistent color.

WALL SLOT LIGHTING

WALLWASHER LIGHTING

NOTE

A grazing light such as a wall slot is appropriate for illuminating interior core walls in open office spaces, but wallwashers or sconces can be used as well. Wall slot lighting accentuates the wall texture and enhances polished surfaces. Wallwashers accentuate wall pigment and work best for ordinary wall finishes with artwork hanging on them.

WALL LIGHTING

ILLUMINATION CRITERIA FOR COMMERCIAL SPACES

The lighting levels given are average figures for these commercial spaces:

1. Grocery store, general light: 70-90 footcandles (fc), or 700-900 lux, in an empty room, which will result in average center-of-aisle illumination of 50 fc.
2. Wholesale merchandise: 30-50 fc (300-500 lux) in an empty room with display lighting added as needed. For spaces with warehouse-style shelving, use 30-50 fc in aisles but take shelving into account.
3. General merchandise: 40-60 fc (400-600 lux) in an empty room with display lighting added at key locations to provide 70-100 fc (700-1000 lux) for secondary merchandise displays and 150-300 fc (1500-3000 lux) for primary displays.
4. Boutique and specialty retail stores: 20-30 fc (200-300 lux) in an empty room for general lighting. Display lighting is added throughout to provide 70-100 fc for most merchandise and 150-300 fc (1500-3000 lux) for primary displays.
5. Back-of-house storage and stock areas: 10-20 fc (100-200 lux) in an empty room.

OTHER RECOMMENDED CRITERIA

The correlated color temperature (CCT) and color rendering index (CRI) measurements for light can be used to help specify lighting fixtures:

Wholesale and grocery	3500 or 4100K > 70 CRI
Boutique/specialty	3000 or 3500K > 80 CRI
General merchandise	3500 or 4100K > 70 CRI
Jewelry, art	3000 or 5000K > 90 CRI

Lighting power density: Listed below are approximate design targets for whole stores, including back of house. These targets are based on HID (high-intensity discharge) systems of T8/compact fluorescent lamps and electronic high-frequency ballasts, including display lights.

Grocery	1.4-2.0 watts/sq ft
Wholesale	1.0-1.4 watts/sq ft
General merchandise	1.2-1.8 watts/sq ft
Department store	2.0-3.0 watts/sq ft
Specialty retail	1.8-3.5 watts/sq ft
Jewelry, china	2.5-4.5 watts/sq ft

DESIGN OPTIONS FOR GENERAL COMMERCIAL LIGHTING

FLUORESCENT STRIP LIGHTS AND LENS TROFFERS provide basic light for the lowest cost and are the easiest to install. They tend to be the most efficient, as well, but appear budget-minded.

HID INDUSTRIAL-STYLE FIXTURES also provide good basic light at low cost but appear budget-conscious. They can be used to create a warehouse motif in a retail outlet.

PARABOLIC LOUVERED SYSTEMS appear more expensive and suggest higher quality merchandise. They should be used in conjunction with valances and/or other perimeter and display lighting.

SUSPENDED DIRECT, DIRECT/INDIRECT, AND INDIRECT SYSTEMS require ceilings taller than 8 ft. These lighting types play a major role in the appearance and style of a space and are generally chosen to reinforce a specific marketing motif.

STRIP LIGHTS/STRIP TROUGH LIGHTS

INDUSTRIAL-STYLE LIGHTING

REFLECTED CEILING PLANS FOR WHOLESALE, GROCERY, AND MERCHANDISE STORES

TROFFER LIGHTING

NOTES

1. Strip lights and strip trough lights are common in large retail grocery stores and many mass merchandise stores. The layout illustrated (above left) produces 60-80 fc in an empty room using two F96T8 lamps in a strip light or open trough in continuous rows at 1.15 watts/sq ft. Lights usually run perpendicular to shelving to allow rearrangement, but parallel lighting is preferable when shelves are fixed.
2. Industrial-style lights are commonly used for lighting warehouse-style discount stores. The layout shown at left produces 30-40 fc in an empty room using one 100-watt metal halide lamp in an industrial-style luminaire at 0.85 watts/sq ft. Using a 150-watt metal halide lamp, the lighting level is about 40-60 fc at 1.27 watts/sq ft.
3. Troffers in lay-in ceilings are common in the discount retail industry and serve as general purpose lighting for hardware and general merchandise. The layout above produces 60-70 fc in an empty room using four F32T8 lamps in a lensed or parabolic luminaire at 1.15 watts/sq ft. With high light level ballasts, this arrangement produces 80-100 fc at 1.58 watts/sq ft.

James Robert Benya, PE, FIES, IALD, Pacific Lightworks; Portland, Oregon
Robert Sardinsky, Rising Sun Enterprises; Basalt, Colorado

DESIGN OPTIONS FOR DISPLAY LIGHTING

TRACK LIGHTING is the most popular and commonly used display lighting system. Use halogen, fluorescent, or high-intensity discharge (HID) display luminaires.

RECESSED DISPLAY LIGHTS are not as flexible as track lights but can be concealed better. This category includes adjustable accent lights and wallwashers. Sources include halogen, low-wattage HID, and compact fluorescent.

DISPLAY MONOPOINT LIGHTS are adjustable lights installed at fixed locations.

VALANCE LIGHTING is used for clothing and other displays in which a niche is created. Full-sized fluorescent lamps work best for the application.

DISPLAY CASE LIGHTING is similar to valance lighting except the light is built into the display cases to illuminate the task. Fluorescent, compact fluorescent, or low voltage incandescent or tungsten halogen lamps are used. Fiber-optic lighting systems may be useful in certain situations.

Among these options, track lighting offers the greatest versatility and the lowest installed cost. However, most energy codes count track light wattage by the foot rather than by the fixture. This makes it advisable to use other display lighting methods whenever possible so track lights can be used where really needed.

NOTE

The maximum angle of elevation for lighting is 45° except when walls are being lighted.

NOTE

Use wallwashers or accent lighting for walls and shelves, track lights or monopoints for floor displays, and valances in wall niches. Display case lighting is suitable for many applications, from jewelry cases to meat and produce counters.

TYPICAL DISPLAY LIGHTING

James Robert Benya, PE, FIES, IALD, Pacific Lightworks; Portland, Oregon
Robert Sardinsky, Rising Sun Enterprises; Basalt, Colorado

REFLECTED CEILING PLAN LAYOUT OF DISPLAY LIGHTING

DRESSING ROOMS

Good lighting helps sell clothing. For higher quality stores, provide attractive light with diffuse illumination of the customer; avoid downlights and track lighting. In lower cost and trendy stores, place the emphasis on fixture style and survivability.

STORE WINDOWS

Use high-wattage track lighting and/or low-voltage accent lighting. Run track vertically along the window sides, across

the top of the window, and possibly along the bottom of the window as well. Provide outlets for portable lighting inside the window.

OTHER SPECIFIC APPLICATIONS

Use high color rendering or special purpose fluorescent lamps for meat cases, fabrics, and similar demanding merchandise. For fine jewelry, consider high color rendering index, high color temperature fluorescent lamps and/or blue-filtered halogen lamps to achieve 4100-5000K.

DISPLAY LIGHTING FOR STORES

LIGHT SOURCE	ADVANTAGES	DISADVANTAGES	APPLICATIONS
Tungsten halogen (for greatest energy efficiency use halogen infrared reflecting [HIR] lamps)	Low cost, ready availability, excellent color, excellent beam control, dimmability, availability in wide range of sizes/wattages	Not energy-efficient, short lamp life	Recessed accent lights, track and monopoints, wallwashers of all types, portable lighting, low voltage lighting, showcase lighting, downlights
Full-size fluorescent lamps (primarily T8)	Low cost, ready availability, very good color, dimmability, energy efficiency, long lamp life	Very poor beam control, care required when used in cold environments	Valance lights, showcase lights, some types of wallwashers
Compact fluorescent (including high power T-5 twin tube)	Low cost, ready availability, very good color, dimmability, energy efficiency, long lamp life	Poor beam control, care required when used in cold environments	Wallwashers of all types, some types of floodlights, downlights
Compact hid (low-wattage metal halide and white high-pressure sodium are main choices)	Energy efficiency, very good beam control, long lamp life, good to very good color	High cost, not dimmable, limited range of sizes and wattages	Recessed accent lights, track and monopoints, wallwashers of all types, portable lighting, downlights

ILLUMINATION CRITERIA

The lighting levels given are average figures:

1. Classrooms with traditional paper tasks: 40-60 footcandles (400-600 lux) in an empty room.
2. Classrooms with mostly computer work: an average of 20-40 footcandles (200-400 lux) in an empty room with task lighting as needed.
3. Art, music, industrial, mechanics, and laboratory classrooms: 50-70 footcandles (500-700 lux) in an empty room, with task lighting as needed.
4. Lecture halls: 20-40 footcandles (fc) task illumination dimmable to 5 fc with cutoff for video/film presentation.
5. Hallways, commons (not including work spaces): 10-20 footcandles (100-200 lux) in an empty room.
6. Libraries: in active stacks, 20 footcandles minimum vertical illumination; for reading rooms, card files, and catalogs, 50-70 fc in an empty room; computer files and computer study/carrell areas, 20-40 fc in an empty room.
7. Gymnasiums: general illumination of 50 footcandles (500 lux) throughout; significantly higher levels may be required for high school or college sports that will be televised.
8. Typical administrative offices: 40-60 footcandles (400-600 lux) in an empty room.

OTHER RECOMMENDED CRITERIA

Visual comfort probability (VCP) is useful only for comparing direct (troffer) lighting systems. A minimum of 70 is recommended. (Note that a high VCP does not guarantee visual comfort.)

The correlated color temperature (CCT) and color rendering index (CRI) measurements for light can be used to help specify lighting fixtures:

Most classrooms	3500 or 4100K > 70 CRI
Commons, lunchrooms	3000 or 3500K > 70 CRI
Medical/dental classes	3500 or 4100K > 80 CRI
Art/graphics classes	4100-5000K > 80 CRI

Lighting power density: Listed are approximate design targets using T8 lamps and electronic high-frequency ballasts or high-intensity discharge (HID) systems (not including task lights):

Classrooms	0.8-1.2 W/sq ft
Lecture halls	1.2-2.0 W/sq ft
Arts and industrial education	1.2-1.8 W/sq ft
Gymnasiums (primary-secondary)	1.2-1.6 W/sq ft
Commons and hallways	0.4-0.8 W/sq ft

TROFFER SYSTEMS, lensed or parabolic, provide good, acceptable light at low cost and are commonly used in schools. Recessed lighting minimizes vandalism and is efficient.

SUSPENDED DIRECT/INDIRECT and INDIRECT SYSTEMS are favored for better lighting comfort and are suited for spaces with ceilings higher than 9 ft.

INDUSTRIAL-STYLE LIGHTING SYSTEMS are often used in industrial education, arts, gymnasium, and other spaces requiring plentiful, inexpensive, durable lighting. If using HID sources, provide quartz auxiliary lamps on some fixtures or an independent instant-on lighting system.

Choose luminaires carefully, considering manufacturer's recommendations.

DESIGN OPTIONS

More information about these lighting systems is available in the section on lighting for offices.

REFLECTED CEILING PLAN

NOTE

A layout with four F32T8 lamps and an electronic ballast in each suspended classroom fixture produces 40-50 fc in the seating area and 20-30 vertical fc on the chalkboard at 0.97

watts/sq ft. The direct/indirect fixtures are designed for traditional classrooms. An indirect lighting system might be used in a computer classroom.

SUSPENDED DIRECT/INDIRECT LIGHTING SYSTEMS

REFLECTED CEILING PLAN

NOTE

This layout, suitable for traditional classrooms, produces 50-60 fc in an empty room using three F32T8 lamps in a lensed or parabolic luminaire at 1.29 watts/sq ft. With a low

light level ballast, it can also produce 40-50 fc at 1.09 watts/sq ft.

For computer classrooms, use computer-optimized parabolics and dimming.

CLASSROOM WITH TROFFERS

16'-0" TO 22'-0"

REFLECTED CEILING PLAN

NOTE

In a 10,000 sq ft gymnasium, average lighting would be 40-50 footcandles at 0.95 watts/sq ft provided by 400-watt metal halide fixtures.

GYMNASIUM LIGHTING

James Robert Benya, PE, FIES, IALD, Pacific Lightworks; Portland, Oregon
Robert Sardinsky, Rising Sun Enterprises; Basalt, Colorado

DESIGN OPTIONS

INDUSTRIAL HID DOWNLIGHT SYSTEMS provide good acceptable light at low cost and thus are frequently used in industrial spaces. High-bay downlights are specifically suited for mounting heights greater than 20 ft. Low-bay downlights generally have lower wattage and are best for mounting heights less than 20 ft. Aluminum reflectors and prismatic glass or acrylic reflectors direct most light downward, although some light is directed upward in certain luminaires. Special aisle-lighters and other types are available.

REFLECTED CEILING PLAN

NOTE

A low-bay layout using HID lighting requires the fewest luminaires. HPS offers the longest lamp life and lowest maintenance costs. Metal halide lighting is preferred for visibility and color rendering.

HID LOW-BAY LAYOUT

ROWS SHOULD BE SPACED (X) UP TO ABOUT 1.5 TIMES THE MOUNTING HEIGHT WITH GAPS UP TO ABOUT 1.0 TIMES MOUNTING HEIGHT

REFLECTED CEILING PLAN

NOTE

Fluorescent luminaires offer superior color and flicker-free operation with electronic ballasts. No warmup time, instant striking, and long lamp life are other advantages of this lighting type.

FLUORESCENT LOW-BAY LAYOUT

FLUORESCENT SYSTEMS are useful for mounting heights up to about 20 ft. They require more fixtures than HID systems but provide more uniform light with softer shadows; use electronic ballasts to eliminate stroboscopy. Fluorescent systems make good task lights for work stations.

SPECIAL APPLICATION LUMINAIRES come in hundreds of different types, each optimized for a specific job, work station, environment, or hazard. Examples include explosion-proof, vapor-tight, and paint booth luminaires.

Choose luminaires for specific applications carefully, taking into account manufacturer recommendations.

ILLUMINATION CRITERIA

The lighting levels given are average figures:

1. Industrial manufacturing—general: 30-50 footcandles (300-500 lux) in an empty room with task lighting as needed.
2. Industrial manufacturing—assembly and rough inspection: 50-70 footcandles (500-700 lux) in an empty room.
3. Industrial manufacturing—fine assembly and moderate inspection: 50-70 footcandles (500-700 lux) in an empty room with task lighting as needed to achieve 100-200 footcandles (fc) depending on type of work.
4. Industrial manufacturing—specialized: refer to the IESNA Lighting Handbook.
5. Lunchrooms and break areas: 20-30 fc (200-300 lux) in an empty room.
6. Hallways and circulation areas (excluding work spaces): 10-20 footcandles (100-200 lux) in an empty room.
7. Warehouses: with high stacks, 20 footcandles minimum vertical illumination on stacks; for general use, 20-40 fc in an empty room.
8. Storage areas: general illumination of 5-10 footcandles (50 to 100 lux).

OTHER RECOMMENDED CRITERIA

ATMOSPHERE/ENVIRONMENT: The amount and type of dirt and other airborne particles present in an application can affect luminaire selection. For spaces where hazardous, corrosive, or explosive vapors or dust are present, special lighting equipment is generally required.

SAFETY: Backup quartz auxiliary lamps are needed for high intensity discharge (HID) systems. Where rotating machinery is used, take precautions to prevent stroboscopic problems by using fluorescent lighting systems or rotating phases of power.

CCT and CRI: Correlated color temperatures (CCT) and the color rendering index (CRI) suitable for industrial uses are listed here:

Heavy industry, storage	2100 to 5000K >20 CRI
Most industrial	3000 to 5000K >50 CRI
Most warehouse	2100 to 5000K >20 CRI
Precise assembly	4100 to 5000K >70 CRI

LIGHTING POWER DENSITY: Listed are approximate design targets using HID systems or T8 lamps and electronic high-frequency ballasts (not including task lights):

Warehouse	0.2-0.5 W/sq ft
Light industrial	0.8-1.2 W/sq ft
Precision industrial and inspection areas	1.2-1.8 W/sq ft
Storage areas	0.1-0.3 W/sq ft
Lunchrooms and hallways	0.6-1.0 W/sq ft

REFLECTED CEILING PLAN

NOTE

In the left aisle shown, two 250-watt HPS aisle lighter downlights illuminate the shelving units at 0.6 W/sq ft. In the right aisle, the task is performed by fluorescent F96T8/HO lamps at 0.5 W/sq ft. The fixture mounting height is about 18 ft above finished floor.

ACTIVE AISLE LIGHTING FOR WAREHOUSES

FLUORESCENT DOWNLIGHTING

HID DOWNLIGHTING

James Robert Benya, PE, FIES, IALD, Pacific Lightworks; Portland, Oregon
Robert Sardinsky, Rising Sun Enterprises; Basalt, Colorado

GENERAL

Outdoor lighting systems include a wide variety of lighting types used to illuminate buildings, parking areas, roads, landscapes, signs, and other outdoor areas.

STREET AND ROADWAY LIGHTING

Four significantly different lighting systems are used to illuminate roads and streets (and often large parking lots). All employ high-intensity discharge (HID) lamps:

1. Standard roadway lights, called cobraheads, are usually mounted to a mast arm and suspended over the roadway at mounting heights of 25-40 ft.
2. Sharp cutoff roadway lights, called shoeboxes, are specifically designed to minimize light pollution and trespass. They are typically mounted between 20 and 40 ft.
3. Traditionally shaped post lights often have a particular theme or design. They are usually less than 25 ft high.
4. High mast lights consist of multiple high-wattage lamps atop poles 60-120 ft high.

STREET AND ROADWAY LIGHTING

LAYOUT OF STREET AND PARKING LOT LIGHTING. Most luminaires for street and parking lighting are categorized according to the lighting patterns they create on the ground. Types I-V are described in the accompanying chart.

Computer point-by-point calculations are recommended. However, it is possible to lay out roadway and parking lot lighting using isolux curves (similar to those illustrated), making sure the overlapping footcandle lines achieve at least 25% of the intended average footcandle level.

AREA FLOODLIGHTING

Floodlighting is used to illuminate exterior fields, lots, yards, docks, and other similar areas. Special care is often needed to minimize light trespass and light pollution.

Floodlights are described by their light distribution. The National Electrical Manufacturers Association (NEMA) developed a system in which floodlight beams are measured in degrees of vertical and horizontal distribution, then rated from 1 (very narrow field angle) to 7 (very wide field angle).

GENERAL PURPOSE FLOODLIGHTS are usually made in rectangular boxes and typically have wide distributions (5V x 6H or 6V x 7H). Applications include work yards, general security and sports lighting, and building floodlighting. Lamps are usually HID from very low wattage (35 W) to 1,000 watts, but some floodlights use compact fluorescent and halogen lamps.

SPORTS LIGHTS are designed to throw narrow to medium wide beams (NEMA 2H x 2V to NEMA 4H x 4V). Most sports lights are round with standard 400-1500 watt HID lamps mounted in an axial position to create a round beam. Some advanced designs use special double-ended metal halide lamps (1500-2000 watts) for more precise optical control with less trespass.

James Robert Benya, PE, FIES, IALD, Pacific Lightworks; Portland, Oregon
 Robert Sardinsky, Rising Sun Enterprises; Basalt, Colorado
 Mark Rea, ed., IESNA Lighting Handbook (Illuminating Engineering Society of North America, 1993)

SHARP CUTOFF FLOODLIGHTS resemble shoebox parking lot luminaires with characteristics of Type IV distribution. These luminaires are designed to be elevated slightly in front to throw light farther. Sharp cutoff floods are especially good for car lots and sports lighting near residential districts where light trespass must be avoided.

LIGHT TRESPASS AND POLLUTION

LIGHT TRESPASS occurs when outdoor night lighting encroaches onto adjacent properties. Trespassing light is often annoying and can be quite offensive. Some cities have ordinances designed to prevent light trespass, although few of these are competently written.

LIGHT POLLUTION occurs when light is emitted upwards into the night sky. It both wastes energy and causes light pollution, a condition in which the upward light strikes dirt and airborne pollution and obscures the view of the night sky. Some municipalities and counties with important observatories have developed lighting ordinances that regulate light sources, cutoff, and hours of operation in an attempt to make astronomy more possible.

Both light trespass and light pollution can be minimized or prevented by using sharp cutoff equipment and careful design practices. For street and roadway lighting, this means using shoebox luminaires, including decorative luminaires that employ shoebox-style optics. For floodlighting, this means using sharp cutoff floodlights and special sports lights equipped with louvers and visors to prevent upward light. These high-performance lights require careful layout to meet design criteria.

LUMINAIRE FOR STREET AND PARKING LIGHTING

CATEGORY	USE
Type I 	Roads and streets where the luminaire is mounted in the median or suspended over the road center. Spacing is 6-7 MH.*
Type II 	Roads and streets where the luminaire is mounted above the road but to the side. Spacing is 5-6 MH.*
Type III 	Roads and streets where the luminaire is to the side and not above the road; also used for parking lots. Spacing is 4-5 MH.*
Type IV 	Parking lots and service areas requiring a forward throw distribution.
Type V 	Parking lots. Spacing is 3-4 MH.*

*MH—multiples of mounting height.

OTHER COMMON TYPES OF EXTERIOR LIGHTING

Exterior luminaires are designed specifically for many outdoor lighting applications. Some of the more common types are described in the accompanying chart.

Choose outdoor lighting with consideration for the elements and for the threat of vandalism or other damage. Some luminaires are composed of plastics or composite materials to resist damage and corrosion. Also keep in mind temperature extremes and the minimum starting temperatures of the lamp and ballast.

LIGHTING INFORMATION SOURCES

The best general purpose reference document for lighting information is the IESNA Lighting Handbook, published by the Illuminating Engineering Society of North America in New York. IESNA Recommended Practices provide in-depth information on specific applications, for example, office lighting, roadway lighting, and residential lighting.

Additional information on new and evolving lighting technologies is available from Advanced Lighting Guidelines, a publication of the U.S. Department of Energy from Battelle Pacific Northwest National Labs, and from Specifier Reports, published by the Lighting Research Center at Rensselaer Polytechnic Institute, Troy, New York.

Additional information on design and applications can be found in a number of textbooks on the subject of architectural lighting design, landscape lighting, and related topics. Popular lighting industry publications offering current projects and industry news include Lighting Design and Application, Architectural Lighting, Lighting Dimensions, and Architectural Record Lighting Supplement.

COMMON EXTERIOR LIGHTING TYPES

TYPE	USE
Bollards 	Walkway and pathway lighting. A typical bollard is 42-48 in. high and uses a lamp ranging from about 35-watt to 100-watt HID (high-intensity discharge).
Step lights 	Walkway and stairway lighting from adjacent retaining walls. The light is mounted at or below the rail height.
Well lights, direct burial lights 	Illumination of trees and structures from below. These are concealed uplights.
Landscape lights 	Includes a wide variety of low-level lights, such as path, planter bed, and wallwash lights and uplights in several styles. For residential landscapes, most lighting systems are low voltage (12V typically) for ease of wiring and safety.
Parking garage lights 	Parking garages. These are a unique type of HID luminaire designed specifically for the low concrete ceilings of garages. They typically are 100- to 175-watt fixtures.
Sign lights 	Illumination of signs. These are designed to be mounted below and in front of a sign and to illuminate upwards evenly.

ILLUMINATION CRITERIA

The lighting levels given here are average figures.

1. Parking lots with pedestrian cross-traffic: from 0.8 fc in places with low activity to 3.6 fc in places with a high level of activity; uniformity of 4:1.
2. Parking lots with minimum pedestrian cross-traffic: from 0.5 fc and uniformity of 4:1 in places of low activity to 2.0 fc with uniformity of 3:1 in places of high activity.
3. Sidewalks and bikeways: from 0.2 fc with 10:1 uniformity in residential areas to 1.0 fc with 4:1 uniformity in commercial areas.
4. Building entrances: from 1.0 fc near inactive entrances to 5.0 fc at active entrances.
5. Outdoor industrial areas: 0.2 fc for storage and dump areas; 2.0 to 5.0 fc for active loading, unloading, and rough work areas; 10 to 20 fc for work areas such as passenger loading, gas pumps, and railroad hump areas.
6. Outdoor sports: from 5 fc for recreational sport areas to 150 fc for major league baseball. Refer to the IESNA Lighting Handbook for more information.

OTHER RECOMMENDED CRITERIA

COLOR OF LIGHT: White light sources like metal halide, fluorescent, and compact fluorescent luminaires are recommended for sports, most applications involving pedestrians, and situations that require color discrimination. Light sources that provide poor color, such as high-pressure sodium fixtures, may be better suited for security lighting. Tungsten sources, including halogen fixtures, offer excellent color rendition but poor energy efficiency and short life.

SURVIVABILITY: Choose fixtures that are physically strong and resistant to vandals and the weather and environment.

STARTING AND OPERATING TEMPERATURE: Fixtures should be able to start and operate at the lowest expected temperature on a site. Minimum starting temperatures for common sources are shown in the accompanying table.

LIGHT TRESPASS: Minimize the light shining onto adjacent properties by using sharp cutoff lighting. Maximum mounting height for a fixture is a function of the cutoff angle.

LIGHT POLLUTION: Minimize light pollution by preventing stray upward light. Use cutoff luminaires.

DESIGN CONSIDERATIONS FOR PARKING AREAS

Poles between 12 ft and 40 ft high are most commonly used for parking areas because they provide good acceptable light at low cost. Pole spacing is generally about 4 times the mounting height; optimum pole heights are 15-20 ft for spacing along every aisle and 30-40 ft for spacing along every other aisle.

High mast poles higher than 40 ft (up to 100 ft) can be used to light large parking areas economically. Poles must be equipped with lowering devices for servicing luminaires.

Floodlights mounted onto buildings are often a low-cost alternative to mounting poles. To minimize light trespass, the farthest distance from the building to the edge of the lot or illuminated area is about 5 times the mounting height.

DESIGN FOR WALKWAYS

Walkways away from a building are usually illuminated by the parking lot lighting system. But near the building (or in areas like a park when there is no parking lot nearby) other lighting should be added. Consider these options:

1. Short "pedestrian" poles: similar to parking lot luminaires these poles are 8-15 ft high and use lower wattage lamps. Spacing is 4-6 times the mounting height.
 2. Low level "bollards": these are typically 42-48 in. high. Spacing is about 4 times the height of the bollards.
 3. Step lights recessed into retaining walls.
 4. Building-mounted wall brackets (wallpacks).
- Keep in mind the overhang of adjacent buildings. Canopies and soffits can serve as locations for recessed lighting to illuminate walks near the building foundation.

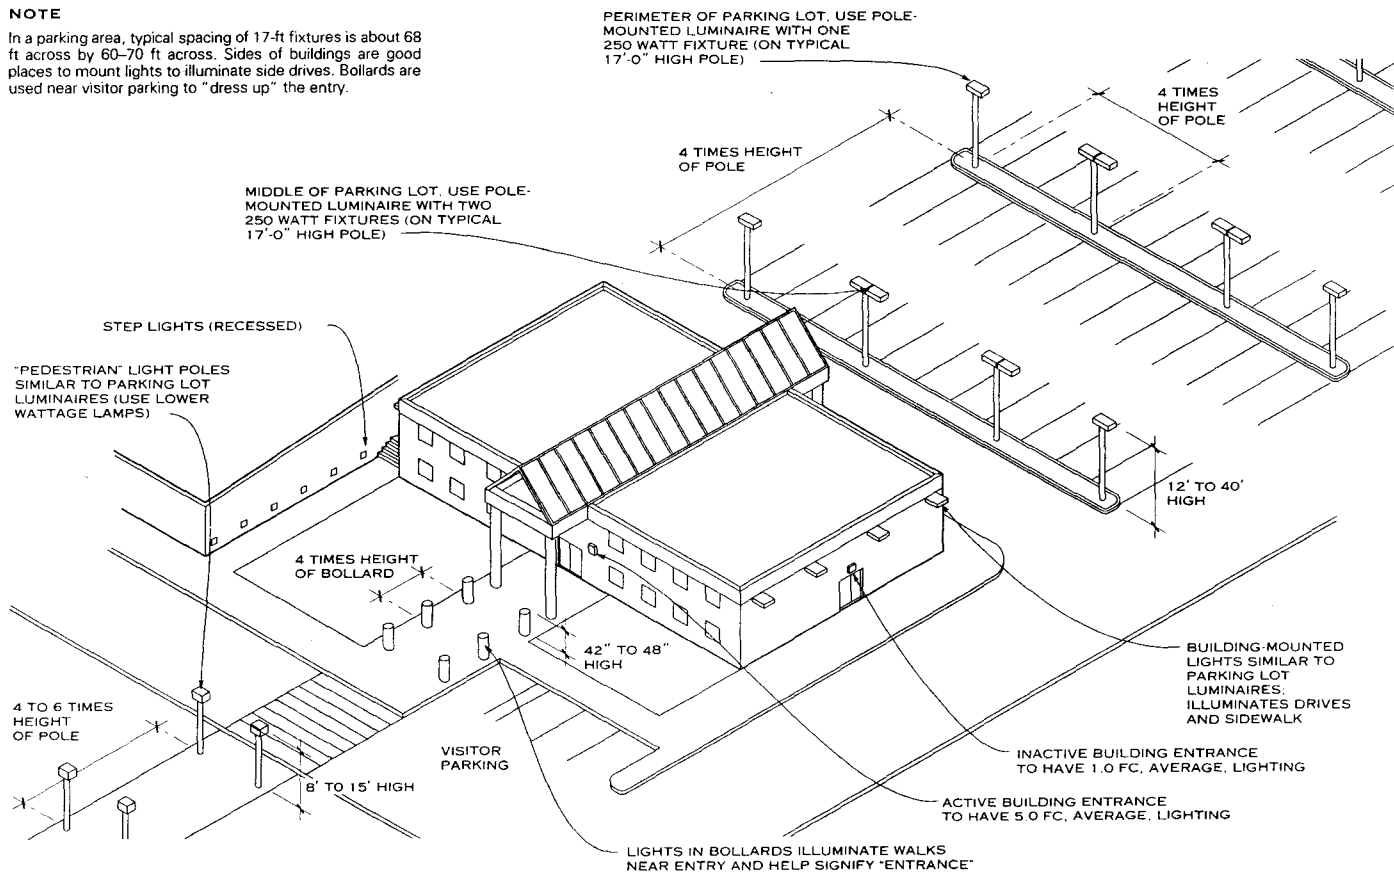

MINIMUM STARTING TEMPERATURES

COMMON LIGHT SOURCES	MINIMUM TEMPERATURE
Tungsten (incandescent, halogen)	No limit
MH, MV HID Lamps	-20°F
HPS lamps	-40°F
Fluorescent HO	-20°F
Fluorescent T12/T8	0°F*
Compact fluorescent amalgam (26-32-42 w)	-10°F*
Standard compact fluorescent	32°F

*These temperatures are with specific low temperature ballast; with standard ballast, the temperature may be as high as 50°F.

NOTE

In a parking area, typical spacing of 17-ft fixtures is about 68 ft across by 60-70 ft across. Sides of buildings are good places to mount lights to illuminate side drives. Bollards are used near visitor parking to "dress up" the entry.

DRIVES AND PARKING AREAS NEAR A BUILDING

James Robert Benya, PE, FIES, IALD, Pacific Lightworks; Portland, Oregon
 Robert Sardinsky, Rising Sun Enterprises; Basalt, Colorado

GENERAL

Ample daylight is available throughout most of North America for lighting interior spaces during a large portion of the working day. Daylight is often used for ambient lighting but may be used for critical visual tasks as well, in each case supplemented with electric light as needed. Daylight is thought by most to be psychologically desirable, and there is growing evidence that it is biologically beneficial and can contribute to enhanced task performance. The variability of the intensity and color of daylight over time stimulates the visual senses, and the view and visual connection with the outdoors that accompanies many daylighting designs is almost universally desired. Proper use of daylight can help reduce unnecessary energy use for electric lighting and cooling, if the electric lighting system is controlled with on-off switching or dimming.

DESIGN STRATEGIES

Daylight has always been an important element of architectural design, and in the era before cheap electric light it was often a major determinant of a building's form. In buildings today daylighting strategies are used in a variety of contexts, both as a strategy to define the quality of experience in an architectural space as well as in a more utilitarian role to reduce unneeded use of electric lighting.

Daylighting usually supplements or complements an electric lighting design, so it is essential that the two be fully integrated. For a given building program and climate, it may be feasible and desirable to create spaces in which the primary light source is daylight. In others, electric lighting will be the primary source, supplemented by daylight. The decision to make daylight the primary source will directly influence other design decisions such as the size of the floor plan, the arrangement of spaces within the floor plan, and the overall massing and configuration of the building. Designs intended to maximize daylight use will either provide perimeter access to each space or utilize low-rise designs that allow skylights to provide daylight. Atriums and light courts can provide some useful daylight in low-rise buildings of two to five stories. The best strategy for daylighting in high-rise buildings is to ensure that no spaces on the floor plan are more than 30 ft from a daylighting source.

DESIGN PROCESS

To be successful, daylighting requires the integration of all major building systems. Daylighting issues should be well defined in the programmatic or schematic phases of design and monitored through construction to occupancy. Early planning is essential, since it may be difficult and costly to add features later in design development. Many architects and lighting designers are skilled in resolving daylighting design issues and trade-offs. However, in designs that push the state of the art, present unusual conditions, or have quantitative performance expectations that must be met, it may be appropriate to use a daylighting consultant with expertise in many of the computer-based tools now available (see discussion below, Design and Analysis Tools).

Although critical design decisions related to plan and section will be determined early, many seemingly small decisions are made in the final stages of design and bid preparation that can influence the success of a daylighted space. These include issues such as interior finishes, furniture specifications, and installation details for controls. After construction is complete, most daylighting systems involving controls and operable systems should be calibrated and commissioned. The final step in the process is to ensure that facility managers and occupants understand the operation of the complete system.

LIGHT PATHS TO A WORK SPACE

Stephen Selkowitz; Lawrence Berkeley National Laboratory; Berkeley, California

SOURCE

The origin of all daylight is the sun but the light may reach a work space via a number of paths. Direct sunlight is intense and varies substantially as the sun's position changes throughout the day (up to 10,000 footcandles (fc)). Daylight from a clear sky can be 10 to 25% of the intensity of direct sunlight (1000-2500 fc). Daylight under partly cloudy conditions can be highly variable; daylight under full overcast conditions can be 5 to 10% of sun conditions (500-1000 fc). Data on daylight availability for various cities and building orientations can be found in several references. Daylight availability at locations in the United States is influenced by latitude and weather patterns. Traditionally overcast climates such as Seattle may have sunshine only 40% of the year while regions like Palm Springs, California, have sunny conditions for 90% of the year.

Exterior conditions (ground, trees, water, adjacent buildings) can all influence interior daylight levels. In some cases the architect can control these conditions to enhance daylight levels. Nearby trees will filter daylight and adjacent buildings may obstruct the view of the sky and block direct sun. In built-up urban environments, windows on lower floors of buildings adjacent to multistory buildings will receive little useful daylight. The south facade of a light-colored building that is struck by direct sunlight can become a very bright light source for the north facing windows of an adjacent building.

Orientation has a major impact on available daylight and influences the degree of difficulty in controlling sunlight on a facade. North orientations in most North American locations receive direct sunlight only in the early morning or late evening in summer. South facades have the longest exposure to direct sun. Given the high altitude angle of the sun in summer, sun control on the south facade is readily addressed with properly sized overhangs. In winter low altitude sun must be controlled by shades, blinds, or other means. Low altitude direct sun on east and west orientations causes glare and cooling problems and is the most difficult to control. Exterior vertical fins or interior vertical blinds provide control but allow some view.

Not only does the intensity of daylight and sunlight vary but the color or appearance varies as well. The characteristic yellow-white of direct sunlight becomes redder as the sun moves lower in the sky and travels through more air mass. The north sky on a clear day can be deep blue, a result of scattering processes in the atmosphere. Cloudy and hazy skies typically have a uniform white appearance. Daylight is a full-spectrum source that, notwithstanding its variability, will faithfully render the color of most materials, something that not all electric lamps can do. The sun and sky are powerful sources of ultraviolet light that can damage pigments in paintings and furnishings. Design in light sensitive applications such as museums must pay particular attention not only to the UV characteristics of daylight but also to the visible light portions, which are responsible for some fading. Certain glazing options will reduce these negative effects of light to acceptable levels.

ENVELOPE AND ROOM DESIGN

Building envelope and room design details can be thought of as the light fixture that controls the distribution of daylight in a space. Envelope decisions include the size, shape, and location of the fenestration and the type of glazing and shading system. Room geometry, size, and surface properties also influence achievable daylight levels.

There are practical limits to room size beyond which conventional window systems are ineffective. The depth limitation of a daylighted zone with windows becomes a fundamental constraint and design determinant. For designs that use diffuse daylight from the sky, clouds, or surrounding environment, it is difficult to provide adequate daylight when the depth of the space is more than 1.5 or 2 times the height of the head of the window. (Designs that redirect daylight and sunlight to the ceiling using light shelves or light redirecting glazings might be able to extend this to 3 times the ceiling height.)

DIFFUSE DAYLIGHT PENETRATION INTO A SPACE

REDIRECTED DAYLIGHT PENETRATION INTO A SPACE

A window of a given size will provide the most daylight deep in a space when it is located as high as possible on the wall. Light-colored walls and ceilings maximize the daylight levels in the rear of a space. Deeper spaces need larger windows to provide more light but larger windows have other drawbacks. The uniformity ratio between the daylight level in the front and back of a room becomes larger as the room becomes deeper and should not exceed a ratio of 10:1. A splayed window reveal will reduce glare and ease the transition from bright exterior to darker interior. Sloped ceiling surfaces may improve daylight utilization but their biggest benefit is typically the greater ceiling height at the perimeter. Interior walls and partitions will reduce daylight levels. Use of light colors or glazed interior partition walls will help mitigate this undesired impact.

Distribution of daylight in a space can be greatly improved if it is introduced from multiple apertures—for example, windows on two sides of a space, or windows and clerestories, or windows and skylights. In low-rise buildings, diffusing skylights are an effective way to daylight a space. The skylights are diffusing and their spacing is optimized based on ceiling height. More elaborate toplighting systems can utilize a variety of roof monitors or clerestories.

RELATIVE INDICATOR OF LIGHT LEVELS WITH VARIOUS DESIGNS

LIGHT LEVELS WITH SKYLIGHTS

TOPLIGHTING SYSTEM TYPES

GLAZING AND SHADING DESIGN

Selection of a glazing system can have a tremendous impact on the performance of a daylighting system. The glazing controls the amount of light admitted, its intensity, and its directionality as it enters a space. The challenge is to admit adequate light to achieve illumination objectives without creating glare or causing overheating or large cooling loads. Numerous glazing systems are available to control solar gain and the transmittance, distribution, and color of light. Conventional clear and tinted glazings are still offered but low-E coated glass or plastic and spectrally selective low-E glazings are becoming more popular. These glazings reduce winter heat loss and reduce cooling load in summer with little additional loss of daylight. They are excellent for admitting daylight but glare control must be provided with shading systems. In an insulating glass unit, both low-E and tinted glazings can be used to optimize performance. Highly reflective glass with very low transmittance has a role in highly glazed facades with limited sun control options, but occupants complain about poor views through these glazings on overcast days or at night. Glazings with a frit layer provide some sun and glare control.

Some new options available to designers promise greater optical control capability. Prismatic glazings can redirect light, and between-glass elements can provide varying degrees of light control and solar control.

Adequate control of sun and glare is often difficult to provide with glazing selection alone. Architectural shading solutions are typically part of the exterior facade. Other shading devices can be positioned outside the glazing, between glazings, or at the interior surface. Shading systems can be static or operable, controlled either by occupants or with motorized, automated controls. Shading systems that are intended to block sunlight alone can be dark, but light-colored systems should be used if the intent is to provide diffuse daylight. Overhangs, fins, shade screens, venetian blinds, vertical blinds, miniature louvers, and roller shades are commonly used systems. Operable systems are often preferred because they can take advantage of the variability of sunlight and daylight. In open plan offices it may be desirable to use motorized, automated shading controls; in single-person offices it is likely that the occupant will use the shading controls as needed.

WINDOW SHADING DEVICES

New types of light redirecting systems such as prismatic glazings provide shading at a task location by redirecting the sunlight to the ceiling. Light shelves can also provide shading as well as some control of daylight levels and light distribution. Simple, flat light shelves with white, diffuse surfaces will provide some shading near the window and brighten the ceiling near the window but will not redirect light deep into a room. The size, shape, location, and surface properties of light shelves will have a significant influence on their ability to redistribute light in a space.

SHADING DEVICES NEAR GLAZING SURFACE

SKYLIGHTS AND SLOPED GLAZING

Light distribution from skylights is intrinsically more uniform than that from windows. Skylight solutions range from simple vacuum-formed plastic domes to sophisticated, multi-layer glazing products. Skylights in work areas with office tasks should provide diffuse light so that its distribution is relatively uniform. Nondiffusing glazings will result in visual hot spots and glare. Light diffusion can be achieved by using diffusing plastic bubble skylights, high transmission glazing with a diffusion screen below, some of the fritted glasses or laminates with diffusing layers, or exterior shading systems. Light wells provide a transition from the roof plane to the lower ceiling plane or the space below. The geometry and surface properties of the wells determine the total light loss. Light wells can reduce the amount of light entering a space from as little as 10% to as much as 85%. Splayed wells with high reflectance finishes are the best performers. Adequate daylight in most climates is provided with skylight areas of about 4 to 8% with relatively high transmittance glazing. Larger areas with proportionally lower transmittance will work as well. A completely glazed roof or sloped glazing may be used but the transmittance of the glazing should be about 5%. The importance of controlling heat gain depends in part on the occupancy of the space and the climate. In most skylight and sloped glazing designs, safety codes require laminated glass or alternative safety solutions; consult code authorities or manufacturers.

DAYLIGHT DISTRIBUTION WITH SKYLIGHT TYPES

LIGHT WELL DESIGN

ELECTRIC LIGHTING INTEGRATION AND CONTROLS

Because people respond to the overall luminous environment, it is important that electric lighting and daylighting be designed and specified as a well-integrated system. The

overall lighting concept includes the controls used to manage the electric lighting system. Many designers believe that an indirect lighting system that illuminates the ceiling and wall surface is a better complement to a daylighted space than a direct lighting system. Such an indirect ambient system might be used with task lights to produce higher illuminance levels where needed. Electric lighting sources may be chosen for their compatibility with color temperature in a daylighted space, their ability to dim, and the ability to quickly restart if switched off.

A well-daylighted space will only save energy if lighting controls are used to turn off or dim electric lighting. For most systems the control options are on-off switching, multilevel switching, or dimming. Dimming is the preferred strategy because it changes light levels smoothly, often making changes in electric light levels unnoticeable in the space. Daylighting controls may also be combined with other forms of lighting control to achieve even greater energy savings. To guarantee energy and cost savings, automatic controls are preferable to manual controls, although occupants should be able to override any automatic system. Switching or dimming systems must be designed with care to capture daylighting savings. The layout of circuits for fixtures must be coordinated with the pattern of available daylight. These zoning issues are more important in open plan spaces than in perimeter single offices. Photocell sensors in automatic control systems must be properly located in the space, and the entire control system must be calibrated after installation. A users' manual for occupants is recommended.

TOTAL BUILDING ENERGY CONSUMPTION

Final daylighting design decisions must account for the interaction of other systems, such as heating and cooling impacts of the glazing and the cooling impacts of electric lighting use. Although the specifics vary with climate and other building design and operation details, the general trend of the lighting-HVAC trade-off is well known. It is useful to estimate the energy savings as a function of "effective aperture" (EA), defined as the fraction of the wall that is glazed (window-to-wall ratios, or WWR) times the visible transmittance (Tv) of the glazing system. An EA of .35 or greater is adequate to provide large daylighting savings; higher levels increase cooling loads with only minimal additional lighting energy savings. Optimal EA values for skylights are even smaller; an EA of .05 provides substantial energy savings.

DESIGN AND ANALYSIS TOOLS

Since many critical architectural decisions that affect daylighting solutions occur early in the design process, it is essential that the design consequences of those decisions be predictable. It is also important that the design intent of a daylighting solution be communicated to all members of the design team so that decisions made later in the process will support and reinforce the original intent. Relatively simple changes late in the process, ranging from a change in paint color to improper sensor position, can have a significant impact on the success of a daylighting plan. However, a number of tools are available to help predict the performance of a daylighting system.

Physical Scale Models: Since lighting scales perfectly, daylighting levels in a small-scale model placed outdoors will be the same as the full-size building space (assuming the model faithfully reproduces all of the parameters that influence light levels, such as geometry and surface reflectances). It is important to account for the effects of partitions and furnishings, which can significantly influence light levels. The continuous variability of the outdoor sky also must be accounted for when trying to compare results of successive measurements. One alternative is to use simultaneous measurements in side-by-side models. In all model measurements, care must be exercised in construction details, and accurate light measurement equipment must be used.

Software: Computer-based tools are increasingly used to estimate daylight levels and their impacts. Some calculate lighting and daylighting quantities only; others calculate daylighting as part of a complete building systems energy analysis. The most sophisticated lighting tools are linked to CAD software. They use either radiosity or raytracing techniques to produce photorealistic images that are not only quantitatively accurate but also assist the designer in understanding the qualitative aspects of daylighting design under a variety of sun and sky conditions. Some whole building energy simulation tools also model daylighting impacts. Those that can account for the hourly operational characteristics of light sensors and shading device operation can assist with understanding the lighting and thermal trade-offs involved in developing efficient building designs.

Stephen Selkowitz; Lawrence Berkeley National Laboratory; Berkeley, California

GENERAL

Sound is energy produced by a vibrating object or surface and transmitted as a wave through an elastic medium. Such a medium may be air (airborne sound) or any solid common building material, such as steel, concrete, wood, piping, gypsum board, etc. (structure-borne sound). A sound wave has amplitude and frequency.

The amplitude of sound waves is measured in decibels (dB). The decibel scale is a logarithmic scale based on the logarithm of the ratio of a sound pressure to a reference sound pressure (the threshold of audibility). The values of a logarithmic scale, such as the decibel levels of two noise sources, cannot be added directly. Instead, use the simplified method described in the table immediately below.

Difference between sound levels (in dB)	0-1	2-3	4-9	>10
Add this number to higher sound level	3	2	1	0

For example, 90 dB + 20 dB = 90 dB; 60 dB + 60 dB = 63 dB.

The frequency of sound waves is measured in Hertz (Hz, also known as cycles per second) and grouped into octaves (an octave band is labeled by its geometric center frequency). An octave band covers the range from one frequency (Hz) to twice that frequency (f to 2f). The range of human hearing covers the frequencies from 20 to 16,000 Hz. Human hearing is most acute in the 1000 to 4000 Hz octave bands.

The human ear discriminates against low frequencies in a manner matched by the A-weighting filter of a sound level meter, measured in dBA, or A-weighted decibels. This is the most universally accepted single number rating for human response to sound.

SOUND AND FREQUENCY

FREQUENCY

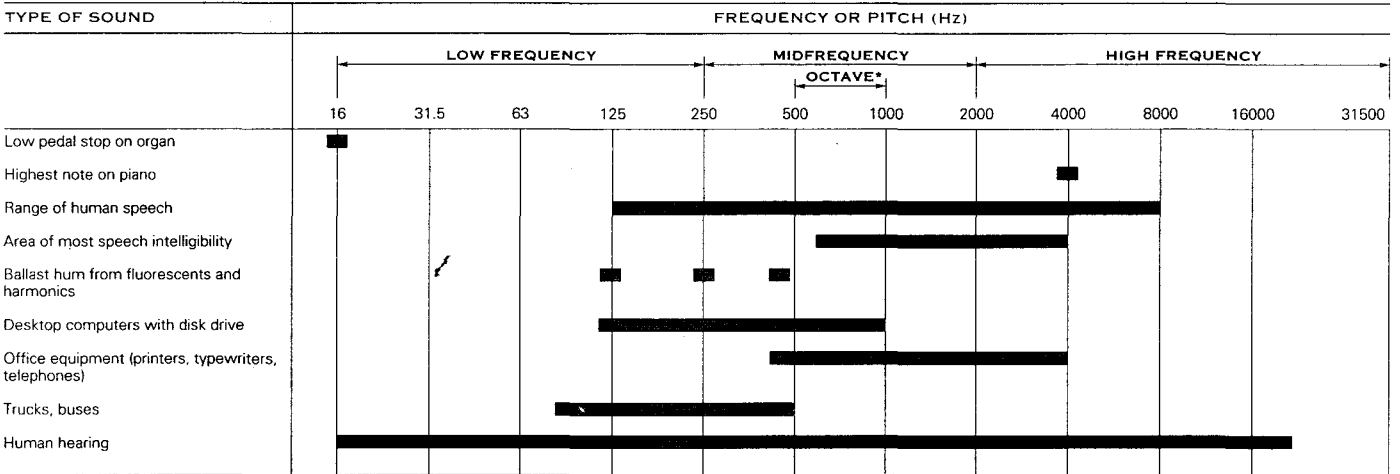

RANGE OF OCTAVE (Hz)	OCTAVE BAND CENTER FREQUENCY (Hz)
22-44	31.5
44-88	63
88-175	125
175-350	250
350-700	500
700-1400	1000
1400-2800	2000
2800-5600	4000
5600-11,200	8000

SUBJECTIVE REACTIONS TO CHANGE IN SOUND LEVEL

CHANGE IN SOUND LEVEL*	CHANGE IN APPARENT LOUDNESS
1 to 2	Imperceptible
3	Barely perceptible
5 or 6	Clearly noticeable
10	Significant change—twice as loud (or half as loud)
20	Dramatic change—four times as loud (or a quarter as loud)

*Measured in decibels (plus or minus)

FREQUENCY OF COMMON SOUNDS

*Octave—a frequency ratio of 2:1

TYPICAL SOUND LEVELS

SOUND LEVEL (dBA)	SUBJECTIVE EVALUATIONS	ENVIRONMENT	
		OUTDOOR	INDOOR
140	Deafening	Near jet engine and artillery fire	—
130	Threshold of pain	Jet aircraft departure (within 500 ft)	—
120	Threshold of feeling	Elevated train	Hard-rock band
110		Jet flyover at 1000 ft	Inside propeller plane
100	Very loud	Power mower, motorcycle at 25 ft, auto horn at 10 ft	Crowd noise in arena
90		Propeller plane flyover at 1000 ft, noisy urban street	Full symphony or band, food blender, noisy factory
80	Moderately loud	Diesel truck at 40 mph at 50 ft	Inside auto at high speed, garbage disposal, dishwasher
70	Loud	Heavy urban traffic	Face-to-face conversation, vacuum cleaner, electric typewriter
60	Moderate	Air-conditioning condenser at 15 ft, near freeway auto traffic	General office
50	Quiet	Large transformer at 100 ft	Large public lobby, atrium
40		Bird calls	Private office, soft radio music in apartment
30	Very quiet	Quiet residential neighborhood	Bedroom, average residence without stereo
20		Rustling leaves	Quiet theater, whisper
10	Just audible	Still night in rural area	Recording studio
0	Threshold of hearing	—	—

Carl Rosenberg, AIA; Acentech, Inc.; Cambridge, Massachusetts

GENERAL

All materials and surfaces absorb some sound greater than 0% and less than 100%. The percentage of incident sound energy that is absorbed by a material, divided by 100, equals the coefficient of absorption, designated α , which ranges from 0 to .99. The coefficient varies as a function of frequency, Hz.

Any material can be tested in a proper laboratory to determine its α values, as per ASTM C423. Some tests give values greater than 1.0, but this is an anomaly caused by the testing procedure; such values should be corrected to be not more than 1.0, since no material can absorb more than 100% of the incident energy that strikes its surface.

SOUND ENERGY ABSORPTION MECHANISMS

There are three mechanisms by which sound energy is absorbed or dissipated as it strikes a surface. In all cases, sound energy is converted to heat, although never enough heat to be felt.

POROUS ABSORPTION entails the use of soft, porous, "fuzzy" materials like glass fiber, mineral wool, and carpet. The pressure fluctuations of a sound wave in air cause the fibers of such materials to move, and the friction of the fibers dissipates the sound energy.

TYPICAL VALUES FOR POROUS ABSORPTION

PANEL ABSORPTION involves installation of thin light-weight panels like gypsum board, glass, and plywood. Sound waves cause panels to vibrate. Sound absorption for a panel is greatest at that resonant frequency.

TYPICAL VALUES FOR PANEL ABSORPTION

CAVITY ABSORPTION entails the movement of air pressure fluctuations across the narrow neck of an enclosed air cavity, such as a space behind a perforated panel or a slotted concrete masonry unit, also called a Helmholtz resonator. The natural frequency at which the resonator most efficiently absorbs sound is related to the volume of the cavity, the size of the neck opening, and the presence of any insulation in the cavity.

NOISE REDUCTION COEFFICIENT

The noise reduction coefficient (NRC) is the arithmetic average of the absorption coefficients, α , at four designated frequencies: 250 Hz, 500 Hz, 1,000 Hz, and 2,000 Hz. These frequencies have been selected because they represent the middle range of most representative sound sources pertinent to architectural applications. Because the NRC value is meant to be only a general indication of a material's efficiency at absorbing sound, it is rounded off to the nearest .05 value and often represented as a .10 range (for example, .50 to .60). NRC ratings can never be less than 0 or greater than 1.00. The following formula can be used to compute the NRC for a particular application:

$$NRC = (\alpha_{250} + \alpha_{500} + \alpha_{1000} + \alpha_{2000})/4$$

SAMPLE DERIVATION OF NRC

SOUND-ABSORBING COEFFICIENTS FOR VARIOUS MATERIALS

The sound-absorbing coefficients for a given material may vary depending on the thickness of the material, how it is supported or mounted, the depth of the air space behind the material, and the facing in front of the material. In general, thicker porous materials absorb more sound; the air space behind a material will increase the absorption efficiency, especially at low frequencies; and thin facings degrade high frequency absorption.

MOUNTING ASSEMBLIES

For consistency in comparing test results, there are set standards for the mounting assembly used in testing absorbent materials. These mounting conditions should be reported along with any and all test data so that the data accurately reflect field conditions. Mounting types A, D, and E are typical for standard sound-absorbing materials. A numerical suffix is used to specify the mounting depth in millimeters; for example, E-400 indicates mounting type E with a 400 mm airspace (a typical 16 in. plenum). Mounting types are specified by ASTM E795.

SOUND-ABSORBING COEFFICIENTS FOR VARIOUS MATERIALS

TYPICAL DATA/MATERIAL	125 Hz	250 Hz	500 Hz	1000 Hz	2000 Hz	4000 Hz	NRC
Marble	.01	.01	.01	.01	.02	.02	.00
Gypsum board, 1/2 in.	.29	.10	.05	.04	.07	.09	.05
Wood, 1 in. thick, with air space behind	.19	.14	.09	.06	.06	.05	.10
Heavy carpet on concrete	.02	.06	.14	.37	.60	.65	.30
Acoustical tile, surface-mounted	.34	.28	.45	.66	.74	.77	.55
Acoustical tile, suspended	.43	.38	.53	.77	.87	.77	.65
Acoustical tile, painted (est.)	.35	.35	.45	.50	.50	.45	.45
Audience area, empty, hard seats	.15	.19	.22	.39	.38	.30	.30
Audience area, occupied, upholstered seats	.39	.57	.80	.94	.92	.87	.80
Glass fiber, 1 in.	.04	.21	.73	.99	.99	.90	.75
Glass fiber, 4 in.	.77	.99	.99	.99	.99	.99	.95
Thin fabric, stretched tight to wall	.03	.04	.11	.17	.24	.35	.15
Thick fabric, bunched 4 in. from wall	.14	.35	.55	.72	.70	.65	.60

NOTE

TYPICAL MOUNTING TYPES ACOUSTICAL PERFORMANCE PER MOUNTING ASSEMBLY

NOTE

Acoustical performance varies with mounting assembly and facing.

or extrapolate from similar constructions. All materials have some absorption values that can be determined from proper test reports.

Carl Rosenberg, AIA; Acentech, Inc.; Cambridge, Massachusetts

GENERAL

The total sound absorbing units (a) provided by a given material are a function of the absorptive properties (α) and surface area (S) of that material as defined by the formula

$$a = S\alpha$$

in which a = sabins (units of sound absorption), S = surface area (measured in sq m or sq ft), and α = the coefficient of absorption.

The total sabins in a room can be determined by adding together the sabins of all the surfaces, which vary as a function of frequency. Since most materials absorb more high-frequency sound waves than low-frequency ones, it is typical to find more sabins in a room at high frequencies than at low frequencies.

In general, sound energy that is not absorbed will be reflected, thus surfaces with low coefficients of absorption can be used to encourage sound reflection when appropriate.

PROPERTIES OF SOUND

The sound properties distance and time are described here:

DISTANCE

Outdoors, sound drops off 6 dB each time the distance from a source is doubled (Inverse Square Law). Indoors, the reflecting sound energy in a room reaches a constant level as a function of the sound absorbing units (sabins) in the room. The noise level in a room can be reduced by adding more absorption, as shown in this formula:

$$\text{Noise reduction (NR)} = 10 \log a_2/a_1$$

TIME

Outdoors, sound ceases when the source stops. Indoors, sound energy lingers and this decay is called reverberation. The reverberation time (RT) is defined as the length of time, in seconds, it takes for sound to decay by 60 dB. Reverberation time is directly proportional to the volume of a space and inversely proportional to the units of absorption (sabins) in it, as expressed in this formula

$$RT = KV/a$$

in which RT = reverberation time in seconds, K = .161 (if volume is in m³) or .049 (if volume is in cu ft), V = volume in m³ or cu ft, and a = total absorption in sabins (metric or English units).

Shorter reverberation times greatly enhance speech intelligibility and are imperative in listening environments for people with hearing impairments and for rooms with live microphones for teleconferencing.

SOUND ABSORPTION

Sound-absorptive materials (such as acoustic tile, glass fiber, wall panels, carpet, curtains, etc.) can be added to a room in order to control or reduce noise levels or shorten reverberation time. Noise control is especially helpful when the noise sources are distributed around a room, as in a gymnasium, classroom, or cafeteria.

While sound-absorptive materials can be added to any surface in a room, the greatest area available for coverage is usually the ceiling. Because many soft porous materials are fragile, they should not be located on surfaces that are susceptible to abuse. For these reasons, sound-absorptive materials are often installed on ceilings.

See the accompanying chart for guidelines on the use of sound absorption treatments.

GUIDELINES FOR USE OF SOUND ABSORPTION

ROOM TYPE	TREATMENT
Classrooms, corridors and lobbies, patient rooms, laboratories, shops, factories, libraries, private and open plan offices, restaurants	Ceiling or equivalent area; add additional wall treatment if room is quite high
Boardrooms, teleconferencing rooms, gymnasiums, arenas, recreational spaces, meeting and conference rooms	Ceiling or equivalent area; add wall treatments for further noise reduction and reverberation control and eliminate flutter or echo
Auditoriums, churches, etc. (list)	Special considerations and complex applications

SOUND OVER DISTANCE

NOTE

The more sound absorption (sabins) inside a room, the lower the noise levels (approaching the drop-off with distance outdoors).

PROPERTIES OF SOUND

AVERAGE COEFFICIENT OF ABSORPTION

One measure of the quality of sound in a room is the average coefficient of absorption (or average noise reduction coefficient-NRC) for all surfaces combined, as determined by this formula:

$$\bar{\alpha} = a/S$$

in which $\bar{\alpha}$ = the average coefficient (at a given frequency or average NRC), a = the total sabins (sound absorbing units), and S = the total surface area in the room (metric or English units; be consistent).

As determined by using the average coefficient of absorption, the quality of sound in a room can be evaluated as .1, .2, or .3. A room with an average coefficient of .1 is rather "live," loud, and uncomfortably noisy; one with an average coefficient of .2 is comfortable, with well-controlled noise; and one with .3 is rather "dead," suitable for spaces in which the emphasis will be on amplified sound, electronic playback, or a live microphone for teleconferencing.

CALCULATION OF AVERAGE COEFFICIENT OF ABSORPTION

(Sample at 1000 Hz)

The volume of this sample room is 9000 cu ft (l x w x h).

SAMPLE CALCULATION 1

SURFACE	MATERIAL	AREA (SQ FT)	α	a
Floor	Carpet	600 sq ft	.37	222
Ceiling	Gypsum board	600 sq ft	.01	6
All 4 walls	Gypsum board	1500 sq ft	.01	15
Total	—	2700 sq ft	—	243

The reverberation time for the sample room with a gypsum board ceiling is calculated as follows:

$$RT = .049V/a = .049 \times 9000 \text{ cu ft}/243 = 1.8 \text{ sec}$$

SAMPLE CALCULATION 2

SURFACE	MATERIAL	AREA (SQ FT)	α	a
Floor	Carpet	600 sq ft	.37	222
Ceiling	Acoustical tile	600 sq ft	.77	462
All 4 walls	Gypsum board	1500 sq ft	.01	15
Total	—	2700 sq ft	—	699

SOUND OVER TIME

NOTE

The more sound absorption (sabins) inside a room, the shorter the reverberation time.

The reverberation time for the sample room with an acoustical tile ceiling is calculated as follows:

$$RT = .049V/a = .049 \times 9000 \text{ cu ft}/699 = .63 \text{ sec}$$

The average coefficient of absorption ($\bar{\alpha}$) in the sample room changes significantly from sample 1 to sample 2. The room with a gypsum board ceiling is rather live and noisy, while the room with an acoustical tile ceiling is comfortable, with well-controlled noise. The calculations that show this follow:

Before: $\bar{\alpha} = a/S = 243/2700 = .09$
 After: $\bar{\alpha} = a/S = 699/2700 = .26$

INDOORS

NOTE

Outdoors, sound waves expand spherically, becoming more dispersed (i.e., quieter) over distance and time. Indoors, sound waves reflect off surrounding surfaces, building up energy so sound drops off less quickly over distance or time.

SOUND PATTERNS

Carl Rosenberg, AIA; Acentech, Inc.; Cambridge, Massachusetts

GENERAL

The property of a material or construction system that blocks the transfer of sound energy from one side to another is transmission loss (TL), which is measured in decibels (dB). Specifically, TL is the attenuation of airborne sound transmission through a construction during laboratory testing according to ASTM E90. Transmission loss values range from 0 to 70 or 80 (or higher). A high TL value indicates a better ability to block sound; that is, more sound energy is "lost" as the sound wave travels through the material.

Sound transmission class (STC) is a single number rating system designed to combine TL values from many frequencies. STC values for site-built construction range from 10 (practically no isolation, e.g., an open doorway) to 65 or 70 (such high performance is only achieved with special construction techniques). Average construction might provide noise reduction in the range of STC 30 to 60.

It is very difficult to measure the STC performance of a single wall or door in the field because of the number of flanking paths and nonstandard conditions. Field performance is measured with noise isolation class (NIC) ratings, which cover effects from all sound transfer paths between rooms.

DERIVATION AND USE OF THE STC CURVE

To determine the STC rating for a particular construction, the STC curve shown in the accompanying figure is applied over the transmission loss (TL) curve for a laboratory test of the construction. The STC curve is then manipulated in accordance with prescribed rules to obtain the highest possible rating. The procedure states that the TL curve cannot be more than 8 dB less than the STC curve in any one-third octave band, nor can the TL curve be more than a total of 32 dB less than the STC curve (average of 2 dB for each of 16 one-third octave band frequencies). Any values from the TL curve that are above the STC curve are of no benefit in the rating. The object is to move the STC curve up as high as possible and to read the STC rating number from the point where the STC curve at 500 Hz crosses the TL curve.

The STC curve has three segments: the first segment, from 125 to 400 Hz, rises at the rate of 9 dB per octave (3 dB per one-third octave); the second segment, from 400 to 1250 Hz, rises at the rate of 2 dB per octave (1 dB per one-third octave); and the third segment, from 1250 to 4000 Hz, flat.

TRANSMISSION LOSS

Design of construction and materials for high transmission loss builds on three principles:

MASS: Lightweight materials do not block sound. Sound transmission through walls, floors, and ceilings varies with the frequency of sound, the weight (or mass) and stiffness of the construction, and the cavity absorption. Theoretically, the transmission loss increases at the rate of 6 dB per doubling of the surface weight of the construction. A single solid panel behaves less well than the mass law would predict, since the mass law assumes a homogeneous, infinitely resilient material/wall.

SEPARATION: Improved TL performance without an undue increase in mass can be achieved by separation of materials. A true double wall with separate unconnected elements performs better than the mass law predicts for a single wall of

BENEFIT OF AIRSPACE IN IMPROVING TRANSMISSION LOSS (TL)

NOTE

If two layers of dense material are separated by an airspace (rather than being continuous), they create two independent walls. The improvement in transmission loss depends on the size of the airspace and the frequency of sound. Avoid rigid ties between layers in all double wall construction. The graph above indicates the approximate improvement in TL when a wall of a given weight is split into two separate walls.

the same weight. The transmission loss tends to increase about 5 dB for each doubling of the airspace between wythes (minimum effective space is approximately 2 in.). Resilient attachment of surface skins to studs or structural surfaces provides a similar benefit, as do separate wythes.

ABSORPTION: Use of soft, resilient, absorptive materials in the cavity between wythes, particularly for lightweight staggered or double stud construction, increases transmission loss significantly. Viscoelastic (somewhat resilient but not fully elastic) materials, such as certain insulation boards, dampen or restrict the vibration of rigid panels such as gypsum board and plywood, increasing transmission loss somewhat. Follow manufacturer-recommended installation details.

NOISE REDUCTION

Noise reduction (NR) depends on the properties of a room and is the actual difference in sound pressure level between

two spaces. It is the amount of sound blocked by all intervening sound paths between rooms, including the common wall but also the floor, ceiling, outside path, doors, etc.

Noise reduction also depends on the relative size of a room. If the noise source is in a small room next to a large receiving room (like an office next to a gymnasium), the noise reduction will be greater than the TL performance of the wall alone because the sound radiating from the common wall between office and gym is dissipated in such a large space. On the other hand, if the noise source is in a large room next to a small one (as from a gym to an office next door), the noise reduction will be far less than the TL of the wall alone because the common wall, which radiates sound, is such a large part of the surface of the smaller room. An adjustment for this ratio, plus the contribution of the absorptive finishes in the receiving room, enters into the calculation of actual noise reduction between adjacent spaces.

GRAPHIC TECHNIQUE TO DETERMINE COMPOSITE TRANSMISSION LOSS (COMBINING TWO DIFFERENT CONSTRUCTION ELEMENTS)

NOTES

1. When a wall or surface of a room is made up of two or more different structures (e.g., a window in an outside wall or a door in an office), the TL performance (or STC) of the composite construction should be evaluated by

- combining the TL (or STC) values of the components of the wall alone, in accordance with the chart above.
2. Note that small gaps and cracks such as the perimeter of an ungasketed door can dramatically degrade the performance of a high TL construction.

SOUND TRANSMISSION CLASS (STC) RATING CURVE

Carl Rosenberg, AIA; Acentech, Inc.; Cambridge, Massachusetts

SOUND ISOLATION CRITERIA

SOURCE ROOM OCCUPANCY	RECEIVER ROOM ADJACENT	SOUND ISOLATION REQUIREMENT (MIN.) FOR ALL PATHS BETWEEN SOURCE AND RECEIVER
Executive areas, doctors' suites, personnel offices, large conference rooms; confidential privacy requirements	Adjacent offices and related spaces	STC 50-55
Normal offices, regular conference rooms for group meetings; normal privacy requirements	Adjacent offices and similar activities	STC 45-50
Large general business offices, drafting areas, banking floors	Corridors, lobbies, data processing; similar activities	STC 40-45
Shop and laboratory offices in manufacturing laboratory or test areas; normal privacy	Adjacent offices; test areas, corridors	STC 40-45
Mechanical equipment rooms	Any spaces	STC 50-60+ ¹
Multifamily dwellings	Neighbors (separate occupancy)	
Bedrooms	Bedrooms	STC 48-55 ²
	Bathrooms	STC 52-58 ²
	Kitchens	STC 52-58 ²
	Living rooms	STC 52-57 ²
Living Rooms	Corridors	STC 52-58 ²
	Living Rooms	STC 48-55 ²
	Bathrooms	STC 50-57 ²
	Kitchens	STC 48-50 ²
School buildings	Adjacent classrooms	STC 50
Classrooms	Laboratories	STC 50
	Corridors	STC 45
Large music or drama area	Adjacent music or drama area	STC 60 ³
Music practice rooms	Music practice rooms	STC 55 ³
Interior occupied spaces	Exterior of building	STC 35-60 ⁴
Theaters, concert halls, lecture halls, radio and TV studios	Any and all adjacent	Use qualified acoustical consultants to assist in the design of construction details for these critical occupancies

¹ Use acoustical consultants when designing mechanical equipment rooms to house equipment other than that used for air handling (e.g., chillers, pumps, and compressors) and heavy manufacturing areas that house equipment that generates noise at or above OSHA allowable levels or generates high vibration levels.
² Ratings depend on nighttime, exterior background levels and other factors directly related to the location of a building. Grades I, II, and III are discussed in "Guide to Airborne, Impact, and Structureborne Noise Control in Multifamily Dwellings," HUD TS-24 (1974).
³ The STC ratings shown are guidelines only. These spaces typically require double layer construction with resilient connections between layers or, preferably, structurally independent "room-within-a-room" construction. The level of continuous background noise, such as that provided by the HVAC system or an electronic masking system, has a significant impact on the quality of construction selected and must be coordinated with the other design parameters.
⁴ Ratings depend on the nature of the exterior background noise—its level, spectrum shape, and constancy—as well as the client's budget and thermal considerations. Use qualified acoustical consultants for analysis of high noise outdoor environments such as airports, highways (especially those with heavy truck traffic), and industrial facilities.

TYPICAL HIGH SOUND ISOLATION CONSTRUCTION

GENERAL

One of the most common goals in the design of sound isolation construction is achievement of acoustical privacy from a neighbor. This privacy is a function of whether the signal from the neighbor is audible and intelligible above the ordinary background noise level in the environment.

Privacy index = noise reduction + background noise

Noise reduction is measured as a field performance where it is evaluated and given an STC value. Background sound levels from steady mechanical heating and ventilating systems, a constant part of our environment, are measured in accordance with ASHRAE standards by a set of uniform curves called noise criteria (NC) ratings. These NC curves are constantly refined, so check the latest ASHRAE guides.

Normal privacy, in which you are aware of a neighbor's activity but not overly distracted by it, can usually be achieved with a privacy index of 68 or higher. Confidential privacy, in which you are aware of the neighbor, usually requires a privacy index of 75 or higher.

A quiet environment with little or no natural background sound (from HVAC systems) between neighbors requires a higher degree of sound separation construction to achieve the same privacy as that in a noisier environment with louder background sound.

IMPACT NOISE DESIGN CRITERIA

Floors are subject to impact or structure-borne sound transmission noises such as footfalls, dropped objects, and scraping furniture. Parallel to development of laboratory sound transmission class (STC) ratings for partition constructions is the development of an impact insulation class (IIC). This is a single-number rating system used to evaluate the effectiveness of floor construction in preventing impact sound transmission to spaces beneath the floor. The current IIC rating method is similar to the STC rating.

Testing for IIC ratings is a complex procedure using a standard tapping machine. Because the machine is portable, it cannot simulate the weight of a person walking across a floor. Therefore, the creak or boom footsteps cause in a timber floor cannot be reflected in the single-figure impact rating produced from the tapping machine. The correlation between tapping machine tests in the laboratory and field performance of floors under typical conditions may vary greatly, depending on the construction of the floor and the nature of the impact.

Often the greatest annoyance caused by footfall noise is the low-frequency sound energy it generates, which is beyond the frequency range of standardized tests. Sometimes this sound energy is near or at the resonant frequency of the building structure.

Whenever possible, to stifle unwanted sounds use carpet with padding on floors in residential buildings and resilient, suspended ceilings with cavity insulation. For especially critical situations, such as pedestrian bridges or tunnels, hire an acoustical consultant.

Slamming doors or cabinet drawers are other sources of impact noise. If possible, bureaus should not be placed directly against a wall. Door closers or stops can be added to cushion the impact of energy from a door so it is not imparted directly into the structure. Common sense arrangements can help minimize problems in multifamily dwellings. For example, kitchen cabinets should not be placed on the other side of a common wall from a neighbor's bedroom.

CONSTRUCTION NOTES

- Edge attachment and junction of walls, partitions, floors, and ceiling can cause large differences in transmission loss (TL) performance. The transverse waves set up in continuous, stiff, lightweight walls or floors can carry sound a long distance from the source to other parts of the structure with little attenuation. Curtain walls, thin concrete floors on bar joists, and wood framed structures are particularly subject to this weakness.
- Properly designed discontinuities such as interrupted floor slab/toppings are helpful in reducing structural flanking.
- A resilient (airtight) joint between exterior wall and partition or partition and floor can appreciably improve TL.
- Continuous pipes, conduits, or ducts can act as transmission paths from room to room. Care must be taken to isolate such services from the structure.

GENERAL

Mechanical system noise, as a major component of acoustics in modern buildings, must be addressed in developing mechanical design and acoustical goals.

Background sound levels from mechanical systems are measured and evaluated by means of noise criteria (NC) ratings as well as by actual A-weighted decibel levels. The noise criteria curves provide a convenient way of defining the ambient noise level in terms of octave band sound pressure levels. The NC curves consist of a family of curves that relate the spectrum of a noise to the environment being specified. Higher noise levels are permitted at lower frequencies since the ear is less sensitive to noise at these levels. The complete octave band frequency of an acceptable ambient noise level can be specified with one NC number.

Mechanical equipment creates noise and vibration from the rotation of the equipment motor. Four aspects of the noise and vibration to be addressed are described here:

MACHINE NOISE: Sound isolation requirements for the walls and floors of a mechanical equipment room depend on the type of equipment to be housed and the sensitivity of adjacent spaces. Chillers can be extremely loud, requiring double walls and extra thick floor slabs. Air-handling units may only require regular wall construction, perhaps STC 50 systems. Major secondary sound paths are duct penetrations, open curbs under rooftop units, and doors; all potential sound paths must be controlled.

FAN NOISE: Rotation of the fan motor and the fan itself generates noise, which is transmitted along the duct path (both supply and return) to the listening space. Typical fan noise control elements include package silencers (inserted into a straight run of duct, often at the wall of the mechanical equipment room) and internal acoustical duct lining (glass fibers adhered to the duct walls). The degree of fan noise attenuation can be determined by calculations based on the size and sound power levels of the fan, the length and configuration of duct runs, the attenuation of the duct systems, the number and type of diffusers, and the room finishes in the listening space.

AIR NOISE: Movement of air through a duct generates turbulence, which creates noise. For sensitive spaces and quiet noise levels, the airflow must be at low velocity (hence the need for large ducts) with smooth inlet and outflow conditions. For extremely quiet noise levels, air velocities at diffusers or terminal devices may need to be below 400 fpm. Volume dampers to control flow for such spaces are critical; keep dampers 10 ft from diffusers, and avoid opposed blade dampers at diffusers. A simple duct layout that provides even distribution of air to all diffusers in a room can eliminate many problems (see preferred duct layout below).

VIBRATION ISOLATION: Rotating equipment generates vibration, which can travel through a structure and be radiated as noise in a distant location. Vibration isolation may entail use of neoprene pads, spring isolators, or inertia bases, depending on the size and power of the rotating equipment, the proximity of sensitive spaces, and the stiffness of the supporting structure. Piping attached to rotating equipment, especially chilled water piping, must also be isolated from the structure to prevent transmission of sound energy. The effectiveness of a vibration isolator depends on the static deflection of the isolator under load; lower frequency mechanical equipment rotation requires greater static deflection isolation to be effective.

NOTE

All diffusers are equidistant from the fan. The system is self-balancing. The duct layout does not need volume dampers.

PREFERRED DUCT LAYOUT

*For convenience in using noise criteria data, the table lists the sound pressure level (SPL) in decibels for each NC curve.

NOISE CRITERIA CURVES

GENERAL

Performance spaces are rooms in which good hearing conditions are particularly critical to the use of the space and exchange of aural information. Such spaces include classrooms, lecture halls, recital halls, theaters, cinemas, concert halls, churches and synagogues. Critical design of a performance space may require assistance from an acoustical consultant, but the primary tools at the architect's direction are outlined here:

LOUDNESS

Audience and performers should be in the same space, and any sound generated by a speaker or musician should be projected efficiently to the audience and captured within the space. The "sending end" of the room (i.e., the stage) should be acoustically hard. Walls near the performer should be angled or splayed to enhance projection and prevent "flutter echoes" at the stage. Walls and ceilings where the audience sits should be hard so they can reflect sound, unless absorptive treatment is needed to eliminate problematic reflections or focusing or to reduce reverberation time (RT) for particular program needs.

QUIET

Good hearing environments should maximize the signal-to-noise ratio; in other words, in addition to the desired signal being well projected (see loudness), unwanted noise should be eliminated. To accomplish this requires very low background sound levels (NC-20 perhaps) from mechanical equipment. Sound lock vestibules eliminate intrusive noise from a lobby and allow latecomers to enter without acoustical interference to the show, and carpeted aisles help reduce footfall noise. Noise from exterior environmental sources should also be considered. Avoid lightweight roofs, which will transmit rain noise.

SPACIOUSNESS

Because of the lateral configuration of our ears, sound signals that are slightly different in each ear allow the listener to hear an acoustical quality called spaciousness, which is usually highly desired, especially for classical music. This sense of spaciousness can be enhanced if the distribution of sound through a large hall is diffused, and the ear literally hears reflections from many facets of the side and rear walls. This diffusion can be enhanced by protrusions and angled surfaces on the side walls.

REVERBERATION TIME (RT)

Refer to the accompanying charts on optimum reverberation times and preferred volume/seat ratios. Room volume and

area of absorption can be calculated to predict RT. The biggest design factor affecting RT is ceiling height. The relationship between the volume of a hall and the number of seats is often a good approximation of sound quality in the room.

In wide halls with high ceilings, seats in the center of the orchestra often suffer from lack of early reflections. Reflecting canopies or arrays over the front rows can bring reflected sound to these seating areas, which otherwise may suffer from poor articulation. Often, seating at the rear of the balcony does not experience this problem, and these seats have excellent acoustics.

PREFERRED VOLUME/SEAT RATIOS

VOLUME/SEAT		SOUND QUALITY OF SPACE
CU FT	M ³	
Less than 200	Less than 6	Quite dead, suitable for speech and cinema
300 to 350	8 to 10	Good for music
Greater than 500	Greater than 14	Good for organ music only, too reverberant for speech

ARTICULATION

Much of the clarity of sound that audiences need for speech intelligibility and clear musical attacks comes from the sound reflected off hard surfaces that reaches listeners within 50 to 80 milliseconds of the direct sound (which always reaches the listener first). To enhance articulation of acoustics in a hall, the design must ensure there are enough surfaces to reduce the time gap between the initial (direct) sound and these early reflections; the initial time delay gap should be less than 50 milliseconds. Sound travels 1120 ft/second (in SI units, 333 m/second), so the initial time delay gap for prime seating locations should not exceed 50 ft (13 m).

OTHER FACTORS

Following are several other features to be considered when designing performance spaces.

FOCUSING

Focusing concentrates sound waves in one area, causing "hot spots" where the sound is louder or unnatural in quality. Concave surfaces either in plan or section can present major focusing problems if they are not identified and treated.

SEATS

The largest area of sound-absorbing surface in a performance hall is the seating. If the seats are made of a sound-reflecting material (wood, vinyl, plastic, etc.), their absorptive properties will change dramatically when they are occupied, since a person introduces about 5 sabins for each seat, which significantly affects reverberation time. Use of upholstered seats or pew cushions makes the RT similar whether the seats are empty or fully occupied and will never make the empty hall RT more dead than it would be when fully occupied.

BALCONIES

Balconies bring additional persons into a given volume and create more intimacy between audience and performer. However, seating under a balcony can be cut off from the main volume of sound if the balcony overhang is too great. A reasonable rule of thumb is that the overhang depth should not exceed the height of the opening (greater ratios are acceptable where live music is not part of the program).

ORCHESTRA PIT

The surface over the orchestra pit should be angled to project sound out to the audience but diffuse so that some energy is reflected back to the performers on stage. The front wall of the orchestra pit should be a hard surface so the front rows of the audience do not hear direct sound and so that more energy is reflected back to the performers on stage. Also, both the front and back walls may need to be treated with movable curtains to vary and control the degree of sound reflected off these surfaces.

SOUND SYSTEM

Electronic sound systems may be used for amplification (making the source louder for a big hall), for playback or recorded material, or for both. Depending on the source, the loudspeakers used to distribute the sound should be located at the center slightly in front of the speaker (for speech amplification) or on the left and right sides (for musical stereo playback or amplification of the orchestra pit). Additional loudspeakers may be needed under a balcony or at the rear of the hall to cover the upper balconies. Special effects loudspeakers are added around the hall as needed. The sound control location must be well placed within the audience area covered by the loudspeakers. Additional transmitters using infrared signals or FM radio signals can be used to meet ADA requirements.

OPTIMUM REVERBERATION TIMES AT MIDFREQUENCIES (500-1000 HZ) FOR PERFORMANCE SPACES

*May go up to 8 seconds in reverberation time

NOTE

The breadth of RT range for each room type is a function of the room volume: the larger the room volume, the closer to the longer end of the range and vice versa.

Carl Rosenberg, AIA; Acentech, Inc.; Cambridge, Massachusetts

GENERAL

Open plan offices can provide great flexibility in office arrangements and work flow. However, because workstations or cubicles do not have full-height partitions, noise can be a major problem in such offices. The extent to which speech is distracting depends on the degree to which it is intelligible. An overheard conversation can be annoying or distracting, while an inaudible murmur is not. When designing open plan offices, the need for communication between workstations should be evaluated in light of work functions and practical separation.

Speech intelligibility and acoustics in an open plan office can be rated in terms of an articulation index (AI), which is a measure of the ratio between a signal (a neighbor's voice or intrusive noise) and steady background noise (ambient noise from mechanical equipment, traffic, or electronic sound masking). AI values range from near 0 (very low signal and relatively high noise; no intelligibility or good speech privacy) to 1.0 (very high signal and low noise; excellent communication or no speech privacy). When communication is desired (e.g., in classrooms or teleconference rooms), it is preferable to have a high AI so people can hear well. In an office, however, it is preferable to have a low AI so people can be freed from distraction and will be better able to concentrate. Average noise requirements for various office functions are shown in the accompanying chart.

ARTICULATION INDEX (AI) FOR OPEN PLAN OFFICES

AI VALUE	NOISE REQUIREMENTS	
>.65	Good communication	Necessary when communication is desirable (conference rooms, classrooms, auditoriums, etc.)
.35	Freedom from distraction	Reasonable work conditions not requiring heavy concentration or speech privacy; hear and understand neighboring conversations
.20	Normal speech privacy	Occasional intelligibility from a neighbor's conversation; work patterns not interrupted
<.05	Confidential speech privacy	Aware of neighbor's conversation but it is not intelligible

DESIGN CONSIDERATIONS

Low AI ratings for open plan office spaces can be achieved in three primary ways: by blocking sound, by covering (masking) sound, and by absorbing sound.

BLOCKING SOUND

Partial-height barriers or partitions are necessary to block direct sound transmission between workstations. The barriers must be high enough and wide enough to interrupt the line of sight between a source and a receiver; hence, the first 4 ft or so of barrier height do not help speech privacy at all. Barrier heights of 5 ft are a minimum requirement for acoustical separation, and heights of 6 ft are typical for normal privacy. The barrier should be able to block sound at least as well as the path for sound traveling over the barrier, which means a minimum laboratory sound transmission class value of 24. Barriers or screens should extend to the floor or leave only an inch or so open at the bottom. There should be no open gaps between adjacent panels. Barriers may need to have sound-absorbing facings to reduce reflections to the next workstation.

COVERING SOUND

The character and level of background sound is perhaps the most important acoustical design consideration for an open plan office. A modest level of background or ambient sound will cover, or mask, annoying, intrusive sounds. The masking sound must be pleasant and neutral with an even tonal spectrum (like the sound of a comfortable ventilation system) that drops off at the high end of the frequency range. There should be no pure tones or annoying characteristics (like the hum of a fluorescent light ballast).

BACKGROUND SOUND LEVEL FOR OPEN PLAN OFFICES

PLAN

SECTION

ARCHITECTURAL SOLUTIONS FOR SOUND CONTROL IN OPEN OFFICES

The sound should be evenly distributed throughout the office so no areas are louder than others. In addition, the sound should not vary in the open plan area by more than 3 decibels in any octave band. Masking sound should be neither too loud nor too quiet, perhaps between 45 and 50 dBA. It should be loud enough to cover intrusive noises but never loud enough to be distracting in itself. Conference rooms and private offices, which require lower levels of background noise, should have plenum treatments so they are shielded from direct exposure to the masking sound.

Normal air conditioning and ventilation could generate enough background noise to mask sound between offices, but this sound source is not well designed for this purpose. Most office buildings use variable volume air distribution, so noise from the HVAC system may be erratic and uneven in distribution and change over time and season. The preferred solution is to install an electronic sound masking system.

Sound masking systems comprise a noise generator, an equalizer to shape the sound spectrum properly, amplifiers, and loudspeakers hidden above an accessible acoustical tile ceiling. Such systems generate a broadband, pleasant sounding, evenly distributed masking noise. The sound in the plenum filters down through the ceiling and provides an even blanket of sound that will mask the intrusive sound from a neighbor. Avoid untreated sound leaks in the ceiling such as openings for return air; these become noticeable "hot spots" and draw unwanted attention to the sound from the ceiling. Masking sound from two channels can improve spatial uniformity. Ceiling height and plenum conditions (fire-proofing, beams, ducts, etc.) will determine loudspeaker spacing and location. Electronic sound masking should be professionally designed and installed.

ABSORBING SOUND

The ceiling in an open plan office is the most important surface to treat with highly efficient sound-absorbing material. Glass-fiber ceiling panels often have NRC values of .85 or higher and are the preferred material for open plan spaces. Regular mineral-fiber acoustical panels have typical NRC values of about .55-.65. Hard sound-reflective materials such as exposed structure or gypsum board will dramatically reduce privacy and raise annoying sound levels in an office. Most ceiling tile manufacturers provide extensive NRC data for their products and have special products with high absorptive performance for use in open plan spaces. Materials must also be selected for their ability to reflect light.

Most sound-absorbing materials are measured in a reverberation chamber in accordance with ASTM C 423 to determine their random incidence sound-absorption coefficients (α) and from these data, manufacturers typically report the noise reduction coefficient (NRC). The NRC value is a good first approximation of the ability of a material to absorb sound from the human speech range. For office acoustics, however, a more useful value is the ability of a material to absorb sound at an incident angle of 40-60° from a flat ceiling and at frequencies weighted to reflect the relative contribution to speech intelligibility. Therefore, a more effective tool for evaluating the effectiveness of ceiling materials for sound absorption is the speech absorption coefficient (SAC), which can be calculated from standard sound absorption coefficients as follows:

$$SAC = \Sigma(0.06\alpha_{250} + 0.15\alpha_{500} + 0.24\alpha_{1000} + 0.32\alpha_{2000} + 0.23\alpha_{4000})$$

OTHER FACTORS

Arrange offices so that entrances are offset, and eliminate direct line of sight or an open view through doorways from one workstation to another. Workstations should be 8-10 ft apart so voice levels are adequately reduced over distance. Higher ceilings can help reduce noise transfer. Light fixtures in the ceiling plane should not have hard lenses or be placed directly above a partition because the fixture can then act as a mirror for sound across the barrier. Absorptive material

may be necessary on some barriers or reflecting surfaces (e.g., walls, file cabinets).

Carpet helps reduce footfall and impact noise and is a great benefit in open offices. Finally, voice levels should be kept to a minimum; even the best acoustical treatments cannot prevent disturbances caused by loud voices.

All the factors outlined in the paragraphs above are interrelated. For example, doubling the distance between adjacent workstations will reduce a nearby conversation by 5 dBA, while raising the height of a 5-ft barrier to 6 ft may reduce the sound path over the top by 3 dBA. Changing from a mineral-fiber acoustical ceiling tile to a glass-fiber ceiling tile may reduce reflected noise by 5 dBA. Adding sound masking may change the ambient level by 10-20 dBA.

An acoustics consultant can evaluate proposed layouts and materials as part of the design process. The acoustical outcome of a design should be analyzed before construction. As a rough initial guideline, offices in which freedom from distraction is the only criterion will require highly efficient sound-absorbing ceilings and an electronic background masking sound at levels between 45 and 50 dBA. For normal speech privacy, these conditions should be augmented by keeping workstations 8-10 ft apart and adding partial-height barriers at least 5 ft high, with increased attention to office layout and reflecting sound paths. Confidential privacy requires higher partitions and more attention to related details and is extremely difficult to achieve in an open plan.

GENERAL

Sound systems are used primarily to provide better listening conditions through sound amplification that increases the loudness of a sound source. Secondary uses of sound systems include recording and playback of audio signals, distribution of audio signals to remote locations, and satisfaction of ADA requirements for provision of assistive listening systems for hearing-impaired individuals.

Sound systems are recommended in all places of assembly, including auditoriums, churches, classrooms, and lecture halls with more than 60 seats; large conference rooms; courtrooms; legislative chambers; and sports arenas, particularly if these facilities will be used by inexperienced speakers. Sound amplification systems should not be used as a substitute for good room acoustical design. The sound system equipment chosen, its location in a space, and the reproduction quality it provides depend on the acoustical properties of that space.

Sound amplification systems should be used when one or more of the following conditions occur: (1) the room volume exceeds 50,000 cu ft; (2) the distance between source and farthest receiver exceeds 50 ft indoors and 25 ft outdoors; (3) the receiver is located beyond 70° horizontally from the source; (4) the room reverberation time exceeds 1.5 sec; and (5) the ambient noise levels are greater than NC-40 indoors or 55 dBA outdoors.

TYPES OF SOUND SYSTEMS

Sound systems are designed to serve a wide variety of functions, program types, and spaces. The primary functions are voice and music reinforcement, assistive listening, paging and emergency announcements, sound masking, and audio recording/playback.

VOICE AND MUSIC REINFORCEMENT

Voice and music reinforcement systems amplify the spoken word or a music program. Voice reinforcement systems are used in virtually all places of public assembly, but use of music reinforcement systems is usually restricted to auditoriums, amphitheaters, arenas, and churches. Loudspeaker locations are dictated by ceiling height and stage layout. Spaces with ceiling heights greater than 25 ft normally have a large "central cluster" loudspeaker system located above and forward of the stage. Low-ceiling spaces, such as classrooms or under balconies in a theater, normally have small (4- or 8-in. diameter) ceiling-mounted loudspeakers in a "distributed" speaker layout. Music reinforcement typically uses large loudspeakers located on either side of the stage, either set on the floor or hung from the building structure.

ASSISTIVE LISTENING

Assistive listening systems provide localized sound reinforcement to listeners who have difficulty hearing the program. These systems are used to comply with ADA requirements. An electrical output from the sound system is routed to a transmitter, either FM or infrared, which radiates a modulated audio signal that is picked up by a receiver carried by the listener. A small in-the-ear headset is connected to the receiver.

PAGING AND EMERGENCY ANNOUNCEMENTS

Paging and emergency announcement systems distribute voice or alarm signals. Codes may require that emergency announcement systems be dedicated, use equipment certified by Underwriters Laboratories (UL), or be capable of operating from emergency power sources. The audio program is transmitted via a distributed ceiling loudspeaker system in a 70.7-volt configuration.

SOUND MASKING

Sound masking systems radiate pink noise, the frequency content of which is adjusted to make speech less intelligible, thus increasing speech privacy. These systems are commonly used in open office environments, where partial-height workstations may make speech privacy difficult to achieve. Loudspeakers in a 70.7-volt configuration are located in the ceiling plenum, and the sound radiates through the ceiling tile into the space below. Precision adjustment and tuning of sound masking systems is crucial to their acceptance by employees.

AUDIO RECORDING/PLAYBACK

Audio media recording/playback systems provide for amplification of sources such as audiotape or compact disc (CD). These systems can function as an element of a larger sound system or they can stand alone. Recording systems use electrical output from the sound system to record the program content to cassette tape or digital audiotape (DAT). Reproducing systems amplify sound from signal storage media, such as cassette tape, DAT, CD, digital video disc (DVD), tape cars, message repeaters, or from a distant origin, such as radio or TV transmissions.

BASIC SOUND AMPLIFICATION SYSTEM

LOUDSPEAKER SYSTEM TYPES

LOUDSPEAKER INSTALLATIONS

To provide good sound coverage, loudspeakers must be properly integrated into the architectural design of a space. Most spaces have an optimum loudspeaker configuration that should be examined before exploring other options. Loudspeakers can be recessed behind architectural elements, assuming a suitably large opening with acoustically transparent grille cloth is provided.

The major loudspeaker installations include central cluster, split cluster, and distributed ceiling types.

CENTRAL CLUSTER LOUDSPEAKER

The central cluster loudspeaker system is located just forward of center stage and elevated a minimum of 20 ft above floor level. Separate low frequency and mid/high frequency loudspeaker components, either individual horn systems or multiway loudspeakers, are used. Listeners must have line-of-sight relationships to loudspeakers in order to receive good sound coverage.

Central cluster systems are not recommended for spaces with ceiling heights less than 20 ft due to sound level differences between the front and rear of the space. Advantages include low cost and naturalness of reproduction because of the inability of the ear to localize sound in the vertical plane.

SPLIT CENTRAL CLUSTER LOUDSPEAKER

The split central cluster loudspeaker system is similar in design and operational concepts to the central cluster system, but separate loudspeaker clusters are located at stage right and stage left locations, as might occur in a church with a separate pulpit and lectern or in a music reinforcement system. Each loudspeaker cluster is designed to cover the entire listener seating area. When the talker is at the stage right location, only that loudspeaker operates, likewise for the stage left location. This system provides greater source localization than the central cluster system since it uses the ability of the ear to localize sound in the horizontal plane.

DISTRIBUTED CEILING LOUDSPEAKER

Distributed ceiling loudspeaker systems use 4-, 8-, or 12-in. diameter, full-range, transformer-coupled cone loudspeakers, typically in a 70.7-volt configuration installed in the ceiling plane. These systems are normally used in spaces with a ceiling height less than 20 ft. The size of the loudspeaker depends on the ceiling height and whether the system will be used for voice or music reproduction. In spaces where the unamplified source to receiver distance exceeds 30 ft, it is often necessary to electrically delay the signal to the loudspeaker so the listener hears the unamplified sound first, followed in several milliseconds by the sound from the amplified ceiling loudspeaker. The signal processing technique of this system type helps to preserve source localization.

Neil Thompson Shade; Acoustical Design Collaborative, Ltd.; Falls Church, Virginia

SOUND SYSTEM ELEMENTS

Sound systems comprise input signal sources, signal processing equipment to alter the properties, of the signal, amplifiers to increase weak signal levels, and loudspeakers to convert electrical signals to acoustical signals.

MICROPHONES

A microphone is a transducer that converts sound waves into electrical AC voltage corresponding to the acoustical characteristics of the source. Microphones can be classified by type, transducer element, or polar pattern. The major microphone types are thin profile lectern, performer's handheld, boundary layer, and lavalier.

LINE LEVEL SOURCES

Line level signal sources include audio formats such as magnetic tape, audio and optical discs, video, telephonic devices, and radio. These sources are classified as recorded audio (magnetic tape, audio discs, and optical discs) or real-time audio (videoconferencing, telephone, and radio).

SOUND MIXERS

Sound mixers combine the electrical output of microphone and line level sources into a composite output signal for distribution to other components of the sound system. Sound mixers are classified as manually operated or automatic hands-off types. Manually operated mixers require placement in the same sound field the audience experiences so the operator can properly adjust the sound system. Automatic microphone mixers control turning on/off of microphones, adjusting gain, and routing of signals.

SIGNAL PROCESSING

Signal processing equipment provides the means for altering the frequency, magnitude, delay time, and distribution of audio signals received from the mixer. Signal processing equipment includes frequency equalizers, crossovers, signal delay lines, and distribution amplifiers. These items can be discrete components, or computer-controlled digital signal processing (DSP) can be used to execute their functions.

AMPLIFIERS

Amplifiers increase the voltage of the audio signals received from the signal processing devices and distribute the stronger signal to the loudspeakers. Amplifiers are configured as either low impedance output for driving 4, 8, or 16 ohm loudspeakers or as 25, 70.7, or 100 constant voltage output driving transformer-coupled loudspeakers.

LOUDSPEAKERS

Loudspeakers convert electrical AC voltage into sound waves. Sound reinforcement loudspeakers have either full-range cone drivers, commonly used for ceiling distributed systems, or multiway loudspeaker systems with separate low frequency and mid/high frequency drivers. Typically, mid/high frequency systems use compression drivers connected to a horn system to provide controlled directional sound coverage output.

INFRASTRUCTURE

Sound system equipment is normally installed in standard 19-in. wide equipment rack enclosures. Signal cables are

AUTOMATIC MICROPHONE MIXER

MANUAL MIXER

SOUND MIXERS

routed from these enclosures to audio wall plates that connect to input and output devices. Normally, metal conduit is used to minimize signal interference and to protect cables.

ELECTRICAL POWER REQUIREMENTS

Sound systems should have dedicated power circuits separate from other building electrical services. The major electrical power load comes from the amplifiers, which can easily exceed the power requirements of all other sound system components by a factor of 100. When computer-controlled sound systems are used, provide electrical power surge protection and a source of uninterruptible power.

HANDHELD PERFORMER'S MICROPHONE

BOUNDARY LAYER MICROPHONE

LAVALIERE MICROPHONE

MICROPHONE TYPES

FULL-RANGE CEILING LOUSPEAKER

HORN LOADED LOW-FREQUENCY LOUSPEAKER

LOUDSPEAKERS

AUDIO EQUIPMENT ROOMS

Equipment rack enclosures are often housed in a dedicated audio equipment room. In this case, clearance should be left around the enclosures to permit maintenance work. When power amplifiers create a large sensible heat load, audio equipment rooms may require forced air cooling.

Locate audio equipment rooms as close as possible to the microphones and loudspeakers to minimize cable length. Often a separate equipment room is required so the power amplifiers can be located close to the loudspeakers.

GENERAL

Crimes such as vandalism, terrorism, burglary, shoplifting, employee theft, assault, and espionage endanger lives and threaten the built environment. Despite this, security as a design consideration has often been inadequately addressed and poorly funded. Now, however, in many jurisdictions police authorities require security plan reviews as part of the building permit process in the same way they review life safety and fire prevention plans.

Security design is more than bars on windows, a security guard booth, a camera, or a wall. Security involves the systematic integration of design, technology, and operation for the protection of three critical assets—people, information, and property. Protection of these assets is a concern in all building types and should be considered throughout the design and construction process, from programming, schematic design, design development, preparation of construction documents, and bidding, through construction.

The most efficient, least expensive way to provide security is during the design process. Architects called on to address security and crime concerns must be able to determine security requirements, know security technology, and understand the architectural implications of security needs.

Designing without security in mind can lead to expensive retrofitting, which may require more security personnel than security equipment designed in from the start. As well, installation of retrofit security equipment can distort key building design elements and inhibit building function. Most important, planning without security can lead to successful claims against owners, architects, and building managers.

The process of designing security into architecture is known as crime prevention through environmental design (CPTED). It involves designing the built environment to reduce the opportunity for and fear of stranger-to-stranger predatory crime. This approach to security design recognizes the intended use of space in a building and is different from traditional crime prevention practice, which focuses on denying access to a crime target with barrier techniques such as locks, alarms, fences, and gates. CPTED takes advantage of opportunities for natural access control, surveillance, and territorial reinforcement. It is possible for natural and normal uses of the environment to meet the same security goals as physical and technical protection methods.

CPTED strategies are implemented by

1. **ELECTRONIC METHODS:** mechanical security products, target-hardening techniques, locks, alarms, CCTV, gadgets
2. **ARCHITECTURAL METHODS:** architectural design and layout, site planning and landscaping, signage, circulation control
3. **ORGANIZATIONAL METHODS:** manpower, police, security guards, receptionists, doormen, and business block watches

CPTED STRATEGIES

CPTED CONCEPTS

Concepts involved in crime prevention through environmental design are described below.

DEFENSIBLE SPACE

Oscar Newman coined the expression "defensible space" as a term for a range of mechanisms, real and symbolic barriers, strongly defined areas of influence, and improved opportunities for surveillance that combine to bring the environment under the control of its residents.

NATURAL ACCESS CONTROL

Natural access control involves decreasing opportunities for crime by denying access to crime targets and creating a perception of risk in offenders. It is accomplished by designing streets, sidewalks, building entrances, and neighborhood gateways to mark public routes and by using structural elements to discourage access to private areas.

SECURITY LAYERING OF SPACES

NATURAL SURVEILLANCE

A design concept intended to make intruders easily observable, natural surveillance is promoted by features that maximize visibility of people, parking areas, and building entrances. Examples are doors and windows that look onto streets and parking areas, pedestrian-friendly sidewalks and streets, front porches, and adequate nighttime lighting.

TERRITORIAL REINFORCEMENT

Physical design can create or extend a sphere of influence. In this setting, users develop a sense of territorial control, while potential offenders perceive this control and are discouraged from their criminal intentions. Territorial reinforcement is promoted by features that define property lines and distinguish private spaces from public spaces such as landscape plantings, pavement design, gateway treatments, and fences.

MANAGEMENT AND MAINTENANCE

Operational and management concepts that maintain buildings and facilities in good working order and that maintain a standard of care consistent with national and local standards contribute to the security effort. Equipment and materials used in a facility should be designed or selected with safety and security in mind.

LEGITIMATE ACTIVITY SUPPORT

Legitimate activity for a space or building is encouraged through use of natural surveillance and lighting and architectural design that clearly defines the purpose of the structure or space. Crime prevention and design strategies can discourage illegal activity and protect a property from chronic problem activity.

ADA AND BUILDING SECURITY

The Americans with Disabilities Act of 1990 (ADA) affects architecture, life safety design, and building security technology dramatically. Sample regulations are listed below. For specifics, please see the act itself.

1. Instructions for access control card readers must be provided in braille for the visually disabled.

2. Door hardware, such as handles, pulls, latches, locks, and other operating devices, must be shaped so they are easy to grasp with one hand. Lever, push-type, and U-shaped mechanisms are acceptable, knobs are not.
3. Elevators must have visual signals to indicate when each call is registered and answered. Elevator doors must remain open for at least 3 seconds.
4. Regulations require counters to be 28 to 34 in. off the floor.
5. Alarm systems for evacuation must provide warnings for the blind, deaf, and nonambulatory staff of the building. Announcements must be louder than 15 dB but not exceed 120 dB for 30 seconds. Visual alarms must flash and be tied into the emergency power circuit. Fire alarms should also incorporate visual strobes to alert individuals who are hearing impaired.
6. ATM controls must be at least 15 to 54 in. high and have operating instructions in braille. Night deposit mechanisms must not require a tight grasp (no knobs).
7. Security vestibules must be accessible to individuals in wheelchairs. A maneuvering clearance of at least 4 ft must be provided.

Areas affected by ADA requirements for building security include vaults, safety deposit box rooms, front desk counters, security desk and information counters, control rooms, life safety equipment, safe-refuge areas, turnstiles and security screening checkpoints, all door and locking hardware, and access control devices.

SECURITY CONTROLS FOR ADA

Randall I. Atlas, Ph.D., AIA, CPP; Atlas Safety & Security Design, Inc.; Miami, Florida

PROJECT-RELATED SECURITY EVALUATION

Security needs for an architectural project should be determined early, preferably as part of the programming and needs definition stage. Surveys of similar existing operations and interviews with personnel at these sites can help identify security concerns.

Once a client, owner, or security consultant has identified the security objectives of a project, the architect must ensure the design supports these objectives. Basic decisions about circulation, access, building materials, fenestration, and other design features can support or thwart overall security aims. The architect's role is to incorporate the basic security requirements and programmatic objectives into the project.

PROJECT DESCRIPTION

The first step in determining site-related security requirements is to identify the location, building type, style of operation, and economic aspects of the project. Security levels (high-low) can be defined by determining which areas, items of equipment, buildings, and activities and personnel are most sensitive or vulnerable.

SITE SELECTION AND EVALUATION FOR THREATS AND VULNERABILITY

Security objectives should be considered when choosing a site. For example, crowded sites can make it difficult to provide an adequate buffer around the perimeter or to control and check on-site circulation.

Once a site has been selected, the crime prevention through environmental design (CPTED) and security analysis process can identify measures to overcome any security deficiencies. The architect should consider conditions on and off the site, including topography; vegetation; adjacent land uses; circulation patterns; sightlines; potential areas for refuge or concealment; existing lighting conditions; and the types and locations of utilities, including their vulnerability to tampering or sabotage.

Steps for determining the threats to and vulnerability of a project and site are outlined here:

1. Identify a mission statement for the project.
 - a. Identify the assets to be protected.
 - b. Determine what is to be protected according to the categories of people, property, and information.
 - c. Determine the replacement value of the information and property to be protected.
2. Determine how critical security is to the design of the project.
 - a. Analyze the mission of the project.
 - b. Determine present posture/operation positions.
 - c. Determine the ease with which the property and information to be protected could be replaced.
 - d. Analyze the value of what is to be protected.

CLASSIFICATIONS FOR VARIOUS LEVELS OF DEFENSE

Randall I. Atlas, Ph.D., AIA, CPP; Atlas Safety & Security Design, Inc.; Miami, Florida

3. Determine the threats to the project.
 - a. Consider threats from sabotage, espionage, terrorism, street crime, disgruntled employees, workplace violence, among others.
 - b. Consider the value of the assets to be protected, the objectives of potential aggressors, the perceived deterrence of security measures, and the risk level at the site.
4. Determine what modes of attack may threaten the project. Among those to be considered are these:
 - a. Covert entry
 - b. Insider alone
 - c. Insider with others
 - d. Bombing
 - e. Surveillance
 - f. Demonstrations
 - g. Aerial attack
 - h. Standoff attack
 - i. Theft, burglary, robbery
 - j. Destruction
 - k. Contamination
 - l. Unauthorized entry
5. Determine the severity of the potential attacks. Which of the following would the perpetrators be most likely to use?
 - a. Tools
 - b. Weapons
 - c. Explosives
6. Determine the vulnerability of the site, considering the state of the following security measures at the site:
 - a. Security force capabilities
 - b. Penetration delay
 - c. Detection capabilities
 - d. Assessment capabilities
 - e. Access controls
 - f. Procedural controls
 - g. Mission requirements
7. Identify the constraints that will affect what security measures are implemented:
 - a. Financial
 - b. Operational
8. Determine the protection required for the project:
 - a. Where is security critical?
 - 1) At the outer perimeter?
 - 2) At the inner perimeter?
 - 3) At the asset?
 - b. What security measures will be implemented?
 - 1) Barrier/delay
 - 2) Detection
 - 3) Assessment
 - 4) Access control
 - 5) Command and control
 - 6) Manpower
 - 7) Security procedures

SECURITY LAYERING

Once the risks, threats, and vulnerabilities of a project have been assessed, analyze the security measures that could be used for the project. The choices fall into three classifications:

organizational (people strategies), electronic (technology and hardware), and architectural (design and circulation patterns). These classifications should be considered for each level of defense or security layer:

1. First level—outer perimeter and site
2. Second level—building exterior
3. Third level—interior control and point security

In defensible space, these security layers are defined as public, semipublic, semiprivate, and private spaces.

LIGHTING FOR SECURITY

Security lighting does not prevent or stop crime, but it can help owners protect people and property. Good pedestrian lighting offers the natural surveillance people need to feel comfortable walking ahead or across a parking lot to their cars. Lighting can prevent surprises from jump-out criminals or give pedestrians the opportunity to request assistance, to turn and go another way, or to retreat.

Security lighting goals should be to achieve a uniform, consistent level of light on both pedestrian and vehicular paths of travel. Lighting is critical for the illumination of street and building names and numbers for effective response by police, fire, and emergency personnel. Design lighting to avoid light intrusion into residential settings.

The quality of lighting may be an important security feature. True-color, full spectrum light rendition can help with identification of vehicles and persons. Car lots and gas stations are examples of building types where metal halide luminaires are used for full spectrum light rendition.

NOTES

1. Proper beam control saves a system from glare, loss of light energy, and light intrusion.
2. Fixtures should be installed to cast a light pattern over a broad horizontal area rather than a tall vertical area.
3. Light surfaces reflect light more efficiently than dark surfaces.
4. Keep in mind the line of sight between the location of a light fixture and objects that may cast a shadow. Careful placement will avoid dark corners behind doors, trashcans, and other features.

RECOMMENDED LIGHTING LEVELS (IN LUMENS) BY BUILDING TYPE

	COMMERCIAL	INDUSTRIAL	RESIDENTIAL
Entrances	10	5	5
Interiors	30-100	30	10
Bathrooms	30	30	30
Elevators and stairs	20	20	20
Public spaces	30	30	—
Private spaces	20	20	20
Self-parking	1.0	1.0	1.0
Attendant parking	2.0	2.0	2.0
Sidewalks	0.9	0.6	0.2

SECURITY LIGHTING FOR COMMERCIAL PROPERTY

A SYSTEMS APPROACH TO SECURITY

An interdependent arrangement of security barriers, technology systems, and security response capabilities yields a responsive and complete security delivery system.

The physical security process primarily consists of fences, building walls, inner walls and doors, and safes and vaults.

The proliferation of electronic security devices and systems, coupled with rapid and substantial advances in the capabilities of these systems, has resulted in a wide array of choices in security technology. To choose effectively among these, architects must gain a basic understanding of the principles and applications of crime prevention through environmental design (CPTED), security design, and operational security.

Use of alarmed surveillance systems can greatly reduce property loss. Reports have shown that even when actual breaking and entering incidents have increased, the amount of property stolen has decreased. This is due in part to the use of alarms, perimeter protection, and intrusion detection systems. However, integrated systems—those that employ the proper procedures, equipment, and people in combination—are the most effective.

In general, the security response capabilities at a particular facility depend on the efforts of the on-site security team. However, architects must design buildings that permit security staff to respond efficiently to incidents requiring their action.

SENSOR SECURITY SYSTEMS

Sensor security systems are commonly designed to protect perimeters or to monitor interior space.

PERIMETER SENSOR SYSTEMS may include the following features: continuous line of detection, in-depth protection, complementary sensors, alarm combination, priority schemes, clear zone, site specific system, sensor configuration, tamper protection, self-test compatibility, suitability for physical and environmental conditions, integration with video system, and integration with barrier delay.

Physical and environmental conditions that affect exterior sensors include topography, vegetation, wildlife, background noise, climate and weather, and soil and pavement.

The conceptual design stage of a perimeter sensor system involves identifying targets, defining threats, establishing security requirements, and developing basic security features.

The final design stage requires defining the clear zone surface, determining sensor locations, completing system engineering and specifications, locating perimeter fencing, and designing power and signal distribution.

Tasks in the construction stage include procuring materials, performing surveys, installing conduit and wiring, applying surface material, and installing outer fences and sensors.

Operation tasks are maintenance, testing, training, and documentation.

INTERIOR DETECTION SYSTEMS offer in-depth protection, detect intruders in time for adequate response, detect tampering, and are able to self-test. As well, they must be properly installed (no loose mountings, wiring in conduits, sensors in proper location for detection).

SAMPLE LAYOUT OF INTERIOR SENSORS

TYPES OF SENSORS AND CONDITIONS OF USE

ULTRASONIC MOTION DETECTORS are used when air turbulence is low and when there are external noise sources that could affect a motion detector that radiated energy outside of the protected area. Use low frequency detectors if audible noise is not objectionable.

MICROWAVE MOTION DETECTORS are used when air turbulence is present in the protected room and when there are no potential false alarm sources outside of the room and in the field of the detector.

PASSIVE INFRARED DETECTORS are used when air turbulence is present in an area or point to be protected. Temperature changes do not affect this type of device, but abrupt changes in light level may cause false alarms.

DETECTORS FOR ROOM BOUNDARIES are used when detectors are needed to give the earliest possible warning of an intrusion. They are used only in conjunction with space detectors for the interior of a room; vibration detectors, acoustic detectors, break beams, and breakwires are suggested.

MULTIPLE SPACE DETECTORS are used jointly when detectors are not affected in the same measure by external noise sources and when false alarm rates can be reduced drastically while still maintaining a reasonable probability of detection.

Multiple space detectors are used singly when one type of detector can protect one part of a room and another detector can protect another part of a room because external noise sources are specifically located.

VIBRATION DETECTORS are used when air turbulence, acoustical noises, and motion outside the room are present. These devices are best suited to protect room boundaries from penetration by drilling or hammering.

ACOUSTIC DETECTORS are used when light air turbulence, vibration, and motion are present outside the room. These devices are most effective in protecting room boundaries from penetration by drilling or hammering.

THERMAL DETECTORS are used to detect temperature rises in small enclosures such as vaults when an intruder uses a torch or burning bar to gain entrance. This device would normally be used in a system that includes other types of intrusion detectors.

ENVIRONMENTAL EFFECTS ON SENSORS

Environmental conditions that affect interior sensors include the electromagnetic energy, nuclear radiation, acoustic energy, thermal energy, optical effects, seismic phenomena, and meteorological conditions.

ACCESS CONTROL SYSTEMS

The following statements describe features of a good access control system:

1. They cannot be bypassed.
2. They allow observation by a protective force guard.
3. They protect the guard.
4. They block passage until access and material control procedures have been performed.
5. They provide secondary inspection of those who cannot pass the automated inspection.
6. They accommodate peak loads.
7. They accommodate vehicles and people.
8. They perform access and material control.
9. They are under surveillance by a central alarm station.
10. They are designed for both entry and exit.

CARD TECHNOLOGIES

BAR CODE cards have a series of vertical or horizontal stripes and spaces printed in a manner that represents coded data. The spaces between the stripes are read optically by a photodetector cell.

EMBOSSED CARDS exhibit pattern codes that are raised or indented in the card's surface and read by their relative position in the card reader.

HOLLERITH CARDS have a pattern of small holes punched into the card that presents specific data to the card reader. This card can be read optically or mechanically. The optical reader depends on the light patterns passing through the holes, while the mechanical reader uses electric read, brush, or switch contacts to read the coded patterns.

INFRARED CARDS depend on encoding information with varying density patterns that are read by infrared detectors. The patterns are optically detected and not visible to the human eye.

MAGNETIC SLUG CARDS have magnetic slugs or metal pieces embedded or layered in them; they are read by magnetic sensing devices. Also known as shim cards, they are generally limited to a single code, making them most suitable for parking operations.

MAGNETIC STRIPE CARDS have stripes or layers of a magnetic material embedded between layers or on a card's surface in vertical columns or horizontal rows. Areas or patterns on this magnetic material can be magnetized in coded patterns and read by magnetic sensing devices.

OPTICAL MEMORY CARDS depend on varied transparency densities arranged in rows, columns, or spots. These patterns are read by a system of light sources and photodetectors.

PROXIMITY CARDS incorporate embedded or laminated RF circuits that utilize electrically tuned circuits that resonate when activated by a transmitter sweeping through the RF range. A receiver picks up the resonating frequency and activates the code deciphering system. Unlike other access cards, the proximity card can be worn or carried and detected at various ranges depending on the design capabilities of the system.

SMART CARDS contain an onboard computer chip and a power supply, normally a lithium battery capable of storing up to six pages of text.

WATERMARK MAGNETIC CARDS contain small oxide particles physically oriented into zones of varying widths. The particles are set while the iron oxide slurry is still fluid; the binary structure spacing of this computer-generated pattern is then oven-cured to create an unalterable 10- or 12-digit code number but leaving another layer of the magnetic stripe available for encoding soft conventional data.

WIEGAND CARDS utilize magnetically embedded unstable ferromagnetic wires formed in a permanently tensioned helical twist. The wiegand card reader uses a magnetic coil that picks up the flux reversal characteristics of the wires and converts them to binary pulses.

VIDEO SURVEILLANCE SYSTEMS

The major components of a video system are the camera, lens, and mount; lighting system; transmission system; synchronization system; video switching equipment; video recorder; video monitor; and video controller.

MAJOR COMPONENTS OF A VIDEO SECURITY SYSTEM

Randall I. Atlas, Ph.D., AIA, CPP; Atlas Safety & Security Design, Inc.; Miami, Florida

GENERAL

Basic security design strategies for building perimeters, interiors, lobbies, stairwells, loading docks, and roofs are outlined here. Also given are specific strategies for practicing crime prevention through environmental design (CPTED) and for addressing the need for bomb resistance.

BUILDING PERIMETER

1. Reduce the number of stairwells that exit to the outside.
2. Make the exit through the lobby whenever possible.
3. Entries should funnel people toward the control point.
4. Don't place any entries behind the control point.
5. Define public vs. private areas.
6. Project the image of a secure building.

INTERNAL AREAS

1. Place occupant services within protected floor space.
2. Control access to critical operation areas.
3. Provide buffer/reception zones in executive areas.
4. Provide multiple paths of entry/exit for executives.
5. Consider creating safe havens in senior executive offices.

BUILDING LOBBY

1. Position the control point between the entry and access to other floors.
2. Move flow past control point.
3. Place restrooms in public areas.
4. Make it possible to secure the lobby level.

COMMON STAIRWELLS

1. Designate stairways for emergency use only whenever possible.
2. Prevent access to floors from the garage and public areas.
3. Place stairs so they exit into the lobby.
4. Use internal stairwells for floor-to-floor transit.

LOADING DOCKS

1. Restrict access to authorized personnel.
2. Control access from the dock into the building.
3. Provide comfort area for drivers on the dock.
4. Make it possible to close off the dock.
5. Place dumpsters within controlled dock area.
6. Give vehicle staging a separate area.

ROOFS

1. Minimize entry points onto the roof.
2. Minimize entry via skylights by using multiple mullions. Solid or fixed diffusers in the light well can also prevent access.
3. Protect roof equipment, such as HVAC cooling towers, from vandalism with roof enclosures with lockable louvered doors spaced far enough from the equipment to allow proper ventilation.
4. Restrict the height of parapets to allow for surveillance from the ground.

ENVIRONMENTAL SECURITY STRATEGIES

1. Establish a physical boundary separating public from private property.
2. Design vehicular and pedestrian traffic patterns to maximize natural surveillance of arrivals and departures.
3. Clearly indicate primary and secondary entrances for employees, as well as a primary entrance for visitors.
4. Ensure that visitors will be processed at the main reception area before they proceed to secondary areas of the facility.
5. Erect physical barriers to separate public reception from private office areas.
6. Establish physical and electronic control over exterior and interior access points.
7. Compartmentalize and electronically control access to critical areas such as computer rooms, executive areas, power and telephone closets, and other restricted areas.
8. Physically separate shipping and receiving areas.
9. Restrict access to inventory storage areas.

10. Limit the number of facility exit doors based on operational necessity and fire loading regulations.
11. Clearly mark site entrances with signs that indicate visitor and vendor processing points.
12. Establish physical control over loading docks, equipment sheds, boiler rooms, and trashbins.
13. Provide adequate lighting and surveillance of employee and visitor parking lots.
14. If possible, separate employee and visitor parking.
15. Provide tenants with the means to control their own office areas.
16. Provide reception personnel with a means of covertly signaling duress situations.
17. Establish a uniform means of identification and access for multitenant sites.
18. Utilize primary and secondary authentication methods for access to highly sensitive areas.
19. Clearly delineate employee, visitor, vendor, and contractor status on badges along with the locations and times they are allowed access.
20. Design floor layout plans with security in mind.

STRATEGIES FOR BOMB RESISTANCE

Key defensive architectural design considerations for bomb resistance are listed here:

1. Establish a secured perimeter around the building as far from the building as possible.
2. Use poured-in-place reinforced concrete for all framing, including slabs, walls, columns, and roofs.
3. Roof and base slabs should be at least 8 in. thick, exterior walls 12 in. thick, and columns spaced no more than 30 ft apart.
4. Use seismic detailing at connection points.
5. Reinforce floor slabs and roofs using a two-way reinforcing scheme.
6. Design windows that comprise no more than 15% of the wall area between supporting columns.
7. Reduce the flying glass hazard by using a plastic mylar coating on the inside face of the windows.
8. Install specially designed blast curtains inside the windows to catch pieces of glass, while permitting the air-blast pressure to pass through the curtain.

9. Design artistically pleasing concrete barriers as planters or works of art and position them near curbs at a distance from the building.
10. Design buildings in a simple geometric rectangular layout to minimize the defraction effect when blast waves bounce off U-shaped or L-shaped buildings and cause additional damage.
11. Drastically reduce or eliminate ornamentation on buildings that could easily break away and endanger building occupants or pedestrians at street level. All external cladding should be of lightweight materials to minimize damage if they become flying objects after an explosion.

PARKING GARAGES**NATURAL ACCESS CONTROL**

1. Garages should be attended or monitored openly with cameras and sound monitors marked with signs.
2. Place all pedestrian entrances adjacent to vehicle entrances.
3. Stairwells should be visible, without solid walls.
4. Place elevators close to the main entrance so the entire interior of the elevator is in view when the doors are open.
5. Elevators must not have permanent stop buttons.
6. Design the ground floor to provide a view of the garage: use wire mesh or stretch cable.
7. Limit access to no more than two designated, monitored entrances.

NATURAL SURVEILLANCE

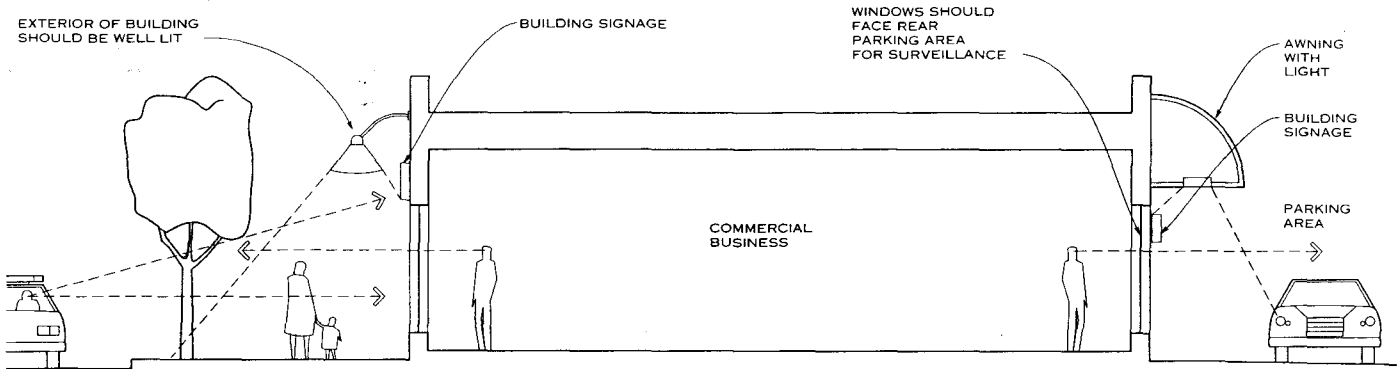

1. All elevators should be monitored by cameras and sound or clear materials should be used for the entire car.
2. Replace retaining walls with stretch cable railings for maximum visibility.
3. Parking areas and driving lanes should be well lighted.

