Exterior insulation and finish systems provide an uninterrupted layer of rigid insulation that is attached by adhesives or mechanical fasteners directly onto the building substrate. A continuous fiberglass mesh layer is then applied and attached by adhesives or mechanical fasteners. A finish coat covers and seals the entire system.

NOTES

1. Insulation panels are made in varying thicknesses from 1 to 4 in., depending on the wall U-factor requirements. They come in varying sizes, generally 2 x 2 ft, 2 x 4 ft, or 2 x 8 ft, depending on manufacturer or system used. Expanded polystyrene (1 to 2 lb/cu ft) is generally used above grade; extruded polystyrene (2 to 3 lb/cu ft) is generally used below grade or in high traffic areas.
2. For areas likely to receive abuse by high impact or high traffic, a heavy duty fiberglass mesh reinforcement layer is used in addition to, or in place of, the standard mesh. Also, zinc casing beads are frequently used at finish layer edges.
3. When mechanical fasteners are used they should be installed flush with or, preferably, recessed into the insulation panel to prevent "bubbles" on the surface. When recessed, some manufacturers provide an insulation plug over the fastener to leave a continuous layer of insulation at the surface before the finish is applied.
4. For walls with damaged or brittle substrates, a mechanically fastened track system is used by some manufacturers to fasten the insulation panels to the substrate.
5. The synthetic-stucco finish layer is generally weather resistant, crack resistant, and vapor permeable and is troweled, rolled, or sprayed onto the surface over the ground coat adhesive. It is generally made from acrylic polymers with an aggregate or silica sand, quartz chips, or marble chips to give it the desired texture. Color is achieved by either tinting the finish coat with pigment or painting the surface.

WATER VAPOR MIGRATION

Water is present as vapor in indoor and outdoor air and as absorbed moisture in many building materials. Within the range of temperatures encountered in buildings, water may exist in the liquid, vapor, or solid states. Moisture related problems may arise from changes in moisture content, from the presence of excessive moisture, or from the effects of changes of state, such as freezing within walls or deterioration of materials due to rotting or corrosion.

In the design and construction of the thermal envelope of buildings (the enclosure of desired temperatures and humidities), the behavior of moisture must be considered, particularly the change of state from vapor to liquid (condensation). Problems arise when moisture comes into contact with a relatively cold surface (temperature below the dew point), such as a window, or within outdoor walls or under-roof ceilings. Excessive condensation within indoor walls that enclose cold spaces must be considered.

While moisture moves in still air by vapor pressure differences, it is important to recognize that moisture in air is moved by the air. Consequently, the causes of air motion must be considered, especially the infiltration and exfiltration at undesirable leakage rates at windows, doors, and other penetrations through the thermal envelope of the building.

Moisture problems in residences generally occur in seasons when the outdoor temperature and vapor pressure are low and there are many indoor vapor sources. These may include cooking, laundering, bathing, breathing, and perspiration for the occupants, as well as automatic washers and dryers, dishwashers, and humidifiers. All of these sources combine to cause vapor pressure indoors to be much higher than outdoors, so that the vapor tends to migrate outward through the building envelope. Vapor cannot permeate glazed windows or metal doors, but most other building materials are permeable to some extent. Walls are particularly susceptible to this phenomenon, and such migration must be prevented or at least minimized by the use of low permeance membranes, called *vapor retarders* (formerly, *vapor barriers*). They are now called *retarders*, not *barriers*, because they do not stop moisture flow completely. A vapor retarder is a material that has a flow rating of one perm or less. (1 perm = 1 grain/hr ft · in. Hg vapor pressure difference; there is no metric perm.)

Vapor retarders should be installed as close as possible to the side of the wall through which moisture enters. Establish the side of moisture entrance in walls of controlled rooms within buildings. However, the beneficial effects of good vapor retarders are lost without adequate air barriers.

Moisture in building materials usually increases their thermal conductance significantly and unpredictably. Porous materials that become saturated with moisture lose most of their insulating capability and may not regain it when they dry out. Dust, which usually settles in airspaces, may become permanently affixed to originally reflective surfaces. Moisture migration by evaporation, vapor flow, and condensation can transport significant quantities of latent heat, particularly through fibrous insulating materials.

Positive steps should be taken to prevent migration of moisture in the form of vapor and accumulation in the form of water or ice within building components. Vapor retarders, correctly located near the source of the moisture, are an effective means of preventing such migration. Venting of moisture laden air from bathrooms, laundry rooms, and kitchens will reduce indoor vapor pressure, as will the introduction of outdoor air with low moisture content.

BUILDING SECTION ANALYSIS FOR POTENTIAL CONDENSATION

Any building section may be analyzed with simple calculations to determine where condensation might occur and what might be done in selecting materials or their method of assembly to eliminate that possibility. The section may or may not contain a vapor retarder, or it may contain an inadequate one; the building section may include cold-side materials of comparatively high resistance to the passage of vapor (which is highly undesirable). With few exceptions, the vapor resistance at or near the warm surface should be five times that of any components. The table gives permeance and permeability of building and vapor retarder materials. These values can be used in analyzing building sections by the following simple method:

- List the materials, without surface films or airspaces, in the order of their appearance in the building section, beginning with the inside surface material and working to the outside.
- Against each material list the permeance (or permeability) value from the table or a more accurate value if available from tests or manufacturers' data. Where a range is

given, select an average value or use judgment in assigning a value based on the character and potential installation method of the material proposed for use.

- Start at the top of the list and note any material that has less permeance than the materials above it on the list. At that point the possibility exists that vapor leaking through the first material may condense on the second, provided the dew point (condensation point) is reached and the movement is considerable. In that case, provide ventilation through the cold-side material or modify the design to eliminate or change the material to one of greater permeance.

ESTIMATED PERMEANCE

MATERIAL	PERM IN. ²
GWB (7/8")	50.0
Vapor retarder	0.6 (lowest)
Insulation	29.0
Wood sheathing	2.9
4" brick veneer	1.1 (next)

EXAMPLE

In this example the vapor retarder transmits 1 grain of moisture per square foot per hour for each unit of vapor pressure difference, or one perm, and nothing else transmits less. However, since the cold brick veneer is nearly as low in permeance, it is advisable to make certain that the vapor retarder is expertly installed, with all openings at pipes and with outlet boxes or joints carefully fitted or sealed. Alternatively, the brick veneer may have open mortar joints near the top and bottom to serve both as weep holes and as vapor release openings. They will also ventilate the wall and help reduce heat gain in summer.

ESTIMATED PERMEANCE

MATERIAL	PERM IN. ²
GWB (7/8")	50.0
Furred space	8" CMU
4" brick veneer	1.1 (lowest)

EXAMPLE

Vapor (under pressure) would easily pass through the interior finish, be slowed by the concrete masonry unit, and be nearly stopped by the cold brick veneer. Unless this design is radically improved, the masonry will become saturated and may cause serious water stains or apparent "leaks" in cold weather. In addition, alternating freezing and thawing of condensation within the masonry wall can physically damage the construction.

PERMEANCE AND PERMEABILITY OF MATERIALS TO WATER VAPOR

MATERIAL	PERM IN. ²
MATERIALS USED IN CONSTRUCTION	
Concrete (1:2:4 mix)	3.2 ⁵
Brick-masonry (4 in. thick)	0.8-1.1

1/16 in. dry	0.14
3/16 in. dry	0.0
Hot melt asphalt	
2 oz/sq ft	0.5
3.5 oz/sq ft	0.1

NOTES

1. The vapor transmission rates listed will permit comparisons of materials, but selection of vapor retarder materials should be based on rates obtained from the manufacturer or from laboratory tests. The range of values shown indicates variations among mean values for materials that are similar but of different density. Values are intended for design guidance only.
2. Usually installed as vapor retarders. If used as exterior finish and elsewhere near cold side, special considerations are required.
3. Low permeance sheets used as vapor retarders. High permeance used elsewhere in construction.
4. Bases (weight in lb/500 sq ft).
5. Permeability (perm in.)

Based on data from ASHRAE Handbook of Fundamentals, 1984 I-P section, chapter 22.

David F. Hill; Burt Hill Kosar Rittelmann Associates; Butler, Pennsylvania
 Marc A. Giaccardo; College of Architecture, Texas Tech University; Lubbock, Texas

NOTES

Shakes can also be applied over any existing wall or roof. Brick or other masonry requires vertical frameboards and horizontal nailing strips.

Over stucco, horizontal nailing strips are attached directly to wall. Nails should penetrate sheathing or studs. Over wood, apply shakes directly just as if on new sheathing.

WOOD SHAKES APPLIED TO EXISTING ROOF

GENERAL NOTES

1. Wood shingles and shakes are cut from wood species that are naturally resistant to water, sunlight, rot, and hail: i.e., red cedar, redwood, and tidewater red cypress. They are typically installed in the natural state, although stains, primers, and paint may be applied.
2. Nails must be hot dipped in zinc or aluminum. Nail heads should be driven flush with the surface of the shingle or shake but never into the wood.
3. Underlayment and sheathing should be designed to augment the protection provided by the shingles or shakes, depending on roof pitch and climate. A low-pitched roof subject to wind driven snow should have solid sheathing and an additional underlayment.

RED CEDAR HANDSPLIT SHAKES

RED CEDAR HANDSPLIT SHAKES

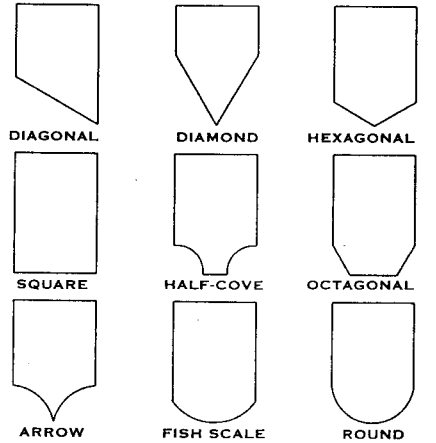

GRADE	LENGTH AND THICKNESS	DESCRIPTION
No. 1 handsplit and resawn	15" starter-finish 18 x 1/2" medium 18 x 3/4" heavy 24 x 3/8" medium 24 x 1/2" medium 24 x 3/4" heavy	These shakes have split faces and sawn backs. Cedar logs are first cut into desired lengths. Blanks or boards of proper thickness are split and then run diagonally through a bandsaw to produce two tapered shakes from each blank.
No. 1 tapersplit	24 x 1/2"	Produced largely by hand, using a sharp bladed steel froe and a wooden mallet. The natural shinglelike taper is achieved by reversing the block, end-for-end, with each split.
No. 1 straight	18 x 3/8" side wall 18 x 3/8" 24 x 3/8"	Produced in the same manner as tapersplit shakes except that by splitting from the same end of the block, the shakes acquire the same thickness throughout.

RED CEDAR SHINGLES

7 SHINGLES, ROOF TILES, AND ROOF COVERING

ROOF PANEL SYSTEM

SIDEWALL PANEL APPLIED TO STUDS

SIDEWALL PANEL APPLIED TO NAILING STRIPS

SIDEWALL PANEL APPLIED TO SHEATHING

NOTES

- With the panel system, shakes and shingles plus sheathing go up in one operation: 8 ft roof panels have 16 hand-split shakes bonded to 6 x 1/2 in. plywood strip, which forms a solid deck when the panels are nailed. A 4 to 12 or steeper roof pitch is recommended.
- After application of starter panels, attach panels directly to rafters. Although designed to center on 16 in. or 24 in. spacing, they may meet between rafters. Use two 6d nails at each rafter.
- 8 ft sidewall panels are of two-ply construction:
 - Surface layer of individual #1 grade shingles or shakes.
 - Backup of exterior grade plywood shakes or shingles is bonded under pressure with exterior type adhesives to plywood backup.
- Lap building paper behind panels 3 in. vertically and horizontally. Stagger joints between panels.
- Application types are determined by local building codes.
- Matching factory-made corners for sidewall or roof panels are available.

WOVEN OUTSIDE AND INSIDE CORNERS (MORE ECONOMICAL)

CORNER BOARDS AT OUTSIDE AND INSIDE CORNERS

WOOD SHINGLES AND SHAKES FOR SIDING

ROOF CONDITION

NOTE

In treating shakes, fire-retardant chemicals are pressure impregnated into the wood cells, and chemicals are then fixed in the wood to prevent leaching. Treatment does not alter appearance. Fire-retardant red cedar shakes are classified as Class C by UL. Class B classification by UL can be met with the addition of the deck constructed of 5/8 in. plywood with exterior glue or 1 in. nominal tongue and groove boards, overlaid with a layer of approved asbestos felt lapped 2 in. on all joints and an 18 in. wide strip of approved asbestos felt between each shake and not exposed to the weather. Decorative stains may be applied.

FIRE RATED CONSTRUCTION

SINGLE COURSING APPLICATION

DOUBLE COURSING APPLICATION

EXPOSURE FOR SHINGLES AND SHAKES USED FOR SIDING (IN.)

LENGTH OF SHINGLES	EXPOSURE OF SHINGLES	
	SGL. COURSE	DBL. COURSE
16	6 to 7 1/2	8 to 12
18	6 to 8 1/2	9 to 14
24	8 to 11 1/2	12 to 20

NAILING: THICKNESS AND NAILS

16" long	5 butts = 2"	3d
18" long	5 butts = 2 1/4"	3d
24" long	4 butts = 2"	4d
25" to 27"	1 butt = 1/2"	5 or 6d
25" to 27"	1 butt = 5/8" to 1 1/4"	7 or 8d

SHEATHING NOTES

- Sheathing may be strip type, solid 1 x 6 in., and diagonal type, in plywood, fiberboard, or gypsum board. Horizontal wood nailing strips (1 x 2 in.) should be used over fiberboard and gypsum sheathing. Space strips equal to shingle exposure.
- Many finishes can be used on red cedar shakes and shingles: solid color or semitransparent ("weathering") stains, exterior latex paint with primer, wood preservative, and bleaches.

SIDEWALL CONDITION

SCHEDULE OF UNDERLAYMENT

SLOPE	TYPE OF UNDERLAYMENT
Normal slope: 4 in 12 and up	Single layer of 15 lb asphalt saturated felt over entire roof
Low slope: 3 in 12 to 4 in 12	Two layers of 15 lb asphalt saturated felt over entire roof

Use only enough nails to hold underlayment in place until shingles are laid.

APPLICATION OF UNDERLAYMENT ON LOW SLOPE ROOFS

SCHEDULE OF SHINGLE TYPES (1)

DESCRIPTION	DESIGN	MATERIAL	U.L. RATING	WEIGHT	SIZE
Three-tab square butt		Fiberglass Organic felts	A C (4)	205-225 lb/sq 235-300 lb/sq	36" x 12"
Two-tab square butt		Fiberglass Organic felts	A C (4)	260-325 lb/sq 300 lb/sq	36" x 12"
Laminated overlay (2)		Fiberglass Organic felts	A C (3)	300 lb/sq 330-380 lb/sq	36" x 14"
Random edge cut		Fiberglass Organic felts	A C (3)	225-260 lb/sq 250 lb/sq	36" x 12"

NOTE: Exposure 5", edge lap 2".

NOTES

1. Exposure 5 in., edge lap 2 in., for all designs.
2. More than one thickness for varying surface texture.
3. Many rated as wind resistant.
4. All rated as wind resistant.

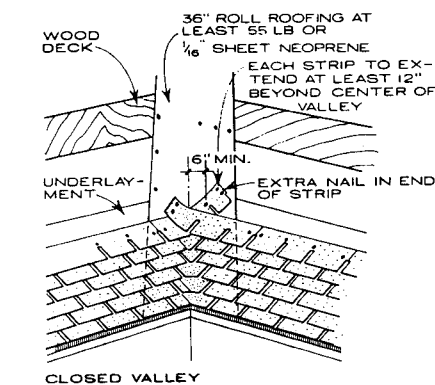

HIP AND RIDGE

OPEN VALLEY
Valley width should be 6" wide at ridge and spread wider at the rate of 1/8" / foot downward to eave. Establish valley width using chalkline from ridge to cove.

APPLICATION DIAGRAMS

EAVE FLASHING

Eave flashing is required wherever the January daily average temperature is 30°F or less or where there is a possibility of ice forming along the eaves.

NORMAL SLOPE—4 IN./FT OR OVER

A course of 90 lb mineral surfaced roll roofing or a course of 50 lb smooth roll roofing is installed to overhang the underlay and metal edge from 1/4 to 3/8 in. Extend up the roof far enough to cover a point at least 24 in. inside the interior wall line of the building. When the overhang requires flashing wider than 36 in., the horizontal lap joint is cemented and located on the roof deck extending beyond the exterior line of the building.

LOW SLOPE—3 TO 4 IN./FT

Cover the deck with two layers of 15# asphalt saturated felt. Begin with a 19 in. starter course laid along the eaves, followed by a 36 in. wide sheet laid even with the eaves and completely overlapping the starter course. The starter course is covered with asphalt cement. Thereafter, 36 in. sheets are laid in asphalt cement, each to overlap the preceding course 19 in., exposing 17 in. of the underlying sheet.

The plies are placed in asphalt cement to a point at least 36 in. inside the interior wall line of the building.

METHOD OF SECURING CAP FLASHING TO CHIMNEY MASONRY

DRIP EDGE DETAILS

NAIL TYPES	NAILING OF SHINGLES RECOMMENDATION	
	DECK TYPE	NAIL LENGTH

ROOFING SLATE

DIAGRAM OF PROPER LAP FOR RISE/RUN

GENERAL NOTES

1. COMMERCIAL STANDARD: The quarry run of 3/16 in. thickness; includes tolerable variations above and below 3/16 in.
2. TEXTURAL: A rough textured slate roof with uneven butts; the slates vary in thickness and size, which is generally not true of slate more than 3/8 in. thick.
3. GRADUATED: A textural roof of large slates; more variation in thickness, size, and color.
4. A SQUARE OF ROOFING SLATE: A number of slates of any size sufficient to cover 100 ft² with a 3 in. lap. Weight per square: 3/16 in.—800 lb; 1/4 in.—900 lb; 3/8 in.—1100 lb; 1/2 in.—1700 lb; 3/4 in.—2600 lb.
5. STANDARD NOMENCLATURE FOR SLATE COLOR: Black, blue black, mottled gray, purple, green, mottled purple and green, purple variegated, red; to be preceded by the word "Unfading" or "Weathering." Other colors and combinations are available.
6. PROPER JOINTING FOR PITCHED ROOFS: Requires a 3 in. minimum vertical overlap. Overlap varies with pitch; see graph above.
7. FELT: With Commercial Standard Slate use 30# saturated felt. With graduated roofs use 30# for 1/4 in. slate and 45#, 50#, or 65# prepared roll roofing for heavier slate.
8. NAIL FASTENING: Use large head, slaters' hard copper wire nails, cut copper, cut brass, or cut yellow metal slating nails. Each slate punched with two nail holes. Use nails that are 1 in. longer than thickness of slate. Cover all exposed heads with elastic cement. In dry climates hot dip galvanized nails may be used.

STANDARD SLATE DIMENSIONS*

LENGTH (IN.)	WIDTH (IN.)
10 [†]	6, 7, 8, 9, 10
12 [†]	6, 7, 8, 9, 10, 12
14 [†]	7, 8, 9, 10, 11, 12
16	8, 9, 10, 11, 12, 14
18	9, 10, 11, 12, 13, 14
20	9, 10, 11, 12, 13, 14
22	10, 11, 12, 13, 14
24	11, 12, 13, 14, 16

*The slates are split in these thicknesses: 3/16, 1/4, 3/8, 1/2, 3/4, 1, 1 1/4, and 1 1/2 in. 1 1/2 in. and larger slates are not often used in these sizes. Random widths are usually used.

Domenic F. Valente, AIA, Architect & Planner; Medford, Massachusetts

FLAT TILE NOTE

Mortar contact is made with 3 tiles.

MORTAR AND TILE PLACEMENT

GENERAL

Concrete tile is manufactured by extruding a mixture of portland cement, sand, and water on individual molds under high pressure. The finish surface of the tile is covered with a cementitious material that has been colored with synthetic oxides. The tiles are cured to required strengths in chambers where humidity and temperature are controlled. Moisture absorption by concrete tiles can lead to structural roof problems, and particular care should be given to specifying the correct concrete tile for a given environment.

For both categories of concrete tile—roll or flat—it is important to adhere to minimum slope requirements as follows:

1. Roll tile and flat tile can be installed on roof decks with slopes of 4 in. per ft or more when at least one layer of 30-lb felt underlayment is applied horizontally and tiles are nailed or wired with a minimum 3 in. headlap. Use of spaced sheathing is not recommended.
2. Any concrete tile can be used on solid-sheathed roof decks with slopes less than 4 in. per ft as long as two or more layers of No. 30 or No. 40 asphalt-saturated (non-perforated) felt are set in hot asphalt or mastic to serve as the underlayment. A single layer of modified bitumen-coated roofing systems roll-good sheet with laps either torched or heat welded is acceptable. Vertical lath stringers with horizontal battens are installed over the underlayment, creating a supporting surface for the tile, which must be installed with at least 4 in. headlap. Do not use spaced sheathing.
3. Regardless of slope, in localities where the January mean temperature is less than 30°F, stricter minimum requirements apply. Refer to the National Roofing Contractors Association manual.

FLAT TILE

When using flat roof tiles, a metal eave-riser with weep holes should be installed at the eave line. During installation, adjust tile spacing to provide uniform exposure, with a minimum 3 in. headlap.

ROLL TILE

When using roll, or mission, tile, apply the first course above a metal bird-stop with weep holes. Fit the underside of the tile with specially formed eave closure strips, fastened inside the tile cover. The heads of all remaining tiles should be aligned with the horizontal guide lines. Adjust roll tile spacing to provide uniform exposure, with at least a 3 in. headlap. Jamming interlocking tiles together (side to side) will restrict movement and result in broken corners.

ROOF SLOPE

For roof slopes 5 in. in 12 and less, solid sheathing may be used with or without battens. Nailing is not required with battens, but every tile should be nailed if battens are not used. In either case, perimeter nailing is required for 3 ft or three courses, whichever is greater, from all eaves, rakes, ridges, hips, or valleys. (Do not nail into valley metal.)

For roof slopes between 5 and 7 in. in 12, nail every other tile over solid sheathing with battens and every tile if battens are not used. For slopes between 7 and 12 in. in 12, every other tile should be nailed over solid sheathing with battens. Perimeter nailing is required in all these situations.

For slopes 12 in. in 12 and greater, nail every tile over solid sheathing with battens; perimeter nailing is necessary.

TILES SET IN MORTAR

The practice of installing cement tiles with mortar over a built-up subroof evolved in high-wind and high-moisture areas of the southeastern United States. In this system, the built-up subroof provides the moisture barrier, and the tiles protect the subroof from solar ultraviolet rays, high winds, and external damage. This concrete tile system can also be used on low-slope roofs, but the minimum is 2 in. in 12. On slopes between 5 in. in 12 and 7 in. in 12, additional mechanical fastening is required for the first three courses of tile in areas subject to high winds. For roofs with steeper slopes, tile should be mechanically fastened.

TYPICAL ROLL TILES

NOTE

This detail is for pitches 4:12 and greater.

FIELD INSTALLATION OF FLAT TILES

RIDGE NAILER OF SUFFICIENT HEIGHT TO MAINTAIN EVEN PLANE OF RIDGE TILES

HIP AND RIDGE DETAIL

ATTACHMENT PROCEDURES FOR CONCRETE ROOF TILES

ROOF SLOPE	FIELD TILE NAILING		NAILING FOR PERIMETER TILE AND TILE ON CANTILEVERED AREAS ¹
	SOLID SHEATHING WITH BATTENS	SOLID SHEATHING WITHOUT BATTENS ¹

7 SHINGLES, ROOF TILES, AND ROOF COVERING

COMPOSITE ROOFING TILES

Fiber cement, cement wood, galvanized steel with acrylic coating, and ceramic slate roofing tiles are popular alternatives to clay or concrete roofing tiles. These composite tiles have been designed to be lighter, stronger, and easier to install than traditional, "natural" tiles. Their strength and combination of materials make them more fire retardant and wind resistant than conventional tiles.

FIBER CEMENT

Fiber cement tiles combine organic fiber with cement, silica, water, and other additives. The resulting product is a roof slate that is lightweight, strong, versatile, and easy to install. The tiles can be made in a variety of distinctive shapes, colors, and textures that mimic natural materials such as slate and patterned wood shingles. Fiber cement tiles resist deterioration and moisture penetration and are immune to pests and fungal growth. They are well-suited for coastal regions and other areas with high humidity.

Fiber cement tiles should be applied to nailable decks only. For plywood decks with rafters spaced 20 in. or less, the plywood should be at least 1/2 in. thick. If rafters are spaced greater than 20 in., 5/8 in. plywood is recommended. To fasten, use standard 1 1/2 in. galvanized 11-gauge flat-head roofing nails with a 3/8 in. head. Flashing should be of a noncorrosive metal not lighter than 28 gauge.

CERAMIC SLATE

Ceramic slate tiles combine the look of natural slate with the fired-in strength and durability of ceramic tile. Such tiles have the thickness, texture, and appearance of older slate but at a fraction of the weight and cost. They are impervious to freeze-thaw cycles, fire, moisture, and efflorescence.

CEMENT WOOD TILES

Cement wood tiles are lightweight tiles that can be used for reroofing as well as for new construction. They have excellent impact resistance and are easily sawn and nailed. As a richly textured, composite product, cement wood tiles create an aesthetic similar to that of heavy cedar shakes yet provide the fire protection associated with cementitious products. Cement wood tiles, with their composite of portland cement and wood fiber, are long lasting. The portland cement is noncombustible and allows for Class A fire ratings, and the wood fibers provide excellent tensile strength and a light weight when compared to standard concrete tiles.

METAL ROOFING TILES

The advantage of metal roofing tiles over traditional clay or concrete tiles is that they are lightweight. They are easier to handle, quicker to install, and, because they require fewer building components, are less costly. Minimum recommended roof pitch for use of metal roofing tiles is a slope of 3 in 12. Roofs with shallower slopes require sealant in all side laps.

Metal roofing tiles usually come in sheets and have a base material of roll-formed 24- to 26-gauge prepainted galvanized or galvalume steel. A layer of crushed and graded stone granules is bonded to the steel panels with an acrylic resin formula and then a clear acrylic overglaze is applied. Slow oven curing completes the process, and the underside of the tile is protected with a final coat of polyester paint. Panels can be installed quickly and are secured to either wood or steel battens, creating a strong, weather-proof construction. The panels can be installed directly over existing roofs, unlike clay or concrete tiles, and are thus ideally suited for retrofitting roofs.

NOTE
When an equal number of full courses cannot be accommodated at the pitch change, a full panel can be bent to suit. When the roofline changes dramatically, install a batten at the pitch change.

FORMED ALUMINUM ROOFING AND SIDING

- NOTES**
1. Endlaps for roofing and siding shall be at least 6 in. and fastened at every rib. Two fasteners may be required when designing for a negative (uplift) loading condition.
 2. Minimum sidelaps shall be equal to one rib or corrugation and laid away from prevailing wind. Fasteners shall be spaced a maximum of 12 in. on center for all types of roofing and siding.
 3. For roofing, fasteners shall pierce only the high corrugation. For siding, fasteners shall pierce either the high or low corrugation. Consult manufacturer for proper sheet metal fasteners and accessories.
 4. Minimum slopes for sheet roofing are as follows:
 - a. 1 in. depth corrugated—3 in 12.
 - b. 1 1/2 in. depth ribbed—2 in 12.
 - c. 1 3/4 in. v-corrugated—2 in 12.
 5. See page on Metal Walls for insulation details and fire rated wall assemblies.

NOTES

Shown here are basic panel designs with an assortment of connection details. A vast array of folded, ribbed, and grooved sheet configurations is available.

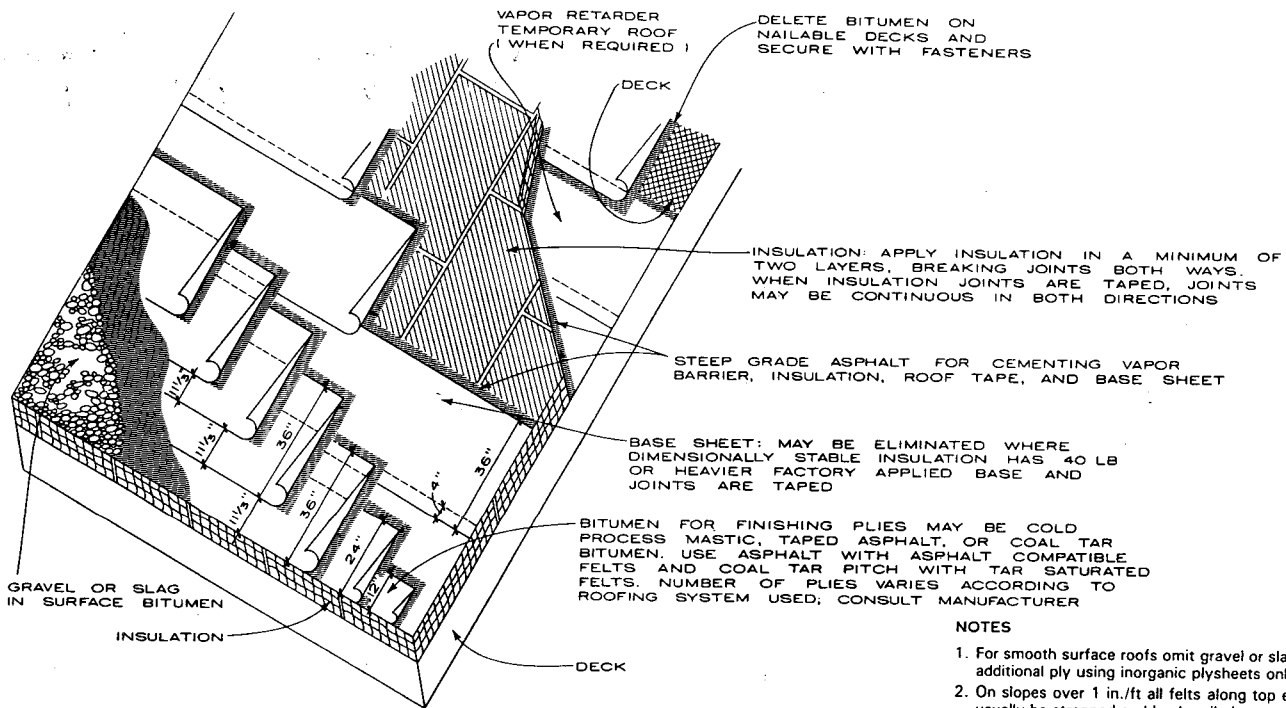

Typical applied finishes available for outer sheets are acrylics, vinyls, alkyds, fluoropolymers, porcelain enamel, and, on aluminum only, various anodized finishes. Length of sheets available is 40 ft. Span and wind load must be considered in the selection of panel components and spacing of girts.

Panels can span from 9 ft 6 in. to 26 ft or more if placed in multispan arrangements. Face panel configuration and wind load value vary.

Consult manufacturers for thermal and acoustical ratings.

Eric K. Beach; Rippeteau Architects, PC; Washington, D.C.

7 ROOFING AND SIDING PANELS

20 YEAR TYPE BUILT-UP ROOF OVER INSULATION

NOTES

1. For smooth surface roofs omit gravel or slag and add additional ply using inorganic plysheets only.
2. On slopes over 1 in./ft all felts along top edge must usually be strapped and back-nailed.
3. When vapor retarder is used, edges of felt should be turned up to a height of 2 in. above cant strip at vertical surfaces. Felts should overlap all roof edges a minimum of 6 in. before application of roofing, 6 in. of felt must be re-turned over the insulation and mopped solidly.

MINERAL SURFACE BUILT-UP ROOF

NOTES

1. Over nonnailable deck or insulation omit rosin paper and cement with asphalt. Nailing strips must be provided.
2. Minimum slope for organic felt: 1/2 in./ft.
3. Minimum slope for fiberglass felt: 0 in./ft.
4. Consult manufacturer for spacing of nails for particular roofing system.

SCHEDULE OF FELT OVERLAP (INCHES)

Organic base sheet	4
Fiberglass or base sheet	2
2-ply felts/plysheets	19
3-ply felts/plysheets	24 ² / ₃
4-ply felts/plysheets	27 ¹ / ₂
Fiberglass mineral	3 if selvage granulated
Surface cap sheet	2 if selvage granulated

PATTERN FOR NAILING BASE SHEET OR VAPOR RETARDER OVER NAILABLE DECK

Kent Wong; Hewlett, Jamison, Atkinson & Luey; Portland, Oregon;
 Developed by Angelo J. Forlidas, AIA; Charlotte, North Carolina; from data furnished by Robert M. Stafford, P.E., Consulting Engineer; Charlotte, North Carolina

THREE-PLY OVER NAILABLE DECK

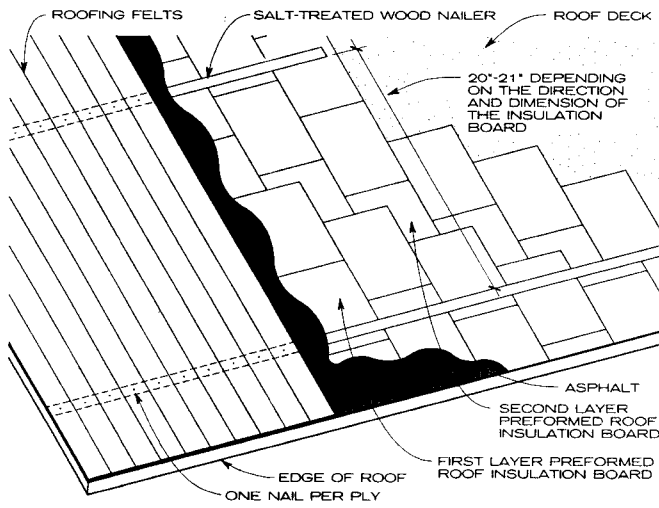

- NOTES**
1. If applied over sheathing panels, add rosin-sized sheathing paper between the deck and base sheet.
 2. In lieu of asphalt, coal tar is an acceptable product.

THREE-PLY OVER NON-NAILABLE DECK

- NOTES**
1. For a more conservative system, specify four plies rather than three.
 2. In lieu of asphalt, coal tar is an acceptable product.

AGGREGATE SURFACE BUILT-UP ROOFING

WOOD NAILER BACKNAILING SYSTEM

GENERAL

A built-up roofing (BUR) system is composed of a base sheet attached to the roof substrate, two or more reinforcing felt ply sheets, and a surfaced cap sheet. Asphalt and coal tar are the bitumens used for built-up roofing. As the heated mopping bitumen fuses with the saturating bitumen in the roofing felts, the layers are welded together. Surfacing include aggregate, minerals, protective or reflective coatings, and smooth surface.

Four types of asphalt and two types of coal tar are presently used as bitumens in built-up roofing systems. The grade of asphalt used for BUR systems should be appropriate for the slope of the roof. Backnailing of felts is recommended for built-up roofing whenever the roof slope exceeds 1/2 in. per ft. Aggregate-surfaced built-up roofing should not be used on slopes exceeding 3 in. per ft.

Reinforcing felts for BUR may be saturated, coated, or impregnated with bitumen and are manufactured from both organic and inorganic materials. Organic felts are manufactured from the fiber of paper, wood, or rags. Saturated felts are saturated with asphalt or coal tar bitumen. Impregnated roofing felts are generally lighter in weight and termed impregnated because their surface is not completely covered (coated) with asphalt. Saturated and coated roofing felts are generally factory coated on both sides and sur-

faced on one or both sides with fine mineral sand or other release agents to prevent adhesion inside the roll prior to application.

Prepared roofing materials are saturated and coated felts with talc, mica, sand, or ceramic granules incorporated into the weather surface of the felts, both to provide weather protection and for decorative purposes. Reinforced flashing membrane consists of a glass-fiber base felt that is laminated with cotton or glass-fiber fabric and coated with asphalt. Rosin-sized sheathing paper is a rosin-coated building paper generally used in built-up roofing to separate felts from wood plank roof decks.

TEMPERATURE

Proper application temperatures are vital to the creation of a quality roof membrane system. Temperatures that are too high can lead to incomplete coverage, voids, and a lack of waterproofing qualities. Temperatures that are too low can lead to poor adhesion, high expansion properties, and low tensile strength.

Bitumens can be heated at high temperatures for short periods of time without damage and must be heated at

high temperatures in order to achieve complete fusion and strong bonding of the plies. There is an optimum viscosity range and an optimum temperature range at the point of application that allow complete fusion, optimum wetting and mopping properties, and the desirable interply bitumen weight. The equiviscous temperature (EVT) is defined as the temperature at which the viscosity of roofing asphalt is 125 centistokes, plus or minus 25°F, at the mop bucket or felt layer immediately prior to application to the substrate. A centistoke is a unit that measures the kinematic viscosity.

$$\text{Centistokes} = [\text{Dynamic Viscosity/Density}] \times \text{Centipoise}$$

The recommended EVT range for roofing asphalt, Types I, II, III, and IV, is the temperature at which a viscosity of 75 centipoise is attained, plus or minus 25°F. The recommended EVT range for coal tar products, types I and III, is the temperature at which a viscosity of 25 centipoise is attained, plus or minus 25°F. One consequence of a change in EVT from 125 centistokes to 75 centipoise, plus or minus 25°F, is the potential need to increase the temperature at which bitumen is heated in the kettle or tanker. Excessive and prolonged heating of asphalt and coal tar products may have a deleterious effect on the quality of the product.

COAL TAR TYPES

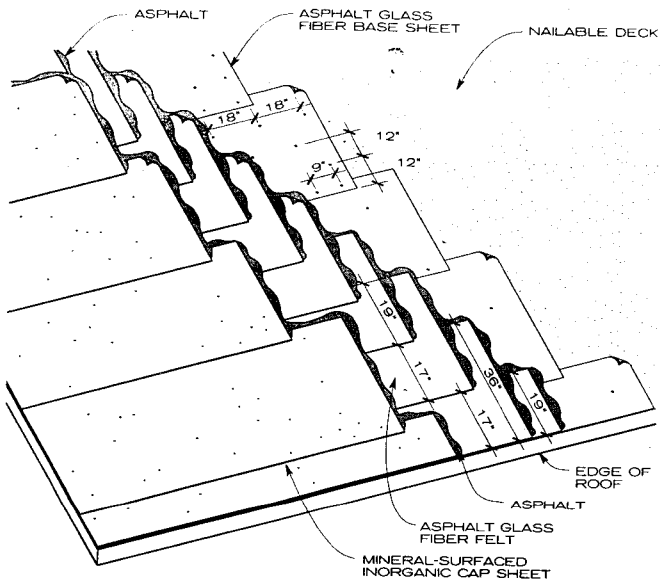

ASTM D-450 TYPE NO.	KIND OF COAL TAR	SOFTENING POINT (°F)	
		MIN.	MAX.
I	Coal-tar pitch	126	140
II	Waterproofing pitch	106	126
III	Coal-tar bitumen	133	147

ASPHALT TYPES

TYPE	KIND OF ASPHALT	SOFTENING POINT (°F)		MAX. TEMP. (°F)
		MIN.	MAX.	
I	Dead level asphalt	151	135	475
II	Flat asphalt	176	158	500
III	Steep asphalt	205	185	525
IV	Special steep asphalt	225	210	525

7 MEMBRANE ROOFING

OVER NAILABLE DECK NOTE

If applied over nailable deck sheathing panels, add a rosin-sized sheathing paper between the deck and base sheet.

MINERAL-SURFACED CAP SHEET BUILT-UP ROOFING

THREE-PLY OVER NAILABLE DECK NOTE

If applied over sheathing panels, add a rosin-sized sheathing paper between the deck and base sheet.

THREE-PLY OVER NON-NAILABLE DECK

NOTE
For a more conservative system, specify four plies rather than three.

SMOOTH SURFACE BUILT-UP ROOFING

BUILT-UP ROOF SURFACING

Surfacing protects the bitumen and felts of a built-up roof from direct sunlight and weather exposure, and may provide other properties such as fire resistance or reflectivity. Surfacing types include aggregate, smooth surfacing, and mineral cap sheet.

AGGREGATE SURFACING

The aggregate in roofing serves as an opaque covering that improves the appearance and fire resistance of the roof and helps resist premature aging and damage from weather, temperature fluctuations, and ultraviolet rays. Aggregate also increases the wind uplift resistance of the roof mem-

brane and permits much heavier pourings of bitumen than would otherwise be possible.

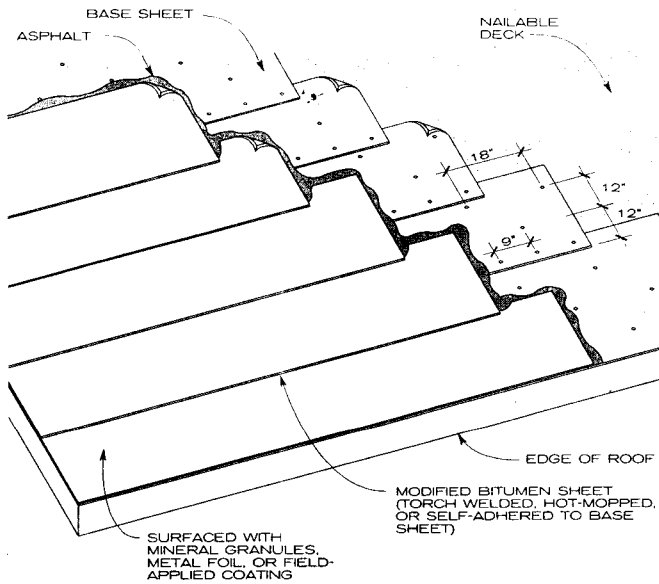

SMOOTH SURFACING

Built-up roof membranes may be left smooth, surfaced with a top coating of hot asphalt. Smooth surfacing should not be confused with a built-up membrane left unsurfaced (exposed felts). Smooth surfaced built-up roofing should be specified only in those circumstances where aggregate-surfaced built-up roofing is impractical, such as when the roof surface exceeds 3 in. per ft, where the proximity of an air-intake or exhaust equipment may cause loose aggregate, or where appropriate aggregate is not available.

MINERAL SURFACED (CAP SHEET)

Some areas of the country, particularly the far western and southern states, use mineral-surfaced cap sheets as the final surfacing for built-up roofing membranes. These specifications are similar to aggregate and smooth-surfaced specifications except that a final layer of prepared roofing material is installed on top of the multiply built-up roof assembly. This specification is not popular in colder climates, primarily because it requires phased construction of the final layer of roofing material.

National Roofing Contractors Association; Rosemont, Illinois
Valerie Eickelberger; Rippeteau Architects, PC; Washington, D.C.

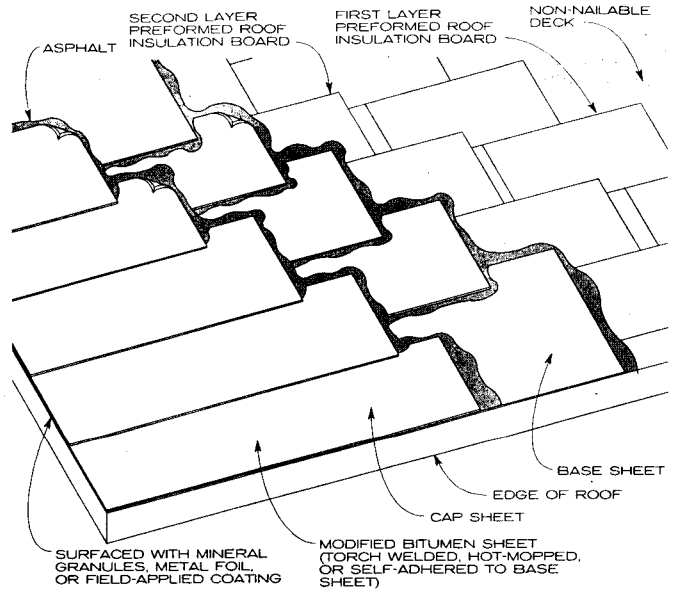

TWO-PLY OVER NAILABLE DECK

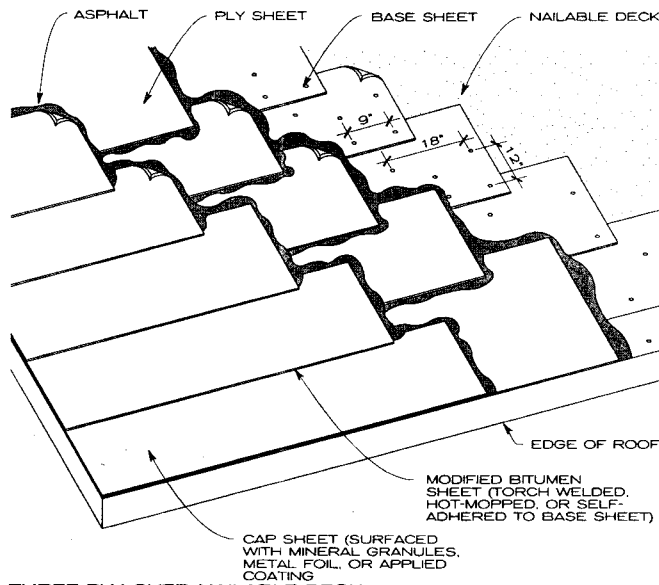

NOTE

If applied over-sheathing panels when the cap sheet is hot-mopped, add a rosin-sized sheathing paper between the deck and base sheet.

TWO-PLY MODIFIED BITUMEN MEMBRANE

TWO-PLY OVER NON-NAILABLE DECK

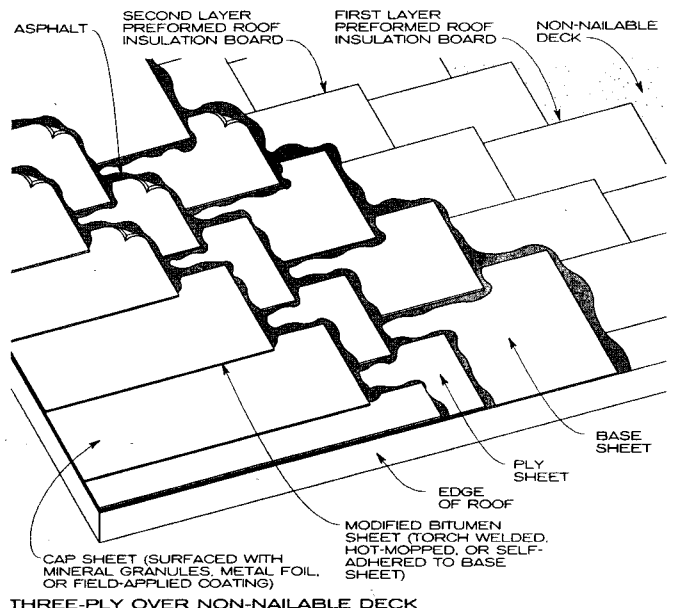

THREE-PLY OVER NAILABLE DECK

NOTE

If applied over-sheathing panels when the cap sheet is hot-mopped, add a rosin-sized sheathing paper between the deck and base sheet.

THREE-PLY MODIFIED BITUMEN MEMBRANE

THREE-PLY OVER NON-NAILABLE DECK

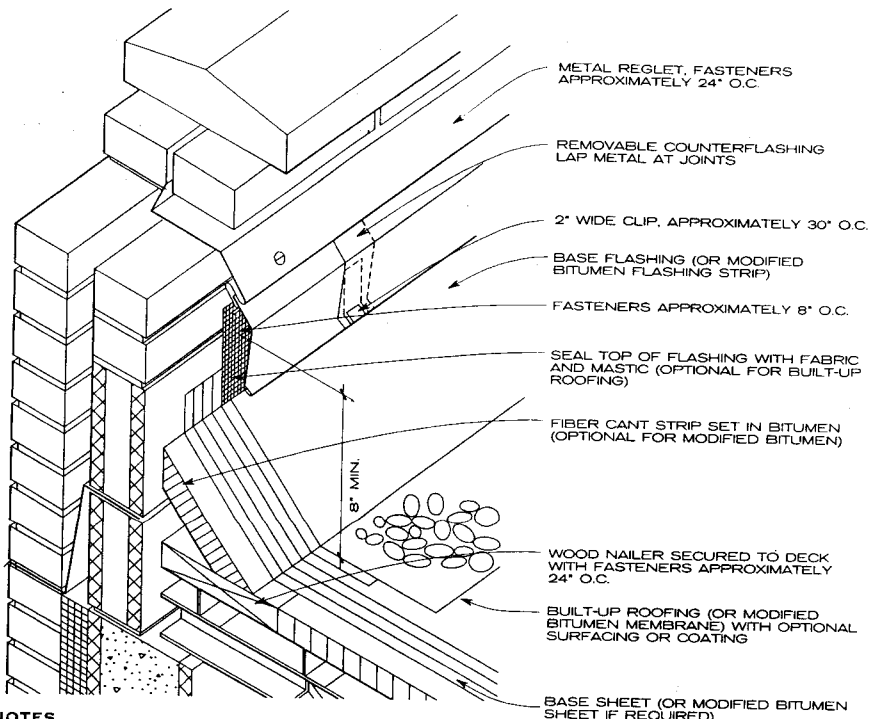

MODIFIED BITUMEN MEMBRANES

Polymer-modified bitumen membranes couple bitumen and polymers with various reinforcements to form a membrane system with improved properties. Modifiers include atactic polypropylene, styrene-butadiene-styrene, and styrene-butadiene-rubber. The modifying compounds impart improved flexibility, cohesive strength, toughness, and resistance to flow at high temperatures. The seams are sealed by torch welding or with hot asphalt. Thickness ranges from 40 to 160 mils.

For some systems a base sheet is fastened to the deck as an underlayment. In the hot-mopped system, the membrane is constructed similar to a built-up roof with hot asphalt mopped between the plies. Self-adhered sheets have a factory-applied asphalt-adhesive coating on the underside. The protective sheet is peeled away to stick the membrane to the roof deck. Torch-applied membrane systems have a factory-applied coating of modified asphalt on the underside of the sheet, which is melted with a propane torch to make the sheet adhere.

Reinforcing materials for polymer modified bitumen membranes include plastic film, polyester mat, glass fiber, felt or fabric, and metal foils, embedded within or laminated onto the modified bitumen sheet. Membranes may be surfaced with liquid coatings, metallic laminates, or ceramic or mineral granules to enhance resistance to weathering, ultraviolet rays, or fire or to improve appearance. Terminations at roof edges, parapets, and other flashings may be torch-applied, hot-mopped, or self-adhered. Laps are formed as the sheet is being applied.

National Roofing Contractors Association; Rosemont, Illinois
Valerie Eickelberger; Rippeteau Architects, PC; Washington, D.C.

- NOTES**
1. This detail should be used only when the deck is supported by the wall.
 2. The joints in the two pieces of flashing should not be soldered. Breaks in soldered joints could channel water behind the flashing. Clips at the bottom of the flashing are not necessary on flashings of 6 in. or less.

BASE FLASHING FOR WALL-SUPPORTED DECK

- NOTES**
1. This detail allows wall and deck to move independently.
 2. This detail should be used where there is any possibility that differential movement will occur between the deck and a vertical surface, such as at a penthouse wall. The vertical wood member should be fastened to the deck only. This is one satisfactory method of joining the two-piece flashing system. Other methods may be used.

BASE FLASHING FOR NON-WALL-SUPPORTED DECK

National Roofing Contractors Association; Rosemont, Illinois
 Valerie Eickelberger; Rippeteau Architects, PC; Washington, D.C.

GENERAL

In general, the details for installation of bitumen roofing, whether built-up roofing or modified bitumen roofing, are similar in many respects. Details for both types of roofing are included where applicable. The details show typical conditions that occur at bitumen roofs, such as roof edge conditions, piping penetrations, and equipment supports.

HEAVY METAL ROOF EDGE

SCUPPER THROUGH ROOF EDGE

COUNTERFLASHING CONCRETE PARAPET

NOTES

1. Envelope shown is for coal tar pitch and low-slope asphalt.
2. Attach nailer to masonry wall.
3. This detail should be used only where the deck is supported by the outside wall.
4. This detail should be used with light-gauge metals, such as 16 oz. copper, 24-gauge galvanized metal, or 0.040 in. aluminum. A tapered edge strip is used to raise the gravel stop. Frequent nailing is necessary to control thermal movement.
5. Wood blocking may be slotted for venting where required.

GRAVEL STOP

EXPANSION JOINT

NOTE

This detail allows for roof maintenance around the equipment support. Continuous support is preferred in lightweight roof systems because equipment weight can be spread over two or more supporting members. Clearance must be provided for removal and replacement of roofing and flashing between parallel supports.

EQUIPMENT SUPPORT ON LIGHT ROOF DECK

National Roofing Contractors Association; Rosemont, Illinois
Valerie Eickelberger; Rippeteau Architects, PC; Washington, D.C.

NOTE

This detail should be used only when the deck is supported by the wall. An expansion joint detail should be used for a deck not supported by a wall.

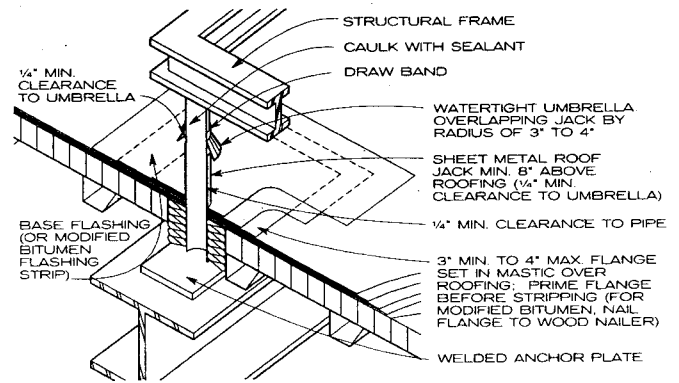

LIGHT METAL PARAPET CAP

NOTE

This detail illustrates one method of eliminating pitch pockets. The curbed system allows for movement in the structural member without disturbing the roof system.

STRUCTURAL MEMBER THROUGH ROOF

NOTE

This detail depicts site-fabricated construction. Many manufacturers now offer prefabricated flashing pieces or permit the use of materials for flashing purposes other than those shown here. Proprietary designs vary widely; consult individual manufacturers about use.

INSULATED DECK STEEL FRAME SUPPORT

EQUIPMENT CURB

NOTE

An area divider is designed simply as a raised double wood member attached to a properly flashed wood base plate that is anchored to the roof deck. Area dividers should be located between the roof's expansion joints at 150 to 200 ft intervals, depending upon climatic conditions and area practices. They should never restrict the flow of water.

AREA DIVIDER

NOTES

1. Minimum 30 in. square, 2 1/2 to 4 lb lead or 16 oz soft copper flashing set on finished roof felts set in mastic. Prime top surface before stripping.
2. Membrane plies, metal flashing, and flash-in plies extend under the clamping ring.
3. Stripping felts extend 4 in. and 6 in. beyond edge of flashing sheet, but not beyond edge of sump.
4. The use of metal deck sump pans is not recommended.

ROOF DRAIN

NOTE

This detail allows for expansion and contraction of pipes without roof damage.

PIPE ROLLER SUPPORT

NOTE

This detail illustrates another method of eliminating pitch pockets and a satisfactory method of grouping piping that must come up above the roof surface.

MULTIPLE PIPE PENETRATION

SITE-FABRICATED DETAIL

PREFABRICATED PIPING BOOT (CONSULT MANUFACTURER FOR SPECIFICATIONS)

PREFABRICATED DETAIL NOTES

1. Sheet lead minimum of 2 1/2 lb per sq ft.
2. Minimum clearance of 12 in. from cant strips and other curbs or pipes.

SINGLE PIPE PENETRATION

National Roofing Contractors Association; Rosemont, Illinois
Valerie Eickelberger; Rippeteau Architects, PC; Washington, D.C.

EPDM SINGLE-PLY ROOFING

Ethylene propylene diene monomer (EPDM) membranes are 30 to 60 mil thick, single-sheet roofing materials. They are available either nonreinforced or reinforced with fabric. Seams in the membrane are spliced and cemented. EPDM membranes are highly resistant to degradation from certain chemicals, ozone, and ultraviolet radiation and have excellent resilience, tensile strength, abrasion resistance, hardness, and weathering properties.

EPDM membranes may be laid loose, mechanically fastened, or fully adhered to either nailable or non-nailable decks. For loose-laid systems, ballast provides resistance

against wind uplift forces. Some membranes require field application of surfacings or coatings to provide weather resistance, aesthetics, or other properties. Specifications for formulation and installation of EPDM membranes vary with the individual manufacturer.

Separation layers of asphalt-saturated organic felt or board-type roof insulation permit the membrane to move relative to the deck without abrasion. Membrane terminations at roof edges, parapets, and other flashings employ material identical to the roof membrane material shaped to conform to the substrate and area being flashed. Standards for EPDM membranes are maintained by ASTM and the Rubber Manufacturers Association.

SINGLE-PLY PVC ROOFING

Polyvinyl chloride (PVC) membranes may be unreinforced or reinforced with glass fibers or polyester fabric 45 to 60 mils thick. Seams are formed by heat or chemical welding, and may require additional caulking. PVC membranes are resistant to bacterial growth, industrial chemical atmospheres, root penetration, and extreme weather conditions. PVC membranes have excellent fire resistance and seaming capabilities.

ASTM Standard D-4434 classes PVC materials into several types and classes depending upon the construction of the sheet material:

- TYPE I: Unreinforced sheet
- TYPE II, CLASS I: Unreinforced sheet containing fibers
- TYPE II, CLASS II: Unreinforced sheet containing fabrics
- TYPE III: Reinforced sheet containing fibers or fabrics

PVC membranes may be laid loose, mechanically fastened, or fully adhered to either nailable or non-nailable decks. For loose-laid systems, ballast provides resistance against wind uplift forces. Some PVC membranes have a factory-applied coating to provide weather resistance, aesthetics, or other properties to the membrane. Some membranes may require field application of surfacings or coatings to provide these properties.

NOTE

Polyvinyl chloride (PVC) is a semirigid material that requires the addition of plasticizers to fabricate a flexible roofing membrane. PVC exhibits excellent weldability for making lap joints or attaching to PVC clad metal flashing.

TYPES OF MEMBRANE

- Unreinforced sheet
- Sheet reinforced with fiberglass or polyester

METHOD OF MANUFACTURE

- Calendering
- Spread coating
- Extruding

GENERAL

Single ply roofing systems are also referred to as flexible sheet roofing systems. Consult manufacturers for specific requirements regarding materials selection and installation requirements. Compatibility of materials comprising total roofing system is essential.

MATERIAL PROPERTIES

- Thickness: Typically 48 and 60 mil; 45 mil minimum
- Color: Typically gray; other colors available

Membrane sheets are laid loose over roof insulation (also laid loose) and secured at the perimeter and around penetrations only. The membrane is then covered with a ballast of river-washed stones (typically 10 lb/sq ft) or appropriate pavers.

This system works efficiently with insulation approved by the membrane manufacturer and on roofs with a slope not exceeding 2 in 12.

LOOSE-LAID BALLASTED SHEETS

Membrane sheets are laid loose over a sloped roof deck and with the insulation on top of it. When the roof deck is dead level, tapered roof insulation is either loose laid or mechanically attached under the membrane to achieve positive slope to drainage. In either instance, a layer of insulation is placed over the membrane and held in place by one of two methods: Either a loose fabric is laid over the insulation, with a minimum of 10 lb/sq ft of ballast laid over the fabric, or insulation with an integrally bonded concrete facing is used in place of the fabric and loose ballast. Membrane manufacturers should be consulted for their approved insulation list. In this roofing system, the membrane is protected from year-round temperature extremes, direct exposure to weather, and damage from other sources. The heat gain or loss is just the same as if the insulation were installed under the membrane. Since the waterproofing membrane is placed on the warm side of the insulation, it functions as a vapor retarder. For high humidity conditions with a dead level roof deck utilizing tapered insulation, a separate vapor barrier should be placed directly beneath the tapered insulation to prevent condensation.

PROTECTED MEMBRANE SHEET

Contaminants to avoid: Bitumen, oils, animal fats, and coal tar pitch. See manufacturer's chemical resistance list.

Minimum standards: ASTM has developed standard test methods to evaluate the materials properties of PVC roof membranes. These test results form a useful basis for comparing various PVC membranes. ASTM's standard specification establishes minimum performance criteria for tensile strength, elongation, tear resistance, heat aging, weathering, and water absorption.

INSTALLATION

General guidelines: It is recommended that all roofing materials be installed on roofs with positive slope to drainage. Check with manufacturers regarding their specific requirements.

Lap joining methods: Hot air or solvent weld

Flashing methods: Membrane or PVC coated metal

Types of preformed accessories available: Inside and outside corners; pipe stacks

Weather restrictions during installation: 0°-120°F temperature range. Substrates and welding/bonding surfaces must be dry.

Method of repair: Clean surface; hot air or solvent weld of PVC patch

For system with no slope limitations which secures membrane to substrate with bonding adhesive and by mechanically fastening the membrane to perimeter and penetrations. System is appropriate for contoured roofs and roofs that cannot withstand weight of ballasted system.

Membrane can be directly applied to deck surface of concrete, wood surfaces, or be applied to compatible insulation that is mechanically fastened to the deck.

FULLY ADHERED SHEETS

TYPICAL PARAPET FLASHING

ALTERNATE PARAPET FLASHING

A mechanically anchored roof system is appropriate for roofs that cannot carry the additional load of ballasted roof systems. Systems are available with fasteners that penetrate the membrane or that require no membrane penetration.

The membrane is anchored to the roof using metal bars or individual clips, and it may be installed over concrete, wood, metal, or compatible insulation.

MECHANICALLY ATTACHED SHEETS

DEAD LEVEL ROOF

CTA Architects Engineers; Billings, Montana

GENERAL

Liquid-applied roofing systems are systems primarily applied as liquids at ambient temperatures. Most of them have some sort of reinforcing fabric that is applied along with the liquid component. Liquid-applied roofing applied over existing roofs is not generally accepted as a "membrane" but as a coating.

Acrylic latex and urethane are the two main types of liquid-applied roofing. Acrylic latex refers to a family of products that use water-based polymers and cure by water evaporation. Liquid-applied urethane roof coatings are chemically cured to form an elastomeric membrane. Because these coatings are applied as liquids, installation is relatively simple, even for roofs with irregular geometries or multiple penetrations. For systems using a reinforcing fabric, a coating is applied to an acceptable surface. While the coating is still wet, a layer of polyester or fiberglass is laid into it followed by an additional layer of coating. Subsequent layers may be added as desired or necessary.

Liquid-applied roofing systems are appropriate for new construction but are most commonly used as enhancements or for repairs to existing roofs, including modified bitumen roofs and built-up roofs.

Advantages of liquid-applied roofing are that it conforms very well to irregular surfaces, is easily applied, and comes in various colors. However, it does cause marginal ponded water performance and is best used in sloped roof situations.

NOTE
Liquid-applied roofing systems may also be used under rigid insulation and ballast for further protection. Refer to "Protected Membrane Roofing" for further details.

LIQUID-APPLIED ROOFING SYSTEMS

LIQUID-APPLIED MEMBRANE TYPES

- NOTES**
1. Attach nailer to masonry wall. Refer to Factory Mutual data sheet # 1-49.
 2. This detail should be used only when the deck is supported by the outside wall.
 3. This detail should be used with light-gauge metals such as a 16-oz copper, 24-gauge galvanized metal, or 0.04-in. aluminum. A tapered edge strip is used to raise the gravel stop. Frequent nailing is necessary to control thermal movement.

GRAVEL STOP

EXPANSION JOINT

LIGHT METAL PARAPET CAP

NOTE
Roof slope minimum is 1/4 in. in 12 or 2%; no maximum.

RETROFIT LIQUID-APPLIED ROOFING OVER EXISTING METAL ROOF

- NOTES**
1. Use minimum 30-in. sq. 2 1/2 lb to 4 lb lead flashing. Set in mastic. Prime top surface before stripping.
 2. Liquid-applied roof coatings, reinforcing fabric, and metal flashing (optional) extend under clamping ring.

ROOF DRAIN

NOTE
Sheet lead minimum of 2 1/2 lb per sq ft.

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland
Rich Boon; The Roofing Industry Educational Institute; Englewood, Colorado

NOTES

There are three generic installation methods for EPDM roofing:

1. Fully Adhered: Membrane roofing is rolled onto the substrate and allowed to relax. Underside is then fully coated with bonding adhesive. After both surfaces are tacky, the membrane is pressed onto the substrate with a push broom. Adjoining sheets must overlap at least 3 in., with laps spliced and cemented. Membrane is mechanically secured at perimeter and penetration edges. Flashing protects all edges, openings, and penetrations.
2. Loose Laid: Roofing in this application is laid loose over the substrate, either deck or rigid insulation, and ballasted in place. It is positioned without stretching, allowed to attain its natural shape, and adjacent sheets spliced with adjoining sheets overlapping at least 3 in. Sheets are cemented and rolled together to seal seams. The membrane is mechanically secured at perimeter and penetration edges, and flashing is installed. For ballast, a sufficient amount of river-washed gravel is laid over the membrane to provide 10 lb/sq ft of weight. As an alternate, a pre-cast roof paver system is applied to hold the roofing membrane.
3. Mechanically Fastened: Membrane roof is directly attached to the roof deck with mechanical fasteners. The substrate is anchored to the roof deck, and the fasteners either go through both membrane and insulation or only go through the insulation and deck, with the membrane held down by retainer and cap over the base. Sealant protects against moisture.

Many EPDM membranes are field surfaced to improve resistance to weathering and fire, or to enhance appearance.

GENERAL NOTES

EPDM elastomeric roofing is synthesized from ethylene, propylene, and a small amount of diene monomer. Manufactured sheets range in thickness from 30 to 60 mils.

Advantages: EPDM roofing exhibits a high degree of resistance to ozone, ultraviolet, extreme temperature and other elements, and degradation from abrasion. It is resilient, strong, elastic, and less prone to cracking and tearing when compared to other forms of membrane roofing.

Disadvantages: Application methods, specific formulas and configurations for adhesives, fasteners, and coatings are unique with each system manufactured. Materials, design, and appropriate use vary widely. Close supervision and regular inspection by manufacturer are a requirement. Labor cost and time allotted for installation may vary.

NOTE

Membrane may be built-up, modified bitumen, or single-ply. If thermoplastic membrane is specified, provide slip sheet between insulation and membrane.

LIGHT METAL PARAPET CAP AT BUILT-UP OR MODIFIED BITUMEN ROOF

NOTES

1. Membrane must be single-ply. If thermoplastic membrane is specified, provide slip sheet between insulation and membrane.
2. Set pavers on pedestals or specify that the top layer of insulation boards have ribs on the top side to facilitate drying.

LIGHT METAL PARAPET AT SINGLE-PLY ROOF

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland
 Rich Boon; The Roofing Industry Educational Institute; Englewood, Colorado

GENERAL

In a typical roofing system, the waterproof membrane system (built-up, modified bitumen, or single-ply) is applied on top of the insulation, which lies on top of the substrate and/or structural deck. The membrane in this situation is exposed to temperature extremes and wear and tear from people walking or working on the roof. In a protected membrane roof (sometimes called the inverted or insulated roof membrane assembly, or IRMA), a layer of extruded polystyrene insulation board protects the membrane. Extruded polystyrene is the only material generally approved for this application because it does not absorb moisture. This roofing system is best used in extreme climates, where it is important to protect the membrane from the elements, or where the rooftop will receive heavy use (e.g., plaza or parking deck applications).

NOTES

1. Ballast weight is a minimum of 10 lb per square foot.
2. Refer to ANSI/SPRI/RMA RP-4 for wind design guidance.
3. In lieu of aggregate or concrete ballast, proprietary insulation boards with concrete topping are available. These boards weigh between 4.5 lb per square foot and 10 lb per square foot, depending on the product selected.

TYPICAL PROTECTED MEMBRANE ROOF SYSTEM

NOTES

1. Standard weight concrete pavers should be used to mark drain locations and to facilitate access to drains.
2. To facilitate placement of insulation boards, etc., the clamping ring and strainer are to be removed from metal drains. A 1/2 in. hardware cloth strainer should be laid at the bottom of the drain bowl.
3. For a thermoplastic membrane, use a 4-mil polyethylene slip sheet between the membrane and the insulation boards. Cut a hole in the sheet at the drain, approximately 2 in. larger than the diameter of the drain bowl.

ROOF DRAIN

GENERAL

Polyurethane foam roofing is spray-applied, seamless, and fully adhered. The foam is made by mixing isocyanate and resin components at a 1:1 ratio. Spray polyurethane foam is a closed-cell foam that provides good insulation and water resistance. These systems are used with a protective coating or stone ballast covering system, which protects the foam roofing from ultraviolet rays and mechanical damage.

These systems can be applied in varying thicknesses to eliminate ponding, to improve drainage, and to meet specified R-values (approximately R-6.25 per inch). Some advantages of spray foam systems are that they can be used over highly irregular surfaces, unusual geometries, or existing sloped metal systems. They are also inherently lightweight and offer good wind uplift resistance.

NOTES

1. Before spray polyurethane foam is applied, all surfaces must be clean, free of contaminants, securely fastened to the substrate, and completely dry. Moisture-sensitive indicators may be needed to detect any moisture within the existing roof assembly. Vapor retarders may be necessary; consult with the manufacturer to coordinate a specific roofing condition with foam application.
2. Most polyurethane foam manufacturers produce three seasonal grades: winter (fast), regular, and summer (slow).
3. If wind speed affects foam quality, use wind screens or discontinue spraying. The surface texture of sprayed foam can vary due to wind, equipment adjustment, spray technique, and characteristics of the system used. Foam that will be elastomeric coated should have a smooth texture resembling orange peel. For an aggregate covering, the texture should be no rougher than popcorn.

NOTES

1. Protection systems fall into two general classifications, protective elastomeric coatings and aggregate. There are seven generic types of elastomeric protective coatings: acrylic, silicone, urethane, butyl, hypalon, neoprene, and modified asphalt. The physical properties of these coatings may vary, and the coating manufacturer should be consulted for recommendations on specific needs.
2. Granules may be applied to the wet uncured protective topcoat to enhance the resistance of the coating systems to UV or mechanical damage.

SPRAY-APPLIED POLYURETHANE FOAM ROOFING SYSTEM

NOTE

On skylights, do not cover weep holes with polyurethane foam or coating.

SKYLIGHT, SCUTTLE, OR VENT CURB

METAL ROOF EDGE

NOTE

This detail should be used only when the deck is supported by the wall. An expansion joint detail should be used for non-wall-supported decks.

LIGHT METAL PARAPET CAP

NOTES

1. Remove clamping ring prior to foam application. Place protective covering over drain bowl opening to prevent overspray from filling bowl.
2. Taper foam toward drain bowl to provide positive drainage.
3. The use of metal deck sump pans is not recommended.

THROUGH-WALL FLASHING INSTALLATION

GENERAL

Modern building materials are often waterproof, but they are not permanently impervious to wind-driven moisture. Gradual shrinkage of some materials and the natural movement of buildings can eventually cause leaks. When moisture enters walls it tends to form pockets of water, which eventually drain into the interior of the building, sometimes by gravity, other times by capillary action. This water will damage interiors, deface exteriors, disintegrate mortar and masonry, and rust steel spandrels, lintels, etc.

Flashings should be used wherever there is any possibility of water entering a structure. Through-wall flashing is the most successful method of permanently preventing leaks, except in areas exposed to earthquakes, where through-wall flashing is not recommended. Through-wall flashing is

made of many different materials, including metals, plastics, and combinations of metals with paper, fabric, or rubber. Materials that are in contact must be compatible without deterioration.

Joints in flashings must be durable and waterproof and should usually lap 4 in. When the flashing is metal, joints should be soldered. Flashing should be extended to within 1/2 in. of the exterior face. End- and edge-formed dams should be used where necessary to control drainage direction. Metal flashing that extends below grade is installed in reglets after the surface waterproofing has been applied below-grade.

COUNTERFLASHING WITH RECEIVER

COUNTERFLASHING INSTALLATION

COUNTERFLASHING WITHOUT RECEIVER

TWO-PIECE COUNTERFLASHING

GENERAL

Careful consideration must be given to flashing systems where a roof and wall meet. The base flashing system must keep water from entering the building and must allow for building movement. Counterflashing turns water away from a wall onto the roof or base flashing. The base flashing is usually inserted into a reglet, which must be capable of supporting the flashing. In high wind areas, clips can be specified for the lower edge of the counterflashing. Counterflashing that is removable is cost effective for the work installation sequence and for repair of roofing systems.

All membrane roofing should have removable counterflashing. Metal counterflashing should be used in conjunction with composition base flashing. Metal base flashings are used with shingle or metal roofs, but are not recommended for use with membrane roofing systems. A metal base

flashing may be used over a composition flashing as a protective cover in locations where the base flashing may be abused by traffic. It is recommended that base flashings be applied over a cant and be extended up the wall a minimum of 10 in. above the roofline.

Receivers for counterflashing should be elevated 10 in. above the finished roof. Install metal counterflashing to cover a minimum of 4 in. of the base flashing. After the counterflashing is installed, the receiver is bent 45 degrees to provide a drip edge. The lower edge of metal counterflashing should be a minimum of 1 in. above a cant. The counterflashing is notched and lapped at inside corners and joints, and seamed at outside corners. The flashing receiver is notched and lapped 4 in. at corners and joints.

7 FLASHING AND SHEET METAL

TYPICAL MANSARD ROOF

SELF-SUPPORTING ROOF

CONTINUOUSLY SUPPORTED ROOF

METAL MANSARD ROOFS

Metal mansard roofs are typically used on one-story commercial structures. Often they conceal rooftop equipment, using batten screens or louvered enclosures. Metal mansard roofs are also used for flat or curved ornamental roofs or canopies for the front of buildings.

Aluminum, copper, stainless steel, galvanized steel, or pre-finished metals may be used for metal mansard roofs. The metal can be prefabricated for several styles of field connection using various seam configurations. Prefinished metals used in curved applications typically have a 15-ft

radius limit. Concave or convex panels normally have a 24-in. minimum radius for standing seams and a 72-in. minimum radius for batten seams. Soft metals are used when the metal must be stretched.

Metal mansard roofs may be continuously supported or self-supporting. Continuously supported roofs have a continuous sheathing substrate. Self-supporting roofs have structural framing with vertical and horizontal members located where needed for metal panel attachment. Mansard roofs require cap and sill flashing.

STANDING SEAM METAL ROOF

NOTES

To allow for expansion and contraction movement in roof panels, some manufacturers set movable cleats into a stationary panel clip system. The cleat is held in position in the center of a slot in the panel clip by two temporary plastic tabs. This allows for correct alignment of the cleat with the roof panel. Once the cleat has been rolled into the panel seam, it will move with the roof panel by forcing the plastic tabs to break under movement pressure.

MOVABLE CLEAT

PAN METHOD OF FORMING STANDING SEAM

FIELD METHOD OF FORMING STANDING SEAM

RIDGE CONSTRUCTION

LOW PITCH STEEP PITCH
TRANSVERSE SEAM AND PANEL SPLICE

Standing seam roofing may be installed on slopes as gentle as 1/4 in./ft. Because of the architectural appearance of the roof system, it is more commonly used on steeper roof slopes, allowing the panels to be seen as part of the overall design.

The spacing of seams may vary within reasonable limits to suit the architectural style of a given building. Preformed sheets (as used with preengineered metal buildings) have seam locations set by locations of prepunched holes in the structural framing members.

The two methods of forming a standing seam are the pan method and the roll method. In the pan method, the

top, bottom, and sides of the individual sheets are preformed to allow locking together at each edge. Seams at the top and bottom of each sheet are called transverse seams. In the roll method, a series of long sheets are joined together at their ends with double flat lock seams. These field-formed seams can be executed either manually or with a seaming machine (a wheeled electronic device which runs along the sheet joint forming the seam).

In either method, cleats (spaced as recommended by the manufacturer) are formed into the standing seam. Seam terminations are usually soldered.

DETAIL 2-SEAM TYPES AT HIP OR RIDGE

DETAIL 3-CONSTRUCTION AT BATTEN

DETAIL 4-CONSTRUCTION AT CLOSURE AND VALLEY

DETAIL 5-EAVE

DETAIL 6-EXPANSION JOINT

DETAIL 7-CONSTRUCTION AT RAKE

NOTES

1. The Bermuda roof may be used for roofs having a slope greater than 2 1/2 in./ft. Wood framing must be provided as shown in detail 1. Dimension "D" and gauge of metal will depend on the size of sheet used. See chart. Consult general notes on metal roofs for recommended surface preparation.
2. Bermuda roof is applied beginning at the eave. The first pan is hooked over a continuous cleat as shown in detail 5. The upper portion of the first and each succeeding pan is attached as shown in detail 3. Cleats spaced on 8 in. centers are nailed to batten

as in A of detail 3. Joint is developed as shown in B of detail 3 and malleted against batten as shown in C of detail 3. All cross seams are single locked and soldered except at expansion joints. Cross seams should be staggered. Expansion joints should be used at least every 25 ft and formed as shown in detail 6. Roofing is joined at hip or ridge by use of a standing seam as shown in A of detail 2. Seam may be malleted down as shown in B of detail 2.

3. Detail 4 shows the method of forming valleys. Valley sections are lapped 8 in. in direction of flow.

Individual closures for sides of valley are formed as shown in A of detail 4 and must be soldered as indicated in B of detail 4. A method of terminating the roof at rake is shown in detail 7. The face plate (optional) is held in place by continuous cleats at both top and bottom. The batten closure is formed as a cleat to hold edge of roof pan as shown in section A-A of detail 7.

See also Metal Roofs for general notes.

DETAIL 2-RIDGE CONSTRUCTION

DETAIL 3-BATTEN JOINT CONSTRUCTION

DETAIL 4-BATTEN CAP CONSTRUCTION

DETAIL 5-TRANSVERSE SEAM

DETAIL 6-GABLE

DETAIL 7-VALLEY

DETAIL 8-EAVES

DETAIL 9-PREFABRICATED BATTENS

NOTES

1. Batten seam roofing may be applied on slopes of 3 in./ft or greater. If the surface to receive the roofing is other than wood, the battens should be bolted into place. All batten fasteners must be countersunk into battens. See general notes on Metal Roofs for recommended surface preparation.
2. The spacing of the wood battens may vary within reasonable limits to suit the architectural style and scale of the building, but the recommended maximum distance is 20 in. between battens. Care should be taken to space the battens in such a manner that waste of metal is held to a minimum. Battens may be shaped as shown in A or B of detail 1.

A is preferred, since it automatically makes allowance for expansion. When battens shown in B are used, care must be taken to provide for expansion by bending the metal where it meets the batten at greater than 90°.

3. Sheets are formed into pans with each side turned up 2 1/8 in. A 1/2 in. flange is turned toward the center of the pan as shown in B of detail 3. At lower end of the pan, the sheet is notched and a hook edge is formed as in A or B of detail 5. For low pitched roofs the upper end of the sheet is formed as in A of detail 5. On steeper roofs the upper end is formed as shown in B of detail 5. Pans

are installed, starting at the eave, and held in place with cleats spaced not over 12 in. on center as shown in A of detail 3. Each pan is hooked to the one below it and cleated into place. After pans are in place, a cap is installed over the batten as shown in B and C of detail 3.

4. A number of manufacturers have developed metal roofing systems using several prefabricated devices. A and B of detail 9 show two common prefabricated battens in use.
5. See also Standing Seam Metal Roofing for details on combination batten and standing or flat seam roofing. See also Metal Roofs for general notes.

GENERAL NOTES

- All sizes and weights of material given in chart are minimum. Actual conditions may require greater strength.
- All galvanized steel must be painted.
- With lead flashing use 16 oz copper cleats. If any part is exposed, use 3# lead cleats.
- Coat zinc with asphaltum paint when in contact with redwood or cedar. High acid content (in these woods only) develops stains.
- Type 302 stainless steel is an all purpose flashing type.
- Use only aluminum manufactured for the purpose of flashing.
- See manufacturer's literature for use and types of flashing.
- In general, cleats will be of the same material as flashing, but heavier weight or thicker gauge.
- In selecting metal flashing, precaution must be taken not to place flashing in direct contact with dissimilar metals that cause electrolysis.
- Spaces marked \otimes in the table are uses not recommended for that material.

GALVANIC CORROSION (ELECTROLYSIS) POTENTIAL BETWEEN COMMON FLASHING MATERIALS AND SELECTED CONSTRUCTION MATERIALS

CONSTRUCTION MATERIALS	COPPER	ALUMINUM	STAINLESS STEEL	GALVANIZED STEEL	ZINC	LEAD	BRASS	BRONZE	MONEL	UNCURED MORTAR OR CEMENT	WOODS WITH ACID (REDWOOD AND RED CEDAR)	IRON/STEEL

Zinc alloy						○	○	○	○	○	○	○
Lead							○	○	○	○	○	○

- Galvanic action will occur, hence direct contact should be avoided.
- Galvanic action may occur under certain circumstances and/or over a period of time.
- Galvanic action is insignificant, metals may come into direct contact under normal circumstances.

GENERAL NOTE: Galvanic corrosion is apt to occur when water runoff from one material comes in contact with a potentially reactive material.

SINGLE LOCK BEAM NOTES

- Field fold end of each adjoining sheet in opposite direction.
- Hook folded edges together and dress down joint with a mallet.

NOTES

- Double fold end of each adjoining sheet in opposite direction with bar folder.
- Slide edges together and dress down joint with a mallet.

DEVELOPMENT OF CAP FLASHING

NOTE: Hem in cap flashing recommended for stiffness; but may be omitted if heavier gauge material used.

METAL REGLETS CAST IN PLACE

REGLET SAWED IN MATERIAL

TYPICAL REGLETS

NOTE: Various types of metal reglets are available for cast in place and masonry work; see manufacturer's literature. Where material permits, reglets may be sawn. Flashing is secured in reglets with lead wedges at max. 12" o.c., fill reglet with nonhardening water-resistant compound.

CORNICE FLASHING WITH METAL ROOF

CORNICE FLASHING WITH CAP FLASHING

CORNICE LEDGE CAP FLASHING AND RECEIVER

TYPICAL PROFILES OF THROUGH WALL FLASHING (PROPORTIONS EXAGGERATED)

DEFINITIONS

BASE FLASHINGS are essentially a continuation of the built-up roofing membrane at the upturned edges, applied in an operation separate from the application of the roof membrane itself.

CAP FLASHINGS (COUNTERFLASHINGS) are normally made of sheet metal and shield the exposed top of the base flashing. Some nonmetallic cap flashings are made of felts, and are made water-resistant with flashing cement.

CONCEALED FLASHINGS are invisible from the exterior or interior of the building. Metal sheet or foil, fabric, plastic, or various combinations of these materials may be used, depending on climate and structural requirements.

EXPOSED FLASHINGS are exposed to view and affect the aesthetics of the building. Metals are almost entirely used. Attention must be paid to the corrosive potential between dissimilar metals.

NOTES

1. Select flashing that is flexible for flashing supports and can withstand expected thermal, wind, and structural movement. Provide expansion joints in place of flashing as required by conditions.
2. Consult manufacturer's literature for choice of flashing materials and details.
3. Avoid sharp bends in bituminous base flashings. Use cant strips with 45° maximum bend.
4. Provision for differential movement between roof deck and wall is recommended.
5. Ribbed or embossed through wall flashing is not recommended for earthquake areas.
6. Base flashing should extend 8 to 12 in. above highest anticipated waterline. Metal counterflashings should lap base flashing at least 4 in. minimum. Lap all vertical joints.
7. At cavity walls with more than 3/4" space between wythes, use flashing of type that provides mechanical bond.

7 FLASHING

GENERAL

A water table is a ledge or slight projection of masonry, wood or other construction on the outside of a foundation wall, or just above. It protects the foundation from rain by throwing the water away from the wall. In the architectural hierarchy of a building form, the water table forms the transitional line between the base and middle sections. A water table is referred to as an offset when the base plane projects out from the upper plane.

SELECTION OF FLASHING METAL

Each commonly used flashing metal has distinctive characteristics, uses, and limitations. Thickness of materials is a function of material size, aesthetic consideration (prevention of oil-canning), and wind uplift due to metal movement during violent storms.

GALVANIZED STEEL

Galvanized steel flashings should be a minimum of 24 gauge with a G-90 galvanized coating. Of commonly used flashing metals, galvanized steel probably is the most common and least expensive. Although galvanized flashing metal may be left exposed, generally it is painted to further protect the steel from corrosion. Before it is painted, galvanized metal must be prepared. Plain galvanized material chemically etched in the field is preferred for surfaces to be painted. Factory etching, in which the metal is dipped in an acid bath, etches it on all sides. As a result, exposed edges often rust. Field etching is preferred because only the surfaces to be painted are etched. After etching, the surface should be primed and finish painted, preferably with two coats.

Galvanized steel is easy to solder, low in cost, and easy to work. All flashing metal transitions and terminations should be soldered fully for permanent installation; however, this should not be done at metal flashing joints where movement caused by thermal expansion is expected or at building expansion joints.

STAINLESS STEEL

Stainless steel retains many of the advantages of other steel products and yet is generally corrosion resistant. In addition to resisting corrosion, stainless steel can be field soldered so as to accommodate difficult transition and termination conditions. If the mill finish appearance is not acceptable, the stainless steel may be field painted after installation by using a primer followed by finish painting.

COPPER

Copper is also among the lifetime materials that are considered maintenance free. It can be soldered and molds very easily, which makes it adaptable to complicated transitions and changes of plane. Since copper can be soldered in the field, it should be terminated with fully soldered conditions. The designer should be aware, however, that the runoff from the metal can stain adjoining building materials. Copper is generally found to be a softer material than other flashing metals. Copper has a moderate coefficient of expansion in that it is higher than steel and yet less than aluminum.

ALUMINUM

Aluminum is among the permanent materials because it corrodes at a slow rate. Aluminum will, however, oxidize and pit over time, depending on the exposure. Since aluminum can only be connected by welding, field conditions are more difficult to accommodate. Although corner conditions can very often be prefabricated, unusual or difficult changes of plane may be difficult to properly accommodate in aluminum. Aluminum also has a high coefficient of expansion and contraction compared with other flashing metals and field welding is difficult. Due to the limitations of in-field fabrications, aluminum is best used on roofs of simple configurations and few transitions.

Joseph J. Williams, AIA; A/R/C Associates Inc.; Orlando, Florida

GABLE ROOF WITH UNOCCUPIED ATTIC

GABLE WITH OCCUPIED SPACE UNDER ROOF

CRAWL SPACE

VENT APPLICATIONS

GENERAL

Attics and crawl spaces must be ventilated to remove moisture and water vapor that has entered the spaces from surrounding air or soil or that has been created by human activity. Generally, crawl spaces (and basements) require a greater amount of ventilation than an equivalent area of attic. The quantity of water vapor depends on the building type (e.g., residence, school, etc.), activity (e.g., bathroom, kitchen, etc.), air temperature, and relative humidity. If the temperature of the ventilated space falls below the dew point temperature, condensation will occur which will deteriorate insulation, framing, etc. This can be avoided by proper detailing to limit moisture infiltration and increase ventilation to remove it if it does enter the space.

BRICK VENT

NOTE

Insect screen must be added to back of tile.

LOUVER

NOTE

Most vents for crawl spaces are set into unit masonry (and are sized accordingly) or concrete. Consult manufacturers. Metal louvers and vents have integral insect screens.

CRAWL SPACE VENTILATION MATERIALS

VENTILATION REQUIREMENTS TO PREVENT CONDENSATION

SPACE	DESCRIPTION	TOTAL NET AREA OF VENTILATION (A)	REMARKS
Joist/rafter (finish ceiling attached to underside of joists)	Flat	$a = A/250$. Uniformly distributed vents at eaves.	Vent each joist space at both ends. Maintain 1 1/2 in. minimum clear path above insulation for ventilation.
	Sloped	$a = A/150$. Uniformly distributed vents at eaves with a continuous ridge vent.	
Attic (unheated)	Gable	$a = A/150$. At least two louvers on opposite sides near ridge or one continuous ridge vent. Uniformly distributed vents at eaves.	Any combination of gable/hip louvers and/or ridge vents may be used to achieve required ventilation. Vent area may be reduced by inclusion of wind-driven or mechanical ventilators. Consult mechanical engineer.
	Hip		
Crawl space/basement		$a = 2L/100 + A/300$ Where L = crawl space/basement perimeter (linear feet)	Provide at least one opening per side, as high as possible in wall.

NOTES

- A = area of space to be ventilated, in square feet.
- The openings in insect screening should not exceed 1/4 in. (6 mm). The effective net area of ventilation is

GABLE RIDGE VENT

SHED RIDGE VENT

RIDGE VENTS

GENERAL

Structural metal panels are used in roofing applications when removal of the existing roof membrane is too costly or undesirable. Metal panel roofs are durable, have good wind and fire resistance ratings, and require little maintenance. The panels are manufactured either from steel or aluminum and are mechanically seamed on the job site. Sealants in tape or gel form are used as a gasket between metal connections. The sealant, applied in the female corrugation to make the roof more weathertight, allows the panels to expand and contract independently of the insulation and structural systems.

Two-part clips concealed inside the standing seams accommodate thermal expansion and eliminate the need for fasteners in the flat parts of the panel. The top part of the clip holds the metal panel, while the base of the clip is fastened to the structural member. A slot between the two parts of the clips allows independent movement. The concealed clip also provides the attachment necessary for wind uplift ratings.

Structural metal roofs can be used with slopes as low as 1/4 in. per ft but may also be used in a steep slope configuration. The panels are available in a wide variety of colors and typically have corrosion-resistant coatings.

Before adding the weight of structural metal roof panels to a building, it is important to verify the load-bearing capacity of the existing roof structure.

SEAM TYPES FOR METAL ROOFING PANELS

7 ROOF SPECIALTIES AND ACCESSORIES

GENERAL

The size and number of scuppers should be carefully determined to control ponding on roofs. Rectangular shapes convey more water (per inch of water depth on the roof) than round shapes. The performance of rectangular shapes approximates that of a broad-crested weir. Standard equations for channel flow are based on test models larger than typical roof scuppers. While downspout sizes normally are based on draining a given area of roof, that flow rate may not pass through a scupper that has been sized to have a cross-sectional area equal to the downspout area.

SCUPPER SIZING PROCEDURES

1. Determine the head (H) in inches of water (typically 1 in. minimum by code) at a point 6 ft back from the scupper opening.
2. Determine the roof drainage area in sq ft (SF).
3. Using rainfall intensity in inches per hour (IPH) from a rainfall data table, determine discharge capacity in gallons per minute (GPM). $GPM = SF \text{ of room area} \times IPH \times 0.0104$. The constant is 7.48 gallons per cubic foot divided by 12 inches per foot divided by 60 minutes per hour.
 $GPM = (0.0104) IPH \times SF$
4. Using H and the GPM, find the aggregate scupper length (L) in the scupper capacity table (below).
5. Select enough individual scuppers to satisfy the total GPM requirement and locate them proportionately.

NOTE

Scupper assemblies from top to bottom (flashing to scupper outlet to conductor head) should be overlapped to ensure that water will be directed away from the wall.

SCUPPER ASSEMBLY ELEVATION

NOTE

Scuppers that empty into a gutter may be integrated with a roof edge. The scuppers are soldered into a formed gravel stop-fascia system. The suggested maximum scupper interval is 10 ft. The front rim of the gutter must be 1 in. below the back edge, and it should be below the nailers used to elevate the roof edge. The drip edge on the fascia should lap the back edge of the gutter a minimum of 1 in. The gutter must be free to move behind the fascia.

COMBINATION SCUPPER AND GUTTER

NOTE
This ventilator may be used for either intake or exhaust with gravity flow.

GOOSENECK GRAVITY VENTILATOR

- NOTES**
1. This detail can be adapted for other uses, such as sign supports.
 2. Many roofing manufacturers offer prefabricated flashing pieces or permit the use of materials other than those shown here for flashing. Specifications on these proprietary designs vary; consult the manufacturers.
 3. For access to areas underneath equipment, vary pipe column height as shown in the accompanying chart.

COLUMN EQUIPMENT SUPPORT

PIPE COLUMN HEIGHT

EQUIPMENT WIDTH (IN.)	COLUMN HEIGHT (IN.)
Up to 24	14
25 to 36	18
37 to 48	24
49 to 60	30
61 and wider	48

ROOF VENT IN SLOPED ROOF

NOTE
All sloped partial or full conical shapes should be based on the same angle (generally 30°).

STATIONARY GRAVITY ROOF VENTILATOR

NOTE
This detail allows for roof maintenance around the equipment or sign. The continuous support, in contrast to the point load of a pipe column support, is preferred for lightweight roof systems. Clearance must be provided for removal and replacement of roofing and flashing between parallel supports.

CONTINUOUS EQUIPMENT SUPPORT CURB

This ventilator may be used on a sloped roof.

ROTATING VENTILATOR

NOTE
This detail allows moisture due to leaks, faulty vapor barriers, or construction work to escape from the roof system.

ROOF RELIEF VENT

NOTE
This detail allows the opening to be completed before the stack is placed. The metal sleeve and the clearance necessary will depend on the temperature of the material handled by the stack.

FLUE STACK ROOF PENETRATION

NOTE
 Roof pavers provide a stable walking service on any flat roof surface and protect the roof membrane from wear and tear. Service walkways should follow the most direct route to equipment to avoid shortcuts by maintenance personnel. Consult mechanical engineer about access needed to mechanical equipment.

SERVICE WALKWAYS ON ROOFS

NOTE
 Ballast pavers are typically made from precast concrete with a non-skid texture on the surface.

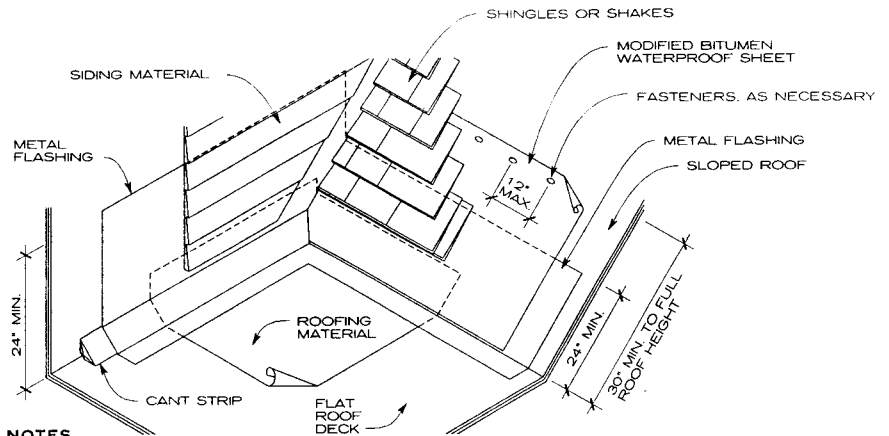

BALLAST PAVERS

MISCELLANEOUS ROOF WALKING SURFACES

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

7 ROOF SPECIALTIES AND ACCESSORIES

NOTES
 1. Modified bitumen sheet specified to provide self-sealing around fastener.
 2. Height of flashing and waterproof sheet depends on local snow probabilities and codes and on the roof slope.

WATERPROOFING AT ROOF TRANSITIONS

HEIGHT OF WATERPROOF SHEET

A (MIN.)	PITCH
5 1/2 in.	6:12 and up
14 1/2 in.	5:12
23 1/2 in.	4:12
to ridge	3:12

NOTE
 Provide gutters where required to protect building; if not required, avoid gutters where icing is common.

ICE DAM DETAILING AT EAVE WITH GUTTER

NOTES
 1. Consult codes for projected local snow heights.

2. Snow accumulation on roofs is generally unequal due to wind action. The resulting unequal load distribution might be aggravated by unequal melting of accumulated snow.

NOTE

Staples are not recommended for any structural or roofing fastenings.

HIGH WIND RESISTANCE DETAIL—COMPOSITION AND ASPHALT SHINGLES

HIGH WIND RESISTANCE DETAIL—GALVANIZED METAL ROOFING

GENERAL

Roofing materials are particularly susceptible to damage from wind uplift and debris borne by high winds. Contributing to this problem is the use of inferior roofing materials and fasteners, substandard workmanship practices, and poor design choices for areas known for frequent or potentially severe high winds. Use of design practices that resist wind uplift and lateral forces can protect the total building system from damage due to high winds and/or hurricanes. Anchoring framing members to the foundation system, tying together all framing, and bracing members, particularly roof trusses, are practices that strengthen and brace the entire building. Only when that has been accomplished are good roofing design and details relevant.

ROOFING FAILURES IN HIGH WIND

Some of the main reasons for roofing material failure caused by high winds are described here:

1. Roof sheathing—Inadequate reinforcement at the edges causes sheathing to separate from the roof truss or rafter. Wafer board, composite board, oriented strand board, or structural particleboard used as sheathing does not provide sufficient wind resistance.
2. Composition shingle and felt underlayment—Use of shingles, attachment adhesives, and/or fasteners not rated

HIGH WIND RESISTANCE DETAIL—BARREL TILE ROOFING

NOTE

After tile roofs are laid up completely, traffic should not be allowed on roof and no work that creates vibration in framing or roof sheathing should be allowed for 72 hours, minimum (24 hours is needed to ensure proper set).

HIGH WIND RESISTANCE DETAIL—S TYPE TILE ROOFING

HIGH WIND RESISTANCE DETAIL—EXTRUDED CONCRETE

for high winds or fasteners used in insufficient numbers, locations, and/or orientation can lead to wind damage.

3. Extruded concrete or clay tile—Poor nailing and/or mortar connections and underlayment failure due to lack of bonding between the underlayment and mortar or mortar and tile can cause failure of the roof. As well, clay tile may shatter when hit with flying debris.
4. Sheet metal—Inadequately adhered and fastened eave flashing, drips, and metal gravel stops can cause failure.

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

7 ROOF SPECIALTIES AND ACCESSORIES

GUTTER DESIGN

Design for gutters and downspouts for buildings depends on the following factors:

1. Design area of the roof (total roof area x pitch factor).
2. Rainfall intensity for the geographic area.
3. Length of gutter and roof area per downspout.

For rectangular gutters, use the rectangular gutter sizing graph on this page to determine size. Choose the depth/width ratio based on the proportions of the gutter desired, stock availability, or other relevant factors. The ratio of depth to width must be known before the actual design width can be determined. For semicircular gutters, first size the downspout from the downspout tables, then size the gutter one inch larger in diameter. For irregularly shaped gutters, determine an equivalent rectangular size and use the rectangular gutter sizing method.

NOTES

1. Most gutters are run level for appearance. However, a slope of 1/16 in. per foot is desirable as a minimum for drainage.
2. For residential work, allow 100 sq ft of design roof area per one sq in. of downspout.
3. The terms "leader" and "conductor" have the same meaning as downspout.

DOWNSPOUT CAPACITY

Intensity in in./hr lasting 5 min.	2	3	4	5	6	7	8	9	10	11
Sq ft roof/sq in. of downspout	600	400	300	240	200	175	150	130	120	110

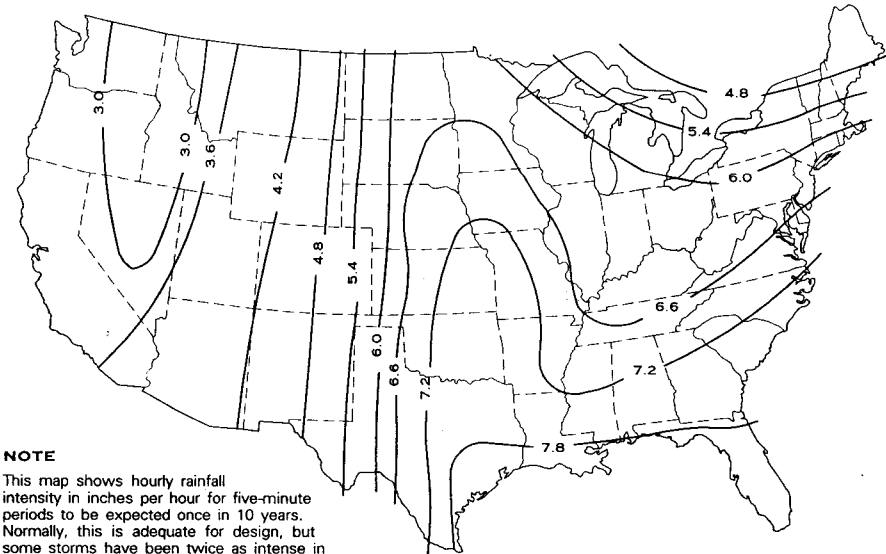

PITCH	FACTOR
Level to 3 in./ft	1.00
4 in./ft to 5 in./ft	1.05
6 in./ft to 8 in./ft	1.10
9 in./ft to 11 in./ft	1.20
12 in./ft	1.30

NOTE

A roof that is level up to a 3 in. per foot slope is considered a "flat" roof and has a pitch factor of 1.0. When a roof is sloped greater than 3 in. per foot, neither a "plan area" nor an "actual area" should be used to size drainage since the pitch affects the area in two ways, by increasing the actual area and by affecting the speed of the runoff. Instead, multiply the plan area (A x B) by the factor shown in the chart above to obtain the design area.

DESIGN AREAS FOR PITCHED ROOFS

NOTE

This map shows hourly rainfall intensity in inches per hour for five-minute periods to be expected once in 10 years. Normally, this is adequate for design, but some storms have been twice as intense in some areas. See local records.

RAINFALL INTENSITY MAP

WIDTH OF RECTANGULAR GUTTERS FOR GIVEN ROOF AREAS AND RAINFALL INTENSITIES

IA = RAINFALL INTENSITY X AREA

L = LENGTH OF GUTTER IN FEET

SAMPLE GUTTER SIZING PROBLEM

A New York City building with a footprint of 120 ft x 30 ft needs a gutter system. The building has a flat roof with a raised roof edge on three sides; a gutter is to be located on one of the 120-ft sides. So each gutter section will be no more than 50 ft, three downspouts will be used with two gutter expansion joints. The area to be drained by each 40-

ft section gutter is 1200 sq ft. The rainfall intensity according to the map is 6 in., and the ratio of gutter depth to width is 0.75. On the chart above, find the vertical line representing L = 40. Proceed vertically along this line to its intersection with the oblique line representing M = 0.75. Move horizontally to the left to intersect the vertical line repre-

DOWNSPOUT SIZES

TYPE	AREA (SQ IN.)	NOMINAL SIZE (IN.)	ACTUAL SIZE (IN.)
Plain round	7.07	3	3
	12.57	4	4
	19.63	5	5
	28.27	6	6
Corrugated round	5.94	3	3
	11.04	4	4
	17.72	5	5
Corrugated rectangular	25.97	6	6
	3.80	2	1 1/4 x 2 1/4
	7.73	3	2 1/8 x 3 1/4
	11.70	4	2 1/4 x 4 1/2
Plain rectangular	18.75	5	3 1/2 x 5
	3.94	2	1 1/4 x 2 1/4
	6.00	3	2 x 3
	12.00	4	3 x 4
	20.00	5	3 1/2 x 4 1/2
	24.00	6	4 x 6

senting IA = 7200. The point of intersection occurs between the oblique line representing gutter widths of 5 and 6 in. With a required gutter width of 6 in. and a depth-to-width (M) ratio of 0.75, calculate the depth of the gutter by multiplying the width (6 in.) by M (0.75) to calculate the gutter depth at 4 1/2 in.

Lawrence W. Cobb; Columbia, South Carolina

TYPICAL GUTTER SHAPES AND SIZES

NOTES

1. Formed and extruded downspout sizes are 3 x 4 to 6 x 6; round sizes are 3, 4, or 5 in. in diameter. (Extruded downspouts are for heavy traffic.)
2. Generally, space downspouts a minimum of 20 ft and a maximum of 50 ft apart.
3. A downspout of 7 sq. in. minimum should be used, except for canopies or small porches.
4. Corrugated shapes resist breakage due to freezing better than straight profiles.
5. Elbows are available in 45-, 60-, 75-, and 90-degree angles.

TYPICAL DOWNSPOUT SHAPES AND SIZES

CONCEALED GUTTER

Jones/Richards and Associates; Ogden, Utah
Lawrence W. Cobb; Columbia, South Carolina

PARTS OF A GUTTER/DOWNSPOUT SYSTEM

GUTTER PLACEMENT IN SNOW ZONES

LEAF GUARD

SNOW GUARD

NOTES

1. Gutters should be placed below the slope line so snow and ice can slide clear. A steeper pitch requires less clearance.
2. Snow guards are installed on roofs to protect gutters from snow slides and snow overloading. They hold the snow in place evenly over the entire roof, allowing it to melt gradually into the gutter system. They also help prevent snow from collecting over the eaves, where it may thaw and refreeze, potentially causing damage.
3. Snow guard placement depends on the roof slope, local snow conditions, the insulation at the roof below, and the length of the rafters. Snow guards typically are staggered on the roof, with the first row starting 2 ft from the eave.

GUTTER PROTECTION

GUTTER BRACKET OR STRAP SIZES (IN.)

GIRTH	GALVANIZED STEEL	COPPER	ALUMINUM	STAINLESS
Up to 15	1/8 x 1	1/8 x 1	3/16 x 1	1/8 x 1
15 to 20	3/16 x 1	1/4 x 1	1/4 x 1	1/8 x 1 1/2
20 to 24	1/4 x 1 1/2	1/4 x 1 1/2	1/4 x 2	1/8 x 2

NOTES

1. Gutter hangers are normally spaced 3 ft on center. Reduce spacing to 1 ft 6 in. o.c. where snow and ice are prevalent.
2. Spike and ferrule hangers are not recommended if girth is greater than 15 in.
3. Hangers are available in many sizes, shapes, and materials and are matched to the design of the gutter used. Consult manufacturers' design manuals.

GUTTER HANGERS

NOTES

1. Continuous gutters may be formed at the installation site with cold forming equipment, thus eliminating joints in long runs of gutter.
2. Gutters and downspouts are available in aluminum, galvanized steel, copper, and stainless steel. Consult manufacturers for custom materials.
3. Girth is the width of the sheet metal from which a gutter is fabricated.
4. Although all joining methods are applicable to most gutter shapes, lap joints are more commonly used. Seal all joints with mastic or by soldering. Lock, slip, or lap joints do not provide for expansion.
5. Expansion joints should be used on all straight runs over 40 ft. In a 10-ft section of gutter that will undergo a 100-degree temperature change, linear expansion will follow these coefficients of expansion (CE) and movements:
Aluminum: CE—.00128; movement—.15 in.
Copper: CE—.00093; movement—.11 in.
Galvanized steel: CE—.0065; movement—.08 in.
6. Always keep the front of the gutter 1/2 in. lower than the back.
7. Use a minimum width of 4 in. except for canopies and small porches. The minimum ratio of depth to width should be 3 to 4.
8. Many custom shapes for gutters and downspouts are available; consult manufacturers' design manuals. See the Sheet Metal and Air Conditioning Contractors National Association (SMACNA) *Architectural Sheet Metal Manual* for gutter sizing and details.

SCUPPER DETAIL AT PARAPET WALL (CONDUCTOR HEAD SIDE)

SCUPPER DETAIL AT PARAPET WALL (ROOF SIDE)

TYPICAL CONDUCTOR HEAD

TYPICAL GRAVEL STOPS

NOTES

1. Overflow openings are recommended in heavy icing areas and for drains that may become plugged with leaves or other debris. Check local codes for elevation of overflow opening.
2. Conductor heads and downspouts should be fabricated of the same material. Recommended minimum for construction of conductor heads is 24 gauge galvanized steel, 0.032 in. aluminum, 16 oz. copper, or 26 gauge stainless steel.
3. Edges of conductor head must be suitably stiff, based on dimensional characteristics.

7 GUTTERS AND DOWNSPOUTS

DOORS AND WINDOWS

Fire Rating and Security	464	Entrances and Storefronts	482
Door and Window Openings	467	Windows	486
Metal Doors and Frames	469	Skylights	498
Wood and Plastic Doors	473	Hardware	503
Specialty Doors	478	Glazing	512

GENERAL

Fire-rated assemblies for door and window openings, used to protect against the spread of fire and smoke, consist of a fire-rated door or window with frame, hardware, and accessories, including gasketing. Each component is crucial to the overall performance of the assembly as a fire barrier. Choices to be made regarding the enclosure of openings in fire-rated walls include the following:

1. Fire-rated wall requirements
2. Size of opening
3. Means of egress
 - a. Required size per occupancy
 - b. Quantity and location
 - c. Direction of egress flow and operation of enclosure
 - d. Hardware requirements
 - e. Window egress requirements
4. Materials and finishes
5. Security
6. Visibility and glazing

FIRE PROTECTION CRITERIA

NFPA 80, Standard for Fire Doors and Fire Windows, is a consensus standard that establishes minimum criteria for installing and maintaining assemblies and devices used to protect openings in walls, ceilings, and floors from the spread of fire and smoke. The degree of fire protection (in hours) required for a given opening is referenced in the model building codes (BOCA, SBCCI, and UBC) and the Life Safety Code (NFPA 101). Fire doors are classified by hourly references determined by testing done in accordance with NFPA 252, Standard Method of Fire Tests of Door Assemblies (also known as UL 10B). Further information is available in chapter 6, section 6 of the NFPA's Fire Protection Handbook.

TYPES OF OPENINGS

4-HR AND 3-HR OPENINGS (formerly class A): located in fire walls or in walls that divide a single building into fire areas.

1 1/2-HR AND 1-HR OPENINGS (formerly class D and B, respectively): located in multistory vertical communication enclosures and in 2-hr rated partitions providing horizontal fire separations.

3/4-HR AND 20-MIN. OPENINGS (formerly class C, E): located in walls or partitions between rooms and corridors with a fire-resistance rating of one hour or less.

The hourly protection rating for openings depends on the use of the barrier, as in exit enclosures, vertical openings in buildings, building separation walls, corridor walls, smoke barriers, and hazardous locations. In most codes, class designations have been replaced by hour classifications.

TYPES OF FRAMES

Fire-rated doorframes can be assembled at the factory or in the field. Frames must be adequately anchored at the jambs and floor according to the manufacturer's specifications. Codes require doors to be installed in accordance with NFPA 80, Section 2-5, Frames, indicates only labeled frames are to be used.

LIGHT-GAUGE METAL FRAME: head and jamb members with or without transom panel made from aluminum (45-min. maximum rating) or light-gauge steel (1 1/2-hr maximum rating); installed over finished wall.

PRESSED STEEL (HOLLOW METAL): head and jamb members with or without solid or glazed transoms or sidelights made from 18-gauge or heavier steel (3-hr. maximum rating); required for most metal doors.

DEFINITIONS

The following definitions are typically used in relation to fire-rated openings:

AUTOMATIC: providing a function without the necessity of human intervention.

FIRE BARRIER: a continuous membrane, either vertical or horizontal (for example, a wall, floor, or ceiling assembly), that is designed and constructed with a specified fire-resistance rating to limit the spread of fire and restrict the movement of smoke.

FIRE RESISTANCE: the property of materials or their assemblies that prevents or retards the passage of excessive heat, hot gas, or flames under conditions of use.

FIRE-RESISTANCE RATING: the time, in minutes or hours, that materials or assemblies have withstood fire exposure in accordance with the test procedure of NFPA 252.

LABELED: equipment or materials marked with the label, symbol, or other identifying mark of an organization concerned with product evaluation and acceptable to the local jurisdiction. This organization must periodically inspect production of labeled equipment, and the manufacturer, by labeling the product, indicates compliance in a specified manner with appropriate standards or performance.

NONCOMBUSTIBLE: a material that, in the form in which it is used and under the conditions anticipated, will not aid combustion or add appreciable heat to an ambient fire.

SELF-CLOSING: as applied to a fire door or other protective opening, self-closing means the door is normally closed and is equipped with an approved device that will ensure closure after the door has been opened.

SMOKE BARRIER: a continuous membrane, either vertical or horizontal, such as a wall, floor, or ceiling assembly, that is designed and constructed to restrict the movement of smoke. A smoke barrier may or may not have a fire-resistance rating.

SECURITY FRAME REINFORCING FOR FIRE-RATED OPENINGS

FIRE-RATED STEEL FRAME ELEVATIONS

DOOR LABEL

FRAME LABEL

NOTE

Various agencies test and rate fire door and window units and assemblies. Manufacturers locate metal labels in accessible but concealed locations (the hinge edge of doors, for example); these labels must remain in place, unpainted, uncovered, and unaltered.

TESTING LABELS

NOTE

The minimum width of each door opening must be sufficient for the occupant load it serves. Verify the following general guidelines for door width with local codes:

1. Dwelling units that are not required to be accessible or adaptable: 29 3/4 in.
2. Hospital and other medical facilities: 36 in.
3. Standard openings: 32 in.

DOOR OPENINGS FOR MEANS OF EGRESS

National Fire Protection Association; Quincy, Massachusetts
Daniel F. C. Hayes, AIA; Washington, D.C.

4-HOUR/3-HOUR CLASSIFICATION

NOTES

1. All hinges or pivots must be steel. Two hinges are required on doors up to 5 ft in height; an additional hinge is required for each additional 2 ft 6 in. of door height or fraction thereof. The same requirement holds for pivots.

1 1/2-HOUR/1-HOUR CLASSIFICATION

2. While wired glass $\frac{1}{4}$ in. thick is the most common material used for glass lights, other materials have been listed and approved for installation. Refer to the UL fire protection directory.

3/4-HOUR/20-MIN. CLASSIFICATION

3. Consult all authorities with jurisdiction before installation of glass lights and louvers.

4. Fusible-link/automatic closing louvers are permitted in fire-rated doors with restrictions; they are not permitted in smoke-barrier doors.

FIRE-RATED DOOR CLASSIFICATIONS

NOTE

When required for egress, such as in sleeping areas in residences, windows must meet the following criteria:

1. Clear opening per sash must be a minimum of 5.7 sq ft.
2. Bars, grilles, or screens must be releasable from inside without use of tools or key.
3. Windows opening onto fire escapes have additional requirements; refer to codes.
4. Check with manufacturers for integral release hardware options for awning, casement, pivot, or other windows.
5. Double-hung window units with fully removable sash that do not require special tools, force, or knowledge to operate may offer greater flexibility in unit selection to meet size requirements for egress openings; verify with manufacturers and code officials.

WINDOW EGRESS REQUIREMENTS

National Fire Protection Association; Quincy, Massachusetts

NOTE

Glazed panel assemblies in fire-rated walls must conform to the size limitations indicated below and to wire glass and other approved material requirements. Multiple panels are permitted, but the aggregate area of all panels and openings must not exceed 25% of the wall surface. Refer to specific codes for details.

GLAZED PANEL REQUIREMENTS

MAXIMUM DOOR SIZES (HOLLOW METAL, ALL CLASSES*)

Single door	4 x 10 ft with labeled single-point or 3-point latching device
	4 x 8 ft with fire exit hardware
Pair of doors	8 x 10 ft active leaf with labeled single-point or 3-point latching device
	8 x 10 ft inactive leaf with labeled 2-point latching device or top and bottom bolts
	8 x 8 ft with fire exit hardware

*Wood door size requirements are similar.

CONSTRUCTION OF SWINGING FIRE DOORS

Outlined here are different types of swinging fire doors and notes about the hardware used with them.

TYPES OF DOORS

1. Composite fire doors: wood, steel, or plastic sheets bonded to and supported by a solid core material.
2. Hollow metal fire doors: flush or panel design with a steel face of not less than 20-gauge steel.
3. Metal-clad fire-doors: flush or panel design consisting of metal-covered wood cores or stiles and rails and insulated panels that are covered with steel of 24-gauge or lighter.
4. Sheet metal fire doors: 22-gauge or lighter steel of corrugated, flush sheet, or panel design.
5. Tin-clad fire doors: wood core with a terne plate or galvanized steel facing (30- or 24-gauge).
6. Wood core doors: wood, hardboard, or plastic face sheets bonded to a wood block or wood particleboard core material with untreated wood edges.

DOOR OPERATION

1. Doors that swing in the direction of egress are preferred for fire-rated doors.
2. Horizontal sliding and revolving doors are permitted with restrictions.

HARDWARE

1. Door hardware is provided by the builder independent of the assembly or furnished by the manufacturer with the door assembly. In either case, the manufacturer prepares the door and frame to receive hardware to ensure the integrity of the fire-rated assembly.
2. Fire doors are hung on steel ball-bearing hinges and must be self-closing. Labeled automatic latches and door closers can be self-operated or controlled by fail-safe devices that activate in a fire.
3. Pairs of doors require coordinators with astragals to ensure that both doors close.
4. Heads and jambs should be sealed with gaskets when smoke control is required.
5. Panic hardware may be required when space occupancy is greater than 100 people.

GUIDE SPECIFICATIONS FROM THE HOLLOW METAL MANUFACTURERS ASSOCIATION (HMMA)

	HMMA 860	HMMA 861	HMMA 862	HMMA 863
DOORS				
Face sheets interior	20 ga.	18 ga.	14 ga.	14 or 12 ga.
Face sheets exterior	18 ga.	16 ga.	14 ga.	14 or 12 ga.
Minimum thickness	1 3/4"	1 3/4"	1 3/4"	2"
Stiffeners	22 ga.	22 ga.	18 ga.	18 ga.
Vertical edges	Continuous weld or interlocking seam welded at top and bottom of door	Continuous weld	Continuous weld	Reinforced by 10 ga. continuous steel channel, continuous weld
Top and bottom edges	Closed with 16 ga. continuous recessed steel channel	Closed with 16 ga. continuous recessed steel channel, spot welded to face sheets	Closed with 12 ga. continuous recessed steel channel, spot welded to face sheets	Reinforced with continuous steel channel, 10 ga. spot welded to face sheets 4" on center
Glass molding and stops	Fixed moldings welded to door on security side; loose stops, 20 ga.	Fixed moldings welded to door on security side; loose stops, 20 ga.	Fixed moldings welded to door on security side; all stops, 16 ga.	Fixed moldings, 12 ga. spot welded to face sheets 5" o.c.; removable glass stops, 14 ga. pressed steel channel
FRAMES				
Interior openings	16 ga. (18 ga. for wood doors, 20 ga. for hollow core wood doors)	16 ga.; 14 ga. for openings over 4' - 0" in width	12 ga.	12 ga.
Exterior openings	16 ga.	14 ga.	12 ga.	12 ga.
Construction	Welded or knocked-down with integral stop and trim	Welded units with integral stop and trim	Welded units with integral stop and trim	Welded units with integral stop and trim
Floor anchors	16 ga. welded inside jambs	14 ga. welded inside jambs	14 ga. welded inside jambs	Same ga. as frame, welded inside jambs with at least 4 spot welds per anchor
Jamb anchors	In masonry walls 16 ga. steel or 0.156" diameter steel wire. For stud partitions, 18 ga. steel anchors welded inside jambs	In masonry walls 16 ga. steel or 0.156" diameter steel wire. For stud partitions, 18 ga. steel anchors welded inside jambs	In masonry walls 14 ga. steel or 0.156" diameter steel wire. For stud partitions, 16 ga. steel anchors welded inside jambs	Same ga. as frame
Loose glazing stops	20 ga. cold-rolled steel	20 ga. cold-rolled steel	16 ga. cold-rolled steel	10 ga. cold-rolled steel

NOTES

- HMMA 860: For use in building projects where traffic is relatively light and hard usage is not anticipated.
- HMMA 861: For use in commercial and industrial applications where rigorous use is anticipated, such as schools, hospitals, industrial buildings, office buildings, hotels, nursing homes, airports, and convention centers.
- HMMA 862: For use in applications where security is paramount due to high susceptibility to vandalism, break-in, and theft, such as entrances and back doors of businesses, storerooms, warehouses, strip stores, apartments, and condominiums. HMMA 862 incorporates testing procedures and performance requirements promulgated by NILECJ for Class IV doors (ASTM F476-84) including jamb/wall stiffness test, jamb/wall stiffness performance, door impact test, door and glazing panel impact resistance performance.
- HMMA 863: For applications in jails, prisons, detention centers, and secured areas in hospitals or courthouses. HMMA 863 requires five tests: static load test, rack test, impact load test, removable glazing stop test, and bullet resistance test.
- Reprinted with permission from the Hollow Metal Manufacturers Association, division of NAAMM.

PERFORMANCE REQUIREMENTS FOR SLIDING GLASS DOOR UNIT SECURITY

PARAMETER	REQUIREMENTS	
	CLASS I UNIT	CLASS II UNIT
Disassembly	No entry	No entry
Latch operator loiding resistance	10 lbf (45 N)	10 lbf (45 N)
Latch loiding resistance	300 lbf (1335 N) plus weight of panel	600 lbf (2670 N) plus weight of panel
Locking device stability	Horizontal - 50 lbf (222 N) Vertical - 50 lbf (222 N) plus weight of panel (10 cycles)	Horizontal - 50 lbf (222 N) Vertical - 50 lbf (222 N) plus weight of panel (10 cycles)
Door panel removal resistance	Horizontal - 100 lbf (445 N) Vertical - 300 lbf (1335 N) plus weight of panel	Horizontal - 100 lbf (445 N) Vertical - 600 lbf (2670 N) plus weight of panel
Locking device strength	300 lbf (1335 N)	600 lbf (2670 N)
Fixed panel fastening strength	300 lbf (1335 N)	600 lbf (2670 N)
Meeting stile fastening strength	150 lbf (667 N)	Horizontal - 100 lbf (445 N) 300 lbf (1335 N)
Glazing impact strength	None	37 ft-lbf (50 Joules)

NOTES

- Table from the National Institute of Justice (NIJ) Standard 0318.00, Physical Security of Sliding Glass Door Units.
- Class I sliding door units provide a minimum level of physical security. Class II sliding door units provide a moderate level of physical security.
- Loiding is a method of manipulating a locking device from the exterior of a sliding glass door unit by means of a thin, flat object or a thin stiff wire that is inserted between the locking stile and the strike so as to force the locking device toward the unlocked position.

McCain McMurray, Architect; Washington, D.C.

SLIDING DOOR UNITS

Sliding glass doors are a particular concern in securing a building. The locking devices should include vertical rod, or lever bolts, at top and bottom; the frame should be solid or reinforced at the locking points; the stile must also be reinforced at the locking points. The operating panels should be designed so that they cannot be lifted out of their tracks when in the locked position. Glazing and other components should be installed from the inside so that entry cannot be gained by disassembly.

SLIDING GLASS DOOR

WINDOW SECURITY DESIGN CRITERIA

The following items should be considered when designing and selecting windows:

- If accessible (residential: 12 ft vertical, 6 ft horizontal; commercial: 18 ft vertical, 10 ft horizontal) and hidden from public view, a higher grade is required.
- If windows are protected by a detection device (such as shutters, security screens, or bars), the window grade could be irrelevant. If security screens, bars, or shutters are used, requirements for fire exiting must be met.
- The existence of windbreaks near a building may provide cover for intruders.
- The use of shades and window coverings may deter intruders, depending on the ease of removal of these devices or the noise from breakage. The use of lockable shutters or roll-down blinds is very effective.
- Window units should at least comply with ASTM F588-85 Standard Test Methods for Resistance of Window Assemblies to Forced Entry for a minimum grade performance and with NIJ-STD-0316, Physical Security of Window Units, for higher grade performance.

FRAME DESIGN ELEMENTS

- A rigid frame and sash is important to resist prying and should be removable from the inside only.
- The quality of the hardware and its placement and anchorage are critical to security. Exposed removable hinges should not be used.
- Special attention must be given to the use of weather stripping, since this can permit insertion of wires to unlock windows.

GLAZING DESIGN ELEMENTS

- Multiple glazing systems provide a greater hazard to entry/exit through broken-out windows.
- Reflective glazing impedes outside daytime surveillance.

MATERIALS AND METHODS FOR WINDOWS

- Class IV. Very heavy fixed frames with laminated glass over 1/4 in. thick security screen, bars, or shutters with special locking device.
- Class III. Heavy duty sash with laminated glass over 1/4 in. thick or polycarbonate glazing 1/4 in. thick. Lock should include at least two heavy duty dead locking bolts.
- Class II. Heavy duty sash with laminated glass or polycarbonate glazing; if wood, sash must be reinforced or heavy; double locks required.
- Class I. Regular glazing in commercial sash with double locks; can be wood frame.

WINDOW JAMB DETAIL

DEFINITIONS

BUCK: a subframe of wood or metal set in a wall or partition to support the finish frame of a door or window; also called door buck or rough buck.

CASING: the finished, often decorative framework around a door or window opening, especially that which is parallel to the surrounding surface and at right angles to the jamb; also called trim.

SUBCASING: finish frame components that support and guide the door or sash.

HEAD: horizontal members at top of door or window.

JAMB: vertical members at sides of door or window.

STOP: integral or applied member that prevents a door or window from swinging past its closed position, or members that guide horizontal or vertical sliding movement.

SILL: horizontal members at bottom of door or window.

THRESHOLD: applied wood, stone, or metal plate, usually weatherproof.

SADDLE: part of a threshold, usually bridging dissimilar flooring materials.

FRAME AND STOP TYPES

OPENING TYPES

DOOR ACCESSORIES

Daniel F. C. Hayes, AIA; Washington, D.C.

NOTE

Weatherproofing for exterior door openings is similar to window weatherproofing.

DOOR OPENING COMPONENTS

NOTE

1. Caulking, sealant, adhesive, or gasket seals window framing and wall joints to form air barrier.
2. These principles are also applicable to door weatherproofing.

MATERIALS

Hollow metal doorframes are available in various steel gauges according to where and how they will be used. Local codes and governing authorities establish minimum gauges, which should always be consulted. Some manufacturers make custom moldings for a specific design, as long as a sufficient quantity is required.

For security, the exterior moldings on exterior doors should be welded into the frame and exposed fasteners should be tamperproof.

TYPES OF FRAMES

Doorframes can be factory or field assembled. All frames must be adequately anchored at the jambs and floor according to the manufacturer's specifications.

LIGHT-GAUGE METAL FRAME: head and jamb members, with or without a transom panel, of aluminum (45 min. maximum rating) or light-gauge steel (1.5 hr maximum rating). Frame is installed over finished wall.

PRESSED STEEL (HOLLOW METAL): head and jamb members, with or without solid or glazed transoms or sidelights, of 18-gauge or heavier steel (3 hr maximum rating). This frame is required for most metal doors.

FINISHES

Hollow metal frames should receive at least one shop coat of rust-inhibitive primer before delivery to the job site. In very corrosive atmospheres, such as saltwater beach locations, is it advisable to have doors and frames hot dipped galvanized for additional protection.

Frames with factory-applied paint finishes in various colors are available from several manufacturers.

STANDARD DOOR AND DOOR CLEARANCE

Tubular stiles and rails compose structural elements.

A flush or recessed panel is held in place by stiles and rails.

A recessed panel door, generally considered an industrial type door, may be used for decorative purposes.

STILE AND RAIL CONSTRUCTION

Relatively wide center panel connected to hinge and lock stile by interlocking and/or welding—forming two exposed vertical seams on door face.

Inverted channel closes top and bottom.

Exterior door is furnished with cap.

STILE AND PANEL CONSTRUCTION

Pan type or enclosed grid construction. No seams visible on face.

Exposed seams may be on vertical edges where two pans join.

Top and/or bottom of door may be flush or recessed.

SEAMLESS FULL FLUSH CONSTRUCTION

DOOR TYPES

NOTES

Door types may be imposed on any door construction.

Defined areas are filled with glass, screening, louvers, or recessed or flush panels unless otherwise noted.

Stiles and rails or muntins make divisions.

FINISHES

Standard: primed and/or galvanized
 Paint: baked enamel
 Applied: vinyl clad
 Textured, embossed: stainless steel, aluminum
 Polished: stainless steel

HOLLOW METAL DOORS

Hollow metal doors are available in steel gauges ranging from 20 to 12; which gauge to use depends on where and how a door will be used. Consult local codes and governing authorities for minimum gauges that may have been established. Some manufacturers will custom make doors to a specific design if an order is large enough.

For security, exterior moldings on exterior doors should be welded into the door and all exposed fasteners should be tamperproof.

FINISHES

Hollow metal doors should receive at least one shop coat of rust-inhibitive primer before delivery to the job site. In very corrosive atmospheres, such as saltwater beach locations, the doors and frames should be hot-dipped galvanized for additional protection.

Doors can be purchased from the manufacturer with factory-applied paint finishes in various colors.

FLUSH WOOD DOORS

CORE MATERIAL

SOLID CORE: wood block, single specie, maximum 2 1/2 in. width, surfaced two sides, no spaces or defects impairing strength or visible through hardwood veneer facing.

HOLLOW CORE: wood, wood derivative, or class A insulation board.

SPECIAL CORES

SOUND-INSULATING CORE: thicknesses of 1 3/4 and 2 1/4 in.; sound transmission class rating of 36 for 1 3/4 in. and 42 for 2 1/4 in. barrier faces separated by a void or damping compound to keep faces from vibrating in unison. Special stops, gaskets, and threshold devices may be required.

LEAD-LINED CORE: 1/32 in. to 1/2 in. continuous lead sheeting from edge to edge inside door construction; may be reinforced with lead bolts or glued. (See UL requirements.)

GROUNDED CORE: wire mesh at center of core, grounded with copper wire through hinges to frame.

WOOD FACE TYPES

Standard thickness face veneers range from 1/16 in. to 1/32 in.; they are bonded to hardwood with a crossband (1/10 in. to 1/16 in.) and are the most economical and widely used veneer type. Face veneers inhibit checking in the finish but are difficult to refinish or repair. They can be used on all cores.

Bonded to a crossband, 1/8 in. sawn veneers are easily refinished and repaired.

Staved-block and stile-and-rail solid cores take 1/4 in. sawn veneers. These are the same as 1/8 in. sawn veneers but do not have a crossband on stile-and-rail solid cores with horizontal blocks. Faces can be cut with decorative grooves.

LIGHT AND LOUVER OPENINGS

Custom made to specifications, this type of door has wood beads and slats that match the face veneer. Space between the opening in the door and the edge of the door can be no less than 5 in.

In hollow-core doors, the cutout area can be at most half the height of the door. Doors with openings greater than 40% are not guaranteed. Weatherproofing of exterior doors is required to prevent moisture from leaking into the core.

FACTORY FINISHING

Partial finishing is available, with sealing coats in place but the final finish applied on the job. Complete factory finishing requires the door to be prefit and premachined.

SPECIAL FACING

For opaque finishes only, high or medium-low density overlay faces of phenolic resins and cellulose fibers can be fused to the inner faces of a hardwood door to serve as a base for the final finish.

Laminated plastic (1/16 in. thick, minimum) can be bonded to a wood back of two or more plies (1/16 in., minimum).

Hardboard, 1/8 in. thick and smooth on one or both sides, can be used as a facing.

GENERAL NOTES: WOOD DOORS

1. Kiln-dried wood: moisture content at 6-12%.
2. Type I doors: fully waterproof bond, exterior and interior.
3. Type II doors: water-resistant bond, interior only.

Daniel F. C. Hayes, AIA; Washington, D.C.

TYPICAL FLUSH DOOR SIZES AND CHARACTERISTICS

HOLLOW METAL DOOR WITH STIFFENED CORE

NOTE

For bonded blocks, stave core is the most economical and widely used. Other materials include particleboard (heavier, more soundproof, economical) and mineral composition (lighter, difficult cutouts and detailing, lower screw strength).

WOOD SOLID CORE DOOR

4. Tolerances: height, width, thickness, squareness, and warp per NWWDA standards; vary with solid vs. builtup construction.
5. Prefit: doors at 3/16 in. less than width and 1/8 in. less in height than nominal size, ±1/32 in. tolerance, with vertical edges eased.

NOTE

Louvers are sized per mechanical requirements. Fire-resistance regulations require closable louvers or preclude installation in smoke-barrier doors and certain fire-rated doors.

VISION OR LOUVERED DOOR

HOLLOW METAL DOOR WITH STILE AND RAIL

NOTE

Acoustical materials may be used to cut sound transmission.

WOOD HOLLOW CORE DOOR

6. Premachining: doors mortised for locks and cut out for hinges when so specified.
7. Premium: for transparent finish; good/custom: for paint or transparent finish; sound: for paint, with two coats completely covering defects.

GENERAL

Panel doors consist of a framework of vertical (stile) and horizontal (rail) members that hold solid wood or plywood panels, glass lights, or louvers in place.

CONSTRUCTION

Doors are made of solid or builtup stiles, rails, and vertical members (muntins), doweled as in NWWDA standards. Stock material includes ponderosa pine or other Western pine, fir, hemlock, or spruce and hardwood veneers. Hardboard, metal, and plastic facings are available in patterns simulating panel doors.

GRADES

Premium (select) grade is used for natural, clear, or stained finishes. Exposed wood is free of defects that affect appearance.

Standard grade is used for opaque finishes. Defects, discoloration, mixed species, and finger joints are permitted if undetectable after finishing.

GLAZING

All glazing in doors must be safety glazing. Insulated glazing is available.

BUILTUP MEMBERS

The core and edge and end strip material is similar to the material used in flush doors. Face veneer is typically hardwood at 1/8 in. minimum thickness.

STICKING, GLASS STOPS, AND MUNTINS

Typical profiles used are cove, bead, or ovolo.

PANELS

Flat panels are typically 3-ply hardwood or softwood. Raised panels are constructed of solid hardwood or softwood built up of two or more plies. Doors 1 ft 6 in. wide or less are one panel wide.

ADA ACCESSIBILITY GUIDELINES

For opening width compliance, use doors 3 ft 0 in. wide. Door projections, such as Dutch door shelves, may be no more than 4 in. if more than 27 in. above finished floor. Thresholds and saddles must be no higher than 1/2 in. with beveled edges. Kickplates are recommended outdoors along accessible routes.

HOLLOW METAL DOOR STILE AND RAIL DETAIL

TYPICAL SIZES AND CHARACTERISTICS

NOTE
Tempered or laminated safety glass should be used in glazed panels.

GLAZED DOOR

Jeffrey R. Vandevoort, Talbott Wilson Associates, Inc.; Houston Texas
Daniel F. C. Hayes, AIA; Washington, D.C.

GENERAL

Consider the following when designing a door: aesthetics (the design and look of the door), operation (how the door moves), fire-resistance ratings/egress requirements, accessibility for people with disabilities, size and weight, location, materials/method of construction, glazing requirements, special requirements (sound transmission, containment of harmful material such as x-rays or projectiles), security issues, energy conservation, electrostatic grounding, hardware, and weatherproofing.

Refer to local, state, and federal codes and trade association and manufacturers' specifications and recommendations for additional information and requirements.

NOTE
Doors that swing, the most common type of door operation, rotate around an axis determined by hinges or pivots.

DOOR AND OPENING CHARACTERISTICS

MEETING EDGE TYPES FOR DOUBLE DOOR LEAVES

DOUBLE-EGRESS DOORS

NOTE
Double-egress doors have a pair of swinging leaves that operate in opposite directions, permitting equal access to two or more means of passage.

DOUBLE DOOR LEAF TYPES

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland
Daniel F. C. Hayes, AIA; Washington, D.C.

DEFINITIONS

ACTIVE LEAF: the primary operating leaf of a door pair.

AIR CURTAIN: a mechanically produced downward stream of air across a door opening intended to prevent transmission of heat and weather.

AUTOMATIC DOOR: a door fully or partially operated with an external mechanism (door opener) triggered by sensor or switch/button, as opposed to manual operation; refer to accessibility and fire code requirements.

HAND: denotes direction of door movement.

LEAF: a door panel.

LEFT-HINGED DOOR: a door with hinges mounted on the left stile of the active panel.

PASSIVE/INACTIVE DOOR: a door that operates independently of and secondarily to the active leaf of a door pair; normally held closed with floor and head bolts; the strike plate of this door receives the latch of the active leaf.

PREHUNG DOOR: door and frame combination fabricated and assembled by the manufacturer and shipped to the site.

RIGHT-HINGED DOOR: a door with hinges mounted on the right stile of the active panel.

STATIONARY (FIXED) DOOR: a nonoperational leaf.

SINGLE-ACTING DOOR

NOTE
The single-acting door, the most common door type, has a leaf that operates in a swinging or sliding motion in only one direction.

SINGLE DOOR LEAF TYPES

SPACE REQUIREMENTS (VARIOUS DOOR WIDTHS—IN.)

	34	36	38	40	42	44
X	21 1/4	23 1/4	25 1/4	23 1/4	25 1/4	27 1/4
Y		12 3/4			16 1/4	
Z		7 1/8			8 7/8	

NOTE
A balanced door is a single-action swinging door mounted on offset pivots. The leaf operates independently of the jamb, and the elliptical trajectory of the leaf requires less clear floor space than a conventional swinging door.

BALANCED DOOR

DOUBLE-ACTING DOOR

Double-acting doors have a leaf that operates in two directions. There is usually no stop present to restrict the motion of the door, but when the door can be stopped, it can be released mechanically to permit access in an emergency.

DOUBLE OR PAIRED DOORS

Double or paired doors have two leaves (of equal or unequal size) that operate either together or independently.

They create a doorway with variable widths suitable for differing occupancy/egress requirements.

NOTE
Swinging doors rotate on hinges or pivots, require adequate floor space to accommodate outswing, and are used for egress openings. See codes for requirements.

SWINGING DOORS

SWINGING DOOR SIZES

DETAIL—EXTERIOR SWINGING DOOR

NOTE
Wood, metal, or glass doors that slide horizontally or vertically on tracks create totally clear openings without the floor space requirements of swinging doors. See codes for egress requirements.

SLIDING DOORS

SPECIAL SWINGING DOORS

DETAIL—SLIDING POCKET

floor space requirements of swinging doors. See codes for egress requirements.

HARDWARE FOR BYPASS DOORS

DETAIL—BYPASS DOOR

Daniel F. C. Hayes, AIA; Washington, D.C.

NOTE
Accordion doors are multipaneled units of relatively narrow wood or fabric that are hinged together. Track-guided hangers/trolleys and optional jamb-side pivots allow the entire assembly to fold together like an accordion. The stacking distance of the panels when open may encroach upon the clear opening dimension or be concealed in a recessed pocket. Sizes vary from traditional doorways to room dividers. Accordion doors require less floor space than swing doors. Refer to codes for egress requirements.

TYPICAL ACCORDION DOOR

NOTE
Bifold doors are wood or metal door pairs hinged together with pivots at the jamb. Track-guided hangers/trolleys allow the doors to fold against each other when they open. Bifold doors require less floor space than swing doors, but the thickness of the door panels reduces the clear opening.

TYPICAL BIFOLD DOOR

TYPICAL FRAMED DOOR

TYPICAL ALL-GLASS DOOR

DOOR WITH REMOVABLE STORM/SCREEN PANEL

COMBINATION STORM/SCREEN DOOR

Daniel F. C. Hayes, AIA; Washington, D.C.

- NOTES**
- Standard commercial doors are designed to wind loads of 20 lb/sq ft.
 - Glazing may be safety glass, plexiglass, or wired glass.
 - Motor operators may be turned on and off by remote electrical switch, radio signal, photoelectrical control, or key lock switch for security.

UPWARD-ACTING SECTIONAL DOORS

NOTE

Typical maximum width for wood panel sectional doors is 24 ft (6 panels); typical maximum height is 18 ft (9 sections).

NOTE

Typical maximum width for flush wood sectional doors is 24 ft (6 panels); typical maximum height is 18 ft (9 sections).

INSTALLATION DETAILS

SECTIONAL DOOR DETAILS

WOOD SECTIONAL DOORS

NOTE

Typical maximum width for aluminum sectional doors is 18 ft (5 panels); typical maximum height is 14 ft (7 sections).

NOTE

Typical maximum width for steel sectional doors is 24 ft (7 panels); typical maximum height is 18 ft (9 sections).

NOTE

Typical maximum width for metal and fiberglass sectional doors is 20 ft (6 panels); typical maximum height is 16 ft (8 sections).

METAL SECTIONAL DOORS

Daniel F. C. Hayes, AIA; Washington, D.C.

OPERATION OF ROLLING DOOR OR SHUTTER IS MANUAL (PUSH-UP) OR MECHANICAL, DRIVEN BY CHAIN, CRANK, OR MOTOR

- NOTES**
1. Motor operators vary from 1/2 HP to 2 HP and may be wall-mounted alongside a curtain hood bracket or bracket-mounted alongside or behind a curtain hood, depending on building conditions. Consult manufacturers for all requirements and clearances.
 2. Rolling fire doors and counter shutters are typically rated up to UL Class A (3-hr rated). Automatic door closure and

hood smoke and flame baffle activation are initiated when fusible link melts or when electromechanical devices are activated by heat detector, smoke detector, or building alarm system.

3. Rolling door jamb guides for fire-rated doors are required to have 3/4 in. clearance below bottom of guide to allow for heat expansion in case of fire.
4. Standard curtain doors are designed to withstand a wind load of 20 lb/sq ft.

STANDARD FLAT

INSULATED NOTES

WOOD (COUNTER SHUTTER ONLY)

1. Solid (curtain) slats are made of roll-formed steel (22 to 16 gauge), either prime-painted galvanized or stainless steel or anodized aluminum.
2. Standard flat (nonperforated) and curved slats may be used in fire-rated applications. Other standard or custom slat designs are available; consult manufacturers.
3. Acrylic vision slats may be inserted within standard slats for light transmission and visibility.
4. Counter shutters are available in standard heights up to 7 ft and widths up to 11 ft.
5. Manual, crank, and motor operators are available for counter shutters.

CURTAIN DOOR AND COUNTER SHUTTER SLAT TYPES

NOTE

Grilles are made either from steel or aluminum rods and links. Custom materials are available from manufacturers.

ROLLING GRILLE DOOR TYPES

NOTE

Electric and pneumatic sensor edge types stop or reverse motor-operated doors if they hit something while closing.

BOTTOM BAR TYPES

WALL OR CEILING ACCESS DOOR CHARACTERISTICS

NOTE
Floor hatches usually open to 90° and may be single or double leaf.

DOOR IN FLOOR

NOTES
1. Hatch cover may be topped with stone, tile, wood, carpet, and the like over a 1/2 in. (minimum) layer of

DETAIL

DETAIL

concrete, providing a flat, vibration-free surface.
2. Frame and hatch are fabricated from aluminum or steel.

FLOOR ACCESS HATCH

Daniel F. C. Hayes, AIA; Washington, D.C.

NOTES

1. Spring-operated, swing-down, and swing-up panels frequently are used for access.
2. Acoustical tile may be fire-rated and recessed in the door.
3. Doors and frames may be galvanized or stainless steel.
4. Other finish ceiling panels are detailed similar to acoustical tiles.

CEILING ACCESS PANELS

FLUSH DOOR

RECESSED DOOR FOR GYPSUM BOARD

FIRE-RATED DOOR

NOTES

1. Doors may be hinged, set in with clips, or fastened with screws. Hinges may be butt or pivot, separate or continuous, surface or concealed.
2. The fire rating of access panels should be similar to the rating of the wall in which they occur. Access panels larger than 144 sq in. require automatic closers.
3. The minimum size for attic and crawl-space often is specified by building code.

WALL ACCESS DOORS

ONE-PIECE GLAZING WITH DEAL TRAY

NOTE
Staggered panels allow sound to pass through them without the use of a microphone system.

ONE-PIECE GLAZING WITH TRANSACTION DRAWER

SECURITY TELLER WINDOWS
GENERAL

Security doors and windows are designed to provide physical and psychological protection for the occupants of the protected space and to notify security personnel of unauthorized entry. Such doors and windows are constructed of hardened materials and hardware and usually include one of the following methods to control passage: card, eye, palm, or thumbprint readers; electronic or other type of locks; and microphone enhanced voice talk-through devices. The level of security required by the owner determines the design and details of these doors and windows.

NOTES

1. Ballistic/forced entry modular units from manufacturers can be combined to form a wall or room.
2. Fire-rated, opaque security doors are available.
3. Ballistic-resistant glazing is manufactured in various thicknesses to attain the required level of resistance (for example, to resist a 9mm, high-powered rifle).
4. To maximize resistance to forced entry, security doors must swing outward (toward the attack side).
5. Custom doors can be fabricated when designed within manufacturers' parameters.
6. Walls must be constructed to meet the same level of resistance as the windows and doors installed in them.

