FOREWORD

The Concrete Reinforcing Steel Institute (CRSI) was organized in 1924 as a cooperative, non-profit organization of producers and fabricators of reinforcing bars and accessories, together with persons or entities otherwise involved in reinforced concrete construction. The Institute has a "Professional Member" classification which opens CRSI activities to designers, specifiers, educators and research personnel actively engaged in reinforced concrete design and construction.

A major objective of the Concrete Reinforcing Steel Institute is to disseminate helpful structural design information for economical and efficient use of materials, and to save designers' time. CRSI has published Design Handbooks since 1952.

This new *CRSI Design Handbook*, 10th Edition, 2008, follows the long-established tradition of providing completed, tabulated designs of common reinforced concrete structural members. The tabulated designs are for normally encountered conditions, and are based on the latest applicable code provisions and materials specifications. All of the tabulated designs in this *Handbook* are prepared in accordance with "Building Code Requirements for Structural Concrete (ACI 318-08)." The majority of the notation used in this *Handbook* follows ACI 318-08. In those instances where other notation had to be introduced, the symbols are defined or shown on figures. Inch-pound units are used throughout this *Handbook*. The reader is encouraged to review the information about soft metric reinforcing bars on Page 1-5.

Since the first *CRSI Design Handbook* in 1952, users of these Handbooks have been cooperative in suggesting to the Design Aids Committee and CRSI Staff, many improvements, clarifications and additional design short-cuts. This professional assistance is very helpful, and is appreciated. Comments regarding this *Handbook* are welcome so that future Handbooks can be further improved. Direct comments to Neal S. Anderson, CRSI Vice President of Engineering.

ACKNOWLEDGEMENTS

A sincere note of appreciation goes to Dr. David P. Gustafson for his tireless efforts on the *Design Handbook*, both for past editions as Vice President of Engineering for CRSI and as Technical Consultant for this 10th edition. The Handbook would not be what it is today were it not for Dr. Gustafson's expertise in reinforced concrete design and construction and his attention to detail.

Also, a note of appreciation to Nicholas Gouwens for his expert assistance in typesetting and reviewing the Handbook manuscript and to Kurt S. Lepinski for his work in updating the Handbook computer programs.

CONTENTS

CHAPTER 1 – Basis and Use of Tabulated Designs

CHAPTER 2 – Strength Design of Columns

CHAPTER 3 – Square and Rectangular Columns

CHAPTER 4 – Round-Tied Columns

CHAPTER 5 – Strength Design of Flexural Members and Development and Splice Design Data for Reinforcing Bars

CHAPTER 6 – Serviceability Requirements

CHAPTER 7 – One-Way Slabs

CHAPTER 8 – One-Way Concrete Joist Construction

CHAPTER 9 – Solid Two-Way Flat Plates — Square Panels

CHAPTER 10 – Two-Way Solid Flat Slabs — Square Panels with Drops

CHAPTER 11 – Waffle Flat Slabs — Square Panels

CHAPTER 12 – Beams

CHAPTER 13 – Square Spread Footings, Pile Caps and Drilled Piers

CHAPTER 14 – Cantilevered Retaining Walls

EXPANDED COLUMN TABLES – Chapter 3 and Chapter 4

CHAPTER 1 – BASIS AND USE OF TABULATED DESIGNS

CHAPTERS 2, 3, AND 4

Columns. The purpose of Chapters 2, 3, and 4 is to provide designs of "short" columns in reinforced concrete by giving column dimensions, and sizes and quantities of reinforcement in accordance with the strength design method of "Building Code Requirements for Structural Concrete (ACI 318-08)." Selecting completed designs of columns from the tabulated designs in Chapters 3 and 4 eliminates the need for charts and diagrams. The appropriate table is entered with values of the factored load and moment, and the column dimensions and reinforcing steel are obtained.

The column tables provide capacities for bending about both major and minor axes. These data permit adjustment for the effects of slenderness in one or both directions, as well as simultaneous bending in both axes.

Load-Moment Tables Instead of Coefficients and Charts. It is extravagant to continually repeat computations to determine the nominal design strength of an assumed section, when a computer program can tabulate the same results for ready reference. Use of these tables eliminates routine calculations and helps prevent the oversight of one or more applicable criteria. However, no handbook can replace the judgment of an experienced Engineer.

Load and Strength-Reduction Factors. The strength design method makes use of two sets of factors. Load factors provide for variable conditions that lead to possible load variances. Strength-reduction factors, or ϕ-factors, provide for variable conditions that lead to possible understrengths. Because different load factors are prescribed for dead, live, wind and earthquake effects, and the factors vary with different combinations of such effects, it is only possible to tabulate nominal design strength in this Handbook. Appropriate load factors must be applied to each effect for as many combinations as circumstances require. Then these tables can be entered with the maximum of the total factored load effects and compared with the design strength.

Since the ϕ-factors are standardized (0.65 for tied columns, and 0.90 for flexure), they were incorporated into the tabulated designs. Hence the tabulated values are the nominal design strength for each column, i.e., the design axial load and moment strengths (ϕP_n and ϕM_n).

Basis and Scope of Tabulated Designs. These tables give the nominal design strength (with ϕ-factors included) for the usual range of sizes of square, rectangular, and round tied "short" columns—using "short" in the Code sense of a column that does not require reduction in capacity for slenderness effects (ACI 10.10).*

Designs are tabulated for Grade 60 (minimum f_y = 60,000 psi) reinforcing bars for the usual range of concrete strengths (f'_c). For the higher concrete strengths now available, designs are also tabulated for Grades 60 and 75. The tabulated designs for Grade 75 (minimum f_y = 75,000 psi) are limited to the use of the large size bars (#11, #14, and #18). Lower strength grades for these sizes are not recommended (by CRSI) for economy. The percentages of longitudinal reinforcement in the tabulated designs vary from one percent, the minimum allowed, to the maximum that can be fitted as single bars at minimum spacings in one layer or ring, but not more than eight percent, the maximum allowed (ACI 10.9.1).

CHAPTERS 5 THROUGH 14

Strength design of flexural members is discussed in Chapter 5. Also included in Chapter 5 is development of reinforcement and lap splices for reinforcing bars.

Strength design consists of two steps—first, a member is proportioned to ensure its strength with the appropriate safety factors, and second, the member must be checked to ensure that deflection and cracking at service load conditions will be controlled. These two design phases—strength and serviceability—are described in Chapters 5 and 6, respectively.

Chapter 7 covers design of one-way solid slabs. Tabulated designs are presented for single spans simply supported, end spans of continuous members simply supported at one end and continuous at the other, and interior spans continuous at both ends.

Chapters 8 through 14 provide designs of reinforced concrete floor systems, footings, pile caps and cantilevered retaining walls. Tabulated designs are given which indicate member dimensions and reinforcement for various span and load conditions. The empirical moment coefficients (ACI 8.3.3) for one-way slab systems and the Direct Design Method (ACI 13.6) for two-way systems are used.

*All references in this *Handbook* to "Building Code Requirements for Structural Concrete (ACI 318-08)" are given as "ACI" followed by appropriate section number.

The tabulated designs in Chapters 7, 8, 9, 10 and 11 give the factored usable superimposed loads (reduced by the proper ϕ-factors) of practical sizes of slabs, joists, flat plates, flat slabs, and waffle flat slabs, with a range of spans and loads, and required reinforcement.

Materials. The tabulated designs are based on a specified concrete compressive strength f'_c = 3,000 psi for footings and retaining walls, and on f'_c = 4,000 psi for one-way solid slabs, beams, joists, flat plates, flat slabs with drop panels, and waffle flat slabs. All designs for flexural members are based on Grade 60 reinforcing bars.

Except for Chapter 12—Beams, the tabulated designs in this *Handbook* give "factored usable superimposed loads" because different load factors are prescribed for different types of loads. The total factored load varies with different combinations of such effects.

Since ϕ-factors are standardized, all tabulated loads have been reduced by the appropriate ϕ-factor. Also, for floor systems, 1.2 times the dead weight of the floor system—based on a conservative unit weight of concrete of 150 pounds per cubic foot—was deducted in tabulating net usable superimposed loads. When transferring total floor loads onto supporting members, the augmented weight of the floor system must be included.

Supplementary References. The following references are recommended to the reader to supplement this *Handbook* and to ensure that the design, detailing and construction techniques meet standards and accepted practices.

3. *Reinforcing Bars: Anchorages and Splices,* CRSI.**

STRUCTURAL INTEGRITY

Requirements for "structural integrity" are included in the ACI Building Code (ACI 7.13 and 13.3.8.5). To comply with the provisions, members of a structure must be effectively tied together. The objective of structural integrity is: If a structure or a part of the structure is subjected to an abnormal loading condition, or if a primary supporting element sustains damage from an unanticipated event, tying the members together should result in confining the resulting damage to a relatively small area.

The Code requirements for achieving structural integrity in reinforced concrete construction focus on the structural detailing of reinforcement. Basically, prescribed amounts of longitudinal reinforcement must be continuous over supports or reinforcing bars that terminate at discontinuous ends of a member have to be anchored with standard hooks or headed bars.

Cast-in-place structural concrete members and systems which are affected by the structural integrity provisions are:

One-Way Joists (ACI 8.13). At least one reinforcing bar in the bottom of a rib has to be continuous over supports or the bar must be spliced with a Class B tension lap splice or a mechanical or welded splice to a bar in the adjacent span. At discontinuous ends of joists, anchorage of at least one bottom bar must be provided with a standard hook or headed bar. Fig. 1-1 shows the structural integrity reinforcement requirements for joist construction.

**Concrete Reinforcing Steel Institute, 933 North Plum Grove Road, Schaumburg, Illinois 60173.

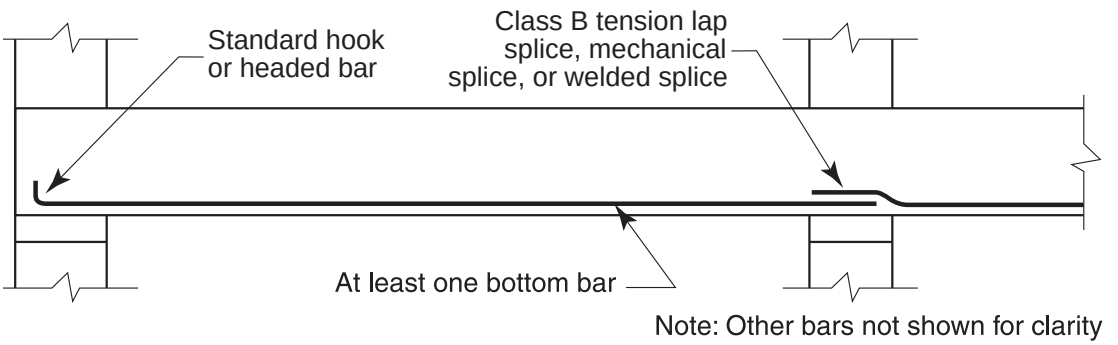

Figure 1-1 Structural Integrity Reinforcement for One-Way Joist Construction

Beams. Beams are categorized as either "perimeter" beams or "non-perimeter" beams. A spandrel beam would be a perimeter beam.

The detailing of top and bottom bars, and stirrups in perimeter beams, is impacted by the structural integrity provisions. At least one-sixth of the $-A_s$ required for negative factored moment at the face of supports (minimum of 2 bars) and one-quarter of the $+A_s$ required for positive factored moment at midspan (minimum of 2 bars) have to be made continuous around the perimeter of the structure. Closed stirrups are also required in perimeter beams. It is not necessary to place closed stirrups within the joints at columns or other supporting girders. It is permissible to provide continuity of the top and bottom bars by splicing the top bars at midspan and the bottom bars at or near the supports. Splicing with Class B tension lap splices, or mechanical or welded splices, is required. See Fig. 1-2.

For non-perimeter beams, the Engineer has two choices to satisfy the structural integrity requirements: (1) provide closed stirrups, or (2) make at least one-quarter of the $+A_s$ required for positive factored moment at midspan continuous (minimum of 2 bars). Splicing the prescribed number of bottom bars over the supports with Class B tension lap splices, mechanical or welded splices, is acceptable. At discontinuous ends of non-perimeter beams, the bottom bars must be anchored with standard hooks or headed bars. See Fig. 1-3.

Two-Way Slabs. In two-way slab construction, all bottom bars within the column strip, in each direction, must be spliced with Class B tension lap splices, mechanical or welded splices. Fig. 13.3.8 in the ACI Building Code shows the locations where the lap splices are permitted. At least two of the bottom bars in the column strip must

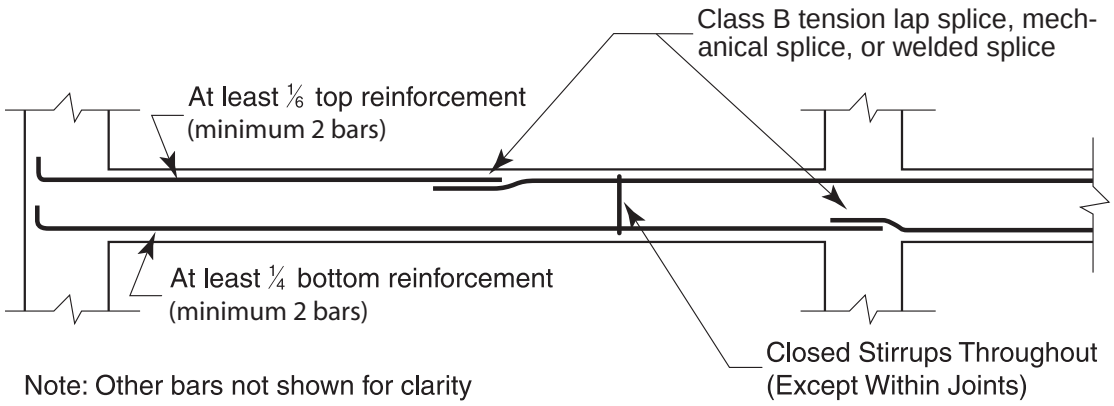

Figure 1-2 Structural Integrity Reinforcement for Perimeter Beams

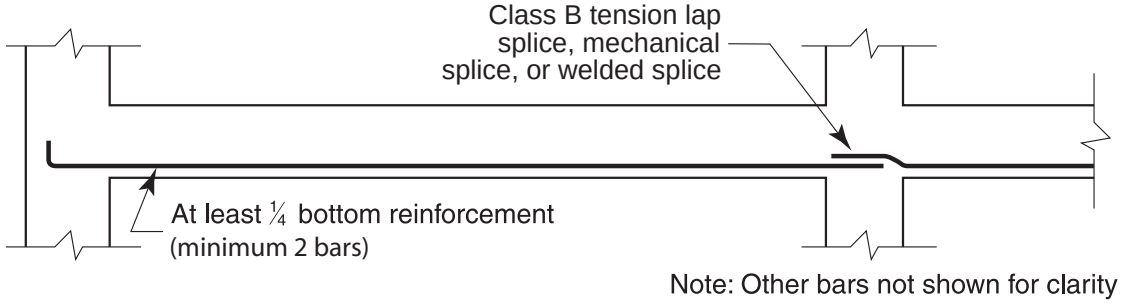

Figure 1-3 Structural Integrity Reinforcement for Non-Perimeter Beams

pass within the core of the columns and be anchored with a hook or headed bar at exterior supports. See Fig. 1-4.

The structural integrity requirements of the ACI Building Code were not incorporated into the various tabulated designs of this *Handbook.* One reason for this exclusion was due to the inability to determine where the bars would be truly continuous (i.e., one piece) and where the bars would be spliced.

As an example, consider a relatively short 14-foot span one-way joist system. Since stock lengths of reinforcing bars from steel mills vary from 40 to 60 feet, this would result in lap splicing the bottom bars within either every two or every three spans. Although the bars could have been assumed to be lap spliced at every support or at midspan, such details were felt to be unrealistic.

Another reason, which applies only to the tabulated designs of beams in Chapter 12, is that the structural integrity requirements are quite different for perimeter and non-perimeter beams. This would have necessitated preparation and printing of two sets of tables: one set for perimeter beams and another set for non-perimeter beams.

Therefore, the tabulated designs in this *Handbook* do not include the structural integrity requirements in order to make them as general as possible. The Engineer using this *Handbook* must evaluate the issue of structural integrity on a case-by-case basis.

NOTICE

The Institute does not prepare project drawings and project specifications. While every precaution is taken to ensure that all data and information furnished are as accurate as possible, the Institute cannot assume responsibility for errors or oversights in the use of such information or in the preparation of project drawings and project specifications. The information given in the tabulated designs should prove useful in preliminary design, in preliminary estimating of quantities of materials, for establishing sizes and clearances, and for comparing different types of construction. Obviously, the tabulated designs apply only to the particular condition of span, loading and material strengths specified. The information in this *Handbook* should not replace the judgment of an experienced structural engineer when selecting types of structural concrete members and systems, proper loads, providing proper stiffness and in obtaining the most economical design.

Tabulated solutions for common structural concrete members and systems are presented in this *Handbook* with examples to illustrate the application of ACI Building Code requirements. It is not possible to prepare tabulated solutions for connections of these members and systems in general. Structural integrity for the completed structure can be provided only by the Engineer familiar with the overall requirements involved.

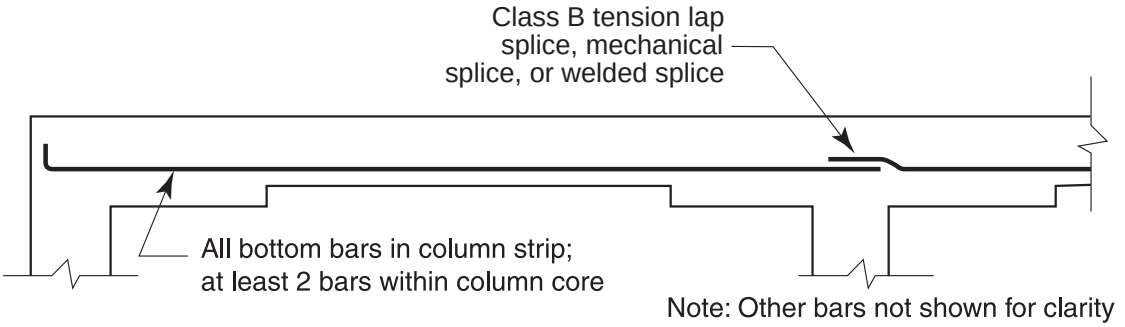

Figure 1-4 Structural Integrity Reinforcement for Two-Way Slab Construction

SOFT METRIC REINFORCING BARS

The tabulated designs in this *Handbook* are based on requirements in the inch-pound version of the ACI Building Code. Consequently, inch-pound units, including the designations for the sizes of reinforcing bars, are used throughout this *Handbook*. Space limitations precluded inclusion of companion tabulated designs in metric units, which would be based on ACI 318M.

It is important for users of this *Handbook* to be aware of current industry practice regarding soft metric reinforcing bars. The term "soft metric" is used in the context of bar sizes and bar size designations. "Soft metric conversion" means describing the nominal dimensions of inch-pound reinforcing bars in metric units, but not physically changing the bar sizes. In 1997, producers of reinforcing bars (the steel mills) began to phase in the production of soft metric bars. Within a few years, the shift to exclusive production of soft metric reinforcing bars was essentially achieved. Virtually all reinforcing bars currently produced and used in the USA are soft metric. The steel mills' initiative of soft metric conversion enables the industry to furnish the same reinforcing bars to inch-pound construction projects as well as to metric construction projects, and eliminates the need for the steel mills and fabricators to maintain a dual inventory. Thus, USA-produced reinforcing bars furnished to any construction project most likely will be soft metric.

Designations of Bar Sizes. The sizes of soft metric reinforcing bars are physically the same as the corresponding sizes of inch-pound bars. Soft metric bar sizes, which are designated #10, #13, #16, and so on, correspond to inch-pound bar sizes #3, #4, #5, and so on. The metric bar designations are simply a re-labeling of the inch-pound bar designations. The following table shows the one-to-one correspondence of the soft metric bar sizes to the inch-pound bar sizes.

Soft Metric Bar Sizes vs. Inch-Pound Bar Sizes

Soft Metric Bar Size Designation	Inch-Pound Bar Size Designation
#10	#3
#13	#4
#16	#5
#19	#6
#22	#7
#25	#8
#29	#9
#32	#10
#36	#11
#43	#14
#57	#18

Minimum Yield Strengths or Grades. Virtually all steel mills in the USA are producing reinforcing bars to meet the metric requirements of the ASTM specifications. Minimum yield strengths in metric units are 280, 350, 420 and 520 MPa (megapascals), which are equivalent to 40,000, 50,000, 60,000 and 75,000 psi, respectively. Metric Grade 420 is the counterpart of standard Grade 60.

Bar Marking. Soft metric reinforcing bars are required to be identified with the Producer's mill designation, bar size, type of steel, and minimum yield strength or grade. For example, consider the marking requirements for a #25, Grade 420 metric bar, which is the counterpart of an inch-pound #8, Grade 60 bar. Regarding the bar size and grade, the ASTM specifications require the number "25" to be rolled onto the surface of the metric bar to indicate its size. For identifying or designating the yield strength or grade, the ASTM specifications provide an option. A mill can choose to roll a "4" (the first digit in the grade number) onto the bar, or roll an additional longitudinal rib or grade line to indicate Grade 420.

Chapter 1 in the CRSI *Manual of Standard Practice* includes a detailed presentation of the inch-pound and metric requirements in the ASTM specifications for reinforcing bars. Appendix A in the *Manual* shows the bar marks used by USA producers to identify Grade 420 soft metric bars. More information about soft metric reinforcing bars is given in Engineering Data Report No. 42, "Using Soft Metric Reinforcing Bars in Non-Metric Construction Projects". EDR No. 42 can be found on CRSI's Website at **www.crsi.org**.

CHAPTER 2 – STRENGTH DESIGN OF COLUMNS

General

Strength design of reinforced concrete columns is a complete design since there are no further serviceability requirements to be satisfied. Strength design of columns consists of determining the critical load combinations and resulting factored loadings for each; selecting a column cross section satisfying all design assumptions for the materials used under loads and moments equal to or larger than the factored loads and moments; and ensuring that slenderness effects do not reduce capacity.

Since the reduction in capacity for slenderness is dependent on the cross-sectional properties, including reinforcement of the column selected, and the factored moments are also dependent on the gross cross section, strength design of columns is in reality a two-stage review of a trial design. The manual calculations for such a review are formidable and become increasingly onerous if several trials are required. The column capacity tables in this *Handbook* can be used to avoid the need to make several trials since the tables cover most of the practicable range encountered in ordinary structures.

Load and Strength-Reduction Factors

The ACI Building Code provides seven principal load combinations with appropriate load factors for each to compute the factored load effects, axial load and moment. When these combinations are simplified by only concerning *D* (dead), *L* (live), and *W* (wind) loads, they result in the following three combinations:

$U = 1.4D$

$U = 1.2D + 1.6L$

$U = 1.2D + 1.0L + 1.6W$ (use whichever of the three is largest)

Use of the column capacity tables in this *Handbook* requires computation for the maximum effects, axial load and moment for the factored (augmented) load above. The load capacities tabulated in Chapters 3 and 4 have been computed for the stated concrete compressive strengths and Grade 60 bars (f_y = 60,000 psi) and Grade 75 bars (f_y = 75,000 psi), reduced by strength- reduction factors ϕ = 0.65 for compression, and ϕ = 0.90 for pure flexure only. The capacities tabulated are, therefore, the maximum usable design capacities for short columns. “Short” columns are those for which no reduction in load capacity for the effect of slenderness need be made.

Design Assumptions

The general assumptions prescribed in the ACI Building Code for strength design of reinforced concrete columns are given as follows:

10.2 – Design assumptions.

10.2.1 – Strength design of members for flexure and axial loads shall be based on the assumptions given in 10.2.2 through 10.2.7, and on satisfaction of applicable conditions of equilibrium and compatibility of strains.

10.2.2 – Strain in reinforcement and concrete shall be assumed directly proportional to the distance from the neutral axis . . .

10.2.3 – Maximum usable strain at extreme concrete compression fiber shall be assumed equal to 0.003.

10.2.4 – Stress in reinforcement below f_y shall be taken as E_s times steel strain. For strains greater than that corresponding to f_y, stress in reinforcement shall be considered independent of strain and equal to f_y.

10.2.5 – Tensile strength of concrete shall be neglected in axial and flexural calculations of reinforced concrete . . .

10.2.6 – The relationship between concrete compressive stress distribution and concrete strain shall be assumed to be rectangular, trapezoidal, parabolic, or any other shape that results in prediction of strength in substantial agreement with results of comprehensive tests.

10.2.7 – Requirements of 10.2.6 are satisfied by an equivalent rectangular concrete stress distribution defined by the following:

10.2.7.1 – Concrete stress of 0.85 f'_c shall be assumed uniformly distributed over an equivalent compression zone bounded by edges of the cross section and a straight line located parallel to the neutral axis at a distance $a = \beta_1 c$ from the fiber of maximum compressive strain.

10.2.7.2 – Distance from the fiber of maximum strain to the neutral axis, *c*, shall be measured in a direction perpendicular to the neutral axis.

10.2.7.3 – For f'_c between 2,500 and 4,000 psi, β_1 shall be taken as 0.85. For f'_c above 4,000 psi, β_1 shall be reduced linearly at a rate of 0.05 for each 1,000 psi of strength in excess of 4,000 psi, but β_1 shall not be taken less than 0.65.”

The computer program used for the preparation of the column capacity tables in this *Handbook* followed

all design assumptions required. An equivalent rectangular stress block for compressive stress distribution in concrete as specifically prescribed was used (ACI 10.2.7). The area of concrete displaced by vertical reinforcing bars was deducted from the total compression on concrete. Where the vertical reinforcing bars are located at varying distances from the neutral axis, such as bars in circular patterns for round columns, or in the sides parallel to the direction of bending for square or rectangular columns, actual bar area and location were considered for each bar.

Load-Moment Interaction Diagrams

Even with the advantage of tabulated load capacities at various control points as provided by this *Handbook*, it is frequently helpful to construct a load-moment interaction diagram. Such a diagram is particularly useful in the evaluation of load effects for the three different load combinations prescribed. The various load-moment capacities can be located conveniently on an interaction diagram, and the effect of changing bar size, or the number of bars, or their arrangement, can be quickly determined. Also, the increase in factored moment as an effect of slenderness may be added.

The intervals, or control points, at which design axial load strengths and moment strengths are tabulated were selected to permit convenient construction of interaction curves, complete from maximum design axial load strength to pure flexure. Sample interaction curves prepared from the load tables in Chapters 3 and 4 are discussed and shown. In the sample interaction curves that follow, attention is particularly directed to these considerations:

1. "Major" versus "minor" axes (MA and MI) capacities. Note that for a square column, if the unbraced height and end restraint conditions are equivalent in both directions, the *minor* axis capacity, except for 4-bar columns, will be smaller and will control the maximum load allowed. Maximum design axial load strength will be equal in both directions for a square column. See Fig. 2-1.

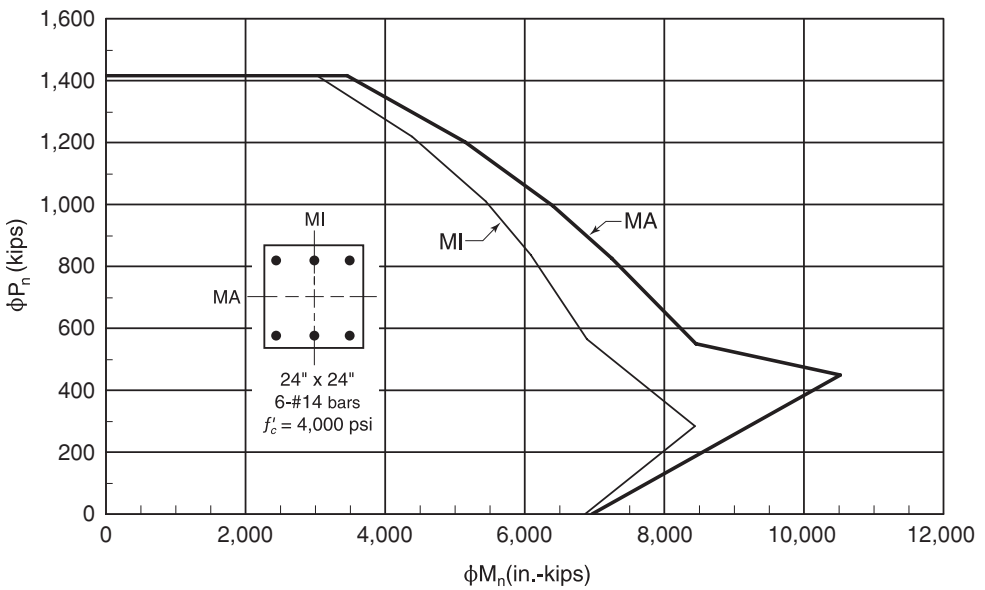

Figure 2-1 Major Axis vs. Minor Axis

2. Round-tied columns versus square. The round-tied column (or circular bar pattern) is less efficient for moment resistance. For equivalent areas of vertical reinforcing bars and concrete, the square column has more capacity than the round-tied column. At the point of maximum design axial load strength, the capacities of the two columns are the same. See Fig. 2-2.

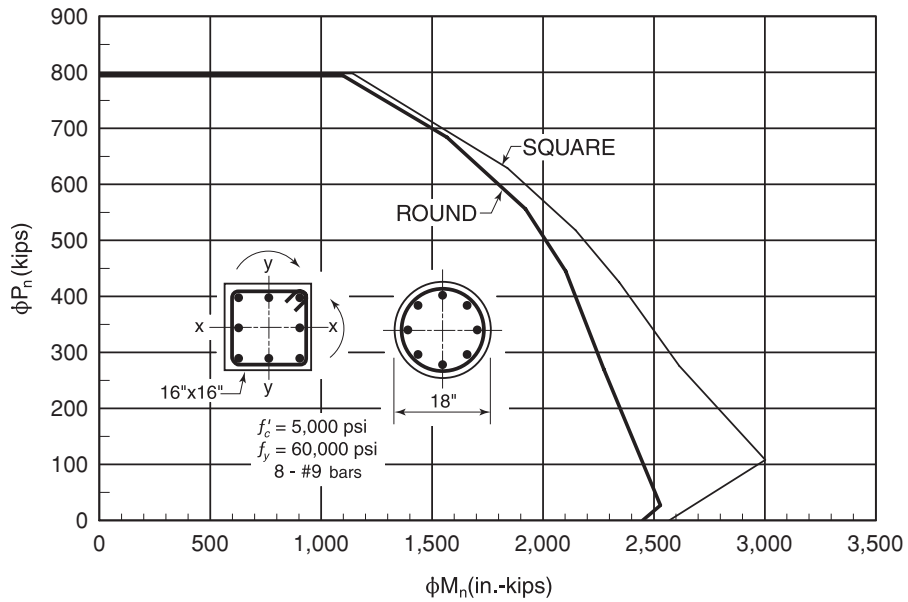

Figure 2-2 Round-Tied vs. Square

3. Grade 60 versus Grade 75 reinforcing bars. Tabulated capacities of columns reinforced with Grade 75 bars have been included in this *Handbook* (in bar sizes #11, #14, and #18). Load-moment interaction curve comparisons for a square column reinforced with Grade 60 and Grade 75 bars are shown in Fig. 2-3.

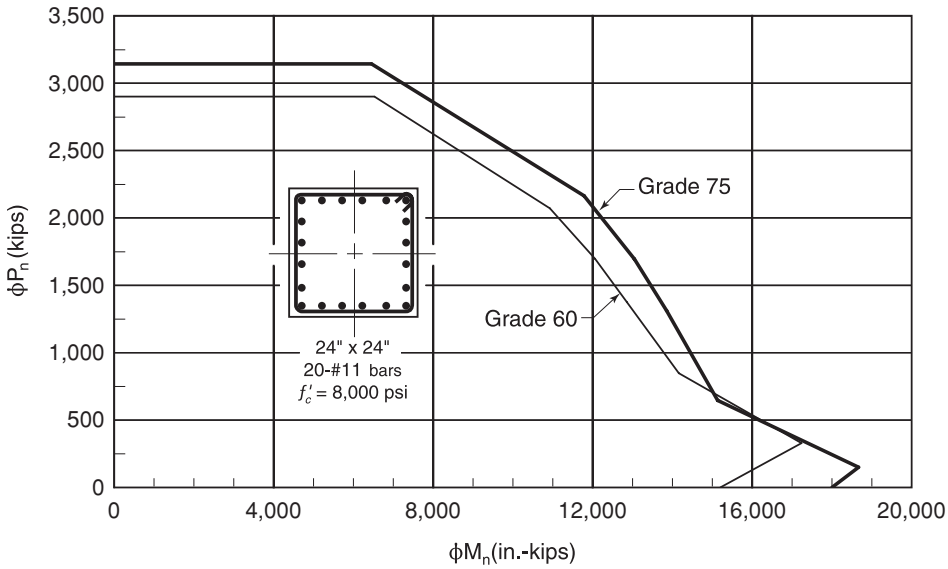

Figure 2-3 Grade 60 vs. Grade 75 Reinforcing Bars

Splices

See Chapter 5 for dowel embedment and lap splices in compression. Tables for tension development lengths and tension lap splice lengths are also provided in Chapter 5. For footing dowel design, see Chapter 13 – Footings.

Special requirements for splices in columns are prescribed by the Code (ACI 12.17). Selection of the tabulated combinations of design axial load and moment strengths in Chapters 3 and 4—the control points on the load-moment interaction diagram—was influenced by the splice provisions.

A point often overlooked in design for lap splices of offset column vertical bars is the reduction in effective depth of the offset bars. This effect can usually be safely neglected when the stress is always compressive with low reinforcement ratios. Particularly with reinforcement ratios in excess of 0.04 and large factored moments, however, nominal moment capacity should be reduced. An approximation for this reduction is:

$$R = (X - X_o)/X$$

where R = reduction of moment capacity
$X_o = 0.5h - d'_c$ for offset bar, and
$X = 0.5h - d_c$ for straight bar

See Fig. 2-4 for a sketch of an offset detail and definition of terms.

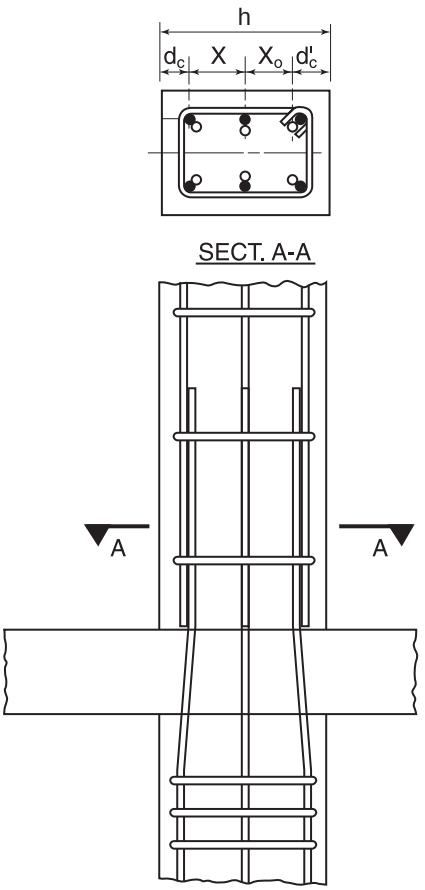

Figure 2-4 Offset Bar Lap Splices – Columns with Bending Moments, #11 Bars and Smaller

CHAPTER 3 – SQUARE AND RECTANGULAR COLUMNS

General. The variety of cross-sectional shapes used for reinforced concrete columns is unlimited, but many columns are square or rectangular because of practical requirements in layout of walls and partitions and ease of forming. In this Chapter, design strength tables for the three most used types of columns are furnished:

1. Square cross section with symmetrical groupings of reinforcing bars in four faces (4F).
2. Square cross section with symmetrical groups of reinforcing bars in two faces (2F).
3. Rectangular cross section with reinforcing bars in all faces; symmetrical groups of reinforcing bars in opposite faces.

Design strengths for the latter two types are tabulated for bending about each axis of symmetry. The major axis (MA) for the square sections (2F) is the axis equidistant from each parallel line through reinforcing bar centers. The minor axis (MI) is the axis through the center of the section at 90º to the major axis. For most (not all) combinations of column size, concrete cover, size and number of reinforcing bars, this type of column will have maximum design moment strength, ϕM_n, bending about the major axis (MA). For the rectangular columns, the major axis is a line parallel to the short sides passing through the center of the section. See Fig. 3-1.