MANAGEMENT

1. Prohibit free access to adjacent buildings without direct monitoring.
2. Designate public and private parking spaces.
3. Operate during hours similar to those of local businesses.
4. Secure the garage when it is closed.

**ROOF AND CANOPY DESIGN****ELEVATORS**

Randall I. Atlas, Ph.D., AIA, CPP; Atlas Safety & Security Design, Inc.; Miami, Florida

**NOTE**

Clear visibility should be maintained from store to sidewalk, street, parking areas, and passing vehicles. Window signs should cover no more than 15% of any window area.

NATURAL SURVEILLANCE FOR COMMERCIAL PROPERTY**COMMERCIAL SECURITY**

Designing safe stores and malls is critical to ensuring strong business draw and retention. Commercial security measures and design must protect the patrons, property, and business information of a business.

COMMERCIAL STOREFRONTS**NATURAL ACCESS CONTROL**

1. Locate cash registers in the front of the store near the main entrance.
2. Clearly mark public paths.
3. Signs should direct patrons to parking and entrances.
4. There should be no easy access to the roof.
5. Shops with rear parking lots should have rear entrances.

NATURAL SURVEILLANCE

1. Plan for good visibility: Windows should face rear parking lots. Signs in windows should cover no more than 15% of the window area. Interior shelving and displays should be no higher than five feet. Unobstructed views should be available from the store to the street, sidewalk, parking areas, and passing vehicles.
2. The building exterior should be well-lighted.
3. Loading areas should not create hiding places.
4. Drainage retention areas should be visual amenities, a landscaped pond or smaller waterway rather than a fenced area, but to be secure they should be visible from nearby buildings and streets.
5. All entrances should be under visual surveillance or monitored electronically.

TERRITORIAL REINFORCEMENT

1. Where possible, mark property boundaries with hedges, low fences, or gates.
2. Distinguish private areas from public spaces.
3. Identify shops with wall signs for those parking in the rear.
4. Specify awnings over rear doors and windows.

COMMERCIAL SHOPPING MALL**NATURAL ACCESS CONTROL**

1. Use signs to mark public entrances clearly.
2. Clearly mark sidewalks and public areas with special paving and/or landscaping.
3. Separate loading zones from public parking zones; designate limited delivery hours.
4. The parking garage should provide no exterior access to adjacent rooftops.

NATURAL SURVEILLANCE

1. Make restroom doors visible from main pedestrian areas and keep them away from outside exits.
2. Parking areas should be well lighted. Use high-intensity lighting in parking garages to minimize hiding places. In addition, all levels of the parking garage should be visible from the street or ground floor.
3. Loading areas should not create dead-end alleys or blind spots.

TERRITORIAL REINFORCEMENT

1. Define property perimeters with landscaping, post-and-pillar fencing, and gates.
2. Keep the number of entrances as low as possible and make them obvious and celebrated.

MANAGEMENT

1. Assign close-in parking for nighttime employees.
2. Help business associations work together to promote shopper and business safety.

COMMERCIAL DRIVE-THROUGHS**NATURAL SURVEILLANCE**

1. Locate ATMs in front of banks facing main roads or as a drive-through in the drive-in teller lanes.
2. Place the ordering station for a restaurant within sight of the restaurant interior.

OFFICE BUILDINGS

Office building security focuses on the safety and security of people, goods, and services. Office building security can assume a high or low profile based on the type and number of building users.

NATURAL ACCESS CONTROL

1. Clearly define public entrances with walkways and signs.
2. Accentuate building entrances with architectural elements, lighting, and landscaping and/or paving stones.

NATURAL SURVEILLANCE

1. Place restrooms where they can be observed from nearby offices.
2. All exterior doors and hallways should be well-lighted, as well as all parking areas and walkways.
3. Dumpsters should not create blind spots or hiding places.
4. Windows and exterior doors should be visible from the street or to neighbors.
5. All four facades should have windows.
6. Do not obstruct windows with signs.

7. Windows and doors should have views into hallways—including peepholes and vision panels.
8. Assign parking spaces to each employee and visitor.
9. Parking areas should be visible from the windows; side parking areas should be visible from the street.
10. Keep shrubbery below 3 ft and tree branches at least 10 ft above the ground for good visibility.

TERRITORIAL REINFORCEMENT

1. Define the perimeter with landscaping or fencing.
2. Design fences to permit visibility from the street.
3. Make exterior private areas easily distinguishable from public areas.
4. Position a security and/or a reception area to screen all entrances.

INDUSTRIAL BUILDINGS

Industrial enterprises need to protect the assets in their facilities. Special security consideration must be given to receiving and outgoing areas to reduce theft. Individual building tenants should have security technology availability for continuous monitoring and supervision of their space.

NATURAL ACCESS CONTROL

1. Avoid creating dead-end spaces.
2. Make site entrances easy to secure.
3. Control entrances to parking areas with fences, gates, or an attendant's booth.
4. Parking should be assigned by shifts and planned so late workers have the close-in spaces.
5. Restrict access to railroad tracks.
6. Plan storage yards for vehicular access by patrol car.
7. Avoid access to roofs via dumpster, loading docks, poles, stacked items, etc.
8. Delivery entrances should be separate, well-marked, and monitored.
9. Place employee entrances close to employee parking and work areas.
10. Separate nighttime parking areas from service entrances.
11. Avoid providing access from one part of the building into other areas.

NATURAL SURVEILLANCE

1. All entrances should be well-lighted, well-defined, and visible to public and patrol vehicles.
2. Parking areas should be visible to patrol cars, pedestrians, parking attendants, and/or building personnel.
3. Position the parking attendant for maximum visibility of the property.
4. Give reception areas a view of parking areas.
5. Use walls only when necessary.
6. Blind alleys, storage yards, and other out-of-the-way places should not offer hiding places.

GENERAL

Designing CPTED (crime prevention through environmental design) and security features into residential buildings and neighborhoods can reduce opportunities for and vulnerability to criminal behavior and help create a sense of community. The goal in residential design is to create safe dwelling places through limited access to properties, good surveillance, and a sense of ownership and responsibility.

SINGLE-FAMILY DWELLINGS

NATURAL ACCESS CONTROL AND SURVEILLANCE

1. Use walkways and landscaping to direct visitors to the proper entrance and away from private areas.
2. All doorways that open to the outside as well as sidewalks and all areas of the yard should be well-lighted.
3. Make the front door at least partially visible from the street and clearly visible from the driveway.
4. Windows on all sides of the house should provide full views of the property. The driveway should be visible from the front or back door and from at least one window.
5. Properly maintained landscaping should provide good views to and from the house.

TERRITORIAL REINFORCEMENT

1. Front porches or stoops create a transitional area between the street and the house.
2. Define property lines and private areas with plantings, pavement treatments, or fences.
3. The street address should be clearly visible from the street with numbers a minimum of 5 in. high and made of nonreflective material.

SUBDIVISIONS

NATURAL ACCESS CONTROL

1. Limit access to the subdivision without completely disconnecting it from neighboring areas. However, try to design streets to discourage cut-through traffic.
2. Paving treatments, plantings and architectural design features such as columned gateways can guide visitors away from private areas.
3. Locate walkways where they can direct pedestrian traffic and remain unobscured.

NATURAL SURVEILLANCE

1. Landscaping should not create blind spots or hiding places.
2. Locate open green spaces and recreational areas so they can be observed from nearby houses.
3. Use pedestrian-scale street lighting in areas with high pedestrian traffic.

TERRITORIAL REINFORCEMENT

1. Design lots, streets, and houses to encourage interaction between neighbors.
2. Accent entrances with changes in street elevation, different paving materials, and other design features.
3. Clearly identify residences with street address numbers that are a minimum of 5 in. high and well-lighted at night.
4. Property lines should be defined with post-and-pillar fencing, gates, and plantings to direct pedestrian traffic.
5. All parking should be assigned.

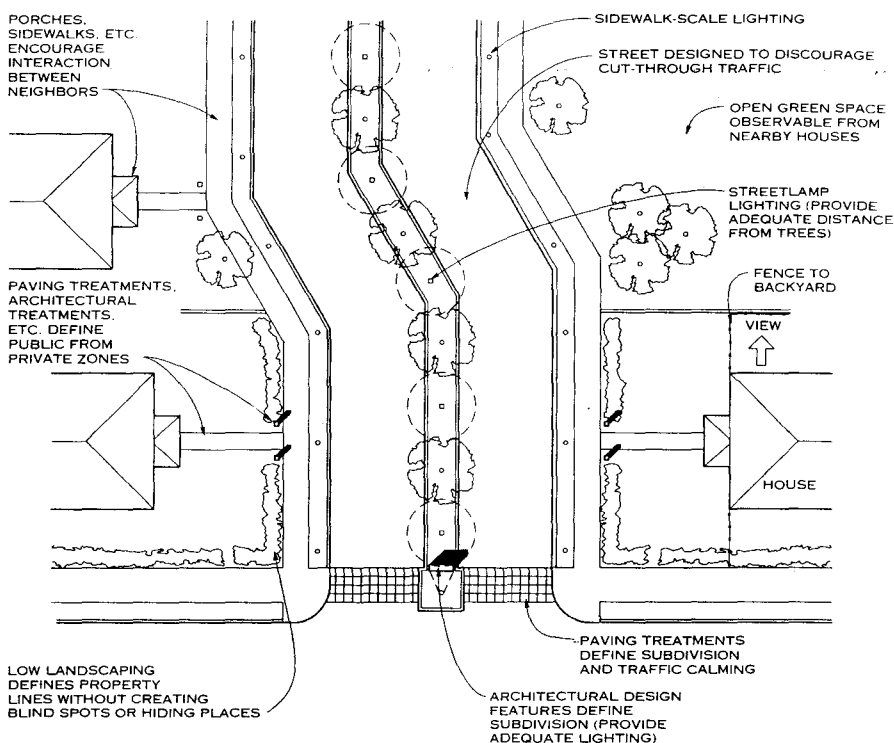

MULTIFAMILY DWELLINGS

NATURAL ACCESS CONTROL

1. Balcony railings should never be made of a solid, opaque material or be more than 42 in. high.
2. Define parking lot entrances with curbs, landscaping, and/or architectural design or a guard booth; block dead-end areas with a fence or gate.
3. Hallways should be well-lighted, and elevators and stairs should be centrally located.
4. Common building entrances should have locks that automatically lock when the door closes.
5. Limit access to the building to no more than two points. No more than four units should share the same entrance.

NATURAL SURVEILLANCE

1. Make exterior doors visible to the street or neighbors, and ensure they are well-lighted.
2. All four building facades should have windows. Site buildings so the windows and doors of one unit are visible from those of other units.

CRIME PREVENTION THROUGH ENVIRONMENTAL DESIGN—PLANNING FOR SUBDIVISIONS

CRIME PREVENTION THROUGH ENVIRONMENTAL DESIGN—PLANNING FOR RESIDENTIAL PROPERTY

3. Assign parking spaces to each unit and locate them next to the unit. Designate special parking spaces for visitors.
4. Parking areas and walkways should be well-lighted.
5. Recreation areas should be visible from a multitude of windows and doors.
6. Dumpsters should not create blind spots or hiding places.
7. Elevators and stairwells should be clearly visible from windows and doors. In addition, they should be well-lighted and open to view—not hidden behind solid walls.
8. Shrubbery should be no more than 3 ft high for clear visibility and tree canopies not lower than 8 ft 6 in.

TERRITORIAL REINFORCEMENT

1. Define property lines with landscaping or post-and-pillar fencing, but keep shrubbery and fences low to allow visibility from the street.
2. Accent building entrances with architectural elements and lighting and/or landscape features.
3. Doorknobs should be 40 in. from window panes.
4. Clearly identify all buildings and residential units with well-lighted address numbers a minimum of 5 in. high.
5. Common doorways should have windows and be key-controlled by residents.
6. Locate mailboxes next to the appropriate residences.

Randall I. Atlas, Ph.D., AIA, CPP: Atlas Safety & Security Design, Inc.; Miami, Florida

SITE SECURITY PLANNING AND DESIGN CRITERIA

The safety and security of a building, its site, and its users should be an important design criteria, similar to such health and safety issues as structural integrity, accessibility, and fire safety. Increased threats to people and property from acts of terrorism, workplace violence, and street crime make it important to identify security issues and establish a plan to manage the risks.

SECURITY ASSESSMENT

An assessment of the security requirements should be made as early as possible, preferably as part of the programming phase and certainly before the design phase. Determining the security requirements is mainly a matter of managing the perceived risks. Although the assessment is the owner's responsibility, the architect should ensure that the security requirements have been identified before the design begins. Failure to identify security issues will surely result in design changes, delays, and cost increases for both the owner and the architect.

The security assessment will answer four questions:

1. What are the assets—persons, places, information, property—that require security protection?
2. What are the criminal or other threats—street crime, workplace violence, terrorism, sabotage—against which the assets must be protected?
3. How vulnerable are the assets to the threats (e.g., if workplace violence is identified as a threat, can unauthorized persons enter private work spaces unchallenged)?
4. What countermeasures are required to mitigate the threat (e.g., is the circulation pattern designed to channel visitors through controlled site-access portals)?

The cost of achieving the correct level of site-based protection may be very high, depending on the nature of the protected assets and the perceived threat to them. After the recommended countermeasures have been identified, organize them according to their priority and ask the owner to select those that are prudent and cost-effective for the project. In the case of federal projects (and many state and local government projects as well), the assessment results in the assignment of a defined level of protection (LOP), with specific countermeasures attached to each level. See the discussion below of the GSA Security Standards.

Risk assessment and security design are especially relevant in schools, hospitals, airports, office buildings, and multi-family apartment buildings. In recent years, terrorists have targeted such buildings because of their "architectural vulnerability," so it is clearly important to address security issues in their design.

SECURITY LAYERING

One way to think about security requirements is as a layering process. The first layer, the site perimeter of the property, is the first, not the last, line of defense. The U.S. Department of State seeks setbacks of at least 100 feet for new buildings, and even at that distance securing the perimeter is difficult in most urban settings. The building skin of the structure is the next layer. Sensitive areas within a building are deeper layers requiring protection, and, finally, at the center of all the layers, are the particular persons, information, or property that may require point protection.

GSA RECOMMENDATIONS FOR SECURITY STANDARDS

In response to bombings of federal office buildings, the federal government has developed security standards for all of its facilities, and an interagency security committee has recommended their adoption as government-wide standards. These standards, known as the GSA Security Standards, encourage a defensible space/crime prevention through environmental design (CPTED) approach that clearly defines and screens the flow of people and vehicles through various layers of public and private space. Edges and boundaries of a property should clearly define the desired circulation patterns and movements. Various screening techniques can be used to separate legitimate users of a building from those who are looking for opportunities to commit crime, workplace violence, or acts of terrorism.

The security standards also address the functional requirements and desired application of security glazing, bomb-resistant design and construction, landscaping and planting designs, site lighting, natural and mechanical surveillance opportunities (e.g., good sight lines, no blind spots, window placement, and proper applications of CCTV). The recommendations are further subdivided according to whether

they should be implemented for various levels of security. For example, a level-one facility might not require an entry control system whereas a level-four facility would require electronic controls with CCTV assessment.

Several state and local governments also have reviewed the standards and applied them to new construction. Consult local and state authorities for specific requirements.

The standards take a balanced approach to security, considering cost-effectiveness, acknowledging acceptance of some risk, and recognizing that federal buildings should not be bunker- or fortress-like, but open, accessible, and attractive. Prudent, rather than excessive, security measures are appropriate in facilities owned by and serving the public.

The architecture and engineering team should address the following issues for renovations or new construction on any federal building (and often for state and local buildings):

SECURITY PLANNING

1. Security risks and needs of building tenants
2. Mylar film on exterior windows
3. Blast standards for current projects and new construction
4. Design standard for blast resistance and street setback for new construction

PERIMETER AND EXTERIOR SECURITY

1. Parking area and parking controls
2. CCTV monitoring
3. Lighting, including emergency backup
4. Physical barriers

ENTRY SECURITY

1. Intrusion detection system
2. Upgrade to current life safety standards
3. Screen persons as well as mail and packages
4. Entry control with CCTV and electric door strikes
5. High-security locks

INTERIOR SECURITY

1. Employee ID, visitor control
2. Access to utilities
3. Emergency power for critical systems
4. Location of day care centers

APPLICATION OF GSA SECURITY STANDARDS TO ALL BUILDING TYPES

Many of the issues addressed in the GSA standards apply to all building types. Among the important security design issues are establishment of (1) hierarchies of public and private spaces; (2) traffic patterns of the site and the building; and (3) opportunities for natural observation of surroundings. Hierarchies of space should proceed from open, pub-

lic areas, to semipublic, to semiprivate, to private spaces. Areas unassigned in the hierarchy become a sort of "no man's land," left unmonitored and unprotected. Traffic patterns of pedestrians and vehicles onto the site and into buildings should be carefully thought-out and controlled. And, finally, all buildings should be designed so that users have a good, unobstructed view of their surroundings.

The following design and planning considerations address both low- and high-threat situations. If neither a high nor a low threat is specified, then the design consideration applies to both situations.

PLANNING

1. Vehicular control
 - Low threat: not required
 - High threat: install barriers to stop a vehicle of a specified size
2. Perimeter vehicle inspection
 - Low threat: not required
 - High threat: install sally port with vehicle arrest device
3. Site lighting
4. Signage to control site circulation
5. Landscaping
 - Avoid dense landscaping in both low and high threat.
6. Minimize the number of entrances to a building.
 - Secure entrances when building is not in use.
 - Clearly identify the function of each entrance (e.g., employees only, deliveries, etc).
7. Install barriers on vulnerable openings such as ground floor windows, exterior fire stairs, roof openings, and skylights. Fence off problem areas to prevent unauthorized access and funnel movement along desired paths.
8. Control access for servicing and deliveries.
9. Use graffiti-resistant exterior finishes and/or landscape with creeping vines.

PARKING

1. Inside the building
 - Low threat: government vehicles, building employees.
 - High threat: government employees who need security
2. On-site controlled
 - Low threat: no restriction
 - High threat: 100-ft standoff
3. Parking on adjacent streets
 - Low threat: government and key employees only
 - High threat: use structural features to prevent parking
4. Parking on adjacent properties
 - Low threat: 5-ft standoff
 - High threat: 100-ft standoff

Site Security Planning for Terrorism continues on the next page.

Randall I. Atlas, AIA, Ph.D., CPP; Atlas Safety and Security Design, Inc.; Miami, Florida
 Anthony DiGreggario; Applied Research Associates; Washington, D.C.
 American Society for Industrial Security; Alexandria, Virginia

Site Security Planning for Terrorism is continued from the previous page.

PARKING (CONTINUED)

5. Parking facility security systems
6. Minimize the number of entrances to a building
 - Functions of the entrances should be clearly identified (e.g., employees only, deliveries, visitors)
 - Secure entrances when the building is not in use
7. Install barriers on vulnerable openings such as ground floor windows, exterior fire stairs, roof openings, and skylights. Fence off problem areas to prevent unauthorized access and funnel movement along desired paths.
8. Control access for servicing and deliveries.
9. Use graffiti-resistant exterior finishes and/or landscape with creeping vines.

SITE

1. Generous wiring and backup power
2. Intrusion detection devices
3. Boundary penetration sensors and motion detection systems
4. Access control systems
5. Contraband, weapons, and explosives detectors
6. Credential readers and positive personnel identification systems
7. Security control and information display systems

EXTERIOR ENTRANCE

1. Lobby
 - Protection from forced entry
2. Employee entrances
 - Same as lobby
3. Garage and service entrances
 - Vehicle arrest devices

ELECTRICAL ENGINEERING

Except for lighting (#5) and vehicle access control (#6), none of the following is necessary in low-threat projects.

1. Exterior connector for emergency power
2. Exterior surveillance
3. Emergency generator
4. Protected utilities and feeders
5. Adequate lighting (including site lighting)
6. Vehicle access control (parking)
7. Emergency communications (parking)
8. CCTV (parking)

FIRE PROTECTION ENGINEERING

1. Secured water supply
2. Dual fire pumps (electric and diesel)
 - Not required in low- or high-threat projects
3. Secured standpipe connection

ELECTRONIC SECURITY

1. Operational control center, fire command center, and security control center located together
 - Low threat: not required
2. Backup control center
 - Low threat: not required
 - High threat: locate in manager's or engineer's office
3. Electrical utility closets, mechanical rooms, and telephone closets
 - Low threat: entry with key should be maintained, with some method of noting times of entry and departure, such as marked by a watchman's clock system
 - High threat: access to mechanical, electrical, and telecommunication rooms should be authorized, programmed, and monitored at the security control center through preidentification of maintenance personnel
4. Elevator recall
5. Door lock
 - Low-threat: key-locked security keying system
 - High-threat: high-security keying system with electronic locks
6. Intrusion detection
 - Low threat: magnetic reed switches with optional sensor to detect breaking glass
 - High-threat: same as for low threat, with balanced magnetic contact switch set and sensor to detect breaking glass
7. Monitoring
 - Low threat: commercial central station
 - High threat: on-site, proprietary security control center; review roof intrusion detection
8. CCTV
 - Low threat: not required
9. Duress alarms
 - Low threat: install in key public contact areas, executive offices, and garages as needed
 - High threat: same as low threat

SUMMARY OF KEY DEFENSIVE ARCHITECTURAL SITE DESIGN CONSIDERATIONS FOR BOMB RESISTANCE

1. Establish a secured perimeter around the building that is as far from the building as possible. Setbacks of 100 ft are desired.

2. Design concrete barriers as flower planters; position them at curbs, spaced less than 4 ft apart.
3. Build new buildings in a simple, geometric, rectangular layout to minimize the "defraction effect" when blast waves bounce off U-shaped or L-shaped buildings causing additional damage.
4. Reduce or eliminate ornamentation on buildings, and use lightweight materials for exterior cladding. During a bomb blast (or even a hurricane), such ornamentation is likely to break away from the building and may injure building occupants or pedestrians at street level.
5. Eliminate potential hiding places near the facility.
6. Provide unobstructed views around the facility.
7. Site the building within view of other occupied facilities.
8. Locate assets stored on site but outside of the building within view of occupied rooms of the facility.
9. Minimize signage that indicates what assets are on the property.
10. Eliminate lines of approach perpendicular to the building.
11. Minimize the number of vehicle access points.
12. Eliminate or strictly control parking below buildings.
13. Locate parking as far from the building as practical (while still addressing ADA spaces and proximity), and place parking within view of occupied rooms or facilities.
14. Illuminate the building exterior and other areas where assets are located.
15. Secure access to power and heating plants, gas mains, water supplies, and electrical and phone service.

CONCLUSION

The design of a building can significantly affect how secure it is from acts of terrorism, workplace violence, and other crimes. The goal for architects is to use architectural design features and elements in a manner that enhances a building's security without compromising its aesthetics and functionality. While there are instances in which a fortress-like structure is the only solution to various security issues, in many cases a simple, well thought-out plan will yield the best results.

DESIGN GUIDELINES

Each commercial development project will have its own set of requirements. This outline is intended as an overview of the subjects the architect, engineer, and owner should consider when planning a small to medium commercial development.

LOCAL PLANNING REGULATIONS

As with all new projects, the designer should research the laws, codes, and ordinances that govern development in the jurisdiction. This may include municipal, township, county, state, and federal regulations as they pertain to land and building development.

ZONING

Confirm that the zoning classification of the property permits the intended use. For example, to build a warehouse the tract of land would have to be zoned for industrial use. The zoning classification also determines what level of development is allowed on a particular tract of land.

BUILDING CODES

The architect should find out what relevant codes/laws require in regard to life safety, welfare, and accessibility. These requirements should provide minimum criteria by which to measure the design and construction of a project. The intended use and type of construction will dictate allowable heights and areas.

Codes vary around the country, so architects must consult the local government for all applicable codes/laws and local amendments. Pertinent laws include the BOCA, UBC, SBCC, NFPA, ASHRAE, ANSI, and the ADA universal accessibility law.

ENVIRONMENTAL ANALYSIS

Environmental issues such as wetlands preservation, potential groundwater contamination, and preservation of native flora and fauna should be considered. Local groups can provide information regarding local environmental issues.

GEOTECHNICAL ANALYSIS

A geotechnical engineer should be retained at the inception of a project to provide a thorough subsurface investigation of the property. The key information provided by such a survey includes the following:

1. Soil quality/type: Soils are described, ranging from their composition to drainage.
2. Bearing capacity: A variety of field and/or laboratory testing, considered in conjunction with anticipated structural dead loads, goes into analyzing how a planned building will react to the soil conditions on a site. Settlement is one issue to be considered here.
3. Foundation recommendations: The geotechnical engineer uses analytical data about the soil quality/type and the bearing capacity of the soil to make recommendations regarding the most efficient/cost-effective foundation system.

LOT COVERAGE

Zoning laws regulate the amount of physical construction that can occur on a given piece of land. Physical construction covers buildings and paved, impervious surfaces (e.g., sidewalks, blacktop). Another measure affecting the allowable building footprint is building setback, the distance that must exist between a structure and the property line. Building setbacks are typically described in terms of front, rear, and side yards; rights-of-way; and property easements. Local municipal ordinances describe required setbacks, which vary based on location and intended use.

PROPERTY SURVEY

Property surveys verify the property boundaries, street lines, contours, pertinent landmarks, rights-of-way, and easements (construction restrictions) of a piece of property.

DRAINAGE EASEMENT

When properties share a common storm water basin, local authorities can hold easements to allow for storm water drainage across multiple properties. Drainage easements are not required when individual property owners are responsible for storm water management.

MAXIMUM BUILDING HEIGHT

The maximum height buildings on a particular site can reach is usually defined in terms of both stories and feet above the finished grade. These criteria are set by local ordinance and building code.

PARKING REQUIREMENTS

Parking requirements typically are a function of intended use and building size (e.g., one space per 250 sq ft of building area). In suburban office park planning, this is commonly the governing factor when maximizing buildable area on small and constricted sites.

UTILITIES

The architect must determine which utilities are required, which are available, how site access will be designed, and where the utility lines will enter the building. Utilities include water, sewer, gas, electric, and telephone.

BUILDING ENTRANCE

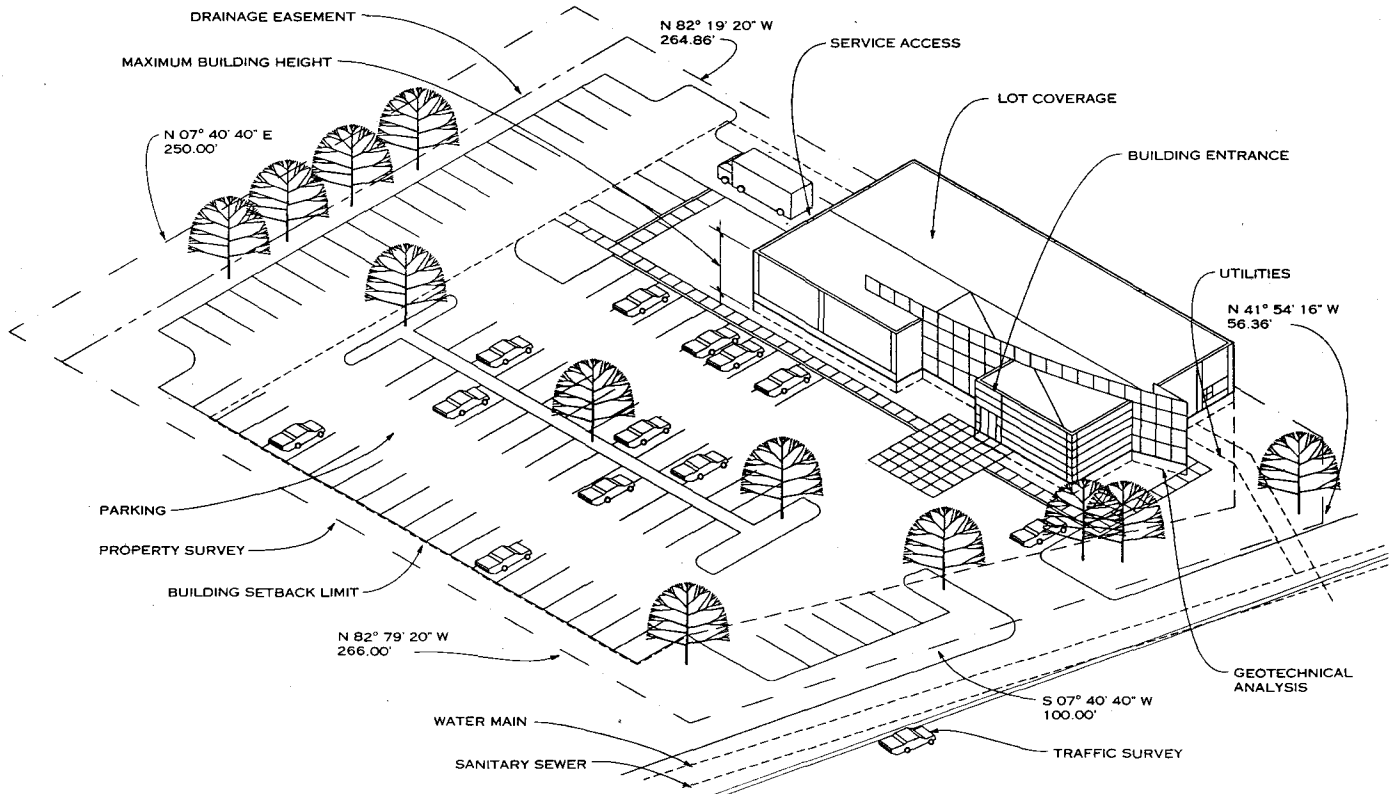

Public exposure, topography, orientation, and parking should be considered in designing and siting the main entrance. To maximize a building's presence on the site and help orient users, the main entrance should be obvious and easily visible. Site topography and the intended use of the building will determine orientation of the entrance, with consideration of sun angles and views. The main entrance should be readily recognizable from the main parking area.

TRAFFIC SURVEY

A typical traffic survey analyzes traffic patterns, densities, generators, and peak periods. This information is used to determine the guidelines/procedures required to provide safe and effective flows of vehicular and pedestrian traffic. Local governing agencies determine the scope and extent of survey required.

SERVICE ACCESS

Architects must consider vehicular service access to both the site and the building. Site design and building orientation must allow for maneuverability of service, delivery, and sanitary vehicles.

SITE DEVELOPMENT DIAGRAM

Greenfield Architects, Ltd.; Lancaster, Pennsylvania

INTRODUCTION

The following pages provide the essential elements of town design. Included are an abstract, a set of diagrams, and criteria for town and community design.

Site planning for development projects should be a sequential process that begins with information gathering and ends with detailed design drawings. The process involves three stages: analysis, design, and implementation. The chart below indicates a planning process; however, this can vary to accommodate the specifics of a particular project. Physical site characteristics, urban or suburban location, and community criteria modify the process. The site planning process includes both architect and landscape architect and, in some cases, biologists, civil engineers, and others. An integrated approach to site development and architecture helps create a quality environment. The text on this page is presented as a checklist for structuring a project.

CLIENT CONTACT AND INPUT

The first step is contact between the client and the site planner. The client may have some development objectives based on financial capabilities and market feasibility. It is important for the site planner to obtain all client data relative to planning the site.

LITERATURE REVIEW

Site planning covers a variety of situations from rural and suburban to high-intensity urban.

There is substantial literature on planning sites and designing neighborhoods of all densities. Recent publications demonstrate a return to the basic town planning principles that have produced orderly community design throughout history.

COMMUNITY INVOLVEMENT

Early in the planning process, contact community groups with an interest in the proposed project. Such efforts yield useful information for community design and are particularly important when a proposed project is adjacent to existing development. Compatibility issues are typically resolved with community participation.

One method of involving the community is the "charrette," a participatory planning process with a limited time frame, usually one day to a week, in which residents, municipal staff, elected leaders, and others participate in the physical design of a project. The planner receives local information useful for the design, and individuals and groups bring their interests to bear at the beginning of the design process, thereby expediting final approvals.

REGIONAL, STATE, AND FEDERAL PLANNING

Some areas of the country have established regional agencies for intercommunity issues, such as water management, transportation, population studies, and pollution control. Some communities have adopted regional planning guidelines.

State and/or federal criteria can also affect projects. State plans may address broad issues applicable to large sites or impose constraints on sites involving issues of statewide concern. Also, some states require environmental impact statements for large-scale projects. The U.S. Army Corps of Engineers is responsible for environmental review of proposed dredge and fill operations in navigable waters and wetlands. The Federal Flood Insurance Program establishes minimum elevations for potential flood areas. Other state, regional, and local authorities also may oversee the protection of air and water quality and other environmental issues.

LOCAL PLANNING INFORMATION

The planner must collect local planning information. Personal contact with planning and zoning agencies is important in order to comprehend local criteria. Following is a list of information to review.

PLANNING DOCUMENTS

Many communities have adopted comprehensive plans that indicate the particular land use and intensity of the site. In addition, information on the availability and/or phasing of public services and utilities, environmental criteria, traffic planning, and population trends can be found in most comprehensive plans. Some communities require that rezoning meet the criteria provided in their comprehensive plans.

In addition to the comprehensive plan, communities may also adopt neighborhood or area plans that refine the comprehensive plan as it relates to a particular locale. Many of these studies stipulate specific zoning categories for individual parcels of land.

URBAN DESIGN PLANS

Some communities have adopted urban design plans for creating a harmonious physical environment. These documents may range from conceptual to those that incorporate specific requirements. Some provide bonuses in land use intensities for incorporating urban amenities such as plazas and squares. There may also be criteria for retrofitting existing areas, a critical need in American cities where a substantial amount of urban area is deteriorated or developed incoherently.

ZONING

Land zoning prescribes the intensity and type of land use allowed. A zoning change is required if the planned project differs. Regulations often need to be modified to allow good community design. Common examples of regulations discouraging good urban form include excessive setbacks and restricted mixed-use development.

PUBLIC WORKS STANDARDS

Local public works criteria significantly affect the design of large sites. Roadway layout, cross sections, and drainage are typical requirements. Excessive roadway standards designed for automobile convenience, with little regard for

the pedestrian are typical of today's public works regulations. Such standards should be modified to allow coherent neighborhood design.

PUBLIC SERVICES AND UTILITIES

Other information that may require additional research includes

1. Availability of potable water, including local and state regulations on wells
2. Availability of public sewer service, access to trunk lines, and available increases in flow. If sewage lines are not immediately available, determine projected phasing of these services, as well as alternatives to sewage collection and treatment, including septic tanks.
3. Access to public roads, existing and projected carrying capacities, and levels of services of the roads. (State and local road departments can provide this information.)
4. Availability and capacities of schools and other public facilities, such as parks and libraries

SITE ANALYSIS

Site analysis is one of the planner's major responsibilities. All the on- and off-site design determinants must be evaluated before design begins. For details, see the following pages on environmental site analysis.

PROGRAM DEVELOPMENT

At the program development stage, background research, citizen input, and site analysis are combined with client input and synthesized into a set of program strategies. Basic elements for program development include market and financial criteria; federal, state, regional, and local planning information; local political climate development costs; the client's objectives; and site opportunities and constraints as developed in the synthesis of environmental site determinants. Balancing the various determinants will lead to an appropriate approach to site development. Consider dwelling unit type, density, marketing, time phasing, and similar criteria, as well as graphic studies of the site, to finalize the program. Develop clear graphic representations of design concepts to present to the client and others who may have input to the process. If the project cannot be accomplished under the existing zoning or public works requirements, requesting a regulatory change becomes a part of the program.

ALTERNATIVE PLAN PREPARATION

Once the program has been accepted by the client, develop several design solutions to meet the program objectives. When an alternative has been accepted, develop it into the preliminary plan. This plan should be relatively detailed, showing all spatial relationships, infrastructure, landscaping, and other relevant information.

PUBLIC REVIEW

A zoning change requires public review. Some communities require substantial data, such as impact statements and other narrative and graphic exhibits, while others may require only an application for the zoning change. Local requirements for changes can be complex, and it is imperative that the planner and the client's attorney are familiar with local criteria.

FINAL DESIGN PLANS

At this stage, the preliminary plans are refined into final site development plans that include fully dimensioned drawings, landscape plans, and site details. Final development plans also include drawings prepared by the engineer or surveyor, such as legal plats and utilities, street, and drainage plans. Upon approval, final design plans are recorded in the public records in the form of plats. Homeowner association agreements, deed restrictions, and similar legal documents must also be recorded, and they become binding on all owners and successive owners, unless changed legally. Bonding may be required for infrastructure and other public facilities. In some instances, the planner may develop specific design standards for the total buildout of the project.

TOWN PLANNING PROCESS

1 SITE, COMMUNITY, AND URBAN PLANNING

TOPOGRAPHICAL SURVEY

SURVEY DATA

The first step in any site analysis is the gathering of physical site data. An aerial photograph and an accurate survey showing the following information are basic to any site analysis process:

1. Scale, north arrow, benchmark, and date of survey
2. Tract boundary lines
3. Easements: location, width, and purpose
4. Names and locations of existing road rights-of-way on or adjacent to the tract, including bridges, curbs, gutters, and culverts
5. Position of buildings and other structures such as foundations, walls, fences, steps, and paved areas
6. Utilities on or adjacent to the tract—location of gas lines, fire hydrants, electric and telephone poles, and street lights; and direction, distance to, and size of nearest water mains and sewers and invert elevation of sewers
7. Location of swamps, springs, streams, bodies of water, drainage ditches, watershed areas, flood plains, and other physical features
8. Outline of wooded areas with names and condition of plant material
9. Contour intervals of 2 to 5 ft, depending on slope gradients, and spot elevations at breaks in grade, along drainage channels or swales, and at selected points as needed

Considerable additional information may be needed, depending on design considerations and site complexities such as soil information and studies of the geological structure of the site. Federal regulations for wetland mapping and conservation may also be relevant.

SUBURBAN SITE ANALYSIS

The site analysis is a major responsibility of the site planner. The physical analysis of the site is developed primarily from field inspections. Using the survey, the aerial photograph, and, where warranted, infrared aerial photographs, the site designer, working in the field and in the office, verifies the survey and notes site design determinants. These should include, but not be limited to, the following:

1. Areas of steep and moderate slopes
2. Macro- and microclimatic conditions, including sun angles during different seasons; prevailing breezes; wind shadows; frost pockets; and sectors where high or low points give protection from sun and wind
3. Solar energy considerations. If solar energy appears feasible, a detailed climatic analysis must be undertaken considering factors such as detailed sun charts; daily averages of sunlight and cloud cover; daily rain averages; areas exposed to the sun at different seasons; solar radiation patterns; and temperature patterns
4. Potential flood zones and routes of surface water runoff
5. Possible road access to the site, including potential conflicts with existing road systems and carrying capacities of adjacent roadways (usually available from local or state road departments)
6. Natural areas that from an ecological and aesthetic standpoint should be saved; all tree masses with name and condition of tree species and understory planting
7. Significant wildlife habitats that would be affected by site modification
8. Soil conditions relative to supporting plant material, areas suitable for construction, erosion potential, and septic tanks, if relevant
9. Geological considerations relative to supporting structures
10. Exceptional views; objectionable views (use on-site photographs)
11. Adjacent existing and proposed land uses with notations on compatibility and incompatibility
12. Potential noise sources, particularly noise generated from traffic that can be mitigated by using plants, berms, and walls and by extending the distance between the source and the receiver

URBAN SITE ANALYSIS

Although much of the information presented for suburban sites may apply equally to urban sites, additional site design criteria may be necessary. The urban environment has numerous design determinants in the form of existing structures, city patterns, and microclimatic conditions.

ENVIRONMENTAL CONSIDERATIONS

1. Air movement: Prevailing breezes characteristic of a region may be greatly modified by urban high-rise structures. Predominant air movement patterns in a city may be along roadways and between buildings. The placement, shape, and height of existing buildings can create air turbulence caused by micro air movement patterns. These patterns may influence the location of building elements such as outdoor areas and balconies. Also, a building's design and placement can mitigate or increase local wind turbulence.
2. Sun and shadow patterns: The sun and shadow patterns of existing structures should be studied to determine how they would affect the proposed building. This is particularly important for outdoor terraces and balconies where sunlight may be desirable. Sun and shadow patterns also should be considered as sources of internal heat gain or loss. Building orientation, window sizes, and shading devices can modify internal heat gain or loss. Studies should include daily and seasonal patterns and the shadows the proposed building would cast on existing buildings and open spaces.
3. Reflections: Reflections from adjacent structures such as glass-clad buildings may be a problem. The new building should be designed to compensate for such glare or, if possible, oriented away from it.

URBAN CONTEXTUAL ANALYSIS

1. Building typology and hierarchy: An analysis of the particular building type (residential, commercial, public) relative to the hierarchy of the various building types in the city is useful in deciding the general design approach of a new building. For example, public buildings may be dominant in placement and design, while residential buildings are subdominant. It is important to maintain any existing hierarchy that reinforces visual order in the city. Any predominant architectural solutions and details characteristic of a building type incorporated in the new building's design can help maintain a recognizable building type.
2. Regional character: An analysis of the city's regional architectural characteristics is appropriate in developing a design solution that responds to unique regional characteristics. Regional characteristics may be revealed through unique architectural types, through vernacular building resulting from local climatic and cultural characteristics, and from historically significant architecture. Historic structures should be saved by modifying them for the proposed new use or by incorporating parts of the existing structure(s) into the proposed design.
3. City form: The delineation of city form created by road layout, location of major open spaces, and architecture-created forms should be analyzed. Elements that delineate city form should be reinforced by architectural development solutions for a particular place within the city. For example, a building proposed for a corner site should be designed to reinforce the corner through building form, entrance, and design details. A building proposed for midblock may be a visually unifying element providing connection and continuity with adjacent buildings. Sites at the ends of important vistas or adjacent to major city squares probably should be reserved for important public buildings.
4. Building scale and fenestration: It is important to analyze building scale and fenestration of nearby structures. Reflecting, although not necessarily reproducing, such detailing in the proposed building can provide visual unity and continuity in the architectural character of the city. One example is the use and placement of cornice lines to define the building's lower floors in relation to adjacent buildings. Cornice lines also can define the building's relationship to pedestrians in terms of scale and use.
5. Building transition: Sometimes it may be appropriate to use arcades and porches to provide transition between the building's private interior and the public sidewalk. Including them may be especially worthy if adjacent buildings have these elements.
6. Views: Important city views of plazas, squares, monuments, and natural features such as waterfronts and parks should be considered. It is important to design the proposed structure to enhance and preserve such views for the public and for inhabitants of nearby buildings, as well as incorporating them as views from the proposed building.

SLOPE

SOILS

VEGETATION

COMPOSITE

ENVIRONMENTAL SITE ANALYSIS PROCESS

If a site has numerous environmental design determinants, the site planner may analyze each environmental system individually in order to comprehend the environmental character of the site more clearly. This can be a complex process, and a site planner/landscape architect with expertise in environmental analysis should be retained to coordinate such an effort.

By preparing each analysis on transparencies, the site planner can use the overlay approach. Values are assigned to each sheet based on impact, ranging from areas of the site where change would have minimal effect to areas where change would result in severe disruption of the site. In essence, the separate sheets become abstractions with values assigned by the site planner and associated professionals. As each sheet is superimposed, a composite develops that, when completed, constitutes the synthesis of the environmental design determinants. Lighter tones indicate areas where modification would have minimal influence, darker tones indicate areas more sensitive to change. The sketches shown simulate the overlay process. The site planner may give greater or lesser weight to certain parameters depending on the particular situation. In assigning values that help determine the site design process, the site planner should consider such factors as the value of maintaining the functioning of the individual site systems, the uniqueness of the specific site features, and the cost of modifying the site plan.

Following is a list of the environmental design determinants that, depending on the particular site, may be considered and included in an overlay format:

1. **SLOPE:** The slope analysis is developed on the contour map; consideration should include the percentage of slope and orientation of slope relative to the infrastructure and land uses.
2. **SOIL PATTERNS:** Consideration may include the analysis of soils by erosion potential, compressibility and plasticity, capability of supporting plant growth, drainage capabilities, possible sources of pollution or toxic wastes, septic tank location (if relevant), and the proposed land uses and their infrastructure.
3. **VEGETATION:** Consideration of indigenous species (values of each in terms of the environmental system) includes size and condition, the succession of growth toward climax conditions, uniqueness, the ability of certain species to tolerate construction activities, aesthetic values, and density of undergrowth.
4. **WILDLIFE:** Consideration of indigenous species includes their movement patterns, the degree of change each species can tolerate, and feeding and breeding areas.
5. **GEOLOGY:** Consideration of underlying rock masses studies the depth of different rock layers and the suitability of different geological formations in terms of potential infrastructure and building.
6. **SURFACE AND SUBSURFACE WATER:** Consideration of natural drainage patterns covers aquifer recharge areas, erosion potential, and flood plains.
7. **CLIMATE:** Consideration of microclimatic conditions includes prevailing breezes (at different times of the year), wind shadows, frost pockets, and air drainage patterns.

COMPUTER APPLICATION

The above process is labor intensive when developed by hand on individual sheets of mylar; however, this particular method of environmental analysis is easily adaptable to the CAD (computer-aided drafting) system. Commercial drafting programs suitable for the overlay approach are readily available. Simplified, the method is as follows:

1. A map, such as a soil map, is positioned on the digitizer and the information is transferred to the processor through the use of the stylus. One major advantage to the use of a computer is that the scale of the map being recorded will be transferred to the selected scale by the processor. A hatched pattern is selected, with a less dense pattern for soil types that would have minimal influence and more dense patterns for soil types more sensitive to change. Once this information is programmed into the computer, it is stored.
2. The same process is repeated for development of the next overlay; for example, vegetation. Once again any scale map may be used. This process is repeated until all overlays have been stored. At any time one or all overlays can be produced on the screen.
3. The individual overlays or any combination of overlays can be drawn on mylar with a plotter. If appropriate for the particular analysis, the plotter will draw in color. The resulting overlay sheets take considerably less time than by hand and may be more accurate. Other benefits are that the site can be studied directly on the computer screen and any part of the overlay can be enlarged for greater detail.
4. The overlay process can be recorded by videotape or by slides from the screen for use in presentations.

1 SITE, COMMUNITY, AND URBAN PLANNING

SITE ANALYSIS MAP

Locate natural, cultural, and scenic features first. These include many buildable areas, such as farm fields, pastures, meadows, and mature woodland; special features, such as stone walls, springhouses, cellar holes, and views into and out of the site; and unbuildable areas, such as steep slopes, wetlands, springs, streams, and ice ponds.

CONVENTIONAL LAYOUT OR "YIELD PLAN"

Sketch an unimaginative but legally correct conventional layout to demonstrate the density that could realistically be achieved on the site and, by comparison, to show local officials and abutters how different a rural village approach is. The sketch here shows how, under 1.5-acre zoning, a 520-acre site would ordinarily be checkerboarded into 300 lots, each with a required minimum area of 60,000 sq ft, leaving no open space whatsoever.

SITE ANALYSIS MAP

VILLAGE PLAN

Designing the development as a traditional village, with lots ranging from 5000 sq ft to 1 acre, achieves slightly greater density on less than one-quarter of the land and preserves nearly 400 acres. This layout is based closely on the site analysis map, with the village located to avoid disturbing the woodlands that provide the only natural habitat in this largely agricultural community. The most special site features are protected by designing around them. Nine "conservancy lots," varying in area from 20 to 60 acres, are limited to one principal dwelling plus two accessory units. This assures significant open space around the perimeter of this 300-lot village. Permanent conservation easements protect these lands from further subdivision and preserve the 150 acres of undivided open space and its trail system, which connects the old springhouse to the lakeshore and leads back to the schoolyard. This open space could be owned by the village government, a local land trust, or a homeowners' association (with automatic membership and authority to place liens on properties of members who fail to pay their dues). Rural views outward from three village streets have also been preserved, with open countryside terminating their vistas. Terminated vistas are also provided by three large public or semipublic buildings (churches, libraries, etc.) positioned at the ends of several streets.

THE NEIGHBORHOOD, THE DISTRICT, AND THE CORRIDOR

The fundamental elements of urbanism are the neighborhood, the district, and the corridor. Neighborhoods are urbanized areas with a full and balanced range of human activity. Districts are urbanized areas organized around a predominant activity. Neighborhoods and districts are connected and isolated by corridors of transportation or open space.

Neighborhoods, districts, and corridors are complex urban elements. Suburbia, in contrast, is the result of simplistic zoning concepts that separate activities into residential subdivisions, shopping centers, office parks, and open space.

THE NEIGHBORHOOD

Cities and towns are made up of multiple neighborhoods. A neighborhood isolated in the landscape is a village.

The nomenclature may vary, but there is general agreement regarding the physical composition of a neighborhood. The neighborhood unit of the 1929 New York Regional Plan, the *quarter* identified by Leon Krier, traditional neighborhood design (TND), and transit-oriented development (TOD) share similar attributes. The population, configuration, and scale may vary, but all of these models propose the following:

1. The neighborhood has a center and an edge. This combination of a focus and a limit contributes to the social identity of the community. The center is a necessity, the edge less so. The center is always a public space—a square, a green, or an important street intersection—located near the center of the urbanized area, unless compelled by geography to be elsewhere. Eccentric locations are justified by a shoreline, a transportation corridor, or a promontory with a compelling view.

The center is the locus of the neighborhood's public buildings. Shops and workplaces are usually here, especially in a village. In the aggregations of neighborhoods that create towns and cities, retail buildings and workplaces are often at the edge, where they can combine with others to draw customers.

The edges of a neighborhood vary in character. In villages, the edge is usually defined by land designated for cultivation or conservation of its natural state. In urban areas, the edge is often defined by rail lines and boulevards, which best remain outside the neighborhood.

2. The neighborhood has a balanced mix of activities: shops, work, school, recreation, and dwellings of all types. This is particularly useful for young, old, and low-income populations who, in an automobile-based environment, depend on others for mobility.

The neighborhood provides housing for residents with a variety of incomes. Affordable housing types include backyard apartments, apartments above shops, and apartment buildings adjacent to workplaces.

3. The optimal size of a neighborhood is 1/4 mile from center to edge, a distance equal to a five-minute walk at an easy pace. Its limited area gathers the population within walking distance of many of its daily needs.

The location of a transit stop within walking distance of most homes increases the likelihood of its use. Transit-oriented neighborhoods create a regional network of villages, towns, and cities accessible to a population unable to rely on cars. Such a system can provide the major cultural and social institutions, variety of shopping, and broad job base that can only be supported by the larger population of an aggregation of neighborhoods.

4. The neighborhood consists of blocks on a network of small thoroughfares. Streets are laid out to create blocks of appropriate building sites and to shorten pedestrian routes. An interconnecting street pattern provides multiple routes, diffusing traffic. This pattern keeps local traffic off regional roads and through traffic off local streets.

Neighborhood streets of varying types are detailed to provide equitably for pedestrian comfort and automobile movement. Slowing the automobile and increasing pedestrian activity encourage the casual meetings that form the bonds of community.

5. The neighborhood gives priority to public space and to appropriate location of civic buildings. Public spaces and public buildings enhance community identity and foster civic pride. The neighborhood plan creates a hierarchy of useful public spaces: a formal square, an informal park, and many playgrounds.

THE DISTRICT

The district is an urbanized area that is functionally specialized. Although districts preclude the full range of activities of a neighborhood, they are not the single-activity zones of suburbia. Rather, multiple activities support its primary identity. Typically complex examples are theater districts, capital areas, and college campuses. Other districts accommodate large-scale transportation or manufacturing uses, such as airports, container terminals, and refineries.

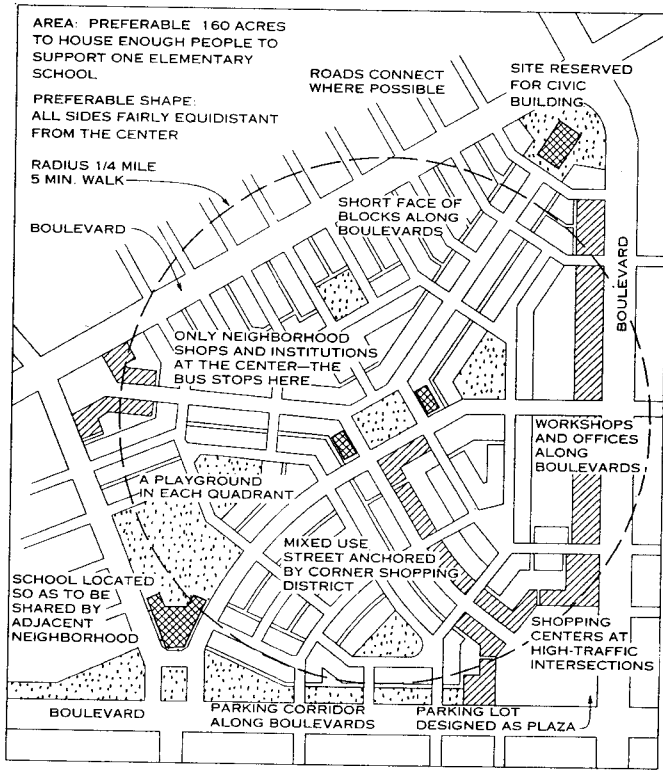

The structure of the district parallels that of the neighborhood. An identifiable focus encourages orientation and identity. Clear boundaries facilitate the formation of special taxing or management organizations. As in the neighborhood, the character of the public spaces creates a community of users, even if they reside elsewhere. Interconnected circulation encourages pedestrians, supports transit viability, and ensures security. Districts benefit from transit systems and should be located within the regional network.

THE CORRIDOR

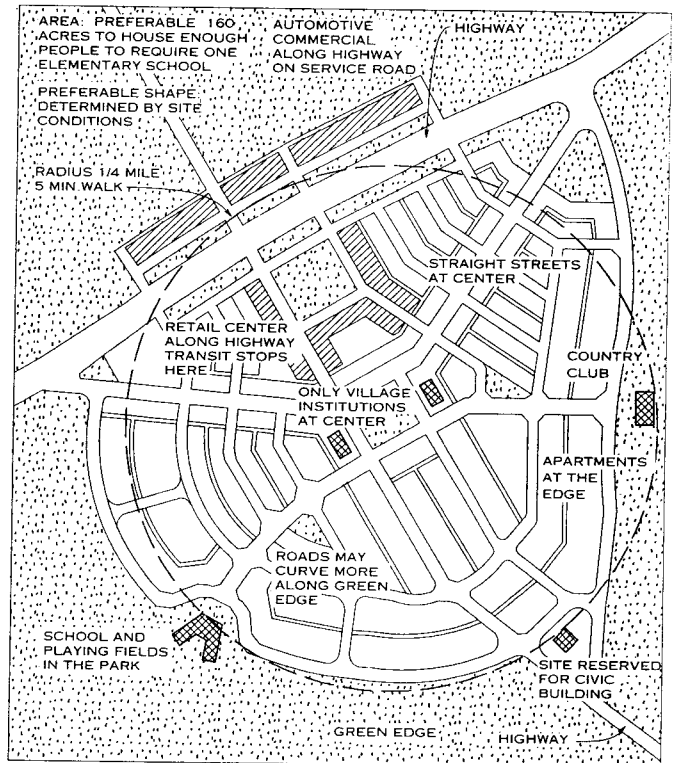

The corridor is the connector and the separator of neighborhoods and districts. Corridors include natural and technical components ranging from wildlife trails to rail lines. The between is not the haphazardly residual space remaining outside subdivisions and shopping centers in suburbia. It is a civic element characterized by its visible continuity and bounded by neighborhoods and districts, to which it provides entry.

The transportation corridor's trajectory is determined by its intensity. Heavy rail corridors should remain tangent to towns and enter only the industrial districts of cities. Light rail and trolley corridors may occur as boulevards at the edges of neighborhoods. As such, they are detailed for pedestrian use and to accommodate building sites. Bus corridors may pass into neighborhood centers on conventional streets.

The corridor may also be a continuous parkway, providing long-distance walking and bicycling trails and natural habitat. Parkway corridors can be formed by the systematic accretion of recreational open spaces, such as parks, schoolyards, and golf courses. These continuous spaces can be part of a larger network, connecting urban open space with rural surroundings.

1 SITE, COMMUNITY, AND URBAN PLANNING

GENERAL

In its short history as a discipline, regional planning has generated a substantial number of models, usually presented as diagrams. Redrawing the main types in a standard graphic form reduces options to a few fundamental models. Most regional plans are hybrids of these few.

Most cities expand through incremental decisions, not by following clear regional plans. But even when followed closely, such plans tend to be implemented in distorted form, due to pressures from natural and man-made conditions. The diagrams of each planning model to the right are accompanied by examples of their application to actual places.

GARDEN CITY/NEIGHBORHOODS, TOWNS AND VILLAGES

This is the ancient natural pattern. A clearly defined core city, composed of neighborhoods, is surrounded by towns and villages that are separated by open landscape. Ideally, each element is relatively self-sufficient. This historical pattern has been overwhelmed as mechanical transportation has permitted the city to absorb the surrounding landscape and to erase its neighborhood structure.

A rationalization of this pattern, designating fixed greenbelts and creating independent new towns (garden cities), was proposed by Howard, and restructuring the core city into self-contained neighborhoods was proposed by Saarinen and Perry.

The garden city has been the underlying concept for suburban growth, although its current form is unrecognizably degenerated. With the late arrival of the office park into the residential/retail suburb, the functional elements of the city are now available in the suburb, and the core city has lost its importance. As conceptualized by Fishman and Garreau, this regional pattern is no longer centroidal. The automobile is able to move equally in all directions, although it tends to reinforce major intersections. These intensified points support commercial development, around which residential areas cluster.

This automobile model can be made pedestrian-oriented by traditional neighborhood development (TND), which reconfigures the activities of the shopping center, office park, and housing subdivision into the form of towns and villages. Of the three models described, this is the one most influenced by market conditions.

LINEAR CITY/CORRIDORS AND WEDGES

The linear city evolved with the advent of the streetcar. Moving along defined axes, the streetcar extended the boundaries of the centroidal city, creating corridors whose width was limited by the walking distance to the tracks. The arrival of the automobile, with its ability to go anywhere, destroyed the disciplined edges of the corridors, creating undifferentiated sprawl.

The remedial model (corridors and wedges) was conceptualized by Olmsted and MacKaye. Through legislation, the urban fabric is channeled along the transportation axes while wedges of open landscape are preserved between these corridors. The wedges are ideally continuous, formed by an irregular agglomeration of valuable natural features. This is the model most influenced by ecological concerns.

TRANSIT-ORIENTED DESIGN

This pattern emerged naturally with the advent of the railroad. Moving along a single axis like the streetcar, but unable to stop as frequently, the railroad creates nodal points of commercial development with residential settlement around them. The advent of the automobile permitted the expansion of these settlements beyond any limit, consuming the landscape.

This model was rationalized and modernized by Calthorpe and Kelbaugh as transit-oriented design (T.O.D.). The T.O.D. creates nodes at intervals most efficient for rail transportation. These mixed-use areas, limited in size by walking distance, are usually surrounded by a residential hinterland connected to the rail system by feeder bus. The commercial uses and other businesses at the nodes may not offer all the services that would make the area self-sufficient (i.e., a town). However, together, several areas linked by rail may be self-sufficient.

This is the model most influenced by the requirements of transportation.

SAVANNAH

ADVANTAGES

1. Excellent directional orientation
2. Lot shape controllable
3. Street hierarchy with end blocks for through traffic
4. Even dispersal of traffic through the grid
5. Straight lines enhance rolling terrain
6. Efficient double-loading of alleys and utilities

DISADVANTAGES

1. Monotonous unless periodically interrupted
2. Does not accommodate environmental interruptions
3. Unresponsive to steep terrain

ORTHOGONAL GRID

NANTUCKET

ADVANTAGES

1. Street hierarchy with long routes for through traffic
2. Even dispersal of traffic through network
3. Intrinsically interesting by geometric variety
4. Responsive to terrain
5. Easily accommodates environmental interruptions
6. Short streets, terminated vistas

DISADVANTAGES

1. None

ORGANIC NETWORK

WASHINGTON, D.C.

ADVANTAGES

1. Street hierarchy with diagonals for through traffic
2. Even dispersal of traffic through the grid
3. Diagonals respond to the terrain
4. Diagonals interrupt monotony of the grid

DISADVANTAGES

1. Uncontrollable variety of blocks and lots
2. High number of awkward lot shapes
3. Diagonal intersections spatially ill defined

GRID WITH DIAGONALS

RIVERSIDE

ADVANTAGES

1. Intrinsically interesting by deflecting vistas
2. Easily accommodates environmental interruptions
3. Highly responsive to terrain
4. Even dispersal of traffic through the network

DISADVANTAGES

1. Little directional orientation
2. Uncontrollable variety of lots
3. No natural hierarchy of streets

CURVILINEAR NETWORK

SITE, COMMUNITY, AND URBAN PLANNING

GENERAL

The urban plan must be assembled of blocks before building frontage and landscape types are assigned. The disposition of blocks has distinct socioeconomic implications.

THE SQUARE BLOCK

This type was an early model for planned settlements in America, particularly in Spanish colonies. It was sometimes associated with agricultural communities, providing four large lots per block, each lot with a house at its center. When the growth of the community produced additional subdivision, replatting created irregular lots (Fig. 1). While this may provide a useful variety, it is more often regarded as a nuisance by a society accustomed to standardized products. A further disadvantage is that discontinuous rear lot lines make alleys and rear-access utilities impractical. Despite these shortcomings, the square block is useful as a specialized type. When platted only at its perimeter, with the center left open, it can accommodate the high parking requirements of certain buildings. The open center, well insulated from traffic, may also be used as a common garden or a playground (Fig. 2).

1. SQUARE BLOCK

2. SQUARE BLOCK

THE ORGANIC BLOCK

This type is characterized by its irregularity; its variations are unlimited. The original organic block was the subdivision of residual land between well-worn paths (Fig. 3). It was later rationalized by Olmsted and Unwin to achieve a controllable, picturesque effect and to negotiate sloping terrain gracefully. The naturalistic block, despite its variety, generates certain recurring conditions that must be resolved by sophisticated platting. At shallow curves, it is desirable to have the facades follow the frontage smoothly. This is achieved by keeping the side lot lines perpendicular to the frontage line (Fig. 4-1). At the same time it is important for the rear lot line to be wide enough to permit vehicular access (Fig. 4-2). At sharper curves, it is desirable to have the axis of a single lot bisect the acute angle (Fig. 4-3). In the event of excessive block depth, it is possible to colonize the interior of the block by means of a close (Fig. 4-4).

3. ORGANIC BLOCK

4. ORGANIC BLOCK

THE ELONGATED BLOCK

The elongated block overcomes some of the drawbacks of the square block. More efficient and more standardized, elongated blocks provide economical double-loaded alleys, with short utility runs, to eliminate the uncontrollable variable of lot depth and maintain the option of altering lot width. By adjusting the block length, it is possible to reduce cross streets toward rural edges or to add them at urban centers. This adjustment alters the pedestrian permeability of the grid and controls the ratio of street parking to building capacity. The elongated block can "bend" somewhat along its length, giving it a limited ability to shape space and negotiate slopes (Fig. 6).

Unlike the square block, the elongated block provides two distinct types of frontage. Residential buildings are placed on the quieter sides of the block (Fig. 5-1). Commercial buildings can be set on the short end of the block, platted to face the busy street; the amount of parking behind these properties is controlled by the variable depth (Fig. 5-2).

5. ELONGATED BLOCK

6. ELONGATED BLOCK

GENERAL

Public open space provides orientation, hierarchy, and communal structure to a neighborhood. The specialized open spaces shown here are derived from the elongated block types. They can also be adjusted to fit both square and organic block types.

LANE

Children often make lanes behind houses into informal playgrounds. The paved surface in front of garages is convenient for ball games. Lanes are particularly successful when they are designed to eliminate through traffic (right). Garage apartments provide supervision.

PLAYGROUND

Playgrounds can be easily extracted from any block by assigning one or several lots to this use. There should be a playground within 500 ft of every residence. The playground should provide both sunny and shaded play areas, as well as an open shelter with benches for parents. Playgrounds must be fenced, lockable, and lit, if they are not to become a nuisance at night.

NURSERY

A nursery can be inserted in the middle of a block, away from major thoroughfares. It requires a limited amount of parking but substantial vehicular drop-off space. The attached playground should be securely fenced and have both sunny and shaded areas. Children's games may be noisy, so it is advisable to locate nurseries where adjacent houses are buffered by outbuildings.

CLOSE

A close is a space shared by buildings inside the block. It may be pedestrian, or it may have a roadway loop around a green area. Its minimum width must coincide with emergency vehicle turning standards. The close is a superior alternative to the cul-de-sac, as the focus is a green rather than pavement. It is especially recommended for communal subgroups such as cohousing or assisted-living cottages. The close provides additional frontage for deep square and organic blocks.

ATTACHED SQUARES

Squares are green spaces that provide settings for civic buildings and monuments, which are located at the center or edge of the square. Buildings play a part, but the space is largely defined by formal tree planting. Squares should be maintained to a higher standard than playgrounds and parks.

DETACHED SQUARES

Squares detached on all sides by roads are particularly formal. Since adjacent buildings provide much of the population that uses a public space, detached squares are less likely to be used than other types. This separation also limits the amount of natural security provided by adjacent windows. The detached square remains appropriate as a means to symbolically enhance important places or institutions.

MARKET PLAZA

Plazas are public spaces that are primarily paved rather than green. They can sustain very intense use by crowds and even by vehicles. Parking lots should be designed as plazas that happen to have cars on them, rather than as single-purpose areas. A smaller shopping center can be transformed into a town center if it has been designed so it can be seamlessly attached to the block system and detailed as a plaza.

CIVIC PLAZA

Civic buildings are often no larger than the private ones that surround them, and their legibility as more important buildings cannot depend solely on architectural expression. Their setting within the block system must communicate their elevated status. Sites on squares or at the terminations of avenues are ideal but not always available. Thus the most dependable technique is to organize and detail the parking areas of civic buildings as plazas.

GREEN

The green is an urban, naturalistic open space. Like the square, it is small, civic, and surrounded by buildings. Unlike the square, it is informally planted and may have an irregular topography. Greens are usually landscaped with trees at the edges and sunny lawns at the center. Greens should contain no structures other than benches, pavilions, and memorials; paths are optional.

PARK

Parks are naturalistic open spaces, like greens, but larger and less tended. They are most successful when created from virgin woodland. Parks have grassy areas only periodically. A knoll or a pond can be used as an important organizing feature. Parks exist within the urban fabric of large cities, but their inherent size usually puts them at the edges of towns and villages. Parks may be edged by public drives, or by houses on very large lots, as long as connections to public paths occur at every block.

BUFFER

The buffer has the basic elements of a green, with the added purpose of buffering the impact of traffic from a highway or boulevard. Shown is a small lot development fronting a green. On the opposite side are larger lots on which houses are placed further back from the roadway edge as another buffer technique.

GENERAL

The traditional increment for platting lots in North America has been the 50-ft width. This subdivision dimension was efficient for many years, creating 25-ft rowhouse and shop-front lots, as well as 50-, 75-, and 100-ft lots suitable for houses. However, the advent of the automobile added a set of dimensional constraints that required new platting standards. The 50-ft width is wasteful, since the basic increment of efficient parking is the double row at 64 ft.

The 64-ft increment, when divided by four, provides the absolute minimum rowhouse lot of 16 ft, which allows one car to be parked with additional room for pedestrian passage. The minimum side yard lot is 32 ft. The minimum perimeter yard lot is 48 ft. The 64-ft lot efficiently provides for the high parking requirement of shopfronts, apartments, and office buildings.

The platting module of 16 ft corresponds to the traditional measure of the rod. Platting in rods, without knowing what building types will occupy the lots, maintains flexibility and ensures maximum density through parking efficiency.

Four building types accommodate the common residential, retail, and workplace uses of urban life. Some buildings, however, cannot be categorized typologically. Buildings dedicated to manufacturing and transportation may be distorted by large-scale mechanical trajectories. Civic buildings, which must express the aspirations of the institutions they embody, should also be exempt from the discipline of type.

COURTYARD BUILDING

This type of building occupies all or most of the edges of its lot and defines one or more private spaces internally. This is the most urban of types as it is able to completely shield the private realm from the public realm. It is common in hot climates, but its attributes are useful everywhere. Because of its ability to accommodate incompatible activities in close proximity, it is recommended for workshops, hotels, and schools. The high security the boundary provides is useful for recolonizing crime-prone urban cores.

SIDE YARD BUILDING

This type of building occupies one side of the lot, with the primary open space on the other side. The view of the side yard on the street front makes this building type appear freestanding, so it may be interspersed with perimeter yard buildings in less urban locations. If the adjacent building is also a side yard type with a blank party wall, the open space can be quite private. This type permits systematic climatic orientation, with the long side yard elevation facing the sun or the breeze.

REAR YARD BUILDING

This type of building occupies the front of its lot, full width, leaving the rear portion as a private space. This is a relatively urban type appropriate for neighborhood and town centers. The building facade defines the edge of the public space, while the rear elevation may reflect different functional purposes. In its residential form, this type is represented by the rowhouse with a rear garden and outbuilding. In its commercial form, the depth of the rear yard can contain substantial parking for retail and office uses.

PERIMETER YARD BUILDING

This building stands free on its lot, with substantial front and rear yards and smaller side yards. It is the least urban of the types, so it is usually assigned to areas away from neighborhood and town centers. This building type is usually residential, but when parking is contained within the rear yard it lends itself to limited office and boarding uses. The rear yard can be secured for privacy by fences and a well-placed outbuilding. The front yard is intended to be semipublic and visually continuous with the yards of neighbors. The illusion of continuity is usually degraded when garage fronts are aligned with the facades, as cars seldom pull in beyond the driveway. To avoid a landscape of parked cars, garages should be set back a minimum of one car's length from the facade or entered sideways through a walled forecourt.

GENERAL

Building delineates public space in an urban setting. Successful spatial definition is achieved when bounding buildings are aligned in a disciplined manner and the defined space does not exceed a certain height-to-width ratio.

Alignment occurs when building facades cooperate to delineate the public space, as walls form a room. Urban building articulation takes place primarily in the vertical plane or facade. If appendages such as porches, balconies, bay windows, and loggias do not obliterate the primary surface of the facade, they do not destroy alignment.

The height-to-width ratio of the space generates spatial enclosure, which is related to the physiology of the human eye. If the width of a public space is such that the cone of vision encompasses less street wall than sky opening, the degree of spatial enclosure is slight. The ratio of 1 increment of height to 6 of width is the absolute minimum, with 1 to 3 being an effective minimum if a sense of spatial enclosure is to result. As a general rule, the tighter the ratio, the stronger the sense of place and, often, the higher the real estate value. Spatial enclosure is particularly important for shopping streets that must compete with shopping malls, which provide very effective spatial definition. In the absence of spatial definition by facades, disciplined tree planting is an alternative. Trees aligned for spatial enclosure are necessary on thoroughfares that have substantial front yards.

NOMENCLATURE

THE FRONTAGE LINE

The lot boundary that coincides with a public thoroughfare or public space. The frontage line may be designed independently of the thoroughfare, to create a specific sense of place.

FACADE

The vertical surface of a building set along a frontage line. The elevation is the vertical surface set along any other boundary line. Facades are subject to control by building height, setback lines, recess lines, and transition lines. Elevations are only subject to building height and setback lines.

SETBACK

The mandatory distance between a frontage line and a facade or a lot line and an elevation.

BUILDING HEIGHT

The defined limit to the vertical extent of a building. The building height should be stated as a number of stories, rather than a prescribed dimension. This prevents the compression of internal ceiling heights. Height may be determined by density and view and not by the requirements of spatial definition, which are addressed by the recess line.

RECESS LINE

A line prescribed for the full width of the facade, above which the facade is set back. The recess line effectively defines the enclosure of public space. Its location is determined by the desired height-to-width ratio of that space, compatibility with the average height of existing buildings, or provision for daylighting at the street level.

TRANSITION LINE

A line prescribed for the full width of the facade, expressed by a variation of material or by a limited projection such as a cornice or a balcony. The transition line divides the facade, permitting shopfronts and signage to vary over time without destroying the overall composition.

GENERAL

Building type is independent of frontage type. For example, a courtyard building may have an arcade, a shopfront, a stoop, or a porch as its frontage type. Frontages can be ranked from most urban to most rural.

ARCADE

The facade overlaps the sidewalk, while the storefront remains set back. This type is excellent for retail use, but only when the sidewalk is fully absorbed so the pedestrian cannot bypass the arcade. An easement for public use of private property is required.

SHOPFRONT

The facade is aligned directly on the frontage line, with the entrance at grade. This type is conventional for sidewalk retail. It is often equipped with an awning or a porch. A transition line should separate the signage from the facade above. The absence of a setback and elevation from the sidewalk prevents residential use on the ground floor, although it is appropriate above.

STOOP

The facade is aligned directly on the frontage line, with the first floor elevated to achieve some privacy for the windows. This type is suitable for residential uses such as row-houses and apartment buildings. An easement may be necessary to accommodate the encroaching stoop. This type may be interspersed with the shopfront.

FORECOURT

The facade is set back and replaced by a low wall at the frontage line. The forecourt thus created is suitable for gardens, vehicular drop-offs, and workshop loading and storage. It should be used sparingly and in conjunction with the shopfront and stoop types, as a continuous blind wall is boring and unsafe for pedestrians. Tree canopies within the forecourt should overhang the sidewalk.

DOORYARD

The facade is set back from the frontage line, with an elevated garden or terrace between. This type can effectively buffer residential quarters from the sidewalk, while removing the yard from public use. The terrace, when roofed, is suitable for restaurants and cafes, as the eye level of the sitter is level with that of passersby.

PORCH AND FENCE

With an encroaching habitable porch, the facade is set back substantially from the frontage line. The porch should be within a conversational distance of the sidewalk. A fence at the frontage line marks the boundary of the yard.

FRONT LAWN

The facade is set back substantially from the frontage line. The front lawn this creates should be unfenced and visually continuous with adjacent yards. The ideal is to simulate buildings sitting in a rural landscape. A front porch is usually not appropriate, since no social interaction with the street is possible at such a distance. The large setback can provide a buffer from heavy traffic, so this type is sometimes found on boulevards.

GENERAL

The urban landscape is a set of interdependent elements that creates a controlled sense of place. It includes thoroughfare type, building type, frontage type, and the form and disposition of landscape.

Public landscaping plays many roles above and beyond that of ornamentation:

1. To correct inadequacies of spatial definition caused by building frontages. Planting steady rows of trees at the edges usually reduces the height-to-width ratio of the street space. Grids of trees are used to fill gaps left by unbuilt lots and surface parking.
2. To adjust the microclimate by providing the appropriate level of shade or sun for buildings and sidewalks. For thoroughfares running east-west, this may involve the use of asymmetrical planting.
3. To support the intended urban or rural character of the public space. Selecting appropriate species and varying the species planted, as well as the regularity of their disposition, can alter the landscape significantly.
4. To create a pleasing visual composition, being careful to mask the aesthetic failure of certain buildings as well as to reveal the successes. Consider seasonal changes of each species.
5. To create a harmonious whole of specific character by coordinating public and private plantings. Selection should vary, to ensure resistance to pests, but not result in an incoherent collection of specimens. Native species should predominate to reduce maintenance, with an emphasis on species that support wildlife compatible with human settlement.

RURAL ROAD

This type is appropriate for buildings at the edges of the neighborhood and along parks and greenbelts. There is no public planting line. The tree species should be episodic, but in coherent clusters. There are no curbs; the drainage is by open swales. Bicycle paths may be paved in asphalt.

RESIDENTIAL ROAD

This type is appropriate for houses outside of neighborhood centers. Since the frontage usually includes a substantial setback, the tree canopy may be quite wide. The rural aspect may be supported by planting several species in imperfect alignment. Roads are detailed with open swales, and, where possible, drainage is through percolation.

RESIDENTIAL STREET

This type is appropriate for residential buildings at neighborhood and town centers. Trees are in continuous planting strips, since the sidewalk does not require unusual width. Plant a single species of tree in steady alignment. A thin, vertical canopy is necessary to avoid nearby building facades. This type is dimensionally interchangeable with the commercial street type and may alternate in correspondence to the building facade. Streets are detailed with raised curbs and closed storm drainage.

COMMERCIAL STREET

This type is appropriate for commercial buildings at neighborhood and town centers. Trees are confined by individual planting areas, creating a sidewalk of maximum width with areas accommodating street furniture. Plant a single species of tree in steady alignment. Clear trunks and high canopies are necessary to avoid interference with shopfront signage and awnings. Streets are detailed with raised curbs with closed storm drainage.

AVENUE

This type is appropriate for approaches to civic buildings. The general principle is a thoroughfare of limited length, with a substantial planted median. At town centers, the median may be wide enough to hold monuments and even buildings. In residential areas, the median may be planted naturalistically to become a parkway or green.

BOULEVARD

This type is appropriate for high-capacity thoroughfares at neighborhood edges. The detailing is similar to that of a commercial street. The effect of the medians is to segregate the slower traffic and parking activity, at the edges, from through traffic, at the center.

HIGHWAYS

DRIVES

ROADS, LANES, PATHS
MORE RURAL

GENERAL

Thoroughfares are endowed with two attributes: capacity and character. Capacity refers to the number of vehicles that can move safely through a segment within a given time. It is physically manifested by the number of lanes and their width and by the centerline radius, the curb radius, and the super elevation of the pavement. Character refers to a thoroughfare's suitability for pedestrian activities and a variety of building types. Character is physically manifested by the thoroughfare's associated building, frontage, and landscape types and sidewalk width.

Conventional traffic engineering practice uses terms such as "collector" and "arterial," which denote only capacity. This is too simplistic and tends to create an environment inhospitable for pedestrians. The following nomenclature more adequately describes the combination of capacity and character necessary to create true urbanism.

NOMENCLATURE

HIGHWAY: A long-distance, medium speed vehicular corridor that traverses open country. A highway should be relatively free of intersections, driveways, and adjacent buildings; otherwise it becomes a strip, which interferes with traffic flow. (Related terms include expressway, a high speed highway with intersections replaced by grade separation, and parkway, a highway designed with naturalistic landscaping, partially accommodated within a wide and varying median.

BOULEVARD: A long-distance, medium speed vehicular corridor that traverses an urbanized area. It is usually lined by parallel parking, wide sidewalks, or side medians planted with trees. Buildings uniformly line the edges.

AVENUE: A short-distance, medium speed connector that traverses an urban area. Unlike a boulevard, its axis is terminated by a civic building or monument. An avenue may be conceived as an extremely elongated square. (A related term is allée, a rural avenue spatially defined by trees aligned on either side but devoid of buildings except at the terminus.)

DRIVE: An edge between an urban and a natural condition, usually along a waterfront, park, or promontory. One side of the drive has the urban character of a boulevard, with sidewalk and buildings, while the other has the qualities of a parkway, with naturalistic planting and rural detailing.

STREET: A small-scale, low speed local connector. Streets provide frontage for high-density buildings such as offices, shops, apartment buildings, and rowhouses. A street is urban in character, with raised curbs, closed drainage, wide sidewalks, parallel parking, trees in individual planting areas, and buildings aligned on short setbacks.

ROAD: A small-scale, low speed connector. Roads provide frontage for low-density buildings such as houses. A road tends to be rural in character with open curbs, optional parking, continuous planting, narrow sidewalks, and buildings set well back. The rural road has no curbs and is lined by pathways, irregular tree planting, and uncoordinated building setbacks.

ALLEY: A narrow access route servicing the rear of buildings on a street. Alleys have no sidewalks, landscaping, or building setbacks. Alleys are used by trucks and must accommodate dumpsters. They are usually paved to their edges, with center drainage via an inverted crown.

LANE: A narrow access route behind houses on a road. Lanes are rural in character, with a narrow strip of paving at the center or no paving. While lanes may not be necessary with front-loaded garages, they are still useful for accommodating utility runs, enhancing the privacy of rear yards, and providing play areas for children.

PASSAGE: A very narrow, pedestrian-only connector cutting between buildings. Passages provide shortcuts through long blocks or connect rear parking areas with street frontages. Passages may be roofed over and lined by shopfronts.

PATH: A very narrow pedestrian and bicycle connector traversing a park or the open country. Paths should emerge from the sidewalk network. Bicycle paths are necessary along highways but are not required to supplement boulevards, streets, and roads, where slower traffic allows sharing of the vehicular lanes.

The Cintas Foundation

GENERAL

Capacity and character are combined and adjusted to achieve a complete series of useful thoroughfare types. The series is best regarded in pairs: keeping the right-of-way width (R.O.W) constant, each pair illustrates one type suitable in two ways, one for a relatively rural condition and another suitable for a more urban condition.

INTRODUCTION

The traditional neighborhood development (TND) ordinance produces compact, mixed-use, pedestrian friendly communities. It can be incorporated in municipal zoning ordinances as an overlay or as a separate district. It is intended to ensure the following conventions:

Traditional neighborhoods share the following characteristics:

1. The neighborhood's area is limited to what can be traversed in a 10-minute walk.
2. Residences, shops, workplaces, and civic buildings are located in close proximity.
3. A hierarchy of streets serves the pedestrian and the automobile equitably.
4. Physically defined squares and parks provide places for formal social activity and recreation.
5. Private buildings form a clear edge, delineating the street space.
6. Civic buildings reinforce the identity of the neighborhood, providing places of assembly for social, cultural, and religious activities.

Traditional neighborhoods pursue certain social objectives:

1. To provide the elderly and the young with independence of movement by locating most daily activities within walking distance
2. To minimize traffic congestion and limit road construction by reducing the number and length of automobile trips
3. To make public transit a viable alternative to the automobile by organizing appropriate building densities
4. To help citizens come to know each other and to watch over their collective security by providing public spaces such as streets and squares
5. To integrate age and economic classes and form the bonds of an authentic community by providing a full range of housing types and workplaces
6. To encourage communal initiatives and support the balanced evolution of society by providing suitable civic buildings

SPECIAL DEFINITIONS

Terms used in a TND ordinance may differ in meaning from their use in conventional zoning ordinances:

ARTISANAL USE: Premises used for the manufacture and sale of items that are made employing only handwork and/or table-mounted electrical tools and creating no adverse impact beyond its lot.

BLOCK: The aggregate of lots and alleys circumscribed by public use tracts, generally streets.

BUILDING HEIGHT: The height measured in stories. Attics and raised basements do not count against building height limitations.

CITIZENS' ASSOCIATION: The organization of owners of lots and buildings associated under articles. The articles shall reference an approved master plan; set standards for building location, construction, and maintenance; provide for maintenance on public tracts; and provide for the construction of new civic buildings by an ongoing special assessment.

FAÇADE: The building wall parallel to a frontage line.

FRONTAGE LINE: The lot line that coincides with a street front.

GREEN EDGE: A continuous open area surrounding the neighborhood proper. The area shall be preserved in perpetuity as a natural area, golf course, or growing or playing fields, or it shall be subdivided into house lots no smaller than 20 acres each.

LIMITED LODGING: Residential premises providing no more than eight rooms for short-term letting and food services before noon only.

LIMITED OFFICE: Residential premises used for business or professional services, employing no more than four full-time employees, one of whom must be the owner.

LOT: A separately platted portion of land held privately.

TND LAND ALLOCATION

MEETING HALL: A building designed for public assembly, containing at least one room with an area equivalent to 10 sq ft per dwelling, or 1300 sq ft, whichever is greater.

NEIGHBORHOOD PROPER: The built-up area of a TND, including blocks, streets, and squares but excluding green edges.

OUTBUILDING: A separate building, additional to a principal building, contiguous with the rear lot line, having at most two stories and a maximum habitable area of 450 sq ft. Outbuildings may be residential retail units. Outbuildings are exempt from building cover restrictions or unit counts.

PARK: A public tract naturalistically landscaped, not more than 10% paved, and surrounded by lots on no more than 50% of its perimeter.

PROHIBITED USES: Uses not permitted in the standard zoning ordinance, as well as automatic food, drink, and newspaper vending machines and any commercial use that encourages patrons to remain in their automobiles while receiving goods or services (except service stations).

SHARED PARKING: A parking place where day/night or weekday/holiday schedules allow the use of parking spaces by more than one user, resulting in a 25% reduction of the required spaces.

SQUARE: A public tract, spatially defined by surrounding buildings, with frontage on streets on at least two sides. Commercial uses shall be permitted on all surrounding lots.

STORY: A habitable level within a building no more than 14 ft in height from floor to ceiling.

STREET LAMPS: A light standard between 10 and 16 ft in height equipped with an incandescent or metal halide light source.

STREET TREE: A deciduous tree that resists root pressure and is of proven viability, in the region with no less than 4-in. caliper and 8-ft clear trunk at the time of planting.

STREET VISTA: The view, framed by buildings, at the termination of the axis of a thoroughfare.

TRACT: A separately platted portion of land held in common, such as a thoroughfare, a square, or a park.

1

SITE, COMMUNITY, AND URBAN PLANNING

GUIDELINES FOR TRADITIONAL NEIGHBORHOOD DESIGN

LAND USE	LAND ALLOCATION	LOTS AND BUILDINGS	STREETS AND PARKING
A1.GENERAL: (a) The TND shall be available as an overlay option for land development in all land use and zoning categories except industrial. (b) A TND requires a minimum parcel of 40 contiguous acres and a maximum of 200 acres. Larger parcels shall be developed as multiple neighborhoods with each individually subject to the provisions of the TND.	B1.GENERAL: (a) Similar land use categories face across streets; dissimilar categories abut at rear lot lines. (b) The average perimeter of all blocks within the neighborhood does not exceed 1300 ft. For block faces longer than 500 ft, an alley or pedestrian path provides through access.	C1.GENERAL: (a) All lots share a frontage line with a street or square. (b) The main entrances of all buildings except outbuildings are on a street or square. (c) Stoops, open colonnades, and open porches may encroach into the front setback. (d) The sides of buildings at corner lots are similar to their fronts.	D1.GENERAL: (a) All streets terminate at other streets. (b) Streetlights are provided along all thoroughfares at 35- to 50-ft intervals. (c) On-street parking is allowed on all local streets. (d) Parking lots are located behind or beside building facades. (e) Parking lots and garages are not adjacent to street intersections, civic use lots, or squares and do not occupy lots that terminate a vista. (f) Shared parking reduces local parking requirements.
A2.PUBLIC: (a) Includes streets, squares, parks, playgrounds, and the like. (b) Civic use lots may be placed within tracts designated for public use. (c) Large-scale recreational uses such as golf courses, schoolyards, and multiple game fields are located only at the edge of the neighborhood.	B2.PUBLIC: (a) A minimum of 5% of the neighborhood area or 3 acres (whichever is greater) is permanently allocated to public use. (b) Each neighborhood contains at least one square, not less than one acre in size, close to the center. (c) No portion of the neighborhood is more than 2000 ft from the square. (d) At least half the perimeter of squares, parks, and waterfronts face streets. (e) At least a quarter of the perimeter of waterfronts, golf courses, greenbelts, and other natural amenities face streets.	C2.PUBLIC: (a) Balconies and open colonnades are permitted to encroach up to 5 ft into thoroughfares and other tracts. Such encroachments shall be protected by easements.	D2.PUBLIC: (a) Parking shared between public and private uses is encouraged.
A3.CIVIC: (a) Contains community buildings such as meeting halls, libraries, post offices, schools, child care centers, clubhouses, religious buildings, recreational facilities, museums, cultural societies, visual and performance arts buildings, municipal buildings, and the like.	B3.CIVIC: (a) A minimum of 2% of the neighborhood area is reserved for civic use. (b) Civic lots are within or adjacent to squares and parks or on a lot terminating a street vista. (c) Each neighborhood has a minimum of one meeting hall and one child care facility.	C3.CIVIC: (a) Civic buildings have no height or setback limitations.	D3.CIVIC: (a) The majority (75%) of the off-street parking for civic structures is behind the buildings.
A4.COMMERCIAL: (a) Contains buildings primarily for business uses, such as retail, entertainment, restaurant, club, office, residential, lodging, artisanal, medical, etc. (b) At least 25% of the building area is designated for residential use.	B4.COMMERCIAL: (a) A minimum of 2% and a maximum of 30% of the neighborhood area is designated for commercial use. (b) Commercial lots have a maximum frontage of 32 ft. (c) A maximum of four lots may be consolidated to construct a single building.	C4.COMMERCIAL: (a) Buildings are built out to a minimum of 80% of their frontage at the frontage line. (b) Buildings have no required setback from the side lot lines. (c) Buildings do not exceed four stories in height and are no less than two stories in height. When fronting a square, buildings are no less than three stories in height. (d) Building coverage does not exceed 70% of the lot area.	D4.COMMERCIAL: (a) Lots front streets no more than four lanes wide; parallel parking and sidewalks minimum 15 ft wide. (b) Rear lot lines coincide with an alley. (c) Streets have curbs with a radius at intersections of 5 to 15 ft. (d) Street trees are aligned on both sides of the street at 35- to 50-ft intervals; when open colonnades are provided, no street trees are necessary. (e) The majority (75%) of the off-street parking is behind the buildings.
A5.HIGH RESIDENTIAL: (a) Contains buildings for residential use, limited office use, cafes, retail, lodging, and artisanal uses. (b) All of the building area above the ground floor is designated for residential use. (c) Outbuildings are permitted.	B5.HIGH RESIDENTIAL: (a) A minimum of 20% and a maximum of 30% of the neighborhood area is designated for high residential use. (b) High residential lots have a maximum frontage of 16 ft. (c) A maximum of eight lots may be consolidated for the purpose of constructing a single building containing one or more residential units.	C5.HIGH RESIDENTIAL: (a) Buildings are built out to a minimum of 70% of their frontage, at a continuous alignment no further than 10 ft from the frontage line. (b) Buildings have no required setback from side lot lines. (c) Buildings do not exceed four stories in height and, when fronting a square, are no less than three stories in height. (d) Building coverage does not exceed 50% of the lot area.	D5.HIGH RESIDENTIAL: (a) Lots front streets no more than three lanes wide, with parallel parking and sidewalks minimum 15 ft wide. (b) Street trees are aligned both sides of streets at 35- to 50-ft intervals. (c) Rear lot lines coincide with an alley. (d) All off-street parking is behind the buildings.
A6.LOW RESIDENTIAL: (a) Contains buildings for residential uses, including art studios, limited offices, limited lodging, and the like. (b) All of the building area above the ground floor is designated for residential use. (c) Outbuildings are permitted.	B6.LOW RESIDENTIAL: (a) A maximum of 60% of the neighborhood area is designated for low residential use. (b) Lots have a maximum frontage of 64 ft. (c) A maximum of two lots may be consolidated for the purpose of constructing a single building.	C6.LOW RESIDENTIAL: (a) Buildings are built out to a minimum of 40% of their frontage at a continuous alignment no further than 30 ft from the frontage line. (b) Side setbacks are no less than 10 ft in aggregate and may be allocated to one side. Buildings are set back no less than 20 ft from the rear lot line. Outbuildings have no required setback. (c) Buildings do not exceed three stories in height. (d) Building coverage does not exceed 50% of the lot area.	D6.LOW RESIDENTIAL: (a) Lots front roads no more than two lanes wide with optional parallel parking and sidewalks minimum 6 ft wide. (b) Street trees are installed on both sides of the street at no more than 50-ft intervals. (c) Rear lot lines may coincide with an alley. (d) All off-street parking is to the side or rear of the building. Where access is through the frontage, garages or carports are located a minimum of 20 ft behind the facade.
A7.WORKPLACE: (a) Contains buildings for uses such as corporate office, light industry, artisanal, warehousing, automotive, and the like.	B7.WORKPLACE: (a) A minimum of 2% and a maximum of 30% of the neighborhood area is designated for workplace use. (b) Lots have a maximum frontage of 64 ft. (c) A maximum of four lots may be consolidated for the purpose of constructing a single building.	C7.WORKPLACE: (a) Buildings are built out to a minimum of 70% of their frontage at a continuous alignment no further than 10 ft from the frontage line. (b) Buildings have no setbacks from side or rear lot lines. (c) Buildings do not exceed three stories in height. (d) Building coverage does not exceed 70% of the lot area. (e) Lots are separated from other use types at the side and rear lot lines by a wall of between 3 and 8 ft high.	D7.WORKPLACE: (a) Lots front streets as wide as necessary to accommodate truck traffic. (b) Street trees are aligned on both sides of the street at 35- to 50-ft intervals. (c) Rear lot lines coincide with an alley. (d) All off-street parking is to the side or rear of the building.

The Cintas Foundation

FIRE APPARATUS ACCESS

Fire apparatus (i.e., pumpers, ladder trucks, tankers) should have unobstructed access to buildings. Check with local fire department for apparatus turning radius (R), length (L), and other operating characteristics. Support systems embedded in lawn areas adjacent to the building are acceptable.

RESTRICTED AREAS

Buildings constructed near cliffs or steep slopes should not restrict access by fire apparatus to only one side of the building. Grades greater than 10% make operation of fire apparatus difficult and dangerous. Avoid parking decks abutted to buildings. Consider pedestrian bridge overs instead.

FIRE DEPARTMENT RESPONSE TIME FACTOR

Site planning factors that determine response time are street accessibility (curbs, radii, bollards, T-turns, culs-de-sac, street and site slopes, street furniture and architectural obstructions, driveway widths), accessibility for firefighting (fire hydrant and standpipe connection layouts, outdoor lighting, identifying signs), and location (city, town, village, farm). Check with local codes, fire codes, and fire department for area regulations.

OUTDOOR LIGHTING

Streets that are properly lighted enable fire fighters to locate hydrants quickly and to position apparatus at night. Avoid layouts that place hydrants and standpipe connections in shadows. In some situations, lighting fixtures can be integrated into exterior of buildings. All buildings should have a street address number on or near the main entrance.

GRAVITY TANK

Gravity tanks can provide a reliable source of pressure to building standpipe or sprinkler systems. Available pressure head increased by 0.434 psi/ft increase of water above tank discharge outlet. Tank capacity in gallons depends on fire hazard, water supply, and other factors. Tanks require periodic maintenance and protection against freezing during cold weather. Locations subject to seismic forces or high winds require special consideration. Gravity tanks also can be integrated within building design.

ACCESS OBSTRUCTIONS

Bollards used for traffic control and fences for security should allow sufficient open road width (W) for access by fire apparatus. Bollards and gates can be secured by standard fire department keyed locks (check with department having jurisdiction).

STREET FURNITURE AND ARCHITECTURAL OBSTRUCTIONS

Utility poles can obstruct use of aerial ladders for rescue and fire suppression operations. Kiosks, outdoor sculpture, fountains, newspaper boxes, and the like can also seriously impede fire fighting operations. Wide podium bases can prevent ladder access to the upper stories of buildings. Canopies and other nonstructural building components can also prevent fire apparatus operations close to buildings.

FIRE HYDRANT AND STANDPIPE CONNECTION LAYOUT

Locate fire hydrants at street intersections and at intermediate points along roads so that spacing between hydrants does not exceed capability of local fire jurisdiction. Hydrants should be placed 2 to 10 ft from curb lines. Siamese connections for standpipes should be visible, marked conspicuously, and be adjacent to the principal vehicle access point to allow rapid connection by fire fighters to the pumping engine.

ON-SITE LAKES

Man-made and natural on-site lakes are used for private fire fighting in suburbs, on farms, and at resorts. A piped supply system to a dry hydrant is preferred for its quantity, flexibility, better maintenance, and accessibility. Man-made lakes with reservoir liners can be berm-supported or sunk in the ground. Lakes and ponds are natural water supplies dependent on the environment. See local codes, fire codes, and fire departments for on-site lake regulations.

DRIVEWAY LAYOUTS

Long dead ends (greater than 150 ft) can cause time-consuming, hazardous backup maneuvers. Use t-turns, culs-de-sac, and curved driveway layouts to allow unimpeded access to buildings.

DRIVEWAY WIDTHS

For full extension of aerial ladders at a safe climbing angle (θ), sufficient driveway width (W) is required. Estimate the required width in feet by: $W = (H-6) \cot \theta + 4$, where preferred climbing angles are 60 to 80°. Check with local fire department for aerial apparatus operating requirements, including width of aerial device with stabilizing outriggers extended.

FIRE HYDRANT PLACEMENT

Fire hose connections should be at least 15 in. above grade. Do not bury hydrants or locate them behind shrubs or other visual barriers. Avoid locations where runoff water and snow can accumulate. Bollards and fences used to protect hydrants from vehicular traffic must not obstruct fire fighters' access to hose connections. "Steamer" connection should usually face the side of arriving fire apparatus.

WHITE NUMBERS ON COLOR SUBDIVIDER, BACKGROUND ALSO ACCEPTABLE

NFPA 704 DIAMOND SYMBOLS

Standard diamond symbols provide information fire fighters need to avoid injury from hazardous building contents. zero (0) is the lowest degree of hazard, 4 is highest. Locate symbols near building entrances. Correct spatial arrangement for two kinds of diamond symbols are shown. Consider integrating symbols with overall graphics design of building. (Refer to "Identification of the Fire Hazards of Materials," NFPA No. 704, available from the National Fire Protection Association.)

FLOOD DAMAGE MANAGEMENT

Flood hazards are caused by building in flood-prone areas. Floods cannot be prevented, but the damage they wreak on man-made properties can be managed, either by altering the flood potential of an area or by avoiding construction in locations subject to flooding. Historically, flood damage management in the United States has focused on the former management technique, attempting to divert floods with structural flood controls—dams, levees, and channel modifications. However, such flood control measures have proved unsatisfactory over time.

Structural flood control projects have tended to encourage development in high hazard areas, often without appropriate land use planning. When a storm exceeds or violates the design parameters of a flood control structure, the damage that results from a flood can exceed what would have occurred if the structure had not been built. For example, floodplain invasion often occurs where levees have been built with the intention of reducing damage to agriculture. Although in some regions levees have reduced the number of high-frequency floods, in general they cause conditions favorable for their own failure by altering erosion patterns and increasing stages.

Recognition of the cost of development in high-risk areas, the uneven distribution of flood hazards on the landscape, and the natural and beneficial values of floodplains have led to more common adoption of nonstructural flood hazard management techniques. In particular, land use management and modified building practices are finding widespread acceptance.

Information on flood damage management and floodplain and wetland conservation is available from the Federal Emergency Management Agency (FEMA), the Natural Hazards Research Applications and Information Center, the U.S. Army Corps of Engineers, the Environmental Protection Agency, the National Park Service, and state and local agencies.

FLOOD HAZARDS

Most flood damage is caused by weather conditions such as hurricanes, fronts associated with midlatitude cyclones, thunderstorms, and melting snow packs. These conditions interact with surface features such as floodplains, coasts, wetlands, and alluvial fans, resulting in floods, mudslides, and erosion. Geologic phenomena such as earthquakes may also trigger floods.

Weather and climate information is available from the National Climate Data Center, regional climate research centers, and state climatology offices. Geologic and hydrologic information is available from the U.S. Geological Survey and state geological and geographical surveys.

FLOOD-PRONE AREAS

FLOODPLAIN: The relatively flat area within which a river moves and upon which it regularly overflows.

Rivers typically meander over their floodplains, eroding the cutbank and redepositing sediments in accretion zones such as point bars, meander belts, and natural levees. Channel shifting may be extreme in alluvial fans. Coastal floodplains, which include barrier islands, shores, and wetlands, have the same relationship to the sea that riverine floodplains have to rivers.

WETLANDS: areas characterized by frequent flooding or soil saturation, hydrophytic vegetation (vegetation adapted to survival in saturated areas), and hydric soils (soil whose chemical composition reflects saturation). Wetlands are often found in floodplains but are more restrictively defined.

FLOOD TYPES

Floods may be classified by their locations or physical characteristics.

RIVERINE FLOOD: great overflows of water from a river channel onto a floodplain caused by precipitation over large areas, melting snow, or both. Over-bank flow is a normal geophysical event that occurs on average every two years for most rivers.

HEADWATER FLOOD: a riverine flood that results from precipitation directly in a basin.

BACKWATER FLOOD: a riverine flood caused by high stages on downstream outlets, which prevent drainage from tributary basins or even reverse the flow.

COASTAL FLOOD: overflows onto coastal lands bordering an ocean, estuary, or lake. Coastal floods are caused by tsunamis (seismic sea waves), hurricanes, and northeasters.

FLASH FLOOD: a local flood of great volume and short duration. Flash floods differ from riverine floods in extent and duration. Flash floods generally result from a torrential rain or "cloudburst" covering a relatively small drainage area. Flash floods may also result from the failure of a dam or sudden breakup of an ice jamb.

FLOOD RISKS

Flood risk is usually expressed as the estimated annual frequency with which a flood equals or exceeds a specified magnitude. The flood risk for a future period of time is the joint probability of the occurrence of the annual flood risk. For example, if a house is situated at the "100-year flood" elevation (1% annual exceedance frequency), then its flood risk for a 30-year period is 26% or approximately a one in four chance it will be flooded to the specified depth or greater.

STANDARD PROJECTED FLOOD (SPF): a flood that may be expected from the most severe combination of meteorological and hydrological conditions characteristic of the geographic area in which the drainage basin is located, excluding extremely rare combinations.

SPFs are used in designing dams and other facilities with high damage potential.

PROBABLE MAXIMUM FLOOD (PMF): the most severe flood that may be expected from a combination of the most critical meteorological and hydrological conditions reasonably possible in a drainage basin. (This term is not a statistical concept.)

PMFs are used in designing high-risk flood protection works and in siting structures and facilities that must be subject to almost no risk of flooding.

LAND USE IN FLOOD ZONES

Land use management is the most effective method of managing flood damage. State control of land use in hazardous areas, authorized by the police-powers clause of the U.S. Constitution, is usually delegated to local planning and zoning boards. Local, state, and federal governments also regulate ecosystems essential for flood damage management, such as wetlands, coastal dunes, and mangrove stands. Land use management often includes setback regulations, which attempt to limit flood-related erosion damage. Regardless of regulations imposed by the government, developers should evaluate building sites for their intrinsic suitability for the intended use.

The National Flood Insurance Program (NFIP) requires that participating local governments adopt minimum floodplain management plans based on data provided by the federal insurance administrator. The NFIP does not require local governments to adopt land use or transportation plans that require preferential development of hazard-free areas or prohibit development of land in high-hazard areas. New construction in coastal zones is required to be located land-

ward of the reach of the mean high tide. Local land use and development or floodplain management plans that are more stringent than NFIP requirements supersede NFIP requirements. The NFIP divides riverine floodplains into floodway and floodway fringes for land use management. Coastal floodplains are divided into coastal high-hazard areas and coastal fringes. Land uses in these areas should always be verified with local agencies.

FLOODWAYS

Floodways include the channel of a watercourse and those portions of the adjoining floodplain required to permit the passage of a flood of specified magnitude at no more than a specified level above natural conditions. The NFIP requires floodways to be large enough to accommodate floods with a 1% annual exceedance frequency (100-year flood) without causing an increase in water levels of more than a specified amount (1 ft in most areas). Some localities object to the acceptability of increased flood levels this NFIP requirement implies. Instead, they define the floodway as the area inundated by floods with a 4% annual exceedance frequency (25-year flood).

Uses permitted in a floodway are those with low flood damage potential that do not obstruct flood flows or require structures, fill, or storage of materials or equipment. Fill is prohibited, and most structures are strongly discouraged. The following uses are generally permitted:

FUNCTIONALLY DEPENDENT USES: facilities and structures that must be located close to water in order to function, such as docking and port facilities and shipbuilding and repair facilities. Water supply and sanitary sewage treatment plants must be floodproofed if they must be located adjacent to bodies of water.

AGRICULTURAL USES: general farming, pasture, outdoor plant nurseries, horticulture, viticulture, truck farming, forestry, sod farming, and wild crop harvesting.

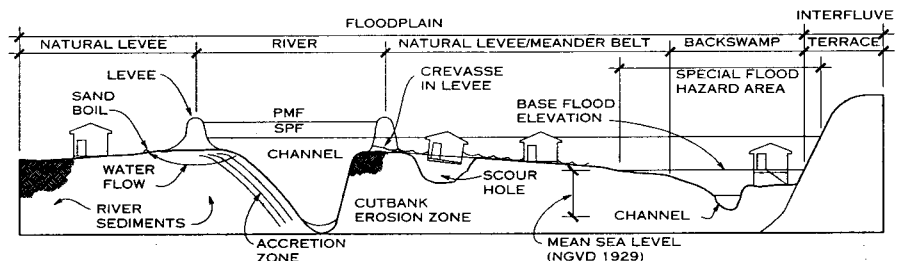

RECREATIONAL USES: golf courses, tennis courts, driving ranges, archery ranges, picnic grounds, boat launching ramps, swimming areas, parks, wildlife and nature preserves, game farms, fish hatcheries, shooting preserves, target ranges, trap and skeet ranges, hunting and fishing areas, and hiking and horseback riding trails.

INCIDENTAL INDUSTRIAL-COMMERCIAL USES: loading areas, parking areas, and airport landing strips (except in flash flood areas).

INCIDENTAL RESIDENTIAL USES: lawns, gardens, parking areas, and play areas.

FLOODWAY FRINGES

Floodway fringes are the portion of the regulatory floodplain outside of the floodway. Floodway fringes are treated as storage area for flood waters. Where permitted, property owners on each side of the floodplain may obstruct flood flows equally.

INVERTED RIVER VALLEY

V-SHAPED RIVER VALLEY

Mattie Fincher Coxie; Baton Rouge, Louisiana

Uses permitted in floodway fringes include those permitted in floodways and elevated or otherwise flood-proofed structures for flood disaster relief. It provides flood damage insurance as an incentive for communities to adopt floodplain management regulations, especially those governing floodplain obstructions and building practices in floodplains. NFIP minimum standards require a low level of flood damage management based on historic conditions.

FLOOD INSURANCE RATE ZONES

The NFIP is a program intended to reduce federal expenditures for flood disaster relief. It provides flood damage insurance as an incentive for communities to adopt floodplain management regulations, especially those governing floodplain obstructions and building practices in floodplains. NFIP minimum standards require a low level of flood damage management based on historic conditions.

States and localities may establish standards higher than NFIPs, in which case these supersede NFIP standards. For example, other governments may control land use in hazardous areas, regulate runoff, have freeboard requirements, or base regulatory flood elevations on historic floods that exceeded the base flood or on the projected effects of future development. The NFIP Community Rating System provides insurance rate reductions as an incentive to adopt higher standards.

The NFIP bases Flood Insurance Rate Zones on the frequency of flooding and the presence of storm surge and waves. Local governments are typically required to regulate building practices in A and V zones as a condition of eligibility for flood insurance.

The most important requirement in A and V zones is that the first floor of new buildings be built equal to or higher than the base flood level, which has a 1% chance of being equaled or exceeded in any given year (100-year flood). The base flood is the still water height for riverine floods. For the Atlantic Coast and the Gulf of Mexico, the base flood includes storm surge plus wave crest height because of northeasters and hurricanes. The base flood for the Pacific Coast includes astronomical tides plus wave run-up caused by tropical cyclones and tsunamis. For major lakes, the base flood includes seiche (sloshing because of wind, seismic activity, and storm surge). The base flood elevation (BFE) is the height of the base flood in reference to mean sea level as defined by the National Geodetic Vertical Datum of 1929 (NGVD 1929).

Local communities may adopt regulatory flood datums (RFD) in place of base flood elevations. RFDs are the base flood plus a freeboard, a factor of safety expressed in feet and used to compensate for uncertainties that could contribute to greater flood height than that computed for a base flood. Freeboard allows for hazards excluded from consideration in figuring the base flood and uncertainties in analysis, design, and construction. Severe structural subsidence, increases in floods because of obstructions in the floodplain, urban runoff, or normal climatic variability, as well as long-term increases in sea level and storms, are often excluded from consideration in determining base flood levels. Urban conditions, low accuracy base maps, and unplanned development are other common sources of uncertainty that justify freeboard.

Some communities require up to a 3-ft freeboard to compensate for inaccurate flood insurance rate maps (FIRMs). The margin of error of base maps may be estimated as plus or minus one-half of the contour interval. Most FIRMs are developed from maps with a contour interval of 5 ft, and a margin of error of -2 1/2 ft. Field survey maps with a contour interval of 2 ft or less are used in some communities; the smaller interval reduces the uncertainty of the risk and the need for freeboard.

The NFIP classifies land either as special flood hazard areas (SFHA)—high-frequency flood, flood-related erosion, and mudslide zones—or low-risk and undetermined flood hazard zones. Zone names that include actuarial risk factors, such as A1-A30 and V1-V30, are being replaced by AE and VE designations with flood depths.

A ZONES (A, AE, A1-A30, AO, AH, AR, A99)

Zones A and AE (formerly A1-A30) are high-risk riverine areas susceptible to inundation by the still-water base flood. AO zones are areas of shallow flooding (1 to 3 ft) without defined channels, usually sheet flow on sloping terrain. AH zones indicate shallow flooding, usually with water ponding. AR zones are areas in which structural flood protection is deficient. A99 zones are areas in which structural flood protection systems are near completion.

The finished floor of the lowest habitable level of residences, usually including basements, must be elevated to the base flood elevation in zone A. Flood-resistant residen-

tial basements are permitted only in communities that meet special NFIP flood criteria and adopt special local standards for their design and construction. Commercial structures must be elevated or otherwise floodproofed to the BFE.

B ZONES

B zones indicate areas subject to inundation by floods with an annual exceedance frequency greater than the base flood with less than a 0.2% annual exceedance frequency (500-year flood). B-zone designations are not used on recent FIRMs because of the lack of statistical validity of most estimates of 500-year floods and the false perception that they are generally safe. On some maps B zones are shown as shaded X zones.

C ZONES

C zones, including all areas that are not in zones A, B, or V, are not necessarily flood free. They may include low-risk interfluvial regions (areas of a watershed above the natural floodplain), moderate-risk floodplain between the interfluvial and the regulatory floodplain, areas with localized nonriverine flooding, high-risk areas with small contributing drainage areas, and floodplains with structural flood protection that may be subject to low frequency catastrophic floods.

D ZONES

D zones are areas of possible but undetermined flood hazard.

X ZONES

X zones include all areas not in zones A or V, combining B and C zones found on older maps. On some maps, X zones that were formerly B zones and X zones within levee systems are shaded.

V ZONES (V, VE, V1-V30, VO)

Velocity zones V and VE (formerly V1-V30) are coastal high hazard areas identified as susceptible to inundation by the base flood, including storm surges with high velocity waves greater than 3 ft. Generally, zone V indicates the inland extent of a 3-ft breaking wave, where the still-water depth during the 100-year flood decreases to less than 4 ft. VO zones are proposed alluvial fan zones with high velocity shallow flow (1 to 3 ft) and unpredictable flow paths.

Elevation and structural requirements are most stringent in coastal high hazard areas. Fill below buildings is prohibited. If construction is permitted by the local government, the lowest horizontal structural member of the lowest habitable floor must be built above the base flood elevation. Rigid frames or semirigid frames with grade beams can resist the impact of storm surge and waves. Semirigid frames with-

out grade beams should be used only in areas not subject to potential scour. Freestanding pole structures are unsafe; large rotations develop at moment connections, causing deflection of pilings under sustained lateral loads that can lead to collapse.

Destruction of coastal dunes and wetlands dramatically increases the inland reach of storm surge and waves and increases the severity of flood damage. Buildings may be destroyed if dunes and wetlands are inadequately protected, even if they conform to legal building requirements.

E AND M ZONES (E, M)

E zones are areas adjoining the shore of a lake or other body of water that are likely to suffer flood-related erosion. M zones are areas with land surfaces and slopes of unconsolidated material in which the history, geology, and climate indicate a potential for mudflow. Setbacks and special building requirements are used in E and M zones.

GENERAL LIMITS OF FLOODPROOFING

METHOD	DEPTH	VELOCITY	WARNING REQUIREMENTS
Levees	4-7'	< 10'/sec	Advance warning required for installation of floodgates in openings
Floodwalls	4-7'	< 12'/sec	
Closures (24 hr maximum)	4-8'	< 8'/sec	5-8 hr advance warning required for installation of closures
Fill	10'+	< 10'/sec	Evacuation time required unless fill connects to higher ground
Piles, piers, and columns	10-12'	< 8'/sec	Adequate evacuation time required

NOTE

Information presented is general and warrants caution. Time available for warning may be severely limited by a flood's rate of rise.

COASTAL DUNES AND BEACHES

Mattie Ann Fincher; Baton Rouge, Louisiana

GENERAL

In setting design parameters, the designer assumes that all vehicles present are "design vehicles." Design vehicles are selected to represent approximately the 85th percentile vehicle in a range from smallest to largest. In the recent past, small or compact car stalls were often separated from large or standard stalls in parking designs. However, a decline in smaller car sales and the increasing use of light trucks, vans, and utility vehicles (LTVUs) for personal transportation have made small-car-only stalls ineffective as a design tool. Therefore, while small car and large car design vehicles—as well as a composite encompassing both small and large—have been given here for reference, parking design must be based on a composite passenger vehicle that includes not only cars but light trucks, vans, and sport/utility vehicles.

NOTES

1. Minimum turn radii at less than 10 mph.
2. Obstructions (columns, walls, light poles, etc.) should be

held a minimum of 6 in. (2 ft preferred) from the edge of the lane given above. See details on the AGS page on driveways and roadways.

May S. Smith, P.E.; Walker Parking Consultants/Engineers, Inc.; Indianapolis, Indiana

GENERAL

Public streets and highways are designed to accommodate a variety of vehicles, up to and including semitrailer trucks. When private driveways and roadways will only serve passenger vehicles, it may be appropriate to use smaller dimensions in some instances. Nonetheless, be certain private roads are wide enough to allow passage of fire and emergency vehicles.

The "level of service" approach employed by traffic engi-

neers can be used as a tool for adapting designs to the specific needs of users. Level of service (LOS) A, which is the most comfortable, allows vehicle movement with little or no constraint. As the level of service decreases, from A to D, the comfort level decreases. LOS D is the minimum dimension for safe maneuvering of a vehicle at low speed.

The level of service selected for a particular application should reflect the needs of the users and of the owner of a property. Make adjustments according to the local vehicle size and mix and any concerns particular to the location.

COMPARISON OF LEVELS OF SERVICE

LEVEL OF SERVICE	LOS D	LOS A
Type of users	Familiar, young adults	Unfamiliar, elderly
Length of stay	Long-term	Short-term
Turnover	Less than 2 per day	More than 5 per day
Type of generator	Industrial	Retail
Location	Urban	Rural
Image	Spec office	Corporate headquarters
Percent small cars	High	Low
Percent light trucks, vans, and utility vehicles	Low	High

RECOMMENDED DESIGN PARAMETERS FOR VEHICULAR CIRCULATION¹

	DRAWING KEY	LOS D	LOS C	LOS B	LOS A
Lane width, straight	W_s				
One lane ²		10'-0"	10'-6"	11'-0"	11'-6"
Multiple lanes		9'-0"	9'-6"	10'-0"	10'-6"
Clearance to obstructions ³	C	0'-6"	1'-0"	1'-6"	2'-0"
Radius, turning (outside front wheel)	R_T	24'-0"	30'-0"	36'-0"	42'-0"
Lane width, turning ^{4,5}	W_T				
One lane		13'-6"	13'-6"	13'-6"	13'-6"
Each additional lane		12'-0"	12'-0"	12'-0"	12'-0"

Source: Mary S. Smith, *Parking Structures: Planning, Design, Maintenance and Repair*, 2d ed. (Chapman and Hall, 1996).

¹ The design parameters recommended are for design speeds ranging from 10 mph (LOS D) to 25 mph (LOS A). Additional dimensions for parking access aisles and turning bays are provided on the AGS page on parking design parameters.
² For all levels of service, use a 15-ft lane to make room for passing a broken-down vehicle.
³ The clearance given is from the edge of a lane to a wall, column, parked vehicle, or other obstruction, as cited in American Association of State Highway and Transportation Officials, *A Policy on Geometric Design of Highways and Streets* (1990) [ASHTO 1990], figure 111-25.
⁴ The dimensions given for LOS D are from AASHTO 1990 figure 111-23, except the clearance cited in that figure has been reduced to 2 ft, per figure 111-25.

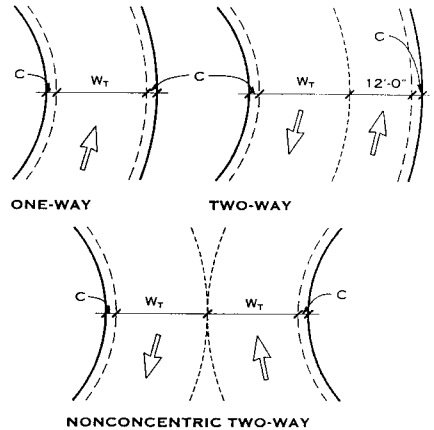

⁵ For all levels of service, use a 20-ft lane to allow room to pass a broken-down vehicle, per AASHTO 1990 figure 111-23.
⁶ The diameters given measure from outside face to outside face of the walls (6-in. walls assumed).
⁷ Turning radii/lane width increased 3 ft because of multiple turns.
⁸ Decrease 3 ft 6 in. to provide 20-ft lane in order to leave room to pass broken-down vehicles.
⁹ Ramp slope, minimum lane width, and clearance to walls control dimensions for double-threaded helix.
¹⁰ The dimensions given assume a straight approach to lane; check turns into lanes with template.

GENERAL

Vehicle dimensions are shown on the AGS page on design vehicles. The U-shaped drive shown here illustrates a procedure for developing any drive configuration, given the design vehicle and its turning radii (R). The tangent (T_G) dimension is an approximate minimum required for transition from one turn direction to another.

U-SHAPED DRIVE

NOTE

For R_C, R_I, R_O, W_S, W_T, and T_G, see the AGS page on vehicle turning radii. For L, OR, and W, see the AGS page on design vehicles.

Source: Mary S. Smith, *Parking Structures: Planning, Design, Maintenance, and Repair*, 2d ed. (Chapman & Hall, 1996).

¹ Minimum vertical clearance for van accessibility is 8 ft 2 in., which requires minimum floor-to-floor heights per LOS C.

² A short circuit in a long run is used to shorten the exit path.

³ In one-way designs, it is necessary to continue on the inbound travel path before connection to the outbound path.

⁴ Due to lower design speeds, the turning radius in parking areas is less than that required for through-circulation elements.

⁵ Clear between face of columns, curbs, or obstructions; check clearance at back of parking stalls with turning template.

⁶ If flow is largely in one direction, the turning bay for a two-lane, concentric design can be reduced by 3 ft.

¹ All dimensions are rounded to the nearest inch.
² These are minimum aisle widths for one-way traffic at each level of service.
³ Figures given are widths for two-way traffic.

KEY
 θ = angle of park
 A = aisle width
 i = interlock reduction
 OV = overhang
 M = module
 SL = stall length
 SO = stripe offset
 SP = stripe projection
 SW = stall width
 VP = vehicle projection
 WO = wall offset
 WP = stall projection

BASIC LAYOUT DIMENSIONS

NOTE
 Stalls adjacent to columns must be wider to provide the same level of service of turn.

SHORT SPAN CONSTRUCTION DETAILS

NOTES

1. Parking stalls for a design vehicle 6 ft 4 in. wide and 16 ft 9 in. long should have a stripe projection of 16 ft 3 in. and parallel stall length of 20 ft 9 in.
2. Small-car-only stalls (7 ft 5 in. wide by 15 ft long) should only be used at constrained locations or in remnants of space. The number of these stalls should not exceed 10% of total parking capacity at a site.
3. Angles between 76 and 89° are not recommended for one-way design because these angles permit drivers of smaller cars to back out and exit the wrong way.
4. Angled parking is not recommended for use with two-way aisles as drivers often attempt to make a U-turn into stalls on the other side of the aisle.
5. Add 1 ft to the module for surface parking bays without curbs or other parking guides (frequent poles or columns or walls) in areas with frequent heavy snowfall.
6. To maintain the same level of service (LOS), reduce the module (M) by 3 in. for each additional inch in stall width (SW) while maintaining minimum aisle width (see footnotes 2 and 3 to accompanying chart). For example,
 8 ft 9 in. @ 90° on 61-ft module = LOS A
 9 ft 0 in. @ 90° on 60-ft 3-in. module = LOS A
7. Columns and light poles may protrude into a parking module a combined maximum of 2 ft as long as they do not affect more than 25% of the stalls in that bay. For example, a 2-ft encroachment by a column on one side of the aisle or 1 ft each from columns on both sides is permissible.

GENERAL

ADAAG (Americans with Disabilities Act Accessibility Guidelines for Buildings and Facilities, 36 CFR 1191, July 26, 1991) requires all cashier booths in new construction (and in alterations that result in the removal of existing islands) to be accessible "to and through" the door. This mandate is found under the requirements for employee work areas or stations. A booth can meet this requirement if it is recessed in the pavement so the interior floor is at the same elevation as the driving lane. An accessible cashier booth can also have a curb ramp and appropriate latch-side clearance for the rear swinging door.

ADAAG recommends—but does not require—that at least one booth be a fully accessible workstation (have a 5-ft diameter wheelchair turning space, adjustable counter, accessible controls, etc.). A booth can meet this requirement with accessible doors on both sides, which allows T turning movements.

COMMERCIAL PARKING ARRANGEMENT

NOTES ON DESIGN GUIDELINES

1. Determine an efficient means of laying out the parking lot (see vehicle and parking space dimension data on other AGS pages on parking). A smaller paved area costs less to build and maintain, offers a shorter walking distance from car to building, lessens water runoff problems, and leaves more space for site landscaping.
2. Provide safe and coherent site circulation routes.
3. Provide access for fire rescue and mass transit vehicles. Consult local requirements.
4. Parking lots should offer direct and easy access for people walking between their vehicles and the building entrances. Pedestrians usually walk in the aisles behind parked vehicles; aisles perpendicular to the building face allow pedestrians to walk to and from the building without squeezing between parked cars. Walking areas should be graded to prevent standing water.
5. Accessible design is now mandatory, requiring designated parking spaces and curb ramps near building entrances. See AGS page on accessible curb ramps and passenger loading.