7. Doors and windows must be anchored in strict accordance with the manufacturer's directions to attain standard of resistance.
8. Ballistic/forced entry windows used in exterior building openings are similar to the teller windows detailed on this page.

TYPICAL SECURITY DOOR HARDWARE AND ACCESSORIES

Edwin Daly, AIA; Joseph Handwerger Architects; Washington, D.C.
William G. Miner, AIA; Washington, D.C.
Daniel F. C. Hayes, AIA; Washington, D.C.

BACKGROUND

A successful storefront or retail entrance attracts the casual passerby. In order to attract, a shopfront must:

1. Catch the eye
2. Identify the shop
3. Display the merchandise in the most appealing way
4. Entice the passerby to enter

SHOP CHARACTER

The character of a retail entrance is influenced by the following factors:

1. Neighborhood or retail development character
2. Types of products sold
3. Accessibility—on foot or by car
4. Glazed area in relation to product
5. Fascia—visibility of shop name
6. Lettering—size, color, style, use of logos
7. Illumination—intensity, color, or use of daylight
8. Color—select predominant, coordinate with interior
9. Finishes—cost, design guidelines, and durability

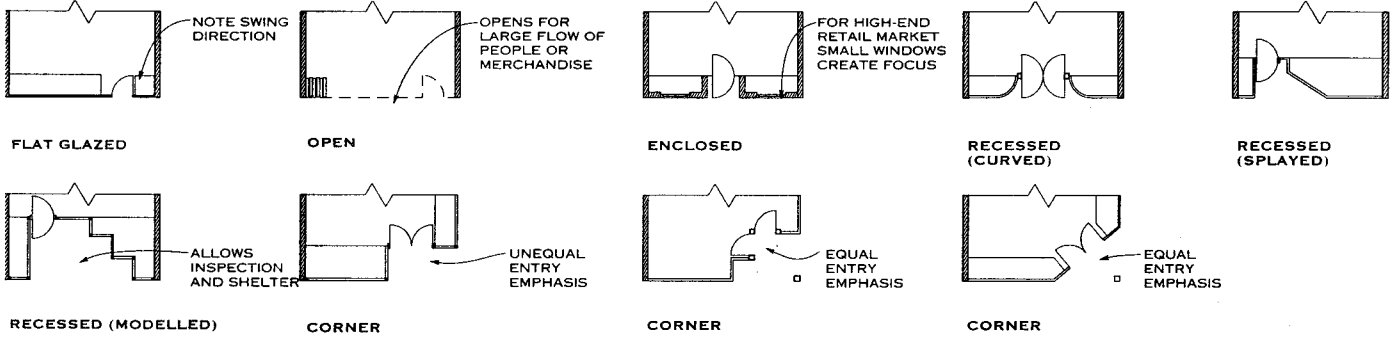

ENVIRONMENTAL FACTORS

The external features of a shop are influenced by the following factors:

1. Solar—shade southern exposures
2. Wind—provide protection with deep lobbies
3. Corrosive—provide protective finishes
4. Street traffic—lobbies or air locks to keep out fumes

STOREFRONT INTERIOR AND EXTERIOR—COMMON ELEMENTS

STOREFRONT TYPES

ALL-GLASS STOREFRONT

REFER TO TABLE BELOW

WINDOW DIMENSIONS

TYPICAL WINDOW DIMENSIONS

VIEW POINT	TYPE OF SHOP	A WINDOW DEPTH	B WINDOW HEIGHT	C SILL HEIGHT
Very close	Jewelry, eyeglass, picture, and books	18" to 36"	up to 36"	30" to 36"
Close	Toys, shoes, electronic, optical, CD's, and gifts	30" to 60"	up to 80"	18" to 30"
Medium	Clothing, china, glass sporting goods, and appliances	40" to 96"	up to 96"	12" to 18"
Distant	Furniture, floor covering, and automobiles	80" to 120"	Ceiling height	0" to 6"

WALL SECTION AT STOREFRONT

TYPICAL STOREFRONT

NOTE
 The head, intermediate horizontal profile, and sill members are screwed to vertical members at predrilled locations.

SNAP-TOGETHER/SCREW SPLINE STOREFRONT ASSEMBLY

GENERAL

Glass and metal frame storefront systems typically are designed to allow good views into and out of ground level commercial spaces. Metal members and glass sections are assembled on site to form both wall and entrance systems, which typically are attached to the floor structure below and ceiling structure above.

NOTES

1. Storefront systems are available in a variety of attachment/assembly types, depending on the structural or aesthetic design and on the manufacturer. Glass and metal materials come in various shapes, colors, profiles, and structural capabilities.

SHEAR BLOCK STOREFRONT ASSEMBLY

2. Consult applicable codes for safety requirements, glass size, thickness, and tempering. ADAAG requires accessible hardware, thresholds, and, in some cases, automatic door openers.
3. Consult manufacturers' data on structural adequacy for required loads and for frame and transom bar reinforcement. Calculations for deflection and wind-load stresses must be considered in the design of storefront systems. Reinforcing for required loads can be provided by steel reinforcing inserts or by use of a heavier metal mullion profile. Consult a structural engineer for analysis and design.
4. The height of entrance doors is typically 7 ft 0 in. Typical door widths are 3 ft 0 in., 3 ft 6 in., pair of 2 ft 6 in., pair of 3 ft 0 in.

Daniel F. C. Hayes, AIA; Washington, D.C.

TYPES AND APPLICATIONS

1. Darkroom revolving doors act as a light barrier.
2. Automated revolving doors for large size doors, for persons with disabilities accessibility, etc.
3. Motorized oval doors for small groups, wheelchairs, or grocery carts.
4. Security revolving doors that are noncollapsible until a magnetic shear lock is automatically released in an emergency.
5. Sliding night door of solid metal construction to close off open quadrant at exterior opening.
6. Manually operated.

DESIGN CONSIDERATIONS

1. Mount entirely on one slab.
2. Do not attach to adjacent walls.
3. Floor must be level.

NOTES

1. Circular glass enclosure walls may be annealed 1/4 in. glass. However, this varies with different government bodies. Some jurisdictions require laminated glass. Tempered glass is not available for this use. Refer to the Consumer Products Safety Commission's standards for glazing.
2. Practical capacity equals 25 to 35 people per minute.
3. Doors fabricated from stainless steel, aluminum, or bronze sections are available. Stainless steel is the most durable; lead times vary with construction techniques. Stainless steel is available in a number of satin and polished finishes. Aluminum is the most common and economical. It is available in anodized or painted finishes. Bronze is most difficult to maintain; satin, polished, or statuary finishes must have a protective lacquer coating. Doors are available with only top and bottom stiles to be used with all-glass storefront doors. Wall enclosures may be all metal, all glass, partial glass, or housed-in construction.
4. Optional heating and cooling source should be placed immediately adjacent to the enclosure.
5. For general planning, use 6 ft 6 in. diameter. For hotels, department stores, airports, or other large traffic areas, use 7 ft or greater diameter.
6. Codes may allow 50% of legal exiting requirements by means of revolving doors. Some do not credit any and require hinged doors adjacent. Verify with local authorities.

REVOLVING DOOR ENCLOSURE DIMENSIONS

LAYOUT TYPES

Jane Hansen, AIA; DeStefano + Partners, Chicago, Illinois

BYPASS DOOR DETAILS

NOTES

1. Sliding glass door wood finishes are available in clear pine with natural varnish, primed, or painted finishes.
2. Cladding for wood doors is available in vinyl or aluminum with electrostatic paint or in anodized aluminum.
3. Aluminum frames are available anodized or with electrostatic paint finishes.
3. Check with manufacturer's literature for material, cladding, and color options.

GLAZING OPTIONS

Standard glazing	Low emissivity insulating glass
	Low emissivity solar insulating glass
Safety glazing	Tempered glass ¹
	Wire glass ¹
	Laminated glass ¹
Nontransparent glass	Obscure glass ¹
	Composite veneer porcelain faced panels
	Glass fiber reinforced plastic
	Spandrel panel
Sound control glazing	Insulated glass

NOTES

1. This glazing can have the same low emissivity coating found on the standard glazings.
2. Most glazing options available with insulating glass with low emissivity films, some also with argon gas.
3. To reduce breakage and avoid injury it is recommended that tempered or safety glass be used.
4. Glazing options vary; check manufacturer's literature for specifics.

Joseph A. Wilkes, FAIA; Annapolis, Maryland

POCKET DOOR DETAILS

PERFORMANCE DATA FOR GLAZING OPTIONS

	ENERGY EFFICIENCY			HEAT GAIN (BTU) ¹	INSIDE GLASS SURFACE TEMPERATURES ²	SHADING COEFFICIENTS ³
	U - VALUE	R - VALUE	CENTER OF GLASS U - VALUE			
Single pane aluminum frame without thermal breaks	1.31	0.76	1.11	216	17°F	1.00
Ordinary double-pane	0.48	2.10	0.55	190	43°F	0.91
Low emissivity insulating glass	0.30	3.30	0.27	150	56°F	0.73
Low emissivity solar insulating glass	0.30	3.30	0.27	76	56°F	0.36

NOTES

1. Relative heat gain Btu/sq ft/hr: When ASHRAE solar heat gain factor is 200 Btu/hr - sq ft and the outdoor air temperature is 14° warmer than the indoor temperature.
2. Inside glass surface temperatures assume the following: outside temperature, 0°F; inside room temperature, 70°F; outside wind velocity, 15 mph; no air movement inside; and uniform heating conditions.
3. The shading coefficients listed above may vary a few percentage points.
4. R and U values based on Lawrence Berkeley method.

ULTRAVIOLET REDUCTION RATES

Double-pane clear	34%
Low emissivity insulating glass	66%
Low emissivity solar insulating glass	84%

NOTE

Low emissivity insulating glass and low emissivity solar windows help reduce ultraviolet rays.

MULTIPLE SLIDING DOOR DETAILS

RELATIVE HEAT GAIN

	HEAT GAIN
Clear	214
Single-pane 3/32 or 1/8 in.	208
Single-pane 3/16 in.	186
Double-pane insulating	152
Double-pane high-performance insulating	
Tinted grey/bronze	165
Single-pane grey 3/16 in.	168
Single-pane bronze 3/16 in.	78
Double-pane high-performance sun insulating	
Medium performance reflective	
Single-pane bronze	106

NOTE

Relative heat gain BTU/sq ft/hr: When ASHRAE solar heat gain factor is 200 BTU/hr - sq ft and the outdoor air temperature is 14° warmer than the indoor temperature.

DEFINITIONS

ABSORPTANCE: the ratio of radiant energy absorbed by a glazing system to the total incident radiant energy in it.

AIR LEAKAGE RATING: a measure of the rate of infiltration around a window or skylight in the presence of a specific air pressure difference. It is expressed in units of cubic feet per minute per square foot of window area (cfm/sq ft) or cubic feet per minute per foot of window perimeter length (cfm/ft). The lower the air leakage rating of a window, the more airtight it is.

COMPOSITE FRAME: a frame made of two or more materials—for example, a frame that is wood on the interior and fiberglass on the exterior.

DOUBLE GLAZING: in general, two thicknesses of glass separated by an air space within an opening intended to improve insulation against heat transfer and/or sound transmission. In factory-made double-glazed units, the air between the glass sheets is thoroughly dried and the space is sealed airtight, eliminating possible condensation and providing superior insulating properties.

EMITTANCE: the ratio of the radiant energy emitted by a surface to that emitted by a blackbody at the same temperature and under the same conditions.

GAS FILL: a gas other than air, usually argon or krypton, placed between window or skylight panes to suppress conduction and convection and thus reduce the U-factor.

LIGHT-TO-SOLAR-GAIN RATIO (LSG): a measure of the ability of glazing to provide light without excessive solar heat gain. It is the ratio between the visible transmittance of a glazing material and its solar heat gain coefficient.

LOW-CONDUCTANCE SPACERS: an assembly of materials designed to reduce heat transfer at the edge of an insulating window. Spacers are placed between the panes of glass in a double- or triple-glazed window.

LOW-EMITTANCE (LOW-E) COATING: microscopically thin, virtually invisible metal or metallic oxide layers deposited on a window or skylight glazing surface primarily intended to reduce the U-factor by suppressing radiative heat flow. A typical type of low-E coating is transparent to the solar spectrum (visible light and short-wave infrared radiation) but reflects long-wave infrared radiation.

REFLECTANCE: the ratio of reflected radiant energy to incident radiant energy.

R-VALUE: a measure of the resistance of a glazing material or fenestration assembly to heat flow. It is the inverse of the U-factor ($R = 1/U$) and is expressed in units of hr x sq ft x °F/Btu. A high-R-value window has a greater resistance to heat flow and a higher insulating value than one with a low R-value.

SHADING COEFFICIENT (SC): a measure of the ability of a window or skylight to transmit solar heat relative to that ability for 1/8-in., clear, double-strength, single glass. This measure is being phased out in favor of the solar heat gain coefficient. The SC is approximately equal to the SHGC multiplied by 1.15 and is expressed as a number without units between 0 and 1. The lower a window's solar heat gain coefficient or shading coefficient, the less solar heat it transmits and the greater shading ability it has.

SOLAR HEAT GAIN COEFFICIENT (SHGC): the fraction of incident solar radiation admitted through a window or skylight, including both directly transmitted radiation and that absorbed and subsequently released inward. The SHGC has replaced the shading coefficient as the standard indicator of a window's shading ability. It is expressed as a number between 0 and 1. The lower a window's solar heat gain coefficient, the less solar heat it transmits and the greater its shading ability. The SHGC can be expressed in terms of the glass alone or can refer to the entire window assembly.

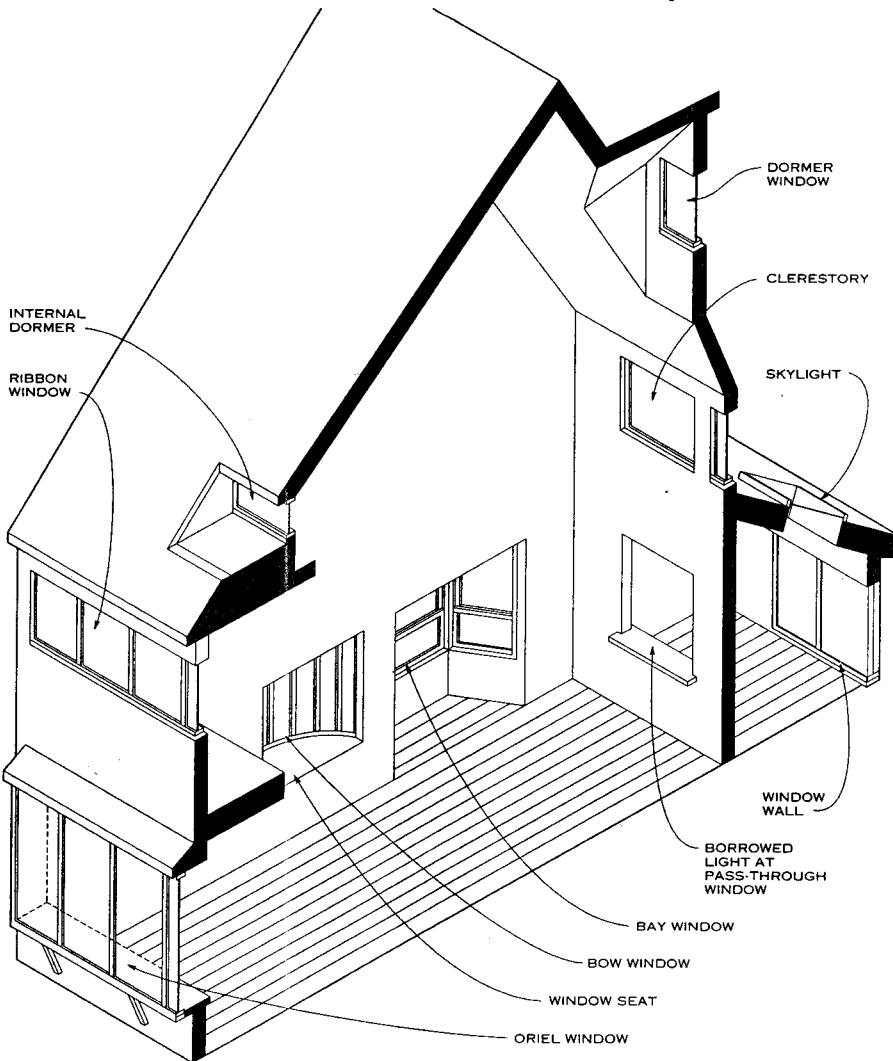

SPECTRALLY SELECTIVE GLAZING: a coated or tinted glazing with optical properties that are transparent to some wavelengths of energy and reflective to others. Typical spectrally selective coatings are transparent to visible light and reflect short-wave and long-wave infrared radiation. Usually the term spectrally selective is applied to glazings that reduce heat gain while providing substantial daylight.

SUPERWINDOW: a window with a very low U-factor, typically less than 0.15, achieved through the use of multiple glazings, low-E coatings, and gas fills.

TRANSMITTANCE: the percentage of radiation that can pass through glazing. It can be defined for different types of light or energy, e.g., visible light transmittance, solar transmittance, or total solar energy transmittance.

U-FACTOR (U-VALUE): a measure of the rate of nonsolar heat loss or gain through a material or assembly. It is expressed in units of Btu/hr x sq ft x °F (W/sq m x °C). Values are normally given for NFRC/ASHRAE winter conditions of 0°F (18°C) outdoor temperature, 70°F (21°C) indoor temperature, 15 mph wind, and no solar load. The U-factor may be expressed for the glass alone or the entire window, which includes the effect of the frame and the spacer materials. The lower the U-factor, the greater a window's resistance to heat flow and the better its insulating value.

VISIBLE TRANSMITTANCE (VT): the percentage or fraction of the visible spectrum (380 to 720 nanometers) weighted by the sensitivity of the eye that is transmitted through the glazing.

NOTES

1. BORROWED LIGHT: an interior wall opening or window that allows light to be transferred into another space.
2. CLERESTORY: the portion of a wall above an adjacent roof level; a fixed or operable window located in this part of a wall.

3. INTERNAL DORMER: a vertical window set below the line of a sloped roof.
4. ORIEL WINDOW: a bay window supported by brackets, corbeling, or cantilevers.
5. WINDOW WALL: a continuous series of fixed or operable sash, separated by mullions, that form an entire non-load-bearing wall surface.

WINDOW CONFIGURATIONS

John Carmody, University of Minnesota; Minneapolis, Minnesota
Stephen Selkowitz, Lawrence Berkeley National Laboratory; Berkeley, California

WINDOWS

NOTES

1. MULLION: a slender vertical member separating lights, sashes, windows, or doors.
2. MUNTIN: nonstructural members separating panes within a sash; also called a glazing bar or sash bar.
3. SASH: the basic unit of a window, consisting of frame, glazing, and gasketing; may be stationary or operable.

PARTS OF A WINDOW

WINDOW SELECTION

Architects choose fenestration products based on many unique priorities and circumstances. Nonetheless, a number of common considerations apply to most situations. Factors affecting window choice are

APPEARANCE: size and shape, operating type and style, frame materials, glass color and clarity.

FUNCTION: visible light transmittance (provision of daylight), glare control, reduction in fading from ultraviolet radiation, thermal comfort, resistance to condensation, ventilation, sound control, maintenance, and durability.

ENERGY PERFORMANCE: U-value; solar heat gain coefficient (SHGC), which is replacing the shading coefficient; air leakage; annual heating and cooling season performance; and peak load impacts.

COST: initial cost of window units and installation, maintenance and replacement costs, effect on heating and cooling plant costs, and cost of annual heating and cooling energy.

Many designers and homeowners find it difficult to assess the impacts of choosing a more energy-efficient window. Although some basic thermal and optical properties (U-factor, solar heat gain coefficient, and air leakage rate) can be identified if a window is properly labeled (see AGS page that discusses NFRC labels), this information does not tell how these properties influence annual energy use for heating and cooling. This must be determined by using an annual energy rating system or by computer simulation.

MANUFACTURED WINDOW UNITS

The manufactured window units discussed here have a self-contained frame and glazing assembly that can be installed in a wall or roof opening. Used in almost all residential and some nonresidential buildings, manufactured window units are fabricated with a variety of glazing, frame, and operating types.

Technical innovations in glazing and frame design have improved window performance considerably in recent years, and determining window performance regarding heat loss, heat gain, and daylight can be complex. Key window performance characteristics are the U-value, which indicates the rate of heat loss and gain; the solar heat gain coefficient (SHGC), which indicates the rate of heat gain; the air leakage rate; and visible transmittance, which indicates the amount of daylight that passes through the window. The SHGC is gradually replacing the shading coefficient (SC) as an index for measuring heat gain through windows.

When selecting windows, it is important to remember that these characteristics are sometimes given for the glazing alone and sometimes for the whole window unit. To reduce confusion, the National Fenestration Rating Council (NFRC) certifies and labels the performance of manufactured window and skylight units based on whole window values.

WARM EDGE SPACER

CONVENTIONAL SPACER

NOTE

The layers of glazing in an insulating unit must be held apart with spacers. Conventional metal spacers reduce the thermal performance of the glazing unit, but new "warm edge" spacers reduce heat loss and condensation with the use of new designs and materials. The spacer must accommodate stress induced by thermal expansion and pressure differences, provide a moisture barrier that prevents fog in the unit, prevent loss of any low-conductance gas from the air space, and create an insulating barrier that reduces the formation of interior condensation at the edge.

INSULATED GLASS EDGE SPACER

Stephen Selkowitz, Lawrence Berkeley National Laboratories; Berkeley, California

TECHNOLOGICAL IMPROVEMENTS

A series of innovations has resulted in more energy gain and loss control in the window assembly or glass itself. Some technological innovations currently appearing in fenestration products are outlined here:

1. Glazing unit structure: Multiple layers of glass or plastic film improve thermal resistance and reduce heat loss attributed to convection between window layers. Additional layers provide more surfaces for low-E or solar control coatings.
2. Low-emittance coatings: Low-E coatings are highly transparent and virtually invisible but have a high rate of reflectance (low emittance) with long-wavelength infrared radiation. This reduces long-wavelength heat transfer between glazing layers by a factor of 5 to 10, which reduces total heat transfer between the layers. Low-E coatings may be applied directly to glass surfaces or to plastic film, which is then suspended in the air cavity between the interior and exterior glazing layers.
3. Low-conductance gas fills: When a low-E coating is used, heat transfer across a gap is dominated by conduction and natural convection. While air is a relatively good insulator, other gases (such as argon, krypton, and carbon dioxide) have lower thermal conductivities. Using one of these nontoxic gases in an insulating glass unit can reduce heat transfer between glazing layers.
4. Solar control glazings and coatings: To reduce cooling loads, specify new types of tinted glass and new coatings that reduce the effect of the sun's heat without sacrificing views. Spectrally selective glazings and coatings absorb and reflect the infrared portion of sunlight while transmitting visible daylight, thus reducing solar heat gain coefficients and resultant cooling loads. Solar control coatings can also have low-emittance characteristics.
5. Warm edge spacers: Heat transfer through metal spacers used to separate glazing layers can increase heat loss and cause condensation to form at the edge of the window. "Warm edge" spacers use new materials and better design to reduce this effect.
6. Thermally improved sash and frame: Traditional sash and frame designs contribute to heat loss and can represent a large fraction of the total loss when high-performance glass is used. New materials and improved designs can reduce this loss.
7. Improved weatherstripping: Weatherstripping today is made of more durable materials that will provide improved reduction in air leakage over a longer time period than did materials in the past.

NOTES

1. Triple-glazed windows with two low-E coatings and argon gas fill.
2. Double-glazed windows with a low-E coating and argon gas fill.
3. Double-glazed windows with a low-E coating.
4. Double-glazed windows.
5. Single-glazed windows.

CONDITIONS THAT LEAD TO CONDENSATION ON WINDOWS

CONDENSATION POTENTIAL

The chart above shows the potential for condensation on glazing (at the center of glass) at various outdoor temperature and indoor relative humidity conditions. Condensation can occur at any point on or above the curves. (Note: All air spaces are 1/2 in.; all coatings are E = 0.10.)

EXAMPLE: At 20°F (-7°C) outside, condensation will form on the inner surface of double glazing when the indoor relative humidity is 52 percent or higher. It will form at an indoor relative humidity of 70 percent or higher if a double-pane window with a low-E coating and argon fill is used.

GENERAL

The National Fenestration Rating Council (NFRC) has developed a fenestration energy rating system based on whole product performance. The system accurately accounts for the energy-related effects of all of a product's component parts and prevents misleading comparisons of information about a single component with whole product properties. At this time, NFRC labels on window units give ratings for U-value, solar heat gain coefficient, and visible light transmittance. Soon labels will include air infiltration rates and an annual fenestration heating and cooling rating. The initial development of the NFRC rating system has focused on window units manufactured mainly for residential applications. In the future, the NFRC will adapt the rating system to commercial glazing and curtain wall systems.

Manufacturers of modern fenestration products want to take credit for the technological advances and increasing complexity of their products but these are not easily visually verified. Thus, in 1989, the NFRC was established to develop a fair, accurate, and credible rating system for these products. State energy codes began to incorporate NFRC procedures in 1992, and the National Energy Policy Act provided for the development of a national rating system. The U.S. Department of Energy has certified the NFRC procedures as the national rating system, and they are now referenced in and being incorporated into the Model Energy Code and ASHRAE Standards 90.1 and 90.2.

NOTE
The total window U-factor takes into account the glass (edge of glass and center of glass) and the frame in a vertical position. Changing the mounting angle can affect the U-factor of a window.

ZONES FOR DETERMINING HEAT LOSS IN WINDOW ASSEMBLY

NOTE

The energy performance of a window unit with muntins on both sides can be comparable to that of a unit with no

muntins if the grid set between the lights is at least 1/8 in. away from both panes of glass.

Visible light transmittance	0.71	0.71	
Air leakage	0.20	0.20	

NFRC ratings are determined for a fixed set of environmental conditions and specific product sizes and may not be appropriate for directly determining seasonal energy performance.

NOTES

1. Ratings of the basic thermal and optical properties of all fenestration products (windows, doors, skylights) must include the effects of the glass, the sash, and the frame and be in accordance with the appropriate National Fenestration Rating Council (NFRC) standard. Products must be labeled with ratings for these properties, and the manufacturer must certify they are in accordance with the NFRC Product Certification Program.
2. The NFRC standards for the basic thermal and optical properties of fenestration products are as follows: NFRC 100 for the U-factor, NFRC 200 for the solar heat gain coefficient (SHGC), NFRC 300 for visible light transmittance, and NFRC 400 for air leakage.

NFRC WINDOW PRODUCT IDENTIFICATION MARK

PROPERTIES OF GLAZING MATERIALS USED IN MANUFACTURED WINDOW UNITS

Three things happen to solar radiation as it passes through a glazing material: some is transmitted, some is reflected, and the rest is absorbed. These three components determine many of the other energy-performance properties of a glazing material. Manipulating the proportion of transmittance, reflectance, and absorptance for different wavelengths of solar radiation has been the source of much recent innovation in window energy performance. The four basic properties of glazing that affect radiant energy transfer are transmittance, reflectance, absorptance, and emittance.

Before the recent innovations in the technology of glass, the primary property of glass was its ability to transmit visible light, and its quality was judged by how clear it was. However, as attention focused on improving the total energy performance of glass, it became clear that transparency to visible light is only part of the picture.

Visible light is a small portion of the electromagnetic spectrum. Beyond the blues and purples lie ultraviolet radiation and other higher energy short wavelengths, from X rays to

gamma rays. Beyond red light are the near-infrared, given off by very hot objects, the far-infrared, given off by warm room-temperature objects, and the longer microwaves and radio waves.

Glazing types vary in their transparency to different parts of the spectrum. On the simplest level, a glass that appears to be tinted green as you look through it toward the outside will transmit more sunlight from the green portion of the visible spectrum and reflect/absorb more of the other colors. Similarly, bronze-tinted glass will absorb the blues and greens and transmit the warmer colors. Neutral gray tints absorb most colors equally.

This same principle applies outside the visible spectrum. Most glass is partially transparent to at least some ultraviolet radiation, while plastics are commonly more opaque to ultraviolet. Glass is opaque to far-infrared radiation but generally transparent to near-infrared.

With the recent advances in glazing technology, manufacturers can control how glazing materials behave in different areas of the spectrum. The basic properties of the substrate material (glass or plastic) can be altered, and coatings can be added to the surfaces of the substrates. For example, a window optimized for daylighting and for reducing

solar heat gain should transmit adequate light in the visible portion of the spectrum but exclude unnecessary heat gain from the near-infrared part of the solar spectrum. On the other hand, a window optimized for collecting solar heat gain in winter should transmit the maximum amount of visible light as well as heat from the near-infrared wavelengths in the solar spectrum, while blocking the lower energy radiant heat in the far-infrared range (an important heat-loss component). These are the strategies of spectrally selective and low-emittance coatings, respectively.

PERFORMANCE OF COMMON GLAZING TYPES

The figures on this page illustrate the solar heat gain and visible light transmittance for common glazing types used in manufactured windows. The figures are for the center of the glass only; the characteristics of the frame must be included to obtain performance information on the whole window unit. The darker arrows indicate the total transmitted and total rejected solar energy. The lighter arrows indicate the amount of transmitted and reflected daylight. Daylight that is neither transmitted nor reflected is absorbed. Not all low-E coatings are the same; use NFRC rated and labeled values.

OUTWARD- AND INWARD-SWINGING WINDOW TYPES

DEFINITIONS

AWNING WINDOW: a unit (or series of mechanically inter-connected units) that swings outward from top-mounted pivots or hinges.

HOPPER WINDOW: a unit (or series of mechanically inter-connected units) that usually swing inward from bottom-mounted pivots or hinges; they may have side-mounted triangular draft barriers.

PROJECTED WINDOW: a window, which operates similarly to awning or hopper windows, in which the hinge or pivot side of the sash frame slides along a track toward the latch side as the window is opened.

DEFINITIONS

CASEMENT WINDOW: a window unit or pair that operates like a door, either on hinges or pivots attached to the jamb or by sliding along tracks at the head and sill.

CREMO(R)INE BOLT: an exposed or concealed fastening mechanism composed of sill and head bolts and strikes connected by rods to a centrally mounted turn-knob device.

FRENCH WINDOW: a pair of tall casements that may serve as a door onto a balcony, porch, or terrace.

LEVER OPERATOR: a gearless mechanism in which a rod sliding through a clasp positions and secures the sash.

OPERATING HARDWARE: hardware used to work a window, including stays, lever operators, roto-operators, and cremo(r)ine bolts.

PIVOT WINDOW: a unit with sash that rotate either vertically or horizontally around center-mounted pivots.

ROTO-OPERATOR: a geared crank-and-worm drive mechanism that positions and secures the sash.

STAY: a bar that holds the sash open in various positions.

TYPICAL CASEMENT WINDOW

FASTENER TYPES

NOTES

1. Window sizes and dimensioning methods are not uniform for all manufacturers. Some manufacturers have no stock sizes, producing only custom work. Check with local suppliers for details.
2. In general, heavier grades of windows offer greater configuration flexibility. Larger operating sash can be produced with heavier members, allowing fixed lights shown for taller steel sash to be avoided, if desired.
3. Insect screens are necessarily installed on the interior and must be taken into account when selecting hardware.
4. The raindrip indicated on the horizontal mullion may be required at ventilating heads if sash are placed flush with the exterior face of the wall.
5. Drawings or specifications must contain the following information: window size and location; installation details for sills, stools, flashing, sealing, and anchors; sash material and finish; glazing material; glazing method (tape, putty, or bead, inside or outside); weatherstripping, insect screen material, and hardware.

VERTICAL SLIDING (DOUBLE-HUNG) WINDOWS

HORIZONTAL SLIDING WINDOWS

DEFINITIONS

DOUBLE-HUNG WINDOW: multiple operating sash in one unit (also comes as triple-hung).

HOSPITAL SILL: a raised stool that allows the meeting rails to be separated for ventilation while the head and sill rails remain sealed to weather penetration.

HORIZONTAL SLIDING WINDOW: a unit having at least two sash, one or more of which slides along horizontal tracks at the top and bottom of the frame.

POCKET COVER: a part of the jamb casing that can be removed to reach the weights or balances for maintenance.

SASH CORD: a rope or chain that connects the sash weight to the sash.

SASH RIBBON: a metal strip that connects the sash with either weights or spring balances.

SASH WEIGHT: a cast-iron or lead cylindrical counterweight.

SINGLE-HUNG WINDOW: a pair of sash, only one of which operates (by vertically sliding).

SPRING BALANCE: a spring-loaded mechanism used in place of a counterweight.

VERTICAL SLIDING WINDOW: a unit with sash that slide vertically in jamb-mounted tracks. Weights, springs, or friction-resistant jambs counterbalancing gravity or mechanical catches embedded in the jamb hold the sash open. The single, double, or triple-operating sash of these windows may stack against each other or, when full ventilation is required, be recessed in pockets above or below the window.

Daniel F. C. Hayes, AIA; Washington, D.C.

GENERAL

An oriel window is a window projecting from the wall face of the upper story of a building and supported on brackets, corbelling, or cantilevered. Oriel windows were often used in late Gothic and Tudor residential architecture.

VERTICAL SECTION

ORIEL WINDOW

GENERAL

A dormer is a vertical window projecting from the sloping roof of a building and having vertical sides or cheeks and a gabled or shed roof.

GENERAL

Roof openings such as skylights, scuttles, and vents must be detailed with care, considering they will be exposed to the same external factors as the roof assembly itself. These factors include wind pressure—both positive and negative—which acts on the framing and/or glazing; rainwater penetration; live loads from snow and ice; dynamic loads from impact; daily cycles of thermal expansion and contraction; drainage of water and melting snow; and abuse from maintenance personnel. In addition, measures must be specified to keep people from falling through these openings.

NOTE
In determining the desired form and size of the skylight unit/assembly, consideration should be given to

1. Environmental conditions, including orientation and winter and summer solar penetration angles at the site
2. Prevailing wind direction and patterns
3. Precipitation quantity and patterns
4. Adjacent topography and landscaping (shade trees, etc.)
5. Coordination with HVAC system
6. Use of shading, screening, or light reflecting/bouncing devices
7. Views desired relative to view obstructions, streetlights, etc.

SKYLIGHTS

SINGLE LEAF

DOUBLE LEAF

SCUTTLES

SCUTTLES

Scuttles, often referred to as roof hatches, provide roof access for maintenance personnel using ladders, a built-in ship's ladder, or stairs; an emergency escape route in the event of a fire; and access for moving large equipment into or out of the building, possibly eliminating the need for extra-large doors in rooms and corridors below.

Scuttles come as preassembled units, often with integral curbs, and are usually made with spring-assisted openings. When glazing is introduced, scuttles can function as skylights as well. For use as smoke/fire vents, scuttles must have automatic opening capability.

If scuttles are to serve as a required means of egress, consult building codes for number, size, and location required; type of access permitted (ship's ladder, stair, etc.); and type of operation permitted (manual force required to open unit or powered opening).

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

SKYLIGHTS

Skylights provide daylight to interior spaces and can reduce dependence on electrical lighting. In passive solar designs, skylights are used to admit direct solar radiation, enhancing space heating, and, when vented properly, to induce convective airflow, reducing cooling loads through natural ventilation.

Skylights are available as preassembled units, which are shipped to the site ready to be installed, or as framed assemblies of stock components, which arrive prefabricated for site assembly. Both fixed and hinged skylights are manufactured. The hinged variety can be opened manually or by remote control devices for venting. Frames are typically mounted on a built-up prefabricated or site-built curb, with integral counterflashing; they can be assembled with or without insulation.

Self-flashing skylight units are available with or without curbs. Those without curbs are intended only for pitched roof assemblies and are not recommended for roof assemblies with finished spaces below.

Framed skylight assemblies are custom designed by manufacturers to meet the necessary wind, roof, and dead loads of the assembly itself. When a skylight is pitched beyond a certain angle, it must be designed to resist environmental factors as does a curtain wall assembly. Roof drainage for rain- and storm water can limit skylight dimensions. Condensate gutters are needed in the body of the skylight assembly and around its perimeter.

FRAMING, GLAZING, AND GASKETS

The heart of a well-designed skylight unit or skylight framed assembly is the detailing of frames, glazing, and sealant systems. Thickness, size, and geometric profile of all glass and acrylic glazing materials should be carefully selected for compliance with building codes and manufacturers' recommendations. The following glazing materials are considered resistant to impact and breakage and are generally approved by codes (listed in descending order of cost):

1. Formed acrylic with mar-resistant finish
2. Formed acrylic
3. Polycarbonates
4. Flat acrylic
5. Laminated glass
6. Tempered glass
7. Clear polished wire glass
8. Textured obscure wire glass

Framed skylights require somewhat greater mullion widths when glazed with acrylics in order to accommodate the expansion and contraction characteristics of plastics. When glazed with glass, framed skylight mullions are spaced according to the standard glass widths: laminated glass (48 in., maximum), wire glass (60 in., maximum), and tempered glass (72 in., maximum). High-performance insulating glass is generally used in preassembled units (and sometimes framed assemblies) and provides important energy savings.

For economy, tinted acrylics should be limited to 1/4 in. thickness. A combination fiberglass sheet and aluminum frame system with high insulating value and good light diffusion can be a cost-effective alternative. Domed acrylic glazing is almost self-cleaning, as the sloped shapes facilitate rain washing of the surface.

Frame systems must be engineered to carry the total resultant forces of the loads imposed on the skylight in accordance with all building codes. Framing, glazing, and gaskets also must be able to resist exposure to airborne pollutants. Frames with thermal breaks incorporated have better energy performance.

Finishes for aluminum frame components are available as mill finish, clear anodized, duranodic bronze or black, acrylic enamel, and fluorocarbon.

Gaskets are especially subject to degradation from solar ultraviolet rays. Excessive expansion and contraction of acrylic glazing can cause "rolling" of the gasket between metal framing. Small valleys created at the bottom of the sloped glazing and the horizontal glazing cap will hold water, which increases the chance of gasket breakdown and subsequent water infiltration.

SECURITY AND SAFETY

Frames or screens to protect glazing from impact, fire brands, or forced entry can be designed into the skylight system. To avoid forced entry, a framed skylight should include deterrents to disassembling the framing, removing the snap-on cover, and melting the glazing (acrylics can easily be burned with a torch). Metal security screens may be required.

FIRE AND SMOKE VENTS

FIRE AND SMOKE VENTING

In certain building types and occupancies, such as those with large expanses of unobstructed space, fire and smoke vents that open automatically with a fire-induced temperature increase are required. Roof vents are often required over stairs, elevator hoistways, high-hazard occupancy areas (to offer explosion relief), and in areas behind the proscenium in theaters. The vents permit smoke, heat, and volatile gases to escape, lower the temperature at floor level, and reduce water damage by limiting active sprinkler heads to those in the immediate area of the fire.

There are two basic types of fire and smoke vents, both commonly available with integral curbs and flashing:

1. Meltdown: plastic glazing that softens and drops out of the frame when exposed to high temperatures (unit must be replaced once exposed to fire).
2. Automatic opening: solid or glazed cover with springs held by a fusible link that melts when the temperature rises, releasing the springs and opening the vent.

Enough vents must be distributed over the entire roof area to ensure early venting of a fire, regardless of its location. The size and spacing of the vents must be determined for each building according to its size and use and the degree of hazard involved. When UL- or FM-listed vents are required, choice of size is generally limited to stock sizes. Venting is based on moving a specific number of cubic feet of air per minute through the vents. Consult building codes for required capacity, size, and spacing.

PERCENTAGE OF ROOF AREA REQUIRED FOR SKYLIGHTING

LIGHT ZONE	LIGHT DESIGN LEVELS (FC)		
	30	60	120
1	3.3	5.2	13.3
2	2.8	4.3	10.8
3	1.8	3.2	6.9
4	1.5	2.8	4.0

Typical roof vent area requirements are 0.67% roof area for low heat release occupancies, 1% roof area for moderate heat release occupancies, and 2% roof area for high heat release occupancies.

Generally, several small units satisfy the total venting area requirement better than a few larger ones (NFPA #204). Roof scuttles are available that may also serve as fire and smoke vents. Consider the spacing of vents relative to interior spaces and their uses, proximity to exits, and, if glazed, their role in daylighting.

Explosion relief vents are a type of fire and smoke vent that opens automatically when interior pressure rises above a predetermined level. Plastic glazed units deform under higher than normal air pressure and are released from their frame.

NOTE
Glazing may be clear, tinted transparent, or white translucent.

DOMe UNIT SKYLIGHT—FLAT ROOF

NOTE
1. Clear and tinted transparent glass, typical; tempered, laminated, and wire glass available.
2. Manual and powered vent operation, venetian blinds, shades, and exterior awnings available. Consult manufacturer.

FLAT PANEL UNIT SKYLIGHT—SLOPED ROOF

PYRAMID FRAMED SKYLIGHT ASSEMBLY

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

INSULATED CURB

WOOD CURB

UNIT SKYLIGHT SECTION

FLAT PANEL UNIT SKYLIGHT SECTION

CURB DETAIL AT SLOPED FRAMED ASSEMBLY

VERTICAL FRAME CURB DETAIL (WOOD FRAME)

SINGLE-PITCH BACK WALL DETAIL AT TOP (MASONRY WALL)

SINGLE-PITCH RAFTER AND SIDE WALL DETAIL (CONCRETE WALL)

SLOPES VARY FROM 10° TO 60°. OPTIMUM SLOPE, 30° (7:12 APPROXIMATELY) TO MINIMIZE THRUST LOADING

NOTE

Options for a pitched skylight include (1) integration of skylight with roof structure at ridge, slope of skylight to match

slope of roof, no end glazing; (2) hip end glazing; and (3) vaulted framing; minimum rise is 22%.

DOUBLE-PITCH FRAMED SKYLIGHT ASSEMBLY

SLOPES VARY FROM 10 TO 60°

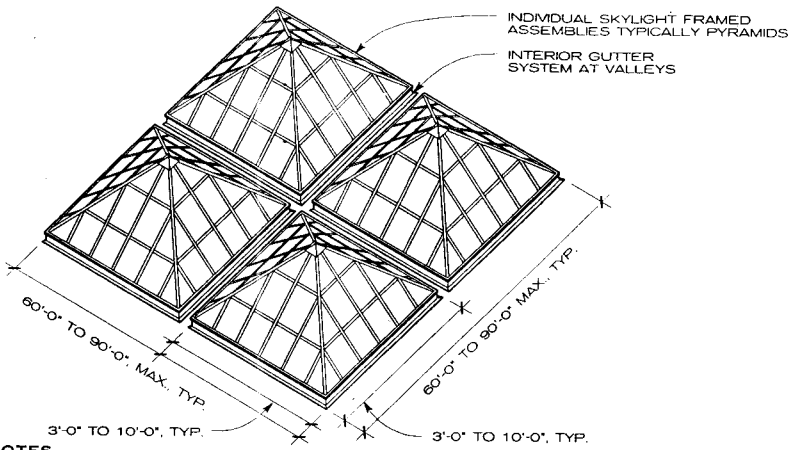

NOTE

Sloped aluminum frame may be segmented or curved.

SINGLE-PITCH FRAMED SKYLIGHT ASSEMBLY

POLYGONAL FRAMED SKYLIGHT ASSEMBLY

NOTES

1. Individual skylights for unit skylights may be pyramids or domes for flat roofs or flat panels for sloped roofs.
2. The number of multiples of individual skylights depends

only on the structural frame system below, although the larger the grid assembly, the more water runoff must be accommodated.

MULTIPLE-GRID SKYLIGHTS—UNIT AND FRAMED ASSEMBLIES

NOTE

Double leaf scuttles are typically specified for larger openings.

ROOF SCUTTLE

NOTE

Vents are manufactured both with and without labels. Consult codes for vent requirements. Fire and smoke vents can be adapted for use as explosion vent.

FIRE AND SMOKE VENT

TYPICAL TUBULAR ALUMINUM FRAME DETAIL

NOTE

Structural gutter system available for multiple and grid network systems of ridge- and pyramid-type enclosures.

MULTIPLE GRID GUTTER SECTION DETAIL

NOTE

Fire and smoke vent section is similar in construction, hardware, and integration with roof assembly. Consult manufacturer for all additional hardware.

SCUTTLE SECTION DETAIL

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

PARTS OF A DOOR

GLOSSARY

- Coordinator:** A device used on a pair of doors to ensure that the inactive leaf is permitted to close before the active leaf.
- Cylinder (of a lock):** The cylindrical shaped assembly containing the tumbler mechanism and the keyway, which can be actuated only by the correct keys.
- Cylinder lock:** A lock in which the locking mechanism is controlled by a cylinder.
- Deadbolt (of a lock):** A lock bolt having no spring action or bevel, and which is operated by a key or turnpiece.
- Door bolt:** A manually operated rod or bar attached to a door providing means of locking.
- Doorstop:** A device to stop the swing or movement of a door at a certain point.
- Electric strike:** An electrical device that permits releasing of the door from a remote control.
- Exit device:** A door locking device that grants instant exit when someone presses a crossbar to release the locking bolt or latch.
- Flush bolt:** A door bolt set flush with the face or edge of the door.
- Hand (of a lock, etc.):** A term used to indicate the direction of swing or movement, and locking security side of a door.
- Lock set:** A lock, complete with trim, such as handles, escutcheons, or knobs.
- Mortise:** A cavity made to receive a lock or other hardware; also the act of making such a cavity.
- Mortise lock (or latch):** A lock designed to be installed in a mortise rather than applied to the door's surface.
- Rabbet:** The abutting edges of a pair of doors or windows, shaped to provide a tight fit.
- Reversible lock:** A lock that, by reversing the latch bolt, may be used by any hand. On certain types of locks, other parts must also be changed.
- Rose:** A trim plate attached to the door under the handle; sometimes acts as a handle bearing.
- Shank (of a handle):** The projecting stem of handle into which the spindle is fastened.
- Spindle (of a handle):** The bar or tube connected with the knob or lever handle that passes through the hub of the lock or otherwise engages the mechanism to transmit the handle action to the bolt(s).
- Stop (of a lock):** The button, or other small device, that serves to lock the latch bolt against the outside handle or thumb piece or unlock it if locked. Another type holds the bolt retracted.
- Strike:** A metal plate or box that is pierced or recessed to receive the bolt or latch when projected; sometimes called "keeper."
- Three-point lock:** A device sometimes required on 3-hour fire doors to lock the active leaf of a pair of doors at three points.

IDEAL ACCESSIBLE DOOR

NOTES

1. See also Hollow Metal Frames and Doors.
2. Face the outside of the door to determine its hand. The outside of the door is the "key side," or that side which would be secured should a lock be used. This would usually be the exterior of an entrance door or the corridor side of an office door.

EXTENSION FLUSH BOLT

MORTISE BOLT

NOTE
A miniature deadlock, with bolt projected or retracted by a turn of the small knob.

LEFT HAND

RIGHT HAND

LEFT HAND REVERSE

RIGHT HAND REVERSE

NOTE

In the architectural hardware industry, the position of the hinges on a door — right or left as viewed from outside the entryway — determines the hand.

BOLT MECHANISMS

DOOR FINISHES

NEAREST U.S. EQUIVALENT	BHMA CODE	FINISH DESCRIPTION	BASE MATERIAL
USP	600	Primed for painting	Steel
US1B	601	Bright japanned	Steel

NOTE

* Also applicable to other base metals under a different Builders' Hardware Manufacturers Association code number.

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

DOORKNOB

NOTE
Doorknobs are not allowed on accessible doors.

PROJECTION
MAX. 2 1/2"

ENTRANCE HANDLE

NOTE

Complete lockset for entrance door handle includes mortise lock, handle outside, and knob and rose inside.

PROJECTION

LEVER HANDLE

PROJECTION: 1 3/4 to 2 1/2 in.
LENGTH: 2 to 4 in.
ROSE: Maximum diameter 1 1/2 to 3 in.
STILE: Larger stile takes larger rose

NOTE

Local codes may require a return or special clearance on lever handle (e.g., fire codes may require return to prevent fire hose from catching behind lever handle). Also, push-type mechanisms and U-shaped handles are acceptable designs. Consult ANSI and ADAAG and manufacturers' catalogs for other approved designs. Maximum height for accessible hardware is 48 in. above finished floor.

PUSH-PULL BAR

NOTE

Double push-pull bars may be used on the pull side of single-acting doors or on either side of double-acting doors.

KNOB, HANDLES, PLATE, AND BAR

PREASSEMBLED

NOTE

Installation requires notch cut in lock side of door to suit case size. Complete factory assembly eliminates much adjustment on the job.

MORTISE

NOTES

1. Installation requires mortise opening in door.
2. See American Standards Association Lock Strikes A-115V-1959 for metal doorframes. To determine lip length, measure from centerline of strike to edge of jamb and add 1/4 in. Outside strike dimensions standard for all lock types shown.

GENERAL NOTES

Based on use characteristics, there are four main types of latches and locks: passage, privacy, entry, and classroom. (In all cases, latch bolt can be operated by handle from either side.)

1. **PASSAGE:** Latches can be operated by handle from either side at all times.
2. **PRIVACY:** Outside handle is locked by push-button inside (or if deadbolt latch, by a turn) and unlocked by emergency key outside.
3. **ENTRY:** Outside handle is made inoperative by mechanical means, other than a key, on inside; latch bolt is operated by key in outside handle or by manual means at inside handle.
4. **CLASSROOM:** Outside handle is locked from outside by key; when outside handle is locked, latch bolt may be retracted by key from outside or by rotating inside handle.

LOCK TYPES

DOOR HARDWARE LOCATIONS

STOPS

COMBINATION

HOLDERS

PLUNGER-TYPE HOLDER OR BOLT
STOPS AND HOLDERS

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

NOTES

1. Use three hinges for doors as high as 7 ft 6 in. Add one hinge for each additional 30 in. in height.
2. In specifying hinges, the following design criteria are important: door material, weight, and dimensions; hinge weight (standard or heavy), material, finish, and special features (e.g., swing clear, spring hinge, etc.); "clearance," that is, distance between door and frame when door is opened 180°; frequency of use; conditions of use (e.g., exterior, corrosive atmosphere, potential for abuse or vandalism, etc.); type of pin tips; and type of screws.

HINGE LOCATION AND SPECIFICATION

HINGE WIDTH

THICKNESS OF DOOR (IN.)	CLEARANCE REQUIRED* (IN.)	OPEN WIDTH OF HINGES (IN.)
1 3/8	1 1/4 1 3/4	3 1/2 4
1 3/4	1 1 1/2 2 3	4 4 1/2 5 6
2	1 1 1/2 2 1/2	4 1/2 5 6
2 1/4	1 2	5 6
2 1/2	3/4 1 3/4	5 6
3	3/4 2 3/4 4 3/4	6 8 10

NOTE

* Clearance is computed for door flush with doorframe.

HINGE TYPE

TYPE OF BUILDING AND DOOR	DAILY FREQUENCY	HINGE TYPE
HIGH FREQUENCY Large department store entrance	5000	Heavy weight
Large office building entrance	4000	
School entrance	1250	
School toilet room	1250	
Store or bank entrance	500	
Office building toilet door	400	
AVERAGE FREQUENCY School corridor door	80	Standard weight anti-friction bearing (except on heavy doors)
Office building corridor door	75	
Store toilet door	60	
Dwelling entrance	40	
LOW FREQUENCY Dwelling toilet door	25	Plain bearing hinges may be used on light doors
Dwelling corridor door	10	
Dwelling closet door	6	

NOTES

1. Swaging is a slight offset of the hinge at the barrel, which permits the leaves to come closer together and improves the operation and appearance of the door.
2. A leaf is one of the two attaching plates that, when fastened together by the hinge pin, form a complete hinge.
3. Bearings (ball, oil-impregnated, or antifriction) offer the best ease of operation and durability.
4. Nonrising pins are a feature of quality hinges. Also available: nonremovable pins (NRP), with set screws; spun pins (FSP), without tips; and floating pins (FTP), with tips driven in both ends.
5. Tolerances: Close tolerances, especially in the pins, prevent excessive wear and are characteristic of high-quality, heavy-duty hinges.
6. A security stud, with matching hole in opposite leaf, is attached to a hinge to prevent door removal even if the pin is removed.
7. Hinges are available in brass, bronze, stainless steel, and carbon steel.

ELEMENTS OF A HINGE

CLOSER, HOLDER, AND DETECTOR — STOP SIDE

CLOSER, HOLDER, AND DETECTOR — HINGE SIDE

NOTES

1. A combination fire and smoke detector, door holder, and closer is available. Ionization, photoelectric, or heat-sensing devices detect smoke or any combustion products and hold open or close the door.
2. Smoke and fire doors are most commonly held open by electromagnetic or pneumatic devices and are released and closed manually or by means of smoke- or fire-detection devices. Most jurisdictions do not allow the old-fashioned fusible-link door closer in areas of human occupation, except for overhead doors. Consult local codes.
3. Some hold-open devices incorporate an electric switch that allows building maintenance staff to turn off the hold-open feature; however, such a switch should never shut off the detector.
4. A combination device (closer/holder/detector) most often is connected to the fire alarm system but may also be used merely to release and close the fire- or smoke-barrier doors without such a connection.
5. Smoke-sensing devices detect both visible and invisible airborne particles. Various operating principles include ionization, photoelectric, resistance, sampling, and cloud-chamber detection.
6. Ionization detection closers contain a small quantity of radioactive material within the sensing chamber. The resulting ionized air permits an electric current flow between electrodes. When smoke particles reduce the flow of ionized air between electrodes to a certain level, the detection circuit responds. Closing mechanisms usually consist of a detector, electromechanical holding device, and a door closer.
7. Ionization detectors sense ordinary products of combustion from sources such as kitchens, motors, power tools, and automobile exhausts.
8. Photoelectric-detection closers consist of a light source and a photoelectric cell. They activate when smoke becomes dense enough to change the reflectance of light reaching the photoelectric device. Photoelectric detectors may be spot or beam type. Closing mechanisms consist of a detector, electromechanical holding device, and a door closer.
9. Other types of smoke detectors include electrical bridging, sampling, and cloud chambers. Each has operating characteristics similar to ionization and photoelectric detectors.
10. Requirements for closers and detectors vary by code and governing jurisdiction. Refer to local building codes, the life-safety code of the National Fire Protection Association (NFPA), and other applicable regulations.

CLOSER AND HOLDER ONLY — STOP SIDE

CLOSER AND HOLDER ONLY — HINGE SIDE

NOTES

1. A combination closer and holder (only) will hold door in open position when incorporated with an independent detector or when wired into any type of fire detecting system.
2. All these units have unlimited hold-open from 0° to approximately 170°, or limited hold-open from 85 to 170° for cross-corridor doors.

COMBINATION CLOSER/HOLDER/ DETECTOR — SURFACE MOUNTED

MODERN TYPE

MODERN TYPE WITH COVER

NOTES

1. Door closers may be surface mounted or concealed in the door, frame, or floor. There are three ways to mount surface closers: hinge side, parallel arm, and top jamb. A wide variety of brackets, including corner and soffit types, is available to meet varying door and frame conditions.
2. Surface-mounted and concealed-in-door closers are used exclusively for single-acting doors; floor closers and frame-concealed closers may be used for either single- or double-acting doors.

CLOSER ONLY — SURFACE MOUNTED

IN FRAME HEAD

IN DOOR HEAD

IN FLOOR

CLOSER ONLY — CONCEALED

NOTES

1. A door closer, when properly installed and adjusted, should control the door throughout the opening and closing swings. It combines three basic components: (a) a power source to close a door; (b) a checking source to control the rate at which the door closes; and (c) a connecting component (arm that transmits the closing force from the door to the frame).
In all modern closers, the power source is a spring and the checking source is a hydraulic mechanism. The spring and checking mechanism is connected to a common shaft, and arms attached to this shaft act as linkage to communicate movement between the door and mechanism. In addition to serving as linkage, the arms, through leverage, can amplify the power of the spring, providing maximum power at the latch point.
2. Additional features for safety and convenience also are available in many types of closers. These include back check, delayed action, adjustable spring power, and a variety of hold-open functions: regular, fusible link, and hospital.
3. A full range of closer sizes is available to suit various door dimensions, locations, and job conditions. The manufacturer's recommendations should be considered carefully.
4. Closers with delayed-action features give a person more time to maneuver through doorways. They are particularly useful on frequently used interior doors such as entrances to toilet rooms. ADAAG requires a closing speed of at least 3 seconds; ANSI requires 5 seconds.

COMBINATION CLOSER/HOLDER/ DETECTOR — SURFACE MOUNTED

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

EXIT DEVICES

NOTES

1. To permit reverse opening of a door in an emergency, a foldable or collapsible stop, in conjunction with a center-hung pivot, is needed. Such devices typically are used on private or semiprivate toilet doors.
2. If a slowly opening, low-powered automatic door mechanism is used, it shall comply with ANSI 156.19-1984. Such doors shall not open to backcheck faster than 3 seconds and shall require no more than 15 lbf to stop door movement. If a power-assisted door is used, its door opening force shall comply with ANSI 4.13.11 and its closing force shall comply with ANSI A156.19-1984.

COMPONENTS FOR REGULAR OPENING

FLOOR HINGE CUTOUTS

GENERAL

Installation of a suitable type and quality of noncorrosive weather stripping around exterior door and window openings can have a significant effect on energy savings in virtually any building. Weather stripping seals joints between a sash or door and its frame, blocking air infiltration. Weather stripping may also be used at interior openings to create smoke, light, or sound seals between spaces.

Materials used for weather stripping include felt, neoprene, pile/brush, kerf-in foam, sponge neoprene, silicone, butyl, and vinyl. Weather stripping should be continuous around the entire perimeter of a door or window, including a weather strip-type threshold at doors. High-quality closers used on exterior doors can ensure that no door is left open. In extreme climates, consider using double weather stripping, combining a neoprene gasket with pile-type sweeps.

Avoid creating conditions that interfere with the operation of other hardware. In particular, consider potential difficulties that may arise for handicapped users. Also, weather stripping must be coordinated with door and frame types. Benefits gained through the use of quality weather stripping can be virtually wasted if an uninsulated hollow metal door is used.

To meet accessibility standards, changes in level greater than 1/4 in. (13 mm) must be ramped at a 1:2 (rise:run) slope. Any vertical change in level (perpendicular to floor) shall not exceed 1/4 in. (6.5 mm) in height.

Since most windows are manufactured with frames, sash, and weather stripping preassembled as a unit, weather stripping details are not shown. However, if custom windows are specified, any appropriate door weather stripping material and configuration may be used.

NOTE

Brush weather stripping is ideally suited for applications requiring low closing force. Nylon brush blocks smoke and air infiltration and can be used on overhead doors, sliding doors, and automatic doors.

- NOTES
- Blast-resistant doors can be designed to offer sound-retarding, watertight, airtight, and radiation-shielded features. Exit bar, key locking, and electronic security systems may be required with these types of doors. Blast-resistant doors are also available as manual or power-operated vertical lift or horizontal sliding doors.
 - When establishing blast door criteria, it is important to consider the following factors:
 - Opening size and whether swing, slide, or vertical lift
 - Direction of door opening in relation to direction of blast force
 - Type of potential blast or hazard, whether chemical, nuclear, steam, pressure (tornado, etc.), or other
 - Amount of potential blast force and angle of incidence or direction of potential blast, if known (assume zero degrees, which gives maximum protection)
 - Whether doors must be operable after blast and whether they will be subjected to repeated blasts (plastic and elastic design properties)
 - Rebound percentage as percentage of reflected pressure (suction phase of blast)
 - Equivalent static design pressure
 - Door operation type (power or manual) and type of hardware required
 - Wall construction, frame, threshold conditions desired
 - UL requirements and other hazards to be controlled, such as fire, smoke, gas fumes, missiles, or noise
 - Primary use, to protect life or equipment or both

Daniel F. C. Hayes, AIA; Washington, D.C.

DEFINITION OF GLASS

Glass is a hard, brittle amorphous substance made by melting silica (sometimes combined with oxides of boron or phosphorus) with certain basic oxides (notably sodium, potassium, calcium, magnesium, and lead) to produce annealed flat glass by a controlled cooling process. Most glasses soften at 932 to 2012°F (500 to 1100°C). The brittleness of glass is such that minute surface scratches in manufacturing greatly reduce its strength.

INDUSTRY QUALITY STANDARDS

ASTM Standard C1036: Specification for Flat Glass.

ASTM Standard C1048: Specification for Heat-treated Flat Glass—Kind HS, Kind FT Coated and Uncoated Glass.

UL Standard 752: Bullet-resistant Material.

UL Standard 972: Burglary-resistant Glazing Material.

AAMA Standard No. 12: Structural Properties of Glass, Aluminum Curtain Wall Series.

ASTM Standard E1300: Practice for Determining the Minimum Thickness of Annealed Glass Required to Resist a Specified Load.

CPSC Standard 16CFR 1201: Standard on Architectural Glazing Materials.

ANSI Z97.1: establishes standards for testing safety glazing material.

ASTM C1172: Specification for Laminated Architectural Flat Glass.

NOTE

Consult glass manufacturers for current information because processes, qualities, finishes, colors, sizes, thickness, and limitations are revised continually. The following information represents one or more manufacturers' guidelines.

BASIC TYPES OF CLEAR GLASS

SHEET GLASS

Sheet glass is manufactured by a horizontal flat or vertical draw process, then annealed slowly to produce a natural flat fired, high gloss surface. It generally is used in residential and industrial applications. Because it is not mechanically polished, inherent surface waves are noticeable in sizes larger than 4 sq ft. For minimum distortion, larger sizes are installed with the wave running horizontally. The width is listed first when specifying.

Sheet glass for architectural applications is either single strength (0.101 in. thick) or double strength (0.134 in. thick). Very little glass is produced in the United States by this process; almost all sheet glass is produced by the float process.

FLOAT GLASS

Generally accepted as the successor to polished plate glass, float glass has become the quality standard of the glass industry. It is manufactured by floating molten glass on a surface of molten tin, then annealing it slowly to produce a transparent flat glass, thus eliminating grinding and polishing.

This process produces a glass with very uniform thickness and flatness, making it suitable for applications requiring excellent optical properties, such as architectural windows, mirrors, and specialty applications. It is available in thicknesses ranging from $\frac{1}{8}$ to $\frac{7}{8}$ in. Float glass is made to the specification requirements of ASTM C1036, and its minimum thickness to resist wind load is established using ASTM E1300.

PLATE GLASS

Transparent flat glass is ground and polished after rolling to make plate glass. Cylindrical and conical shapes can be bent to a desired curvature (within limits). Only glass for specialty applications is produced by this method; it is not produced for widespread use in architectural applications.

VARIATIONS OF BASIC GLASS TYPES

PATTERNED GLASS

Patterned glass is known also as rolled or figured glass. It is made by passing molten glass through rollers that are etched to produce the design. Designs include flutes, ribs,

grids, and other regular and random patterns, which provide translucency and a degree of obscurity. Usually only one side of the glass is imprinted with a pattern. Patterned glass is available in thicknesses of $\frac{1}{8}$, $\frac{3}{16}$, and $\frac{1}{2}$ in.

WIRE GLASS

Wire glass is available as clear polished glass or in various patterns such as square welded mesh, diamond welded mesh, and linear parallel wires. Some distortion, wire discoloration, and misalignment are inherent. Some $\frac{1}{4}$ in. wired glass products are recognized as certified safety glazing materials for use in hazardous locations (for example, fire-rated windows, doors, and skylights). For applicable fire and safety codes that govern their use, refer to ANSI Z97.1.

CATHEDRAL GLASS

Cathedral glass is known also as art glass, stained glass, or opalescent glass. It is produced in many colors, textures, and patterns. Cathedral glass is usually $\frac{1}{8}$ in. thick and is used primarily in decorating leaded glass windows. Specialty firms usually contract this type of glass.

OBSCURE GLASS

Obscure glass is used to obscure a view or create a design. The entire surface on one or both sides of the glass can be sandblasted, acid etched, or both. When a glass surface is altered by any of these methods, the glass is weakened and may be difficult to clean.

STRENGTHENED GLASS

Glass can be strengthened by either a controlled heating and cooling process or by immersion in a chemical bath. Both processes have glass thickness, size, and use restrictions that should be verified.

HEAT-TREATED GLASS

Heat-strengthened (Kind HS) and tempered (Kind FT) glass are produced by reheating annealed float glass close to its softening point and then rapidly quenching (cooling) it with high velocity blasts of air. Both types have greatly increased mechanical strength and resistance to thermal stresses. Before it is heat-treated, the glass must be fabricated to its exact size and shape (including any holes), because neither type of glass can be altered after heat treatment.

Most manufacturers heat-treat the glass using a horizontal process that can introduce warpage, kinks, and bowing into the finished product, which may create aesthetic or technical concerns. A vertical process may still be available that produces long marks or depressions into the glass surface near the suspended edge. The heat treatment quenching pattern on the surface of the glass can become visible as a pattern of light and dark areas at certain oblique viewing angles and with polarized light. This effect can be more pronounced with thicker glass and may be an aesthetic consideration. Refer to ASTM C1048 for allowable tolerances and other properties.

Heat-strengthened glass is generally two to three times stronger than annealed glass. It cannot be cut, drilled, or altered after fabrication. Unlike tempered glass, it breaks into large, sharp shards similar to broken annealed glass. Heat-strengthened glass is not acceptable for safety glazing applications.

TEMPERED GLASS

Tempered glass is generally four to five times stronger than annealed glass. It breaks into innumerable small, cube-shaped fragments. It cannot be cut, drilled, or altered after fabrication; the precise size required and any special features (such as notches, holes, edge treatments, etc.) must be specified when ordering.

Tempered glass can be used as a safety glazing material provided it complies with the ANSI and CPSC references listed on the following "Glass Products" page under the "Laminated Glass" heading. Tempered glass can be used in insulating and laminated assemblies and in wired, patterned, and coated processes. All float and sheet glass $\frac{1}{8}$ in. or thicker may be tempered.

CHEMICALLY TREATED GLASS

Chemically treated glass is produced by submerging annealed float glass in a bath of molten potassium salts. The larger potassium ions in the bath exchange places with the smaller sodium ions in the glass surface, creating a surface compression layer that strengthens the glass. Chemically treated glass breaks into large, sharp shards similar to broken annealed glass. It does not have the visual distortion that can be caused by a heat-treated strengthening process. At present, chemical strengthening is primarily limited to the glass lights of laminated security glass.

HEAT-ABSORBING OR TINTED GLASS

This type of float glass was developed to help control solar heat and glare in large areas of glass. It is available in blue, bronze, gray, or green and in thicknesses ranging from $\frac{1}{8}$ to $\frac{1}{2}$ in. The glass absorbs a portion of the sun's energy because of its admixture contents and thickness (see graphic); it then dissipates the heat to both the exterior and interior. The exterior glass surface rejects some heat, depending on the sun's position. Heat-absorbing glass has a higher temperature when exposed to the sun than does clear glass; thus the central area expands more than the cooler shaded edges, causing edge tensile stress buildup. When designing heat-absorbing or tinted glass windows, consider the following:

1. To minimize shading problems and tensile stress buildup at the edges, provide conditions in which glass edges warm as rapidly as the exposed glass (for example, framing systems with low heat capacity and minimal glass grip or stops). Structural rubber gaskets can be used.
2. The thicker the glass, the greater the solar energy absorption.
3. Indoor shading devices such as blinds and draperies reflect energy back through the glass, thus increasing the temperature of the glass. Spaces between indoor shading devices and the glass, including ceiling pockets, should be vented adequately. Heating elements always should be located on the interior side of shading devices, directing warm air away from the glass.
4. The glass can be heat-treated to increase its strength and resistance to edge tensile stress buildup.

SOLAR PERFORMANCE OF HEAT-ABSORBING OR TINTED GLASS

SPANDREL GLASS

Spandrel glass is available tinted or with reflective, ceramic frit (patterned and solid colors), direct-to-glass polyvinylidene fluoride (Kynar 500 resin) coatings. It can be heat-treated or laminated and is available as insulating glass units. Insulation and vapor retarders can be added to spandrel glass; consult with spandrel glass manufacturers for guidelines.

SOUND CONTROL GLASS

Laminated, insulating, laminated insulating, and double laminated insulating glass products commonly are used for sound control. STC ratings from 31 to 51 are available depending on glass thicknesses, air space size, polyvinyl butyral film thickness, and the number of laminated units used in insulating products.

Thomas F. O'Connor, AIA, FASTM; Smith, Hinchman & Grylls; Detroit, Michigan

GLAZING

TYPICAL INSULATING OR SPACED CONSTRUCTION SECURITY GLASS PROFILE

DEPENDENT ON DEGREE OF SECURITY PROTECTION REQUIRED, THICKNESS CAN RANGE FROM 3/8" (10 MM) TO APPROXIMATELY 2 1/2" (64 MM)

BONDING LAYER, POLYVINYL BUTYRAL (PVB) FOR GLASS LAYERS AND POLYURETHANE FOR POLYCARBONATE PLASTIC LAYERS

TYPICAL MULTILAYER SECURITY GLASS PROFILE

SECURITY GLASS

Security glass is composed of multiple layers of glass and/or polycarbonate plastic laminated together (under heat and pressure) with a polyvinyl butyral (for glass) or polyurethane plastic (for polycarbonate) film. It is available in multilayer laminated glass, insulating, laminated insulating, and double laminated insulating or spaced configurations, generally in thicknesses from 3/8 in. (10 mm) to 2 1/2 in. (64 mm) as a laminated product and up to about 4 3/4 in. (121 mm) for insulating and spaced construction products. Bullet-resistant glass should be tested to UL 752 and burglar-resistant to UL 972. Consult manufacturers for blast-resistant glass. Security glass products, depending on type, are subject to size limitations, and some are not recommended for exterior applications; consult with the manufacturer for glazing requirements and restrictions on use.

COATED GLASS

A reflective or low emissivity coating can be applied to the surface of monolithic glass. Generally, only pyrolytically applied "hard" coatings, which have scratch resistance, are used on exposed glass surfaces. During glass manufacture, pyrolytic coatings are sprayed onto the glass before it cools, which integrates them with the glass surface. Magnetically sputtered or "soft" coatings can also be applied to the glass surface but must be protected from the elements as part of an insulating or laminated glass product. The range of coating types, aesthetic appearances, and thermal performance available for pyrolytic coatings is generally less than that available for sputtered coatings.

ULTRACLEAR GLASS

The high clarity and high visible light transmittance that characterize ultraclear glass comes from the special soda lime mixture it is made from, which minimizes the iron content that normally gives a slight greenish color to clear flat glass. Ultraclear glass is generally available in thicknesses from 1/8 in. to 3/4 in. (3 mm to 19 mm). It can be heat strengthened, tempered, sand blasted, etched, or assembled into laminated glass. Ultraclear glass is used for commercial display cases, museum cases, display windows, frit-coated spandrel glass, aquariums, mirrors, shelving, security glass, and other uses in which clarity and better color transmittance are required.

LAMINATED GLASS

A tough, clear plastic polyvinyl butyral (PVB) sheet (interlayered), ranging in thickness from 0.015 to 0.090 in. (0.381 to 2.3 mm), is sandwiched, under heat and pressure, between lights of sheet, plate, float, wired, heat-absorbing, tinted, reflective, low emissivity, or heat-treated glass or combinations of each. When laminated glass breaks, the particles tend to adhere to the plastic film. Laminated glass is manufactured to the specification requirements of ASTM C1172. Laminated safety glass should be manufactured to comply with ANSI Z97.1 and CPSC 16CFR 1201.

DEPENDENT ON PVB AND GLASS LIGHT THICKNESS, LAMINATED GLASS CAN VARY FROM 1/4" (6 MM) TO 3/4" (19 MM) IN THICKNESS

POLYVINYL BUTYRAL (PVB) THICKNESS RANGES FROM 0.03" (0.8 MM) TO 0.09" (2.3 MM)

LAMINATED GLASS PROFILE

BENT GLASS

Clear, tinted, ceramic frit-coated spandrel, pyrolytically coated, patterned, laminated, and wire glass are among glass types that can be bent in thicknesses to about 1 in. (25 mm) and to a minimum radius of about 4 in. (102 mm). Sharp angle bends to 90°, edgework, pattern cutting, and tempering (meeting safety glazing standards) and heat-strengthening are also available. Bent glass can be fabricated into insulating glass units. Bent glass tolerances must be compatible with the glazing system. Size, configuration, and product availability vary by fabricator.

PHOTOVOLTAIC GLASS

There are two types of photovoltaic (PV) glass: crystalline silicon sandwiched between two lights of glass and thin-film amorphous silicon applied to an interior facing glass surface. When these arrangements are exposed to sunlight, they generate either DC or AC power, which is transferred by concealed wiring to the building's power system.

PHOTOVOLTAIC GLASS (IN A PRESSURE BAR FRAMING SYSTEM)

Pressure bar or structural silicone flush glazed curtain walls and skylights, awnings, sunshades, light shelves, and roof panels are some of the systems that can incorporate PV glass. For curtain walls and skylights, the pressure bar type allows easy concealment of the wiring. Shadow patterns from the cap on the PV glass surface must be considered in system design. Flush glazed systems have no shadow patterns, but wiring concealment is more difficult and the PV module on the glass must be kept from reacting with the structural silicone sealant. Both types of PV glass are used for opaque curtain wall spandrel panels and can be used for curtain wall or skylight vision glass if the quality of daylighting and visibility is acceptable. Consult PV glass and metal framing system manufacturers to determine availability, suitability, and cost for a particular application.

DECORATIVE SILK-SCREENED (OR FRIT) GLASS

Annealed clear or tinted glass is washed and ceramic frit paint (in standard or custom color) silk-screened on its surface in a standard or custom pattern or design (such as dots, holes, lines, or a logo) and then dried in an oven. The frit-coated glass is then subjected to very high temperatures in a tempering furnace to fire the ceramic frit permanently to the glass surface. As a result, silk-screened glass will be either heat strengthened or tempered after firing. Reflective and low emissivity coatings can also be applied to the glass surface. Silk-screened glass can be used monolithically or for insulating or laminated glass products.

AVERAGE PERFORMANCE VALUES OF 1/4 IN. (6 MM) UNCOATED GLASS

GLASS TYPE	% TRANSMITTANCE			% REFLECTANCE AVERAGE DAYLIGHT	SHADING COEFFICIENT
	AVERAGE DAYLIGHT	TOTAL SOLAR	ULTRAVIOLET		
Ultraclear	91	89	85	8	1.04
Clear	89-88	78-76	71-62	9-8	0.95-0.94
Clear laminated	86-84	67-64	<1	8-7	0.86-0.83

Gray	46-43	49-42	25-32	5-6	0.72-0.66

Thomas F. O'Connor, AIA, FASTM; Smith, Hinchman & Grylls; Detroit, Michigan

LEADED STAINED GLASS

Decorative stained glass is characterized by pieces of glass joined together with cames (H-shaped strips) of various widths. Varying the widths adds to the window's decorative effect. Joints are soldered on both sides of the panel. To prevent leakage, a mastic waterproofing material is inserted between the glass and came flange.

Another method of joining the pieces of glass is banding the edges of the glass with a copper foil tape burnished to the glass and then soldered with a continuous bead of solder on both sides.

Bracing bars are fastened to the sash at frequent intervals to strengthen and support the leaded glass. Round bars tied to the leaded glass with twisted copper wires are the most flexible and resilient, allowing for great amounts of thermal movement. Where this system is not suitable, galvanized steel flat bars can be soldered to the surface of the leaded glass.

When the glass requires detail painting, shading, or texturing, it must be done with special mineral pigments and fired at temperatures of 1000 to 1200°F or higher to ensure absolute permanency.

INSTALLATION

It is recommended that decorative glass be installed into specially designed metal frames provided with glazing beads and sealed with a modern flexible glazing material. However, with proper maintenance, high-quality wood frames with suitable division bars are acceptable.

A stained glass studio should be consulted for the location of division bars, mullions, and muntins to best complement the artistic design. Decorative glass weighs approximately 4 lb/sq ft.

OUTSIDE PROTECTION GLASS

Properly made decorative glass does not necessarily need additional glazing to make it waterproof, but it is valuable for insulating purposes and to afford some protection from external damage. Frames should be designed with a 3/4 in. ventilated space between glass and should be arranged for the protection glass to be installed from the exterior and the decorative glass from the interior. Clear glass or textured glass 3/16 to 1/4 in. thick is most successful.

Depending on geographic location and economics, insulating glass should be considered as the protective outside glazing.

Acrylic and polycarbonate are two types of plastic protection material that can be employed when protection from vandalism is needed. Outside protection glass should be installed by the stained glass studio whenever possible to ensure an integrated system.

GLAZING SEALANTS

Exterior decorative glass must be pressed into a deep back bed of mastic compound or glazing tape. When outside protection glass is used, a watertight seal is not required, and foam tape compressed between the glazing bead and glass may suffice.

SIZE LIMITATIONS

Decorative glass panels should not exceed 12 sq ft, making it necessary to divide larger openings with metal division bars: tee bars for single glazed windows, and special channel bars for windows with outside protection glass.

GLASS COLORS

Machine-made and blown glass from the United States, England, France, and Germany are available in most solid colors; also mixed colors and textures. Uniformity of color will vary from glass of different batches. Special colors are derived by "sumping," or kiln firing.

WORKERS' PROTECTION

Work in decorative glass studios involves handling and storage of many toxic substances and waste such as lead, fluxes, patinas, cleaners, and solvents. The Occupational Safety and Health Administration has established guidelines for use by studios, including blood testing, cleaning, air purification, respirators, work clothing, and toxic waste handling.

Randall S. Lindstrom, AIA; Ware Associates, Inc.; Chicago, Illinois
Joseph A. Wilkes, FAIA; Annapolis, Maryland
Bobbie Burnett Studio; Annapolis, Maryland

DECORATIVE GLASS PANELS

H-SHAPED CAME METHOD

COPPER FOIL METHOD

ALUMINUM FRAMES FOR DECORATIVE GLASS

WOOD FRAMES FOR DECORATIVE GLASS

FACETED STAINED GLASS

A 20th century development in the art of stained glass introduced the use of glass dalles 8 x 12 x 1/4 in., cast in hundreds of different colors that can be cut to any shape and used, in combination with opaque matrix of epoxy resin or reinforced concrete 3/8 to 1 in. in thickness, to create translucent windows and walls of great beauty.

SIZE LIMITATIONS

No single panel of faceted glass should exceed 16 sq ft. The length to width ratio of each panel should not exceed 4:1. Large openings must have horizontal supports to support the weight of stacked panels. When panels are to be stacked vertically, a minimum matrix thickness of 3/8 in. is recommended. Joints between panels should be sealed with flexible caulking, as described below.

INSTALLATION

Faceted glass can be installed in frames of masonry, metal, or wood. Frames must be detailed to support the weight of the glass and matrix (approximately 10 to 13 lb/sq ft) and the thicker edge of epoxy panels. A stained glass studio should be consulted for the location of division bars and mullions to coordinate with the design.

OUTSIDE PROTECTION GLASS

Because of its high resistance to breakage, waterproof construction, and excellent insulating qualities, faceted glass does not usually need outer glazing. If protection is required, 3/4 to 1 in. ventilated space between the outer surface of the faceted glass and the inside surface of the protection glass is recommended. Divisions in the protection glass should be designed by the artist to complement the design.

GLAZING SEALANTS

Faceted glass panels should be set into a non-hardening caulking such as butyl, acrylic, silicone, or polysulfide, used both as a bedding and finish bead. For spaces in excess of 1/4 in. between faceted glass and frame, fillers such as ethafoam are recommended under the caulking bead. A clearance of 3/16 in. should be allowed between the frame and panel edge for proper expansion and contraction. Neoprene spacers are used to ensure proper clearance.

Further information is available from the Stained Glass Association of America.

LATHING SYSTEMS

SOLID PARTITION SYSTEMS

NOTES

Self-furring paperbacked reinforcing is available in diamond mesh, welded wire, and hexagonal woven wire. Paperbacks are available to conform to Federal Specifications UU-B-790, Type 1, Grade A, Style 2 for highly water-vapor resistant paper.

Metal lath is also manufactured in large diamond mesh 27 x 96 in., 2.5 or 3.4 lb/sq yd, painted steel or galvanized; 1/8 in. flat rib 27 x 96 in., 2.75 or 3.4 lb/sq yd painted or galvanized; 3/8 in. rib expanded 27 x 96 in., 3.4 lb/sq yd painted or galvanized and 3/4 in. rib expanded 24 x 96 in., 5.4 lb/sq yd painted.

Other types of lath are available from some manufacturers.

GYPSUM LATH

Gypsum lath is composed of an air entrained gypsum core sandwiched between two sheets of fibrous absorbent paper and used as a basecoat for gypsum plaster.

1. PLAIN GYPSUM LATH: 3/8 and 1/2 in. thick, 48 in. long, and 16 in. wide (16 1/8 in. in the Western U.S.).
2. PERFORATED GYPSUM LATH: Plain gypsum lath with 3/4 in. diameter holes punched 4 in. o.c. in both directions to provide mechanical key to plaster.
3. INSULATING GYPSUM LATH: Plain gypsum lath with aluminum foil laminated to the backside as insulator or vapor barrier.
4. LONG LENGTH GYPSUM LATH: 16 and 24 in. wide, in lengths up to 12 ft, available insulated or plain with square or vee-jointed Tongue and Groove edges or interlocking as ship-lap edge.

SOLID PLASTER PARTITION CONSTRUCTION

PARTITION CONSTRUCTION	THICKNESS	MAXIMUM HEIGHT
3/4" cold-rolled channels Diamond mesh lath and plaster	2"	12'-0"
3/4" cold-rolled channels Diamond mesh lath and plaster	2 1/2"	16'-0"
1 1/2" cold-rolled channels Diamond mesh lath and plaster	3"	20'-0"
1 1/2" cold-rolled channels Diamond mesh lath and plaster	3 1/2"	22'-0"

NOTE: Maximum partition length is unrestricted if less than 10 ft tall. Twice the height if over 10 ft tall; one and one half the height if over 14 ft tall and equal to the height if over 20 ft tall.

NOTES

Prefabricated metal studs are used as the supporting elements of lath and plaster hollow partitions. They are available in 1 5/8, 2, 2 1/2, 3 1/4, 4, and 6 in. widths. Lengths are available in various increments up to 24 ft. Prefabricated studs are usually of the nonload bearing type, but load bearing metal studs also are manufactured. Designs vary with the manufacturer, and most manufacturers produce a line of related accessories, such as clips, runners, stud shoes, and similar articles.

HOLLOW PARTITION SYSTEMS

DEFINITIONS

- AGGREGATE:** Inert material used as filler with a cementitious material and water to produce plaster or concrete. Usually implies sand, perlite, or vermiculite.
- BASECOAT:** Any plaster coat applied before the finish coat.
- BEAD:** Light gauge metal strip with one or more expanded or short perforated flanges and variously shaped noses; used at the perimeter of plastered surfaces.
- BROWN COAT:** In three-coat plaster, the brown coat is the second coat; in two-coat plaster, the base coat.
- CALCINED GYPSUM:** Gypsum that has been partially dehydrated by heating.
- CLIP:** A device made of wire or sheet metal for attaching various types of lath to the substructure and lath sheets to one another.
- FIBERED PLASTER:** Gypsum plaster containing fibers of hair, glass, nylon, or sisal.
- FINISH COAT:** The final coat of plaster, which provides the decorative surface.
- FURRING:** Grillage for the attachment of gypsum or metal lath.
- GAUGING:** Cementitious material, usually calcined gypsum or portland cement combined with lime putty to control set.
- GROUND:** A formed metal shape or wood strip that acts as a combined edge and gauge for various thicknesses of plaster to be applied to a plaster base.
- GYPSUM:** Hydrous calcium sulphate, a natural mineral in crystalline form.
- GYPSUM LATH:** A base for plaster; a sheet having a gypsum core, faced with paper.
- GYPSUM READY MIX PLASTER:** Ground gypsum that has been calcined and then mixed with various additives to control its setting and working qualities; used, with the addition of aggregate and water, for basecoat plaster.
- HYDRATED LIME:** Quicklime mixed with water, on the job, to form a lime putty.
- LIME:** Obtained by burning various types of limestone, consisting of oxides or hydroxides of calcium and magnesium.
- LIME PLASTER:** Basecoat plaster of hydrated lime and an aggregate.
- NEAT PLASTER:** Basecoat plaster, fibered or unfibered, used for job mixing with aggregates.
- PERLITE:** Siliceous volcanic glass containing silica and alumina expanded by heat for use as a lightweight plaster aggregate.
- PLASTER:** Cementitious material or combination of cementitious materials and aggregate that, when mixed with water, forms a plastic mass that sets and hardens when applied to a surface.
- PORTLAND CEMENT:** Manufactured combination of limestone and an argillaceous substance.
- SCRATCH COAT:** In three-coat plastering, the first coat, which is then scratched to provide a bond for second or brown coat.
- SCREED:** A device secured to a surface which serves as a guide for subsequent applications of plaster. Thicknesses and widths vary with the thicknesses desired for each operation.
- STUCCO PORTLAND CEMENT:** Plaster used in exterior application.
- VERMICULITE:** Micaceous mineral of silica, magnesium, and alumina oxides made up in a series of parallel plates or laminae and expanded by heat for use as a lightweight plaster aggregate.

NOTES

Keene's cement plaster is a specialty finish coat of gypsum plaster primarily used where a smooth, dense, white finish is desired. Thickness, proportions of mixes of various plastering materials, and finishes vary. Systems and methods of application vary widely depending on local traditions and innovations promoted by the industry.

GENERAL NOTES

1. Certain accessory items are available in high impact PVC plastic and can be utilized with stucco, interior veneer, and conventional plaster items. Stock color is white. Special colors available on request from manufacturer.
2. Extruded aluminum shapes used mostly for stucco are available in a variety of anodized finishes.

FASCIA CORNER
MOLDING

SOFFIT DETAIL

NOTE

Framing details for exterior cement plaster (stucco) are similar to details shown. Wind loads must be considered in designing framing systems for exterior stucco work. Galvanized mesh is available for exterior applications and use in humid areas. Ventilation strips should be used for ventilating all dead airspaces. Where plenum or attic spaces are closed off by ceiling installation, ventilation shall be provided with a minimum of 1/2 sq. in./sq. ft. of horizontal surface.

SUSPENDED PLASTER CEILING AT RECESSED LIGHT FIXTURE

NOTE

Penetrations of the lath and plaster ceiling—at borrowed light openings, vents, grilles, access panels, and light troffers, for example—require additional reinforcement to distribute concentrated stresses if a control joint is not used. Where a plaster surface is flush with metal, as at metal access panels, grilles, or light troffers, the plaster should be grooved between the two materials.

SUSPENDED PLASTER CEILING AT FURROWED MASONRY WALL

NOTE

When interior walls are furrowed from an exterior masonry wall and insulated, the ceiling should stop short of the furrowed space. This allows wall insulation to continue above the ceiling line to ceiling or roof insulation, thus forming a complete insulation envelope. In a suspension system that abuts masonry wall, provide 1 in. clearance between ends of main runners or furring channels and wall face.

HANGERS CAST IN CONCRETE

STEEL WOOD FRAMING CONCRETE

CONTROL JOINT DETAIL

NOTE

Control joints shall be spaced no further than 30 ft on center in each direction for large plastered ceiling areas. Area shall not exceed 900 sq ft without provision for expansion control. Exterior plaster soffits should have control joints spaced no further than 25 ft on center. For portland cement plaster (stucco) areas, interior or exterior, control joints should be placed at 10 ft on center and areas should not exceed 100 sq ft without provisions for expansion/contraction control. Control joints are spaced closer for cement plaster because of its inherent shrinkage during curing.

NOTE

Details shown are for furred (contact) ceilings that are attached directly to the structural members. The architect or ceiling designer should give consideration to the deflection and movement of the structure, since movement and deflection of more than 1/320 of the span will cause cracking of plaster ceilings. If spacing of structural members exceeds the maximum span of furring members shown in the span charts, the addition of suspended main runners between structural members will be required. Flat rib lath may be attached directly to wood framing members, but is subjected to stresses created by the inherent properties of wood members.

James E. Phillips, AIA; Enwright Associates, Inc.; Greenville, South Carolina

9 PLASTER AND GYPSUM BOARD

DIRECTIONS FOR USING TABLES

1. Select lath and plaster system.
2. Determine spacing of cross furring channels from Table 1—Lath Span.
3. Determine spacing of main runners from Table 2—Maximum Spacing between Runners.
4. Determine hanger support spacing for main runner from Table 3—Maximum Spacing between Hangers.
5. Calculate area of ceiling supported per hanger.
6. Select hanger type from Table 4—Hanger Selection.
7. Select tie wire size from Table 5—Tie Wire Selection.

TABLE 1. LATH SPAN

	LATH TYPE	WEIGHT/SQ. FT.	SPAN (IN.)
Gypsum lath	3/8" plain	1.5#	16
	1/2" plain	2.0#	16
	1/2" veneer	1.8#	16
	5/8" veneer	2.25#	16
	3/8" perforated	1.4#	16
Metal lath	Diamond mesh	0.27#	12
	Diamond mesh	0.38#	16
	1/8" flat rib	0.31#	12
	3/8" flat rib	0.38#	24

TABLE 2. MAXIMUM SPACING BETWEEN RUNNERS

CROSS FURRING TYPE	CROSS FURRING SPACING			
	12"	16"	19"	24"

3/8" diam. pencil rod	2'-6"	-	2'-0"	-
3/4" CRC, HRC (0.3 lb/ft)	-	4'-6"	3'-6"	3'-0"
1" HRC (0.41 lb/ft)	5'-0"	-	4'-6"	4'-0"

CRC = Cold rolled channel
HRC = Hot rolled channel

FURRED AND SUSPENSION SYSTEM COMPONENT SELECTION DETAIL

- SUSPENSION SYSTEM TIE WIRES AS REQUIRED
- MAIN RUNNER CHANNEL
- 3/4" CROSS FURRING CHANNEL

NOTE
Dimensional requirements for support spacing, runner spacing, hanger spacing, hanger type selection, and tie wire selection are given in tables on this page.

TABLE 3. MAXIMUM SPACING BETWEEN HANGERS

MAIN RUNNER TYPE	MAIN RUNNER SPACING				
	3'-0"	3'-6"	4'-0"	4'-6"	5'-0"
3/4" CRC (0.3 lb/ft)	2'-0"	-	-	-	-
1 1/2" CRC (0.3 lb/ft)	3'-0"*	-	-	-	-
1 1/2" CRC (0.875 lb/ft)	4'-0"	3'-6"	3'-0"	-	-
1 1/2" HRC (1.12 lb/ft)	-	-	-	4'-0"	-
2" CRC (0.59 lb/ft)	-	-	5'-0"	-	-
2" HRC (1.26 lb/ft)	-	-	-	-	5'-0"
1/2" x 1/2" x 3/16" ST1	-	5'-0"	-	-	-

*For concrete construction only—a 10-gauge wire may be inserted in the joint before concrete is poured.

TABLE 4. HANGER SELECTION

MAX. CEILING AREA	MIN. HANGER SIZE
12 sq. ft.	9-gauge galvanized wire
16 sq. ft.	8-gauge galvanized wire
18 sq. ft.	3/16" mild steel rod*
25 sq. ft.	1/4" mild steel rod*
25 sq. ft.	3/16" x 1" steel flat*

*Rods galvanized or painted with rust inhibitive paint and galvanized straps are recommended under severe moisture conditions.

TABLE 5. TIE WIRE SELECTION

	SUPPORT	MAX. CEILING AREA	MIN. HANGER SIZE
Cross furring		8 sq. ft.	14-gauge wire
		8 sq. ft.	16-gauge wire (two loops)
Main runners	Single hangers between beams	8 sq. ft.	12-gauge wire
		12 sq. ft.	10-gauge wire
	Double wire loops at supports	16 sq. ft.	8-gauge wire
		8 sq. ft.	14-gauge wire
		12 sq. ft.	12-gauge wire
		16 sq. ft.	11-gauge wire

ERECTION OF METAL LATH SUSPENSIONS

Metal lath suspensions commonly are made below all types of construction for fire rated plaster ceilings. The lath is supported by framing channels and furring channels suspended with wire hangers from the floor or roof structure above. Framing channels normally are spaced up to 4 ft. o.c. perpendicular to joists and should be erected to conform with the contour of the finished ceiling. Framing channels normally are furred with 3/4 in. channels placed at right angles to the framing. Spacing varies by lath types and weights. The lath should be lapped at both sides and ends and secured to the 3/4 in. channels with wire ties every 6 in. Where plaster on metal lath ceilings abuts masonry walls, partitions, or arch soffits, galvanized casing beads should be installed at the periphery.

NOTE
The time required for field installation of furring and lath and the weight of a three-coat plaster finish are factors to consider when designing this system.

PLASTER DOME BUILT IN PLACE (VAULTS CONSTRUCTED SIMILARLY)

RUN-IN-PLACE CORNICE

BRACKETED CORNICE RUN IN PLACE WITH STUCK-ON ORNAMENT

TYPES OF ORNAMENTAL PLASTER

RUN-IN-PLACE: This type of ornament is moulded or applied in its final position while in its plastic state using a three-coat plaster system. This method requires installation of the furring, lath, base plaster coats, and finish plaster ornament and surfaces on site, a time-consuming process that results in relatively heavy assemblies. It is typically used to repair or replace sections of damaged existing and historic plaster ornament.

CAST PLASTER ORNAMENT: This type of ornament, which can be made in panels, is run, cast, or fabricated in a shop and installed after hardening. Joints between sections of ornament are finished in the field. Typically gypsum plaster reinforced with glass fibers, cast plaster is fabricated by laying or spraying the material into a mold. Castings are reinforced with jute rope, burlap, wood lath, or metal framing, depending on the casting size and installation methods. Controlled shop fabrication processes, reduced on-site time, and the ability to fabricate thinner, lighter sections often make this method less costly than run-in-place.

NOTES

MODELS: Models are the "positive" form of the cast ornament and can be fabricated from clay, plaster, or wood as necessary to achieve the desired appearance. When existing ornament is being matched, it can serve as the model.

MOLDS: Typically made of urethane or silicone rubber, molds from which ornament is cast are "negative" forms produced from models. Molds for run-plaster ornament are sheet metal templates cut to the profile of the molding and attached to a wood backing called a "slipper."

ATTACHMENT: Small cast ornament is typically applied using a plaster "slip" made of plaster and water as an adhesive. Large sections of cast plaster ornament are attached with screws or hung with metal hangers.

GLASS FIBER-REINFORCED GYPSUM CORNICE

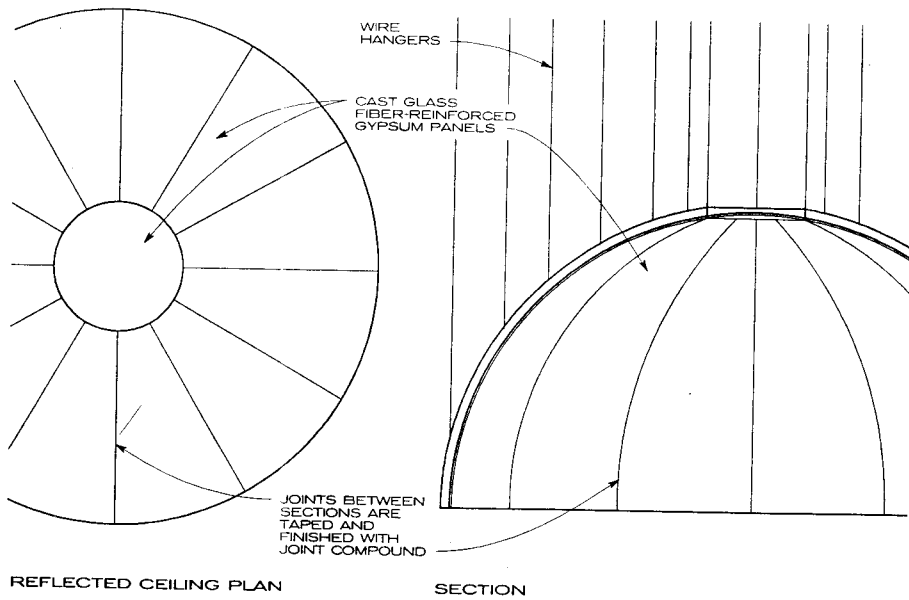

CAST PLASTER ORNAMENT ATTACHED WITH SCREWS

CAST PLASTER CORNICE AND BEAM SCREWED AND HUNG

Reed A. Black; Oehrlein & Associates; Washington, D.C.

TWO-PIECE GLASS FIBER-REINFORCED GYPSUM COLUMN

NOTE
 Cast fabrications are typically lighter and require less on-site construction time than built-in-place plaster systems. Large cast sections may require structural reinforcing and special cradles for fabrication, shipping, and erection.

CAST GLASS FIBER-REINFORCED GYPSUM DOME (VAULTS ARE SIMILAR)

COFFERED CEILING

NOTE
 Columns may be fabricated in one piece without joints and seams when they do not have to fit around the building structure.

TWO-PIECE CAST PLASTER COLUMN

TYPES OF GYPSUM PANEL PRODUCTS

DESCRIPTION	THICKNESS (IN.)	WIDTH/EDGE (FT)	STOCK LENGTH (FT)
Regular gypsum wallboard used as a base layer for improving sound control; repair and remodeling with double layer application	1/4	4, square or tapered	8-10
Regular gypsum wallboard used in a double wall system over wood framing; repair and remodeling	3/8	4, square or tapered	8-14
Regular gypsum wallboard for use in single layer construction	1/2, 5/8	4, square or tapered	8-16
Rounded taper edge system offers maximum joint strength and minimizes joint deformity problems	3/8 1/2, 5/8	4, rounded taper	8-16
Type X gypsum wallboard with core containing special additives to give increased fire resistance ratings. Consult manufacturer for approved assemblies	1/2, 5/8	4, tapered, rounded taper, or rounded	8-16
Aluminum foil backed board effective as a vapor barrier for exterior walls and ceilings and as a thermal insulator when foil faces 3/4" minimum air space. Not for use as a tile base or in air conditioned buildings in hot, humid climates (Southern Atlantic and Gulf Coasts)	3/8 1/2, 5/8	4, square or tapered	8-16
Water resistant board for use as a base for ceramic and other nonabsorbant wall tiles in bath and shower areas. Type X core is available	1/2, 5/8	4, tapered	8, 10, 12
Prefinished vinyl surface gypsum board in standard and special colors. Type X core is available	1/2, 5/8	2, 2 1/2, 4, square and beveled	8, 9, 10
Prefinished board available in many colors and textures. See manufacturers' literature	5/16	4, square	8
Coreboard for use to enclose vent shafts and laminated gypsum partitions	1	2, tongue and groove or square	8-12
Shaft wall liner core board type X with gypsum core used to enclose elevator shafts and other vertical chases	1, 2	2, square or beveled	6-16
Sound underlayment gypsum wallboard attached to plywood subfloor acts as a base for any durable floor covering. When used with resiliently attached gypsum panel ceiling, the assembly meets HUD requirements for sound control in multifamily dwellings	3/4	4, square	6-8
Exterior ceiling/soffit panel for use on surfaces with indirect exposure to the weather. Type X core is available	1/2, 5/8	4, rounded taper	8, 12
Sheathing used as underlayment on exterior walls with type X or regular core	1/2	2, tongue and groove	8
	1/2, 5/8	4, square	8, 9, 10

ROUNDED TAPER TYPES OF EDGES

MAX. BENDING FOR DRYWALL

THICKNESS	BENDING RADII	
	LENGTHWISE	WIDTH
1/4"	5'-0"	15'-0"
3/8"	7'-6"	25'-0"
1/2"	20'-0"	-

Shorter radii may be obtained by moistening face and back so that water will soak well into core of board.

MAXIMUM ALLOWABLE PARTITION HEIGHT (5 PSF LOADING, L240 DEFLECTION, 25 GA STUDS)

STUD SPACING (IN.) (FACING ON EACH SIDE)	STUD DEPTH (IN.)				
	1 3/8"	2 1/2"	3 3/8"	4"	6"
16 (1/2 one-ply)	9'-6"	12'-6"	16'-0"	17'-3"	20'-0"
24 (1/2 one-ply)	8'-3"	10'-9"	13'-6"	14'-3"	15'-0"
24 (1/2 two-ply)	8'-9"	11'-3"	13'-6"	14'-3"	15'-0"

* 1 3/8" stud with single layer of gypsum wallboard recommended for chase walls and closets only.

NOTE: A large range of adhesives, sealants, joint treatments, and texture products are available from the manufacturers of most gypsum board products. Consult available literature for current recommendations and products.

Face layer 3/8 in. type X gypsum board applied at right angles to studs, with 1 in. type S drywall screws spaced 12 in. o.c. Sound tested with 1 in. glass fiber friction fit in stud space. (NLB)	
2 HOURS	30 TO 34	2 1/4"	One layer 3/8 in. type X gypsum wallboard or veneer base applied vertically to each side of 1 in. gypsum board panels (solid or laminated) with laminating compound combed over entire contact surface. Panel supported by metal runners at top and bottom and horizontal bracing angles of No. 22 gauge galvanized steel 3/4 in. x 1 1/4 in. spaced 5 ft. 0 in. o.c. or less on shaft side. (NLB) *Limiting height shown is based on interior partition exposure conditions. Shaft wall exposure conditions may require reduction of limiting height.	
	35 TO 39	4 1/8"	Four layers 3/8 in. type X gypsum wallboard or veneer base applied at right angles to one side of 1 1/2 in. metal studs 24 in. o.c. Base layer attached to studs with 1 in. type S drywall screws 12 in. o.c. Second layer attached to studs with 1 1/2 in. type S drywall screws using only two screws per board. Third layer attached with 2 1/2 in. type S drywall screws similar to second layer. Steel strips 1 1/2 in. wide vertically applied over third layer at stud lines and attached 12 in. o.c. to studs with 2 1/2 in. type S drywall screws. Third layer also attached to top and bottom track with 2 1/2 in. type S drywall screws placed midway between studs. Face layer attached to steel strips with 1 in. type S drywall screws 8 in. o.c. at each stud. Stagger joints of each layer. (NLB)	
	40 TO 44	3 1/2"	1 in. x 24 in. proprietary type X gypsum panels inserted between 2 1/2 in. floor and ceiling J track with T section of 2 1/2 in. proprietary C-T metal studs between proprietary gypsum panels. Two layers of 1/2 in. type X gypsum wallboard applied to face of C-T studs. Base layer applied at right angles to studs with 1 in. type S drywall screws 24 in. o.c. and face layer applied at right angles to studs with 1 1/2 in. type S drywall screws 8 in. o.c. Stagger joints 24 in. o.c. each layer. (NLB)	
	45 TO 49	3 1/2"	1 in. x 24 in. proprietary type X gypsum panels inserted between 2 1/2 in. floor and ceiling track with tab-flange section of 2 1/2 in. metal I studs between proprietary gypsum panels. One layer of 1/2 in. proprietary type X gypsum wallboard or veneer base applied at right angles to each side of metal I studs with 1 in. type S drywall screws 12 in. o.c. Sound tested using 1 1/2 in. glass fiber friction fit in stud space. (NLB)	
	50 TO 54	4"	1 in. x 24 in. proprietary type X gypsum panels inserted between 2 1/2 in. floor and ceiling track with tab-flange section of 2 1/2 in. metal I studs between proprietary gypsum panels. One layer of 1/2 in. proprietary type X gypsum wallboard or veneer base applied at right angles to flanges of I studs adjacent to proprietary gypsum panels with 1 in. type S drywall screws 12 in. o.c. Resilient channels spaced 24 in. o.c. horizontally, screw attached to opposite flanges of I studs with 3/8 in. type S screws, one per channel-stud intersection. 1/2 in. proprietary type X gypsum wallboard or veneer base applied parallel to resilient furring channels with 1 in. type S drywall screws 12 in. o.c. Sound tested using 1 in. glass fiber friction fit in stud space. (NLB)	
3 HOURS	40 TO 44	4 1/8"	2 in. x 24 in. laminated gypsum board panels installed vertically between floor and ceiling 20 gauge J runners with 25 gauge steel H members between panels. Panels attached at midpoint to 2 1/2 in. leg of J runners with 2 1/2 in. type S-12 drywall screws. H studs formed from 20 or 25 gauge 2 in. x 1 in. channels placed back to back and spot welded 24 in. o.c. Base layer 3/8 in. gypsum wallboard or veneer base applied parallel to one side of panels, with 1 in. type S drywall screws 12 in. o.c. to H studs. Rigid furring channels horizontally attached 24 in. o.c. to H studs with 1 in. type S drywall screws. Face layer 3/8 in. gypsum wallboard or veneer base attached at right angles to furring channels with 1 in. type S drywall screws 12 in. o.c. Stagger joints 24 in. o.c. each layer and side. (NLB)	
	45 TO 49	5 1/4"	3/4 in. x 24 in. proprietary type X gypsum panels inserted between 2 1/4 in. floor and ceiling tracks and fitted to 2 1/4 in. slotted metal I studs with tab-flange. First layer 3/8 in. type X gypsum board applied at right angles to studs with 1 in. type S drywall screws 24 in. o.c. Second layer 3/8 in. type X gypsum board applied parallel to studs with 1 1/2 in. type S drywall screws 42 in. o.c. starting 12 in. from bottom. Third layer 3/8 in. type X gypsum board applied parallel to studs with 2 1/4 in. type S drywall screws 24 in. o.c. Resilient channels applied 24 in. o.c. at right angles to studs with 2 1/4 in. type S drywall screws. Fourth layer 3/8 in. type X gypsum board applied at right angles to resilient channels with 1 in. type S drywall screws 12 in. o.c. Sound tested with 1 in. glass fiber friction fit in stud space. (NLB)	

2 HOUR FIRE RATING

Two layers of 5/8 in. type X gypsum wallboard or veneer base around beam. Base layer attached with 1 1/4 in. type S drywall screws 16 in. o.c., face layer attached with 1 1/4 in. type S drywall screws 8 in. o.c. to horizontally installed U-shaped steel channels (25 gauge steel 1 1/16 in. wide and 1 in. legs) located not less than 1/2 in. from beam flanges. Upper channels secured to steel deck units with 1/2 in. type S pan head screws spaced 12 in. o.c. U-shaped brackets formed of steel channels spaced 24 in. o.c. suspended from the upper channels with 1/2 in. type S pan head screws and supported steel channels installed at lower corners of brackets. Outside corners of gypsum board protected by 0.020-in.-thick steel corner beads crimped or nailed. (2 hour restrained or unrestrained beam)

3 HOUR FIRE RATING

One layer 1/2 in. type X gypsum wallboard or veneer base applied at right angles to rigid furring channels with 1 in. type S drywall screws 12 in. o.c. Wallboard end joints located midway between continuous channels and attached to additional pieces of channel 54 in. long with screws at 12 in. o.c. Furring channels 24 in. o.c. attached with 18 gauge wire ties 48 in. o.c. to open web steel joists 24 in. o.c. supporting 3/8 in. rib metal lath or 3/16 in. deep, 28 gauge corrugated steel and 2 1/2 in. concrete slab measured from top of flute. Furring channels may be attached to 1 1/2 in. cold-rolled carrying channels 48 in. o.c. suspended from joists by 8 gauge wire hangers not over 48 in. o.c. (3 hour unrestrained beam)

1 HOUR FIRE RATING

Base layer 1/2 in. gypsum wallboard or veneer base tied to column with 18 gauge wire 15 in. o.c. Face layer 1/2 in. gypsum wallboard or veneer base applied with laminating compound over entire contact surface.

2 HOUR FIRE RATING

Base layer 1/2 in. type X gypsum wallboard or veneer base against flanges and across web openings fastened to 1 1/8 in. metal studs with 1 in. type S drywall screws 24 in. o.c. at corners. Face layers 1/2 in. type X gypsum wallboard or veneer base screw-attached to studs with 1 in. type S drywall screws 12 in. o.c. to provide a cavity between boards on the flange. Face layers across the web opening laid flat across the base layer and screw attached with 1 1/8 in. type S drywall screws 12 in. o.c. Metal corner beads nailed to outer layer with 4d nails 1 1/8 in. long, 0.067 in. shank, 1/16 in. heads, 12 in. o.c.

NEW WALL ASSEMBLIES

FIRE RATING	STC	WALL THICKNESS (IN.)	CONSTRUCTION DESCRIPTION	WALL SECTIONS
1 Hour	40	Varies	EXTERIOR WALL FURRING: One layer 5/8 in. aluminum foil-backed gypsum wallboard applied to 3/4 x 1 1/2 in. Z furring channel 24 in. o.c., vertically applied with method appropriate to exterior wall. Use 1 in. type S drywall screws 8 in. o.c. to edges and 12 in. o.c. to intermediate Z channel flange. Insulate cavity with 24 x 1 1/2 in. rigid foam.	
1 Hour	40	8 1/8	SECURITY WALL (15 minute): One base layer of 13-gauge steel expanded metal mesh with nominal 1 x 2 1/2 in. grid-spacing under one layer of 3/4 in. plywood applied to one side of 6 in. metal studs 8 in. o.c. with 1 1/2 in. screws. One face layer of 5/8 in. type X gypsum wallboard applied to each side with 1 in. type S drywall screws 12 in. o.c. Stagger joints 16 in. o.c. each layer and side.	
1 Hour	52	10 3/4	CAVITY WALL: One layer 5/8 in. type X gypsum wallboard applied to outside face of two rows of 1 5/8 in. metal studs (air space 9 1/2 in. between inside wallboard faces) 24 in. o.c. with 1 in. type S drywall screws 8 in. o.c. to edges and 12 in. o.c. to intermediate studs. Crossbrace at third points vertically with 5/8 in. wallboard gussets 9 1/2 x 12 in. Use 3 1/2 in. fiberglass insulation in cavity.	
1 Hour	47	3 1/2	PREFINISHED GYPSUM WALL PANELS: One layer, 1/2 in. type X prefinished vinyl surface gypsum wall panels (prebowed) applied vertically at joints to each side of 2 1/2 in. metal studs 24 in. o.c. with 1 in. type S drywall screws 30 in. o.c. Attach to intermediate studs with 3/8 in. bead of adhesive. Attach at top and bottom with 1 3/8 inch matching finish nails 12 in. o.c. Attach aluminum batten retainer to panels at studs with 1 in. type S drywall screws 12 in. o.c. Install matching finish batten over retainers and 2 in. glass fiber insulation in cavity. Stagger joints 24 in. o.c. each side.	
1 Hour	45	5	PREFINISHED GYPSUM WALL PANELS: Base layer 1/4 in. regular gypsum wallboard nailed to 2 x 4 wood studs 16 in. o.c. with 1 3/8 in. 4d coated nails, 12 in. o.c., fire stopped at mid-height. Face layer 1/2 in. type X prefinished vinyl surface gypsum wall panels (prebowed) applied vertically to each side with laminating compound and 5/8 in. drywall screws, 12 in. o.c., at top and bottom. Stagger joints 24 in. o.c. each layer and side. Cover exposed fasteners with suitable molding.	
2 Hour	50	5 3/4	WATER-RESISTANT WALL (ONE SIDE): One layer 5/8 in. water-resistant gypsum wallboard applied to wet side of 3 3/8 in. 20-gauge metal studs 16 in. o.c. with 1 in. type S drywall screws 12 in. o.c. Opposite side, two layers 5/8 in. gypsum wallboard installed vertically. Use 3 in. fiber insulation in cavity. Stagger joints 24 in. o.c. each layer and side.	
2 Hour	45	8 1/4	BULLET-RESISTANT WALL (ONE SIDE): Base layer of 1/4 in. steel plate bolted to each side of steel tube framed wall with 4 x 1/4 in. steel tube at top, bottom, and 4 ft o.c., horizontally. Two layers each side 5/8 in. type X gypsum wallboard on 7/8 in. furring channels 24 in. o.c. applied with 1 in. type S drywall screws. Stagger joints 24 in. o.c. each layer and side.	

NOTE

One layer 5/8 in. type X gypsum wallboard applied with 1 in. type S drywall screws perpendicular to the cross tees of a drywall suspension system suspended from a steel deck. Concrete floors 2 1/2 in. thick.

DRYWALL SUSPENSION SYSTEM

NOTE

Base layer 5/8 in. type X gypsum wallboard applied at right angles to 2 x 10 wood joists with 1 in. type S drywall screws 16 in. o.c. Resilient furring channels spaced 24 in. o.c. and nailed through baseboard into and at right angles to joists. Face layer of 5/8 in. same type wallboard screwed to furring channel with same type screws. Tongue-and-groove sub- and finish floor.

NOTE

Special shapes and dimensions are available in all tile types. Consult manufacturers for details.

SPECIAL TILE SHAPES

GENERAL

Tile used for architectural floor and wall applications are manufactured compositions of natural clay or mixtures of clay and other ceramic materials (e.g., shale and porcelain). Relatively thin in relation to their facial area, they can be textured, sculptured, embossed, patterned, or engraved on the surface and are available either glazed or unglazed.

Generally, tile dimensions are nominal. Check with manufacturers for specific dimensions.

DEFINITIONS

CERAMIC MOSAIC TILE is formed either by the dust-pressed or the plastic method. Usually 1/4 to 3/8 in. thick with a facial area of less than 6 sq in., it may be made of either porcelain or natural clay and may be plain or have an abrasive mixture throughout.

CONDUCTIVE TILE has specific properties of electrical conductivity but retains other normal physical properties of tile.

DECORATIVE THIN WALL TILE is a glazed tile with a thin body that is usually nonvitreous. It is suitable for interior decorative residential use when breaking strength is not a requirement.

WINDOWSILL OR STEP NOSING

PAVER TILE TRIM UNITS

GLAZED TILE has an impervious facial finish of ceramic materials that is fused to the body of the tile. The body may be nonvitreous, semivitreous, vitreous, or impervious.

IMPERVIOUS TILE has a water absorption rate of 0.5% or less.

MOUNTED TILE is assembled into units or sheets to facilitate handling and installation. Tile may be face-mounted, back-mounted, or edge-mounted. Material applied to the face of the tile usually is easily removed, but material bonded to the back is integrated into the tile installation.

NATURAL CLAY TILE is a ceramic mosaic or paver tile with a distinctive, slightly textured appearance. It is made by the dust-pressed or plastic method from clays that have a dense body.

NONVITREOUS TILE has a water absorption rate of more than 7%.

PAVER TILE is glazed or unglazed porcelain or natural clay tile formed by the dust-pressed method with a facial area of 6 sq in. (39 sq cm) or more.

PORCELAIN TILE is a ceramic mosaic or paver tile generally made by the dust-pressed method. It is dense, impervious, fine-grained, and smooth with a sharply formed face.

QUARRY TILE is glazed or unglazed tile made by the extrusion process from natural clay or shale. It usually has a facial area of 6 sq in. (39 sq cm) or more.

SEMVITREOUS TILE has a water absorption rate between 3 and 7%.

UNGLAZED TILE is a hard, dense tile of uniform composition that derives color and texture from the materials used to make it.

VITREOUS TILE has a water absorption rate between 0.5 and 3%.

WALL TILE is a glazed tile with a body suitable for interior use. Usually nonvitreous, it is not required or expected to withstand excessive impact or freezing and thawing conditions.

TYPES OF MORTAR

PORTLAND CEMENT MORTAR

A mixture of portland cement and sand (for floors) or lime (for walls) used for thick-bed installation.

DRY-SET MORTAR

A mixture of portland cement with sand and additives, imparting water retention that eliminates the need to soak tiles.

LATEX PORTLAND CEMENT MORTAR

A mixture similar to dry-set but with latex (an emulsion of polymer particles in water) added to replace all or part of the water in the mortar. It provides better adhesion, density, and impact strength than dry-set mortar, and it is more flexible and resistant to frost damage.

MODIFIED EPOXY EMULSION MORTAR

As with epoxy mortars, this mixture contains a resin and hardener along with portland cement and sand. Although it is not as chemically resistant as epoxy mortar, it binds well. Compared with straight portland cement, it allows little or no shrinkage.

METHODS OF INSTALLATION

In a thick-bed process tiles may be applied over a portland cement mortar bed $\frac{3}{4}$ to 2 in. thick. The thick-bed allows for accurate slopes or planes in the finished tile work and is not affected by prolonged contact with water. If the backing surface is damaged, cracked, or unstable, use a membrane between the surface and the mortar bed.

In a thin-set process, tiles are set or bonded to the surface with a thin coat of material varying from $\frac{1}{32}$ in. to $\frac{1}{8}$ in. thickness. Bonding materials include dry-set mortar, latex portland cement mortar, organic adhesive, epoxy mortar or adhesive, and modified epoxy emulsion mortar. Thin-set application requires a continuous, stable, and undamaged surface.

THIN-SET MORTAR WITHOUT PORTLAND CEMENT

EPOXY MORTAR

A two-part mixture (resin and hardener with silica filler) used where chemical resistance is important. It has high bond strength and high resistance to impact. This mortar and furan mortar are the only two that can be recommended for use over steel plates.

EPOXY ADHESIVE

Mixture similar to epoxy mortar in bonding capability, but not as chemical or solvent resistant.

ORGANIC ADHESIVE

A one-part mastic mixture that requires no mixing. It remains somewhat flexible (as compared with portland cement mortar), and has good bond strength but should not be used for exterior or wet applications.

FURAN MORTAR

A two-part mixture (furan resin and hardener) excellent for chemical resistant uses and its high temperatures (350°F) tolerance.

GROUT

Grout is used to fill joints between tiles and is selected with a compatible mortar. Types include:

PORTLAND CEMENT BASED GROUTS

Include commercial portland cement grout, sand-portland cement grout, dry-set grout, and latex portland cement grout.

EPOXY GROUT

A two- or three-part mixture (epoxy resin hardener with silica sand filler) highly resistant to chemicals. It has great bond strength. This grout and furan grout are made for different chemical and solvent resistance.

FURAN RESIN GROUT

A two-part furan mixture (similar to furan mortar) that resists high temperatures and solvents.

SILICONE RUBBER GROUT

An elastomeric mixture of silicone rubber. It has high bond strength, is resistant to water and staining, and remains flexible under freezing conditions.

Use over solid backing, over wood or metal studs. Preferred method for showers and tub enclosures. Ideal for remodeling.

CEMENT MORTAR

Use for remodeling or on surfaces that present bonding problems. Preferred method of applying tile over gypsum plaster or gypsum board in showers and tub enclosures.

ONE-COAT METHOD

Use over gypsum board, plaster, or other smooth, dimensionally stable surfaces. Use cementitious backer units in wet areas.

DRY-SET MORTAR

Use over gypsum board, plaster, or other smooth, dimensionally stable surfaces. Use water-resistant gypsum board in wet areas.

ORGANIC ADHESIVE

WALL DETAILS

Use over dry, well-braced studs or furring. Preferred method of installation in showers and tub enclosures.

CEMENT MORTAR

Use in dry interior areas in schools, institutions, and commercial buildings. Do not use in areas where temperatures exceed 125°F.

LATEX - PORTLAND CEMENT MORTAR

Use in wet areas over well-braced wood or metal studs. Stud spacing not to exceed 16 in. o.c., and metal studs must be 20 gauge or heavier.

DRY-SET MORTAR (CEMENTITIOUS BACKER)

Use where a fire resistance rating of 2 hours is required with tile face exposed to flame. Stud spacing not to exceed 16 in. o.c. and mortar dry-set minimum thickness $\frac{3}{32}$ in.

DRY-SET MORTAR (FIRE-RATED WALL)

VERTICAL AND HORIZONTAL EXPANSION JOINTS

Tile Council of America, Inc.; Princeton, New Jersey
Jess McIlvain, AIA, CCS, CSI; Jess McIlvain and Associates; Bethesda, Maryland

Use over structural floors subject to bending and deflection. Reinforcing mesh mandatory; mortar bed 1 1/4 to 2 in. thick and uniform.

CEMENT MORTAR

Use on level, clean slab-on-grade construction where no bending stresses occur and expansion joints are installed. Scarify existing concrete floors before installing tile.

DRY-SET OR LATEX PORTLAND CEMENT MORTAR

FLOORING DETAILS—CEMENT

Use over wood floors that are structurally sound and where deflection, including live and dead loads, does not exceed 1/360 of span.

CEMENT MORTAR

Use in residential, light commercial, and light institutional construction. Recommended where resistance to water, chemicals, or staining is needed.

EPOXY MORTAR AND GROUT

FLOORING DETAILS—WOOD

TILE SHOWER RECEPTOR

Use where moderate chemical exposure and severe cleaning methods are used, such as in commercial kitchens, dairies, breweries, and food plants.

EPOXY MORTAR AND GROUT

Use over concrete floors in residential construction only. Will not withstand high impact or wheel loads. Not recommended in areas where temperatures exceed 140°F.

ORGANIC OR EPOXY ADHESIVE

Use in light commercial and residential construction, deflection not to exceed 1/360, including live and dead loads. Waterproof membrane is required in wet areas.

DRY-SET MORTAR

Use over wood or concrete floors in residential construction only. Not recommended for use in wet areas.

ORGANIC ADHESIVE

BLEND PATTERN

SIDE-SLIP OR END PATTERN

END-MATCH, BOOK-MATCH, OR QUARTER-MATCH PATTERNS

MARBLE WALL FACING PATTERN

MARBLE WALL FACING PATTERNS

Stone with distinctive texture and markings, such as certain marbles, lends itself to specific pattern arrangements. The markings vary depending on whether the marble veneer is cut with or across its setting bed.

BLEND PATTERN: Panels of the same variety of stone, but not necessarily from the same block, are arranged at random.

SIDE-SLIP OR END-SLIP PATTERN: Panels from the same block are placed side by side or end to end in sequence to give a repetitive pattern and blended color in the horizontal or vertical.

END-MATCH OR BOOK-MATCH PATTERNS: In an end-match pattern, the adjacent faces of panels A and B are finished and panel B is inverted above panel A. In a book-match pattern, panel B is placed next to panel A.

VENEER CUTTING

Quarry blocks are reduced to slabs by a gang saw. The gang saw consists of a series of parallel steel blades in a frame that moves forward and backward. The most productive and precise gang saws use diamond-tipped blades with individual hydraulic blade tensioners; others are fed a cutting abrasive in a stream of water.

Marble blocks can be sawn either parallel or perpendicular to the bedding plane. The perpendicular cut is referred to as an across-the-bed or vein cut. The parallel cut is a with-the-bed or Fleuri cut. Other marbles produce a pleasing surface only when sawn in one direction and are generally available only in that variety.

VENEER PATTERNS

Only certain marbles lend themselves to specific pattern arrangements, such as a side-slip or end-slip pattern, which require a constant natural marking trend throughout the marble block. Formal patterns require selectivity, which usually increases the installed cost of the marble veneer. Usually, material sawn for a vein cut can be matched; Fleuri cuts can only be blended.

NOTE

Although the above arrangements of matched panels indicate an almost perfect match of veining lines, such perfection is impossible because a portion of the marble block is lost during the sawing process and because the vein shifts. Ideally, jointing should be planned for groupings of four panels of equal size.

TYPICAL FINISHES AND COMMON SIZES OF STONE WALL PANELS FOR INTERIOR USE

STONE	GRADE	FINISH	MIN. THICKNESS (IN.)	MAX. FACE DIMENSION (IN.)	NOTES
Granite	Building (exterior) Veneer Masonry	Polished Honed	3/4 - 1 1/4 *	5 x 5	<ul style="list-style-type: none"> This very hard and durable surface is not likely to stain. Many colors and grains are available.
Marble	Group A (exterior) Group B Group C Group D	Polished Honed	1/2 - 3/8 *	4 x 7	<ul style="list-style-type: none"> The most colorful and interesting marbles are in groups B, C, and D; however, some filling of natural voids may be required. Many colors and patterns are available.
Limestone	Select Standard Rustic Variegated	Smooth Tooled Polished	7/8 - 3	4 x 9	<ul style="list-style-type: none"> Soft and easy to shape, limestone shows wear and may discolor over time. Colors range in the buffs and grays.
Slate	Ribbon Clear	Natural cleft Sand rubbed Honed	1 - 1 1/2	2 - 6 x 5	<ul style="list-style-type: none"> Ribbon stock is distinguished by its ornamental, integral bands, which are usually darker than the rest of the stone. Colors range in the pastel hues.

* 1/4 - 1/2 in. tiles (usually a face dimension of 12 in. x 12 in.) available. Tiles can be directly applied to a wall with adhesive or thin-set mortar similar to flooring applications. Tiles are not recommended for walls over 8 ft high.

NOTES

1. Sizes and thicknesses shown are only indicative of some of the common sizes and thicknesses used. Intended use and size generally dictate minimum thickness.

2. Joint width between panels should be specified. Traditionally, it has been 1/16 in. minimum.

FINISHES

POLISHED: A glossy surface that brings out the full color of the stone. Generally, polished finishes can only be used on hard, dense material such as granite or marble.

HONED: A satin smooth surface with little or no gloss.

THERMAL: A planar surface with flame finish applied by mechanically controlled means to ensure uniformity. Surface coarseness varies depending on the grain structure of the stone. Generally, thermal finishes are used on granite.

RUBBED: A planar surface with occasional slight scratches.

MARBLE AND GRANITE PATTERNS

TYPICAL FINISHES AND COMMON SIZES OF STONE TILES AND PAVERS

STONE	FINISH	THICKNESS (IN.)(MIN.)	FACE DIMENSION (IN.)(MAX.)	HA
Granite	polished	$\frac{3}{8}$ - $\frac{1}{2}$ (tiles)	12 x 12 (tiles)	N/A
	honed thermal	$1\frac{1}{4}$ - 4 (pavers)	15 x 30 (pavers)	
Marble	polished	$\frac{1}{4}$ - $\frac{1}{2}$ (tiles)	12 x 12 (tiles)	10
	honed	$1\frac{1}{4}$ (pavers)	24 x 24 (pavers)	
Limestone	smooth	$1\frac{3}{4}$ - 2 $\frac{1}{2}$ (pavers)	24 x 36 (pavers)	10
Slate	natural cleft	$\frac{1}{4}$ - 1	12 x 12 to 24 x 54	8
	sand-rubbed			
Flagstone	natural cleft semirubbed	$\frac{1}{2}$ - 4	12 x 12 to 24 x 36	8

NOTES

1. *Ha*, the abrasive hardness value, is the reciprocal of the volume of the material abraded multiplied by ten. A minimum value of 10 is recommended for flooring. Stones with a difference of 5 or more in *Ha* value should not be used together because they will wear differently.
2. Joint width should always be specified; $\frac{1}{16}$ to $\frac{1}{8}$ in. is considered standard.
3. Only attempt to set stone flooring over a wood subfloor after the subfloor has been reinforced to ensure against deflection.

4. Lippage is a condition that occurs when tiles are installed with a thin-bed method over an uneven surface. Tiles may "lip," one edge higher than their neighbors, giving the finished surface a ragged appearance. In some conditions, a certain amount of lippage is unavoidable. As a general rule, the recommended maximum variation of the finished surface should be no more than $\frac{3}{16}$ in. cumulative over a 10 ft. 0 in. lineal measurement, with no more than $\frac{1}{32}$ in. variation between individual tiles.

Mark Forma; Leo A. Daly Company; Washington, D.C.

NOTE
In colder climates, protection against frost expansion may be necessary.

EXTERIOR STAIR SECTION

METAL PAN WITH STONE SAFETY TREAD

STEEL SUBTREAD AND RISER WITH STONE TREAD

WALL STRINGER

OPEN STRINGER

STONE STAIRS WITH STEEL FRAME

STONE SANDWICH FLOOR PANEL (PREFAB)

STONE STAIRS WITH CONCRETE FRAME

DESIGN FACTORS FOR STONE STAIRS

Stone used for steps should have an abrasive resistance of 10 (measured on a scale from a minimum of 6 to a maximum of 17). When different varieties of stone are used, their abrasive hardness should be similar to prevent uneven wear.

Dowels and anchoring devices should be noncorrosive. If a safety tread is used on stairs, a light bush hammered soft finish or nonslip finish is recommended.

To prevent future staining, dampproof the face of all concrete or concrete block, specify low alkali mortar, and provide adequate drainage (slopes and weep holes).

STONE THRESHOLDS

Eric K. Beach; Rippeteau Architects, PC; Washington, D.C.
Building Stone Institute; New York, New York; George M. Whiteside, III, AIA, and James D. Lloyd; Kennett Square, Pennsylvania

Terrazzo is a material composed of stone chips and cement matrix and is usually polished. There are four generally accepted types, classified by appearance:

1. **STANDARD TERRAZZO:** The most common type; relatively small chip sizes (#1 and #2 size chips).
2. **VENETIAN TERRAZZO:** Larger chips (size #3 through #8), with smaller chips filling the spaces between.
3. **PALLADIANA:** Random fractured slabs of marble up to approximately 15 in. greatest dimension, 3/8 to 1 in. thick, with smaller chips filling spaces between.
4. **RUSTIC TERRAZZO:** Uniformly textured terrazzo in which matrix is depressed to expose chips, not ground or only slightly ground.

MATRIX DATA

Two basic types exist: portland cement and chemical binders. Color pigments are added to create special effects. Limeproof mineral pigments or synthetic mineral pigments compatible with portland cement are required. Both white and grey portland cement is used depending on final color.

CHEMICAL BINDERS

All five types of chemical binders provide excellent chemical and abrasion resistance, except for latex, which is rated good.

1. **EPOXY MATRIX:** Two component resinous matrix.
2. **POLYESTER MATRIX:** Two component resinous matrix.
3. **POLYACRYLATE MATRIX:** Composite resinous matrix.
4. **LATEX MATRIX:** Synthetic latex matrix.
5. **CONDUCTIVE MATRIX:** Special formulated matrix to conduct electricity with regulated resistance, use in surgical areas and where explosive gases are a hazard.

PRECAST TERRAZZO

Several units are routinely available and almost any shape can be produced. Examples include: straight, coved, and splayed bases; window sills; stair treads and risers; shower receptors; floor tiles; and wall facings.

STONE CHIPS

Stone used in terrazzo includes all calcareous serpentine and other rocks capable of taking a good polish. Marble and onyx are the preferred materials. Quartz, granite, quartzite, and silica pebbles are used for rustic terrazzo and textured mosaics not requiring polishing.

SAND CUSHION TERRAZZO

BONDED TERRAZZO

MONOLITHIC TERRAZZO

THIN-SET TERRAZZO

DIVIDER STRIPS

TERRAZZO BASE

TERRAZZO SYSTEMS

TERRAZZO SYSTEM	MINIMUM ALLOWANCE FOR FINISH	MINIMUM WEIGHT/ SQ FT	CONTROL JOINT STRIP LOCATION	SUGGESTED PANEL SIZE AND DIVIDER STRIP LOCATION	COMMENTS
Sand cushion terrazzo	2 1/2"	27 lb	At all control joints in structure	9 to 36 sq ft	Avoid narrow proportions (length no more than twice the width) and acute angles
Bonded underbed or strip terrazzo	1 3/4"	18 lb	At all control joints in structure	16 to 36 sq ft	Avoid narrow proportions as in sand cushion
Monolithic terrazzo	1/2"	7 lb	At all control joints in structure and at column centers or over grade beams where spans are great	At column centers in sawn or recessed slots maximum 24 x 24 ft	T or L strips usually provide decorative feature only
Thin-set terrazzo (chemical binders)	1/4"	3 lb	At all control joints	Only where structural crack can be anticipated	
Modified thin-set terrazzo	3/8"	4 1/2 lb	At all control joints	Only where structural crack can be anticipated	
Terrazzo over permanent metal forms	Varies, 3" minimum	Varies	Directly over beam	Directly over joist centers and at 3 to 5 ft on center in the opposite direction	
Structural terrazzo	Varies, 4" minimum	Varies	At all control joints at columns and at perimeter of floor	Deep strip (1 1/2 in. min.) at all column centers and over grade beams	Use divider strip at any location where structural crack can be anticipated

NOTES

1. Venetian and Palladiana require greater depth due to larger chip size; 2 3/4 in. minimum allowance for finish 28 lb/sq ft.
2. Divider and control joint strips are made of white alloy of zinc, brass, aluminum, or plastic. Aluminum is not satisfactory for portland cement matrix terrazzo; use brass and plastic in chemical binder matrix only with approval of binder manufacturer.
3. In exterior terrazzo, brass will tarnish and white alloy of zinc will deteriorate.

John C. Lunsford, AIA; Varney Sexton Sydnor Architects; Phoenix, Arizona

LINEAR METAL CEILINGS

PANS

Dimensions: Typical widths range from 4 to 8 inches (100 to 200 mm).

Materials: Roll-formed sheet steel is for interior applications only; roll-formed aluminum can be used for interior or exterior applications.

Surface: Surfaces can be smooth, perforated or unperforated, or textured.

Finish: Baked polyester enamels, metallic coatings, and brushed or polished aluminum with a clear coating are available.

CARRIERS

Material: Roll-formed sheet steel is for interior use only, while roll-formed aluminum is suitable for interior or exterior applications.

Finish: The finish is flat black baked polyester enamel.

ACCESSORIES

Possible accessories include integral light fixtures and air diffusers, trim channels, splices, and end caps.

OPTIONS

Fire-rated and acoustically rated systems are available.

EXTERIOR APPLICATIONS OF LINEAR METAL CEILINGS

Wind loads must be factored in when exterior applications of linear metal ceilings and soffits are planned. Wind loads are determined by geographic conditions and a building's height above the ground. Linear metal systems must be engineered to withstand uplift pressure. Rigid bracing is used instead of suspension wires to support these systems.

LINEAR BAFFLE CEILINGS

Steel or aluminum baffles hung from a suspended ceiling framework mask exposed plenum areas. Baffles are available in a variety of profiles and depths ranging from 4 to 12 inches (100 to 300 mm).

TYPES OF ACOUSTICAL CEILING UNITS

ACOUSTICAL TILE

These prefabricated, sound-absorbing ceiling units are installed in a concealed suspension system or directly attached to the substrate with adhesive or staples. Typical size is 12 by 12 inches (305 by 305 mm).

ACOUSTICAL PANEL

These prefabricated, sound-absorbing ceiling units are installed in a suspension system. Typical sizes are 24 by 24 inches (610 by 610 mm) and 24 by 48 inches (610 by 1210 mm).

CONSTRUCTION OF ACOUSTICAL CEILING UNITS

CAST (MOLDED)

These ceiling units are composed of mineral fibers, fillers, binders, and water mixed together to form a slurry. The slurry is cast on trays and heat cured. The pattern and sound-absorbing qualities are created by the treatment of

the material face in the wet stage. After drying, acoustical units are painted; if color is added to the slurry, the unit will be colored throughout.

NODULAR

Nodular tiles are composed of mineral fibers, perlite, fillers, binders, and water mixed together to form a dry slurry. The slurry is formed into sheets, dried, and cut. The surface is inherently porous and is subsequently textured by mechanical fissuring and embossing; ceiling units are then painted.

WET-FELTED

Wet-felted tiles are composed of mineral fibers, fillers, binders, and water mixed together to form a slurry. The slurry is poured onto felts, drained, compacted, dried, and cut. Textures are created by mechanical perforation, fissuring, and stippling. Surface finishes include paint, fabric, polyester film, and vinyl-coated aluminum.

GLASS FIBER WITH FACING

This type of tile consists of nonwoven fiberglass insulation with a fabric or vinyl film surface finish.

SPECIAL FLOORING

Special flooring manufacture is a constantly changing industry with myriad products and companies. Choose products to meet the requirements of a specific application after consultation with manufacturers. Select a well-established, reputable manufacturer with a tested and proven product. Have the product installed by experienced, factory-trained personnel.

RESINOUS FLOORING

EPOXY RESIN FLOORING: This abrasion- and impact-resistant, broadcast and/or trowel-applied, two-component epoxy resin floor is made of graded aggregates and mineral oxide pigments. Typical thicknesses are 1/8 and 1/4 in. Epoxy resin flooring can be applied to a variety of substrates and usually cures overnight, depending on the humidity. It is chemical resistant, fire retardant, and odor free and may be made slip resistant with a satin finish.

ACRYLIC RESIN FLOORING: This two- or three-component system is based on methyl methacrylate acrylic (MMA) resins; it has a low VOC. Four types are available in varying thicknesses: primer/sealers (8-10 mils), coatings (1/16 in.), toppings (1/16 - 3/16 in.), and overlays (1/16 - 3/8 in.). The system comprises graded aggregates, mineral oxide pigments, and pigmented topcoats. Typically, a 1/8 in. thick floor is sufficient for light loads and pedestrian traffic and a 1/4 in. thick floor is required for normal to heavy loads. Heavy-duty loads require a floor 1/2 in. thick or thicker. Uses include animal housing/runs, industrial, institutional, coolers/freezers, cafeterias, food preparation, and multipurpose recreational facilities.

LATEX RESIN FLOORING: This trowel-applied, jointless floor offers low absorption and good chemical resistance. Chemical-resistant types are available to handle a variety of anticipated chemical spills. A waterproof membrane may be used to make the floor entirely waterproof, and it may be turned up at the base to form an integral covered base. Uses include showers, laboratories, animal research housing, pharmaceutical plants, and TV studios.

MAGNESIUM OXYCHLORIDE FLOORING

This is a fireproof, trowel-applied, seamless, hard surface floor that is slip resistant in both wet and dry locations. Durable and simple to install, it is used primarily in commercial kitchens and manufacturing locations such as welding shops. Its use is not recommended when standing water or mineral corrosives will be present. The standard color is red, although some earth tones may be available.

EPOXY MARBLE CHIP FLOORING AND SEAMLESS QUARTZ FLOORING

This seamless decorative flooring consists of ceramic-coated quartz or colored quartz aggregates in clear epoxy. It may be broadcast or trowel-applied in thicknesses of 1/16, 1/8, or 1/4 in. Available in a wide range of aggregate colors, it may be slip resistant and is typically installed over concrete substrate. It is used in laboratories, locker rooms, and light manufacturing and institutional locations.

ELASTOMERIC LIQUID FLOORING

Conductive elastomeric liquid flooring—a multiple- or single-part system applied over concrete, metal, or wood substrates—consists of elastomeric resins, nonsparking aggregates, and a carbon or metallic conductive agent. Typically applied in thicknesses of 1/4 or 1/2 in., it may be applied to a wide variety of substrates and in a series of coats to achieve a smooth finish. Durable, easy to install, jointless (no divider strips), and waterproof are characteristics of this type of floor.

Elastomeric liquid flooring is designed to provide static control and spark resistance that can prevent electrostatic damage to electronic products as well as the conductivity required to prevent fire or explosions in high-hazard environments. The slab and conductive surface must be grounded and the floor well maintained in order for the floor to keep the required conductivity and static dissipative properties. Typical installations requiring these qualities include clean rooms and electronic manufacturing and assembly facilities. Typical installations requiring the conductive capabilities of elastomeric liquid flooring include arsenals, ammunition plants, chemical processing facilities, and hazardous explosive areas. End user static control and spark resistance must be clearly specified to ensure appropriate levels of resistance. People working in these environments must wear conductive footwear.

EPOXY RESIN FLOORING

ACRYLIC RESIN FLOORING

LATEX RESIN FLOORING

MAGNESIUM OXYCHLORIDE FLOORING

EPOXY MARBLE CHIP/ SEAMLESS QUARTZ FLOORING

ELASTOMERIC LIQUID FLOORING

PLASTIC LAMINATE FLOORING

ASPHALT TILE FLOORING
FLOOR COATINGS

PLASTIC LAMINATE FLOORING

Plastic laminate flooring generates and retains low static levels. It has a low sheen, matte finish. Durable, flexible, and easily maintained, it is used exclusively as the top finish surface for access flooring. Applied to access floor substrates of steel, aluminum, wood, or particleboard with moisture-resistant adhesives, this type of flooring consists of a formulated, washable, surface sheet over a melamine-impregnated printed pattern sheet with core layers of phenolic-impregnated kraft paper. Typical tile size is 24 x 24 in., with standard thicknesses of 1/16, 5/64, and 1/8 in., depending on load. Three quality grades are available. Floors must meet or exceed ANSI, NEMA, and NFPA codes and criteria.

ASPHALT PLANK FLOORING

A smooth, heavy-duty, comfortable, long-lasting, low maintenance tile floor, asphalt plank flooring is used in post offices, warehouses, and industrial locations. Tiles are set in adhesive troweled over a concrete substrate. An acrylic protective base coat is applied in two to three layers after the tiles have been set. A topcoat of two to three layers is applied to give the floor a high gloss for easier maintenance. Standard tile size is 1/2 x 12 x 24 in. Other available thicknesses are 1/4 - 3 in. Standard available colors are black and red.

MASTIC FILLS

Products described in other categories may also be considered in this one. Examples include self-adhering floor or deck coatings, traffic toppings, and underlayers that also fill cracks or uneven surfaces. Taken literally, this heading can include "mud set" mortar for tile over uneven substrates.

FLOOR TREATMENT

METALLIC-TYPE STATIC-DISSEMINATING AND SPARK-RESISTANT FINISH

This product is designed to provide static-control properties and spark-resistance capabilities that can prevent electrostatic damage to electronic products, as well as the conductivity required to prevent fire or explosions in high-hazard environments. Maintenance of the floor is critical in order to keep the required conductivity and static-dissipative properties. Typical installations requiring static-dissipative products include clean rooms and electronic manufacturing and assembly facilities. Typical installations requiring conductive products include arsenals, ammunition plants, and chemical processing and other explosive hazardous areas. End user static control and spark resistance must be clearly specified to ensure appropriate levels of resistance. People working in these environments must wear conductive footwear.

Dry-shake metallic floor hardener is blended with plasticizing agents and conductive binders. This blend is applied to the surface of plastic concrete and becomes an integral part of the floor surface. It can be applied with a mechanical spreader, by hand, or with a shovel. Concrete admixture, air content, and floor finish requirements are strictly defined by metallic floor hardener manufacturers in terms of compatibility and amount, etc.

SLIP-RESISTANT FLOOR TREATMENT

These cementitious or noncementitious coatings are specifically designed to provide a nonskid finish for interior or exterior floors. Silica or synthetic aggregates provide the nonskid capability. The treatment is formulated for use on concrete or masonry surfaces and may be brushed or rolled on or trowel- or fluid-applied.

MORTARED BRICK PAVERS ON WOOD FRAMING

MORTARLESS BRICK PAVERS ON WOOD FRAMING

MORTARED BRICK SLAB

MORTARLESS BRICK PAVERS ON CONCRETE SLAB

MORTARED BRICK PAVER ON CONCRETE SLAB

TRANSVERSE SECTION LONGITUDINAL SECTION

REINFORCED BRICK MASONRY SLABS

LIVE LOAD (PSF)	MAXIMUM CLEAR SPAN		
	$t = 2 \frac{1}{4}$ IN. 1 #2 EACH JOINT	$t = 3 \frac{1}{2}$ IN. 1 #2 EACH JOINT	$t = 6 \frac{1}{4}$ IN. 1 #3 EVERY 3RD JOINT 1 #2 OTHER JOINTS
30	6'-10"	10'-5"	14'-5"
40	6'-3"	9'-9"	13'-8"
50	5'-10"	9'-2"	13'-1"
100	4'-6"	7'-3"	10'-11"
250	1'-10"	5'-0"	7'-10"

NOTES

1. Design parameters for the table above: The compressive strength average of the brick is 8000 psi. The mortar is type M (1:1/4:3), portland cement:lime:sand. Reinforcement steel is ASTM A 82-66, $f_y = 20,000$ psi. A simple span loading condition was assumed.

$$M = \frac{wl^2}{8}$$

2. All mortar joints are 1/2 in. thick for the slabs shown, except as noted.

BRICK PAVERS ON STEEL DECK

TYPICAL BRICK AND CONCRETE PAVER TYPE AND NOMINAL SIZE

Brick pavers: 4 x 4 in., 4 x 8 in., 4 x 12 in.; 1/2 to 2 1/2 in. thick. Concrete pavers: 12 x 12 in., 12 x 24 in., 18 x 18 in., 18 x 24 in., 2 3/8 to 3 in. thick.

NOTES

1. Brick paving assemblies are classified by type of paving surface and type of base supporting the surface. Interior brick paving may be adapted to suspended diaphragm bases, reinforced brick structural slabs with mortar joints, and conventional concrete slabs on grade.
2. In residential wood joist design, the additional weight of brick pavers must be considered to ensure selection of a suitable grade and joist size. For mortared paving, deflection and diaphragm action must be considered in order to maintain the integrity of the mortar joints.

