WIDE-MODULE CONCRETE JOIST CONSTRUCTION

INTRODUCTION

Wide-module joist systems, which are also referred to as "skip-joist" systems, may be defined as joist systems with clear spacings between ribs of more than 30 in. Since this spacing exceeds the spacing limit for joists, as specified by ACI 8.13, the wide-module joists are subject to the design requirements for T-Beams (ACI 8.12).

Of the two types of joist construction, the standard and wide-module, the wide-module is preferred when a 4.5-inch top slab is used. The 4.5-inch top slab is needed when the floor/ceiling assembly is required to have a 2-hour fire-resistant rating. As a result of this floor slab thickness, the most economical system is the one which structurally takes advantage of this thickness, as the wide-module system does.

DIMENSIONS OF STANDARD FORMS

Joist widths for tabulated designs in this Chapter vary from 6 in. to 10 in. Standard forms for the pan spaces between ribs are 40-in., 53-in. and 66-in. wide and 12, 14, 16, 20 and 24-in. deep. Standard-end forms consist of square-end forms: tapered-end forms are usually not available.

See Fig. 8-14 for recommended bar details for wide-module joist construction.

When the supporting beam is wider than the column, it is recommended that the clear span of the joists be considered as ($\ell_{c\text{-}c}$ – column width).

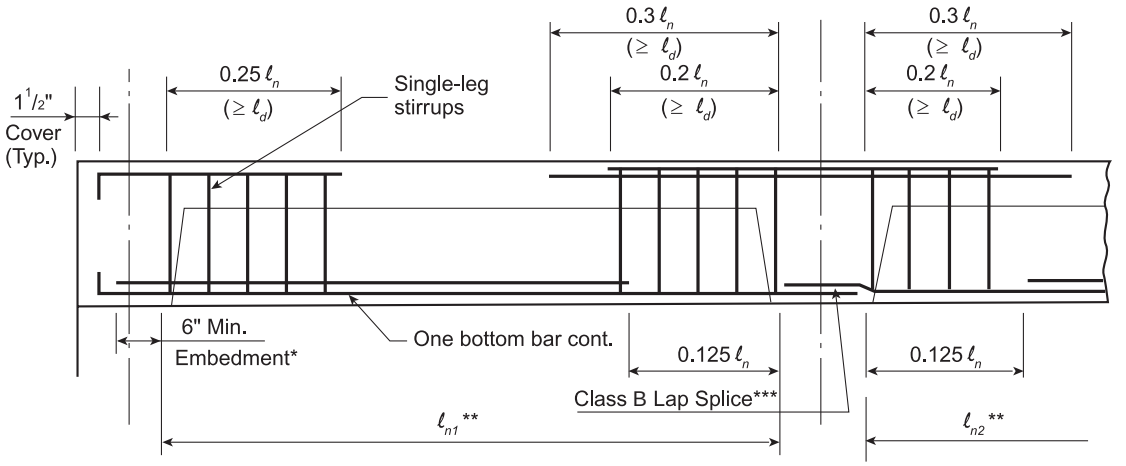
Since the top concrete cover of the joist and girder each have the same minimum value, e.g., 1½ in., it may be necessary to increase the girder top concrete cover by lowering the girder top reinforcement and reduce the effective depth for negative moment calculations, in order to avoid interference with the joist negative moment reinforcement.

The following tables will help in stirrup style selection and bar positioning.

MAXIMUM BAR SIZE FOR INDIVIDUAL BARS IN THE BOTTOM OF A WIDE-MODULE RIB

Stirrup Style	No. of Bars	Rib Width at Bottom				
		6″	7″	8″	9″	10″
"L"	2	#6	#9	#11	#14	#14
	3	–	#4	#6	#8	#10
"L" (alt.) or "U"	2	#4	#8	#10	#11	#14
	3	–	–	#5	#8	#9

1. Maximum bar sizes are based on clear spacing requirements of ACI 7.6.1.
2. Side taper of ribs not considered.
3. Based on 1½-in. concrete cover, #4 stirrups.



*If support width ≤ 12", hook two bottom bars.

**If bearing on masonry or structural steel, use c.-c. lengths.

***If lap area extends beyond 0.125 ℓ_n cut-off, consider lapping hooks (i.e., ⌐). ℓ_{dh}

Figure 8-14 Recommended Wide-Module Joist Bar Details

MAXIMUM BAR SIZE FOR 2-BAR BUNDLES IN THE BOTTOM OF A WIDE-MODULE RIB

Stirrup Style	No. of Bars	Rib Width at Bottom				
		6″	7″	8″	9″	10″
"L"	1	#9	#11	#11	#11	#11
	2	#3	#5	#6	#8	#9
"L" (alt.) or "U"	1	#8	#11	#11	#11	#11
	2	–	#4	#5	#7	#8

1. Maximum bar sizes are based on clear spacing requirements of ACI 7.6.1 and 7.6.6.5.
2. Side taper of ribs not considered.
3. Based on 1½-in. concrete cover, #4 stirrups.

GENERAL STRUCTURAL CONSIDERATIONS

Since the wide-module "joists" are technically classified as beams, their design must conform to the requirements of T-Beams (ACI 8.12). Principal requirements are:

1. **Minimum concrete cover.** 1½ in. to stirrups and main flexural bars (top, bottom, and sides) instead of ¾ in. (ACI 7.7.1).
2. **Design shear strength.** $\phi V_c = \phi 2\sqrt{f'_c}\, b_w d$ instead of $\phi V_c = \phi 2.2\sqrt{f'_c}\, b_w d$ (ACI 11.2.1.1).
3. **Minimum area of shear reinforcement.** $A_v = 50(b_w s)/f_y$ when factored shear $V_u > 0.5\phi V_c$ (ACI 11.4.6.3).
4. **Reinforcing steel requirements and recommended details.** Alternative arrangements to provide required shear reinforcement include the common open U-stirrup. With minimum rib widths, the maximum size of the main tensile reinforcement becomes limited by concrete cover requirements. Also with minimum rib widths, fabricating constraints may require wider U-stirrups. In these cases, the U-stirrups may be angled to fit. For minimum rib widths, the use of single leg stirrups simplifies placing the reinforcement. A special note should be included on placing drawings to require alternating the stirrup positions. See Fig. 8-15.

Welded wire reinforcement (plain or deformed) can also be used as shear reinforcement. The vertical wires are developed by two horizontal wires spaced at 2 in. maximum at the top and at the bottom.

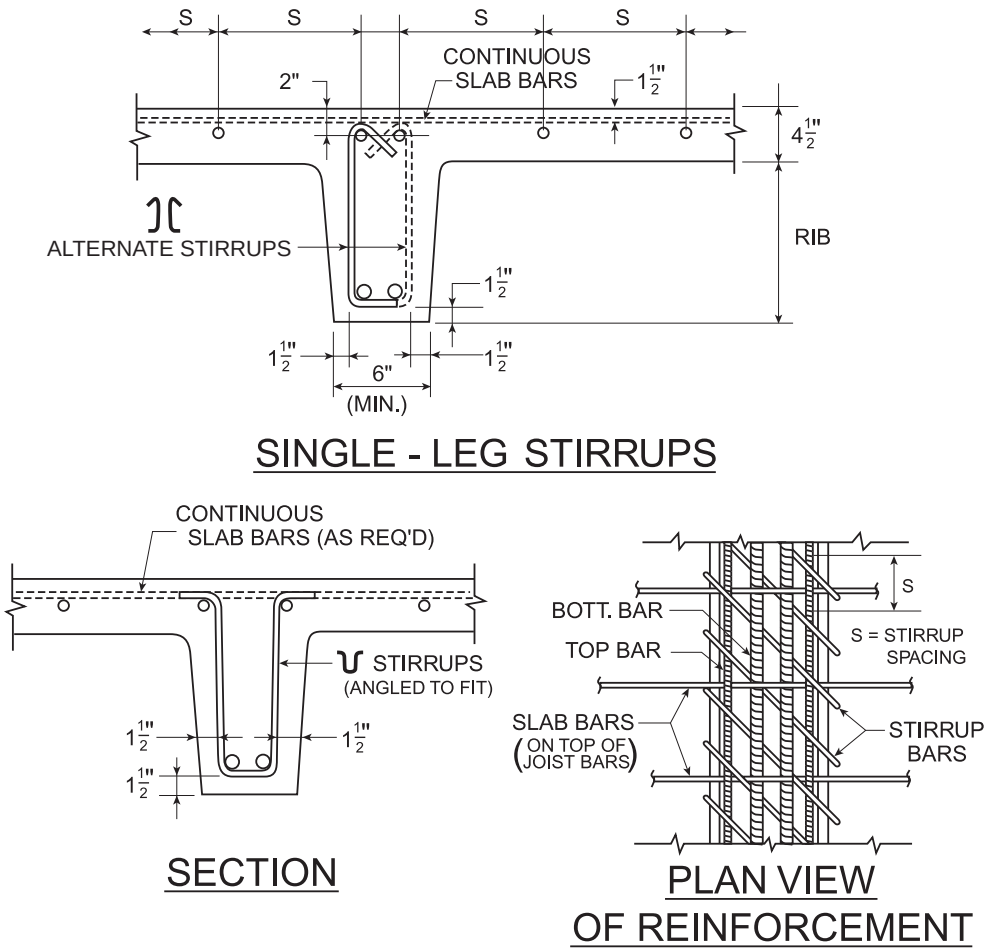


Figure 8-15 Details for Single Leg and Common U-Stirrup Applications for Shear Reinforcement in Wide-Module Joist Construction

TABULATED DESIGNS

Because the wide-module joist tabulated designs, and their use, are very similar to the standard size joists, only their differences will be discussed.

Scope. End spans and interior spans, but not single spans, are covered in the tabulated designs. Tapered-end forms are not considered, since stirrups are used to provide for shear capacity.

Load Strengths Tabulated. Usable superimposed factored load strength is given in pounds per foot. The first line for a specific clear span gives the superimposed load strength, the second line lists the single-leg stirrup size and minimum distance (in.) from the face of support that the stirrups must extend. Required constant stirrup spacing is noted at the bottom in each load table.

DESIGN FROM LOAD TABLES (MULTIPLE SPAN WIDE-MODULE JOIST CONSTRUCTION)

Example 1. Select a wide-module joist floor design with about a 6 ft. joist spacing and review calculations to support a service live load of 75 psf and an allowance of 30 psf for superimposed dead loads (partitions, ceiling, etc.) on a clear span of 28 ft. See Fig. 8-17 for layout.

Try: 16 + 4½ with 9-in. ribs 66 in. apart (6'-3" c.-c.)

Superimposed factored load $w_u = 1.2D + 1.6L$
$= 1.2(30) + 1.6(75)$
$= 156$ psf $(6.25) = 975$ plf

Read from table on Page 8-117:

End Span: Tabulated strength = 1,198 plf
Top bars #4 at 7.5" at first interior support
Bottom bars 2- #8 (per rib)
Single-leg stirrups: #3 spaced at 8" for 136" from face of support or 18- #3 spaced at 8"

Interior Span: Tabulated strength = 1,393 plf
#4 spaced at 7.5" top bars,
1- #5 and 2- #6 bottom bars
Single-leg stirrups: #3 spaced at 8" for 98" or 14 - #3 spaced at 8"

Concrete quantity (from Table 8-3):

524 plf = 524/6.25 = 84 psf

Load strength was not limited by deflection, so approximate immediate live load deflection will be:

$$\left(\frac{75}{30+75}\right)\left(\frac{\ell_n}{360}\right) = \frac{\ell_n}{504} \text{ (or less)}$$

This calculation is sufficient to satisfy ACI 9.5.2.1 that deflection be computed for ℓ_n/h ratios above 18.5 for end spans and 21 for interior spans. The estimated deflection above would be considered satisfactory, without further calculations for all floors and roofs "not supporting or attached to non-structural elements likely to be damaged by large deflections" (ACI Table 9.5(b)).

See Fig. 8-18 details of reinforcing bars for this example.

SINGLE LEG STIRRUP AT 6 IN. CONSTANT SPACING-DISTANCE (IN.)

(1) For gross section properties, see Tables 8-3(a), 8-3(b), and 8-3(c).
(2) Computation of deflection is not required above horizontal line (thickness ≥ $\ell_n/18.5$ for end spans, $\ell_n/21$ for interior spans).
(3) Single leg stirrup size space at X in. c.-c. Distance over which stirrups must extend from face of support at each end (in.).

SINGLE LEG STIRRUP AT 8 IN. CONSTANT SPACING-DISTANCE (IN.)												

(1) For gross section properties, see Tables 8-3(a), 8-3(b), and 8-3(c).
(2) Computation of deflection is not required above horizontal line (thickness ≥ $\ell_n/18.5$ for end spans, $\ell_n/21$ for interior spans).
(3) Single leg stirrup size space at X in. c.-c. Distance over which stirrups must extend from face of support at each end (in.).

SINGLE LEG STIRRUP AT 12 IN. CONSTANT SPACING-DISTANCE (IN.)

(1) For gross section properties, see Tables 8-3(a), 8-3(b), and 8-3(c).
(2) Computation of deflection is not required above horizontal line (thickness ≥ $\ell_n/18.5$ for end spans, $\ell_n/21$ for interior spans).
(3) Single leg stirrup size space at X in. c.-c. Distance over which stirrups must extend from face of support at each end (in.).

WIDE-MODULE (1) ONE-WAY JOISTS MULTIPLE SPANS	40″ Forms + 8″ Ribs @ 48″ c.-c. 11″ Deep Rib + 5.0″ Top Slab = 16.5″ Total Depth FACTORED USABLE SUPERIMPOSED LOAD (PLF)											f'_c = 4,000 psi f_y = 60,000 psi

SINGLE LEG STIRRUP AT 10 IN. CONSTANT SPACING-DISTANCE (IN.)

(1) For gross section properties, see Tables 8-3(a), 8-3(b), and 8-3(c).
(2) Computation of deflection is not required above horizontal line (thickness ≥ $\ell_n/18.5$ for end spans, $\ell_n/21$ for interior spans).
(3) Single leg stirrup size space at X in. c.-c. Distance over which stirrups must extend from face of support at each end (in.).

CHAPTER 9 – SOLID TWO-WAY FLAT PLATES — SQUARE PANELS

General. The tabulated designs presented in this Chapter are for flat plates defined as solid uniform depth concrete slabs, reinforced in two directions to transfer loads directly to supporting columns without capitals, beams, or drop panels. Spandrel edges of the flat plate are assumed to extend at least to the outer face of the edge and corner columns. Where architectural or construction considerations permit cantilevered edges, this modification can be performed for moderate span cantilevers with minor adjustments of the reinforcement tabulated, and will improve the structural performance of the flat plate.

Flat Plate Advantages. The two-way flat plate is one of the most efficient structural systems for economy. Flat plates can be constructed in minimum time with minimum field labor because the flat plate utilizes the simplest possible formwork and reinforcing steel layout. Flat plates result in minimum story height for required clear headroom, and provide for greatest flexibility in layout of columns, partitions, small openings, etc. Where requirements of the project permit direct application of the ceiling finish to the flat plate soffit, elimination of ceiling construction permits additional substantial cost and construction time savings compared to other structural systems.

Flat plates have become increasingly economical and widely used as the cost of field labor has increased relative to materials. They have been applied with particular advantage to multi-story motel, hotel, hospital, dormitory, and apartment buildings. The principal limitation on use of flat plate construction is imposed by the shear area, the perimeter about the column-plus-plate depth, times the plate depth available. For industrial loads or longer spans, the solid flat slab (with capitals or drop panels or both) may be preferable. See Chapter 10. For long spans, the reduced dead load and increased stiffness of the waffle flat slab will usually result in overall economy. See Chapter 11.

Since the span and load limits for maximum economy vary with local costs and may depend upon other requirements of the project, the tabulated designs in this Handbook cover the partly overlapping practicable ranges of span and load for each of the three principal two-way structural systems.

Design Considerations. In Chapter 13 of the ACI Building Code, design requirements are combined for all types of two-way slab construction, since the fundamental behavior is the same for all. Chapter 13 applies to flat plates; flat slabs with capitals, drop panels, or both; waffle flat slabs; and two-way slabs supported on monolithic beams. The requirements for distribution of reinforcement are made dependent by elastic analysis upon the relative stiffness of all participating structural elements. Rather complex provisions for calculation of stiffness include for flat plates assumption of infinite column stiffness at the joints within the depth of the plate, increased slab stiffness within the column at the joints, and torsional stiffness of the portion of the plate within and at right angles to the width of the column. Even the *Direct Design Method* provides for adjustment of moments based on the results of three-dimensional stiffness calculations.

The most critical problem in the design, however, is not the distribution of reinforcement in the flat plate for elastic analysis. If the proper total area of reinforcement (based on M_o, the total static moment for a span) is provided, redistribution before failure load is reached will usually ensure its effectiveness. The Code permits a 10 percent adjustment of negative and positive factored moments, provided the total static moment, M_o, for a panel in the direction considered is not less than $q_u \ell_2 \ell_n^2/8$ (ACI 13.6.7). Shear transfer of gravity load and moment, however, is not capable of such redistribution. The Code requires that shear developed by transfer of balanced gravity loads be combined with shear created by transfer of a portion of the moment due to unbalanced gravity loads and horizontal forces. This shear and the transmission of remaining moment through flexure to the columns by properly anchored flexural reinforcement are the critical elements for a safe design.

All prescribed design methods, including the Direct Design Method, the Equivalent Frame Method, and the provision for use of any rational method, including limit design, consist essentially of reviewing a trial design. If additional trials are necessary due to a change in any dimension (stiffness) of any participating structural element, the entire process must be repeated. The time required for a completely manual design, probably through several trials, makes use of a computer or a computer-produced set of design tables the logical procedure for any routine structure.

Scope of Flat Plate Tabulated Designs. In this Chapter, tabulated designs for flat plates are presented for typical square exterior edge and interior floor panels. (Types E and I in location diagram, Fig. 9-1).

Corner panels (C) and first interior panels (IC, EC, IE) require combinations of appropriate exterior panel reinforcement. To present the entire range considered practicable for flat plates, complete designs are tabulated for spans from 12′-0″ to 31′-0″; factored superimposed loads from 50 psf to 350 psf; plate (slab) thicknesses from 5 to 10 inches. Minimum size square columns satisfying Code requirements for shear transfer are included with each load and span combination.

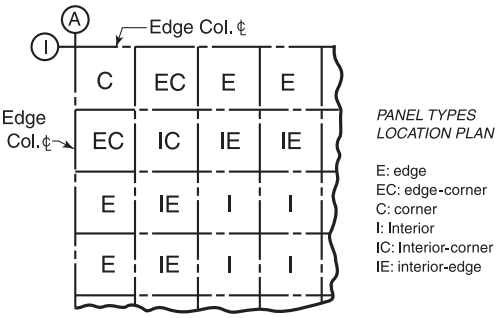

Figure 9-1 Panel Nomenclature

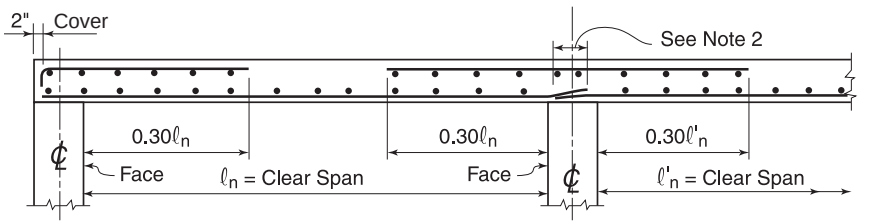
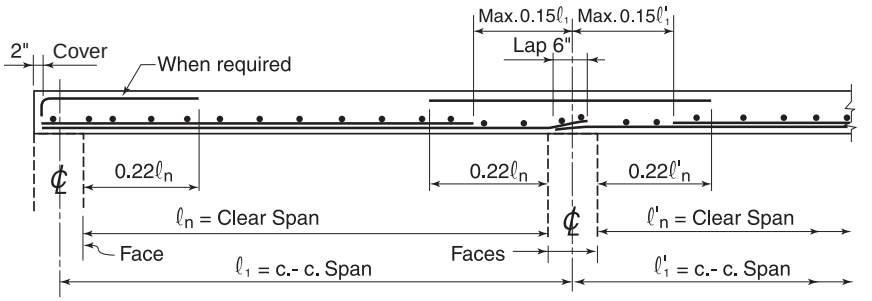
All tabulated designs conform to ACI 318 minimum requirements for shear without use of shearhead reinforcement.

To aid in quantity estimates for cost comparisons of alternative designs, concrete and reinforcing steel average quantities per square foot are given in the tabulated designs for the six panel types identified in Fig. 9-1. Reinforcing steel quantities include all reinforcement in the flat plate, except integrity steel (ACI 13.3.8.5).

Basis of Tabulated Designs. All tabulated designs are prepared for normal-weight concrete, f'_c = 4,000 psi, and Grade 60 reinforcing bars with f_y = 60,000 psi. The tabulated designs use load factors (1.2*D* and 1.6*L*) and ϕ-factors as prescribed in the 2008 Code, and follow the "Direct Design Method" of ACI 13.6. All designs tabulated satisfy the minimum thickness requirements of ACI 9.5.3.2 so that deflection calculations are not required by the Code. Crack control requirements of ACI 13.3.2 have been satisfied by the spacing of reinforcing bars. Anchorage and development requirements were applied to select bar sizes for full development when anchored and cut-off per the recommended reinforcement details. See Fig. 9-2.



(a) Column Strip



(b) Middle Strip

Notes:

1. Top bars must be concentrated within width of the column plus 1.5*h* on each side of the column (ACI 13.5.3.2 and 13.5.3.4).
2. Integrity reinforcement is required (ACI 13.3.8.5). All bottom bars in the column strip must be continuous or spliced over the support with Class B tension lap splices. At least two of the column strip bottom bars in each direction must pass within the column core and be anchored at exterior supports.

Figure 9-2 Typical Bar Length Details

The tabulated designs are applicable within the following limitations established for the Direct Design Method, Section 13.6.1:

1. Minimum of three spans continuous in each direction.
2. Ratio of panel length to width not to exceed 2.0.
3. Successive span lengths (in the same direction) to differ not more than one-third the longer span.
4. Individual column centers not to be offset more than 10 percent of the span in the direction of the offset, in either direction from the grid of lines connecting centers of successive columns.
5. Service live load cannot exceed two times service dead load (i.e., Actual loads before application of load factors).

USE OF FLAT PLATE TABULATED DESIGNS

Direct Applications Within Dimensional Limitations of Tabulated Designs. Limitations within the tables are:

1. Square column sizes as tabulated
2. Square panels
3. Minimum three panels continuous
4. Equal spans
5. Edge of slab flush with outer face of edge column
6. Live load $\leq 2 \times$ dead load (unfactored loads)
7. Uniformly distributed gravity loads only. See Section 13.6.1.5 (Code and Commentary). For lateral load analyses, see "Equivalent Frame Method," Sections 13.5.1, 13.5.3, 13.7, and Commentary Section R13.7.

Example 1: *Preliminary Selection.* Compare alternate designs in order to make a preliminary selection for a flat plate intermediate floor, which is subjected to a 100 psf superimposed factored load on square panels 20 feet center-to-center of columns. Lay out the reinforcement for the design selected.

Solution: Read "Square Edge Panel" only since minimum required size of interior columns here is less than exterior columns.

Slab Thickness, h (inches)	Min. Edge Col., $c_1 = c_2$ (inches)	Reinforcing Steel Edge Panel, E
7	20	2.04 psf
7½	18	2.08 psf
8	17	2.08 psf
8½	16	2.09 psf

If the 16-in. square column is inadequate for vertical loads from upper floors, the next choice would be the 8-in. plate with 17 in. $\times$ 17 in. square columns. If this column size proves adequate for loads from above, and the size fits architectural requirements, the tabulated designs can be used directly. Note that total reinforcing steel quantities are given for three types of exterior and interior panels. See Fig. 9-1, Panel Nomenclature. Not only should these data make preliminary estimates more accurate, but it should serve as a reminder that tabulated reinforcement for exterior panels runs both ways in corner panels and that the first interior column top bars tabulated under "Edge" panels will be used at both ends of the center panel in a three-bay frame, etc.

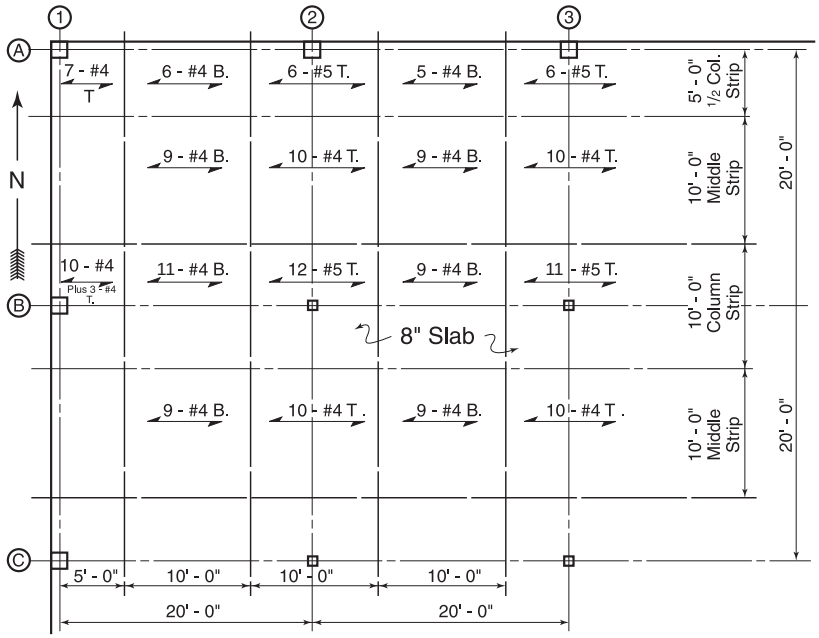


Figure 9-3 Plan – East-West Bars (North-South Bars Same) – Example 1

The reinforcement required for the 8-in. slab is listed in the tabulated design on Page 9-26. The layout of the required reinforcement is shown in Fig. 9-3. Concentration of top reinforcement over edge columns may be achieved by closer spacing within width of the column plus 1.5*h* on each side of the column (ACI 13.5.3.2). See Fig. 9-3.

Adjustment of Tabulated Designs to Project Conditions. In practice, the usual variations from the limitations of the tabulated designs will occur in one or more of the following areas:

1. Non-square panels
2. Non-equal consecutive spans
3. Minor cantilevers
4. Major cantilevers

Moment. Adjustments up to 10 percent are permitted by the Code in negative and positive factored moments, provided the total factored static moment for a span in each direction, M_o, is not reduced.

Shear. Adjustments to accomodate a number of the usual variations should not require a new shear analysis at the exterior column. Non-square panels, non-equal consecutive spans, cantilevers of any type, will generally reduce critical shear. Use of larger than minimum size square columns (where $v_c = 4\sqrt{f'_c}$), may require a new shear analysis if ACI Eq. 11-32 controls shear strength, i.e., when $(\alpha_s d/b_o + 2) < 4$. With major cantilevers, a new shear analysis will be desirable as it will usually allow use of smaller exterior columns, and facilitate use of straight bar embedment to satisfy "structural integrity" requirements of the ACI Building Code. See the "Manual Example" for the complete shear analysis required. A cantilever sufficiently loaded to develop a minimum (dead load) moment at the exterior column centerline equal to that at interior column centerlines will generally permit use of the interior span design, including the minimum size interior column.

Example 2: *Non-square Panels.* Consider the same conditions as in Example 1 (100 psf superimposed load on an intermediate floor) except with $\ell_1 = 20'\text{-}0''$; $\ell_2 = 18'\text{-}0''$. As the ratio of spans in opposite directions, ℓ_2/ℓ_1, varies from 1.0 for square panels, the ACI Building Code provides for varying distribution of moment to the column and middle strips only where beams are used.

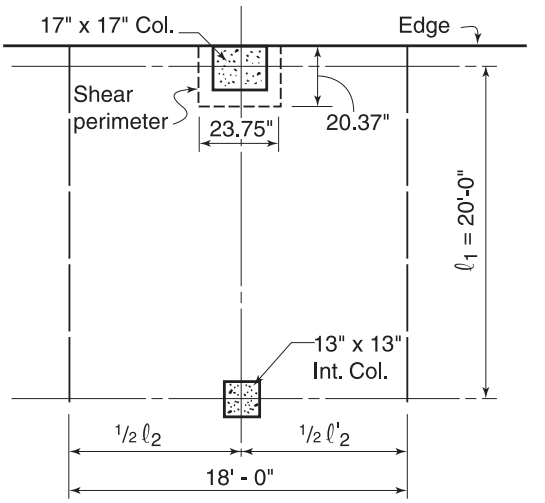
For ratios ℓ_2/ℓ_1 close to 1.0, the simplest adjustment is to provide reinforcing steel and minimum column size as tabulated for the larger span in both directions in the flat plate.

Moment – Compare tabulated reinforcing steel for $\ell_1 = 20'\text{-}0''$ and $\ell_2 = 18'\text{-}0''$ assuming square panels in both directions:

Location		$\ell_1 = 20'\text{-}0''$	$\ell_2 = 18'\text{-}0''$
End Panel			
Col. strip	Top Ext.	10-#4 plus 3-#4	9-#4 plus 3-#4
	Bot.	11-#4	8-#4
	Top Int.	12-#5	13-#4
Middle strip	Bot.	9-#4	8-#4
	Top Int.	10-#4	9-#4
Interior Panel			
Col. strip	Top	11-#5	12-#4
	Bot.	9-#4	8-#4
Middle strip	Top	10-#4	9-#4
	Bot.	9-#4	8-#4

Note that changes in reinforcement are too minor to justify making two designs for less than about this ratio of $\ell_2/\ell_1 = 18/20$. At this ratio, the reinforcing steel in the short span direction could be reduced in the bottom of the column strip in the end span; in the top of the column strip at the first interior column and at other interior columns; and by one bar at other locations. See Fig. 9-4.

Possible reduction of the size of the interior column would be too slight to justify the attempt by inspection. The exterior column dimension in the ℓ_2 direction could be reduced slightly without a new shear analysis. The



Read "Minimum Square Column"

Minimum Column	$\ell_1 = \ell_2 =$ 20′-0″	$\ell_1 = \ell_2 =$ 18′-0″
Exterior	17 in.	13 in.
Interior	13 in.	11 in.

Figure 9-4 Non-Square Panel (Example 2)

total shear and the total exterior panel moment are now reduced 18/20. It will be possible to reduce the column to 17 in. × 15 in. (c_1 = 17 in. and c_2 = 15 in.) which reduces the critical shear section area and the moment of inertia of same less than 10 percent.

Example 3: *Non-equal consecutive spans.* Exterior span ℓ_1 = 20′-0″; first interior span ℓ_1 = 18′-0″, both panels, ℓ_2 = 20′-0″. Tabulated bottom reinforcing steel does not need to be changed. Top reinforcing steel at the centerline of a common (interior) support must be that required for the larger span (ACI 13.6.3.4). Thus, top reinforcement for both column and middle strip must be provided as tabulated for the larger span. From the comparison in Example 2, provide 12-#5 bars Top in the column strip and 10-#4 bars Top in the middle strip over the first interior column centerline.

Example 4: *Minor cantilevers.* On the flat plate in Example 1, a small "eyebrow" cantilever for shade is desired, extending 4′-0″ outside the building edge which is flush with the outer face of the edge columns. The overall depth of this cantilever is 8 inches. Any cantilever will reduce the unbalanced moment to be transferred to the exterior column. For small cantilevers of this type, re-calculation of the entire column shear analysis is seldom justifiable in terms of reduced column size, savings in reinforcing steel, etc. It will usually be sufficiently accurate and always safe merely to extend all top bars from the exterior column strip straight into the cantilever and as near to the edge as concrete cover requirements permit (2 inches for exposed edges). The hooked ends of the top bars required for flush edges, see Fig. 9-2, will be eliminated as the cantilever extension gives ample development length for anchorage.

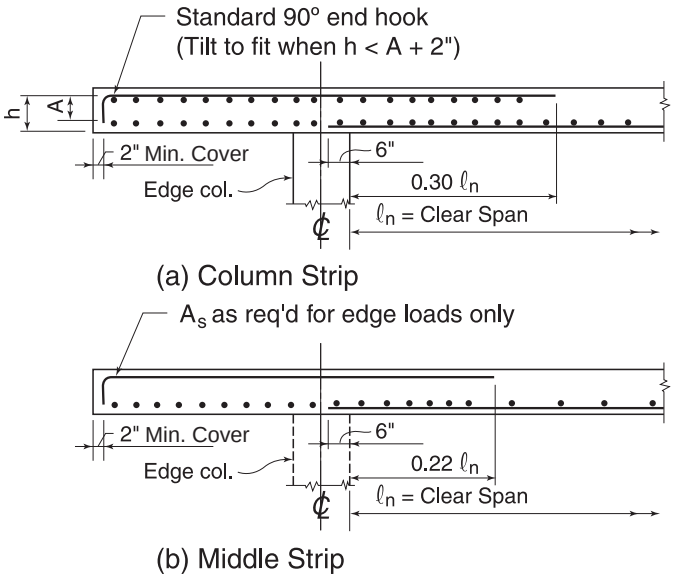


Figure 9-5 Cantilever Details

The one addition to tabulated reinforcement will be top bars into the cantilever from the middle strip. The dead load of the slab (h = 8 inches) is 100 psf. The factored dead load D = 1.2 × 100 = 120 psf. Assume the specified service live load equals 30 psf. The factored live load L = 1.6 × 30 = 48 psf. The total factored load = 120 + 48 = 168 psf. The factored moment:

$$M_u = \frac{168(4)^2}{2}(12/1000)/(10) = 161 \text{ in.-kips for the } 10'\text{-}0'' \text{ wide middle strip}$$

$$\text{Req'd } A_s = \frac{1.7 f_c' bd}{2 f_y} - \frac{1}{2}\sqrt{\frac{2.89(f_c' bd)^2}{(f_y)^2} - \frac{6.8 f_c' b M_u}{\phi (f_y)^2}}^{*}$$

$$= \frac{1.7(4)(120)(6.5)}{2(60)} - \frac{1}{2}\sqrt{\frac{2.89((4)(120)(6.5))^2}{(60)^2} - \frac{6.8(4)(120)(161)}{0.90(60)^2}}$$

$$= 0.46 \text{ in.}^2$$

Min. $A_s = 0.0018bh = (0.0018)(8)(10)(12) = 1.73$ in.^{2} at maximum spacing 5h or 18 inches.

Use 10-#4 bars spaced at 12 inches on center. These bars must extend inward beyond the outer face of the edge column only 19 inches for full development at the face of the cantilever (see Chapter 5, Table 5-2(b)), but should extend 0.22 ℓ_n into the span past the inner face of the column to ensure anchorage past the negative moment area. See Fig. 9-5. Note that these bars are marked "When required," as in this example. The Code does not require top bars at the edge of the middle strip unless cantilever, spandrel wall loads, etc., are present. Note that top and bottom bars in the ℓ_2 span half column strip are merely repeated (same size and spacing) in the cantilever.