LANDSCAPING

Plants in parking areas can help relieve the visually overwhelming scale of large parking lots. To maximize the effect

FIRE LANE

of landscaping, consider the screening capabilities of plants. Low branching, densely foliated trees and shrubs can soften the visual impact of large parking areas. High branching canopy trees do not create a visual screen at eye level but do provide shade. When possible, create islands large enough to accommodate a mixture of canopy trees, flowering trees, evergreen trees, shrubs, and flowers. Consider using evergreens, and avoid plants that drop fruit or sap.

SPEED BUMP

SPEED HUMP

NOTE
Use of a speed hump eliminates the need for an accessible curb ramp.

SPEED CONTROL DEVICES

AUTOMOBILE OVERHANG REQUIREMENTS

Mary S. Smith, P.E.; Walker Parking Consultants/Engineers, Inc.; Indianapolis, Indiana

1 AUTOMOBILES, ROADS, AND PARKING

SINGLE-THREADED HELIX

DOUBLE-THREADED HELIX

DOUBLE-THREADED CIRCULAR HELIX

NOTES

1. Floor-to-floor circulation in a parking structure is typically provided either by parking ramps or express ramps (those without parking) or a combination of both.
2. Almost all ramp systems are based on helical patterns, whether a fully circular express helix or a combination of straight runs and turning bays at the end.
3. The two fundamental helical patterns are the single-threaded helix, which rises one full floor in each 360° of revolution, and the double-threaded helix, which rises two floors with each complete revolution.
4. Express helices can be either single threaded or double threaded. Parking ramps can also be configured in single- and double-threaded patterns.
5. On a site that can accommodate two parking modules in width but is short (less than 200 ft), a single-threaded helix can be used only with two-way traffic flow and 90° parking.
6. Application of a two-bay single-threaded helix arrangement may be limited by the desirable number of turns, spaces passed, etc. of the selected level of service and/or by flow capacity considerations.

HELIX-SHAPED PARKING BAYS

ONE-WAY FLOW

TWO-WAY FLOW

CIRCULAR FLOW

TWO-BAY SINGLE-THREADED HELIX

ONE-WAY FLOW

TWO-WAY FLOW

NOTES

1. The two-bay double-threaded helix can be taller and accommodate more spaces than the two-bay single-threaded model; however, it requires a longer site (typically more than 200 ft in length). Because this design may offer less desirable wayfinding and user-friendliness to unfamiliar users, it is most often used for predominantly employee parking.
2. A two-bay double-threaded helix may have either one-way or two-way traffic flow. The former has one up and one down route, while the latter provides two up routes and two down ones.

TWO-BAY DOUBLE-THREADED HELIX

ONE-WAY FLOW

TWO-WAY FLOW

NOTES

1. The split-level design is a modification of the single-threaded helix in which the parking bays are flattened and speed ramps are used to accomplish a vertical rise. Split-level parking structures may have either two-way or one-way traffic flow.
2. Although they provide a level facade, split-level parking structures have a number of disadvantages. The main ones are loss of stalls (compared to a typical two-bay single-threaded helix), difficult design for turns and speed ramp, and poor efficiency (the square footage of parking area per stall is too high).

SPLIT LEVEL

Mary S. Smith, P.E., Walker Parking Consultants/Engineers, Inc.; Indianapolis, Indiana
William T. Mahan, AIA; Santa Barbara, California

THREE-BAY SIDE-BY-SIDE

FOUR-BAY SIDE-BY-SIDE

END-TO-END

CAMELBACK

SINGLE-THREADED HELIX COMBINATIONS

THREE-BAY DOUBLE-THREADED HELIX

THREE-BAY SINGLE-THREADED INTERLOCKED HELIX

NOTES

1. Traffic can be routed in either a single-threaded or double-threaded pattern on the same configuration of flat and sloped parking bays.
2. The three-bay double-threaded helix option provides quicker vertical circulation and better flow capacity. However, because the flow is different on every other floor, making it confusing for unfamiliar users, this design works best for employee parking.
3. The interlocked helix offers better wayfinding (because it has the same flow pattern on every floor) but reduced flow capacity. The flow capacity is especially low during periods of high turnover because inbound and outbound traffic must merge at every floor.

COMBINATION SLOPED AND FLAT BAYS

FOUR-BAY SIDE-BY-SIDE WITH SIDE FLAT BAYS

FOUR-BAY SIDE-BY-SIDE HELIX WITH END FLAT BAYS

NOTES

1. As a parking structure footprint becomes wider, it is generally preferable to add flat parking bays and keep the floor-to-floor circulation at the far end of the structure. Similarly, when a parking structure is longer than needed for floor-to-floor circulation, keep the ramps at one end and add flat areas close to the ultimate destination of those using the facility.
2. Totally flat floor parking combined with express ramps yields the best combination of wayfinding, user-friendliness, and security. Express ramps may be designed to require traffic to circulate through the floors or to allow vehicles to pass directly from floor to floor. The latter arrangement provides the greatest flow capacity and ease of access in very large structures (those with more than 2000 parking spaces).

 11'-0" WIDE X 14'-6" HIGH

TYPICAL PLAN OF OPEN DOCK
 SINGLE DOOR (PREFERRED) 9'-0" WIDE X 10'-0"
 HIGH. DOUBLE DOOR (OPTIONAL) 20'-0" WIDE
 X 10'-0" HIGH

NOTES

1. Allow for off-street employee and driver parking.
2. Entrances and exits should be of reinforced concrete when excessive twisting and turning of vehicles are expected.
3. Average gate (swing or slide) 30 ft 0 in. wide for two-way traffic. People gate 5 ft 0 in. wide with concrete walkway 4 ft 0 in. to 6 ft 0 in. wide.
4. For yard security use a 6 ft 0 in. high chain link fence with barbed wire on top.
5. On-site fueling facilities are desirable for road units.
6. Provide general yard lighting from fixtures mounted on building or on 24 ft 0 in. high minimum poles at fence line. Mercury vapor or high pressure sodium preferred.
7. Tractor parking requires 12 ft 0 in. wide x 20 ft 0 in. long slot minimum. Provide motor heater outlets for diesel engines in cold climates.
8. Trailer parking requires 10 ft 0 in. wide slot minimum. Provide 10 ft 0 in. wide concrete pad for landing gear. Score concrete at 12 ft 0 in. o.c. to aid in correct spotting of trailer.
9. 4 ft 0 in. wide minimum concrete ramp from dock to grade. Slopes of 3 to 15% (10% average), score surface for traction.
10. Vehicles should circulate in a counter-clockwise direction, making left hand turns, permitting driver to see rear of unit when backing into dock.
11. Double trailers are backed into dock separately.

 The Operations Council, American Trucking Association; Washington, D.C.

1 TRUCKS, TRAINS, AND BOATS

- NOTES**
1. Given clearances are the recommended minimums of the American Railway Engineering Association. Actual requirements vary from state to state.
 2. Clearances shown are for the tangent track and new construction. Clearances for reconstruction work or for alteration are dependent on existing physical conditions and, where reasonably possible, should be improved to meet the requirements for new construction.
 3. On curved track, the lateral clearances each side of track center line shall be increased 1 1/2 in. per degree of curvature.
 4. Common state requirement for lateral clearance of poles is 8 ft 6 in. (varies from 8 to 12 ft).
 5. Standard American railroad gauge of 4 ft 8 1/2 in. is measured between the inner faces of the rails.

NOTE

The 6 ft 4 in. dimension will accommodate cars with either flush sliding doors or plug doors. Cars with hinged double doors require full clearance of 8 ft. Where 6 ft 4 in. platform is used, full clearance should be provided on opposite side, except inside buildings. (Several states allow a platform height of 4 ft 6 in. for refrigerator cars only, if the full lateral clearance of 8 ft is provided.)

NOTE

Ramp travels laterally on rail mounted to edge of dock for positioning to rail car opening. It adjusts above and below dock level and locks to the rail when in the lowered position. Self-stores in vertical position when not in use. Available in varying lengths and widths.

RAILWAY CLEARANCES

RAIL DOCK RAMPS

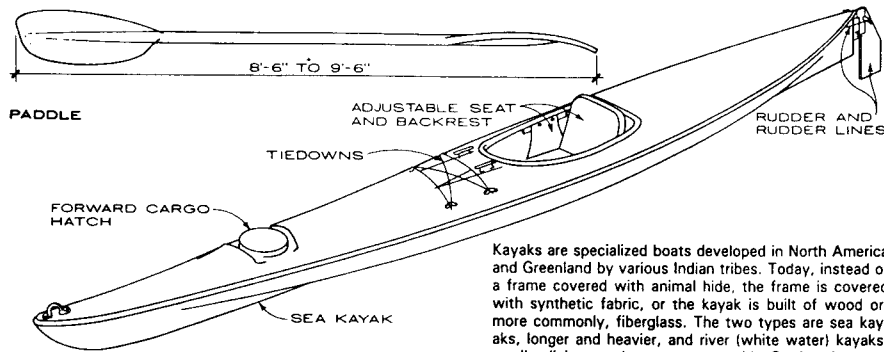

TYPICAL BUMPING POSTS

TYPICAL RAILROAD CAR TYPES AND SIZES (ACTUAL CAR SIZES VARY GREATLY EVEN AMONG LIKE CAR TYPES)

Ed Hesner, Rasmussen & Hobbs Architects; Tacoma, Washington
N. Claiborne Porter Jr., AIA; Anchorage, Alaska

Kayaks are specialized boats developed in North America and Greenland by various Indian tribes. Today, instead of a frame covered with animal hide, the frame is covered with synthetic fabric, or the kayak is built of wood or, more commonly, fiberglass. The two types are sea kayaks, longer and heavier, and river (white water) kayaks, smaller, lighter, and more maneuverable. Sea kayaks range in length from 10 ft. 6 ins. to 23 ft. Their beam varies from 33 ins. to 17½ ins. White water kayaks are shorter and narrower to be more responsive in river rapids.

KAYAK

WINDSURFER

CANOE

Canoes have shallow draft, and they range in length from 12 ft. to 35 ft. They can be paddled, sailed, or motored, and they can be loaded with equipment. They are constructed of wood, fiberglass, or aluminum.

ROWING SHELL

ROWING SHELL STORAGE RACK

Storage for rowing shells requires: two racks 8 feet apart for single and double; three racks 8 feet apart for eight-oared. Shells used daily should not be stored higher than 6 ft. Storage racks can be adapted easily to hold kayaks or canoes by adjusting the spacing between racks and the height between horizontal members.

Racing shells, built primarily of carbon fiber or plastic, are narrow and unstable in the water. There are two rowing styles: sweep rowing, where oarsmen work one oar with both hands; and sculling, where each oarsman works two oars, one in each hand. Sweeps are 12 ft. to 13 ft. long; sculling oars are 9 ft. 6 ins. to 10 ft. long.

DINGHIES

Dinghies are small boats used as auxiliaries to larger craft. They also can be sailed and raced on their own. They vary in length from 6 ft. to 16 ft., and they are 2 ft. 10 ins. to 5 ft. 6 ins. in beam. They are constructed of wood or fiberglass, and they can be rigged for sail, rowing, or motoring.

DINGHY STORAGE RACK

Dinghy racks store the small boats year round, and should be weather-treated. The rack members are fastened with countersunk bolts to avoid damaging dinghies. Racks must be able to support the weight of the boats and anyone climbing on the racks.

Timothy B. McDonald; Washington, D.C.

MONOHULL SAILBOAT

FULL KEEL

FIN KEEL

FIN KEEL / CENTER BOARD

CENTER BOARD

MONOHULL - BASIC UNDERWATER HULL SHAPES

MULTIHULL

DEFINITIONS

1. Length overall—LOA—boat's greatest length excluding bowsprits rudder or other extensions.
2. Length of water line—LWL—boat's greatest length at the water level excluding extensions such as rudders.
3. Beam—boat's maximum breadth.
4. Draft—distance from the waterline to the bottom of the boat's keel determining the least depth of water the boat can operate in: i.e., the amount it draws.
5. Displacement—weight of the water that the boat displaces.

NOTES FOR BASIC RIGS

LATEEN

Ancestor of the fore and aft rigs shown here. It dates back thousands of years and is still used in many parts of the world.

CATBOAT RIG

Traditionally puts a lot of sail area on one short mast, as shown here, which is stepped far forward in the boat.

SLOOP

Design with two basic sails, mainsail and headsail; the latter, called a "fractional rig," is set either to the masthead or some distance below the masthead.

CUTTER

Like the sloop, a cutter rig has one mast carrying two headsails instead of one. The inner sail is the forestay sail and the outer sail is the jib.

YAWL

Unlike the sloop or cutter, the yawl is a two masted rig consisting of a mainmast and a mizzen mast that is stepped abaft (behind) the rudder post. The mizzen sail is much smaller than the main sail.

KETCH

Like the yawl, the ketch is also a two-masted rig; however, the mizzen mast is stepped forward of the rudder post and is larger than the yawl's mizzen. This placement dictates a smaller mainsail.

SCHOONER

Usually two-masted but can be three-masted. Commonly the foremast is the shorter of the two, and may be gaff or marconi rigged or at times a combination of both.

A combination of mast and rigging placement (where the mast is stepped), along with size, type and number of sails, make up the main differences in sailboat rigs. Today the most common is the marconi rig distinguished by a triangular mainsail, but it is not unusual for boats to be rigged with a traditional gaff, which is a four-sided sail that hangs from a spar called a gaff. In some instances marconi and gaff rigs are used together as shown on the schooner below.

Headsails are triangular sails set ahead of the mast. Basic headsails are the jib, working jib, staysail, and genoa. The working jib, unlike other jibs, does not overlap the mast and is often attached to a boom for easier control. Jibs and genoas do overlap the mast and mainsail. The forestaysail is combined with the jib to create a double-headsail and is used primarily on cutters and schooners.

Spinnakers, usually the largest sail set before the mast, come in several different shapes and sizes according to use.

BASIC BOAT RIGS

Timothy B. McDonald; Washington, D.C.

TYPICAL FIXED DOCK

NOTES

1. Launching ramps are for sheltered waters only.
2. A finger pier or courtesy pier may be provided alongside the ramp. In tidal waters, these piers should be of floating construction.

BOAT LAUNCHING RAMP

DOCKING PLAN

Stephen B. Soulé; Soulé and Associates, P.C.; Salisbury, Maryland

NOTES

1. Wood marine construction must be pressure treated with a preservative. Wood preservatives for use in marine applications fall into two general categories—creosote and waterborne. To select a specific preservative, the wood-attacking agents in local waters must be identified. A preservative may then be chosen based on the standards of the American Wood Preserver's Association. In some saltwater locations, wood construction may not be a viable option.
2. Waterborne preservatives are recommended for decks because creosote stains shoes and bare feet. Optional deck materials include untreated wood materials such as cedar and recycled plastic products.
3. The preservative selected should be approved by the Environmental Protection Agency.
4. Optional materials for piles include steel, concrete, and fiberglass. Wood, steel, concrete, aluminum, and vinyl may be used for bulkheads.
5. Deck height above water is determined by average deck levels and probable water level. Maintain a 12 in. minimum dimension between water and deck. Floating docks may be required in tidal waters. Consult manufacturers for construction information.
6. Cross-bracing should be minimized to avoid entanglement of swimmers.

DIMENSIONS FOR SLIPS AND FINGER PIERS (FT)

BOAT LENGTH	SLIP LENGTH	SINGLE SLIP WIDTH	DOUBLE SLIP WIDTH
20	23	10	20
25	28	12	25
30	33	14	27
35	38	15	31
40	43	18	34
45	48	19	36
50	53	20	38
55	58	22	42
60	63	23	44

FLOATING DOCK—DETAIL NOTES

1. Floating docks must be engineered for the specific site and loading conditions. Docks can be designed to accommodate boats in a wide range of sizes as well as all utilities.
2. Docks can be anchored by pilings or by mooring chains and anchors. Piling material can be steel, concrete, or treated timber. Guide piles must be designed so that the top of all piles is above the 100-year flood elevation. Special

- cial consideration should be given to breakwaters for wave attenuation.
3. Flotation should be designed to provide minimum freeboard at full loading. Floats can be made of concrete, steel, aluminum, and plastic.
4. Docks may be constructed of steel, aluminum, concrete, or timber materials. Joints must be designed to withstand all applied forces.

TYPICAL FLOATING DOCK ARRANGEMENTS

5. Decking material can be timber, concrete, steel, plastic, or fiberglass.
6. All components should be designed in a manner that will minimize or eliminate corrosion.
7. Utility systems with accessible utility chases should be designed into the dock structure.

GANGWAY—DETAIL

Stephen B. Soulé; Soulé and Associates, P.C.; Salisbury, Maryland

INTRODUCTION

More than 75 AIA contract and administrative forms are in print today. The ancestor of all of these was the Uniform Contract, an owner-contractor agreement first published in 1888. This was followed, in 1911, by the AIA's first standardized General Conditions for construction. The 1997 edition of AIA Document A201 is the fifteenth edition of those General Conditions.

Many practices common in the construction industry today became established through their inclusion in the AIA General Conditions for Construction and other AIA standardized documents. Arbitration, the one-year correction period, and the architect's role in deciding disputes are just three of these. While the AIA documents have had a profound influence on the industry, the influence also flows the other way. The AIA regularly revises its documents to take into account recent developments in the construction industry and the law. New standardized documents for design/build and for different types of construction management were published in the late 1990s, and documents for international practice are under consideration.

Because the AIA documents are frequently updated, users should consult an AIA component chapter or obtain a current copy of the "AIA Contract Documents Price List" to determine which are the current editions.

The relationship of the documents to the industry—influencing it, and in turn being influenced by it—is paralleled by the relationship of the documents to the law. AIA documents are intended for nationwide use and are not drafted to conform to the law of any one state. With that caveat, AIA contract documents provide a solid basis of contract provisions that are enforceable under the law existing at the time of publication. Case law on contracts for design and construction has for the past century been based largely on the language of AIA standardized documents and contracts derived from them. These court cases are listed in *The American Institute of Architects Legal Citator*, in which recent cases are summarized with all cases keyed to the specific provisions in the AIA documents to which they relate.

The AIA documents are organized in two ways: in a letter series and in cross-series families:

The document letter series is a system of classification that cuts across the various families and identifies the specific purpose of each document. The letter designations indicate the following:

- A Series—owner-contractor documents
- B Series—owner-architect documents
- C Series—architect-consultant documents
- D Series—architect-industry documents
- G Series—architect's office and project forms

Documents grouped in a family are coordinated to tie together the various legal and working relationships for the same project types. Documents within the same family may be in different series but are linked by common terminology and procedures. Documents in a family may adopt one another by reference. For example, the relevant terms of A201 are adopted by reference in A101, A111, A401, B141, B151, and C141.

The preceding paragraphs contain several references to "standardized documents," a term that covers most AIA documents. AIA standardized documents are intended to be used in their original, printed form. Much of the efficiency these documents bring to a transaction depends on this use. When people with experience in the construction industry see a standardized document, they are familiar with it and can quickly evaluate the proposed transaction based on the modifications made to it—if those modifications stand out. If modifications are blended into retyped or scanned document text, this advantage is lost.

Modifications used with AIA documents may themselves be derived from another type of document published by the AIA. These are model documents, the language of which is intended to be reproduced and adapted by users. One such repository of model text is A511, which is intended for use in developing supplementary conditions, an important component of the contract for construction. B511 serves a similar purpose with respect to owner-architect agreements.

AIA documents are currently available in both printed and electronic form. The software package AIA Contract Documents: Electronic Format for Windows™ enables users to access and print out the AIA documents. Modifications are clearly shown: deleted language appears with strike-throughs, and added language is underscored.

DOCUMENT SYNOPSSES

These synopses are meant to be used as a quick reference for determining the appropriate uses for each of the contract documents and administrative forms published by the American Institute of Architects. That purpose naturally presumes independent judgment on the reader's part, as well as advice of counsel.

A SERIES

The documents in the A Series of AIA documents relate to various forms of agreement between an owner and a contractor.

A101, STANDARD FORM OF AGREEMENT BETWEEN OWNER AND CONTRACTOR—STIPULATED SUM, is a standard form of agreement between owner and contractor for use when the basis of payment is a stipulated sum (fixed price). The A101 document adopts by reference and is designed for use with AIA Document A201, General Conditions of the Contract for Construction, thus providing an integrated pair of legal documents. When used together, A101 and A201 are appropriate for most projects. For projects of limited scope, however, use of AIA Document A107 might be considered.

A101/CMa, STANDARD FORM OF AGREEMENT BETWEEN OWNER AND CONTRACTOR—STIPULATED SUM—CONSTRUCTION MANAGER-ADVISER EDITION, is a standard form of agreement between owner and contractor for use on projects when the basis of payment is a stipulated sum (fixed price) and when, in addition to the contractor and the architect, a construction manager assists the owner in an advisory capacity during design and construction. The document has been prepared for use with AIA Document A201/CMa, General Conditions of the Contract for Construction—Construction Manager-Adviser Edition. This integrated set of documents is appropriate for use on projects when the construction manager serves only in the capacity of an adviser to the owner, rather than as constructor (the latter relationship is represented in AIA documents A121/CMc and A131/CMc). A101/CMa is suitable for projects when the cost of construction has been predetermined, either by bidding or by negotiation.

A105, STANDARD FORM OF AGREEMENT BETWEEN OWNER AND CONTRACTOR FOR A SMALL PROJECT, and A205, GENERAL CONDITIONS OF THE CONTRACT FOR CONSTRUCTION OF A SMALL PROJECT, are intended to be used in conjunction with one another. The two documents are only sold as a set, and they share a common instruction sheet. They have been developed for use when payment to the contractor is based on a stipulated sum (fixed price) and when the project is modest in size and brief in duration. A105 and A205 are two of the three documents that comprise the Small Projects family of documents. They have been developed for use with AIA Document B155, Standard Form of Agreement Between Owner and Architect for a Small Project. These documents are specifically coordinated for use as a set.

Caution: Although A105, A205, and B155 may share some similarities with other AIA documents, the Small Projects documents should not be used in tandem with other AIA document families without careful side-by-side comparison of contents.

A205 is considered the keystone document of the Small Projects family, since it is specifically adopted by separate reference into both A105 and B155. A205 is a vital document, in that it is used to allocate proper legal responsibilities among the parties, while providing both a common ground and a means of coordination within the Small Projects family. In order to maintain the condensed nature of this document, arbitration and other alternate dispute resolution (ADR) provisions have been omitted. ADR provisions may be included in A105 under Article 6.

A107, ABBREVIATED STANDARD FORM OF AGREEMENT BETWEEN OWNER AND CONTRACTOR FOR CONSTRUCTION PROJECTS OF LIMITED SCOPE—STIPULATED SUM. As an abbreviated form of agreement between owner and contractor, this document is intended for use when the basis of payment is a stipulated sum (fixed price). It is appropriate for construction projects of limited scope not requiring the complexity and length of the combination of AIA Documents A101 and A201. A107 contains abbreviated General Conditions. It may be used when the owner and contractor have already established a working relationship (e.g., a previous project of like or similar nature) or when a project is relatively simple in detail or short in duration.

A111, STANDARD FORM OF AGREEMENT BETWEEN OWNER AND CONTRACTOR—COST PLUS A FEE WITH A NEGOTIATED GUARANTEED MAXIMUM PRICE. This standard form of agreement between owner and contractor is appropriate for use on most projects requiring a negotiated guaranteed maximum price, when the basis of payment to

the contractor is the cost of the work plus a fee. A111 adopts by reference and is intended for use with AIA Document A201, General Conditions of the Contract for Construction, thus together the two documents offer an integrated pair of legal documents.

A121/CMc (AGC 565), STANDARD FORM OF AGREEMENT BETWEEN OWNER AND CONSTRUCTION MANAGER WHERE THE CONSTRUCTION MANAGER IS ALSO THE CONSTRUCTOR. This document represents the collaborative efforts of the American Institute of Architects and the Associated General Contractors of America. The AIA designates this document A121/CMc, while AGC calls it AGC Document 565. A121/CMc is intended for use on projects for which a construction manager, in addition to serving as adviser to the owner, assumes financial responsibility for construction. The construction manager provides the owner with a guaranteed maximum price proposal, which the owner may accept, reject, or negotiate. Upon the owner's acceptance of the proposal by execution of an amendment, the construction manager is contractually bound to provide labor and materials for the project.

A121/CMc divides the construction manager's services into two phases: the preconstruction phase and the construction phase, portions of which may proceed concurrently in order to fast track the process. A121/CMc is coordinated for use with AIA Document A201, General Conditions of the Contract for Construction and B141, Standard Form of Agreement Between Owner and Architect. Check Article 5 of B511 for guidance in this regard.

Caution: To avoid confusion and ambiguity, do not use this construction management document with any other AIA or AGC construction management document.

A131/CMc (AGC 566), STANDARD FORM OF AGREEMENT BETWEEN OWNER AND CONSTRUCTION MANAGER WHERE THE CONSTRUCTION MANAGER IS ALSO THE CONSTRUCTOR—COST PLUS A FEE, NO GUARANTEE OF COST. Similar to A121/CMc, this CM-constructor agreement is also intended for use when the owner seeks a constructor who will take responsibility for providing the means and methods of construction. However, the method of determining cost of the work diverges sharply in the two documents: A121/CMc allows for a guaranteed maximum price (GMP), while A131/CMc uses a control estimate. A131/CMc employs the cost-plus-a-fee method, which allows the owner to monitor cost through periodic review of the control estimate, which is revised as the project proceeds.

It is important to note that, while the CM-constructor is assuming varied responsibilities, there are still just three primary players on the project—the owner, the architect, and the CMc. The A201 General Conditions continue to apply, although they are modified (in part) by the A131/CMc agreement.

Caution: To avoid confusion and ambiguity, do not use this construction management document with any other AIA or AGC construction management document.

A171, STANDARD FORM OF AGREEMENT BETWEEN OWNER AND CONTRACTOR—STIPULATED SUM—FOR FURNITURE, FURNISHINGS, AND EQUIPMENT, is used for acquisition of furniture, furnishings, and equipment (FF&E) when the basis of payment is a stipulated sum (fixed price). A171 adopts by reference and is intended for use with AIA Document A271, General Conditions of the Contract for Furniture, Furnishings, and Equipment. It may be used in any arrangement between the owner and the contractor in which the cost of FF&E has been determined in advance, either through bidding or negotiation.

A177, ABBREVIATED OWNER-CONTRACTOR AGREEMENT FORM—STIPULATED SUM—FOR FURNITURE, FURNISHINGS, AND EQUIPMENT, is an abbreviated document that philosophically derives much of its content from a combination of the more complex and lengthy A171 and A271 documents. Its abbreviated terms and conditions may be used when a contractor for furniture, furnishings, and equipment (FF&E) has a prior working relationship with the owner or when a project is relatively simple in detail or short in duration.

Caution: This document is not intended for use with major construction work that may involve life safety systems or structural components.

A191, OWNER-DESIGN/BUILDER AGREEMENTS, contains two agreements to be used in sequence by an owner contracting with one entity serving as a single point of responsibility for both design and construction services. Design/build entities may be architects, contractors, or even businesspersons, as long as they comply with governing laws.

CONSTRUCTION INFORMATION SYSTEMS

Document Synopses, A Series, *continued from previous page*

especially those pertaining to licensing and public procurement regulations. The first agreement covers preliminary design and budgeting services, while the second deals with final design and construction. Although it is anticipated that an owner and a design/builder entering into the first agreement will later enter into the second, the parties are not obligated to do so and may conclude their relationship after the terms of the first agreement have been fulfilled.

A201, GENERAL CONDITIONS OF THE CONTRACT FOR CONSTRUCTION: The General Conditions are an integral part of the contract for construction in that they set forth the rights, responsibilities, and relationships of the owner, contractor, and architect. While not a party to the contract for construction between owner and contractor, the architect does participate in the preparation of the contract documents and performs certain duties and responsibilities described in detail in the General Conditions. Because A201 is typically adopted by reference into certain other AIA documents (e.g., owner-architect agreements, owner-contractor agreements, and contractor-subcontractor agreements), it is often called the "keystone" document.

Since conditions vary by locality and by project, supplementary conditions are usually added to amend or supplement portions of the General Conditions as required by a particular project. Review the model language provided in A511 as a guide when creating supplementary conditions for A201.

A201/CMa, GENERAL CONDITIONS OF THE CONTRACT FOR CONSTRUCTION—CONSTRUCTION MANAGER-ADVISER EDITION, is an adaptation of AIA Document A201 developed for construction management projects with a fourth player—a construction manager—added to the team of owner, architect, and contractor. Under A201/CMa, the construction manager has the role of independent adviser to the owner, thus the document carries the CMa suffix. A major difference between A201 and A201/CMa occurs in Article 2, Administration of the Contract, which deals with the duties and responsibilities of both the architect and the construction manager-adviser. Another major difference implicit in A201/CMa is the use of multiple construction contracts directly with trade contractors.

Caution: It is vital that A201/CMa not be used in combination with documents that assume the construction manager will take on the role of constructor, give the owner a guaranteed maximum price, or contract directly with those who supply labor and materials for the project.

A201/SC, FEDERAL SUPPLEMENTARY CONDITIONS OF THE CONTRACT FOR CONSTRUCTION, is intended for use on certain federally assisted construction projects. For such projects, A201/SC adapts A201 by providing (1) necessary modifications of the General Conditions, (2) additional conditions, and (3) insurance requirements for federally assisted construction projects.

A271, GENERAL CONDITIONS OF THE CONTRACT FOR FURNITURE, FURNISHINGS, AND EQUIPMENT: When the scope of a contract is limited to furniture, furnishings, and equipment (FF&E), A271 is intended to be used in a manner similar to that in which A201 is used for construction projects. The document was jointly developed by the AIA and the American Society of Interior Designers (ASID). Because the Uniform Commercial Code (UCC) has been adopted in virtually every jurisdiction, A271 has been drafted to recognize the commercial standards set forth in Article 2 of the UCC and uses certain standard UCC terminology. Except for minor works, A271 should not be used for construction involving life safety systems or structural components.

A305, CONTRACTOR'S QUALIFICATION STATEMENT: An owner preparing to request bids or to award a contract for a construction project often requires a means of verifying the background, history, references, and financial stability of any contractor being considered. The time frame for construction and the contractor's performance history, previous experience, and financial stability are important factors for an owner to investigate. This form provides a sworn, notarized statement with appropriate attachments to elaborate on important aspects of the contractor's qualifications.

A310, BID BOND: This simple one-page form was drafted with input from the major surety companies to ensure its legality and acceptability. A bid bond establishes the maximum penal amount that may be due the owner if the selected bidder fails to execute the contract and provide any required performance and payment bonds.

A312, PERFORMANCE BOND AND PAYMENT BOND: This form incorporates two bonds, one covering the contractor's performance and one covering the contractor's obligations to pay subcontractors and others for material and labor. In

addition, A312 obligates the surety to act responsively to the owner's requests for discussions aimed at anticipating or preventing a contractor's default.

A401, STANDARD FORM OF AGREEMENT BETWEEN CONTRACTOR AND SUBCONTRACTOR is intended for use in establishing the contractual relationship between the contractor and subcontractor. It spells out the responsibilities of both parties and lists their respective obligations, which are written to parallel AIA Document A201, General Conditions of the Contract for Construction. Blank spaces are provided in which the parties can supplement the details of their agreement. A401 may be modified for use as a subcontractor-sub-contractor agreement.

A491, DESIGN/BUILDER-CONTRACTOR AGREEMENTS: This document contains two agreements to be used in sequence by a design/builder and a construction contractor. The first agreement covers management consulting services to be provided during the preliminary design and budgeting phase of the project. The second agreement covers construction. It is presumed that the design/builder has contracted with an owner to provide design and construction services under the agreements contained in AIA Document A191.

Although it is anticipated that a design/builder and a contractor entering into the first agreement will later enter into the second, the parties are not obligated to do so and may conclude their relationship after the terms of the first agreement have been fulfilled. Parties also may forgo entering into the first agreement and proceed directly to the second.

A501, RECOMMENDED GUIDE FOR COMPETITIVE BIDDING PROCEDURES AND CONTRACT AWARDS FOR BUILDING CONSTRUCTION: This guide outlines appropriate procedures in the bidding and award of contracts when competitive lump sum bids are requested in connection with building and related construction. The guide is a joint publication of the AIA and the Associated General Contractors of America (AGC).

A511, GUIDE FOR SUPPLEMENTARY CONDITIONS is a guide for modifying and supplementing A201, the General Conditions of the Contract for Construction. Although A201 is considered the keystone in the legal framework of the construction contract, it is a standard document and thus cannot cover all the particulars of a specific project. A511 provides model language with explanatory notes to help users adapt A201 by developing supplementary conditions that address local circumstances.

This document is printed with a column containing the model text and an adjacent column of explanatory notes. The AIA permits excerption of the model text under a limited license for reproduction granted for drafting supplementary conditions for a particular project.

A511/CMa, GUIDE FOR SUPPLEMENTARY CONDITIONS—CONSTRUCTION MANAGER-ADVISER EDITION: Similar to A511, the A511/CMa document is a guide to model provisions for supplementing A201/CMa, the General Conditions of the Contract for Construction, Construction Manager-Adviser Edition. A511/CMa should only be employed—as should A201/CMa—on projects for which the construction manager is serving in the capacity of adviser to the owner (as represented by the CMa document designation) and not in situations in which the construction manager is also the constructor (CMc document-based relationships).

Like A511, this document contains suggested language for supplementary conditions, along with notes on appropriate usage. In addition, many important distinctions are made to ensure consistency with other construction manager-adviser documents.

Caution: CMc documents are based on utilization of the A201 document, which in turn should be modified using A511 as a guide.

A521, UNIFORM LOCATION OF SUBJECT MATTER, is a joint publication of the AIA and the Engineers Joint Contract Documents Committee (EJCDC), which is composed of the National Society of Engineers, American Consulting Engineers Council, and American Society of Civil Engineers. By consensus of these organizations, the AIA and EJCDC documents follow the tabular guide in A521 with regard to the placement of subject matter among the various contract and bidding documents. A521 is a tabulation to guide the user in the proper placement and phrasing of information customarily used on a construction project. This document shows the importance of maintaining uniformity in location and language from document to document with respect to subject matter. Inconsistencies in either area may cause confusion, delay, or unanticipated legal problems.

A571, GUIDE FOR INTERIORS SUPPLEMENTARY CONDITIONS: Similar to A511, AIA Document A571 is intended as

an aid to practitioners preparing supplementary conditions for interiors projects. It provides information to help users address local variations in project requirements when A271, General Conditions of the Contract for Furniture, Furnishings, and Equipment, is used.

A701, INSTRUCTIONS TO BIDDERS, is used when competitive bids are to be solicited for construction of a project. Coordinated with A201 and its related documents, A701 contains instructions for procedures to be followed by bidders in preparing and submitting their bids, including bonding. Specific instructions or special requirements, such as the amount and type of bonding, are to be attached to A701 as supplementary conditions.

A771, INSTRUCTIONS TO INTERIORS BIDDERS: Similar to A701, A771 is used for projects dealing with furniture, furnishings, and equipment (FF&E). It parallels A701 but contains minor changes to maintain consistency with A271 and its related FF&E documents.

B SERIES

The documents in the B Series relate to various forms of agreement between an owner and an architect for professional services.

B141, STANDARD FORM OF AGREEMENT BETWEEN OWNER AND ARCHITECT WITH STANDARD FORM OF ARCHITECT'S SERVICES, is a flexible contracting package that allows architects to offer a broad range of services to clients spanning the life of a project, from conception to completion and beyond. It is structured in a multipart format consisting of an agreement form—the Standard Form of Agreement, which contains initial information, terms and conditions, and compensation—and a services form—the Standard Form of Architect's Services: Design and Contract Administration, which defines the architect's scope of services. The scope defined approximates the level of services in the prior edition of B141. The separation of the scope of services from the rest of the owner-architect agreement allows users the freedom to choose alternative scopes of services. The AIA intends to publish additional scopes of services that correlate to the terms and conditions of B141.

B151, ABBREVIATED STANDARD FORM OF AGREEMENT BETWEEN OWNER AND ARCHITECT, is intended for use on construction projects of limited scope when the complexity and detail of AIA Document B141, Standard Form of Agreement Between Owner and Architect, are not required and when services are based on these five phases: schematic design, design development, construction documents, bidding and negotiation, and construction. This document may be used with a variety of compensation methods, including percentage of construction cost, multiple of direct personnel expense, and stipulated sum. B151 is intended for use in conjunction with A201, General Conditions of the Contract for Construction.

B155, STANDARD FORM OF AGREEMENT BETWEEN OWNER AND ARCHITECT FOR A SMALL PROJECT, is intended for use on a project that is modest in size and brief in duration. It adopts the A205 document by reference as it pertains to the architect's responsibilities in administering the construction contract between owner and contractor.

B155 is one of three documents that comprise the Small Projects family of documents. It has been developed for use with AIA Document A105, Standard Form of Agreement Between Owner and Contractor for a Small Project, and A205, General Conditions of the Contract for Construction of a Small Project. These documents are specifically coordinated for use as a set.

Caution: Although A105, A205, and B155 may share some similarities with other AIA documents, the Small Project documents should not be used in tandem with other AIA document families without careful side-by-side comparison of contents.

B161, STANDARD FORM OF AGREEMENT BETWEEN OWNER AND ARCHITECT FOR DESIGNATED SERVICES, has been replaced by AIA DOCUMENT B163.

AIA DOCUMENT B162, SCOPE OF DESIGNATED SERVICES, has been replaced by AIA DOCUMENT B163.

B163, STANDARD FORM OF AGREEMENT BETWEEN OWNER AND ARCHITECT FOR DESIGNATED SERVICES, is the most comprehensive AIA owner-architect agreement. This three-part document contains, among other things, a thorough list of 83 possible services divided among nine phases, covering pre-design through supplemental services. This detailed classification allows the architect to estimate more accurately the time and personnel costs required for a particular project. Both owner and architect benefit from the ability to clearly establish the

continues on following page

Document Synopses, B Series, continued from previous page

scope of services required for a project, as responsibilities and compensation issues are negotiated and defined. The architect's compensation may be calculated on a time/cost basis through use of the worksheet provided in the instructions to B163.

Part One of the document deals with variables typical of many owner-architect agreements, such as compensation and scope of services. The scope of services is delimited through use of a matrix that allows the parties to designate their agreed-upon services and responsibilities. Part Two contains detailed descriptions of the specific services found in the matrix. Part Three contains general descriptions of the parties' duties and responsibilities. The list of services in B163 has been expanded to include construction management and interiors services.

B171, STANDARD FORM OF AGREEMENT BETWEEN OWNER AND ARCHITECT FOR INTERIOR DESIGN SERVICES, is intended for use when the architect agrees to provide an owner with design and administrative services for the procurement of interior furniture, furnishings, and equipment (FF&E). Unlike B141, which is used for building design, this document includes programming of the interior spaces and requirements as part of the overall package of basic services. The authority to reject goods is left in the hands of the owner rather than the architect, since the procurement of goods is governed by the Uniform Commercial Code (UCC), which would in turn make the architect's mistaken rejection or acceptance of goods binding upon the owner. B171 is coordinated with and adopts by reference AIA Document A271, General Conditions of the Contract for Furniture, Furnishings, and Equipment. When B171 is used, it is anticipated that A271 will form part of the contract between the owner and the contractor for FF&E.

B177, ABBREVIATED FORM OF AGREEMENT FOR INTERIOR DESIGN SERVICES, is similar to B171 but has less complexity and detail. B177 may be used when the owner and architect have a continuing relationship from previous work together or when the project is relatively simple in detail or short in duration.

B181, STANDARD FORM OF AGREEMENT BETWEEN OWNER AND ARCHITECT FOR HOUSING SERVICES, has been developed with the assistance of the U.S. Department of Housing and Urban Development and other federal housing agencies. It is primarily intended for use in multi-unit housing design. B181 requires the owner, rather than the architect, to furnish cost-estimating services. B181 is coordinated with and adopts by reference AIA Document A201, General Conditions of the Contract for Construction.

B188, STANDARD FORM OF AGREEMENT BETWEEN OWNER AND ARCHITECT FOR LIMITED ARCHITECTURAL SERVICES FOR HOUSING PROJECTS, is a unique addition to the AIA Documents collection. Unlike its distant cousin B181, B188 is intended for use when the architect will provide limited architectural services in connection with a development housing project. It anticipates that the owner will have extensive control over management of the project, acting in a capacity similar to that of a developer or speculative builder of a housing project. As a result, the owner or separate consultants retained by the owner likely will provide the engineering services, specify the brand names of materials and equipment, and administer payments to contractors, among other project responsibilities. B188 is not coordinated for use with any other AIA standard form contract.

B352, DUTIES, RESPONSIBILITIES AND LIMITATIONS OF AUTHORITY OF THE ARCHITECT'S PROJECT REPRESENTATIVE: When and if the owner wants additional project representation at the construction site on a full- or part-time basis, B141 and other AIA owner-architect agreements reference B352 to establish the duties, responsibilities, and limitations of authority of the project representative.

The project representative is employed and supervised by the architect. In contrast, up until the early 1950s, B352 predecessor documents called the representative "the Clerk of the Works," because such persons were hired by the owner but supervised by the architect. The split between hiring and supervision caused numerous problems, which have been resolved under B352 by designating the architect as both employer and supervisor. B352 is coordinated for use with both B141 and B163, as well as with A201.

B431, ARCHITECT'S QUALIFICATION STATEMENT, is a standardized outline of information that a client may wish to review prior to selecting an architect for a particular project. It may be used as part of a request for proposals (RFP) or as a final check on the credentials of an architect. Under some circumstances, B431 may be attached to the owner-architect

agreement, for example, to show the team of professionals and consultants expected to be employed on the owner's project.

B727, STANDARD FORM OF AGREEMENT BETWEEN OWNER AND ARCHITECT FOR SPECIAL SERVICES, is the most flexible of the AIA owner-architect agreements in that the description of services is left entirely up to the ingenuity of the parties. Otherwise, many of the terms and conditions are very similar to those found in AIA Document B141. B727 is often used for planning, feasibility studies, and other services (such as construction administration) that do not follow the complete phasing sequence of services set forth in B141 and other AIA documents. If construction administration services are to be provided, care must be taken to coordinate B727 with the appropriate General Conditions of the Contract for Construction.

B801/CMa, STANDARD FORM OF AGREEMENT BETWEEN OWNER AND CONSTRUCTION MANAGER WHERE THE CONSTRUCTION MANAGER IS NOT A CONSTRUCTOR, is intended for use on projects for which construction management services are assumed by a single entity who is separate and independent from the architect and the contractor and who acts solely as an adviser (CMa) to the owner throughout the course of the project.

B801/CMa is coordinated for use with AIA Document B141/CMa, Standard Form of Agreement Between Owner and Architect—Construction Manager-Adviser Edition. Both B801/CMa and B141/CMa are based on the premise that there will be a separate, and possibly multiple, construction contractor(s) whose contracts with the owner are jointly administered by the architect and the construction manager under AIA Document A201/CMa, General Conditions of the Contract for Construction—Construction Manager-Adviser Edition.

Caution: B801/CMa is not coordinated with and should not be used with documents in which the construction manager acts as the constructor (i.e., contractor) for the project, such as AIA Documents A121/CMc or A131/CMc.

B901, STANDARD FORM OF AGREEMENT BETWEEN DESIGN/BUILDER AND ARCHITECT, contains two agreements to be used in sequence by a design/builder and an architect. The first agreement covers preliminary design, and the second covers final design. It is presumed that the design/builder has previously contracted with an owner to provide design and construction services under the agreements contained in AIA Document A191. Although it is anticipated that a design/builder and an architect entering into the first agreement will later enter into the second, the parties are not obligated to do so and may conclude their relationship after the terms of the first agreement have been fulfilled.

Design/build entities may be architects, contractors, or even businesspersons, as long as they comply with the governing laws, especially those pertaining to licensing and public procurement regulations. Prior to proceeding in this fashion or entering into either agreement contained in this document with any other entity, architects are advised to contact their legal, insurance, and management advisers.

C SERIES

The documents in the C Series relate to various forms of agreement between an architect and other professionals, including engineers, consultants, and other architects.

C141, STANDARD FORM OF AGREEMENT BETWEEN ARCHITECT AND CONSULTANT, establishes the respective responsibilities and mutual rights of the architect and the consultant. C141 is most applicable to engineers but may also be used for consultants in other disciplines who provide services to architects. The provisions of C141 are in accord with those of B151 and A201, General Conditions of the Contract for Construction.

C142, ABBREVIATED ARCHITECT-CONSULTANT AGREEMENT, adopts the terms of a prime agreement between owner and architect by reference.

C727, STANDARD FORM OF AGREEMENT BETWEEN ARCHITECT AND CONSULTANT FOR SPECIAL SERVICES, is intended for use when other C Series documents are inappropriate. It is often used for planning, feasibility studies, post-occupancy studies, and other services that require specialized descriptions.

C801, JOINT VENTURE AGREEMENT FOR PROFESSIONAL SERVICES, is meant to be used by two or more parties to provide for their mutual rights and obligations. It is intended that the joint venture, once established, will enter into a project agreement with the owner to provide professional services. The parties may be all architects, all engineers, a combination of architects and engineers, or another combination of professionals. The document pro-

vides a choice between two methods of joint venture operation. The "Division of Compensation" method assumes that services provided and the compensation received will be divided among the parties in the proportions agreed to at the outset of the project. Each party's profitability then depends on individual performance of preassigned tasks and is not directly tied to that of the other parties. The "Division of Profit and Loss" method is based on each party performing work and billing the joint venture at cost plus a nominal amount for overhead. The ultimate profit or loss of the joint venture is thus divided at completion of the project between the parties based on their respective interests.

D SERIES

The documents in the D Series, known as the Architect Industry documents, are applicable to a broad range of projects.

D101, METHODS OF CALCULATING THE AREA AND VOLUME OF BUILDINGS, establishes definitions for and describes methods of calculating the architectural area and volume of buildings. D101 also covers interstitial space, office, retail, and residential areas.

D200, PROJECT CHECKLIST, is a convenient list of tasks a practitioner may perform on a given project. This checklist will help the architect recognize required tasks and locate the data necessary to fulfill assigned responsibilities. By providing space for notes on actions taken, assignment of tasks, and time frames for completion, D200 may also serve as a permanent record of the owner's, contractor's, and architect's actions and decisions.

F SERIES

The F Series offered accounting forms for architects. With the exception of F5002, INVOICE FOR ARCHITECTURAL SERVICES, separate editions of F Series forms have been discontinued due to the preponderance of commercially available computer software on this subject. F1001 through F3002 are included in the book *Standardized Accounting for Architects* by Robert F. Mattox, FAIA.

G SERIES

The documents in the G Series relate to office administration, securing of goods and services, and administering and closing out of project agreements.

G601, REQUEST FOR PROPOSAL—LAND SURVEY, allows owners to request proposals from a number of surveyors based on information deemed necessary by the owner and architect. G601 also allows owners to fine-tune a request for proposal (RFP) by checking appropriate boxes and filling in project specifics to avoid costs associated with requesting unnecessary information. The document may also form the agreement between owner and land surveyor once an understanding is reached.

G602, REQUEST FOR PROPOSAL—GEOTECHNICAL SERVICES: Similar in both structure and format to AIA Document G601, G602 is an RFP that can evolve to form an agreement between owner and geotechnical engineer. G602 allows the owner to tailor the proposal request to address the specific needs of a project. In consultation with the architect, the owner establishes the parameters of service required and evaluates submissions based on criteria such as time, cost, and overall responsiveness to the terms set forth in the RFP. When an acceptable submission is selected, the owner signs the document in triplicate, returning one copy to the engineer and one to the architect, thus establishing an agreement between owner and geotechnical engineer.

G604, PROFESSIONAL SERVICES SUPPLEMENT, is intended to formalize procedures for authorizing supplemental professional actions, such as expanding the scope of basic services, incurring reimbursable expenses, or proceeding with certain additional services. The document should only be used in conjunction with an earlier agreement for professional services and is meant to provide a written record of such authorizations, with particulars of activities, time spans, and compensation involved.

G612, OWNER'S INSTRUCTIONS REGARDING THE CONSTRUCTION CONTRACT, INSURANCE AND BONDS, AND BIDDING PROCEDURES, is formatted as a questionnaire in three parts. Part A relates to the contracts, Part B covers insurance and bonds, and Part C deals with bidding procedures. The sections follow a project's normal chronological sequence to provide information when it will be needed. Because many of the items relating to the contract will have some bearing on the development of construction documents, it is important to place Part A in the owner's hands at the earliest possible phase of the project. The owner's responses to Part A will lead to selection of the

continues on following page

Dale Elickson, FAIA; The American Institute of Architects, Washington, D.C.

1 CONSTRUCTION INFORMATION SYSTEMS

Document Synopses, G Series, continued from previous page

appropriate delivery method and contract forms, including the general conditions. Part B naturally follows after the selection of the general conditions, because insurance and bonding information depends on the type of general conditions chosen. Answers to Part C will follow as the contract documents are further developed.

G701, CHANGE ORDER, may be used as written documentation of changes in the work, contract sum, or contract time that are mutually agreed to by the owner and contractor. G701 provides space for the signatures of the owner, architect, and contractor and for a complete description of the change.

G701/CMa, CHANGE ORDER—CONSTRUCTION MANAGER-ADVISER EDITION: The purpose of this document is essentially the same as that of G701. The major difference is that the signature of the construction manager-adviser is required along with those of the owner, architect, and contractor to validate the change order.

G702, APPLICATION AND CERTIFICATE FOR PAYMENT, and G703, CONTINUATION SHEET: These documents provide convenient and complete forms on which the contractor can apply for payment and the architect can certify that payment is due.

The forms require the contractor to show the status of the contract sum to date, including the total dollar amount of the work completed and stored to date, the amount of retainage (if any), the total of previous payments, a summary of change orders, and the amount of current payment requested. G703, Continuation Sheet, breaks the contract sum into portions of the work in accordance with a schedule of values required by the general conditions.

The form serves as both the contractor's application and the architect's certification. Its use can expedite payment and reduce the possibility of error. If the application is properly completed and acceptable to the architect, the architect's signature certifies to the owner that a payment in the amount indicated is due to the contractor. The form also allows the architect to certify an amount different than the amount applied for, with explanation provided by the architect.

G702/CMa, APPLICATION AND CERTIFICATE FOR PAYMENT—CONSTRUCTION MANAGER-ADVISER EDITION, and G703, CONTINUATION SHEET: Though the use and purpose of G702/CMa is substantially similar to that of G702, the construction manager-adviser edition expands responsibility for certification of payment to include both architect and construction manager. Similarly, both architect and construction manager may certify a different amount than that applied for, with each initialing the figures that have been changed and providing written explanation(s) accordingly. The standard G703, Continuation Sheet, is appropriate for use with G702/CMa.

G704, CERTIFICATE OF SUBSTANTIAL COMPLETION, is a standard form for recording the date of substantial completion of a work or a designated portion thereof. The contractor prepares a list of items to be completed or corrected, and the architect verifies and amends this list. If the architect finds that the work is substantially complete, the form is prepared for acceptance by the contractor and the owner. Appended to the form is a list of items to be completed or corrected. The form provides for agreement as to the time allowed for completion or correction of the items, the date when the owner will occupy the work or designated portion thereof, and a description of responsibilities for maintenance, heat, utilities, and insurance.

G705, CERTIFICATE OF INSURANCE, has been replaced by AIA Document G715.

G706, CONTRACTOR'S AFFIDAVIT OF PAYMENT OF DEBTS AND CLAIMS: The contractor submits this affidavit with the final request for payment, stating that all payrolls, bills for materials and equipment, and other indebtedness connected with the work for which the owner might be responsible have been paid or otherwise satisfied. G706 requires the contractor to list any indebtedness or known claims in connection with the construction contract that have not been paid or otherwise satisfied. The contractor may also be required to furnish a lien bond or indemnity bond to protect the owner with respect to each exception.

G706A, CONTRACTOR'S AFFIDAVIT OF RELEASE OF LIENS, supports AIA Document G706 in the event the owner requires a sworn statement of the contractor stating that all releases or waivers of liens have been received. In such event, it is normal for the contractor to submit G706 and G706A, along with attached releases or waivers of liens for the contractor, all subcontractors, and others who may have lien rights against the owner's property. The contractor is required to list any exceptions to the sworn statement provided in G706A and may be required to furnish the owner with a lien bond or indemnity bond to protect the owner with respect to such exceptions.

G707, CONSENT OF SURETY TO FINAL PAYMENT: By obtaining the approval of the surety for final payment to the contractor and the agreement of the surety that final payment will not relieve the surety of any of its obligations, the owner may preserve its rights under the bonds.

G707A, CONSENT OF SURETY TO REDUCTION IN OR PARTIAL RELEASE OF RETAINAGE, is a standard form for use when a surety company is involved and the owner-contractor agreement contains a clause whereby retainage is reduced during the course of the construction project. When duly executed, G707A assures the owner that such reduction or partial release of retainage does not relieve the surety of its obligations.

G709, PROPOSAL REQUEST, is used to obtain price quotations required in the negotiation of change orders. G709 is not a change order or a direction to proceed with the work; it is simply a request to the contractor for information related to a proposed change in the construction contract.

G710, ARCHITECT'S SUPPLEMENTAL INSTRUCTIONS, is used by the architect to issue additional instructions or interpretations or to order minor changes in the work. The form is intended to assist the architect in performing obligations as interpreter of the contract document requirements in accordance with the owner-architect agreement and the general conditions. This form should not be used to change the contract sum or contract time. If the contractor believes that a change in the contract sum or contract time is involved, other G Series documents must be used.

G711, ARCHITECT'S FIELD REPORT, is a standard form for the architect's project representative to use in maintaining a concise record of site visits or, in the case of a full-time project representative, a daily log of construction activities.

G712, SHOP DRAWING AND SAMPLE RECORD, is a standard form by which the architect can schedule and monitor shop drawings and samples. Since this process tends to be complex, the schedule provided in G712 shows the progress of a submittal, which in turn contributes to the orderly processing of work. G712 can also serve as a permanent record of the chronology of the submittal process.

G714, CONSTRUCTION CHANGE DIRECTIVE, replaces former AIA Document G713, Construction Change Authorization. G714 was developed as a directive for changes in the work that, if not expeditiously implemented, might delay the project. In contrast to a Change Order (AIA Document G701), G714 is to be used when the owner and contractor, for whatever reason, have not reached agreement on proposed changes in the contract sum or contract time. Upon receipt of a completed G714, the contractor must promptly proceed with the change in the work described therein.

G714/CMa, CONSTRUCTION CHANGE DIRECTIVE, CONSTRUCTION MANAGER-ADVISER EDITION, is designed to effect the same type of substantive changes in the work described in the synopsis of G714, above. The difference between the two lies not in purpose but in execution: Whereas the owner and architect must both sign the G714 in order for the directive to become a valid contractual instrument, G714/CMa requires execution by owner, architect, and construction manager-adviser.

G722/CMa, PROJECT APPLICATION AND PROJECT CERTIFICATE FOR PAYMENT, and G723/CMa, PROJECT APPLICATION SUMMARY: These documents are similar in purpose to the combination of G702 and G703 but are for use on construction management projects on which a construction manager serves as an adviser to the owner.

Each contractor submits separate G702/CMa and G703/CMa documents to the construction manager-adviser, who collects and compiles them to complete G723/CMa. G723/CMa then serves as a summary of the contractors' applications, with project totals being transferred to a G722/CMa. The construction manager-adviser can then sign the form, have it notarized, and submit it along with the G723/CMa (which has all of the separate contractors' G702/CMa forms attached) to the architect for review and appropriate action.

REFERENCES

Information on the AIA documents may be obtained from the publications listed below. Information on the documents is also available on the AIA website at www.aiaonline.com.

"AIA Contract Documents Price List." This publication is available free from AIA distributors or by calling (800) 365-2724. It lists the current edition of each AIA document.

American Institute of Architects. *The Architect's Handbook of Professional Practice*, 12th ed. Washington, D.C.: The AIA Press, 1994. The Handbook has been the architecture profession's premier manual of practice since it was first published in 1917. It contains sample copies of most of the AIA documents.

The Documents Supplement Service. This is a subscription service through which users of the Handbook can receive sample copies of new AIA documents as they are published. Subscribers also receive the *Supplement*, a newsletter of articles and comment on the AIA documents. Subscriptions may be obtained by calling (800) 365-2724.

"Promises, Promises: Forging Healthy Project Relationships." This is a series of continuing education manuals, each of which may be used either for seminar presentation or for self-study.

Advanced Contract Concepts. This manual covers the essentials of contract law: the elements of a contract, the fundamental principles of agency and negligence law, and the use of standard contract documents. It also includes an overview of the recent, major changes to two AIA standard contract documents: A201, General Conditions of the Contract for Construction, and B141, Standard Form of Agreement Between Owner and Architect.

Design Service. This manual addresses the general responsibilities of the architect and the owner in B141, Standard Form of Agreement Between Owner and Architect. Specifically, these responsibilities include establishing a program and budget, setting basic project parameters, and agreeing on the architect's scope of services. The manual also includes an overview of the Standard Form of Architect's Services: Design and Contract Administration, the first scope of services published with B141.

Design and Contract Administration: Contract Conditions. Contract conditions form the framework within which the owner and architect carry out their responsibilities to one another. This manual addresses the contract conditions that generally apply over the course of the owner-architect relationship, including compensation and billing, project timing and duration, responsibilities of the owner, and ownership and use of documents.

Contract Administration Services. This manual covers roles and responsibilities of owner, architect and contractor as a project moves into construction.

Contract Administration—Office. This manual addresses contract administration from the architect's perspective when "back in the office" and not in the field visiting the owner's site. It covers project initiation, submittals, changes, timing issues, suspension and termination, and special provisions, such as property insurance.

Construction Contract Administration Conditions—Field. This manual addresses construction contract administration conditions relevant to the architect's services on the job site, administering the contract, and evaluating the work as it progresses, as well as subcontractor relations, contractor's payments, claims, corrections to the work, and project closeout.

INTRODUCTION

It is useful to have different ways of organizing construction information so the varying interests of those who view, use, and manipulate it can be accommodated. UniFormat and MasterFormat offer two commonly accepted ways of organizing information about construction projects and building operations.

MasterFormat emphasizes a view of construction focused on products, offering the perspective of product manufacturers, suppliers, specifiers, and contractors. MasterFormat names components (building materials, products, and activities) that have specifiable characteristics.

UniFormat focuses on performance requirements and coincides with the way users, owners, and designers view construction. UniFormat names systems and assemblies that have a determinable function.

MASTERFORMAT

MasterFormat, with its list of products and activities, looks at construction in the way the parts are specified, purchased, and installed. The term products here means materials, components, and equipment that a contractor incorporates into the work of a project.

MasterFormat arranges information for project manuals into six major groups (introductory information, bidding requirements, contracting requirements, facilities and spaces, systems and assemblies, and construction products and activities). For details, see the AGS pages on MasterFormat.

Architects use MasterFormat in the following ways:

1. To arrange information in project manuals
2. To catalog product information with the numbers and titles used to specify those products and activities in construction documents
3. To arrange cost information and build a cost model for construction activities and associated products according to how they are specified in construction documents
4. To prepare keynotes for drawings that associate items with specifications in construction documents
5. To arrange facility management and construction market information in the way products and activities are specified in construction documents

UNIFORMAT

UniFormat is a method of arranging construction information for a range of building types based on the physical systems and assemblies that make up a facility. Construction is viewed according to the way in which elements are used, thus systems and assemblies are characterized by their function with no identification of the products they comprise. Nine level 1 UniFormat categories and their associated classes and subclasses define the basic parts of a building, each characterized by its function.

Titles in UniFormat levels 1 through 3 can be applied to most project descriptions and preliminary cost estimates. Levels 4 and 5 are available for use on detailed, complex projects. Levels 4 and 5 titles and detailed lists provide a checklist to ensure comprehensive and complete application of UniFormat.

UniFormat is intended to help architects achieve consistency in economic evaluation of projects; enhance design program information reporting; and promote consistency in filing information for facility management, drawing details, and construction market data. More specifically, it is used to organize design descriptions, cost summaries, and performance specifications of systems and assemblies (e.g., HVAC systems and exterior wall assemblies).

Architects use UniFormat for these tasks:

1. Performing economic analysis of construction alternatives, particularly in early design stages
2. Building an evolving construction cost model arranged by the functional parts of a facility
3. Arranging descriptions of the functional parts of a project so they communicate how a design is intended to accomplish an owner's construction program
4. Arranging project manuals for applications when design-build delivery is employed
5. Filing drawing details
6. Filing facility management and construction market information

APPLICATION OVERVIEW

On this and the following AGS page on UniFormat are basic strategies for numbering and titling information about systems and assemblies for uses other than construction doc-

uments. The methods described are not rigid; rather, they are meant to help UniFormat users develop an understanding of the system that will allow them to apply it consistently. Information is included about using UniFormat to organize cost information and preliminary project descriptions, arrange project manuals, and organize facility management and construction market information.

Level 1 UniFormat titles cover the major categories of construction information according to function. These letters and titles are fixed and should not be changed in application:

PROJECT DESCRIPTION

- A—SUBSTRUCTURE
- B—SHELL
- C—INTERIORS
- D—SERVICES
- E—EQUIPMENT AND FURNISHINGS
- F—SPECIAL CONSTRUCTION AND DEMOLITION
- G—BUILDING SITEWORK
- Z—GENERAL

The category Project Description is a collection of basic information that introduces a project and includes bidding, proposal, and contract requirements. It can be used as a stand-alone contracting structure for construction projects and is especially suitable for design-build applications. The Project Description level does not have a letter designation, allowing it to appear first in the list of titles.

Like the Project Description, Category Z—General does not represent a building system or assembly. It is designated by the last letter of the alphabet to keep this category last if the system is expanded beyond building construction for a project.

Level 1 categories are divided into classes of information to make level 2 categories. These carry the letter of their parent category plus a two-digit number. Alphanumeric designations and titles of level 2 classes are fixed and should not be changed in application.

Levels 3 and 4 are created by further subdividing level 2 classes. These subclasses carry the alphanumeric designation of their parent category and class plus a two-digit number. Level 3 designations should not be changed in application. Alphanumeric designations for level 4 are unassigned within a group of level 3 subclasses and number extension are assigned by the user. The user-assigned number should carry the alphanumeric designation of the parent level 3 subclass plus a two-digit number or the corresponding MasterFormat number.

Titles presented below level 4 are level 5 subclasses, developed by presenting specialized design solutions of the level 4 parent subclasses. Particular materials may be identified to differentiate one specialized solution from another. Titles at level 5 are examples of information included in their level 4 subclass.

No alphanumeric designation is assigned. Users may assign extensions. Level 5 and some level 4 titles correspond to MasterFormat numbers and titles.

The UniFormat numbering system can expand to allow for additional numbers and titles at any level. User-defined numbers and titles that fit within the established framework of UniFormat can be added.

SELECTING UNIFORMAT NUMBERS AND TITLES

Not all UniFormat titles will be used for every project. UniFormat is an expandable structure that can accommodate additional titles to meet specific requirements. However, designated numbers and titles should not be changed in order to maintain a consistent arrangement.

UniFormat titles are generic, descriptive titles independent of any design solution. They are the starting point for describing systems and assemblies. Be sure to incorporate these parent titles when creating a user-defined level 3, 4, or 5 title, so systems and assemblies titles are complete, clear, and descriptive. Users can add further systems and assemblies numbers and titles for projects that include items other than building construction, such as heavy civil engineering construction or process facilities.

Some users may want to add MasterFormat materials and methods information to a document organized according to UniFormat. MasterFormat numbers may be added throughout the design process as materials and methods are determined.

The transition from a document organized according to Uni-

Format to one organized according to MasterFormat may be easier if MasterFormat extensions are used. If these five-digit number extensions have been added, a document organized according to UniFormat can be searched or sorted according to a MasterFormat five-digit extension to regroup information according to MasterFormat.

USING UNIFORMAT

Below and at the beginning of the next AGS page are explanations of several uses for UniFormat.

ARRANGING COST INFORMATION

The list of elements or systems in UniFormat can be used as the basis of a system for organizing cost information which may be reported in varying degrees of detail. As design decisions are made, information about costs can be refined. This arrangement makes possible a comparison of cost information for various building elements, which may be particularly useful during early design phases.

A UniFormat cost model can be used in tandem with a cost model organized according to MasterFormat. The two models render a different view of a project and provide details appropriate for different requirements. For example, a cost model organized according to UniFormat can provide information about the cost of a concrete structure as compared to the cost of a steel structure. A cost model organized according to MasterFormat can provide information about the cost of all the concrete and steel on a project regardless of the structural system chosen.

Value analysis requires a consistent naming scheme carried throughout a project. UniFormat is particularly useful for this type of analysis, which requires attaching a cost to a particular use or facility function rather than to particular products and activities. Using MasterFormat numbers as suffixes to element designations helps the value analyst evaluate change proposals.

ARRANGING PRELIMINARY PROJECT DESCRIPTIONS

Preliminary project descriptions are described in the CSI *Manual of Practice* in chapter FF/180, "Preliminary Project Descriptions and Outline Specifications." A preliminary project description helps an owner understand the various components and systems proposed by an A/E for a project. It also serves a requirement normally included in a design services agreement for which the A/E must submit a report after completing the schematic design but before proceeding to design development. These descriptions may serve as the basis for an estimate of probable construction costs.

UniFormat provides a logical sequence of systems and assemblies for describing a construction project before all materials and methods have been determined. UniFormat is used to organize, and serves as a checklist for preparing, preliminary project descriptions at various levels of detail. As a design progresses, both descriptions and estimates of probable construction costs can be refined.

ARRANGING PROJECT MANUALS

Arranging project manuals, or portions of them, according to UniFormat is appropriate when performance specification is the method employed for all or some of the project. Performance specification can be used at many levels, from a single product to major subsystems or entire projects. It allows the owner to access a range of options, from existing technology to innovative systems and developing technologies. As well, performance specification encourages full bidding competition based on nonrestrictive requirements. Design-build projects make use of performance specification in its broadest application.

Whether an entire building or only a portion of it is specified using performance specifications, UniFormat can be used to organize this type of specification for elements crossing MasterFormat section and division boundaries. For conventional projects with project manuals organized according to MasterFormat, specifiers can include systems and assemblies before Division 1—General Requirements. According to UniFormat, systems and assemblies can be numbered and sequenced in this part of the project manual with the appropriate assignment of UniFormat numbers and titles. CSI *Manual of Practice* chapters FF/120, "Methods of Specifying," and SP/090, "Performance Specifying," provide detailed discussions about this application.

ARRANGING CONSTRUCTION MARKET INFORMATION

Market information reporting agencies can use UniFormat to describe the facility being reported. UniFormat can also be used to assemble, store, and report information about elements separate from and in addition to reports on prod-

continues on next page

1

CONSTRUCTION INFORMATION SYSTEMS

continued from the previous page

ucts and activities. This helps show trends for major elements containing products and activities crossing MasterFormat section and division boundaries.

ORGANIZING DRAWINGS

UniFormat numbers and titles can be used as a file-naming convention for library files of standard details and schedules. The Uniform Drawing System (UDS) provides a detailed description for this application.

Library files are named differently from project files because the classification and indexing requirements are different. Library file naming should be grouped by building systems, assemblies, or use because that is the most natural way to search for them. Project detail files must also be organized to make it easy to produce project contract documents, record documents, and facility management documents from several files. Naming a detail file for a project requires the sheet identification, coordinates on the sheet, and a detail identifier.

UDS recommends an 8-character designator for naming library schedule files. A numbering system based on UniFormat can be used for preliminary phases of a project. UniFormat numbers can be used during the construction documents phase for schedules made up of assemblies of materials that might otherwise have separate MasterFormat numbers.

ARRANGING FACILITIES MANAGEMENT INFORMATION

UniFormat is used for preliminary project descriptions to communicate systems and assemblies concepts to a building owner. Once preliminary project descriptions have been refined, UniFormat can be used to communicate a building's functional systems and assemblies for real estate due-diligence reports and to organize maintenance and operation programs and data.

UniFormat can be used to document how systems and assemblies function; therefore, it is an organizational concept well-suited to describing systems design intent during facility commissioning. Project descriptions can be refined throughout the design process, making it easier to carry out the commissioning authority's performance testing and acceptance program. Facility personnel can then use the project descriptions to store information about systems maintenance and operations.

ARRANGING INFORMATION FOR DESIGN-BUILD APPLICATIONS

Design-build project delivery has created a need for an organizational structure that allows owners and design-build entities to communicate functional performance requirements. UniFormat provides this organizational structure.

UNIFORMAT AND MASTERFORMAT USED TOGETHER

UniFormat and MasterFormat can be used in all applications that have traditionally been the domain of MasterFormat. The 1998 edition of UniFormat includes cross-references to MasterFormat to help users apply both organizational principles. These applications include organizing project manuals; assigning specification numbers and titles; and organizing and filing cost information, drawing details, and facility management and construction market information.

Both systems can be characterized as "single," "serial," or "parallel":

1. Single applications use only UniFormat or MasterFormat exclusively throughout the application.
2. In serial applications, such as a project manual, a number and title are applied to each item based on either UniFormat or MasterFormat. Both organizational principles can be used in the same application.
3. Parallel applications are those in which each item is named with numbers and titles from UniFormat and MasterFormat. This is a powerful method in many applications, such as organizing cost information, in which information about a cost-estimate line item can be tracked to a product and to a system or assembly.

LEVELS 1 THROUGH 3 NUMBERS AND TITLES

PROJECT DESCRIPTION

- 10—PROJECT DESCRIPTION
1010 Project Summary

- 1020 Project Program
1030 Existing Conditions
1040 Owner's Work
1050 Funding

20—PROPOSAL, BIDDING, AND CONTRACTING

- 2010 Delivery Method
2020 Qualifications Requirements
2030 Proposal Requirements
2040 Bid Requirements
2050 Contracting Requirements

30—COST SUMMARY

- 3010 Elemental Cost Estimate
3020 Assumptions and Qualifications
3030 Allowances
3040 Alternates
3050 Unit Prices

CONSTRUCTION SYSTEMS AND ASSEMBLIES

ELEMENT A—SUBSTRUCTURE

- A10 Foundations
A1010 Standard Foundations
A1020 Special Foundations
A1030 Slab On Grade

A20 Basement Construction

- A2010 Basement Excavation
A2020 Basement Walls

ELEMENT B—SHELL

- B10 Superstructure
B1010 Floor Construction
B1020 Roof Construction

B20 Exterior Enclosure

- B2010 Exterior Walls
B2020 Exterior Windows
B2030 Exterior Doors

B30 Roofing

- B3010 Roof Coverings
B3020 Roof Openings

ELEMENT C—INTERIORS

- C10 Interior Construction
C1010 Partitions
C1020 Interior Doors
C1030 Fittings

C20 Stairs

- C2010 Stair Construction
C2020 Stair Finishes

C30 Interior Finishes

- C3010 Wall Finishes
C3020 Floor Finishes
C3030 Ceiling Finishes

ELEMENT D—SERVICES

- D10 Conveying
D1010 Elevators and Lifts
D1020 Escalators and Moving Walks
D1090 Other Conveying Systems

D20 Plumbing

- D2010 Plumbing Fixtures
D2020 Domestic Water Distribution
D2030 Sanitary Waste
D2040 Rain Water Drainage
D2090 Other Plumbing Systems

D30 Heating, Ventilating, and Air Conditioning (HVAC)

G30 Site Civil/Mechanical Utilities

- G3010 Water Supply
G3020 Sanitary Sewer
G3030 Storm Sewer
G3040 Heating Distribution
G3050 Cooling Distribution
G3060 Fuel Distribution
G3090 Other Site Mechanical Utilities

G40 Site Electrical Utilities

- G4010 Electrical Distribution
G4020 Site Lighting
G4030 Site Communications and Security
G4090 Other Site Electrical Utilities

G90 Other Site Construction

- G9010 Service Tunnels
G9090 Other Site Systems

ELEMENT Z—GENERAL

- Z10 General Requirements
Z1010 Administration
Z1020 Quality Requirements
Z1030 Temporary Facilities
Z1040 Project Closeout
Z1050 Permits, Insurance, and Bonds
Z1060 Fee

Z20 Contingencies

- Z2010 Design Contingency
Z2020 Escalation Contingency
Z2030 Construction Contingency

The Construction Specifications Institute; Alexandria, Virginia

INTRODUCTION

MasterFormat is a master list of numbers and titles for organizing information about construction requirements, products, and activities into a standard sequence. Many different delivery methods, products, and installation types are used on construction projects. Successful completion of projects requires effective communication among the people involved. Information retrieval is nearly impossible without a standard filing system familiar to each user. MasterFormat offers a standard filing and retrieval scheme applicable throughout the construction industry. It is a uniform system used for organizing information in project manuals, organizing cost data, filing product information and other technical data, identifying drawing objects, and presenting construction market data.

MasterFormat is produced jointly by the Construction Specifications Institute (CSI) and Construction Specifications Canada (CSC). It is updated periodically; the information on the pages in AGS comes from the 1995 edition.

HISTORY

Since it was introduced in 1963, the 16-division CSI format has been widely accepted for standard practice in the United States and Canada. First published as part of the CSI Format for Construction Specifications, it was later used as the basis for the Uniform System for Construction Specifications, Data Filing and Cost Accounting—Title One Buildings, published in 1966. The Uniform System was developed and endorsed by the American Institute of Architects, American Society of Landscape Architects, Associated General Contractors of America, Council of Mechanical Specialty Contracting Industries (now the Associated Specialty Contractors), Producers' Council, National Society of Professional Engineers, and Construction Specifications Institute. In 1966 a similar effort in Canada produced the Building Construction Index (BCI), which was based on the 16-division format that had been introduced by the Specification Writers Association of Canada (renamed Construction Specifications Canada in 1974).

In 1972 the U.S. and Canadian formats were merged and published as the Uniform Construction Index (UCI). The UCI was a comprehensive framework for organizing information contained in project manuals, as well as a base of information for filing data and classifying project costs.

In 1978 Construction Specifications Canada joined with the Construction Specifications Institute to produce the first edition of MasterFormat, introduced by CSI as MP-2-1 and by CSC as Document 004E. This document incorporated a complete organizational format for project manuals, including bidding requirements, contract forms, and conditions of the contract in addition to the 16-division list of numbers and titles primarily used for specifications.

The first revised edition of MasterFormat, published in 1983, retained the basic principles of organization from the previous edition but added information to respond to the needs of the engineering disciplines. The 1988 edition, based on input from MasterFormat users, incorporated revisions and additions recognizing new products and developments in the construction industry.

The 1995 edition, the titles of which are published in the tenth edition of *Architectural Graphic Standards*, is the result of an extensive public review and coordination with industry users. It incorporates many minor revisions in numbers and titles and several changes in style and presentation. Some significant rearrangements of numbers and titles, particularly in divisions 1, 2, 13, 15, and 16, have been made.

BASIC ORGANIZATION

The numbers and titles in MasterFormat are grouped under these general headings:

INTRODUCTORY INFORMATION (00001 to 00099)
 BIDDING REQUIREMENTS (00100 to 00499)
 CONTRACTING REQUIREMENTS (00500 to 00999)
 FACILITIES AND SPACES (no numbering)
 SYSTEMS AND ASSEMBLIES (no numbering)
 CONSTRUCTION PRODUCTS AND ACTIVITIES (Divisions 1-16)

The first grouping, Introductory Information, is used for indexing. The second and third groupings, Bidding Requirements and Contracting Requirements, are for defining relationships, responsibilities, and processes for construction. The last three groupings, Facilities and Spaces, Systems and Assemblies, and Construction Products and Activities, are used to describe the physical aspects of construction.

TITLES

MasterFormat arranges related construction products and activities into 16 level one titles, called divisions. The numbers and titles of the divisions are as follows:

Division 1—General Requirements
 Division 2—Site Construction
 Division 3—Concrete
 Division 4—Masonry
 Division 5—Metals
 Division 6—Wood And Plastics
 Division 7—Thermal And Moisture Protection
 Division 8—Doors And Windows
 Division 9—Finishes
 Division 10—Specialties
 Division 11—Equipment
 Division 12—Furnishings
 Division 13—Special Construction
 Division 14—Conveying Systems
 Division 15—Mechanical
 Division 16—Electrical

The level two titles (formerly called broadscope titles) identify clusters of products and activities that have an identifying characteristic in common. Usually, the titles are a logical categorization of the division title. Sometimes, particularly in divisions 2, 13, 15, and 16, they are arbitrary breakdowns of the division to reduce it to a more manageable size. Level two titles are the highest level generally used in titling and arranging units of construction information. In MasterFormat, level two titles are presented as all uppercase letters and boldface type.

MasterFormat shows both numbers and titles at level three. Level three titles are presented as first letter uppercase and boldface type. Level three numbers are presented as the last three digits of the five-digit designation in boldface type.

MasterFormat suggests titles at level four but does not indicate numbers. Users should create numbers by interpolating between assigned numbers when using level four titles or creating new titles. Level four titles are presented alphabetically in regular (nonbold) type.

A key word index of requirements, products, and activities is included in MasterFormat to help find appropriate numbers and titles for construction subjects. Alphabetized entries may refer to either level two or level three numbers.

RELATIONSHIP TO UNIFORMAT

CSI and CSC also publish UniFormat, which provides numbers and titles for the functional elements that make up construction product systems and assemblies. UniFormat can be used to organize project descriptions and preliminary specifications. It is particularly suited to organizing cost estimates for value analysis because its organization by function corresponds to value analysis techniques. MasterFormat and UniFormat are complementary for applications in which reference to both products and functional elements may be useful (e.g., project manuals and cost estimating).

The 1995 edition of MasterFormat establishes a location for these systems and assemblies but does not include the associated numbers and titles, deferring to UniFormat for these. In MasterFormat systems and assemblies fall immediately before the list of construction products and activities (Divisions 1-16) (see the list of level two MasterFormat titles on the accompanying AGS page).

APPLICATION OVERVIEW

The following brief discussion is an overview of how to use MasterFormat numbers and titles for various applications. Refer to the CSI Application Guide for more detailed analysis.

PROJECT MANUALS

MasterFormat is the fundamental standard for titling and arranging project manuals containing bidding requirements, contracting requirements, and specifications.

INTRODUCTORY INFORMATION: Indexing documents included in this grouping are found at the beginning of project manuals. They are not actual contract documents but may be incorporated in a contract document by reference.

BIDDING REQUIREMENTS and CONTRACTING REQUIREMENTS: Often referred to as Series (rather than Division) Zero documents, these documents are not specifications but definitions of the relationships, processes, and responsibilities for projects. The Bidding Requirements documents do not become a part of the construction contract. The Contracting Requirements documents are contract forms and conditions of the contract.

In these two groups, level two and level three MasterFormat numbers have been assigned to provide a consistent identification, but it is not necessary to renumber or retitling printed forms and standard documents published by various professional societies.

FACILITIES AND SPACES and SYSTEMS AND ASSEMBLIES: MasterFormat indicates a location but does not include standard numbers and titles for these groupings. Facility and space titles are often project specific, and neither CSI nor CSC has a master list of numbers and titles for these groupings. Refer to UniFormat for system and assembly numbers and titles.

CONSTRUCTION PRODUCTS AND ACTIVITIES: The heart of MasterFormat remains the 16 divisions defined by the level one specification titles. Divisions 1 through 16 remain a complete method of numbering and titling sections of specifications, both for arranging master guide specifications or for arranging a project specification.

PRODUCT DATA

Identifying product data with MasterFormat numbers and titles is practical because of the relationship between products and specifications. Particular uses in this application include arranging publications in a technical library; filing information on products, methods, suppliers, and subcontractors; and inventorying construction products.

COST ESTIMATING

MasterFormat is useful for identifying unit prices and cost report items for products and activities, arranging a database of product and activity unit costs, arranging and tabulating a project budget according to a product and activity breakdown, and relating cost items to specifications and drawings. MasterFormat is not particularly useful for value analysis, which requires assigning cost to particular functional elements, rather than to particular products and activities.

DRAWING ELEMENTS

MasterFormat is used to keynote applications and has been found useful for linking drawing objects to specification sections. It is also used to identify CAD layer organizations.

CONSTRUCTION MARKET DATA

Market data reporting agencies routinely use MasterFormat to list products for a project being bid. This practice allows users to quickly identify sales potential for their products and services on a particular project.

FACILITY MANAGEMENT

Facility managers can identify data associated with products used in the building they manage with MasterFormat numbers. They can be used in filing systems for maintenance and operating instructions, procurement, maintenance work orders, shop drawings, warranties, operating histories, operating costs, and other data related to the life cycle of a facility.

LEVEL TWO NUMBERS AND TITLES

The list of subordinate titles (level two) under each MasterFormat division title (level one) outlines the scope of each division.

INTRODUCTORY INFORMATION

00001 Project Title Page

07500 Membrane Roofing
07600 Flashing and Sheet Metal
07700 Roof Specialties and Accessories
07800 Fire and Smoke Protection
07900 Joint Sealers

DIVISION 8—DOORS AND WINDOWS

08050 Basic Door and Window Materials and Methods
08100 Metal Doors and Frames
08200 Wood and Plastic Doors
08300 Specialty Doors
08400 Entrances and Storefronts
08500 Windows
08600 Skylights
08700 Hardware
08800 Glazing
08900 Glazing Curtain Wall

DIVISION 9—FINISHES

09050 Basic Finish Materials and Methods
09100 Metal Support Assemblies
09200 Plaster and Gypsum Board
09300 Tile
09400 Terrazzo
09500 Ceilings
09600 Flooring
09700 Wall Finishes
09800 Acoustical Treatment
09900 Paints and Coatings

DIVISION 10—SPECIALTIES

10100 Visual Display Boards
10150 Compartments and Cubicles
10200 Louvers and Vents
10240 Grilles and Screens
10250 Service Walls
10260 Wall and Corner Guards
10270 Access Flooring
10290 Pest Control
10300 Fireplaces and Stoves
10340 Manufactured Exterior Specialties
10350 Flagpoles
10400 Identification Devices
10450 Pedestrian Control Devices
10500 Lockers
10520 Fire Protection Specialties
10530 Protective Covers
10550 Postal Specialties
10600 Partitions
10670 Storage Shelving
10700 Exterior Protection
10750 Telephone Specialties
10800 Toilet, Bath, and Laundry Accessories
10880 Scales
10900 Wardrobe and Closet Specialties

DIVISION 11—EQUIPMENT

11010 Maintenance Equipment
11020 Security and Vault Equipment
11030 Teller and Service Equipment
11040 Ecclesiastical Equipment
11050 Library Equipment
11060 Theater and Stage Equipment
11070 Instrumental Equipment
11080 Registration Equipment
11090 Checkroom Equipment
11100 Mercantile Equipment
11110 Commercial Laundry and Dry Cleaning Equipment
11120 Vending Equipment
11130 Audiovisual Equipment
11140 Vehicle Service Equipment
11150 Parking Control Equipment
11160 Loading Dock Equipment
11170 Solid Waste Handling Equipment
11190 Detention Equipment
11200 Water Supply and Treatment Equipment
11280 Hydraulic Gates and Valves
11300 Fluid Waste Treatment and Disposal Equipment
11400 Food Service Equipment
11450 Residential Equipment
11460 Unit Kitchens
11470 Darkroom Equipment
11480 Athletic, Recreational, and Therapeutic Equipment
11500 Industrial and Process Equipment
11600 Laboratory Equipment
11650 Planetarium Equipment

11660 Observatory Equipment
11680 Office Equipment
11700 Medical Equipment
11780 Mortuary Equipment
11850 Navigation Equipment
11870 Agricultural Equipment
11900 Exhibit Equipment

DIVISION 12—FURNISHINGS

12050 Fabrics
12100 Art
12300 Manufactured Casework
12400 Furnishings and Accessories
12500 Furniture
12600 Multiple Seating
12700 Systems Furniture
12800 Interior Plants and Planters
12900 Furnishings Restoration and Repair

DIVISION 13—SPECIAL CONSTRUCTION

13010 Air-Supported Structures
13020 Building Modules
13030 Special Purpose Rooms
13080 Sound, Vibration, and Seismic Control
13090 Radiation Protection
13100 Lightning Protection
13110 Cathodic Protection
13120 Pre-Engineered Structures
13150 Swimming Pools
13160 Aquariums
13165 Aquatic Park Facilities
13170 Tubs and Pools
13175 Ice Rinks
13185 Kennels and Animal Shelters
13190 Site-Constructed Incinerators
13200 Storage Tanks
13220 Filter Underdrains and Media
13230 Digester Covers and Appurtenances
13240 Oxygenation Systems
13260 Sludge Conditioning Systems
13280 Hazardous Material Remediation
13400 Measurement and Control Instrumentation
13500 Recording Instrumentation
13550 Transportation Control Instrumentation
13600 Solar and Wind Energy Equipment
13700 Security Access and Surveillance
13800 Building Automation and Control
13850 Detection and Alarm
13900 Fire Suppression

DIVISION 14—CONVEYING SYSTEMS

14100 Dumbwaiters
14200 Elevators
14300 Escalators and Moving Walks
14400 Lifts
14500 Material Handling
14600 Hoists and Cranes
14700 Turntables
14800 Scaffolding
14900 Transportation

DIVISION 15—MECHANICAL

15050 Basic Mechanical Materials and Methods
15100 Building Services Piping
15200 Process Piping
15300 Fire Protection Piping
15400 Heating Fixtures and Equipment
15500 Humid-Generation Equipment
15600 Refrigeration Equipment
15700 Heating, Ventilating, and Air Conditioning Equipment
15800 Air Distribution
15900 HVAC Instrumentation and Controls
15950 Testing, Adjusting, and Balancing

DIVISION 16—ELECTRICAL

16050 Basic Electrical Materials and Methods
16100 Wiring Methods
16200 Electrical Power
16300 Transmission and Distribution
16400 Low-Voltage Distribution
16500 Lighting
16700 Communications
16800 Sound and Video

The Construction Specifications Institute; Alexandria, Virginia
Construction Specifications Canada

GENERAL

The steps of the Problem Seeking® process cover both qualitative (establish the goals, uncover and test concepts, and state the problem statements) and quantitative (collect and analyze fact and determine needs) information.

The information index is a framework of key words used to seek information. These words are specific enough to cover the scope of major factors and universal enough to

be negotiable for different building types. The index establishes the interrelationship of information regarding goals, facts, concepts, and needs.

The Problem Seeking methodology covers four major categories of information: function refers to people, activities, and relationships; form includes site, quality, and social/psychological environment; economy addresses operating costs and life-cycle costs; and time entails historical aspects, present conditions, and future projections.

PROGRAMMATIC CONCEPTS

The programmatic concepts illustrated here and on the next page refer to abstract ideas intended mainly as functional solutions to clients' performance problems without regard to physical response. These diagrams briefly explain some of the concepts that recur on nearly every project, regardless of building type.

INFORMATION INDEX

FUNCTION	GOALS	FACTS	CONCEPTS	NEEDS	PROBLEM
People Activities Relationships	Mission Maximum number Individual identity Interaction/privacy Hierarchy of values Prime activities Security Progression Segregation Encounters Transportation/parking Efficiency Priority of relationships	Statistical data Area parameters Personnel forecast User characteristics Community characteristics Organizational structure Value of potential loss Time-motion study Traffic analysis Behavioral patterns Space adequacy Type/intensity Physically challenged guidelines	Service grouping People grouping Activity grouping Priority Hierarchy Security controls Sequential flow Separated flow Mixed flow Functional relationships Communications	Area requirements by organization by space type by time by location Parking requirements Outdoor space requirements Functional alternatives	Unique and important performance requirements that will shape building design
FORM					
Site Environment Quality	Bias on site elements Environmental response Efficient land use Community relations Community improvements Physical comfort Life safety Social/psychological environment Individuality Way-finding Projected image Client expectations	Site analysis Soil analysis FAR and GAC Climate analysis Code survey Surroundings Psychological implications Point of reference/entry Cost/sq ft Building or layout efficiency Equipment cost Area per unit	Enhancements Special foundations Density Environmental controls Safety Neighbors Home base/officing concepts On premise: fixed, free, group address Off premise: satellite, telecommuting, virtual office Orientation Accessibility Character Quality control	Site development costs Environmental influences on cost Building cost/sq ft Building overall efficiency factor	Major form considerations that will affect building design
ECONOMY					
Initial budget Operating costs Life-cycle costs	Extent of funds Cost-effectiveness Maximum return Return on investment Minimizing of operating costs Maintenance and operating costs Reduction of life-cycle costs Sustainability	Cost parameters Maximum budget Time-use factors Market analysis Energy source-costs Activities and climate factors Economic data Green building rating system	Cost control Efficient allocation Multifunction/versatility Merchandising Energy conservation Cost reduction Recycling	Budget estimate analysis Balance budget Cash flow analysis Energy budget (if required) Operating costs (if required) Green building rating Life-cycle costs (if required)	Attitude toward the initial budget and its influence on the fabric and geometry of the building
TIME					
Past Present Future	Historic preservation Static/dynamic activities Change Growth Occupancy date Availability of funds	Significance Space parameters Activities Projections Durations Escalation factors	Adaptability Tolerance Convertibility Expansibility Linear/concurrent scheduling Phasing	Escalation Time schedule Time/cost schedule	Implications of change and growth on long-range performance

PRIORITY

The concept of priority evokes questions regarding order of importance, such as relative position, size, and social value.

HIERARCHY

The concept of hierarchy is related to a goal about the exercise of authority and is expressed in symbols of authority.

CHARACTER

The concept of character is based on a goal concerning the image the client wants to project in terms of values and the generic nature of a project.

DENSITY

A goal for efficient use of land or space or for high degrees of interaction may lead to low, medium, or high density.

SERVICE GROUPING

Should services be centralized or decentralized? Each distinct service will be one or the other to implement a specific goal.

ACTIVITY GROUPING

Should activities be integrated or compartmentalized?

Programmatic concepts continue on the next page

Steven A. Parshall, FAIA; HOK Consultants; Houston, Texas

Programmatic concepts continued from the previous page

PEOPLE GROUPING

Look for concepts derived from the physical, social, and emotional characteristics of people—as individuals, in small groups, and in large groups.

HOME BASE

Home base is related to the idea of territoriality—an easily defined place where a person can maintain his or her individuality.

RELATIONSHIPS

The correct interrelation of spaces promotes efficiencies and effectiveness of people and their activities. This concept of functional affinities is the most common programmatic concept.

COMMUNICATIONS

A goal to promote the effective exchange of information or ideas in an organization may call for networks or patterns of communication: Who communicates with whom?

NEIGHBORS

Is there a goal for sociality? Will the project be completely independent or is there a mutual desire to be interdependent, to cooperate with neighbors?

ACCESSIBILITY

Can first-time visitors find where to enter the project? The concept of accessibility also applies to provisions for persons with disabilities beyond signs and symbols. Do we need single or multiple entrances?

SEPARATED FLOW

A goal for segregation may relate to people (such as prisoners and the public), to automobiles (such as campus traffic and urban traffic), or to people and automobiles (such as pedestrian traffic and automobile traffic).

MIXED FLOW

Common social spaces, such as town square or building lobbies, are designed for multidirectional, multipurpose traffic. The concept of mixed flow may be apropos if the goal is to promote chance and planned encounters.

SEQUENTIAL FLOW

The progression of people (as in a museum) and things (as in a factory) must be carefully planned. A flowchart diagram will communicate this concept of sequential flow much more easily than words.

ORIENTATION

Provide a bearing, or point of reference, within a building, a campus, or a city. Relating periodically to a place, thing, or structure can prevent a feeling of being lost.

EXPANSIBILITY CONVERTIBILITY VERSATILITY

EXTERIOR CHANGES

INTERIOR CHANGES

MULTIFUNCTION

FLEXIBILITY

Flexibility covers the following three concepts: expansibility (accommodating growth through expansion), convertibility (allowing for changes in function), and versatility (providing the most for the money through multifunctional spaces).

TOLERANCE

This concept may well add space to the program. Is a particular space tailored precisely for a static activity or is it provided with a loose fit for a dynamic activity—one likely to change?

SAFETY

Which major ideas will implement the goal for life safety? Look to codes and safety precautions for form-giving ideas.

SECURITY CONTROLS

The degree of security control varies depending on the value of the potential loss—minimum, medium, or maximum. These controls are used to protect property and to control personnel movement.

ENERGY CONSERVATION

There are two general approaches to achieving an energy-efficient building: (1) keep the heated area to a minimum by making use of conditioned but nonheated outside space, such as exterior corridors, and (2) keep heat flow to a minimum with insulation, correct orientation to sun and wind, compactness, sun controls, wind controls, and reflective surfaces.

ENVIRONMENTAL CONTROLS

What controls for air temperature, light, and sound will be required to provide for people's comfort inside and outside the building? Look to the climate and sun angle analysis for answers.

PHASING

Will phasing of construction be required to complete a project on a time and cost schedule if the project proved infeasible in the initial analysis? Will the urgency for the occupancy date determine the need for concurrent scheduling or allow for linear scheduling?

COST CONTROL

This concept is intended as a search for economy ideas that will lead to a realistic preview of costs and a balanced budget to meet the extent of available funds.

Steven A. Parshall, FAIA; HOK Consultants; Houston, Texas

INTRODUCTION

The MASTERSPEC® master specification system is a product of the American Institute of Architects and is published by Architectural Computer Services, Inc. (ARCOM). It includes libraries for architectural/structural/civil, structural/civil, mechanical/electrical, interiors construction, interiors FF&E, and landscape architecture and has small project, outline, short form, and full length versions. The MASTERSPEC system is endorsed or recommended by major design and construction documentation organizations in the United States.

MASTERSPEC® specification sections are used to produce project specifications for bidding and construction. These specifications describe materials and products, assemblies, and systems for a construction, as well as requirements for submittals, manufacture, installation, performance, and warranties. Bidding requirements, contract requirements, and project specifications are usually bound together in the project manual.

MASTERSPEC® sections are numbered and titled according to CSI MasterFormat and include all 16 of its divisions. Each section includes a broad range of products and options for each subject area. Users edit each section to tailor it to a specific project. When a firm does repetitive types of projects, MASTERSPEC sections may be edited to produce office masters that contain only those products and materials typically specified by the firm or by a particular client. These office masters are then edited to produce individual project specifications.

MASTERSPEC SECTION DESCRIPTIONS

DIVISION 1

01000—GENERAL REQUIREMENTS—This Section includes the Evaluations only. It contains background information on various subjects, including specification formats and contracting procedures, that apply to all Division 1 Sections.

01013—SUMMARY OF WORK (FF&E)—This Section summarizes the Work of the Furniture, Furnishings, and Equipment (FF&E) contracts and provides information to those who do not have access to the Agreement or bidding information. The Section includes the following:

01023—ALLOWANCES (FF&E)—This Section specifies provisions for lump-sum and unit-price allowances for Furniture, Furnishings, and Equipment (FF&E). It defines allowances, describing what is and is not included, and lists allowance quantities and amounts.

01028—APPLICATIONS FOR PAYMENT (FF&E)—This Section specifies administrative and procedural requirements governing the Furniture, Furnishings, and Equipment (FF&E) Contractor's Applications for Payment. It also contains requirements for preparing and submitting the Schedule of Values.

01033—ALTERNATES (FF&E)—This Section specifies provisions for proposed changes received before the Furniture, Furnishings, and Equipment (FF&E) Contract is awarded. The Section describes add alternates, deduct alternates, and alternates for the purpose of cost comparison.

01038—MODIFICATION PROCEDURES (FF&E)—This Section specifies procedures for changing the Furniture, Furnishings, and Equipment (FF&E) Contract Sum or Schedule.

01043—COORDINATION (FF&E)—This Section specifies coordination with the Work of construction contractors and other Furniture, Furnishings, and Equipment (FF&E) contractors.

01100—SUMMARY—This Section provides a framework in which to summarize the Work of the Project as covered in detail in the Contract Documents. It also provides general information to individuals who need to know general contract provisions.

01125—SUMMARY OF MULTIPLE CONTRACTS—This Section specifies the contractual responsibilities of each contract and the Project Coordinator relating to the Work, coordination, and temporary facilities and controls.

01140—WORK RESTRICTIONS—This Section specifies restrictions on the Contractor's use of the premises and requirements for continued Owner occupancy and Owner occupancy of the Project before Substantial Completion.

01210—ALLOWANCES—This Section specifies provisions for cash allowances, including lump-sum, unit-cost, contingency, and testing and inspecting allowances. It also specifies provisions for quantity allowances.

01230—ALTERNATES—This Section specifies provisions for change of scope and cost-comparison-type alternates. It also includes a sample "Schedule of Alternates" to help the specifier develop the Section.

01250—CONTRACT MODIFICATION PROCEDURES—This Section specifies administrative and procedural requirements for changes to the Contract Sum and the Contract Time, and the Contractor's preparation of Proposal Requests for changes to the Contract.

01270—UNIT PRICES—This Section specifies provisions for unit prices. It includes a sample list of unit prices and a sample unit-price schedule to help the specifier develop the Section.

01290—PAYMENT PROCEDURES—This Section specifies administrative and procedural requirements for the Contractor's Applications for Payment. This Section also contains requirements for preparing and submitting the Schedule of Values.

01303—SUBMITTALS (FF&E)—This Section specifies administrative and procedural requirements for processing Shop Drawings, Product Data, and Samples. The Section includes the following:

01310—PROJECT MANAGEMENT AND COORDINATION—This Section specifies administrative procedures required for Project management and coordination of construction operations and activities, including scheduling and conducting Project meetings.

01320—CONSTRUCTION PROGRESS DOCUMENTATION—This Section specifies administrative and procedural requirements for the Contractor's Construction Schedule, various schedules and reports required for performance of the Work, and construction photographs. It includes both Gantt-chart and critical path method (CPM) schedules.

01322—PHOTOGRAPHIC DOCUMENTATION—This Section specifies requirements for submitting construction photographs and videotapes. The services contained in this Section can vary extensively. For many projects, the few paragraphs in Division 1 Section "Construction Progress Documentation" may eliminate the need for this separate Section.

01330—SUBMITTAL PROCEDURES—This Section specifies Action and Informational Submittals, including Shop Drawings, Product Data, Samples, and other miscellaneous submittals.

01400—QUALITY REQUIREMENTS—This Section specifies general quality-assurance and quality-control requirements. Specific requirements for individual elements of the Work are specified in the appropriate Sections in Divisions 2 through 16. The Section Text is primarily for field tests and inspections of fabricated in-place construction rather than standard product testing.

01403—QUALITY CONTROL (FF&E)—This Section specifies provisions for product or material testing when it is the responsibility of the FF&E Contractor. The Section includes responsibilities for tests, inspections, and sample taking; written test reports; qualification of testing agencies; and repair and protection of the Work exposed to testing and sample taking.

01420—REFERENCES—This Section specifies general definitions for the Specifications and other Contract Documents including the Drawings. Definitions in this Section are not intended to intrude on legal and construction agreement matters; they supplement those definitions contained in AIA Document A201, 1997 edition. Most of the Section Text can be considered basic procedural requirements.

01422—REFERENCE STANDARDS AND DEFINITIONS (FF&E)—This Section specifies general definitions for Specifications and other FF&E Contract Documents including Drawings. Definitions in this Section are not intended to intrude on legal matters; they supplement those definitions contained in AIA Document A271, 1990 edition, and in ASID Document ID320, 1996 edition. Most of the Section Text can be considered basic procedural requirements.

01500—TEMPORARY FACILITIES AND CONTROLS—This Section specifies requirements of a temporary nature, including items not actually incorporated into the Work. It includes temporary utility services, construction and support facilities, and security and protection facilities.

01600—PRODUCT REQUIREMENTS—This Section specifies general requirements for products, materials, and equipment, including their delivery, storage, and handling, and selection of products by the Contractor. This Section also specifies administrative and procedural requirements for handling requests for substitutions made after award of the Contract, and general and procedural requirements for warranties.

01613—DELIVERY, STORAGE, AND HANDLING (FF&E)—This Section specifies requirements for handling goods on the Project Site.

01623—INSTALLATION (FF&E)—This Section specifies general requirements for Divisions 2 through 16 Sections. It includes requirements for examining the installation area, handling goods during installation, and disposing of unused materials.

01633—SUBSTITUTIONS (FF&E)—This Section specifies requirements for substitutions when specified goods are not available. It includes submittals required for proposed substitutions.

01700—EXECUTION REQUIREMENTS—This Section specifies administrative and procedural requirements for: examination of conditions, preparation for construction, construction layout, field engineering and surveying, general installation of products, coordination of Owner-installed products, progress cleaning, starting and adjusting, protection of installed construction, and correction of the Work.

01703—CONTRACT CLOSEOUT (FF&E)—This Section specifies administrative and procedural contract closeout provisions. It is primarily a summary Section; most of the provisions in this Section are the termination of requirements specified in other Sections. Basic contract closeout requirements are in the General and Supplementary Conditions.

01731—CUTTING AND PATCHING—This Section specifies administrative and procedural requirements for cutting and patching. It must be carefully coordinated with other Sections to avoid overlapping or conflicting requirements, such as those contained in Divisions 15 and 16.

01732—SELECTIVE DEMOLITION—This Section specifies the demolition of selected portions of existing buildings, structures, and site improvements, and the removal, salvage, and disposal of demolished materials.

01770—CLOSEOUT PROCEDURES—This Section specifies administrative and procedural contract closeout provisions. Most of the provisions in this Section cover the completion of requirements specified in other Sections. This Section specifies provisions for Project Record Documents, operation and maintenance manuals, and demonstration and training. If these subjects require more detailed treatment, delete them from this Section and use the applicable MASTERSPEC Supplemental Sections.

01781—PROJECT RECORD DOCUMENTS—This Section specifies procedures to be followed when developing Project Record Documents. It should be used when specific Project requirements are more extensive than requirements specified in Division 1 Basic Section "Closeout Procedures." The Section Text deals primarily with Record Drawings because they are the one type of Project Record Document most likely to be expanded beyond requirements in the Basic Section.

01782—OPERATION AND MAINTENANCE DATA—This Section specifies requirements for preparing and submitting emergency, operation, and maintenance manuals.

01820—DEMONSTRATION AND TRAINING—This Section specifies administrative and procedural requirements for instructing Owner's personnel in the operation and maintenance of systems, subsystems, and equipment. It should be used when specific Project requirements are more extensive than requirements specified in Division 1 Basic Section "Closeout Procedures."

DIVISION 2

02060—BUILDING DEMOLITION—This Section specifies the demolition, removal, and disposal of existing buildings, structures, and site improvements; and the removal, salvage, and disposal of demolished materials.

02080—UTILITY MATERIALS—This Section specifies materials and methods for application with utility piping installations outside the building. Piping specialties, joining materials, joint construction, identification materials and devices, and installation requirements common to more than one Division 2 Section are included. This Section supplements other Division 2 Sections; it must be edited and used with other Sections for a complete piping system specification.

02085—INTERCEPTORS—This Section specifies interceptors used with sanitary sewerage and storm drainage systems. These interceptors are located outside the building and include metal and concrete types.

02230—SITE CLEARING—This Section specifies site clearing, including tree and vegetation removal and root grubbing, tree protection, topsoil stripping and stockpiling, capping and removal of site utilities, and removal of minor site improvements.

02231—TREE PROTECTION AND TRIMMING—This Section specifies the protection and trimming of trees that interfere with, or are affected by, temporary or new Work.

02240—DEWATERING—This Section specifies construction dewatering requiring more extensive treatment than that specified in other Division 2 Sections.

MASTERSPEC continues on the next page.

ARCOM: Salt Lake City, Utah, and Alexandria, Virginia

02260—EXCAVATION SUPPORT AND PROTECTION—This Section specifies general procedures and primary requirements for excavation support and protection systems.

02300—EARTHWORK—This Section specifies excavating, filling and backfilling, compacting, and grading inside and outside building limits. This Section also includes base and subbase materials for pavements; granular drainage course under slabs-on-grade; drainage and separation geotextile fabrics; and trench excavation and backfilling for utility and underground services.

02361—TERMITE CONTROL—This Section specifies initial soil treatment by applying chemical termiticides to the soil under and around susceptible structures during construction for preventive control of subterranean termites, and the option of using bait products to supplement soil treatment. According to the EPA-Registered Label, one manufacturer's bait product may be specified without also specifying soil treatment, if permitted by authorities having jurisdiction.

02455—DRIVEN PILES—This Section specifies Evaluations only for the following Sections covering types of driven piles:

02456—CONCRETE-FILLED STEEL PILES—This Section specifies concrete-filled steel shell and steel pipe piles.

02457—PRESTRESSED CONCRETE PILES—This Section specifies prestressed, precast concrete driven piles.

02458—STEEL H PILES—This Section specifies steel H-section piles and protective coatings.

02459—TIMBER PILES—This Section specifies preservative-treated round timber piles.

02466—DRILLED PIERS—This Section specifies drilled piers with straight or belled shafts and includes excavation, casings, slurries, reinforcement, concrete fill, and testing and inspecting.

02510—WATER DISTRIBUTION—This Section specifies water piping and specialties for potable-water service and fire-protection water service outside the building. This Section is not intended for municipal distribution systems.

02511—HOT-MIX ASPHALT PAVING—This Section specifies hot-mix asphalt paving for new and existing pavements and emulsified-asphalt surface treatments.

02525—WATER SUPPLY WELLS—This Section specifies cable-tool, rotary drilled, reverse-rotary drilled, and driven water wells with jet, line-shaft turbine, and submersible turbine well pumps and accessories.

02530—SANITARY SEWERAGE—This Section specifies sanitary sewerage outside the building.

02535—PROCESS MATERIAL SEWERAGE—This Section specifies process material sewerage outside the building and includes chemical-waste drainage piping, structures, and neutralization tanks; double-contained piping and structures; and chemical-waste force mains.

02540—SEPTIC TANK SYSTEMS—This Section specifies a sewage disposal system for use where a public sanitary sewerage system is not available.

02551—HYDRONIC DISTRIBUTION—This Section specifies piping for hydronic distribution systems outside the building. Piping includes pipes, fittings, valves, insulation, and specialties for the following:

02553—NATURAL GAS DISTRIBUTION—This Section specifies natural gas distribution piping and specialties outside the building to the point of delivery. The point of delivery is the service-meter assembly outlet. This may be only the service-regulator or service-shutoff valve if there is no meter.

02554—FUEL-OIL DISTRIBUTION—This Section specifies fuel distribution piping and specialties and fuel-oil storage tanks and accessories outside the building. Equipment in this Section is suitable for use with Grades No. 1 or No. 2 fuel oil.

02555—STEAM DISTRIBUTION—This Section specifies piping for low-pressure steam and condensate distribution systems outside the building. Piping includes pipes, fittings, valves, insulation, and specialties for the following:

02584—UNDERGROUND DUCTS AND UTILITY STRUCTURES—This Section specifies products used in underground electrical distribution for power and communications, including ducts, duct banks, handholes, and utility structures such as vaults and manholes.

02630—STORM DRAINAGE—This Section specifies gravity-flow and force-main storm drainage outside the building.

02666—POND AND RESERVOIR LINERS—This Section specifies impervious, flexible-membrane pond and reservoir liners for use with neutral aqueous solutions. Consult membrane manufacturers for proper membrane selection if required for lining or covering complex liquid toxic-waste holding ponds.

02711—FOUNDATION DRAINAGE SYSTEMS—This Section specifies foundation and underslab, subsoil drainage systems. It also includes in-plane wall drainage materials that work separately or in conjunction with other foundation drainage products.

02751—CEMENT CONCRETE PAVEMENT—This Section specifies cast-in-place concrete pavement construction including related formwork, reinforcement, concrete mix proportions, placement, and finishes.

02764—PAVEMENT JOINT SEALANTS—This Section specifies joint sealants, including backer materials, for concrete-to-concrete and concrete-to-asphalt pavement joints.

02768—STAMPED CEMENT CONCRETE PAVEMENT—This Section specifies cement concrete pavement, either integrally or surface colored, receiving a surface-imprinted stamped finish.

02780—UNIT PAVERS—This Section specifies paving for exterior applications using brick, concrete, rough-stone, and asphalt-block pavers installed by several methods. Installation methods include ungrouted, mortarless applications; portland cement mortar setting-bed methods; and bituminous setting-bed applications.

02791—PLAYGROUND SURFACE SYSTEMS—This Section specifies both loose fill and non-loose fill, impact-attenuating protective surfacing systems for outdoor use at ground-level locations, made from natural organic or inorganic materials or synthetic rubber-based formulations, and designed for use under and around public playground equipment. Surface systems that have and have not been determined to be accessible according to ASTM PS 83, *Specification for Determination of Accessibility of Surface Systems under and around Playground Equipment*, are specified.

02813—LAWN SPRINKLER PIPING—This Section specifies piping and valves, sprinklers and irrigation specialties, and controls and wiring for lawn sprinkler piping. Components in this Section will be downstream from the water distribution piping, valves, backflow preventers, and water meters specified in Division 2 Section "Water Distribution."

02821—CHAIN-LINK FENCES AND GATES—This Section specifies chain-link fence fabric, framing, fittings, swing and slide gates, privacy slats, gate operators, and access control for residential, commercial, and industrial applications according to ASTM standards and the Chain Link Fence Manufacturers Institute's (CLFMI) *Product Manual*. Residential fence and gate heights are limited to 6 feet (1.8 m) with fence line posts at a maximum spacing of 10 feet (3 m) o.c. Industrial fence and gate heights are limited to 12 feet (3.66 m) and less with fence line posts at a maximum spacing of 10 feet (3 m) o.c. Galvanized-coated, Zn-5-AL-MN alloy-coated (Zinc-5 percent aluminum-mischmetal alloy), aluminum-coated, and PVC-coated steel and aluminum-alloy fencing are included.

02832—SEGMENTAL RETAINING WALLS—This Section specifies freestanding retaining walls built from dry-laid concrete masonry units designed specifically for constructing segmental retaining walls. This Section includes both earth-reinforced retaining walls and gravity retaining walls. Alternate provisions are included to leave selection of the particular retaining wall unit design up to the Contractor, within some general appearance parameters, and to require that the Contractor provide structural design for the walls based on the units selected.

02881—PLAYGROUND EQUIPMENT AND STRUCTURES—This Section specifies public playground equipment suitable for children 2 through 12 years old and located in play areas at child-care facilities, institutions, multiple-family dwelling sites, parks, schools, recreational facilities, restaurants, and similar public areas.

02900—LANDSCAPING—This Section specifies trees, shrubs, ground covers, plants, and lawns. The Section includes preparation of planting pits and beds, topsoil, soil amendments, fertilizers, and mulches.

02930—LAWNS AND GRASSES—This Section specifies planting materials, including topsoil, soil amendments, and fertilizers for new seeded, sodded, sprigged, and plugged lawns and grassed areas. This Section also includes provisions for hydroseeding and reconditioning existing lawns.

02955—TREES AND SHRUBS—This Section specifies trees and shrubs and includes preparation of planting pits and beds, topsoil, soil amendments, fertilizers, and mulches.

02956—GROUND COVER AND PLANTS—This Section specifies ground covers and plants and includes preparation of planting beds, topsoil, soil amendments, fertilizers, and mulches.

DIVISION 3

03300—CAST-IN-PLACE CONCRETE—This Section specifies cast-in-place, normal-weight and lightweight concrete for general building construction including related formwork, reinforcement, concrete materials and admixtures, vapor retarders, concrete mix requirements, placement, as-cast and applied finishes, curing, repairs, and field quality control.

03301—CAST-IN-PLACE CONCRETE (LIMITED APPLICATIONS)—This Section specifies cast-in-place concrete for projects using small quantities of concrete or noncritical applications of concrete. It is for simple projects where the Architect edits the Section Text with minimal or no direction from the structural engineer. The Section Text permits the setting of minimum quality standards for the Project by referencing ACI 301, *Specification for Structural Concrete*. For projects requiring detailed specifications and significant control of cast-in-place concrete, use Division 3 Section "Cast-in-Place Concrete."

03331—CAST-IN-PLACE ARCHITECTURAL CONCRETE—This Section specifies cast-in-place, formed, architectural concrete that requires special concrete materials, formwork, placement, and finishes.

03361—SHOTCRETE—This Section specifies requirements for pneumatically applied shotcrete work that may be used for repairing existing concrete structures or for new construction. Materials, mixes, and application procedures for both the wet- and dry-mix processes are included.

03410—PLANT-PRECAST STRUCTURAL CONCRETE—This Section specifies plant-precast, conventionally reinforced and prestressed, structural concrete units.

03450—PLANT-PRECAST ARCHITECTURAL CONCRETE—This Section specifies plant-precast, conventionally reinforced, architectural concrete units with conventional finishes, thin brick facings, or stone facings. Prestensioned or posttensioned, precast, prestressed concrete units and noncomposite insulated, precast concrete units are also included.

03470—TILT-UP PRECAST CONCRETE—This Section specifies tilt-up concrete wall panels that are site precast and finished, and tilted into place on-site. This Section specifies related formwork, reinforcement, concrete materials and admixtures, concrete mix requirements, placement, as-cast and applied finishes, bondbreakers, curing, repairs, and field quality control.

03490—GLASS-FIBER-REINFORCED PRECAST CONCRETE—This Section specifies plant-manufactured, glass-fiber-reinforced precast concrete units stiffened and supported by plant-attached framing panels produced from cold-formed steel studs or rolled carbon-steel structural shapes used primarily to clad building exteriors.

03511—CEMENTITIOUS WOOD-FIBER DECK—This Section specifies cementitious wood-fiber deck consisting of units composed of long strands of wood fibers combined with either portland cement or magnesium-oxysulfate hydraulic cement, and bonded under pressure. Monolithic, composite, and insulated composite tile or plank units are used to construct roof decks or form decks.

03520—LIGHTWEIGHT CONCRETE ROOF INSULATION—This Section specifies lightweight concrete roof insulation, with an oven-dry unit weight not exceeding 50 lb/cu. ft. (800 kg/cu. m), primarily used as fill over metal roof deck or structural concrete substrates.

03532—CONCRETE FLOOR TOPPING—This Section specifies factory-packaged, high-strength, iron-aggregate and emery-aggregate cementitious concrete floor toppings.

03542—CEMENT-BASED UNDERLAYMENT—This Section specifies cement-based, polymer-modified, self-leveling underlayment for application below interior finish flooring.

03930—CONCRETE REHABILITATION—This Section specifies concrete patching and repair including the removal of deteriorated concrete and reinforcement. Patching materials specified include job-mixed patching mortar, packaged-cementitious and polymer-modified patching mortars, cast-in-place concrete, and preplaced aggregate concrete. This Section also specifies floor joint repair, epoxy crack injection, corrosion-inhibiting treatments, polymer overlays and sealers, and structural reinforcement with both steel and composites.

MASTERSPEC continues on the next page.

DIVISION 4

04410—STONE MASONRY VENEER—This Section specifies stone laid in mortar and applied either to concrete or masonry back-up or to frame construction. It includes stone installed in rubble, ashlar, and polygonal or mosaic patterns made from cut stone, split stone, or rough stone as extracted from the quarry or as collected from stream banks and similar deposits. It includes veneers mechanically attached to the back-up by anchors or ties built into the mortar joints and veneers adhered with mortar similar to the setting method used for ceramic wall tile. The Section is written primarily for exterior veneers for buildings and for concrete retaining walls, but could easily be modified to include interior facings of stone masonry.

04720—CAST STONE—This Section specifies cast stone building units used as architectural features, facing, trim, or site accessories. Cast stone is defined as architectural pre-cast concrete building units intended to simulate natural cut stone.

04810—UNIT MASONRY ASSEMBLIES—This Section specifies clay and concrete masonry for engineered and empirically designed applications.

04815—GLASS UNIT MASONRY ASSEMBLIES—This Section specifies glass unit masonry assemblies for wall, window, skylight, and floor applications. It includes exterior and interior applications and three installation methods. One method requires edges of glass-block assemblies to be retained by perimeter channel frames or chases. A second method allows edges of assemblies to be separated from perimeter construction but anchored to it by perforated metal strips (called *panel anchors*) embedded in horizontal mortar joints of glass-block assemblies and fastened to perimeter construction at ends. A third method uses a metal grid into which the glass block is inserted and adhesively secured with a silicone sealant.

04851—DIMENSION STONE CLADDING—This Section specifies dimension stone, set with mortar or sealant joints, for exterior cladding of buildings. Dimension stone cladding may be specified as field set, with or without mortar, and with individual anchors or a grid-type anchoring system. It may also be specified in the form of prefabricated assemblies. Dimension stone cladding systems may be specified to be engineered by the Installer to comply with performance criteria or may be fully designed and detailed.

04901—CLAY MASONRY RESTORATION AND CLEANING—This Section specifies requirements for quality masonry restoration. Some requirements are suitable for historic restoration projects, and some are more suited for ordinary rehabilitation and cleaning of nonhistoric structures. Because masonry restoration work can involve an assortment of materials and conditions, it is difficult to develop a master section that includes restoration and cleaning procedures other than those that are typical. The intent is to provide guidelines and information that can be adapted to fit individual cases.

04902—STONE RESTORATION AND CLEANING—This Section specifies requirements for quality stone restoration. Some requirements are suitable for historic restoration projects, and some for ordinary rehabilitation and cleaning of nonhistoric structures. Because stone restoration work can involve an assortment of materials and conditions, it is difficult to develop a master section that includes restoration and cleaning procedures other than those that are typical. The intent is to provide guidelines and information that can be adapted to fit individual cases.

DIVISION 5

05120—STRUCTURAL STEEL—This Section specifies fabricating and erecting structural steel for building construction, including miscellaneous subframing units that may be part of the general framing system. Also included are extensive options for surface preparation and shop prime painting.

05210—STEEL JOISTS—This Section specifies open-web K-series steel joists, LH-series long-span steel joists, DLH-series deep long-span steel joists, and steel joist girders as defined by the Steel Joist Institute.

05310—STEEL DECK—This Section specifies steel roof and floor deck classified as roof deck, acoustical roof deck, cellular roof deck, composite floor deck, cellular metal floor deck with electrical distribution, noncomposite form deck, and noncomposite vented form deck.

05400—COLD-FORMED METAL FRAMING—This Section specifies cold-formed steel, load-bearing, and curtain-wall studs; floor and roof joists; rafters and ceiling joists; and roof trusses. This Section also includes gypsum sheathing and air-infiltration barriers.

05500—METAL FABRICATIONS—This Section specifies representative products made from steel and iron, including shapes, plates, bars, sheet, tubes, and pipe. It also includes selected fabrications made from aluminum, bronze, and

stainless steel, including nosings and tread plate. The Section includes miscellaneous steel framing for supporting overhead doors, ceiling hung toilet compartments, operable partitions, wood framing, countertops, and various equipment.

05511—METAL STAIRS—This Section specifies straight-run, steel-framed stairs with metal-pan, abrasive-coating-finished formed-metal, metal plate, and steel bar grating treads. It includes preassembled metal stairs for commercial applications, industrial stairs, and steel-framed ornamental stairs. It also includes steel tube railings for preassembled metal stairs.

05521—PIPE AND TUBE RAILINGS—This Section specifies pipe and tube handrails and railings fabricated from steel, aluminum, and stainless steel. While this Section specifies primarily functional, rather than ornamental, railings, it could also be used to specify ornamental railings made from pipe and tube shapes.

05530—GRATINGS—This Section specifies metal bar gratings, expanded metal gratings, formed-metal plank gratings, and extruded-aluminum plank gratings.

05580—FORMED-METAL FABRICATIONS—This Section specifies miscellaneous items that are shop fabricated from ferrous- and nonferrous-metal sheet to custom designs and that are not specified in other Sections. Products that could be included are sheet metal fabrications that 1) are brake formed to a custom or semicustom design; 2) are exposed to view where appearance is the primary concern; and 3) are not normally furnished as part of other work, such as window trim made by the window manufacturer. This Section includes only a limited number of examples of items satisfying the above criteria; other examples include mullion covers, miscellaneous boxes, counters, cabinets, and shelves.

05700—ORNAMENTAL METAL—This Section specifies products custom fabricated from various metals and used in building construction for functional, architectural, and decorative purposes where appearance is the primary concern. Ornamental metal includes both items made entirely from custom-fabricated components and those made entirely or partially from standard manufactured products that require some custom fabrication, finishing, and assembly. The emphasis in this Section is on custom metal that is fabricated, finished, and installed to exacting standards requiring high-quality materials and skillful workmanship. Where products meet these criteria and are not part of other assemblies and systems, such as window walls, doors and entrances, hardware, or prefabricated specialty items, they belong in this Section.

05715—FABRICATED SPIRAL STAIRS—This Section specifies metal spiral stairs with steel pipe or tube central supporting columns and radiating treads produced as standard manufactured products.

05720—ORNAMENTAL HANDRAILS AND RAILINGS—This Section specifies ornamental handrails and railings fabricated from aluminum, copper alloys, stainless steel, and steel and iron. It also includes glass- and plastic-supported railings, and illuminated railings. This Section covers railings assembled from standard shapes rather than those constructed from custom shapes. Ornamental railings made from custom shapes are specified in Division 5 Section "Ornamental Metalwork."

05811—ARCHITECTURAL JOINT SYSTEMS—This Section specifies exterior and interior building joint systems, with and without fire barriers, that accommodate movement resulting from one or more causes such as thermal changes, seismic forces, or wind sway.

DIVISION 6

06100—ROUGH CARPENTRY—This Section specifies conventional wood framing for floors, ceilings, roofs, walls, and partitions as well as sheathing, subflooring, and underlayment. Also included is incidental rough carpentry required for support or attachment of other construction and not specified in another Section. Exposed items of rough carpentry included in this Section are limited, generally, to structural framing members. Timbers incidental to wood frame construction are included as well as engineered wood products.

06105—MISCELLANEOUS CARPENTRY—This Section specifies miscellaneous wood framing, incidental rough carpentry required for support or attachment of other construction, structural-use panels, underlayment, minor interior wood trim, shelving, and clothes rods. It is intended for projects that do not require wood framing or extensive use of other carpentry items. The Section includes pressure-preservative-treated and fire-retardant-treated wood. Miscellaneous concealed rough carpentry such as furring, blocking, grounds, and nailers can be specified using this Section. If the Project requires significant amounts of wood framing, sheathing, or subflooring, use 06100—ROUGH CARPENTRY instead.

06130—HEAVY TIMBER CONSTRUCTION—This Section specifies construction using rectangular solid-wood framing members 5 inches nominal (114 mm actual) and larger in both dimensions (timbers).