CONCRETE PAVERS ON CONCRETE SLAB

3. Reinforcement of brick masonry paving can eliminate the need for a separate reinforced concrete slab or other rigid base. Reinforced brick paving can be used to span an open space and is a practical system for relatively short spans. For continuous span application, an assembly combining both reinforced brick masonry and steel decking can be used.
4. Maintenance: Brick floors are abrasion resistant and hard-wearing. Coatings and waxes are desirable on interior brick floors, where they enhance appearance and make surfaces easier to clean. Prewaxing brick pavers on the exposed face facilitates cleaning, and applying a sealer locks in loose sand particles and provides an impervious finish.

PARQUET FLOOR PATTERNS

NOTES

1. Flooring can be manufactured from practically every commercially available species of wood. For marketing purposes in the United States, wood flooring is roughly grouped according to species and region. Various grading systems are used with various species, and often specifications differ for boards of different sizes in a given species. For instance, recommended nail size and spacing vary among the several board sizes typically available in oak.
2. Use information given here for preliminary decision-making only. Precise specifications must be obtained from a supplier or from the appropriate industry organization (see table above).
3. Several considerations regarding selection and installation of wood flooring are applicable throughout the industry; these are illustrated on this page.
4. The table above shows typical grades and sizes of boards by species or regional group. Grade classifications vary, but in each case it can be assumed that the first grade listed is the highest quality and that the quality decreases with each succeeding grade. The best grade typically minimizes or excludes features such as knots, streaks,

NOTE
Cross-sectional dimensioning systems vary among species, patterns, and manufacturers. Trade organizations provide percentage multipliers for computing coverage.

CROSS-SECTIONAL DIMENSIONS

spots, checks, and torn grain and will contain the highest percentage of longer boards. Grade standards have been reduced in recent years for practically all commercially produced flooring, hence a thorough review of exact grade specifications is in order when selecting wood flooring.

5. End matching gives a complete tongue-and-grooved joint all around each board. Board length is reduced as required to obtain the matched ends.

- TONGUE AND GROOVE**
- NOTES**
1. Jointed flooring must be face nailed, usually with fully barbed flooring brads.
 2. Tongue-and-grooved boards are blind nailed with spiral floor screws, cement-coated nails, cut nails, or machine-driven fasteners; follow the manufacturer's recommendations.

FASTENING

PARQUET FLOORING

THICKNESS (IN.)	FACE DIMENSIONS (IN.)
Individual strips	
5/16	2 x 12 typical strips can be cut, mitered, etc. to obtain pieces required for special patterns
Square panels	
5/16 (most common), 7/16, 1 1/16, 3/4	6 x 6, ±6 1/2, x ±6 1/2, 12 x 12, 19 x 19; other sizes available from certain manufacturers

Rippeteau Architects, P.C.; Washington, D.C.

GENERAL

Wood flooring is visually attractive and provides an excellent wearing surface; however, wood requires particular care in handling and installation. Minimize moisture damage to wood floors by avoiding proximity to wet areas. In addition, installation of wood floors should occur after all "wet" jobs have been completed and after the heating plant and all permanent lighting have been installed to ensure constant temperature and humidity.

Expansion and contraction is a fact of life for most wood flooring. Perimeter base details that allow for movement and ventilation are included in the details on this page. Wood structures require adequate ventilation in basements and crawl spaces. Under a slab on or below grade, moisture control can be further enhanced by use of a vapor barrier; this provision should be carefully considered for each installation.

Wearing properties of wood flooring vary from species to species and should be considered along with appearance when specifying wood floors. In addition, grain pattern affects the durability of a given species. For instance, industrial wood blocks are typically placed with the end grain exposed because it presents the toughest wearing surface. The thickness of the wood above the tongues in tongue-and-groove flooring may be increased for extra service.

EXPANSION PLATE AT DOORWAY/ JOINT WITH DISSIMILAR CONSTRUCTION

STRIPS OVER PLYWOOD UNDERLAYMENT

PRESSURE-SENSITIVE "DO-IT-YOURSELF" PANELS (PREFINISHED)

STRIPS OVER VENTILATED SLEEPERS

STRIPS OVER STAGGERED 2X4 SLEEPERS

DOUBLE COURSE OF SLEEPER STRIPS

STRIPS OVER CUSHIONED SLEEPERS

NOTE
Provide a vapor barrier under a slab on grade.

METAL CHANNEL RUNNERS WITH CLIPS

NOTE
Typical blocks are 3 x 6 in. up to 4 x 8 in. with depths of 2 to 4 in. Urethane finish coats are available for nonindustrial uses.

INDUSTRIAL WOOD BLOCK

PARQUET BLOCKS SET IN MASTIC

NOTE
For parquet flooring, the subfloor must be 3/4 in. tongue-and-groove plywood, minimum, with mastic over it.

STRIPS OVER SUBFLOOR ON WOOD JOISTS

GENERAL

The wood flooring types shown on this page are those most commonly used for sports facilities. The specifics of each floor system differ from manufacturer to manufacturer. Some flooring systems are proprietary and protected by patents. Manufacturers can custom configure flooring systems for special uses.

The type of wood sports flooring chosen for a particular situation depends on the following criteria:

1. Cost
2. The performance of the floor
3. Sport(s) to be played on the floor
4. Other uses to which floor will be put
5. Durability
6. The environment in which the floor will be used

GRADES OF WOOD SPORTS FLOORING

Maple is the wood most commonly used for sports flooring in the United States. Maple sports flooring is available in three grades, which designate only the appearance of the floor and not its performance or durability.

FIRST GRADE: nearly free of defects; least color variation, with very little dark hardwood; used in premier sports venues where appearance is of primary concern.

SECOND AND BETTER: may have tight, sound knots and other slight imperfections and some color variation; floor has a generally light appearance.

THIRD GRADE: all defects and color variations permitted; floor is mostly dark heartwood; used when cost is a consideration.

MAPLE FLOOR SYSTEM CHARACTERISTICS

SYSTEM	COST	PERFORMANCE	DURABILITY	STABILITY
Proprietary	High	High	High	High
Sprung	High	High	Medium	High
Sleeper	Medium	Medium	Medium	High
Cushioned	Low	Medium	High	Medium
Channel	Low	Low	High	High
Mastic	Low	Low	High	Medium

FINISHES AND GAME LINES

Wood sports floors are sanded, sealed, and finished with at least two coats of sealer and two coats of finish.

Game lines are painted between the last coat of sealer and the first coat of finish. Game line paint must be compatible with sealer and finish.

60 Revere Drive, Suite 500
Northbrook, IL 60062

NOTES

1. Lowest cost
2. Easy to install
3. Suitable for multipurpose applications
4. Use where floor performance is not critical

MASTIC APPLIED SYSTEM

NOTES

1. Good performance characteristics
2. Relatively low cost
3. Susceptible to moisture damage

CUSHIONED SYSTEM

NOTES

1. Good performance
2. Can have dead spots
3. Susceptible to moisture damage
4. More difficult installation

SLEEPER SYSTEM

NOTES

1. Superior performance
2. Dimensionally stable
3. Suitable for multipurpose applications
4. A higher cost system

PROPRIETARY FLOATING SYSTEM—ROBBINS BIO-CHANNEL®

NOTES

1. Dimensionally stable in all environments
2. Good multipurpose floor
3. Limited performance characteristics

CHANNEL AND CLIP SYSTEM

NOTES

1. Low cost
2. Fast installation
3. Dimensionally stable in all environments
4. Good multipurpose floor
5. Limited performance characteristics

NAIL-IN-CHANNEL SYSTEM

NOTES

1. Superior performance
2. High cost
3. Susceptible to moisture damage
4. More difficult installation

SPRUNG SYSTEM

NOTES

1. Superior performance
2. Dimensionally stable
3. Suitable for multipurpose applications
4. A higher cost system

PROPRIETARY SYSTEM—CONNOR/AGA REZILL CHANNEL®

RESILIENT FLOORING DETAILS

PREPARING THE BASE

The primary issue concerning resilient flooring is preparation of an adequate base. Resilient flooring has no structural properties and will gradually conform to the topographies of the underlying surface. Bumps will "telegraph" through new flooring. Cracks in the substrate will result in cracks in the resilient flooring.

Rising damp will defeat resilient flooring. Properly cured slabs above grade are excellent substrates for resilient flooring. Slabs on grade and below grade must be proofed against groundwater. Tips for preparation of various base types follow:

NEW CONCRETE FLOORS: Allow a 30-day curing period. Apply sealer to the slab.

OLD CONCRETE FLOORS: Verify damp control. Remove all existing surface coatings. Wirebrush and sweep dusty, porous surfaces, and apply primer.

LIFT SLABS: Remove curing compounds before resilient flooring is installed.

PREPARING OLD WOOD FLOORS

TYPE OF SUBFLOOR		COVER WITH
Single wood floor	Tongue and groove not more than 3 in.	Hardboard or plywood, 1/4 in. or heavier
	Not tongue and groove	Plywood 1/2 in. or heavier
Double wood floor	Strips 3 in. or more	Hardboard or plywood 1 in. or heavier
	Strips less than 3 in., tongue and groove	Renail or replace loose boards, remove surface irregularities

BACKGROUND

The word "carpet" comes from the Latin *carpere*, "to-card wool." Carpet production in the U.S. has grown from 100 million square yards in 1910 to over 1 billion square yards in the 1990s. Three events account for the increase.

1. 1930s: man-made fibers developed
2. 1950s: tufting replaced weaving
3. 1960s: tufting machine combined with piece dyeable bulked continuous filament (BCF) nylon. This gave the industry the ability to produce carpet styles with long color lines of up to 50 or more colors without large inventory costs.

CARPET FIBERS

Until the 1930s, nature accounted for 100% of face fiber production for floor coverings. The uncertain supply of desirable wools from about 20 countries, as well as variation in fiber length and increasing costs of scouring and processing, encouraged development of man-made fibers. Man-made fibers are easy to clean, mildew resistant, moth-proof, and nonallergenic.

WOOL

Of 1992 U.S. carpet production, 1% was wool. Its qualities have been copied but never quite duplicated. The natural tendency of animal fibers to stretch and return to their original length makes wool carpet resilient, with excellent recovery from crushing. Problems of supply make it the most expensive fiber and the only one requiring antimoth treatment.

COTTON

Negligible current usage. Tufted carpet was an offshoot of the "tufted" bedspread cottage industry in the South and had single-color, loop, or cut-pile fibers made of cotton.

NYLON

Of 1992 carpet production, 80% was nylon, a petrochemical engineered for carpet use, with easy dyeing characteristics. Successfully introduced into carpet in continuous filament, it was later cut and processed in staple lengths (like wool) to give more natural qualities to the finished product. Recent developments combine topical treatments with modified extrusions to give antisoil properties to the fibers. Adequate maintenance provisions should accompany specifications for these products, since soil will cause fiber damage unless removed by vacuuming and cleaning.

ACRYLIC

Negligible current usage. This hydrocarbon synthetic is considered to be the most wool-like of all man-made fibers.

POLYPROPYLENE (OLEFIN)

Of 1992 production, 12% and growing. This man-made hydrocarbon normally lacks resilience and the ability to be post-dyed. Its simplified extrusion capabilities plus the ability to be solution-dyed prior to extrusion, encouraged many carpet makers to install polypropylene fiber-making facilities.

POLYESTER

Of 1992 production, 7%. A high tensile strength synthetic made by the esterification of ethyl glycol, it has easy care and water-repellent qualities.

CARPET CONSTRUCTION

Woven carpet represents 2% of the total carpet production in the U.S. today. Whether hand-knotted, loomed, or mechanically produced, there are many similarities in production methods. The side-to-side progression in hand-knotted production is accelerated in a loom as the shuttle propels the weft (or wool) yarn back and forth over the 12 or 15 ft width of the finished carpet. This is missing in tufted and later methods. Common to all, however, is a progression of the leading edge of this 12-15 ft finished width in the direction of manufacture. This sets up the direction of lay of the finished face fibers, always in the opposite direction. The exception is in hand-knotted carpet, where the direction of lay of the face fibers falls to one side or the other, depending on the style of knot; the direction of lay changes during cleaning to follow the direction of brushing.

In tufted or woven broadloom, it is imperative that the direction of lay run in the same direction within a continuous installation. Otherwise, adjacent pieces, although perfectly seamed, will appear mismatched in color and texture.

VELVET CONSTRUCTION

AXMINSTER CONSTRUCTION

WILTON CONSTRUCTION

KNITTED CONSTRUCTION

FLOCKED CONSTRUCTION

NEEDLEPUNCHED CONSTRUCTION

TUFTED CONSTRUCTION

FUSION BONDED CONSTRUCTION

CONSTRUCTION MODES

VELVET: Simplest of all carpet weaves. Although the simplicity of the loom does not permit patterned designs, beautiful yarn color combinations can produce tweed effects. Pile forms as the warp yarns loop over removable "wires" inserted consecutively across the loom (weft-wise). Alternate height wires create high-low loop texture, while wires with a raised knife blade at the trailing end are used to create cut-pile upon retraction.

AXMINSTER: Has a smooth cut-pile surface, with almost all of the yarn appearing on the surface. Colors and patterns are limited only by the number of tufts in the carpet. Identifying feature is the heavy ribbed backing that only allows the carpet to be rolled lengthwise.

WILTON: Basic velvet loom, improved in the early 1800s by a Jacquard mechanism that feeds yarn through as many as six separate punched hole patterns to vary the texture or colored design. Uses only one color at a time on the surface; the other yarns remain buried; thus the reputation that Wiltons have a hidden quality because of the extra "hand" or feel this gives the finished carpet.

KNITTED: Resembles weaving in that knitted carpet is a warp-knitted fabric composed of warp chains, weft-forming yarns, and face yarns and is knitted in single operation. Warp chain stitches run longitudinally and parallel to each other. The backing yarns are laid weft-wise into the warp stitches and pass over three or four rows of warp stitches overlapping in the back of the carpet for strength and stiffness. As in tufted carpet, latex is applied to the back for stability and tuft lock. An additional backing may also be attached. Knitted carpets usually are solid colors or tweeds, with level loop textures.

FLOCKED: Made by propelling short strands of pile fiber (usually nylon) electrostatically against an adhesive-coated, prefabricated backing sheet (usually jute). As many as 18,000 pile fibers per inch become vertically embedded in the adhesive before a secondary backing is laminated to the fabric and the adhesive is cured. The pile fibers can be dyed prior to flocking or the finished surface can be printed after fabrication.

NEEDLEPUNCHED: First made of polypropylene fibers in solid colors for outdoor use (patios and swimming pools), they are now made for indoor and automotive use as well, using wool, nylon, acrylic, and/or olefin fibers in variegated colors and designs. They are made by impinging loose layers of random, staple carpet fibers into a solid sheet of polypropylene, from both sides, by means of thousands of barbed needles until the entire mass is compressed to a solid, bonded fiber mass of indoor/outdoor carpet.

TUFTED: This technique developed from an early method for making tufted bedspreads. Spacing of as many as 2000 needles on a huge sewing machine (12-15 ft wide) determines the carpet gauge. Face yarn is stitched through the primary backing, where it is bonded to a secondary backing with latex before curing in a drying oven. To conserve energy, some mills substitute hot-melt adhesive for latex, though this results in a loss of ability to pass flammability tests. "Single needle" tufting machines have a small stitching head that moves from side to side during carpet construction. They are used mainly for special orders for odd-shaped spaces to eliminate installation waste.

FUSION BONDED: This process produces dense cut-pile or level-loop carpet in solid or moresque colors. For cut-pile, the face yarn, fed simultaneously from the total width of the supply roll, or "beam," is folded back and forth between two vertically emerging primary backings as they are coated with a viscous vinyl paste that hardens, binding the folded face yarns alternately to the vertical backing sheet on each side. Final operation is a mid-line cutting that separates the vertical "sandwich" into two identical cut-pile finished rolls. To make loop-pile fusion-bonded carpet, one primary backing and the cutting operation are omitted. Fusion bonding is especially suited to making carpet tiles.

ORIENTAL RUGS: Defined by Oriental Rug Retailers of America as "a rug of either wool or silk, knotted entirely by hand by native craftsmen in some parts of Asia, from the shores of the Persian Gulf, north to the Caspian Sea, and eastward through Iran, the Soviet Union, Afghanistan, Pakistan, India, China, and Japan." An Oriental rug is classed an antique if it is more than 75 years old, semi-antique if less than 75 years old, and new if made in the past 15 years.

Dhurrie and Kilim rugs are flat woven rugs; they usually cost less than hand-knotted Orientals. They can be either machine- or hand-made and have primitive as well as modern designs. Other types of rugs are ryas from Scandinavia, Native American woven rugs, and Greek flatotakis. Braided and rag rugs are also available. Many carpet and rug makers offer custom designs (some computer aided) in a variety of fibers and modes of construction.

Neil Spencer, AIA; North Canton, Ohio

USES FOR CARPET

Carpet may be used in locations other than the floor. Tapestries, traditionally hung on walls, were useful as well as beautiful: they prevented through-wall drafts and were acoustically beneficial. In modern use, edges of full room carpeting may be upturned and used as a wall base. Used with wood trim and glued, carpet may be used in a wainscot, wall, or ceiling panel application. Flame-resistance of carpet should be checked before specifying.

STRETCH-IN TACKLESS

Over separate cushion. Best condition for maximum carpet wear and most effective cleaning.

DIRECT GLUE DOWN

For large surface areas that make power-stretching and tackless installations prohibitive. Adhesive must be tailored to match carpet backing and substrate, as recommended by carpet manufacturer.

DOUBLE GLUE DOWN

Developed to counter early fiber failure, occurring in direct glue-down carpets in heavy traffic areas, due to lower than normal resilience level of man-made fibers. Provides ease of large area coverage plus benefits of separate pad.

CARPET CUSHION OR UNDERLAYMENT

Four major categories of carpet cushion are

1. Felt padding
2. Sponge rubber
3. Urethane foam
4. Foam rubber

Four reasons for considering separate carpet cushion in wall-to-wall installations are

1. Adds as much as 50% to the life of the carpet.
2. Absorbs as much as 90% of the traffic noise.
3. Can reduce installation costs by eliminating need for repairs to imperfect substrate.
4. Improves thermal environment by insulation, which varies depending on material.

ACCESSIBILITY FOR PERSONS WITH DISABILITIES

Carpet should be securely attached, have a firm underlayment (if provided), and have a level loop, textured loop, level cut pile, or level cut/uncut pile texture. The maximum pile thickness should be 1/2 in. (13 mm). Exposed edges should be fastened to floor surfaces and have trim along the entire length of the exposed edge. Carpet edge trim should not exceed 1/2 in. in height; if more than 1/4 in., the trim should be beveled 1:20.

Neil Spencer, AIA; North Canton, Ohio

NOTE

If rolling traffic is a factor, carpet may be of maximum density for minimum resistance to rollers. Select only level loop or dense low cut pile for safety.

FIBER CHARACTERISTICS

FEATURES	NYLON	POLYPROPYLENE	POLYESTER	ACRYLIC	WOOL
Durability	EX	EX	VG	G	VG
Soil Resistance	G	F	F	F	G to EX
Resilience	G to EX	P	G	F	EX
Abrasion resistance	EX	EX	EX	G	G
Cleanability	VG	VG	VG	VG	VG

EX - Excellent, VG - Very good, G - Good, F - Fair, and P - Poor.

MAINTENANCE PROGRAMMING

The following maintenance-related factors should be considered in the selection of carpet:

COLOR: Carpets in the mid-value range show less soil than very dark or very light colors. Consider the typical regional soil color. Specify patterned or multicolored carpets for heavy traffic areas in hotels, hospitals, theaters, and restaurants.

TRAFFIC: The heavier the traffic, the heavier the density of carpet construction.

TOPICAL TREATMENT: The soil-hiding qualities of advanced generation fibers do not reduce the need for regular maintenance. Regular cleaning is important to remove hidden dirt that may contribute to early fiber failure.

PLACEMENT: The location of carpeted areas within a building affects the maintenance expense. Walk-off carpet areas can help reduce tracked-in soil near entrances.

DEFINITIONS

CARPET TILES: Square 18 to 36 in. modules, dense cut-pile or loop, heavy backed. Can be made to cover flat, regular wiring, low-voltage lighting systems ("safe-lites"), or under-floor utilities.

CARPET WEAR: As defined by fiber manufacturers, refers to percentage of face fiber lost over the life of a guarantee.

COMMERCIAL: Includes all contract, institutional, transportation; any use where carpet is specified by other than the end user.

RESIDENTIAL: Includes all carpet specified and purchased for residential use by the owner.

LIFE CYCLE COSTING: Permits comparison of diverse flooring methods by totaling initial cost, installation, and detailed predictable maintenance expenses over the expected life of the carpet.

TRAFFIC: Expressed in terms of floor traffic (person) per unit of time or as light, medium, or heavy, to define need for matching carpet construction, which normally increases in density as traffic increases. See table at left.

PILE HEIGHT: Height of loop or tuft from the surface of the backing to the top of the pile, measured in fractions, or decimals, of an inch.

PILE WEIGHT (face weight): Total weight of pile yarns in the carpet (measured in oz/sq yd excluding backing).

PILE DENSITY: D = 36 times the finished pile weight, in oz/yd, divided by the average pile height.

$$\text{WEIGHT DENSITY (WD)} = \frac{(\text{Face weight})^2 \times 36}{\text{Pile height}}$$

PITCH (in woven carpet): The number of yarn ends in a 27 in. finished width of carpet.

GAUGE: In tufted carpet, the number of needles per inch across the width of the finished carpet.

STITCHES: Number of rows of yarn ends per inch, finished carpet. Tufts per sq in.: Calculation made by multiplying pitch x wires for woven carpet, or gauge x stitches per inch for tufted.

DERNIER: Weight in grams of 9000 meters (9750 yd) of a single extruded filament of nylon. Based on the standard weight of 450 meters of silk weighing 5 centigrams.

FILAMENT: Continuous strand of extruded synthetic fiber, combined into a "singles" yarn by simply twisting, without the need for spinning.

PLY: Refers to the number of strands of "singles" yarn twisted together (for color or texture) to create a two-ply or three-ply yarn system.

POINT: A single tuft of carpet tile.

BCF: Bulked continuous filament.

CUT-PILE PATTERN: Plush or saxony type carpet with woven, tufted, or printed design or pattern.

LEVEL LOOP: Carpet made from uncut tufts in looped form and having all tufts the same pile height.

CUT-PILE VELVET: Solid color, tweed, or heather blend yarns that give smooth velvety or velour texture.

CUT AND LOOP: Carpet with areas of both cut pile and loop pile, most often with the cut pile being higher than the loop.

FREEZE: Cut pile carpet made from highly twisted yarns that are heat-set to give a curled random configuration to the pile yarns.

PRIMARY BACKING: The matrix used in making tufted carpet, consisting of woven or nonwoven fabric, usually jute or polypropylene, into which pile yarn tufts are stitched.

SECONDARY BACKING: The woven or nonwoven material adhered to the underside of a carpet during construction to provide additional tuft bind for tufted carpet and dimensional stability and body. Usually jute, or polypropylene, latex foam, or vinyl.

WALL-COVERING MATERIALS

NOTES

- In some installations, fabric-wrapped panel systems have advantages over standard adhesive-applied wall coverings. There is generally less damage to the original wall surface, less surface preparation is needed, and an acoustical or tackable wall panel (which improves the STR or NRC rating of a wall) can be added to a room and concealed behind the fabric wrapping. In addition, the fabric or backing panel can be easily changed.
- For wrapped panels, fabric or other wall covering should cure to room temperature and humidity conditions before installation.
- Instruct installer to cut and hang three test panels for architect's inspection and approval before cutting other material from the roll.
- The following terms apply to wall coverings:
 - Bolt: typically three continuous rolls of wall covering
 - Double cutting: trimming method that overlaps edges and forms a butt joint with a single cut
 - Single roll: from 30 to 36 sq ft wall covering
 - Double roll: from 60 to 72 sq ft wall covering
 - Railroading: installing wall covering in horizontal direction
 - Underlayment: any paper, fabric, or other liner material used to prepare a wall for installation of a wall covering
- Avoid exposed wall-covering edges. Specify continuous metal or plastic edge trim where required; wrap covering into any reveals that occur.

FIBER CHARACTERISTICS FOR FABRIC WALL COVERINGS (RATING SCALE OF 1-5)

FIBER/FABRIC	TYPE	DESCRIPTION/SOURCE	GENERAL PROPERTIES							
			DIMENSIONAL STABILITY	RESILIENCY AND ELASTICITY	STRENGTH	ELECTRICAL CONDUCTIVITY	HEAT CONDUCTIVITY	ABSORBENCY	MOISTURE REGAIN	SPECIFIC GRAVITY
Cotton	Natural	Soft, fibrous matter from seed pod of cotton plant	5	2	3	5	5	5	7 to 11%	1.54
Linen	Natural	Strong, lustrous yarn or fabric from the flax plant	5	1	4	5	1	5	8 to 12%	1.52
Wool	Natural	Protein fiber of hair taken from sheep	1	5	1	2	2	5	15%	1.32
Silk	Natural	Single filament protein fiber extruded from silkworm	5	4	4	2	2	4	11%	1.25
Acetate	Man-made	Modified cellulosic fibers	2	1	1	3	3	2	6%	1.32
Viscose rayon	Man-made	Regenerated cellulosic fiber made from wood or other pulp	3	1	1	4	4	5	11 to 14%	1.50 to 1.53

Polyester	Man-made	Petroleum-based synthetic polymer	5 ^d	5	5	1	1	1 ^e	0.2 to 0.8%	1.38

NOTES

- The ratings for these charts use the following numerical system of 1 to 5, "1" meaning the property or resistance level is least applicable and "5" meaning the property or resistance level is most applicable. Also the following notes apply to the charts:
 - Hydrogen peroxide below 90°F will harm fiber.
 - Petroleum products safe; acetone harmful to fiber.
 - Will degrade if wet.
 - Carpet beetles will attack fabric.
 - Hydrogen peroxide is not harmful to fiber.
 - Fabric may shrink at high temperatures.
 - Long exposure will degrade fabric.
 - May shrink at high temperatures if not heat set.
 - Fabric will wick moisture.
 - Fabric is resistant if behind glass.
 - Will harm at high temperatures and concentrations.
- These charts are a general guide to the most significant performance-related properties of common untreated or natural fibers. There are many other properties associated with fibers and, particularly, fabrics, which can have many fiber-blend permutations. Consult the fabric manufacturer for those properties (and ASTM results) relevant to the individual installation.
- Care must be taken in cleaning any fabric used in an architectural installation. Consult fabric manufacturer for recommended cleaning procedures.
- The following are definitions of various terms used in the charts:

Strength—evaluated in terms of breaking, tearing, or bursting strength.

Electrical conductivity—the ability of a fiber or fabric to carry or transfer electrical charges. Low conductivity fabrics build up static electrical charge.

RESISTANCE LEVELS OF FIBER/FABRIC (RATING SCALE OF 1-5)

FIBER/FABRIC	RESISTANCE LEVEL OF FIBER/FABRIC TO				
	INSECTS AND MICROORGANISMS	OXIDIZING AGENTS (CHLORINE BLEACHES)	ORGANIC DRY CLEANING SOLVENTS (NAPHTHA, ETC.)	SUNLIGHT	AGE
Cotton	5 ^c	1	5	2	5
Linen	5 ^c	1	5	1	4
Wool	1	1	5	2	5
Silk	5 ^d	2 ^a	5	1	2
Acetate	4	5 ^a	5 ^b	2	4
Viscose rayon	not applicable	2	5	2	5
Olefin	5	not applicable	1	2	5
Acrylic	5	5 ^a	5	5	5
Nylon	5	not applicable	1	4 ^a	5
Polyester	5	5	5	4 ^b	5

- Heat conductivity—the ability of a fiber or fabric to carry or transfer heat.
- Specific gravity—related to the weight of a fiber, expressed as the density of the fiber in relation to the density of an equal volume of water at 40°C.
- Consult standards developed by the Association for Contract Textiles, the American Society for Testing and Materials, and the American Association of Textile Chemists and Colorists to establish performance guidelines for commercially installed textiles:

VERTICAL APPLICATION—Direct glue wall coverings

 - Flammability: ASTM E84 rated (see local code for building occupancy ratings).
 - Colorfastness to light: AATCC 16A or E/class 4 minimum at 40 hours.

- Colorfastness to wet and dry crocking: AATCC 8 class 3 minimum.
- VERTICAL APPLICATION—Panel or upholstered applications
- Flammability: ASTM E84 rated (see manufacturer and local code for specific applications).
 - Breaking/tensile strength: ASTM D3597, 50 pounds minimum/warp and weft directions.
 - Yarn/seam slippage: ASTM D3597, 25 pounds minimum/warp and weft directions.
 - Colorfastness to light: AATCC 16A or E/class 4 minimum at 40 hours.
 - Colorfastness to wet and dry crocking: AATCC 8/class 3 minimum.

NOTES

1. In these types of fabric panels the fabric is permanently bonded to the substrate and/or core material. Panels can be manufactured to any size or shape with any corner or edge details; aluminum edge frames can be added for extra stiffness.
2. Panels are fastened to wall surfaces with magnets, foam tape, hook and loop, liquid adhesive, mechanical metal strip, or clip, with optional base support brackets.

PREFABRICATED FABRIC-WRAPPED PANELS

WALL COVERING INSTALLATION

When selecting a wall covering, it is necessary to consider the installation location, traffic patterns, light sources (both natural and man-made), and acoustical requirements. Consider the following when preparing a wall:

1. Wall covering weights vary from 7 to 12 oz per square yard (Type I); 13 oz per square yard (Type II); and 22 or more oz per square yard (Type III). The limited thickness and opacity of Type I and II materials may make wall surface imperfections and colors visible.
2. Before fabrics or other pervious wall coverings are installed, they are usually backed with a paper layer or liquid-applied acrylic coating to prevent seam slippage and adhesive bleed-through, as well as to increase stability and provide a neutral background for light-colored wall coverings. Backings allow the wall covering to be applied with conventional paper-hanging techniques.
3. Wall surfaces should be clean, smooth, dry, and structurally intact. Low spots should be filled and sanded, loose paint and other coverings removed, glossy surfaces sanded to roughen them slightly, and all dust removed.
4. The proper wall primer should be used on wall surfaces, particularly new gypsum wallboard. Not all water-based adhesives can be used over latex paint primer. Consult manufacturers for compatibility of adhesives and primer materials.
5. There are three basic adhesive types: wheat-based (the traditional paste, no longer popular), clay-based (traditionally used for heavy-duty applications), and vinyl (formulated for improperly prepared or problem wall surfaces).
6. When specifying adhesives, ask manufacturers and installers for recommendations to prevent buckling, sagging, delamination, and environmental considerations such as off-gassing.

ESTIMATING WALL COVERING MATERIALS

Wall coverings can be estimated by two methods:

Square Foot Method (no pattern repeat):

1. Measure the length of all walls and calculate the total.
2. Multiply the total combined length of the walls by the greatest wall height rounded up to the nearest foot to determine the total wall area.
3. Add 15% to the total area to account for waste.
4. Find the total area of all doors and windows wider than the width of a strip of wall covering.
5. Subtract total door and window area from total wall area. This will be the approximate square foot amount of wall covering required.
6. Divide the approximate square foot amount of wall covering by the number of square feet in each roll or bolt (refer to manufacturer's literature) to determine the number required for each job.

Panel Method (patterns and materials with highly visible seams):

1. Determine the trimmed width of material (54 in. wide becomes 52 in. wide).
2. On a scaled floor plan, place vertical seams in locations not less than 6 in. from inside and outside corners.
3. Adjust seam locations as necessary for desired seam arrangement, then count the panels. Count partial-width panels as whole widths.
4. Determine the panel height by measuring the floor-to-ceiling height and adding one pattern repeat for vertical patterns.
5. Multiply the number of panels by the adjusted panel height to determine the total material length required.
6. For wall coverings sold by linear yard, divide total length by three to determine the number of yards needed to complete the work. For wall coverings sold by the square foot, convert the total length of material into square feet and divide by the number of square feet in each roll or bolt (check with manufacturer).

SPECIAL ACOUSTICAL SYSTEMS

SOUND ISOLATION

When it is necessary to isolate a high noise area from a building or a "quiet room" from a high surrounding noise level, floors, walls, and ceilings should be built free of rigid contact with the building structure to reduce sound and vibration transmission.

CUSTOM WALLS

Auditoriums, concert halls, and other special acoustically conditioned space may require both absorptive and reflective surfaces and, in some cases, surfaces that can be adjusted for varying absorption coefficients to "tune" the space.

SPECIAL PATTERNS AND PROFILES

Screen printed, scored, and face-cut acoustical panels with a variety of edge treatments are available in narrow profile, tegular ceilings. Compatible grid systems, some offering features to facilitate partition and equipment attachment, install in similar fashion to conventional T-bar components.

LOOSE BATTS

USE: Reduce sound transmission through or over partitions; installed over suspended acoustical tile. Also used between gypsum wall partitions.

MATERIALS: Expanded fiberglass or mineral fiber.

STC: Based on total designed system; can range from 40 to 60.

**ISOLATION HANGER
CEILING ISOLATION HANGER**

Isolates ceilings from noise traveling through the building structure. Hangers are also available for isolating ceiling systems to shield spaces from mechanical equipment and aircraft noise.

PERFORATED METAL CEILING

METAL PAN CEILING

**LINEAR METAL CEILING
METAL CEILINGS**

USE: Sound absorption depends on batt insulation. MATERIALS: Bent steel, aluminum, or stainless steel. NRC: 0.70 to 0.90. FINISH: Painted, anodized, or stainless steel.

PANEL TYPES

WALL TREATMENT

ACOUSTICAL MASONRY UNITS

1. USE: sound absorption and diffusion.
2. MATERIALS: concrete masonry units 4, 6, 8, or 12 in. thick, with fiberglass or metal baffle in the slotted area for sound absorption; quadratic residue sequence shaped surface for sound diffusion.
3. NRC: 0.45 to 0.85.

NOTE

Acoustical masonry units are available with glazed, split rib, and ground face masonry finishes. The units offer better sound absorption at low frequencies than at middle to high frequencies and can be used as load-bearing structural walls. Painting slightly reduces the NRC rating of these units.

ACOUSTICAL MASONRY UNITS

DIFFUSIVE WALL TREATMENT

1. USE: sound diffusion/scattering.
2. MATERIALS: factory-assembled wood, fiberglass, or fiberglass-reinforced gypsum panels with integrally shaped surfaces.
3. NRC: typically less than 0.30.
4. THICKNESS: up to 18 in. depending on panel shape.

NOTE

Wall panels may be used individually or grouped to form a monolithic wall system. Panels function best if they are installed 4 ft. above the floor surface (ear height) and extend to a minimum of 8 ft. above the floor surface. Maximum panel size varies with the manufacturer up to 4 x 8 ft.

DIFFUSIVE WALL TREATMENT

ABSORPTIVE WALL TREATMENT

1. USE: sound absorption.
2. MATERIALS: factory- or field-assembled fabric wrapped glass fiber or mineral wood panels.
3. NRC: 0.55 to 1.0.
4. THICKNESS: one, two, or four inches.
5. PANEL TYPES: absorptive, high-impact, tackable, and special acoustical characteristics.
6. EDGE PROFILES: square, bevel, radius, and chamfer.
7. EDGE REINFORCEMENT: chemical treatment, metal, plastic, and wood.
8. INSTALLATION HARDWARE: mechanical clips, impaling pins, magnetic fasteners, hook and loop tape, and adhesives (the last two require installation of a metal angle at panel bottom to carry the weight of the panel).

NOTE

Wall panels may be used individually or grouped to form a monolithic wall system. The NRC coefficient varies with the thickness of the material, the acoustical transparency of the fabric, and the installation mounting. Panels are more effective at absorbing mid- and high-frequency sound. Vinyl facing over an acoustical core increases low-frequency absorption and decreases mid- and high-frequency absorption. Panels are not recommended for installation in high abuse areas unless perforated metal or high-density scrim facing protects the acoustical core. Maximum panel size varies with the manufacturer up to 4 x 12 feet.

SPRAY-ON ACOUSTICAL MATERIAL

1. USE: sound absorption.
2. MATERIALS: aerated concrete, mineral, or cellulose fibers spray-applied to metal lath or directly to hard surfaces such as concrete, steel, masonry, or gypsum wall-board.
3. NRC: 0.35 to 1.0.

NOTE

This material is available in thicknesses of 1/2 to 1 1/2 in. with abuse-resistant surfaces and fire protection ratings. Applying spray-on acoustical material to lath increases low-frequency sound absorption and makes it possible to accommodate irregular shapes. The NRC rating of this material depends on how it is mounted and the thickness of the material.

SPRAY-ON ACOUSTICAL MATERIAL

Michael G. Lawrence, AIA; M Lawrence Architects; Washington, D.C.
Neil Thompson Shade; Acoustical Design Collaborative, Ltd.; Falls Church, Virginia

GENERAL

Sound travels in waves through matter. Sound transmission can be reduced by interfering with the travel and reflection of sound waves. The details on this page show methods of dampening sound waves by reducing reflection, increasing absorption, and/or providing a mass barrier.

COMPOSITION OF COATINGS

GENERAL

Coatings are thin surface facings applied in liquid form which solidify to protect building components from harmful exposure. Appropriate coating selection depends upon performance, appearance, cost, and rate of deterioration of the substrate should the coating fail. Coatings are made up of the prepared substrate, prime coats or undercoats, and finish or topcoats, all of which should be compatible for adhesion and resistance to deterioration.

DESIGN CONSIDERATIONS

Environmental and ambient conditions affect coating performance. Resistance to sun, moisture, pollution, chemicals, extremes of temperature, soiling, and abrasion will determine a set of coatings, from which a selection is made based on remaining criteria. Design considerations should also include:

1. Flow, or ease of application.
2. Leveling or smoothing after application.
3. Drying time, of which two factors are important: (a) set-to-touch or surface drying, when surface resists contaminants, and (b) through-dry, when all layers are dry and ready to recoat.
4. Permeability: moisture migration through coating.
5. Wetting: penetration of coating to a lower level. Lower wetting ability requires greater surface preparation.
6. Film thickness: amount of protection provided by coating.
7. Adhesion between layers.
8. Flexibility: accommodation to changes in moisture and temperature.
9. Abrasion, impact, and stain resistance and ease of cleaning.

TYPES

Coatings are classified by appearance—clear, semitransparent, or opaque, and are water-based or organic solvent-based. Coatings are composed of a vehicle—alone when clear, or with pigments when semitransparent or opaque. The vehicle is in turn composed of binder and solvent. The binder is the nonvolatile part of the vehicle which forms the film of the coating and which bonds pigments when they are used. Additives for special properties, such as driers, stabilizers, plasticizers, and thinners, are included in the binder. The solvent is the volatile part of the vehicle which dissolves the binder to adjust viscosity, and which evaporates as the coating changes from liquid to solid state. Pigment adds opacity and/or color to the vehicle.

Clear coatings only slightly obscure the surface of the substrate. They are used when it is important to preserve appearance, such as the grain of wood or the color of an exposed concrete aggregate. Clear coatings are composed of a vehicle only, solvent and binder, with no pigment added. Sealers, waterproofing, and varnishes are typical examples of clear coatings.

Semitransparent coatings partially obscure the substrate surface. They can modify the appearance of the substrate by changing the color of wood without hiding its grain. Semitransparent coatings are composed of solvent, binder, and limited pigment. Stains are exemplary of this group.

Opaque coatings completely obscure the surface of the substrate. The color and/or texture of the substrate are changed; the original appearance unimportant or undesirable. Opaque coatings are made up of pigment, solvent, and binder. Paints are opaque coatings.

Coating properties are determined by the binder, which forms the surface film and bonds to the substrate. A combination of binders will alter the properties displayed by a coating, as will additives that modify the formation of the

TYPES OF COATINGS

coating. Binders composed of small molecules (e.g., drying oils) penetrate rough surfaces and adhere well but dry slowly and are not chemically resistant. Binders composed of large molecules, built-up or polymerized of smaller molecules, yield strong, chemically resistant films but are susceptible to dissolution in the same solvent when formulated for solvent evaporation only. Large molecules may be formed by reaction between small molecules as in linseed oil; they may be made before application and dissolved in solvent to lower viscosity; or they may be formed by a combination of these two methods.

Pigments hide the substrate by adding opacity and color, but may also increase durability and protective characteristics by screening UV radiation, controlling transmission of moisture and gases, and inhibiting degradation or corrosion of the substrate. Colored pigments absorb some light rays while reflecting others, and white pigments absorb little light, so their hiding efficacy depends on the ability to scatter and reflect incident light. Scattering and reflecting ability in turn depends upon the size, distribution, and refractive index of the pigment particles. Pigment also determines the gloss of the coating finish through its relative proportion to binder and solvent in the vehicle.

Environmental exposure concurrent with or following application of the coating may affect the coating or the substrate. Some types of exposure to consider are atmospheric contamination, such as sulfurous or marine air which may discolor coatings and accelerate chalking and deterioration; mildew in humid environments; and sudden drops or rises in temperature at the time of application, which may flatten or blister a freshly applied coating.

EXTERNAL FACTORS

A number of external factors affect the stability of a coating.

SOLAR RADIATION/UV RADIATION can fade colored pigments, cause chemical reaction in some binders or solvents, and degrade the substrate if the coating is not UV opaque. It may be necessary for the coating to reflect, scatter, or absorb visible light to avoid this problem.

TEMPERATURE: Solar radiation raises the temperature of the coating, causing expansion and accelerating solvent evaporation. Exposure to heat through convection of hot air or other gases, or by conduction through the substrate (as through accidental exposure to fire) may also affect coating performance. Freezing temperatures hinder proper curing of some vehicles.

RAIN: A heated coating can undergo thermal shock when exposed to rain. Rainwater can also be absorbed and cause swelling of the coating or leach pigments from the coating. Rain may also penetrate through cracks or checks and freeze, causing damage to the coating and the substrate.

WATER VAPOR: Vapor may be required to properly cure some coatings. Under some conditions water vapor should be allowed to permeate the coating to prevent condensation, while at other times permeation must be prevented to protect the substrate.

EFFECT OF PIGMENT CONTENT ON GLOSS OF COATING

CHEMICAL FUMES: Generated by chemical processes or by burning fossil fuels, chemical fumes can leave deposits on the coating, by reacting directly with it or by entering solution with rainwater or condensation.

DUST, DIRT: Dust penetrates porous coatings, collects airborne pollutants, and can stain and degrade the coating in reaction with rainwater. Marring of the coating may also be intentional, as with graffiti.

ABRASION, IMPACT: Coatings can be abraded by high-velocity flow of gaseous or liquid substances, by traffic, vandalism, or airborne dust. Impact may be through natural causes such as hailstones, may be accidental, or may be intentional, as with vandalism.

SURFACE WATER: External fresh or sea water can rise and fall, exposing normally submerged portions of the surface to solar radiation and oxygen and subjecting the coating and substrate to differential thermal expansion between the exposed and submerged portions of the surface.

CHEMICAL SOLUTIONS: Coatings may be submerged in chemical solutions such as sea water, sewage, oils, lubricants, or solvents and some of these may react with specific constituent parts of the coating, degrading or dissolving it.

SELECTION CONSIDERATIONS

Coating selection should be based on external environmental factors (see above), type and degree of exposure to these factors, including an estimate of speed of substrate deterioration should the coating fail. Conditions over the coating may vary over time, across a surface, or within the substrate, and contingencies should be planned. The possibility of an alkaline substrate such as concrete becoming moist through penetration or condensation should be considered before a non-alkaline-resistant coating is applied. Differential wear on walking or other surfaces should be considered, as well as applications of higher performance coatings.

The in-place cost of a coating accounts for surface preparation and application as well as the coating itself. Failure may result in permanent damage to the substrate, or may require complete removal and preparation for a new coating. The properties of the principal binder should determine the selection of a coating, with modifications and additions to the formulation made for specific job requirements.

SAFETY AND HEALTH CONSIDERATIONS

Hazards associated with coating application and surface preparation include toxic fumes from strong solvents; toxic dust from sandblasting, grinding, or fire; and toxicity of coating solvents when absorbed through skin or inhaled. In addition, use of photochemically reactive solvents may be limited or restricted by air-pollution controlling ordinances.

James W. Laffey; Washington, D.C.

PAINTS AND COATINGS: PROPERTIES

TYPE	PRINCIPAL BINDER	BASE/CURE	TYPICAL USES	COMPARATIVE COST RANGE	IN-SERVICE LIFE RANGE IN YEARS	GLOSS RETENTION	STAIN RESISTANCE	WEATHER RESISTANCE	ABRASION IMPACT RESISTANCE	FLEXIBILITY
Clear	Acrylic, methyl methacrylate copolymer	solvent; water	Waterproofing and surface sealer against dirt retention, graffiti; for vertical surfaces of concrete, masonry, stucco; may be pigmented.	moderate to high	5 to 10	excellent to good	fair	excellent to good	good	good

	Styrene, butadiene	water	Interior coating for gypsum board, plaster, masonry. Limited exterior use over cementitious substrate, as filler over rough porous surfaces.	moderate to low	4 to 6	poor to fair	fair	poor	fair	good
	Urethane, one or two part	moist or chemical cure ³	Heavy-duty wall and floor coatings. Resistance to stains, chemicals, graffiti, scrubbing, solvents, impact, abrasion.	high to very high	15 to 20	excellent	good to excellent	good to excellent	good to excellent	excellent
	Vinyl, polyvinyl chloride-acetate	solvent	Residential metal siding and trim, gutters, leaders, baseboard heating covers, when shop-applied, baked-on.	high	up to 15	good	fair	good	good	good to excellent
	Vinyl, polyvinylidene chloride	water	Metal and concrete surfaces in contact with dry and wet food, potable water, wastewater, jet and diesel fuels.	high	up to 10	good	fair	good	good	good
	Vinyl, polyvinyl acetate	water	Exterior and interior vertical surfaces, such as masonry, concrete, wood, plaster, gypsum board, metals. Permeable to vapor.	moderate to low	5 to 8	good to fair	fair	good	good to fair	good
	Bituminous, coal tar pitch, asphalt; emulsions, cut-backs	solvent	Waterproofing of metals, concrete, masonry, portland cement plaster, piping when below grade or immersed.	low	10 to 15 protected	not a factor		good	poor	fair
Cement	water	Leveling coat over porous masonry or concrete not subject to abrasion or scrubbing. Cement and oil used as primers for metal surfaces.	low	varies	flat finish	poor	poor for color	good	poor	

¹ Solvent-based, oil-modified urethane is also available; for use on interior/exterior vertical and horizontal wood surfaces. Cost is moderate.

² May be obtained as water-reducible coating; use as field-applied coating very limited; generally used as tank linings.

³ Solvent base, oil-modified urethane is also available; for use on vertical and horizontal surfaces. Cost is moderate, but durability is lower than for other types.

NOTES

- Solvent-based acrylic is impermeable to water vapor, high gloss.
- Water-based acrylic is semigloss, water vapor permeable.
- Phenolic varnish has a dark tint; will darken with age; may be topcoated with clear alkyd.
- Clear varnishes are not recommended for exterior wood because of limited durability.
- Urethane may be formulated to yield hard, glossy surface so that graffiti can be removed with strong solvents.
- Fillers may be required when using clear coatings over hardwood, such as oak; abraded wood may limit choice; consult manufacturer's literature.
- Stains may be used as surface sealers to change color of wood and then be topcoated with clear coatings.
- Stains over exterior wood surfaces generally will provide better protection than clear coatings, but usually will not last as long as opaque coatings.
- Alkyd may be modified with silicone for better color retention.
- Epoxy-esters have intermediate properties between two-part epoxies and alkyds and phenolics.
- Bitumen-epoxy formulations are available for use as heavy-duty waterproofing of underground piping, structural members.
- Phenolic may chalk upon exterior exposure; high degree of resistance to acids, alkalis, and solvents; some formulations available for surface temperatures of up to 300-350°F.
- Polyesters available glass fiber reinforced; also used widely for baked-on factory applied finishes for formed metal wall panels.
- Silicone for high temperature applications generally with aluminum pigment.
- Polyvinyl chloride film is used for factory-applied finishes for formed metal wall panels.
- Cement paint will absorb rainwater and will darken until water evaporates; requires moist curing after application; if not properly cured will tend to dust and rub off.
- For high performance coatings under severe conditions, life expectancy may be less.

James W. Laffey; Washington, D.C.

GENERAL

Paints and coatings are in liquid form before and during application, after which they cure to form a non-self-supporting film. They cannot exist without a solid, generally rigid substrate to receive and support them. Since a coating bonds itself firmly and continuously to the substrate, the exposure, condition, and properties of the substrate, as well as its surface characteristics and defects, directly affect the coating during and after application.

NOTES

Movement in the substrate, which may crack the coating, may result from

1. Thermal expansion/contraction due to exposure to solar radiation; sources of heat outside the substrate, such as heat-generating equipment adjacent to it; and heat-generating processes contained by the substrate.
2. Differential thermal movement between the substrate and the coating it supports, caused by variations in exposure. For example, rain may suddenly cool a coating over a hot substrate or solar radiation may heat a coating over a cold substrate.
3. Shrinking/swelling due to changes in the internal moisture content of the substrate. Under extreme conditions, variations may be as much as 5% or more across the grain in wood.
4. Deflection under load, vertical or horizontal, which induces tensile and compressive stresses in the substrate that may affect the coating.
5. Restrained end conditions of the substrate, which may cause bending stresses. Vibration in the substrate will result in cyclical stress reversals.

POROUS: SMOOTH	POROUS	PLASTER WOOD GYPSUM BOARD
POROUS: ROUGH	POROUS	MASONRY CONCRETE

SURFACE SUBSTRATE TYPICAL MATERIAL

NOTES

Absorption at the surface of the substrate and that of the substrate itself may vary and affect the choice of coating or its performance characteristics:

1. Glassy dense surfaces, even applied over a porous substrate, will prevent absorption of a coating. Such surfaces may require roughening by sandblasting or acid etching to ensure proper adhesion of most coatings.
2. Porous substrates may have varying degrees of absorption within a continuous surface (for example, different rates of absorption in bands of spring and summer growth of wood). Different rates of absorption will result in different degrees of adhesion and may cause a coating to crack along junction lines between such bands.
3. The rough surface of a porous substrate may cause varying degrees of absorption in an application, even though the absorption of the substrate does not vary significantly. For instance, when the roughness of a surface prevents the application of a film of uniform thickness over it, different rates of absorption may result. This will cause changes in the gloss of the coating, overpigmentation in areas of excessive absorption of the vehicle, and varying degrees of adhesion.

SUBSTRATE ABSORPTION

NOTES

Chemicals may be contained within the substrate or absorbed by it:

1. Soluble alkaline salts in concrete or mortar may be dissolved and crystallize on the surface.
2. Resin streaks in wood may react with the coating and bleed through, or old coatings may react chemically with new ones.
3. Rust deposits may stain some coatings and may impair adhesion.
4. Sealants used in joints may stain the substrate and/or coating.
5. Fasteners may corrode; loose particles of metal may lodge themselves in the substrate and corrode after the coating is applied.
6. Admixtures, form oils, curing agents, and antifreeze solutions used when concrete is cast may prevent proper adhesion of coatings or may react with them.
7. If cleaning solutions used during surface preparation are not completely removed before the coating is applied, they may react with the coating or impair its absorption and/or adhesion.

CHEMICALS IN SUBSTRATE

UNEVEN	POROUS	KNOTS GREASE, OIL SPILLS
IMPAIRED	POROUS OR DENSE	SATURATED SUBSTRATE WET SURFACE GLASSY
PREVENTED	DENSE	MILL SCALE HEAVY COAT OF RUST

NOTES

Uneven or impaired adhesion results in coating failure. Adhesion of the coating to the surface of a substrate is affected by

1. Surface defects such as knots, resin streaks in the wood, or surface contaminants such as oil, grease, or salt deposits over any type of substrate. Such defects impair bonding of the coating to the substrate, creating weak spots where vapor may condense. When the vapor expands, it breaks or lifts the film.
2. Moist or wet surfaces. These may impair adhesion of certain coatings. In particular, moisture collection at the bonding surface of coatings may result in blistering or lifting of the film.
3. Use over glassy surfaces. Incomplete adhesion to glassy surfaces may result in flaking and peeling of the film.
4. Deposits of mill scale, heavy coats of rust, and salts. These prevent adhesion.
5. Surface defects and contaminants that have not been corrected or removed before a coating is applied.

ADHESION TO SUBSTRATE

NOTES

Moisture may penetrate a porous substrate as

1. Water vapor migrating from high vapor pressure areas, such as warm, humid interior spaces, to low vapor pressure areas, such as cold, dry outdoors. If the dew point occurs within the substrate, vapor will condense, especially if the coating is of low permeability and blocks its free passage to the outdoors.
2. Water vapor penetrating a permeable coating to condense on a cold impermeable substrate such as metal.
3. Rain penetrating into the substrate through faulty joints, damaged or faulty flashings, or cracks in the coating.
4. Water absorbed when the substrate was exposed to rain or ground moisture while improperly stored before or during construction.
5. Water that was a constituent part of the substrate during construction and has not yet evaporated. Generally a slow process, this condition often occurs in concrete, mortar, or gypsum plaster since more water is generally used than is required by the hydration process.
6. Moisture in the substrate when the coating is applied, which may prevent proper adhesion.
7. Moisture penetrating the substrate after application of a coating, which may destroy the bond between substrate and coating.

MOISTURE IN SUBSTRATE

CONDITION SUBSTRATE EFFECT

NOTES

When new coatings are applied over previously coated substrate, the surface stability of the old coating may affect the performance of the new coating. All coatings deteriorate over a period of time, and deterioration of a coating may result in

1. Chalking, which leaves behind loose pigment. Chalking occurs when the vehicle is broken down by weathering, particularly solar radiation. Suitable coatings may be applied to surfaces that are chalking with little or no surface preparation, although loose chalk should always be removed as a minimal measure.
 2. Checking and cracking. Breaks can develop in coatings as they lose flexibility with age. These occur when stresses imposed on the coating by thermal or moisture movements in the substrate exceed the strength of the coating.
 3. Crumbling, flaking, and peeling. Generally caused when moisture and airborne pollutants penetrate the coating, crumbling, flaking, and peeling may follow checking and cracking.
- Coatings that have deteriorated until extensive checking is evident generally should not be used as a receiving surface for new coatings. Cracked, crumbling, flaking, or peeling surfaces should never be used, and the old coating must be completely removed from the substrate before application of a new coating.

COATINGS AS SUBSTRATE

EXTERIOR

SUBSTRATE	COATING SYSTEM TOPCOAT; TYPE AND BASE	PRINCIPAL BINDER	COATING GLOSS	COLOR RETENTION	SUB-STRATE SURFACE CONDITION	NOTES TO DESIGNER OR SPECIFIER			
Wood Dry, Vertical	SIDING, vertical/horizontal • recommended moisture content not over 12% • protected from moisture or limited occasional exposure to water Typical components: • veneered plywood siding • MDO plywood siding • hardboard siding • redwood siding • cedar siding, shingles, and shakes	clear; solvent	topcoat	phenolic, tung oil	gloss semigloss	poor	dry only	<ol style="list-style-type: none"> 1. Clear coatings are not recommended for plywood. 2. Light color stains have shorter durability than heavily pigmented ones. 3. PVA is used on yellow pine and red cedar. 4. Acrylic is resistant to ultraviolet rays, thus doesn't become brittle or yellowed. 5. No coating for wet wood has been recommended; wood should be dry before any coating is applied. 6. Opaque stains hide surface imperfections and will last longer but will also hide the wood grain. 7. Wood requires primer to equalize absorption; hardboards require filler to smooth out grain. 8. Always use oil-based primer under any coating on cedar and redwood. 9. Backprime and edge seal wood in locations subject to occasional moisture penetration or to water vapor migration and/or condensation. Unless properly sealed, only permeable coatings such as acrylic should be used; even then, they may peel. 10. Clear phenolic coatings may be protected with alkyd-type clear coatings for better color retention. 11. All knots and pitch streaks should be sealed with shellac and all nails set and nail holes filled. 12. Even galvanized, ferrous metal nails may corrode and stain water-based coatings because such coatings allow water vapor to penetrate to the nails, increasing the possibility of rusting. 13. Alkyds may react with chemicals in previous coatings. 14. Clear finishes for trim and doors may be pigmented to stain the wood, or a staining primer may be used. 15. Extensive surface preparation, when required, applies to both previously coated and uncoated surfaces but principally to previously coated ones. 	
			primer	self-priming, topcoat, or shellac					dry only
		stain; water, or solvent	topcoat	alkyd, oil base, self-priming (solvent)	flat	fair			dry only
		opaque; solvent	topcoat	alkyd	gloss semigloss	good			dry only

		opaque; water	topcoat	acrylic	semigloss flat	excellent			may be damp
	primer		alkyd, oil base acrylic, emulsion				dry only		
	TRIM • recommended moisture content not over 12% • occasional exposure to moisture or water Typical components: • shutters • doors • accent areas of limited size • railings	clear; solvent	topcoat	urethane, one part oil modified	gloss semigloss	fair			dry only
			primer	self-priming					dry only
		stain; solvent	topcoat	none recommended					
		opaque; water or solvent	topcoat	alkyd, oil base (solvent)	gloss semigloss	good			dry only
			primer	alkyd, oil base					dry only
Wood Floors Dry		clear; solvent	topcoat	none recommended				<ol style="list-style-type: none"> 1. Clear coatings for exterior floors are not recommended because ultraviolet radiation may degrade not only the coating but the substrate as well. Once the substrate fails, it has to be completely refinished before it can receive another coating; clear coatings may last one to two years and may require yearly maintenance. 2. Pigmented coatings only are recommended for wood exposed to sunlight; pigments used should block penetration of ultraviolet radiation to the substrate. 3. Water-based coatings generally are porous and not sufficiently abrasion resistant for use on surfaces subject to abrasion. 4. Urethane has excellent resistance to abrasion, alkali, acids, solvents, strong detergents, and fuels. Clear urethane is not recommended for exterior exposure due to possible degradation of the substrate by ultraviolet radiation. 	
	primer		not applicable						
	clear; solvent	topcoat	urethane, one part moist cure	gloss semigloss	fair		dry only		
		primer	self-priming; follow for hardwood recommended				dry only		
	clear; solvent	topcoat	urethane, one part, moisture cure	gloss, semigloss	fair		dry only		
		primer	self-priming				dry only		
Concrete, Masonry, and Stucco Dry, Vertical	clear; solvent	topcoat	silicone (min. 5% solution)	flat	N/A		<ol style="list-style-type: none"> 1. Solvent-based coatings are not recommended for use over exterior concrete or masonry surfaces as such coatings form an impermeable film, preventing the escape of any moisture that may still be present in or may later penetrate the substrate. Condensation at the interface of coating and substrate may also contain soluble alkaline salts; either one or both may cause blistering or peeling. Solvent-based coatings should only be used when the substrate is completely dry and there is no possibility of substantial moisture penetration. 2. Water-based coatings generally allow water vapor to escape to the outside and do not present the same problem as solvent-based coatings. 3. Silicone should be considered more as a water repellent than a coating film. 4. Heavy-bodied, water-based coatings are available as fillers for rough surface masonry units.

McCain McMurray, Washington, D.C.

DEFINITION

Special coatings are adhesive materials that have been developed for specific purposes such as resisting severe or corrosive environments or other forms of abuse. Special skills and techniques are usually required to mix, handle, and apply these materials.

A "special coating system" includes applied materials used in prime, intermediate, and finish coats. Factors that influence the choice of a system include

1. Substrates
2. Environmental conditions and surroundings
3. Cost

Prime and finish coats should be specified from the same manufacturer to eliminate many compatibility problems.

Proper substrate preparation, priming, and spread rate thickness are important for successful application of special coatings. Application is made by spray, brush, roller, or trowel.

SURFACE PREPARATION

The major reason coatings fail is poor surface preparation, which impairs adhesion. No coating is better than the surface over which it is applied. Surfaces must be prepared by a method suited to how they will be used and the exposure they will receive, in accordance with manufacturers' recommendations and the Steel Structures Painting Council (SSPC).

METAL SURFACES

Before a coating is applied, metal surfaces must be thoroughly cleaned, eliminating all visible deposits of surface dirt, grease, oil, and other deposits. Loose mill scale, rust, paint, and other detrimental foreign matter must also be removed. Grind rough welds and sharp edges, and remove weld spatter.

The SSPC recommends a variety of methods for preparing steel surfaces before application of a coating:

- SSPC-SP-1 Solvent Cleaning
- SSPC-SP-2 Hand Tool Cleaning
- SSPC-SP-3 Power Tool Cleaning
- SSPC-SP-5 White Metal Blast Cleaning
- SSPC-SP-6 Commercial Blast Cleaning
- SSPC-SP-7 Brush-off Blast Cleaning
- SSPC-SP-8 Pickling
- SSPC-SP-10 Near White Blast Cleaning

CONCRETE AND MASONRY SURFACES

Coatings adhere best to clean and slightly rough substrates. Grease, dirt, oils, efflorescence, laitance, and other surface deposits must be removed before additional surface preparation begins. Cleaning may be achieved by methods such as mechanical abrasion, abrasive blast, high pressure water wash, or acid etching. If cleaning solutions are applied, they must be completely removed before the coating is applied. Surfaces must be dry. If the surface is very smooth, it must be abraded or roughened slightly.

TYPES OF SPECIAL COATINGS

CEMENTITIOUS COATINGS

Polymer-modified, inorganic coatings can be ideal on concrete and masonry substrates. These coatings are primarily used on vertical surfaces above or below grade, on the exterior or interior, and on new construction or restoration and renovation work for aesthetics, permeability, and moisture resistance. They are also useful for walls subject to positive or negative hydrostatic pressure.

ABRASION-RESISTANT COATINGS

Epoxy or elastomeric seamless coating may be used over substrates of brick, stucco, concrete, block, drywall, and plywood in both interior and exterior applications. These coatings may be weatherproof and resist chemicals. Abrasion resistance may be inherent or achieved through an additional topcoat.

ELASTOMERIC COATINGS

Acrylic polymer coatings may be used over exterior concrete, masonry, and stucco surfaces. These thick, dirt-resistant, membrane-like coatings are flexible in a range of temperatures, displaying an ability to follow expansion and contraction of surfaces without rupturing or wrinkling. They are very high-build materials that bridge small cracks and protect against deterioration from moisture penetration of the substrate. Like other special coatings, these typically should not be used to bridge building expansion joints. Acrylic polymer coatings are available in smooth and textured finishes.

HIGH-BUILD GLAZED COATINGS

Acrylic resin, elastomeric, or epoxy coatings may be suitable for use over exterior or interior concrete, block, masonry, plaster, stucco, wood, and metal surfaces in vertical or horizontal applications. Applied in multiple coats or thick single coats, these coatings usually provide resistance to chemicals and abrasion. These high-performance coatings provide good adhesion and hardness, producing a tile-like gloss finish. Some systems may be reinforced with fiberglass mesh between base and seal coats to increase maximum impact resistance.

FIRE-RESISTANT PAINTS

Fire-resistant paints are able to withstand fire and protect the substrate for short periods of time, usually less than one hour. They will not support combustion and do not deteriorate readily under fire conditions. They will reduce or prevent the spread of flame over a combustible surface. In some cases they may be used as one component of a fire-rated assembly. The products of such an assembly are non-combustible, and the coating, which prevents oxygen from reaching the substrate, contains chemicals that inhibit the release of volatile gases necessary for combustion.

To be eligible for listing as a fire-retardant paint, a coating must either reduce the flame spread of the surface to which it is applied by at least 30% or have a flame spread rating of 70 or less as tested under current ASTM E-84 guidelines. Manufacturers may recommend a three- to five-year schedule for reapplying the coating in order to maintain its fire-resistant capability. Fire-resistant paints can be used to coat wood, drywall, plaster, and metal.

INTUMESCENT PAINTS

Intumescent paint is a type of fire-resistant paint that behaves differently than typical such products in a fire condition. When subjected to flame or intense heat, intumescent paints liquefy, allowing escaping gases to form an insulating layer of char, which forms a protective layer around the substrate. Fire-resistant designs have been tested by independent laboratories to establish application requirements and the extent of protection available. Incompatible paints used as a topcoat with intumescent paints may prevent the chemical reactions necessary to form the intumescent char, thereby reducing or negating the fire-resistant property.

GRAFFITI-RESISTANT COATINGS

Graffiti-resistant coatings permit the easy removal of graffiti without damage to the substrate. The system comprises a multicoat base system that increases the hardness of the substrate and a sacrificial, multicoat topcoat system. Cleaners can be nontoxic and do not require sandblasting, solvents, or toxic materials. Additional topcoats can be added after cleaning, if desired, to reinforce the sacrificial protection layer.

COATING SYSTEMS FOR STEEL

Selection of steel coating systems for tanks and piping are primarily governed by substrate and service conditions. Industry specific standards also affect specifications. Water treatment, food processing, energy production, and chemical processing industries have different requirements and standards that should be verified prior to specification. Water tanks in most U.S. jurisdictions must meet very stringent National Sanitation Foundation (NSF) requirements for potable water storage.

EXTERIOR COATING SYSTEM FOR STEEL STORAGE TANKS

Choice of coating for steel storage tank exteriors depends on tank condition and location, the weather during application, and the service conditions. A number of two-part epoxy systems and urethane systems have been formulated to address these concerns. Coatings may possess rust-inhibitive qualities, the ability to cure at low-temperatures, and excellent weathering ability and may offer galvanic protection. Dry-fall ability may be desirable in some instances and is available from alkyd products. Compatible products can be used as metal fillers and to accelerate curing rates. Local regulations regarding the content of volatile organic compounds (VOCs) will influence product selection and application techniques.

INTERIOR COATING SYSTEM FOR STEEL STORAGE TANKS

Choice of coatings for steel storage tank interiors is affected by tank condition and location and service conditions. A number of two-part epoxy systems and phenolic systems have been formulated to address these concerns. These products are designed to provide sustained immersion service in food processing, petrochemical, and water treatment industries for use in freshwater, saltwater, and severe chemical environments. National Sanitation Foundation (NSF) approvals may be necessary in certain applications.

COATING SYSTEM FOR STEEL PIPING

Coatings for steel piping are subject to many of the same conditions as coatings for steel tanks. Coatings for piping used for chemical service must be selected to match the level of chemical exposure expected. Mild exposures may permit the use of an acrylic coating, while aggressive chemical and moisture exposure may require the use of chlorinated rubber coatings. Severe chemical exposures typically require a two-part epoxy system.

The American Society of Mechanical Engineers and ANSI publish standardized color codes for pipe identification. For example, red means fire protection equipment; yellow, dangerous materials; blue, protective materials; green, safe materials; yellow with a black legend or stripe, radioactive materials.

CHEMICAL-RESISTANT COATINGS

Chemical-resistant coatings are selected according to substrate type and actual chemical exposure. Formulations of this product type vary widely from manufacturer to manufacturer and are subject to changes caused by technological advances and environmental legislation. Dry-film thick-

nesses, cure rates, and application methods also vary among product types and manufacturers. End user program requirements and consultation with manufacturers is recommended before specifying these products. In-place or laboratory testing may be advisable in critical conditions.

NOTE
 Creating an efficient and unhampered space is important in the design of intensive care units. Several manufacturers offer modular units to help organize the distribution of services to the patient. These services include medical gases such as oxygen and nitrous oxide, air and vacuum service, communications, and power. Wall-mounted systems organize services in vertical or horizontal raceways or modules and are designed for beds that position the patient's head against a wall. Modules can be custom designed to serve the particular needs of each ICU and are flexible and adaptable to meet the needs of individual patients. These modules can be designed to serve one or two patient beds.

TYPICAL LAYOUT/PLAN

SINGLE VERTICAL WALL-MOUNTED MODULE

VERTICAL WALL-MOUNTED MODULES

VERTICAL CHASE WITH HORIZONTAL RACEWAY

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland
 Andrew Summers; University Park, Maryland

NOTE
 Freestanding intensive care unit modules help organize and distribute patient services by accommodating situations in which the patient's bed is not against a wall, thereby allowing hospital staff access to the patient from all sides, particularly near the head. This system also reduces the clutter, inconvenience, and danger of disconnection created by long cords and hoses stretching from a wall-based system to a remote bed. In the rectangular and triangular models, the module is installed permanently, with all wiring and pipes accessed through the top of the unit. The pivoting module column pivots on fixed points in the floor and ceiling, rotating around a zone centered on the patient's chest.

Some of the services provided at the modules are electricity, nurse call, physiological monitor, telephone, emergency power, and medical gas piping (typically, oxygen, air, and vacuum). Each module can accommodate the design and component flexibility required by individual health care facilities.

GENERAL NOTES

1. Wall guards, panels, and trim are typically attached to a finished wall surface with adhesive or screws. Panels are typically made of high-density fiberglass and covered with vinyl acrylic cladding, but they may also have fabric coverings in low impact areas.
2. Most wall and corner guard manufacturers supply inside and outside connector trim pieces, as well as end caps. Consult manufacturers.
3. For all wall and corner guard installations, it is important to provide backup blocking behind areas where fasteners are attached, particularly for handrail-type guards.

GENERAL NOTES

- Column and beam covers are designed to conceal and protect structural and mechanical components, although they also have aesthetic value. They are installed according to the manufacturers' designs, which may differ from one company to the next. Some are designed with one section of the cover permanently fixed in place and the other section removable. In other designs, more than one section of the cover is removable. Column and beam covers can be used in interior and exterior locations.
- The most common materials used for the cover superstructure are base metals of extruded aluminum (.063 to .25 in. thick), stainless steel (18 to 11 gauge), and galvanized steel (18-gauge base with finish cover). Factory-applied mechanical finishes include anodized (for aluminum); satin or mirror finish (on brass, aluminum, or stainless steel); Kynar coating (on galvanized steel); and embossed patterns on any base metal. Other factory-applied finishes include baked enamel, powder coat, and primer (for field painting). Clear lacquer coatings are sometimes applied in the field to preserve mirror or other finishes. For high-traffic and highly vulnerable areas where protection from graffiti is also a concern (e.g., mass transit facilities), use of factory-applied ceramic/porcelain veneer on steel is recommended.

DOUBLE-ACCESS FIREPLACE

CORNER FIREPLACE

HEAT-CIRCULATING FIREPLACE

DUCTED HEAT-CIRCULATING FIREPLACE

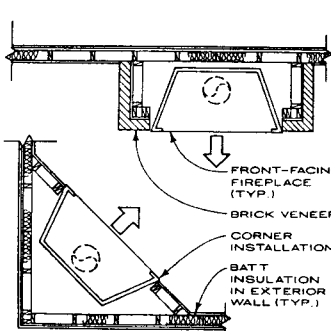

- GENERAL NOTES**
1. Verify local/state codes for maximum and minimum chimney height clearances above roof deck.
 2. Chimney pipe requires a 2-in. clearance to combustible surfaces. In a multichase installation, chimney pipes should be 20 in. apart, center to center. Chase top must be constructed of noncombustible material.
 3. See manufacturer's specifications for chimney joint band and stabilizer locations.
 4. Fire-stop spacer must be used whenever a ceiling, floor, or sidewall is penetrated.
 5. No special floor support is usually necessary for prefabricated fireplaces; however, local/state codes should be checked to determine exact requirements.
 6. Facing material must not obstruct louvered or screened area at sides, top, or bottom of fireplace opening; however, noncombustible finishing material may be used over the black metal on fireplace fronts. See manufacturer's specifications.
 7. Inadequate ventilation can occur from air conditioning, heating, or other mechanical systems that generate negative air pressures in the fireplace room. Plan for proper ventilation to ensure smoke-free operation.
 8. There is no minimum or maximum horizontal distance for outside air access line.
 9. A noncombustible hearth extension must extend at least 8 in. on either side of firebox openings and 16-20 in. in front of firebox.
 10. Distances from combustible walls perpendicular to the front of the fireplace—including mantles—vary. Consult manufacturer's specifications.
 11. Outlet grilles must be at least 10 in. below ceiling for ducted heat-circulating fireplace.
 12. Room furnishings such as drapes, curtains, and chairs must be at least 4 ft 0 in. from firebox opening.

GENERAL NOTES

- 1. APPLIANCE CLASSIFICATIONS:** Metal solid-fuel heaters efficiently heat areas ranging in size from a single room to an entire house. They are classified according to the fuel that powers them: woodstoves (cordwood) or pellet stoves (densified biomass). Woodstoves manufactured today burn both softwood and hardwood species of cordwood, which have variable moisture and Btu content but are readily accessible and manually prepared for use.
- 2. BURNING TECHNOLOGIES:** Current EPA regulations for solid-fuel appliances have resulted in woodstoves significantly more efficient than those produced before. The key to efficiency is igniting and burning the smoke and gases released during combustion, particularly during extended and reduced heat burns. Burning smoke and gases reduces fuel consumption, polluting emissions, and the frequency of chimney maintenance. Woodstoves must meet EPA standards for efficiency and cleanliness of burning. EPA standards differ for catalytic and noncatalytic technology, and within the latter category, for wood-burning and pellet-burning stoves.
- 3. APPLIANCE CONFIGURATIONS:** Both woodstoves and pellet stoves can be freestanding, a fireplace insert, or built in. Freestanding appliances are often chosen in new construction or for renovation when no chimney exists. Fireplace inserts are often used to retrofit an open fireplace to increase efficiency and heat output. Built-in heaters are chosen to achieve the look and performance of the fireplace insert without the expense of building a masonry fireplace and chimney. Instead, the built-in uses a high temperature metal chimney, usually concealed in a chase. Noncombustible materials such as brick, stone, or ceramic tile are applied around the appliance face to give the look of a traditional fireplace.
- 4. HEAT DISTRIBUTION, APPLIANCE PLACEMENT, AND SIZING:** The design of an appliance determines how it distributes heat. If the outside walls of the firebox are directly exposed to living space, the appliance is primarily a radiant heater. The heat created when waves of infrared energy from a stove strike solid objects is very comfortable in large open areas but may not be able to reach remote areas of a house.

Convection heaters feature double-wall construction. Radiant energy is converted to currents of warm air in the space between the firebox and the surrounding

metal cabinet. Natural convection currents of warm air moving through the house, cooling, and returning to the heater distribute heat gradually or with the assistance of an electric blower.

With the advent of clean glass technology, purely convection heaters completely surrounded by cabinets became rare. Much more common is a third type of heater, which combines the heat distribution qualities of the first two. A combination radiant/convection heater employs a cabinet around part of the heater for convection, but radiant energy is emitted from exposed parts of the firebox wall and the ceramic glass of the loading door. The combination offers even distribution of heat, delivering the radiant energy that heats immediate rooms comfortably and the convection currents that gradually deliver heat to more distant areas. Glass cleaning air wash technology and high-efficiency burning give the user a clear view of the fire and make the stove easier to operate.

Although a central location and open spaces provide optimum heat distribution, both radiant and combination stoves distribute heat satisfactorily if they are placed in a room of adequate size. Placement is often determined by how the living space is used and by the location of the chimney.

The performance of EPA-certified appliances on low burns allows some tolerance for oversizing an appliance for a heating area. However, appliances much too large for the area to be heated makes operation in mild weather difficult. Also important are heating expectations: A stove intended for occasional, recreational, or emergency use can be sized differently from one intended as a primary heat source. Manufacturers' recommendations for heating area capacity may not take into account local climate or the specifics of heat loss; consult a certified dealer.

- 5. AESTHETICS:** The material used to construct a stove has little effect on heating performance. Cast iron offers decorative features such as arches, curves, and relief work unattainable with steel. Steel stoves may come in styles varied through a choice of legs or pedestals, arched door frames, and brass or gold-plated accents. Stoves with soapstone panels are another option. Air wash technology, which keeps the glass clean, is perhaps the most popular design feature in all stoves.

RADIANT

CONVECTION

COMBINATION RADIANT/CONVECTION

HEAT DELIVERY SYSTEMS

NOTE

Noncatalytic systems create the conditions necessary to burn combustible gases without the use of catalysts. The technology has a number of characteristics: Firebox insulation keeps temperatures high. Devices that reflect heat back into the firebox create the gas turbulence needed for complete combustion and give the gases a long route hot enough for them to burn before being cooled. Heated secondary air supplies ensure that enough oxygen is present. This secondary air is usually fed to the fire above the fuel bed through ducts with small holes.

NONCATALYTIC STOVE SYSTEM

NOTE

Pellets are a consistently low-moisture fuel made from dried ground wood waste or other biomass waste compressed into small cylinders about 6 mm (1/4 in.) in diameter and 25 mm (1 in.) long. The pressure and heat used for their production binds the pellets together without the need for additives. Pellets usually burn cleanly because they are fed to the combustion chamber at a controlled rate and are matched with the right amount of combustion air. Pellet-burning stoves generally can operate at lower emission levels than natural firewood appliances. Some pellet stoves also burn corn.

TYPICAL DENSIFIED PELLET APPLIANCE

NOTE

A catalyst is a substance that effects a reaction without being consumed in the process. The catalyst in a catalytic combustion appliance is a coated ceramic honeycomb through which exhaust gas is routed. The catalytic coating, usually palladium and/or platinum, lowers the ignition temperature of the gases from 1000° to 500° F as they pass through, causing them to ignite. This arrangement allows catalytic appliances to operate at low firing rates and still burn cleanly. Because the catalyst restricts gas flow through the appliance, these units always include a bypass damper into the flue. The damper is opened when the appliance is loaded; when a hot fire has been established, it is closed, forcing the gases through the combustor for an extended clean burn.

CATALYTIC SOLID-FUEL APPLIANCE

Walter Moberg Design, Inc.; Portland, Oregon
Hearth Education Foundation; Austin, Texas

CHIMNEYS AND DRAFT

The woodstove chimney and pellet stove vent are essential components of the solid-fuel heating system. For woodstoves, factory-built metal chimneys offer precise sizing (optimum draft is obtained by matching the cross-sectional area of the flue outlet), safety (heat-tested to 2100 °F, according to UL 103), and low maintenance (insulation reduces condensation). Masonry chimneys often need to be downsized with a UL 1777-listed stainless steel, poured or factory-built liner that extends from the appliance to the top of the chimney. Liners improve startup and draft, improve safety, and reduce and simplify maintenance.

Follow code or manufacturers' requirements for chimney clearance and height. For safety, follow the 2 ft/10 ft/3 ft rule: The chimney must terminate at least 2 ft higher than anything within 10 ft and extend at least 3 ft above the roof penetration. High-efficiency stoves may need added height to ensure adequate draft; a minimum height of 14 ft from appliance to chimney top is generally recommended.

Pellet appliances often use lower temperature double-wall pellet venting. Mechanical venting for some appliances can be totally horizontal if clearances to adjacent structures and openings are met, but additional vertical venting is recommended in case of unexpected shutdown. Mechanical draft pellet venting that penetrates the roof can terminate as little as 1 ft above the penetration; natural draft venting must be at least 2 ft higher than anything within 10 ft.

CHIMNEY TYPES FOR WOODSTOVES AND PELLET STOVES

THROUGH-THE-WALL INSTALLATION—FACTORY-BUILT CHIMNEY

Walter Moberg Design, Inc., Portland, Oregon
Hearth Education Foundation, Austin, Texas

INSTALLATION

Underwriters Laboratories tests and lists most woodstoves tested for close clearances to unprotected combustibles. Brick or sheet metal protectors are not usually necessary, and their use in any case cannot reduce required clearance to less than 12 in. Use of double wall connector pipe from the appliance to the chimney may be recommended to reduce clearances for woodstoves, but such pipe must be listed for use with both the appliance and the chimney to which it will be connected.

Pellet appliances are listed by UL (but to a different standard) for very close clearances. They are usually vented with listed pellet venting from the appliance to the outside.

Unlisted appliances should be installed according to the provisions of NFPA 211.

Acceptable floor protection materials and minimum size for these stoves are specified by the manufacturers; if not, follow NFPA 211 or local code requirements.

NOTE

Chimney height must meet minimum draft requirements, generally 14 ft from stove to the chimney cap.

CALCULATING CHIMNEY HEIGHTS WITH PITCHED ROOFS

NOTE

Chimney must meet manufacturers' recommendations for minimum height.

STANDARD CEILING INSTALLATION—FACTORY-BUILT CHIMNEY

PARALLEL INSTALLATION

NOTE

All clearances shown are subject to change based on manufacturers' specifications, local codes, and any clearance reduction systems used.

MINIMUM CLEARANCES TO COMBUSTIBLES (IN.)

SINGLE WALL CONNECTOR (RESIDENTIAL)					
A	B	C	D	E	F
15	21	18	30	11	25

DOUBLE WALL CONNECTOR (LISTED MOBILE HOME OR RESIDENCE, CLOSE CLEARANCE)					
A	B	C	D	E	F
8	14	16	28	7	21

NOTE

Floor protection is required as follows: Minimum extension beyond loading door, 18 in.; beyond other sides, 8 in.

TYPICAL LISTED SOLID-FUEL APPLIANCE CLEARANCES

NOTES

- For stoves with legs 2 to 6 in., hearth pad should be 4-in. hollow masonry with 24-gauge (min.) sheet metal cover.
- With legs taller than 6 in., hearth pad should be 2-in. solid masonry with 24-gauge (min.) sheet metal cover.
- Stoves with legs shorter than 2 in. must be installed on a noncombustible floor even if there is a hearth pad.

SOLID-FUEL APPLIANCE WALL CLEARANCE REDUCTION SYSTEM

NOTE
Flagpoles must withstand wind loads while the flag is flying. The combination wind load on pole and flag should be considered. Refer to wind load tests by the National Association of Architectural Metal Manufacturers (NAAMM).

FLAGPOLE DESIGN

NOTE
Brackets are made of cast aluminum, bronze, and stainless steel; designs vary.

VERTICAL WALL-MOUNTED FLAGPOLE

OUTRIGGER WALL-MOUNTED FLAGPOLE

NOTE
A revolving truck allows free movement of the flag while flying; a second truck is typically used as backup only, not simultaneously with the first truck.

RIGID VINYL INSERTS MAGNETIC SLIDING WINDOW INTERIOR SIGN TYPES

ACCESSIBLE SIGNAGE FOR PERSONS WITH DISABILITIES

1. Accessible signs should identify permanent rooms and spaces, including room numbers, emergency exits, and toilet facilities. If room numbers are not used, signs such as "Cafeteria" must be accessible.
 - a. Letters and numerals: raised 1/32 in. minimum, uppercase, sans serif, 3/8 to 2 in. in height, and accompanied by grade 2 Braille.
 - b. Pictogram borders should be at least 6 in. high.
 - c. Surfaces should have a nonglare finish; level of sheen must be "eggshell" or less.
 - d. Provide contrast between the characters and background.
 - e. Mounting: 60 in. above finished floor to centerline of sign, preferably on the latch side of door or the closest wall space. Do not mount within the swinging path of a door or where a person cannot approach within 3 in. of the sign.
2. Directional and informational signs for permanent functional spaces (such as signs to auditoriums or elevators) should be accessible.
 - a. Character proportions should comply with ADAAG 4.30.2.
 - b. Characters should be at least 3 in. high; increase character height as viewing distance increases.
3. Identify such accessible features as assistive listening devices, parking, and text telephones. When not all such features are accessible, identify the accessible ones (e.g., toilet rooms and parking) and provide directional signage from inaccessible ones. Use pictograms at least 6 in. high accompanied by a verbal description.

GENERAL NOTES

EXTERIOR SIGNS

1. Identify entrance and exit of site and building, accessibility information, parking lot location, and facility identification.
2. Signs should be 6 ft 0 in. min. from face of curb, 7 ft 0 in. from grade to bottom of sign, and 100-200 ft from intersections.
3. Building signage materials: fabricated aluminum, illuminated plastic face, back lighted, cast aluminum, applied letter, die raised, engraved, and hot stamped.
4. Plaque and sign materials: cast bronze, cast aluminum, plastic/acrylic, stone (cornerstone), masonry, and wood.
5. For accessibility signage, designate building entrance access, identify parking areas, and direction to facilities. See ADAAG and state regulations for specific requirements.

DIRECTORIES AND MAPS

1. Locate these in main entrances and/or lobbies with appropriate information for persons with disabilities.
2. Place directory information adjacent to "You are here" information.
3. Directories should be placed in stair/elevator lobbies of each floor.
4. Mounting choices: surface mounted, semirecessed, full recessed (flush), cantilevered, chain suspended, rigidly suspended, mechanically fastened, or track mounted.

INTERIOR SIGNS

1. Lightweight freestanding signs should not be used in high-traffic areas. Use when specific location/information maneuverability is required.
2. Electronic, computer, and videotex technologies can provide an innovative and highly flexible directory/sign display system for mapping and/or routing, information (facility and local), advertisement and messages, and management tie-in capabilities.
3. Where changeability and flexibility is a design priority, a modular system is recommended. Rigid vinyl, aluminum, and acrylic inserts as well as magnetic systems may be used.
4. For maximum ease of reading interior signs, any given line in a sign should not exceed 30 characters in width, including upper and lower case letters and spaces between words.
5. Choose the height and "weight" of letter styles and symbols for readability. Consider background materials and contrast when choosing a color scheme.
6. Permanent mounting:
 - a. Vinyl tape/adhesive backing, usually factory applied.
 - b. Silastic adhesive, usually supplied with vinyl tape strips to hold sign in place until adhesive cures.
 - c. Mechanically fastened; specify hole locations.
7. Semipermanent: vinyl tape square can be used on inserts.
8. Changeable: dual-lock mating fasteners, magnets, magnetic tape, or tracks may be used.

GENERAL NOTES

- Construction of locker frame and door typically is of 16 gauge steel for sides and back. Top and bottom are typically 20 to 24 gauge steel. Finishes vary. Number plates, a shelf, and coat hooks on back and side walls are generally included. Other construction such as plastic laminate and wood is also used for club facilities.
- Door types may be solid, perforated (all or part), or louvered (all or part), and ordered in a variety of steel mesh patterns or in special finishes. Doors and locks may be provided with noise-deadening de-

- Locking mechanisms include built-in adjustable combination lock, built-in flat or grooved key, and latching locker handle (for padlock use). All locking mechanisms are available for surface or recessed applications.
- Optional locker equipment includes sloping top for nonrecessed locations with corner miters available, 6 in. legs for open base installation, interior partitions (some models), multiple shelves, coat rods (for models over 18 in. deep), closed base and closed-end base for legs, and attachable bench elements.

- Ventilation within locker spaces should provide 15 cu ft/min. air movement for locker.
- Handicapped user access may suggest use of some multiple tier lockers; shelf and coat hooks on single tier lockers are out of reach of most handicapped.
- Bench arrangements may be attached to locker front or may be freestanding and require a raised installation. Finishes of lockers may be varied as conditions dictate such as stainless steel bottoms or sides when used in areas where long-term chemical contamination may affect finishes.

ELEVATIONS

LOCKERS

Checking lockers for heavy duty use are available in enameled steel or stainless steel. Locks are provided with built-in multiple coin selector, which is owner adjustable for coins, tokens, or "free" operation. They may be installed on legs or recessed and may be made movable. Overall height is 6 ft 0 in. on most models, 5 ft 0 in. on some.

ELEVATION

CHECKING LOCKERS

GENERAL

Portable fire extinguishers can serve as a first line of defense against fires of limited size, even property equipped with automatic sprinklers or other fixed protection equipment. The following are criteria for selecting fire extinguishers:

1. Type and severity (size, intensity, and speed of travel) of potential fire hazard.
2. Environmental conditions of potential fire hazard (ambient temperature conditions, presence of fumes, etc.).
3. Effectiveness of extinguisher on potential fire hazard.
4. Ease of use.
5. Suitability for its environment.
6. Any anticipated adverse chemical reactions between the extinguishing agent and the burning materials.
7. Any health and operational safety concerns (exposure of operators during fire control efforts).
8. Training and physical capabilities of available personnel to operate extinguisher.
9. Upkeep and maintenance requirements.

NOTES

1. To comply with the Americans with Disabilities Act of 1990, fire extinguishers that protrude more than 4 in. into walks, halls, corridors, passageways, or aisles must be recessed into the wall.
2. The authority with jurisdiction over the location dictates

the number, type, and placement of fire extinguishers and fire extinguisher cabinets.

3. All extinguishers without wheels must be installed on hangers or brackets, mounted in cabinets, or set on shelves. Extinguishers weighing up to 40 lb should be no more than 5 ft above the floor. The top of extinguishers with a gross weight greater than 40 lb should be no more than 3 ft 6 in. above the floor.
4. Halon-type extinguishers are no longer manufactured as a result of an international environmental agreement.
5. These standards and classifications are taken from the National Fire Protection Association Publication 10, *Portable Fire Extinguishers*, 1994 ed. Always check local code requirements before specifying fire extinguishers.

CLASSIFICATION OF OCCUPANCIES BY HAZARD TYPE

1. **LIGHT (LOW) HAZARD:** Light hazard occupancies have few Class A combustible materials, including furnishings, decorations, and contents. This may include offices, classrooms, churches, or hotels.
2. **ORDINARY (MODERATE) HAZARD:** Ordinary hazard occupancies have more Class A combustibles and Class B flammables in light hazard occupancies. They include certain dining areas, mercantile shops, and research operations.
3. **EXTRA (HIGH) HAZARD:** Places with more Class A combustibles and Class B flammables than ordinary hazard occupancies present are extra hazard occupancies. Likely locations include woodworking, vehicle repair, and paint shops and cooking areas.

DISTRIBUTION OF FIRE EXTINGUISHERS

The minimum number of fire extinguishers needed to protect a property from Class A fires is determined by the accompanying tables; frequently, additional extinguishers are installed. Fire extinguishers rated for Class B fires are placed a maximum travel distance of 50 ft from the hazard (smaller rated extinguishers are placed no more than 30 ft from the hazard). Fire extinguishers rated for Class C fires shall be required in locations with energized electrical equipment that would require a nonconducting extinguishing medium. For Class D fires, extinguishers are located not more than 75 ft from the Class D hazard.

FIRE CLASSIFICATIONS FOR SELECTING FIRE EXTINGUISHERS

LETTER SYMBOL AND COLOR	PICTURE SYMBOL	DESCRIPTION
Green 		Class A: Fires involving ordinary combustible materials (such as wood, cloth, paper, rubber, and many plastics) that require the heat-absorbing (cooling) effects of water or water solutions, or the coating effects of certain dry chemicals that retard combustion.
Red 		Class B: Fires involving flammable or combustible liquids, flammable gases, greases and similar materials that are best extinguished by excluding air (oxygen), inhibiting the release of combustible vapors, or interrupting the combustion chain reaction.
Blue 		Class C: Fires involving energized electrical equipment where safety to the operator requires the use of electrically nonconductive extinguishing agents.
Yellow 		Class D: Fires involving combustible metals (such as magnesium, titanium, zirconium, sodium, lithium, and potassium).

FIRE EXTINGUISHER SIZE AND PLACEMENT FOR CLASS A HAZARDS

	LIGHT HAZARD OCCUPANCY	ORDINARY HAZARD OCCUPANCY	EXTRA HAZARD OCCUPANCY
Min. rated single extinguisher	2-A ¹	2-A ¹	4-A ²
Max. floor area per unit of A	3,000 sq ft	1,500 sq ft	1,000 sq ft
Max. floor area for extinguisher	11,250 sq ft	11,250 sq ft	11,250 sq ft
Max. travel distance to extinguisher	75 ft	75 ft	75 ft

¹ Up to two water-type extinguishers with 1-A rating can be used to fulfill the requirements of one 2-A rated extinguisher for light hazard occupancies.

² Two 2 1/2 gallon (9.45 L) water-type extinguishers can be used to fulfill the requirements of one 4-A rated extinguisher.

MULTIPURPOSE DRY CHEMICAL (CLASS A, B, AND C FIRES)

Capacity (lb)	2 1/2	5	6	10	20

Discharge time	2 1/2 lb, 12 sec; 5 lb, 22 sec; 10 lb, 23 sec; 15 lb, 26 sec; 20 lb, 25 sec			
Recharge	After use			
Pressure source	Compressed gas			
Temperature effect	Will operate at - 40°F			
Electrical conductivity	Will not conduct			

NOTE: Pressurized liquid carbon dioxide is released, changed into a gas, and appears as a cloud of white "snow," smothering fire.

REGULAR DRY CHEMICAL (CLASS B AND C FIRES)

Capacity (lb)	2 1/2	5	1/2	6	10	20
Height (in.)	14 1/8 to 14 5/8	14 5/8 to 15 1/4	14 5/8 to 15 1/4	15 1/2 to 16 1/4	20 to 20 1/2	23 1/4 to 24
Diameter (in.)	3	4 1/4	4 1/4	5	5 to 6	7
Class	10B:C	10B:C	40B:C	40B:C	60B:C	120B:C
Effective range	10 to 20 ft					
Discharge time	5 lb, 10 sec; 10 lb, 11 sec; 20 lb, 15 sec; 30 lb, 34 sec					
Recharge	After use					
Pressure source	Compressed gas					
Temperature effect	Will operate at - 40°F					
Electrical conductivity	Will not conduct					

NOTE: A siliconized sodium bicarbonate base (the traditional dry chemical design) extinguishes fire. A base of potassium bicarbonate is also available.

PRESSURIZED WATER

Capacity (gal)	2 1/2
Height (in.)	24 1/2
Diameter (in.)	7
Weight (lb)	28
Class	2A
Effective Range	30 ft
Discharge time	50 seconds
Recharge	Weigh cylinder and check annually; in all cases, follow instructions on label
Pressure source	Compressed air
Temperature effect	Will freeze
Electrical conductivity	Will conduct

NOTE

Water quenches fire and cools area.

SODIUM CHLORIDE

Capacity (lb)	30
Height (in.)	27 3/4
Diameter (in.)	7
Class	FM
Effective range	4 to 6 ft
Discharge time	28 seconds
Recharge	After use
Pressure source	Compressed gas
Temperature effect	-40 to +120
Electrical conductivity	Will not conduct

NOTES

1. Sodium chloride dry powder is dispersed over a burning combustible metal or alloy; heat from fire causes dry powder to cake and form exterior crust that excludes air and dissipates heat.
2. For lithium and lithium alloy Class D fires, a copper-based extinguishing agent is used.

FIRE HOSE RACK AND REELS

NOTE

Recommended hose size for use with building standpipes should not exceed 1 1/2 in. in diameter and 100 ft in length. A larger hose used by amateurs is likely to tangle, cause excessive water damage, and create injuries.

A connection for 2 1/2 in. hose should be available to each station for the use of firemen. Many codes require 2 1/2 in. outlets at all standpipes.

By using a reducing coupling 1 1/2 in. hose can be attached. When a 2 1/2 in. stream is required the coupling may be removed. Industrial installations use 2 1/2 in. hoses and train personnel in the use of the heavier equipment. Valves may be located 5 ft 6 in. above floor (check local code).

Lined synthetic fiber plastic hose is recommended for use on standpipe installations. Cotton rubber lined

hose is standard for fire department and heavy equipment hose.

Tables show rack and reels for 1 1/2 and 2 1/2 in. lined hose only. Consult manufacturer's literature for rack and reel dimensions when other types and sizes of hose are used.

75' 1 1/2" LINED HOSE, RACK, AND ANGLE VALVE; 2 1/2 GAL EXTINGUISHER

SECTION THROUGH AWNING FRAME

FRAMEWORK DETAILS

FRAME CHARACTERISTICS

GENERIC CLASSIFICATION	COMMON STANDARDS	YIELD STRENGTH (PSI)	MODULUS OF ELASTICITY (PSI)	REMARKS
Steel pipe	ASTM A53E ASTM A53S	35,000	29 x 10 ⁶	Obtainable in black iron or galvanized. Nominal sizes are larger than equivalent nominal sizes for most tubing. Relatively thick walls. Available only in round shape.
Mild steel tubing	AISI 1018 AISI 1020 ASTMA513 Type 1 ASTM A135	32,000 35,000 - 44,000 32,000 30,000 - 35,000	29 x 10 ⁶	Generally hot-rolled materials, which preserve ductility. Easily worked and welded. Must be painted or otherwise coated to provide corrosion protection. Can be obtained galvanized in certain sizes.
Aluminum tubing	6061 - T6 6063 - T6 6063 - T5	37,000 31,000 21,000	10 x 10 ⁶	Note lower value for modulus of elasticity; this will produce larger deflections. Welded joints will cause materials to lose their heat treatment and result in locally reduced strength. Designer must take this into account. Good corrosion resistance. Lightweight. Available round, square, and rectangular.
Electrical metallic tubing	UL797		29 x 10 ⁶	Difficult to specifically determine the steel properties since UL797 only requires that it be mild, ductile steel. Available only in round shape.
High-strength coated tubing (cold-formed)	ASTM A500 Gr. B.	46,000 - 52,000	29 x 10 ⁶	Strong, relatively lightweight, thin-wall tubing with corrosion protection. Designer should take adequate account of the thin-wall characteristics, less ductile properties, and higher strength of the product as compared to mild steel tubing. Available in round or square shapes.
Stainless steel tubing	AISI Type 304	30,000 - 50,000	28 x 10 ⁶	Excellent strength, corrosion resistance, and weldability.

FRAMEWORK DETAILS

NOTE

Consideration should be given to alternating download (snow, wind, and material weight) and upload (wind) anchors on each awning frame. Provide blocking behind anchors as necessary.

FIXED WALL ANCHORS

THREADED FRAME DIAMETERS

FRONT BAR SPAN LENGTHS	PIPE DIAMETERS
2'-0" to 4'-0"	3/8" (or 1/2" Solid)
4'-1" to 6'-0"	1/2"
6'-1" to 9'-6"	3/4"
9'-7" to 11'-6"	1"

RETRACTABLE AWNING—HINGE DETAIL

FIXED AWNING—ROOF MOUNT DETAIL

NOTES

1. Awnings and canopies are custom manufactured and engineered to provide sun and rain protection for windows, entrances, and walkways. They can be illuminated with backlighting or graphically embellished and used as signage as well.
2. Code requirements as well as design needs may determine the shape, size, graphics, materials, and lighting chosen. After lighting is installed, the underside of the awning or canopy is finished with a "ceiling," normally a prismatic glass, eggcrating, or an open weave vinyl coated polyester or other translucent fabric in order to hide the hardware and maximize light reflection.
3. Climatic conditions, wind and snow load requirements, and local design customs will affect the construction details of the awning or canopy framework systems.
4. A variety of methods are used to apply graphics to the awning, such as silk screening, hand painting, air brush, cut-out lettering, heat color transfer, pressure-sensitive graphics, and eradicating.
5. Slip fittings with set screws or direct tube-to-tube welding are the most common frame construction practices. Welded joints are more rigid, but shipping, assembly, and disassembly are easier and quicker with slip fitting joints.

Industrial Fabrics Association International; St. Paul, Minnesota
Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

NOTE
Generally, this is the most economical louver type.

EXPOSED MULLION LOUVER

GENERAL NOTES

1. Metal architectural louvers allow airflow through a wall for ventilation, especially of machine exhaust. They protect the interior space from vandalism, weather, insects, or birds and can be used to obscure unsightly views. Louvers can be fabricated in standard rectangles or custom shapes such as circles, triangles, and ellipses. Radiused corners and other details are available from some manufacturers. Penthouses frequently incorporate louvered walls to screen equipment and provide airflow.
2. Standard louver materials are 16-, 18-, or 20-gauge galvanized or cold-rolled steel and 8-, 12-, or 14-gauge extruded aluminum alloy. Other metals can be used for special applications. Translucent fiberglass is a standard blade material when daylighting is desirable. Fasteners are either aluminum or stainless steel. The dimensions shown are the most common; other sizes are available.

LOUVER INSTALLATION IN CURTAIN WALL

FLANGE MOUNT DETAIL

NOTE
This louver type offers a visual line uninterrupted by exposed vertical supports.

CONTINUOUS HORIZONTAL LOUVER

3. Factory finishing is recommended for maximum control of color and durability. The finish for steel louvers is baked enamel, which comes in a variety of colors. Aluminum finishes include mill, clear lacquer, baked enamel, and anodic. Fluorocarbon polymeric finish coatings (kynar), which can be applied to steel or aluminum, resist chalking, ultraviolet deterioration, salts, chemicals, and pollutants.
4. Mechanically assembled extruded aluminum louvers are the most common type of louver assembly on the market. Mechanical fasteners are better than welding in extruded aluminum alloy construction because annealing occurs near the weld, weakening the material along both sides. Also, repairs are easier if mechanical fasteners are used.

ANGLE SUBFRAME DETAILS

NOTE
Adjustable operating louvers are available with manual, electric, or pneumatic actuators. Free area 38 to 58%.

ADJUSTABLE OPERATING LOUVER

5. With sheet metal, welding an assembly of louvers is easier and less expensive than using clip angles and screws to fasten the blades to the framework.
6. Free area is the net area of free airflow through a louver, generally measured in square feet or as a percentage of the area in the louver type selected. Manufacturers' free area ratings should include the effects of bird or insect screens, which reduce free area.
7. For all louvers servicing mechanical equipment, consult a mechanical engineer for design and specification of the louvers. Louvers are rated for air performance and water penetration and certified through the Air Movement and Control Association. The Building Services Resources and Information Association also rates the performance of metal louvers.

MISCELLANEOUS LOUVER ACCESSORIES

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

GENERAL

Louver blades come in many shapes, sizes, and performance types that vary with the manufacturer; the blades illustrated here represent the basic types. Some blades are fixed only; others can be opened and shut. The center-to-center dimensions given are approximate; generally, standard blades (not specialty blades such as acoustic, air-foil, etc.) are designed with minimal overlap so they can obstruct views but maximize the free area.

NOTE

Louvers utilizing this blade design completely obscure views and are tamperproof and storm-resistant. This blade prevents nearly 100% of wind-driven rain from entering (generally tested with winds up to 30 mph for one hour).

HORIZONTAL STORM-RESISTANT BLADE

NOTE

Acoustically insulated air-foil blades block sound from inside or out and accommodate high air velocities. Free area is 29%; blades may be fixed or operable.

FIXED AIR-FOIL ACOUSTICAL BLADE

NOTE

This blade type provides high water resistance and a free area of about 50%. Typically employed in louvers with jamb and mullion drains, it is not designed to protect against wind-driven rain.

DOUBLE DRAINABLE LOUVER BLADE

NOTE

Louvers utilizing this blade design completely obscure views and are tamperproof and completely stormproof.

VERTICAL STORM-RESISTANT BLADE

AUTOMATIC EXHAUST DAMPER/LOUVER

NOTE

Standard blades are suitable for most applications where water infiltration is not a concern. Free area is approximately 48%. Single operating panels should not exceed 48 in. wide x 96 in. high. This blade can be either fixed or operable.

STANDARD BLADE

NOTE

Designed to provide high free area (55%) and low water penetration, this blade is not recommended for use with hidden mullions; louvers that employ these blades contain integral drains in their mullions that direct water away from the inside of the louver. All drain troughs must be kept free of debris. Not designed to hinder wind-driven rain.

HIGH-PERFORMANCE DRAINABLE BLADE

NOTE

These shallow louver blades can allow a very high free area (from 32 to 73%). They are often used when standard-depth louvers are not practical.

SHALLOW AIR CONDITIONING BLADE

NOTE

Acoustically insulated blades block sound from inside or out and prevent weather infiltration. Free areas range from 21 to 29%. Blades may be fixed or operable.

FIXED ACOUSTICAL LOUVER

NOTE

Step blades help prevent water infiltration. Free area is approximately 48%.

STEP BLADE PROFILE

NOTE

Designed to provide a high free area (55%), this blade accommodates high air velocities and protects against wind-blown precipitation.

HIGH-PERFORMANCE STANDARD BLADE

AUTOMATIC INTAKE DAMPER/LOUVER

GENERAL NOTES

1. Postal Service approved mail receptacles are required for apartment houses containing three or more apartments with a common building entrance and street number.
2. Individual compartments should be large enough to receive long letter mail 4 1/2 in. wide and bulky magazines 14 1/2 in. long and 3 1/2 in. in diameter.
3. An outdoor installation should preferably be at least 15 ft from a street or public sidewalk, protected from driving rain, and visible from at least one apartment window.
4. All installations must be adequately lighted to afford better protection to the mail and enable carriers to read addresses on mail and names on boxes.
5. A directory, in alphabetical order, is required for installations with more than 15 compartments.
6. Each compartment group is supplied with mounting hardware for master lock.
7. One mailbox door is required for the Postal Service master lock and cannot be used for mail distribution.
8. Call buttons with telephone can be integrated into frame with mailboxes.
9. Depending on occupancy, a certain number of compartments shall be assigned to persons using wheelchairs. Key slots shall be no more than 48 in. from floor. Consult ADAAG and local codes for other requirements.
10. Use of collection boxes is subject to approval by local offices of the United States Postal Service.

HMC Group; Ontario, California

INDIVIDUAL PANELS
NOTE

This manually operated system is for panels more than 16 ft tall (40 ft max. typically), which are supported by two carriers on each panel.

HINGED PAIRS
NOTE

This manually operated system is for panels up to 18 ft in height and typically is used for straight runs only. Each panel has one carrier.

CONTINUOUSLY HINGED

NOTE

Panels are hinged together to form a continuous panel train. This type is manually operated for systems with a total wall weight under 3700 lb and operated with an electric motor for weights exceeding 3700 lb. This type of panel is typically suitable for straight run applications only.

PANEL OPERATION TYPES

PARALLEL STACK

CENTER STACK

PERPENDICULAR STACK

REMOTE STACK

NOTE

Dimensions given are for planning purposes only; consult manufacturer for specifics. Panels with automatic bottom seals require a wider stack storage area; dimensions given are for fixed, adjustable, or operable bottom seals.

NOTE

Panel wall width for individual and paired panels is unlimited. Sound transmission coefficient ratings for typical panels are available up to 55.

STORAGE ARRANGEMENTS FOR PANEL STACKS

TOP-HUNG FOLDING PARTITION
DETAIL

NOTE

The bottom carrier handles about 90% of the panel's weight.

FLOOR-SUPPORTED FOLDING
PARTITION DETAIL

PLAN

NOTE

Acoustical inner liners can be added to these partitions. Typical partitions are either built of laminated panels or individual vinyl-clad steel panels with extruded vinyl hinges.

ACCORDION PARTITIONS

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

GENERAL

Movable wall systems of non-load bearing interior partitions offer flexibility for office environments in which functions and layouts may change quickly or repeatedly. Generally, they are manufactured either as one-piece self-contained panels or as two-piece systems in which structure and cladding are independent of each other. In either case, floor and ceiling tracks are installed on finished (carpeted, etc.) floors and fastened to suspended ceiling grids. Height adjustment and leveling are accomplished with components included in a typical panel assembly. Panels may be attached to each other or independently fixed into floor and ceiling channels, offering more flexibility. Typically, movable wall systems delineate space, provide visual and sound privacy, channel power and telecommunications cable, and support storage and work surface components. Various manufacturers offer different features for electric and telecommunications cable raceways and access, opening treatments, connection details, panel/cladding and finish materials, sound transmission coefficient ratings, fire ratings, and demountability/mobility options. Consult manufacturers for specific features.

ONE-PIECE PANELS

One-piece panels are composite panels typically made from sheet steel or aluminum with a core of insulation and structural ribs for stiffness. Panels are typically 2 3/8 to 3 in. thick, although other thicknesses are available.

TWO-PIECE PANELS

These panels are manufactured as separate structural and cladding systems. The structure is made from steel members that are factory-assembled into panel-sized components and then installed. Panel cladding material varies and may include regular and high-impact vinyl-clad gypsum, insulation-filled sound control panels, or sandwich panels (steel sheets with a honeycomb infill), among others. Panel cladding is typically 1/2 to 3/4 in. thick.

GENERAL NOTES

1. Suspended ceilings are usually ineffective as a sound barrier. Consequently, when a series of soundproofed offices are planned under such a ceiling, the chances of sound travel over partitions should be considered. Baffles installed tightly above each run of the slab will eliminate cracks through which sound can easily pass.
2. The perimeter of the partition installation—ceiling, floor, and sides—should be gasketed with a factory-applied sealant. All door frames should be fitted with a factory-applied rubber liner at the head and jambs that compresses when the door is closed.
3. For extra sound control, all doors should have a continuous drop seal and threshold and glazing in doors and partitions should have double lights that are hermetically sealed.

NOTE

Wall panel sizes range from 6 to 60 in. wide, up to a single panel height of 1 ft.

PANEL TYPES

NOTE

Various locking devices fasten panels to the floor. Consult manufacturers.

PLAN OF VAULT DOOR

UNDERWRITERS LABORATORIES (UL) PERFORMANCE SPECIFICATIONS FOR VAULTS

Class 1 1/2 hr attack resistance time	Not shown — available for application only in existing buildings where structural support (floor load) is critical (does not comply with Bank Protection Act).
Class 2 1 hr attack resistance time	A. 18 in. reinforced concrete B. 8 in. average thickness UL listed modular panel
Class 3 2 hr attack resistance time	A. 27 in. reinforced concrete B. 13 in. average thickness UL listed modular panel.

INSURANCE SERVICES OFFICE NOTES

- The size, configuration, and specific requirements of all equipment and alarm systems that might be included in a bank vault will vary with different manufacturers and design considerations.
- Class 2 is the minimum vault panel rating that will meet the requirements of regulation P of the Bank Protection Act.
- Concrete used in vault construction should develop an ultimate compression strength of at least 3000 lb/sq. in.
- With fire-resistive materials to meet local building codes, steel lining is not considered acceptable as burglary-resistant material equivalencies for UL vault construction and does not meet the Bank Protection Act requirements. Special approval is required.
- Class 1 UL listed vault is positioned as equal or superior to the 5R vault classification.
- Class 2 UL listed vault is positioned as superior to the 9R vault classification.
- Class 3 UL listed vault is positioned as superior to the 10R vault classification.
- The above UL listed vaults are superior to traditional ISO and Bank Protection Act construction.
- The Class 2 UL listed vault is recommended throughout the industry as minimum protection for safe deposit vault operations. A 2-hour, Class 3, is preferable.

GENERAL

Federally insured banks and savings institutions are regulated under the Bank Protection Act of 1968 as revised in 1973, which only recognizes vaults with walls, floor, and ceiling of reinforced concrete at least 12 in. thick. Revisions to the BPA in 1991 should be consulted when planning a new vault. The following comparative classification charts are used to rate security vaults.

MINIMUM NUMBER OF GRIDS FOR DEFORMED BARS

12 in. concrete thickness	3 grids
18 in. concrete thickness	4 grids
27 in. concrete thickness or over	5 grids

MINIMUM NUMBER OF GRIDS FOR #6 EXPANDED STEEL

12 in. concrete thickness	2 grids
18 in. concrete thickness	3 grids
27 in. concrete thickness or over	4 grids

REINFORCING

No. 5 (5/8 in. diameter) deformed steel reinforcing bars located on 4 in. centers in horizontal and vertical rows to form a grid, or expanded steel bank vault mesh weighing 6 lb/sq ft per grid and having a diamond pattern of 3 x 8 in.

Grids are to be located not less than 4 in. apart and shall be staggered in each direction. The number of grids required depends on the thickness of the wall, floor, and ceiling (and specific insurance requirements).

Krommenhoek/McKeown and Associates; San Diego, California

BANK EQUIPMENT REQUIREMENTS

1. **STANDARDS:** Comply with the latest edition of "Comptroller's Manual for National Banks"; see the section on "Minimum Security Devices and Procedures." Higher standards may be specified in the construction documents. The following requirements are based on the Comptroller's Manual.
2. **SURVEILLANCE SYSTEM (general)** devices should be:
 - a. Capable of enlarging images of persons to produce a 1 in. vertical head size.
 - b. Reasonably silent in operation.
 - c. Taking at least one picture every 2 seconds and operating not less than 3 min.
3. **SURVEILLANCE SYSTEM (other than walk-up or drive-in at teller's station or windows):**
 - a. Placed to reproduce identifiable images of persons either leaving the banking office or in a position to transact business at each station or window.
 - b. Capable of actuation by initiating devices located at each teller's station or window.
4. **SURVEILLANCE SYSTEM (walk-up or drive-in at teller's station or windows):**
 - a. Placed to reproduce identifiable images of persons either leaving the banking office or in a position to transact business at each station or window, and capable of actuation by initiating devices located at each teller's station or window.
 - b. Capable of actuation by initiating devices located at each teller's station or window. Such devices may be omitted when the teller is effectively protected by a bullet-resistant barrier. However, if the teller is vulnerable to larceny or robbery, access to actuate a surveillance system should be available.
5. **ROBBERY ALARM SYSTEM:**
 - a. Provide for banking offices at which the police ordinarily can arrive within 5 minutes after an alarm is actuated; all other banking offices should be provided with appropriate devices for promptly notifying the police that a robbery has occurred or is in progress.
 - b. Signals the police, through an intermediary, indicating that a crime against the banking office has occurred or is in progress.
 - c. Capable of actuation by initiating devices located at each teller's station or window, except those protected by bullet-resistant barrier.

- d. Safeguarded against accidental transmission.
 - e. Equipped with a visual and audible signal capable of indicating improper functioning of or tampering with the system.
 - f. Equipped with an independent source of power sufficient to assure continuously reliable operation of the system for at least 24 hr.
6. **BURGLARY ALARM SYSTEM:**
 - a. Provide for each banking office.
 - b. Capable of detecting promptly an attack on the outer door, walls, floor, or ceiling of each vault and each safe not stored in a vault.
 - c. Signals the police, through an intermediary, indicating that a crime against the banking office has occurred or is in progress. Where police cannot arrive within 5 minutes, a loud bell audible inside and 500 ft outside should be provided.
 - d. Safeguarded against accidental transmission.
 - e. Equipped with a visual and audible signal capable of indicating improper functioning of or tampering with the system.
 - f. Equipped with an independent source of power (such as a battery) sufficient to assure continuously reliable operation of the system for at least 80 hr in the event of failure of the usual source of power.
 7. **WALK-UP AND DRIVE-IN TELLER'S STATIONS OR WINDOWS:**
 - a. Tellers should be effectively protected by bullet-resistant barriers from robbery or larceny. Such barriers should be of glass at least 1 3/8 in. in thickness, or of material of at least equivalent bullet-resistance. Pass-through devices should not afford a person outside a direct line of fire.
 8. **VAULTS, SAFES, AND SAFE DEPOSIT BOXES:** Requirements are described in detail in the manual. See also the Bank Vault page in this chapter.
 9. **NIGHT DEPOSITORIES:**
 - a. Should consist of a receptacle chest having cast or welded steel walls, top, and bottom, at least 1 in. thick; a steel door at least 1 1/2 in. thick, with a combination lock; and a chute, made of steel that is at least 1 in. thick, securely bolted or welded to the receptacle and to a depository entrance of strength similar to the chute. Each depository entrance should be equipped with a burglar alarm and be designed to protect against the "fishing" of a deposit from the deposit receptacle, and "trapping" of a deposit for extraction.

10. AUTOMATED TELLER MACHINES (ATMs):

- a. Should weigh at least 750 lb empty or be securely anchored to the premises. Cash dispensing machines should contain, among other features, a storage chest of cast or welded steel walls, top, and bottom, at least 1 in. thick, with a tensile strength of at least 50,000 psi. Any doors should be constructed of steel at least equivalent in strength to the storage chest and equipped with a combination lock and a relocking device that will effectively lock the door if the combination lock is punched. The housing covering the mechanism for removing the cash from the storage chest should be designed as to provide burglary resistance at least equivalent to the storage chest and should also be designed to protect against the "fishing" of cash from the storage chest. The cash dispensing control and delivering mechanism should be protected by steel, at least 1/2 in. in thickness, securely attached to the storage chest. A cash dispensing machine that also receives deposits should have a receptacle chest having the same burglary resistant characteristics as that of cash dispensing storage chest and should be designed to protect against the fishing and trapping of deposits. Necessary ventilation for the automated machines should be designed so as to avoid significantly reducing the burglary resistance of the machines. The cash dispensing machine should also be designed so as to be protected against actuation by unauthorized persons, should be protected by a burglar alarm, and be located in a well-lighted area.

ATM ACCESSIBILITY

ADA Accessibility Guidelines (ADAAG) Section 4.34 regulate automatic teller machines (ATMs) and require that they be accessible as per 4.1.3, that their controls comply with 4.27 (height of forward reach 48 in., height of side reach 54 in.), that they have clear floor space in compliance with 4.24 (30 x 48 in.), and that they be usable by persons with impaired vision. Each ATM must comply, except where two or more are provided at a location; then only one must comply. Drive-up-only ATMs are not required to comply with clear floor space and reach requirements of 4.27 and 4.34.

11 TELLER AND SERVICE EQUIPMENT

MECHANICAL ACTIONED ORGAN (TRACKER)

ELECTROMECHANICAL OR ELECTROPNEUMATIC ORGAN

PIPE ORGANS

Organ builders recommend that the pipes and casework be located within the space they are to serve, not in an organ chamber. Organ and console, located in proximity to one another, should be placed so that sound can travel freely and directly to the listeners. No furnishings, people, or other barriers should be located in front of the organ pipes. Drafts and sudden temperature changes to the pipes may necessitate more frequent tuning.

While blowers may be built in to the organ casework, quieter operation can be achieved placing the blower in a remote space. However, air for the blower should be drawn from the room in which the organ is located to avoid tuning changes. Sound isolation, power requirements, serviceability, and need for a large duct chase to the organ must be considered when designing the blower room.

The number of stops or ranks required for an organ installation is related to musical flexibility rather than the loudness of an organ. The number of manuals will also vary depending on need for flexibility in the musical program. The table below outlines general guidelines to select the number of ranks for an organ installation.

ELECTROMECHANICAL AND ELECTROPNEUMATIC ORGANS

In these types of instruments, air that passes from the wind-chests into the pipes is controlled by either electromechanical or electropneumatic means. The required size of the organ pipe space will vary depending on the organ builder, but 8 sq ft per rank may be used as a general rule of thumb. If height is available, divisions may be stacked, reducing the floor area required by approximately 25%. All pipes must be accessible for tuning.

Weight of the organ will also vary. A general average is 450 lb per rank. If the organ is enclosed in a case, 50 lb per rank should be added. A stacked arrangement of pipe divisions will increase the floor loading proportionately.

MECHANICAL ACTIONED ORGANS

Commonly known as tracker organs, these instruments introduce air into the pipes through a valve mechanically attached to the keys on the console. The size of tracker organs is measured in terms of stops rather than ranks. Tracker organs are self-contained in wooden cases that house pipes, wind-chests, manuals, and mechanical

components. Such wooden cases may be designed to complement the architecture of the surrounding space. Compared to electromechanical and electropneumatic organs, a tracker organ will usually require more height for pipe cases but consequently less floor area. Often used in chapels because of their compactness, tracker organs are not limited to use in small worship spaces. In larger installations the console may be separated from the pipe chests by a limited distance, but must nonetheless be fixed, due to the mechanical connections between manuals and pipes.

Blowers for this type of instrument are built into the organ casework. Electrical power for the blower must be provided.

Mechanical actioned organs have an average weight of 400-500 lb per stop. A 3 ft 0 in. minimum access space behind the instrument is required for servicing and tuning.

Additional information is available through the Associated Pipe Organ Builders of America.

GENERAL SIZE REQUIREMENTS BASED UPON VARIOUS SEATING CAPACITIES

NO. OF SEATS	NO. OF STOPS	NO. OF RANKS	NO. OF DIVISIONS (1)	LOWEST PRINCIPAL (2)
150	4-9	6-12	2-3	4'
200	9-13	12-16	3	8'
250	12-18	16-23	3	8'
300	15-25	18-34	3	8'
400	20-30	26-44	3	16'
500	25-35	34-50	3-4	16'
750	30-45	44-64	4	16'
1000	35-50	50-78	4	16'

MINIMUM DIMENSIONS FOR A TRACKER ORGAN CASE BASED UPON VARIOUS NUMBERS OF STOPS

NO. OF SEATS	NO. OF STOPS	NO. OF RANKS	NO. OF DIVISIONS	LOWEST PRINCIPAL	W WIDTH	D DEPTH	H HEIGHT
150	4-9	6-12	2-3	4	10'	28"	10'
200	9-13	12-16	3	8	12'	28"	12'
250	12-18	16-23	3	8	15'	36"	14'
300	15-25	18-34	3	8	18'	42"	17'
400	20-30	26-44	3	16	20'	48"	23'
500	25-35	34-50	3-4	16	22'	52"	25'
750	30-45	44-64	4	16	22'	56"	25'
1000	35-50	50-78	4	16	22'	60"	25'

NOTE
Dimensions given are the maximum length, height, and width found if several models and styles exist.

STRINGS

BASS DRUMS

REEDS

HARP

NOTE
Harp are made in various sizes. A typical larger model is shown. The widest dimension is at the "soundboard" and equals 22 in. A harp case is 25 in. wide x 84 in. deep. Total weight, including harp and case, is approximately 200 lb.

MARIMBA XYLOPHONE

	L	H	D ₁	D ₂	WEIGHT
Marimba	87	36	33	16	175 lb
Xylophone	54	34	32	13	70 lb

NOTE: All dimensions are in inches. Many sizes are manufactured. The sizes given above are typical larger size that are available.

41 KEY ACCORDION

ONE PIECE SOUSAPHONE

TWO PIECE TUBA

FRENCH HORN
MELLOPHONE 22"x13"x16"
EUPHONIUM 36"x14"x18"

TENOR TROMBONE
BASS 37"x12"x14"

FLUTE PICCOLO 10"x3"x2"

TRUMPET

CORNET

BRASS

MUSIC RACK, WHEN OPEN INCREASES "H" 8" TO 10"

NOTE

Electronic organs are manufactured in many different types, styles, and models. Much smaller units than that shown are available as well as models weighing several tons. In general, allow space 72 in. wide x 72 in. long x 72 in. high. Also required is a clearance of approximately 50 in. to rear of unit for servicing. Consult organ manufacturers for exact details and models available.

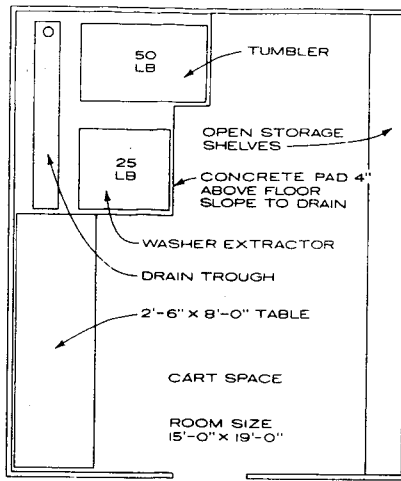

Pipe organs are designed to fit the building in which they are to be used. After factory assembly and testing, they are disassembled and shipped. Pipes may vary from less than 1 in. to more than 30 ft in length. A single organ may have thousands of pipes. Basic components are the pipes, wind chest, blower, valve mechanism, and keyboards.

John A. Lesire, AIA; Arlington, Virginia

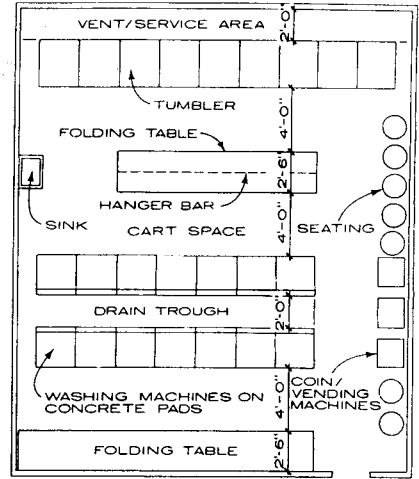

11 INSTRUMENTAL EQUIPMENT

20 UNIT APARTMENT BUILDING

20-30 UNIT MOTEL

COIN-OPERATED LAUNDRY

DRYER SIZES

CAPACITY (LB)	WIDTH	DEPTH
30	31"	44"
50	38"	44"
75	38"	49"
100	46"	62"
200	72"	54"

NOTES

1. Drain trench underneath or behind washers is for washing machine overflow and is sized to contain one complete dump from all machines.
2. Variables that determine size of on-premise laundry machines for hotels include number of rooms and hotel occupancy (at 10 lb of laundry per room).
3. Variables that determine the mix of single, double, and triple load washing machines and size of tumblers in laundrettes include the neighborhood and clientele expected.
4. Heavy-duty machines have fewer parts prone to breakage than coin-operated residential machines.
5. Tumbler capacity is twice washer capacity for permanent press fabrics.
6. Venting, electrical, and gas lines should run overhead and drop down to machines.
7. Washing machines in apartment buildings are generally coin-operated residential sizes.
8. Stackable dryers can provide a maximum utilization of space.
9. Commercial laundries must be accessible to persons with disabilities. Front-loading machines with accessible coin boxes are required.

COIN-OPERATED LAUNDRY

ON-SITE LAUNDRY

EXHAUST DUCT

WASHER/EXTRACTOR SIZES

CAPACITY (LB)	WIDTH	DEPTH
20	28"	30"
20-30	30"	32"
30-40	34"	36"
40-50	36"	44"
50-60	46"	40"

Above 60 lb, sizes may vary with manufacturer. Minimum clearances: 18 in. sides, 24 in. behind, and 48 in. front.

TUMBLER SIZES

CAPACITY (LB)	WIDTH	DEPTH
30	32"	45"
50	39"	47"
65	39"	53"
100	47"	64"

Minimum clearances: 24 in. behind, none sides, 48 in. front.

UTILITY HOOKUP

Duane Fisher; Richard Newlon Associates; Washington, D.C.

EXAMPLES OF MOST COMMONLY USED VENDING MACHINE TYPES

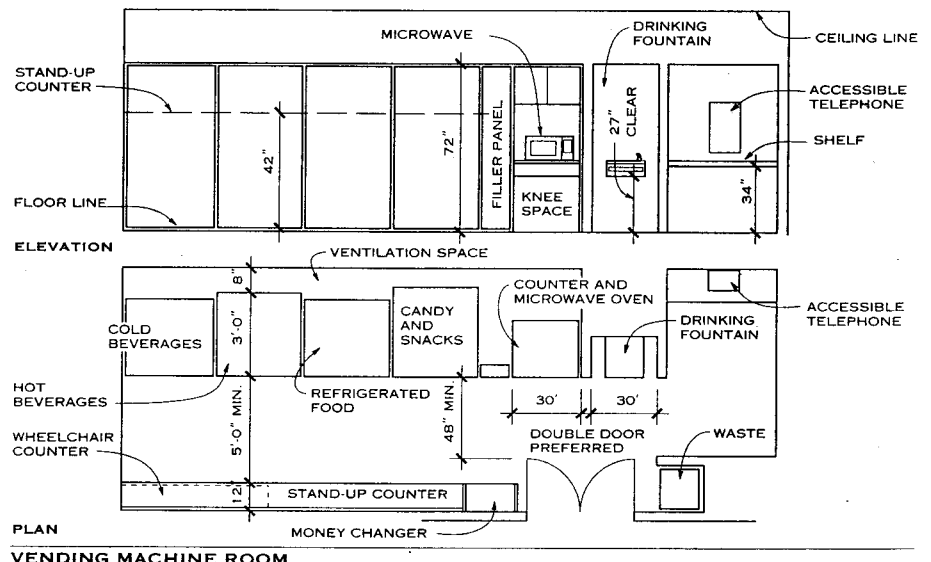

NOTE: Equipment dimensions are the most commonly used. Minimum and maximum dimensions are indicated in parenthesis

EQUIPMENT AND CLEARANCE DIMENSIONS

GUIDELINES

1. Front clearance of 5 ft preferred for machines.
2. Double door or larger than 3 ft wide door is preferred for vending machine area.
3. Americans with Disabilities Act (ADA) accessibility guidelines regarding reach heights, floor spaces, and clearance requirements must be followed.
4. Service access of machines is generally from the front. Some cigarette machines require access from the top.
5. Hot water is not required. Some beverage units require cold water supply with shut-off valve. Overflow waste collects into internal tray.
6. Refrigerated vending machines and microwave ovens require a rear wall clearance of up to 8 in. to permit cooling.
7. Electric service is 115 volt. Separate circuit for each machine is preferred. Amperages vary widely from 2 to 20 amp.
8. Merchandising flexibility is important.
9. Electronic controls allow multipricing.

VENDING MACHINE ROOM

Charles A. Szoradi, AIA; Washington, D.C.

11 VENDING EQUIPMENT

SECTION—MULTIMEDIA CONFERENCE ROOM

PLAN—MULTIMEDIA CONFERENCE ROOM

GENERAL

Teleconferencing is voice or data communication between remote locations and the origination site. Videoconferencing is teleconferencing with visual images added to voice and data communications. Generally, a videoconference space includes two video screens (with speaker for each), one screen for a video image from a remote location and another for supplementary images, such as those from a visual presenter, computer, or videocassette recorder.

SCREENS

Rear projection screens or large-screen monitors may be used for videoconferencing. When using a rear projection screen, it is possible to use brighter lights in the conference room during viewing than with a regular video monitor. (The forward projection screen may be perforated for sound. Forward projection systems do not need specially dedicated rooms but are usually mounted in a recess in the ceiling. They are not recommended for videoconference rooms since the high light levels required for video cameras tend to wash out forward projection screens.)

PROJECTORS

Slide, video, and overhead projectors are used in multimedia conference rooms. Video projectors are manufactured in three-lens CRT systems and single-lens LCD "light valve" systems. Three-lens projectors are best for screens up to 10 ft wide, a typical size for conference rooms, and are relatively inexpensive. If an audiovisual room is small, mirrors can be used to increase the image size for rear projection. For extra large conference rooms, with screens typically 15 to 25 ft wide, one-lens projectors can be placed any distance from the screen. This setup offers a bright, sharp image but presently is very expensive compared to the three-lens systems.

SPEAKERS AND MICROPHONES

Speaker placement is very important in a videoconference space. Speaker size usually depends on the size and shape of the space to be served.

There are three main types of speakers: Playback speakers, matched with prerecorded audio and video discs and tapes, are the largest speakers and offer the highest quality sound. Teleconference speakers, located below and near the center of the video screen, bring the audio feed from the remote videoconference space. Voice reinforcement speakers amplify voices from microphones in the same space. Microphones are placed at strategic locations in the videoconference space, including on tables, for primary participant involvement; on a stand, for secondary participant involvement; as a wireless or clip-on feature, for moderator/coordinator; and on the ceiling ("choir" microphones) to pick up specific sounds desired (to minimize feedback, these must be kept as far from the speakers as possible).

NOTE

A rear projection video camera and projection screen may be used with this arrangement; the room size depends on the screen size and video camera distance preferred.

VIDEOCONFERENCE ROOM

AUXILIARY VIDEO MONITORS

Space used by secondary videoconference participants may need auxiliary monitors to display supplementary video images such as charts or graphics that need close scrutiny. The main videoconference screen usually does not require this backup video screen.

MISCELLANEOUS EQUIPMENT

Some videoconference spaces are equipped with remote control systems, which control all electronic functions, including light and sound, from a central control panel. Some spaces are also equipped with special light fixtures that are tilted away from the screen area, shining more light on participants and less on the screen area.

Other equipment typically includes a videocassette player, an amplifier for speakers, an automatic microphone mixer, compact disc player, audiocassette player, matrix switcher, and coder/decoder equipment to convert analog signals to digital signals for fiber-optic transmission.

NOTE

This wall unit may be assembled on a portable console for mobility.

TYPICAL VIDEO MONITOR VIDEOCONFERENCE WALL

NOTE

Ratio of screen height to width: video 3:4; HDTV, 9:16.

TYPICAL REAR PROJECTION VIDEOCONFERENCE WALL

VIDEOCONFERENCE PODIUM

NOTE
This system is typically operated by remote control and may be linked with motorized projection screen operation. Some models are equipped with a trapdoor-type closer.

RETRACTABLE RECESSED VIDEO PROJECTOR MOUNT

NOTE
This system requires half the space of a direct-projected rear projection system. Rear projection offers the best image quality of all projectors.

REAR PROJECTION VIDEO SCREEN FOR SMALL PROJECTION ROOM

NOTE
Ceiling tile may be installed under the metal housing and cut around a trapdoor with a tile piece attached. The tensioned screen edge keeps it taut, good for three-lens video and data projection, which require perfect convergence.

MOTORIZED RECESSED PROJECTION SCREEN

NOTE
This mounting is for forward screens up to 20 ft wide and rear screens up to 12 ft wide.

METAL FRAME SURFACE-MOUNTED PROJECTION SCREEN

NOTE
Single-lens video projectors do not require a predetermined distance or screen size for placement; they may be placed at any distance and focused like a slide projector. These projectors produce bright, high-resolution images.

VIDEO PROJECTORS

OVERHEAD PROJECTOR

NOTE
This forward projection screen is typically made of silver lenticular fiberglass that is matte white, glass-beaded, and flame and mildew resistant.

SPRING ROLLER-OPERATED PROJECTION SCREEN

NOTE
This mount is for rear projection screens up to 20 ft wide and forward projection screens up to 30 ft wide.

METAL FRAME/TENSION CABLE PROJECTION SCREEN MOUNT

NOTE
The image may be viewed in the room or a remote location.

VISUAL PRESENTER

VIDEO MONITOR MOUNTING

NOTE
This framing detail is for screens approximately 6 ft high by 8 ft wide, maximum.

NOTE
This framing detail is for heavy-duty use, for screens up to 10 ft high by 25 ft wide.

REAR PROJECTION SCREEN FRAMING

SPEAKER INSTALLATION DETAIL

Polysonics; Washington, D.C.

GENERAL

A typical computer workstation in the office is equipped with a central processing unit (CPU), monitor, keyboard, and mouse. Various peripheral devices to help store, process, and retrieve data (printers, plotters, scanners, tape backup units, etc.) can be attached.

LOCAL AREA NETWORK (LAN)

LANs have changed the layout of computer equipment in the office. In years past, each workstation had its own printer, modem, scanner, etc. With the introduction of networks, these peripheral devices are now shared among a group of users. For example, one printer/modem/scanner can easily service as many as 20 users.

NOTE

Monitors display information to be processed. Available in one of three general types—monochrome, gray-scale, or color—they vary in diagonal screen dimensions from 13 to 21 in. (some are available between 9 and 13 in.).

MONITOR

DESK TOP

TOWER TYPE

NOTE

The central processing unit (CPU) is where computer data are stored, processed, and retrieved. CPUs are rated by processing speed (megahertz, MHz), hard-disk capacity (megabytes, MB, or gigabytes, GB), and random access memory (RAM).

CENTRAL PROCESSING UNIT (CPU)

NOTE

Laser printers are typically used in larger business settings where speed, performance, and print quality are important. Most laser printers are rated at 4 to 8 pages per minute (ppm); some may be rated as high as 20 ppm.

LASER PRINTER

NOTE

Inkjet printers are generally more economical than laser printers. They are typically rated at 2 to 4 pages per minute (some may be as high as 8 ppm) and used in smaller business settings or home offices. The print quality is generally not as crisp as that from a laser printer.

INKJET PRINTER

NOTE

The keyboard is a primary computer input device.

KEYBOARD

NOTE

A tape backup unit is an external storage device, typically used to copy and save data in case a hard disk crashes.

TAPE BACKUP UNIT

NOTE

A mouse is a pointing device used to move a cursor around a screen. It is helpful in operating a computer with a graphical user interface.

MOUSE

NOTE

A modem is used to transmit data from one computer to another computer or other device, such as a fax machine, via telephone lines.

MODEM

NOTE

Scanners allow a computer to read pictures or words from printed pages. This material is then stored in data files in the computer.

SCANNER

NOTE

A plotter is a device that draws with a plotting pen. It is typically used to plot or print graphics from CAD-type programs.

PLOTTER

Elin Landenburger; Alexandria, Virginia

Provides positive weather seal; protects dock from wind, rain, snow, and dirt. Retains constant temperature between dock and vehicle.
CUSHIONED DOCK SHELTER

Automatic or manual operation for high volume docks where incoming vehicle heights vary widely; must be installed in a preformed concrete pit. Exact dimensions provided by manufacturer.
PIT TYPE DOCK LEVELER

Manual operation for high or medium volume docks where pit type levelers are impractical or leased facilities are being used.
EDGE OF DOCK LEVELER

Used for low volume docks where incoming vehicle heights do not vary. Use portable type leveler such as a throw plate.
LOADING DOCK WITHOUT LEVELER

SILL FOR PIT LEVELER

SILL FOR EDGE OF DOCK LEVELER

DOCK SILL WITHOUT LEVELERS

ROOM PLAN

ROOM PLAN

NO. OF CONTAINERS	A	B	C
3			11'-10"
4	9'-8"	7'-0"	13'-5"
5			17'-1"
6	10'-6"	8'-0"	
8	11'-6"	9'-1"	
10	12'-6"	10'-9"	

UNIT "B" & "C" COMPACTOR WITH STORAGE CONTAINERS

APARTMENT SELECTION GUIDE

The daily refuse output of 15 to 30 apartments is approximately 1/2 cu yd (13 1/2 cu ft) weighing about 75 lb. At standard compaction ratios of 4 or 5 to 1, a compactor will reduce the refuse to an approximate volume of 3 cu ft.

If the apartments are large, averaging two or three bedrooms, use the figure of 15 apartments per bag. If apartments average one or two bedrooms, use 20 to 25 apartments per compacted bag, and if the units are small efficiency apartments or one-bedroom apartments occupied by young working people or the elderly, use the figure of 30 apartments per compacted bag per day.

AVERAGE HOUSEHOLD COMPACTOR

ROOM PLAN

UNIT "D" INDUSTRIAL COMPACTOR

UNIT "E" COMBINATION SHREDDER COMPACTOR

Walter H. Sobel, FAIA, & Associates; Chicago, Illinois

BOTTLE AND CASE DIMENSIONS

SIZE	BOTTLE DIMENSIONS (IN.)			WEIGHT
	BORDEAUX	BURGUNDY	CHAMPAGNE	
375 ml	Diameter	2.4	2.6	2.8
	Length	9.5	9.5	10.5
	Incremental height	2.1	2.3	2.5
750 ml	Diameter	3.0	3.2	3.5
	Length	12.0	11.8	12.5
	Incremental height	2.6	2.8	3.0
1.5 L	Diameter	3.8	4.2	4.4
	Length	14.0	14.0	14.8
	Incremental height	3.3	3.6	3.8

NOTES

1. Bordeaux bottles represent the majority of wine from Italy, and from parts of France and the United States.
2. Burgundy bottles are from some parts of France and the United States.
3. Champagne bottle sizes are universal.
4. Incremental height of bottles is used where bottles are stacked staggered.

PREMANUFACTURED CELLARS

BOTTLE CAPACITY	HEIGHT (IN.)	WIDTH (IN.)	DEPTH (IN.)
50	34	24	24
465	74	52	27
765	80	73	49
1950	80	73	108

GENERAL NOTES

1. The ideal temperature range is 55-58°F. Temperature consistency is very important. Avoid diurnal swings in temperature, but a yearly variation of 5-10° is acceptable.
2. Relative humidity should stay in the 60-80% range. Lower humidity promotes evaporation loss through bottle corks; higher humidity allows mold, which breaks down the cellulose in labels and storage structures.

PSYCHROMETRIC CHART

3. Larger cellars should accommodate a range of storage options from individual bottles to full cases.
4. Air conditioning equipment may be single unit or split systems. Use systems designed for wine storage. Standard commercial refrigeration is too cold and lowers humidity. Standard room units are not designed to operate at low enough temperatures and coils tend to ice up.
5. In humid areas, provide a vapor barrier installed on the warm side of walls and ceilings.

SAMPLE ESTIMATION OF AREA REQUIREMENTS

To find the area required for a cellar to hold 2000 bottles of wine:

1. 2000 bottles (divided by) 12 = 166.66 cases
Total weight = 5800 lbs.
2. One case occupies approximately one square foot of wall area.
3. Assume cases are raised off the floor one foot, and bottles are stacked five feet high. Therefore, 33.33 linear feet of wall area is required (166.66 (divided by) 5).
4. Assuming a minimum 3 ft aisle between storage bins along walls yields a cellar 5 ft wide by 16 ft long.

BOTTLE STORAGE CONFIGURATIONS

PLAN

SECTION

WOOD FRAME CELLAR FOR 875 BOTTLES

J.T. Devine, AIA, and Robert E. Anderson, AIA; Robert E. Anderson Architect, AIA; Santa Rosa, California

GENERAL NOTES

1. Food service equipment must meet the sanitation and safety construction standards of the National Sanitation Foundation, an independent nonprofit organization dealing with public health issues. Other organizations involved in standards for food service equipment are Underwriters Laboratories (UL) and the American Society of Mechanical Engineers.
2. Food service equipment is either fabricated from a custom design or selected from a catalog. There are many variations in equipment specifications for such elements as power supply, door swings, finish, metal type, metal gauge, capacity, and accessories. These food service equipment pages show typical layouts and equipment for a mid-sized hotel kitchen that must produce a la carte meals, room service meals, banquets, etc. Equipment size and type will vary according to variables such as dining room size, menu type, and building type.
3. Prefabricated and custom-built walk-in refrigerators and freezers are specified differently. Consult a food service consultant for sizing, since these units can be specified to an infinite variety of sizes and shapes.
4. Food service equipment is primarily gas-powered, unless fumes are a concern, in which case electricity is used. If possible, steam is the preferred energy source because of its economy and efficiency.
5. Confer with a qualified food service consultant to determine the precise equipment and layout for the space to be served.

NOTES

1. Wood is used only for dining room or bakery production tables. Hard rock maple and pecan cutting tops are usually specified. Not to be used for nonbakery food production; cracks in wood surface can harbor bacteria.
2. Plastic laminate should not be used where cutting, chopping, or carving will occur. It will not warp or crack; it is an inexpensive substitute for stainless steel for nonfood production or decorative countertops, where codes allow.
3. Stainless steel is the most commonly used material for all areas in a commercial kitchen. Although relatively expensive, it is extremely durable. Cold-rolled steel stock is formed under pressure; welded connections are used only within equipment (bolted connections are used to connect pieces of equipment).
4. Galvanized iron and sheet metal are used as underbracing for equipment and as an inexpensive substitute for stainless steel for legs, tables, and interior shelves.
5. Other materials, including glass, ceramic tile, copper, and brass, may be used for food service equipment, but all surfaces that come into contact with food or the food handler should be smooth and nonporous and resist chipping or wear under frequent use. Surfaces must also resist the corrosive effects of salt, food acids, and oils.

MATERIALS USED IN FOOD SERVICE EQUIPMENT

GAUGE AND USE OF GALVANIZED STEEL

GAUGE	RECOMMENDED USE
12	Support channels and bracing
14	Undershelves and partitions
16	Undershelves and side panels
18	Utensil drawers, hoods, body panels, interior partitions

GAUGE AND USE OF STAINLESS STEEL

GAUGE	TYPICAL USE
8 and 10	Support elements for heavy equipment or at stress points
12	Heavily used tabletops, pot sinks, or other surfaces that will receive a great amount of wear
14	Tabletops, sinks, shelves, and brackets that will be used frequently or that will hold heavy objects
16	Small equipment tops and sides that will carry light objects; shelves under equipment and heavily used side panels
18	Side panels that are not exposed to much wear, equipment doors, hoods, and partitions
20	Covers for supported or insulated panels, such as refrigerators or insulated doors

NOTE

Tubular metal pieces should be welded, coved together, and sanded smooth. A layer of cork-based sound-deadening material may be applied to the underside of tabletops

and finished with aluminum lacquer. Consult health codes for types of lacquer permitted.

FABRICATED WORKTABLE

FABRICATED WORKTABLE WITH SINK

John Birchfield; Birchfield Foodsystems, Inc.; Annapolis, Maryland

GENERAL

Exhaust hoods remove air, water vapor, grease, and food odors from the kitchen area and air and water vapor from dish washing areas. Ovens and steam-jacketed kettles only require hoods that remove air, heat, and water vapor, but if large amounts of grease from a broiler, char-broiler, fryer, or grill are present, the hood system must extract this pollutant before the air is drawn outside by fans. This is done with grease "cartridges," or with stainless steel extractors, both of which violently blow the exhausted air around. This flings the grease particles to the sides of the baffles; then they are collected in a trough for easy removal, or run out a drain. The extractors can usually be washed in a standard kitchen dishwasher. Consultation with code officials and food service consultants is of utmost importance when designing exhaust hoods.