Example 5: *Major cantilevers.* A major cantilever is defined for purposes of these examples as one that will justify a complete new shear analysis to reduce the size of the exterior column. The simplest illustration is a cantilever just sufficient to produce the same dead load moment at the edge column centerline as the minimum negative moment at an interior column. For this condition, the shear analysis at the interior column will apply and all columns, edge and interior.

* The expression is from Chapter 5.

For the design in Example 1, $\ell_1 = \ell_2 = 20'\text{-}0''$; the factored live load q_{Lu} = 100 psf; h = 8 inches; the minimum cantilever to create interior column conditions is easily calculated. See "Edge Panel" load table on Page 9-26. Read "$-M$ at 1st Interior Column"; $-M_{int}$ = 135 ft-kips. The dead load fraction of this factored moment cannot exceed

$$\frac{100 \times 1.2}{100 + 100 \times 1.2} = \frac{120}{220} \times \text{the total factored panel moment.}$$

The cantilever moment cannot exceed:

$$-M = \frac{120}{220} \times 135 = -74 \text{ ft-kips}$$

Assume the 8-in. plate thickness is unchanged in the cantilever and a light spandrel beam weighing 125 plf (factored dead load = 150 plf) is present.

$$-M_{\text{cant}} = \frac{(20)(0.120)}{2} \ell_c^2 + (20)(0.150)\,\ell_c = -74 \text{ ft-kips}$$

where ℓ_c = clear cantilever span

Solving for ℓ_c: $-M_{\text{cant}} = 1.2(\ell_c)^2 + 3.0\,\ell_c = -74$ ft-kips; ℓ_c = 6.7 feet

Caution:

The design shear strength of the concrete for two-way action is the smallest of the values computed from ACI Eqs. 11-31 to 11-33:

$$\phi V_c = \phi(2 + 4/\beta)\sqrt{f'_c}\, b_o d \quad \text{(ACI Eq. 11-31)}$$

$$\phi V_c = \phi(\alpha_s d/b_o + 2)\sqrt{f'_c}\, b_o d \quad \text{(ACI Eq. 11-32)}$$

$$\phi V_c = \phi 4\sqrt{f'_c}\, b_o d \quad \text{(ACI Eq. 11-33)}$$

Since all tabulated designs in this Chapter use square columns, the governing ϕV_c is the smaller of the values computed from Eq. 11-32 and Eq. 11-33. For two-way slab systems with rectangular columns, Eq. 11-31 must also be included in the determination of the governing value of ϕV_c. Design shear strength will be sharply reduced by Eq. 11-31, for example, in two-way slabs at long narrow (wall-like) rectangular columns. In Eq. 11-31, β = ratio of long/short sides of column. Note that nominal unit shear strength, $v_c = 4\sqrt{f'_c}$ applies up to $\beta = 2$, and that the equation gradually reduces shear strength until about equal (at section d/2 from face of support) to that for one-way shear (at section d from face of support).

ACI Eq. 11-32 accounts for a reduction in shear strength where the ratio b_o/d increases. Design shear strength, ϕV_c, of two-way slabs will be controlled by Eq. 11-32, particularly for combinations of relatively shallow slabs and large columns.

DIRECT DESIGN OF FLAT PLATES

The procedure presented in the 2008 ACI Building Code and Commentary has been used in the preparation of the tabulated designs in this Chapter. The following outline presents the major steps in this procedure:

1. Select slab thicknesses within minimum prescribed thicknesses to avoid deflection calculations. See Fig. 9-6.
2. Compute factored load $U = 1.2D + 1.6L$.
3. Select first trial square column size. A minimum of 10 inches, or previously tabulated size in table, whichever is greater.
4. Calculate the total factored static moment,

$$M_o = \frac{q_u \ell_2 (\ell_n)^2}{8} \quad \text{(ACI Eq. 13-4)}$$

5. Calculate the exterior panel moments: $-M_{int} = k_1 M_o$ and $+M = k_2 M_o$; and $-M_{ext} = k_3 M_o$.

Calculate interior panel moments: $-M = 0.65 M_o$ and $+M = 0.35 M_o$.

6. Select flexural reinforcement. Use largest size (minimum number) of reinforcing bars which will satisfy steel areas required for flexure and minimum reinforcement (for temperature and shrinkage) within maximum spacing limits. See Fig. 9-2 "Typical Bar Length Details."
7. Compute shear constants for moment transferred by eccentricity of shear at exterior and interior columns (A_c, J, C_{AB} and C_{CD}).

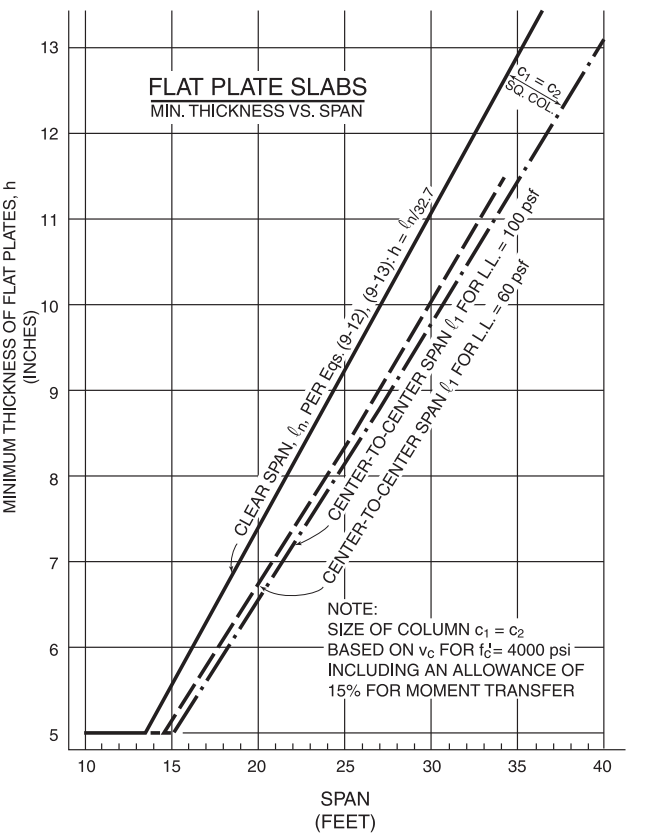

Figure 9-6 Minimum Thickness

8. Compute shear and unbalanced moment at centroid of column shear area, A_c.

9. Compute fraction of unbalanced moment transferred to column by shear, γ_v, for interior and edge columns. At edge columns, the unbalanced moment transferred by eccentricity of shear between the slab and edge column is $0.3M_o$ (ACI 13.6.3.6). At interior columns, the unbalanced moment is determined from ACI Eq. 13-7.

At interior columns, compute the maximum shear stress, v_u, for two conditions: (1) full load, and (2) maximum unbalanced moment plus load causing same. Repeat Steps 3 through 8 if necessary until $v_u \leqq v_c$ in Step 9, where v_c is based on $(\alpha_s d/b_o + 2)\sqrt{f'_c}$ or $4\sqrt{f'_c}$, whichever is smaller.

10. At exterior columns, compute the additional top reinforcement required to resist the fraction at the unbalanced moment within the "effective width" ($1.5h + C_2$) in the column strip.

11. Compute average weights of reinforcing steel (psf) for various panels.

Note on Computation Procedure. Minimum sizes of edge and interior columns were calculated separately.

ACI 318 MOMENT COEFFICIENTS FOR DISTRIBUTING M_o IN END SPAN

Coefficients for distributing M_o in an end span are given in ACI 13.6.3.3 for five conditions:

Condition / Negative and Positive Factored Moments	Exterior edge unrestrained	Slab with beams between all supports	Slab without beams between Interior supports		Exterior edge fully restrained
			Without edge beam	With edge beam	
Interior negative factored moment, k_1	0.75	0.70	0.70	0.70	0.65
Positive factored moment, k_2	0.63	0.57	0.52	0.50	0.35
Exterior negative factored moment, k_3	0.00	0.16	0.26	0.30	0.65

MANUAL EXAMPLE

Review the tabulated design for an intermediate flat plate floor, which is subjected to a superimposed factored live load of 200 psf on an 8-in. thick slab in a square panel: $\ell_1 = \ell_2 = 22'\text{-}0''$. Specified strengths of the concrete and reinforcing bars are f'_c = 4,000 psi (150 pcf) and f_y = 60,000 psi. The minimum columns shown are 30-in. square (exterior) and 26-in. square (interior).

End Span

From table on Page 9-27:

Column Strip Reinforcement:
- Top Ext = 16 - #4 bars (with 5 additional bars)
- Bottom = 12 - #5 bars
- Top 1st Int = 15 - #6 bars

Middle Strip Reinforcement:
- Bottom = 12 - #4 bars
- Top 1st Int = 11 - #4 bars

$q_u = q_{Du} + q_{Lu} = 1.2\,(100) + 200 = 320$ psf $= 0.320$ ksf

$\ell_n = 22 - (30/2 + 26/2)/12 = 19.667$ ft

$M_o = q_u \ell_2 (\ell_n)^2/8 = 0.320(22)(19.667)^2/8$
$= 340.376$ ft-kips

Factored Moments (ACI 13.6.3.3):
- Ext Col = 0.26 (340.376) = –88.498 ft-kips (tabulated: 88)
- Bottom = 0.52 (340.376) = +176.996 ft-kips (tabulated: 177)
- 1st Int Col = 0.70 (340.376) = –238.263 ft-kips (tabulated: 238)

Required Flexural Reinforcement in End Span:

$$\text{Required } A_s = \frac{1.7 f'_c bd}{2 f_y} - \frac{1}{2}\sqrt{\frac{2.89(f'_c bd)^2}{(f_y)^2} - \frac{6.8 f'_c b M_u}{\phi (f_y)^2}}$$

For f'_c = 4,000 psi, f_y = 60,000 psi, and ϕ = 0.90:

$A_s = 0.680\,d - \sqrt{0.462d^2 - 0.0252\,M_u}$

where M_u is in units of in.-kips/ft and A_s is in units of in.^{2}/ft

Slab thickness, h = 8 in.

$d = h$ – (concrete cover + d_b) = 8 – 1.5 = 6.5 in.

Exterior Column (Top Bars):

$M_u = 12\,(88.498)/11 = 96.543$ in.-kips/ft

$A_s = 0.680\,(6.5) - \sqrt{0.462\,(6.5)^2 - 0.0252\,(96.543)}$
$= 0.286$ in.^{2}/ft

$A_{s(total)} = 0.286\,(11) = 3.146$ in.^{2}

All reinforcement in column strip = 3.146 in.^{2} (tabulated: 16 - #4 bars; A_s = 3.20 in.^{2})

Verify section is tension-controlled so that $\phi = 0.90$:
From Page 5-4 with f'_c = 4,000 psi and f_y = 60,000 psi, max $\rho = 0.0181$ for $\varepsilon_t = 0.005$.

Actual $\rho = A_s/bd = \dfrac{3.20}{11(12)(6.5)} = 0.0037 < \rho_{max}$; $\phi = 0.90$

Bottom Bars:

Column strip $M_u = 0.60\ (176.996) = 106.198$ ft-kips

$M_u = 12\ (106.198)/11 = 115.852$ in.-kips/ft

$A_s = 0.680(6.5) - \sqrt{0.462(6.5)^2 - 0.0252(115.852)}$

$= 0.346$ in.^{2}/ft

$A_{s(total)} = 0.346(11) = 3.806$ in.^{2}

(tabulated: 12 - #5 bars; $A_s = 3.72$ in.^{2})

Actual $\rho = \dfrac{A_s}{bd} = \dfrac{3.72}{11(12)(6.5)} = 0.0043 < \rho_{max}$; $\phi = 0.90$

Middle strip $M_u = 0.40\ (176.996) = 70.798$ ft-kips

$M_u = 12(70.798)/11 = 77.234$ in.-kips/ft

$A_s = 0.680(6.5) - \sqrt{0.462(6.5)^2 - 0.0252(77.234)}$

$= 0.228$ in.^{2}/ft

$A_{s(total)} = 0.228(11) = 2.508$ in.^{2}

(tabulated: 12 - #4 bars; $A_s = 2.40$ in.^{2})

Actual $\rho = \dfrac{A_s}{bd} = \dfrac{2.40}{11(12)(6.5)} = 0.0028 < \rho_{max}$; $\phi = 0.90$

First Interior Column (Top Bars):

Column strip $M_u = 0.75\ (238.263) = 178.697$ ft-kips

$M_u = 12(178.697)/11 = 194.942$ in.-kips/ft

$A_s = 0.680(6.5) - \sqrt{0.462(6.5)^2 - 0.0252(194.942)}$

$= 0.598$ in.^{2}/ft

$A_{s(total)} = 0.598(11) = 6.578$ in.^{2}

(tabulated: 15 - #6 bars; $A_s = 6.60$ in.^{2})

Actual $\rho = \dfrac{A_s}{bd} = \dfrac{6.60}{11(12)(6.5)} = 0.0077 < \rho_{max}$; $\phi = 0.90$

Middle strip $M_u = (1–0.75)(238.263) = 59.566$ ft-kips

$M_u = 12(59.566)/11 = 64.981$ in.-kips/ft

$A_s = 0.680(6.5) - \sqrt{0.462(6.5)^2 - 0.0252(64.981)}$

$= 0.191$ in.^{2}/ft

$A_{s(total)} = 0.191(11) = 2.101$ in.^{2}

(tabulated: 11 - #4 bars; $A_s = 2.20$ in.^{2})

Actual $\rho = \dfrac{A_s}{bd} = \dfrac{2.20}{11(12)(6.5)} = 0.0026 < \rho_{max}$; $\phi = 0.90$

Shear Constants at Exterior Column (ACI R11.11.7.2):

$b_1 = 30 + 6.5/2 = 33.25$ in.

$b_2 = 30 + 6.5 = 36.5$ in.

$A_c = (2 \times 33.25 + 36.5)\ 6.5 = 669.5$ in.^{2}

$C_{AB} = (33.25)^2(6.5/669.5) = 10.734$ in.

$C_{CD} = 33.25 - 10.734 = 22.516$ in.

$$J = \frac{b_1 d^3}{6} + \frac{2d\,(C_{AB}^3 + C_{CD}^3)}{3} + b_2 d\, C_{AB}^2$$

$$J = \frac{33.25(6.5)^3}{6} + \frac{2(6.5)(10.734^3 + 22.516^3)}{3} + 36.5(6.5)(10.734)^2$$

$= 1{,}522 + 54{,}824 + 27{,}336$

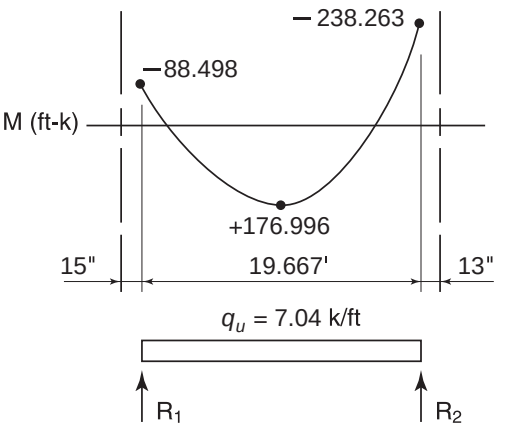
$= 83{,}682$ in.^{4}

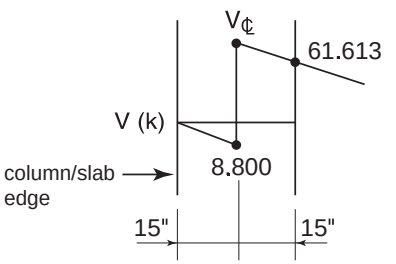
Factored Moments and Shears at Column Centerline

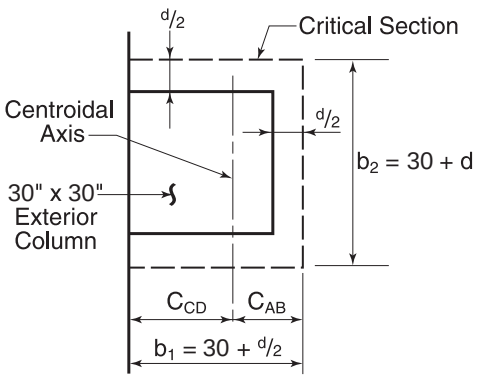
$$R_1 = \frac{7.04(19.667)}{2} - \frac{(238.263 - 88.498)}{19.667}$$

$= 69.228 - 7.615 = 61.613$ kips

$R_2 = 69.228 + 7.615 = 76.843$ kips







$V_{ext} = 61.613 + 7.04\ (30)/12 = 79.213$ kips

Unbalanced moment transferred by shear is $0.3M_o$ (ACI 13.6.3.6).

$M_{unb} = 0.3\ (340.376) = 102.113$ ft kips

$\gamma_f = 1/(1 + (2/3)\sqrt{b_1/b_2})$

$= 1/(1 + (2/3)\sqrt{33.25/36.5}) = 0.611$

$\gamma_v = 1 - \gamma_f = 1 - 0.611 = 0.389$

Maximum shear stress, v_u:

$$v_u = \frac{V_{ext}}{A_c} + \frac{\gamma_v M_{unb} C_{AB}}{J}$$

$$= \frac{79.213}{669.5} + \frac{0.389(102.113 \times 12)(10.734)}{83{,}682}$$

$= 0.118 + 0.061 = 0.179$ ksi

$b_o = 2b_1 + b_2 = 2(33.25) + 36.5 = 103.0$ in.

For square columns:

$v_c = (\alpha_s d/b_o + 2)\sqrt{f'_c} \le 4\sqrt{f'_c}$

$= [(30)(6.5)/103.0 + 2]\sqrt{f'_c} = 3.893\sqrt{f'_c} < 4\sqrt{f'_c}$

$\phi v_c = 0.75(3.893)\sqrt{4000}/1000 = 0.185$ ksi

$v_u < \phi v_c$, Okay

Determine the Number of Extra Bars Required in Column Strip at Exterior Column:

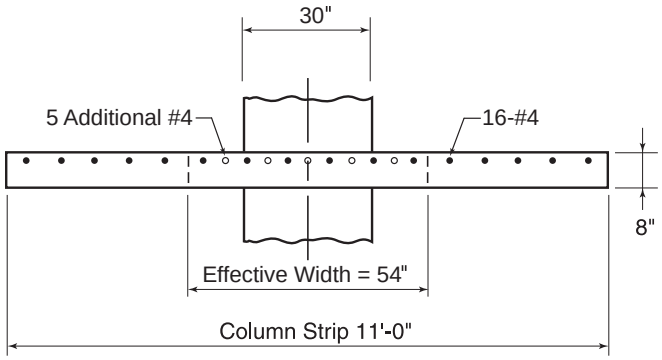
$M_{unb} = 88.498$ ft-kips

$M_u = \gamma_f M_{unb}$

$= 0.611(88.498) = 54.072$ ft-kips

"Effective Width" $= 30 + 1.5\ (8)2 = 54$ in.

Bar Layout:



Bar spacing $= 11 \times 12/16 = 8.25$ in.

Try 5 additional bars (as per tabulated design on Page 9-27) for a total of 11-#4 bars in "effective width"

$A_s = 2.20$ in.^{2} for 11-#4 bars

$a = A_s f_y/(0.85 f'_c b) = 2.20(60)/(0.85)(4)(54)$

$= 0.719$ in.

$\phi M_n = \phi A_s f_y (d - a/2)$

$= 0.90(2.20)(60)(6.5 - \frac{0.719}{2})/12$

$= 60.791$ ft-kips

$\phi M_n > \gamma_f M_{unb}$, Okay

Actual $\rho = \frac{A_s}{bd} = \frac{2.20}{54(6.5)} = 0.0063 < \rho_{max}$; $\phi = 0.90$

Interior Span

From table on Page 9-27:

Column Strip Reinforcement:
Bottom = 13-#4 bars
Top = 11-#7 bars
Middle Strip Reinforcement:
Bottom = 10-#4 bars
Top = 11-#4 bars

$q_u = 0.320$ ksf

$\ell_n = 22 - (26)/12 = 19.833$ ft

$M_o = 0.320(22)(19.833)^2/8 = 346.146$ ft-kips

Factored Moments (ACI 13.6.3.2):
Bottom $= 0.35(346.146) = 121.151$ ft-kips
Top $= 0.65(346.146) = 224.994$ ft-kips

Required Flexural Reinforcement:
$d = 6.5$ in.

Bottom Bars:
Column Strip: $M_u = 0.60(121.151)$
$= 72.691$ ft-kips

$M_u = 12(72.691)/11 = 79.299$ in.-kips/ft

$A_s = 0.680(6.5) - \sqrt{0.462(6.5)^2 - 0.0252(79.299)}$

$= 0.232$ in.^{2}/ft

$A_{s(total)} = 0.232(11) = 2.552$ in.^{2}

(tabulated: 13-#4 bars; $A_s = 2.60$ in.^{2})

Actual $\rho = \frac{A_s}{bd} = \frac{2.60}{11(12)(6.5)} = 0.0030 < \rho_{max}$;
$\phi = 0.90$

Middle Strip: $M_u = 0.40(121.151) = 48.460$ ft-kips

$M_u = 12(48.460)/11 = 52.866$ in.-kips/ft

$A_s = 0.680(6.5) - \sqrt{0.462(6.5)^2 - 0.0252(52.866)}$

$= 0.155$ in.^{2}/ft

$A_{s(total)} = 0.155(11) = 1.705$ in.^{2}

(tabulated: 10-#4 bars; $A_s = 2.00$ in.^{2})

Min $A_s = 0.0018\ bh = 0.0018\ (11 \times 12)(8)$

$= 1.90$ in.^{2}

Top Bars:

Column Strip: $M_u = 0.75(224.994) = 168.746$ ft-kips

$M_u = 12(168.746)/11 = 184.087$ in.-kips/ft

$A_s = 0.680(6.5) - \sqrt{0.462(6.5)^2 - 0.0252(184.087)}$

$= 0.563$ in.^{2}/ft

$A_{s(total)} = 0.563(11) = 6.193$ in.^{2}

(tabulated: 11-#7 bars; $A_s = 6.60$ in.^{2})

Actual $\rho = \dfrac{A_s}{bd} = \dfrac{6.60}{11(12)(6.5)} = 0.0077 < \rho_{max}$;

$\phi = 0.90$

Middle Strip: $M_u = 0.25\ (224.994) = 56.249$ ft-kips

$M_u = 12(56.249)/11 = 61.363$ in.-kips/ft

$A_s = 0.680(6.5) - \sqrt{0.462(6.5)^2 - 0.0252(61.363)}$

$= 0.181$ in.^{2}/ft

$A_{s(total)} = 0.181(11) = 1.991$ in.^{2}

(tabulated: 11-#4 bars; $A_s = 2.20$ in.^{2})

By inspection, actual $\rho < \rho_{max}$; $\phi = 0.90$

Shear Constants:

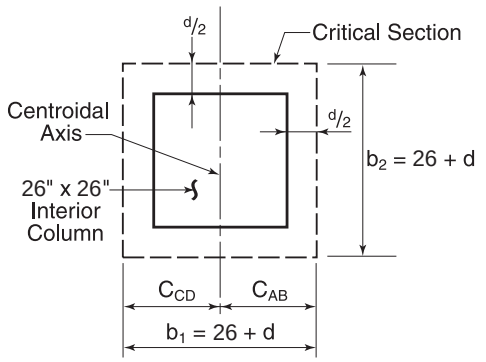
$b_1 = b_2 = 26 + 6.5 = 32.5$ in.

$A_c = 4\ (32.5)\ 6.5 = 845.0$ in.^{2}

$C_{AB} = C_{CD} = 32.5/2 = 16.25$ in.

$$J = \frac{b_1 d^3}{6} + \frac{d(b_1)^3}{6} + \frac{d(b_1)^3}{2} = \frac{d\,b_1}{6}\,(d^2 + 4\,b_1^2)$$

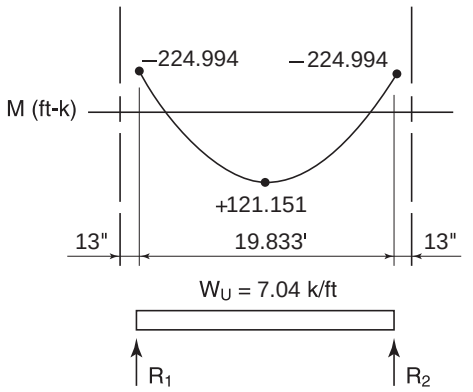
$$J = \frac{6.5\,(32.5)}{6}\,(6.5^2 + 4\,(32.5)^2) = 150{,}243 \text{ in.}^4$$



Factored Moments and Shears at Column Centerline:

$$R_1 = R_2 = 76.843 + \frac{7.04(19.833)}{2} + \frac{7.04(26)}{12}$$

$= 76.843 + 69.812 + 15.253 = 161.908$ kips



$M_{int} = 0.07\ [(q_{Du} + 0.5\ q_{Lu})\ \ell_2\ (\ell_n)^2 - q'_{Du}\ \ell'_2\ (\ell'_n)^2]$... (ACI Eq. 13-4)

Where q'_{Du}, ℓ'_2 and ℓ'_n refer to the shorter span

$M_{int} = 0.07\ [(0.120 + 0.100)(22)(19.833)^2$

$- 0.120\ (22)\ (19.833)^2]$

$= 0.07\,[1{,}903.804 - 1{,}038.438] = 60.576$ ft-kips

Maximum Shear Stress:

$b_o = 4b_1 = 4\,(32.5) = 130.0$ in.

$V_{int} = 161.908$ kips,

$M_{int} = 60.576$ ft-kips (i.e., full load on one side, dead load only on other side)

With moment, $V = q_u\ \ell/2 + q_{Du}\ \ell/2$

$= 7.04(22)/2 + 2.64(22)/2 = 106.480$ kips

$\gamma_f = 1/(1 + (2/3)\sqrt{b_1/b_2}) = 0.600$

$\gamma_v = 1 - \gamma_f = 0.400$

$$v_u = \frac{V}{A_c} + \frac{\gamma_v MC_{AB}}{J}$$

$$v_u = \frac{106.480}{845.0} + \frac{0.400\,(12 \times 60.576)\,16.25}{150{,}243}$$

$= 0.126 + 0.032 = 0.158$ ksi

$$v_c = (\alpha_s d/b_o + 2)\sqrt{f'_c} \le 4\sqrt{f'_c}$$

$$v_c = [40\ (6.5)/130.0 + 2]\sqrt{f'_c} \le 4\sqrt{f'_c}$$

$= 4\sqrt{f'_c}$

Use $v_c = 4\sqrt{f'_c}$

$\phi v_c = 0.75(4)\sqrt{4000}/1000 = 0.190$ ksi

$\phi v_c > v_u$, Okay

With $V_{int} = 161.908$ kips and $M = 0$ (i.e., full load on both sides of column)

$$v_u = \frac{V_{int}}{A_c} = \frac{161.908}{845.0} = 0.192 \text{ ksi}$$

$\phi v_c = 0.190$ ksi $\approx v_u$, Okay within 15%

CHAPTER 10 – TWO-WAY SOLID FLAT SLABS – SQUARE PANELS WITH DROPS

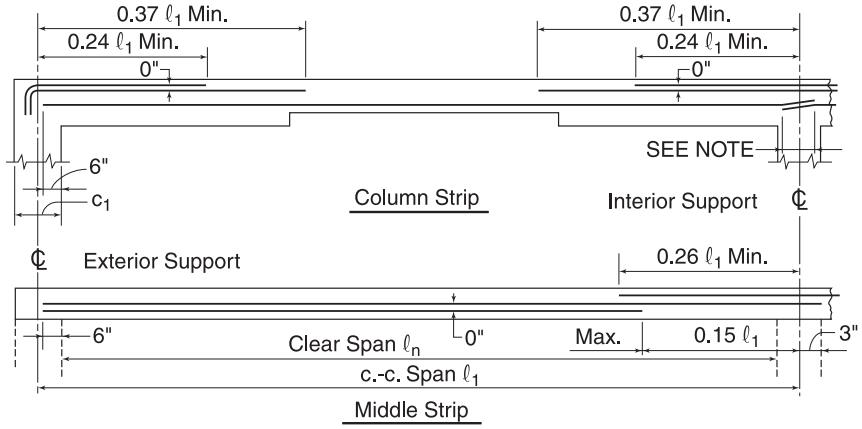
General. Two-way solid flat slabs under the provisions of Chapter 13 in the ACI 318 Building Code, include two-way reinforced slabs with capitals or brackets, drop panels, or both. The use of both capitals and drop panels, commonly used in the early years of two-way slab construction, is less favored today because of the higher formwork costs. In this Chapter, therefore, the tabulated designs presented are for two-way reinforced solid slabs with drop panels only. Capitals and brackets could also be used to provide the necessary critical shear section for transfer of heavy loads from slab to column, but the entire structural analysis and subsequent determination of the required flexural reinforcement would have to be revised. For the tabulated designs in this Chapter, required column sizes were kept to a maximum of $0.083\ell_n$ by increasing the depth of the drop panel for simpler forming and maximum economy for the negative reinforcement. Normal-weight concrete, with f'_c = 4,000 psi, and Grade 60 (f_y = 60,000 psi) reinforcing bars are used in the tabulated designs.

Flat Slab Advantages. The two-way flat slab designs in this Chapter are heavy duty designs, compared to the flat plates of Chapter 9. For the combination of heavier loads and longer spans, the flat slab with adjustment of drop panel depth will require less concrete and reinforcement and can utilize smaller columns than the flat plate for the slight added cost of forming drop panels. These designs are most efficient for square or nearly square panels. For parking garages, storage buildings, or industrial structures, the drop panel soffit is usually an acceptable exposed ceiling. For longer spans, the waffle flat slab (Chapter 11) will provide increased stiffness with less dead weight for overall economy. The choice of a two-way system, however, usually depends upon varying conditions of the structure and other requirements. For this reason, the tabulated designs in Chapters 9, 10, and 11 cover the practicable range of load and span combinations for each, overlapping somewhat.

Design Considerations. All design requirements for flat plates apply equally to flat slabs. Only the design considerations in addition to those described in Chapter 9, applicable because of the drop panels, will be presented in this Chapter.

Column Sizes. The minimum column size for the flat slab designs in this Chapter was taken as 12 inches square. Only square columns are included in the tabulated designs. The Code permits conversion of round columns to square columns of equivalent area for calculation of clear span, but actual round column cross-sections should be used for the critical shear sections. Minimum size interior and exterior columns are established separately.

Drop Panels. The tabulated designs presented begin with the minimum size drop panel (ACI 13.3.7) extending one-third of the span length from the column centerline and projecting 2-1/4 in. below for slab thicknesses of 9 in. or less; for slab thicknesses greater than 9 in., the projection below starts at 4-1/4 in. As shear on the critical section around the column becomes critical with heavier loads, column size is increased up to the maximum considered practical, $0.083\ell_n$. With further



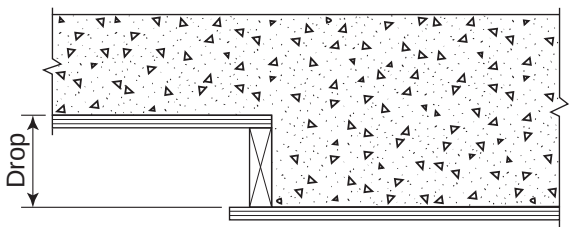
NOTE: Integrity reinforcement is required (ACI 13.3.8.5). All bottom bars in the column strip must be continuous or spliced over the support with Class B tension lap splices. At least two of the column strip bottom bars in each direction must pass within the column core and be anchored at exterior supports.

Figure 10-1 Recommeded Bar Details for Two-Way Solid Flat Slabs

increases in load, shear around the column ("punching" shear $v_c = \left(\frac{\alpha_s d}{b_o} + 2\right)\sqrt{f'_c}$ governed by ACI Eq. 11-32 or $v_c = 4\sqrt{f'_c}$ governed by ACI Eq. 11-33) becomes larger and drop panel depth is increased. Simultaneously, shear around the edge of the drop panel ("beam" shear, $v_c = 2\sqrt{f'_c}$) increases, and drop panel extension into the span is increased in one increment to forty percent of the span, when $v_u > v_c$. Note: The modification factor, λ, for lightweight concrete is excluded from the expressions for v_c, because the tabulated designs in this Chapter are based on normal-weight concrete.

Drop Panels—Projections Below Slab Based on Standard Nominal Lumber Dimensions.

Nominal Size	Actual Size (in.)	Add for Thickness of Plywood (in.)	Total Drop Panel Projection
2x	1 ½	¾	2 ¼
4x	3 ½	¾	4 ¼
6x	5 ½	¾	6 ¼



Control of Deflections (or Minimum Slab Thickness). Minimum thickness/span ratios were observed in preparation of the tabulated designs so that extremely complex deflection calculations in routine designs can be avoided. See Table 10-1, "Minimum Thickness of Two-Way Slabs," for which no deflection calculations are required (ACI 9.5.3).

Flexural Reinforcement. Flexural reinforcement has been selected with the limitations of maximum $\rho < 0.75\rho_b$ and maximum spacing $s \le 2h$, based on overall slab thickness, h (ACI 13.3.2). Bar sizes have been selected for the area of steel required so that the spacing of bars is not less than 3 inches: nor greater than the maximum permitted. For top reinforcement, CRSI recommends a minimum of #4 bars spaced at 12 inches on center for rigidity under construction for traffic. The tabulated reinforcing steel weight per square foot is based on the bar lengths shown in Fig. 10-1. The bar lengths suggested in Fig. 10-1 as standard details are applicable to ratios of adjoining spans up to 1.50 under uniform load. "Integrity reinforcement" is required by ACI 318 (ACI 13.3.8.5). The tabulated reinforcing steel weights do not include "integrity reinforcement."