Two separate tables for square columns are presented. Output and resulting format for the two tables are different. The square columns with symmetrical groupings of reinforcing bars in four faces provide the same design moment strength in each direction and require one line in the tables (Pages 3-12 through 3-15). Square columns with reinforcing bars in two faces only provide a different bending resistance in each direction. *Both directions must be evaluated separately for slenderness effects*, particularly when effective length differs due to different lateral bracing in the two directions. Since the same format was used for square columns with reinforcing bars in two faces and all rectangular columns, this type of square column design was tabulated at the beginning of each rectangular column design strength table.

Scope. The tabulated column designs presented on Pages 3-12 through 3-106 are for a concrete compressive strength, f'_c, of 4,000 psi and Grade 60 (f_y = 60,000 psi) reinforcing bars. Tabulated designs for concrete compressive strengths of 5,000, 6,000 and 8,000 psi in combination with Grade 60 bars are provided on the enclosed CD-ROM. Also included in the enclosed CD-ROM are tabulated designs for concrete strengths of 6,000, 8,000, and 10,000 psi in combination with Grade 75 (f_y = 75,000 psi) reinforcing bars.

CRSI recommends use of Grade 60 reinforcing bars as the standard grade for economy in the majority of structures. The ASTM A615 Specification for carbon-steel reinforcing bars includes Grade 75 bars in bar sizes #3 through #18. For example, Grade 75 could provide cost savings and other possible advantages in high-rise construction especially when combined with higher strength concretes. CRSI recommends that the availability of Grade 75 bars in any size should be investigated before the higher grade is specified. The ASTM A706 Specification covers low-alloy steel reinforcing bars in a single grade, i.e., Grade 60 (f_y = 60,000 psi).

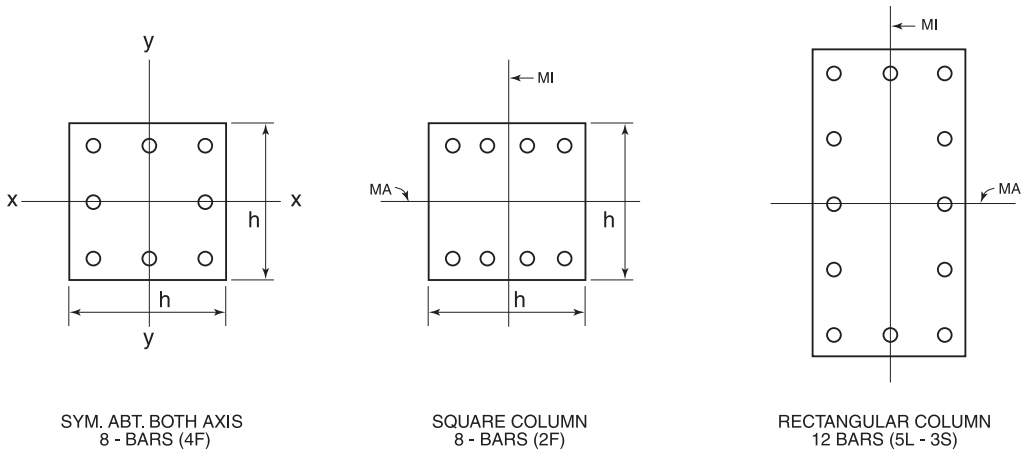

Figure 3-1 Bar Pattern Designation – Major and Minor Axis

Column sizes using Grade 60 reinforcing bars are shown for minimum size sides, 10 inches. For rectangular columns of each width, increasing depth increments up to depth = 2 times width are presented, maximum of 48 inches. Design strengths and reinforcement for various size combinations of rectangular columns with proportions exceeding 2:1 can be determined as fractions of strengths given. For bars in the two short faces only, 10 × 40 equals half the (MA) design moment strength of 20 × 40 if concrete cover and spacing permit use of half the number of bars. Similarly, 20 × 80 will provide twice the (MI) design moment strength of 20 × 40 for bars in long faces only.

Vertical reinforcing bar combinations are shown to provide reinforcing steel to concrete cross section ratios from 1 to 8 percent. Sizes of Grade 60 bars begin with #5 in smaller size columns and continue up to the largest size practicable for each size column. Not all bar combinations possible between 1 and 8 percent are shown. As column size increases, minimum bar size is increased to avoid designs with excessive numbers of vertical bars with equally excessive tie requirements. For Grade 75 bars, only the largest sizes, #11, #14 and #18, are used in the tabulated designs on the enclosed CD-ROM.

ACI Building Code Requirements. A number of Code requirements apply to square and rectangular columns.

1. *Design Assumptions.* See Chapter 2.
2. *Load Factors.* Three principal load factor combinations are prescribed for the required strength:

$U = 1.4D$
$U = 1.2D + 1.6L$
$U = 1.2D + 1.0L + 1.6W$

Column design must provide strength equal or larger than the largest value of U, determined by the three combinations above, or five in seismic design categories. Other factors apply for various special conditions.

In practice, the second load combination above will control most column designs, except in high-rise buildings, narrow buildings with few columns and no other lateral bracing greatly stiffer than the columns. For this reason, and for concise examples only, the final values of the required strength, U, (expressed as ϕP_n, ϕM_n) will be used in the examples in this Chapter. The required factored loads and factored moments (P_u, M_u) must be determined for the conditions of the structure to enter the column tables.

3. *Slenderness effects.* All design strengths tabulated in Chapters 3 and 4 are for "short" columns. Slenderness effects are not considered in the tabulated designs in Chapters 3 and 4.
4. *Biaxial Bending.* Column design strengths (ϕP_n, ϕM_n) are tabulated for uniaxial bending, with eccentricities in the direction of major (MA) and minor (MI) axis. A single value suffices for the table of square columns symmetrically reinforced where design axial load and moment strengths, MA and MI, are equal. Corner columns and any other columns subjected to known factored moments simultaneously about each axis must be designed for biaxial bending (ACI Commentary R10.3.6 and R10.3.7).
5. *Splices.* Special requirements for splices in columns are prescribed by the Code (ACI 12.17). Consideration of the splice requirements was made in the selection of the tabulated combinations of design axial load and moment strengths – the control or key points on the $\phi P_n - \phi M_n$ interaction diagram.
6. *Ties and Concrete Cover.* Recommended typical tie arrangements, suitable for prefabricated column cages or in-place free-standing erection, are shown in the *ACI Detailing Manual*. Each corner bar and alternate interior bars (with clear spacings equal or less than 6 inches) must have lateral support of a tie corner within an included angle not larger than 135º, (ACI 7.10.5.3). For cast-in-place columns, minimum concrete cover to ties is 1½ inches (ACI 7.7.1). Minimum sizes of ties are #3 for vertical (longitudinal) bars up to #10, and #4 for #11, #14, or #18 vertical bars. The calculated design strengths are based on depths, d', from the nearest face to the center of bars as shown in Table 3-1.

No column designs using mixed bar sizes are tabulated in this Chapter. If such designs are attempted, the largest bar size in the column face will establish depth, d'.

Table 3-1 Depth from Nearest Face to Center of Vertical Bars*

Bar Size	#5	#6	#7	#8	#9	#10	#11	#14	#18
Depth, d' (in.)	2.19	2.25	2.31	2.38	2.44	2.51	2.71	2.85	3.12

* Based on 1-1/2 in. concrete cover to the tie.

7. *Limiting Vertical (Longitudinal) Reinforcement.* The minimum number of vertical reinforcing bars is four in tied columns. The minimum area of vertical reinforcing bars is 0.01 and maximum 0.08 times the gross area of the column cross section (ACI 10.9.1). Where columns are larger than required for loadings,

the minimum limiting area of vertical bars can be reduced to 0.005 times the gross area. When the vertical bar area is reduced below 0.01 times gross area, computations for the design axial load strength, design moment strength, and minimum bar area must be based on an *effective gross area* reduced proportionately (ACI 10.8.4). This provision avoids waste of reinforcing steel for upper floors of a multi-story column made to a uniform size for form reuse from bottom to top. See Design from Tables Section in this Chapter. For lower floors in high-rise construction, the use of Grade 75 reinforcing bars in combination with maximum available concrete strength often can reduce congestion of vertical bars where compression controls design.

Costs for each item in reinforced concrete column construction vary in different localities. A few general principles for economy of column design are applicable, however, throughout the industry.

1. Form reuse through utilization of the same cross section over an entire floor and for all stories in a multi-story column saves form costs and erection time.
2. High placing costs of reinforcing steel can be reduced by designing for the fewest (or largest practicable size) reinforcing bars.
3. High cost per pound of ties versus vertical (longitudinal) bars can be reduced by using the least number of largest practicable size vertical bars.
4. Concrete costs can be reduced for both material and placing if interfering interior ties are eliminated as in 4-, 6-, or 8-bar columns requiring only one tie per set. Faster placing and easier consolidation with lower slump (less expensive) concrete will result.
5. Lap splices are least expensive where the required lap length is practicable, and where required design moment strength can be developed. #14 and #18 bars cannot be lap spliced except in compression to #11 or smaller bars; also for compression-only applications, staggered end-bearing mechanical splices offer economy. Partial lap splices in bundled bars staggered for one-half or two-thirds tensile capacity require no additional reinforcing steel. Two-story lengths for large bars eliminate one-half the required number of butt splices.

The design strength tables in this Chapter follow these principles for economy. No mixed bar size designs were used. The minimum size bar was gradually increased so that all practicable combinations for minimum numbers of bars are presented. The tables include design load and moment strengths at zero and 50 percent tension in the bars on the tension (convex) side of the columns. These values provide guidance to prescribe the most economical splicing arrangements without tedious calculations of critical tension. Bundled bar designs, as such, were not feasible for tabulation, but the design strengths shown for eight or more bars, #11 or less in size, can be applied where tabulated bars are arranged in bundles. In most cases, the bundled arrangement can be devised to increase the design moment strength above that tabulated in at least one, sometimes both directions.

Table 3-2 Maximum Spacing of Column Ties (ACI 7.10.5.2)*

Vertical bar size	Size and spacing of ties, (inches)		
	#3	#4	#5
#5	10	–	–
#6	12	–	–
#7	14	–	–
#8	16	16	–
#9	18	18	–
#10	18	20	–
#11	**	22	22
#14	**	24	27
#18	**	24	30

* Maximum spacing not to exceed least column dimension.
** Not allowed.

DESIGN FROM TABLES

Select interior rectangular columns for the conditions in Fig. 3-2, maintaining a uniform size for form reuse and a maximum width, not to exceed 16 in. Use f'_c = 4,000 psi, if possible. First floor story height is 16′-0″ and the unbraced length, ℓ_u, is 13′-3″. For all other floors, story height is 11′-6″ and the unbraced length, ℓ_u, from finished floor to the bottom of the beam is 8′-9″.

Assume the structure is braced (non-sway columns). For these conditions, the load factor combination of $1.2D + 1.6L$ will control the design, 1.2 times the dead load and dead load moment, if any, plus 1.6 times live load and unbalanced live load moments. See Fig. 3-2. Note that the factored moments are so small that it is unnecessary to consider separately the full load and partial load for unbalanced moment. Maximum $P_u \leq 0.80(0.65)[0.85f'_c\,(A_g - A_{st}) + f_y\,A_{st}]$(ACI 10.3.6.2) will control this column design for all floors if slenderness effects may be neglected.

Make a preliminary evaluation whether slenderness effects must be considered. For members braced against sidesway, slenderness effects can be neglected if $k\ell_u/r < 34 - 12\,M_1/M_2$ . . . (ACI 10.10.1)

Take $k = 1.0$ and $r = 0.30\ (16) = 4.8$ in.

$k\ell_u/r = (1)(105)/(4.8) = 22$

Roof: $34 - 12(91/262) = 30 > 22$

Intermediate Floors: $34 - 12(262/262) = 22$

First Floor: $k\ell_u/r = (1)(159)/(4.8) = 33$

First F1oor: 34 12(0/262) = 34 > 33

Slenderness effects can be neglected for this column stack. Final designs may, therefore, be selected directly from the tables. As a quick check for design strengths, find maximum design axial load strength ϕP_n and corresponding value of design moment strengths ϕM_n for comparison to maximum factored loads and moments P_u and M_u.

For f'_c = 4,000 psi and column size 16″ x 20″, enter table on Pages 3-28 and 3-29 for rectangular columns and read maximum ϕP_n and corresponding value of ϕM_n:

Location	Bars	ϕP_n (kips)	ϕM_n (in.-kips)
1st Floor	14-#10 5L-4S	1,089 ($>P_u$ = 1,036)	1,797 ($>M_u$ = 262)
2nd Floor	8-#11 3E	933 ($>P_u$ = 816)	1,614 ($>M_u$ = 262)
3rd Floor	6-#8 2L-3S	705 ($>P_u$ = 596)	1,438 ($>M_u$ = 262)
4th Floor	4-#9 2E	683 ($>P_u$ = 375)	1,389 ($>M_u$ = 262)

Note that P_u at the 4th floor level is only 375 kips. Read design strengths for 4-bar arrangements with rho nearest to 1.00% to apply oversize column reduction (ACI 10.8.4):

Calculate the ratio: $P_u/\phi P_n = 375/683 = 0.55$
For 4–#9 bars, $A_s = 4.00$ in.^{2}
Reduce A_s by ratio 0.55; $(0.55)(4.00) = 2.20$ in.^{2}
$\phi M_n \approx 0.55(1{,}389) = 764$ in.-kips > 262
Use 4–#7 bars; $A_s = (4)(0.60) = 2.40$ in.^{2}

Apply same procedure to roof column.

Roof: 155/683 < 0.5, use minimum $A_s = 0.005A_g$
Minimum $A_s = (0.005)(16 \times 20) = 1.60$ in.^{2}
$\phi M_n \approx 0.5(1{,}389) = 695$ in.-kips > 91
Use 4-#6 bars; $A_s = (4)(0.44) = 1.76$ in.^{2} > 1.60

Select minimum sizes and maximum spacings for ties from Table 3-2. See Fig. 3-3 for details.

Splices. All vertical (longitudinal) bars are in compression only. Select lap splice lengths as follows from Chapter 5, noting that the beam is 33-in. deep.

5th Floor: minimum standard lap splice length (Table 5-1) for #6 bars above = 23 in. Use lap length = 23 in.

4th Floor: minimum standard lap splice length (Table 5-1) for #7 is bars 27 in.; compression embedment length for #8 bars below is 22 in. Use lap length = 27 in.; cut off discontinued bars at 2 in. below finished floor. Extend 4-#8 bars.

3rd Floor: minimum standard lap splice length (Table 5-1) for #8 bars is 30 in.; minimum compression embedment length for #11 bars below is 31 in. Use lap length = 31 in.; cut off bars at 2 in. below finished floor. Extend 6-#11 bars.

2nd Floor: minimum standard lap splice length (Table 5-1) length for #11 bar is 43 in.; minimum compression embedment for #11 below is 31 in. Use lap length = 43 in.; cut-off bars at 2 in. below finished floor. Extend 8-#11 bars.

Footing. Design bearing strength of column (ACI 10.14.1) = $\phi(0.85f'_cA_1) = 0.65(0.85)(4)(16 \times 20) = 707$ kips. Excess compression on base of the column = 1,036 – 707 = 329 kips. Assuming the footing f'_c is at least equal to 3,000 psi and $\sqrt{A_2/A_1} = 2$, the design bearing strength of the footing = $(2)(0.60)(0.85)(3)(16 \times 20) = 1{,}061$ kips. Dowels must provide (ACI 15.8.2.1) $A_s = (0.005)(16 \times 20) = 1.60$ in.^{2}; and transfer (ACI 15.8.1.2) 329 kips by compression embedment.

Use 6– #10 dowels, 2L-3S; from Table 5-1, the required embedment length for f_y = 60 ksi is 28 in. For transferring 329 kips, the required embedment =

$$\frac{329(28)}{6(1.27)(60)} = (0.72)(28) = 20 \text{ in.}$$

Length of compression lap splice of #10 dowels to #10 column bars; from Table 5-1, the required lap length for f_y = 60 ksi is 38 in. For transferring 329 kips, the required lap length = 0.72(38) = 28 in.

See Figs. 3-2 and 3-3 for details of splice arrangements.

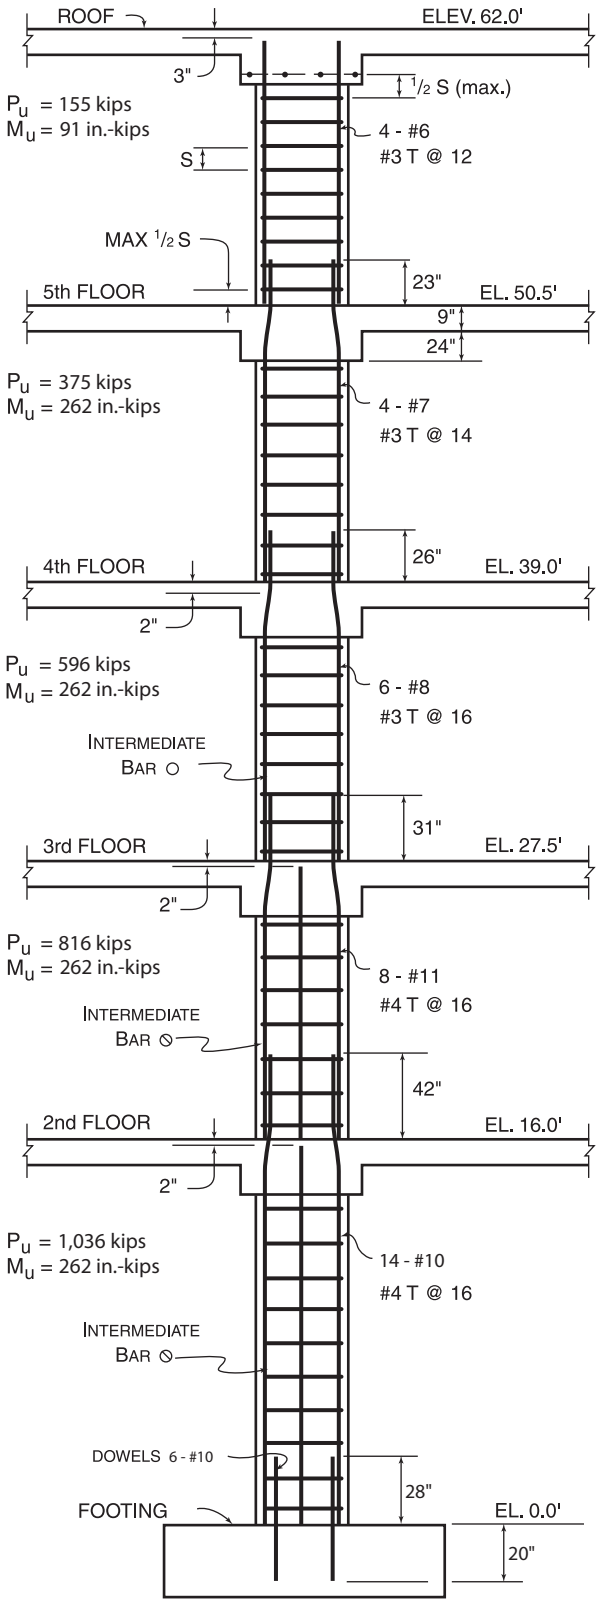

Figure 3-2 Lap Splices and Cut-off Details

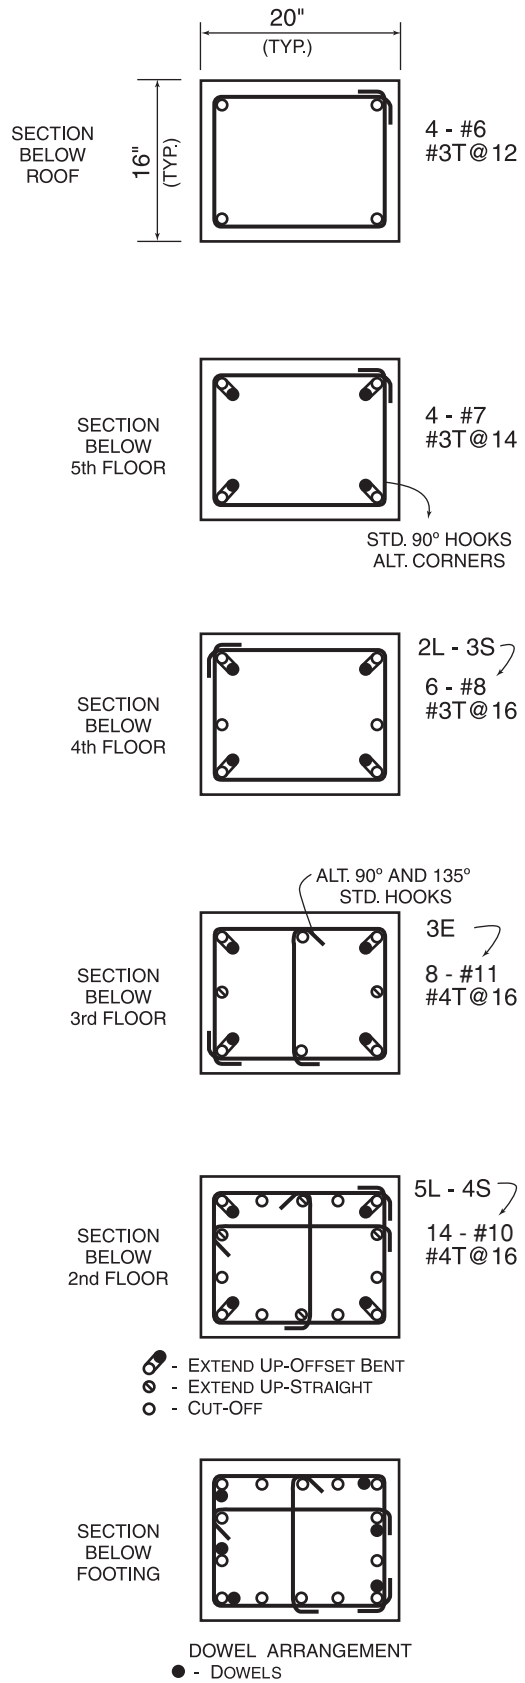

Figure 3-3 Multi-Story Column—Plan Sections

MANUAL EXAMPLE

Review a rectangular column 12″ × 24″ with f'_c = 6,000 psi and 10-#14 Grade 60 vertical (longitudinal) reinforcing bars. Compute values of ϕP_n and ϕM_n at control points (ϕM_n about major axis, MA). Compare computed values versus the tabulated values printed out for 10-#14, 5L-2S from the enclosed CD-ROM. The printed-out values are displayed in Table 3-3.

The dimensions in Fig. 3-4 are based on 1½ inches of concrete cover to the #4 ties. For f'_c = 6,000 psi, β_1 = 0.75 (ACI 10.2.7.3). E_s = 29 × 10^6 psi (ACI 8.5.2). Strength-reduction factors: ϕ = 0.65 for compression and ϕ = 0.90 for flexure (ACI 9.3.2).

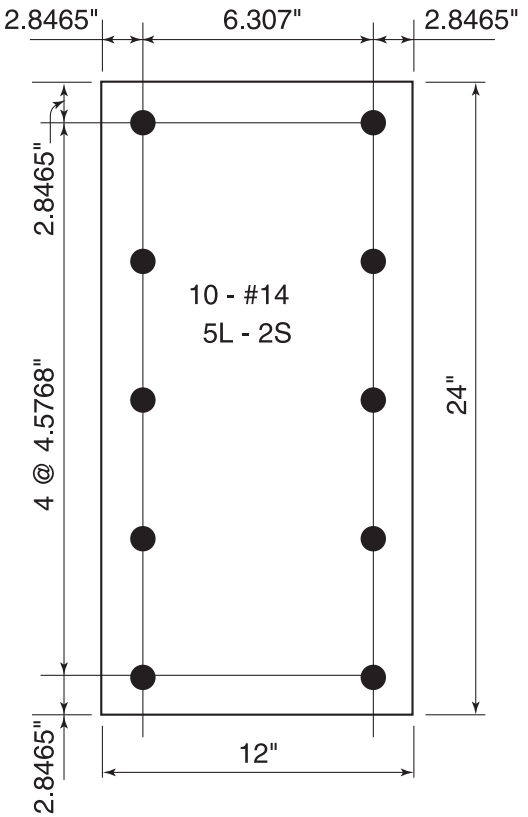

Figure 3-4 Dimensions – Manual Example

In the general case, (Fig. 3-5), the distance from the extreme compression fiber to the neutral axis, c, has to be determined by iteration. The distance, c, can be expressed in terms of the tensile strain, $\varepsilon_s = f_s/E_s$, in the outermost bars:

$$c = \frac{d_{sn}}{1 + f_s/(E_s \varepsilon_c)}$$

Where:

d_{sn} = maximum distance to bars from extreme compression surface. Maximum distance is d_{s5} in Fig. 3-5.

f_s = tensile stress in outermost bars.

ε_c = maximum compressive strain in concrete = 0.003 (ACI 10.2.3).

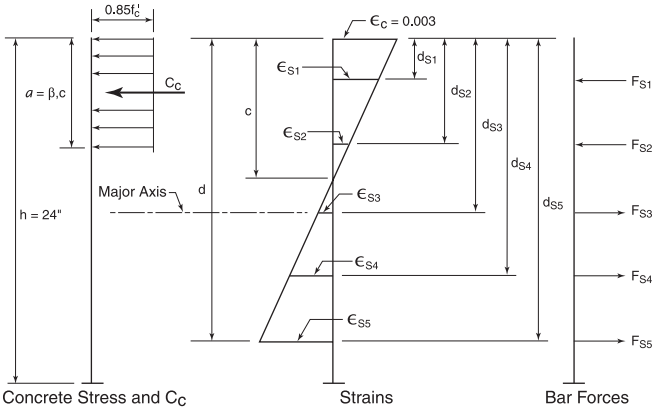

Figure 3-5 General Case

For bars located in the compression zone, i.e., $d_{si} < \beta_1 c$, the compressive force must be reduced by $0.85 f'_c A_b$ to subtract the force from the concrete resisting compression. In this example, the force reduction for 2-#14 bars in a row (stress = 0.85(6) = 5.1 ksi) = 0.85(6)(4.5) = 22.95 kips.

1. $\phi P_{n(max)}$ and ϕM_n

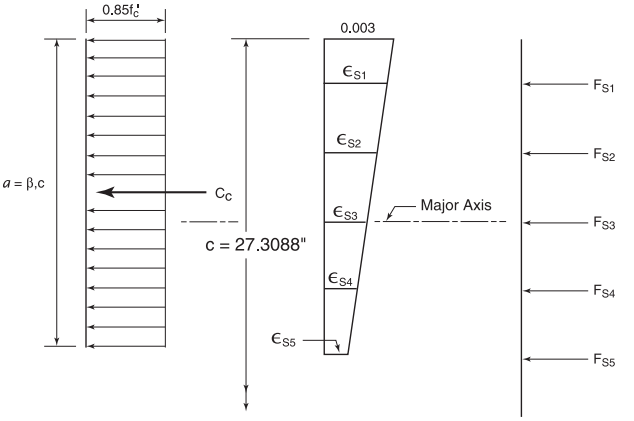

Figure 3-6 $\phi P_{n(max)}$ and ϕM_n

The value of $\phi P_{n(max)}$ can be solved directly by ACI Eq. 10-2:

$$\phi P_{n(max)} = 0.80\ \phi[0.85 f'_c\ (A_g - A_{st}) + f_y A_{st}]$$

$$\phi P_{n(max)} = 0.80(0.65)[0.85(6)(288 - 22.5) + 60(22.5)]$$

$$= 1{,}406 \text{ kips (tabulated = 1,406)}$$

Note that $\phi P_{n(max)}$ was calculated as 1,406.106 kips; then $P_n = 1{,}406.106/\phi = 1{,}406.106/0.65 = 2{,}163.240$ kips.

For this condition, the exact value of strain in the outermost bars (Row 5) is not evident (Fig. 3-6). The entire cross section will be in compression so $c > h$. Expressing the bar forces and the compression resultant in the concrete, C_c, in terms of c, and equating the sum of forces to 2,163.240 kips:

$C_c = 0.85 f'_c ab$
$C_c = 0.85(6)(0.75c)(12) = 45.90c$
Σ Bar Forces (Rows 1 through 5) + $45.90c$
$= 2{,}163.240$ kips
Solving, $c = 27.3088$ in.

From Fig. 3-5, the bar (row) strains, stresses, forces, and moments of the forces about the major axis of the column can be expressed:

$\varepsilon_{si} = \varepsilon_c(1 - d_{si}/c)$

$f_{si} = E_s \varepsilon_{si}$ ($\leq$ 60 ksi)

$F_{si} = f_{si} A_s$ (in this example. $A_s = 4.5$ in.^{2} for 2-#14 bars in a row)

General equation for force F_{si} in row i:

$$F_{si} = \left[(c\text{-}d_{si})\left(\frac{0.003}{c}\right)(E_s) - \beta f'_c\right] A_b \leq f_y A_b$$

where the $\beta f'_c$ term only applies if $d_{si} < \beta c$

$M_{si} = F_{si}(h/2 - d_{si})$

Bars (compression forces and moments about major axis):

Row	d_{si} (in.)	ε_{si}	f_{si} (ksi)	F_{si} (kips)	M_{si} (in.-kips)
1	2.8465	0.0026873	60.000	247.050*	2,261.372
2	7.4233	0.0021845	60.000	247.050*	1,130.674
3	12.0000	0.0016817	48.769	196.510*	0
4	16.5768	0.0011790	34.191	130.909*	−599.144

				909.764	1,985.151

*F_{si} reduced by 22.95 kips/row.

Compute the concrete compression resultant, C_c, and moment, M_c, about the major axis.

The depth of the equivalent rectangular stress block:

$a = \beta_1 c = 0.75(27.3088) = 20.4816$ in.
$C_c = 0.85(6)(20.4816)(12) = 1{,}253.474$ kips
$M_c = 1{,}253.474(12 - 20.4816/2) = 2{,}205.111$ in.-kips

ΣForces = 0
$-P_n + 909.764 + 1{,}253.474 = 0$
$P_n = 2{,}163.238$ kips
$\phi P_{n(max)} = (0.65)(2{,}163.238) = 1{,}406$ kips
(tabulated = 1,406)

$\Sigma M_{MA} = 0$
$-M_n + 1{,}985.151 + 2{,}205.111 = 0$
$M_n = 4{,}190.262$ in.-kips
$\phi M_n = (0.65)(4{,}190.262) = 2{,}724$ in.-kips
(tabulated = 2,724)

Table 3-3 Print-Out from Enclosed CD-ROM – Values of ϕP_n and ϕM_n at Control Points

RECTANGULAR TIED COLUMNS 12″ X 24″

2. ϕP_{ot} and ϕM_{ot} (Point of Zero Tension in Extreme Bars)

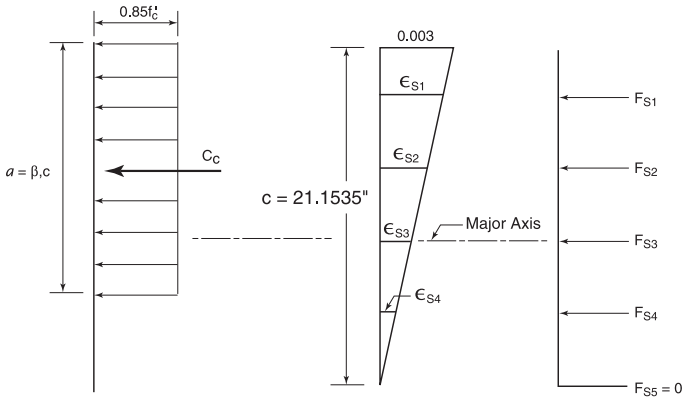

Figure 3-7 ϕP_{ot} and ϕM_{ot} (Point of Zero Tension)

For this condition, the c distance is easily determined by inspection from Fig. 3-7 because $\epsilon_{s5} = f_{s5}/E_s = 0$; hence, $c = 24 - 2.8465 = 21.1535$ in., or by the equation:

$$c = \frac{d_{sn}}{1 + f_s/(E_s \epsilon_c)}$$

$$c = \frac{21.1535}{1 + 0/(29{,}000 \times 0.003)} = 21.1535 \text{ in.}$$

Note that the point of "zero tension" is defined, in this Chapter, as the load/moment combination resulting in zero strain at the center of the vertical bars on the tension face. The diameter of the bar is neglected because the stress in the bar on either side of its center reverses sign and totals zero. Where two layers of bars are used, as with bundled bars, the same definition (to centroid of bundle) is satisfactory for practical use in designing splices.

Bars (compression forces and moments about major axis):

Row	d_{si} (in.)	ε_{si}	f_{si} (ksi)	F_{si} (kips)	M_{si} (in.-kips)
1	2.8465	0.0025963	60.000	247.050*	2,261.372
2	7.4233	0.0019472	56.469	231.161*	1,057.955
3	12.0000	0.0012981	37.646	146.457*	0
4	16.5768	0.0006491	18.823	84.703*	–387.669
5	21.1535	0	0	0	0
				709.371	2,931.658

*F_{si} reduced by 22.95 kips/row.

Compute the concrete compression resultant, C_c, and moment, M_c, about the major axis:

$a = 0.75\ (21.1535) = 15.8651$ in.
$C_c = 0.85\ f'_c ab = 0.85(6)(15.8651)(12) = 970.944$ kips
$M_c = 970.944\ (12 - 15.8651/2) = 3{,}949.266$ in.-kips

ΣForces = 0
$-P_n + 709.371 + 970.944 = 0$
$P_n = 1{,}680.351$ kips
$\phi P_n = (0.65)(1{,}680.315) = 1{,}092$ kips
(tabulated = 1,092)

$\Sigma M_{MA} = 0$
$-M_n + 2{,}931.658 + 3{,}949.266 = 0$
$M_n = 6{,}880.924$ in.-kips
$\phi M_n = (0.65)(6{,}880.924) = 4{,}473$ in.-kips
(tabulated = 4,473)

3. 25% Tension

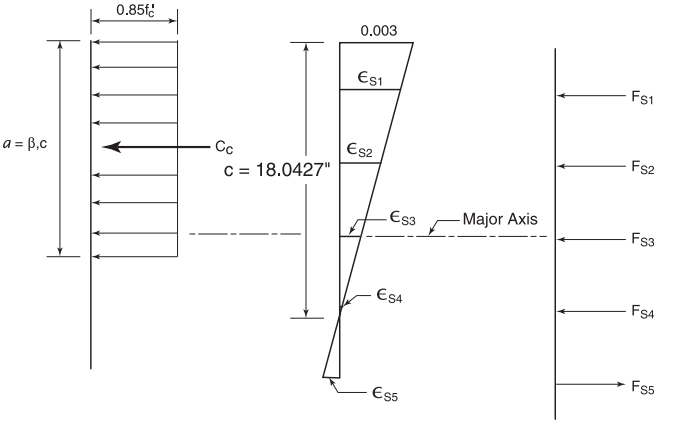

Figure 3-8 25% Tension

The tensile stress in the Row 5 bars = 0.25(60) = 15 ksi. The distance:

$$c = \frac{21.1535}{1 + 15/(29{,}000 \times 0.003)} = 18.0427 \text{ in.}$$

Bars (forces and moments about major axis):

Row	d_{si} (in.)	ε_{si}	f_{si} (ksi)	F_{si} (kips)	M_{si} (in.-kips)
1	2.8465	0.0025267	60.000	247.050*	2,261.372
2	7.4233	0.0017657	51.205	207.472*	949.537
3	12.0000	0.0010047	29.136	108.162*	0
4	16.5768	0.0002437	7.067	31.801*	–145.547
5	21.1535	–0.0005172	–15.000	–67.500	617.861
				526.985	3,683.223

*F_{si} reduced by 22.95 kips/row.