NOTES

1. CFM requirements for exhaust hoods are determined by the length of the hood and the equipment types underneath. Typical requirements range from 150 to 450 CFM per linear foot of hood.
2. Some codes may require a higher exhaust rate. To make up this air differential and to prevent more air from being drawn from surrounding areas, introduce air through a supply duct. The supplied air should make up 50 to 85% of the total exhaust.

NOTE

Single exhaust hoods are available for single cooking lines. Dimensions and capacities of exhaust hoods vary with particular kitchen cooking requirements.

TYPICAL EXHAUST HOOD REQUIREMENTS

NOTE

Channel edges and bullnose edges are used only when water will not be spilled on the table surface.

margin at the hood to handle thermal surges, crosscurrents, etc.

EXHAUST HOOD CHARACTERISTICS

ELEVATED TABLE-MOUNTED SHELF

NOTE

Hand sinks are typically required by code near every major work area in the kitchen. Some are equipped with an electronic eye or foot levers to encourage workers to wash their hands.

WALL-MOUNTED HAND SINK

CHROME-PLATED WIRE SHELF

STAINLESS STEEL POSTS (INDENTED TO AID IN SHELF SUPPORT)

FLOOR-MOUNTED LEG (OPTIONAL)

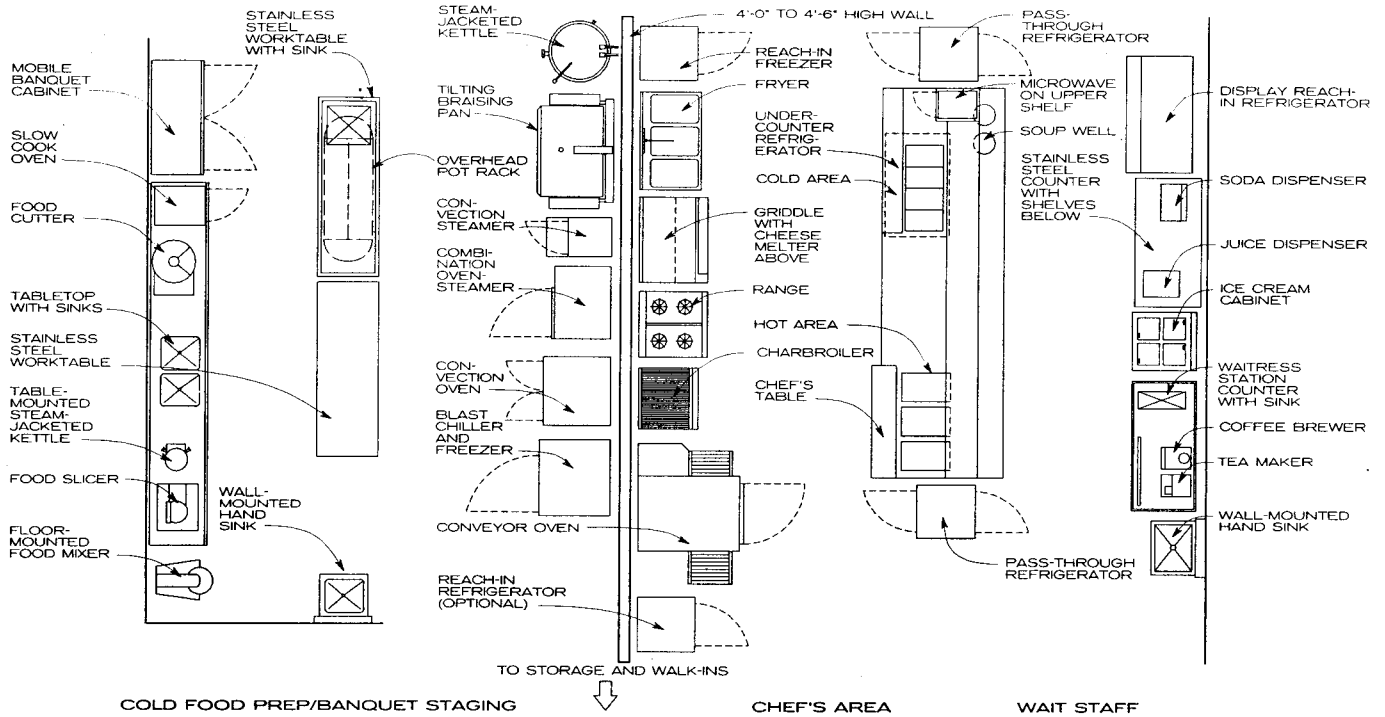

ADJUSTABLE BULLET FEET

NOTE

This shelf may be used in dry storage rooms and walk-in refrigerators and freezers. Shelving may be mounted to the wall for stability and can be attached to other modular units.

MODULAR WIRE SHELVING UNIT

John Birchfield; Birchfield Foodsystems, Inc.; Annapolis, Maryland

TYPICAL KITCHEN PLAN

CHEF'S SIDE

WAIT STAFF PICK-UP SIDE

NOTE

The chef's table is the heart of the kitchen operation; it is here the hot and cold food is arranged on plates for pick-up by the wait staff. Since both kitchen and wait staffs need access, the table is usually placed in an island configuration. Usually custom-built to meet the chef's requirements.

CHEF'S TABLE

NOTE

This unit is typically placed either at end of the chef's table or in the wall separating the service area from the kitchen.

PASS-THROUGH REFRIGERATOR

NOTE

This unit has a motor capacity from 1/4 to 1 HP and a maximum load of 500 to 1000 lb.

UNDERCOUNTER REFRIGERATOR FREEZER

NOTE

This cabinet is used to keep preplated meals hot.

MOBILE BANQUET CABINET

NOTE

This unit provides cook/chill and cook/freeze options.

BLAST CHILLER AND FREEZER

John Birchfield; Birchfield Foodsystems Inc., Annapolis, Maryland

NOTE

Fryers cook food by immersing it in hot fat and are powered by either gas or electricity. Fryers can be either freestanding, table mounted, modular (electric only), or drop-in (electric only). Typical capacities range from 15 to 75 lb of shortening or fat. Two modular units with a filter dump station between them is a common fryer configuration.

FRYER

NOTE

Griddles, also called grills, have a flat, heated surface that cooks food quickly. They can be freestanding units, part of a range, table models, or part of a modular unit and are either gas- or electric-powered.

GRIDDLE WITH CHEESE MELTER

NOTE

The range is often the most heavily used piece of equipment in a food service facility. The open-top gas range is preferred by cooks, especially for sauteing, because the flame is visible and easily adjusted. Electric models are available.

RANGE

NOTE

A charbroiler cooks food rapidly, one side at a time, usually with radiant heat produced by gas or electricity. There are many types: freestanding top burner broilers, charbroilers, salamanders (small above-the-range broilers for last minute browning), conveyor broilers, and rotisseries.

CHARBROILER

NOTE

Also called a tilting skillet or tilting frying pan, this braising pan can be used for grilling, steaming, braising, sauteing, or stewing. It holds a large volume of food, typically 20 to 40 gallons. The pan body tilts down so that liquids can be poured off, and also to aid in cleaning.

TILTING BRAISING PAN

NOTE

Low- (5 lb per sq in.) and no-pressure steamers are used to prepare vegetables, seafood, eggs, rice, and pasta and work very efficiently. They are powered by gas, electricity, direct steam, or a steam coil.

CONVECTION STEAMER

NOTE

Also called a "combi," it combines a convection oven with a steamer in one piece of equipment. It is popular because of its versatility.

COMBINATION OVEN-STEAMER

NOTE

A conveyor oven moves food through a heated cavity at a predetermined speed, ensuring even cooking time and allowing high-volume production. Heating is by convection or radiant heat, on one or both sides of the belt. Pizzas, cookies, hamburgers, and seafood all travel this route.

CONVEYOR OVEN

NOTE

Primarily used to roast meats, this oven can also be used to warm hot foods and proof bread or dough. Designed to cook at 200 to 240°F, these ovens reduce shrinkage of roast meats up to 40% and save energy.

SLOW-COOK OVEN

NOTE

Used for chopping meats and vegetables, this machine is similar in function to a food processor. It is also called a "buffalo chopper." Another larger type is a vertical cutter mixer (VCM), with a capacity of 30 to 45 quarts.

FOOD CUTTER

NOTE

Motor capacity varies from 1/5 to 1/2 HP.

FOOD SLICER

NOTE

This is used to mix/process large quantities of food, especially if a variety of attachments is required.

FOOD MIXER

John Birchfield; Birchfield Foodsystems Inc.; Annapolis, Maryland

TYPICAL BAKERY AREA PLAN

NOTE
 Convection ovens need less energy and less space than other commercial kitchen ovens. A fan circulates heat evenly throughout the oven chamber, and the interior shelves can be stacked very close together.

NOTE
 The rack is loaded, usually with baked goods, and wheeled into the oven. The rack rotates on a carousel or a ceiling hung bracket, baking food with a steady, even heat. Rack ovens are powered by gas, electricity, or oil.

CONVECTION OVEN

RACK OVEN

NOTE
 Used for storage of baked goods and ingredients like flour, sugar, and rice. Bin can be stored under open-based tables.

NOTE
 This unit proofs bakery items (emits the moist, low heat that dough needs to rise), then, after a specified amount of time, issues cold air to halt the rising.

ROLLING INGREDIENT BIN

RETARDER/PROOFER

NOTE
 A steam-jacketed kettle is used for soups, stews, sauces, boiled meats, etc. The kettle is double-walled; heat comes from an inner jacket that contains the steam. The kettle can be mounted either on a pedestal, on legs, on a yoke (trunnion) for tilting, on the wall, or on a tabletop.

STEAM-JACKETED KETTLE

NOTE
 This stand can hold up to four steam-jacketed kettles on pinions, or trunnions, which enable tilting and pouring.

TRUNNION STAND

NOTE
 Dimensions shown are for medium-use kitchens; review unusual conditions, such as use of extra large pots or need for wider support spans, with a structural engineer.

OVERHEAD POT RACK

NOTE
 Baker's tables are used exclusively for making baked goods. Any other use that could bring bacteria-laden foods into contact with the wood surface is prohibited.

BAKER'S TABLE

DISPLAY REACH-IN REFRIGERATOR

NOTE
Multipurpose table unit used to store cups and glasses and to prepare soft drinks, coffee, tea, and other beverages.

WAITRESS STATION COUNTER

ICE CREAM CABINET

TYPICAL DISHWASHING AREA PLAN

NOTE
The sink illustrated is a fairly common type, but depth of sinks, number of sinks, and size of drainboards can vary.

POT AND PAN SINK

SOILED DISH TABLE

NOTE
Typically this is mounted on the soiled dish table.

TABLE-MOUNTED GLASS RACK SHELF

NOTE
A spray of hot water and detergent washes the dishes, followed by a rinse of 180°F water or chemicals to sanitize them. Sometimes an exhaust hood is used; the design of machines varies greatly.

DISHWASHING MACHINE

CLEAN DISH TABLE

John Birchfield; Birchfield Foodsystems Inc.; Annapolis, Maryland

NOTE
This drops into a cutout in the wait staff counter.

DROP-IN SODA DISPENSER

NOTE
Typically tea makers sit on top of the wait staff counter.

TEA MAKER

NOTE
Coffee brewers sit on top of the wait staff counter.

COFFEE BREWER

NOTE
Juice dispensers sit on top of the wait staff counter.

JUICE DISPENSER

TYPICAL BAR EQUIPMENT LAYOUT

NOTE
These units vary according to use, with different cover opening styles (hinged or sliding), condiment tray configurations, and placement of ice dividers in chest.

ICE CHEST

NOTE
Bottle rails are attached to the front of sinks, ice chests, or other bar equipment. Lockable models are available.

BOTTLE RAIL

NOTE
A sink with drainboard may be substituted for this.

GLASS WASHER

NOTE
A mechanical glass washer may be substituted for this.

SINK WITH WORKBOARD

BAR HAND SINK

GLASS STORAGE BIN

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

NOTE
Frosters chill mugs, glasses, and plates to minus 10°F on interior shelves. Usually they are placed under the front bar.

FROSTER

NOTE
These are used to cool beverages to between 34° and 40°F.

BOTTLE COOLER

NOTE
This dispenses water, soda, wine, and other drinks.

MECHANICAL POSTMIX BAR DISPENSER

BLENDER STATION

TWO KEGS = 48"
(ONE KEG: 23",
THREE KEGS: 60",
FOUR KEGS: 80")

NOTE
The dispenser shown is a direct draw system. Kegs may be up to 300 ft away from the bar (usually in a walk-in cooler).

BEER DISPENSER

REMOTE BEVERAGE DISPENSER DETAIL

ICE CREAM CABINET

NONREFRIGERATED: 24"
REFRIGERATED: 48" TO 95"

BACK-BAR DRY STORAGE CABINET

TEE TOWER

DRAUGHT ARM BEER DISPENSING FAUCETS

CAPPUCCINO/ESPRESSO MACHINE

NOTE
These are also called bottle steps.

LIQUOR DISPLAY SHELVES

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

GENERAL NOTES

1. See kitchen and laundry layout pages for locations of washers, dryers, and dishwashers and their respective wall chases for pipes and vents.
2. Check manufacturers' catalogs for "open-door" dimensions if door clearances may be a problem.
3. All dimensions given are actual ones, but certain variations in body design may affect the actual depth of particular models. Check all units for exact voltage. Some units available with gas.

NOTE
Front-loading washers may be equipped with an integral top if not mounted under a counter.

BUILT-IN (UNDERCOUNTER) FRONT-LOADING WASHER

FREESTANDING TOP-LOADING WASHER

NOTE
Do not place dishwasher farther than 10 ft from sink, typically, for proper drainage.

BUILT-IN DISHWASHER

ELEVATION

SECTION

UTILITY CONNECTION BOX (RECESSED)

NOTE
Front-loading dryers may be equipped with an integral top if not mounted under a counter.

BUILT-IN (UNDERCOUNTER) FRONT-LOADING DRYER

NOTE

PORTABLE DISHWASHER

STACKED WASHER-DRYER COMBINATION

FREESTANDING FRONT-LOADING DRYER

TRASH COMPACTOR

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

GENERAL NOTES

1. Electric and gas ranges are available. Smooth surface electric cooktops have radiant and halogen heating elements or an induction coil below a glass-ceramic top. Radiant heating elements (below surface or surface units, plug-in, coil, or solid plate) provide heat directly from resistance elements. Halogen-type elements usually combine radiant elements with a halogen light source, which allows the element to heat up faster than a radiant element alone. Other range options include griddles and charbroilers. Induction elements consist of a high frequency induction coil beneath a glass-ceramic surface. Metal cooking utensils are heated by magnetic friction without directly heating the cooktop surface. Induction elements are considered energy-efficient.
2. Ovens are available in gas or electric, either as conventional, combination radiant/convection, or microwave

- models. Convection ovens have a dedicated third element (in addition to the top and bottom elements) surrounding the convection fan at the rear of the oven, which circulates heated air evenly throughout the oven, eliminating any unevenness in temperature.
3. All dimensions shown should be used as general guidelines only; consult manufacturers for specific dimensions.

NOTE

Freestanding range/ovens may have front-mounted controls; if so, the backsplash area may be eliminated.

FREESTANDING RANGE/OVEN

FREESTANDING RANGE WITH LARGE AND SMALL OVENS

NOTE

Drop-in ranges typically hang from and are supported by the countertop and do not rest on the cabinet or floor below.

DROP-IN RANGE OVEN

NOTE

Conventional or microwave ovens may be installed above a counter-height range/stove.

FREESTANDING RANGE WITH UPPER AND LOWER OVENS

NOTE

Single wall ovens may be installed in a wall cabinet (at eye level) or under the counter in a base cabinet.

BUILT-IN SINGLE WALL OVEN

NOTE

Radiant and halogen cooktops typically require a 5 in. min. free area between the countertop and any combustible material below (typically shelving). Downdraft fan assemblies are located directly under a vent (rear pop-up vents offer the best free space under a counter). Available two-element cooktops are approximately 12 in. wide.

DROP-IN RANGE COOKTOP

NOTE

Range hoods vent through filters back into the room (self-venting) or through ducts and filters to the outdoors. Accessories such as fans, filters, and lights vary greatly in design configuration. Some ranges and cooktops are equipped with downdraft venting, which may eliminate the need for an overhead range hood. Fans typically vent from 50 to 350 cu ft/min (CFM) of air for standard residential cooktop use. For commercial ranges, consult a design professional for CFM requirements.

RANGE HOOD

NOTE

Venting may be directed to the outside or recirculated.

BUILT-IN MICROWAVE OVEN

BUILT-IN DOUBLE WALL OVEN

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

GENERAL NOTES

1. Ultra energy-efficient refrigerators/freezers are available in AC models for conventional utility power and DC models for alternative (remote) energy applications. Some models use 60 to 90% less energy than standard energy-efficient models. Many standard refrigerator and freezer manufacturers have CFC-free models, which means no CFCs were used in the insulation or in the coolant system. Consult manufacturers.
2. See manufacturers' catalogs for actual dimensions of specific units, which may include the number of burners, refrigerator size, sink size, finish materials, and options such as garbage disposal, range hood, microwave oven, ice maker, dishwasher, or freezer.

GENERAL NOTES
Lamps consist of three components:
1. Light source.
2. Reflector or diffuser.
3. Support structure.

Various combinations of these components create an unlimited variety of lamps for accent lighting, task lighting, ambient lighting, and general lighting. Each type of bulb creates different qualities and quantities of light; consult manufacturer for specific attributes. Light can be reflected in specific directions for accent, task, or ambient lighting or diffused for general lighting.

NOTES

1. Open classroom layouts are based on modular partition dimensions: 48 in. wide x 60 in. or 72 in. high.
2. Partitions are available with hinges to connect with standard height cabinets, or with casters for freestanding use.
3. Surfaces for partitions are vinyl, porcelain enameled steel, chalkboard, or tackboard.
4. Carrels may be ordered with 31 in. high desktops for use with wheelchairs.
5. Typical seat height is 17 in.
6. Unit dimensions are to farthest extremity.

BOOK CAPACITY PER GROSS FLOOR AREA

Many variables must be considered: size and kind of books, book lifts, carrels, number and width of aisles, ultimate capacity, and so on. Variances run from 13 1/2 to 19 books/sq ft. For a rule of thumb allow 16 books/sq ft of gross area. The average dead load of books is 25 lb/cu ft.

PEWS AND FRONTAL

INTRODUCTION

Ecclesiastical furnishings are as much a part of the ambience, symbolism, and meaning of a worship environment as the structure and architecture itself. Virtually all ecclesiastical furnishings are available from manufacturers in pre-designed, prefabricated form. For pews and chairs, in particular, such stock or semicustom items can be quite satisfactory and economical. When special scale, material, or symbolism is desired, custom-designed and custom-built furnishings may be more appropriate, as is often true for chancel/sanctuary furnishings such as the pulpit, communion table, font, and clergy chairs. Illustrations on this and the following page give information about the general size and character of such furnishings. The theological and liturgical attitudes of each church should guide the design and execution of ecclesiastical furnishings.

PEWS

Most pew manufacturers offer a diverse selection of styles, materials, and finishes, and many will custom build special designs prepared by architects. Pew ends contribute most to style and are available in numerous designs, from closed to semiopen to fully open. Kneelers are optional, some are available with hydraulic pistons to govern speed (and noise) when they are lowered and raised. Other options include book, card, pencil, and communion cup holders.

When planning pew locations, leave spaces at the ends of some pews for wheelchair users. Distribute these open areas around the sanctuary, leaving room at some locations for two to three wheelchair users to sit together.

STACKING CHAIRS

A variety of stacking or modular chairs are available and well suited for use in small churches, chapels, and choir areas, where flexibility of arrangement or complete removal is desired. Like pews, these chairs may be upholstered in differing degrees and equipped with kneelers, book holders, and other features. Most manufacturers offer an interlocking device that enables users to join rows of chairs together for temporarily fixed arrangements. In some jurisdictions, interlocking is a code requirement. Stacking capability allows efficient storage of chairs. When worship spaces are large enough to require a sloped floor for proper sight and sound lines, chairs are generally not advisable. (Stacking chairs are illustrated on the following page.)

PULPIT

The pulpit (Protestant) has historically been a fixed chancel/sanctuary furnishing. However, increasing demand for multiple uses of worship space often requires that all furnishings be movable. Among the most important features of a pulpit is an adjustable top, to accommodate the different heights of speakers. A drop-down step may also be desirable. A pulpit should include a concealed reading lamp

PEW SPACING

BACK-TO-BACK BETWEEN PEWS			PEW LENGTH*		
NO. OF SPACES	2'-10" SPACING	3'-0" SPACING	NO. OF PERSONS	1'-8" PER PERSON	1'-10" PER PERSON
5	14'-2"	15'-0"	3	5'-0"	5'-6"
10	28'-4"	30'-0"	5	8'-4"	9'-2"
20	56'-8"	60'-0"	7	11'-8"	12'-10"
30	85'-0"	90'-0"	9	15'-0"	16'-6"
			11	18'-4"	20'-0"
			12	20'-0"	

*Minimum space allowed per person is 1 ft 6 in. Based on NFPA 101 Life Safety Code (1985), the maximum number of seats allowed in a row with aisles at both ends of the row is 14; maximum length allowed for a row is 21 ft 0 in.

(especially where A/V darkening is employed), A/V controls, and a built-in clock. Although lavalier or wireless microphones are used extensively, provide a concealed microphone cable raceway and pad the pulpit top to minimize the noise of rustling notes, which sensitive microphones may amplify.

AMBO/READING DESK

The ambo (Roman Catholic), or movable reading desk, is for reading or preaching. It requires an adjustable top to allow for the heights of various users. As shown, the top may be removable to accommodate readers in wheelchairs. A shelf pulled out from behind allows a book to be brought over the lap of a wheelchair-bound person. Size and scale of the desk will vary, depending on the size of the room.

LECTERN/SONG LEADER DESK

Lectors or song leaders use this very flexible, open, and mostly transparent stand. Its top is sloped, with a book stop much like the ambo but of smaller scale.

COMMUNION RAIL

Communion rails should provide for comfortable kneeling and perhaps for the disposition of individual communion cups. In worship spaces also used for concerts or drama, communion rails may need to be easily removable.

STACKING CHAPEL/CHOIR CHAIRS

CLERGY/PRESIDER CHAIR

ALTAR/COMMUNION TABLE

In most churches, the altar or communion table is the primary focus and therefore the most visually prominent furnishing. Style and symbolism of the altar/table are deeply rooted in the liturgy of individual churches, and their design usually requires the participation and theological direction of both clergy and laity. Appropriateness of scale and material is particularly important and widely variable. The altar/table is among the furnishings most suited for artist collaboration in design and execution.

BAPTISMAL FONT

A font for baptizing infants and/or adults may be placed in various locations, including at the chancel/sanctuary or at the entrance to the church in the narthex. In some cases, the font may be alternately moved between these locations. Space for family and friends to gather around the font

is usually required. In many churches, the font must be in a position that permits the entire assembly to view the baptism.

BAPTISTRY

Churches practicing baptism by submersion require an altogether different style of baptistry, involving a pool or tank that allows full entry by laity and clergy. Prefabricated baptistry tanks are available and custom installations possible. For churches practicing infant baptism by submersion, allow for a pool 36 x 36 x 10 in. deep. For adult immersion, provide a 4 x 4 ft recessed area in the floor with a drain adjacent to the baptistry for water poured over the candidate. Baptistry water is to be heated and continuously circulated by a pump. Significant evaporation may take place and a means for automatic or regular refilling should be accom-

modated. Some areas may require water treatment. Some traditions may require, draining the pool back into the earth. When immersion or submersion is required, locate changing rooms and toilet facilities close to the baptistry.

TABERNACLE

The tabernacle generally associated with Roman Catholic, Orthodox, and Episcopalian (ambry, rather than tabernacle) churches is a very significant element in the worship environment, acting as the place of repose for the consecrated Host—the Body of Christ. It often has a highly artistic and custom furnishing. Pay careful attention to the liturgical attitudes of the individual church, and for Roman Catholic churches review the document *Environment and Art in Catholic Worship* to guide the design and placement of the tabernacle.

NOTE: May have a solid front

FIRE INSULATED FILE CABINETS

PLANNING

- Users' filing needs should be tabulated in inches and in turn converted into number of cabinets. Consult manufacturer for inches available in specific cabinets.
- For open space planning, the following square footage allowances should be used for files and use clearance:

TYPES	SPACE ALLOWANCE (FT ²)
Vertical and 36 in. lateral files	10
Lateral file for computer printout	15

NOTE: All dimensions shown are approximate. Consult manufacturer for actual dimensions.

FILE CLEARANCES

	VERTICAL FILES	LATERAL FILES
A	106-120	82-94
B	29	18
C	48-62	46-58
D	18-26	16-22
E	30-36	30-36

DIMENSIONS FOR PLANNING

NOTES

- Basic types accommodate multiple configurations of drawers, doors, and shelves.
- 6 in. drawer accommodates cards and vouchers not exceeding 5 in. in one direction.
- 12 in. drawer accommodates letter and legal files.
- 15 in. drawer accommodates computer printouts.
- Files are available to five-drawer height. Files more than five drawers high are not recommended.
- Typical overfile storage is 26 or 37 in. high.

These units are designed to resist forced entry and are fabricated from heavy gauge steel plate. They are available only in legal size vertical format and are essentially the same size as fire insulated cabinets. They are available with or without fire protection.

SECURITY FILES

TYPE	WEIGHT*
5-drawer	1350
5-drawer fire insulated	1650
4-drawer	1050
4-drawer fire insulated	1400
2-drawer	650
2-drawer fire insulated	825

Associated Space Design, Inc.; Atlanta, Georgia

FORM, TEXTURE, AND SIZES OF SOME TYPICALLY USED INTERIOR PLANTS

PLANT HEIGHT AND CALIPER
INTERIOR PLANT SPECIFICATIONS

NOTE
Plant height should be measured as overall height from the base of the growing container to mean foliage top. Isolated outstanding branches should not be included in height. (Since most plants are installed in movable planters, this overall height measurement should be utilized.)

FOLIAGE WIDTH AND ORIGIN

NOTE
Foliage width should be measured across the nominal mean width dimension. Isolated outstanding branches should not be included in foliage width. Origin or start of foliage should be measured from the soil line.

CANE HEIGHTS

NOTE
Many plant varieties are grown from rooted canes, with the plant being made up of one or more canes. The number of canes must be specified, if plant form is to be identified. Cane heights should always be measured from the base of the growing container.

OTHER PLANT SPECIFICATION FACTORS

1. Accurately describe plant form (e.g., multistem vs. standard tree form, clump form) and foliage spread desired. Indicate "clear trunk" measurements on trees, if desired. These measurements are from soil line to foliage origin point. Specify caliper, if significant.
2. Indicate lighting intensities designed or calculated for interior space where plants will be installed.
3. Indicate how plants will be used (i.e., in at-grade

- planter or in movable decorative planter). If movable decorative planters are used, indicate interior diameter and height of planter for each plant specified, since growing container sizes vary considerably.
4. Specify both botanical and common plant names.
5. Indicate any special shipping instructions or limitations.
6. Specify in-plant height column, whether plant height is measured as overall height or above-the-

- soil line height. Recommended height measurements:
Interior plants: overall plant height (i.e., from bottom of growing container to mean foliage top).
Exterior plants: above-the-soil line height.
7. Indicate whether plants are to be container grown or balled and burlapped (B & B) material.
8. Indicate location of all convenient water supply sources on all interior landscaping layouts.

Richard L. Gaines; Plantscape House; Apopka, Florida

MOVABLE PLANTER/AT-GRADE PLANTER UPLIGHTING / PLANTING DETAILS
UPLIGHTING AND ELECTRICAL NEEDS

1. May be of some benefit to plants, but inefficient for plant photosynthesis because of plant physiological structure. Chlorophyll is usually in upper part of leaf.
2. Uplighting should never be utilized as sole lighting source for plants.
3. Waterproof duplex outlets above soil line with a waterproof junction box below soil line are usually adequate for "atmosphere" uplighting and water fountain pumps.

FOLIAGE BURN FROM DIRECT HEAT CONTACT

HVAC EFFECT ON PLANTS

1. Air conditioning (cooled air) generally is not detrimental to plants, even if it is "directed" at plants. The ventilation here is what counts! Good ventilation is a must with plants; otherwise oxygen and temperatures build up. Heat supply, on the other hand, when "directed" at plants, can truly be disastrous. Plan for supplies directed away from plants, but maintain adequate ventilation.
2. Extended heat or power failures of sufficient duration can damage plant health. The lower limit of temperature as a steady state is 65°F for plant survival. Brief drops to 55°F (less than 1 hr) are the lower limit before damage. Temperatures up to 85°F for only 2 days a week can usually be tolerated.
3. The relative humidity should not be allowed to fall below 30%, as plants prefer a relative humidity of 50-60%.

Richard L. Gaines; Plantscape House; Apopka, Florida

ABOVE-GRADE PLANTER AT-GRADE PLANTER FLOOR PLANTER DETAILS

GREENHOUSE EFFECT RAISES NEED FOR ADEQUATE VENTILATION

TEMPERATURE REQUIREMENTS

1. Most plants prefer human comfort range: 70-75°F daytime temperatures and 60-65°F nighttime temperatures.
2. An absolute minimum temperature of 50°F must be observed. Plant damage will result below this figure. Rapid temperature fluctuations of 30-40°F can also be detrimental to plants.
3. "Q-10" phenomenon of respiration; for every 10°C rise in temperature, plants' respiration rate and food consumption doubles.
4. Both photosynthesis and respiration decline and stop with time, as temperatures go beyond 80°F. Beware of the greenhouse effect!

WATER SUPPLY REQUIREMENTS

1. Movable and railing planters are often watered by watering can. Provide convenient access to hot and cold potable water by hose bibbs and/or service sinks (preferably in janitor's closet) during normal working hours, with long (min. 24 in.) faucet-to-sink or floor distances. Provide for maximum of 200 ft travel on all floors.
2. At-grade floor planters are usually watered by hose and extension wand. Provide hose bibbs above soil line (for maximum travel of 50 ft) with capped "tee" stub-outs beneath soil line. If soil temperature is apt to get abnormally low in winter, provide hot and cold water by mixer-faucet type hose bibbs.
3. High concentrations of fluoride and chlorine in water supply can cause damage to plants. Provide water with low concentrations of these elements and with a pH value of 5.0-6.0. Higher or lower pH levels can result in higher plant maintenance costs.

RAILING PLANTER DETAIL

MOVABLE DECORATIVE PLANTER DETAIL

STORAGE REQUIREMENTS

Provide a secured storage space of approximately 30 sq ft for watering equipment and other maintenance materials. It may be desirable to combine water supply and janitor needs in the same storage area.

AIR POLLUTION EFFECTS ON PLANTS

Problems result from inadequate ventilation. Excessive chlorine gas from swimming pool areas can be a damaging problem, as well as excessive fumes from toxic cleaning substances for floor finishes, etc. Ventilation a must here!

Control 660

Detection and Alarm 662

Fire Suppression 663

GENERAL

Air-supported structures are lightweight, totally free span structures that maintain stability in space and resist loads with a pressure differential between the interior and exterior. This method of support leaves the interior free of support devices that could interfere with the efficient use of space. The roof and side walls can be a single structural element in pure tension, a fabric envelope. The only compression members are the slightly pressurized air inside and the rigid base of the membrane.

STRUCTURAL MEMBRANE

The structural membrane is usually a nylon, fiberglass, or polyester fabric coated with polyvinyl chloride. Such skins have a life span from 7 to 10 years and offer fire retardation that passes NFPA 701. A urethane topcoat will reduce dirt adhesion and improve service life. Fluorocarbon top finishes further enhance characteristics and can double service life. Teflon-coated fiberglass membranes have a life expectancy of more than 25 years. This material is not combustible, passing ASTM E84, with a flame spread rating of 10, smoke developed < 50, and fuel contributed, 10. An acoustical liner (NRC = 0.65) is also available.

NOTES

- Most air-supported structures are primarily designed to resist wind loads. Mechanical blowers must maintain 3 to 5 psf pressure inside the structure at all times. Architectural elements of the building must be detailed to avoid loss of air pressure.
- Consult building codes to determine requirements for all air-supported structures.

GROUND-MOUNTED AIR STRUCTURES

The shape of ground-mounted air structures permits the structure to meet the ground vertically, allowing gravity loads to resist the membrane tension. The semicircular cross-section of the membrane structure has a curvature radius large enough to allow the fabric alone to carry wind forces that may affect the building. If lightweight fabrics are used, catenary cables or webbing may be required as well. Webbing is typically sewn into the fabric seams, forming a one-way system; cables are incorporated into pockets in a one-way system or formed into a cable net harness that is placed over the fabric in a two-way system.

SPAN LIMITATIONS	VAULT	DOMES
Without cables	D = 120 ft	D = 150 ft
With cables	D = 400 ft	D = 600 ft

BASIC CONFIGURATION OF GROUND-MOUNTED AIR STRUCTURES

SUPERELLIPSE PLAN

PROGRESSION PLAN

LONG-SPAN DOME STRUCTURE TYPES

NOTE

For temporary structures, anchorage system may be water tanks, sandbags, earth screw anchors, etc., depending on conditions.

TYPICAL GROUND-MOUNTED AIR-SUPPORTED STRUCTURE

SINGLE MEMBRANE

This is the most common type of air-supported structure. The internal pressure (P_1) is kept approximately 0.03 psi above the external atmospheric pressure (P_0). It is this pressure difference that keeps the dome inflated.

DOUBLE MEMBRANE

The air space between the two membranes is used for insulation and security. If the outer skin is punctured, the inner skin will remain standing. Both single and double membrane air-supported structures require the constant use of blowers to keep them inflated.

DUAL MEMBRANE

The internal and external pressures are the same in a dual membrane structure. Only the area between the skins is pressurized. This inflated area can be sealed, eliminating the need for constant use of blowers, although blowers are recommended to make up losses from leakage.

AIR-INFLATED STRUCTURES

NOTE

The membrane must be patterned to carry loads without wrinkling. Structural behavior is nonlinear with large displacements. The roof shape must be established so that under maximum loads the horizontal components of the cable forces result in minimum bending moment in the compression ring. Consult an air-supported structures specialist to integrate structural and architectural requirements.

LONG-SPAN DOME STRUCTURE

WEDGE INSERT

SURFACE-MOUNTED FABRIC ENVELOPE

NOTE

Beam design is based on actual uplift of air structure at the design inflation pressure and wind load.

CONTINUOUS ANCHORAGE DETAILS

NOTE

The perimeter compression ring must be independent of the support structure to prevent radial restraint.

LONG-SPAN STRUCTURE SUPPORT DETAIL

Paul Gossen, Geiger Engineers, P.C.; Suffern, New York

GENERAL NOTES

- Doors—standard sizes:
2 ft 6 in., 3 ft 0 in., 3 ft 6 in., 4 ft 0 in., 5 ft 0 in. wide x 6 ft 6 in. high; 4 ft 0 in. or 5 ft 0 in. wide by 6 ft 6 in. or 7 ft 0 in. high.
Sliding, double action, and display doors are available. ADA requires a 32-in. clear opening. Doors are manually or electrically operated.
- Prefabricated insulated panels (nominal size)—standard sizes:
Thickness: 4 in.
Width: 11.5 in., 23 in., 46 in.
Height: 7 ft 6 in., 8 ft 6 in., 10 ft 6 in., 11 ft 6 in.
Finish material: aluminum, galvanized steel, or stainless steel.
- Walk-in unit sizes:
Width: 3 ft 11 in., 5 ft 10 in., 7 ft 9 in., 9 ft 8 in., 11 ft 7 in.
Length: 5 ft 10 in., 7 ft 9 in., 11 ft 7 in., 13 ft 6 in., 15 ft 5 in., 17 ft 4 in., 19 ft 3 in.
Height: 7 ft 6 in., 8 ft 6 in., 9 ft 6 in., 10 ft 6 in., 11 ft 6 in.
Available accessories: stationary or mobile shelf units and adjustable cantilevered shelves, windows, interior partitions, meat rails, floor racks, ramps, and walk-ins.
- Check local codes for drainage requirements.

DRAIN AND VENT DETAIL

CLEANROOM DESIGN

A cleanroom is an environment in which specific particle control must be maintained for manufacturing and aseptic functions. Precise control of temperature, humidity, pressure, noise, and vibration are often part of cleanroom design criteria. Cleanrooms range in size from mini-environment enclosures to thousands of square feet, as is required for microelectronics fabrication (fab).

Cleanrooms are classified by standards that reference particle presence by quantity and size. Federal Standard 209E English classification references the number of 0.5 micrometer (μm or micron) particles per cubic foot. (A micrometer is 10^{-6} meter.) The International Organization for Standardization (ISO) is developing a series of integrated standards for cleanrooms. ISO standards reference the number of 0.1 micron particles per cubic meter.

Cleanroom applications expand with the advance of technology. Cleanroom contamination can originate from workers and materials and includes human skin cells, spittle, hair (100 microns), tobacco smoke, cosmetics, bacteria (0.2 to 0.12 microns), viruses, dust, pollen, solvents, and moisture.

High-efficiency particulate air (HEPA) filters are very efficient (nominally 99.99 percent) in removing particles down to 0.3 micron in supply air. Ultra-low penetration air (ULPA) filters are very efficient (nominally 99.9995 percent) down to 0.12 micron particles. Supply air is distributed downward through modular ceiling filters (nominally 2 ft by 4 ft) gel-sealed into tracks.

Cleanroom air velocity can range from 10 ft per minute (FPM) in Class 10,000 (M6.5) up to 100 FPM in Class 1 (M1.5) with up to 600 air changes per hour. The percentage of room filter coverage affects contamination control. Filter coverage is based on the cubic ft per minute (CFM) of air required for the cleanroom classification and the CFM of air delivered per filter.

Class 1 cleanrooms utilize 100 percent ULPA coverage with air supplied vertically downward with minimal turbulence through a perforated raised-access floor. This airflow pattern is generally known as vertical laminar flow (VLF). VLF resists depositing contaminants on surfaces and captures particles in the cleanroom. The free area of floor panels and adjustment dampers below the panels balance the cleanroom airflow.

In higher cleanroom classes, air may be supplied with controlled turbulence for diffused coverage and returned through low wall return grilles. Pharmaceutical and food applications require aseptic detailing, with smooth, impervious, and cleanable surfaces. The walls and floor join with a radiused cove and require return air extraction by low wall return grilles.

Pressurization is a delicate balance between process exhaust and makeup air replenishment. Manufacturing cleanrooms are usually maintained at positive pressure with respect to adjacent areas to resist particle infiltration from the other areas. Cleanrooms with biohazards, however, are precisely controlled to a negative pressure. As the biohazard increases, the pressure must be maintained at a greater negative pressure.

The Centers for Disease Control and Prevention (CDC) and the National Institutes of Health (NIH) establish practices for biohazard containment including protocol, safety clothing and equipment (primary barrier), and the facility (secondary barrier). CDC/NIH have determined the biosafety levels (BSLs) for materials, which range from BSL-1 (low) to BSL-4 (high). Safety equipment includes class I, II, and III biological safety cabinets (BSC), which are small cleanroom-type workstations. A class III BSC is completely closed to the room environment. BSL-3 or BSL-4 cannot recirculate any room air, and exhaust air must be treated.

Portable cleanrooms and component modularity allow workspace reconfiguration for changing processes and equipment. Cleanroom design is supported by operational protocol, including having workers wear specified apparel and enter through gowning rooms and air showers. All materials entering or exiting cleanrooms must move through pass-through openings with interlocked doors. Operational protocols must be in place from the beginning of construction through testing and certification of the cleanroom as well as during use.

Cleanrooms constructed for microelectronics mitigate conductivity and static control interference with special materials and coatings. To minimize airborne molecular contamination, cleanroom construction materials are evaluated and selected for low outgassing characteristics. Vibration control is essential to cleanroom manufacturing processes involving photolithography, optics, and lasers.

GENERAL COMPARISON OF CLEANROOM STANDARDS

HISTORIC ENGLISH CLASS	FEDERAL STANDARD 209E	ISO 14644-1 CLASS	LIMIT OF NUMBER OF PARTICLES PER M ³ OF AIR BY SIZE						
			0.1 μm	0.2 μm	0.3 μm	0.5 μm	1.0 μm	5.0 μm	
		1	10	2					
		2	100	24	10	4			
1	M 1.5	3	1000	237	102	35	8		
10	M 2.5	4	10,000	2,370	1,020	353	83		
100	M 3.5	5	100,000	23,700	10,200	3,530	832	29	
1000	M 4.5	6	1,000,000	237,000	102,000	35,300	8,320	293	
10,000	M 5.5	7				353,000	83,200	2,930	
100,000	M 6.5	8				3,530,000	832,000	29,300	
		9				35,300,000	8,320,000	293,000	

NOTE

Only particle number limits for 0.5 micron particle size cor-

relate directly with Federal Standard 209E. Limits for different particle sizes vary somewhat between standards.

CLEANROOM CLASSIFICATION BY INDUSTRY OR APPLICATION

INDUSTRY OR APPLICATION	CONTAMINATION FOCUS	HISTORIC ENGLISH CLASSIFICATION, FEDERAL STANDARD 209E, ISO 14644-1

SECTION THROUGH BIOTECHNOLOGY CLEANROOM (CLASS 1000/M4.5)

IDC Architects, Inc.; Portland, Oregon

NOTES

1. If the sauna framing does not extend to the ceiling of the room outside the sauna, an exterior finish that encloses the top of the sauna is recommended.
2. A 1-in. gap is recommended between the bottom of the door and the threshold for ventilation.
3. Wood-framed baseplates should be made of pressure-treated wood; all other framing may be standard wood framing. Metal framing is not recommended because of its high heat-conductance property.

SAUNA CONSTRUCTION

NOTE

Design benches for a width of 24 in. per person (sitting) and a length of 72 in. per person (reclining).

TYPICAL SAUNA PLAN CONFIGURATIONS

Richard J. Vitullo, AIA; Oak Leaf Studio Architects; Crownsville, Maryland

SAUNAS

A sauna is a dry heat bath taken in a well-insulated room lined with untreated, kiln-dried softwood and heated by igneous rocks. The purpose of the sauna is to induce perspiration, which cleanses the pores in the skin by removing impurities and lactic acid built up from physical exertion.

Because of the dryness of the air in a sauna (25% humidity, average), the body can accept the higher temperatures a sauna produces (180°F, average). It is usually better to lie down than to sit up in a sauna, for the temperature rises about 18°F for every foot above the floor level. If a bather is lying down, the heat is equally dispensed over the entire body. Saunas should be located near a shower for the cool-down portion of the sauna.

Saunas may be prefabricated (precut pieces assembled on the site), modular (factory-built complete panels joined on the site), or custom built.

NOTES

1. The larger the sauna, the more heat is required; hence, the ceiling should be kept as low as possible within the limits imposed by the benches, which generally require 7 ft clear height.
2. A 24 in. wide, 6 ft 8 in. high, nonlockable door that opens outward is standard in a sauna. This door size maximizes bench space, minimizes heat loss, and provides safe entrance. A 36 in. wide door could make a design compatible with ADA guidelines, but wheelchair access is discouraged to protect the metal and plastic components of a wheelchair from excessive heat. Instead, an attendant can assist wheelchair-bound sauna users (liability and safety issues should be considered).
3. Because of the weight of the door, a pair of 4-in. brass butt hinges with ball bearings is recommended. A heavy ball or roller catch keeps the door closed. Door handles are made of wood.
4. Indirect lighting is recommended in a sauna. The best position for the light is above and slightly behind the bather's normal field of view; the switch is always outside the room.
5. Softwoods like western red cedar and redwood are used in the finish wall surfaces and bench construction of a sauna. Softwoods absorb humidity, keeping the atmosphere dry, and do not absorb heat as readily as hardwoods, keeping the surface comfortable to the touch. Wood should be kiln-dried to a 6 to 11% moisture content.
6. In private saunas, a water bucket and dipper for creating a burst of steam are common accessories. However, these are often not provided in public saunas to prevent misuse by unknowledgeable bathers, as premature or excessive water application can damage heater parts.

NOTE

A sauna suite offers a complete heating and cooling cycle with indoor and outdoor cooling areas.

SAUNA SUITE PLAN

BENCH DIMENSIONS

NOTE

Air must be able to flow freely into and out of a sauna and should be changed 4 to 6 times per hour. Fresh air is provided through updraft action by combining an air inlet in the sauna wall directly below the heater with an air outlet located at least 6 in. from the ceiling and 24 in. higher than the inlet. A vent space below the door may also be used.

AIR VENT AND TEMPERATURE DIAGRAM

NOTE
The control box may be installed either on the heater (below it, usually) or apart from it but within 6 ft of the heat-sensing device inside the sauna. Controls include a thermostat, heat indicator light, light switch, and timer. The output capacity of the heater depends on the volume of the sauna room, but it generally ranges from 1700 to 15,000 watts. Stones completely cover the electric elements to filter the harsh heat and electromagnetic field.

SAUNA HEATER

STEAM ROOMS

Steam bathing has effects similar to the sauna but in a very different climate. Unlike the dry heat of a sauna, a steam bath (or Roman bath) is taken in a warm, moist atmosphere with temperatures up to 125°F and humidity near 100%. As with the sauna, the critical factor in steam bathing is the bather's interaction between heat and cold.

NOTES

1. Avoid use of exposed, untreated materials that are subject to decay or corrosion.
2. Steam room ceilings should be sloped a minimum of 2 in./ft to prevent condensation from collecting and dripping. Sloping from the middle to the edges reduces the height necessary to accomplish this. The ceiling should be no more than 8 ft high.
3. Use of vents inside the steam room is not recommended, but if they are installed, they must be positive closing with a vaportight seal and waterproof ducts.
4. Flooring should be skid-resistant, with a floor drain for condensation runoff and cleaning.
5. The steam generator must be compatible with the construction materials and the volume of the steam room. Residential steam generators can handle 50 to 500 cu ft, while larger models can service up to 1500 cu ft. Controls for the generator may be located inside or outside the room. The dimensions of the generator range from 13 to 17 in. high, 12 to 16 in. deep, and 7 to 8 in. wide.

NOTE

Floors must be waterproof; cement, tile, and vinyl are appropriate materials. Provide a drain for commercial construction.

Two levels are recommended in a sauna because the top level provides access to higher heat ranges.

SAUNA BENCH AND FLOORING CONSTRUCTION

CUSTOM

PREFABRICATED

NOTES

1. The tongue-and-groove boards used for interior finishes should be at least 5/8 in. thick but no wider than six times their thickness; they are made from softwoods like western red cedar or redwood. Blind nailing with galvanized, aluminum, or stainless steel nails is recommended.

2. Vapor barriers under paneling (whether attached to the insulation or separate) must be vaporproof and heat-resistant and act as a heat reflectant. Foil-backed, mineral-based insulation, R-11 minimum, is recommended.

SAUNA WALL CONSTRUCTION—DETAILS

Richard J. Vitullo, AIA; Oak Leaf Studio Architects; Crownsville, Maryland

NOTE

1. Walls, ceiling, floor, and benches must be completely covered with a waterproof finish such as tile, marble, or acrylic. Exposed gypsum board or plaster is not recommended.
2. All joints must be filled with waterproof sealant.

STEAM ROOM WALL CONSTRUCTION

PREFABRICATED BOOTH

NOTES ON BOOTHS

1. Prefabricated booths are manufactured in a wide variety of designs, shapes, finishes, and sizes. Consult manufacturers for available design options.
2. Exterior finish materials that can be applied to wall panels include brick, cast stone, enameled steel panels, stainless steel, and aluminum.
3. Suitable glazing materials include tempered safety glass, unbreakable polycarbonate and impact-resistant acrylic sheets, and insulated and treated glazing.
4. Manufacturers usually offer bullet-resistant construction as an option for windows, walls, and floors up to Class VII protection. Hardening of HVAC, lighting, and other systems is also available.
5. Consult engineers and manufacturers for wind load design depending on site conditions. Appropriate stiffening and anchorage details may be necessary.
6. Lavatory or storage facilities may be built into booths, usually those 8 x 10 ft or larger.

ADA-COMPLIANT BOOTH

PREFABRICATED SHELTER

SHELTER SECTION

NOTES ON SHELTERS

1. Use a switch-operated wall fan to make a smoking shelter. Consult manufacturers for available fan capacities.
2. Benches are typically specified for shelter interiors. Consult manufacturers for sizes and attachment details.

SHELTER PLAN TYPES

BOOTH PLAN TYPES

BULLET-RESISTANT WALL DETAILS

GENERAL NOTES

1. No construction can be bulletproof, but bullet-resistant construction is possible. Protected areas should be designed to withstand a level of attack based on the threat at that location, in particular the type of arms expected.
2. Each component in a bullet-resistant system must be bullet resistant; there can be no weak links and no gaps.
3. Consult a specialist in bullet-resistant construction.
4. A truly effective protection plan combines a bullet-resistant system with appropriate detection, alarm, communication, escape, and retaliation capabilities.
5. The complete bullet-resistant environment makes it possible for personnel to escape, retaliate against attack, summon help, and defend themselves against the threat of gunfire, flame, and chemical or mechanical attack.

BULLET-RESISTANT DOOR ASSEMBLY NOTES

1. The entire unit should be certified as bullet resistant by an independent testing laboratory.
2. Bullet-resistant doors are heavier than regular doors, so the doorframe and hinges must be properly reinforced and/or of heavy weight.
3. The doorframe must be constructed of bullet-resistant material equivalent to that of the door itself. A proper fit between the door and the frame is required to prevent gaps that could permit ballistic penetration. Ideally, the door and frame should be supplied by the manufacturer as a single unit.
4. Use of appropriate hardware is important. The lockset should be mortised with $\frac{5}{8}$ in. minimum throw on the latch bolt and thoroughly armored to prevent the door from unlatching after assault.
5. The door should be equipped with a heavy-duty closer to ensure it closes completely.

BULLET-RESISTANT WINDOW ASSEMBLY NOTES

1. The entire unit should be certified as bullet resistant by an independent testing laboratory.
2. All elements in a bullet-resistant window assembly must be bullet resistant, including voice communication systems and trays.

3. The window framework must be bullet resistant as well as substantial enough to retain the glazing material under the impact of a projectile.
4. The window should be designed so the bullet-resistant framework and the bullet-resistant glass become an integral unit.

BULLET-RESISTANT COMPOSITE WALL PANEL

TYPICAL BULLET-RESISTANT MATERIALS

MATERIAL	FUNCTIONS AND CHARACTERISTICS	THICKNESS	WEIGHT	REMARKS
Steel	Cost-effective shielding against direct assault Thin Can be fabricated for retrofit Easy installation	$\frac{1}{8}$ -1 in.	6-24 psf	
Glass	Cost-effective vision-panel shield Scratch resistant, chemical resistant Substantial assault can defeat glass	$1\frac{3}{16}$ -2 in.	15-31 psf	One-way security glass is available $\frac{5}{8}$ - $1\frac{1}{8}$ in. thick, weight 7.1-18.2 psf
Plastics (acrylic)	Lighter weight and more impact resistant than glass Spall resistant Relatively high cost Substantial assault can defeat plastic	$1\frac{1}{4}$ in.	7.8 psf	Glass-clad polycarbonate is available $1-1\frac{11}{16}$ in. thick, weight 9.6-17.6 psf
Composites	Can be opaque or transparent Lighter weight alternative for direct assault shielding Composite vision panels can be made stronger than glass Workable, suitable for custom installation Relatively high cost	$\frac{1}{4}$ - $1\frac{1}{8}$ in.	2.5-11.5 psf	Available in 4 x 8 ft sheets

GENERAL

Radio frequency (RF) shielding consists of a barrier or shield of electrically conductive materials designed to protect sensitive electronic equipment from the disruptive effects of conducted or radiated electromagnetic interference (EMI).

RF shielding of rooms, large areas, or buildings (called architectural shielding) is designed to contain EMI within a given space (e.g., to protect cardiac pacemakers from EMI generated by magnetic imaging resonance [MRI] equipment) or to protect electronic devices from distortion by outside EMI (e.g., to protect computer data or medical ultrasound images from distortion by radio, television, or cellular phone signals).

Shielding from electromagnetic energy is achieved by metalizing walls, floors, and ceilings in a room or area. Metallizing isolates a space from energy transmitted through the air (radiated) or through a wire (conducted). Typically, RF shielding is created with knockdown galvanized steel modular rooms or architectural shielding achieved with copper paint or sheeting. Proper shielding requires RF treatment of all mechanical and electrical penetrations into an area, which is achieved by using RF-shielded doors and components for plumbing, HVAC systems, and electrical conductors for power, data, and telephone lines.

Rooms or areas may be RF tested to determine the level of shielding achieved, called shielding effectiveness. Shielding effectiveness typically ranges from 40 dB for commercial

WALL SURFACE (FINISH) APPLIED OVER SHIELDING (WALLPAPER, FABRIC, PAINT, OR GYPSUM WALLBOARD)

NOTE
When applying wall and floor finishes over shielding, use nonintrusive methods such as adhesive.

COPPER COATING DETAIL FOR WALLS, FLOORS, AND CEILINGS

requirements (99% reduction in radiation) to more than 100 dB (99.999% reduction) for military, government, and hospital MRI enclosures. Shielding effectiveness is always stated in dB of reduction over a frequency range expressed in hertz.

ROOM CONTAINING RF-EMITTING EQUIPMENT

The range of frequency that must be shielded varies from 60 Hz for AC power through the kHz (kilohertz) and MHz (megahertz) range for radio, TV, and cellular phones to the GHz (gigahertz) range for microwave energy such as radar.

ROOM CONTAINING RF-SUSCEPTIBLE EQUIPMENT

RF-SHIELDED SPACES

NOTE
Design for shielding against interference from electromagnetic radiation is based on the electromagnetic frequency spectrum. Since all radiated energy occurs in wave form, interference can be identified by its frequency, which is expressed in hertz. The diagram above shows where each type of radiated energy occurs in the electromagnetic spectrum. The lowest frequencies are in the range represented by electrical power and AM radio, the highest in the range represented by gamma rays (used in medical linear accelerators).

Each frequency range in the spectrum may require its own shielding design. In many modern projects, the designer and builder must contend with more than one frequency band at a time. A modern hospital, for instance, may require as many as five different shielding solutions, such as magnetic shielding for a 60 Hz power substation, magnetic and EMI shielding for MRI equipment, RF/EMI shielding for sensitive medical equipment, X-ray shielding for diagnostic X-ray equipment, and gamma ray shielding for a linear accelerator.

ELECTROMAGNETIC SPECTRUM

NOTE

EXTERIOR WALL—SECTION

ISOLATED ROOMS

Isolated rooms incorporate special constructions to reduce intrusive noise and vibration from outside a room or to contain the sound and impact energy generated within a room. Typical applications include music practice rooms, sound studios, testing chambers, mechanical equipment rooms near sensitive areas, spaces exposed to nearby aircraft flyovers, and offices under gymnasiums. Construction of isolated rooms can be very expensive. It is therefore wise to isolate high-noise sources from acoustically critical uses early in the space planning and layout design phase.

The correct design of an isolated room is a "box-within-a-box." The inner box, which is the four walls, ceiling, and floor of the isolated room, should be an airtight enclosure constructed of dense, impervious materials; this box must be isolated by resilient supports from the surrounding structure. The base structure that supports the isolated room must be as rigid and massive as possible.

The most effective floor construction is a "floated" concrete pad, which is separated from the base building structure by steel springs, neoprene, or glass fiber isolation mounts. This slab can support inner walls. Any necessary structural bracing to the base building structure should be with a resilient, nonrigid connection. The ceiling of the box can be suspended from resilient hangers, or it can be supported from the walls of the inner box.

An isolation mat provides uniform deflection of the floating concrete floor under a wide range of design loads. It consists of 2-in.-thick, high-density, precompressed molded fiberglass isolation pads, separated by low-density acoustical fiberglass.

Cerami + Associates; New York, New York

INTERIOR WALL—SECTION

Avoid all flanking paths between an isolated room and the base building structure. To ensure that wall penetrations and connections to outside services are as well isolated as the room itself, provide flexible connections in ducts and conduit between the inner and outer box and resilient supports for all piping. Weather stripped or sound-rated doors and double-glazed, acoustical windows should be part of the continuous, air-tight enclosure that defines the inner box.

NOISE REDUCTION

The degree of noise reduction that can be attained by an isolated room depends on the type of construction, its resiliency, the elimination of flanking paths, and the amount of dead airspace surrounding the inner box. A well-built isolated room can achieve field performance ratings of STC 60 to 70 for airborne sound and ratings of IIC 80 to 90 for impact noise. However, even minor flanking paths and acoustical short circuits through non-airtight joints can easily decrease these results by 10 points or more. The sound isolation between spaces will be only as great as the weakest sound path.

The advice and assistance of a qualified acoustical consultant should be sought in both the planning and design of isolated rooms and their related special constructions.

PREFABRICATED UNITS

In addition to field-erected isolated rooms as described above, several manufacturers make prefabricated units. These rooms are sold as self-contained music practice

rooms, audiometric booths, and control booths for manufacturing plants. Although the detailing of these structures is proprietary, one will find the same design approach as outlined here: an airtight box separated from the building structure. The degree of noise reduction that these prefabricated rooms can attain depends on the parameters used for field-erected rooms.

TYPICAL SHIELDED ROOM DESIGN REQUIREMENTS

LEAD SHEET IN WOOD CONSTRUCTION

STEEL STUD AND LEAD-COATED GYPSUM BOARD

GENERAL

There are three ways to protect humans from harmful exposure to radiation: Keep people a sufficient distance from the radiation source, limit their time of exposure, and contain the radiation source with a protective shield.

Factors to consider in designing a protective shield are the type, characteristics, and amount of radiation; the type of construction; and the properties of the shielding system. It is important to think of an enclosure for a radiation source as a sealed module. Each component in the system must be lined with lead, and all of the connections must overlap to prevent leaks. Joint details are the most important design element once the shielding system has been selected.

Retain a radiation consultant to analyze project requirements and prescribe the necessary shielding system. The thickness of lead needed is based on the amount of radiation at the site and should be determined by an expert.

NOTES ON LEAD SHIELDING

1. Lead sheets are available in sizes from 1/64 to 1 in. thick.
2. Specify lead requirements in increments of 0.5 mm, with a minimum thickness of 1 mm (1/24 in.).
3. Adequate physical support is required for sheet lead installations.
4. For health and environmental considerations, lead sheet, plate, and brick are designed to be installed behind other materials.
5. Door and window frames must be lined with lead equal to the wall shielding level. Lead glass or lead acrylic glazing must be chosen to match wall and frame shielding levels.
6. Hinges and hardware for lead-lined doors must be designed to carry the weight of the lead.

LEAD-LINED BLOCK IN CONCRETE FRAME

Jessica Powell; Rippeteau Architects, PC; Washington, D.C.

HEAD/JAMB

REINFORCED JAMB

THRESHOLD DETAIL

LEAD-LINED DOOR DETAILS

NOTES

1. Lead-lined doors consist of a continuous sheet of lead sandwiched between two wood core panels; they generally measure 1 3/4 in. plus the thickness of the lead, which is specified by the architect or radiation physicist. Typically, the lead sheet is a minimum 1 3/4 in. thick and is covered with a flush-type wood veneer or plastic laminate. For lead thicknesses greater than 3/16 in., consult the manufacturer for door thicknesses. Use pivot or continuous hinges specifically designed to carry the weight of lead-lined doors. Depending on the thickness of the lead and the weight of the door, it may be necessary to reinforce the doorframe. Steel door frames are lined with lead of the same thickness as walls and doors. Lead-lined doors are available with leaded louvers or view windows.
2. For lead-lined wallboard and plywood, an unpierced lead sheet is laminated to a sheet of fire-rated wallboard or plywood. Lead thickness is specified by an architect or radiation physicist. Lead joint strips and screw plugs cover any construction gaps or penetrations.
3. Lead-lined shielding barriers are modular, custom-designed units with clear glazing material on top and a lead-lined opaque panel below. Glazing may be either lead acrylic or lead glass. Check local regulations to ensure that movable radiation shielding is permitted.
4. View windows are formed from telescoping steel frames (for walls 4 1/2 to 7 in. thick) with lead. These windows may include voice transmission passages and an adjust-

FIXED LEAD-LINED HOLLOW METAL VIEW WINDOW

ROUGH FRAME SLEEVE FITS OVER CABINET TO SECURE TO WALL

LEAD-LINED PASS-THROUGH CABINET

able glass stop. The stop permits installation of one to eight pieces of lead glass as required for radiation protection. Minimum thickness for the glass is 1/4 in., which is equivalent to 2 mm of lead. Windows can be laminated with float glass for increased protection.

5. An X-ray cassette transfer box installed between diagnostic and film processing rooms facilitates quick transfer of developed and undeveloped X rays. These boxes are constructed of steel panels lined with a specified lead thickness.

MEDICAL X-RAY PRODUCT APPLICATION GUIDELINES

APPLICATION	X-RAY COMPONENTS	SHIELDED DOORS	CONTROL WINDOWS
Linear accelerator (LINAC) room	Borated lead walls, lead brick	Borated polyethylene and lead	Telescopic widths 4 7/8 to 7 in. (typical), larger widths available
X-ray rooms, dental x-ray	Stationary or mobile control screens, lead-lined wallboard and plywood	Lead-lined in various lead thicknesses and door sizes	
CAT scan room, PET scan, cardiac catheterization	Lead-lined wallboard and plywood, lead brick (PET scan)	Lead-lined hollow metal and lead-lined solid-core wood doors	
Implant radiology	Interlocking lead brick, lead-lined plywood	Lead-lined doors and frames	

SEMIPERMANENT

PORTABLE

RADIATION SHIELDING BARRIERS

ALTERNATE METHOD IS TO INSTALL SHEET LEAD BEHIND BOX AT INSIDE OF OPPOSITE WALL SURFACE

ELECTRICAL, PLUMBING, AND HVAC PENETRATION SHIELDING

6. Leaded X-ray glass is used for all windows in X-ray protection rooms. Typical material uses lead-barium glass with more than 60% heavy metal oxide, including at least 55% lead oxide. Typical glass sizes range from 8 x 10 in. to 48 x 96 in. Glass thickness is 8 mm (lead equivalent 1.8-2.0 mm) to protect against 100 kV X-rays, 11 mm (lead equivalent 2.5-2.7 mm) to protect against 150 kV X-rays, and 14 mm (lead equivalent 3.0-3.2 mm) to protect against 200 kV X-rays.

Jessica Powell; Rippeteau Architects, P.C.; Washington, D.C. John Soltis; Tecknit Shielding Systems; Passaic, New Jersey

GENERAL

Architectural fabric structures have undergone rapid development since the early 1970s and now can be considered a mature building technology. Due to improvements in materials, structural analysis, and environmental control, these structures can often be considered permanent buildings. This technology, with unique properties that make it useful for certain applications, offers an important alternative to conventional construction.

Fabric structures of a nonpneumatic kind fall into two categories. One type has a fabric membrane with a rigid frame support, usually of metal, and the other is a self-supporting fabric membrane kept in tension with a supporting structure of steel or concrete. The rigid frame structures typically form pyramidal or long, continuous geometric shapes like sheds or barrel vaults. The self-supporting structures rely on opposing curves to distribute the necessary tension and typically form saddle, conical, or hyperboloid (anticlastic) shapes.

The structure that creates and maintains tension on the fabric can consist of cables and masts, a compression ring, trussed gridwork, or tied edges. These mechanisms create pretension in the fabric sufficient to keep it taut at all times. Any compressive loads imposed on the fabric will be balanced or at most reduced by the prestress created by the structure.

MATERIALS

The intended life span of the structure is an important factor in design decisions, fabrication details, and the cost of architectural fabric structures. The life span is most affected by the fabric material or membrane selected. Fabric is a directional material and does not have the same strength or elongation in all directions under a load. Materials with little creep are preferable for tensioned structures, as original prestress can be lost if the fabric stretches or deforms. Details allowing for retensioning must be incorporated if materials with moderate to high creep are used. Generally, the materials used in a membrane are composites consisting of a woven substrate protected with an applied coating.

The membrane is the principal structural component of a self-supporting or tensioned fabric structure. Two materials are generally used for membranes—polyvinyl chloride (PVC)-coated materials and fluorocarbon (Teflon)-coated glass fiber fabric. PVC-coated polyester is a composite material composed of vinyl coating over both faces of a woven polyester fabric. The material is inexpensive, strong, translucent, and easy to fabricate but has a limited life span and is only fire resistant; for these reasons it is only used in temporary or

semipermanent structures. Fluorocarbon-coated glass fiber fabric is classified as a noncombustible material. Besides its advantages in fire safety, this fabric is extremely long-lasting, self-cleaning, and translucent and is the accepted material for most permanent installations. Development continues in fabric technology, and new products such as silicon-coated glass fiber may offer an improvement in the range of material characteristics.

DESIGN

In recent years, the structural design of fabric structures has improved due to the increased use of the computer in the engineering process. The first step in the design process aided by computer modeling is the definition of an acceptable surface geometry, such as the hyperboloid. A membrane mesh or network is then developed representing the surface as a grid of lines. This graphic model is "pre-stressed," and the reactions are analyzed in an iterative, or repetition-based, process. Live loads such as wind, rain, or snow are applied to the model and the stresses calculated in order to select the fabric and design the supporting structure or foundation.

The design, fabrication, and construction of fabric structures require close coordination among the architect, engineer, fabricator, and installer throughout the process to ensure the strict quality control this technology requires. However, since most of the work is completed in the factory, minimizing on-site construction time, it is not unreasonable to maintain tight specifications.

APPLICATIONS

Applications for fabric structures include the semipermanent and temporary fabric-and-frame structures applied to agricultural, greenhouse, and storage uses. Improved materials have allowed use of these structures for waste treatment facilities, tennis courts, and pool facilities. More elaborate configurations, curved in plan and section, serve as outdoor concert halls, enclosed sports facilities, and atrium spaces for larger structures such as office buildings, medical facilities, shopping malls, and airports. Fabric structures are not a substitute for conventional construction, but their unique qualities enable them to perform certain building tasks very efficiently. In general, special performance requirements, such as the need for long spans or for natural lighting, encourage the use of this building system.

ENVIRONMENTAL CONSIDERATIONS

Under certain circumstances, a tensioned fabric structure can reduce energy consumption in a building. The natural light from the translucent surface reduces artificial lighting

requirements, the reflectivity of the skin reduces heat gain, and the radiation of waste heat from the warm fabric surface to a cool sky results in an energy-efficient building in warm climates. In cold climates, a second skin or liner is normally used, often with glass fiber insulation in the cavity to further reduce heat loss. These structures can be as energy-efficient as conventional buildings in many applications.

FABRIC STRUCTURE ANCHORAGE DETAILS

FABRIC EDGE CLAMP ATTACHMENT DETAIL

ALTERNATE EXTERIOR MAST TOP DETAIL

GENERAL

The two primary ways of attaching fabric to anchorages are with edge catenary cables or clamps. Catenaries allow free-form design. When a tighter connection between fabric and building structure is required (e.g., on roofs, skylights, and air structures), a clamp system is used, in which the fabric is sandwiched between clamping bars or plates, which are bolted to the structure. Some membrane structures use both kinds of attachment. Air structures sometimes have sleeves and cables plus a fabric closure panel that extends beyond the cable.

Tensile structures usually are custom designed, and anchoring and connection details are customized also. However, basics, such as clamping systems, have become more standardized. Some frame and connection materials have been adapted from other industries, such as space frames and marine rigging. To determine the appropriate design aesthetic for a project, consider the following aspects:

1. Tensile structures are flexible, and the details must be designed to move under loads.
2. Tensile structures weigh a fraction of the amount of other buildings, and many of the materials are translucent.
3. Lateral forces play a much greater role in tensile structures than in conventional structures.

TYPICAL CONE-SHAPED TENSILE FABRIC STRUCTURE

EDGE OR CATENARY CABLE ATTACHMENT DETAIL

4. Make sure the physical resolution of each element's force vector (the angle of direction and magnitude) is accurate.
5. Details, material specifications, and reaction forces affecting interfacing structures should be developed with a consulting engineer or a design/build firm with the ability to design such structures.

RELATIVE FABRIC CHARACTERISTICS

FABRIC TYPE	STRENGTH	DIMENSIONAL STABILITY	FIRE RATING	DURABILITY	RESISTANCE TO SOILING	SOLAR TRANSMISSION	COST	TYPICAL USES	LIFE SPAN	REMARKS
PVC-coated polyester	5	3	3	3	3	2	4	Temporary to semipermanent	3-15 years	Large selection of products; top coatings are required for durability, can enhance appearance, and provide improved UV and fire resistance
PVC polyester scrim laminate	2	2	2	1	1	2	5	Temporary	1 year	Limited applications in architecture
PVC-coated fiberglass	4	4	4	3	3	2	3	Temporary to permanent	5-15 years	Limited availability; can be produced to order
PVC-coated Kevlar	5	3	3	3	2	2	2	Semipermanent	5-10 years	Kevlar has strength and durability but is UV sensitive; seams generally hand-sewn
PTFE-coated fiberglass	4	5	5	5	5	4	1	Permanent	25 years or more	Most durable material, now with a 25-year record of use
Silicon-coated fiberglass	3	5	5	4	2	5	2	Semipermanent to permanent	20 years	Seam strength has been a weakness
PTFE fiberglass laminate	3	5	5	5	4	5	1	Semipermanent to permanent	20 years	Relatively new material

NOTES

1. Relative comparisons are based on a scale from 0-5, with 0 a poor rating and 5 a very good one. The ratings are intended to provide a general relative comparison of the materials listed.
2. For the cost rating, the least expensive material has the highest rating.
3. All materials listed are composites. Generally, the material strength is provided by a scrim or woven textile that has been sealed and protected with a coating or film.
4. Plastic, PVC, and polyester materials are subject to degradation from ultraviolet (UV) light, while glass fabrics and scrimms are degraded by prolonged contact with moisture.

FRAMING SYSTEMS COMPONENTS

DEFINITIONS

Pre-engineered metal buildings are available in standard framing sizes and types from various manufacturers. The following definitions are those used by the metal building industry:

BAY refers to the dimension along a wall between the centerlines of wall columns and the dimension from the outside of an end wall corner column to the centerline of the first adjacent wall column. Spacings range from 18 to 30 ft, with 20 to 25 ft most common.

WIDTH is measured from the surface of the outside wall girts. Inside clearance varies.

EAVE HEIGHT is measured from the bottom of a wall column to the top of an eave strut. Nominal 2-ft increments vary from 10 to 30 ft.

LOADS, other than those provided by the manufacturer, should be specified during the structural design phase.

Future additional loads also should be considered. Roof live loads are those loads, including snow load, exerted on a roof except dead, wind, and lateral loads. Commonly available in 12, 20, or 40 psf. Dead load is the weight of all permanent roof framing and covering materials only and varies with the manufacturer.

LATERAL LOADS are dead loads other than the metal building framing, such as sprinklers, mechanical and electrical systems, and ceilings. They are commonly available in 15, 20, or 25 psf.

WIND LOAD is loading caused by the wind blowing from any horizontal direction. Site and atmospheric conditions needing special consideration should be specified.

SEISMIC LOAD is required for earthquake zones and must be specified for individual designs.

AUXILIARY LOADS are dynamic live loads other than basic design loads, such as cranes, materials handling systems, and impact loads.

DIAGONAL BRACING normally is required in the plane of the columns and beams in one or more bays to prevent racking and to resist lateral loading perpendicular to the span of the frames.

GIRTS are horizontal structural members that transmit lateral loads (pressure and suction) from the exterior walls to the columns. Sag rods may be needed to support the girts about the weak axis and to achieve design economy.

ANCHOR BOLTS are necessary to resist reactions at column bases. Foundations must be designed for reactions transmitted by the column bases and anchor bolts.

NOTE

The user should verify that individual manufacturer's standard practice and any special design considerations meet or exceed established engineering principles, local practice, and applicable building codes.

OCCUPANCY SENSORS

There are several types of occupancy sensors for turning lights on and off. They include ultrasonic, infrared, visible light, and audible sound sensors. The first two methods are by far the most prevalent. The infrared is a line-of-sight sensor, but will have some dead spots primarily at long distances from the sensor. The ultrasonic sensor has no dead spots, but is more sensitive to incidental air motion and may respond inappropriately. Either technique can be used in most applications; however, there are applications where the ultrasonic or the infrared occupancy sensor has a slight advantage.

Most occupancy sensor designs have controls that allow selection of a turnoff time and a means to set the sensor's sensitivity to motion. The placement of the sensor is important since it must cover the desired active area. Sensors are generally designed for placement in the ceiling, where there is a clear view of the area to be scanned. Recently simpler occupancy sensors have been designed to be wired directly into the wall switch. Care must be exercised since it is possible there may be many dead spots because the height of the sensor is about four feet off the floor and some active areas could be blocked by furniture.

Sensors are available that can scan an area from 200 sq ft up to about 4000 sq ft. The amount of energy they will save depends upon the amount of power they are controlling and the time of occupancy. Controlling small areas maximizes the time not in the space but controls little power; in controlling large areas, the occupancy time is increased while the controlled power is increased. It is important to have some knowledge of the occupancy time to determine the cost effectiveness of implementing this strategy. The best applications are spaces with limited occupancy such as lavatories, reproduction rooms, filing spaces, and storage spaces. They are also best used in spaces that are separated so that the on-off operation of the lamp does not disturb occupants in other spaces.

PHOTOCELL PLACEMENT

A key element in a successful daylight control system where there are visual tasks is the placement and calibration of the sensing photocell. The ideal position for the placement of the sensing photocell to maintain constant illuminance is on the task being performed. This poses two problems: interference with the task and communication with the lighting control system. Some systems have photocells that sense the illuminance outdoors. This approach is very difficult to calibrate because there is no information about the illuminance on the task. Most systems place the sensing photocell on the ceiling and view the task and the surrounding area. Thus, the information from the photocell can be easily interfaced with the lighting control to properly change the electric light levels. The photocell must also be shielded in such a manner as to block any direct daylight from the window. However, to maintain the specified illuminance on the task, the sensing system must be calibrated at night (no daylighting) and during the day with daylighting available. The reason for this is that the ratio of the electric light and daylight illuminance falling on the task is not the illuminance measured by the sensing photocell. The nighttime calibration (no daylight) is simple and the photocell output sets the light control to provide the specified illuminance. The second calibration is taken during the day, where the daylight on the task is not sufficient and requires an electric lighting contribution in order to provide the specified light level. The photocell output to the control is adjusted so that the electric lights provide sufficient light, supplementing the daylight to maintain the specified task illuminance.

The mechanics of the second calibration could be accomplished electronically with the proper computer software or with a two-cell photocell that independently senses either the electric lights or area surrounding the task. These techniques have been demonstrated and have been shown properly to maintain the specified illuminance on the task.

COMPUTERIZED EMS FOR HVAC AND LIGHTING

Rudolph R. Verderber; Lawrence Berkeley Laboratory; Berkeley, California

OCCUPANCY SENSORS

PHOTOCELL PLACEMENT

There are many applications (stores, shopping malls, atria, etc.) where there are no critical visual tasks. In these applications, the location of the photocell has many more options. In such applications the sensing photocell can be placed to view the outside as well as the interior space. The more important aspect is the ease of communication with the electrical lighting controls.

COMPUTERIZED ENERGY MANAGEMENT AND CONTROL SYSTEMS

Today virtually all new buildings incorporate an energy management system (EMS) that controls the HVAC system. Lighting control systems are being designed that will communicate with the EMS and can receive its commands. The simplest, least expensive technique is the use of relays to turn lights on and off at prescribed times based upon the normal working periods. Some states (e.g., California) require automatic lighting control that will at least turn off the lighting for all new construction. For buildings that have an EMS, retrofitting with lighting relay systems is a low cost, effective energy conservation strategy. The relay system can be installed in the electric closet to control branch circuits.

This scheduling technique can be more effective if the occupants must turn on their lights when they arrive at their workspace and the control automatically turns them off at the prescribed times, e.g., at lunch periods and in the evenings. This latter technique is particularly effective if the workforce has scattered starting times. In factories or disciplined offices where all staff is required to start at a particular time, turning on the lights automatically is suitable.

Buildings with automatic control of the lighting must have a suitable override system to accommodate occupants who must work during off hours. The override methods include telephone codes or conveniently located override switches.

The lighting scheduling strategy can also include reducing the light levels during the periods when the space is being maintained or cleaned. Most cleaning crews do not require the full light levels used by the occupants during the normal work periods.

MULTILEVEL SWITCHING

The effectiveness of the simplest low cost method of switching fluorescent lighting systems (relays) can be enhanced by proper wiring of the ballasts in the fixture. By wiring the ballasts to different control points, one can obtain three or four levels of illuminance. For example, in a four-lamp fixture with split wiring, one can obtain full, 1/2, and 0 light levels. Three-lamp fixtures or six-lamp fixtures can obtain full, 2/3, 1/3, and 0 light levels. This flexibility allows these systems to provide lower light levels over some spaces (aisles, storerooms, washrooms, etc.) that do not require full light levels. It enhances the savings for the scheduling strategy as it can reduce the light levels during cleaning periods since the cleaning operation usually does not require full light levels. Other lighting control strategies (lumen depreciation and daylighting) can also be considered. Although the latter two strategies are more energy efficient with continuous dimming controls, they are still cost effective, since the lighting control equipment cost will be less than the dimming control system. The multilevel systems can also address the state lighting codes that require fluorescent lamps to be operated at full and 1/2 illuminance levels.

FOUR-LAMP FIXTURE WITH TWO 2-LAMP BALLASTS

THREE-LAMP FIXTURE WITH ONE 2-LAMP BALLAST AND ONE SHARED 2-LAMP BALLAST

SIX-LAMP FIXTURE WITH THREE 2-LAMP BALLASTS

MULTILEVEL SWITCHING

CONTINUOUS DIMMING LIGHTING CONTROLS

Fluorescent lamps can be continuously dimmed with either standard magnetic ballasts or the new electronic ballasts. Lamps operated with magnetic ballasts are dimmed by conditioning the input power, i.e., the input voltage to the ballast is chopped, reducing the duty cycle. This technique requires switching devices that must control large power levels and is usually cost-effective when switching a large number of lamps. When fluorescent lamps are dimmed much below 50% of full light output, the filament voltage must be maintained at 3 to 4 volts in order to preserve the lamp life. When the duty cycle is reduced, the filament voltage is also reduced, which will accelerate lamp failure at the very low dimming levels, below 50% of full light output. Thus, techniques that condition input power have a practical dimming range. The fact that this technique is only cost-effective when controlling many lamps limits applications to control strategies that demand independent control of small areas, such as tuning and most daylighting strategies.

Electronic dimming ballasts dim fluorescent lamps by limiting the lamp current by a low voltage signal to the ballast's output circuit. The electronic ballasts have feedback circuits that permit the filament voltage to maintain the proper voltage at the very low dimming levels, down to 10% of full light output. Thus, the specified life of fluorescent lamps is still maintained when operated in the dimming mode at very low light levels. The low voltage method of communication allows the control of either large or small areas independent of the electrical power distribution, i.e., the branch circuits. The system efficacy is slightly reduced at the lower light levels since full filament voltage must be maintained; however, the energy use is always reduced. Dimming fluorescent lamps with electronic ballasts permits the effective application of all the lighting control strategies. Since the lamps can be safely dimmed over a wider range, the percentage of energy savings for each lighting control strategy will be maximized. There are additional savings because the electronic lamp-ballast system is more efficacious than the magnetic lamp-ballast systems.

LAMP IN OPEN AIR

LAMP IN FIXTURE

LAMP LIGHT OUTPUT VS. TEMPERATURE IN CONTROLLED AND UNCONTROLLED FIXTURES

ENERGY SAVINGS WITH LIGHTING CONTROLS

Lighting controls are used to provide the proper illumination in accordance with the activity in a space. In addition to improving the quality of the illuminance, considerable energy reduction can be achieved. The amount of energy reduction depends upon the number of control strategies that can be conducted, which depends upon the sophistication of the lighting control equipment. The control strategies include scheduling, tuning, lumen depreciation, and daylighting. Lighting controls also permit load shedding, which is effective in reducing utility demand charges.

Controlling lights with relays limits one to scheduling, turning lights on in the morning and off at night. For some special applications, such as malls and airports, where there is abundant daylighting, relay controls can be effectively employed. Some controls permit the dimming of magnetic ballasts by conditioning the input power. With this method, controlling large banks of luminaires is best considered. Dimming techniques that control large areas limit the strategies to scheduling, lumen depreciation, and simple daylighting applications, that is, where large areas of the space have similar daylighting patterns. The newly introduced dimming electronic ballast systems can perform all of the lighting control strategies. These systems can dim fluorescent lamps over a greater range without any loss in lamp life. It is also economically feasible to dim small areas as well as large areas, i.e., a small number of luminaires. This is because the low voltage control wiring can control lamps independently of the electrical distribution. This allows independent control of daylighted spaces where visual tasks are essential and the daylight distribution is not uniform. These spaces are generally found in offices where there is a great variety of important visual tasks performed during the day.

There have been several lighting control demonstrations that have measured the energy savings for each control strategy. The savings for each technique depends upon the architecture, the operation of space, the type of lamp-ballast system, and the lighting control equipment.

THERMAL CONTROL OF FLUORESCENT LAMPS

The light output from fluorescent lamps is very sensitive to lamp wall temperature and is 10 to 20% below maximum lumen output in most fixtures. There are fixtures available and new techniques being developed that can cool the lamp wall temperature to optimize both the lumen output and the efficiency. There are air handling fixtures in which the return air from the room flows over the lamps, cooling them to near the desired 40°C temperature. New techniques are being developed to employ slots for convective cooling and thermal bridges to obtain reduced lamp wall temperatures.

Of particular interest are many compact fluorescent lamp fixtures in which the internal fixture temperature is sufficiently high that, in addition to the reduction in lumen output and efficiency, there can be premature lamp and/or ballast failures.

By the use of the cooling techniques, full light output can be attained, not only increasing efficiency (reducing operating costs) but also reducing initial and maintenance costs since fewer fixtures (lamps and ballasts) will be required to provide the prescribed light levels.

VENETIAN BLIND CONTROL FOR DAYLIGHTING

Daylighting is most visually effective for a diffuse sky. This condition is generally for the north facing windows. Direct sunlight provides the highest luminance levels, but is usually too high and uncomfortable due to excessive glare. In fact, the discomfort glare may invoke an occupant to perceive the need for higher electric light levels. To effectively take advantage of daylight in the east, west, and south facing spaces, window treatments are needed. Venetian blinds are available that can block or divert the direct sunlight to reduce its glare. Venetian blinds are available that are either manual or automatic. The automatic systems are controlled by responding to a photocell that senses the direction of the sunlight.

The area controlled by either automatic or manual venetian blinds should be coordinated with the electric light control in the same area. This usually requires independent daylight control of relatively small areas. For example, if one designs a system where one photocell controls a large area, occupants may operate the manual blinds in their spaces differently, which will cause the photocell to sense the daylighting from only one area. This could result in one area meeting the specified light levels while other areas are seriously under-illuminated. This illustrates why the daylighting strategy is best applied with lighting control systems that control relatively small areas. There are unique architectural designs that have excellent symmetry with respect to the sun direction that have good results with control systems for relatively large areas. This requires integration of the internal space (usually open floor plans) with the proper positioning of the building with the north, east, south, and west directions.

PRACTICAL CONTINUOUS DIMMING RANGES

RANGES OF ENERGY SAVINGS WITH LIGHTING CONTROLS

	SCHEDULING	TUNING	LUMEN DEPRECIATION	DAYLIGHTING ¹
Relays	10 to 30%	NA	NA	15 to 25%
Magnetic ballasts ²	30 to 40%	NA	6 to 10%	20 to 27%
Electronic ballasts ²	17 to 50%	25%	8 to 12%	25 to 50%

NOTES

1. Energy savings in the daylight area only.
2. Continuous dimming systems.

Rudolph R. Verderber; Lawrence Berkeley Laboratory; Berkeley, California

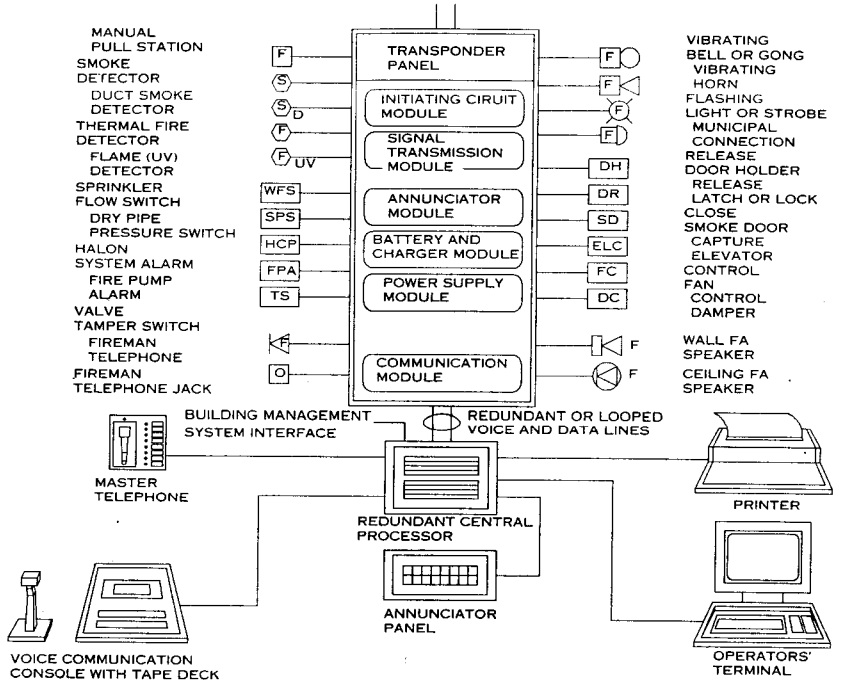

GENERAL

The simplest fire alarm system is a self-contained, UL approved residential smoke detector. It senses products of combustion, sounds an alarm, and signals when the battery needs replacement. Most municipalities require the use of smoke detectors in houses, apartments, and motel/hotel rooms. Check local codes for requirements.

More complex systems are needed in buildings where public safety is an issue, such as schools, hospitals, office buildings, and other commercial establishments or institutions. Although there are still applications for small hard-wired and relay-operated alarm signaling systems, the trend is to use microprocessor-based digital multiplex systems that not only signal the presence of a fire but also initiate other measures, including conditioning fans and dampers, for smoke control, closing fire doors and shutters, releasing locked doors, capturing elevators, and transmitting voice messages. Voice communication is required in high-rise buildings of specific group occupancies as defined by the BOCA code. It is also recommended for large low-rise buildings to enhance life safety.

Fire alarm systems can either function alone or be integrated with security and building management functions. Processors and their peripheral equipment are generally located in a manned central command center accessible to firemen. Depending on the degree of reliability desired, redundancy can be provided in wiring and processors, along with battery backup.

Alarm system control cabinets can be 36 in. wide x 8 in. deep. They must have battery backup, be UL approved, conform to NFPA no. 72, and may also require local approval. In small systems where only one cabinet may be required, all the functions required at the command center can be incorporated in the same cabinet and located in the main entrance lobby. In larger systems, remote cabinets are generally located in wiring closets throughout the building and can be programmed to function independently of the central processor, should it fail.

ELECTRONIC FIRE ALARM/COMMUNICATION SYSTEM FUNCTION DIAGRAM

SIGNALING SYSTEM TYPES

- NONCODED: Evacuation signal sounds continuously.
- MASTER CODED: Signal repeats four rounds.
- SELECTIVE CODED: Same as "master coded" except individual and assigned number code of up to three groups per round.
- PRESIGNAL: Same as "selective coded" except signals sound only at selected areas to prompt investigation. If hazard is determined, evacuation signal is initiated by key.
- VOICE: Direct (by microphone) or automatic prerecorded messages are transmitted over speakers, following an "alert" signal.

AUDIBLE ALARMS

Audible alarms must have an intensity and frequency that attract the attention of those with partial hearing loss. Such alarms should produce a sound that exceeds the prevailing sound level in the space by at least 15 dbA or exceeds maximum sound level with a duration of 60 seconds by 5 dbA, whichever is louder. Sound levels should not exceed 120 dbA.

VISUAL ALARMS

Visual alarm signals should be integrated into the building alarm system. Alarm stations should give both audible and visual signals. Visual alarm signals should have the following characteristics:

1. Lamp: xenon strobe type or equivalent.
2. Lamp color: clear or nominal white (i.e., unfiltered or clear filtered white light).
3. Maximum pulse duration: 0.2 sec with a maximum duty cycle of 40%. The pulse duration is defined as the time interval between initial and final points of 10% of maximum signal.
4. Intensity: 75 candela minimum.
5. Flash rate: 1 Hz min., 3 Hz max.
6. Place the alarm 80 in. above the highest floor level within the space or 6 in. below the ceiling, whichever is lower.
7. In any space required to have a visual alarm, generally all areas must be within 50 ft of the signal (measured horizontally). In large spaces, such as auditoriums, exceeding 100 ft across, with no obstructions over 6 ft high, devices may be placed around the perimeter, spaced a maximum of 100 ft apart, in lieu of suspending devices from the ceiling.

Range in size from 4 to 12 in. diameter. Can be recessed behind a grille. Operation can be single stroke or continuous.

BELL AND COVER

Approximately 12 in. high x 10 in. wide x 3 in. deep, surface or flush. Provided in lieu of jack plates for a total system. Door can be glass or plastic pane.

FIREMAN TELEPHONE CABINET

HORN/SPEAKER/VISUAL SIGNAL

Approximately 7 in. high x 5 in. wide surface or semi-recessed mounted. Mounted 54 in. above finished floor to lever per ADA. Can be provided with break glass rod feature. Operation can be coded or noncoded.

Richard F. Humenn; PE; Joseph R. Loring & Associates, Consulting Engineers; New York, New York
JRS Architect; Mineola, New York

GENERAL

The purpose of a fire suppression system is to extinguish or mitigate the effects of a fire. Selection of the extinguishing medium most appropriate for a project is based on availability, compatibility, cost, and code requirements.

CODES AND STANDARDS

Most model, state, and local codes have a separate fire protection section that mandates certain types of fire suppression systems based on occupancy types, potential fire hazards, height, and area of the structure. Insurance companies, such as Factory Mutual, American Risk Insurers, and American Risk Management, have developed design standards to be followed by the clients they insure. In addition, the National Fire Protection Association (NFPA) has developed consensus standards for various suppression systems that are referenced and required to be followed by most codes.

It is important that an adequate code search be made before the design phase of any project to ensure that the proper codes are complied with.

BASIC DEFINITIONS

Although the exact nature of fire and the combustion process is still not completely understood, it is known that three things are necessary for a fire to be maintained: fuel, oxygen, and a temperature high enough to start ignition or maintain combustion. All fire extinguishing methods remove one or all of these elements, causing the fire to be extinguished.

Fires are classified as class A, B, C, or D:

CLASS A fires occur in solid, combustible materials such as wood and paper.

CLASS B fires occur in combustible liquids such as oil and gasoline.

CLASS C fires are electrical in nature, such as a short circuit that causes a spark capable of igniting other substances.

CLASS D fires occur in metals with their own fuel supply.

Building occupancy and other, specific areas within a building are classified as light, ordinary, or extra hazard, according to the potential for fire. Light hazard occurs in office buildings, schools, and public buildings. Ordinary hazard is similar to warehouses and stores with large amounts of combustible material. Extra hazard occurs where there is considerable potential for easily started, large fires. These classifications are more fully explained in the applicable NFPA standards.

The term "automatic" is often used when referring to fire suppression systems. In this context, automatic means operation of the system without human intervention when fire conditions occur.

SYSTEM TYPES

Three general types of systems are used for suppression of fires: water-based, chemical-based (either liquid or powder), and gas-based.

WATER-BASED SYSTEMS use either water mixed with chemicals that add fire-extinguishing characteristics or undiluted water to cool the fire below ignition temperature or deprive it of oxygen.

CHEMICAL-BASED SYSTEMS interfere with the combustion process and deprive the fire of oxygen.

GAS-BASED SYSTEMS interfere with the combustion process and deprive the fire of oxygen.

WATER-BASED SYSTEMS

The medium most often used to extinguish fires is water. It is readily available, inexpensive, and easy to apply. The most important factor in the use of water-based systems is adequate water pressure. When pressure from the building water supply is inadequate to supply fire standpipe and sprinkler systems, a special fire pump, manufactured and installed specifically for fire suppression systems, is used to increase water pressure. The fire pump is installed in strict conformance with NFPA-20.

Fire standpipe, foam, and sprinkler systems are described on the second AGS page on Fire Suppression Systems.

GAS-BASED SYSTEMS

Some gas-based systems use inert gases, and others use chemical gases.

INERT GASES

These systems are used when chemicals that may react to water are present or when water will cause unacceptable damage. The gases (generally carbon dioxide or nitrogen) are discharged either directly onto a fire or used to reduce the oxygen level in a room or area to a point below that required to sustain combustion. (Note, however, that this low level also will not sustain life.)

The gas is stored compressed in high pressure cylinders or tanks and is connected to a piping system with open heads. A quick opening valve at the storage location detects heat, fire, or smoke at the hazard being protected, then opens to allow gas to enter the piping system and discharge out all the heads.

OTHER GASES (HALON ALTERNATIVES)

Chemical gases interfere with the combustion process, and chemical gas systems are often used to protect computer and electronic equipment and areas. The systems operate in the same way as inert gas systems, but a lower concentration of gas is usually required. Halon is no longer permitted because of environmental concerns. Many halon alternatives are available, but their use must be approved by authorities having jurisdiction.

Because of the force exerted by the discharging gas, hung ceilings should be reinforced in areas where heads are located and the heads mounted so they can resist the force of discharge.

CHEMICAL SYSTEMS

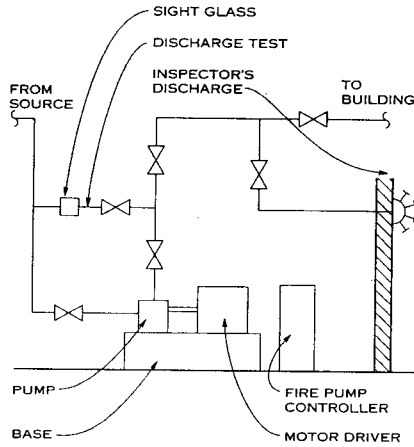

Both wet and dry chemical systems require extensive cleanup after a fire has been extinguished.

DRY CHEMICALS

This system is used to protect areas for which water is not a suitable extinguishing medium, such as chemical storage areas and cooking areas with exhaust ductwork that vents grease. A powdered chemical is stored in high-pressure cylinders or tanks connected to a piping system with open heads. Upon detecting heat, fire, or smoke at the hazard being protected, a quick opening valve at the storage location opens, allowing the powder to enter the piping system and discharge from all of the heads simultaneously.

WET CHEMICALS

The recent shift from animal fats to vegetable fats for cooking required a different medium for fighting fires in kitchens. This medium is a wet chemical, which operates in the same manner as the dry chemical system.

WATER-BASED SYSTEMS

Three types of water-based fire suppression systems are detailed on this page: fire standpipe, foam, and sprinkler. Other system types are discussed on the other AGS fire suppression page.

FIRE STANDPIPE (FSP)

A fire standpipe system is a network of water-filled pipes, hose valves, and fire hose that allows the direct application of water onto a fire. The most common system configuration has hose valves only, which are connected to system piping to allow fire department personnel to connect their hose to the system. Mains are installed in high fire-rated areas such as stairwells. Hose valves are located so that all parts of the building can be reached with a 100-ft length of hose and a 20-ft water stream from the hose nozzle.

It is accepted practice to supply sprinkler heads from FSP mains in various areas throughout a building. Each connection point is provided with a flow alarm. A test connection is installed at each point to permit authorities to visually verify that the water discharged from one sprinkler head is actually flowing and will initiate an alarm. This test connection is combined with a drain line to permit the entire branch to be drained for maintenance and repair.

FOAM

A foam system consists of a water supply, chemical additive injector, piping, and heads placed to discharge foam. The system uses an additive injected into the water supply to produce a soapsuds-like discharge. This system is used to extinguish fires in flammable liquids that are lighter than water. The foam floats on top of the liquid and deprives the fire of oxygen.

SPRINKLER SYSTEMS

A sprinkler system uses water distributed through a network of valves, piping, and nozzles whose primary purpose is to set off an alarm and mitigate the effects of a fire, not necessarily to extinguish it. When a fire condition is present, the heat of the fire melts the element of a closed sprinkler head, allowing water to discharge automatically onto the fire.

The sprinkler piping system is sized using one of two methods, schedule or hydraulic. The schedule method uses pipe sizes based on a minimum available water pressure and the number of heads connected to the piping that appears in NFPA-13. The hydraulic method uses a remote area (that farthest from the water supply source) based on occupancy type, flow of water over the remote area, flow of water at each design point, and pressure available in the system.

MAJOR SYSTEM COMPONENTS

The major operating components of a sprinkler system are the operating valve assembly, piping, and nozzles (referred to as heads for some systems).

The operating valve assembly admits water to or sends an alarm upon the flow of water in the system. There are many types of operating valves, and the type of system installed determines the type of valve used.

Heads or nozzles distribute water in a special, predetermined pattern based on the requirements of the system. They are available in a wide variety of configurations, including upright, pendant, or sidewall, and can be closed or open. They have different temperature ratings to open the head, various orifice diameters for the discharge of water, standard or quick response, and standard or extended coverage. They can be installed in a hung ceiling as concealed, flush, or exposed fixtures.

SPRINKLER SYSTEM TYPES

WET PIPE: This automatic system uses piping filled with water under pressure and closed heads. The operating valve assembly, called an "alarm check valve," initiates an alarm when water flows and prevents the reverse flow of water into the building service if the system is supplied with water from a fire department connection. When a fire condition exists, the heat melts (fuses) a temperature-sensitive element in the head, causing the head to open and water to flow.

DRY PIPE: This automatic system uses piping filled with air under pressure and closed heads. The operating valve assembly is called a "dry pipe valve." An air compressor is required to make up air lost through leakage. Both water and compressed air are supplied only to the dry pipe valve. When a head fuses due to a fire condition, it lowers the air pressure, opens the valve, and permits water to enter the piping; the water then flows only from the open heads.

PREACTION: This automatic system uses closed heads and piping filled with air under atmospheric pressure. Water is supplied to the operating valve assembly, called a "preaction valve." An ancillary smoke or fire detection system initiates a signal upon detection of heat, fire, or smoke. The signal causes the preaction valve to enter the piping system. Water will not flow out of the heads unless they fuse due to a fire condition.

DELUGE: Used to protect high hazard areas and specific equipment, this automatic system uses piping filled with air under atmospheric pressure and open heads. Water is supplied to the operating valve assembly, called a "deluge valve." An ancillary smoke or fire detection system is required to initiate a signal upon detection of heat, fire, or smoke at the hazard being protected. This signal will open the deluge valve, admitting water throughout the piping system and allowing water to discharge out of all the heads connected to the piping network.

ANTIFREEZE: A wet pipe automatic system is filled with an antifreeze solution instead of water to protect areas subject to freezing but too small for a dry pipe system. Operations are similar to those of the standard wet pipe system.

WATER MIST: This automatic system uses high pressure water flowing through nozzles designed to discharge very small droplets of water directly onto a fire. A water pump is required to produce the high system pressure. Water is supplied to the pump, which is activated by ancillary heat, fire, or smoke detectors adjacent to the hazard protected.

CONVEYING SYSTEMS

Elevators 666

Escalators and Moving Walks 672

Material Handling 673

GENERAL

An elevator system is a major building component and as such must be carefully considered throughout the design process. Decisions about the number, size, speed, and type of elevators for an installation are based on a number of factors, including the handling capacity and quality of service desired. Proper selection also depends on the type of tenancy, number of occupants, and building design (number of floors, floor heights, building circulation, and other factors). In addition, passenger elevators on accessible routes should comply with the requirements of the Americans with Disabilities Act Accessibility Guidelines (ADAAG).

Consult representatives of the elevator industry or elevator engineers during the decision-making process to ensure selection of the most suitable elevator system for an application. Because elevator installation is highly regulated, it is advisable to consult local code officials.

Elevators should be located where they can provide efficient, easily reached service. As well, the operational systems (hoistway pit and machine room) and passenger spaces (lobby and elevator car) must be accommodated.

ELEVATOR SYSTEMS

An elevator system includes a hoistway, machine room, elevator car, and waiting lobbies.

HOISTWAY

The hoistway is a vertical shaft for the travel of one or more elevators. It includes a pit and usually terminates at the underside of the machine room in a traction system and at the underside of the roof over the hoistway in a hydraulic system. Access to the elevator car and hoistway is normally through hoistway doors at each floor serviced by the elevator system. Hoistway design is determined by the characteristics of the elevator system selected and by applicable code requirements for fire separation, ventilation, soundproofing, and nonstructural elements.

MACHINE ROOM FOR TRACTION ELEVATOR

The machine room for a traction elevator is usually located directly above the hoistway but could also be situated below, to the side, or to the rear of it. The machine room contains elevator hoisting machinery and electronic control equipment. Adequate ventilation, soundproofing, and structural support for the elevator must be supplied. Also, the machine room must have a self-closing, self-locking access door. Local codes may forbid placement of electrical or mechanical equipment not associated with the elevator in the machine room.

MACHINE ROOM FOR HYDRAULIC ELEVATOR

Normally located near the base of the hoistway, a machine room for hydraulic elevators contains a hydraulic pump unit

and electronic controls. Provisions should be made for adequate ventilation and soundproofing, and the room must have a self-closing, self-locking access door. Local codes may forbid placement of electrical or mechanical equipment not associated with the elevator in the machine room.

ELEVATOR CAR

Guided by vertical rails on each side, the elevator car conveys passengers or freight between floors. It is constructed within a supporting platform and frame. Design of the car focuses on ceiling, wall, floor, and door finishes and accompanying lighting, ventilation, and elevator signal equipment.

The car and frame of a hydraulic elevator system are supported by a piston or cylinder.

The car and frame of a traction elevator system are supported by the hoist machine. The elevator and its counterweight are connected with steel ropes.

LOBBIES

Elevator waiting areas are designed to allow free circulation of passengers, rapid access to elevator cars, and clearly visible elevator signals. All elevator lobbies must be enclosed with the exception of that at the entry level of the main building.

ELEVATOR TYPES

HYDRAULIC ELEVATORS use an oil hydraulic driving machine to raise and lower the elevator car and its load. Lower speeds and the piston length restrict the use of this system to heights of approximately 55 ft. Although it generally requires the least initial installation expense, this elevator type requires more power to operate.

TRACTION ELEVATORS are power elevators in which the energy is applied by means of an electric driving machine. Medium to high speeds and virtually limitless rise allow this elevator type to serve high-rise, medium-rise, and low-rise buildings.

GEARED TRACTION ELEVATOR SYSTEMS are designed to operate within the range of 100 to 450 ft/min, restricting their use to medium-rise buildings.

GEARLESS TRACTION ELEVATOR SYSTEMS are available in preengineered units with speeds of 500 to 1200 ft/min. They offer the advantages of a long life and a smooth ride.

SERVICE ELEVATORS in industrial, residential, and commercial buildings are often standard passenger elevator packages modified for service use.

FREIGHT ELEVATORS are usually classed as general freight loading, motor vehicle loading, industrial truck, or concentrated loading elevators. General freight loading elevators may be electric drum type or traction or hydraulic elevators.

PRIVATE RESIDENTIAL ELEVATORS may be installed only in a private residence or to serve a single unit in a building with multiple dwelling units. By code, elevators in private residences are limited in size, capacity, rise, and speed.

BUILDING CHARACTERISTICS

Physical building characteristics (such as building height and hoistway location) are considered with population characteristics to determine the size, speed, type, and location of elevator systems. Characteristics that particularly affect the elevator systems are

1. Height: Determine the distance of elevator travel from lowest terminal to top terminal, the number of floors, and the floor height.
2. Building use: Identify the location of heavily used building entrance areas, such as those leading to cafeterias, restaurants, auditoriums, and service areas. Typically, plan a building so that no prospective passengers must walk more than 200 ft to reach an elevator.

The elevator selection process must begin with a thorough analysis of how people will occupy the building. Four issues are pertinent:

1. Total population and density: Determine this figure for each floor.
2. Peak loading: Identify the periods when elevators will carry the highest traffic loads.
3. Waiting time: This is the length of time a passenger is expected to wait for the next elevator to arrive.
4. Demand for quality: Smooth operation may be as important as fancy finishes.

NOTE
These dimensions are general guidelines for selecting an elevator using height as a criterion.

ELEVATOR TYPES

ELEVATOR TYPES BY USE

NEED/USE	ELEVATOR TYPE			
	PRIVATE RESIDENTIAL	HYDRAULIC	GEARED TRACTION	GEARLESS TRACTION
Private houses	X			
Low-rise, low speed		X		
Medium-rise, moderate speed			X	
High-rise, high speed				X
Low initial cost		X		
No penthouse, lightweight construction		X		
Freight, low-rise		X	X	
Freight, high-rise			X	

Rippeteau Rollins Architecture + Design; Washington, D.C.

GENERAL

Guidelines for selecting an elevator for a private residence can be simplified to a few parameters. By code, residential elevators are limited in size, capacity, rise, and speed and can be installed only in a private residence or in a multiple dwelling as a means of access to a single residence. Preengineered systems generally offer only a few options for speed, capacity, aesthetic design, and electronic controls.

BUILDING POPULATION analysis involves identifying the needs of prospective users. Relevant information includes the type of expected occupancy (mixed or single occupancy and whether the elevator must accommodate an unassisted wheelchair user), the number of passengers expected to occupy the elevator in one trip, and elevator service in a given time period.

BUILDING CHARACTERISTICS affect elevator selection by establishing the building height (distance of elevator travel) and hoistway location. In private residences, the elevator may occupy a tier of closets, an exterior shaft, a room corner, or a stairwell.

ELEVATOR SYSTEMS FOR PRIVATE RESIDENTIAL USE

Two types of elevator systems are commonly used in private residences:

WINDING-DRUM MACHINE

This type of traction elevator employs a grooved drum around which the hoisting cable wraps as it operates. This elevator type does not require a counterweight or a machine room above the hoistway, making it more practical for small places than a standard traction system.

HYDRAULIC ELEVATOR

Hydraulic elevators in private residential use employ either a standard hole-less arrangement or a roped hydraulic machine. Both types eliminate major construction and drilling, making the system economical and an excellent selection for retrofit applications.

NOTES

- DIMENSIONS:** Dimensions may vary among manufacturers and according to the elevator system. Elevators carrying greater loads or operating at higher speeds require more clearance overhead and in pit areas. Elevator cars with higher interior clearances also require more overhead clearance in the hoistway. The dimensions given here are appropriate for most applications. For exact dimensions required in specific circumstances, consult manufacturers.
- ELEVATOR CARS:** Typical car sizes, A x B, are 36 x 36 in., 42 x 42 in., and 36 x 48 in. The maximum platform size allowed by the National Elevator Code for residential elevators, ANSI A17.1, is 12 sq ft; however, this platform size does not meet the National Handicapped Access Code, ANSI A117.1, for use by an unassisted wheelchair-bound person.
- LOAD CAPACITY:** The load capacity of drum-type machines is 500 lb; speed is 30 ft/min. The load capacity of traction and hydraulic machines is 750 lb; speed is 36 ft/min.
- POWER SUPPLY:** Elevators operate on a 220/230 volt, single-phase power supply. A disconnect switch must be provided within sight of the machine. A 110V, single-phase power supply is required to light the machine area of the hoistway.
- HOISTWAY ENCLOSURES:** Enclosures are recommended for all hoistways. The fire rating of these enclosures and the access doors must be consistent with the fire rating of the building. See local codes.
- GUIDE RAILS:** Manufacturers usually provide guide rails in 5-ft sections, although some manufacturers offer rails that can span the distance from floor structure to floor structure. If a third guide rail is required, it is supplied in 3 ft 4 in. sections. If an existing structure cannot support guide rails, manufacturers can provide a self-supporting elevator tower that transmits the load to its base. This tower requires increased horizontal clearance in the hoistway. Elevator cars can be provided with openings on two sides; when this option is employed, guide rails must be located accordingly. Consult manufacturers.

NOTE

Standard car size is 36 in. wide x 48 in. deep x 80 in. high. Other car depths available are 36 in. and 60 in.

RESIDENTIAL ELEVATOR PLANS

ROPED HYDRAULIC ELEVATOR TYPES

Rippeteau Rollins Architecture + Design; Washington, D.C.

GENERAL

Medium- and high-rise buildings require geared traction and gearless traction elevator systems. The main difference between the two systems lies in travel speed. General design considerations involving hoistway machine room, and elevator planning are similar.

Both geared and gearless drive units are governed by electronic controls, which coordinate car leveling, passenger calls, collective operation of elevators, door operation, car acceleration and deceleration, and safety applications. A broad range of control systems is available to meet individual building requirements.

Structural requirements call for the total weight of the elevator system to be supported by the machine beams and transmitted to the building (or hoistway) structure. Consult with elevator consultants and structural engineers.

NOTES

1. Pit depths, overhead clearances, and penthouse sizes should be in accordance with ASME requirements. Local codes may vary from these requirements.
2. All overhead dimensions for passenger elevators are based on standard 8-ft-high cabs.
3. Layout dimensions of the passenger elevator are based on center-opening entrances. Other types are available.
4. The machine room for traction elevators is usually located directly above the hoistway. Space must be provided for the elevator drive, electronic control equipment, and governor; provide sufficient clearance for equipment installation, repair, and removal. Adequate lighting and ventilation (temperature maintained between 65 and 100°F or 18 and 38°C are required by codes, and sound insulation should be provided. Machine room sizes may vary depending on number of cars, type of control, etc. Check with elevator consultant for requirements.
5. Check local codes for required fire enclosures.

NOTE

This is a very specialized application, and consultation with experts is advised. Traction elevators with basement machine rooms are used in new and existing buildings where overhead clearance is limited.

ELEVATOR PLANNING DETAILS

BUILDING PREPARATION FOR ELEVATOR INSTALLATION

The following base building preparatory work is required in order to install elevator equipment properly:

1. An enclosed elevator equipment room with electrical outlets, adequate lighting, and heating and ventilation sufficient to maintain the room at a temperature between 50°F (minimum) and 100°F (maximum).
2. Adequate supports and foundations to carry the loads of all equipment, including supports for guide rail brackets.
3. Complete connections from the electric power mains to each controller, including necessary circuit breakers and fused main line disconnect switches.
4. Electric power of the same characteristics as the permanent supply for construction, testing, and adjusting.
5. Trenching and backfilling for any underground piping or conduit.
6. Divider beams for rail bracket support as required.
7. Cutting of walls, floor, etc. and removal of any obstructions; setting of anchors and sleeves.
8. Grouting of doorsills, hoistway frames, and signal fixtures after installation of elevator equipment.
9. All painting, except as otherwise specified.
10. Temporary enclosures, barricades, or other protection from open hoistways and elevator work areas while the elevator is being installed.
11. Temporary elevator service prior to completion.
12. Heat and smoke sensors as required by NFPA.
13. All telephone wiring to machine room control panel, and installation of telephone instruments.
14. A standby power source when elevator operation from an alternate power supply is required.
15. Adequate storage facilities for elevator equipment before and during installation.
16. A means to disconnect the elevator's main line power supply automatically to protect the machine room equipment from water damage.
17. A plumb and legal hoistway; a pit of proper depth with a pit ladder for each elevator; drains, lights, access doors, waterproofing, and hoistway ventilation, as required.

Rippeteau Rollins Architecture + Design; Washington, D.C.

SINGLE CAR

FOUR-EIGHT CAR ARRANGEMENT

PAIRED CARS

THREE-SIX CAR ARRANGEMENT

NOTES

1. Elevators should be centrally located, near the main entrance, and easily accessible on all floors. Groups of elevators should be arranged to minimize walking distance between cars. Lobby space must be sufficient to accommodate group movement. Elevators may not open into a corridor.
2. The largest practical grouping of elevators in a building is eight cars. One row of more than four cars is generally unacceptable. With groupings of four or six cars, waiting

lobbies may be closed at one end, forming an alcove, or open at both ends.

3. In buildings with several elevator groupings, one group may serve lower floors, while others serve as express elevators to upper floors.
4. When four or more elevators serve all or the same part of a building, they must be located in no fewer than two hoistways, but no more than four elevators can be located in any one hoistway.
5. Consider the option of rear access for trash removal.

ELEVATOR LOBBY PLANNING

NOTE

An Area of Rescue Assistance is defined in the Americans with Disabilities Act Accessibility Guidelines as "an area, which has direct access to an exit, where people who are unable to use stairs may remain temporarily in safety to await further instructions or assistance during emergency evacuation."

The elevator lobby and shaft must be pressurized for smokeproof enclosure as required by the local building official. The pressurization system must be activated by smoke detectors in locations approved by the local building official. The system's equipment and ducts must be of 2-hour fire-resistant construction.

ELEVATOR LOBBY DESIGNED AS AREA OF RESCUE ASSISTANCE (ARA)

NOTE

Observation and glassback elevators travel outside of a hoistway or in a hoistway open on one side. Machinery is concealed or designed to be inconspicuous. Elevators may be engineered for hydraulic, geared, or gearless use. Cabs can be custom designed with more than 75% of wall area as glass. Only the rear panel is glass in glassback cabs. Safety barriers must be provided at floor penetrations and the ground floor, completely surrounding that part of the elevator not enclosed by the hoistway. This is a very specialized application; consultation is advised.

GLASS-WALLED ELEVATOR CARS

GENERAL

Hydraulic elevator systems are used primarily in low-rise installations, where moderate car speed (up to 150 ft per minute) is required. A car is connected to the top of a long piston that moves up and down in a cylinder. The car moves up when hydraulic fluid is pumped into the cylinder from a reservoir, raising the piston. The car is lowered when the hydraulic fluid returns to the reservoir. The up and down motions of the elevator car are controlled by the hydraulic valve.

The main space planning elements of a hydraulic elevator system are the machine room, usually located at the base, and the hoistway, which serves as a fire-protected, ventilated passageway for the elevator car. Adequate structure must be provided at the base of the hoistway to bear the load of the elevator car and its supporting piston or cylinder.

NOTES

1. The elevator pit should be reinforced to sustain the vertical forces generated by the system configuration. Consult manufacturer's representatives. All pit depths and overhead clearances should be in accordance with ASME requirements. Local codes may vary from these requirements.
2. Car and hoistway dimensions of preengineered units are for reference purposes only. A variety of units is available. Consult manufacturers for dimensions of specific systems.
3. Hoistway walls usually serve primarily as fireproof enclosures. Check local codes for required fire ratings.
4. Guide rails extend from the floor of the pit to the underside of the overhead (top of hoistway). Consult the elevator manufacturer for the special requirements of excessive floor heights.
5. Rail brackets typically are at each floor level. A bracket is required at the top of the hoistway, and an intermediate bracket may be required for certain floor-to-floor heights. Consult manufacturer.
6. Some hydraulic applications may require jack hole block-outs in the floor of the pit.

PISTON AND CYLINDER DETAIL

HOLED HYDRAULIC ELEVATOR

HYDRAULIC ELEVATOR DIMENSIONS (FT-IN.)

RATED LOAD (LB)	A	B	C	D	E
2000	5-8	4-3	7-4	5-11	3-0
2500	6-8	4-3	8-4	5-11	3-6
3000	6-8	4-7	8-4	6-3	3-6
3500	6-8	5-3	8-4	6-11	3-6
4500	5-8	7-10	7-5	10-0	4-0

NOTE

"A" and "B" dimensions are "clear inside." Rated speeds are 75 to 200 ft/min.

HOLELESS HYDRAULIC ELEVATOR

NOTES

1. A machine room, meeting code requirements and ventilated for temperatures between 65° and 100°F (18° and 38°C), must be provided for all elevators. It is usually located next to the hoistway at or near the bottom terminal landing. Room size may vary depending on the number of cars, capacity, and speed.
2. Machinery consists of a pump and motor drive unit, hydraulic fluid storage tank, and electronic control panel. Adequate ventilation, lighting, and entrance access (usually 3 ft 6 in x 7 ft) should be provided.

MACHINE ROOM

Rippeteau Rollins Architecture + Design; Washington, D.C.

GENERAL

General freight elevators with capacities of 2000 to 8000 lb satisfy a variety of material-handling requirements. Industrial truck freight elevators require special design considerations to handle truckloads of 10,000 to 20,000 lb or more.

General freight or industrial truck elevators may have either hydraulic or traction drive systems similar to those of other elevator systems. However, the units are usually custom-designed with vertical bipart doors and special structural support to accommodate heavy loads and eccentric loading conditions. Freight elevators usually have simple control systems and operate at slower speeds than other elevators. Their capacity must be sized for the largest expected load.

HYDRAULIC FREIGHT ELEVATOR

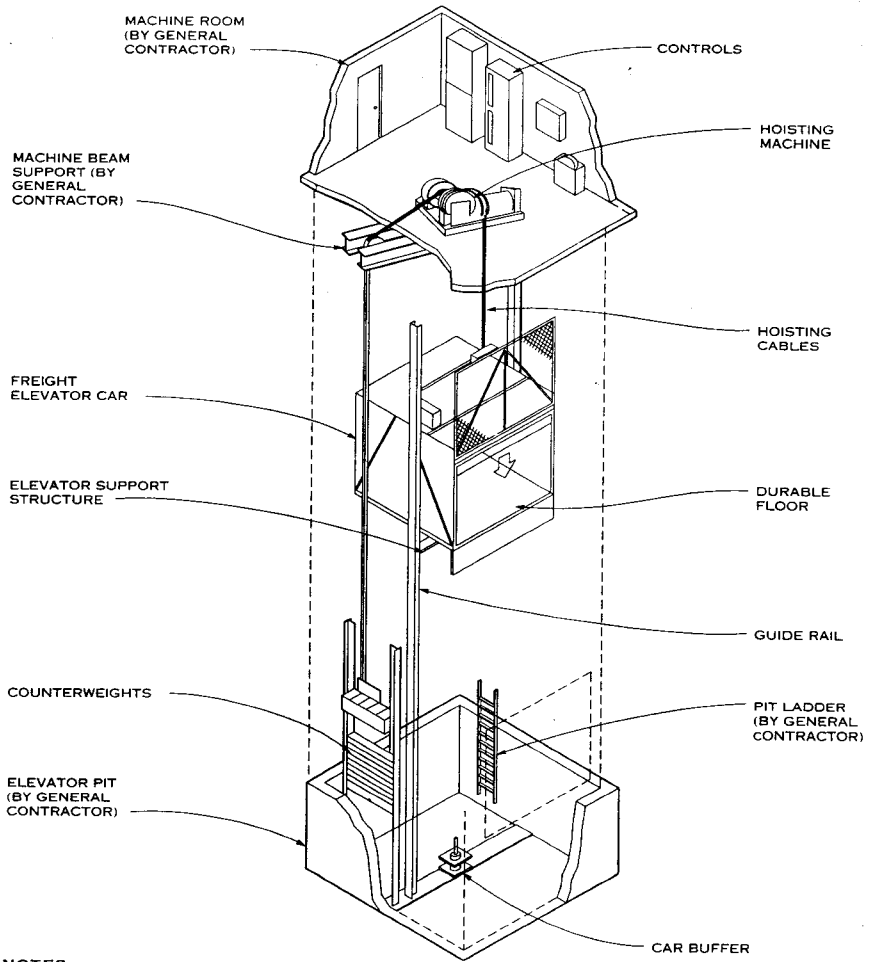

TRACTION FREIGHT ELEVATOR

NOTE

G = 5 in. (127 mm) for regular counterbalanced hoistway doors and 6 3/4 in. (172 mm) for pass-type counterbalanced hoistway doors. Pass-type doors are required when floor heights are less than 11 ft (3350 mm) for 7-ft (2134 mm) openings and less than 12 ft 6 in. (3810 mm) for 8-ft (2458 mm) openings.

KEY PLAN

NOTES

1. Hoistway walls: Local building codes govern design characteristics; consult with appropriate agencies to determine requirements such as fire rating.
2. Traction elevators: The hoisting machine may be mounted directly overhead or at the side of the hoistway at any level, including the lowest landing. Special structural design considerations are necessary based on forces created by the use of traction equipment.
3. Guide rail bracket support: Freight elevators create horizontal forces greater than those created by passenger elevators. Vertical steel is installed within the hoistway to provide bracket support at elevations with bracket locations.
4. Truckable sills: At the edge of the building floor (leading into the elevator hoistway), a structural steel angle must be in place to avoid deterioration of the building floor through continued use of hand trucks, battery-operated pallet lifts, forklifts, etc.
5. Flooring: A variety of materials may be used for flooring in a freight elevator, including checkered steel plate, non-skid materials, galvanized steel, or high-density wood.

Rippeteau Rollins Architecture + Design; Washington, D.C.

GENERAL

Escalators are a very efficient form of vertical transportation for very heavy traffic where the number of floors served is limited, normally a maximum of five to six floors. Escalators are not usually accepted as a required exit.

Dimensions shown are general and will vary somewhat with the manufacturer. Consult manufacturers for structural support, electrical supply, and specific dimensional requirements.

ESCALATOR PROFILE

Moving passenger conveyors are particularly useful in transportation terminals, sports arenas, and exposition centers where large numbers of people must move long distances horizontally. The conveyors may be arranged in any combination of horizontal runs and inclines with a practical maximum of 12°.

It is generally not economical to provide moving sidewalks for distances less than 100 ft; for distances greater than 300 ft they invoke passenger frustration by their slow operating speed. Narrower units (26 in.) accommodate one adult; 40 in. widths allow for both walking and standing passengers.

Ramp slope	15 to 23%	10 to 37%	3 to 16%			Up to 10%	Manually operated

NOTE

Data and figures given here represent the ranges of general specification available on forklift trucks. Aisle width is controlled by type of forklift and pallet size used in a warehouse. Specific data and applications should be obtained

Narrow aisle operations without limiting pallet sizes and rack openings.

REACH TRUCK

Allows access to multiple level pick slots; an efficient technique with a large item base that has limited space for selection line.

ORDER PICKER TRUCK

Ideal for moving large volumes of material where maneuvering area is not limited.

COUNTERBALANCE TRUCK

Allows narrow aisle operations. Forks can rotate 180° which allows access to both sides of the aisle without turning the truck around.

TURRET TRUCK

AUTOMATIC GUIDED VEHICLES (AGV)

NOTE

These vehicles are used throughout industry for transporting product from point to point with repeatable accuracy. They are totally automatic and require little or no human interface. The AGV follows a guidepath on the floor or can be radio controlled. The relatively low cost of changing or adding a guidepath makes the AGV a flexible system.

AGV's are controlled by a computer and are powered by industrial batteries.

AGV - DIMENSIONS AND CAPABILITIES

Load capacity	Up to 93,000 lbs
Lift height	Up to 15' - 7"
Turning radius	2' - 0" to 18' - 0"
Weight with battery	2000 to 22,000 lbs
Overall length	6' - 1" to 34' - 4"
Overall width	3' - 6" to 9' - 4"
Overall height	12 1/2" to 7' - 6"
Fork length	Up to 5' - 0"
Travel speeds	Up to 200 FPM

NOTE

Data and figures given are general specifications. AGV's are designed for specific tasks with dimensions and capabilities varying from application to application. Please consult the AGV manufacturer or material handling engineer for specific data.

St. Onge, Ruff & Associates; York, Pennsylvania
Richard J. Vitullo, AIA; Oakleaf Studio; Crownsville, Maryland

from material handling engineers. The trucks presented are electrically powered (excluding the hand jack) using industrial batteries as a source of energy. Industrial batteries typically must be charged after each 8-hr shift. Two batteries

per truck are typical to allow back-to-back shift operation. The charging operation should take place in an area segregated from the warehouse or production area and must be designed to meet the various OSHA requirements.

GENERAL

Material-conveying systems are designed to carry either bulk material or unit items. Bulk materials include agricultural and food products, chemicals, solid fuels, pastes, and powders. Unit materials include luggage, envelopes, cases, parts, part bins, pallets, bags, and cans.

Conveyors are usually designed as complete systems by engineers who specialize in such systems. The choice and design of a conveying system should include consideration of material properties, containment, damage, capacity, speed, loading and unloading, control, reliability, safety, and maintainability.

Access to conveyors must be provided for equipment maintenance, clearing of load jams, and loading and unloading. Because mechanical conveyors have inherent safety hazards, guards and emergency stop controls are required to reduce the chance of injuries. Most conveyors are used in a controlled access environment such as a security area or industrial plant. Equipment accessed or used by the public must be specifically designed for safety.

NOTE

Vibratory conveyors, used for bulk materials and small unit items or parts, consist of a pan or tube that vibrates or oscillates to move the material. Energy efficiency is low. Most uses involve flow control or material alignment in processing applications.

VIBRATORY CONVEYORS

NOTE

Segmental conveyors are used for both bulk and unit materials. Although slow and not energy-efficient, they have durable carrying surfaces and can handle heavy loads and materials that are hot, abrasive, or fragile. They allow pre-

cise control and positioning of material and can be configured in complex and multiple curves. They are expensive and used for specialty applications.

NOTE

Screw conveyors are only used for bulk materials. They can convey hot, wet, or dusty materials but become plugged by sticky or stringy material; they are not suitable for fragile materials. They can have multiple inlets and discharges and are often used for mixing and flow control.

SCREW CONVEYORS

SEGMENTAL CONVEYORS

SKIRTBOARDS KEEP MATERIAL ON BELT, USUALLY METAL WITH RUBBER SEALING STRIPS SPACED 2/3 OF THE BELT WIDTH; CONTINUOUS ON FLAT BELTS, AT LOADING POINT ON TROUGHED BELTS

RETURN IDLER

SLOPED LOADING CHUTE

BELT WIDTH FOR BULK MATERIALS VARIES FROM 18" TO MORE THAN 6'-0"

2'-6" MIN.

TAIL PULLEY

PROVIDE SERVICE ACCESS AT TAIL PULLEY, DRIVE AREA, AND ALONG ONE SIDE

NOTE

Belt conveyors, used for both bulk and unit materials, are often chosen for superior speed, capacity, length, energy efficiency, and economy. They vary in width from one inch

to more than 8 feet and in length from less than a foot to more than a mile. At steeper angles, belts must have skirtboards to retain material and roughened surfaces or flights

to keep it from sliding. Belts typically are made of rubber-covered fabric; belt slippage and alignment can be a problem.

BELT CONVEYORS

Alpha Engineers, Inc.; Pocatello, Idaho

NOTE
Unit conveyors use rollers or wheels on stationary shafts to carry items that must have a flat bottom surface. Rollers may be gravity or power driven. Gravity units are economical and often portable. Items move independently on rollers, allowing materials to be paused or accumulated. Systems often use sensors and automated diverters to sort and direct items to different destinations.

UNIT CONVEYORS

CRESCENT BAGGAGE CONVEYOR

BAGGAGE CLAIM CONVEYOR

Alpha Engineers, Inc.; Pocatello, Idaho

GENERAL

Waste and linen chutes should extend full diameter through the roof and be capped with a metal safety vent or glass explosion cap. Sprinklers or flushing spray are recommended at alternate floors. Bottom-hinged hopper doors are commonly used for waste and loose linen. Square side-hinged doors are used for bagged linen. "B" label doors are recommended. To prevent clogging, door size is restricted in proportion to chute diameter. Type "H" hopper discharge doors are installed when discharge is built into wall and the receptacle is a cart or bin. Type "A" direct-open discharge doors (not shown) are commonly used when discharge is into a compactor.

AVERAGE WASTE PRODUCTION/DAY

BUILDING	AMOUNT
Apartment	5 lb/apartment + 1 lb/bedroom
Dormitory	3 lb/person
Hospital	8 lb/bed
Nursing home	6 lb/person
Hotel, motel	3 lb/room
School	10 lb/room + 1/4 lb/pupil

AVERAGE LINEN PRODUCTION/DAY

BUILDING	AMOUNT
Hospital	15 lb/bed
Hotel, motel	12 lb/bed

WASTE OR LINEN CHUTE

NOTES

1. Fire stops may be required at underside of every slab; check local codes.
2. Chute material: #18 - #16 U.S. gauge aluminized steel or stainless steel.

NOTES

1. Chutes should be used only for first class mail. The chute dimensions should be 2 x 8 in. and extend in a vertical line from beginning point to a receiving box or mailroom. A chute must be accessible its entire length. Chutes in pairs have a divider and dual receiving boxes.
2. Receiving boxes must be placed near the building's main entrance or near the loading area for U.S. Postal Service (USPS) mail collection. Using the shortest line, receiving boxes may not be placed more than 100 ft from the entrance used by the collection person. Locations require local postmaster approval. Receiving boxes must be placed on the same floor the collection person uses to enter the building. Doors must operate freely. Door openings must be at least 12 x 20 in. and not more than 18 x 30 in.
3. Auxiliary boxes should be located near receiving box if receiving box is too small to accommodate the volume of first class mail.
4. A bundle drop must accept a bundle at least 6 1/2 in. wide by 11 1/2 in. long and 4 in. high. To prevent removal of mail, the deposit opening must be fully protected by inside baffle plates. Inlet doors must be inscribed "Letters" and "Letter Mail Tied in Bundles." The bottom of the opening must be at least 61 in. above floor level.

MAIL CHUTE PLAN

MAIL CHUTE AND COLLECTION BOXES

NOTES

1. All installations must comply with USPS requirements and are subject to inspection.
2. Floor penetrations may need fire stopping methods.
3. USPS provides listing of approved manufacturers.

PLANS OF TYPICAL DUMBWAITER

ELEVATOR CAPACITY

CAR SIZE			CAPACITY (LB)
W	D	H	
18"	18"	24"	25-75
20"	20"	30"	100
28"	24"	36"	150-250
32"	30"	42"	300-350
36"	36"	48"	400-500

Capacity is determined by the maximum weight of the contents to be transported and the size of the dumbwaiter car. Maximum capacity is 500 lb. Normal speed is 50 ft per minute. The car platform may not exceed 9 sq ft. Car heights cannot exceed 4 ft. Machines may be located above, below, or adjacent to the hatchway. Drum type machines have a maximum rise of 35 to 40 ft; traction type machines have unlimited range of travel.

DUMBWAITERS

NOTE

Consult manufacturer's literature for specific dimensions and load capacity.

Plumbing 690

Special Systems 704

Heat Generation Equipment 705

Refrigeration and Heat Transfer 710

HVAC Systems 716

Air Distribution 726

GENERAL

The primary purpose of insulation is to retard the flow of heat and water vapor from pipes, ducts, and equipment. An insulation system consists of the insulation itself; a jacket to cover it; and, if needed, an additional jacket to provide specific characteristics such as weather protection or the ability to be repeatedly cleaned. Code limitations for flame spread and amount of smoke developed established for components in fireproof and noncombustible buildings apply to these insulation system elements.

COMMON INSULATION TYPES

The insulation materials described here are identified by generic names rather than manufacturers' trade names.

FIBERGLASS INSULATION (ASTM C 547) is fibrous glass made plain or with a heat-resistant binder to help the fiberglass hold its shape. Material with a density of 3 to 5 lb/cu ft typically has an R value of 3.8 to 4.5.

Felted glass fiber without any binder is available in rolls. With a thermosetting resin binder, it is available in varying degrees of stiffness. The form most commonly used for pipe is molded and shaped into semicircular sections. A cover is needed to protect this type of insulation from physical damage, permit it to be firmly attached to the pipe, and prevent penetration of water vapor. Fiberglass insulation, recommended for temperatures from 35° to 800°F, is available in thicknesses from 1/2 to 5 in. for 1/2-in. to 33-in. pipe.

CELLULAR GLASS INSULATION (ASTM C 552) is pure glass with closed-cell air spaces. It offers a flame spread of 5, smoke developed rate of 0, and 0 perm rating; typical R value is 2.6. Form-fitting covers are used for standard components. The type of jacket used for abrasion resistance depends on the severity of service. Recommended applications include temperatures ranging from -450° to +450°F (adhesive type varies with the temperature). Cellular glass insulation, impervious to common acids and corrosive environments and hard enough to cut with a saw, is used when an extremely strong, impermeable material is required.

METAL SHIELD SUPPORT

PIPE INSULATION WITH NONMETALLIC JACKET

ELASTOMERIC PLASTIC INSULATION (ASTM C 534) is an expanded foam, closed-cell material made from nitrile rubber and polyvinyl chloride resin. Typical R value is 3.6, and the perm rating is only 0.17. This material does not require a jacket except for appearance. The flame rating of 50 is valid for all thicknesses. For material 3/8 in. thick and less, a smoked-developed rating of 50 has been established; with 1-in. thickness, the rating is close to 150. Because of the high rating, building codes do not allow use of this type of insulation in all types of construction.

Commonly called "rubber," elastomeric plastic insulation is available in 1/2 and 3/4 in. thicknesses for pipe sizes up to 5 in. in diameter (iron pipe size). Recommended applications for pipe include temperatures from 35° to 220°F, except for sheets, which can be used only up to 180°F because of the adhesive used to apply them to a tank. This flexible insulation is used in pipe spaces and boiler and mechanical equipment rooms, where code requirements may be relaxed and the ease of application could make it the most cost-effective material.

FOAMED PLASTIC INSULATION is a continuously molded, closed-cell rigid product made from foaming plastic resin. Plastic materials typically used are polyurethane (C 591), polystyrene (C 578), and polyethylene. A factory-applied jacket is usually provided. Typical R value is 6.7. The fire rating varies by manufacturer because of the wide variety in composition of materials in this category of insulation. Although the materials are combustible, they can be made self-extinguishing. Foamed plastic is recommended for low temperatures, including cryogenic applications, and for moderate temperatures, generally up to 220°F.

CALCIUM SILICATE (ASTM C 533) insulation is a rigid material compounded from silica, asbestos-free reinforcing fibers, and lime. At 500°F, it has an R value of 2.0. A field-applied jacket is required.

MINERAL FIBER (ASTM C 553) insulation is a rigid material composed of rock and slag made into fibers and bound together with a heat-resistant inorganic binder; typical R value is 4.9. This material is good for high temperature work.

HARD MATERIAL SUPPORT

PIPE INSULATION WITH METALLIC JACKET

JACKETS

A jacket is any material (excluding cement and paint) that can be directly applied to insulation on a pipe, duct, or vessel in order to cover or protect the insulation. The type of jacket chosen depends on the application. Jackets come in various forms and types, which can be divided into three general categories: rigid (plastic, aluminum, or stainless steel), membrane (glass cloth, coated papers, treated papers, and foil- or cloth-laminated papers), and mastic. The most common jacket for fiberglass insulation is an all-service jacket or ASJ, which comprises laminated kraft paper, fiberglass cloth (skrim), and either aluminum foil or metalized film as a vapor barrier. This jacket type is sometimes called an FSK (foil, scrim, and kraft) jacket.

INSTALLATION

Proper installation of insulation on a pipe or duct is critical to the longevity of an insulation system. Typical installations of insulation on the outside of a duct, elastomeric insulation around a pipe, insulation with a nonmetallic jacket, and insulation with a metallic jacket are illustrated on this page.

American Society of Plumbing Engineers: Westlake, California
Michael Frankel, CIPE, Utility Systems Consultants; Somerset, New Jersey

GENERAL

A building service is that portion of the supply piping on private property that extends below frost depth from the public utility main into the building. It includes the connection to the main, valves, pressure-reducing devices, backflow prevention devices, meters, and other requirements specific to the individual utility company.

BUILDING WATER SUPPLY SERVICE

The water supply service for commercial buildings is often divided into two separate services at the public main—potable water and fire protection water—because of different requirements. However, a single, combined service is sometimes used.

BACKFLOW PREVENTION

It is extremely important for a utility company to protect the public water supply from contamination flowing from any building to which it is supplying water. The device used to accomplish this is the backflow preventer (BFP), which prevents contaminated water from flowing backward into the potable water supply.

There are four types of BFP, and the degree of hazard in a particular situation determines which type is selected and installed:

AIR GAP: This BFP provides a physical separation between the supply of potable water and the storage tank or piping distribution network. This is a passive method and is considered the only absolutely safe concept.

REDUCED PRESSURE ZONE: This type of BFP is a mechanical device used when a high hazard is present. Liquids attempting to flow in reverse discharge out of the BFP instead. When installed in a building water supply, the RPZ backflow preventer should be located as close to the public water main as is practical.

DOUBLE CHECK VALVE: This is a mechanical device often used on fire protection water supplies and for smaller size piping that supplies equipment that has a back pressure and is not considered a high hazard.

VACUUM BREAKER: This mechanical device is used when there is no back pressure, such as for a submerged water supply to a water closet. It uses a flexible diaphragm that allows water to flow through in only one direction; it closes on itself, stopping flow in the reverse direction.

NONRESIDENTIAL POTABLE WATER SERVICE

After connecting a plumbing system to the public water main, it is necessary to provide a method of shutting off the water supply to the building without entering it. A curb valve installed close to the property line is used to serve this function. A second shutoff valve is provided inside the building at the service entrance.

For facilities labeled high hazard, a reduced pressure zone BFP should be installed as close to the public main as is reasonable to protect the public water supply from contamination. Because of the potentially large discharge of water, an aboveground, heated enclosure is recommended. For less hazardous locations, a double check valve assembly may be permitted. No water is discharged from a double check valve.

Water meters are necessary to measure the amount of water used in a facility. The arrangement of the water meter assembly is specific to each utility. The meter could be located in an outside pit or exposed inside the building. The meter used should be selected for accuracy. A compound meter, consisting of separate sections for low and high flows, is often used for applications such as multiple dwellings and dormitories.

A strainer may be required before the meter if solids are present in the water supply. A second backflow preventer may be required on individual water branches supplying specific equipment inside a building.

WALL HYDRANT

A wall hydrant is a water supply fixture on the exterior of a building used to attach hoses that maintenance personnel use for cleaning purposes, such as washing walkways. If freezing conditions are even a remote possibility, a non-freeze type hydrant should be installed. To prevent backflow, wall hydrants should be provided with an integral vacuum breaker.

CONCEALED TYPE

Michael Frankel, CIPE; Utility Systems Consultants; Somerset, New Jersey

FIRE PROTECTION WATER SUPPLY

The purpose of the fire protection water supply is to provide a reliable source of water with the lowest reasonable pressure loss at the maximum flow rate for the most demanding fire-fighting requirements. The system is supplied with water from the site, either from an underground public water main or an elevated or on-grade storage tank of adequate size. The system design and components should strictly conform to various code requirements, including those written by insurance carriers that insure the building.

For larger sites, it is common practice to have a dedicated fire protection water main that can be divided into sections. This division is accomplished with valves that are placed to allow water to reach various portions of the site from two directions. Fire hydrants placed about 250 feet apart in easily accessible places allow fire department pumps to connect directly to a site main. When possible, the hydrants should be located adjacent to significant hazards and a minimum of 50 feet from building walls.

It is good engineering practice to have two separate building water services. However, if only one public main is available, the domestic water and fire protection water services should be divided outside the building so they enter it separately.

Each connection to the public or site water main should have a means of shutting off the water supply to the building that does not require entry. This can be accomplished by installing a valve on the building service branch. A second shutoff valve must be provided inside the building at the service entrance for the use of building occupants.

The fire department must be able to determine quickly whether the valves that control mains and building water supplies on a site are open or closed. A valve mounted on a post extending above grade (a post indicator valve or PIV) is used for this purpose.

TYPICAL ELEVATED WATER TANK

To protect the public potable water main against contamination, a double check valve assembly is commonly provided on the building fire protection service. A reduced pressure zone (RPZ) backflow preventer may be required if there is a source of contaminated water, such as a lake or stream, that a fire department could use as a supply of water in emergency conditions.

Because the water in a fire protection system remains stagnant for long periods, freezing is a major concern. The underground building service water supply line must be buried below the frost line. The depth of frost penetration varies with the climate at the project site; this dimension can be obtained from the National Fire Protection Association. Observation of the minimum depth of bury is important, even in areas not normally subject to frost but where freezing temperatures are occasionally experienced.

GAS SERVICE

Fuel gas building service connects to a public main installed by a franchised public utility obligated to provide gas to every customer requesting it. As part of this service, the utility company usually supplies and installs the service line from the utility main to the property free of charge, in addition to providing a regulator/meter assembly in or adjacent to the building.

TYPICAL FIRE HYDRANT

NOTE
For additional meters, the minimum center-to-center dimension is 1 ft 6 in.

TYPICAL RESIDENTIAL BUILDING GAS SERVICE

It is important to advise the utility company in writing of the proposal to use gas at a site. This letter should list all the equipment to be connected, the gas requirements of that equipment, and the gas pressure required. Include the location or address of the project and the proposed start date of construction.

The meter assembly usually consists of a main pressure reducer (regulator) to reduce the higher pressure in the utility company mains to the lower pressure used by equipment in the building. The meter is selected by the utility company; exact dimensions are provided upon receipt of the gas letter. The meter assembly for private residences and apartments in multiple dwellings is relatively small. A main meter could be located either indoors or outdoors, although outdoors is preferred to avoid problems from gas accumulation caused by leakage. Individual gas meters, such as those used for private residences and multiple dwellings, are almost always located indoors.

If different gas pressures are required in a single facility, it is more cost-efficient to provide the higher pressure needed for the largest equipment and then to install a pressure regulator at the equipment that requires a lower pressure.

TYPICAL POST INDICATOR VALVE

Michael Frankel, CIPE; Utility Systems Consultants; Somerset, New Jersey

CAST-IRON PIPE

Cast-iron (CI) pipe and fittings are manufactured in two weight classes: standard and extra heavy. Each class is available either with hub and spigot ends (ASTM A-74) or hubless (CISPI 301 pipe and CISPI 310 fittings).

High-silicon (acid-resistant ASTM A-861) hub-and-spigot cast-iron pipe and fittings are manufactured for laboratory drainage service. Hub-and-spigot pipes are joined with caulked or compression gasket joints and hubless pipe with compression couplings.

Cast-iron pipe is used for nonpressure, sanitary and storm water gravity drainage service above and below grade. The most commonly used pipe above grade is hubless, service-weight cast-iron; below grade it is service-weight, hub-and-spigot pipe with compression gaskets. High-silicon pipe uses caulked joints aboveground and sealing sleeves below grade. Some codes require extra heavy class pipe below grade.

STEEL PIPE

Carbon steel (CS) pipe is available in a variety of alloys, the most common being ASTM A-53 for general service and ASTM A-106 for high pressure, high temperature service. Stainless steel (SS) pipe encompasses a variety of alloys and is widely used in the chemical, pharmaceutical, and food processing industries; the most commonly used materials are type 304 and 316.

Steel pipe is manufactured either seamless (extruded) or welded. Wall thickness, known as "schedule," ranges from schedule 5 (thinnest) to schedule 160 (thickest). Steel pipe can be joined by welding or with flanges or threaded joints.

COPPER TUBE

Available as either hard (annealed) or drawn (soft) temper, seamless copper (CU) tube can be joined by soldering, brazing, flared joints, and flanges. It is manufactured for specific applications in the following types:

ASTM B-88. Types K, L, and M (thickest to thinnest wall) are used primarily for potable water service and noncritical laboratory gases. Type L hard temper is often used above-ground and type K soft temper underground.

ASTM B-819. Similar to B-88, this tubing is cleaned for laboratory and health care facilities and available only in types K and L hard temper. It is joined mostly by brazing.

ASTM B-75. Termed capillary tubing, this is available only in small diameters and soft temper and is generally used to

connect instruments in laboratory service. It is joined with flare joints and by soldering.

ASTM B-280. Type ACR is available only in small diameters and soft temper and is generally used for air conditioning and refrigeration service. It can be joined with flared fittings or by soldering.

ASTM B-306. Known as DWV for drainage, waste, and vent, this tubing is used for drainage service and is joined by soldering. It has the thinnest wall of any copper product.

ASTM B-837. Type G is primarily used for fuel gas service. It is joined by using soldering and flare fittings.