Table 10-1 Minimum Thickness, *h*, of Two-Way Slabs*

(Expressed as fraction of longer clear span, ℓ_n)

1. Slabs without Interior Beams or with Interior Beams with $\alpha_{fm} \le 0.2$

   a. Flat Plates+ (no drop panels) Min. h = 5 inches
   Interior panels . . . . . $\ell_n/33$
   Exterior panels, no edge beams. . . . . $\ell_n/33$
   Exterior panels, with edge beams*** . . . . $\ell_n/33$

   b. Flat Slab+ (with drop panels) Min. h = 4 inches
   Interior panels . . . . . $\ell_n/36$
   Exterior panels, no edge beams. . . . . $\ell_n/33$
   Exterior panels, with edge beams*** . . . . $\ell_n/36$

2. Slabs with Interior Beams with $\alpha_{fm} > 0.2$**

   a. $\alpha_{fm} \le 2.0$ Min. h = 5 inches

   $h = \left(\frac{1.1}{36 + 5\beta(\alpha_{fm} - 0.2)}\right)\ell_n$ ACI Equation 9-12 with f_y = 60,000 psi

   b. $\alpha_{fm} > 2.0$ Min. h = 3.5 inches

   $h = \left(\frac{1.1}{36 + 9\beta}\right)\ell_n$ ACI Equation 9-13 with f_y = 60,000 psi

where β = ratio of clear spans in long to short direction

Minimum h expressions for different values of α_{fm} and β are as follows:

	Minimum h for different β					
α_{fm}	1.0	1.2	1.4	1.6	1.8	2.0
0.3	$\ell_n/33.2$	$\ell_n/33.3$	$\ell_n/33.4$	$\ell_n/33.5$	$\ell_n/33.5$	$\ell_n/33.6$
0.4	$\ell_n/33.6$	$\ell_n/33.8$	$\ell_n/34.0$	$\ell_n/34.2$	$\ell_n/34.4$	$\ell_n/34.5$
0.6	$\ell_n/34.5$	$\ell_n/34.9$	$\ell_n/35.3$	$\ell_n/35.6$	$\ell_n/36.02$	$\ell_n/36.4$
0.8	$\ell_n/35.5$	$\ell_n/36.0$	$\ell_n/36.5$	$\ell_n/37.1$	$\ell_n/37.6$	$\ell_n/38.2$
1.0	$\ell_n/36.4$	$\ell_n/37.1$	$\ell_n/37.8$	$\ell_n/38.5$	$\ell_n/39.3$	$\ell_n/40.0$
1.2	$\ell_n/37.3$	$\ell_n/38.2$	$\ell_n/39.1$	$\ell_n/40.0$	$\ell_n/40.9$	$\ell_n/41.8$
1.4	$\ell_n/38.2$	$\ell_n/39.3$	$\ell_n/40.4$	$\ell_n/41.5$	$\ell_n/42.5$	$\ell_n/43.6$
1.6	$\ell_n/39.1$	$\ell_n/40.4$	$\ell_n/41.6$	$\ell_n/42.9$	$\ell_n/44.2$	$\ell_n/45.5$
1.8	$\ell_n/40.0$	$\ell_n/41.5$	$\ell_n/42.9$	$\ell_n/44.4$	$\ell_n/45.8$	$\ell_n/47.3$
2.0	$\ell_n/40.9$	$\ell_n/42.5$	$\ell_n/44.2$	$\ell_n/45.8$	$\ell_n/47.5$	$\ell_n/49.1$
>2.0	$\ell_n/40.9$	$\ell_n/42.5$	$\ell_n/44.2$	$\ell_n/45.8$	$\ell_n/47.5$	$\ell_n/49.1$

* Minimum thickness unless deflection is computed, and is within maximim allowable computed deflection (ACI 9.5.3). Grade 60 reinforcing bars assumed.

** For exterior panel, α_f for edge beams not less than 0.8. Otherwise, minimum h must be increased at least 10 percent.

\+ Ratio of long to short span not greater than 2.

*** Slabs with beams along exterior edges. Value of α_f for edge beams not less than 0.8.

USE OF FLAT SLAB TABULATED DESIGNS

Direct Applications Within Dimensional Limitations of Tables

These limitations are:

1. Square column sizes as tabulated
2. Square panels
3. Minimum three panels continuous
4. Equal spans
5. Edge of slab flush with outer face of edge column
6. Live load $\leq 2 \times$ dead load (unfactored loads)
7. Concrete in slab, f'_c = 4,000 psi: normal-weight, w = 150 pcf
8. No edge beams
9. Uniformly distributed gravity loads only

Example 1. ***Preliminary Selection.*** Compare alternate designs to make a preliminary selection of a flat slab intermediate floor with square panels 20 feet center-to-center of columns; the superimposed factored load is 400 psf.

Slab Thickness	Drop Panel	Min Square Column $c_1 = c_2$		Concrete c.f. per s.f.	Reinforcing Steel	
		Edge	Interior		Edge Panel	Interior Panel
8″	6¼″x 6′-8″	18″	20″	0.725	3.24 psf	2.78 psf
8½″	4¼″x 6′-8″	18″	20″	0.748	3.06 psf	2.71 psf
9″	4¼″x 6′-8″	19″	20″	0.789	3.03 psf	2.68 psf

No meaningful reduction in the required amount of reinforcing steel is gained by increasing the slab thickness beyond 8 inches. Concrete quantities, of course, increase. Column and drop panel sizes are essentially the same. Use the 8-inch slab design.

For direct applications within the limitations of the tabulated designs, the tabulated reinforcement can be transferred directly from the tables to the design drawings. Concentration of top reinforcement over edge columns may be achieved by closer spacing, up to 50 percent of the column strip top bars, within the center third of the width of the column strip. Note that one special detail must be developed for the top bars at flush corner columns to ensure that a critical section cannot develop diagonal to the grid. Concentration of reinforcement over the corner column is achieved by addition of bars, top and bottom, in each direction, within the width of the column.

Preliminary Estimates

Preliminary estimates of reinforcing steel and concrete quantities for various structural systems are often required to make a selection. The tabulated designs in this Handbook permit rapid estimates of reinforcing steel and concrete quantities for various systems to support a required load.

Adjustment of Tabulated Designs to Project Conditions

In practice, the usual variations from the limitations of the tabulated designs will occur in one of the following areas:

Variations *within* limitations of the Direct Design Method:

1. Non-square panels where $\ell_2/\ell_1 > 2.0$
2. Non-equal consecutive spans where $\ell'_1/\ell_1 < 1.50$
3. Cantilevers
4. Use of edge beams

Variation *outside* limitations of the Direct Design Method:

5. Entire superimposed load is a movable type of live load (warehouse, storage, etc.) and the service live load, $L >$ two times the service dead load, D, i.e., $L > 2D$.
6. Consecutive spans or non-square panels exceed the limits of 1.50 or 2.0, respectively.

Variations of the first three types listed are illustrated by the examples in Chapter 9 for flat plate design and will require similar treatment for flat slab design.

MANUAL EXAMPLE

To illustrate the design assumptions, applicable Code requirements, and the procedures used in the preparation of the flat slab tabulated designs, one of the designs will be reviewed with detailed calculations performed.This review will assist or guide any user wishing to extend the scope of the designs to longer spans or heavier loads.

Review the tabulated design (Page 10-18) for an intermediate flat slab floor with square panels; $\ell_1 = \ell_2 = 20'\text{-}0''$; the floor has an 8-in. slab plus 4.25-in. drop panels; factored live load = 300 psf; normal-weight concrete, f'_c = 4,000 psi; Grade 60 reinforcing bars, f_y = 60,000 psi. The spans and the dimensions of the columns and drop panels are shown in Fig. 10-2.

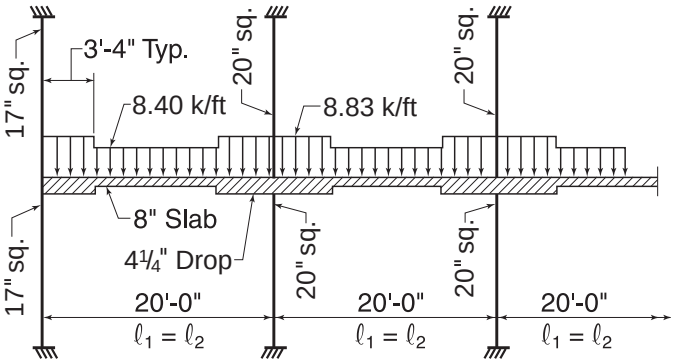


Figure 10-2 Factored Loads and Dimensions of Frame

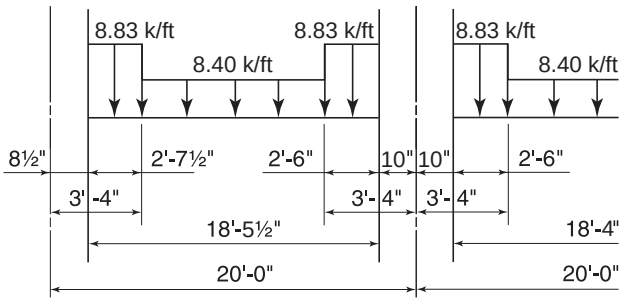
Ratio of Service Live Load to Service Dead Load:

$$L/D = \frac{300/1.6}{100} = 1.875 < 2.0, \text{ Okay}$$

Factored Loads

q_{Du} = 1.2(8/12)(150) = 120 psf = 0.120 ksf (slab)
q_{Du} = 1.2(4.25/12)(150) = 64 psf
= 0.064 ksf (drop panel)
Total q_{Du} = 20(0.120) + (20/3) (0.064)
= 2.40 + 0.43 = 2.83 kips/ft (floor)
q_{Lu} = 20(0.300) = 6.00 kips/ft (floor)
q_u = 2.83 + 6.00 = 8.83 kips/ft (drop panel)
q_u = 2.40 + 6.00 = 8.40 kips/ft (slab)

End Span



Total Static Moment, M_o :
M_o = 8.40(18.458)^2/8 = 357.746 ft-kips (slab)
M_o = (8.83 – 8.40)(2.6)^2/2
= 1.453 ft-kips (drop panel)
M_o = 357.746 + 1.453 = 359.199 ft-kips

Panel Moments (ACI 13.6.3.3)

Exterior Column (Negative Factored Moment)
M_u = 0.26(359.199) = 93.392 ft-kips
Column strip resists 100% of M_u; 1.00(93.392)
= 93.392 ft-kips
(tabulated: 93.4) (ACI 13.6.4.2)
Bottom (Positive Factored Moment)
M_u = 0.52(359.199) = 186.783 ft-kips
(tabulated: 186.8)
Column strip resists 60% of M_u; 0.60(186.783)
= 112.070 ft-kips (ACI 13.6.4.4)
Middle strip resists 40% of M_u; 0.40(186.783)
= 74.713 ft-kips
First Interior Column (Negative Factored Moment)
M_u = 0.70(359.199) = 251.439 ft-kips
(tabulated: 251.4)
Column strip resists 75% of M_u; 0.75(251.439)
= 188.579 ft-kips (ACI 13.6.4.1)
Middle strip resists 25% of M_u; 0.25(251.439)
= 62.860 ft-kips

Flexural Reinforcement

For f'_c = 4,000 psi and f_y = 60,000 psi:
Required $A_s = 0.680\, d - \sqrt{0.462d^2 - 0.0252\, M_u}$
where M_u is in units of in.-kips/ft and A_s is in units of in.^{2}/ft. See Chapter 5.
At support, h = 8 + 4.25 = 12.25 in.
d = 12.25 – 0.75 (concrete cover) – 0.75 (avg. d_b)
= 10.75 in. (drop panel)
Slab thickness, h = 8 in.
d = 8 – 0.75 (concrete cover) – 0.75 (avg. d_b)
= 6.5 in. (slab)

Exterior Column

Column Strip Top Bars (d = 10.75 in.)

M_u = 12(93.392)/10 = 112.070 in.-kips/ft

$A_s = 0.680(10.75) - \sqrt{0.462(10.75)^2 - 0.0252(112.070)}$

$= 0.199$ in.^{2}/ft

Total $A_s = 0.199(10) = 1.99$ in.^{2}

(tabulated: 10–#4 bars; $A_s = 2.00$ in.^{2})

Column Strip Bottom Bars (d = 6.5 in.)

M_u = 12(112.070)/10 = 134.484 in.-kips/ft

$A_s = 0.680(6.5) - \sqrt{0.462(6.5)^2 - 0.0252(134.484)}$

$= 0.404$ in.^{2}/ft

Total $A_s = 0.404(10) = 4.04$ in.^{2}

(tabulated: 13–#5 bars; $A_s = 4.03$ in.^{2})

Middle Strip Bottom Bars (d = 6.5 in.)

M_u = 12(74.713)/10 = 89.656 in.-kips/ft

$A_s = 0.680(6.5) - \sqrt{0.462(6.5)^2 - 0.0252(89.656)}$

$= 0.265$ in.^{2}/ft

Total $A_s = 0.265(10) = 2.65$ in.^{2}

(tabulated: 13–#4 bars ; $A_s = 2.60$ in.^{2})

First Interior Column

Column Strip Top Bars (d = 10.75 in.)

M_u = 12(188.579)/10 = 226.295 in.-kips/ft

$A_s = 0.680(10.75) - \sqrt{0.462(10.75)^2 - 0.0252(226.295)}$

$= 0.404$ in.^{2}/ft

Total $A_s = 0.404(10) = 4.04$ in.^{2}

(tabulated: 13–#5 bars; $A_s = 4.03$ in.^{2})

Middle Strip Top Bars (d = 6.5 in.)

M_u = 12(62.860)/10 = 75.432 in.-kips/ft

$A_s = 0.680(6.5) - \sqrt{0.462(6.5)^2 - 0.0252(75.432)}$

$= 0.223$ in.^{2}/ft

Total $A_s = 0.223(10) = 2.23$ in.^{2}

(tabulated: 11–#4 bars; $A_s = 2.22$ in.^{2})

Summary – Flexural Reinforcement – End Span

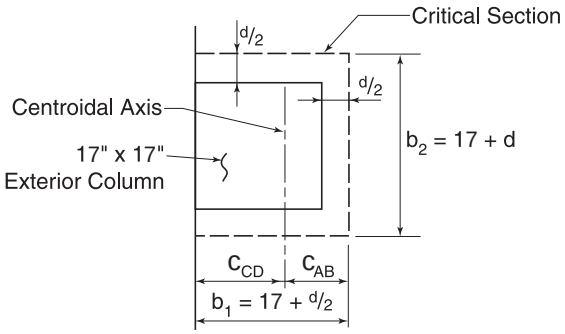
Location	Size-No.	A_s	d	b	$\rho = A_s/bd$	Max. ρ	ϕ = 0.90	Min. A_s
Column Strip								
Exterior Top Bars	10-#4	2.00	10.75	120	0.0016	0.0181	Yes	2.65
Bottom Bars	13-#5	4.03	6.50	120	0.0052	0.0181	Yes	1.73
Interior Top Bars	13-#5	4.03	10.75	120	0.0031	0.0181	Yes	2.65
Middle Strip								
Bottom Bars	13-#4	2.60	6.50	120	0.0033	0.0181	Yes	1.73
Interior Top Bars	11-#4	2.22	6.50	120	0.0029	0.0181	Yes	1.73

Min. $A_s = 0.0018bh$ { For h = 12.25 in., Min. $A_s = 0.0018(120)(12.25) = 2.65$ in.^{2} ; For h = 8.00 in., Min. $A_s = 0.0018(120)(8.00) = 1.73$ in.^{2}

For transfer of unbalanced moment by flexure, 3-#4 bars are required within effective width; hence, A_s in column strip is 2.60 in.^{2}, which is ≈ Min. A_s of 2.65 in.^{2}

With f'_c = 4,000 psi and f_y = 60,000 psi, Max. ρ = 0.0181 for ϵ_t = 0.005 (Page 5-4).

Shear Constants at Exterior Column (ACI R11.11.7.2):



b_1 = 17 + 10.75/2 = 22.38 in.

b_2 = 17 + 10.75 = 27.75 in.

b_o = 2(22.38) + 27.75 = 72.5 in.

A_c = 72.5(10.75) = 779.38 in.^{2}

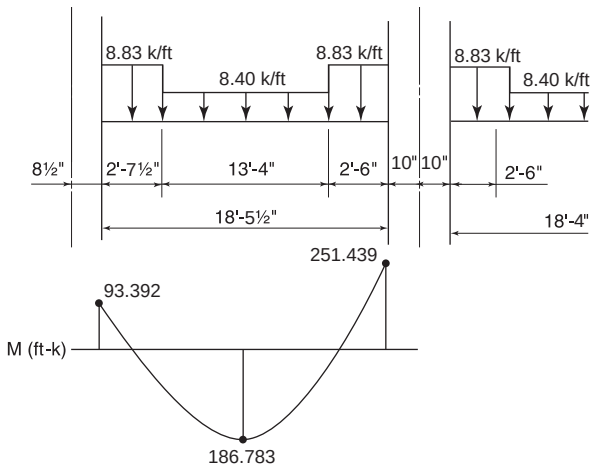
$c_{AB} = (22.38)^2 (10.75/779.38) = 6.91$ in.

c_{CD} = 22.38 – 6.91 = 15.47 in.

$J = 22.38(10.75)^3/6 + 2(10.75)(6.91^3 + 15.47^3)/3 + 27.75(10.75)(6.91)^2$

$= 4{,}634 + 28{,}898 + 14{,}244 = 47{,}776$ in.^{4}

Factored Moments and Shears at Face of Exterior Column



V_u (at ext col face) = 8.40(18.458)/2

+ (8.83 – 8.40)(5.125)/2

– (251.439 – 93.392)/18.458

= 77.524 + 1.102 – 8.562

= 70.064 kips

V_u (at C.L. ext col) = 70.064 + 8.83(8.5/12)

= 76.319 kips

V_{ext} = 70.064 + 8.83(17/12) = 82.573 kips

Shear Check at Exterior Column

$v_c = (\alpha_s d/b_o + 2)\sqrt{f'_c} \le 4\sqrt{f'_c}$

$v_c = (30 \times 10.75/72.5 + 2)\sqrt{f'_c} = 6.45\sqrt{f'_c}$

Use $v_c = 4\sqrt{f'_c}$

$\gamma_f = 1/[1 + (2/3)\sqrt{b_1/b_2}]$

$= 1/[1 + (2/3)\sqrt{22.38/27.75}] = 0.626$

(tabulated: 0.626)

$\gamma_v = 1 - \gamma_f = 1 - 0.626 = 0.374$

$v_u = V_{ext}/A_c + \gamma_v Mc_{AB}/J$

Where $M = 0.3M_o$ (ACI 13.6.3.6)

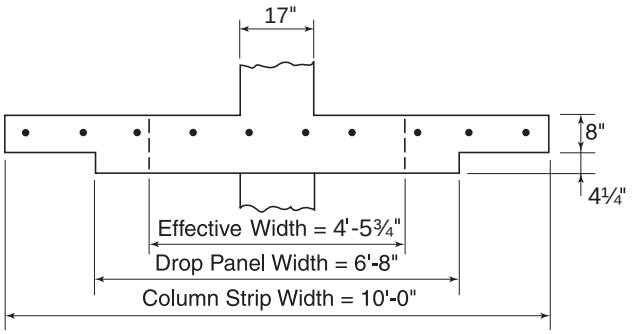
$= 0.3(359.199) = 107.760$ ft-kips

$v_u = 82.573/779.38 + 0.374(107.760 \times 12 \times 6.91)/47{,}776$

$v_u = 0.106 + 0.070 = 0.176$ ksi or 176 psi

$\phi v_c = 0.75\ (4)\sqrt{4000} = 190$ psi $> v_u$, Okay

Determine the Number of Extra Bars Required in Column Strip at Exterior Column



$\gamma_f M_u = 0.626(93.392) = 58.463$ ft-kips

"Effective Width" = 17 + 1.5(12.25)2 = 53.75 in.

10–#4 bars are required to resist exterior $-M_u$ in column strip

Note: 4 bars are located where d = 6.5 in. and 6 bars are located where d = 10.75 in.

Try 3 additional bars (as per tabulated design) for a total of 7 bars in the effective width

$A_s = 7(0.20) = 1.40$ in.^{2} for 7–#4 bars

$a = A_s f_y/0.85 f'_c\ b = 1.40(60)/0.85(4)(54)$

$= 0.458$ in.

$$\phi M_n = \phi A_s f_y \left(d - \frac{a}{2}\right)$$

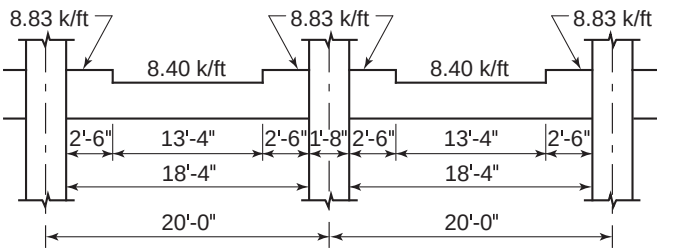
$\phi M_n = 0.90(1.40)(60)(10.75 - 0.458/2)/12$

$\phi M_n = 66.282$ ft-kips $> \gamma_f M_u$, Okay

Actual $\rho = \dfrac{A_s}{bd} = \dfrac{1.40}{(53.75)(10.75)}$

$\rho = 0.0024 < \rho_{max}$; $\phi = 0.90$

Interior Span



Total Static Moment, M_o:

$M_o = 8.40(18.333)^2/8 = 352.904$ ft-kips (slab)

$M_o = (8.83 - 8.40)(2.5)^2/2$

$= 1.344$ ft-kips (drop panel)

$M_o = 352.904 + 1.344 = 354.248$ ft-kips

Panel Moments

Bottom (Positive Factored Moment)

$M_u = 0.35(354.248) = 123.987$ ft-kips

Column strip resists 60% of M_u; 0.60(123.987)

$= 74.392$ ft-kips (ACI 13.6.4.4)

Middle strip resists 40% of M_u; 0.40(123.987)

$= 49.595$ ft-kips

Top (Negative Factored Moment)

$M_u = 0.65(354.248) = 230.261$ ft-kips

Column strip resists 75% of M_u; 0.75(230.261)

$= 172.696$ ft-kips (ACI 13.6.4.1)

Middle strip resists 25% of M_u; 0.25(230.261)

$= 57.565$ ft-kips

Flexural Reinforcement

Column Strip Bottom Bars (d = 6.5 in.)

$M_u = 12(74.392)/10 = 89.270$ in.-kips/ft

$A_s = 0.680(6.5) - \sqrt{0.462(6.5)^2 - 0.0252(89.270)}$

$= 0.264$ in.^{2}/ft

Total $A_s = 0.264(10) = 2.64$ in.^{2}

(tabulated: 13–#4 bars; $A_s = 2.60$ in.^{2})

Middle Strip Bottom Bars (d = 6.5 in.)

$M_u = 12(49.595)/10 = 59.514$ in.-kips/ft

$A_s = 0.680(6.5) - \sqrt{0.462(6.5)^2 - 0.0252(59.514)}$

$= 0.175$ in.^{2}/ft

Total $A_s = 0.175(10) = 1.75$ in.^{2}

(tabulated: 9–#4 bars ; $A_s = 1.80$ in.^{2})

Column Strip Top Bars (d = 10.75 in.)

$M_u = 12(172.696)/10 = 207.235$ in.-kips/ft

$A_s = 0.680(10.75) - \sqrt{0.462(10.75)^2 - 0.0252(207.235)}$

$= 0.370$ in.^{2}/ft

Total $A_s = 0.370(10) = 3.70$ in.^{2}

(tabulated: 12–#5 bars; $A_s = 3.72$ in.^{2})

Middle Strip Top Bars (d = 6.5 in.)

$M_u = 12(57.565)/10 = 69.078$ in.-kips/ft

$A_s = 0.680(6.5) - \sqrt{0.462(6.5)^2 - 0.0252(69.078)}$

$= 0.204$ in.^{2}/ft

Total $A_s = 0.204(10) = 2.04$ in.^{2}

(tabulated: 10–#4 bars; $A_s = 2.00$ in.^{2})

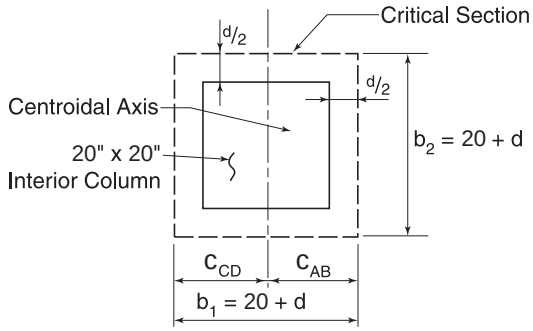
Summary – Flexural Reinforcement – Interior Span

Location	Size-No.	A_s	d	b	$\rho = A_s/bd$	Max. ρ	$\phi = 0.90$	Min. A_s
Column Strip								
Top Bars	12-#5	3.72	10.75	120	0.0029	0.0181	Yes	2.65
Bottom Bars	13-#4	2.60	6.50	120	0.0033	0.0181	Yes	1.73
Middle Strip								
Top Bars	10-#4	2.00	6.50	120	0.0026	0.0181	Yes	1.73
Bottom Bars	9-#4	1.80	6.50	120	0.0023	0.0181	Yes	1.73

Min. $A_s = 0.0018bh$ { For h = 12.25 in., Min. A_s = 0.0018(120)(12.25) = 2.65 in.^{2} ; For h = 8.00 in., Min. A_s = 0.0018(120)(8.00) = 1.73 in.^{2}

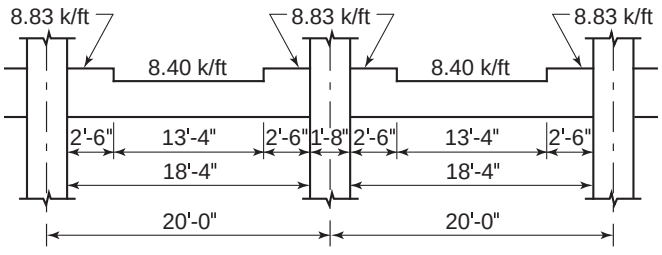
With f'_c = 4,000 psi and f_y = 60,000 psi, Max. ρ = 0.0181 for ϵ_t = 0.005 (Page 5-4).

Shear Constants



$b_1 = b_2 = 20 + 10.75 = 30.75$ in.
$b_o = 4(30.75) = 123$ in.
$A_c = 123(10.75) = 1{,}322$ in.^{2}
$c_{AB} = c_{CD} = 30.75/2 = 15.38$ in.
$J = d b_1 (d^2 + 4b_1^2)/6$
$= 10.75(30.75)((10.75)^2 + 4(30.75)^2)/6$
$= 214{,}745$ in.^{4}

Factored Moments and Shears at Centerline of Interior Column



Maximum factored shear, V_u, and no unbalanced moment (full factored load on adjacent spans)

$V_u = 8.40(18.33) + (8.83 - 8.40)(2.5 + 2.5 + 20/12)$
$V_u = 153.972 + 2.867 = 156.839$ kips

For checking shear due to combined effects (i.e., direct shear plus transfer of unbalanced moment) the factored moment:

$M_{int} = 0.07\,[(q_{Du} + 0.5q_{Lu})\,\ell_2\,\ell_n^2 - q'_{Du}\,\ell'_2(\ell'_n)^2]$ . . . . (ACI Eq. 13-7)

where q'_{Du}, ℓ'_2 and ℓ'_n refer to the shorter span

$M_{int} = 0.07[(0.120 + 0.150)(20)(18.333)^2 - 0.120(20)(18.333)^2]$
$= 0.07[1{,}814.934 - 806.637] = 70.581$ ft-kips

With factored moment M_{int} = 70.581 ft-kips, the factored shear is:

$V_u = q_u\,\ell/2 + q_{Du}\,\ell/2$ (i.e., full factored load on one span and factored dead load only on other span)
$V_u = 8.40(20)/2 + (8.83 - 8.40)(2.5) + 2.40(20)/2 + 0.43(2.5)$
$= 84.0 + 1.075 + 24.0 + 1.075 = 110.150$ kips

Shear Check at Interior Column

$v_c = (\alpha_s\, d/b_o + 2)\sqrt{f'_c} \le 4\sqrt{f'_c}$
$v_c = (40 \times 10.75/123 + 2)\sqrt{f'_c} = 5.496\sqrt{f'_c}$
Use $v_c = 4\sqrt{f'_c}$

For factored shear V_{int} = 156.839 kips and no unbalanced moment

$v_u = V_u/A_c$
$v_u = 156.839/1{,}322 = 0.119$ ksi or 119 psi
$\phi v_c = 0.75(4)\sqrt{4000} = 190$ psi > v_u, Okay

For factored shear V_u = 110.150 kips and factored moment M_{int} = 70.581 ft-kips

$\gamma_f = 1/[1 + (2/3)\sqrt{b_1/b_2}]$
$= 1/[1 + (2/3)\sqrt{30.75/30.75}] = 0.60$
$\gamma_v = 1 - \gamma_f = 1 - 0.60 = 0.40$
$v_u = V_u/A_c + \gamma_v\, M_{int}\, c_{AB}/J$
$= 110.150/1{,}322 + 0.40(70.581 \times 12)(15.38)/(214{,}745)$
$v_u = 0.083 + 0.024 = 0.107$ ksi or 107 psi
$\phi v_c = 190$ psi > v_u, Okay

Check one-way shear at distance d beyond edge of drop panel. The section for checking one-way shear is located 2.500 + 6.5/12 = 3.042 ft from the face of the left or right column.

$V_u = (18.333/2 - 3.042)(8.40) = 51.446$ kips
$\phi V_n = \phi 2\sqrt{f'_c}\, b_w d$
$= 0.75(2)\sqrt{4000}(20 \times 12)(6.5)/1{,}000$
$= 147.994$ kips
$\phi V_n > V_u$, Okay

CHAPTER 11 – WAFFLE FLAT SLABS — SQUARE PANELS

GENERAL CONSIDERATIONS

Description. Waffle flat slabs, as illustrated in Fig. 11-1, consist of rows of concrete joists at right angles to each other with solid heads at the columns. The joists are commonly formed by using standard square "dome" forms of the sizes described in the following section on "Standard Dome Data," and the domes are omitted around the columns to form the "solid heads." The top slab over the dome forms is usually reinforced with welded wire reinforcement and can be of various thicknesses. Standard dome forms provide waffle panels in modules of either 2 feet, 2.5 feet, or 3 feet. Depending on required size of solid head, there will either be a joist or a row of domes on the column centerline according to whether the number of joists framing into the solid head is odd or even. The column size selected must be of sufficient size to keep factored shear in the solid head within design strength values or supplemental shear capacity must be provided. Alternatives are headed shear stud reinforcement (ACI 11.11.5), shear reinforcement consisting of bars or wires and single-leg or multiple-leg stirrups (ACI 11.11.3), or structural steel shearheads (ACI 11.11.4).

For design purposes, waffle slabs are considered as flat slabs, with the solid heads acting as drop panels. Joists in each direction are divided into two bands or strips—a column strip including all joists that frame into the solid head, and a middle strip filling in between consecutive column strips. A second set of similar strips of joists runs at right angles to the first. Each joist rib typically contains two bottom bars. Straight bars are provided over column centerlines for negative factored moment.

Stirrups can be used in the joist ribs, as necessary.

Advantages of Waffle Flat Slabs. Waffle flat slabs allow a considerable reduction in dead load as compared to conventional solid flat slabs. See Table 11-1. Thus, it is particularly advantageous where the use of longer spans and/or heavier loads are desired without the use of deepened drop panels or support beams. The geometrical shape formed by the joist ribs is often architecturally desirable, as is the resulting flush soffit. Also, waffle flat slabs provide for relatively easy accommodation of electrical and mechanical utilities. See Fig.11-1.

Standard Dome Data. The square "dome" forms used for the waffle slabs designs tabulated in this Handbook are designed to meet the recommendations of the "Concrete Joist Construction — Recommended Industry Practice", CRSI *Manual of Standard Practice* for domes up to 20-inch depths. The standard domes are:

(1) 30-inch × 30-inch square domes with 3-inch flanges; from which 6-inch wide joist ribs at 36-inch centers are formed: These are available in standard depths of 8, 10, 12, 14, 16 and 20 inches.

(2) 24-inch × 24-inch square domes with 3-inch flanges; from which 6-inch wide joist ribs at 30-inch centers are formed. These are available in standard depths of 8, 10, 12, 14, 16 and 20 inches.

(3) 19-inch × 19-inch square domes with 2½-inch flanges, from which 5-inch wide joist ribs at 24-inch centers are formed. These are available in standard depths of 8, 10, 12 , 14 and 16 inches.