Compute the concrete compression resultant, C_c, and moment, M_c, about the major axis:

$a = 0.75(18.0472) = 13.5320$ in.
$C_c = 0.85(6)(13.5320)(12) = 828.158$ kips
$M_c = 828.158(12 - 13.5320/2) = 4{,}334.579$ in.-kips

ΣForces = 0
$-P_n + 526.985 + 828.158 = 0$
$P_n = 1{,}355.143$ kips
$\phi P_n = (0.65)(1{,}355.143) = 881$ kips (tabulated = 881)

$\Sigma M_{MA} = 0$
$-M_n + 3{,}683.223 + 4{,}334.579 = 0$
$M_n = 8{,}017.802$ in.-kips
$\phi M_n = (0.65)(8{,}017.802) = 5{,}212$ in.-kips
(tabulated = 5,212)

4. 50% Tension

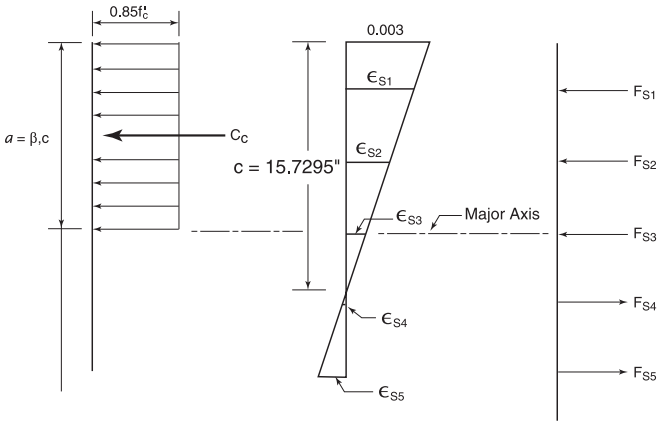

Figure 3-9 50% Tension

The tensile stress in the Row 5 bars = 0.50(60) = 30 ksi. The distance:

$$c = \frac{21.1535}{1 + 30/(29.000 \times 0.003)} = 15.7295 \text{ in.}$$

Bars (forces and moments about major axis):

Row	d_{si} (in.)	ε_{si}	f_{si} (ksi)	F_{si} (kips)	M_{si} (in.-kips)
1	2.8465	0.0024571	60.000	247.050*	2,261.372

				367.587	4,434.753

*F_{si} reduced by 22.95 kips/row.

Compute the concrete compression resultant, C_c, and moment, M_c, about the major axis:

$a = 0.75\ (15.7295) = 11.7971$ in.
$C_c = 0.85(6)\ (11.7971)(12) = 721.983$ kips
$M_c = 721.983\ (12 - 11.7971/2) = 4{,}405.143$ in.-kips

ΣForces = 0
$-P_n + 367.578 + 721.983 = 0$
$P_n = 1{,}089.561$ kips
$\phi P_n = (0.65)(1{,}089.561) = 708$ kips (tabulated = 708)

$\Sigma M_{MA} = 0$
$-M_n + 4{,}434.753 + 4{,}405.143 = 0$
$M_n = 8{,}839.896$ in.-kips
$\phi M_n = (0.65)(8{,}839.896) = 5{,}746$ in.-kips
(tabulated = 5,746)

5. 100% f_y (ϕP_b and ϕM_b, Balance Point on Interaction Diagram)

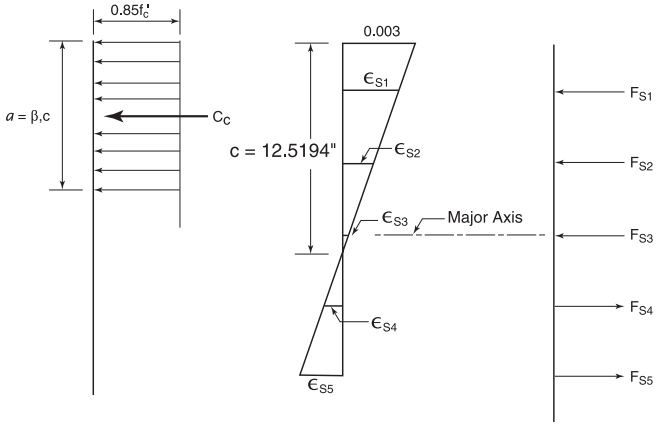

Figure 3-10 100% f_y (ϕP_b and ϕM_b Balance)

The tensile stress in the Row 5 bars = f_y = 60 ksi. The distance:

$$c = \frac{21.1535}{1 + 60/(29.000 \times 0.003)} = 12.5194 \text{ in.}$$

Bars (forces and moments about major axis):

				2.826	5,937.890

*F_{si} reduced by 22.95 kips/row.

Compute the concrete compression resultant, C_c, and moment, M_c, about the major axis:

$a = 0.75(12.5194) = 9.3895$ in.
$C_c = 0.85(6)(9.3895)(12) = 574.637$ kips
$M_c = 574.637(12 - 9.3895/2) = 4{,}197.867$ in.-kips

ΣForces = 0
$-P_n + 2.826 + 574.637 = 0$
$P_n = 577.463$ kips
$\phi P_n = 0.65(577.463) = 375$ kips (tabulated = 375)

$\Sigma M_{MA} = 0$
$-M_n + 5{,}937.890 + 4{,}197.867 = 0$
$M_n = 10{,}135.757$ in.-kips
$\phi M_n = (0.65)(10{,}135.757) = 6{,}588$ in.-kips
(tabulated = 6,588)

6. ϕP_n, ϕM_n ($\varepsilon_t = 0.005$)

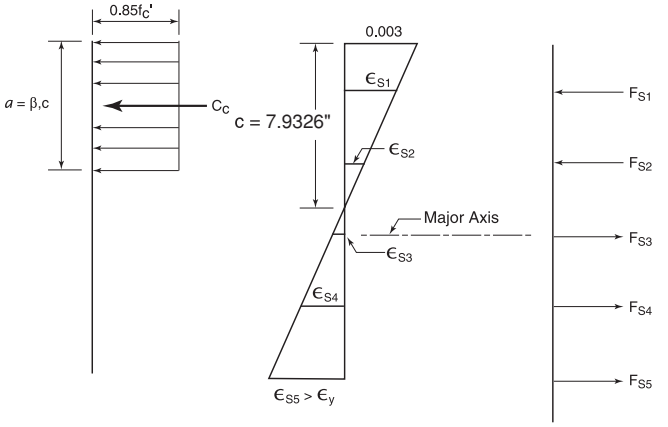

Figure 3-11 ϕP_n, ϕM_n ($\varepsilon_t = 0.005$)

For this condition, the tensile strain in the outermost bars (Row 5) is 0.005. The value of c can be solved for directly:

$c = d_{sn}(0.003)/(0.003 + 0.005)$
$= 21.1535(0.003)/(0.003 + 0.005)$
$= 7.9326$ in.

Bars (forces and moments about major axis):

Row	d_{si} (in.)	ε_{si}	f_{si} (ksi)	F_{si} (kips)	M_{si} (in.-kips)
1	2.8465	0.0019235	55.781	228.065*	2,087.595
2	7.4233	0.0001926	5.586	25.136*	115.043
3	12.0000	–0.0015383	–44.609	–200.742	0
4	16.5768	–0.0032691	–60.000	–270.000	1,235.722
5	21.1535	–0.0050000	–60.000	–270.000	2,471.445
				–487.541	5,909.805

*F_{si} reduced by 22.95 kips/row.

Compute the concrete compression resultant, C_c, and moment, M_c, about the major axis:

$a = 0.75(7.9326) = 5.9494$ in.
$C_c = 0.85(6)(5.9494)(12) = 364.105$ kips
$M_c = 364.105(12 - 5.9494/2) = 3{,}286.150$ in.-kips

ΣForces = 0
$-P_n - 487.541 + 364.105 = 0$
$P_n = 123.436$ kips
$\phi P_n = (0.9)(-123.436) = -111$ kips (tabulated = –111)

$\Sigma M_{MA} = 0$
$-M_n + 5{,}909.805 + 3{,}286.150 = 0$
$M_n = 9{,}195.955$ in.-kips
$\phi M_n = (0.9)(9{,}195.955) = 8{,}276$ in.-kips
(tabulated = 8,276)

7. ϕM_n ($\phi P_n = 0$)

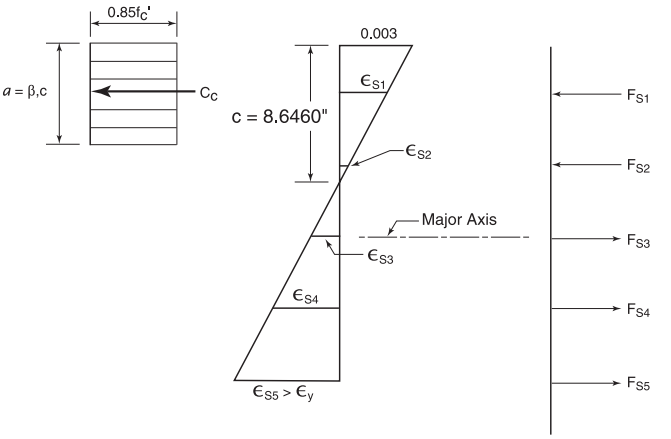

Figure 3-12 ϕM_n ($\phi P_n = 0$)

For this condition, the tensile stress in the outermost bars (Row 5) is 60 ksi, but the exact value of the strain is not evident: $\varepsilon_{s5} > \varepsilon_y$ (Fig. 3-12). *A trial-and-error solution is required.* After several trials (manually), the neutral axis is determined to be located between Row 2 and Row 3. Expressing the bar forces and the concrete compression resultant, C_c, in terms of c and summing forces:

$$[(c - 2.8465)\left(\frac{0.003}{c}\right)(29{,}000 - 5.1](4.5) +$$
$$(c - 7.4233)\left(\frac{0.003}{c}\right)(29{,}000)(4.5) + 0.85\,(6)(0.75c)(12)]$$
$$= (12 - c)\left(\frac{0.003}{c}\right)(29{,}000)(4.5) + 270 + 270$$

Solving, $c = 8.6460$ in.

Bars (forces and moments about major axis):

Row	d_{si} (in.)	ε_{si}	f_{si} (ksi)	F_{si} (kips)	M_{si} (in.-kips)
1	2.8465	0.0020123	58.357	239.656*	2,193.691
2	7.4233	0.0004242	12.302	55.359	253.361
3	12.0000	–0.0011638	–33.750	–151.875	0
4	16.5768	–0.0027518	–60.000	–270.000	–1,235.736
5	21.1535	–0.0043399	–60.000	–270.000	2,471.445
				–396.860	6,154.233

*F_{si} reduced by 22.95 kips/row.

Compute the concrete compression resultant, C_c, and moment, M_c, about the major axis:

$a = 0.75(8.6460) = 6.4845$ in.
$C_c = 0.85(6)\ (6.4845)(12) = 396.851$ kips
$M_c = 396.851(12 - 6.4845/2) = 3,475.522$ in.-kips

Because $\varepsilon_t = 0.00434 > 0.00207$ and $\varepsilon_t < 0.005$, ϕ must be determined:

$$\phi = 0.65 + \frac{(0.9 - 0.65)}{(0.005 - 0.00207)}(\varepsilon_t - 0.00207)$$

$$\phi = 0.65 + 85.324(0.00434 - 0.00207)$$
$$= 0.8437$$

ΣForces = 0
$-P_n - 396.860 + 396.851 = 0$
$P_n = 0$; hence, $\phi P_n = 0$ (tabulated = 0)

$\Sigma M_{MA} = 0$
$-M_n + 6,154.233 + 3,475.522 = 0$
$M_n = 9,629.755$ in.-kips
$\phi M_n = (0.8437)(9,629.755) = 8,125$ in.-kips
(tabulated = 8,125)

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

RECTANGULAR TIED COLUMNS 16" x 26"

Short columns – no sidesway

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

RECTANGULAR TIED COLUMNS 20" x 36"

Short columns – no sidesway
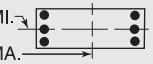
Bending on major or minor axis



f'_c = 4,000 psi f_y = 60,000 psi
ϕM_n in inch-kips ϕP_n in kips

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

RECTANGULAR TIED COLUMNS 22" x 36"

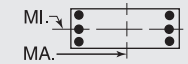
Short columns – no sidesway
Bending on major or minor axis



f'_c = 4,000 psi f_y = 60,000 psi
ϕM_n in inch-kips ϕP_n in kips

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

RECTANGULAR TIED COLUMNS 22" x 42"

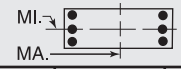
Short columns – no sidesway
Bending on major or minor axis



f'_c = 4,000 psi f_y = 60,000 psi

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

RECTANGULAR TIED COLUMNS 24" x 26"

Short columns – no sidesway
Bending on major or minor axis

f'_c = 4,000 psi f_y = 60,000 psi
ϕM_n in inch-kips ϕP_n in kips

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

RECTANGULAR TIED COLUMNS 24" x 30"

Short columns – no sidesway
Bending on major or minor axis

f'_c = 4,000 psi f_y = 60,000 psi
ϕM_n in inch-kips ϕP_n in kips

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

RECTANGULAR TIED COLUMNS 24" x 34"

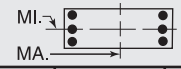
Short columns – no sidesway
Bending on major or minor axis



f'_c = 4,000 psi f_y = 60,000 psi
ϕM_n in inch-kips ϕP_n in kips

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

RECTANGULAR TIED COLUMNS 24" x 42"

Short columns – no sidesway
Bending on major or minor axis

f'_c = 4,000 psi f_y = 60,000 psi
ϕM_n in inch-kips ϕP_n in kips

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

RECTANGULAR TIED COLUMNS 24" x 46"

Short columns – no sidesway
Bending on major or minor axis

f'_c = 4,000 psi f_y = 60,000 psi
ϕM_n in inch-kips ϕP_n in kips

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

RECTANGULAR TIED COLUMNS 24" x 48"

Short columns – no sidesway
Bending on major or minor axis

(1) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.
(2) L = long face, S = short face, E = each face; 3E = 3 bars each face; 2L-3S = 2 bars each long face and 3 short face.

CHAPTER 4 – ROUND-TIED COLUMNS

General. Reinforced concrete round columns are most frequently used for structures with large, open areas and few partitions. The round column is usually formed with standard prefabricated forms available in diameter multiples of 1 or 2 inches, which leave a smooth finish suitable for exposed use. Paint or decorative finish treatment, if used, is ordinarily applied directly to the structural concrete. Reusable round column steel forms or one-use waterproofed fiber forms are both commercially available.

The ACI Building Code permits round columns provided with either tied or spiral lateral reinforcement. Other variations possible include conical column capitals to increase available perimeter for shear resistance. Round, spirally reinforced columns with capitals and flat slabs with drop panels are the original heavy duty concrete floor system developed as the preferred construction to replace earlier systems of timber and masonry.

In this Chapter, the design axial load and moment strengths (capacities) of "short", round-tied columns are tabulated for 12-inch to 36-inch diameters in 2-inch increments with f'_c = 4,000, 5,000, 6,000, and 8,000 psi, and Grade 60 reinforcing bars; and for 24-inch to 48-inch diameters in 2-inch increments with f'_c = 6,000, 8,000, and 10,000 psi, and Grade 75 reinforcing bars. The tabulated capacities cover the allowable range of vertical bar areas (0.01 to 0.08 times A_g).

Spirals Versus Ties. Spiral reinforcement conforming to minimum code requirements (ACI 10.9.3, Eq. 10-5) ensures maximum ductile behavior for concrete columns, even at loading to failure. This property is essential for earthquake resistance (ductile frames), for blast resistance, and desirable in ordinary structures. For absolute minimum size round columns (maximum capacity for a given size), spiral reinforcement must be used. The Code permits use of

$$\phi P_{n\,(\max)} = 0.85\phi[0.85 f'_c\,(A_g - A_{st}) + f_y A_{st}],$$

for spiral columns (ACI 10.3.6.1) compared to

$$\phi P_{n(\max)} = 0.80\phi[0.85 f'_c\,(A_g - A_{st}) + f_y A_{st}],$$

for tied columns (ACI 10.3.6.2).

The reduction in design strength for spiral columns is also less than for tied columns, i.e., the strength-reduction factor, ϕ = 0.75, for spirally reinforced columns versus ϕ = 0.65 for tied columns (ACI 9.3.2.2). For columns with heavy axial loads, subject to relatively small factored moments, and using the maximum allowed vertical bar area, these two code provisions encourage the use of spiral reinforcement to achieve the minimum size of a round column.

Spiral reinforcement is more costly, by weight, than vertical reinforcing bars. The spiral weight for the minimum column area to qualify for the two special code provisions cited above is considerable. For this reason, it will ordinarily be more economical to achieve the required load capacity for a designated size round-tied column by increasing the vertical bar area or concrete strength, where possible.

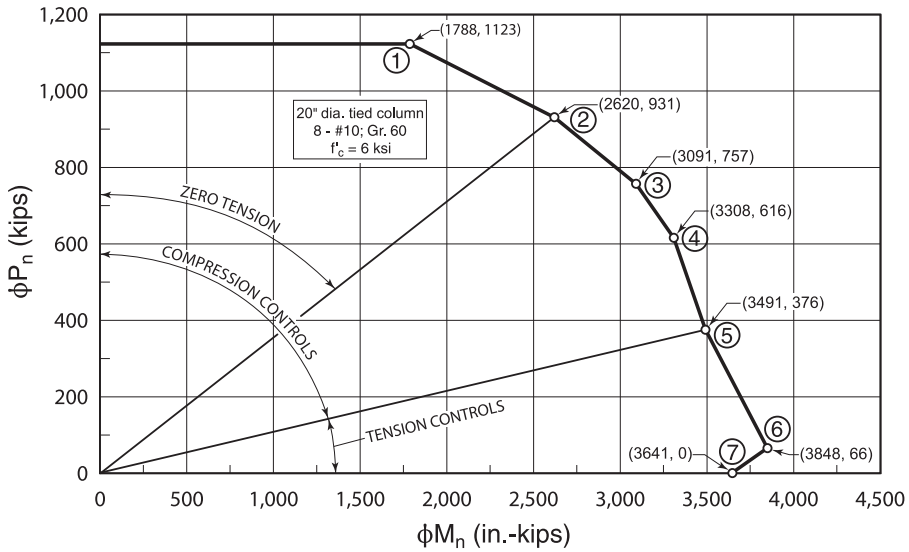

Figure 4-1 Control Points for Load-Moment Interaction Curves

Tabulated designs for "short" spirally reinforced columns are provided on the enclosed CD-ROM. The tables cover 12-inch to 36-inch diameters in 2-inch increments with f'_c = 4,000, 5,000, 6,000, and 8,000 psi and Grade 60 reinforcing bars; and for 24-inch to 48-inch diameters in 2-inch increments with f'_c = 6,000, 8,000, and 10,000 psi and Grade 75 reinforcing bars. In all of the tables, the minimum yield strength of the spiral reinforcement is 60,000 psi.

Load-Moment Interaction Curves. Fig. 4-1 was constructed from the tabulated values for column capacity on Page 4-28. "Control points" for column load-moment interaction curves refer to values of ϕP_n and ϕM_n necessary to construct the interaction diagram from maximum design axial load and corresponding moment strength to pure design moment strength, and limiting values convenient for compliance with various Code requirements.

The control points on the load-moment interaction diagram in Fig. 4-1 identify:

1. The coordinates of Point 1 are the maximum design axial load strength, $\phi P_{n(max)}=0.80\phi\,[0.85f'_c\,(A_g - A_{st}) + f_y A_{st}]$, for round-tied columns (ACI 10.3.6.2); and the corresponding design moment strength, ϕM_n.

2. Point 2 is the zero tension point. Location of this point is convenient where end-bearing splices are used (ACI 12.17.4). At Point 2, the stress in the bars nearest the tension face is zero. For a larger factored moment, the stress becomes tensile. The coordinates of Point 2 are designated ϕP_{ot} and ϕM_{ot}.

3. At Point 3, the tensile stress in the bars nearest the tension face of the column is 25 percent of the specified yield strength. For Grade 60 reinforcing bars, the tensile stress is 0.25 (60,000) = 15,000 psi. Point 3 is not a "control point", per se. The coordinates of the point, ϕP_{15}, ϕM_{15}, are tabulated for convenience in constructing the load-moment ($\phi P_n - \phi M_n$) interaction curve.

4. At Point 4, the tensile stress in the bars nearest the tension face of the column is 50 percent of f_y, that is, 30,000 psi for Grade 60 reinforcing bars. The coordinates of Point 4 are designated ϕP_{30} and ϕM_{30}.

5. At Point 5, ϕP_b and ϕM_b are the design axial load and moment strengths at balanced strain conditions. At this point, the tensile steel reaches the strain corresponding to its specified yield strength, f_y, i.e., "100% f_y", and concrete compressive strain reaches its assumed ultimate value of 0.003.

ACI 10.3.3 defines the column section as being compression-controlled, with ϕ = 0.65 (tied) or 0.75 (spiral), when the extreme steel strain is less than or equal to f_y/E_s.

6. Point 6 is the condition where the strain in the extreme tension steel is equal to 0.005. ACI 10.3.4 defines the column section as being tension-controlled, with ϕ = 0.90, when the extreme steel strain is equal to or greater than 0.005.

When the extreme steel strain is between f_y/E_s (compression-controlled) and 0.005 (tension-controlled), the column section is in a transition region where the ϕ-factor is assumed to vary linearly with the extreme steel strain.

7. Point 7, the last control point, is the pure design moment strength when the design axial load strength is zero.

Concrete Cover. All column design axial load and moment strengths (capacities) tabulated in this *Handbook* were calculated using the specified concrete cover prescribed for cast-in-place columns, 1½ inches to ties or spirals (ACI 7.7.1). For all column vertical bars, #10 and smaller; 3/8 inch was allowed for #3 ties, and for #11, #14, and #18 vertical bars, ½ inch for #4 ties, as the minimum sizes of ties permitted (ACI 7.10.5.1).

The radial distances, d_r, from the nearest point on the face of the column to the center of vertical bars, used in calculations are shown in Table 4-1:

Table 4-1 Depth from Nearest Face to Center of Vertical Bars*

Bar Size	#5	#6	#7	#8	#9	#10	#11	#14	#18
d_r (in.)	2.19	2.25	2.31	2.38	2.44	2.51	2.71	2.85	3.12

* Based on 1-1/2 in. concrete cover to the tie or spiral.

Steel Areas and Bar Orientation. In some design handbooks, calculations for tabulated design axial load and moment strengths of round columns are based on the assumption that the behavior of the vertical bars is the same as that of a vertical steel tube of equivalent cross-sectional area and average diameter equal to ($h - 2d_r$). The equivalent area tube method increases in accuracy with increasing numbers of vertical bars and gives a single average design moment strength for bending in any direction. Since the ACI Building Code permits the use of round-tied columns with a minimum of four vertical bars (minimum of six vertical bars with spirals), the design axial load and moment strengths in this Chapter have been computed using actual bar areas, oriented so that one bar is located on the x-axis for bending about the x-axis. See Fig. 4-2. The bar-by-bar method is, of course, more accurate than the equivalent tube method.

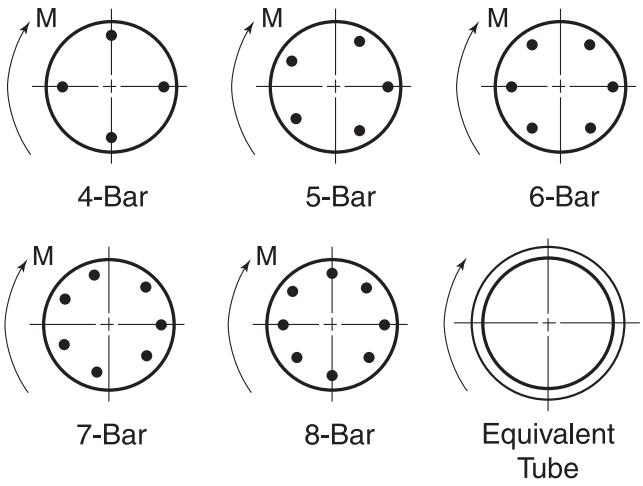

Figure 4-2 Orientation of Bar Patterns Used for Calculation of Load Capacity Tables

It is not practicable to prescribe orientation of vertical bars in round columns when more than four bars are used, and not advisable without rigorous field inspection when using only four bars. For this reason, it is prudent to base calculations on the bar arrangement giving minimum design moment strength and to use this value for the design moment strength in any direction.

Tie Patterns. As a general rule, in selecting column reinforcement for maximum economy, the required steel area should be furnished in the largest size bars practicable. Fewer bars simplify and speed up field assembly. For this reason, 4-bar arrangements should be considered when feasible. Note that for the 4-bar round column an economical square tie may be used. See Fig. 4-3 and Table 4-2 for suggested tie arrangements.

TABLE 4-2 Minimum Tie Sizes and Maximum Spacings*

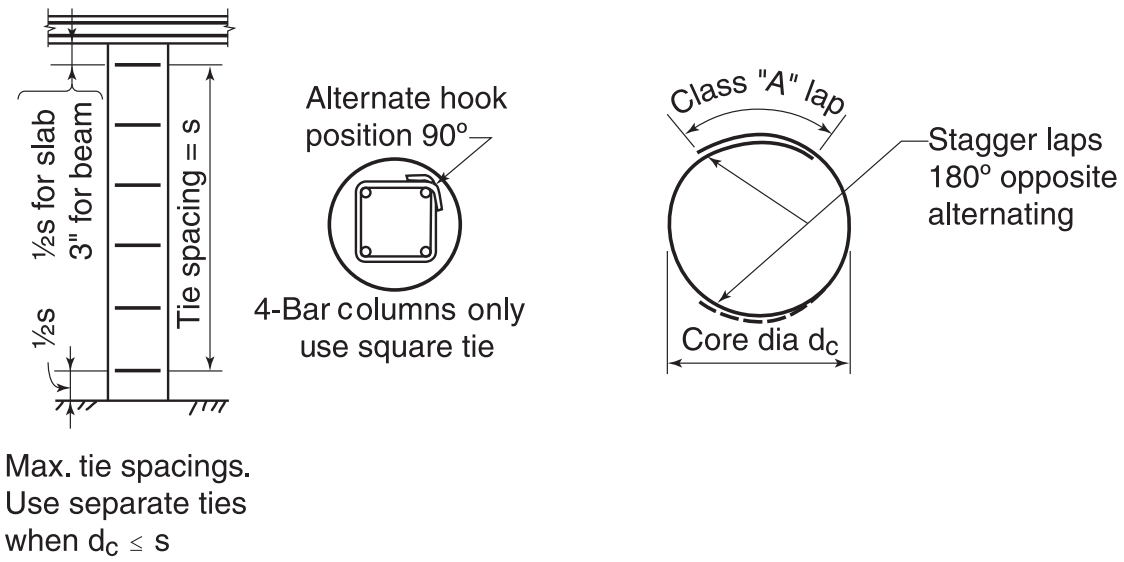

Figure 4-3 Suggested Ties

USE OF TABLES FOR ROUND-TIED COLUMNS

Example 1

Select a round-tied column for an intermediate floor in a flat slab parking garage. Story height is 9′-0″. Concrete compressive strength, f'_c, in the columns above is 4,000 psi. Grade 60 reinforcing bars are used throughout. Column height (clear) between floor and drop panel is 8′-0″. The entire structure at this level is braced against sidesway. The service dead load is 200 kips; the service live load, using loads per square foot specified in the applicable building code after all reductions permitted in live load by the local building code, is 160 kips. Unbalanced factored live load on the floor above requires that the column resist a factored moment of 147 ft-kips.

$P_u = 1.2(200) + 1.6(160) = 240 + 256 = 496$ kips
$M_u = 147$ ft-kips = 1,764 in.-kips

For this example, assume the column above has an 18-in. diameter, and that it is desired to maintain the same size through this floor and two floors below. Previous investigation of the column above indicates that slenderness effects need not be considered since $k\ell_u/r = [(1.0)(96)/(0.25)(18)] = 21.4 < 22$ (ACI 10.10.1(b) with $M_1 = M_2$).

Enter the table on Page 4-13 with $P_u = 496$ kips and $M_u = 1{,}765$ in.-kips. Interpolating as necessary, read:

Vertical Bars	ϕP_n (kips)	ϕM_n (in.-kips)	*Rho*,%
5 – #14	496	1,901	4.42
6 – #14	496	2,184	5.31
7 – #11	496	1,907	4.29

Use an 18-in. diameter column with 7 – #11 vertical bars and #4 ties spaced at 18 in.; $f'_c = 4{,}000$ psi.

Example 2

Select a column design for the columns that are two floors below those of Example 1. From structural analysis, $P_u = 1{,}104$ kips and the factored moment M_u due to unbalanced gravity load is 127 ft-kips = 1,524 in.-kips.

Refer to the table on Page 4-13; none of the tabulated designs provide the required combination of

$$\phi P_n \geq 1{,}104 \text{ kips and } \phi M_n \geq 1{,}524 \text{ in.-kips}$$

Tied columns with an 18-in. diameter and with $f'_c = 4{,}000$ psi will not suffice. At this point, there are three options:

1. Use a larger diameter column
2. Use a higher f'_c
3. Use a spiral in combination with options (1) or (2) if minimum diameter is essential.

Consider Option 1; try a 22-in. diameter column with $f'_c = 4{,}000$ psi; enter the table on Page 4-14 and read for 11 – #11 vertical bars:

$\phi P_n = 1{,}177$ kips and $\phi M_n = 1{,}879$ in.-kips, okay

Consider Option 2; try an 18-in. diameter column with $f'_c = 8{,}000$ psi; enter the table on Page 4-35 and read for 10 – #10 vertical bars:

$\phi P_n = 1{,}251$ kips and $\phi M_n = 1{,}787$ in.-kips, okay

Example 3

Part of the structure in Examples 1 and 2 includes a ground floor with a ceiling height of 15 feet. For these exterior columns, $P_u = 828$ kips and factored moments due to unbalanced gravity load are $M_u = +62$ ft.-kips at the top and –35 ft.-kips at the bottom. For evaluating slenderness effects, this floor is also braced by elements other than columns against sidesway. Again, it is desired to use an 18-in. round column.

Slenderness effects have to be considered since $k\ell_u/r = 1.0(15)(12)/(0.25)(18) = 40 > 22$

$$e = \frac{M_u}{P_u} = \frac{(62)(12)}{828} = 0.9 \text{ in.}$$

Min. $e = 0.6 + 0.03h = 0.6 + 0.03(18) = 1.14$ in.
Use min. $e = 1.14$ in.

Refer to the table on Page 4-28 for $f' = 6{,}000$ psi. Allow about 100 percent reserve in ϕM_n for slenderness effects; required $\phi M_n = 828(1.14)(2) = 1{,}890$ in.-kips.

Try an 18-in. diameter column with 6-#11 vertical bars:

$E_c = 57{,}000\sqrt{f'_c}$ (ACI 8.5.1)

$E_c = 57{,}000\sqrt{6{,}000} = 4.4 \times 10^6$ psi

$$I_g = \frac{\pi h^4}{64} = \frac{\pi(18)^4}{64} = 5{,}150 \text{ in.}^4$$

For a tube equivalent in area to 6 – #11 vertical bars, $A_s = (6)(1.56) = 9.36$ in.^{2}; $d = 18 - 2(1.50) - 2(0.5) - 1.41 = 12.59$ in.; $\Delta = 6(1.56)/\pi(12.59) = 0.24$ in.; the inner diameter $d_1 = 12.59 - 0.24 = 12.35$ in.; and the outer diameter $d_2 = 12.59 + 0.24 = 12.83$ in.

The moment of inertia for the reinforcing steel:

$$I_{se} = \frac{\pi(d_2^4 - d_1^4)}{64} = \frac{\pi(27{,}096 - 23{,}263)}{64} = 188 \text{ in.}^4$$

The total factored axial load, $P_u = 828$ kips is given in this example. To calculate β_{dns}, the factored dead load and factored live load are required. Assume the dead load and live load are in same proportions as in Example 1. Then

$$\beta_{dns} = \frac{1.2(200)}{1.2(200) + 1.6(160)} = 0.48$$

$$EI = \frac{0.2E_c I_g + E_s I_{se}}{1 + \beta_{dns}} \text{ . . . . . .(ACI 10.10.6.1, Eq. 10-14)}$$

$$EI = \frac{0.2(4.4 \times 10^6)(5{,}150) + (29 \times 10^6)(188)}{1 + 0.48} = 6.75 \times 10^9$$

Critical load, P_c, for $k = 1.0$ (braced frame):

$$P_c = \frac{\pi^2 EI}{(k\ell_u)^2} = \frac{\pi^2 (6.75 \times 10^9)}{(1 \times 15 \times 12)^2} = 2{,}056 \text{ kips}$$

Moment magnification factor, δ_{ns},

$$\delta_{ns} = \frac{C_m}{1 - \dfrac{P_u}{0.75 P_c}} \geq 1.0 \quad \text{(ACI 10.10.6, Eq. 10-12)}$$

$$C_m = 0.6 + 0.4 \frac{M_1}{M_2} \quad \text{(ACI 10.10.6.4, Eq. 10-16)}$$

$$C_m = 0.6 + 0.4(35/62) = 0.826$$

$$\delta_{ns} = \frac{0.826}{1 - \dfrac{828}{(0.75)(2{,}056)}} = 1.78$$

Magnified moment, $M_c = \delta_{ns} M_2 = (1.78)(828)(1.14)$

$$M_c = 1{,}680 \text{ in.-kips}$$

The column must be able to resist

$$P_u = 828 \text{ kips and } M_u = M_c = 1{,}680 \text{ in.-kips}$$

From Page 4-28, for an 18-in. diameter column with 6 – #11 vertical bars, and interpolating as necessary:

$\phi P_n = 828$ kips and $\phi M_n = 1{,}676$ in.-kips, okay.

Example 4

The interior columns in the 15-ft high portion of the structure of Example 3 must support a factored load, $P_u = 1{,}104$ kips and resist factored moments 994 in.-kips at the top and –427 in.-kips at the footing

$$e = \frac{994}{1104} = 0.9 \text{ in.} < \text{min. } e = 0.6 + 0.03h = 1.14 \text{ in.}$$

$$C_m = 0.6 + 0.4\left(\frac{-427}{944}\right) = 0.43$$

For architectural reasons, 18-in. diameter round columns are desired. Use $f'_c = 6{,}000$ psi to match the exterior columns in Example 3. See table on Page 4-28. Try 11-#11 vertical bars.

From Example 3:

$E_c = 4.4 \times 10^6$ psi

$I_g = 5{,}150$ in.^{4}

$\beta_{dns} = 0.48$

$A_s = (11)(1.56) = 17.16$ in.^{2} The equivalent tube has $\Delta = 11(1.56)/\pi\,(12.59) = 0.43$ in.; an inner diameter $d_1 = 12.59 - 0.43 = 12.16$ in.; and an outer diameter $d_2 = 12.59 + 0.43 = 13.02$ in.

The moment of inertia for the reinforcing steel:

$$I_{se} = (0.0491)\,(d_2^4 - d_1^4) = (0.0491)\,(28{,}737 - 21{,}864)$$

$I_{se} = 337$ in.^{4}

$$EI = \frac{0.2E_c I_g + E_s I_{se}}{1 + \beta_{dns}}$$

$$EI = \frac{(0.2)(4.4 \times 10^6)(5.15 \times 10^3) + (29 \times 10^6)(337)}{1 + 0.48}$$

$$EI = 9.67 \times 10^9$$

Critical load, $P_c = \dfrac{\pi^2 EI}{(k\ell_u)^2}$

$$P_c = \frac{(\pi)^2 (9.67 \times 10^9)}{(180)^2} = 2{,}946 \text{ kips}$$

Moment magnification factor,

$$\delta_{ns} = \frac{C_m}{1 - \dfrac{P_u}{0.75 P_c}} \geq 1.0$$

$$\delta_{ns} = \frac{0.43}{1 - \dfrac{1104}{(0.75)(2{,}946)}} = 0.86 < 1.0,\ \delta_{ns} = 1.0$$

Magnified moment, $M_c = \delta_{ns} M_2 = (1.00)(1{,}104)(1.14)$

$$M_c = 1{,}259 \text{ in.-kips}$$

The column must be able to resist $P_u = 1{,}104$ kips and $M_u = M_c = 1{,}259$ in.-kips.

From Page 4-28, for an 18-in. diameter column with 11-#11 vertical bars, and interpolating as necessary: $\phi P_n = 1{,}104$ kips and $\phi M_n = 1{,}738$ in.-kips, okay.

Manual Example

Review a round-tied column 20 inches in diameter with $f'_c = 6{,}000$ psi and 6–#9 vertical (longitudinal) reinforcing bars. Compute values of ϕP_n and ϕM_n at control points. Compare computed values versus the tabulated values in this Chapter. The printed-out values are displayed in Table 4-3.