06150—WOOD DECKING—This Section specifies tongue-and-groove wood decking, both solid and laminated.

06185—STRUCTURAL GLUED-LAMINATED TIMBER—This Section specifies structural glued-laminated units including beams, purlins, arches, trusses, and columns.

06192—METAL-PLATE-CONNECTED WOOD TRUSSES—This Section specifies wood trusses factory fabricated from dimension lumber and metal connector plates.

06200—FINISH CARPENTRY—This Section specifies non-structural carpentry work that is exposed to view and is not specified in other Sections. Included are standing and running trim, stairs and railings, exterior siding, and interior paneling. Siding includes lumber, plywood, and hardboard siding. Paneling includes plywood, hardboard, and board paneling. Standard manufactured paneling is specified in this Section, while custom wood paneling is specified in

- 06402—INTERIOR ARCHITECTURAL WOODWORK and
- 06420—PANELWORK. In general, use this Section for work that is not shop fabricated and for siding and paneling types that are included only in this Section.

06401—EXTERIOR ARCHITECTURAL WOODWORK—This Section specifies fabricated wood products for use on the exterior of the building. Architectural woodwork is distinguished from other forms of wood construction by being manufactured in a woodworking plant and by complying with standards of quality for material and workmanship. It includes items of woodwork permanently attached to the building and exposed to view. Architectural woodwork generally involves items custom fabricated for an individual project, as opposed to mass-produced moldings or furniture. If required, woodwork can be specified to be shop finished rather than field finished.

06402—INTERIOR ARCHITECTURAL WOODWORK—This Section specifies fabricated wood products for use on the interior of the building. Architectural woodwork is distinguished from other forms of wood construction by being manufactured in a woodworking plant and by complying with standards of quality for material and workmanship. It includes items of woodwork permanently attached to the building and exposed to view. Architectural woodwork generally involves items custom fabricated for an individual project, as opposed to mass-produced moldings or furniture. Woodwork can be specified to be shop or field finished.

06420—PANELING—This Section specifies custom-manufactured paneling. Board paneling, flush wood paneling, laminate-clad paneling, and stile and rail paneling are included. Paneling fabricated from premanufactured sets of sequence-matched panels and custom-veneered paneling are included.

06605—INTERIOR PLASTIC ORNAMENTATION—This Section specifies molded- or extruded-plastic ornamentation for interior use, made of polystyrene, polyurethane, or fiberglass-reinforced polyester (FRP), including columns, moldings, chair rails, panel moldings, medallions, rosettes, domes, dome rims, stair brackets, niches, pilasters, pediments, window and door casings, plinths, wainscots, and custom shapes.

DIVISION 7

07131—SELF-ADHERING SHEET WATERPROOFING—This Section specifies self-adhering, positive-side sheet waterproofing for concealed substrates, both vertical and horizontal, of plaza decks, below-grade walls, and planters. It also specifies plaza deck pavers.

07132—ELASTOMERIC SHEET WATERPROOFING—This Section specifies EPDM or butyl sheet waterproofing for concealed substrates, both vertical and horizontal, of plaza decks, below-grade walls, and planters. It also specifies plaza deck pavers.

07133—THERMOPLASTIC SHEET WATERPROOFING—This Section specifies PVC positive-side waterproofing for concealed substrates, both horizontal and vertical, of plaza decks, below-grade walls, and planters. It also specifies plaza deck pavers.

07141—COLD FLUID-APPLIED WATERPROOFING—This Section specifies cold fluid-applied polyurethane and latex-rubber waterproofing for concealed substrates, both vertical and horizontal, of plaza decks and below-grade walls. It also specifies plaza deck pavers.

MASTERSPEC continues on the next page.

ARCOM; Salt Lake City, Utah, and Alexandria, Virginia

1

CONSTRUCTION INFORMATION SYSTEMS

07142—HOT FLUID-APPLIED WATERPROOFING—This Section specifies hot fluid-applied, rubberized-asphalt waterproofing for concealed substrates, both vertical and horizontal, of plaza decks and below-grade walls. It also specifies plaza deck pavers.

07160—BITUMINOUS DAMPPROOFING—This Section specifies bituminous dampproofing for use above and below grade, including hot-applied asphalt and both emulsion- and cut-back- (solvent) type, cold-applied asphalt compounds of fibrated, semifibrated, or nonfibrated types.

07161—MODIFIED CEMENT WATERPROOFING—This Section specifies acrylic- and polymer-modified, cement-based waterproofing. It is usually applied on exterior, below-grade concrete and masonry walls, but may be applied on the interior of exterior walls and floors.

07162—CRYSTALLINE WATERPROOFING—This Section specifies cementitious waterproofing treatment with crystalline-type waterproofing. It is frequently applied on interior, below-grade concrete and masonry walls; may be applied on slabs below grade; and may be concealed behind or below applied finishes specified in other Sections. This product can also be used for waterproofing the exterior of walls below grade.

07163—METAL-OXIDE WATERPROOFING—This Section specifies metal-oxide waterproofing, which is an oxidizing iron and cement mixture. It is usually applied on interior surfaces of walls and slabs below grade, and may be concealed behind or below applied finishes specified in other Sections. This product can also be used for waterproofing the exterior of walls below grade.

07170—BENTONITE WATERPROOFING—This Section specifies panel and sheet membrane bentonite waterproofing systems used underground for types of construction where room to excavate beyond the walls is limited, where the walls are to be constructed against piling, or where the excavation must be backfilled over or against concrete before the concrete has had time to cure (such as a tunnel under a street).

07180—TRAFFIC COATINGS—This Section specifies cold liquid-applied, elastomeric, waterproof-barrier coatings with integral wearing surfaces for building areas housing equipment or subject to pedestrian and vehicular traffic.

07190—WATER REPELLENTS—This Section specifies clear, liquid-applied, penetrating, and film-forming water repellents for vertical and nontrafficked horizontal surfaces of brick, concrete unit masonry, concrete, portland cement plaster (stucco), and stone.

07210—BUILDING INSULATION—This Section specifies common types of general building insulation that are installed at the Project site as separate elements rather than as components of a prefabricated or field-assembled system specified in another Section. Exterior insulation and finish systems are examples of such assemblies. Also included is insulation that could be specified here or in other Sections. Examples of this include insulation used for masonry, gypsum board assemblies, and veneer plaster that are typically installed at the same time and by the same personnel performing noninsulation work.

07241—EXTERIOR INSULATION AND FINISH SYSTEMS—CLASS PB—This Section specifies Class PB exterior insulation and finish systems (EIFS) consisting of a decorative protective composite coating, or lamina, and an inner layer of rigid, cellular thermal insulation. Both field-applied systems and prefabricated panels are specified. Systems with molded, expanded polystyrene board (Type I) and glass-fiber-faced polyisocyanurate insulation are included. Exterior cement-board sheathing is included for both standard applications and prefabricated panels. Other types of sheathing and metal framing for prefabricated panels are included by reference to other Sections specifying those materials. An option is included for specifying joint sealants in Division 7 Section "Joint Sealants" or in this Section with reference to the "Joint Sealants" Section.

07242—EXTERIOR INSULATION AND FINISH SYSTEMS—CLASS PM—This Section specifies Class PM exterior insulation and finish systems (EIFS) consisting of a decorative protective composite coating, or lamina, and an inner layer of rigid, cellular thermal insulation. Only field-applied systems applied with extruded-polystyrene foam insulation (Type IV) are specified.

07311—ASPHALT SHINGLES—This Section specifies asphalt shingles for roofing applications. Shingles with fiber mats (fabric core) of either organic felt or fiberglass are included. A variety of generic shingles are specified in the Text, and other types can easily be added. This Section applies to roofs with a slope from 2 inches per foot (1:6) to very steep slopes, such as mansard roofs, when manufacturers' recommendations are considered.

07313—METAL SHINGLES—This Section specifies metal shingles, in both individual shingles and panel form. In most cases, shingle panels resemble hand-split cedar shakes.

07315—SLATE SHINGLES—This Section specifies natural-slate shingles for steep, sloped, standard-slate roofs including underlayment, flashing, and accessories for slate roofing.

07317—WOOD SHINGLES AND SHAKES—This Section specifies wood shingles and shakes for both roofing and wall applications. Western red cedar shingles and shakes, southern yellow pine shakes, western red cedar shingle panels, and fancy-but western red cedar shingles are included.

07320—ROOF TILES—This Section specifies both hand-fired clay tile and concrete tile for roofing applications. A variety of shaped and flat tile units, including Spanish "S," Mission Barrel, Roman, French, and flat units, are included. Provisions for commonly used special shapes at eaves, rakes, ridges, and hips are also included, as well as underlayments, fasteners, and other accessories normally used with roof tiles.

07411—MANUFACTURED ROOF PANELS—This Section specifies factory-preformed metal roof panels for field installation without field forming. The Section includes panels of aluminum- and metallic-coated steel with and without applied finishes; and copper, stainless steel, and terne-coated stainless steel, which do not have applied finishes. Insulated roof panels and metal panel assemblies that are substantially preformed but require final mechanical seam closure in the field by means of a portable seaming machine are also included.

07412—MANUFACTURED WALL PANELS—This Section specifies factory-preformed metal wall panels for field installation without field forming. The Section includes panels of uncoated stainless steel and of aluminum- and metallic-coated steel with and without applied finishes. Insulated wall panels, both factory and field assembled, are also included.

07460—SIDING—This Section specifies vinyl, aluminum, and steel siding including commonly used accessories.

07511—BUILT-UP ASPHALT ROOFING—This Section specifies built-up asphalt roofing, including roofing insulation, base flashings, aggregate and paver ballast for protected membranes, roof walkways, and auxiliary roofing materials.

07512—BUILT-UP COAL-TAR ROOFING—This Section specifies built-up coal-tar roofing, including roofing insulation, base flashings, aggregate and paver ballast for protected membranes, roof walkways, and auxiliary roofing materials.

07531—EPDM SINGLE-PLY MEMBRANE ROOFING—This Section specifies EPDM single-ply membrane roofing, including roof insulation, base flashings, aggregate and paver ballast, walkways, and auxiliary roofing materials.

07532—CSPE SINGLE-PLY MEMBRANE ROOFING—This Section specifies CSPE single-ply membrane roofing, including roof insulation, base flashings, aggregate and paver ballast, walkways, and auxiliary roofing materials.

07533—THERMOPLASTIC SINGLE-PLY MEMBRANE ROOFING—This Section specifies thermoplastic single-ply membrane roofing, including roof insulation, base flashings, aggregate and paver ballast, walkways, and auxiliary roofing materials.

07546—COATED POLYURETHANE FOAM ROOFING—This Section specifies sprayed polyurethane foam insulation with an elastomeric protective coating for roofing applications.

07551—APP-MODIFIED BITUMINOUS MEMBRANE ROOFING—This Section specifies APP-modified bituminous membrane roofing, including roofing insulation, base flashings, aggregate and paver ballast for protected membranes, and auxiliary roofing materials.

07552—SBS-MODIFIED BITUMINOUS MEMBRANE ROOFING—This Section specifies SBS-modified bituminous membrane roofing, including roofing insulation, base flashings, aggregate and paver ballast for protected membranes, roof walkways, and auxiliary roofing materials.

07553—SELF-ADHERING MODIFIED BITUMINOUS MEMBRANE ROOFING—This Section specifies self-adhering, cold-applied, rubberized-asphalt composite sheet roofing for protected roof membrane applications. Roof insulation, mortar-faced roof insulation, aggregate ballast, and paver ballast are also included.

07561—HOT FLUID-APPLIED ROOFING—This Section specifies hot fluid-applied, rubberized-asphalt roofing for protected roof membrane applications. Roof insulation, mortar-faced roof insulation, aggregate ballast, and paver ballast are also included.

07610—SHEET METAL ROOFING—This Section specifies custom-fabricated (shop- or field-formed versus factory-roll-formed) metal roofing. This Section also includes prefinished, field-painted, and uncoated metal roofing.

07620—SHEET METAL FLASHING AND TRIM—This Section specifies sheet metal flashing and trim work related to or used in conjunction with roofing work and the general waterproof integrity of the building structure. This Section includes shop- and field-fabricated sheet metal accessories, trim, and flashing commonly used at the perimeter or penetrations of roofing or waterproofing work and where not integral with membrane systems. Metal waterproofing, flashing, and cap flashing are usually included in this Section.

07710—MANUFACTURED ROOF SPECIALTIES—This Section specifies manufactured roof specialties including copings, fasciae, gravel stops, gutters and downspouts, reglets, and counterflashing. This Section covers roof specialties listed in the 1995 edition of CSI's *MasterFormat*, except roof expansion assemblies.

07716—ROOF EXPANSION ASSEMBLIES—This Section specifies standard, factory-fabricated, roof expansion joint cover assemblies, including products designed to resist the effects of earthquake motions. This Section can be used alone, or provisions can be included in other Division 7 Sections.

07720—ROOF ACCESSORIES—This Section specifies accessory units installed on or in roofing, including curbs and equipment supports, relief vents in the form of gravity ventilators, ridge vents, roof hatches (also called *scuttles*), heat and smoke vents of both collapsible dome (gravity) type and pop-up (hatch) type, and snow guards.

07810—PLASTIC UNIT SKYLIGHTS—This Section specifies prefabricated skylights with formed, monolithic, single- and double-sheet plastic glazing, and integral curb or curb-mounted frame design.

07811—SPRAYED FIRE-RESISTIVE MATERIALS—This Section specifies sprayed fire-resistive materials for protecting structural steel for both concealed and exposed applications. It includes not only low-density cementitious and sprayed-fiber products used predominantly for concealed locations but also a variety of medium- and high-density products for exposed locations requiring a more finished appearance and greater resistance to physical abuse, deterioration from weather, air erosion, and high humidity.

07821—BOARD FIRE PROTECTION—This Section specifies calcium silicate and slag-wool-fiber boards used for fire protection of steel columns, steel beams, metal- and wood-framed walls, and solid walls. These materials form the encasing material for various assemblies with fire-resistance ratings. Another use for mineral-fiber board fireproofing is protection of HVAC ducts.

07841—THROUGH-PENETRATION FIRESTOP SYSTEMS—This Section specifies through-penetration firestop systems.

07920—JOINT SEALANTS—This Section specifies joint sealants including elastomeric sealants, solvent-releasing sealants, latex sealants, acoustical sealants, and preformed sealants for a variety of applications.

DIVISION 8

08110—STEEL DOORS AND FRAMES—This Section specifies standard steel doors and frames fabricated to comply with ANSI A250.8 and established Steel Door Institute standards.

08114—CUSTOM STEEL DOORS AND FRAMES—This Section specifies commercial hollow-metal doors and frames custom fabricated from steel, galvanized steel, and stainless-steel sheet to specific design requirements. This Section includes provisions for glazing, louvers, sidelights, and transoms of similar construction. Provisions are also included for fire-, sound-, and thermal-rated assemblies.

08125—INTERIOR ALUMINUM FRAMES—This Section specifies extruded-aluminum framing members for interior (usually) wood doors; glass sidelights, borrowed lights, clerestory glazing, and fixed windows; and gypsum wall-board partitions.

08163—SLIDING ALUMINUM-FRAMED GLASS DOORS—This Section specifies sliding aluminum-framed glass doors for exterior locations.

08211—FLUSH WOOD DOORS—This Section specifies non-fire-rated and fire-rated architectural flush wood doors. Both solid- and hollow-core units are covered, including those with face panels of wood veneer, plastic laminate, and hardboard.

MASTERSPEC continues on the next page

08212—STILE AND RAIL WOOD DOORS—This Section specifies stile and rail doors made from lumber, wood veneers, and wood composites including plywood, particleboard, fiberboard, and laminated-strand lumber. Doors of special design and construction, which may include custom-made doors, are specified along with doors of stock design and construction. Fire-rated doors with wood-veneered and -edged mineral-core stiles, rails, and panels are also included.

08263—SLIDING WOOD-FRAMED GLASS DOORS—This Section specifies sliding glass doors, bare- and primed-wood framed, and wood framed and clad with aluminum or vinyl on exterior exposed surfaces, for exterior locations.

08305—ACCESS DOORS—This Section specifies prime-painted steel, zinc-coated steel, and stainless-steel access doors installed in acoustical ceilings and masonry, concrete, gypsum board assemblies, and plaster walls and ceilings.

08314—SLIDING METAL FIRE DOORS—This Section specifies sliding metal fire doors of composite and hollow-metal construction. These doors are primarily intended for fire separation doors in industrial and commercial applications.

08321—INSULATING SECURITY DOORS—This Section specifies standard insulating security door assemblies, manufactured as a unit, complete with door, frame and hardware. Although intended primarily for fire and theft protection of documents in file rooms, they are also used for vault protection of other valuables.

08331—OVERHEAD COILING DOORS—This Section specifies flexible metal-curtain-type overhead coiling (rolling) service doors and counter doors, including fire-rated assemblies. Overhead coiling doors are fabricated from steel, stainless steel, and aluminum. Fire-rated doors are fabricated from steel and stainless steel.

08334—OVERHEAD COILING GRILLES—This Section specifies galvanized steel, stainless-steel, and aluminum overhead coiling (rolling) grilles with straight in-line pattern and with the option of glazed panels.

08343—ICU/CCU ENTRANCE DOORS—This Section specifies combination swing/slide manual ICU/CCU entrance door assemblies.

08346—SOUND CONTROL DOORS—This Section specifies non-fire-rated and fire-rated swinging steel door and frame systems with minimum sound transmission class (STC) ratings ranging between 43 and 52.

08351—FOLDING DOORS—This Section specifies non-acoustical and non-fire-rated accordion and panel folding doors with vinyl, wood, and other finishes; and bifold doors of wood, metal, and polyvinyl chloride (PVC) construction. These doors are intended as visual separation devices and primarily apply to commercial and institutional installations; however, by appropriate modification, they may accommodate light commercial and residential construction.

08361—SECTIONAL OVERHEAD DOORS—This Section specifies sectional overhead doors moved by a counterbalance mechanism and rollers along a steel track system and fabricated from flat steel or ribbed steel panel sections framed with steel members; paneled wood or flush wood panel sections framed with wood members; and aluminum, translucent (fiberglass-reinforced) plastic, and glass or plastic vinyl panel sections framed with aluminum members.

08410—ALUMINUM ENTRANCES AND STOREFRONTS—This Section specifies standard interior and exterior aluminum entrance and storefront systems. Entrance systems include swinging doors, framing, hardware, vestibule enclosures, transoms, and sidelights. Storefront systems include fixed glazing areas and framing.

08450—ALL-GLASS ENTRANCES—This Section specifies frameless tempered-glass entrances, including swing doors, sidelights, transoms, and related accessories.

08460—AUTOMATIC ENTRANCE DOORS—This Section specifies only the Evaluations for the following new Sections covering types of automatic entrance doors:

08461—SLIDING AUTOMATIC ENTRANCE DOORS—This Section specifies sliding automatic entrance door systems that include not only door operators and controls but also aluminum doors, sidelite and transom frames, and accessories.

08462—SWINGING AUTOMATIC ENTRANCE DOORS—This Section specifies swinging automatic entrance door systems that include not only door operators and controls but also aluminum doors, transom frames, and accessories. Bifolding operation is also included.

08470—REVOLVING ENTRANCE DOORS—This Section specifies conventional, circular, revolving entrance doors consisting of manual and power-assisted door leaves, or wings, rotating about a center post with a speed-control unit to limit rotation speed.

08510—STEEL WINDOWS—This Section specifies readily available stock and custom types of steel window units. It describes window types (operations) and window grades (classifications) in addition to performance requirements and finishes, and other options.

08520—ALUMINUM WINDOWS—This Section specifies various types of commonly used stock aluminum window units. The Section includes normally available options for window type, grade, and performance class. It also includes different glazing methods, finishes, and other options. The Section is primarily intended for generic specifying of competitive window types. When specific manufacturers' product names are inserted, the Text can be shortened to facilitate proprietary specifying.

08550—WOOD WINDOWS—This Section specifies various types of commonly used stock wood window units. The Section includes a variety of normally available options for window type and performance grade. It also includes different glazing methods, finishes, and other options. The Section is primarily intended for generic specifying of competitive window types. When specific manufacturers' product names are inserted, the Text can be considerably shortened to facilitate proprietary specifying.

08610—ROOF WINDOWS—This Section specifies venting and fixed insulating-glass units for installation on sloping roof surfaces.

08630—METAL-FRAMED SKYLIGHTS—This Section specifies aluminum-framed skylights with retaining-cap- or structural-sealant-glazing systems and glass or plastic glazing.

08631—TRANSLUCENT-INSULATING-PANEL SKYLIGHTS—This Section contains only the Evaluations for the following new Sections that specify aluminum-framed skylights glazed with different types of translucent, insulating panels:

- 08632—POLYCARBONATE-INSULATING-PANEL SKYLIGHTS
- 08633—FIBERGLASS-SANDWICH-PANEL SKYLIGHTS

08632—POLYCARBONATE-INSULATING-PANEL SKYLIGHTS—This Section specifies aluminum-framed skylights glazed with translucent, cellular-polycarbonate insulating panels.

08633—FIBERGLASS-SANDWICH-PANEL SKYLIGHTS—This Section specifies aluminum-framed skylights incorporating translucent, insulating, fiberglass-reinforced-polymer, sandwich panels.

08710—DOOR HARDWARE—This Section specifies Evaluations only for the following new Sections covering different specifying methods for door hardware:

08711—DOOR HARDWARE (SCHEDULED BY NAMING PRODUCTS)—This Section specifies hardware applied to doors, formally called *finish hardware*, *builder's hardware*, or *architectural finish hardware*. The Section uses manufacturers' product names or references to BHMA standards in the Door Hardware Schedule to indicate door hardware requirements.

08712—DOOR HARDWARE (SCHEDULED BY DESCRIBING PRODUCTS)—This Section specifies hardware applied to doors, formally called *finish hardware*, *builder's hardware*, or *architectural finish hardware*. The Section uses product descriptions in the Door Hardware Schedule to indicate door hardware requirements.

08716—POWER DOOR OPERATORS—This Section specifies power door operators normally furnished separately from doors and frames. These door operators are adaptable to a variety of door designs and sizes. Power door operators that aid the physically handicapped by acting as an automatic door operator and that comply with the requirements of BHMA A156.19, ADA accessibility guidelines, and ANSI A117.1 are also included.

08800—GLAZING—This Section specifies monolithic, laminated, and insulating glass along with the glazing materials required for their installation. This Section serves two primary purposes: 1) It covers glazing work normally subcontracted to installers of glazing; and 2) it is the Section that other Sections cross-reference to avoid repeating glazing requirements. In the latter case, edit this Section after the other Sections are substantially complete.

08801—SECURITY GLAZING—This Section specifies glazing products intended to resist abuse, physical attack, forced entry, and ballistics. Products included are laminated glass, glass/polycarbonate laminates, and laminated and monolithic polycarbonate sheets.

08814—MIRRORING GLASS—This Section, which is new to the Basic Version, specifies unframed and unbacked, fully silvered mirrored glass and pyrolytic mirrored glass for mounting on walls and ceilings.

08825—DECORATIVE GLASS—This Section specifies glass products for interior applications, including acid etched, sandblasted, silk screened, beveled, patterned, and laminated glass with integral decoration.

08840—PLASTIC GLAZING—This Section specifies light-transmitting plastic sheets that are glazed into openings as substitutes for glass. Included are acrylic glazing in the form of monolithic sheets and double-walled, structured sheets; and polycarbonate glazing in the form of monolithic sheets and double-walled, structured sheets.

08920—GLAZED ALUMINUM CURTAIN WALLS—This Section specifies standard and custom glazed aluminum curtain wall systems installed using stick, unit, and unit-and-mullion system methods.

08925—STRUCTURAL-SEALANT-GLAZED CURTAIN WALLS—This Section specifies standard and custom, 4-sided and 2-sided, structural-sealant-glazed curtain walls incorporating aluminum framing systems.

08960—SLOPED GLAZING SYSTEMS—This Section specifies standard and custom conventionally glazed and structural-sealant-glazed sloped glazing systems incorporating aluminum framing systems.

DIVISION 9

09210—GYPSUM PLASTER—This Section specifies gypsum lath and plaster; metal lath, furring, accessories, and support systems; and plastic accessories.

09215—GYPSUM VENEER PLASTER—This Section specifies gypsum-based veneer plaster on gypsum base, unit masonry, or monolithic concrete. Metal support systems, sound-attenuation insulation, thermal insulation, and cementitious backer units are also specified because they are integrated with veneer plaster construction. Veneer plaster materials and applications may be cross-referenced from other Division 9 Sections, such as "Gypsum Board Shaft-Wall Assemblies."

09220—PORTLAND CEMENT PLASTER—This Section specifies portland cement plaster including metal framing, furring, lath, and accessories; plastic accessories; job-mixed portland cement finish; and factory-prepared finishes such as stucco, acrylic based, and exposed aggregate.

09251—FACTORY-FINISHED GYPSUM BOARD—This Section specifies vinyl-film-faced, gypsum board panels and associated trim.

09253—GYPSUM SHEATHING—This Section specifies paper-surfaced and glass-mat gypsum sheathing attached to steel framing on exterior walls and air-infiltration barriers installed over the sheathing.

09260—GYPSUM BOARD ASSEMBLIES—This Section specifies gypsum board assemblies and metal support systems. Sound attenuation insulation and cementitious backer units for tile are also specified because they are often components of gypsum board assemblies.

09265—GYPSUM BOARD SHAFT-WALL ASSEMBLIES—This Section specifies non-load-bearing, steel-framed gypsum board assemblies that provide fire-resistance-rated enclosures for vertical shafts and horizontal enclosures.

09271—GLASS-REINFORCED GYPSUM FABRICATIONS—This Section specifies factory-molded products fabricated with glass-reinforced gypsum (GRG), for interior use.

09310—CERAMIC TILE—This Section specifies unglazed and glazed ceramic tile, including ceramic mosaic, quarry, paver, and wall tile; tile setting and grouting materials; accessories; and installation requirements.

09385—DIMENSION STONE TILE—This Section specifies natural stone tile for flooring, wall facing, and trim for commercial and residential installations. *Dimension stone tile* is defined as modular units less than ¾ inch (19 mm) thick fabricated from natural stone. Stone thresholds are also in the Section Text.

09400—TERRAZZO—This Section specifies cementitious, modified-cement-resin, and synthetic-resin terrazzo for flooring, base, stair treads, landings, and risers. Cementitious terrazzo includes standard and rustic cast-in-place systems and precast products. Resinous "thin-set" terrazzo includes cast-in-place, polyacrylate-modified-cement and epoxy-resin systems.

09451—INTERIOR STONE FACING—This Section specifies dimension stone used for interior wall facing, trim, moldings, base, countertops, and window stools.

09511—ACOUSTICAL PANEL CEILINGS—This Section specifies ceilings consisting of acoustical panels and exposed suspension systems, including special-use types for exterior locations, high-temperature and -humidity locations, and clean rooms.

MASTERSPEC continues on the next page.

ARCOM; Salt Lake City, Utah, and Alexandria, Virginia

1

CONSTRUCTION INFORMATION SYSTEMS

09512—ACOUSTICAL TILE CEILINGS—This Section specifies ceilings consisting of acoustical tiles and concealed suspension systems.

09513—ACOUSTICAL SNAP-IN METAL PAN CEILINGS—This Section specifies ceilings consisting of acoustical snap-in metal pans and concealed suspension systems. Types of metal pan ceiling units include both perforated and unperforated snap-in steel, stainless steel, or aluminum pans.

09547—LINEAR METAL CEILINGS—This Section specifies strip, decorative, linear metal ceilings.

09580—SUSPENDED DECORATIVE GRIDS—This Section specifies open-cell grid, plenum mask ceiling systems.

09600—STONE PAVING AND FLOORING—This Section specifies dimension stone paving and flooring installed on a thick, mortar setting bed. It also includes metal edging and stone thresholds.

09621—FLUID-APPLIED ATHLETIC FLOORING—This Section specifies polyurethane floorings, intended for use in athletic-activity areas, that are homogenous or installed over resilient underlayment.

09622—RESILIENT ATHLETIC FLOORING—This Section specifies rubber, vinyl, and thermoplastic-rubber-blend floor coverings in interlocking-tile or roll form and designed for use in athletic-activity or support areas.

09635—BRICK FLOORING—This Section specifies brick flooring for interior applications subject to pedestrian and light vehicular traffic. Three setting methods included for the specifier's choice are loose-laid brick flooring with sand-filled, hand-tight joints; thicket mortared brick flooring, with or without grouted joints; and thin-set mortared brick flooring, also with or without grouted joints. Where the same brick pavers are selected for both flooring (interior applications) and paving (exterior applications) and use either the same or different setting methods and beds, there can be advantages to combining them into one Section and choosing a section number that represents the major application. Brick flooring could also be included with unit masonry if the bricklayer's method is used for installation.

09636—CHEMICAL-RESISTANT BRICK FLOORING—This Section specifies chemical-resistant brick flooring installed with mortars, grouts, and setting beds that offer varying degrees of chemical protection based on specific user requirements. The Section may also include a protective membrane on the subfloor.

09640—WOOD FLOORING—This Section specifies solid- and engineered-wood flooring that is either factory or site finished.

09644—WOOD ATHLETIC-FLOORING ASSEMBLIES—This Section specifies hard maple, finish flooring and sub-flooring assemblies designed for use as athletic playing or exercising surfaces. Subflooring systems include those with enhanced shock-absorbing properties.

09651—RESILIENT TILE FLOORING—This Section specifies solid vinyl, rubber, and vinyl composition floor tile and resilient wall base and accessories typically installed with resilient floor tile.

09652—SHEET VINYL FLOOR COVERINGS—This Section specifies sheet vinyl floor coverings, with and without backings, for commercial projects.

09653—RESILIENT WALL BASE AND ACCESSORIES—This Section specifies rubber and vinyl wall base, stair treads, and accessories for use with resilient flooring and carpet.

09654—LINOLEUM FLOOR COVERINGS—This Section specifies linoleum tile and sheet floor coverings.

09671—RESINOUS FLOORING—This Section specifies decorative, general-use, and high-performance or special-application resinous flooring systems applied as self-leveling slurries or troweled or screeded mortars.

09677—STATIC-CONTROL RESILIENT FLOOR COVERINGS—This Section specifies static-dissipative vinyl composition, homogenous (solid) vinyl, and rubber floor tile; static-dissipative rubber sheet floor covering; conductive homogenous (solid) vinyl and rubber floor tile; and conductive vinyl and rubber sheet floor covering.

09680—CARPET—This Section specifies tufted, fusion-bonded, and woven carpet, as well as carpet cushion for commercial installations.

09681—CARPET TILE—This Section specifies carpet tile for commercial installations.

09771—FABRIC-WRAPPED PANELS—This Section specifies custom-fabricated, back-mounted, fabric-wrapped panels for ceilings and walls, in which the fabric is not adhered to the core material.

09772—STRETCHED-FABRIC WALL SYSTEMS—This Section specifies concealed-fastener, site-assembled, site-upholstered systems for ceilings and walls.

09841—ACOUSTICAL WALL PANELS—This Section specifies shop-fabricated acoustical panels that are wall mounted as opposed to freestanding or ceiling baffles. Both spline-mounted and back-mounted units are included.

09900—PAINTING—This Section specifies general surface preparation, materials preparation, and application principles for interior and exterior painting.

09920—INTERIOR PAINTING—This Section specifies general surface preparation, materials preparation, and application principles for interior painting.

09931—EXTERIOR WOOD STAINS—This Section specifies general surface preparation, material preparation, and application principles for exterior wood stains.

09945—MULTICOLORED INTERIOR COATINGS—This Section specifies polychromatic paint.

09950—WALL COVERINGS—This Section specifies vinyl, fiberglass, and textile wall coverings and wallpaper.

09960—HIGH-PERFORMANCE COATINGS—This Section specifies high-performance coatings for architectural and industrial applications.

09963—ELASTOMERIC COATINGS—This Section specifies a specially designed acrylic polymer containing elastomeric coatings for use on the exterior of masonry, concrete, and stucco structures. These coatings are dirt resistant, flexible in a range of temperatures, and very high-build materials that bridge small cracks and protect against deterioration resulting from moisture penetration of the substrate.

09967—INTUMESCENT PAINTS—This Section specifies intumescent-type, fire-retardant paint primarily for interior combustible and noncombustible substrates.

09975—HIGH-TEMPERATURE-RESISTANT COATINGS—This Section specifies general surface preparation, materials preparation, and application principles for high-temperature-resistant coatings used on the interior and exterior.

09980—WOOD-VENEER WALL COVERINGS—This Section specifies flexible wood-veneer wall covering.

09981—CEMENTITIOUS COATINGS—This Section specifies polymer-modified cementitious coatings to use above or below grade on the exterior or interior over masonry and concrete. After curing, these coatings produce a durable, hard, weather-resistant surface.

DIVISION 10

10100—VISUAL DISPLAY BOARDS—This Section specifies the most commonly used types of standard chalkboards, markerboards, and tackboards. Emphasis is placed on prefabricated units. Provisions are also included for traditional slate chalkboards and other field-assembled types.

10155—TOILET COMPARTMENTS—This Section specifies standard metal, plastic-laminate, and solid-plastic toilet compartments and screens.

10180—STONE TOILET COMPARTMENTS—This Section specifies marble and granite toilet compartments and screens, compartment doors, and associated fittings and hardware.

10190—CUBICLES—This Section specifies curtain and IV tracks and curtains and accessories for cubicles, dressing areas, tubs, and showers.

10200—LOUVERS AND VENTS—This Section specifies fixed and adjustable metal louvers, acoustical louvers, blank-off panels for louvers, and wall vents (brick vents). Louvers connected to ductwork, and those that are not, are properly specified in this Section. This Section specifies louvers made from extruded aluminum, formed galvanized steel, and formed stainless steel. Fixed-blade louvers specified include those with horizontal and vertical blades, drainable and nondrainable blades, and sightproof blades. Adjustable louvers specified include those with drainable and nondrainable blades, both fixed and adjustable blades combined in a single frame and single-blade units, and insulated units.

10265—IMPACT-RESISTANT WALL PROTECTION—This Section specifies various types of impact-resistant wall protection systems, including wall guards, handrails, and corner guards, as well as door and door frame protection systems. It also includes related impact-resistant wall covering products. The Section can be expanded to include any complete protection system or streamlined to specific wall and corner-guard applications only.

10270—ACCESS FLOORING—This Section specifies standard access flooring systems, including accessories. Not only does it include systems suitable for data centers, computer rooms, clean rooms, and other applications, but also those intended primarily for general office uses.

10350—FLAGPOLES—This Section specifies metal and fiberglass flagpoles, including ground-set, wall-mounted, and roof-mounted flagpoles. Metals include aluminum, steel, stainless steel, and bronze.

10405—BANNERS—This Section specifies banners of woven, nonwoven, and knit materials, for interior and exterior use.

10416—DIRECTORIES AND BULLETIN BOARDS—This Section specifies directories and bulletin boards fabricated from standard components common to several manufacturers. The Section can be used for specifying customized units by inserting additional requirements for materials and fabrication.

10425—SIGNS—This Section specifies panel signs, dimensional letters and numbers, and cast metal plaques. It includes typical materials and processes commonly used by a wide number of sign manufacturers.

10436—POST AND PANEL SIGNS—This Section specifies exterior, freestanding, illuminated and nonilluminated post and panel signs. It covers typical materials and processes used by a variety of sign manufacturers. The most commonly used panels, from the single-sheet variety to illuminated hollow-box-type units, are specified. Graphic image processes are also included.

10437—PYLON SIGNS—This Section specifies freestanding, illuminated and nonilluminated pylon signs. It covers typical materials and processes used by a variety of sign manufacturers. The most commonly used signs, from the upright-slab type to the tall, slender, square pylon-type unit, are specified. Graphic image processes are also included.

10505—METAL LOCKERS—This Section specifies standard, factory-fabricated wardrobe and athletic metal lockers. Commonly specified accessories and optional features, such as locker-room benches, are also included.

10520—FIRE-PROTECTION SPECIALTIES—This Section specifies portable fire extinguishers; their mounting brackets; and cabinets for fire extinguishers, hose valves, and rack and hose assemblies.

10550—POSTAL SPECIALTIES—This Section specifies standard mail chutes, receiving and collection boxes, horizontal- and vertical-type mailboxes, neighborhood delivery and collection box units, and parcel lockers.

10605—WIRE MESH PARTITIONS—This Section specifies standard- and heavy-duty wire mesh partitions, exterior (galvanized) partitions, wire mesh window guards, stairway partitions, and insert panels for railing systems.

10615—DEMOUNTABLE PARTITIONS—This Section includes only the Evaluations for the following Sections specifying demountable partitions:

- 10616—SITE-ASSEMBLED DEMOUNTABLE PARTITIONS
- 10620—DEMOUNTABLE UNITIZED-PANEL PARTITIONS

10616—SITE-ASSEMBLED DEMOUNTABLE PARTITIONS—This Section specifies reusable, demountable partition systems consisting of gypsum board panels or metal-faced gypsum board panels supported by concealed framing. This new Section replaces

- 10617—DEMOUNTABLE GYPSUM PANEL PARTITIONS and
- 10618—DEMOUNTABLE METAL PANEL PARTITIONS, both dated 11/92.

10620—DEMOUNTABLE UNITIZED-PANEL PARTITIONS—This Section specifies reusable, demountable, partition systems consisting of factory-assembled unitized panels.

10651—OPERABLE PANEL PARTITIONS—This Section specifies acoustically rated, manually and electrically operated, flat-panel partitions supported from an overhead track.

10653—FIRE-RATED OPERABLE PANEL PARTITIONS—This Section specifies acoustically rated, manually operated, flat-panel partitions, fire rated one hour or one and one-half hours, supported from an overhead track.

10655—ACCORDION FOLDING PARTITIONS—This Section specifies acoustically rated, manually and electrically operated, accordion folding partitions supported from a single overhead track.

MASTERSPEC continues on the next page.

ARCOM; Salt Lake City, Utah, and Alexandria, Virginia

10671—METAL STORAGE SHELVING—This Section specifies post and shelf storage units.

10680—MOBILE STORAGE UNITS—This Section specifies manually and electrically operated storage units consisting of carriages that glide on rails to open an aisle where access is required.

10750—TELEPHONE SPECIALTIES—This Section specifies prefabricated telephone specialties, including telephone booths and other enclosures, telephone housings, telephone-enclosure entrances for built-in telephone booths, and directory storage units. The Text is based on standard products of several manufacturers but can be adapted to specify similar standard and custom-designed units.

10753—WALL-MOUNTED TELEPHONE ENCLOSURES—This Section specifies prefabricated, wall-mounted, shelf-type telephone enclosures and wall-mounted, panel-type telephone housings. The Text is based on standard products of several manufacturers but can be adapted to specify similar standard and custom-designed units.

10801—TOILET AND BATH ACCESSORIES—This Section specifies standard toilet and bath accessories and mirror units commonly used in commercial and institutional applications.

DIVISION 11

11054—LIBRARY STACK SYSTEMS—This Section specifies stationary single-tier and multitier shelving for library materials.

11062—FOLDING AND PORTABLE STAGES—This Section specifies folding and portable stage platforms, seating-platform risers, standing choral risers, and acoustical shell systems that might be used indoors in schools, churches, banquet facilities, and multipurpose auditoriums.

11063—STAGE CURTAINS—This Section specifies examples of stage curtain fabrics and draw-travel curtain rigging commonly used in small- to medium-sized theater/auditorium installations without fly spaces.

11132—PROJECTION SCREENS—This Section specifies standard rear- and front-projection screens. It includes both manually and electrically operated, roll-up front-projection screens with almost any screen surface and rear-projection screens made of glass or acrylic plastic.

11150—PARKING CONTROL EQUIPMENT—This Section specifies basic parking control equipment for public and private installations including gate operators and controls and cashier's or parking attendant's booths.

11160—LOADING DOCK EQUIPMENT—This Section specifies dock bumpers, dock levelers, truck levelers, truck restraints, dock lifts, dock seals, dock shelters, and transparent strip door curtains. Dock bumpers include laminated-tread, molded- and extruded-rubber, and steel-face types. Both mechanical and hydraulic dock levelers are covered, including those permanently installed in pits and those attached at the edge of the dock. Truck restraints include both wall- and driveway-mounted types. Hydraulic dock lifts of the single-scissors type for permanent installation in pits are the only dock lift included. Dock shelters include rigid frame, flexible frame, and inflatable types.

11172—WASTE COMPACTORS—This Section specifies general-purpose, commercial, wet- or dry-waste compactor units for processing solid, nonhazardous, building-generated waste.

11307—PACKAGED SEWAGE PUMP STATIONS—This Section specifies small- and medium-size, factory-assembled, sewage pump stations.

11400—FOOD SERVICE EQUIPMENT—This Section specifies food service equipment for use in commercial, industrial, and institutional projects.

11451—RESIDENTIAL APPLIANCES—This Section specifies major residential appliances. It includes freestanding and built-in kitchen and laundry appliances, and both gas and electric equipment for residential and incidental nonresidential applications. Appliances included are restricted to units that may be purchased as standard manufactured items.

11460—UNIT KITCHENS—This Section specifies standard, factory-fabricated and -assembled unit kitchens including cabinetry, appliances, sinks, faucets, and accessories.

11610—LABORATORY FUME HOODS—This Section specifies standard laboratory fume hoods used for educational laboratories and research facilities. It includes conventional hoods, bypass hoods, and restricted bypass hoods; with or without airflow design, auxiliary air, and variable air volume (VAV) control. It also includes walk-in hoods, perchloric acid hoods, and radioisotope hoods. It includes hood stands and specifies casework supporting bench-type hoods by referencing

- 12347—METAL LABORATORY CASEWORK or
- 12348—WOOD LABORATORY CASEWORK.

11695—MAILROOM EQUIPMENT—This Section specifies equipment used to process incoming and outgoing mail. It replaces Section 11910—MAILROOM EQUIPMENT AND FURNITURE, dated 10/88, that is being withdrawn from the Interiors Library Construction Version.

DIVISION 12

12050—FABRICS—This Section evaluates fibers, textiles, and leather for use as wall coverings, vertical hangings, floor coverings, and furniture upholstery.

12100—ART—This Section evaluates the integration of art, both as a form of cultural expression and as decorative enhancement, into commercial interiors projects. Project coordination with work of other contracts and with a team of consultants is discussed.

12311—METAL FILE CABINETS—This Section specifies vertical and lateral metal file cabinets.

12320—RESTAURANT AND CAFETERIA CASEWORK—This Section specifies cashier counter, wait stations and other casework for food service facilities. This section can be modified to include more extensive custom display equipment by inclusion of additional detailed requirements.

12347—METAL LABORATORY CASEWORK—This Section specifies standard manufactured metal laboratory casework and common accessories, including cabinets, countertops, sinks, and service fixtures.

12348—WOOD LABORATORY CASEWORK—This Section specifies standard manufactured wood laboratory casework and common accessories, including cabinets, countertops, sinks, and service fixtures. The Text includes both wood-faced cabinets and plastic-laminate-faced cabinets.

12353—DISPLAY CASEWORK—This Section specifies manufactured cabinets and display cases for retail storage and merchandising.

12356—KITCHEN CASEWORK—This Section specifies stock-manufactured kitchen and vanity cabinets made from wood and wood products faced with wood, plastic laminate, vinyl, or a combination of these materials. Countertops made of plastic-laminate and solid-surfacing material are included so all components are in a single Section.

12359—METAL MEDICAL CASEWORK—This Section specifies standard manufactured metal medical casework and common accessories, including stainless-steel countertops, sinks, and shelving. It includes casework typically used in operating rooms, emergency rooms, x-ray rooms, central sterile supply, and similar spaces for the storage of instruments and supplies. It does not include laboratory casework, which is specified in Division 12 Section "Metal Laboratory Casework," or plastic-laminate countertops, which are specified in Division 6 Section "Interior Architectural Woodwork."

12361—MAILROOM CASEWORK—This Section specifies manufactured casework used in document distribution workrooms and to process incoming and outgoing mail.

12483—CUSTOM RUGS—This Section specifies custom-designed, 100 percent wool, hand-tufted area rugs installed over finish flooring.

12493—CURTAINS AND DRAPES—This Section specifies stationary and movable curtains and drapes, and window treatment hardware for commercial installations.

12496—WINDOW TREATMENT HARDWARE—This Section specifies hardware for manually operated and motor-operated draperies and curtains.

12510—OFFICE FURNITURE—This Section specifies desks, tables, and credenzas for office and computer-support applications.

12511—HORIZONTAL LOUVER BLINDS—This Section specifies manually operated and motor-operated venetian blinds.

12512—VERTICAL LOUVER BLINDS—This Section specifies manually operated and motor-operated vertical vane blinds.

12520—SHADES—This Section specifies manually operated and motor-operated roll shades, including blackout and mesh shades.

12521—CUSTOM UPHOLSTERED SEATING—This Section specifies specially designed, wood frame, upholstered seating.

12522—OFFICE SEATING—This Section specifies seating for office and computer-support applications.

12523—HEALTHCARE SEATING—This Section specifies patient and guest seating in hospitals and extended-care facilities. Sleeper chairs for guests and recliners and rockers for patients are also included.

12525—PLEATED SHADES—This Section specifies 2 basic types of pleated shades: accordion pleated shades with 1 fabric thickness and shades with multiple-fabric thicknesses forming air spaces (sometimes referred to as cellular shades).

12551—TRADING DESKS—This Section specifies modular desk units and equipment support for trading rooms for banks, insurance companies, and other financial institutions; trading support; data processing; reservation centers; 911 emergency facilities; and video production facilities.

12562—CLASSROOM FURNITURE—This Section specifies library seating and furniture for the display, storage, review, and checkout of library materials.

12563—DORMITORY FURNITURE—This Section specifies dressers, desks, chairs, nightstands, wardrobes, tables, beds, and other furniture items for residence hall rooms and lounge areas.

12567—LIBRARY FURNITURE—This Section specifies library seating and furniture for the display, storage, review, and checkout of library materials.

12571—AUDIO-VISUAL SUPPORT FURNITURE—This Section specifies lecterns, presentation equipment carts, and cabinets.

12574—OUTDOOR FURNITURE—This Section specifies movable, wood or metal tables and chairs designed to withstand temperature extremes and limited weathering.

12610—FIXED AUDIENCE SEATING—This Section specifies upholstered and nonupholstered interior assembly-space seating. Although exterior seating is not included, the Section Text could be modified to specify exterior fixed seating in stadiums.

12630—RESTAURANT FURNITURE—This Section specifies tables and seating for dining.

12634—CUSTOM FURNITURE—This Section specifies specially designed tables, desks, credenzas, etc.

12635—PATIENT ROOM FURNITURE—This Section specifies bedside cabinets, wardrobe units, desks, vanities, and chests of drawers designed specifically for healthcare applications.

12638—GUEST ROOM FURNITURE—This Section specifies guest room furniture sets including armoires (perhaps with a bar unit or other built-ins), credenzas, nightstands or bedside tables, writing desks, lounge chairs, and headboards. Also specified in this Section are mattresses and box springs, and guest bedroom seating.

12639—BANQUETTES—This Section specifies built-in, upholstered, custom seating.

12651—INTERLOCKING CHAIRS—This Section specifies multiple seating systems (ganged or tandem) with optional modular tabletops for waiting, reception, and lounge areas.

12677—ORIENTAL RUGS—This Section specifies antique, semiantique, and new, handmade imported rugs and rug pads.

12680—FOOT GRILLES—This Section specifies foot grilles, which are generally rigid sections of treads designed to remove foot traffic debris set in a recessed frame in the floor.

12690—FLOOR MATS AND FRAMES—This Section specifies commonly used types of recessed and surface installed floor mats for buildings other than single-family residential work.

12700—SYSTEMS FURNITURE—This Section specifies panel-hung-component systems, freestanding-component systems, desk systems supporting work-surface-mounted screens and other components, and beam systems.

12760—TELESCOPING STANDS—This Section specifies telescoping stands for interior applications consisting of multiple-tiered benches or chairs on interconnected, folding platforms. These systems are constructed of steel, wood and steel, or polyethylene plastic and steel, and can be operated manually or automatically.

12815—INTERIOR PLANTS—This Section specifies requirements for selecting, laying out, and placing plants provided by an interior landscape contractor.

12830—INTERIOR PLANTERS—This Section specifies movable, decorative planters with or without integral subirrigation systems.

MASTERSPEC continues on the next page.

ARCOM; Salt Lake City, Utah, and Alexandria, Virginia

1 CONSTRUCTION INFORMATION SYSTEMS

DIVISION 13

13041—MODULAR VAULTS—This Section specifies modular vault panels and doors that are prefabricated and site assembled.

13052—SAUNAS—This Section specifies panel-built, or modular, saunas and custom-cut, or precut, saunas, furnished as complete units including heating, lighting, controls, and accessories.

13090—RADIATION PROTECTION—This Section specifies materials and methods for typical radiation protection systems used in medical x-ray rooms and radiation therapy rooms. It includes lead sheet, lead glass, and lead glazing plastic; lead-lined finish materials; and other lead-lined products, such as doors, frames, view windows, modular shielding partitions, and film transfer cabinets. The Section also specifies lead bricks, borated polyethylene, and neutron shielding doors and frames for radiation therapy applications. Signs indicating the thickness of the lead shielding provided are also included.

13100—LIGHTNING PROTECTION—This Section specifies lightning protection for buildings, building elements, and building site components.

13110—CATHODIC PROTECTION—This Section specifies passive cathodic protection systems that use magnesium or zinc sacrificial anodes to protect steel and iron piping and tanks. Modify the Section Text to include aluminum piping and tanks; include electrical conduit protection by adding "steel conduit" to "piping."

13125—METAL BUILDING SYSTEMS—This Section specifies metal building systems, complete with structural framing, roofing and siding panels, personnel doors, windows, and accessories.

13720—INTRUSION DETECTION—This Section specifies local intrusion detection equipment. It includes the detection devices and the central control and processing and equipment necessary for control. The Text of this Section specifies a system ready to be monitored by a remote station if required by a project. Various types of remote signaling systems are accommodated, but Specifications are not included for those external systems. The Section may also be edited to specify intrusion detection that can interface with an integrated building management system specified in another Section.

13810—CLOCK CONTROL—This Section specifies systems for displaying automatically adjusted time throughout a facility, for initiating time-scheduled audible and visual signals to announce events, and for initiating scheduled equipment operation via relays. The components specified use hard-wired or carrier-current distribution of time and program signals from a master unit. Equipment includes master clock- and program-control units, and various types of indicating clocks and audible and visual signal equipment, such as bells, horns, lights, and mechanical equipment. This Section covers a combination master clock- and program-control system. However, it can be modified to cover an independent master clock-control system or an independent program-control system.

13845—LIGHTING CONTROLS—This Section specifies wired, programmable, lighting control systems using low-voltage control circuits. Manual, low-voltage lighting controls are also specified.

13851—FIRE ALARM—This Section specifies local fire alarm and detection systems for buildings. It includes the panels necessary to control the systems and the various peripheral devices associated with detecting fires, initiating alarms, and indicating alarms with audible and visible signals. The Section also includes equipment for communicating alarm, supervisory, and trouble signals to a remote alarm receiving station.

13915—FIRE-SUPPRESSION PIPING—This Section specifies combined systems of standpipes and sprinklers for buildings and includes the following:

13916—FIRE-SUPPRESSION SPRINKLERS—This Section specifies wet- and dry-pipe, fire-suppression sprinklers for buildings and includes piping, sprinklers, specialties, and accessories. Use Division 13 Section "Fire-Suppression Piping" for preaction and deluge piping, sprinklers, specialties, and accessories; and combined (standpipe and sprinkler) systems.

13920—FIRE PUMPS—This Section includes only the Evaluations and Drawing Coordination and Specifications Coordination checklists for the following Sections covering fire pumps for building fire-suppression systems:

- 13921—ELECTRIC-DRIVE, HORIZONTAL FIRE PUMPS
- 13922—DIESEL-DRIVE, HORIZONTAL FIRE PUMPS
- 13926—ELECTRIC-DRIVE, VERTICAL-TURBINE FIRE PUMPS
- 13927—DIESEL-DRIVE, VERTICAL-TURBINE FIRE PUMPS

13921—ELECTRIC-DRIVE, HORIZONTAL FIRE PUMPS—This Section specifies electric-drive, horizontal fire pumps for building fire-suppression systems and includes the following:

13922—DIESEL-DRIVE, HORIZONTAL FIRE PUMPS—This Section specifies diesel-drive, horizontal fire pumps for building fire-suppression systems and includes the following:

13926—ELECTRIC-DRIVE, VERTICAL-TURBINE FIRE PUMPS—This Section specifies electric-drive, vertical-turbine fire pumps for building fire-suppression systems and includes the following:

13927—DIESEL-DRIVE, VERTICAL-TURBINE FIRE PUMPS—This Section specifies diesel-drive, vertical-turbine fire pumps for building fire-suppression systems and includes the following:

13956—FIRE-EXTINGUISHING FOAM PIPING—This Section specifies fixed, low-expansion, aqueous film-forming foam, fire-extinguishing systems for hydrocarbon-liquid fires. Foam systems are normally used on, but not limited to, Class B (flammable-liquid) fires.

13966—HALOGEN AGENT EXTINGUISHING PIPING—This Section specifies Halon 1301 halogen agent, fire-extinguishing systems.

13967—CLEAN-AGENT EXTINGUISHING SYSTEMS—This Section specifies clean-agent extinguishing systems. These systems use alternative agents that are substitutes for fixed, Halon 1301 extinguishing systems. Specified agents and related components in this Section are limited to those that are Factory Mutual approved and Underwriters Laboratories listed. Other agents are included in NFPA 2001, *Clean Agent Fire Extinguishing Systems*. See the Evaluations for further discussion.

13975—STANDPIPES AND HOSES—This Section specifies standpipes for buildings and includes the following:

DIVISION 14

14100—DUMBWAITERS—This Section specifies preengineered electric dumbwaiter units, commonly used for floor-to-floor transfer of small-sized materials such as books, parts, food, etc., in a low- to medium-rise application. Car size is limited by the Code to 9 sq. ft. (0.84 sq. m) of platform and a height of 4 feet (1219 mm).

14210—ELECTRIC TRACTION ELEVATORS—This Section specifies preengineered electric traction elevators for either passenger or freight use. Substantial generic descriptions are included, however, to enable manufacturers to bid either custom or preengineered equipment. This Section can be modified to specify custom electric traction elevators.

14240—HYDRAULIC ELEVATORS—This Section specifies preengineered hydraulic elevators, including holess and roped hydraulic types, for either passenger or freight use. Substantial generic descriptions are included, however, to enable manufacturers to bid either custom or preengineered equipment.

14310—ESCALATORS—This Section specifies standard preengineered, heavy-duty, and exterior escalators.

14320—MOVING WALKS—This Section specifies moving walks as defined by ASME A17.1, which includes power-driven, continuous treadmill units used for conveying passengers along either a horizontal surface or an inclined ramp. It is intended for specifying preengineered units for normal installations, traveling either horizontally or between floors, rising one story at a time. The Section Text can be amplified to cover custom-engineered units and units with special requirements such as exceptionally long or curved runs or rises, custom profiles, or the use of custom materials in balustrade construction.

14420—WHEELCHAIR LIFTS—This Section specifies special-purpose lifts used to transport nonambulatory and semiambulatory persons from one level of a building to another. It includes vertical wheelchair lifts, inclined wheelchair lifts, and inclined stairway chair lifts. It also includes requirements for standard runway enclosures offered by manufacturers of vertical wheelchair lifts.

14512—TRACK VEHICLE SYSTEMS—This Section specifies self-propelled container systems that travel on electrified tracks.

14559—SELECTIVE VERTICAL CONVEYORS—This Section specifies vertical transport systems operated by a single motor that continuously moves a chain in a single direction, much like a ferris wheel. Containers hook into the chain as it passes their receiving station and are transported to other vertical locations.

14560—CHUTES—This Section specifies gravity-type, metal chutes used to convey waste and linen.

DIVISION 15

15050—BASIC MECHANICAL MATERIALS AND METHODS—This Section specifies materials and methods for application with mechanical equipment and piping system installations inside the building. Piping specialties, joining materials, joint construction, identification materials and devices, and installation requirements common to more than one Division 15 Section are included. This Section supplements other Division 15 Sections. It must be edited and used with other Sections for a complete system specification.

15060—HANGERS AND SUPPORTS—This Section specifies hangers and supports for mechanical system piping and equipment.

15075—MECHANICAL IDENTIFICATION—This Section specifies identification materials and devices, and installation requirements. Use this Section for complex projects requiring comprehensive specifications for labeling and identifying mechanical installations. Use the Specifications in Division 15 Section "Basic Mechanical Materials and Methods" for simple projects.

15081—DUCT INSULATION—This Section specifies rigid and flexible duct, plenum, and breaching insulation and field-applied jackets for HVAC systems. This Section includes applications for indoor and outdoor ducts.

15082—EQUIPMENT INSULATION—This Section specifies blanket, board, and block insulation and field-applied jackets for HVAC equipment. This Section includes applications for indoor and outdoor equipment.

15083—PIPE INSULATION—This Section specifies preformed pipe insulation and field-applied jackets for plumbing and HVAC piping systems and for diesel-engine cooling piping and exhaust pipes. This Section includes applications for indoor and outdoor piping.

15100—VALVES—This Section specifies general duty valves common to most mechanical piping systems. Valves specified in this Section include gate, globe, ball, butterfly, plug, and check valves.

15121—PIPE EXPANSION FITTINGS AND LOOPS—This Section specifies pipe expansion fittings and loops for steel and copper piping for mechanical systems, and the following:

15122—METERS AND GAUGES—This Section specifies meters and gauges for mechanical piping systems; thermometers, pressure gauges, and test plugs; flow-measuring systems; flowmeters and flow indicators; thermal-energy flowmeters; and water meters.

15170—MOTORS—This Section specifies small and medium electric motors for use on ac power systems up to 600 V, according to NEMA standards. The Section includes the common requirements for referencing by other Sections where motors are integral components of the specified equipment. This Section does not include dc motors, synchronous motors, wound-rotor motors, and motors rated more than 600 V. Special motor types and features are also not included; these items may be covered in the individual equipment Sections or added to this Section. Previous Edition: Same Section number and title, dated 3/91. Related Sections: Refer to the Specifications Coordination checklist at the end of this Section. Summary of Changes: The following changes were made in this edition:

- SI (metric) units were added.
- "Submittals" Article was added to the Text.
- UL standard in "Quality Assurance" Article was deleted from the Text.
- Service factor was based on NEMA MG 1 requirements.
- List of unusual service conditions was added to "Basic Motor Requirements" Article in the Text.
- Specification for energy-efficient motors was updated.
- Terminology was changed to match NEMA MG 1.
- Specification for temperature rise and insulation class was added.
- Bearing specification and specification for motors applied on variable-frequency controllers were improved.
- Option for requiring thermal protection on motors above a certain size was added.
- "Source Quality Control" Paragraph was added to "Polyphase Motors" Article in the Text.
- Installation requirements were updated.
- "Commissioning" Article was deleted from the Text.

15181—HYDRONIC PIPING—This Section specifies piping systems for hot-water heating, chilled-water cooling, and condenser water. This Section includes pipes, fittings, special-duty valves, and hydronic specialties.

MASTERSPEC continues on the next page.

15182—STEAM AND CONDENSATE PIPING—This Section specifies steam and condensate piping and specialties for systems up to 125 psig (860 kPa), inside the building.

15185—HYDRONIC PUMPS—This Section specifies the following categories of hydronic pumps for hydronic systems:

15186—STEAM CONDENSATE PUMPS—This Section specifies steam condensate pumps for low-pressure steam systems.

15189—HVAC WATER TREATMENT—This Section specifies automatic and manual water-treatment systems for hot-water heating, steam and condensate piping, chilled-water, and condenser water systems; and water-treatment chemicals.

15191—FUEL OIL PIPING—This Section specifies fuel oil and diesel fuel piping, specialties, and accessories within the building. Equipment in this Section is suitable for No. 2 and lighter fuel oil and diesel fuel.

15194—FUEL GAS PIPING—This Section specifies natural and liquefied petroleum gas piping, specialties, and accessories within the building.

15212—LABORATORY AIR AND VACUUM PIPING—This Section specifies laboratory compressed-air and vacuum piping, designated as "laboratory air" and "laboratory vacuum"; laboratory gas alarm systems; and related specialties.

15221—CHEMICAL-WASTE PIPING—This Section specifies chemical-waste and vent piping, and specialties for laboratory systems.

15241—MECHANICAL VIBRATION CONTROLS AND SEISMIC RESTRAINTS—This Section specifies vibration isolators, vibration isolation bases, vibration isolation roof curbs, and seismic restraints and snubbers.

15252—LABORATORY AIR EQUIPMENT—This Section specifies compressed-air equipment and accessories for laboratory applications. Typical equipment applicable to this Section includes air compressors, receivers, dryers, air purification systems, and air-filter assemblies.

15253—LABORATORY VACUUM EQUIPMENT—This Section specifies vacuum equipment for laboratory applications. Typical equipment applicable to this Section includes vacuum pumps and receivers.

15411—WATER DISTRIBUTION PIPING—This Section specifies water distribution piping inside the building. Most piping specified is suitable for potable water, but some non-potable-water piping is included.

15420—DRAINAGE AND VENT PIPING—This Section specifies soil, waste, and vent piping and storm drainage piping inside the building.

15430—PLUMBING SPECIALTIES—This Section specifies plumbing specialties for water distribution systems; soil, waste, and vent systems; and storm drainage systems.

15440—PLUMBING FIXTURES—This Section specifies plumbing fixtures and related components, including the following:

15441—WATER DISTRIBUTION PUMPS—This Section specifies pumps for building potable-water systems.

15444—PACKAGED BOOSTER PUMPS—This Section specifies packaged booster pumps to maintain pressure in the building water distribution piping; compact, packaged booster pumps; constant-speed-drive, packaged booster pumps; and variable-speed-drive, packaged booster pumps.

15445—SEWAGE PUMPS—This Section specifies sewage pumps for the building sanitary drainage systems, and wet-pit-mounted, vertical sewage pumps; quick-disconnect-system, submersible sewage pumps; stationary, submersible sewage pumps; sewage-pump, reverse-flow attachment; submersible, grinder sewage pumps; submersible, cutter sewage pumps; sewage pump basins; packaged, sewage pump units; and packaged, wastewater pump units.

15446—SUMP PUMPS—This Section specifies sump pumps for building storm drainage systems, and wet-pit-mounted, vertical sump pumps; submersible sump pumps; compact, submersible sump pumps; sump pump basins; sump pump pits; and packaged, drainage pump units.

15450—POTABLE-WATER STORAGE TANKS—This Section specifies potable-water storage tanks for indoor installations. This Section may also be used for nonpotable-water applications.

15465—COMPRESSED-AIR EQUIPMENT—This Section specifies equipment and accessories for building compressed-air systems operating at 200 psig (1380 kPa) and less.

15466—MEDICAL AIR EQUIPMENT—This Section specifies medical and dental air equipment and accessories for healthcare facilities. Typical equipment applicable to this Section includes air compressors, dryers, air purification systems, and filter assemblies.

15467—MEDICAL VACUUM EQUIPMENT—This Section specifies medical and dental vacuum equipment and accessories for healthcare facilities. Typical equipment applicable to this Section includes vacuum pumps and vacuum exhausters (oral evacuation).

15469—WATER SOFTENERS—This Section specifies water softeners and accessories for water-supply systems.

15480—DOMESTIC WATER HEATERS—This Section specifies only the Evaluations for the following water heater Sections for domestic water systems:

15481—COMPRESSED-AIR PIPING—This Section specifies piping and piping specialties for building compressed-air systems operating at 200 psig (1380 kPa) and less.

15482—MEDICAL GAS PIPING—This Section specifies medical gas piping and specialties for healthcare facilities. Typical medical gas systems applicable to this Section are oxygen, air, vacuum, nitrous oxide, nitrogen, carbon dioxide, waste anesthetic gas evacuation, and dental vacuum (oral evacuation).

15485—ELECTRIC, DOMESTIC WATER HEATERS—This Section specifies electric water heaters and accessories for domestic water systems.

15486—FUEL-FIRED, DOMESTIC WATER HEATERS—This Section specifies fuel-fired water heaters and accessories for domestic water systems.

15487—DOMESTIC WATER HEAT EXCHANGERS—This Section specifies heat exchangers and accessories for generating hot water for domestic water systems, and the following:

15501—HEATING BOILERS AND ACCESSORIES—This Section includes Evaluations, Drawing Coordination, and Specifications Coordination only for the following Sections covering fuel-fired and electric boilers used for building heating systems:

- 15512—CAST-IRON BOILERS: Gas-fired, oil-fired, or combination gas/oil-fired boilers for hot water or low-pressure steam.

- 15513—CONDENSING BOILERS: Gas-fired boilers for hot water.

- 15514—FINNED WATER-TUBE BOILERS: Gas-fired boilers for hot water.

- 15515—STEEL WATER-TUBE BOILERS: Gas-fired, oil-fired, or combination gas/oil-fired, heating or power boilers for low-temperature and high-temperature hot water or low-pressure and high-pressure steam.

- 15518—FIRE-TUBE BOILERS: Gas-fired, oil-fired, or combination gas/oil-fired boilers for low-temperature and high-temperature hot water or low-pressure steam; and firebox boilers for hot water or low-pressure steam.

- 15519—ELECTRIC BOILERS: Electric-resistance boilers for hot water or steam.

15511—RADIANT HEATING PIPING—This Section specifies radiant heating piping, including pipes and tubes for embedded heat-transfer heating loops, manifolds, fittings, special-duty valves, and piping specialties.

15512—CAST-IRON BOILERS—This Section specifies gas-fired, oil-fired, or combination gas/oil-fired boilers for heating hot water or low-pressure steam.

15513—CONDENSING BOILERS—This Section specifies gas-fired boilers for heating hot water.

15514—FINNED WATER-TUBE BOILERS—This Section specifies gas-fired boilers for heating hot water.

15515—STEEL WATER-TUBE BOILERS—This Section specifies gas-fired, oil-fired, or combination gas/oil-fired heating or power boilers for low- and high-temperature heating hot water or low- and high-pressure steam.

15518—FIRE-TUBE BOILERS—This Section specifies gas-fired, oil-fired, or combination gas/oil-fired boilers; Scotch or Scotch marine boilers for low-temperature and high-temperature heating hot water or low-pressure and high-pressure steam; and firebox boilers for heating hot water or low-pressure steam.

15519—ELECTRIC BOILERS—This Section specifies electric-resistance boilers for heating hot water or steam.

15520—FEEDWATER EQUIPMENT—This Section specifies feedwater equipment used to return condensate and makeup water to both high- and low-pressure steam boilers. Feedwater units specified in this Section include vacuum units and those with cast-iron or steel receivers.

15530—REFRIGERANT PIPING—This Section specifies refrigerant piping used for air-conditioning applications, including pipes, tubing, fittings, specialties, special-duty valves, and refrigerants.

15550—BREACHINGS, CHIMNEYS, AND STACKS—This Section specifies breachings, chimneys, and stacks for fuel-burning equipment, including double-wall metal vents, refractory-lined metal breachings and stacks, and fabricated breachings.

15560—FUEL-FIRED H&V UNITS—This Section includes only the Evaluations for the following new Sections specifying fuel-fired H&V units including direct- and indirect-fired units and destratification H&V units:

- 15561—DIRECT-FIRED, MAKEUP AIR UNITS
- 15562—INDIRECT-FIRED, PACKAGED H&V UNITS
- 15563—DESTRATIFICATION H&V UNITS

15561—DIRECT-FIRED, MAKEUP AIR UNITS—This Section specifies direct-fired, makeup air units that do not employ heat exchangers. Gas is burned in the airstream, and products of combustion are introduced to the space. These units include only those that are natural-gas and propane-gas fired and that are suitable for indoor and outdoor applications.

15562—INDIRECT-FIRED, PACKAGED H&V UNITS—This Section specifies indirect-fired, packaged H&V units factory assembled from standard components. Custom components and accessories can be added. Units typically include duct furnaces in parallel or series airflow, depending on heating requirements, with attached plenums housing fans, mixing sections, and other accessories. Units are suitable for indoor and outdoor applications.

15563—DESTRATIFICATION H&V UNITS—This Section specifies destratification H&V units that are large, fuel-fired units consisting of a fan, casing, and an industrial, fire-tube heat exchanger. These units are used to heat large areas of industrial buildings and warehouses. They are centrally placed in the space and circulate large volumes of air to distribute the heat throughout the space and to limit stratification. Accessories are limited.

15585—DEAERATORS—This Section specifies deaerators used to lead feedwater to steam boilers and to remove oxygen and other gases.

15610—FURNACES—This Section specifies gas- and oil-fired furnaces used in residential and light-commercial construction. It also specifies auxiliary equipment used with furnaces, including controls, filters, air cleaners, and humidifiers.

15620—FUEL-FIRED HEATERS—This Section specifies gas- and oil-fired unit heaters and duct furnaces and gas-fired, tube-type, infrared heaters. The unit heaters specified include the types normally mounted overhead indoors. The duct furnaces include both indoor and outdoor types. Tube-type infrared heaters covered include forced-draft and vacuum-vented-type units and multiple-burner, vacuum-vented systems.

15621—INDIRECT-FIRED ABSORPTION WATER CHILLERS—This Section specifies indirect-fired, hot-water and steam absorption chillers. One- and two-stage absorption chillers are specified. Single-stage absorption chillers are available from about 100- to 1700-tons (350- to 6000-kW) cooling capacity. Two-stage absorption chillers start at 350 tons (1230 kW), with the largest units providing 1500-tons (5275-kW) chilling capacity. They are used with air-conditioning systems applicable to public, institutional, commercial, and industrial buildings. The Section does not apply to chillers used for process chilling or other industrial purposes, nor does it apply to direct-fired absorption machines.

15622—DIRECT-FIRED ABSORPTION CHILLERS—This Section specifies direct-fired, two-stage absorption chillers. They range from 30- to 1100-tons (100- to 3870-kW) chilling capacity. Direct-fired, two-stage absorption chillers are used with air-conditioning systems applicable to public, institutional, commercial, and industrial buildings. Absorption chillers are not commonly used for process chilling or other industrial purposes where loads are more volatile.

15625—CENTRIFUGAL WATER CHILLERS—This Section specifies electrically driven centrifugal water chillers.

15628—RECIPROCATING WATER CHILLERS—This Section specifies reciprocating water chillers, including water-cooled, condenserless, and outdoor air-cooled types.

MASTERSPEC continues on the next page

ARCOM; Salt Lake City, Utah, and Alexandria, Virginia

1

CONSTRUCTION INFORMATION SYSTEMS

15640—PACKAGED COOLING TOWERS—This Section updated specifies factory-fabricated, mechanical-draft cooling towers.

15661—FLUID COOLERS—This Section specifies factory-fabricated, packaged, closed-circuit, mechanical-draft fluid coolers.

15663—EVAPORATIVE CONDENSERS—This Section specifies factory-fabricated, packaged evaporative condensers.

15671—CONDENSING UNITS—This Section specifies air- and water-cooled condensing units usually coupled to direct-expansion refrigerant coils in air-conditioning systems within buildings.

15672—AIR-COOLED CONDENSERS—This Section specifies air-cooled condensers used for air-conditioning systems.

15684—ROTARY-SCREW CHILLERS—This Section specifies rotary-screw chillers. Both single- and twin-screw compressors are included, along with air- or water-cooled condensers. This equipment Specification is based on capacities ranging from 20 to 1300 tons (70 to 4570 kW).

15710—HEAT EXCHANGERS—This Section specifies hydronic and steam heat exchangers for HVAC applications. Shell-and-tube heat exchangers and plate heat exchangers are also included.

15736—SELF-CONTAINED AIR-CONDITIONING UNITS (15 TONS AND SMALLER)—This Section specifies packaged air-conditioning units containing a refrigerant compressor and controls, with either integral water-cooled condensing or integral or remote air-cooled condensing. These units are designed for indoor installations, usually in the finished space, for capacities through 15 tons (50 kW).

15737—SELF-CONTAINED AIR-CONTAINING UNITS (LARGER THAN 15 TONS)—This Section specifies packaged air-conditioning units containing a refrigerant compressor and controls, with either integral water-cooled condensing or remote air-cooled condensing. These units are designed for indoor installations for capacities larger than 15 tons (50 kW).

15738—SPLIT-SYSTEM AIR-CONDITIONING UNITS—This Section specifies air-conditioning units consisting of two factory-made assemblies with a direct-expansion refrigeration system. The separate components include an evaporator coil and a fan, and a compressor and condenser. Units may be configured to operate as heat pumps.

15745—WATER-SOURCE HEAT PUMPS—This Section specifies water-source heat pumps used for air-conditioning systems in residential, commercial, industrial, and institutional buildings. The types specified in this Section are rooftop units to 25 tons (88 kW); vertical stack units to 2 tons (7 kW); concealed horizontal and vertical units to 25 tons (88 kW); exposed, floor-mounted console units to 1 1/2 tons (1.8 kW); and unit ventilator units to 4 tons (14 kW).

15752—HUMIDIFIERS—This Section specifies steam-injection, self-contained, heated-pan, and heat-exchanger humidifiers for application on ducted HVAC systems; and steam-injection and self-contained humidifiers for discharging vapor directly into conditioned space.

15761—AIR COILS—This Section specifies air coils using steam, hot water, electric resistance, chilled water, and refrigerants not integral to equipment.

15763—FAN-COIL UNITS—This Section specifies hydronic or direct-expansion cooling fan-coil units with or without supplemental hydronic, steam, and electric heat, including units for concealed installation with external duct connections and units with finished cabinets for surface and recessed mounting in ceilings or walls.

15764—RADIATORS—This Section specifies baseboard radiators, convectors, finned-tube radiators, and steel radiators for hot-water and steam heating systems.

15766—CABINET UNIT HEATERS—This Section specifies hydronic, steam, and electric cabinet unit heaters.

15767—PROPELLER UNIT HEATERS—This Section specifies hot-water, steam, and electric unit heaters.

15768—UNIT VENTILATORS—This Section specifies electric, hydronic, and steam unit ventilators.

15769—RADIANT HEATING PANELS—This Section specifies electric and hydronic radiant heating panels designed as surface-mounting units and for installing in lay-in ceilings with an exposed-grid support system.

15775—ELECTRIC HEATING CABLES—This Section specifies electric heating cables used for radiant heating, snow melting and ice stopping, pipe freeze protection, and hot-water-temperature maintenance.

15782—ROOFTOP UNITS—This Section specifies rooftop cooling units used for air-conditioning systems in commercial, industrial, and institutional buildings. Units contain air-cooled, direct-expansion refrigeration with heating options such as gas fired, hot water, and steam.

15783—COMPUTER-ROOM AIR-CONDITIONING UNITS—This Section specifies floor- and ceiling-mounted unitary air-conditioning units, and their accessories, intended specifically for computer-room applications.

15784—PACKAGED TERMINAL AIR-CONDITIONING UNITS—This Section specifies packaged, freestanding or through-the-wall, terminal air-conditioning and heat-pump units, including their accessories and controls.

15812—FIBROUS-GLASS DUCTS—This Section specifies rectangular and round fibrous-glass ducts for heating, ventilating, and air-conditioning systems.

15815—METAL DUCTS—This Section specifies rectangular, round, and flat-oval metal ducts; and duct fittings, supports, and liners for HVAC air-distribution systems. Applications include supply-, return-, outside-air, and exhaust ducts. Leakage testing, duct construction static-pressure classes, and leakage classes are specified in this Section.

15816—HVAC CASINGS—This Section specifies field-erected sheet metal casings used as equipment enclosures and plenums. HVAC casings can be field or factory fabricated; this Section allows for either method to be specified.

15820—DUCT ACCESSORIES—This Section specifies duct accessories, including dampers, actuators, duct silencers, turning vanes, duct-mounted access doors and panels, flexible ducts, flexible connectors, and duct accessory hardware.

15834—AIR CURTAINS—This Section specifies air curtains for insect and thermal protection of entranceways. Optional features for air curtains specified in this Section include heating coils and indirect-fired gas heaters, filters, intake louvers, and adjustable discharge nozzles.

15845—AIR TERMINALS—This Section specifies ducted air-control and distribution devices used in commercial air-distribution systems that control air volume and air temperature.

15846—AIR-TO-AIR ENERGY RECOVERY UNITS—This Section specifies energy recovery units designed for air-to-air energy transfer, including heat wheels, heat-pipe heat exchangers, and fixed-plate exchangers. Section includes devices for built-in air movement systems and those packaged as self-contained units.

15850—FANS—This Section includes the supporting documents (Evaluations, Drawing Coordination, and Specifications Coordination) for the following Sections specifying fans:

- 15851—CENTRIFUGAL FANS for indoor installations
- 15852—AXIAL FANS for indoor installations
- 15853—POWER VENTILATORS for indoor or outdoor installations

15851—CENTRIFUGAL FANS—This Section specifies centrifugal fans for indoor installations.

15852—AXIAL FANS—This Section specifies axial fans for indoor installations.

15853—POWER VENTILATORS—This Section specifies power ventilators for indoor or outdoor installations.

15854—CENTRAL-STATION AIR-HANDLING UNITS—This Section specifies central-station air-handling units with coils for indoor installations.

15855—DIFFUSERS, REGISTERS, AND GRILLES—This Section specifies outlet and inlet air terminals, including diffusers, registers, and grilles.

15861—AIR FILTERS—This Section specifies factory-fabricated air-filter devices and media used to remove particulate matter from air for HVAC applications.

15900—HVAC INSTRUMENTATION AND CONTROLS—This Section specifies control components, required for a complete control system, found in most HVAC control systems.

15940—SEQUENCE OF OPERATION—This Section specifies control sequences in HVAC systems. It includes examples of operation sequences that require editing to make them apply to the specific equipment and systems installed, desired operational intent, and Project conditions.

15990—TESTING, ADJUSTING, AND BALANCING—This Section specifies testing, adjusting, and balancing air and water distributions, measuring electrical performance of HVAC equipment, setting quantitative performance of HVAC equipment, verifying that automatic control devices are properly functioning, measuring sound and vibration, and reporting results of the activities and procedures specified in this Section.

DIVISION 16

16050—BASIC ELECTRICAL MATERIALS AND METHODS—This Section specifies basic materials and methods for electrical installations, including basic Specifications for raceways, building wire, supporting devices, concrete bases, and electric identification. It also includes electrical demolition, electrical component touchup painting, cutting and patching for electrical construction, and electricity-metering equipment for Owner's and utility company's use.

16060—GROUNDING AND BONDING—This Section specifies grounding of low- and medium-voltage systems and equipment. It also covers minimum requirements for grounding electronic and other specialized systems and equipment, including those for data processing and telecommunications. This Section also provides options for specifying grounding requirements beyond the safety minimums for both power and electronic systems.

16071—SEISMIC CONTROLS FOR ELECTRICAL WORK—This Section specifies anchorage, fastening, and bracing devices used to prevent undesired movement of electrical components during earthquakes. It can be edited for use in any of the following Project situations:

16075—ELECTRICAL IDENTIFICATION—This Section specifies identification for electrical work, including raceways, cables, and equipment; warning and caution signs; and buried-cable warning tape. It is applicable on projects where identification requirements are more complex than can be covered by the basic electrical identification specifications included in Division 16 Section "Basic Electrical Materials and Methods."

16120—CONDUCTORS AND CABLES—This Section specifies low-voltage building wires and cables, including taps and splices.

16121—CONTROL/SIGNAL TRANSMISSION MEDIA—This Section specifies transmission media used for control and signal circuits for building projects. The Section includes copper conductor cables, optical fiber cables, and associated equipment for use in buildings, typically for interconnecting components of electronic data-processing, telephone, television, teleconferencing, building management and protection, and satellite communication systems.

16122—UNDERCARPET CABLES—This Section specifies flat cables for undercarpet installations in building projects. Undercarpet cables are available in two types to accommodate power and telecommunications branch circuits.

16124—MEDIUM-VOLTAGE CABLES—This Section specifies single-conductor and multiconductor cables, cable splices, and terminations for electrical distribution systems with voltages from 2001 to 35,000. This Section also specifies accessory products used directly with medium-voltage cables including splices, terminations, separable connectors, and fault indicators.

16130—RACEWAYS AND BOXES—This Section specifies electrical conduits, tubing, surface raceways, and wireways used for electrical power and signal distribution; electrical outlet, device, floor, pull, and junction boxes; raceway fittings; cabinets; and hinged-box assemblies.

16138—UNDERFLOOR RACEWAY—This Section specifies underfloor raceways, including conventional flattop, trench type, flush type, and cellular; service fittings; and junction boxes. It also specifies materials and labor for raceway connections to cellular metal deck specified in Division 5 and cellular concrete floor raceway specified in Division 3.

16139—CABLE TRAYS—This Section specifies metal cable trays used for supporting electrical wires and cables. Cable trays are also used for supporting electrical conduit and tubing systems and mechanical tubing and piping.

16140—WIRING DEVICES—This Section specifies electrical wiring devices including receptacles, snap switches, plugs, and plug connectors. This Section also specifies wall plates, floor service outlets, poke-through assemblies, telephone/power service poles, and multioutlet assemblies. Receptacle types specified include ground-fault circuit interrupters, integral surge suppression units, and isolated-ground receptacles. This Section also specifies simple dimmer switches but does not include dimmer systems. (See Division 16 Section "Lighting Control Equipment.")

MASTERSPEC continues on the next page.

ARCOM; Salt Lake City, Utah, and Alexandria, Virginia

- 16145—LIGHTING CONTROL DEVICES—This Section specifies devices for automatic control of lighting including time switches, photoelectric relays, occupancy sensors, and multipole lighting relays and contactors.
- 16215—ELECTRICAL POWER MONITORING AND CONTROL—This Section specifies an electronic interface with circuit protective devices in a power distribution system for both remote and local monitoring, metering, and control of individual circuits. It also specifies optional integration with the building automation system to extend the capabilities of that system.
- 16231—PACKAGED ENGINE GENERATORS—This Section specifies simple systems using a single diesel-engine generator set for emergency or standby electrical power applications. Use this Section to specify systems with standby ratings from 20 through 1500 kW, supplying systems rated 600 V and less.
- 16264—STATIC UNINTERRUPTIBLE POWER SUPPLY—This Section specifies 3-phase, on-line, static-type, uninterruptible power supply (UPS) units rated from 5 to 750 kVA for systems 600 V and less. This Section can be used to specify lower-rated units in this range that are suitable for location in a computer room or other finished space. Higher-rated units are usually installed separately from the loads served.
- 16265—CENTRAL BATTERY INVERTER—This Section specifies central battery inverters for supplying power to emergency and standby lighting and power circuits. These units combine a battery source with a charger and inverter. Units obtain power from a normal ac supply and are arranged to sense failure of that supply. When failure occurs, units transfer the load to the battery through the inverter. The approximate capacity range of equipment specified in this Section is from 0.5 to 20 kVA.
- 16280—POWER FACTOR CORRECTION CAPACITORS—This Section specifies capacitor-type, power factor correction equipment for use in electrical power systems rated 600 V and less. It also specifies fixed capacitors and automatic power factor correction units.
- 16288—VOLTAGE REGULATORS—This Section specifies voltage regulators and the power distribution units that often combine voltage regulators with other equipment for particular application in computer rooms and other environments.
- 16289—TRANSIENT VOLTAGE SUPPRESSION—This Section specifies transient voltage surge suppressors for application on low-voltage electrical power systems.
- 16312—SECONDARY UNIT SUBSTATIONS—This Section specifies indoor and outdoor secondary unit substations, including common types and configurations of incoming and transformer sections. This Section does not specify secondary distribution equipment directly but refers to other Sections for those requirements.
- 16315—OVERHEAD ELECTRICAL DISTRIBUTION—This Section specifies medium- and secondary-voltage overhead electrical power distribution up to 35 kV. It includes pole-mounting transformers and other equipment and materials used for upgrades or for extensions for projects associated with buildings or related construction.
- 16341—MEDIUM-VOLTAGE SWITCHGEAR—This Section specifies fusible metal-enclosed interrupter switchgear and metal-clad circuit-breaker switchgear used in indoor and outdoor equipment up to 34-kV class. This Section also specifies major accessory components used with medium-voltage switchgear, including grounding and test devices, fuses, emergency operating stations, and switchgear control batteries and chargers.
- 16350—MEDIUM-VOLTAGE TRANSFORMERS—This Section specifies transformers up to about 2500 kVA with medium-voltage primaries. Transformers in this Section are for both indoor and outdoor installation and are liquid-filled and dry-type distribution and power transformers.
- 16410—ENCLOSED SWITCHES AND CIRCUIT-BREAKERS—This Section specifies enclosed switches and circuit breakers rated 600 V and less where applied as individually mounted disconnecting means, service disconnecting means, and circuit overcurrent protection. Enclosed switches include fused and nonfused types rated 800 A and less. Circuit breakers include integrally fused circuit breakers and molded-case circuit breakers with thermal-magnetic and electronic trip units.
- 16415—TRANSFER SWITCHES—This Section specifies transfer switches and associated equipment rated 600 V and less for emergency and standby power systems. It specifies automatic transfer switches with and without bypass/isolation switches, and it specifies nonautomatic transfer switches. It also specifies the remote annunciator panels and annunciator and control panels sometimes used with automatic transfer-switch installations.
- 16419—FUSED POWER CIRCUIT DEVICES—This Section specifies bolted-pressure switches and other high-pressure contact switches rated 800 to 6000 A, 600 V or less, and accommodating Class L or Class T fuses.
- 16430—SWITCHGEAR—This Section specifies metal-enclosed, drawout, power, circuit-breaker switchgear rated 600 V and less, for use in ac systems.
- 16441—SWITCHBOARDS—This Section specifies dead-front distribution switchboards rated 600 V and less.
- 16442—PANELBOARDS—This Section specifies branch-circuit and distribution panelboards rated 600 V and less. It includes load-center-type and power-distribution panelboards with circuit-breaker or fused-switch devices. The Section also includes panelboards with integrally mounted transient voltage surge suppressor (TVSS) devices, panelboards with motor-starter branch devices, and panelboards with internal contactors and other features.
- 16450—ENCLOSED BUS ASSEMBLIES—This Section specifies standard low-voltage feeder and plug-in enclosed bus assemblies for power distribution in buildings.
- 16461—DRY-TYPE TRANSFORMERS (1000 V AND LESS)—This Section specifies dry-type distribution and specialty transformers rated 1000 V and less. Specialty transformers include buck-boost and control and signal units.
- 16481—MOTOR CONTROLLERS—This Section specifies general-purpose controllers rated 600 V and less used for starting, stopping, and controlling the speed of ac motors. This Section specifies manual controllers and magnetic and solid-state units. It also specifies auxiliary devices such as push buttons, selector switches, pilot lights, and control relays used with controllers. This Section specifies individually enclosed and mounted controllers. Basic controllers for use in group-mounted installations such as motor-control centers, switchboards, and motor-starter panelboards are specified in their respective Sections.
- 16482—MOTOR-CONTROL CENTERS—This Section specifies conventional, modular, freestanding motor-control centers operating at 600 V, ac and less.
- 16491—FUSES—This Section specifies cartridge fuses, rated 600 V and less, for use in switches, panelboards, switchboards, controllers, and motor-control centers. Use this Section with Sections specifying the above equipment.
- 16511—INTERIOR LIGHTING—This Section specifies factory-fabricated interior lighting fixtures and lighting fixtures mounted on exterior building surfaces used for general, supplemental, task, and emergency lighting applications.
- 16521—EXTERIOR LIGHTING—This Section specifies factory-fabricated exterior lighting fixtures, poles, and accessories.
- 16555—STAGE LIGHTING—This Section specifies stage lighting equipment for live performances in moderate-size auditoriums in schools, community centers, museums, and corporate centers. This Section also specifies stage lighting fixtures and control systems, including dimmer banks and a control console. Use this Section for limited-scope projects.
- 16570—DIMMING CONTROLS—This Section specifies three types of modular dimming systems and a range of wired, programmable, low-voltage lighting control systems. Time switches, photoelectric relays, and occupancy sensors are included. This Section also specifies relays and contactors required to execute on-off control commands for lighting circuits. Manual, low-voltage lighting control switches are also specified.
- 16715—PREMISES TELEPHONE WIRING—This Section specifies premises wiring for residential and light-commercial telephone distribution, with one to four service lines installed. Some projects may require that the cable and cable-terminating work for the system be provided under a separate telephone equipment contract. In such cases, delete those items and use this Section to specify the empty raceway system and the service provisions that will be required for the system.
- 16722—INTERCOMMUNICATION EQUIPMENT—This Section specifies direct-connected, manually switched and user-programmable, multichannel, microprocessor-switched, voice intercommunication equipment independent of telephone and other voice-data communication systems. This Section includes commercial, institutional, and industrial applications, but not residential systems, either single or multifamily.

16723—SCHOOL INTERCOM AND PROGRAM EQUIPMENT—This Section specifies voice intercommunication equipment for use in elementary and secondary schools. The Section permits the specifier to select between manually and microprocessor-switched equipment. The manually switched system is specified as the conventional, direct-connected, keyed system. The microprocessor-switched system is user programmable and can be upgraded in the future. Both systems are specified with the usual options for selective paging and for clock and program interface. The ability to transmit programmed audio material to classrooms and other spaces is also specified.

16725—NURSE CALL—This Section specifies basic visual and audiovisual patient-nurse communication equipment for healthcare facilities. Section organization permits the specifier to select between two equipment options: visual/ tone and audiovisual/voice. Both types of equipment are primarily used in small institutions. The selection is based on communication needs, existing equipment coordination requirements, staff preference, and budgetary planning.

16726—PUBLIC ADDRESS AND MUSIC EQUIPMENT—This Section specifies public address and music equipment. It can be used to specify equipment for background music, announcements, and paging and for giving instructions in such locations as stores, public places, waiting rooms, warehouses, offices, industrial plants, and schools. Features covered in this Section, such as the paging console, can be deleted for projects that do not require them. Other features may be added.

16727—SOUND-MASKING EQUIPMENT—This Section specifies electronic sound-masking equipment to help achieve privacy for normal conversation in indoor spaces, particularly in open office areas.

16740—COMMUNICATION AND DATA-PROCESSING EQUIPMENT—This Section specifies basic interior wiring for telecommunications systems in buildings. The communication wiring specified in this Section is suitable for local area networks (LANs) and telephone systems for voice and data communications. LAN media included in this Section support generic low- and high-speed LANs for data transmission rates up to 100 Mbps or more. System components included in this Section are items such as copper and fiber-optic cable, connecting blocks, outlet assemblies, cross connects, and patch panels.

16850—TELEVISION EQUIPMENT—This Section specifies closed-circuit television (CCTV) and master antenna television (MATV) systems. For MATV systems, this Section includes the options of off-air antennas, a community antenna television (CATV) service, a local CCTV system, and television receive-only earth stations as signal sources for television program material. Both fiber-optic and copper cabling are included for transmitting video signals.

PRELIMINARY SUBSURFACE INFORMATION

- A. Collect available information for soil, rock, and water conditions, including the following:
 1. Topographic and aerial mapping.
 2. Geological survey maps and publications.
 3. Local knowledge (history of site development, experience of nearby structures, flooding, subsidence, etc.).
 4. Existing subsurface data (boreholes, well records, water soundings).
 5. Reconnaissance site survey.
 6. Previous studies.
- B. Evaluate available information for site acceptability. If available data are insufficient, consult a geotechnical engineer to perform a limited subsurface investigation to gather basic information.
- C. Consult geotechnical engineer for potential foundation performance at each site as part of the selection process.

DETAILED SUBSURFACE INFORMATION

After selection of a potential site a subsurface and laboratory test investigation should be carried out by a qualified geotechnical engineer before design is undertaken.

The investigation should provide an adequate understanding of the subsurface conditions and the information should be assessed to determine potential foundation behavior.

The engineer should evaluate alternative foundation methods and techniques in conjunction with the architect.

The engineer or architect should provide inspection during construction to ensure that material and construction procedures are as specified and to evaluate unexpected soil, rock, or groundwater conditions that may be exposed by excavations.

SOIL TYPES AND THEIR PROPERTIES

DIVISION	SYMBOLS			SOIL DESCRIPTION	VALUE AS A FOUNDATION MATERIAL	FROST ACTION	DRAINAGE
	LETTER	HATCHING	COLOR				
Gravel and gravelly soils	GW		Red	Well-graded gravel, or gravel-sand mixture, little or no fines	Excellent	None	Excellent
	GP		Red	Poorly graded gravel, or gravel-sand mixtures, little or no fines	Good	None	Excellent
	GM		Yellow	Silty gravels, gravel-sand-silt mixtures	Good	Slight	Poor
	GC		Yellow	Clayey-gravels, gravel-clay-sand mixtures	Good	Slight	Poor
Sand and sandy soils	SW		Red	Well-graded sands, or gravelly sands, little or no fines	Good	None	Excellent
	SP		Red	Poorly graded sands, or gravelly sands, little or no fines	Fair	None	Excellent
	SM		Yellow	Silty sands, sand-silt mixtures	Fair	Slight	Fair
	SC		Yellow	Clayey sands, sand-clay mixtures	Fair	Medium	Poor
Silt and clays LL < 50	ML		Green	Inorganic silts, rock flour, silty or clayey fine sands, or clayey silts with slight plasticity	Fair	Very high	Poor
	CL		Green	Inorganic clays of low to medium plasticity, gravelly clays, silty clays, lean clays	Fair	Medium	Impervious
	OL		Green	Organic silt-clays of low plasticity	Poor	High	Impervious
Silt and clays LL > 50	MH		Blue	Inorganic silts, micaceous or diatomaceous fine sandy or silty soils, elastic silts	Poor	Very high	Poor
	CH		Blue	Inorganic clays of high plasticity, fat clays	Very poor	Medium	Impervious
	OH		Blue	Organic clays of medium to high plasticity, organic silts	Very poor	Medium	Impervious
Highly organic soils	Pt		Orange	Peat and other highly organic soils	Not suitable	Slight	Poor

- NOTES
1. Consult geotechnical engineers and local building codes for allowable soil bearing capacities.
 2. LL indicates liquid limit.

NOTES

1. For deep excavations, several tiers of bracing may be necessary.
2. If a subgrade of the excavation is used to install spread footings or mats, proper dewatering procedures may be required to avoid disturbing the bearing level.
3. At times, it may be possible to improve the bearing stratum by excavating compressible materials and replacing them with compacted granular backfill.
4. For evaluation of problems encountered with sheeting and shoring, consult a foundation engineer.
5. Local codes and OSHA regulations must be considered. Consult a foundation engineer for excavation design.
6. Proximity of utilities and other structures must be considered in excavation design.

CONCRETE

NOTES

1. A mandrel is a member inserted into a hollow pile to reinforce the pile shell while it is driven into the ground.
2. Timber piles must be treated with wood preservative when any portion is above the groundwater table.
3. Uncased piles smaller than 30 inches should be installed using a continuous flight hollow stem auger with grout injected under pressure. Alternatively, a heavy wall casing is used to compact zero slump concrete to enlarge the base of the pile and assure pile continuity.
4. Uncased piers 30 inches in diameter and larger are installed using various types of augers and may be enlarged at the base using a belling tool in some soils. Refer to ACI 336.1 and ACI 336.3.

2 PILES AND CAISSONS

TYPES OF WATER SUPPLY

Water supply systems commonly employed for residential use are public water supply systems (mains); wells; cisterns/ rainwater catchments; natural springs; natural waterways (ponds, lakes, streams, rivers); and distillation.

GENERAL NOTES

- All water supply systems should be inspected, tested, and approved by local or state authorities, as required, before operation.
- Flush newly installed systems with fresh water, disinfect to remove contaminants, and perform bacteriological and chemical tests as required. Repeat testing on a regular basis, biennially or as recommended by health authorities.
- Surface contamination can extend to depths of 20 ft (or greater, depending on soil material). Seal casing/piping joints and voids surrounding the piping to prevent contamination seepage.
- Depending on the source, groundwater is generally cleaner and more pure than surface water. The ultimate use of the water (for toilet or laundry, irrigation, watering farm animals, human drinking and bathing) determines purity requirements. Consider disinfection and filtration systems to remove harmful bacteria and excessive impurities and minerals that affect water taste or quality.
- "Graywater" (water retrieved from bathing, laundry, or kitchen sources) can easily be filtered, stored, and recycled for nonpotable uses such as toilets, car washing, or irrigation. In addition, it can be processed through natural biological systems and returned to potable uses.

WELLS

Well details given here are generally from the *Manual of Individual Water Supply Systems* prepared by the Environmental Protection Agency's Office of Drinking Water (1982).

WELL LOCATION: Wells should be located at least 100 ft from (septic tank) sewage disposal. Check local codes.

CAPACITY OF WELL, PUMP, AND PRESSURE TANK: After drilling, test capacity for at least 4 hrs at a constant yield and drawdown. Determine minimum acceptable well capacity from the chart on this page titled "Determining Recommended Pump Capacity," then add a factor of safety and usage, preferably 100%. Use the same chart to determine the required pump capacity. The capacity of the pressure tank is figured by multiplying the pumping rate by 5 or 10 (42 gal minimum).

If a well does not have a pump capacity shown in the chart on this page, provide a smaller well pump and storage tank followed by a circulating pump and pressure tank.

DISINFECTION: Wells and associated piping should be disinfected before they are put into operation.

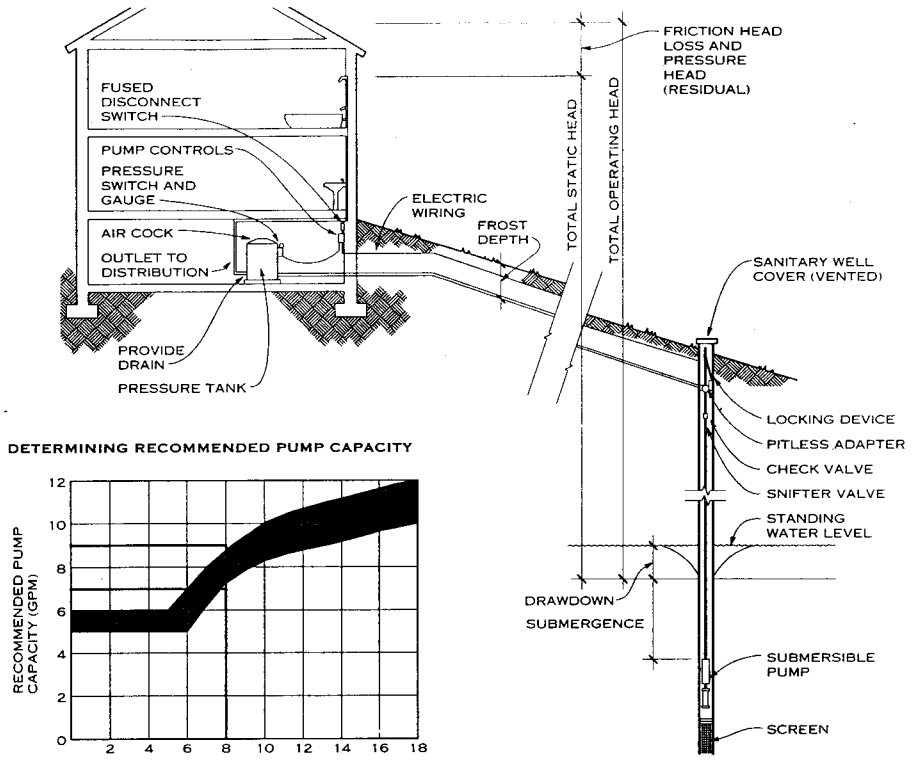

TYPES OF WELL PUMPING SYSTEMS: Pumping systems used for wells include a centrifugal pump with a motor aboveground and below the water level in the well; a jet pump, which has both pump and motor aboveground; and direct and reciprocating pumps in the well with a motor aboveground. (An artesian well is one in which the power of the water pressure elevates a column of water above the original water level without pumps.)

CISTERNS

Cisterns are man-made collection reservoirs (usually covered to stop evaporation) that store rainwater collected from roofs or paved areas called catchments. Cisterns are made of steel, polyethylene, concrete, and other chemically inert materials.

TYPES OF WELLS

TYPE	DEPTH	DIAM.	REMARKS
Dug	To 50 ft	3-20 ft	"Wishing well" type; masonry lining; can absorb surface contamination; susceptible to periodic dry spells
Bored	To 100 ft	2-30 in.	Bored with augers; vitrified tile or steel pipe casing; seal joints to 20-ft depth to prevent surface contamination
Driven	To 50 ft	1-2 in.	Driven by well-points; coupled pipe section casing; quick and cheap but shallow depth
Drilled	To 1000 ft	4-24 in.	Drilled by percussion or rotary bit; plastic or steel casing installed after full depth is drilled; expensive, large machinery required but greatest depths/water availability and constancy

DETERMINING RECOMMENDED PUMP CAPACITY

TYPICAL DRILLED WELL AND DOMESTIC WATER DISTRIBUTION

ROOF CATCHMENT CALCULATION FOR CISTERN DESIGN

Nonresistive materials are used for catchment areas and drainpipes. Water from cisterns may be used for emergencies only or for garden watering, cleaning, toilet flushing, bathing, laundry, dishwashing, or other, nonpotable uses.

Major factors used to estimate cistern capacity are amount of rainfall in the catchment area, effective collections surface, storage capacity, user water consumption per day, longest dry period for the region, and availability of other sources of water for emergencies. Basically, cistern size comes down to the relationship between how fast the tank is emptied and how fast it is filled and how much of a buffer is required. For residential use, consumption ranges from 30-50 gal/person/day. Water is produced at a rate between 0.4 and 0.6 gal/sq ft of catchment area per in. of rain. Consult local meteorological records and codes to determine cistern design.

SAND FILTER DIVERSION VALVE CISTERN TYPES FOR WATER PURIFICATION

NOTES ON CISTERNS

- Locate cisterns as close as practical to the ultimate point of use and away from potential flooding to avoid contamination.
- Screen inlet and outlet piping to prevent the entrance of debris, insects, or animals.
- Provide sump, drainage, and lockable access for annual cleaning and disinfection of the storage tank.

CAPACITIES OF TANKS AND CISTERNS (GALLONS)

DEPTH (FT)	SQUARE TANK SIZES			ROUND TANK SIZES (DIAM.)

GENERAL

Subsurface drainage systems are very different engineering designs than surface drainage systems. Surface drainage systems intercept and collect storm water runoff and convey it away from a building and site with the use of large inlets and storm drains. Subsurface drainage systems typi-

cally are smaller in size and capacity, designed to intercept the slower underground flows of a natural groundwater table, underground stream, or infiltration of soils from surface sources. Surface and subsurface systems typically require discharge either through a pumping station or by gravity drainage to an adequate outfall.

NOTES

1. The depth of a drain determines how much subsurface water levels will be reduced.
2. When a perforated drain is used, install it with the holes facing down.
3. When used to intercept hillside seepage, the bottom of a trench should be cut a minimum of 6 in. into underlying impervious material.

TYPICAL PERIMETER FOOTING DRAIN

SECTION

PLAN

NOTES

1. Subsoil drainage systems are laid out to meet the needs of a site. A grid, parallel lines, or random pattern at low points in the topography is used to collect subsurface water.
2. Depth and spacing of subsoil drainage pipes depend on soil conditions. Geotechnical design may be required to ensure effective operation of a subsoil drainage system.

SECTION

PLAN

UNDER-BUILDING SUBSOIL DRAINAGE

TYPICAL SUBSURFACE DRAIN

NOTE

Dry wells provide an underground disposal system for surface runoff, but their effectiveness is in direct proportion to the porosity of surrounding soils, and they are efficient only for draining small areas. High rainfall runoff rates cannot be absorbed at the rather low percolation rates of most soils, so the difference is stored temporarily in a dry well. Efficiency is reduced during extended periods of wet weather, when receiving soils are saturated and the well is refilled before it drains completely.

NOTE
Ditches in open surface drainage systems typically are covered with grass, either seeded with a protective covering or laid with sod.

OPEN SYSTEM

SURFACE DRAINAGE SYSTEM TYPES (IMPERVIOUS PAVING)

GENERAL

Surface drainage systems are designed to collect and dispose of rainfall runoff to prevent the flow of water from damaging building structures (through foundation leakage), site structures, and the surface grade (through erosion). The two basic types of surface drainage are the open system and the closed system.

The open system, which utilizes a ditch/swale and culvert, is used in less densely populated, more open areas where the flow of water above grade can be accommodated fairly easily. The closed system, which utilizes pipes, an inlet/catch basin, and manholes, is used in more urban, populated areas, where land must be used efficiently and water brought below the surface quickly to avoid interference with human activity. The two systems are commonly combined where terrain, human density, and land uses dictate.

A pervious or porous paving system is often used for parking and other hard site surfaces. This drainage system allows water to percolate through the paved surface into the soil, similar to the way the land would naturally absorb water.

NOTES

- All slopes, grades, swales, and other drainage features must be laid out according to the ADA, without restricting accessible routes for persons with disabilities.
- Lay out grades so runoff can safely flow away from buildings. If drains become blocked, backed-up water should not accumulate around the foundation.
- An open system, or one in which water is kept on top of the surface as long as possible, is generally more economical than a closed system.
- Consider the effect of ice forming on the surface when determining slopes for vehicles and pedestrians.
- Consult local codes on such criteria as intensity and duration of rainstorms and allowable runoff for the locality.
- Formulas given on this page are meant for approximation only. Consult a qualified engineer or landscape architect to design a site-specific system.

RUNOFF VELOCITY

VELOCITIES (Channel)	MIN. (ft/sec)	MAX. (ft/sec)
Grass—athletic field	0.5	2
Walks—long.	0.5	12*
Walks—transverse	1	4
Streets—long.	0.5	20
Parking	1	5
Channels—grass swale	1	8
Channels—paved swale	0.5	12

*8.3% maximum for handicapped access

CLOSED SYSTEM

NOTE

Following is a simplified method for calculating the approximate runoff of areas less than 100 acres:

$Q = C \times I \times A$
 $Q = \text{flow (cu ft/sec)}$
 $C = \text{surface runoff value (see table)}$
 $I = \text{intensity (in./hr; obtain from local codes)}$
 $A = \text{area of site (acres)}$

For example, assume the local code requires $I = 5 \text{ in./hr.}$

$Q = C \times I \times A$
 $Q = 0.9 \times 5 \times 0.23$
 $Q = 1.04 \text{ cu ft/sec}$
 $Q = \text{approximate volume of water per second entering the V-channel from the parking lot}$

CALCULATION OF RUNOFF

SURFACE RUNOFF VALUES (C)

SURFACE	VALUE
Roofs	0.95-1.00
Pavement	0.90-1.00
Roads	0.30-0.90
Bare soil—sand	0.20-0.40
Bare soil—clay	0.30-0.75
Grass	0.15-0.60
Commercial development	0.60-0.75
High-density residential development	0.50-0.65
Low-density residential development	0.30-0.55

NOTE

All values are approximate.

POROUS PAVING SYSTEM

POROUS PAVING MATERIALS

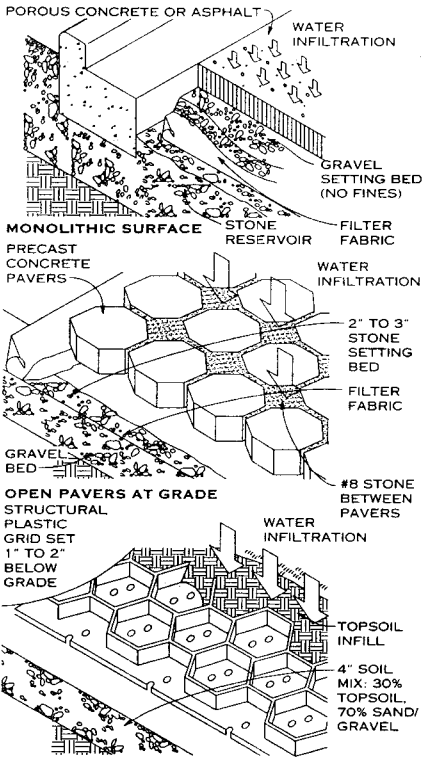

The two principal types of porous paving are a monolithic surfacing material and unit pavers. Monolithic porous paving is stone aggregate bound with asphalt or portland cement. The aggregate must be sorted to exclude the "fines" or sand-sized particles that normally fill the voids between larger pieces. Without the fines, the paving material allows water to run through it. Generally, porous asphalt and concrete are both strong enough for parking and roadway surfaces and pedestrian uses. Precast unit pavers, with shapes that allow water to flow through them, can also give surface stability for parking or driveways. Paver types are available for exposed placement or for burial just below the surface. In the latter case, the soil-pea gravel or vegetation in the pavers is exposed and can help percolate precipitation into the ground.

To reduce runoff and increase water absorption, porous paving must be underlaid with a bed of unbound aggregate. The unbound aggregate acts as a structural support and forms a reservoir to hold precipitation until it can percolate into the soil. Use of porous paving may permit use of a significantly smaller and simpler storm drainage system.

SLOPES

DESCRIPTION	MIN. %	MAX. %	REC. %

STRUCTURAL GRID/PAVERS BELOW GRADE
 POROUS PAVING TYPES

METHOD FOR SIZING CHANNELS

Channels and pipes for handling water runoff may be sized by determining the flow of water (Q) with the formula $Q = Va$. V is the velocity of the runoff water in ft/sec as determined by the Manning formula, and "a" is the cross-sectional area of water given in square feet. For a given Q, adjust the channel or pipe shape, size, and/or slope to obtain the desired velocity (one that will not erode earth, grass ditches, or other features).

The Manning formula is $V = 1.486/n \times r^{0.67} \times S^{0.5}$, in which n = values relating to surface characteristics of channels (see table), r = hydraulic radius (see table), and S = slope (the drop in ft/length).

For example, assume a 200-ft concrete V-channel for which
 W = 2 ft
 h = 0.5 ft
 S = 0.005 (1 ft/200 ft)
 r = 0.37 (calculated using V-channel properties)
 $V = (1.486/0.015) \times 0.25^{0.67} \times 0.005^{0.5}$
 = 2.6 ft/sec (see runoff velocity table on first AGS surface drainage page).

To check flow, follow these steps:

$Q = Va$ ("a" from channel properties)
 = 2.6 x 0.5 = 1.3 cu ft/sec.

Use the formula for calculating runoff ($Q = C \times I \times A$; given on the first AGS surface drainage page) to determine the flow required for a site; compare it to the capacity of a channel sized according to the Manning formula to determine whether the channel design is satisfactory.

n VALUES FOR MANNING FORMULA

CHANNEL SURFACE	n
Cast iron	0.012
Corrugated steel	0.032
Clay tile	0.014
Cement grout	0.013
Concrete	0.015
Earth ditch	0.023
Cut rock channel	0.033
Winding channel	0.025

POROUS PAVING AND STONE RESERVOIR DETAIL

NOTES ON POROUS PAVING

1. Soils around porous paving installations must have a minimum percolation rate of about 1/2 in./hr and should not be more than about 30% clay. On sites where the slope is greater than 3%, terracing the paved areas allows the bottom of each reservoir to remain level.
2. Proper specification and supervision are important in the installation of porous paving materials. Soil under the reservoir must not be unduly compacted during construction.
3. Porous concrete can withstand heavier loads than porous asphalt. Because it does not soften in hot weather and may be more susceptible to freeze-thaw damage, it is better suited to warmer climates. Additives may be introduced to improve cold climate performance.

4. Porous asphalt has good freeze-thaw resistance but is best suited for areas in which traffic is limited, such as employee parking.
5. While clogging of monolithic porous paving is generally not a problem, recommended maintenance may include use of a hydrovac once or twice a year, as well as the prompt removal of leaves and windblown sand.
6. The reservoir below porous paving has no fixed depth but is designed according to the slope of the site, the soil percolation rate, and the size of the design storm. Consult a civil engineer or landscape architect.

GENERAL

The grate design chosen for a particular application depends on the priorities assigned to each of the functions listed below. Local conditions may require inclusion of some or all of the performance features in a design.

CAPACITY: Interception of storm water is generally considered the most important function a grate can perform. The geometry and size of the openings affect this ability. Consult a civil engineer or hydrologist for individual grate capacities.

SCREENING OF LARGE DEBRIS: An inlet grate must act as a strainer to prevent harmful debris from entering sewer lines. A well-designed grate prevents objects such as branches, sticks, sheets of semirigid material, and chunks of wood, which can easily pass by large curb openings (such as open-throat type), from entering the catch basin.

PASSING OF SMALL DEBRIS: Organic material such as grass clippings, leaves, small stones, or twigs may be permitted to pass into the catch basin as they are not a hazard in sewer lines. Provide grate openings wide enough, long enough, or of special design to pass this debris and still meet requirements for roadway-safe grates.

STRENGTH: Inlet grates placed in roadways must be designed to withstand heavy traffic loads. The most generally accepted specifications for highway loading criteria come from the American Association of State Highway and Transportation Officials (AASHTO).

PERMANENCY: An inlet grate should be designed to match or exceed the expected life of the installation. Steel, aluminum, and cast iron are generally accepted materials for inlet grates, although other materials such as brass, chrome, and structural polyethylene are used in special applications.

BICYCLE SAFETY: Grates can be made safer for bicycle and pedestrian traffic through attention to design and installation. Options include diagonal bars set at a 45° angle; slotted grates, provided the slots are 1 1/4 to 2 1/4 in. wide and a maximum of 9 in. long and the transverse (cross) bars are spaced so a bicycle wheel cannot drop lower than about 1 in.; and bars transverse to the direction of traffic and storm water flow and slanted to conduct water into the catch basin. Grate design does not ensure safe usage; attention must be paid to usage patterns of probable users. Consult traffic engineers and local codes for more information.

Consider clogging hazards and the geometry of flow-through efficiency when designing for bicycle safety. Use of vane-shaped or sloped bars, rather than conventional vertical bars, may improve the capacity of a grate to pass storm water. Grates with these types of bars are safe for bicycles; consult manufacturers. Do not allow gutter slopes to be substantially swaled into the curb, which could create a pocket in the roadway affecting the safety of bicycles and other traffic.

GRATE SIZING

Most grates are oversized to prevent buildup of water; see manufacturers' catalogs for free area. The following formula for sizing grates is based on a given allowable depth of water over the grate.

$$Q = .66 CA (64.4 d)^{0.5}$$

- where A = free area (sq ft)
- d = allowable depth of water above grate (ft)
- C = orifice coefficient (0.6 for square edges, 0.8 for round)
- .66 = clogging factor

SECTION

2. Locate drainage structures with grated openings on or beyond the periphery of traveled ways to minimize contact with pedestrian or vehicular traffic. Grates that may come into contact with feet or narrow wheels must be constructed to prevent penetration by heels, crutch and cane tips, and slim tires but still have sufficient openings to pass the expected runoff.

Joseph P. Mensch, P.E.; Wiles Mensch Corporation; Reston, Virginia
Kurt N. Pronske, P.E.; Reston, Virginia

GENERAL

Natural filtration devices in the environment retain and treat pollutants such as sediment, fertilizer, pesticides, and air pollutants before they can enter water bodies. Increasing development, however, compromises the ability of the landscape to prevent water resource contamination. Typically, when land is developed, trees that formerly intercepted rainfall and pollutants are felled; natural depressions that temporarily ponded water are graded, soil is compacted; and the thick leaf-litter humus layer of the forest floor, which had absorbed rainfall, is scraped off or erodes.

Once a site has been developed, it can no longer store as much water, and rainfall is immediately transformed into runoff and transported to rivers, lakes, wetlands, or other surface water systems. Once construction is complete and some vegetation has returned to the site, expansive impervious surfaces such as rooftops and parking lots prevent most runoff from percolating into the soil. Instead, it must be directed off site by a surface drainage system of curbs, culverts, gutters, and storm sewers.

Measures for managing pollutants include methods of construction and land development that replace natural pollution filtration pathways (e.g., forests, wetlands) with similar filtering mechanisms. Water detention systems retain water, provide for percolation to groundwater, and filter pollutants out of water runoff. These systems comprise detention basins, constructed wetlands, and other temporary and permanent erosion control measures.

When choosing appropriate runoff control measures for a site, consider the following factors: the sensitivity of the local ecosystem; slope of the site; depth of the water table; proximity to bedrock, foundations, and wells; land consumption; land use restrictions; high sediment input; and thermal impacts to downstream areas.

NATURAL WETLAND SYSTEMS

Wetlands naturally detain and filter water. Scattered throughout the United States, from tropical areas to tundra, they form in depressions in the landscape where the water table is near or at the surface of the soil. They may be as small as a tabletop or span tens of thousands of acres. There is no single, correct, ecologically sound definition for wetlands, primarily because of their diversity. These systems are an important part of the ecosystem because they produce food and timber, purify drinking water, absorb and store floodwater, suppress storm surges, and help maintain biodiversity. Water is supplied to a wetland either by surface sources (e.g., streams or rivers) or by groundwater.

CROSS-SECTION OF NATURAL FRESHWATER, NONTIDAL WETLANDS

The sensitivity of wetlands determines appropriate buffer distances between them and developed areas. Buffers, which may range from 30 to 300 ft or more, should respond to the effect runoff may have on the wetland ecosystem. (Consult a wetlands scientist to formulate buffer distances.)

In general, four wetland sensitivity issues should be taken into account: hydrology—the wetland's source of water could be altered by development; vegetation—the plant species in a wetland have different levels of hardiness; ecological state—more pristine systems are more sensitive to development and runoff pollution; and animal species—for instance, nesting birds need greater buffer distances than wintering waterfowl.

ON-SITE RUNOFF CONTROL MEASURES

Architects can use several on-site measures to control runoff in development projects. One of the most commonly used is a simple open storage area for runoff. The configuration of such open systems varies, depending on the desired level of pollutant treatment. Typically called storage ponds, detention basins, or (when made to resemble a natural environment) a constructed storm water wetland, open systems generally operate more thoroughly with increased retention time.

Simple storage ponds are typically dry between storms after runoff has evaporated or infiltrated the groundwater. Dry

ponds sometimes include a wet lower area for additional runoff retention. Wet ponds are permanently wet, allowing pollutants to settle to the bottom. Wet ponds that extend runoff retention time with control devices can remove a very high percentage of particulate pollutants.

Constructed storm water wetlands (engineered, shallow marshlike areas) retain runoff for long periods, allowing pollutants to settle out of the water column and providing biological, chemical, and physical processes for breaking down pollutants. Wetland vegetation slows the velocity of storm water, reducing erosion and allowing pollutants to settle. Many organic and inorganic compounds are removed from wetlands by the chemical processes of absorption, precipitation, and volatilization.

Constructed storm water wetlands can also filter excess nutrients such as nitrogen and phosphorus contained in runoff from gardens and septic tanks. To correctly size a wetland used for storm water runoff control, consider the total volume and velocity of water entering and leaving the system.

Potential advantages of using constructed storm water wetlands are that they have relatively low capital and operating costs, offer consistent compliance with permit requirements, and greatly reduce operational and maintenance costs.

COMPARATIVE ASSESSMENT OF THE EFFECTIVENESS OF URBAN BEST MANAGEMENT PRACTICES (BMPs)

URBAN BMP OPTIONS	POLLUTANT REMOVAL RELIABILITY	LONGEVITY*	APPLICABILITY TO MOST DEVELOPMENTS	WILDLIFE HABITAT POTENTIAL	ENVIRONMENTAL CONCERNS	COMPARATIVE COSTS	SPECIAL CONSIDERATIONS
Storm water wetlands	Moderate to high, depending on design	20+ years expected	Applicable to most sites if land is available	High	Stream warming, natural wetland alteration	Marginally higher than wet ponds	Recommended with design improvements and with the use of micropools and wetlands
Extended detention ponds	Moderate but not always reliable	20+ years but frequent clogging and short detention common	Widely applicable but requires at least 10 acres of drainage area	Moderate	Possible stream warming and habitat destruction	Lowest cost alternative in size range	Recommended with design improvements and with the use of micropools and wetlands
Wet ponds	Moderate to high	20+ years	Widely applicable but requires drainage area of more than 2 acres	Moderate to high	Possible stream warming, tropic shifts, habitat	Moderate to high compared to conventional	Recommended, with careful site evaluation
Multiple pond systems	Moderate to high (redundancy increases reliability)	20+ years	Widely applicable	Moderate to high	Selection of appropriate pond option minimizes overall environmental impact	Most expensive pond option	Recommended
Infiltration trenches	Presumed moderate	50% failure rate within 5 years	Highly restricted (soils, groundwater, slope, area, sediment input)	Low	Slight risk of groundwater contamination	Cost-effective on smaller sites, rehab costs can be considerable	Recommended with pre-treatment and geotechnical evaluation
Infiltration basins	Presumed moderate, if working	60–100% failure within 5 years	Highly restricted (soils, groundwater, slope, area, sediment input)	Low to moderate	Slight risk of groundwater contamination	Construction cost moderate, but rehab cost high	Not widely recommended until longevity is improved
Porous pavement	High, if working	75% failure within 5 years	Extremely restricted (traffic, soils, groundwater, slope, area, sediment input)	Low	Possible groundwater impacts, uncontrolled runoff	Cost-effective compared to conventional asphalt when working properly	Recommended in highly restricted applications with careful construction and effective maintenance
Sand filters	Moderate to high	20+ years	Applicable for smaller developments	Low	Minor	Comparatively high construction costs and frequent maintenance	Recommended, with local demonstration
Grassed swales	Low to moderate but unreliable	20+ years	Low-density development and roads	Low	Minor	Low compared to curb and gutter	Recommended, with check-dams, as one part of a BMP system
Filter strips	Unreliable in urban settings	Unknown but may be limited	Restricted to low-density areas	Moderate if forested	Minor	Low	Recommended as one element of a BMP system
Water quality inlets	Presumed low	20+ years	Small, highly impervious catchments (less than 2 acres)	Low	Resuspension of hydrocarbon loadings, disposal of hydrocarbon and toxic residuals	High compared to trenches and sand filters	Not currently recommended as a primary BMP option

*Based on current designs and prevailing maintenance practices

NOTE

The variety of urban BMPs available to remove pollutants from urban runoff differs widely in performance, longevity,

feasibility, cost, and environmental impact. As the matrix shows, storm water wetlands are an attractive BMP choice at many development sites.

Carrie Fischer, "Design for Wetlands Preservation," topic II.A.1 in *Environmental Resource Guide* (Washington, D.C.: The American Institute of Architects, 1992).
 Thomas Schueler; Metropolitan Washington Council of Governments; Washington, D.C.