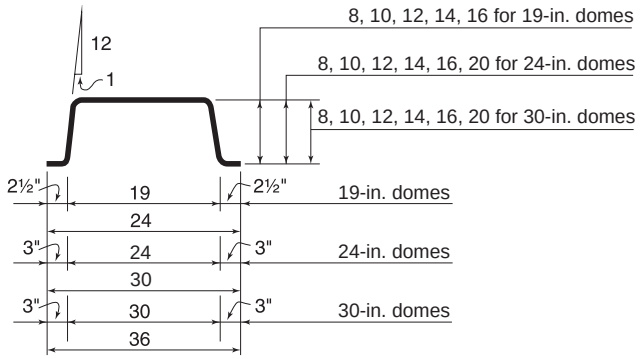

Table 11-1 Standard Dome Dimensions and Other Data

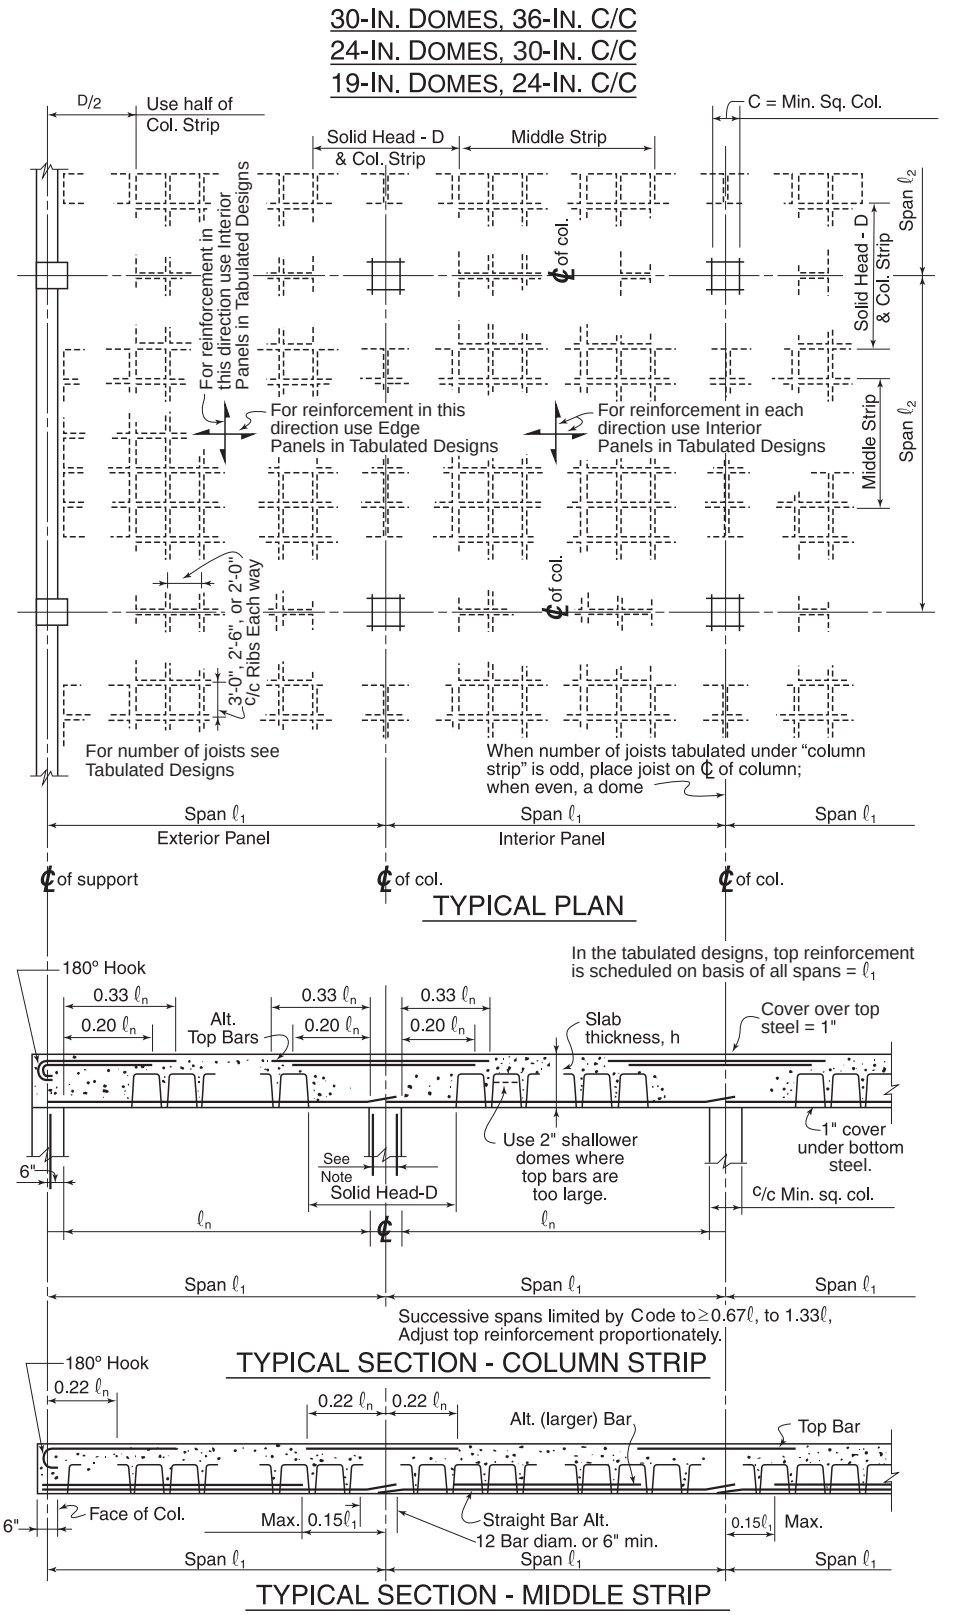
Dome Size	Dome Depth (in.)	Volume of Dome (ft^3)	Floor Dead Load (psf) per Slab Thickness			
			3 in.	4 in.	4.5 in.	5 in.
19-in.	8	1.56	79	92	98	104
	10	1.91	91	103	110	116
	12	2.25	103	116	122	128
	14	2.58	116	128	134	141
	16	2.90	129	141	148	154
24-in.	8	2.52	77	89	96	102
	10	3.11	88	100	107	113
	12	3.68	99	112	118	124
	14	4.23	111	124	130	136
	16	4.76	123	136	142	148
	20	5.78	149	161	167	174
30-in.	8	3.98	71	84	90	96
	10	4.92	80	93	99	105
	12	5.84	90	103	109	115
	14	6.74	100	113	119	125
	16	7.61	111	123	129	136
	20	9.30	132	145	151	157



NOTE: Integrity reinforcement is required (ACI 13.3.8.5). All bottom bars in the column strip must be continuous or spliced over the support with Class B tension lap splices. At least two of the column strip bottom bars in each direction must pass within the column core and be anchored at exterior supports. For other end support conditions; see Figs. 11-2 and 11-3.

Figure 11-1 Reinforcing Bar Details and Layout of Joists and Domes

DESIGN CONSIDERATIONS IN WAFFLE FLAT SLAB CONSTRUCTION

Economy. In order to maintain maximum economy, it is important that a uniform depth and the same size dome forms be used throughout a floor system, or structure, if possible. Construction costs will also be reduced by selecting a floor system that has sufficient design shear strength to resist the required factored loads without using joist stirrups and with the smallest size solid head. The amount of flexural reinforcement and, if necessary, the top slab thickness can be changed to provide the required design moment strengths for different spans, areas, or floors of a structure.

Alternate Dome Layouts.

1. For layouts that do not meet the standard 2-foot, 2.5-foot, or 3-foot modules, it is preferable that the required additional width be obtained by increasing the width of the ribs framing into the solid column head. If the off-modular amount is small (less than 6 inches), the forms for one rib only can be spaced farther apart to make up the necessary bay width. Special filler size domes are also available on a limited basis to fill out column spacings that are not multiples of 3 feet, 2.5 feet, or 2 feet. Sketching the spacings for a typical panel, correlated with the column spacings, should be a part of the early planning.

2. In some designs, large size top bars are required. To obtain sufficient concrete cover, shallower standard domes may be used around the solid head.

Service Load Deflections. The tabulated designs of waffle flat slabs are based on strength (safety) requirements for superimposed factored loads ranging from 50 psf to 500 psf. All waffle flat slab tabulated designs are within a maximum span-depth ratio of 33 for exterior panels and 36 for interior panels (ACI 9.5.3.2). In this range, the Code does not require deflection computations. Waffle flat slabs, due to their lighter dead weight, provide considerably more depth and stiffness than economically comparable solid flat slabs. Where conditions of the structure impose limitations on acceptable deflection, the deflection should be estimated to determine if it is acceptable for the conditions of the structure under consideration. For relatively high ratios of permanent load to total load, calculated creep deflections may be reduced by extending the top straight bars sufficiently to act in compression.

An example of calculating approximate deflections for waffle flat slabs is given in Chapter 6. The term "t_e", (average equivalent thickness) represents the thickness of a solid flat plate having the computed equivalent stiffness of the waffle slab; "t_e" can be computed as the average of the gross moments of inertia of the solid head area and ribbed area. Since all solid head areas tabulated are within one rib module of $L/3$, the area of solid head can be taken as 1/9 the total bay area. Assume the solid head area twice as effective, as it is in the area of maximum moment. "t_e" required for the deflection formula can then be calculated from:

$$(t_e)^3 = \frac{1}{10}\left[\, 2(t_s)^3 + 8(t_r)^3 \right]$$

where:

t_s = thickness of the solid head

t_r = equivalent thickness of ribbed area

Values of t_e for various standard dome sizes and top slab thicknesses calculated as above, are tabulated in Tables 11-2 through 11-4.

Tables 11-2 through 11-4 also give the maximum span and load for various rib and top slab combinations within the limit of $\Delta = L/360$. The maximum span and load values based on the gross moment of inertia, I_g, were calculated using the equation for slab deflection given in Chapter 6, which is in terms of $wL^4/(t_e)^3$.

Code deflection limits are also expressed as fractions of the span, L.

It is, therefore, possible to solve for a limiting unit load, w, at any given L/t_e ratio which results in a deflection of $L/360$.

Setting Δ_{max} = the deflection limit $= \dfrac{L}{360} = \dfrac{kqL^4}{E_c(t_e)^3}$

where $k = 0.1028$ (see Chapter 6)

$w = 144q$, load in psf

q = load in psi

$E_c = 3.5 \times 10^6$ psi

and solving for w_{max}:

$$w_{max} = \frac{(3.5 \times 10^6)(144)}{(0.1028)(L/t_e)^3(360)}$$

$$w_{max} = 13.6 \times 10^6\ (t_e/L)^3 \text{ for } \Delta = L/360$$

Direct comparison by inspection of the required service live load versus the maximum load for $L/360$ or $L/180$ deflection limits should aid in the selection of tabulated designs meeting deflection criteria applicable to the structure under consideration. If creep deflection must be limited to $L/360$, the sum of service live load plus two times the estimated long-term service loads should be used for this comparison. (Creep factor = 2.0, ACI 9.5.2.5) If detailed estimates are required, such as for camber, for construction loads, or when E_c is lower, the tabulated equivalent thicknesses will save computations.

For heavily reinforced waffle slabs, more refined calculations are required. The Code requires using the transformed (cracked) section moment of inertia and the gross section moment of inertia to determine the *effective* moment of inertia. Usually $I_e \approx I_g$ except in ribbed areas in which case the transformed section moment of inertia of the ribbed area must be combined with the gross moment of inertia to determine equivalent thickness.

Caution: All deflection serviceability criteria are based upon *service*, not *factored* loads. Actual loads are to be used except in computing long-term deflection where a creep factor, *not a load factor*, is required for long-term loads.

The effective moment of inertia, I_e, is computed as:

$I_e = (M_{cr}/M_a)^3 I_g + [1 - (M_{cr}/M_a)^3] I_{cr}$ . . (ACI Eq. 9-8)

in which:

Cracking moment, $M_{cr} = f_r I_g / y_t$

Modulus of rupture, $f_r = 7.5\sqrt{f'_c}$ for normal-weight concrete

Actual moment, $M_a =$ maximum moment of service load $(D + L)$

and $y_t =$ distance from centroid to extreme tension fiber of gross section.

Maximum Load (psf) for Immediate (Elastic) Deflection of *L*/360**			504	457	416	379	346	318	292

* Based on gross moment of inertia.

** For long-term (creep) deflection limited to *L*/360, multiply the long-term loads, including the waffle slab weight, times 2; deduct from loads shown above. Result is maximum superimposed service live load.

Bar Spacing. For crack control in two-way slabs, the spacing of reinforcing bars is limited to 2*h* (ACI 13.3.2). This limit does not apply to waffle slabs (ACI Commentary R13.3.2). Spacing of top bars cannot exceed 5*h* nor 18 inches (ACI 7.12). In the tabulated designs, bar sizes have been selected for the area of steel required so that their spacing is not less than 3 inches nor greater than the maximum permitted.

CRSI recommends a minimum of #4 bars spaced at 12 inches on center for rigidity under construction traffic.

Openings. Outside the solid head in waffle flat slabs, small openings may be located anywhere through the thin top slab between joists. The space available in one such dome will usually accommodate most service openings for electrical, plumbing, etc., needs. The Code

requirement for total area of flexural reinforcement is maintained by the reinforcement in the joists. Larger openings must be treated as provided in the Code (ACI 13.4).

Edge Conditions. Joists parallel to the discontinuous edge may be selected from the tabulated designs for interior panels as these joists are continuous. For the design strips perpendicular to the discontinuous edge, joists may be selected from the tabulated designs for exterior panels, provided that the exterior edge frames integrally into columns as shown in the tabulated designs.

For corner panels, joists in the design strips in both directions may be selected from the tabulated designs for end panels under the same edge conditions as for other discontinuous joists. See Fig. 11-2.

Maximum Load (psf) for Immediate (Elastic) Deflection of *L*/360**			504	457	416	379	346	318	292

* Based on gross moment of inertia.

** For long-term (creep) deflection limited to *L*/360, multiply the long-term loads, including the waffle slab weight, times 2; deduct from loads shown above. Result is maximum superimposed service live load.

Cantilever Edges. Architectural or construction requirements frequently make cantilevered edges necessary. "Balanced" negative edge moments under full uniform load are often advantageous for: (1) many architectural exterior conditions require that exterior columns be set back from light outer cladding of other materials; and (2) often continuous "eyebrow" canopies are used to block direct sunlight. The variation in loads, spans, and thicknesses encountered in such cantilevered edge conditions precludes any standard detail or design recommendation. Reinforcement for these negative cantilever moments can be combined with top reinforcement from exterior panel strips and will usually improve performance of the waffle flat slab. Gravity loads on the exterior columns are nearly balanced, reducing gravity moments in the columns and positive moments and deflections in the exterior panel. See Fig. 11-3.

The simplest detail for full-depth waffle slab cantilevered edges is to extend top bars, anchored at the edge with end hooks, and add top bars similarly anchored to meet area of steel required for negative factored moment. For cantilever spans long enough to involve deflection limits, bottom bars may be extended as compression reinforcement to reduce creep deflections, and to ensure development of at least two bars past the edge column centerline.

Stirrups. When factored shears exceed the relatively low values prescribed for the concrete shear strength, stirrups are required as indicated in the tabulated designs. The notation used to describe the stirrups required for rib depths to 20 inches is explained in the notes on Page 11-24. Regarding the last character in the stirrup notation, a "one" indicates that single vertical bars properly anchored at spacing < 0.5*d* are necessary in the joist ribs from the face of the solid head area to the first cross rib. This distance is equal to the length of one dome form. For convenience in placing, stirrups are assembled in units. When the last character in the stirrup notation is a "two," it indicates that stirrups are required in the joist ribs to the second cross rib from the face of the solid head. Sizes and spacings of stirrup legs are: #3 bars spaced at 4 inches (see Fig. 11-4) for joist ribs 8 inches and 10 inches deep; and #4 bars spaced at 6 inches for ribs 12, 14, and 16 inches deep. For the 20-inch rib depths, the size, spacing, and arrangement of the stirrups must be specified.

DESCRIPTION OF TABULATED DESIGNS

Scope. Tabulated designs are presented for waffle flat slab floor construction using the standard 19-inch × 19-inch, 24-inch × 24-inch, and 30-inch × 30-inch domes as described on Page 11-1. For each of the standard dome depths, tabulated designs are given for 3-inch, 4-inch, 4.5-inch, and 5-inch top slabs. Spans range from 15 feet to 57 feet for 30-inch domes, 15 feet to 47.5 feet for 24-inch domes, and 14 feet to 38 feet for 19-inch domes, for superimposed factored loads up to the maximum (shear) strength, for both typical square interior panels and for strips perpendicular to the wall in square edge panels that are built integrally with exterior columns.

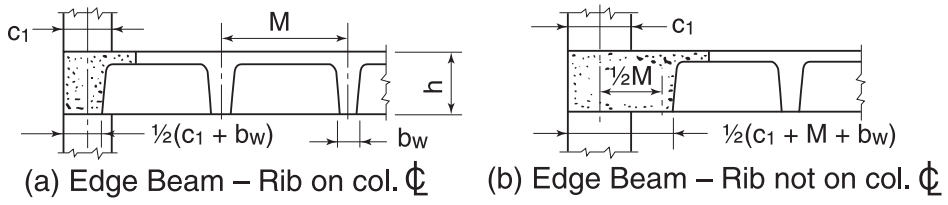

Figure 11-2 Edge Conditions for Tabulated Designs

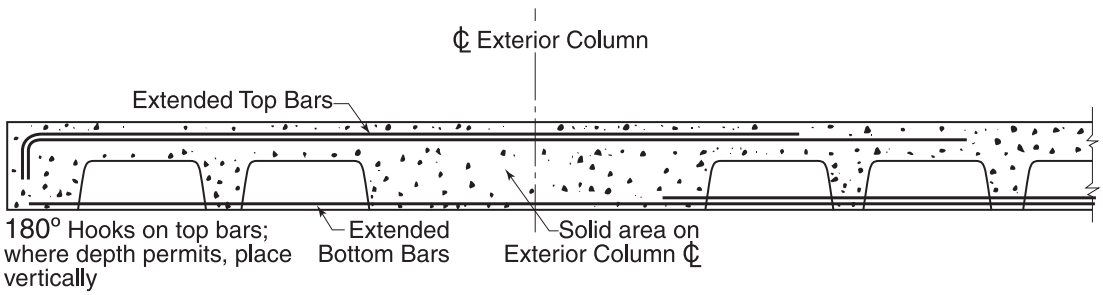

Figure 11-3 Cantilever Edge Reinforcement

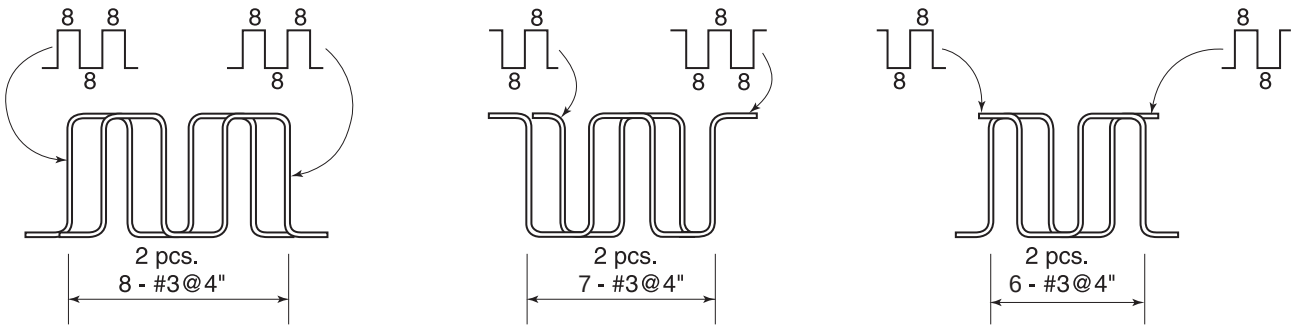
The tabulated designs are based on the use of square columns, with the exterior columns located flush with the edge. Total slab thickness, size of solid head (drop panel), minimum size of column, reinforcing bars required, and average weight of reinforcing steel and volume of concrete per square foot of floor area are given in the tabulated designs. The Code requires "integrity reinforcement" (ACI 13.3.8.5). The tabulated values of reinforcing steel weight do not include integrity reinforcement. Under "Edge Panels," all total factored panel moments are given to serve as an aid in modifying the flush column design to any location of edge columns.

Organization. The tabulated designs are presented in three parts; first, 19-inch × 19-inch domes for a 24-inch module, then, 24-inch × 24-inch domes for a 30-inch module, and last, 30-inch × 30-inch domes for a 36-inch module. In each part, the 3-inch top slab designs are given first, followed by 4-inch, 4.5-inch, and 5-inch top slab designs, each in order of total depth, beginning with the shallowest.

Explanation. For a sample preliminary design and comparisons of material quantities for cost estimating, see Fig. 11-5. The data "Total Weight of Reinforcing Steel" (psf) and "Concrete" (cf/sf) are given for each separate tabulated design (one line across the page) for convenient plotting, as in Fig. 11-5. See Fig. 11-1 for the bar lengths and bending details, which are used as a basis for the tabulated weight of reinforcing steel. The tabulated design shows reinforcing bars in one direction. "Total Weight of Reinforcing Steel" includes identical bars both ways for square interior panels, and includes one set of interior bars, plus one set of edge panel bars, for the square edge panel. Integrity reinforcement is not included in the reinforcing steel quantity. Stirrups, shear reinforcement at columns, and any welded wire reinforcement used in the top slab are not included as these items are usually estimated separately. The concrete quantities are for the waffle slab and solid head only. They do not include concrete in columns or any added beams.

The tabulated designs give the "Square Column" side dimensions in inches which is the minimum size of support that will keep punching shear stress equal to or less than $4\sqrt{f'_c}$ (ACI 11.11.2.1, Eq. 11-33) and $(\alpha_s d/b_o + 2)\sqrt{f'_c}$ (ACI Eq. 11-32) for use without shear reinforcement. For moderate loads and spans, the column sizes tabulated are not excessive, but for heavier loads or longer spans, maximum column size was limited to $\ell/15$. These sizes, marked by an asterisk, "*", require



Alternate detail: Plain or deformed welded wire reinforcement "ladder style" stirrups. Size and spacing of vertical legs to provide equivalent areas to reinforcing bar stirrups. Welded wire reinforcement ladders must include two longitudinal anchor wires top and bottom. (ACI 12.13.2.4)

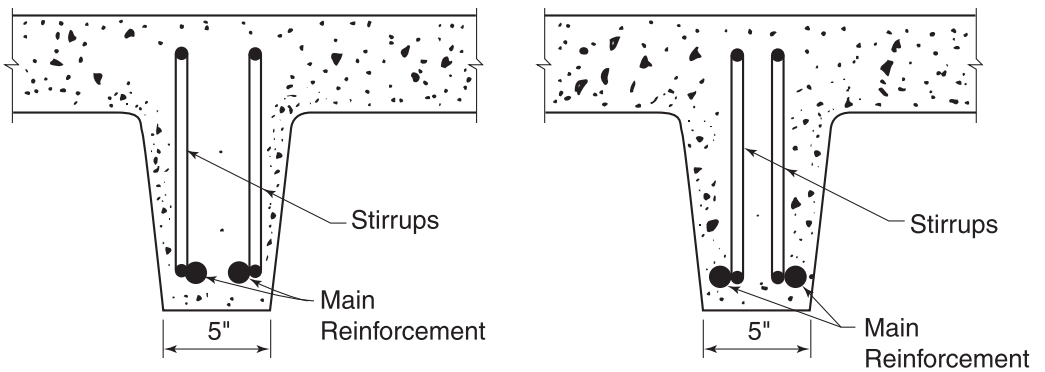


Figure 11-4 Typical Stirrups for Tabulated Designs (Minimum Width Rib Shown)

the use of headed shear stud reinforcement (ACI 11.11.5), or other types of shear reinforcement, or concrete caps or brackets to reduce column size. If equivalent stiffness round columns are used and caps are desirable, standard conical cap forms are available with diameters in multiples of 6 inches. Columns are shown square as they are usually more easily fitted into wall construction. See Fig. 11-6. If square shear caps are used, the minimum effective angle of slope with the horizontal is 45 degrees (ACI 13.1.2), and so the depth below the solid head should be equal or larger than the projection beyond the faces of the column on all sides.

The tabulated designs are for square panels only. For the design of rectangular panels (with the ℓ_1/ℓ_2 limitation of 2.0), the factored superimposed load values tabulated for the longer span may be used, and tabulated reinforcement adjusted in both directions. All loads tabulated are factored superimposed loads. "Factored superimposed load" consists of live load, floor finishes, partition allowance, and everything except the weight of the structural concrete, multiplied by the appropriate load factors.

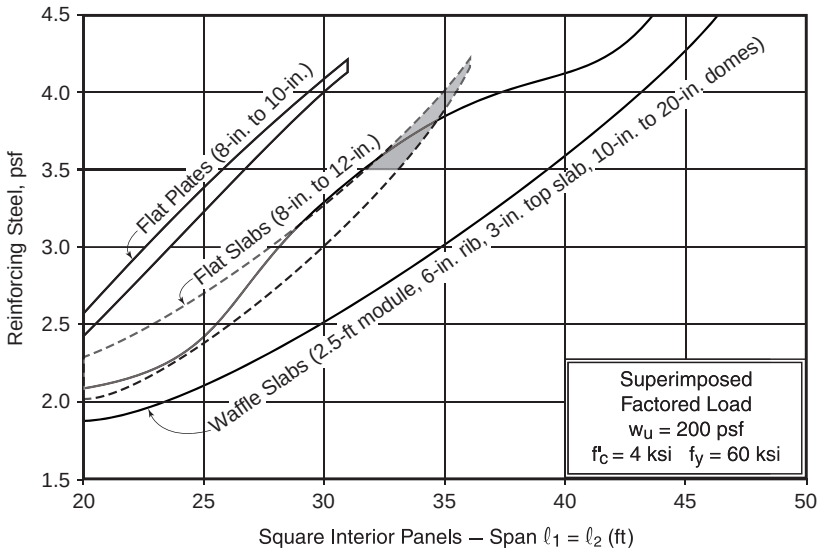

Figure 11-5 Preliminary Design and Material Quantity Estimates for Flat Plates, Flat Slabs, and Waffle Flat Slabs from Tabulated Designs

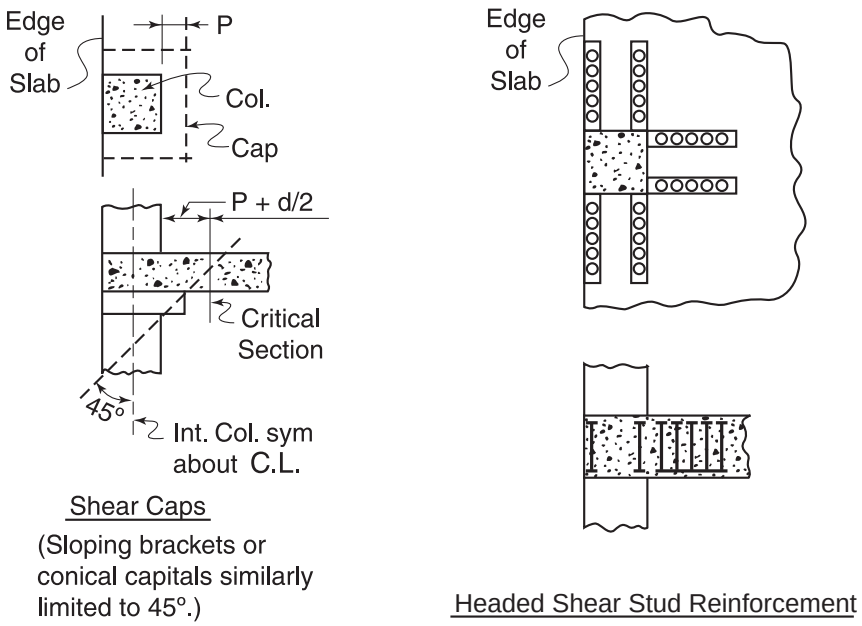

Figure 11-6 Alternate Punching Shear Designs at Columns Marked "*"

Dead weight of the waffle flat slab (based on 150 pounds per cubic foot) has been deducted. Strength-reduction factors, "ϕ-factors" (ACI 9.3), have been applied. Total load to be distributed to supporting columns, beams, and walls will consist of superimposed factored load, plus the factored dead load of the waffle slab itself (1.2 × actual weight).

BASIS OF TABULATED DESIGNS

General. All waffle flat slab tabulated designs presented in this Chapter are based on the "Strength Design" method and the "Direct Design Method" of analysis (ACI 13.6). Limitations of the Direct Design Method and the tabulated designs are: (1) at least three continuous panels in each direction, (2) ratio of length to width of panels not to exceed 2.0, (3) successive span lengths cannot vary more than 33 percent of the longer span, (4) ratio of live to dead (actual) load not to exceed two, and (5) uniformly distributed gravity loads only (ACI 13.6.1).

Design Assumptions. In applying the Direct Design Method, it is assumed that a waffle slab panel is composed of column strips and a middle strip, similar to those used in ordinary flat slab design. The column strip consists of the joist ribs and adjacent top slab framing directly into the solid head section. The remaining ribs and top slab comprise the middle strip of the panel. The solid head over columns is treated as if it were a drop panel in conventional flat slab construction. The individual ribs are designed as joists. Each rib contains two straight bottom bars. In the middle strips, one of the bottom bars, the larger if two sizes are used, is cut off and the other is extended, as shown in Fig. 11-1. Straight top bars are used and are generally of two lengths in the column strips to provide the negative moment reinforcement (ACI 13.3.8).

A layer of 6 × 6 – W3 × W3 welded wire reinforcement is assumed to be placed in the top slab over the domes in all cases.

The effective depth, *d*, of the waffle flat slab is computed on the basis of 1 inch of concrete cover for both the top and bottom reinforcement, plus an allowance of one bar diameter because the bars cross each other; thus, *d* equals the total depth minus 1.75 inches. For square panels, therefore, it is not necessary to specify the placing sequence as it is immaterial in which direction bars are at the greater depth as long as the design is based on the smaller effective depth.

The recommended reinforcing bar details shown in Fig. 11-1 conform to minimum lengths required by the Code (ACI 13.3.8). Based on practice, some minimum anchorages were increased to be practicable for usual conditions. For unusually high ratios of movable live load to dead-plus-fixed-live load, moving loads, concentrated loads, or openings, special analyses should be made and bar lengths increased as required. Integrity reinforcement has to be provided (ACI 13.3.8.5). If moment reversals are anticipated (due to moving live load or unfavorable ratios of adjacent spans), some bars should be continuous in both top and bottom. For waffle flat slabs with only two continuous spans, the amount, distribution, and lengths of reinforcing bars will require adjustment determined by a special analysis.

USE OF TABULATED DESIGNS

The first step is to select the module, 2-feet, 2.5-feet, or 3-feet, best suited to the span and depth within span ranges given in the *Scope* (Page 11-7). Requirements for fire resistance in the legally adopted building code or project requirements for embedded conduits may require the 5-inch top slab; if not, a thinner top slab will be slightly more economical. The next step is to enter the appropriate tabulated design with the center-to-center span of columns and factored superimposed loads. See Chapter 5 for load factors and load combinations.

For preliminary design and material quantity estimates, see Fig. 11-5.

For the same span and loads, end span positive factored moments and negative factored moment (at first interior column) are larger. The basic design can be selected from either the edge or interior panel tablulated designs, depending on which type predominates in the actual building layout. The preliminary selection of sizes should be adequate for the required superimposed factored load with minimum use of stirrups in the ribs or shear reinforcement at columns. If a special long span or heavy load condition exists in a small area of the total layout, the shear reinforcement may be used to advantage in this area to avoid increasing depth in the entire layout. The same size forms should be used throughout a building for maximum economy.

If the basic design is selected from the interior span (interior panel) tabulated design, the corresponding tabulated design of the end span (edge panel) should also be checked to ensure that the end span will provide the required strength.

The tabulated designs furnish pertinent design and estimating data, including the sizes and the number of

reinforcing bars, weight of reinforcing steel per square foot, and average quantity of concrete per square foot. If reinforcing bar detailing information for a particular tabulated design is desired, Fig. 11-1 should be useful.

Adaptation of Tabulated Designs to Non-Standard Situations. For tabulated designs requiring modification, necessary additional data are presented for convenience in making adjustments. Factored moments for the exterior panel are tabulated for use in adjusting designs requiring top slab thicknesses other than the standard thicknesses tabulated, concrete compressive strengths, f_c', other than 4,000 psi, or in deflection calculations.

See Chapters 9 and 10 for examples illustrating some of these adjustments. Chapter 9, "Flat Plates," presents the fundamental approach to "Direct Design" of two-way slabs under the ACI Building Code for the simplest application. Chapter 10, "Flat Slabs with Drop Panels," illustrates the additional computations required by the presence of the drop panels. This Chapter emphasizes solution of requirements to accommodate the two-way joists. To avoid duplication, the various design aids and explanations are not repeated in each Chapter. The three Chapters should be studied as a unit for full utilization of the tabulated designs, explanations for adjustment to project conditions, and use of the various design aids.

Other special conditions outside the range of the tabulated design include: (1) lateral load analysis on unbraced waffle slab-column frames and (2) rectanglar columns where ratio $c_1/c_2 = \beta_c > 2$. For two-way slabs that are required to resist moments due to lateral loads in frames not braced against side-sway, factored moments and required bar lengths must be determined by special analyses rather than those for gravity load alone (ACI 13.3.8.4). For rectangular columns where $\beta_c > 2$, or for square or rectangular columns where $\alpha_s d/b_o < 2$, the nominal shear strength of concrete, v_c, in two-way slabs is reduced, i.e., less than $4\sqrt{f_c'}$ (ACI 11.11.2).

For unbraced frames otherwise within limitations for the Direct Design Method (ACI 13.6), gravity load moments in the tabulated designs may be combined with lateral load moments from a separate analysis with suitable load factors applied (ACI 9.2).

TABULATED DESIGNS—EXAMPLES

The following examples will illustrate use of the tabulated designs.

Example 1. Select a tabulated design of a waffle flat slab floor system with center-to-center spans of columns $\ell_1 = \ell_2 = 30'\text{-}0''$ for a service live load of 100 psf plus ceiling and floor finish of 20 psf. Maximum column size preferred is 16-in. square. Normal-weight concrete with $f_c' = 4{,}000$ psi will be used with Grade 60 ($f_y = 60{,}000$ psi) reinforcing bars. A 3-in. thick top slab will satisfy fire rating requirements. Factored superimposed load $w_u = 1.2D + 1.6L = 1.2 \times 20 + 1.6 \times 100 = 184$ psf. Use 30 in. × 30 in. dome forms for a $3'\text{-}0''$ module.

From the tabulated designs on Page 11-84 for the span and dome size, select the 12 + 3 waffle flat slab with solid head $12'\text{-}6''$ square. Stirrups are required for a distance of one module to the first cross rib from the solid head. (Where depth is available, maximum economy is usually achieved with depth adequate to enable use of the solid head tabulated without stirrups.) The factored superimposed load = 200 psf > 184 psf, okay.

To complete the final design, see Page 11-84 for the reinforcement, minimum column sizes required, and average quantities of reinforcing steel and concrete per square foot. Minimum column sizes are: exterior 15 in.* square and interior 15 in.* square. Reinforcing steel: 3.07 pounds per square foot (psf), exterior panels; and 2.79 pounds per square foot (psf), interior panels. Concrete: 0.705 cubic feet per square foot (cf/sf).

Note that this design will provide a floor system with a total depth of 15 in. (which is a reasonable minimum) and the (square) column sizes are within the preliminary limit established of 16 in. square. To achieve these limits, however, shear reinforcement (*) is noted around the exterior and interior columns, and stirrups are required in the ribs around the drop head at interior columns.

Minimum size columns are part of the architectural requirements and so provisions for shear reinforcement are required. The last character in the stirrup notation, i.e., the "one" indicates that such stirrups extend from the face of the solid head to the first cross rib (36 in.). See Fig. 11-4 for details and note that the vertical legs of stirrups are #4 bars spaced at 6 in.

Providing a shear cap is one option for satisfying the two-way shear requirements ($v_u \le v_c$) at the exterior columns. Assume that it satisfies architectural requirements here. The asterisk (*) after minimum size square exterior column ($c_1 = c_2 = 15$ in.*) indicates that $4\sqrt{f_c'} < v_u \le 6\sqrt{f_c'}$.

Proportioning shear cap. A shear cap will stiffen the exterior column, very slightly increasing $-M_{ext}$. It will reduce clear span very slightly, reducing $-M_{ext}$. It will usually be within acceptable limits of accuracy to neglect these minor effects as though the increases were equal to the decreases since the shear cap will be proportioned to the next higher dimension in integral inch-units. A direct solution for the minimum size shear cap is difficult, but trial solutions with the benefit of the peripheral shear constants in Table 11-5 are relatively simple.

Total factored load = superimposed factored load
+ (1.2) (0.705 × 150)
= 184 + 127
w_u = 311 psf

Take (conservatively) $V_u = (0.311)(30 \times ½ \times 30) = 140$ kips

Try a shear cap projecting 11 in. (11-in. depth) which will add 11 in. to column dimensions. Use $c'_1 = c'_2 = 26$ in. The peripheral shear constraints, from Table 11-5, for $c'_1 = c'_2 = 26$ in. and $h = 15$ in., are:

$c_{AB} = 10.19$ in.; $A_c = 1{,}385$ in.^{2} and $J_c = 175{,}700$ in.^{4}

Read on Page 11-84: $M_{edge} = -254$ ft-kips; $M_{bot} = +611$ ft-kips and $M_{int} = -683$ ft-kips

$M_o = (254 + 683)/2 + 611 = 1{,}080$ ft-kips

Unbalanced gravity load moment transferred by shear = $0.3M_o$ (ACI 13.6.3.6).
$0.3M_o = 0.3(1{,}080) = 324$ ft-kips

Take shear transfer coefficient (conservatively), $\gamma_v = 0.40$ (ACI 11.11.7.1).

$$v_u = \frac{V_u}{A_c} + \frac{\gamma_v M c_{AB}}{J_c}$$

$$v_u = \frac{140{,}000}{1{,}385} + \frac{(0.40)(324)(12)(1{,}000)(10.19)}{(175{,}700)}$$

$v_u = 101 + 90 = 191$ psi

$\phi v_c = (0.75)(4)\sqrt{4{,}000}$

$\phi v_c = 190$ psi $\approx v_u$, okay

Nominal shear strength of concrete ($v_c = 4\sqrt{f'_c}$) is controlled by ACI Eq. 11-33, because in ACI Eq. 11-32, $(\alpha_s d/b_o + 2) = (30 \times 14)/109 + 2 = 5.85 > 4$.