The dimensions in Fig. 4-4 are based on 1½ inches of concrete cover to the #3 ties. For $f'_c = 6{,}000$ psi, $\beta_1 = 0.75$ (ACI 10.2.7.3), $E_s = 29 \times 10^6$ psi (ACI 8.5.2). Strength–reduction factors: $\phi = 0.65$ for compression and $\phi = 0.90$ for flexure (ACI 9.3.2).

Table 4-3 Interaction Table for Chapter 4 Manual Example

ROUND TIED COLUMNS 20" DIAMETER														
Short Columns – no sidesway												$f_c' = 6{,}000$ psi ϕM_n in inch-kips		$f_y = 60{,}000$ psi ϕP_n in.-kips
BARS	RHO	Max. Cap		0% f_y		25% f_y		50% f_y		100% f_y		$\varepsilon_t = 0.005$		$\phi P_n = 0$

6-#9	1.91	1645	1004	2487	789	2794	638	2913	523	2927	333	2949	111	2353

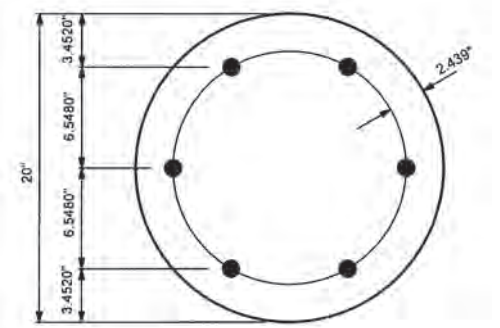

Figure 4-4 Dimensions – Manual Example

In the general case, (Fig. 4-5), the distance from the extreme compression fiber to the neutral axis, c, has to be determined by iteration. The distance, c, can be expressed in terms of the tensile strain, $\varepsilon_s = f_s / E_s$, in the outermost bars:

$$c = \frac{d_{sn}}{1 + f_s/(E_s \varepsilon_c)}$$

Where:

d_{sn} = Maximum distance to bars from extreme compression surface

f_s = Tensile stress in outermost bars.

ε_c = Maximum compressive strain in concrete
= 0.003 (ACI 10.2.3)

E_s = Modulus of elasticity of bars
$= 29 \times 10^6$ psi

For those bars which are located in the concrete compression zone ($d_{si} < \beta_1 c$), their compressive stress must be reduced by $0.85 f_c'$ to account for the area of the concrete occupied by the reinforcing bar or their compressive force must be reduced by $0.85 f_c' A_b$. In this example, the reduction for a #9 bar is:

$$0.85(6) = 5.1 \text{ ksi, or}$$
$$5.1(1) = 5.1 \text{ kips}$$

1. $\phi P_{n(max)}$ and ϕM_n

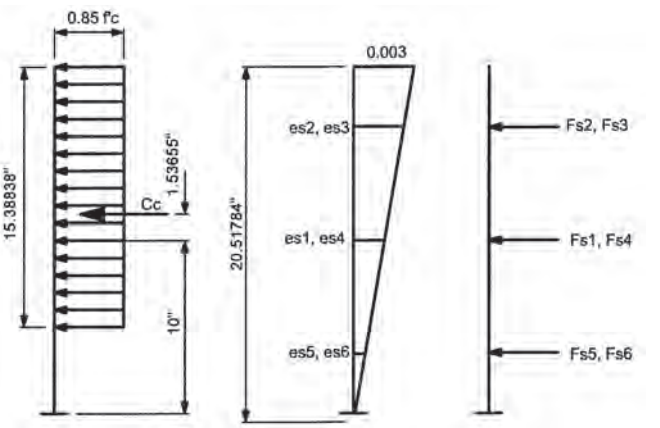

Figure 4-6 $\phi P_{n(max)}$ and ϕM_n

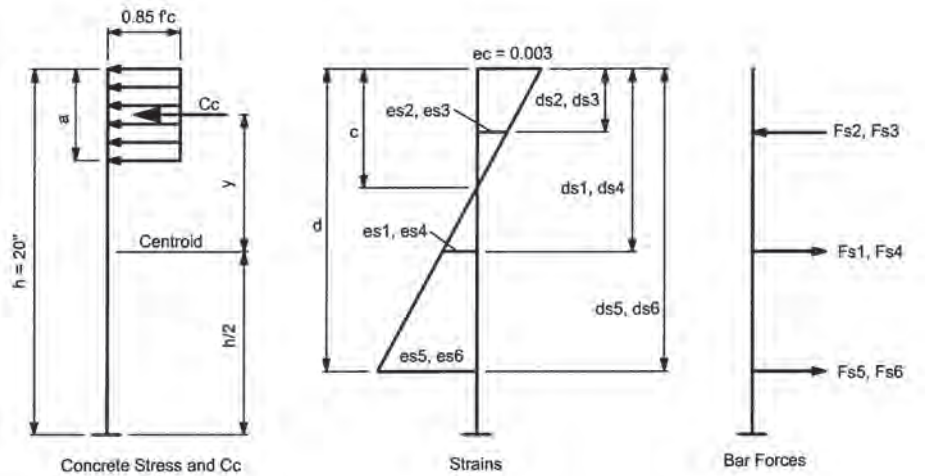

Figure 4-5 General Case

The value of $\phi P_{n(max)}$ can be solved directly by ACI Eq. 10-2:

$$\phi P_{n(max)} = 0.80\phi[0.85 f'_c (A_g - A_{st}) + f_y A_{st}]$$
$$= 0.80(0.65)[0.85(6)(314.16 - 6) + 60(6)]$$
$$= 1{,}004 \text{ kips (tabulated = 1,004)}$$

For this condition, the exact value of strain in the outermost bars (bars 5 and 6) is not evident (Fig. 4-6). The entire cross-section will be in compression, so $c > h$.

Through iteration, $c = 20.51791$ in.

From Fig. 4-5, the bar strains, stresses, forces, and moments of the forces about the column centroid can be expressed:

$$\varepsilon_{si} = \varepsilon_c (1 - d_{si}/c)$$
$$f_{si} = E_s \varepsilon_{si} (\leq 60 \text{ ksi})$$
$$F_{si} = f_{si} A_b (A_b = 1 \text{ in.}^2)$$
$$M_{si} = F_{si}(h/2 - d_{si})$$

Bars forces and moments about column centroid are tabulated below:

Bar	d_{si} (in.)	ε_{si}	f_{si} (ksi)	F_{si} (kips)	M_{si} (in.-kips)
1	10.0000	0.0015379	44.598	39.498*	0
2	3.4520	0.0024953	60.000	54.900*	359.486
3	3.4520	0.0024953	60.000	54.900*	359.486
4	10.0000	0.0015379	44.598	39.498*	0
5	16.5480	0.0005804	16.833	16.833	-110.222
6	16.5480	0.0005804	16.833	16.833	-110.222
				222.462	498.525

*F_{si} reduced by 5.1 kips

Compute the concrete compression resultant based on the rectangular stress block, C_c, and moment, M_c, about the column centroid. For a circular segment with a height of a:

α = One-half the subtended angle (radians)
$= \cos^{-1}[(h - 2a)/h]$

A_c = Area of concrete compression zone
$= h^2 [2\alpha - \sin(2\alpha)]/8$

y = Distance of concrete compression zone centroid from the column centroid
$= 2h^3 \sin \alpha^3/(24 A_c)$

The depth of the equivalent stress block:

$a = \beta_1 c = 0.75(20.51791) = 15.38843$ in.

Properties of the concrete compression zone:

$\alpha = \cos^{-1}[(20 - 2(15.38843))/20]$
$= 2.13985$ rad

$A_c = 20^2 [2(2.13985) - \sin(2 \times 2.13985)]/8$
$= 259.37708$ in.^{2}

$y = 2(20)^3 \sin(2.13985)^3/(24 \times 259.37708)$
$= 1.53656$ in.

Concrete compression resultant, C_c, and moment, M_c, about the column centroid:

$C_c = 0.85 f'_c A_c$
$= 0.85(6)259.37708 = 1{,}322.823$ kips

$M_c = C_c(y)$
$= 1{,}322.823(1.53656) = 2{,}032.597$ in.-kips

Σ Forces = 0
$-P_n + 222.462 + 1{,}322.823 = 0$
$P_n = 1{,}545.285$ kips
$\phi P_n = (0.65)(1{,}545.285) = 1{,}004$ kips
(tabulated = 1,004)

Σ Moments = 0
$-M_n + 498.528 + 2{,}032.597 = 0$
$M_n = 2{,}531.125$ in.-kips
$\phi M_n = (0.65)(2{,}531.125) = 1{,}645$ in.-kips
(tabulated = 1,645)

2. ϕP_{ot} and ϕM_{ot} (Point of zero tension)

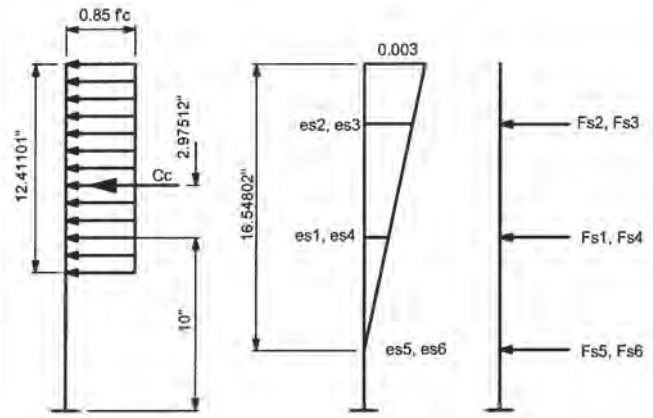

Figure 4-7 ϕP_{ot} and ϕM_{ot} (Point of Zero Tension)

For this condition, the c distance is easily determined by inspection from Fig. 4-7 because ε_{s5}, $\varepsilon_{s6} = f_{s5}/E_s = f_{s6}/E_s = 0$; hence, $c = 20 - 3.4520 = 16.5480$ in., or by the equation:

$$c = \frac{d_{sn}}{1 + f_s/(E_s \varepsilon_c)}$$

$$= \frac{16.5480}{1 + 0/(29{,}000 \times 0.003)} = 16.5480 \text{ in.}$$

Note that the point of "zero tension" is defined in this Chapter as the load-moment combination resulting in zero strain at the center of the column longitudinal bar on the tension face. The diameter of the bar is neglected because the stress in the bar on either side of its center reverses sign and totals zero. Where two layers of bars are used, as with bundled bars, the same definition (to centroid of bundle) is satisfactory for practical use in designing splices.

Bars forces and moments about column centroid are tabulated below:

Bar	d_{si} (in.)	ε_{si}	f_{si} (ksi)	F_{si} (kips)	M_{si} (in.-kips)
1	10.0000	0.0011871	34.426	29.326*	0
2	3.4520	0.0023742	60.000	54.900*	359.486
3	3.4520	0.0023742	60.000	54.900*	359.486
4	10.0000	0.0011871	34.426	29.326*	0
5	16.5480	0	0	0	0
6	16.5480	0	0	0	0
				168.451	718.972

*F_{si} reduced by 5.1 kips

The depth of the equivalent stress block:

$a = 0.75(16.5480) = 12.4110$ in.

Properties of the concrete compression zone:

$$\alpha = \cos^{-1}[(20 - 2(12.4110))/20]$$
$$= 1.81430 \text{ rad}$$

$$A_c = 20^2[2(1.81430) - \sin(2 \times 1.81430)]/8$$
$$= 204.82916 \text{ in.}^2$$

$$y = 2(20)^3 \sin(1.81430)^3/(24 \times 204.82916)$$
$$= 2.97511 \text{ in.}$$

Concrete compression resultant, C_c, and moment, M_c, about the column centroid:

$C_c = 0.85(6)204.82916 = 1{,}044.629$ kips

$M_c = 1{,}044.629(2.97511) = 3{,}107.886$ in.-kips

Σ Forces = 0

$-P_n + 168.451 + 1{,}044.629 = 0$

$P_n = 1{,}213.080$ kips

$\phi P_n = (0.65)(1{,}213.080) = 789$ kips

(tabulated = 789)

Σ Moments = 0

$-M_n + 718.972 + 3{,}107.886 = 0$

$M_n = 3{,}826.858$ in.-kips

$\phi M_n = (0.65)(3{,}826.858) = 2{,}487$ in.-kips

(tabulated = 2,487)

3. 25% Tension

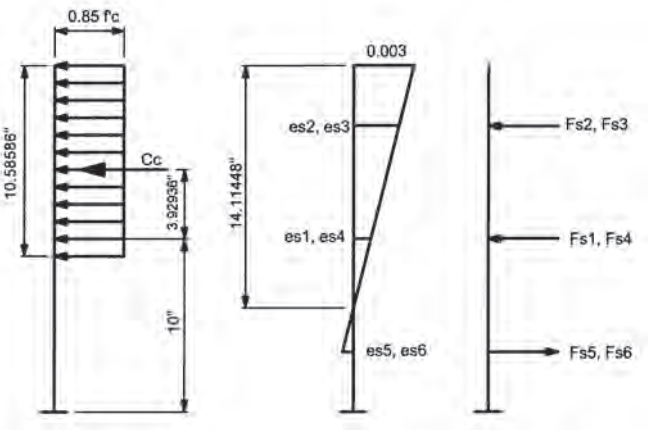

Figure 4-8 25% Tension

The tensile stress in bars 5 and 6 = 0.25(60) = 15 ksi.

$$c = \frac{16.5480}{1 + 15/(29{,}000 \times 0.003)} = 14.11448 \text{ in.}$$

Bars forces and moments about column centroid are tabulated below:

Bar	d_{si} (in.)	ε_{si}	f_{si} (ksi)	F_{si} (kips)	M_{si} (in.-kips)
1	10.0000	0.0008745	25.361	20.261*	0

*F_{si} reduced by 5.1 kips

The depth of the equivalent stress block:

$a = 0.75(9.79373) = 7.34529$ in.

Properties of the concrete compression zone:

$$\alpha = \cos^{-1}[(20 - 2(7.34529))/20] = 1.30210 \text{ rad}$$

$$A_c = 20^2[2(1.30210) - \sin(2 \times 1.30210)]/8 = 104.61592 \text{ in.}^2$$

$$y = 2(20)^3 \sin(1.30210)^3/(24 \times 104.61592) = 5.71088 \text{ in.}$$

Concrete compression resultant, C_c, and moment, M_c, about the column centroid:

$$C_c = 0.85(6)104.61592 = 533.541 \text{ kips}$$

$$M_c = 533.541(5.71088) = 3{,}046.988 \text{ in.-kips}$$

Σ Forces = 0

$-P_n - 21.194 + 533.541 = 0$

$P_n = 512.347$ kips

$\phi P_n = (0.65)(512.347) = 333$ kips (tabulated = 333)

Σ Moments = 0

$-M_n + 1{,}456.740 + 3{,}046.988 = 0$

$M_n = 4{,}503.728$ in.-kips

$\phi M_n = (0.65)(4{,}503.728) = 2{,}927$ in.-kips (tabulated = 2,927)

6. $\varepsilon_t = 0.005$

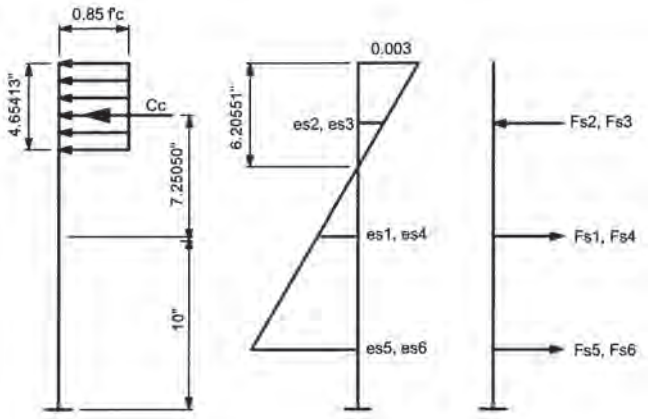

Figure 4-11 $\varepsilon_t = 0.005$

$c = 16.5480(0.003)/(0.003 + 0.005) = 6.20551$ in.

Bars forces and moments about column centroid are tabulated below:

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.
(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.
(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.
(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.
(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.
(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.
(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

(1) See "Control Points for Interaction Curves – Round Columns"; Fig. 4-1.

(2) "0% f_y" indicates zero tension in bars on the tension side, "50% f_y" indicates 50% f_y stress in bars on the tension side, and "100% f_y" indicates 100% f_y stress (i.e., balance point) in bars on the tension side.

CHAPTER 5 – STRENGTH DESIGN OF FLEXURAL MEMBERS AND DEVELOPMENT AND LAP SPLICE DESIGN DATA FOR REINFORCING BARS

INTRODUCTION

Strength design of flexural members utilizes the design assumptions given in Chapter 2 for columns. These assumptions recognize that, as the nominal strength of reinforced concrete is approached, the plastic range of the materials is reached, and stress and strain are no longer proportional. At nominal strength, the actual concrete stress distribution in the member is not triangular but curvilinear. It is also assumed that the reinforcing steel behaves elastically. The tabulated designs in this *Handbook* are based on an assumed rectangular concrete stress distribution at nominal strength (ACI 10.2.7).

Strength design consists of two steps: first, a member is proportioned to ensure its strength using appropriate safety factors; and second, the member must be checked to ensure that deflection and cracking at service load conditions will be within acceptable limits. Strength design is described in this Chapter; serviceability, in Chapter 6.

STRENGTH DESIGN–GENERAL PRINCIPLES

General. Strength design of flexural members is based on the concept that after the yield strength of the reinforcement is reached, the reinforcement continues to elongate until the maximum compressive fiber strain of the concrete section is reached. The design limitations of the ACI Building Code ensure that sections will be underreinforced for flexure, so that yielding of the reinforcement occurs before the concrete crushes. The nominal flexural strength of a section is computed as the resistance when the reinforcement reaches the yield strength.

Load Factors. Load factors provide for safety against overloads. The ACI Building Code requires that the actual or specified dead, live, wind, earthquake and other service load effects each be increased by an appropriate load factor to determine the factored loads. The design strength at each section of a member must be equal to, or greater than, the effect of the factored loads. The greatest factored load combination controls the design. The combinations to be reviewed (ACI 9.2.1) are:

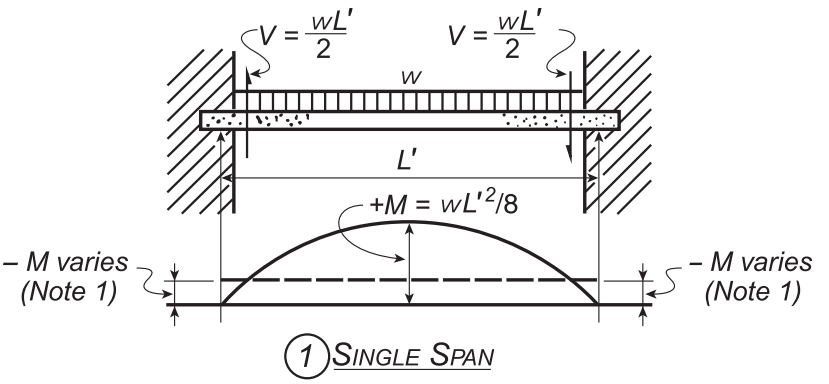
$$U = 1.4(D + F)$$
$$U = 1.2(D + F + T) + 1.6(L + H) + 0.5(L_r \text{ or } S \text{ or } R)$$
$$U = 1.2D + 1.6(L_r \text{ or } S \text{ or } R) + (1.0L \text{ or } 0.8W)$$
$$U = 1.2D + 1.6W + 1.0L + 0.5(L_r \text{ or } S \text{ or } R)$$
$$U = 1.2D + 1.0E + 1.0L + 0.2S$$
$$U = 0.9D + 1.6W + 1.6H$$
$$U = 0.9D + 1.0E + 1.6H$$

where:

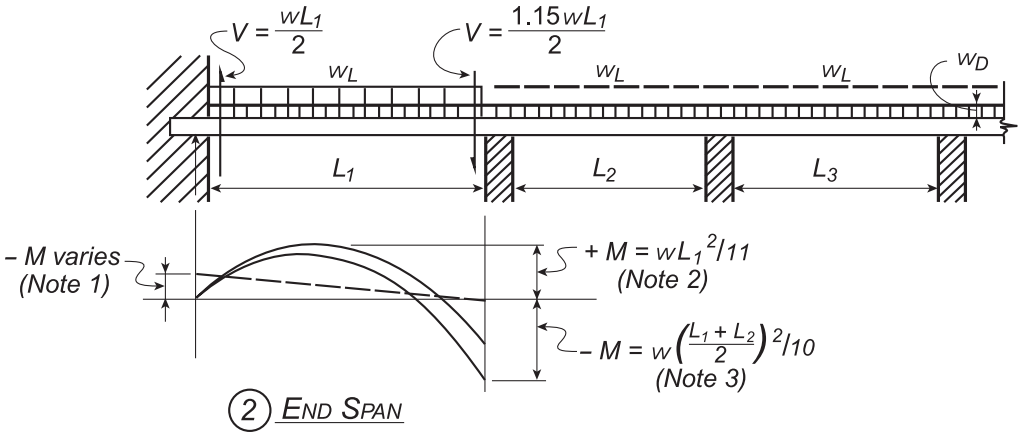
D = **Dead Load**
E = **Earthquake Load**
F = **Fluid Load**
H = **Soil Load**
L = **Live Load**
L_r = **Roof Live Load**
R = **Rain Load**
S = **Snow Load**
T = **Temperature, Creep and Shrinkage Load**
W = **Wind Load**

Strength-Reduction Factors. The second portion of the safety factor, called strength-reduction factor or ϕ-factor, is prescribed to recognize possible sources of understrength, such as variations in quality (strength) of materials, permissible tolerances in dimensions and in location of reinforcement, and approximations in structural analysis. The Code permits the following ϕ-factors for flexural members: 0.90 for flexure, and 0.75 for shear and torsion. In this *Handbook*, the term **usable** indicates that all relevant ϕ-factors have been applied in the computation of the tabulated usable factored load capacities. No further consideration of the proper ϕ-factors is required in these tables.

Maximum Usable Superimposed Factored Load. Factored load capacity in the tabulated designs is the least value as determined by shear, development of reinforcement, and flexure. As tabulated in Chapters 7 through 11 of this *Handbook*, factored load capacity is the combination of live loads and any dead load other than the weight of the floor system itself, multiplied by their appropriate load factors, that are *superimposed* on the structural member being designed. Except in Chapter 12 (Beams), 1.2 (the dead load factor) times the weight of the floor has been deducted from the total factored load capacity to obtain the tabulated values of the net *superimposed* factored load capacity. When the required load capacity is computed, only superimposed dead loads, such as ceilings, floor finishes, partitions, and the like times the load

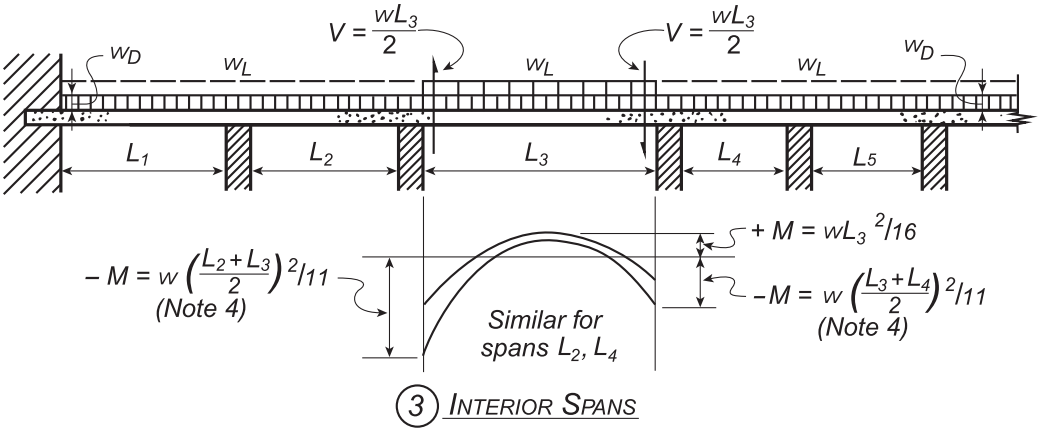


Note 1. For a single span, $+M = wL'^2/8$ and no theoretical negative moment is developed. When members are built into masonry walls or made monolithic with concrete walls, beams, or columns, restraint occurs causing some negative moment. In the tabulated designs in this *Handbook*, to prevent top cracking adjacent to the supports, separate hooked top bars are shown in the tops of members at supports. The hooks on these bars can be placed in an inclined position when the depth of the member is insufficient to accommodate them in a vertical position.



Note 2. For all end spans, a coefficient for positive moment, $+M = wL_1^2/11$, was used for the condition of no restraint at the discontinuous end. If the discontinuous end is monolithic with the support, the ACI Building Code permits use of the coefficient $+M = wL'^2/14$ and the total tabulated capacities (when positive moment governs) may increase up to 27 percent.

Note 3. When only two spans are continuous, the ACI Building Code requires an increase in negative moment to $-M = wL^2/9$ and capacities should be reduced or reinforcement may be increased to maintain tabulated capacity.



Note 4. For continuous slabs with spans ≦10'-0", the ACI Building Code permits a negative moment of $-M = wL^2/12$. The tabulated designs are based upon $-M = wL^2/11$ throughout, except in those short span slabs.

Figure 5-1 Moment and Shear Coefficients for One-Way Members

factor for dead load, need be included along with other loads times their prescribed load factors. An example problem reviews the use of the tabulated designs.

Frame Analysis. The ACI Building Code prescribes an elastic analysis for all indeterminate concrete structures. For buildings of the usual type of construction, spans, and story heights, the Code permits the use of approximate methods of analysis for the determination of elastic moments and shears within certain ranges of variation in span lengths and loads. The tabulated designs for all continuous floor systems in this *Handbook* are based on the approximate methods of analysis (ACI 8.3.3 and 13.6). The limitations on the use of one-way moment coefficients are that two or more spans be continuous, that the longer of adjacent spans not exceed the shorter by more than 20 percent, that loads are uniformly distributed, and that the (unfactored) unit live load does not exceed three times the (unfactored) unit dead load (ACI 8.3.3). For two-way slabs, according to ACI 13.6, the number of continuous spans must be three or more, the length-to-width ratio of panels cannot exceed 2.0, successive span lengths must not differ by more than one-third of the longer span, live load cannot exceed two times the dead load, and the direct design method is applicable to uniformly distributed gravity loads only.

Conservatively, no consideration for redistribution of stress due to inelastic behavior of frames loaded beyond first yielding has been made. The two-way slab factored moments in the tabulated designs in Chapters 9, 10 and 11 can be adjusted up to 10 percent (ACI 13.6.7).

Moments and shears for beams and one-way slab systems have been computed as shown in Fig. 5-1.

Flexural Computations. For flexural members, which are reinforced with tension steel only, the design moment strength, from equilibrium of internal moment and forces (Fig. 5-2), is:

$$\phi M_n = \phi A_s f_y (d - a/2) \qquad (1)$$

where:

$$a = \frac{A_s f_y}{0.85 f_c' b} \qquad (2)$$

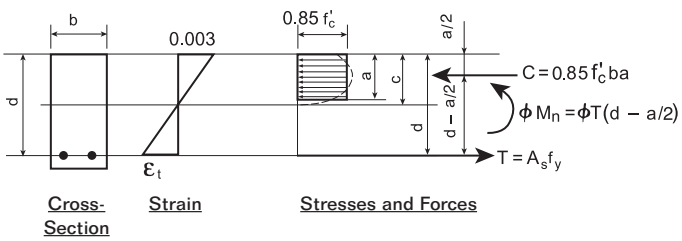


Figure 5-2 Reinforced Concrete Section with Tension Steel Only

It is conservative to use these equations if there is no compression reinforcement. Substituting Equation (2) into Equation (1), replacing φM_n with M_u, and then solving for the required A_s:

$$A_s = \frac{0.85 f_c' b d}{f_y} - \sqrt{\left(\frac{0.85 f_c' b d}{f_y}\right)^2 - \frac{1.7 f_c' M_u b}{\phi f_y^2}} \qquad (3)$$

Equation (3) can be simplified for different concrete compressive strengths. If b = 12 inches (1 ft. width), f_y = 60,000 psi, assuming φ = 0.90, and M_u is in units of in.-kips/ft:

f_c', psi	Equation (3) per ft. width
3,000 psi	$A_s = 0.510\,d - \sqrt{0.260\,d^2 - 0.0189\,M_u}$
4,000 psi	$A_s = 0.680\,d - \sqrt{0.462\,d^2 - 0.0252\,M_u}$
5,000 psi	$A_s = 0.850\,d - \sqrt{0.723\,d^2 - 0.0315\,M_u}$
6,000 psi	$A_s = 1.020\,d - \sqrt{1.040\,d^2 - 0.0378\,M_u}$

By introducing the variable R_n:

$$R_n = \frac{M_u}{\phi b d^2}$$

it is possible to develop a somewhat simpler expression for the required A_s:

$$A_s = \frac{0.85 f_c' b d}{f_y}\left[1 - \sqrt{1 - \frac{2 R_n}{0.85 f_c'}}\right] \qquad (4)$$

Likewise, Equation (4) can be simplified for different concrete compressive strengths. If b = 12 inches (1 ft. width), f_y = 60,000 psi, assuming φ = 0.90, and M_u is in units of in.-kips/ft:

f_c', psi	Equation (4) per ft. width
3,000	$A_s = (0.510\,d)\left[1 - \sqrt{1 - 0.0726\,M_u/d^2}\right]$
4,000	$A_s = (0.680\,d)\left[1 - \sqrt{1 - 0.0545\,M_u/d^2}\right]$
5,000	$A_s = (0.850\,d)\left[1 - \sqrt{1 - 0.0436\,M_u/d^2}\right]$
6,000	$A_s = (1.020\,d)\left[1 - \sqrt{1 - 0.0363\,M_u/d^2}\right]$

The strength-reduction factor, φ, is equal to 0.90 when the net tensile strain, ε_t, in the extreme tension steel is ≥ 0.005 (ACI 10.3.4). Referring to Fig. 5-2, ε_t can be expressed as:

$$\varepsilon_t = 0.003\,(d/c - 1) \geq 0.005$$

Solving for c with $\varepsilon_t \geq 0.005$:

$$c \leq 0.003\,d/0.008$$

From Equation (2) with $c = a/\beta_1$:

$$c = \frac{A_s\,f_y}{0.85\,f_c'\,\beta_1\,b}$$

where:

f_c', psi	β_1
$\leq$ 4,000	0.85
5,000	0.80
6,000	0.75
7,000	0.70
$\geq$ 8,000	0.65

Equating and solving for ρ where $\rho = A_s/bd$:

$$\rho \leq \left(\frac{0.85\,f_c'\,\beta_1}{f_y}\right)\left(\frac{3}{8}\right) \qquad (5)$$

Note that Equation (5) is an expression for the maximum value of ρ for which ε_t is not less than 0.005 and, therefore, $\varphi = 0.90$, i.e., a "tension-controlled" section.

The variable ρ in Equation (5) can be solved for different concrete strengths. If f_y = 60,000 psi:

f_c', psi	Equation (5)
3,000	$\rho \leq 0.0135$
4,000	$\rho \leq 0.0181$
5,000	$\rho \leq 0.0213$
6,000	$\rho \leq 0.0239$

In summary, for flexural members which are reinforced with tension steel only, the required A_s can be determined by two methods:

Method 1:

$$A_s = \frac{0.85\,f_c'\,b\,d}{f_y} - \sqrt{\left(\frac{0.85\,f_c'\,b\,d}{f_y}\right)^2 - \frac{1.7\,f_c'\,M_u\,b}{\phi\,f_y^{\,2}}}$$

Method 2:

$$A_s = \left(\frac{0.85\,f_c'\,b\,d}{f_y}\right)\left[1 - \sqrt{1 - \frac{2\,R_n}{0.85\,f_c'}}\right]$$

where:

$$R_n = \frac{M_u}{\phi\,b\,d^2}$$

Use Equation (5) as a check for $\varepsilon_t \geq 0.005$ (to confirm $\varphi = 0.90$).

Example: f_c' = 4,000 psi; f_y = 60,000 psi; b = 24 in.; d = 12.5 in.; M_u = 250 ft-k; φ = 0.90 (assumed)

Method 1:

$$\frac{0.85\,f_c'\,b\,d}{f_y} = \frac{0.85\,(4{,}000)\,24\,(12.5)}{60{,}000} = 17.00\ \text{in}^2.$$

$$\frac{1.7\,f_c'\,M_u\,b}{\phi\,f_y^2} = \frac{1.7\,(4{,}000)\,250\,(12{,}000)\,24}{0.9\,(60{,}000)^2} = 151.1\ \text{in}^4.$$

$$\text{Required } A_s = 17.00 - \sqrt{(17.00)^2 - 151.1} = 5.26\ \text{in}^2.$$

Method 2:

$$R_n = \frac{M_u}{\phi\,b\,d^2} = \frac{250\,(12{,}000)}{0.9\,(24)\,12.5^2} = 889\ \text{psi}$$

$$\frac{2\,R_n}{0.85\,f_c'} = \frac{2\,(889)}{0.85\,(4{,}000)} = 0.523$$

$$\frac{0.85\,f_c'\,b\,d}{f_y} = \frac{0.85\,(4{,}000)\,24\,(12.5)}{60{,}000} = 17.00\ \text{in.}^2$$

$$\text{Required } A_s = 17.00\,[1 - \sqrt{1 - 0.523}] = 5.26\ \text{in.}^2$$

From Equation (5):

$$\rho \leq \frac{0.85\,f_c'\,\beta_1}{f_y}\left(\frac{3}{8}\right) = \frac{0.85\,(4{,}000)\,0.85}{60{,}000}\left(\frac{3}{8}\right) = 0.0181$$

$$\rho_{act} = A_s/(b\,d) = 5.26/(24\ x\ 12.5) = 0.0175$$

0.0175 < 0.0181

OK ($\rho_{act} \leq \rho_{max}$, $\varepsilon_t \geq 0.005$ and $\varphi = 0.90$)

Comparison to Earlier Codes

Alternatively, the maximum ρ, based on a minimum value of ε_t of 0.005, can be compared to the previous Code limit of 0.75 ρ_b. The expression for ρ_b is:

$$\rho_b = \frac{0.85\,\beta_1\,f_c'}{f_y}\,\frac{87{,}000}{87{,}000 + f_y} \qquad (6)$$

Calculating the ratio of maximum ρ from Equation (5) divided by Equation (6):

$$\frac{\rho_{max}}{\rho_b} = \left(\frac{3}{8}\right)\left(\frac{87{,}000 + f_y}{87{,}000}\right)$$

For f_y of 60,000 psi, this ratio equals 0.634. Therefore, with the ε_t limit of 0.005, the maximum ρ in the current Code when f_y = 60,000 psi is 63 percent of ρ_b, compared to the previous limit of 75 percent of ρ_b.

Other Simplifications

From Equation (1), if M_u is substituted for φM_n and re-arranging the terms, the required area of steel is:

$$A_s = \frac{M_u}{(\phi f_y j) d} \quad (7)$$

where:

$$j = 1 - a/2d \quad (8)$$

Substituting Equation (2) into Equation (8):

$$j = 1 - \frac{f_y \rho}{0.85\,(2)\,f'_c} \quad (9)$$

If the reinforcement ratio is assumed to be the maximum value from Equation (5), then substituting into Equation (9):

$$j \geq 1 - \frac{3\beta_1}{16}$$

The variable j can be tabulated for different values of concrete compressive strength:

f'_c, psi	j
3,000	0.841
4,000	0.841
5,000	0.850
6,000	0.859

This minimum value for j can be used to approximate the required A_s. For the example:

$$j \geq 1 - \frac{3\beta_1}{16} = 1 - \frac{3\,(0.85)}{16} = 0.841$$

The required area of steel is:

$$A_s \approx \frac{M_u}{\phi f_y j d} = \frac{M_u}{0.90\,(60{,}000)\,0.841\,(d)} = \frac{M_u}{45{,}400\,d}$$

$$A_s \approx \frac{250\,(12{,}000)}{45{,}400\,(12.5)} = 5.28 \text{ in.}^2$$ which is equivalent to the required A_s of 5.26 in^2.