BRASS PIPE

Brass pipes (BR) are made of an alloy of copper and zinc that conforms to ASTM B-43. The proportion of copper varies from 85% (in red brass) to 67% (in yellow brass). Brass pipe is joined by threading, soldering, brazing, or using flanged fittings.

Larger brass pipes are used for potable water and sometimes for branch drainage lines. Fittings and castings made from an alloy different than the pipe may not be suitable for potable water service.

GLASS PIPE

Glass pipe (GL) is made from a low expansion borosilicate glass with a low alkali content. It is used for laboratory gravity waste service and is available in sizes up to 6 inches in diameter. Glass pipe must conform to ASTM C-599.

PLASTIC PIPE

Plastic (PL) has become the material of choice for piping systems used to convey a variety of liquids, including chemical drainage, pharmaceuticals, sewage, water, liquid fuel, and fuel gases. To convey potable water, plastic pipe must be listed by NSF International.

Plastic materials used for pipe are either thermoplastic or thermosetting. Thermoplastics, the most commonly used pipe materials, soften when heat is applied and rearden when cool so the pipe can be extruded or molded into shapes. Thermosetting plastics must be cured by heating or with a curing chemical to achieve permanent shapes; once shaped, they cannot be reformed.

Subclassifications of plastic pipe are based on the pipe material; the two most common are polyolefins and fluoroplastics.

Following is an explanation of the terms used in various consensus standards for plastic pipe:

1. SDR means standard dimensional ratio. The SDR is found by dividing the average outside diameter of a pipe by the wall thickness. This designation has yielded a series of preferred industry standard numbers that are constant for all sizes of pipe.
2. DR means dimensional ratio and is often incorrectly used interchangeably with SDR. The DR is found in the same way as the SDR and means the same thing but is used when a product does not have the preferred SDR number established by prevailing standards.
3. OD Controlled is the designation used when the outside diameter of a pipe is the controlling factor in its selection.
4. ID Controlled is the designation used when the inside diameter of a pipe is the controlling factor in its selection.
5. PR is a designation used when the pressure rating is the controlling factor in the selection of a pipe.
6. Schedule is a designation used to match the standard dimensions for metallic pipe sizes. The pressure rating of the pipe varies with pipe size. Some standards use iron pipe size (IPS) in lieu of schedule to keep a wall thickness consistent with iron pipe.
7. Plastic pipe can be joined with heat fusion (either butt or socket fusion), flanged joints, solvent cement, or threaded pipe of schedule 80 wall thickness or greater. Consult manufacturers for specific recommendations.

PIPE FITTINGS

Fittings are used to connect pipes to one another, to change the direction of flow of fluids within a pipe, and to change the size of a pipe run. Often one fitting is used to provide all these features. An alternative to changing direction with fittings is to bend the pipe itself, but this method is rarely used except for soft temper copper tubing.

Drainage pipe requires special long radius Y-type fittings to achieve the best flow characteristics. These fittings are called sanitary or drainage-type fittings. In addition to the common fittings illustrated, manufacturers make many specialty combination drainage fittings, primarily for multiple-dwelling construction.

In general, fittings are made of the same material as the pipe to which they are attached, with the following exceptions: Fittings for copper tubing are either of a cast copper alloy that conforms to ANSI B16.18 or wrought copper that conforms to ANSI 16.22.4. Threaded fittings for steel pipe are generally cast-iron pressure fittings that conform to ANSI B-16.4 or malleable iron-banded fittings that conform to ANSI B-16.3.

FIXTURES AND TRAPS

Plumbing codes establish a minimum acceptable standard for the design, materials, and installation of plumbing systems. Some aspects of these systems may be subject to other regulations as well. For example, health department requirements and utility company rules regulate the public supply of water and gas and the disposal of storm water and sanitary drainage effluent. The information that appears here is general and not meant for design purposes.

A PLUMBING FIXTURE is any approved receptacle specifically designed and manufactured to receive human (sanitary) or other waterborne effluent (waste) that discharges directly into the sanitary drainage system.

A FIXTURE UNIT is a dimensionless, arbitrary, and comparative value assigned to a plumbing fixture to represent the probable flow of water into the fixture or the effluent it discharges into the drainage system as compared to the function of other fixtures. The effluent discharged is different from the water input so they are separated into drainage fixture units (DFU) and water fixture units (WFU).

A FIXTURE TRAP is a U-shaped section of pipe deep enough to prevent the passage of sewer gas into a fixture. Traps must be self-cleaning, provide a liquid seal of at least 2 in. (larger when required), conform to local code requirements regarding minimum size, have an accessible cleanout, and be able to drain a fixture rapidly. All traps must be vented, unless waived by local codes. All fixtures directly connected to the sanitary drainage system must be trapped and vented.

GENERAL

A joint is required to connect pipe to itself, a fitting, or a piece of equipment. The joint type selected for a particular application depends on the pipe material and wall thickness, pipe contents, system pressure, system temperature, disassembly requirements, and the applicable plumbing code.

NOTE
Caulked joints are only used to connect metal hub-and-spigot end pipes. Suitable for above- or belowground installation, this labor-intensive, rigid, nonpressure joint has largely been replaced with no-hub compression couplings aboveground and compression gaskets belowground.

CAULKED JOINT

NOTE
Compression gasket joints, used only with hub-and-plain end pipes, are flexible pressure joints suitable for gravity drainage and pressurized liquid systems compatible with the pipe and gasket.

COMPRESSION GASKET JOINT

NOTE
Compression coupling joints are rigid nonpressure joints used to join plain end drainage pipes. They are suitable for gravity drainage systems.

COMPRESSION COUPLING

NOTE
Threaded joints can be used for any pipe with walls thick enough to have threads cut. This rigid pressure joint is generally limited to 4-in. pipe as it is difficult to turn larger pipe. Threaded ends come tapered (for plumbing and utility pipe per ANSI B-2.1) and standard (for process pipe systems).

THREADED JOINT

NOTE
Solvent cement joints are rigid pressure joints used only with plastic pipe. Each plastic requires a specific solvent/cement combination recommended by the manufacturer. A joint created with solvent cement looks like a soldered joint, but the cement is used to soften and dissolve the plastic, after which it hardens into a homogeneous joint.

SOLVENT CEMENT JOINT

NOTE
Soldered and brazed joints, used to join copper and copper alloy pipe and fittings, are rigid pressure-type joints. The distinction between soldering and brazing is the temperature required to melt the filler metal that enters the joint by capillary action. Solder requires a temperature of 950°F or less, while brazing uses a higher temperature.

Flux is required for solder and some types of brazing filler metal but is prohibited for use with gases installed in health care facilities. Filler metal for soldering consists of 50% tin and 50% lead. No lead is permitted for potable water systems, where an alloy of 95% tin and 5% antimony or a proprietary solder is used.

Soldered joints are used for relatively low pressure applications. Brazing filler metal is of two types: those containing 30-60% silver constitute the BAG class, while those with copper and phosphorus are known as BCuP type. Brazing produces joints stronger than the pipe itself. When used in health care facilities, no flux is permitted.

SOLDERED AND BRAZED JOINT

NOTE
Flared joints are rigid pressure joints used for relatively low pressure applications on small diameter pipes made of soft copper or other metals. They are commonly used with capillary piping in laboratories and small diameter underground water piping. Proprietary types of flared fittings are available for high-pressure applications.

FLARED JOINT

NOTE
Welded joints are rigid pressure joints formed as butt-fused joints or socket welds. Butt-fused joints are created by melting prepared end metal pipes or square end plastic pipes then butting them together and fusing them, which forms a homogeneous joint upon hardening. Metal pipe ends are externally heated and melted with an electric arc or flame and filler metal added to form the joint. For plastic pipe, the ends are melted separately and brought together to form the joint with the use of a special machine. For a socket weld, a plain pipe end is placed inside a socket and the end of the socket fitting is welded to the exterior of the pipe to form a rigid joint.

WELDED JOINTS

NOTE
Flanged joints are rigid pressure-type joints that use bolts to connect the mating pipe ends, with or without an additional gasket between the ends. Flanges can be installed on the pipe end by welding, threading, or brazing.

FLANGED JOINT

NOTE
Heat-fused joints, used only for thermoplastic pipe, are rigid pressure joints. A special socket fitting has resistance heating wire embedded near the outer edge facing the pipe to be joined, complete with pigtailed extended outside the fitting. An external electrical power source is connected to the wire pigtailed to generate the heat to melt both the inside of the socket and the outside of the pipe in the area where the wire is embedded. When the material is cool, a rigid joint has been formed and the pigtailed are cut off.

HEAT-FUSED JOINTS

NOTE
Split coupling (grooved) joints require two types of pipe end preparation, roll grooving (shoulder) and cut grooving. The latter method is stronger, but roll grooves must be used when the pipe is too thin for a groove. Couplings must conform to AWWA C606. These rigid pressure-type joints are well-suited for both pressure and nonpressure lines.

SPLIT COUPLING JOINT

ROOF AND FLOOR DRAINS

A floor drain removes liquids from interior, normally occupied areas of a building and discharges them into either the sanitary or an industrial waste drainage system. A commonly cited standard for floor drains is ANSI A-112.21.

A roof drain removes rainwater from roofs and other areas exposed to the weather (such as balconies or canopies) and discharges the effluent into the storm water drainage system. Specialized drain types are available for installation in specific exposed or interior locations; consult drain manufacturers for details.

Major components of drains are outlined below:

The **GRATE** or **DOME** is the component that allows liquid into a drain body while excluding larger solids. Grates are available in a wide variety of shapes, slot configurations, materials, and load-bearing capability from light to extra heavy. The high dome on the roof drain allows storm water to enter the drain if some debris accumulates at the bottom. A generally accepted practice has the open area of a grate twice that of the discharge pipe. Generally, an adjustable grate allows the grate top to be adjusted to the finished floor level.

A **SEDIMENT TRAP** or **BUCKET** is installed inside a floor drain to trap solids not eliminated by the grate. When space is not available for a sediment bucket, another method is to install a secondary grate.

A **FLANGE** is the part of the drain body that anchors the drain into a slab.

A **FLASHING RING** is provided to secure any flashing directly to the drain body to prevent leakage around the drain. Often, roof drains are provided with an integral gravel stop to keep gravel from built-up roofing from entering the drain.

An **UNDER-DECK CLAMP** is used to secure the drain body to a slab through an opening prior to the installation of any roof, slab finish, or piping.

ROOF DRAIN

INTERIOR STORM WATER DRAINAGE PIPE SIZING

The size of storm water lines is based on the area (in sq ft) of the roof to be drained, the pitch of the pipe, and the rate of rainfall in inches per hour (obtained from the authority having jurisdiction).

To design a drainage system for a project, begin by locating the roof drains and designing the piping network. Next, establish the rainfall rate, and calculate the area contributing rain to each roof drain, including the side wall area (half of the area, in sq ft, of any two adjacent vertical walls).

At each design point add all of the area (in sq ft) for all drains together. In the table sizing horizontal drains, look under the pitch established for the piping in a project and find the figure that equals or exceeds the drainage area calculated. Find the applicable pipe size in the column labeled "diameter of drain."

For vertical drain lines, use the table for sizing vertical lines. Use the table for gutters and leaders to find the pipe size for gutters and leaders draining small areas of roof.

15	59,500	2,473	84,000	3,491	119,000	4,946

*The figures in this chart are based on a maximum rate of rainfall of 4 in./hr. Where maximum rates are more or less than 4 in./hr, adjust the figures for drainage by multiplying by 4 and dividing by the local rate in inches per hour.

DRAINAGE AND WASTE PIPE SIZING

The sizing of drainage and waste lines from fixtures is based on total DFUs, the pitch of the drainage pipe, and the classification of the line as a branch, stack, or building drain.

The fixture schedule shows the minimum size line permitted from a fixture. At each design point, add all DFUs together. Enter the chart based on line classification and the pitch of the pipe, and find a figure equal to or greater than the DFUs calculated. Read horizontally to find the pipe size.

The minimum pitch for branches 3 in. and smaller is 1/4 in./ft. For lines 4 in. and larger, it is 1/8 in./ft. A branch interval is the rough equivalent of one floor level. The minimum pitch for building drains (main lines inside the building) and building sewers (main lines outside the building that connect with the public sewer) is 1/16 in./ft.

BUILDING DRAINS AND SEWERS¹

MAXIMUM NUMBER OF FIXTURE UNITS THAT MAY BE CONNECTED TO ANY PORTION OF BUILDING DRAIN OR BUILDING SEWER²

DIAMETER OF PIPE (IN.)	SLOPE PER FOOT			
	1/16 IN.	1/8 IN.	1/4 IN.	1/2 IN.

12	2900	4600	5600	6700
15	7000	8300	10000	12000

¹ On-site sewers that serve more than one building may be sized according to current standards and specifications of the administrative authority for public sewers.

² Consult local building codes for exact requirements.

³ No more than 2 water closets or 2 bathroom groups (except in single-family dwellings, no more than 3 water closets or 3 bathroom groups) may be installed.

EJECTOR PUMP FOR SUBMERSIBLE PUMP SYSTEM

PUMP SYSTEMS

Ejector pumps are intended to transport sanitary waste with large suspended solids. Sump pumps transport turbid, non-sanitary effluent with small suspended solids. They use different impellers. Minimum recommended pump running time is one minute for optimum reliability.

To find the basin depth, use the following approximate dimensions as a guide, assuming duplex pumps and starting from the invert of the inlet pipe.

1. From the invert of the inlet pipe, allow 6 in. to the high water alarm.
2. From the high water alarm, allow 6 in. to pump 2 start in a duplex installation.

American Society of Plumbing Engineers; Westlake, California
Michael Frankel, CIPE, Utility Systems Consultants; Somerset, New Jersey

DRAINAGE BRANCHES AND STACKS

MAXIMUM NUMBER OF FIXTURE UNITS THAT MAY BE CONNECTED TO VARIOUS BRANCHES¹

DIAMETER OF PIPE (IN.)	ANY HORIZONTAL FIXTURE BRANCH ² (DFU)	ONE STACK OF THREE OR FEWER BRANCH INTERVALS (DFU)	STACKS WITH MORE THAN THREE BRANCH INTERVALS	
			TOTAL FOR STACK ³ (DFU)	TOTAL AT ONE BRANCH INTERVAL (DFU)
1 1/2	3	4	8	2
2	6	10	24	6
2 1/2	12	20	42	9
3	20 ⁴	48 ⁴	72 ⁴	20 ⁴
4	160	240	500	90
5	360	540	1100	200
6	620	960	1900	350
8	1400	2200	3600	600
10	2500	3800	5600	1000
12	3900	6000	8400	1500
15	7000			

¹ Consult local building codes for exact requirements.

² Does not include branches of the building drain.

³ Size stacks according to the total accumulated connected load at each story or branch interval. Stacks may be

reduced in size as this load decreases, to a minimum diameter of half the largest size required.

⁴ No more than 2 water closets or bathroom groups within each branch interval and no more than 6 water closets or bathroom groups on the stack.

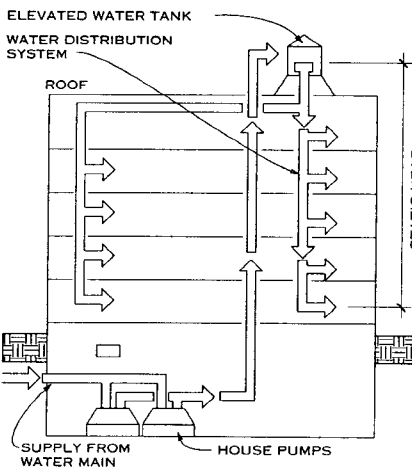

SUMP OR EJECTOR FOR VERTICAL LIFT SUBMERGED PUMP SYSTEM

CAPACITY OF SUMP AND EJECTOR BASINS (GAL/FT DEPTH)

DIAMETER (FT)	CIRCULAR		SQUARE	
	GALLONS	SIDE (FT)	GALLONS	
2.0	23.50	2.0	30.00	
2.5	36.72	2.5	45.00	
3.0	52.88	3.0	67.50	
3.5	71.91	3.5	90.00	
4.0	94.00	4.0	120.00	
4.5	110.32	4.5	149.60	
5.0	146.89	5.0	187.00	
6.0	158.64	6.0	270.00	
7.0	170.00	7.0	365.50	
8.0	181.00			
9.0	193.00			
10.0	204.00			

3. From pump 2 start, allow 6 in. to pump 1 start.
4. Below pump 1 start, the dimension of the liquid capacity depends on a 1- to 5-min. operating period of the selected pump. The lower level of the storage portion is pump(s) stop. The table on capacity of sump and ejector basins gives the storage capacity of different size basins.
5. Allow 6 in. from pump stop to the inlet of the pump.
6. Allow 1 ft to the basin bottom from the inlet of the pump. This dimension varies according to manufacturer.

DOWNFEED WATER SUPPLY SYSTEM

UPFEED WATER SUPPLY SYSTEM

7. Sewage and waste effluents have the same hydraulic characteristics as water. Ejector discharge lines should be a minimum of 3 in. and sump discharge lines should be a minimum of 2 in. to prevent stoppages. The pump head is found by adding the distance from the bottom of the basin to one foot higher than the point of discharge and the friction loss of water through the discharge pipe.
8. Duplex pumps generally require a minimum diameter of 4 ft.

SIZING POTABLE WATER LINES

Water lines are sized according to flow rate in gallons per minute (GPM), the allowable pressure loss of water flowing through the pipe, and the velocity of the flowing water that has been calculated for each specific project. The GPM is found using "Hunters Curve," which converts water fixture units (WFUs) into GPM. This information is available in the ASPE (American Society of Plumbing Engineers) Data Book. A simplified general procedure for sizing potable water lines is outlined here.

Obtain the elevation and location of the water main and the lowest residual water pressure from the utility company. Also determine the requirements regarding the need for and location of the water meter, backflow preventer (BFP), and shutoff valves. Run the piping from the source into the building on the plans.

When the water source is a well, design the service using good engineering practice. Choose the well location in conjunction with the authority having jurisdiction.

Calculate the available water pressure to a point just inside the building. First, add together all the service losses, such as that caused by the difference in elevation between the main and the point of entry, the water meter, the backflow preventer (if any), valves, and the friction loss of water in the building service. Subtract that figure from the residual pressure in the main.

Calculate the required water pressure for the building by determining the operating pressure for the most remote fixture (ask the manufacturer), the height from the point of entry to the highest fixture, and an estimated friction loss through the water distribution system. If the figure determined is equal to or less than the available pressure, no booster pressure system will be required. If the pressure required is greater than that available, a booster pressure system must be provided.

The friction loss of water flowing through pipes can be obtained from the ASPE Data Book or Cameron's Hydraulic Data (Ingersol Rand). The decision to use an upfeed or downfeed distribution system and the choice of method used to boost the water pressure are based on cost, available space conditions, and aesthetic considerations.

Generally available methods for boosting water pressure include an elevated tank, constant running of booster pumps, and a hydropneumatic system similar to those used for well pump systems. A generally accepted maximum water pressure is 80 psig. Pressures above that require a pressure regulating valve (PRV).

FUEL GAS LINE SIZING

Fuel gases are natural gas (mostly methane) and liquefied petroleum gas (LPG), mostly propane. Natural gas has a heating value of about 1,000 British thermal units per cubic foot, although this value varies in different parts of the country.

LPG has a heating value of about 2,500 Btu/cu ft. Most installations require a meter and a regulator to reduce the pressure to about 7 to 10 in. water column pressure at the building, referred to as low pressure. Higher pressures are common, particularly to supply boilers. All pressure requirements are obtained from the utility company. The applicable code is NFPA-54 (the sizing table is used with permission from the National Fire Protection Association, Quincy, Mass.).

Gas lines are sized according to the cubic feet per hour (cfh) flow, allowable friction loss for the piping distribution network, and a diversity factor if applicable. A conservative method of sizing is described here:

1. First, establish the location of equipment using gas, then ask the manufacturer for the cfh flow for each piece of equipment. With the piping network drawn on plans, measure the total horizontal and vertical run, in feet, from the meter to the most remote device. (Vertical runs are ignored for natural gas only.) Next, establish a friction loss for the system. It is common practice to use a loss of 0.3 in. of water column in low pressure systems.
 2. At each design point add the cfh flows for all the equipment. Be sure to apply any applicable diversity factors to allow for the possibility that not all devices will be used at once.
 3. To determine what size gas line is needed, look in the table called "Low-Pressure Gas Pipe Sizing Schedule." First, find the column showing the length of the total pipe run for the application (this is the only distance used). Find the required pipe size in the column on the left at the intersection of the distance column that equals or exceeds the measured distance of the pipe in the project and the row showing the cfh value that meets or exceeds the cfh value calculated for that project.
- The table has been prepared for use with natural gas at a specific gravity of 0.60. To use it for LPG at a specific gravity of 1.50, multiply the cfh figure by 0.63.

VENT PIPE SIZING

The purpose of a vent system is to limit the pneumatic pressure in a drainage system to plus or minus one inch of water column. Vent systems terminate in the outside air and connect directly to every fixture trap.

Vent lines are sized using three factors: drainage fixture units (DFUs), the size of the drainage line (or stack) to which the fixtures are connected, and the length of the vent line from the fixture to the vent stack.

The drainage and vent system is assumed to be drawn on the plans and the drainage system sized. At each design point, enter the chart horizontally with the size of the drainage line and the total DFUs. Using the measured length of the vent from the fixture to the vent stack, select a figure equal to or greater than that length. Read vertically up to find the vent line size. The minimum size vent for fixtures is found in the fixture schedule.

GENERAL

Valves are used to turn on or off, control the flow of, prevent the reverse flow of, and adjust the pressure of fluids in a piping system. Operation can be linear (straight up and down) or rotary (multiturn or quarter turn). Valves are classified by the shape of their closure member. Plastic valves are suitable for use in most utility services and are rapidly replacing metallic valves due to their increased corrosion resistance and lower cost. Valves are selected according to resistance to flow; throttling ability; system working pressure; intended service, such as WOG (water, oil, gas), WWP (water working pressure), or WSP (working steam pressure); and jointing method.

NOTE
Gate valves have a wedge-shaped closure member seated into a metal recess. Used for on-and-off control, generally for liquids, they are available in a wide variety of sizes, body shapes, stem configurations, body and internal materials, and pressure ranges. They are not recommended for throttling service, and they have low resistance to flow.

GATE VALVE

TYPICAL GATE VALVE DIMENSIONS (IN.)

NOMINAL SIZE	A	B	C	D	E
2	7	6	11 3/4	14 3/8	6
2 1/2	7 1/2	7	12 3/4	16 1/16	6
3	8	7 1/2	14 1/16	18 1/8	8
3 1/2	8 1/2	8 1/2	15 1/4	19 7/8	8
4	9	9	16 7/8	21 3/4	10
5	10	10	20 3/4	26 7/8	12
6	10 1/2	11	23 1/2	30 9/16	12
8	11 1/2	13 1/2	29 3/4	39	14
10	13	16	35 3/4	46 7/8	16
12	14	19	41 1/4	55	18

NOTE
Ball valves are named for the round closure member that consists of a round port drilled through the valve and sealed tightly on a resilient seat when turned. Classified as a quarter turn valve, the body is available in one-, two-, or three-

BALL VALVE

American Society of Plumbing Engineers; Westlake, California
Michael Frankel, CIPE, Utility Systems Consultants; Somerset, New Jersey

NOTE
Globe valves, named for the round shape of the body, have a closure member that is generally a disc sealed on a resilient seat. Body types include straight through and angle configurations. Used primarily for throttling service, they have a high resistance to flow because of the diverted passage of fluid around the seat.

GLOBE VALVE

NOTE
Plug valves are named for the tapered, cylindrical closure member, which has a port through it that seals tightly on a resilient seat when turned. Classified as a quarter turn valve, they are available either lubricated (larger sizes) or nonlubricated. They are used primarily for fuel gas service but also for both throttling and shutoff service. They have low resistance to flow and are well-suited for power actuation.

PLUG VALVE

piece construction. Used for throttling and shutoff service, ball valves are suitable for liquids and gases. They are well-suited for power actuation and have low resistance to flow. They are often used for medical gas service when specifically cleaned and packaged for health care facilities.

BALL CHECK

LIFT CHECK

SWING CHECK

NOTE
Check valves prevent the reverse flow of fluids. The most commonly used valves are lift and swing types, although ball closures are also available. When used for sanitary drainage service, check valves are referred to as backwater valves.

CHECK VALVES

NOTE
Butterfly valves use a thin, rotating disk in the flow path as the closure member, seating on a resilient seal at the perimeter of the valve body. Classified as a quarter turn valve, they are used for both throttling and shutoff service. When no leakage is desired, a "bubble tight" seat is used. Butterfly valves have low resistance to flow and are well-suited for power actuation.

BUTTERFLY VALVE

NOTE
This pipe sleeve is for an exterior wall above or below grade. For gas service, extend the sleeve 1 in. beyond the inside face of the wall and 4 in. beyond the outside face of the wall.

PIPE SLEEVE IN EXTERIOR WALL

NOTE
Pipe sleeve is typically two pipe sizes larger than the outside diameter of the pipe or insulation.

ADJUSTING WATER PRESSURE

If the pressure from a water source is sufficient to supply the most hydraulically remote fixture in a building, a street pressure system is the most economical to use. However, when the pressure is not adequate, it must be increased. When it is excessive, it must be reduced.

For high-rise buildings, several height zones are required to keep available pressure within reasonable limits.

EXCESSIVE WATER PRESSURE

There is no precise water pressure value below which the pressure will never damage a water distribution system and above which it will always damage the system. Water pressure in a water distribution system is considered excessive if it will damage, or create conditions that will damage, components of the water distribution system or create a nuisance such as water splashing out of a fixture during use or excessive noise in the distribution piping.

A widely accepted maximum water pressure value is 70 psi. Often, the maximum permissible water pressure is stipulated by code.

PRESSURE-REDUCING METHODS

Excessive pressure is reduced to an acceptable level by means of a pressure-regulating valve (PRV). This valve lowers and automatically maintains water pressure within predetermined design parameters for both dynamic flow and static conditions. It is a closure device that opens and closes an orifice in response to fluctuations in outlet (regulated) pressure. The degree to which the valve closes depends on the ability of a sensing mechanism to detect changes in water pressure at the outlet side of the valve.

Pressure-regulating valves fall into two general categories: direct-operated and pilot-operated. Very often, a single PRV is not capable of reducing low and high flow rates. When this situation occurs, two PRVs are used in parallel.

PRESSURE-BOOSTING SYSTEMS

Water pressure in a building may be increased by means of these pressure-boosting systems: elevated water tanks, booster pumps, and hydropneumatic tanks. A combination of two such systems, called a hybrid system, may be used when a single type is impractical or uneconomical.

PUMPS USED FOR WATER SYSTEMS

The pump most often used for water service is the baseplate-mounted centrifugal pump. This type of pump should be directly installed on a housekeeping pad with proper grouting or with vibration isolation devices separating the pump base and the building structure. This arrangement helps prevent noise caused by the transfer of vibration from the pump to the building structure. Vibration isolation devices installed between the pump suction and discharge connections and the distribution piping will prevent transfer of vibration to the connected piping.

ELEVATED WATER TANK

In an elevated water tank system, water is pumped from the level where the building water service enters the building up to an elevated water storage tank, commonly called a gravity tank or a house tank. The pump most often used is the centrifugal pump, and it is commonly called a house pump when used for this service.

The house tank is located above the highest and most hydraulically remote point in a building water supply system. The height of the tank provides additional static head, increasing the pressure in the water distribution system.

Advantages of the elevated water tank system are these:

1. It is less complex than either of the other two systems.
2. The least number of components are required to control and operate the system.
3. The system is more efficient and costs less to operate than the other systems.
4. A smaller pump capacity is required than for either of the other two systems.
5. Pressure fluctuations in the system are small.
6. Maintenance requirements are minimized.

Disadvantages of the elevated water tank system in comparison to the other two systems are these:

1. An exposed tank (or the enclosure around it) may be considered unsightly.
2. The building structure may require reinforcement to support the additional weight of the tank and water.

3. The water in the tank and the supply pipes from the tank are subject to freezing if the tank is exposed.
 4. Water pressure on the highest floors may be inadequate for some fixtures.
 5. A catastrophic tank failure could flood the roof.
- The capacity of the house tank depends on the type of facility it will serve. Refer to recommended minimum domestic storage volume for a multiple dwelling gravity tank.

To use the figure, first determine the number of people the system will serve. If this figure is not available, estimate by counting two people per bedroom or four people per apartment, whichever is larger. Multiply the number of people by the gallons (liters) required per person to find the total domestic storage capacity. Add to this figure constant uses of water, such as HVAC makeup and fire protection water storage, if any. Finally, select a standard storage tank size equal to or larger than the required amount of stored water.

The capacity of the house pump(s) is determined by the quantity of water stored for domestic use. In general, a house pump should be capable of replacing the domestic reserve in about 1/2 to 2 hours; 1 hour is a generally accepted value. A duplex pump arrangement (two pumps in parallel), with each pump full size, should be provided so the system is not impaired if one pump is out of service.

A common problem with the gravity tank system is the lack of adequate water pressure on the upper floors of a building unless the tank is elevated to an impractical height. Under these conditions, a hybrid system comprised of an elevated tank plus a small booster pump or small hydropneumatic system used only for the top several floors is suitable.

BOOSTER PUMP SYSTEM

A booster pump system is supplied from a water source with insufficient pressure. A control system senses variations in the distribution system and adjusts either the speed of the pump or a pressure-regulating valve to maintain a constant pressure of acceptable value.

Two types of booster pump controls are available for adjusting pressure and flow in the water distribution system: constant speed and constant pressure.

HYDROPNEUMATIC TANK SYSTEM

In a hydropneumatic tank system, water is pumped from the water source into a pressure tank for storage. The air in the tank is compressed by the water entering the tank. As the pressure in the tank increases, the pressure in the water distribution system also increases. This arrangement allows the pumps to shut down periodically to conserve energy. During these periods, the system is still able to satisfy the demand for water from that stored in the tank.

A separate air compressor is provided to compensate for any air absorbed by the water. Control of the system is achieved with a combination pressure and level control, which adds water or air to the pressure tank at predetermined levels.

Since the total amount of stored water is relatively small, a pressure tank may run out of water during periods of peak demand unless a very large tank is selected. The fill pumps (house pumps) thus must be sized to meet the peak demands of a building at the lowest calculated system pressure. The piping arrangement of such a system includes a tank bypass arrangement to allow the fill pumps to supply the building directly if a sustained peak demand occurs and there is not enough water in the pressure tank to supply the demand for an extended period.

Because of very high initial cost and the large amount of floor space required, hydropneumatic tank systems are no longer considered for supplying an entire building with water. Booster pumps have replaced hydropneumatic tanks for this application. However, some of these systems still operate in older buildings.

Small hydropneumatic systems are often used with house tank systems or as part of a hybrid system to allow booster pumps to be shut down periodically. A pressure tank may be located anywhere in a building.

HYBRID SYSTEM

A hybrid is a combination of two systems. The most common is a small hydropneumatic system used in conjunction with a booster pump for economy in facilities where little or no water is used for extended periods of time. Examples are office buildings or factories that have practically no water usage at night because they are closed. Another hybrid system, with a small booster pump assembly, is used to provide a higher pressure to the upper floors when a house tank is used but the height of the tank is limited.

ELEVATED WATER TANK PIPING ARRANGEMENT

Michael Frankel, CIPE; Utility Systems Consultants; Somerset, New Jersey

GENERAL

Plumbing systems directly affect the health and safety of the public and are distinguished from other piping systems by the following requirements:

1. The design, materials, and installation of the systems are directly regulated by a plumbing code.
2. System design must be approved by an authorized plumbing code official charged with assuring code compliance.
3. A permit for installation of the systems must be obtained from authorities having jurisdiction (AHJ).
4. Systems should be installed by an entity duly licensed by local authorities to install plumbing systems. (This may not be required in some jurisdictions.)
5. Plumbing design plans and installed systems are required to be inspected and approved by an authorized code official charged with code enforcement.

FIXTURE UNITS

The fixture unit (FU) is an arbitrary, comparative, dimensionless value assigned to a specific plumbing fixture, device, or piece of equipment. FU values represent the probable flow of water the fixture will discharge into a drainage system or use (demand) from a potable water supply system. The value is assigned by comparison to a lavatory, which has a value of 1 for both water demand and waste discharge.

Since waste discharge and water demand FUs are different, the designation DFU for drainage fixture units and WFU for potable water fixture units can be used to differentiate between them.

PLUMBING FIXTURES

A plumbing fixture is any approved receptacle specifically designed and approved to receive human and other waterborne waste and discharge that discharges directly into a sanitary drainage system, usually with the addition of water. Ideal fixture materials should be nonabsorbent, nonporous, nonoxidizing, smooth, and easily cleaned.

Plumbing codes usually mandate the number and type of fixtures that must be provided for specific building uses based on the proposed population. Provisions for persons with disabilities have been made an integral part of code requirements, mandating the number and layout of and barrier-free access to those fixtures.

EQUIVALENT LENGTH OF PIPING

When calculating pressure loss through a pressurized piping system, a factor to incorporate is the equivalent length of pipe. This is the actual measured pipe run plus an additional length, expressed as a number of feet of straight pipe that would have the same friction loss as that occurring from turbulence through various fittings, valves, etc. The table entitled "Pressure Loss in Fittings and Valves," shown on the AGS page on Potable Water System Sizing, gives the straight run of pipe for both liquid and gas systems equal to valves and fittings for different pipe sizes. A generally accepted and conservative method of quickly finding the equivalent run is to add 50% of the measured distance to the actual pipe run.

DEVELOPED LENGTH OF PIPING

Used only for the vent system, the developed length of an individual or common vent is measured from the connection with the fixture trap arm to the connection with the branch vent or vent stack. This is the measurement used to size vent piping. The developed length of a branch vent is taken from the connection with a waste branch that is farthest from the point being sized. The developed length of a vent stack is taken from its connection with the soil or waste stack to its terminal above the roof.

PLUMBING SYSTEM TYPES

The basic plumbing systems are sanitary and waste drainage discharging into a sanitary sewer, vent, storm water drainage, potable water (cold water, hot water, and hot water circulation), and fuel gas systems.

SANITARY AND WASTE DRAINAGE SYSTEMS

Sanitary and waste drainage systems convey waterborne effluent from plumbing fixtures and other equipment to an approved point of disposal that discharges into a sanitary sewer or an approved private sanitary treatment system. The drainage system receives all liquid waste except storm water or unacceptably treated process or chemical drainage. Effluent containing bodily waste is referred to as "sanitary drainage." Clear water waste, such as that from equipment, sinks, or showers is referred to as "waste drainage." Untreated waste containing chemical effluent

must be treated before discharge into the sewer system or the environment. Treatment can be carried out either by a public utility or on site with a private treatment plant approved by the local jurisdiction.

The building sewer (or building drain) is the lowest portion of the drainage system inside a building; it is the main line that carries effluent outside the building. The house sewer is a continuation of the building sewer that runs from outside the building to the point of disposal. A stack is a vertical pipe more than three stories high. A shorter stack is considered a branch. A branch line is any drainage line connecting to a stack or the building drain.

VENT PIPING SYSTEMS

The purpose of a vent system is to limit the pneumatic pressure in a drainage system to plus or minus one inch of water column. Vent systems terminate in the outside air and connect directly to every fixture trap.

Vent lines are sized using three factors: drainage fixture units, the size of the drainage line (or stack) to which the fixtures are connected, and the developed length of the vent line from the fixture to the vent stack.

STORM WATER DRAINAGE SYSTEMS

The purpose of the storm water drainage system is to remove rainwater from roofs and other areas exposed to the weather. Roof drains and gutters convey the storm water to an approved point of disposal. Other areas that require storm water drainage include balconies, walkways, canopies, and awearays. Rainwater enters the storm water drainage system by means of drains.

There are two classifications of roof drainage: conventional and controlled flow (also called limited discharge). Only the conventional roof drainage system, which removes stormwater as quickly as it falls, will be discussed. Information on controlled flow systems can be obtained from the manufacturer of roof drains or standard engineering references.

FUEL GAS SYSTEMS

Fuel gas systems deliver gas used to provide light or heat energy in the volume and pressure required to operate all connected devices.

Many different gases are used as fuel gas. Where easily and cheaply available, the two major fuel gases—natural gas (NG) and liquefied petroleum gas (LPG)—are preferred. Other gases are used because of availability. Around the United States, the Btu/cu ft of natural gas can vary from 950 to 1075. Consult the local utility company for the exact value in the project area. The most commonly available natural gas has a Btu value of 1050/cu ft.

POTABLE WATER DISTRIBUTION SYSTEM

The water distribution system must be able to provide an adequate quantity of water at acceptable pressure to all fixtures and equipment during periods of maximum building demand and minimum pressure. The actual quantity of water used varies with building use, time of day, and building occupancy.

A street pressure system is suitable when the water pressure supplied from a public water main is sufficient to supply all fixtures and equipment in a building without the use of a pressure boosting system. This generally requires that the static pressure in the public main be no less than 50 pounds per square inch (psi).

A hot water system heats raw water from ambient temperature to a desired higher temperature and delivers the heated water to all plumbing fixtures and equipment requiring hot water. The recommended hot water temperature at the heater is 140°F to avoid the possibility of Legionnaires' disease. A booster hot water system can be used to heat primary service hot water to a higher temperature for a specific purpose.

A hot water recirculation system ensures hot water is quickly available to plumbing fixtures. Generally accepted practice requires that hot water delivered to terminal points of the system reach utilization temperature in 20 seconds or less. Some codes also require a form of temperature maintenance if the distance of a fixture from the heater exceeds a set distance, often 50 ft.

CODES AND STANDARDS

Plumbing codes establish minimum acceptable standards for design and installation of plumbing systems and selection of the components they comprise. Regional building codes and the plumbing codes associated with them have found general acceptance in large areas of the country. However, some states and large cities have adopted their own plumbing codes, while some local authorities that use

a regional building code have adopted a plumbing code other than the one usually associated with that building code. Because of the lack of standardization, the plumbing code used for each specific project must be obtained from the responsible jurisdictional authority.

Information pertaining to plumbing system design in local plumbing codes should be the primary criteria for determining accepted methods and sizing. The tables and charts on these AGS pages are used only to illustrate discussions of sizing procedures and design methods. They should not be used for actual design purposes except where no such information is provided in the plumbing code.

The word "approved" is often used in conjunction with components and devices that come in contact with potable water and products used for human consumption or use. Nonetheless, a responsible code official or agency must examine and test these items to determine whether they are suitable for a particular intended use. Only materials and devices approved by the local jurisdiction can be used in plumbing systems. Plumbing design drawings and utility services also must be examined and found to be in compliance with local codes, rules, and regulations.

TYPICAL WATER SUPPLY AND DRAINAGE FROM A PLUMBING FIXTURE

Michael Frankel, CIPE; Utility Systems Consultants; Somerset, New Jersey

SANITARY AND WASTE DRAINAGE SYSTEMS

Sanitary and waste drainage systems remove approved liquid waste from all fixtures and equipment for disposal into the sanitary sewer.

DESIGN CONSIDERATIONS

1. Plumbing codes require that any substance harmful to either the building drainage system, the public sewer, or the municipal sewage treatment process be prevented from entering the public sewer system by the installation of an approved interceptor. Such materials include grease, flammable liquids, sand, or other substances local authorities determine are objectionable.
2. When ultra-low flow (ULF) water closets (1.6 gallons per flush) are required by code, take care not to place these fixtures at the end of a long run with shallow pitch and few other fixtures. Field experience has shown such a setup regularly produces stoppages because it does not provide enough water to create the necessary scouring action in the drainage pipe.
3. Where public sewers are available, connect the house sewer to the public sewer. Plugged outlets called laterals are often provided for future connections to the public sewer. If no laterals are available, a direct connection is made. Some jurisdictions require a house trap on the building sewer inside a building; others do not.
4. In the absence of public sewers, a private sewage disposal system must be provided. The most commonly used is a septic tank system, which depends on bacterial action to change most solids into a liquid, which is then discharged into an underground absorption field. The basic principle is to have the volume of household effluent conditioned by the septic tank and the discharge from the tank absorbed into the ground as quickly as it is discharged. Laundry machines should be routed to separate drywells since the soap and other chemicals retard or stop bacterial action in a septic tank. Grease should be disposed of separately. The design, selection, and location of septic tank system components are strictly governed by local codes, requirements of which vary widely.
5. Install piping in trenches with particular care to avoid sagging and other movement. The configuration of the backfill requirements varies between plastic and metal pipe.
6. Construct pipe passing through walls, floors, and roofs so it adequately seals against moisture penetration.

VENT SYSTEM

A vent system equalizes the pneumatic pressures, both positive and negative, within a sanitary piping network.

DESIGN CONSIDERATIONS

1. The size of a vent stack should be a minimum of half the size of a drainage stack. The size of a branch vent should be a minimum of half the size of the branch drainage line it serves.
2. Each individual fixture vent must rise above the flood level of the fixture served before it is connected to another vent line so as not to act as a waste line in the event the drain line becomes blocked.
3. To size a vent stack, use the DFU (drainage fixture unit) load for the entire drainage stack and the full developed length of the vent from the lowest connection up to the roof. Vent stacks must be undiminished in size for the entire length.
4. For branch vents, use the longest developed length, from the point where the size is being determined to the farthest connection to a branch waste line.
5. Building traps, where installed, should have a vent called a fresh air inlet. The inlet should be half the size of the building drain, with a minimum size of 4 in.
6. Vent pipes that pass through a roof must remain open under all circumstances. The two most common causes of blockage in exposed pipes are frost closure and snow closure. Local codes and authorities will provide the minimum height needed to avoid closure by accumulated snow on a roof. This dimension is often 2 ft 0 in.
7. In the absence of specific code requirements, the following can be used as a guide for locating vent extensions: The vent extension should not be located under or within 10 ft of any window, door, or ventilating opening unless it is 2 ft above that opening. If the terminal is through a building wall, it should be located a minimum of 10 ft from the property line, a minimum of 10 ft above grade, and not under any overhang.

FUEL GAS SYSTEMS

Fuel gas systems deliver gas at the required pressure for heat and light energy to all connected equipment and devices in a facility.

DESIGN CONSIDERATIONS

1. The specific gravity of the available gas, which varies with the Btu content of the gas, is critical to calculating the pipe size. Gas with a value of 1050 Btu/cu ft has a specific gravity of 0.60. LPG has a specific gravity of 1.50. The local utility company can provide the correct value for the project site. To size piping with a specific gravity different than 0.60, which was used as a basis for the sizing table that appears on the AGS page called Pipe Fittings and Pipe Size Schedule, multiply the flow rate by the factor found in the multipliers table below.
2. A utility company may provide several different types of service, each with a different cost (or rate). Specific types of service may be unavailable or known by different names in various localities:
 - FIRM SERVICE** provides a constant supply of gas under all conditions without exception. This service comes at the highest rate.
 - INTERRUPTIBLE SERVICE** allows the utility company to stop the gas supply to the facility under predetermined conditions and to start it again when these conditions no longer exist. The most common condition usually occurs when the outside temperature falls below a certain point. The rate for interruptible service is lower than that for firm gas; however, it is necessary to have a backup source of fuel, such as fuel oil or liquid petroleum gas, when using this service.
 - LIGHT OR HEAVY PROCESS SERVICE** is used when large volumes of gas are required for manufacturing applications.
 - COMMERCIAL/INDUSTRIAL SERVICE** is used when large volumes of gas are required for space heating and industrial process use.
 - TRANSPORT GAS** is reserved for large users that buy gas at the wellhead and have it transported to the site via utility company mains.

MULTIPLIERS FOR SPECIFIC GRAVITIES OTHER THAN 0.60

SPECIFIC GRAVITY	MULTIPLIER	SPECIFIC GRAVITY	MULTIPLIER
0.35	1.31	1.00	0.78
0.40	1.23	1.10	0.74
0.45	1.16	1.20	0.71

0.80	0.87	1.90	0.56
0.85	0.84	2.00	0.55
0.90	0.82	2.10	0.54

STORM WATER DRAINAGE SYSTEM

Storm water drainage systems remove rainwater from all exposed portions of a building for discharge to an approved point of disposal.

DESIGN CONSIDERATIONS

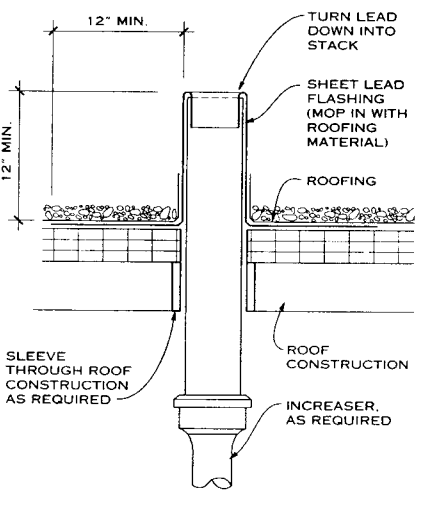

1. Most codes require a fail-safe method of removing excess rainwater from a roof before water accumulates to the point at which structural damage will occur. The preferred method is use of rectangular holes through the parapet called scuppers to allow water to drain down the side of the building. Another method places secondary drains immediately adjacent to the primary drain but with a water inlet elevation about 3 in. higher than the roof. The applicable plumbing code must be consulted for the size and routing of the secondary roof drainage system.
2. The final point of disposal into a public sewer system can be either a storm water sewer that accepts only storm water or a combined storm water and sanitary sewer into which both types of effluent are drained.
3. When no public sewers are available, storm water is discharged into dry wells, site gullies, watercourses, and recharge basins, which are large storage basins that allow water to both evaporate and be absorbed into the ground.
4. The following information must be obtained before designing a storm water drainage system:
 - ULTIMATE POINT OF DISPOSAL:** Find out whether storm water on the site will drain to a storm sewer (a sewer dedicated to storm water), a combined sewer (a sewer receiving both sanitary drainage and storm water), a watercourse, a street, or a gully on the site.

RESTRICTIONS: Find out if any storm water management programs or restrictions are in effect for the project site.

JURISDICTION: Find out which authorities are responsible for approval of plumbing plans and installations at the site.

- NOTES**
1. This diagram generally illustrates plumbing drainage solutions that constitute good plumbing practice. Because of variations in local code, some of the items shown may be prohibited in some areas, while others may far exceed the minimum requirements of a local code.
 2. Always consult local codes for exact requirements and for such items as fixture unit values, pipe sizing, pipe materials, general regulations, and special conditions.
 3. Forty-five degrees or less from vertical may be considered as straight stock in sizing, except that no fixtures or branches may be connected within 2 ft. of offset.

Killebrew/Rucker/Associates, Inc., Architects/Planners/Engineers; Wichita Falls, Texas
 Michael Frankel, CIPE; American Society of Plumbing Engineers, Somerset, New Jersey

REVERSE TRAP NOTE

Water is introduced into the fixture only through the rim by a gravity flush tank. This action is low cost and used mostly for residential projects. Reverse traps may be used with flush tanks or valves.

BLOWOUT NOTE

Water is introduced at high velocity through jets at the bottom of the waterway in blowout action. This action is used for public facilities and industrial projects because of its ability to remove larger objects thrown into the fixture. Blowouts are used with flush valve water supply only.

SIPHON JET NOTE

Water is introduced into the fixture both through the rim and by a jet at the bottom of the waterway. Quiet flushing and moderate cost make this the most commonly used flushing action. Less costly variations include "washout" and "washdown" actions that do not use the jet. The siphon jet can be used with flush valves or tanks.

FIXTURE FLUSHING ACTION TYPES

GRAVITY FLUSH TANK NOTE

Water enters the tank through a ball cock and is stopped when the float valve reaches a predetermined level. The handle raises the flapper to release all the water in the tank into the fixture and stops when the flapper closes. Gravity flush tanks require 10 psi water pressure.

PRESSURE-ASSISTED FLUSH TANK NOTE

Water enters a pressure tank installed inside an outer tank, partially filling the tank and compressing the air inside. When flushing is started, the air pressure causes the quick release of water into the fixture. Pressure-assisted flush tanks require 30 psi water pressure.

FLUSH VALVE NOTE

Flush valves are available in a wide variety of manual and automatic operation fixtures, some with infrared and other proximity sensors. Once flushing has started, a measured quantity of water is quickly introduced into the fixture. Flush valves require 25 psi water pressure.

FIXTURE WATER SUPPLY TYPES

NOTES

1. Flush valves and tanks can be installed on either floor-mounted or wall-mounted water closets.
2. ADA 4.16 (Water Closets) describes grab bar requirements for water closets. ADA 4.17 (Toilet Stalls) describes approach, floor space, and grab bar require-

FRONT AND SIDE APPROACH

SIDE APPROACH

FRONT APPROACH

ments for water closets within toilet stalls (see AGS ninth edition page on "Accessible Water Closets, Stalls, Urinals, and Lavatories"). Water closet height should be 17-19 in. to the top of the toilet seat. Seats should not spring up. The force required to activate controls should be a maximum of 5 lbf. Mount controls on the wide side of the toilet no more than 44 in. above the floor.

3. For rough-in dimensions, refer to manufacturers' manuals.
4. Special toilet types are sometimes used, such as vacuum-vented toilets, composting toilets, and chemical toilets.
5. Current code requires that water closet flush valves and tanks be limited to 1.6 gal. maximum per flush of water.

WATER CLOSET MOUNTING TYPES AND CLEARANCES

NOTE

This low, basinlike plumbing fixture is designed to be straddled for bathing the posterior parts of the body.

BIDET

URINALS

NOTES

1. Urinals require flush valves as source of water supply.
2. ADA 4.18 (Urinals) requires 30 x 48 in. clear floor space in front of urinals to allow a forward approach. Urinals should be stall type or wall-hung with an elongated rim a maximum of 17 in. above the floor. Shields, if provided, should not extend beyond the front of the urinal rim and must have a clearance of 29 in. Flush controls should be accessible and no more than 44 in. above the floor.
3. If used, urinal tanks should be 92-94 in. above the floor.
4. Battery stalls, except accessible ones, should be installed 21-24 in. on center.
5. For styles and rough-in dimensions, refer to manufacturers' manuals.

PLAN

SLAB LAVATORY

SIDE ELEVATION

FRONT ELEVATION

NOTE

Slab lavatories typically are rectangular with rectangular basins and are spaced from the finish wall with 2-in. escutcheons. A vitreous china leg with brackets can serve as an alternate means of support. A lavatory may be ADA compliant when installed with an offset drain.

PLAN

FLAT-BACK LAVATORY

SIDE ELEVATION

FRONT ELEVATION

NOTE

Flat-back lavatories generally are rectangular with rectangular or semi-oval basins. Support is provided by metal legs with brackets or by concealed arms.

PLAN

SHELF-BACK LAVATORY

SIDE ELEVATION

FRONT ELEVATION

NOTE

Shelf-back lavatories generally are rectangular with rectangular or semi-oval basins and are supported by integral wall supports or by concealed arms.

PLAN

WHEELCHAIR ACCESSIBLE LAVATORY

SIDE ELEVATION

FRONT ELEVATION

NOTE

Wheelchair accessible lavatories must be supported with a concealed arm carrier. Pipes should be covered and cannot obstruct access. Faucet levers should be accessible or photoelectric.

PLAN

WALL-MOUNTED WASH SINK

SIDE ELEVATION

FRONT ELEVATION

NOTE

Wash sinks are supported with concealed wall brackets or angle supports.

GENERAL

Lavatories are available in vitreous china, cast acrylic resin, enameled cast iron, enameled steel, and stainless steel. The most commonly used means of support is the chair or wall carrier with concealed arms. Consult manufacturers' data for specific fixture design and support recommendations.

PLAN

NOTE

Corner lavatories are available angled with an oval basin or rectangular with an offset rectangular basin. They are supported with wall brackets or concealed arms.

CORNER LAVATORY

PLAN

NOTE

Built-in (or drop-in) lavatories come in oval, rectangular, and circular shapes. Typically self-rimming, they are also available with metal rims or rimless for undercounter installations. They may meet ADA requirements if placed in an accessible counter.

BUILT-IN LAVATORY

PLAN

NOTE

Pedestal lavatories may be either wall-mounted or free-standing. Consult manufacturers for specific designs, forms, and dimensions.

GENERAL

Bathtubs are available in many shapes and installation types, including rectangular recessed, corner recessed, rectangular or oval drop-in, and clawfoot (freestanding). Bathtubs can be surrounded by ceramic tile, solid surfacing, or molded fiberglass or acrylic one-piece units. Bathtubs are available in the following materials:

FIBERGLASS: An economical and common choice, gel-coated fiberglass (also known as FRP) is lightweight and easily installed. Because the material can be molded, fiberglass tubs are available in a variety of shapes. Although not as durable as cast iron or acrylic, fiberglass can easily be repaired.

ACRYLIC: In terms of durability, acrylic is a step up from fiberglass, with which it is usually reinforced. Because acrylic is light and easily formed into different shapes, it is a good choice for whirlpools and other large tubs that would be too heavy in cast iron. Acrylic is a good insulator and, thus, keeps water warm longer.

CAST IRON: Very heavy and extremely durable, traditional enamel-coated cast iron resists staining and scratching. It cannot be molded as freely as acrylic or fiberglass, so there are fewer shapes and styles from which to choose.

ENAMELED STEEL: This is a lighter weight, less expensive alternative to cast iron.

Whirlpool baths are usually made of fiberglass-reinforced acrylic, which can be fabricated in a variety of shapes—standard oblongs, round tubs for two, cloverleaf or hour-glass designs, or free-form shapes. Air mixed with water streams through jets in the side of the tub, giving the whirlpool its soothing, therapeutic character. Models may have 3 to 10 jets, including some aimed to massage feet, back, or neck. Jet direction can usually be adjusted; some jets can also be adjusted to deliver a pulsating or steady stream or to regulate intensity. Pumps range from 1/2 to 3 horsepower, and the intensity of the flow varies accordingly. In-line heaters are recommended to keep the water warm without refilling the tub.

SQUARE

RECTANGULAR

CORNER NOTE

Materials for bases include acrylic with fiberglass reinforcement, enameled steel, and terrazzo.

TYPICAL INTERIOR DRINKING FOUNTAINS

NOTES

1. Drinking fountains (DF) use only water at ambient temperatures; electric water coolers (EWC) use an integral or remote chiller to cool water for drinking.
2. Use air-cooled condensers for normal room temperatures and water-cooled units for high room temperatures and larger capacities. Many models are available with hot and cold water supply, a cup-filling spout, or refrigerated compartments.
3. Install half of required fountains as accessible, but design the layout so accessible fountains do not obstruct movement of the visually impaired.
4. Special explosion-proof fountains are recommended for use in hazardous atmospheres. Corrosion-resistant fountains are available for harsh environments.
5. Consult local building codes for the minimum number of drinking fountains required.

GENERAL

A domestic hot water (also called service hot water) system heats raw water from the ambient temperature to a desired higher temperature using a unique heat exchanger called a hot water generator. An important ancillary part of the service hot water system is hot water temperature maintenance. This system keeps the water in the piping system hot, so that when hot water is drawn from a fixture or equipment it will reach design temperature quickly even when the system has not been used for some time.

LEGIONNAIRES' DISEASE

Outbreaks of Legionnaires' disease in plumbing systems have been traced to domestic hot water distribution systems. The problem originates when the outlet temperature of the water at a heater is lower than 140°F (60°C), the temperature at which bacteria is destroyed. Therefore, it is highly recommended that all water for domestic purposes be heated initially to a temperature of 140°F and lowered to the final temperature with a mixing valve.

HOT WATER SYSTEM SIZING

Hot water usage and flow rates are characterized by intermittent periods of peak, sustained, and low-to-zero flows. The pattern of usage varies widely, depending on the building type and use, time of day, time of year, population, and connected equipment and fixtures. The final temperature of the water should be high enough to meet the minimum requirements of the connected equipment.

STORAGE-TYPE WATER HEATER SIZING

Storage-type heaters are sized using the total volume of hot water required for the estimated duration of maximum demand. This total volume can be provided by any combination of hot water storage capacity and water heater recovery (makeup) rate. The storage and recovery values depend on the project type. The major advantage of using a storage-type heater is that the instantaneous demand for heating medium is considerably less than that for instantaneous-type heaters.

To estimate the hot water demand for a project, use the table on this page: First, select the facility type in the heading closest to that of the project. Next, count the total number of each type of fixture at the project, and find the hot water demand for each fixture in the facility type column in the table. Multiply the gallons (or liters) per hour value for each fixture by the total number of individual fixtures. Add the resulting figure for all fixture types together to determine the total connected (demand) load for the building in gallons (liters) of water per hour.

Find the actual hourly demand for the facility by multiplying the total connected load by the demand factor shown at the bottom of the hot water demand table. This will yield the total volume of hot water to be used by the facility during a 1-hour period.

DURATION OF PEAK USE

BUILDING TYPE	PEAK DURATION (HR)
Motel	2
Hotel	3
Apartment house	3
Nursing home	3
Office	2
Food service	1-4 (varies with type)

In addition to the total hourly demand, a certain amount of hot water should be stored. The recommended volume for storage is a function of the actual hourly demand. The storage requirement is found by multiplying the total hourly demand by the storage capacity factor found at the bottom of the water demand table. This figure is the usable volume of hot water required to be stored.

The recovery requirement and the storage requirement represent one hour's peak use of hot water. Select any combination of heating capacity (recovery) and storage capacity capable of meeting this peak hour. If the duration is longer than one hour, proceed to the next step.

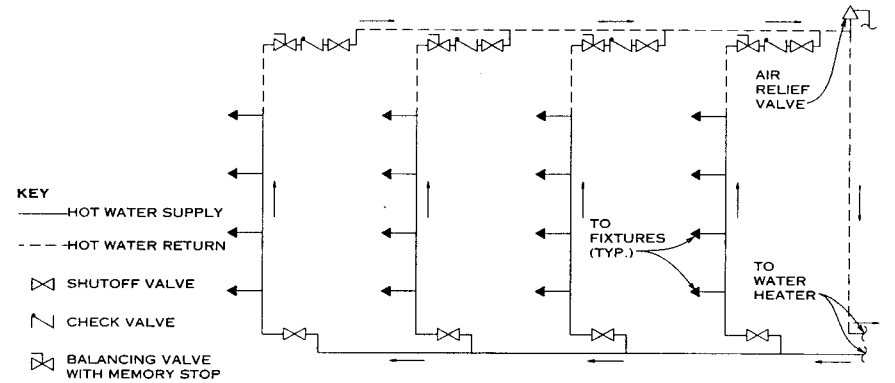

Refer to the duration of peak use table to determine if the facility should have more than a 1-hour peak usage duration. If so, multiply the actual hourly demand by the number of hours of peak duration to find the total volume (in gallons or liters) of hot water required for the entire peak period. Select a recovery rate and storage tank capacity combination to cover the total number of gallons. For example, if the actual hourly demand is 1000 gal/hr for a duration of 3 hours, the total volume of hot water required will be 3000 gal. If the usable storage volume is 1000 gal, the recovery

MINIMUM HOT WATER TEMPERATURE FOR PLUMBING FIXTURES AND EQUIPMENT

USE	MIN. TEMP. (°F)
Lavatory	
Hand washing	105
Shaving	115
Showers and tubs	110

Michael Frankel, CIPE; Utility Systems Consultants; Somerset, New Jersey

HOT WATER GENERATOR TYPES

Hot water generators can be direct or indirectly fired and are classified as either fully instantaneous, semi-instantaneous, or storage-type heaters. They use a heating medium or fuel source such as oil, fuel gas, electricity, hot water, steam, or solar panels to transfer heat from the heating medium to the water in the heating vessel.

INSTANTANEOUS-TYPE HEATER

Fully instantaneous-type heaters consist of a unit that heats water as quickly as the demand flow rate requires. They have no storage and a high water heating (recovery) rate. Advantages include compact size, low initial cost, and factory preparation for installation. Disadvantages are difficult control of outlet water temperature and high instantaneous Btu requirements for the heating medium. This type of heater is almost always indirectly fired using either steam or hot water supplied from a central heating plant, steam utility system, or boiler. An accurate approximation of steam required can be calculated by multiplying the GPM requirements by 50 lb/hr.

Point-of-use heaters are a small, direct-fired instantaneous type used for isolated and remote locations where it is not economical to run piping from the central service hot water system. Often, these units are electric in-line instantaneous heaters installed below an individual fixture or 5-gallon (20-liter) units installed on a shelf or in a hung ceiling adjacent to a toilet room or similar installation.

SEMI-INSTANTANEOUS TYPE HEATERS

Semi-instantaneous type heaters are similar to the fully instantaneous type except they have a very small water storage capacity, which permits better control of outlet water temperature. This type of heater can be either directly or indirectly fired and is preferred over the fully instantaneous type.

STORAGE-TYPE HEATERS

Storage type heaters have a large storage capacity and lower recovery rate. This type of system consists of either a combination storage tank with a direct or indirect immersion heater inside the tank or a separate water heater and storage tank. Use of this system should be considered when high peak surge loads are encountered for short periods of time and when there is a limited source of heat energy. Disadvantages include the large amount of floor space required and the high initial cost. Advantages include a low instantaneous heat energy demand rate.

HOT WATER TEMPERATURE MAINTENANCE

Generally accepted practice requires that hot water delivered to terminal points of the system reach the desired temperature in 20 seconds or less. Some codes also require some form of temperature maintenance if the distance from the heater exceeds a set figure, often 50 ft (15 m). Use of a temperature maintenance system will result in a large saving of water otherwise wasted waiting for hot water to reach the desired temperature at the fixture.

To accomplish heating in 20 seconds, two methods are available to maintain the hot water temperature. The first uses a separate water circulation pump and recirculation piping system to return the cooler hot water from the end of the system back to the heater for reheating, thereby keeping the primary water hot.

The second method uses a self-regulating electrical heater wire attached directly to the primary hot water pipe under the insulation, thereby eliminating the need for a separate circulation piping system. This wire becomes hot only when the temperature of the water pipe drops to a predetermined point. The self-regulating feature supplies only enough heat to keep the water at a predetermined temperature; it is not simply an on or off feature. The use of the self-regulating cable is not generally economical when the length of recirculation piping is less than half the length of the primary hot water pipe.

BOOSTER HEATERS

If the temperature of hot water for a project is higher than 140°F (60°C), it is common practice to install a separate booster heater in the area of use rather than to heat water for the entire project to the higher temperature.

RELIEF VALVE DISCHARGE

Temperature and pressure relief valves may operate suddenly and at any time to relieve the considerable pressure built up inside a heater. Because scaldingly hot water thus could splash unexpectedly in a large area, it is important to route the discharge from relief valves to a safe location.

TYPICAL TANK SIZES

CAPACITY (GAL.)	HEIGHT (IN.)	DIAMETER (IN.)
30	48	22
50	60	24
75	60	26
100	74	28
120	76	30

NOTES

1. Available as gas, oil, or electric-fired models.
2. A flue is required for oil or gas models only.
3. Electric-fired heaters have the lowest initial cost and the highest operating cost.
4. Consult manufacturer for makeup capacity.

TYPICAL RESIDENTIAL WATER HEATER

NOTES

1. Heater size is based on the size of the faucet and the voltage and capacity available from the electric service.
2. Route temperature and pressure discharge to a safe location.
3. Point-of-use heaters are available in sizes from .25 to 2 GPM; storage is available up to 5 gallons.

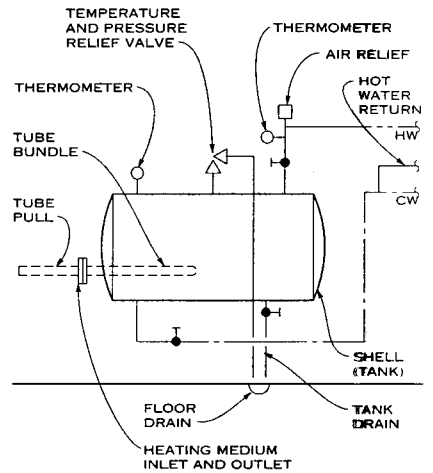

TYPICAL POINT-OF-USE HEATERS

NOTE

Typical sizes range from 16 to 36 in. in diameter, up to 80 in. high. Size is based on gallons per minute (GPM) and the temperature difference of inlet cold water (CW) and outlet hot water (HW). For sizes, refer to manufacturers' standards.

TYPICAL SEMI-INSTANTANEOUS WATER HEATER

TYPICAL TANK SIZES

CAPACITY (GAL.)	LENGTH (IN.)	DIAMETER (IN.)
500	100	48
1000	150	52
1500	170	58
2000	178	64
3000	144	84
4000	144	96

NOTES

1. This system is used for projects for which the flow rate of the heating medium, whether hot water, steam, oil, or electric, is limited.
2. Size is based on hourly hot water demand and temperature difference between inlet and outlet water.
3. These dimensions are for horizontal tanks. Vertical tanks are available, as well as custom tanks of various capacities.

TYPICAL STORAGE HEATER

Michael Frankel, CIPE; Utility Systems Consultants; Somerset, New Jersey

POTABLE WATER DISTRIBUTION SYSTEM

A potable water system delivers water suitable for human consumption at appropriate pressure and volume to all plumbing fixtures and equipment. Water should be delivered to the most remote fixture within an acceptable range of pressures. Water pressure is considered excessive if it will cause damage or create a nuisance. A widely accepted pressure value is 70 psi. Often, the maximum permissible water pressure is stipulated by code.

DESIGN CONSIDERATIONS

ESTIMATING MAXIMUM WATER DEMAND: Maximum instantaneous water demand is estimated using water supply fixture units (WFU) converted to gallons per minute (gpm). The supply demand curve converts WFU to gpm using "Hunters Curve," which is derived from a statistical method of estimating how often various fixtures would be used simultaneously.

The conversion of WFUs is separated into two categories, one for flush valves and one for flush tanks. Since the flush valve has a much higher flow rate, its conversion from WFUs shows a larger flow rate of water. The section for flush tanks is also used to size all piping networks without flush valves and hot water piping.

WATER VELOCITY: Generally accepted practice limits the velocity of water in piping to 8 feet per second (fps) to avoid excessive noise and prevent erosion of the piping. The velocity should be lowered to 4 fps to avoid corrosion when softened water is used and to avoid water hammer when any quick closing valves are installed. All branches containing a flush valve or quick closing valve should have shock absorbers installed downstream of the last fixture.

FACTORS AFFECTING DESIGN OF A PUBLIC WATER MAIN: Obtain the location, elevation, and size of the water main from the local water purveyor. Also helpful is a topographical map showing the relative ground elevations and any obstructions (trees, boulders, curbs, etc.) that would interfere with the run from the main into the building. If possible, find out the frost depth for the project site. When this information is unavailable, a dimension of 5 ft 0 in. to the centerline would be a generally safe figure for depth of bury.

STATIC AND RESIDUAL WATER PRESSURE: The actual water present in the water main is critical to the design of the water supply system. The static pressure is the water pressure in the main when no water is flowing in an immediate connection adjacent to the project site. The residual pressure is the water pressure available in the main when a considerable amount of water is flowing from any connection, usually a fire hydrant, close to where the building water supply will be connected to the public main. This information is obtained by means of a flow test, often called a hydrant flow test. The residual (lower) pressure is used to size the project water supply distribution network.

MINIMUM FIXTURE OPERATING PRESSURE: Various plumbing fixtures and devices require a minimum pressure to ensure proper operation. Generally accepted values are given in the accompanying table, but these must be verified by the manufacturer.

MINIMUM OPERATING PRESSURES FOR SOME FIXTURES

FIXTURE	PRESSURE (PSI)
Basin faucet	8
Basin faucet, self-closing	12
Bathtub faucet	5
Dishwasher	15-25
Garden hose, 50 ft (15 m), and sill cock	30
Laundry tub cock, 1/4 in. (0.64 cm)	5
Shower	12
Sink faucet, 3/8 in. (0.95 cm)	10
Sink faucet, 1/2 in. (1.3 cm)	5
Urinal flush valve	15
Water closet, ball cock	15
Water closet, flush valve	15-25
Water closet, low silhouette tank type	30-40
Water closet, pressure tank	20-30

CALCULATING AVAILABLE WATER PRESSURE

The pressure available for friction loss in a piping system is that pressure inside the building after all losses through the building service have been subtracted. The building water

service is the run of pipe from the public water main connection to a point inside the building beyond the devices required by the local water authority. Devices that codes or regulations might require include those listed here. The figure after each item is a general loss in pressure caused by the fixture. For exact pressure loss figures, consult the equipment manufacturer.

1. Connection to main, including street elbow (5 psi)
2. Curb valve (usually 2 psi)
3. Building shutoff valves (usually 3 psi each)
4. Strainer (5 psi dirty but varies according to type)
5. Water meter (5 psi but varies according to type and flow)
6. Backflow preventer (maximum 12 psi but varies according to type and flow)
7. Water softener (varies according to manufacturer and flow rate)
8. Pressure lost by the flow of water through the building service pipe run
9. Allowance for future development adjacent to project site, if justified (5 psi)

PRESSURE LOSS IN FITTINGS AND VALVES EXPRESSED AS EQUIVALENT PIPE LENGTH (FT)

NPS (IN.)	90 ELL		90 TEE		VALVES		
	ELL	ELL	SIDE RUN	TEE	GATE	CHECK	KGLOBE
1/2	1	.5	2	.4	4	4	18
3/4	2	.5	3	.5	5	5	23
1	2.5	1	4.5	.6	7	7	30
1 1/4	3	1	5.5	.7	9	9	38
1 1/2	4	1.5	7	.9	10	10	45
2	5.5	2	9	1	13	13	58
2 1/2	7	2.5	12	1.2	16	16	70
3	9	3.5	15	1	1.5	20	86
4	12.5	5	21	1	2.1	25	113

NOTE

Allowances are for streamlined soldered fittings and recessed threaded fittings. For threaded fittings, double the allowances shown in the table.

SIMPLIFIED PIPE SIZING BASED ON PRESSURE LIMITATIONS

1. Prepare or obtain complete plans, including a riser diagram, of the building under design. These plans should show the number and location of all plumbing fixtures and equipment requiring water and their WFU values for design purposes.
2. Locate the public water main and determine its elevation and residual pressure. Plan the building water service, determining what connected devices are required by local codes and regulations. Using this information, calculate the available pressure in psi to a point 2 ft 0 in. above the floor elevation inside the building.
3. Determine the elevation of the highest fixture. This is called the static height. A fixed pressure will be required in order to lift the water to that elevation. Multiply the static height by 0.433 to calculate the static height pressure loss in psi.
4. Find out the minimum operating pressure, in psi, required for proper fixture operation.
5. Measure the longest run of piping and add half of that distance to calculate total equivalent run. Divide the total by 100 to convert the figure to pressure loss per 100 ft.
6. Add the figures resulting from items 3 and 4 above to calculate all the fixed pressure losses for the building.
7. Subtract the fixed pressure losses (item 6) from the available pressure (item 2) to find the pressure available to overcome the water friction in the piping network. Dividing the equivalent length of piping (in 100s) into the available pressure will give the friction loss per 100 feet, which is the figure used for sizing purposes. For example: if the available pressure is 10 psi, and the total equivalent run is 200 feet, divide 2 into 10, which results in 5 psi per 100-foot run available for friction loss. In general, if the pressure required for friction loss is more than the pressure available from the building service, a water pressure booster system will be required.
8. Using the riser diagram or plans with the WFU marked and starting from the point farthest from the building supply, add all of the WFU together at each design point where a fixture or branch will connect to the pipe being designed.
9. Convert the WFU into gpm. If a flush valve is connected to the piping, use the flush valve figure. Using the flow of water in copper pipe, enter with the gpm and friction loss. Read the pipe size appearing at the intersection of gpm and friction loss or gpm and velocity, whichever is

the determining factor. Continue this method first for each branch and then the main. Add any continuous demand separately.

SIMPLIFIED PIPE SIZING BASED ON VELOCITY

This method is the same as that for pipe sizing based on water pressure, except that the velocity of the water is the determining factor. Use 4 fps where the pressure is marginal and 8 fps where significant pressure is available.

SUPPLY DEMAND CURVE FOR MORE THAN 240 FIXTURE UNITS

SUPPLY DEMAND CURVE FOR 240 AND FEWER FIXTURE UNITS

FLOW OF WATER IN COPPER PIPE (TYPE L ONLY)

GENERAL

When a floor-mounted support cannot be installed, wall-mounted supports can be used if the wall structure is strong enough to support the entire weight of the fixture. In such installations, the support arms are attached to a plate bolted directly into the wall structure.

NOTE

This support typically is used with a vitreous china lavatory.

EXPOSED ARM FIXTURE SUPPORT

NOTE

When using lavatories of the flat slab type (that is, without a backsplash), manufacturers typically require a 2 to 6 in. space between the wall finish and the rear of the lavatory to prevent water accumulation.

CONCEALED ARM FIXTURE SUPPORT

NOTE

An enameled cast-iron high-back lavatory is supported on a hanger-type support.

INTERCEPTORS

There are a number of substances that, if discharged into a plumbing system, have the potential to create safety or health problems or cause stoppages. In addition, some substances are not easily treated in a public sewage treatment system. Interceptors separate and retain such substances from drainage effluent, preventing their discharge into the sewage system.

GREASE INTERCEPTORS (TRAPS)

Grease is discharged from fixtures within food preparation areas such as kitchens and cafeterias. It is lighter than water and floats to the surface. It coats the inside of piping causing stoppages and is not easily treated in a sewage treatment plant. It must be removed from the waste stream before discharge into the drainage system.

Their size is based on intended capacity of retained grease, inflow into the grease trap, and the total volume of grease laden water that may flow through the grease trap. Grease traps should be located as close to the discharging fixture as practical and may be installed on or under a floor. A device to control the inflow is necessary to slow the water flow and allow grease sufficient retention time to float to the top of the interceptor for storage and removal. A vent connecting to the sanitary vent system should be provided.

OIL INTERCEPTOR

Oil and other volatile flammable liquids and vapors are a potential fire hazard, and the toxic vapors released are harmful when inhaled. Relatively small amounts are discharged mainly from machine shops, automobile repair shops, and parking garages. This oil is lighter than water and floats to the surface. It must be removed and stored in a safe location. An oil interceptor collects all volatile liquids entering the interceptor and stores them at the top of the unit for removal.

HAIR INTERCEPTOR

Hair discharged from barbershops and beauty parlors will create stoppages in the drainage system. A hair trap, installed on each fixture instead of a standard P trap, will trap all the hair.

LAYOUT DIMENSIONS

FLOW RATE (GPM)	GREASE CAP (LB)	LENGTH	HEIGHT	WIDTH
4	8	16 3/4	11	10
7	14	19	12	10 3/4

35	70	32 1/2	21	18 1/4
50	100	35 1/2	24 1/4	20 3/4

GREASE INTERCEPTOR

SAND INTERCEPTOR

Whenever there is a chance that sand or other small solids heavier than water may enter a drainage system, they must be removed and stored for disposal. A common source is foundation drains that discharge into a public sewer. Sand removal is accomplished with a sand interceptor.

Since the solids are heavier than water, the principle of retention is to have the solids settle to the bottom of the interceptor. When sand reaches a predetermined level, it must be cleaned.

PRECIOUS METALS INTERCEPTOR

In precious metal refining, polishing, and jewelry manufacturing, it is desirable to recover the small solids (fines) that would ordinarily be washed down the drain during polishing, cleanup, and washing. Small amounts from fixtures have a fixture trap type. Larger amounts require a floor-mounted type.

SHOCK ABSORBER

Whenever a water control valve closes very quickly in normal operation, such as those installed on water closets, clothes and dish washing machines, the sudden stopping of water starts a shock wave. This shock wave, commonly called water hammer, greatly increases pressure in the piping that over a period of time could cause the pipe or joint to fail. A shock absorber, installed in the water line between the source and the equipment, will lower the pressure to acceptable levels. The absorber size is based on line size, flow rate, and water pressure.

ACID NEUTRALIZER

Acids are a common class of chemicals discharged from laboratories, schools, and manufacturing facilities. The acids must be neutralized before they are discharged into the sanitary drainage system of a building. For small amounts, this is accomplished with an acid neutralizer that uses limestone chips as the neutralizing agent. Small amounts from fixtures use a fixture trap type. Larger quantities of acid require an acid sump installed either on or under the floor.

TYPICAL BOILER EQUIPMENT FOR NATURAL DRAFT INSTALLATION

BOILERS AND BURNERS

Two main elements determine overall boiler efficiency: (1) heat transfer surface of boiler and its condition—clean or fouled; (2) burner's ability to convert fuel's calorific (heat) value into useful heat.

Burner efficiency depends on the proper combustion of fuel (air-fuel ratio) and the maintenance (annual tune-up) of the burner. To handle a boiler properly and efficiently, the maintenance staff must be trained to operate the unit and to conduct efficiency tests, which include testing for CO₂, stack temperature, smoke, and draft.

NOTE: Air pollution regulations must be obtained from authorities having jurisdiction.

RATINGS

- Gross rating = input in Btu/hr.
- Net rating = output in Btu/hr. = gross rating x efficiency.

3. FUEL RATINGS

FUEL	HEAT VALUE	EFFICIENCY (%)
Anthracite coal	14,600 Btu/lb	65-75
No. 2 oil	140,000 Btu/gal	70-80
No. 4 oil	145,000 Btu/gal	70-80
No. 6 oil	150,000 Btu/gal	70-80
Natural gas	1052 Btu/cu ft	70-80
Electricity	1 W = 3.4 Btu/h	95-100

- Example: If boiler-burner combination is 80% efficient, No. 2 fuel oil is burned, and the total heat load is 168,000 Btu/hr, what is the required firing rate?

$$\text{Firing rate} = \frac{\text{gross rating}}{\text{fuel rating} \times \text{efficiency}}$$

$$= \frac{168,000 \text{ (Btu/hr)}}{140,000 \text{ (Btu/gal)} \times 0.8} = 1.5 \text{ gal/hr}$$

NOTE: Gross and net ratings are found on equipment plates.

CONTROLS

Automatic fuel burning equipment requires a control system that will provide a prescribed sequence of operating events and will take proper corrective action if failure occurs in the equipment or its operation. The basic requirements for oil burners, gas burners, and coal burners (stokers) are the same. The controls can be classified as operating controls, limit controls, and interlocks.

Operating controls initiate the normal starting and stopping of the burner in response to the primary sensor acting through appropriate actuators.

Examples of primary sensors are: a room thermostat for a residential furnace; a pressure actuated switch for a steam boiler; a thermostat for a hot water heater. Since the heat output of a burner may be widely distributed, the location of the primary sensor is important.

An actuator is defined as a device that converts the control system signal into a useful function. Actuators generally consist of valves, dampers, or relays.

Ignition for oil or gas burners is achieved by an electric spark or by a pilot gas flame, all supervised by a flame safeguard system which must meet legal and insurance underwriter's requirements. After ignition is proved, the flame safeguard system then permits the main fuel (gas or oil) to enter the burner for on-line combustion.

Limit controls and interlocks function only when the system exceeds prescribed unsafe operating conditions. They actuate electric switches that will close the fuel valve in the event of an unsafe condition, such as (1) excessive temperature in the combustion chamber or heat exchanger, (2) excessive pressure in a boiler or hot water heater, (3) low water level in a boiler and in larger commercial and industrial burners, (4) high or low gas pressure, (5) low oil pressure, (6) low atomizing media pressure, and (7) low oil temperature when firing residual fuel oil. Separate limit and operating controls are always recommended.

HIGH PRESSURE GUN TYPE BURNER (NO. 2 FUEL OIL)

NOTE: FOR DOMESTIC INSTALLATIONS UP TO 10 FAMILIES AND SINGLE STORY COMMERCIAL INSTALLATIONS UP TO 10,000 SQ FT

LOW PRESSURE GUN TYPE BURNER (NO. 4 FUEL OIL AND/OR GAS)

NOTE: FOR LARGE DOMESTIC, SEMICOMMERCIAL, AND COMMERCIAL INSTALLATIONS

CAST IRON SECTIONAL TYPE BOILER

HORIZONTAL ROTARY TYPE BURNER DIRECT DRIVE (NO. 6 FUEL OIL)

NOTE: ALSO AVAILABLE WITH BELT DRIVE, USED IN DOMESTIC, SEMICOMMERCIAL, COMMERCIAL, AND HEAVY INDUSTRIAL

LOCAL HEATING SYSTEMS

Electric energy is ideally suited for local space heating because it is simple to distribute and control. Electric heating systems are widely used in residences, schools, and commercial and industrial facilities. Heating units are placed in individual rooms or spaces but may be combined into zones with automatic temperature controls. Electric in-space heating systems may utilize natural convection, radiant, or forced air units.

NOTE
 Natural convection units for wall or floor placement (and surface or recessed installations) have elements of bare incandescent wire, bare low-temperature wire, or sheathed

wires. A liner or reflector is usually placed between elements so that part of the heat output is distributed by radiation and part by convection. Small capacity units (up to about 1650 W) operate at 120 V; higher capacity units oper-

ate at 208 V or more. Because natural convection air currents are critical to the distribution of heat from these units, they must be installed so that airflow across the resistor element will not be impeded.

NATURAL CONVECTION UNITS

NOTE
 Radiant heating units are designed primarily to heat objects, rather than space. Current flowing through a high-resis-

tance wire heats up the element or surface of the unit. Heat is transferred from the unit to surfaces or occupants primarily by radiation. Manufacturers' recommendations for

installation clearances should be strictly followed. For an effective system, it is important to locate radiant heating units carefully in relation to the objects being heated.

RADIANT HEATING UNITS

NOTE
 Forced air units combine convection heating with fan-powered air circulation. Such units are available in a wide range

of capacities to suit a variety of heating loads and occupancy types. Unit ventilators are commonly located on an

outside wall, where they have access to outdoor air intake and can prevent cold air downdrafts from window areas.

FORCED AIR UNITS

NOTE
 Electric resistance can be used as a heat source in a variety of central heating systems. An electric boiler with an immersion heating element can provide hot water for a heating-only system with radiator or convector terminal units or for an all-water or air-water HVAC system. An electric furnace, with a heating coil, fan, and air filter, can pro-

vide warm air for a central all-air HVAC (or heating-only) system. This system is essentially a small-capacity version of a single-zone, all-air system. Electric resistance elements can also be inserted in ductwork or at terminal boxes to provide heating capability in central HVAC systems. Other means of heating with electricity include heat pumps and

integrated heat recovery systems. In a heat pump, electricity drives a compressor that operates a vapor compression refrigeration loop in a reverse cycle, providing heat at the evaporator coil. Integrated heat recovery captures heat generated by some process (e.g., electric lighting) and uses it to heat a space or building (rather than contributing to the space cooling load).

CENTRAL HEATING SYSTEMS

Walter T. Grondzik, P.E.; Florida A&M University, Tallahassee, Florida

CHIMNEY CONSTRUCTION

The chimney should be supported on a foundation of masonry or reinforced concrete or other noncombustible material having a fire resistance rating of not less than 3 hr. When installed on an appliance, the chimney should be so supported as to not place excessive stress on the appliance. The base of the chimney should be secured to prevent movement of the chimney and anchor lugs should be used for this purpose whenever possible.

A cleanout section may be used in the chimney assembly but must not be used above the chimney inlet.

CLEARANCES

Chimneys of the medium heat appliance or commercial-industrial incinerator type are not intended to be enclosed in walls of combustible materials. These chimneys should be placed in fire resistive or noncombustible shafts where they extend through any story of a building above that in which the connected appliance is located.

An enclosed chimney may be placed adjacent to walls of combustible material with the following minimum clearances:

- 10 to 15 in. I.D. requires 16 in. clearance
- 15 to 21 in. I.D. requires 18 in. clearance
- 21 to 27 in. I.D. requires 20 in. clearance
- 27 to 36 in. I.D. requires 22 in. clearance

Where the chimney passes through a roof of combustible material it shall be installed with an insulated thimble and flashing. This insulated thimble may be installed at zero inch clearance to combustibles.

The chimney should extend at least 3 ft above the highest point where it passes through the roof and 2 ft higher than any ridge within 10 ft.

MEDIUM HEAT CHIMNEYS

ROOF PENETRATION

STACK DIAMETER—SINGLE BOILER VENT OR STACK

BOILER HORSE-POWER	STACK DIAMETER (IN.)	A (IN.)	B (IN.)	C (IN.)
15-20	6	15	15	12
25-40	8	20	20	16
50-60	10	25	25	20

50-60	13	14	15	16	17	18
70-100	16	17	19	20	21	23
125-200	21	22	24	26	28	30
250-350	26	28	32	34	34	40
400-600	32	34	38	40	42	46

VENT STACKS

The purpose of a vent stack is to conduct the products of combustion to a point of safe discharge (atmosphere). Forced draft design eliminates the need for a stack designed to create a draft. An offset type of stack connection to the stub vent on the boiler is preferred. A direct vertical connection can also be made when boiler vent outlets can withstand the direct vertical load of the stack, including the effect of wind and guy wires.

STACK CONSTRUCTION

The stack can be terminated several feet above the top of the roof. (State and local codes may govern the stack height above the roof.) If down drafts are unavoidable, the stack outlet can be provided with a ventilator. Minimum 12 gauge steel is recommended for stack sections. If the stack will be inaccessible, the use of a noncorrosive material (e.g., glass lining) should be considered.

A rain cap or hood should be used at the top of the stack to minimize the entrance of rain or snow.

BREECHING DIAMETER—SINGLE AND MULTIPLE BOILERS

BOILER HORSE-POWER	MINIMUM BREECHING DIAMETER (IN. OD)			
	A (IN.) 1 BOILERS	B (IN.) 2 BOILERS	C (IN.) 3 BOILERS	D (IN.) 4 BOILERS

VENT STACKS

(FIELD ERECTED CUSTOM-DESIGN COOLING TOWERS ARE AVAILABLE FOR USE WITH CASINGS OF MASONRY OR CONCRETE TO BLEND WITH BUILDING APPEARANCE)

SUPPORT ON TWO STEEL BEAMS EACH DESIGN FOR 1/360 SPAN OR MAX. 1/2 IN. DEFLECTION WHEN BEAM IS UNIFORMLY LOADED WITH 65% OF TOWER'S OPERATING WEIGHT

NOTES

1. Cooling towers cool water for reuse in refrigeration condensers or other heat exchangers. Standard ratings are in tons of refrigeration when cooling 3 gal/min per ton from 95 to 85°F with ambient air at 78°F wet bulb. Selection is based on performance at local outdoor design conditions. Frequently the local outdoor ambient wet bulb temperature used for selection is equal to or exceeded by 1% of summer hours.
2. Fans move air horizontally (crossflow) or up (counterflow) against water falling and wetting the fill or packing, to expose maximum water surface to the air. Reduced air flow reduces tower performance. Architectural enclosures should minimize obstruction to air flow.
3. Warm water is distributed at the top of the cooling tower by spray nozzles or basins with multiple orifices, and cooled water is collected in a basin at the bottom and pumped to condensers. Water is cooled by evaporating a very small portion. Water droplets may also be carried out by the air stream. Minerals and impurities present in all water increase concentration as pure water evaporates, so a little water is "bled" and chemicals are added to minimize scaling, corrosion, or biological fouling of condenser tubes. Towers for critical or large systems should be multicell for maintenance without shutdown.
4. Fan, motor, and water splashing noise may be a nuisance. Fan noise is reduced by two speed motors (about 8 dB at half speed, 15% power, and 60% capacity) and by intake and discharge attenuators (about 12 dB) with 10% power increase. Tower noise is louder in line with fan discharge and intake than in other directions. Each doubling of distance decreases noise about 6 dB. Barriers can reflect some noise from critical directions. Locate towers for free air movement. Avoid hot air recirculation, long piping from pumps and condensers, and inadequate substructures. Cooling towers should be located so that noise and water droplet carryover and fog at air discharge in cold weather will not be a nuisance. Consider seismic and wind load in anchoring tower to supports; towers are usually designed to withstand 30 psf wind load. Basins may be heated for winter use.

ENCLOSURE CONSIDERATIONS

Provide liberal wall openings on air inlet sides and mount tower so that air outlet is at top of enclosure. Consider effect of wind on nearby structure and enclosure to minimize hot, moist discharge air from being recirculated into inlet.

A = Height of enclosure above tower outlet. Minimize or extend shroud up from tower.

B = If enclosure walls have no opening, horizontal distance from tower inlet must increase greatly.

(Power for fan must be increased.)

Consult cooling tower manufacturer for minimum "B" dimension.

NOTE

Refrigeration machines move heat from one place to another: Kitchen refrigerators move heat from the storage compartment to the surrounding room. Air conditioners move heat from a room to the outdoors. The efficiency of air conditioning equipment is indicated by a seasonal energy efficiency rating (SEER), an index of the Btus moved per watt of electrical input energy. The higher its SEER, the more efficient and less costly a piece of equipment is to operate.

A large quantity of heat is required to boil or evaporate a liquid. This latent heat is the key to moving large quantities of heat with a small amount of refrigerant. To move heat from an area of low temperature to an area of high temperature (e.g., a building at 75°F to its surrounding environment at 95°F), the refrigeration equipment or air conditioner utilizes a fluid that boils and condenses within this range of temperatures and operating pressures.

REFRIGERATION CYCLE

TYPICAL BUILDING APPLICATION

NOTE

During a cooling cycle, an evaporator coil absorbs heat from the building interior. This heat is absorbed by the refrigerant as it changes from a low pressure liquid to a vapor. This low pressure refrigerant vapor is then drawn into a compressor, where it is compressed into a high pressure vapor at high temperature. The resulting high pressure refrigerant vapor is discharged into a condenser coil, where it gives up the latent heat absorbed in the evaporator and the heat added during compression and returns to a high pressure liquid state. This high pressure liquid is forced through an expansion device in which the pressure and temperature are rapidly decreased, making it possible for the evaporator to again absorb heat from the building.

See the pressure-enthalpy diagram on the following ACS page on Refrigeration and Heat Transfer Principles.

TYPICAL COOLING CYCLE TEMPERATURES AND PRESSURES

NOTE

The cooling cycle may be reversed to extract heat from a low temperature source, such as outside air, to heat a building. The basic equipment is unchanged with the exception of a four-way reversing valve and controls that permit the condenser and evaporator to exchange functions. A heat pump is more efficient than electric resistance heating because the only action required is pumping the refrigerant from a low pressure vapor to a high pressure vapor. The efficiency of a heat pump, measured as a coefficient of performance (COP), is a function of the temperature of the heat source.

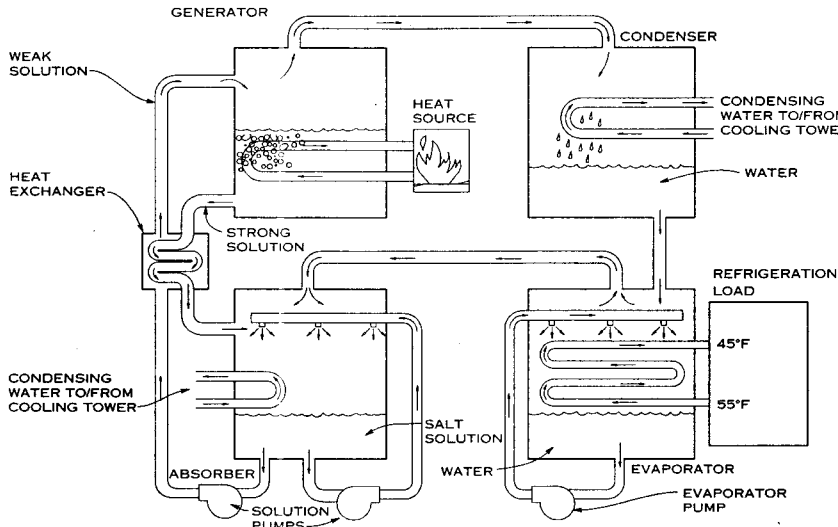

HEAT PUMP

Jeff Haberl, Ph.D., P.E.; Texas A&M University; College Station, Texas

NOTE
A large building air conditioning system typically includes a chiller, cooling tower, and one or more air-handling units. The arrangement shown at left offers substantial flexibility in equipment location and distribution. Chilled water is generated in a chiller (vapor compression or absorption) and circulated to air-handling units strategically located in the building. Condensing water from the chiller is circulated to an exterior cooling tower, where heat from the building is rejected to the outside environment. The chiller and air-handler(s) may be located virtually anywhere in the building and the cooling tower at an appropriate exterior location.

CHILLER AND COOLING TOWER

out the building. Cooling towers are typically installed in such large systems to increase efficiency. Air conditioning equipment transferring heat to 85°F water in a cooling tower will require less input energy to the compressor than the same equipment transferring heat to 95°F outside air.

In an absorption cooling cycle, cooling is generated by absorbing and desorbing water in a salt solution. Just as common table salt absorbs water on a damp day, a strong salt solution (e.g., lithium bromide) will draw water out of moist air when it is sprayed into an enclosed tank (absorber). If this moist air is connected to another tank that contains water that is evaporating, it will transfer water vapor to the absorber tank to replace the water that was drawn into the lithium bromide solution. Eventually, this strong lithium bromide solution becomes diluted and is pumped into a generator tank, where excess water is boiled off. The strong solution is then cooled in a heat exchanger and fed back into the absorber, where it can absorb more water. The water that was driven off in the generator is passed into a condenser, where it cools, condenses, and is then drawn back into the evaporator.

The refrigeration effect then draws off the (low pressure) evaporator at 45–55°F to produce chilled water. Since the absorption cycle accomplishes cooling without compressing a vapor, it can operate with reduced amounts of electricity as long as adequate amounts of heat are available for the generator and cooling for the condenser and absorber.

Because an absorption cooling cycle does not use a compressor, it is quieter and vibrates less than a vapor compression chiller. Absorption refrigeration is ozone friendly and can be configured to operate in systems with limited or no electricity (e.g., recreational vehicles).

NOTE

In large buildings it is impractical to move heat with air only because duct sizes would have to be excessively large;

therefore, a chiller (water tank) is added to the evaporator, and chilled water is circulated to air-handling units through-

ABSORPTION CYCLE

NOTE

Refrigeration cycles are analyzed with a pressure-enthalpy diagram such as the one shown here. Values for the heat absorbed and rejected by the refrigerant and for the work of the compressor can be read from the diagram once the operating temperatures of the refrigeration cycle are known. Following is a sample refrigeration calculation, in which points A, B, C, and D exhibit the following figures for pressure (psi), temperature (°F), and enthalpy (Btu/lb):

- A—310 psi, 130°F, and 47 Btu/lb
- B—90 psi, 45°F, and 47 Btu/lb
- C—90 psi, 45°F, and 109 Btu/lb
- D—310 psi, 170°F, and 122 Btu/lb

Refrigeration equipment is designed with a pressure-enthalpy diagram for the refrigerant being used. The refrigeration effect is calculated by finding the enthalpy difference from Point C to Point A in the diagram at left with this formula:

$$q_{\text{evaporator}} \text{ (heat absorbed in evaporation)} = h_c - h_a$$

In the example, then, $109 - 47 = 62$ Btu/lb.

The heat rejected in the condenser is calculated by finding the enthalpy difference from Point D to Point A:

$$q_{\text{condenser}} \text{ (heat rejected by condenser)} = h_d - h_a$$

In the example, $122 - 47 = 75$ Btu/lb.

The work required of the compressor is calculated by finding the enthalpy difference from Point D to Point C:

$$q_{\text{work}} = h_d - h_c$$

In the example, $122 - 109 = 13$ Btu/lb.

The coefficient of performance (COP), which is a figure of merit for refrigeration cycles, is calculated by comparing the heat absorbed in the evaporator to the work exerted by the compressor.

$$\text{COP} = \frac{\text{heat absorbed in the evaporator}}{\text{heat energy into the compressor}} = \frac{h_c - h_a}{h_d - h_c}$$

In the example, $62 \div 13 = 4.76$.

PRESSURE-ENTHALPY DIAGRAM FOR FREON 22

Jeff Habert, Ph.D., PE; Texas A&M University; College Station, Texas

GENERAL

Computers generate great quantities of heat in concentrated areas. To ensure proper operation, a precise temperature and humidity environment is required. The range of control may be as narrow as 72°F (±2°F) temperature and 50% humidity (±5%).

The air conditioning equipment should be able to meet the changing conditions created by relocation of equipment, facility expansion, and changes in heat output. Hot spots can result if flexibility is not built into the system.

DOWNFLOW AND UPFLOW SYSTEMS

Downflow systems are preferable for a number of reasons. Air is returned through the top of the unit and supplied out through the bottom into a raised floor, thereby permitting high quantities of air without disturbing the occupants. Perforated floor outlets can easily be moved, providing flexibility in room layout. The units themselves also form part of the floor grid and can easily be moved.

Upflow systems are used in areas where there is no raised floor (often the case in retrofit situations). They are also used in large rooms when the air is distributed by a ductwork system. Upflow systems are not as flexible as downflow systems for reorganizing equipment in a room.

REUNDANCY

All systems should be designed with redundancy to provide full, continuous cooling. The degree of redundancy should be weighted against the consequences of downtime of the equipment. A minimum of 25% redundancy is recommended but 100% may be warranted, depending on future expansion and the degree of backup required.

VAPOR BARRIERS

It is difficult and costly to maintain a computer room at a relative humidity of 50% (±5%) throughout the year without a vapor barrier. In addition, room partitions should extend beyond the false ceiling to help prevent migration of moisture to and from adjoining areas.

TYPES OF SYSTEMS

Spot coolers: Direct forced air, located at ceiling in return air plenum or on floor; short ducting can be used. Capacity: 1 to 3.5 tons.

Local units for small systems: Forced air can be used for direct spot cooling, ducted or for pressurized raised floor. Capacity: 3 to 5 tons.

Local units for large systems: Forced air can be used with pressurized raised floor installation. Capacity: 6 to 25 tons.

Mainframe cooling systems: Independently generated chilled water circulated to computer's coolant distribution unit (CDU), an intertwined coiled heat exchanger that distributes special coolant directly to the computer in a closed loop system. Capacity: 2.5 to 15 tons.

METHODS OF HEAT REJECTION

Self-contained air-cooled: Uses air within building return air plenum; limited to small capacity units.

External air-cooled: Uses outdoor condenser unit; refrigerant lines generally are limited to 100 ft above, 30 ft below, or 200 total ft from computer room to outdoor unit.

Water-cooled: Uses closed loop condenser water pumped to an external cooling tower to remove heat from condenser within computer room fan-coil unit. Distance from cooling tower to computer room can be longer than that in an external air-cooled system.

Glycol-cooled: Uses closed loop glycol to carry rejected heat to external dry cooler or cooling tower, which allows greater separation of computer room from outside air. With additional coils, the system can provide "free cooling" during colder weather. This system is preferred in areas where ambient temperature is below -10°F.

Chilled water: Chilled water is pumped from a remote chilled water plant to local fan-coil unit.

Combination unit: May use two or more means of heat rejection to service the system during certain hours of operation or as a backup in case of primary system failure.

PLANNING ISSUES

1. Evaluate availability of building services and systems, mechanical chases, and electrical power capacities.

2. Determine the overall heat load and plan size of system with client and engineer. Design for built-in redundancy with multiple circuits.
3. Use qualified engineers to design and engineer the systems and to supervise testing and certification.
4. Detail the construction of walls, ceiling, and floors to provide a complete vapor seal and adequate airflow.
5. Evaluate energy efficiency ratios of various kinds of proposed equipment.
6. Select a system with high reliability and low noise level.
7. Do not ventilate the space when unoccupied.

RULES OF THUMB FOR COOLING LOAD ESTIMATES

1. Room design conditions
 - a. Temperature: 72°F (±2°F)
 - b. Relative humidity: 50% (±5%)
2. Sensible heat ratio: 0.85-0.98
 - a. Sensible heat gain: 115-200 Btu/sq ft
 - b. Total heat gain: 120-240 Btu/sq ft
3. Load density (SF/ton): 50-100
4. Air quantity (CFM/ton): 600-900
5. Ventilation rate (CFM/person): 15-20 maximum
6. Humidification (lb moisture/100 CFM of outside air): 3

GENERAL

A fan-coil unit is the water-to-air heat exchange component of an all-water or air-water HVAC system. In an all-water system, all space conditioning needs are handled by one or more fan-coil units. In an air-water system, the fan-coil units carry the majority of space loads, while a separate central air system handles ventilation requirements. In effect, a fan-coil unit is a small, packaged air-handling unit with a motor and fan, water coil for cooling and/or heating, air filter, condensate pan, housing, and controls. Fan-coil units are available for exposed, recessed, or concealed installations and are located in or adjacent to an occupied space. A short length of ductwork may be used with concealed units to transfer supply/return air to or from the fan-coil housing.

Controls generally are an integral part of the fan-coil package, and each unit establishes a thermal zone. A typical control sequence permits intermittent or continuous air circulation and limited control of airflow; the majority of load control is achieved through operation of a water control valve at the coil. Thermostats are typically integral with the unit. Maintenance of the components occurs in the occupied space, so convenient access must be considered during the design process. Provision for drainage of the condensate from latent cooling must also be addressed.

A complete all-water fan coil system consists of several fan-coil units (one for each thermal zone), a chiller, an air-cooled condenser or cooling tower, a boiler (if central heating is required), a piping distribution network, and necessary circulation pumps. Two-, three-, and four-pipe configurations are used for the water distribution network. In a two-pipe system, each fan-coil unit is connected to a single supply pipe and a single return pipe. The entire system operates in either cooling or heating mode; the supply pipe provides either cold or hot water. This arrangement is economical, but not operationally flexible because one space cannot be heated while another space is cooled.

In a four-pipe system, each fan-coil unit is connected to two supply pipes (one hot, one cold) and two return pipes (one hot, one cold). Independent heating and cooling water networks permit complete flexibility of operation from zone to zone. A four-pipe system is more expensive to install than a two-pipe system. A three-pipe system is a hybrid arrangement that provides two supply pipes to each fan-coil unit (one hot and one cold) but only a single return pipe. Hot and cold return water streams are mixed and returned to the chiller and boiler at some intermediate temperature. Although operationally flexible and cheaper than a four-pipe system, a three-pipe system is very energy inefficient.

Fan-coil units may be installed as part of an air-water HVAC system. In such a system the components noted above would be supplemented with an independent central air supply system (with air-handling units, ductwork, and air supply devices) that provides ventilation air. Often the quantity of supply air is small enough that it can be exhausted without need for a return air system. Although fan-coil units can be provided with outside air intakes (if installed at a wall), adequate control and conditioning of outside airflows in such a configuration is problematic.

COMPONENTS OF A FAN-COIL UNIT

NOTE

High-rise fan-coil units are available for stacked, vertical installations. Use of a stacked configuration can minimize the amount of piping required to connect the units to the distribution network and simplify collection of condensate. In this configuration the units are normally furred into the walls of the rooms being served (often in a corner).

WASTE HEAT SOURCES FOR HEAT RECOVERY SYSTEMS

1. Flues of fuel burning heating boilers and furnaces.
2. Refrigeration systems hot gas and condenser water.
3. Exhaust gases from diesel engine and gas turbine driven electric power generating equipment.
4. Cooling water from diesel engine cooling jackets and air compressor aftercoolers.
5. Exhaust steam and condenser water from steam turbine driven electric generators and refrigeration units.
6. Exhaust air from toilet rooms, mechanical equipment rooms, transformer vaults, kitchen range hoods, laundries, laboratory hoods, hospital operating rooms, locker rooms, shower rooms, and swimming pools.
7. Wastewater from washing machines and dishwashers.
8. Internal heat gain from lights, people, and appliances.
9. Heat recovery systems may consist of a direct or indirect heat transfer from airstreams, liquids, refrigerants, water, or gases.

APPLICATIONS FOR WASTE HEAT RECOVERY SYSTEMS

1. Building space heating.
2. Preheating ventilation outdoor air intake.
3. Air conditioning systems supply air reheat.
4. Preheating domestic hot water and boiler feed water.

NOTE
Counterflow, indirect air-to-air sensible heat transfer. No leakage between airstreams. Alternate evaporation, condensation, and capillary migration of fluid in porous wick lining of tubes. Coil tilting or fact and bypass damper control. Efficiency 50-70%. Modular sizes to 54 in. x 138 in. x 8 rows deep.

HEAT PIPE

DUAL CONDENSER WATER CHILLER

NOTE
Sensible heat absorbing aluminum or stainless steel mesh. Dessicant impregnated for latent heat transfer. Leakage 4-8% between opposing airstreams. Added purging section reduces cross-contamination to less than 1%. Speed variations or face and bypass damper capacity control. Efficiency 70-80%. Sizes to 144 in. diameter.

THERMAL WHEEL

NOTE
Heat transfer from cooled to heated areas. Individually controlled heat pump terminal units with air and water coils. Auxiliary heater operation when heat loss exceeds heat gain. Heat rejector operation when heat gain exceeds heat loss. Tank stores excess capacity. Loop water 60-90°F.

WATER LOOP HEAT PUMPS

NOTE
Indirect sensible heat transfer between remote airstreams with no cross-contamination. Exhaust airstream coil construction to suit application. Antifreeze fluid for low air temperatures. Bypass valve temperature control. Computerized equipment selection. Efficiency 50-70%. Modular coils to 20,000 cfm.

RUNAROUND COILS

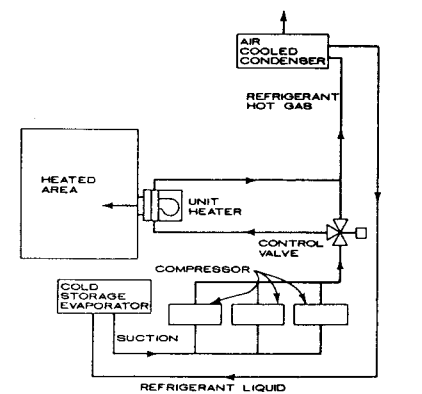

NOTE
Counterflow, direct air-to-air type heat exchanger. Sensible heat transfer only. No leakage between airstreams. Corrugated aluminum or stainless steel construction. Washdown spray manifold for dirty exhaust airstreams. Bypass damper temperature control. Modular sizes to 10,000 cfm. Efficiency 60-80%.

PLATE TYPE HEAT EXCHANGER

NOTE
Direct flue gas to feed water heat transfer for high pressure steam boilers. Boiler flue gas at 500°F leaving economizer at 325°F, heats feed water from 200 to 248°F. Mixing valve maintains minimum stack temperature leaving economizer to prevent moisture condensation in stack.

BOILER FLUE ECONOMIZER

NOTE
Rejected heat from cold storage refrigeration system used to heat occupied areas. For heating, hot gas refrigerant from compressor discharge flows through space heating units to extract heat. When heating is not required, hot gas refrigerant flows directly to air cooled condenser for heat rejection to outdoor air.

REFRIGERANT HOT GAS

Syska and Hennessy, Consulting Engineers: New York, New York

GENERAL

Although shelter from the weather and protection from harsh climates are historic reasons for constructing buildings, the mere act of building does not in itself result in desirable and acceptable interior environments. Thus, climate control is a critical performance attribute of a successful building, and the creation of a comfortable, healthy environment for building occupants is an important goal of the building design process.

An HVAC (heating, ventilating, and air conditioning) system is a requirement in virtually all types and sizes of buildings. Second only to structural systems, HVAC systems represent a technical area of design, which must be generally understood and properly coordinated during the design process. HVAC systems have a significant impact on the budget and space of a building project because they

1. represent a substantial percentage of the construction budget for most building types
2. can consume up to 10% of the floor area of a building
3. reach into and affect aesthetically most building spaces
4. contribute greatly to building energy use and operating expense
5. account for the majority of occupant complaints

The design of HVAC systems is not greatly influenced by building code requirements, except in relation to energy efficiency, ventilation, and central plant equipment safety. Nonetheless, HVAC systems have a major impact on occupant satisfaction, on building construction and operating costs, and often on building layout and spatial efficiency. Lack of specific code requirements for many system aspects makes the architect's role in the design process critical to the successful incorporation of HVAC systems.

Building occupant and owner expectations demand that a climate control system do a good to excellent job of controlling space temperature, interior relative humidity, air distribution (air speed and patterns), and indoor air quality. In many situations such demands can only be met through design of an active (mechanical) HVAC system.

The ASHRAE (American Society of Heating, Refrigerating, and Air-Conditioning Engineers) definition of an HVAC system, in fact, describes a system that must be able to simultaneously control the temperature, relative humidity, speed, and quality of air in occupied spaces. These four factors generally (but not exactly) overlay the factors that define thermal comfort and indoor air quality—mean radiant temperature (MRT) being the critical exception.

Increasing demands for control of indoor air quality tend to require the design and installation of a quality HVAC system. Of the three primary means of mitigating indoor pollutants—source control, filtration, and dilution—dilution (through ventilation and exhaust) and filtration (through system and equipment selection) are directly related to HVAC system design, installation, and operation.

SYSTEM TYPES

Climate control systems may be classified as either active or passive in nature. Passive systems use no purchased energy resources, normally are assembled of "architectural" building elements doing double duty (such as glazings, walls, floors, finishes), and require superb design coordination. See the discussion of passive climate control systems in chapter 18 of *Architectural Graphic Standards*.

Active climate control (HVAC) systems use purchased energy resources and employ task-specific, single-purpose elements (such as pumps, fans, ducts, and diffusers). Although engineering consultants usually design HVAC systems, it is wise to coordinate their work with architectural design efforts. Active systems are the focus of this chapter of *Architectural Graphic Standards*.

HVAC systems are categorized by scale and by means of energy transfer to and from occupied spaces of a building:

A LOCAL SYSTEM serves only a single space, and all of the system components are usually located in or directly adjacent to the space being conditioned.

A CENTRAL SYSTEM serves multiple spaces, and the major components are usually located in a dedicated mechanical room or rooms.

A DISTRICT SYSTEM serves multiple buildings, as in a campus or central business district heating-cooling loop, with major components located in a convenient, dedicated plant.

CENTRAL SYSTEMS

Central systems are further categorized by the means of heat transfer used to convey heat to and from the spaces served by the system. Two primary media are used for this purpose: water and air. Water is a very effective means of transferring heat, requiring substantially less volume to move a given quantity of heat than is possible with air as a medium. For the same heating or cooling load, the water distribution container (pipe) size will be several times smaller than an equivalent air distribution container (duct). On the other hand, air distribution is convenient, as the air being used to transport heating or cooling from a central location can simply be dumped into the space. Water distribution systems require some type of terminal device to exchange heat between the water and the air in the space to be cooled.

Those central systems that use only air to distribute heating and cooling effects to the occupied spaces are called all-air systems, which require a ductwork distribution tree. An all-water system uses only water to supply and remove heat from the spaces; such a system requires a piping distribution network. Air-water systems deliver both air and water to the occupied spaces and require both ductwork and piping distribution networks:

Central systems are secondarily classified by the location of the primary comfort control mechanism relative to the occupied spaces. In a number of systems, control resides at the air-handling unit, which makes changes in zoning and distribution layout difficult or impossible. Other systems use control mechanisms (terminals) located adjacent to occupied spaces, which provide greater flexibility of change but require distribution of more equipment throughout the building, often in tight or hard-to-reach places.

SYSTEM COMPONENTS

A number of components are required for the operation of a typical HVAC system. The components of a local system are generally packaged into a single unit that is installed through a wall or roof; air supply is usually introduced to the space directly from openings in the unit. The implications of installing potentially noisy mechanical equipment in or directly adjacent to an occupied space must be considered when selecting a local HVAC system.

Central system components are distributed throughout a building, with a range of equipment choices available for most systems. The typical central system requires an air-handling unit, ductwork, air supply and return devices, a chiller, a boiler, an exterior condenser, and controls. Some of the many options for locating these components are illustrated in the schematic diagrams on this page. More detailed system schematics for the most common central HVAC systems are included elsewhere in this chapter of *Architectural Graphic Standards*.

It is sometimes helpful to organize HVAC system components into subsystems, that is, source, distribution, delivery, and control components. Source components involve the generation of a heating or cooling effect and typically include chillers (vapor compression or absorption), boilers (electric, gas, oil, coal), cooling towers or air-cooled condensers, heat pumps, and perhaps solar collectors.

Distribution components involve transfer of a heating/cooling effect from the source to occupied spaces and typically include ductwork, piping, air-handling units (with fans, filters, coils, and accessories), pumps, stand-alone fans, and air terminal units. Delivery components are used to introduce a heating-cooling effect into the occupied spaces and typically include baseboard radiators, unit heaters, convector cabinets, fan-coil units, induction units, diffusers, and radiant panels.

DESIGN ISSUES

The design of an HVAC system should follow a process similar to that used for overall building design. The first steps in the design process are nontechnical and generally independent of the system solution eventually chosen. Active involvement of the architect in these first steps is critical to a successful design. Some key steps in the process are discussed below.

DESIGN INTENT

HVAC system design should begin with a clear and explicit statement of what the system is expected to do. Design intent should ideally be defined during the programming phase of a project but certainly no later than the early stage of schematic design. Design intent should examine the operation of the HVAC systems under all possible conditions (weekdays, weekends, emergencies, predictable renovations, and the like). The process of defining the intent will lead to explicit design criteria—measurable targets for system performance—that can be used to select an appropriate system.

ZONING

An HVAC zone is an area of a building (not necessarily coincident with a room or rooms) that requires a separate controller in order to reasonably provide conditions amenable to thermal comfort. Such control is typically provided by a thermostat that senses room air temperature. Thus, each thermal zone has its own thermostat.

Ideally, any area of a building that responds to loads differentially across time from other building areas should be considered for separate control. Such differential response usually is caused by the timing of loads, with solar radiation, occupant, and equipment loads affecting this timing. For example, an office with east-facing glazing should not be controlled from a thermostat in an office (even if adjacent) with south-facing glazing. A conference room should not be controlled from an office, even if solar exposures are the same, as the occupancy schedules are so different.

Zoning is a critical part of the HVAC system design process and should involve the active participation of the architect. Using too many zones wastes money, while too few cause discomfort. Establishing appropriate zones is as much a qualitative as a quantitative process and requires a clear understanding of building functions and owner expectations. Zones are so critical to HVAC system success that many systems are defined primarily by their zoning capabilities. As zoning depends on building layout, it should occur during schematic design.

COMPARISON OF MANAGEMENT, OPERATION, AND DESIGN PROBLEMS IN COMMERCIAL BUILDINGS

BASIS OF PROBLEM	RELATIVE FREQUENCY
Heating, ventilating, and air conditioning	5.4
Elevators	2.7
Building design	1.5
Loading docks	1.2
Indoor air quality	1.0
Cleaning services	1.0

NOTE

Relative frequency suggests that problems with HVAC systems are twice as prevalent as problems with elevator systems and five times as prevalent as problems with cleaning services.

HVAC SYSTEM SPACE REQUIREMENTS AS A PERCENTAGE OF GROSS BUILDING FLOOR AREA

GROSS FLOOR AREA (SQ FT)	DOMICILE-RELATED OCCUPANCIES (%)	INSTITUTIONAL OCCUPANCIES (%)	ASSEMBLY-BASED OCCUPANCIES (%)	LABORATORY OCCUPANCIES (%)
10,000	6	8	9	11
50,000-100,000	4	6	7	10
500,000	3	4	5	8

NOTE

The values for HVAC systems in this table include space for central equipment (chillers, boilers, pumps) and air circulation equipment (fans). HVAC space requirements tend to

SYSTEM SELECTION

Properly done, HVAC system selection can be a complex process. Normally, several system types would function adequately in any given building application. Careful matching of system characteristics to design criteria can help achieve the best match for the system intent. The earlier in the design process a system can be selected, the greater the opportunity for systems coordination.

System characteristics that should be considered during the selection process include life-cycle cost (including purchase, installation, and operating costs), energy consumption, space (and volume) requirements, noise, vibration, locational flexibility, operational flexibility, adaptability to changes in occupancy and/or room layout, ventilation capabilities, smoke control capabilities, aesthetics, reliability, maintainability, appropriateness to owner/operator personnel resources, and ability to provide thermal comfort. The relative importance of these criteria, as well as system capabilities, will vary from project to project. Use of a project-specific, weighted selection matrix can assist in the selection process.

SYSTEM DESIGN

The specifics of HVAC system design are normally assigned to an engineering consultant with appropriate expertise. The detailed design, normally conducted during the design development phase, involves selection of a number of manufactured equipment items (such as chillers, cooling towers, air-handling units, diffusers) to meet load and performance requirements, as well as design of numerous field-fabricated elements (such as ductwork and piping networks) to connect and support the major equipment items.

In a typical building, most of the HVAC system components are hidden from view behind mechanical room walls or above suspended ceilings. Thus, detailed design is driven by considerations of functionality and economics. Two exceptions to this "no-see" situation are the air supply and return devices (and/or water terminal units) and the exterior condenser.

COMMISSIONING

Commissioning is a systematic process of ensuring that building systems are designed, installed, and operating so they will meet design intent. The dynamic and complex nature of HVAC systems, as well as their direct impact on occupant satisfaction and building operating costs, makes them a good candidate for commissioning.

The commissioning process typically involves functional testing of equipment and performance testing of systems and system interactions. For complex buildings or systems, commissioning may involve peer review of design concepts and solutions. Whatever the scope of commissioning, planning for this activity should begin as early in the design process as possible.

SAMPLE SYSTEM SELECTION MATRIX

SELECTION CRITERION	RELATIVE WEIGHT	SYSTEM	
		#1 RATING/POINTS	#2 RATING/POINTS
First cost	9	5/45	8/72
Space requirements	10	7/70	8/80
Energy use	7	9/63	5/35
Reliability	6	8/48	7/42
Noise	8	7/56	4/32
Aesthetics	4	10/40	8/32
Overall evaluation		322 points	293 points

DESIGN COORDINATION

HVAC systems may place substantial space and volume demands on the design process and tend to interact with virtually all other building systems (including envelope, electrical power, lighting, fire protection, acoustical, circulation, data). Key activities for coordinating HVAC and other building systems include (but are not limited to) the following:

1. Ensuring HVAC system design intent supports overall building design intent
2. Coordinating HVAC zones with other zones, such as fire protection and alarm, lighting, and smoke control
3. Locating major equipment components to minimize distribution length and size and to minimize negative aesthetic impacts
4. Locating major equipment components to minimize negative impacts on room acoustics, circulation patterns, and building flexibility
5. Coordinating ductwork with elements of other systems, such as structural beams and columns, lighting fixtures, and plumbing and fire protection pipes
6. Locating terminal device (such as VAV or mixing boxes) and control devices (such as valves, dampers, and actuators) so they are accessible for regular maintenance
7. Giving more than rudimentary consideration to selection of air supply and return devices, such as diffusers, registers, and grilles. (These devices can have a dramatic effect on thermal and acoustical comfort and on aesthetics.)
8. Coordinating system controls with design intent. (Although controls are highly technical in implementation, failures are often conceptual.)
9. Providing operations and maintenance manuals and procedures to assist the owner in running the HVAC system

HEAT TRANSFER UNDER SUBFLOOR

HEAT TRANSFER IN CONCRETE TOPPING SLAB

HEAT TRANSFER THROUGH CONCRETE UNDERLAYMENT

HEAT TRANSFER IN SLAB ON GRADE

HEAT TRANSFER AT SUSPENDED FLOOR

HEAT TRANSFER THROUGH CEILING

NOTES

1. Spacing for grid pipes is closer (3 to 4 in.) at exterior walls than in interior spaces (12 to 18 in. apart).
2. Grid pipe layouts have a lower pressure drop than serpentine pipe layouts. Serpentine layouts are generally

easier to install and less costly to fabricate, but due to the higher pressure drop they are more expensive to operate.

RADIANT HEATING LAYOUTS

GENERAL

Radiant heating systems transfer heat from hot water tubing (or electric cables) embedded in the floor or ceiling to a medium that will distribute heat to the specified space. The tubing or cables are laid out to maximize heat distribution to the areas of greatest heat loss. The choice of hot water or electric cable heat is made based on installation, energy, and total life-cycle costs and code constraints. Consult a mechanical engineer.

For appropriate applications, properly designed and operated radiant heating systems will provide greater comfort at lower operating costs than other heating systems because of the inherent nature of the human body's thermal functions. About 70% of the body's heat is transferred by radiation (via electromagnetic waves, like light), 25% by convection (via air or water), and 5% by conduction (via physical contact).

In terms of overall system configuration, a radiant floor, wall, or ceiling is equivalent to a radiator, convactor, or any other terminal heating element. The primary caveat is that a suitable control system must be provided to ensure that floor surface temperatures do not rise above 75° F or, if ceiling systems are used, above 120° F. Thermostats for radiant systems can generally be set several degrees lower for heating than thermostats for other types of systems. Finish floor should not be of a thermal insulating material; ceramic tile or wood flooring would be suitable.

Alfred Greenberg, P.E., C.E.M.; Murray Hill, New Jersey

HVAC SYSTEM FUNDAMENTALS

In the broadest sense, the term "air conditioning" means that, to the extent required for a particular space condition, a quantity of air must be

1. Mixed with the required amount of outside (fresh) air.
2. Filtered to remove specified amounts of particulate and/or gaseous elements.
3. Heated and/or cooled as conditions dictate and as directed by an appropriate temperature control system.
4. Humidified or dehumidified to meet space requirements.
5. Under certain conditions, ionized, ozonated, or otherwise treated to provide specific space conditions.
6. Delivered to the air-conditioned spaces and distributed in a quiet, draft-free manner.

Conditioning of the air is basically performed within an enclosure called an air-handling unit (shown in its most generalized form). The components need not be located within the central air-handling unit to perform their functions effectively. Space limitations, the operating and control results desired, and energy optimization considerations may affect where the components are situated.

Sources of electric power, heating and cooling media, water, steam, natural gas, etc. are often remote from the air-handling unit. However, in packaged air-conditioning equipment such as air heating units, room air conditioners, and many rooftop units, the heating and/or cooling "plant" is part of the package.

To the extent that an air-conditioning system does not provide all of the functions described above, it may not be furnishing the total space air conditioning required for optimum comfort and health. The tendency to use the term "air conditioning" synonymously with "cooling" should be altogether discouraged. It falsely implies that the other functions of air conditioning, such as proper filtration and humidification, are less important to total health and comfort and may be eliminated.

The types of air-conditioning systems used and the selection and organization of their components are the most critical and complex elements in the proper design of an HVAC system. For the optimum health, safety, and comfort of occupants and materials within the air-conditioned spaces, and to ensure the optimum life-cycle economics for a particular installation, this process should be entrusted only to experienced and knowledgeable engineers.

ALL-AIR SYSTEMS

In an all-air system, the heating and refrigerating plants may be located in a central mechanical room some distance from the conditioned space or may be contained within the all-air system as packaged units in the air-conditioned spaces or on the roof. The air-handling unit is designed to mix outside and return air as desired, then to filter, heat, cool, and humidify the air before it is delivered to conditioned spaces. It may also exhaust portions of the return air based on how much return air is brought in.

Air-conditioning functions do not necessarily occur within the air-handling unit. Depending on the specific design criteria and space conditions, some air-conditioning elements may be remote from the air-handling unit.

Some common all-air systems are single-duct, constant or variable volume airflow; dual duct (rarely used); multizone; single-duct with powered terminal and either constant or variable volume airflow; and a single-duct system with self-contained airflow volume controls and thermostats in each diffuser in the conditioned space.

SPATIAL REQUIREMENTS

The dimensions between system components shown in the accompanying illustration are the minimum required for proper inspection and maintenance of walk-in units (units with air quantities of 15,000 cu ft/min. or more). Spacing for smaller units may be somewhat less but must allow adequate access for inspection and maintenance.

All spaces between unit components should have hinged access doors designed to prevent air leakage when the doors are closed. For smaller units, the entire panel between components should open. For walk-in units, access doors should be a minimum of 30 x 60 in. Access doors should be designed to open from the inside.

The floors of the sections between components should be pitched to facilitate drainage of liquids that may form. Light switches and electronic controls should be located on the outside of the unit enclosures. If a fan is situated on the inside of a unit enclosure, the return air inlets must have safety screens. Walk-in unit interiors should have permanent vapor-proof and explosion-proof lighting.

NOTES

1. Minimum outside air damper: usually two positions.
2. Variable outside air damper: closed when only minimum outside air is desired (for example, when outside air temperature is extremely high or low). Designed to open in response to the capability of outside air to contribute to a building's heating or cooling needs. Exhaust and return air dampers are controlled to operate in accordance with the setting of the variable outside air damper.
3. Preheat coil (PHC): required only if the temperature and distribution of the return air mixture could cause freezing temperatures within the casing.
4. Air-handling unit (AHU): may be field- or factory-fabricated. Pitch the floor of the AHU casing between components as required and provide piped floor drains to remove any moisture that develops.
5. Direct expansion coil (DXC): cooling coil may be a DXC if refrigerant is used instead of chilled water.
6. Humidifier (H): may use steam or water as the humidification medium.
7. Reheat coil (RHC): used in the air-handling unit only when a fixed discharge air temperature is to be supplied to all areas served by the duct system. If different spaces require varying temperatures, a separate reheat coil may be placed in each duct serving a different temperature zone.

COMPONENTS OF A BASIC ALL-AIR SYSTEM

NOTES

1. The primary factors in determining spatial requirements for a basic HVAC system are space for proper air flow, thermodynamic heat transfer, and service and maintenance.
2. The net cross-sectional area (in sq ft) of the interior of an air-handling unit should be at least equal to the total air supply (measured in cu ft/min) divided by 500.
3. The aspect ratio of the casing of the air-handling unit should fit the space available, considering maintenance requirements and the ability of personnel to enter the unit to perform required tasks.
4. A single-width single-inlet (SWSI) fan is shown. If a double-width, double-inlet (DWDI) fan is used, it may be incorporated into the air-handling unit casing. This arrangement generally decreases the overall length of the system and the height required at the fan; however, the required width at the fan will increase.

GENERAL SPATIAL REQUIREMENTS FOR ALL-AIR SYSTEMS

Air-handling units may be located anywhere that suits building space conditions and offers proximity to the conditioned spaces. However, careful consideration must be given to the outside air duct location and the noise and vibration that will emanate from the fans.

Alfred Greenberg, P.E., C.E.M.; Murray Hill, New Jersey

TEMPERATURE AND HUMIDITY CONTROLS FOR ALL-AIR SYSTEMS

CONTROLS FOR ALL-AIR SYSTEMS

The typical sequence of operation for an air-handling system is outlined here:

1. When the supply air fan has been turned on but the motor is not yet turning, minimum outside air damper D_1 and exhaust air damper D_2 open, the latter to its minimum position to match the amount of incoming air. The exhaust air and return air dampers are interlocked: When the exhaust air damper is shut, the return air damper is fully open; when the exhaust air damper is fully open, the return air damper is minimally open.
2. When dampers are in proper open positions, the supply air fan starts running and the return air fan is turned on, either manually or electrically. This sequence is necessary to prevent the supply air fan from sucking air out of the air-handling unit and collapsing the casing and to keep the return air fan from blowing excess air into the casing and "bursting the bubble."
3. Space thermostat T_1 and humidistat H_1 take control of the system. If humidification is required, H_1 controls the operation of control valve V_3 at the humidifier in the air-handling unit. If heating is required, T_1 controls the operation of reheat coil control valve V_4 . If cooling is needed, T_1 controls the cooling coil control valve V_2 . At this time, control valves V_1 , V_3 , and V_4 are closed. Control valve V for the preheat coil is controlled by a thermostat on the discharge side of the coil.
4. Many control system variations are possible to improve comfort and conserve energy. In one commonly used variation, an "economizer cycle" is established in which an outdoor thermostat is added to the control system. This permits the system to decide whether T_1 should open the heating or cooling coil control valve damper to initiate heating or cooling, depending on the season, or whether heating or cooling can be accomplished by opening variable outside air damper D_3 proportionally.
5. On a balmy spring or autumn day, it may be possible for total space conditioning needs to be supplied by fully open outdoor air dampers. In this case, damper D_1 would be fully open for exhaust air and fully closed for return air. D_2 and D_3 would be fully open, and V_1 through V_4 fully closed.

DIRECT-EXPANSION SYSTEMS

The term "direct expansion" means that a chemical refrigerant is used in the refrigeration circuit to remove heat and reject it, usually to the outdoors. Direct-expansion systems come in "cooling only" mode or in specially designed heat pumps, which can furnish either heating or cooling.

The most common direct-expansion system is the packaged unit installed through the wall or in a window. These can also be floor-mounted in or out of the air-conditioned space or located on the roof. Another type of direct-expansion system is the "split" system, in which the heat rejection components of the condenser and compressor are packaged separately and can be located remotely from the evaporator and fan, which must be in the air-conditioned space. The two subassemblies, which are attached to the system with refrigerant piping, may be as close as on opposite sides of a wall or up to 100 ft away.

DIRECT-EXPANSION SYSTEM

NOTES

1. Valves A and B are closed during the heating season.
2. Valves C and D are closed during the cooling season.
3. A majority of existing buildings with central heating and cooling use the two-pipe distribution system.

ALL-WATER SYSTEM

ALL-WATER SYSTEMS

The term "all-water system" is a misnomer, since all air-conditioning systems furnish conditioned "fresh" air to the air-conditioned spaces. All-water systems may have fan coil or radiant panel terminal units with separate all-air systems to supply the "fresh" air. "Fresh" air furnished through openings in the walls behind the fan coil units is not considered properly conditioned because most fan coil units are not designed to provide satisfactory filtering and humidity control or to prohibit the entry of outdoor noise.

In the vast majority of all-water systems, water is used to provide either heating or cooling through a two-pipe distribution system. A freeze protection chemical can be added to some systems when needed. When clients demand simultaneous heating or cooling everywhere, the piping will be either a three- or four-pipe distribution system and the heating and cooling plants must be able to run at all times. The three-pipe system is seldom used because it is difficult to operate properly and to run efficiently.

GENERAL

The process of removing heat from a refrigerant is called condensing. It is during the condensing process, in a refrigerant cycle, that the refrigerant rejects heat absorbed during the evaporation and compression processes, is reconverted to liquid state, and becomes ready to repeat the cycle.

To convert the refrigerant from gaseous to liquid state heat exchangers called condensers are used. Air-cooled and water-cooled condensers are the predominant types used in the building construction industry.

In the less than 50-ton-capacity range, water-cooled condensers can be used where water sources such as a lake, river, or well are available for once-through use without recirculation of water.

Dry coolers of up to 25-ton capacity are normally used where water is scarce, as well as in computer rooms and other special air conditioning applications. In areas where the winter ambient temperature is below the water freezing temperature, glycol is added to the condenser water. The heat rejection to the outdoor air is by sensible heat transfer, which depends on the dry bulb temperature of the air.

In refrigeration systems larger than 50-ton capacity, water-cooled condensers are used to cool the recirculating condenser water. Both the closed circuit evaporative cooler and the cooling tower operate on the principle of evaporative cooling, which depends on the wet bulb temperature of the air. Closed circuit evaporative coolers are available in sizes up to 300 tons and are used when contamination of the condenser water by direct contact with outdoor air cannot be tolerated.

Use of a cooling tower is generally acceptable in most installations in the building construction industry. The temperature of the water leaving the cooling tower is about 7 to 10°F above the wet bulb temperature of the outside air entering the tower. In cold winter climates the cooling towers can be used directly to make chilled water and thereby eliminate mechanical refrigeration.

NOTE

For water-cooled condensers using city, well, or river water, the return is run higher than the condenser so that it is always full of water. Water flow through the condenser is regulated by a supply line control valve, which is actuated from condenser head pressure control to maintain a constant condensing temperature with variations in load. City water systems usually require check valves and open sight drains, as shown.

WATER-COOLED CONDENSER

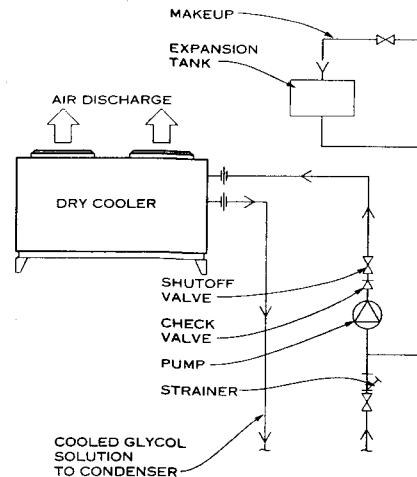

BLOW-THROUGH TYPE

The condenser water is circulated inside the tubes of the unit's heat exchanger. Heat flows from the condenser water through the heat exchanger tubes to the spray water outside, which cascades downward over the tubes. Air is forced upward through the heat exchanger, evaporating a small percentage of the spray water, absorbing the latent heat of vaporization, and discharging the heat to the atmosphere.

The remaining water falls to the sump to be recirculated by the pump. The water consumed is the amount evaporated plus a small amount that is bled off to limit the concentration of impurities in the pan.

The condenser water circulates through the clean, closed loop of the heat exchanger and is never exposed to the airstream or the spray water outside the heat exchanger tubes.

NOTE

In the dry cooler, the condenser water-glycol solution is circulated inside the finned tubes of the dry cooler's heat exchanger. Heat flows from the condenser water-glycol solution through the heat exchanger tube walls to the fins. Propeller fans draw air over the fins, and the heat from the fins is transferred to the air passing over them.

An aquastat that senses the temperature of the solution as it leaves the dry cooler cycles the fans to maintain the desired temperature.

DRY COOLER

NOTE

Water flows from the pump to the tower basin and is discharged under pressure to the condenser and back to the tower, where it is cooled through the spray deck. Since it is usually desirable to maintain condenser water temperature above a predetermined minimum, return water is partially bypassed around the tower through a control valve to maintain desired supply water temperature.

In this condenser water system, air is continuously in contact with the water. Special consideration for chemical treatment and allowance for impurities, scale, and corrosion in the condenser and piping system is then required.

The amount of water flow required depends on the refrigeration system used and the available temperature of the condenser water. Lower condenser water supply temperature results in increased refrigeration machine efficiency.

COOLING TOWER

DRAW-THROUGH TYPE

NOTE

Evaporative condensers combine the functions of a cooling tower and a water-cooling condenser. Latent heat transfer is more effective as a means of heat dissipation. This permits a smaller sized unit than an equivalent tonnage air-cooled unit and considerable energy savings in fan horsepower.

Installations can be either indoors in an equipment room with appropriate ducts or ground or roof mounted outdoors. Adequate protection from freezing must be provided for outdoor installations.

For sizing of condensing units, the manufacturer's rating is the only reliable method of determining unit capacity.

Multiple evaporative condensers may be connected in parallel or an evaporative condenser may be connected in parallel with a shell and tube condenser. Proper piping and traps must be installed in these cases to prevent unequal loading or overloading.

EVAPORATIVE CONDENSERS

Walter T. Grondzik, P.E.; Florida A&M University; Tallahassee, Florida

GENERAL

Condensing furnaces are high-efficiency units that extract heat from exhaust gases to the point at which water and combustion by-products are condensed out of the gases. The condensed water is typically disposed of in a floor drain. These furnaces contain a multipass heat exchanger that recovers enough hot flue gas heat to yield annual fuel utilization efficiencies (AFUEs) in the range of 89 to 97%. Because the resulting flue gases are at a very low temperature, they can be vented directly through a roof or side wall via PVC plastic pipe.

VENTING CONSIDERATIONS

Do not join the vent of a condensing furnace with other flues in the building, such as conventional furnace and boiler flues, hot water heater flues, and laundry vents or fireplace flues. The exhaust gases from a condensing furnace are cooler and therefore are not buoyant enough to create a draft in a large, vertical flue. As a result, the gases will condense inside conventional flues and corrode the flue materials. If abandoned chimneys are to be used, they must be fitted with specially designed chimney liners. Very cold chimneys will require insulation to prevent condensation within the liner.

INDUCED DRAFT

Condensing furnaces should be power-vented, so consideration must be given to proper power supply. The exhaust blower is usually a component of the built-in furnace. The fan-induced draft enables the system to be sealed-combustion, so it uses 100% outside air for combustion. Use of indoor air for combustion should be avoided, since it may contain traces of bleach, fabric softeners, salt, paint strippers, or glues that can cause the condensing furnace to corrode rapidly.

VENT SIZING

Size the exhaust pipe correctly. Manufacturers specify the maximum length and number of elbows that a given pipe diameter can handle. Exhaust and intake vents are typically no larger than 2-in. diameter PVC pipe.

VENT SLOPING

Slope the exhaust pipe down toward the furnace rather than down toward the outside. The exhaust piping must be pitched at least 1/4-in. per foot so condensate can drain freely back through the furnace, where it can be disposed of.

VENT LOCATIONS

Run the exhaust and intake pipes out the same side of the building. The pipes must be next to each other so that wind pressure is the same on both pipes.

FURNACE SIZING

The furnace must not be oversized, as this leads to short firing cycles and can cause corrosion from "condensate dwell" or excessive "wet-time." Because the furnace seldom gets hot enough to dry out, condensate forms in vulnerable areas. The condensate then becomes increasingly acidic, and corrosion results.

CONDENSATE DRAINAGE

The furnace must be level or pitched slightly toward the drain so condensate can drain out. If the condensate cannot be drained by gravity, install a special purpose condensate pump to pump it to an acceptable drain (do not use a sump). Condensing furnaces must be kept away from freezing temperatures because they contain water and will be damaged if they freeze.

DOWNFLOW APPLICATION—CLOSET

UPFLOW APPLICATION—BASEMENT

HORIZONTAL APPLICATION—ATTIC

NOTE
This configuration may also be used in a crawl space with the system suspended on hangers from the floor joists.

Larry O. Degelman, P.E.; Texas A&M University; College Station, Texas

GENERAL NOTES

Chilled water is the most common medium for transferring heat from any type of cooling equipment, such as cooling coils and heat exchangers, to some source of refrigeration.

A chilled water system is a closed circuit system that recirculates water between a mechanical refrigeration water chilling unit and remote cooling equipment, usually operating with water temperatures in the range between 40 and 55°F. There are five types of refrigeration units used in chilled water systems:

1. Centrifugal chiller, with electric motor or steam turbine drive.
2. Reciprocating chiller, with electric motor drive.
3. Rotary screw chiller, with electric drive.
4. Steam absorption chiller.
5. Direct-fired absorption chiller, using fuel oil or gas for firing.

NOTE
A typical reciprocating package chiller, ideally suited to smaller jobs requiring less than 200 tons of cooling. The rotary screw machines are in this range of capacity.

When a chilled water piping system also is used to circulate hot water for winter heating, it is called a dual temperature water system. The design water temperature of chilled water systems usually falls in a rather narrow range because of the necessity for dehumidification and to avoid a possible freeze-up in the chiller. Chilled water supply temperatures usually range from 42° to 60°F for normal comfort applications.

Design flow rates depend on the type of terminal apparatus and the supply temperature. In general, a higher temperature rise (or a greater temperature difference between supply and return temperatures) reduces the initial cost and the operating cost of the distribution system and pumps required and increases the efficiency of the chillers. In a given chilled water system, the selection of the design flow rate and the supply temperature, therefore, are closely related.

NOTE
A two-stage absorption chiller, steam powered for efficient production of 200 to 800 tons of cooling.

Although lower chilled water temperatures permit higher rises (or larger temperature difference), lower chiller efficiencies result. Water treatment may be required in chilled water systems to control corrosion rate, scaling, or algae growth.

Layout of piping systems for chilled water distribution varies greatly depending on system capacity, extent of distribution, type of terminals used, and control scheme to be employed.

Refrigerants that attack the ozone layer above the earth are being phased out and replaced with refrigeration systems that do not degrade the ozone layer, such as R-123, R-134A, and ammonia. This concern has also expanded the use of absorption chillers, both steam and direct-fired types.

NOTE
A centrifugal chiller with a flooded cooler and condenser. This unit is typically used in ranges of 150 to 1200 tons.

PACKAGE WATER CHILLERS

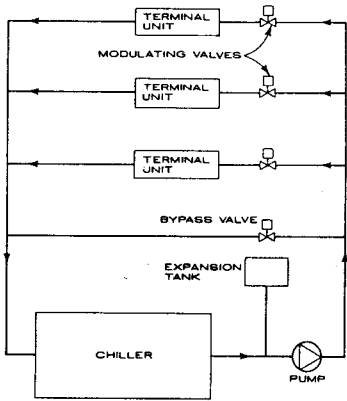

FIGURE 1
ELEMENTARY CHILLED WATER SYSTEM

NOTE
A chilled water system basically consists of a refrigeration water chilling unit, a chilled water recirculating pump, terminal cooling equipment, and an expansion tank. A chilled water bypass valve may be required in systems with two-way modulating valve control at the terminal units. As the cooling load on the terminal equipment decreases, the modulating valve closes and reduces the flow through the terminal. When the water flow through the terminal units is significantly throttled, the bypass valve opens gradually to prevent system pressure buildup and to maintain the water flow required for the proper operation of the chiller.

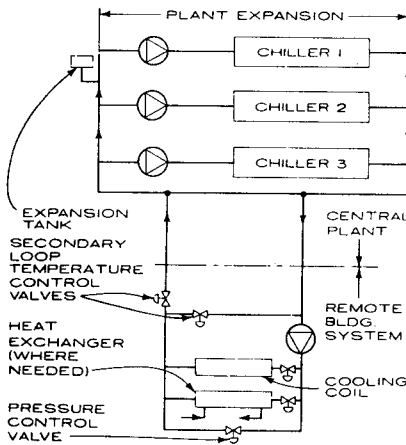

FIGURE 2
PRIMARY/SECONDARY CHILLED WATER PUMPING AND DISTRIBUTION SYSTEM

NOTE
In large campus type applications, the chilled water system consists of multiple chillers and primary and secondary system pumps. The terminal cooling equipment may be chilled water cooling coil of a central air-conditioning unit, closed loop heat exchanger or any other secondary or terminal cooling water system.

The primary loop does not require a pressure control device. The secondary loop pressure control valve operates as described under Elementary Chilled Water System.

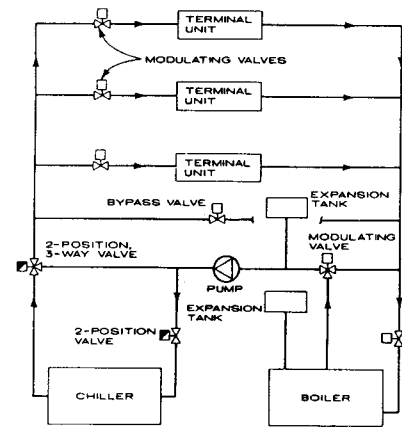

FIGURE 3
TWO-PIPE DUAL TEMPERATURE SYSTEM

NOTE
In a two-pipe dual temperature system hot water is circulated through the terminal units during cold weather and chilled water is circulated during the hot weather. The distribution system may be divided into zones, each of which is capable of changeover from heating to cooling, independent of the other zones.

When the hot and chilled water supply to each terminal unit is in two separate pipes, but the return is in a common pipe, the system is called a three-pipe system. In a four-pipe system, separate supply and return mains for both hot and chilled water are run to each terminal unit.

GENERAL

This and the accompanying page describe several HVAC systems commonly used in medium to large buildings. Systems covered are single duct with terminal reheat, single duct with variable volume, dual duct, and multizone.

CONSTANT VOLUME SINGLE-DUCT WITH TERMINAL REHEAT

This system provides a constant flow of air to the zone(s) served by the HVAC system. Zone temperature is maintained by changing the temperature of the constant airflow. Dehumidification is provided by the combination of a cooling coil and a reheat coil in the terminal mixing box in each zone. Cooling is provided by a cooling coil that uses either direct expansion of the refrigerant or chilled water provided by a central plant. Heating is provided in the outside air preheat coil and in the reheat coil using hot water from a boiler. Normally, the amount of outside air provided corresponds with the amount of ventilation appropriate for anticipated occupancy levels.

Winter and summer operation of the system is best understood by tracing the system state points on a psychrometric

chart. The state points for summer conditions of 95°F, 50% RH outdoor conditions, zonal conditions of 78°F and 50% RH, and system set points of 10% outside air, cooling coil set point of 55°F, and a maximum reheat coil set point of 110°F. The preheat coil is assumed inactive in the summer and the cooling coil is inactive in the winter when the mixed air is less than 55°F.

During summer conditions, the mixed airstream (point C, 80°F, 50% RH), which consists of 10% outside air (points B and B', 95°F, 50% RH) and 90% return air (point A, 78°F, 50% RH), is cooled to 55°F and 90-100% RH as it passes through the cooling coil (point D). This 55°F air is then provided to the terminal box in each zone, where it is reheated to meet the zonal cooling load; in this case, the 55°F, 90-100% RH air is reheated to 65°F and 70% RH in the terminal mixing box before it enters the zone.