STORM WATER WETLANDS

Storm water wetlands can be defined as constructed systems explicitly designed to mitigate the effects of storm water quality and quantity on urban development. They temporarily store storm water runoff in shallow pools that create growing conditions suitable for emergent and riparian wetland plants. In combination, the runoff storage, complex microtopography, and emergent plants in the constructed wetland form an ideal matrix for the removal of urban pollutants.

Unlike natural wetlands, which often express the underlying groundwater level, storm water wetlands are dominated by surface runoff. Storm water wetlands can best be described as semitidal, in that they have a hydroperiod characterized by a cyclic pattern of inundation and subsequent drawdown, occurring 15-30 times a year, depending on rainfall and the imperviousness of the contributing watershed.

Storm water wetlands usually fall into one of four basic designs:

SHALLOW MARSH SYSTEM: The large surface area of a shallow marsh design demands a reliable groundwater supply or base flow to maintain sufficient water elevation to support emergent wetland plants. Shallow marsh systems take up a lot of space, requiring a sizable contributing watershed (often more than 25 acres) to support a shallow permanent pool.

POND/WETLAND SYSTEM: A pond/wetland design utilizes two separate cells for storm water treatment, a wet pond and a shallow marsh. The multiple functions of the latter are to trap sediments, reduce incoming runoff velocity, and remove pollutants. Pond/wetland systems consume less space than shallow marsh systems because the bulk of the treatment is provided by a deep pool rather than a shallow marsh.

EXTENDED DETENTION WETLAND: In extended detention wetlands, extra runoff storage is created by temporarily detaining runoff above the shallow marsh. This extended detention feature enables the wetland to occupy less space as temporary vertical storage partially substitutes for shallow marsh storage. A growing zone is created along the gentle side slopes of extended detention wetlands, from the normal pool level to the maximum extended detention water surface.

POCKET WETLANDS: Pocket wetlands are adapted to serve small sites (from one to ten acres). Because the drainage area is small, pocket wetlands usually do not have a reliable base flow, creating a widely fluctuating water level. In most cases, water levels in the wetland are supported by excavating down to the water table. In drier areas, a pocket wetland is supported only by storm water runoff, and during extended periods of dry weather it will have no shallow pool at all (only saturated soils). Due to their small size and fluctuat-

ing water levels, pocket wetlands often have low plant diversity and poor wildlife habitat value.

The selection of a particular wetland design usually depends on three factors: available space, contributing watershed area, and desired environmental function. However, storm water wetlands are not typically located within delineated natural wetland areas, which provide critical habitat and ecosystem services and are protected under local, state, and federal statutes. Storm water wetlands should also not be confused with constructed wetlands used to mitigate the permitted loss of natural wetlands under wetland protection regulations. The primary goal of wetland mitigation is to replicate the species diversity and ecological function of the lost natural wetland; whereas the more limited goal of storm water wetlands is to maximize pollutant removal and create generic wetland habitat.

Storm water wetlands are also distinguished from natural wetlands that receive storm water runoff as a consequence of upstream development. Although not intended for storm water treatment, wetlands influenced by storm water are common in urban settings. Storm water runoff that becomes a major component of the water balance of a natural wetland can severely alter the functional and structural qualities of the wetland. The end result is a storm water-influenced natural wetland that is more characteristic of a storm water wetland than a natural one.

NOTE

Most of the shallow marsh system is 0-18 in. deep, a depth that creates favorable conditions for the growth of emergent wetland plants. A deeper forebay is located at the major inlet, and a deep micropond is situated near the outlet.

SHALLOW MARSH SYSTEM

NOTE

The pond/wetland system consists of a deep pond that leads to a shallow wetland. The pond removes pollutants and reduces the space required for the system.

POND/WETLAND SYSTEM

Carrie Fischer, "Design for Wetlands Preservation," topic II.A.1 in *Environmental Resource Guide* (Washington, D.C.: The American Institute of Architects, 1992).
Thomas Schueler, Metropolitan Washington Council of Governments; Washington, D.C.

COMPARATIVE ATTRIBUTES OF FOUR STORM WATER WETLAND DESIGNS

ATTRIBUTE	SHALLOW MARSH	POND/WETLAND	EXTENDED DETENTION WETLAND	POCKET WETLAND
Pollutant removal capability	Moderate; reliable removal of sediments and nutrients	Moderate to high; reliable removal of nutrients and sediment	Moderate; less reliable removal of nutrients	Moderate; can be subject to resuspension and groundwater displacement
Land consumption	High; shallow marsh storage consumes space	Moderate, as vertical pool substitutes for marsh storage	Moderate, as vertical extended detention substitutes for marsh storage	Moderate, but can be shoehorned into site
Water balance	Dry weather base flow normally recommended to maintain water elevations; groundwater not recommended as primary source of water supply to wetland			Water supply provided by excavation to groundwater
Wetland area/watershed area	Minimum ratio of .02	Minimum ratio of .01	Minimum ratio of .01	Minimum ratio of .01
Contributing watershed area	Drainage area of 25 acres or more, with dry weather Q*	Drainage area of 25 acres or more, with dry weather Q*	Minimum of 10 acres required for extended detention	1-10 acres
Deepwater cells	Forebay, channels, micropool	Pond, micropool	Forebay, micropool	Micropool, if possible
Outlet configuration	Reversed slope pipe extending from riser, withdrawn approximately 1 ft below normal pool; pipe and pond drain equipped with gate valve			Broad-crested weir with half-round trash rack and pond drain
Sediment cleanout cycle (approximate)	Cleanout of forebay every 2-5 yr	Cleanout of pond every 10 yr	Cleanout of forebay every 2-5 yr	Cleanout of wetland every 5-10 yr, on-site disposal and stockpile mulch
Native plant diversity	High, if complex microtopography is present	High, with sufficient wetland complexity and area	Moderate; fluctuating water levels impose physiological constraints	Low to moderate, due to small surface area and poor control of water levels
Wildlife habitat potential	High, with complexity and buffer	High, with buffer, attracts waterfowl	Moderate, with buffer	Low, due to small area and low diversity

*Q—coefficient of runoff

EXTENDED DETENTION WETLAND

POCKET STORM WATER WETLAND

Carrie Fischer, "Design for Wetlands Preservation," topic II.A.1 in *Environmental Resource Guide* (Washington, D.C.: The American Institute of Architects, 1992).
 Thomas Schueler; Metropolitan Washington Council of Governments; Washington, D.C.

GENERAL

Unit paving assemblies are principally used for applications such as shopping plazas, building entrances, walkways, patios, residential driveways, and residential parking areas. However, they may be used for streets with heavy vehicular traffic and for industrial floors or other special conditions. Consult with a landscape architect or engineer for appropriate design guidelines.

NOTES

1. Paver units are selected according to color, texture, abrasion resistance, and resistance to weathering. The texture of the unit affects slip resistance—the coarser the

RECTANGULAR

SQUARE

HEXAGONAL

NOTE

Rectangular, square, and hexagonal pavers are available in both brick and concrete.

TYPICAL PAVER SHAPES

TYPICAL PAVER SIZES IN IN. (MM)

RECTANGULAR*		SQUARE	HEXAGONAL	
W	L	W & L	W	L
4 (100)	8 (200)	4 (100)	6 (150)	6 (150)
3 5/8 (92)	7 5/8 (194)	6 (150)	8 (200)	8 (200)
3 1/2 (89)	7 1/2 (190)	8 (200)	12 (300)	12 (300)
7 5/8 (194)	7 5/8 (194)	12 (300)		
8 (200)	8 (200)	16 (400)		

*Check with manufacturer for availability of chamfers.

NOTE

The height of pavers varies with the manufacturer and application but is usually 1 1/4 (32), 2 1/4 (57), 2 5/8 (67), or 2 3/4 (70).

INTERLOCKING

NOTES

1. Voids may be filled with grass, ground cover, or gravel.
2. Grass pavers may be used to control erosion.

GRASS PAVER TYPES

texture, the better the slip resistance. Abrasion resistance refers to the wear and tear an assembly is subjected to under normal use. According to ASTM C902, "Standard Specification for Pedestrian and Light Traffic Paving Brick," an abrasion index classification determines the type of unit required for an intended exposure. A dense, hard-burned extruded brick with 8000 psi compressive strength that conforms to ASTM C902, Class SX, Type 1, resists both abrasion and weathering and is adequate for most heavy-traffic exterior applications. Molded brick with 4000 psi compressive strength that conforms to ASTM C902, Class SX, Type 2, is adequate for most exterior pedestrian applications. If materials other than brick are used for paving, consult the manufacturer to learn which products are suitable for use as pavers in a particular application.

2. Assess potential traffic loads when planning unit paving installations. Heavy vehicular loads require a rigid or semi-rigid continuous base, while a flexible base and flexible paving are suitable for light vehicular loads (residential-type). Use either base type for pedestrian traffic. Choose a bond pattern based on expected traffic patterns; traffic should travel perpendicular to the long dimension of the paving unit. For vehicular areas, use a gravel subbase

FLEXIBLE (MORTARLESS) PAVER

NOTES

1. Unit paving assemblies are classified according to the type of base supporting the paver, either rigid (mortared) or flexible (mortarless). Base types are a reinforced or unreinforced concrete slab on grade that accepts either rigid or flexible pavers (rigid); asphalt or bituminous concrete that accepts flexible pavers only (semirigid continuous); a compacted gravel, sand, or sand-cement mixture that accepts flexible pavers only (flexible); and suspended diaphragm or structural floor and roof assemblies, which vary by design and accept either rigid or flexible pavers.
2. Setting bed (cushion) material, placed between base and paving surface, functions as a leveling layer to help refine the finished grade and compensate for irregularities in the base and paver unit surfaces. Setting bed material can be a 1- or 2-in. layer of sand, pea gravel, stone screenings, roofing felt, asphalt (7% asphalt, 93% sand with a neoprene tack coat), or mortar. Sand for setting beds, bases, joints, and mortar should conform to ASTM C144, "Aggregate for Masonry Mortar." Use mortar setting or leveling beds only in conjunction with concrete and asphalt bases; the thickness of the bed may vary from 1/2 to 2 in.

PAVER ASSEMBLY TYPES

BLOCK PAVERS

3. Grass rings are available with close ring spacing for pedestrian use or with wide ring spacing for vehicular use.

(minimum 6 in. crushed gravel) compacted to 95% and paver sizes 8 in. square or smaller. Consult an engineer to accurately define paver sizes, shapes, gravel depth, concrete base depth, and concrete reinforcement requirements.

3. Proper subgrade preparation of areas to be paved is important. Remove all vegetation and organic material, and consider the location of existing or proposed underground utilities and storm drainage, as well as user convenience.
4. Plan for surface and subsurface drainage. Slope paving away from buildings, retaining walls, etc. at 1/8 to 1/4 in. per foot. Rigid paving always requires adequate surface drainage, with the long dimension of the mortar joints running parallel to the direction of runoff. Flexible paving requires both surface and subsurface drainage.
5. To prevent horizontal movement of flexible (mortarless) paving assemblies, use a curb of brick soldier coursing set in concrete, landscape timbers, or other edging material.
6. There are three major types of unit paver joint material: mortar, grout (portland cement and sand without hydrated lime), and a dry mixture of grout.

RIGID (MORTARED) PAVER

3. Membranes are installed in unit paving assemblies for several purposes: to control the passage of moisture, reduce weed growth, prevent the sand course from filtering into lower courses, and as a bond break. Consider using bond breaks between rigid paving and rigid bases to accommodate differential movement. Membranes are of sheet or liquid material that can resist moisture, rot, and decay. Sheet material includes asphalt roofing felt, polyethylene film, vinyl, neoprene, and rubber. Liquid types are asphalt, modified urethane, or polyurethane bitumen; these are preferred for irregular surfaces.
4. Use base materials, including gravel, concrete, and asphalt, for support, drainage, and/or ground swell protection. For maximum drainage efficiency and to prevent upward capillary action, specify clean, washed gravel.
5. Expansion joints can alleviate thermal and moisture movement, especially in rigid or mortared assemblies. Expansion joints are generally located parallel or adjacent to curbs and edgings, at right angle turns, around interruptions (e.g., manhole cover assemblies), at set distances in long runs of masonry, and where dissimilar materials meet.

2 PAVING AND SURFACING

EDGE DRAINAGE AT FLEXIBLE PAVING

EDGE DRAINAGE AT RIGID PAVING

NOTES

1. Drainpipes may be omitted at well-drained areas.
2. Provide positive outflow for drainpipes.
3. Do not use unsatisfactory soil (expanding organic).
4. Satisfactory soil must be compacted to 95%.
5. Handtight paving joints are preferred over mortar joints. However, when mortar joints are required and freezing and thawing are frequent, use latex-modified mortar.
6. Concrete footing for edging should be 10 to 14 in. wide and 6 to 8 in. deep. It is preferable to place the bottom of the footing at freezing depth. If the freezing depth is deeper than the bottom of the footing, provide 4 in. of gravel below the footing.
7. Interlocking pavers are available in concrete, hydraulically pressed concrete, asphalt, and brick in different weight classifications, compressive strengths, surface textures, finishes, and colors. Consult local suppliers for availability.
8. Subject to the manufacturer's recommendations and local code requirements, interlocking concrete pavers may be used in areas subject to heavy vehicle loads at speeds of 30 to 40 mph.
9. Concrete interlocking paver sizes are based on metric dimensions.
10. When paver shape permits, the herringbone pattern is recommended for paving subject to vehicular traffic.
11. Continuous curb or other edge restraint is required to anchor pavers in applications subject to vehicular traffic.

FOUNTAIN NOZZLE TYPES

SURGE REDUCTION DEVICES

CONCRETE BASIN JOINT DETAILS

GENERAL

Materials used in fountain and pool design should be durable and resist damage caused by water, cracks, weather, stains, and freeze-thaw cycles. Suitable materials include stone, concrete, brick, tile, and metals such as copper, bronze, cast iron, and steel. Fiberglass, acrylic, and waterproof membranes such as PVC, EPDM, and butyl are commonly used.

OVERALL DESIGN CONSIDERATIONS

SCALE: Consider the size of the water feature in relation to its surroundings.

BASIN SIZING: For width, consider fountain height and prevailing winds. For depth, consider weight (1 cu ft water = 62.37 lb). Consider children playing near or in the pool. Allow space for lights, nozzles, and pumps. Local codes may classify basins of a certain depth as swimming pools. Nozzle spray may be cushioned to prevent excessive surge.

BOTTOM APPEARANCE: When clear water is maintained, bottom appearance is important. Enhance the bottom with patterns, colors, materials, three-dimensional objects, or textures. Dark bottoms increase reflectivity.

EDGES OR COPINGS: In designing the water's edge, consider the difference between the operating water level and the static water level. Loosely defined edges (as in a pond) make movement into the water possible both visually and physically. Clearly defined edges (as in a basin) use coping to delineate the water's edge.

LIPS AND WEIRS: A lip is an edge over which flowing water falls. A weir is a dam in the water that diverts the water flow or raises the water level. If volume and velocity are insufficient to break the surface tension, a reglet on the underside of the edge may overcome this problem.

FOUNTAIN LIP SECTIONS

PIPE SCHEMATIC FOR DRY CENTRIFUGAL PUMP

WATER FORM FOR FOUNTAINS

STATIC WATER: Form and reflectivity are design considerations for water contained in pools and ponds.

FALLING WATER: The effect of falling water depends on water velocity and volume, the container surface, and the edge over or through which the water moves.

FLOWING WATER: The visual effect of a volume of flowing water can be changed by narrowing or widening a channel, placing objects in the path of the water, and changing the direction of the flow or the slope and roughness of the bottom and sides.

JETS: A pattern is created by forcing water into the air with a jet. Jet types include single orifice nozzles, tiered jets, aerated nozzles, and formed jets in a wide variety of forms, patterns, and types.

SURGE: A contrast between relatively quiet water and a surge (a wave or a splash) is made by quickly adding water, raising or lowering an object or moving it back and forth in the water, or introducing strong air currents to the water.

WATER EFFECTS SYSTEM

The water effects system comprises the pump, nozzles, and piping that move water through the fountain. The combination of nozzles, spray rings, eyeballs, pipes, weirs, and/or channels in a fountain or pool requires a pump system to generate water pressure, a suction line to bring water to the pump, and a discharge line to move water from the pump to the nozzles.

Fountain nozzles come in four basic types: aerating nozzles, spray heads, smooth-bore nozzles, and formed nozzles. Aerating nozzles (also known as bubbler jets, geyser nozzles, or foam nozzles) are characterized by white frothy water created by combining air and water. Spray heads are characterized by combinations of thin clear water jets coming from a distribution head in the shape of a fan or circle (suction or in-

VERTICAL TURBINE PUMP

line strainer required). Smooth-bore nozzles are characterized by a clear, thin solid stream jet of water that breaks up into small droplets as it reaches its maximum height or distance. Formed nozzles are typified by a thin sheet of water that originates in a jet of varied size and shape. The thinness of the sheet of water makes the tolerances in the jet very tight (suction or in-line strainer required).

Fountains are usually closed water systems, i.e., the pump continuously cycles the water in the basin to the nozzles and back to the basin again. The pumps used to generate water pressure and operate the water effects of a fountain are largely powered by electric motors. Three types of pumps are commonly used: submersible, dry centrifugal, and vertical turbine pumps.

Submersible pumps, used for low volume fountains, are among the simplest pumping systems. A watertight electric motor and pump are set under the water of the fountain basin. The pump is usually equipped with a motor of 1/2 to 1 horsepower and moves a maximum of 100 gallons per minute (gpm). This type of pump requires fewer pipe penetrations in the basin wall than dry centrifugal or vertical turbine pumps.

Dry centrifugal pumps, most commonly used for larger water features, consist of an electric motor, a pump, a suction line, and a discharge line. This pump type ranges from 1/4 to 100 horsepower.

Vertical turbine pumps, used in large water features, are able to move tremendous amounts of water. They require a pump and motor, a water sump located in an equipment vault, a gravity feed mechanism to fill the sump, and a discharge line. These pumps are more energy-efficient than those with suction lines, as gravity moves water to the pump. The electric motor is not submerged in water, making a watertight seal less important. Vertical turbine pumps can move up to 5000 gpm.

GENERAL

Selection criteria to use when choosing a fence for a particular application include the degree of privacy or openness and sense of enclosure desired; the aesthetic and stylistic nature of the materials and setting; cultural and historical precedents; and security issues. Consider, as well, materials and maintenance requirements, soil conditions at the site and the foundations and anchorage required; topography, climate, and wind conditions at the site; the effects a design will have on neighbors and adjacent natural features; the size of the property; and the permanence and cost of the structure.

Local zoning and building codes often regulate the height of a fence and its relationship to the property line. Fences should not obstruct traffic sight lines at intersections but should prevent access to potential danger (e.g., unattended children at swimming pools or pedestrians at a construction site).

NOTE
A retaining wall positioned to be invisible to the viewer (a "ha-ha") can prevent unwanted entry by outsiders.

RETAINING WALL AS FENCE

PHYSICAL BARRIER TYPES

LOW BARRIERS

NOTES

1. Gates permit personnel and vehicles to pass through barriers. Construction techniques and operation of gates are similar to door methods; refer to AGS chapter 8 for further information on these subjects.
2. Compression bracing extending from the upper extremity to the lower connection point of a gate is often required; tension can be modulated through rods and turnbuckles to prevent warpage and sagging. Large or heavy gates can be fitted with rollers or wheels to aid operation; metal tracks mounted in paving prevent uneven surface wear.
3. Hardware should be made of noncorrosive materials. Latches with internal padlock hasps or locking mechanisms are available for security protection.

Daniel F. C. Hayes, AIA; Washington, D.C.

NOTE
 Materials used for this type of fence are steel or aluminum in wrought or cast form.

LINE POST

GATEPOST

NOTE

For fences 5 ft and taller, a horizontal or diagonal brace, or both, is used for greater stability. Post spacing should be

equidistant and should not exceed 10 ft o.c.

CHAIN-LINK FENCE AND GATE—ELEVATION

CHAIN-LINK FENCE MATERIALS

MATERIAL	SIZES AVAILABLE*
Wire gauge	Usually no. 11 or no. 9 For especially rugged use, use no. 6 For tennis courts, no. 11 is generally used
Wire mesh	Usually 2" For tennis courts, usually 1 5/8" or 1 3/4" of chain-link steel that has been coated with hot dip galvanizing after weaving Top and bottom selvage may be barbed or knuckled
Corner and end posts	For lawn fences, usually 2" outside diameter For estate fences, 2 in. for low, 2 1/2 in. for medium, and 3" outside diameter for heavy or high For tennis courts 3" outside diameter
Line or intermediate posts	For lawn fences, 1 3/8" or 2" outside diameter round For estate fences, etc., 2", 2 1/4", or 2 1/2" H or I sections For tennis courts, 2 1/2" round outside diameter or 2 1/4" H or I sections
Gateposts	Same or next size larger than corner posts; footings should be 3'-6" deep
Top rails	1 3/8" outside diameter except some lawn fence may be 1 3/8" outside diameter
Middle rails	On 12'-0" fence, same as top rail
Gates	Single or double; any width desired Accessible routes require clear opening width of 32" min. and 18" latchside clearance; latches must be accessible
Post spacing	Line posts 10'-0" o.c.; 8'-0" o.c. may be used on heavy construction

*Sizes given are not standard but represent the average sizes used.

COATINGS

Protective coatings, such as zinc and aluminum, can be used on metal fencing. Also available are various decorative coatings, including vinyl bonding and organic coatings; these are available from most manufacturers.

VINYL-COATED WIRE FABRIC MESH

Vinyl-coated wire fabric mesh is suitable for residential, commercial, and industrial applications. The mesh comes in five sizes—1, 1 1/4, 1 1/2, 1 3/4, and 2 in.—and in four gauges—11, 9, 6, and 3.

SPECIAL FENCING

ORNAMENTAL: This fencing type uses vertical struts only; no chain-link fabric is required. Ornamental fencing is ideal for landscaping or as a barrier fence.

ELEPHANT FENCE: This fence can actually stop an elephant, hold back a rock slide, or bring a small truck to a halt. Its size is specified as gauge 3 with a 2 in. mesh.

SECURITY FENCE: This fabric is nonclimbable and cannot be penetrated by gun muzzles, knives, or other weapons. It is suitable as a security barrier for police stations, prisons, reformatories, hospitals, and mental institutions. Mesh sizes available are 3/8 in. for maximum security, 1/2 in. for high security, 5/8 in. for super security, and 1 in. for standard security.

POST SIZES FOR HEAVY-DUTY GATES

ASA SCHEDULE 40 PIPE SIZES (IN.)	SWING GATE OPENINGS (FT)	
	SINGLE	DOUBLE
2 1/2	Up to 6	Up to 12
3 1/2	Over 6 to 18	Over 12 to 26
6	Over 13 to 18	Over 26 to 36
8	Over 18 to 32	Over 36 to 64

WOOD PRIVACY FENCES

WOOD BOUNDARY FENCES

NOTES

1. Untreated wood materials such as white oak or tamarack can last up to 10 years; cypress, redwood, and sassafras up to 15 years; red and white cedar up to 20 years; and black locust and osage orange up to 25 years. Weather and insect preservative treatments can extend the useful

life to 25 to 30 years for most species. Verify life expectancies and compatibility with finishes and hardware with manufacturers.

2. Fasteners should be made of noncorrosive materials such as aluminum alloys or stainless steel; high quality hot-

3. Virgin or recycled plastic may be used as an alternative material for the fences illustrated on this page.

Daniel F. C. Hayes, AIA; Washington, D.C.

GENERAL

Consistent with the philosophy of crime prevention through environmental design (CPTED), architects use a combination of design and operational tools to address projects requiring site security. These tools include access control of pedestrians on the site, natural and mechanical surveillance of occupants of the property, and clear definition of public and private space through a combination of real and symbolic barriers.

When terrorism, workplace violence, or street crime is possible on a site, the U.S. General Services Administration recommends the following for all government buildings:

1. Eliminate potential hiding places near the facility.
2. Provide an unobstructed view around the facility.
3. Place the facility within view of other occupied facilities.

4. Locate assets stored on site but outside the facility within view of occupied rooms in the facility.
5. Minimize the signage or indication of assets on the property.
6. Set the facility a minimum of 100 ft from the facility boundary, if possible.
7. Eliminate lines of approach perpendicular to the building.
8. Minimize the number of vehicle access points.
9. Eliminate or strictly control parking beneath facilities.
10. Locate parking as far from the building as practical,

11. Illuminate the exterior of the building and/or exterior sites where assets are located.
 12. Secure access to power/heat plants, gas mains, water supplies, and electrical and phone service.
- Design elements commonly used to create real and symbolic barriers to increase site security include bollards/planters, curbs, vehicle barriers, gates, security lighting, and signage.

NOTE

Active barriers at access/egress points in high security areas should be fully engaged until vehicles are cleared for passage. A visible signal light or drop arm should indicate the status of the barrier to approaching vehicles. Operating time should not exceed 3-4 seconds. In case of power failure, the barrier system must be able to maintain its position to prevent access but be capable of manual operation; it also should be connected to emergency power. Remote controls should include a status indicator.

INTRODUCTION

Playing is vital to the physical, emotional, and social growth of children. To encourage healthy growth, the play environment must challenge children at their level of development yet reassure them as they investigate their physical limits. Each stage of development results in different types and levels of interaction and activity. The outdoor play environment becomes increasingly important as the boundaries of the child's world stretch beyond the home and primary care. Play equipment should be selected and designed to attract, fascinate, and sustain the interest of the age groups who will use it, while promoting agility, strength, and balance.

Playing may consist of imitation, role play, and fantasy play, as well as more active pursuits. Space and equipment must be provided to encourage jumping, climbing, swinging, sliding, crawling, hanging, running, building, sitting, and meeting. Designs should provide opportunities for children to be imaginative and to interact socially. Think of the equipment as a flexible, three-dimensional system that allows children to move in every direction and challenges them with a consistently changing space.

Three age groups must be considered in designing playgrounds. Toddlers (3 to 5 years) should be separated from older children by a fence they can see through. This makes it easier for caregivers to supervise the younger children but allows the toddlers to feel part of things. Early elementary (6 to 9 years) and late elementary (9 to 12 years) children have traditionally been separated, but another option is to design equipment that has several levels of difficulty, allowing use by both groups.

Most traditional play equipment is designed to stand alone as single units, although these may be linked together. Where space or other conditions limit the scope of development, such equipment is useful. However, because a child's play activity tends to proceed in a continuous flow, integrated play areas have proved more successful than arrangements of individual items. Combining several materials, colors, and textures also makes the play space more inviting. A variety of options is available to the designer in both custom and manufactured products.

DESIGN SUGGESTIONS

The design of a playground should meet the needs and sustain the interest of the children who will use the site. Using nonrepetitive elements and semitransparent features creates mystery and surprise. Dynamic, movable components

GROWTH AND DEVELOPMENT

NOTES

Two methods of expanding the capabilities of an integrated playground are:

1. **LINKING OF EQUIPMENT:** Connecting activity centers with links that are in themselves play structures, thus multiplying the possible uses of all of the structures involved.
2. **JUXTAPOSITIONING EQUIPMENT:** Placing units close enough together to generate interaction from one to the other; also increases the play potential and interest of the area.

allow more creative opportunities for children, and a variety of textures stimulates the sense of touch. Children never tire of playing with sand and water. Manufacturers offer a wide variety of water features for the playground, including wading pools and fountains. Water elements also encourage adult interaction. Space for congregating can be provided as semienclosed refuge or open areas. Bridges add interest to equipment and can provide connections between structures; they also create more climbing and refuge space. In addition to traditional plank bridges, there are arched, rope, suspension, or tire bridges. Suspension bridges may be designed to meet specifications provided in the Americans with Disabilities Act (ADA).

If a theme such as a ship, castle, or fort is incorporated in the playground, the equipment will automatically encourage the child's imagination. However, don't replicate these themes too closely. Leave most of the creation to the child.

Adults should not be separated from the play area. Ample seating should be provided, and the equipment should be interesting to adults, too, since their presence gives security, instruction, and approval.

Practical concerns should be taken into account in designing a playground: how does the equipment appear from the surrounding area? What are the views from the site? How much noise will travel to and from the playground? The design should consider the time of day the equipment will be used and be suitable for use all year. Drainage is important, especially around swings and berms, and shade is especially desirable over metal slides.

SAFETY AND MATERIALS

No playground is completely safe. The potential for accidents is inherent in the element of risk involved in most play. Nonetheless, playground equipment should provide challenging activities in the safest way possible.

Round, square, and rectangular timber should be pine or fir (oak warps, redwood splinters). Color should be in the form of stain, not paint, and all edges should be beveled or rounded. Steel pipe, sheets, chain, and drums can be vinyl coated. Chain, rope, and tires are available in plastic. Use of concrete and stone should be kept to a minimum. Hardware should be galvanized, and joints and connections covered or recessed.

Most important, a bed of absorbing ground cover, such as pine bark or wood chips (12 in. deep), pea gravel (10 in. deep), or sand (10 in. deep), should be installed beneath the equipment. Hardwood chips and rubberized surfacing are easier for persons with disabilities to travel over. Asphalt, packed dirt, and exposed concrete are not acceptable play surfaces.

A safety zone of at least 4 ft should surround the entire play area, with 7 ft in front of slides, 9 ft in front of swings, and 4 to 5 ft on the sides of the swings. Allow 65 to 70 sq ft of play space per child.

EQUIPMENT FOR CHILDREN WITH DISABILITIES

The ADA has raised a new understanding of the need to include children with disabilities in play activity wherever possible. Several elements will encourage the participation of children with disabilities. Bump stairs, transfer platforms, accessible suspension bridges, and slides (provided there is enough traction), as well as components that can be manipulated from a wheelchair, are all useful. Many persons with disabilities have some upper-body mobility, and horizontal ladders and rings can help children strengthen the upper body. Ramps and handrails should be used wherever possible.

MANUFACTURED VERSUS CUSTOM EQUIPMENT

Manufacturers of playground equipment offer products in timber, plastic, or powder-coated steel. Available as either individual items or in predesigned arrangements, these products are durable and easy to install and offer a variety of accessories. Because they are designed as modular units, they can be used to create a limitless number of compositions and can be expanded at a later date. Some have no need for foundations. All products must conform to the Consumer Product Safety Code.

Custom-designed equipment has the advantage of being site and situation specific. In addition, the manipulation of landforms by the designer can result in a much more interesting and creative site. Most of the materials used by manufacturers are readily available to designers, making custom design of equipment an affordable option.

GENERAL

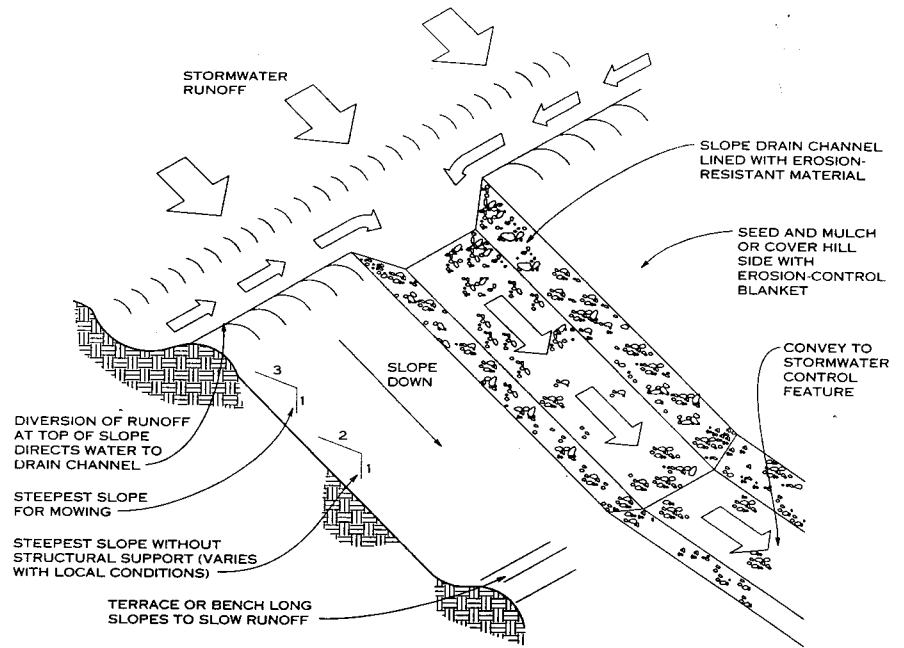

Embankment stabilization is required when steep slopes are subject to erosion from stormwater runoff or flowing streams. Erosion can damage the site and pollute waterways with sediment.

The need for mechanical stabilization can be reduced through careful site gradings that divert or slow the velocity of runoff. Avoid disturbing stable, natural stream banks. Check with regulatory agencies before planning to grade stream banks, wetlands, or floodplains.

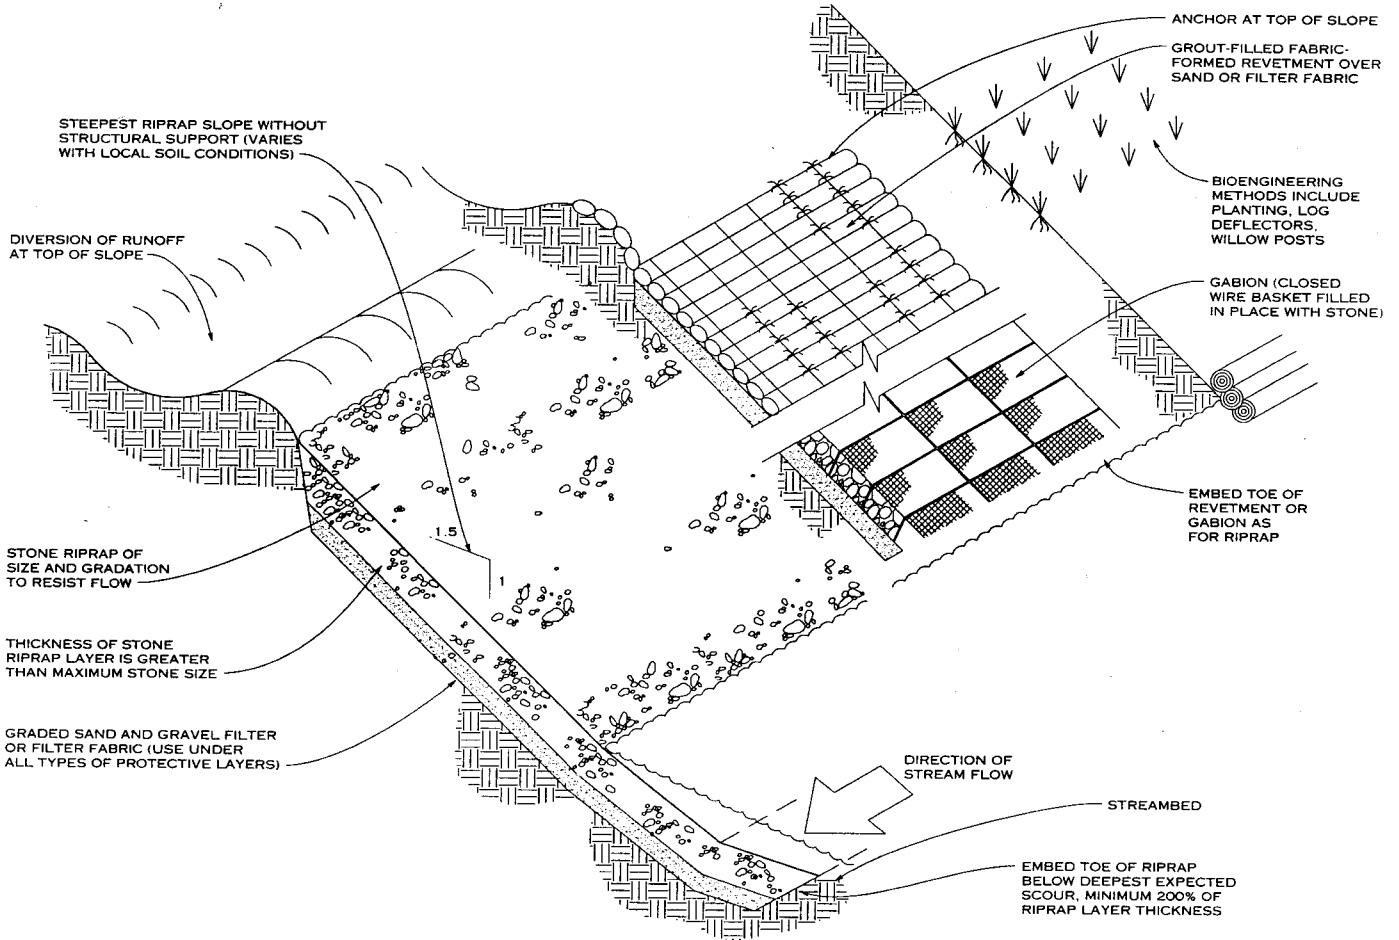

Numerous proprietary products are available for stream bank stabilization and erosion control; consult manufacturers.

NOTES

1. Control erosion during construction with silt fences, straw bales, sediment ponds, and seeding and mulching. Follow local and state guidelines and regulations.
2. Line channels with erosion-resistant material (sod, stone riprap, erosion-control blanket). Channel dimensions and lining should be designed for expected runoff.
3. At the bottom of the slope drain channel, the flow should be conveyed to a storm sewer, detention pond, constructed wetland, or other control method that meets regulations.

GRADING AND EROSION CONTROL

STREAM BANK STABILIZATION

James E. Sekela, P.E.; Pittsburgh, Pennsylvania

GENERAL

Retaining walls are designed and constructed to resist the thrust of the soil, which can cause the wall to fail by overturning, sliding, or settling. In stone walls, resistance to soil thrust can be helped by battering the stonework (that is, recessing or sloping the masonry back in successive courses).

Garden-type retaining walls, usually no higher than 4 ft, are made from small building units of stone, masonry, or wood. For higher walls, reinforced concrete is more commonly used. Terracing may be built with walls of wood, stone, brick, or concrete.

Walls less than 2 ft high do not require drains or weep holes. Pressure-treated wood is recommended for any design in which wood is in contact with the ground. Redwood may be substituted if desired.

- NOTES**
- H = height of wall, A = area of footing, W = composite weight of wall; T = lateral thrust of soil on wall; d = width of base of wall; M_0 = overturning moment of a retaining wall; M_R = resisting moment; w = lateral force on wall in psf; BC = bearing capacity of soil.
 - The overturning moment of a retaining wall (equal to $T \times H/3$) is resisted by the resisting moment of the wall. For symmetrical sections, the resisting moment equals $W \times d/2$. Using a safety factor of 2, $M_R \geq 2 \times M_0$ (assume 33° angle of repose of soil).
 - The lateral (sliding) thrust of soil on a wall must be resisted. The resisting force is the weight of the wall multiplied by the coefficient of soil friction. Using a safety factor of 1.5, $W \geq 1.5T$, where $T = (w \times H^2)/2$.
 - The bearing capacity of the soil must resist vertical forces (settling)—the weight of the wall plus any soil bearing on the base plus any vertical component of the soil thrust for a wall with any surcharge. Using a safety factor of 1.5, $BC \geq 1.5W/A$.

FORCES RESISTED BY RETAINING WALLS

NOTE
Stagger vertical joints from course to course 6 in. horizontally. The thickness of the wall at any point should not be less than half the distance from that point to the top of the wall.

Donald Neubauer, P.E.; Neubauer Consulting Engineers; Potomac, Maryland

NOTES

1. Materials and construction practices for concrete masonry retaining walls should comply with "Building Code Requirements for Concrete Masonry Structures (ACI 531)."
2. Use fine grout when grout space is less than 3 in. in the least dimension. Use coarse grout when the least dimension of the grout space is 3 in. or more.
3. Steel reinforcement bars should be clean, free from harmful rust, and in compliance with applicable ASTM standards for deformed bars and steel wire.
4. Alternate vertical bars may be stopped at the mid height of the wall. Vertical reinforcement is usually secured in place after the masonry work has been completed and before grouting.
5. Designs shown are based on an assumed soil weight (vertical pressure) of 100 pcf. Horizontal pressure is based on an equivalent fluid weight for the soil of 45 pcf.
6. The walls illustrated are designed with a safety factor against overturning of not less than 2 and a safety factor against horizontal sliding of not less than 1.5. Computations in the table for wall heights are based on level backfill. One method of providing for additional loads from sloping backfill or surface loads is to consider them as additional depth of soil. In other words, an extra load of 300 psf can be treated as 3 ft of extra soil weighing 100 psf.
7. The top of masonry retaining walls should be capped or otherwise protected to prevent water from entering unfilled hollow cells and spaces. If bond beams are used, steel is placed in the beams as the wall is constructed. However, horizontal joint reinforcement may be placed in each joint (8 in. o.c.) and the bond beams omitted.
8. Allow 24 hrs for masonry to set before grouting. Pour grout in 4 ft layers, with one hour between each pour. Break long walls into panels 20 to 30 ft long with vertical control joints. Allow seven days for finished walls to set before backfilling. Prevent water from accumulating behind walls by means of 4 in. diameter weep holes spaced 5 to 10 ft apart (with screen and graded stone) or by a continuous drain with felt-covered open joints combined with waterproofing.
9. When backfill height exceeds 6 ft, provide a key under the footing base to resist the tendency of the wall to slide horizontally.
10. Heavy equipment used in backfilling should not come closer to the top of the wall than a distance equal to the wall height.
11. A structural engineer should be consulted for the final design.

TYPICAL CANTILEVER RETAINING WALL

WITH IMPERMEABLE BACKFILL

WITH PERMEABLE BACKFILL

DRAINAGE DETAILS FOR RETAINING WALLS

NOTE

Long retaining walls should be broken with vertical control joints into panels 20 to 30 ft long. These panels must be designed to resist shear and other lateral forces while permitting longitudinal movement.

SECTION

DETAIL

SECTION

NOTE

For retaining walls taller than a certain height, double- or triple-depth walls may be needed. Fill composition varies from crushed stone to granular soil, according to conditions. Consult a structural engineer.

PRECAST CONCRETE CRIB WALL SYSTEM

Donald Neubauer, P.E.; Neubauer Consulting Engineers; Potomac, Maryland

- NOTES**
- Design straight garden walls (without piers) with sufficient thickness to provide lateral stability.
 - To resist 10 psf wind pressure, the height above grade (H) and thickness (T) should relate as follows: $H \leq .75T^2$ (H and T are in inches).

STRAIGHT GARDEN WALLS

STONE

BRICK (NO DRIP SHOWN)

NOTE

In general, through-wall flashing should be used immediately under the coping of garden walls. However, this decision depends on several factors, including the type of coping used, the number of joints used, and the climatic conditions of the area (whether there is high or low precipitation and the number of freezing and thawing cycles).

COPING DETAILS

REQUIRED EMBEDMENT FOR PIER FOUNDATION*

WALL SPAN (FT)	WIND LOAD (10 PSF)			WIND LOAD (15 PSF)			WIND LOAD (20 PSF)		
	4	6	8	4	6	8	4	6	8
8	2'-0"	2'-3"	2'-9"	2'-3"	2'-6"	3'-0"	2'-3"	2'-9"	3'-0"
10	2'-0"	2'-6"	2'-9"	2'-3"	2'-9"	3'-3"	2'-6"	3'-0"	3'-3"
12	2'-3"	2'-6"	3'-0"	2'-3"	3'-0"	3'-3"	2'-6"	3'-3"	3'-6"
14	2'-3"	2'-9"	3'-0"	2'-6"	3'-0"	3'-3"	2'-9"	3'-3"	3'-9"
16	2'-3"	2'-9"	3'-0"	2'-6"	3'-3"	3'-6"	2'-9"	3'-3"	4'-0"

*For wall sizes shown within heavy lines, a 24-in. diameter foundation is required. All other values have been obtained using an 18-in. diameter foundation.

NOTE

To figure the vertical spacing and size of reinforcing steel required for panel walls, consider the probable wind load and the wall span between piers. Consult a structural engineer for assistance.

NOTES

- The radius of curvature (R) of a 4-in. thick serpentine wall should be no more than twice the height of the wall above finished grade.
- The depth (D) of curvature of a serpentine wall should be no less than half the height of the wall above grade (max. height = 5 ft 0 in., typical).

SERPENTINE GARDEN WALLS

PIER-AND-PANEL SYSTEM

PIER TYPES

NOTE

The pier-and-panel wall is composed of a series of relatively thin (4-in. thick) reinforced brick masonry panels, which are braced intermittently with masonry piers. This wall is relatively easy to build and is economical because of the narrowness of the panels. It is also easily adapted to varying terrain conditions.

PIER-AND-PANEL GARDEN WALLS

NOTES

- Copings and caps prevent water from entering the inner wall from above by shedding water to the sides, where it is thrown clear of the wall, usually by means of a drip edge.
- Anchor coping as necessary. If the coping material is different from the wall material, compare their thermal and moisture expansion characteristics and make provisions for differential movement.

COPING TYPES FOR WALLS

*For wall sizes shown within heavy lines, 12 x 16 in. piers are required. All other values have been obtained with 12 x 12 in. piers.

Dennis Carmichael; EDAW, Inc.; Alexandria, Virginia

FREESTANDING GARDEN WALLS

Freestanding garden walls provide a physical or visual barrier to outdoor areas. Walls higher than eye level (approximately 5 ft 6 in.) provide both a physical and visual barrier; typically they are situated near and designed to blend with an adjacent architectural structure. Walls designed under eye level provide a sense of partial enclosure while maintaining a view, which is sometimes framed by the wall design.

SOLID MASONRY

GRAOUTED REINFORCED MASONRY

FREESTANDING MASONRY GARDEN WALLS

BRICK MASONRY SITE STEPS

Dennis Carmichael; EDAW, Inc.; Alexandria, Virginia

Design factors that should be addressed when designing freestanding garden walls include these:

1. Quality and durability of materials (unit material, mortar, and reinforcement) and detailing when exposed over time to rain, wind, sun, thermal movement, and degradation
2. Appearance of both sides of the wall
3. Foundation design
4. Adjacent plantings

STUCCO OVER CMU

STONE VENEER OVER REINFORCED CONCRETE

STONE MASONRY SITE STEPS

WOOD SITE BENCH

BRICK VENEER SEAT WALL

NOTES

1. Provide handrails on both sides of all stairs along accessible routes.
2. Step surfaces should be sloped so water will not accumulate on the walking surface.
3. These details are for reference only. Consult ADAAG for tread and handrail requirements for specific applications and BOCA for riser-to-tread ratios.

NATURAL FIELDSTONE (UNCOURSED) ASHLAR (COURSED)
MORTARED STONE WALLS

DOUBLE TIER WALL SINGLE TIER WALL
DRY STACK STONE WALLS

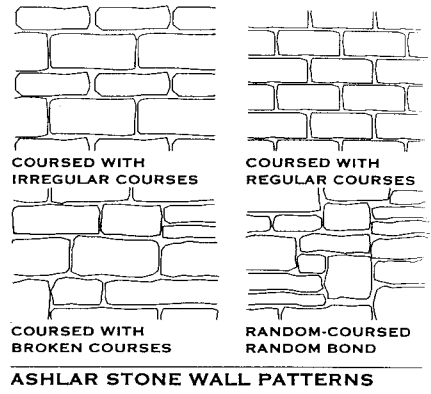

STONE HEDGE CORNISH HEDGE

STONE HEDGES

STONE WALL COPINGS

ASHLAR STONE WALL PATTERNS

RANDOM RUBBLESTONE WALL PATTERNS

NOTE
Most types of stone can be used for stone walls, but granite, limestone, sandstone, and slate are preferred. Ashlar and rubble are the main types of stonework used for walls. Ashlar is stone that has been cut and squared and can be laid in straight courses to create a uniform, stable wall; its surface can have any texture. Rubblestone has not been cut or dressed, and stability is largely achieved by using header stones that run through the wall, binding it together.

Dennis Carmichael; EDAW, Inc.; Alexandria, Virginia

GENERAL

The physical environment of the site, the design needs of the project, and the design character of the trees are all factors that must be considered in selecting trees and preparing a landscape plan for a building.

Soil conditions (acidity, porosity) at the site, the amount and intensity of sunlight and precipitation, and the seasonal temperature range in the area create the physical environment in which trees must be able to survive. As well, consider how the location and topography of the site will direct the wind, resulting in cold winds and cooling breezes that can affect the health of trees.

Trees can be used to address the design needs of a project by directing pedestrian or vehicle movement, framing vistas, screening objectionable views, and defining and shaping exterior space. Trees can also be used to modify the microclimate of a site and to help conserve building energy use from heating, cooling, and lighting systems.

The design character of the trees themselves plays a part in which species are best suited for a particular application. The shape of a tree can be columnar, conical, spherical, or spreading, and the resulting height and mass will change over time as the tree matures. Some trees grow quickly and others more slowly, and their color and texture varies from coarse to medium to fine, affecting their character. The appearance of deciduous trees changes with the seasons, while the effect of an evergreen remains relatively constant.

PHYSICAL CHARACTERISTICS OF TREES

NOTE
The vertical angle of the sun changes seasonally; therefore, the area of a building subject to the glare of reflected sunlight varies. Plants of various heights can screen sun (and artificial light) glare from adjacent surfaces.

GLARE PROTECTION

NOTE
Large masses of plants physically and chemically filter and deodorize the air, reducing air pollution. (Top) Particulate matter trapped on the leaves is washed to the ground during rainfall. Gaseous pollutants are assimilated by the leaves. (Bottom) Fragrant plants can mechanically mask fumes and odors. As well, these pollutants are chemically metabolized in the photosynthetic process.

AIR FILTRATION

NOTE
Shelter belt wind protection reduces evaporation at ground level, increases relative humidity, lowers the temperature in summer and reduces heat loss in winter, and reduces blowing dust and drifting snow. The amount of protection afforded is directly related to the height and density of the shelter belt.

WIND PROTECTION

NOTE
In summer, trees obstruct or filter the strong radiation from the sun, cooling and protecting the area beneath them. In winter, evergreen trees still have this effect, while deciduous trees, having lost their leaves, do not.

SHADE PROVISION

NOTE
A combination of deciduous and evergreen trees and shrubs reduces sound more effectively than deciduous plants alone. Planting trees and shrubs on earth mounds increases the attenuating effects of a buffer belt.

SOUND ATTENUATION

NOTE
Mature trees absorb or delay runoff from stormwater at a rate 4 to 5 times that of bare ground.

RUNOFF REDUCTION

James Urban, ASLA; James Urban Landscape Architecture; Annapolis, Maryland

NOTES

- For container-grown trees, use fingers or small hand tools to pull the roots out of the outer layer of potting soil; then cut or pull apart any roots circling the perimeter of the container.
- Incorporate commercially prepared mycorrhiza spores in the soil immediately around the root ball at rates specified by the manufacturer.
- During the design phase, confirm that water drains out of the soil; design alternative drainage systems as required.
- Thoroughly soak the tree root ball and adjacent prepared soil several times during the first month after planting and regularly throughout the following two summers.
- The planting process is similar for deciduous and evergreen trees.

TREE PLANTING DETAIL (BALLED AND BURLAPPED PLANTS)

NOTES

- For container-grown shrubs, use fingers or small hand tools to pull the roots out of the outer layer of potting soil; then cut or pull apart any roots that circle the perimeter of the container.
- Incorporate commercially prepared mycorrhiza spores in the soil immediately around the root ball at rates specified by the manufacturer.
- Confirm that water drains out of the soil during the design phase; design alternative drainage systems as required.

SHRUB PLANTING DETAILS

GENERAL RANGE OF SOIL MODIFICATIONS AND VOLUMES FOR VARIOUS SOIL CONDITIONS

POSTCONSTRUCTION SOIL CONDITION	MIN. WIDTH PREPARED SOIL FOR TREES (X)	TYPE OF PREPARATION
Good soil (not previously graded or compacted, topsoil layer intact)	6 ft or twice the width of the root ball, whichever is greater	Loosen the existing soils to the widths and depths shown in details above.
Compacted soil (not previously graded, topsoil layer disturbed but not eliminated)	15 ft	Loosen the existing soils to the widths and depths shown in details above; add composted organic matter to bring the organic content up to 5% dry weight.
Graded subsoils and clean fills with clay content between 5 and 35%	20 ft	Minimum treatment: loosen existing soil to widths and depths shown, add composted organic matter to bring organic content up to 5% dry weight. Optimum treatment: remove top 8-10 in. or the existing material, loosen existing soils to the widths and depths shown, add 8-10 in. of loam topsoil.
Poor quality fills, heavy clay soils, soils contaminated with rubble or toxic material	20 ft	Remove existing soils to the widths and depths shown, replace with loam topsoil.

James Urban, ASLA; James Urban Landscape Architecture; Annapolis, Maryland
American Nursery & Landscape Association (formerly AAN); Washington, D.C.

SOIL IMPROVEMENT

The quality of soil available for planting varies widely from site to site, especially after construction activity has occurred. The nature of construction results in compaction, filling, contamination, and grading of the original soil on a site, rapidly making it useless for planting. Previous human activity at a site can also affect the ability of the soil to support plants.

During the design phase, assumptions must be made regarding the probable condition of the soil after construction is complete. The health of existing or remaining soil determines what types of soil preparation will be required and the volume of soil to be prepared. Conditions will vary from location to location within a project, and details must be condition-specific. For large projects or extreme conditions, it is useful to consult an expert experienced in modifying planting soils at urban sites.

NOTES

- If site or design constraints prohibit use of the dimensions shown on this page, follow the guidelines for planting in urban areas.
- Whenever possible, the soil improvement area should be connected from tree to tree.
- Always test soil for pH and nutrient levels and adjust these as required.
- Loosen soil with a backhoe or other large coarse-tilling equipment when possible. Tilling that produces large, coarse chunks of soil is preferable to tilling that results in fine grains uniform in texture.
- The bottom of planting soil excavations should be rough to avoid matting of soil layers as new soil is added. It is preferable to till the first lift (2 to 3 in.) of planting soil into the subsoil.

STANDARD ROOT BALL SIZES FOR NURSERY-GROWN SHADE TREES

CALIPER* (IN.)	HEIGHT RANGE (FT-IN.)	MAX. HEIGHT (FT)	MIN. BALL DIA. (IN.)	MIN. BALL DEPTH (IN.)
1/2	5-6	8	12	9
3/4	6-8	10	14	10-1/2
1	8-10	11	16	12
1-1/4	8-10	12	18	13-1/2
1-1/2	10-12	14	20	13-1/2
1-3/4	10-12	14	22	14-1/2
2	12-14	16	24	16
2-1/2	12-14	16	28	18-1/2
3	14-16	18	32	19-1/2
3-1/2	14-16	18	38	23
4	16-18	22	42	25
5	18-20	26	54	32-1/2

*Up to and including the 4-in. caliper size, the caliper measurement indicates the diameter of the trunk 6 in. above ground level. For larger sizes, the caliper measurement is taken 12 in. above ground level.

NOTES

- See American Standard for Nursery Stock, ANSI Z60.1, for complete list of nursery standards for other types and sizes of trees and shrubs.
- See International Society of Arboriculture's "Principles and Practices of Planting Trees and Shrubs," 1997.

CONSTRUCTION AROUND EXISTING TREES

Great care should be taken not to compact, cut, or fill the earth within the crown area of existing trees. Most tree roots are located in the top 6 to 18 in. of the soil and often spread considerably farther than the drip line of the tree. Compaction can cause severe root damage and reduce the movement of water and air through the soil. To avoid compacting the earth, do not operate equipment or store materials within the crown spread.

Before construction begins, inject the soil within the crown area of nearby mature trees with commercially prepared kelp-based fertilizer and mycorrhiza fungus developed to invigorate tree roots. Prune tree roots at the edge of the root save area, as roots pulled during grading can snap or split well into the root save area. Rot and disease that enters dying roots in compacted or filled areas can move into the tree if root pruning has not been carried out. Install tree protection fencing and silt protection at the limits of construction activity near trees.

During construction, apply additional water in the canopy area to compensate for any root loss beyond the crown spread. Have all mature trees inspected by a certified arborist before construction begins to identify any special problems. Remove all deadwood and treat all trees for existing insect and disease problems. When possible, begin fertilization and problem treatments at least one full growing season before construction.

Removal of significant portions of the crown will affect the health of a tree by reducing its ability to photosynthesize in proportion to the mass of its trunk. Younger, healthier trees withstand construction impacts better than older trees.

FILLING AROUND EXISTING TREE

NOTE

If construction operations must take place within the crown spread area, install 6 in. of wood chips on top of the soil to protect it. Use plywood matting over mulch in areas where equipment must operate. Protect the trunk of the tree with planking loosely cabled around the tree to reduce scarring by equipment. Remove planking, matting, and mulch as soon as operations are finished.

NOTE

A barrier such as that illustrated can keep construction equipment and personnel from compacting the soil around tree roots.

NOTE

A root prune trench severs roots with a clean cut, protecting remaining roots from cracking, rot, and disease.

ROOT PRUNE TRENCH

NOTE

Fewer roots are severed by tunneling under a tree than by digging a trench beside it.

UNDERGROUND UTILITY LINE NEAR EXISTING TREES

CUTTING GRADE AROUND EXISTING TREE

FILLING GRADE AROUND EXISTING TREE

TREE STRUCTURE—PARTS AND GROWING CHARACTERISTICS

GENERAL

Areas of dense urban development leave little room for tree roots to develop. Large areas of pavement, competition with foundations and utilities for space below ground, and extensive soil compaction and disruption limit the amount of soil available for trees. When the area of ground around the tree open to the rain and sun is less than 400 to 500 sq ft per tree, the following design guidelines should be followed to encourage the growth of large healthy trees.

Five major parts of the tree structure must be accommodated in the design process:

CROWN GROWTH: The tree crown expands every growing season at a rate of 6 to 18 in. per year. Once the crown reaches a competing object such as a building or another tree canopy, the canopy growth in that area slows and then stops. Eventually the branches on that side of the tree die. As the canopy expansion potential is reduced, the overall growth rate and tree health are also reduced.

TRUNK GROWTH: The tree trunk expands about 1/2 to 1 in. per year. As the tree increases in size, the lower branches die and the trunk lengthens. Tree trunks move considerably in the wind, especially during the early years of development, and are damaged by close objects.

TRUNK FLARE: At the point where the trunk leaves the ground, most tree species develop a pronounced swelling or flare as the tree matures. This flare grows at more than twice the rate of the main trunk diameter and helps the tree remain structurally stable. Any hard object placed in this area, such as a tree grate or confining pavement, will either damage the tree or be moved by the tremendous force of this growth.

ZONE OF RAPID ROOT TAPER: Tree roots begin to form in the trunk flare and divide several times in the immediate area around the trunk. In this area, about 5 to 6 ft away from the trunk, the roots rapidly taper from about 6 in. in diameter to about 2 in. Most damage to adjacent paving occurs in this area immediately around the tree. Keeping the zone of rapid taper free of obstructions is important to long-term tree health. Once a tree is established, the zone of rapid taper is generally less susceptible to compaction damage than the rest of the root zone.

ROOT ZONE: Tree roots grow radially and horizontally from the trunk and occupy only the upper layers (12 to 24 in.) of the soil. Trees in all but the most well-drained soils do not have taproots. A relationship exists between the amount of tree canopy and the volume of root-supporting soil required (see the accompanying chart). This relationship is the most

critical factor in determining long-term tree health. Root-supporting soil is generally defined as soil with adequate drainage, low compaction, and sufficient organic and nutrient components to support the tree. The root zone must be protected from compaction both during and after construction. Root zones that are connected from tree to tree generally produce healthier trees than isolated root zones.

SOIL MODIFICATIONS

Thoroughly till organic matter into the top 6 to 12 in. of most planting soils to improve the soil's ability to retain water and nutrients. (Do not add organic matter to soil more than 12 in. deep.) Use composted bark, recycled yard waste, peat moss, or municipal processed sewage sludge. All products should be composted to a dark color and be free of pieces with identifiable leaf or wood structure. Recycled material should be tested for pH and certified free of toxic material by the supplier. Avoid material with a pH higher than 7.5.

Modify heavy clay or silt soils (more than 40% clay or silt) by adding composted pine bark (up to 30% by volume) and/or gypsum. Coarse sand may be used if enough is added to bring the sand content to more than 60% of the total mix. Improve drainage in heavy soils by planting on raised mounds or beds and including subsurface drainage lines.

Modify extremely sandy soils (more than 85% sand) by adding organic matter and/or dry, shredded clay loam up to 30% of the total mix.

SOIL VOLUME FOR TREES

*The ultimate tree size is defined by the projected size of the crown and the diameter of the tree at breast height.

NOTE

For example, a 16-in. diameter tree requires 1000 cu ft of soil.

NOTE

Soil volume provided for trees in urban areas must be sufficient for long-term maintenance.

SOIL VOLUME—REQUIREMENTS FOR TREES

NOTE

The interconnection of soil volumes from tree to tree has been observed to improve the health and vigor of trees.

SOIL VOLUME—INTERCONNECTION

NOTES

1. Coarse plantings keep pedestrians out of planters.
2. Curbs protect planters from pedestrians and deicing salts.
3. Underground steam lines must be insulated or vented to protect planter soil.

SOIL PROTECTION FROM COMPACTION AND DEGRADATION

NOTE

If visually symmetrical tree planting is required, symmetrical soil volumes are also required to produce trees of similar crown size.

VISUALLY SYMMETRICAL TREES

James Urban, ASLA; James Urban Landscape Architecture; Annapolis, Maryland

2 PLANTING

GENERAL

Traditional urban designs in which trees are regularly spaced in small openings within paved areas generally result in poor tree performance. This is because such designs generally do not provide adequate soil for root growth and ignore the fact that trees must significantly increase trunk size every year. As well, competition for space, both at ground level and below, is intense in urban areas.

NOTE
Best design option: Planting trees between sidewalks and buildings creates the fewest conflicts between roots and paving by permitting rooting activity on adjacent property.

NOTE
Acceptable design option: Planting between curbs and sidewalks in a continuous unpaved planting bed provides good soil levels for trees but contributes to root/paving conflicts as trees mature.

NOTE
Difficult design option: In highly developed areas with parking adjacent to the curb, planting in long narrow tree openings with an 18-in. wide walk along the curb accommodates pedestrians exiting cars. Root/paving conflicts are probable.

NOTE
Most difficult (and most expensive) design option: Tree openings are undersized for future trunk/root development. Severe root/paving conflicts are very likely.

SIDEWALK PLANTING OPTIONS

Although it is possible to design uncompacted soil volumes for trees under pavement, this is very expensive and the soil is never as efficient as that in open planting beds. Increasing trunk size can only be accommodated by using flexible materials that can change configuration over time. Urban designs that have flexible relationships between trees, paving, and planting beds and large areas of open planting soil offer the best opportunity for long-term tree health and lower maintenance costs.

NOTE
Best design option: Separate planting and walking areas. Avoid small disconnected soil volumes to minimize root/paving conflicts.

NOTE
Acceptable design option: Each tree has a smaller canopy with less yearly growth. More disease and insect problems are likely. Ground plantings eliminated by shade over time.

NOTE
Difficult design option: Shading, slow tree growth, and poor health are problems. Root/paving conflicts are likely.

NOTE
Most difficult (and most expensive) design option: Slow tree growth and severe root/paving conflicts are to be expected.

PLAZA TREE PLANTING OPTIONS

CONTINUOUS SOIL TRENCH
NOTE
A continuous soil trench provides very good soil but in limited quantity. Use in areas where adjacent backfill is compacted soils or fills.

STRUCTURAL SOIL
NOTE
Structural planting soils replace subgrade material with a fill that can be compacted to meet normal engineering compaction requirements and still support root growth below the pavement. The principle is that when the gravel is compacted, the soil is not because the amount of soil in the mix is insufficient to fill all the voids. Hydrogel, a cross-linked potassium copolymer, is used to help bind the mixture during the mixing process. The soil mix includes ASHTO #4 gravel (100 lb calculated dry weight), shredded clay loam (15-18 lb), hydrogel (0.03 lb), and water ±10 (including the water calculated in the gravel and the soil). For further information, contact the Urban Horticulture Institute at Cornell University (Ithaca, NY).

ROOT PATH TRENCH
NOTES

1. In urban areas where the pavement subgrade is compacted soil that is free from rubble, toxic, or poorly drained fills, a system of root paths can be installed to guide roots under the pavement, where they have room to grow. These roots grow deeper in the soil, causing fewer root/paving conflicts than roots left to exploit the normal minor weaknesses in paving and subgrades.
2. A root path trench is made by installing a length of strip drain material (a 12-in. wide x 1-in. thick plastic drain core wrapped in filter fabric) in a narrow trench and backfilling with loam topsoil. This allows air and water to flow more freely into the soil under the pavement. Install geotextile fabric and the gravel base material and then the paving.
3. Root paths cannot replace larger soil trenches or structural planting soil in areas in which existing soil conditions are extremely poor for root exploration.

TREE SOIL INTERCONNECTION OPTIONS UNDER PAVING

James Urban, ASLA; James Urban Landscape Architecture; Annapolis, Maryland

ROOFTOP PLANTER

SELECTING PLANTS FOR ROOFTOP PLANTING

When choosing plants for a rooftop setting, consider the factors outlined below:

WIND TOLERANCE: Higher elevations and exposure to wind can cause defoliation and increase the transpiration rate of plants. High parapet walls with louvers can reduce wind velocity and provide shelter for plants.

HIGH EVAPORATION RATE: The drying effects of wind and sun on the soil in a planter reduce soil moisture rapidly. Irrigation, mulches, and moisture-holding soil additives (diatomaceous earth or organic matter) help reduce this moisture loss.

RAPID SOIL TEMPERATURE FLUCTUATION: The variation in conduction capacity of planter materials results in a broad range of soil temperatures in planters of different materials. Cold or heat can cause severe root damage in certain plant species. Proper drainage helps alleviate this condition.

TOPSOIL: Improve topsoil in planters to provide optimum growing conditions for the plants selected. A general formula calls for adding fertilizer (determined by soil testing) and one part peat moss to five parts sandy loam topsoil. More specific requirements for certain varieties of plants or grasses should be considered.

ROOT CAPACITY: Choose plant species carefully, considering their adaptation to the size of the plant bed. If species with shallow, fibrous roots are used instead of species with a coarse root system, consult with a nursery advisor. Consider the ultimate maturity of the plant species when sizing a planter.

PLANTING DETAILS

SOIL DEPTH: Minimum soil depth in a planter varies with the plant type: for large trees, the soil should be 36 in. deep or 6 in. deeper than the root ball; for small trees, 30 in. deep;

NOTE

Young trees planted in lawn areas face substantial competition from the roots of grasses.

TREES PLANTED IN LAWNS

for shrubs, 24 in. deep; and for lawns, 12 in. deep (10 in. if irrigated).

SOIL VOLUME: To determine sufficient soil volume, see chart on Soil Volumes for Trees (on another AGS page in this section).

SOIL WEIGHT: The saturated weight of normal soil mix ranges from 100 to 120 pcf, depending on soil type and compaction rate. Soils can be made lighter by adding expanded shale or perlite. Soils lighter than 80 pcf cannot provide structure adequate to support trees.

DRAINAGE FABRIC: Plastic drainage material should be a minimum of 1/2 in. thick. Most drainage material comes with a filter fabric attached, but the overlap joints provided are not wide enough for the unconsolidated soils found in planters. A second layer of woven filter fabric, delivered in rolls greater than 10 ft in width, should be installed. Tuck the fabric over the exposed top of the drainage material to keep soil out of the drainage layer.

INSULATION: Most planters do not require insulation; however, in colder climates planters with small soil volumes located over heated structures may require insulation. Consult local sources for a list of cold-hardy plants.

NOTE

Tree guards can protect young trees from trunk damage caused by bicycles. If made too small, however (less than 30 in. in diameter), they can damage the tree as it grows and are difficult to remove. The high cost and potential harm to trees outweigh the minor protection tree guards afford a trunk. They should only be used in areas with particularly high traffic.

TREE GUARDS

NOTE

Tree grates decorate the base of a tree but provide no significant benefit. Many aspects of tree grates can damage a tree or reduce its potential for growth.

TREE GRATES

NOTE

Alternatives to tree grates (and guards) include softer, organic coverings that suit the purpose better, are less expensive, and require less maintenance over the life of the tree.

TREE BASE PROTECTION

James Urban, ASLA; James Urban Landscape Architecture; Annapolis, Maryland

CONCRETE

Concrete Forms and
Accessories 184

Concrete Reinforcement 189

Cast-in-Place Concrete 192

Precast Concrete 201

GENERAL

Formwork costs are a substantial part of the total cost of putting concrete in place—anywhere from 35 to 60 percent. Thus, by developing design elements and details that simplify or standardize form requirements, the architect can help contain overall costs:

1. Reuse forms: This is crucial to economy of construction. The designer can facilitate form reuse by standardizing the dimensions of windows, columns, beams, and footings, using as few different sizes of each as possible. Where columns must change size, hold one dimension (e.g., width) constant, while varying the other (depth). This enables at least half of the form panels to be used many times. Repeat the same floor and column layout from bay to bay on each floor and from floor to floor. This improves labor productivity and permits reuse of many forms.
2. Use a preconstruction mockup: The architect and builder should agree on the location and desired appearance of architectural surfaces before any of the exposed concrete work begins. Specify a full-scale preconstruction mockup to help achieve this and to avoid postconstruction disagreements.
3. Handle forms in large panels: This also reduces construction costs. Wherever possible, make uninterrupted formed areas the same size. Increasing the size of such areas enables the builder to combine form panels into gangs for efficient crane use.
4. Simplify design details: Intricacies and irregularities cost more and often do not add proportionately to the aesthetic effect.

NOTES

1. Commonly made of steel-framed plywood, panels are also available in aluminum. Wall ties (typically flat ties) and wall forms are held together by slotted pins that run through adjoining holes. A wedge pushed down into the slot alongside the wall form tightens the joint. Service life can be extended by turning or replacing the plywood face.
2. Reusable plastic liners may be attached to inner surfaces to produce patterned concrete.
3. For maximum economy, panels can be assembled in large gangs and set in place by crane.

HAND-SET MANUFACTURED WALL FORMS

RECOMMENDED LOW-COST FORMWORK

MID-COST FORMWORK

HIGH-COST FORMWORK

NOTE

In general, the least costly design to form has columns the same width or narrower than the beams they support, allowing the beam form to be erected in a continuous line. In mid-cost formwork design, the beam bottom forms are cut to fit around the column tops. In high-cost formwork design, the beam forms are fitted into pockets on both sides of the column forms.

BEAM-TO-COLUMN FORMWORK ECONOMIES

RECOMMENDED FOOTING DESIGN

NOTE

When stepped footings are required, use fewer steps and design them to standard lumber and plywood dimensions or modular divisions of these dimensions.

WALL FOOTINGS

NOTE

Installing and removing ties and patching tie holes are some of the most labor-intensive operations in forming walls. Also, getting a durable, inconspicuous patch often proves difficult. Avoid this problem by specifying smooth cone fittings at the tie ends, then either leaving the resulting uniform tie holes exposed or plugging them with pre-formed concrete plugs and a bonding agent. Leave no exposed corrodible metal within 1 1/2 in. of concrete surface. Contractors may propose tie spacing wider than 2 ft o.c. to reduce the total number of ties to save money, but this calls for stronger ties and heavier form supports.

FORM TIE PATTERN

RECOMMENDED LOW-COST FORMWORK

MID-COST FORMWORK

HIGH-COST FORMWORK

NOTE

Flat beams designed to be equal in depth to the floor assembly are the least costly, since they most efficiently accommodate flying form construction. Deeper, narrower beams cost more, but if deeper beams are needed, costs can be controlled by making the beam the same thickness as the column depth and at least partially upturned. The most costly option is a column thicker than the beam, since this requires a column collar with construction joint.

SPANDREL BEAM FORMWORK ECONOMIES

SLAB FORMWORK NOTE

Adapting design elements to the modular sizes of formwork lumber and plywood and dimensioning parts of the structure to fit the modules can save the expense of custom formwork. For example, to save the waste and time of sawing and piecing together the edge form, make the depth of the drop in a slab equal to the actual size of standard lumber plus 1/4 in. for the plywood's thickness.

STANDARD LUMBER FORMS

TILT-UP WALL FORMWORK NOTE

In tilt-up construction, walls are cast on the completed floor slab, which must be level, smoothly finished, and treated with a bond-breaking agent to permit easy separation. The wall is then tilted or lifted into vertical position and fastened to the adjoining wall piece. This method reduces formwork and labor and eliminates transportation requirements that may limit panel size.

FORM SHEATHING JOINT DETAILS

NOTE
Verify size and spacing of components for each job. The combination of plyform sheathing, studs, walers, and ties must be chosen carefully to safely resist concrete pressure and limit deflection of the form face. Steel and aluminum studs and walers may be used in place of wood.

TYPICAL JOB-BUILT WALL SECTION

NOTES

1. The typical wood and plywood framing details shown must be modified as necessary to accommodate the lateral pressure of fresh concrete on the forms. Studs and walers of aluminum or steel are frequently used. Lateral pressure varies depending on the rate at which the form is filled, the temperature of the concrete, vibration procedures, and the type of admixtures used in the concrete.
2. Consult manufacturers' recommendations for safe working loads on ties. Consult the American Concrete Institute's *Formwork for Concrete* (SP-4) for detailed design recommendations.
3. A great variety of form ties are commercially available (see AGS page on concrete formwork hardware). For architectural surfaces exposed to weather, choose a tie that leaves no corrodible metal closer than 1 1/2 in. from the concrete surface. Ties should be tight fitting and sealed as necessary to prevent leakage at holes in the forms.
4. Ties fitted with wood or plastic cones should leave depressions at least as deep as the surface diameter of the cone. The holes may be filled with recessed plugs or left unfilled if noncorroding ties are used.
5. Provide cleanout doors at the bottom of wall forms.

Tucker Concrete Form Company; Stoughton, Massachusetts
Mary K. Hurd; Engineered Publications; Farmington Hills, Michigan

GENERAL NOTES

1. Scaffolding, steel shores, or wood posts may be used under stringers depending on loads and height requirements.
2. For flat slabs of flat plate forming, metal "flying forms" are commonly used.

3. Patented steel forms or fillers can be special ordered for unusual conditions; see manufacturers' catalogs. Fiber forms are also on the market in similar sizes. Plyform deck is required for forming.
4. Plyform is usually $\frac{5}{8}$ in. minimum thickness, Exposure 1.

TYPICAL PAN FORM

TYPICAL CENTERING

NOTES

1. Forms are available in steel and lightweight fiberglass. Consult manufacturers for forms with different dimensions and rib-form variations. Typically three types are available: nail-down flange (simplest, but produces rough, nonarchitectural surface); slip-in type (based on

- nail-down form but with board insert for smooth appearance); and adjustable (without flanges; produces smooth rib).
2. Consult ANSI A48.1-1986 for complete pan form standards.

TYPICAL PAN FORM FOR ONE-WAY SLAB

TYPICAL SLAB AND SHALLOW BEAM FORMING

TYPICAL SLAB AND HEAVY BEAM FORMING

Tucker Concrete Form Company; Stoughton, Massachusetts

NOTES

1. Standard waffle slab forms are square for ease of use and economy. Dimensions vary slightly from manufacturer to manufacturer. Consult ANSI A48.2-1986 for complete dome form standards.
2. Forms are available in steel and lightweight fiberglass. Consult form manufacturer for options in material, textures, and dimensions.

TYPICAL DOME FORM FOR WAFFLE OR TWO-WAY SLAB

NOTE

Waterstops are flexible barriers used to prevent the passage of liquids and gasses under pressure through joints in concrete slabs. Waterstops are typically made of polyvinyl chloride, and their shapes vary according to application. If a center bulb is specified, it must remain unembedded in the center of the joint.

SLAB FORMWORK WITH WATER STOP

NOTE

This type of formwork is used to fireproof structural steel beams by wrapping them in concrete.

TYPICAL SUSPENDED FORM WITH COIL SADDLE-TYPE HANGERS

GENERAL

Concrete formwork hardware includes ties, anchors, hangers, and spacers used to hold forms and reinforcements in place against the forces of unhardened concrete and other loads applied during construction. Concrete ties are tensile units adapted to hold concrete forms together and may be classified by use or by load-carrying capacity. Classified by use are two main concrete tie types: "continuous single member," in which the entire tie rod extends through the wall and through both sides of the formwork (this can be a pull-out tie or a snap-off tie), and "internal disconnecting," in which the tensile unit has an inner part with threaded connections to removable external members. Classified by load-carrying capacity are light-duty (safe working loads of up to 3750 lb) and heavy-duty (loads of more than 3750 lb) concrete ties. Safe working load should be set at no more than half the tie's ultimate strength. Other hardware systems and configurations may be available; consult manufacturers for complete details.

NOTE
Coil ties are medium- to heavy-duty ties fabricated to accept a threaded bolt, which passes through the formwork lumber.

COIL TIES

NOTE
Flat ties are light-duty ties used with a wedge and bolt to secure and space modular wall forms.

FLAT TIE

NOTE
Generally used for heavy-duty loads of up to 50,000 lb, the taper tie system is a versatile forming system whose parts are removed after the concrete sets and may be reused. Ties may be installed after forms are in place.

STEEL TAPER TIE

NOTE
Fiberglass form ties, straight rods secured with reusable external metal grippers, have safe working loads ranging from 2250 to 25,000 psi. The ties are readily broken off or cut at the concrete surface, then ground flush.

FIBERGLASS FORM TIE

NOTE
Snap ties are a type of through tie for light-duty use, fabricated so the exposed ends of the tie can be snapped off at the breakback (a notch in the rod). The antiturn device makes it easier to break off the exposed end.

SNAP TIES

NOTE
Rock anchors are used with coil ties to facilitate one-side forming of walls.

ROCK ANCHOR

NOTE
Steel wedges are placed at the outside threaded ends of pull-out or snap tie rods, holding the formwork in place. Plastic or wood cones may be placed on the tie rod at the formwork wall surface, so that when the formwork is removed the tie rod ends are set back for subsequent finishing (with plugs, etc.).

TIE ROD ACCESSORIES

NOTE
This light-duty system is suitable for job-set forms.

CAM LOCK BRACKET/TIE SYSTEM

NOTE
The coil anchor is embedded near the top of a concrete lift to support the formwork of the succeeding lift. The reusable he-bolt is threaded into the coil.

HE-BOLT WITH COIL ANCHOR

NOTE
She-bolts are reusable heavy-duty tie components threaded onto an internal tie rod permanently embedded in the concrete. They are typically used with crane-handled forms.

SHE-BOLT/TIE ROD

NOTE
Bar supports are used to maintain the reinforcement's design distance from the wall sides or slab bottom. They are typically made of stainless steel or epoxy- or plastic-coated steel.

REINFORCING BAR AND MESH SUPPORTS

Mary K. Hurd; Engineered Publications; Farmington Hills, Michigan

GENERAL

Steel reinforcement for concrete consists of reinforcing bars and welded wire fabric. Bars are manufactured by hot-roll process as round rods with lugs, or deformations, which inhibit longitudinal movement of the bar in the surrounding concrete. Bar sizes are indicated by numbers. For sizes #3 through #8, the numbers are the number of eighths of an inch in the nominal diameter of the bars. Numbers 9, 10, and 11 are round and correspond to the former 1 in., 1 1/8 in., and 1 1/4 in. square sizes. Sizes #14 and #18 correspond to the former 1 1/2 in. and 2 in. square sizes. The nominal diameter of a deformed bar is equal to the actual diameter of a plain bar with the same weight per foot as the deformed bar. Epoxy-coated, zinc-coated (galvanized), and stainless steel reinforcing bars are used when corrosion protection is needed; stainless steel also has nonmagnetic properties. In some instances, a fiber-reinforced plastic (FRP) rebar is used for highly specialized concrete reinforcement because of its high tensile strength and light weight, corrosion resistance, and dielectric (nonconductive) properties. FRP rebars are manufactured in the same sizes as steel rebars and also have deformations on the surface. Consult manufacturers for further information.

Welded wire fabric is used in thin slabs, shells, and other designs in which available space is too limited to give proper cover and clearance to deformed bars. Welded wire fabric, also called mesh, consists of cold drawn wire (smooth or deformed) in orthogonal patterns; it is resistance welded at all intersections.

Wire in the form of individual wire or groups of wires is used in the fabrication of prestressed concrete.

ASTM STANDARD REINFORCING BAR SIZES

ASTM SIZE DESIGNATION	AREA (SQ IN. ACTUAL)	WEIGHT (LB/FT. ACTUAL)	DIAMETER (IN. ACTUAL)
#18	4.00	13.600	2.257
#14	2.25	7.650	1.693
#11	1.56	5.313	1.410
#10	1.27	4.303	1.270
#9	1.00	3.400	1.128
#8	0.74	2.670	1.000
#7	0.60	2.044	0.875
#6	0.44	1.502	0.750
#5	0.31	1.043	0.625
#4	0.20	0.668	0.500
#3	0.11	0.376	0.375

NOTE

Metrication of reinforcing bars is being considered in the United States; as of October 1995, a decision had not been made about what metric rebar sizes would apply in the United States. Metrication may result in a reengineering of reinforced concrete structures using the new bar sizes.

NOTES

- Lap splice lengths are multiples of tension development lengths; Class A = 1.0 lb, Class B = 1.3 lb (ACI 12.15.1) Values of lb for bars in beams or columns are based on transverse reinforcement meeting minimum requirements for stirrups in ACI 11.5.4 and 11.5.5.3, or meeting tie requirements in ACI 7.10.5; and are based on minimum cover specified in ACI 7.7.1.
- Conditions that require Category 1 or Category 2 lap splice lengths should be avoided if at all possible for the larger bar sizes. These inordinately long lengths present possible construction problems due to placing, congestion, etc. Options available in trying to avoid Category 1 or 2 conditions include:
 - Increasing the concrete cover to more than one bar diameter and/or increase the bar c-c. spacing to more than three bar diameters.
 - Utilizing the Av allowance in ACI 12.2.3 (b) for beams or columns. Note that if ties or stirrups meet the minimum Av requirement, Category 1 lengths are reduced to Category 5 lengths and Category 2 lengths are reduced to Category 6 lengths.
- The ACI 318-89 code does not allow lap splices of #14 or #18 bars. The values tabulated for those bar sizes are the tension development lengths.
- Top bars are horizontal bars with more than 12 in. of concrete cast below the bars.
- #11 and smaller edge bars with c-c. spacing not less than 6db are assumed to have a side cover not less than 2.5db. Otherwise, Category 5 applies rather than Category 6.
- For lightweight aggregate, multiply the values above by 1.3.
- For epoxy-coated reinforcing bars, multiply the values above by one of the following factors:
 - Cover < 3db or c-c. spacing < 7db multiply top bars by 1.31 and all other bars by 1.50.
 - Cover > 3db and c-c. spacing > 7db multiply top bars and all other bars by 1.20.
- See CRSI's *Reinforcement: Anchorages, Lap Splices and Connections* manual for tables of tension development and lap splices for other concrete strengths and epoxy-coated rebars.

COLUMN REINFORCEMENT

GENERAL

Admixtures are those ingredients in concrete other than portland cement, water, and aggregates that are added to the mixture immediately before or during mixing. Admixtures can be classified by function as follows: air-entraining admixtures; water-reducing admixtures; retarding admixtures; accelerating admixtures; superplasticizers; finely divided mineral admixtures; miscellaneous admixtures that aid workability, bonding, dampproofing, gas-forming, grouting (nonshrink), and coloring and help reduce permeability and inhibit corrosion.

Concrete should be workable, finishable, strong, durable, watertight, and wear-resistant. These qualities can usually be achieved by selecting suitable materials or by changing the mix proportions. Sometimes air-entraining admixtures are necessary, but in most cases admixtures can be forgone. No admixture can substitute for good concreting practice.

The major reasons for using admixtures are to reduce the cost of concrete construction; to achieve certain properties in concrete more effectively; to ensure the quality of concrete during mixing, transporting, placing, and curing in adverse weather conditions; and to overcome certain emergencies during concreting operations.

NOTES

1. The effectiveness of an admixture depends on such factors as type, brand, and amount of cement; water content; aggregate shape, gradation, and proportions; mixing time; slump; and concrete and air temperatures.
2. Trial mixtures should be made with the admixture and the job materials at temperatures and humidities anticipated on the job to ensure compatibility with other admixtures and job materials and to allow observation of how the properties of the fresh and hardened concrete are affected by local conditions.
3. The cost of using admixtures should be compared with the cost of changing the basic concrete mixture. Determine how using an admixture will affect the cost of transporting, placing, finishing, curing, and protecting the concrete.
4. Recommended total air contents for different exposure conditions are shown for different aggregate sizes in the table below.

TOTAL TARGET AIR CONTENT FOR CONCRETE¹

NOMINAL MAXIMUM AGGREGATE SIZE (IN.)	AIR CONTENT (PERCENT) ²		
	SEVERE EXPOSURE ³	MODERATE EXPOSURE ³	MILD EXPOSURE ³
3/8	7 1/2	6	4 1/2
1/2	7	5 1/2	4
3/4	6	5	3 1/2
1	6	4 1/2	3
1 1/2	5 1/2	4 1/2	2 1/2
2 1/2	5	4	2
3	4 1/2	3 1/2	1 1/2

¹ Experience shows that hardened concrete with the air contents specified in this table, as sampled and tested in the plastic state, performs satisfactorily. The air content of hardened concrete may be somewhat different.

² Project specifications often allow the air content of the delivered concrete to be within several percentage points of the table target values.

³ Severe exposure is an environment in which concrete is exposed to wet freeze-thaw conditions, de-icers, or other aggressive agents. Moderate exposure is an environment in which concrete is exposed to freezing but will not be continually moist, not exposed to water for long periods before freezing, and will not be in contact with de-icers or aggressive chemicals. Mild exposure is an environment in which concrete is not exposed to freezing conditions, de-icers, or aggressive agents.

CONCRETE ADMIXTURES BY CLASSIFICATION

TYPE OF ADMIXTURE	DESIRED EFFECT	MATERIAL
Accelerators (ASTM C 494, Type C)	Accelerate setting and early-strength development	Calcium chloride (ASTM D 98); Triethanolamine, sodium thiocyanate, calcium formate, calcium nitrate, calcium nitrite
Air detrainers	Decrease air content	Tributyl phosphate, dibutyl phthalate, octyl alcohol, water-insoluble esters of carbonic and boric acid, silicones
Air-entraining admixtures (ASTM C 260)	Improve durability in environments of freeze-thaw, de-icers, sulfate, and alkali reactivity; Improve workability; segregation and bleeding are reduced or eliminated	Salts of wood resins (Vinsol resin); some synthetic detergents; salts of sulfonated lignin; salts of petroleum acids; salts of proteinaceous material; fatty and resinous acids and their salts; alkylbenzene sulfonates; salts of sulfonated hydrocarbons
Alkali-reactivity reducers	Reduce alkali-reactivity expansion	Pozzolans (fly ash, silica fume), blast-furnace slag, salts of lithium and barium, air entraining agents
Bonding admixtures	Increase bond strength	Rubber, polyvinyl chloride, polyvinyl acetate, acrylics, butadiene-styrene copolymers
Coloring agents	Colored concrete	Modified carbon black, iron oxide, phthalocyanine, umber, chromium oxide, titanium oxide, cobalt blue (ASTM C 979)
Corrosion inhibitors	Reduce steel corrosion activity in a chloride environment	Calcium nitrite, sodium nitrite, sodium benzoate, certain phosphates of fluosilicates, fluoaluminate
Dampproofing admixtures	Retard moisture penetration into dry concrete	Soaps of calcium or ammonium stearate or oleate; butyl stearate; petroleum products
Finely divided mineral admixtures		
Cementitious	Hydraulic properties; partial cement replacement	Ground granulated blast-furnace slag (ASTM C 989); natural cement; hydraulic hydrated lime (ASTM C 141)
Pozzolans	Pozzolanic activity; improve workability, plasticity, sulfate resistance; reduce alkali reactivity, permeability, heat of hydration; partial cement replacement; filler	Diatomaceous earth, opaline cherts, clays, shales, volcanic tuffs, pumicites (ASTM C 618, Class N); fly ash (ASTM C 618, Class F and C), silica fume
Pozzolanic and cementitious	Same as cementitious and pozzolan categories	High calcium fly ash (ASTM C 618, Class C); ground granulated blast-furnace slag (ASTM C 989)
Nominally inert	Improve workability; filler	Marble, dolomite, quartz, granite
Fungicides, germicides, and insecticides	Inhibit or control bacterial and fungal growth	Polyhalogenated phenols; dieldrin emulsions; copper compounds
Gas formers	Cause expansion before setting	Aluminum powder; resin soap and vegetable or animal glue; saponin; hydrolyzed protein
Grouting agents	Adjust grout properties for specific applications (i.e., non-shrink grout for setting steel on masonry or concrete, fill reglets and cracks)	See air-entrained admixtures, accelerators, retarders, workability agents
Permeability reducers	Decrease permeability	Silica fume; fly ash (ASTM C 618); ground slag (ASTM C 989); natural pozzolans; water reducers; latex
Pumping aides	Improve pumpability	Organic and synthetic polymers; organic flocculents; organic emulsions of paraffin, coal tar, asphalt, acrylics; bentonite and pyrogenic silicas; natural pozzolans (ASTM C 618, Class N); fly ash (ASTM C 618, Classes F and C); hydrated lime (ASTM C 141)
Retarders (ASTM C 494, Type B)	Retard setting time to offset effect of hot weather, to delay initial set for difficult placement, or for special finishing, such as exposed aggregate	Lignin; borax; sugar; tartaric acids and salts
Superplasticizers* (ASTM C 1017, Type 1)	Flowing concrete; reduce water-cement ratio	Sulfonated melamine formaldehyde condensates; sulfonated naphthalene formaldehyde condensates; lignosulfonates
Superplasticizer* and retarder (ASTM C 1017, Type 2)	Flowing concrete with retarded set; reduce water	See superplasticizers and water reducers
Water reducer (ASTM C 494, Type A)	Reduce water demand at least 5%	Lignosulfonates; hydroxylated carboxylic acids; carbohydrates (also tend to retard set so accelerator is often added)

* Superplasticizers are also referred to as high-range water reducers or plasticizers. These admixtures often meet

both ASTM 494 and C 1017 specifications simultaneously.

Robert W. Shuldes, P.E.; Portland Cement Association; Skokie, Illinois

SPREAD FOOTINGS

PILE-SUPPORTED FOUNDATIONS

DISCONTINUOUS FOOTINGS

STEP FOOTINGS

NOTES

1. Test soils to determine their allowable bearing capacity. Refer to local building codes.
2. "H" is a function of the passive resistance of the soil, generated by the moment applied to the pier cap.
3. Piers may be used under grade beams or concrete walls. For very heavy loads, pier foundations may be more economical than piles.

BELL PIER FOUNDATION

NOTES

1. Set pier into a socket in rock to transmit high compression or tension loads into rock by bond.
2. Pier shaft should be poured in dry conditions if possible, but tremie pours can be used.

SOCKET PIER FOUNDATION

AREAWAY WALL

 Mueser Rutledge Consulting Engineers; New York, New York

GENERAL

Factors to consider in the design and construction of all slabs on grade include the intended use of the slab or slab section, the condition and preparation of a uniform subgrade, quality of concrete, adequacy of structural capacity, type and spacing of joints, finishing, curing, and application of special surfaces. The subgrade support must be reasonably uniform and the upper portion of the subgrade (called the base) should be of uniform material and density. Both should be properly compacted. A thin layer of compactable granular fill may be placed immediately beneath the slab to act as a percolation barrier.

Wear resistance (abrasion) is directly related to the condition of the top portion of the concrete slab. Surface hardness and abrasion resistance may be provided by special additives or hardeners to the surface. The quality of the overall concrete slab will be enhanced by proper water-to-cement ratio, reasonable slump limits, and well-graded aggregates with the maximum size of the coarse aggregate as large as placing will permit. Exterior concrete subjected to freeze-thaw cycles should have 4 to 7% entrained air.

Reinforcement in concrete slabs is unnecessary where frequent joint spacings are used. Where less frequent joint spacings are used, reinforcement is placed in the slab, at or above the mid-depth (generally 1/2 down from the top surface) to act as crack control. Common contraction joint spacing is 15 to 25 ft, depending on the thickness of the slab and the construction type. Checkerboard placement of slabs is no longer recommended by American Concrete Institute (ACI) 302.1 "Guide for floor and slab construction," where strip placement of slabs is recommended for large areas.

Three types of joints are recommended:

1. ISOLATION JOINTS (also called expansion joints): Allow movement between slab and fixed parts of the building such as columns, walls, and machinery bases.
2. CONTRACTION JOINTS (also called control joints): Induce cracking at preselected locations.
3. CONSTRUCTION JOINTS: Provide stopping places during floor construction. Construction joints also function as control and isolation joints.

Sawcut control joints should be made as early as is practical after finishing the slab and should be filled in areas with wet conditions, hygienic and dust control requirements, or con-

siderable traffic by hard wheel vehicles, such as forklifts. A semirigid filler Shore Hardness "A" of at least 80 should be used in joints supporting forklift traffic.

Concrete floor slabs are monolithically finished as a general procedure by floating and troweling to a smooth and dense top surface finish. ACI 302 provides specific guidance for appropriate finishing procedures to control the achievable floor flatness. ACI 302, ACI 360, and ACI 117 provide guidance for flatness selection and the techniques by which flatness and levelness are produced and measured. Two systems are used. The preferred method of measuring flatness and levelness (documented in ACI 302 and ACI 117) is the F-Number System. Special finishes are available to improve appearance as well as surface properties. These include sprinkled (shake) finishes or high-strength toppings, either as monolithic or separate (two-stage floor) surfaces. Where propagation of water vapor is undesirable, a water-proof vapor barrier, with permeance not to exceed 0.20 perms, can be used.

THICKNESS DESIGN

In general, the controlling loading to a slab on grade is the heaviest concentrated loading that it will carry. This is frequently the axle loading of an industrial lift truck or the set of post loadings from heavy rack storage shelves. The concrete slab thickness required will depend on the loading itself, the modulus of rupture of the concrete (usually based on the compressive strength of the concrete), the selected factor of safety used in the design, and the modulus of subgrade reaction (k) of the soil support system (subgrade). Procedures and examples are shown in ACI 360, ACI 330, and ACI 302. Class 1, 2, and 3 floors should be no thinner than 4 or 5 inches. Loading and usage frequently require floors thicker than 6 inches.

DOWEL SIZE AND SPACING (IN.)

SLAB DEPTH	DOWEL DIA.	TOTAL DOWEL LENGTH	DOWEL SPACING CENTER TO CENTER
5-6	3/4	16	12
7-8	1	18	12
9-10	1 1/4	18	12

CLASSIFICATION OF CONCRETE SLABS ON GRADE

CLASS	RECOMMENDED SLUMP (IN.)	RECOMMENDED 28-DAY COMPRESSIVE STRENGTH (PSI)	USUAL TRAFFIC	USE	SPECIAL CONSIDERATIONS	CONCRETE FINISHING TECHNIQUE
1	5	3000	Light foot	Residential surfaces; mainly with floor coverings	Grade for drainage; level slabs suitable for applied coverings; curing	Single troweling
2	5	3500	Foot	Offices and churches; usually with floor covering Decorative	Surface tolerance (including elevated slabs); nonslip aggregates in specific areas Colored mineral aggregate; hardener or exposed aggregate; artistic joint layout	Single troweling; nonslip finish where required As required
3	5	3500	Foot and pneumatic wheel	Exterior walks, driveways, garage floors, and sidewalks	Grade for drainage; proper air content; curing	Float, trowel, or broom finish
4	5	4000	Foot and light vehicular traffic	Institutional and commercial	Level slab suitable for applied coverings; nonslip aggregate for specific areas and curing	Normal steel trowel finish
5	4	4000	Industrial vehicular traffic—pneumatic wheel	Light-duty industrial floors for manufacturing, processing, and warehousing	Good uniform subgrade; surface tolerance; joint layout; abrasion resistance; curing	Hard steel trowel finish
6	4	4500	Industrial vehicular traffic—hard wheels	Industrial floors subject to heavy traffic; may be subject to impact loads	Good uniform subgrade; surface tolerance; joint layout; load transfer; abrasion resistance; curing	Special metallic or mineral aggregate; repeated hard steel troweling
7	4	Base 3500	Industrial vehicular traffic—hard wheels	Bonded two-course floors subject to heavy traffic and impact	Base slab—Good uniform subgrade; reinforcement; joint layout; level surface; curing Topping—Composed of well-graded all-mineral or all-metallic aggregate; Mineral or metallic aggregate applied to high-strength plain topping to toughen; surface tolerance; curing	Clean-textured surface suitable for subsequent bonded topping Special power floats with repeated steel trowelings
8	2	Topping 5000-8000	As in classes 4, 5, and 6	Unbonded toppings—Freezer floors on insulation, on old floors, or where construction schedule dictates	Bond breaker on old surface; mesh reinforcement; minimum thickness 3" (nominal 75mm) abrasion resistance, and curing	Hard steel trowel finish
9	5	4000 or higher	Superflat or critical surface tolerance required. Special materials-handling vehicles or robotics requiring specific tolerances	Narrow-aisle, high-bay warehouses; television studios	Varying concrete quality requirements. Shake-on hardeners cannot be used unless special application and great care are employed. Proper joint arrangement	Strictly follow finishing techniques as indicated in section 7.15 of ACI 302

Boyd C. Ringo; Cincinnati, Ohio

- NOTES**
1. Structural engineer to determine reinforcement specifications and specific placement in stairs.
 2. Check codes for dimensions and clearances for accessibility standards.

U-TYPE CONCRETE STAIRS

NOTE
Extend hinge only as required by stair width, unless otherwise permitted by structural engineer.

FREESTANDING CONCRETE STAIR

NOTE
Use of helicoidal concrete stairs depends on very stiff fixed end support and small support deflection.

HELICOIDAL CONCRETE STAIR

NOTE
Reinforcement must develop full bond in masonry walls and have full development length in concrete walls.

CANTILEVER CONCRETE STAIR

Krommenhoek/McKeown and Associates; San Diego, California
Karlsberger and Companies; Columbus, Ohio

GENERAL NOTES

1. The information presented on these pages is intended only as a preliminary design guide. All structural dimensions for slab thickness, beam and joint sizes, column sizes, etc., should be calculated and analyzed for each project condition by a licensed professional engineer.

2. Spans shown are approximate and are based on use of mild reinforcing steel. Spans may be increased 25 to 50% with the use of prestressing. For spans greater than 40 ft, consider posttensioning.

NOTES

1. Advantages: Inexpensive formwork; ceilings may be exposed; minimum thickness; fast erection; flexible column location.
2. Disadvantages: Excess concrete for longer spans; low shear capacity; greater deflections.
3. Appropriate building types: Hotels, motels, dormitories, condominiums, hospitals.
4. A flat plate is best for moderate spans because it is the most economical floor system and has the lowest structural thickness. Avoid penetrations for piping and ductwork through the slab near the columns. Spandrel beams may be necessary.

NOTES

1. Advantages: Longer spans than flat plate; typically posttensioned; minimum thickness.
2. Disadvantages: Must reuse formwork many times to be economical.
3. Appropriate building types: High-rise buildings; same use as flat plates if flying forms can be used more than 10 times.
4. A banded slab has most of the advantages of a flat plate but permits a longer span in one direction. It can resist greater lateral loads in the direction of the beams.

FLAT PLATE

BANDED SLAB

NOTES

1. Advantages: Economical for design loads greater than 150 psf.
2. Disadvantages: Formwork is costly.
3. Appropriate building types: Warehouses, industrial structures; parking structures
4. Flat slabs are most commonly used today for buildings supporting very heavy loads. When live load exceeds 150 lb per sq ft, this scheme is by far the most economical.

NOTES

1. Advantages: Minimum concrete and steel; minimum weight, hence reduced column and footing size; long spans in one direction; accommodates poke-through electrical systems.
2. Disadvantages: Unattractive for a ceiling; formwork may cost more than flat plate.
3. Appropriate building types: Schools, offices, churches, hospitals, public and institutional buildings, buildings with moderate loadings and spans.
4. This is the best scheme if slabs are too long for a flat plate and the structure is not exposed. The slab thickness between joints is determined by fire requirements. Joists are most economical if beams are the same depth as the joists. Orient joists in the same direction throughout the building and in the long direction of long rectangular bays.

FLAT SLAB

JOIST SLAB

Russell S. Fling, P.E., Consulting Engineer; Columbus, Ohio

3

CAST-IN-PLACE CONCRETE

**NOTES**

1. Advantages: Uses less concrete than joist slab; lower rebar placing costs; joist space used for mechanical systems. Permits lights and equipment to be recessed between joists.
2. Disadvantages: Similar to joist slab; joists must be designed as beams; forms may require special order.
3. Appropriate building type: Same as for joist slabs, especially for longer fire ratings.
4. Ensure the availability of formwork before specifying skip joists. For larger projects, a skip joist slab should be less expensive than a joist slab, and it permits lights and equipment recessed between joists.

SKIP JOIST**NOTES**

1. Advantages: Longer two-way spans; attractive exposed ceilings; heavy load capacity.
2. Disadvantages: Formwork costs more and uses more concrete and steel than a joist slab.
3. Appropriate building types: Prominent buildings with exposed ceiling structure; same types as are suitable for flat slab but with longer spans.
4. Column spacing should be multiples of pan spacing to ensure uniformity of drop panels at each column. Drop panels can be diamond-shaped, square, or rectangular.

WAFFLE SLAB

Russell S. Fling, P.E., Consulting Engineer; Columbus, Ohio

**NOTES**

1. Advantages: Long span in one direction.
2. Disadvantages: Beams interfere with mechanical services; more expensive forms than flat plate.
3. Appropriate building types: Parking garages, especially with posttensioning.
4. This scheme is most favored for parking garages, but the long span of about 60 ft must be prestressed unless beams are quite deep. Shallow beams will deflect excessively.

ONE-WAY BEAM AND SLAB**NOTES**

1. Advantages: Long span in two directions; small deflection; can carry concentrated loads.
2. Disadvantages: Same as for one-way beams, only more so.
3. Appropriate building types: Portions of buildings in which two-way beam framing is needed for other reasons; industrial buildings with heavy concentrated loads.
4. The high cost of the formwork and structural interference with mechanical systems make this scheme unattractive unless heavy concentrated loads must be carried.

TWO-WAY SLAB AND BEAM

GENERAL

Architectural concrete and structural concrete are both made from portland cement, aggregate, and water, but they have entirely different concrete mix designs. A variety of architectural finishes and colors can be achieved by changing the mix of these three simple ingredients. The cost of production usually determines the limit of finish choices. There are three basic ways to change the appearance of a concrete surface finish:

MATERIAL VARIATION involves changing the size, shape, texture, and color of the coarse and fine aggregate, particularly in exposed aggregate concrete, and choosing white or gray cement.

MOLD OR FORM VARIATION involves changing the texture or pattern of the concrete surface by means of form design, form liners, or joint/edge treatments.

SURFACE TREATMENT involves treating or tooling the surface after the concrete has cured.

Design drawings for architectural concrete should show form details, including openings, joints (contraction, construction, and rustication), and other important specifics. Other factors that affect concrete surfaces are mixing and placing techniques, slump control, curing methods, and release agents.

NOTES

1. Choosing a placing technique (pumping vs. bottom drop or other bucket type) is an important step toward achieving a desired architectural concrete surface and finish. Evaluate whether architectural concrete forms can also be used for structural concrete. Verify that the vibrators used are of the proper size, frequency, and power.
2. Shop drawings should be carefully checked to determine form quality and steel reinforcement placement. Require approval of forms and finishes; field mockup is advised to evaluate the appearance of the concrete panel and the quality of workmanship.
3. Release agents are chemical treatments applied to the liner or face of the form that react with the cement to prevent it from sticking to the form. The safest way to select a release agent is to evaluate several products on a test panel under actual job conditions. The curing compound, used to retard or reduce evaporation of moisture from concrete or to extend curing time, is typically applied immediately after final finishing of the concrete surface. Consult manufacturers and the American Concrete Institute for more detailed information about the compatibility of these treatments and the form surface material or other finishes and surfaces to be applied to the concrete.

EXPOSURE METHODS FOR ARCHITECTURAL CONCRETE SURFACES

METHOD	FINISH EFFECT	COLOR SOURCE	FORM SURFACE	CRITICAL DETAILS
1. As cast	Remains as is after form removal, usually exhibits board marks or wood grain	Cement first influence, fine aggregate second influence	Smooth and textured	Slump = 2 1/2 to 3 1/2" Joinery of forms Proper release agent Point form joints to avoid marks
2. Abrasive blasted surfaces				
a. Brush blast	Uniform scour cleaning	Cement and fine aggregate have equal influence	All smooth	Scouring after 7 days Slump = 2 1/2 to 3 1/2"
b. Light blast	Blasted to expose fine and some coarse aggregate (sand blast, water blast, air blast, ice blast)	Fine aggregate primary, coarse aggregate and cement secondary	All smooth	10% more coarse aggregate Slump = 2 1/2 to 3 1/2" Blasting between 7 and 45 days Water and air blasting used where sand blasting prohibited 1500 PSI concrete compressive strength, min.
c. Medium exposed aggregate	Blasted to expose coarse aggregate (sand blast, water blast, air blast, ice blast)	Coarse aggregate	All smooth	Higher than normal coarse aggregate Slump = 2 to 3" Blast before 7 days
d. Heavy exposed aggregate	Blasted to expose coarse aggregate (sand blast, ice blast) 80% visible	Coarse aggregate	All smooth	Special mix coarse aggregate Slump = 0 to 2" Blast within 24 hours Use high-frequency vibrator
3. Chemical retardation of surface set	Chemicals expose aggregate Aggregate can be adhered to surface	Coarse aggregate and cement	All smooth, glass fiber best	Chemical grade determines etch depth Stripping scheduled to prevent long drying between stripping and washoff
4. Mechanically fratured surfaces, scaling, bush hammering, jack-hammering, tooling	Varied	Fine and coarse cement and aggregate	Textured	Aggregate particles 3/8" for scaling and tooling 2 1/2" minimum concrete cover over reinforced steel 4000 PSI concrete compressive strength, minimum
5. Combination/fluted	Striated/abrasive blasted/irregular pattern Corrugated/abrasive Vertical rusticated/abrasive blasted Reeded and bush hammered Reeded and hammered Reeded and chiseled	The shallower the surface, the more influence fine aggregate and cement have	Wood or rubber strips, corrugated sheet metal, or glass fiber	Depends on type of finish desired Wood flute kerfed and nailed loosely
6. Grinding and polishing	Terrazzo-like finish	Aggregate and cement	All smooth	Surface blemishes should be patched 5000 PSI concrete compressive strength, minimum

ARCHITECTURAL FEATURE AT CORNER

HORIZONTAL FORMWORK JOINT

NOTE

A notch at the joint between two form members reduces the bearing area at the point of contact, improving the tightness of the joint. A non-notched joint is acceptable, but a notch is recommended.

FORM LINER JOINT

NOTE

Placing the inner sheet above the outer sheet reduces shadows, particularly on smooth surfaces.

JOINTS IN FORMWORK

3

CAST-IN-PLACE CONCRETE

AGGREGATE

Aggregate is one of three components of concrete and greatly affects the final appearance of the concrete surface. Aggregate should be selected on the basis of color, hardness, size, shape, gradation, method of exposure, durability, availability, and cost. Aggregate hardness and density must be compatible with structural requirements and weathering conditions.

Sources for coarse and fine aggregates should be kept the same for an entire job to avoid variations in the final surface appearance, particularly in light-toned concrete. Following are the common types of aggregate available:

QUARTZ is available in clear, white, yellow, green, gray, and light pink or rose. Clear quartz is used as a sparkling surface to complement other colors and pigmented cements.

GRANITE is known for its durability and beauty and is available in shades of pink, red, gray, dark blue, black, and white. Traprock such as basalt can be used for gray, black, or green.

MARBLE probably offers the widest selection of colors—green, yellow, red, pink, gray, white, and black.

LIMESTONE is available in white and gray.

MISCELLANEOUS GRAVEL, after being washed and screened, can be used for brown and reddish-brown finishes. Yellow ochers, umbers, buff shades, and pure white are abundant in riverbed gravels. Check local supplies.

CERAMIC exhibits the most brilliant and varied colors when vitreous materials are used.

EXPANDED LIGHTWEIGHT SHALE may be used to produce reddish-brown, gray, or black aggregate. Porous and crushable, this shale produces a dull surface with soft colors. It should be tested for iron staining characteristics and must meet ASTM C 330.

RECYCLED CONCRETE aggregate is produced when old concrete is crushed. Primarily used in pavement work, this material generally has a higher absorption rate and lower density than conventional aggregate. It should be tested for durability, gradation, and other properties, as with any new aggregate source.

EXPOSED AGGREGATE

An exposed aggregate surface is a decorative finish for concrete work achieved by removing the surface cement to expose the aggregate. Aggregates suitable for exposure may vary from 1/4 in. to a cobblestone more than 6 in. in diameter. The extent to which the pieces of aggregate are revealed is largely determined by their size. Size is generally selected on the basis of the distance from which it will be viewed and the appearance desired.

Aggregates with rough surfaces have better bonding properties than those with smoother surfaces; bond is important, particularly when small aggregate is used. For better weathering and appearance, the area of exposed cement matrix between pieces of aggregate should be minimal, which makes the color of cement in exposed aggregate concrete less important.

SUGGESTED VISIBILITY SCALE

AGGREGATE SIZE, IN. (MM)	DISTANCE AT WHICH TEXTURE IS VISIBLE, FT (M)
1/4-1/2 (6-13)	20-30 (6-9)
1/2-1 (13-25)	30-75 (9-23)
1-2 (25-50)	75-125 (23-38)
2-3 (50-75)	125-175 (38-53)

MISCELLANEOUS CONCRETE JOINT/EDGE SHAPES

D. Neil Rankins; RGA/Virginia; Richmond, Virginia

SURFACE TEXTURE/FORM LINER

Patterned forms and liners make it possible to simulate in concrete the textures of wood, brick, and stone at a lower cost. The texture and resulting shadow patterns conceal minor color variations or damage that would be conspicuous and unacceptable on a smooth surface. Use of rustication strips at joints in textured liners simplifies form assembly work.

NOTES

- The choice of liner material may depend on whether the work is precast, cast-in-place, or tilt-up. Thin liners that work well for horizontal casting may wrinkle and sag in vertical forms, where sturdier liner materials are required. Form liners such as plastic foams can usually be used only once, while many elastomeric liners are good for 100 or more uses with reasonable care.
- Reusable aluminum wall forms, textured with various patterns, can also be used; sections are held together with metal pins. Typical sizes are 3 x 8 ft and larger.
- Making a preconstruction mock-up is helpful in choosing patterned liner materials. If built on site, the mock-up can be used as a reference standard for inspectors and workers. If ribbed liners are specified, the largest aggregate particle should be smaller than the rib.
- Typical form liner materials are
 - Plyform: Sandblasted, wire-brushed, or striated plyform can be used as form sheathing or as a liner inside other structurally adequate forms.
 - Unfinished sheathing lumber: Used to produce rough, board-marked concrete, this lumber can be used as form sheathing or liner. Ammonia spray on wood will raise grain and accentuate the wood pattern.
 - Rigid plastics: ABS, PVC, and high-impact polystyrene sheets can be molded or extruded to produce nearly any pattern or texture. Although typically supplied in sheets of 4 x 8, 4 x 10, and 4 x 12 ft, they can be special ordered in lengths up to 30 ft or longer.
 - Glass fiber-reinforced plastics (GFRP): These look much like other plastics but are stronger and more durable, particularly laminated GFRP. Extruded GFRP is less expensive (and less durable). Custom lengths up to 40 ft are available.
 - Elastomeric plastics: These rubbery liners, typically polyurethane, are the most costly, but they are very strong and durable and flexible enough to accommodate finer details. Standard sheets in sizes up to 4 x 12 ft are available, as are larger custom sheets. Typically attached to form sheathing with adhesive, they are sensitive to temperature change and may deform; consult manufacturers.
 - Polystyrene foam: Single-use liners are used to produce unique patterns for specific jobs.
- Joints in the forms and liners must be executed carefully and the liners handled properly to achieve high-quality workmanship. Check liners for compatibility with release agents and adhesives.

NOTE

Consult manufacturers for other available patterns.

REUSABLE FORM LINER PATTERNS

INTEGRALLY COLORED CEMENT

Colored concrete can provide a cost-effective simulation of natural stone or other building materials. Two standard types of cement are available, offering different shades of color: standard gray portland cement and white cement. Integrally colored concrete is made by adding mineral oxide pigments to concrete mixes made with one of these two types. Fine aggregates should be selected carefully, since they can enhance the color effect. The amount of coloring material should not exceed 10% by weight of the cement; any excess pigment may reduce concrete strength, and strong colors can be achieved with less than 10% pigment. White cement is used when lighter, more delicate shades of concrete are desired, although it is more expensive; darker hues can be produced using gray cement.

NOTES

- Variations in all components of the concrete mix make color formulas only approximate. After a basic color is selected, the exact shade may be determined by preparing a number of small panels, varying the ratio of pigment to cement, with aggregate playing a more important role in exposed aggregate mixes. To evaluate panels properly, store them for about five days under conditions similar to those on the construction site. Panels lighten as they dry.
- Batching, mixing, placing, and curing practices must be uniform, and sources of ingredients must be constant throughout a job to maintain color uniformity. Avoid admixtures that contain calcium chloride, since it can cause discoloration. Clean forms and nonstaining release agents are vital. Consult pigment manufacturers' recommendations.
- Pigments should meet the quality standards of ASTM C979. Finely ground iron oxides are the most widely used pigments for coloring concrete. Colors and their sources include blue (cobalt oxide), brown (brown iron oxide), buff (yellow iron oxide), green (chromium oxide), red (red iron oxide), gray/slate (black iron oxide).
- Color-conditioning admixtures offer integral color and have additives that improve workability, better disperse color and cement, and reduce color bleeding for improved uniformity. Consult manufacturers.

SHEET METAL FORM INSERT

NOTE

In flat concrete work, a rotary saw may be used to make a contraction joint.

CONTRACTION JOINTS

TYPICAL CONSTRUCTION JOINT

RUSTICATION AT CONSTRUCTION JOINT

CONCRETE REPAIR

Damage or deterioration of concrete can occur at any time during service life. Minor repairs may be required during initial construction, for example, filling form tie holes; patching lifting loops on precast concrete; or repairing broken edges on beams, walls, and columns. Distress may result from inadequate design or construction, or deterioration, natural effects, or exposure to aggregate chemicals. Most repairs improve appearance, blending adjacent surfaces by matching texture and color. The repair area should be permanently bonded to the adjacent concrete and sufficiently impermeable to liquid penetration to keep it from shrinking or cracking. Repairs should withstand freeze/thaw cycles as well as surrounding concrete does.

The American Concrete Institute defines generally acceptable architectural concrete surfaces as those with minimal color and texture variation and minimal surface defects when viewed at 20 ft. Most architectural concrete contains some irregularities, such as blowholes or bugholes. Criteria for acceptability should be defined in advance, but patches should match the surrounding area as much as possible.

EPOXY OVER TIE SOLID PLUG PATCH

NOTE

Solid plugs may be made of precast mortar, plastic, or lead. Mortar of a drytamp consistency will be less likely to smear on surrounding concrete. If surrounding concrete is smooth, recess plug or patch.

TIE HOLE TREATMENT OPTIONS

REPAIR MATERIALS

Prepackaged cementitious and latex-modified cementitious repair materials are available, with formulations for thin or thicker repairs. Where aesthetics are important, use the same cement and aggregates as in the surrounding work. Most types of Portland cement are acceptable, but match the original type, if possible. Certain prepackaged mixes must conform to ASTM C 928. Aggregates should match the existing concrete aggregate, if possible. For exposed aggregate, matching the texture and color may require special mixtures to meet the specifications. Any admixture used in concrete work can be used in repair mixtures. Bonding agents may be required for some repairs, especially thin ones; they are typically either cement-based, latex-based (ASTM C 1059), or epoxy-based (ASTM C 881). Acrylics, methyl methacrylates, and polymers are less expensive than epoxy bonding agents but are more likely to shrink. Repaired areas should be sealed or coated to the same specifications as the surrounding concrete work to protect against natural forces, corrosives, and chemicals.

NOTE

Larger and thicker patches should be anchored mechanically to the surrounding concrete.

PATCHING OF DEFECTIVE CONCRETE SURFACES

GUIDELINES FOR PATCHING

1. Design patch mix to match original, with small amount of white cement; may eliminate coarse aggregate or hand-plate it. Trial and error, the only reliable match method, should be performed on a mock-up first.
2. Remove defective concrete down to sound concrete; for exposed aggregate concrete, chip slightly deeper than maximum size of aggregate.
3. Clean area; saturate with water and apply bonding agent to base of hole and to water of patch mix.
4. Pack patch mix to density of original.
5. Place exposed aggregate by hand.
6. Bristle-brush after setup to match existing material.
7. Moist-cure to minimize shrinking.
8. Use form or finish to match original.

PROTECTIVE AND DECORATIVE COATINGS

Concrete surfaces may require a sealer or coating to protect against severe weather, chemicals, or abrasions; to prevent dusting of the surface layer; to harden the surface layer; or to add a decorative finish.

Sealers are usually clear and are expected to penetrate the surface without leaving a visible film. Coatings are clear or opaque and, while they may have some penetration, they leave a visible film on the surface. Sealers and coatings should allow vapor emission from the concrete but at the same time keep moisture from penetrating after curing.

Decorative coatings usually protect as well and are formulated in a wide selection of colors. Decorative coatings include water-based acrylic emulsion; elastomeric acrylic resin; liquid polymer stain; solvent-based acrylic stain; portland cement-based finish coating; and water-based acidic stain (a solution of metallic salts).

PROTECTIVE COATINGS AND SEALERS

FINISH	USE
Cementitious acrylic polymeric coating	Aesthetic treatment
2-component epoxy coating	Protects damp or under-water surfaces
Solvent-based aliphatic urethane coating	Resists graffiti, chemicals, abrasion
Epoxy coal tar-based coating	Waterproof, resists corrosion
Coal tar-modified epoxy resin coating	Nonskid waterproof surface membrane
Water-based epoxy coating	Chemical, abrasion resistance for interiors
Vinyl ester-based coating	High chemical resistance
Aliphatic urethane coating	Chemical, abrasion
Solvent-based acrylic methacrylate copolymer sealer	Reduces water penetration
Silane/siloxane sealer penetrating water repellent	Protects from deicers and freeze/thaw damage

NOTES

1. Floor-hardening agents are applied to reduce dusting and increase hardness slightly at the surface.
2. Consult a qualified specialist to determine the correct coating or sealer for a particular application.
3. There may be restrictions on the use of solvent-based coatings and sealers in some areas due to the presence of VOCs (volatile organic compounds).

CRACKING IN CONCRETE CONSTRUCTION

Cause	SLABS ON GRADE				BEAMS, WALLS, COLUMNS, AND STRUCTURAL SLABS			
	SURFACE CRAZING	PLASTIC SHRINKAGE	EARLY CONCRETE VOLUME CHANGES	OTHER CRACKING		SETTLEMENT CRACKS	OTHER CRACKING	
Cause	Shrinkage of cement paste at exposed concrete surfaces due to concrete mix, too-wet excessive bleeding, over-troweling surface, rapid drying of surface	Water at the concrete surface evaporates too rapidly due to job site conditions such as low humidity, high wind speeds, high concrete temperatures, high to moderate air temperatures	As concrete cools and hardens, concrete volume shrinks; cracking will occur if slab is restrained at any point	Subgrade settlement	Premature excessive loading on slab	Same as for slabs on grade; also, heavier amounts of reinforcement and nature of formed or shored construction	Flexible forms and insufficient vibration can increase likelihood	Subgrade or formwork settlement, early volume changes, construction overloads, errors in design and detailing
Effect	Unightly cracking of surface layer although surface is probably sound	Parallel cracking, fairly wide at the exposed surface but shallow; doesn't typically extend to slab edge; crack spacing and length vary greatly	Random or regularly spaced cracks, usually passing completely through slab; during sawcutting of joints, crack may jump ahead of sawcut	Slab will bend and crack	Punch-through at edge by heavy equipment, etc.	Longitudinal cracks develop over reinforcement bars; can cause reinforcement bar corrosion		General cracking
Preventive measures	Reduce amount and rate of shrinkage at concrete surface by avoiding wet mixes, limiting bleeding by increasing sand or air content, limiting troweling/not troweling too early, curing as soon as possible	Reduce rate at which surface moisture evaporates by erecting windbreaks or building walls before slab, avoiding wet mixes, dampening subgrade before concrete pour, curing as soon as possible, avoiding vapor barrier under slab unless necessary	Not always preventable; careful joint design or reinforcement may help; other measures: tool or sawcut joints 1/4 of slab thickness, min.; time sawcut according to concrete curing rate; locate contraction joints at columnlines, min.; for unreinforced slabs, space joints at 24 to 36 times slab thickness, max.; posttension at slab; isolate slabs from adjoining structures with preformed joint filler or if continuity is required, increase slab reinforcement	Compact subgrade well	Generally, curing periods of 4 to 7 days, followed by 1 to 2 days of drying	Proper form design and sufficient vibration or re-vibration; use lowest possible slump, increase concrete cover		Consult with structural concrete engineer or consultant to prevent

NOTE

Expect some cracking in concrete construction. Generally, cracking is controlled with joints and reinforcement; how-

ever, not all cracks indicate errors or performance problems, and not all cracks need to be repaired.

Grant Halvorsen, S.E., P.E.; Wheaton, Illinois

3 CAST-IN-PLACE CONCRETE

GENERAL CONSIDERATIONS

- Concrete strength is usually 5000 psi at 28 days and at least 3,000 psi at time of prestressing. Use hardrock aggregate or lightweight concrete. Low slump controlled mix is required to reduce shrinkage. Shrinkage after prestressing decreases prestress strength gains.
- Post-tensioning systems can be divided into three categories depending on whether the tendon is wire, strand, or bar. Wire systems use 0.25 in. diameter wires that have a minimum strength of 240,000 psi and are usually cut to length in the shop. Strand systems use tendons, made of seven wires wrapped together, that have a minimum strength of 270,000 psi and are cut in the field. Bar systems use bars ranging in diameter from $\frac{3}{8}$ to $1\frac{3}{8}$ in. in diameter, with a minimum strength of 145,000 psi; they may be smooth or deformed. The system used determines the type of anchorage used, which in turn affects the size of breakout required, in the edge of slab or beam, for the anchorage to be recessed.
- Grease and wrap tendons, or place in conduits to reduce frictional losses during stressing operations. Limit length of continuous tendons to about 10 ft if stressed from one end. Long tendons require simultaneous stressing from both ends to reduce friction loss. Tendons may be grouted after stressing or left unbonded. Bonded tendons have structural advantages that are more important for beams and primary structural members.
- Minimum average prestress (net prestress force per area of concrete) = 150 to 250 psi for flat plates, 200 to 500 psi for beams. Exceeding these values by much causes excessive prestress losses because of creep.
- Field inspection of post-tensioned concrete is critical to ensure proper size and location of tendons and to monitor the tendon stress. Check tendon stress by measuring elongation of the tendon, and by monitoring gauge pressures on the stressing jack.
- Make provisions for the shortening of post-tensioned beams and slabs caused by elastic compression, shrinkage, and creep. After the post-tensioning is complete, build shearwalls, curtain walls, or other stiff elements that adjoin post-tensioned members and isolate them with an expansion joint. Otherwise, additional post-tensioning force will be required to overcome the stiffness of the walls and prevent cracking.
- Fire tests have been conducted on prestressed beam and slab assemblies according to ASTM E119 test procedures; they compare favorably with conventionally reinforced concrete. There is little difference between beams using grouted tendons and those using ungrouted tendons.