This approximate Equation (7) for determining the required A_s can be derived for other concrete compressive strengths:

f'_c, psi	Equation (7)
3,000	$A_s \approx \frac{M_u}{45{,}400\,d}$
4,000	$A_s \approx \frac{M_u}{45{,}400\,d}$
5,000	$A_s \approx \frac{M_u}{45{,}900\,d}$
6,000	$A_s \approx \frac{M_u}{46{,}400\,d}$

For manually determining the required A_s, Equation (7) can be simplified further by assuming φ = 0.90, $j \approx 0.90$, f_y = 60 ksi, and with M_u in units of ft-kips, the required area of steel is:

$$A_s \approx \frac{M_u}{\phi f_y j d} \approx \frac{M_u\,(12)}{0.90\,(60)\;0.9(d)} \approx \frac{M_u}{4d}$$

After calculating the approximate required A_s and selecting the reinforcement, the actual design moment strength, ϕM_n, should be calculated for the selected reinforcement and compared to M_u; and the steel reinforcement ratio, ρ, for the required selected reinforcement should be compared with 0.63 ρ_b (when f_y = 60,000 psi) to confirm that φ = 0.90 (a tension-controlled section).

For the example:

$$A_s \approx \frac{M_u}{4d} \approx \frac{250(12)}{4(12.5)} \approx 5.00 \text{ in.}^2$$

Instead of selecting the reinforcement in this example, calculate ϕM_n for A_s = 5.00 in.^{2}:

$$a = \frac{A_s f_y}{0.85 f'_c b} = \frac{5.00(60)}{0.85(4)(24)} = 3.68 \text{ in.}$$

$$\phi M_n = \phi A_s f_y (d - a/2)$$
$$= 0.90(5.00)(60)(12.5 - \frac{3.68}{2})/12$$

ϕM_n = 239.9 ft-kips < M_u; need larger amount of A_s

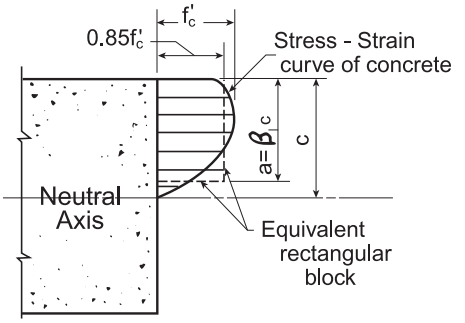
Need 4 to 5 percent additional design moment strength because of simplifying assumption of $j = 0.9$; hence try approximately 4 to 5 percent more A_s. If the required A_s is 1.05(5.00) = 5.25 in.^{2}, then:

$$a = \frac{5.25(60)}{0.85(4)(24)} = 3.86 \text{ in.}$$

$$\phi M_n = 0.90(5.25)(60)(12.5 - \frac{3.68}{2})/12$$
$$= 249.7 \text{ ft-kips} \approx M_u$$

confirm that $\varphi = 0.90$:

$$\rho = \frac{A_s}{b\,d} = \frac{5.25}{(24)(12.5)} = 0.0175 < 0.63\rho_b;\ \varphi = 0.90$$



For doubly-reinforced sections, additional tensile reinforcement balanced by force in compression reinforcement need not be reduced by the 0.75 factor (ACI 10.3.3).

Figure 5-3 Rectangular Stress Block for Strength Design

Rectangular Beam with Compression Reinforcement. When effects of the compression reinforcement are neglected in flexural computations, the same formulas and limit on tension reinforcement percentage apply. For designs tabulated in this *Handbook*, compression reinforcement has been neglected, but should be considered when it is necessary to compute creep deflection.

T-Beams. When the flange thickness h equals or exceeds the depth of the equivalent rectangular stress block a, the section may be designed as rectangular beam with an effective flange width (ACI 8.12).

When the flange thickness is less than a:

$$\phi M_n = \phi[(A_s - A_{sf})f_y(d - a/2) + A_{sf}f_y(d - 0.5h)]$$

where A_{sf} = the steel area necessary to develop the compressive strength of the overhanging flanges, i.e.:

$$A_{sf} = 0.85(b - b')hf'_c/f_y$$

and $a = (A_s - A_{sf})f_y/0.85f'_c\,b'$

*For use in spirally-reinforced columns with spirals conforming to ACI 7.10.4 and 10.9.3. Regarding anchorage and lap splicing of spirals, the ACI Building Code requirements are:

7.10.4.4 – Anchorage of spiral reinforcement shall be provided by 1-1/2 extra turns of spiral bar or wire at each end of a spiral unit.

7.10.4.5 – Spiral reinforcement shall be spliced, if needed, by any one of the following methods:

(a) Lap splices not less than the larger of 12 in. and the length indicated in one of (1) through (5) below:

(1) deformed uncoated bar or wire . . . . . .48 d_b

(2) plain uncoated bar or wire . . . . . .72 d_b

(3) epoxy-coated deformed bar or wire . . . . . .72 d_b

(4) plain uncoated bar or wire with a standard stirrup or tie hook in accordance with ACI 7.1.3 at ends of lapped spiral reinforcement.The hooks shall be embedded within the core confined by the spiral reinforcement . . . . . .48 d_b

(5) epoxy-coated deformed bar or wire with a standard stirrup or tie hook in accordance with ACI 7.1.3 at ends of lapped spiral reinforcement. The hooks shall be embedded within the core confined by the spiral reinforcement . . . . . .48 d_b

(b) Full mechanical or welded splices in accordance with 12.14.3.

DOWEL EMBEDMENT

Minimum compression dowel embedment required by ACI 12.3.2 for Grade 60 (f_y = 60,000 psi) reinforcing bars and all concrete with $f'_c \geq$ 3,000 psi = 22 bar diameters ($22d_b$). See Table 5-1.

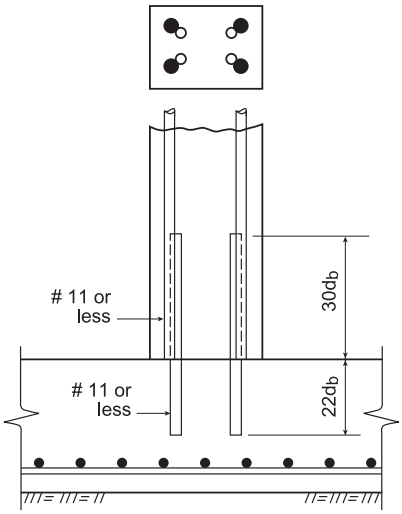

Figure 5-4 Footing Dowels to Column Vertical Bars—Lap Splices for Compression Only (#11 Bars or Smaller)

COMPRESSION LAP SPLICES

Based on the provisions in ACI 12.16.1, for Grade 60 bars, bar sizes #3 through #11, and all concrete with $f'_c \geq$ 3,000 psi, lap lengths = 30 bar diameters ($30d_b$). See Table 5-1. Lap splices are not permitted for #14 and #18 bars, except if spliced to #11 and smaller bars (ACI 12.16.2 and 15.8.2.3). Use the $30d_b$ dimension with the smaller bar.

TENSION DEVELOPMENT LENGTHS AND TENSION LAP SPLICE LENGTHS

ACI 12.2.2 and 12.2.3 present the provisions for determining tension development length ℓ_d. ACI 12.2.1 requires that ℓ_d be not less than 12 inches.

Section 12.2.2 Provisions for Tension ℓ_d

For the following conditions:

- bars with clear spacing not less than d_b, with concrete cover not less than d_b, and for bars in beams or columns with stirrups or ties throughout ℓ_d not less than the minimum required by the Code;
- bars with clear spacing not less than 2 d_b and with concrete cover not less than d_b,

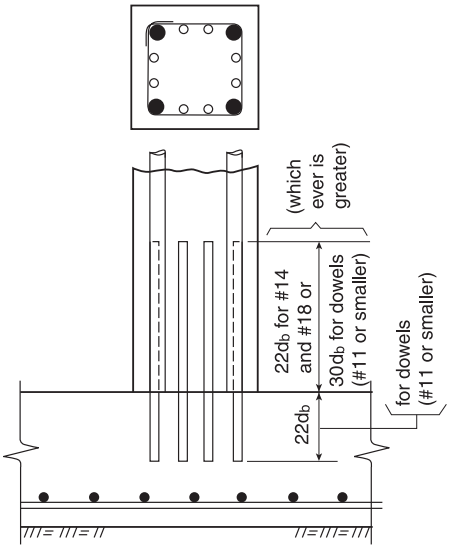

Figure 5-5 Footing Dowels (#11 Bars or Smaller) to Column Vertical Bars (#14 or #18)—Lap Splices for Compression Only

the tension development lengths are:

Bar sizes #3 through #6 $\ell_d = (0.04 f_y\ \psi_t\ \psi_e / \lambda\sqrt{f'_c})\ d_b$

Bar sizes #7 through #18 $\ell_d = (0.05 f_y\ \psi_t\ \psi_e / \lambda\sqrt{f'_c})\ d_b$

For other cases:

Bar sizes #3 through #6 $\ell_d = (0.06 f_y\ \psi_t\ \psi_e / \lambda\sqrt{f'_c})\ d_b$

Bar sizes #7 through #18 $\ell_d = (0.075 f_y\ \psi_t\ \psi_e / \lambda\sqrt{f'_c})\ d_b$

Where:

ψ_t = 1.3 for "top" bars

ψ_t = 1.0 for "other" bars

ψ_e = 1.0 for uncoated bars and zinc-coated (galvanized) bars

ψ_e = 1.5 for epoxy-coated bars with concrete cover < $3d_b$, or clear spacing < $6d_b$

ψ_e = 1.2 for other concrete cover and clear spacing conditions of epoxy-coated bars

The product of $\psi_t\ \psi_e$ need not be taken greater than 1.7.

λ = 0.75 for lightweight aggregate concrete

λ = 1.0 for normal-weight concrete

Tables 5-2(a) through 5-2(h) and Tables 5-4(a) through 5-4(b) present values of tension ℓ_d based on ACI 12.2.2. All tabulated data are for Grade 60 (f_y = 60,000 psi) reinforcing bars, uncoated and epoxy-coated, in normal-weight concrete having a compressive strength, f'_c , ranging from 3,000 to 10,000 psi. Tables 5-4(a) and (b) list ℓ_d in terms of multiples of d_b.

Tension Lap Splices

Tension lap splices (minimum of 12 inches) are specified as Class A or Class B (ACI 12.15.1). The classes are multiples of tension development lengths: Class A = $1.0\ell_d$ and Class B = $1.3\ell_d$ without the 12 inch minimum of ACI 12.2.1. Tables 5-2(a) through 5-2(h) and Tables 5-4(a) through 5-4(b) present values of Class A and Class B tension lap splice lengths based on ACI 12.2.2 and 12.15.1. All tabulated data are for Grade 60 (f_y = 60,000 psi) reinforcing bars, uncoated and epoxy-coated, in normal-weight concrete having a compressive strength, f'_c, ranging from 3,000 to 10,000 psi.

The lap Class depends on the ratio of area of reinforcing steel provided to that required and the percentage of reinforcement spliced at any one location, as shown in the following table:

$\frac{A_{s\ provided}}{A_{s\ required}}$	Maximum Percent of A_s Spliced within Required Lap Length	
	50%	100%
≥ 2	Class A	Class B
≤ 2	Class B	Class B

Section 12.2.3 Provisions for Tension ℓ_d

The provisions in Section 12.2.3 are applicable to all conditions of clear spacing, concrete cover and transverse reinforcement. Tension development length is calculated by ACI Code Eq. 12-1:

$$\ell_d = \left(\frac{3}{40} \frac{f_y}{\lambda \sqrt{f'_c}} \frac{\psi_t \psi_e \psi_s}{\left(\frac{c_b + K_{tr}}{d_b} \right)} \right) d_b$$

where:

c_b = spacing or concrete cover dimension; use the smaller of either the distance from the center of the bar to the nearest concrete surface or one-half the center-to-center spacing of the bars being developed

ψ_s = 0.8 for bar sizes #3 through #6

ψ_s = 1.0 for bar sizes #7 through #18

The quantity $(c_b + K_{tr})/d_b$ is limited to a maximum value of 2.5. The K_{tr} term accounts for the beneficial effect of transverse reinforcement.

$K_{tr} = 40A_{tr}/sn$

A_{tr} = total area of all transverse reinforcement within the spacing s, which crosses the potential plane of splitting through the bars being developed

s = maximum c.-c. spacing of transverse reinforcement within ℓ_d

n = number of bars being developed along the plane of splitting

The notation ψ_t, ψ_e and λ are defined in the preceding discussion of Section 12.2.2.

For simplification, K_{tr} can be taken as zero even if transverse reinforcement is present.

The provisions in ACI 12.2.3 normally do not lend themselves to extensive tabulation of tension development lengths and tension lap splices. Only limited cases and conditions can be tabulated. Tables 5-3(a) through 5-3(h) are examples of such limited tabulation. The tables give values of tension ℓ_d and tension lap splice lengths, based on Code Section 12.2.3, for walls and slabs. The values for "Lap Class A" are also the values of ℓ_d, because the required lap length for a Class A tension lap splice is 1.0 ℓ_d.

An important restriction on the use of Tables 5-3(a) through 5-3(h) is described in Note 3, i.e., it is assumed that the notation c_b in the quantity, $(c_b + K_{tr})/d_b$, in ACI Code Eq. 12-1 is governed by concrete cover rather than by one-half the center-to-center spacing of the bars.

Standard End Hooks

Tables 5-5(a) and 5-5(b) give the minimum tension development (embedment) lengths ℓ_{dh} for standard end hooks on Grade 60 (f_y = 60,000 psi) uncoated and epoxy-coated reinforcing bars in normal-weight concrete.

For 180º hooks at right angles to exposed concrete surfaces, CRSI recommends that a minimum 2 inches of concrete cover be provided to the tail of the hook (ACI 7.7). The minimum tension embedment lengths which will provide the recommended 2 inches of concrete cover to the tail of the hook are given in Table 5-7.

Headed Reinforcing Bars

ACI 318-08 contains new provisions for the development of headed and mechanically anchored deformed bars in tension. Tables 5-6(a) and 5-6(b) give the minimum development (embedment) lengths ℓ_{dt} for headed reinforcing bars of Grade 60 (f_y = 60,000 psi) uncoated and epoxy-coated bars in normal-weight concrete (ACI 12.6). Use of headed reinforcing bars is limited to the following conditions:

- $f_y \leq$ 60,000 psi
- Bar Size ≤ #11
- Normal-weight concrete
- Net bearing area, A_{brg}, ≥ 4 A_b where A_b is the area of the headed bar. Net bearing area is equal to the total area of the head, minus the area of the bar, A_b.
- Clear concrete cover for bars ≥ 2 d_b, and
- Clear spacing between bars ≥ 4 d_b

Code Provisions Used in Tabulated Designs

The provisions in ACI 12.2.2 and 12.2.3 are used in the computer programs for producing the tabulated designs in the *Handbook*. Whenever the required tension development length is checked versus the available embedment length and other criteria of Code Chapter 12, the programs select the shorter ℓ_d calculated from ACI 12.2.2 or 12.2.3.

#14	N/A	121	181	93	139	158	237	139	209
#18	N/A	161	241	124	186	210	316	186	278

Notes:

1. Tabulated values are based on a minimum yield strength of 60,000 psi. Lengths are in inches.
2. Tension development lengths and tension lap splice lengths are calculated per ACI 318-08, Sections 12.2.2 and 12.15, respectively.
3. Tabulated values for beams or columns are based on transverse reinforcement and concrete cover meeting minimum Code requirements.
4. Cases 1 and 2, which depend on the type of structural member, concrete cover, and center-to-center spacing of the bars, are defined as:

Beams, Columns	Case 1	Concrete cover at least 1.0 d_b **and** c.-c. spacing at least 2.0 d_b
	Case 2	Concrete cover less than 1.0 d_b **or** c.-c. spacing less than 2.0 d_b
All Others	Case 1	Concrete cover at least 1.0 d_b **and** c.-c. spacing at least 3.0 d_b
	Case 2	Concrete cover less than 1.0 d_b **or** c.-c. spacing less than 3.0 d_b

5. Lap splice lengths (minimum of 12 inches) are multiples of tension development lengths; Class A = 1.0 ℓ_d and Class B = 1.3 ℓ_d (ACI 12.15.1). When determining the lap splice length, ℓ_d is calculated without the 12-inch minimum of ACI 12.2.1.
6. ACI 318 does not allow tension lap splices of #14 or #18 [#43 or #57] bars. The tabulated values for those bar sizes are the tension development lengths.
7. Top bars are horizontal bars with more than 12 inches of concrete cast below the bars.
8. For epoxy-coated bars, if the c.-c. spacing is at least 7.0 d_b and the concrete cover is at least 3.0 d_b, then Case 1 lengths may be multiplied by 0.918 (for top bars) or 0.8 (for other bars).
9. For Grade 75 (minimum yield strength of 75,000 psi) reinforcing bars, lengths must be multiplied by 1.25.
10. For lightweight aggregate concrete, multiply the tabulated values by 1.33.

Notes:

1. Tabulated values are based on a minimum yield strength of 60,000 psi. Lengths are in inches.
2. Tension development lengths and tension lap splice lengths are calculated per ACI 318-08, Sections 12.2.2 and 12.15, respectively.
3. Tabulated values for beams or columns are based on transverse reinforcement and concrete cover meeting minimum Code requirements.
4. Cases 1 and 2, which depend on the type of structural member, concrete cover, and center-to-center spacing of the bars, are defined as:

Beams, Columns	Case 1	Concrete cover at least 1.0 d_b **and** c.-c. spacing at least 2.0 d_b
	Case 2	Concrete cover less than 1.0 d_b **or** c.-c. spacing less than 2.0 d_b
All Others	Case 1	Concrete cover at least 1.0 d_b **and** c.-c. spacing at least 3.0 d_b
	Case 2	Concrete cover less than 1.0 d_b **or** c.-c. spacing less than 3.0 d_b

5. Lap splice lengths (minimum of 12 inches) are multiples of tension development lengths; Class A = 1.0 ℓ_d and Class B = 1.3 ℓ_d (ACI 12.15.1). When determining the lap splice length, ℓ_d is calculated without the 12-inch minimum of ACI 12.2.1.
6. ACI 318 does not allow tension lap splices of #14 or #18 [#43 or #57] bars. The tabulated values for those bar sizes are the tension development lengths.
7. Top bars are horizontal bars with more than 12 inches of concrete cast below the bars.
8. For epoxy-coated bars, if the c.-c. spacing is at least 7.0 d_b and the concrete cover is at least 3.0 d_b, then Case 1 lengths may be multiplied by 0.918 (for top bars) or 0.8 (for other bars).
9. For Grade 75 (minimum yield strength of 75,000 psi) reinforcing bars, lengths must be multiplied by 1.25.
10. For lightweight aggregate concrete, multiply the tabulated values by 1.33.

Notes:

1. Tabulated values are based on a minimum yield strength of 60,000 psi. Lengths are in inches.
2. Tension development lengths and tension lap splice lengths are calculated per ACI 318-08, Sections 12.2.3 and 12.15, respectively, with bar sizes limited to #3 through #11.
3. When the variable "c_b" from ACI 12.2.3 was calculated, it was assumed that concrete cover controlled. That is, c.-c. spacing was assumed to be greater than 1.0 d_b plus twice the concrete cover.
4. Lap splice lengths (minimum of 12 inches) are multiples of tension development lengths; Class A = 1.0 ℓ_d and Class B = 1.3 ℓ_d (ACI 318 12.15.1). When determining the lap splice length, ℓ_d is calculated without the 12-inch minimum of ACI 12.2.1.
5. Top bars are horizontal bars with more than 12 inches of concrete cast below the bars.
6. For epoxy-coated bars, if the c.-c. spacing is at least 7.0 d_b and the concrete cover is at least 3.0 d_b, then lengths may be multiplied by 0.918 (for top bars) or 0.8 (for other bars).
7. For Grade 75 (minimum yield strength of 75,000 psi) reinforcing bars, lengths must be multiplied by 1.25.
8. For lightweight aggregate concrete, multiply the tabulated values by 1.33.

Notes:

1. Tabulated values are based on a minimum yield strength of 60,000 psi. Lengths are in inches.
2. Tension development lengths and tension lap splice lengths are calculated per ACI 318-08, Sections 12.2.3 and 12.15, respectively, with bar sizes limited to #3 through #11.
3. When the variable "c_b" from ACI 12.2.3 was calculated, it was assumed that concrete cover controlled. That is, c.-c. spacing was assumed to be greater than 1.0 d_b plus twice the concrete cover.
4. Lap splice lengths (minimum of 12 inches) are multiples of tension development lengths; Class A = 1.0 ℓ_d and Class B = 1.3 ℓ_d (ACI 318 12.15.1). When determining the lap splice length, ℓ_d is calculated without the 12-inch minimum of ACI 12.2.1.
5. Top bars are horizontal bars with more than 12 inches of concrete cast below the bars.
6. For epoxy-coated bars, if the c.-c. spacing is at least 7.0 d_b and the concrete cover is at least 3.0 d_b, then lengths may be multiplied by 0.918 (for top bars) or 0.8 (for other bars).
7. For Grade 75 (minimum yield strength of 75,000 psi) reinforcing bars, lengths must be multiplied by 1.25.
8. For lightweight aggregate concrete, multiply the tabulated values by 1.33.

Table 5-4(a) – Tension Development and Lap Splice Lengths for Bars, Multiples of Bar Diameter

f'_c = 5,000 psi

BAR SIZES	LAP CLASS	UNCOATED BARS				EPOXY-COATED BARS			
		TOP		OTHER		TOP		OTHER	
		Case 1	Case 2	Case 1	Case 2	Case 1	Case 2	Case 1	Case 2
#3 to #6	A	$44d_b$	$66d_b$	$34d_b$	$51d_b$	$58d_b$	$87d_b$	$51d_b$	$77d_b$
	B	$58d_b$	$86d_b$	$44d_b$	$66d_b$	$75d_b$	$113d_b$	$66d_b$	$100d_b$
#7 to #18	A	$55d_b$	$83d_b$	$43d_b$	$64d_b$	$72d_b$	$108d_b$	$64d_b$	$96d_b$
	B	$72d_b$	$108d_b$	$55d_b$	$83d_b$	$94d_b$	$141d_b$	$83d_b$	$124d_b$

Notes:

1. ACI 318-08 facilitates expressing tension development lengths and tension lap splice lengths as multiples of bar diameters. These tables present these values, for various concrete strengths, for both uncoated and epoxy-coated bars.
2. Tabulated values are based on a minimum yield strength of 60,000 psi.
3. Tension development lengths and tension lap splice lengths are calculated per ACI 318, Sections 12.2.2 and 12.15, respectively.
4. Tabulated values for beams or columns are based on transverse reinforcement and concrete cover meeting minimum Code requirements.
5. Cases 1 and 2, which depend on the type of structural member, concrete cover, and center-to-center spacing of the bars, are defined as:

Beams, Columns	Case 1	Concrete cover at least 1.0 *db* **and** c.-c. spacing at least 2.0 d_b
	Case 2	Concrete cover less than 1.0 d_b **or** c.-c. spacing less than 2.0 d_b
All Others	Case 1	Concrete cover at least 1.0 d_b **and** c.-c. spacing at least 3.0 d_b
	Case 2	Concrete cover less than 1.0 d_b **or** c.-c. spacing less than 3.0 d_b

6. Lap splice lengths (minimum of 12 inches) are multiples of tension development lengths; Class A = 1.0 ℓ_d and Class B = 1.3 ℓ_d (ACI 12.15.1). When determining lap splice length, ℓ_d is calculated without the 12-inch minimum of ACI 12.2.1.
7. ACI 318 does not allow tension lap splices of #14 or #18 bars. The tabulated values for those bar sizes are the tension development lengths.
8. Top bars are horizontal bars with more than 12 inches of concrete cast below the bars.
9. For epoxy-coated bars, if the c.-c. spacing is at least 7.0 d_b and the concrete cover is at least 3.0 d_b, then Case 1 lengths may be multiplied by 0.918 (for top bars) or 0.8 (for other bars).
10. For Grade 75 (minimum yield strength of 75,000 psi) reinforcing bars, lengths must be multiplied by 1.25.
11. For lightweight aggregate concrete, multiply the tabulated values by 1.33.

Notes:

1. Tabulated values are based on a minimum yield strength of 60,000 psi. Lengths are in inches.
2. Tension development lengths of standard hooks are calculated per ACI 318-08, Section 12.5.
3. For bar sizes #3 through #11 only:
   a. If concrete cover conforms to ACI 12.5.3(a), then a modification factor of 0.7 may be applied but the length must not be less than 8.0 d_b nor 6 inches.
   b. If hook is enclosed in ties or stirrups per ACI 12.5.3(b) or 12.5.3(c), then a modification factor of 0.8 may be applied but the length must not be less than 8.0 d_b nor 6 inches.
   b. When applying modification factors noted above, see Table 5-7 for minimum hook embedment needed to provide 2 inches of concrete cover to tail of 180° hooks.
4. For Grade 75 (minimum yield strength of 75,000 psi) reinforcing bars, lengths must be multiplied by 1.25.
5. For lightweight aggregate concrete, multiply the tabulated values by 1.33.

CHAPTER 6 – SERVICEABILITY REQUIREMENTS

General. Strength design permits the utilization of larger percentages of tension reinforcement without compression reinforcement, and allows advantageous use of higher strength reinforcement. Shallower construction can result. Once the safety of the member or floor system is determined by strength design, it is necessary to confirm that both deflection and cracking are within tolerable limits at service load levels. If the required reinforcement is provided as small bars spaced close together, crack control requirements are easier to satisfy.

Deflection Control. Deflections must be computed and compared to allowable limits for particular loading combinations when the thickness used is less than the minimums tabulated below (ACI 9.5.2.1).

For one-way construction:

Member	Minimum Thickness, h †			
	Simply Supported	One End Continuous	Both Ends Continuous	Cantilever
Solid slabs	$\ell/20$	$\ell/24$	$\ell/28$	$\ell/10$
Beams or joists	$\ell/16$	$\ell/18.5$	$\ell/21$	$\ell/8$

† Members not supporting or attached to partitions or other construction likely to be damaged by large deflections.

Values of h for normal-weight concrete and Grade 60 reinforcing bars.

ℓ = c.-c. spans.

For two-way flat plate construction without beams: Exterior and interior panels: $h \geq \ell_n/33$ (5 in. min.). For the effects of edge beams, drop panels, rectangular panels, edge panels, and corner panels, see Table 10-1.

Computed deflections are limited to values that are acceptable for various conditions of loading and design requirements. These acceptable limits are given as fractions of the span lengths and vary with the use of a structure. For example, a floor supporting partitions or supporting a ceiling below can tolerate much less deflection, because of cracking of the supported elements, than the same floor without a ceiling or partitions. If the problem is that of establishing clearance under a flexural member and over, say, a plate glass store front, many factors, such as age, moisture content, actual E_c, settlement of supports, realistic end restraints, and the like, have an influence on the actual deflection.

When the computed long-term deflection exceeds the allowable, one of the most satisfactory means of decreasing these creep-caused deflections is the addition of compressive reinforcement.

Deflection Computations.†† The calculation of deflections requires the computation of E_c, the modulus of elasticity of the concrete, and I_e, the effective moment of inertia of the cross-section.

The modulus of elasticity for concrete $E_c = w^{1.5}\, 33\sqrt{f'_c}$. Use the specified concrete compressive strength f'_c for preliminary calculations. For normal-weight concrete, E_c may be taken as $57{,}000\sqrt{f'_c}$ (ACI 8.5.1). Taking f'_c as 3000 psi, E_c = 3,122,000 psi; and for f'_c = 4,000 psi, E_c = 3,605,000 psi.

The effective moment of inertia, I_e, is a function of the gross moment of inertia, I_g, the cracked moment of inertia, I_{cr}, and the ratio of the cracking moment, M_{cr}, to the actual (service load) moment, M_a.

For values of I_g and I_{cr} for solid sections, see Table 12-1; for standard joist or waffle slab sections, see Table 8-1, Gross Section Properties, for I_g, and the load capacity tables footnote for I_{cr} with each individual combination of bars and for M_{cr}. Determining the cracking moment:

$$M_{cr} = f_r I_g / y_t$$

where $f_r = 7.5\sqrt{f'_c}$ for normal-weight concrete and y_t is the distance from the neutral axis of the solid section to the tension fiber.

Code Equation (9-8) for calculating the effective moment of inertia I_e is

$$I_e = (M_{cr}/M_a)^3 I_g + [1 - (M_{cr}/M_a)^3] I_{cr}$$

One-way slabs, joists and beams. For the uniform load conditions upon which all of the tabulated designs in this *Handbook* are based, deflections can be estimated from the relationship $\Delta = KwL'^4\, 1728/E_c I_e$ where K is a constant related to the degree of restraint at either

†† It should be emphasized that the calculations illustrated result in a *computed* deflection only. The results are useful to determine compliance with minimum code limits. These results may be used as a starting point to estimate *actual* deflections, but must be modified to reflect other parameters such as the need for camber, effects of restraint, shrinkage, probable curing and construction sequences — all of which influence the actual deflection. The *computed* deflections tabulated in this *Handbook* should be evaluated to determine adjustments necessary for use in preparing estimates of *actual probable deflection*.

end; w is the uniform load, plf; L' is the appropriate span in feet; E_c is the modulus of elasticity of the concrete, psi; and I_e is the effective moment of inertia of the cross-section, in.^{4}, and Δ is in inches.

Three conditions of restraint have been tabulated for one-way flexural members:

(1) Simple, single span, $+M = wL'^2/8$;

The value of K for a single span when $+M = wL'^2/8$ is given in textbooks as $K = 5/384$. Settlement of the supports has little effect on this coefficient.

(2) End span of continuous member, $+M = wL'^2/11$.

For end spans with $+M = wL'^2/11$, the value of K is not so readily found in textbooks. A value of K for gravity loads is obtained by the conjugate beam concept as $K = 3.25/384$, assuming no settlement of supports.

(3) For interior spans with $+M = wL'^2/16$ the same limitations apply and the same method can be used, resulting in $K = 2/384$.

These coefficients are summarized in the table below:

Values of K in $\Delta = KwL'^4\ 1728/E_cI_e$		
Type of Restraint	Maximum Positive Moment	Value of K
Simple Span	$+wL'^2/8$	5/384
End Span	$+wL'^2/11$	3.25/384
Interior Span	$+wL'^2/16$	2/384

Applications

One-Way Systems. All factored load capacity tables in this *Handbook* can be used without the need to compute deflection for all floor and roof systems where they do not support non-structural elements liable to be damaged by service load deflections greater than $\ell/360$. For one-way systems where capacity is controlled by deflection, such values are so noted.

When the one-way floor or roof system supports elements liable to be damaged by deflections greater than $\ell/360$, the designs can be selected above the horizontal line in each table, which identifies minimum depth/span ratio above which the Code does not require deflection computations. Alternatively, design aids can be used to determine values of E_c and I_e for calculation of deflection, or deflection can be conservatively estimated from known loading conditions (tabulated) and the deflection equation for the tabulated loading pattern. See examples in Chapters 7 and 8.

Retaining Walls. Deflection at the top of all retaining wall designs has been computed assuming the base of the wall is fixed. Thickness/height proportions were selected for the tabulated designs so that deflection is less than $h_w/240$. The exposed face should be cambered if a vertical face design is desired. If a battered face is on the exposed side, no further precaution is needed.

Two-Way Slab Systems. Slab thickness, h, for flat plates and flat slabs; or rib-plus-slab, h, for waffle flat slabs may be compared to the limits in Table 10-1, to ensure that deflection computations are not required.

If it becomes necessary to compute deflections of two-way slab systems, due to use of less depth than that of the minumum depth/span ratios or to estimate camber required for level floors, some simplifications may be made. Since the cracking moment/actual moment ratio $(M_{cr}/M_a) \rightarrow 1.0$ for joist and waffle slabs, use of an average gross moment of inertia gives reasonable results. For solid slabs, use of an average (M_{cr}/M_a) ratio for computation of I_e and center-to-center spans should be conservative.

The simplest way to estimate maximum elastic deflection at service (elastic) loading for a two-way flat slab or a waffle slab is to use an elastic plate on point supports.* Simplifying assumptions, justifiable for such estimates, include, in addition to the usual assumptions of elasticity and homogeneity: (1) basically uncracked behavior, i.e., use of gross moment of inertia, (2) average moment of inertia based on ratio of twice the solid head or drop area to total area, (3) spans c.-c. of columns neglecting size of column, and capital, if any, and (4) load on panel is uniformly applied.

The basic plate formula* for deflection, Δ, at the center of interior panels is:

$$\Delta = k\,\frac{wL^4}{E_c t_e^{\,3}}\,(144) \text{ in inches, where}$$

w = service load, psf
L = longer span of panel, feet
L' = shorter span of panel, feet
t_e = equivalent average thickness, inches (Measure of moment of inertia)
k = coefficient depending on ratio of spans

Notes: All terms must be expressed in consistent units. This equation is similar in form to that for one-way slab deflection given previously.

*S. Timoshenko and S. Woinowsky-Krieger, *Theory of Plates and Shells*, Second Edition, McGraw-Hill Co., 1959.

For uniformly loaded rectangular panels, values for k are:

Ratio spans L/L' =	1	1.1	1.2	1.3	1.4	1.5	2.0*
k =	0.0634	0.0532	0.0467	0.0423	0.0391	0.0368	0.0319

* Limiting ratio for Direct Design – ACI 13.6.1.2.
For "checkerboard loading," square panels: k = 0.0539.
For alternate bays loaded, which produces largest deflections, basic formula is modified for square panels to: $\Delta = 0.1028 \frac{wL^4}{E_c t_e^3}$ and is applicable when five or more bays are continuous transversely to direction of loaded bays. These formulas conservatively assume point support at all columns.

Example

This example illustrates the deflection computation of a waffle slab. Deflection of a flat slab would be computed in a similar manner.

A typical load test following requirements of the ACI Building Code on a standard waffle flat slab will serve to illustrate the simplified procedure suggested for computing deflection.

Design Data:

Roof with square panels of 36-foot spans, 6-inch wide ribs on a 3′-0″ module with 30 × 30 × 12 standard forms; top slab thickness 4 inches. Total depth = 12 + 4 = 16 inches. Solid head of 18′-0″.

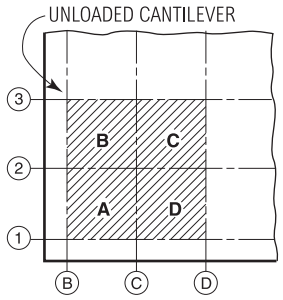
Load Test Data:

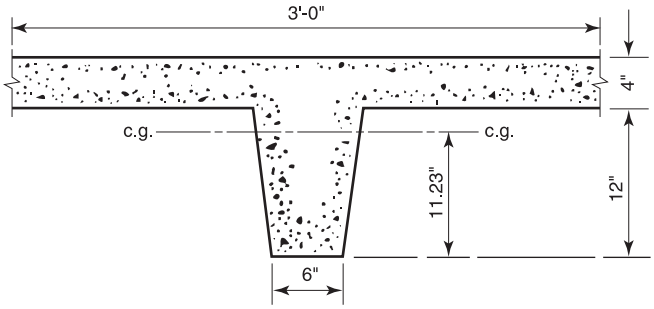
Test Load = Average 15-inch depth of water
= 78 psf

Four panels loaded between column centerlines 1 and 3 and centerlines B and D including one corner panel, two edge panels, and one interior panel. Immediate and 24-hour readings were taken at centers of each panel as follows:

Location	Mark	Immediate†	24-hour†
Corner panel	A	–0.240 in.	–0.288 in.
Edge panel	B	–0.180 in.	–0.192 in.
Interior panel	C	–0.096 in.	–0.108 in.
Edge panel	D	–0.204 in.	–0.264 in.

† Probable accuracy of measurement ± 0.024 in.





Solution: (Note: See Chapters 10 and 11 for explanation of procedure for computing equivalent average thickness, t_e, for solid flat slab and waffle flat slab respectively.)

Solid Head Area, $I_h = \frac{12 \times 16^3}{12}$ = 4,096 in.^{4} per 12 in. width

Waffle Area:

Use rib width 6 in.