An 11-in. deep shear cap projecting 11 in. from the column will be adequate. Note that the shear analysis was actually made for a square column head 26 × 26 in., whereas the face of the shear cap will be at $c_1 + 11$ in. = 26 in. deep and $c_2 + (2)(11) = 37$ in. wide. See Fig. 11-7.

Complete Example 1 by reading the required flexural reinforcement from the tabulated design on Page 11-84:

Edge panel

Strips parallel to edge same as interior panels.
Strips at right angles to edge,

Column strip
13-#5 plus 4-#5 in 60-in. effective width; Top bars at edge
1-#7, 1-#8 } Bottom bars per rib in 5 ribs
20-#6 Top bars at first interior column

Middle strip
No top bars required at edge (ACI 13.6.6.1)
2-#6 Bottom bars per rib in 5 ribs
14-#5 Top bars at first interior column centerline

Interior panels

Column strip – 18-#6 Top bars at other interior columns
2-#6 Bottom bars per rib in 5 ribs

Middle strip – 14-#5 Top bars on other column centerlines
2-#5 Bottom bars per rib in 5 ribs

Stirrups #4 bars spaced at 6 in. extending 36 in. in (20) ribs at all interior column solid heads.

Example 2. Select a waffle flat slab floor system with square panels and center-to-center spans of columns $\ell_1 = \ell_2 = 36'\text{-}0''$ for a superimposed factored load $w_u = 150$ psf.

In the tabulated designs on Page 11-84, read for $\ell_1 = \ell_2 = 36'\text{-}0''$ and $w_u = 150$ psf:

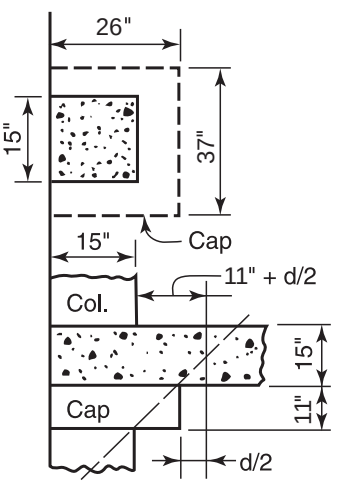

Figure 11-7 Shear Cap

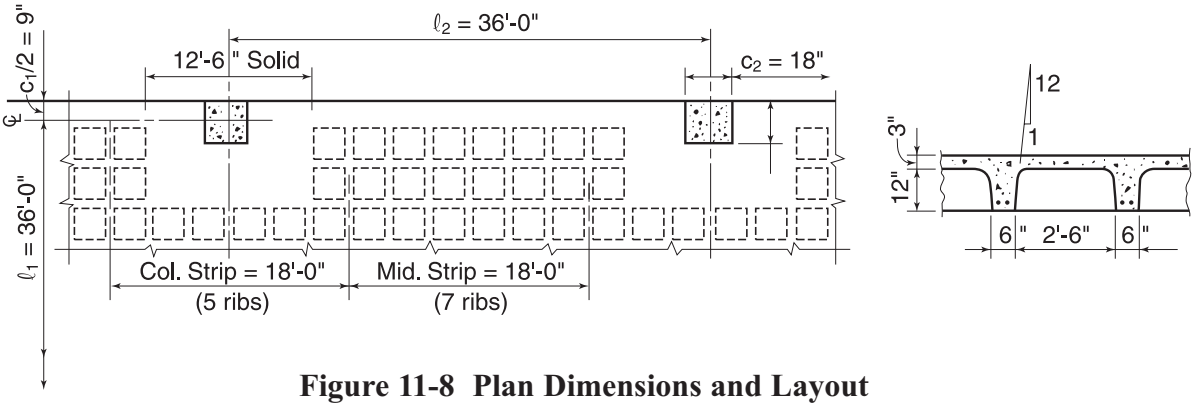

Figure 11-8 Plan Dimensions and Layout

12″ + 3″, 6-in. ribs @ 36 in. This design requires square exterior columns $c_1 = c_2 = 20$ in.*

Shear reinforcement is required at exterior columns. Interior columns are 18 in. square. Stirrups are required at interior columns. If these column dimensions are satisfactory, this design should suffice.

SPECIAL DETAILS

Examples 1 and 2 illustrate the various adjustments required for designs outside the conditions tabulated. For these and similar adjustments, the design aids (tables, curves, etc.) of this Chapter and Chapters 9 and 10 should reduce design time to a minimum.

Special details will have to be developed to complete the design of an actual project. It is impossible to tabulate designs for the variety of edge conditions which may be required. As noted, cantilever edges are structurally desirable and will simplify design. Minimum solid sections as flush depth edge beams are shown in Fig. 11-2. These beams must be investigated for torsion, as well as flexure and vertical shear. Whenever architectural requirements preclude cantilever edges and permit spandrel edge beams projecting below the slab, the use of such spandrel beams will stiffen edges for better structural performance.

Where use of headed shear stud reinforcement is desirable to maintain uniform floor depth or column size for a few panels with longer spans or heavier loads than the remainder of a floor system, a special design will be required. Design of headed shear stud reinforcement is prescribed by the Code (ACI 11.11.5 and Commentary). Other types of shear reinforcement are stirrups (ACI 11.11.3) and structural steel shearheads (ACI 11.11.4). For total depth of solid head less than 12 inches, the feasibility of fabricating and placing shear reinforcement, other than headed shear stud reinforcement, should be investigated.

MANUAL EXAMPLE

To illustrate the design assumptions, applicable Code requirements, and the procedures used in the preparation of the waffle flat slab tabulated designs, one of the tabulated designs will be reviewed with all calculations performed longhand. This review should also provide guidance to extend the scope of the tabulated designs to longer spans or heaver loads; to use other compressive strengths of concrete; or conditions of support other than the tabulated size square colums.

Review the tabulated design, on Page 11-84, for an intermediate waffle flat slab floor with square panels; $\ell_1 = \ell_2 = 36'\text{-}0''$; 12-in. deep ribs plus 3-in. top slab depth; 6-in. wide ribs at a 3′-0″ module; superimposed factored live load = 100 psf; normal-weight concrete; f'_c = 4,000 psi; Grade 60 reinforcing bars, f_y = 60,000 psi; 18-in. square columns (exterior and interior). For plan dimensions and layout, see Fig 11-8.

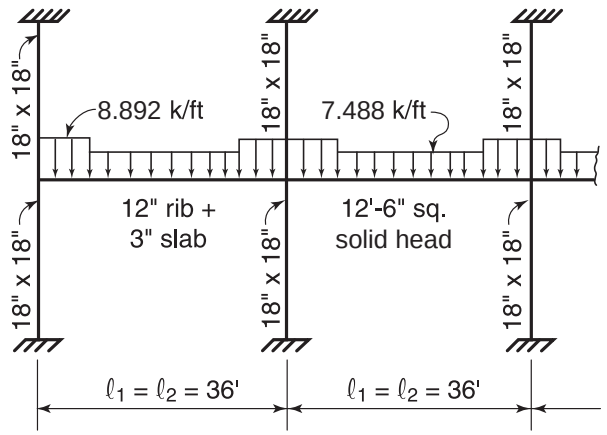

Figure 11-9 Schematic of Waffle Flat Slab Frame and Factored Loads

Factored Loads

Floor (joist) dead load = 90 psf (Table 11-1)

Joist w_D = 1.2 (90) = 108 psf = 0.108 ksf

Solid head w_D = 1.2 (15/12) 150 = 225 psf = 0.225 ksf

w_L = 100 psf = 0.100 ksf

Floor w_D = 36 (0.108) + (1/3)(36)(0.225 – 0.108)
= 3.888 + 1.404 = 5.292 kips/ft

Floor w_L = 36(0.100) = 3.6 kips/ft

$w_D + w_L$ = 5.292 + 3.6 = 8.892 kips/ft (solid head)

$w_D + w_L$ = 3.888 + 3.6 = 7.488 kips/ft (outside head)

Ratio of Service Live Load to Service Dead Load:

L/D = [100/1.6]/90 = 0.69 < 2, Okay... (ACI 13.6.1.5)

End Span

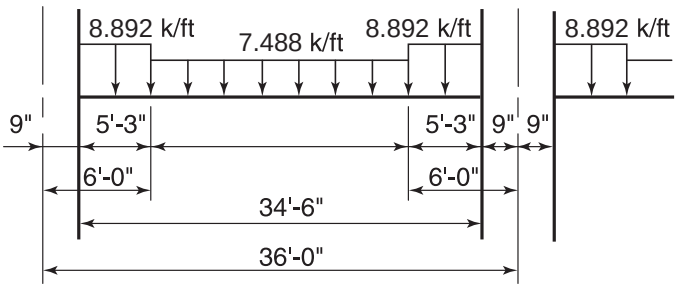
Total Static Moment, M_o:

M_o (outside head) = $7.488(34.5)^2/8$ = 1,114.074 ft-kips

M_o (head) = $(8.892 - 7.488)(5.25)^2/2$ = 19.349 ft-kips

M_o = 1,114.074 + 19.349 = 1,133.423 ft-kips

Panel Moments (ACI 13.6.3.3)



Exterior Column (Negative Factored Moment)

M_u = 0.26(1,133.423) = 294.690 ft-kips
(tabulated: 295)

Column strip resists 100% of M_u; 1.00(294.690) = 294.690 ft-kips (ACI 13.6.4.2)

Bottom (Positive Factored Moment)

M_u = 0.52(1,133.423) = 589.380 ft-kips
(tabulated: 590)

Column strip resists 60% of M_u; 0.60(589.380) = 353.628 ft-kips (ACI 13.6.4.4)

Middle strip resists 40% of M_u; 0.40(589.380) = 235.752 ft-kips

First Interior Column (Negative Factored Moment)

M_u = 0.70(1,133.423) = 793.396 ft-kips
(tabulated: 794)

Column strip resists 75% of M_u; 0.75(793.396) = 595.047 ft-kips (ACI 13.6.4.1)

Middle strip resists 25% of M_u; 0.25(793.396) = 198.349 ft-kips

Flexural Reinforcement

$$\text{Required } A_s = \frac{1.7 f_c' bd}{2 f_y} - \frac{1}{2}\sqrt{\frac{2.89(f_c' bd)^2}{(f_y)^2} - \frac{6.8 f_c' b M_u}{\phi (f_y)^2}}$$

For f_c' = 4,000 psi, f_y = 60,000 psi and ϕ = 0.90:

Required $A_s = 0.680d - \sqrt{0.462d^2 - 0.0252M_u}$ where M_u is in units of in.-kips/ft and A_s is in units of in.^{2}/ft

d = (3 + 12) – 1 (concrete cover) – 0.75 (avg. d_b)
= 13.25 in.

Exterior Column (Column Strip Top Bars)

M_u = 12(294.690)/12 = 294.690 in.-kips/ft

$A_s = 0.680(13.25)^2 - \sqrt{0.462(13.25)^2 - 0.0252(294.690)}$
= 0.426 in.^{2}/ft

Total A_s = 0.426(12) = 5.11 in.^{2}

(tabulated: 11–#6 bars; A_s = 4.84 in.^{2})

Column Strip Bottom Bars

M_u = 12(353.628)/12 = 353.628 in.-kips/ft

$A_s = 0.680(13.25) - \sqrt{0.462(13.25)^2 - 0.0252(353.628)}$
= 0.513 in.^{2}/ft

Total A_s = 0.513(12) = 6.16 in.^{2}

(tabulated: 5–#7 bars and 5-#8 bars;
A_s = 6.95 in.^{2})

Middle Strip Bottom Bars

M_u = 12(235.752)/24 = 117.876 in.-kips/ft

$A_s = 0.680(13.25) - \sqrt{0.462(13.25)^2 - 0.0252(117.876)}$
= 0.170 in.^{2}/ft

Total A_s = 0.170(24) = 4.08 in.^{2}

(tabulated: 14–#5 bars; A_s = 4.34 in.^{2})

First Interior Column (Column Strip Top Bars)

M_u = 12(595.047)/12 = 595.047 in.-kips/ft

$A_s = 0.680(13.25) - \sqrt{0.462(13.25)^2 - 0.0252(595.047)}$
= 0.879 in.^{2}/ft

Total A_s = 0.879(12) = 10.55 in.^{2}

(tabulated: 23–#6 bars; A_s = 10.12 in.^{2})

First Interior Column (Middle Strip Top Bars)

$M_u = 12(198.349)/24 = 99.175$ in.-kips/ft

$A_s = 0.680(13.25) - \sqrt{0.462(13.25)^2 - 0.0252(99.175)}$
$= 0.144$ in.^{2}/ft

Total $A_s = 0.144(24) = 3.46$ in.^{2}

(tabulated: 19–#5 bars; $A_s = 5.89$ in.^{2})

The maximum spacing of the top bars in the middle strip is limited to 18 in. (ACI 13.3.2). The calculated total required $A_s = 3.46$ in.^{2}; 12-#5 bars would provide an $A_s = 3.72$ in.^{2} But the spacing of the 12-#5 bars in the 24′-0″ wide middle strip would be 288/11 = 26 in. > 18 in., which exceeds the Code limit.

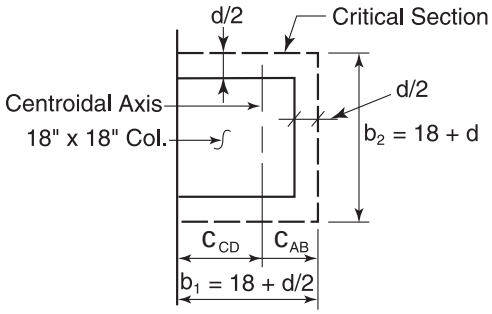
The computer program prescribes 19-#5 bars whose spacing is 288/19 = 15 in. < 18 in., Okay

Verify $\phi = 0.90$ for flexure; for $f'_c = 4{,}000$ psi and $f_y = 60{,}000$ psi, maximum $\rho = 0.0181$ for $\varepsilon_t = 0.005$ and $\phi = 0.90$.

Location	Tabulated Design	A_s, in.^{2}	b, in.	d, in.	ρ
Column strip top bars at exterior column	11-#6	4.84	144	13.25	0.0025
Column strip bottom bars	5-#7 and 5-#8	6.95	144	13.25	0.0036
Middle strip bottom bars	14-#5	4.34	288	13.25	0.0011
First Interior Column strip top bars	23-#6	10.12	144	13.25	0.0053
Middle strip top bars	19-#5	5.89	42	13.25	0.0106

In all cases, actual $\rho <$ maximum ρ, so $\phi = 0.90$.

Shear Constants at Exterior Column (ACI R11.12.6.2):



$b_1 = 18 + 13.25/2 = 24.625$ in.

$b_2 = 18 + 13.25 = 31.25$ in.

$b_0 = 2 \times 24.625 + 31.25 = 80.50$ in.^{2}

$A_c = 80.50 \times 13.25 = 1{,}066.625$ in.^{2}

(tabulated in Table 11-5; $A_c = 1{,}067$ in.^{2})

$c_{AB} = (2)(13.25)(24.625)^2/2 = 7.533$ in.

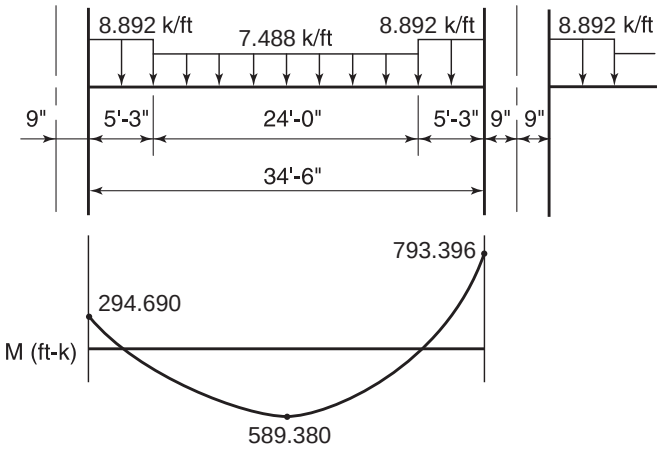
(tabulated in Table 11-5; $c_{AB} = 7.53$ in.)

$c_{CD} = 24.625 - 7.533 = 17.092$ in.

$J_c = b_1 d^3/6 + 2d[(c_{AB})^3 + (c_{CD})^3]/3 + b_2 d c_{AB}$
$= 24.625(13.25)^3/6 + 2(13.25)[(7.533)^3 + 17.092^3)]/3$
$+ 31.25(13.25)(7.533)^3$
$= 9{,}547.125 + 47{,}882.539 + 23{,}496.428$
$= 80{,}926$ in.^{4}

(tabulated in Table 11-5; $J_c = 80{,}900$ in.^{4})

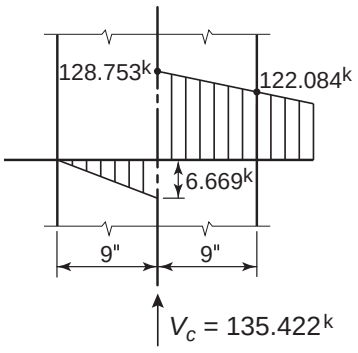
Factored Moments in End Span:



Calculate Factored Shear, V_u, at Centerline of Exterior Column

V_u (at exterior column face)
$= 7.488(34.5)/2 + (8.892 - 7.488)(5.25)$
$- (793.396 - 294.690)/34.5$
$= 122.084$ kips

V_u (at centerline exterior column)
$= 122.084 + 8.892(18/12)$
$= 135.422$ kips



Exterior Column

Shear Check at Exterior Column:

$v_c = (\alpha_s d/b_0 + 2)\sqrt{f'_c} \le 4\sqrt{f'_c}$ (ACI Eq. 11-32)
$= (30 \times 13.25/80.50 + 2)\sqrt{f'_c} = 6.94\sqrt{f'_c}$

ACI Eq. 11-35 governs: use $v_c = 4\sqrt{f'_c} = 4\sqrt{4{,}000} = 253$ psi

$\phi v_c = 0.75(253) = 190$ psi or 0.191 ksi

$$v_u = \frac{V_u}{A_c} + \frac{\gamma_v M_u c_{AB}}{J_c} \quad \text{(ACI R11.11.7.2)}$$

where:

$\gamma_v = (1 - \gamma_f)$ (ACI Eq. 11-37)

$\gamma_f = 1/(1 + (2/3)\sqrt{b_1/b_2})$ (ACI Eq. 13-1)

$= 1/(1 + (2/3)\sqrt{24.625/31.25} = 0.628$

$\gamma_v = 1 - \gamma_f = 1 - 0.628 = 0.372$

Where $M_u = 0.3M_o$ (ACI 13.6.3.6)

$M_u = 0.3(1{,}133.423) = 340.027$ ft-kips

$v_u = 135.422/1{,}066.625 + 0.372(12 \times 340.027) \times (7.533/80{,}926) = 0.127 + 0.141$

$= 0.268$ ksi, $> \phi v_c$, N.G.

An option would be to use headed shear stud reinforcement to provide the required design shear strength (ACI 11.11.5).

Another option is to use the provisions in ACI 13.5.3.3: If $0.75V_c > V_u$, γ_f can be adjusted up to 1.0.

$0.75\phi V_c = 0.75\phi(4\sqrt{f'_c})b_o d$

$= 0.75(0.75)(4\sqrt{4{,}000})(80.50)(13.25)/1{,}000$

$0.75\phi V_c = 151.783$ kips $> V_u$, so γ_f can be adjusted up to 1.0

For $\gamma_v = 0.372$, total $v_u = 0.268$ ksi > 0.190 ksi, N.G.

Therefore, limit total v_u to 0.190 ksi and solving for required γ_v.

$0.190 = 135.422/1{,}066.625 + \gamma_v(12 \times 340.027)(7.533)/80{,}926$

$\gamma_v = 0.166$

$\gamma_f = 1 - \gamma_v = 1 - 0.166 = 0.834$

The computer program optimizes γ_f to 0.882; thus, $\gamma_v = 1 - 0.882 = 0.118$

Shear check for $\gamma_v = 0.118$

$v_u = 135.422/1{,}066.625 + 0.118(12 \times 340.027)(7.533)/80{,}926$

$v_u = 0.127 + 0.045$

$v_u = 0.172$ ksi $< \phi v_c$, Okay

Determine Number of Extra Top Bars Required in Column Strip at Exterior Column:

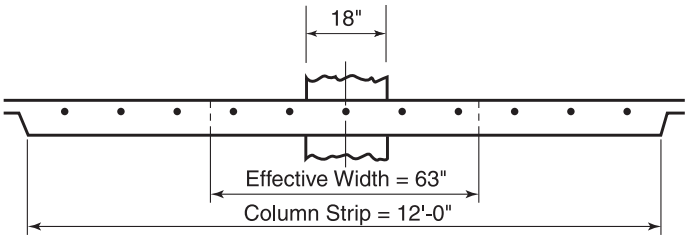
Unbalanced $M_u = 0.26M_o = 0.26(1{,}133.423) = 294.690$ ft-kips

$\gamma_f M_u = 0.882(294.690) = 259.917$ ft-kips

Effective Width = 18 + 1.5(15)2 = 63 in.

Bar Layout: 11 – #6 top bars are required to resist exterior $-M_u$ in column strip

Bar spacing = 12 × 12/11 ≈ 13 in.



Try 6-#6 additional top bars (as per tabulated design) for a total of 11 – #6 reinforcing bars in the effective width

Calculate design moment strength, ϕM_n

$A_s = (11)(0.44) = 4.84$ in.^{2} for 11–#6 top bars

$a = A_s f_y/(0.85 f'_c b) = 4.84(60)/(0.85(4)63) = 1.356$ in.

$\phi M_n = \phi A_s f_y(d - a/2)$

$= 0.90(4.84)(60)(13.25 - 1.356/2)/12$

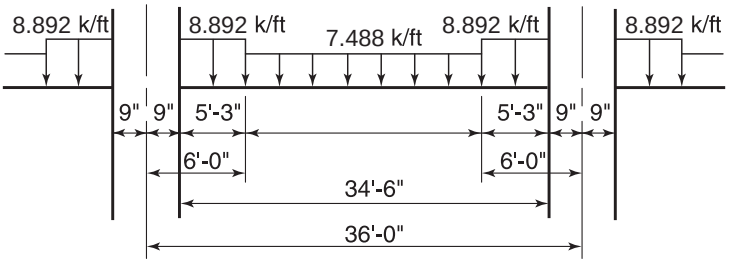
$\phi M_n = 273.818$ ft-kips $> \gamma_f M_u$, Okay

ACI 13.5.3.3 limits the amount of flexural reinforcement in the effective width so that $\varepsilon_t \geq 0.010$. For $f'_c = 4{,}000$ psi and $f_y = 60{,}000$ psi, a value of $\varepsilon_t = 0.010$ corresponds to $\rho_{max} = 0.011$. For the 11-#6 top bars in the effective width:

$$\rho = \frac{A_s}{bd} = \frac{4.84}{63(13.25)} = 0.0058$$

$\rho < \rho_{max}$, Okay

Interior Span



Total Static Moment, M_o:

$M_o = 1{,}133.423$ ft-kips (the same value as in the end span)

Panel Moments

Bottom (Positive Factored Moment)

M_u = 0.35(1,133.423) = 396.698 ft-kips

Column strip resists 60% of M_u;
0.60(396.698) = 238.019 ft-kips (ACI 13.6.4.4)

Middle strip resists 40% of M_u;
0.40(396.698) = 158.679 ft-kips

Top (Negative Factored Moment)

M_u = 0.65(1,133.423) = 736.725 ft-kips

Column strip resists 75% of M_u;
0.75(736.725) = 552.544 ft-kips (ACI 13.6.4.1)

Middle strip resists 25% of M_u;
0.25(736.725) = 184.181 ft-kips

Flexural Reinforcement

Column Strip Bottom Bars

M_u = 12(238.019)/12 = 238.019 in-kips/ft

$A_s = 0.680(13.25) - \sqrt{0.462(13.25)^2 - 0.0252(238.019)}$
= 0.343 in.^{2}/ft

Total A_s = 0.343(12) = 4.12 in.^{2}
(tabulated: 10–#6 bars; A_s = 4.40 in.^{2})

Middle Strip Bottom Bars

M_u = 12(158.679)/24 = 79.340 in.-kips/ft

$A_s = 0.680(13.25) - \sqrt{0.462(13.25)^2 - 0.0252(79.340)}$
= 0.116 in.^{2}/ft

Total A_s = 0.116(24) = 2.78 in.^{2}
(tabulated: 14–#4 bars; A_s = 2.80 in.^{2})

Column Strip Top Bars

M_u = 12(552.544)/12 = 552.544 in.-kips/ft

$A_s = 0.680(13.25) - \sqrt{0.462(13.25)^2 - 0.0252(552.544)}$
= 0.813 in.^{2}/ft

Total A_s = 0.813(12) = 9.76 in.^{2}
(tabulated: 30–#5 bars; A_s = 9.30 in.^{2})

Middle Strip Top Bars

M_u = 12(184.181)/24 = 92.091 in.-kips/ft

$A_s = 0.680(13.25) - \sqrt{0.462(13.25)^2 - 0.0252(92.091)}$
= 0.134 in.^{2}/ft

Total A_s = 0.134(24) = 3.22 in.^{2}
(tabulated: 19–#5 bars; A_s = 5.89 in.^{2})

Verify ϕ = 0.90 for flexure; for f'_c = 4,000 psi and f_y = 60,000 psi, maximum ρ = 0.0181 for ε_t = 0.005 and ϕ = 0.90.

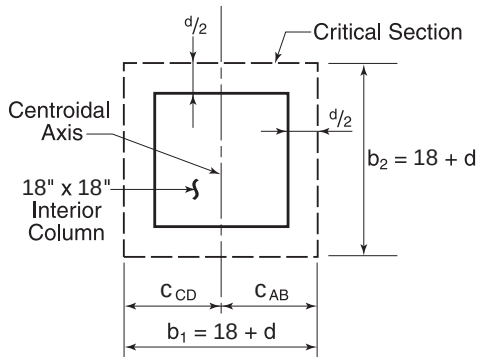
Location	Tabulated Design	A_s, in.^{2}	b, in.	d, in.	ρ
Column strip bottom bars	10-#6	4.40	144	13.25	0.0023
Middle strip bottom bars	14-#4	2.80	288	13.25	0.0007
Column strip top bars	30-#5	9.30	144	13.25	0.0049
Middle strip top bars	19-#5	5.89	42	13.25	0.0106

In all cases, actual ρ < maximum ρ, so ϕ = 0.90.

The maximum spacing of the top bars in the middle strip is limited to 18 in. (ACI 13.3.2). The calculated total required A_s = 3.22 in.^{2}; 11-#5 bars would provide an A_s = 3.41 in.^{2} But the spacing of the 11-#5 bars in the 24'-0" wide middle strip would be 288/11 = 26 in. > 18 in., which exceeds the Code limit.

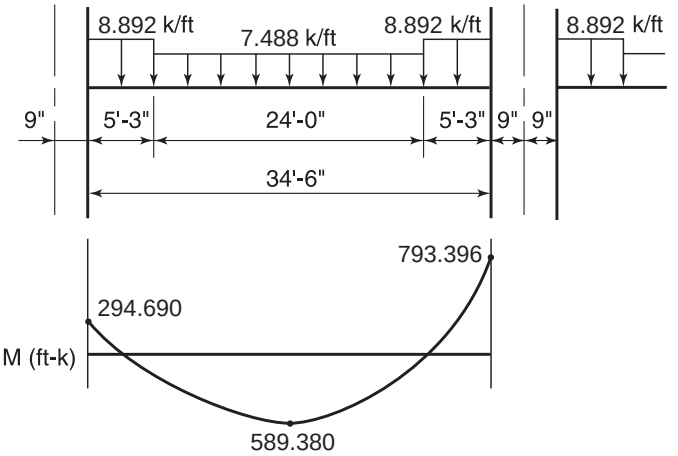
The computer program prescribes 19-#5 bars whose spacing is 288/19 = 15 in. < 18 in., Okay

Shear Constants at Interior Column (ACI R11.12.6.2):



b_1 = b_2 = 18 + 13.25 = 31.25 in.
b_0 = 4 × 31.25 = 125 in.
A_s = 125 × 13.25 = 1,656.250 in.^{2}
(tabulated in Table 11-5; A_c = 1,656 in.^{2})
c_{AB} = c_{CD} = 31.25/2 = 15.625 in.
(tabulated in Table 11-5; c_{AB} = 15.63 in.)
J_c = $(db_1/6)[d^2 + 4b_1^2]$
J_c = (13.25(31.25)/6)[(13.25)^2 + 4(31.25)^2]
= 281,688 in.^{4}
(tabulated in Table 11-5; J_c = 281,700 in.^{4})

Factored Moments in End Span



Calculate Factored Shear, V_u at Centerline of First Interior Column:

V_u (at first interior column face) = 7.488(34.5)/2
+ (8.892 – 7.488)(5.25) + (793.396 – 294.690)/34.5
= 150.994 kips

V_u (at centerline first interior column)

= 150.994 + 7.488(34.5)/2
+ (8.892 – 7.488)(5.25) + 8.892(18/12)
= 300.871 kips

For checking shear due to combined effects (i.e., direct shear plus transfer of unbalanced moment), the factored moment is:

$M_{int} = 0.07[(w_D + 0.5\,w_L)\,\ell_2\,\ell_n^2 - w_D'\ell_2'(\ell_n')^2]$. . . . . (ACI Eq. 13-7)

where w_D', ℓ_2' and ℓ_n' refer to the shorter span

$M_{int} = 0.07\,[(0.126 + 0.050)36(34.5)^2 - 0.126(36)(34.5)^2]$
= 0.07 [7,541.424 – 5,398.974]
= 149.972 ft-kips

Shear Check:

With factored moment M_{int} = 149.972 ft-kips, the factored shear, V_u, is:

$V_u = w_u\ell/2 + w_D\ell/2$ (i.e., full factored load on one span and factored dead load only on other span)

V_u = 7.488(36)/2 + (8.892 – 7.488)5.25
+ 3.888(36)/2 + 1.404(5.25)
= 134.784 + 7.371 + 69.984 + 7.371
V_u = 219.510 kips

Shear Check at First Interior Column

$v_c = (\alpha_s d/b_o + 2)\sqrt{f_c'} \le 4\sqrt{f_c'}$ (ACI Eq. 11-32)

$v_c = (40 \times 13.25/125 + 2)\sqrt{f_c'} = 6.24\sqrt{f_c'}$

ACI Eq. 11-33 governs: use $v_c = 4\sqrt{f_c'} = 4\sqrt{4{,}000} = 253$ psi

$\phi v_c = 0.75(253) = 190$ psi

Case 1: For factored shear V_{int} = 300.871 kips and no unbalanced moment

v_u = 300.871/1,656.250 = 0.182 ksi or 182 psi

ϕv_c = 190 psi > v_u, Okay

Case 2: For factored shear V_u = 219.510 kips and factored moment M_{int} = 149.972 ft-kips

$\gamma_f = 1/(1 + 2/3\sqrt{b_1/b_2})$ (ACI Eq. 13-1)
$= 1/(1 + 2/3\sqrt{31.25/31.25}) = 0.60$

$\gamma_v = 1 - \gamma_f = 1 - 0.60 = 0.40$

$v_u = V_u/A_c + \gamma_v\,M_{int}\,c_{AB}/J_c$

v_u = 219.510/1,656.250 + 0.40(149.972 × 12) ×
15.625/281,668 = 0.133 + 0.040
= 0.173 ksi or 173 psi

ϕv_c = 190 psi > v_u, Okay

TABLE 11-5 PERIPHERAL SHEAR CONSTANTS AT COLUMNS

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

(Continued on next page)

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

(Continued on next page)

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

(Continued on next page)

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

(Continued on next page)

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

(Continued on next page)

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

(Continued on next page)

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

(Continued on next page)

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

(Continued on next page)

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f_c'}$ but less than $6\sqrt{f_c'}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f_c'}$ but less than $6\sqrt{f_c'}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f_c'}$ but less than $6\sqrt{f_c'}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

NOTES *Factored shear stress for the column size so designated is greater than $4\sqrt{f'_c}$ but less than $6\sqrt{f'_c}$. Headed shear stud reinforcement, shear reinforcement (bars or wires and single- or multiple-leg stirrups), structural steel shearheads, or shear caps must be provided with columns indicated.

(1) Average reinforcing steel weight (psf) includes twice the flexural reinforcement tabulated (tabulated reinforcement placed in each direction). Shrinkage and temperature reinforcement, integrity reinforcement, and shear reinforcement are not included.

(2) The notation "3 S 4 1" for the stirrups: the first character "3" is the bar size, i.e., #3; the "S" stands for "stirrup"; and the "4" is the spacing of the stirrups in inches. The last character indicates the length over which stirrups are required in each joist rib; the "1" denotes the length from the face of the solid head to the first cross rib, i.e., a length of one module; a "2" indicates stirrups are required to the second cross rib from the face of the solid head, i.e., a length of two modules.

CHAPTER 12 – BEAMS

INTRODUCTION

General. The tabulated designs of rectangular beams in this Chapter are based on the Strength Design Method in the ACI Building Code. Appropriate load factors must be applied to service dead and live loads before using the tabulated designs. In the tabulated designs, the nominal design strength has been reduced to a usable factored load capacity by the prescribed strength-reduction ϕ-factors.

The tabulated designs are based on $f'_c = 4{,}000$ psi and $f_y = 60{,}000$ psi (Grade 60 reinforcing bars). Variations in f'_c between 3,000 psi and 5,000 psi will not significantly affect load capacity for flexural design strength nor the flexural reinforcement required. For $f'_c > 4{,}000$ psi, the minor reductions in stirrup requirements can usually be neglected since the potential reduction, $(2\sqrt{f'_c} - 63)$ psi, is sharply limited by the maximum spacing requirements (ACI 11.4.5) and minimum stirrup requirements (ACI 11.4.6).