PRESTRESSED OR POST-TENSIONED BEAM

NOTES FOR DIAGRAM ABOVE

- Prestressing force compresses entire cross-section of the beam, thereby reducing unwanted tension cracks.
- Permanent tension is introduced into tendon and "locked in" with the stressing anchorage in one of two ways. The principle in both cases is the same. In prestressed concrete, the tendon is elongated in a stressing bed before the concrete is poured. In post-tensioned concrete, the tendon is elongated after concrete has been poured and allowed to cure by means of hydraulic jacks pushing against the beam itself. Post-tensioned beams permit casting at the site for members too large or heavy for transporting from factory to site.
- Internal vertical forces within the beam are created by

- applying tension on the tendon, making the tendon begin to "straighten out." The tension reduces downward beam deflection and allows shallower beams and longer spans than in conventionally reinforced beams.
- Auxiliary mild reinforcement provides additional strength, controls cracking, and produces more ductile behavior.
- Use stirrups to provide additional shear strength in the beam and to support the tendons and longitudinal mild reinforcement. Stirrups should be open at the top to allow the reinforcing to be placed before the tendon is installed. After the tendons are placed, "hairpins" that close the stirrups may be used when required.

SOLID FLAT SLAB

HOLLOW CORE SLAB

NOTES

1. Normal weight (150 pcf) or lightweight concrete (115 pcf) is used in standard slab construction. Topping concrete is usually normal weight concrete with a cylinder strength of 3000 psi. All units are prestressed with strand release when concrete strength is 3500 psi.
 2. Strands are available in various sizes, strengths and placements according to individual manufacturers.
- Strand designation code (SDC):
 78 - S
 — straight
 — diameter of strands in sixteenths
 — number of strands
3. Camber varies substantially depending on slab design, span, and loading. Nonstructural components attached to members may be affected by camber variations. Calculations of topping quantities should recognize camber variations.
 4. Safe superimposed surface loads include a dead load of 10 psf for untopped concrete and 15 psf for topped concrete. The remainder is live load.

NOTE
All sections are not available from all producers; check availability with local manufacturers.

HOLLOW CORE SLAB TYPES

Sidney Freedman; Precast/Prestressed Concrete Institute; Chicago, Illinois

DOUBLE TEE (DT)

NOTES

- Safe loads shown indicate dead load of 10 psf for untopped members and 15 psf for topped members. Remainder is live load.
- Contact manufacturers in the geographic area of the proposed structure to determine availability, exact dimensions, and load tables for various sections.
- Check camber for its effect on nonstructural members (partitions, folding doors, etc.), which should be placed with adequate allowance for error. Calculations for topping quantities should also recognize camber variations.
- Normal-weight concrete is assumed to be 150 lb/cu ft; lightweight concrete is assumed to be 115 lb/cu ft.

PANEL VARIATIONS

NOTE
Pocket connection may be at top of panel.

BEARING PANEL CONDITIONS

SPANDREL CONDITIONS

Sidney Freedman; Precast/Prestressed Concrete Institute; Chicago, Illinois

WALL PANELS

Carefully distinguish between the more specialized architectural wall panel and the structural wall panel that is a derivative of floor systems. Always work with manufacturers early in the design process. Careful attention must be given to manufacturing and joint tolerance during design. Thoroughly examine joint sealants for adhesion and expected joint movement.

FINISHES

Form liner molds provide a wide variety of smooth and textured finishes. Finishes after casting but prior to hardening include exposed aggregate, broom, trowel, screed, float, or stippled. After hardening, finishes include acid-etched, sandblasted, honed, polished, and hammered rib.

COLORS

Select a color range, as complete uniformity cannot be guaranteed. White cement offers the best color uniformity, gray cement is subject to color variations even when supplied from one source. Pigments require high-quality manufacturing and curing standards. Fine aggregate color requires control of the mixture gradation; coarse aggregate color provides the best durability and appearance.

VERTICAL SECTION AT TIE

NOTE

Panel requires accurate location of ties and reinforcement and established concrete quality control.

SANDWICH WALL CONSTRUCTION

TWO-STAGE SEALANT JOINTS

JOINT DETAILS

GENERAL

Architectural precast concrete is subject to the same erection and manufacturing tolerances as other building materials. When such tolerances are considered in the design stage, the task of determining and specifying them is simpler. By requiring realistic tolerances, architects strengthen and simplify their standards for acceptance. Unrealistic, close tolerances are costly, particularly for custom-produced elements.

Tolerances set the limits of size and shape for precast concrete units. Three groups of tolerances should be established in precast concrete design: product (manufacturing) tolerances, erection tolerances, and interfacing tolerances. Product and erection tolerances usually do not cause site problems. Tolerances are most problematic at the interface of precast concrete and other building materials.

Tolerances should be established for the following reasons:

STRUCTURAL: To ensure that structural design properly accounts for factors sensitive to variations in dimensional control. Examples include eccentric loading condition, bearing areas, hardware and hardware anchorage locations, and locations of reinforcing or prestressing steel.

FEASIBILITY: To ensure acceptable performance of joints and interfacing materials in the finished structure.

VISUAL: To ensure that the variations will be controllable and result in a structure that is visually acceptable.

ECONOMIC: To ensure ease and speed of production and erection by having agreed-upon dimensions for precast concrete products.

LEGAL: To avoid encroaching on property lines and to establish a standard against which the work can be compared in event of a dispute.

CONTRACTUAL: To establish a known acceptability range and responsibility for developing, achieving, and maintaining mutually agreed-upon tolerances.

BOWING DEFINITIONS FOR PANELS

GUIDELINES FOR PANEL THICKNESS¹

PANEL DIMENSIONS ²	8 FT	10 FT	12 FT	16 FT	20 FT	24 FT	28 FT	32 FT

¹ This table should not be used for panel thickness selection.
² This table shows a relationship between overall flat panel dimensions and thicknesses below which suggested

ELEVATION

- A = Plan location from building grid datum $\pm 1/2$ in.¹
 - A₁ = Plan location from centerline of steel $\pm 1/2$ in.²
 - B = Top elevation from nominal top elevation: exposed individual panel $\pm 1/4$ in.; nonexposed individual panel $\pm 1/2$ in.; exposed relative to adjacent panel $1/4$ in.; non-exposed relative to adjacent panel $1/2$ in.
 - C = Support elevation from nominal elevation: maximum low $1/2$ in.; maximum high $1/4$ in.
 - D = Maximum plumb variation over height of structure or 100 ft, whichever is less 1 in.¹
 - E = Plumb in any 10 ft of element height $1/4$ in.
 - F = Maximum jog in alignment of matching edges $1/4$ in.
 - G = Joint width (governs over joint taper) $\pm 1/4$ in.
 - H = Joint taper max. $3/8$ in.
 - H₁₀ = Joint taper over 10 ft length $1/4$ in.
 - I = Max. jog in alignment of matching faces $1/4$ in.
 - J = Differential bowing or camber as erected between adjacent members of the same design $1/4$ in.
- ¹ For precast buildings taller than 100 ft, tolerances A and D can increase at the rate of $1/8$ in. per story to a maximum of 2 in.
² For precast concrete erected on a steel frame building, this tolerance takes precedence over tolerance on dimension A.

ERECTION TOLERANCES FOR WALL PANELS

WARPING DEFINITIONS FOR PANELS

- A = Overall length and width (measured at neutral axis of ribbed members): 10 ft or under $\pm 1/8$ in.; 10 to 20 ft $\pm 1/8$ in.; $\pm 1/16$ in.; 20 to 40 ft $\pm 1/4$ in.; each additional 10 ft $\pm 1/16$ in. per 10 ft.
 - B = Total thickness or flange thickness $-1/8$ in., $+1/4$ in.
 - C = Rib thickness $\pm 1/8$ in.
 - D = Rib to edge of flange $\pm 1/8$ in.
 - E = Distance between ribs $\pm 1/8$ in.
 - F = Angular variation of plane of side mold $\pm 1/32$ in. per 3 in. of depth or $\pm 1/16$ in., whichever is greater.
 - G = Variation from square or designated skew (difference in length of the two diagonal measurements) $\pm 1/8$ in. per 6 ft of diagonal or $\pm 1/2$ in., whichever is greater.*
 - H = Length and width of blockouts and openings within one unit $\pm 1/4$ in.
 - H₁ = Location and dimensions of blockouts hidden from view and used for HVAC and utility penetrations $\pm 1/4$ in.
 - H₂ = Some types of window and equipment frames require more accurate types of openings. When this is the case, the minimum practical tolerance should be defined with input from the producer.
 - I = Dimensions of haunches $\pm 1/4$ in.
 - J = Haunch bearing surface deviation from specified plane $\pm 1/8$ in.
 - K = Difference in relative position of adjacent haunch bearing surfaces from specified relative position $\pm 1/4$ in.
 - L = Bowing $\pm L/360$ max. 1 in.
 - M = Differential bowing between adjacent panels of the same design $1/2$ in.
 - N = Local smoothness $1/4$ in. in 10 ft. (does not apply to visually concealed surfaces).
 - O = Warping of distance from nearest adjacent corner $1/16$ in. per ft.
 - P = Location of window opening within panel $\pm 1/4$ in.
 - Q = Position of plates ± 1 in.
 - R = Tipping and flushness of plates $\pm 1/4$ in.
- * Applies both to panel and to major openings in the panel.

Position tolerance for cast-in items measured from datum line location as shown on approved erection drawings: weld plates ± 1 in.; inserts $\pm 1/2$ in.; handling devices ± 3 in.; reinforcing steel and welded wire fabric where position has structural implications or affects concrete cover $\pm 1/4$ in.; otherwise $\pm 1/2$ in.; tendons $\pm 1/8$ in.; flashing reglets $\pm 1/4$ in.; flashing reglets at edge of panel $\pm 1/8$ in.; reglets for glazing gaskets $\pm 1/16$ in.; groove width for glazing gaskets $\pm 1/16$ in.; electrical outlets, hose bibs, etc. $\pm 1/2$ in.; haunches $\pm 1/4$ in.

TOLERANCES FOR PANELS, SPANDRELS, AND COLUMN COVERS

HOLLOW CORE SLAB DETAILS

FLOOR-TO-BEARING WALL CONNECTIONS

SPANDREL CONNECTION

FLOOR-TO-WALL CONNECTIONS

GENERAL

To fasten members to foundations, set them on shims, tighten nuts to level, then fill space with nonshrink grout.

NOTE

Vertical posttensioning can be used to resist uplift forces; moment resistance is achieved.

POSTTENSIONED WALL-TO-FOUNDATION CONNECTION

NOTE

The girder sits on the bearing pad, which provides uniform bearing and accommodates small movements due to shrinkage, creep, and temperature changes.

DOWELED BEAM-TO-COLUMN CONNECTION

NOTE

Steel haunches are smaller than concrete bearing pads, which is important if headroom is critical.

2. Rigid connection.
3. Possible volume change restraint problems.

WELDED ALIGNMENT

NOTE
Alignment plate is welded to one plate only to allow for possible volume change of panels.

WELDED ALIGNMENT

COLUMN COVER CONNECTION

NOTES
1. Avoid use of this detail at both ends of slab to prevent excessive restraint.
2. Rotation of wall elements and effects on bracing wall connections and volume changes must be considered.

SLAB-TO-WALL CONNECTION

NOTE
One-piece spandrels may require support and restrict placement of concrete.

PRECAST PERMANENT FORMWORK

GENERAL

Tilt-up concrete construction is a fast, economical method of enclosing a building with durable, load-bearing walls. The wall panel units are formed and cast horizontally at the job site, on either the building slab floor or on a temporary casting slab. Since the panels do not have to be transported, there are fewer restrictions on panel size. Wood formwork is typically used to define the edges, reveals, details, and openings in the panel. Once the concrete has reached sufficient strength, the panels are lifted, or tilted up, by crane and placed on isolated or continuous foundations (usually grade beams). The panels are braced against the floor slab or a brace foundation until they are tied to the roof and floor system and become an integral part of the completed structure. Although tilt-up concrete construction is mainly restricted to buildings of one story, walls up to four stories tall have been cast and lifted into position.

DESIGN

Panel thickness varies from 5 1/2" to 11 1/4" in. depending on height, loads, span, depth of reveals, surface finish, local codes, and construction practices. Full-height panel widths of 20 ft and weights of 30,000 to 50,000 lb are typical. Spans of 30 ft are common for spandrel panels, as are can-

tilers of 10 to 15 ft. Panels are designed structurally to resist lifting stresses, which frequently exceed in-place loads. Floor slab design must accommodate panel and crane loads.

FINISH

Most of the finishes used for factory precast concrete are possible in tilt-up construction. Panels can be cast either face down or face up, depending on desired finish and formwork methods. The face-down method, however, is usually easier to erect. Casting method, desired finish, and available aggregates affect concrete mix design. Control of the concrete mix design and placement of the concrete in the forms are more difficult than with factory-cast units. Discoloration occurs if cracks and joints in the casting are not sealed. Commonly used finishes are as follows:

1. Sandblasting (light, medium, or heavy exposure)
2. Fracture (similar to bushhammered)
3. Form liner (metal deck, plastic, fiberglass, EPS)
4. Paint (usually textured)
5. Brick or tile veneer
6. Aggregate (cast face down in sand bed)

NOTE

The rigging and anchor configuration shown is the most common for tilt-up construction for plain panels without openings. Other configurations may be required depending on the size and shape of the panel; consult a tilt-up construction specialist.

MASONRY

Masonry Mortar 210

Masonry Accessories 212

Masonry Units 218

Glass Unit Masonry 244

Stone 247

INTRODUCTION

Mortar and grout are the cementitious bonding agents that integrate masonry units into masonry assemblies. Because concrete, masonry mortar, and grout contain the same principal ingredients, some designers assume what is good practice for one will also be good practice for another. In reality, the three materials differ in proportions, working consistencies, methods of placement, and structural performance.

Mortar and grout structurally bind masonry units together, whereas concrete is usually itself a structural material. One of the most important functions of concrete elements is to carry load, whereas the principal function of mortar and grout is to develop a complete, strong, and durable bond with masonry units. Concrete is poured into nonabsorbent forms with a minimum amount of water. Mortar and grout are placed, with much more water, between absorptive forms (masonry units). The water/cement ratio, as mixed, is very important in concrete work, but it is less important in working with mortar or grout for brick masonry. When mortar or grout is placed with masonry units, the water/cement ratio rapidly decreases because of the bricks' absorbency. It is important to distinguish between the requirements for concrete, masonry mortar, and grout.

ASTM SPECIFICATIONS

ASTM C 270—MORTAR FOR UNIT MASONRY

This standard specification covers four types of mortar in each of two methods: proportion specifications and property specifications. When specifying a particular mortar type, either the proportion or the property requirements should be given, but not both. When neither proportion nor property specifications are specified, the proportion specification is mandated. Table 1 shows the proportion requirements for types M, S, N, and O mortars.

Mortar conforming to the property specifications must be established by tests of laboratory prepared mortar, which should be mixed from the mortar materials to be used in the masonry structure. Table 2 provides the property requirements for types M, S, N, and O mortars.

Although ASTM C 270 uses the same letters to designate mortar type under both the proportion and property specifications, the properties of these mortar types are not equivalent. A mortar mixed to the type N proportion specification will have a laboratory prepared compressive strength significantly higher than that of a type N mortar required by the property specifications. Mortars may be made with either portland cement or masonry cement.

ASTM C 476—GROUT FOR MASONRY

This is the standard specification governing grout for reinforced and nonreinforced masonry assemblies. Two types of grout, fine and coarse, are specified by proportions of ingredients. Both types should be proportioned within the limits given in Table 5.

Grout consists of cementitious materials and aggregate thoroughly mixed with sufficient water to attain the desired consistency. Grout should be wet enough to pour without segregation of the constituents. Grout can be used to bond two wythes of masonry, to provide additional material to resist load, or to bond steel reinforcement to masonry so the two materials exert common action under load.

MATERIALS

PORTLAND CEMENT

Portland cement, a hydraulic cement, is the principal cementitious ingredient of mortar and grout. Three types of portland cement covered by ASTM C 150—Standard Specification for Portland Cement are recommended:

Type I: For general use when the special properties of Types II and III are not required

Type II: For use when moderate sulfate resistance or moderate heat of hydration is desired

Type III: For use when high early strength is desired

The allowable stresses for the structural design of brick masonry are based on the results of tests in which only portland cements were used. The use of blended hydraulic cements and natural cements is not recommended unless the strength of the masonry is first established by appropriate tests. For nonstructural masonry, such cements may be substituted for regular portland cement without testing.

HYDRATED LIME

Hydrated lime, a dry powder, is made by adding water to quicklime, thus converting the calcium oxide into calcium hydroxide. Hydrated lime can be used without extra preparation and thus is more convenient to use than quicklime.

Grace S. Lee; Rippeteau Architects, PC; Washington, D.C.
 Brian E. Trimble; Brick Institute of America; Reston, Virginia
 Stephen S. Szoke, P.E.; National Concrete Masonry Association; Herndon, Virginia

ASTM C 207—Hydrated Lime for Masonry Purposes is available in four types: S, SA, N, and NA. Because unhydrated oxides and plasticity are not controlled in types N or NA, only type S hydrated lime should be used for masonry mortar and grout.

MASONRY CEMENT

These proprietary mortar mixes are widely used in mortar because of their convenience and good workability. Masonry cements, however, should not be used in grout. The requirements for masonry cement are covered in ASTM C 91—Standard Specification for Masonry Cement. Masonry cements are prepackaged as types M, S, or N mortar mixes. Most building codes have lower allowable stresses when masonry cements are used.

AGGREGATE

Either natural or manufactured aggregate may be used. Gradation limits are given in ASTM C 144 and C 404 for aggregate used in mortar and grout. Only fine aggregate may be used in mortar; fine and coarse aggregate may be used in grout. Gradation can be easily altered by adding fine or coarse sands. Only clean sand is recommended for use in masonry mortar and grout.

WATER

Clean, potable water that is free of deleterious acids, alkalis, or organic materials is suitable for masonry mortar and grout.

COLOR AND OTHER ADMIXTURES

Many different types of admixtures can be added to mortar grouts. Admixtures are used in mortar to provide color, enhance workability, reduce water penetration, accelerate curing, and substitute for conventional materials. Admixtures are used in grout to increase fluidity, accelerate curing, and decrease shrinkage. Admixtures must be used with extreme caution so the performance of the masonry is not affected. Admixtures containing chlorides should never be used because they tend to corrode metal.

Air entrainment has the detrimental effect of reducing the bond between mortar and masonry units or reinforcement. The use of air-entraining portland cements (types IA, IIA, or IIIA) and air-entrained lime (types SA and NA) for masonry mortar and grout may not be appropriate. Two different air-entraining agents should not be used in the same mortar or grout. Air-entraining admixtures should not be used in structural masonry. Building codes mandate lower allowable flexural tension stresses if air-entrained cements or lime are used in mortar.

TABLE 1: PROPORTION REQUIREMENTS FOR MASONRY MORTARS*

MORTAR	TYPE	PROPORTIONS BY VOLUME (CEMENTITIOUS MATERIALS)					AGGREGATE RATIO (MEASURED IN DAMP, LOOSE CONDITIONS)
		PORTLAND CEMENT OR BLENDED CEMENT	MASONRY CEMENT			HYDRATED LIME OR LIME PUTTY	
			M	S	N		
Cement-lime	M	1	—	—	—	1/4	Not less than 2 1/4 and not more than 3 times the sum of the separate volumes of cementitious materials.
	S	1	—	—	—	over 1/4 to 1/2	
	N	1	—	—	—	over 1/2 to 1 1/4	
	O	1	—	—	—	over 1 1/4 to 2 1/2	
Masonry cement	M	1	—	—	1	—	
	S	—	1	—	—	—	
	N	—	—	1	—	—	
	S	1/2	—	—	1	—	
	O	—	—	—	1	—	

NOTE

* Two air-entraining materials shall not be combined in mortar.

TABLE 2: MORTAR PROPERTY SPECIFICATION REQUIREMENTS¹

MORTAR	TYPE	AVERAGE COMPRESSIVE STRENGTH AT 28 DAYS MIN. PSI (MPA)	WATER RETENTION MINIMUM %	AIR CONTENT MAXIMUM %	AGGREGATE RATIO (MEASURED IN DAMP, LOOSE CONDITIONS)
Cement-lime	M	2500 (17.2)	75	12	Not less than 2 1/4 and not more than 3 1/2 times the sum of the separate volumes of cementitious materials.
	S	1800 (12.4)	75	12	
	N	750 (5.2)	75	14 ²	
	O	350 (2.4)	75	14 ²	
Masonry cement	M	2500 (17.2)	75	See note 3	
	S	1800 (12.4)	75	See note 3	
	N	750 (5.2)	75	See note 3	
	O	350 (2.4)	75	See note 3	

NOTES

- Laboratory prepared mortar only.
- When structural reinforcement is incorporated in cement-lime mortar, the maximum air content is 12%.
- When structural reinforcement is incorporated in masonry cement mortar, the maximum air content is 18%.

TABLE 3: GUIDE FOR THE SELECTION OF MASONRY MORTAR¹

LOCATION	BUILDING SEGMENT	MORTAR TYPE	
		RECOMMENDED	ALTERNATIVE
Exterior, above grade	Load bearing wall	N	S or M
	Non-load bearing wall	O ²	N or S
	Parapet wall	N	S
Exterior, at or below grade	Foundation wall, retaining wall, manholes, sewers, pavements, walks, and patios	S ³	M or N ³
Interior	Load bearing wall	N	S or M
	Non-bearing partitions	O	N

NOTES

- This table does not include many specialized mortar uses, such as chimney reinforced masonry and acid-resistant mortar.
- Type O mortar is recommended for use where the masonry is unlikely to be frozen when saturated, or unlikely to be subjected to high winds or other significant lateral loads. Types N or S mortar should be used in other cases.
- Masonry exposed to weather in a nominally horizontal surface is extremely vulnerable to weathering. Mortar for such masonry should be selected with due caution.

RECOMMENDED TYPES

MORTAR

No single type of mortar is best suited for all purposes, but there are several rules for selecting mortar type. Never use a mortar that is stronger in compression than needed by the structural requirements. Always select the mortar weakest in compression that is consistent with the performance requirements of the project. However, this guideline should be coupled with good engineering judgment; for example, it would be uneconomical and unwise to change mortar types in various parts of a structure. If mortar is used with reinforcement in a collar joint or in a cell of a hollow unit, then the air content must be less than 12% for portland cement-lime mortars and 18% for masonry cements. The use of mortar is recommended only in unreinforced collar joints of 3/4 in. (19 mm) or less.

Following are the recommended uses for different types of mortar:

Type N mortar: A medium strength mortar suitable for general use in exposed masonry above grade and recommended specifically where high compressive or transverse masonry strengths are not required.

Type S mortar: A high strength mortar suitable for general use and specifically for circumstances where high transverse strength of masonry is desired; for reinforced masonry, where mortar bonds the facing and backing; and for areas subject to winds greater than 80 mph (130 kph).

Type M mortar: A high strength mortar suitable for general use and recommended specifically for masonry below grade or in contact with earth, such as foundations, retaining walls, or paving.

Type O mortar: A low strength mortar suitable for use in non-load bearing applications in walls of low axial compressive strength and where masonry is not subject to severe weathering.

TABLE 5: GROUT PROPORTIONS BY VOLUME

TYPE	PARTS BY VOLUME OF PORTLAND CEMENT OR BLENDED CEMENT	PARTS BY VOLUME OF HYDRATED LIME OR LIME PUTTY	AGGREGATE (MEASURED IN A DAMP, LOOSE CONDITION)	
			FINE	COARSE
Fine grout	1	0 - 1/10	2 1/4 - 3 times the sum of the volumes of cementitious materials	—
Coarse grout	1	0 - 1/10	2 1/4 - 3 times the sum of the volumes of cementitious materials	1 - 2 times the sum of the volumes of cementitious materials

Brick more than 75% solid
Net area equals gross area

Hollow unit
Full mortar bedding
(requires alignment of crosswebs)

Hollow unit
Face shell bedding

NET CROSS-SECTIONAL AREA

GROUT

Grout should be mixed thoroughly in a plastic mix suitable for placement without separation of the constituents. Add enough water to achieve a slump of 8 to 11 in. (200 to 275 mm). The compressive strength of the grout should match that of the brick masonry but must have a minimum compressive strength of 2000 psi (13.9 MPa).

Fine grout: Can be used for grouting interior vertical spaces between two wythes of masonry or aligned, unobstructed vertical spaces in hollow masonry units. See Table 4 for grout space requirements.

Coarse grout: May be used when the grout space exceeds 2 in. (50 mm) in width. If the minimum grout space dimension exceeds 6 in. (150 mm), a larger aggregate size may be specified.

- a > Minimum grout space dimension
- b > Minimum grout space dimension plus horizontal bar diameter plus horizontal protrusions (see table)

- a > Minimum grout space dimension plus horizontal bar diameter plus horizontal protrusions (see table)

TABLE 4: GROUT SPACING REQUIREMENTS

SPECIFIED GROUT TYPE	MAXIMUM GROUT FOUR HEIGHT (FT)	MINIMUM WIDTH OF GROUT SPACE (IN.)	MINIMUM GROUT SPACE DIMENSIONS FOR GROUTING CELLS OF HOLLOW UNITS (IN. X IN.)
Fine	1	3/4	1 1/2 x 2
	5	2	2 x 3
	12	2 1/2	2 1/2 x 3
	24	3	3 x 3
Coarse	1	1 1/2	1 1/2 x 3
	5	2	2 1/2 x 3
	12	2 1/2	3 x 3
	24	3	3 x 4

NOTES

- Grout space dimension is the clear dimension between any masonry protrusion and shall be increased by the diameters of the horizontal bars within the cross section of the grout space.
- Area of vertical reinforcement should not exceed 6% of the area of the grout space.

GROUT SPACE REQUIREMENTS

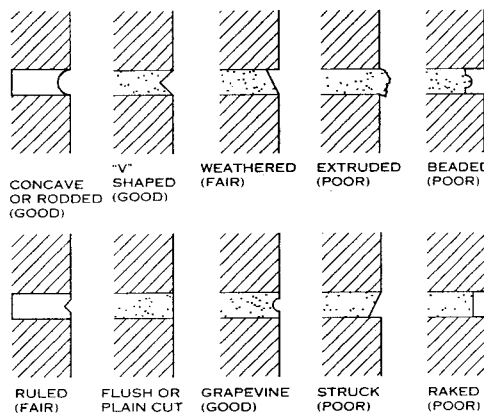

TYPES OF JOINTS

Mortar serves multiple functions:

- Joins and seals masonry, allowing for dimensional variations in masonry units.
- Affects overall appearance of wall color, texture, and patterns.
- Bonds reinforcing steel to masonry, creating composite assembly.

MORTAR JOINT FINISH METHODS

- Troweled: Excess mortar is struck off. The trowel is the only tool used for shaping and finishing.
- Tooled: A special tool is used to compress and shape mortar in the joint.

TYPES OF JOINTS (WEATHERABILITY)

TERMS APPLIED TO JOINTS

MORTAR JOINTS

Grace S. Lee; Rippeteau Architects, PC; Washington, D.C.

 Stephen S. Szoke, P.E.; National Concrete Masonry Association; Herndon, Virginia

GENERAL

Masonry construction has not always required the inclusion of metal elements. Historically, composite masonry construction consisted of multiple wythes of masonry bonded together by headers. However, contemporary masonry walls require ties between the inner and outer wythes, which are then anchored to the structural frame. Many people use the terms *wall tie* and *anchor* interchangeably, but in practice the term *tie* refers to combining a wythe of masonry to its backing system, while *anchor* refers to a component that secures structural elements to a structural support. A fastener is a device used to attach nonstructural elements to masonry. Anchors and ties with flexible components can accommodate differential movement between the structural frame and the masonry wall by allowing for in-plane movement.

CORROSION PROTECTION

The durability of any metal accessory is usually based on its ability to resist corrosion. Since masonry walls are often subject to moisture, metal items must be protected, either by galvanizing them or by use of corrosion resistant metals. The following ASTM standards apply to corrosion protection of carbon steel metal accessories based on their location and the size of the piece:

1. ASTM A 641—Mill galvanizing: joint reinforcement, interior
2. ASTM A 153—Hot-dip galvanized: joint reinforcement, wire ties, and wire anchors, exterior or moist interior
3. ASTM A 153—Hot-dip galvanized: sheet metal ties, exterior or moist interior
4. ASTM A 525—sheet metal ties, interior
5. ASTM A 123 or A 153—steel plates and bars

Corrosion protection is also provided by stainless steel anchors and ties conforming to ASTM A 167, Type 304.

ANCHORS AND REINFORCEMENT

Selection of anchors and reinforcement is determined by the relationship of the masonry element to the structural support. Reinforcing bars may be placed horizontally or vertically in masonry. The reinforcement may be placed in the cores or cells of masonry units or between wythes of masonry. The use of dovetail slots welded on steel or concrete columns requires coordination during the steel or concrete fabrication stage. The type of anchor specified, including its size, diameter, and spacing, should be called out on the contract documents.

MASONRY TIES

Wall ties perform one or more functions: they provide a connection, transfer lateral loads, permit in-plane movement to accommodate differential movements, and may act as horizontal structural reinforcement. As shown on this page, wall ties include unit ties, joint reinforcement, adjustable unit ties, and adjustable joint reinforcement. Wall tie spacing is listed in a table on the AGS page on Anchorage and Reinforcement. The ties should be staggered in alternate rows, and only one row of ties should be located in the same bed joint to allow proper embedment in the mortar.

In wall construction in which masonry wythes are built up together and the joints align, a single piece is laid over both wythes. Where one wythe of masonry is laid up before the other wythe or when joints do not align, adjustable ties may be necessary. Adjustable ties are advantageous for several reasons: (1) interior wythes can be constructed before the exterior wythe, allowing the structure to be enclosed faster; (2) the risk of damage to the ties when the exterior wythe is constructed is reduced; (3) adjustable ties can more readily accommodate construction tolerances; and (4) adjustable ties can accommodate larger differential movements. However, adjustable ties must be installed properly or the tie may be rendered useless. Location of the first piece is critical since the second piece must engage the first and be properly embedded in the exterior wythe. Large eccentricities may occur between the two pieces, which would result in less strength and stiffness than anticipated.

WEEP HOLE DETAILS

BRICK OR BLOCK VENT

WEEP HOLE DETAILS

WEEP HOLES AND VENTS

With proper design and installation, weep holes and discharge water and moisture as vapor in wall cavities must always be used with flashing. When vents are located at the bottom of the wall, directly above flashing and in junction with small openings at the top of the cavity, void is vented, allowing moisture removal from the wall. The type of weep hole chosen is not critical as long as properly sized and spaced at the required locations. Weep holes are sometimes created by placing greased or oiled tubes or coils into the mortar and then extracting them when the mortar is ready to be tooled. For CMUs, under adverse weather conditions, it may be necessary to install weep holes at the base of the first course at all openings as well as at the head joints for wall cavity venting. Weep holes should never be located below grade and should be small enough to keep out rodents.

NAILING BLOCK

NAILING RECEIVERS (SET IN MASONRY)

NAILING BLOCKS AND WALL PLUGS

The procedure for attaching other materials, fixtures, and the like to brick masonry is relatively simple and can be executed either during or after construction. Postconstruction fasteners, such as lag bolts and shields, are commonly used because of their flexibility in placement. However, when the precise location of the fastener is determined, nailing blocks and metal wall plugs are an acceptable means of attachment to brick masonry. They are placed in mortar joints as the bricks are laid.

Wood nailing block should be of seasoned softwood to prevent shrinkage and be treated to inhibit deterioration. They should only be placed in the head joint. Metal wall plugs are made of galvanized metal and may contain wooden or fiber inserts. Such plugs may be placed in either the head or bed joints of masonry.

GALVANIC CORROSION (ELECTROLYSIS) POTENTIAL BETWEEN COMMON CONSTRUCTION MATERIALS

CONSTRUCTION MATERIALS	COPPER	ALUMINUM	STAINLESS STEEL	GALVANIZED STEEL	ZINC	LEAD
FLASHING MATERIALS						
Copper		●	●	●	●	●
Aluminum			○	○	○	●
Stainless steel				●	●	●
Galvanized steel					○	○
Zinc alloy						○
Lead						

- NOTES
- Galvanic action will occur, hence direct contact should be avoided.
 - Galvanic action may occur under certain circumstances and/or over a period of time.
 - Galvanic action is insignificant; metals may come into direct contact under normal circumstances.
2. Galvanic corrosion is apt to occur when water runoff from one material comes in contact with a potentially reactive material.

INTRODUCTION

The various materials and elements used to construct a building are in constant motion. All building materials change in volume in response to internal or external stimuli, such as temperature changes, moisture expansion, and elastic deformation due to loads or creep. Restraining such movements may cause stresses within the building elements, which in turn may result in cracks.

To avoid cracks, the building design should minimize volume change, prevent movement, or accommodate differential movement between materials and assemblies. A system of movement joints can prevent cracks and the problems they cause. Movement joints can be designed by estimating the magnitude of the several types of movements that may occur in masonry and other building materials.

MOVEMENTS OF CONSTRUCTION MATERIALS

The design and construction of most buildings do not allow precise prediction of movements of building elements. Volume changes depend on material properties and are highly variable. Age of material and temperature at installation also influence expected movement. When mean values of material properties are used in design, the actual movement may be underestimated or overestimated. Designers should use discretion when selecting the applicable values. The types of movement affecting various building materials are indicated in the table.

CONTROL JOINTS

Stephen S. Szoke, P.E.; National Concrete Masonry Association; Herndon, Virginia

MOVEMENT JOINTS

There are various types of movement joints in buildings: expansion joints, control joints, building expansion joints, and construction joints. Each type of movement joint is designed to perform a specific task and should not be used interchangeably.

Expansion joints are used to separate brick masonry into segments to prevent cracking from changes in temperature, moisture expansion, elastic deformation due to loads, and shrinkage and creep in concrete framed buildings. Expansion joints may be horizontal or vertical. They are formed of elastomeric materials placed in a continuous, unobstructed opening through the brick wythe. This construction allows the joints to close if the size of the brickwork increases. Expansion joints must be located so the structural integrity of the brick masonry is not compromised. In some cases expansion joints are necessary in concrete masonry walls. Architects often designate these joints as control joints.

Control joints are used in concrete or concrete masonry to create a plane of weakness that, used in conjunction with reinforcement or joint reinforcement, controls the location of cracks caused by volume changes resulting from shrinkage and creep. A control joint, usually vertical and formed of inelastic materials, will open rather than close. Control joints must be located so the structural integrity of the concrete masonry wall is not affected.

A building expansion (isolation) joint is used to separate a building into discrete structural sections so that stresses developed in one section will not affect the integrity of the

TYPES OF MOVEMENT OF BUILDING MATERIALS

BUILDING MATERIAL	THERMAL	REVERSIBLE MOISTURE	IRREVERSIBLE MOISTURE	ELASTIC DEFORMATION	CREEP
Brick masonry	x	—	x	x	x
Concrete masonry	x	x	—	x	x
Concrete	x	x	—	x	x
Steel	x	—	—	x	—
Wood	x	x	—	x	x

GROUPED MULTIPLE WYTHE MASONRY

EXPANSION JOINTS

entire structure. The isolation joint is a through-the-building joint, including the roof assembly.

A construction (cold) joint is used primarily in concrete construction when construction work is interrupted. Construction joints are located where they will least impair the strength of the structure.

SPACING OF EXPANSION AND CONTROL JOINTS

No single recommendation on the positioning and spacing of expansion and control joints can be applicable to all structures. Each building should be analyzed to determine the extent of movement expected within that particular structure. Provisions should be made to accommodate these movements and their associated stresses with a series of expansion and control joints.

Generally, spacing of expansion joints is determined by considering the amount of expected wall movement and the size of compressibility of the expansion joint and expansion joint materials. Expansion joints are often sized to resemble a mortar joint, usually 3/8 in. (10 mm) to 1/2 in. (13 mm). The maximum size of the expansion joint may depend on the sealant capabilities. Extensibility of highly elastic expansion joint materials is typically in the range of 25 to 50%. Compressibility of backing materials can range up to 75%.

Expansion and control joints do not have to be aligned in cavity walls; however, they should be aligned in multiwythe walls.

CONTROL JOINT SPACING FOR MOISTURE CONTROLLED, TYPE I CONCRETE MASONRY UNITS

RECOMMENDED SPACING OF CONTROL JOINTS	VERTICAL SPACING OF JOINT REINFORCEMENT

EXPANSION JOINT AT MASONRY CAVITY WALL

EXPANSION AND CONTROL JOINTS

PURPOSE

Flashing in masonry construction is necessary to collect moisture that enters the wall system and to channel it to the exterior through weep holes. Moisture enters masonry walls through condensation, penetration of wind-driven rains, failed sealant joints, interfaces with other components, or other components themselves, such as windows or roofs.

There are two types of flashing. Exposed flashings can be applied to all masonry construction, while use of embedded flashing is usually limited to drainage walls. Masonry is a durable, long-lasting construction material. Thus, the flashing materials selected should also be durable and have a long life, especially embedded flashing materials, which are difficult to replace.

MATERIALS

Flashing may be made of sheet metal (copper, lead, stainless steel, galvanized steel, or aluminum), plastic, or composite materials (usually paper-backed, coated, metallic sheet, or fibrous glass mesh). When selecting flashing materials, avoid those that would have cathodic reactions with mortar, other metals, or other construction materials. The thickness of the flashing material specified should take into account the span between embedment, bends, or connections. Copper may cause a patina, which may be desir-

able. Lead and galvanized metal may result in some white staining, but this may be minimal if coated materials are used. Choose aluminum as an embedded flashing only if it is properly coated, so it will not react with the mortar. Polyethylene should not be used as flashing unless it has been chemically stabilized so it will not deteriorate when exposed to sunlight (ultraviolet radiation). Asphalt-impregnated building paper (building felt) is not an acceptable flashing material. Adhered flashings must be held back from the face of the wall to avoid deterioration and staining caused by high temperatures.

INSTALLATION

Embedded flashing is typically used in drainage walls at the base, above all openings, at sills and shelf angles, and under copings. Continuous embedded flashing should be lapped at least 6 in. and sealed with an appropriate sealer. Discontinuous flashing should have the ends turned up at least 1 in. to form a dam. Dams prevent water collected on the flashing from draining off the ends of the flashing back into the wall system or into framing or mullions.

Embedded flashing should extend at least 8 in. vertically within the wall system; it should extend at least 1 1/2 in. into the interior wythe and through the exterior wythe at least 1/4 in. to form a drip. The drip minimizes possible staining. Sometimes, it may be necessary to avoid the drip, as with rough textured units and ribbed, scored, or fluted masonry units. The flashing must be carefully brought to the surface

of the recessed portion of the masonry. Plastic flashing is often exposed and cut off flush with the face of the masonry. If the flashing is recessed and does not reach the surface, water collected on it may be channeled by mortar under the flashing and back into the wall system.

Weep holes are required in the head joints of the course of masonry immediately above all embedded flashing. Weep holes may be open head joints, holes formed with nylon rope or oiled rods, plastic or metal tubes, fibrous rope, or cotton sash cord. Open head joints are often fitted with vents or screens to keep out insects or rodents. Formed weep holes should have a minimum diameter of 1/4 in.; tubes used for weep holes should have a minimum inside diameter of 1/4 in. Weep holes are preferred as open head joints occurring no more than 32 in. on center, although in brick masonry it is generally recommended that they be spaced no more than 24 in. on center. If cord or rope is used, the material should be at least 16 in. long. Weep holes other than open head joints should be spaced no more than 16 in. on center.

Drainage within the wall system is critical for proper performance. Placing two to six inches of gravel or drainage material immediately above embedded flashing will help ensure proper drainage within the wall and effective channeling of water to the weep holes. The drainage material or pea gravel will act as a drainage field within the wall system and help keep mortar droppings from clogging the weep holes.

BRICK BONDS

When a circular masonry wall is to be laid up in running bond, the projections of the corners of units beyond the face of the units on the courses above and below may need to be limited for aesthetic reasons. Generally, projections of approximately 1/8 in. for nominal 8 in. long units and 1/4 in. for nominal 16 in. long units are acceptable. If the wall surface is to be stuccoed or otherwise covered, projections of 1/2 to 3/4 in. may not be objectionable. However, if it is desirable to obtain a smooth appearance for the curve or limit the shadows created by the projected corners, the projections should not exceed those indicated above. Projections of less than 1/8 in. are usually impractical because of construction tolerances.

BRICK AND TILE CLASSIFICATION

Brick and tile are classified according to the specific location where they are used. Standard specifications have been developed to produce uniform requirements for brick. The American Society for Testing and Materials (ASTM) publishes the most widely accepted standards on brick. Standard specifications include strength, durability, and aesthetic requirements.

CLASSIFICATIONS

TYPE OF BRICK UNIT	ASTM DESIGNATION
Building brick	C 62
Facing brick	C 216
Hollow brick	C 652
Paving brick	C 902
Ceramic glazed brick	C 126
Thin brick veneer units	C 1088
Sewer and manhole brick	C 32
Chemical resistant brick	C 279
Industrial floor brick	C 410
TYPE OF TILE UNIT	
Structural clay load bearing tile	C 34
Structural clay non-load bearing tile	C 56
Structural clay facing tile	C 212
Structural clay non-load bearing screen tile	C 530
Ceramic glazed tile	C 126

GENERAL REQUIREMENTS

Terms used in each standard for classification may include exposure, appearance, physical properties, efflorescence, dimensional tolerances, distortion, chipping, core, and frogs. Bricks can be classified by use, grade, type, and/or class in most specifications. All options should be specified, as each ASTM standard has minimum requirements for grade and type that apply automatically if an option is omitted. If the desired requirements are not specified, a delivery may contain bricks unsuitable for the intended use.

EXPOSURE

Specific grades of brick are required to accommodate the various climates found in the United States and the differ-

ent applications in which brick can be used. Bricks must meet a grade of SW, MW, or NW based on the weathering index and the exposure they will receive. The weathering index is the product of the average annual number of freezing cycle days and the average annual winter rainfall in inches (see map below). The exposure is related to whether the brick is used on a vertical or horizontal surface and whether the unit will be in contact with the earth (see table 3). A higher weathering index or a more severe exposure will require face brick to meet the SW requirements. The grade is typically based on physical properties of the brick. The grades for each specification are listed in table 2.

TABLE 2: GRADE REQUIREMENTS FOR FACE EXPOSURES*

EXPOSURE	WEATHERING INDEX	
	LESS THAN 50	50 AND GREATER
In vertical surfaces:		
In contact with earth	MW	SW
Not in contact with earth	MW	SW
In other than vertical surfaces:		
In contact with earth	SW	SW
Not in contact with earth	MW	SW

*See map below.

TABLE 3: EXPOSURE

ASTM STANDARD	MORE SEVERE EXPOSURE	LESS SEVERE EXPOSURE
C 62 Grade	SW	MW NW
C 216 Grade	SW	MW
C 652 Grade	SW	MW
C 902 Grade	SX	MX NX
C 126 ¹	—	—
C 1088 Grade	—	Exterior Interior
C 32 sewer ²	SS	SM
Grade manhole	MS	MM

NOTES

1. No requirements for durability.
2. Based on durability and abrasion.

APPEARANCE

Brick types are related to the appearance of the unit, and specifically to limits on dimensional tolerances, distortion tolerances, and chippage. The brick type can be selected depending on whether a high degree of precision is necessary, a wider range of color or size is permitted, or a characteristic architectural effect is desired. The types of brick for each specification are listed in table 4.

TABLE 4: APPEARANCE

ASTM STANDARD	TIGHTER TOLERANCES		LOOSER TOLERANCES	
C 62			None	
C 216 Type	FBX		FBS	FBA
C 652 Type	HBX	HBS	HBB	HBA
C 902 application	PX		PS	PA
C 126 Grade	S		SS	—
C 1088 Type	TBX		TBS	TBA
C 32 sewer manhole			None	None

AESTHETICS AND SHAPES

Brick is readily available in many sizes, colors, textures, and shapes, all adaptable for virtually any style or expression. Brick's small module can be related to the scale of the wall, and its sizes can be combined to create different appearances and patterns. Sizes available are shown in table 1.

When specifying the size of units, dimensions should be listed in the following order: width by thickness by length. The size of the brick influences cost because larger units require fewer bricks, normally resulting in less labor. Specially shaped bricks are available to add interest to a wall, including water table bricks, radials, caps, copings, corners, and others. Consult the manufacturer for specific sizes and availability.

 Brian E. Trimble; Brick Institute of America; Reston, Virginia

GENERAL

Concrete masonry units (CMU) conform to ASTM standard specifications. The most common concrete masonry units used in building construction are load bearing units and concrete brick. Non-load bearing units may be specified for partitions and are commonly used for fire protection of steel columns and fire-rated partitions.

Type I or moisture-controlled units are specified to obtain a uniform degree of volume change due to moisture loss in a particular climate. The specification of Type I units facilitates the location of control joints. Type II or non-moisture controlled units may be more economical but will typically require closer spacing of control joints.

In addition to type, concrete bricks are specified by grade. Grade N is intended for use as architectural veneer and facing units in exterior walls and for use when high strength and resistance to moisture penetration and severe frost action are desired. Grade S is intended for general masonry where moderate strength and resistance to frost action and moisture penetration are required.

Concrete masonry units are available in a variety of colors, sizes, textures, configurations, and weights to accommodate design, detailing, and construction. Colors are now provided with lightfast metallic oxide pigments conforming to ASTM C 979. The textures may be smooth, ground, split, ribbed, or otherwise prepared to maximize design versatility. Smooth finishes and more color options are available with prefaced, "integral glazed" concrete masonry units.

Concrete masonry units are specified as width by height by length. The nominal dimensions are usually 3/8 in. larger than the actual unit dimensions. The most common nominal widths of concrete masonry units are 4 in., 6 in., 8 in., 10 in., and 12 in. The nominal heights are mostly 8 in. and 4 in., except concrete bricks are typically 2 2/8 in. high. The nominal lengths are usually 16 or 18 in. Concrete brick length is usually 8 in. but is often 12 in. Lengths may be 18 or 24 in. in some regions. These longer lengths are usually more economical for placement.

The weight of the units also varies. Depending on the aggregate used, concrete masonry units are typically made using concretes with densities ranging from 85 to 140 pcf. The lighter units tend to provide more fire resistance and have an improved noise reduction coefficient, and they often are more economical to place in the wall. Heavier units tend to provide increased compressive strength, better resistance to sound penetration, higher water penetration resistance, and greater thermal storage capabilities.

GENERAL

Masonry walls have long served as foundations for structures. Today, most masonry foundation walls consist of single wythe, hollow or solid masonry unit construction, depending on the required bearing capacity. The wall systems may be used as perimeter walls for slab-on-grade construction or to form crawl spaces or basements. The walls are reinforced as necessary to resist lateral loads. Generally, such reinforcement should be held as close to the interior face shell as possible, to provide the maximum tensile strength most economically.

Foundation systems, especially basement walls, need to do more than simply support the structure. They must protect against heat, insect infestation (particularly termites), fire, and penetration of water and soil gas.

Thermal protection may be provided with interior furring and batts or rigid board insulation, an exterior rigid board insulation and protection system, or with integral insulation strategies. The latter include foamed-in-place insulation, granular fill insulations, and premolded polystyrene inserts. Use of interior and exterior insulation rather than premolded inserts allows reinforcing steel to be installed more easily.

Optimal insect protection can be achieved using interior or integral insulation and a termite shield. Metal flashing materials often perform well as termite shields. For exterior insulation strategies in locations where termites are a concern, the termite shield must extend over the exterior insulation.

Waterproofing and dampproofing are specified by building codes, as discussed in chapter 7. Generally, waterproofing makes the foundation or basement wall resistant to air infil-

tration and thereby resistant to soil gases such as radon. Typical waterproofing consists of a minimum 3/4 in. coat of cement stucco parging and an appropriate liquid-applied membrane, but some liquid-applied membranes alone or combined with built-up membranes are acceptable. Surface-bonding mortar mixes are also effective for resisting water and soil-gas penetration. A good perimeter drainage system in contact with open air or connected to a sump pit should be used for effective drainage.

If radon is a major concern, the top course of the masonry and the course of masonry at or below the slab should be constructed of 100% solid units or hollow units fully filled with grout. French drains (drainage channels at the interfaces of foundation walls and floor slabs), which often are used to collect and drain condensation moisture in basements, should be avoided in areas where soil-gas entry is a concern.

Architectural masonry units may be used to improve the appearance of foundation walls, often in the above-grade portion of the walls. Masonry units with architectural finishes facing the interior can be used for economical construction of finished basement space.

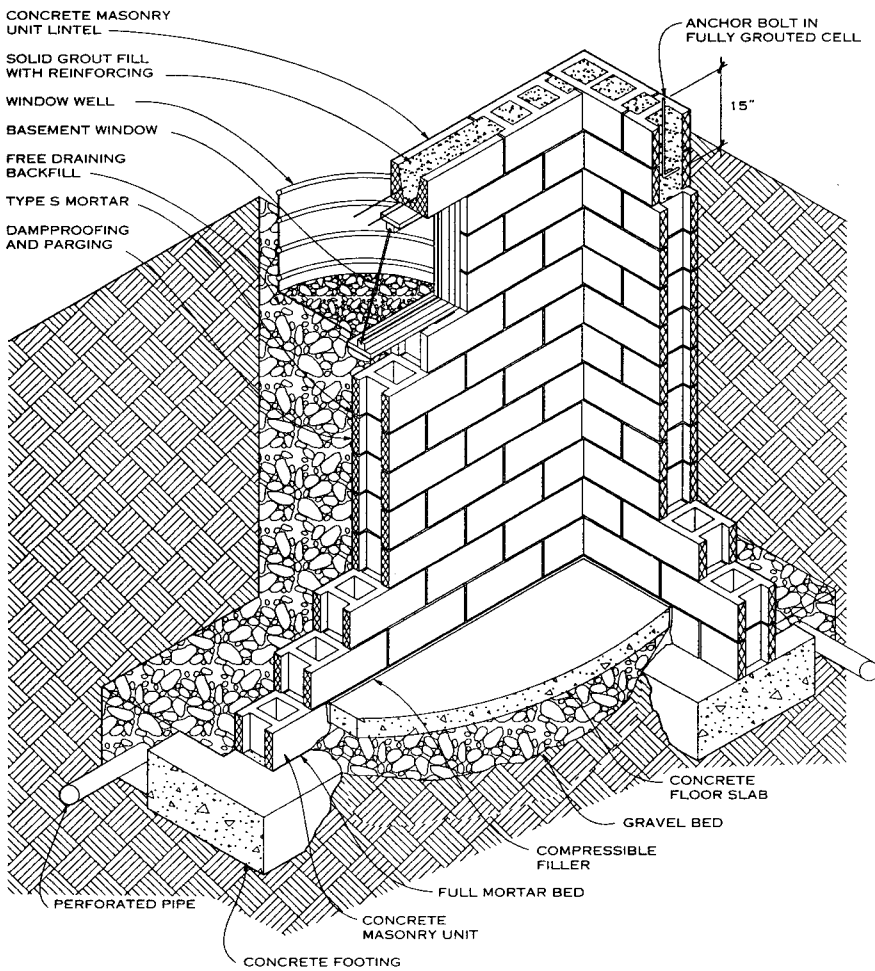

Masonry easily accommodates any floor plan, and returns and corners increase the structural performance of the wall for lateral load resistance. Returns and corners that support porches, fireplaces, and the like may also serve as wine cellars. Returns for window wells permit an increase in daylighting, making below-grade areas more attractive as habitable space.

THICKNESS OF FOUNDATION WALLS

FOUNDATION WALL CONSTRUCTION	NOMINAL THICKNESS (IN.)	MAXIMUM DEPTH OF UNBALANCED FILL (FT)
Masonry of hollow units, ungrouted	8	5
	10	6
	12	7
Masonry of solid units	8	5
	10	7
	12	7
Masonry of hollow or solid units, fully grouted	8	7
	10	8
	12	8

NOTE

Drainage must be provided on surface and below grade to remove ground water from foundation wall. The backfill must be granular and soil conditions nonexpansive.

Where:

- P = allowable total horizontal projection of corbeling
- p = allowable projection of one unit
- t = nominal wall thickness (actual thickness plus the thickness of one mortar joint)
- h = nominal unit height (actual height plus the thickness of one mortar joint)
- d = nominal unit bed depth (actual bed depth plus the thickness of one mortar joint)

NOTE

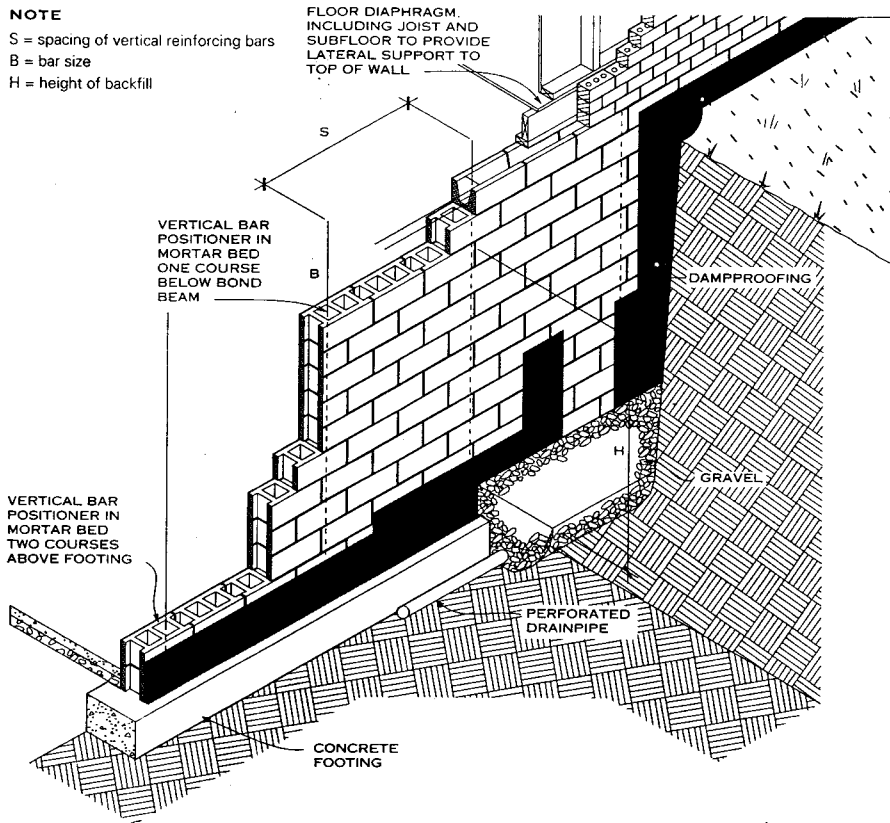

Corbeling is used to increase wall thickness to suit bearing requirements above foundation. Corbeling may be equal on both sides of the wall.

SINGLE WYTHE MASONRY WALL WITH STEEL FRAME

SINGLE WYTHE MASONRY

Single wythe masonry wall construction is common for both load bearing and non-load bearing interior and exterior walls. These systems are frequently used as interior partitions for fire protection.

Single wythe walls may be integrally insulated with precast fill insulation, foamed-in-place insulation, or site cast or factory installed molded polystyrene inserts. Single wythe walls may also be insulated on the interior or exterior. The insulation may be adhered or mechanically

SINGLE WYTHE MASONRY WALL WITH WOOD FRAME

fastened directly to the masonry, or it may be installed in conjunction with conventional furring or studding systems. The benefits of thermal mass are generally optimized with integral and exterior insulation strategies.

When single wythe walls are used as exterior walls and a high degree of water penetration resistance is required, the use of integral water repellents; exterior coatings, sealers, or finishes; or both may be required for concrete masonry construction. Clay masonry does not require these treatments.

ELECTRICAL OUTLET BOX IN CMU WALL

GENERAL

Design of multistory bearing wall buildings is based on combined structural action of the floor and roof system with the masonry walls. Floors carry the vertical loads and, acting as diaphragms, also distribute lateral loads to the walls. In masonry bearing wall buildings, lateral forces from winds or earthquakes are usually resisted by shear walls parallel to the direction of the lateral force. By their shearing and flexural resistance, these walls transfer lateral forces to the foundation.

The action of roof and floor diaphragms affects the distribution of lateral forces to the shear walls. Diaphragms are classified into three groups: rigid, semirigid (or semiflexible), and flexible. In design, the rigid diaphragm is assumed to distribute horizontal forces to vertical shear walls in proportion to their relative rigidities (longer or thicker walls being more rigid than shorter or thinner walls). More complex design approaches may consider the diaphragms to be semirigid or flexible. The distribution of loads in these more complex designs is similar to continuous beam design and design based on tributary areas, respectively.

For the diaphragms to be effective, there must be adequate connections between the roof and floor systems and the masonry walls. In many instances, adequate connection is achieved with the walls supported on masonry bond beams. Horizontal members (roofs and floors) are often connected to the walls with reinforcing steel. Adequate connections may be reinforcing steel into bond beams or may be coordinated with the masonry wall reinforcement. Connections will vary with the requirement to resist loads.

REINFORCEMENT

In many applications, single wythe walls are reinforced. The term *partially reinforced* is erroneous. Reinforcement schedules are designed for a particular application, and all the required reinforcement is necessary.

Walls are often partially grouted, that is, only the cells or cavities of the wall containing reinforcement are grouted. When walls are partially grouted, special units or construction fabric are used for vertical containment of the grout. Horizontal containment is usually provided by mortaring the webs of the masonry units. When steel placement is frequent, it may become economical or necessary to fully grout the walls.

Structural components of a building using reinforced masonry combine the tensile strength of reinforcement with the compressive strength of the masonry to resist design loads. Walls, columns, pilasters, and beams are designed to resist dead, live, wind, seismic, and lateral earth pressures using reinforced masonry. The benefits of incorporating reinforcement are improved ductility, structural integrity, and resistance to flexural and shear stresses. Reinforced masonry walls are extensively used for warehouses, institutional buildings, retaining walls, shear walls, basement walls, and load bearing walls, particularly in multistory hotels and apartment buildings. Reinforced masonry provides economical construction, especially when a high degree of resistance to lateral loads is necessary.

Seismic performance categories A and B require no special provisions. In many instances, the wind loads will govern the minimum reinforcing levels in seismic performance category C and above.

For designs in seismic performance category C, vertical reinforcement of at least 0.20 in. in cross-sectional areas shall be provided continuously from support to support at each corner, at each side of each opening, and at the ends of walls. Horizontal reinforcement of not less than 0.20 in. shall be provided at the bottom and top of all openings and extend not less than 24 in. nor less than 40 bar diameters past the opening. Horizontal reinforcement should be installed continuously at structurally connected roof and floor levels, at the tops of walls, and at the bottom of the wall or at the top of the foundation; maximum spacing is 10 ft unless uniformly distributed joint reinforcement is provided.

For designs in seismic performance categories D and E, walls shall be reinforced both vertically and horizontally. Requirements in addition to those for seismic performance category C include that spacing shall not exceed 4 ft, except for designs using moment resisting space frames, where the spacing of principal reinforcement shall not exceed 2 ft. Also, the diameter of the reinforcement shall not be less than 3/8 in., except for joint reinforcement.

STANDARD MATERIALS SELECTION FOR REINFORCED MASONRY

MASONRY UNITS		MORTAR AND GROUT		REINFORCEMENT	
ASTM C 90	Load bearing Concrete Masonry Units	ASTM C 270	Mortar for Unit Masonry Construction	ASTM A 82	Steel Wire, Plain
ASTM C 216	Facing Brick (solid masonry units made from clay or shales)	ASTM C 476	Grout for Masonry	ASTM A 615	Deformed and Plain Billet-Steel Bars
ASTM C 652	Hollow Brick (hollow masonry units made from clay or shale)			ASTM A 616	Rail-Steel Deformed and Plain Bars
				ASTM A 706	Low-Alloy Steel Deformed Bars
				UBC 24-15	Joint Reinforcement for Masonry

METHODS OF REINFORCING

NOTE
 C = 24 in. minimum but not less than 40 bar diameters. In seismic performance category C,
 S = 10 ft maximum; in seismic performance categories D and E, S = 4 ft maximum.

REINFORCED LOAD BEARING BRICK OR CMU WALLS

MULTI-WYTHE MASONRY

Multiwythe masonry construction is common for many applications, both load bearing and non-load bearing and for interior and exterior walls. These systems are frequently used as exterior walls or other applications when exposed architectural masonry units are required on one or both sides of the masonry. Such walls are constructed with full collar joints between wythes of masonry. The most common multiwythe wall is the composite wall, which consists of a clay brick wythe and a concrete masonry wythe with a 1/2 in. collar joint, and brick headers or anchors. The collar joint is often difficult to fill and may be filled by parging the backup or by grouting. Generally the method of filling the joint should not be specified. The mason should be permit-

ted to use the method that is most effective based on the talent available, the wall configuration, and the construction sequence. Often a single wythe of the wall might be reinforced. See the section on single wythe walls for a discussion of reinforced masonry. In multiwythe construction the collar joint may contain reinforcement. If this is so, the collar joint width must be increased to provide adequate coverage for the reinforcement. The diameter of the reinforcement should not exceed half the collar joint thickness. When fine grout is used there must be at least 1/4 in. between the reinforcement and the masonry. When coarse grout is used, the space must be at least 1/2 in.

Multiwythe walls may be constructed as partially grouted walls, using cavity wall or multiwythe wall construction. For

this type of wall, the grout is contained horizontally with building fabric and vertically with dams. The dams are typically masonry units placed within the cavity. In partially grouted hollow wall construction, flashing may be necessary at horizontal interruptions in the cavity.

Insulation for exterior walls may be integral in a wythe of masonry or may be on the exterior of the wall, but it is usually on the interior. The insulation may be adhered or mechanically fastened directly to the masonry, or the insulation system may be part of a conventional furring or studing system. The benefits of thermal mass are generally optimized with integral and exterior insulation strategies.

GENERAL

Cavity walls consist of two wythes of masonry separated by at least a 2 in. airspace. The airspace may be increased to 4 1/2 in. with only minor increases in tie size and or spacing. If the cavity is to be more than 4 1/2 in., the wall system should be appropriately engineered. Either or both wythes of the wall system may be load bearing.

The cavity wall is a drainage-type wall that provides excellent resistance to water penetration. The mass and discontinuity of construction provided by the metal ties result in optimal sound penetration resistance. The calculated fire resistance of cavity walls usually exceeds 4 hours. Interior and exterior wythes may be considered as thermal mass for specific thermal requirements. Either or both wythes may be used to provide the desired architectural finishes, interior or exterior. For these reasons, the masonry cavity wall is generally preferred.

When the cavity wall is selected because of its thermal performance, generally only the interior wythe is load bearing. This construction permits the insulation layer to be continuous within the wall and pass the slabs, minimizing thermal bridges. The insulation may be granular fill or rigid board insulation. If rigid board insulation is selected, there must be a nominal 1 in. airspace between the back of the exterior wythe and the exterior surface of the insulation board. The insulation board may be held in place with the wall ties. Two-piece adjustable ties serve well for this application. Seams in the insulation should be made with tongue-and-groove joints, shiplapped, or sealed with tape. If the ties selected are not appropriate for holding the insulation against the backup wythe, then the rigid board insulation should be adhered or mechanically fastened to the backup. If granular fill is used, it is necessary to select weep hole systems that will permit drainage but keep the granular fill within the wall system. Typical cavity walls may contain 2 to 4 1/2 in. of granular fill insulation or 3 1/2 in. of rigid board insulation.

4 MASONRY UNITS

BRICK VENEER ON WOOD STUD BACKUP

ANCHORED VENEERS

Masonry veneers provide an aesthetic, durable, noncombustible, weather resistant finish for structural masonry or light framing construction. The inherent mass of the veneer provides increased thermal performance, sound penetration resistance, and fire resistance. Anchored veneers typically consist of nominal 3 or 4 in. wythes of masonry tied to a backing system. Veneers are not intended to support any loads other than their own weight. All lateral loads are intended to be transferred to the backing system. Empirical design permits the construction of masonry veneers with a nominal thickness of 4 in. to heights of three stories, 30 ft

Grace S. Lee; Rippeteau Architects, PC; Washington, D.C.
 Brian E. Trimble; Brick Institute of America; Reston, Virginia

BRICK VENEER ON STEEL STUD BACKUP

at the plate and 38 ft at the gables. For veneers with a nominal thickness of 3 in., the height is limited to two stories, 20 ft at the plate and 28 ft at the gable. For building heights greater than two stories, the brick veneer must be supported by a shelf angle at every floor.

Veneers are drainage-type walls. Although a nominal 1 in. airspace is acceptable for drainage in most low-rise, residential applications, a minimum 2 in. airspace between the back of the masonry and the exterior surface of the backing or exterior sheathing is recommended for masonry veneers in mid-rise and high-rise construction.

SHELF ANGLE DETAIL

THIN BRICK VENEER ON CMU

THIN BRICK VENEER ON WOOD FRAME

ADHERED VENEERS

Thin brick veneer, also referred to as adhered veneer, is an application of thin brick veneer units—between 1/2 to 1 3/4 in. thick—on a backing system. Adhered veneer relies on the bonding agent between the thin brick units and the backup substrate. This construction may be classified as either thin bed set or thick bed set. The thin brick can be adhered to a stud backing, attached to a concrete masonry backing, cast into a concrete panel, or laid into a preformed modular panel. Thin brick panels can be prefabricated or laid in place, depending on the size or intricacies of the project.

MASONRY UNITS

GENERAL

The fireplace and chimney are usually large elements in residences, but their scale can be adapted to any architectural style. The purpose of the residential fireplace has changed over the years from heating to decoration. However, increasing public interest in renewable forms of energy has instigated a new demand for fireplaces for heating homes. Fireplace design and construction are governed by building and mechanical codes. The internal diagram of a working fireplace shows the several required parts and their vertical organization. Each part is illustrated on succeeding pages.

The main function of the fireplace and chimney is to sustain combustion and carry smoke away safely. Their design is

based on empirical data proven with years of safe performance. The charts on the following pages show the appropriate sizes of fireplace and chimney elements. One of the most important design decisions is the location of the fireplace. To prevent heat loss to the exterior, it is best to locate a fireplace at the center of the house. Again to improve performance, a fireplace should not be located opposite an outside door or near an open stairway leading to an upper floor, a forced air furnace, or a return air register. Combustion can be improved by providing a measured supply of outside air, independent of room air, to the fireplace. This is done by installing an air duct from the exterior of the house to the fireplace. The chimney must be properly sized to carry the combustion products away. Two factors primarily affect the chimney draft: size of the fireplace

opening and height of the chimney. The figure on the following page should be used to size the flue accurately based on these factors.

Several distinct types of fireplaces are currently used in residential applications. Single-face fireplace styles are the most popular and include the conventional fireplace, the Rumford fireplace, the Rosin fireplace, and air circulating fireplaces. Multiface fireplaces are also popular and include the see-through fireplace, the corner fireplace, and the free-standing fireplace. The masonry heater, or masonry stove, is a specialized type of fireplace and is the most efficient of all these types.

CONVENTIONAL FIREPLACE

FIREPLACES BACK TO BACK IN PARTY WALL

RUMFORD FIREPLACE

CONVENTIONAL FIREPLACES

The design of single-face fireplaces has been well documented, resulting in the development of a reasonably accurate set of design dimensions for fireplace openings, dampers, and flue liners.

Single-face fireplaces can be efficient radiant heaters. The amount of heat radiated and reflected into the room is directly proportional to the masonry surface area exposed to the fire. The Rumford fireplace is a variation of the single-face fireplace with a shallow firebox, a high throat, and widely splayed sides, all features that contribute to optimal direct radiant heating.

In addition, the energy efficiency of new fireplaces can be improved by following these recommendations:

1. Locate the fireplace on the interior of the house.
2. Supply outside air for combustion and maintenance of positive room pressure.
3. Provide glass fireplace screens to prevent unwanted air infiltration when the fireplace is not in use.

Grace S. Lee; Rippeteau Architects, PC; Washington, D.C.

4 MASONRY UNITS

GENERAL

Masonry heaters make use of two basic principles to obtain high combustion and heating efficiencies—controlled air intake to the combustion chamber/firebox and a heat exchange system of baffled chambers through which hot combustion gases are circulated. Such heaters are efficient, clean burning devices.

Brick masonry heaters or masonry stoves used in North America are adapted from those used in northern and eastern Europe, which were employed for cooking as well as heating. Modern masonry heaters come in a wide variety of shapes and sizes. The size and layout of the house, the climate, and the needs of the homeowner are all considered in the design of a masonry heater. For optimum performance, however, it should be located near the center of the house. Masonry heaters may be custom built on site or assembled from prefabricated components. Modern masonry heaters may incorporate fire viewing, bake ovens, stoves, and warming benches.

Two safety concerns that apply to brick masonry heaters but are not listed in the major model building codes are the integrity of the enclosing walls of the heater and the temperature of the exterior surfaces of the walls:

To maximize the integrity of masonry heater walls, they should be constructed of two wythes of brick (ASTM C 216 or C 62 for facing brick) with a nominal 1-in. airspace between them. Fill the airspace with a compressible, non-combustible material such as insulation, and tie both wythes together with corrosion-resistant metal ties. Add horizontal joint reinforcement every sixth course (only at exterior wythe).

To safeguard against the effects of the high surface temperatures of the heater (between 100° and 190°F), a minimum 12-in. clearance should be observed between the heater and any combustibles and there should be a 20-in. extended hearth in front.

NOTE
For clearances from specific types of firebox openings and other requirements, consult ASTM E 1602 and local codes. Most clearances may be reduced if an engineered protection system is provided.

CLEARANCE TO COMBUSTIBLES FOR MASONRY HEATERS

NOTE
In Finnish or contraflow heaters, heated air is forced from the top of the smoke chamber down through the baffles on the sides of the heater, while room air rises by convection along the exterior surfaces of the masonry. This construction allows for even heating of the masonry and efficient radiant heating of the room. The baffles converge below the firebox and open out to the flue at the base of the chimney.

FINNISH (FOUNTAIN-STYLE) HEATER

GERMAN TILE/BRICK HEATER (GRUNDOFEN)

NOTE
Russian heaters are typically deep with a small opening to the firebox, above which is a system of either vertically or horizontally aligned baffles in place of the smoke chamber. After circulating through the baffle system, exhaust gases pass directly into the flue.

RUSSIAN (MULTIFLUE) HEATER

SWEDISH TILE HEATER (KAKELUGN)

CLAY FLUE LININGS

NOTES

1. Availability of specific clay flue liners varies according to location. Generally, round flue liners used in construction with reinforcing bars are available in the western states, while rectangular flue liners are commonly found throughout the eastern states. Check with local manufacturers for available types and sizes.
2. Nominal flue size for round flues is interior diameter; nominal flue sizes for standard rectangular flues are the exterior dimensions and, for modular flue linings, the outside dimensions plus 1/2 in.

INSULATION OF WOOD FRAMING MEMBERS AT A CHIMNEY

BRICK CHIMNEY CONCEALED BEHIND STUD WALL

BRICK CHIMNEY EXPOSED

CHIMNEY FRAMING AND INSULATION

3. Areas shown are net minimum inside areas.
4. All flue liners are generally available in 2 ft lengths.
5. Fireplace flue sizes can be approximated using the following rules of thumb: One-tenth the area of fireplace opening recommended; one-eighth the area of opening recommended if chimney is higher than 20 ft and rectangular flues are used; one-twelfth the area is minimum required; verify with local codes.

HIGH FORMED DAMPER (IN.)

A	B	C
32	15 1/4	9 1/4
36	19 1/4	9 1/4
40	23 1/4	9 1/4
44	27 1/4	9 1/4
48	31 1/4	9 1/4

HIGH FORMED DAMPERS provide correct ratio of throat-to-fireplace opening with an optional preformed smoke shelf, which can reduce material and labor requirements. They are useful for both single and multiple opening fireplaces.

FORMED DAMPER (IN.)

WIDTH OF OPENING	DAMPER DIMENSIONS (IN.)		
	A	B	C
24 to 26	28 1/4	26 3/4	24
27 to 30	32 1/4	30 3/4	28
31 to 34	36 1/4	34 3/4	32
35 to 38	40 1/4	38 3/4	36
39 to 42	44 1/4	42 3/4	40
43 to 46	48 1/4	46 3/4	44
47 to 50	52 1/4	50 3/4	48

FORMED STEEL DAMPERS are designed to provide the correct ratio of throat-to-fireplace opening, producing maximum draft. These dampers are equipped with poker type control and are easily installed.

SQUARE FORMED DAMPER (IN.)

TOP OUTLET			OVERALL SIZE	
E	F	H	L	W
17	17	17	41	27
17	17	25	45	27
17	23	25	49	27

SQUARE FORMED DAMPERS have high sloping sides that promote even draw on all-sides of multiple opening fireplaces. They are properly proportioned for a strong draft and smokefree operation.

FORMED STEEL DAMPERS

DOOR DIMENSIONS (IN.)

A	B
6	8
8	8, 10
10	10, 12
12	8, 10, 12, 16, 18

CLEANOUT OR ASHPIT DOOR

DUMP DIMENSIONS (IN.)

A	B
3 1/2	4 1/2
7	9
7	10

NOTE

Ash dumps and cleanout doors are available in heavy gauge steel or cast iron. See local manufacturers for available types and sizes.

ASH DUMP

NOTES

1. Locate bottom of damper minimum 6 to 8 in. from top of fireplace opening.
2. Mineral wool blanket allows for expansion of metal damper walls.
3. Dampers are available in heavy gauge steel or cast iron. Check with local suppliers for specific forms and sizes.
4. A cord of wood consists of 128 cu ft or a stack 4 ft high and 8 ft wide, with logs 4 ft long.
5. A face cord of wood consists of 64 cu ft or a stack 4 ft high and 8 ft wide, with logs 2 ft long.
6. Logs are cut to lengths of 1 ft 4 in., 2 ft 0 in., 2 ft 6 in., and 4 ft. Allow 3 in. minimum clearance between logs and each side of fireplace.

Timothy B. McDonald; Washington, D.C.

GENERAL

Multifaced fireplaces have more than one face of the firebox open to the room. There are three types of multifaced fireplaces: projected corner, with two adjacent sides open; double faced, with two opposite sides open; and three faced, with only one side built of masonry construction. Multifaced fireplaces usually are not as energy-efficient as conventional, single-faced fireplaces because there is less mass surrounding the fire to hold and radiate heat to the room. However, multifaced fireplaces usually are located on the interior of a space, not on an exterior wall, and their energy-efficiency can be augmented by the features discussed below.

The addition of energy-efficient features to fireplace design can increase both the combustion of the wood and the ability to heat the room or building. Energy-efficient features for conventional fireplaces include glass doors, damper controls, and outside air intake to the firebox. Designs that increase radiant heat also are energy-efficient. For example, the obliquely flared sides of Rumford-type fireplaces increase radiant heat. Air-circulating fireplaces increase the amount of radiant heat emanating from a fireplace through natural convection or by forced-air circulation.

SINGLE HIGH DOUBLE LOW

DAMPER ARRANGEMENT

TYPICAL DIMENSIONS (IN.)

A	B	D
28	24	30
32	30	35
36	30	35
40	30	35
48	30	37

NOTE

The fireplace must be located and designed to allow proper updraft through both openings. Exterior doors should not be located opposite the fireplace on either side because they may cause cross-drafts through the fireplace.

TWO-FACED FIREPLACE

TYPICAL DIMENSIONS (IN.)

A	B	C	D
28	26½	20	32
32	26½	20	32
36	26½	20	32
40	30	20	35
48	30	20	35
54	30	20	37
60	30	20	37

NOTE

The sides of the fireplace are partially enclosed by recessing the brick into the wall behind the fireplace. This design helps eliminate smoke from cross-drafts.

THREE-FACED, WIDE FRONT FIREPLACE

NOTE

This design is similar to the projected-corner fireplace.

THREE-FACED, WIDE FRONT FIREPLACE—SECTION

TYPICAL DIMENSIONS (IN.)

A	B	D
28	27½	32
32	27½	32
36	27½	32
40	27½	32
48	27½	32

NOTE

The narrowness and length of narrow-front fireplaces require that they be fitted with two square-end dampers. To allow for expansion, the dampers should be neither solidly embedded in mortar nor mechanically fastened to steel angles.

THREE-FACED, NARROW FRONT FIREPLACE

TYPICAL DIMENSIONS (IN.)

A	B	C	D
28	26½	16	34
32	26½	16	34
36	26½	16	34
40	30	16	34
48	30	20	38
54	30	20	37
60	30	20	37

NOTE

The significant difference between a projected-corner fireplace and a conventional single-faced fireplace is the shape of the damper. A projected-corner fireplace uses a square-end damper instead of a tapered-end damper. The open side should have a short wall to help stop the escape of combustible gases when cross-drafts occur.

PROJECTED-CORNER FIREPLACE

GENERAL

Structural clay facing tile is chosen as an attractive and durable wall system in many specialized applications, especially when maintenance and resistance to vandalism are considered. Applications include walls and partitions in correctional facilities, schools, public buildings, and food processing facilities. Structural clay tile can be glazed or unglazed, load bearing or non-load bearing, and behaves similarly to brick. Structural clay tile is manufactured in many sizes and shapes. Numbers and letters shown on the units in the figures indicate the standard shape classifications of structural clay facing tile used by manufacturers.

WALL SECTIONS AND PROPERTIES

WALL TYPE NUMBER	1	2	3	4	5

TERRA-COTTA

Terra-cotta is a high grade of weathered or aged clay, which, when mixed with sand or with pulverized fired clay, can be molded to a hardness and compactness not obtainable with other materials. Used extensively until the 1930s, terra-cotta has been largely replaced with ceramic veneer.

Terra-cotta was usually hollow cast in blocks, open to the back to reveal internal webbing.

Ceramic veneer is not hollow cast but is a veneer of glazed ceramic tile that is ribbed on the back. It is frequently attached to metal ties that are anchored to the building.

Other types of terra-cotta are:

1. Brownstone terra-cotta. A dark red or brown block, which is hollow cast. Used extensively in the mid- to late-19th century.
2. Fireproof construction terra-cotta. Inexpensive and lightweight, these rough-finished hollow building blocks span beams. The blocks are available but not used widely today.
3. Glazed architectural terra-cotta. Hollow units were hand cast in molds or carved in clay and heavily glazed. Sometimes called architectural ceramics, this terra-cotta type was used until the 1930s.

NOTES

Ceramic veneer can be anchored or adhered to masonry.

The ceramic veneer manufacturer should provide scale shop drawings as detailed from the architect's drawings. To be used for setting, the shop drawings should indicate all dimensions and sizes of joints, and all anchors, hangers, expansion, and control or pressure-relieving joints.

Nonferrous metal anchors should be embedded in the masonry and encased for protection from corrosion.

The minimum thickness of anchored-type ceramic veneer, exclusive of ribs, should be 1 in.

Ceramic veneer should be set true to line in setting mortar. Spaces between anchored ceramic veneer and backing walls should be filled with grout: spaces 3/4 in. or more in width with pea gravel and spaces 3/4 in. with mortar.

The minimum thickness of adhesion-type ceramic veneer, including ribs, should be 1/4 in. with ribbed or scored backs.

An evenly spread coat of neat portland cement and water should be applied to the wall and the entire back of the ceramic veneer panel about to be set. Then one half of the setting mortar coat should be immediately applied on the chosen wall area and the other on the ceramic veneer piece's entire back. Tap the piece into place on the wall to completely fill all voids, with the total thickness of the mortar averaging 3/4 in. There should be some excess mortar forced out at the joints and edge of the ceramic veneer.

MOLD-PRESSED CERAMIC VENEER

The minimum thickness of the exposed faces of mold-pressed ceramic veneer is 1 in. Backs of special shapes should be open and ribbed.

For placement, turn all units bottom-side up and fill solidly with grout filler for mold-pressed ceramic veneer. When the fill has set sufficiently to permit handling, set the units.

When applied to soffits, each piece of ceramic veneer, in addition to the usual centers and wooden wedges, shall be supported by bent and vertical wooden shores. A constant upward pressure is needed until the mortar coat has set.

Adhesion can be tested with a 1 x 1 x 4 in. vitrified test bar. First dissolve vinyl acetate in methyl iso-butyl ketone. Apply to the ceramic veneer surface and test bar. The adhesive is heated by means of an infrared lamp until bubbling ceases. Press the two surfaces together until cool. Then knock or pry off test bar.

TERRA-COTTA VENEER PRECAST PANEL

Terra-cotta precast panels have a keyback design, which allows each piece to easily become an integral part of the precast unit through a mechanical bond. No fasteners are needed.

GENERAL

Glass block is a diverse building material whose many applications exhibit its multifaceted characteristics. The varying forms of glass block — type, thickness, size, shape, and patterns — along with the methods of installation can combine to create unique design solutions. Applications range from entire facades, windows, interior dividers, and partitions to skylights, floors, walkways, and stairways. In all applications, glass block units permit the control of light, both natural and artificial, for function or drama. Glass block also allows for control of thermal transmission, noise, dust, and drafts. With the use of thick-faced glass block or solid 3 in. bullet-resistant block, security can also be achieved.

MORTAR

An optimum mortar mix for installing glass block units is 1 part portland cement, 1/2 part lime, and 4 parts sand.

The table below gives the number of glass block that can be installed with a mortar batch consisting of:
 1.0 cu ft (1 bag/94 lb) portland cement
 0.5 cu ft (20 lb) lime
 4.0 cu ft (320 lb) sand

GLASS BLOCK/MORTAR BATCH

SERIES	BLOCK SIZE ¹	BLOCK NUMBER ²
Regular	4 x 8	350
	6 x 6	350
	8 x 8	260
	12 x 12	190
Thin	4 x 8	450
	6 x 6	450
	8 x 8	335

NOTES

1. Includes 15% waste
2. Based on a 1/4 in. exposed joint

SOUND TRANSMISSION¹

STC ²	SIZE	PATTERN	ASSEMBLY CONSTRUCTION
31	8" x 8" x 3"	All patterns	Silicone system
37 ³	8" x 8" x 4"	All patterns	Mortar
40	8" x 8" x 4" with LX fibrous filter	All patterns	Mortar
50	8" x 8" x 4" thick faced block	Thick block	Mortar
53	8" x 8" x 3" solid units	Solid block	Mortar

NOTES

1. Tested in accordance with ASTM E90-90 "... Measurement of Airborne Sound Transmission Loss..."
2. STC rating value in accordance with ASTM E413-87 "Classification for Rating Sound Insulation."
3. Test method and STC rating value in accordance with ASTM E90-81 and ASTM E413-73 accordingly.

THERMAL PERFORMANCE/LIGHT TRANSMISSION^{1,2}

BLOCK TYPE	HEAT TRANSMISSION ² U-VALUE (BTU/HR FT ² °F)	THERMAL RESISTANCE ² R-VALUE (HR FT ² °F/BTU)	THERMAL EXPANSION COEFFICIENT (1/°F)	VISIBLE LIGHT TRANSMISSION (%)	SHADING COEFFICIENT ⁴

NOTES

1. Values equal ± 5%.
2. Winter night values.
3. To calculate instantaneous heat gain through glass block panels, see ASHRAE Handbook of Fundamentals, 1985, section 22.41.B.
4. Based on 8 in. square units: ratio of heat gain through glass block panels vs. that through a single light of double strength sheet glass under specific conditions.

Grace S. Lee; Rippeteau Architects, PC; Washington, D.C.

4 GLASS UNIT MASONRY

The basic glass block unit is made of two halves fused together with a partial vacuum inside. Faces may be clear, figured, or with integral relief forms.

Glass block is available in thicknesses ranging from a minimum of 3 in. for solid units to a maximum of 4 in. (nominal) for hollow units. Metric thicknesses range from 76 to 98 mm.

SQUARE

- 4 1/2 in. x 4 1/2 in.
- 6 in. x 6 in. (5 3/4 in. x 5 3/4 in. actual)
- 1/2 in. x 7 1/2 in.
- 8 in. x 8 in. (7 3/4 in. x 7 3/4 in. actual)
- 9 1/2 in. x 9 1/2 in.
- 12 in. x 12 in. (11 3/4 in. x 11 3/4 in. actual)

- 115 mm x 115 mm
- 190 mm x 190 mm
- 240 mm x 240 mm
- 300 mm x 300 mm

Metric sizes are available from foreign manufacturers through distributors in the United States.

Some manufacturers provide thick blocks for critical applications where a thick-faced, heavier glass block is needed. These blocks have a superior sound transmission rating properties. Their faces are three times as thick as regular units.

THICK BLOCK

Solid glass block units (glass bricks) are impact resistant and allow through vision.

Solar control units have either inserts or exterior coatings to reduce heat gain. Coated units require periodic cleaning to remove alkali and metal ions that can harm the surface coating. Edge drips are required to prevent moisture run-down on the surface.

End block units have a rounded, finished surface on one edge. They may be used to end interior partitions or walls as well as space dividers when installed horizontally.

END BLOCK

45° BLOCK

CORNER BLOCK

A few manufacturers have special shapes to execute corner designs. These units also may be placed together for varying patterns and forms.

SPECIAL SHAPES (CORNERS)

Surface decoration may be achieved with fused-on ceramic, etching, or sandblasting. Glass block units may be split or shipped in halves in order to apply some decoration to the inside. Blocks then must be resealed. Resealed blocks will not perform the same under various stresses as factory sealed units. Placement in walls or panels should be limited to areas receiving minimum loading.

MAXIMUM PANEL DIMENSIONS

PERIMETER SUPPORT METHOD	REGULAR SERIES			THIN SERIES		
	AREA (SQ FT)	HEIGHT (FT)	WIDTH (FT)	AREA (SQ FT)	HEIGHT (FT)	WIDTH (FT)
EXTERIOR						
Channel type restraint	144	20	25	85	10	25
Panel anchors	144	20	25	85	10	25
Channels or panel anchors with intermediate stiffener	250	20	25	150	20	25
INTERIOR						
Channel type restraint	250	20	25	150	20	25
Panel anchors	250	20	25	150	20	25

NOTE
Maximum exterior panel sizes are based on a design wind load of 20 lb/sq ft with a 2.7 safety factor.

NOTE
Full bed of mortar typically 1/2 in. wide at face of wall. Mortar to be type S optimum mixture:
1 part portland cement
1/2 part lime
4 parts sand

GLASS BLOCK PANEL COMPONENTS

- NOTES**
1. Area of exterior unbraced panel should not exceed 144 sq ft.
 2. Area of interior unbraced panel should not exceed 250 sq ft.
 3. Panels are designed to be mortared at sill, with head and jambs providing for movement and settling. Deflection of lintel at head should be anticipated.
 4. Consult manufacturers for specific design limitations of glass block panels. Thickness of block used also determines maximum panel size.

NUMBER OF BLOCKS FOR 100 SQ FT PANEL

BLOCK SIZE (NOMINAL)	6"	8"	12"
Number of blocks	400	225	100

GLASS BLOCK PANELS

NOTE
Expansion joints should be installed at every change of direction of a multicurved wall, at points of curved wall intersection with straight walls, and at center of curvature in excess of 90 degrees.

GLASS BLOCK EXPANSION JOINT

INTERMEDIATE EXPANSION JOINTS AND SUPPORTS

- NOTES**
1. It is suggested that curved areas be separated from flat areas by intermediate expansion joints and supports, as indicated in these drawings.
 2. When straight, ladder-type reinforcing is used on curved walls, the innermost parallel wire may be cut periodically and bent to accommodate the curvature of the wall.

RADIUS MINIMUMS FOR CURVED PANEL CONSTRUCTION

BLOCK SIZE	INSIDE RADIUS (IN.)	NUMBER OF BLOCKS IN 90° ARC	JOINT THICKNESS (IN.)	
			INSIDE	OUTSIDE
4" x 8"	32	13	1/8	5/8
6" x 6"	48 1/2	13	1/8	5/8
8" x 8"	65	13	1/8	5/8
12" x 12"	98 1/2	13	1/8	5/8

CURVED PANEL CONSTRUCTION

Grace S. Lee; Rippeteau Architects, PC; Washington, D.C.

TYPICAL SUPPORT DESIGN CRITERIA

When specifying supports and shelf angles, the installed weight and deflection limitation of the glass block should be taken into account. Local building codes should be checked for any limits on panel sizes or installation details.

INSTALLED WEIGHT OF GLASS BLOCK

TYPE OF UNIT	INSTALLED WEIGHT (LB/SQ FT)
Regular	20
Thin	16
Thick	26
Solid	38

DEFLECTION LIMITATIONS

Maximum deflection of structural members supporting glass block panels shall not exceed:

$$\frac{L}{600}$$

Where L = distance between vertical supports

ELEVATION

SHELF ANGLES IN MULTIPLE VERTICAL PANELS

SUPPORT IN MULTIPLE HORIZONTAL PANELS

NOTE

Panels with an expansion joint stiffener incorporating a concealed vertical plate should be limited to 10 ft maximum height.

GENERAL

Natural stone is used in building as a facing, veneer, and decoration. The major factors affecting the suitability and use of stone fall under two broad, but overlapping categories: physical and structural properties and aesthetic qualities. The three factors of building stone that most influence their selection by architects for aesthetic reasons are pattern, texture, and color. Consideration also should be given to costs, availability, weathering characteristics, physical properties, and size and thickness limitations.

Stone patterns are highly varied, and they provide special features that make building stone a unique material. Texture is varied, ranging from coarse fragments to fine grains and crystalline structures. Texture also varies with the hardness of minerals composing the stone. To accurately compare stone colors, the rock color chart published by the Geological Society of America (Boulder, CO) is recommended. Samples also may be used to establish acceptable color ranges for a particular installation.

Pattern, texture, and color all are affected by how the stone is fabricated and finished. Granites tend to hold their color and pattern, while limestone color and pattern changes with exposure. Textures may range from rough and flamed finishes to honed or polished surfaces. The harder the stone, the better it takes and holds a polish.

The three rock classes are igneous, sedimentary, and metamorphic. Common construction stones are marketed under the names given in the table below, although specialty stones such as soapstone and serpentine also are available. Each stone has various commercial grades. Limestone grades are A, statuary; B, select; C, standard; D, rustic; E, variegated; and F, old Gothic. Marble is graded A, B, C, or D on the basis of working qualities, uniformity, and flaws and imperfections.

PHYSICAL PROPERTIES OF STONE

The physical characteristics of a particular stone must be suitable for its intended use. It is important to determine the physical properties of the actual stone being used rather than using values from a generic table, which can be very misleading. Considerations of the physical properties of the stone being selected include modulus of rupture, shear strength, coefficient of expansion, permanent irreversible growth and change in shape, creep deflection, compressive strength, modulus of elasticity, moisture resistance, and weatherability. Epoxy adhesives, often used with stone, are affected by cleanliness of surfaces to be bonded and ambient temperature. Curing time increases with cold temperatures and decreases with warmer temperatures.

FABRICATION AND INSTALLATION

With the introduction of new systems of fabrication and installation and recent developments in the design and detailing of stone cutting, support, and anchorage, costs are better controlled. Correct design of joints, selection of mortars, and use of sealants affect the quality and durability of installation. Adequate design and detailing of the anchorage of each piece of stone are required. The size and thickness of the stone should be established based on physical properties of the stone, its method of anchorage, and the loads it must resist. Appropriate safety factors should be developed based on the variability of the stone properties as well as other considerations such as imperfect workmanship, method of support and anchorage, and degree of exposure of the cladding installation. Relieving angles for stone support and anchorage may be necessary to preclude unacceptable loading of the stone. The stone should be protected from staining and breakage during shipment, delivery, and installation.

Since stone cladding design and detailing vary with type of stone and installation, the designer should consult stone suppliers, stone-setting specialty contractors, industry standards (such as ASTM), and other publications to help select and implement a stone cladding system. Resource information is available in publications such as the Indiana Limestone Institute's *Indiana Limestone Handbook* and the Marble Institute of America's *Dimensioned Stone*, (vol. 3).

STONE CLASSIFIED ACCORDING TO QUALITIES AFFECTING USE

CLASS	COLOR	TEXTURE	SPECIAL FEATURES	PARTING	HARDNESS	CHIEF USES
Sandstone	Very light buff to light chocolate brown or brick red; may tarnish to brown	Granular, showing sand grains, cemented together	Ripple marks; oblique color bands ("cross bedding")	Bedding planes; also fractures transverse to beds	Fairly hard if well cemented	General; walls; building; flagstone
Limestone	White, light gray to light buff	Fine to crystalline; may have fossils	May show fossils	Parallel to beds; also fractures across beds	Fairly soft; steel easily scratches	All building uses
Marble	Highly varied; snow white to black; also blue-gray and light to dark olive green; also pinkish	Finely granular to very coarsely crystalline showing flat-sided crystals	May show veins of different colors or angular rock pieces or fossils	Usually not along beds but may have irregular fractures	Slightly harder than limestone	May be used for building stone but usually in decorative panels
Granite (light igneous rock)	Almost white to pink-and-white or gray-and-white	Usually coarsely crystalline; crystals may be varicolored; may be fine grained	May be banded with pink, white, or gray streaks and veins	Not necessarily any regular parting but fractures irregularly	Harder than limestone and marble; keeps cut shape well	Building stone, but also in paneling if attractively colored
Dark igneous rock	Gray, dark olive green to black; Laurvikite is beautifully crystalline	Usually coarsely crystalline if quarried but may be fine grained	May be banded with lighter and darker gray bands and veins	Not necessarily any regular parting but may fracture irregularly	About like granite; retains cut shape well	Building stone, but also used in panels if nicely banded or crystalline
Lavas	Varies: pink, purple, black; if usable, rarely almost white	Fine grained; may have pores locally	Note rare porosity	Not necessarily any regular parting, as a rule, but some have parallel fractures	About as strong as granite; if light colored, usually softer	Good foundation and building stone; not decorative
Quartzite	Variable: white, buff, red, or brown	Dense, almost glassy ideally	Very resistant to weather and impact	Usually no special parting	Very hard if well cemented, as usually the case	Excellent for building but hard to "shape"
Slate	Grayish-green, brick red, or dark brown, usually gray; may be banded	Finely crystalline; flat crystals give slaty fracture	Some slate have color-fading with age	Splits along slate surface, often crossing color bands	Softer than granite or quartzite; scratches easily	Roofing; blackboards; paving
Gneiss	Usually gray with some pink, white, or light gray bands	Crystalline, like granite, often with glassy bands (veins)	Banding is decorative; some bands very weak, however	No special parting; tends to break along banding	About like granite	Used for buildings; also may be decorative if banded

NOTES

1. A course is a horizontal row of stone. Bond pattern is described by the horizontal arrangement of vertical joints. (See also Brickwork.) Structural bond refers to the physical tying together of load bearing and veneer portions of a composite wall. Structural bond can be accomplished with metal ties or with stone units set as headers into the backup.
2. Ashlar masonry is composed of squared-off building stone units of various sizes. Cut ashlar is dressed to specific design dimensions at the mill. Ashlar is often used in random lengths and heights, with jointing worked out on the job.
3. All ties and anchors must be made of noncorrosive material. Chromium-nickel stainless steel types 302 and 304 and eraydo alloy zinc are the most resistant to corrosion and staining. Use stainless steel type 316 in highly corrosive environments (polluted or near the sea). Copper, brass, and bronze will stain under some conditions. Local building codes often govern the types of metal that may be used for some stone anchors.
4. Nonstaining cement mortar should be used on porous and light colored stones. At all corners use extra ties and when possible, larger stones. Joints for rough work are usually 1/2 to 1 1/2 in. and 3/8 to 3/4 in. for ashlar. Prevent electrochemical reaction between different metals combined in the same assembly by properly isolating or coating them.

NOTES

Use of the steel stud support system as shown requires an architect or engineer to develop adequate and realistic performance criteria, including thorough consideration of the long-term durability and corrosion resistance of light gauge members, mechanical fasteners, and other system components; provisions for adequate thermal movement; development of adequate system strength and stiffness; recognition of the structural interaction between the stone support system; and consideration of vapor retarders and flashing to control moisture migration. It also is important that adequate provisions be developed to ensure quality workmanship necessary to implement the system and to achieve the expected quality and durability.

The stone thickness depicted is a minimum of 1 1/2 in. Thicker stone materials can use the same type of support system; however, engineering analyses of the system will be necessary to ensure proper performance and compliance with recommended design practices.

Design criteria for stone anchorage must include consideration of the particular stone's average as well as lowest strength values for safety, particularly at anchorage points. The proposed stone should be tested for adequate design properties and values. Stone anchorage size and location depend on establishing the particular stone's strength values, natural faults, and other properties; the stone's thickness and supported area; the expected lateral as well as gravity loading; and the amount of thermal movement to be accommodated.

WALL SECTION

Shown here is the most common method of anchoring a cornice, which has a projection large enough to be balanced in the wall.

The bed joint immediately below the heavy cornice is open far enough back to remove any compressive stress that would have a tendency to break off stone below.

ANCHORAGE DIMENSIONS

Standard flat stock anchors are made of strap 1 and 1 1/2 in. wide by 1/8, 3/16, and 1/4 in. thick. Lengths vary up to 6, 8, 10, and 12 in. Dovetail anchors are usually 4 1/4 in. overall with 3 1/2 in. projection for face of concrete. Bends are 3/4, 1, and 1 1/4 in.

Round stock anchors are made from stock of any diameter: 1/4 and 3/8 in. are most common for rods; 1/8 in. (#11 ga.) through 3/16 in. (#6 ga.) for wire anchors; and 1/4 and 3/8 in. are most common for dowels. Dowel lengths are usually 2 to 6 in.

NOTES

1. Refer to page on 3 in. stone veneer for additional anchorage information.
2. Allow for tolerances by including correct shimming to prevent installation fitting problems or performance failure.
3. Stone anchorage systems should be designed by a professional engineer experienced in stone cladding design.
4. Sizes may differ widely from the standard sizes listed here.
5. Specify stainless steel.

7'-0"	1 1/4" THICK	1 5/8" x 2 1/8"
10'-0"	1 1/4" THICK	1 5/8" x 3 1/4"
15'-0"	1 1/4" THICK	1 5/8" x 4 7/8"

- NOTES**
1. "X" = dimension between strut and outside face of stone.
 2. "X" = 1 1/8" for 7/8" marble.
 3. "X" = 1 3/4" for 1 1/4" marble.

- NOTES**
1. Engineering design of all supports for this type of construction is essential.
 2. Grid strut spacing is subject to engineering design.

PREASSEMBLED STONE UNIT WITH EPOXY ON STEEL FRAME

STONE UNIT PRECAST WITH CONCRETE BACKUP

PREASSEMBLED PANELS

Preassembled stone panel technology offers savings in on-site labor and accurate component stone unit joining.

Shipping and erection stresses on the stone panels and stone anchorage system to the preassembled units should be evaluated.

Design of sealant joints between preassembled units should include at least the following: thermal movement, fabrication and erection tolerances, irreversible material growth or shrinkage, and sealant movement potential.

STONE ON STEEL FRAME WITH EPOXY JOINTS

Stone units are mounted in a steel frame plus expansion anchors and dowel pins (as recommended by manufacturer). Joints in stone are epoxied and held to approximately 1/8 in. when finished for delivery. All stones in the assembly are anchored as a unit to the structure. Preassembled unit installation reduces individual leveling, plumbing, and aligning, and on-site joint sealing is not as extensive as with individual stone panels.

COMPOSITE ASSEMBLIES OF STONE AND CONCRETE

Stone units are bonded to reinforced precast concrete panels with bent stainless steel anchors. A moisture barrier and a bonding agent are installed between the stone and concrete in conditions where concrete alkali slats may stain stone units.

STONE AND STEEL ASSEMBLIES WITH SEALANT JOINTS

Stone units are shimmed and anchored to a steel frame using standard stone connecting hardware. Joints may be sealed on site, along with joints between assemblies.

TYPICAL JOINT PROFILES

LUG SILL

STONE SILL TYPES

STONE LUG SILL PROFILES

GENERAL

A traditional structural stone wall typically consists of two independent faces (interior and exterior) of closely fitted stones with a code-prescribed percentage of bonding unit stones that extend the full thickness of the wall. Together, these two stone faces create a massively thick wall, rarely less than 24 in. thick. An interior finish backup stud or furred wall with a vapor barrier and insulation typically completes the wall system.

For structural stone walls, it is best to lay the stone in regular courses, 12 to 15 in. high per course. Limiting the height from the top of one level course to the top of the next level course ensures that the wall joints will be consistently bridged, thereby avoiding long continuous vertical joints both perpendicular to and parallel to the plane of the wall face. This will help prevent long cracks from developing, which can cause large sections of the wall to split and fall off. Control joints should be built into masonry construction in wall sections up to 30 ft long to account for expansion and contraction of the stone.

NOTES

1. A simple rule-of-thumb for masonry construction is to rely on gravity, not the bond of mortar, as the predominant "bonding agent" for stone.
2. Consult codes to determine the minimum percentage of bonding units per structural stone wall. Some codes require that 15% of the face area be composed of bonding units.

PROPERTIES OF METALS

Basic metals and their alloys are classified in two broad categories, ferrous and nonferrous. Ferrous metals are mainly iron, and nonferrous metal alloys normally contain no iron.

FERROUS METALS

Iron, steel, and their alloys are usually the most cost-effective metal choices for structural applications.

Iron that contains no trace of carbon is soft, ductile, and easily worked, but it rusts in a relatively short time and is susceptible to corrosion by most acids.

The characteristics of the many types of cast iron vary widely among six basic groups: gray, malleable, ductile, white, compacted graphite, and high alloy iron. All cast irons have high compressive strengths, but tensile and yield strengths vary widely depending on basic type. Cast iron is relatively corrosion-resistant but cannot be hammered or beaten into shapes.

Gray irons are rather brittle because they have a high carbon and silicon content. Castings of gray iron possess excellent damping (absorbing vibrations) and are produced in eight ASTM classes or grades with tensile-strength ratings from 20,000 to 60,000 psi. Applications include decorative shapes, such as fences and posts, gratings, and stair components, as well as utility uses such as manhole covers and fireplugs.

Malleable iron, which is more expensive than gray iron, has been used for decades in applications that require great toughness and high ductility. This low-carbon white iron is cast, reheated, and slowly cooled, or annealed, to improve its workability.

Ductile iron is made by adding magnesium to molten iron shortly before the metal is poured into molds. The magnesium alters the surface-tension mechanism of the molten iron and precipitates the carbon out as small spheres instead of flakes, which make the iron casting more ductile. Ductile iron is less brittle, stiffer, stronger, and more shock-resistant than gray iron. Ductile iron castings are more expensive than gray iron but usually less than malleable iron. Ductile iron is the fastest growing segment of the metal casting industry.

Ductile irons are produced in strength ratings from 55,000 to 130,000 psi. Ductile castings using a special austempering heat-treating process offer much higher tensile strengths, ranging from 125,000 to 230,000 psi. Called ADI castings, they rival or surpass certain alloy steel castings in tensile and yield strengths.

White iron castings, which are extremely hard and brittle, are used primarily in industrial machinery parts that experience high wear and require abrasion resistance.

The characteristics of compacted graphite iron fall between those of gray and ductile iron. The properties of this metal are so difficult to control during production that very few metal casters manufacture it.

High alloy irons are gray, ductile, or white irons with an alloy content of 3 to more than 30%. Their properties are significantly different from those of unalloyed irons.

Wrought iron or steel is relatively soft, corrosion- and fatigue-resistant, and machinable. It is easily worked, making it ideal for railings, grilles, fences, screens, and various types of ornamental work. It is commercially available in bars, rods, tubing, sheets, and plates.

Carbon steel is iron that contains low to medium amounts of carbon. A higher carbon content increases metal strength and hardness but reduces its ductility and weldability. The corrosion resistance of carbon steels is improved by galvanizing, which is a hot zinc dipping process, or applying an organic coating. Some architectural uses include structural shapes such as welded fabrications or castings, metal studs and joists, fasteners, wall grilles, and ceiling suspension grids.

High strength, low alloy (HSLA) steels have better corrosion resistance than carbon steels, and they are chosen when weight is a consideration and higher strength is specified. Low alloy steels are seldom used in exterior architectural applications that involve water runoff because adjacent materials could become stained with rust.

Typical elements used to modify steel include the following:

1. Aluminum for surface hardening.
2. Chromium for corrosion resistance.
3. Copper for atmospheric corrosion resistance.
4. Manganese in small amounts for additional hardening, in larger amounts for better wear resistance.
5. Molybdenum, combined with other metals such as chromium and nickel, to increase corrosion resistance and raise tensile strength without reducing ductility.
6. Nickel to increase tensile strength without reducing ductility; in high concentrations, nickel improves corrosion resistance.
7. Silicon to strengthen low alloy steels and improve oxidation resistance; larger amounts produce hard, brittle castings that are resistant to corrosive chemicals.
8. Sulfur for free machining, especially.
9. Titanium to prevent intergranular corrosion of stainless steels.
10. Tungsten, vanadium, and cobalt for hardness and corrosion resistance.

Stainless steels are at least 11.5% chromium. Nickel is added to boost atmospheric corrosion resistance; molybdenum is added when maximum corrosion resistance is needed, such as when iron will come into contact with sea water. Stainless steel is used in construction for flashing, coping, fasciae, wall panels, floor plates, gratings, handrails, hardware, fasteners, and anchors. Decorative shapes and statuary can be cast in stainless steel.

NONFERROUS METALS

Nonferrous metals and their alloys can be categorized into seven major groups for architectural applications: those based on aluminum, copper (pure copper, brasses, and bronzes), lead, zinc, tin, nickel, and magnesium. Another approach is to divide nonferrous alloys into two groups: heavy metals (copper-, zinc-, lead-, and nickel-based) and light metals (aluminum- and magnesium-based).

ALUMINUM

The nonferrous metal workhorse for architectural applications is aluminum. It has good forming and casting characteristics and offers good corrosion resistance. When exposed to air, aluminum does not oxidize progressively because a hard, thin oxide coating forms on the surface and seals the metal from its environment.

Aluminum and its alloys, numbering in the hundreds, are widely available in common commercial forms. Aluminum alloy sheets can be formed, drawn, stamped, or spun. Many wrought or cast aluminum alloys can be welded, brazed, or soldered, and aluminum surfaces readily accept a wide variety of finishes, both mechanical and chemical.

Although it is light in weight, commercially pure aluminum has a tensile strength of about 13,000 psi. Most aluminum alloys lose strength at elevated temperatures. At subzero temperatures, on the other hand, aluminum is stronger than at room temperature but no less ductile. Cold-working the metal may nearly double its tensile strength. Aluminum can be further strengthened by alloying it with elements such as manganese, silicon, copper, magnesium, zinc, or lithium. The manganese-based aluminum alloy 3003 is used for roofing, sheet metal, siding, and electrical conduit.

BRASS, COPPER, AND BRONZE

Good thermal and electrical conductivity, corrosion resistance, and easy forming and joining all make copper and its alloys useful in construction. However, copper and many of its alloys have relatively low strength-to-weight ratios, and their strength is even further reduced at elevated temperatures. These metals are offered in rod, plate, strip, sheet, and tube shapes; forgings; castings; and electrical wire.

These metals can be grouped according to composition in several general categories: copper, high-copper alloys, and many types of brass and bronze. Monel metal is a copper-nickel alloy that offers excellent corrosion resistance; it is often used for corrosion-resistant fasteners.

Bronze originally was a copper-tin alloy, but today there are aluminum bronzes, silicon bronzes, and leaded phosphor bronzes, among others. Phosphor bronze is a copper-tin-phosphorus alloy; and leaded phosphor bronze is composed of copper, lead, tin, and phosphorus.

Brass is copper with zinc as its principal alloying element. It is important to know that some brass alloys may be called bronzes even though they have little or no tin in them. Some common nonbronze brass alloys are commercial bronze (90% copper, 10% zinc), naval brass (60% copper, 29% zinc, and .1% tin), Muntz metal (60% copper, 40% zinc), and manganese bronze (58% copper, 39% zinc, and 1% tin and iron). When a metal is identified as bronze, the alloy cannot contain zinc or nickel; if it does, it is probably brass. Architectural bronzes and bronzes are actually all bronzes; they are used for doors, windows, door and window frames, railings, trim and grilles, and finish hardware. Muntz metal, also called malleable brass, is a bronze alloy resembling extruded architectural bronze in color. It is available in sheet and strip and is used in flat surfaces in architectural compositions in connection with extruded architectural bronze.

Copper-based alloys characteristically form adherent films that are relatively impervious to corrosion and protect the base metal from further attack. Certain alloy systems darken rather rapidly from brown to black outdoors. Under most outdoor weather conditions, however, copper surfaces, such as roofs or statuary, develop a blue-green patina. Lacquer coatings can help retain the original alloy color.

LEAD

An extremely dense metal, lead is corrosion-resistant and easily worked. Alloys are added to it to improve properties such as hardness and strength. Typical applications of lead include waterproofing, sound and vibration isolation, and radiation shielding. It can be combined with tin alloy to plate iron or steel, which is commonly called "terneplate." Care should be taken how and where lead is used because lead vapors and lead dust are toxic if ingested.

ZINC

Although it is corrosion-resistant in water and air, zinc is brittle and low in strength. Its major use is in galvanizing (dipping hot iron or steel in molten zinc), although zinc is also used to create sand-cast or die-cast components. Major building industry uses are roofing, flashing, nails, plumbing hardware, structural parts, and decorative shapes.

TIN

Key properties of tin are its low melting point (450° F), relative softness, good formability, and readiness to form alloys. Principal uses for tin are as a constituent of solder, a coating for steel (tinplate, terneplate), and an alloy with other metals that can be cast, rolled, extruded, or atomized. Tin is most popular as an alloy for copper, antimony, lead, bismuth, silver, and zinc. Pewter alloys contain 1 to 8% antimony and 0.5 to 3% copper. Alloy metal in tin solders ranges from 40% lead to no lead and 3.5% silver.

NICKEL

Whitish in color, nickel is used for plating other metals or as a base for chromium plating. Nickel polishes well and does not tarnish. It is also widely applied as an additive in iron and steel alloys as well as other metal alloys. Nickel-iron castings are more ductile and more resistant to corrosion than conventional cast iron. Adding nickel makes steel more resistant to impact.

CHROMIUM

A hard, steel-gray metal, chromium is commonly used to plate other metals, including iron, steel, brass, and bronze. Plated cast shapes can be brightly polished and do not tarnish. Several steel alloys, such as stainless plate, contain as much as 18% chromium. Chromium does not rust, which makes chromium alloys excellent for exterior uses.

MAGNESIUM

Lightest of all metals used in construction, pure magnesium is not strong enough for general structural functions. (For comparison, if a block of steel weighs 1,000 lb, equal volumes of aluminum and magnesium weigh 230 lb and 186 lb respectively.) Combining other metals such as aluminum with magnesium results in lightweight alloy materials used in ladders, furniture, hospital equipment, and wheels for automobiles.

METAL MATERIALS

METAL CORROSION

Corrosion, which is caused by galvanic action, occurs between dissimilar metals or between metals and other material when sufficient moisture is present to carry an electrical current. The galvanic series shown in the table below is a useful indicator of corrosion susceptibility caused by galvanic action. The metals listed are arranged in order from the least noble (most reactive to corrosion) to the most noble (least reactive to corrosion). The farther apart two metals on the list are, the greater the deterioration of the less noble one will be if they come in contact under adverse conditions.

Metal deterioration also occurs when metals come in contact with chemically active materials, particularly when moisture is present. For example, aluminum corrodes when in direct contact with concrete or mortar, and steel corrodes when in contact with certain treated woods.

Pitting and concentration cell corrosion are other types of metal deterioration. Pitting takes place when particles or bubbles of gas are deposited on a metal surface. Oxygen deficiency under these deposits sets up anodic areas, which cause pitting. Concentration cell corrosion is similar to galvanic corrosion; the difference is in the electrolytes. Concentration cell corrosion can be produced by differences in ion concentration, oxygen concentration, or foreign matter adhering to the surface.

SHAPING AND FABRICATION OF METALS

Many different manufacturing processes are applied to metal to produce structural forms and shapes required in the construction and ornamentation of buildings.

Rolling hot or cold metal between pressurized rollers produces most of the readily available, standard construction material shapes. Baked enamel-coated aluminum is cold rolled to make siding and gutters.

In the extruding process, heated metal ingots or bars are pushed through a die orifice to produce a wide variety of simple and complex shapes. Sizes are limited only by the size or capacity of the die.

THE GALVANIC SERIES

Anode (least noble) +	
	Magnesium, magnesium alloys
	Zinc
	Aluminum 1100
	Cadmium
	Aluminum 2024-T4
	Steel or iron, cast iron
	Chromium iron (active)

	Type 304, 316 stainless (passive)
	Silver
	Titanium
Cathode (most noble) -	Graphite, gold, platinum

Robert C. Rodgers, P.E.; Richmond Heights, Ohio

Casting is a process in which molten metal is poured into molds or forced into dies and allowed to solidify in the shape of the mold or die. The casting process is used with virtually all metals; however, surface quality and physical characteristics are greatly affected by the metal alloy and casting process selected. Almost all metals can be cast in sand molds. Only aluminum, zinc, and magnesium are ordinarily cast in metal dies in what is called either a die-casting or permanent-mold process. Round, hollow building products such as cast-iron pipe for plumbing and sewer applications are made by centrifugal casting machines.

In the drawing process, either hot or cold metal is pulled through dies that alter or reduce its cross-sectional shape to produce architectural product configurations. Common drawn products are sheets, tubes, pipes, rods, bars, and wires. Drawing can be used with all metals except iron.

Forging is hammering hot metal or pressing cold metal to a desired shape in dies of a harder metal. The process usually improves the strength and surface characteristics of the metal. Aluminum, copper, and steel can be forged.

Machining is used to finish areas of castings or forgings requiring highly precise fits or contours. Shapes can also be machined from heavy plate or solid blocks of metal.

Bending produces curved shapes in tubing, pipe, and extrusions.

Brake forming of metal plate or sheet metal is a process of successive pressings to achieve shapes with straight-line angles.

In the spinning process, ductile types of sheet metal (usually copper or aluminum) are shaped with tools while being spun on an axis.

Embossing and coining are stamped metal with textured or raised patterns.

Blanking is shearing, sawing, or cutting metal sheets with a punch press to achieve a desired configuration.

Perforating is punching or drilling holes through flat plate or sheet metal.

WEIGHTS OF METALS FOR BUILDINGS

MATERIAL	SPECIFIC GRAVITY	DENSITY	
		(LB/CU FT)	(LB/CU IN.)
Magnesium	1.76	110	0.064
Aluminum	2.77	173	0.100
Zinc	7.14	446	0.258
Cast iron	7.22	450	0.260

Steel	7.85	490	0.283
Brass	8.47	529	0.306
Copper and bronze	8.92	556	0.322
Lead	11.35	708	0.410

TYPES AND PROPERTIES OF BRASS

NAME	ARCHITECTURAL-BRONZE	COMMERCIAL BRONZE	MUNTZ METAL
Composition (%)			
Copper (Cu)	56.5	90.0	60.0
Zinc (Zn)	41.25	10.0	40.0
Lead (Pb)	2.25		
Color	Bronze	Bronze	Light yellow
Cold workability	Very poor	Excellent	Fair
Machinability	Good	Poor	Good
Weldability	Poor	Gas, carbon arc, metal arc	Gas, carbon arc, metal arc, spot and seam welding for thin sheets
Hot workability (and soldering and polishing)	Very good	Very good	Very good
Other properties	Excellent forging and free-machining	Very ductile	High strength; low ductility

Piercing punches holes through metal without removing any of the metal.

Fusion welding is used to join metal pieces by melting filler metal (welding rod) and the adjacent edges briefly with a torch and then allowing the molten metal to solidify. Two common types of fusion welding are electric-arc and gas. Electric-arc or metallic-arc welding normally uses metal welding rods as electrodes in the welding tool.

Gas welding is also known as oxyacetylene welding because it uses a mixture of oxygen and acetylene to fuel the flames produced by the blowtorch. Oxyacetylene blowtorches are widely used in construction work to cut through metal structural beams and metal plates.

Soldering is a metal joining process that uses either hard or soft solder. The metal pieces being joined together do not melt as they do in the welding process because solders melt at much lower temperatures. Soft solders consist of tin with a high percentage of lead and melt at temperatures of 360° to 370°F. Hard solders are composed of tin and a low content of antimony or silver and melt at temperatures ranging from 430 to 460°F.

Brazing, which is sometimes called hard soldering, also joins two pieces of metal together by torch melting a filler rod material between them. The filler has a high content of copper and melts between 800 and 900°F.

MELTING TEMPERATURES OF METALS

BASE METAL	MELTING TEMPERATURES	
	DEGREES C	DEGREES F
Aluminum	660	1220
Antimony	631	1168
Cadmium	321	610
Chromium	1857	3375

Nickel	1453	2647
Silver	962	1764
Tin	232	450
Zinc	420	788
Zirconium	1852	3366

GENERAL

The finishes commonly used on architectural metals fall into three categories:

MECHANICAL FINISHES are the result of physically changing the surface of the metal through mechanical means: the forming process itself or a subsequent procedure performed either before or after the metal is fabricated into an end-use product.

CHEMICAL FINISHES are achieved by means of chemicals, which may or may not have a physical effect on the surface of the metal.

COATINGS are applied as finishes, either to the metal stock or the fabricated product. These coatings either change the metal itself, through a process of chemical or electrochemical conversion, or they are simply applied to the metal surface.

Application environments, service requirements, and aesthetics together determine which metal finish or coating is best to specify. Finishes are usually selected for both appearance and function: Chromium plating on metal bathroom water faucets and handles or baked enamel on sheet metal lighting fixtures, for example, must be attractive as well as functionally protective.

For structural and exterior metal building products, such as steel framing products, metal siding, and outdoor lighting fixtures, function and operating environments are more important criteria. From a design standpoint, it is important to recognize how various finishes and coatings resist wear, corrosion, and erosion. To choose the right coating or finish, architects must know which material or process is best suited for a specific application.

MECHANICAL FINISHES

AS-FABRICATED FINISHES are the texture and surface appearance given to a metal by the fabrication process.

BUFFED FINISHES are produced by successive polishing and buffing operations using fine abrasives, lubricants, and soft fabric wheels. Polishing and buffing improve edge and surface finishes and render many types of cast parts more durable, efficient, and safe.

PATTERNED FINISHES are available in various textures and designs. They are produced by passing an as-fabricated sheet between two matched-design rollers, embossing patterns on both sides of the sheet, or between a smooth roll and a design roll, embossing or coining on one side of the sheet only.

DIRECTIONAL TEXTURED FINISHES are produced by making tiny parallel scratches on the metal surface using a belt or wheel and fine abrasive, or by hand rubbing with steel wool. Metal treated this way has a smooth, satiny sheen.

PEENED FINISHES are achieved by firing a stream of small steel shot at a metal surface at high velocity. The primary aim of shot peening is increasing the fatigue strength of the component; the decorative finish is a by-product. Other nondirectional textured finishes are produced by blasting metal, under controlled conditions, with silica sand, glass beads, and aluminum oxide.

CHEMICAL FINISHES

CHEMICAL CLEANING cleans the metal surface without affecting it in any other way. This finish is achieved with chlorinated and hydrocarbon solvents and inhibited chemical cleaners or solvents (for aluminum and copper) and pickling, chlorinated, and alkaline solutions (for iron and steel).

ETCHED FINISHES produce a matte, frosted surface with varying degrees of roughness by treating the metal with an acid (sulfuric and nitric acid) or alkali solution.

The **BRIGHT FINISH** process, not used widely, involves chemical or electrolytic brightening of a metal surface, typically aluminum.

CONVERSION COATING is typically categorized as a chemical finish, but since a layer or coating is produced by a chemical reaction, it could be considered a coating as well. Conversion coatings typically prepare the surface of a metal for painting or for receiving another type of finish but are also used to produce a patina or statuary finish. A component is treated with a dilute solution of phosphoric acid or sulfuric acid and other chemicals that convert the surface of the metal to an integral, mildly protective layer of insoluble crystalline phosphate or sulphate or the like. Such coatings can be applied by either spray or immersion and provide temporary resistance to a mildly corrosive environment. They can be specified for gray, ductile, and malleable iron castings as well as steel castings, forgings, or weldments, such as railings and outdoor furniture.

COATINGS

ORGANIC COATINGS on metal can provide protection only or serve both protective and decorative functions. The former category includes primers or undercoats, pigmented topcoats in hidden areas, and clear finishes. Organic coatings serving double duty include pigmented coatings in visible areas, clear finishes used for gloss, and transparent or translucent clear finishes with dyes added.

Organic coatings usually fall under the general categories of paints, varnishes, enamels, lacquers, plastisols, organosols, and powders. Literally hundreds of different organic coating formulations offer an almost unlimited range of properties. Many organic coatings are applied with brushes and rollers, but dipping and spraying of paints account for most industrial and commercial building projects. Dipping is useful for coating complex metal parts, but spraying is used for most architectural applications. Spraying is fast and inexpensive, and new computer-controlled guns can follow even complex curvatures. Conventional spraying, however, has two disadvantages. For one thing, there is no easy, inexpensive way to collect and re-use the coating material. And when solvent-based paints are used, there is the added problem of meeting environmental restrictions.

ELECTRODEPOSITION, an increasingly popular alternative to spraying, is similar to electroplating, except that organic resins are deposited instead of metal. Electrodeposition is based on the principles of electrophoresis—the movement of charged particles in a liquid under the influence of an applied voltage.