$X_{c.g.}$ = 11.23 in. from bottom

For 36 in. width:

$$I_w = \frac{36 \times 4^3}{12} + (144)(2.77)^2 + \frac{6 \times 12^3}{12} + (72)(5.23)^2$$
$$= 4{,}130 \text{ in.}^4$$

For 12 in. width, I_w = 4,130/3 = 1,377 in.^{4}

$$\frac{\text{Area of Solid Head}}{\text{Area of Total Panel}} = \frac{(18)(18)}{(36)(36)} = \tfrac{1}{4}$$

Multiply ratio of solid area by two because stiffness in the area of maximum moment has most effect on deflection.

$$\text{Average } I_{gross} = \frac{4{,}096 \times 2 + 1{,}377 \times 3}{5} = 2{,}464 \text{ in.}^4/12 \text{ in.}$$

Compute equivalent average thickness, t_e:

$\frac{12 \times t_e^3}{12}$ = 2,464 in.^{4} $\quad t_e^3$ = 2,464 in.^{3} and t_e = 13.5 in.

Load $w = \frac{78}{144}$ psi

L = 36 × 12 in.

Take E_c = 3,500,000 psi

Estimated deflection $\Delta = k \frac{wL^4}{E_c t_e^3}$

The selection of the proper coefficient k usually requires some study of the loading pattern when attempting to predict results of a load test since the exact k values were derived for a uniform load pattern extending far beyond the usual practicable limits of test loading. For this example, approximate k as the coefficient for an interior panel with all the surrounding panels loaded at least two bays distant is usual. For a square interior panel, this computed deflection would be:

$$\Delta = 0.0634 \times \frac{78}{144} \times \frac{(36 \times 12)^4}{3.5 \times 10^6 \times 2{,}464} = 0.141 \text{ in.}$$

To correlate computed deflection with the conditions of this test in which half the surrounding panels were loaded, a lower coefficient than for all panels loaded is proper. The "checkerboard" loading coefficient of 0.0539 is probably more appropriate, although it does not model the load test either. Try a value of 0.055.

$$\Delta = \frac{0.055}{0.0634} \times 0.141 = 0.122 \text{ in.} = 0.01 \text{ ft}$$

Measured $\Delta = 0.009$ ft. This correlation is probably closer than could be usually expected.

Crack Control. To control crack widths, flexural reinforcement must be well-distributed in the zones of maximum concrete tension. Bar spacing in two-way slabs should not be greater than 2*h* (ACI 13.3.2).

The final crack width after a period of time depends on the magnitude of (1) flexural cracking, (2) shrinkage, (3) creep, and (4) temperature movements. The effects of the last three items may be partially counteracted in many ways.

T-Beams. Where the top flanges of major T-beams are in tension, part of the negative moment reinforcement must be distributed over an effective flange width (ACI 10.6.6). The effective flange width is the smaller of: the width defined for flexural design (ACI 8.12), or a width equal to 1/10 of the span. If the effective flange width exceeds 1/10 the span, some longitudinal reinforcement must be placed in the outer portions of the flange.

Skin Reinforcement. If the depth of the web of a beam exceeds 36 inches, longitudinal skin reinforcement must be provided in the vertical faces of the web to control the crack width in the web (ACI 10.6.7). Without web reinforcement, the crack width in the web could be wider than at the tension reinforcement level. The skin reinforcement must be uniformly distributed along both side faces of the web for a distance *h*/2 from the tension face. Spacing of the skin reinforcement should not exceed the same limits as flexural reinforcement for one-way slabs and beams (see next Section). The Code permits inclusion of the skin reinforcement in computation of design moment strength, provided a compatibility analysis is made to determine the stresses in the individual bars.

Maximum Spacings for Reinforcing Bars. It is generally agreed that the size and spacing of flexural cracks are a function of steel stress, the amount of concrete cover over bars, and the area of concrete surrounding and tributary to the area of an individual bar.

One-Way Slabs and Beams. According to the ACI Building Code, reinforcing bars must not be spaced farther apart than the spacing calculated from Code Eq. (10-4):

$$s = 15\left(\frac{40{,}000}{f_s}\right) - 2.5c_c \le 12\left(\frac{40{,}000}{f_s}\right)$$

where f_s can be taken as 40 ksi for Grade 60 bars and c_c = concrete cover.

For one-way slabs with ¾ inches of concrete cover to the flexural reinforcement, the maximum bar spacing is 12 inches. For beams with #4 stirrups and 1½ inches of concrete cover to the stirrups, the maximum bar spacing is 10 inches.

CHAPTER 7 – ONE-WAY SLABS

ONE-WAY SOLID SLABS

This Chapter presents tabulated designs for uniform depth solid concrete slabs reinforced for flexure in one direction and only for temperature and shrinkage in the other direction. The tabulated factored usable superimposed loads were obtained as the least value determined by shear, or positive or negative flexure.

GENERAL CODE CONSIDERATIONS

Factored moments are computed from the empirical coefficients of ACI 8.3.3,* as an elastic beam free to rotate on unyielding supports. ACI 8.3.3 limits the use of empirical moment coefficients to ratios of live load to dead load—unfactored gravity loads—of not more than three. Since part of the superimposed gravity load may be dead load, the ratio of live to dead load may vary in each instance. Therefore, superimposed gravity loads are tabulated well above three times the dead weight of the slab itself.

The recommended reinforcement details in Fig. 7-1 show where straight reinforcing bars are cut off, anchored, and extended in accordance with current standard practices and the *ACI Detailing Manual.* These practices have worked satisfactorily for many years for normal load and span ratios. Necessary modifications must be made when the conditions of an individual design require them. A practical, economical design should use no more than two or three bar sizes for slabs across an entire floor. The bar sizes tabulated in the load tables must be adjusted to fit tabulated areas for simple, fast placing in the entire floor or roof slab, which may include variable spans and loads. Such adjustments can be made with smaller bar sizes at closer spacings without checking anchorages. Larger bars may be substituted at larger spacings if tension development length and crack control requirements are satisfied. For example, some top bars should be extended to be continuous throughout the span if the ratio of live to dead load exceeds three.

SCOPE OF TABULATED DESIGNS

These tabulated designs for one-way solid slabs give the *factored usable superimposed load,* in pounds per square foot. In other words, the tabulated loads are net factored superimposed loads. Total factored load was calculated and reduced by the prescribed strength-reduction factors (ϕ-factors), from which 1.2 times the slab weight was deducted using a unit weight of 150 pounds per cubic foot (pcf). One set of material strengths is used: normal-weight concrete with $f_c' =$ 4,000 psi and reinforcing bars with $f_y =$ 60,000 psi.

Three cases of end restraint are considered: (1) single spans simply supported; (2) end spans free on one end and continuous on the other; and (3) interior spans continuous on both ends.

Factored usable superimposed loads are tabulated for slabs with various ratios of flexural reinforcement: single spans for the minimum, $\rho \geqq 0.0018bh$, $\rho \approx 0.0025bd$, $\rho \approx 0.0050bd$, $\rho \approx 0.0075bd$, and $\rho \approx 0.0100bd$; end and interior spans for minimum recommended top reinforcing steel, $\rho \approx 0.0018bh$, $\rho \approx 0.0025$, 0.0050, 0.0075, and $0.0100bd$.

For $f_c' = 4{,}000$ psi and $f_y = 60{,}000$ psi, the maximum $\rho = 0.0181$ for tension-controlled sections. All of the ratios of flexural reinforcement are less than 0.0181 so that the strength-reduction factor, ϕ, is 0.90 for flexure.

The recommended minimum reinforcement * is a variable percentage since for adequate rigidity of top bars under ordinary construction traffic in monolithic construction, minimum size #4 bars at a maximum spacing of 12 inches are recommended. For thin slabs, this practical minimum is well within Code limits, i.e., $A_s = 0.0018bh$ spaced at 18 inches or $3h$ maximum. An exception is made for thin single span slabs where cross traffic is not expected. The recommended maximum reinforcement ratio, $\rho \leq 0.010bd$, is the maximum for economy is most routine applications. Bar spacing is also limited by the Code's requirements for crack control (ACI 10.6.4). For ¾ inches of concrete cover, which is used in the tabulated designs, the maximum bar spacing is 12 inches. The limit on top reinforcement for a balanced design at continuous supports controls the bottom reinforcement where end spans and interior spans are equal.

Temperature-shrinkage reinforcement in structural floor and roof slabs is tabulated for reinforcing bars with $f_y =$ 60,000 psi.

BASIS FOR DESIGN

Flexural design is based on factored moments computed by the coefficients per ACI 8.3.3. See Chapter 5.

* In all cases, equal or greater than the minimum prescribed in ACI 10.5.4.

Design shear strength, ϕV_n, was calculated in accordance with ACI 11.2. Both "short" and "long" formulas were compared and the larger value of ϕV_n was used. Tension development of reinforcing bars has been checked in accordance with ACI Chapter 12, applied to bars anchored in accordance with the recommended reinforcement details in Fig. 7-1. Elastic deflections for all full tabulated superimposed loads divided by 1.6 are less than $\ell/360$. Thus, the tabulated designs need not be investigated for any live load deflection. Creep deflections will vary according to proportion of the superimposed service loads of long-term duration. Where long-term deflection limits of the Code apply, e.g., slabs supporting or attached to brittle partitions, long-term deflection must be computed. See example, Chapter 6.

ASSUMPTIONS IN DESIGN

It was assumed that end restraint at free ends of the slab has a negligible effect on the positive moment. Top bars tabulated in Single Span tables provide at least one-third of the area tabulated for bottom reinforcing steel but not less than #4 in size, except for short single span slabs, nor at spacings more than 12 inches. The top reinforcing steel is sufficient for free ends supported by monolithic beams or girders, where the Code moment coefficient = 1/24 $w_u \ell_n^2$ applies, as well as the ordinary incidental restraint when end bearing is provided by masonry walls.

For interior spans, tabulated top reinforcing steel at continuous supports is based upon an adjoining span equal to the span being considered. This condition will fit the typical case where the adjacent span slab thickness is equal, the span lengths are equal, and the spans are loaded with the same uniformly distributed load. This condition should always be adequate where the adjoining spans are shorter or more lightly loaded. In order to fit unequal spans, provide the top steel area tabulated for the longer span and have that reinforcement extend one-third the longer span length on both sides of the support.

For end spans, top reinforcing steel at the continuous interior supports is calculated for an interior span of the *same slab thickness.* This condition will fit the typical practical situation. Where slabs of varying thickness are used for special load-span conditions, the tabulated top steel area for the shallower span must be provided using added straight top bars for any deficiency.

USE OF LOAD TABLES — SINGLE SPAN

Single Span Example 1 – Design a single span solid slab floor to span 12′-8″ clear between masonry bearing walls for the following superimposed service loads. Space permits a 6-in. depth.

Live load	150 psf
Floor finish	13 psf
Ceiling	8 psf

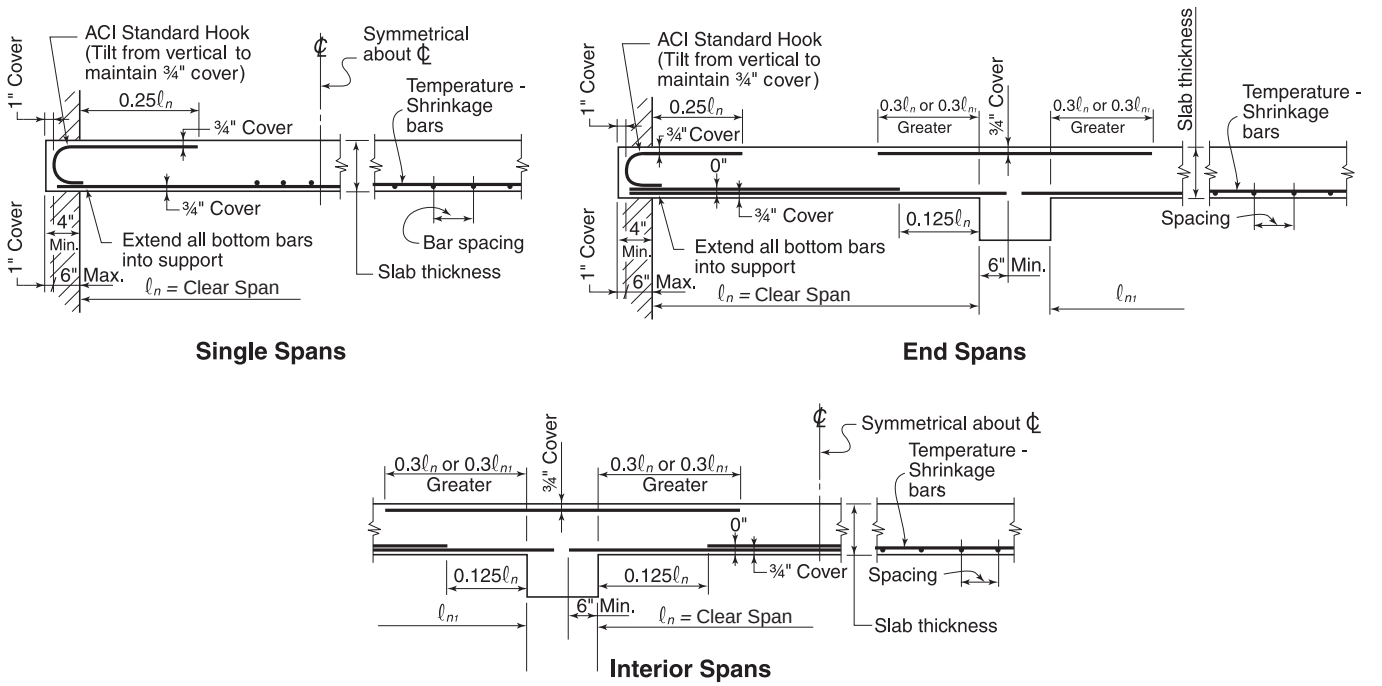


Figure 7-1 Recommended Bar Details – Solid Slabs

Solution:

Strength Design

The total factored superimposed load requirement is:

Live load $150 \times 1.6 = 240$ psf
Dead load $(13 + 8) \times 1.2 = \underline{25}$
$w_u = 265$ psf

Since the clear span is 12′-8″ and a minimum bearing width of 4 inches is recommended, the span center-to-center of bearings for design is 12′-8″ + 2″+ 2″ = 13′-0″.

Try each load table beginning with minimum reinforcement to determine if the 6-in. depth is feasible.

See Page 7-5, $\rho \approx 0.0018$: $w_u =$ 49 psf capacity < 265
See Page 7-6, $\rho \approx 0.0025$: $w_u =$ 83 psf capacity < 265
See Page 7-7, $\rho \approx 0.0050$: $w_u = 220$ psf capacity < 265
See Page 7-8, $\rho \approx 0.0075$: $w_u = 296$* psf capacity > 265
Use design from Page 7-8; $\rho \approx 0.0075$; $h = 6$ in.

Bottom bars	#6 spaced at 12 in.
Top bars	#4 spaced at 12 in.
Temp.-shrinkage bars	#3 spaced at 10 in.

Recommended bar details are shown in Fig. 7-1.

Serviceability Check

1. Deflection – Note asterisk on Page 7-8 load (296*) indicates an elastic deflection of $\ell/360$ at a service load of 296/1.6.

$$\text{Live load deflection} = \left(\frac{240}{296}\right)\left(\frac{13 \times 12}{360}\right) = 0.35 \text{ in.}$$

2. Crack control – The maximum spacing permitted by ACI 10.6.4: $s = 12(40{,}000/f_s) = 12(40{,}000/40{,}000) = 12$ in. The spacing of the #6 bottom bars is 12 in. = 12 in., Okay.

Single Span Example 2 – Design a minimum depth roof slab for a single clear span of 16 ft between supporting monolithic beams for the following superimposed service loads:

Live load, $L = 30$ psf
Roofing material, $D = 15$ psf

Solution:

Strength Design

Augment and accumulate loads for factored superimposed capacity required:**

$30 \times 1.6 + 15 \times 1.2 = 66$ psf. See table on Page 7-8, $\rho \approx 0.0075$. Select a 5-in. slab, $w_u = 89$* psf capacity.

** Note: Total factored load superimposed on the supporting beams is the sum of 1.2 times the slab weight, $1.2 \times 63 + 66$ psf = 142 psf times half span 8 feet = 1,136 plf.

Reinforcing bars required are:

Bottom bars	#5 spaced at 10 in.
Top bars	#3 spaced at 12 in.
Temp.-shrinkage bars	#3 spaced at 11 in.

Serviceability Check

1. Deflection – Note asterisk next to w_u. Live load deflections are approximately

$$\left(\frac{1.6 \times 30}{89}\right)\left(\frac{16 \times 12}{360}\right) = 0.29 \text{ in.}$$

2. Crack Control – Spacing of #5 bars is 10 in.< 12 in., Okay.

Single Span Example 3 – Repeat requirements of Example 1, $\ell_n = 13'\text{-}0''$; $D = 21$ psf, $L = 150$ psf and $w_u = 265$ psf, with the additional serviceability requirement that rigid partitions are to be attached to the slab so that the design must meet the deflection limit of $\ell_n/480$ for the sum of elastic live load deflection plus creep deflection. Assume that the partition weight is equivalent to 20 psf additional uniform dead load.

The computed long-term deflection occurring after installation of partitions plus the computed elastic deflection due to service live loads is limited by the Code to $\leq \ell_n/480$. Assume that partition installation will be scheduled last. An estimated 50 percent of the long-term deflection due to dead weight of slab, floor finish, and ceiling will have occurred. Determine minimum thickness required for these design conditions.

Strength Design

Accumulate total superimposed factored load

$$w_u = (1.2)(20 + 21) + (1.6)(150) = 289 \text{ psf}$$

From:
Page 7-7, 7-in. slab with $\rho \approx 0.0050$, $w_u = 343$ psf
Page 7-8, 6½-in. slab with $\rho \approx 0.0075$, $w_u = 389$* psf.

Serviceability Check

The deflection limit will control this design. Accumulate an equivalent factored load which would result in an immediate deflection equal to (360/480) times $\ell/360$. Try a 7½-in. slab. $D = 94$ psf.

Effect of partitions on long-term deflection; if duration ≥ 5 years, $\xi = 2.0$ (ACI 9.5.2.5); if no compression reinforcement, the multiplier $\lambda = 2.0$.

$$\begin{aligned}\text{Equiv. } w_u &= (D + L)(1.6)(480/360) = (D + L)(2.13)\\ &= [(2)(20) + 21 + 94 + 150](2.13)\\ &= (305)(2.13) = 650 \text{ psf}\end{aligned}$$

From Page 7-8, $\rho \approx 0.0075$, for 7½-in. slab: $w_u = 582$* psf

Try an 8-in. slab, D = 100 psf.

Equiv. w_u = (305 + 6)(2.13) = 662 psf

From Page 7-8, $\rho \approx 0.0075$, for 8-in. slab: w_u = 714* psf

Use the 8-in. slab (note asterisk).

Live load deflection = $\left(\frac{1.6 \times 150}{714}\right)\left(\frac{13 \times 12}{360}\right)$ = 0.15 in.

$\frac{\ell_n}{480} = \frac{13 \times 12}{360}$ = 0.33 in.

Select reinforcement from table on Page 7-8, ρ = 0.0075;

Bottom bars	#7 spaced at 11 in.
Top bars	#4 spaced at 12 in.
Temp.-shrinkage bars	#3 spaced at 7 in.

MANUAL CALCULATION—LOAD TABLES FOR SINGLE SPAN

Example 4. Single Span—Derive the factored usable superimposed load value tabulated for an 8-in. solid slab with recommended minimum reinforcement on a single span of 14 ft. From Page 7-5 with $\rho \geq 0.0018\,bh$ (recommended minimum reinforcement), h = 8 in. and #3 bottom bars spaced at 7 in., the factored usable superimposed load is 119 psf. Derive the load value of 119 psf.

Flexure

Compute the design moment strength,

$\phi M_n = \phi A_S f_y\ (d - a/2)$

Where A_S = 0.189 in.^{2}/ft for #3 bottom bars spaced at 7 in.

$a = \frac{A_s f_y}{0.85 f_c' b} = \frac{0.189(60)}{0.85(4)(12)}$ = 0.28 in.

$d = h$ – cover – $0.5d_b$

d = 8 – 0.75 – 0.375/2 = 7.06 in.

ϕM_n = 0.90(0.189)(60)(7.06 – 0.28/2)/12 = 5.89 ft-kips/ft

Equate $M_u = \phi M_n$ where $M_u = w_u \ell^2/8$

$w_u\,(14)^2/8 = 5.89$

w_u = 0.240 klf or 240 psf

w_D = 8/12(150) = 100 psf (8-in. slab)

Factored usable superimposed load =
240 – 1.2(100) = 120 psf (tabulated = 119, Okay)

Shear

Design shear strength is the larger of (ACI 11.2):

$\phi V_c = 2\phi\sqrt{f_c'}\,b_w d$, or . . . . . (ACI Eq. 11-3)

$\phi V_c = \phi\left(1.9\sqrt{f_c'} + 2500\,\rho_w \frac{V_u d}{M_u}\right) b_w d$ (ACI Eq. 11-5)

$\phi V_c = 2(0.75)\sqrt{4{,}000}(12)(7.06)/1000$ = 8.04 kips/ft

At the critical section, a distance d from the face of the support, for uniformly distributed load,

$\frac{V_u d}{M_u} = \frac{w_u(\ell_n/2 - d)d}{w_u d(\ell_n/2 - d/2)} = \frac{\ell_n/2 - d}{\ell_n/2 - d/2}$

$\frac{V_u d}{M_u} = \frac{(14)(12)/2 - 7.06}{(14)(12)/2 - 7.06/2} = 0.96$

$\phi V_c = 0.75(1.9\sqrt{4{,}000}$
$+ 2500\left(\frac{0.189}{7.06 \times 12}\right)(0.96))(12)(7.06)1000)$
= 7.98 kips/ft

Take ϕV_c = 8.04 kips/ft

At a distance d from the face of the support,

$V_u = w_u(\ell_n/2 - d)$

Equate $V_u = \phi V_n$

$w_u\,(14/2 - 7.06/12) = 8.04$

w_u = 1.25 klf or 1,250 psf

Design moment strength governs; hence, w_u = 120 psf

Tension Development of #3 bottom bars

Check tension development of #3 bottom bars spaced at 7 in.

Concrete cover = 0.75 in. = 0.75/0.375 = $2d_b$

Spacing = 7 in. = 7/0.375 = $19d_b$

From Table 5-2(b) under "Uncoated Bars" and "Other Bars"; for "Case 1" and "Lap Class A":

ℓ_d = 15 in.

Check available embedment length vs. 15 in.

Maximum $+M_u$ occurs at midspan; the distance from midspan to the end of the #3 bars = 7 ft = 84 in. plus the embedment beyond the face of the support; total embedment provided, 84 + embedment > ℓ_d of 15 in., Okay.

Check $\ell_d \leq M_n/V_u + \ell_a$ . . . . . (ACI 12.11.3, Eq. 12-5)

Where $M_n = \phi M_n/\phi$ = 5.89/0.90 = 6.54 ft-kips/ft

V_u at support = $w_u(\ell_n/2)$

= 0.240(14/2) = 1.68 kips/ft

ℓ_a = embedment beyond center of support; assume ℓ_a is at least 1 in.

M_n/V_u = 6.54(12)/1.68 = 46.7

46.7 + 1 = 47.7 in. > ℓ_d, Okay

SOLID ONE-WAY SLABS—SINGLE SPAN

***Service loads corresponding to 1/1.6 of the tabulated superimposed load results in calculated immediate deflection of 1/360 span.**

"H" – Use hooked or headed bars.

USE OF LOAD TABLES FOR END SPAN AND INTERIOR SPAN

Example 5. End Span and Interior Span—Select a solid slab design for a floor supported by monolithic beams at (clear) spacings of 15 ft. Superimposed service loads are: live load = 120 psf; celing construction = 10 psf; floor finish = 10 psf. No masonry partitions will be supported nor attached to the slab.

Augment and accumulate the superimposed factored loads:

Live load $120 \times 1.6 = 192$ psf
Dead load $20 \times 1.2 = \underline{24}$
Superimposed $w_u = 216$ psf

For equal loads and spans, the end span is most critical for thickness (factored shear is 1.15 times that in interior spans). Select end span design first, if it is desired to use the same depth of slab throughout.

See table for **End Span** mininum thickness tabulated, Page 7-18. Select thickness, h = 5½ in.; factored usable superimposed load w_u = 250* psf with $\rho \approx$ 0.0075.

Bottom bars: #5 spaced at 10 in.
Top bars: #5 spaced at 9 in.
Temperature-shrinkage bars: #3 spaced at 11 in.
Top bars at free end: #4 spaced at 12 in. Provide end hooks; see Fig. 7-1 for recommended bar details.

Interior Spans

Since exterior span top steel is used for interior span top steel, see table on Page 7-23 for minimum thickness. For h = 5½ in. (determined from end span), factored usable superimposed load w_u = 292 psf > 216.

Read reinforcement for $\rho \approx 0.0075$:
Bottom bars: #5 spaced at 12 in.
Top bars: #5 spaced at 9 in. (same as exterior span)
Temperature-shrinkage bars: #3 spaced at 11 in.

Serviceability Check

1. Deflection—Maximum deflection occurs in the end span. (See Chapter 6). At a service load, (1/1.6)(216) = 135 psf, the live load deflection limit is $\ell/360$. (Note asterisk in load capacity table.) Service live load, L = 120.

$$\text{Live load deflection} = \left(\frac{120}{135}\right)\left(\frac{15 \times 12}{360}\right) = 0.44\,\text{in.} < \ell/360$$

2. Crack Control—For ¾ in. of concrete cover, bar spacing is limited to 12 in. (ACI 10.6.4). Note that the maximum bar spacing used, #5 spaced at 12 in., is satisfactory.

Example 6. End Span and Interior Span—Some areas of interior spans in the same floor system described in Example 5 have to support partitions (service load = 10 psf) which would be damaged by large deflections. The partitions will be installed last, after an estimated 50 percent of other long-term load deflection occurs. Service live load (offices) in this area of the floor is 60 psf. Check long-term deflection.

Account for long-term sustained service load effects = (2) long-term load of partitions + (1)($D + L$) = (2)(10) + (69 + 10 + 10 + 60) = 169 psf equivalent superimposed load. Enter table for $\rho \approx 0.010$ on Page 7-24 with h = 5½ in. clear span = 15′-0″, and read factored usable superimposed load, w_u = 380 psf, which causes less deflection than $\ell/360$.

(380)(360/480) = 285 psf which causes less deflection than $\ell/480$.

Equivalent service live load, L = 285/1.6 = 178 psf > 169. Thus, long-term deflection should be satisfactory.

For a complete manual calculation, see Pages 7-11 through 7-14.

MANUAL CALCULATION

Example 7. End Span— Derive the factored usable superimposed load tabulated for an 7-in. solid slab with a percentage of reinforcement, $\rho \approx 0.0075$, on an 18-ft span. $f'_c = 4{,}000$ psi.

From the table on Page 7-18 with $\rho \approx 0.0075$, $h = 7$ in., and with #6 top bars at the first interior support which are spaced at 9 in. and #6 bottom bars spaced at 11 in., the factored usable superimposed load is 299 psf. Derive the load value of 299 psf.

Flexure

Compute the design positive moment strength based on the #6 bottom bars spaced at 11 in.:

$$\phi M_n = \phi A_s f_y (d - a/2)$$

Where $A_s = 12/11(0.44) = 0.480$ in.^{2}/ft for #6 bottom bars spaced at 11 in.

$$a = \frac{A_s f_y}{0.85 f'_c b} = \frac{0.480(60)}{0.85(4)(12)} = 0.71 \text{ in.}$$

$$d = h - \text{cover} - 0.5d_b$$

$$d = 7.0 - 0.75 - 0.375 = 5.87 \text{ in.}$$

$$\phi M_n = 0.90(0.480)(60)(5.87 - 0.71/2)/12 = 11.91 \text{ ft-kips/ft}$$

Equate $+M_u = \phi M_n$ where $+M_u = w_u \ell_n^2/11$

$$w_u(18)^2/11 = 11.91$$

$$w_u = 0.404 \text{ klf or } 404 \text{ psf}$$

Compute the design moment strength based on the #6 top bars at the first interior support which are spaced at 9 in.:

$$\phi M_n = \phi A_s f_y (d - a/2)$$

Where $A_s = (12/9)(0.44) = 0.587$ in.^{2}/ft for #6 top bars spaced at 9 in.

$$a = \frac{A_s f_y}{0.85 f'_c b} = \frac{0.587(60)}{0.85(4)(12)} = 0.86 \text{ in.}$$

$$d = h - \text{cover} - 0.5d_b$$

$$d = 7.0 - 0.75 - 0.375 = 5.87 \text{ in.}$$

$$\phi M_n = 0.90(0.587)(60)(5.87 - 0.86/2)/12 = 14.37 \text{ ft-kips/ft}$$

Equate $-M_u = \phi M_n$ where $-M_u = w_u \ell_n^2/10$

$$w_u(18)^2/10 = 14.37$$

$$w_u = 0.444 \text{ klf or } 444 \text{ psf}$$

Positive ϕM_n governs flexural capacity; hence, $w_u = 404$ psf

Factored usable superimposed load $= 404 - 1.2(150 \times 7/12) = 299$ psf (tabulated = 299, okay)

Recalculating – M_u:

$$-M_u = w_u(\ell_n)^2/10$$

$$= .404\ (18)^2/10$$

$$= 13.09 \text{ ft-kips/ft}$$

Shear

Compute design shear strength based on ACI Eq. 11-3,

$$\phi V_c = 2\phi\sqrt{f'_c}\, b_w d$$

$$= 2(0.75)\sqrt{4{,}000}(12)(5.87)/1{,}000 = 6.68 \text{ kips/ft}$$

A factored superimposed load based on ACI Eq. 11-5 cannot be derived directly because the quantity $V_u d/M_u$ is dependent on the load.

Equate $V_u = \phi V_c$

Compute V_u at a distance d from the face of the support; at the support, maximum $V_u = 1.15\ w_u \ell_n/2$ (ACI 8.3.3):

$$V_u = 1.15\ w_u(\ell_n/2 - d) \le \phi V_c$$

$$1.15\ w_u(18/2 - 5.87/12) = 6.68$$

$$w_u = 0.714 \text{ klf or } 714 \text{ psf}$$

Flexural capacity governs; hence, the factored usable superimposed load = 299 psf

Tension Development

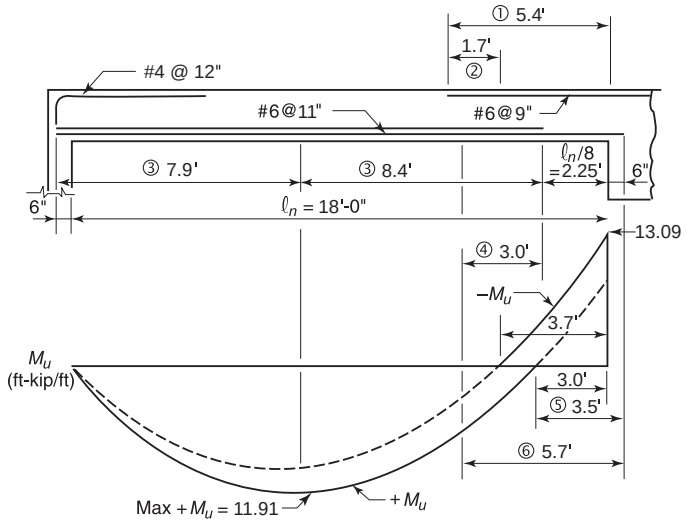
#6 top bars at the first interior support which are spaced at 9 in.

Concrete cover = 0.75 in. = $0.75/0.75 = 1.0d_b$

Spacing = 9 in. = $9/0.75 = 12.0d_b$

From Table 5-2(b) under "Uncoated Bars" and "Other Bars"; for "Case 1" and "Lap Class A" (for h = 7 in., this is less than 12 in. of concrete below the #6 bars):

ℓ_d = 29 in. = 2.42 ft



Top Bars:

Check ℓ_d = 29 in. vs. embedment length provided and check embedment lengths provided beyond the point where the bars are no longer required to resist flexure; i.e., check the Dimension labeled ① vs. ACI 12.1.1 and Dimension ② vs. ACI 12.10.3.

Dimension ① = 5.4 ft > ℓ_d = 2.42 ft, okay

Dimension ② = 1.7 ft > $12d_b$ = 12(0.75) = 9.0 in. = 0.75 ft, okay

Dimension ② = 1.7 ft > d = 5.87 in. = 0.49 ft, okay

Bottom Bars:

#6 bottom bars spaced at 11 in.

Concrete cover = 0.75 in. = 0.75/0.75 = $1.0d_b$
Spacing = 11 in. = 11/0.75 = $15d_b$

From Table 5-2(b) under "Uncoated Bars" and "Other Bars"; for "Case 1" and "Lap Class A":

ℓ_d = 29 in. = 2.42 ft

At the inflection point, ACI 12.11.3 requires checking,

$$\ell_d \le \frac{M_n}{V_u} + \ell_a \quad \text{. . . . . (ACI Eq. 12-5)}$$

Where $M_n = \frac{\phi M_n}{\phi} = \frac{11.91}{0.90}$ = 13.23 ft-kips/ft

$V_u = w_u\,(\ell_n/2 - 2.4) = 0.404(18/2 - 2.4)$ = 2.67 kips/ft

ℓ_a is the larger of $12d_b$ or d

$12d_b$ = 12(0.75) = 9 in.

d = 5.87 in.

Use $\ell_a = 12d_b$ = 9 in.

$$\frac{M_n}{V_u} + \ell_a = \frac{13.23(12)}{2.67} + 9 = 59.5 + 9 = 68.5 \text{ in.}$$

68.5 in. > ℓ_d = 29 in., okay

Check ℓ_d = 29 in. vs. embedment length provided, and check embedment lengths provided beyond the point where the bars are no longer required to resist flexure, i.e., check the Dimension labeled ③ vs. ACI 12.1.1, check the Dimensions labeled ④ and ⑤ vs. ACI 12.10.3, and check the Dimension labeled ⑥ vs. ACI 12.1.1.

Dimension ③ = 7.90 ft or 8.4 ft > ℓ_d = 2.42 ft, okay

Dimension ④ = 3.0 ft > $12d_b$ = 12(0.75) = 9 in. = 0.75 ft, okay

Dimension ④ = 3.0 ft > d = 5.87 in. = 0.49 ft, okay

Dimension ⑤ = 3.5 ft > $12d_b$ = 9 in. = 0.75 ft, okay

Dimension ⑤ = 3.5 ft > d = 5.87 in. = 0.49 ft, okay

Dimension ⑥ is the distance from the end of the bottom bars (#6 spaced at 22 in.) to the point on the factored moment diagram where ϕM_n of the #6 bars spaced at 22 in. = 6.15 ft-kips/ft = M_u.

MANUAL CALCULATION

Example 8. Interior Span— Derive the factored usable superimposed load tabulated for an 8-in. solid slab with minimum reinforcement on a 15-ft span.

From the table on Page 7-20 with minimum reinforcement, h = 8 in., and with #4 top bars spaced at 12 in. and #3 bottom bars spaced at 7 in., the factored usable superimposed load is 181 psf. Derive the load value of 181 psf.