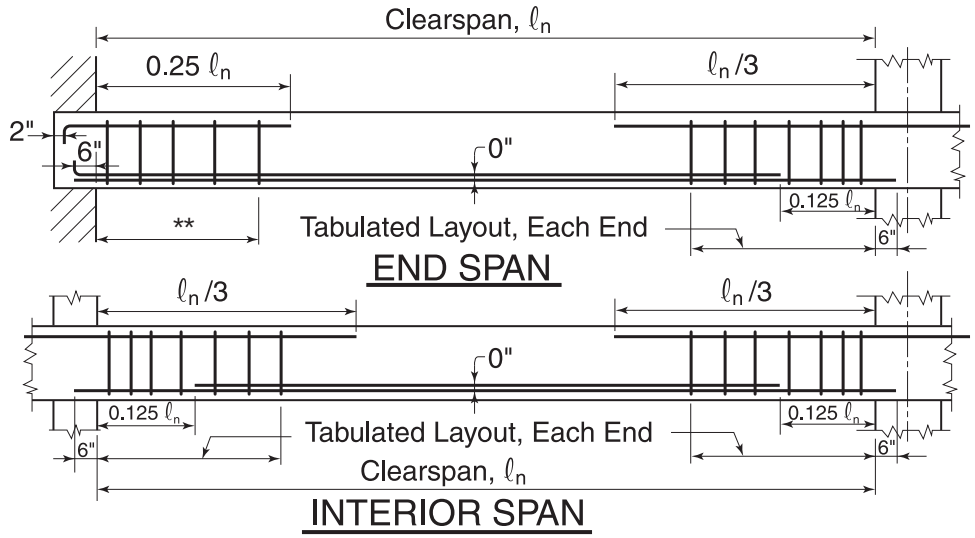
Unlike the other tabulated designs in this Handbook, the factored dead weight of the beam has not been deducted. The total load capacities have been reduced by strength-reduction or ϕ-factors with no deduction for dead weight of the beam. Most of the dead weight of a floor system is in the tributary slabs or joists; therefore, selfweight of a beam is typically only a small part of the dead load it must support.

Complete beam designs for uniformly distributed loads are presented on two lines in the tabulated designs. The first line is for open U-stirrups where torsion is negligible. The second line is for closed stirrups required to resist combined torsion and shear. Load capacity, torsional moment strength with open stirrups, and torsional moment strength with closed stirrups are tabulated for the usual range of suitable spans. Deflection for all tabulated loads meets the ACI Code general limit, $\ell/360$, (ACI 9.5.2.6).*

Scope. Two sets of beam designs are tabulated. One set utilizes "normal" proportions. See Pages 12-22 to 12-81. The other set matches the depths of standard joist construction but considers the wide beam widths commonly required for uniform depth joist-beam floor or roof construction. See Pages 12-82 to 12-109.

Both sets of tabulated designs, beams of normal proportions and joist-band (wide) beams for joist construction, are further subdivided into "Exterior Span" and "Interior Span" beams for the different moment conditions present. See Fig. 12-1 "Recommended Bar Details for Beams." Figs. 12-2 and 12-3 "Typical Beam Section at Support" and "Typical Girder Section at Support" show adjustments required to apply the beam designs tabulated for use as girders where effective depth is reduced so that the girder reinforcing steel fits under crossing beam bars. For stirrup details, see Fig. 12-4.

*Exceptions are noted *, X, or Y. See footnotes on tables.



** See Note 5 in tabulated designs.

Figure 12-1 Recommended Bar Details for Beams

Spans range from 12 to 54 feet, utilizing widths approximately one-half to two-thirds the depth, for the beams of normal proportions. For the joist-band (wide) beams for use with joists, depths range from 12.5 inches in increments the same as those for standard joists with 4.5-inch top slabs to 28.5 inches, utilizing widths from 24 to 48 inches.

Note that eight different clear span lengths are provided for each combination of beam depth and width and that the tabulated designs are divided into two pages. The first page is for the first four spans and the second page is for the last four spans. The specific beam overall depths, widths, and clear spans used in the tabulated designs are as follows:

(Bot. and shrinkage-temperature bars in slab not shown.)

Figure 12-2 Typical Beam Section at Support

Selection of Beam Sizes. One of the main advantages of reinforced concrete construction is the wide range of possible sizes for the structural members. Reinforced concrete beams may be wide and shallow or narrow and deep. For uniform depth joist-beam construction, using a single flat bottom form for a level ceiling that facilitates construction, the beams will be shallow and require more flexural reinforcement. Ordinarily, these shallow beams are proportioned to a width that eliminates or minimizes shear reinforcement, which is costlier per pound than the larger flexural reinforcing bars. For minimum flexural reinforcement, the Code requires that $A_s = 3\sqrt{f'_c}\, b_w d/f_y \geq 200\, b_w d/f_y$ (ACI 10.5.1). With shallow beams, deflections are more critical and must be carefully controlled.

Criteria for Selection of Flexural Reinforcement Area. The ratio of flexural steel, $\rho = A_s/bd$, used in these designs lies between minimum and maximum limits set by the Code (ACI 10.5.1) and (ACI 10.3.4), respectively. The ratio, ρ, is based on the web width, b_w, of the rectangular section so that the tabulated designs are conservative for the positive design moment strength when slabs are on one or both sides, and slabs may be of any depth.

The values of ρ used to develop the tables for the designs of each beam cross section (h by b_w) are:

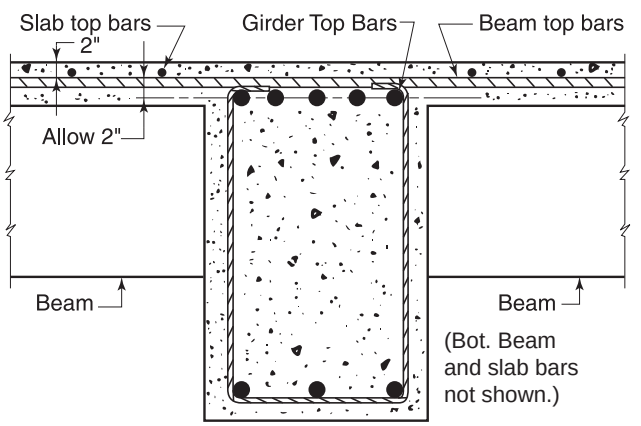
a. Minimum $\rho = 0.0033$ (ACI 10.5.1)

b. $\rho = 0.21\rho_b = 0.0060$

c. $\rho = 0.42\rho_b = 0.0120$

d. Maximum $\rho = 0.63\ \rho_b = 0.0181$ (ACI 10.3.4)

Where ρ_b is the balanced ratio ($\rho_b = 0.0285$ for f'_c = 4,000 psi and f_y = 60,000 psi).



Note: Top bars of beam and slab form two-way mat for crack control (ACI 10.6).

Figure 12-3 Typical Girder Section at Support

Stirrups. The ACI Building Code provides an upper limit on the factored torsional moment, T_u, due to the continuity of the slab and spandrel beam, where open stirrups are permitted (ACI 11.5.2.2). This upper limit on the factored torsional moment is:

$$T_u \leq \phi 4\sqrt{f_c'}\left(\frac{A^2_{cp}}{p_{cp}}\right)$$

The stress $4\sqrt{f_c'}$ is equal to the assumed cracking stress. When T_u is more than:

$$T_u > \phi \sqrt{f_c'}\left(\frac{A^2_{cp}}{p_{cp}}\right)$$

Closed stirrups are required to resist combined shear and torsion.

Beams are exempt from the minimum stirrup requirements if total depth, h, does not exceed 10 in. (ACI 11.4.6.1-d); and for beams monolithic with slabs if h does not exceed 24 in. and h is not greater than the larger of 2.5 times thickness of flange, or one-half the width of the web (ACI 11.4.6.1-e). This latter provision greatly reduces stirrup requirements in the shallow joist-band (wide) beam sizes.

Special Design Data. In addition to the load capacity and stirrup (open or closed) requirements for the usual range of spans, the tabulated designs include design data for making short-cut design adjustments for: (1) spans outside the ranges tabulated, (2) design of girders with concentrated load patterns, (3) adjustment of flexural reinforcement for unusual end restraint conditions, and (4) actual deflection predictions where necessary for fit of other materials, and camber. The tabulated designs include values of:

$+\phi M_n$ = positive design moment strength as individual beams

$-\phi M_n$ = negative design moment strength as individual beams

C = deflection coefficient such that $\Delta = (C \times 10^{-9})(w\ell_n^4)$

The tabulated designs also include the total weight of the steel reinforcement (flexural reinforcement and stirrups).

BASIS FOR DESIGN

Load Capacities. The tabulated designs are based on uniformly distributed loads. Moments and shears are calculated using simplified coefficients (ACI 8.3.3). Materials are normal-weight concrete, $w_c \simeq 150$ pcf, with f_c' = 4,000 psi, and reinforcing bars with f_y = 60,000 psi. The design moment strengths were computed using the rectangular stress block specified in the Code (ACI 10.2.7).

Flexure. See Chapter 5 for a general explanation of moment coefficient analyses. The general limitations of the moment coefficients are of particular interest in the design of beams. The tabulated designs in this Chapter will require adjustments when the particular project conditions of adjacent span lengths exceed the limit 1.20 for long/short span; live load, L, exceeds three times dead load, 3D, unfactored; or where concentrated loads occur as in girder design.

Concentrated Loads. Girder design can be simplified by use of the tabulated beam designs, but the concentrated beam loads must be combined for flexure with the uniform load moments. Both positive and negative design moment strengths are listed (in the second-to-last column) for each tabulated beam design. In using the tabulated designs to select a girder design, use (h – 2 inches) to allow for lowered top bars; that is, for a girder with overall depth 30 inches, select a tabulated design for h = 28 inches. This adjustment should result in the correct negative design moment strength. Positive moment strength should be based on the overall depth of h = 30 inches. See the girder design (Example 2) under "Beam Tables–Examples of Use." See Fig. 12-3.

Variable Span Lengths. At the ends of beams, continuous over interior supports, the total area of top reinforcement, used as a basis for computing negative moment design strength, is shown as straight top bars. When designs selected for adjoining spans do not provide the same area of top bars, adjustment of the total top reinforcement should be made by varying the size or number of top bars in proportion to the average of the two spans. End span reinforcement governs at the first interior support where spans are equal.

Shear. Shear has been computed assuming the load capacity shown is uniformly distributed along the entire length of the beam. For concentrated loads or partial loadings (uniform distribution on part of the beam), the shear capacity should be checked even though these loads may produce bending moments equivalent to those for the tabulated uniform load capacity.

The quickest solution to take into account concentrated loads, as on girders, is to compute the sum of the concentrated load shear and the uniform load shear, and select a tabulated stirrup pattern for the same size beam under uniform load generating shear equal to this sum.

For girders supporting a single beam at the center, flexural design will control. The tabulated stirrup design for an equivalent uniform load moment will suffice at the support, and a stirrup pattern for a lower uniform load may be selected and extended from the support throughout the span. For girders resisting loads from two or more beam loads, the stirrup pattern for a heavier load (than equivalent for moment) will be required. In either case, the design time to determine a tabulated stirrup size and spacing at the support for the combined shear will be less than for complete manual computation of the required stirrups. See the girder design (Example 2) under "How to Use Tabulated Designs." Concentrated loads may require an essentially uniform stirrup spacing between face of the support and the load point.

Partial loadings in particular may require stirrups beyond the pattern required for full uniform load. In many cases, it will suffice to provide an arbitrary extension of stirrup reinforcement across the span between the points where shear calculations based on only full uniform load indicate stirrups are no longer required.

All of these adjustments can usually be made without separate calculations, by visual selection of tabulated stirrup patterns as illustrated in the examples.

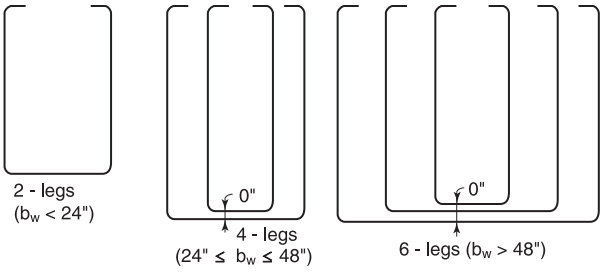
The first line of each tabulated design shows open U-stirrups required with negligible torsion. See Fig. 12-4, "Typical Open Stirrups and Closed Stirrups." These designs suffice for vertical shear due to tabulated load capacity, including a factored torsional moment

$T_u \le \phi\sqrt{f'_c}\left(\frac{A^2_{cp}}{p_{cp}}\right)$ (ACI 11.5.1a).

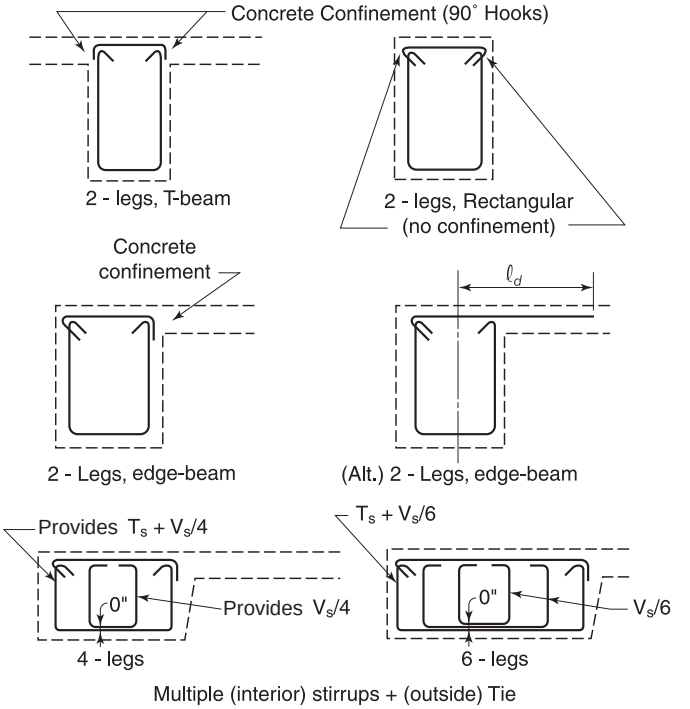
Torsion. Closed stirrups for shear plus maximum torsion are shown on the second line of each tabulated design. See Fig. 12-4 for details appropriate for *two-piece* closed stirrups, necessary for practicable field assembly. These designs are for $T_u \le \phi 4\sqrt{f'_c}\left(\frac{A^2_{cp}}{p_{cp}}\right)$

This torsional moment is the maximum required for the common case where torsion (as in a spandrel) results from the interior of the (statically indeterminate) structure (ACI 11.5.2.2). It is assumed that minor cracking at this stress with stirrups yielding will reduce torsional stiffness, like a hinge, precluding any increase in torsion load. Statically determinate torsion effects requiring torsional moment strength for stability to maintain equilibrium, as in cantilever supports, where the required torsional resistance is equal to the factored torsional moment (ACI 11.5.2.1). Such designs must be "custom made" if T_u required exceeds $\phi 4\sqrt{f'_c}\left(\frac{A^2_{cp}}{p_{cp}}\right)$.

For such designs, where multiple closed stirrups are required, note that only the outer two legs are proportioned for torsion. All interior legs resist only vertical shear. See Fig. 12-4.



(a) Open stirrups for shear plus torsion; $T_u \le \phi\sqrt{f'c}\,(A^2_{cp}/p_{cp})$



(b) Various closed two-piece "stirrups"; required only with torsion where; $\phi\sqrt{f'c}\,(A^2_{cp}/p_{cp}) < T_u \le \phi\ 4\sqrt{f'c}\,(A^2_{cp}/p_{cp})$. For $b_w \ge 24$", add interior open stirrups as required above.

NOTE: In the absence of specific ACI Code limitations on maximum beam widths for 2-leg, 4-leg, or 6-leg stirrup combinations, the limits shown above were applied by CRSI. Users of this Handbook should apply their best judgment to set maximum width limits for their designs. Also see ACI R11.4.7.

Figure 12-4 Typical Open Stirrups and Closed Stirrups

Development of Flexural Reinforcement. See Fig. 12-1. The recommended detail at free ends in the end spans of beams consists of straight extension of all bottom bars and properly anchored top bars. The recommended details and bar sizes are compatible for uniform loads and spans that vary by no more than 20 percent, the limitation of coefficients for design (ACI 8.3.3). Where a short span is located between two long spans at or near $\ell_{n1} = 1.2\ \ell_{n2}$ and the expected live load varies from zero to 100 percent, approximately 20 percent of the top reinforcement should be made continuous across the shorter span because a negative bending moment can develop across the entire shorter span. At other cases of long-short spans near the limit 1.20, it will suffice to extend top bars in the shorter span to $0.40\ \ell_{n2}$ where ℓ_{n2} is the short span.

The tabulated designs were prepared with optimum bar sizes selected for the recommended details in Fig. 12-1. The computer program computes the "exact" steel area required for flexure. Steel areas furnished are by the least number of largest bars that could be developed, as well as steel areas for the next lower sizes, down to #4. The number of bars required in each size was then compared to the minimum number required for crack control and to the maximum number allowed for fit. Unsuitable sizes were rejected. The bar size selected was the largest size whose area did not exceed the area of the smaller usable size by more than 5 percent, for economy in placing.

Thus, for project conditions within the stated limitations, the tabulated beam designs herein can be used as the basis for a tentative design. Commonly, however, it may be expected that conditions special or even unique to a particular project will occur. In these cases, the tabulated designs must be appropriately adjusted. Adjustments may or may not require a change in the required steel areas. If so, these adjustments for moment conditions other than those used for the tables (see "Flexure" on Page 12-3) are straightforward arithmetic.

The "art" of design in reinforced concrete begins after this straightforward arithmetic. The selection of bar sizes and detail arrangements is a vital part of this art. The most frequent adjustment of tabulated designs (or converting theoretically required steel areas to actual bars) occurs when said bars must fit *between* other bars. If column bars are spaced to provide four spaces through which beam bars must pass, and tabulated beam designs show numbers higher than four, an adjustment is required. In some cases, column bar sizes may be revised or column bars may be bundled to provide clearances. (Bundling of beam bars is also permitted, but may be counterproductive as bundled bars in flexural tension areas involve further Code restrictions.) In cases where only the top bars tabulated cause fitting problems, the excess above those fitting through the column may be located outside the column in the beam flange. See "Crack Control" on Page 12-11.

In remaining cases, a change in tabulated number of bars will be required. If a larger bar size is necessary, the development length of the larger bars must be checked. Conformance to development requirements in the Code may require longer extensions.

The "Recommended Bar Details for Beams" (Fig. 12-1) are for general use (by CRSI). They satisfy Code requirements for development with uniform beam loading, common girder loadings combining some uniform load and one or more concentrated beam loads (excepting the case of "pure" third point concentrated loads).

HOW TO USE TABULATED DESIGNS

Steps in selecting a tabulated design and adjusting it to special conditions of a project are reviewed below:

Beam Dimensions

Step 1. Consider an entire floor building layout, comparing conditions along the entire length of continuous beams in one direction. Decide whether conditions are similar enough to justify one width for all interior beams and one for all spandrel beams. A width for minimum stirrups will be most economical. Depth of all beams should normally be held uniform for practical reasons (head room and formwork economy). Take the controlling span conditions (highest shear); with equal spans, it is usually the first interior support on the end span side.

Enter END SPAN beam tables with controlling load (kips/foot) and clear span (feet) for the interior beam lines for cases where spans are not equal. Select width-depth combination within established architectural limits for near-to-minimum stirrups. If possible for the controlling condition, use width-depth combination adequate on second or third line in tables, since all other spans will require less than the controlling condition. Record flexural reinforcement bar sizes as tentative choices, and stirrup pattern designation number.

Step 2. Continue selections in INTERIOR SPAN tables for remainder of the continuous line of beams. Enter for same width/depth combination with load and span data for each (the span, and often load, may be same as for end span). Record flexural reinforcement bottom bar sizes and number as tentative choices, as

well as stirrup designation number for each span. For top bars, if adjacent spans vary, average spans on both sides of support and enter tables with average span and load for each end of the span considered.

Step 3. Reconcile tentative design. Check size and location of spaces between the column vertical bars and the space outside same in beam if the beam is wider than the column for bottom bars, and possible location outside the column vertical bars in slab adjacent to the column for top bars. Be sure bars selected will fit in these spaces. If possible use the same size bars throughout as bottom bars; then, similarly for top bars. If two bar sizes are tabulated for bottom bars for say, END SPAN, try to use the same two sizes throughout.

Step 4. Adjust the basic design as necessary where project conditions lie outside Code limits on moment coefficients and shears. Adjust factored moments and shears, adjust bar lengths and sizes, and note conditions where factored shear is higher or non-uniform. For higher factored shear, select stirrup pattern from other beam designs having required design shear strength instead of stirrup pattern tabulated for beam selected. Be sure space is available for bars selected. Record flexural reinforcement, and stirrup patterns for design drawings.

Step 5. Consider torsion. Closed stirrups for torsion are seldom necessary for beams supporting slabs on both sides. If slab loading is unequal, or if interior openings are present only on one side, compute factored torsional moment, T_u, as the difference in end moments from the slabs with live load on one side only. If $T_u \le \phi\sqrt{f'_c}(A^2_{cp}/p_{cp})$, neglect torsion. Where larger T_u exists, beam has to be designed for combined shear and torsion.

Step 6. Structurally detail the reinforcement to comply with the requirements for structural integrity (ACI 7.13).

Exterior Line Spandrel Beams

Same steps as for interior lines of beams except:

Step 1. In addition to factored gravity loads and spans, design data to enter the tabulated designs should include factored torsional moment, T_u. Factored torsional moment may be actual factored end moments from continuity or $T_u \le \phi\, 4\sqrt{f'_c}(A^2_{cp}/p_{cp})$, whichever is less; or actual cantilever type factored torsional moment required for equilibrium if larger than the lesser of $\phi 4\sqrt{f'_c}(A^2_{cp}/p_{cp})$ or continuity end moment torsion. Two values of design torsional moment strength, ϕT_n, are given in the tabulated designs. The value on the first line corresponds to $\phi T_n = \phi\sqrt{f'_c}(A^2_{cp}/p_{cp})$. The value of ϕT_n on the second line corresponds to $\phi\, 4\sqrt{f'_c}(A^2_{cp}/p_{cp})$.

Where $T_u > \phi\, 4\sqrt{f'_c}(A^2_{cp}/p_{cp})$, use a larger beam section if possible; otherwise a special design is required, and torsional reinforcement could be very costly. For $\phi\sqrt{f'_c}(A^2_{cp}/p_{cp}) < T_u \le \phi\, 4\sqrt{f'_c}(A^2_{cp}/p_{cp})$, use the tabulated designs. Try to select beam dimensions where $T_u \le \phi\sqrt{f'_c}(A^2_{cp}/p_{cp})$ so that no (closed) stirrups are required for torsion, except perhaps where only one span in a long series of spandrel spans has to resist a special factored torsional moment, and it would require a disproportionately large beam section.

Step 2, 3, and 4. Same as for interior beams, unless factored torsional moment, $T_u > \phi\, 4\sqrt{f'_c}(A^2_{cp}/p_{cp})$. In this case, record T-designations for closed stirrups.

Step 5. Sketch cross-sections of the spandrel beams and fit flexural reinforcement inside an appropriate closed stirrup shape. Each closed stirrup should be formed in two pieces for facilitating field assembly. See suggested shapes, Fig. 12-4. Finally, add tabulated additional longitudinal face reinforcement (A_ℓ) bars inside the closed stirrups. These bars, with a nominal diameter at least 1/24 of the stirrup spacing, must be distributed around the perimeter of the beam spaced not more than 12 inches apart (around the perimeter) with at least one bar, principal or added, in each corner of the stirrups (ACI 11.5.6.2).

Step 6. Structurally detail the reinforcement to comply with the requirements for structural integrity (ACI 7.13).

Girders

All steps listed for beams apply to girders. One additional consideration here is that the effective depth of the girder should be taken as 2 inches less than the actual depth, *h*, to allow space for beam bars to cross above top girder bars.

The main difference between beams and girders is in the variable load patterns commonly associated with girders. To apply the tabulated uniformly loaded beam designs herein to girders with one or more concentrated loads, equivalent uniform beam loadings must be selected separately for factored shear and moment. Alternatively, total factored moment may be used as a basis for design. See next to last column of tables for design moment strengths, $-\phi M_n$ and $+\phi M_n$. If width/depth dimensions are selected for factored moment requiring flexural reinforcement on the fourth

line (heaviest) for each size, the stirrup pattern from one of the preceding lines will often suffice for the girder shear.

BEAM TABLES–EXAMPLES OF USE

Example 1. Design Beam B1. See Fig. 12-5 for plan dimensions. Service live load = 150 psf. In addition to floor loads, make allowance for a future partition; a service line load of 200 plf. f'_c = 4,000 psi. f_y = 60,000 psi. Conditions permit use of total depth, h = 30 in. Clear span, ℓ_n = 30 ft.

Actual Loads

Slab: (6/12)(150)	=	75 psf
Ceiling and floor finish	=	10 psf
		85 psf

Estimate weight of beam stem:
(18 × 24)(150)/(144) = 450 plf

Factored Loads

Contributory area *DL* = 1.2(85)(14)	=	1,428 plf
Contributory area *LL* = 1.6(150)(14)	=	3,360
		4,788 plf
Beam stem *DL* = 1.2(450)	=	540
Future partition = 1.2(200)	=	240
	w_u =	5,568 plf

Step 1. Enter End Span tables for Beam B1 (end span) on Page 12-40. Enter tables for $h = 30''$ and $\ell_n = 30'$.
Read: • 14 × 30, capacity = 5.70 kips/ft > 5.57
Top: 3-#11 bars; Bottom: 2-#14 bars; #5 stirrups
• 16 × 30, capacity = 6.36 kips/ft > 5.57
Top: 4-#11 bars; Bottom: 3-#11 bars; #5 stirrups
• 18 × 30, capacity = 8.05 kips/ft > 5.57
Top: 3-#14 bars; Bottom: 3-#14 bars; #5 stirrups
• 20 × 30, capacity = 5.90 kips/ft > 5.57
Top: 3-#11 bars; Bottom: 3-#11 bars; #4 stirrups

Compare designs:

Any one of the designs can be selected.

16 × 30 design avoids use of #14 bars required in 18 × 30 design.

Both the 16 × 30 and the 20 × 30 designs use #11 flexural reinforcement, but the 20 × 30 design uses #4 open stirrups while the 16 × 30 design uses #5 open stirrups.

The 14 × 30 design is selected for this example.

Flexural reinforcement is tabulated for load capacity = 5.70 kips/ft and factored load is 5.568 kips/ft. Reduction is possible in the ratio (5.57/5.70) = 0.98, but 2% is insignificant.

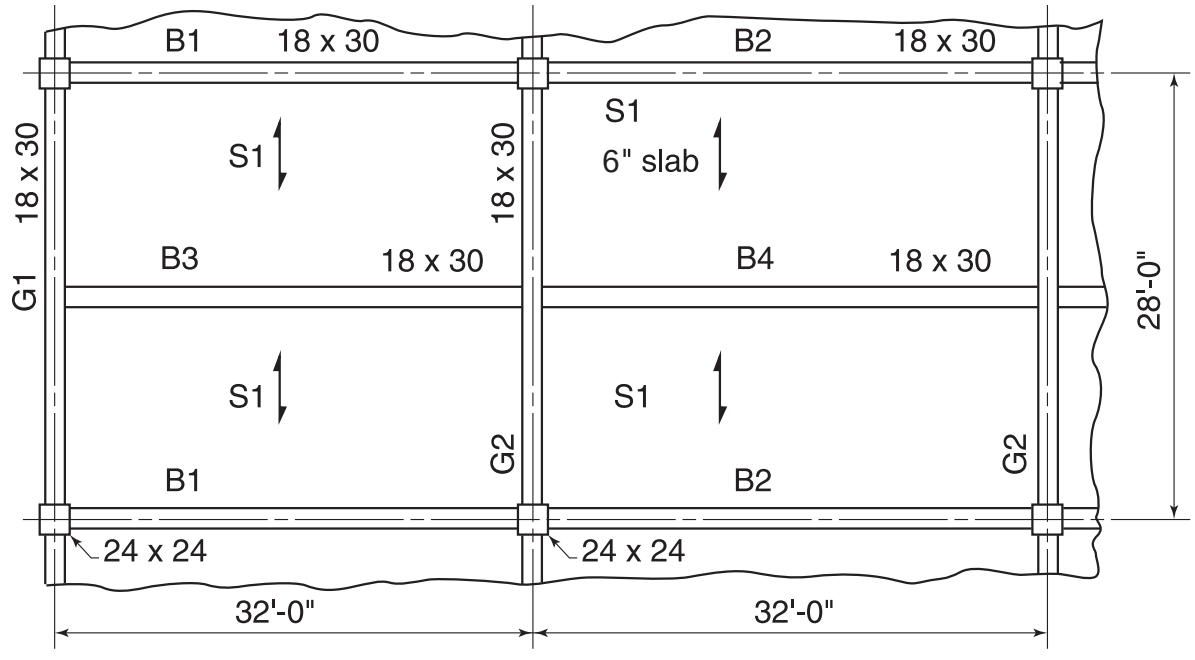


Figure 12-5 Plan Dimensions – Examples 1 and 2

At discontinuous end, $-M_u$ = (11/16) ($-M_u$ for interior column).

Bottom bars: 2-#14

Top bars: 3-#11. (Over first interior column, A_s = 4.68 in.^{2})

At discontinuous end, required A_s = (11/16)(4.68) = 3.22 in.^{2} Use 4-#8 bars with standard 90° end hooks.

Adjustment of open stirrup quantities or pattern by 98% is not feasible since stirrups are nearly spaced at max s; d = 27.2″; max $s = d/2$ = 13.6″ ≈ 13″. Stirrup pattern is 145K; see Page 12-14; 14-#5: 1 @ 2″ and 13 at each end (EE).

Example 2. See Fig. 12-5. Design interior girder, G2. In addition to loads from beams, a line load (partition) of 200 plf is supported by the girder. Clear span, ℓ_n = 26 ft. Assume overall depth, h, not to exceed 30 in.

Step 1. Convert to uniform loads.

Concentrated load at center = 5.568 kips/ft (32 ft) = 178.2 kips. Assume stem width = 18″:

Uniform Loads:

Stem	(18 × 24)(150/144) = 450 plf	× 1.2 = 540 plf
Partition	= 200	× 1.2 = 240 plf
	Factored total load =	780 plf

Concentrated load factored moment, M = (178.2 × 26)/8 = 579 ft-kips. Equivalent uniform load, $w = (11 \times M)/\ell_n^2$ for end moment, $w = 11(579)/(26)^2$ = 9.42 kips/ft

Total equivalent factored uniform load (for $-M_u$), w_u = 9.42 + 0.78 = 10.20 kips/ft

Factored positive moment, $+M_u = 579 + 0.78(26)^2/16$ = 612 ft-kips

Or total equivalent uniform load (for $+M_u$), $w_u = (16 \times 579)/(26)^2 + 0.78$ = 14.48 kips/ft

Step 2. Enter Interior Span Tables. See Page 12-68. Enter tables for h = 28″ under "Interior Spans." Read for ℓ_n = 26 ft:

18 × 28, capacity = 10.80 kips/ft > 10.20, Okay

Bottom bars: 3-#11

Top bars: 3-#14

Stirrup designations: 145GeJ and 315C

Torsional design moment strength (with open stirrups) = 13 ft-kips

Estimate T_u for G2 with live load on one side only:

w_u (live load) = 1.6(0.150)(14) = 3.36 kips/ft

$$T_u = \frac{1}{11}(3.36)(30.5)^2 = 284 \text{ ft-kips}$$

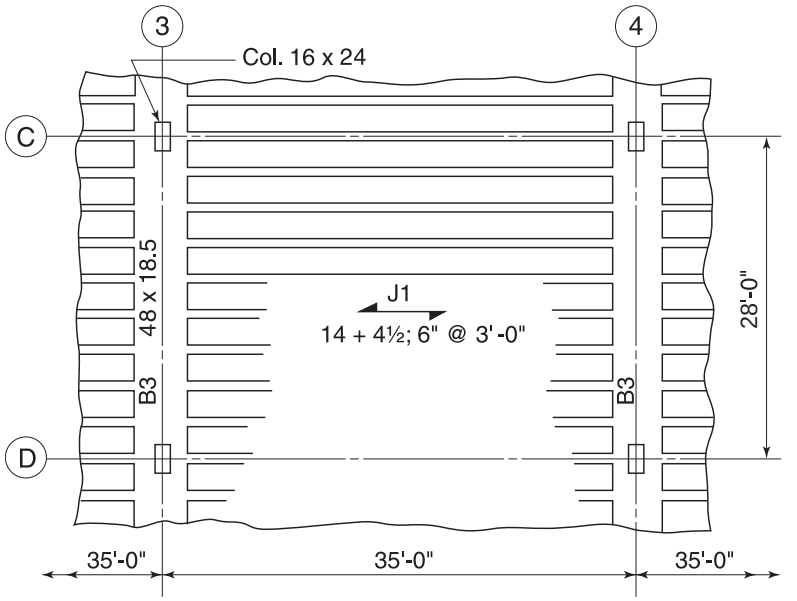

Figure 12-6 Plan Dimensions Joist-Band Beam Floor

This total unbalanced torsional moment will be distributed (see Fig. 12-5) among the B3-B4 tee-beams, which have an estimated flexural stiffness, $2K_b$ = $1{,}700E_c$; and to two sides of girder G2, which have an estimated torsional stiffness $(60E_c)2 = 120E_c$.

$$T_u \text{ in G2} = \frac{K_t}{2K_t + 2K_b}(284)$$
$$= \frac{60}{1820}(284) = 9 \text{ ft-kips} < 13$$

Closed stirrups and additional longitudinal bars for torsion are not required.

Check shear: Max $V_u = (178.2/2) + (0.78 \times 13) = 99.2$ kips

Equivalent w_u for shear = (99.2/13) = 7.63 kips/ft < 10.80. Initial stirrup spacing — Okay

Step 3. Bottom bars; equivalent w_u = 14.48 kips/ft and $+M_u$ = 612 ft-kips. See Page 12-70; use h = 30″. For ℓ_n = 26′-0″, a beam 20″ × 30″ with 3-#14 (A_s = 6.75 in.^{2}) bottom bars capacity = 15.28 kips/ft and $+\phi M_u$ = 734 ft-kips. Reduction in A_s is possible in the ratio (734–612)/734 = 0.17, but is not pursued. Use 3-#14.

Step 4. Adjust initial stirrup spacing for equivalent w_u = 7.63 kips/ft for full span. For the tabulated design above the one selected for negative design moment strength, the shear strength = 7.88 kips/ft, stirrup pattern 125J. See Page 12-68: 12-#5, 1 @ 2″, 10 @ 12″ each end (EE).

Example 3. See Fig. 12-6. Design a joist-band beam, B3, for typical interior clear spans, ℓ_n, = 26′-0″, with f'_c = 4,000 psi and f_y = 60,000 psi for the following loads: partitions 20 psf, floor plus ceiling finish, 5 psf, and a specified service live load = 50 psf. Overall depth, h = 18.5″.