Electrodeposition offers several advantages: The coating builds up to a uniform thickness without runs or sags; very little paint is wasted; low levels of volatile organic compounds (VOCs) are emitted; and coatings can be deposited even into deeply recessed areas of a complex shape. Electrodeposition also has disadvantages. Coating thickness is limited, and because only one coat can be applied this way, subsequent coats must be sprayed.

POWDER COATING is perhaps the best known environmentally acceptable painting process. Powder coatings offer several advantages. Because the paints are solventless, they are safer and "greener." In addition, the paints cost less and last a long time.

Powdered paints are formulated in much the same way as solvent-based paints, with the same pigments, fillers, and extenders, but are dry at room temperatures. Heat-reactive or "heat-latent" hardeners, catalysts, or cross-linkers are used as curing agents.

Powder coatings are either thermoplastic or thermosetting. As the term implies, thermoplastic coatings, which include vinyl, polyethylene, and certain polyesters, are melted by heat during application. Before such coatings are applied, the surface must be primed to ensure good adhesion. Thermosetting paints undergo a chemical change; they cannot be remelted by heat. The thermosets do not require a primer. Coating powders include epoxies, polyurethanes, acrylics, and polyesters.

COMPARATIVE APPLICABILITY OF VARIOUS FINISHES FOR ARCHITECTURAL APPLICATIONS

TYPE OF FINISH OR TREATMENT	METAL			
	ALUMINUM	COPPER ALLOYS	STAINLESS STEEL	CARBON STEEL AND IRON
MECHANICAL FINISHES				
As fabricated	Common to all of the metals (produced by hot rolling, extruding, or casting)			
Bright rolled	Commonly used (produced by cold rolling)			Not used
Directional grit textured	Commonly used (produced by polishing, buffing, hand rubbing, brushing, or cold rolling)			Rarely used
Nondirectional matte textured	Commonly used (produced by sand or shot blasting)			Rarely used
Bright polished	Commonly used (produced by polishing and buffing)			Not used
Patterned	Available in light sheet gauges of all metals			
CHEMICAL FINISHES				
Nonetch cleaning	Commonly used on all of the metals			
Matte finish	Etched finishes widely used	Seldom used	Not used	Not used
Bright finish	Limited uses	Rarely used	Not used	Not used
Conversion coatings	Widely used as pretreatment for painting	Widely used to provide added color variation	Not used	Widely used as pretreatment for painting
COATINGS				
Organic	Widely used	Opaque types rarely used; transparent types common	Sometimes used	Most important type of finish
Anodic	Most important type of finish	Not used	Not used	Not used
Vitreous	Widely used	Limited use	Not used	Widely used
Metallic	Rarely used	Limited use	Limited use	Widely used
Laminated	Substantial uses	Limited use	Not used	Substantial uses

NOTE

For more information, see the "Metal Finishes Manual for Architectural and Metal Products," published by the Architectural Metal Products Division of the National Association of Architectural Metal Manufacturers.

Robert C. Rodgers, P.E.; Richmond Heights, Ohio

METAL MATERIALS

GENERAL

The two most common methods of applying powdered finishes to metal are spraying and dipping, the same as those used for solvent-based paint. Electrostatic spraying is used to apply powder films from 1 to 5 mil thick. A mixture of air and powder moves from a hopper to a spray gun. The mixture is charged electrostatically as it passes through the spray gun, causing it to stick to any grounded metal object. Powder that falls to the floor is recycled.

For coatings thicker than 5 mil, fluidized-bed dipping is used. The powder is placed in a special tank into which air is blown, turning the powder into a fluid-like mass. Parts are dipped in the "fluid" and baked to cure the finish.

ANODIC COATINGS

Anodic oxides are widely used to protect aluminum and many of its alloys from corrosion. When the metal is anodized in one of a variety of acids, a protective oxide is formed on the surface. Depending on the acid, the oxide may range from thin and nonporous to thick and porous. Three types of anodizing are used for aluminum: chromic, sulfuric, and hardcoat.

CHROMIC ANODIZING results in a relatively soft coating and is the least used of the three types, but it does offer several advantages. It has excellent corrosion resistance, so rinsing is not as important. It is suitable for complex cast parts and offers a coating of the most consistently uniform thickness and the most enduring fatigue strength.

SULFURIC ANODIZING, the most widely used method, produces a harder coating than chromic anodizing, but it can be scratched. It offers a pleasing appearance and can be dyed in several colors. Corrosion resistance is good.

HARDCOAT ANODIZING produces a relatively thick, extremely hard coating that can be dyed in a range of colors. Corrosion resistance is good. Hardcoats are porous, making them suitable as a base for paints and adhesives.

Since all anodic processes produce porous aluminum-oxide coatings, sealing is usually desirable. The coating is immersed in hot water, the oxide is hydrated, and the pores swell shut. Several manufacturers claim that their sealing agents do the same thing through catalytic action at lower temperatures. Chromic- and sulfuric-anodized coatings nearly always are sealed, but hardcoats are not.

VITREOUS COATINGS are composed of inorganic glossy materials (glass). Porcelain enamels are the most commonly used vitreous coating for architectural applications. Although one of the hardest and most durable finishes, they are brittle. Deformation of metal surfaces can cause cracking and splitting. Porcelain enamel coatings come in a wide range of colors and finishes and are typically applied to steel and aluminum (bathtubs, sinks, column covers). Embossed patterns and textures may be applied by altering the metal backing surface or the coating itself.

HOT DIPPING of ferrous metal objects consists of immersing clean parts into a molten bath of the desired coating metal. In general, molten aluminum, lead, zinc, and some alloys can be applied as hot-dip coatings to irons. Each offers specific advantages. Hot-dip coatings are particularly suitable for intricately shaped cast ferrous items such as metal roofing components and nails and other fasteners.

METALLIC PLATING is done by either electrodeposition or electroplating.

In electrodeposition, an electrical current is carried across an electrolyte and an organic resin substance deposited on an electrode (the metal object being painted). In electroplating, the "substance" is a metal, such as chromium, in an electrolyte. Water usually serves as the solvent in the electrolyte. Although chromium is commonly used for plating, many metals can be deposited on the substrate.

Similarly, a wide range of plating quality is available. For example, a thin coating of zinc will protect a metal compo-

nent from rust or corrosion for a short time. Chromium plating, on the other hand, protects longer and looks better.

Materials widely used to plate complex metal components include bronze, brass, chromium, cadmium, chromates, copper, lead, lead-tin, nickel, phosphates, silver, tin-nickel, and tin-zinc. Not all of these materials can be deposited on all metal substrates. For example, zinc electroplate can be used on steel but not on cast iron. Therefore, coating/substrate compatibility is a crucial consideration in matching coating performance to application requirements. Typical applications for plating include food servicing areas, plumbing fixtures, exterior metal, and architectural products.

LAMINATED COATINGS

Lamination involves bonding preformed plastic films to metals with adhesives. Laminated coatings provide finishes for products such as interior paneling, partitions, and exterior metalwork. Three types of plastic film are widely used: polyvinyl chloride (PVC), polyvinyl fluoride (PVF), and acrylic.

PVC films provide excellent stain and abrasion resistance. Available in five or six colors, these laminates may come with graining or embossing to simulate wood grain, leather, or fabric. Film thicknesses range from 0.004 in. to 0.041 in., but most common and most economical are those from 0.008 and 0.014 in.

PVF films are usually laminated in a thickness of 0.002 in. and have a smooth, medium gloss surface. Despite their thinness, they are very strong, tough, and weather resistant, making them particularly suited to exterior applications such as siding materials. Their color range is limited, but they resist staining and chemical damage well.

Acrylic films are low cost products that stand up well to weather and are widely used for exterior metalwork. They resist UV radiation and yellowing and retain their flexibility with aging. They are usually applied in a thickness of 0.003 in. and are reasonably priced.

REPRESENTATIVE ARCHITECTURAL USES AND COMPARATIVE PROPERTIES OF COATINGS

² For light nonstructural welding only.

Robert C. Rodgers, P.E.; Richmond Heights, Ohio

STRUCTURAL WELDING

Structural welds can be made with hundreds of different welding processes. The most common are forms of shielded metal arc and oxyfuel gas welding. These processes are designed for the specific welding conditions: type of metal, structural requirements, weld position, and joint specifications. Normally, however, the designer does not specify the process which is to be used to make a welded joint. The designer specifies the type and size of weld needed for the specific joint and leaves the details of how the joint is to be made up to the fabricator.

The two most important types of structural welds are fillet welds and groove welds. They are the most useful in structural applications. Back welds are used in conjunction with single groove welds to complete the weld penetration. Plug, slot, and flare welds are of secondary importance and are limited in application.

FILLET WELD JOINTS

With a triangular cross section, fillet welds join two surfaces approximately at right angles to each other in lap, tee, and corner joints. They are also used with groove welds as reinforcements in corner joints.

FILLET WELDS

Groove welds are welds made in a groove between adjacent ends, edges, or surfaces of two parts to be joined in a butt, tee, or corner joint.

The edge or ends of parts to be groove welded are usually prepared by flame cutting, arc air gouging, or edge planing to provide square, vee, bevel, U-, or J-shaped grooves that are straight and true to dimension. The preparation is done to ensure that the base metal is welded evenly completely through the joint. With thicker metal it is also done to open up the joint area for welding. Relatively thin material may be groove welded with square cut edges.

EXAMPLES OF COMPLETE PENETRATION GROOVE WELDS

The two types of groove welds are complete penetration and partial penetration. A complete penetration weld is one that achieves fusion of weld and base metal throughout the depth of the joint. It is made by welding from both sides of the joint, from one side to a backing bar, or back welding the first weld.

GROOVE WELDS

FILLET WELD NOMENCLATURE
The model cross section of a fillet weld is a right triangle with equal legs. The leg size designates the effective size of the weld. The length of a fillet weld is the distance from end-to-end of the full size fillet, measured parallel to its root line. For curved fillet welds the effective length is equal to the throat length, measured along a line bisecting the throat area.

The cross section of a fillet weld may differ from the right triangle model in several ways. The included angle of the weld may vary from 60° to 135°, or unequal leg welds may be employed. When unequal leg welds are used, the use of the normal throat size as the effective size in weld strength calculations will, in most cases, be conservative. However, when the included angle of weld deposit is substantially greater than 90°, the effective throat size should be determined from the actual dimensions of the weld according to American Welding Society specifications.

FULL PENETRATION GROOVE WELD NOMENCLATURE

Except where backing bars are employed, specifications require that the weld roots generally must be chipped or gouged to sound metal before making the second weld. For purposes of stress computation, the throat dimension of a full penetration groove weld is considered to be the full thickness of the thinner part joined, exclusive of weld reinforcement, such as backing bars.

EXAMPLES OF PARTIAL PENETRATION GROOVE WELDS

Partial penetration groove welds are employed when stresses to be transferred do not require full penetration, or when welding must be done from one side of a joint only and it is not possible to use backing bars or to gouge weld roots for back welds. The application of partial penetration groove welds is governed by specifications and may limit the effective throat thickness or the thickness of the material on which they are to be used.

JOINT PREQUALIFICATION

Welded joints that conform to all American Welding Society code and specification provisions for design, material, and workmanship are prequalified joints. There are a variety of specific fillet and groove welded joints that meet most structural work requirements and are recommended for general use in buildings and bridges. Joints that are not prequalified under the AWS code are required to be qualified by tests as prescribed by the code.

For quick reference and more advanced consideration, the prequalified joints are shown in AWS "Structural Welding Code-Steel."

FLARE WELD NOMENCLATURE

Flare welds are special cases of groove welds in which the groove surface of one or both parts of a joint is convex. This convexity may be the result of edge preparation, but more often one or both components consists of a round rod or rounded shape. Complete penetration in a flare weld is usually difficult to achieve and the quality of the weld is difficult to control; therefore, design values should be applied conservatively and special considerations need to be taken in certain instances.

FLARE WELDS

PLUG AND SLOT WELDS

Plug and slot welds are used in lap joints to transmit shear loads, prevent buckling of lapped parts, or join component parts of built-up members. Round holes or slots are punched or otherwise formed in one component of the joint before assembly. With parts in position, weld metal is deposited in the openings, which may be partially or completely filled, depending on the thickness of the punched material. AWS "Structural Welding Code-Steel" should be consulted for allowable proportion and spacing of holes and slots and the depth of welds.

It is necessary to distinguish between plug or slot welds and fillet welds placed around the inside of a hole or slot. Fillet welds in a slot are easier to make and inspect and are usually preferred over fillet welds in round holes or plug and slot welds.

PLUG AND SLOT WELDS

PARTIAL PENETRATION GROOVE WELD NOMENCLATURE

Edge preparation of base material for partial penetration groove welds is similar to that for full penetration groove welds, but it usually covers less than the full thickness. The effective throat thickness and, hence, the weld strength of partial penetration groove welds is normally limited to less than the full joint thickness.

The use of partial penetration welds is subject to AWS code and other specification provisions. These are more restrictive in bridge specifications than in building codes.

BASIC WELDING SYMBOLS

The three basic parts needed to form a welding symbol are: an arrow pointing to the joint, a reference line upon which the dimensional data are placed, and a weld device symbol indicating the weld type required. The tail of the welding symbol is only necessary to indicate additional data, such as specification, process, or detail references.

The arrow indicates the joint where the weld is to be made. The basic weld device symbol or device indicates the type of weld to be made, for example: fillet, U-groove, bevel, or plug. The position of the basic weld symbol or device indicates which side of the joint is to be welded. The bottom side of the reference line is designated as the arrow side, meaning any welding operation shown on this side of the reference line is to be performed on the same side of the joint as the arrow. When an operation is shown on the top side of the reference line it is to be performed on the joint side opposite the arrow.

The weld dimensions, size, length, pitch, etc., are placed on the reference line next to the weld device. These dimensions read from left to right regardless of which side the arrow is on.

FILLET WELDS

The dimensions needed for fillet welds are weld size and length and, for intermittent fillet welds, pitch. The weld size is equal to the weld leg size, assuming that the legs are equal. In the rare instance that the legs are not equal, the size is not given in the welding symbol but instead the weld legs are dimensioned in the drawing to avoid confusion. If there is a typical weld size for a particular drawing, the size may be noted in the notes and left off of the symbol. If the joint is to be welded on both sides, then both sides must be dimensioned, even if they are the same.

If the length of a fillet weld is omitted, it is understood to mean that the weld is to extend the full distance between abrupt changes in the part of the joint outlined specified by the weld symbol arrow. If the same size fillet is required for the full length of all sides of a particular joint, regardless of abrupt changes in its direction, the weld-all-around symbol can be used to simplify the drawing.

INTERMITTENT FILLET WELDS

Pitch is used with intermittent fillet welds to give the center to center dimensions between welded sections. When using pitch, length is the dimension of the individual weld sections.

COMPLETE PENETRATION GROOVE WELDS

When detailing complete penetration groove welds the dimensions usually include the weld size, root opening, the groove angle for vee, bevel, J, and U welds, and the groove radii for J and U welds. The length of groove welds is not given, because the welds are accepted to go from end to end of pieces welded. Any deviation from this requires additional detailing.

UNSYMMETRICAL GROOVE WELD CALLOUT

Normally the weld size of a complete joint penetration groove weld is understood to be the full thickness of the thinner metal connected, and its dimension need not be shown on the welding symbol. However, if the preparation of a double groove weld is not symmetrical, the size of each side of the weld must be shown.

The root opening is shown near the root of the groove device. The groove angle is to be shown within the groove

BASIC WELD DEVICE SYMBOLS

BACK WELD	FILLET WELD	PLUG OR SLOT	GROOVE SQUARE	OR BUTT JOINTS					
				V	BEVEL	U	J	FLARE V	FLARE BEVEL

SUPPLEMENTARY WELD SYMBOLS

BACKING	SPACER	WELD-ALL-AROUND	FIELD - WELD	FLUSH	CONVEX

NOTE: For additional basic and supplementary weld symbols, see the American Welding Society A2.4-79.

THESE PARTS OF WELD SYMBOL ALWAYS READ THE SAME DIRECTION REGARDLESS OF WHICH DIRECTION THE ARROW IS POINTING

NOTES

1. Size, weld symbol, length of weld, and spacing must read in that order from left to right along the reference line. Neither orientation of reference line nor location of the arrow alters this rule.
2. The perpendicular leg of Δ , ∇ , ∇ , ∇ weld symbols must be at left.
3. Arrow and other side welds are of the same size unless otherwise shown. Dimensions of fillet welds must be shown on both the arrow side and the other side symbol.
4. The point of the field weld symbol must point toward the tail
5. Symbols apply between abrupt changes in direction of welding unless governed by the "all-around" symbol or otherwise dimensioned.
6. These symbols do not explicitly provide for the case that frequently occurs in structural work, where duplicate material (such as stiffeners) occurs on the far side of a web or gusset plate. The fabricating industry has adopted the following convention: when the billing of the detail material discloses the existence of a member on the far side as well as on the near side, the welding shown for the near side shall be duplicated on the far side.

STANDARD LOCATION OF ELEMENTS OF A WELDING SYMBOL

faces of the device and above the root opening. The angle is understood to be the total, or included, angle of the groove.

There is no provision for dimensioning radii of U and J groove welds in the AWS welding symbol. This is usually covered by the fabricator's standard weld proportions, with reference to AWS prequalified joints. If not, it must be shown by note or sketch in the drawing.

PARTIAL PENETRATION GROOVE WELDS

Partial penetration groove welds require all of the same dimensions as complete penetration groove welds, plus two additional dimensions: effective throat and weld size. With partial penetration groove welds, the weld preparation usually is less than the thickness of the material being welded. Because of this the weld size must always be given. The effective throat must also be given because it

PARTIAL PENETRATION GROOVE WELD CALLOUT

can vary from the weld size due to welding process, welding position, or the groove angle used. Depending on these factors, the depth of weld deposit, or the effective throat, can be less than the depth of the groove, or weld size.

Partial penetration groove welds can be used as intermittent welds. Consideration must be given to the transition at the beginning and end of the weld. Therefore, contract design drawings should only specify the effective weld length and the required effective throat. The shop drawings should then show the groove depth and geometry that will provide for the required effective throat.

PLUG AND SLOT WELDS

The size for plug welds specifies the diameter of the punched hole. For slot welds the size includes the width and length of the slot. Plug and slot welds will be completely filled unless the depth of the filling is shown inside the weld symbol. Slot welds are noted by detail references in the tail that refer to dimensioned sketches of the slot for clarity. The arrow and other side indicates which side of the joint is to be punched. The flush weld symbol is used if the top of the weld is to be leveled off.

CONTOUR SYMBOLS

The flush and convex symbols are used to modify the shape of the weld face. The contour symbols are placed over the weld device. Almost all of the basic weld symbols can be combined with each other and with the spacer, backing bar, back weld, and contour symbols to create many different welds.

American Institute of Steel Construction; Chicago, Illinois

MOMENT-RESISTING FRAME

A moment-resisting frame's lateral stability and resistance to wind and seismic forces depend on a fixed connection of beams and columns. A moment-resisting connection is achieved when the top and bottom flanges of each beam are welded to the flanges of the connecting columns with full-depth welds. By directly welding the beam web to the column flange, the beam's horizontal reaction to wind forces is transferred to the column. (A connection using web angles and high-strength bolts is also permitted.) The building's floors are designed to act as diaphragms that connect all of the columns and beams, enabling the building to react as a unit.

Moment-resisting frames are uneconomical in tall steel buildings because the larger lateral forces in such buildings can be handled more efficiently by compression and tension diagonal members, as found in braced frames. To save costs, often the upper stories of a braced frame building use moment-resisting beam-column connections to resist wind loads.

MOMENT-RESISTING STEEL FRAME

MOMENT-RESISTING FRAME

RIGID FRAME

Rigid frame construction combines columns and a beam or girder welded together to make a rigid connection. Such a frame can carry vertical loads and resist horizontal forces, either wind or seismic. Rigid frame buildings are usually single story and are available with provisions for cranes, balconies, and mezzanines. The roofs are generally sloped, which permits the use of combined roof decks and waterproofing systems; the slope varies but is usually at least 1 in 12.

Because they span fairly long distances relatively cheaply (widths range between 30 and 130 ft), rigid frame structures are used for recreational buildings; warehouses; light industrial buildings; and commercial buildings, such as supermarkets, automobile dealer showrooms, and garages. Bay sizes are usually 20 to 24 ft but may be extended to 30 ft. The roof profile is most often configured as a symmetrical gable, but such a profile is not a structural necessity. Roofs and side walls are usually covered with 26-gauge colored steel siding; insulation options vary. Some manufacturers offer precast concrete and masonry siding. Pre-engineered buildings most often use rigid frames for roof and wall supports.

CROSS BRACING CONNECTION—END

VERTICAL BRACING DETAILS

FRAMED TUBE

In the framed tube system, structural steel members form the load bearing exterior perimeter wall; this wall is designed so the entire building becomes, in effect, a structural steel tube. The tubular strength is achieved in two ways: the exterior columns are spaced closely together, perhaps 6 ft on center, and connected to spandrel beams; the structure is stiffened by the floors to form a torsionally rigid tube. The spandrel beams are generally very deep, in units of feet as opposed to inches. The columns and spandrel beams are welded together to create a moment-resisting connection. Often this system is referred to as a pierced tube, the pierced areas being the window openings.

The framed tube system is most economical for very tall buildings. The World Trade Center Towers in New York and

FRAMED TUBE

NOTE

PERIMETER WALL DETAIL

SPANDREL AND COLUMN DETAILS

FRAMED TUBE

the Sears Tower in Chicago are the most conspicuous examples. Systems like that at the Sears Tower, a combination of nine framed tubes in a 3 by 3 array, are sometimes called bundled tubes.

BRACED CORE

In the braced core system, walls around elevator shafts and stairwells are designed to act as vertical trusses that cantilever up from the foundation. The chords of each truss are building columns; the floor beams act as ties. Diagonals placed in a K pattern (occasionally in an X pattern) complete the truss. A system employing knee braces is used in seismic areas because of its greater ability to dissipate earthquake energy. Braced core systems can be used efficiently in single-story buildings as well as in buildings over 50 stories.

GENERAL

A space frame is a three-dimensional truss with linear members that form a series of triangulated polyhedrons. It can be seen as a plane of constant depth that can sustain fairly long spans and varied configurations of shape.

NOTES

1. The prime attributes of space frame structural systems are their light weight; inherent rigidity; their wide variety of form, size, and span; and compatible interaction with other building support systems, primarily HVAC.
2. Most systems are designed for specific applications, and a structural engineer with space frame experience should always be consulted. Manufacturers can provide the full range of capabilities—loading, spans, shapes, specific details—for their products. Standardized systems in 4- and 5-ft modules are available.
3. Metal space frames are classified as noncombustible construction and can usually be exposed when 20 ft above the floor. However, an automatic fire extinguishing system or a rated ceiling may be required. Consult applicable building and fire codes.
4. The finishes commonly available are paint, thermoset polyester, galvanizing, stainless steel, or metal plating.

SUPPORT TYPES

Many proprietary node systems are available for specific applications and budgets. Keep field connections to a minimum; welded connections often eliminate joint pieces.

COMMON PATTERNS

NOTE

Select a space frame module that is compatible with the building planning module in shape (e.g., a square module with orthogonal plan) and size (a multiple of the planning

module); is consistent with the limitations of the interfacing systems (e.g., the maximum span of the roof deck or mullion spacing of the glazing system); and satisfies the spatial and aesthetic effects in scale and form.

MODULE SELECTION AND CHARACTERISTICS

NOTE

Square tubes or angles within their span range are often the most economical.

MEMBER SHAPES

NOTE

Space frame supports are at panel joints only, not along members.

PRELIMINARY JOIST SELECTION

The accompanying tables are not to be used for final joist design but are intended as an aid in selecting steel joists for preliminary design and planning. Determining the final design must be a separate and thorough process, involving a complete investigation of pertinent conditions; this page is not intended to support that effort. Consult a structural engineer.

An example of how to use the information presented here follows: Assume a particular clear span. By assuming a joist spacing and estimating the total load, a joist can immediately be selected from the table. Then proceed with preliminary design studies.

NOTES

1. Total safe load = live load + dead load. Dead load includes the weight of the joists. For dead loads and recommended live loads, see pages on weights of materials. Local codes will govern.
2. Span should not exceed a depth 24 times that of a nominal joist.
3. For more information, refer to the standard specifications and load tables adopted by the Steel Joist Institute.

NOTE

The following information applies to both open-web and long-span steel joists.

JOIST DESIGNATION:

For greater economy, the K-series joist replaced the H-series joist in 1986.

ROOF CONSTRUCTION: Joists are usually covered with steel decking topped with either rigid insulation board or lightweight concrete fill and either a roof of built-up felt and gravel or single-ply roofing with ballast. Plywood, poured gypsum, or structural wood fiber deck systems can also be used with a built-up roof.

CEILING: Ceiling supports can be suspended from or mounted directly to the bottom chords of joists, although suspended systems are recommended because of dimensional variations in actual joist depths.

FLOOR CONSTRUCTION: Joists are usually covered by 2 1/2 to 3 in. of concrete on steel decking. Concrete thickness may be increased to accommodate electrical conduit or electrical/communications raceways. Precast concrete, gypsum planks, or plywood can also be used for the floor system.

VIBRATION: Objectionable vibrations can occur in open web joist and 2 1/2 in. concrete slab designs for open floor areas at spans between 20 and 40 ft, especially at 28 ft. When a floor area cannot have partitions, objectionable vibrations can be prevented or reduced by increasing slab thickness or modifying the joist span. Attention should also be given to support for framing beams, which can magnify a vibration problem when unsupported.

OPENINGS IN FLOOR OR ROOF SYSTEMS: Small openings between joists are framed with angles or channel supported on the adjoining two joists. Larger openings necessitating interruption of joists are framed with steel angle or channel headers spanning the two adjoining joists. The interrupted joists bear on the headers.

ROOF DRAINAGE: On level or near level roofs, especially those with parapet walls, roof drainage should be carefully considered. Roof insulation can be sloped, and joists can be sloped or obtained with top chords that slope in one or both directions. Overflow scuppers should be provided in parapet walls. If roof slope is less than 1/4 in. per ft, the roof system should be investigated to ensure stability under ponding conditions.

BOTTOM CHORD EXTENSION DETAIL

PRELIMINARY JOIST SELECTION

The accompanying tables should not be used for final joist design but are intended to speed selection of steel joists for preliminary design and planning.

Determining the final design must be a separate, thorough process, involving a complete investigation of pertinent conditions; this page is not to be used for that purpose. Consult a structural engineer.

An example of how to use the information presented here follows: Assume a particular clear span. By assuming a joist spacing and estimating the total load, a joist can immediately be selected from the table. Then proceed with preliminary design studies.

NOTES

- Total safe load = live load + dead load. Dead load includes the weight of the joist. For dead loads and recommended live loads, see pages on weights of materials. Local codes will govern.
- Span should not exceed 24 times the depth of a nominal joist for roofs, 20 times the depth of a nominal joist for floors.
- For more information, refer to standard specifications and load tables adopted by the Steel Joist Institute.

LH AND DLH BRIDGING

BRIDGING SPACING (FT)	
CHORD SIZE	MAXIMUM SPACING (FT)
02-04	11
05-06	12
07-08	13
09-10	14
11-14	16
15-17	21
18-19	26

NOTE

Welded horizontal bridging is used for typical joist spans. Check joist bridging requirements when joist spans require midspan bolted diagonal bridging. For spans of more than 60 ft, all bridging should be bolted diagonal bridging.

Charles M. Ault; Setter, Leach & Lindstrom, Architects & Engineers; Minneapolis, Minnesota

METAL DECKING

Some of the many types of metal decking available are:

1. Roof deck
2. Floor deck (noncomposite)
3. Composite floor deck interacting with concrete
4. Permanent forms for self-supporting concrete slabs
5. Cellular deck (composite or noncomposite)
6. Acoustical roof deck
7. Acoustical cellular deck (composite or noncomposite)
8. Electric raceway cellular deck
9. Prevented roof deck (used with lightweight insulating concrete fill)

INSTALLATION AND DESIGN

All metal floor and roof decks must be secured to all supports, generally by means of puddle welds made through the deck to supporting steel. Steel sheet lighter than 22 gauge (0.0295 in. thick) should be secured by use of welding washers. Shear studs welded through the floor deck also serve to secure the deck to supporting steel.

Side laps between adjacent sheets of deck must be secured by button-punching standing seams, welding, or screws, in accordance with the manufacturer's recommendations.

Decks used as lateral diaphragms must be welded to steel supports around their entire perimeter to ensure development of diaphragm action. More stringent requirements may govern the size and/or spacing of attachments to supports and side lap fasteners or welds.

Roof deck selection must consider construction and maintenance loads, as well as the capacity to support uniformly distributed live loads. Consult Steel Deck Institute recommendations and Factory Mutual requirements.

Floor deck loadings are virtually unlimited in scope, ranging from light residential and institutional loads to heavy-duty industrial floors utilizing composite deck with slabs up to 24 in. thick. Designers can select the deck type, depth, and gauge most suitable for the application.

Roof-mounted mechanical equipment should not be placed directly on a metal roof deck. Equipment on built-up or pre-fabricated curbs should be supported directly on main and supplementary structural members and the deck must be supported along all free edges. Heavy items such as cooling towers that must be elevated should be supported by posts extending through pitch pockets directly onto structural members below the deck. Openings through the deck may be handled as discussed above.

FIRE RESISTANCE RATINGS

Fire resistance ratings for roof deck assemblies are published by Underwriters Laboratories and Factory Mutual. Ratings of 1 to 2 hr are achieved with spray-on insulation; a 1-hr rating with a suspended acoustical ceiling and a 2-hr rating with a metal lath-and-plaster ceiling.

Floor deck assembly fire resistive ratings are available both with and without spray-applied fireproofing and with regular weight or lightweight concrete fill. Ratings from 1 to 3 hr are possible using only concrete fill; consult Underwriters Laboratories Fire Resistance Index for assembly ratings.

Consult the manufacturer's literature and technical representatives for additional information. Consult the *Steel Deck Institute Design Manual for Floor Decks and Roof Decks* and the *Tentative Recommendations for the Design of Steel Deck Diaphragms* by the Steel Deck Institute.

ADVANTAGES OF METAL ROOF DECKS

1. A high strength-to-weight ratio reduces roof dead load.
2. Metal roof decks can be erected in most weather conditions.

3. A variety of depths and rib patterns is available.
4. Acoustical treatment is possible.
5. Metal roof decks can serve as the base for insulation and roofing.
6. Fire ratings can be obtained with standard assemblies.
7. Metal roof decks can provide a lateral diaphragm.
8. Metal roof decks can be erected quickly and economically.
9. Metal roof decks make it easy to create roof slopes for drainage.

ROOF DECK ACCESSORIES

NOTES

1. Small openings (up to 6 x 6 in. or 6 in. in diameter) usually may be cut in a roof or floor deck without reinforcing the deck.
2. Openings up to 10 x 10 in. or 10 in. in diameter require reinforcing of the deck either by welding a reinforcing plate to the deck all around the openings or providing channel-shaped headers and/or supplementary reinforcing parallel to the deck span. Reinforcing plates should be 14-gauge sheets with a minimum projection of 6 in. beyond all sides of the opening, and they should be welded to each cell of the deck.
3. Larger openings should be framed with supplementary steel members so that all free edges of the deck are supported.

OPENINGS IN DECK

NOTE

Preformed recessed sump pans are available from deck manufacturers for use at roof drains.

RECESSED SUMP PAN

ROOF DECK TYPES

TYPE	PROFILE	REMARKS	SPAN (FT-IN.)	WIDTH (IN.)	MAX. LENGTH (FT-IN.)
Economy		Most economical deck for shorter spans; use with 1 in. or more insulation	2'-6" to 8'-0"	32" to 33"	42'-0"
Narrow rib (1 in. wide)		Use with 1/2 in. insulation; max. surface area on top for adhering insulation	4'-0" to 11'-0"	36"	42'-0"
Intermediate rib (1 3/4 in. wide)		Use with 1 in. insulation	4'-0" to 11'-0"	36"	42'-0"
Wide rib (2 1/2 in. wide)		Use with 1 in. insulation	5'-0" to 12'-0"	36"	42'-0"

 Walter D. Shapiro, P.E.; Tor, Shapiro & Associates; New York, New York

COMPOSITE FLOOR DECK WITH CONCRETE FILL

TYPE	PROFILE	REMARKS	SPAN (FT-IN.)	WIDTH (IN.)	MAX. LENGTH (FT-IN.)
Shallow deck		Convex embossments bond with concrete fill; reverse deck for concave embossments	5'-0" to 12'-0"	36"	42'-0"
Intermediate deck		Convex embossments	6'-0" to 13'-0"	24" or 36"	42'-0"
Deep deck		Convex embossments	7'-0" to 14'-0"	24" or 36"	42'-0"

NONCOMPOSITE FLOOR DECK WITH CONCRETE FILL

TYPE	PROFILE	REMARKS	SPAN (FT-IN.)	WIDTH (IN.)	MAX. LENGTH (FT-IN.)
Shallow deck		Narrow rib	2'-0" to 5'-6"	30", 35", 36"	42'-0"
Intermediate deck		Narrow rib	3'-0" to 10'-0"	32", 33"	42'-0"
Intermediate deck		Narrow rib	4'-0" to 11'-0"	32"	42'-0"
Intermediate deck		Narrow rib	4'-0" to 11'-0"	30", 36"	42'-0"
Deep deck		Wide rib	5'-6" to 14'-0"	24", 36"	42'-0"

COMPOSITE AND NONCOMPOSITE CELLULAR FLOOR DECK WITH CONCRETE FILL

TYPE	PROFILE	SPAN (FT-IN.)	WIDTH (IN.)	CELL CROSS-SECTIONAL AREA
3 x 12 in. cellular deck (for steel frames requiring studs)		12'-0" to 15'-0"	24", 36"	17.7 sq in./cell (35 sq in./sheet)
3 x 8 in. cellular deck (not suitable for structural studs)		12'-0" to 15'-0"	24"	17.4 sq in./cell (52.2 sq in./sheet)
1.5 x 6 in. cellular deck (for thinner total slabs)		4'-0" to 8'-0"	24", 30", 36"	6 sq in./cell (24 sq in./sheet)

NOTE

Electric raceways may be built into floor slabs by using cellular deck or special units that are blended with plain deck. Two-way distribution is achieved by using trench ducts that sit astride the cellular units at right angles.

Using trench ducts with composite floor deck may reduce or eliminate entirely the effectiveness of composite action at the trench duct. This is also true for composite action between steel floor beams and concrete fill. Trench duct locations must be taken into account in deciding whether composite action is possible.

ELECTRICAL TRENCH DUCT

NOTE

A convenient, economical means of supporting lightweight acoustical ceilings is attaching a suspension system to hanger tabs at side laps, piercing tabs driven through the deck, or pre-punched tabs in the roof deck. Do not use this tab-and-metal deck arrangement to support plaster ceilings, piping, ductwork, electrical equipment, or other heavy loads. Such elements must be suspended directly from structural members or supplementary subframing.

FLOOR DECK ACCESSORIES

METAL FLOOR DECKING

Two items to keep in mind when designing with metal decking:

1. When lightweight concrete is used in the construction, use galvanized deck material.
2. In a fireproof assembly, metal components should be unprimed.

ADVANTAGES OF METAL FLOOR DECKS

1. Metal floor decks provide a working platform, eliminating temporary wood planking in high-rise use.
2. Composite decks provide positive reinforcement for concrete slabs.
3. Both noncomposite and composite decks serve as forms for concrete, eliminating the need for forming and stripping.
4. Consult the Underwriters Laboratories directory for specific fire rating requirements.
5. Acoustical treatment is possible.
6. Electric raceways may be built into the floor slab.
7. Metal floor decking provides economical floor assemblies.

		12		13 1/2	
		Normally available in all joist sizes			

NOTES

- The tables above provide maximum joist spans, in feet and inches. For multiple spans, span is either to the right or left of the interior support.
- Interior bearing supports for multiple span joists should consist of structural (bearing) walls or beams.
- Bearing stiffeners should be installed at all support points and concentrated loads. End bearing stiffeners are not required for floor joists 54 mil or thicker, spanning 14 ft or less, for one-story houses (walls and roof only) in areas with maximum ground snow load of 30 psf or less.
- Joists supporting a roof and single wall only may cantilever up to a maximum of 24 in. measured from the centerline of the bearing point, provided that bearing stiffeners are installed at the end of the cantilever and the bearing point and no punchouts are allowed in the cantilevered section. Hole reinforcements may be used to cover up holes.
- Deflection criteria: L/480 for live loads; L/240 for total loads.

OPENINGS GREATER THAN OR EQUAL TO 4 FEET (LOAD-BEARING WALL)

GENERAL

Lightweight steel framing is cold-formed, which means the components are manufactured by brake-forming and punching galvanized coil and sheet stock. Steel framing members consist of two basic types of components that are C-shaped in section: one type has 1/4-in. flanges folded inward and the other has no flanges. Studs, joists, and rafters are made with flanges to stiffen them so they will more readily stand vertically. Components without flanges, called tracks, have unpunched solid webs. For added strength, tracks are sized slightly larger than the flanged members so the tracks will fit snugly inside them as sill or top plates or as part of posts or headers.

Steel framing is strong and versatile. The strength (and load-carrying capacity) of a member can be increased simply by increasing the thickness, or gauge, of the metal; the dimensions of the member, or the spacing, do not necessarily have to be increased. There is little limitation on the length of steel framing members; joists or studs may be fabricated in lengths up to 40 ft. If handled with care, steel framing is straight and consistent; also, it is not affected by moisture content.

Disadvantages of steel framing include lack of insulating qualities, difficulty in cutting compared to wood, and dangerously sharp edges. Consult the American Iron and Steel Institute (AISI) for further information.

BRACING

Buildings must be properly braced to resist racking under wind and seismic loads. Diagonal strap bracing is sloped to resist racking forces in tension and fastened by screws or welds to studs and plates. Properly spaced lateral steel bracing resists stud rotation and minor axis bending under wind, seismic, and axial loads; it is especially critical during construction, before sheathing or finishes are installed.

NOTE

The top detail is for one-to-two story buildings and the bottom detail for buildings greater than two stories. Steel channel, plate, and anchor size depend on applied uplift and horizontal shear forces.

DIAGONAL STABILITY BRACING ANCHORAGE DETAILS

NOTE

If sheathing is not installed on members, bridging is required on both flanges.

JOIST OR RAFTER BRIDGING

WELD ATTACHMENT (FOR 3 3/8" OR SMALLER STUDS; 16-GAUGE OR HEAVIER)

SCREW ATTACHMENT (FOR 3 3/8" TO 8" STUDS)

NOTE

Channels to be spaced as required by design.

LATERAL BRACING ATTACHMENT

NOTE

Number of rows of bridging as required by design.

WALL BRIDGING

NOTE

Strap forces may require additional stiffening of the bottom track or structural angle.

DIAGONAL STABILITY BRACING ANCHORAGE

NOTE

Strap forces may require additional stiffening of top and bottom track or structural angle.

DIAGONAL STABILITY BRACING AT INTERMEDIATE FLOOR

GENERAL

Lally columns are prefabricated structural units that consist of a load-bearing steel column, filled with concrete. This creates a column with increased load-bearing capacity in a space no larger than a standard column. Fireproof lally columns have a thin steel shell and a layer of insulating material between the shell and the structural steel. Fire ratings range from two to four hours depending on the thickness of the insulating material. The protective steel shell allows fireproof lally columns to be left exposed in either interior or exterior applications.

FIREPROOF COLUMNS TYPICAL COLUMN BASE AND CAP ATTACHMENTS TO STEEL SHELL BEAM CONNECTIONS

TYPICAL LALLY COLUMN ASSEMBLIES

Eric Gastier; Alexandria, Virginia

GUIDELINES

1. Width of stair:
 - a. Dwelling stairs: minimum 36 in. treads.
 - b. Public exit stairs: minimum 44 in. treads.
 - c. Rescue assistance area (ADA): 48 in. between handrails.
2. Treads:
 - a. Dwellings: 9 in. minimum (nosing to nosing).
 - b. Other (ADA): 11 in. minimum (nosing to nosing).
 - c. Uniform width within one flight.
3. Risers:
 - a. Dwellings: 8 1/2 in. maximum.
 - b. Other (ADA): minimum 4 in., maximum 7 in.
 - c. Uniform height within one flight.
4. Nosing: maximum 1 1/2 in. with 60° under nosing; maximum 1/2 in. radius at edge.
5. Stair rails:
 - a. Height in dwellings: 36 in.
 - b. Height in exit stairs: 42 in.
 - c. Rails should be arranged so that a sphere 4 in. in diameter cannot be passed through.

- d. Rails should be arranged to discourage climbing.
 - e. Concentrated load nonconcurrently applied at the top rail shall be 200 lb per ft in vertical downward and horizontal direction. The test loads are applicable for railings with supports not more than 8 ft apart.
6. Handrails:
 - a. Dwellings: on one side only, required.
 - b. Other (ADA): required on both sides.
 - c. Height: 34 to 38 in.
 - d. Grip surface: 1 1/4 to 1 1/2 in.
 - e. Clearance at wall: 1 1/2 in.
 - f. Projecting or recessed.
 - g. Extension at top of run: 12 in.
 - h. Extension at bottom of run: 12 in. plus width of tread.
 - i. When a guardrail more than 38 in. high is used, a separate handrail should be installed (ASTM).
 - j. Nothing should interrupt the continuous sliding of hands.
 7. Regulators and standards: building codes, ADA, ASTM, ANSI, NFPA, and OSHA.

INDUSTRIAL AND SERVICE STAIRS

PAN-TYPE STAIR CONSTRUCTION

Charles A. Szoradi, AIA; Washington, D.C.

GENERAL NOTES

1. Materials for ladders and supports include galvanized steel and aluminum. Galvanized steel ladders are fastened to the wall with galvanized steel fasteners; aluminum ladders are fastened with stainless steel fasteners.
2. All fixed wall ladders must conform to OSHA/ANSI A14.3 standards. Also consult local codes for design requirements.

NOTE

Cages should be used on ladders at hazardous locations or on short ladders at high locations.

FIXED VERTICAL LADDER (50 FEET OR LESS)

FIXED VERTICAL LADDER (UP TO 24 FEET)

NOTE

The maximum rise between treads depends on exact ladder height and angle.

FIRE ESCAPE

ELEVATION - FIRE ESCAPE

NOTE

7 to 12 ft from landing to grade at front of building (12 ft minimum at alleys or thoroughfares less than 30 ft wide).

PLAN - FIRE ESCAPE

TYPICAL STAIR TREADS

RETRACTABLE ESCAPE LADDER

FIRE ESCAPE NOTES

1. In general, exterior fire escapes are not permitted as any part of the required means of egress for new buildings, but may be continued as a component in the means of egress in existing buildings. New fire escapes for existing buildings are permitted only where exterior stairs cannot be utilized due to lot lines that limit stair size or due to sidewalks, alleys, or streets at grade level. Access by windows is generally not permitted.
2. For other specific requirements, refer to applicable national and local building codes.
3. For standards for fire escapes as well as for stairs and means of egress, consult ANSI 117.1, OSHA, and NFPA 1010 (Life Safety Code).
4. Since fire escapes are mounted outside of the building envelope, consideration must be given to exterior lighting provided on the building itself or general street lighting that would illuminate it.
5. Standard fire escapes are typically designed to support a live load of 100 lb/sq ft; stair treads shall be designed to support a concentrated live load of 250 lb at any point.

ESCAPE LADDER NOTES

1. Located adjacent to windows or balconies, the retractable aluminum escape ladder is used solely for emergency exit, rescue, or supplemental escape route. Also provides access to mechanical equipment or other secured spaces. Not to be used as any component in the means of egress.
2. Consult manufacturer for mounting details. Refer to national and local building codes for specific requirements concerning access opening types, sill heights, clearances, and maximum installation heights allowed. In some instances, a balcony may be used at any level to access the ladder.

GENERAL

Wrought iron is a commercial form of iron with a relatively soft and malleable fibrous structure. The term literally means "fashioned" or "formed" iron and is widely associated with ironwork details. ASTM A 186 defines wrought iron as iron with a carbon content between 0.03 and 0.05%, a material prevalent up to the 19th century. Iron with such a low carbon content is scarce today, so most fabricators use steels containing combinations of iron with a higher percentage of carbon for ornamental details. Low carbon steel or mild steel is the most desirable of these.

NOTES

1. Steel and iron are the metals most frequently used for ornamental structures. Other popular metals are aluminum (favored for its light weight and rust resistance), polished bronze, brass, and copper. Blacksmiths primarily

produce custom work today; a smaller proportion of their work is restoration.

2. Working with iron is a craft not readily mastered by generalists; low bidders may not be qualified to deliver a high-quality product. Check references for similar types of jobs performed or jobs at similar costs. Consult the National Ornamental and Miscellaneous Metal Association (NOMMA) and the Artists-Blacksmiths Association of North America for more information on references and lists of blacksmith shops in the United States.

3. NOMMA publishes voluntary guidelines for joint finishes in ornamental work. They are Finish #1 (no evidence of a welded joint); Finish #2 (completely sanded joint, some undercutting and pinholes); Finish #3 (partially dressed weld with splatter removed); and Finish #4 (good quality, uniform undressed weld with minimal splatter).

METAL GRILLWORK INSTALLATION—DETAILS FOR MASONRY OPENINGS

CRIMPED AND WELDED MEMBERS

MISCELLANEOUS CONNECTIONS

GENERAL

Perforated metals were initially created to fulfill industrial needs such as minimizing the weight of a particular component or controlling the passage of fluids or gasses. As an architectural component, perforated metals can be used as control devices or simply as decoration. They can serve as sound suppression acoustical devices in ceilings, walls, and grilles; when incorporated into light fixtures, grilles, or ceiling and wall components, they can filter light and obscure views. Since perforated metals retain a great deal of their strength and also ventilate well, they are often employed in furniture and other designs. Because they can bend and interrupt wavelengths of many types, perforated metals are used to contain microwave radiation and the EMI/RFI radiation emitted by electrical devices.

NOTES

1. Metal is typically perforated with hole-punching machines, which work best on sheets .008 in. to 3/4 in. thick. Specialized equipment is available for thicker metal.
2. The intended use of the perforated metal sheet determines the size, shape, and pattern of the holes punched. The strength and stiffness required vary according to use. Since perforated materials can be used in different applications involving a wide range of geometries, materials, and loading conditions, design data are given in very general form.
3. The enormous number of perforating patterns possible with round holes, squares, slots, and other special perforations make it impractical to list every pattern combination. The numbered perforations listed by the Industrial Perforators Association (IPA) are considered standard.
4. For design and tolerances of perforated metals, consult the IPA.
5. Round holes from .020 in. to more than 6 in. in diameter make up the majority of all perforated metal sheets produced. This is because round holes can be produced with greater efficiency and less expense and are generally stronger than other hole shapes.

6. Nonstandard end patterns may require special dies. Unperforated borders may cause distortions of the finished sheet. Roller leveling may be used to correct some of these distortions but may not always work. To calculate the (round) holes per square inch:

$$\% \text{ Open area} = \frac{78.54 \times D \times D}{L \times W}$$

NOTE

Spacing can be specified as a center-to-center dimension, a percentage of open area, or holes per square inch.

TYPICAL TERMS FOR SPECIFYING PERFORATED METAL

ROUND HOLES

IPA NUMBERS	PERFORATIONS (IN.)	CENTERS (IN.)	HOLES PER SQ IN.	% OPEN AREA	LINE	S*/S, STRENGTH

131	3/4	1		51	Staggered	.250	.192

S* = yield strength of perforated material
 S = yield strength of unperforated material (strength for 60° standard staggered pattern)

Length direction = parallel to straight row of holes
 Width direction = direction of stagger

CHECKLIST OF PERFORATING COST INFLUENCES

1. Material type: The least expensive material may not save money; a higher strength alloy may allow thickness to be reduced.
2. Material thickness: Thinner materials can be perforated easier and faster.
3. Hole shape and pattern: Round holes are the most economical; the 60x° staggered round hole pattern is the strongest, most versatile, and most common.
4. Hole size: Do not go below a 1-to-1 ratio of hole to size to sheet thickness; stay with a 2-to-1 ratio or larger if possible.
5. Bar size: Do not use bars with less than a 1-to-1 ratio with sheet thickness.
6. Center distance: This controls the feed rate and thus the conduction rate. If possible, choose a pattern with longer center distance.
7. Open areas: Extreme open area proportions tend to increase distortion; if possible, stay under 70 percent.
8. Margins: Keep side margins to a minimum to reduce distortion. Use standard unfinished end margins if possible.
9. Blank areas: Consider the die pattern when determining blank areas; consult the metal supplier.
10. Standardization: Specify standard hole patterns, material dimensions, and tolerances when possible. Before specifying a "special," ask the perforator what can be done with existing tooling.
11. Accept normal commercial burrs unless otherwise specified.

NOTE

This standard IPA option is stronger than straight row patterns but not as strong as a 60x° staggered arrangement. It is also not as versatile in providing compact hole spacing and high open areas as the 60x° arrangement.

45° STAGGERED ROUND HOLE PATTERN

CLOSED PUNCH

NOTE

A straight line pattern of holes is weaker than a staggered arrangement and can stretch the material more. Dark holes in the drawings above indicate the punch patterns.

STRAIGHT LINE ROUND HOLE PATTERN

45° STAGGERED PATTERN (SPECIAL) ROUND HOLE OPEN AREAS

SQUARES

IPA NUMBER	PERFORATIONS (IN.)	CENTERS (IN.)	OPEN AREA	LINE
200	2/10	1/4	64%	Straight
201	1/4	3/8		
202	3/8	1/2	56%	Straight
203	1/2	11/16	53%	Straight
204	3/4	1	56%	Straight
205	1	1 1/4		Straight
206	1	1 3/8		Straight

SQUARE HOLE OPEN AREAS

NOTE

Square holes, principally used for grilles and machine guards, offer optimal visibility and throughput. Typically punched in a straight line, in either straight or staggered patterns, square holes make for weaker perforated sheets than round hole patterns and are generally more expensive. Sharp corners make square hole tooling wear out faster than round hole tooling.

GUIDE FOR SELECTING CARBON STEEL FOR PERFORATING APPLICATIONS

TYPE	DESCRIPTION	RECOMMENDED SIZE					CARBON CONTENT	TYPICAL MECHANICAL PROPERTIES				APPROXIMATE RELATIVE COST (10-GA. H.R. STEEL = 100)	
		SHEETS			COILS			TENSILE PSI	YIELD, PSI	% ELONG 2 IN.	HARD- NESS	SHEETS	COILS
		TH	W	L	TH	W							
HOT-ROLLED STEELS													
Commercial quality (SAE or ASI 1008; ASTM A 569)	A low-cost sheet steel with moderate drawing and forming qualities for use when finish is unimportant. For best perforating results specify pickled and oiled for removal of oxides.	7 to 16 ga.	up to 60 in.	up to 144 in.	7 to 16 ga.	up to 60 in.	0.10 max.	45,000 to 60,000	30,000 to 40,000	28 to 38	55 to 70	100 pickled and oiled-104	95 99
Drawing quality (SAE or AISI 1008; ASTM A 621)	This quality is intended for use when forming requirements are too severe for commercial quality. Pickling and oiling to remove oxides is recommended. In-stock availability is not as great as commercial quality.	7 to 16 ga.	up to 60 in.	up to 144 in.	7 to 16 ga.	up to 60 in.	0.10 max.	45,000 to 60,000	30,000 to 40,000	28 to 38	55 to 70	103	98
High-strength, low alloy (USS Cor-Ten or equivalent; ASTM A 375)	Good formability because of low carbon content in combination with relatively high Yield and Tensile properties permit these steels to be used in lighter gauges to reduce weight in applications in which strength is important. Readily available.	7 to 16 ga.	up to 60 in.	up to 144 in.	11 to 14 ga.	up to 60 in.	0.12 max.	70,000 min	50,000 min	22 min	80 to 90	132	126
Abrasion-resisting (C .35-.50; Mn 1.50-2.00; P .050 max.; S .055 max.; Si .15-.35)	High manganese content in combination with intermediate carbon greatly enhances resistance to abrasion; can improve part life 2 to 10 times. Moderate formability.	7 to 16 ga.	up to 60 in.	up to 144 in.	N.A.	N.A.	.35 to .50	100,000 to 120,000	55,000 to 70,000	10 to 20	210 to 225 (Bhn.)	118	N.A.
COLD-ROLLED STEELS													
Commercial quality (SAE or AISI 1008; ASTM A 366)	Cold rolled steels have improved surface finishes and tighter size tolerances than hot rolled steels. They are available in two classes: Class 1 is intended for exposed applications; Class 2 is for unexposed use. Three finishes can be specified: Matte is the standard finish. It is uniformly dull and suitable for painting. Commercial bright finish is a relatively bright, intermediate finish. Luster finish is smooth and bright and most suitable for plating. Because perforating alters surface appearance, surface preparation after perforating may be required before application of the final finish.	7 to 28 ga.	up to 60 in.	up to 18 ft	11 to 28 ga.	up to 60 in.	0.10 max.	40,000 to 50,000	25,000 to 35,000	30 to 40	45 to 60	119 (16 ga.)	113
Drawing quality (ASTM A 619)	Recommended for use when forming requirements are too severe for commercial quality. Can be supplied (Class 1) free of fluting or stretcher straining when intended for use in a reasonably short time. Available in mill quantities.	7 to 28 ga.	up to 60 in.	up to 18 ft	11 to 28 ga.	up to 60 in.	0.10 max.	40,000 to 50,000	20,000 to 30,000	38 to 40	40 to 50	125 (16 ga.)	120
Drawing quality special milled (ASTM A 620)	For use when the material must be free of surface disturbances without roller leveling immediately before use and essentially free from significant changes in mechanical properties over an extended period of time. Available in mill order quantities.	7 to 28 ga.	up to 60 in.	up to 18 ft	11 to 28 ga.	up to 60 in.	0.10 max.	40,000 to 50,000	20,000 to 30,000	38 to 40	40 to 50	127 (16 ga.)	122
CORROSION-RESISTANT STEELS													
Galvanized (ASTM 525)	A versatile, low-cost, corrosion-resistant steel with a zinc coating applied in a continuous hot-dip process. Available in commercial, drawing, and other qualities.	10 to 20 ga.	up to 60 in.	up to 18 ft	12 to 28 ga.	up to 60 in.	0.10 max.	45,000 to 55,000	35,000 to 45,000	25 to 35	50 to 65	147 (20 ga.)	145
Mill-bonderized galvanized	Galvanized sheet with a coating of mill-bonderized phosphate for immediate painting without flaking or peeling.	16 to 26 ga.	up to 60 in.	up to 18 ft	16 to 26 ga.	up to 60 in.	0.10 max.	45,000 to 55,000	35,000 to 45,000	25 to 35	50 to 65	149 (20 ga.)	N.A.
Galvanealed (coating designation A 60)	Heat-treated galvanized sheet, dull gray without spangles with a rough texture well suited to painting. Can withstand temperatures to 750° without flaking. Less ductile than regular galvanized coating.	14 to 26 ga.	up to 48 in.	up to 18 ft	14 to 26 ga.	up to 48 in.	0.10 max.	40,000 to 55,000	32,000 to 42,000	25 to 35	50 to 65	150 (20 ga.)	147
Electro-galvanized (ASTM A 591)	A thin zinc coating is applied to cold rolled steel by electroplating so as not to appreciatively affect the weight-thickness relationship. Smooth, without spangles, it is recommended as an undercoat for painted finishes. Available in commercial and drawing qualities.	14 to 26 ga.	up to 60 in.	up to 18 ft	14 to 26 ga.	up to 60 in.	0.10 max.	40,000 to 50,000	25,000 to 35,000	30 to 40	45 to 60	146 (20 ga.)	144
Aluminized, type 1 (ASTM 463)	Sheet steel coated on both sides with aluminum combines the properties of both metals. Type 1 is provided in two weights, regular and light, and is available in commercial and drawing qualities. If the heaviest Type 2 aluminized coating is desired, consult with a supplier or the steel manufacturer.	14 to 26 ga.	up to 60 in.	up to 18 ft	14 to 26 ga.	up to 60 in.	0.10 max.	50,000 to 60,000	35,000 to 45,000	18 to 28	60 to 70	162 (20 ga.)	157

ORNAMENTAL METAL

NOTES

1. Follow all local code requirements for ramp design, rail diameter, and rail clearances; also see ASTM, ANSI, ADA, and OSHA requirements.
2. Verify allowable design stresses of rails, posts, and panels.
3. Verify the structural value of fasteners and anchorage to building structure for both vertical and lateral forces.
4. ASTM E-985 requirements:
GUARDRAILS - Protect occupants at or near the outer edge of a ramp, landing, platform, balcony, or accessible roof. Railing systems usually are not provided where the vertical distance between adjacent levels is 24 in. or less. Railing members should be arranged to discourage climbing. Provide 4 in. high toeboards where tools or other objects could be dislodged. Concentrated load non-concurrently applied at the top rail shall be 200 lb/ft in the horizontal and vertical direction. The test loads are applicable for railings with supports not more than 8 ft apart.
HANDRAILS - Corridors, ramps, and walkways having a slope of at least 1 in 20 shall have handrails. When a guardrail of more than 38 in. height is used, a separate handrail shall be installed. Nothing should interrupt the continuous sliding of hands. The ends of the handrail shall be returned to walls or arranged to avoid projecting rail ends.

NOTES

1. A large selection of prefabricated assemblies to cover interior expansion joints is available from various manufacturers to satisfy most joint and finish conditions.
2. Fire-rated barrier-type inserts are available and applicable to most assemblies.
3. Expansion joint covers that will respond to differential movement, both laterally and horizontally, should be provided at joints in structures located where seismic action (earth tremors and quakes) may be expected or where differential settlement is anticipated.

Heavy Timber Construction	341		

WOOD AS A CONSTRUCTION MATERIAL

Approximately nine of every ten buildings constructed in the United States each year are framed with wood, including most single-family and multifamily residences and a large percentage of commercial, institutional, and public buildings. Wood is favored as both a structural material and a finish material for its economy, architectural flexibility, and visual qualities. Many contractors know how to build with it. Small work crews can handle most wood members without special lifting equipment; cutting and fastening can be accomplished on site with hand or portable power tools; and the skills needed for wood construction are easily learned. Yet wood is one of the most difficult materials for the designer to master, because it is virtually the only building material that is vegetable rather than mineral. With this vegetable origin comes a host of idiosyncrasies relating to directional properties, strength, stiffness, grain patterns, shrinkage, distortion, decay, insect damage, and fire resistance.

Today most wood comes from younger forests, with trees typically smaller than those harvested a few decades ago. Large solid timbers are increasingly hard to obtain, and the general quality of lumber is declining. As a result architects and builders must depend more and more on manufactured wood products such as laminated wood, laminated veneer lumber, parallel strand lumber, and manufactured wood I-joists and trusses. These products tend to be straighter, stronger, stiffer, less prone to distortion, and more economical of trees than conventional solid lumber, but they are not always suitable for display in a building.

TYPES OF WOOD CONSTRUCTION

Building codes categorize wood construction into two distinct types—heavy-timber and light wood-frame.

Heavy-timber construction, consisting of exposed columns, girders, beams, and decking large enough to be slow to catch fire and burn, is permitted for use in relatively large buildings across a broad spectrum of uses. Because of its large member dimensions and spans, heavy-timber construction is best suited to buildings with regular, repetitive bays. Heavy-timber buildings are engineered in accordance with the National Design Specification for Wood Construction, published by the American Wood Council.

Light wood-frame construction is made up of nominal 2 in. (38 mm) framing members spaced closely together and normally concealed by interior finish materials such as plaster, gypsum board, or wood paneling. Light wood-frame construction, with its small members and close member spacings, adapts readily to even the most intricate spaces and architectural forms. However, because such construction is less resistant to fire than heavy-timber construction, building codes severely limit the heights and areas of light wood-frame buildings. The maximum height generally permitted in residential light wood-frame buildings is three stories, although four stories are possible if an approved sprinkler system is installed. Most light wood-frame engineering can be done following values from tables in the CABO One and Two Family Dwelling Code, which has been widely adopted by states and municipalities.

WOOD AS A STRUCTURAL MATERIAL

On the basis of performance per unit weight, typical construction lumber is at least as strong and stiff as structural steel. Because of its microstructure of longitudinal cells, wood has different structural properties in its two principal directions. Parallel to the grain, wood is strong and stiff; perpendicular to the grain, it is weak and deformable. Fasteners that act in a direction parallel to the grain can transmit considerably more force than those that act perpendicular to the grain. The strength of wood varies with the duration of the load: For short-term loads such as those from snow, wind, and impact, allowable stress values are 15 to 100% higher than those allowed for normal-term loads. Under very long term loading, however, wood has a tendency to creep, and reduced stress values must be used.

WOOD AS A FINISH MATERIAL

Wood is used as a finish material in buildings of every kind. Limited quantities of wood finish may be used even in the most fire-resistant types of construction. With proper protection from water and sunlight, wood can serve as a durable exterior material for cladding, trim, and even roofing. For interior finishes, despite recent concerns regarding the depletion of rare or old-growth species, woods of many types remain commonly available in solid or veneer form, exhibiting great variety in hardness, grain figure, color, suitability for different finishes, and cost. Finish woods are readily available in many preformed shapes and are also easily shaped and cut in the field. Wood and wood products

HEAVY-TIMBER CONSTRUCTION

LIGHT WOOD-FRAME CONSTRUCTION

may be finished with transparent or opaque coatings or serve as a base for applied plastic laminates.

SELECTION OF INTERIOR FINISH WOOD MATERIALS

Following are the major factors that influence lumber selection for finish wood applications as specified by the Architectural Woodwork Institute:

AESTHETIC CHARACTERISTICS: Different species exhibit a variety of colors, grains (open or close grain), and figures (grain patterns) that are further distinguished by the sawing method (plain sawn, quarter sawn, rift sawn) and finishing characteristics (receptivity to finish processes, such as fillers, stains, etc.).

AVAILABILITY: The availability of particular species varies by season and popularity.

SIZE LIMITATIONS: Some species produce longer and/or wider members.

STRENGTH, HARDNESS, AND DENSITY: The ability of selected lumber to sustain stress; resist indentation, abuse, and wear; and carry its anticipated load contributes to its suitability for particular uses.

DIMENSIONAL STABILITY: Swelling and shrinking due to relative humidity and moisture content changes varies according to the species and product type.

ADAPTABILITY FOR EXTERIOR USE: Certain species are more durable when used in exterior applications. Heartwood of all species is more resistant to damage by the elements than sapwood. The following species are rot resistant and acceptable for exterior use: Eastern and Western red cedar; redwood; mahogany, and teak.

FIRE RETARDANCE: Natural fire retardant qualities and acceptability of treatment vary with species. Flame Spread Classification is the generally accepted measurement for fire rating of materials. Fire-retardant treatments and build-up of members can be used to improve the fire rating of wood materials.

PRESERVATIVE TREATMENTS: Certain species used for architectural woodwork can be treated with preservative compounds to extend their life when exposed to the elements.

LUMBER PRODUCTION

Commercially marketed lumber includes trees of dozens of species roughly divided into softwoods, which are the ever-green species, and hardwoods, those species that drop their leaves in the fall. Nearly all framing lumber comes from the comparatively plentiful softwoods. Hardwoods, with their greater range of colors and grain figures, are used primarily for interior finishes, flooring, cabinets, and furniture.

Seen under a low-power magnifier, wood is made up primarily of hollow tubular cells of cellulose that run parallel to the long axis of the tree trunk. When the tree is harvested, both the hollows and the walls of these tubes are full of watery sap. The tree is sawed into rough lumber while in this saturated or "green" condition. Finish lumber is seasoned (dried of much of its moisture), either by stacking it in the open air for a period of months or, more commonly, by heating it in a kiln for a period of days. During seasoning, moisture evaporates first from the hollows of the tubes, and then from the cellulose walls of the tubes, causing the lumber to shrink. By the time the lumber leaves the kiln, it is considerably smaller. Further shrinkage usually occurs after the lumber has been incorporated into a building, as the moisture content in the wood comes gradually to equilibrium with the moisture content of the surrounding air. Wood absorbs moisture during damp weather and gives it off during dry weather in a never-ending cycle of swelling and shrinking, a fact that must be taken into account when detailing wood components of building.

Most lumber is surfaced after seasoning to reduce it to its final dimensions and give it smooth faces. Edges are rounded to make the lumber easier and safer to handle.

TYPICAL SAWING OF A LARGE LOG

BEFORE MACHINING		AFTER MACHINING	
Nominal (rough) thickness		AWI finished thickness (in.)	
In.	Quarters	Hardwoods	Softwoods
1	4/4	3/4	3/4
1 1/4	5/4	1	1 1/16
1 1/2	6/4	1 1/4	1 3/8
2	8/4	1 3/4	1 1/2
2 1/2	10/4	2	2 1/4
3	12/4	2 1/2	2 1/2

LUMBER THICKNESS

LUMBER GRADING

Wood is a natural product and thus varies greatly in appearance and structural properties. Consequently, elaborate systems of grading have been established to indicate the quality of each piece of lumber. Within each species of wood there are two grading systems, one based on structural strength and stiffness, the other on appearance. Appearance is graded visually. Structural grading is based either on visual inspection, the sizes and positions of knots and other defects, or structural properties as measured by machines that flex each piece of lumber.

Strength and stiffness values for wood are tabulated elsewhere in this chapter of AGS. They vary considerably from one species and grade to another. When engineering a wood structure, it is necessary to know what species and grade will be specified. If in doubt, base structural calculations on the weakest species and grade locally available.

JOINING WOOD

Nailing is the most common method of joining light structural members. Nails are inexpensive to buy and install and may be driven by hand or with a pneumatic gun. When applied in proper size, number, and spacing, they form a strong, resilient joint. Sheet metal straps, anchors, and brackets can be nailed to connections where greater resistance to tension or shear is necessary. Detailed nailing requirements for light wood-frame construction are included in building codes. Heavy-timber construction typically relies on bolts and lag screws, together with fabricated metal connecting devices.

In finish wood construction, nearly headless finish nails are used for improved appearance. Screws, concealed or embedded fasteners, splines, and fitted and glued joints provide greater mechanical stiffness and optimal appearance. The Architectural Woodwork Institute has established standards for finish joinery based on appearance and cost.

MOISTURE MOVEMENT IN WOOD

The shrinkage of wood as it dries is not uniform. Wood shrinks very little along the length of the grain, somewhat in the radial direction of a cylindrical log, and more in the tangential direction of the log, as shown in the accompanying graph. One consequence of the difference between the radial and tangential shrinkage is that radial splits called checks form during seasoning, especially in lumber of large

dimension. In addition, pieces of lumber distort noticeably in accordance with their original positions in the tree trunk. For pieces of lumber that must stay flat, such as flooring, outdoor decking, baseboards, casings, and paneling, vertical-grain lumber, which is sawed so the annual growth rings are more or less perpendicular to the broad face of the board, is often specified. One particular sawing pattern that produces vertical-grain lumber is called quarter-sawing. For ordinary framing, seasoning distortions are of little consequence, so plain-sawn boards are used.

A number of accepted wood detailing practices have been developed in response to the great moisture movement that occurs in wood and the distortions that result from the differing rates of shrinkage along the three axes of the grain. In applying wood siding, it is necessary to use nailing patterns that do not restrain the cross-grain seasonal shrinking and swelling of the wood. Horizontal bevel siding is nailed so that each board is fastened by one row of nails only, creating a sliding joint at each overlapping edge to allow for movement. Tongue-and-groove siding boards are nailed at the tongue edge only, the other edge being restrained by the tongue of the adjacent board sliding freely in its groove. Vertical board-and-batten siding is nailed only at the centers of the boards and battens, allowing for free expansion and contraction of the wood.

Because wood shrinkage is so much greater in the tangential direction than in the radial, plain-sawn boards tend to cup noticeably in a direction opposite to the curvature of the annual rings. Plain-sawn decking and flooring should be laid with the "bark side" of each board facing down to reduce the raising of edges. On outdoor decks, this practice will also minimize puddling of water on the boards. Vertical-grain flooring and deck boards are preferable to plain-sawn boards, not only because they minimize cupping but because their tighter grain pattern wears better underfoot.

Broad interior finish pieces are frequently given a relieved back, a hidden groove or grooves that reduce the effective thickness of the piece and thus the tendency of the piece to cup. Many stock millwork patterns include relieved backs. Boards may be relieved on site by cutting multiple grooves with a table saw. Cupping can also be minimized by back priming, painting the back surface of each piece a day or more before installation. After the piece has been installed and the exposed side has been painted or varnished, the back priming causes the back side to absorb and give off moisture at about the same rate as the exposed side, minimizing distortions.

DECAY AND INSECTS

Wood provides food and habitat to various insects and decay-causing fungi. For the most part, decay and insect attack can be avoided by detailing a building in a way that keeps wood dry at all times. Wood components should be kept at least 6 in. (150 mm) away from the soil. Details that trap and hold moisture, such as connections in exterior decks and railings, should be avoided unless preservative-treated wood or decay-resistant species such as redwood, cedar, or cypress are used.

FIRE

Wood burns easily, giving off highly toxic combustion products, so it is important to design wooden buildings for fire safety. The first step is to follow the height and area restrictions of the building codes, along with code provisions for easy egress from wooden buildings. Smoke and heat alarms are essentials in wooden residential buildings. Heavy-timber buildings have a natural resistance to fire because their massive timbers are slow to ignite and burn in comparison to the smaller framing members in light wood-frame construction. Light wood-frame buildings have internal hollow passages that encourage the spread of fire; these must be closed off at each floor by wood blocking or the floor platform framing. Light wood-frame buildings are generally finished with interior surfaces of gypsum plaster or gypsum wallboard, which are highly resistant to fire.

JAMB NOTE

By reducing the effective thickness of the woodwork, relieved backs reduce the tendency of the wood to cup.

GENERAL DESIGN INFORMATION

For floor construction where live loading is heavier than customarily found in residential occupancies, tabular data are provided.

The tabulated spans are based on bending strength using the live load indicated in each table heading plus a dead load of 10 psf. In calculating the required modulus of elasticity for the tabulated span, the live load only was used, since this is in accordance with established practice for design of floor joists.

SPAN

While the effective span length for an isolated beam is customarily taken as the distance from face to face

of supports plus one-half the required length of bearing at each end, it is the practice in designing joists spaced not over 24 in. apart to consider the span as the clear distance between supports.

NET SIZES OF LUMBER

Joists are customarily specified in terms of nominal sizes, but calculations to determine the allowable span and required modulus of elasticity are based on actual sizes.

DESIGN STRESSES

Unit design values for design of wood joists are given in the National Design Specification for Wood Construc-

tion, available from the American Forest & Paper Association.

ADJUSTMENT OF MODULUS OF ELASTICITY

The modulus of elasticity values listed in the span tables for joists are those required for the tabulated spans if deflection under the live load is limited to $\ell/360$. Where other deflection limits are acceptable, the tabular E values may be adjusted by multiplying them by the following factors:

- For limit of $\ell/300$: 0.833
- For limit of $\ell/240$: 0.667
- For limit of $\ell/180$: 0.500

NOTE: The required modulus of elasticity, E, in 1,000,000 psi is shown below each span, if deflection under the live load is limited to $\ell/360$.

American Forest and Paper Association; Washington, D.C.

GENERAL DESIGN INFORMATION

For floor construction where live loading is heavier than customarily found in residential occupancies, tabular data are provided.

The tabulated spans are based on bending strength using the live load indicated in each table heading plus a dead load of 10 psf. In calculating the required modulus of elasticity for the tabulated span, the live load only was used, since this is in accordance with established practice for design of floor joists.

SPAN

While the effective span length for an isolated beam is customarily taken as the distance from face to face

of supports plus one-half the required length of bearing at each end, it is the practice in designing joists spaced not over 24 in. apart to consider the span as the clear distance between supports.

NET SIZES OF LUMBER

Joists are customarily specified in terms of nominal sizes, but calculations to determine the allowable span and required modulus of elasticity are based on actual sizes.

DESIGN STRESSES

Unit design values for design of wood joists are given in the National Design Specification for Wood Construc-

tion, available from the American Forest & Paper Association.

ADJUSTMENT OF MODULUS OF ELASTICITY

The modulus of elasticity values listed in the span tables for joists are those required for the tabulated spans if deflection under the live load is limited to $\ell/360$. Where other deflection limits are acceptable, the tabular E values may be adjusted by multiplying them by the following factors:

- For limit of $\ell/300$: 0.833
- For limit of $\ell/240$: 0.667
- For limit of $\ell/180$: 0.500

NOTE: The required modulus of elasticity, E, in 1,000,000 psi is shown below each span, if deflection under the live load is limited to $\ell/360$.

American Forest and Paper Association, Washington, D.C.

DESIGN LOAD TABLES

FLOOR AND ROOF BEAMS—DESIGN TABLES 20 POUNDS PSF

REQUIRED VALUES FOR FIBER STRESS IN BENDING (f) AND MODULUS OF ELASTICITY (E) FOR THE SIZES SHOWN TO SUPPORT SAFELY A LIVE LOAD OF 20 POUNDS PER SQUARE FOOT WITH A DEFLECTION LIMITATION OF 1/300 l = SPAN IN INCHES.

Table with columns: SPAN OF BEAM, NOMINAL SIZE OF BEAM, MINIMUM "f" & "E" IN PSI FOR BEAMS SPACED: (6'-0", 7'-0", 8'-0"), SPAN OF BEAM, NOMINAL SIZE OF BEAM, MINIMUM "f" & "E" IN PSI FOR BEAMS SPACED: (6'-0", 7'-0", 8'-0").

CEILING JOISTS—10 LB/SQ FT LIVE LOAD (GYPSUM WALLBOARD CEILING)
 No attic storage and roof slope not steeper than 3 IN 12.

MAXIMUM ALLOWABLE LENGTHS L BETWEEN SUPPORTS

	24	L = 17-8 F _b = 1310	18-9 1480	19-9 1640	20-8 1790	

NOTE: L in feet and inches; E and F_b in pounds per square inch as shown above.

DESIGN CRITERIA

1. Maximum allowable deflection = 1/240 of span length.
2. Live load of 20 lb/sq ft plus dead load of 10 lb/sq ft determine required fiber stress value.

NOTE

For rafters, design values in F_b may be greater than the design values for normal duration of load, by the following amounts:

- 15% for 2 months' duration, as for snow.
- 25% for 7 days' duration, as for construction loading.

NOTE

(Applicable to this page and the following pages on joist and rafter sizes.)

SPANS LIMITED BY DEFLECTION: The weight of plaster itself was ignored in the assumed loads for the deflection computations, because the initial deflection from the dead load occurs before plaster sets. The influence of live loads, rather than dead loads, when the ratio of live to dead loads is relatively high, is the principal factor to be considered. Also with joisted floors, flooring and bridging serve to distribute moving or concentrated loads to adjoining members. The omission of the plaster weight in load assumption applies to deflection computations only; the full dead and live load is considered when computing for strength.

E = modulus of elasticity
 F_b = extreme fiber stress in bending
 L = span length between supports

LIVE LOAD ASSUMPTIONS: Uniformly distributed.

PARTITIONS: Spans shown are computed for the given live load plus the dead load and do not provide for additional loads such as partitions. Where concentrated loads are imposed the spans should be recomputed to provide for them.

SECTION MODULUS

LUMBER SIZES (NOMINAL)	S (IN. ³)
2 x 3	1.56
2 x 4	3.06
2 x 6	7.56
2 x 8	13.14

4 x 6	17.65
4 x 8	30.66
4 x 10	49.91
4 x 12	73.83

SECTION MODULUS

$$S = \frac{bd^2}{6}$$

(IN.³)

DESIGN CRITERIA

STRENGTH: 15 psf dead load plus 20 psf live load determines required fiber stress.

RAFTERS: Spans are measured along the horizontal projection, and loads are considered as applied on the horizontal projection.

DEFLECTION: For 20 psf live load. Limited to span in inches divided by 240.

FLAT OR SLOPED RAFTERS—20 LB LIVE LOAD
FLAT ROOF OR CATHEDRAL CEILING WITH NO ATTIC SPACE—SUPPORTING GYPSUM WALLBOARD CEILING

NOTE: The required modulus of elasticity, E, in 1,000,000 psi is shown below each span.

DESIGN CRITERIA

STRENGTH: 15 psf dead load plus 30 psf live load determines required fiber stress.

RAFTERS: Spans are measured along the horizontal projection, and loads are considered as applied on the horizontal projection.

DEFLECTION: For 30 psf live load. Limited to span in inches divided by 180.

MEDIUM OR HIGH SLOPE RAFTERS—30 LB LIVE LOAD
HEAVY ROOF COVERING—NO CEILING LOAD—SLOPE OVER 3 IN 12

GENERAL

Wood may be destroyed by decay fungi; by insects like carpenter ants and termites; and by marine borers in saltwater exposures. Four conditions must exist before these organisms can destroy wood: (1) a free oxygen supply; (2) a moisture level in the wood above the fiber saturation point (20%); (3) a temperature in the range of 50 to 90°F; (4) the presence of a food source, in this case, the wood.

In most indoor environments, where moisture levels are generally low, wood will last for a very long time. In certain indoor environments, however, and in many exterior environments, wood cannot be kept dry or out of the proximity of moisture. Most building codes recognize this by requiring the use of pressure-treated wood or naturally resistant wood species where building components come into contact with concrete, masonry, or exposed soil. This requirement also covers floor joists and crawl space support members within 12 to 18 in. of exposed soil.

DECAY-RESISTANT WOOD

When specifying a wood that will resist decay, the choice is between naturally decay-resistant wood or wood treated with preservatives. The first requires use of the heartwood of naturally decay-resistant woods such as Western red cedar, bald cypress, redwood, and others that contain natural poisons called extractives, which are not palatable to decay-causing organisms. However, not all grades or species of these woods are suitable for some structural situations. Treating wood with preservatives is a process that impregnates wood with chemicals through a pressure-treatment process. Use of nonpressure treatments such as spraying, dipping, and brushing is mostly limited to field treatment of wood during construction or remedial treatment of existing wood in place.

PRESSURE-TREATED WOOD

There are two processes commonly used for pressure treating wood, the full cell and modified full cell processes. In both, the wood is placed in a large, cylindrical tank and the preservative forced under pressure into its cells.

In the modified full-cell process the preservative coats the walls of the wood cells and is absorbed when the process is finished the wood cell cavities are empty of preservatives. Most over-the-counter pressure-treated wood is treated with this process. In the full-cell process, a vacuum is introduced at the beginning to force the air out of the wood cell cavities, which then remain filled with preservative after treatment. The full-cell process is used in most creosote and pentachlorophenol treating for wood used in severe environments, including applications such as utility poles, railroad ties, saltwater piles, and timber bridges. Regardless of which process is used, the wood is generally dried to a 20% moisture content prior to treatment to promote maximum penetration of the preservative.

PENETRATION AND RETENTION OF PRESERVATIVES

Penetration and retention are the two measures that define the effectiveness of preservation methods. Penetration depends on the species of wood and the size of the lumber member being treated. Some species that resist preservative penetration, such as Douglas fir, are incised with small slits to make treatment more effective. Others, such as Southern yellow pine, are easily treated without incisions. While the sapwood of some species is readily penetrated, the heartwood of most resists penetration (although the

heartwood of all species naturally resists decay). While the penetration of preservatives is hard to determine without damaging the wood, retention of the preservative can be measured directly by weighing the wood, stated in terms of pounds (of the chemical retained) per cubic foot (pcf). Retention standards are set by the American Wood Preservers' Association and enforced through chemical analysis of treated wood by an independent third-party agency approved by the American Lumber Standard Committee (ALSC). A quality mark outlining pertinent information can be found on complying wood stock.

PRESERVATIVE TYPES

Three classes of preservatives are in use today: creosote, oil-borne (organic), and waterborne (inorganic).

CREOSOTE is a coal-tar product that is dissolved in a distilled solution or petroleum oil. It is an effective preservative in applications with extreme exposure to decay or insect attack (marine borers in saltwater environments, such as marine piles or bridge timbers). Wood treated with the full-cell process is more effective in these applications, but the creosote may bleed into the surroundings, causing contamination. Most utility poles, freshwater piles, and fenceposts are treated with the empty-cell process, which yields a clean, nonbleeding surface. Creosote-treated products cannot be painted, but epoxy shellac and coal-tar pitch are acceptable sealants. This type of preservative can last from thirty to sixty years. Clean air standards prohibit the use of creosote in many areas.

ORGANIC OIL-BORNE PRESERVATIVES are carried in organic solvents such as liquefied isobutane and are used to treat most softwoods and hardwoods. These preservatives include pentachlorophenol (penta), copper naphthenate, tributyl tin oxide (TBTO), and copper 8-quinolinolate.

Penta extends the service life of wood by twenty to forty years and is used to treat utility poles, fenceposts, and highway timbers. Tinted light to dark brown, penta-treated wood accepts adhesives and finishes reasonably well once the oil medium has evaporated. Polyurethane, shellac, varnish, and latex enamel are effective as sealants. Penta can migrate to the surface of wood, leach into the surrounding soil, and contaminate groundwater. Only slowly does it break down into biodegradable compounds.

Plywood and other wood treated with copper-8-quinolinolate can be used in applications where food is harvested, transported, or stored. The chemical is dissolved in liquid petroleum gas or light hydrocarbon solvents so the surface is clean and free of solvent odor. Consult with the treatment company regarding applicable FDA and USDA acceptances.

INORGANIC WATERBORNE PRESERVATIVES are the most popular and commonly available types used for treating wood. They include chromated copper arsenate (CCA), ammoniacal copper arsenate (ACA), and ammoniacal copper zinc arsenate (ACZA). These preservatives are related chemically and have a lot in common. Chromium holds the other components in the wood and prevents leaching; ammonia helps carry copper, zinc, and arsenic deeper into the wood; arsenic guards against attack by termites and fungi. Southern yellow pine is usually treated with CCA, and Douglas fir and other western woods with ACA and ACZA. The various formulations of CCA vary in the amount of chromium, copper, and arsenic they contain. The oxide form of CCA, type C, is widely preferred for most construction. During the treatment process, CCA is water soluble, but air drying for a few days renders it insoluble. This is

TERMITE PROTECTION DETAILS

because the chromium reacts chemically with the wood permanently bonding itself and the copper and arsenic to the cell walls, preventing leaching during its service life. CCA-treated wood can last up to forty years.

Another waterborne preservative is borax, which has promise due to its effectiveness against fungi and insects and its low-toxicity to people and animals. However, it leaches out when the wood gets wet.

FINISHING OF PRESERVATIVE-TREATED WOOD

Waterborne preservatives are recommended when clean, odorless, and paintable wood products are required. Wood treated with such preservatives may be used indoors if sawdust and construction debris are cleaned up. Painting wood treated with creosote or oil-borne pentachlorophenol is not recommended, as it is difficult to use, requiring extensive care and an aluminum-based paint. Paintable waterborne pentachlorophenol treatments are available. For certain interior applications in commercial, industrial, or farm buildings, creosote- or penta-treated wood may be used if exposed surfaces are sealed with two coats of urethane or epoxy paint or shellac. Guidelines for precautions in these cases are outlined in an EPA-approved consumer information sheet for each preservative treatment.

FASTENERS

CCA, ACA, and ACC are corrosive to uncoated metals. For aboveground construction, hot-dipped or hot-tumbled galvanized steel and stainless steel fasteners are recommended. Joist hangers and framing anchors should also be corrosion resistant. For below-grade construction, such as treated wood foundation systems, types 304 and 316 stainless steel Type H silicon bronze, ETP copper, and monel fasteners are required. Adhesives work well with CCA-treated wood. Phenolresorcinol, resorcinol, and melamine-formaldehyde structural adhesives are used in glulam beams made from treated wood members. On job sites, use adhesives recommended for use with treated wood.

PRECAUTIONS FOR USE AND HANDLING

The chemical formulations used for preservative treatment of wood are registered with the EPA, which has approved guidelines for the use of pressure-treated wood to ensure safe handling and avoid environmental or other health hazards. Some guidelines for use and handling follow:

1. Dispose of treated wood by ordinary trash collection or burial. Treated wood should never be burned in open fires or in stoves, fireplaces, or residential boilers.
2. Avoid frequent inhalation of sawdust from treated wood. Whenever possible, sawing and machining of treated wood should be done outdoors.
3. Avoid frequent or prolonged skin contact with penta- or creosote-treated wood.
4. After handling treated wood products, wash exposed areas thoroughly before eating or drinking.

¹ American Wood Preservers' Association (AWPA) Standards detail plant operating procedures for pressure treatment of wood. These standards include minimum vacuum, pressure, and penetration requirements and maximum steaming parameters. AWWA also details minimum retention requirements, sampling zones for assay and maximum redrying temperature allowances for each preservative, commodity, and wood species. For a copy of the AWWA standards booklet, write to the American

Wood Preservers' Association, P.O. Box 286, Woodstock, MD 21163-0286. For other wood species, contact the relevant organization.

² ACA, ACZA, and CCA are the most commonly available waterborne preservatives. Ammoniacal copper quat (ACQ) is also approved by AWWA as a waterborne preservative for Southern pine, Western hemlock, Hem-fir, and Douglas fir as lumber, timbers, plywood, and fenceposts.

³ Copper naphthenate is also approved by AWWA as an oilborne preservative for specific wood species and applications excluding saltwater use.

⁴ Assay retentions are based on two assay zones—0 to 0.5 in. and 0 to 2.0 in.

⁵ Not recommended where cleanliness and freedom from odor are necessary.

Southern Pine Council; Kenner, Louisiana
American Plywood Association; Tacoma, Washington

GENERAL

Building construction materials are tested for four criteria related to performance during a fire: fire resistance, flame spread, fuel contributed, and smoke developed. Fire resistance is the material's ability to resist burning while retaining its structural integrity. Flame spread measures the rate at which flames travel along the surface of a material. Fuel contributed is a measure of how much combustible matter a material furnishes to a fire. Smoke developed is a measure of the surface burning characteristics of a material.

How fire spreads through wood structures depends on the size and arrangement of wood members and the details that restrict or encourage air movement around them. Larger cross sections take longer to burn. As wood burns, it develops an outer layer of charcoal, which insulates the wood beneath and slows burning. This "char" layer proceeds through the burning wood at an average rate of 1 1/2 in. per hour. Various design strategies can be used to resist fire damage to a wood structure and its spread to adjacent areas, but the most important is to protect the wood members by means of coverings, coatings, or treatments.

FIRE-RETARDANT TREATMENT

Modern fire-retardant treatment (FRT) of wood consists of pressure treatment with aqueous solutions of various organic and inorganic chemicals, followed by kiln drying to reduce moisture content to 19% or less for lumber under 2 in. thick and 15% or less for plywood. All proprietary FRTs must conform to UL classifications. FRT wood is commonly used in plywood sheathing, roof trusses, rafters, floor joists, studs, staging, and shingles and shakes. Fire-retardant chemical combinations include zinc chloride, ammonium sulfates, borax or boric acid, and lesser amounts of sodium dichromate. Ammonium phosphates are no longer used because they cause rapid disintegration of wood.

Fire retardants work when fire-retardant chemicals react with the tars and gases normally produced by burning wood. The resultant carbon char acts as thermal insulation (greater than on untreated wood), slowing the rate of burning. Gases released from the FRT wood are diluted with carbon dioxide and water vapor, lessening the chance of flashback, in which wood gases are ignited by high temperatures and then explode.

FRT STANDARDS AND CLASSIFICATIONS

Interior fire retardants meet Class I ratings, which are required by code for vertical exit ways and special areas. Class II ratings are required for horizontal exit ways, but this rating is rarely reached with untreated wood. FRT lumber and plywood are recognized substitutes for noncombustible materials for insurance purposes. Many codes accept FRT wood products for a variety of applications.

Both the flame spread index and smoke-developed index give numerical scales for a material's fire classification. The flame spread index is the primary test for fire performance, according to ASTM E-84, which mandates a flame spread rating of 25 or less. In the Model Building Codes, flame spread ratings are classified as 0-25 (Class I or A), 26-75 (Class II or B), and 76-200 (Class III or C).

A smoke-developed index of 450 or less is permitted for FRT wood. The UL FR-S listing applies only to treated products with a UL-723 (ASTM E-84) flame and smoke classification not exceeding 25 in a 30-min. test. The classification applies to the species tested and does not pertain to the structures in which the materials are installed.

Fire retardants come in interior and exterior types. Interior fire retardants are used on wood trusses and studs; exterior retardants protect exterior lumber, siding, roof shakes and shingles, and scaffold planking. The latter type offers durable, nonleachable, long-term fire protection in outdoor or moist (relative humidity of 95% or greater) conditions.

Some codes count Class C or Class B FRT shingles and shakes as noncombustible materials. For wood exposed to the weather, specify exterior-type retardants that retain their protective properties under the standard rain test.

Interior Type A wood is appropriate for interior and weather-protected applications with less than 95% relative humidity. In rare instances, when relative humidity is less than 75%, Type B can be specified. Interior Type A is used when a wood with low hygroscopicity (the rate at which the chemical draws moisture from the air) is required.

FRT INTERIOR WOODWORK

Instead of solid lumber, it is often desirable to build members of treated cores clad with untreated veneers 1/32 in. thick or less. Most codes discount this narrow finishing in determining the flame spread index of the wood, permit-

NOTE

Wood shakes and shingles are further classified as class B or C. Rather than stamp each piece, each bundle is tagged with an identification mark.

TYPICAL FIRE-RETARDANT TREATED WOOD IDENTIFICATION MARK

Use of untreated wood in about 10% of the combined wall and ceiling surface area. Sizes and species currently being treated (flame spread index less than 25) include red oak and Western red cedar up to 4/4 and yellow poplar up to 8/4. Color and finishes are affected by FRTs.

FINISHING AND FINISHES

FRT lumber and plywood can be lightly sanded for cosmetic cleaning after treatment. Painting and staining are possible but not always successful, particularly transparent finishes. Test finishes for compatibility before application.

Treated lumber may be end cut, but ripping and extensive surfacing will normally void the UL label. To the extent possible, materials should be pre-cut before treatment, otherwise a wood treater should be consulted. Treated plywood can be cut in either direction without loss of fire protection.

Intumescent coatings are sometimes used to reduce flammability of wood surfaces in both opaque and transparent finishes. Under high heat, these coatings expand or foam, creating an insulating effect that reduces flame spread.

FLAME SPREAD INDEX

NOTE
Adhesive is applied to one surface only.

ADHESIVE APPLICATIONS

RECOMMENDED ADHESIVE BEAD PATTERNS

ADHESIVES SUMMARY

CLASS	FORM	PROPERTIES	TYPICAL USES
Urea resin	Dry powders or liquids; may be blended with melamine or other resins	High strength under both wet and dry conditions; moderately durable under damp conditions; moderate to low resistance to temperatures above 120°F; white or tan color	Hardwood plywood for interior use and furniture; interior particleboard; flush doors; furniture core stock
Phenol resin*	Dry powders or liquids	High strength under both wet and dry conditions; very resistant to moisture and damp conditions; dark red in color	Primary adhesive for exterior softwood plywood and flakeboard
Resorcinol resin and phenol-resorcinol resins	Liquid; hardener supplied separately	High strength under both wet and dry conditions; very resistant to moisture and damp conditions; dark red color	Primary adhesive for laminated timbers and assembly joints to withstand severe service conditions
Polyvinyl acetate resin emulsions	Liquid; ready to use	Generally high strength in dry conditions; low resistance to moisture and elevated temperatures; joints tend to yield under continued stress; white or yellow color	Furniture assembly, flush doors, bonding of plastic laminates, architectural woodworking
Cross-linkable polyvinyl acetate resin emulsions	Similar to polyvinyl acetate resin emulsions but includes a resin capable of forming linkage	Improved resistance to moisture and elevated temperatures; improved long-term performance in moist or wet environment; color varies	Interior and exterior doors, molding and architectural woodworking
Contact adhesives	Typically an elastomer base in organic solvents or water emulsion	Initial joint strength develops immediately upon pressing, increases slowly over a period of weeks; dry strength generally lower than those of conventional woodworking glues; water resistance and resistance to severe conditions variable; color varies	For some nonstructural bonds; high-pressure decorative laminates to substrates. Useful for low-strength metal and some plastic bonding.
Mastics (elastomeric construction adhesives)	Puttylike consistency, synthetic or natural elastomer base, usually in organic solvents	Gap filling; develops strength slowly over several weeks; water resistance and resistance for severe conditions vary; color varies	Lumber and plywood to joists and studs; gypsum board; styrene and urethane foams
Thermoplastic synthetic resins (hot melts)	Solid chunks, pellets, ribbons, rods, or films; solvent-free	Rapid bonding; gap filling; lower strength than conventional woodworking adhesives; minimal penetration; moisture resistant; white to tan color	Edge banding of panels; films and paper overlays
Epoxy resins	Chemical polymers, usually in two parts, both liquid; completely reactive, no solvents	Good adhesion to metals, glass, certain plastics, and wood products; permanence in wood joints not adequately established; gap-filling	Used in combination with other resins for bonding metals, plastics, and materials other than wood; fabrication of cold-molded wood panels
Protein glues (casein and hide)	Dry powders or reconstituted liquid	Bonds extremely well to wood; moisture resistant	Interior applications; laminating beam

*Most types used in the U.S. are alkaline-catalyzed. The general statements refer to this type.

Data: Adapted from Table 100-G-12, *Architectural Woodwork Quality Standards* (6th ed., version 1.1, 1994)

GENERAL

Adhesives have been used for bonding wood for centuries, but until the 1930s they were limited to only a few naturally derived substances—those based on animal or vegetable proteins, gums, or resins. Stepped-up materials research efforts during World War II spurred the development of synthetic adhesives for bonding metals, concrete, glass, rubber, plastics, and wood.

Many of these synthetic adhesives are used to manufacture products such as plywood, oriented-strand board (OSB), and laminated timbers. They can also be used during construction to attach plywood subfloors to floor joists, adhere ceramic tiles to floors or walls, attach drywall, and the like. In addition to their structural use, adhesives also can be used to eliminate squeaks in floors and for some mechanical fastening.

Adhesives are composed of a base component, dispersion medium, and various additives that impart specific properties. The elastomeric base of a construction-type adhesive accounts for 30 to 50% of its weight. Depending on its

intended application, this base is made of natural rubber (isoprene) or synthetic rubbers such as neoprene, butyl, polyurethane, polysulfide, nitrile, styrene-butadiene, or butadiene acrylonitrile. Additives include tackifiers, flow and extrusion modifiers, curing agents, antioxidants, and fillers. Together, the base and the additives are dispersed (or dissolved) in a liquid, typically an organic solvent or water.

Currently, most adhesives use organic solvents, but water-based adhesives are gaining in popularity because they do not emit harmful vapors, are easy to clean up, and can be discarded as regular trash. During the specification process, disposal of the containers from organic solvents must be considered. Many jurisdictions are enacting clean air statutes in which organic solvents are targeted as air pollutants. In addition, organic solvents can have adverse effects on the workers who apply them as well as future building occupants. One drawback to most water-based adhesives is that they tend only to resist water, while the solvent-based adhesives are waterproof.

CONSTRUCTION ADHESIVES

Construction adhesives are defined as elastomer-based extrudable mastics, which means that the main adhesive component is elastic and will continue to maintain some of its flexibility indefinitely. Mastics are a type of adhesive with high viscosity, or resistance to flow. A construction adhesive is a substance capable of holding materials together by surface attachment.

Adhesives used for building have been formulated to tolerate many of the often adverse conditions that exist at most job sites, such as extreme temperatures and temperature fluctuations. They are excellent for filling gaps, and thus work on both smooth and rough surfaces. Because they form bond lines up to 1/4 in. thick, they can bridge gaps between ill-fitting pieces. The degree of adhesion depends on the surface conditions of the materials; ice, dirt, grease, or other contaminants will all have a negative effect.

Many of the characteristics of modern adhesives are described in the table. Note that most adhere to wood, but performance depends on careful consideration of physical and chemical compatibility of glue and wood, processing requirements, mechanical properties, and durability under design conditions.

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

GENERAL NOTES

1. Nails are made of many materials for diverse uses. When selecting nails, follow the recommendation of the manufacturer of the material to be fastened, as well as building codes when applicable.
2. Select nails so as to avoid galvanic action between the nail and the nailed material.
3. Select nail head size according to the strength and area of the material to be held.
4. In wood framing the correct size and number of nails must be used at any given point to withstand stress. Procedures for calculating nailed connections can be found in National Design Specifications for Wood Construction (Washington: National Forest Products Association [American Forest and Paper Association]).
5. Base nail selection on the type(s) of wood or other materials to be assembled, joined, or connected.
6. Nails with serrated or helically threaded shanks have increased holding power. Such nails are difficult, if not impossible, to remove without destroying the surrounding material.
7. Where nails are exposed to moisture or weather, for example, in exterior stucco lath, use nonferrous (aluminum or zinc-coated) nails.
8. Choose nails for automatic nailing equipment specifically for the equipment used. See ANSI "Safety Requirements for Power Actuated Fastening Systems" and OSHA regulations.

COMMON NAIL SIZES

LENGTH	PENNY	GAUGE	DIA. OF HEAD (IN.)	NAILS/LB
1	2	15	¹¹ / ₆₄	847
1 1/4	3	14	¹³ / ₆₄	543

ROUGH CONSTRUCTION

NAME	SHAPE	MATERIAL	FINISH
COMMON		Steel or aluminum	Smooth
ANNULAR		Steel, hardened steel, copper, brass, bronze, silicon bronze, nickel silver, aluminum, monel, or stainless steel	Bright, hardened
HELICAL			
COMMON CUT STRIKE		Steel or iron	Bright or zinc-coated
DOUBLE-HEADED		Steel	Bright or zinc-coated
		Aluminum	Bright
SQUARE		Steel	Smooth, bright, zinc-coated
ROUND WIRE			
ANNULAR		Aluminum	Bright or hard

ROOFING

NAME	SHAPE	MATERIAL	FINISH
SIDING & SHINGLE		Steel, copper, or aluminum	Smooth, bright, zinc- or cement-coated
ROOFING (BARBED)		Steel or aluminum	
ROOFING		Steel	Bright or zinc-coated
NONLEAKING ROOFING			
SHINGLE NAIL		Steel or cut iron	Plain or zinc-coated
CUT SLATING (NONFERROUS)		Copper, muntz metal, or zinc	
GUTTER SPIKE (ROUND)		Steel	Bright or zinc-coated
GUTTER SPIKE (ANNULAR)		Copper	Bright

FINISH WORK

NAME	SHAPE	MATERIAL	FINISH
WALLBOARD		Steel or aluminum	Smooth, bright, blued, or cement-coated
FINE NAIL		Steel	Bright
LATH			Blued or cement-coated
LATH		Steel or aluminum	Smooth, bright, blued, or cement-coated
CASING OR BRAD			Bright or cement-coated
FINISHING		Steel	Smooth

MISCELLANEOUS

NAME	SHAPE	MATERIAL	FINISH
CEMENT		Steel	Smooth, bright, or oil-quenched
CEMENT (FLUTED HELICAL)			Hardened
OFFSET (LATH)			Bright, blued, or zinc-coated
HOOKED (LATH)			
STAPLE			

Charles F. D. Egbert, AIA; Architect: Washington, D.C.

NOTE: For tying unnotched 2x rafters to top wall plates; for uplift and lateral load resistance.

TWO-SIDED RAFTER TIE

NOTE: Ties one or two top plates to notched rafters for tension cord connections.

ONE-SIDED RAFTER TIES

NOTE: Ties notched rafter to stud on same plane as rafter for tension load connection.

RAFTER-TO-STUD TIE

NOTE: Ties stud to bottom plate for tension load connection.

STUD TIE

STRAP: For tying varied tension load connections, e.g., joists at ridge, wall-to-floor connections, etc.

T- AND L-STRAPS: For varied vertical to horizontal connections.

TIES

NOTES

1. For utmost rigidity, strength, and service, each type of fastener requires joint designs adapted to wood strength along and across the grain and to dimensional changes that may occur with variations in moisture content.
2. For forces such as wind uplift and lateral loads (wind and earthquake), the foundation, floor-to-floor, and roof connections are the main areas of concern, although, in varying degrees, all connections taken together will resist

TRUSS ANCHOR
NOTE: Provides tension for wood-to-wood or wood-to-masonry connections for wood trusses and joists.

TRUSS ANCHORS

NOTE: Provides floor-to-floor tension connection; for nailed or bolted connections.

FLOOR TIE ANCHOR

NOTE: Transfers tension loads between floors; ties studs/posts to foundation.

METAL HOLD-DOWN/UPLIFT ANCHOR

NOTE: Anchors sill plate to concrete or CMU foundation wall and/or studs.

SILL PLATE ANCHORS/SIDE INSTALLATION

NOTE: Anchors sill plate to concrete or CMU foundation wall.

SILL PLATE ANCHORS/CENTERLINE INSTALLATION

ANCHORS

- these forces. In some joints, the fastener or connector is the only resistor to the applied load.
3. Most fasteners used to join wood framing or to attach metal connectors to framing are made of steel, with a hot-dipped galvanized coating the most typical finish used. Stainless steel, or finishes such as a corrosion-resistant primer or a copolymer coating, can also be used. In the presence of moisture, metals used for nails

NOTE: Anchors sill plate and stud to concrete or CMU foundation wall.

METAL HOLD-DOWN/UPLIFT STRAP

POST CAP AND BASE
POST CAP/BASE: For varied post cap or base connections.
COLUMN BASE
COLUMN BASE: Attaches wood post to concrete embedment to resist high uplift loads.

COLUMN CAPS AND BASES

NOTE: Joist connector (in wide variety of sizes).

JOIST HANGERS

FRAMING ANCHOR
FRAMING ANCHOR: For varied wood-to-wood two-way connections; optional bendable extensions allow three-way connections.

BACK-UP CLIP
BACK-UP CLIP: To provide back-up support for gypsum board in lieu of wood framing; can save wood material.

NOTE: Anchors sill plate to concrete or CMU foundation wall.

Z-CLIP
Z-CLIP: Secures 2x blocking between joists and/or trusses.

METAL ANGLE
METAL ANGLE: Provides varied wood-to-wood or wood-to-concrete anchorage.

ROOF TRUSS CLIP
ROOF TRUSS CLIP: Provides alignment control between roof truss and nonbearing walls; slot permits load-induced truss movement.

VARIOUS CLIPS AND ANCHORS

and other fasteners may corrode when in contact with material treated with certain preservatives. Fasteners made of hot-dipped galvanized steel, copper, silicon bronze, and 304 and 316 stainless steel have performed well in wood treated with ammoniacal copper arsenate (ACA) and chromated copper arsenate (CCA), the most common preservatives for wood. Of course, provision should always be made to avoid galvanic action between dissimilar metals.

Richard J. Vitullo, AIA: Oak Leaf Studio; Crownsville, Maryland

Length intervals = 1/8 in. increments up to 1 in., 1/4 in. increments from 1 1/4 in. to 4 in., 1/2 in. increments from 4 1/2 in. to 6 in.

Length intervals = 1/4 in. increments up to 6 in., 1/2 in. increments from 6 1/2 in. to 12 in., 1 in. increments over 12 in.

Length intervals = 1/2 in. increments up to 8 in., 1 in. increments over 8 in.

Self-locking nuts have a pin that acts as a ratchet, sliding down the thread as the bolt is tightened, to prevent loosening from shock and vibration.

The bolt's clamping force causes protrusions on the washer to flatten partially, closing the gap between the washer and the bolt head. Measurement of the gap indicates whether the bolt has been tightened adequately.

NUTS

Fiberglass nuts and bolts are noncorrosive and nonconductive. Bolts are available in 3/8 in., 1/2 in., 5/8 in., 3/4 in., and 1 in. standard diameters.

FIBERGLASS NUTS AND BOLTS

Interference body bolts are driven into reamed or drilled holes to create a joint in full bearing.

INTERFERENCE BODY BOLTS

High tension, stainless steel helical inserts are held in place by spring-like pressure, and they are used to salvage damaged threads. They also eliminate thread failure due to stress conditions.

HELICAL INSERTS

NOTES

1. Bent bolts are specialty items made to order.
2. D = bolt diameter; C = inside opening width; T = thread length; L = inside length of bolt; A = inside depth.

Timothy B. McDonald; Washington, D.C.

BLIND RIVETS FOR USE IN A JOINT THAT IS ACCESSIBLE FROM ONLY ONE SIDE

RIVETS
STANDARD RIVETS AVAILABLE WITH SOLID, TUBULAR AND SPLIT SHANKS OF STEEL, BRASS, COPPER, ALUMINUM, MONEL METAL AND STAINLESS STEEL; IN DIAMETERS OF 1/8" TO 7/16" AND LENGTHS OF 3/16" TO 4 IN.

Self-drilling fasteners: used to attach metal to metal, wood, and concrete. Consult manufacturer for sizes and drilling capabilities.

SELF-DRILLING FASTENERS

Set Screws: headless with socket or slotted top; made in sizes 4 in. to 1/2 in., and in lengths 1/2 in. to 5 in. Square head sizes 1/4 in. to 1 in., and lengths 1/2 in. to 5 in.

SET SCREWS

SHEET METAL GIMLET POINT
Sheet metal gimlet point: hardened, self-tapping. Used in 28 gauge to 6 gauge sheet metal; aluminum, plastic, slate, etc. Usual head types.

SHEET METAL BLUNT POINT
Sheet metal blunt point: hardened, self-tapping. Used in 28 to 18 gauge sheet metal. Made in sizes 4 to 14 in usual head types.

THREAD CUTTING- CUTTING SLOT
Thread cutting, cutting slot: hardened. Used in metals up to 1/4 in. thick in sizes 4 in. to 5/16 in. in usual head types.

6 WOOD AND PLASTIC FASTENINGS

PLATFORM FRAMING

NOTES

WESTERN OR PLATFORM FRAMING

Before any of the superstructure is erected, the first floor subflooring is put down making a platform on which the walls and partitions can be assembled and tilted into place. The process is repeated for each story of the building. This framing system is used frequently.

FIRESTOPPING

All concealed spaces in framing, with the exception of areas around flues and chimneys, are to be fitted with 2 in. blocking arranged to prevent drafts between spaces.

EXTERIOR WALL FRAMING

One story buildings: 2 x 4's, 16 in. or 24 in. o.c.;
2 x 6's, 24 in. o.c.
Two and three stories: 2 x 4's, 16 in. o.c.;
2 x 6's, 24 in. o.c.

BRACING EXTERIOR WALLS

Because floor framing and wall frames do not interlock, adequate sheathing must act as bracing and provide the necessary lateral resistance. Where required for additional stiffness or bracing, 1 x 4's may be let into outer face of studs at 45° angle secured at top, bottom, and to studs.

BRIDGING FOR FLOOR JOISTS

May be omitted when flooring is nailed adequately to joist; however, where nominal depth-to-thickness ratio of joists exceeds 6, bridging would be installed at 8 ft. 0 in. intervals. Building codes may allow omission of bridging under certain conditions.

Steel bridging is available. Some types do not require nails.

Timothy B. McDonald; Washington, D.C.

NOTE

1. Geotextile material may be used under and around drainage layers and backfill if soil conditions warrant.
2. Stud size and spacing vary with material grade and back-

fill depth. In general, 42 in. backfill requires 2 x 4 at 12 in. o.c., 64 in. requires 2 x 6 at 16 in. o.c., and 84 in. requires 2 x 6 at 12 in. o.c.

TYPICAL BASEMENT WALL

BUILT-UP PERIMETER BEAM AT STAIRS

INTRODUCTION

The construction of treated wood foundations is similar to the construction of standard wood light-frame walls except for two factors: (1) the wood used is pressure treated with wood preservatives, and (2) the extra loading and stress requirements caused by below-grade conditions must be accommodated in the design and detailing of the fasteners, connections, blocking, wall corners, and the like.

As with standard masonry or concrete foundation systems, treated wood foundations require a good drainage system in order to maintain dry basements and crawl spaces. However, the drainage system typically used with treated wood foundations is different from that used with masonry or concrete systems. The components of a drainage system suitable for use with a treated wood foundation are

1. A highly porous backfill material, which directs water down to a granular drainage layer.
2. A porous granular drainage layer under the entire foundation and floor system to collect and discharge water.
3. Positive discharge of water by means of a sump system designed for the soil type. This drainage system, developed for treated wood foundations, takes the place of the typical porous backfill over a perimeter drain tile.

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland
American Forest & Paper Association; Washington, D.C.

CRAWL SPACE WALL

MINIMUM SOIL COVER ON SHALLOW FOOTINGS

BASEMENT WALL WITH EXTERIOR KNEE WALL

NOTE

For less than 48 in. backfill, use standard framing methods and fasten stairwell header to top plate with three 10d toenails.

STAIR OPENING AT PERIMETER WALL

NOTES

1. Characteristics of a treated wood foundation system:
 - a. All framing is standard 2x construction.
 - b. Can be erected in any weather and when site access for concrete or masonry is a problem.
 - c. Deep wall cavities allow use of high R-value insulation without loss of interior space.
 - d. Wiring and finishing are easily achieved.
2. Treated wood foundations are not appropriate for all sites. Selection of the proper foundation system for a project depends on site conditions, including soil types, drainage conditions, ground water, and other factors. Wet sites in low areas, especially areas with coarse-grained soil, should be avoided if a full basement is desired, although a crawl space-type foundation can be used in these cases. Consult a soils engineer to determine the viability of any foundation system.
3. Lumber and plywood used in treated wood foundations must be grade-stamped for foundation use and are typically pressure treated with chromated copper arsenate. Treated wood products used in foundation construction are required to contain more preservative than treated wood used in applications such as fencing and decking. Codes generally call for hot-dipped galvanized fasteners above grade and stainless steel fasteners below grade.

4. Avoid skin contact and prolonged or frequent inhalation of sawdust when handling or working with any pressure-treated wood product.
5. Consult applicable building codes and the American Forest & Paper Association's "Permanent Wood Foundation System—Design, Fabrication, Installation Manual" for requirements and design guidelines. In the early stages of a project, consult with the building code officials for the area or jurisdiction to assess their familiarity with and willingness to approve this type of system.
6. The vertical and horizontal edge-to-edge joints of all plywood panels used in these systems should be sealed with a suitable sealant. Consult the American Plywood Association Source List "Caulks and Adhesives for Permanent Wood Foundation System, Form H405" for a list of high-performance caulking compounds.
7. Correct materials and details of construction are very important for treated wood foundations. If the contractor to be used for the installation is unfamiliar with this foundation system, the design should include the use of pre-fabricated foundation panels. Most problems with treated wood foundations can be traced to improper installation by inexperienced workers.
8. Since this type of foundation system depends especially on the first floor deck to absorb and distribute any backfill loads, backfilling cannot occur until the first floor deck is complete.

NOTES

1. At an outside corner, soil pressures tend to force the wall sections together, making reinforcement unnecessary.
2. Three studs should be used at the corner to support interior finishes.

OUTSIDE CORNER DETAILS

DETAIL 1

DETAIL 2

DETAIL 3

- NOTES**
1. At inside corners, soil pressures tend to force the wall panels apart, making additional structural reinforcement necessary.
 2. Detail no. 1 provides the required additional reinforcement with a treated plywood splice plate and additional nailing below grade.

INSIDE CORNER DETAILS

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland
American Forest & Paper Association; Washington, D.C.

NOTES

1. Joists to be butted end to end over pressure-treated wood sleepers.
2. Floor stiffness will be increased by blocking between every joist above each sleeper.

WOOD SLEEPER FLOOR SYSTEM

SUSPENDED WOOD FLOOR

NOTES

1. Fasteners and connector plates transfer soil pressure thrust from wall sheathing and studs to floor system; type and amount of fasteners and connectors depend on height of backfill.
2. Wind uplift anchor straps and anchor nails spaced as required by code.

WALL ANCHORAGE DETAIL

OUTSIDE CORNER PROTECTION DETAIL

NOTE

All wood members within 18 in. of the ground should be bottom treated.

MAIN BEAMS AND COLUMNS

NOTES

1. For backfill heights up to 4 ft 6 in. and if width of opening is 4 ft 0 in. to 5 ft 6 in., use double sill plates and double full-length wall studs.
2. For backfill heights up to 4 ft 6 in. and if width of opening is 6 ft 0 in. to 9 ft 0 in., use triple sill plates and triple full-length wall studs.
3. For backfill heights of 48 in. or less, nailing and fastening can conform to the appropriate building code.
4. For backfill heights greater than 4 ft 6 in. or openings wider than 9 ft 0 in., contact engineer for design.

SHEAR WALL ANCHORAGE

SHEAR WALLS AS RACKING RESISTANCE

Foundation walls may be subject to racking loads, which occur parallel to a wall and can cause shearing forces along the plane of the wall. Racking loads are caused by soil pressure and other lateral forces such as earthquake and wind. Walls, connections, and fasteners must be designed to resist these forces. Generally, soil pressure comes into play for backfill greater than 24 in. in height; check anticipated wind and earthquake forces to determine how best to accommodate them.

Check long shear walls or those with a length-to-width ratio greater than 2:1 for diaphragm deflection, particularly if the structure is built on a slope. The unequal heights of the backfill on a slope apply unequal loads to the end walls or walls parallel to the floor joist system. These walls, having received these loads by the diaphragm action of the floor system, then act as shear walls. Internal shear walls, accommodated within interior partitions, also may be needed.

The strength of a diaphragm or shear wall depends on careful nailing of the plywood to the structural members. Plywood joints should be staggered to increase stiffness.

LINTELS FOR WIDE OPENINGS

WINDOW OPENING

NOTES

1. Steel lintels are selected from steel beam design tables on the basis of floor, wall, and roof openings.
2. Wood lintels over openings in bearing walls may be engineered as beams.
3. Composite beams, such as glued laminated beams, also are appropriate in some applications. Plywood box beams are used for garage doors. Steel flitch plates can add strength without adding extra width to a composite beam.
4. Check with local codes and standards for fire resistance requirements.

INSULATED WALL DETAILS

IN-LINE FRAMING

IN-LINE FRAMING WITH WIDE OPENING

REDUCED SILL PLATE AND RIM JOIST DETAILS

NOTES

1. Some framing details rely on techniques that reduce the amount of lumber in wood construction. Among these are in-line framing details and corner details with metal framing clips for gypsum board. These types of details were developed to conserve wood resources, reduce material cost and job-site waste, and enhance energy efficiency by reducing thermal bridging across wall systems and increasing insulation cavities. When wood levels are to be reduced, a structural engineer should first be consulted.
2. Gypsum board installed at inside corners with metal clips or wood backers does not get fastened to either. The sheet resting against the backer or clips is installed first so the second sheet (which is nailed to the stud) will lock the first sheet in place. The "floating joint" that results is recommended to reduce cracks in the corner.

REDUCED WOOD FRAMING DETAILS

ROOF DIAPHRAGM PERIMETER

TIES BETWEEN FLOORS

NOTE

It is essential to provide a continuous path of resistance from roof to foundation in order to dissipate both lateral and uplift forces. Connections along this load path will guarantee uninterrupted resistance. Seismic and wind forces are transferred from the roof diaphragm to shear walls and through the walls into the ground at the foundation. Shear walls resist horizontal forces in the roof and floor diaphragms and so must be connected to them. It is important to apply wall sheathing to the full wall height, nailing it to the top plate, blocking, or rim joist and also to the mud sill or bottom plate. Shear wall height/width ratios are an important consideration; consult a structural engineer for their design. The details illustrated show several connection paths; for each specific design, a structural engineer familiar with seismic and wind resistant construction should be consulted. Many of the requirements for high wind situations apply to seismic loading as well, except in shear wall design.

Ties between floors: Wood members (studs) must be sized for the load-carrying capacity at the critical net section.

GENERAL

In the 16th and 17th centuries half timber structures were built with strong timber foundations, supports, and studs. The spaces between the framework were filled in with either stone, brick, plaster, or boarding laid horizontally. Today the primary structure is wood stud or masonry backup, and the half timber construction is attached as veneer. Half timber is an inherently leaky type of wall construction in which the timbers are subject to premature decay.

TYPICAL INTERMEDIATE PANEL SPLINE DETAILS

GENERAL

Structural building panels are factory-assembled composite panels ready for installation as a complete structural and/or insulating wall section. The material of each component of the panel system is very important when selecting a panel manufacturer. Components include the skin, foam core, adhesive, and optional exterior or interior finish. The application for which the panel is intended determines the materials used. Consult manufacturers for specifications.

Sizes vary from 4 by 8 ft panels weighing about 100 lb to 8 by 28 ft panels that must be installed using a crane.

PANEL TYPES

There are two main types of structural building panels—stress-skin panels and foam core panels:

STRESS-SKIN PANELS are manufactured by gluing and nailing plywood skins to both sides of a wood frame, resulting in a unit that performs like an I-beam. Stress-skin panels are not necessarily insulated.

STRUCTURAL FOAM CORE PANELS fall into two groups: sandwich panels and unfaced panels. Sandwich panels are rigid-foam panels faced with two structural-grade skins, usually made of oriented-strand board (OSB) or plywood. Depending on the application and the manufacturer, these foam core panels may or may not include framing members within the core. Unfaced structural foam core panels look like panels of stick-framing with rigid foam between the members instead of fiberglass batt insulation. Interior and exterior finishes are applied to these panels in the field.

The skins of structural building panels (like I-beam flanges) resist tension and compression, while the wood frame or core (like an I-beam web) resists shear and prevents buckling of the skins.

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

ROOF FRAMING WITH RAFTERS AND TRUSSES

ROOF FRAMING WITH RIDGE BEAM

TYPICAL CORNER DETAIL

All structural foam core panels are insulated with a core of expanded polystyrene (EPS), extruded polystyrene, or urethane foam, from 3 1/2 to 11 1/4 in. thick. Urethane panels are either glue-laminated like polystyrene or foamed in place (either in the factory or in the field). Urethane has an R-value of 6 or 7 per inch versus R-5 for extruded polystyrene and R-4 for EPS foam. Urethane is about twice as strong in compression as polystyrene and has a perm rating of less than one, which technically qualifies it as a vapor barrier. EPS has a perm rating of from 1 to 3 and may require a vapor barrier. EPS, however, is inert, nontoxic (if ingested), and resilient; it doesn't feed microorganisms and is generally cheaper than urethane. Consult manufacturers on CFC and formaldehyde content in the foam core and skin material as it varies among manufacturers. Regarding flammability of both foam core types, consult with the manufacturer about the individual product.

APPLICATIONS

In above-grade applications, the most common materials for exterior facings are plywood OSB or finish materials like T-111 plywood, tongue-and-groove pine, and other wood siding material. For below-grade situations, pressure-treated plywood skins and splines are used. Generally, structural building panels should not be used for plumbing walls, as the spaces needed for plumbing runs would compromise the insulation and structural integrity of the panel.

For roof applications it is best to use a vented structural foam panel, either integral or field-installed. Many asphalt-shingle manufacturers will not warrant their product when it is installed on unvented panels because of overheating, which accelerates deterioration.

NOTE
Consult local codes for all electrical installations.

TYPICAL WIRE CHASE LOCATIONS IN PANELS

TYPICAL WINDOW DETAILS

TYPICAL REINFORCED DOOR OPENING DETAIL

CHARACTERISTICS

Using structural building panels generally enhances the speed of construction because the panels replace three different steps in standard construction: framing, sheathing, and insulation. Panel systems offer superior energy performance compared to a stick-frame house of similar cost and standard of construction. This is largely because the rigid insulation has higher R-values, there are fewer seams to seal, and conductive heat is not lost through air infiltration around the framing. Structural building panels also offer good resistance to lateral loads.

Panels can be susceptible to infestation by insects such as carpenter ants and termites, which eat through wood and tunnel through the foam core material, reducing insulation value and even compromising structural integrity. Use of termite shields, foam cores treated with insect repellent, and other strategies should be considered.

NOTES

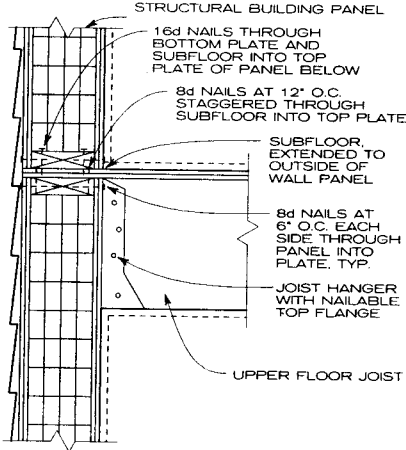

1. Since structural building panels are a relatively new building system, code officials should be consulted early and often to prevent any misunderstandings or delays in the code approval process. Also, check with manufacturers to determine whether their product has received compliance approval with BOCA, ICBO, SBCCI, or HUD.
2. The seams are the part of a structural building panel system most prone to infiltration and weakness and most likely to show the results of expansion and contraction. Tight spline connections with sealant at all edges—top, bottom, and sides—can greatly increase thermal efficiency.

SIMPLE FRAMING: This illustration shows the "positive" or downward bending that occurs in conventional framing with simple spans.

CANTILEVERED FRAMING: This illustration shows the combination of "positive" (downward) and "negative" (upward) bending that occurs with beams spliced at quarterpoint producing supported beam and cantilevered beam. The two types of bending counterbalance each other, which produces more uniform stresses each other, and uses material more efficiently. In-line joists simplify plywood subflooring.

MOMENT SPLICE: Compression stress is taken in bearing on the wood through a steel compression plate. Tension is taken across the splice by means of steel straps and shear plates. Side plates and straps are used to hold sides and tops of members in position. Shear is taken by shear plates in end grain. Bolts and shear plates are used as design and construction considerations require.

TYPICAL TIMBER FRAME (SHOWING TWO ROOF AND FLOOR TYPES)

GENERAL

Timber frame buildings are characterized by large, exposed timber structural members. The distinction between timber framing and other types of heavy timber construction is somewhat subjective, but in a true timber frame, the posts, beams, and braces are connected to one another with elegant, largely all-wood joints based on very old traditions. Sound timber frame construction requires high standards of design, engineering, and workmanship. It can be compared to the craftsmanship of cabinetmaking, rather than to conventional wood frame construction.

One of the reasons timber frame construction faded from popularity around 1900, after centuries of dominance, was the cost of its labor-intensive building methods. During the past twenty years, techniques have been developed that offset this drawback: the frame can be prefabricated in shops with heavy tools, and structural, insulated wall panels can be used to build the walls. Connection details in true timber frame construction are still rooted in the ancient wood-pegged, mortise-and-tenon joint. More modern wood connectors of steel can be used, depending on budget and aesthetics, but many would say the resulting structure would not be a true timber frame.