During the winter, the preheat coil heats outside air to 45°F. The mixed airstream (point C, 69°F, 50% RH), which consists of 10% outside air (point B, 35°F, 50% RH) that has been preheated to 45°F and 35% RH (point B') and 90% return air (point A, 72°F, 50% RH), passes through the cooling coil where it is cooled to 55°F and 80% RH and is heated in the terminal box to 90°F and 25% RH.

ADVANTAGES

1. Can provide heating and cooling as needed.
2. Good dehumidification.
3. Boiler and chiller can be installed at central plant.
4. Air-handling unit runs continuously, providing good ventilation.
5. Long equipment life.
6. An economizer can be added to take advantage of free cooling during appropriate conditions.

DISADVANTAGES

1. No humidification, so this type of system may produce very dry conditions indoors during winter.
2. Requires distribution ductwork to each zone.
3. Air-handling unit runs continuously, which can cause excessive electricity consumption.
4. Reheat coils require plumbing run to each zone or electric resistance heating.
5. Use of reheat during dehumidification uses unnecessary heating in the summer.
6. Chiller and boiler both must operate except in extreme winter conditions.

PSYCHROMETRIC CHART—WINTER

PSYCHROMETRIC CHART—SUMMER

CONSTANT VOLUME SINGLE-DUCT SYSTEM WITH TERMINAL REHEAT

VARIABLE VOLUME SINGLE-DUCT WITH REHEAT

This system provides a variable flow of air to the zone or zones served by the HVAC system. The amount of air is regulated by opening and closing individual terminal mixing boxes in each zone. Static pressure is maintained by varying the fan speed. During cooling, the temperature in each zone is maintained by changing the flow rate of the air. During heating, the cooling coil is inactive and the heating coil heats the main supply air to the minimum temperature necessary to meet the maximum load of any zone served. In the winter a thermostat in each zone regulates the heated airflow to meet the zone load. Dehumidification is provided by the combination of a cooling coil and a reheat coil. Humidification is not provided but can be added by inserting a humidification device immediately after the fan. Cooling is provided by a cooling coil that uses either direct expansion of the refrigerant or chilled water provided by a central plant. Hot water from a boiler provides heating in the outside air preheat coil and in the main reheat coil. Normally, a fixed amount of outside air is provided, corresponding to the amount of ventilation appropriate for anticipated occupancy levels.

Winter and summer operation of the system is best understood by tracing the system state points on a psychrometric

chart. The state points for summer conditions of 95°F and 50% RH outdoors, zonal conditions of 78°F and 50% RH, and system set points of 10% outside air, cooling coil set point of 55°F, and a maximum reheat coil set point of 110°F. The preheat coil is assumed to be inactive in the summer; the cooling coil is inactive in the winter when the mixed air is less than 55°F.

In summer conditions the mixed airstream (point C, 80°F, 50% RH), which consists of 10% outside air (points B and B', 95°F, 50% RH) and 90% return air (point A, 78°F, 50% RH), is cooled to 55°F and 90-100% RH as it passes through the cooling coil (point D). This 55°F air is then reheated to 65°F and 70% RH in the main reheat coil. Reheating must be controlled to maintain RH at or below 60% in all zones served in summer conditions. The amount of air entering each zone is then modulated to meet the cooling load.

During the winter the preheat coil heats outside air to 45°F; the cooling coil is inactive. The mixed airstream (point C, 69°F, 50% RH), which consists of 10% outside air (point B, 35°F, 50% RH) that has been preheated to 45°F and 35% RH (point B') and 90% return air (point A, 72°F, 50% RH), passes through the cooling coil unaffected and is heated in the main reheat coil to 110°F, 15% RH.

ADVANTAGES

1. Can provide heating and cooling as needed.
2. Average dehumidification.
3. Boiler and chiller can be installed at central plant.
4. Air-handling unit runs continuously at variable volume, which provides adequate ventilation.
5. Long equipment life.
6. An economizer can be added to take advantage of free cooling during appropriate ambient conditions.
7. Does not require piping into individual zones.

DISADVANTAGES

1. No humidification, so this type of system may produce very dry conditions indoors during winter.
2. Requires distribution ductwork to each zone.
3. Volume of air provided to air-handling units varies, which can result in inadequate ventilation if not properly balanced.
4. One main reheat coil for the entire system can result in a very cold building in extremely humid climates. Could require humidity sensor to moderate supply air temperature to maintain humidity at or below 60% RH.
5. Use of reheat during dehumidification uses unnecessary heating in the summer.
6. One main heating coil may cause hot interior zones when internal loads require year-round cooling.

PSYCHROMETRIC CHART—WINTER

PSYCHROMETRIC CHART—SUMMER

VARIABLE VOLUME SINGLE-DUCT SYSTEM WITH REHEAT

Jeff Haberl, Ph.D, PE; Texas A&M University; College Station, Texas

CONSTANT VOLUME DUAL-DUCT

A constant volume dual-duct system provides a constant flow of air to zone(s) served by the HVAC system. Zone temperature is maintained by changing the temperature of the constant airflow that leaves the terminal mixing box in each zone. Dehumidification is provided by the cooling coil and any remixing of air in the terminal mixing boxes. Humidification is not provided in the system shown but can be added by inserting a humidification device immediately after the main heating coil. Cooling is provided by a cooling coil that uses either direct expansion of the refrigerant or chilled water provided by a central plant. Heating is provided in the outside air preheat coil and in the main heating coil using hot water from a boiler. Normally, the fixed amount of outside air provided corresponds to the appropriate amount of ventilation for anticipated occupancy levels. However, in a dual-duct system both hot and cold airstreams are always available to each terminal mixing box. The temperature of the air leaving the cooling coil is always between 45°F (winter) and 55°F (summer). Air leaving the heating coil is either fixed at 110°F or can be moderated by an outside reset thermostat. Varying amounts of hot and cold air are mixed in the terminal boxes to achieve the required cooling or heating load.

Winter and summer operation of the system is best understood by tracing system state points on a psychrometric chart. The state points for summer and winter are the same as those indicated for the constant volume single-duct system with reheat (see the AGS page on this system).

In summer conditions the mixed airstream (point C, 80°F, 50% RH), which consists of 10% outside air (points B and B', 95°F, 50% RH) and 90% return air (point A, 78°F, 50% RH), is either cooled to 55°F and 35% RH (point B') and 90% return air (point A, 78°F, 50% RH) as it passes through the cooling coil (point D) or heated to 110°F and 20% RH as it passes through the main heating coil. Both the 55°F cold air and 110°F hot air are then made available to the terminal mixing box, where the two airstreams are mixed to produce a constant flow, variable temperature airstream to meet the cooling and dehumidification load (point F).

During winter conditions the preheat coil heats outside air to 45°F. The mixed airstream (point C, 69°F, 50% RH), which consists of 10% outside air (point B, 35°F, 50% RH) that has been preheated to 45°F and 35% RH (point B') and 90% return air (point A, 72°F, 50% RH), passes through the cooling coil where it is cooled to 55°F and 82% RH or is heated in the main heating coil to 110°F and about 15% RH. Both

the 45°F cold air and 110°F hot air are then made available to the terminal mixing box, which mixes the two to produce a constant flow, variable temperature airstream to meet the heating load (point F). This type of system does not provide humidification so may produce extremely dry conditions indoors during the winter.

ADVANTAGES

Constant volume dual-duct systems have the same advantages as those listed in numbers 1-5 on the AGS page on constant volume single-duct systems with reheat. An economizer can be added to reduce the mixed air to 55°F so the cooling load can be reduced.

DISADVANTAGES

Constant volume dual-duct systems have the same disadvantages as those listed in numbers 1-3 and 5-6 on the AGS page on constant volume single-duct systems with reheat.

NOTE

This system can easily be modified to make a variable volume dual-duct system. Install a variable speed controller on the main fan and modify the terminal mixing boxes to allow for varying airflow rates. An economizer can also be added to reduce winter cooling loads.

PSYCHROMETRIC CHART—WINTER

PSYCHROMETRIC CHART—SUMMER

CONSTANT VOLUME DUAL-DUCT SYSTEM

CONSTANT VOLUME MULTIZONE

A constant volume multizone system provides a constant flow of air to the zones served by the system. Zone temperature is maintained by changing the temperature of the constant airflow that leaves the multizone unit. Dehumidification is provided by the cooling coil and any remixing of air from the heating coil before it enters a zone. The system shown does not provide humidification, but a dehumidification device can be added just after the main heating coil for each zone. Cooling is provided by a cooling coil that uses either direct expansion of the refrigerant or chilled water provided by a central plant. Heating is provided in the outside air preheat coil and in the main heating coil using hot water from a boiler. Normally, a fixed amount of outside air corresponds to the amount of ventilation appropriate for the occupancy level. In a multizone system both hot and cold airstreams are always available to each zone. The temperature of the air leaving the cooling coil is always between 45°F (winter) and 55°F (summer). Air leaving the heating coil is fixed at 110°F

or can be moderated by an outside reset thermostat. Varying amounts of hot and cold air are mixed according to the required cooling or heating load in each zone.

Summer and winter operation of the system is best understood by tracing system state points on a psychrometric chart. The state points for summer and winter conditions are the same as those indicated for the constant volume single-duct system with reheat (see the AGS page on this system).

During summer conditions the mixed airstream (point C, 80°F, 50% RH), which consists of 10% outside air (points B and B', 95°F, 50% RH) and 90% return air (point A, 78°F, 50% RH), is either cooled to 55°F and 35% RH as it passes through the cooling coil (point D) or is heated to 110°F and 20% RH as it passes through the main heating coil. Both the 55°F cold air and 110°F hot air are then made available to each zone to meet the cooling and dehumidification load.

During winter conditions the preheat coil heats outside air to 45°F. The mixed airstream (point C, 69°F, 50% RH), which consists of 10% outside air (point B, 35°F, 50% RH) that has been preheated to 45°F and 35% RH (point B') and 90% return air (point A, 72°F, 50% RH) passes through the cooling coil where it is cooled to 55°F and 80% RH or is heated in the main heating coil to 110°F and about 15% RH. Both the 55°F cold air and 110°F hot air are then made available to the individual zones to meet the heating load (point F). This type of system does not provide humidification and so may produce extremely dry conditions indoors in the winter.

ADVANTAGES

Constant volume multizone systems have the same advantages as those listed in numbers 1-6 on the AGS page on constant volume single-duct systems with reheat. An economizer can also be added to reduce winter cooling loads.

DISADVANTAGES

Constant volume multizone systems have the same disadvantages as those listed in numbers 1-3 and 5-6 on the AGS page on constant volume single-duct systems with reheat.

UPFLOW (HIGH BOY)

DOWNFLOW (COUNTERFLOW)

HORIZONTAL

WARM AIR FURNACES

EXTENDED PLENUM SYSTEM

PERIMETER RADIAL SYSTEM

DUCT SYSTEM LAYOUTS

OVERHEAD AIR SYSTEM WITH DUCTED RETURN

NOTES

1. Warm air furnace units are designed primarily for residential, small commercial, or classroom heating. Cooling can be added to these units by installing a cooling coil downstream from the furnace, with refrigerant compressor and condenser located remotely outside the building.
2. A duct system from the furnace unit can be installed above the ceiling or in a furred down soffit. Distribution systems above the ceiling are usually the radial type with high wall registers.
3. Duct systems also may be installed below living spaces, in a crawl space or a basement.
4. Two- or three-story buildings using similar warm air furnace and cooling coil combinations are centrally air conditioned via vertical extension of the branch ductwork through walls and partitions. Since all variations of warm air heating and cooling systems recirculate their air within the building envelope, it is a crucial design requirement to leave adequate return air passage, from each space supplied with air, to the furnace room.

FLOOR AREA REQUIRED BY WARM AIR FURNACE

OUTPUT CAPACITY (BTU/HR)	FURNACE FLOOR AREA (SQ FT)*
Up to 52,000	2.4
52,000-84,000	4.2
84,000-120,000	6.6
120,000-200,000	13.1

* Based on net floor area occupied by the upflow or downflow furnace. Low-boy unit requires 50% more floor area. Space for combustion air should be added as required by local codes. Provide adequate space for service.

CONDENSING UNIT

Jeff Haberl, Ph.D., P.E.; Texas A&M University; College Station, Texas

GENERAL

Three types of devices are used to supply and return air: diffusers, registers, and grilles. Diffusers are generally intended for ceiling-mounted supply air applications and are designed to provide good mixing of supply air with room air. Registers are used for supply or return air applications and may be appropriate for ceiling, sidewall, or floor installations. Grilles are less sophisticated devices primarily intended for return air applications. As the air supply and return devices are often the only element of an HVAC system seen by building occupants, have a direct impact on thermal and acoustical comfort, and have an indirect impact on indoor air quality, selection and specification of these devices is an important part of the design process.

Diffusers and registers are selected to deliver a specified airflow with appropriate throw (in terms of both distance and direction) and acceptable noise generation. Diffusers, manufactured of steel or aluminum, are available in a wide range of shapes, sizes, surface appearances, finishes, and installation detailing. Registers come in a more restricted range of shapes and sizes. Grilles are generally square/rectangular in shape. Typical diffuser designs and installations are shown in the diagrams on this page.

RETURN GRILLES AND SUPPLY DIFFUSERS

NOTE

Terminal devices (or boxes) are a key element of many common HVAC systems, including variable air volume (VAV) and dual-duct systems. These devices are usually located adjacent to the zones they serve and require space/volume for transitions and connections to the central air distribution network and to the supply air devices. Terminal boxes should be installed in readily accessible locations to permit adjustment and maintenance.

TYPICAL DIMENSIONS FOR TERMINAL BOXES (IN.)

BOX CAPACITY (CFM)	DUAL-DUCT MIXING BOX	SINGLE-DUCT VAV BOX	FAN-POWERED TERMINAL BOX	INDUCTION TERMINAL BOX
225	12 x 21 x 34	8 x 12 x 52	16 x 32 x 26	10 x 18 x 42

GENERAL

The six diagrams on the AGS pages on multiple interior zone HVAC systems describe systems found in K-12 schools and small commercial office buildings.

FOUR-PIPE, SINGLE-ZONE AIR-HANDLING UNIT

Zonal air-handling units (AHUs) in this system provide heating and cooling for specific zones. Each AHU has a blower, filter, and heating and cooling coils. A fixed amount of fresh air to the units is pretempered to 55°F in a preconditioning unit. Both chilled and hot water are simultaneously provided to zonal and preconditioning units to carry the loads on the cooling and heating coils. Chilled water is provided by a chiller located in a central mechanical room (which contains a heat-rejecting condensing unit), and hot water is provided by a boiler, often located in the same mechanical room. Some single-zone AHUs run continuously. Newer units may

have a variable volume fan that regulates airflow according to zone loads. The chiller or boiler must operate when any single zonal unit requires cooling or heating.

Each unit is controlled by a zone thermostat that adjusts the supply-air temperature to meet heating or cooling loads. The preconditioning unit is controlled to maintain 55°F by preheating air in winter and precooled it in the summer. The temperatures of the chilled water and hot water supplied to the units may be controlled with an outside reset thermostat.

ADVANTAGES

1. This system can provide heating and cooling as needed.
2. The system offers good dehumidification.
3. The boiler and chiller are installed at a central location.
4. The system operates with minimal distribution ductwork.
5. Zonal air-handling units can be shut down without affecting adjacent areas.

6. Chiller efficiency is higher than for individual heat pumps.
7. The boiler and chiller have a long life (25 years).

DISADVANTAGES

1. A four-pipe system is slightly more expensive than a two-pipe system.
2. The hot water and chiller water loop must run even if only one zone needs heating or cooling.
3. The entire system is shut down when the loop fails.
4. The water-cooled condenser tower needs frequent service and water quality checks.
5. The temperature is higher in an air-cooled condenser than a water-cooled condenser, making chillers less efficient.
6. This system may require more energy than others because of the energy needed to run a four-pipe central loop.
7. The system has no humidification.

FOUR-PIPE, SINGLE-ZONE AIR-HANDLING UNIT

PACKAGED SPLIT SYSTEM WITH INDIVIDUAL HEAT PUMPS

PACKAGED SPLIT SYSTEM WITH INDIVIDUAL HEAT PUMPS

This system provides heating and cooling for individual zones with zonal heat pumps. Each heat pump unit contains a blower, filter, and heating/cooling coil. A fixed amount of fresh air to the units is pretempered to 55°F in a preconditioning heat pump unit. Each heat pump has its own heat rejection (or ambient heat source during cold weather). Emergency electric resistance heating is often provided for severe conditions.

The zonal heat pumps cycle on and off when the zone thermostat calls for heating or cooling. Airflow to the zones also cycles on and off according to zone demand. In general, the heat pump that preconditions outside air must run continuously to provide adequate preconditioned fresh air.

ADVANTAGES

1. Installation, system operation, and maintenance are simple.
2. No mechanical room is required.
3. Ductwork is only required for fresh air.
4. The initial cost is low.
5. This system is well-suited to spaces that require many zones of individual temperature control.

DISADVANTAGES

1. The noise level of this system is generally high.
2. Maintenance costs are high.
3. Overall efficiencies of individual heat pumps are less than that of one large chiller.
4. The system needs electric resistance heating when the outside air temperature is below 35°F.
5. Humidity control can be problematic if there is no preconditioning unit and zonal heat pumps are oversized.
6. Wall penetration is required for refrigerant lines to and from the condenser/evaporator.
7. Equipment life may be relatively short (typically 10 years).
8. The system has no humidification.

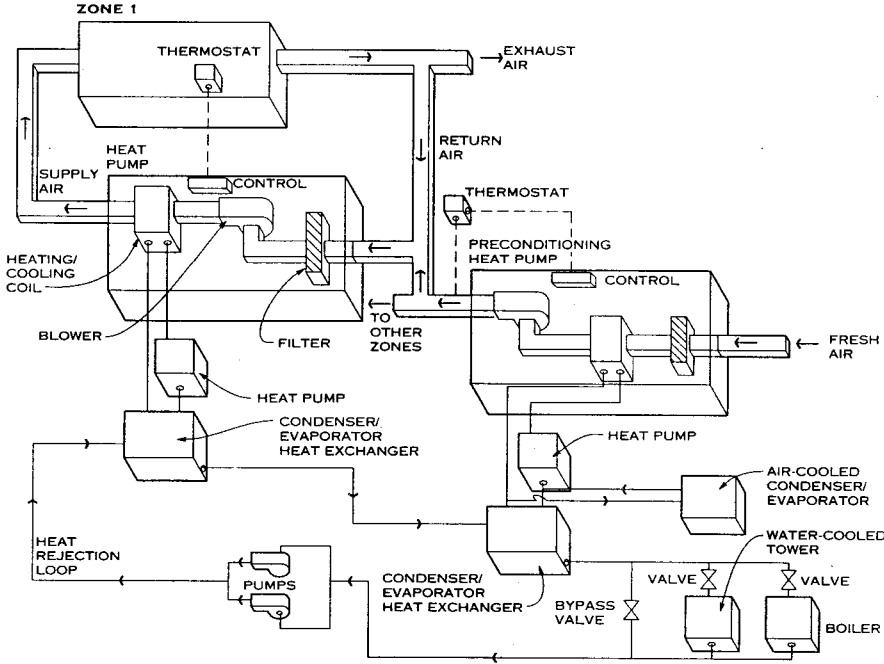

Jeff Haberl, Ph.D., P.E.; Texas A&M University; College Station, Texas

TWO-PIPE WATER LOOP HEAT PUMP WITH PACKAGED SPLIT SYSTEM

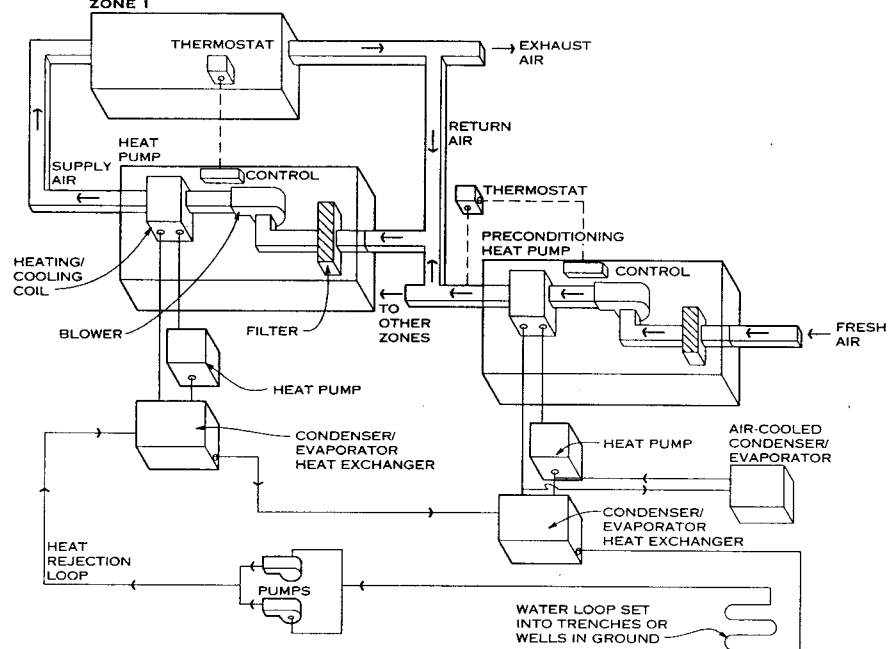

In this system, zonal heat pumps provide heating and cooling for individual zones. Each heat pump unit has a blower, filter, and heating/cooling coil. A fixed amount of fresh air to the units is pretempered to 55°F in a preconditioning heat pump unit. The system has a heat rejection loop, and each heat pump is connected to it with a heat exchanger. The heat rejection loop is maintained within a preset temperature range (e.g., 40–100°F) using a central boiler in the winter and one or more heat rejecting cooling towers in the summer. Usually, this type of system does not need emergency electric resistance heating for severe conditions. The

heat rejection loop must operate when one or more heat pumps are running. In some cases, a variable speed loop can be used, although care must be taken to provide adequate flow to keep the heat pump heat exchangers from freezing up and/or to avoid heat transfer problems in the boiler caused by low flow.

The zonal heat pumps cycle on and off when the zone thermostat calls for heating or cooling. Air flow to the zones also cycles on and off according to zone demand. In general, to provide an adequate source of preconditioned fresh air, the outside air preconditioning heat pump must run continuously. An air-cooled condenser can be provided for the preconditioning units to allow for the main loop to be shut down.

TWO-PIPE WATER LOOP HEAT PUMP WITH PACKAGED SPLIT SYSTEM

TWO-PIPE, GROUND-COUPLED WATER LOOP HEAT PUMP WITH PACKAGED SPLIT SYSTEM

Jeff Habert, Ph.D., P.E.: Texas A&M University; College Station, Texas

TWO-PIPE, GROUND-COUPLED WATER LOOP HEAT PUMP WITH PACKAGED SPLIT SYSTEM

This system has zonal air-handling units (AHUs) that provide heating and cooling for individual zones. Each zonal heat pump contains a blower, filter, and heating/cooling coil. A fixed amount of fresh air to the units is pretempered to 55°F in a preconditioning heat pump unit. Each heat pump is connected to the system heat rejection loop with a heat exchanger. However, in contrast to the water loop system that has an auxiliary boiler and heat rejection tower, this water loop rejects heat in a series of wells or trenches that put it in direct contact with the earth. This heat rejection loop is also maintained within a preset temperature range (e.g., 40–100°F) using the thermal mass of the earth it contacts. This type of system does not need emergency electric resistance heating for severe conditions. The ground-coupled heat rejection loop must operate when one or more heat pumps are running. A variable speed heat rejection loop can be used, although care must be taken to provide adequate flow to avoid freeze-up of the heat pump heat exchangers.

Zonal heat pumps cycle on and off whenever the zone thermostat calls for heating or cooling. Airflow to the zones also cycles on and off according to zone demand. In most cases, the outside air preconditioning heat pump runs continuously to provide an adequate source of preconditioned fresh air.

EVALUATION OF SYSTEM FEATURES

The following advantages/disadvantages apply to both systems described on this page, unless otherwise noted.

ADVANTAGES

1. The systems conserve energy by recovering heat from interior zones and/or waste heat.
2. The systems do not require wall penetrations to provide for the rejection of heat from air-cooled condensers.
3. Air-cooled preconditioning allows fresh air to be supplied without running the main loop.
4. The noise level can be lower than that of air-cooled equipment because individual condenser fans are eliminated and the compression ratio is lower.
5. The systems can be maintained locally, as no special chiller repairmen are required for the heat pumps (a special repairman is needed for the boiler in the system without ground coupling).
6. Units have a longer service life than air-cooled heat pumps.
7. The entire system does not shut down when a zonal unit fails.
8. Ground-coupled systems normally do not need a boiler and cooling tower. The mechanical room to house the loop pumps can be minimized.
9. The life-cycle cost of the two-pipe water loop heat pump with packaged split system (without ground coupling) compares favorably with that of central systems when installation costs, operating costs, and system life are considered.

DISADVANTAGES

1. The initial cost for these systems may be higher than for systems that use multiple unitary HVAC equipment.
2. Cleanliness of the piping loop must be maintained.
3. The water-cooled tower needs frequent service and water quality checks (this does not usually apply to the ground-coupled system).
4. If air-cooled preconditioning is not used, the loop must run 24 hr/day when any zone needs cooling or heating.
5. The entire system shuts down when the loop fails.
6. More maintenance will be required than for some other systems since the heat-pump equipment and air-handling units are decentralized.
7. These systems have no humidification.
8. In the ground-coupled system, soil type, moisture content, composition, density, and uniformity affect the success of this method of heat exchange.
9. In the ground-coupled system, the pipe material and the corrosiveness of the local soil and groundwater may affect heat transfer and service life.
10. In the ground-coupled system, a large area is needed in which to drill wells.

FOUR-PIPE MULTIZONE SYSTEM WITH COLD DECK BYPASS

Multizone air-handling units (AHUs) provide heating and cooling for several zones (typically 4 to 10). Each multizone unit contains a blower, filter, heating coils, cooling coils, and bypass dampers. Chilled water and hot water are simultaneously provided to the zonal units to carry loads on the cooling and heating coils respectively. Chilled water is provided by a chiller located in a central mechanical room (which contains a heat-rejecting condensing unit) and hot water is provided by a boiler, often located in the same mechanical room. The multizone units run continuously. The chiller or boiler must operate when any multizone unit or pre-conditioning unit requires heating or cooling. Newer units may contain a variable volume fan that regulates the airflow according to the zone loads.

Each zone is controlled by a zone thermostat that changes the temperature of the supply air to meet heating or cooling loads. The supply air is conditioned by an arrangement of dampers that allows the correct portion of air either to flow across or to bypass the cold deck. A reheat coil can be provided for locations with extremely humid conditions. A pre-heat coil can be provided for extreme winter conditions. The temperature of the chilled water and hot water supplied to the units may be controlled with an outside reset thermostat.

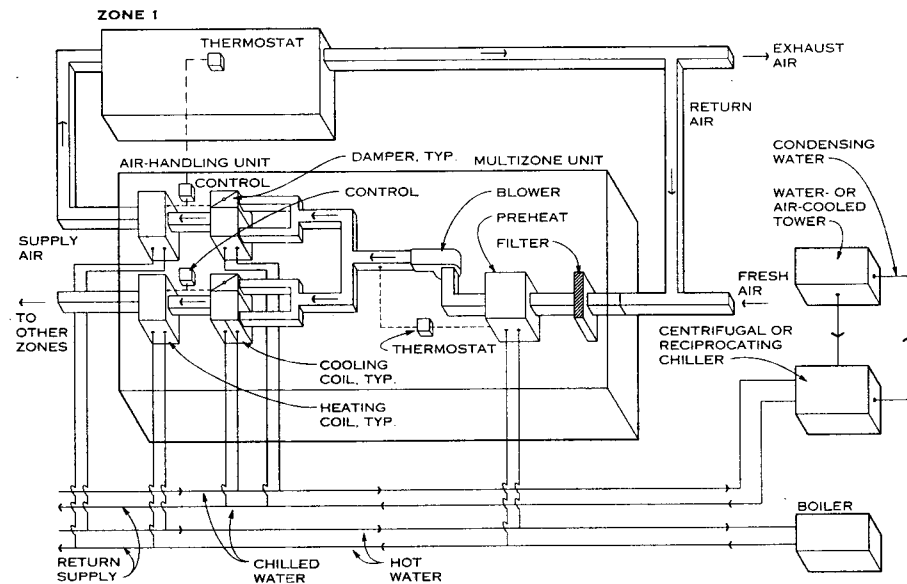

ADVANTAGES

1. The system supplies several zones from centrally located AHUs.
2. No pipes are required that could leak in occupied areas.

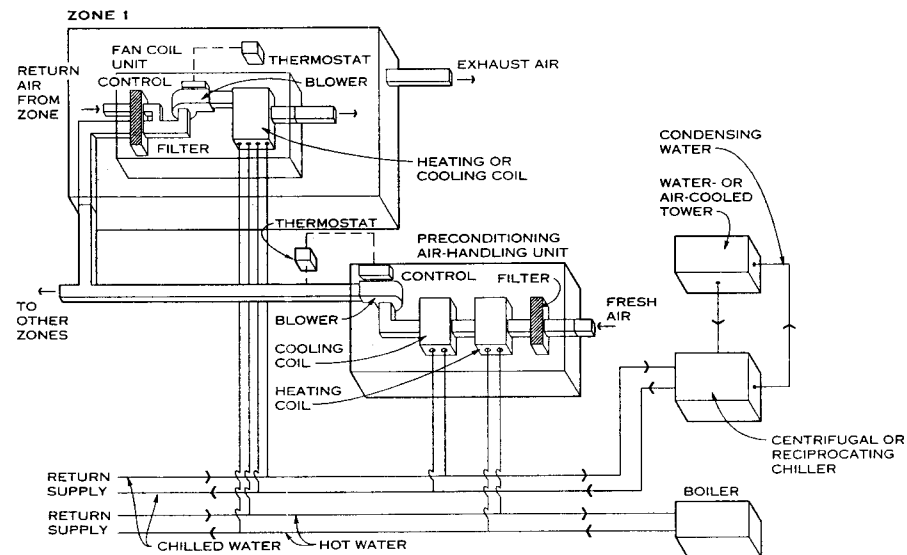

3. The system can provide heating and cooling as needed.
4. The boiler and the chiller are centrally located.
5. Chiller efficiency is often higher than that of individual heat pumps.
6. The system offers good dehumidification.

DISADVANTAGES

1. The hot water and chiller water loop must run when only one zone needs heating or cooling.
2. The chiller and boiler require service by specially trained repairmen.
3. A water-cooled condenser tower needs frequent service and water quality checks.
4. Additional space is required for distribution ductwork.
5. The air-cooled condenser temperature is higher than that of a water-cooled condenser, making the chiller less efficient.
6. The central system may use more energy because the loop has to run more often.
7. The system has no humidification.

FOUR-PIPE MULTIZONE SYSTEM WITH COLD DECK BYPASS

FOUR-PIPE FAN COIL UNITS

In this system, fan coil units in each zone provide heating or cooling for that zone. Each fan coil unit contains a blower, filter, and heating-cooling coil. A fixed amount of fresh air to the units is pretempered to 55°F in a preconditioning unit that serves a number of zones. Chilled water and hot water are simultaneously provided to the zonal units and the preconditioning units to carry loads on the cooling and heating coils respectively. Chilled water is provided by a chiller located in a central mechanical room (which contains a heat-rejecting condensing unit) and hot water is provided by a boiler, which is often located in the same mechanical room. The zonal fans can either run continuously and modulate temperature or turn on and off as needed to satisfy the zone thermostat. Newer units may contain a variable volume fan that regulates the airflow depending upon zone loads.

Each zonal fan coil unit is controlled by a zone thermostat, which changes the temperature of the supply air to meet heating or cooling loads. The preconditioning maintains a temperature of 55°F by preheating the air in the winter and precooling it in the summer. The temperature of the chilled water and hot water supplied to the units may be controlled with an outside reset thermostat.

ADVANTAGES

1. The system provides all-season heating and cooling at each unit.
2. The boiler and chiller are installed at a central location.
3. The only ductwork needed is for preconditioned air (about 10-20% of fan coil air).
4. Chiller efficiency is higher than that of individual heat pumps.
5. The zonal fan coil unit can be shut down for maintenance without affecting adjacent areas.
6. No summer/winter changeover is required.
7. This system operates more simply than the others described in this AGS section on multiple interior zone HVAC systems.
8. Cooling of preconditioned air may not be required in northern climates with hot, dry summers.

DISADVANTAGES

1. Four-pipe systems are slightly more expensive to install than two-pipe systems.
2. The hot water and chilled water loop must run when only one zone needs heating or cooling.
3. The chiller and boiler need servicing by specially trained repairmen.
4. Noise from individual units may be a problem.
5. The water-cooled condenser tower needs frequent service and water quality checks.
6. The air-cooled condenser temperature is higher than that of a water-cooled condenser, making the chiller less efficient.
7. This central system may use more energy because of the frequent running of the loop.
8. Decentralized maintenance of zonal units can require additional maintenance time.
9. Zonal units need a sanitary sewer connection to drain condensate. These drains can be a maintenance concern.
10. The system has no humidification.

FOUR-PIPE FAN COIL UNITS

Jeff Haberl, Ph.D., P.E.; Texas A&M University; College Station, Texas

DUCT CONSTRUCTION

Ductwork must be permanent, rigid, nonbuckling, and nonrattling. Joints in ductwork should be airtight. Galvanized iron or aluminum sheets are usually used in the construction of ducts. The ducts may be either round or rectangular in cross section.

In general, supply ducts should be constructed entirely of noncombustible material. Supply ducts serving a single family dwelling need not meet this requirement, except for the first 3 ft from the unit, provided they are used in conjunction with listed heating units, are properly constructed from a base material of metal or mineral, and are properly applied. Warm air ducts passing through cold spaces or located in exposed walls should have 1 to 2 in. of insulation.

Supply ducts must be securely supported by metal hangers, straps, lugs, or brackets. No nails should be driven through duct walls, and no unnecessary holes should be cut in them.

Supply ducts should be equipped with an adjustable locking type damper for air volume control. The damper should be installed in the branch duct as far from the outlet as possible, where it is accessible.

Automatic smoke dampers are required wherever ductwork passes through a rated smoke barrier partition.

Return systems having more than one return intake may be equipped with balancing dampers.

Attention should be given to the elimination of noise. Metal ducts should be connected to the unit by strips of flexible fire resistant fabric. Electrical conduit and piping, if directly connected to the unit, may increase noise transmission. Return air intakes immediately adjacent to the unit may also increase noise transmission. Installation of a fan directly under a return air grille should be avoided.

DUCT MATERIAL THICKNESS

ROUND DUCT DIA. OR RECTANGULAR DUCT WIDTH (IN.)	GALVANIZED IRON U.S. GAUGE	ALUMINUM B & S GAUGE
	Ducts enclosed in partitions	
14 or less	30	24
Over 14	28	24
	Ducts not enclosed in partitions	
14 or less	28	24
Over 14	26	23

DUCT LESS THAN 60" WIDE USE 1/8" X 1" GALVANIZED IRON HANGER. DUCT OVER 60" WIDE USE 1/8" X 1 3/8" GALVANIZED IRON HANGER

NOTE

On ducts over 48 in. wide hangers shall turn under and fasten to bottom of duct. When cross-sectional area exceeds 8 sq ft duct will be braced by angles on all four sides.

ABBREVIATIONS
 AHU—air-handling unit; VAV—variable air volume

SYSTEM DIAGRAM

NOTE

This all-air central system has only one point of control (one thermostat = one zone). The system operates with a constant airflow from the air-handling unit and through the diffusers, with the thermostat controlling supply air temperature in response to load. Any number of diffusers may be provided to meet air distribution needs. Numerous air-handling unit configurations are available. This type of system may be found in residential, retail, and industrial buildings, and in interior (core) spaces of complex buildings. Multiple systems may be used to provide multiple zones.

SINGLE-ZONE SYSTEM

SYSTEM DIAGRAM

NOTE

This all-air central system can serve approximately ten zones per air-handling unit. The system operates with constant airflow from the air-handling unit and through the diffusers, with thermostats controlling the supply air temperature of individual zones in response to load. A dedicated supply duct serves each zone and can provide good control of space conditions at moderate energy cost. Because zone control occurs at the air-handling unit, this is not a flexible system. The numerous supply ducts make system layout and coordination critical. Multiple air-handling units may be used to provide additional zoning capability.

MULTIZONE SYSTEM

SYSTEM DIAGRAM

NOTE

This all-air central system can serve a virtually unlimited number of zones. The system meets loads by providing a varying airflow through the diffusers in each zone under the control of zone thermostats. VAV systems are very flexible because zone control occurs at VAV boxes located near the conditioned spaces. Since a VAV system is essentially a cooling-only system, some means of space heating must be provided (an independent heating system; fan-powered or induction terminals with electric or hot water heating). VAV systems can provide excellent comfort with good energy efficiency, but air-quality issues must be seriously examined during system design. Several fan/air supply control options are available to minimize system energy use at part loads.

VARIABLE AIR VOLUME (VAV) SYSTEM

SYSTEM DIAGRAM

NOTE

This all-air central system can serve a virtually unlimited number of zones. The system meets loads by varying the supply air temperature through the diffusers in each zone under the control of zone thermostats. The system is very flexible because zone control occurs at coils (electric or hot water) located near the conditioned spaces. A terminal reheat system can provide excellent comfort conditions (by providing constant airflow and humidity control) and simultaneous heating and cooling; unfortunately, the reheat approach wastes substantial energy and is generally to be avoided unless the reheat comes from renewable energy sources (waste or reclaimed heat or solar energy). Terminal heating may be combined with variable volume air delivery.

TERMINAL REHEAT SYSTEM

Walter T. Grondzik, P.E.; Florida A&M University; Tallahassee, Florida

ABBREVIATION
AHU—air-handling unit

NOTE

This all-air central system can serve a virtually unlimited number of zones. The system meets loads in the various zones by mixing hot and cold airstreams from the air-handling unit in response to zone thermostats. The system is very flexible because zone control occurs in mixing boxes located near the conditioned spaces. A dual-duct system provides good comfort and air-quality conditions at reasonable energy cost. The need for two separate supply air distribution ducts requires excellent coordination between air distribution and other services. Dual-duct systems may be designed with either constant or variable volume air supply.

SYSTEM DIAGRAM

DUAL-DUCT SYSTEM

SYSTEM DIAGRAM

FAN-COIL SYSTEM

SYSTEM DIAGRAM

INDUCTION SYSTEM

SYSTEM DIAGRAM

RADIANT PANEL SYSTEM

NOTE

This all-water or air-water central system can serve a virtually unlimited number of zones. The system meets loads in the various zones by controlling the flow of chilled or hot water to the radiant panel elements in response to zone thermostats. Design coordination must address the installation of the panel elements within the array of interior surfaces (ceiling, floor, and walls). All-water configurations are not true "air conditioning" systems; with a separate central air supply, the system can provide the control of conditions expected of an air conditioning system. Space cooling with radiant panels is problematic because of condensation from latent cooling loads.

NOTE
Numbers in drawing refer to general requirements, below.

SCHEMATIC DIAGRAM OF TYPICAL RESIDENTIAL ELECTRICAL LAYOUT

GENERAL REQUIREMENTS

1. A minimum of one wall-switch-controlled lighting outlet is required in every habitable room, hallway, stairway, attached garage, and outdoor entrance. Exception: In habitable rooms other than kitchens and bathrooms one or more receptacles controlled by a wall switch are permitted in lieu of lighting outlets.
2. In every kitchen, family room, dining room, den, breakfast room, living room, parlor, sunroom, bedroom, recreation room, and similar rooms, receptacle outlets must be installed so that no point along the floor line is farther than 12 ft, measured horizontally, from an outlet, including any wall space 2 ft or more wide and the wall space occupied by sliding panels in exterior walls.
3. A minimum of two #12 wire 20-A small appliance circuits are required to serve only small appliance outlets, including refrigeration equipment, in the kitchen, pantry, dining room, breakfast room, and family room. Both circuits must extend to the kitchen; the other rooms may be served by one or both of them. No other outlets may be connected to these circuits, except a receptacle installed solely for an electric clock. In kitchen and dining areas, receptacle outlets must be installed at each and every counter space wider than 12 in.
4. A minimum of one #12 wire 20-A circuit must be provided to supply the laundry receptacle(s), and it may have no other outlets.
5. At least one receptacle outlet must be installed in the bathroom near the basin and must be provided with ground fault circuit interrupter protection.
6. Code requires sufficient 15- and 20-A circuits to supply three watts of power for every square foot of floor space, not including garage and open porch areas. Minimum code suggestion is one circuit per 600 sq ft, one circuit per 500 sq ft is desirable.

7. A minimum of one exterior receptacle outlet is required (two are desirable) and must be provided with ground fault circuit interrupter protection.
8. A minimum of one receptacle outlet is required in basement and garage, in addition to the one in the laundry. In attached garages it must be provided with ground fault circuit interrupter protection.
9. Many building codes require a smoke detector in the hallway outside bedrooms or above the stairway leading to upper floor bedrooms.
10. Disconnect switches are required.

NOTE
Refer to the National Electrical Code (NEC) for further information on residential requirements.

LEGEND FOR FIRST FLOOR AND BASEMENT PLANS

- A = Mount receptacles at countertop locations 2 in. above backsplash.
- B = Mount receptacle 48 in. above finish floor (AFF).
- C = Range and oven outlet boxes should be wall mounted, 36 in. AFF. Use flexible connections to units.
- D = Switch and outlet for exhaust fan. The switch should be wall mounted above the sink backsplash and the outlet blank cover mounted adjacent to the fan wall opening. A separate switch may be omitted if the fan is supplied with an integral switch.
- E = Dishwasher receptacle is wall mounted behind unit, 6 in. AFF.
- F = Equipped with self-closing gasketed waterproof cover.
- G = Mount 42 in. AFF.

- NOTES**
1. Wiring shown as exposed indicates absence of finished ceiling in basement level. All BX cable run through framing members. Attachment below ceiling joists is not permitted.
 2. Connect to two incandescent porcelain lamp holders with pull chain. Mount two evenly spaced ceiling fixtures in crawl space.
 3. Connect to shutdown switch at top of stairs.
 4. Boiler wiring safety disconnect switch should have red wall plate, clearly marked "BOILER ON-OFF."

FIRST FLOOR PLAN OF ELECTRICAL EQUIPMENT AND DEVICES

Charles B. Towles, P.E.; TEI Consulting Engineers; Washington, D.C.

AVERAGE WATTAGES OF COMMON ELECTRICAL DEVICES

TYPE	WATTS
Air conditioner, central	2500-6000
Air conditioner, room type	800-2500
Blanket, electric	150-200
Clock	2-3
Clothes dryer	4000-6000
Dishwasher	1000-1500
Fan, portable	50-200
Food blender	500-1000
Freezer	300-500
Frying pan, electric	1000-1200
Furnace blower	380-670
Garbage disposal	500-900
Hair dryer	350-1200
Heater, portable	1000-1500
Heating pad	50-75
Heat lamp (infrared)	250
Iron, hand	600-1200
Lamp, incandescent	10 upward
Lamp, fluorescent	15-16
Lights, Christmas tree	30-150
Microwave oven	1000-1500
Mixer	120-250
Power tools	up to 1000
Projector, slide or movie	300-500
Radio	40-150
Range (all burners and oven)	8000-14000
Range top (separate)	4000-8000
Range oven (separate)	4000-5000
Refrigerator	150-300
Refrigerator, frostless	400-600
Sewing machine	60-90
Stereo (solid-state)	30-100
Television	50-450
Vacuum cleaner	250-1200
Washer, automatic	500-800
Water heater	2000-5000

BRANCH CIRCUIT PROTECTION

Lighting (general purpose)	#14 wires	15 A
Small appliances	#12 wires	20 A
Individual appliances	#12 wires	20 A
	#10 wires	30 A
	#8 wires	40 A
	#6 wires	50 A

Heating plant, i.e., forced-air furnace ^{9,10}	600	115	2 # 12	20 A	1	
Attic fan ⁹	300	115	2 # 12	20 A	1 or more	5-20R

- ¹ Wherever possible, use actual equipment rating.
- ² Number of wires does not include equipment grounding wires. Ground wire is No. 12 AWG for 20-A circuit and No. 10 AWG for 30-A and 50-A circuits.
- ³ May be direct connected. For a discussion of disconnect requirements, see NEC Article 422.
- ⁴ Equipment ground is provided in each receptacle.
- ⁵ Heavy-duty appliances regularly used at one location should have separate circuits. Only one such unit should be attached to a single circuit.
- ⁶ Separate circuit serving only one other outlet is recommended.
- ⁷ Should not be connected to a circuit with appliances or other heavy loads.
- ⁸ Separate circuit recommended.
- ⁹ Recommended that all motor-driven devices be protected by a local motor-protection element unless motor protection is built into the device.
- ¹⁰ Connect through disconnect switch equipped with motor-protection element.
- ¹¹ National Electrical Manufacturers Association (NEMA).

NOTE
In metal stud construction, cables are passed through pre-cut openings in place of field-drilled holes.

TYPICAL WIRING IN WOOD CONSTRUCTION

Charles B. Towles, P.E.; TEI Consulting Engineers; Washington, D.C.

GANG SIZE

GANG	HORIZONTAL (IN.)	
	HEIGHT	WIDTH
2	4 1/2	4 7/16
3	4 1/2	6 3/8
4	4 1/2	8 7/16
5	4 1/2	10
6	4 1/2	11 13/16

NOTES

1. Add 1 13/16 in. for each added gang. Screws are 1 13/16 in. o.c.
2. Plates are made in plastic, brass (.04 to .06 in. thick), stainless steel, and aluminum.
3. All devices to be approved by Underwriters Laboratories and to comply with the National Electrical Code.
4. All devices to be of NEMA configuration.
5. Ground fault circuit interrupter or circuits are required in baths, garages, unfinished basements, outdoors at grade level, and within 6 ft of kitchen sinks.

NOTE

Outlets and switches shown are those most generally used. The number of gangs behind one wall plate depends on the type of devices used.

MONUMENT FLOOR OUTLET

NOTE.

Unit is adjustable to accommodate varying floor thicknesses. When abandoned, the floor fitting is replaced with a flat plate.

POKE-THROUGH ELECTRICAL BOX

RECEPTACLES AND SWITCHES

NOTES

1. Outlets and switches shown are those most generally used. Number of gangs behind one wall plate depends on the type of devices used.
2. Symbols used are ASA standard.
3. Interchangeable devices (miniature devices) available in various combinations using any of the following—switch, convenience outlet, radio outlet, pilot light, bell button—in one gang. Combined gangs are available.

SWITCH AND OUTLET LOCATIONS

SWITCH WIRING DIAGRAMS

Charles B. Towles, P.E.; TEI Consulting Engineers; Washington, D.C.

THREADED COUPLING

THREADLESS SET-SCREW COUPLING

THREADLESS COMPRESSION COUPLING

- NOTES**
1. Manufactured in 10 ft lengths in diameters from 1/2 to 6 in. Consult manufacturers.
 2. Rigid steel conduit provides heavy-duty protection of wiring from mechanical injury and corrosion and protects surroundings against fire hazard from overheating or arcing of enclosed conductors.

RIGID STEEL CONDUIT

SQUEEZE-TYPE CONNECTOR

FLEXIBLE TO EMT COUPLING

NOTE
Manufactured in diameters from 5/16 to 4 in.

FLEXIBLE METALLIC CONDUIT

Robert T. Faass, Consulting Engineer; Seabrook, Maryland
Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

LOCKNUT BUSHING CONNECTION

THREADED CONNECTOR

THREADLESS CONNECTORS

ing from mechanical injury and corrosion and protects surroundings against fire hazard from overheating or arcing of enclosed conductors.

LIQUID TIGHT TO RIGID COUPLING

NONMETALLIC LIQUID TIGHT CONDUIT

- NOTES**
1. Manufactured in various grades according to temperature, range, and resistance factors (moisture, corrosion, and chemicals) in 1/4 to 6 in. diameters.
 2. Frequently used for equipment connections in damp or wet locations and outdoors. Consult electrical engineer.

FLEXIBLE LIQUID TIGHT CONDUIT

NOTES

1. Manufactured in 10 ft lengths and 1/2 to 4 in. diameters. Consult manufacturers.
2. Uses similar types of threadless couplings and connections as rigid steel conduit.

ELECTRICAL METALLIC TUBING (EMT)

NOTES

1. All threadless connections are joined by means of solvent cement.
2. Commonly used for underground installation or cast into concrete.
3. Manufactured in heavy wall and light wall construction, in 10 ft lengths and 1/2 to 6 in. diameters.
4. Ground wire required for power cables.

RIGID NONMETALLIC CONDUIT

NOTES

1. Conduit outlet bodies are installed as pull outlets for conductors.
2. Fittings are manufactured for rigid steel, EMT, and non-metallic conduit. Many shapes are available. Consult manufacturers.

CONDUIT OUTLET BODIES

ONE-PIECE RACEWAY

NONMETALLIC

METAL FLOOR RACEWAY

SURFACE RACEWAY SYSTEMS

ARMORED (BX)
NOTE

Armored cable is manufactured with 2-, 3-, and 4-conductor insulated wire in sizes 14, 12, 10, 8, 6, 4, 2; its internal bonds help the armor itself serve as a bonding conductor.

METAL-CLAD (MC)
NOTE

Manufactured in sizes and specs similar to armored cable, metal-clad cable is available with a separate insulated ground conductor and in larger sizes. It may be clad in aluminum or steel, corrugated, smooth, or with metal interlocking tape and may be factory assembled with quick connect adapter units for access floor or ceiling wiring systems. Consult an electrical engineer before installation.

NONMETALLIC SHEATHED (NM, ROMEX)
NOTE

Manufactured in 2- and 3-conductor PVC insulated wire in sizes 14, 12, 10, 8, 6, and 4 with or without ground wire, nonmetallic sheathed cable is permitted in residential and many other building types up to three stories.

NOTE
Flat conductor cable has combinations of 3, 4, and 5 conductors for easy access under carpet squares; data, communications, and TV flat cable are available. Consult manufacturers before installation.

CABLES

OCTAGONAL
NOTE
Commonly used for flush ceiling outlets, octagonal boxes may also be used as a floor box for monument receptacles.

FLUSH FLOOR
NOTE
Boxes are mounted to wood floor structure (nonadjustable) or cast-in-place concrete with leveling screws. Concrete boxes include cast-iron, stamped steel, or nonmetallic materials. This is a heavy-duty box, in comparison to a standard octagonal floor box for monument receptacle.

**WEATHERPROOF (4 1/2\"/>
NOTE
Metallic and nonmetallic versions; knockout locations vary. Utility and exterior boxes not gangable; switch and masonry boxes may be. Flush mounting in concrete requires a concrete tight box and rigid conduit and tubing; in CMU construction, a raceway or tubing is threaded through the cavities.**

ELECTRICAL BOXES

WALL-MOUNT CABLE RACK

CENTER-HUNG CABLE RACK
NOTE

CABLE TRAY SYSTEM
NOTE

Cable trays protect and carry a large number of insulated cables in a limited space. For more protection or where heat buildup is not a problem, perforated or solid bottoms and top covers are available. Many fittings, bends, and tees (horizontal and vertical) are available. Consult manufacturers for materials other than aluminum or steel.

CABLE CHANNEL
NOTE
Cable channel can be used as a branch cable tray to carry a single large cable or conduit or several small ones.

CONDUIT AND CABLE SUPPORTING DEVICES

Charles B. Towles, P.E.; TEI Consulting Engineers; Washington, D.C.

POKE THROUGH SYSTEMS

Poke-through systems are used in conjunction with overhead branch distribution systems that run in accessible suspended ceiling cavities to outlets in full-height partitions. When services are required at floor locations without adjacent partitions or columns, as in open office planning, they must either be brought down from a wireway assembly (known as a power pole) or up through a floor penetration containing a fire-rated insert fitting and flush or above-floor outlet assembly. To install a poke-through assembly, the floor slab must either be core drilled or contain preset sleeves arranged in a modular grid. Poke-through assemblies are used in conjunction with cellular deck and under-floor duct systems when the service location required does not fall directly above its associated system raceway.

With one floor penetration, the single poke-through assembly can serve all the power, communications, and computer requirements of a work station. Distribution wiring in the ceiling cavity can be run in raceways. The more cost-effective method is to use armored cable (BX) for power and approved plenum-rated cable for communications and data when the ceiling cavity is used for return air. To minimize disturbance to the office space below when a poke-through assembly must be relocated or added, a modular system of prewired junction boxes for each service can be provided, although it is more common to elect this option for power only. A different type of working system must be selected for a floor slab on grade, above a lobby or retail space, above mechanical equipment space, or above space exposed to the atmosphere.

DESK EQUIPMENT LAYOUT

NOTE

Computer and telephone cabling is often combined as an integrated voice/data cabling system, eliminating the need for three raceways except when extra capacity is needed.

POKE-THROUGH HARDWARE SYSTEM/ZONE JUNCTION BOX

SECTION

NOTE

Computer and telephone cabling is often combined as an integrated voice/data cabling system, eliminating the need for three raceways except when extra capacity is needed.

CELLULAR DECK SYSTEM WITH TRENCH HEADER DUCTS

CELLULAR DECK SYSTEMS

The low initial cost of a poke-through system makes it both viable and attractive for investor-owned buildings when tenants are responsible for future changes and for corporate buildings with limited construction budgets. Poke-through systems are effective when office planning includes interconnecting workstation panels containing provisions (base raceways) to extend wiring above the floor, reducing the number of floor penetrations needed for services.

Based on the projected frequency of changes in office furniture layouts, a corporate or government organization may elect to invest in a permanent raceway system to minimize cost and disturbance to occupants when changes or additions are made. When structural design dictates the use of metal decking, a cellular floor raceway system utilizing trench header ducts is the most likely choice.

Cellular raceways come in a variety of sizes and configurations ranging from 1 1/2 to 3 in. high with cells 8 or 12 in. o.c. and 2 or 3 cells per section. An overall floor deck can be full cellular, where bottom plates are provided throughout, or blended as shown.

Trench header ducts come in various sizes and configurations. The height is adjustable for slab depths above cells of 2 1/2 to 4 in. and widths vary from 9 to 36 in. Cover plates are 1/4 in. thick, with lengths from 6 to 36 in., and can either be secured with spring clips or flush, flathead bolts. Two versions of trench design are available: One has a compartmental bottom tray with a grommeted access hole for each cell it crosses; the other has a bottomless trench duct consisting of side rails and a separate wireway in the middle, with grommeted access holes only for the power cells.

When service is needed, the floor is core drilled above the desired cell, the cell top is drilled into, and an afterset insert with above-floor fitting is attached. If data and communication wiring can occupy the same cell, with power wiring in an adjacent cell, two separate service fittings are required for each workstation.

When it is necessary to eliminate or minimize core drilling, a modular pattern of preset service flush outlets can be provided along the cellular sections before the floor is poured (as shown). Upon activation, one flush outlet can serve all the power, communication, and data requirements of a workstation.

The modular grid and frequency of preset locations will determine the convenience of service provisions for the workstations.

Richard F. Humenn, P.E.; Joseph R. Loring & Assoc., Consulting Engineers; New York, New York

NOTES

Where projected frequency of future changes is relatively high, a raised access floor system will provide the maximum flexibility and lowest cost to relocate or add services for workstations. When used in conjunction with a modular system of power, communication and data wiring plug-in receptacles, and cable connector sets, changes can be made without the need of an electrician or wiring technician. Advantages come at a premium, as access floor systems are the highest in initial cost of all systems described in this section.

A raised access floor is essentially a basic computer floor that is restricted in application to distribute only power, communication, and data services to workstations. The absence of air distribution and high density of cabling associated with computers permit raised floor height to be reduced to nominal 6 in. As the depth of standard 2 ft sq formed steel floor panel is less than 2 in., over 4 in. clear height under the panels provides sufficient clearance to accommodate hardware associated with distributing services. Virtually any variety of above-floor or flush outlets can be mounted on a floor panel and connected to lengths of cable with plug or connector fitting at the other end.

Access floors can be provided with or without stringers, which are used to minimize "creep" effect. Laser beam equipment speeds up accurate leveling of pedestal heights. For a custom installation without ramps or steps, the base floor is structurally designed to be depressed below permanent building elements such as lobbies, stairs, and toilets. Panels can be ordered with factory-installed carpeting or, alternatively, magnetic-backed carpet squares can be added after installation.

The introduction of an access floor does not necessarily require an increase in floor-to-floor height, and if so, the cubage added is at a much lower per unit cost than for the rest of the building. When special attention is given to coordinating lighting with other elements in the suspended ceiling or when lighting is provided below as from the workstations, the cavity can be compressed to compensate for the raised floor.

RAISED ACCESS FLOOR SYSTEM / MODULAR PLUG-IN DISTRIBUTION

NOTES

Undercarpet flat cable wiring has developed into a viable system to serve workstations. By code, it can only be used with carpet squares to afford an acceptable degree of access. Although there are some limitations in performance for flat communication (telephone) and computer (data) cables, improvements are continually being made. Flat cables are now available for Local Area Network (LAN) distribution, applicable where communication and data requirements are extensive.

Cables originate at transition boxes located at various intervals along core corridor walls and/or columns that are individually served from distribution centers in utility closets. Boxes can also be cast in the floor or atop a poke-through insert. Cables are not permitted to pass under fixed partitions and must be carefully mapped out to minimize crossovers and clutter.

To install a service fitting, an interface base assembly must first be secured directly to the concrete floor at the flat cable location. The base assembly stabs into conductors of the flat cable and converts them to round wire. When the service fitting is attached, it is activated and ready for use.

Careful consideration must be given to the application of this system based on limitations that may or may not be acceptable under different conditions. For instance, it may be ideal for small areas or renovation of existing buildings where the poke-through or power pole systems are unacceptable or cannot be used. In new buildings where poke-through has been chosen as the base system, the flat cable system is a viable solution in areas where poke-through outlets cannot be installed, such as slab on grade.

Where frequent changes and additions are contemplated, the resulting wear and tear on expensive, glued down carpet tiles may become a distinct disadvantage.

Although this system appears to be simple and inexpensive, it is highly labor intensive and actual installed initial costs and outlet relocation costs are comparable to cellular deck with trench header ducts.

FLAT CABLE WIRING SYSTEM

Richard F. Humenn, PE; Joseph R. Loring & Associates, Inc., Consulting Engineers; New York, New York
 Gary A. Hall; Hammel Green and Abrahamson; Minneapolis, Minnesota

GENERAL

UPS (uninterruptible power supply) is designed to provide continuous power with specific electrical characteristics by conditioning utility company power, battery power, or generator-supplied power.

Uninterruptible power supply (UPS) systems closely control the power supply voltage and frequency to critical equipment such as computers, communications systems, and medical instrumentation.

UPS systems are either on line, with power routing through them continuously, or off line, with power routed through them only when the incoming power is interrupted or departs from the design characteristics. The time required for an off-line, solid-state UPS to automatically switch on varies with the type of switch selected: The quicker the switch, the more expensive the switching equipment in general. The time needs to be matched to the tolerances of the critical equipment being supplied by the UPS to prevent loss of data or other problems.

Battery backup time is selected to allow a controlled shut-down of equipment or to allow a backup generator to be started and stabilize at full power.

Redundant UPS systems may be required if UPS power loss cannot be tolerated for system maintenance or equipment breakdown.

Some equipment can produce electrical disturbances that are fed back into the electrical circuit. This must be prevented through filtering in order to maintain clean power to the other equipment being supplied by the UPS.

The UPS unit and battery should be placed close together. Some UPS cabinets contain sealed batteries; others require separate batteries.

TYPICAL UNINTERRUPTIBLE POWER SUPPLY SYSTEM DIAGRAM

SOLID-STATE UPS SIZES

KVA	W (IN.)	D (IN.)	H (IN.)	WEIGHT (LB)
25	28	32	70	1400
50	72	36	72	4000
125	72	36	72	5600

10.0	36	19	52	10

NOTE

A wide variety of UPS systems is available for smaller applications, ranging from desktop models for single microcomputers to floor models that can supply several computers or other equipment.

UPS UNDER 10 KVA

NOTE

Standby generators provide emergency power during power outages, when life safety lighting and/or critical equipment power requirements are beyond the capacity of battery units or when required by code (as in hospitals or high-rise buildings). Engines should be located away from main electrical switchgear. Engine rooms must have adequate ventilation for engine- and generator-radiated heat and must be protected against extreme environments under all conditions of airflow.

There must be enough room around a power generating unit to service it and to remove the unit. Standby generators require frequent inspections, tests under load conditions, and maintenance. Provisions must be made to prevent vibration transmission to nearby occupied areas. In addition to the cooling methods illustrated, cooling by remote radiator, heat exchanger, submerged pipe, cooling tower, and evaporative cooler should be considered. See National Electric Code for working space requirements and proper application.

EMERGENCY ENGINE GENERATOR WITH CONTROL PANEL

NOTE

Battery-powered lighting equipment provides the minimal emergency illumination required for personnel safety and evacuation in buildings not requiring standby generator power. It is also used in buildings requiring standby generator power for the central control, telephone switchboard, generator, and electrical switchgear rooms to provide lighting for critical operations and troubleshooting if the generator fails to start. The batteries, which require frequent inspection, tests, and maintenance, are available in lead calcium, nickel cadmium, and wet lead acid.

EMERGENCY LIGHTING BATTERY SYSTEMS

NOTE

Used to light exit passageways during power outages. Typically powered by lead calcium or nickel cadmium batteries.

REMOTE FIXTURE

NOTE

Used with an emergency lighting battery system, this remote fixture may have one or two heads.

EXIT AND EMERGENCY LIGHTING

WITH EMERGENCY LIGHTING

NOTE

Available in solid acrylic, cast aluminum with acrylic letters, steel, or polycarbonate housing, these signs may be side-top, or back-mounted or recessed. They can be powered by standard AC or battery pack.

EXIT SIGNS

NOTE

This unit protects network data and telecommunications equipment and eliminates a wide range of potential power problems: spikes, surges and extended overvoltage conditions, noise, sags, extended brownouts, and harmonics and frequency variations common with standby generator operation. Power rating ranges from 1000 to 3000 V.

DATA AND TELECOMMUNICATIONS PROTECTION

Charles B. Towles, P.E.: TEI Consulting Engineers; Washington, D.C.

NOTE
All buildings and equipment should be grounded to protect people and equipment from fault currents. A complete interconnected system should be installed according to the requirements of the National Electrical Code and the National Electrical Safety Code. The structural steel of the building is connected to a buried "ground grid" to provide this requirement. All electrical equipment is connected with this system to provide a direct path to earth. Specify the number of ground rods and conductor size according to National Electrical Code requirements.

BUILDING GROUND GRID

SMALL EQUIPMENT

MEDIUM EQUIPMENT

LARGE EQUIPMENT

NOTE
Codes vary slightly regarding bonding requirements for metal bodies on rooftops. Generally, if a metal body is in a zone of protection (lower than adjacent air terminals) and within 6 ft or a calculated bonding distance, it should be bonded to the lightning protection system. Smaller, secondary size materials may be used for these connections. Metal bodies taller than the air terminals and less than 3/16 in. thick require air terminal protection. Those greater than 3/16 in. thick are protected if adequately bonded.

ROOFTOP EQUIPMENT BONDING AND PROTECTION

FASTENER TYPES

MISCELLANEOUS ROOFTOP EQUIPMENT

NOTE
In some cases, especially on tall structures, it may be advantageous to substitute the steel frame of a structure for portions of the usual conductor system, normally the downleads. Connections are made to cleaned areas of the building steel, at grade and at roof level, and the columns serve to connect the roof and ground systems.

STEEL FRAME AS CONDUCTOR

NOTE
Adhesives are typically used for flat roof installation.

TOP-MOUNTED AIR TERMINAL (LIGHTNING ROD) DETAIL

GENERAL

A lightning protection system is an integrated arrangement of air terminals, bonding connections, arresters, splicers, and other fittings installed on a structure in order to safely conduct to ground any lightning discharge to the structure.

Lightning protection systems and components are grouped into three categories (U.L. classes) based on building height and intended applications. Class I equipment and systems are for ordinary buildings under 75 ft in height. Class II is for those over 75 ft in height, and Class II Modified is a special group covering only large, heavy-duty stacks and chimneys similar to those used at power plants. Each of these system types comprises five or six major groups of components:

1. Air terminals (lightning rods) located on the roof and building projections.
2. Main conductors that tie the air terminals together and connect them with the grounding systems.
3. Bonds to metal roof structures and equipment.
4. Arresters to prevent power line surge damage.
5. Ground terminals, typically rods or plates driven or buried in the earth.
6. Tree protection (usually applicable only to residential work).

Each of these types of equipment and the methods for their installation is covered in the accompanying drawings.

Beyond these material requirements, other factors to be considered relative to lightning protection systems include selection of codes for compliance, inspection criteria (again based on code), criteria to evaluate competence of installing personnel, and requirements for annual inspection and maintenance.

OVERALL SYSTEMS DESIGN NOTES

1. Air terminals should be located around the perimeter of flat roof buildings and along the ridge of pitched roof buildings spaced at 20 ft on center maximum and located not more than 2 ft from ridge ends, outside corners, and edges of building walls.
2. Full-size main conductors should connect all air terminals.
3. Additional air terminals should be located in the center of large open flat spacings not to exceed 50 ft.
4. Cable runs connecting these center roof air terminals should be no longer than 150 ft without a lead back to the perimeter cable.
5. Gently sloping roofs are classed as flat under the rules shown above.
6. Downlead cables to ground should be connected to the roof perimeter cable at a maximum spacing of 100 ft on center. Buildings with a perimeter of 250 to 300 ft should have three downleads. For each additional 100 ft or fraction thereof add one downlead.
7. No building or structure should have fewer than two downleads.
8. Arresters should be installed on the electric and telephone services and on all radio and television lead-ins to a structure. Responsibility and jurisdiction for the installation of these devices can vary with locality, so special consideration may have to be given to these items.
9. Trees adjacent to residences pose a special hazard. It is recommended that all trees larger than an adjacent structure and within 10 ft of it be fully protected. Consult codes or manufacturer for recommendations on materials and installation requirements.
10. On-site inspections and certification of completed systems, installer competency certification, and guaranteed inspection/maintenance options are all available under existing standards. Consult codes and standards for specifics.

NOTE

Primary high-voltage service is received at a site via various stages, from the formation of electrical energy (water power, turbines, etc.) to substations that receive the elec-

tricity at high voltage and distribute this energy at a lower voltage via switchgear to the point of use. At each stage, protective devices (switches or circuit breakers) are installed. Transformers are installed to reduce voltage along the lines for the requirements of the end user.

PRIMARY SERVICE DISTRIBUTION

NOTE

When buildings cover a large area, such as a college campus or medical center, the use of medium voltages of 5 to 34 kV for distribution feeders is usually required. Therefore,

the utility company terminates its primary feeders on the owner's metal-clad or metal-enclosed switchgear, which may be inside or of exterior weatherproof construction. Code clearance in front and back of board must be provided in accordance with the National Electrical Code.

PRIMARY SWITCHGEAR WITH PRIMARY POWER FROM TWO SERVICES

TYPICAL PAD SIZES

POWER	A	B
150 - 300 kVA	75 in.	80 in.
500 - 1500 kVA	84 in.	84 in.

NOTES

1. Pad-mounted transformers with weatherproof, tamper-proof enclosures permit installation at ground level without the danger of exposed parts. Three-phase units up to 1500 kVA are normally used with underground primary and secondary feeders. The customer's grounding grids or grounding electrical conductors should not be connected at pad-mounted transformer locations.
2. High voltage compartment requires 10-ft clearance for on-off operation of the insulated stick located on the transformer (known as "hot stick" operation).

PAD-MOUNTED TRANSFORMER

NOTE

Overhead distribution lines are supported by poles from the origin of the electrical service to the termination point. Poles are fabricated out of various kinds of wood (e.g., pine or cedar) or steel, depending on the type of equipment to be supported, weather conditions, and cost of materials. Transformers mounted directly onto the poles or on platforms provide the required low voltage service to the final point. Spacing between the poles, height of the poles, and clearances between electrical lines and the ground depend upon the type of terrain, weather environment, and obstructions (e.g., inhabited area, waterways, railroads, roadways, etc.). See the National Electrical Safety Code for restrictions.

OVERHEAD POLE CONFIGURATION

NOTE

Manholes are provided for splicing and pulling of electrical cables for underground distribution. Size ductbanks emanating out of the manhole according to the latest edition of the National Electrical Code.

MANHOLE DETAILS

NOTE

Underground vaults are generally used for utility company transformers where all distribution feeders are underground. These systems usually constitute a network or spot network. Vaults are often located below the sidewalks and have grating tops. Transformer is usually liquid filled; if an oil-filled transformer is used, an oil interceptor is recommended before discharge to building storm sewer.

UNDERGROUND VAULT

UNDERGROUND DUCT BANK

Charles B. Towles, P.E.; TEI Consulting Engineers; Washington, D.C.

SINGLE-PHASE THREE-PHASE

NOTE
Rated secondary voltages: 208, 240, or 480. Immersed in oil, self-cooled.

POLE-MOUNTED TRANSFORMERS

NOTE
Provides convenient control of lighting and power circuits from control stations.

REMOTE CONTROL SWITCH

NOTE
Rated voltage: 600 VAC. For circuits that are closed and opened repeatedly, various design combinations are allowed. Used for all classes of magnetically held loads, open or closed.

CONTACTOR

NOTE
Rated secondary voltages: 120/208 or 240 volts or three phase. Primarily mounted on indoor floors and walls.

DRY TRANSFORMER

NOTE
Automatically transfers loads from a normal source to the emergency source.

AUTOTRANSFER SWITCH

POLE RACK NOTE
Power factor correction on either low or high voltage systems. Types, indoor or outdoor. Size and voltage as required. Switched or floating.

CAPACITOR

NOTE
Secondary substation transformer with high to low voltage. Primarily a commercial type for the outdoors. Optional external fan cooling.

LIQUID-FILLED TRANSFORMER

NETWORK TYPE NOTE
Maximum voltage: 125/216 VAC or 277/480 VAC. Interrupting capacity 30,000 and 60,000 A. RMS. SYM. A fault on primary cable or network transformer will open protector to isolate fault from system.

PROTECTOR

LOW VOLTAGE NOTE
Rated voltages: 240 VAC, 480 VAC, 600 VAC, and 250 VDC. Manual or electric operation. Electromechanical or solid-state breaker trip devices. Stationary or drawout types.

DISTRIBUTION CIRCUIT BREAKER

Charles B. Towles, P.E.; TEI Consulting Engineers, Washington, D.C.

NOTE

A secondary unit substation, sometimes called a power center, is a close-coupled assembly consisting of three-phase power transformers, enclosed high voltage incoming line sections, and enclosed secondary low voltage outgoing sections encompassing the following electrical ratings:

Transformer kVA: 112.5 through 2500 (self-cooled rating) liquid-filled, dry-type, or cast coil.
 Primary voltage: 2.4 kV thru 34.5 kV.
 Secondary voltage: 208, 240, 480, or 600 V (max.).

See National Electrical Code for aisle space, ventilation, servicing area, and special building condition requirements.

SECONDARY UNIT SUBSTATION

MANUAL NOTE

Manual single-phase starters are designed to give positive, accurate, trouble-free overload protection to single phase motors rated up to 1 HP. Typical applications are fans, machine tools, motors, HVAC, etc. Maximum voltage is 240 V AC.

MAGNETIC NOTE

Magnetic motor starters are designed for across-the-line control of squirrel cage motors or as primary control for wound rotor motors. Starters can be furnished for non-reversing, reversing and two-speed applications. Maximum voltage is 600 V AC; maximum horsepower is 200 HP.

COMBINATION NOTE

Magnetic combination starters are designed for across-the-line control of squirrel cage motors or as primary control for wound rotor motors. In addition, they provide a disconnect means and short-circuit protection. They are available for nonreversing or reversing applications.

MOTOR STARTERS

SOLID-STATE NOTE

This unit is a reduced voltage motor starter, used to reduce starting current and high starting torque. Typical applications for controllers are in motors used in cranes, belt-driven equipment, conveyors, material handling facilities, compressors, and woodworking equipment. Available for AC motors 5 to 900 HP.

NOTE

Metering compartment, main disconnect, check meters, and low voltage distribution section. See manufacturer's literature for type, size, and arrangements. See National Electrical Code for required aisle space, servicing area, and room layout.

SWITCHBOARD

NOTE

Motor control centers provide a method for grouping motor control, associated control, and distribution equipment. It is designed to operate machinery, industrial processes, and commercial building systems.

LOW-VOLTAGE MOTOR CONTROL CENTER

NOTE

Plug-in and feeder busways carry current from 50 to 5000 amps. They are utilized when large blocks of low voltage power (up to 600 V) must be transmitted over long distances or when taps must be made at various points, as in vertical risers in office buildings. Codes limit locations in buildings where different types of busways may be installed. Consult an electrical engineer before using this system. Busway housing may be hung from an overhead support, mounted to a wall, or braced to the structure in vertical riser installation.

BUSWAY SYSTEM

Charles B. Towles, P.E.; TEI Consulting Engineers; Washington, D.C.

MULTIPLE METER BANK WITH MAIN CIRCUIT BREAKER
 1. Rated voltages: 120/240 V, 3-wire, single-phase or 208/120 V, 4-wire, three-phase.
 2. Either indoor or outdoor construction.
 3. Number of sockets as required by application.

MOLDED CASE
 1. Rated voltages: 120 VAC, 240 VAC, 600 VAC, 125 VDC, and 250 VDC.
 2. Frame sizes: 100, 150, 225, 400, 600, 800, 1200 A poles, 2 or 3 above 100 A.
 3. Current limiting types with fuses.

MOLDED CASE WITH GROUND FAULT
 1. Rated voltages: 120 VAC or 120/240 VAC.
 2. Frame size: 100 A ratings, 15-30 A poles, 1 or 2.

NOTE
 Knockout holes allow conduit connections from all sides.

PANELBOARD DIMENSIONS

MAXIMUM NUMBER OF CIRCUITS	BOX DIMENSIONS (IN.)		
	WIDTH	HEIGHT	DEPTH
12	9-15	13-20	3 ³ / ₄ -4 ⁵ / ₈
20	9-15	20 ¹ / ₄ -24	3 ³ / ₄ -4 ⁵ / ₈
30	12-15	30-33	3 ³ / ₄ -4 ⁵ / ₈
40	14-15	34-39	4-4 ⁵ / ₈

HIGH-PRESSURE CONTACT
NOTE
 High-pressure contact switches may be top or bottom feed; 600 V AC max; 800-4000 A.

RESIDENTIAL AND COMMERCIAL PANELBOARD

PLUG FUSE
 1. Rated voltage: 125
 2. Ampere rating: 1-30
 3. Fuse types: S, T

KNIFE BLADE FUSE
 1. Rated voltage: 250 and 600
 2. Ampere ratings: 70-6000
 3. Fuse types: K1, RK1, K5, RK5, J, H, G, and L

CARTRIDGE FUSE
 1. Rated voltage: 250 and 600
 2. Ampere rating: 1/10-60
 3. Fuse types: K1, RK1, K5, RK5, J, H, and G

NOTE
 Cartridge and knife blade fuses are available for short circuit protection up to 200,000 A (Rms).

FUSES

CIRCUIT BREAKER

FUSE BOX DISCONNECT SWITCHES

FUSIBLE SWITCH DISTRIBUTION PANEL BOARDS

GENERAL

Fluorescent technology offers among the highest efficacies of all lamps for high color quality white light and is three to five times more efficient than incandescent technology. Fluorescent lamps, as well as high-intensity discharge (HID) lamps, work on an electric-discharge principle and require a ballast. Light in a fluorescent lamp is produced when fluorescent powders are activated by ultraviolet-energy generated by a mercury arc.

Fluorescent lamps are available in many types. Variations in phosphor chemistry, gas fill, size, and electrical input make possible many colors, efficiencies, sizes, and light outputs.

PHOSPHORS

Phosphors are the chemical powders that line the inside of a fluorescent tube. Their composition is responsible for the color, quality, and efficiency of light emanating from a fluorescent lamp. Among "white" sources, halophosphate phosphors such as cool white and warm white were the most popular types from the 1950s through the 1970s. In the 1980s trichromatic rare earth (RE) phosphors were developed, which offered greater efficiency and improved color rendering. These are now the predominant phosphors available in T10, T8, and compact fluorescent lamps; they are also available in most T12 sizes.

Trichromatic phosphors are available in two grades on the color rendering index (CRI) and a number of color temperatures. So-called "thin-coat" trichromatic phosphors have a CRI in the low to mid 70s; "thick-coat" phosphors have a CRI in the low 80s. By comparison, cool white halophosphate lamps had a CRI of 62. Both triphosphor series are available in a number of color temperatures, including warm-3000K, neutral-3500K, and cool-4100K. Very cool-5000K and 6500K-colors are available in some types.

Other, specialized phosphors are available in some straight-tube fluorescents, although these are usually much less efficient. Some high-CRI white lamps, with CRIs over 90, are available for applications that demand color matching; the lamps highest on the CRI are available at the highest Kelvin temperatures, up to 7500K. Colors, particularly red, blue, and gold, are used for special effects.

FLUORESCENT STRAIGHT TUBES

Fluorescent straight-tube lamps are the predominant lamp type in indoor commercial lighting. Because of their widespread use, much attention has been focused on developing a wide variety and more efficacious versions.

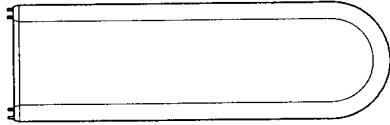

The T12 (1 1/2-in. diameter) was the predominant shape for decades, and by far the most popular of these was the F40T12, rapid-start, 40W, cool white (CW) four-footer. As a requirement of the Energy Policy Act of 1992, manufacturers stopped making this lamp for U.S. use in October 1995.

"Energy-saver" lamps, with krypton added to the gas fill, are direct substitutes for most "standard" or full-wattage lamps. The light output in these lamps is reduced along with the reduction in power input. A 34W lamp is the energy-saver version of the standard 40W F40T12. It is intended for use in environments of 60°F or warmer.

TUBE DIAMETER

Among straight-tube fluorescents, tube diameter is an important determinant of efficacy. Generally, the narrower the tube, the higher the efficacy. In the 1980s lamps of smaller diameter and thus of higher efficacy were devel-

STRAIGHT TUBE FLUORESCENT SHAPES AND TYPICAL NOMINAL LENGTHS

TUBE SHAPE	BASE
T2 right angle, 20" 	
T5 miniature bipin, 46" 	
T8 medium bipin, 48" 	
T8 medium bipin u-bent, 22 7/16" 	
T10 medium bipin, 48" 	
T12 medium bipin, 48" 	
T8 single pin slimline, 96" 	
T12 single pin slimline, 96" 	
T12 recessed double contact, 96" 	

NOTE

Lamps are not to scale; nominal length is from back of socket to back of socket.

oped. Compared to the "standard" F40 CW, the T10 lamp provides increased light output and improved color, with a slight increase in electrical input. The thick-coat triphosphor T8 lamp provides the same light output, improved color, and a significant decrease in electrical input.

T8 lamps use 20% fewer watts than standard F40s and operate even more efficiently when used on electronic ballasts. In 1995 efficient indoor lighting design generally uses a combination of T8 series lamps with electronic ballasts.

The next straight-tube development is the T5 shape, introduced in Europe in 1995. These lamps, which use miniature bi-pin bases, offer further efficacy gains but are manufactured in lengths compatible with European building module dimensions of 600 mm and 1200 mm rather than the 2-ft and 4-ft dimensions standard in the United States. Therefore, T5 lamps need their own, dedicated luminaires.

LENGTH AND SHAPE

Straight-tube fluorescents are available in a wide range of lengths, from 6 to 96 in. In general, the longer the tube, the higher the efficacy.

A number of variants of the straight-tube shape are available. The U-shaped lamp is essentially a straight-tube lamp bent in half. It comes with center-to-center leg-spacings of 1 5/8 in. (16, 24, 31W T8), 3 5/8 in. (35, 40W T12), or 6 in. (32W T8; 34, 40W T12). Circular fluorescents basically are straight tubes bent in a circle. They are available in outside diameters of 6 1/2 in. (20W), 8 1/4 in. (22W), 12 in. (32W), and 16 in. (40W) T9 shapes. Straight tubes with outer glass jackets are designed for locations outdoors or in other sub-zero temperatures.

Fred Davis, C.L.E.P.; Fred Davis Corp., Energy and Lighting, Medfield, Massachusetts

BALLASTS AND STARTING MODES

The ballast provides the proper electrical characteristics to start and operate a fluorescent lamp. The starting process occurs in two stages: First, a sufficient voltage between an electrode and ground ionizes the gas (mercury plus an inert gas) in the lamp. Next, a voltage must develop across the lamp sufficient to extend the ionization throughout the lamp and to develop an arc.

The three starting modes for ballasts for fluorescent lamps are preheat, instant-start, and rapid-start. Each ballast type is used only with compatible lamps. Electronic ballasts are available in both instant-start and rapid-start designs.

For the preheat mode, a separate starter button is often used to heat the electrodes before high voltage is applied across the lamp. The instant-start mode applies a high voltage (400 to 1000 V) across the lamp to ionize the gas and initiate arc discharge. This design provides the lowest energy consumption, sometimes at the expense of lamp life. In the rapid-start mode, electrodes (cathodes) are heated continuously by means of low voltage windings built into the ballast, allowing a gentle start. A variation cuts power to the cathodes after the arc is struck. Ballast factor is the percentage of a lamp's rated lumens produced when operated on a specific commercial ballast.

ELECTRONIC BALLASTS

Electronic ballasts improve the efficacy of lamps by driving them at high frequencies, above 15 kHz. Such ballasts eliminate flicker and are much lighter than electromagnetic ballasts. The improvement in efficacy made possible by electronic ballasts alone is approximately 10-12% for 4-ft lamps and 5% for 8-ft lamps, compared to operation at 60 Hz. Electronic ballasts are available that operate one, two, three, or four 4-ft T8 lamps at once.

Like magnetic ballasts, most electronic ballasts are designed so actual lumen output is as close to the rated lumens as possible. However, some electronic ballasts have been designed to deliberately provide higher than rated lumens (ballast factor > 1.0), while others have been designed for lower than rated lumens (ballast factor < 0.9). The ballast factor should be consulted carefully to ensure that the lighting design meets the desired light output.

FLUORESCENT FAMILIES

Fluorescent lamp families differ from each other in base type, starting characteristics, and "loading" (the amount of electrical energy applied per length of lamp). Generally, the most efficacious lamp family is the T8, and it should be used where appropriate. Applications requiring high output may call for multiple fluorescent lamps, efficient high-intensity discharge, or one of the higher loading families. For low light levels, any fluorescents are more efficacious than incandescent lamps.

Subminiature lamps use a T2 bulb with a "right-angle" base. They are available in 8-in. 6W, 12-in. 8W, and 20-in. 13W sizes.

Preheat fluorescent lamps utilize separate starters. These T5, T8, T12, and T17 lamps range in length from 6 to 60 in. The smallest of these uses a miniature bipin base. Lamp lifetime is 6000 to 7500 hours for T5s and T8s, 9000 for T12 and T17. These lamps are not commonly used in commercial general lighting.

The rapid-start T12 lamp, which operates at 430 mA with a medium bipin base, was formerly the mainstay of commercial lighting, even though it is available in only F30 36-in. and F40 48-in. sizes. The Energy Policy Act of 1992 eliminated inefficient halophosphate 4-ft full-wattage (40W) versions, leaving trichromatic phosphor types available for full wattage. Energy savers of all phosphors are available in 25W and 34W. 32W cathode-cutout 4-ft lamps cut electrical input to the cathode after starting, but they should not be used in situations with frequent on and off switching.

T8 lamps, operating at 265 mA, are the lamps of choice for energy-efficiency. They are available in 2-ft 17W, 3-ft 25W, 4-ft 32W, 5-ft 40W, and 8-ft 59W sizes. The 8-ft lamp has single-pin bases, for instant start only. The remainder have medium bipin bases and can operate on instant-start or rapid-start ballasts as long as they are specific to the T8 lamp. Rated life on instant-start ballasts is 15,000 hours, as opposed to 20,000 hours on rapid-start ballasts; however, in typical use, with 8- to 12-hr burn cycles on electronic ballasts, actual life difference is minimal.

Slimline lamps are single-pin based and range from 2 to 8 ft. They operate on instant-start ballasts. The F96 T12 lamp was the standard lamp in 8-ft luminaires.

High output lamps operate at 800 mA and produce approximately 45% more light than slimlines of the same length, although at lower efficacy. They have recessed double con-

tact (RDC) bases and rated life ranges from 9000 to 12000 hours. Very high output lamps operate at 1500 mA and range as high as 215 watts.

COMPACT FLUORESCENTS

Compact fluorescents were developed in the early 20th century to put the efficiency of fluorescent technology into a package small enough to compete with incandescent lamps in some application niches. Technological improvements have provided several generations of ever smaller, brighter glass shapes.

These glass shapes are fitted to either plug-in pin bases, which need a separate ballast, or to screw-in bases with ballasts built in. Compact fluorescents are used in a variety of luminaires, including most types that were historically designed for incandescent. For best efficiency, fixtures should be designed around the photometrics particular to the compact fluorescent.

Lamps with plug-in pin bases are dedicated for a ballast type. Two-pin lamps are preheat types that contain a glow starter in the lamp base, whereas four-pin lamps work with electronic ballasts that incorporate the starting function. As with straight-tubes, when compared to magnetic ballasts, electronic ballasts for compact fluorescents are lighter and more efficacious and eliminate flicker. Base-down operation of some compact fluorescents yields fewer than rated lumens; others have amalgam chemistry that offsets this phenomenon. Optimum output is close to horizontal.

REPRESENTATIVE COMPACT FLUORESCENT CHARACTERISTICS

Fred Davis, C.L.E.P.; Fred Davis Corp., Energy and Lighting; Medfield, Massachusetts

GENERAL

Incandescent lamps are the least efficient electric lighting sources, converting only 7-12% of electrical input to visible light. They operate on the principle of electric resistance: As electric current flows through a filament, resistance causes it to heat to a temperature high enough to glow, or incandescence.

Despite the many efficient alternatives to incandescents, they remain popular in certain applications because they can be dimmed easily and inexpensively and because they sparkle the most brilliantly. Incandescents have traditionally worked best for low-lumen applications, but LED and electroluminescent technologies now offer low-wattage alternatives. Switching on instantly and interchangeability among a variety of wattages are other advantages of incandescents. Most important, the small filament size of halogen reflector lamps makes them the most efficient type in narrow-beam applications.

The low initial price of incandescent lamps and luminaires can be misleading because their operating costs are relatively high. Such costs include not only electricity, but also the cost of replacing lamps. Another factor to consider is lamp life: As a rule, light output decreases over time. Therefore, if a lower lumen level is acceptable, a lower wattage lamp should be considered.

INCANDESCENT TECHNOLOGY IMPROVEMENTS

Incandescent technology has improved over the years, but the efficacy of the most efficient incandescents—more than 30 lumens per watt for infrared reflecting halogen—is still far lower than that of the least efficient fluorescents.

Early improvements in incandescent technology included the coiled-coil filament and the use of inert gases as fill material in the lamp. For greater efficacy still, krypton gas is used: It is less conductive than the standard argon-nitrogen mixture but more expensive.

Tungsten-halogen lamps use a halogen regenerative cycle to keep the filament from evaporating. A halogen additive in the fill gas, usually iodine or bromine, reacts chemically with tungsten molecules that have evaporated off the filament. The tungsten is then redeposited onto the filament instead of on the bulb wall. The lamp operates at an extremely high temperature, which necessitates that a special glass envelope, usually quartz, surround the filament.

The high temperature of tungsten-halogen lamps also gives them greater efficacy than standard incandescents—their color temperature is 200 to 300° K higher. The small, vertical filaments in tungsten-halogen lamps allow for very efficient reflectors. As a result, some low-wattage halogen reflectors are more energy-efficient than some compact fluorescent types for relatively narrow-beam applications.

A further improvement in halogen lamps involves infrared-reflective (IR) film. A very thin dichroic coating applied to the halogen lamp or capsule reflects infrared (heat) energy back onto the filament, allowing visible light to pass through. The hotter filament increases lumen output, thus improving efficacy.

Lamps whose outside bulb walls are made of quartz require special handling, as oils from bare hands can damage them. Many manufacturers now enclose the halogen capsule in an outer glass envelope, eliminating this problem.

AREA SOURCES

General service area lamps range from a 15-watt A15 to a 1500-watt PS52. They are designed for 120V, 125V, and 130V volt circuits. Besides the most popular A, or arbitrary, shape, other shapes include PS, or pear straight. Halogen capsule versions of A-type shapes provide slightly better efficacy than standard incandescents.

Decorative shapes include FL (flame), B (bulbular), and G (globe). These are usually less efficient than standard incandescents, and efficient design will use low-wattage versions if necessary. The T (tubular shape) has been used in exit signs and for illuminating mirrors and pictures, which can also use linear and compact fluorescents if color is appropriate.

Tungsten halogen lamps are also available in noncapsule versions. Single-ended T3 and T4 tungsten halogen lamps range from 75 to 1500 watts, with the mini-candelabra screw base being the most common base. Double-ended tungsten halogens are linear shapes ranging up to 1500 watts. Small, low-voltage halogen type lamps are often used in reflectorized luminaires; usually under 2 in. in length, they use bipin bases, and range from 5 to 150 watts. IR versions of some linear halogen wattages provide substantial energy savings.

REFLECTOR SOURCES

The most popular flood and spot lamps were R (reflector) shapes, both R30 and R40 sizes. Flood R30 lamps had a beam spread of 130 degrees and much of the light in the outer part of the beam was often trapped in luminaires, especially recessed luminaires. Most are no longer manufactured. The newer ER (ellipsoidal reflector) and BR (bulged reflector) shapes maintain more lumens in the center of the beam than the R design.

PAR (parabolic reflector) lamps use a hard glass outside lens and are available in both "spot" (smooth glass lens) and "flood" (stippled lens) versions. Halogen versions range from 35 to 120 watts, in PAR16, 20, 30, and 38 shapes, all of which use a medium screw socket. Beam spread ranges from 8 to 50 degrees. Other designations such as FL (flood), SP (spot), V (very), N (narrow), and W (wide) may not be standardized, and rated beam spreads should be verified. Halogen infrared technology is available in some PAR38 versions and affords the highest efficacy among incandescent reflectors.

Small, low-voltage halogen reflector lamps, usually 12 volts, are used in luminaires with transformers for the purpose. MR11 and MR16 shapes, originally used in slide projectors, became popular in display and other accent lighting applications. Wattages range from 20 to 75. Like line-voltage halogen PARs, MRs come in a very wide range of beam spreads.

HIGH-INTENSITY DISCHARGE

High-intensity discharge (HID) lamps are the most common electric lights other than incandescent and fluorescent. In rough order of increasing efficacy, the categories of HID lamps include mercury vapor, metal halide, high-pressure sodium, and low-pressure sodium. The highest efficacies among them, however, have the poorest color qualities.

Like fluorescents, HID lamps use a ballast to provide proper starting and operating voltages. Light is produced by an electric arc discharging through a mixture of gases. Unlike fluorescents, HID lamps use a fairly compact arc tube that operates under very high temperature and pressure. The small point source makes HID lamps and luminaires compact and powerful. Most are particularly suited to outdoor applications or large rooms with high ceilings, as long as frequent switching is not needed. Clear lamps offer best optical control; coated lamps offer more diffuse light.

Unlike incandescents and fluorescents, HID lamps require a warmup period to reach full light output. After power is applied, temperature and pressure in the mixture of gases and metals gradually builds, forcing vapors into the arc and releasing light. Depending on lamp type, warmup, ranges from 2 to 15 minutes. If power is extinguished, HID lamps must cool before the arc can restrike. Restrike time lasts from 1 to 15 minutes, depending on lamp type. A few "instant restrike" types are available.

Over time, HID lamps may shift in color and the lumen output of some may drop substantially. For these, lamp change-outs should be planned well before the end of rated life. Rating the life of HID lamps is based on 10-hour cycles, as opposed to the three hours for rating incandescents and fluorescents. As with fluorescents, strobe effects with moving machinery should be avoided. HID lamps may have medium, mogul, or numerous other base types. A very few specialized types may be interchanged with metal halide, high-pressure sodium, and mercury vapor lamps.

METAL HALIDE

Originally developed in 1965, metal halide technology has continually improved. Today, its high efficacy and good color qualities make metal halide the best choice for many indoor and outdoor applications.

Common metal halide lamps have a color temperature of around 3500-4300K, and a CRI of 65-70. In addition, there are warm color lamps, 2700-3200K. In the early 1990s, some metal halide lamps were developed with very high CRIs, up to 93. Wattages range from 32 to 1500 watts, with a large variety of lamp and base configurations.

Metal halide lamps contain various metal halides and mercury. When the halide vapor approaches the high temperature in the central core of the arc, it dissociates into the halogen and the metal, with the metals radiating the appropriate spectra. Most metal halide lamps must be used in luminaires made to withstand an explosive rupture of the arc tube. Many should be used in luminaires that include a device to automatically turn the lamp off if the fixture is opened or broken. Most lamps should be turned off for a minimum of 15 minutes at least once per week.

Varieties of metal halide lamps include universal position burning, lamps optimized for burning in specific positions, cool or warm color temperatures in clear or phosphor coatings, safety lamps that extinguish if the outer envelope breaks, lamps with internal shielding that can withstand a rupture of the arc tube for use in open luminaires, and compact lamps that produce a high CRI in a small arc tube.

Electronic ballasts available for some metal halide types offer lighter weight, increased efficacy of 4-10%, less flicker, improved color and lumen maintenance, and increased life. Metal halide lamps with ceramic arc tubes have recently been introduced. These provide improved color control, more than 80 CRI, and higher efficacy.

HIGH-PRESSURE SODIUM

High-pressure sodium (HPS) lamps are highly efficacious, ranging from 65 to 125 lumens per watt (including ballast losses). They have a gold-pink color, 1900-2100K. CRI is poor, under 25. They are used where color rendering is not critical—in street, security, and industrial lighting.

Using xenon gas as an aid in starting, HPS lamps produce light by electric current passing through vaporized sodium. HPS lamps do not need enclosure (except from precipitation), and are fairly insensitive to operating position. So-called "deluxe" HPS have a CRI of 65. "White" HPS lamps of 2500-2800K have a CRI over 75. These improvements in color quality come at the cost of efficacy.

ALL LAMPS—COMPARISON OF GENERAL CHARACTERISTICS

LAMP TYPE	LAMP LUMENS PER WATT	HOURS LIFE	COLOR RENDITION	RELIGHT TIME
Incandescent	10 - 30	750 - 4000	Excellent	Immediate
Fluorescent	55 - 100	7500 - 24000	Good to excellent	Immediate
Metal halide	80 - 125	3000 - 20000	Good to excellent	10-15 min.
High-pressure sodium	65 - 140	16000 - 24000	Fair	Less than 1 minute
Low-pressure sodium	up to 180	18,000	Nonexistent	0-5 minutes
Mercury vapor	30 - 63	16000 - 24000	Fair to good	3-5 minutes

*M = metal halides; S = high-pressure sodium; L = low pressure sodium; H = mercury.

LOW-PRESSURE SODIUM

Low-pressure sodium (LPS) lamps were first introduced in 1932 and have the highest efficacy of any light source available. However, the most important characteristic of LPS lamps is that they are monochromatic. The starting gas is neon, which emits a reddish glow as the lamp heats up. At full output, light from LPS is monochromatic yellow, and there is no color rendering ability. LPS comes in tubular lamps, from 18 to 180 watts, and is used for security and some roadway lighting.

MERCURY VAPOR

Developed in the early 1900s, mercury vapor is the least efficient of the HID sources. The technology involves excitation of mercury in a vaporized state. It is available in clear or phosphor coatings. The phosphors work much as they do with fluorescents, to convert ultraviolet to visible light and to improve color rendering. Because efficacy and color quality is so much better, metal halide is preferred over mercury vapor in most situations.

OTHER LAMP TYPES

Electrodeless lamps first appeared commercially in the 1990s. These are sources excited by electromagnetic energy passing through the glass lamp without using an electrode. Coupling energy into a lamp at high frequencies forms plasma conditions that allow long life and fairly high efficacies. However, these high-frequency and microwave-powered sources must contain radiation within the lamp. The first products range from 23 to 85 watts, with efficacies from 48 to 70. Prototypes of a high-wattage sulfur lamp have shown the potential for high efficacy.

Other efficient lamp types are used in applications requiring low lumen levels, such as in exit signs. Energy consumption in exit signs is important because they are on continuously. Very low wattages allow an exit sign to use under 2 watts, compared to 20-50 watts with incandescent lamps.

Small light-emitting diodes (LEDs) are p-n junction semiconductor lamps. First used as indicator lights, they are now available in exit sign strips. Electroluminescent lamps are thin, flat area sources in which light is produced by a phosphor excited by a pulsating electric field. Typically, green panels are used in LED exit signs. Radioactive tritium tubes are self-contained sources requiring no power supply.

REPRESENTATIVE HID SHAPES

GENERAL

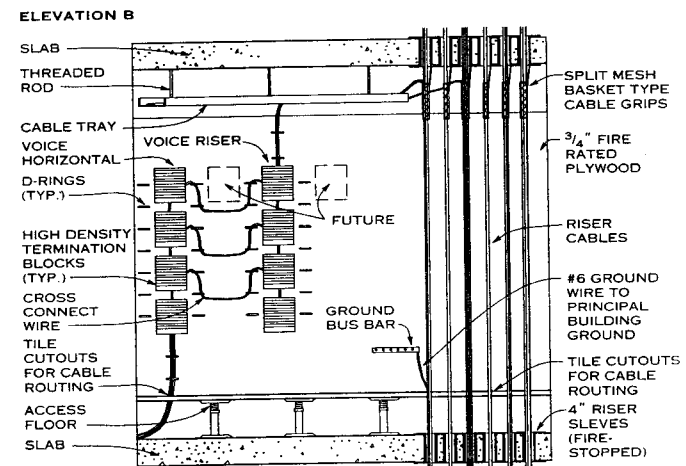

Horizontal telecommunications cabling may be routed between telecommunications closets and workstations via access floors, cellular decks, ceiling plenums, and under-carpet schemes. Access floor distribution facilitates the installation of future cabling as well as the movement of floor boxes and cable feed-throughs to accommodate furni-

ture relocations. Cellular decks provide similar underfloor cable pathways, yet lack the flexibility of relocatable floor boxes. Other distribution approaches include under floor, plenum routing, which requires poke-through fittings for access to workstations, and ceiling routing which is most appropriate for drywall installations. Under-carpet distribution utilizes special cable to provide a relocatable cabling system with minimal modifications to building structures.

Telecommunications closets provide the transition points between riser and horizontal cabling and accommodate associated cable termination hardware and transport electronics. Closets should be designed with respect to service area, environmental, lighting, fire protection, security, and cable pathway requirements. Overhead cable tray, access floors, and D-rings facilitate cable distribution.

NOTE

This information is for preliminary planning and design only. For final layouts and design, investigate current rules and regulations of the athletic organization or other authority whose standards will govern.

ORIENTATION

No standard—consider time of day for games; months when played; location of field, surrounding buildings and stands. East-northeast recommended by NCAA (home plate to center field).

BASEBALL FIELD

DETAIL OF PITCHER'S MOUND

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

BASEBALL EQUIPMENT

BASES

DETAIL OF HOME BASE BATTER'S AND CATCHER'S BOX

PLAN OF LITTLE LEAGUE BASEBALL FIELD

NOTE
The infield shall be graded so that the baselines and home plate are level.

PLAN OF SOFTBALL FIELD

NOTES

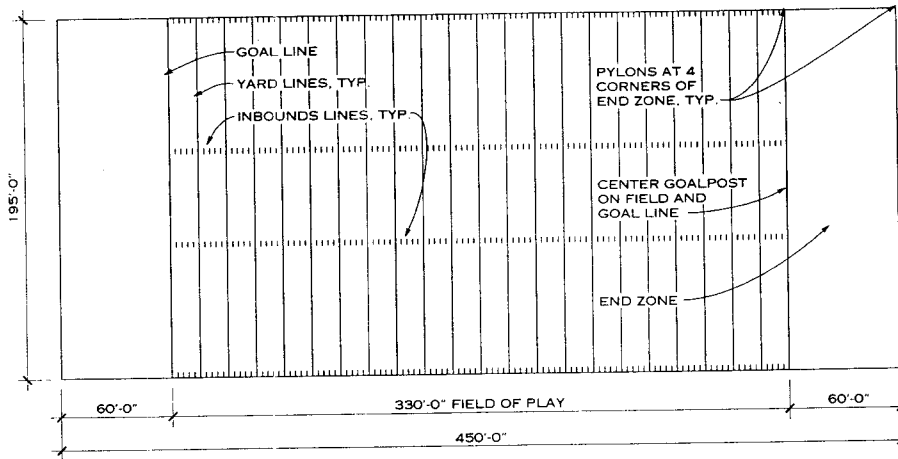

1. Baselines should be level; if the diamond must pitch, the slope should not be more than 2% from third to first base, or vice versa. The minimum slope of turf areas outside the skinned area is 1% when there is good subsoil drainage, 2.5% when drainage is poor.
2. The softball backstop is covered in detail on page 674.

NOTES

1. In the National Football League (NFL), the playing field is 360 ft long by 160 ft wide. The preferred orientation of the field is with the long axis stretching northwest to southeast; there is no recommended slope. (For further information, contact the NFL in New York City.)
2. All lines are 4 in. wide, except the goal lines and yellow lines, which are 8 in. wide. All lines are marked with a nontoxic material.
3. The goalpost must be padded as prescribed by the NFL.

NATIONAL FOOTBALL LEAGUE FIELD

NOTES

1. In the Canadian Football League (CFL), the playing field is 450 ft long by 195 ft wide. The preferred orientation is with the long axis running northwest to southeast; there is no recommended slope. (For further information, contact the CFL in Toronto.)
2. All lines are 4 in. wide except the goal lines and yellow lines, which are 8 in. wide. All lines are marked with a nontoxic material.
3. The goalpost must be padded as prescribed by the CFL.

CANADIAN FOOTBALL LEAGUE FIELD

NFL, CFL, NCAA, AND HIGH SCHOOL

NOTE

Goalposts should be padded to 6 ft or as prescribed by the NFL or CFL. They should be yellow or white.

OPTIONAL NCAA AND HIGH SCHOOL

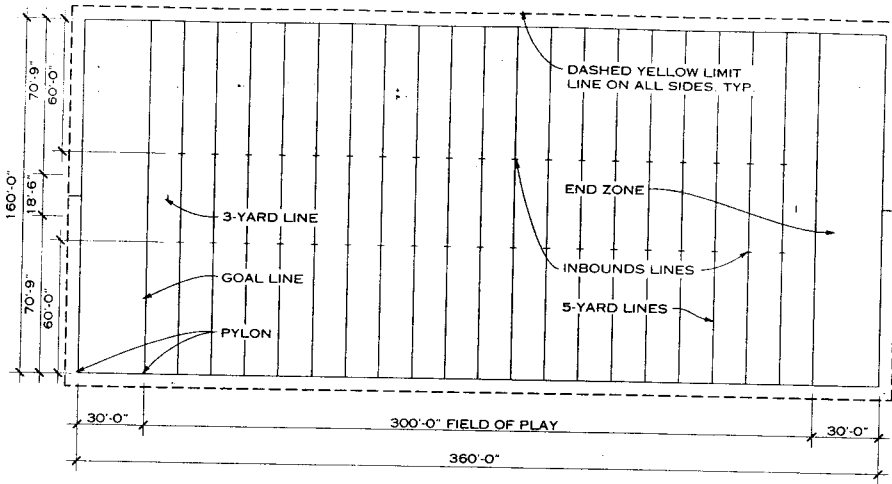

NOTE

The football is a prolate spheroid with a long axis of 11 to 11 1/4 in.; it weighs 14 to 15 oz.

FOOTBALL

GOALPOSTS

Dean Cox, AIA; Collins Rimer Gordon Architects; Cleveland, Ohio

NATIONAL COLLEGIATE ATHLETIC ASSOCIATION FIELD

NOTES

1. In the National Collegiate Athletic Association (NCAA), the playing field is 360 ft long by 160 ft wide, with an additional 12 ft recommended (6 ft minimum required) on all sides. The preferred orientation of the field is with the long axis stretching northwest to southeast. The field should be graded away from the centerline; subsoil drainage may be necessary.
2. All field dimension lines are 4 in. wide and should be marked with a white, nontoxic material. All measurements are from the edge of the line closest to the center of the playing field.
3. End zone marking should not overlap goal lines, sidelines, and end lines.
4. Inbounds lines are located 60 ft from the sidelines for college football (53 ft 4 in. for high school). Marks should be 4 in. wide by 2 ft long.
5. Goalposts should be padded to a height of 6 ft. The color of the posts should be yellow or white.

TOUCH FOOTBALL FIELD

NOTES

1. In touch football, the playing field is 300 ft long by 120 ft wide, with an additional 6 ft allowed on all sides. The preferred orientation is with the long axis running northwest to southeast; the recommended slope for proper drainage is 1%, which should run away from each side of the long-axis centerline.
2. All measurements are from the inside edge of the lines, which are 4 in. wide and marked with a white, nontoxic material.
3. The goalposts are similar to those used in college football.

ARENA FOOTBALL FIELD

NOTE

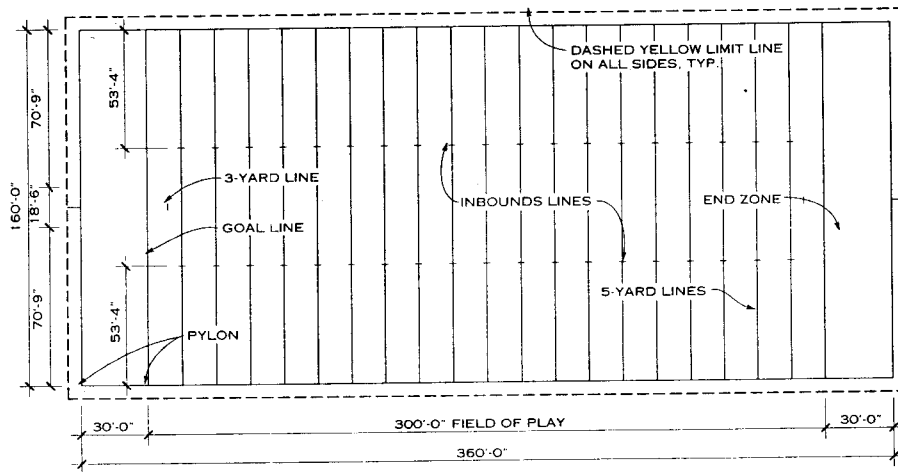

The playing field is made of padded artificial turf. For more information, contact Gridiron Enterprises in Chicago.

NOTES

1. The stadium layout shown is generic and should be modified to suit the needs of a particular project.
2. Lighting, drainage, and fencing systems are not shown on the layout illustrated, but they must be considered when applicable to a project.
3. Refer to other Architectural Graphic Standards sports pages for information regarding individual events that might be held in a multipurpose high school stadium.
4. Seating is shown here schematically; actual sizes should be based on the requirements of a project. It is recommended that the seating assembly be placed over concrete paved areas.
5. A chain-link fence, 4 ft high, is usually located outside the track area and extended around the remaining track and field events.
6. Striping is usually provided on the track to allow for measured lanes for running events.
7. Other support facilities include locker areas, restrooms, concession stands, and additional field equipment storage space.

MULTIPURPOSE HIGH SCHOOL STADIUM

NOTES

1. In high school football, the field is 360 ft long x 160 ft wide, with an additional 12 ft recommended (6 ft minimum required) on all sides. The preferred orientation of the field is with the long axis stretching northwest to southeast. The field should be graded away from the centerline; subsoil drainage may be necessary.
2. All field dimension lines are 4 in. wide and should be marked with a white, nontoxic material. All measurements are from the edge of the line closest to the center of the playing field.
3. End zone marking should not overlap goal lines, sidelines, and end lines.
4. Inbounds lines are located 53 ft 4 in. from the sidelines for high school football (as compared to 60 ft for college football). Marks should be 4 in. wide x 2 ft long.
5. Goalposts should be padded to a height of 6 ft. The color of the posts should be yellow or white.

HIGH SCHOOL FOOTBALL FIELD

Dean Cox, AIA; Collins Rimer Gordon Architects; Cleveland, Ohio
Behnke Associates, Inc. Landscape Architects/Planners; Cleveland, Ohio

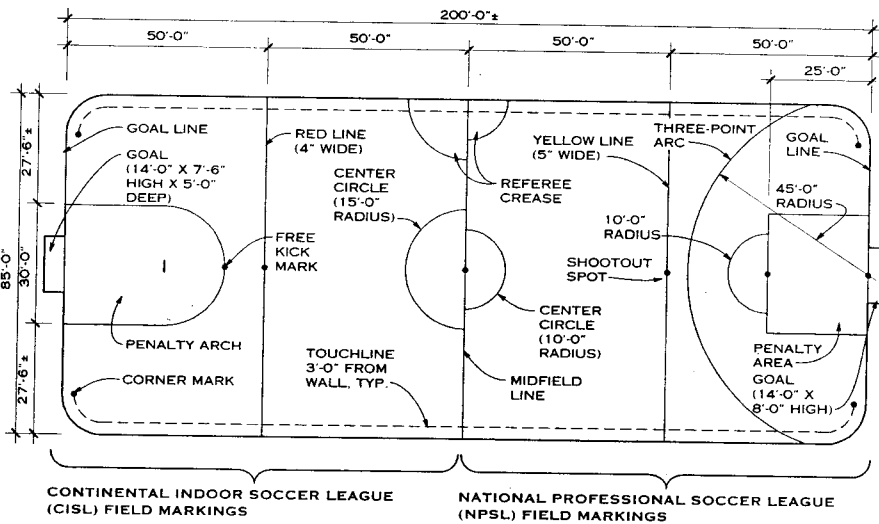

NOTE

The dimensions given are in accordance with regulations of the United States Soccer Federation (USSF) and the Federa-

tion Internationale de Football Association (FIFA). All field marking lines should be no more than 5 in. (12 cm) wide.

PROFESSIONAL SOCCER

NOTE

Indoor soccer, in both the USSF or the FIFA, is typically played in hockey arenas within the existing rink walls on an

artificial playing surface affixed to the rink surface.

INDOOR SOCCER

NOTES

- Professional soccer balls are 27 in. (68.58 cm) in circumference and weigh 14-16 oz (396-453 grams).
- In the northern hemisphere, the length of the field should be oriented northwest-southeast for the best sun angle during the fall playing season.

- The preferred drainage on a field is a longitudinal crown with a 1% slope from the center to each side.
- In addition to the architectural differences between them, indoor and outdoor soccer are very different in nature. Refer to the appropriate governing bodies for details.

U.S. Soccer Federation; Chicago, Illinois

NOTES

- The goalposts and crossbar must not be wider than 5 in. or narrower than 4 in. and must present a flat surface to the playing field. The net must be attached to the ground, the goalposts, and the crossbar, and it must extend back from and level with the crossbar for 2 ft (61 cm).
- Indoor soccer goals measure 14 ft wide (inside the posts) and 7 ft 6 in. from the playing surface to the underside of the crossbar.

SOCCER GOAL

NOTE

Use of a corner flag post is compulsory.

CORNER FLAG POST

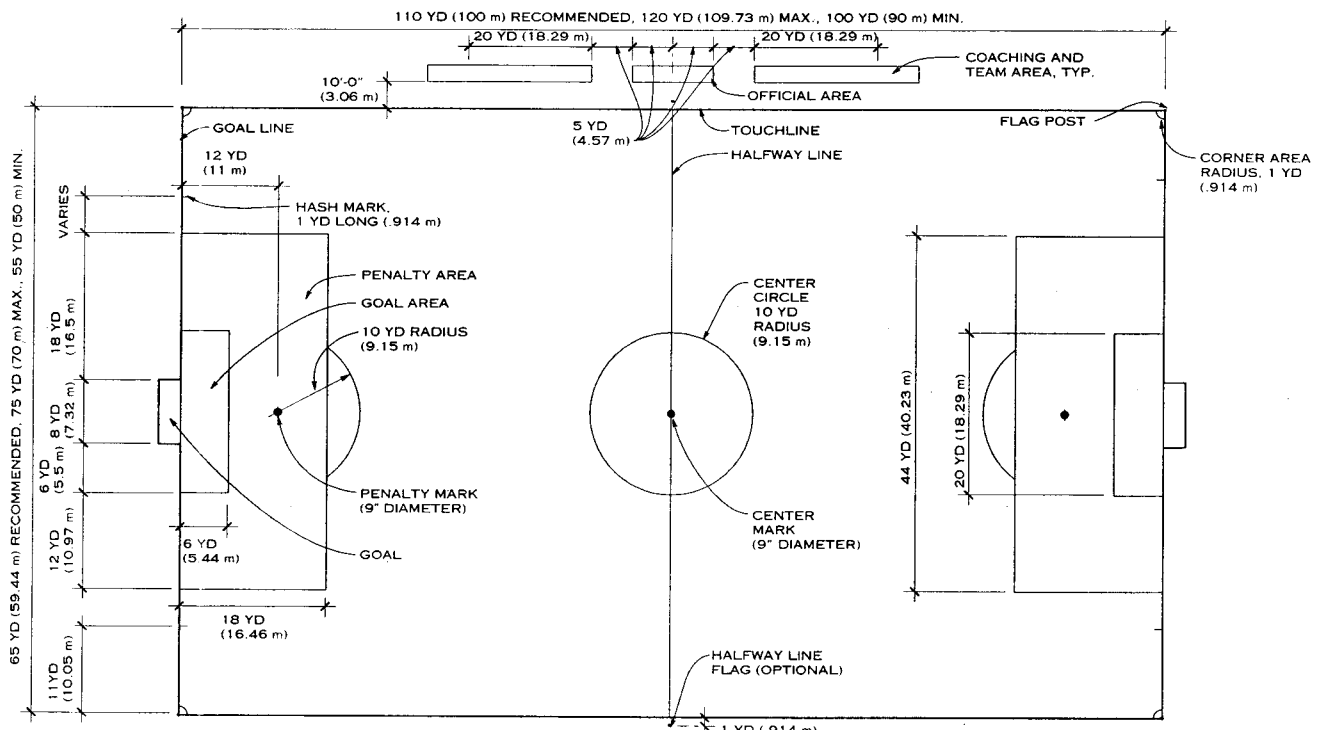

NOTE

For new facilities, the minimum width of the field should be 70 yd (64.01 m) and the minimum length 115 yd (105.15 m).

Recommended field dimensions are 75 yd (68.58 m) wide x 120 yd (109.73 m) long.

NCAA SOCCER

NOTE

Recommended field dimensions for middle school soccer are 55 yd (50 m) wide x 100 yd (90 m) long. Field marking lines should be 4 in. (0.10 m) wide.

HIGH SCHOOL SOCCER

U.S. Soccer Federation; Chicago, Illinois

BOCCE

The playing field is 60 x 12 ft (18.28 x 3.65 m). Although orientation is of minor importance, it is preferred that the long axis run north-south. The surface should be flat without slope when it is stone, dust, or clay with adequate under-drainage and 1% slope in any direction when turf.

The ball is 4 1/2 in. in diameter and weighs 32 oz.

Further information is available from the International Bocce Association, Inc.

BOCCE BALL (BOCCIE)

FIELD HOCKEY

The playing field is 300 x 180 ft (91.4 x 54.9 m) with an additional 10 ft (3.05 m) safety zone recommended on all sides. The preferred long axis orientation is northwest-southeast. Recommended grading is a 1% slope on each side of the longitudinal axis. All measurements shown are from the inside edge of the lines. Lines are 3 in. wide and marked with a white, nontoxic material.

The field hockey ball is 8 1/8 to 9 1/4 in. (20.8 - 23.5 cm) in circumference and weighs 5 1/2 oz. (155 g). The stick is 3 ft (1 m) long with a wooden head and cane handle with a cork or rubber insert.

Further information is available from the U. S. Field Hockey Association.

FIELD HOCKEY

LACROSSE

The playing field is 300 ft (100.58 m) long and from 160 to 180 ft (48 - 55m) wide, with an additional 15 ft (6.10 m) recommended on all sides. The preferred long axis orientation is northwest-southeast and preferred drainage is a 1% slope away from each side of the longitudinal axis. All dimensions shown are to the inside of the lines except for the centerline. Lines are 2 in. wide and marked with a white, nontoxic material. Flexible flag markers are placed at each corner and on field sidelines at the centerline.

Diameter of lacrosse ball is 2 1/2 in.; the stick is 3 to 6 ft in length.

Further information is available from the National Collegiate Athletic Association.

LACROSSE

RUGBY

The playing field is 156 x 69 m with an additional 3 m safety zone recommended on all sides. The preferred long axis orientation is northwest-southeast; recommended grading is a 1% slope from each side of the axis. All measurements are from the inside line edges, which are marked with a white, nontoxic material.

RUGBY

TEAM HANDBALL

The playing field is 131 ft 3 in. x 65 ft 8 in. (40 x 20 m), with an additional 6 ft (2 m) unobstructed space on all sides. Preferred orientation is northwest-southeast along the longitudinal axis with a 1% slope away from each side of that axis. All dimensions shown are from the inside line edges except the centerline. All lines are 2 in. wide and marked with a white, nontoxic material.

The men's handball is 23 in. (58.4 cm) in circumference and weighs 16 oz. (453.6 g).

TEAM HANDBALL

PREFERRED GRADING

SUBSOIL DRAINAGE
RECTANGULAR SPORTS FIELDS

DRAINAGE DIAGRAMS
SPORTS COURTS

BASEBALL AND SOFTBALL DIAMONDS

NOTES

It is preferable that the baselines be level. If the diamond must pitch, the average slope shall be 2% from first base to third base or vice versa.

The minimum slope for drainage on turf areas outside the skinned area is 1% when adequate subsoil drainage is provided. The maximum is 2.5%.

SYNTHETIC SURFACE
PLAYING SURFACES

TYPICAL GRADING AND DRAINAGE
DETAILS COURT SURFACES

Paved playing surfaces should be in one plane and pitched from side to side, end to end, or corner to corner diagonally, instead of two planes pitched to or from the net. Minimum slope should be 1 in. to every 10 ft. Subgrade should slope in the same direction as the surface. Perimeter drains may be provided for paved areas. Underdrains are not recommended beneath paved areas.

PLAYING FIELDS

Preferred grading for rectangular field is a longitudinal crown with 1% slope from center to each side.

Grading may be from side to side or corner to corner diagonally, if conditions do not permit the preferred grading.

Subsoil drainage should slope in the same direction as the surface. Subdrains and filter course are to be used only when subsoil conditions require. Where subsoil drainage is necessary, the spacing of subdrains is dependent on local soil conditions and rainfall.

Subdrains are to have a minimum gradient of 0.15%.

Baseball and softball fields should be graded so that the bases are level.

LINE PAINTING

All line markings should be acrylic water-base paint only. Oil-base or traffic paints crack, craze, or peel. Spray painting usually is used. High quality courts should be hand painted. Accuracy of track layouts should be verified by registered land surveyor.

EDGE CONDITIONS

Sheryl Ananich; Tomblinson Harburn Associates; Flint, Michigan
J. Paul Raeder; Beckett & Raeder, Inc.; Ann Arbor, Michigan
Lawrence Cook Associates P.C., Architects; Falls Church, Virginia

TYPICAL SOFTBALL BACKSTOP

REGULATION BASEBALL BACKSTOP

BACKSTOP SIZE AND DIMENSION

Height and width of baseball backstops are to be determined by sports authorities and local requirements.

Posts for backstop heights up to 16 ft: use 3 in. outside diameter; posts for backstop heights 18 to 24 ft: use 4 in. outside diameter; top, intermediate, and bottom rails: 1 5/8 in. outside diameter.

WIRE MESH FABRIC

Fabric shall be chain link with galvanized coating or aluminum (optional PVC-coated steel). All ferrous metal parts are to be hot dip galvanized after fabrication.

BASKETBALL STANDARDS

NCAA: Minimum backboard support overhang is 4 ft; minimum outside diameter of post is 3 1/2 in.

AAU: 5 ft 5 in. overhang (and optional NCAA overhang of 4 to 6 ft) requires minimum post outside diameter of 4 1/2 in.

Concrete footing: minimum 2 ft diameter and 4 ft depth. Method of bracing and backboard support varies with manufacturer.

REMOVABLE POST

BASKETBALL STANDARDS

TRACK SPECIFICATIONS

GOVERNING BODY	LENGTH OF TRACK	WIDTH OF TRACK	RADIUS REQUIREMENTS	INCLINATION	LANE WIDTH	CURB DIMENSIONS AND MATERIAL
International Amateur Athletic Foundation (IAAF)	Not less than 400 m	Minimum 7.32 m (6 lanes), but 8 lanes, each 1.22 m wide, recommended	World records cannot be set on a track when outside lane has a curve radius greater than 50 m	Maximum lateral inclination 1:100; maximum downward inclination in the running direction 1:1000 (lateral inclination down toward inside lane)	Minimum width of 1.22 m (48 in.); the 5 cm wide right lane line is included in the width of the lane	Should be 5 cm x 5 cm, concrete or other material; if curb is raised to allow drainage under it, maximum height is 6.5 cm
National Collegiate Athletic Association (NCAA)	No specified length	6.40 m minimum (6 lanes)	No recommendation	Same as IAAF	Same as IAAF but will permit lanes of at least 91.4 cm (3 ft) if track is not wide enough to accommodate at least 8 wider lanes	Minimum height is 5.08 cm (2 in.) and maximum width is 10.16 cm (4 in.); use concrete, wood, or other suitable material with edges rounded
National Federation of State High School Associations (NFHS)	400 m is standard	No minimum width	No recommendation	Maximum lateral inclination is 2:100; maximum inclination in the running direction is 1:1000	Recommended width 1.07 m (42 in.); the 5 cm wide right lane line is included in the width of the lane	Curb will be 5 cm (2 in.) high with a rounded top of solid material
USA Track and Field (USAT&F)	No specified length	No specified width	Same as IAAF	Same as IAAF	Same as NFHS	Same as IAAF, except must be unbroken on curves and straightaways

NOTE

Information in the chart comes from current rules of the governing bodies of track and field and is subject to change. For

a specific rules determination, contact the appropriate governing body.

NOTE

When designing a track, consider the official sizes and needs of the interior playing fields and the location and layout of field events. Necessary radii dimensions for several different types of playing field are shown above. Be sure to allow the

necessary sideline area for safety and comfort. Use of the International Broken-Back Curve design can permit a wider facility with a layout that still meets all rules.

TRACK AND PLAYING FIELD CONFIGURATION

Kathleen O'Meara; OM Architecture; Baltimore, Maryland
 U.S. Tennis Court and Track Builders Association; Ellicott City, Maryland
 National Federation of State High School Associations; Kansas City, Missouri

17 TRACK AND FIELD

ORIENTATION

It is often difficult in siting a track/playing field to reconcile the requirements regarding wind direction and facing the setting sun. Thus, when possible, it is common to provide alternative directions for running, jumping, and throwing.

SURFACE

Synthetic materials provide a consistently good track surface capable of continuous and unlimited use in most weather conditions. Maintenance is minimal, consisting of periodic cleaning with hose or brush, repainting line markings when necessary, and making an occasional repair.

Cinder surfaces require considerable maintenance by a skilled groundsman every time a track is used. They are not suitable for all-weather use and seldom provide a consistently good running surface. They are, however, much cheaper to construct and are suitable for club use and training.

NOTE

All white lines are 55 mm wide.

METHOD OF MARKING LANES

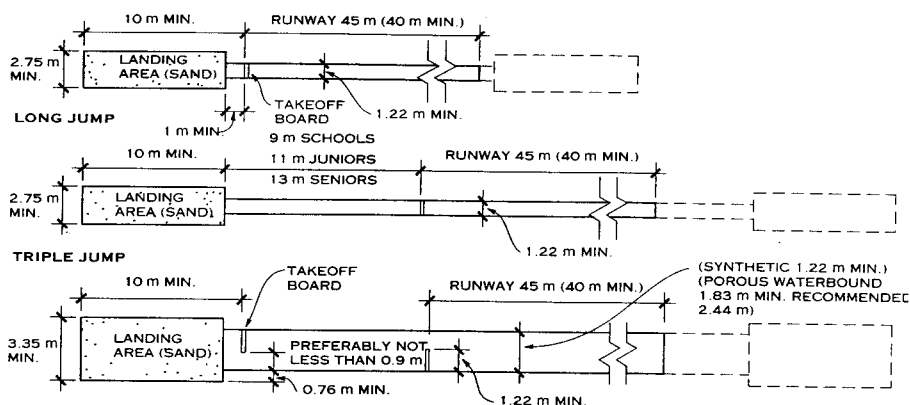

400 M TRACK AND FIELD EVENTS—CONSTRUCTION DETAILS

These details are based on international standards. For additional information, consult the International Amateur Athletic Foundation (IAAF).

These details were provided by the National Playing Fields Association, London, England.

NOTE

To avoid adverse wind conditions during competition, landing areas for the long and triple jumps are desirable at both ends of the runway. A surround of paving slabs (450 x 600 mm) is an advantage. Takeoff board to be of wood or other suitable rigid material, set level with surface and painted white. See detail.

SECTION OF SAND LANDING AREA LONG AND TRIPLE JUMP

NOTE
 If the surface is porous waterbound, the distance between the edgings should be increased to 4.27 m.

JAVELIN THROW

NOTES
 A. Detachable soft landing units each 1 x 2 m.
 B. Concrete platforms each 1 x 2.45 m x 75 mm thick minimum and set level with runway surface.

 1 m
 2 m
 ALTERNATIVE POSITION OF DETACHABLE UNITS
 POSITION OF DETACHABLE UNITS
 0.8 m THE DEPTH OF CUSHIONING VARIES ACCORDING TO THE STANDARD OF COMPETITION

The soft landing area to be 5 x 5 m minimum. The distance between uprights or extension arms to be 3.660 m minimum/4.370 m maximum. A larger soft landing unit with a 1.300 m extension for the pole vault box cutout giving a total size of 5 x 6.300 m may be provided. The diagram shows a double runway with detachable A units and thus gives a choice of runways according to the wind direction.

For outdoor use, soft landing units should be laid on duckboards on an ash base or other suitable materials (e.g., precast concrete paving on a porous base with 50 mm open joints).

SOFT LANDING AREAS

SITE ISSUES FOR OUTDOOR TENNIS COURTS

The overall area required for an individual tennis court is at least 60 x 120 ft. The outside dimensions of the playing lines are 36 x 78 ft for doubles.

Consider the position of the sun when deciding how to orient the court. In particular, plan around the extreme sun angles of late afternoon and early morning so players do not have to look directly into the sun when serving or tracking the ball.

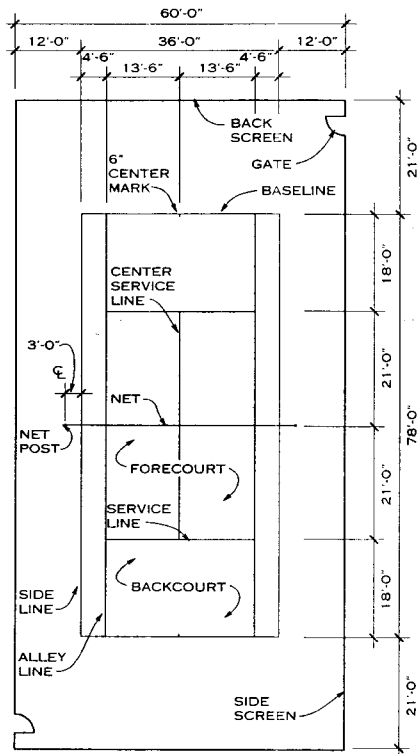

Design the area surrounding the court to minimize distractions. A solid, dark background is desirable. White backgrounds and any movement such as pedestrians or traffic, particularly at the ends of the court, can be distracting. Landscaping or background curtains can be used as screens; however, the space directly over the court must be free from overhanging limbs or other obstructions and the minimum clear height at the fence should be 18 ft. When selecting vegetation, avoid species that would distract with irregular shadow patterns, stain the court surface, or require constant maintenance to clean up fallen leaves, needles, or fruit.

If outdoor lighting is used, locate fixtures outside the playing lines, preferably parallel to the alley lines, and outside the fence. Placement is especially important with fast-dry surfaces that can be damaged by rain dripping off the fixtures.

A high, dry site with well-drained, compacted soil is preferable. Ensure proper drainage of the court surface and the sub-surface, and redirect any water from the surrounding area. Water under the court is a prime cause of surface cracking, heaving of fence posts, and undulating pavement. Employ open swales, closed drains, or a combination of the two systems to drain water from the area.

NOTE

The Americans with Disabilities Act requires that tennis courts be accessible to both players and spectators in wheelchairs. At least one court must be fully accessible in a small facility; more may be required in a large facility. Curb cuts, walkways to and from the courts, gateways, drinking fountains, restrooms, locker rooms, and other spectator or player amenities must comply with federal, state, and local codes on accessibility. As well, adequate parking for persons with disabilities must be provided.

TYPICAL INDIVIDUAL TENNIS COURT

SWALE WITH GRAVEL TRENCH DRAIN

SITE DRAINAGE

NOTE

Provide at least one gate for every two tennis courts.

TYPICAL MULTIPLE TENNIS COURT LAYOUT

SURFACE TYPE	% SLOPE	RATIO OF SLOPE
Hard surface	0.833% to 1%	1:120 to 1:100
Grass surface	1%	1:100
Soft surface	0.28% to 0.35%	1:360 to 1:288

NOTES

- Courts must slope as one true plane, with no more than three courts sloped together in the same direction. A slope from side to side is best, followed by an end-to-end slope; diagonally sloped courts are the least satisfactory.
- Never slope a court to or from the net or to or from the centerline.

COURT SURFACE SLOPE

NORTHERN	
42.5° latitude Boston, Chicago	
8 AM	1° east of true north
Noon	true north-south
4 PM	1° west of true north

CENTRAL	
37.5° latitude Richmond, San Francisco	
8 AM	9° east of true north
Noon	true north-south
4 PM	9° west of true north

SOUTHERN	
32.75° latitude Charleston, Dallas	
8 AM	17.25° east of true north
Noon	true north-south
4 PM	17.25° west of true north

NOTE

Base the orientation of a tennis court on the latitude in which it is built, the season(s) it will be used, and the time of day it will be used. It may be necessary to compromise the three factors. A critical determining factor will be the solar orientation of the court during early morning (8 AM) and late afternoon (4 PM) hours, since the angle of the sun is at its most distracting to players and spectators at those times. It is best to locate the longitudinal axis of the court perpendicular to the azimuth of the sun between 8 AM and 4 PM.

COURT ORIENTATION

OUTDOOR LIGHTING FOR TENNIS COURTS

Kathleen O'Meara; OM Architecture; Baltimore, Maryland
 U.S. Tennis Court and Track Builders Association; Ellicott City, Maryland
 National Federation of State High School Associations; Kansas City, Missouri

OUTDOOR PLAYING SURFACES

Tennis playing surfaces are categorized as porous or nonporous. Geographic location is a key factor in the selection of playing surface for a site. The northeastern United States has numerous freeze-thaw cycles per year, which affect maintenance and the useful life of tennis courts. In the western states, the sun bleaches the color out of hard courts and dries out clay or fast-dry courts. Mildew or algae may be problems at courts in southern states like Florida.

Intended use and player preference are considerations in choosing a court surface. Tennis players commonly classify courts as soft- or hard-surfaced.

Soft courts include clay, fast-dry, and sand-filled synthetic turf. Soft courts are easy on a player's feet and legs and provide cool, glare-free surfaces. They are less expensive to construct than hard surfaces but may require annual resurfacing or repair and the daily maintenance of watering, brooming, and rolling the surface.

Hard courts include asphalt and concrete with acrylic coatings or roll or sheet goods coverings. They are generally more durable, require less maintenance, and offer longer playing seasons in cold climates than soft courts. A resilient layer or layers can be incorporated in a hard surface, providing a cushioned, nonporous, all-weather surface that softens the impact on a player's legs and back. Hard surfaces are generally more expensive to construct than soft surfaces and are easily damaged by street shoes and play equipment such as skateboards or in-line skates.

VISIBILITY IN INDOOR COURTS

A highly reflective ceiling surface and indirect lighting reduce shadows and provide the most even lighting conditions.

For optimum color contrast between the court, background, and ball, medium dark colors are best up to 8 ft along the sides of the court and 12 to 14 ft high behind the court area. Above these zones, white or light matte finish is best.

Perimeter curtains and dividing nets can also be used to provide a background that reduces distractions and keeps the ball from going into adjacent courts. These are generally black or green and are hung so the top of the divider is 12 ft above the floor, stopping 1/2 to 2 in. above the court surface.

NET ELEVATION

CENTER STRAP ANCHOR

NET POST

NOTE

The net should be installed with the recommended tension of 500 to 550 lb.

MOVABLE WALL ASSEMBLY FOR COURT CONVERSION—DETAIL

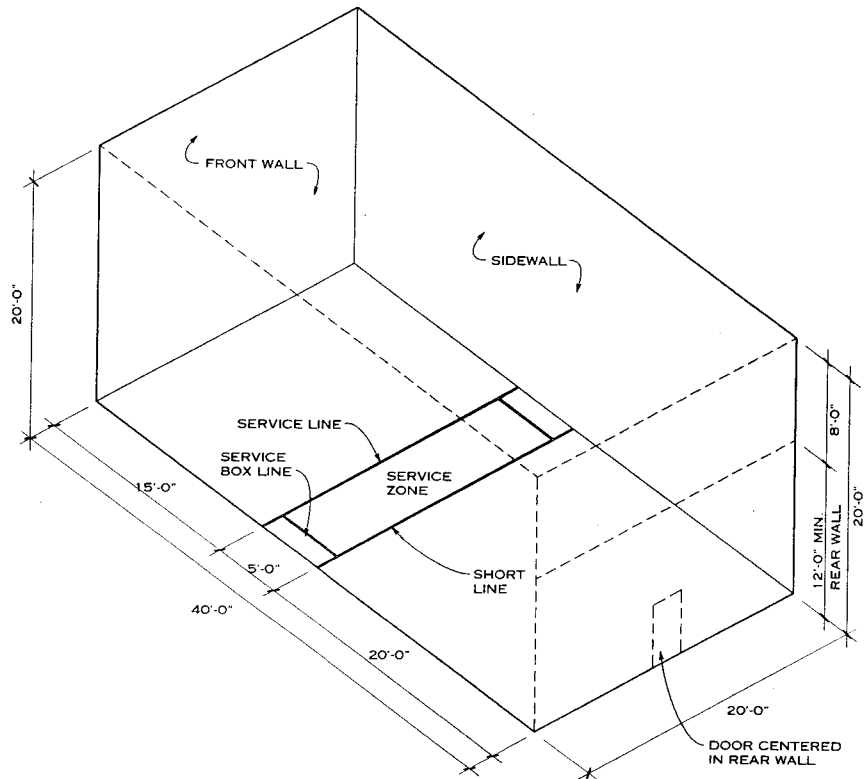

DOOR AT JAMB—DETAIL

NOTES

1. Racquetball and handball use essentially the same size court; however, handball may be played on courts with one, three, or four walls, indoors or outdoors. For a standard one-wall handball court, the wall should be 20 ft from the outside edge of one sideline to the outside edge of the other sideline and 16 ft high, including any top line. For three-wall handball, the side walls should be 44 ft long but the court marked for 40 ft long.
2. Temperature and humidity requirements for racquetball courts must be maintained during storage, installation, and operation. The range for temperature is 65 to 78°F and for humidity is 40 to 60%.
3. All lines should be 1 1/2 in. (38 mm) wide, painted red. Racquetballs are 2 in. in diameter; handballs are 1 7/8 in. in diameter.
4. Materials and installation of glass wall systems must comply with the safety and performance standards for walls established by the appropriate court sport association, the manufacturer, and local building codes. For this and other guidelines, contact the U.S. Handball Association or the U.S. Racquetball Association.
5. A movable rear wall unit may be specified to convert a racquetball court that is 40-ft long into a 32-ft long squash court. The World Squash Federation sanctions the use of a 20-ft wide racquetball court for squash, which normally has a court 21 ft wide.

COURT WALL-DETAIL

MATTE FINISH OR UNFINISHED MAPLE OR ASH FLOORING OVER WOOD SLEEPERS, 12" O.C.

GLASS WALL SYSTEM-DETAIL

FRONT WALL AND SIDEWALL LINES

COURT MARKINGS

NOTES

1. All playing walls of the court should be constructed of the same materials, with a hard, smooth finish and strength and deflection characteristics as defined by the World Squash Federation or the United States Squash Racquets Association.
2. A squash court may be constructed from a number of materials, providing they have suitable ball rebound characteristics and are safe for play as recommended by the governing squash association.

NOTE
All lines on a singles court should be 2 in. wide (50 mm), painted red.

INTERNATIONAL SINGLES SQUASH COURT (SOFT BALL)

NOTES

1. Lines on a doubles court should be 1 in. wide, except the upper game line, which should be a 1 1/2 in. wide bevel.
2. The ceiling height of the doubles court should be a minimum of 24 ft high, with the lighting at that height.

NORTH AMERICAN DOUBLES SQUASH COURT (HARD BALL)

Kenneth D. Jaffe; U.S. Squash Racquets Association; Bala-Cynwyd, Pennsylvania

NOTE
A practice vaulting buck is similar to a vaulting horse but is only 2 ft 9 in. (825 mm) long.

VAULTING AND POMMEL HORSE

NOTE
A safety zone mat is placed snugly around the board for all round-off entry vaults.

VAULTING BOARD

NOTE
Floor plates, installed flush with the top of the floor finish, are used to anchor horizontal bars, ring frames, etc., to the floor. Plates must be used with eye screw attachments.

NOTE
Bar height typically adjusts in 50 mm increments.

UNEVEN BARS

PARALLEL BARS

BALANCE BEAM

NOTES

- The dimensions and specifications on this page are for general reference only. Refer to the appropriate safety manual for specific requirements for recreational or training gymnastics or for state, regional, national, and international competitions: Federation Internationale de Gymnastique (FIG); U.S.A. Gymnastics (USAG); National Collegiate Athletic Association (NCAA); and National Federation of State High School Associations (NFSH).
- A clearance of 5 to 6 ft is recommended from one apparatus to another, including corresponding mat area or obstructions such as other apparatus, walls, or columns. Each competitive area must have its own physical space, which may not overlap another competitive area. The floor exercise area must be free of obstructions. Leave room for mounting, dismounting, and vaulting areas.

BADMINTON

VOLLEYBALL

- NOTES**
1. Space behind each baseline to back fence is 15 ft minimum.
 2. Space from each sideline to side fence is 10 ft minimum.
 3. Fence shall be 8 ft high unless otherwise noted.
 4. Ball is a punctured tennis ball.

PADDLE TENNIS

PLATFORM TENNIS

CROQUET

LAWN BOWLING

NOTES

1. Flooring must be permanently level and able to withstand point loads.
2. Traditionally designed billiard tables weigh about 1.5 tons spread over eight legs.
3. Lighting must not produce harsh shadows, but some modeling of the ball is desirable. Avoid direct or reflected glare. True color rendering is important in snooker. An overall

TABLE DIMENSIONS (FT.-IN.)

TYPE OF TABLE	PLAYING SURFACE		TABLE SIZE	
	W	L	W	L
English (Snooker)	7-2	14-4	8-2	15-4
Standard 9 ft	4-2	8-4	5-2	9-4
Standard 8 ft	3-8	7-4	4-8	8-4
Standard 7 ft	3-2	6-4	4-2	7-4
Oversized 8 ft	3-10	7-8	4-10	8-8

bright light is needed for each table; natural lighting is not essential. Lighting at the table surface should be approximately 375 lumens, which can be achieved with three 150-watt tungsten filament lamps suspended in a lighting trough. Fluorescent lamps are unacceptable.

4. Some sound insulation is required to prevent distractions from outside the playing area.

BILLIARDS, POCKET BILLIARDS, AND SNOOKER

NOTES

1. Flooring should be level and slightly resilient; do not use nonskid material.
2. Walls should provide a uniformly dark, matte background with enough contrast to help players follow the ball.
3. Lighting often varies for different standards of play, but 150 to 500 lumens at table height is the acceptable range. Do not use fluorescent or natural lighting; tungsten halogen lighting is preferable.
4. Sectional tables are stored upright when not in use.

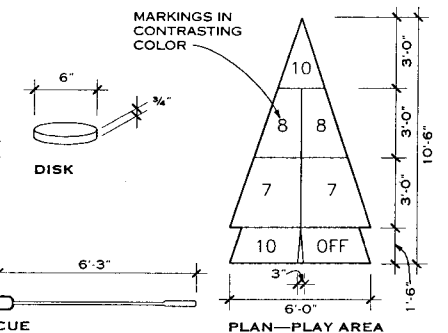

TABLE TENNIS

NOTE

All lines are 3/4 to 1 in. wide, standard, measured to the center of the line. The court is concrete, stained green.

DARTS

SHUFFLEBOARD

HORSESHOES

NOTE
For a 10-ft board, Point B must be 8 ft 0 in. (8 ft 6 in. is safer).

LONGITUDINAL SECTION AT CENTERLINE (TYPE III POOL)

PERMITS AND RESTRICTIONS

In most areas, permits are required from building, health, plumbing, and electrical departments and zoning boards. Check for setback restrictions and easements covering power and telephone lines, sewers, and storm drains.

CONSTRUCTION AND SHAPES

Residential pools are generally made of gunite (a mixture of pea stone, sand, cement, fly ash, and water sprayed on a steel reinforcement rod framework), a vinyl liner with a structural wall backup and formed floor (steel or thermoplastic vertical wall sections and lightweight concrete or sand base), or a prefabricated fiberglass shell (used primarily where high water tables and nonfrost penetrating conditions exist). Shapes are virtually unlimited within limitations for safety and minimum dimensions.

FILTERING

Filtration is the mechanical process of removing insoluble matter from swimming pool water. Pool water carrying particulate matter, solids, and debris is passed through filtering media and returned to the pool.

Pool water flows through the filters by pressure or vacuum. As water passes through the filter, particulate matter and solids collect on the surface of the filter medium. The ability to hold and screen fine particles varies according to filter type. Three basic media are used for swimming pool filtration—diatomaceous earth, sand, and cartridge filters.

Filters are sized by dividing the pool volume by the required turnover time (established by the local board of health), then dividing that figure by 60 min/hr, which equals the flow rate in GPM. Divide the flow rate in GPM by the filtration rate (established by the board of health), which is in GPM/sq ft. The result is the required filter area in sq ft.

HEATERS AND PUMPS

Pool heaters have become a necessity for user comfort and maintenance of proper chemical balance. Heater size is determined by the frequency of pool use, the size of the pool, and the average outside air temperature. Use a pool cover to minimize evaporation. A solar cover can add heat to a pool.

The size of a pool pump establishes the limit of the volume of water that can be recirculated. The pump causes water to flow and determines the direction of flow. Pump capacity is measured in GPM for flow and in feet of head for pressure.

In most swimming pools, filtered pool water is returned below the water surface; thus, after the pump has been primed and all air expelled, the pump need only overcome the friction in the piping system and the pressure drop across the filter to maintain consistent circulation.

WATER TREATMENT

Pool water must be disinfected and recirculated. Seven principal factors are balanced by basic chemically treated water: total alkalinity, pH balance, calcium hardness, free available disinfectant, total disinfectant, total dissolved solids, temperature.

7-POINT GRID DIMENSION PLAN

Many alternative combinations of chemicals are available for water treatment, but growing concern over using chemical treatment alone has led to the development of ozone-based systems. Ozone generators are used to disinfect and oxidize the water, making it more easily filtered and decreasing the amount of sanitizer needed.