Step 1. Compute factored loads:

Joist-slab system		
(0.61 c.f.)(150)	=	92
Partitions	=	20
Floor and ceiling finishes	=	5
Factored dead load (total)	=	117 psf × 1.2 = 141 psf
Factored live load	=	50 psf × 1.6 = 80 psf
		Area factored load, q_u = 221 psf

Step 2.

For beam width b = 48″. Added line load for beam stem:

(1.2) [18.5 – (0.61)(12)](48)(150/144) = 671 plf

$w_u = (0.221 \times 35) + 0.671 = 8.41$ kips/ft

Step 3. Enter Interior Span tables for joist-band beams, Page 12-103, for ℓ_n = 26 ft., h = 18 in. and b = 48 in.

Read for third design: capacity = 11.02 kips/ft > 8.41. Okay

Open stirrups: 184E

See Fig. 12-4: 4 stirrup legs are required.

See Page 12-14. “184E” is 18-#4, 1 @ 2″, 17 @ 7″ at each end (E.E.)

Spacing of 7″ ≈ 0.5d so no real reduction in stirrups is possible.

Flexural reinforcement:

Top: 7-#11 bars; Bottom: 6-#10 bars

It is possible to reduce the top flexural reinforcement by 8.41/11.02 = 0.76, but the 24% reduction is not made here.

Top: use 7-#11 bars
Bottom: use 6-#10 bars
} See Fig. 12-7

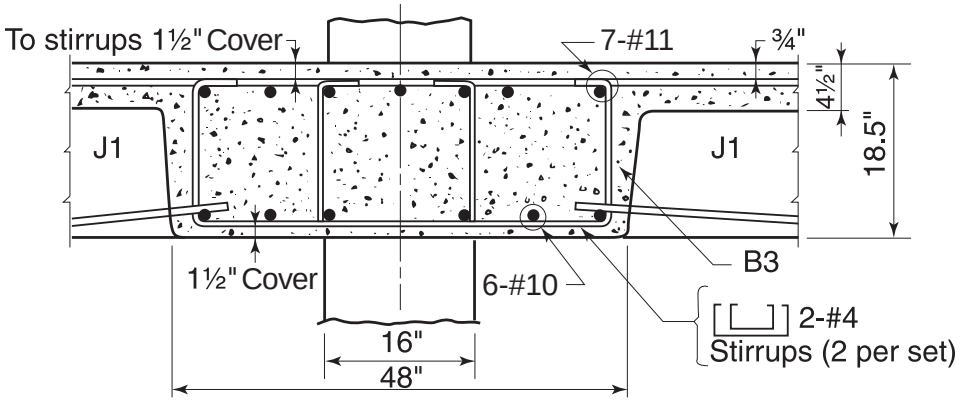

Figure 12-7 Joist-Band Beam B3

$k = \sqrt{2\rho n + (\rho n)^2} - \rho n$ $\quad C = [4k^3 + 12n\rho\,(1-k)^2]$ $\quad I_{cr} = Cd^3$

*These coefficients are based on E = 3,605,000 psi for normal-weight concrete with f'_c = 4,000 psi. They are applicable, however, for most purposes for 3000 psi < f'_c < 5,000 psi.

DESIGN FOR SERVICEABILITY

Control of Deflections. For routine use of the tabulated beam designs, it should not be necessary to compute live load deflection. Unless marked with an *, X, or Y, to footnote references, all the tabulated load capacities with 100 percent of the live load cause deflection less than ℓ/360. Thus, live load deflection automatically conforms to the usual limit required (ACI 9.5.2.6). Where necessary, the coefficients tabulated for each beam design should be helpful in computing the deflection for any special requirements such as stricter deflection limits, or to subtract superimposed dead loads. When long-term (creep) deflections must be determined, it will be necessary to compute the sum of the service dead load and long-term portion of the service live load, as well as the proper coefficient for creep since these values vary with type of loading considered. Where conditions require that an estimated deflection for a particular beam be prepared, the coefficients in Table 12-1 will be convenient for determination of gross and cracked moments of inertia required.

COEFFICIENTS FOR DEFLECTION COMPUTATIONS

If live load is limited by the requirement that immediate deflection is not to exceed 1/360 times the span, the following formulas may be used to determine maximum load:

Single Span $\quad W = 5{,}250\, I/L^3$
End Span $\quad W = 8{,}050\, I/L^3$
Interior Span $\quad W = 13{,}050\, I/L^3$

in which W = actual load(not multiplied by load factors) in plf
L = span in feet
I = average effective moment of inertia in in.^{4}

Moment of inertia for a reinforced concrete member can involve complex manual computations. The Code permits use of the *average* of positive and negative moment sections, that is, midspan and face of support (ACI 9.5.2.4).

The *effective* moment of inertia, I_e, is

$$I_e = \left(\frac{M_{cr}}{M_a}\right)^3 I_g + \left[1 - \left(\frac{M_{cr}}{M_a}\right)^3\right] I_{cr} \qquad \text{(ACI Eq. 9-8)}$$

in which the cracking moment for normal-weight concrete, $M_{cr} = 7.5\sqrt{f_c'}\, I_g/y_t$ and M_a = actual service load moment. Values of I_g per foot of width are equal to t^3, where t is the overall depth of the member. The transformed moment of inertia:

$$I_{cr} = d^3\,[4k^3 + 12\,n\rho\,(1-k)^2]$$

where: $n = E_s/E_c$

$$k = \sqrt{2\rho n + (\rho n)^2} - \rho n$$

is tabulated in Table 12-1 for $0.009 \le \rho \le 0.018$. For $\rho < 0.009$, a conservative solution is to use I_{cr} for $\rho = 0.009$ and (M_{cr}/M_a) = 0.5.

Note: For intermediate values of depth or reinforcement ratio, straight line interpolation is sufficiently accurate. For depths beyond the range tabulated, use value of *C* (bottom line) for computation of I_{cr}.

Crack Control. Chapter 6 in this Handbook includes a discussion of Code requirements for crack control. All tabulated designs here comply with crack control requirements for beam stems (ACI 10.6).

Top bars in beams, and also in girders, must be physically located above the beam stem in usual situations where the beam supports the slab and girders support the beams. Crack control at the top surface is mainly dependent upon the one or two layers of slab bars above the top beam bars, and both slab and beam bars above top girder bars. Tabulated designs provide number of top bars accordingly.

For isolated T-beams, I-beams, or other flanged shapes, top bars must be spaced across the width of flanges in tension (ACI 10.6.6).

The Code requirements for crack control with Grade 60 reinforcing bars (distribution of flexural reinforcement in beams—ACI 10.6) are:

1. Only deformed bars may be used.
2. Tension reinforcement must be well distributed in zones of **maximum** concrete tension.
3. Where flanges are in tension, part of the main tension reinforcement shall be distributed in the effective flange width or a width equal to 1/10 of the span, whichever is smaller.
4. Spacing of reinforcing bars must not exceed

$$s = 15\left(\frac{40{,}000}{f_s}\right) - 2.5c_c \quad \text{(ACI Eq. 10-4)}$$

but not greater than

$$12\left(\frac{40{,}000}{f_s}\right)$$

where $f_s = (2/3)\ f_y$, psi (assumed)

c_c = concrete cover, in.

Maximum spacing of reinforcing bars, computed by ACI Eq. 10-4 and assuming f_y = 60,000 psi (Grade 60 reinforcing bars) and 1½ inches concrete cover, is as follows:

#3 stirrups - 10¼ in.
#4 stirrups - 10 in.
#5 stirrups - 9½ in.

When the effective depth, *d*, of a beam exceeds 36 inches, skin reinforcement is also required for crack control (ACI 10.6.7). In the tabulated designs in this Chapter, only the beams with overall depths, *h*, of 42 inches and 48 inches will require skin reinforcement, A_{sk}. For *h* = 42 inches or 48 inches, 3-#3 reinforcing bars in each face of the web would provide the required A_{sk}. Skin reinforcement is not listed in the tabulated designs. For beams with rather large cross sections, as in these cases for *h* = 42 inches or 48 inches, the recommended minimum longitudinal bar size is a #5.

MAXIMUM NUMBER OF BARS IN BEAM STEMS

The practical problem of physically fitting the reinforcing bars into the width of stem available between stirrups at Code-required concrete cover and clear spacings between bars limits the *maximum* number of given size bars in a single layer. These Code requirements, for minimum concrete cover and spacing, are based on practical problems of placing concrete, weather, and fire resistance (ACI 7.6.1, 7.6.2, and 7.7.1). The ACI Building Code concrete cover requirements and the concrete cover used in the tabulated designs are shown in Fig. 12-8. Maximum number of bars in beam stems are based on concrete cover and clear spacings (Fig. 12-9) and overall (not nominal) bar diameter.

Tables 12-2(a) and 12-2(b) give the minimum and maximum number of reinforcing bars in a single layer in beam stems. The values in the tables are based on combining the Code requirements for crack control and the provisions for clear spacings. An "N.A." in the tables indicates that the maximum number of reinforcing bars, based on the required clear spacing including aggregate size and concrete cover, is less than the minimum number of bars which are required for crack control.

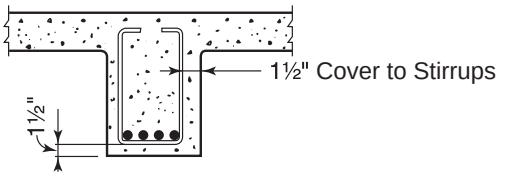

Figure 12-8 Concrete Cover Requirements for Cast-in-Place Beams

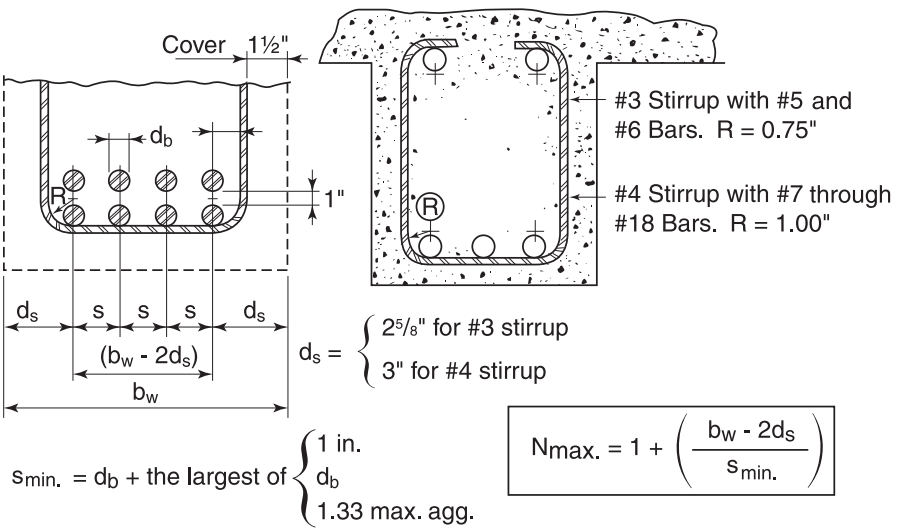

Figure 12-9 Maximum Number of Bars in Beam Stems

Table 12-2(a) – Minimum and Maximum Number of Bars in a Beam (Single Layer)

48	6	21	6	20	6	19	6	18	6	17	6	15	6	13	6	12	6	9

1. Minimum number of bars is based on crack control requirements of ACI 10.6.
2. Maximum mumber of bars is based on clear spacing requirements of ACI 3.3.2(c) and ACI 7.6.1.
3. Overall bar diameter, rather than nominal bar diameter, was used in calculating the maximum number of bars.

STIRRUP DESIGNATION NOTATION

Stirrup layout pattern is in the following format:

N1 N2 S3 S4 S5 where:

N1 is a two digit number denoting the number of stirrups at each end of the beam.

N2 is a one digit number representing the size designation of the reinforcing bar.

S3 definition depends on whether S4 and S5 are also listed. If S4 and S5 are not listed, then S3 is the symbol for the maximum spacing of the stirrups (inches).

If S4 and S5 are listed, then S3 is the symbol for the intermediate spacing of the stirrups, required at a distance *d* from the face of the support (inches).

S4 is the symbol for the number of stirrups at the intermediate spacing.

S5 is the symbol for the spacing of the remainder of the stirrups (inches).

Note that first stirrup is always 2 inches from the face of the support.

The physical meaning of symbols S3, S4 and S5 are as follows:

S3, S5 (Stirrup Spacings)

Symbol	Spacing	Symbol	Spacing
A	3″	0	16″
B	4″	P	17″
C	5″	Q	18″
D	6″	R	19″
E	7″	S	20″
F	8″	T	21″
G	9″	U	22″
H	10″	V	23″
I	11″	W	24″
J	12″	X	25″
K	13″	Y	26″
M	14″	Z	27″
N	15″		

S4 (Stirrup Number)

Symbol	No.	Symbol	No.	Symbol	No.	Symbol	No.
a	1	n	14	A	27	N	40
b	2	o	15	B	28	0	41
c	3	p	16	C	29	P	42
d	4	q	17	D	30	Q	43
e	5	r	18	E	31	R	44
f	6	s	19	F	32	S	45
g	7	t	20	G	33	T	46

l	12	y	25	L	38	Y	51
m	13	z	26	M	39	Z	52

Examples:

294B means 29-#4: 1 @ 2″, 28 @ 4″ Each End

175K means 17-#5: 1 @ 2″, 16 @ 13″ Each End

275CgF means 27-#5: 1 @ 2″, 7 @ 5″, 19 @ 8″ Each End

305CqH means 30-#5: 1 @ 2″, 17 @ 5″, 12 @ 10″ Each End

SPECIAL STIRRUP LAYOUT REQUIREMENTS

For deep, narrow beam cross sections, closed stirrup requirements for full design torsional moment strength, $\phi T_n \geq T_u \geq \phi 4\sqrt{f'_c}(A^2_{cp}/p_{cp})$, plus high shear may become impracticable for placing reinforcement. Similarly, in shallow beams heavily reinforced for flexure in cases of short spans and high vertical shear, the limited depth precludes use of larger sizes for closed stirrups and the full $\phi T_n \geq T_u$ cannot be developed. These situations indicate that a larger section should be used or that a special design is required (perhaps full $\phi T_n \geq T_u$ is more than required, etc.).

Some intermediate situations may also arise, particularly where a large number of closed stirrups for full $\phi T_n \geq T_u$ are required at a very small intermediate spacing. These layouts are outside the range of the standardized notation in this Chapter for stirrup patterns and must be considered a special case design.

SELECTION OF OPEN STIRRUPS/CLOSED STIRRUPS FOR FLEXURAL MEMBERS UNDER SHEAR OR COMBINED SHEAR AND TORSION

Three principal points that should be kept in mind are:
(1) For structural safety, adequate shear and torsion reinforcement is very important, since the failure mode is brittle. The Code provisions are, properly, conservative to avoid failure with no warning signs as in the ductile flexural mode, that is, cracking, deflection, etc.
(2) For economy in construction, the selection of shear-torsion reinforcement is also important. Per pound, the small pieces of small bars require disproportionately large amounts of high cost shop labor and field labor in placing.
(3) For economy in design time, a complete step-by-step procedure to meet each applicable Code requirement is prohibitive—design aids to avoid all the Code calculations are essential.

Structural analysis can usually be done quickly to establish maximum shear and torsion at the section located a distance, d, from face of supports. The coefficients (ACI 8.3.3) for shear are generally applicable for uniform loads, and are reasonable even where a triangular loaded slab area contributes shear load to the beam. The former assumption results in a linear decrease in shear from face of the support toward midspan. Similarly, torsion from slabs under uniform load is also generally assumed to decrease linearly from the same critical section, d, from face of support.

A refinement used only with heavy live loads (warehouse loads, etc.) when a real probability of partial load exists is to consider a minimum live load shear at interior midspans equal to $w_{v\ell}\,\ell/8$. Usually, shear at midspan is taken as zero.

A corollary of the three points made is that design time is more cost-effective applied to a quick, conservative analysis than a meticulous "minimum weight" layout of an intricate pattern of stirrup spacings. An "exact" minimum weight solution for stirrups with an intricate layout pattern closely following the linear decrease in total shear can be run off from a computer. It is merely a valuable time-saving start in the design process. Adjustment into a simpler pattern can be performed. If necessary to use the maximum spacing, $d/2$, larger size stirrup substitutions may be made, e.g., #4 for #3 at double spacing, #5 for #4 at 1.5 times spacing.

The stirrup layout patterns shown in this Handbook are "minimum cost" solutions. Minimum cost solutions for simple placing of reinforcement were limited to three spacings: the first stirrup located 2 inches from face of support as a minimum clearance, an intermediate spacing, and finally a maximum spacing, usually $d/2$ for open stirrups, and $d/4$ for closed stirrups.

In all cases, the largest practical reinforcing bar size as limited by width or depth of the beam was used. See the following tabulation for minimum width of beam to allow for bend radii at corners of stirrups.

Stirrup	Minimum Width of Beam
#3	10 in.
#4	12 in. – 14 in.
#5	14 in.

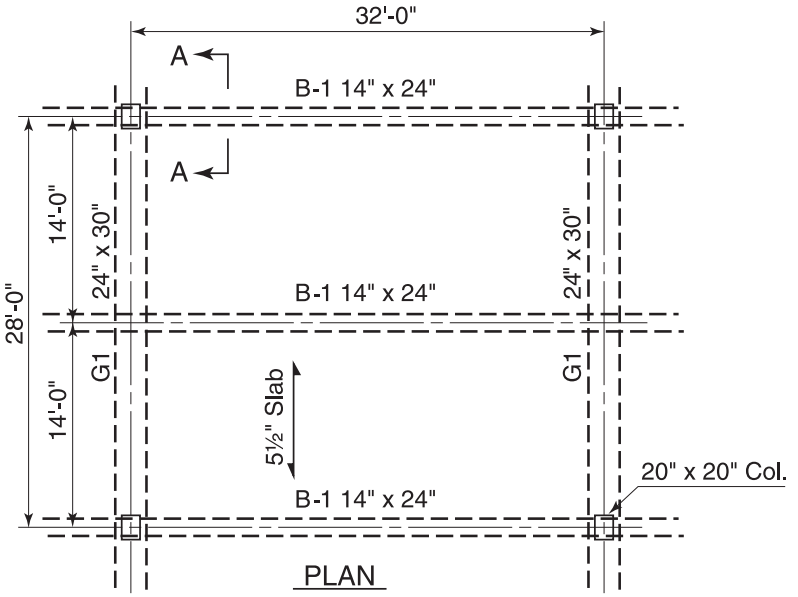
The applicable Code provisions were considered in stirrup selections presented in this Chapter. These requirements affecting both size and *layout* (spacings) of stirrup patterns are listed as follows:

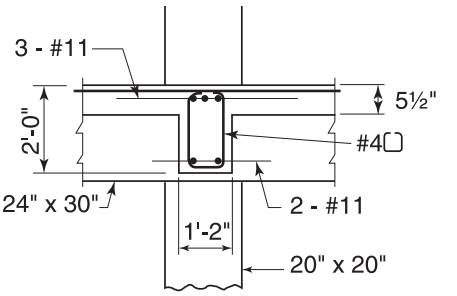
Code Requirements for Stirrup Size and Layout

11.4.4	Extend $(d - d')$ and anchor per 12.13.
11.4.5.1	Maximum spacing, $s = 0.5d$.
11.4.5.3	When $V_s > 4\sqrt{f'_c}\ b_w d$, maximum $s = 0.25d$.
11.5.6.1	Closed stirrups – maximum spacing is $p_h/8 < 12$ in.
12.13.2.1	For #5 or smaller, a standard hook (90° or 135°) enclosing a longitudinal bar. Stirrups used in tabulated designs are #3, #4, or #5. (Anchorage of #6, #7, and #8 stirrups must conform to 12.13.2.2.)

Figs. 12-1 and 12-4 show typical details recommended for flexural reinforcement and shear/torsion, respectively.

MANUAL EXAMPLE – BEAM B-1
(TORSION NEGLIGIBLE)





MATERIALS
f'_c = 4,000 psi
f_y = 60,000 psi

FLOOR LOAD
5½″ slab = 69 psf
Ceilings = 4
Partitions = 20
93 psf
Service live load = 125 psf
q_u = 1.2(93) + 1.6(125) = 312 psf

BEAM B-1 (Spanning between girders, G1)

Loads
Floor (0.312) (14) = 4.37
Beam Stem ((18.5 (14)/144) (0.15) (1.2) = 0.32
w_u = 4.69 kips/ft

See tables on Page 12-64: For ℓ_n = 30′-0″, h = 24 in. and b_w = 14 in.; select third tabulated design with load capacity = 4.72 kips/ft – Okay

Review tabulated design

Flexure
$+M_u = w_u \ell_n^2/16$
$+M_u$ = (4.69) $(30)^2/16$ = 263.8 ft-kips
d = 24 – (1.5 + 0.5[#4 stirrup] + 1.41/2) = 21.3 in.

$$\text{Required } A_s = \frac{1.7 f'_c b_w d}{2 f_y} - \frac{1}{2}\sqrt{\frac{2.89(f'_c b_w d)^2}{(f_y)^2} - \frac{6.8 f'_c b_w M_u}{\phi (f_y)^2}}$$

$$= \frac{1.7\,(4)\,(14)\,(21.3)}{2(60)} - \frac{1}{2}\sqrt{\frac{2.89(4 \times 14 \times 21.3)^2}{(60)^2} - \frac{6.8(4)\,(14)\,(263.8 \times 12)}{(0.90)\,(60)^2}}$$

Required A_s = 3.02 in.^{2}

Bottom bars tabulated: 2-#11
A_s provided = 2(1.56) = 3.12 in.^{2} > 3.02 - Okay

Confirm section is tension-controlled so ϕ = 0.90

$$\text{Actual } \rho = \frac{A_s}{b_w d} = \frac{3.12}{(14)(21.3)} = 0.0105$$

From Chapter 5; for f'_c = 4,000 psi and f_y = 60,000 psi:

Max ρ = 0.0181 for ϕ = 0.90
Actual ρ = 0.0105 < max ρ ; hence, ϕ = 0.90

$-M_u = w_u \ell_n^2/11$

$-M_u$ = (4.69) $(30)^2/11$ = 383.7 ft-kips

d = 24 – (1.5 + 0.5 + 1.41/2) = 21.3 in.

$$\text{Required } A_s = \frac{1.7\,(4)\,(14)\,(21.3)}{2(60)} - \frac{1}{2}\sqrt{\frac{2.89\,(4 \times 14 \times 21.3)^2}{(60)^2} - \frac{6.8\,(4)\,(14)\,(383.7 \times 12)}{(0.90)\,(60)^2}}$$

Required A_s = 4.64 in.^{2}

Top bars tabulated: 3-#11

A_s provided = 3(1.56) = 4.68 in.^{2} > 4.64 – Okay

Confirm section is tension-controlled so ϕ = 0.90

$$\text{Actual } \rho = \frac{A_s}{b_w d} = \frac{4.68}{(14)(21.3)} = 0.0157$$

Max ρ = 0.0181 for ϕ = 0.90
Actual ρ = 0.0157 < max ρ ; hence, ϕ = 0.90

Torsion

Assume Beam B-1 fixed at both ends. Conservatively, slab width = 30 ft.

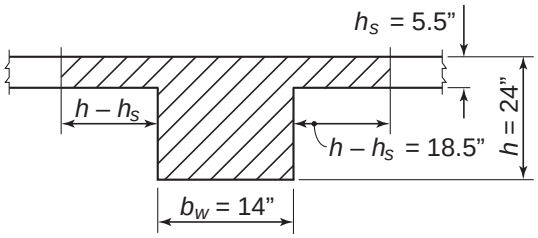
Gross moment of inertia of slab,

$I_g = 360\ (5.5)^3/12 = 4{,}990\ \text{in.}^4$

Flexural stiffness of slab,

$$K_s = \frac{4I_gE_c}{\ell} = \frac{4(4{,}990)\ E_c}{(14)\ (12)} = 118.8\ E_c$$

Torsional moment of inertia, J, of Beam B-1,



Beam Section for Calculating *J*

$J = (b_w)^3(h)/3 - (b_w)^4/5 + 2\ [(h_s)^3(h - h_s)/3 - (h_s)^4/5]$

$J = (14)^3\ (24)/3 - (14)^4/5 + 2[(5.5)^3(18.5)/3 - (5.5)^4/5]$
$= 15{,}955\ \text{in.}^4$

Torsional stiffness of Beam B-1,

$$K_t = \frac{GJ}{\ell} = \frac{(0.45E_c)\ (15{,}955)}{(30)(12)} = 19.9E_c$$

Assume slab live loads and partitions in alternate panels.

Fixed-end moment:

$-M_u = w_u(\ell_n)^2/12$

$-M_u = (1.6 \times 0.125 + 1.2 \times 0.020)\ (14)^2/12 = 3.66$ ft-kips/ft

$\Sigma K_s = (118.8\ E_c)\ (2) = 237.6\ E_c$ Slabs = 92%

$K_t =$ $19.9\ E_c$ Beam = 8%

$257.5\ E_c$ Total = 100%

$T_u = (3.66)\ (15 - 21.3/12)\ (0.08) = 3.87$ ft-kips at each end of B-1

Compare T_u vs. $\phi\sqrt{f'_c}\left(\frac{A^2_{cp}}{p_{cp}}\right)$

$A_{cp} = 14 \times 24 = 336\ \text{in.}^2$

$p_{cp} = 2(14 + 24) = 76$ in.

$$\phi\sqrt{f'_c}\left(\frac{A^2_{cp}}{p_{cp}}\right) = 0.75\ \sqrt{4{,}000}\ (336)^2/76$$
$$= 70{,}462\ \text{in.-lb}$$
$$= 5.87\ \text{ft-kips}$$

$T_u = 3.87$ ft-kips < 5.87 ft-kips, so torsion is resisted by concrete and no torsion reinforcement is required.

Shear

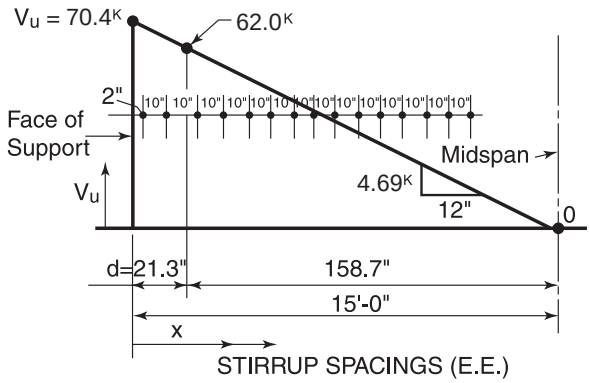
$\phi V_c = \phi\, 2\sqrt{f'_c}\, b_w d = 0.75(2)\sqrt{4{,}000}\ (14)\ (21.3)/1{,}000$
$= 28.3$ kips

At $d = 21.3$ in. from face of support

$V_u = 4.69\ (15 - 21.3/12) = 62.0$ kips

Maximum size stirrups, see Page 12-15.

For $b = 14$ in., #4 stirrups



Use #4 U-shaped stirrups; determine required spacing:

$$s = \frac{\phi A_v f_y d}{(V_u - \phi V_c)} = \frac{(0.75)(0.40)(60)(21.3)}{(62.0 - 28.3)} = 11.4'' > d/2 = 10''$$

Extend stirrups until $V_u = 0.5\ \phi V_c = 0.5(28.3) = 14.2$ k

Extend to (14.2 kips/4.69 kips/ft) = 3.03 ft from midspan

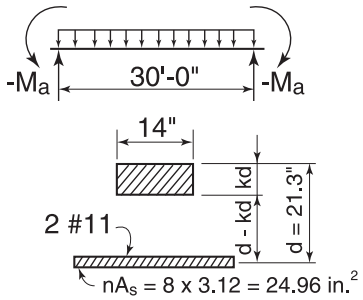
Spaced at 10″, (15 – 3.03)12/10 = 15 spaces are required

Use: 16-#4; 1 @ 2″, 15 @ 10″ at each end of beam

See Page 12-64; read "164H". See Page 12-14 for pattern.

Deflection

Calculate I_{cr} for positive moment section



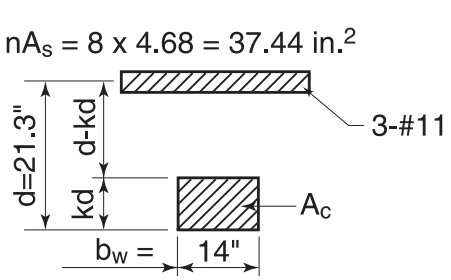
$n = E_s/E_c = 29 \times 10^6/57{,}000\ \sqrt{4{,}000} = 8$

$14(kd)^2/2 = 24.96(21.3 - kd)$

Solving: $kd = 7.11$ in.

$I_{cr} = 14(7.11)^3/3 + 24.96(21.3 - 7.11)^2 = 6{,}703\ \text{in.}^4$

Calculate I_{cr} for negative moment section



$14(kd)^2/2 = 37.44\ (21.3 - kd)$

Solving: $kd = 8.33$ in.

$I_{cr} = 14(8.33)^3/3 + 37.44\ (21.3 - 8.33)^2 = 8{,}996$ in.^{4}

$I_g = b_w h^3/12 = 14(24)^3/12 = 16{,}128$ in.^{4}

Take average service load as (1.2D + 1.6L)/1.4, conservatively.

Average service load = 4.69/1.4 = 3.35 kips/ft

$\pm M_a = w(\ell_n)^2/16 = 3.35(30)^2/16 = 188.4$ ft-kips

$$I_e = \left(\frac{M_{cr}}{M_a}\right)^3 I_g + \left[1 - \left(\frac{M_{cr}}{M_a}\right)^3\right] I_{cr} \quad \text{(ACI Eq. 9-8)}$$

Where:

$$M_{cr} = 7.5\sqrt{f'_c}\, I_g/y_t = \frac{7.5\sqrt{4{,}000}\,(16{,}128)}{12(12{,}000)} = 53.1 \text{ ft-kips}$$

$$I_e = \left(\frac{53.1}{188.4}\right)^3 (16{,}128) + \left[1 - \left(\frac{53.1}{188.4}\right)^3\right]\left(\frac{6{,}703 + 8{,}996}{2}\right)$$
$$= 8{,}035 \text{ in.}^4$$

Deflection

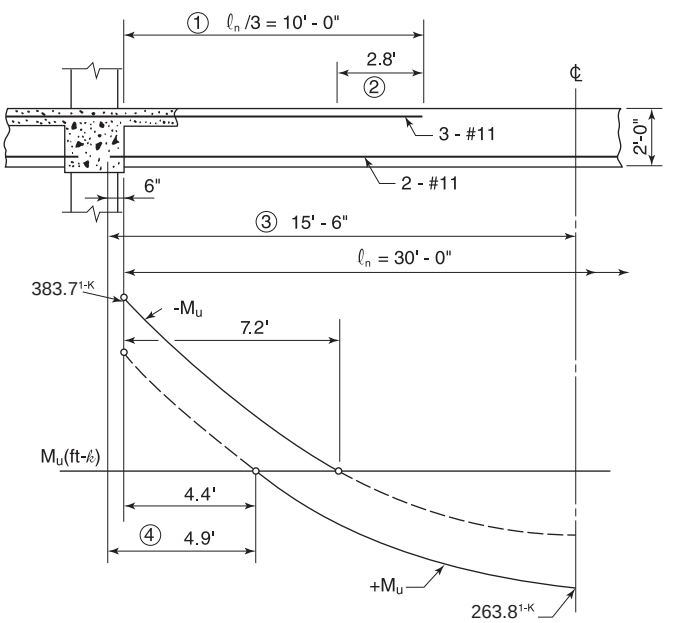
$$\Delta = \frac{2w\,(\ell_n)^4}{384 E_c I_e} = \frac{2(3{,}350/12)\,(360)^4}{(384)(57{,}000\sqrt{4{,}000})(8{,}035)} = 0.84 \text{ in.}$$

Compare calculated $\Delta = 0.84$ in. with tabulated deflection coefficient, $C = 311$.

Deflection based on $C = \Delta_c$
$= (C \times 10^{-9})$ (w in kips/ft) (ℓ_n in ft)^4

Thus, C corresponding to calculated $\Delta = 0.84$ in. is:

$$C = \frac{0.84 \times 10^9}{(3.35)\,(30)^4} = 310 \text{ (tabulated } C = 311)$$



Development

Top bars: 3-#11

Concrete cover = 1.5 + 0.5 (#4 stirrups) = 2 in. = 2/1.41 or $1.4d_b$;

Chapter 5; from Table 5-2(b), Case 1;
$\ell_d = 87$ in. $= 7.25$ ft

Dimension ① = $10.0' > \ell_d = 7.25'$, okay

Dimension ② = $2.8' > 12d_b = 1.41'$, okay
$> d = 1.78'$, okay
$> \ell_n/16 = 1.88'$, okay
} (ACI 12.10.3 and 12.12.3)

Bottom bars: 2-#11

Concrete cover = 2 in. or $1.4d_b$ as for the #11 top bars

Chapter 5; from Table 5-2(b), Case 1;
$\ell_d = 67$ in. $= 5.58$ ft

At inflection point, check $\ell_d \le M_n/V_u + \ell_a$ (ACI Eq. 12-5)

$a = A_s f_y/0.85 f'_c b_w$

$a = 3.12\ (60)/0.85(4)\ (14) = 3.93$ in.

$M_n = A_s f_y(d - a/2)$

$M_n = 3.12\ (60)\ (21.3 - 3.93/2)/12 = 301.6$ ft-kips

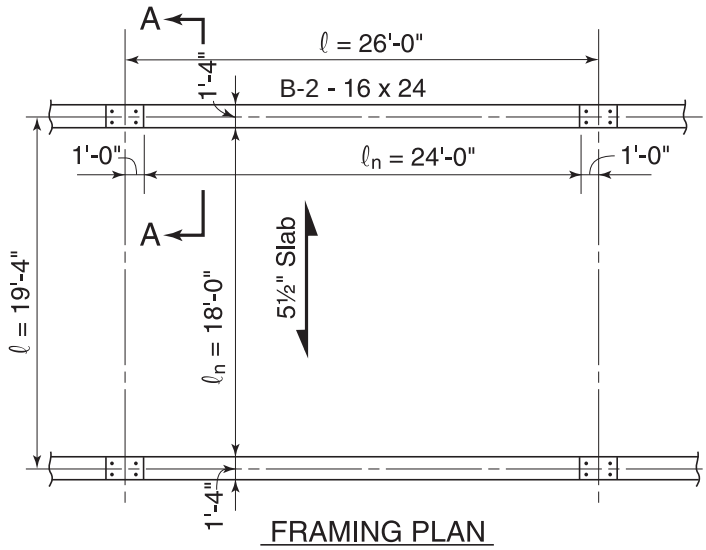
$V_u = 70.4 - 4.69\ (4.4) = 49.8$ kips

ℓ_a is larger of $12d_b = 16.9''$ or $d = 21.3''$

$M_n/V_u + \ell_a = 301.6(12)/49.8 + 21.3 = 94.0''$
$> \ell_d = 67''$, okay.