Typically, posts in timber-framed buildings are spaced in a grid, 8 to 16 ft apart. These relatively large posts support beams, girts, connectors, plates, and principal rafters. In turn, those members support rafters, purlins, summer beams, and joists, which are spaced at 2 to 6 ft centers. The relatively large timbers make timber frame construction inherently fire resistant, qualifying as Class IV construction under most building codes.

The walls and roof in a timber frame, freed of the task of supporting great loads, can be made of materials that need to function only as a rain screen and curtain walls. These materials are attached to the outside of the larger, struc-

tural members, enclosing the space while exposing the timbers to the interior and protecting the frame from deterioration.

Nonstructural foam-core panels with an exterior layer of wood sheathing, a foam core, and an interior drywall finish layer are extremely energy efficient and cost-effective for use in wall and roof construction in a timber frame. Sometimes it is preferable to use structural foam-core panels, with oriented-strand board (OSB) or plywood sheathing on both sides, as they better resist warping and lateral forces and provide a better nailing surface for attaching interior trim, cabinets, artwork, etc. These structural panels are typically installed outside a layer of gypsum board that is back-screwed to the inner OSB skin.

ANATOMY OF A TIMBER FRAME BUILDING

In the design process, the general layout of timbers is determined first, based on the rough program and layout of spaces. Once the wood species has been selected, each timber is sized individually. Next, the connection details, or joinery, and the embellishments and finishes are designed.

A typical timber frame can be divided into four major systems: walls, floors, roof, and bents. Walls, in the terminology of timber framing, are planar compositions of timbers parallel to the ridge. Bents run perpendicular to the walls and are often the primary preassembled sections of the building. Usually, bents include the principal structural posts of the frame and the major supporting rafters. The space between two bents is called a bay and is generally between 10 and 16 ft wide. If the roof structure is not included in the bent system, a large timber plate is set at the top of the bent or wall for the roof framing to rest on.

TIMBER FRAME ROOF TYPES

ROOF SYSTEMS

More than any other factor, the arrangement of timbers in the roof determines whether the walls or the bents will be the principal structural unit. Frames are often defined by the type of roof they support, since the roof is usually the most difficult aspect of the frame to design, detail, and erect. The choice of roof system most appropriate to a particular building depends on the shape and pitch of the roof, the loading, wood species, available timber length, floor plan, and personal aesthetic preferences.

NOTES

1. Wood shrinks considerably across the grain but very little along the grain, and all dimensions based on sections through plates and sills must account for this shrinkage. Bents that connect principal rafters directly to the posts and are not interrupted by plates will have negligible differential movement between roof and wall joints.
2. Timber systems that rely on full-length plates, sills, ridgepoles, or tie beams tend to require timbers of considerable length, which are scarce. Therefore, these long lengths must be assembled from shorter members tied together with scarf joints. Since most sawmills cannot obtain timbers longer than 30 ft, it is important to consult with a structural engineer and local sawmill to determine the most practical dimensions for the timbers before the design is completed.
3. Depending on budget or aesthetic priorities, hybrid systems can be devised, such as timber frame walls with conventional roof framing or conventional stud walls with a timber frame roof. Consult a structural engineer about the design, detailing, and integration of these systems.

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland
Tedd Benson and Ben Brungraber, Ph.D., PE; Benson Woodworking Co., Inc.; Alstead, New Hampshire

NOTE

For basic structural rigidity within a timber frame, the knee brace is a critical component. It is typically used between the upper ends of vertical posts and horizontal beams, but may also be used at the base of a post or to brace an inclined member, such as a rafter. Rigidity in a frame can be achieved by using a few well-placed long braces or several shorter braces. Braces typically should not be shorter than half the length of the beam-to-beam span of the post.

KNEE BRACE

NOTE

The basic mortise-and-tenon joint can be very effective in resisting both tension and compression forces. To increase tensile strength, increase the depth and thickness of the tenon and use additional pegs if the width and length of the tenon allow.

BASIC MORTISE-AND-TENON JOINT

NOTE

A beveled shoulder or housed joint is used to connect all load-bearing beams, such as bent and connecting girts and summer beams, to posts. Angled variations can be used when principal rafters join to posts or for diagonal braces. The depth of the shoulder depends on loading, torsion, other joinery in the area, and wood species.

SHOULDERED MORTISE-AND-TENON JOINTS

TUSK AND SOFFIT TENON JOINTS

DOVETAIL MORTISE AND TENON

RAFTER JOINT

OPEN MORTISE-AND-TENON JOINTS

LAP JOINTS

WOOD JOINERY

Most timber framing joints are variations on the mortise and tenon, in which a tongue on one timber is received by a slot in the other and locked with rounded pegs driven through holes drilled through both parts of the joint. The simplest version of this joint is used in compression situations or for situations with minimal loading. Knee braces and collar ties generally use an angled variation.

Spline joints are similar to a mortise and tenon, except that a third member, called a spline or "free tenon" (usually hardwood), is introduced to connect between mortised timbers and to serve as the tie. Spline joints are an effective way to achieve minimum end and edge distances without being dependent on the size and capacity of the receiving post or beam.

FOUR-WAY SPLINE JOINT

SINGLE SPLINE JOINT

NOTE

Using through-splines made of hardwood leaves all the pegs loaded parallel to the grain, with plenty of available end-grain distance, and avoids loaded edges in the posts. Spline edges often are left prominent to achieve a decorative effect.

SPLINE JOINTS

NOTE

A tying joint is a combination of joints used to connect several members. The intersection of a principal post, a plate, a tie beam, and a rafter is known as a tying joint.

TYING JOINT

ELEVATION

NOTE

Scarf joints are lap joints used to splice two or more shorter timbers into one long timber. Although there are many variations, scarf joints are used primarily for plates and sills that demand long continuous timber.

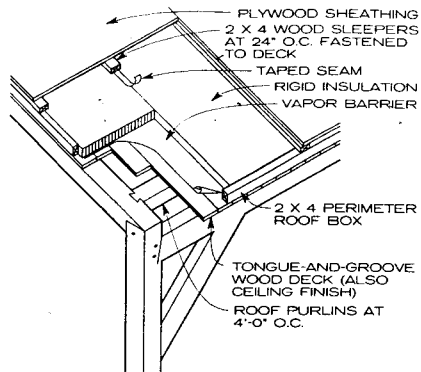

SCARF JOINT

Lap joints, such as simple overlaps or dovetails, constitute the other broad category of joints used in timber frames. Scarfs, used to splice timbers along their length, are variations of the lap joint.

Joints are chosen on the basis of the tasks they are to fulfill, including locking the frame together, bearing weight, and transferring forces and building loads from one timber to another.

Compound joinery, such as where two timber valley rafters meet at a purlin, is one of the difficult aspects of timber framing. The complex geometry and the precision required demand master-level craftsmanship.

NOTES

1. Pole embedment depth depends on soil, slope and seismic zone.
2. Cross-bracing between poles may be required to resist lateral loads if shallow embedment. Treat all exposed surfaces with approved pressure treatment.
3. Pole notching for major beams can help align beams and walls that otherwise would be out of plumb due to pole warp. Notching improves bearing of major beams but weakens poles.
4. Roofs, walls and floors should be insulated to suit local climatic conditions. Wall and soffit insulation should meet continuously at the joint. Penetration of insulation should be minimal.
5. Various siding types can be used.
6. Dapping is a U.S. carpentry term for cutting wood to receive timber connectors.

POLE CONSTRUCTION

Timothy B. McDonald; Washington, D.C.

GENERAL

Residential log buildings have become a significant part of the home construction industry. The log house industry comprises two main segments: manufactured, or milled, houses built from kits and custom-built log houses. Houses built from kits use logs that have been machined or milled to a uniform shape in a variety of profiles. Although kit-built houses can be put together quickly and with few construction skills, the finished product tends to look artificial. Custom-built log houses are produced from hand-peeled, hand-hewn logs in their natural profile. These houses more closely resemble a traditional log structure. Kits for hand-hewn houses are also available, but their reconstruction on site is often complicated because of longer log lengths and the heavier weight of the logs. A hydraulic crane is usually required. Many building officials require a structural engineer's approval to accompany the plans, whether the log house company generates these plans or an architect hired by the owner.

NOTES

1. Hewing logs square removes most of the sapwood, which reduces the weight of the log and its susceptibility to insect damage and rot. The flat surfaces of square logs are also easy to work with.
2. Damage from rot (fungal decay) can be prevented or controlled in several ways: remove sapwood, which is high in cellulose and lignum on which fungi feed; reduce the log's moisture content to 20% or less by air or kiln drying; or provide proper air circulation under floors and around foundations. Generous roof overhangs and properly maintained gutters help keep water off the sides of the building.
3. Insect damage from termites, beetles, and carpenter ants can be prevented by properly seasoning the wood (kiln or air drying) and by providing continuous vapor barriers under ground floors. Also, good air circulation can help prevent infestations.
4. Exposed interior logs must be coordinated carefully with placement of plumbing, electrical wiring, and mechanical equipment.
5. Good drainage around the building is important, since log buildings are susceptible to rot.
6. Manufacturers of prefabricated log structures offer milled log details to reduce air leakage and improve weatherability of the wall. Such details include tongue-and-groove joints, dovetailing use of steep splines, and butyl gaskets.
7. Spaces between individual logs (chink area) are filled with chinking, which can vary from less than an inch to three or more inches in width.

ROOF STRUCTURE—DETAILS

ROOFS

The roof system on a log house should be carefully thought-out. Since many log houses are built in areas of high snow loading, log roof systems are more complex than those in conventionally framed structures. Although log roof members are desirable from an aesthetic standpoint, engineered values for logs are difficult to obtain because the logs are not graded. It is therefore necessary to build a structural roof of engineered materials over the log roof, resulting in, essentially, two structural roofs. The engineered roof can be buried in the insulation or cold roof space, but doing this adds considerably to the cost of the structure. Log or timber framed trusses can be used to support purlins (and produce a dramatic visual effect), but this is also an expensive alternative.

ADJUSTABLE BASE USING SHIMS

ADJUSTABLE POST BASE IN CRAWL SPACE APPLICATION MITIGATION OF SETTLING—DETAILS

NOTE

Shrinkage varies according to the moisture content of the logs and the humidity level at the building site.

WALL SETTLING IN LOG CONSTRUCTION

SETTLING DETAILS

Log movement and settling caused by shrinkage can be a significant problem in log construction. The problem can be mitigated through careful detailing.

Shrinkage problems are more prevalent in custom-built houses, which use full round logs, than in manufactured or milled log structures because the latter use kiln-dried logs. Although custom log companies keep shrinkage to a minimum by using dead standing trees, the moisture content usually is still higher than in kiln-dried logs.

Arthur Thiede: Log Homes Connect; Hailey, Idaho

NOTE

Clear spans for glued-laminated longitudinal beams are from 20 to 100 ft. For sawn lumber beams, clear spans can

be made up to 25 ft. Wood species used are generally Douglas fir-larch or Southern pine.

TYPICAL LONGITUDINAL BEAM BRIDGE

NOTE

Clear spans for glued-laminated decks are approximately 35 ft.

TYPICAL LONGITUDINAL DECK SUPERSTRUCTURE

INTRODUCTION

Although wood was probably the first material used to construct a bridge, in the 20th century concrete and steel have become the major bridge construction materials. Wood is still widely used for short- and medium-span bridges. The strength, light weight, and energy absorption properties of timber make it a desirable material for bridge construction. Timber can carry short-term overloads without adverse effects. Large wood members are fire resistive, impervious to continuous freezing and thawing, and resist the harmful effects of de-icing agents.

In modern applications, the life of timber bridges is extended to forty years or longer through the use of preservative-treated wood, which requires little or no maintenance. The specifications and standards for the preservative treatment of wood maintained by the American Wood Preservers Association (AWPA) are the most widely used and comprehensive documents covering treatment procedures for sawn lumber, glued-laminated timber (glulam), piling, and poles used for timber bridges.

STRUCTURAL CHARACTERISTICS

All timber bridges consist of two basic components—the superstructure and the substructure. The superstructure is the framework of the bridge span and includes the deck, floor system, main supporting members, railings, and other incidental components. The five basic types of superstructure are beam, deck (slab), truss, arch, and suspension. The substructure is the portion of the bridge that transmits loads from the superstructure to the supporting rock or soil. Timber substructures include abutments and bents. Abutments support the two bridge ends, while bents provide intermediate support for multiple-span crossings.

TIMBER SUPERSTRUCTURES

LONGITUDINAL BEAM (in bridge design, the longitude is measured in the direction of traffic flow): The simplest and

most common timber bridge superstructure, the longitudinal beam type consists of a deck system supported by a series of timber beams between two or more supports. Beams are constructed from logs, sawn lumber, glued-laminated timber (glulam), or laminated veneer lumber (LVL).

LONGITUDINAL DECK: Longitudinal deck or slab superstructures are constructed of glulam, nail-laminated sawn lumber, or stress-laminated lumber decks placed longitudinally between supports, with the wide dimension of the lamination vertical. In this type of superstructure, the deck is designed to resist all applied loads and deflection without additional supporting members or beams. Nonetheless, transverse distributor beams are usually attached to the underside of the deck to help distribute the load. Maximum clear spans are approximately 35 ft.

TRUSS: Trusses are structural frames consisting of straight members connected to form a series of triangles. Trusses can span distances of up to 250 ft. In bridge applications, a typical truss superstructure consists of two main trusses, a floor system, and bracing. This type is classified as a deck truss (in which the deck is at or above the level of the top chord) or a through truss (in which the deck is near the bottom chord). When the height of a through truss is insufficient for overhead bracing, it is called a half-through or pony truss. Timber trusses are constructed in many geometric configurations, but two of the most popular are the bowstring truss and parallel chord truss.

ARCH: Arches used in clear span timber bridge construction have glued-laminated timbers for the main members. This type of superstructure, called a glulam deck arch, probably best shows the versatility of glulam in bridge construction. The glulam arches are manufactured in segmental, circular, or parabolic shapes. Two basic arch types are used: the two-hinge arch (for short spans of 80 ft or less) and the three-hinge arch (for long spans of between 80 and 200 ft). The roadway for deck arch bridges is supported by glulam

LONGITUDINAL DECK DETAILS

NOTE

T-section may be preferable over box section for long spans because of ease of inspection and maintenance.

TYPICAL STRESS-LAMINATED TIMBER SUPERSTRUCTURES

post bents connected to the arches with steel gusset plates. Use of this design is most practical when considerable height is required and when foundations can be constructed to resist horizontal end reactions. It is particularly suitable for deep crossings because long clear spans result in substantial substructure cost savings.

SUSPENSION: Timber suspension bridges consist of a timber deck structure suspended from flexible steel cables or chains supported by timber towers. This superstructure type is capable of spanning clear distances of more than 500 ft and is normally used only when span requirements make other bridge types impractical or when it is not feasible to use intermediate bents.

TIMBER SUBSTRUCTURES

ABUTMENTS: Abutments support the bridge ends and contain roadway embankment material. The simplest timber abutment is a sawn lumber or glulam spread footing placed directly on the surface of the embankment if foundation materials permit. Another type is the post abutment, in which the superstructure is supported on sawn lumber or glulam posts connected to a spread footing. Pile abutments may be used if soils cannot hold footings.

BENTS: Bents are intermediate supports between abutments used for multiple-span bridges. They are made from timber piles or sawn lumber frames, depending on height requirements and soil conditions.

GENERAL DESIGN CRITERIA

For design criteria and specifications for timber bridges, refer to the current edition of the American Association of State Highway and Transportation Officials (AASHTO) Standard Specifications for Highway Bridges and "Timber Bridges: Design, Construction, Inspection, and Maintenance," U.S. Department of Agriculture, August 1992.

NOTES

1. Includes West Coast and eastern hemlocks.
2. Includes western and northeastern pines.
3. Categories refer to semitransparent oil base stain.
4. Use pressure preservative treated material only. All materials below deck surfaces should be pressure treated.

WALKWAYS AND RAMPS

STEPS AND STAIRS

POSTS AND FOOTINGS

FASTENERS

1. Use hot-dipped galvanized fasteners to avoid corrosion and staining.
2. To reduce board splitting by nailing: blunt nail points; pre-drill (3/4 of nail diameter); stagger nailing; place nails no closer to edge than one-half of board thickness.
3. Avoid end grain nailing and toenailing if possible.
4. Use flat washers under heads of lag screws and bolts, and under nuts.
5. Hot-dipped galvanized casing nails or stainless steel deck screws are best decking fasteners.
6. Plated ring shank or spiral groove shank nails are suitable for arid climates.

MOISTURE PROTECTION

1. All wood members should be protected from weather by pressure treatment or field application of preservatives, stains, or paints.
2. All wood in direct contact with soil and concrete must be pressure treated.
3. Bottoms of posts on piers should be 6 in. above grade.
4. Sterilize or cover soil with membrane to keep plant growth away from wood members so as to minimize moisture exchange.
5. Treat all ends, cuts, holes, etc. with preservative before placement.
6. Decking and flat trim boards, 2 x 6 and wider, should be kerfed on the underside with 3/4 in. deep saw cuts at 1 in. o.c. to prevent cupping.
7. Avoid horizontal exposure of end grain or provide adequate protection by flashing or sealing. Avoid or minimize joint situations where moisture may be trapped by using spacers and/or flashing, caulking, sealant, or plastic roofing cement.

SHOP FABRICATED

LOW DECK EDGES

LOW DECK EDGES

CONSTRUCTION

1. WOOD SELECTION: Usual requirements are good decay resistance, nonsplintering, fair stiffness, strength, hardness, and warp resistance. Selection varies according to local climate and structure.
2. BRACING: On large decks, or decks where post heights exceed 5 ft, lateral stability should be achieved with horizontal bracing (metal or wood diagonal ties on top or bottom of joists, or diagonal application of decking) in combination with vertical bracing (rigid bolted or gusseted connections at tops of posts, knee bracing, or cross bracing between posts), and/or connection to a braced building wall. Lateral stability should be checked by a structural engineer.

The Bumgardner Architects; Seattle, Washington
Mark J. Mazz, AIA; CEA, Inc.; Hyattsville, Maryland

APA TRADEMARKS

GRADE DESIGNATIONS

Structural panel grades are generally identified in terms of the veneer grade used on the face and back of the panel (e.g., A-B, B-C, etc.) or rated by a name suggesting the panel's intended end use (e.g., APA-rated Sheathing, APA-rated Sturd-I-Floor, etc.).

VENEER GRADES

Veneer grades define veneer appearance in terms of natural unprepared growth characteristics and the number and size of repairs allowable during manufacture. The highest quality veneer grades are N and A. The minimum grade of veneer permitted in Exterior plywood is C-grade. D-grade veneer is used only for backs and inner plies of panels intended for interior use or applications protected from exposure to permanent or severe moisture.

- N—Smooth surface "natural finish" veneer. Select, all heartwood or all sapwood. Free of open defects. Allows not more than 6 repairs, wood only, per 4 x 8 panel, made parallel to grain and well matched for grain and color.
- A—Smooth, paintable. Not more than 18 neatly made repairs, boat, sled, or router type, parallel to grain permitted. May be used for natural finish in less demanding applications. Synthetic repairs permitted.
- B—Solid surface. Shims, circular repair plugs, and tight knots to 1 in. across grain permitted. Some minor splits and synthetic repairs permitted.
- C—PLUGGED—Improved C-grade veneer with splits limited to 1/2 in. width, knotholes and borer holes limited to 1/4 x 1/2 in. Admits some broken grain. Synthetic repairs permitted.
- C—Tight knots to 1 1/2 in. Knotholes to 1 in. across grain and some to 1 1/2 in. if total width of knots and knotholes is within specified limits. Synthetic or wood repairs. Discoloration and sanding defects that do not impair strength permitted. Limited splits allowed. Stitching permitted.
- D—Knots and knotholes to 2 1/2 in. width across grain and 1/2 in. larger within specified limits. Limited splits allowed. Stitching permitted. Limited to interior and Exposure 1 panels.

SPAN RATINGS

APA-rated Sheathing, APA-rated Sturd-I-Floor, and APA-rated Siding carry numbers in their trademarks called span ratings. These denote the maximum recommended center-to-center spacing in inches of supports for the panels in construction applications. Except for APA-rated Siding panels, the span rating in the trademark applies when the long panel dimension is across supports, unless the strength axis is otherwise identified. The span rating in the trademark of rated Siding panels applies when installed vertically.

The span rating in APA-rated Sheathing trademarks appears as two numbers separated by a slash, such as 32/16, 48/14, etc. (An exception is APA-rated Sheathing intended for use on walls only. The trademarks for these contain a single number similar to the span rating for APA-rated Siding.) The left-hand number denotes the maximum recommended spacing of supports when the panel is used for roof sheathing with the long dimension or strength axis of the panel across three or more supports. The right-hand number indicates the maximum recommended spacing of supports when the panel is used for subflooring with the long dimension or strength axis of the panel across three or more supports. A panel marked 32/16, for example, may be used for roof decking over supports 32 in. o.c. or for subflooring over supports 16 in. o.c.

The span ratings in the trademarks on APA-rated Sturd-I-Floor and Siding panels appear as a single number. APA-rated Sturd-I-Floor panels are designed specifically for single-floor (combined subfloor underlayment) applications under carpet and pad and are manufactured with span ratings of 16, 20, 24, 32, and 48 in. The span ratings for APA-rated Sturd-I-Floor panels, like those for APA-rated Sheathing, are based on application of the panel with the long dimension or strength axis across three or more supports.

APA-rated Siding is available with span ratings of 16 and 24 in. Span-rated panels and lap siding may be applied direct to studs or over nonstructural wall sheathing (Sturd-I-Wall construction), or over nailable panel or lumber sheathing (double wall construction). Panels and lap siding with a span rating of 16 in. may be applied direct to studs spaced 16 in. o.c. Panels and lap siding bearing a span rating of 24 in. may be applied direct to studs 24 in. o.c. All rated siding panels may be applied horizontally direct to studs 16 or 24 in. o.c., provided horizontal joints are blocked. When used over nailable structural sheathing, the span rating of rated siding panels refers to the maximum recommended spacing of vertical rows of nails rather than to stud spacing.

GROUP NUMBER

Plywood can be manufactured from more than 70 species of wood. These species are divided, on the basis of bending strength and stiffness, into five groups under U.S. Product Standard PS 1-83. Strongest species are in Group 1, the next strongest in Group 2, and so on. The group number that appears in the trademark on some APA trademarked panels—primarily sanded grades—is based on the species of face and back veneers. Where face and back veneers are not from the same species group, the higher group number is used, except for sanded and decorative panels 3/8 in. thick or less. These are identified by face species because they are chosen primarily for appearance and used in applications where structural integrity is not critical. Sanded panels greater than 3/8 in. are identified by face species if C or D grade backs are at least 3/8 in. and are no more than one species group number larger. Some species are used widely in plywood manufacture, others rarely. Check local availability before specifying if a particular species is desired.

CLASSIFICATION

GROUP 1	GROUP 2		GROUP 3	GROUP 4	GROUP 5
Apitong	Cedar,	Hemlock,	Alder, Red	Aspen,	Basswood
Beech, American	Port	Western	Birch, Paper	Bigtooth	Poplar,
Birch,	Oxford	Maple, Black	Cedar, Alaska	Quaking	Balsam
Sweet	Cypress	Mengkulang	Fir, Subalpine	Catwo	
Yellow	Douglas	Meranti,	Hemlock,	Cedar,	
Douglas Fir No. 1 ^a	Fir No. 2 ^a	Red ^b	Eastern	Incense	
Kapur	Fir,	Mersawa	Maple,	Western Red	
Keruing	Balsam	Pine,	Bigleaf	Cottonwood,	
Larch, Western	California	Pond	Pine,	Eastern	
Maple, Sugar	Red	Red	Jack	Black	
Pine,	Grand	Virginia	Lodgepole	(Western	
Caribbean	Noble	Western	Ponderosa	Poplar)	
Ocote	Pacific Silver	White	Spruce	Pine,	
Pine, Southern	White	Spruce,	Redwood	Eastern	
Loblolly	Lauan,	Black	Spruce,	White	
Longleaf	Almon	Red	Engelmann	Sugar	
Shortleaf	Bagtikan	Sitka	White		
Slash	Mayapis	Sweetgum			
Tanoak	Red	Tamarac			
	Tangile	Yellow-Poplar			
	White				

NOTES

- a. Douglas Fir from trees grown in the states of Washington, Oregon, California, Idaho, Montana, and Wyoming and the Canadian provinces of Alberta and British Columbia shall be classed as Douglas Fir No. 1. Douglas Fir from trees grown in the states of Nevada, Utah, Colorado, Arizona, and New Mexico shall be classed as Douglas Fir No. 2.
- b. Red Meranti shall be limited to species having a specific gravity of 0.41 or more based on green volume and oven dry weight.

Bloodgood, Sharp, Buster Architects and Planners; Des Moines, Iowa
American Plywood Association; Tacoma, Washington

APA-RATED SIDING PANELS

For exterior siding, fencing, etc. Can be manufactured as conventional veneered plywood, as a composite, or as an overlaid oriented strand board siding. Both panel and lap siding available. Special surface treatment such as V-groove, shallow channel groove, deep groove (such as APA Texture 1-11), kerfed groove, brushed, rough-sawn, and texture-embossed (MDO). Span Rating (stud spacing for siding qualified for APA Sturd-I-Wall applications) and face grade classification (for veneer-faced siding) indicated in trademark Exposure Durability Classification: Exterior. Common thicknesses: 1/32, 3/8, 1/2, 5/8, 3/4.

303-PLYWOOD SIDING FACE GRADES

CLASS	GRADE	WOOD PATCHES	SYNTHETIC PATCHES
Special Series 303	303-OC ^{2,3}	Not permitted	Not permitted
	303-OL ⁴	Not applicable for overlays	
	303-NR ⁵	Not permitted	Not permitted
303-6	303-SR ⁶	Not permitted	Permitted as natural defect shape only
	303-6-W	Limit 6	Not permitted
303-18	303-6-S	Not permitted	Limit 6
	303-6-S/W	Limit 6 - any combination	
	303-18-W	Limit 18	Not permitted
303-30	303-18-S	Not permitted	Limit 18
	303-18-S/W	Limit 18 - any combination	
	303-30-W	Limit 30	Not permitted
303-30-S	303-30-S	Not permitted	Limit 30
	303-30-S/W	Limit 30 - any combination	

NOTES

1. Limitations on grade characteristics are based on 4 x 8 ft panel size. Limits on other sizes vary in proportion. All panels except 303-NR allow restricted minor repairs such as shims. These and such other face appearance characteristics as knots, knotholes, splits, etc., are limited by both size and number in accordance with panel grades. 303 OC being most restrictive and 303-30 being least. Multiple repairs are permitted only on 303-18 and 303-30 panels. Patch size is restricted on all panel grades. For additional information, including finishing recommendations, see APA Product Guide: 303 Plywood Siding, E300.
2. Check local availability.
3. "Clear"
4. "Overlaid" (e.g., Medium Density Overlay siding)
5. "Natural Rustic"
6. "Synthetic Rustic"

APA TEXTURE 1-11

Special 303-Siding panel with grooves 1/4 in. deep, 3/8 in. wide, spaced 4 or 8 in. o.c. Other spacings may be available on special order. Edges shiplapped. Available unsanded, textured, and other surfaces. Exposure Classification: Exterior. Thicknesses: 1/32 and 5/8 only.

APA SANDED AND TOUCH-SANDED PANELS (3,4,6)

APA A-A

Use where appearance of both sides is important for interior applications such as built-ins, cabinets, furniture, partitions; and exterior applications such as fences, signs, boats, shipping containers, tanks, ducts, etc. Smooth surfaces suitable for painting. Exposure Durability Classification: Interior, Exposure 1, Exterior. Common thicknesses: 1/4, 3/8, 1/2, 5/8, 3/4.

APA A-B

For use where appearance of one side is less important but where two solid surfaces are necessary Exposure Durability Classification: Interior, Exposure 1, Exterior. Common thicknesses: 1/4, 3/8, 1/2, 5/8, 3/4.

APA A-C

For use where appearance of only one side is important in exterior applications, e.g., soffits, fences, structural uses, boxcar and truck linings, farm buildings, tanks, trays, commercial refrigerators, etc. Exposure Durability Classification: Exterior. Common thicknesses: 1/4, 3/8, 1/2, 5/8, 3/4.

APA A-D

For use where appearance of only one side is important in interior applications, e.g., paneling, built-ins, shelving, partitions, etc. Exposure Durability Classification: Interior, Exposure 1. Common thicknesses: 1/4, 3/8, 1/2, 5/8, 3/4.

APA B-B

Utility panels with two solid sides. Exposure Durability Classification: Interior, Exposure 1, Exterior. Common thicknesses: 1/4, 3/8, 1/2, 5/8, 3/4.

APA B-C

Utility panel for farm service and work buildings, boxcar and truck linings, containers, tanks, agricultural equipment, as a base for exterior coatings and other exterior uses. Exposure Durability Classification: Exterior. Common thicknesses: 1/4, 3/8, 1/2, 5/8, 3/4.

APA B-D

Utility panel for backing, sides of built-ins, industry shelving, slip sheets, separator boards, bins, and other interior or protected applications. Exposure Durability Classification: Interior, Exposure 1. Common thicknesses: 1/4, 3/8, 1/2, 5/8, 3/4.

APA UNDERLAYMENT

For application over structural subfloor. Provides smooth surface for application of carpet and pad and has high concentrated and impact load resistance. Touch-sanded. Exposure Durability Classification: Interior, Exposure 1. Common thicknesses: 3/8, 1/2, 5/8, 3/4, 1 1/2.

APA C-C PLUGGED

For use as underlayment over structural subfloor, refrigerated or controlled atmosphere storage rooms, pallet bins, tanks, truck floors, linings and other exterior applications. Touch-sanded. Exposure Durability Classification: Exterior. Common thicknesses: 3/8, 1/2, 5/8, 3/4, 1 1/2.

APA C-D PLUGGED

For open soffits, built-ins, cable reels, walkways, separator boards, and other interior or protected applications. Not a substitute for underlayment or APA-rated Sturd-I-Floor as it lacks puncture resistance. Exposure Durability Classification: Interior, Exposure 1. Common thicknesses: 3/8, 1/2, 5/8, 3/4, 1 1/2.

APA SPECIALTY PANELS

APA DECORATIVE

Rough-sawn, brushed, grooved, or other faces. For paneling, interior accent walls, built-ins, counter facing, exhibit displays. Can also be made by some manufacturers in Exterior for siding, gable ends, fences, etc. Use recommendations for exterior panels vary with the particular product; check with manufacturer. Exposure Durability Classification: Interior, Exposure 1. Exterior. Common thicknesses: 5/16, 3/8, 1/2, 5/8.

APA HIGH-DENSITY OVERLAY (HDO)

Has a hard semi-opaque resin-fiber overlay both sides. Abrasion-resistant. For concrete forms, cabinets, countertops, signs, tanks. Also available with skid-resistant screen-grid surface. Exposure Durability Classification: Exterior. Common thicknesses: 3/8, 1/2, 5/8, 3/4.

APA MEDIUM-DENSITY OVERLAY (MDO)

Smooth, opaque, resin-fiber overlay one or both sides. Ideal base for paint, indoors and outdoors. Available as a 303 Siding. Exposure Durability Classification: Exterior. Common thicknesses: 1 1/2, 3/8, 1/2, 5/8, 3/4, 1 1/2, 1 3/2, 2 1/2.

APA MARINE

Ideal for boat hulls. Made only with Douglas fir or western larch. Special solid-jointed core construction. Subject to special limitations on core gaps and face repairs. Also available with HDO or MDO faces. Exposure Durability Classification: Exterior. Common thicknesses: 1/4, 3/8, 1/2, 5/8, 3/4.

APA B-B PLYFORM CLASS I AND II

Concrete form grades with high reuse factor. Sanded both sides and mill-oiled unless otherwise specified. Special restrictions on species. Class I panels are stiffest, strongest, and most commonly available. Also available in HDO for very smooth concrete finish, in Structural I (all plies limited to Group 1 species), and with special overlays. Exposure Durability Classification: Exterior. Common thicknesses: 1 1/2, 5/8, 3/4.

APA PLYRON

Hardboard face on both sides. Faces tempered, untempered, smooth, or screened. For countertops, shelving, cabinet doors, flooring, etc. Exposure Durability Classification: Interior, Exposure 1, Exterior. Common thicknesses: 1/2, 5/8, 3/4.

APA PERFORMANCE-RATED PANELS (1,2)

APA-RATED SHEATHING

Specially designed for subflooring and wall and roof sheathing. Also good for broad range of other construction and industrial applications. Can be manufactured as a conventional veneered plywood, as a composite, or as a non-veneered panel. For special engineered applications, veneered panels conforming to PS1 may be required. Exposure Durability Classification: Exterior, Exposure 1, Exposure 2. Common thicknesses: 5/16, 3/8, 1/2, 5/8, 3/4, 1 1/2, 1 3/2, 2 1/2.

APA STRUCTURAL I AND II RATED SHEATHING

Unsanded all-veneer PS1 plywood grades for use where strength is of maximum importance; for box beams, gusset plates, stressed-skin panels, containers, pallet bins. Structural I is more commonly available. Exposure Durability Classification: Exterior, Exposure 1. Common thicknesses: 5/16, 3/8, 1/2, 5/8, 3/4, 1 1/2, 1 3/2, 2 1/2.

APA-RATED STURD-I-FLOOR

Specially designed as combination subfloor-underlayment. Provides smooth surface for application of carpet and pad and possesses high concentrated and load impact resistance. Can be manufactured as a nonveneered panel. Available square-edged or tongue-and-grooved. Exposure Durability Classification: Exterior, Exposure 1, Exposure 2. Common thicknesses: 1 1/2, 5/8, 3/4.

APA-RATED STURD-I-FLOOR 48 OC (2-4-1)

For combination subfloor-underlayment on 32- and 48-inch spans and for heavy timber roof construction. Manufactured only as conventional veneered plywood. Available square-edged or tongue-and-grooved. Exposure Durability Classification: Exposure 1. Thickness: 1 1/2.

NOTES FOR SANDED AND PERFORMANCE-RATED PANELS

1. Specify performance-rated panels by thickness and span rating. Span ratings are based on panel strength and stiffness. Since these properties are a function of panel composition and configuration as well as thickness, the same span rating may appear on panels of different thickness. Conversely, panels of the same thickness may be marked with different span ratings.
2. All plies in Structural I panels are limited to Group 1 species. Structural II panels are seldom available.
3. Exterior sanded panels, C-C Plugged, C-D Plugged, and Underlayment grades can also be manufactured in Structural I (all plies limited to Group 1 species).
4. Some manufacturers also produce panels with premium N-grade veneer on one or both faces. Available only by special order.
5. Can also be manufactured in Structural I (all plies limited to Group 1 species).
6. Also available in 1 1/2, 1 3/2, 1 1/2, 2 1/2 in. thicknesses.

Bloodgood, Sharp, Buster Architects and Planners; Des Moines, Iowa
American Plywood Association; Tacoma, Washington

NOTES—EXTERIOR AND INTERIOR PANELS

- ¹ Available in Group 1, 2, 3, 4, or 5 unless otherwise noted.
- ² Standard 4 x 8 panel sizes; other sizes available.
- ³ Also available in Structural I.
- ⁴ Maximum recommended support spacing for roofs and floors is indicated in sheathing and single layer floor trademarks. Wall span ratings are included in rated siding panels.
- ⁵ Exposure 2 allowed but not typically produced.
- ⁶ Special improved grade for structural panels.
- ⁷ Special construction to resist indentation from concentrated loads.
- ⁸ Interior type panels with exterior glue are identified as Exposure I.
- ⁹ Also available as nonveneer or composite panels.

FIBERBOARD SHEATHING

NOTE
Nail siding through gypsum board to studs; refer to manufacturer's recommendations for specific installation instructions.

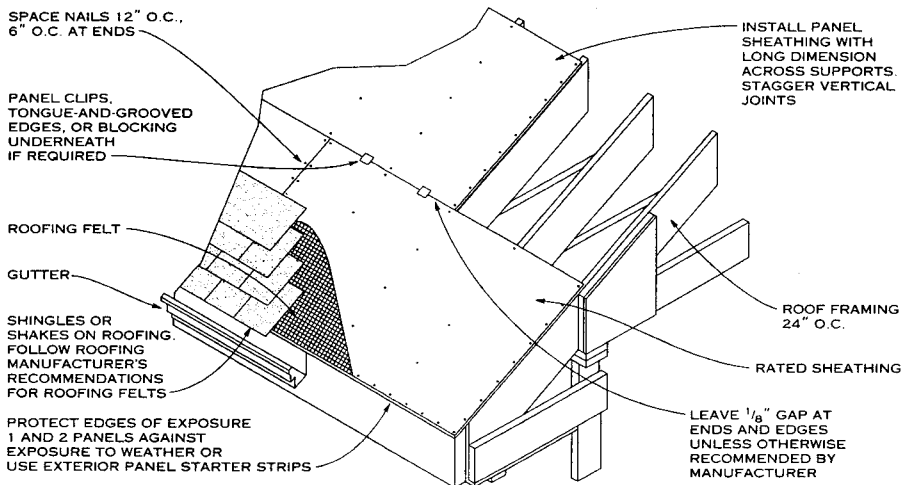

GYPHUM BOARD SHEATHING

RIGID INSULATION SHEATHING

STRUCTURAL WALL SHEATHING

NOTE
Cover roof sheathing as soon as possible with roofing felt for extra protection from moisture before roofing is applied.

STRUCTURAL ROOF SHEATHING

SHEATHING MATERIALS

CHARACTERISTICS	STRUCTURAL SHEATHING	GYPHUM	FIBERBOARD	PLASTIC
Available base	Yes	No	Only high-density	No
Vapor barrier	No	No	If asphalt-treated	Yes
Insulation R value (1/2 in. thickness)	1.2	0.7	2.6	Varies with manufacturer
Corner bracing provided	yes	Yes (see manufacturer's recommendations)	Only high-density	No
Panel sizes (ft, except plastic in in.)	4 x 8, 4 x 9, 4 x 10	2 x 8, 4 x 8, 4 x 10, 4 x 12, 4 x 14	4 x 8, 4 x 9, 4 x 10, 4 x 12	16 x 96, 24 x 48, 224 x 96, 48 x 96, 48 x 108
Panel thickness (in.)	5/16, 3/8, 7/16, 1/2, 19/32, 5/8, 23/32, 3/4, 7/8, 1, 1 1/8	1/4, 3/8, 1/2, 5/8	1/2, 25/32	1/2 to 6 (for roof)
Other remarks	Plywood grades commonly used for roof and wall sheathing have span ratings of 12/0, 16/0, 20/0, 24/0, 24/16, 32/16, 40/20, and 48/24; exposure durability classifications are Exposure 1 and Exterior. For unsupported edges, refer to manufacturer's recommendations.	Fire-rated panels are available in 1/2 and 5/8 in. thicknesses.	Also called insulation board. Can be treated or impregnated with asphalt. Available in regular and high-density panels.	Considered an effective vapor barrier, so walls must be well vented. Some products emit toxic fumes when burned; refer to manufacturer's specifications.

David S. Collins, FAIA; American Forest & Paper Association; Cincinnati, Ohio

APA RATED STURD-I-FLOOR

SPAN RATING (MAXIMUM JOIST SPACING, IN.)	PANEL THICKNESS (IN.)	NAIL SIZE AND TYPE	FASTENING			
			GLUE/ NAILED	NAILED ONLY	GLUE/ NAILED	NAILED ONLY
			SPACING (IN.)			
			PANEL EDGE	INTERMEDIATE		
16	¹⁹ / ₃₂ , ⁵ / ₈ , ²¹ / ₃₂	6d ring or screw shank ³	12	6	12	12
20	¹⁹ / ₃₂ , ⁵ / ₈ , ²³ / ₃₂ , ³ / ₄	6d ring or screw shank ³	12	6	12	12
24	¹¹ / ₁₆ , ²³ / ₃₂ , ³ / ₄	6d ring or screw shank ³	12	6	12	12
48	1 ¹ / ₈	8d ring or screw shank ⁴	6	6		

- NOTES**
- For conditions not listed, see APA literature.
 - Use only APA Specification AFG-01 adhesives, properly applied. Use only solvent based glues on nonveneered panels with sealed surfaces and edges.
 - 8d common nails may be substituted if ring or screw-shank nails are not available.
 - 10d common nails may be substituted with 1¹/₈ in. panels if supports are well seasoned.
 - Space nails 6 in. for 48 in. spans and 12 in. for 32 in. spans.

UNDERLAYMENT NAILING SCHEDULE

Use 3d ring shank nails for underlayment up to 1/2 in. thickness, 4d for 19/32 in. and thicker. Use 16 gauge staples, except that 18 gauge may be used with 1/4 in. thick underlayment. Crown width should be 3/8 in. for 16 gauge staples, 2/16 in. for 18 gauge. Length should be sufficient to penetrate subflooring at least 5/8 in. or extend completely through. Space fasteners at 3 in. along panel edges and 6 in. each way in the panel interior, except for 1 1/2 in. or thicker underlayment applied with ring shank nails. In this case, use 6 in. spacing along edges and 8 in. spacing each way in the panel interior. Unless subfloor and joists are of thoroughly seasoned material and have remained dry during construction, countersink nail heads below surface of the underlayment just prior to laying finish floors to avoid nail popping. Space joints 1/32 in. If thin resilient flooring is to be applied, fill and thoroughly sand joints.

APA PANEL SUBFLOORING¹

PANEL SPAN RATING (OR GROUP NUMBER)	PANEL THICKNESS (IN.)	MAXIMUM SPACING ^{2,3,5} (IN.)
24/16	⁷ / ₁₆ , 1/2	16
32/16	¹⁵ / ₃₂ , 1/2, ⁵ / ₈ , ²³ / ₃₂	16 ⁴
40/20	¹⁹ / ₃₂ , ⁵ / ₈ , ²³ / ₃₂ , ³ / ₄	20 ⁴
48/24	²³ / ₃₂ , ³ / ₄ , 1 ¹ / ₈	24
1 ¹ / ₈ in., Groups 1 and 2	1 ¹ / ₈	48

- NOTES**
- Applies to APA rated sheathing grades only.
 - The spans assume plywood continuous over two or more spans with long dimension across supports.
 - In some nonresidential buildings, special conditions may require construction in excess of minimums given.
 - May be 24 in. if 3/4 in. wood strip flooring is installed at right angles to joists.
 - Spans are limited to the values shown because of the possible effect of concentrated loads.

SUBFLOORING NAILING SCHEDULE

For 7/16 in. panel, use 6d common nails at 6 in. o.c. at panel edges, 12 in. o.c. at intermediate supports. For 19/32 to 1/8 in. panels, use 8d common nails at 6 in. o.c. at panel edges, 12 in. o.c. at intermediate supports. For 1 1/8 and 1 1/4 in. panels up to 48 in. span, use 10d common nails 6 in. o.c. at panel edges and 6 in. o.c. at intermediate supports.

PLYWOOD UNDERLAYMENT¹

PLYWOOD GRADES AND SPECIES GROUP	APPLICATION	MIN. PLYWOOD THICKNESS (IN.)
Groups 1, 2, 3, 4, and 5 UNDERLAYMENT INT-APA (with interior or exterior glue), or UNDERLAYMENT EXT-APA (C-C plugged) EXT	Over smooth subfloor	1/4
	Over lumber subfloor or other uneven surfaces	1 1/32
Same grades as above, but Group 1 only	Over lumber floor up to 4 in. wide. Face grain must be perpendicular to boards	1/4

- NOTES**
- For tile, carpeting, sheet goods, or other nonstructural flooring (consult Tile Council of America for recommendations regarding ceramic tile).
 - Where floors may be subject to unusual moisture conditions, use panels with exterior glue (Exposure 1) or UNDERLAYMENT C-C Plugged EXT-APA. C-D Plugged is not an adequate substitute for underlayment grade, since it does not ensure equivalent dent resistance.
 - Recommended grades have a solid surface backed with a special inner ply construction that resists punch-through and dents from concentrated loads.

GLUED FLOOR SYSTEM

- For complete information on glued floors, including joist span tables (based on building code criteria and lumber sizes), application sequence, and a list of recommended adhesives, contact the American Plywood Association.
- Place APA STURD-I-FLOOR T&G across the joists with end joints staggered. Leave 1/8 in. space at all end and edge joints.
- Although tongue and groove is used more often, square edge may be used if 2 x 4 blocking is placed under panel edge joints between joists.
- Based on live load of 40 psf, total load of 50 psf, deflection limited to 1/360 at 40 psf.
- Glue to joists and at tongue and groove joints. If square edge panels are used, block panel edges and glue between panels and between panels and blocking.

GLUED FLOOR NAILING SCHEDULE

Panels should be secured with power driven fasteners or nailed per APA STURD-I-FLOOR table, above.

CONNECTIONS TO OPEN WEB STEEL JOIST

NAILING SCHEDULE

Use 6d common smooth, ring shank, or spiral thread nails for plywood 1/2 in. thick or thinner and 8d for plywood to 1 in. thick. Use 8d ring shank or spiral thread or 10d common smooth for 2-4-1 and 1 1/8 in. panels. Space nails 6 in. at panel edges and 12 in. at intermediate supports, except for 48 in. or longer spans where nails should be spaced 6 in. at all supports.

NOTES

- Applicable to APA rated panel sheathing.
- All panels will support at least 30 psf live load plus 10 psf dead load at maximum span. Uniform load deflection limit is 1/180 span under live load plus dead load, or 1/240 under live load only.
- Special conditions may require construction in excess of the given minimums.
- Panel is assumed to be continuous across two or more spans with long dimension across supports.

Bloodgood, Sharp, Buster Architects and Planners; Des Moines, Iowa
American Plywood Association; Tacoma, Washington

Pitched trusses are very economical for spans up to 70 ft (with an average spacing of 15 ft), since the member sizes are small, the joint details relatively simple, and the trusses easily fabricated.

All pitched trusses require either knee braces to columns or some other provision for lateral restraint against wind or other forces.

A typical span (l) / depth (d) ratio for the Pratt, Howe, or Belgian truss is 4 to 6, which gives a relatively normal slope of 4:12 to 6:12. Fink trusses are preferred where the slope is steep (over 7:12). Scissors trusses and other types of raised lower chord pitched roof trusses are used for special conditions where clearance or appearance requires an arched bottom chord. Consult with structural engineer to check deflection.

PITCHED TRUSSES

TECO Products; Collier, West Virginia
Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

GENERAL

The first wood trusses were developed for bridge design, with the kingpost truss the earliest form. It uses a primary engineering principle: a triangle will hold its shape under a load until its side members or its joints are crushed.

QUEENPOST

Next came the queenpost truss, in which the peak of the kingpost was replaced by a horizontal crosspiece to allow a longer base.

NOTES

Further amplifications permitted greater flexibility to overcome different spanning challenges and to integrate various combinations of inclined wood braces, wood arches, steel tension rods, etc.

NOTES

1. A built-in camber of approximately 1 in. per 40 ft span will be introduced in the top and bottom chords during fabrication.
2. When lumber is not adequately seasoned, the trusses should be inspected periodically and adjusted, if necessary, until moisture equilibrium is reached.
3. These truss designs are meant only as a guide. To develop specific designs, including bracing and anchorage, consult a structural engineer.

SPLIT RING CONNECTOR

NOTE

Shear plate connectors are commonly used to connect wood truss members to steel gusset plates but may be used to connect wood to wood.

CONNECTORS

NOTE
Knee braces are useful where building supports depend on truss for stability.

DETAIL—KNEE BRACE

NOTE
Top chord lateral bracing is achieved by fastening roof sheathing to joists or purlins, which are securely fastened to the truss.

DETAIL—BRACE OF JOIST AND PURLIN TO TRUSS

DETAIL—LATERAL AND VERTICAL SWAY BRACING

TECO Products: Collier, West Virginia
Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

NOTE
A greater center depth minimizes deflection and thrust on walls.

**SCISSORS
PITCHED TRUSSES**

SEGMENTAL BOWSTRING

SEGMENTAL BOWSTRING

BOWSTRING

Bowstring trusses are theoretically the most efficient and economical of all wood truss types for larger spans, particularly over 80 ft, although spans up to 250 ft are obtainable. Connections are simple and designed to give minimum stresses to the web members. A typical span (l)/depth (d) ratio for bowstring trusses is 6 to 8.

Connections and knee brace requirements are similar to that of pitched trusses, since lateral load forces have a similar effect on them. The bottom chord members may also be glue laminated to eliminate splices.

BOWSTRING TRUSSES

DETAIL—STEEL ANGLE BRACE TO WOOD PLATE

NOTE
End grain bearing of posts provides support for the truss.

DETAIL—WOOD STRAP AT WOOD COLUMN

NOTE
This detail for use with light vertical and horizontal loads.

DETAIL—STEEL FRAMING ANCHOR

NOTE
With scissor trusses, use slotted holes in steel to allow for thrust.

DETAIL—BEARING ON MASONRY WALL

FLAT PRATT

FLAT HOWE

WARREN

Flat trusses are generally less economical than pitched or bowstring trusses, since connections are usually more complicated and higher side walls are required. But because of their geometry, flat trusses allow the smallest roof area versus pitched or bowstring trusses for the same span. As in pitched trusses, the maximum span for flat trusses is about 70 ft.

A typical span (l)/depth (d) ratio for all types of flat trusses is generally 8 to 10.

FLAT TRUSSES

Combinations of flat truss types are sometimes useful. For instance, a truss may be built having one-half Pratt and one-half Howe design. Warren trusses may have ends of either Pratt or Howe designs incorporated, depending on the type of support. In general, Warren trusses are used for shorter spans.

Flat trusses do not require knee braces since the upper and lower chords take the place of a lateral brace.

TECO Products; Collier, West Virginia
Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

RESIDENTIAL TYPE TRUSSED FLOOR JOIST STEEL PLATE CONNECTED

DUCT SIZES

Ease of running electrical and mechanical services through framing is a major advantage of trussed joists. Most manufacturers provide a large rectangular open panel at midspan; this void will generally accommodate a trunk line.

Sizes given here are approximations. Because web size and angles vary with different brands, the designer is cautioned to verify individual sizes carefully. Note that shape E is the duct that will fit in a flat truss with double chords top and bottom.

NOTES

- Spans are clear, inside to inside, for bottom chord bearing. Values shown would vary very slightly for a truss with top chord loading.
- Spans should not exceed 24 x depth of truss.
- Designed deflection limit under total load is $\ell/240$ for roofs, $\ell/360$ for residential floors, and $\ell/480$ for commercial floors.
- Roof spans include a +15% short term stress.
- Asterisk (*) indicates that truss has double chords, top and bottom.
- Spans shown are for only one type of lumber; in this case—#2 Southern pine, with an f_b value of 1550. Charts are available for other grades and species. Lumber and grades may be mixed in the same truss, but chord size must be identical. Repetitive member bending stress is used in this chart.

Michael Bengis, AIA; Hopatcong, New Jersey

6 WOOD TRUSSES

GENERAL

Monoplaner trusses are usually made up from 2 x 4 or 2 x 6 lumber. Spacing, normally 24 in. o.c., varies for special uses, especially in agriculture. Camber is designed for dead load only. Bottom chord furring generally is not required for drywall ceiling. Joints in plywood floor or roof should be staggered. Many trusses are approved by model codes, such as BOCA, ICBO, FHA, and SBC.

$$\text{CAMBER (USUAL)} = \frac{L(\text{FT})}{60}$$

BRACING

Adequate bracing of trusses is vital. Sufficient support at right angles to plane of truss must be provided to hold each truss member in its designated position. Consider bracing during design, fabrication, and erection. In addition, provide permanent bracing/anchorage as an integral part of the building. Strongbacks are often used.

TYPES OF FABRICATED TRUSSES

PLYWOOD WEB TRUSS (WOOD CHORDS AND FLANGES)

OPEN WEB TRUSS (STEEL WEB WOOD CHORD)

OPEN WEB TRUSS (WOOD CHORDS AND WEB, METAL PLATE CONNECTORS)

Timothy B. McDonald; Washington, D.C.

NOTES

1. The average spacing for light trusses (trussed rafters) is 2 ft o.c. but varies up to 4 ft. The average combined dead and live loads is 45 lb per sq ft. Spans are usually between 20 and 32 ft but can be as much as 50 ft.
2. Early in the design process, consult an engineer or truss supplier for pre-engineered truss designs to establish the most economical and efficient truss proportions. The supplier may provide final truss engineering design.
3. Permanent and temporary erection bracing must be installed as specified to prevent failure of properly designed trusses.
4. Some locales require an engineer's stamp when prefab trusses are used. Check local codes.
5. Member forces in a truss rise rapidly as the lower chord is raised above the horizontal.

PITCHED CHORD TRUSSES

NOTES

- Spans are clear, inside to inside, for bottom chord bearing. Values shown would vary only slightly for a truss with top chord loading.
- Designed deflection limit under total load is $l/240$ for roofs, $l/360$ for residential floors, and $l/480$ for commercial floors.

- Spans should not exceed 24 in. x depth of truss.
- Roof spans include a +15% short-term stress.
- Spans shown are for only one type of lumber; in this case—#2 Southern pine, with an f_b value of 1550. Charts are available for other grades and species. Lumber and grades may be mixed in the same truss, but chord size must be identical. Repetitive member bending stress is used in this chart.

PITCHED TRUSSES

PARALLEL TRUSSES

GENERAL

Metal plate-connected wood trusses have been used in building construction since 1953, when the metal connector plate was invented. These proprietary metal plates are available in a range of styles and tooth orientations. The metal plates are punched with barbs that grab onto the wood truss, thus reducing the hand nailing required to fabricate a structure. Plate size for a given truss is based on a combination of the tooth withdrawal strength of the plate, the tensile and shear strength of the steel, and the net sectional area of the lumber.

This system is primarily used for roofs with either pitched or parallel chord trusses. It is occasionally employed for floors with parallel chord trusses. Individual trusses are cut from 2 x 4 in. or 2 x 6 in. lumber and can be spaced 24 in. or 48 in. o.c. For typical residential construction, 24 in. o.c. is used. Exceptionally long spans are possible with metal plate-connected trusses, allowing the large, unencumbered interior spaces often required in commercial, agricultural, and other nonresidential building types.

Camber is designed for dead load only:
Camber (in.) = Length (ft)/60

BRACING

Providing adequate bracing for trusses is essential, both during installation and in the overall roof design. Truss members must be held in place with supports that meet them at right angles. Truss chords and web members are placed in a vertical, plumb position and maintain that position, resisting applied design loads, throughout the life of the structure. Permanent bracing and anchorage are expected to be an integral part of construction, and strong-backs are often used for this purpose.

Movement by crane can damage trusses. Crane spreader bars are used to avoid this "out-of-plane" buckling. Special stiffening may be applied to trusses during erection.

GENERAL

A wood I-joist is made of a web with top and bottom flanges. It is similar in shape and profile to the steel I-beam, but while the steel component is forged from a single ingot, the wood member is a composition. Plywood or oriented strand board (OSB) is used for the web of the wood I-joist, and either solid lumber or laminated-veneer lumber for the flanges. Many manufacturers produce wood I-joists under different trade names, and each differs in its dimensions, as well as span and deflection, loading, and performance characteristics. Consult manufacturers for details and performance criteria.

Compared to solid lumber, wood I-joists have both relative advantages and disadvantages:

ADVANTAGES

1. Easier to handle and lighter weight, with about 50% less wood material per joist than an equivalent solid wood member.
2. Makes efficient use of a natural resource—the I-joist can be made from second and third growth timber stands, with no need for old growth trees.
3. Available in lengths up to 60 ft, priced per linear foot.
4. Greatest strength when loaded parallel to plane of web.
5. A high degree of uniformity, with no crowns, checks, or loose knots.
6. Plumbing and HVAC can easily be run through web structure (based on the manufacturer's guidelines).
7. Starts with dry materials, so there is much less shrinkage than with solid lumber.
8. Wood I-joists can generally be set at wider on-center spacing, thus reducing installation time.

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

NOTE
Check building code for appropriate detail in areas of high lateral load.

STUD BEARING WALL DETAILS

DISADVANTAGES

1. Material costs are generally more (per linear foot) than for solid lumber (for standard residential floor joist dimensions and spans).
2. Contractors are less familiar with wood I-joists and can create problems by cutting holes into webs and weakening the member.

NOTE
Joist must be designed to carry the load-bearing wall.

CANTILEVER DETAILS

3. Less lateral stiffness than solid lumber.
4. Can be shifted by winds during construction due to light weight.
5. Some adhesives used in laminated-veneer components may pose indoor air-quality problems.

NOTE
Connection between joists must provide adequate load transfer between members.

STRUCTURAL GLUED LAMINATED TIMBER

The term "structural glued laminated timber" refers to an engineered, stress-rated product made of wood laminations bonded with adhesives, with the grain approximately parallel lengthwise. Laminated pieces can be end-joined to form any length, or glued edge-to-edge to make wider pieces, or of bent pieces curved during gluing.

STANDARD DEPTHS

Dimensional lumber surfaced to 1 1/2 in. (38 mm) is used to laminate straight members and members that have a curvature within the bending radius limitations for the species. Boards surfaced to 3/4 in. (19 mm) are recommended for laminating curved members when bending radius is too short to permit the use of dimension lumber, provided that the bending radius limitations for the species are observed. Other lamination thicknesses may be used to meet special requirements.

STANDARD WIDTHS

Nominal width	3	4	6	8	10	12	14	16
in.	2 1/8	3 1/8	5 1/8	6 3/4	8 3/4	10 3/4	12 1/4	14 1/4
Net finished width	57	79	130	171	222	273	311	362

* 3, 5, 8 1/2, and 10 1/2 in. for southern pine

CAMBER

Camber is curvature (circular or parabolic) made into structural glued laminated beams opposite the anticipated deflection movement. The recommended minimum camber is one and one-half times dead load deflection. After initial dead load deflection and additional plastic deformation (creep) has taken place, this usually will produce a near level floor or roof beam under dead load conditions. Additional camber or slope may insure adequate drainage of roof beams. On long-span roof beams and floor beams of multistory buildings, additional camber may be needed to counter the optical illusion of the beam sagging.

FIRE SAFETY

The self-insulating qualities of heavy timber cause a slow burning. Good structural details, elimination of concealed spaces, and use of vertical fire stops contribute to its fire performance. Heavy timber retains its strength under fire longer than unprotected metals.

Building codes generally classify glued laminated timber as heavy timber construction if certain minimum dimensional requirements are met. Codes also allow for calculation of one-hour fire ratings for exposed glued laminated timbers. See Council of American Building Officials National Evaluation Service Committee Report No. NER-250.

It is not recommended that fire-retardant treatments be applied to glued laminated timber as they do not substantially increase the fire resistance of heavy timber construction. In considering fire-retardant treatments, the reduction of strength related to type and penetration of treatment, the compatibility of treatment and adhesive, the use of special gluing procedures, the difficulty of application, and the effect on wood color and fabrication procedures must be investigated.

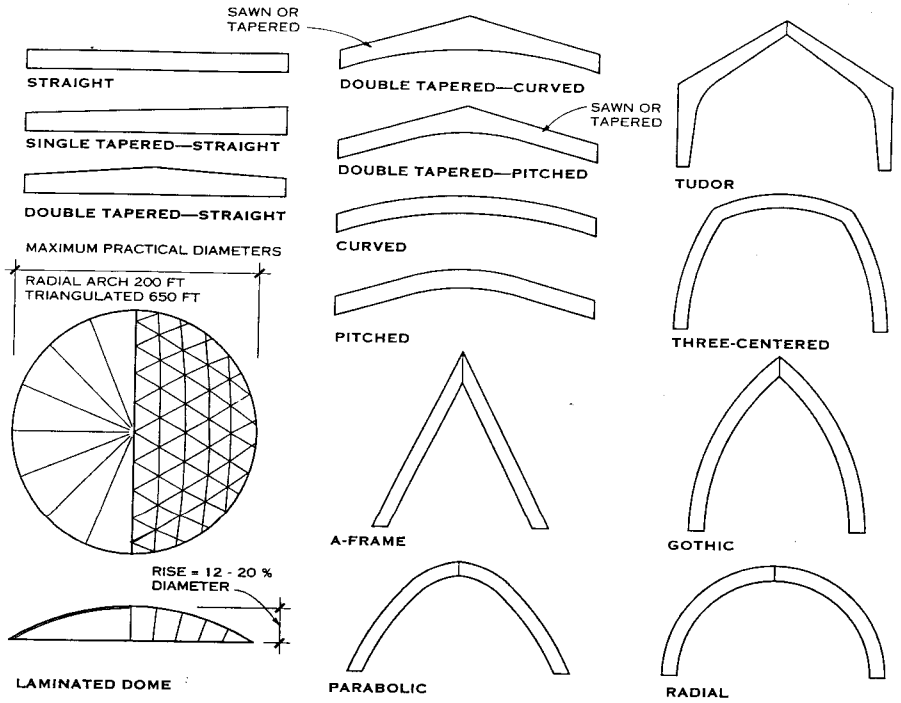

A-SINGLE CANTILEVER
B-SUSPENDED
C-DOUBLE CANTILEVER
D-SINGLE END SUSPENDED

CANTILEVERED AND CONTINUOUS SPAN

Cantilever beam systems may be composed of any of the various types and combinations of beams shown above. Cantilever systems generally permit longer spans or larger loads per size member than do simple span systems.

For economy, the negative bending moment at the support of a cantilevered beam should be equal in magnitude to the positive moment.

Roger W. Kipp, AIA; Thomas Hodne Architects, Inc.; Minneapolis, Minnesota

STRUCTURAL GLUED LAMINATED TIMBER SHAPES

NOTES ON SHAPES

1. Beam names describe top and bottom surfaces of the beam. Sloped or pitched surfaces should be used on the tension side of the beam.
2. The three hinged arches and frames shown above produce horizontal reactions requiring horizontal ties or modified foundations.
3. The triangulated and the radial arch are the two basic types of structural glued laminated wood dome systems available. Both systems require a tension ring at the dome spring line to convert axial thrusts to vertical loads.

Consideration must be given to the perimeter bond beam design since wind forces will produce loads in this member. The length of main members of the radial arch system, which must span a distance greater than half the dome diameter, limit the maximum practical dome diameter. The far smaller members of the triangulated dome result in the greater diameters. The triangulated system can be designed for five or more segments with an equal number of peripheral supports at each segment.

4. More complicated shapes may be fabricated. Contact the American Institute of Timber Construction (AITC) and the American Plywood Association (APA).

CONNECTION DESIGN

The design of connections for glued laminated timbers is similar to the design of connections for sawn lumber. Since glued laminated timbers often are much larger than sawn lumber and the loads transferred also are larger, the effect of increased size should be taken into account in the design of connections. In addition to being designed for strength to transfer loads, connections also should be designed to avoid splitting of the member and to accommodate swelling and shrinking of the wood.

BEAM END CONNECTIONS

Beam end connections should be designed to carry both induced horizontal and vertical loads. Bolts or fastenings at the end of the beam should be located toward the bottom of the beam so that the effect of shrinkage between the bottom of the beam and the fastening is minimized. Bolts or connectors located near or above the beam's neutral axis should not be used on large glued laminated beams or girders since the concentration of the tension perpendicular to grain due to restraint of shrinkage, and shear stresses acting at fasteners located in these beam areas tend to cause splitting of the member.

SUSPENDED LOADS

In cases where it is not possible for the suspending system to be carried on top of the beam, it is good practice to place the fastener above the neutral axis, particularly when other than light loading is involved or when a number of loads are to be suspended from the member. For heavy loads, a saddle detail placing loads directly on top of the beam is recommended.

Very light loads may be suspended near the bottom of a glued laminated timber. The distance above the beam bottom must exceed the specified edge distance of the fastener used.

PURLIN TO BEAM CONNECTIONS

The preferred purlin to beam connection method is to transfer the end reaction by bearing perpendicular to grain in a saddle type connection extending over the beam top.

When the end reaction of the beam or purlin is relatively small, the hanger can be fastened to the face of the girder. The bolts or connectors in the main carrying beam or girder should be placed above the neutral axis of the member, and in the supported member should be placed near the bottom to avoid potential splitting.

SPLICE CONNECTIONS

At beam splice connections occurring over columns, it is important to allow for movement in the upper portions of the beam due to end rotation. Slotted connections will help to reduce the problem by allowing for some beam movement.

CONCEALED AND PARTIALLY CONCEALED PURLIN HANGERS

Partially concealed purlin hangers are used for normal loads. Concealed hangers are appropriate for relatively light loads, as well as connections where the support plate at the base is notched into the member, should be designed as notched beam reactions.

It is recommended that the support for the purlin be close to the bottom of the member to utilize the maximum effective area for shear. End fastenings should not include rows of bolts or other fasteners perpendicular to the grain. Glued laminated timbers, although relatively dry at the time of manufacture, may shrink when the members reach equilibrium moisture content in place. This may cause tension perpendicular to the grain and result in splitting.

ALLOWABLE UNIT STRESS RANGES FOR STRUCTURAL GLUED LAMINATED TIMBER²—NORMAL DURATION OF LOADING

SPECIES	EXTREME FIBER IN BENDING ³	TENSION PARALLEL TO GRAIN	COMPRESSION PARALLEL TO GRAIN	HORIZONTAL SHEAR	COMPRESSION PERPENDICULAR TO GRAIN	MODULUS OF ELASTICITY
DRY CONDITIONS OF USE—MOISTURE CONTENT IN SERVICE LESS THAN 16%						
Douglas fir - larch	1600 TO 2400	700 TO 1300	875 TO 1750	80-165	560 TO 650	1.5 TO 1.9
Hemlock fir	1600 TO 2400	825 TO 1150	825 TO 1550	155	375 TO 500	1.4 TO 1.8
Southern pine	1600 TO 2600	650 TO 1250	950 TO 1750	90-200	560 TO 650	1.3 TO 1.9
California redwood	1600	900	1400	125	315	1.1
WET CONDITIONS OF USE FACTORS—MOISTURE CONTENT IN SERVICE 16% OR MORE (REQUIRES WET-USE ADHESIVES)						
	0.8	0.8	0.73	0.875	0.53	0.833

NOTES

- Multiply dry-condition-of-use stress ranges by the above factors for corresponding wet-conditions-of-use value.
- Values given are for members loaded perpendicular to wide faces of laminations. For ranges of allowable stresses for members loaded primarily as axial members or loaded parallel to the wide face of laminations, see current American Institute of Timber Construction Publication AITC 117—Design (Table 2).
- Values shown are for the tension zones of the member.

NOTES

- Total load carrying weight capacity includes beam weight. Floor beams are designed for uniform loads of 40 psf live load and 10 psf dead load.
- Allowable stresses: $F_b = 2,400$ psi (modified volume factor), $F_v = 165$ psi, $E = 1,800,000$ psi.
- Deflection limits: roof = $1/180$, floor = $1/360$.
- Values are for preliminary design purposes only. For complete information see the American Institute of Timber Construction *Timber Construction Manual*.
- AITC tables extend to members up to 40 feet in span. American Plywood Association (APA) tables extend up to 48 feet in span. The design of members of far greater span is possible using good engineering practice.

APPEARANCE GRADES

Structural glued laminated timber is produced in three appearance grades that do not modify design stresses, fabrication controls, grades of lumber used, or other provisions of the applicable standards. A textured (rough sawn) surface may be called for instead of the surfacing described. In all grades, laminations will possess the natural growth characteristics of the lumber grade.

INDUSTRIAL APPEARANCE GRADE

Void filling on lamination edges is not required. The wide face of laminations exposed to view will be free of loose knots and open knotholes. Edge joints on the wide face will not be filled. Members will be surfaced on two sides only, an occasional miss being permitted.

ARCHITECTURAL APPEARANCE GRADE

On exposed surfaces, knotholes and other voids wider than 3/4 in. (19 mm) will be dressed with clear wood inserts or a wood-tone colored filler. Inserts will be selected for similarity of the grain and color to the adjacent wood. The wide face of laminations exposed to view will be free of loose knots and open knotholes; all voids greater than 1/16 in. (2 mm) wide in edge joints on this face will be filled. Exposed faces must be surface smooth. Misses are not permitted. The corners on the wide face of laminations exposed to view will be eased. The current practice for eased edges is for a radius between 1/8 in. (3 mm) and 1/2 in. (13 mm).

PREMIUM APPEARANCE GRADE

Similar to architectural grade except that all knotholes and other voids on exposed surfaces will be replaced with wood inserts or a wood-tone colored filler. Remaining knots will be limited in size to 20% of the net face width of the lamination, with no more than two maximum size knots occurring in a 6 ft (1.8 m) length.

FINISHES

Glued laminated timber finishes include sealers, stains, and paints.

End sealers retard moisture transmission and minimize checking and normally are applied to the ends of all members.

Two types of sealers protect against soiling, control grain raising, minimize checking, and serve as a moisture retardant. Penetrating sealers provide limited protection and are used when the final finish requires staining or a natural finish. Primer and sealer coats provide maximum protection by sealing the surface of the wood but should not be specified for a natural or stained final finish. Wood color is modified by any sealer application; therefore, wood sealers followed by staining will look different from stained, untreated wood.

Roger W. Kipp, AIA; Thomas Hodne Architects, Inc.; Minneapolis, Minnesota

NOTE
Very light loads may be placed near bottom of beam; however, the heavier the load the higher on the beam the suspension points should be located.

SUSPENDED LOAD—BENT PLATE ATTACHED TO SIDE

RAFTER TO BEARING WALL

NOTE
The detail above is just one of a large variety of special connections and connection assemblies possible using structural glued laminated timber. It is critical that connections be designed carefully in accordance with good engineering practice.

SPECIAL CONNECTION

NOTE
This detail is recommended for use with heavy loads.

SUSPENDED LOAD—SADDLE

NOTE
An abrupt notch in the end of a wood member reduces the effective shear strength of the member and may permit a more rapid migration of moisture in the lower portion of the member causing potential splitting. The shear strength of the end of the member is reduced and the exposed end grain may also result in splitting because of drying. At inclined beams, the taper cut should be loaded in bearing.

NOTCHED BEARING CONDITION

GLUED LAMINATED COLUMNS

RAFTER TO COLUMN CONDITION

STEEL COMPRESSION BOX

CONNECTION DESIGN

The design of connections for glued laminated timber and sawn timber is similar. Glued laminated timbers and their loads, however, often are much larger than sawn lumber, so the effect of increased size should be taken into account in the design.

Used to add strength to transfer loads, connections should be designed to avoid splitting and to accommodate swelling and shrinking.

GLUED LAMINATED COLUMNS

Structural glued laminated timber columns offer higher allowable stresses, controlled appearance, and the ability to fabricate variable sections. For simple rectangular columns, the slenderness ratio (the ratio of the unsupported length between points of lateral support to the least column dimension) may not exceed 50. The least dimension for tapered columns is the sum of the smaller dimension and one-third the difference between the smaller and greater dimensions. Spaced columns consist of two or more members with longitudinal axes parallel, separated at the ends and at the midpoint by blocking, and joined at the ends by shear fastenings. The members act together to carry the total column load; because of the end fixity developed, a greater slenderness ratio than allowed for solid columns is permitted.

LAP SIDING APPLICATION

APA STURD-I-WALL CONSTRUCTION RECOMMENDATIONS (SIDING DIRECT TO STUDS AND OVER NONSTRUCTURAL SHEATHING)

PANEL SIDING DESCRIPTION (ALL SPECIES GROUPS)	NOMINAL THICKNESS OR SPAN RATING (IN.)	MAX. STUD SPACING (IN.)		NAIL SIZE (USE NONSTAINING BOX, SIDING, OR CASING NAILS) ^{1,2}	NAIL SPACING (IN.)	
		FACE GRAIN VERTICAL	FACE GRAIN HORIZONTAL		PANEL EDGES	INTERMEDIATE
APA MDO EXT	1 1/32 and 3/8	16	24	6d for panels 1/2\"/>		
	1/2 and thicker	24	24			
APA rated siding EXT	16 o.c.	16	24	8d for thicker panels	6 ⁴	12
APA rated siding EXT	24 o.c. ³	24	24			

NOTES

- If siding is applied over sheathing thicker than 1/2 in., use next regular nail size. Use nonstaining box nails for siding installed over foam insulation sheathing.
- Hot-dipped or hot-tumbled galvanized steel nails are recommended for most siding applications. For best performance, stainless steel nails or aluminum nails should be considered. APA tests also show that electrically or mechanically galvanized steel nails appear satisfactory when plating meets or exceeds thickness requirements of ASTM A641 Class 2 coatings and is further protected by yellow chromate coating.
- Only panels 1 1/32 in. and thicker that have certain groove depths and spacing qualify for 24 in. o.c. Span Rating.
- For braced wall sections with 1 1/32 in. or 3/4 in. siding applied horizontally over studs 24 in. o.c., space nails 3 in. o.c. along panel edges.

MINIMUM BENDING RADII FOR PLYWOOD PANELS

	PANEL THICKNESS (IN.)				
	1/4	3/8	1/2	5/8	3/4
Across grain (ft)	2	3	6	8	12
Parallel to grain (ft)	5	8	12	16	20

NOTE

The types of plywood recommended for exterior siding are APA grade trademarked medium density overlay (MDO), Type 303 siding or Texture 1-11 (T1-11 special 303 siding). T1-11 plywood siding is manufactured with 3/8 in. wide parallel grooves and shiplapped edges. MDO is recommended for paint finishes and is available in a variety of surfaces. 303 plywood panels are also available in a wide variety of surfaces. The most common APA plywood siding panel dimensions are 4 x 8 ft but the panels are also available in 9 and 10 ft lengths, lap siding to 16 ft.

COUNTER AND BACKSPLASH DETAILS

GENERAL

The Architectural Woodwork Institute's Quality Standards classify custom-manufactured cabinets in three categories: premium, custom, and economy. The materials, joinery, and finish quality are delineated in the specifications for cabinet shops to follow. Premium is the highest grade, with close tolerances reserved for only the finest cabinets. Custom-grade cabinets, the most common, are made from very good materials with durable joinery. Economy-grade cabinets are used for utilitarian and inexpensive residential cabinets.

The AWI Quality Standards classify cabinet parts as exposed, semiexposed, and concealed, and specify a minimum grade for each. The finish to be used is specified as paint grade or stain grade or whether plastic laminate or other material will be used.

To prevent movement caused by wood shrinkage, use only kiln-dried solid lumber or panel product for base supports.

ABBREVIATIONS

The following abbreviations are used on the three AGS pages on cabinet details: MDF—medium-density fiberboard; PBI—industrial particleboard.

ELEVATION NOTE

Flush overlay construction offers a clean, contemporary design because only the doors and drawer fronts are visible in elevation. The grain between doors and drawer fronts can be matched by cutting all pieces from the same panel. This cabinet style lends itself well to the use of plastic laminate for exposed surfaces. Conventional and concealed hinges are available for a variety of door thicknesses. Door and drawer joinery and materials may vary from the selection shown in the details.

FLUSH INSET CONSTRUCTION (WITH FACE FRAME)—HORIZONTAL SECTIONS

TYPICAL CABINET ELEVATION

REVEAL OVERLAY CONSTRUCTION

In this style of cabinet construction, the separation between doors and drawer fronts is accented by the reveal. The style is suited equally to either wood or plastic laminate construction. The details shown at left show a reveal at all vertical and horizontal joints, but the designer may vary this arrangement.

A reveal greater than 1/2 inch would require the addition of a face frame, which would change the hinge requirements. With or without a face frame, this style allows the use of conventional or concealed hinges. Door/drawer joinery and materials may vary from selections shown in the drawings.

FLUSH INSET CONSTRUCTION WITHOUT FACE FRAME

In this style of construction, all door and drawer faces are flush with the face of the cabinet. This style allows the use of door and drawer fronts with different thicknesses.

Conventional as well as concealed hinges are available for a variety of door thicknesses. The material chosen for the case and doors and drawers influences the choice of hinges. Avoid conventional butt hinges when hinge screws would be attached to the edge-grain of panel products.

Flush inset construction without any face frame is generally an expensive style because increased care is necessary to fit and align the doors and drawers. The design features of this case-work style are the same as for conventional flush construction with face frame except that here the face frame has been eliminated.

This style does not lend itself to the economical use of plastic laminate covering finishes. Door/drawer joinery and materials may vary from selections shown in details.

FLUSH INSET CONSTRUCTION WITH FACE FRAME

In this style of construction, all door and drawer faces are flush with the face of the cabinet. This style allows the use of different thicknesses for door and drawer fronts.

Conventional as well as concealed hinges are available for a variety of door thicknesses. The hinges chosen depend on the case and door/drawer material chosen. Avoid conventional butt hinges when hinge screws would be attached to the edge-grain of panel products.

Flush inset construction with face frame is generally the most expensive of the four cabinet door styles because, in addition to the cost of providing the face frame, there is the cost of the increased care needed to fit and align the doors and drawers.

This style does not lend itself well to the economical use of plastic laminate surfaces. Door/drawer joinery and materials may vary from the selections shown.

MINIMUM NOMINAL THICKNESS AND MATERIAL FOR CABINET COMPONENTS

COMPONENTS	MATERIALS	MIN. NOMINAL THICKNESS
Body members (ends, divisions, bottoms, tops)	Panel product	3/4 in.
Face frames, rails	Lumber or panel product	3/4 in.
Shelves ¹	Lumber	3/4 in. for spans up to 36 in. 1 1/16 in. for spans up to 48 in.
	Veneer core plywood	3/4 in. for spans up to 36 in. 1 in. for spans up to 48 in.
	Medium density particleboard or fiberboard	3/4 in. for spans up to 32 in. 1 in. for spans up to 42 in.
Backs	Panel product	1/4 in.
Mounting or hanger strips	Lumber or panel product	1/2 in.
Drawer sides, backs, subfronts	Lumber or panel product	1/2 in.
Drawer bottoms	Panel product	1/4 in.
Drawer fronts	Lumber or panel product	3/4 in.
Stile and rail cabinet doors and drawers ²	Lumber	3/4 in.
Frames for glass doors ³	Lumber	3/4 in.
Frameless glass doors	Frameless glass	1/4 in.
Flush cabinet doors and drawer fronts ⁴	Medium density particleboard or fiberboard	3/4 in. up to 30 in. width by 80 in. height

¹ Consult a woodworking professional for shelf specifications to carry anticipated loads.
² Give special consideration to building very wide and/or very tall doors of this thickness; consult manufacturer for guidelines.
³ Thickness of glass for doors should meet local code.
⁴ Use like materials and thicknesses for face of cabinet doors and drawer fronts. Veneer core doors cannot be guaranteed against warping, telegraphing, or delamination.

NOTES

1. Because of its stability, plywood is preferable to solid lumber or other materials as backup.
2. To join stile to rail, mortise and tenon or dowelled joints are used. Stile to stile joints at outside corners are spline joints or lock miters; inside corners are butt jointed.

SECTION - FULL HEIGHT WALL PANEL

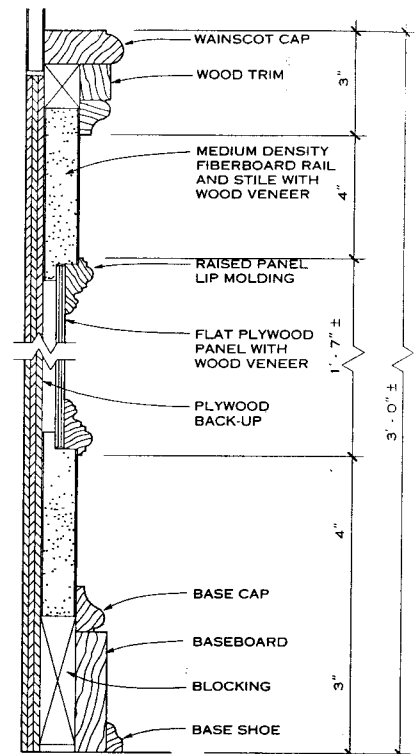

INTERIOR WALL PANEL DETAILS

Architectural interior paneling consists of a series of thin sheets of wood (panels) framed together by means of stouter strips of wood, vertical (stiles) and horizontal (rails), to form either a door, screen, or lining for internal walls. Paneling was first used as a wall covering in England in the 13th century. Up to the 16th century, the framing was almost as massive as half-timber construction. Then it was progressively lightened until by the middle of that century when the thickness of the framing was reduced to an inch. Today, inch thick or less panels are made from veneers over plywood or composition boards, which can be treated for fire protection. The stiles and rails are made from solid wood or veneered boards. Rim and lip moldings and other trims are almost exclusively made from solid wood.

GUIDELINES

Construction details on this page are for shop-built stairs using Premium Grade Standards of the Architectural Woodwork Institute. Wood stairs used in private, residential applications usually are not governed by the ADA; however, wood stairs in commercial facilities and places of public accommodation must conform to ADA accessibility guidelines (ADAAG). Details on these two pages depict both alternatives.

1. Check current local building codes and regulations for requirements that may differ from the general recommendations provided here.
2. Interior stair width: 36 in. minimum.
3. Minimum headroom is 6 ft 8 in. as measured vertically from a diagonal line connecting tread nosings to the underside of the finished ceiling or stair landing directly above the stair run. Recommended headroom is 7 ft.
4. Only handrails and stair stringers may project into the

- required width of a stair.
 Handrail projection: 3/2 in. maximum.
 Stringer projection: 1 1/2 in. maximum.
- For a stair to comply with ADAAG, no projections are allowed into the minimum required stair width.
5. The width of a landing or platform should be at least as wide as the stair.
 6. The maximum vertical rise of a stair between landings is 12 ft.
 7. Riser height: 4 in. min. and 7 in. max.
 Tread width: 11 in. min., measured from riser to riser.
 Variation in adjacent treads or risers should not exceed 3/16 in. The maximum difference allowed the tread width or riser height within a flight of stairs is 3/8 in. ADAAG requires uniform treads and risers.
 Nosings project 1 1/2 in. max. Check codes and ADAAG for other restrictions.

8. Height of handrail above stair nosings: 30 to 34 in.; 34 to 38 in. per ADAAG. Guardrail height at landings: 36 or 42 in.; check local code.
9. Design handrails that can be gripped easily and fit the hand. Recommended diameter is 1 1/4 to 1 1/2 in. for round handrails and a similar size for an elliptical or rounded square edge section. Handrails should be structurally designed so that both downward (vertical) and lateral (horizontal) thrust loads are considered.
10. Extensions of handrail at top and bottom of stair may affect total length of required run. Verify extensions required by local codes or ADAAG when designing a stair.
11. Refer to related stair topics in chapters 1, 3, 4, 5, and 9.

OVERDOOR DETAILS

WOOD CORBELS

GENERAL

Woodwork is considered an ornament when it has a special or unique design that does not fall within the standard categories of architectural woodwork as defined by the Architectural Woodwork Institute.

Some typical uses for ornamental wood include pediment heads, mantels, ornamental grilles, fluted pilasters, cupolas, finials, medallions, corbels, balusters, posts, and columns. Within the classification of ornamental wood are combinations of flat or molded solid lumber, or cored lumber components with wood veneer faces with, or without, the addition of moldings. All joinings between ornamental members should be designed for functional as well as decorative purposes.

Wood ornamentation is an art that can take shape in an almost infinite number of forms and designs, limited only by the mechanical production constraints of woodworking shops. "Wood" ornaments can also be produced in larger quantities (in molds) with the synthetic material polyurethane. Once cured, the polyurethane can be painted and substituted for the wood ornaments.

GENERAL

Interior trim is a generally decorative treatment applied after wall, floor, and ceiling finishes have been installed. It can be made of flat or molded wood from single pieces of wood or built-up pieces that give a more complex and decorative appearance. Interior trim conceals joints between different materials and blocks air infiltration through walls, which typically is greatest at material joints. Interior trim also frames wall and ceiling openings (door and window/skylight trim), defines planar edges (crown and base molding), and acts as a visual divider between dissimilar materials (chair rail).

The Architectural Woodwork Institute differentiates wood trim according to its length. Standing wood trim is trim that can be accommodated easily with single lengths of wood (depending on species), such as crown moldings, fascias, soffits, chair rails, baseboards, and shoe moldings. Running trim is usually made up of finger-jointed wood to achieve the lengths customarily needed for this type of trim.

NOTES

1. Blocking that receives moldings should be set plumb, level, true, and straight, with no distortion, and should be provided for full surface contact. Attach blocking to substrates with nails, screws, or bolts.
2. Woodwork should be stored in a dry, ventilated space. If this is not possible, seal the ends of all pieces as soon as possible. Moldings should be at optimum moisture content at the time of installation and should be allowed to acclimate to project conditions before installation.
3. Joints in adjacent and related members should be staggered. Cope at inside corners and miter at outside corners to produce tight-fitting joints with full surface contact throughout the length of the joint; use scarf joints (face mitered) for end-to-end joints in trim.
4. Blind nail where possible, and use finishing nails in exposed areas. Predrill as required to eliminate splitting; set exposed nail heads for filling.
5. Most flat trim like baseboards and casing has a ploughed or relieved back, which gives wide trim a degree of flexibility, allowing it to fit snugly against a wall surface.
6. The molding profiles illustrated are a small sampling of those available from most millwork shops. Custom profiles should be shown on drawings full size. Dimensions given are for typical stock molding profiles.

NOTE

Casings are used to finish the joint between the window or door head and side jambs and wall finish. Often a casing used at windows is also used as apron material, with the wide side toward the stool.

CASINGS

NOTE

Stools are used as interior caps on windowsills and receive casing from above and apron below. They are specified by width of rabbet and degree of bevel.

STOOLS

NOTE

Baseboards and base moldings are used at the juncture of wall and floor exclusively. Baseboard may be one piece (with integral base cap) or flat with optional base cap. Separate caps and shoes are flexible and facilitate a close fit to uneven wall and floor surfaces.

BASEBOARD AND BASE MOLDINGS

TYPICAL WOOD TRIM AND MOLDINGS

TYPICAL WINDOW TRIM

TYPICAL CORNICE TRIM

MOLDING CONNECTION DETAILS

TYPICAL DOOR AND BASE TRIM

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

NOTE

Crown moldings are applied alone at the joint between wall and ceiling or together with other moldings in a built-up cornice, typically toward the top of the cornice assembly, measured edge to edge.

CROWN MOLDINGS

NOTE

This molding is used on outside corners.

CORNERS

NOTE

Stops are used at jambs to guide windows and stop doors.

STOPS

NOTE

Cap or rake moldings are used at head of door and window trim and at top of wainscots.

CAP OR RAKE MOLDINGS

NOTE

Cove moldings are used at inside corners, such as wall-to-wall or ceiling-to-wall.

COVE MOLDINGS

NOTE

Often integrated with cornices, picture moldings are used as continuous projecting supports for picture hooks. Custom-made hooks are available to fit these profiles.

PICTURE MOLDINGS

NOTE

These moldings are used in panels to conceal joints, over window jamb edges in a multiple-opening window, and as astragals at middle joints of double-leaf doors.

PANEL STRIPS, BATTENS, AND ASTRAGALS

NOTE

Chair rails were originally meant to protect the wall surface from chair backs; applied typically 1/2 up from the floor, either alone or atop wainscot paneling.

CHAIR RAILS

NOTE

Bed moldings are used at the bottom of built-up cornices and at other vertical-to-horizontal junctures.

BED MOLDINGS

BASE CAPS

NOTES

1. Half-rounds are used to conceal vertical and horizontal joints. Quarter-rounds are used at inside corners and as base shoe.
2. Base caps are applied at the top of the baseboard, flush against the wall.

BASE CAPS AND ROUNDS

NOTE

Backbands are applied as trim at the outer edge of door jamb and head, among other uses.

BACKBANDS

NOTE

Panel moldings are typically used as door and wainscot trim, mitered together and arranged in rectangles.

PANEL MOLDINGS

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

HARDWOOD PLYWOOD CORE TYPES

GENERAL

Architectural wood panels are made from wood material that is cut or formed into sheet products that are referred to as the "panel core." These sheets are used alone (with or without a finish) or laminated together with other veneer products to make plywood. A great variety of panels are manufactured using different core materials and adhesives or binders and various forming techniques and surface treatments. The characteristics of the panels vary with these differences in material and construction.

PANEL CORE TYPES

Panel cores, which serve as the substrate for laminates and veneers on the outer surface, are classified by ingredients and methods of manufacture. The following types of panel cores are suitable for architectural use:

INDUSTRIAL GRADE PARTICLEBOARD CORE

This core type is made by using heat and pressure to bond together synthetic resin or binder and wood particles of various sizes. Employed in a wide variety of architectural woodwork applications, industrial grade particleboard is especially well suited as a substrate for high-quality veneers and decorative laminates. When used as panels without any surface layers, the product is called particleboard. When used with wood veneer on the surface, the panels are referred to as particle-core plywood. Particleboard core classified by density or weight per cubic ft falls into three categories:

1. Low density—less than 40 lb per cubic ft (640 kg per cubic meter)
2. Medium density—40 to 50 lb per cubic ft (640 to 800 kg per cubic meter)
3. High density—more than 50 lb per cubic ft (800 kg per cubic meter)

MOISTURE-RESISTANT PARTICLEBOARD CORE

Some medium-density industrial particleboard is bonded with phenolic resins, which makes it more resistant to swelling when exposed to moisture. Phenolic resins, unlike urea resins, do not emit significant quantities of formaldehyde. The most common grades are type 2-M-2 (M-2 exterior glue) and 2-M-3 (M-3 exterior glue).

CHARACTERISTICS OF CORE MATERIAL PERFORMANCE

PANEL TYPE	FLATNESS	VISUAL EDGE QUALITY	SURFACE UNIFORMITY	DIMENSIONAL STABILITY	SCREW HOLDING	BENDING STRENGTH	AVAILABILITY
Industrial particleboard core (medium-density)	Excellent	Good	Excellent	Fair	Fair	Good	Ready
Medium-density fiberboard core (MDF)	Excellent	Excellent	Excellent	Fair	Good	Good	Ready
Veneer core—all hardwood	Fair	Good	Good	Excellent	Excellent	Excellent	Ready
Veneer core—all softwood	Fair	Good	Fair	Excellent	Excellent	Excellent	Ready
Lumber core—hardwood or softwood	Good	Good	Good	Good	Excellent	Excellent	Limited
Standard hardboard core	Excellent	Excellent	Excellent	Fair	Good	Good	Ready
Tempered hardboard core	Excellent	Good	Good	Good	Good	Good	Limited
Moisture-resistant particleboard core	Excellent	Good	Good	Fair	Fair	Good	Limited
Moisture-resistant MDF core	Excellent	Excellent	Good	Fair	Good	Good	Limited
Fire-resistant particleboard core	Excellent	Fair	Good	Fair	Fair	Good	Limited

NOTE

Characteristics of core material performance are influenced by the grade and thickness of the core and specific gravity of the core species. Visual edge quality is rated before treatment with edge bands or fillers and, for lumber core, assumes the use of "clear edge" grade. Surface uniformity

FIRE-RETARDANT PARTICLEBOARD CORE

Medium-density industrial particleboard may be treated during manufacture to carry a UL Class 1 fire rating stamp (flame spread 20, smoke developed 25). This material can be used as substrate for paneling requiring a Class 1 rating.

MEDIUM-DENSITY FIBERBOARD (MDF) CORE

MDF is made from wood particles reduced to fibers in a moderate-pressure steam vessel, combined with resin, and bonded together under heat and pressure. The surface is flat, smooth, uniform, dense, and free of knots or grain pattern. MDF is useful as a substrate for paint, thin overlay materials, veneers, and decorative laminates. The homogeneous edge allows machining and paint finishes. MDF is one of the most stable mat-formed panel products and is widely used as an architectural panel.

MOISTURE-RESISTANT MDF CORE

Some MDF is bonded with an exterior resin to produce a highly water-resistant product.

VENEER CORE (PLYWOOD)

This panel product is made up of alternating layers of thin veneer and is commonly known as plywood. Adhesive is placed between the layers, and the panels are pressed until the adhesive is set; heat is often used to speed the cure. The two outside layers, often selected for species, grain, and appearance, are called the face veneers.

HARDBOARD CORE

Hardboard is made of interfelted fibers consolidated under heat and pressure to a density of 31 lb per cubic ft or more. Available with either one side (S1S) or two sides (S2S) smooth, hardboard is often used for casework backs, drawer bottoms, and divider panels. Architectural woodworkers typically use two types of hardboard core: standard (untempered) and tempered, which is standard hardboard that has been subjected to a curing treatment to increase its stiffness, hardness, and weight.

is directly related to the performance of fine veneers placed over the surface. Dimensional stability is usually related to exposure to wide variations in relative humidity. Screw holding and bending strength are influenced by proper design and engineering.

PLYWOOD TYPES

The term "plywood" means a panel product made of three or more layers (plies) of wood or wood products (veneers or overlays and/or core materials) that have been laminated into a single sheet (panel). Plywood falls into two groups according to materials and manufacturing:

HARDWOOD PLYWOOD panels are made from hardwood or decorative softwood veneers over a core material such as medium-density particleboard, medium-density fiberboard, or low-density lumber.

SOFTWOOD PLYWOOD panels are made with softwood face veneers and are seldom incorporated into finished architectural woodworking projects because of the instability of the core material and core voids.

This is the slicing method most often used to produce veneers for high-quality architectural woodworking. Slicing is done parallel to a line through the center of the log. A combination of cathedral and straight-grain patterns results, with a natural progression of pattern from leaf to leaf.

PLAIN-SLICED (FLAT-SLICED) VENEER

Quarter slicing, roughly parallel to a radius line through the log segment, simulates the quarter-sawing process used with solid lumber. In many species the individual leaves are narrow as a result. A series of stripes is produced, varying in density and thickness among species. "Flake" is a characteristic of this slicing method in red and white oak.

QUARTER-SLICED VENEER

Rift veneers are produced most often in red and white oak, rarely in other species. Note that rift veneers and rift-sawn solid lumber are produced so differently that a "match" between them is highly unlikely. In both cases the cutting is done slightly off the radius lines, minimizing the "flake" associated with quarter slicing.

RIFT-SLICED (RIFT-CUT) VENEER

To create rotary-cut veneers, the log is center mounted on a lathe and "peeled" along the path of the growth rings, like unwinding a roll of paper. This provides a bold, random appearance. Rotary-cut veneers vary in width, and matching at veneer joints is extremely difficult. Almost all softwood veneers are cut this way. Rotary-cut veneers are the least useful in fine architectural woodwork.

¹Cost reflects raw veneer costs weighted for waste or yield characteristics and degree of labor difficulty.

²Seasonal factors may affect availability.

³Availability of blond teak is very rare.

NOTE

When quartered or plain sliced are listed on the same line, the width dimensions are listed with quartered first and plain sliced second.

MATCHING BETWEEN ADJACENT VENEER LEAVES

It is possible to achieve certain visual effects by the manner in which the leaves are arranged. Rotary cut veneers are difficult to match, therefore most matching is done with sliced veneers. Matching of adjacent veneer leaves must be specified. Consult your AWI woodworker for choices.

BOOK MATCHING

Book matching is the most commonly used match in the industry. In it, every other piece of veneer is reversed so adjacent pieces (leaves) are "opened" like the pages of a book. Because the "tight" and "loose" faces alternate in adjacent leaves, they reflect light and accept stain differently. The veneer joints match, creating a symmetrical pattern that yields maximum continuity of grain.

SLIP MATCHING

Adjoining leaves are placed (slipped out) in sequence without being turned, thus all the same face sides are exposed. The grain figure repeats but joints do not show grain pattern. All faces have some light refraction.

END MATCHING

End matching is often used to extend the apparent length of available veneers for high wall panels and long conference tables. End matching occurs in two types:

ARCHITECTURAL END MATCH: Leaves are individually book or slip matched, alternating end-to-end and side-to-side. Architectural end matching yields the best continuous grain patterns for length as well as width.

PANEL END MATCH: Leaves are book or slip matched on panel subassemblies, with sequenced subassemblies end matched, resulting in some modest cost savings on projects where applicable. For most species, panel end matching yields a pleasing, blended appearance and grain continuity.

RANDOM MATCHING

Veneer leaves are placed next to each other in a random order and orientation, producing a casual board-by-board effect in many species. Conscious effort is made to mismatch the grain at joints.

RUNNING MATCHING

Each panel face is assembled from as many veneer leaves as necessary. This often results in an asymmetrical appearance, with some veneer leaves of unequal width.

BALANCE MATCHING

Each panel face is assembled from an odd or even number of veneer leaves of uniform width before edge trimming.

BALANCE AND CENTER MATCHING

Each panel face is assembled from an even number of veneer leaves of uniform width before edge trimming. Thus, there is a veneer joint in the center of the panel, producing horizontal symmetry.

Typical methods of cutting ²	Plain slicing or half-round on rotary lathe	Quarter slicing	Offset quarter on rotary lathe	Rotary lathe

¹ The headings above refer to the face veneer pattern, not to the method of cutting. Face veneer patterns other than those listed are obtainable by special order.

² The method of cutting for a given face veneer pattern shall be at mill option unless otherwise specified by the

buyer in an explicit manner to avoid the possibility of misunderstanding. For example, plain-sliced veneer cut on a vertical slicer or plain-sliced veneer cut on a half-round rotary lathe could be specified.

FACING MATERIAL TYPES

Wood product substrates are classified in two main facing material categories: decorative laminates/overlays and wood veneers.

DECORATIVE LAMINATES/OVERLAYS

This finish surface category can be broken down into the following broad groups:

HIGH-PRESSURE DECORATIVE LAMINATES are formed under heat and pressure from resin-impregnated kraft paper substrates with decorative plastic face materials and a clear protective top sheet. This assembly, commonly called plastic laminate, offers resistance to wear and many stains and chemicals. Common uses include casework exteriors, countertops, and wall paneling.

THERMALLY FUSED DECORATIVE PANELS are flat pressed from a thermoset polyester or melamine resin-impregnated web, and most have been prelaminated to industrial particleboard or medium-density fiberboard substrates when they arrive at the woodwork fabricator. Performance is similar to that of high-pressure decorative laminates. Common uses include casework interiors, furniture, shelving, display materials, and decorative paneling.

MEDIUM-DENSITY OVERLAYS are made from pressed resin-impregnated paper overlays and are highly resistant to moisture. They are available applied to cores suitable for both interior and exterior uses. The seamless panel face and uniform density offer a sound base for opaque finishes and paint.

VINYL FILMS, FOILS, AND LOW BASIS WEIGHT PAPERS are decorative facing materials that, although they have limited use in custom architectural woodwork, are suitable for some installations.

WOOD VENEERS

Wood veneers are produced in a variety of industry standard thicknesses. The slicing process is controlled by a number of variables, but the thickness of the veneer has little bearing on the quality of the end product.

There are two types of veneers, hardwood and softwood. Hardwood veneers are available in many domestic and imported wood species and are normally plain sliced, but certain species can be rift sliced, quarter sliced, or rotary cut. Softwood veneers are usually sliced from Douglas fir, but pine and other softwoods are available. Most softwood veneer is rotary cut, but plain-sliced and rift-sliced (vertical grain) softwoods can be obtained with a special order.

Most veneers are taken from large trees, but some are sliced from fast-growing trees, dyed, and reglued in molds to create "grain" patterns. The color of these reconstituted veneers is established during manufacture because the high percentage of glue line resists later staining.

The manner in which a log segment is cut with relation to the annual rings of the tree determines the appearance of the veneer. Individual pieces of veneer, referred to as "leaves," are kept in the order in which they were sliced for reference during installation. The group of leaves from one slicing is called a "fitch" and is identified by a number and the gross square feet it contains. The faces of the leaves with relation to their position in the log are identified as the "tight face" (toward the outside of the log) and the "loose face" (toward the inside or heart of the log).

NOTES

- To achieve balanced construction, panel products should be absolutely symmetrical from the center line. Materials used on either side should contract and expand or exhibit moisture permeability at the same rate as the veneer.
- In panel construction, the thinner the facing material, the less force it can generate to cause warping. The thicker the substrate, the more it can resist a warping movement or force.
- Wood veneer standards: For hardwood plywood, the face veneer characteristics of the Hardwood Plywood and Veneer Association (HPVA) have generally been adapted for use. These face grades apply to custom architectural woodwork.
- Flame spread factors: The fire rating of the core material determines the rating of the assembled panel. Fire-retardant veneered panels must have a fire-retardant core. Particleboard core is available with a Class I (Class A) rating, but MDF is not currently available with a fire rating. Existing building codes, except where locally amended, provide that facing materials 1/32 in. or thinner are not considered in determining the flame spread rating of the panel. For more information, refer to the Architectural Woodwork Institute guide "Fire Code Summary."

- For additional information, refer to Architectural Woodwork Quality Standards, 6th edition (version 1.1), 1994, Architectural Woodwork Institute (AWI).
- Lumber grades indicated in the charts on this page are according to AWI quality standards:
Grade I: Pieces are selected for uniform grain and color on exposed faces and edges.
Grade II: Pieces are selected for uniform grain on exposed faces and edges.
Grade III: No matching for grain or color is required.
- AWI recognizes three levels of workmanship for wood screens, blinds, and shutters:
CUSTOM GRADE: Most conventional architectural woodwork falls within this grade. High-quality workman-

	Raised panels	3/4" (19 mm)		3/4" (19 mm)		1/2" (13 mm)	

ship, materials, and installation are required for work with this designation.
PREMIUM GRADE: This specification requires careful oversight to guarantee the highest quality workmanship, materials, installation, and execution of design intent. It is typically reserved for special projects or project features.
ECONOMY GRADE: This grade indicates the minimum expectations for quality, materials, and installation within the scope of AWI standards.

- All exterior screens and shutters must be treated with a wood preservative in accordance with AWI Quality Standards, Section 100.
- Pivot pins for use in damp or coastal areas must be manufactured of nylon, stainless steel, or brass.
- Exterior grade panel products are recommended for blinds and shutters because once installed they are typically kept open, with one face constantly exposed to the sun and other weathering (and drying) conditions, while the other face is likely to retain moisture.

- NOTES**
1. Consult a soils engineer to determine soil types and groundwater levels and their effect on drainage and waterproofing methods. Consult a waterproofing specialist to determine a specific design approach for problem soils and conditions.
 2. Most waterproofing materials require a stable, rigid, and level substrate. Generally, a mud slab (subslab that is nonreinforced and nonstructural) is used when the waterproofing material is placed below the structural slab and/or when a solid working surface is needed on unstable soils. When waterproofing materials are placed on top of the structural slab, a protective cover, such as another concrete slab, is required.
 3. Bentonite clay waterproofing is usually manufactured in the form of corrugated cardboard panels with bentonite clay material filling the corrugation voids. When moistened, the clay swells and takes on a gel-like consistency, forming an impermeable barrier when confined. Bentonite panels may be placed over a substrate of compacted earth, sand, and pea gravel (or mud slab, for reinforced slabs greater than 6 in. thick). Since the panels swell when hydrated, pressure is exerted on adjacent construction. For slabs less than 6 in. thick, which may be adversely affected by bentonite swelling, special panels, made to accommodate the swelling, are required. A 6-mil polyethylene vapor barrier between the mud slab and gravel base will provide additional protection against water penetration. Consult with a structural engineer and the manufacturer to assure proper use and structural adequacy.
 4. Protect membrane waterproofing or coatings during construction and backfilling. Protection materials include the following (select according to soil, climate, and cost requirements):
 - a. Composite drainage material: Recommended when water is frequently present in soils surrounding foundations. Usually made up of a rigid open-weave material, approximately 3/4 in. thick, covered on both sides by a geotextile filter fabric preventing small stones or other materials from clogging the drainage route of water inside. Typically terminated at drain tiles at the bottom of the foundation. Higher in cost than other protection board materials.
 - b. Rigid insulation boards: Used above frostline or if ground temperatures are low. Usually made of expanded polystyrene. Minimum thickness is 1/4 in. (when used as protection board only), up to 1 1/2 in. thick (or greater, if desired) which gives an R-8 insulating value.
 - c. Protection board: Used only to protect waterproofing; does not drain or insulate. Usually made of 1/8 in. asphalt-impregnated fiberboard or, as mentioned above, 1/4 in. extruded polystyrene. Least expensive.
 5. Footing drains are recommended when groundwater level may rise above top of floor slab or when the foundation is subject to hydrostatic pressure after heavy rain. Composite drainage material conveys water to the drain tile, thus reducing hydrostatic pressure.
 6. Special negative-side coating on interior face of foundation wall is only recommended when exterior is not accessible.
 7. Bentonite clay water stop should be placed on top of footing, at vertical concrete keyed joints, and along inside edge of outermost vertical rebars before pouring the concrete wall.
 8. Grout, packed around pipes penetrating the foundation, should have a mixture of iron oxide. Iron oxide chemically alters the grout to be more water-resistant.

7 WATERPROOFING AND DAMPPROOFING

BASIC COMPONENTS OF WATERPROOFING SYSTEMS

GENERAL

The basic components, subsystems, and features for a building deck waterproofing system are the structural building deck or substrate to be waterproofed, waterproofing membrane, protection of membrane, drainage, insulation, and wearing course. See following pages for generic membrane applications.

SUBSTRATE

The substrate referred to is reinforced cast-in-place structural concrete. Precast concrete slabs pose more technical problems than cast-in-place concrete and the probability of lasting watertightness is greatly diminished and difficult to achieve because of the multitude of joints which have the capability of movement and must be treated accordingly.

The concrete used for the substrate should have a minimum density of 1762 kg/m³ (110 lb/ft³) and have a maximum moisture content of 8% when cured.

SLOPE FOR DRAINAGE

A monolithic concrete substrate slope of a minimum 11 mm/m (1/8 in./ft) should be maintained. Slope is best achieved with a monolithic structural slab and not with a separate concrete fill layer.

MEMBRANE

Detection of leakage can be a significant problem when the membrane is not bonded to the structural slab or when additional layers of materials separate it from the structural slab. Therefore, only membranes that can be bonded to the substrate should be used.

The membrane should be applied under dry, frost-free conditions on the surface as well as throughout the depth of the concrete slab.

When the membrane is turned up on a wall, it is preferable to terminate it above the wearing surface to eliminate the possibility of ponded surface water penetrating the wall above the membrane and running down behind it into the building.

Penetrations should be avoided wherever possible. For protection at such critical locations, pipe sleeves should be cast into the structural slab against which the membrane can be terminated by flashing onto the pipe sleeve.

Treatment at reinforced and nonreinforced joints depends on the membrane used. See following pages.

Two concepts can be considered in the detailing of expansion joints at the membrane level: the positive seal concept directly at the membrane level and the watershed concept with the seal at a higher level than the membrane. Where additional safeguards are desired, a drainage gutter under the joint could be considered. Flexible upward support of the membrane is required in each case to provide watershed-type drainage. Expansion joint details should be considered and used in accordance with their movement capability.

The positive seal concept entails a greater risk than the watershed concept, since it relies fully on positive seal joinery of materials at the membrane level, where the membrane is most vulnerable to water penetration. Since the precision required is not always attainable, this concept is best avoided.

The watershed concept, although requiring a greater height and more costly concrete forming, is superior in safeguarding against leakage, having the advantage of providing a monolithic concrete water dam at the membrane level. However, if a head of water rises to the height of the materials joinery, this concept becomes almost as vulnerable as the positive seal concept. Therefore, drainage is recommended at the membrane level.

PROTECTION BOARD

The membrane should be protected from damage throughout construction. Protection board should be applied after the membrane is installed. The proper timing of application after placement of the membrane is important and varies with the type of membrane used. Follow the manufacturer's printed instructions.

DRAINAGE SYSTEM

Drainage should be considered as a total system from the wearing surface down to the membrane, including use of multilevel drains.

Drainage at the wearing surface is generally accomplished in one of two ways: (1) by an open joint and pedestal system permitting the rainwater to penetrate rapidly down to the membrane level and subsurface drainage system; and (2) by a closed-joint system designed to remove most of the rainwater rapidly by slope

to surface drains and to allow a minor portion to infiltrate to the membrane.

A drainage course of washed, round gravel or prefabricated drainage composite should be provided above the protection board, over the membrane. This permits water to filter to the drain and provides a place where it can collect and freeze without damaging the wearing course.

INSULATION

When required, insulation should be located above the membrane, but not in direct contact with it.

PROTECTION OR WORKING SLAB

A concrete slab could be placed soon after the membrane, protection board, drainage course, and insulation, if required, have been installed. It would serve as protection for the permanent waterproofing materials and insulation below, provide a working platform for construction traffic and storage of materials (within weight limits), and provide a substantial substrate for the placement of the finish wearing course materials.

WEARING COURSE

The major requirements for the wearing course are a stable support of sufficient strength, resistance against lateral thrust, adequate drainage to avoid ponding of water, and proper treatment of joints. Under a thick-set mortar bed supporting masonry units, a prefabricated drainage composite helps resist freeze-thaw damage to the wearing course by expediting water flow down to the subsurface drainage system.

Joints in which movement is anticipated should be treated as expansion joints. Various compression seals are available that can be inserted into a formed joint under compression. Most of these, however, are not flush at the top surface and could fill up with sand or dirt.

Wet sealants are the materials most commonly used in moving joints at the wearing surface level. Dimension A is the design width dimension or the dimension at which the joint will be formed. The criterion normally used for determining this dimension with sealants capable of ± 25% movement is to multiply the maximum expected movement in one direction by 4. Generally, this is expected to be about three-fourths of the total anticipated joint movement, but if there is any doubt, multiply the total anticipated joint movement by 4. It is better to have the joint too wide than too narrow. Dimension B (sealant depth) is related to dimension A and is best established by the sealant manufacturer. Generally, B is equal to A for widths up to 13 mm (1/2 in.), 15 mm (5/8 in.) for a 16 mm (5/8 in.) width, and 16 mm (5/8 in.) for 19 mm (3/4 in.) and greater widths. This allows some tolerance for self-leveling sealants.

SUBSTRATE

The building deck or substrate referred to is reinforced cast-in-place structural concrete.

The structural slab should have a finish of sufficiently rough texture to provide a mechanical bond for the membrane, but not so rough to preclude achieving continuity of the membrane across the surface.

The concrete should be cured a minimum of 7 days and aged a minimum of 28 days, including curing time, before application of the bituminous membrane. Curing is accomplished chemically with moisture and should not be construed as drying. Liquid or chemical curing compounds should not be used unless approved by the manufacturer of the built-up bituminous membrane as the material may interfere with the bond of the membrane to the structural slab.

MEMBRANE

A built-up bituminous waterproofing membrane consists of components joined together and bonded to its substrate at the site. The major membrane components include primers, bitumens, reinforcements, and flashing materials.

Surfaces to receive waterproofing must be clean, dry, reasonably smooth, and free of dust, dirt, voids, cracks, laitance, or sharp projections before application of materials.

Concrete surfaces should be uniformly primed to enhance the bond between the membrane and the substrate, so as to inhibit lateral movement of water.

The number of plies of membrane reinforcement required is dependent upon the head of water and strength required by the design function of the wearing surface. Plaza deck membranes should be composed of not less than three plies. The composition of the membrane is normally of a "shingle" or "ply-on-ply" (phased) construction.

For application temperatures, follow the recommendations of the manufacturers of the membrane materials.

Over reinforced structural slab joints, one ply of 6-in.-wide membrane reinforcement should be applied before application of the bituminous membrane.

Nonreinforced joints should receive a bead of compatible sealant in a recessed joint before application of the membrane.

At expansion joints, gaskets and flexible preformed sheets are required inasmuch as bituminous membranes have little or no movement capability. Since such materials must be joined to the bituminous membrane, the watershed concept should be used.

Reinforce all intersections with walls and corners with two layers of woven fabric embedded in hot bitumen.

Flashing membranes should extend above the wearing surface and the highest possible water level and not less than 150 mm (6 in.) onto the deck membrane.

The flashing should extend over the wall dampproofing or membrane waterproofing not less than 100 mm (4 in.).

Drains must be provided with a wide metal flange or base and set slightly below the drainage level. Metal flashing for the drain, if required, and the clamping ring should be set on the membrane in bituminous plastic cement. The metal flashing should be stripped in with a minimum of two plies of membrane reinforcement and three applications of bituminous plastic cement.

Penetrations through the membrane such as conduits and pipes should be avoided whenever possible. Penetrations must be flashed to a height above the anticipated water table that may extend above the wearing surface.

The built-up bituminous membrane should be protected from damage. Protection board should be placed on the waterproofing membrane when the final mopping is being placed. It will then be adhered to the membrane.

SUBSTRATE

The building deck or substrate referred to is reinforced cast-in-place structural concrete.

Polymeric, latex, or other organic chemical-based admixtures or modifiers can coat the concrete particles and reduce the ability of the membrane to bond to the substrate. Admixtures should not be used in the concrete unless determined that they are acceptable for use with the membrane.

The underside of the concrete deck should not have an impermeable barrier. A metal liner or coating that forms a vapor barrier on the underside traps moisture in the concrete and destroys or prevents the adhesive bond of the membrane to the upper surface of the concrete.

The surface should be of sufficiently rough texture to provide a mechanical bond for the membrane, but not so rough as to preclude achieving continuity of the membrane of the specified thickness across the surface.

The concrete should be cured a minimum of 7 days and aged a minimum of 28 days, including curing time, before application of the liquid-applied membrane. Curing is accomplished chemically with moisture and should not be construed as drying. Liquid or chemical curing compounds should not be used unless approved by the manufacturer of the liquid-applied membrane as the material may interfere with the bond of the membrane to the structural slab.

MEMBRANE

The membrane should be applied under dry, frost-free conditions on the surface as well as throughout the depth of the concrete slab. Use manufacturer's requirements for the particular membrane.

TERMINATION ON WALLS

A liquid-applied membrane, because of its inherent adhesive properties, may be terminated flush on the wall without the use of a reglet. However, the use of a reglet in a concrete wall has the advantage of providing greater depth protection at the terminal.

TERMINATION AT DRAINS

Drains should be designed with a wide flange or base as an integral part. The drain base should be set flush with the structural slab. Vehicular supporting drains generally require additional weep holes drilled into them (see detail).

TREATMENT AT REINFORCED JOINTS

One recommended treatment of reinforced concrete joints in the structural slab is to apply a double layer of membrane over the crack. This type of detail is quite limited and implicitly relies on the membrane's crack-bridging ability. An alternative approach is to prevent the membrane from adhering to the substrate for a finite width centered on the joint or crack by means of a properly designed compatible bond-breaker tape.

TREATMENT AT NONREINFORCED JOINTS

Since the joints are not held together with reinforcing steel, some movement, however slight, should be anticipated and provided for, since the liquid-applied membrane has limited ability to take movement.

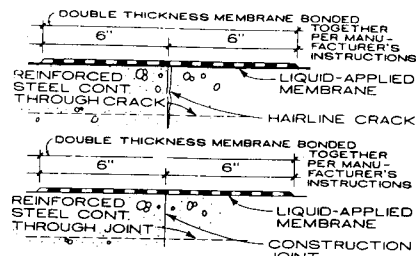

TREATMENT AT EXPANSION JOINTS

Gaskets and flexible preformed sheets lend themselves better to absorbing large amounts of movement. Since such materials, when used at an expansion joint, must be joined to the liquid-applied membrane, the watershed concept should be used.

PROTECTION BOARD

The liquid-applied membrane should be protected from damage prior to and during the remainder of deck construction. The proper timing of the application of the board is important and the manufacturer's printed instructions should be followed.

Reference: ASTM C 898. Highlights of text and figures are reprinted with permission from ASTM Committee C-24 of the American Society for Testing and Materials.

INSULATION DEFINED

The word insulate comes from the Latin "insula," meaning island, i.e., an isolated and/or separated place or condition. An insulating material is one that isolates sources of electricity, heat, or sound energy. Building insulation should effectively isolate heat, sound or both.

Nature seeks consonance. This explains why heat (energy) moves toward cold (lack of energy). A balance and harmony is being sought. The primary concept of insulators is to resist the natural tendency of energy to flow from the source and affect the surroundings. By this definition, any material that effectively blocks, absorbs, slows down, or reflects heat and sound is a building insulator.

VAPOR AND MOISTURE

In conjunction with thermal insulators is the necessary concern for vapor retarders and barriers. Although heat energy moves in a variety of ways such as direct radiation, convection, and conduction, one primary vehicle for heat transfer is air. Air expands when it is heated and gains the capacity to hold more water vapor. When warm and moist air is cooled, it condenses and loses the capacity to hold the same amount of vapor. The water vapor condenses, dew-point is reached, and the water vapor becomes liquid in the same manner that moisture occurs on the warm side (outer surface) of a cold glass of iced tea on a hot and humid day. Since an insulator is normally placed on the warm side of the building, closest to the interior to resist the flow of heat to cold, it follows that this is also where the greatest potential for moisture and moisture damage may occur inside the building section.

It is virtually impossible to construct a perfect vapor barrier. The word "barrier" is used in common building terminology. Construction vapor barriers are actually very effective vapor retarders made of such materials as polyethylene and various facings on insulation that do not totally stop moisture vapor transmission. When a retarder reduces the transmission of moisture to one perm or less, it may be referred to as a vapor barrier.

GLASS FIBERS

The fibers of glass fiber insulation have firm and cylindrical cross sections that only touch at tangent points. Therefore, there is little heat transmitted by conduction. In addition, glass fibers trap a large amount of air, which increases insulation potential.

CELLULOSE FIBERS

The fibers of cellulose and other blown or hand packed insulators are softer fibers that have wider contact points. This permits more heat transfer through conduction than glass fibers. These fibers also trap a large quantity of air that increases insulation value.

GRANULAR

CELLULAR

Vermiculite and perlite insulation are composed of small, rock-like, rounded granules that have small contact points that limit heat conduction. Spaces between the granules contain insulating air.

Extruded, molded, and foamed plastic insulations are cellular or honeycombed. Walls of the cells conduct heat around the cells. Cells contain a large volume of air that greatly increases insulation value.

HEAT FLOW PARALLEL

HEAT FLOW PERPENDICULAR

If fibrous insulation is used, the direction of the fibers in relation to the direction of the heat flow will affect the rate of heat movement. Under equal conditions, fibers perpendicular to heat flow transmit heat slower than fibers parallel to heat flow.

If there are many small fibers of insulation material within a given space, they provide more surface area than larger fibers in the same area. Since thickness of air films surrounding any fiber is essentially the same under still air conditions, smaller fibers provide more surface and more air. Larger fibers may leave larger gaps and paths that allow air to flow by means of convection. Granular and cellular insulation also possess air films. If the cell or space between granules is too large, convection currents can occur that will transmit heat across the space.

7 THERMAL PROTECTION

THERMAL INSULATION

Thermal insulation controls heat flow under temperatures ranging from absolute zero to 3000°F. This broad range can be subdivided into four general temperature regimes that classify applications for various types of insulation:

1. **LOW TEMPERATURES:** Insulation for vessels containing cryogenic materials, such as liquefied natural gas.
2. **AMBIENT TEMPERATURES:** Insulation for building structures.
3. **MEDIUM TEMPERATURES:** Insulation for tanks, pipes, and equipment in industrial process heat applications.
4. **HIGH TEMPERATURES:** Refractory or other specialized insulation materials used in foundry work, nuclear power facilities, the aerospace industry, and so on.

Architects and builders are generally concerned with the design and material performance of building insulations that operate within ambient temperature limits. As temperatures range much above or below ambient conditions, design and performance requirements change and must be matched with insulation materials that withstand the stress introduced by extreme temperatures, large temperature differentials, and thermal cycling.

BUILDING INSULATION—THERMAL FUNCTIONS

The two major functions of building insulations are to (1) control temperatures of inside surfaces that affect the comfort of occupants and aid or deter condensation and (2) conserve energy by reducing heat transmission through building sections that determine the energy requirements for both heating and cooling. Economics in fuel consumption can be calculated with reasonable accuracy and balanced against initial costs of insulation and the costs for heating and cooling with equipment (see figure).

ADDITIONAL FUNCTIONS

Thermal insulations may also perform several other functions:

1. Add structural strength to a wall, ceiling, or floor section.
2. Provide support for a surface finish.
3. Impede water vapor transmission.
4. Prevent or reduce damage to equipment and structure from exposure to fire and freezing conditions.
5. Reduce noise and vibration.

BASIC MATERIALS

Thermal insulation is made from the following basic materials:

1. **MINERAL FIBROUS:** Material such as glass, rock, slag, or asbestos that is melted and spun into thin fibers.
2. **MINERAL CELLULAR:** Material such as foamed glass, calcium silicate, perlite, vermiculite, foamed concrete, or ceramic.
3. **ORGANIC FIBROUS:** Material such as wood, cane, cotton, hair, cellulose, or synthetic fibers.
4. **ORGANIC CELLULAR:** Material such as cork, foamed rubber, polystyrene, or polyurethane.
5. **METALLIC:** Aluminum or other foils, or metallized organic reflective membranes that must face air, gas filled, or evacuated spaces.

PHYSICAL STRUCTURE AND FORM

Thermal insulation is available in the following physical forms:

1. **LOOSE FILL:** Dry granules, nodules, or fibers poured or blown into place.
2. **FLEXIBLE OR SEMIRIGID:** Blankets and batts of wool-like material.
3. **RIGID:** Boards and blocks.
4. **MEMBRANE:** Reflective insulation.
5. **SPRAY APPLIED:** Mineral fiber or insulating concrete.
6. **POURED-IN-PLACE:** Insulating concrete.
7. **FOAMED-IN-PLACE:** Polyurethane, urea formaldehyde.

MECHANISMS OF HEAT TRANSFER

Heat flows through materials and space by conduction, convection, and radiation. Convection and conduction are functions of the roughness of surfaces, air movement, and the temperature difference between the air and surface. Mass insulations, by their low densities, are designed to suppress conduction and convection across their sections by the entrapment of air molecules within their structure. Convective air currents are stilled by the surrounding matrix of fibers or cells, and the chances of heat transfer by the collision of air molecules is reduced. Radiant heat transfer between objects operates independently of air currents and is controlled by the character of the surfaces (emissivity) and the temperature difference between warm objects emitting radiation and cooler objects absorbing radiation.

The resistance of these modes of heat transfer may be retarded by the elements of a building wall section.

1. **OUTSIDE SURFACE FILMS:** The outside surface traps a thin film of air, which resists heat flow. This film varies with wind velocity and surface roughness.
2. **MATERIAL LAYERS:** Each layer of material contributes to the resistance of heat flow, usually according to its density. A layer of suitable insulation is normally many times more effective in resisting heat transfer than the combination of all other materials in the section.
3. **AIRSPACE:** Each measurable airspace also adds to the overall resistance. Foil faced surfaces of low emissivities that form the boundaries of the airspace can further reduce the rate of radiant transfer across the space.
4. **INSIDE SURFACE FILM:** The inside surface of the building section also traps a thin film of air. The air film thus formed is usually thicker because of much lower air velocities.