Flexure

Compute the design positive moment strength based on the #3 bottom bars spaced at 7 in.:

$$\phi M_n = \phi A_s f_y\ (d - a/2)$$

Where A_s = 12/7(0.11) = 0.189 in.^{2}/ft for #3 bottom bars spaced at 7 in.

$$a = \frac{A_s f_y}{0.85 f_c' b} = \frac{0.189(60)}{0.85(4)(12)} = 0.28 \text{ in.}$$

$$d = h - \text{cover} - 0.5d_b$$

$$d = 8.0 - 0.75 - 0.19 = 7.06 \text{ in.}$$

$$\phi M_n = 0.90(0.189)(60)(7.06 - 0.28/2)/12 = 5.88 \text{ ft-kips/ft}$$

Equate $+M_u = \phi M_n$ where $+M_u = w_u \ell_n^2/16$

$$w_u(15)^2/16 = 5.88$$

$$w_u = 0.418 \text{ klf or } 418 \text{ psf}$$

Compute the design moment strength based on the #4 top bars spaced at 12 in.:

$$\phi M_n = \phi A_s f_y\ (d - a/2)$$

Where A_s = 12/12(0.20) = 0.20 in.^{2}/ft for #4 top bars spaced at 12 in.

$$a = \frac{A_s f_y}{0.85 f_c' b} = \frac{0.20(60)}{0.85(4)(12)} = 0.29 \text{ in.}$$

$$d = h - \text{cover} - 0.5d_b$$

$$d = 8.0 - 0.75 - 0.25 = 7.0 \text{ in.}$$

$$\phi M_n = 0.90(0.20)(60)(7.0 - 0.29/2)/12 = 6.17 \text{ ft-kips/ft}$$

Equate $-M_u = \phi M_n$ where $-M_u = w_u \ell_n^2/11$

$$w_u(15)^2/11 = 6.17$$

$$w_u = 0.301 \text{ klf or } 301 \text{ psf}$$

Negative ϕM_n governs flexural capacity; hence, w_u = 301 psf

Factored usable superimposed load = 301 – 1.2(100) = 181 psf (tabulated = 181, okay)

Recalculating $+M_u$:

$$+M_u = w_u \ell_n^2/16$$

$$= 0.301\ (15)^2/16$$

$$= 4.23 \text{ ft-kips/ft}$$

Shear

Compute the design shear strength based on ACI Eq. 11-3,

$$\phi V_c = 2\phi\sqrt{f_c'}\, b_w d$$

$$= 2(0.75)\sqrt{4{,}000}(12)(7)/1{,}000 = 7.97 \text{ kips/ft}$$

A factored usable superimposed load based on ACI Eq. 11-5 cannot be derived directly because the quantity $V_u d/M_u$ is dependent on the load.

Equate $V_u = \phi V_c$

Compute V_u at a distance d from the face of the support; at the support, maximum $V_u = w_u \ell_n/2$ (ACI 8.3.3):

$$V_u = w_u(\ell_n/2 - d\ )$$

$$w_u(15/2 - 7/12) = 7.97 \text{ k/ft}$$

$$w_u = 1.15 \text{ klf or } 1{,}150 \text{ psf}$$

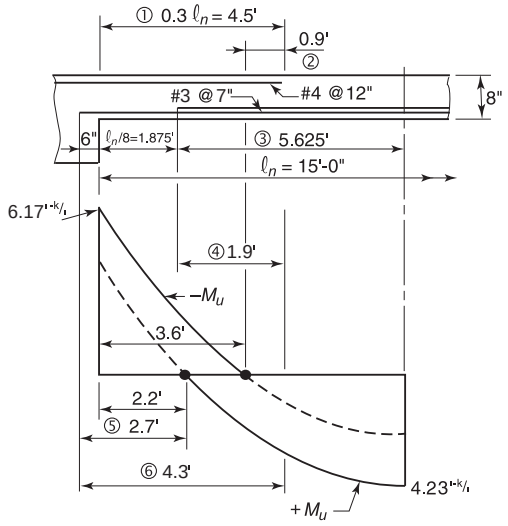
Flexural capacity governs; hence, the factored usable superimposed load = 181 psf

Tension Development

#4 top bars are spaced at 12 in.

Concrete cover = 0.75 in. = 0.75/0.5 = 1.5 d_b

Spacing = 12 in. = 12/0.5 = 24 d_b



From Table 5-2(b) under "Uncoated Bars" and "Other Bars"; for "Case 1" and "Lap Class A" (for h = 8 in., less than 12 in. of concrete will be cast below the #4 bars):

ℓ_d = 19 in. = 1.58 ft

Check ℓ_d = 19 in. vs. embedment length provided and check embedment lengths provided beyond the point where the bars are no longer required to resist flexure; i.e., check the Dimension labeled ① vs. ACI 12.1.1 and Dimension ② vs. ACI 12.10.3.

Dimension ① = 4.5 ft > ℓ_d = 1.58 ft, okay

Dimension ② = 0.9 ft > 12d_b = 12(0.5) = 6.0 in. = 0.5 ft, okay

Dimension ② = 0.9 ft > d = 7 in. = 0.58 ft, okay

#3 bottom bars spaced at 7 in.

From Table 5-2(b) under "Uncoated Bars" and "Other Bars"; for "Case 1" and "Lap Class A":

ℓ_d = 15 in. = 1.25 ft

At the inflection point, ACI 12.11.3 requires checking,

$$\ell_d \le \frac{M_n}{V_u} + \ell_a \quad \text{. . . . . (ACI Eq. 12-5)}$$

Where $M_n = \dfrac{\phi M_n}{\phi} = \dfrac{5.88}{0.90}$ = 6.53 ft-kips/ft

$V_u = w_u(\ell_n/2 - 2.2) = 0.301(15/2 - 2.2) = 1.59$ kips/ft

ℓ_a is the larger of 12 d_b or d

12d_b = 12(0.375) = 4.5 in.

d = 7 in.

Use ℓ_a = 7 in.

$$\frac{M_n}{V_u} + \ell_a = \frac{6.53(12)}{1.59} + 7 = 49.3 + 7 = 56.3 \text{ in.}$$

56.3 in. > ℓ_d = 15 in., okay

Check ℓ_d = 15 in. vs. embedment length provided, and check embedment lengths provided beyond the point where the bars are no longer required to resist flexure, i.e., check the Dimension labeled ③ vs. ACI 12.1.1, check the Dimensions labeled ④ and ⑤ vs. ACI 12.10.3, and check the Dimension labeled ⑥ vs. ACI 12.1.1.

Dimension ③ = 5.625 ft > ℓ_d = 1.25 ft, okay

Dimension ④ = 1.9 ft > 12 d_b = 12(0.375) = 4.5 in. = 0.4 ft, okay

Dimension ④ = 1.9 ft > d = 7 in. = 0.58 ft, okay

Dimension ⑤ = 2.7 ft > 12 d_b = 4.5 in. = 0.4 ft, okay

Dimension ⑤ = 2.7 ft > d = 7 in. = 0.58 ft, okay

Dimension ⑥ is the distance from the end of the bottom bars (#3 spaced at 14 in.) to the point on the factored moment diagram where ϕM_n of the #3 bars spaced at 14 in. = 2.96 ft-kips/ft = M_u.

Dimension ⑥ = 4.3 ft > ℓ_d = 1.25 ft, okay

CHAPTER 8 – ONE-WAY CONCRETE JOIST CONSTRUCTION

GENERAL CONSIDERATIONS

Description. Concrete joist construction is a method of construction consisting of a monolithic combination of regularly spaced joists (ribs) and a thin slab of concrete cast in place to form an integral unit with the supporting beams, columns, or walls. In *one-way concrete joist* construction, the joists are arranged in one direction between parallel supports. In the first part of this Chapter, the term "concrete joist construction" refers only to joists formed by removable standard size forms,* and limited to dimensions and proportions conforming to ACI 8.13. The limits in ACI 8.13 are: (1) maximum 30 in. clear spacing between ribs; (2) minimum width of rib = 1.0/3.5 times the depth of rib but not less than 4 in.; and (3) minimum slab thickness $^1/_{12}$ of clear distance between ribs but not less than 1½ in. Practical considerations for ease of placing reinforcing bars and vibrating concrete and tolerances in concrete cover usually make it desirable to use a minimum rib width of 5 in.

*Types and sizes listed in Chapter 10, "Recommended Industry Practice for Concrete Joist Construction", CRSI *Manual of Standard Practice*.

Wide-module joist construction is covered on Pages 8-90 through 8-168.

Standard Dimensions of Forms. Joist (rib) widths tabulated for design in this Chapter vary from 5 in. to 7 in. Standard forms for the pan spaces between ribs are 20-in. or 30-in. wide and 8, 10, 12, 14, 16, or 20 in. deep. Standard end forms consist of square end forms. Tapered end forms for the 20-in. width taper to 16-in. in a distance of three feet. The 30-in. wide tapered end form tapers to 25 in. in three feet. See Fig. 8-1. Note that the structural integrity requirements of ACI 7.13 are not included in the reinforcement details shown in Fig. 8-1.

Basic Features of Joist Construction. In general, joist construction was developed to save dead weight and reinforcement. As desired spans increase, the utility of solid slab construction is rapidly offset by the increase in dead load of the slab itself. Joist construction enables the designer to provide the depth required for adequate stiffness and efficient utilization of the reinforcement without excessively high dead load-live load ratios. Standard size re-usable forms make it pos-

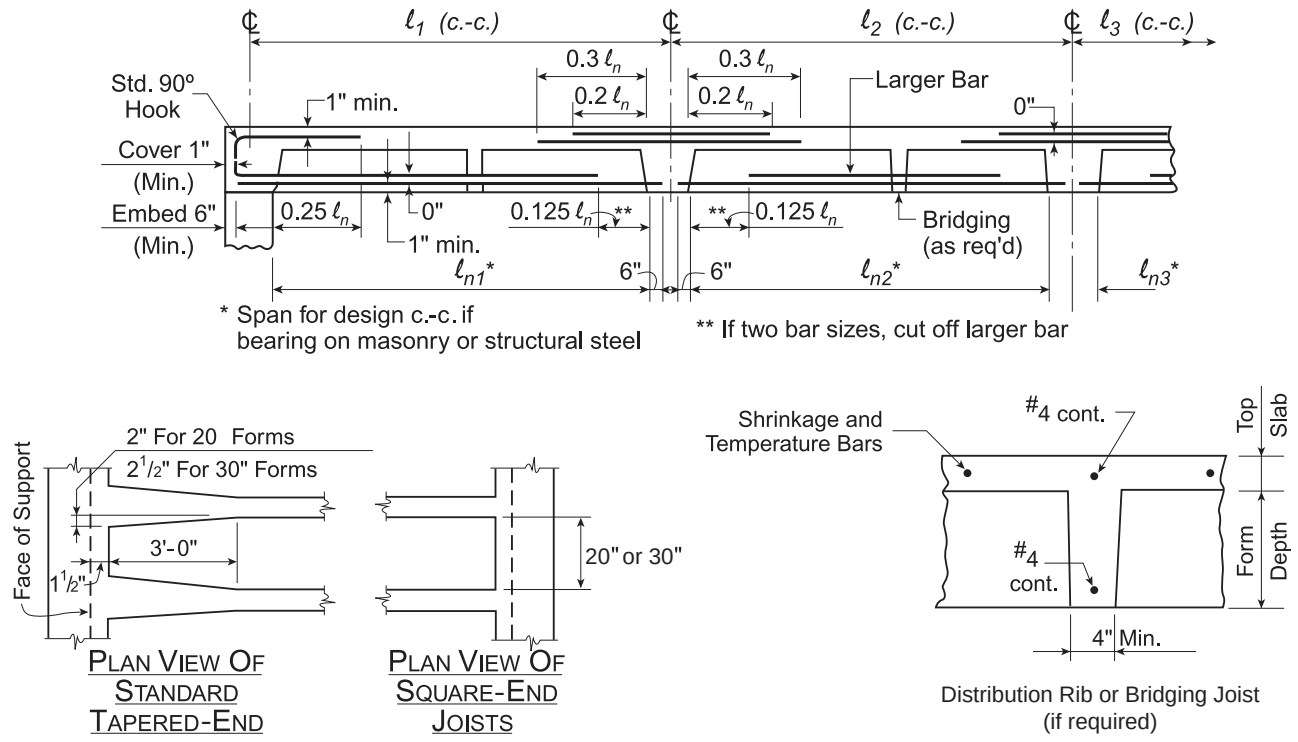

Figure 8-1 Recommended Bar Details – Multiple Spans

sible to reasonably optimize and eliminate unnecessary dead weight for overall economy. Longer spans or relatively heavy loads can be accommodated by using special tapered-end forms which permit widening of the ribs in areas of high shear. Special architectural ceiling effects may be achieved by leaving the rib patterns exposed or by integrating acoustic material and lighting fixtures with the rib patterns. Additional stiffness on column lines or under partitions in the direction of the joists is easily provided by an increased spacing of the standard forms leaving wider ribs at these points. Where openings are required under such partitions for piping or conduits, the use of two joist ribs with a special half-width filler form will provide the additional stiffness for the partition and a thin slab in the area of required openings.

Joist-Band System. Many span combinations can be designed for uniform depth construction by supporting the joists on wide "band-beams." Instead of selecting joist depth and supporting beam sizes separately to achieve minor reductions in material, the modern design for maximum overall economy is to make both joist system and framing beams the same depth. The usual procedure is to select a standard joist depth suitable for the beams as well, even if the joist is deeper than required for the joist design. Often, deflection limits for the beam can be satisfied by orienting the system so that beams span in the shorter direction. Alternatively, for live loads less than 100 psf, the live load reductions permitted in many adopted building codes for beams can often be applied for maximum economy in reinforcement to beams oriented in the long direction, when such reductions are not applicable to design of the joists.

Preliminary dimensions and flexural reinforcement required for wide band-beams, where factored shear is resisted by concrete, can be selected quickly from the joist load tables. See "Design From Load Tables" sections.

Separate beam forms are eliminated in one-way joist construction. The same deck forms the joist and beam soffit; ends of removable forms are used to form beam sides; and width of the beam can be adjusted for the occasional irregular spans. Overall building heights are reduced while maintaining the same clear ceiling height at a uniform depth. The simplified formwork, faster construction, level ceiling with no obstructing beams to complicate piping, conduit or ductwork, and reduced height of walls, columns and vertical services — all make for net overall economy in the complete building.

DESIGN CONSIDERATIONS FOR JOIST CONSTRUCTION

Economy. Maximum overall economy in joist construction, as in any reinforced concrete design, is achieved only by considering the relatively high costs of formwork and construction time versus material costs. Almost invariably overall economy is achieved by maximum re-use of the same forms throughout a project, not only throughout each floor, but also the same layout and size of forms for all floors and the roof. The use of special filler forms to match rib spacing module to column spacing can often be avoided by use of one wider joist at the edge or on column lines. Use of square-end joists (non-tapered) simplifies forming. Tapered-end load strength increases have been shown in load tables. Load strengths controlled by design shear strength are indicated by an asterisk. When the asterisk appears after the load strength for square-end joists (first line) and not on the load strength for tapered-end joists (second line), the tapered-end is required to develop the full design strength of the reinforcement.

For a continuous floor system with many identical spans, it will usually be advantageous to select a uniform design depth adequate for all interior spans with square ends and to utilize tapered ends to increase shear capacity in end spans only. For a continuous three-bay floor system with two end spans and only one interior span, select a uniform depth adequate with square-end joists in end spans is recommended.

Shrinkage and Temperature Reinforcement. Shrinkage and temperature reinforcement in the concrete top slab over forms and in a direction normal to the span of the joists should be of reinforcing bars or welded wire reinforcement at least equal in area to the values in the following table and increased where necessary for flexure in the slab, giving due consideration to concentrated loads:

Top Slab Thickness	Bars	Welded Wire Reinforcement**
3"	#3@15*	12 x 12 – W6.5 x W6.5
3½"	#3@17	12 x 12 – W7.6 x W7.6
4"	#3@15	12 x 12 – W8.6 x W8.6
4½"	#3@12	12 x 12 – W9.7 x W9.7
5"	#3@12	12 x 12 – W10.8 x W10.8

Reinforcement based on f_y = 60,000 psi.
* Maximum spacing permitted by ACI 7.12.2.2 (5 times slab thickness ≤ 18 in.).
** Commonly available styles.

Distribution Ribs or Bridging Joists. Load distribution ribs are ribs normal to direction of span. As the name implies, load distribution ribs are provided to equalize joist deflection and thus ensure that the effect of concentrated or unequal loads is resisted by a number of joists.* Load distribution ribs are often omitted for roofs designed for uniform load only. For floor construction, use distribution ribs at least 4 in. wide, reinforced with at least one #4 bar continuous in both top and bottom, and spaced as follows:

- None in spans less than 20 feet,
- One near the center of spans from 20 to 30 feet, and
- Two near the third points of spans over 30 feet

Openings. One of the inherent advantages of joist construction is that single openings can be located through the thin slab between ribs without significant loss of structural strength to the system. Larger openings which interrupt one or more joists must be provided with header joists normal to the interrupted joists to distribute the load to adjacent full-length joists. Joists adjacent to such openings will require additional reinforcement, or increased width, or both. Very large openings should be framed by supporting beams.

Control of Deflections. The ACI Building Code requires that computed deflection be limited (ACI 9.5.1). A method of computing deflections and limits for various loading conditions are prescribed (ACI 9.5.2). See "Manual Example" sections for a general explanation.

Under the prescribed method of computation for deflection, computed deflection is a function of continuity, concrete modulus of elasticity, and effective moment of inertia, in addition to load and span. Deflection coefficients are taken as 5/384, 3.25/384, and 2/384, respectively, for single, end, and interior spans for one-way joists designed with the approximate moment coefficients (ACI 8.3.3). The load strengths tabulated in this Chapter are for joists of normal-weight concrete (w = 150 pcf) and f'_c = 4,000 psi, for which $E_c = 3.6 \times 10^6$ psi (ACI 8.5.1). The effective moment of inertia, I_e, is a function of the ratio of the cracking moment, M_{cr}, to the actual maximum moment, M_a, as well as the ratio of the cracked to gross section moment of inertia.

Since M_a is a function of the service load causing the deflection, a direct solution is not feasible for the load limited by deflection as under previous ACI Codes. Tabulations of loads limited by a given deflection limit or elastic deflections resulting from the loads limited by strength design are not very useful, since deflection increments are not proportional to load increments but to the total previous load, plus the load increment.

To comply with the Code requirements for deflection conservatively without tedious iterative trial and error calculations, all joist load capacities tabulated in this Chapter have been investigated for deflection. Load strengths designated by a plus sign will cause a computed elastic live load(1) deflection equal to $\ell/480$ for multiple span joists and $\ell/360$ for single span joists. All other load strengths are controlled by strength in shear (marked *) or flexure (unmarked). The haunch effect for tapered ends has conservatively been neglected for deflection computations. Also, the value M_a has been taken conservatively as the maximum applied moment for an upper bound deflection solution in the computer program, since the maximum cracking in some cases will have occurred before the load pattern for maximum deflection occurs.

Long-Term Deflections. For loading conditions where much of the superimposed service load is added "dead load" or relatively long-term live load, it may be necessary to compute long-term deflection or to estimate deflection due to partial loads to establish required camber or clearance to other connected elements. For these purposes, the following design aids will provide all of the required data, except M_a for which the actual service load must be known:

a. Table 8-1 "Gross Section Properties."
b. Load strength table with "Properties for Design" table at bottom.
c. Code Equation (9-8) relating M_{cr}/M_a and I_{cr}/I_g to solution for I_e:
$$I_e = (M_{cr}/M_a)^3 I_g + [1 - (M_{cr}/M_a)^3] I_{cr}$$
d. Deflection coefficients for each span and continuity conditions in the load tables.

To determine the elastic deflection for a given service (actual) load, w_a, the five-step procedure is:

Step 1. Calculate M_a. (= $\frac{1}{8} w_a \ell^2$ for single spans; = $\frac{1}{11} w_a \ell^2$ for end spans; = $\frac{1}{16} w_a \ell^2$ for interior spans). Use actual service load for w_a.

Step 2. Read M_{cr} in Table 8-1. (Positive value only for single span; both positive and negative for continuous spans). Compute M_{cr}/M_a value or values.

* "Effective Width of One-Way Monolithic Joist Construction as a Two-Way System", Structural Bulletin No. 8, Concrete Reinforcing Steel Institute, 1983.

(1) "Live load" is actual service load (which is equal to the superimposed factored load divided by the load factor for live load, i.e., 1.6).

Step 3. Read I_{cr}/I_g under load strength table. (Positive for single spans; positive and negative for continuous spans.)

Step 4. Use Code Eq. 9-8 with values of M_{cr}/M_a, and I_{cr}/I_g and calculate values of I_e/I_g. (Positive only for single spans; positive and negative for continuous spans.) Compute average I_e (continuous spans only).

Step 5. Read "Deflection Coefficient" from load table. Compute deflection, Δ:

$$\Delta = (\text{Defl. Coeff.}) \frac{w_a}{I_e}$$

It will always be conservative to use this value for elastic deflection with the multiplier factors for long-term deflection given in ACI 9.5.2.5.

Crack Control. ACI 10.6 limits the spacing of flexural reinforcement in tension zones to control cracking. The maximum spacing of reinforcing bars, s, is limited to the smaller value calculated by:

$$s = 15\left(\frac{40}{f_s}\right) - 2.5c_c \text{ or } s = 12\ (40/f_s)$$

Where:

f_s = calculated flexural tensile stress in reinforcement at service loads, ksi. The value of f_s can be taken as $(2/3)\,f_y$.

c_c = clear concrete cover, in. (distance or dimension from nearest concrete surface in tension to the surface of the flexural tension reinforcement).

In this Chapter, two locations for maximum spacing are investigated: the approximation of the longer bottom bar tensile stress at the point in which the shorter bar starts (at 0.2 ℓ_n from the face of the support), and for the top bars at the center of the interior support.

Unequal Continuous Spans. Bending moments are computed from the clear span for factored positive moment in continuous spans and from the average of the two adjacent clear spans for factored negative moment. The limitations are that the larger of two adjacent spans does not exceed the shorter by more than 20 percent and that the unit live load (unfactored) does not exceed three times the unit dead load (unfactored). See ACI 8.3.3.

The values tabulated under End Spans apply accurately only when there are two additional approximately equal spans continuous with the one under consideration. If there is only one adjacent span, the factored negative moment should be $w_u\ell_n^2/9$ instead of $w_u\ell_n^2/10$, and load values should be reduced accordingly. Load values obtained from factored positive moment would not change.

The load strengths tabulated under Interior Spans apply accurately only when there are two additional approximately equal spans continuous with each end of the span under consideration. If either end is continuous with an end span, the factored negative moment should be $w_u\ell_n^2/10$ instead of $w_u\ell_n^2/11$ and the top reinforcement tabulated for End Spans should be used. Load values obtained from factored positive moment would not change.

TABULATED DESIGNS

Scope. Since the tables for standard joist construction cover many pages, a general outline of the table arrangement will be helpful. The tables are divided into two main sets: (1) multiple spans, and (2) single spans. Recommended requirements and an illustrative example for each set are shown. Each set is subdivided into two parts, the first for 20-in. wide forms and the second for 30-in. wide forms. Within each such set, the tables are divided by depth of form and thickness of top slab.

Load Strengths Tabulated. These tables are based upon the strength design method. These tables give the usable superimposed factored load strength in pounds per square foot of floor (psf). If the floor system is a part of the primary lateral force resisting structure, alternate combinations of factored loads including lateral force moments must also be considered. Capacities have been reduced by the applicable strength-reduction, ϕ-factors, and 1.2 times the dead weight of the joist construction itself has been deducted. Material strengths are f'_c = 4,000 and f_y = 60,000 psi. The practicable range of widths, depths, spacings, spans and joists, and combinations of reinforcing bars are shown. Strengths are computed as the least of those determined by design moment strength (positive or negative bending), design shear strength, development of reinforcement, or deflection.

The effects of superimposed dead loads (other than the weight of the joist construction itself) and of live loads augmented by the proper loads factors are combined: $w_u = 1.2D + 1.6L$. The total superimposed factored load is then compared with the tabulated capacities.

The appropriate empirical bending moment coefficients (ACI 8.3.3) are used; in the case of end spans, the factored positive moment is taken as $w_u\ell_n^2/11$, i.e., without restraint at the outer end.

Live Load Limitations. ACI 8.3.3 establishes moment and shear coefficients for cases where the unit live load (unfactored) does not exceed three times the unit dead load (unfactored). The tabulated designs are based upon these coefficients.

Since the dead load in such analyses includes not only the weight of the concrete slab but also any ceilings, floor finishes, partitions and similar immovable features, it is impossible to predetermine when the ratio of live load to dead load will exceed three. The user is cautioned to check the ratio of live to dead loads in the higher strengths. If the ratio is greater, the effect of unbalanced panel loads may require more accurate analysis and appropriate adjustments made in bar areas and cut-off points.

The tabulated designs in this Chapter apply for the particular conditions described. For final designs, the numerous variables in loads, stiffness, continuity and in the quality of materials have to be considered.

Details of Reinforcement. The arrangement of reinforcing bars, bar supports, the bar spacing, and the embedment of bars conform generally to the *ACI Detailing Manual*. Typical details recommended are shown in Figs. 8-1 and 8-2.

Basis of Load Tables. These tabulated designs were developed by a computer program. The program is based on the following procedures, assumptions, and Code provisions.

Factored moment coefficients from ACI 8.3.3:

End span factored positive moment = $w_u\ell_n^2/11$

End span factored negative moment = $w_u\ell_n^2/10$ at continuous end

End span "free end" factored negative moment = $w_u\ell_n^2/33$ (allow $^1/_3$ factored positive moment)

Interior span factored positive moment = $w_u\ell_n^2/16$

Interior span factored negative moment = $w_u\ell_n^2/11$

Single span factored positive moment = $w_u\ell'_n{}^2/8$ where ℓ' = clear span plus 4 in.

Single span "free end" factored negative moment = $w_u\ell'_n{}^2/24$ (allow $^1/_3$ factored positive moment)

Design moment strength was determined in accordance with the strength design method. See Chapter 5. The effect of compression reinforcement has been neglected. Compression reinforcement should be considered, however, if undertaking a computation of long-term deflection for camber or fitting to other attached elements. Critical sections investigated for minimum strength are (1) positive moment at midspan, (2) negative moment at face of support including average width of tapered end if used, (3) shear and moment at and development lengths from bar cut-off points and inflection points, (4) shear at a distance d from the face of the support with average width of square or tapered end, and (5) shear at root of taper where used.

Top Reinforcement. Combinations of two bottom reinforcing bars tabulated begin at the smaller of $\rho = \frac{3\sqrt{f'_c}}{f_y}$; $\rho = \frac{200}{f_y}$; or $\frac{4}{3}$ times the required tension reinforcement (ACI 10.5.1) where ρ, the tension reinforcement ratio, is based on a rectangular concrete area,

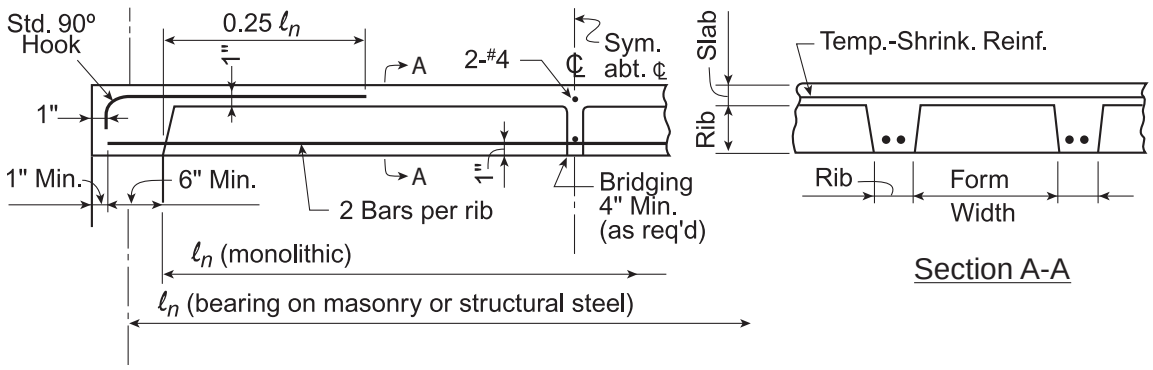

Figure 8-2 Recommended Bar Details – Single Span

bd, plus the two triangular areas inside the sloping form sides. The maximum size for bottom bars in the tabulated designs was determined as the least allowed for (1) maximum reinforcement such that $\varepsilon_t \geq 0.005$ so that the cross section is tension-controlled and therefore $\phi = 0.90$, (2) minimum bar spacing and concrete cover prescribed (ACI 7.6 and 7.7.1, respectively), or (3) load strength for flexure less than for shear with tapered end.

The areas of the two bottom bars control the joist capacity when load strength is controlled by flexure, since the strength established by the bottom bars is used to select top bars. The area of top steel tabulated is as near the theoretical area required as possible, for minimum number of bars, limited by the available choice of bar sizes and spacings in 0.5-in. increments. The computer program selects the largest size bar, with maximum spacings, not to exceed 107 percent of the theoretical area required.

Where tabulated areas of top steel for adjoining spans are unequal, the larger area of top steel as tabulated will be satisfactory, since the Code provides for calculating the factored moment on the basis of the average of adjacent spans (ACI 8.3.3). No redistribution of factored negative moment is permitted for adjustment of tabulated top bar areas (ACI 8.4).

Shear. Factored shear is calculated assuming full uniform load (no partial span loads) as $w_u \ell_n/2$ at all supports except the first interior support for continuous end span joists which is taken as 1.15 $w_u \ell_n/2$ (ACI 8.3.3).

Critical sections at which design shear strength is investigated are (1) distance, *d*, from face of support for interior supports (2) distance, *d*, from center of bearing for free ends (3) at the root of the taper, if used, (4) at bar cut-off points where tension steel ratio, ρ, is minimum. Design shear strength is computed by both prescribed formulas (ACI 11.2.1 and 11.2.2) and the maximum value was used. For standard joists, V_c is permitted to be 10 percent more than that specified in Chapter 11 of the ACI 318 Building Code (ACI 8.13.8). For tapered ends, factored shear was computed at sections three inches apart, beginning at *d* from the center of bearing to midspan. It was determined that critical sections for a full uniform load condition are at the root of the taper in spite of the variable design shear strength as reinforcement ratio changes with variable width.

Development of Reinforcement. Development of reinforcement is investigated, including end anchorage for tabulated bars cut off as shown in recommended bar details, Figs. 8-1 and 8-2. Substitution of equivalent areas of smaller top bars is conservative and requires no further computation of development. Bar sizes are selected so that development would satisfy Code requirements (ACI 12.10, 12.11, and 12.12) and, therefore, not limit the load strength as determined by flexure, shear, or deflection. See Fig. 8-10.

To understand how to extend the scope of the tabulated designs or to adapt same to non-typical conditions, a manual example is included preceding each of the sets of load tables.

DESIGN FROM LOAD TABLES (MULTIPLE SPAN JOIST CONSTRUCTION)

Example 1. Using 30-in. wide forms, select a joist floor design and review calculations to support a service live load equal to 65 psf and an allowance for superimposed service dead loads of 20 psf for partitions, 3 psf for bridging, and 12 psf for ceiling and mechanical loads on clear spans of 27 feet. A 3-in. thick top slab will satisfy the adopted building code for fire and use requirements. See Fig. 8-3 for layout.

Try: 12 + 3 with 6-in. ribs at 36 in. (Page 8-29) using standard square-end joists.

Superimposed factored load = (1.2)(20+3+12)+(1.6)(65)
= 42 + 104
= 146 psf

Read from table:

End span: Tabulated capacity = 147 psf
Top bars #4 at 8" at first interior support

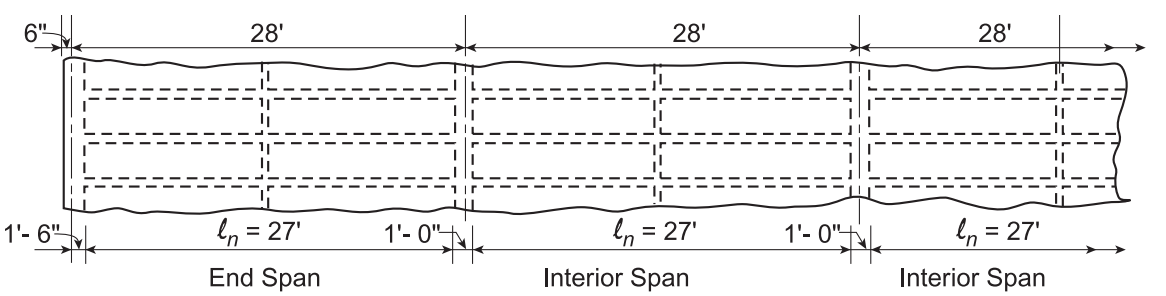

Figure 8-3 Multiple Span Layout – Example 1

Bottom bars 1-#5 and 1-#6 (per rib)
Weight of bars = 1.04 psf for above bars only.

See "Recommended Details," Fig. 8-1. Top bars at exterior edge, $A_s \approx {}^1/_3(0.31 + 0.44)$ in 36 in. $= \frac{0.75}{9} = 0.083$ in.^{2}/ft. Use # 4 at 12" with standard 90° end hooks.

Interior spans: Tabulated capacity = 147 psf
Top bars #4 at 9"
Bottom bars 1-#4 and 1-#5 (per rib)
Weight of bars = 0.93 psf. Add for shrinkage and temperature reinforcement, if required.

Concrete quantity (from Table 8-1, normal-weight concrete) = 67 psf

Including bridging (3 psf) $= \left(\frac{67+3}{150}\right)(144) = 0.67$ c.f./s.f.

Load capacities limited by deflection of $\ell_n/480$ are marked with double asterisks in the tabulated designs. The load strength for the design selected is not limited by deflection, and so the upper limit on the immediate live load deflection will be

$$\left(\frac{65}{146/1.6}\right)\left(\frac{\ell_n}{480}\right) = \ell_n/674 \text{ or less.}$$

This calculation is sufficient to satisfy the Code requirement (ACI 9.5.2.1) that deflection be computed for ℓ_n/h ratios above 18.5 for end spans and 21 for interior spans (values below horizontal lines in table exceed these limits). The estimated deflection above would be considered satisfactory without further calculations for all floors and roofs "not supporting or attached to non-structural elements likely to be damaged by large deflections." (ACI 9.5, Table 9.5(a)).

Example 2. *Unequal spans within limitations of table.* For the same loads as in Example 1, select a joist floor design for alternate clear spans: 22.5 ft., 27 ft., 22.5 ft., etc. Note that this variation in span is the maximum permitted without analysis to adjust the coefficients (ACI 8.3.3); the longer span exceeds shorter span 20 percent. See Fig. 8-4.

Try: 12 + 3 with 6-in. ribs at 36 in., using standard square-end joists as in Example 1, Superimposed factored load = 146 psf. See Page 8-29.

End span. Interpolate in second column between strengths 135 and 155 psf for spans of 22 and 25 feet, respectively.

Strength $= \frac{1}{2}(135 + 155) = 145$ psf, O.K.

Read Top bars: #4 at 11" at exterior span first interior support
Bottom bars: 1- #4 and 1- #5 (per rib)
Weight (of these bars) = 0.71 psf

For top bars at exterior edge, $A_s \approx 1/3\ (0.20 + 0.31)$ in 36 in. = 0.06 in.^{2}/ft. Use #3 at 12" with standard 90° end hooks. (CRSI recommends a minimum of #4 at 12" where cross traffic on top bars is expected, but at the exterior edge such traffic can be avoided.)

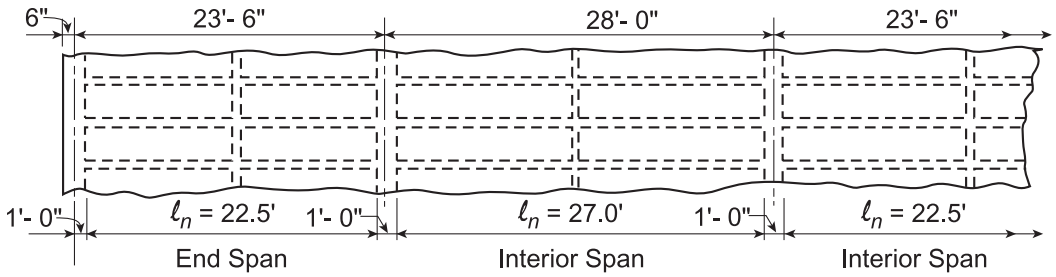

Figure 8-4 Multiple Span Layout – Example 2

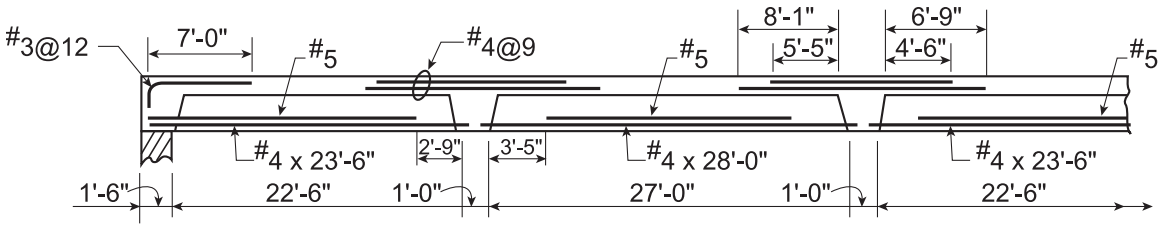

Figure 8-5 Bar Length Details – Example 2

Interior span. For tabulated capacity = 147 psf

(Check whether top bar design for interior or exterior span controls.)