Dimension ③ = $15.5' > \ell_d = 5.58'$, okay
Dimension ④ = $4.9' > 12d_b = 1.41'$, okay
$> d = 1.77'$, okay
} (ACI 12.10.3)

Since closed stirrups are not provided, structural integrity (ACI 7.13.2.5) would require lap splicing (Class B) of at least 25 percent of the bottom A_s required at midspan to the bottom bars in the adjacent spans. Hence, the above check on Dimension ④ would be affected.



FRAMING PLAN

Review the tabulated design of an interior span of a continuous beam, designated as Beam B-2 in this example, for combined shear and torsion only. Beam B-2, a spandrel beam, is subjected to uniformly distributed factored gravity loads, and a uniformly distributed factored torsional moment over its clear span, $\ell_n = 24'\text{-}0''$.

Assume Beam B-2 with b_w = 16 in. and h = 24 in. This is the first tabulated design on Page 12-64 with a load capacity = 4.07 kips/ft.

Reinforcement tabulated:

Top bars: 3-#8, A_s = 2.37 in.^{2}

Bottom bars: 2-#8, A_s = 1.58 in.^{2}

Stirrup pattern for shear and negligible torsion: 113H

Stirrup pattern for combined shear and maximum torsion: 184F

Torsion

The effects of torsion can be neglected when

$$T_u < \phi\sqrt{f'_c}\left(\frac{A^2_{cp}}{p_{cp}}\right) \text{ (ACI 11.5.1-a)}$$

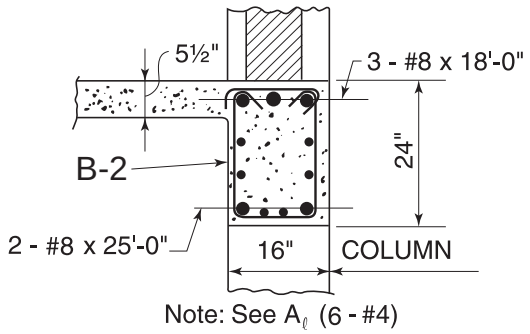
For Beam B-2:

$A_{cp} = 16 \times 24 = 384$ in.^{2}

$p_{cp} = 2(16 + 24) = 80$ in.

$T_u = 0.75\sqrt{(4000)}(384)^2/(80)(12{,}000) = 7.3$ ft-kips

For a uniformly distributed factored torsional moment applied over the 24-ft clear span, the computed value, T_u = 7.3 ft-kips, would be the (total) factored torsional moment at a distance, d, from the face of the support where open stirrups could be used.



SECTION A-A

The effective depth, d, for the 3-#8 top bars and #4 stirrups:

$d = 24 - (1.5 + 0.500 + 1.000/2) = 21.5$ in. or 1.79 ft

The tabulated value of T_u is the (total) factored torsional moment at the face of the support.

For Beam B-2 (at face of support):
$T_u = 12/(12 - 1.79)(7.3) = 8.6$ ft-kips (tabulated = 9), okay

Closed stirrup capacity:

When a beam uses closed stirrups, the beam can be designed for:

$$\text{Max } T_u = \phi 4\sqrt{f'_c}\left(\frac{A^2_{cp}}{p_{cp}}\right) \text{ (ACI 11.5.2.2-a)}$$

For Beam B-2 (at a distance d from face of support):

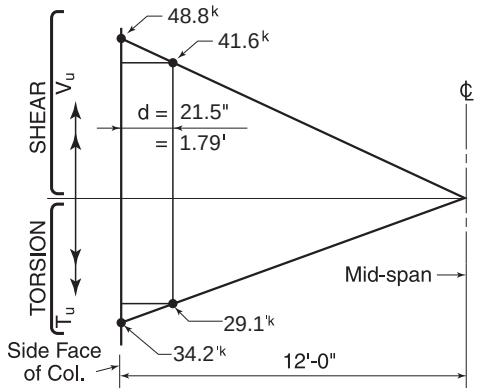
Max $T_u = (0.75)(4)\sqrt{4{,}000}(384)^2/(80)(12{,}000) = 29.1$ ft-kips

For Beam B-2 (at face of support):

Max T_u = 12/10.21 (29.1) = 34.2 ft-kips (tabulated = 34), okay

Combined shear and torsion considerations:

Reinforcement required for combined shear and torsion:



At distance d from face of support:
$V_u = 4.07\ (12 - 1.79) = 41.6$ kips
$T_u = 29.1$ ft-kips (previously calculated)

Check adequacy of cross-sectional dimensions

$$\sqrt{\left(\frac{V_u}{b_w d}\right)^2 + \left(\frac{T_u p_h}{1.7 A_{oh}^2}\right)^2} \le \phi\left(\frac{V_c}{b_w d} + 8\sqrt{f_c'}\right) \text{(ACI Eq. 11-18)}$$

Where:

$p_h = 2(x_1 + y_1) = 2(12.500 + 20.500)$

$p_h = 66.0$ in.

$A_{oh} = (x_1)(y_1) = (12.500)(20.500)$

$A_{oh} = 256$ in.^{2}

$$\sqrt{\left(\frac{41{,}600}{16(21.5)}\right)^2 + \left(\frac{29.1 \times 12{,}000(66.0)}{1.7\ (256)^2}\right)^2} = 240 \text{ psi}$$

Compute maximum shear and torsion capacity for this cross section:

$0.75\ (2\sqrt{4{,}000} + 8\sqrt{4{,}000}) = 474$ psi

$240 < 474$, okay

Stirrups required for shear.
$\phi V_s = V_u - \phi V_c$

Where:
$\phi V_c = \phi 2\sqrt{f_c'}\, bd = 0.75(2)\sqrt{4{,}000}(16)(21.5)/1000$
$= 32.6$ kips
$\phi V_s = 41.6 - 32.6 = 9.0$ kips

$$\text{Required } A_v = \left(\frac{V_s s}{\phi f_{yt} d}\right) \text{ (ACI Eq. 11-15)}$$

For shear, max $s = d/2 \approx 10$ in.

For combined shear and torsion, max $s = p_h/8$ or 12 in.

Max $s = 66.0/8 = 8.25$ in. < 12 in., use 8 in.

For $s = 8$ in., required $A_v = \dfrac{(9.0)(8)}{(0.75)(60)(21.5)} = 0.074$ in.^{2}

Vertical stirrups required for torsion:

$$T_n = \frac{2A_o A_t f_{yt}}{s} \cot\theta \text{ (ACI Eq. 11-21)}$$

$A_o = 0.85\ A_{oh} = 0.85\ (256) = 218$ in.^{2}

$$A_t = \frac{T_n s}{\phi 2\ A_o\ f_{yt} \cot\theta}$$

$$\text{Required } A_t = \frac{29{,}100\ (12)\ (8)}{0.75(2)\ (218)\ (60{,}000)\ (1)} = 0.142 \text{ in.}^2$$

For combined shear and torsion, the required area of stirrups spaced at 8 in.:

$A_v/2 + A_t = 0.074/2 + 0.142$
$= 0.18$ in.$^2 <$ #4 (0.20 in.^{2}), okay

Min area of closed stirrups,

$$A_v + 2A_t = 0.75\sqrt{f_c'}\ \frac{b_w s}{f_{yt}} \ge \frac{50 b_w s}{f_{yv}} \text{ (ACI Eq. 11-23)}$$

$$\frac{50 b_w s}{f_{yt}} = \frac{50\,(16)\,(8)}{60{,}000} = 0.11 \text{ in.}^2 < 0.20 \text{ in.}^2\text{, okay}$$

Longitudinal bar area required for torsion:

$$A_\ell = \frac{A_t}{s}\, p_h\, \frac{f_{yt}}{f_y} \cot^2\theta \text{ (ACI Eq. 11-22)}$$

$$A_\ell = \left(\frac{0.142}{8}\right)(66.0)(1)(1)$$
$= 1.17$ in.^{2} (tabulated = 1.3), okay

$$\text{Min } A_\ell = \frac{5\sqrt{f_c'}\ A_{cp}}{f_y} - \frac{A_t}{s}\, p_h\, \frac{f_{yt}}{f_{y\ell}} \text{ (ACI Eq. 11-24)}$$

where $A_t/s \ge 25\ b_w/f_{yt}$

$25\ b_w/f_{yt} = 25\ (16)/60{,}000 = 0.007$

$A_t/s = (0.142/8) = 0.018 > 0.007$, Okay

$$\text{Min } A_\ell = \frac{5\sqrt{4{,}000}\,(384)}{60{,}000} - \left(\frac{0.142}{8}\right)(66.0)\frac{60{,}000}{60{,}000} = 0.85 \text{ in.}^2$$

Torsion reinforcement must be provided for a distance (b_t + d) past the point where theoretically required (ACI 11.5.6.3):

$b_t + d = 16 + 21.5 = 37.5$ in. or 3.13 ft

Torsion reinforcement is not required where $T_u \leq 7.3$ ft-kips. The point where $T_u = 7.3$ ft-kips is 9.44′ from face of support. Since 9.44 + 3.13 = 12.57′ > 12.0′, torsion reinforcement is required over the entire span of Beam B-2.

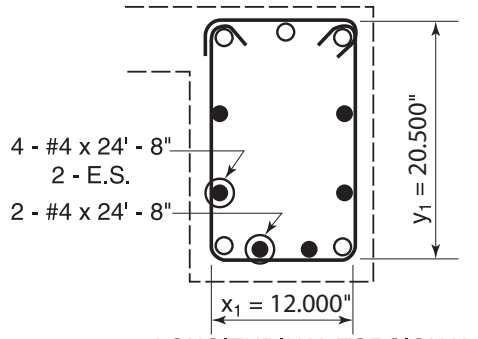
Stirrup pattern tabulated is 184F, stirrups extend 2″ + 17(8) = 138″ each side of midspan (within 6″ of midspan), okay.

6-#4 = 6 × 0.20 = 1.20 in.^{2} > 1.17 okay

Auxiliary longitudinal reinforcement for torsion, A_ℓ: ●

Main flexural reinforcement, A_s: ○

A_ℓ length – 2[136″ (extension into span)
+ 24″ (column)] = 296″ = 24′–8″



LONGITUDINAL TORSIONAL REINFORCEMENT, A_ℓ

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches ($b - 2''$).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360 <$ deflection $< \ell_n/240$
X – $\ell_n/240 <$ deflection $< \ell_n/180$
Y – deflection $> \ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For $b > 24$ in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as $w/1.4$.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

f_c' = 4,000 psi
f_y = 60,000 psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

f_c' = 4,000 psi
f_y = 60,000 psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

f_c' = 4,000 psi
f_y = 60,000 psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

f_c' = 4,000 psi
f_y = 60,000 psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).

(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.

(3) For superimposed factored load capacity, deduct 1.2 × stem weight.

(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$

(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation: N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

f_c' = 4,000 psi
f_y = 60,000 psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

f_c' = 4,000 psi
f_y = 60,000 psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

f_c' = 4,000 psi
f_y = 60,000 psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation: N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation: N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation: N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation: N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360 <$ deflection $< \ell_n/240$
X – $\ell_n/240 <$ deflection $< \ell_n/180$
Y – deflection $> \ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For $b > 24$ in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as $w/1.4$.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation: N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches (b – 2″).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360$ < deflection < $\ell_n/240$
X – $\ell_n/240$ < deflection < $\ell_n/180$
Y – deflection > $\ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For b > 24 in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation: N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

(1) See "Recommended Bar Details", Fig. 12-1. For girders, use tabulated beam depth – 2 inches ($b - 2''$).
(2) In "Layers" column, first line is number of layers for bottom bars, second line is for number of layers for top bars.
(3) For superimposed factored load capacity, deduct 1.2 × stem weight.
(4) Total capacities tabulated causing deflection in excess of $\ell_n/360$ are designated thus: * – $\ell_n/360 <$ deflection $< \ell_n/240$
X – $\ell_n/240 <$ deflection $< \ell_n/180$
Y – deflection $> \ell_n/180$

(5) For each beam design, first line is for open stirrups, second line is for closed ties. See Fig. 12-4. At free ends, use stirrups tabulated for "Interior Spans". For $b > 24$ in., provide 4 legs (two stirrups) of size and spacing tabulated. For stirrup nomenclature, see page 12-14.

Other notation:
N/A – STIRRUPS ARE NOT REQUIRED
** – MAXIMUM SPACING IS LESS THAN 3 INCHES. NOT RECOMMENDED
*** – SHEAR STRESS IS GREATER THAN $10\sqrt{f_c'}$
**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as $w/1.4$.

$f_c' = 4{,}000$ psi
$f_y = 60{,}000$ psi

**** – TORSION STRESS EXCEEDS ALLOWABLE

(6) $+\phi M_n$ and $-\phi M_n$ are design moment strength capacities for rectangular section $b \times h$
(7) Midspan elastic deflection (in.) = $C \times (w/1.4) \times \ell_n^4$, where w = tabulated load (k/ft.), ℓ_n in ft.
"Average service load" is taken as w/1.4.

CHAPTER 13 – SQUARE SPREAD FOOTINGS, PILE CAPS AND DRILLED PIERS

This Chapter covers square spread footings for individual columns, pile caps for individual columns, and drilled pier (caisson) foundations.

SQUARE SPREAD FOOTINGS FOR INDIVIDUAL COLUMNS

The function of a spread footing is to distribute the total downward load of a column, pier or wall (including the weight of the footing itself) over a sufficient area of soil to keep the bearing pressure within that allowable for the soil encountered. Also, the centroid of the downward load should coincide with that of the soil pressure prism to avoid eccentricities and overturning.

Net factored axial load capacities for columns bearing on individual square spread footings are included in the tabulated designs in this Chapter. The footing designs are based on concrete with a compressive strength f'_c = 3,000 psi and reinforcing bars with f_y = 60,000 psi. In the tabulated designs, 1.2 times the weight of the footing has been deducted from the total factored load on the footing.

Allowable soil pressures are usually recommended by a geotechnical engineer, or set by the statutory building code as safe bearing capacities per square foot, where "safe" means for "service loads." The service load from column to footing is the computed dead load plus live load. For strength design, the total factored load becomes 1.2 × dead load plus 1.6 × live load (or other combinations as in ACI 9.2). A load factor of 1.4 times the "safe soil bearing capacity" will provide about the same "safety factor" on soil for 1.2 dead plus 1.6 live load from the column. Therefore, the tabulated designs are arranged for factored capacities of 1,400, 2,800, 4,200... psf, corresponding to the safe bearing capacities of 1,000, 2,000, 3,000... psf.

Usually, in design practice, and invariably throughout these tabulated designs, soil pressures are assumed uniformly distributed across the bottom of the footing. If the distribution pressure is high directly underneath the column and decreasing toward the edges of the footing, the footing bending moment would be reduced. If the distribution pressure is high around the edges of the footing and low in the center, the footing bending moment would be increased.

To meet the first functional requirement of a footing, all downward loads in the column from the floors above are accumulated. All dead loads will be multiplied by a factor of 1.2, as required by ACI 9.2.l. Included under this load factor are all floor finishes, ceilings, piping, ducts, partitions, cases, storage racks, fixed mechanical equipment, or any similar permanent, known, unvarying loads. Similarly, all live loads are augmented by a factor of 1.6 as required by ACI 9.2.l. Live loads are only the specified superimposed live loads, suitable values for which are specified in all statutory building codes with allowable reductions for column design. The effects of all wind, earthquake and other loads that should be used in the design of the column are similarly computed and properly augmented.

The effects of these various loadings will be combined into a required column strength, *U,* which is the largest from the equations in ACI 9.2:

$U = 1.4D$
$U = 1.2D + 1.6L$
$U = 1.2D + 1.0L + 1.6W$ (whichever is larger)

This maximum column required strength is the one to be used in entering the tabulated designs in this Chapter.

The strength-reduction factors, ϕ (ACI 9.3) have already been incorporated into the tabulated designs.

A footing can usually be made square, centered under the column it supports, and of size such as those tabulated. Rectangular footings can be substituted when space is restricted in one direction and not in the other. Round, octagonal, and other footing shapes can be used. Approximations are possible for such shapes from tabulated designs.

A word of caution: No tables or methods of computation can replace sound engineering judgment, especially in dealing with soil conditions. Selection of the footing design for an appropriate soil bearing capacity must be based on knowledge of the soil's characteristics.

Design Considerations

The general design considerations leading to the footing tabulated designs involve both code requirements and normal design and construction practices. Some of these considerations are listed below:

(1) Choice of materials. Normal-weight concrete with a specified compressive strength of 3,000 psi is usually the most economical choice. Higher strength concrete can be used where the depth or the weight of the footing is very critical and must be minimized, but usually savings in concrete volume do not offset

higher unit price. Lower strength concretes will reduce shear and increase development lengths. Grade 60 reinforcing bars (f_y = 60,000 psi) are the standard grade recommended for overall economy.

(2) Design for concentric load. Only special designs consider moment transfer from column to footing, which are outside the scope of the tabulated designs.

(3) Size of column. Again, conservatively, the smallest practicable reinforced concrete square tied column was assumed for design of the footings. Normally, for the loads shown, a larger column will be used with consequent reduction of factored shears and moments. For much larger columns on small footings with high soil bearing capacity, it may be worthwhile to reduce the reinforcement in proportion to the square of the ratio of reduced cantilever span to the tabulated dimension (except when minimum reinforcement controls).

(4) Effective depth. Average effective depth was used to compute both design shear strength and the required flexural reinforcement. For square footings, it is normal to require equal flexural reinforcement each way.

(5), Shear. Both two-way and one-way shear have been considered.

(6) Length of reinforcing bars. As is common practice, all reinforcing bars are shown as equal length. For each tabulated design, the bar size is the maximum for the available development length and minimum spacing. For very large footings, alternate length bars may be used, but an additional step in design is required to satisfy the stringent code requirements for bars cut off in tension zones (ACI 12.10.5).

(7) Minimum area of shrinkage and temperature reinforcement, A_s = 0.0018bh (ACI 10.5.4 and ACI 7.12)

Scope of Load Tables

The scope of the tabulated designs provide a range of safe bearing capacity from 1,000 psf to 15,500 psf in increments of 500 psf, which was considered adequate to include the poorest soil normally encountered to high quality bearing clays. Footing sizes offered cover the range 4′-0″ to 20′-0″ square, considered adequate for most structures using individual footings.

Basis of Tabulated Designs

See Fig. 13-1 for the material strengths, concrete cover, effective depth d, arrangement of reinforcing bars, and design shear strengths used in the preparation of the tabulated designs.

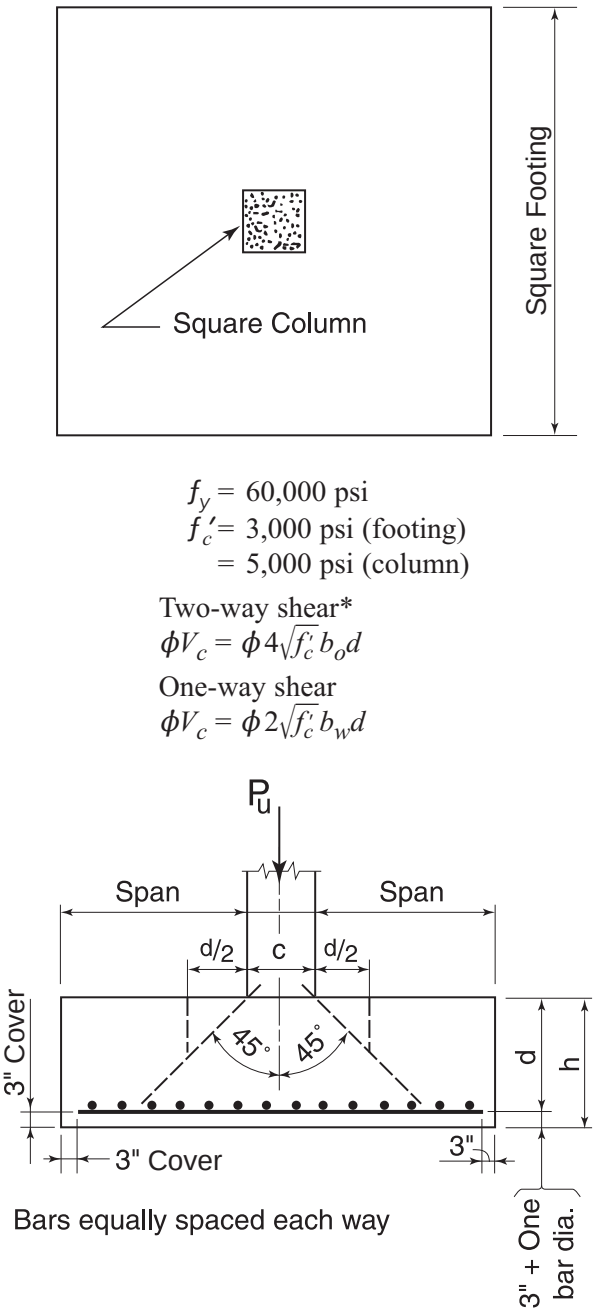

Figure 13-1 Footing Dimensions

*ACI Eq. 11-31 is not applicable for square columns. For the column sizes and footing thicknesses in the tabulated designs, ACI Eq. 11-32 does not control design shear strength.

Use of Tabulated Designs

The tabulated designs plus details of Fig. 13-1 are arranged to provide a complete design for square spread footings. Select the table for the appropriate safe soil bearing capacity and enter the table with the maximum column factored load, $P_u = 1.2D + 1.6L$, proceed down the last column of the table, and select the first design with a column design capacity larger than the factored load. For quick estimates, the volume of concrete, the size and the number of bars, and the total weight of reinforcing bars are included in the tabulated designs.

The Manual Example on Page 13-4 illustrates the computations of the computer program used to prepare the tabulated designs. It will be noted that the process of preparing tabulated designs reverses the normal design procedure. Beginning with a selected increment of footing size and safe soil bearing capacity, the minimum column size, depth, and required reinforcement are determined. Since the weight of the footing must be deducted from the total load on the soil, the computer program uses a convergent system of trial depths to select the tabulated depth which is determined by shear for the net load.

DEVELOPMENT OF DOWELS IN FOOTINGS

Table 13-1 gives the minimum compression development lengths, ℓ_d, for Grade 60 (f_y = 60,000 psi) reinforcing bars in concrete with $f'_c \geq$ 3,000 psi. For minimum footing thickness, add 3 inches of bottom concrete cover.

Table 13-1 Compression ℓ_d for Grade 60 Reinforcing Bars with $f'_c \geq$ 3,000 psi

Compression ℓ_d (inches)								
#5	#6	#7	#8	#9	#10	#11	#14	#18
14	17	19	22	25	28	31	38	50

When the dowel compression development length exceeds the available length for a given footing thickness, three possibilities are:

(1) Add a monolithic concrete cap suffciently thick to provide the required embedment length.

(2) Use a greater number of smaller diameter dowels to provide the required area of dowels and embedment length within the thickness selected.

(3) Thicken the footing to provide necessary embedment length.

This discussion considers dowels in compression only. Dowels in tension are excluded here.

Dowels are required to transfer only the *excess* compression above bearing allowed on the footing or on the gross area of column (ACI 15.8.1.2). The column dowels must provide a minimum area of 0.5 percent times the gross area of the column. (ACI 15.8.2.1).

The strength-reduction factor, $\phi = 0.65$, is identical to that for compression in tied columns (ACI 9.3.2.2-b). Design bearing strength on full sections (as on the base of the column) is $\phi(0.85 f'_c A_1)$ (ACI 10.14.1). If the load bearing, A_1, is one half or less than the area resisting the bearing load, A_2, the design bearing strength is $2\phi(0.85 f'_c A_1)$.

Example 1. Dowels for Minimum Size Columns

From the Manual Example of a footing design on Page 13-4, take an 18 in. × 18 in. column with P_u = 1,345 kips on a footing 38-in. deep. Column concrete f'_c = 5,000 psi; longitudinal column bars are 8 percent of gross area of column; f_y = 60,000 psi. Footing concrete f'_c = 3,000 psi.

Design bearing strength of column concrete
$= 0.85\phi f'_c = (0.85)(0.65)(5{,}000) = 2{,}763$ psi

Design bearing strength of footing concrete
$= 2(0.85)\phi f'_c = 2(0.85)(0.65)(3{,}000) = 3{,}315$ psi

Note that the design bearing strength is always critical on the column until the compressive strength of the column concrete is twice that of the footing.

Column compression is transferred by a combination of concrete bearing and steel bearing. The design bearing strength of the column is then (2,763)(18 × 18) = 895 kips

Excess compression to be transferred by dowels,
$P_u - 895 = 1{,}345 - 895 = 450$ kips

Area of dowels required = 450/60 = 7.50 in.^{2}, which is greater than the minimum area of dowels = $0.005A_g$ = 0.005(18)(18) = 1.62 in.^{2}

Embedment depth available = 38 – 3 = 35 in.
Maximum size bar (see Table 13-1):

For #11 bar, compression ℓ_d = 31 in. < 35 in.

Area of #11 bar = 1.56 in.^{2}

Number of bars required: 7.50/1.56 = 5 – #11 bars

Total length of dowel = embedment (compression ℓ_d) in footing plus compression lap splice in column. Compression lap splice in column with f'_c = 5,000 psi; see Table 5-1; for a #11 bar, the lap length = 0.83(43) = 36 in. if column tie area ≥ 0.0015*hs* or 43 in. with lesser ties. With vertical bars equal to 8 percent of the column area, ties will usually satisfy these requirements (ACI 12.17.2.4). Dowel length is 31 + 36 = 67 in.

Example 2. Dowels for Columns with Minimum Longitudinal Reinforcement

Select dowels for a 26 in. × 26 in. column with 8-#9 longitudinal bars (1.18 percent); f_y = 60,000 psi; column concrete f'_c = 5,000 psi. Same factored load as in Example 1, P_u = 1,345 kips. Footing concrete f'_c = 3,000 psi.

Design concrete bearing strength of footing
= $2(0.85)\phi f'_c = 2(0.85)(0.65)(3{,}000) = 3{,}315$ psi

Design concrete bearing strength of column
= $0.85\phi f'_c = 0.85(0.65)(5{,}000) = 2{,}763$ psi (controls)

Total compression = 1,345(1,000)/(26 × 26)

= 1,990 psi < 2,763 psi

There is no excess compression since the total compression load is less than the controlling design bearing strength. The Code nevertheless requires dowels with a total minimum area = 0.005(26)(26) = 3.38 in.^{2} (ACI 15.8.2.1).

Try: 4 – #9 dowels (A_s = 4.00 in.^{2}).

From Table 13-1, for a #9 bar, compression ℓ_d = 25 in.

From Table 5-1, the compression lap length of the #9 dowels = 34 in. (the required length would be less than 34 in. if the reduction for column ties was considered (ACI 12.17.2.4).) Dowel length is 34 + 25 = 59 in.

Use: 4 – #9 × 4′-11″ dowels

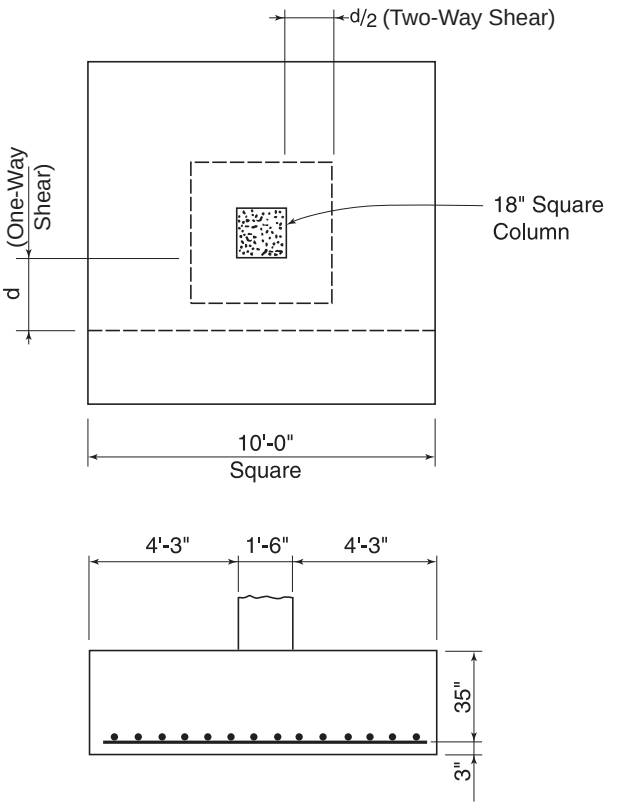
Manual Example

For a safe allowable soil bearing capacity of 10,000 psf, determine the maximum column capacity, and the minimum depth and required reinforcement for a 10′-0″ square footing. Use f'_c = 3,000 psi and f_y = 60,000 psi for the footing. The design should be adequate for any square column *larger* than that required for a tied column with f'_c = 5,000 psi, and 8 percent Grade 60 vertical reinforcement. See Fig. 13-1, and the following plan view and elevation of the footing. Compare results to tabulated designs on Page 13-15.

Soil Calculations:

Safe allowable bearing capacity, q_a = 10,000 psf (given)
Total factored bearing capacity, q_t = 14,000 psf
For first trial, assume footing thickness 3′-2″ (38”)
Net factored soil pressure = q_s

$q_s = q_t = 14{,}000 - 1.2(38/12)(150) = 13{,}430$ psf



Factored column load, P_u:

$$P_u = \frac{(10 \times 10)(13{,}430)}{1000} = 1{,}343 \text{ kips}$$

Minimum size square tied column:

f'_c = 5,000 psi; f_y = 60,000 psi; ρ = 0.08;

Maximum axial design strength (ACI Eq. 10-2):
$\phi P_{n(max)} = 0.80\phi\,[0.85 f'_c\,(A_g - A_{st}) + f_y\,A_{st}]$

Substituting $A_{st} = \rho A_g$ and ϕ = 0.65 and solving for:
$\phi P_{n(max)}/A_g = 0.442 f'_c(1 - \rho) + 0.520 f_y \rho = 4.53$ ksi

Min. size of square column, $c = \sqrt{\frac{P_u}{4.53}} = \sqrt{\frac{1{,}343}{4.53}}$
= 17.22 = 18 in.
Min. size of square column = 18 in. × 18 in.

Two-way shear

Design shear strength, $\phi V_c = \phi 4\sqrt{f'_c} b_o d$ on a critical section located at a distance $d/2$ from the face of the column (ACI 11.11.2). See plan view of the footing.

Compute the minimum effective depth for the maximum size bar that can be developed in the span length. Embedment length available for tension development = 51 – 3 = 48 in. Assume #9 bars per tabulated design. See Chapter 5 for required tension ℓ_d. From Table 5-2(a), Case 1, ℓ_d = 62 in.; from Table 5-3(a), ℓ_d = 41 in.

for 2 in. or 3 in. of concrete cover, provided the c.-c. spacing of the bars > twice the concrete cover plus one bar diameter (Note 3 under Table 5-3(a)). If the applicable ℓ_d is 41 in., the available embedment length of 48 in. > 41 in. From the tabulated design on Page 13-15, the c.-c. spacing of #9 bars = $(12 \times 10 - 3 - 3 - 1.128)/(9 - 1) = 14.11$ in. which is greater than 2(3) + 1 = 7 in.; hence, ℓ_d = 41 in.

$d = 38 - 3 - 1.128 = 33.87$ in.

For two-way shear, $b_o = 4(18 + 33.87) = 207.5$ in.

Total factored shear V_u

$$V_u = \frac{(13{,}430)}{1000}\left(10 \times 10 - \frac{51.87}{12} \times \frac{51.87}{12}\right)$$
$$= 1{,}092 \text{ kips}$$

$\phi V_c = 0.75(4)\sqrt{3{,}000}(207.5)(33.87)/1{,}000$
$\phi V_c = 1{,}154$ kips > V_u, okay

One-way (beam) shear

Design shear strength, $\phi V_c = \phi 2\sqrt{f'_c} b_w d$ on a critical section located at a distance d from the face of the column. See plan view of the footing.

$$V_u = \frac{(51 - 33.87)}{12}(10)(13{,}430)/1{,}000 = 192 \text{ kips}$$

$\phi V_c = 0.75(2)\sqrt{3{,}000}(120)(33.87)/1{,}000$
$\phi V_c = 334$ kips > V_u, okay

Selection of bar size – The bar size and number of bars are selected by the following process:

1. Compute the required number of each bar size that would satisfy the total required A_s.
2. Reject bar sizes that are too large to be fully developed by anchorage (as straight bars).
3. Reject bar sizes for which the required number results in A_s more than 10 percent higher than A_s required (to save tonnage).
4. Reject bar sizes that require spacing at more than 18 in.
5. Reject bar sizes that require a total number of bars 25 percent more than the minimum number for bar sizes passing criteria 1 through 4 (to avoid high placing cost).
6. If more than one choice remains, select from the remaining choices the same bar size used for the preceding smaller footing if this bar size is one of those remaining. If not, select the bar size remaining that gives the least weight of reinforcing bars.

Required flexural reinforcement

Factored moment is computed at the face of the column at the critical section prescribed (ACI 15.4.2.-a).

$$M_u = \frac{1}{2}(13{,}430)(10)(4.25)^2/1{,}000$$
$$= 1{,}213 \text{ ft.-kips}$$
$$= 1{,}213(12/10) = 1{,}455 \text{ in.-kips/ft.}$$

From Chapter 5 with f'_c = 3,000 psi and b = 12 in.:

$$A_s = 0.510(d) - \sqrt{0.260d^2 - 0.0189M_u}$$
$$= 0.510(33.87) - \sqrt{0.260(33.87)^2 - 0.0189(1{,}455)}$$
$$= 0.815 \text{ in.}^2\text{/ft.} = 8.15 \text{ in.}^2$$

∴Use 9-#9 bars (#9 bars used in 9'-6" footing)

Need to check that $\varepsilon_t \geq 0.005$, which is required in the ACI Building Code for ϕ =0.90.

From Chapter 5, $\rho_{max} = 0.01355$

$$\rho = \frac{A_s}{bd} = \frac{9.00}{12(10)33.87} = 0.01329 < 0.01355, \text{ OK}$$

Quantities of materials

Weight of reinforcing bars:

Weight = (2)(9)(3.40)(9.5) = 581 pounds

$$\text{Volume of Concrete} = \frac{(10 \times 10)(38/12)}{27}$$
$$= 11.7 \text{ cubic yards}$$

Notes: 1. Epoxy-coated bars of the same size and number may be used except where an "*" is printed. In which case, use: smaller bars (with increased number of bars); hooked or headed bars; increased f'_c, or larger footing.
2. Reinforcing steel quantities do not include footing dowels.

CONCENTRICALLY LOADED SQUARE SPREAD FOOTINGS