NOTES

1. The drawings above illustrate the use of a 7-point dimension grid that expresses the minimum desirable dimensions to be used when specifying or designing a rectangular pool for residential use.
2. Width, length, and depth dimensions may apply to residential pools of any shape.
3. The minimum length with diving board and wading area is 32 ft. The average length of a residential pool is 32-40 ft.
4. Standards for residential swimming pools have been published by the National Spa and Pool Institute (1989).

VINYL POOL LINER OVER STRUCTURAL POLYMER WALL

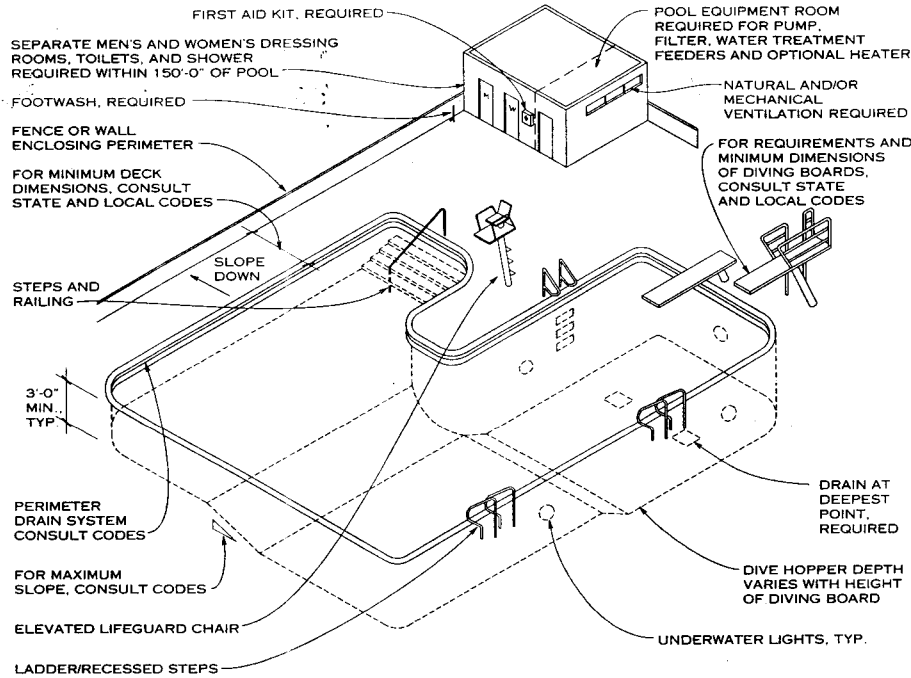

FIBERGLASS SHELL POOL

FORMED CONCRETE (GUNITED) WALL AND DECK

Robert D. Buckley, AIA; robert d. buckley * architect; Kalamazoo, Michigan
D. J. Hunsaker; Counsilman/Hunsaker & Associates; St. Louis, Missouri
National Swimming Pool Foundation; Merrick, New York

GENERAL NOTES

- Public pools are those operated and intended for the collective use of unrelated persons, whether or not a fee is charged. Semipublic pools are those intended for use by housing facility occupants and their invited guests. Private residential pools are those located on private property for use by the owner's family and/or invited guests.
- Special purpose pools are those designed for specific uses and not defined as public, semipublic, or private residential.
- A spa is defined as a special facility that is not drained, cleaned, or refilled after each individual use and may include hydrojet circulation, hot water, cold water, mineral bath, air induction bubbles, or any combination of these.
- The water supply serving a public swimming pool and all plumbing fixtures, including drinking fountains, lavatories, toilets, and showers, must meet all applicable requirements for potable water. All portions of the water distribution system serving the swimming pool and auxiliary facilities must be protected against backflow.
- Swimming pools must be designed and constructed to withstand all anticipated loadings for both empty and full conditions.
- A hydrostatic relief valve must be provided for in-ground swimming pools in areas with a high water table.
- Provisions must be made for complete, continuous circulation of water through all areas of the swimming pool.
- The shape of any swimming pool must not impair swimmer safety or the circulation of water through all areas of the pool.

NOTES

- All swimming pools must be equipped with a filtration system for clarifying the water; the system must be an integral part of the circulation system and consist of one or more filter units, either sand, diatomaceous earth, or cartridge type.
- Every swimming pool must be equipped with a disinfectant feeder as required to keep the microbiological, chemical, and physical characteristics of the pool water within prescribed limits.
- All swimming pools must have the water depth marked

plainly at or above the waterline on the vertical wall where possible and on the edge of the deck next to the pool; depth markers must be 25 ft or less on center.

- When visitor or spectator areas are provided at swimming pools, there must be an absolute separation between those areas and the pool area. Provide separate toilets for visitors and spectators.
- Every public pool must have a readily accessible room or area designated and equipped for emergency care.

TYPICAL PUBLIC SWIMMING AND DIVING POOL REQUIREMENTS

STANDARD DIMENSIONS FOR PUBLIC SWIMMING POOLS IN FT-IN. (M)¹

Source: National Spa and Pool Institute (NSPI), Alexandria, Virginia

¹The dimensions given are the currently recommended standards for public swimming pools and are not designed for sanctioned competition.

²L₂, L₃, and L₄ combined represent the minimum distance from the tip of a board to the pool wall opposite the diving equipment.

6-LANE LAP POOL

TYPICAL PUBLIC POOL SHAPES

DIVING BOARD DIMENSIONS

There must be a completely unobstructed, clear vertical distance of 13 ft above any diving board, measured from the center of the front end of the board. This area must extend horizontally at least 8 ft behind, 8 ft to each side, and 16 ft ahead of point A (see key).

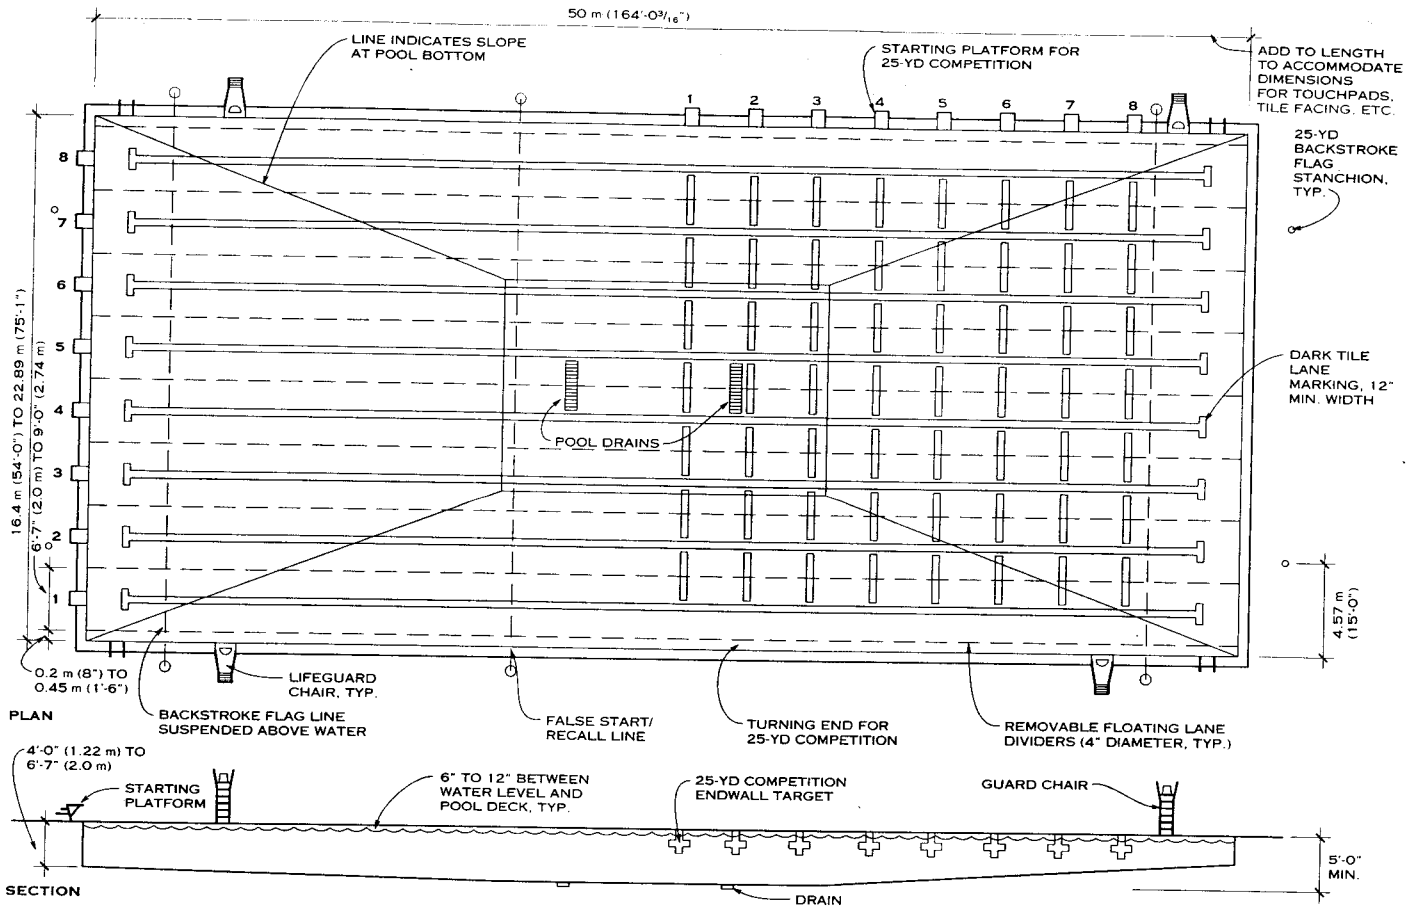

For diving board placement, observe these minimum distances from the pool edge or adjacent boards:

Deck-level board to pool side:	8 ft
1-meter board to pool side:	10 ft
3-meter board to pool side:	11 ft
1-meter or deck-level board to 3-meter board:	10 ft
1-meter or deck-level board to another 1-meter or deck-level board:	8 ft
3-meter board to another 3-meter board:	10 ft

STANDARD DIMENSIONS KEY

Robert D. Buckley, AIA; robert d. buckley * architect; Kalamazoo, Michigan
D. J. Hunsaker; Counsilman/Hunsaker & Associates; St. Louis, Missouri
National Swimming Pool Foundation; Merrick, New York

NOTE

A 25-meter pool width will provide 10 lanes for training or competition and accommodate international meets of any distance. An economical alternative for pool length is 70

meters with at least one bulkhead to separate training and competition areas.

50-METER COMPETITION SWIMMING POOL

NOTES ON POOL DESIGN

- The information on this page is based on current standards and rules for swimming races, competition diving, and other aquatic competitions stipulated by the following aquatic sport organizations:
FINA (Federation Internationale de Natation Amateur) governs international competition, including the Olympic Games.
US Swimming (United States Swimming, Inc.) governs open and age group levels in the United States.
US Diving (United States Diving, Inc.) governs open and age group levels in the United States.
NCAA (National Collegiate Athletic Association) governs all collegiate competition.
NFHS (National Federation of State High School Associations) governs all high school competition.
- Because they represent different groups and/or skill levels within a sport, the regulatory organizations do not always agree on the dimensions and features required for a pool facility. In addition to complying with the rules of pertinent organizations, the engineering of a swimming pool must follow the design regulations of any local, state, or federal agency that has jurisdiction over the facility. Sanitary and structural considerations vary almost as much between agencies as competitive guidelines do.
- Consult the *Official Swimming Pool Design Compendium* (Merrick, N.Y.: National Swimming Pool Foundation, rev. ed. 1997) for specific rules of all the governing bodies.
- Swimming pool dimensions shall be measured from the inside walls or from the tile or timing devices attached to the walls. Touchpads for automatic timing may be used if they do not shorten the race course beyond minimum specifications. Markings on the finish pad and bulkheads

- must conform to required markings on the endwalls. Visible numbers identifying lanes must be provided.
- Endwalls and movable bulkheads serving as endwalls must be parallel and vertical for a distance of 3 ft 6 in. (1.0668 m) below the overflow level of the water. No protrusions are permitted below the surface. Endwalls should be finished with a nonslip surface.

NOTE

For endwall target design, see the rules of the appropriate governing organization.

LANE END MARKINGS

- All ladders, steps, or stairs must be recessed into side walls or easily removed for competition.
- Lighting at water level should be 100 footcandles. (FINA standards dictate 600 lux at water level.)
- Lane markers must be continuous, clearly visible floats that indicate the lateral limits of each lane. They must be attached to and stretched between the endwalls and anchored at surface water level in a recessed receptacle. Solid color floats are recommended within 15 ft 0 in. (4.572 m) of both endwalls in contrast with the center portion of the lane markers.
- Backstroke flag lines are required for all events in which the backstroke is swum. At least three 12-18 in. long pennants of two or more alternating colors must hang from the line.

NOTES ON POOL DIMENSIONS

- When a range of dimensions is given, consult the appropriate governing organization (FINA, USS, NCAA, or NFHS) for specific dimensions.
- Depending on the governing organization, pool size, and competition type, the following information applies for dimensions from the starting platform end of the pool:
To the backstroke flag line, the dimension ranges from 15 ft 0 in. (4.57 m) to 16 ft 4 in. (4.98 m).
For 50-m pools, the dimension to the false start/recall stanchion ranges from 42 ft 0 in. (10.973 m) to 65 ft 7 in. (20.0 m).
For 25-yd and 25-m pools, the dimension to the false start/recall stanchion ranges from 33 ft 1 in. (10.08 m) to 60 ft 1 in. (18.31 m).

ALTERNATE STARTING PLATFORMS

PLAN NOTES

1. In pools with a water depth of 3 ft 6 in. to 4 ft at the starting end (measured at the end wall or any point within 12 in. of the end wall), starting platforms shall be no more than 18 in. above the water surface; otherwise, the swimmers must start from the deck or in the water.
2. In pools with a water depth less than 3 ft 6 in. in the starting end, the swimmers must start in the water.

¹ All dimensions in the US Diving and NCAA section of this chart are rounded up, even when the dimension is only fractionally greater than the next lowest inch.

² Dimension C (plummet to adjacent plummet) applies to platforms with widths as specified in this chart. If platform widths are increased, dimension C must be increased by

half the additional width(s).

 D. J. Hunsaker; Counsilman/Hunsaker & Associates; St. Louis, Missouri
 National Swimming Pool Foundation; Merrick, New York

REAR ELEVATION

3-METER DIVING BOARD

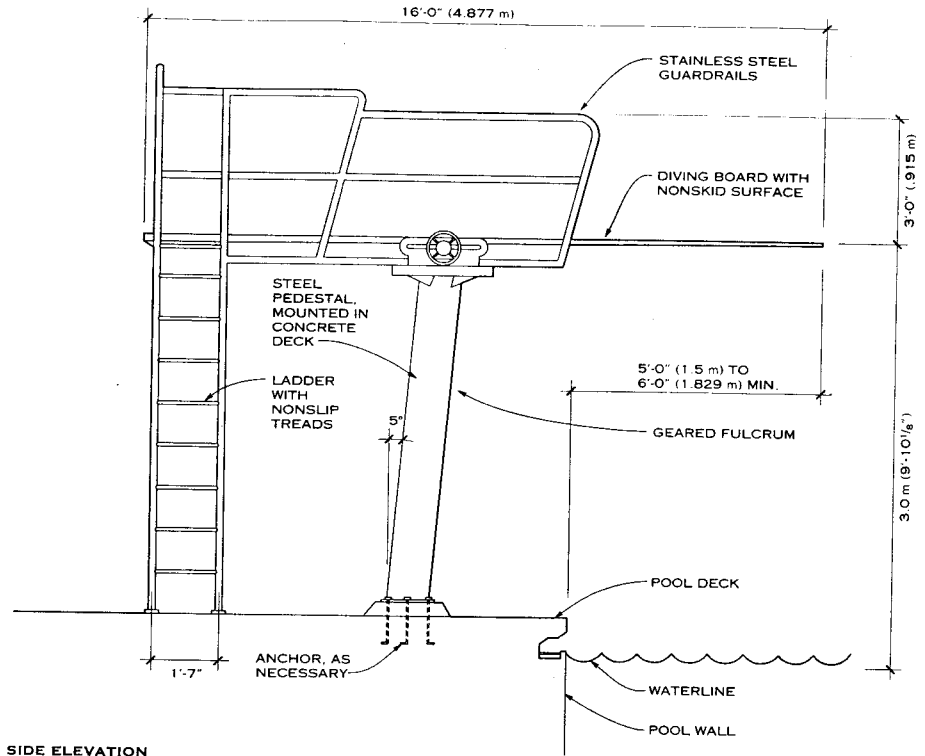

REAR ELEVATION

1-METER DIVING BOARD

NOTES

- Both 1- and 3-meter boards are required for amateur, collegiate, and international meets. Consult the *Official Swimming Pool Design Compendium* (Merrick, N.Y.: National Swimming Pool Foundation, rev. ed. 1997) for specific FINA, US Diving, NCAA, and NFHS details and specifications.
- When a range of dimensions is given, consult the appropriate governing organization for specific dimensions.
- When selecting a 1- or 3-meter diving tower, pay special attention to the materials it is made of. Differences in wall tubing thickness, anchorage, and fulcrum materials influence the flexibility and spring from the tower.

SIDE ELEVATION

SIDE ELEVATION

- A fulcrum, which can be moved and set at varying positions between 5 ft 6 in. (1.676 m) and 7 ft 6 in. (2.286 m) from the rear of the diving board, is required. The board must remain horizontal with the fulcrum in any position. The range of movement of the fulcrum may be limited under certain conditions. Consult with the appropriate governing body for diving competition regulations.
- A water agitation system is recommended that produces water surface agitation extending 5 ft (1.524 m) beyond the end of the board with a width of 2 ft (6096 m).
- The maximum depth reduction rate of diving pools that do not exceed minimum depth requirements shall be 6.25% for a distance of 20 ft (6.096 m) forward and 6 ft (1.829 m) back and to the sides. Deeper pools may have proportionally steeper depth reduction rates.
- Three choices are available for diving board supports for 1- and 3-meter boards: a manufactured cantilevered steel stand; a manufactured cast aluminum stand; and a cast-in-place concrete platform with a fulcrum assembly mounted directly to the top of the slab.

Robert D. Buckley, AIA; robert d. buckley * architect; Kalamazoo, Michigan
 D. J. Hunsaker; Counsilman/Hunsaker & Associates; St. Louis, Missouri
 National Swimming Pool Foundation; Merrick, New York

NOTE

In these drawings, S/S stands for stainless steel.

ROLLOUT GUTTER SYSTEM

NOTE

In addition to the stainless steel system shown, gutters may be designed as an integral part of the concrete deck edge.

FULLY RECESSED GUTTER SYSTEM

NOTES ON PERIMETER OVERFLOW

1. A perimeter overflow system must be provided on all public swimming pools. The system must be designed and constructed to maintain the water level of the pool at the operating level of the overflow rim or weir device. Applicable codes determine the dimension from the deck to the water level.
2. When used as the only overflow system on a pool, a perimeter overflow system must extend around a minimum of half the swimming pool perimeter. Perimeter overflow systems must be connected to the circulation system with a system surge capacity of not less than 1 gal/sq ft of pool surface.
3. The perimeter overflow system in combination with the upper rim of the pool must constitute a handhold. It must be designed to prevent entrapment of a swimmer's arms, legs, or feet and to permit inspection and cleaning.
4. In some states, the hydraulic capacity of the overflow system must be sufficient to handle 100% of the circulation flow.
5. Rollout and/or zero depth flush perimeter overflow systems are most commonly used in recreational pools and walk-in shallow areas. Competitive pools that have semirecessed gutters along their length to trap wave surge and prevent reflected waves must have fully recessed gutters at the ends or provide a visual barrier that can be seen by competing swimmers.

SEMIRECESSED OPEN GUTTER SYSTEM

NOTE

The zero depth gutter system is typically used for walk-in or leisure-type pools only, if necessary.

ZERO DEPTH GUTTER SYSTEM

SEMIRECESSED GUTTER SYSTEM

NOTE

Surface skimmers are not recommended for use in competitive pools.

SKIMMER DETAIL

competitive use the water level is raised to the gutter lip. Waves then flow over the lip and are returned through the surge tank without rebound.

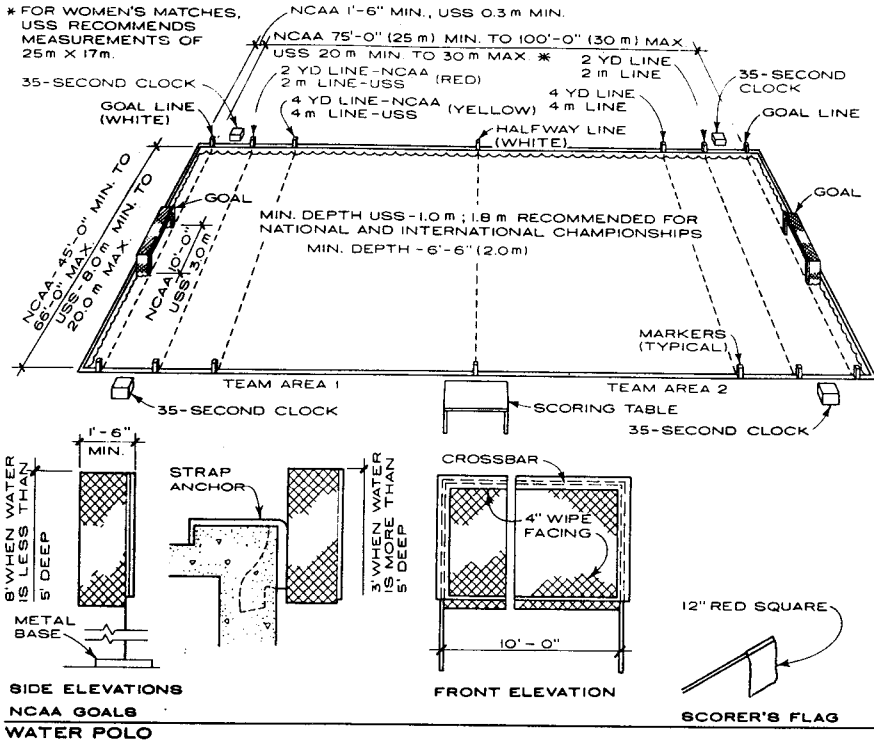

SURFACE SKIMMERS

If surface skimmers are used, provide one for each 500 sq ft or fraction thereof of the pool surface. When two or more skimmers are used, they must be located so they maintain effective skimming action over the entire surface of the pool. To obtain the most effective skimming action, locate the skimmers with regard to the prevailing wind and drift, shape of the pool, and water circulation pattern. Use of directional inlet fittings will help ensure a proper circulation pattern.

Skimmers may not be permitted in larger pools; see local health department codes for limitations on public pool use. Skimmers are not recommended for use in competitive pools.

Surface skimmers are available from many swimming pool suppliers. Metal or plastic units come in various capacities. An access cover in the deck provides for removal and cleaning of the strainer. Surface skimmers should comply with the joint National Swimming Pool Institute-National Sanitation Foundation performance standards

Robert D. Buckley, AIA; robert d. buckley * architect; Kalamazoo, Michigan
D. J. Hunsaker; Counsilman/Hunsaker & Associates; St. Louis, Missouri
National Swimming Pool Foundation; Merrick, New York

NOTES

1. Distinctive marks must be provided on both sides of field of play indicating goal lines, 2 and 4 yd (or meter) lines, and 1/2 distance between goal lines. These must be clearly visible from any position within the field of play. Allow sufficient space on walkways so referees may move freely from end to end of field of play. Provide space at goal lines for goal judges.
2. There must be distinctive markers on both ends of the pool to denote the ejection area on the goal line or the ends of the field of play 2 yd (2.0 m) from the corner of the field of play and to the right of the goal at the corner where the goal judge is located.

GOAL REQUIREMENTS

Posts and crossbar, rigid and perpendicular. USS, wood or metal, 3 in. sq. painted white; NCAA, metal 1 1/2 in. diameter, painted yellow or orange. Nets to hang loosely on frame. For USS, the underside of the crossbar must be 0.90 m above water surface when water is 1.50 m or more in depth, and 2.40 m from the bottom of the bath when the depth of the water is less than 1.50 m.

Frames are custom made, with bracing placed where necessary. It is recommended that they be collapsible for easy storage. Anchorage methods depend on pool design, with those above commonly used, or brass couplings may be placed in pool walls to which frame is attached. If pool is longer than required length, one of the goals may be floated and anchored with guy wires.

NOTES

1. To decrease turbidity caused by boat wake, an island running down the center of the lake may be built in addition to turn islands. Floating breakwaters may also

- be used; islands should be rippedrap to prevent soil erosion.
2. A gradual (ratio 6:1) sandy slope along shorelines lets wave action die without rolling back.

WATER SKI LAKE

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland

POLO Mallet

POLO BALL 3 1/4" DIA.

SIDE BOARDS

OUTDOOR POLO FIELD

STANDARD DRESSAGE ARENA

HEIGHTS AND TYPES OF FENCES WILL VARY WITH SIZE AND LOCATION OF RODEO BE AT LEAST 5'-0" HIGH AND OF A MINIMUM DIMENSION TO CONTAIN ROUGH STOCK

STANDARD BARREL COURSE

POLO

Outdoor or high goal polo is played with two teams of four players each. There can be as many as forty horses per team, and stabling and picket areas are needed for the horses. Spectator stands to accommodate three to six thousand people are needed, depending on the level of play.

The field surface should be grass cut smooth and short enough for the ball to roll straight and easily. The field side boundaries are 10 in. high side boards with a minimum of 10 yards run on, known as the safety zone, beyond. Goal posts must be vertical and light enough to break upon collision. Goal posts are 10 ft. high, and 8 yds. apart. About twenty balls are used in a game.

Arena polo is played at smaller clubs or indoors where less space is available. A playing area of 300 ft. by 150 ft. is considered ideal. Goals, at opposite ends of the field, are 10 ft. in width by 12 ft. in height, inside measurement. In smaller arenas the goal size may be reduced, but to not less than 8 ft. in width by 10 ft. in height. The arena shall be clearly marked at the center and at points 15 yds. and 25 yds. perpendicular to each goal. The inflated arena polo ball shall be not less than 4 1/4 in. nor more than 4 1/2 in. in diameter.

Further information: United States Polo Association, Oak Brook, Ill.

DRESSAGE

The arena should be on as level ground as possible. The standard arena is 60 meters x 20 meters. The small arena is 40 meters x 20 meters. The enclosure itself should consist of a low fence about 0.30 meters high. The part of the fence at letter A should be easily removable to let competitors in and out of the arena. Arenas must be separated from the public by a distance of not less than 20 meters.

The letters, clearly marked, should be placed outside the enclosure about 0.50 meters from the fence. A red line painted on the fence 20 cm. high locates the exact point of the letters on the track. The center line, throughout its length, and the three points D, X, and G should be as clearly marked as possible, without frightening the horses. It is recommended, on grass arenas, to mow the grass on the center line shorter than other parts of the arena, and on a sand arena, to roll or rake the center line.

An exercise area must be provided far enough away from the arena so as not to disturb the competitors.

SHOW

Horse show rings vary in size according to type of activity performed. A basic outdoor ring size for hunters and jumpers is 150 ft. x 300 ft. Combined training requires a stadium show ring of 80 meters x 80 meters, as well as a dressage ring. The appropriate breed or show association should be contacted for current and specific regulations.

Flat classes need a level arena with solid footing. There should be one definite opening for an "in" gate; preferable are separate openings for in and out gates. Rings for flat classes should be large enough to accommodate comfortably the number of horses.

Show management must provide sufficient area for schooling horses. It is recommended that separate schooling areas be provided for hunters and jumpers since different types of jumps are used for each. Jumps may vary from a single jump consisting of a single bar 4 in. in diameter and 6 ft. long, hung in cups from two uprights, to various combinations of two and three fences, water jumps, banks, and ditches—depending on the skill level of the class.

Further information: American Horse Show Association, New York, N.Y.

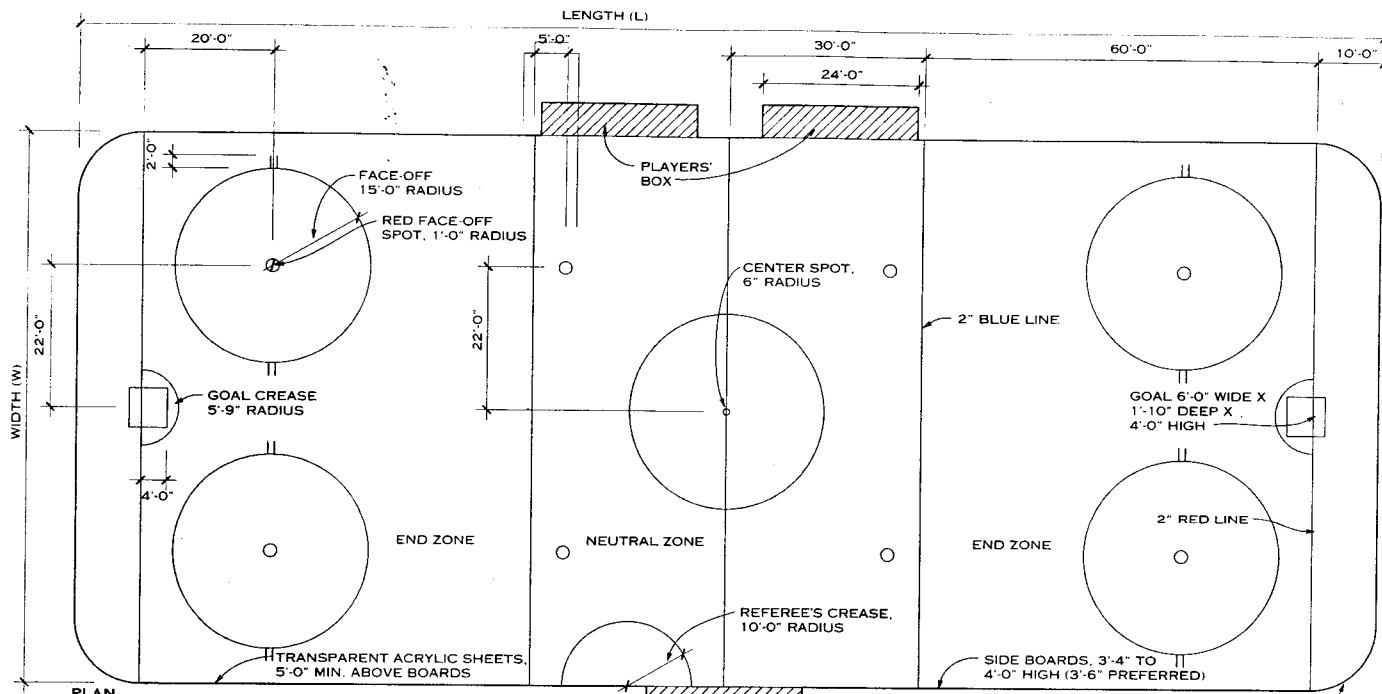

RODEO

Rodeo consists of several events involving timed contests such as calf roping and barrel riding, and rough stock events such as steer wrestling and bull riding. Arenas may vary in size but must be enclosed with fencing to control the various livestock. Barriers and chutes for timed events should be at the opposite end of arena from chutes for rough stock events. Stables, pens, and corrals for holding stock must be provided, as well as area for contestants to exercise their animals. Grandstand seating is standard; the number of spectators varies with the number and competition level of rodeo participants.

Barrels must be regulation 55 gal. size metal or rubber and enclosed on both ends.

Further information: International Professional Rodeo Association, Pauls Valley, Okla.

Theodore M. Ceraldi & Associates, Architects; Nyack, New York

ICE HOCKEY RINK SIZE

RINK TYPE	L (FT)	W (FT)
NHL	200	85
Olympic	200	100
NCAA	200	85
High School	200	85

NOTE
For year-round rinks, provide a heating system below the ice surface to prevent permafrost and movement in the subsurface soil.

ICE HOCKEY RINKS

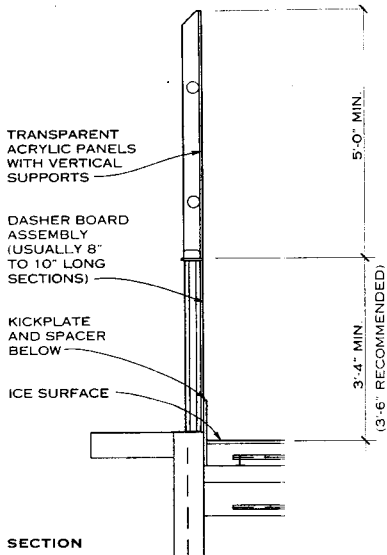

NOTE
The vehicle dimensions shown represent two of the available models. Consult the manufacturer for additional information.

ZAMBONI ICE RESURFACER

CURLING

Dean Cox, AIA; Collins Rimer Gordon Architects; Cleveland, Ohio

ICE HOCKEY GOAL

ANCILLARY SPACES AT ICE RINKS

The design of an ice rink must include planning for the ancillary space requirements described here:

1. Large hinged swing gates that open into the ice rink, usually at one end, are needed to accommodate the Zamboni, a machine used for resurfacing the ice.
2. An area is needed outside the main ice rink for disposal of ice removed by the Zamboni. This space customarily is large enough to allow 1/2 to 1 cu yd of ice to melt into a drainage sump. However, some smaller indoor facilities simply remove the scraped ice to the exterior of the building.
3. A header trench 3 ft wide x 3 ft deep should be located at one side of the ice rink to accommodate piping connections to underfloor systems.
4. Floor surfaces where access to the rink is required for skaters and a Zamboni normally consist of a rubber betting assembly or similar material.

GENERAL NOTES

1. The details shown on this page represent typical systems. Actual details must be modified as appropriate for individual projects.
2. The details shown indicate options for seasonal and year-round operations. Which design, detailing, underfloor heating, insulation, and other features are chosen depends on the anticipated operation of a particular rink.
3. Considerations affecting ice rink design and planning include requirements for underfloor drainage, ventilation, and humidity control; subsoil conditions at the site; the requirements of refrigeration plants, the ice-making system, and lighting and other electrical features; and maintenance and operational needs.
4. It is recommended that a qualified consultant be involved in the design and planning of ice rink systems.

Dean Cox, AIA; Collins Rimer Gordon Architects; Cleveland, Ohio

YEAR-ROUND RINK (NATURAL SAND FLOOR WITH INSULATION)

SEASONAL ARENA OR CURLING RINK (CONCRETE FLOOR WITH INSULATION)

SEASONAL HOCKEY OR CURLING RINK (SAND FLOOR WITH NO INSULATION)

Beginner/novice	8%	25%
Intermediate	15%	40%
Advanced intermediate/expert	25%	70%
Average Olympic downhill	23%	30%

BASE LODGE

Base lodge size in sq ft = (mountain capacity/seat turnover rate x sq ft/person).

Seat turnover rate—number of persons served per seat per day depends upon weather and temperature.

Typically: 3 (cold/overcast)
5 (warm/clear)

Typical sq ft/person at ski lodge:
30 (local ski area)
35 (destination ski area)

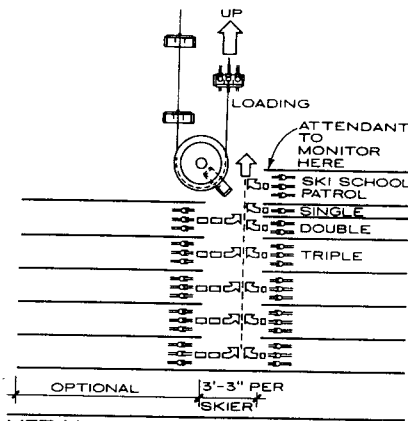

Edge of lodge to be: minimum 100 ft
optimal 150 ft
suitable 100-300 ft
from lift terminals.

Stairs with long treads (14-16 in.) and low risers (6 in.) to accommodate ski boots.

Protect entry/doorways from snowfall/dripping.

Locate windows above snow level.

Ski rental space = 3 sq ft per rental setup (skis, boots, poles).

LIFT MAZE

LIFT MAZE AREA REQUIRED FOR 10-MINUTE LIFT LINE

LIFT TYPE	WIDTH (EACH ROW)	AREA (SQ FT)
Double	5 ft 0 in.	2500
Triple	7 ft 6 in.	3750
Quad	10 ft 0 in.	5000

LIFT CHAIRS

NOTE
Lift mazes to be located downhill of or to the side of loading point.

Mazes to be graded as flat as possible.

Approach to loading point to be graded at 3% downhill for distance of 50 ft minimum.

MAZE ROW

UNLOADING STATION

SNOWMAKING MACHINE MOUNT

SNOWMAKING MACHINE CARRIAGE

SNOWMAKING MACHINE SLED

MAINTENANCE AND SNOWMAKING EQUIPMENT

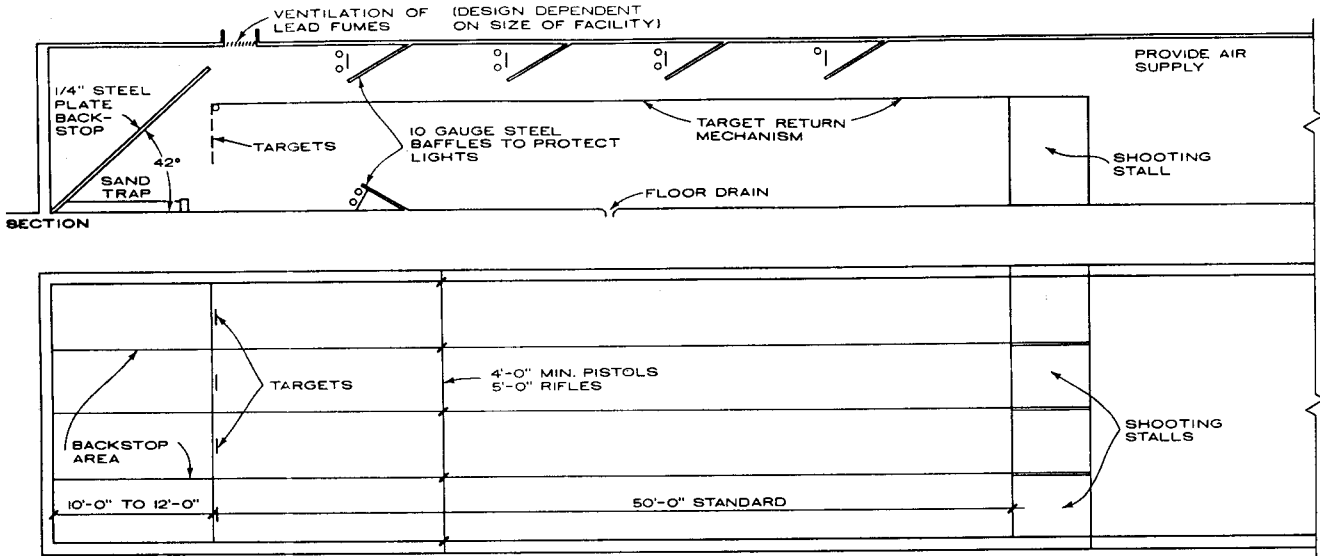

OVERSNOW VEHICLES

MAINTENANCE BUILDING

Area required: 100 sq ft per oversnow vehicle includes vehicle storage, parts and general storage, office, toilets. Does not include snowmaking system.

Doors: 16-20 ft wide, 14-16 ft high for main vehicle entry doors.

Eliot W. Goldstein, AIA, and Chan Li Lin; James Goldstein & Partners; Millburn, New Jersey

PLAN DESIGN PROBLEMS

When planning a firearms range, the following safety considerations must be made:

1. Placement of traps; use of stalls and placement of firing line; provision for space for spectators; protection from ricochet; prevention of spilled powder explosions.
2. Ventilation adequate to dissipate lead fumes.

3. Noise abatement.
4. Lighting.

The use of range design consultants is advisable. Contact the National Rifle Association for information.

TARGET SHOOTING

Archery ranges should be orientated, in the northern hemisphere, so the archer is facing north $\pm 45^\circ$. The range surface is to be turf, and free from obstructions or hard objects; likewise, spaces behind and to either side should be clear.

Target backings are made of stitched compressed straw rope called mat or buttress. Targets are made of thick paper with five concentric color zones. Both the mat and target are slanted at a 15° angle off vertical away from the archer.

Modern bows often are wood composites, fiberglass, and graphite. Lengths vary from 72 in. (1.82 M) to 62 in. (1.57 M). Bows are categorized by their draw weight, the amount of energy needed to pull a 28 in. (71 cm) arrow to full draw. Male archers usually use a 50 lb. to 55 lb. bow; female archers usually use 35 lb. to 40 lb. bow.

Arrow shafts are made of wood, graphite, or aluminum tubing. The flecking is made of plastic or feathers.

ARCHERY

Wooden nonskid flooring is ideal. A rubber piste is used on slippery floors. When a special metallic piste is used, a rubber mat must be placed beneath it to prevent hits on the floor being registered by the electronic scoring device. In competitive fencing, the score is kept by an electronic

apparatus, which records each hit, and is linked to the fencers by wires. The wires are kept from trailing the ground by a spring-loaded spool. These spools often are recessed in a pit at each end of the piste.

STRATEGIES OF CLIMATE CONTROL

The bioclimatic chart (Olgvy, *Design with Climate*, updated by Givoni and Arens) is presented here in standard psychrometric format. Plotting temperature and humidity data on the chart identifies cooling strategies for buildings dominated by envelope loads. The heavy lines in Figure 1 delineate limits within which ventilation, massive construction, evaporative space cooling, and clothing can maintain thermal comfort indoors.

VENTILATION

Whole-house (exhaust) fans provide up to 20 air changes per hour and, like continuous cross ventilation, maintain indoor temperatures close to the outdoors. As long as outdoor conditions are within the comfort zone, "air-exchange ventilation" maintains indoor comfort. "Body ventilation" is best provided by ceiling (paddle) fans. They are effective up to 70% relative humidity and 85°F ET* (effective temperature), with a maximum air speed of 3 fps and light clothing (0.4-0.6 clo).

THERMAL MASS

A very massive building envelope can maintain indoor comfort if outdoor air temperature does not exceed the thermal mass limit on the chart (roughly equal to 89°F ET*). This requires that (1) the envelope is shaded or reflective enough that its average daily outside surface temperature is no higher than the daily mean air temperature; (2) the envelope is massive enough to average daily temperature fluctuations; and (3) there is no daytime ventilation of the indoors. Nighttime ventilation extends the upper limit by cooling the envelope from both sides.

EVAPORATIVE SPACE COOLING

Intake ventilation air is evaporatively cooled by drawing it through wetted mats or filters. The technique is suited to arid and semiarid regions and requires a fan-powered ventilation system. The limits are 71.5°F wet-bulb temperature and in excess of 105°F dry bulb, which is a conservative upper bound.

OTHER CLIMATIC ELEMENTS

Wind speeds and direction are important for site analysis and for orienting the building for shelter from winter winds and to capture cooling breezes. Solar radiation data ("irradiation" or "insolation") is necessary for solar heating and daylighting design. Insolation, measured in BTU/sq ft/day or per hour, is a function of latitude, sky conditions, and angle of incidence to the receiving surface (see Kusuda and Ishii, 1977). Ground temperatures at various depths can be estimated from well-water temperatures (see Labs, 1981).

TERMINOLOGY

The effective temperature, ET*, refers to any set of temperature and humidity conditions that gives the same sensation of comfort as the stated temperature at 50% relative humidity (RH). ET* plotted here assumes light office clothing (0.6 clo) and very little air movement. One can feel as comfortable at 80°F with 20% RH as at 76°F at 80% RH; both are 78°F ET*. The ASHRAE comfort zone is bounded by an upper humidity limit of about 62°F dew point; 65°F is a conservative limit. A mean daily dew-point temperature of 50°F produces diurnal air temperature swings in excess of 30°F.

FIGURE 1 BUILDING BIOCLIMATIC CHART (AFTER GIVONI)

FIGURE 2 EXAMPLE ANALYSIS: KANSAS CITY (WATSON AND LABS)

PLOTTING DATA ON THE CHART

Combined temperature and humidity conditions at any moment can be plotted as a point on the chart. Graphing hourly data tracks the daily pattern, but daily maximum and minimum temperatures with their coincident humidities are usually adequate. Plotting a single day for each month summarizes the year at a glance (see Watson and Labs, 1983).

Example: Figure 2 plots 7 months of the year in Kansas City and shows ASHRAE summer air-conditioning design

temperatures. The daily minimum dry-bulb temperature is coupled with the daily minimum dew point, while the daily maximum dry bulb is coupled with the daily maximum wet bulb. Much of the year falls below the lower comfort limit of 68°F ET* and is "underheated." Conditions exceeding 78°F ET* are "overheated." Ventilation satisfies most cooling needs, but the fact that design temperatures exceed the ventilation limit shows that some air conditioning is necessary.

Donald Watson, FAIA; Rensselaer Polytechnic Institute; Troy, New York

DESIGN FOR ENERGY CONSERVATION

Regional design for energy conservation aims to minimize use of conventionally powered heating, cooling, and lighting by using natural energy available at the building site. Site planning and building orientation, massing, and envelope design are the principal means for managing climate-driven conduction, convection, radiation, and vapor transfer. Climatic design strategies are selected in response to outdoor microclimatic conditions, defined as "underheated" or "overheated" with respect to indoor human comfort parameters.

CLIMATIC REGIONS (MAP 1)

Map 1 delineates regions according to climatic control strategies. Regions exceeding 8000 annual heating degree days (HDD) are predominantly "underheated," in which cooling is subordinate to solar heating and heat conservation strategies. Regions with fewer than 2000 annual HDD require little heating in comparison to cooling and are predominantly "overheated" for design purposes. The large temperate region between 2000 and 8000 HDD has both heating and cooling requirements that must be balanced so that design features favoring heating do not add to the cooling load, and vice versa.

MAP 1: U.S. REGIONS BASED UPON CLIMATIC DESIGN CONDITIONS

Suitability of ventilation and evaporative cooling are related to atmospheric humidity during summer months. Regions having a combined July and August average dew point temperature greater than 65°F may be considered "humid," and those averaging less than 50°F dew point may be considered "arid." The entire southeast quadrant of the U.S. has mean daily humidities exceeding comfort limits under still air conditions. The main control problem in this region is to balance ventilation with dehumidification and mechanical cooling.

The 50°F dew point temperature is an arbitrary way of defining atmospheric aridity, but it is convenient since it produces an outdoor daily temperature range of roughly 30°F dry-bulb. Arid and semi-arid conditions favor evaporative and radiative cooling and generally disfavor summer daytime ventilation. While massive building envelopes can be advantageous in any region with a significant number of days having average daily temperatures in the upper 70s, mass is especially valuable in arid regions with extremely high daily maxima.

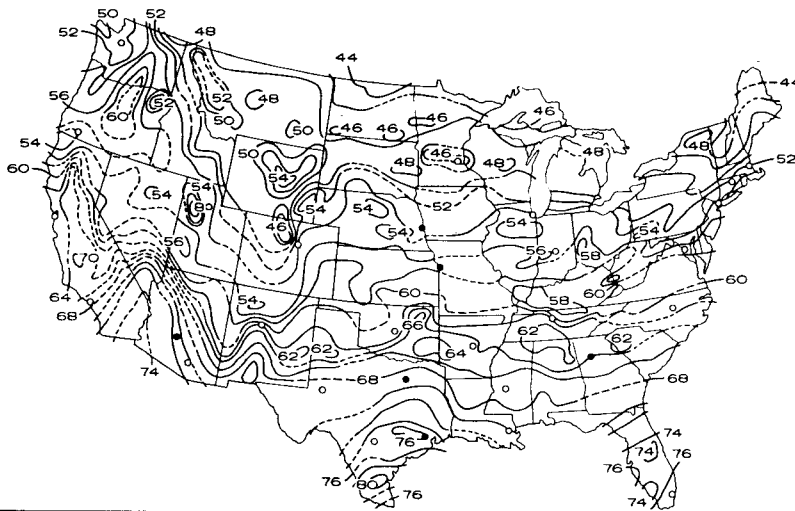

MAP 2: PASSIVE SOLAR HEATING POTENTIAL OF SOUTH WINDOWS (BTU/SQ FT/DAY)
DATA SOURCE: DR. DOUGLAS BALCOMB, SOLAR ENERGY RESEARCH INSTITUTE

SOLAR HEATING POTENTIAL (MAP 2)

Map 2 depicts solar heating capability in relation to heating load for envelope-dominated buildings. The lines plot the average daily solar gain transmitted through vertical south-facing double glazing, coincident with the need for heat. It is calculated by the relation

$$\text{Average solar gain} = \frac{\text{sum}(\text{solar gain} \times \text{HDD})}{\text{sum}(\text{HDD})}$$

HDD is the base 65°F degree days. The units are Btu/sq ft of glazing. Values assume a ground reflection of 30%. The map indicates that, for instance, useful solar gains are the same in Philadelphia, PA; Huntsville, AL; Oshkosh, WI; and Eugene, OR.

MAP 3: DEEP-GROUND TEMPERATURES (°F)
DATA SOURCE: NATIONAL WELL WATER ASSOCIATION

UNDISTURBED GROUND TEMPERATURE (MAP 3)

At "steady state" depth (20-30 ft), ground temperature is the same as well water temperature, as plotted on Map 3. Ground temperatures vary considerably throughout the first 10 ft of earth and are elevated by heat losses from buildings. Heated buildings lose some heat to the deep ground throughout most of the U.S., but the earth is not an effective heat sink in the regions where cooling is most needed. Earth-tempered design requires special analysis of thermal soil-structure interaction.

NOTES

To visualize the thermal impacts on differently exposed surfaces four locations are shown approximately at the 24°, 32°, 40° and 44° latitudes. The forces are indicated on average clear winter and summer days. The air temperature variation is indicated by the outside concentric circles. Each additional line represents a 2°F difference from the lowest daily temperature. The direction of the impact is indicated according to the sun's direction as temperatures occur. (Note the low temperatures at the east side, and the high ones in westerly directions.)

The total (direct and diffuse) radiation impact on the various sides of the building is indicated with arrows. Each arrow represents 250 Btu/sq ft · day radiation. At the bottom of the page the radiations are expressed in numerical values.

The values show that in the upper latitudes the south side of a building receives nearly twice as much radiation in winter as in summer. This effect is even more pronounced at the lower latitudes, where the ratio is about one to four. Also, in the upper latitudes, the east and west sides receive about 2½ times more radiation in summer than in winter. This ratio is not as large in the lower latitudes; but it is noteworthy that in summer these sides receive two to three times as much radiation as the south elevation. In the summer the west exposure is more disadvantageous than the east exposure, as the afternoon high temperatures combine with the radiation effects. In all latitudes the north side receives only a small amount of radiation, and this comes mainly in the summer. In the low latitudes, in the summer, the north side receives nearly twice the impact of the south side. The amount of radiation received on a horizontal roof surface exceeds all other sides.

Experimental observations were conducted on the thermal behavior of building orientation at Princeton University's Architectural Laboratory. Below are shown the summer results of structures exposed to the cardinal directions. Note the unequal heat distribution and high heat impact of the west exposure compared to the east orientation. The southern direction gives a pleasantly low heat volume, slightly higher, however, than the north exposure.

ROOM TEMPERATURE IN DIFFERENTLY ORIENTED HOUSES

ORIENTATION: CONCLUSIONS

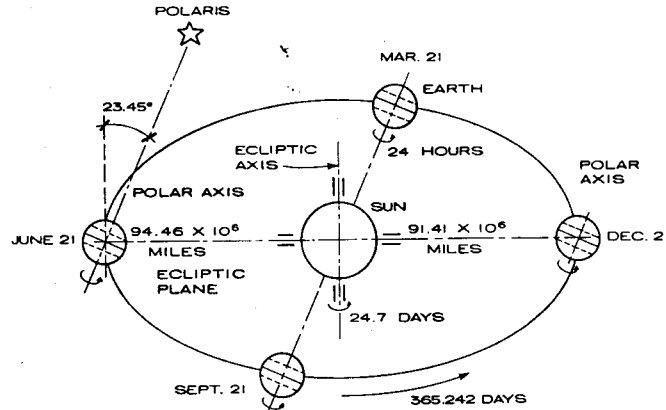

1. The optimum orientation will lie near the south; however, will differ in the various regions, and will depend on the daily temperature distribution.
2. In all regions an orientation eastward from south gives a better yearly performance and a more equal daily heat distribution. Westerly directions perform more poorly with unbalanced heat impacts.
3. The thermal orientation exposure has to be correlated with the local wind directions.

SOLAR ANGLES WITH RESPECT TO A TILTED SURFACE

ANNUAL MOTION OF THE EARTH ABOUT THE SUN
SOLAR CONSTANT

The sun is located at one focus of the earth's orbit, and we are only 147.2 million km (91.4 million miles) away from the sun in late December and early January, while the earth-sun distance on July 1 is about 152.0 million km (94.4 million miles).

Solar energy approaches the earth as electromagnetic radiation at wavelengths between 0.25 and 5.0 μm . The intensity of the incoming solar irradiance on a surface normal to the sun's rays beyond the earth's atmosphere, at the average earth-sun distance, is designated as the solar constant, I_{sc} . Although the value of I_{sc} has not yet been precisely determined by verified measurements made in outer space, the most widely used value is 429.2 Btu/sq ft · hr (1353 W/sq m) and the current ASHRAE values are based on this estimate. More recent measurements made at extremely high altitudes indicate that I_{sc} is probably close to 433.6 Btu/sq ft · hr (1367 W/sq m). The unit of radiation that is widely used by meteorologists is the langley, equivalent to one kilogram calorie/square centimeter. To convert from langleys/day to Btu/sq ft · day, multiply Ly/day by 3.67. To convert from W/sq m to Btu/sq ft · hr, multiply the electrical unit by 0.3172.

SOLAR ANGLES

At the earth's surface the amount of solar radiation received and the resulting atmospheric temperature vary widely, primarily because of the daily rotation of the earth and the fact that the rotational axis is tilted at an angle of 23.45° with respect to the orbital plane. This tilt causes the changing seasons with their varying lengths of daylight and darkness. The angle between the earth-sun line and the orbital plane, called the solar declination, δ , varies throughout the year, as shown in the following table for the 21st day of each month.

JAN -19.9°	APR +11.9°	JUL +20.5°	OCT -10.7°
FEB -10.6°	MAY +20.3°	AUG +12.1°	NOV -19.9°
MAR 0.0°	JUN +23.5°	SEP 0.0°	DEC -23.5°

Very minor changes in the declination occur from year to year, and when more precise values are needed the almanac for the year in question should be consulted.

The earth's annual orbit about the sun is slightly elliptical, and so the earth-sun distance is slightly greater in summer than in winter. The time required for each annual orbit is actually 365.242 days rather than the 365 days shown by the calendar, and this is corrected by adding a 29th day to February for each year (except century years) that is evenly divisible by 4.

To an observer standing on a particular spot on the earth's surface, with a specified longitude, LON, and latitude, L, it is the sun that appears to move around the earth in a regular daily pattern. Actually it is the earth's rotation that causes the sun's apparent motion. The position of the sun can be defined in terms of its altitude β above the horizon (angle HOQ) and its azimuth ϕ , measured as angle HOS in the horizontal plane.

At solar noon, the sun is, by definition, exactly on the meridian that contains the south-north line, and consequently the solar azimuth ϕ is 0.0°. The noon altitude β is:

$$= 90^\circ - L + \delta$$

Because the earth's daily rotation and its annual orbit around the sun are regular and predictable, the solar altitude and azimuth may be readily calculated for any desired time of day as soon as the latitude, longitude, and date (declination) are specified.

COMPASS ORIENTATION

The above map is the isogonic chart of the United States. The wavy lines from top to bottom show the compass variations from the true north. At the lines marked E the compass will point east of true north; at those marked W the compass will point west of true north. According to the location, correction should be done from the compass north to find the true north.

- EXAMPLE:** On a site in Wichita, Kansas, find the true north.
- STEP 1.** Find the compass orientation on the site.
 - STEP 2.** Locate Wichita on the map. The nearest compass variation is the 10°E line.
 - STEP 3.** Adjust the orientation correction to true north. The graphical example illustrates a building which lies 25° east with its axis from the compass orientation.

1. COMPASS ORIENTATION 2. COMPASS VARIATION 3. ORIENTATION CORRECTION

ORIENTATION PRINCIPLES

Orientation in architecture encompasses a large segment of different considerations. The expression "total orientation" refers both to the physiological and psychological aspects of the problem.

At the physiological side the factors which affect our senses and have to be taken into consideration are: the thermal impacts—the sun, wind, and temperature effects acting through our skin envelope; the visible impacts—the different illumination and brightness levels affecting our visual senses; the sonic aspects—the noise impacts and noise levels of the surroundings influencing our hearing organs. In addition, our respiratory organs are affected by the smoke, smell, and dust of the environs.

On the psychological side, the view and the privacy are aspects in orientation which quite often override the physical considerations.

Above all, as a building is only a mosaic unit in the pattern of a town organization, the spatial effects, the social intimacy, and its relation to the urban representative directions—aesthetic, political, or social—all play a part in positioning a building.

THERMAL FORCES INFLUENCING ORIENTATION

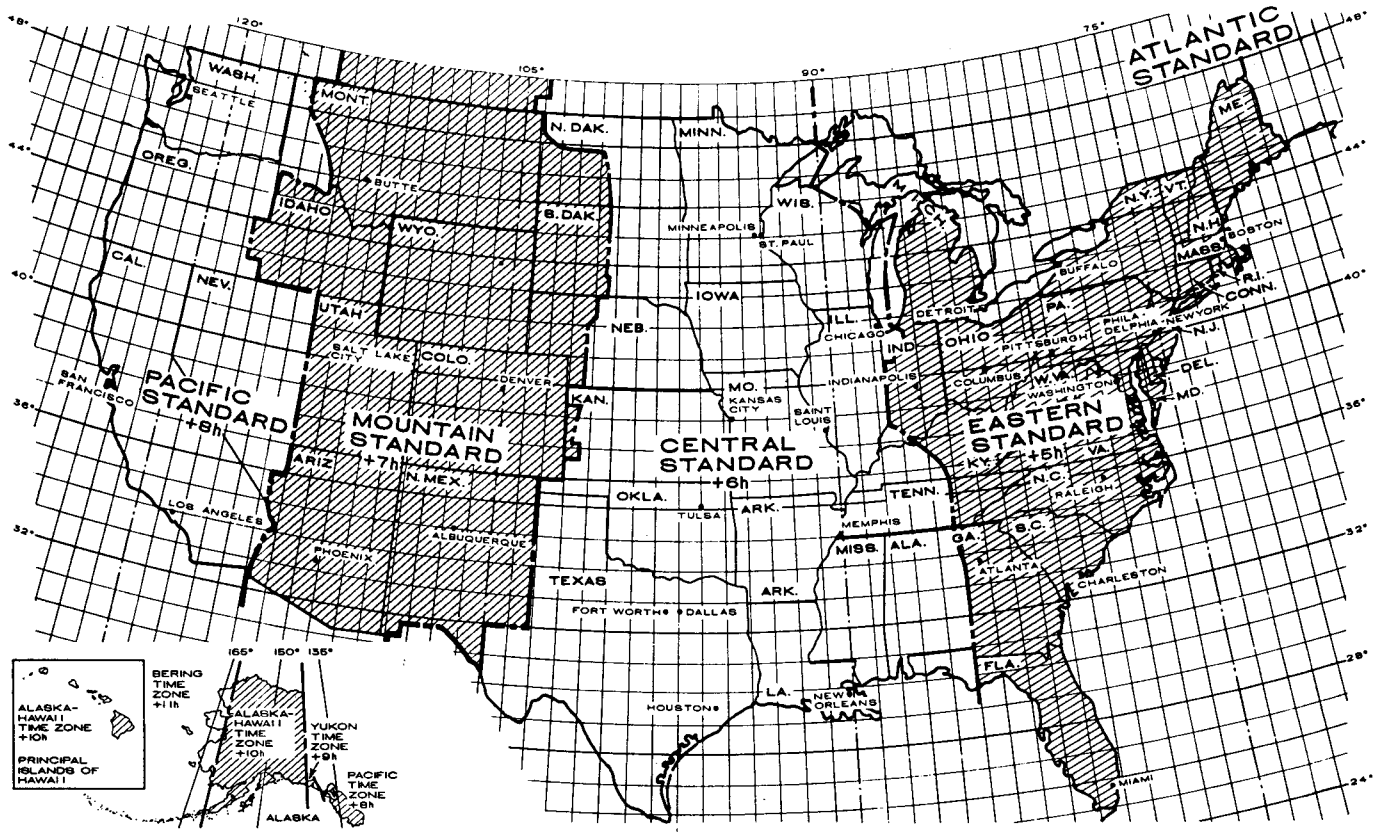

The climatic factors such as wind, solar radiation, and air temperature play the most eminent role in orientation. The position of a structure in northern latitudes, where the air temperature is generally cool, should be oriented to receive the maximum amount of sunshine without wind exposure. In southerly latitudes, however, the opposite will be desirable; the building should be turned on its axis to avoid the sun's unwanted radiation and to face the cooling breezes instead.

At right the figure shows these regional requirements diagrammatically.

Adaptation for wind orientation is not of great importance in low buildings, where the use of windbreaks and the arrangement of openings in the high and low pressure areas can help to ameliorate the airflow situation. However, for high buildings, where the surrounding terrain has little effect on the upper stories, careful consideration has to be given to wind orientation.

Victor Olgay, AIA; Princeton University; Princeton, New Jersey

STANDARD TIME ZONES OF THE UNITED STATES

NOTE: Greenwich Standard Time is 0 h.

SOLAR TIME

Solar time generally differs from local standard or daylight saving time, and the difference can be significant, particularly when DST is in effect.

Because the sun appears to move at the rate of 360°/24 hr, its apparent motion is 4 min/1° of longitude. The procedure for finding AST (apparent solar time), explained in detail in the references cited previously, is

$$AST = LST + ET + 4(LSM - LON)$$

where ET = equation of time (min)

LSM = local standard time meridian (degrees of arc)

LON = local longitude, degrees of arc

4 = minutes of time required for 1.0° rotation of earth

The longitudes of the six standard time meridians that affect the United States are: eastern ST, 75°; central

ST, 90°; mountain ST, 105°; Pacific ST, 120°; Yukon ST, 135°; Alaska-Hawaii ST, 150°.

The equation of time is the measure, in minutes, of the extent by which solar time, as told by a sundial, runs faster or slower than civil or mean time, as determined by a clock running at a uniform rate. The table below gives values of the declination and the equation of time for the 21st day of each month of a typical year (other than a leap year). This date is chosen because of its significance on four particular days: (a) the winter solstice, December 21, the year's shortest day, $\delta = -23^\circ 27'$ min; (b) the vernal and autumnal equinoxes, March 21 and September 21, when the declination is zero and the day and night are equal in length; and (c) the summer solstice, June 21, the year's longest day, $\delta = +23^\circ 27'$ min.

EXAMPLES

Find AST at noon, local summer time, on July 21 for Washington, D.C., longitude = 77°; and for Chicago, longitude = 87.6°.

SOLUTIONS

In summer, both Washington and Chicago use daylight saving time, and noon, local summer time, is actually 11:00 a.m., local standard time. For Washington, in the eastern time zone, the local standard time meridian is 75° east of Greenwich, and for July 21, the equation of time is -6.2 min. Thus noon, Washington summer time, is actually

$$11:00 - 6.2 \text{ min} + 4 \times (75 - 77) = 10:46 \text{ a.m.}$$

For Chicago, in the central time zone, the local standard time meridian is 90°. Chicago lies 2.4° east of that line, and noon, Chicago summer time, is

$$11:00 - 6.2 \text{ min} + 4 \times 2.4 = 11:03 \text{ a.m.}$$

The hour angle, H, for these two examples would be

$$\text{for Washington: } H = 0.25 \times (12:00 - 10:46)$$

$$= 0.25 \times 74 = 18.8^\circ \text{ east}$$

$$\text{for Chicago: } H = 0.25 \times (12:00 - 11:03)$$

$$= 14.25^\circ \text{ east}$$

18 SOLAR RADIATION AND BUILDING ORIENTATION

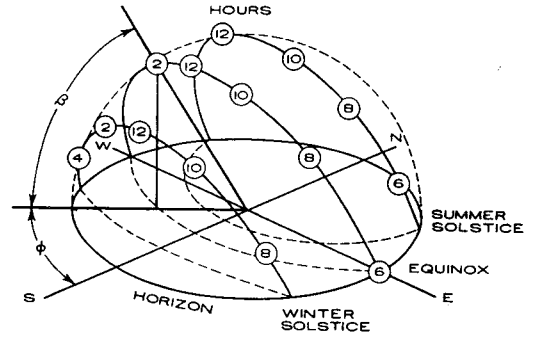

SOLAR ANGLES

The position of the sun in relation to specific geographic locations, seasons, and times of day can be determined by several methods. Model measurements, by means of solar machines or shade dials, have the advantage of direct visual observations. Tabulative and calculative methods have the advantage of exactness. However, graphic projection methods are usually preferred by architects, as they are easily understood and can be correlated to both radiant energy and shading calculations.

SOLAR PATH DIAGRAMS

A practical graphic projection is the solar path diagram method. Such diagrams depict the path of the sun within the sky vault as projected onto a horizontal plane. The horizon is represented as a circle with the observation point in the center. The sun's position at any date and hour can be determined from the diagram in terms of its altitude (β) and azimuth (ϕ). (See figure on right.) The graphs are constructed in equidistant projection. The altitude angles are represented at 10° intervals by equally spaced concentric circles; they range from 0° at the outer circle (horizon) to 90° at the center point. These intervals are graduated along the south meridian. Azimuth is represented at 10° intervals by equally spaced radii; they range from 0° at the south meridian to 180° at the north meridian. These intervals are graduated along the periphery. The solar bearing will be to the east during morning hours, and to the west during afternoon hours.

SOLAR PATH DIAGRAMS (CONTINUED)

The earth's axis is inclined 23°27' to its orbit around the sun and rotates 15° hourly. Thus, from all points on the earth, the sun appears to move across the sky vault on various parallel circular paths with maximum declinations of ±23°27'. The declination of the sun's path changes in a cycle between the extremes of the summer solstice and winter solstice. Thus the sun follows the same path on two corresponding dates each year. Due to irregularities between the calendar year and the astronomical data, here a unified calibration is adapted. The differences, as they do not exceed 41', are negligible for architectural purposes.

DECLINATION OF THE SUN

DATE	DECLINATION	CORRESP. DATE	DECLINATION	UNIFIED CALIBR.
June 21	+23°27'			+23°27'
May 21	+20°09'	July 21	+20°31'	+20°20'
Apr. 21	+11°48'	Aug. 21	+12°12'	+12°00'
Mar. 21	+0°10'	Sep. 21	+0°47'	+0°28'
Feb. 21	-10°37'	Oct. 21	-10°38'	-10°38'
Jan. 21	-19°57'	Nov. 21	-19°53'	-19°55'
Dec. 21	-23°27'			-23°27'

The elliptical curves in the diagrams represent the horizontal projections of the sun's path. They are given on the 21st day of each month. Roman numerals designate the months. A cross grid of curves graduate the hours indicated in arabic numerals. Eight solar path diagrams are shown at 4° intervals from 24°N to 52°N latitude.

EXAMPLE

Find the sun's position in Columbus, Ohio, on February 21, 2 P.M.:

STEP 1. Locate Columbus on the map. The latitude is 40°N.

STEP 2. In the 40° sun path diagram select the February path (marked with II), and locate the 2 hr line. Where the two lines cross is the position of the sun.

STEP 3. Read the altitude on the concentric circles (32°) and the azimuth along the outer circle (35°30'W).

CALCULATION OF SOLAR POSITION

The solar position to any location and time can be accurately calculated by relating the spherical triangle formed by the observer's celestial meridian, the meridian of the sun, and the great circle passing through zenith and the sun. The following formulas can be used to find the solar altitude and azimuth angles:

$$\sin \beta = \cos L \cos \delta \cos H + \sin L \sin \delta$$

$$\cos \phi = (\sin \beta \sin L - \sin \delta) / (\cos \beta \cos L)$$

where:

- β = solar altitude above the horizon
- L = latitude of the location; conventionally negative for southern hemisphere latitudes
- δ = declination of the sun at the desired date, which is the angle between the earth-sun line and the equatorial plane (north declinations are conventionally positive; south declinations negative)
- H = hour angle of the sun = $0.25 \times$ (number of minutes from local solar noon); H is zero at solar noon and changes 15 degrees per hour
- ϕ = solar azimuth, which is the angular distance measured from the south between the south-north line and the projection of the earth-sun line in the horizontal plane

CALCULATION OF SOLAR IRRADIATION

It is necessary to know the amount of solar energy falling on exposed surfaces in order to evaluate the importance of solar shading. Because shading devices primarily protect surfaces from direct solar irradiation, only these energy calculations are described here.

The magnitude of direct solar irradiation is, first of all, a function of the sun's altitude and the apparent solar constant and atmospheric extinction coefficient. The latter two parameters take into account the annual variation of the earth-sun distance and the atmospheric water vapor content. The intensity of direct solar irradiation under clear atmospheric conditions at normal incidence can be calculated by:

$$I_{DN} = A \exp (-B/\sin \beta)$$

where:

- I_{DN} = direct normal solar intensity at the earth's surface on clear days
- exp = base of natural logarithms
- A = apparent solar constant or apparent normal incidence intensity at air mass zero
- B = atmospheric extinction coefficient

The following tables indicate direct normal solar irradiation on clear days as a function of solar altitude on the solstices and the equinoxes.

I_{DN} AS A FUNCTION OF SOLAR ALTITUDE (BTU/SQ FT/HOUR)

β	JUNE 21	MAR. 21/ SEPT. 21	DEC. 21
5	33	55	77
10	106	142	173
15	156	195	226
20	189	228	258
25	212	250	279
30	229	266	294
40	251	286	314
50	264	298	325
60	272	306	332
70	277	310	336
80	280	313	339
90	281	314	339

SOLAR IRRADIATION

The direct irradiation received by any given surface is also a function of the angle of incidence of the solar beam relative to that surface. The angle of incidence is the angle between the direct solar rays and a line normal to the irradiated surface.

For horizontal surfaces, the cosine of the angle of incidence is equal to the sine of the solar altitude. The direct irradiation on horizontal surfaces is thus calculated by:

$$I_{DH} = I_{DN} \times \sin \beta$$

For vertical surfaces, the incident angle depends on the solar altitude and the surface-solar azimuth. The surface-solar azimuth (γ) is the angular distance between the solar azimuth and the azimuth of the surface. The surface azimuth is the angle between south and the normal to the surface, measured counterclockwise from south. The direct irradiation on vertical surfaces can thus be calculated by:

$$I_{DV} = I_{DN} \times \cos \beta \cos \gamma$$

In the following tables, calculated values of solar position in degrees, and direct irradiation in BTU/sq ft/hour are given for horizontal surfaces and various vertical orientations. The tables indicate values for 26°N to 46°N latitude at 4° intervals on the solstices and the equinoxes.

SOLAR-SURFACE ANGLES

The direction of the earth-sun line OQ is defined by the solar altitude A (angle HOQ) and the solar azimuth B (angle HOS). These can be calculated when the location (latitude), date (declination), and time of day (hour angle) are known. The surface azimuth S is the angle SOP between the south-north line SON and the normal to the surface OP. The surface-solar azimuth G is the angle HOP.

The angle of incidence θ depends on the orientation and tilt of the irradiated surface. For a horizontal surface, θ_h is the angle QOV between the earth-sun line OQ and the vertical line OV. For the vertical surface shown above as facing SSE, the angle of incidence θ_v is the angle QOP between the earth-sun line OQ and the normal to the surface, OP. For surfaces such as solar collectors, which are generally tilted at some angle T upward from the horizontal, the incident angle θ_t may be found from the equation:

$$\cos \theta_t = \cos A \cos S \sin T + \sin A \cos T$$

Gary L. Powell, Ph.D.; Salt River Project; Phoenix, Arizona

BASIC PRINCIPLES

The diagrams presented in this discussion are based on an isolated building. Neighboring buildings and landscaping can substantially affect airflow and should be taken into account when evaluating ventilation strategies.

As wind approaches the face of a building the airflow is slowed, creating positive pressure and a cushion of air on the building's windward face. This cushion of air, in turn, diverts the wind toward the building sides. Airflow as it passes along the sidewalls separates from building wall surfaces and, coupled with high-speed airflow, creates suction (negative pressure) along these wall surfaces. On the building leeward side a big slow-moving eddy is created. Suction on the leeward side of the building is less than on the sidewalls (see Figure 1).

If windows are placed in both windward and leeward faces, the building would be cross ventilated and eddies will develop against the main airflow direction (see Figure 2). Ventilation can be enhanced by placing windows in sidewalls due to the increased suction at this location; also, greater air recirculation within the building will occur due to air inertia (see Figure 3). Winds often shift direction, and for oblique winds, ventilation is best for rooms with windows on three adjacent walls (see Figure 4) than on two opposite walls (see Figure 5). However, if wind is from the one windowless side, then ventilation is poor, since all openings are in suction (see Figure 6).

If the building configuration only allows for windows in one wall, then negligible ventilation will occur with the use of a single window, because there is not a distinct inlet and outlet. Ventilation can be improved slightly with two widely spaced windows. Airflow can be enhanced in these situations by creating positive and negative pressure zones by use of architectural features such as wing walls (see Figure 7). Care must be exercised in developing these features to avoid counteracting the natural airflow, thereby weakening ventilation (see Figure 8).

AIR JETS

As airflow passes through a well-ventilated room, it forms an "air jet." If the windows are centered in a room, it forms a free jet (see Figure 9). If, however, the openings are near the room walls, ceiling, or floor, the airstream attaches itself to the surface, forming a wall jet (see Figure 10). Since heat removal from building surfaces is enhanced with increased airflow, the formation of wall jets is important in effecting rapid structure cooling. To improve the overall airflow within a room, offsetting the inlet and outlet will promote greater mixing of room air (see Figure 11).

VENTILATION AIR CHANGE RATE

The natural air change rate within a building depends on several factors: speed and direction of winds at building site; the external geometry of building and adjacent surroundings; window type, size, location, and geometry; and the building's internal partition layout. Each of these factors may have an overriding influence on the air change rate of a given building.

Natural ventilation can be accomplished by wind-driven methods or by solar chimneys (stack effect). However, the stack effect is weak and works best during hours when air temperatures are highest and ventilation may not be desirable. In many areas ventilation is best accomplished during the night hours when temperatures are lowest. The night average wind speed is generally about 75% of the 24-hr average wind speed reported by weather bureaus. Often wind speeds are insufficient to accomplish effective people cooling; therefore, ventilating for structure cooling rather than people cooling should be the first design goal. As a rule of thumb, an average of 30 air changes per hour should provide adequate structure cooling, maintaining air temperatures most of the time within 1.5°F of outdoor temperatures.

EXTERNAL EFFECTS

The leeward wake of typical residential buildings extends roughly four and one-half times the ground-to-eave height. For buildings spaced greater than this distance, the general wind direction will remain unchanged. For design purposes, vegetation should be considered for its effect on wind speed, which can be as great as 30-40% in the vegetation's immediate vicinity. Its effect on wind direction is not well established and should not be relied upon in establishing ventilation strategies.

RULE OF THUMB EXAMPLE

Determine inlet window opening area to achieve 30 air changes per hour in a house of 1200 sq ft with a ceiling height of 8 ft and awning windows with insect screens.

Required airflow (CFM)
= House volume x air changes per hr/60
Required airflow = (1200 x 8) x 30/60 = 4800 CFM

From local National Oceanic and Atmospheric Administration (NOAA) weather data, determine site wind conditions for design month. For the example above, average wind speed at 10 m above ground level = 7 mph or 616 ft/min at 30° incidence angle to the house face. Note that site wind speeds are generally less than NOAA data, usually collected at airports.

To determine the required inlet area, divide the house airflow by the wind speed passing through openings in the windward building face. To establish this wind speed,

the site wind speed must be modified by the effects of building angle relative to wind direction and porosity of the window opening.

Figure 12 charts the effect of wind incidence angle on airflow rates (based on wind tunnel tests on model buildings with equal inlet and outlet areas equaling 12% of inlet wall areas). Table 1 establishes porosity factors for typical window arrangements. By multiplying the site wind speed by the window air speed factor (WAF) and window porosity factor (WPF), the effective wind speed can be determined. Therefore:

$$\text{Inlet window area} = \frac{\text{Airflow}}{\text{Wind speed} \times \text{WAF} \times \text{WPF}}$$

$$\text{Inlet window area} = \frac{4800}{616 \times 0.35 \times 0.75} = 29.7 \text{ sq ft}$$

In the example above, therefore, providing a total of 60 sq ft of insect screened awning windows will provide the required ventilation of 30 air changes per hour.

For best results, the 60 sq ft of windows should be split equally between inlets and outlets. However, adequate airflows can be maintained for anywhere from 40/60 to 60/40 split between inlets and outlets.

FIGURE 9

FIGURE 10

FIGURE 11

WINDOW SIZE

Airflow within a given room increases as window size increases, and to maximize airflow, the inlet and outlet opening should be the same size. Reducing the inlet size relative to the outlet increases inlet velocities. Making the outlet smaller than the inlet creates low but more uniform airspeed.

FIGURE 12

TABLE 1 POROSITY FACTORS

WINDOW TYPE	FACTOR
Fully open awning or projecting window	0.75
Awning window with 60% porosity insect screen	0.65
60% porosity insect screen only	0.85

CLIMATE

Cold climates in North America are generally north of the 40th parallel. Very cold is identified by the southern boundary of the 32°F mean annual temperature and includes most of Canada and Alaska except along the Pacific coast. Permafrost extends from below Hudson Bay and just north of the southern coast of Alaska to the Arctic Circle. The Arctic Circle designates the southernmost point where continuous daylight in summer and continuous darkness in winter exist.

PLANNING DETERMINANTS

Cold climates generally require multidisciplinary considerations for extremes of physical, economic, sociological, and environmental conditions. These include very cold temperatures, high winds, drifting snow, continuous darkness and low sun angles, permafrost, minimal and costly transportation and communication, and subsequent isolation.

DESIGN

Responses to planning determinants suggest aerodynamic design, isolation from permafrost, maximum insulation, self-sufficient utilities, backup systems for emergency, privacy without isolation, variety, and color. Labor is costly, suggesting maximum prefabrication. (Modular components can be used where barges can navigate.)

THERMOPILES AND PROBES

Both self-contained convection (passive) and mechanically refrigerated (active) systems are used for new construction and stabilization of existing foundations, either directly as pipe piles or in smaller pipes (probes) that can be placed beside a pile or under slab or foundation. Passive systems rely on natural convection of a liquid or gas medium to remove heat from the ground to keep it frozen; active systems use pumps and refrigeration technology. Recent concerns regarding global warming have caused renewed interest in the design parameters for passive systems.

UTILITIES

Utilidors or utiliducts are the most common way to provide protection, easy access, and insulation of utility lines to avoid disturbance to the permafrost. Human waste at isolated facilities may be handled by compost privies (waterless toilets) and chemical toilets or self-contained treatment systems. Disposal systems include incineration and sewage lagoons.

PERMAFROST, ICE WEDGES AND LENSES, AND FROST HEAVE

DEFINITION OF PERMAFROST: Ground of any kind that stays colder than the freezing temperature of water throughout several years. Depth can extend to 2,000 ft below active layer.

TERMS

ACTIVE LAYER: Top layer of ground subject to annual freezing and thawing. Up to 10 ft or only 18 in. over some permafrost.

FROST HEAVING: Lifting or heaving of soil surface created by the freezing of subsurface frost-susceptible material.

FROST-SUSCEPTIBLE SOIL: Soil that has enough permeability and capillary action (wickability) to expand upon freezing.

ICE LENSE (TABER ICE): Subsurface pocket of ice in soil.

ICE WEDGE: Wedge-shaped mass of ice within thaw zone. Wedges range up to 3 or 4 ft wide and 10 ft deep.

PERELETOK: Frozen layer at the base of the active layer that remains unthawed during some cold summers.

RESIDUAL THAW ZONE: Layer of unfrozen ground between the permafrost and active layer. This layer does not exist when annual frost extends to the permafrost, but is present during some warm winters.

SITE PLANNING

Blowing snow with high winds, low sun angles, and long periods of darkness are the dominant design factors. Minimizing obstructions that cause snow drifting and

placing the long axis of a structure parallel to the prevailing wind help. Buildings can be spaced to avoid the long shadows cast by low winter sun angles. Darkness is a physical and psychological problem that suggests adequate lighting and signage.

CONDITION OF BUILDINGS ON PERMAFROST

CONDITION 1: Building elevated on piles allows the dispersion of building heat to prevent ground thaw and allow the wind to remove snow. Wooden piles, with low thermal conductivity, induce minimal heat into frozen ground while thermopiles can remove heat to retain frozen state.

CONDITION 2: Building elevated on non-frost-susceptible gravel pad to provide insulation in addition to existing ground cover. Rigid insulation adds to the protection from thaw of the permafrost. Thermoprobes are used to re-freeze fill and keep permafrost frozen.

GENERAL

Successful design of building envelopes for cold regions requires that all air-vapor retarders, wind barriers, and insulation be continuous. Air-vapor retarders prevent warm,

moist indoor air from entering and condensing in portions of the envelope. Wind barriers prevent cold outdoor air from entering the insulation. Seal the wind barrier and air-vapor retarder at all joints and penetrations in the envelope to prevent air leakage and moisture problems. Metal or con-

crete bridging across the insulated layer can cause thermal short circuits. Minimize thermal short circuits with continuous insulation; this saves energy and reduces condensation and mold. Adequate slopes and continuity at flashing prevent problems due to snow and ice on roofs.

STRATEGIES OF CLIMATE CONTROL

Underheated conditions occur in both humid and arid regions and dominate much of the U.S. The strategies are to minimize conduction and infiltration losses and to take advantage of winter solar gain. Humidity affects sky clearness and availability of solar radiation, making optimization of solar glazing area one of the main opportunities of regional design. Moisture movement through the building shell must be controlled. It is driven by air leakage (exfiltration) and by vapor diffusion, which is related to temperature differences.

MINIMIZE CONDUCTION LOSSES

Minimize ratio of envelope to heated floor area. Minimize foundation perimeter length. Insulate envelope components in proportion to indoor-outdoor temperature difference. Minimize areas of windows, doors, and other envelope components of inherently low R value. Detail to avoid thermal bridging. Provide movable insulation for glazed areas.

MINIMIZE INFILTRATION LOSSES

Plant vegetation to create wind-sheltered building sites. Shape building to minimize exposure to winter wind. Orient doors and windows away from winter wind. Specify weatherstripping and infiltration barrier.

CAPTURE SOLAR GAIN

Provide high-transmittance south-facing glazing. Provide thermal mass indoors to store solar gains.

INSULATION

Insulation requirements are proportional to heating loads. The foundation is often underinsulated and can be a major source of heat loss. The desirable insulation level depends on basement temperature and insulation levels in the rest of the building. An approximate thermal optimum is:

$$R_{ins} = \frac{T_{bsmt} - T_0}{T_1 - T_0} R_{ref} - R_{wall}$$

R_{ins} = R value to be added to basement wall above grade

R_{ref} = R value of superstructure wall

R_{wall} = R value of uninsulated basement foundation wall

T_{bsmt} = average seasonal temperature of basement

T_1 = average seasonal temperature of living space

T_0 = average seasonal outdoor temperature

The added foundation insulation above grade is R_{ins} . It should decrease with depth by R - 2 per foot in ordinary soils and R - 1.5 in wet soils. A horizontal skirt can be used to reduce floor perimeter losses. Exterior insulation keeps the wall warm and eliminates condensation and thermal bridges. As seasonal basement temperature decreases, losses to it from the superstructure increase, and basement ceiling R value should increase. As a very rough rule, the basement ceiling R value should be greater than $(R_{ref} - R_{ins})$.

SOLAR DESIGN AND DAYLIGHTING

The most advantageous south glazing area depends on thermal and climatic factors. Rules of thumb have been prepared (Los Alamos National Laboratory) and more sophisticated methods are available for desktop computers.

The advantage of glazing for daylighting has to be weighed against the penalty of winter heat loss. In predominantly cloudy climates, skylighting can be designed without significant shading, but not without concern for glare. In clear, sunny climates and in warmer regions, daylight glazing may require shading to reduce undesired heat gain. South glazing has the combined advantages of daylighting, winter heat gain, and economical summer shading.

BASEMENT FOUNDATION AND FLOOR INSULATION

CLIMATE: IMPLICATIONS

Although classified as arid and overheated, severe desert climates in the United States typically have four distinct periods for determining comfort strategies. The hot dry season, occurring in late spring, early summer, and early fall, has dry, clear atmospheres that provide high insolation levels, high daytime air temperatures, very high sol-air temperatures, and large thermal radiation losses at night producing a 30 to 40°F daily range. Nighttime temperatures may fall below the comfort limits and are useful for cooling. Low humidity allows effective evaporative cooling. The hot humid season occurs in July and August. In addition to high insolation, it is characterized by high dew point temperatures (above 55°F), reducing the usefulness of evaporative cooling for comfort conditioning. Cloudiness and haze prevent nighttime thermal reradiation, resulting in only a 20°F or less daily range. Lowest nighttime temperatures are frequently higher than the comfort limits. Thus refrigeration or dehumidification may be needed to meet comfort standards. The winter season typically has clear skies, cold nights, very low dew point temperatures, a daily range of nearly 40°F, and the opportunity for passively meeting all heating requirements from isolation. The transitional or thermal sailing season occurs before and after the winter season and requires no intervention by environmental control systems. This season can be extended by the passive features of the building. Other desert climates have similar seasons but in different proportions and at cooler scales.

MINIMIZE SOLAR AND CONDUCTIVE GAINS

Solar radiation is the greatest liability to comfort conditions in this region. Summer solar intensity is highest on horizontal surfaces. A vented attic above an insulated ceiling is very effective. Ideally the entire building, both transparent and opaque surfaces, should be shaded, as well as outdoor pedestrian and living areas (ramadas and pergolas). Plant trees to shade roof and east and west walls, and to develop a modified microclimate around the building. Shape massing to minimize solar load on envelope; thus multistory schemes with narrow east-west exposures are efficient. Cluster buildings to shade one another; position carport or garage as a buffer on the west side. Use light-colored surfacing on walls and roof.

Insulate envelope components in proportion to the difference between sol-air and indoor temperatures. In addition, use radiant barriers in attic, cathedral ceilings, and walls. Perimeter insulation of slab-on-grade floors is desirable but not critical. In this region, deep-ground temperatures are too high and soil conductivity is too low for the earth to be a useful cooling sink. But low conductivity makes the soil a good buffer against surface conditions. Earth berms work.

SELECTIVE FENESTRATION

Shading of glass during the full overheated period also has the highest priority. Minimize glass on the west. Balance fenestration between north and south, although both orientations require solar control. For all uses, residential and light commercial, direct solar gain is not desired except in the coldest months. For small area windows that will be shaded, single pane glazing is acceptable. With larger areas

(over 20 sq ft), in addition to the conductive heat gain, the higher inside surface temperature of single glazing raises the mean radiant temperature and adversely affects comfort. Generally fenestration should be double pane with a low "e" coating on the inside surface of the outside pane. If fenestration is unshaded, replace low "e" coating with "heat mirror," which also reduces visible transmission. Multiple glazing should have low conductance frames, using either thermal breaks, if metal, or thermally resistant materials such as wood or plastic. Clear, sunny skies make daylighting dependable and predictable for design. Although glazings with low shading coefficients block considerable insolation, they also prevent daylighting the space, thus requiring higher wattages for electric lighting. Small windows and skylight areas are effective but apertures need exterior shade to avoid solar gain and high contrast. Reflected light from the ground and from light shelves is useful, but glare from uncontrolled reflecting surfaces must be kept from view.

VENTILATION

Although nighttime breezes are slight, design for ventilation. Arrange floor plans for internal air movement, especially to cool thermal mass. Wholehouse fans, powered ventilation and economizer cycle systems are strongly recommended for accelerated night cooling.

THERMAL MASS AND INSULATION

Uninsulated Mass Construction: Vernacular house designs in hot, arid regions use low mass construction for sleeping areas, and high mass for daytime activity areas. These strategies also apply to other building types. The low mass zone is ventilated or is mechanically cooled off quickly at night, while the high massive zone has little window area and cools off slowly.

Uninsulated exterior mass delays the transfer of heat to the interior. Its usefulness depends on occupancy and space-conditioning schedules. For example, a masonry west wall can relieve an office building by delaying peak loads during business hours, but would be inappropriate for a west-facing bedroom. The delay rate of most mass materials is approximately 40 to 50 minutes per inch thickness. A completely shaded, uninsulated massive wall can do no better than maintain an average daily temperature near the outdoor average, unless the space is well ventilated at night. Uninsulated mass walls have low R values and generally are not economically suitable for heated and air-conditioned buildings. Insulating a mass wall in a composite construction is beneficial in most climates.

Adobe or rammed earth walls for thermal mass can be more expensive than poured concrete or concrete masonry units. Most economical may be full weight concrete block (not lightweight aggregate) with open cells filled by a weak sand or gravel grout to add mass and conductivity. Free-standing interior walls or partitions of mass materials allow thermal access to both sides, and they are protected from the elements (important if earthen materials).

Insulated Mass Construction: Insulation outside the mass has the greatest benefit. It reduces heat gain while allowing

the wall to discharge heat during nighttime ventilation. In winter it doubles usefulness with thermal storage for passive solar heat. Insulation also allows less mass to be used to reduce interior temperature swings. Calculation of the thermal dampening, delay rate and storage dynamics of composite walls is complex and benefits from computer modeling. A minimum of 2 in. thickness and a maximum of surface area can stabilize the interior environment, whether mechanically or passively conditioned.

Insulating inside the mass or adding mass outside an insulated frame wall (brick veneer) improves performance over either case alone. Both are inferior to outside insulation and slightly less effective than walls with integral insulation (masonry with core insulation). An ideal wall would have thermal mass on both surfaces with resistance insulation between. The optimal insulation and mass combinations vary with climate and conditioning hours of the building. Carpeting on the floor slab and the use of paper faced dry-wall reduces the immediate thermal effect of their mass. Lightweight wall construction, if used, should have minimum R-19.

MECHANICAL EQUIPMENT

Zone cooling for two or more units of mechanical equipment to provide comfort control, minimize duct lengths, and allow partial cooling when one unit is inoperative. Thermostat setbacks can be used to discharge the thermal mass at night when costs are lower. Place outdoor equipment away from doors and windows. Because of lower efficiencies, and defrost requirements below 45°F, heat pumps are not preferred. Multiple fuel heating and cooling units are recommended. Refrigeration units should have SEER above 10. (Supply ducts sized for silence have velocities below 600 fpm, for efficiency below 1000 fpm and never more than 1500 fpm.) Ducts should be inside the insulated building envelope.

Evaporative space coolers can provide comfort more than 90% of the cooling season at elevations above 1500 ft and more than 50% of the cooling season at elevations below 1500 ft throughout the Southwest. Operating costs for electricity and water are between 25 to 30% of refrigeration. Two stage evaporative units perform well in the most demanding locations at operating costs of 30 to 35% of refrigeration but cannot provide 100% comfort during peak humid times. Evaporative cooling requires exhaust, and security is a risk if open windows are used. Exhaust through chimneys or provide secondary cooling through barometric dampers to a vented attic or ducted to attached garages or sunspaces.

Multiple speed ceiling fans over seating and beds can add to comfort choices and extend the capacities of cooling systems by providing comfort at higher temperatures.

CONSTRUCTION DETAILS

1. Coolant and refrigerant pipes from remote evaporative towers and condensers should be insulated for their entire length.
2. Roof construction similar to the cold climate roof detail is also appropriate in hot locations.
3. Exposed wood (especially in small cross sections) and many plastics deteriorate from excessive heat and high ultraviolet exposure.
4. Although vapor barriers may not be critical to control condensation, they are important as a building wrap or wind shield, both to control dust penetration and to avoid convective leaks from high temperature differentials.
5. Avoid thermal bridges such as extensive cantilevered slabs.
6. Radiant barriers and details appropriate to humid overheated climates are at least as effective, but assembly must avoid holes where convection would leak their thermal advantage.
7. Ventilate building skin (attic or roof, walls) to relieve sol-air heat transfer.

STRATEGIES OF CLIMATE CONTROL

Humid overheated conditions are most severe along the Gulf Coast, but occur across the entire southeastern U.S. Atmospheric moisture limits radiation exchange, resulting in daily temperature ranges less than 20°F. High insulation gives first priority to shading. Much of the overheated period is only a few degrees above comfort limits, so air movement can cool the body. Ground temperatures are generally too high for the earth to be useful as a heat sink, although slab-on-grade floor mass is useful. The strategies are to resist solar and conductive heat gains and to take best advantage of ventilation.

MINIMIZE SOLAR GAINS

1. Plant trees to shade roof and east and west walls.
2. Shape building to minimize solar load on envelope.
3. Shade all glazing during overheated period.
4. Shade north elevation in subtropical latitudes.
5. Use light-colored surfacing on walls and roof.

MINIMIZE CONDUCTIVE GAINS

1. Insulate envelope components in proportion to sol-air-indoor temperature difference.
2. Use radiant barrier in attic space.
3. Consider thermally massive envelope materials to reduce peak air-conditioning loads.
4. Use slab-on-grade instead of crawl space and insulate only at perimeter.

PROMOTE VENTILATION LOSSES

1. Orient building to benefit from breezes.
2. Use plantings to funnel breezes into building, but be careful not to obstruct vent openings.
3. Use wing walls and overhangs to direct breezes into building.
4. Locate openings and arrange floor plan to promote cross ventilation.

5. Plan interior for effective use of whole-house fan.
6. Ventilate building envelope (attic or roof, walls).

SPACE VENTILATION

"Air-change ventilation" brings outdoor temperatures indoors by breezes or whole-house exhaust fans. Whole-house fans yield about 20 air changes per hour (ACH) and are useful only as long as outdoor conditions are within comfort limits (72°-82°F). They may offer 30-50% savings in electricity costs over air conditioning. Whole-house fans do not provide high enough airflow rates for body ventilation. Ceiling (paddle) fans are recommended for air movement and can maintain comfort with indoor temperatures up to 85°F ET*. Air conditioning is necessary above 85°F ET*. The issue of when to ventilate and when to air condition is a function of building type, occupancy hours, heat and moisture capacity of the structure, and climatic subregion. Humidity is a factor, as night air may be cool but excessively humid.

ROOFS AND ATTICS

The attic should be designed to ventilate naturally. Most of the heat gain to the attic floor is by radiation from the underside of the roof. While ventilation is unable to interrupt this transfer, most of it can be stopped by an aluminum foil radiant barrier. Foil facings on rigid insulation and sheathing can be used as radiant barriers when installed facing an airspace.

Roof spray systems can dissipate most of the solar load, leaving the roof temperature near the ambient dry-bulb instead of the sol-air temperature. The theoretical lowest temperature that the roof can be cooled to by evaporation is the wet-bulb, but is not attainable under real daytime conditions. The cost-effectiveness of spray systems depends on the roof section, R value, building type, climatic region, and other factors. Spray systems are most advantageous for poorly insulated flat roofs.

WALLS

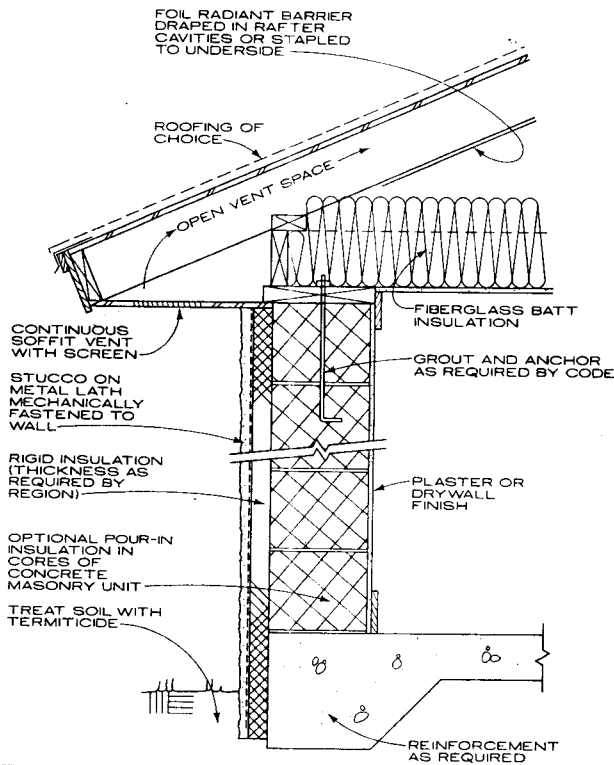

Radiant barriers enhance the performance of walls by reducing solar gain. They are most effective on east and west walls and are recommended for predominantly overheated regions (< 2000 heating degree days (HDD), > 2500 cooling degree days (CDD)). They are not recommended on south walls except where CDD exceed 3500. Radiant barriers must face an airspace and can be located on either side of the wall structure. Outside placement allows the cavity to be vented. This enhances summer wall performance, but admitting cold air degrades it during winter. Venting is recommended for regions having more than 3500 CDD. Discharging the cavity into the attic ensures best vent action. Thermal mass in walls reduces peak air-conditioning loads and delays peak heat gain. By damping off some of the peak load, massive walls help keep indoor temperatures in the range where ceiling (paddle) fans and airflow from cross ventilation provide comfort.

DAYLIGHTING

Windows and skylights should be shaded to prevent undesired heat gain. North- and south-facing glazing is shaded most easily for predictable daylighting. Light-colored reflective sunshades and ground surfaces will bounce the light and minimize direct gain. Cloudy or hazy sky conditions are a source of brightness and glare.

ENERGY-EFFICIENT WALL SECTION: VENTED SKIN MASONRY WALL WITH INSIDE INSULATION

ENERGY-EFFICIENT WALL SECTION: VENTED SKIN WALL WITH RADIANT BARRIER

Donald Watson, FAIA; Rensselaer Polytechnic Institute; Troy, New York
Kenneth Labs; New Haven, Connecticut

The term "alternate energy systems" describes uses of climatic resources—sun, wind, precipitation/humidity, and temperature—to provide all or part of the energy requirements of a building. Their development has paralleled the uncertain cost and availability of conventional energy supplies. New design concepts—passive solar and cooling and daylighting designs—have become part of recommended building practice. More advanced technologies have been developed, but their widespread use awaits either more experience with them or more penalizing energy prices. Some can be easily incorporated into a building design, requiring only careful design integration of architectural and heating, cooling, and lighting systems. A number of factors can change the economic constraints upon what is and is not cost-justified: the need for emergency preparedness, the prospect of interruptible or increasingly costly conventional fuel supplies, environmental pollution from fossil fuel combustion, and limited capacity of existing power plants. These concerns suggest that they be given full consideration together with energy conservation/load reduction techniques so that our long-term reliance upon conventional and nonrenewable energy sources can be minimized.

The practical approach to alternate energy system design begins with analysis of the energy requirement of the building "end use": the temperature, humidity, air flow, and lighting levels required for human comfort, and the related power demands for productive activity. The various sources for supplying heating, cooling, lighting, and electric power can then be matched to the end use in terms of "thermodynamic" efficiency, comfort, operational cost, and reliability. High levels of energy conservation and renewable energy use can make life-cycle economic gains possible, such as by downsizing mechanical system sizes or through "off-peak" loading of the building's energy requirement to reduce or eliminate "demand charges," as is possible when a building has a large energy storage system.

The figure diagrams the various alternate energy system components. The building itself is shown as an energy collection, storage, and distribution system. Choices include system components that are separate from the building (though presumably nearby) and those that must be integrated with it.

SITE AND BUILDING AS ENERGY COLLECTION, STORAGE, AND DISTRIBUTION SYSTEM

REMOTE ENERGY COLLECTORS (ELECTRICAL)

Three contenders for alternate electric power are windmills, microhydro dams, and photovoltaic panels. Photovoltaic systems use the photons of sunlight to generate electricity across a grid of cells in a solar collector. These can be mounted on the roof of a building or can be "remote," since electricity is easily distributed from its point of collection. Site engineering concerns are major, but building design criteria are minor, limited only to storage battery location and the electric distribution system within the building. The economic viability of these choices is greatly improved by reduction of the electric load requirement achievable by energy-efficient lighting and equipment.

REMOTE ENERGY STORAGE (THERMAL)

Energy storage near a building site has proved to be viable when the site is large enough, made part of seasonal (6-month) storage, and serves groups of buildings (district heating/cooling). These include:

Underground thermal storage: Heat generated by solar collectors (either air type or liquid type) can be stored within a large mass of earth, in existing caverns, or in newly dug clay or soil beds. In Kerava Solar Village near Helsinki, Finland, solar collectors mounted on the south-facing roofs of 44 apartments supply solar-heated water to a 400,000 gal water tank which in turn heats 338,500 cu ft of rock surrounding the tank embedded 66 ft in the earth.

Acquifer systems: A variation of thermal storage that is "charged" by solar collectors are systems using natural or man-made aquifers for seasonal storage, thus utilizing groundwater temperature for heating and cooling, generally relying upon a water-to-water heat pump to change the groundwater temperature to the end-use requirement for heating and cooling.

Ice storage systems: Ice storage systems use ice-making, either "seasonal" for 6-month storage or "diurnal," at night for next-day use, to provide building cooling. The advantage of making ice in winter is obvious, imposing

only the cost of a large storage area logically located within the subgrade basement of a building, but which can also be separate. Diurnal systems are cost-effective when there are advantages of "off-peak" utility rates and/or significantly cooler nighttime temperatures.

Solar ponds: Solar ponds are salt ponds that exploit the temperature gradient effect of salt water. First documented by Russian scientist von Kaledzinsky in 1902, water a few feet below a confined body of salt water reaches temperatures up to 185°F due to the varying salinity of the water: The bottom of the pond is a bed of salt in which heat is efficiently stored because heated salt-rich water does not rise, while the surface of relatively fresh water above is clear, allowing solar heat to be transmitted through it and at the same time insulating the denser layers below. In Israel and Australia, such solar ponds have been used as a source of thermal energy and to drive engines for electric generation. While only half as efficient as a solar collector, the relatively low cost of solar ponds (reportedly ten times less costly per unit of collector surface) indicates their potential.

INTEGRATED BUILDING SYSTEMS

A building designed to efficiently use climatic resources for heating, cooling, lighting, and electric power generation is properly considered an alternate energy system. Means for doing so are tabulated in the table and summarized below as a checklist for designers.

South wall: The south-facing wall of a building (in the Northern hemisphere) is an efficient energy resource. The low-angled winter sun can bring into a building interior the benefits of winter heat and light. Shading the south facade in summer can be efficiently accomplished with relatively short overhangs. Because of this, passive solar heating, summer shading, and year-round daylighting can

and ought to be made part of south-wall design. Solar heat can be stored in thermal storage placed in the sun behind glass or ducted/piped to the building interior.

Roof: The roof of a building can be used for mounting "active" solar collectors for heating, photovoltaic collectors for generating electricity, or skylights for daylighting. In hot climates, the roof is also an alternate energy resource if used for evaporative or radiant cooling.

Atrium: Atria design can be integrated into a "whole building" daylighting system and combined with the mechanical air movement system wherein it can economically replace ducting in ventilative cooling and heat recovery systems. Skylights, enhanced with light and heat reflectors, can be designed to reflect sunlight deep within a building.

Below-ground/basement: The below-ground construction of a building can be used for thermal storage, as described above. In single-storied or low-rise buildings, "ground coupling" utilizes the relatively stable temperatures of the surrounding earth to provide an economical heating/cooling flywheel effect.

OTHER ENERGY FLOWS WITHIN A BUILDING

Alternate energy design addresses all energy and resource requirements involved in building construction and use, including plant growth in interior and exterior gardens; water collection, purification, and reuse; and resource recycling and organic waste treatment/nutrient recovery. These energy flows, together with the ecological role of the surrounding landscape, are properly considered as biological system requirements of living efficiently within the limits of climate and environment.

EXAMPLES OF ENERGY-EFFICIENT ARCHITECTURAL ELEMENTS

ELEMENTS	HEATING	COOLING	LIGHTING
South wall	South-facing glass Trombe wall Sunspace	Reflective glass Sunshades	Venetian blinds Light shelf
Roof	Active solar collectors South-facing clerestories	Evaporative cooling Skytherm (radiant cooling)	Skylighting Photovoltaic collectors
Atrium	South-oriented glazing Storage mass in sun	Shaded courtyard Ventilating chimney	Light shaft Light reflectors
Ground/basement	Thermal storage	"Coolth" storage	

Donald Watson, FAIA; Rensselaer Polytechnic Institute; Troy, New York

ENERGY-CONSERVING DESIGN: NONRESIDENTIAL BUILDINGS

Energy-conserving design for nonresidential buildings is justified by savings in operating costs which result in a lower "life-cycle" investment. For large buildings of all types, the best opportunities are most likely to be found in electricity costs; depending upon the demand charges of the local utility, "peak load" reduction and/or "shifting" (diurnal or seasonal) measures may prove to be cost-effective. Concurrently, lower electric use by effective daylighting and by cooling load reduction (window orientation and solar controls) will be cost-effective, since these loads are typically interrelated and use expensive forms of energy. When these loads and costs are reduced, heating cost reduction by solar and energy-conserving techniques also applies to larger buildings. Energy-conserving opportunities are best addressed by a whole-systems team approach of architecture, HVAC, lighting, and controls engineering. For example, high levels of insulation or of thermal mass may be cost justified when these also result in substantially reduced mechanical system sizes and power requirements.

The architect should consider the following items in designing an energy-efficient nonresidential building, regardless of size and building type.

SITE PLANNING AND ORIENTATION

1. ORIENT THE LONGER WALLS OF A BUILDING TO FACE NORTH-SOUTH

Walls that face the equator (e.g., the noonday sun) are ideal for windows oriented to admit daylighting with minimum cost for shading or sun control (i.e., relatively small horizontal overhangs create effective shading). Walls and windows facing east and west, on the other hand, are sources of undesirable overheating and are difficult to shade effectively. In a cool climate, windows facing the equator can gain useful wintertime heating from the sun. (See also "Daylighting" criteria.)

2. PROVIDE SUN SHADING TO SUIT CLIMATE AND USE VARIATIONS

Buildings can be located in groups to shade one another. Landscaping and sun shading can be used to shade building surfaces, especially windows, during overheated hours. Functions can be located within a building to coincide with solar gain benefit or liability. For example, cafeterias are ideally exposed to noontime winter sun in cool and temperate climates or placed in the midday shade in warm climates; low-use areas (storage areas) can be used as climatic buffers placed on the east or west in hot climates or on the north in cool climates.

3. CREATE COURTYARDS AND ENCLOSED ATRIUMS

Semienclosed courtyards (in warm climates) and enclosed atriums (in temperate and cool climates) can be formed by groups of buildings to provide areas for planting, shading, water fountains, and other microclimatic benefits. Atriums can also be used as light courts and

ventilating shafts. Indoor or outdoor planted areas provide evaporative cooling for local breezes when located near buildings.

4. USE EARTH BERMS FOR CLIMATIC BUFFERING

Earth berms (sloped or terraced, formed simply by grading earth against the wall of a building) help to buffer the building against temperature extremes of both heat and cold. The planting on earth berms also provides evaporative cooling near the building. Earth berms can be construction cost savers because the foundation does not have to be as deep (in single-storied construction); the earth and ground cover is often less costly than other wall finishing materials. Its long-term maintenance can also be lower than conventional materials.

DAYLIGHTING

5. PLACE WINDOWS HIGH IN THE WALL OF EACH FLOOR

Windows placed high in the wall near the ceiling provide the most daylight for any given window area, permitting daylight to penetrate more deeply into the interior.

6. USE LIGHT SHELVES

Light shelves are horizontal projections placed on the outside and below a window to reflect sunlight into the interior. Typically placed just above eye level, the light shelf reflects daylight onto the interior ceiling, making it a light-reflecting surface (instead of a dark, shaded surface typical of a conventional interior ceiling). At the same time, the light shelf shades the lower portion of the window, reducing the amount of light near the window, which is typically overlit. The result is more balanced daylighting with less glare and contrast between light levels in the interior.

7. SIZE WINDOWS ACCORDING TO USE AND ORIENTATION

Because window glass has little or no resistance to heat flow, it is one of the primary sources of energy waste and discomfort. Window areas should be shaded against direct solar gain during overheated hours. Even when shaded, windows gain undesired heat when the outdoor temperature exceeds the human comfort limit. Window areas should therefore be kept to a reasonable minimum, justified by clearly defined needs for view, visual relief, ventilation, and/or daylighting. Double glazing should be considered for all windows for energy efficiency and comfort in cool and temperate climates. In warm climates, double, tinted, or reflective glass should be considered, depending upon building size and use.

8. USE SKYLIGHTING FOR DAYLIGHTING, WITH PROPER SOLAR CONTROLS

Skylighting that is properly sized and oriented is an efficient and cost-effective source of lighting. Consider that for most office buildings, sunlight is available for nearly the entire period of occupancy and that the lighting re-

quirement for interior lighting is only about 1% of the amount of light available outside. Electric lighting costs, peak demand charges, and work interruptions during power brownouts can be greatly reduced by using daylight. Cost-effective, energy-efficient skylights can be small, spaced widely, with "splayed" interior light wells that help reflect and diffuse the light. White-painted ceilings and walls further improve the efficiency of daylighting (by as much as 300% if compared with dark interior finishes). Skylights should include some means to control undesired solar gain by one or more of the following means: (a) Face the skylight to the polar orientation; (b) provide exterior light-reflecting shading; (c) provide movable sunshades on the inside, with a means to vent the heat above the shade.

ENERGY-EFFICIENT LIGHTING

9. USE TASK LIGHTING, WITH INDIVIDUAL CONTROLS

Lamps for task lighting are ideally located near the work surface and are adjustable to eliminate reflective glare. The energy-efficient advantages are that less light output is required (reduced geometrically as a function of its closer distance to the task) and the lamp can be switched off when not needed.

Note: General light levels should be reduced below conventional standards and sources of reflective glare from ceiling lights and windows eliminated in areas where cathode ray tubes (CRTs) are used.

10. USE THE CEILING AS A LIGHT-REFLECTIVE SURFACE

By using "uplights," either ceiling pendants or lamps mounted on partitions and/or cabinets, the ceiling surface can be used as a light reflector. This has several advantages: (a) fewer fixtures are required for general area ("ambient") lighting; (b) the light is indirect, eliminating the sources of visual discomfort due to glare and reflection, (c) if light shelves are used, the ceiling is the light reflector for both natural and artificial light, an advantage for the occupant's sense of visual order.

11. EMPLOY A VARIETY OF LIGHT LEVELS

In any given interior, a variety of light levels improves visual comfort. Light levels can be reduced in low-use areas, storage, circulation, and lounge areas. Daylighting can also be used to provide variety of lighting, thereby reducing monotone interiors.

12. PROVIDE SWITCHING CHOICES, TO ACCOMMODATE SCHEDULE AND DAYLIGHT AVAILABILITY

Areas near windows that can be naturally lit should have continuous dimming controls to dim lights that are not needed. Other areas should have separate switching to coincide with different schedules and uses. Consider occupant-sensing light switches in areas of occasional use, such as washrooms, storage, and warehouse areas.

Donald Watson, FAIA; Rensselaer Polytechnic Institute; Troy, New York

THERMAL CONSTRUCTION

13. USE ENERGY-EFFICIENT LIGHTS AND LUMINAIRES

Use the most efficient light source for the requirement: these might be fluorescent bulbs, high-intensity discharge lamps, or high-voltage/high-frequency lights. Compact fluorescent lights with high-efficiency ballasts have advantages of low wattage, low waste heat, long life, and good color rendering. Incandescent lights use less energy when switched on, so these are appropriate for occasional use and short-term lighting. Luminaires should also be evaluated for how efficiently they diffuse, direct, or reflect the available light.

THERMAL CONSTRUCTION

14. PLACE INSULATION ON THE OUTSIDE OF THE STRUCTURE

Insulation is one of the most cost-effective means of energy conservation. Insulation placed on the outer face of a wall or roof protects the structure from the extremes of the outside temperature (with the added benefit of lengthening the life of the roof waterproofing membrane) and adds the massiveness of the structure to the thermal response of the interior (see Criteria 15). In localities where "resistance insulation" is not available, the combination of airspaces and high capacitance materials (such as masonry and/or earth berms) should be designed for effective thermal dampening or time lag (the delay and diffusion of outside temperature extremes that are transmitted to the interior). As an alternative to insulating roof structures in hot climates, a "radiant barrier" consisting of a continuous sheet of reflective foil with a low emissivity coating and an airspace around it serves as an effective shield against undesired heat gain.

15. UTILIZE THERMAL MASS ON BUILDING INTERIOR

In office buildings, thermally massive construction (such as masonry and concrete which have good heat storage capacity) benefits the energy-efficient operation of heating and cooling equipment as follows:

(a) Cooling benefits: Thermal mass absorbs the "overheating" that is inevitable in an office space due to the buildup of heat from people, equipment, lighting, rising afternoon temperature, and solar gain. The more thermal mass that is effectively exposed to an interior space (ceiling and walls), the greater is the saving on air conditioning in the afternoon, with the potential to delay the overheating until early evening when electric rates may be lower and/or outdoor air may be low enough to cool the mass by night ventilation. (The "night cooling" option is especially favorable in warm, dry climates due to predictably cooler nighttime temperatures.)

(b) Heating benefits: In temperate and cool climates, thermal mass helps absorb and store wintertime passive solar heat. This is especially effective if the thermal mass is on the building interior and directly heated by the sun (made possible by design of various corridor, stairway, and half-height partition arrangements).

ENERGY-EFFICIENT MECHANICAL SYSTEMS

16. USE LIGHT-CONSTRUCTED VENTILATED ROOFS IN HOT CLIMATES

In hot climates, the roof is the primary source of undesired heat gain. Energy-efficient roof designs should be considered. One of the best for hot climates is a ventilated double roof wherein the outside layer is a light-colored and lightweight material which shades the solar heat from the inner roof, which should be well insulated. As described in Strategy 14, a "radiant barrier" can be considered as an alternative to resistance insulation to serve as a shield against thermal transfer through the ceiling portion of the roof structure.

ENERGY-EFFICIENT MECHANICAL SYSTEMS

17. USE DECENTRALIZED AND MODULAR SYSTEMS

Heating and cooling equipment is most efficient when sized to the average load condition, not the "peak" or extreme condition. Use modular unit boilers, chillers, pumps, and fans in series so that the average operating load can be met by a few modules operating at peak efficiency rather than a single unit that is oversized for normal conditions. Zone the distribution systems to meet different loads due to orientation, use, and schedule. Use variable-air-volume (VAV) systems to reduce fan energy requirements and to lower duct sizes and costs (the system can be designed for the predominant load, not the sum of the peak loads). Decentralized air-handling systems have smaller trunk lines and duct losses. Dispersed air handlers, located close to their end use, can be reduced in size from conventional system sizes if hot and chilled water is piped to them (a decentralized air-handling system with a centralized plant).

18. USE ECONOMIZER/ENTHALPY CYCLE COOLING

Economizer/enthalpy cycle cooling uses outdoor air when it is cool enough for direct ventilation and/or when the outdoor air has a lower heat content than indoor air (so that it can be cooled evaporatively without raising indoor humidity). Although useful in all climates, direct or indirect evaporative cooling systems are especially effective in hot, dry climates.

19. USE ENERGY-EFFICIENT EQUIPMENT

The energy efficiency of mechanical equipment varies greatly. Consider heat pumps for cooling and for heating to replace separate chiller and boiler units. Heat pumps can also use local water sources or water storage (see Criteria 20 below). Newly developed mechanical heating equipment, such as gas-fired pulse combustion boilers, is achieving very high (up to 85%) annual operating efficiencies.

20. USE ENERGY STORAGE FOR COOLING

Chilled water storage has several advantages: It permits water chilling or ice-making at night under more favorable ambient conditions and possible lower electric rates;

SMART BUILDING CONTROLS

perhaps more important, it reduces or eliminates peak-hour energy consumption, thereby reducing demand charges.

21. USE HEAT RECOVERY FOR HEATING

In cool and temperate climates, heat can be recovered from warm zones of a building and recirculated to underheated areas. Recoverable heat sources include equipment, process heat, and passive solar gain. Heat recovery wheels or coils can be used where indoor air needs to be ventilated, transferring heat into the incoming fresh airstream. In all climates, process heat or active solar heat (e.g., from solar collectors) can be used for domestic hot water or for tempering incoming fresh air.

"SMART BUILDING" CONTROLS

22. USE SMART THERMOSTATS

"Duty-cycling" temperature controls can be programmed for different time schedules and thermal conditions, the simplest being the day-night setback. Newer controls are "predictive," sensing outdoor temperature trends and then selecting the system operation most appropriate to the condition.

23. USE OCCUPANCY- AND DAYLIGHT-SENSING LIGHTING CONTROLS

Automatic switching of lights according to the building occupant schedule and the daylight condition is recommended, with manual override for nighttime occupancy. Photosensors should be placed in areas that can be predictably lit by natural light.

24. BE PREPARED FOR RAPID INNOVATION IN BUILDING CONTROL SYSTEMS

Newly developing "smart" building systems include microprocessing for thermal and light control, fire and air-quality precautions, equipment failure, and operations/maintenance requirements (along with new communication and office management systems). These innovations require that electric wiring be easily changed, such as through "double-floor" construction.

ENERGY-EFFICIENT ATRIUM DESIGN

In its original meaning, an atrium was the open courtyard of a Roman house. Today an atrium is a glazed courtyard on the side of or within a building. If issues of heating, cooling, and lighting are ignored, atrium designs can add significantly to the energy cost of the building as well as require above-average energy to maintain comfort within them. On the other hand, energy-efficient atrium spaces can contribute savings through natural lighting, passive heating, and natural cooling strategies. (Any multistoried space raises concerns for fire safety and requires special attention.)

Atrium spaces are more responsive to the influence of the outside climate than conventional buildings, and their design therefore will follow local climate requirements. Design also will depend on the specific function and goals of the atrium: to supply daylighting for itself or to adjacent spaces; to provide comfort for sedentary human occupancy or plants; or to serve only as a semiconditioned space for circulation. The challenge of energy-efficient atrium design is to combine various and perhaps conflicting requirements for passive heating, natural cooling, and daylighting using the geometry of the atrium, its orientation, and solar and insulation controls at the glazing surfaces. These architectural choices need to be integrated with the mechanical engineering to assure that the passive energy opportunities will in fact effectively reduce building energy use.

PASSIVE SOLAR HEATING OPPORTUNITIES

Atriums designed with large glass areas overheat during the day, providing potentially recoverable heat to parts of the adjacent building, such as its outer perimeter, which can be transferred by air or by an air-to-water heat pump. In cool climates and in buildings with a predominant heat load (such as a residential or hotel structure), using this solar heat gain can be cost-effective. In such a case, vertical glass facing the south captures winter sun while incurring minimum summer heat gain liability. If the atrium space requires sedentary occupant comfort, heat storage within the space and energy-efficient glazing also are beneficial.

NATURAL COOLING OPPORTUNITIES

To reduce required cooling in an atrium, protection from the summer sun is essential. Natural cooling can be accomplished by glass orientation, protective coatings as part of the glazing, and shading devices, which may or may not be movable. In hot, sunny climates, relatively small amounts of glass can meet daylighting objectives while reducing the solar gain liability. In warm, humid climates with predominantly cloudy skies (the sky is nonetheless a source of undesirable heat gain), the north-facing orientation should be favored for large glazed areas. Mechanical ventilation should facilitate the upward flow of natural ventilation. Spot cooling by air conditioning lower atrium areas is a relatively efficient means of keeping some areas comfortable for occupancy without fully conditioning the entire volume of air.

DAYLIGHTING OPPORTUNITIES

An atrium with the predominant function to provide natural lighting takes its shape from the predominant sky condition. In cool, cloudy climates, the atrium cross-section ideally would be stepped outward as it gets higher in order to increase overhead lighting. In hot, sunny locations with clear sunny skies, the cross-section is like a large lighting fixture designed to reflect, diffuse, and make usable the light from above. Daylighting design is complicated by the movement of the sun as it changes position with respect to the building throughout the day and the year.

WINTERGARDEN ATRIUM DESIGN

Healthy greenery can be incorporated in atrium design. The designer needs to know the unique horticultural requirements for the plant species for lighting, heating, and cooling, which could be quite different from those for human occupancy. Generally, plants need higher light levels and cooler temperatures than might be comfortable for humans. The most efficient manner to keep plants heated is with plant bed or root heating, as with water tubes or air tubes in gravel or earth. Plants also benefit from gentle air movement, which reduces excessive moisture that might rot the plants and circulates CO₂ needed for growth.

RELATIVE IMPORTANCE OF DESIGN PRINCIPLES IN VARIOUS CLIMATES

ATRIUM ENERGY-DESIGN PRINCIPLE	COLD/CLOUDY SEATTLE CHICAGO MINNEAPOLIS	COOL/SUNNY DENVER ST. LOUIS BOSTON	WARM/DRY LOS ANGELES PHOENIX MIDLAND, TX	HOT/WET HOUSTON NEW ORLEANS MIAMI
HEATING				
H1 To maximize winter solar heat gain, orient the atrium aperture to the south.	●	■	△	
H2 For radiant heat storage and distribution, place interior masonry directly in the path of the winter sun.		■	●	
H3 To prevent excessive nighttime heat loss, consider an insulating system for the glazing.	●	■		
H4 To recover heat, place a return air duct high in the space, directly in the sun.	■	●	△	
COOLING				
C1 To minimize solar gain, provide shade from the summer sun.		■	■	●
C2 Use the atrium as an air plenum in the mechanical system of the building.	■	■	■	■
C3 To facilitate natural ventilation, create a vertical "chimney" effect with high outlets and low inlets.	■	■	■	●
LIGHTING				
L1 To maximize daylight, use a stepped section (in predominantly cloudy areas)	■	△	■	■

INTRODUCTION

This page concerns thermal storage applications for heating and cooling buildings and heating domestic or service water. Nearly 80% of the energy used in buildings is for these purposes. The discussion here focuses on thermal storage in materials that are not an integral part of the building structure.

LIMITED CAPACITY HEATING/COOLING DEVICE

This includes applications where the momentary demand for heating/cooling exceeds the capacity of the heating/cooling device. In such cases thermal storage is used in conjunction with limited capacity heating/cooling equipment to meet peak demand.

LOW-COST ENERGY

The availability of low-cost energy often does not coincide with the need. Thermal storage can be charged with low-cost energy when it is available and discharged when the stored energy is needed later. A conventional heating or cooling appliance may be used to augment stored energy. Waste heat from refrigeration equipment may be useful for heating service water. Because the demand for hot water may not coincide with the availability of waste heat, waste heat storage is required.

APPLICATIONS

Limited capacity appliance: The most widespread application of thermal storage is probably that of storage-type electric resistance water heaters. A tank of water is heated by an electric resistance element that is not of sufficient capacity to heat the water during peak demand for hot water. However, enough hot water is stored so that when the peak demand occurs, there is sufficient hot water stored to satisfy demand.

By using thermal storage in conjunction with a smaller air-conditioning unit than would normally be used to handle a given cooling load, a substantial savings in operating costs can often be realized. The savings comes primarily from operating the unit at night. The lower heat rejection temperature at night means that the compressor does less work even though it accomplishes the same amount of cooling. Since the need for cooling is usually greatest during the day, the coolness generated at night must be stored for use during the day. Chilled water storage, ice reservoirs, and phase change materials are being used increasingly in buildings for coolness storage.

Off-peak power: Storage of warmth generated by off-peak power can effectively reduce operating costs. Off-peak power is often available from electric utility companies at a significantly lower cost than normal electric power. Energy storage is essential for the customer to satisfy their needs throughout the day when off-peak power is not available and yet realize the savings resulting from use of off-peak power. Off-peak rates are widely available for domestic water heating and to a lesser degree for space heating and air conditioning.

Waste heat: Without thermal storage, use of waste heat may not be feasible because waste heat is often not available when heating is needed. Heat that is normally dumped to the atmosphere from refrigeration condensers can be used to heat buildings and service water. A rapidly growing approach to waste heat recovery is the use of a heat exchanger in the refrigerant line leaving the compressor of an air conditioner.

The envelope and structure of many buildings are of sufficiently low mass that the amount of heat that can be stored in those components is so small as to be not worth the trouble. A wood-frame building is an example of a low-mass structure. A thermal storage chamber could be installed in the building to store coolness during the summer and to store heat during the winter. The chamber could be cooled during the summer by nighttime ventilation, by evaporative cooling, or by the nighttime operation of mechanical cooling equipment. During the winter the storage chamber could be heated by passive gain to the building.

Active solar heat storage: Thermal storage is usually an essential part of solar water and space heating systems. Solar heat is collected and stored during the day and released at night as needed. Commercial applications are similar.

PRINCIPAL DESIGN CONCERNS

Quality of thermal energy to be stored: Energy to be stored must be available at a temperature level sufficient for it to be useful when needed.

Suitability of storage media: Certain thermal storage materials are more appropriate than others for a given thermal storage task. For example, a phase change material (PCM) with a phase change temperature of 150°F would be inappropriate for passive solar heating/cooling because the temperatures available for storage are not that high.

Encouraging thermal gradients in the storage media: A heat source that has a much higher temperature than the heat storage media will give up its heat to that storage much more readily than will a heat source that is close to the temperature of the storage media. A similar effect occurs with storage of coolness. The greater the temperature difference between the stored energy and that needed to satisfy the load, the less energy must be expended to satisfy the load.

Interface with auxiliary heating/cooling system: It is usually not cost-effective to size a thermal storage system to handle the entire load under all conditions. Some type of auxiliary system is therefore necessary to supplement the storage system. The two systems should be configured so that the thermal storage can be drawn upon first to satisfy the entire load. Once the quality of energy in the thermal storage has been depleted to the point that it is no longer practical to use alone, then the auxiliary system can be used to augment the flow of heat from the storage media. If the thermal storage is entirely depleted, then the auxiliary system can assume the entire load.

When both thermal energy generated at off-peak rates and heat such as solar energy are to be stored, the solar heat storage should be separated from heat produced by off-peak power. If they are not separated, the electric heaters, commonly used for off-peak storage, can heat the stored energy to a temperature level above which the solar collectors would collect little useful heat.

In instances where the cost of conventional energy does not vary with the time of day, the storage and auxiliary systems should be controlled so that the relatively inexpensive stored energy is consumed before the more expensive conventional fuel. This may not be the best practice where the cost of the conventional fuel varies with the time of day.

Duration of thermal storage: The duration over which warmth or coolness is stored is an important factor. At present, thermal storage is most often used in applications of several hours' to several days' duration.

Choice of heat transfer fluid: All other factors being equal, less energy is needed to transport the same amount of heat in a system using a liquid such as water than in a system using air; that is, the pumping energy used to move water is a fraction of the fan energy needed to move the same amount of heat with air. Often factors other than pumping costs will determine the fluid to be used.

CHARACTERISTICS OF HEAT STORAGE MATERIALS

Thermal storage materials may be separated into sensible heat storage materials and phase change materials. Sensible heat storage materials such as water and rock change temperature as heat is added or removed, but they do not change in physical state. Phase change materials also change in temperature as heat is added or removed over a portion of their heating/cooling cycle, but at the temperature at which they change phase, heat can be added or removed without a change in temperature.

SENSIBLE HEAT STORAGE MATERIALS

Both water and rock are commonly used sensible heat storage materials. Water may be contained by a tank, an aquifer, a cavern or mine, or a pond. Rock is most frequently used in pebble form. Heat is added to or removed from the water while it is in liquid form and added to or removed from rock in solid form. In some types of sys-

tems the same water used to store heat can also be used as the heat transfer fluid. This precludes the cost and inefficiency inherent with heat exchangers. Where water is used for thermal storage, thermal gradients can be encouraged by the choice and location of supply and return openings to the tank, by use of a diffuser to minimize mixing of fluid entering the tank, and by use of diaphragms, baffles, segmented tanks, or multiple tanks. Containers having a high ratio of height to diameter are also useful for encouraging stratification.

Water has a higher heat capacity than pebbles; thus the volume of water needed to store a given quantity of heat is about one-third of the volume of pebbles needed.

When air is the heat transfer fluid used to charge and discharge a pebble bed, no heat exchanger is required.

Where pebbles are used for thermal storage, temperature gradients can be developed easily and preserved by charging the bed with air moving through in one direction and discharging it with air moving through in the opposite direction. An alternative approach involves charging and discharging the bed with flow in one direction only. One-way flow significantly lessens the quality of heat available from the pebble bed and results in a considerable lag before recently added heat is available from the bed.

PHASE CHANGE MATERIALS

Water is often used as a thermal storage medium for cooling buildings. If water is cooled to the freezing point, it changes phase and becomes ice. Once the water reaches its freezing point, then heat must be removed from the water until it has solidified before it can drop further in temperature.

Materials other than water exist which change phase at temperatures suitable for a variety of thermal storage applications. A given PCM can be selected because it has a phase change temperature that is suited for the temperature of the heat available to be stored and for the load.

As a PCM passes through its phase change point, it can absorb a great deal of heat. A PCM continues to absorb heat at a constant temperature until it has completely changed phase. Primarily due to their high heat capacity at the phase change temperature, PCMs store much more heat than can water or pebbles in the same volume. Thus, a phase change system takes up far less space in a building than does a sensible heat storage container to store the same quantity of useful heat.

The efficiency of a solar collector depends on the temperature difference between the collector and the surrounding air. The lower the temperature at which the collector must operate, the higher its efficiency. If a sensible heat storage medium is uniform in temperature because efforts were not made to encourage stratification, then the collectors will not operate as efficiently as they would if they were connected to a stratified storage. Since a PCM can absorb heat for a long time at the phase change point, a solar collector delivering heat to a PCM can often operate more efficiently than it would if it were delivering heat to a sensible heat storage container at a uniform temperature.

SYSTEM SIZING

The variation of the load over time must be known or estimated. The temperature level of the energy needed to satisfy the load must be known. An estimate must be made of the amount of heat available for storage and of the temperature level of that heat.

A number of computer programs exist that can be used to estimate the heating and cooling load of residential and small commercial buildings. Several such programs are EEDO, CALPASS, SLR, and FLOAD. For large buildings the most well-documented, verified, and maintained computer program for building energy requirement estimating is DOE2.1c. The program has a separate thermal storage module that can be used for thermal storage studies.

ENERGY ANALYSIS

An energy analysis can be accomplished by a variety of techniques: manual, graphic, calculator, microcomputer, and mainframe computer. The purpose of energy analysis is to evaluate mathematically the energy required to maintain the interior environment of proposed or existing buildings and their support systems. When estimating energy needs of a proposed or existing building, it is necessary to account for the energy use in each of the following categories:

1. Offsetting heat losses through the building envelope (heating).
2. Offsetting heat gains through the building envelope (cooling).
3. Heating or cooling ventilation air.
4. Offsetting or using heat gain from occupants, lights, and process loads.
5. Offsetting or using solar gain.
6. Energy required for lights and miscellaneous use.
7. Motor loads for air movement and energy transfer.
8. Heating domestic hot water.
9. Energy used to reheat and recool.
10. Energy for humidification and dehumidification.
11. Energy for vertical, horizontal movement of people.
12. Miscellaneous—convenience outlets, etc.
13. Food service.

With the wide range of energy analysis tools available, it is important to select the appropriate tool for each design stage. Less sophistication is needed in the early design stages than in the final stages. To obtain maximum benefit from energy analysis, the process should start in the early schematic design stages. Following is a possible energy analysis sequence.

SCHEMATIC DESIGN PHASE

Calculated manually, graphically, or with simple computer programs, analysis in the schematic design phase should take into consideration building orientation and solar and daylighting impact on the energy required for heating, cooling, and lighting. The ideal analysis tool is a micro-computer program that permits the designer to incorporate more and more data about the building as the design progresses, without reentering previous data. Results of the schematic analysis should guide the designer in deciding on orientation, massing, and building configuration. The decision made in these early studies will have a major impact on optimum energy use in the final design.

DESIGN DEVELOPMENT PHASE

As design decisions become final and construction materials are selected, the energy analysis should be upgraded. The analysis procedure should allow adjustments for daylighting and building mass. Operating, occupancy, lighting, and motor profiles should be accommodated. Also to be considered are mechanical equipment responses and ventilation loads. As a minimum, the analysis procedure should include a variable base degree hour or bin factor for weather data.

CONSTRUCTION DOCUMENT PHASE

As the construction documents near completion, a more sophisticated analysis can be made. An hour-by-hour analysis can be made by a mainframe computer. The mechanical equipment can be modeled as it would respond to the hourly heating and cooling loads. Thus, energy wasted by mechanical systems is accounted for. Profiles of building operation, occupancy, lighting, etc. are adjusted to the final design, and the energy needs projection is close to that of the final building.

Energy analysis for existing buildings being modified or recycled can be done by any of the above procedures that track building operation, occupancy, lighting, ventilation, and motor profiles. This can be done by mainframe computers on an hour-by-hour analysis or by microcomputers using programs with a variable base degree hour or bin method of processing weather data. Existing buildings are easier to analyze than new buildings because operational profiles are known.

For an energy analysis to provide maximum benefit to the designer, the building's annual energy use should be broken down as in the example at right. As modifications are made, projected increase or decrease percentages should be shown.

EXAMPLE OF TOTAL ANNUAL ENERGY USE BY FUEL TYPE	ENERGY USE PER YEAR	PERCENT OF TOTAL	REDUCTION IN ENERGY USE	PERCENT OF REDUCTION
ELECTRICITY (In kilowatt hours)				
Cooling	42,424 KWH	(16.3%)	-16,753 KWH	(28.3%)
Lighting	150,573 KWH	(58.0%)		
Motor operation	58,829 KWH	(22.7%)	-21,598 KWH	(26.9%)

PASSIVE SOLAR DESIGN

Passive solar heating and cooling systems, which rely on natural energy flow through and around a building, are divided into three generic categories, including:

1. **DIRECT SYSTEMS:** Heat is collected directly within the space or, for cooling, lost or dissipated directly from the space.
2. **INDIRECT SYSTEMS:** Heat gain or loss occurs at the weatherskin.
3. **ISOLATED SYSTEMS:** Heat gain or loss occurs away from the weatherskin. Cooling, for example, can include induced air precooled from the earth's mass using air to earth heat exchangers ("coolth" tubes) or cooling ponds. Systems can be combined depending on thermal needs.

SPACE HEATING CONCEPTS

As part of any passive system's development, energy conservation elements should be considered. With passive solar heating, minimizing and preventing heat loss is fundamental to ensure that the heating system is most effective. These elements include adequate insulation, building orientation, surface-to volume ratios, and appropriate materials, texture, and finish choices. The space heating success depends on adequate solar energy collection, storage, distribution, and control, all of which occur by natural, nonchemical means using the three basic heat transfer processes: conduction, convection, and radiation. Efficient passive system operation often involves some user control to alter or override energy flows within a building or at its weatherskin.

1. Solar collection surfaces generally are transparent or translucent plastics, fiberglass, or glass oriented in a southerly direction. Material degradation can be caused by solar exposure and other weather elements. Insulating these collection areas to control nighttime loss is especially important in extreme climates.
2. Thermal storage materials include concrete, brick, sand, tile, stone, and water or other liquids. Phase change materials such as eutectic salts and paraffins also are feasible. Storage should be placed to receive maximum solar exposure, either directly or indirectly. Adequate thermal storage capacity allows the sun's heat to be absorbed and retained until it is needed, and it helps to reduce internal temperature fluctuations.
3. Heat distribution occurs naturally by conduction, convection, and radiation. Generally, fans and other mechanical energy distribution equipment are avoided; however, sometimes they are required for fine-tuned operations.
4. Control mechanisms such as vents, dampers, movable insulation, and shading devices can assist in balanced heat distribution.

SPACE COOLING CONCEPTS

Passive solar cooling, like passive heating, tempers interior space temperatures using natural thermal phenomena. A structure designed for natural cooling should incorporate features that reduce external heat gains and dissipate internal heat gains, including adequate insulation, overhangs, shading, orientation, surface color and texture, proper ventilation, and similar factors. When possible, external heat gain should be controlled before it reaches or penetrates the weatherskin.

When cooling is necessary, heat dissipation is accomplished by cooling interior thermal mass, air, or both with conduction, convection, and radiation. Evaporation in hot arid regions and dehumidification in hot humid regions are primary cooling design concerns. Many passive cooling concepts and methods exist:

1. **Site cooling:** through vegetative control, water bodies, and adjacent land forms and materials.
2. **Earth cooling:** by using groundwater or the earth's mass with earth sheltering or "coolth" tubes.
3. **Radiative cooling:** heat loss to the sky or cooler objects.
4. **Ventilative cooling:** cross ventilation through spaces, double roofs, attics, or walls, induced or forced ventilation by pressure or temperature differences.
5. **Vapor cooling:** evaporative cooling to remove sensible heat, dehumidification to remove latent heat.
6. **Flywheel cooling:** cooling by internal thermal mass or rockbeds.

PASSIVE SOLAR TYPES

		HEATING	COOLING
DIRECT SYSTEMS	DIRECT GAIN/LOSS Direct gain is the most common passive solar building approach; most structures use it to some degree. Collection and storage are integral with the space. Southerly oriented glazing (collector) admits winter solar radiation to the space beyond. Thermal storage, incorporated within the building structure, absorbs solar energy. During the cooling season, windows, walls, and roofs can be operable or openable for natural or induced ventilation, cooling both the mass and space.		
	THERMAL STORAGE WALL — MASS WALL Thermal storage walls are based on a "sun to mass to space" concept. Collection and storage are separated from the space, but linked thermally. Energy is transferred by conduction through the wall, then by radiation to the space. A mass wall can be vented during the day, if warranted, to the interior by a convective heat flow. (If vents are used, then the mass wall is often referred to as a Trombe wall.) In the mass wall system, storage usually is in masonry or concrete directly behind the south glazing. Mass walls should be vented to the exterior and shaded during summer months.		
INDIRECT SYSTEMS	THERMAL STORAGE WALL — WATER WALL Water wall systems use a liquid, often held in barrels or tubes directly behind south-facing glass acting as the thermal storage medium. Solar radiation is absorbed by the contained water. This energy is released gradually as needed to the interior. Potential water problems are corrosion and bacteria and algae growth. A water wall should be shaded or vented to the exterior during cooling periods. Provide freeze protection where required.		
	ROOF POND In a roof pond system the liquid storage mass is in the ceiling or roof. During heating seasons, insulation panels are moved to expose the storage mass to the sun in the day. Energy is absorbed by the roof pond. At night the panels are replaced over the storage, allowing stored heat to radiate to the building's interior. The process is reversed in summer. The roof pond, insulated from the high summer sun during the day, absorbs the building's internal heat. At night the insulation is opened to allow stored heat to radiate to the sky.		
ISOLATED SYSTEMS	SUNSPACE In sunspace designs, solar collection and primary thermal storage often are isolated from living spaces, although variations are possible. The solar system functions independently of the building interior, although heat can be drawn from the sunspace as needed. (Thermal storage in the living area is classed as an indirect system.) Even on clear winter days sunspaces may overheat sometimes because of large glazed areas. For cooling, the sunspace can be used to induce a convective flow from the exterior, and should be shaded, preferably on the exterior.		
	THERMOSIPHON Thermosiphon, natural convection systems, rely on the rise and fall of heated and cooled elements such as air. As temperatures change, air moves without mechanical assistance. When the sun warms a collector surface, warm air rises. Simultaneously cooler air is pulled from the storage bottom, causing a natural convection loop. Heat is convected into the space or stored in the thermal mass until needed. In cooling seasons, collectors may be used as a thermal chimney. Warm air rises, inducing precooled air from the ground or other source up through the storage mass to cool it.

PASSIVE SOLAR HEATING—DESIGN PROCEDURE

The focus of this section is on winter heating between U.S. latitudes 32°N and 48°N. The following design and calculation procedure is applicable to

1. Building types that have space heating requirements dominated by heat loss through the exterior skin of the building.
2. Buildings with a small internal heat contribution from lights, people, and equipment such as residences, small commercial, industrial, and institutional buildings, and large daylight buildings whose internal heat gain is only a small portion of their total heating requirement.

Passive solar heating systems are integral to building design. The concepts relating to system operation must be applied at the earliest stages of design decision making.

Passive systems demand a skillful integration of all the architectural elements within each space—glazing, walls, floor, roof, and in some cases even interior surface colors. The way in which the glazing and thermal mass (heat storage materials, i.e., masonry, water) are designed generally determines the efficiency and level of thermal comfort provided by the system. Two concepts are critical to understanding the thermal performance of passively heated space. They are

1. That the quantity of south glazing, insulating properties of the space, and the outdoor climatic conditions will determine the number of degrees the

average indoor temperature in a space is above the average outdoor temperature on any given day (ΔT).

2. That the size, distribution, material, and in some cases (direct gain systems) surface color of thermal mass in the space will determine the daily fluctuation above and below the average indoor temperature (see Figure 1).

Calculating heat gain and loss is a relatively straightforward procedure. The storage and control of heat in a passively heated space, however, is the major problem confronting most designers. In the process of storing and releasing heat, thermal mass in a space will fluctuate in temperature, yet the object of the heating system is to maintain a relatively constant interior temperature. For each system, the integration of thermal mass in a space will determine the fluctuation of indoor temperature over the day.

EXAMPLE

In a direct gain system, with masonry thermal mass, the major determinant of fluctuations of indoor air temperature is the amount of exposed surface area of masonry in the space; in a thermal storage wall system, it is the thickness of the material used to construct the wall. The following is a procedure for sizing both direct gain and thermal storage wall systems.

FIGURE 1
DAILY TEMPERATURE FLUCTUATION

DIRECT GAIN

Direct gain systems are characterized by daily fluctuations of indoor temperatures, which range from only 10°F to as much as 30°F. The heating system cannot be turned on or off, since there is little control of natural heat flows in the space. To prevent overheating, shading devices are used to reduce solar gain, or excess heat is vented by opening windows or activating an exhaust fan.

The major glass areas (collector) of each space must be oriented to the south ($\pm 30^\circ$) for maximum solar heat gain in winter. These windows can serve other functions as well, such as openings for light and for views.

Each space must also contain enough mass for the storage of solar heat gain. This implies masonry in the building, but the masonry can be as thin as 4 in. in cold climates and 1½–2 in. in very mild climates.

SOUTH GLAZING: One criterion for a well-designed space is that it gains enough solar energy, on an average sunny day in winter, to maintain an average space temperature of $\pm 68^\circ\text{F}$ over the 24-hr period. By establishing this criterion, it is possible to develop ratios for the preliminary sizing of south glazing. Table 1 (see next page) lists ratios for various climates and locations.

In a direct gain system, sunlight can also be admitted into a space through clerestories and skylights as well as vertical south-facing windows. This approach may be taken (1) for privacy, (2) because of shading on the south

facades, (3) because spaces are located along facades other than south, and (4) to avoid direct sunlight on people and furniture. Use the following guidelines when designing clerestories and skylights:

1. **CLERESTORY:** Locate the clerestory at a distance in front of interior mass wall of roughly 1 to 1.5 times the height of the clerestory above the finished floor. Make the ceiling of the clerestory a light color to reflect and diffuse sunlight down into the space. In regions with heavy snowfall, locate the sill of the clerestory glazing 18 in. or more above the roof surface (see Figure 2, next page).
2. **SAWTOOTH CLERESTORIES:** Make the angle (as measured from horizontal) equal to or smaller than the altitude of the sun at noon on December 21, the winter solstice. Make the underside of the clerestories a light color (see Figure 3, next page).
3. **SKYLIGHT:** Use a south-facing or horizontal skylight with a reflector to increase solar gain in winter, and shade both horizontal and south-facing skylights in summer to prevent excessive solar gain (see Figure 4, next page).