Top bars #4 at 9" > #4 at 12". Use at *all* interior supports.

Bottom bars: 1- #4 and 1- #5 (per rib)

Weight (of these bars) = 0.93 psf

Concrete quantity (Table 8-1) = 67 psf for normal-weight concrete, including bridging:

$$\frac{(67+3)}{150}(144) = 0.67 \text{ c.f./s.f.}$$

Immediate deflection is less than $\ell_n/480$ for full superimposed load. Approximate live load deflection: $\Delta_{LL} \approx \ell_n/674$ as in Example 1.

Bar lengths. See Fig. 8-5 for details.

Example 3. Unequal loads within the limitation of $L \leq 3D$. For the layout in Fig. 8-3, Example 1, provide for a service live load = 100 psf in the first interior span and service live load in other spans = 50 psf. Dead load in all spans will be as in Example 1. Use the same joist sizes.

End span (same as Example 1):

Top bars, exterior edge #4 at 12

Bottom bars per rib 1- #5 plus 1- #6

Top bars, first interior support #4 at 8"; but check requirements of first interior span and use the larger.

1st Interior Span.

Superimposed factored load

$$= (1.2)(20+3+12)+(1.6)(100)$$
$$= 42 + 160$$
$$= 202 \text{ psf}$$

Read from table.

Superimposed load capacity = 199 * Square end

= 251 Tapered end

Bottom bars per rib 1- #5 plus 1- #6

For top bars, linearly interpolate for w_u = 202, between 251 for #5 at 9″ and 195 for #4 at 7″.

Top bars: Use #5 at 10½″ (spacing to nearest ½ in.)

Other Interior Spans – Same as Example 1

Bar length details. See Fig. 8-6.

Example 4. *Wide flat beams*. Assume the interior beams supporting the joist floor of Example 1 (see Fig. 8-3) have clear spans of 20 ft. Select a preliminary design for these beams to maintain a uniform depth for simple formwork.

From Example 1:

Service live load, L = 65 psf

Superimposed service dead load = 35 psf

Joist dead load = 67 psi

Total service dead load, D = 102 psf

Total superimposed factored load on interior beams,

$w_u = 1.2D + 1.6L$

$(28)[(1.2)(102) + (1.6)(65)]/1000 = 6.34$ klf

To estimate how wide the beams supporting the joist floor has to be, use the joist tabulated design for square ends. In the load table, Page 8-29, read the maximum superimposed load (controlled by shear on a square end) for an interior span of 20 ft = 322* psf. Load per linear foot = (3)(0.322) = 0.97 klf.

Ratio of effective beam depth to joist depth with 1 in. concrete cover for joists and 2 in. cover for beams = $\frac{12.5}{13.5}$

Ratio of allowable joist shear to beam shear = 1.10.

Required width of beam without stirrups,

$$b = \left(\frac{6.34}{1.10}\right)(6)\left(\frac{13.5}{12.5}\right)(1.10) = 41 \text{ in.}$$

Read in tabulated design, maximum superimposed load controlled by flexure for interior span joist with span = 20 ft, w_u = 247 psf.

Total load per linear ft = (3)[247 +(67)(1.2)] = 3(247 + 80)

Total load = (0.327)(3) = 0.98 klf

Required area of steel in joist system at d = 13.5 in.:

Top bars #4 at 11", $A_s = \left(\frac{36}{11}\right)(0.20) = 0.65$ in.^{2}

Bottom bars 2- #4, A_s = 0.40 in.^{2}

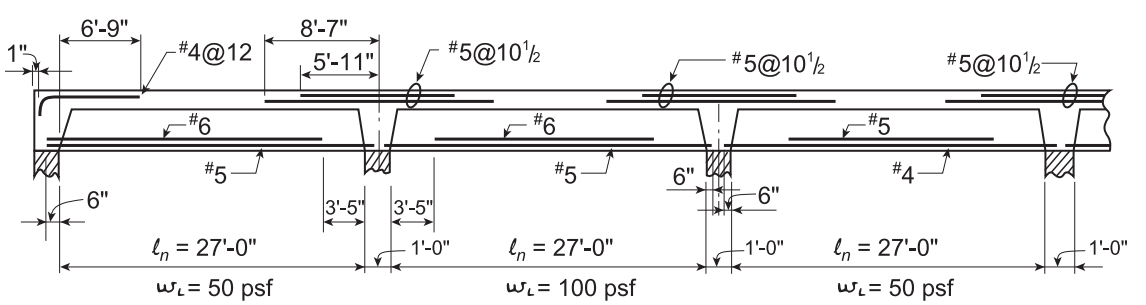

Figure 8-6 Bar Length Details – Example 3

Required beam reinforcement for d = 12.5 in.:

Beam, A_s = (Joist, A_s)$\left(\frac{6.34}{0.98}\right)\left(\frac{13.5}{12.5}\right)$ = 6.99 (Joist, A_s)

Top steel: A_s = (6.99) (0.65) = 4.54 in.^{2}
Use 6-#8 bars (A_s = 4.74 in.^{2})

Bottom steel: A_s = (6.99)(0.40) = 2.80 in.^{2}
Use 5-#7 bars (A_s = 3.00 in.^{2})

Note: To complete this preliminary design for interior spans, dead load of the solid beam area, reduced clear span for the joist design, possible live load reductions for the beam usually permitted for live loads equal to or less than 100 psf, and provision of nominal stirrups which will also support top beam bars (say #3 at 12") are possible refinements. See Chapter 12 for such examples.

MANUAL EXAMPLE

To extend designs beyond the scope of the tabulated designs and to know how the tabulated designs are computed, detailed computations are presented as a review for the design of the interior span used in Example 1.

Review

See Fig. 8-7

Joist $\left(\frac{192}{144}\right)(150)\left(\frac{12}{36}\right)$	=	67 psf
Bridging	=	3 psf
Partitions	=	20 psf
Ceiling and mechanical	=	12 psf
	D =	102 psf
	L =	65 psf

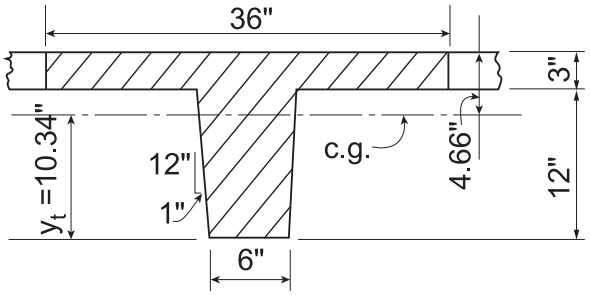

Figure 8-7 Gross Section – Example 1

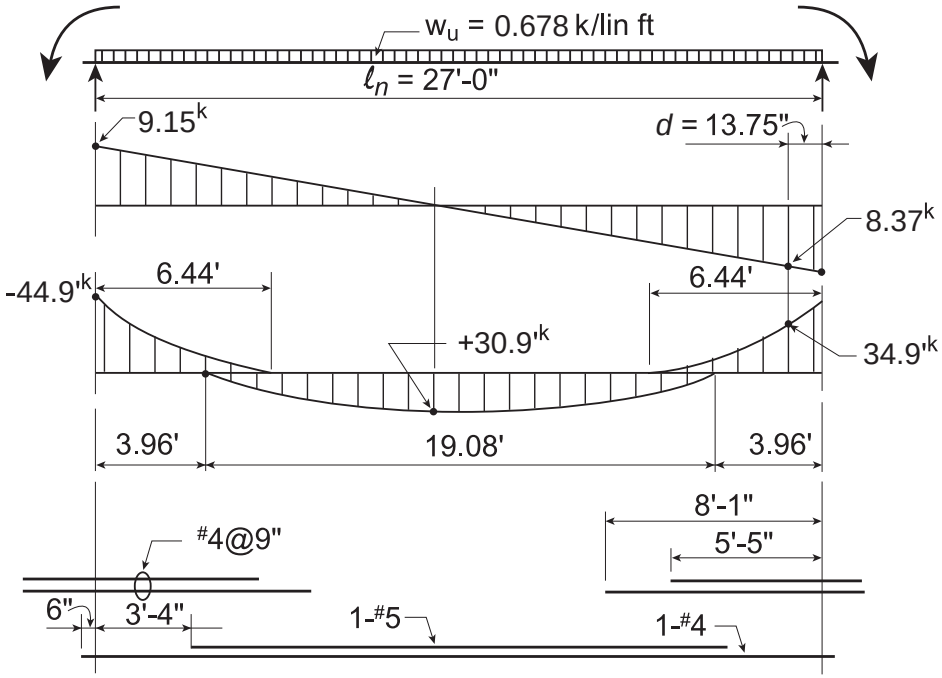

Figure 8-8 Strength Design – Example 1

Interior Span – See Fig. 8-8

$w_D + w_L = w_u = 1.2D + 1.6L = [(1.2)(0.102) + 1.6(0.065)]\frac{36}{12}$
$= (0.122 + 0.104)(3)$

$w_u = 0.678$ k/ft

Factored shear = 1/2 $w_u \ell_n = \frac{1}{2}(0.678)(27) = 9.15$ kips

Flexure

$-M_u = \frac{w_u \ell_n^2}{11} = (0.678)(27)^2/11 = -44.9$ ft-kips

$+M_u = \frac{w_u \ell_n^2}{16} = (0.678)(27)^2/16 = +30.9$ ft-kips

Required $A_s = \frac{M_u}{f_y(d - a/2)}$

$a = \frac{A_s f_y}{0.85 f_c' b} = \frac{60}{3.4}\frac{A_s}{b} = 17.65\frac{A_s}{b}$

Try 1-#4 and 1-#5: $A_s = 0.51$ in^2.

$+\phi M_n$: $a = (17.65)\frac{(0.51)}{36} = 0.25$ in.

$c = a/\beta_1 = 0.25/0.85 = 0.29$ in.

$d = 15 - 1 - 0.625/2 = 13.69$ in.

$\varepsilon_t = 0.003\,(d/c - 1)$
$= 0.003\,(13.69/0.29 - 1) = 0.139$

$\varepsilon_t > 0.005$, so $\phi = 0.90$

Try #4@ 9″

$-\phi M_n$: $a = (17.65)\frac{(0.20)(12/9)(3)}{(6.19)} = 2.28$ in.

$c = 2.28/0.85 = 2.68$ in.

$d = 15 - 1 - 0.500/2 = 13.75$ in.

$\varepsilon_t = 0.003\,(13.75/2.68 - 1) = 0.012$

$\varepsilon_t > 0.005$, so $\phi = 0.90$

Design moment strength, ϕM_n, provided:

$\phi M_n = \phi A_s f_y (d - a/2)$

$+\phi M_n = (0.90)(0.51)(60)\left(13.69 - \frac{0.25}{2}\right)\frac{1}{12}$
$= +31.1$ ft-kips $> +M_u = 30.9$ ft-kips

$-\phi M_n = (0.90)(0.80)(60)\left(13.75 - \frac{2.28}{2}\right)\frac{1}{12}$
$= -45.4$ ft-kips $> -M_u = -44.9$ ft-kips

Note that the flexural strength is controlled by the two bottom bars per rib. Top bars are spaced to the nearest 0.5 in. to match the flexural strength predetermined by the bottom bar selection.

Shear. Factored shear, V_u, at distance d from support. See Fig. 8-8.

$V_u = 9.15 - (0.678)\left(\frac{13.75}{12}\right) = 8.37$ kips

Design shear strength ("short" formula)

$b_w = \left[\frac{8.29 + 6.0}{2}\right] = 7.14$ in.

$\phi V_c = (1.10)\,\phi\, 2\sqrt{f_c'}\, b_w d$
$= (1.10)(0.75)(2)\sqrt{4{,}000}\,(7.14)(13.75)/1{,}000$
$= 10.25$ kips > 8.37 kips, Okay.

Design shear strength was also computed by the "long" formula, compared to that by the short formula, and the larger value used as a basis for superimposed load capacities marked by one asterisk. In this case, the short formula gave the larger value. Long formula:

$\phi V_c = (1.10)\phi\left[1.9\sqrt{f_c'} + 2{,}500\,\rho_w\,\frac{V_u d}{M_u}\right] b_w d$

$A_s = 0.20\,(12/9)(3) = 0.80$ in^2.

$\rho_w = \frac{0.80}{(7.14)(13.75)} = 0.00815$

$\frac{V_u d}{M_u} = \frac{(8.37)(13.75)}{(34.9)(12)} = 0.275$

$\phi V_c = (1.10)(0.75)[1.9\sqrt{4{,}000} + (2{,}500)(0.00815)(0.275)]$
$(7.14)(13.75)/1{,}000$
$= 10.19$ kips < 10.25 kips by short formula

Development of reinforcement. See Fig. 8-10.

Bottom bars

#4; concrete cover = 1″ or $2d_b$
c.-c. spacing to #5 = 3.65″ or $7.3d_b$

#5; concrete cover = 1″ or $1.6d_b$
c.-c. spacing to #4 = 3.65″ or $5.8d_b$

Top bars #4 @ 9″
concrete cover = 1″ or $2d_b$
c.-c. spacing = 9″ or $18d_b$

Chapter 5; Table 5-3(b):

Bar Location	ℓ_d
#4 Bottom	12″ = 1′
#5 Bottom	17″ = 1.42′
#4 Top	15″ = 1.25′

Embedment from point of maximum tension to cut-off (ACI 12.1; 12.12.2):

Dimension ① = 5.40′ > ℓ_d = 1.25′ for shorter top bars

Dimension ② = 5.53′ > ℓ_d = 1.25′ for longer top bars

Dimension ③ = 10.12′ > ℓ_d = 1.42′ for shorter (#5) bottom bars

Extension of cut-off the greater of $12d_b$ or d beyond zero theoretical stress (ACI 12.10.3) or $\ell_n/16$ (ACI 12.12.3):

d for top bars $= \frac{13.75}{12} = 1.14$ ft

#4 bar: $12d_b = 6$ in.

$\ell_n/16 = 27/16 = 1.69$ ft

d for bottom bars $= \frac{13.69}{12} = 1.14$ ft

#5 bar: $12d_b = 7½$ in.

Dimension ④ $= 1.66' \approx 1.69'$ for longer top bar (#4)
Dimension ⑤ $= 2.83' > 1.14'$ for shorter top bar (#4)
Dimension ⑥ $= 2.71' > 1.14'$ for shorter bottom bar (# 5)
Dimension ⑦ $= 4.46' > 1.14'$ for longer bottom bar (#4)
Embedment of continuing bars, ℓ_d, beyond the point of zero theoretical stress in cut-off bars not less than ℓ_d (ACI 12.10.4):
Dimension ⑧ $= 6.59' > \ell_d = 1.0'$ for # 4 bottom bar

The shorter top bars are cut off in a tension zone, which is permissible if at the cut-off

$V_u < (2/3)\ \phi V_c$ (ACI 12.10.5.1):

$V_u = 5.49$ kips $< (0.667)\ \phi V_c = (0.667)(10.25) = 6.84$ kips

Bottom bars at inflection point (ACI 12.11.3):

The quantity $\left(\frac{M_n}{V_u} + \ell_a\right)$ must be larger than ℓ_d.

$M_n = \frac{30.9}{0.90} = 34.3$ ft-kips $\quad V_u = 6.47$ kips

ℓ_a = the greater value, d or $12d_b = 1.14$ ft

$\frac{M_n}{V_u} + \ell_a = \frac{34.3}{6.47} + 1.14 = 6.44$ ft > 1.42 ft: Okay

To conform to the requirements for structural integrity, the #4 bottom bar has to be lap spliced over the support to a bottom bar in the adjacent spans (ACI 7.13.2.1). A Class B tension lap splice is required. Detailing the #4 bar for structural integrity would affect the check of Dimension 8.

Interior Span-Serviceability Requirements

Cracked Section Properties – See Fig. 8-11

$n \quad = E_s/E_c = 29 \times 10^6/3.644 \times 10^6 = 7.96 = 8$

$+I_{cr} \quad = 643$ in.^{4}

$+I_{cr}/I_g = 643/3{,}541 = 0.181$ (Tabulated 0.181)

$-I_{cr} \quad = 734$, $-I_c/I_g = 0.207$ (Tabulated 0.207)

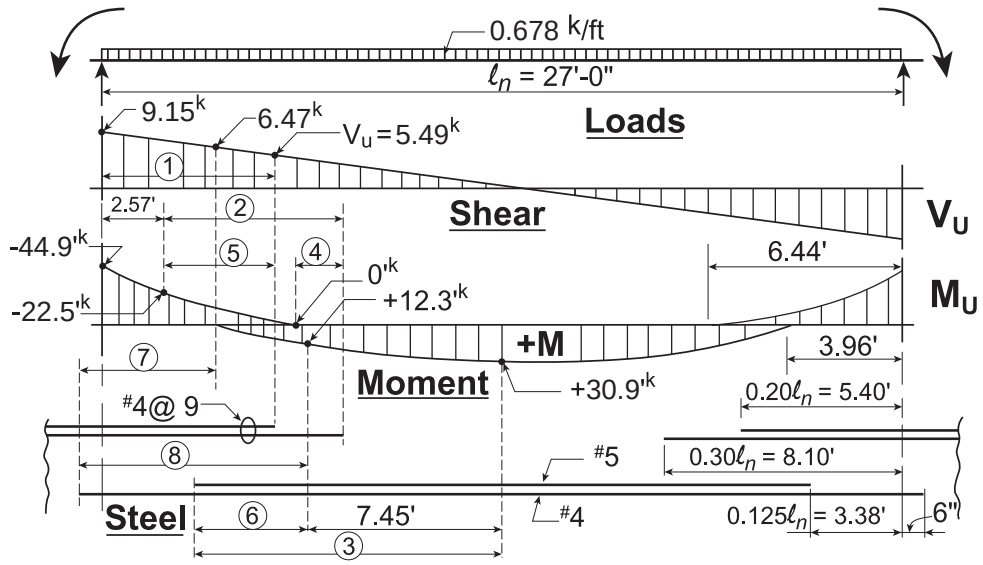

Figure 8-10 Embedment Lengths Available vs. Required Development Lengths

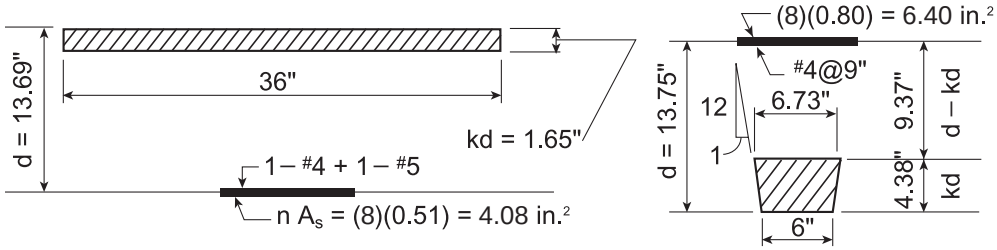

Figure 8-11 Cracked Section – Example 1

$+M_{cr}$ = 13.5 ft-kips, $-M_{cr}$ = 30.1 ft-kips
(From Table 8-1)

Total service load, w_s

$w_s = (102 + 65)\ 36/12 = 501$ plf

Maximum moment, M_a

$$\pm M_a \approx \frac{w_s \ell_n^2}{16} = (0.501)(27)^2/16 = 22.8 \text{ ft-kips}$$

$$I_e = \left(\frac{M_{cr}}{M_a}\right)^3 I_g + \left[1 - \left(\frac{M_{cr}}{M_a}\right)^3\right] I_{cr}$$

$\leq I_g$ (ACI 9.5.2.3, Eq. 9-8)

$$+I_e = \left(\frac{13.5}{22.8}\right)^3 (3{,}541) + \left[1 - \left(\frac{13.5}{22.8}\right)^3\right](643)$$

$= 735 + 510 = 1{,}245$ in.^{4}

$$-I_e = \left(\frac{30.1}{22.8}\right)^3 (3{,}541) + \left[1 - \left(\frac{30.1}{22.8}\right)^3\right] 734 > I_g$$

Use $-I_e = 3{,}541$ in.^{4}

Average effective moment of inertia,

I_e = Average of ($+I_e$ and $-I_e$) (ACI 9.5.2.4)
= (0.5)(1,245 + 3,541)
= 2,393 in.^{4}

Live load deflection $\Delta_L = \left(\frac{2}{384}\right) \frac{w \ell_n^4}{E_c I_e}$

where w is load per inch

Tabulated deflection coefficient, DC = 3.938 (Page 8-29)

$$\left(\frac{2}{384}\right) \frac{(27)^4(12)^3}{E_c} (3) = 3.9377$$

$$\Delta_L = \frac{(3.938)(65)}{(2{,}393)} = 0.11 \text{ in.}$$

$$< \frac{\ell_n}{480} = \frac{(27)(12)}{480} = 0.675 \text{ in.}$$

Note: The service load negative moment at the support is less than the service load positive moment at mid-span. The use of two bottom bars per rib is necessarily within all spacing limitations imposed for crack control. All spacings tabulated for top bars are within the crack control limits. For these reasons, no serviceability condition investigation for crack control is required for joist tabulated designs in this Chapter.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/18.5$ for end spans, $\ell_n/21$ for interior spans).
(4) Exclusive of bridging joists and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/18.5$ for end spans, $\ell_n/21$ for interior spans).
(4) Exclusive of bridging joists and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/18.5$ for end spans, $\ell_n/21$ for interior spans).
(4) Exclusive of bridging joists and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/18.5$ for end spans, $\ell_n/21$ for interior spans).
(4) Exclusive of bridging joists and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/18.5$ for end spans, $\ell_n/21$ for interior spans).
(4) Exclusive of bridging joists and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/18.5$ for end spans, $\ell_n/21$ for interior spans).
(4) Exclusive of bridging joists and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/18.5$ for end spans, $\ell_n/21$ for interior spans).
(4) Exclusive of bridging joists and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/18.5$ for end spans, $\ell_n/21$ for interior spans).
(4) Exclusive of bridging joists and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/18.5$ for end spans, $\ell_n/21$ for interior spans).
(4) Exclusive of bridging joists and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/18.5$ for end spans, $\ell_n/21$ for interior spans).
(4) Exclusive of bridging joists and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

DESIGN FROM LOAD TABLES (SINGLE SPAN JOIST CONSTRUCTION)

Example 5: Using 30-in. wide forms, select a design and review calculations for a service live load of 180 psf and an allowance of 26 psf for superimposed service dead loads (bridging joist, 3 psf, and floor finish, 23 psf) on a floor system. The clear span is 15.5 ft, bearing 6 in. at each end on masonry walls. Provide a 3-in. top slab. The bearing at each end is assumed to be 4 in.

For design, span ℓ_n = 15.5
+ 2 × dist. center to face of bearing
= 15.5 + 2 × 0.25
= 16′-0″

If available depth permits, select design with a total depth such that ℓ_n/h is about 20. Try 8″ + 3″; see table, Page 8-66.

Superimposed factored load
= 1.2 × 26 + 1.6 × 180 = 319 psf

Try 8 + 3 with 5 in. joists at 35 in. and ℓ_n = 16 ft.

Maximum tabulated capacity, square-end = 370 * psf
tapered-end = 374 * psf

Use the tapered-end design with two #6 straight bottom bars (max. tabulated capacity = 291* psf (square), = 330 psf (tapered)). Note that tabulated designs for square-end joist is controlled by shear (marked with one asterisk). The span, ℓ_n, is greater than 16 h (below solid line in table). For simple spans greater than 16 h, the Code requires that computed immediate deflection due to live load be less than $R_n/360$ for floors not supporting nor attached to non-structural elements likely to be damaged by large deflections (ACI 9.5.2.6). No deflection computations are required in using these tabulated designs unless they are intended to support such elements.

If the deflection was computed for this design, it would be less than $\ell_n/360$ for a live load = $\frac{330}{1.6}$ = 206 psf, > the live load = 180 psf.

(Note that a plus sign in these columns indicates factored load capacities (1.6L) for which deflection equals $\ell_n/360$.)

See recommended bar details, Fig. 8-2. Both bottom bars extend 5 in. into the support for minimum end cover of 1 in. Although not required for a perfectly free end, hooked top bars extending 0.25 ℓ_n into the span are recommended as a practical precaution against top cracking due to inadvertent end restraint at the supports. The total area of such top bars should be approximately equal to the area of the smaller bottom bar. Use 3-#4 bars with 90º end hooks to fit into the 11-in. depth with proper concrete cover. End hooks of 90º for # 4 bars are 0.8 × 10 = 8 in. deep. See Table 5-5(a), Chapter 5. Note that #4 bars will be fully developed 0.7 × 10 = 7 in. from end hook.

Provide per rib: 2 – #6 × 16′-4″ Bottom
3 – #4 × 4′-5″ Top

For a detailed review of this design, see the Manual Example on Page 8-52.

Example 6: *Single Span – Design Strength Controlled by Deflection*. As noted, all designs for single span joists have been investigated for deflection. The superimposed load causing an immediate deflection equal to $\ell_n/360$ was computed, multiplied by the live load factor, 1.6, and compared to the superimposed factored loads determined by flexure strength and shear strength. Superimposed factored load strengths limited by deflection equal to $\ell_n/360$ are designated by a plus sign. These superimposed loads were determined as follows for the joist slab design of Example 5, used on a span of ℓ_n = 23 ft.

Dead load (joist)	=	54 psf
Live load	=	85 psf
Total service load	=	139 psf
w_D = 1.2 × 54	=	65 psf
w_L = 1.6 × 85	=	136 psf
Factored load w_u	=	201 psf

From Table 8-1(a), I_g = 1,223 in.^{4}; M_{cr}, = 6.1 ft -kips
Read from load table, Page 8-66, I_{cr}/I_g = 0.406

Maximum actual moment, $M_a = \frac{(0.139)(35/12)(23)^2}{8}$
= 26.8 ft-kips
M_{cr}/M_a = 6.1/26.8 = 0.228

Using Code Equation (9-8):
$I_e/I_g = (M_{cr}/M_a)^3 + [1 - (M_{cr}/M_a)^3]I_{cr}/I_g$
$= 0.228^3 + [1 - (0.228)^3]0.406$
= 0.413
From load table, Page 8-66, deflection coefficient = 5.039. Immediate live load deflection,

$$\Delta_L = \frac{(DC)(w)}{I_c} = \frac{(5.039)(85)}{(0.413)(1{,}223)} = 0.85 \text{ in.}$$

$$\frac{\Delta}{\ell_n} = \frac{0.85}{(12)(23)} = \frac{\ell_n}{325} > \frac{\ell_n}{360}$$

Superimposed factored load = 1.6 × 85 = 136 psf
Therefore > 123 + tabulated

Note: It is very difficult to manually solve for the superimposed load causing a given deflection since the quantity, M_a, includes this load. The necessary trial and error iteration is, however, convenient by computer.

MANUAL EXAMPLE

To extend designs beyond the scope of the tabulated designs or to know how the tabulated strengths were computed, detailed computations are presented for the design in Example 5.

Review: Example 5
Loads: See Table 8-1 Gross Section Properties

Joist: (150.3)(150/144)(12/35) = 54 psf
Bridging: (Allow) = 3 psf
Wearing surface (floor finish) = 23 psf
Dead load = 80 psf

Factored load, w_u

$w_u = 1.2D + 1.6L = (1.2 \times 80) + (1.6 \times 180) = 384$ psf

Superimposed factored load = 384 – (1.2 × 54) = 319 psf

2 – #6 = 0.88 in.^{2}

$$\rho = \frac{0.88}{(35)(9.5)} = 0.00265$$

$$a = \frac{A_s f_y}{0.85 f_c' b} = \frac{(0.88)(60)}{0.85(4)(35)} = 0.44 \text{ in.}$$

From Flexural Computations section in Chapter 5:
$\rho_{max} = 0.0181$
$\rho = 0.00265 < 0.0181$, so $\phi = 0.90$

Design moment strength, ϕM_n

$\phi M_n = (0.90)(0.88)(60)(9.5 - 0.44/2)/12$
= 36.7 ft-kip

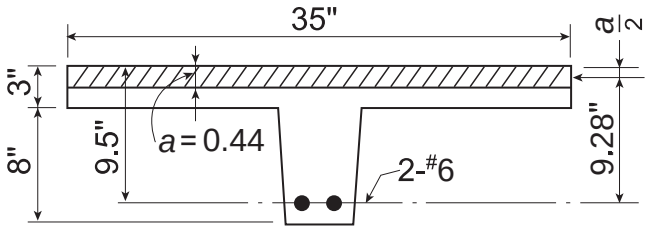

Figure 8-12 Section Dimensions

Maximum design strength for positive moment, w_u, in psf.

$$w_u = \frac{(8)(36.7)(1{,}000)}{(35/12)(16)^2} = 393 \text{ psf}$$

Maximum superimposed design strength for positive moment
= 393 – (1.2 × 54)
= 393 – 65 = 328 > 319 psf. Bending moment not critical.

Shear
For square-end, average width
b = ½(6.83 + 5.25) = 6.04 in.
d = 9.50 in.; A_s = 0.88 in.^{2}

$$\rho_w = \frac{0.88}{9.5 \text{ x } 6.04} = 0.0153$$

Short formula for shear strength, ϕV_c:

$\phi V_c = (1.10)\ \phi\ (2)\ \sqrt{f_c'}\ b_w d$
= (1.10)(0.75)(2) $\sqrt{4{,}000}$ (6.04)(9.5)/1,000
= 5.99 kips

Long formula for shear strength, ϕV_c, at a distance, d, from the support:

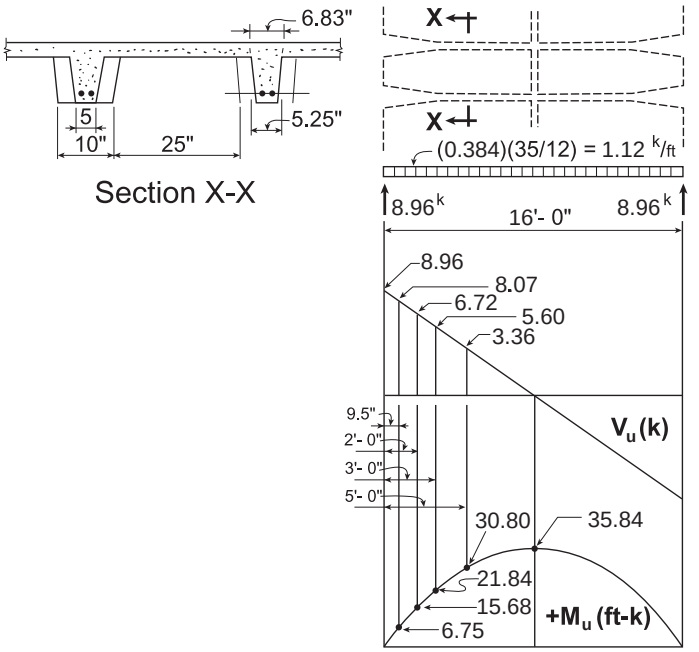

Figure 8-13 Simple Span Analysis

On Square End

$\phi V_c = (1.10)\ \phi\ (1.9\sqrt{f_c'} + 2{,}500\ \rho_w V_u d/M_u) b_w d$
= (1.10)(0.75)[1.9$\sqrt{4{,}000}$ + 2,500 (0.0153)
(8.07 × 9.5)/(6.75 × 12)](6.04)(9.5)/1,000
ϕV_c = 7.40 kips < 8.07, tapered end joist is required.

Maximum factored superimposed load with square end joists:

$$w_u = \frac{7{,}400}{(35/12)(8.00 - 9.5/12)} - 1.2 \text{ x } 54$$

= 287 psf (291 * Tabulated)

On Tapered End. Shear investigation of a tapered-end joist using the long formula is too complex for manual solution when straight bars are cut off within the taper. The simplest method is to have the allowable and actual shear checked every 2 in. from midspan to a distance, *d*, from the face of the support. Even with the simplification offered by full length bars, the solution is complex. Results of the manual solution are listed in Table 8-2. Note that the critical section with both long and short formulas for shear occurred at the root of the taper for a 16 foot span. Since the tapered length is a constant 36 in., the location of the critical section for all spans cannot be predicted.

TABLE 8-2 SUMMARY SHEAR CALCULATIONS – EXAMPLE 5

Quantity	Distance from Support			
	d	2'-0"	3'-0"	5'-0"

ϕV_c (long formula), kips	10.87	7.88	6.06	5.85

Maximum ϕV_c at start of taper = 6,060 lb

$$\left.\begin{array}{l}\text{Maximum factored}\\ \text{superimposed load}\\ \text{for shear}\end{array}\right\} = \frac{6060}{\left(\frac{35}{12}\right)(5)} - (54)(1.2)$$

$$= 416 - 65 = 351 \text{ psf}$$

(330 Tabulated)

COMPUTED DEFLECTIONS

The computation procedure prescribed by the Code is too long for routine use as a manual calculation. For this reason, the necessary properties of the joist design sections, gross and cracked, have been tabulated in this Chapter. See Table 8-1 Gross Section Properties and "Design Properties" (cracked) under each load table. A deflection coefficient is also tabulated opposite each span for each joist section in the load tables.

This coefficient, DC = $\frac{k\ell_u^4(\text{spacing}/12)(1/12)}{384E_c}$, where k = 5 for single spans. The effect of the tapered haunch is conservatively neglected. Using these design aids, deflection is computed for the example as follows:

1. In load table, read DC = 1.18 for ℓ_n = 16′-0″. Under "Design Properties," read I_{cr}/I_g = 0.406.
2. In Table 8-1(a), read I_g = 1,223 in.^{4} and + M_{cr} = 6.1 ft-kips
3. Compute maximum moment at service load.
   $D + L$ = 80 + 180 = 260 psf.
   $$M_a = \frac{(0.260)(35/12)(16)^2}{8} = 24.3 \text{ ft-kips}$$
4. Using Code Equation (9-8):
   M_{cr}/M_a = 6.1/24.3 = 0.251
   I_{cr} = 0.406 (1,223) = 497 in.^{4}
   $I_e = (M_{cr}/M_a)^3 I_g + [1 - (M_{cr}/M_a)^3] I_{cr}$
   $= (0.251)^3(1{,}223) + [1 - (0.251)^3]497$
   = 508 in.^{4}
5. Immediate live load deflection, Δ_{LL}
   $$\Delta_{LL} = \frac{(DC)w = (1.18)(180)}{I_e \qquad 508} = 0.42 \text{ in.}$$
   $$= \frac{0.42\,\ell_n}{16 \times 12} = \ell_n/457$$

Development. Bar sizes in a single span must be small enough so that at the supports the quantity,

$$\left(\frac{M_n}{V_u} + \ell_a\right) \geq \ell_d$$

$M_n = \frac{36.7}{0.90} = 40.8$ ft-kips
V_u = 8.96 kips
ℓ_a = 2 in. (embedment beyond center of support)

Chapter 5; Table 5-2(b)

Bar Size	Cover	c.-c. spacing	ℓ_d
#6	1″ or 1.33d_b	2.50″ or 3.33d_b	43″= 3.58′

$$\frac{M_n}{V_u} + \ell_a = \frac{40.8}{8.96} + \frac{2}{12} = 4.72 \text{ ft} > 3.58 \text{ ft, OK}$$

The embedment length provided, from midspan (max. M_u) to the end of the bars, must be ≥ ℓ_d: 8.5′ > 3.58′, Okay.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/16$).
(4) Exclusive of bridging joist and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/16$).
(4) Exclusive of bridging joist and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/16$).
(4) Exclusive of bridging joist and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/16$).
(4) Exclusive of bridging joist and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/16$).
(4) Exclusive of bridging joist and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/16$).
(4) Exclusive of bridging joist and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/16$).
(4) Exclusive of bridging joist and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/16$).
(4) Exclusive of bridging joist and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/16$).
(4) Exclusive of bridging joist and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/16$).
(4) Exclusive of bridging joist and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.

(1) For gross section properties, see Tables 8-1(a) and 8-1(b).
(2) First load is for standard square joist ends; second load is for special tapered joist ends.
(3) Computation of deflection is not required above horizonal line (thickness ≥ $\ell_n/16$).
(4) Exclusive of bridging joist and tapered ends.
*Controlled by shear capacity. +Capacity at elastic deflection = $\ell_n/360$.