THERMAL STORAGE MASS: The two most common materials used for storing heat are masonry and water. Masonry materials transfer heat from their surface to the interior at a slow rate. If direct sunlight is applied to the surface of a dark masonry material for an extended period of time, it will become uncomfortably hot, thereby

giving much of its heat to the air in the space rather than heat conducting it away from the surface for storage. This results in daytime overheating and large daily temperature fluctuations in the space. To reduce fluctuations, direct sunlight should be spread over a large surface area of masonry. To accomplish this:

1. Construct interior walls and floors of masonry at least 4 in. in thickness.
2. Diffuse direct sunlight over the surface area of the masonry either by using a translucent glazing material—placing a number of small windows so that they admit sunlight in patches—or by reflecting direct sunlight off a light-colored interior surface first (see Figure 5, next page).
3. Use the following guidelines for selecting interior surface color and finishes:
 - a. Masonry floors of a medium to dark color.
 - b. Masonry walls of any color.
 - c. Lightweight construction (little thermal mass) of a light color to reflect sunlight onto masonry surfaces.
 - d. No wall-to-wall carpeting over masonry floors.

By following these recommendations, one can control temperature fluctuations in the space on clear winter days to approximately 10°–15°F. These temperature fluctuations are for clear winter days and for at least 6 sq ft of exposed masonry surface area for each square foot of south glazing.

THERMAL STORAGE WALLS

The predominant architectural expression of a thermal storage wall building is south-facing glass. The glass functions as a collecting surface only and admits no natural light into the space. However, windows can be included in the wall to admit natural light and direct heat and to permit a view.

Either water or masonry can be used for a thermal storage wall (a masonry thermal storage wall with thermocirculation vents is often referred to as a Trombe wall). Since the mass is concentrated along the south face of the building, there is no limit to the choice of construction materials and interior finishes in the remainder of the building.

SOUTH GLAZING: The criterion for a double-glazed thermal storage wall is the same as for a direct gain sys-

tem—that it transmit enough heat on an average sunny winter day to supply a space with all its heating needs for that day. Tables 1 and 2 (see next page) list guidelines for sizing the glazing of masonry or water walls, respectively.

WALL DETAILS: While the procedure above gives guidelines for the overall size (surface area) of a thermal storage wall, the efficiency of the wall as a heating system depends mainly on its thickness, material, and surface color. (See Table 3, next page.) If the wall is too thin, the space will overheat during the day and be too cool in the evening; if it is too thick, it becomes inefficient as a heating source, since little energy is transmitted through it.

The choice of wall thickness, within the range given for each material in Table 3 (see next page), will determine the air temperature fluctuation in the space over the day. As a general rule, the greater the wall thickness, the smaller the indoor fluctuation. Table 4 (see next page) can be used to select a wall thickness.

The greater the absorption of solar energy at the exterior face of a thermal wall, the greater the quantity of incident energy transferred through the wall in the building. Therefore, make the outside face of the wall dark (preferably black) with a solar absorption of at least 85%.

45°F	0.12	0.23	0.13	0.26

- NOTES**
- 1. No convective connections to building.
 - 2. Temperatures listed are for December and January (usually the coldest months) and are monthly averages.
 - 3. Low heat loss: Space with a net load coefficient (NLC)
 - 4. High heat loss: Space with an NLC = 6 Btu/day/sq ft/°F. A space with a large amount of exposed external surface area.
 - 5. The NLC is the total building heat loss less the loss through the solar aperture.

TABLE 3. SUGGESTED MATERIAL THICKNESS FOR INDIRECT GAIN THERMAL STORAGE WALLS

MATERIAL	RECOMMENDED THICKNESS
Brick (common)	10 to 14 in.
Concrete (dense)	12 to 18 in.
Water	6 in. or more

NOTE: When using water in tubes, cylinders, or other types of circular containers, have a container of at least a 9 1/2 in. diameter or holding 1/2 cu ft (31 lb, 3.7 gal) of water for each one square foot of glazing.

TABLE 4. APPROXIMATE SPACE TEMPERATURE FLUCTUATIONS AS A FUNCTION OF INDIRECT GAIN THERMAL STORAGE WALL MATERIAL AND THICKNESS

MATERIALS	THICKNESS (IN.)					
	4	8	12	16	20	24
Brick (common)	—	24°	11°	7°	—	—
Concrete (dense)	—	28°	16°	10°	6°	5°
Water (31°F)	—	18°	13°	11°	10°	9°

NOTE: Assumes a double glazed thermal wall. If additional mass is located in the space, such as masonry walls and/or floors, then temperature fluctuations will be less than those listed. Values are given for clear winter days.

Edward Mazria, AIA, Architect; Edward Mazria & Associates; Albuquerque, New Mexico

PRINCIPLES

Thermal storage wall systems are solar space heating devices that can also be used for space cooling in some climates. They consist generally of south-facing massive walls, an airspace, and are then sealed to the exterior by a glass or plastic glazing system. As solar radiation is transmitted through the glazing material, the wall is heated during sunlit hours; in turn the heated wall then radiates warmth to the interior space during the night. Additional components can be added to enhance cold climate performance, such as selective surface foils, night insulation systems, reflectors, and exterior vents to control overheating in mild climates.

FIGURE 1

WALL PERFORMANCE

Figure 1 illustrates the characteristic performance of three thermal storage walls during one clear January day 24-hr cycle in a well-insulated house with 1/2 sq ft of wall for each square foot of room area, located in the U.S. Pacific Northwest. The two thicknesses of concrete wall shown in the graph demonstrate that by adding wall depth the resulting fluctuation in interior space temperature is reduced, and wall peak temperature is shifted toward the night hours when heat is most needed. Also it can be seen that by using a water wall with the same volume as the 12 in. concrete wall, the response of the wall to solar heating is enhanced; however, maximum heat transmission to the building interior occurs earlier in the evening when less heat is needed.

FIGURE 2

TEMPERATURE FLUCTUATION

Figure 2 illustrates space temperature fluctuations that can be expected for a one-day cycle using three different wall materials of varying thicknesses and the same design conditions as depicted in Figure 1. The wall types shown are solid brick, concrete or concrete masonry units grouted solid, and water.

WALL AREA VS. FLOOR AREA

Figure 3 gives rule of thumb guidelines for surface area of storage wall, using a wall thickness of between 8 and 18 in., compared to square feet of floor area to be heated for four latitudes. Example: Find the required wall area for a 250 sq ft room located at 40° north latitude with an average outdoor temperature of 34°F during the coldest winter month. On the "Y" axis find 34°, move right on the graph to the 40° latitude line, and then down the graph to the "X" axis, finding the wall vs. floor ratio of 0.45. Multiply 0.45 times the floor area of 250 sq ft, for a suggested wall area of 112.5 sq ft.

MASS WALL WITH OUTSIDE VENTING

MASS WALL WITH INSULATED CURTAIN

FIGURE 3

WATER WALLS

Thermal storage walls of the water container type are generally designed as an integral part of the heated space. Fiberglass, plastic, glass, or metal containers can be used; however, if steel is used, a rust inhibitor should be added to the water, and in all cases algicide should be added to prevent algae growth. Water containers are also manufactured that fit within wood-framed walls and appear as translucent windows from the interior or that can be covered with dry wall.

INTERNAL MASS

Mass thermal walls can also be used within rooms that are directly heated by solar radiation entering through windows (direct gain system), but where the wall is not directly illuminated by the sun. In this application the wall acts as a heat sink, absorbing excess spacial heat during sunlit hours and giving back heat during the night, reducing spacial temperature swings. As a rule of thumb, provide internal mass wall area at the rate of six times the direct gain window area.

COOLING

The use of thermal storage walls for cooling involves the isolation of the wall from the exterior and, in particular, solar radiation during the sunlit hours, then exposing the wall surfaces to air jets of cool night air either by forced or natural ventilation to reduce the wall's internal temperature. The wall then functions as a heat sink during the warm hours the following day, to absorb internal spacial heat, thereby maintaining comfortable indoor temperatures.

W. Fred Roberts Jr., AIA; Roberts & Kirchner Architects; Lexington, Virginia

SOLAR RADIANT ENERGY

Solar energy reaches the earth's surface in the form of electromagnetic radiation in the wavelength band between 0.3 and 3.0 micrometers (μm). Beyond the earth's atmosphere, at the average earth-sun distance (about 93 million miles) the radiant flux density on a surface normal to the solar rays is now thought to be 1377 W/sq m or 437 Btu/hr · sq ft. This quantity, known as the solar constant, is apparently subject to minor fluctuations caused by small changes in the sun's output of shortwave (ultraviolet) radiation. An earlier value, 1353 W/sq m or 429.2 Btu/hr · sq ft continues to be widely used pending further measurements from outer space.

At the surface of the earth, solar irradiance falling on horizontal surfaces varies from zero at sunrise to a maximum that, at sea level, may be as high as 325 Btu/hr · sq ft (945 W/sq m) at noon on a clear day. The intensity falls to zero again at sunset. Clear day irradiance values for horizontal and tilted surfaces with varying orientations are given in ASHRAE Publication GRP 170. Values for average day conditions can be found in "Hourly Solar Radiation Data for Vertical and Horizontal Surfaces on Average Days in the United States and Canada" published by the National Bureau of Standards in their Building Science Series 96. A wealth of data on horizontal irradiance is to be found in the "Climatic Atlas of the U.S." and in the publications of the National Weather Service, Asheville, NC. Methods of estimating direct, diffuse, and reflected radiation are given in Chapter 26, 1977 ASHRAE Handbook of Fundamentals.

SOLAR COLLECTION AND UTILIZATION

Solar radiant energy can be put to use at low and moderate temperatures by flat plate collectors, Figure 1, in which a blackened sheet of metal is used to absorb the incoming radiation and convert it to heat. This heat is then conducted to a fluid that passes through tubes or passages integral with or attached to the plate. To minimize loss of heat from the absorber plate, glazing (single or double, with glass or a heat resistant plastic) is used to reduce convection and to suppress longwave radiation exchange with the sky. The rear surface of the collector plate is insulated carefully, preferably with glass fiber that can withstand the relatively high temperatures (300 to 400°F) that can exist under "stagnation" conditions. This occurs when the collector is exposed to full sunshine with no heat transfer fluid flowing through it. The entire unit is contained within a weatherproof box, and connecting pipes or ducts are provided to bring the fluid to the collector and to carry it away after it has been heated. Details of many types of flat plate collectors are given in Chapter 58, 1978 ASHRAE Handbook of Applications. Performance calculations and test data are given in ASHRAE Publication GRP 170.

When high temperatures are required for industrial or power generation applications, concentrating collectors must be used. These reflect or refract a large amount to solar energy onto a relatively small absorber area, thus reducing the surface available for heat loss and enabling the fluid to attain temperatures that can exceed 1000°F. Such collectors must "track the sun" because they can use only the direct beam radiation from the solar disk. Some concentrating collectors remain essentially fixed, but these are limited to concentration ratios of less than 3 : 1.

SOLAR ENERGY UTILIZATION SYSTEMS

A system for using solar energy consists of an array of collectors, a storage subsystem, and another subsystem, which is generally quite conventional, for distributing the heated fluid and returning it to storage. Pumps or fans are used to circulate the heat transfer fluid, and control devices are used to start and stop the circulators. Auxiliary or standby heat sources are generally needed to carry part of the load when demand is exceptionally heavy and the thermal storage is depleted due to long periods of unfavorable weather.

Figure 2 shows a simple system for providing space heating and domestic hot water, using a drain-down procedure in which the collectors are emptied whenever the pump P1 stops. A differential controller senses the temperatures of the collector plate and the water and starts the circulating pump P1 when the sun has heated the plate above the water temperature. The pump is stopped when the plate temperature drops to

FIGURE 1. TYPICAL FLAT PLATE COLLECTOR

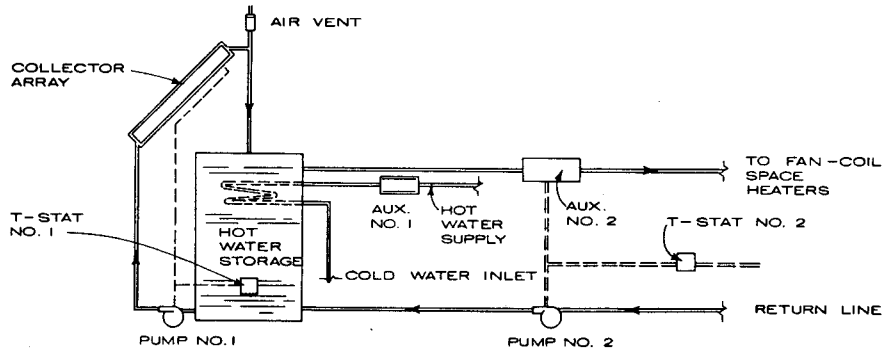

FIGURE 2. DRAIN-BACK SOLAR WATER SYSTEM

FIGURE 3. SOLAR WATER HEATING SYSTEM

the point where collection of heat is no longer possible.

Domestic hot water is provided by a pipe coil or a small tank located near the top of the main storage tank. The domestic hot water system operates under full line pressure whereas the main tank is at essentially atmospheric pressure, so any leakage would normally be into the main tank. Because of the very remote possibility of a back flow from the main tank into the city water supply, some plumbing codes require a double wall heat exchanger for this service. An auxiliary heater is provided to ensure an adequate supply of hot water at all times.

Since solar heat collection systems work more efficiently when the temperature difference between the collector and the ambient air is relatively low, fancoil units with large areas of finned tube heat transfer surface are generally selected for the space heating assignment. These can be used with water temperatures as low as 100°F. The auxiliary heat source in many solar installations will be electricity, and the heater may use simple direct resistance elements. When cooling is required as well as heating, a heat pump may

prove to be a wise choice, particularly when large amounts of auxiliary energy are likely to be needed.

FREEZE PROTECTION FOR LIQUID SYSTEMS

When water is used as the heat transfer fluid, freeze protection must always be provided, since there is no location within the continental United States where freezing has never been known to occur. The drain-down system shown in Figure 2 is a fail-safe method to provide such protection but it has certain disadvantages that, in many applications, make the use of a freezing point depressant advisable. Figure 3 shows a widely used system in which water plus ethylene glycol or propylene glycol, or some similar antifreeze fluid, is circulated through the collector array by pump P1. A double wall heat exchanger is used to transfer the collected heat to the service hot water which is under full line pressure, and a standby heater is provided to raise the temperature of the sun heated water to the conventional 140°F. Since domestic hot water is rarely actually used at 140°F, it is beneficial to use a lower thermostat setting for the hot water and to use less cold water for dilution.

AIR SYSTEMS

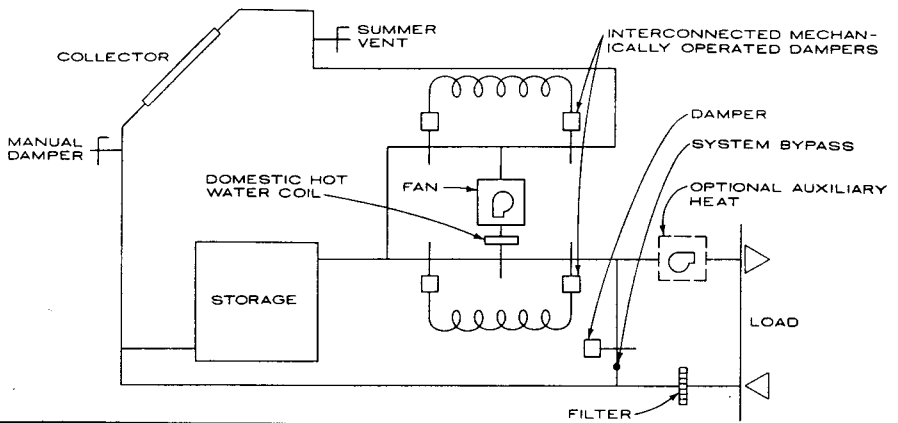

Air collectors carry serious limitations, primarily because the temperatures that they deliver are low and the space requirements for air ducts are high. Air collectors can be appropriate, however, for applications requiring low process heat or involving the regeneration of desiccant material for dehumidification.

The key issue in air system design is to minimize air leakage in areas where cold outside air is present—between collectors, for example, or in uninsulated chases. One effective installation approach entails mounting the collectors integrally with the roof and keeping all duct connections below the roof. Air collectors have also been mounted on flat roofs, at an angle, with housings erected to protect the back of the collector enclosures and their ductwork. Steps should always be taken to prevent exposure of collector connections and ductwork to the weather.

An air system's heat storage container should allow air moving to and from the container to circulate through the entire storage mass, without "short-circuiting." The container should be adequately insulated, and all joints—especially around the top—should be tightly sealed. Do not install a drain at the bottom of the container; it might provide access for animals, insects, or odors.

The system's fan and duct configuration must allow for the delivery of heated air directly from collectors to load, from collectors to storage, and, indirectly, from storage to load. This requires two pairs of interconnected dampers. Solar fan components that provide integral fan dampers and controllers are available. If a coil is to be used to heat water, it should be located beyond the fan to minimize any chance of its freezing.

These issues, reviewed here as a checklist for architects, have been thoroughly documented. Correction measures can be incorporated into the specification, manufacture, and installation of active solar collection systems.

AIR SYSTEM

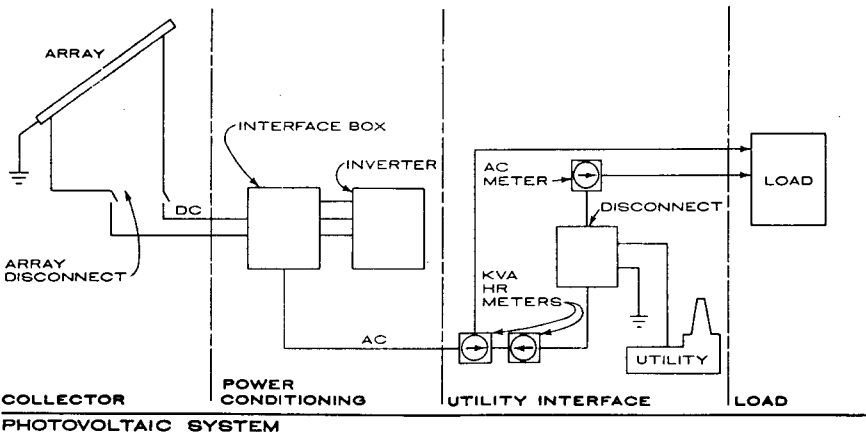

AIR SYSTEM MODES

PHOTOVOLTAIC CELL

PHOTOVOLTAIC MODULE

PHOTOVOLTAIC SYSTEM

PHOTOVOLTAIC SYSTEMS

Photovoltaic (PV) solar systems convert sunlight into direct current. Their rapidly decreasing cost may well make them competitive within the next decade with some sources of electricity. At present, however, the lack of cost-effective battery storage limits common PV system applications to the public utilities, which are uniquely capable of both supplying additional energy and purchasing excess energy.

The basic collection component of a PV system is the photovoltaic cell, a layered semiconductor that is generally fashioned from crystalline silicon. A group of cells, usually interconnected both in series and parallel, is encapsulated to form a module. An array is an assembly of modules.

The major factors considered in the sizing of a PV array are its anticipated loads and its power conditioning system (PCS) capacities. The design of an array depends on the module to be installed. Since no single module provides the commonly required voltage, several modules must be installed in series to achieve the proper voltage; groups of similar modules are then connected in parallel to provide the required amperage. The design of an array must facilitate this grouping of modules in series and parallel.

Modules can be installed in three ways: integrally (replacing the sheathing and roofing); applied (set directly on the sheathing, as roofing, or directly on the roofing itself); and standoff, or rack mounted (above the roof and either parallel or at an angle to it). The primary installation considerations are the tilt and orientation of the roof and the vent requirements of the module. The latter consideration can seriously affect system efficiency. Modules are adversely affected by heat, losing approximately ±0.003% efficiency for each degree Fahrenheit rise in temperature. Applied installations, therefore, are less efficient, because the modules are unable to discharge heat. Rack mounting, which allows air to circulate freely behind the modules, is often the most efficient installation technique. Some PV systems capture the heat discharged by the modules and supply it directly to interior spaces as heated air or exhaust it directly to the exterior; in these installations, the collectors are attached and ducted as they would be in an air collector system.

The major component of the PCS is the inverter, which converts the DC power generated by the array into AC power used by the load. The PCS also synchronizes the PV array's power output to make it compatible with the local utility company's output. The number of available PCS capacities is limited and is thus a controlling factor in the sizing of PV systems.

Stephen Weinstein, AIA; The Ehrenkrantz Group; New York, New York

The design of a solar collector array and its support structure can have an important influence on overall building appearance and be a key determinant of the total cost of the solar heating system. It is also the aspect of the system that the architect can most easily control.

Because there are no industry standards for collector size, piping, or mounting hardware, it is essential that the architect know which collector system will be installed before he or she begins final detailing and design. If the collector array is to be selected as part of a total bid package, for example, sizing and coordination problems may result, and the architect may lose control of the array's structural underpinnings and the building's overall appearance.

ANCHORING THE SUPPORT STRUCTURE

Rooftop collector supports should be anchored directly to structural members, not to wood or metal decking; otherwise, wind-induced uplift forces and point loading may cause roofing—and possibly structural—failure. In steel buildings, vertical supports must be secured directly to joists or beams. In wood buildings, securing the collector supports directly to structural members will normally require the installation of some form of blocking, under the decking and between rafters, to transfer the load.

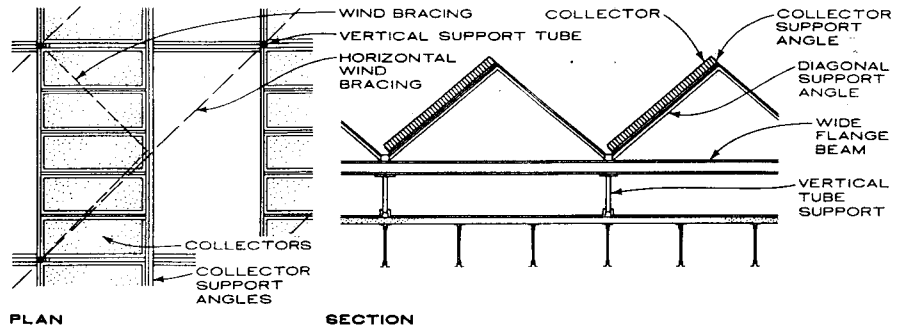

DESIGNING THE ARRAY

When a collector array is to be placed on a light steel-framed roof, the direction of the joints in the array's support structure becomes a critical design issue. It is often necessary to stagger the array's vertical supports to ensure an even distribution of the load. Some roofs cannot support such a load and thus must be clear-spanned. The array support structure in such cases is likely to be particularly expensive; intricate long-span space-frame structures are invariably costly and cost-ineffective.

AVOIDING ROOFING PROBLEMS

Leaky roofs are a persistent problem in solar installations. Problems can be anticipated and minimized by following these guidelines:

- Minimize roof penetrations. Collector supports constructed of pipe, if used in a large array as shown, require one roof penetration for every 60 sq ft of roof area, approximately; long-span design, by comparison, calls for one roof penetration roughly every 225 sq ft. Roof penetrations can also be avoided by using solar piping supports that rest directly on the roof, as shown; these prevent undue roof stress caused by pipe movement.
- Properly detail the flashing of vertical supports at the roofline. Except on pitched roofs (and often even then), wood-blocking bolted directly through the roof will ultimately generate leaks, regardless of the amount of roofing cement applied. The best approach is to use a neoprene roofing sleeve. The next best is base flashing and canopy detail. Less preferable is a pitch pocket, properly constructed. Other approaches—those using site-fabricated curbs and other techniques—tend to fail. If blocking is to be secured directly to a sloped roof, then roofing cement should be applied between each layer of shingles, between shingles and deck, and between shingles and blocking.

PIPE SUPPORT

SLOPED ROOF

- Do not create dams. Any form of continuous blocking or curb will—unless installed at a right angle to the slope of a pitched roof—invariably dam a portion of the roof and ultimately cause built-up roofing to fail.
- Specify that all work be performed by the appropriate trade. Support flashing, for instance, is often installed by the steel erector or the plumbing contractor rather than by the roofing contractor.
- Protect the roof. Specify that the roof in general be protected during construction and that permanent walkways be installed to provide access to the system once it is in use.
- Mount collectors on a sloped roof unless the pitch is so flat that the loss of year-round efficiency in performance will be too great. When collectors and

- sloped roof are parallel, allow a 1½ in. airspace between them to prevent deterioration of the roofing material and the collector enclosures. Do not mount collectors integrally with the roofing unless the collectors are specifically designed for integral mounting; as a rule, only air collectors are so designed. In cold regions, mount collectors as near the roof peak as possible to minimize damming and snow buildup and to lessen the chance of a dangerous snow slide—a particular threat when an array is located above an entry.
- On a flat roof, mount collectors between 2 ft 6 in. and 3 ft above the roof rather than directly on the roof. This prevents snow buildup, permits adequately sloped pipe runs, and—most important—allows for the installation of proper roof penetrations and for future roof repair and replacement.

Stephen Weinstein, AIA; The Ehrenkrantz Group; New York, New York

SHADING DEVICES

The effect of shading devices can be plotted in the same manner as the solar path was projected. The diagrams show which part of the sky vault will be obstructed by the devices and are projections of the surface covered on the sky vault as seen from an observation point at the center of the diagram. These projections also represent those parts of the sky vault from which no sunlight will reach the observation point; if the sun passes through such an area the observation point will be shaded.

SHADING MASKS

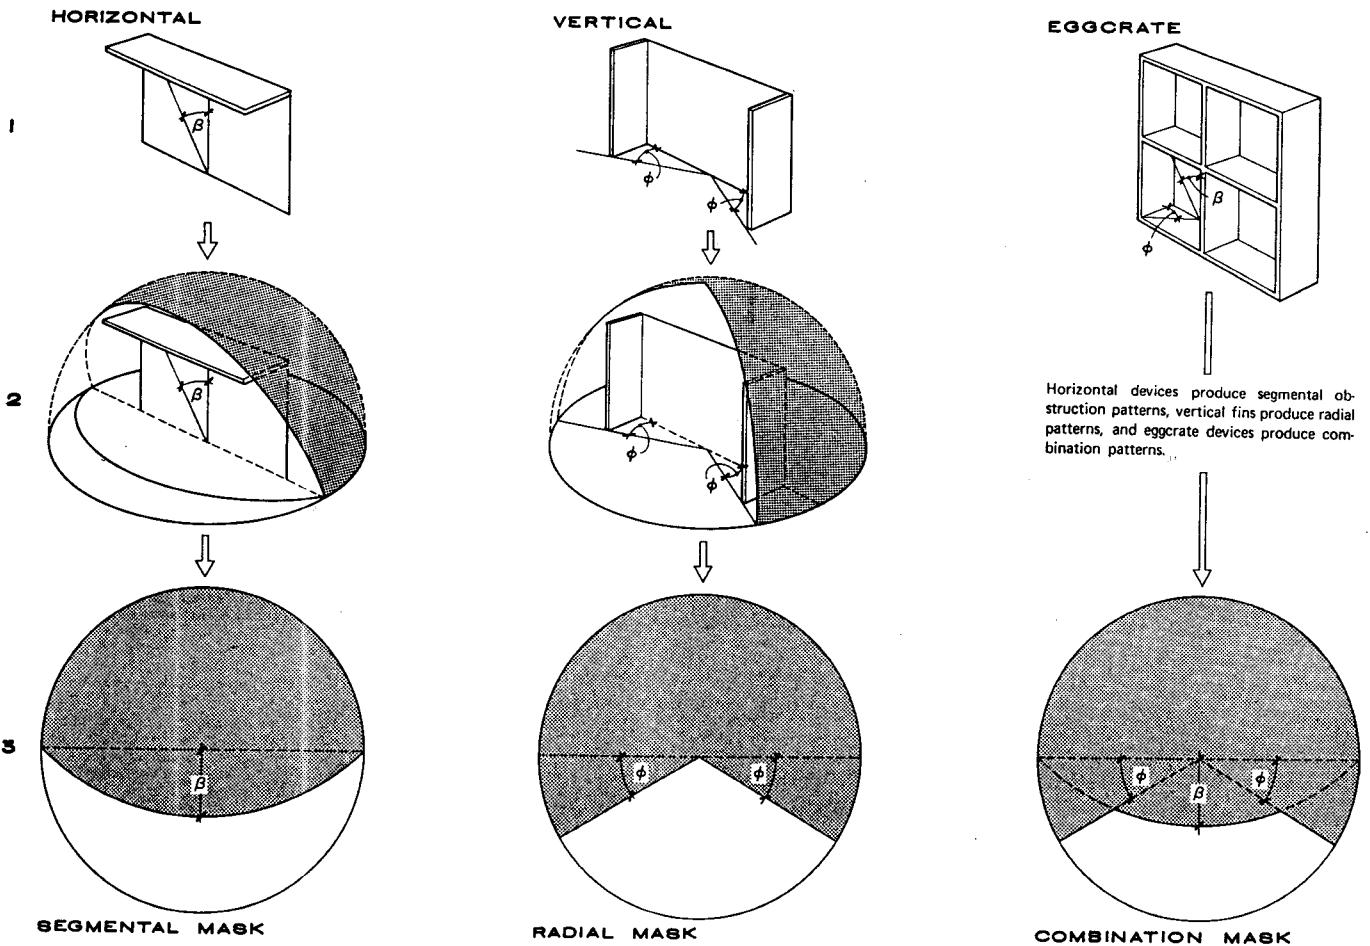

Any building element will define a characteristic form in these projection diagrams, known as "shading masks." Masks of horizontal devices (overhangs) will create a segmental pattern; vertical intercepting elements (fins) produce a radial pattern; shading devices with horizontal and vertical members (eggcrate type) will make a combinative pattern. A shading mask can be drawn for any shading device, even for very complex ones, by geometric plotting. As the shading masks are geometric projections they are independent of latitude and exposed directions, therefore they can be used in any location and at any orientation. By overlaying a shading mask in the proper orientation on the sun-path diagram, one can read off the times when the sun rays will be intercepted. Masks can be drawn for full shade (100% mask) when the observation point is at the lowest point of the surface needing shading; or for 50% shading when the observation point is placed at the halfway mark on the surface. It is customary to design a shading device in such a way that as soon as shading is needed on a surface the masking angle should exceed 50%. Solar calculations should be used to check the specific loads. Basic shading devices are shown below, with their obstruction effect on the sky vault and with their projected shading masks.

SHADING MASK PROTRACTOR

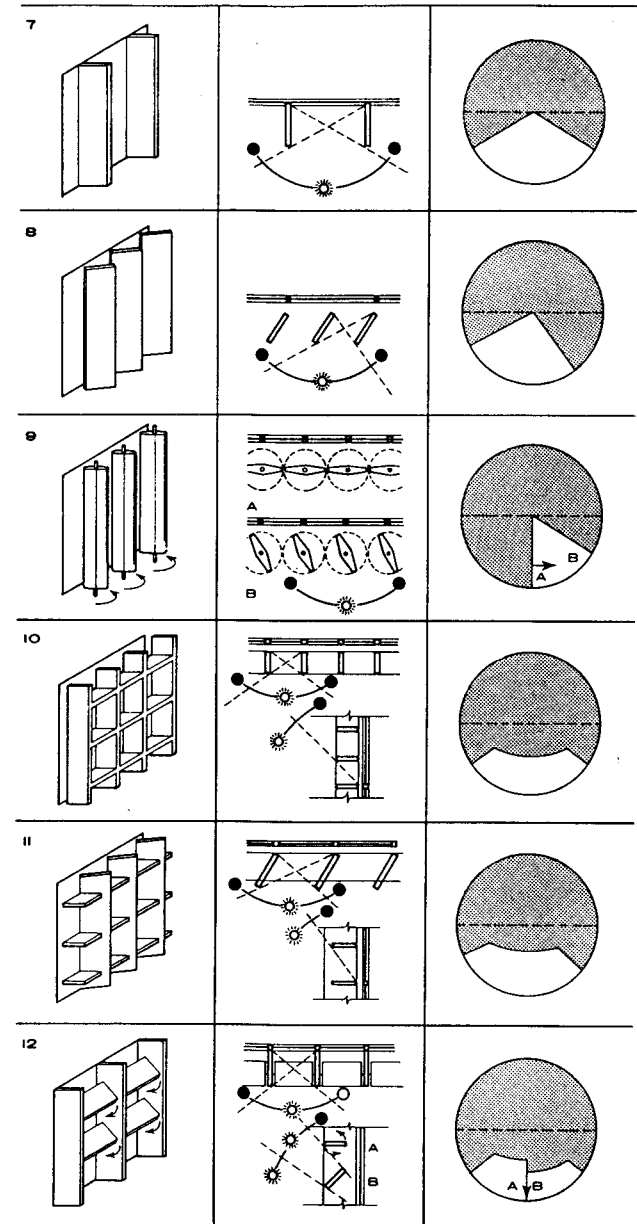

The half of the protractor showing segmental lines is used to plot lines parallel and normal to the observed vertical surface. The half showing bearing and altitude lines is used to plot shading masks of vertical fins or any other obstruction objects. The protractor is in the same projection and scale as the sun-path diagrams (see pages on solar angles); therefore it is useful to transfer the protractor to a transparent overlay to read the obstruction effect.

SHADING MASK PROTRACTOR

Victor Olgay, AIA; Princeton University; Princeton, New Jersey

EXAMPLES OF VARIOUS TYPES OF SHADING DEVICES

The illustrations show a number of basic types of devices, classified as horizontal, vertical, and eggcrate types. The dash lines shown in the section diagram in each case indicate the sun angle at the time of 100% shading. The shading mask for each device is also shown, the extent of 100% shading being indicated by the gray area.

General rules can be deduced for the types of shading devices to be used for different orientations. Southerly orientations call for shading devices with segmental mask characteristics, and horizontal devices work in these directions efficiently. For easterly and westerly orientations vertical devices serve well, having radial shading masks. If slanted, they should incline toward the north, to give more protection from the southern positions of the sun. The eggcrate type of shading device works well on walls facing southeast, and is particularly effective for southwest orientations. Because of this type's high shading ratio and low winter head admission; its best use is in hot climate regions. For north walls, fixed vertical devices are recommended; however, their use is needed only for large glass surfaces, or in hot regions. At low latitudes on both south and north exposures eggcrate devices work efficiently.

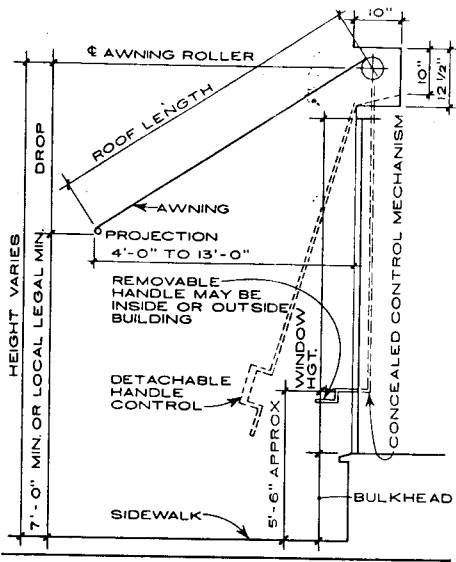

Whether the shading devices be fixed or movable, the same recommendations apply in respect to the different orientations. The movable types can be most efficiently utilized where the sun's altitude and bearing angles change rapidly: on the east, southeast, and especially, because of the afternoon heat, on the southwest and west.

HORIZONTAL TYPES 1. Horizontal overhangs are most efficient toward south, or around southern orientations. Their mask characteristics are segmental. 2. Louvers parallel to wall have the advantage of permitting air circulation near the elevation. Slanted louvers will have the same characteristics as solid overhangs, and can be made retractable. 4. When protection is needed for low sun angles, louvers hung from solid horizontal overhangs are efficient. 5. A solid, or perforated screen strip parallel to wall cuts out the lower rays of the sun. 6. Movable horizontal louvers change their segmental mask characteristics according to their positioning.

VERTICAL TYPES 7. Vertical fins serve well toward the near east and near west orientations. Their mask characteristics are radial. 8. Vertical fins oblique to wall will result in asymmetrical mask. Separation from wall will prevent heat transmission. 9. Movable fins can shade the whole wall, or open up in different directions according to the sun's position.

EGGCRATE TYPES 10. Eggcrate types are combinations of horizontal and vertical types, and their masks are superimposed diagrams of the two masks. 11. Solid eggcrate with slanting vertical fins results in asymmetrical mask. 12. Eggcrate device with movable horizontal elements shows flexible mask characteristics. Because of their high shading ratio, eggcrates are efficient in hot climates.

DIAGRAMMATIC SECTION RECESSED BOX INSTALLATION

AWNING MATERIALS :

1. Painted cotton duck
2. Vinyl-coated cotton duck
3. Vinyl-laminated polyester
4. Solution-dyed acrylic
5. Vinyl-coated polyester
6. Acrylic-coated polyester
7. Vinyl-coated polycotton
8. Solution-dyed modacrylic

AWNING OPERATORS:

1. Detachable handle control
2. Gear box & shaft (concealed or exposed) with removable handle inside or outside of building
3. Electric control

RETRACTABLE WINDOW AWNINGS: Retractable awnings are manufactured in widths from 10 to 50 ft. Pitch can vary from horizontal to 45 degrees.

NOTE

Rolling shutters provide sun control not only by shading windows from direct sun rays but also by way of two dead airspaces—one between shutter and window, the other within the shutter extrusions to serve as insulation. The dead airspaces work as well in winter to prevent the escape of heat from the interior. In addition, shutters are useful as privacy and security measures. They can be installed in new or existing construction and are manufactured in standard window sizes.

ROLLING SHUTTERS

Graham Davidson, Architect; Washington, D.C.

TERRACE OR ROOF AWNINGS

INTERMEDIATE BOW 3/4" DIA. HOOD BOW CURB BOW

CANOPIES - LOW CURVED BOW SHOWN

NOTE

External blinds protect the building interior from solar gain and glare, but can be raised partially or fully to the head when not needed. Manual or electric control is from inside the building.

EXTERNAL VENETIAN BLINDS

TERRACE OR ROOF AWNINGS

To provide complete sun protection and shade, the overall length of the awning bar should extend 3 in. past the glass line on both sides. For proper sunshade protection, awnings should project at least as far forward from the face of the window as the bottom of the window is below the front bar of the awning.

The wall measurement of an awning is the distance down the face of the building from the point where the awning attaches to the face of the building (or from the center of the roller in the case of the roller type awning).

The projection of an awning is the distance from the face of the building to the front bar of the awning in its correct projected position.

Right and left of an awning are your right and left as you are facing the awning looking into the building.

Framework consists of galvanized steel pipe, with non-rattling fittings. Awning is lace-on type canvas with rope reinforced eave. Protector hood is galvanized sheet metal or either bronze, copper, or aluminum.

Sizes of members should be checked by calculation for conditions not similar to those shown on this page.

Consult local building code for limitations on height and setback.

COVERED WALKWAYS

Covered walkways are available with aluminum fascia and soffit panels in a number of profiles. The fascia panels are supported with pipe columns and steel or aluminum structural members if necessary. Panels can cantilever up to 30% of span. Canopy designs can be supported from above.

Another method of providing covered exterior space is with stressed membrane structures. Using highly tensile synthetic fabric and cable in collaboration with compression members, usually metal, dynamic and versatile tentlike coverings can be created. Membrane structures are especially suited to temporary installations.

NOTE

These miniature external louvers shade windows from direct sunlight and glare while allowing a high degree of visibility, light, ventilation, insect protection, and daytime privacy. Much like a woven metal fabric, they are not strong architectural elements but present a uniform appearance in the areas covered. The solar screen is installed in aluminum frames and can be adapted to suit most applications.

SOLAR SCREEN SIZES

MATERIAL	LOUVERS	TILT	VERTICAL SPACING	SIZE (WIDTHS)
Aluminum	17"	17°	1" o.c.	18"-48"
Bronze	17", 23"	20°	1/2" o.c.	Up to 72 1/2"

Aluminum screens are available in black or light green. Bronze screens come in black only.

18 THERMAL TRANSMISSION

GLASS FIBER INSULATION BOARD

SAND AND GRAVEL CONCRETE

NOTES: Standard unit of area 1 sq ft.
Standard unit temperature differential 1°F.

HEAT FLOW RATE

FOOTNOTES

- Resistances are representative values for dry materials and are intended as design (not specification) values for materials in normal use. Unless shown otherwise in descriptions of materials, all values are for 75°C mean temperature.
- Includes paper backing and facing if any. In cases where insulation forms a boundary (highly reflective or otherwise) of an airspace, refer to appropriate table for the insulating value of the airspace. Some manufacturers of batt and blanket insulation mark their products with R value, but they can ensure only the quality of the material as shipped.
- Average values only are given, since variations depend on density of the board and on the type, size, and depth of perforations.
- Thicknesses supplied by different manufacturers may vary depending on the particular material.
- Values will vary if density varies from that listed.
- Data on rectangular core concrete blocks differ from the data for oval core blocks because of core configuration, different mean temperature, and different unit weight. Weight data on oval core blocks not available.
- Weight of units approx. 7 1/2 high by 15 1/2 long are given to describe blocks tested. Values are for 1 sq ft area.
- Thermal resistance of metals is so low that in building constructions it is usually ignored. Values shown emphasize relatively easy flow of heat along or through metals so that they are usually heat leaks, inward or outward.
- Spaces of uniform thickness bounded by moderately smooth surfaces.
- Values shown not applicable to interior installations of materials listed.
- Winter is heat flow up; summer is heat flow down.
- Based on area of opening, not on total surface area. Based on data from ASHRAE Handbook of Fundamentals, 1977, Chapter 22.

	0.46	Summer	2.17

NOTES

The thermal conductivity of glass is relatively high ($k = 7.5$), and, for single glazing, most of the thermal resistance is imposed at the indoor and outdoor surfaces. Indoors, approximately two-thirds of the heat flows by radiation to the room surfaces and only one-third flows by convection. This can be materially affected by the use of forced airflow from induction units, for example. The inner surface coefficient of heat transfer, h_i , can be substantially reduced by applying a low emittance metallic film to the glass.

For glazing with airspaces, the U value can be reduced to a marked degree by the use of low emittance films. This process imparts a variable degree of reflectance to the glass, thereby reducing its Shading Coefficient. Manufacturers' literature should be consulted for more details on this important subject. Also consult Chapter 27 of the 1981 ASHRAE Handbook of Fundamentals.

FOOTNOTES

- Resistances are representative values for dry materials and are intended as design (not specification) values for materials in normal use. Unless shown otherwise in descriptions of materials, all values are for 75°C mean temperature.
 - Includes paper backing and facing if any. In cases where insulation forms a boundary (highly reflective or otherwise) of an airspace, refer to appropriate table for the insulating value of the airspace. Some manufacturers of batt and blanket insulation mark their products with R value, but they can ensure only the quality of the material as shipped.
 - Average values only are given, since variations depend on density of the board and on the type, size, and depth of perforations.
 - Thicknesses supplied by different manufacturers may vary depending on the particular material.
 - Values will vary if density varies from that listed.
 - Data on rectangular core concrete blocks differ from the data for oval core blocks because of core configuration, different mean temperature, and different unit weight. Weight data on oval core blocks not available.
 - Weight of units approx. 7^{5/8} high by 15^{5/8} long are given to describe blocks tested. Values are for 1 sq ft area.
 - Thermal resistance of metals is so low that in building constructions it is usually ignored. Values shown emphasize relatively easy flow of heat along or through metals so that they are usually heat leaks, inward or outward.
 - Spaces of uniform thickness bounded by moderately smooth surfaces.
 - Values shown not applicable to interior installations of materials listed.
 - Winter is heat flow up; summer is heat flow down.
 - Based on area of opening, not on total surface area.
- Based on data from ASHRAE Handbook of Fundamentals, 1977, Chapter 22.

SOLAR GAINS THROUGH SUNLIT FENESTRATION

Heat gains through sunlit fenestration constitute major sources of cooling load in summer. In winter, discomfort is often caused by excessive amounts of solar radiation entering through south facing windows. By contrast, passive solar design depends largely on admission and storage of the radiant energy falling on south facing and horizontal surfaces. Admission takes place both by transmission through glazing and by inward flow of absorbed energy. With or without the sun, heat flows through glazing, either inwardly or outwardly, whenever there is a temperature difference between the indoor and outdoor air. These heat flows may be calculated in the following manner.

The solar heat gain is estimated by a two-step process. The first step is to find, either from tabulated data or by calculation, the rate at which solar heat would be admitted under the designated conditions through a single square foot of double strength (1/8 in.) clear sheet glass. This quantity, called the solar heat gain factor (SHGF), is set by (a) the local latitude; (b) the date, hence the declination; (c) the time of day (solar time should be used); (d) the orientation of the window.

Tabulated values of SHGF are given in the 1981 ASHRAE Handbook of Fundamentals, Chapter 27, for latitudes from 0° (the equator) to 64° N by 8° increments and for orientations around the compass from N to NNW, by 22.5° increments. Selected values from the 40° table are given in an adjacent column.

Each individual fenestration system, consisting of glazing and shading devices, has a unique ability to admit solar heat. This property is evaluated in terms of its shading coefficient (SC), which is the ratio of the amount of solar heat admitted by the system under consideration to the solar heat gain factor for the same conditions. In equation form, this becomes:

$$\text{solar heat gain (Btu/sq ft} \cdot \text{hr)} = \text{SC} \times \text{SHGF}$$

Values of the shading coefficient are given in Chapter 27 of the 1981 ASHRAE Handbook of Fundamentals for the most widely used glazing materials alone and in combination with internal and external shading devices. Selected values for single and double glazing are given below:

SHADING COEFFICIENT FOR SELECTED GLAZING SYSTEMS

TYPE OF GLASS	SOLAR TRANSMISSION	SHADING COEFFICIENT, SC
Clear		
1/8 in.	0.86	1.00
1/4 in.	0.78	0.94
Heat absorbing		
1/8 in.	0.64	0.83
1/4 in.	0.46	0.69
Insulating glass, clear both lights		
1/8 + 1/8 in.	0.71	0.88
1/4 + 1/4 in.	0.61	0.81
Heat absorbing out		
Clear in, 1/4 in.	0.36	0.55

For combinations of glazing and shading devices, see the ASHRAE chapter cited above.

The heat flow due to temperature difference is found by multiplying the U-value for the specified fenestration system by the area involved and by the applicable temperature difference:

$$Q = A \times [\text{SC} \times \text{SHGF} + U \times (t_o - t_i)]$$

The same equation is used for both summer and winter, with appropriate U-values, but in winter the conduction heat flow is usually outward because the outdoor air is colder than the indoor air.

Example: find the total heat gain, in Btu/sq ft · hr, for 1000 sq ft of unshaded 1/4 in. heat absorbing single glass, facing west, in Denver (40°N latitude) at 4:00 P.M. solar time on October 21. Indoor air temperature is 70°F; outdoor air temperature is 40°F.

Solution: from the accompanying table, for 4:00 P.M. on October 21 find the SHGF for west facing fenestration on October 21 to be 173 Btu/sq ft · hr. For 1/4 in. heat absorbing glass, SC = 0.69 and U for winter conditions is 1.10 Btu/sq ft · hr · °F.

$$Q = 1000 \times [0.69 \times 173 + 1.10 \times (40 - 70)]$$

$$= 1000 \times (119.4 - 33.0) = 86,400 \text{ Btu/hr}$$

Even though the outdoor air is 30° cooler than the indoor air, the net heat gain through the window in question would be equivalent to 7.2 tons of refrigeration.

For the same window area in summer, on August 21 at 4:00 P.M. solar time, SHGF = 216, and the air temperatures may be taken as 95°F outdoors and 78°F indoors. The total heat gain will be:

$$Q = 1000 \times [0.69 \times 216 + 1.04 \times (95 - 78)]$$

$$= 1000 \times (149.0 + 17.7) = 166,700 \text{ Btu/hr}$$

$$= 13.9 \text{ tons of refrigeration}$$

The cooling load can be reduced by selecting a fenestration system with lower shading coefficient and U-value. Under the same conditions, a double glazed window with two lights of 1/4 in. clear glass and a highly reflective translucent inner shading device would have U = 0.52 and SC = 0.37. The cooling load would then be reduced to 88,760 Btu/hr or 7.4 tons of refrigeration.

SOL-AIR TEMPERATURE

When the opaque surfaces of a structure are struck by solar radiation, much of the energy is absorbed by the irradiated surface, raising its temperature and increasing the rate of heat flow into the roof or wall. The time lag between the onset of irradiation and the resulting rise in the indoor surface temperature depends on the thickness and mass per unit area of the building element and on the thermal conductivity, specific heat, and density of the materials. The time lag is negligible for an uninsulated metal roof, but it can be a matter of hours for a massive concrete or masonry wall.

Heat flow through sunlit opaque building elements is estimated by using the sol-air temperature, t_{sa} , defined as an imaginary outdoor temperature that, in the absence of sunshine, would give the same rate of heat flow as actually exists at the specified time under the combined influence of the incident solar radiation and the ambient air temperature.

$$t_{sa} = I \times \text{Abs.}/h_o$$

where I = solar irradiance (Btu/sq ft · hr)

Abs. = surface absorptance, dimensionless

h_o = outer surface coefficient (Btu/sq ft · hr · °F)

Surface absorptances range from as low as 0.30 for a white surface to 0.95 for a black built-up roof. Values of h_o range from the conventional 4.0 for summer with an assumed wind speed of 7.5 mph to a still air value of 3.0.

Example: find the rate of heat flow through a 1000 sq ft uninsulated black built-up roof, U = 0.3, under strong summer sunshine, I = 300 Btu/sq ft · hr, still air with 100°F outdoors, 78°F indoors.

Solution: the sol-air temperature is found from

$$t_{sa} = 300 \times \frac{0.95}{3.0} + 100 = 195^\circ\text{F}$$

The rate of heat flow, neglecting the time lag, is

$$Q = 1000 \times 0.3 \times (195 - 78) = 35,100 \text{ Btu/hr}$$

With no sunshine on the roof, the heat flow is

$$\text{heat flow} = 1000 \times 0.3 \times (100 - 78) = 6600 \text{ Btu/hr}$$

The effect of the solar radiation is thus to increase the heat flow rate by 88%. A more massive roof with a lower U-value would show considerably less effect of the incoming solar radiation.

SOLAR INTENSITY AND SOLAR HEAT GAIN FACTORS FOR 40°N LATITUDE

GENERAL

For years the building industry in the United States has depended upon a seemingly endless supply of high quality materials, supplies, and energy resources. Manufacturers have been producing building materials abundantly, and architects generally have been specifying them for reasons of aesthetics, budget, performance, code compliance, and availability. Consideration is rarely given to the environmental impact of using these materials, i.e., what environmental "costs" go into extracting, producing, shipping, and installing them. These costs include depletion of nonrenewable raw materials and resources; production of waste by-products; and exposure of toxicity to the air, water, soils, and inhabitants of nearby areas.

For the building industry of the future, it will be good business to use materials that are environmentally friendly, sustainable, and renewable and that contain recycled materials. A building industry that depends upon depletable resources to manufacture its materials will become more and more costly as the resources are depleted. More important, the world in which we build will become more and more uninhabitable because of the toxins and waste left by our present materials and methods of construction. To do its part in keeping the world safe to live in, the architecture profession must incorporate procedures and standards of resource conservation into our design philosophies.

BUILDING MATERIALS ANALYSIS

LIFE CYCLE OF BUILDING MATERIALS

To analyze a building material from an environmental standpoint, an understanding of the life cycle of that material must be reached. Examine the environmental burdens that accrue through extraction or acquisition of the raw materials and their processing/manufacture and the packaging, distribution, use, and ultimate recovery (reuse/recycling) or disposal of the finished product.

Three aspects of the life of a building material are most significant in considering environmental impact: Is the raw material renewable or nonrenewable? How much total waste or how many toxic by-products are produced in its production and during the life of the product? How much energy is consumed in its life cycle? A building material that is both environmentally "pure" and readily available—that is, one made from a 100% renewable raw material that uses only renewable energy in its extraction, production, and transport and can be infinitely reclaimed and recycled (as well as healthy to the occupants of a building)—will be hard to find. Even to have that "perfect" material as a goal, we need a frame of reference from which to choose materials based on environmental concerns, something like ingredient and nutrition labeling on food products. If this information was available on materials for the building industry, we would be able to specify materials that are healthy and "nutritious" for a sustainable planet.

EMBODIED ENERGY OF BUILDING MATERIALS

The embodied energy of a building material comprises all the energy consumed in acquiring and transforming the raw materials into finished products and transporting them to the building site. The life-cycle chart below details where energy is consumed in producing building materials. The embodied energy or energy "content" of a building material will act as a rough guide to its environmental friendliness. The energy content reflects the material's "closeness" to

the earth; the more it is refined or processed, the more energy it "contains" and hence the more "expensive" it is environmentally.

If we must produce and use high-energy materials, it is important that we not waste that energy by burying them in a landfill but rather reuse or recycle them.

To compare one material to another, we must take into account the following characteristics:

1. Regional availability—local extraction/manufacture
2. Recyclability (how many times the material can be recycled and retain viability)
3. Reusability
4. Durability and life span
5. Toxicity of the product or of the materials used to maintain the product during its life
6. Efficiency of product's performance as an architectural component
7. Savings on other materials not used because this product is used
8. Savings in energy not consumed over the life span of the building because this product is used
9. Any combination of these factors

Some construction methods and systems bind materials together to render them difficult or costly to recycle or reuse. One example of this is reinforced concrete, which efficiently uses steel in its role of spanning distances but also makes it impractical to recycle after a building has outlived its usefulness. A structural steel frame, although it uses a great deal more steel than a similar reinforced concrete frame, can be unbolted, disassembled, and reused or melted down and reformed infinitely.

NOTE

Evaluating whether a certain material is used in construction is a complicated process involving many factors. Certain regions or markets may be more familiar with or more suitable for certain types of construction or materials, and this may be an unavoidable factor that nullifies all others in determining which structural or other material is used.

LIFE-CYCLE CHECKLIST FOR BUILDING MATERIALS

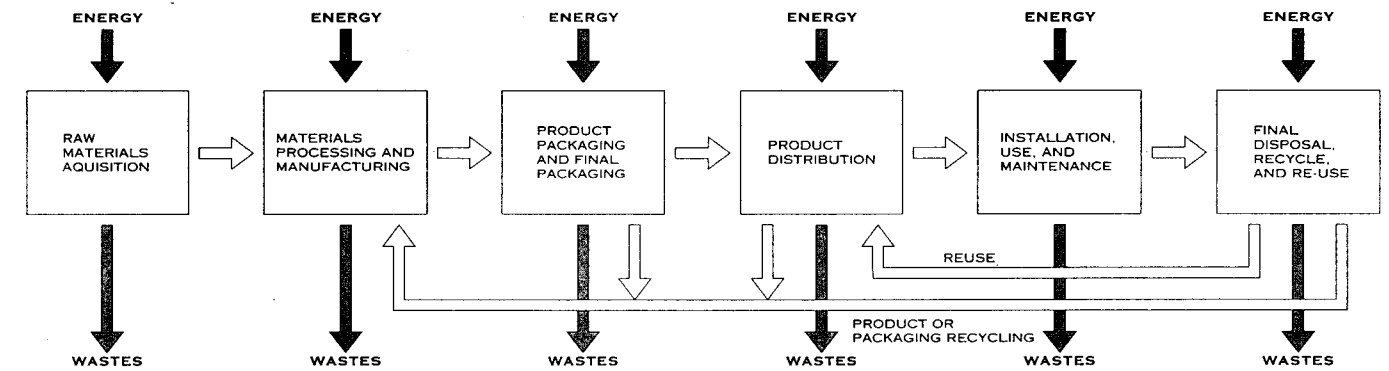

This checklist can be used to analyze the environmental impact of building materials:

1. Raw material acquisition (mining, harvesting, drilling, extraction)
 - a. Is the resource renewable or sustainable (reproducible indefinitely)?
 - b. How much nonrenewable waste is produced?
 - c. What is the amount and type of energy consumed? (Is it sustainable?)
 - d. How does acquisition affect the environment? (Does it destroy forests or other habitats, produce silt or toxic runoff or air pollution?)
2. Raw material processing and manufacturing
 - a. How much nonrecyclable waste is produced?
 - b. What is the type and amount of energy consumed to manufacture the product?
 - c. What toxicity to air, water, or soils is produced by processing?

APPROXIMATE VALUE OF EMBODIED ENERGY IN BUILDING MATERIALS

MATERIALS	ENERGY CONTENT (BTU/LB)
Low energy materials	
Sand/gravel	18
Wood	185
Sand-lime brickwork	730
Lightweight concrete	940
Medium energy materials	
Gypsum board	1,830
Brickwork	2,200
Lime	2,800
Cement	4,100
Mineral fiber insulation	7,200
Glass	11,100
Porcelain	11,300
High energy materials	
Plastic	18,500
Steel	19,200
Lead	25,900
Zinc	27,800
Copper	29,600
Aluminum	103,500

3. Product packaging and final packaging (for shipping)
 - a. Is packaging recyclable or made of recycled material?
 - b. Is packaging excessive?
 - c. Does packaging use nonrenewable resources (e.g., petroleum or materials harmful to the environment, such as CFC insulation packing material)?
4. Product distribution
 - a. Would the product travel an excessive distance from the manufacturing site to the building site when more local products could be used?
 - b. What is the type and amount of energy consumed to transport the material?
5. Product installation, use, maintenance
 - a. Does installation produce excessive and/or nonrenewable site waste?
 - b. What energy is consumed to install and maintain the product?
 - c. Does installation, use, or maintenance of the product pollute the outdoor or indoor environment for installers or occupants?
 - d. How durable is the product and what is its rate of degradation?
 - e. Does the product add to the energy efficiency of the building?
6. Disposal, recycling, reuse
 - a. Does the product use virgin materials wisely?
 - b. Is it recyclable after use and, if so, to what degree?
 - c. Can the product be reused?
 - d. What energy is consumed to recycle the product?
 - e. What energy is consumed to dispose of its nonrecyclable elements?
 - f. What is the toxicity to the environment when the product is thrown away?

LIFE-CYCLE CHART

Energy consumption considerations of building materials should not override basic respect for the earth. Degradation of the landscape in materials extraction, transport, and manufacturing, as well as in construction, should be minimized.

Richard J. Vitullo, AIA; Oak Leaf Studio; Crownsville, Maryland
AIA Environmental Resource Guide

LIFE CYCLES OF BRICK, GLASS, AND PAINT

	BRICK AND MORTAR	GLASS	PAINT
Raw material acquisition and preparation	<ul style="list-style-type: none"> Most clays, shales, sand, portland cement, and hydrated lime used in brick and mortar production are mined from open pits using modern surface mining equipment, causing land and habitat disturbance. Reclamation of open pits into lakes, landfills, etc. is a common occurrence. Domestic resources of clay and shale are almost unlimited. Energy is consumed in clay mining and processing in the form of fuels (natural gas, propane, oil, coal, etc.) used to mine, crush, and haul the materials. 	<ul style="list-style-type: none"> The principal raw materials used in the formation of soda-lime glass (which accounts for 77% of total glass production) are glass sand, limestone, soda ash, and cullet. Glass sand and limestone are mined from open pits (see brick section for environmental effects). The four main components of glass are all available in large quantity. Atmospheric emissions, runoff into streams and groundwater, and habitat alteration are potential adverse impacts from mining. Suspended solids from mine runoff can increase turbidity of streams. Soda ash is obtained from underground mines, which have minor adverse environmental impact. 	<ul style="list-style-type: none"> The raw materials for titanium dioxide and pigment extenders are mined from the earth, and the environmental impacts of mining operations include runoff from tailings waste, which leads to increased turbidity of water.
Raw material processing and manufacture	<ul style="list-style-type: none"> Stormwater runoff from clay and shale processing and storage is a concern. "Waste" products are sometimes used as raw materials in production of brick, such as sewage sludge, incinerator ash, fly ash, waste glass, papermaking sludge, metallurgical wastes, and rice husk and slag. Particulate matter is the primary emission in the manufacture of brick: Dust results from materials handling and pollutants such as CO₂, chlorine, and fluorine from kiln firing. 	<ul style="list-style-type: none"> Wastes generated during the processing of glass sand include solid waste (clay and sand particles), water effluent, and air emissions. Large quantities of water are needed to process glass sand, and the wastewater contains clay particles in suspension. The fabrication of coatings and sealants used with glass can result in some VOC emissions. 	<ul style="list-style-type: none"> The major pigment in paints is titanium dioxide, the manufacture of which can produce wastes such as sulfuric acid, metal sulfates, and metal chlorides. Wastes from manufacture include runoff from equipment cleaning (solvents), obsolete stock, spills, etc.
Product packaging and final packaging	<ul style="list-style-type: none"> Prepackaged mortar is shipped in bags; ready-mixed mortar is shipped to a site in wet state in bulk. Bricks have very little packaging and are usually bound by steel straps and set on wood pallets. 	<ul style="list-style-type: none"> Because they are so breakable, glass products are packaged with fairly substantial but usually recyclable materials. 	<ul style="list-style-type: none"> Containers for paints are classified as hazardous waste in some jurisdictions.
Product distribution	<ul style="list-style-type: none"> Transporting bricks to a site requires energy in the form of fossil fuels; however, bricks usually are manufactured close to the site. 	<ul style="list-style-type: none"> Glass is transported easily as it is usually made into fairly lightweight units. 	<ul style="list-style-type: none"> Choose paints that are made as close to the building site as possible to save energy for transportation.
Product installation, use, and maintenance	<ul style="list-style-type: none"> Bricks not used in a construction project are shipped back to the manufacturer for recycling. 	<ul style="list-style-type: none"> Glass is an inert material and is easily specified for building projects. It is very easily maintained, although care must be exercised with coated glass products to avoid damaging the coating during cleaning. 	<ul style="list-style-type: none"> Paint can generate VOC emissions during application and drying; initial emissions can be significant. Pigments may also contain toxic compounds, a concern when burning demolition waste, sanding surfaces, etc. Citrus oil solvent, an alternative solvent, can cause irritation or allergies but dries quickly. Alternative paints can use natural oils, such as linseed, tung, pine, etc. instead of petrochemicals, as well as alternatives for fillers, driers, pigments, resins, etc. that are less toxic than conventional materials.
Final disposal, reuse, or recycling	<ul style="list-style-type: none"> The minimum life expectancy of a brick building is 100 years or more. If constructed properly, a brick building can last 1000 years. 	<ul style="list-style-type: none"> A small amount of glass is recycled from older buildings; certain types of flat glass can be recycled into glassphalt, an asphalt substitute, for paint additives, etc. 	<ul style="list-style-type: none"> During demolition and renovation projects, lead contained in paints made before 1978 may be released as dust or chips, causing adverse health effects to building inhabitants. Some paints contain a significant proportion of recycled material, both postconsumer and plant waste.

ENERGY CONSUMPTION AND WASTE GENERATION

Energy consumption totals	<ul style="list-style-type: none"> The embodied energy at point-of-use for one pound of brick and mortar is approximately 4000 Btus/lb. 	<ul style="list-style-type: none"> The embodied energy in glass is approximately 11,100 Btus/lb. 	<ul style="list-style-type: none"> Embodied energy at the point-of-use for conventional water-based paint is 33,034 Btus/lb; for conventional oil-based paint it is 41,642 Btus/lb.
Waste generation totals	<ul style="list-style-type: none"> Acid rain is an effect of fluorine and chlorine pollutants in the atmosphere. Greenhouse gases (CO₂) are released during fuel use in mining and processing. Very little solid waste results from the manufacture of brick; waste materials are recycled into new material. 	<ul style="list-style-type: none"> Air pollutants generated during the melting of glass from the combustion of fuel and vaporization of raw materials include nitrogen oxides, VOCs, etc. 	<ul style="list-style-type: none"> Many of the materials used to manufacture paints are derived from petrochemicals. Oil and natural gas extraction is responsible for a variety of environmental pollutants, such as air emissions and toxic solid wastes.

DESIGN CONSIDERATIONS

<ul style="list-style-type: none"> Brick construction can help conserve energy by its insulating value, thermal mass qualities (storing solar heat gain), and the efficiency with which it is made and transported to building sites. Brick contributes strength and durability to the life span of a building. Brick has relatively low embodied energy and is a non-toxic inert material that is relatively harmless to the environment throughout its life cycle. Select products with recycled content when possible. To reduce cooling loads in hot climates, specify light-colored facing materials. Make sure brick and mortar facings are properly installed and maintained to ensure optimal, long-term performance, particularly relating to moisture resistance. Use of a masonry backup wall is preferred. 	<ul style="list-style-type: none"> When properly specified and installed, glass is highly energy efficient. It permits less use of artificial lighting, resulting in an energy savings. Glass is inert and has virtually no adverse impact on indoor air quality. Use of glass aids in the solar heat gain of building interiors. Specify high-performance glazing (spectrally selective for commercial buildings, low-E for residential buildings) in almost all geographic regions and building applications. Avoid reusing salvaged glass in exterior building envelopes because of poor energy performance. 	<ul style="list-style-type: none"> Architects and builders must consider the issues surrounding exposure to and disposal of lead-based paint materials during demolition or renovation projects. Paints greatly extend the useful life of the built and manufactured environment, resulting in savings of energy and materials and a corresponding reduction of environmental pollution. If performance won't be compromised, waterborne formulations should be specified rather than oil-based formulations. Always ventilate spaces being painted directly into the outdoors. Never allow contaminated air to circulate into a building's HVAC system.
--	--	--

LIFE CYCLE OF COMMON BUILDING MATERIALS

	ALUMINUM	STEEL	PARTICLEBOARD
Raw materials acquisition and preparation	<ul style="list-style-type: none"> Manufacturing depletes the mineral bauxite, a finite resource (only 125 years remain at the current rate of consumption). Bauxite strip mining causes loss of large tracts of land, including some loss of tropical forests and habitats. Reclamation of strip mines reduces long-term effects but some species may be lost. Other raw materials consumed during acquisition include lime, caustic, soda, crude oil, and coal. Degradation of ground and surface water and air may occur from mining. 	<ul style="list-style-type: none"> Manufacturing depletes supplies of iron ore, limestone, and coal, all finite resources. Processing of coal into coke produces toxic air pollutants. Deep pit mining causes loss of virgin forests and lands; land reclamation may reduce long term effects. Degradation of ground and surface water and air may occur from mining. 	<ul style="list-style-type: none"> Approximately 90% of the wood component of this product comes from sawmill waste; if managed, sustainable and renewable wood cellulose sources are used, natural resource depletion is eliminated; if sawmill waste from old growth trees is used, those forests and habitats will be lost. Size of wood chips varies from 25mm to particles as fine as flour. 98% of the resin binder in particleboard is urea formaldehyde (urea is derived from petroleum and formaldehyde from natural gas); 1.6% of the resin used is phenol formaldehyde (phenol is derived from coal tar and petroleum).
Raw materials processing and manufacturing	<ul style="list-style-type: none"> Smelting and ingot casting is energy intensive. Different finishes vary in their environmental burdens: anodized and powdered paint coatings have few negative environmental effects, while electroplating and related finishes are highly polluting. 	<ul style="list-style-type: none"> Raw materials and resources used in processing include nickel, manganese, chromium, lubricating oils, solvents, acids, and alkalies. Iron is produced from iron ore, coke, and lime, which is heated in blast furnaces. Steel is made from iron by either the basic oxygen furnace method, using 30% scrap, or the electric furnace method, using all scrap steel and iron. 	<ul style="list-style-type: none"> Gaseous formaldehyde emissions occur in drying and mat pressing stages of processing.
Product packaging and final packaging	<ul style="list-style-type: none"> Packaging of materials varies; choose products that use minimal packaging or packaging made of recycled materials and/or that is itself recyclable. 		
Product distribution	<ul style="list-style-type: none"> Distribution varies; choose products made and/or distributed from a place as close to the building site as possible. 		
Product installation, use, and maintenance	<ul style="list-style-type: none"> Generally a low maintenance material, depending on finish. Painted aluminum surfaces require periodic repainting; anodized finishes and powdered paint coatings require occasional cleaning. 	<ul style="list-style-type: none"> Maintenance depends on which alloy is used (e.g., stainless steel), whether electrolytic treatment has been done (e.g., galvanized steel), and whether a coating has been applied. Preparation of the surface for repainting or other maintenance may require use of solvents or acids. Weathering steel, which forms a protective oxidized coating, is also available. 	<ul style="list-style-type: none"> Most uses are for applications such as cabinet and furniture core stock (MDF), nonstructural floor underlayment, and manufactured home decking. Since the uses are located in protected and confined areas beneath finishes, degradation and maintenance are minimized. Nonetheless, some interior air pollution from offgassing may occur.
Final disposal, reuse, or recycle	<ul style="list-style-type: none"> Scrap can be recovered, recycled, and reused endlessly; use of recycled aluminum reduces total energy requirements by 90-95%, however, only 15-20% of aluminum in construction is recovered and recycled since it is "bound up" with other materials and difficult to separate. Final disposal causes no ill environmental effects, except ground water contamination from coatings and landfill overcrowding. 	<ul style="list-style-type: none"> By way of magnetic separating processes, scrap is easily recovered and recycled. Recycled steel saves energy and raw materials and reduces contamination of the environment. Final disposal causes no ill environmental effects except groundwater contamination from coatings and landfill overcrowding; steel eventually oxidizes back into a natural state. Limited sorting of steel alloys required in recycling. 	<ul style="list-style-type: none"> Since particleboard is usually bound tightly into assemblies with other materials and finishes such as laminates, recycling is difficult, although possible.
Energy consumption totals	<ul style="list-style-type: none"> The aluminum industry accounts for 1.4% of annual world energy consumption. Embodied energy at point-of-use for one pound of aluminum is estimated at 102,500 BTUs. Aluminum produced from recovered scrap and recycled aluminum rather than bauxite ore saves 80% of total energy consumption. 	<ul style="list-style-type: none"> Embodied energy at point-of-use for one pound of steel is estimated at 19,200 BTUs. Processes using scrap steel and iron save energy by skipping blast furnace energy consumption. 	<ul style="list-style-type: none"> Embodied energy at point-of-use for one pound of underlayment particleboard is estimated at 7,000 BTUs, 30-40% of which is derived from the resin adhesive. Energy consumed in production is mostly used for heat to dry particles, heat resins, and create steam for hot presses. Depending on the manufacturing plant, wood, gas, and oil are used for energy; however, 78% of the total energy bound up in wood products comes from the burning of wood waste.
Waste generation total	<ul style="list-style-type: none"> Bauxite refining yields large volumes of mud containing trace amounts of hazardous waste. Although most airborne emissions are contained by wet scrubbing, small amounts of carcinogenic hydrocarbons escape during smelting and forming. Fabrication and finishing may produce heavy metal sludges and large amounts of waste waters that require treatment with toxic chemicals. Solid wastes include used potliners of carbon, insulation material, fluoride, and cyanide. 	<ul style="list-style-type: none"> Both deep pit and strip mining of iron ore, coal, and limestone yield large amounts of discarded rock and soil, resulting in erosion and contamination of water by dissolved toxic minerals. The production of one ton of steel creates 1.5 tons of waste materials. Mine spoils from coal mining may acidify nearby soils and water. Coke ovens may emit toxic sulphur dioxide fumes, carbon monoxide, and other particulate emissions; processing limestone into lime releases carbon dioxide emissions into the air. Liquid wastes produced by processing include lubricants, electrolytic coatings, pickling solutions, paints, and contaminated water. Solid wastes include by-products from the processing of iron ore, limestone, and coal. 	<ul style="list-style-type: none"> Most solid waste from particleboard manufacturing is recovered in the mill or used as fuel; panel trim pieces and defective panels are ground up and put back into raw material stock. Production of resins results in waste waters that may contain toxic monomers.
Conclusion for designers	<ul style="list-style-type: none"> Although its embodied energy is very high, when compared pound for pound to alternative materials aluminum may be preferable as it is very strong and durable, lightweight, and readily recyclable. Specify aluminum products that are made fully or partially from recycled scrap. Consider designs that will facilitate recycling; avoid, if possible, mixed-material assemblies. Anodized finishes and powdered paint coatings may be the most environmentally friendly finishes. In applications where the uniquely advantageous characteristics of aluminum are not needed, consider low energy-consuming alternative materials that are recyclable. 	<ul style="list-style-type: none"> Since many steel products are made totally or partially from recycled steel, steel is considered less environmentally harmful than other alternatives. Steel can be used very efficiently in reinforced concrete as a structural material. However, this practice usually binds the steel permanently with the concrete, making it nonrecyclable. Steel, regardless of coating, treatments, and alloys, can be recovered and recycled easily. 	<ul style="list-style-type: none"> Urea formaldehyde (UF) particleboard offgasses formaldehyde into indoor air. Levels of emission are higher in spaces with high temperature and humidity levels; all emission levels decrease over time. Specify low-emitting, UF-bonded particleboard where practical, or consider sealing UF particleboard or using phenol formaldehyde-bonded particleboard (exterior grade plywood, etc.).

AIA Environmental Resource Guide

RESOURCE CONSERVATION METHODS AND SYSTEMS

Choosing building materials containing recycled materials is but one step in the process of environmentally conscious design. Sensitive environmental design takes the holistic view, regarding every aspect of how a building works in its context. Consideration must be given to how a building performs and relates to its surroundings throughout its life, before (design and specification), during (construction), and after (lifetime maintenance and energy costs) it is built. The following guidelines can be used for designing with resource conservation goals:

1. Design with nature's patterns in mind so the building works with them and the resources of its site rather than overpowering and controlling them. The following methods will help you achieve this goal:
 - a. Building and site planning. To achieve the goal of overall environmental design, it is critical to orient the building to the landscape at the site. Working with site features will allow you to take advantage of natural systems, such as ventilation by means of windrows and chimneys or full-spectrum light sources.
 - b. Earth-sheltered design. Solar heat and light can be used to reduce the nonrenewable energy requirements of a building. The temperature-moderating feature of the earth is an aspect of the surrounding environment often ignored. Through earth berms, earth-covered roofs, and underground design, a building can make use of the consistent 55° F± of the earth below the local frost line or at least the inherent R-

value of earth material. A well-designed earth-sheltered structure also reduces the need for exterior maintenance of building materials.

2. Preserving existing site features may benefit the local habitat and make the building harmonize with the site.
 - a. Tree, plant, and soil preservation. Establish environmental priorities for the building site. Inventory natural features such as viable trees and shrubs and wetland areas. Trees provide an enormous environmental benefit to the health of buildings (shading, etc.), sites (soil enrichment from leaves, etc.), and birds and other wildlife. Locate buildings, driveways, and land to be disturbed during construction far enough from existing trees to avoid root compaction. A good rule of thumb is to stay out of the drip line of a tree during construction. Have a landscape architect, arborist, forester, or environmental consultant assist in the survey.
 - b. Construction and demolition site waste recycling or reuse. The construction of a single-family home in the U.S. generates 2.5 tons of waste. Since landfill overcrowding has caused dumping fees to increase significantly, it is becoming economically feasible to recycle construction and demolition wastes. Identify materials that could be used more efficiently, salvaged, reused on site, or recycled. Common materials that generally can be recycled from construction sites are (with percentages based on total site waste volume): wood (27%), cardboard/paper (18%), gypsum board (15%), insulation (9%), roofing (8%), metals (7%), concrete/asphalt rubble (6%), landscaping debris (5%), and miscellaneous (5%). These are national averages, and each site will be different. Identify positions for recy-

cling bins on site so materials can be separated as they are recovered. Prevent storm sewer and ground water pollution and reduce soil erosion with sensitive design and site construction methods.

3. Energy-efficient design should reduce or eliminate nonrenewable fossil fuel consumption for heating, cooling, and lighting. Although it is good to create a building with resource conservative materials, it is critical to ensure that once the building is built it either continues to conserve energy resources or uses renewable energy resources throughout its life. Consider using durable, low-maintenance materials. Where practical, design full-cycle systems such as solar water heating that will capture renewable energy on site. The following equipment can help achieve this goal:
 - a. Heat recovery ventilators. This system extracts the heat from the air as it is exhausted and transfers that it to incoming air (or the reverse in the summer). This system allows a tight, energy-efficient building to be ventilated but still retain the heat-energy used to maintain the indoor environment. Depending on the climate, this system can be up to 80% efficient in recovering energy and is recommended for either very cold or very hot, humid climates. Consult with a mechanical engineer or equipment manufacturer.
 - b. Ground source heat pump. Like earth-sheltered building design, this system takes advantage of the stability of underground temperatures. Long lengths of copper tubing are buried either horizontally or vertically in the earth and circulated with a heat-exchanging medium.

NONTOXIC BUILDING MATERIALS

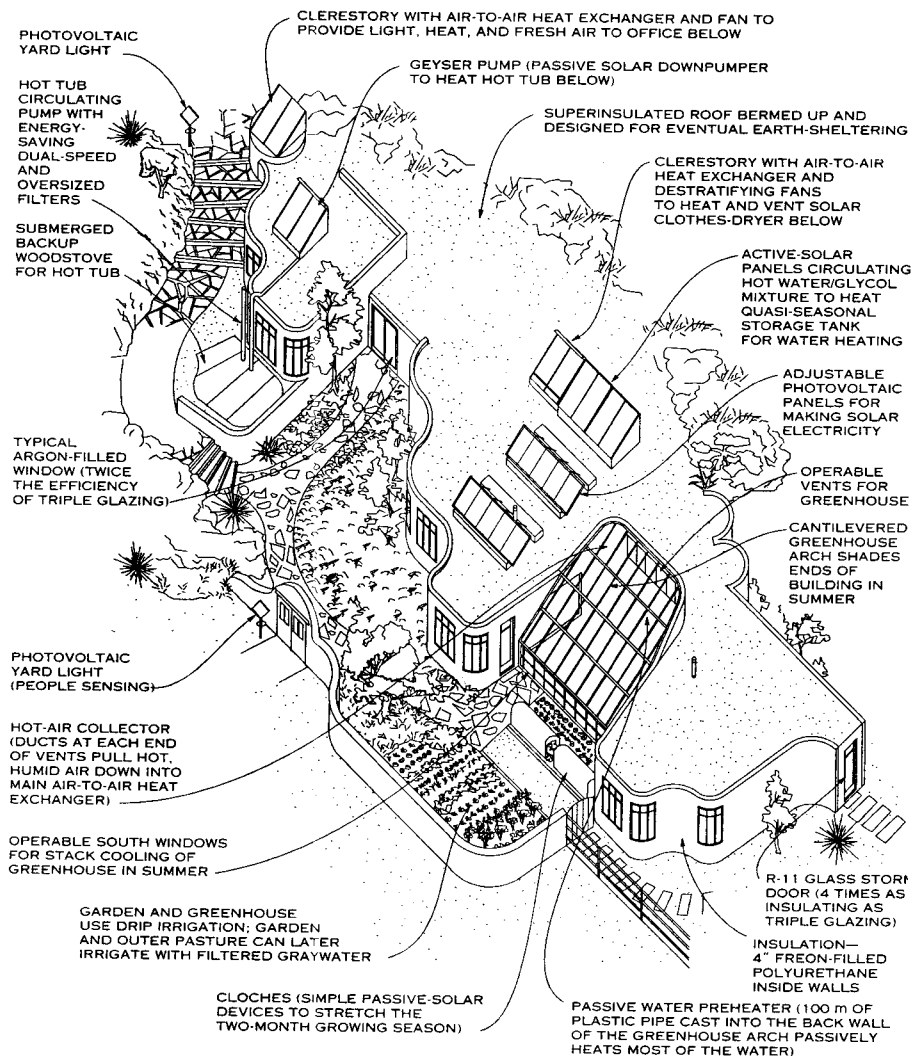

Some building materials contain substances or release particles that can be an irritant and cause the medical problem called "sick building syndrome." Some of these airborne substances can also cause long-term problems such as chronic allergies and even cancer. Chemically sensitive people are at risk, as well as otherwise healthy installers or building occupants. The origins of these toxic substances—including by-products of manufacture and installation (e.g., chemicals released as adhesives and mastic cure), by-products of decay and age (e.g., offgassing of particleboard or plywood), and by-products of burning (e.g., toxic fumes from plastics)—are varied.

The U.S. Environmental Protection Agency (EPA) has identified five major causes of indoor air pollution:

1. Biogenic particles—mold, bacteria, etc.
2. Combustion by-products—tobacco products, gas ranges, furnaces, and fireplaces
3. Organic chemicals—benzene, formaldehyde
4. Natural substances—radon, lead
5. Fibrous materials and airborne particles—fiberglass, asbestos, pollen, dust, etc.

Ideally, materials and systems selected for a building should be durable, easily maintained, safe for the installer and user, and produced without excess energy use. Good maintenance features allow a material to be cleaned of other hazards and irritants, such as mold, moisture, and dust, with nontoxic cleaners and treatments. However, building materials should not be chosen for good maintenance features alone, as hazardous materials like vinyl, synthetics, and plastics can be very easy to clean.

As in any design process, designing a healthy building requires establishing priorities. However, this may not be an easy task, as it can be difficult to define "healthy" and difficult to implement "healthy" practices. Alternative products are not as well known or marketed as standard products, making them harder to find. In addition, these products can be more expensive and occasionally more difficult to install or apply if contractors are unfamiliar with them. Nonetheless, carefully selecting appropriate alternatives where possible and minimizing the most toxic materials and methods make constructing a "healthier" building an achievable goal.

NOTES

- This chart is intended as a guide to selecting environmentally friendly materials. As a rule of thumb, use locally produced environmentally friendly materials to save transportation-related energy.
- In comparing building materials, the choice that promotes resource conservation may not always be as straightforward as it appears. For example, wood may seem a better choice than plastic for a park bench, as it is a natural, renewable material rather than a petroleum-

based one. However, in an outdoor usage, where durability and good maintenance characteristics are preferred, offgassing from plastic is not an issue. When the aesthetics of wood are not important, plastic made from recycled soda bottles may be an appropriate solution. Choosing recycled plastic would conserve wood materials—old-growth cedar, redwood, or chemically treated pine—and reuse something made from a nonrenewable resource, making it an acceptable solution sympathetic

with resource conservation principles. At issue is the definition of a "resource" that must be conserved. A great deal of material and embodied energy are tied up in existing plastic. The reuse of these materials not only allows those resources to continue a useful life but also saves the embodied energy that would have been used to create a new product in its place. Plastic, particularly, is very durable and very slow to degrade.

SAMPLE LIFE-CYCLE FLOWCHART (STEEL FRAMING AND FASTENERS)

GENERAL

Flowcharts such as that illustrated above are an important element in the documentation of life-cycle analysis findings for building materials. Life-cycle flowcharts provide a comprehensive picture of the resources, energy, and environmental emissions associated with the creation and use of a given building material. Each flowchart encompasses the entire "life" of a material, from cradle to grave or cradle to cradle. (A cradle-to-cradle life cycle reflects the fact that some materials can be reused or recycled.)

Using a "streamlined" life-cycle methodology, the AIA *Environmental Resource Guide* (ERG) combines both quantitative and qualitative analyses. It defines the major life-cycle phases to include

1. Acquisition and preparation of raw materials
2. Manufacture of the building material
3. Installation and use of the material in buildings
4. Reuse, recycling, or disposal of the material at the time buildings are renovated or demolished

The life-cycle flowchart begins by showing the raw materials extracted from the earth, harvested from plants, or obtained from animals. The individual procedures involved in the acquisition processes are identified and related to

specific changes that each raw material undergoes. Each box in the flowchart names a procedure, identifies its components, indicates if one or more materials are combined, and shows what wastes or recyclable/reusable materials are released by the procedure.

Each stage of the life cycle may contain several phases. For example, the manufacturing and fabrication stage may include product packaging and product distribution phases, among others. Regardless of the labels given to each stage, the flowchart depicts the continuous progression of the building material in its various forms, identifying the input and output associated with each process.

The flowchart denotes the release of wastes into air and water and onto the land for each stage of the process. It also indicates points at which recycling and reuse of materials or material by-products occur.

An ideal flowchart shows the consumption and release of energy throughout the life cycle of a building material. The difficulty in obtaining information on exact energy amounts for all processes, however, usually prevents inclusion of these data on the chart. Energy data generally require narrative discussion due to variability that cannot be presented succinctly enough to fit in the chart.

After the material to be studied has been identified and defined ("scoping"), an environmental analysis proceeds in four steps as outlined below. As noted, the life-cycle flowchart is a key component in the first step.

1. INVENTORY ANALYSIS is a fact-finding effort to identify and quantify the environmental inputs and outputs associated with the material being analyzed over its entire life cycle. The life-cycle flowchart pictorially represents the findings of this step, while the report further elaborates on the findings in textual and tabular formats.
2. IMPACT ASSESSMENT classifies the data from the inventory into categories that describe potential impacts on the environment and ecosystems, human health and welfare, energy use, and building operation.
3. IMPACT EVALUATION incorporates the values of stakeholders in determining the importance of the impact categories.
4. INTERPRETATION involves identifying opportunities for improving the life-cycle performance of materials at any point in the life cycle.

Although the material assessments in the ERG are prepared on a generic basis for categories of building materials (e.g., concrete, brick, steel, glass, etc.), the methodology can also be applied selectively to a proprietary product.

David Natella and Joel Ann Todd; The Scientific Consulting Group, Inc.; Gaithersburg, Maryland
 Chart reprinted from American Institute of Architects, *Environmental Resource Guide* (John Wiley & Sons, 1998)

PRIORITIES FOR SUSTAINABLE BUILDINGS

It is rarely possible to do everything we would like to reduce the environmental impact of building projects. It takes time to research alternative design and construction systems, new materials may lack proven track records, costs may be excessive, or clients may not be interested. Therefore, it makes sense to determine which efforts will do the most good.

Material selection is one of the most visible green building strategies and often the easiest to point to, but it is not usually the most important. Outlined on this page are other factors to consider and a list of priorities in green design.

A BASIS FOR ESTABLISHING PRIORITIES

To make objective decisions about which investments of time and money will contribute the most toward reducing environmental impact, consider several related factors:

1. The most significant environmental risks of the project: These may be global in nature or more specific to the region or site. Prioritizing them is difficult as they often are unrelated so cannot be compared directly.
2. How buildings contribute to these risks and how significantly the measures we adopt can help the situation.
3. The specific opportunities presented by each individual project: For some projects an architect can dramatically affect building performance in one area with little investment, while addressing other environmental impacts may prove very expensive and only minimally effective.
4. The available resources and agenda of the client: Often measures can be taken at no additional cost—some may even save money—to reduce environmental impacts. Other measures might increase the first cost of a building but save money over time.

All the measures listed on this page are important and should be implemented whenever feasible within the constraints of a particular project.

SAVE ENERGY

Design and build energy-efficient buildings. Ongoing energy use is the single greatest source of environmental impact from a building; thus, buildings designed for low energy use can have a significant effect on the environment. An integrated design approach takes advantage of energy savings that result from interaction between separate building elements (e.g., windows, lighting, and mechanical systems).

SAMPLE STRATEGIES

1. In buildings with skin-dominated energy loads, incorporate high levels of insulation and high-performance windows to make buildings as airtight as possible.
2. Minimize cooling loads through careful building design, glazing selection, lighting design, and landscaping.
3. Meet energy demand with renewable energy resources.
4. Install energy-efficient appliances, lighting, and mechanical equipment.

RECYCLE BUILDINGS

Reuse existing buildings and infrastructure instead of developing open space. Existing buildings often contain a wealth of material and cultural resources and contribute to a sense of place. As well, the workmanship and quality of materials that went into them is almost impossible to replicate today.

SAMPLE STRATEGIES

1. Maximize energy efficiency when restoring or renovating buildings.
2. Handle any hazardous materials appropriately (lead paint, asbestos, etc.).

CREATE COMMUNITY

Design communities to reduce dependence on the automobile and foster a sense of community. Address transportation as part of the effort to reduce environmental impacts. Even the most energy-efficient, state-of-the-art passive solar house will carry a big environmental burden if its occupants have to get in a car to commute 20 miles to work.

SAMPLE STRATEGIES

1. Design communities that provide access to public transit, pedestrian corridors, and bicycle paths.
2. Work to change zoning to permit mixed use development so homeowners can walk to the store or to work.
3. Plan home offices in houses to permit telecommuting.
4. Site buildings to enhance the public space around them and maximize pedestrian access.

Arkin Tilt Architects; Albany, California
 Environmental Building News; Brattleboro, Vermont
 Real Goods Solar Living Center; Hopland, California

REDUCE MATERIAL USE

Optimize design to make use of smaller spaces, and utilize materials efficiently. Smaller is better relative to the environment. For all materials, using less is almost always preferable, provided the durability or structural integrity of a building is not compromised. Reducing the surface area of a building reduces energy consumption. Reducing waste both helps the environment and reduces cost.

SAMPLE STRATEGIES

1. Reduce the building footprint and use space more efficiently.
2. Simplify building geometry to save energy and materials.
3. Design building dimensions to optimize material use and reduce waste.

PROTECT AND ENHANCE THE SITE

Preserve or restore local ecosystems and biodiversity. In fragile ecosystems or ecologically significant environments, such as old-growth forests or remnant stands of native prairie, this might be the highest priority.

SAMPLE STRATEGIES

1. Protect wetlands and other ecologically important areas on a parcel of land to be developed.
2. On land that has been ecologically damaged, work to reintroduce native species.
3. Protect trees and topsoil during construction.
4. Avoid pesticide use. Provide construction detailing that minimizes the need for pesticide treatments.
5. With on-site wastewater systems, provide responsible treatment to minimize groundwater pollution.

SELECT LOW IMPACT MATERIALS

Specify low environmental impact, resource-efficient materials. Most environmental impacts associated with building materials occur before installation. Raw materials have been extracted from the ground or harvested from forests, pollutants have been emitted during manufacture, and energy has been invested during production.

SAMPLE STRATEGIES

1. Avoid materials that generate a lot of pollution (VOCs, HFCs, etc.) during manufacture or use.
2. Specify materials with low embodied energy (energy used in resource extraction, manufacturing, and shipping).
3. Specify materials salvaged from other uses.
4. Avoid materials that unduly deplete limited natural resources.
5. Avoid materials made from toxic or hazardous constituents (benzene, arsenic, etc.).

MAXIMIZE LONGEVITY

Design for durability and adaptability. The longer a building lasts, the longer the period over which to amortize its environmental impacts. Designing and building a structure that will last a long time necessitates consideration of how the building can be modified to satisfy changing needs.

SUSTAINABLE BUILDING EXAMPLE—REAL GOODS SOLAR LIVING CENTER

SAMPLE STRATEGIES

1. Specify durable materials. This is usually even more important than selecting materials with low embodied energy.
2. Assemble the materials to prevent premature decay.
3. Design for easy maintenance and replacement of less durable components.
4. Design for adaptability, especially in commercial buildings.
5. Allocate an appropriate percentage of building funds for ongoing maintenance and improvement.

SAVE WATER

Design buildings and landscapes that use water efficiently. This is largely a regional issue. In some parts of the country, reducing water use is much higher on the priority list.

SAMPLE STRATEGIES

1. Install water-efficient plumbing fixtures and appliances.
2. Collect and use rainwater.
3. Provide low water use landscaping (xeriscaping).
4. Separate and use graywater for landscape irrigation where codes permit.
5. Provide for groundwater recharge through effective storm water infiltration designs.

MAKE THE BUILDING HEALTHY

Provide a safe, comfortable indoor environment. Although some people separate the indoor and outdoor environments, the two are integrally related and the health of its occupants should be ensured in any "sustainable" building.

SAMPLE STRATEGIES

1. Design air distribution systems for easy cleaning and maintenance.
2. Avoid mechanical equipment that could introduce combustion gases into the building.
3. Avoid materials with high rates of VOC off-gassing such as standard particleboard, some carpets and adhesives, and certain paints.
4. Control moisture to minimize mold and mildew.
5. Provide for continuous ventilation in all occupied buildings. In cold climates, heat recovery ventilation will reduce the energy penalty of ventilation.
6. Give occupants some control of their environment with features like operable windows, task lighting, and temperature controls.

MINIMIZE CONSTRUCTION AND DEMOLITION WASTE

Return, reuse, and recycle job site waste. For more and more materials, sorting and recycling job site waste pays off economically. It also can generate a good public image.

SAMPLE STRATEGIES

1. Sort construction and demolition waste for recycling.
2. Donate reusable materials to nonprofit or community groups that can use them to build or improve housing stock.

NOTE
Aluminum frame light shelves with insulated translucent fiberglass panels fold against the windows to increase insulation values and reflect light deep into the space.

LIGHT SHELF

PLAN DETAIL

SECTION

NOTE
Ventilated wall cavities effectively reduce unwanted heat buildup in extreme cooling climates. An inner membrane reflects solar gain from low afternoon sun and waterproofs.

VENTILATED WALL CAVITY

NOTE

A ventilated air cavity located over a perforated radiant barrier will carry heat from reflected radiation out of the building before it can migrate down through the insulation.

VENTILATED AIR CAVITY DETAIL AT ROOF

NOTE

The two basic methods of straw bale construction are load bearing (the bales carry the weight of the roof) and non-load bearing (typically a post-and-beam system). The illustration shows one of many accepted techniques.

Straw bale construction lends itself to a variety of styles and finishes. The raw material is the waste of another industry, cultivation of grain for food. Straw bale construction is a long-lasting durable building method. Homestead-

NOTE

Graywater systems can be used to "recycle" lavatory and shower water for subsurface plant irrigation.

GRAYWATER SYSTEM

Arkin Tilt Architects; Albany, California

STRAW BALE CONSTRUCTION SYSTEM

ers in the Great Plains started building with bales in the late 19th century, and many of these structures still stand today.

When laid flat and stacked like bricks in a "running bond" pattern, plastered or stuccoed straw bale walls are ±24 in. thick. They have an insulating value of as much as R-57, three times the value of typical insulated wood walls. These thick walls present opportunities for niches, deep window sills and seating areas, and "truth windows."

GENERAL

Indoor environmental quality (IEQ) refers to many complex elements and properties that affect the occupants of a building. A healthy indoor environment promotes the comfort, health, and well-being of the building's users. Unhealthy indoor environments can result in such health problems as headaches, burning and itching eyes, respiratory difficulties, skin irritation, nausea, and fatigue. Conditions associated with poor IAQ are

SICK BUILDING SYNDROME, a condition in which at least 20% of a building's occupants experience health or comfort problems that cannot be attributed to a specific illness but are clearly linked to time spent in the building;

BUILDING-RELATED ILLNESS, a condition with identifiable symptoms that can be traced to a specific building source (for example, Legionnaires' disease, caused by *legionella* bacteria, which may be found in cooling towers and room unit air conditioners);

MULTIPLE CHEMICAL SENSITIVITY, a condition in which a person is sensitive to a number of chemicals, even at very low concentrations.

FACTORS THAT AFFECT IAQ

HVAC DESIGN

1. The HVAC system can be a source of contaminants; for example, improperly drained condensate pans promote microbial growth.
2. The HVAC system can serve as a pathway for transporting contaminants into the indoor environment; for example, contaminated outside air may be introduced into the building through fresh air intakes.
3. The quantity of outside air should, at a minimum, meet the requirements of ASHRAE 62-1989. Many building codes, such as the Standard Building Code, have officially incorporated the ASHRAE standard by reference, making ventilation standards an enforceable regulation.
4. Negative pressurization of special-use areas, such as smoking lounges, toilets, and garages, in relation to adjacent areas can prevent migration of contaminated air.
5. Pollutants can be transported throughout the building via elevator shafts, crawl spaces, utility tunnels or chases, doors, operable windows, stairways, and party walls. Air movement can also occur through accidental openings such as cracks and holes. All of these pathways are influenced by the HVAC design.

BUILDING COMMISSIONING

1. A good building commissioning plan, based on ASHRAE Guideline 1-1989, organizes design, construction, operation, and maintenance efforts and also provides IAQ guidelines for managers and maintenance personnel.
2. A flush-out period allows off-gassing of building products to occur before the building is occupied. Use caution during the flush-out stage to prevent materials from acting as sinks (i.e., absorbing volatile organic compounds [VOCs] released from another material and later releasing those VOCs into the air).

CONSTRUCTION IN OCCUPIED BUILDINGS

1. Proper containment of the construction area generally includes shutting off the HVAC, blocking air grilles, installing a temporary exhaust system, and constructing temporary barriers.
2. Contaminants in the airstream can be reduced by using HEPA and activated charcoal filtration.

BUILDING MATERIALS AND EQUIPMENT

1. Release of VOCs from materials and equipment starts with installation and diminishes gradually. Use appropriate ventilation to prevent IAQ problems.
2. To analyze the impact of building materials on IAQ, evaluate the total VOCs within a space (taking into account that certain materials act as sinks for other materials), the volume of the space, duration of emissions, and the ventilation capacity of the HVAC system.

MOISTURE CONTROL

1. Damp, deteriorating materials provide a breeding ground for microbiological organisms and pests. Prevent water intrusion, which can occur through leaks and inadequate vapor retarders.
2. Contamination from moist areas can spread to other spaces via pollutant pathways.

OPERATIONS

1. Spatial changes that increase the occupant population, introduce more physical activity, increase equipment loads, rearrange workstations, or modify spaces to spe-

NOTES

1. Mineral wool fiber suspended ceiling tile should be installed in a well-ventilated area. Avoid breathing dust from the tile.
2. Install a return air diffuser within 10 ft of photocopy and fax machines and computer printers.

TRANSPORT OF CONTAMINANTS THROUGH HVAC PATHWAY

1. Special-use areas, such as smoking lounges, can contribute to IAQ problems.
2. Housekeeping and maintenance should include not only publicly visible areas but also mechanical rooms, crawl spaces, and above-ceiling areas used as air plenums. Special attention should be given to bathrooms, break rooms, and kitchens.
3. Material Safety Data Sheets (MSDSs) provide information on hazardous chemicals in specific cleaning compounds. Discourage use of products high in VOCs that would be used in large quantities, such as wax on hardwood floors. Cleaning products with strong odors or contaminants should be used after business hours, with additional ventilation. These products should be stored according to manufacturers' directions, in proper containers in a storage area maintained under negative pressure with local exhaust properly designed and maintained.

4. The EPA's Integrated Pest Management (IPM) program is geared to educational facilities but can be used for other types of facilities as well. The program uses a combination of methods, many of which are low-cost, aimed at eliminating conditions that attract pests. Caulk or seal cracks, crevices, and holes to prevent pests from entering the building. Architects may also specify that low-toxicity pesticides be applied to interior surfaces or wall cavities during construction.
5. Change HVAC filters regularly.

EQUIPMENT OPERATION AND MAINTENANCE

1. Copiers, computers, and laser printers emit VOCs during operation. If possible, isolate this equipment from building occupants by locating it in well-ventilated spaces with independent exhaust systems. Equipment should be turned off when not in use for long periods of time. Large copying or printing jobs may be scheduled for unoccupied times.
2. The chemicals used to maintain and clean this equipment may be additional sources of hazardous emissions.

HAZARDOUS SUBSTANCES

1. Asbestos fibers can be released from products and inhaled, causing lung illnesses. (See the page on Asbestos Abatement in this book for health effects and hazard control.)
2. Lead can be found in paint applied before 1978, in some water sources, and in some household products (vinyl mini-blinds, for example). The most significant health hazard associated with lead is neurological damage to children. Lead contamination is usually caused by ingesting lead-based paint chips or inhaling fine lead dust.

REGULATIONS

IAQ: At this time there are no federal regulations governing indoor air quality. More than twenty federal agencies are involved in policy-making efforts regarding IAQ.

ASBESTOS: OSHA and EPA regulations govern asbestos in buildings and asbestos during construction. EPA also has regulations governing disposal of asbestos. The Department of Transportation has regulations governing transportation of asbestos. Also, state and local regulations may be more stringent than federal.

LEAD: OSHA regulations govern exposure to lead during construction projects. EPA regulations govern certain lead-based paint activities and disposal of lead. DOT regulations may apply to transportation of waste classified as hazardous. State and local regulations may be more stringent than federal.

RADON: There are no current federal regulations regarding radon. The EPA has established guidelines, and some states have established regulations, most of which apply to residential construction.

RESOURCES

The following agencies and organizations provide materials on indoor air quality, asbestos, lead, radon, and health issues related to the indoor environment: U.S. Environmental Protection Agency (www.epa.gov); National Institute of Building Sciences (www.nibs.org); Department of Housing and Urban Development (www.hud.gov); American Lung Association (www.ala.org).

CONSULTANTS

Diagnosing and resolving IEQ issues require a methodical, interdisciplinary approach. Although some problems may be easily resolved, others require lengthy investigations and exhaustive measurements to identify sources and implement controls. A coordinated, comprehensive effort by a team of architects, mechanical engineers, and industrial hygienists is recommended as the most effective way to achieving a healthful indoor environment.

INTRODUCTION

Historic buildings are tangible evidence of the nation's history and culture. They add interest, identity, and variety to our streets and neighborhoods. At the same time, because of their age, methods of construction, materials, and finishes, they present special challenges to architects. Historic buildings frequently involve materials and systems that are difficult to evaluate in terms of their physical behavior, especially when applying modern standards and codes. Because historic buildings are essentially different from new buildings in these respects, it is important to remember that the approaches that would be taken in designing a new building generally do not apply to the preservation, rehabilitation, or restoration of a historic building.

UNDERSTANDING HISTORIC PRESERVATION OBJECTIVES

Almost any historic preservation project will involve a variety of work, which may include stabilization, repair, and partial or total replacement of deteriorated historic materials. Overall "preservation objectives" must be balanced against the client's needs for building alterations and additions, life safety, seismic code requirements, and a host of other real-life demands on the building program. When undertaking rehabilitation work on a historic building, there are two basic objectives: to preserve historic materials and to preserve the historic character. If these objectives are met, then the building will continue to convey its sense of history.

Historic materials are those materials used in construction (e.g., the wooden siding, the slate roof, or the terra-cotta cornice) of a building. Although every building has undergone repair, replacement, and alteration over the years, the purpose of any preservation project should be to retain as much as possible of the surviving historic materials in the course of treatment. By historic character we mean those tangible features of the building that help to distinguish it from other buildings. Aspects that give a historic building its individuality may include its overall form or shape, materials, craftsmanship details, interior spaces, and applied detailing. The historic character can be seriously affected by small changes; for example, applying a layer of paint to a historically unpainted building, replacing windows with new ones of different size and shape, or introducing a suspended ceiling within a tall room.

Each historic building is unique in its evolution, use, performance, and maintenance. Part of this uniqueness involves the changes to the building in its past, to its finishes, form, or floor plan. The architect should remember that changes that may have occurred in the past frequently have acquired historic value or possess architectural significance in their own right, just as the new work on historic buildings may acquire some historic significance in the future. A building is not fixed in time at the date of its construction but represents a continuity of history.

Many historic buildings are rehabilitated for new uses. If the primary objective is to preserve the historic building while accommodating new needs, the architect must first understand the building and the character of its materials, features, and spaces. The challenge is to make both the historic building and new uses work together. The federal government's Standards for Rehabilitation, from the Secretary of the Interior's Standards for the Treatment of Historic Properties, rev. 1992, provides a framework to guide work on historic buildings when repairs, alterations, and additions are planned for a continued or new use. (It should be noted that there are separate Standards for Preservation, Restoration, and Reconstruction.) The ten rehabilitation standards are general principles that present a balance between preserving the historic character and making respectful changes in order to accommodate continuing or new uses; the guidelines present recommended treatments and approaches that help meet the Standards and also explain the consequences of undertaking irresponsible work. The Guidelines are organized in broad categories such as materials (masonry, wood and architectural metals); roofs; windows; storefronts; structural systems; interior spaces, features, and finishes; and mechanical systems.

The Standards and Guidelines form the basis for the following historic preservation section in Architectural Graphic Standards. The guidance recommends the identification of character-defining spaces, features, materials, and finishes as a first step in the rehabilitation process and suggests a hierarchy in selecting appropriate work, from minor actions such as maintenance and repair of historic materials to major actions such as the replacement of deteriorated and missing features and design for new additions. Considering the unknown conditions that will be encountered during the progress of any work on historic buildings, frequent reference to the Standards and Guidelines is recommended when planning and executing a project.

19 INTRODUCTION

UNDERSTANDING THE HISTORIC BUILDING AS A SYSTEM

The architect should remember that building materials are not inert and that they have many other properties than their compressive or tensile strength. The architect should never look at the materials in isolation, but as part of the historic building system. Such systems will react to changes in the environment, and the materials are frequently chemically active. Both the systems and the materials will react to almost any human intervention. For example, applying a chemical coating to the exterior walls of a building is a treatment that could affect the transmission of moisture and vapor through the walls.

COMMON REHABILITATION PROJECT PROBLEMS

The following is a list of problem areas that frequently arise in rehabilitation projects which should be investigated and considered in advance. A historic preservation specialist may be required to address some of these problem areas.

1. **Moisture problems:** Perhaps the single most pervasive problem of existing buildings is the penetration of moisture both from within and without. Without understanding the cause (rather than the symptoms) of this problem, it is difficult to select a remedial solution. Many high-tech products (coatings, water repellents) may cause more harm than good. To reduce moisture problems, buildings should be made weathertight (e.g., install proper gutters and downspouts, repair roof, repaint cracks, provide proper surface grading).
2. **Hard-to-find crafts:** Stonecutters, wood-carvers, slaters, stencilers, wood turners, parquet floor layers, ornamental plasterers, gilders, grainers, and marblers provide custom art and craft services, generally for large-scale restoration and rehabilitation projects. The architect should provide a sample or prototype of the specific effect desired to the craftsman in order to establish preservation objectives and work quality. The sample may be an isolated artifact, may be in place on the historic building, or may even be on another building.
3. **Hard-to-find replacement materials:** Careful, long-range planning may be required to obtain special materials such as decorative terra cotta or certain brownstones, sandstones, and marbles. Some metal components may be difficult to repair or fabricate, especially deteriorated ornamental sheet metal cornices, window hoods, roof cresting, and certain ornamental metal shingles.
4. **Energy conservation:** Improving the energy performance of historic buildings is a generally desirable goal, but some energy-conserving features, such as tinted glazing, can alter the historic appearance of the building. Any energy conservation treatments that will visually or physically alter the building's historic features should be carefully evaluated. Furring out the inside surface of exterior walls for insulation will require that paneling and trim be carefully removed and reapplied, otherwise the extra thickness of the insulation and wall finish will change the architectural relationships between openings, wall surfaces, and trim.
5. **The unintended impact of new technology:** Problems can result from the indiscriminate application of modern architectural practices to historic buildings. The introduction of high-strength portland cements, elastomeric compounds, water repellents, or epoxy coatings may create a host of secondary problems not anticipated by the architect; these problems may result from using standardized specifications.

FOR THE RECORD

Working on a historic building is both a challenge and an opportunity. If the building is significant, the architect has a responsibility not only to preserve it but to leave a record for the future. Such a record should include a summary of the research; measured drawings of the building before rehabilitation; information discovered during work on the building; and documentation of the work as planned and as carried out. Measured drawings should follow the Standards for Architectural and Engineering Documentation, 1983, developed by the Historic American Buildings Survey/Historic American Engineering Record of the National Park Service.

THE SECRETARY OF THE INTERIOR'S STANDARDS FOR THE TREATMENT OF HISTORIC PROPERTIES (REV. 1992)

STANDARDS FOR REHABILITATION

1. A property shall be used as it was historically or be given a new use that requires minimal change to its distinctive materials, features, spaces, and spatial relationships.
2. The historic character of a property shall be retained and preserved. The removal of distinctive materials or alteration of features, spaces, and spatial relationships that characterize a property shall be avoided.
3. Each property shall be recognized as a physical record of its time, place, and use. Changes that create a false sense of historical development, such as adding conjectural features or elements from other historic properties, shall not be undertaken.
4. Changes to a property that have acquired historic significance in their own right shall be retained and preserved.
5. Distinctive materials, features, finishes, and construction techniques or examples of craftsmanship that characterize a property shall be preserved.
6. Deteriorated historic features shall be repaired rather than replaced. Where the severity of deterioration requires replacement of a distinctive feature, the new feature shall match the old design, color, texture, and, where possible, materials. Replacement of missing features shall be substantiated by documentary and physical evidence.
7. Chemical or physical treatments, if appropriate, shall be undertaken using the gentlest means possible. Treatments that cause damage to historic materials shall not be used.
8. Archeological resources shall be protected and preserved in place. If such resources must be disturbed, mitigation measures shall be undertaken.
9. New additions, exterior alterations, or related new construction shall not destroy historic materials, features, and spatial relationships that characterize the property. The new work shall be differentiated from the old and shall be compatible with the historic materials, features, size, scale and proportion, and massing to protect the integrity of the property and its environment.
10. New additions and adjacent or related new construction shall be undertaken in such a manner that, if removed in the future, the essential form and integrity of the historic property and its environment would be unimpaired.

INTRODUCTION

This checklist indicates the range of preservation factors that should be considered when rehabilitating historic buildings. It is not exhaustive, and some factors will not apply to all structures or preservation projects.

CHECK HISTORIC PRESERVATION DESIGNATION AND AVAILABLE DOCUMENTATION

Is your building a local landmark or located in a locally designated historic district? Is it in a historic district listed in the National Register of Historic Places? Does it contribute to the historic significance of the district?

What historical or architectural documentation is available about the building(s) or site? For example:

- National Register nominations
- recorded by Historic American Buildings Survey/Historic American Engineering Record
- state or local historical survey or inventory
- local documents, views, photographs in libraries, archives, historical societies

CHECK LEGAL REQUIREMENTS

Are there easements or local ordinances governing alterations to the property (deed records, zoning offices)?

Depending on the current or anticipated use, how does the 1990 Americans with Disabilities Act, a federal civil rights law, apply to your historic building?

How do state and local building codes apply to your historic building? What effect will they have upon its character and integrity? Are code variances available? Are there code equivalency possibilities for your particular building?

Will there be federal funds involved in the project, which will require review by the State Historic Preservation Office and consultation with the Advisory Council on Historic Preservation? Will federal investment tax credits be used? If so, are you familiar with the Secretary of the Interior's Standards for Rehabilitation and Guidelines for Rehabilitating Historic Buildings as well as the National Park Service certification procedures in Chapter 1, Title 36 of the Code of Federal Regulations, Part 67? Have you obtained a copy of the Historic Preservation Certification Application form from the State Historic Preservation Office?

Note that for federal investment tax credits, the Secretary's Standards (36 CFR 67) take precedence over local requirements.

EVALUATE HISTORIC CHARACTER AND SIGNIFICANCE OF STRUCTURE

Have you identified, listed, and prioritized the character defining aspects of the building? These may include its form, materials, workmanship, features, color, and spatial relationships, that is, those tangible aspects of the building that define its historic character.

Usually, original materials and features are central to the building's historical significance; sometimes, however, an original feature may not be as important as the changes that have been made to it over time. For example, if a brick building was painted at an early date, its painted appearance may be an important aspect of its historic character.

What is the original configuration of the building? What architectural changes have been made over time? Changes may include

- additions such as a porch, wing, or upper story.
- changes to surfaces and finishes (unpainted to painted, slates to asphalt, polychrome to monochrome).
- blocking of windows, removal of shutters.
- changes to grade.
- change to a cornice; loss of stairs or steps.
- false fronts.
- changes to basic plan (single family to multiple family).

Most buildings change over time with different occupancies and uses. These changes are an integral part of the building's historic character and should be evaluated very carefully prior to work.

Has the architectural integrity of the building been assessed? Architectural integrity means the intactness of the building as an architectural system (its plan, features, materials, finishes, structural system, and the presence of architectural features).

ASSESS PHYSICAL CONDITION

Are there gross physical problems that threaten the building's architectural and structural integrity?

Has a structural survey been performed to determine deficiencies due to settlement, deflection of beams, seismic inadequacy, and cuts through structural members for mechanical pipes and ducts?

Is there inherent materials damage, such as materials failure due to poor original design, poor original materials, severe environmental or moisture problems, neglect, improper maintenance, etc.?

Is there man-inflicted damage, such as ornamentation removed, inappropriate coatings, bad repointing or cleaning, insensitive additions, or partitioning of significant interior spaces? Are historic features hidden behind later alterations? These may include ornamental ceilings or cornices hidden above dropped ceilings.

What aspects of the Americans with Disabilities Act apply to your rehabilitation project? Are there accessible public entrances? Is there proper signage?

DEVELOP PRESERVATION PROJECT PLANS

Will it be necessary to write unique specifications rather than use standard specifications for work performed on a historic building?

Will testing be needed to determine the performance of the materials or the systems? Note that it may be necessary to review test results with consultants or laboratories.

Will the project involve hard-to-find replacement materials such as terra-cotta or ornamental metals that may require critical path logistical planning?

Will the project require hard-to-find crafts such as stone carving or ornamental plastering? If so, can the necessary expertise be found?

Can samples or models be made available to establish the standard of craftsmanship for the project?

Will the project involve energy conservation measures? Have measures been chosen that retain historic materials and finishes to the maximum extent possible?

Will new uses require upgrading the live loading capacity of wooden floor joists? How do the preservation objectives affect the decision-making? For instance, it is better to double up existing joists with a parallel member than to remove historic materials, and if an ornamental ceiling would be damaged by this approach, a structural engineer should investigate other alternatives.

Are new additions and adjacent new construction sympathetic to the historic building, site, or district? Minimize adverse effects by maintaining the scale, shape, materials, and detailing of the adjacent historic structures.

What protective measures will be taken to preserve important character-defining features and finishes during the construction work?

Will the project involve making bathrooms and amenities accessible to persons with disabilities? Have options been studied to achieve access without threatening or destroying significant interior spaces, features, and finishes?

Will rehabilitation work on the building result in the loss of distinctive historic fabric or seriously damage the historic character? Loss of historic fabric or change of historic character can occur on the exterior when

- storefronts are altered.
- visible skylights are added on top of an existing building.
- new dormers are added on prominent roofs.
- whole new floors are added on top of an existing building.
- porches are enclosed.
- new window openings are created.
- tinted films or reflective coatings are added to windows.
- new window sash are historically inappropriate in configuration and detailing.

Loss of fabric or change of character often occurs on the interior when

- interiors are partitioned and significant sequences of spaces are lost.
- plaster is removed to expose brickwork.
- interiors are gutted to reconfigure spaces, insert new floor levels, or create new atria.
- significant stairs are removed or altered.

Will there be a professional on site during construction to ensure work is carried out according to established preservation principles?

Have construction personnel received adequate training in undertaking historic preservation work?

SOURCES OF TECHNICAL PRESERVATION INFORMATION

PRESERVATION ASSISTANCE DIVISION

National Park Service
P.O. Box 37127
Washington, DC 20013-7127

The Preservation Assistance Division has developed numerous technical publications on preserving and rehabilitating historic buildings. These publications are available from the Superintendent of Documents, Government Printing Office, Washington, DC 20402. Write to the Preservation Assistance Division at the above address for a free copy of the current Catalog of Historic Preservation Publications, which includes stock numbers and prices. Free leaflets are also available on the preservation of historic landscapes and accessibility to historic buildings. "America's Landscape Legacy" defines designed and vernacular landscapes, and includes a selected bibliography and listing of professional contacts. "Preserving the Past and Making it Accessible for People with Disabilities" explains accessibility and preservation requirements, describes the administrative process in meeting both, and suggests organizations and officials to contact for further information.

STONE AND BRICK

STONE, RUBBLE AND TERRA-COTTA

MASONRY - TYPICAL LOAD-BEARING WALL SECTIONS

Lee H. Nelson, FAIA, H. Ward Jandl, Anne Grimmer, Kay D. Weeks; Preservation Assistance Division, National Park Service; Washington, D.C.
Eric J. Gastier; Darrel Downing Rippeteau Architects, PC, Washington, D.C.

INTRODUCTION

The function of masonry units such as brick or stone is related to the thickness of a wall, the mortar, the bond, and the quality of workmanship. The relationship of all these materials determines the historic building's structural soundness as well as its appearance. While masonry is among the most durable of historic building materials, it is also the most susceptible to damage by improper maintenance or repair techniques and harsh or abrasive cleaning methods.

Stone is one of the more lasting of masonry building materials and has been used throughout the history of American building construction. In the 17th and 18th centuries, stone was often used only for decorative details, trimwork, foundations, and chimneys on brick buildings. Where stone was plentiful, however, it was used to construct even simple houses and outbuildings. Stonework on most buildings was roughly finished, but more elaborate stone structures often featured finely tooled or carved decorative surfaces. The kinds of stone most commonly encountered on historic buildings in the U.S. include various types of sandstone, limestone, marble, granite, slate, and fieldstone.

Brick varied considerably in size and quality. Before 1870, brick clays were pressed into molds and were often unevenly fired. The quality of brick depended on the type of clay available and the brick-making techniques; by the 1870s—with the perfection of an extrusion process—bricks became more uniform and durable.

Terra-cotta is also a kiln-dried clay product popular from the late 19th century until the 1930s. Brownstone terra-cotta was the earliest type used throughout the last half of the 19th century. It was hollow cast, glazed or unglazed, and was generally used in conjunction with brick to imitate brownstone. Fireproof terra-cotta was developed for use in high-rise buildings. Inexpensive, lightweight, and fireproof, these rough-finished hollow building blocks were well suited to span I-beams in floor, wall, and ceiling construction. Glazed architectural terra-cotta consists of hollow units hand cast in molds or carved in clay and heavily glazed and fired. The development of the steel-frame office building in the early 20th century and the eclectic taste of the time contributed to the widespread use of architectural terra-cotta.

Adobe, which consists of sun-dried earthen bricks, was one of the earliest permanent building materials used in the U.S., primarily in the Southwest where it is still a popular building material.

Mortar is used to bond together masonry units. Historic mortar was generally quite soft and consisted primarily of lime, sand, and other additives such as crushed oyster shells, partially burned lime, animal hair, particles of clay, or pigments to color the mortar to match or contrast with the masonry units. While natural cement was included in some mortars beginning in the early 19th century, most historic mortar did not contain portland cement until after 1880 when it was used in combination with the newly available, harder extruded bricks, which required a more rigid and nonabsorbing mortar.

Traditional stucco, sometimes referred to as plaster, was also heavily lime based and had much the same composition as historic mortar, with regional variations that reflected the availability of certain materials. Like mortar, the composition of stucco increased in hardness with the addition of portland cement toward the end of the 19th century. In the 18th and 19th centuries, stucco was often scored to resemble cut stone and was used as a finish coat directly over stone, brick, or log construction. In the early 20th century, stucco took on significance as a building material in its own right and was applied (often with a decorative textured finish) directly over wood or metal lath attached to the building's structural framework.

Concrete has a long history, being variously made of tabby, volcanic ash, and later of natural hydraulic cements; the latter was first given limited use in the early 19th century in some mortars before the introduction of portland cement in the 1870s. From that time on, concrete has been used in its precast form for structural blocks or "cast stone" to simulate entire stone facades or smaller architectural details. In the 20th century, this has further evolved into precast structural elements.

PRESERVATION APPROACHES

Masonry features that are important in defining the overall historic character of the building include walls, brackets, railings, cornices, window architraves, door pediments, steps, and columns, with tooling and bonding patterns, coatings, color, and joint details.

Making inappropriate visual changes to historic masonry surfaces in the process of rehabilitation, such as applying paint or other coatings to masonry that has been historically unpainted, can easily change the entire character of the building. Similarly, paint should not be removed from historically painted masonry.

The various causes of mortar joint deterioration (such as leaking roofs or gutters, differential settlement of the building, capillary action, or extreme weather exposure) should be identified before selecting an appropriate remedial treatment.

Masonry should only be cleaned in order to halt deterioration or to remove heavy soiling. Cleaning masonry surfaces when they are not heavily soiled in order to create a new appearance can needlessly introduce chemicals or moisture into historic materials. If it is determined that cleaning is appropriate, tests should be conducted prior to cleaning and observed over a sufficient period of time so that both the immediate effects and the long-range effects are known.

Brick or stone surfaces should be cleaned with the gentlest method possible, such as water and detergents, using natural bristle brushes. They should never be sandblasted using dry or wet grit or other abrasives. These methods of cleaning permanently erode the surface of the material. Cleaning methods involving water or liquid chemical solutions should not be used when there is any possibility of freezing temperatures, and chemical products should never be used that will damage masonry, such as using acid on limestone or marble.

If repainting of historically painted masonry is necessary, the damaged paint should be removed to the next sound layer using the gentlest method possible prior to repainting. Colors should be used that are historically appropriate to the building and district.

Masonry walls and other masonry features should be repaired whenever there is evidence of deterioration. This may include disintegrating mortar, loose bricks, damp walls, or damaged plasterwork.

In preparation for repointing, deteriorated mortar should be removed by carefully hand-raking the joints to avoid damaging the masonry. Never use electric saws.

Old mortar should be duplicated in strength, composition, color, and texture. Repointing with mortar of high portland cement content can create a bond that is stronger than the historic material, damaging historic masonry as a result of the differing coefficient of expansion and the differing porosity of the material and the mortar.

When repointing, the use of traditional materials and caulking is strongly recommended rather than synthetic caulking compounds and "scrub" coating techniques. Old mortar joints should be duplicated in width and in joint profile.

Stucco should be repaired by removing only the damaged material and patching with new stucco that duplicates the old in strength, composition, color, and texture. Mud plaster should be used as a surface coating over unfired, unstabilized adobe, in order to bond to the adobe. Cement stucco, on the other hand, will not bond properly, enabling moisture to become entrapped between materials. Concrete may be repaired by cutting the deteriorated portion back to a sound surface, then removing the source of deterioration—often corrosion on metal reinforcement bars—by sandblasting or chemical cleaning of the re-bars. The new concrete patch must be applied carefully so it will bond satisfactorily with, and match, the historic concrete.

Masonry features may be repaired by patching, piecing in, or consolidating the masonry using recognized preservation methods. Repair may also include the limited replacement in kind of those extensively deteriorated or missing parts of masonry features such as terra-cotta brackets or stone balusters when there are surviving prototypes.

A masonry feature that is too deteriorated or damaged to repair should be replaced in kind whenever possible. If the historic form and detailing are still evident, they should be used as a model to reproduce the feature.

If a masonry feature is completely missing and there is sufficient historical, pictorial, and physical documentation, the missing feature should be accurately reproduced. In the absence of documentation, the replacement masonry feature may be a new design that is compatible with the size, scale, and color of the historic building.

Finally, for both repair and replacement treatments, using the same kind of material is always preferred; however, if this is not technically or economically feasible, a compatible substitute material with the same visual and physical qualities may be considered.

INTRODUCTION

Wood has played a central role in American building during every period and in every style. Because it can be easily shaped by sawing, planing, carving, and gouging, wood is used for architectural features such as clapboards, cornices, brackets, entablatures, shutters, columns, and balustrades. These features may be important in defining the building's historic character and thus their retention, protection, and repair are important in rehabilitation projects.

PRESERVATION APPROACHES

While loss of some exterior wood to weathering is inevitable, taking steps to maximize its retention should be an integral part of any work on a historic building. Radical changes to the historic appearance of wood surfaces should be avoided, such as changing the type of finish or its color, or stripping historically painted surfaces to bare wood, then applying clear finishes or stains in order to create a "natural" look. Special finishes, such as marbling or graining, are evidence of individual craftsmanship and should be preserved. The causes of wood deterioration should be identified and corrected, such as faulty flashing, leaking gutters, cracks and holes in siding, deteriorated caulking, or insect or fungus infestation.

Painted wood surfaces should be inspected to determine whether repainting is necessary or if cleaning is all that is required. Paint should not be removed that is firmly adhering to and, thus, protecting wood surfaces. If surfaces need painting, deteriorated paint should only be removed to the next sound layer, using the gentlest method possible (hand scraping/sanding).

Precautions need to be taken when removing lead-based paint. Personal protective gear should be worn, and the environment should be protected from lead-laden dust and debris. All toxic residue should be disposed of in compliance with applicable laws.

It is never appropriate to use destructive paint removal methods such as propane or butane torches, sandblasting, or waterblasting. These methods can irreversibly damage woodwork and could penetrate through to damage interior fabric. Electric hot-air guns may be used effectively on decorative wood features and electric heat plates on flat wood surfaces when paint is so deteriorated that total removal is necessary.

Wood features can be repaired by patching, consolidating, or otherwise reinforcing the wood using recognized preservation methods. A wood feature too deteriorated to repair should be replaced in kind whenever possible. If the historic form and detailing are still evident, they should be used to restore the feature. If a wood feature is missing and there is sufficient historical, pictorial, and physical documentation, the missing feature should be restored. Replacing a deteriorated or missing wood feature based on insufficient documentation can create a false historic appearance and can have a more significant negative impact on the historic character than not replacing the feature at all. For both repair and replacement, using the same kind of material is always preferred. If this is not feasible, a compatible substitute material may be used if it conveys the same historic appearance as wood and is physically and chemically compatible.

INTRODUCTION

Architectural metal features—such as cast-iron facades, porches, and steps; sheet metal cornices, siding, roofs, roof cresting, and storefronts; and cast or rolled metal doors, window sash, entablatures, and hardware—are often highly decorative and may be important in defining the overall historic character of the building.

Metals commonly used in historic American building construction include lead, tin, zinc, copper, bronze, brass, iron, steel, and, to a lesser extent, nickel alloys, stainless steel, and aluminum. A high degree of craftsmanship went into fabrication of the metals in older American buildings. Often it was local artisans who designed and built fine staircases, exterior light standards, railings, or metal sculptures.

PRESERVATION APPROACHES

Before beginning any preservation work on metal features, it is critical that the metal be correctly identified; different metals have unique properties and thus require distinct preservation treatments. Inappropriate treatments to metal features can inadvertently result in their damage or loss.

Changes to architectural metal finishes can result in changing the historic character of a building.

Protecting architectural metals from corrosion should be the focus of a cyclical maintenance program. Proper drainage should be provided so that water does not stand on flat, horizontal surfaces or accumulate in curved, decorative features.

Incompatible metals should never be placed together without a reliable separation material or galvanic corrosion of the less noble metal will occur; e.g., copper corrodes cast iron, steel, tin, and aluminum.

Architectural metals should be carefully cleaned with the gentlest method possible to remove corrosion prior to repainting or applying other appropriate protective coatings. Local codes should also be checked to ensure compliance with environmental safety requirements. For some metals, such as bronze or copper, the surface coating or patina may serve as a protective coating and should not be removed. Soft metals such as lead, tin, copper, terneplate, and zinc should be cleaned with appropriate chemical methods because their finishes can be abraded by blasting methods, such as grit blasting.

The paint used to protect historic metal surfaces often contains lead. Care should be taken if lead-based paints are removed. Workers should wear protective gear, and lead-laden dust and other debris should not be introduced into the air. Any toxic residue that has been removed should be disposed of in compliance with local, state, and federal laws.

Harder metals, such as cast iron, wrought iron, and steel, may be hand scraped and wire-brushed to remove paint buildup and corrosion. If these methods prove ineffective, low-pressure grit blasting may be appropriate if the surface is not damaged or abraded. Adjacent wood or masonry should be protected from all cleaning efforts.

Applying appropriate paint or other coating systems immediately after cleaning decreases the corrosion rate of metals or alloys. If an architectural metal is being repainted, the colors should be appropriate to the historic building or district.

Architectural metal features can often be repaired by patching, splicing, or otherwise reinforcing the metal following recognized preservation methods. Repairs also involve the limited replacement in kind of those extensively deteriorated or missing parts of features when there are surviving prototypes. Examples are porch railings or roof cresting. An architectural metal feature that is too deteriorated to repair should be replaced in kind whenever possible. If the historic form and detailing are still evident, they can be used to guide the new work.

If an architectural metal feature is completely missing and there is sufficient historical, pictorial, and physical documentation, the missing features should be accurately restored. In the absence of sufficient documentation, the replacement metal feature may be a new design that is compatible with the size, scale, material, and color of the historic building.

Finally, for both repair and replacement treatments, using the same kind of metal is always preferred. If this is not feasible, a compatible substitute material may be used if it conveys the same visual appearance as the historic material and is chemically and physically compatible.

INTRODUCTION

The roof—with its shape; features such as cresting, dormers, cupolas, and chimneys; and the size, color, and patterning of the roofing material—is an important design element of many historic buildings. In addition a weathertight roof is essential to the long-term preservation of the entire structure.

Historic roofing is in large measure a reflection of available materials, levels of construction technology, the weather, and cost. For example, throughout the country in all periods of history, wood shingles have been used—their size, shape, and detailing differing according to regional craft practices. European settlers used clay tile for roofing as early as the mid-17th century. In some cities, such as New York and Boston, clay was popularly used as a precaution against fire. The Spanish influence in the use of clay tiles is found in the southern, southwestern, and western states. In the mid-19th century, tile roofs were often replaced by sheet-metal roofs, which were lighter and easier to install and maintain. Another practice settlers brought to the New World was slate roofing, and evidence of its use dates from the mid-17th century. Slate has been popular for its durability, fireproof qualities, and its decorative applications. The use of metals for roofing and roof features dates from the 18th century and includes the use of sheet iron, corrugated iron, galvanized metal, tinplate, and zinc. Awareness of these and other traditions of roofing materials and their detailing will contribute to more sensitive treatments.

PRESERVATION APPROACHES

The configuration of a historic building can be radically changed by adding new features to the roof, such as dormer windows, vents, skylights, or mechanical and service equipment. Adding an additional floor or floors at the roofline is possibly the most difficult rehabilitation change to accomplish without dramatically changing the historic character of the building. For this reason, the roof's shape, size, color, and patterning should be retained in any preservation project.

Routine maintenance of the building includes cleaning of gutters and downspouts and replacing deteriorated flashing. Roof sheathing should also be checked for proper venting to prevent moisture condensation and water penetration and to ensure that materials are free from insect infestation. When water and debris are permitted to collect, damage may occur to roof fasteners, sheathing, and the underlying structure.

In certain cases, such as storm or fire damage, only portions of a roof or a damaged roofing feature will need repair. The repaired area should match the visual qualities of the historic roof. Some repairs involve less difficulty than others. Normally, individual slates can be replaced without major disruption to the rest of the roof; replacing flashing, on the other hand, can require substantial removal of surrounding materials. If it is the substrate or a support material that has deteriorated, many of the more durable surface materials such as slate or tile can be reused if handled carefully during the repair.

A roof feature that is too deteriorated to repair should be replaced in kind, whenever possible. With some exceptions, most historic roofing materials are available today. Manufacturers of more common roofing materials can usually fill orders for less frequently requested items, such as unusual tile or embossed metal shingles.

For both repair and replacement of historic roofing, compatible substitute materials may be considered if the same kind of material is technically or economically infeasible; however, the substitute material needs to convey the same visual appearance and be physically and chemically compatible with the surrounding materials.

INTRODUCTION

As one of the few parts of a building serving both as an interior and exterior feature, windows are nearly always an important part of the historic character of a building. In most buildings, windows also comprise a considerable amount of the historic fabric of the wall plane and thus are deserving of special consideration. It is essential that the historic character of the windows be assessed together with their physical condition before specific repair or replacement work is undertaken. Emphasis should be placed on repairing existing windows, where possible, and improving their performance, such as with retrofitting weatherstripping to reduce air infiltration. Replacement windows should closely match the historic ones.

PRESERVATION APPROACHES

Technology and prevailing architectural styles have shaped the history of windows in the United States, starting in the 17th century with wooden casement windows with tiny glass panes seated in lead cames. From the transitional single-hung sash in the early 1700s to the true double-hung sash later in the same century,

VENETIAN WINDOW FROM THE OLD STATE HOUSE DOVER, DE (MCCUNE ASSOCIATES, RESTORATION ARCHITECTS)

these early wooden windows were characterized by small panes, wide muntins, and the way in which decorative trim was used on both the exterior and interior of the window. As the sash thickness increased by the turn of the 19th century, muntins narrowed in width but increased in thickness according to the size of the window and design practices. Regional traditions continued to have an impact on window design, such as with the long-term use of "French windows" in the deep South. By the mid-19th century, two-over-two lights were common; the manufacturing of plate glass in the United States by the late 19th century allowed for dramatic use of large sheets of glass in commercial and office buildings. With mass-produced windows, mail order distribution, and changing architectural styles, it was possible to obtain a wide range of window designs and light patterns in sash. Popular versions of Arts and Crafts houses constructed in the early 20th century frequently utilized smaller lights in the upper sash set in groups or pairs and saw the reemergence of casement windows. In the early 20th century, the desire for fireproof building construction in dense urban areas contributed to the growth of a thriving steel window industry along with a market for hollow metal and metal clad wooden windows.

PRESERVATION APPROACHES

An in-depth survey of the condition of existing windows should be undertaken early in the planning of a rehabilitation to allow time to fully explore repair and upgrading methods and possible replacement options, if merited. Peeling paint, broken glass, stuck sash, and high air infiltration are no indication that existing windows are beyond repair and that their performance cannot be enhanced.

The wood and architectural metal which comprise the window frame, sash, muntins, and surrounds should be maintained through appropriate surface treatments such as cleaning, rust removal, limited paint removal, reapplication of protective coating systems, and reglazing where necessary.

Windows should be made weathertight by recaulking and replacing or installing weatherstripping. These actions also improve thermal efficiency. Retrofitting or replacing windows should never be a substitute for proper maintenance of the sash, frame, and glazing.

Window frames and sash can be repaired by patching, splicing, consolidating, or otherwise reinforcing historic materials.

Window repair can include replacement of deteriorated components such as sash cords, muntins, and sills.

Serviceable window hardware such as brass lifts and

sash locks can be reused in the course of repairs and should not be discarded in favor of new hardware.

Thermal efficiency can be improved with weatherstripping, storm windows, caulking, interior shades, and, if historically appropriate, blinds and awnings. Replacing historic multipaned sash with new thermal sash is inappropriate when the historic sash are in repairable condition.

Interior storm windows should have airtight gaskets, ventilating holes, and/or removable clips or operability features to ensure proper maintenance and to avoid potential condensation damage to historic windows.

Exterior storm windows should be selected that do not damage or obscure the windows and frames. It is not appropriate to install new exterior storm windows that are inappropriate in size and are not painted the same color as the sash trim.

Tinted or reflective glazing should never be used on character-defining or other conspicuous elevations. Lightly tinted glazing could be used on non-character-defining elevations if other energy retrofitting alternatives are not possible and after conclusively establishing a need for such a treatment.

A historic window that is too deteriorated to repair should in most cases be replaced in kind, that is, using the same kind of material (wood for wood; steel for steel) and

using the same sash and pane configuration and other design details.

In some cases, the historic windows (frame, sash, and glazing) may be completely missing. The preferred option for replacement is always an accurate restoration using historical, pictorial, and physical documentation.

Where fixed windows are being installed, the glass and frames should be set in the same planes as the historic sash, with all detailing duplicated.

When replacing historic multipaned sash with new sash, true integral muntins should be utilized, particularly on smaller buildings, windows on large buildings close to the pedestrianway, on ornate windows, where windows are part of a significant interior space, and where a building has high historic merit.

On certain types of large buildings, particularly high-rises, aluminum windows may be a suitable replacement for historic wooden sash provided wooden replacements are not practical and the design detail of the historic windows can be matched. Historic color duplication, custom contour panning, incorporation of 3/8 in. deep trapezoidal exterior muntin grids where applicable, retention of the same glass-to-frame ratio, matching of the historic reveal, and duplication of the frame width, depth, and such existing decorative details as arched tops should all be components in aluminum replacement windows selected for use on historic buildings.

LATE 19TH CENTURY MILL WINDOW

REPAIR WHENEVER POSSIBLE. IN SOME CASES, REPLACEMENT OF SASH AND REUSE OF FRAMES AND HARDWARE MAY BE POSSIBLE.

WOOD REPLACEMENT WINDOW

APPROPRIATE WHEN HISTORIC WINDOW IS BEYOND REPAIR. IN MANY CASES, PIGGYBACK INTERIOR STORM PANELS ATTACHED TO NEW SASH AND/OR INTERIOR MOUNTED INSECT SCREENS ARE SUITABLE UPGRADED FEATURES. EXTERIOR APPEARANCE OF HISTORIC WINDOW SHOULD BE RETAINED.

ALUMINUM REPLACEMENT WINDOW (CUSTOM)

APPROPRIATE IN SOME CASES, PARTICULARLY IN EARLY 20TH CENTURY HIGH-RISES. SPECIAL FEATURES TO BE SPECIFIED: BEVELED RAIL AND STILE EDGES, CUSTOM CONTOUR PANNING, CUSTOM COLOR, TRAPEZOIDAL EXTERIOR MUNTIN GRID, AND CLOSELY MATCHED SIGHT LINES.

REPAIR/REPLACEMENT STRATEGIES FOR HISTORIC WOOD WINDOWS

Eric J. Gastier; Darrel Downing Rippeteau Architects, PC, Washington, D.C.

ACCESSIBLE ENTRANCE DESIGN

Providing entrances that are accessible to everyone requires a balance between historic preservation goals and the special needs of persons with disabilities. Careful planning is required to achieve solutions that provide the highest level of access with the fewest level of impact to character-defining materials and features. Each building should thus be evaluated to determine the best design and best placement of accessibility features. Solutions on a primary facade may range from a minimal threshold wedge to a small ramp to much longer ramps, inclines, and grade changes. Designing a ramp that does not exceed 1 in. of rise for every 12 in. of run and is as unobtrusive as possible are dual preservation goals. (It should be noted that regrading to 1 in. of rise for 20 in. of run eliminates the need for handrails.) Retaining existing doors and hardware and using an automatic door opener are also recommended, whenever possible. If a significant primary facade would be threatened or destroyed in the process of providing

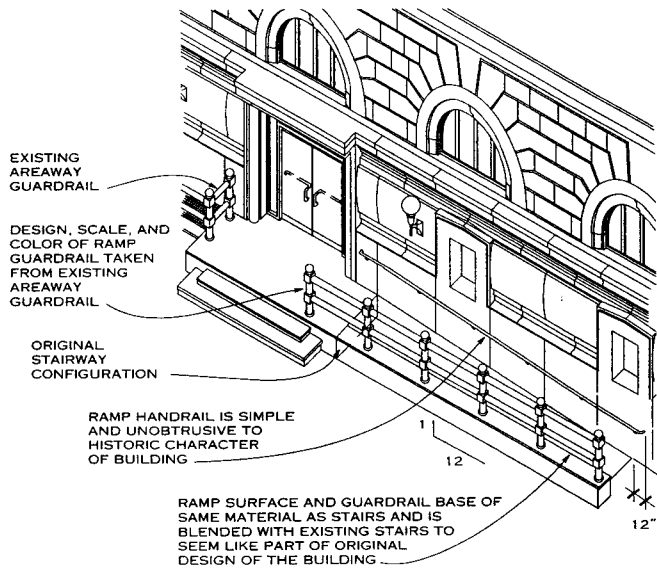

access, a secondary facade may be used to provide an alternative public entrance. In general, nonmechanical means of overcoming physical barriers are preferable because mechanical devices require more maintenance and can easily break down.

If there is inadequate space for an accessible ramp, an incline or vertical lift may be considered. Each type of lift requires adequate maneuvering space at the head and foot of steps. Mechanical motors and electrical activators must have proper covers to reduce breakdowns. Lifts are often allowed for retrofit work but are generally not allowed in new construction. If new construction is to be part of an overall rehabilitation project, it may be possible to locate accessible entrances in a new addition with service to the historic building.

New additions, built to achieve accessibility requirements, should be
 1. properly scaled (not too large in comparison to adjacent features).

2. of compatible materials (similar in quality, type, color values).
3. of compatible design (differentiated from the historic elements).
4. "reversible" (basic integrity of building left intact if a new accessibility feature were to be removed).

If the historical significance of a major facade would be threatened or destroyed if a new ramp or lift were added, every effort should be made to find a convenient alternative public entrance. Alternative public entrances located close to parking areas may provide a more direct path of travel for persons with disabilities. With careful planning, successful solutions can usually be found to balance accessibility and historic preservation requirements.

ACCESSIBLE RAMP INTEGRATED WITH ENTRY

NOTES

1. Temporary ramp solution complies with ADA, and the design is durable and refined enough to be in place until a permanent solution is constructed.
2. Both designs retain the symmetry of the entry portal, allow maximum circulation, and are compatible with building color and historic character.
3. Temporary ramp should be easily "reversible" to original design.

ACCESSIBLE RAMP REPLACING ENTRY

PLATFORM LIFT INTEGRATED INTO STAIR ENTRY

ACCESSIBLE DOORS INTEGRATED INTO EXISTING ENTRY

INTRODUCTION

Entrances and porches are quite often the focus of historic buildings, particularly when they occur on primary elevations. Together with their functional and decorative features such as doors, steps, balustrades, pilasters, and entablatures, they can be extremely important in defining the overall character of a building.

Usually entrances and porches were integral components of a historic building's design; for example, porches on Greek Revival houses, with Doric or Ionic columns and pediments, echoed the architectural elements and features of the larger building. Central one-bay porches or arcaded porches are evident in Italianate style buildings of the 1860s. Doors of Renaissance Revival style buildings frequently supported entablatures or pediments. Porches were particularly prominent features of Eastlake and Stick Style houses; porch posts, railings, and balusters were characterized by a massive and robust quality, with members turned on a lathe. Porches of bungalows of the early 20th century were characterized by tapered porch posts, exposed post and beams, and low-pitched roofs with wide overhangs. Art Deco commercial buildings were entered through stylized glass and stainless steel doors.

PRESERVATION APPROACHES

The materials that comprise entrances and porches—masonry, wood, and architectural metal—should be protected and maintained through appropriate surface treatments such as cleaning, rust removal, limited paint removal, and reapplication of protective coating systems. The overall condition of materials should be evaluated to determine whether more than protection and maintenance are required.

Removing or radically changing primary entrances will in most cases change the overall appearance of the building. Entrances and porches should never be removed be-

cause the building has been reoriented to accommodate a new use.

If barrier-free access is required to a historic building, it should be introduced in a way that does not destroy significant material or interfere with the historic design.

Entrances and porches can be repaired by reinforcing deteriorated historic materials—patching, splicing, and reinforcing with epoxies are examples. Limited replacement in kind of extensively deteriorated or missing parts of repeated features may be undertaken where there are surviving prototypes. Examples include balustrades, cornices, entablatures, columns, sidelights, and stairs.

Only when an entire entrance or porch is too deteriorated to repair—or is missing—should total replacement be considered. If the historic form and detailing are still evident, this evidence should be used to restore the entrance or porch.

If the entrance or porch is missing, restoration should be based on historical, pictorial, and physical evidence rather than on conjectural designs or the availability of elements from neighboring buildings.

When insufficient documentation exists for an accurate restoration, the replacement entrance or porch may be a new design that is consistent with the size, scale, material, and color of the historic building. Care must be taken not to create a false historic appearance in the new work.

Compatible substitute material may be considered if replicating with the historic material is technically or economically infeasible; the substitute material needs to convey the same visual appearance and be physically and chemically compatible. It is important to note that historic exterior wood elements were typically of rot-resistant species.

INTRODUCTION

The storefront is usually the most prominent feature of a historic commercial building, playing a crucial role in a store's advertising and merchandising strategy. Although a storefront usually does not extend beyond the first story, the rest of the building is often related to it visually in form and detail. Planning should always consider the entire building; window patterns on the upper floors, cornice elements, and other decorative features should be carefully retained, in addition to the storefront itself.

The earliest extant storefronts in the United States, dating from the late 18th and early 19th centuries, had bay or oriel windows and provided limited display space. The 19th century witnessed the progressive enlargement of display windows as plate glass became available in increasingly larger sizes. The use of cast-iron columns and lintels at ground floor level permitted structural members to be reduced in size. Recessed entrances provided shelter for sidewalk patrons and further enlarged display areas. In the 1920s and 1930s, aluminum, colored structural glass, stainless steel, glass block, neon, and other new materials were introduced to create Art Deco storefronts. The growing appreciation of historic buildings in recent years has prompted many owners to remove inappropriate changes and restore the historic appearance of their storefronts.

PRESERVATION APPROACHES

Functional and decorative features that make up the historic storefront include display windows, lower window panels, transoms, business signs, entrance doors, and entablatures. Materials that make up a storefront—cast iron, bronze, wood, pressed metal, structural glass—should be identified before undertaking any preservation work.

Removal of inappropriate, nonhistoric cladding and later alterations such as oversized awnings and signs can enhance a historic storefront.
